Background: Acute kidney injury (AKI) is involved in subsequent chronic kidney disease (CKD) development, and effective treatments to prevent AKI to CKD progression are lacking. Mesenchymal stem cells (MSCs) are emerging as a promising cellular therapy to impede such progression. MSCs repair injured tissue through secretion of various humoral factors. Among these factors, tumor necrosis factor-α-induced protein 6 (TSG-6) has a central role in the anti-inflammatory effects of MSCs. However, the mechanisms by which MSCs secrete TSG-6 and exert anti-inflammatory effects are not fully clarified. In this study, we investigated these mechanisms using TSG-6-overexpressing MSCs.

Methods: MSCs infected with an adeno-associated virus carrying TSG-6 cDNA or an empty adeno-associated virus were designed as TSG-6 MSCs and null MSCs, respectively. Extracellular vesicles (EVs) were isolated from MSC culture supernatants by ultracentrifugation. MSCs were injected through the abdominal aorta into rats with ischemia-reperfusion injury (IRI) to evaluate their anti-inflammatory and anti-fibrotic effects. We also examined whether TSG-6 secreted from MSCs affected polarization of monocytic THP-1 cell-derived macrophages to the immunosuppressive M2 phenotype. Additionally, we explored natural compounds that increased TSG-6 expression in MSCs.

Results: Most TSG-6 was immediately secreted in EVs and was not stored intracellularly. Administration of TSG-6 MSCs more strongly suppressed renal fibrosis and inflammation in IRI rats than null MSCs. Although EVs and conditioned medium from TSG-6 MSCs (TSG-6 MSC-CM) strongly promoted polarization of M2 macrophages, TSG-6 MSC-CM after EV depletion promoted it only slightly. Moreover, TSG-6 MSC-CM enhanced regulatory T cell induction. Additionally, MSCs treated with indole-3-carbinol had enhanced TSG-6 expression and markedly suppressed IRI-induced renal fibrosis.

Conclusions: TSG-6 is secreted in EVs from MSCs and exerts potent anti-inflammatory effects by promoting M2 macrophage polarization and regulatory T cell induction. Administration of MSCs with enhanced TSG-6 secretion is a promising therapeutic strategy to impede AKI to CKD progression.

Efficient and Programmable Particle Delivery for Genome Editing in Human Kidney Organoids

Nicole Vo, Benjamin S. Freedman. *University of Washington, Seattle, WA.*

Background: Kidney organoids are complex structures that resemble nephrons and can be used to develop gene therapy approaches. Gene editing in organoids, much like in tissues, has great potential but currently suffers from inefficiency and lack of specificity. There is a critical need for the development of methods for efficient and precise genome editing.

Methods: We developed CaSh (Calcium Shock), a method that improves transfection and transduction, and CaSh-Pro, a programmable version that targets specific cell types. To enable better detection of genome editing events, we developed a fluorescence-on (tdTomato) reporter system in human iPS cells. Intact kidney organoids were transfected with CRISPR ribonucleoprotein (RNP) complexes. To improve delivery, identified molecular targeting agents (MTAs) specifically recognizing podocytes, proximal tubules, or endothelial cells in live imaging assays, and tethered these to Cas9. Genome editing events or adeno-associated virus (AAV) transduction were detected by changes in fluorescence in specific cell types.

Results: CaSh dramatically improved genome editing by CRISPR-Cas9 ribonucleoprotein from ~ 2% in organoids without CaSh to 15% with CaSh. CaSh-Pro, which incorporates specific MTAs, resulted in substantially enhanced editing in the targeted cell types of podocytes (~12%) (**Figure 1**) or tubules (~5%), as detected by tdTomato co-localization with a specific marker, relative to negative controls including untreated, no MTA, or generic IgG. Finally, CaSh improved transduction of AAV8 encoding a red fluorescent reporter protein into proximal tubular epithelial cells, resulting in ~15% efficiency at 1 x 10^5 genome copies (gc)/cell, compared to negative controls.

Conclusions: CaSh and CaSh-Pro provide versatile protocols for biological discovery, therapeutics development, and genome editing. Our innovative method improves specificity and efficiency enabling a wide variety of potential applications such as testing gene therapies in specific cell types as a surrogate for tissues. Gene editing can be achieved in a clinically effective range (> 10%) and in specific cell types, enabling future studies of phenotypic rescue in human models.

Genome Therapy in Kidney Organoids Reveals that Canonical NFκB Signaling Governs Tubular Senescence, Cytotoxicity, and Immunogenicity in Response to Adeno-Associated Viruses (AAV)

Navin R. Gupta,[1] Haruka Oishi,[2] Kenta Inomata,[2] Ryuji Morizane.[2,3] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Massachusetts General Hospital, Boston, MA; [3]Harvard University Wyss Institute for Biologically Inspired Engineering, Boston, MA.*

Background: Genome therapy is revolutionizing the treatment of inherited diseases by directly editing the human genome. Due to its potential to irreversibly alter human DNA, systemic gene therapy raises significant concerns, demanding a new approach to preclinical evaluations. These concerns are further illustrated by recent tragedies in clinical trials, which have led to organ failures and patient fatalities. Due to high blood flow, the kidney emerges as a focal point for drug-related toxicity.

Methods: Human stem cell-derived kidney organoids are nephron-rich, highly structured 3-dimensional tissue capable of exocrine and endocrine functions, have modeled human genetic and non-genetic disease, kidney injury and repair, and nephrotoxicity testing. Here we use kidney organoids as a pre-clinical platform for CRISPR genome editing via adeno-associated virus (AAV) delivery, a common genome editing strategy in clinical trials that have raised safety concerns. Although AAV is of limited pathogenesis in humans, clinical use has required supraphysiologic titers often met with toxicity.

Results: Kidney organoids validated the tropism of differing AAV serotypes for human kidney. Applying immunostaining to organoid cryosections and electrochemiluminescence-based mesoscale discovery to their supernatants, we found that AAV drives tubular genotoxicity, cytotoxicity, and immunogenicity. RNA-sequencing identified an association between tubular injury and IL-1β activation of the canonical NFκB pathway. Targeted inhibition of canonical NFκB signaling prevented the fibrotic loss of nephrons by ameliorating $p21^+$ senescence in injured tubules.

Conclusions: Our findings demonstrate the translational utility of kidney organoids as a pre-clinical testing platform for genome therapy, which may inform clinical trials of strategies that limit organ failures and death.

Metabolic Responses in Human Kidney Organoids to Tumor Necrosis Factor-Alpha Stimulation: Integration of Proteomic and Metabolomic Signatures

Moritz Lassé,[1] Jennifer L. Harder,[3] Sandra D. Laufer,[1] Fabian Braun,[1] Markus M. Rinschen.[1,2] Rinschen Lab. *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Aarhus Universitet, Aarhus, Denmark; [3]University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Tumor necrosis factor-alpha (TNF-alpha) is a cytokine involved in systemic inflammation and has a profound impact on metabolic processes within cells. Studying its effects on kidney cells using organoids can reveal insights into renal inflammatory responses and metabolic dysregulation associated with kidney diseases. This study aimed to identify and analyze the metabolic shifts in human kidney organoids following TNF-alpha treatment, focusing on energy metabolism, amino acid metabolism and generation of uremic toxins.

Methods: TNF-alpha exposed Kidney organoids were analyzed using proteomics and targeted metabolomic mass spectrometric analyses. Altered metabolites were integrated with proteome-scale networks. We quantified changes in key catalytic enzymes and metabolites involved in major metabolic pathways including the citric acid cycle, amino acid metabolism, and the production of known uremic toxins.

Results: TNF-alpha stimulation resulted in significant metabolic rewiring of the organoid cells. We observed altered protein expression upon TNF-alpha exposure, particularly in amino acid, energy, and nucleotide metabolism. Top proteins involved were associated with adverse clinical outcomes in proteinuric disease in the NEPTUNE cohort. Enhanced energy demand was evident by an increased production of TCA cycle metabolites. Crucially, we also detected increased metabolite markers of kidney injury, inflammation, amino acid metabolism and apoptosis to be upregulated. Conversely, there was a marked decrease of metabolites related to energy production, nucleotide synthesis, and protein synthesis. These downregulated metabolites highlight a possible reduction in biosynthetic and energy-related processes under inflammatory conditions. Altered metabolites were integrated with proteome-scale networks.

Conclusions: TNF-alpha induces complex metabolic responses in human kidney organoids, characterized by orchestrated response of shifts in critical metabolites across various pathways. The observed metabolic reprogramming may represent an adaptive response to inflammation or a pathogenic mechanism contributing to disease progression. These findings emphasize the importance of renal metabolic responses to inflammation and may guide future therapeutic strategies targeting metabolic disturbances in kidney diseases.

TH-PO422

Neonatal Kidney Stem/Progenitor Cells (nKSPCs) Downregulate Activation of Human Neutrophils In Vitro

Junyu Chen,[1,2] Mieke Gouwy,[2] Paul Proost,[2] Sara Akalay,[2] Hildo C. Lantermans,[1] Lambertus P. Van den Heuvel,[3,2] Fanny O. Arcolino,[1] Elena Levtchenko.[1] Translational Paediatric Nephrology. *[1]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Katholieke Universiteit Leuven, Leuven, Belgium; [3]Radboud Universiteit, Nijmegen, Netherlands.*

Background: Neonatal Kidney Stem/Progenitor Cells (nKSPC), a novel type of kidney progenitor cell, isolated from urine of preterm neonates, have demonstrated immunoregulatory capacity and can inhibit proliferation of T-lymphocytes in mixed lymphocyte reaction. Our group is testing nKSPC as a potential source of cell therapy in the context of kidney transplantation. Neutrophils play important roles in ischemia-reperfusion injury (IRI), a common occurrence in kidney transplantation. In this study, we examined the capacity of nKSPC to inhibit human neutrophils *in vitro*.

Methods: Freshly isolated neutrophils activated by TNF-α were co-cultured with nKSPC at varying ratios (10:1 to 500:1). CD16 and CD66b as markers related to neutrophil activation were measured by Fluorescence-Activated Cell Sorting (FACS). Apoptosis was analyzed by Annexin V assay in FACS. Assessing neutrophil-produced reactive oxygen species (ROS), we employed a Luminol assay under multiple stimuli (TNF-α, IL-1β, fMLF, PGN). Neutrophil chemotaxis was investigated by Boyden chamber assay.

Results: Neutrophils, stimulated by TNF-α, exhibit increased CD66b and decreased CD16 expression, indicating activation. TNF-α also induced apoptosis of neutrophils. Co-culturing with nKSPC significantly reduced TNF-α-induced neutrophil activation and apoptosis. TNF-α, IL-1β, fMLF, and PGN stimulation promoted ROS production in neutrophils, and a co-culture with nKSPC inhibited this induction. Neutrophil chemotaxis induced by TNF-α was not inhibited by nKSPC.

Conclusions: Our *in vitro* data show the immunomodulatory capacity of nKSPC on neutrophils with decreased activation, reduction of apoptosis and abolishing ROS production.

TH-PO423

Progressive Tubulointerstitial Damage through Constitutive Activation of the NF-kB Pathway in Renin Lineage Cells

Irina Simonova,[1] Florian Gembardt,[1] Anne Steglich,[1] Jan Sradnick,[1] Vladimir T. Todorov,[1,2] Christian Hugo.[1] Working Group Hugo, University Clinic Carl Gustav Carus, Dresden. *[1]Universitatsklinikum Carl Gustav Carus, Dresden, Germany; [2]Universitat Witten/Herdecke Institut fur Physiologie und Pathophysiologie, Witten, Germany.*

Background: NF-κB (Nuclear factor κB) is a family of related transcription factors that play a pivotal role in many inflammatory processes including immune mediated kidney disease potentially linking inflammation, injury or regeneration. Various inflammatory signals activate NF-κB through TNF (tumor necrosis factor) and other cyto- and chemokine, B or T cell receptors. Activated IKK (inhibitor of NF-kB kinase) complex plays a major role in degradation of IκBα(NF-kB inhibitor α) after which the NF κB dimer p65/ RelA translocates to the nucleus and activates inflammatory genes. We investigated the impact of NF-κB(IKK) activation specifically in RLC (renin-lineage cells) well known as an important niche involved in regeneration and replacement of damaged mesangial and epithelial cells of the murine kidney. RLC of adult mice make up about 10% of all kidney cells including JGA, mesangial, epithelial and smooth-muscle cells

Methods: We created transgenic mouse line mRen-Cre-IKKca with targeted overexpression of IKK2 in RLCs leading to constitutive activation of the NF-kB pathway. The data were collected at 1, 3 and 6 months of age for IKK2 and WT male and female animals. We analyzed functional parameters, morphological changes (PAS) and the expression of Renin, aSMA,Na+/K+ ATPase, SLC4A4, AQP1, AQP2, AE1, Calb1, serum and 24h urine samples

Results: Data showed in IKK2 mice significant increase of urine volumes (in WT μ=1850ml, in IKK2 μ=5186ml) as well as α1-Microglobulin amounts in 24h urine(in WT μ=1.12μg, in IKK2 μ=14.24μg) already at the age of 3M compared to WT but slight rise of urine albumin amounts only at 6M. PAS stainings demonstrated progressive tubulo-interstitial damage solely in mRen-Cre-IKKca mice starting at 3M of age. IHC staining of AQP2 (principal cells in collecting duct) was significantly reduced at 3M and 6M compared to WT. Other markers will clarify these changes

Conclusions: Our study reveals a profound renal phenotype of mice with NF-kB pathway activation specifically in RLCs linking this inflammation signaling with progressive injury and insufficient regeneration. The transgenic mice developed tubulo-interstitial damage starting at 3M of age(increased α1-Microglobulin, PAS, concomitant reduction of AQP-2) while only slight albumin rise at 6M indicates that glomerular changes appear later and less severe

Funding: Government Support - Non-U.S.

TH-PO424

Renal Progenitor Cells Isolated from Urine of Patients with IgA Nephropathy Formed Renal Spheroids That Can Recapitulate Typical IgA1 Deposition

Fabio Sallustio,[1] Francesca Giannuzzi,[1] Angela Picerno,[1] Silvia Maiullari,[1] Francesca Montenegro,[1] Antonella Cicirelli,[1] Alessandra Stasi,[1] Giuseppe De Palma,[2] Giovanni B. Pertosa,[1] Paola Pontrelli,[1] Michele Rossini,[3] Vincenzo Di leo,[1] Mariella Errede,[1] Roberto Tamma,[1] Domenico Ribatti,[1] Loreto Gesualdo.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Istituto Tumori Bari Giovanni Paolo II IRCCS, Bari, Italy; [3]Azienda Ospedaliero-Universitaria Consorziale Policlinico di Bari, Bari, Italy*.

Background: The creation of renal spheroids and organoids from stem cells represents a suitable model for drug studies and in the simulation of nephrotoxicity and renal disease. However, it requires the use of sophisticated differentiation protocols and the administration of growth factors with a precise temporal order. Here we show that adult human renal progenitor cells (ARPCs) isolated from the urine of healthy subjects or patients with IgA Nephropathy (IgAN) can form spheroids and long tubular-like structures naturally, recapitulating typical IgA1 deposits.

Methods: Spheroids and tubular-like structures were generated by using an ARPC mixed cell population method and characterized by immunofluorescence and flow cytometry, using CD133, NanoG, Oct3/4, GATA-3, SSEA4, CD249, Aminopeptidase N, ZO-1, Uromodulin, and Lotus antibodies. ELISA;CAM assays; PKH-26 labeling was used for cell tracking.

Results: Spheroids derived from ARPCs without the use of chemokines or growth factors generated very long tubular-like structures that expressed structural and functional markers of renal tubules sharing structural similarities with regions of nephrons, such as the distal convoluted tubule, loop of Henle and the proximal convoluted tubules. Furthermore, the spheroids secreted high levels of renin and exhibited angiogenic properties. To study whether spheroids derived by urinary ARPCs can be used to establish in vitro models recapitulating renal diseases, we generated IgAN patient-specific renal spheroids. ARPCs formed spheroids in which IgA1 deposits could be observed after 4, 8 and 15 days of culture with patient serum (p=0.004, p=0.0029 and p=0.0012, respectively). In contrast, no positive signal was detected either with inactivated IgAN serum or in spheroids derived from the urine of healthy patients cultured with IgAN serum.

Conclusions: The ability of urinary ARPCs to form spheroids and differentiate into tubular-like structures without the need for external chemokines is a significant advancement in the field, opening new avenues in the study of pathological mechanisms and in the for regenerative medicine for kidney diseases.

Study Sex Differences in Genetic Kidney Diseases Using Organoid Xenotransplantation Model

Yun Xia. *Nanyang Technological University, Singapore, Singapore*.

Background: Chronic kidney disease (CKD) affects about 10% global population, with higher prevalence in women but faster progression in men. A deeper understanding of how the interplay between genetic sex and systemic sex hormones modifies human kidney disease constitutes a pivotal advancement toward precision medicine, which promises equitable benefits for women (including pregnant women), men, and transgender individuals alike. Despite mounting evidence that sex disparity must be taken into consideration in studying human kidney diseases and developing therapies, limited progress has been made due to the lack of suitable experimental models.

Methods: In this study, we harness this organoid xenotransplantation methodology to investigate the combined effects of genetic sex and systemic sex hormones on human genetic kidney disease. Single cell RNA-sequencing (scRNAseq), genetic perturbation, and pharmacological interference are employed to dissect the mechanism underlying sex differences manifested in different sex contexts.

Results: Induced pluripotent stem cells (iPSCs) derived from patients with autosomal recessive PKD (ARPKD) and autosomal recessive PKD (ARPKD) can be differentiated into kidney organoids. scRNAseq of kidney organoids detected enriched expression of androgen and estrogen receptors in the proximal tubule. Upon xenotransplantation into immunocompromised mice, kidney organoid grafts grown in male mice exhibited higher cystic index compared with the same patient iPSC derived kidney organoids grafted in female mice. Analyses of kidney organoid grafts revealed increased tubular injury, proliferation, and activation of androgen signalling in kidney organoids grafted in male host mice, compared with those grafted in female host mice. Genetic ablation or pharmacological inhibition of androgen receptor effectively inhibited cyst severity. Comparatively, genetic sex of the kidney organoid itself showed less impact on the severity of cystogenesis.

Conclusions: Organoid xenotransplantation model represents a feasible platform to comprehend sex disparity in human diseases, to distinguish the impact of genetic sex on human diseases from those imparted by systemic sex hormones, as well as to test candidate therapeutics targeting principal sex hormone signalling pathways for treating human diseases.

TH-PO426

Sexual Dimorphism in the Regenerative and Polyploid Response of Kidney Tubule during Aging

Elena Lazzeri, Giulia Antonelli, Giulia Carangelo, Paola Romagnani. *Universita degli Studi di Firenze, Firenze, Italy*.

Background: Kidney function declines with age, leading to chronic kidney disease (CKD). Although a higher prevalence of CKD in females, men experience a faster CKD progression. The cellular mechanisms underlying this difference in CKD development during ageing remain to be clarified. A link has been hypothesized between a regenerative and polyploid response and ageing. Whereas the decline in the regenerative potential of stem cells is associated with tissue ageing, the increase of polyploidy preserves tissue function during ageing. In the kidney, a regenerative and polyploid response takes place after AKI. Whereas renal progenitors (RPC) generate new tubular cells (TC) to recover structural integrity, TC enter alternative type of cell-cycle to become polyploid and to recover kidney function. Here, we aimed to investigate how these two adaptive responses act differently in females and males during ageing.

Methods: Female and male mice were analyzed at 2, 6, 12, 20 months of age. Pax2/Confetti mice were used to study the regenerative response driven by RPC (Pax2+cells). Pax8/FUCCI2aR and h-Pax8/Confetti mice were used to study the polyploid response. In the first one polyploid TC are identified by combining DNA content with FUCCI2aR technology. In the second one polyploid TC are identified as multicolored TC following recombination of Confetti reporter genes. scRNAsequencing was performed in female and male mice at 2 and 20 months of age.

Results: During ageing, male mice experienced an earlier and faster kidney function decline than females. Pax2/Confetti mice revealed that females were endowed with a higher number of RPC, which have a greater capacity to expand clonally, showing a better regenerative capacity than males during ageing. Analysis of the polyploid response in Pax8/FUCCI2aR and in h-Pax8/Confetti mice revealed that whereas the polyploid fraction increased in aged females, it was reduced in aged males. Indeed, polyploid TC in aged males accumulated DNA damage, which resulted in additional rounds of polyploidization, genetic instability and death. scRNAsequencing analysis profiled the ageing-related stress responses of polyploid TC in aged males.

Conclusions: These insights might explain why females are more capable to compensate kidney function decline, whereas males are more susceptible to an earlier and faster progression to CKD during ageing.

TH-PO427

Bowman Capsular Laser Irradiation Induces Parietal Migration of Renin Cells in Longitudinal Three-Dimensional Intravital Microscopy

Patrick Arndt,[1] Jan Sradnick,[1] Shila Azizolli,[1] Sagor Halder,[1] Vladimir T. Todorov,[1,2] Christian Hugo.[1] *[1]Experimental Nephrology, Division of Nephrology, Department of Internal Medicine III, University Hospital Carl Gustav Carus, TU Dresden, Dresden, Germany; [2]Institute of Physiology and Pathophysiology, Center of Biomedical Education and Research (ZBAF), Faculty of Health - School of Medicine, Witten/Herdecke University, Witten, Germany*.

Background: Renin cells reside in the juxtaglomerular apparatus and serve as progenitors capable of migrating into the glomerulus following injury. These glomerular repair processes involve an individual intraglomerular-juxtaglomerular feedback mechanism. Using longitudinal intravital microscopy and a laser injury model to induce localized damage in individual glomeruli allows for controlled observation of repair processes. Laser irradiation of the Bowman capsule provides further insights into the migration processes of renin cells modeling glomerular damage and tubulointerstitial injures similar to Bowman capsule rupture in ANCA-associated GN.

Methods: Renin tdTomato reporter mice were subjected to doxycycline treatment for 3 weeks. Intravital microscopy was performed through an implanted body window using an upright 2-photon microscope for 3 hours on day 1 and after 96 hours. Laser injury was induced by focusing 100% laser power for 5 to 20 seconds at 12x to 48x zoom on one Z-plane. 3D processing was performed with Bitplane Imaris 10.1. Tdtomato+ cells and parietal epithelial cells were identified through immunohistochemistry in PFA-fixed kidney cryosections.

Results: The targeted use of a laser injury model induced reproducible capsular and trans-capsule injuries in murine nephrons. In 39 nephrons with capsular injury, renin cells migrated parietally in 36% and intraglomerularly towards the laser irradiated area in 41% of all cases. In 8 nephrons (20%), the renin cells migrated both parietally and intraglomerularly. No migration occurred in 23% of the nephrons with capsular injury. Migrating renin cells were able to connect to capsular injuries opposite from the juxtaglomerular apparatus with a tdTomato signal chain keeping contact to their niche of origin.

Conclusions: Longitudinal intravital microscopy combined with a capsular-targeted laser injury model and 3D image analysis in transgenic mice revealed an additional pathway for renin cell migration. Besides direct migration towards intraglomerular injuries, renin cells are also capable of parietal migration towards capsular damage linking

them to glomerular-tubulointerstitial regeneration. Further research may investigate the juxtaglomerular feedback system of renin cell recruitment/migration, transdifferentiation and regenerative site-specific responses.

TH-PO429

Navigating the Translation of LoAc Compound Efficacy in ADPKD

David J. Henderson,[1] Julia M. Adam,[1] Xiaofang Wang,[2] Claire Whitworth,[1] Susan Macdonald,[1] Li Jiang,[2] Tom Moore,[1] Catherine L. Kelleher,[1] Vicente E. Torres,[2] Adele Rowley.[1] *[1]Mironid Ltd, Glasgow, United Kingdom; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Elevated cAMP signalling is known to promote cystogenesis in Autosomal Dominant Polycystic Kidney Disease (ADPKD). Phosphodiesterase 4 (PDE4) enzymes degrade cAMP and contribute to its compartmentalized signalling. We have previously described novel small molecules (LoAc®) that allosterically activate long isoforms of PDE4 and lower intracellular cAMP both *in vitro* and *in vivo*. Here we discuss translation of the LoAc® approach from bench to bedside, with an emphasis on differentiation and on biomarker development.

Methods: The effects of LoAc® compound MR-L22 were examined in the *Pkd1*$^{RC/RC}$ mouse model of ADPKD, dosed once daily by oral gavage from post-natal weeks 4-16. Test groups were compared to groups receiving vehicle alone or tolvaptan. Urinary biomarker assays were conducted in Han Wistar rats, where cAMP was measured by either ELISA or LC-MS. *Ex vivo* studies in primary human cells were used to demonstrate efficacy in samples from multiple ADPKD patient donors.

Results: LoAc® treated *Pkd1*$^{RC/RC}$ mice exhibit reduced kidney cystic indices, kidney weight/body weight ratios (Kw/Bw) and MRI measured total kidney volumes (TKV). LoAc® administration protected kidney function and despite delivering similar reductions in renal cAMP, induced less polyuria than tolvaptan. Similarly, LoAc®-driven changes in protein expression and phosphorylation overlap with, but are distinct from, those measured after tolvaptan treatment. Experiments using cells from human ADPKD donors show that LoAc® compounds not only suppress AVP-stimulated cyst expansion but also the endogenous cystic disease drive, further differentiating LoAc® from tolvaptan as well as against a range of other clinical strategies. In rats, reduced cAMP in the urine can be detected after a single oral dose of LoAc® compound and correlate with cystic disease in LoAc® treated *Pkd1*$^{RC/RC}$ mice. Urinary cAMP offers an accessible, mechanism-related, biomarker of LoAc® compound activity *in vivo* and provides important step in managing the translation of the LoAc® approach in ADPKD.

Conclusions: LoAc® compounds suppress cystic disease progression in key translational models of ADPKD and are differentiated from clinically evaluated strategies. Urinary cAMP represents an accessible biomarker of LoAc® compound activity for translation to clinical studies.

PYC-003, a Peptide-Conjugated Oligonucleotide for the Treatment of Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Clarissa Mcdonagh, Anna Mills. PYC-003 Pharmacology Team. *PYC Therapeutics, Nedlands, WA, Australia.*

Background: ADPKD is a severe disease that causes kidney failure, affecting 1 in 1,000 people. Roughly 80% of ADPKD cases are caused by mutations in one copy of the *PKD1* gene leading to deficient PC1 protein. Addressing the root cause, PYC-003 is designed to upregulate PC1 expression.

Methods: PYC-003 effects on PC1 protein was determined by western blot and cyst shrinkage tested in 3D patient-derived models. A PYC-003 mouse surrogate molecule was intravenously injected into B6 mice where drug distribution was measured after 3 days using miRNAscope.

Results: PYC-003 raises PC1 protein in HEK293 cells to 1.6-fold. PYC-003 prevented cyst formation and reduces cyst area. A single dose of the PYC-003 mouse surrogate showed uniform renal distribution.

Conclusions: PYC-003 shows potential to be a treatment for ADPKD by increasing PC1 protein, preventing the formation of cysts *in vitro* and exhibiting enhanced renal delivery. PYC-003 is undergoing IND-enabling studies in preparation for anticipated clinical trials scheduled to begin in Q1 2025.

Funding: Commercial Support - PYC Therapeutics

TH-PO431

Development of a Nonviral Genetic Medicine for ADPKD Administered through Targeted Transcutaneous Ultrasound-Mediated Delivery

Margarita Krivega, Julia Poniatowski, Surabhi Rao, Elizabeth Del Greco, David Kim, Victor Foster, Oliver Chen, Bert J. Frederich, Katie Benthall, Nana Ingram, Glenda Arauz, Celia Ortiz, David Satyadi, Charles S. Levine, Jonathan Chan, Tanaya Ghosh, Belinda Cabriga, Dhruv Bole, Ivan Krivega, Steven Feinstein, Kenneth Greenberg. *SonoThera, South San Francisco, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the formation and growth of fluid-filled renal cysts, often leading to kidney failure. The most frequent genetic cause of ADPKD are monogenic mutations in the PKD1 gene. Ultrasound mediated gene delivery (UMGD) is an effective approach for noninvasive targeted transgene delivery into renal cells, enabling the development of a nonviral gene replacement therapy for ADPKD.

Methods: Using genetic engineering and screening of next generation DNA payload formats, we developed an optimized DNA construct expressing a full-size PKD1 protein. Transgenic PKD1 expression was assessed in vitro in relevant renal cells. To evaluate

the potential of UMGD as a nonviral ADPKD treatment option, we delivered genetic constructs to the cystic kidney of an ADPKD mouse model using proprietary acoustic energy profiles and FDA-approved ultrasound components.

Results: Testing multiple variants of codon-optimized full-size PKD1 open reading frame sequences along with proximal tubular epithelial cells-specific promoter enabled robust transgenic PKD1 protein expression in ADPKD cystic cells. SonoThera's highly optimized and proprietary acoustic energy profiles has enabled the targeted delivery of optimized genetic constructs to the cells of cystic kidneys of an ADPKD mouse model.

Conclusions: High levels of tissue-specific transgenic full-length PKD1 expression along with the favorable efficacy and safety profile of ultrasound mediated transgene delivery to the cystic cells in ADPKD kidney supports further translation of this approach into clinical development for the treatment of ADPKD.

TH-PO432

Kidney-Targeted Delivery of Nonviral Nucleic Acids Using Noninvasive Transcutaneous Ultrasound Enables Safe, Re-dosable, Titratable, and Durable Gene Expression in Mice and Nonhuman Primates

Bert J. Frederich, Jonathan Chan, Surabhi Rao, Victor Foster, Adel Alonso, Celia Ortiz, Elizabeth Del Greco, Oliver Chen, David Satyadi, David Kim, Dhruv Bole, Nana Ingram, Katie Benthall, Margarita Krivega, Julia Poniatowski, Tanaya Ghosh, Belinda Cabriga, Charles S. Levine, Ivan Krivega, Kenneth Greenberg, Steven Feinstein. *Sonothera, South San Francisco, CA.*

Background: Effective kidney-targeted delivery of genetic medicines has been elusive despite significant research. Transcutaneous ultrasound-mediated gene delivery (UMGD) offers a noninvasive, targeted approach to overcome these challenges

Methods: SonoThera is developing a proprietary ultrasound-guided nonviral gene therapy platform for selective kidney targeting in a safe, redosable, durable, and titratable manner. In vivo bioluminescence imaging of firefly luciferase reporter gene expression was conducted using an IVIS imaging system at various time points in the kidneys of both wild-type and polycystic kidney disease (Nek8JCK) mouse models. Kidney tissue obtained from mice and nonhuman primates was analyzed for reporter gene presence and expression using ddPCR, RNAscope, snRNA-seq, and immunohistochemistry. Multiple clinical and molecular safety assessments were conducted in mice and nonhuman primates using established methods.

Results: SonoThera's UMGD platform enabled robust, durable, redosable, and titratable transgene expression in wild-type mouse kidneys, with durable gene expression observed for over a year following a single treatment. Renal disease-relevant cell types including podocytes, tubular epithelial cells, and endothelial cells were effectively transfected in mice and nonhuman primates. Robust delivery and transgene expression were confirmed in the polycystic kidney mouse model (Nek8JCK). Safety assessments, including clinical observations, blood urea nitrogen, creatinine levels, and a proinflammatory cytokine panel, indicated excellent tolerability and safety following single and repeat treatments in mice and nonhuman primates.

Conclusions: These results provide strong support for the continued development of UMGD for the treatment of renal disease.

Funding: Commercial Support - Sonothera Inc.

TH-PO433

Untapped Potential of the ADPKD Treatment Landscape

Jennifer Lafave, Ellie Mcclatchy, Bridget Bergan, Meghan Weiss. *Spherix Global Insights, Exton, PA*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is identified by nephrologists as one of the top three renal conditions with the highest unmet need for new treatment options. Tolvaptan is currently the only FDA-approved treatment that is available for ADPKD, underscoring a significant opportunity for new entrants to foster market growth.

Methods: Data was collected in January 2024 in partnership with 101 US nephrologists via an online survey.

Results: Despite the availability of tolvaptan, two-thirds of nephrologists agree that there is a lack of effective treatment options for ADPKD (64%), and half believe that there is little they can do to treat these patients beyond blood pressure control and dietary guidance (49%). Current treatment regimens include ACE inhibitors/ARBs, fluid intake of at least three liters per day, SGLT2 inhibitors, and tolvaptan. Nearly all nephrologists (87%) report that they have prescribed tolvaptan to at least one of their ADPKD patients and express that the REMS program is not a barrier to their use of the drug. However, they also report that they encounter patient resistance to starting therapy with tolvaptan, especially since the most ideal patients often present as asymptomatic, are unable to tolerate the required water intake, and may be hesitant to begin a long-term treatment regimen that has monitoring requirements. Nephrologists report that 17% of their ADPKD patients are currently being treated with tolvaptan and just under one-third (32%) of users report being highly satisfied with the drug. Looking forward, nearly two-thirds of nephrologists anticipate that the biggest change in their management of ADPKD patients will be the introduction of new treatment options. Although their awareness of pipeline agents for ADPKD is low, physicians primarily seek new agents that effectively slow the progression of eGFR decline with no serious adverse events, good long-term safety profiles, and are supported by both clinical and outcomes data.

Conclusions: As new agents for ADPKD advance in their clinical trials, physician education on efficacy and safety data will be key in helping to drive the evolution of ADPKD treatment where significant unmet needs remain.

TH-PO434

Ameliorative Effect of Anti-microRNA-21 Oligonucleotide Synthesized from Serinol Nucleic Acid on Animal and Human Models of Cystic Kidney Disease

Yuhei Noda,[1] Noritoshi Kato,[1] Yuka Sato,[1] Kayaho Maeda,[1] Tamio Yamaguchi,[3,2] Shizuko Nagao,[2] Tomoki Kosugi,[1] Yukiko Kamiya,[5,4] Hiroyuki Asanuma,[4] Shoichi Maruyama.[1] *[1]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [2]Fujita Ika Daigaku, Toyoake, Japan; [3]Suzuka Iryo Kagaku Daigaku, Suzuka, Japan; [4]Nagoya Daigaku, Nagoya, Japan; [5]Kobe Yakka Daigaku, Kobe, Japan*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most frequent single-gene disorders. It is characterized by the prolific emergence of renal cysts originating from the renal tubules, which proliferate within the bilateral kidneys due to the disturbance of manifold cellular processes. These aberrations include abnormal tubular epithelial cell proliferation, anomalous apoptotic events, and perturbations in mitochondrial metabolism. MicroRNAs (miRNAs) are endogenous small RNAs that regulate gene expression at the post-transcriptional level via sequence-specific hybridization. It has been reported that miR-21 is upregulated in ADPKD and is involved in cyst formation. In the present study, we assessed the effect for cystic disease using an anti-miRNA oligonucleotide targeting miR-21 synthesized from serinol.

Methods: In this study, we synthesized anti-miR-21 oligonucleotides from serinol nucleic acid to improve nuclease resistance and affinity to nucleic acid molecules and evaluated renal function and cyst growth in vivo mouse model. In vitro, anti-miR-21 oligonucleotides treatment was evaluated for inhibition of cyst enlargement in primary cultured renal tubular cells derived from ADPKD patient.

Results: In a mouse model of cystic kidney disease, systemically administered anti-miR-21 oligonucleotides accumulated mainly in the kidney, suggesting effective drug delivery to the diseased kidney, in addition to successfully suppressing renal cyst growth and improving renal function in mice. Anti-miR-21 oligonucleotides markedly suppressed miR-21 expression in microRNA in situ hybridization of miR-21 in the cystic kidney tissue. Western blotting of kidney tissue showed that it affected molecules associated with proliferation, mitochondrial metabolism, apoptosis, and fibrosis pathways characteristic in multiple cystic kidneys. In vitro, anti-miR-21 oligonucleotides significantly reduced cyst size and ameliorated the characteristic decrease in Ca2+ concentration in primary cultured human cells derived from ADPKD patient.

Conclusions: The favorable effect of anti-miR-21 oligonucleotide on cystic kidney model animals and human ADPKD cells showed its potential as a clinical therapeutic agent for ADPKD.

TH-PO435

RGLS8429-Mediated miR-17 Inhibition Leads to Acute PKD1/2 De-repression and Ameliorates Preclinical ADPKD

Ronak Lakhia,[1] Jesus A. Alvarez,[1] Harini Ramalingam,[1] Patricia Cobo-Stark,[1] Laurence M. Biggers,[1] Jianfeng Huang,[2] Tania M. Valencia,[2] Edmund C. Lee,[2] Vishal Patel.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Regulus Therapeutics Inc, San Diego, CA.*

Background: ADPKD is caused by reduced *PKD1/2* gene dosage. However, drugs that improve *PKD1/2* levels are not available. We have shown that microRNA-17 directly represses *PKD1/2* and aggravates ADPKD progression. Thus, our goals were to characterize the next-gen anti-miR-17 drug RGLS8429 and its impact on *PKD1/2* and ADPKD.

Methods: We treated murine and human ADPKD kidney cell lines and mouse models with PBS, control oligo, or RGLS8429 to assess for miR-17 inhibition, *PKD1/2* de-repression, and therapeutic efficacy before or after PKD onset and in synergy with tolvaptan. We used multi-omic analyses to uncover early cellular and molecular events modulated by RGLS8429.

Results: RGLS8429, a 9-nt oligonucleotide, inhibits the miR-17 miRNA family and de-represses direct miR-17 targets, including *PKD1/2*. It reduces 3D cyst size in multiple mouse and human ADPKD cell lines. In the Ksp^{Cre};$Pkd1^{F/RC}$ model, RGLS8429 effectively delivers to kidney cysts, even if administered after significant disease, and leads to a rapid *Pkd1/2* de-repression within just 3 days of starting treatment. Remarkably, early RGLS8429 treatment prevents cyst formation, while treatment initiation at later disease stages stabilizes cyst burden and prolongs survival, with ~50% of mice surviving nearly 1 year and, in some cases, showing disease resolution. Further, we demonstrate therapeutic synergy between RGLS8429 and tolvaptan in the Pcy model. Finally, we produced a high-resolution cellular atlas by profiling >160,000 single nuclear transcriptomes (snRNA-seq),

uncovering 26 kidney cellular clusters. We noted rapid transitions in cellular states within 10 days after treatment initiation, with a reduced abundance of immune cells and principal cells with fibroinflammatory signatures and the emergence of 'healthier' proximal tubule cell types. We used a multi-layered, sequential RNA-seq and proteomics approach to map early molecular events onto these cellular neighborhoods.

Conclusions: RGLS8429-mediated acute pharmaceutical *PKD1/2* de-repression holds the potential for a significant disease-modifying effect in ADPKD. This promising drug is currently being evaluated in Phase 1b ADPKD clinical trials.

TH-PO436

Development of a Pkd1 mRNA Stabilizing Oligonucleotide for the Treatment of ADPKD

Ronak Lakhia, Maggie Zumwalt, Laurence M. Biggers, Harini Ramalingam, Patricia Cobo-Stark, Vishal Patel. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Nearly 80% of individuals with ADPKD harbor a pathogenic mutation in one copy of the *PKD1* gene. We have identified a miR-17 binding motif in the 3′ untranslated region (3′UTR) of *PKD1* that represses mRNA translation emanating from the other remaining allele. Here we have engineered an oligonucleotide directly targeting the *PKD1* 3′UTR to sterically hinder miR-17 interaction with *PKD1* mRNA and enhance its translation.

Methods: We designed a 16-base pair oligonucleotide that specifically binds to the miR-17 binding motif in the *Pkd1*3′-UTR (*Pkd1* oligo). Next, we tested *Pkd1* oligo in *Pkd1*$^{+/+}$ and *Pkd1*$^{RC/-}$ kidney epithelial cells. We used CRISPR-based live-cell imaging and qRT-PCR of *Pkd1* mRNA to quantify the abundance and transcript degradation rates to determine the *Pkd1* mRNA half-life. We performed 3D cystogenesis assays and western blot to assess for phenotypic benefit. Finally, we characterized the effect of our oligo in multiple human ADPKD kidney cell lines. In each experiment, a non-targeting scramble oligonucleotide was used as a control.

Results: Live-cell imaging of endogenous *Pkd1* mRNA and qRT-PCR revealed that *Pkd1* oligo treatment increased *Pkd1* mRNA abundance in both *Pkd1*$^{+/+}$ and *Pkd1*$^{RC/-}$ cells. In addition, *Pkd1* oligo prolonged *Pkd1* mRNA half-life compared to control oligo-treated cells. Moreover, we find that enhancement of *Pkd1* mRNA by *Pkd1* oligo translates to increased PC1 protein in both *Pkd1*$^{+/+}$ and *Pkd1*$^{RC/-}$ cells. Phenotypically we find that *Pkd1* oligo-treatment leads to reduced cyst size, enhanced mitochondrial membrane potential, and reduced pCREB expression in *Pkd1*$^{RC/-}$ cells. Finally, we find that treatment of multiple human ADPKD kidney cell lines with *Pkd1* oligo enhances *PKD1/PC1*, improves mitochondrial metabolism, reduces cyst size and pathogenic marker expression.

Conclusions: Our studies are the first to demonstrate the feasibility of oligonucleotides to raise endogenous *PKD1/PC1*expression. More broadly, our work suggests a novel 3′-UTR-based therapeutic approach for treating other haploinsufficient disorders by amplifying the healthy gene copy.

TH-PO437

Patient Cyst Type Composition Predicts Responsiveness to Therapeutic Intervention in Autosomal Polycystic Kidney Disease

Johannes Roeles,[1] Axel Giesler,[1] Jan H. Braesen,[2] Jessica Schmitz,[2] Frank Friedersdorff,[3,4] Michael Kottgen,[5] E. Wolfgang Kuehn,[5] Roland Schmitt,[1,6] Kai M. Schmidt-Ott,[1] Christian Hinze.[1] Hinze Lab. *[1]Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany; [2]Hannover Medical School, Nephropathology Unit, Department of Pathology, Hannover, Germany; [3]Charité Universitätsmedizin Berlin, Department of Urology, Berlin, Germany; [4]Evangelisches Krankenhaus Königin Elisabeth Herzberge, Department of Urology, Berlin, Germany; [5]University of Freiburg Faculty of Medicine, Department of Nephrology and Primary Care, Freiburg, Germany; [6]University Hospital Schleswig-Holstein, Department of Nephrology and Hypertension, Kiel, Germany.*

Background: Autosomal polycystic kidney disease (ADPKD) is the main genetic cause of end stage renal disease. High variability of disease progression and inability of current models to accurately predict clinical efficacy hamper drug development and individualized patient care.

Methods: We analyzed 15 cyst wall samples from 5 ADPKD patients and 3 samples of tumor adjacent normal kidney tissue from 3 patients using single nucleus RNA sequencing (snRNA-seq) and immunofluorescence (IF) imaging. For cysts, the composition of cyst fluids was measured. An additional cohort of ca. 370 cyst from 9 patients was analyzed using machine learning aided IF image analysis to validate results.

Results: Integrated snRNA-seq analysis enabled clear identification of all major kidney cell types. Based on the expression of megalin (LRP2) or aquaporin 2 (AQP2) in the cyst epithelium, cysts could be categorized into proximal tubule-like (LRP2^{+}) and collecting duct-like (AQP2^{+}) cysts. Moreover, multiple cysts contained LRP2^{+} and AQP2^{+} populations within the same cyst (mixed cysts). Our gene expression analysis strongly suggests a differential responsiveness of cyst types to therapeutic interventions, including diet modifications, preclinical compounds, and drugs tested in clinical trials. The mechanistic amenability to drugs targeting epithelial injury and inflammation (MCP-1 inhibitors, Bardoxolone) depended mainly on pure versus mixed cyst identity. By contrast, expression of molecular targets for modulating solute-water transport (Vaptans, CFTR inhibitors) was cell type-specific. Importantly, the analysis of ca. 370 cysts from 9 additional patients revealed highly variable ratios of LRP2^{+} to AQP2^{+} to mixed cysts between patients.

Conclusions: Our study reveals an intra- and inter-individual heterogeneity of cyst types, which predicts the differential responsiveness of patients to treatment. The frequent detection of proximal tubule and mixed cysts calls for critical re-evaluation of current disease models and drug development efforts, which focus mainly on the collecting duct. Future strategies determining the individual cyst type composition are warranted to significantly improve treatment of patients with ADPKD.

A Ketogenic Diet Alters Liver Cyst Progression in a Rodent Model of Polycystic Kidney Disease and Is Dependent on GPR109A

Jacob A. Torres, Brina A. Aceves, Melina Messing, Nickolas J. Holznecht, Shreya Krishnan, Roxanna Razavi, Anna G. Seligson, Thomas Weimbs. *University of California Santa Barbara, Santa Barbara, CA.*

Background: Polycystic Liver Disease (PLD) often co-occurs alongside Autosomal Dominant Polycystic Kidney Disease (ADPKD), a genetic disorder characterized by the growth of numerous cysts in the kidneys. Our lab has demonstrated that a low-carbohydrate, high-fat ketogenic diet, can slow and partially reverse kidney cyst growth in animal models of PKD in a mechanism involving the ketone beta-hydroxybutyrate (BHB). Furthermore, clinical evidence has found that ketogenic dietary interventions appear to be safe, feasible, and potentially beneficial for ADPKD patients. However, the impact of a ketogenic diet on PLD remains unexplored. This study aims to investigate the effects of a ketogenic diet and the BHB receptor, GPR109A, on PLD using an orthologous rodent model of PKD to build on the existing knowledge of the beneficial effects of such a diet on kidney cyst progression in ADPKD.

Methods: We utilized wild-type and *Gpr109a*-knockout mice with a tamoxifen-inducible *Pkd1*$^{fl/fl}$:ROSA-Cre system. Mice were induced on postnatal day 28 through postnatal day 30. Three days post-induction, the mice were segregated into two groups for a twelve-week dietary intervention: one group was fed a low carbohydrate (~5% of total calories), high-fat (~80% total calories) ketogenic diet, while the other group was maintained on standard chow. Following this period, tissues were harvested and subjected to a comprehensive analysis to assess disease progression, including histological and immunohistochemical analysis.

Results: Our study revealed a marked manifestation of hepatic cysts in the induced animals, as depicted by a significant increase in both the number and size of bile ducts, liver mass, and collagen deposition when compared to uninduced controls. Treatment with a ketogenic diet significantly reduced liver mass and fibrosis and was dependent on *Gpr109a*. Additionally, the localization of immune cells exhibited distinctly different patterns in treated versus untreated cystic animals.

Conclusions: We find that a ketogenic diet significantly blunts the growth of the liver due to PLD and markedly decreases collagen deposition. These findings underscore the potential of ketogenic dietary interventions as a novel therapeutic strategy for PLD and the importance of the receptor GPR109A.

TH-PO439

The Receptor GPR109A Modifies Cystic Disease Progression and the Effect of Beta-Hydroxybutyrate in Polycystic Kidney Disease

Jacob A. Torres, Nickolas J. Holznecht, Brina A. Aceves, Elizabeth H. Sharpe, Margaret Schimmel, Maria Shapiro, David A. Asplund, Shagun Agrawal, Bradley C. Kroes, Sebastian Strubl, Thomas Weimbs. *University of California Santa Barbara, Santa Barbara, CA.*

Background: Our lab's research has demonstrated that ketogenic metabolic therapies (KMT) can effectively slow and reverse the progression of polycystic kidney disease (PKD) in multiple rodent models of the disease. Moreover, we have discovered that the beneficial effects of KMT are largely mediated by the action of the metabolite beta-hydroxybutyrate (BHB). This finding opens up the possibility of developing BHB supplementation as a potential treatment for PKD. In addition to its role as an energy substrate, BHB acts as a signaling molecule and binds to the receptor GPR109A. GPR109A is expressed on macrophages and epithelial cells, regulating the activity of adenylate cyclase, a known contributor to PKD progression. Given the integral role GPR109A plays in cellular signaling, it is strongly implicated in mediating the effect of KMT in PKD, highlighting its potential as a therapeutic target.

Methods: Three-week-old Pkd1RC/RC mice with and without concurrent Gpr109a gene inactivation were treated with BHB until 3 months of age and then euthanized for

analysis. Additionally, 4-week-old Pkd1:Nestin-Cre mice with and without Gpr109a were treated with a ketogenic diet for 4 weeks and then euthanized for analysis.

Results: Loss of GPR109A causes a worsening of cystic disease progression in the Nestin-Cre mouse, altering the effect of a ketogenic diet on PKD. Additionally, GPR109A Knockout in the Pkd1RC/RC mouse caused a loss of some of the beneficial effects of BHB supplementation.

Conclusions: We found that loss of GPR109A caused a worsening of disease in the Nestin:Cre mouse and a partial loss of BHB's effect in the Pkd1RC/RC mouse. These results indicate that GPR109A is at least partially involved in slowing the progression of PKD, regulating the endogenous action of BHB as well as the beneficial effect of KMT on PKD progression.

Real-Life Data from a Ketogenic Metabolic Therapy Program for Autosomal-Dominant Polycystic Kidney Disease Suggests Significant Benefits to Participants

Emily G. Muensterman,[1] Kelly L. Welsh,[2] Diana Bruen,[1,4] Jacob A. Torres,[1,3] Thomas Weimbs,[1,3] Jessianna Saville.[2,1] *[1]Santa Barbara Nutrients, Inc., Santa Barbara, CA; [2]Kidney Nutrition Institute, Titusville, FL; [3]University of California Santa Barbara, Santa Barbara, CA; [4]The PKD Dietitian, Henrico, VA.*

Background: ADPKD, the most common genetic form of chronic kidney disease, lacks pharmacological treatments to halt or reverse its progression. Recent studies indicate that nutrition and lifestyle factors, such as renal microcrystals (calcium oxalate/phosphate/uric acid) and metabolic issues (persistent hyperglycemia/insulin resistance), contribute to ADPKD progression. Dietary interventions aiming to reduce renal microcrystals through citrate supplementation and urine alkalization, and to improve metabolism via ketosis or beta-hydroxybutyrate (BHB) supplementation, have shown promise in animal models. Recent human clinical studies also support the potential benefits of these interventions.

Methods: The Ren.Nu program, developed in 2021 by renal dietitians and PKD-focused scientists, helps patients adopt a plant-focused, kidney-safe, ketogenic lifestyle to improve metabolic health and reduce renal microcrystal burden. It uses KetoCitra®, a medical food with exogenous BHB, citrate, minerals, and alkaline base. Nearly 200 ADPKD patients have completed the personalized medical nutrition therapy group program. The first year of development focused on methodology refinement, and since 2022, clinical and quality of life (QOL) data have been collected. This is not a formal clinical trial but an assessment of a real-life dietary program.

Results: Analysis of outcomes for 103 participants from baseline to program completion revealed significant improvements. Participants adhered well to the diet and lifestyle changes, evidenced by consistently elevated blood BHB levels and reduction in fat weight loss. There was a 6.3% increase in the estimated glomerular filtration rate (eGFR) from 58.4 to 61.6 mL/min/1.73m2 (P<0.001). The program reduced kidney pain, headaches, and hypertensive medication use. Biomarkers (total-, HDL-, LDL-cholesterol, triglycerides, potassium, phosphorus, bicarbonate) remained stable, indicating safety.

Conclusions: Our evaluation and ongoing clinical experience with the Ren.Nu program indicates that its dietary and lifestyle interventions, combined with the medical food, KetoCitra®, are feasible and safe. Several ongoing and planned controlled clinical studies will further assess the long-term effects on metabolic health, lithogenic risk, and renal outcomes.

TH-PO441

Metabolite Changes while Adhering to a Ketogenic Diet in Autosomal Dominant Polycystic Kidney Disease

Martine G. Knol,[1,2] Sita Arjune,[4] Maatje D. van Gastel,[1] Jacob A. Torres,[3] Thomas Weimbs,[3] Roman-Ulrich Mueller,[4] Markus M. Rinschen.[2,5] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Aarhus Universitet, Aarhus, Denmark; [3]University of California Santa Barbara, Santa Barbara, CA; [4]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany; [5]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany*.

Background: A dysregulated metabolism in Autosomal Dominant Polycystic Kidney Disease (ADPKD) contributes to cystogenesis. A ketogenic intervention, currently under investigation, profoundly changes metabolism and may offer protective effects in ADPKD. Various metabolites, including those from one-carbon metabolism, branched-chain amino acids, tryptophan, and glutamine, have been linked to altering disease progression in ADPKD. This study aimed to discover which metabolites change during ketogenic interventions using LC/MS/MS in the KETO-ADPKD trial.

Methods: Targeted metabolomics was performed using LC/MS/MS. Urine and serum samples from the KETO-ADPKD trial (n=63) were used. Participants followed a ketogenic diet (n=23), a 3-day water fast once monthly (n=21), or a control diet (n=19). Additionally, serum and kidney tissue were measured from Han:SPRD PKD rats (n=18) and WT rats (n=18) on a ketogenic or control diet.

Results: The average age was 41±9.6, and 44% were women. Of 21 participants, we had serum samples on baseline and 3 months after the ketogenic diet. 112 metabolites were quantified in the serum. Serum analysis revealed changes in 6 upregulated and 7 downregulated metabolites after a 3-month ketogenic diet. An increase in ketone bodies indicated adherence to a ketogenic diet. Further increases in citric acid and homocysteine, and decreases in hypotaurine, aspartate, and kynurenine were observed. In the spot urine, 89 metabolites were quantified and normalized to urinary creatinine. After 3 months, 9 metabolites were significantly more excreted, out of which 5 were aromatic amino acid metabolites (so-called uremic toxins), and 1 metabolite, tyrosine, was downregulated. We assessed the effect of the ketogenic diet in PKD rats and WT rats in kidney tissue and serum to compare to the human data, providing similar signatures.

Conclusions: Profound changes in ketosis-induced metabolism were observed. Of special interest are the decreased abundance of hypotaurine and kynurenine, which were found in both humans and animals. Elevated kynurenine levels, a uremic toxin, have been described before in ADPKD, and their relevance in cyst progression should be further studied. How hypotaurine is regulated in ADPKD and whether it plays a part in the pathophysiology still need to be unraveled.

TH-PO442

Early Insights from Grease II: Safety and Efficacy of a Ketogenic Diet in ADPKD

Maria Ferri,[1] Carla Pezzuoli,[5] Giulia Ligabue,[2] Silvia Giovanella,[2] Francesca Testa,[1] Marco Ferrarini,[2] Francesca Ciurli,[3] Maria Amicone,[4] Antonio Pisani,[4] Riccardo Magistroni.[2,1] AOU Policlinico di Modena, Nephrology Unit. *[1]AOU Policlinico di Modena, Nephrology Unit, Modena, Italy; [2]University of Modena and Reggio Emilia, Dep. CHIMOMO, Modena, Italy; [3]Nephrology, Dialysis and Kidney Transplant Unit, IRCCS, AOU, Bologna, Italy; [4]AOU Federico II, Nephrology Unit, Napoli, Italy; [5]Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Italy*.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a systemic disorder marked by the progressive formation and enlargement of kidney cysts, ultimately leading to kidney failure. Common extra-renal manifestations include polycystic liver disease, cerebral aneurysms, and cardiac valve abnormalities. The primary genetic causes are mutations in the PKD1 and PKD2 genes. Currently, Tolvaptan, a vasopressin-2 receptor antagonist, is the only approved therapy, which primarily slows kidney function decline without addressing extra-renal complications. Research indicates that cyst-lining epithelial cells in ADPKD are glucose-dependent due to metabolic alterations, including defective glucose metabolism, impaired beta-oxidation, and abnormal mitochondrial activity(Warburg effect). Thus, dietary manipulation to induce ketosis and deprive these cells of glucose is a promising therapeutic strategy.

Methods: The Grease II study is a phase II, 24-month randomized, parallel-group, two-arm superiority trial with a 1:1 allocation. It aims to evaluate the efficacy of a ketogenic diet (Modified Atkins Diet - MAD) compared to a balanced normocaloric diet (BND) in 92 patients with rapidly progressive ADPKD. During the run-in period blood pressure and lipid abnormalities will be normalized, if necessary. The primary outcome is the difference in kidney volume enlargement between the two groups, assessed by MRI at baseline and after 12 months. To mitigate potential biases from glycogen depletion induced by the ketogenic diet, MRIs will be performed after a 30-day switch to the BND diet for both groups. Secondary outcomes include, renal function comparison between the two groups, calculated using the CKD-EPI formula on creatinine and cystatin, at the end of the study(24 months of follow up).

Results: We anticipate achieving three primary endpoints: confirmation of MAD's tolerability through questionnaire data, confirmation of safety monitored via laboratory tests and clinical observations, reduction in Total Kidney Volume, measured by MRI, in the MAD group. Secondary endpoints include improvements in renal function and the impact of MAD on exploratory biomarkers.

Conclusions: The study is on going and 23 patients were recruited. This study was funded by the Italian ministry of Health - RF-2021- 12374522

Funding: Government Support - Non-U.S.

Dietary Lysine Supplementation Causes Metabolic Dysregulation and Kidney Cyst Growth in Mice with Polycystic Kidney Disease

Randee Sedaka, Jifeng Huang, Shinobu Yamaguchi, Caleb R. Lovelady, Emily Hallit, Aida Moran-Reyna, Sejal Sanjay Shinde, Jung-Shan Hsu, Malgorzata Kasztan, Takamitsu Saigusa. Dept of Medicine/Div of Nephrology, Dept of Pediatrics/Div of Pediatric Hematology Oncology. *The University of Alabama at Birmingham, Birmingham, AL*.

Background: High casein protein diet induces renal hypertrophy, macrophage (MΦ) infiltration, and accelerated cyst growth in polycystic kidney disease (PKD) mice. Early cyst growth during casein protein load is associated with higher expression of glutamine transporter Snat3 and energy metabolism markers prior to increases in kidney MΦ

number. It is unknown whether plant-based protein similarly exacerbates PKD. Here, we determined the effect of wheat- or casein-based diet on cyst growth, as well as how specific amino acids abundant in these respective diets contribute to disease progression in mice lacking *Pkd1*.

Methods: Adult tamoxifen inducible global *Pkd1* knockout (*Pkd1*KO) mice were fed a high protein (60%) casein or wheat-gluten (WG) diet for 6 weeks. Kidneys were harvested for histology, MΦ quantification, and mitochondrial function. The most abundant amino acid in casein and WG diets were Lysine (Lys) and glutamine (Gln), respectively. Thus, *Pkd1*KO mice were gavaged with Lys (6.8g/kg/day), Gln (5.3g/kg/day) or phosphate buffered saline (PBS) for 4 weeks to assess cyst growth, glomerular filtration rate (GFR) and kidney tissue analysis.

Results: WG-fed *Pkd1*KO mice had fewer kidney MΦs, cytokines and cysts versus casein-fed counterparts. Mitochondrial oxygen consumption rate was similar between diets. Although both Lys and Gln gavaged *Pkd1*KO mice had higher GFR compared to PBS treated counterparts, only Lys gavaged mice had increased kidney cysts with higher expression of energy metabolism and fatty acid catabolism markers. Further, Lys treated mice had elevated renal Snat3 expression and urinary ammonia excretion, but lower blood urea nitrogen compared to Gln counterparts. Neither Lys nor Gln supplementation altered inflammatory cytokine expression relative to PBS treated mice.

Conclusions: Plant-based protein retarded the inflammation and cyst growth observed in casein-fed *Pkd1*KO mice. Lys, the most abundant amino acid in casein versus WG diet, increased Gln transport, energy metabolism and cyst growth in early PKD.

Evaluating the Safety and Effectiveness in Adult Korean Patients Treated with Tolvaptan for Management of Autosomal Dominant Polycystic Kidney Disease (ESSENTIAL): Final Report

Hayne C. Park,[1] Yong Chul Kim,[3] Yeonsoon Jung,[2] Yaerim Kim,[4] Yun Kyu Oh.[5]
[1]Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [2]Kosin University, Busan, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [5]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Seoul, Republic of Korea.

Background: Tolvaptan, a selective vasopressin V2 receptor antagonist, was first approved by Korean FDA in 2015 as a treatment option in autosomal dominant polycystic kidney disease (ADPKD). To prescribe Tolvaptan safely and effectively, we designed the phase 4 clinical trial among Korean ADPKD patients with chronic kidney disease (CKD) stage 1-3.

Methods: A total of 117 Korean patients aged 19 to 50 with rapidly progressing ADPKD were enrolled in the study. Tolvaptan was prescribed for 24 months with the maximum tolerable dose up to 120mg per day. The primary outcome was the incidence of treatment emergent adverse events (TEAEs) including hepatic adverse events. The secondary outcomes were the annual mean percent change of total kidney volume (TKV) and the annual mean change of estimated glomerular filtration rate (eGFR).

Results: A total of 489 TEAEs occurred in 106 (90.6%) patients. A total of 17 cases (14.5%) of hepatic adverse events occurred during the study period and mostly within the first 18-month period. However, liver enzymes were normalized after drug discontinuation. Although it was not statistically significant, patients with a previous history of liver disease as well as those with mild elevation of liver enzyme showed higher frequency of hepatic adverse events. Comparing with the predicted value from calculation, Tolvaptan attenuated both TKV growth and eGFR decline rate.

Conclusions: Although the incidence of hepatic adverse events was higher in Korean ADPKD patients compared to the previous studies, Tolvaptan can be prescribed safely and effectively using meticulous titration and 1-month interval monitoring.

Funding: Commercial Support - Korea Otsuka Pharmaceuticals

Effectiveness of Tolvaptan on Kidney Replacement Therapy in Patients with Autosomal Dominant Polycystic Kidney Disease: A Retrospective Cohort Study from the TriNetX Global Collaborative Network

Ming-Ju Wu,[1,2] Cheng-Hsu Chen.[1,2] *[1]Taichung Veterans General Hospital, Taichung, Taiwan; [2]National Chung Hsing University, Taichung, Taiwan.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a major genetic contributor to end-stage kidney disease (ESKD). Current evidence on tolvaptan primarily focuses on slowing estimated glomerular filtration rate (eGFR) decline and kidney volume growth. However, direct confirmation of its effectiveness in reducing the need for hemodialysis in ESKD remains limited.

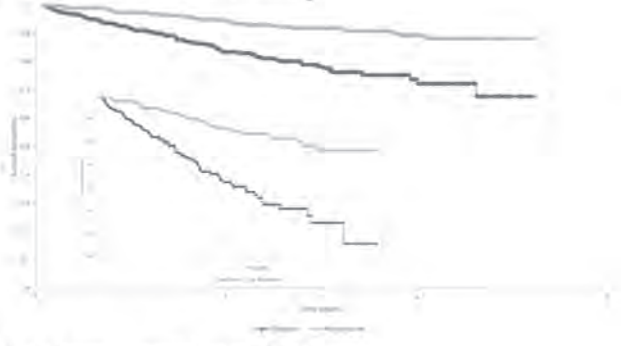
Methods: We enrolled ADPKD patients aged ≥18 years using TriNetx data from Sep 2, 2018, to Sep 3, 2023. Propensity score matching (PSM) ensured baseline comparability (standardized mean difference (SMD) <0.1).

Results: After 1:1 PSM, both groups comprised 673 patients. The average age was 45, with generally good health (3-5% diabetes, 2-3%). Baseline eGFR averaged ~50 ml/min/1.73m^2. Post-matching, all SMDs were <0.1, indicating successful matching. Tolvaptan users exhibited lower eGFR (47.3±26.5 vs. 53.5±34.3, p=0.001) and higher risk of stage 4-CKD (HR: 2.44, 95% CI:1.65, 3.60) compared to non-users. However, tolvaptan users showed significantly reduced chances of initiating hemodialysis (HR:0.362, 95%CI:0.18, 0.75), experiencing urinary tract infections (HR:0.58, 95%CI:0.35, 0.96), and all-cause mortality (HR:0.36, 95CI:0.18, 0.70). Lower eGFR in tolvaptan groups was not observed when refill time was ≥9. Kaplan-Meier curves for hemodialysis initiation indicated higher survival rates among tolvaptan users across age and refill time subgroups.

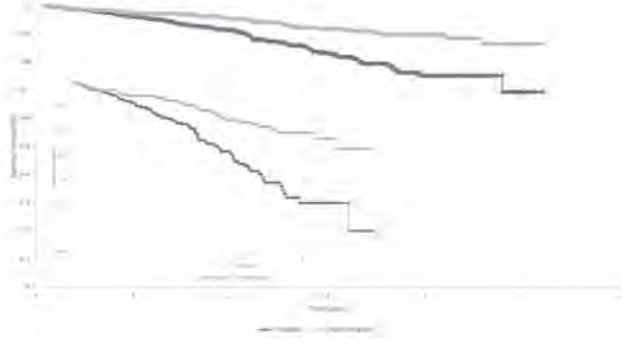
Conclusions: This real-world study, employing precise matching, reveals tolvaptan's role in reducing hemodialysis initiation risk in ADPKD, despite initial hemodynamic-induced lower eGFR. With more frequent refills, differences in subsequent eGFR became statistically insignificant.

Figure 1, In comparison to the non-tolvaptan group, the tolvaptan-treated group showed a higher likelihood of progressing to stage 4 (figure A) and stage 5 CKD (figure B) (both log-rank tests p<0.0001). Two Kaplan-Meier curves were presented per outcome with different scales to highlight the differences) (outcome: one month after the index event)

A. CKD stage 4 (log-rank test p<0.0001)



B. CKD stage 5 (log-rank test p<0.0001)



Kaplan-Meier survival curves

TH-PO446

Combination Treatment of Difelikefalin and Tolvaptan for Late-Stage Polycystic Kidney Disease

Ashlyn Y. Anderson, Daniel R. Kapusta, Kara Johnson, Madison G. Haggard, Jacob K. Meariman, Ian B. Denys, Mihran V. Naljayan, Juan Gao.
LSU Health New Orleans, New Orleans, LA.

Background: We have previously reported that, in the early stages of polycystic kidney disease (PKD), combination treatment of the kappa opioid agonist, difelikefalin, and the V2 vasopressin receptor antagonist, tolvaptan, maintained glomerular filtration rate and ameliorated polyuria and polydipsia associated with tolvaptan monotreatment. This current study tested the hypothesis that combination treatment of difelikefalin and tolvaptan can protect against worsening of PKD in the late stages.

Methods: Six-month old PKD mice were divided into five groups and were treated daily (dose titrated to decrease urine osmolality) for 3-months with either difelikefalin, tolvaptan, a combination of difelikefalin and tolvaptan (D+T), a combination of difelikefalin and half does of tolvaptan (D+1/2T), or vehicle. Metabolic studies were performed monthly to measure 24-hour urine output and water intake during the study period. Glomeruli filtration rate (GFR; beginning, midterm, endpoint) and total kidney volume (TKV, calculated as length, width, and depth of kidneys after mice were sacrificed) were determined in each group. Kidney tissue cAMP levels were also measured after mice were sacrificed.

Results: Treatment of PKD mice with difelikefalin, tolvaptan, D+T, and D+1/2T all prevented a decline in GFR over time. D+1/2T reduced the ratio of kidney weight to body weight by 12% compared to PKD mice treated with vehicle. None of the treatments caused a statistically significant reduction in TKV. Compared to vehicle, treatment with D+1/2T produced increases in 24-hr urine volume and decreases in urine osmolality measured monthly in PKD mice that were greater in magnitude than responses produced by difelikefalin alone, but less than mice treated with tolvaptan or D+T. The combination treatments of D+T and D+1/2T both significantly decreased renal cAMP levels compared with vehicle.

Conclusions: Together, these results suggest that combination treatment of difelikefalin and tolvaptan preserves kidney filtration function, reduces side effects, and decreases necessity of dose escalation of tolvaptan in late stages of PKD. (Funding DoD W81XWH-22-1-0046)

Investigational New Drug (IND)-Enabling Studies to Support the Development of 2-Deoxy-D-Glucose (2DG) for the Treatment of ADPKD

Matteo Federici,[1] Scott J. Weir,[3] Carolyn J. Vivian,[3] Alan S. Yu,[2] Alessandra Boletta.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; [3]University of Kansas Institute for Advancing Medical Innovations, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the growth of fluid-filled cysts due to abnormal epithelial proliferation. We have demonstrated that ADPKD cyst epithelial cells undergo metabolic reprogramming, which can be targeted using 2DG. Our preclinical data indicate that 2DG retards the disease progression in PKD models. Previously tested in >300 individuals, 2DG showed to be safe at 45-63 mg/kg/day. We have designed a Phase 1b clinical trial to evaluate safety/tolerability in ADPKD patients assuming a ceiling dose of 32 mg/kg/day. We now present our development program and the IND-enabling studies required to support this clinical trial

Methods: Our program was discussed in a pre-IND meeting with the FDA. The purpose was to reach agreement on chemistry, manufacturing, and controls (CMC) and nonclinical studies to be completed prior to the IND submission. We manufactured a GMP batch of 2DG drug substance, with ongoing stability testing. Nonclinical GLP studies are being conducted in two species to determine the toxicity/toxicokinetic profile of 2DG when administered by oral gavage. The studies include dose escalation to determine the maximum tolerated dose followed by 7-day repeat-dose to assess tolerance, 28-day repeat-dose toxicity, safety pharmacology on CNS, respiratory, cardiovascular systems, and genotoxicity studies

Results: The FDA generally agreed with our development program and gave helpful recommendations to optimize the nonclinical plans. The GMP batch passed all quality controls for release. Preliminary data showed stability at least up to one year. In the dose escalation study 2DG resulted well tolerated at single dose up to 1,600 mg/kg in the rat and 480 mg/kg in the dog (human equivalent dose of ~256 mg/kg). Transient clinical signs were observed only at 1,600 mg/kg in rats. No major gross findings at necropsy in both species. Bacterial reverse mutation test showed negative mutagenic response.

Conclusions: Our hypothesis is that 2DG will be an effective and safe treatment for ADPKD. The results from current nonclinical studies, along with CMC information and clinical trial plans, will be ultimately included in the IND submission to seek FDA approval for initiating the clinical study. Future efforts will focus on securing funds for the clinical trials.

Diagnosis and Management of Polycystic Kidney Disease in a Commercially Insured Population

Yun Han,[1] Michael Heung,[1] Areeba Jawed,[1] Jennifer L. Bragg-Gresham,[1] Fang Xu,[2] Yoshihisa Miyamoto,[2] Pranav S. Garimella,[3] Rajiv Saran.[1]
[1]University of Michigan, Ann Arbor, MI; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of California San Diego, La Jolla, CA.

Background: Since the approval of vasopressin V2-receptor antagonist tolvaptan to treat polycystic kidney disease (PKD) in April 2018, there has been an increase in diagnosis of PKD. Generally reserved for younger patients with aggressive disease, tolvaptan is associated with increased healthcare costs in managing PKD. We sought to investigate contemporary diagnostic and management practices among commercially insured patients with newly diagnosed PKD.

Methods: Patients with PKD were identified in Optum Clinformatics™ Data (2016-2020, 38.7 million beneficiaries) by ICD-10 diagnosis codes. A one-year look-back window was utilized to identify newly diagnosed PKD, determined by the initial diagnosis codes on or after January 1, 2017. CPT codes were used to identify kidney imaging: ultrasound, magnetic resonance imaging (MRI), and computed tomography (CT); brain vascular imaging: magnetic resonance angiography (MRA) and computed tomography angiography (CTA); genetic testing; kidney related surgery; and tolvaptan. Utilization of these services were analyzed one year prior to and two years following the PKD diagnosis, except for surgery and tolvaptan (post-diagnosis only).

Results: A total of 15,260 newly diagnosed PKD patients were identified (mean age: 57.9 years). Service utilization included nephrologist visit (59.3%), kidney MRI (10.2%), CT (43.3%), brain MRA or CTA (12.6%), ultrasound (40.9%), genetic consultation (3.4%), kidney-related surgery (0.6%), and tolvaptan (2.2%).

Conclusions: PKD-related health service utilization varied with low use of advanced imaging procedure among a large commercially insured population. Findings may underscore the need for standardized care protocols and enhanced awareness of PKD management strategies to improve disease outcomes.

Early Treatment with 2-Deoxy-D-Glucose Reduces Proliferative Proteins in the Kidney and Slows Cyst Growth in a Hypomorphic Pkd1 Mouse Model of Autosomal Dominant Polycystic Kidney Disease

Daniel Atwood, Zhibin He, Makoto Miyazaki, Charles L. Edelstein.
University of Colorado Anschutz Medical Campus, Aurora, CO.

Background: There is enhanced aerobic glycolysis (Warburg effect) in the cyst lining epithelial cells in ADPKD that contributes to cyst growth. The glucose mimetic, 2-Deoxy-d-glucose (2-DG) inhibits glycolysis. The effect of early and late administration

of 2-DG on cyst growth and kidney function was determined in Pkd1RC/RC mice, a hypomorphic PKD model orthologous to human disease.

Methods: Mice were treated with 2-DG (100 mg/kg/d IP) from 50-120 (Early treatment) or 150 to 350 days old (Late treatment). An array of mTOR and autophagy proteins was measured in the kidney by immunoblot analysis. Cre-lox technology was used to Pkd1, Rictor double knockout mice. Proliferation measured by PCNA IHC

Results: Early administration of 2-DG decreased cyst indices (See table). 2-DG decreased proliferation of cells lining the cyst. Late administration of 2-DG had no effect on cyst growth (See Table). 2-DG suppressed autophagic flux in kidneys evidenced by no increase in LC3-II 2 hrs after IP injection of bafilomycin and a decrease in autophagy proteins, ATG3, ATG5 and ATG12-5. 2-DG had no effect on p-mTOR or p-S6 (mTORC1). 2-DG decreased both functional p-4E-BP1 isoforms, p-c-Myc and p-ERK that are known to promote proliferation and cyst growth in PKD. 2-DG decreased p-AKTS473, a marker of mTORC2. However, knockout of Rictor (mTORC2) in Pkd1 knockout mice did not change the PKD phenotype.

Conclusions: In summary, 2-DG decreases proliferation in cells lining the cyst and decreases cyst growth by decreasing proteins that are known to promote proliferation. The present study reinforces the therapeutic potential of 2-DG for use in patients with ADPKD.

Itaconate Controls the Severity of Autosomal Dominant Polycystic Kidney Disease

Ewud Agborbesong, Shasha Cheng, Peter C. Harris, Xia Zhou, Xiaogang Li. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetically inherited disease in which inflammation plays a role in renal cyst growth. Itaconate has emerged as a key immunoregulatory metabolite with diverse roles in inflammation and immunity. However, the role of itaconate in cyst growth and its therapeutic potential in ADPKD is unknown.

Methods: We performed 1) quantitative real-time PCR to examine the expression of aconitate decarboxylase (Acod1) in *Pkd1* mutant renal epithelial cells and tissues, 2) clonogenic assay to assess the effects of itaconate derivative 4-octyl itaconate (4-OI) on *Pkd1* mutant renal epithelial cell growth, and 3) western blot and immunostaining analysis in *Pkd1* homozygous (PN24) renal epithelial and macrophage (RAW264.7) cells treated with 4-OI. Light microscopy was used to assess the effect of 4-OI on RAW264.7 cell activation in a *Pkd1* mutant microenvironment. Furthermore, $Pkd1^{RC/RC}$ mice were treated with 4-OI to evaluate its effect on cyst growth.

Results: We found that the expression of itaconate-synthesizing enzyme, Acod1, was downregulated in PN24 cells compared to *Pkd1* heterozygous (PH2) control cells and in $Pkd1^{RC/RC}$ mouse kidneys compared to wild type kidneys. Treatment with 4-OI decreased 1) PN24 cell proliferation as examined with clonogenic assay, 2) the activation of PKD associated signaling pathways, including Akt, Erk, Stat3, p65, and S6, and 3) the expression of histone modifying enzymes including JMJD2A, a JmjC histone lysine demethylase (KDM), Smyd2 and Smyd3, both histone lysine methyltransferases (KMTs). In addition, we found that treatment with 4-OI altered mitochondrial dynamics by decreasing mitochondrial fission, and increasing mitochondrial fusion as determined by MitoTracker Red staining. Consistent with its immunoregulatory role, 4-OI treatment affected macrophage polarization of RAW264.7 cells stimulated with condition medium from PN24 cells. Importantly, treatment with 4-OI delayed cyst growth in $Pkd1^{RC/RC}$ mice as seen by a decrease in cystic index, kidney weight (KW)/body weight (BW) ratio and blood urea nitrogen (BUN) levels.

Conclusions: Collectively, itaconate contributes to ADPKD by modulating epigenetic reprogramming, cell proliferation, mitochondrial dynamics, and immune response/inflammation, and treatment with itaconate derivatives may be a viable therapeutic strategy for ADPKD.

Increased Urinary Ferritin in Patients with Autosomal Dominant Polycystic Kidney Disease

Madhulika Sharma,[1,2] Nicole Sommer,[1,2] Matthew A. Kavanaugh,[1,2] Pamela V. Tran,[1,2] Alan S. Yu,[1,2] Darren P. Wallace.[1,2] *[1]The University of Kansas School of Medicine, Kansas City, KS; [2]The Jared Grantham Kidney Institute, Kansas, KS.*

Background: Polycystic kidney disease (PKD) is the fourth leading cause of renal failure among adults, yet reliable blood or urine diagnostic and prognostic biomarkers are lacking. Diagnosis is usually made by ultrasound or MRI scanning to estimate height adjusted total kidney volume (htTKV) or PKD mutation analysis, which are expensive. We previously showed that ferritin accumulates in the cystic epithelial cells of PKD kidneys due to loss of ferritinophagy. Here, we evaluate the potential of ferritin as a biomarker of ADPKD progression.

Methods: Cystic fluid from ADPKD patients, urines and urinary extracellular vesicles (UEVs) from normal and ADPKD patients, primary cultures of cyst epithelial cells from ADPKD kidneys and tubule epithelial cells from normal human kidneys (NHK) were obtained from age matched individuals with the assistance of the Kansas Clinical Research Core and Biomaterials and Biospecimens Core at the Kansas PKD Center. ADPKD and NHK cells were grown in low serum, and conditioned media were obtained for the measurement of ferritin by Western blot analysis. Cystic fluid, urine, UEVs and conditioned media were evaluated for ferritin expression via Western blots and ELISA. Urine from normal and PKD ($Pkd^{RC/RC}/Pkd2^{+/-}$) mice was also assessed for ferritin expression.

Results: Ferritin was detected as monomer, dimer, and tetramer units in the cystic fluid of ADPKD patients. Of the urine samples tested, ferritin was detected in one ADPKD patient, and it was not detected in any of the normal individuals. Conditioned media from ADPKD cells had 5 times higher ferritin compared to media from NHK cells. UEVs from ADPKD patients also had significantly more ferritin compared to UEVs from normal age matched individuals. These ferritin levels in UEVs appeared to correlate partially with the Mayo Imaging Classification categories. Moreover, we found that ADPKD mice had increased urinary ferritin compared to WT mice.

Conclusions: Ferritin, secreted by cyst epithelial cells, accumulates in cystic fluid and urine of ADPKD patients and appears to correlate with disease progression. Further studies will test the potential role of ferritin as a diagnostic, prognostic, and a response biomarker for ADPKD.

Association between Age and Body Mass Index in Patients with End-Stage Autosomal Dominant Polycystic Kidney Disease (ADPKD) in the United States and Japan

Tatsuya Suwabe,[1,2] Vicente E. Torres,[2] Lisa E. Vaughan,[2] Charles D. Madsen,[2] Peter C. Harris,[2] Junichi Hoshino,[3] Saori Nishio.[4] *[1]Toranomon Byoin, Minato-ku, Japan; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Juntendo Daigaku, Bunkyo-ku, Japan; [4]Hokkaido Daigaku, Sapporo, Japan.*

Background: Dietary interventions have been proposed to delay the progression of ADPKD. Body mass index (BMI) has been associated with ADPKD progression. However, the long-term effects of dietary interventions and BMI have not been proven.

Methods: Cross-sectional analysis using data from the United States Renal Data System (USRDS) and the Japanese Society for Dialysis Therapy Renal Data Registry (JRDR) to compare the ages and their relation to BMI and other clinical characteristics at initiation of renal replacement therapy (RRT) in these two populations, and their possible association with different dietary habits.

Results: The study included 3,556 patients (1,877 men and 1,679 women; mean age 58.1±13.1 years) who initiated RRT in 2006 and 2007 from the USRDS (2,491) and JRDR (1,065). The mean ages at initiation of RRT were 56.6±13.1 years in the United States and 61.6±12.5 years in Japan (p<0.0001). BMI was 28.2±7.1 kg/m2 in the USRDS and 22.0±3.3 kg/m2 in the JRDR (p<0.0001). Japanese participants were the oldest at time of RRT, followed in descending order by Asian Americans, White Americans, and African Americans. Japanese participants also had the lowest BMI, followed in ascending order by Asian Americans, White Americans, and African Americans. Univariable and multivariable analyses showed that BMI was significantly and inversely associated with age at initiation of RRT in the entire cohort, as well as separately in both the American and Japanese participants. Estimated GFR was not associated with age at initiation of RRT overall and in the USRDS populations, and was significantly, but positively correlated in the JRDR population. As expected, comorbidities were associated with age at initiation of RRT.

Conclusions: BMI is significantly associated with age at initiation of RRT in patients with ADPKD in both the United States and Japan. Japanese had lower BMI and were older than US people of various ethnicities at the initiation of RRT. The lower-calorie diets consumed in Japan are likely associated with lower BMI and a slower progression of ADPKD.

Redefining Overweight and Obesity (OW/OB) in a Large Cohort of Patients with ADPKD

Sol M. Carriazo Julio,[1,3] Taher Dehkharghanian,[1] Mauricio A. Miranda Cam,[1,3] Yasmina Sarie,[3] Xuewen Song,[3] Timothy L. Kline,[2] Saima Khowaja,[1] Korosh Khalili,[1] York Pei.[1,3] *[1]University Health Network, Toronto, ON, Canada; [2]Mayo Clinic Minnesota, Rochester, MN; [3]University of Toronto, Toronto, ON, Canada.*

Background: Emerging data indicate OW/OB are risk factors for accelerated progression in ADPKD patients. Thus, an accurate diagnosis is crucial to implement appropriate therapeutic measures and avoid unnecessary treatments if not indicated. The traditional BMI formula used to define OW/OB does not take into account the excess of weight attributed to large cystic kidney and liver in ADPKD. Here we define the prevalence and clinical characteristics of ADPKD patients with OW/OB in a large cohort using a formula recommended by KDIGO

Methods: Cross-sectional analysis of patients with *PKD1* and *PKD2* mutations from the Toronto PKD Registry who had clinical and MRI measurements of total kidney volume (TKV) and total liver volume (TLV) was performed. BMI was calculated by the formula: weight (kg)/height (m^2)), while estimated BMI (eBMI) was calculated with the formula proposed by KDIGO: adjusted body weight (body weight (kg) - TKV (kg) - TLV (kg) + weight of normal kidneys and liver/ height (m^2)

Results: **Table 1** shows clinical characteristics of the study cohort (n=693) and subgroups defined by eBMI category. The median weight and BMI pre and post adjustment were 73 kg and 25,1 kg/m^2 and 71.8 kg, and 24,3 kg/m^2 respectively. A total of 352 (50.7%) patients were initially classified as OW/OB but the number decreased to 314 (45.3%) post adjustment; 10.7% of those initially classified as OW/OB were reclassified as having normal weight, and 80 (11.5%) of the study cohort were classified into a milder BMI category post adjustment

Conclusions: OW/OB are highly prevalent among patients with ADPKD and are associated with worse prognoses. Using eBMI for an accurate diagnosis of OW/OB can help avoid unnecessary treatment for those previously misclassified

Table 1. Clinical characteristics of the subgroups defined by eBMI category.

Table 1.	Underweight (n=22) <18,5 kg/m^2	Normal weight (n=357) 18.5-25 kg/m^2	Overweight (n=217) 25-30 kg/m^2	Obesity (n=97) >30 kg/m^2

Prognostic Value of Skeletal Muscle Mass and Body Mass Index in PKD

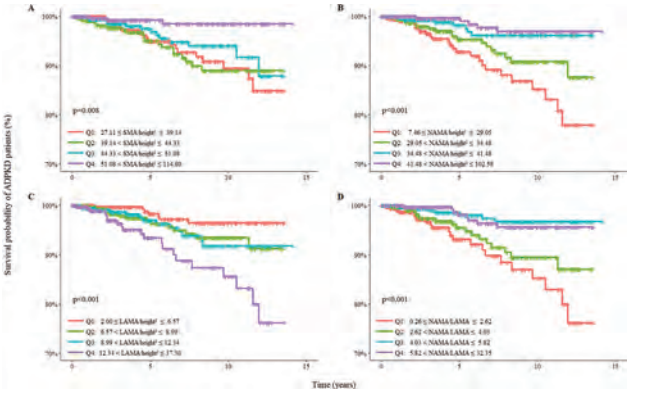
Dha Woon Im,[1] Jiyun Jung,[2] Yon Su Kim,[4] Kook-Hwan Oh,[4] Dong Ki Kim,[4] Hajeong Lee,[4] Seung Seok Han,[4] Eunjeong Kang,[4] Sehoon Park,[4] Sung Joon Shin,[3] Jangwook Lee,[3] Jeongin Song,[3] Jae Yoon Park,[3] Yong Chul Kim.[4] *[1]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [2]Dongguk University College of Medicine, Gyeongju, Gyeongsangbuk-do, Republic of Korea; [3]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [4]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Low muscle mass is a well-established risk factor for the progression of chronic kidney disease (CKD). However, little is known about the impact of muscle mass on mortality in patients with autosomal dominant polycystic kidney disease (ADPKD). This study aimed to investigate the effect of muscle mass on mortality in individuals with ADPKD.

Methods: We collected clinical information on 1273 ADPKD patients from Seoul National University Hospital between 2006 and 2019, and obtained CT image at lumbar 3rd vertebra to measure the skeletal muscle area (SMA) by artificial intelligence. SMA was classified as low attenuation muscle area (LAMA) and normal attenuation muscle area (NAMA) according to muscle quality, and divided by height^2 to adjust the body size. Tracked through 2020, we estimated hazard ratio (HR) and 95% confidence interval (CI) on Cox-proportional hazard model adjusted by sex, age, MAYO classification, serum creatinine, blood urea nitrogen, and glucose.

Results: During the average of 5.14 years, more than half of the patients were female, and the mean (standard deviation) age was 47.2 (12.6) years. We observed 55 deaths, and the average of SMA/height^2, NAMA/height^2, and LAMA/height^2 was 45.4 cm^2/m^2, 35.5 cm^2/m^2, 9.9 cm^2/m^2, respectively. We found significant protective effects of SMA (HR 0.94, 95% CI 0.89–0.98) and NAMA (HR 0.94, 95% CI 0.90–0.97) on mortality while weak adverse effect in LAMA (HR 1.06, 95% CI 1.00–1.12). According to body mass index classification, those who had normal weight (18.5≤BMI<25) showed prominently positive health effects with NAMA increase (HR 0.95, 95% CI 0.91–0.99).

Conclusions: In ADPKD, greater muscle mass, especially high-quality muscle mass, is associated with a reduced risk of mortality.



Survival probability according to quartile of (A) skeletal muscle area (SMA)/height^2, (B) normal attenuation muscle area (NAMA)/height^2, (C) low attenuation muscle area (LAMA) /height^2, and (D) NAMA/LAMA.

TH-PO455

Overweight and Obesity Are Associated with Lower Kidney Blood Flow in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Carissa L. Birznieks, Wei Wang, Cortney Steele, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. *University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Background: We have previously reported that overweight and obesity are independently associated with more rapid progression in adults with early-stage ADPKD. Renal blood flow (RBF) precedes the decline in eGFR and is associated with faster kidney growth. We now evaluated whether overweight and obesity are also associated with changes in renal blood flow.

Methods: 150 non-diabetic adults (25-60 years of age) with ADPKD and an eGFR ≥60 ml/min/1.73m^2 who participated in a randomized controlled trial of pravastatin therapy were categorized based on baseline body mass index (BMI) as normal weight (n=68 [45%], overweight (n=53 [35%], or obese (n=26 [17%]. RBF was measured by phase contrast MRI, analyzed using Segment for Research (Medviso), and adjusted for body surface area (BSA) prior to analysis. The association of baseline BMI with baseline RBF was assessed using multivariable linear regression.

Results: Participants were 40±10 years (mean±s.d), 65% female, with a baseline RBF of 635±214 ml/min/1.73m^2, and a baseline eGFR of 90±21 ml/min/1.73m^2. BSA-adjusted RBF was lower in a stepwise manner with increasing BMI category (**Figure**). After adjustment for demographics, systolic blood pressure, blood glucose, HDL, eGFR, and height-adjusted total kidney volume, both overweight (β-estimate: -116.8; 95% CI: -168.8 -64.8) and obesity (β-estimate: -289.2; 95% CI: -361.5, -216.9) remained significantly associated with lower RBF as compared to normal weight participants. For every one unit increase in BMI, RBF was 20.6 ml/min/1.73m^2 lower (95% CI: -25.2, -16.1) in the fully adjusted model.

Conclusions: Overweight and obesity are associated with lower RBF in patients with early-stage ADPKD. Prior research in adults without ADPKD have been discordant, reporting both higher and lower RBF with overweight or obesity. Further research is needed to evaluate whether reduced RBF may be a mechanism by which obesity is associated with faster progression in patients with ADPKD.

Glucagon-Like Peptide 1 Receptor Agonist (GLP-1 RA) Delays Cyst Growth in ADPKD

Jiao Wu, Shasha Cheng, Yingying Zhang, Xiaoyan Li, Xia Zhou, Xiaogang Li. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ADPKD is the most frequent genetic cause of chronic kidney disease (CKD), accounting for 6-10 % of patients on dialysis in the United States. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are a class of drugs utilized to treat type 2 diabetes mellitus and obesity due to its profound glycemic control effect and weight lowering. In this study, we tested the effect of one of the most popular GLP-1RA, Semaglutide, and the underlying mechanisms on the progression of ADPKD.

Methods: To determine the effect of GLP-1RA in ADPKD, we treated *Pkd1$^{flox/flox}$:Pkhd1-Cre* mice and *Pkd1$^{RC/RC}$* mice with Semaglutide (10 ug/kg) via daily intraperitoneal injection. Kidneys were collected from *Pkd1$^{flox/flox}$:Pkhd1-Cre* mice at PN25 and from *Pkd1$^{RC/RC}$* mice at PN91. Kidneys and renal tubular cells treated with Semaglutide were analyzed by H&E staining, WB, qRT-PCR, as well as immunofluorescence, immunohistochemistry, and TUNEL staining. Additionally, we utilized transmission electron microscopy to identify mitochondrial changes in *Pkd1* mutant cells and kidneys.

Results: We found that the expression of GLP-1R was decreased in *Pkd1* mutant renal epithelial cells and kidneys. Treatment with Semaglutide (10ug/kg) delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and increased cyst lining epithelial cell apoptosis in *Pkd1* mutant mice (all $p < 0.05$). Treatment with Semaglutide could reduce total kidney volumes in living *Pkd1$^{RC/RC}$* mice as examined by ultrosoud, as well as decrease the recruitment of macrophages and the expression of fibrotic markers, including fibronectin and a-SMA, resulting in a decrease of interstitial fibrosis in *Pkd1* mutant kidneys as examined by picrosirius red and a-SMA staining. Notably, we found that treatment with Semaglutide 1) decreased glucose uptake, ATP generation and glycolysis characterized by a decrease of the expression of the key glycolytic enzymes, and 2) normalized the structure of mitochondria and the expression of the genes involved in mitochondrial metabolism, in *Pkd1* mutant renal epithelial cells and kidneys.

Conclusions: This study highlights a role of downregulation of GLP-1R in abnormal glycolysis and mitochondrial metabolism in *Pkd1* mutant kidneys and suggests that GLP-1RA therapy may be a novel therapeutic strategy for ADPKD.

Novel Use of Recombinant Dimeric IgA Monoclonal Antibodies as Cyst-Targeted Therapeutics in Polycystic Kidney Disease

Margaret Schimmel, Thomas Weimbs. *University of California Santa Barbara, Santa Barbara, CA.*

Background: The sole approved treatment for autosomal dominant polycystic kidney disease demonstrates limited efficacy and causes adverse side effects[1]. Urgent development of more effective therapies is imperative. While biological drugs, such as IgG monoclonal antibodies, offer increased target specificity and decreased off-target effects compared to small molecule drugs, they are unable to reach a large portion of target proteins present in cyst lumen due to their structure. Thus, we engineered a human dimeric IgA1 (dIgA) antibody - an isotype that is naturally secreted onto luminal surfaces, to target the cMET receptor on cyst-lining epithelial cells of Pkd kidneys. dIgAs have the unique ability to cross epithelial barriers via binding the polymeric immunoglobulin receptor (pIgR). We previously found pIgR highly upregulated in Pkd cyst-lining cells, giving rise to this novel dIgA targeting approach.

Methods: Human IgA1 chains are co-expressed in HEK293F cells and purified using Ni-NTA and AEX chromatography to obtain dimeric IgA suitable for in vitro functional testing as well as preliminary preclinical studies. Cystic (Bpk) and wildtype (WT) mice were treated once daily for 1 week with vehicle (PBS) or 20mg/kg anti-cMET dIgA.

Results: Our anti-cMET dIgA mAb has shown potent antagonistic function in the nanomolar range in vitro, and the ability to transytose via pIgR. The dIgA accumulated and remained stable for multiple days in cyst lumen after a single injection. 1-week cMET-dIgA treatment slowed cyst growth and improved kidney function in a rapid-onset Pkd mouse model.

Conclusions: We have shown it is feasible to utilize antagonistic mAbs against a number of growth factors/receptors implicated in PKD to slow cyst progression and even ameliorate kidney dysfunction, provided they are in dIgA format. This approach has the potential to eliminate all extra-renal side effects seen with small molecule drugs, and thus, would be tolerable and effective during long-term treatment in PKD clinical trials.

Adeno-Associated Virus 1 (AAV1) CFTR Gene Therapy Successfully Reduces Cysts in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease

Liudmila Cebotaru. *The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the formation of multiple large cysts that lead to end-stage renal disease by the sixth decade of life. Current therapies for ADPKD involve treatment of the symptoms associated with kidney disease and/or organ transplantation. Cyst growth involves fluid secretion into the cyst lumen through the action of CFTR, located at the luminal membrane. We showed that CFTR correctors such as VX-809 alter the location of CFTR in cystic epithelia from the apical to the basolateral membrane, thereby reducing cyst formation. Here, we propose the novel hypothesis that a gene therapy based on CFTR can prove effective in reducing kidney damage in ADPKD.

Methods: To provide data showing that kidney transduction via systemic delivery is feasible, approximately 1-month-old, Pkd1$^{R3277C/R3277C}$ mice were injected intraperitonially with 2 × 10^{12} VP/kg of AAV1 containing either GFP or Δ27-264CFTR, a truncated version of CFTR that increases expression of endogenous CFTR via biomolecular interaction with endogenous CFTR defined as transcomplementation. Animals were necropsied 2 months after treatment and the kidney tissue was anaylised by immunoflourescence microscopy and H&E staining. Also the vector genome and DNA expression was quantified by real time PCR.

Results: The cyst area and size were less in the CFTR- compared to GFP-vector treated animals. We detected vector genomes at >4x10^5 vector genomes/ug DNA and mRNA expression at 4-8x10^4 copies/ug DNA after vector instillation. Tissues were co-stained with either NHE3 or ENaC to highlight proximal or collecting duct expression, respectively. Expression of GFP and CFTR above background levels consistent with protein expression were generated by both vectors. We detected more GFP in the vector-treated cystic cells compared to surrounding tissue suggesting that AAV1 is more specific for cysts than the cells surrounding the cysts. We detected more CFTR IF at the basolateral membrane in AAV1-CFTR treated kidneys suggesting that CFTR was restored to its normal location.

Conclusions: These experiments demonstrate convincingly that kidneys of RC/RC animals can be transduced by AAV1 and that phenotypic correction of defective function can be achieved by over expression of CFTR. Also the data suggests that CFTR plays a critical role in ADPKD.

Effectiveness of MQ232 in an Orthologous ADPKD Mouse Model

Xiaofang Wang,[1] Li Jiang,[1] Jinghua Hu,[1] Nicolas Gilles,[2] Vicente E. Torres.[1]
[1]Mayo Clinic Minnesota, Rochester, MN; [2]Universite Paris-Saclay, Gif-sur-Yvette, France.

Background: The vasopressin V2 receptor (V2R) inverse agonist Tolvaptan ameliorates the development of polycystic kidney disease (PKD) in orthologous *Pkd1* and *Pkd2* mouse models and is the only currently approved drug for the treatment of autosomal dominant PKD (ADPKD). However, its benefits are hindered by the dose limiting aquaretic effect and potential hepatotoxicity. Mambaquaretin-1 (MQ1) is a peptide isolated from the venom of the green mamba snake that selectively blocks V2R. Vasopressin binds tightly to the V2R which can simultaneously activate G protein and β-arrestin signaling. Satavaptan, a Tolvaptan-related V2R inverse agonist, inhibits Gαs signaling and cAMP production while activating β-arrestin signaling. In contrast, MQ1 inhibits both V2R activated pathways.

Methods: To confirm the efficacy of MQ1 in an orthologous *Pkd1* mouse model and its relative potency compared to tolvaptan, we have treated male *Pkd1*$^{RC/RC}$ mice with MQ232 (an optimized modification of MQ1), 4 nanomoles/kg/hr via osmotic minipump, or with tolvaptan, 0.2% in powdered food and vehicle via osmotic minipump, along with control mice, from 4 to 16 weeks of age. Osmotic minipumps were replaced every 4 weeks.

Results: MRI kidney volumes at baseline were the same. Tolvaptan and MQ232 reduced kidney and cyst volumes and cAMP (Table 1). MQ lowered plasma urea. Both reduced the kidney tissue levels of p-Thr202/Tyr204 ERK1/2, p-Ser235/236 S6, p-Ser473 Akt, p-Thr308 Akt, and p-Ser9 GSK3β, more markedly in the MQ232 treated mice (Figure 1).

Conclusions: MQ232 ameliorates PKD in an ADPKD orthologous mouse model and is at least as effective as tolvaptan. Studies to further characterize the dose response effectiveness of MQ232 are in progress.

Enteropeptidase Inhibitor SCO-792 Ameliorates Disease Progression in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease

Takuro Kawamura,[1] Fumihiko Hattanda,[1] Shun Takenaka,[1] Kanako Watanabe-Kusunoki,[1] Jun Sugama,[2] Yusuke Moritoh,[2] Masanori Watanabe,[2] Daigo Nakazawa,[1] Tatsuya Atsumi,[1] Saori Nishio.[3] *[1]Department of Rheumatology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan; [2]SCOHIA PHARMA, Inc, Fujisawa, Japan; [3]Department of Hemodialysis and Apheresis, Hokkaido University Hospital, Sapporo, Japan.*

Background: Excess branched-chain amino acids activate the mammalian target of the rapamycin (mTOR) pathway, leading to disease progression of autosomal dominant polycystic kidney disease (ADPKD). Enteropeptidase inhibitor SCO-792 decreases amino acid absorption by inhibiting the digestive enzyme that converts protein to amino acids. This study aims to investigate the effects of SCO-792 on ADPKD model mice.

Methods: *Pkd1* gene conditional knockout mice (*Pkd1$^{flox/flox}$ Mx-1-Cre mice*) were randomly assigned to a vehicle group and a group treated with SCO-792 (SCO group). The vehicle group was fed a normal diet from day 28. The SCO group was fed a diet containing 0.003% (w/w) SCO-792 starting on day 28, and the dose level was increased to 0.01% from day 42. All mice were sacrificed at 98 days of age. We analyzed the phenotype of cystic kidneys by measuring kidney/body weight ratio (KW/BW) and kidney cystic index (CI), defined as the percentage of areas occupied by cysts. Additionally, we performed immunofluorescence staining of Ki-67 for kidney tissue to evaluate cell proliferation. We also conducted western blotting of the signaling pathway of cyst growth by using the whole kidney protein.

Results: Until day 42, there was no significant difference in body weight between the two groups. Following the administration of 0.01% SCO-792, the SCO group exhibited a significant reduction in body weight compared to the vehicle group. KW/BW tended to be lower in the SCO group than in the vehicle group. CI of the SCO group was significantly lower than the vehicle group (28.2 ± 10.8% vs 42.8 ± 13.6%, p=0.037). Serum urea nitrogen levels in the SCO group were significantly lower than the in vehicle group. The SCO group showed a significant decrease in Ki-67-positive cells in kidney compared to the vehicle group. In western blotting, phosphorylated-S6 protein was significantly downregulated in the SCO group compared to the vehicle group.

Conclusions: In the ADPKD mouse model, SCO-792 ameliorates renal cyst growth and kidney function decline by inhibiting the mTOR pathway activation.

Inhibition of Anoctamin 3 Attenuates Cystogenesis in Autosomal Dominant Polycystic Kidney Disease

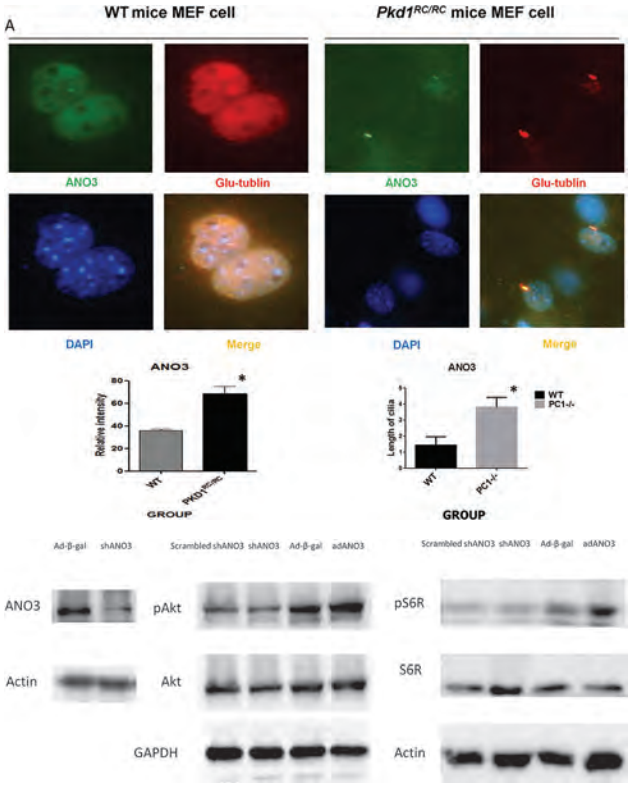
Tao Xu. Shanghai Jiaotong Medical University Affliated Shanghai 6th Hospital. *Shanghai Jiao Tong University, Shanghai, China.*

Background: Autosomal dominant polycystic kidney disease(ADPKD) is the most common inherited kidney disease, which is characterized by progressive growth of renal cysts. As we reported Anoctamin 1, one of chlorine channels family promotes both ciliogenesis and cyst formation in PKDcells. Wherever another member Anoctamin3(ANO3) was recently shown to be involved in ADPKD progression in our research. It seems there is nobody reported.

Methods: 1.RT RCR,WB and Immunohistochemistry to detect ANO3 in kidney tissue of ADPKD patients and normal kidndy tissue. 2.3Dculture to vertify the function of ANO3 in cysts formation in RCTE and IMCD3 cell with siANO3. 3.Co-immunofluorescence to investigate the impact of ANO3 on cilia and PC2 by siANO3. 4.WB to test the effect of ANO3 in proliferation signaling pathways. 5.To measure the kidney cyst index of Ano3$^{-/-}$:Pkd1 $^{flox/flox}$:CAG-creER$^+$mice by HE staining and MRI.

Results: 1.ANO3 located in renal tubules and renal cyst and high expression in human and mouse ADPKD kidneys. 2.shANO3 attenuated cyst formation in 3D culture cells. 3.ANO3 was localization on ciliary body and shANO3 increased the cilia length and the expression of PC2. 4.ShANO3 could attenuated cyst formation by inhibiting phosphorylation of AKT and mTOR signal pathways. 5.Cyst index of *PKD1 $^{flox/flox}$CAG-creER$^+$*mice was significantly decrease than which in PKD1$^{RC/RC}$mice.

Conclusions: Our data indicate inhibition of Anoctamin3 attenuates cystogenesis in ADPKD by decreasing phosphorylation of AKT and mTOR signal pathways.



TH-PO462

Targeting Growth Hormone/JAK2 Signaling as a Novel Therapy for Polycystic Kidney Disease Treatment

Fiona Macleod,[1,2] Maria Fragiadaki.[1,2] Maria Fragiadaki Lab. *[1]Queen Mary University of London Faculty of Medicine and Dentistry, London, United Kingdom; [2]The University of Sheffield Faculty of Medicine Dentistry and Health, Sheffield, United Kingdom.*

Background: PKD is characterized by renal cyst growth, fibrosis, and renal failure due to mutations in PKD1 or PKD2, leading to dysregulated JAK/STAT signaling. Our previous studies have shown elevated Growth Hormone (GH) levels and excessive JAK2/STAT5 activation in ADPKD mouse models. This study explores the therapeutic potential of targeting the GH/JAK/STAT pathway in ADPKD.

Methods: We conducted cystogenesis and proliferation assays in human cells. We employed three strategies to antagonise GH/JAK2 signaling: (i) GH receptor antagonist (GHA), (ii) ruxolitinib (a small molecule JAK2 inhibitor), and (iii) siRNA-mediated silencing of GHR/STAT5. Proliferation was measured by flow cytometry and qPCR. Ruxolitinib or vehicle control was administered to $Pkd1^{nl/nl}$ mice (n=20), and kidney function, fibrosis, inflammation and RNA-seq analyses were performed. GH and IGF-1 levels were measured by ELISA and GH receptor levels determined by immunohistochemistry.

Results: GH levels were elevated (~3-fold, P<0.01) in $Pkd1^{nl/nl}$ mice. GH receptor (GHR) was expressed in renal cyst-derived human cells and murine $Pkd1^{nl/nl}$ kidneys. RNA-seq analysis revealed that GH induces proliferation via mitogenic factors, including a ~4-fold increase in cyclin D1 expression (P<0.0001). GH stimulated significant increases in cell cycle progression and mitosis (P<0.01). Critically, ruxolitinib or GHA effectively countered GH-induced proliferation, inflammation, and STAT5 transcriptional activity (Ruxo-P<0.05; GHA-P<0.001) in renal cells. GH enhanced cyst growth in vitro, an effect fully antagonised by ruxolitinib, GHA, or GHR/STAT5 siRNA. In vivo, ruxolitinib treatment (50mg/kg) significantly reduced phosphorylation and activity of JAK2, which in turn led to improved renal function (P<0.05), reduced kidney size (P<0.05), and decreased fibrosis (P<0.01). Bulk-RNA-seq coupled with spatial transcriptomics revealed the transcriptome changes responsible for the anti-fibrotic and anti-proliferative properties of ruxolitinib treatment.

Conclusions: Our findings demonstrate the therapeutic potential of GH/GHR/JAK2/STAT5 antagonism in experimental ADPKD. Antagonizing JAK2 signaling leads to decreased fibrosis and improved renal function. We propose JAK2 antagonism as a promising strategy to decelerate the progression of ADPKD. These findings have implication for additional renal diseases characterised by fibrosis.

TH-PO463

Exploring Therapeutic Potential of Neuropeptide Y in an ADPKD Mouse Model

Xiaobo Sun, Yan Huang, Xiaofang Wang, Li Jiang, Vicente E. Torres, Jinghua Hu. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common form of monogenic cystic kidney disease that often leads to End Stage Renal Disease (ESRD). Addressing the aberrant cAMP-PKA signaling pathway within cyst-lining renal epithelial cells has emerged as a promising therapeutic avenue for ADPKD patients. This study endeavors to delve into the influence of Neuropeptide Y (NPY) and its kidney-specific G_i-coupled receptors on modulating cAMP-PKA signaling and consequent ADPKD progression in the $Pkd1^{RC/RC}$ mouse model.

Methods: $Pkd1^{RC/RC}$ mice, aged 3 weeks and exhibiting similar Total Kidney Volume (TKV), were chosen and allocated randomly into control, Low dose NPY, and High dose NPY groups (n = 10/gender/group). Subsequently, these $Pkd1^{RC/RC}$ mice received intraperitoneal injections of 0.1mg/kg or 0.3mg/kg NPY for a further 12 weeks. Following the study period, magnetic resonance imaging (MRI) was conducted to ascertain Total Kidney Volume (TKV), while kidney samples were harvested for cystic index and cystic volume analysis. Plasma samples were also collected for Blood Urea Nitrogen (BUN) assessment. Statistical analysis was carried out utilizing two-way ANOVA.

Results: A significant reduction in TKV was observed in NPY-treated groups in comparison to the control group. Furthermore, although statistical significance was not attained, a dose-dependent downward trend in cystic index and cystic volume was noted. We observed a statistically significant decrease of BUN levels in low dose NPY group (22.2 ± 4.5 mg/dL) as compared to control (26.4 ± 6.0 mg/dL), while BUN in high dose treatment group also showed a trend of decrease (23.4 ± 5.7 mg/dL).

Conclusions: Our current study underscores the therapeutic potential of NPY in decelerating ADPKD progression within a preclinical mouse model. Future directions will entail 1) optimizing and augmenting NPY dosage for ADPKD mice treatment, 2) delineating and functionally distinguishing kidney-expressed NPY receptors in human and mouse renal epithelial cells, and 3) investigating the molecular interplay between NPY and Polycystin signaling in the context of ADPKD.

TH-PO464

Vascular Endothelial Growth Factor Receptor 2 (VEGFR2) Blockade as New Therapeutic Opportunity for Polycystic Kidney Disease

Laura Nuñez-Gonzalez,[1] Lucia Tejedor,[2] María Pereira Hernández,[1] Ana Barcia de la Iglesia,[1] Adrian Cordido,[1] Miguel A. Garcia-Gonzalez,[1] Marta Ruiz-Ortega.[2] *[1]Instituto de Investigacion Sanitaria de Santiago de Compostela, Santiago de Compostela, Spain; [2]Universidad Autonoma de Madrid, Madrid, Spain.*

Background: Polycystic Kidney Disease (PKD) encompasses a group of genetic disorders characterized by the presence of multiple cysts in the renal parenchyma, alongside extrarenal manifestations such as hepatic cysts, termed Polycystic Liver Disease (PLD). Autosomal Dominant Polycystic Kidney Disease (ADPKD), the dominantly inherited form, arises from mutations in genes *PKD1* and *PKD2*. Despite extensive research efforts, the precise mechanism underlying cystogenesis in PKD remains elusive. This study focuses on investigating the role of NOTCH signaling in ADPKD, given its documented activation in various progressive kidney diseases. Cystogenesis progression is marked by pronounced inflammation, with interstitial fibroblasts and macrophage polarization releasing chemokines, cytokines, and growth factors. Additionally, GREMLIN (one of the key mediators of NOTCH pathway) has emerged as a key mediator of chronic kidney disease in preclinical studies, with urinary levels proposed as potential biomarkers for renal diseases.

Methods: To assess the involvement of the Gremlin-VEGFR2 signaling pathway in cystic disease, we examined the expression of pathway proteins in both human samples and an orthologous murine model of ADPKD. Additionally, we validated the inhibition of VEGFR2 as a potential therapeutic strategy using an orthologous rapid progressive mouse model: B6.*Pkd1 cko/cko TamCre.*

Results: Our findings revealed upregulation of Gremlin/VEGFR2 pathway proteins in ADPKD, evident through transcriptomic and proteomic overexpression in ADPKD mouse kidney tissues, as well as in urine and cystic fluid from ADPKD patients. Treatment with Semaxinib, a specific VEGFR2 inhibitor, yielded beneficial effects in a short term-treatment in a rapid progressive ADPKD mouse model, including significant improvement in renal function (measured by BUN levels) as well as a significant reductions in cystic area.

Conclusions: This study sheds light on the altered role of the Gremlin/VEGFR2 pathway in cystogenesis and cyst growth progression in ADPKD. Moreover, the efficacy of a VEGFR2 inhibitor as demonstrated in a preclinical ADPKD model suggests a promising therapeutic avenue for PKD diseases.

Role of Advanced Imaging Metrics in Predicting Outcomes in Patients Affected with Polycystic Kidney Disease

Timothy L. Kline,[1] Adriana Gregory,[1] Aaron Cohen,[2] Erin Ables,[2] Fouad T. Chebib,[8] Doug Landsittel,[3] Vicente E. Torres,[1] Peter C. Harris,[1] Frederic F. Rahbari-Oskoui,[4] Arlene B. Chapman,[5] Michal Mrug,[6] Alan S. Yu.[7]
[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Indiana University, Bloomington, IN; [3]University at Buffalo, Buffalo, NY; [4]Emory University, Atlanta, GA; [5]University of Chicago Division of the Biological Sciences, Chicago, IL; [6]The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL; [7]The University of Kansas Medical Center, Kansas City, KS; [8]Mayo Clinic in Florida, Jacksonville, FL.

Background: The CRISP and HALT-A studies have provided significant longitudinal data on patients affected with ADPKD. This study utilized this data to compare advanced imaging metrics with a model built upon clinical information for predicting kidney health outcomes.

Methods: A cohort of 582 patients from the CRISP and HALT-A studies were included, all of whom had complete data for the following 'base model' variables: age, sex, serum creatinine, BMI, diastolic BP, hemoglobin, and CO2. Using the T2-weighted coronal sequences, standard imaging metrics such as total kidney volume (TKV) were measured. Additionally, from these same series, advanced imaging metrics were calculated using a previously developed AI-based tool, including total kidney cyst volume (TKCV), total cyst number (TCN), renal parenchyma volume (RPV), and cyst parenchyma surface area (CPSA). Statistical analyses were performed to compare the predictive power of these advanced imaging metrics with the base model, as well as explore their incorporation into the model.

Results: The analysis demonstrated that individual advanced imaging metrics (TKCV, TCN, RPV, CPSA) were comparable to the base model in predicting kidney health outcomes (see Table). The analysis demonstrated that individual advanced imaging metrics (TKCV, TCN, RPV, CPSA) were 1) comparable to the entire base model for prognosis of kidney failure, 2) were statistically significant and led to improvements in predicted risk when added to the base model.

Conclusions: Advanced imaging metrics offer valuable insights into kidney structure in PKD patients. Their individual predictive power for kidney health outcomes is on par with a multivariable model (i.e. the base model) and also their addition to the base model further improves the model's predictive potential. Further research is needed to explore the potential of these imaging techniques in clinical practice and their ability to predict long-term outcomes in PKD patients.

Automated Segmentation of Individual Kidney Cysts in Routine Abdominal CT Images

Adriana Gregory,[1] Jeeho Im,[1] Muhammed Khalifa,[1] Fouad T. Chebib,[2] Vicente E. Torres,[1] Peter C. Harris,[1] Bradley J. Erickson,[1] Timothy L. Kline.[1]
[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Mayo Clinic in Florida, Jacksonville, FL.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disorder characterized by the development and growth of many cysts in the kidneys. Total kidney volume (TKV) is the main imaging biomarker used for disease progression prediction; however, advanced biomarkers like total cyst number (TCN) and cyst-parenchyma surface area have been shown to provide complementary information to TKV in MR imaging. Automated methods to segment individual kidney cysts in CT images of patients affected by PKD are still needed.

Methods: A 3D deep learning model using the nnUNet architecture was trained (n=60 CT images) to learn cyst edges and cores. Then, a postprocessing algorithm was applied to convert the semantic edge-core representation to instance (individual) cyst level segmentations. A 5-fold cross-validation was done to improve model robustness. The model was tested on 15 CT images not seen during training. The test set was manually segmented by two blinded readers to establish interobserver variability and the target performance for the model. The similarity between segmentations was assessed by Dice score, Bland Altman, and linear regression.

Results: The automated segmentation approach performed on par with human readers. Table1 shows the assessment metrics results. Significant agreement was observed between the readers and between each reader with the automated model. Figure1 presents an example test case.

Conclusions: This is the first model trained to segment individual cysts in contrast-enhanced CT images of patients affected by ADPKD. The initial results show good agreement between the model and segmentations of two expert readers.

Funding: NIDDK Support

Similarity metrics

	Reader1 vs Reader2	Reader1 vs Auto	Reader2 vs Auto
†Dice Score	0.88 ± 0.07	0.86 ± 0.05	0.88 ± 0.06

†Mean ± st. dev.

TCV and TCN: total cyst volume and number

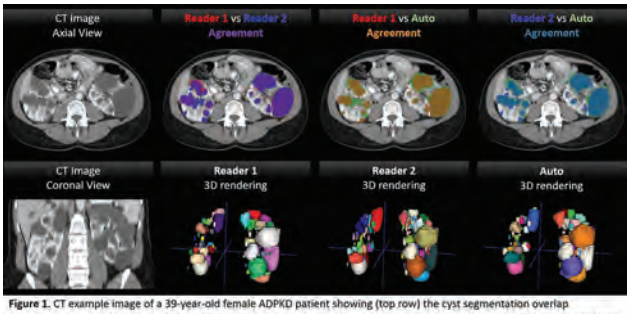

Figure 1. CT example image of a 39-year-old female ADPKD patient showing (top row) the cyst segmentation overlap agreement between the readers (Dice=0.89) and between each reader with the automated segmentation (Dice=0.87 and 0.88, respectively). (Bottom row) the 3D renderings of the readers and automated model segmentations (TCN: Reader1 183 cysts, Reader2 199 cysts, and automated 180 cysts). The cyst colors are not expected to match as they are assigned randomly.

TH-PO467

Phenotypic Characterization of Patients with ADPKD with PKD1 and PKD2 Pathogenic Variants Using Advanced Imaging Biomarkers

Abdul Hamid Borghol,[1] Fadi George Munairdjy Debeh,[1] Ahmad Ghanem,[1] Stefan N. Paul,[1] Bassel Alkhatib,[1] Nay Nader,[1] Adriana Gregory,[2] Hana Yang,[2] Christian Hanna,[2] Neera K. Dahl,[2] Timothy L. Kline,[2] Peter C. Harris,[2] Fouad T. Chebib.[1] *[1]Mayo Clinic in Florida, Jacksonville, FL; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), caused by *PKD1* and *PKD2* pathogenic variants, is the fourth leading cause of kidney failure. The aim of this study is to compare the clinical and imaging biomarkers of ADPKD-*PKD1* and ADPKD-*PKD2* patients.

Methods: In this retrospective study, 602 ADPKD patients of the Mayo Clinic database were included based on having a pathogenic variant in *PKD1T* (50%), *PKD1NT1* (15%), *PKD1NT2* (14%), or *PKD2* (21%), and an abdominal imaging prior to any event that could affect kidney volume. Advanced imaging biomarkers were then assessed using an automated cyst segmentation deep learning model as shown in **Figure**.

Results: Of the included ADPKD patients, 408 (64.8%) were female, with a mean (±SD) age of 42.5 (±14.0) years. ADPKD-*PKD1T* and ADPKD-*PKD1NT1* patients had larger height-adjusted total kidney volume (htTKV), cyst-parenchymal surface area (CPSA), and total cyst number (TCN) compared to ADPKD-*PKD1NT2* and ADPKD-*PKD2*, with *PKD1T* showing the highest median htTKV (759.9mL/m), CPSA (1190 cm^2), and TCN (374). Additionally, median cyst index, defined by the fraction of total cyst volume (TCV) over TKV, was the highest in *PKD2* (0.43) and the lowest in *PKD1NT2* (0.28). Detailed analysis of the advanced imaging biomarkers is shown in **Table**.

Conclusions: ADPKD-*PKD1T* and ADPKD-*PKD1NT1* patients have bigger kidneys with more cysts, that occupy a larger total surface area of the parenchyma, compared to ADPKD-*PKD1NT2* and ADPKD-*PKD2* patients.

Table

	PKD1T	*PKD1NT1*	*PKD1NT2*	*PKD2*	p-value
N	303	90	82	126	
Age at imaging (yrs), mean (±SD)	38.5 (12.7)	43.8 (13.7)	44.6 (13.4)	48.9 (14.5)	<0.01
Height-adjusted total kidney volume (htTKV) (mL/m), median (Q1 – Q3)	759.9 (474.6 – 1236.9)	710.1 (461.4 – 1252.1)	538.0 (338.5 – 802.1)	651.0 (357.4 – 1388.3)	0.07
Percentage of patients with MIC-1C (%)	37.1%	23.6%	26.8%	36.9%	0.04
Total cyst volume (TCV) (mL), median (Q1 – Q3)	543.7 (246.9 – 1006.2)	466.2 (203 – 1094.1)	250.2 (96.3 – 563.6)	487.9 (147.2 – 1330.2)	0.02
Renal parenchymal volume (RPV) (mL), median (Q1 – Q3)	738.1 (539.6 – 1067.7)	705.9 (511.8 – 1115.2)	622 (479.7 – 864)	585.6 (422.7 – 937.7)	0.7
Cyst-parenchymal surface area (CPSA) (cm^2), median (Q1 – Q3)	1190 (636.8 – 2128.3)	1119.6 (532.3 – 2155.7)	785.6 (358.6 – 1308.9)	759 (330 – 1709.3)	<0.01
Total cyst number (TCN), median (Q1 – Q3)	374 (217 – 599)	362 (190.7 – 562)	298 (157 – 444)	225 (122.3 – 425.3)	<0.01
Cyst index (TKV/TCV), median (Q1 – Q3)	0.41 (0.29 – 0.49)	0.35 (0.27 – 0.54)	0.28 (0.17 – 0.43)	0.43 (0.24 – 0.57)	<0.01

Long-Term Trajectories of Kidney Function in ADPKD: Follow-Up of CRISP and HALT-PKD-Study A Cohorts

Frederic F. Rahbari-Oskoui,[1] Chelsie Parker,[3] Doug Landsittel,[2] Erin Ables,[3] Lilian Golzarri-Arroyo,[3] Peter C. Harris,[6] Arlene B. Chapman,[9] Vicente E. Torres,[6] Michal Mrug,[4] Fouad T. Chebib,[7] Kyongtae T. Bae,[10] William M. Bennett,[8] Alan S. Yu.[5] Consortium for Radiologic Imaging Studies of Polycystsic kidney disease (CRISP) and The HALT-PKD Trial. *[1]Emory University, Atlanta, GA; [2]University at Buffalo, Buffalo, NY; [3]Indiana University, Bloomington, IN; [4]The University of Alabama at Birmingham, Birmingham, AL; [5]The University of Kansas Medical Center, Kansas City, KS; [6]Mayo Clinic Minnesota, Rochester, MN; [7]Mayo Clinic in Florida, Jacksonville, FL; [8]Legacy Health System, Portland, OR; [9]University of Chicago Pritzker School of Medicine, Chicago, IL; [10]The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

Background: Previously, we reported trajectories of estimated Glomerular filtration rate (eGFR) decline in 241 patients in the CRISP study. However, those reports were limited by the relatively small sample size and lack of external validation in other PKD cohorts. This study aimed to develop long term trajectories in a large PKD cohort that included the observational CRISP study and the HALT-PKD-Study A hypertension trial.

Methods: 721 patients (age 15-49 with baseline eGFR >60 mL/min/1.73 m^2) were included and followed for up to 21.2 years. Routine laboratory and detailed genetic results, and Mayo imaging class (MIC) were used in linear mixed models (including a term for age^2 and interactions with age) by forcing in essential variables and using a forward selection process to select other clinical biomarkers. Polynomial graphics and slopes of eGFR were calculated for each MIC per decade of life. Goodness of fit was assessed by calculating mean differences between observed and predicted eGFRs over 10-year age intervals.

Results: The best gender-specific polynomial trajectory models were developed by including age, sex, serum creatinine, ADPKD genotype mutation strength group, MIC, serum CO_2 and uric acid, and hemoglobin levels, diastolic blood pressure (DBP), race, presence of hypertension, and body mass index. The slopes of decline of eGFR vary widely from -0.39 to -5.89 (from slow to fast progressors) and continuously accelerated in time within each MIC.

Conclusions: We developed more robust, gender-specific, long-term trajectories of eGFR for each MIC category over 21.2 years of follow up, in a well-characterized ADPKD cohort. Serum CO_2, uric acid, hemoglobin, race, presence of hypertension, BMI and DBP were identified as additional parameters of relevance. External validation of these models is underway, on the Mayo PKD registry.

Predicting the Relationship between Treatment Effects on Total Kidney Volume and eGFR in ADPKD Trials Using a Novel Modeling Approach

Alan S. Yu,[1] Chelsie Parker,[2] Lilian Golzarri-Arroyo,[2] Doug Landsittel,[3] Rekha Garg,[4] Edmund C. Lee.[4] CRISP Consortium. *[1]The University of Kansas Medical Center, Kansas City, KS; [2]Indiana University, Bloomington, IN; [3]University of Buffalo, Buffalo, NY; [4]Regulus Therapeutics Inc, San Diego, CA.*

Background: TKV is accepted by the FDA as a surrogate endpoint that is reasonably likely to predict clinical benefit in ADPKD and the most commonly used response biomarker for proof-of-concept intervention trials. However, the magnitude of treatment effect on TKV that would be predictive of a meaningful improvement in a clinical outcome, such as eGFR, is unknown. Inference of this from observational studies has previously been approached by examining inter-individual variance in the relationship between TKV and GFR slopes over time.

Methods: We developed a novel approach to modeling the intra-individual relationship between TKV and eGFR. Patients from the CRISP IV dataset were stratified by Mayo Imaging Class (MIC). Linear mixed models were fitted to eGFR with a fixed effect of log(TKV) and random intercepts, and the average slope within each MIC was estimated.

Results: We find that within each MIC there is a consistent, linear relationship between log(TKV) and eGFR (Fig. 1). The model predicts that within classes 1C–1E, for each 1% point per year reduction in TKV growth rate, the rate of eGFR decline would be reduced by approximately 0.4 to 0.5 mL/min/1.73 m^2 per year.

Conclusions: We have developed a new model that provides a framework for defining the magnitude of treatment effect on TKV that would support accelerated approval of a drug for ADPKD.

Funding: NIDDK Support

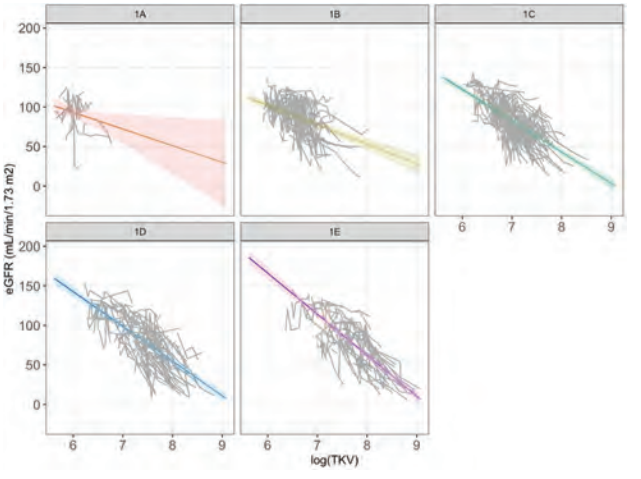

Fig. 1. Relationship between $\log_e$(TKV) and eGFR, subdivided by Mayo Imaging Class. Individual patient trajectories are shown in grey (N=487). Colored lines and shading show the modeled linear relationship and 95% confidence intervals from linear mixed models.

TH-PO470

Correlation of Total Kidney Volume (TKV), Total Liver Volume (TLV), and Combined TKV and TLV with Abdominal Symptoms in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Mauricio A. Miranda Cam,[1] Taher Dehkharghanian,[1] Saima Khowaja,[1] Xuewen Song,[1] Yasmina Sarie,[1] Korosh Khalili,[1] Timothy L. Kline,[2] York Pei.[1]
[1]University Health Network, Toronto, ON, Canada; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.

Background: Mass effect (e.g. early satiety, flank pain, abdominal distention and pain) symptoms from polycystic kidney and liver enlargement can result in clinically significant symptoms and complications, and negatively impact the quality of life in patients with ADPKD. Several studies have documented a significant correlation of these symptoms with TKV or TLV. Here we report a single center correlative study of mass effect symptoms with TKV, TLV, and combined TKV+TLV

Methods: Prospective study at the Center of Innovative Management in PKD in Toronto between October 2017-July 2021. All study patients had a clinical diagnosis of ADPKD based on kidney imaging, underwent a research protocol for detailed clinical and laboratory data, genetic testing and MRI measurements of height-adjusted (ht-) TKV, TLV, and combined TKV+TLV. Volume measures were divided by quintiles (Q). Mass-effect symptoms were assessed using a standardized research questionnaire and by review of their medical records

Results: The study cohort comprises 250 patients, with a mean age of 46 years and 56.4% female. Their median htTLV, htTKV, and htTKLV were 1182, 702, and 1884 ml/m, respectively. We found that Q4-Q5 discriminate patients with mobility limitation by all volumetric groups whereas Q5 discriminates the severity of abdominal distention and abdominal pain by htTLV and htTKLV (Figure 1). The lower bound of Q5 in htTKV, htTLV, and htTKLV were 1009, 1337, 2323 ml/m, respectively

Conclusions: Our study suggest specific thresholds that correlate with clinically important "mass effect" symptoms (i.e. mobility limitation, severity of abdominal distention and pain). Multivariate analysis will be performed to further delineate the effects of age, sex, and cystic organ volumetric with "mass effect" symptoms

TH-PO471

Multicenter Longitudinal Cohort of Children and Adults with ADPKD: The PKD-Renal Research Consortium (PKD-RRC)

Stephen L. Seliger,[1] Terry J. Watnick,[1] Reem Mustafa,[2] Lisa M. Guay-Woodford,[3] Darren P. Wallace,[2] Alan S. Yu.[2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]The University of Kansas Medical Center, Kansas City, KS; [3]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Further progress in the clinical-translational investigation of ADPKD requires utilization of large, well-phenotyped, longitudinal cohorts of participants with linked biospecimens.

Methods: Patients with ADPKD have been enrolled in longitudinal observational cohorts at 3 sites: Children's National Hospital; Univ of Kansas Medical Center; and Univ of Maryland School of Medicine. In the NIH-supported PKD-RRC, a joint harmonized longitudinal database was created combining data in multiple demographic and clinical domains. Extracts of data and linked biospecimens (blood, urine, DNA) are available to investigators through a standardized request process. Baseline characteristics of study participants are displayed for pediatric ADPKD participants and for adults, the latter subdivided by imaging-based Mayo risk classification.

Results: The joint clinical database includes data on 416 participants with ADPKD and 1,432 individual study visits, and comprises 609 variables across multiple health and clinical domains. The database includes 59 pediatric (age ≤18) and 357 adults with ADPKD (table). Among adults, those at higher risk of progression per Mayo imaging classification had earlier diagnosis and were more likely to be male and to have hypertension and gross hematuria (p<.05)

Conclusions: The PKD-RRC joint clinical database of adults and children with ADPKD, linked to stored biospecimens, provides a robust resource for clinical and translational investigation. Enrollment and follow-up of this cohort remains ongoing.

Funding: NIDDK Support

Qualitative Analysis and Comparison of Externally Led, Patient-Focused Drug Development (EL-PFDD) Concepts for Autosomal Recessive Polycystic Kidney Disease (ARPKD) against Standardized Outcomes in Nephrology (SONG) Initiatives

Belle A. Soyfer,[1] Sorin V. Fedeles,[1,2] Wendy Vanasco,[1] Ronald D. Perrone,[3] Max C. Liebau,[4] Erum A. Hartung,[5] Katherine M. Dell,[7] Lisa M. Guay-Woodford,[5] Elise Hoover,[8] Dorothee Oberdhan.[6] *[1]Critical Path Institute, Tucson, AZ; [2]Yale University School of Medicine, New Haven, CT; [3]Tufts Medical Center, Boston, MA; [4]Universitatsklinikum Koln Klinische Infektiologie, Koln, Germany; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]Otsuka Seiyaku Kabushiki Kaisha, Chiyoda-ku, Japan; [7]Cleveland Clinic Children's Hospital, Cleveland, OH; [8]PKD Foundation, Kansas City, MO.*

Background: ARPKD is an area of huge unmet need with no approved treatments. An EL-PFDD meeting in 2023 collected patient and caregiver concepts regarding burden of disease and treatment preferences. The Standardized Outcomes in Nephrology (SONG) initiatives previously captured qualitative data from large international cohorts including pediatric CKD, but the EL-PFDD focused specifically on individuals and families with ARPKD.

Methods: A thematic synthesis and comparison among SONG-Transplant (Tx), SONG-Children and Adolescents (SONG-Kids), SONG-Polycystic Kidney Disease (PKD, focused on autosomal dominant PKD), and the ARPKD EL-PFDD was conducted.

Results: All participants from the EL-PFDD and SONG-PKD had a diagnosis of ADPKD, compared to 6% in SONG-Kids and 27% in SONG-Tx. The EL-PFDD represented patients and caregivers while the SONG had additional concepts from healthcare professionals, as well. Common themes included disease inevitability, multi-organ involvement, treatment complications, blood pressure, kidney function, graft function and loss, self-esteem, desire for normality, mental health, and life participation. Exploratory findings between the EL-PFDD and SONG-Kids found disease inevitability and uncertainty, treatment complications and risks, blood pressure, kidney function, life participation, treatment, and failure to thrive. Concepts unique to the EL-PFDD included heterogeneous disease, body image related to extended abdomen and height, deficiencies of currently available treatment options, and goals for future research. Additionally, the EL-PFDD discussed supportive ARPKD therapies, unmet needs of currently available treatment options, and goals for future research.

Conclusions: The EL-PFDD meeting captured patient and caregiver insights that will impact the advancement of biomarkers and drugs whose benefits are aligned with the patient experience. The EL-PFDD highlighted the need for ARPKD-specific standardized outcomes due to its unique pathophysiology distinct from pediatric CKD etiologies. The analysis of combined elements from the SONG initiatives and EL-PFDD will facilitate future development of outcome tools and treatment plan designs.

Sex and Aging Influence the Association between Kidney Prognosis and Anemia in Patients with ADPKD: Attribute-Based Medicine (ABM) Insights

Ken Tsuchiya,[1] Hiroshi Kataoka,[1] Shun Manabe,[1] Yusuke Ushio,[1] Momoko Seki,[1] Kosaku Nitta,[1] Toshio Mochizuki,[2] Junichi Hoshino.[1] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]PKD Nephrology Clinic, Tokyo, Japan.*

Background: Although anemia is traditionally considered a marker of poor renal prognosis in CKD, the significance and the prognostic role of anemia in ADPKD remains clearly unexplored. Recently, the significance of ABM has been underscored, and the effects of anemia on CKD progression may differ between young male and elderly female patients with ADPKD. We aimed to examine the effects of sex and aging to CKD progression of ADPKD using various levels of anemia.

Methods: We enrolled 553 ADPKD patients. Renal outcome, defined as a 30% reduction in eGFR or initiation of renal replacement therapy, was assessed using Cox regression analysis. Five thresholds of anemia were considered: 1) Hb <12 g/dL in men and Hb<11 g/dL in women; 2) Hb<13 g/dL in men and Hb<12 g/dL in women; 3) Hb<11 g/dL; 4) Hb<12 g/dL; 5) Hb<13g/dL. For subgroup analyses, cross-classification (4 groups) of sex × 50 years was also used for analyses per attribute.

Results: The cohort's median age was 43 years old, with median eGFR of 55.9 mL/min/1.73 m^2, and a median total kidney volume of 1335.4 ml. Over a median follow-up period was 9.1 years, renal outcomes were observed in 236 patients. Multivariable Cox analyses revealed that anemia (2: Hb<13.0 g/dL in men, Hb<12.0 g/dL in women; HR=1.81, P=0.0004) had the strongest association with kidney disease progression in the entire cohort. Subgroup analyses showed significant associations between kidney disease progression and anemia (5: Hb<13.0 g/dL; HR=3.46 in men <50 years old, HR=3.11 in men ≥50 years old), anemia (4: Hb<12.0 g/dL; HR=2.00 in men <50 years old), and anemia (3: Hb<11.0 g/dL; HR= 2.18 in women ≥50 years old).

Conclusions: In ADPKD patients, a higher threshold for anemia (Hb<13.0 g/dL in men, Hb<12.0 g/dL in women) was associated with kidney prognosis. Furthermore, cross-classification analysis revealed differential associations between higher thresholds of anemia and renal prognosis in male and younger patients, while a lower threshold (Hb<11.0 g/dL) was associated with renal prognosis in elderly women (women ≥50 years old). These findings underscore the utility of ABM care, employing cross-classification, in managing anemia in ADPKD patients.

Long-Term Changes in Liver and Kidney Cyst Volumes following Foam Sclerotherapy

Cassie Howe,[1] Ryan Helland,[1] Lisa E. Vaughan,[2,1] Timothy L. Kline,[1] Adriana Gregory,[1] Vicente E. Torres,[1] Marie C. Hogan.[1] Div of Nephrology, Mayo Clinic. *[1]Mayo Clinic Research Rochester, Rochester, MN; [2]Mayo Quantitative Health Sciences, Rochester, MN.*

Background: This medical center uses sotradecol foam sclerotherapy (SFS) in managing symptomatic kidney/ liver cysts. Using ultrasound & fluoroscopy, kidney/ liver cysts (≥5cm; up to 4/session) are targeted for SFS. A drain is placed into the cyst, contrast injected, aspirated & sclerosant instilled (3% sodium tetradecyl sulfate). We have performed SFS in >200 individuals & evaluated durability in a subset of patients with longerm sequential imaging.

Methods: Cases from 1/2017-12/2021 with available TKCV /TLCV (per Targeted Kidney or Liver or Cyst analysis) and with long-term image follow up were segmented using a deep-learning algorithm and cyst segmentation software (pre, post procedure and last imaging). Median TKCV/ TLCV percent change per patient were evaluated using the 1-sample Wilcoxon signed rank test. Changes in liver and kidney cyst volumes over time were modeled using linear mixed effects regression methods with time modeled as a restricted cubic spline term.

Results: One hundred forty five SFS sessions were performed on 102 unique individuals (62 kidney, 74 liver, 9 combined liver/ kidney cysts). A total of n=78 kidney cysts in 34 patients and n=138 liver cysts in 46 patients with pre and post imaging within 6 mo prior to procedure & at least 2 mo post-procedure, respectively. Median [interquartile range, IQR] % reductions in TKCV were -92.0% [IQR-98.2%, -82.7%]; (p<0.001) & for TLCV -83.1% [IQR -93.5%, -52.9%]; (p <0.001). Among 12 patients with multiple follow-up images available (2 follow-up images for all patients), there were a total of 72 cysts (30 liver & 42 kidney cysts). Both liver & kidney cyst volumes sharply declined to near 0 around 1 year follow-up, and then remained relatively stable several years later (P<0.001 for non-linear associations for both liver & kidney cyst volumes using LRT test). **Figure 1.**

Conclusions: Foam sclerotherapy is durable and is an option for management of individuals with symptomatic large kidney and liver cysts.

Cell-Free and Concentrated Ascites Reinfusion Therapy Is More Effective for Refractory Ascites in Patients with Autosomal Dominant Polycystic Kidney Disease

Shigekazu Kurihara,[1,2] Tatsuya Suwabe,[1] Masayuki Yamanouchi,[1] Yoshifumi Ubara,[1] Yuji Kamijo,[2] Naoki Sawa.[1] *[1]Toranomon Byoin Bunin, Kawasaki, Japan; [2]Shinshu Daigaku, Matsumoto, Japan.*

Background: Refractory ascites is one of frequent complications in patients with autosomal dominant polycystic kidney disease (ADPKD). Cell-free and Concentrated Ascites Reinfusion Therapy (CART) is known to be an effective treatment for refractory ascites. However, its efficacy in patients with ADPKD is unknown.

Methods: In this retrospective cohort study, we enrolled all patients (age > 18 years) with refractory ascites, who were treated with CART or simple abdominal paracentesis between January 2013 and December 2023 at the Toranomon Hospital Kajigaya in Japan. Patients who were diagnosed as liver or kidney cystic infection at the time of CART or paracentesis were excluded. Patients who underwent CART at least once were assigned in the CART group. Patients who had never undergone CART and underwent only paracentesis were assigned in the paracentesis group. We compared clinical characteristics and overall survival between the two groups, and analyzed factors associated with overall survival of the patients.

Results: A total of 42 patients underwent CART or paracentesis. 14 patients were excluded due to diagnosis of cyst infection. We enrolled 18 patients in the CART group (male 4; age 54.3±8.8 years, median observational periods 747 days) and 10 patients in the paracentesis group (3; 58.2±6.3 years, 568 days). There were no significant differences in clinical characteristics of the patients at baseline between two groups. 4 patients died in the CART group, while 6 patients died in the paracentesis group during the observation period. Kaplan-Meier survival curves indicated that patients in CART group had better overall survival(p=0.035). Univariable and multivariable cox proportional hazards regression analyses revealed CART and hemodialysis were significant factors associated with overall survival. The change in serum albumin level was +0.15 g/dL in the CART group and -0.10 g/dL in the paracentesis group (p=0.006). The patients in CART group had significantly more overall adverse events including mild adverse events such as transient fever; however, no serious adverse events were observed.

Conclusions: In patients with ADPKD accompanied by refractory ascites, CART improves overall survival without increasing serious complications compared to abdominal paracentesis.

TH-PO476

Early PKD Observational Cohort (EPOC) Study: Advancing Early Detection of Polycystic Kidney Disease

Vinamratha Rao,[1] Catherine Creed,[1] Rebecca J. Lepping,[1] Arlene B. Chapman,[2] Darren P. Wallace,[1] Reem Mustafa,[1] Alan S. Yu.[1] *[1]The University of Kansas Medical Center, Kansas City, KS; [2]University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease, often leading to renal failure. Early intervention, especially in children, is hindered by the lack of reliable biomarkers to detect and monitor early cyst growth. Longitudinal data, biospecimens and imaging from children and young adults are needed to address this gap.

Methods: EPOC is an observational longitudinal study of individuals aged 4-35 with an eGFR>80ml/min per 1.73m2. Individuals with ADPKD, siblings known to be unaffected and those with uncertain diagnosis ("at-risk" siblings), and healthy unaffected volunteers, were recruited from the University of Kansas, University of Chicago and Children's Mercy Hospital Kansas City. Clinical history, vital signs, serum chemistry, and urine protein were collected at baseline and annually up to 5 years. Urine, urinary

exosomes, plasma, sera and DNA are stored in a biorepository. For ADPKD participants, abdominal MRI scans were performed at baseline and every 2 years to measure height-adjusted total kidney volume(HtTKV).

Results: The EPOC study enrolled 51 healthy controls, 112 individuals with ADPKD, 7 unaffected siblings, and 21 at-risk siblings, with a balanced gender distribution of 56% females. The cohort was predominantly White (80%), with 10% Asian, 8% Black or African American, 1% Native Hawaiian/Pacific Islander, and 6% Hispanic or Latino ethnicity. The median age was 22.2 years (range:4.1-34.7). 82% of those with ADPKD had family history of the disease. Of the 102 genotyped individuals, 88% had PKD1 mutations, 9% PKD2, 2% IFT140, and 1% had both PKD1 and PKD2 mutations. The median baseline HtTKV was 365.6 ml/m (IQR: 267-528.7 ml/m, N=98), with Mayo Imaging Classifications of 10.2% (Class 1A), 22.4% (Class 1B), 26.5% (Class 1C), 20.4% (Class 1D), and 20.4% (Class 1E). Common baseline complications in the ADPKD group included hypertension (39%), flank pain (37%), and urinary tract infection (28%).

Conclusions: We have recruited a cohort of children and young adults with very early ADPKD. This biorepository is uniquely poised to facilitate discovery of novel biomarkers and prognostic models in pediatric ADPKD. The inclusion of unaffected controls and at-risk siblings is novel, providing critical comparative data for understanding early-stage disease.

Correlation between PKD1 Mutation Type and Height-Adjusted Total Kidney Volume in Chinese Patients with ADPKD: Genotype-Phenotype Analysis

Zhiying Liu, Jiayi Zhang, Shu Qu, Mengshi Li, Yang Li, Hong Zhang, Xu-jie Zhou. *Peking University First Hospital, Beijing, China*.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common inherited kidney disease but with allelic and genetic heterogeneity. This study aims to explore the association between PKD1 mutation types and height-adjusted total kidney volume (htTKV) in Chinese ADPKD patients.

Methods: We evaluated genotype-phenotype correlations in 379 subjects with affected ADPKD between August 25, 2017 and April 2, 2024. Patients with complex genotypes (mosaic, digenic, or diallelic) were excluded. We performed regression analysis to examine the effects of age, sex, and mutation type on htTKV natural log scale.

Results: 90.5% of the patients got molecularly diagnosed with PKD1 (82.3%, n=312) and PKD2 (7.9%, n=30) in the current study. PKD1 truncating mutations accounts for 67.3% of the patients (Figure 1). Men had more severe disease than women with lower eGFR and larger htTKV (Figure 2, A and B). Patients with nonsense and frameshift mutations showed faster eGFR decline compared to missense mutations (Figure 2C). Patients with PKD1 truncating mutations generally have larger htTKV than non-truncating mutations (P<0.005) (Figure 2D). Allelic effect on htTKV was more significant in splicing, frameshift and nonsense mutation classes (Figure 2E).

Conclusions: In Chinese ADPKD patients, we confirmed that kidney cyst severity differs by mutation types in PKD1. Patients with PKD1 truncating mutations have higher TKV and lower eGFR, particularly frameshift and nonsense mutations. Assessment of mutation types may predict renal prognosis and aid in caring for high-risk ADPKD patients.

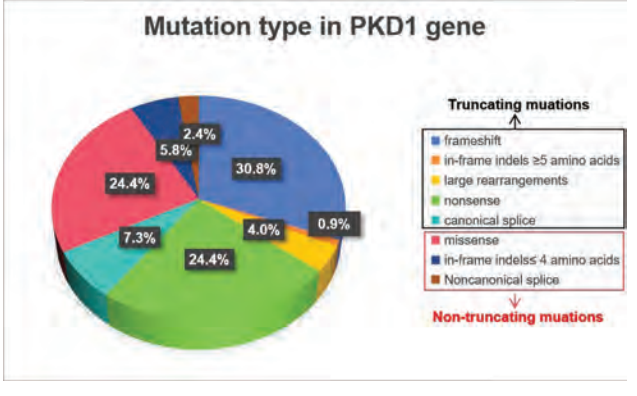

Figure 1. Categories of mutation type in PKD1 population.

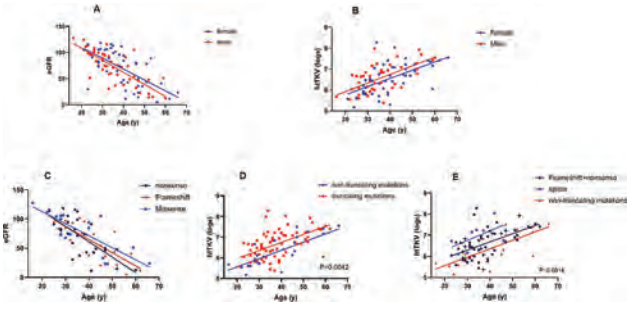

Figure 2. Sex and allelic effects on ADPKD phenotype in PKD1 population.

TH-PO478

Correlation of Genotype with Age at Disease Onset and Hypertension Diagnosis in Autosomal Dominant Polycystic Kidney Disease

Dimitra Gkalitsiou,[1] Eirini Evangelou,[1] Maria Konsta,[2] Kiriaki Vasiliou,[1] Aggeliki Poula,[1] Niki Markou,[1] Tsielestina Poulli,[1] Danai Palaiologou,[3] Konstantina Kanellopoulou,[1] George I. Tsirpanlis.[1] *[1]General Hospital of Athens Georgios Gennimatas, Nephrology Department, Athens, Greece; [2]Department of Rheumatology, Sismanoglion General Hospital, Athens, Greece; [3]Genesis Genoma Lab, Genetics Diagnosis, Clinical Genetics & Research, Athens, Greece*.

Background: Autosomal Dominant Polycystic Kidney Disease is the predominant genetic disease leading to End Stage Kidney Disease. Genetic identity could correlate to disease profile. Correlations between genetic and phenotypic characteristics in a cohort of ADPKD patients are investigated.

Methods: Genetic analysis was conducted in 85 ADPKD patients, using targeted Next Generation (tNGS) or Sanger Sequencing and Multiplex ligation-dependent probe amplification (MLPA). Medical history, clinical and laboratory data, including MRI for Total Kidney Volume (TKV) measurement, were recorded and subsequently correlated to the respective genotypes.

Results: Eighty-five patients (43 females, 42 males, 33±16 years old) were included. The mean age at diagnosis was 21.5±13 (0.6-69) years. Familial history of ADPKD was present in 58 patients (68%). The mean age at which the affected parent reached ESKD was 53.0±9 years. Hypertension was diagnosed in 60 patients (71%) within the study cohort. The mean age at HTN diagnosis was 31±11 years. In the assessment based on height-adjusted TKV and age, Mayo Clinic Imaging Categories revealed that 9% of patients were classified as 1A, 20% as 1B, 29% as 1C, 29% as 1D, and 13% as 1E. Mutations in PKD1 gene were detected in 70 patients (82%), with 61% exhibiting truncating and 39% non-truncating mutations, while PKD2 mutations were identified in 15 patients (18%). The average age of ADPKD diagnosis varied among genetic subgroups. Patients carrying PKD1-truncating mutations were diagnosed at 17.6±11 years, those with PKD1-non-truncating mutations at 24.5±12 years, and those with PKD2 at 27.3±16 years (p = 0.01). Moreover, the mean age at which the affected parent reached ESKD was 50±8 years, 55±10 and 60±7 years in PKD1-truncating, PKD1-non-truncating and PKD2 patients respectively (p = 0.04). Additionally, the mean age of HTN diagnosis was 29±12 years in PKD1-truncating, 30±10 years in PKD1-non-truncating and 40±7 years in PKD2 patients (p = 0.05).

Conclusions: Mutation type correlates with the age of ADPKD diagnosis, renal survival within families and hypertension onset. Patients with PKD1-truncating mutations manifest an earlier onset of both disease and hypertension compared to those with PKD2 mutations.

TH-PO479

Association of Tumor Necrosis Factor Receptor 1 (TNFR1) and TNFR2 with Kidney Volume and Function in Patients with ADPKD

Seyda G. Ozcan,[1] Metin Ergul,[2] Durdane Y. Ersoy,[1] Mevlut T. Dincer,[1] Ibrahim M. Bolayirli,[1] Necmi Eren,[2] Nurhan Seyahi.[1] *[1]Istanbul Universitesi-Cerrahpasa Cerrahpasa Tip Fakultesi, Fatih, Turkey; [2]Kocaeli Universitesi, Kocaeli, Turkey*.

Background: ADPKD is a genetic disorder with numerous kidney cysts, leading to increased kidney volume and compromised kidney function. TNF receptors (TNFR1,TNFR2) mediate the intracellular effects of TNF-α, an inflammatory cytokine that may influence cyst growth in ADPKD. We aimed to investigate the association between TNFR1/TNFR2 levels and kidney function and volume in ADPKD patients.

Methods: We recruited adult ADPKD patients(Mayo Class IC-E). Serum TNFR1/TNFR2 levels were measured using ELISA. Kidney volumes were assessed using MRI.

Kidney function was evaluated using serum creatinine and cystatin C-based eGFR. Statistical analysis was performed to determine correlations between TNFR levels, kidney volumes, and function.

Results: We examined a total of 50 patients. Demographic, clinical, and laboratory data are shown in Table 1. No significant correlations were found between kidney volume and TNFR1/TNFR2 levels. There was a weak negative correlation between eGFR and TNFR1(r=-0.332,p=0.019). TNFR1 and TNFR2 levels were not significantly different between Mayo stages D-E and C.

Conclusions: TNFR1 may be associated with decreased kidney function in ADPKD. Longitudinal studies are needed to determine if a causal relationship exists between TNFR levels and kidney function. Further research is warranted to explore other potential biomarkers influencing kidney enlargement and functional decline in ADPKD patients.

Association between Nephrolithiasis and Kidney Disease Progression in Patients with Autosomal Dominant Polycystic Kidney Disease from a Single-Center, Prospective Cohort

Hongran Moon, Hyunjin Ryu, Yong Chul Kim, Yun Kyu Oh. *Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Nephrolithiasis is a common complication in Autosomal dominant polycystic kidney disease (ADPKD) patients. A few in vitro and in vivo studies showed that kidney and ureter stone formation could accelerate renal disease progression in ADPKD. However, its association between nephrolithiasis and renal function deterioration remains unknown in ADPKD patients.

Methods: This single-center prospective cohort study, HOPE-PKD, analyzed 410 subjects who underwent abdominal CT scans within a year before enrollment. Subjects were divided into stone (n=80, 19.5%) and no-stone (n=330, 80.5%) groups based on CT findings. The primary outcome was the initiation of renal replacement therapy due to end-stage renal disease, and the secondary outcome was a composite of a 50% decline in eGFR, doubling of serum creatinine, or initiation of renal replacement therapy.

Results: There was no statistical difference in baseline characteristics between the stone and no-stone cohorts. During a median 5.18 [interquartile range 3.41 - 8.03] year of follow-up, the primary and secondary outcomes occurred in 51 (12.4%) and 96 (23.4%) patients, respectively. In the unadjusted Cox regression analysis, there was no significant difference in the survival analysis between the two groups. However, after adjusting possible confounding factors (age, sex, body mass index, eGFR, comorbidity of hypertension and diabetes, serum uric acid, phosphorous, calcium level, results of PKD1 and PKD2 gene analysis, and Mayo classification), the stone group showed an increased risk of the primary and secondary outcome of HR 2.84 (95%CI 1.26 - 6.38; p-value 0.012) and HR 1.83 (95% CI 1.03 - 3.27; p-value 0.041), respectively compared to the no-stone group (Figure 1).

Conclusions: This study demonstrates an association between nethrolithiasis and adverse renal outcome in ADPKD patients, underscoring the need for further clinical studies to enhance renal outcomes.

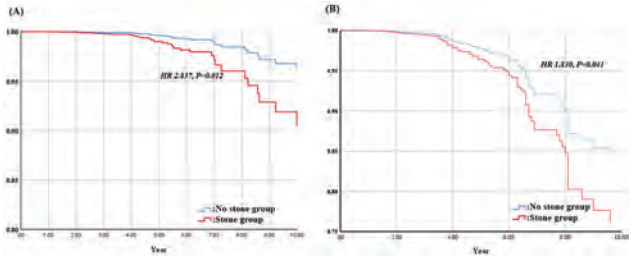

Figure 1. Survival curve for primary outcome (A) and secondary outcome (B) obtained by means of multivariate Cox regression model, in model 4.

TH-PO481

Effect of Oral Antibiotic Exposure on Urine Lithogenic Profile in ADPKD

Wei Wang,[1] Anna Ostrow,[1] Jelena Klawitter,[1] Kristen L. Nowak,[1] Erin R. Coleman,[1] Diana George,[1] Lama Nazzal,[2] Huilin Li,[2] David S. Goldfarb,[3] Berenice Y. Gitomer,[1] Michel Chonchol.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]New York University, New York, NY; [3]New York University Grossman School of Medicine, New York, NY.*

Background: Oral antibiotic use alters the gut microbiome leading to an increase in urine oxalate and risk for nephrolithiasis. However, this novel risk factor has not been explored in ADPKD patients who are frequently treated with oral antibiotics for recurrent urinary tract (UTI) and kidney cyst infections. The high incidence of KSD in patients with ADPKD underscores the importance of understanding this potential risk factor for progression.

Methods: Diagnosis of ADPKD was based on imaging or genetic testing and participants were required to have an eGFR ≥ 45 ml/min/1.73m^2. Subjects were recruited nationally between 2021-2024 and were stratified based on recent antibiotic use within the previous 6 months or no antibiotic use within the previous 3-years (control group). All participants had no history of KSD within the previous 5-years. Diet was assessed by ASA24 dietary intake tool (NCI) on 3-separate occasions and subjects completed a 24-hour urine and stool collection. The urine stone risk profile was assessed by Litholink™ (Labcorp, Itasca, Illinois).

Results: To date 15 participants with a history of antibiotic use (mean age 41±8 years) and 13 participants with no antibiotic use (mean age 41±8 years) have completed the study. All participants are female most likely due to the higher prevalence of UTI in females. Mean eGFR was 80±10 ml/min/1.73m^2 in subjects with recent antibiotic use and 79±12 ml/min/1.73m^2 in control subjects. The mean age 24-hour urine calcium excretion was significantly higher in patients with antibiotic use compared to the control subjects (136.5±63.5 vs. 91.2±52.7 mg/day P= 0.05). The supersaturation of calcium phosphate was also higher in patients with recent exposure to antibiotics compared to controls (0.67±0.69 vs. 0.28±0.22, P=0.06), however it did not reach significance. Urinary oxalate and citrate excretion did not differ between groups.

Conclusions: Patients with recent exposure to antibiotics have higher daily urine calcium excretion levels despite no apparent dietary differences. Analysis of additional subjects and fecal samples will be necessary to fully evaluate the potential effects of antibiotics in this patient population.

TH-PO482

Kidney Stone Incidence Rate in Patients with ADPKD, 2000-2023

Anna Ostrow,[1] Zhiying You,[1] David Turnbull,[2] Tom Belnap,[2] Sanjiv Anand,[2] Lama Nazzal,[3] Huilin Li,[3] David S. Goldfarb,[4] Kristen L. Nowak,[1] Berenice Y. Gitomer,[1] Michel Chonchol.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Intermountain Healthcare, Salt Lake City, UT; [3]New York University, New York, NY; [4]New York University Grossman School of Medicine, New York, NY.*

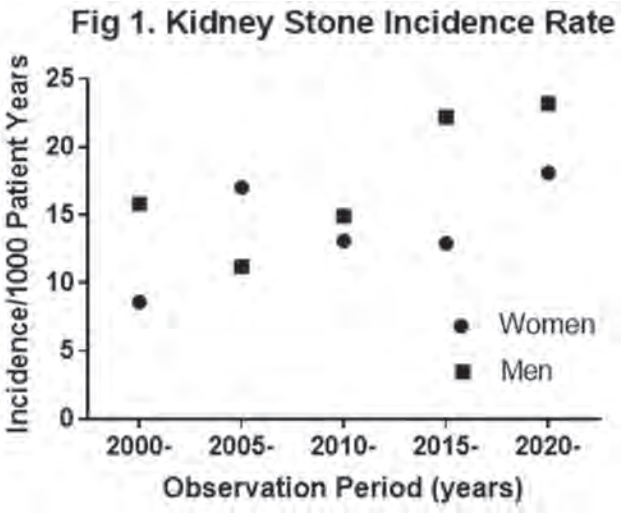
Background: The incidence of kidney stone disease (KSD) has increased in the general population in recent times. However, trends in KSD among patients with autosomal dominant polycystic kidney disease (ADPKD) remain poorly understood. Thus, the goal of the current study is to define the incidence of KSD from 2000-2023 according to sex and age in an ADPKD population.

Methods: De-identified data from Intermountain Healthcare, an integrated healthcare delivery system in Utah, was utilized for the study after approval by the respective Institutional Review Boards. Overall, 976 subjects aged ≥ 18 years with an ADPKD diagnosis were included in the study. Among these, 183 had a diagnosis of KSD based on ICD-9 or ICD-10 codes during the observation period. Incidence rates of KSD were calculated per 1000 patient years and summarized by sex across 5-year intervals and by age.

Results: The overall incidence rate of KSD increased from 11.1/1000 patient years between 2000-2004 to 20.3/1000 patient years between 2020-2023. This increase was observed in both male and female patients with a slightly higher incidence in men (23.2/1000 patient years compared to women (18.1/1000 patient years in women) in the period 2020-2013 (Figure 1). The incidence rate of KSD remained fairly constant across age groups.

Conclusions: Similar to the general population, incidence rate of KSD has increased recently among ADPKD patients. As KSD may contribute to the overall morbidity of ADPKD, periodic monitoring of urine stone risk factors in patients with ADPKD should be considered.

Funding: NIDDK Support, Private Foundation Support



TH-PO483

Kidney Stone Incidence in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Anna Ostrow,[1] Adriana Gregory,[2] Timothy L. Kline,[2] Peter C. Harris,[2] Neera K. Dahl,[2] Bradley J. Erickson,[2] Kristen L. Nowak,[1] Vicente E. Torres,[2] David S. Goldfarb,[3] Berenice Y. Gitomer,[1] Michel Chonchol.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Mayo Clinic Minnesota, Rochester, MN; [3]New York University Grossman School of Medicine, New York, NY.*

Background: Nephrolithiasis, or kidney stone disease (KSD), is a common comorbidity in patients with ADPKD and is associated with an increased risk of more rapid decline in kidney function. However, incident rates of kidney stones within the ADPKD population have not been well examined. This study aimed to characterize the incidence of symptomatic kidney stone disease in an ADPKD patient population.

Methods: We focused on data from the Mayo Clinic repository (Olmstead County, MN). The observation window was defined as January 1st, 1994, to December 31st, 2023. Of 3,428 total ADPKD patients, 2,792 aged ≥ 18 years were included who had a recorded serum creatinine lab measurement between 1994 and 2023. Follow-up time per patient was calculated using the dates of their first and last serum creatinine measurements within the observation window, and initial stone diagnosis was defined as the earliest recorded date of KSD after 1993. Incidence rates were calculated per 1,000 person-years between males and females and across age groups.

Results: Of 2,792 eligible patients (1,256 males and 1,536 females), 545 had evidence of overall KSD (19.5%), while 380 had evidence of an initial diagnosis within this time period. The overall incidence rate was 27.9 per 1,000 person-years. KSD incidence rates remained similar in both males and females with ADPKD between 1994 and 2023 (Figure 1), with the highest overall rate observed in patients aged 18-29. We found the clearest increase in rates between 1994 and 2000, and the highest incidence per 1,000 person-years between 2000 and 2006.

Conclusions: In patients with ADPKD, a high incidence rate of KSD occurs in both males and females. Overall, the incidence rate of KSD has increased between 1994 and 2023.

Funding: NIDDK Support, Private Foundation Support

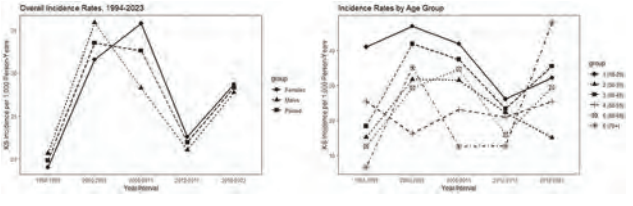


Figure 1. KSD incidence rates by 5-year interval and age group, 1994-2023.

TH-PO484

Xanthine Oxidase in Rats, Mice, and Humans with Polycystic Kidney Disease

Zhibin He,[1] Wei Wang,[1] Daniel Atwood,[1] Berenice Y. Gitomer,[1] Michel Chonchol,[1] Allen Davidoff,[2] Charles L. Edelstein.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Xortx Therapeutics Inc, Calgary, AB, Canada.*

Background: Raising uric acid (UA) worsens PKD in rodents (Edelstein, AJP, 2024). Xanthine oxidase (XO) results in the formation of uric acid and generates reactive oxygen species like H_2O_2. There is increasing evidence that increased XO in addition to UA plays role in disease.

Methods: To gain insight into whether increased XO is associated with cyst growth, XO activity was measured in PCK rats, $Pkd1^{RC/RC}$ (RC) mice and 34 patients at HALT-PKD study 24 month visit. XO in rodents (iU/ug): Fluorometric assay kit that detects H_2O_2. XO in humans (ng/mL): ELISA that directly measures XO. Fast progressors (N=17) defined as increase in height corrected total kidney volume (TKV) of >7%/yr. Fast and slow progressors were matched for clinical characteristics including age, gender, Pkd1 mutation. Values=means

Results: Kidney XO was higher in PCK rats vs. RC mice (19 vs. 6, P<0.05). **PCK rats:** XO was lower in serum (119 vs 145, P<0.01), kidney (19 vs 34, P<0.05) and liver (1505 vs 2173, P<0.01) vs wildtype. Higher cyst index correlated with lower serum (R^2 0.66, P=0.09) and kidney (R^2=0.47, P=0.02) XO. **RC mice:** No correlation between cyst index and serum XO (R^2=0.06, p=NS) or kidney XO (R^2=0.06, NS). Oxypurinol decreased cyst growth (Edelstein et al. AJP, 2024) and decreased both serum UA and serum XO (91 vs. 171, p<0.05). **Patients:** Serum UA was higher with eGFR<60 vs >60 (8.5 vs. 6, P<0.05). Higher TKV correlated with lower eGFR (R^2 0.24, P=0.008). Correlation between higher serum UA and higher total kidney volume (R^2=0.02, P=0.003). Fast progressors had higher TKV (1523 vs 583, P=0.003), lower eGFR (65 vs 91, P=0.005) and higher serum UA (8.1 vs 5.5, P<0.01) than slow progressors. Serum XO activity was the same between eGFR>60 vs <60 (8.5 vs 6.3,NS). Correlation between higher serum XO and lower eGFR showed a trend (R^2=0.08, P=0.07). No correlation between serum XO and TKV (R^2=0.009, NS). XO activity was the same in fast and slow progressors (7.7 vs 9.2, P=NS).

Conclusions: In summary, in rodents with PKD, there was no correlation between increased serum or kidney XO activity and cyst index. In PKD patients there was a trend towards higher serum XO and lower GFR. In conclusion, serum XO needs to be measured in a larger group of patients from the HALT-PKD study.

Renal Uric Acid Crystals Trigger Cystogenesis and CKD in Polycystic Kidney Disease

Nickolas J. Holznecht,[1] Sebastian Strubl,[1,2] Jacob A. Torres,[1] Peter C. Harris,[3] Roman-Ulrich Mueller,[2] Thomas Weimbs.[1] *[1]University of California Santa Barbara, Santa Barbara, CA; [2]Universitat zu Koln, Koln, Germany; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: We have reported that renal tubular calcium oxalate crystals trigger transient tubule dilation in normal kidneys facilitating their excretion. In ADPKD kidneys, the same reno-protective mechanism triggers cystogenesis and worsen disease progression. Since hyperuricemia and uric acid (UA) kidneys stones are common in individuals with ADPKD, we investigated the impact of UA crystals on disease progression in a novel, orthologous heterozygous ($Pkd1^{+/-}$) rat model that is genetically identical to human ADPKD.

Methods: $Pkd1^{+/+}$ and $Pkd1^{+/-}$ rats were treated with UA and the uricase inhibitor oxonic acid for 14 days followed by a washout period for 56 days. To investigate the preventative and therapeutic potential, respectively, of treatment with beta-hydroxybutyrate (BHB) and citrate, we treated rats with BHB/citrate either concurrently during UA challenge, or for 28 days at the end of the washout period.

Results: Challenging $Pkd1^{+/-}$ rats with hyperuricemia diet leads to tubular UA crystal deposition which triggers cystogenesis and ongoing, progressive PKD as well as an acute inflammatory response (neutrophils, macrophages) that transitions into chronic inflammation, fibrosis, and cystic progression in $Pkd1^{+/-}$ rats. In contrast, $Pkd1^{+/+}$ rats recover after UA crystal clearance. Concurrent treatment with BHB/citrate prevents UA crystal deposition. Treatment with BHB/citrate after the UA washout leads to regression of inflammation, fibrosis and cystogenesis.

Conclusions: In contrast to all other existing PKD rodent models, our novel, orthologous, heterozygous $Pkd1^{+/-}$ rat model closely resembles human ADPKD patients ($PKD1^{+/-}$). We show that crystal injury triggers de-novo cystogenesis in $Pkd1^{+/-}$ rats that otherwise do not develop PKD. Therefore, a second-hit genetic mutation is not necessary for cystogenesis. Rather, a specific renal injury controlled by diet, such as hyperuricemia-induced

UA crystals, can trigger PKD onset and progression in a heterozygous context. Our results have immediate clinical implications and suggest that avoidance of renal injury triggers is critical for the management of ADPKD. Furthermore, BHB/citrate treatment is promising as a preventative measure and as a disease-modifying therapy.

TH-PO486

Death-Specific Risk Factors among US Veterans with Autosomal Dominant Polycystic Kidney Disease

Michal Mrug,[1,2] Julia W. Gallini,[2] Christine L. Jasien,[2] Phillip H. Chumley,[1,2] Xiangqin Cui.[3,2] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Veterans Health Administration, Washington, DC; [3]Emory University, Atlanta, GA.*

Background: Identifying and addressing death-specific risk factors in people with autosomal dominant polycystic kidney disease (ADPKD) is critical for improving healthcare outcomes and reducing mortality in this patient population.

Methods: To identify death-specific risk factors for ADPKD, we used a cohort of 12,217 ADPKD patients that we recently established using nationwide VA electronic health record data from 1999-2020. Of these patients, 5,342 were identified as deceased based on the VA death index. We used these data to conduct a survival analysis on the time to death from the first use of ADPKD diagnosis ICD codes in the VA database on the whole cohort.

Results: The multivariable Cox regression analysis yielded the following key findings: 1) A higher hazard for death was associated with older age at diagnosis (hazard ratio [HR] per year 1.056; p<0.001) and a longer delay in the ADPKD diagnosis after the initial encounter (HR per year 1.012; p=0.002). 2) A lower hazard of death was associated with a higher estimated glomerular filtration rate (eGFR) at the time of ADPKD diagnosis (HR 0.981; p<0.001) and female gender (HR 0.733; p=0.001).

Conclusions: While some of the identified death-specific risk factors cannot be modified, others, especially the delay in the ADPKD diagnosis after the initial encounter, are potentially modifiable. Together, these findings suggest that interventions leading to earlier ADPKD diagnosis may delay death in patients with ADPKD. However, it is important to note that this study was conducted on a predominantly male population of US veterans, limiting the generalizability of the results.

TH-PO487

A Family with Autosomal Dominant Alport Syndrome with Phenotypic Variability

Sadaf Akbari, Meenakshi Sambharia. *The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.*

Introduction: Alport syndrome (AS) is a glomerulopathy, characterized by glomerular hematuria, progressive hearing loss and ocular abnormalities. It is inherited in X-linked, Autosomal Dominant (AD) and Recessive (AR) manner. Mutations in COL4A3 are responsible for ADAS.

Case Description: A 32 YO female with no past history was referred for microscopic hematuria/high blood pressure. She had microscopic hematuria with normal creatinine. Family history was significant for AS in her father who had been on dialysis since the age of 46 years. Father was diagnosed with AS based on a kidney biopsy showing features of AS, progressive hearing loss, lenticonus. Given normal renal function we decided to proceed with genetic testing to confirm AS instead of a kidney biopsy. Results revealed a heterozygous missense mutation in COL4A3 c.3955G>A (p.Gly1319Arg) which was reported as variant of uncertain significance(VUS). Her father was then tested and was found to have the same mutation. It was determined that despite it being reported as VUS it was likely causative of AS in both of them. Upon further history, multiple family members were on dialysis/had kidney disease including paternal and maternal uncle. While the Pt herself did not have any ocular or hearing abnormalities and preserved kidney fucntion, her father had all the classical symptoms by mid-30's.

Discussion: Compared to X-linked and ARAS, ADAS is considered least severe with majority of pts having hematuria and only a few with CKD and needing dialysis. A study found that in ADAS there was no significant difference in males and females in term of kidney survival. Extra-renal features are rare in ADAS, but our Pt's father had classical extra-renal features of lenticonus and early onset progressive sensorineural hearing loss. To the best of our knowledge till date this mutation has not be known to cause ADAS. The complexity of ADAS diagnosis and management is compounded by the broad range of phenotypic expressions observed in patients. In addition, individuals often exhibit a spectrum of symptoms, from severe to completely asymptomatic within families sharing the same genetic mutation. The absence of symptoms and preserved kidney function may suggest genetic modifiers, variable expressivity, incomplete penetrance, or the influence of other protective genetic or environmental factors.

TH-PO488

Resolution of Two Intronic Noncanonical Splicing Variants Located in X-linked Alport COL4A5 Gene

Si Ting Lim,[1,2] Chee Teck Koh,[1,2] Alwin Hwai Liang Loh,[3] Jia Liang Kwek,[4] Jason Choo Chon Jun,[4] Irene Y. Mok,[4] Cynthia C. Lim,[4] Hui-Lin L. Chin,[1,2] Jun Li Ng,[1,2] Hui Kim Yap,[1,2] Kar Hui Ng,[1,2] Yaochun Zhang.[1,2] *[1]National University of Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [2]Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore; [3]Singapore General Hospital Division of Pathology, Singapore, Singapore; [4]Singapore General Hospital, Singapore, Singapore.*

Introduction: Variants located at intronic non-canonical sites are challenging to interpret due to limited literature. We report two families carrying two different intronic variants at non-canonical splicing sites of the *COL4A5* gene which causes X-linked Alport syndrome.

Case Description: Proband 1 first presented at age 4 with isolated persistent microhematuria with no extrarenal manifestations. She progressed to A3 albuminuria by age 20, but kidney function remained normal at age 41. Her mother developed kidney failure at 60. Her son had persistent microhematuria and proteinuria since age 2, progressing to chronic kidney disease (CKD) by age 9. Proband 2 first presented at age 3 with microhematuria and recurrent gross hematuria and persistent subnephrotic proteinuria. He later developed stage 3 CKD and bilateral kidney cysts by age 14. His 44-year-old mother has microhematuria, persistent proteinuria with FSGS, bilateral renal cysts, but normal renal function. His 28-year-old maternal uncle was diagnosed with Alport syndrome at age 15, progressing to kidney failure and underwent a transplant. He has bilateral sensorineural hearing loss needing hearing aids. In both probands, anti-COL4A5 immunofluorescence staining patterns were abnormal but not characteristic of classic X-lined or autosomal recessive disease. Electron microscopy showed GBM thinning for one case, while the other displayed thin and thick basement membranes with lamina densa multilamination. Whole exome sequencing identified variant c.1032+4A>G in proband 1 and c.1032+3_1032+6delAAGT in proband 2, both located at intron 18 of *COL4A5*. To assess their impact on pre-mRNA splicing, exons 17-19 with introns 17-18 from probands and healthy controls were subcloned and transfected into HEK293 cells. The wild type construct produced a 300 bp band, while the mutant plasmids generated a truncated transcript. Sanger sequencing confirmed a skipping of exon 18.

Discussion: Skipping of exon 18 results in truncation of a critical domain of the protein, hence, both variants can be rendered a "strong" criterion in PVS1 according to the revised ACMG variant interpretation guidelines. This suggested both variants are likely pathogenic.

TH-PO489

Unveiling X-linked Alport Syndrome: Genetic Testing in FSGS

Nitika Agrawal, Steven T. Heidt, Pravir V. Baxi. *Rush University Medical Center, Chicago, IL.*

Introduction: FSGS is often considered in the evaluation of patients with CKD and proteinuria. As a histopathologic pattern of injury with various causes, investigating the underlying etiology of podocyte injury is crucial, given its potential therapeutic implications. Recent advances in genetic testing have revealed pathogenic variants of Alport's syndrome (AS) in patients presenting with biopsy findings of FSGS. Here, we present a patient with biopsy proven FSGS subsequently found to have X-linked AS.

Case Description: An 18 y/o man with CKD was evaluated for HTN at age 7, at which time he had a normal creatinine (Cr) and microscopic hematuria without proteinuria. He was started on an ACE-i. At age 16, he developed proteinuria, with a biopsy showing FSGS and acute interstitial nephritis (AIN). There was insufficient sample for EM analysis. A course of steroids was prescribed for the AIN. Now, he has developed significant HTN, rising Cr, and worsening proteinuria. He had no history of vision or hearing issues. Further evaluation of his family revealed siblings with microscopic hematuria. Genetic testing was done now 11 yrs after the biopsy and showed a mutation within the COL4A5 gene, consistent with X-linked AS.

Discussion: FSGS of genetic origin can appear at different ages and exhibit varying degrees of proteinuria and foot process effacement. Recent advancements have shed light on the role of COL4A3-5 mutations in the development of FSGS amongst patients diagnosed with primary FSGS or steroid-resistant nephrotic syndrome. AS diagnosis has significant implications not only for the patient but also their family members who are at risk for the spectrum of systemic manifestations of the condition. Early diagnosis also allows for patients to be enrolled in clinical trials to help our therapeutic options. This case underscores the importance of accurately classifying patients with FSGS and highlights the pivotal role of genetic testing in managing CKD.

TH-PO490

A Case of Autosomal Dominant Hereditary Nephritis

Faten Aqeel, John Sperati, Lois J. Arend, Mohamad A. Hanouneh. *Johns Hopkins University, Baltimore, MD.*

Introduction: Alport syndrome, or hereditary nephritis, results from genetic mutations in collagen IV protein genes, leading to a basement membrane disorder. It can be inherited through X-linked (COL4A5 gene defect), autosomal recessive (AR), or autosomal dominant (AD) (COL4A3 or COL4A4 gene defects). This disorder causes a progressive glomerular disease and often involves sensorineural hearing loss and ocular abnormalities.

Case Description: A 47-year-old woman with Crohn's disease, receiving infliximab, is evaluated for CKD stage IIIA and proteinuria (UACR 838 mg/g Cr). No history of hearing or ocular issues is reported. She has a family history of ESRD in two maternal aunts. Serology shows positive ANA (1:640), and anti-histone antibodies. The kidney biopsy showed variable glomerular basement membrane width; areas of thinning alternated with thickened sections having variable lucency (Fig 1A). No immune complex electron-dense deposits were noted. Irregular staining of the glomerular capillary walls for COLIV alpha5 chain was observed (Fig 1B left) compared to the normal control tissue (Fig 1B right). Genetic testing revealed heterozygous pathogenic variant in COL4A4 c.2402G>T (p.Gly801Val). She was diagnosed with AD Alport syndrome. She was referred for ocular and auditory evaluations. She began treatment with losartan and Empagliflozin. After 6 months, her kidney function remained stable, and UACR improved to 397 mg/g Cr.

Discussion: Though her positive serology likely stems from an immunologic effect of infliximab, there's no evidence of immune complex-related kidney disease. The observed GBM abnormalities align with a COL4-related disorder. While variable alpha5 staining hints at COL4A5 gene abnormalities, her family history suggests otherwise; with her maternal grandfather lived longer without ESRD. With a heterozygous genetic mutation, she has AD disease. Her variable COL4A5 staining reflects deficiency of normal A3-A4-A5 trimer formation. AD Alport's is typically less severe than AR and often lacks hearing loss and eye issues (occurs in <10 – 25%).

TH-PO491

Unusual Glomerular Abnormalities in a Patient with Combined COL4A5-NPHS1 Variants

Abdelrahman Alwan,[1] Carol Vincent,[1] Dmitry A. Lyalin,[2] Alexei V. Mikhailov.[1] *[1]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC; [2]Virginia Commonwealth University, Richmond, VA.*

Introduction: Collagen IV a5 (gene *COL4A5*) isoform is an essential part of the glomerular basement membrane (GBM) *lamina densa.* Pathogenic variants in *COL4A5* are associated with X-linked Alport syndrome. Nephrin (gene *NPHS1*) is a major component of the podocyte slit diaphragm; pathogenic *NPHS1* variants are autosomal recessive and manifest as childhood proteinuria. We present the first case of a patient with combined pathogenic *COL4A5-NPHS1* variants resulting in unique glomerular abnormalities

Case Description: A 5-year old female (proband) presented with recurrent gross hematuria and proteinuria 80 mg albumin/g creatinine. Renal function was normal; no hearing or ocular abnormalities were detected. Her sister (3 y.o.) exhibited similar symptoms; father was diagnosed with Alport syndrome. Panel-based DNA sequencing identified pathogenic heterozygous *COL4A5* c.1633G>A (p.G545S) and *NPHS1* c.2417C>A (p.A806N) variants in the proband, her father and sister. Whole exome sequencing did not identify additional pathogenic/likely pathogenic variants of renal significance. The kidney biopsy revealed immature glomeruli, 5% global glomerulosclerosis, and small foci of interstitial fibrosis and tubular atrophy. Electron microscopy showed the characteristic Alport-like GBM changes. Filamentous slit diaphragms were detected in 39.9% of filtration slits between non-effaced foot processes compared to 74.9% in control (acute tubulointerstitial nephritis). In some glomeruli several, or all, capillary segments were abnormal, displaying thin irregular GBMs with large gaps covered by podocytes forming tight junctions between each other and the underlying cells. Such capillaries never contained red blood cells, and were lined by cells lacking the endothelial morphology, displaying intraluminal cross-bridges with foci of aberrant GBM formation (Figure 1).

Discussion: Two previous reports of combined *COL4A5-NPHS1* variants describe hematuria and moderate proteinuria detected at 2.5-6 years of age. A kidney biopsy done in one patient showed GBM gaps. In our patient, both pathogenic variants lead to a severe mosaic glomerular capillary malformation. We hypothesize that Alport-associated alterations in GBM positioning of extracellular matrix proteins and changes in nephrin-associated signaling combine to affect the developmental cues resulting in this striking phenotype.

TH-PO492

Alport Syndrome in Iceland: Epidemiology and Outcomes

Saga Ingadóttir,[1] Olafur S. Indridason,[2] Sindri Valdimarsson,[2,3] Hjordis Thorsteinsdottir,[3] Vidar O. Edvardsson.[2,1] *[1]School of Health Sciences, University of Iceland, Reykjavik, Iceland; [2]Landspitali, Reykjavik, Iceland; [3]Domus barnalaeknar, Reykjavik, Iceland.*

Background: Alport syndrome (AS) is caused by mutations in the collagen IV genes, COL4A3, COL4A4 and COL4A5. Three types of AS have been described: X-linked AS (XLAS), autosomal recessive AS (ARAS) and autosomal dominant AS (ADAS). The aim of this study was to examine the epidemiology and outcomes of AS in Iceland.

Methods: This was a retrospective study of all Icelandic AS cases in the period 1968-2023. Affected individuals were identified through diagnosis codes, the Icelandic Renal Registry, and family tracing. Medical records were reviewed for the confirmation of diagnosis. End-stage kidney disease (ESKD) was defined as the need for kidney replacement therapy. Clinical characteristics, family history and genetic testing were used for the diagnosis of X-linked AS. The diagnosis of autosomal AS was made in individuals with persistent haematuria in whom a secondary cause had been excluded.

Results: We identified 76 individuals with AS, 52 with XLAS (13 males) and 24 individuals with autosomal AS (8 males). Diagnosis was confirmed with genetic testing in 45 of the 52 XLAS patients and in 2 autosomal AS cases. The mean (±SD) age at XLAS diagnosis was 28.5±22.3 years and 9.4±9.6 years for autosomal AS. The prevalence of AS in January 2024 was 17.7 per 100,000 population. The average yearly incidence of XLAS in the last 10 years was 0.54 individuals per 100,000 population. Five autosomal AS patients (20.8%) had some degree of proteinuria at latest follow-up, but all had normal kidney function. A total of 10 individuals with XLAS developed ESKD, 7 men and 3 women, at the median (range) age of 19 (16-25) and 60 (37-69) years for males and females, respectively.

Conclusions: The prevalence of AS in Iceland appears to be similar to other western countries. A high proportion of males but only a few females with XLAS progress to ESKD. The outcomes of individuals with autosomal AS are excellent.

Ocular Coherence Tomography Unveils Alport Syndrome: A Critical Tool in Detecting Collagen IV Nephropathies

Abdelrahman Ibrahim, Zena Altawallbeh, Monica P. Revelo Penafiel, Martin C. Gregory, Laith Al-Rabadi. *University of Utah Health, Salt Lake City, UT.*

Background: Alport Syndrome (AS) and Focal Segmental Glomerulosclerosis (FSGS) pose diagnostic challenges due to overlapping clinical, histopathological, and genetic features. AS is characterized by mutations in collagen genes (COL4A3, COL4A4, COL4A5), leading to glomerular basement membrane (GBM) abnormalities, while FSGS can be primary, autoimmune mediated, or secondary to systemic causes or to genetic mutations, including mutations in the collagen 4 genes. Optical Coherence Tomography

(OCT) aids in identifying these conditions by demostrating temporal macular thinning in COL4 nephropathies. We describe two cases presenting with proteinuria that were initially diagnosed as primary FSGS and treated with long term steroid therapy. Subsequent genetic testing and OCT imaging were carried out.

Methods: Genetic analysis was conducted using next-generation sequencing (NGS) with copy number variation (CNV) analysis. Mutations were confirmed through polymerase chain reaction (PCR) and Sanger sequencing. Under high-resolution spectral OCT done by ophthalmologists, the Temporal Thinning Index (TTI) was measured using the formula: TTI = {(N1 + N2) – (T1 + T2)} / (N1 + N2) × 100. Severe thinning is defined as TTI exceeding 2 standard deviations above the mean for healthy eyes.

Results: Case 1: We identified a novel deletion in COL4A5 exons 8 and 9. OCT: TTI 8.21 OD and 8.36 OS, indicating severe temporal thinning, consistent with Alport Syndrome. Case 2: We detected two variants in COL4A3: a missense mutation (COL4A3:c.2452G>A; p.Gly818Arg) and a novel nonsense mutation (COL4A3:c.4722G>A; p.Trp1574*). OCT: TTI 10.5 OD and 10.8 OS, suggesting severe temporal thinning, indicative of Alport Syndrome.

Conclusions: OCT assists clinicians when the diagnosis of a COL4 nephropathy is unclear. Earlier use of OCT could have established a precise diagnosis in these cases, thus avoiding unnecessary immune suppression. These findings highlight OCT's vital role in distinguishing COL4A nephropathy from primary FSGS, guiding diagnosis, management, and genetic counseling. In broader contexts, OCT can potentially assist in more accurately assessing the prevalence of COL4 nephropathies, identifying individuals for phenotype studies, and exploring potential therapeutic options.

TH-PO494

Variants Involving Podocyte and Extracellular Matrix Proteins in Alport Syndrome: A Case Series

Stefan N. Lujinschi,[1,2] Bogdan Obrisca,[1,2] Bogdan Sorohan,[1,2] Elena-Emanuela Rusu,[1,2] Roxana A. Jurubita,[1,2] Gener Ismail.[1,2] *[1]Institutul Clinic Fundeni, Bucuresti, Romania; [2]Universitatea de Medicina si Farmacie Carol Davila din Bucuresti, Bucuresti, Romania.*

Background: Caused by mutations of type IV collagen genes (COL4), Alport syndrome (AS) displays a wide phenotype. Recent studies have highlighted AS as one of the leading causes of focal and segmental glomerulosclerosis (FSGS). There is a growing body of evidence favoring the modifier role of variants involving podocyte and extracellular matrix proteins in AS.

Methods: We conducted a retrospective case series study including 6 patients with COL4 mutations and simultaneous variants involving podocyte or non-collagen basement membrane proteins, aiming to describe the influence of such variants on the phenotypic spectrum of AS.

Results: We identified 8 different COL4A3 and COL4A4 variants. Two patients had multiple COL4 variants: one had digenic AS and the other had 2 different COL4A3 variants. There were 5 variants of uncertain significance (VUS), 2 pathogenic and one likely-pathogenic variant. All the variants were heterozygous. There were 7 variants involving podocyte and extracellular matrix proteins, including: LAMA5, LAMB2, NUP107, NPHS2, MYO1E and PLCE1. All the variants were heterozygous VUS. Four patients had nephrotic syndrome or nephrotic range proteinuria, one had nephritic syndrome and one had acute tubulointerstitial nephritis. Only 2 patients had hearing loss. Four patients had a family history of kidney disease. Only 2 subjects developed end-stage kidney disease (at 29 and 39 years old respectively). There were 2 cases of FSGS and one case of thin basement membrane disease on kidney biopsy (3/6 patient). Five patients received renin-angiotensin system inhibitors. Only 2 patients were treated with sodium-glucose transport protein 2 inhibitors. Both experienced an important drop in proteinuria (82% and 88% respectively) when compared to baseline. Three patients received immunosuppression, all having nephrotic syndrome.

Conclusions: Although mutations of podocyte and extracellular matrix proteins do not usually cause genetic nephrotic syndrome in heterozygous form, the presence of such variants influenced the phenotype of patients with AS followed in our clinic, as most of them presented with nephrotic syndrome or nephrotic range proteinuria.

TH-PO495

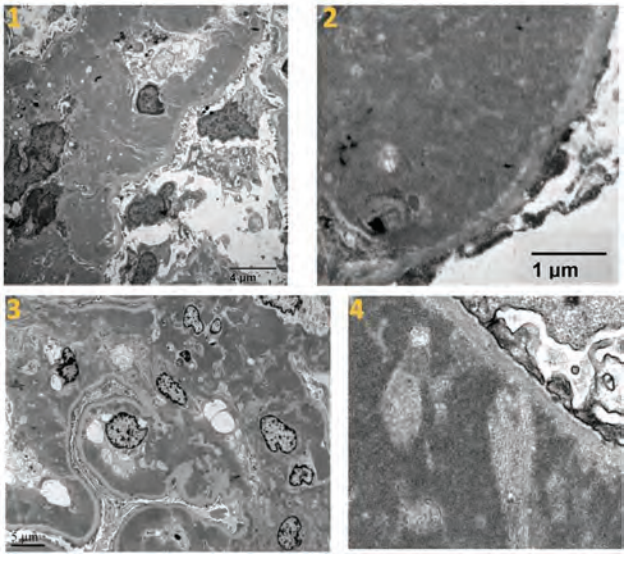
Role of Family History and Genetic Testing in Diagnosing Rare Diseases

Katrina Gonzales, Weixiong Zhong, Tripti Singh. *University of Wisconsin-Madison, Madison, WI.*

Introduction: Fibronectin nephropathy (FN) is an autosomal dominant disease characterized by proteinuria, hematuria, and decline in kidney function [1]. The diagnosis is made with kidney biopsy (KB) showing fibrillary mesangial and subendothelial deposits immunoreactive to fibronectin [1, 2]. There is no treatment and there is a risk of recurrence after transplant [3]. We present two cases of FN that reinforce the need for dedicated family history (FH) and genetic analyses.

Case Description: A 44-year-old female presented for evaluation of proteinuria. Her mother had membranoproliferative glomerulonephritis (MPGN) at age 45, and later ESKD requiring transplant. Physical exam was benign. Urine protein creatinine ratio (UPCR) was 1.26 gm/gm, hepatitis panel, ANA, C3, C4 and kidney ultrasound were normal. Image 1 is the patient's KB results; however, there was insufficient sample, and it did not reveal a diagnosis. Due to the FH of MPGN and to help with her diagnosis, the patient allowed a re-analysis of her deceased mother's KB. There were many similarities between the KBs. A genetic test for the mutation W1925R in the FN1 gene was positive, leading to diagnosis of FN for her, and likely for her mother [4]. She is now on lisinopril, with recent UPCR .65 gm/gm.

Discussion: FN is diagnosed with KB. This patient was unique since she did not have classic findings on KB, but her mother had MPGN and later ESKD. The FH prevented a second KB, and instead received a diagnosis from a genetic test. This case demonstrates the vital role of FH and the benefit of having a multi-disciplinary team, specifically nephrologist, renal pathologist, and genetic counselor.



Patient (1, 2) and mother KB (3, 4) shows large amounts of subendothelial and mesangial electron-dense deposits with vague fibrillary structure under high-power magnification. The mother's KB was post-transplant with recurrent disease.

TH-PO496

Unwrapping the Enigma: A Rare Case of MYH9 Nephropathy

Samiya Yasin, Samina Fazal, Akinwande A. Akinfolarin. *Baylor Scott & White Health, Dallas, TX.*

Introduction: The MYH9 gene encodes the non-muscle myosin heavy chain IIA expressed in various tissues including podocytes and mesangial cells. Mutations in this gene lead to MYH9 related disorders (MYH9-RD) with an autosomal dominant pattern of inheritance characterized by macrothrombocytopenia with variable risk of non-hematologic features including nephropathy, cataracts and hearing loss. Lack of a family history does not rule out disease, as some mutations are sporadic.

Case Description: A 56-year-old Caucasian female with a past medical history of thrombocytopenia in childhood was found to be hypertensive with an elevated creatinine (Cr) 3.23 mg/dl and a reduced eGFR 15 ml/min/1.73m2 during her wellness check which prompted a referral to nephrology. She had no skin rash, hematuria, dysuria, leg swelling or hemoptysis. She denied a history of kidney stones, recurrent urinary tract infections, hearing loss, cataracts or nonsteroidal anti-inflammatory (NSAID) use. Urinalysis showed proteinuria without hematuria, Urine Protein Creatinine ratio (UPCR) 4236 mg/g. Platelet count was 30,000 K/uL. Renal ultrasound revealed bilateral echogenic kidneys with no hydronephrosis, calculi or masses. Work up for proteinuria including antinuclear antibody (ANA), antineutrophil cytoplasmic antibodies (ANCA), anti-double stranded DNA, anti Glomerular basement membrane antibody, HIV, hepatitis panel, complements and immunofixation were negative. A renal biopsy was deferred due to thrombocytopenia. Hematology was consulted and a diagnosis of idiopathic thrombocytopenic purpura (ITP) was made. Genetic testing revealed a pathogenic mutation of c.4270G>A (p. Asp1424Asn) in exon 31 of MYH9 gene. Her blood pressure and antiproteinuric regimen was optimized with subsequent improvement in proteinuria. She was provided counseling by the genetic counselling team.

Discussion: There is great heterogeneity among renal and nonrenal manifestations of MYH9 related disorders including age at presentation, quantity of proteinuria and rate of progression to ESRD. Disease prevalence is underestimated due to misdiagnosis. MYH9-RD should be considered in any patient presenting with renal failure and thrombocytopenia, as early diagnosis and therapy with RAAS blockade may slow progression to ESRD.

TH-PO497

A Boy with Steroid-Resistant Nephrotic Syndrome and Cortical Blindness

Fang Wang, Huijie Xiao, Liuyu Sun, Yali Ren. *Peking University First Hospital, Beijing, China*.

Introduction: Renal involvement in primary mitochondrial disorders may be a dominant or non-dominant feature. Primary mitochondrial disorders should be considered in the etiology of steroid-resistant nephrotic syndrome due to focal segmental glomerulosclerosis. The aim of this study is to describe the prominent extra-neurologic phenotype including steroid-resistant nephrotic syndrome associated with focal segmental glomerulosclerosis characterized by abnormal mitochondria in podocytes, cortical blindness and pancreatitis in a Chinese boy with primary mitochondrial disease.

Case Description: A 5-year-old previously healthy Han ethnicity boy experienced loss of vision after fever and proteinuria 3.5 months before admission to our hospital. Proteinuria did not improve after 5 weeks of prednisolone at 10 mg thrice daily (2mg/kg/d). His personal history indicated he was very prone to fatigue and motor coordination was not good. His past medical history was negative for systemic illness, rash or joint pain. Family history was not remarkable for renal disease. Physical examination showed edema in face and both legs, and less muscle volume of lower extremities. Laboratory findings revealed hypoalbuminaemia (24 g/L), significant proteinuria (2.98 g/24h), normal renal function, and increased level of serum lactate (three times). The serum level of C3 and C4 was normal. The anti-nuclear antibody, anti-DNA antibody, anti-neutrophil cytoplasm antibodies, and anti-hepatitis B virus were all negative. Brain MRI (three times) indicated bilateral parietal occipital lesions and cerebellar atrophy. Visual evoked potentials were absent bilaterally. Renal biopsy revealed focal segmental glomerulosclerosis (collapsing variant). Electron microscope examination revealed mitochondrial abnormality in the renal tissue. Mitochondrial DNA (mtDNA) screening using peripheral blood and urine specimens for common point mutations was negative. Four and a half months after the onset of disease, he was diagnosed with acute pancreatitis with acute peritonitis.

Discussion: The multi-organ impairments of our young patient associated with elevated serum lactate levels and prominent abnormal mitochondria in the podocytes indicated a mitochondrial disease. Screening for the blood lactate level should be included in initial workup for clinically presumed unknown causes of proteinuria or nephrotic syndrome.

TH-PO498

Clinical and Genetic Assessment for the Mechanisms Underlying Phenotypic Diversity in Steroid-Resistant Nephrotic Syndrome Caused by TRPC6 Variants

Hiroyasu Tsukaguchi,[1,2] Huong Quynh Tran Thuy,[1] Mikio Hayashi,[4] Kenji Fukui.[3] Div of Nephrology. *[1]Kansai Medical University, Second Department of Internal Medicine, Hirakata, Japan; [2]Kansai Medical University Hospital, Clinical Genetics Center, Hirakata, Japan; [3]Osaka Medical and Pharmaceutical University, Faculty of Medicine, Department of Biochemistry, Takatsuki, Japan; [4]Kansai Medical University, Department of Physiology, Hirakata, Japan*.

Background: Histologically, 30% of children and 10% of adult individuals with steroid resistant nephrotic syndrome (SRNS) are characterized by Focal Segmental Glomerulosclerosis (FSGS). More than 60 podocyte-related gene mutations have been reported in monogenic SRNS. Among these, *TRPC6* variants account for approximately 6% of familial FSGS and 2% in sporadic cases. Individuals with *TRPC6* variants show a considerable clinical diversity with regards to age onset and disease progression. However, the mechanisms underlying the heterogeneity remain investigated.

Methods: To analyzing the molecular basis of TRPC6 glomerulopathy, we investigated the clinical-genetic features of *TRPC6* variants in our SRNS cohort (*n*=39, average onset of proteinuria 4.6 years, ESRD 7.6 years)

Results: Genetic analysis revealed *TRPC6* variant is the most frequent cause of SRNS (n=8, 21%), followed by *NUP107* (*n*=5), *PLCE1*(*n*=3), *COL4A3,A5*(*n*=2). The eight *TRPC6* variants remarkably clustered into two distinctive cytoplasmic domains: Four in the N-terminal Ankyrin repeat 3 (AR3 163-189 (p.Y173D, R175W, R175G) and the other four C-terminal helix (CH1 and CH2 853-920, p.E875V, 867_868Del, S893N, R895C). Three patients exhibited NS in early childhood around age 3, two manifested in childhood (age 3-12), while the remaining 3 developed NS in adolescence. In familial cases, for example, affected individuals with p.R175W or p.R875V showed discordant age onset and disease severity. The 3D structure analysis with the homo-tetrameric TRPC6 complex revealed that all pathogenic *TRPC6* variants alter the residues composing Ca-permeable pore in the center of the protein complex. Expression studies with HEK293 cells showed that *TRPC6* variants are expressed on the cell surface, supporting that an excessive Ca influx through the gain-of-function of channel may contribute to the podocyte injury.

Conclusions: TRPC6 channelopathy was found to be the most frequent cause in our SRNS cohort. The pathogenic variants likely disrupt the integrity of AR3-CH2 interface, which confers a Ca-binding site for channel inactivation. Remarkable clinical heterogeneity suggests that channel activity may be regulated by other modifying factors. Further studies will be required to address how the excessive Ca influx affect the cytoskeletal organization in the podocytes.

TH-PO499

Combined Genetics and Ultrastructural Examination in Diagnosis and Treatment Decisions of Focal and Segmental Glomerulosclerosis

Roberta Fenoglio, Dario Roccatello. *CMID, Nephrology and Dialysis Unit, San Giovanni Bosco Hospital and University of Turin, Torino, Italy*.

Background: FSGS defines a histologic lesion that represents a pattern of injury associated to different pathologic conditions affecting both children and adults. Better understanding the role of Genetics in FSGS and response to treatment in different forms is of vital importance in this rare and multifaceted condition. We analyzed a cohort of pts with FSGS examined both with EM and genetic testing (GT). Main aims of study were: 1) assessment of GT in primary and secondary forms; 2) analysis of response to therapy according to histologic and genetic classification

Methods: This is a retrospective observational study on patients that received a histological diagnosis of FSGS, including EM, and underwent NGS genetic testing from January 2020 to June 2023. Primary and secondary forms of FSGS were distinguished by degree of pedicle fusion at EM, according to Mayo Clinic classification. Clinical, laboratory, genetic data and used therapies were recorded.

Results: 33 pts receiving a histologic diagnosis of FSGS with EM examination underwent NGS testing. Of these, 25 had available genetic results and were included. Ten patients were females, 15 were males; mean age was 40.8 years; 20 were Caucasian, 4 Black, 1 Asian. Based on EM, 11 were classified as primary forms, 14 as secondary forms. 12 patients presented with nephrotic syndrome (10 had a primary form). 7 had nephrotic range proteinuria, 6 had subnephrotic proteinuria. 6 primary and 8 secondary forms had a positive GT (p=0.78). All primary forms received immunosuppressive therapies (rituximab-based regimens); all secondary forms received support therapy. 9 primary and 9 secondary forms had at least a PR to treatment (4 CR in primary and 1 CR in secondary group) (p=0.33). Among primary forms, 5 of 6 patients with a positive GT had at least a PR with a strong immunosuppressive therapy. In secondary forms group 4 of 8 patients had at least PR with offered support therapy.

Conclusions: Percentage of positive GT did not differ in primary and secondary forms of FSGS as defined by Mayo Clinic classification. Thus a positive GT should not be considered a unique feature of secondary forms. In conclusion, as clinical presentation and light microscopy are not sufficient for an accurate diagnosis, combining EM and GT is of utmost importance in proper classification and management of FSGS.

TH-PO500

May-Hegglin Anomaly-Associated Nephropathy: A Case Series

Matthew D. Nguyen, Marrey Ruby L. Quizon, Vu Q. Nguyen, Ryan E. Fekrat, Arif N. Demirci, Ramy M. Hanna. *University of California Irvine Nephrology Hypertension & Kidney Transplantation, Orange, CA.*

Introduction: May-Hegglin Anomaly (MHA) is a rare autosomal dominant disease associated with a mutation in MYH-9 gene and it is characterized by macrothrombocytopenia, large platelets and neutrophils with abnormal cytoplasmic inclusions. Clinical features of this disease include hearing loss, early cataracts, and renal failure. The MYH-9 gene is associated with MYH-9 Related Disorders (MYH9-RD), such as Fecthner (FTNS) and Sebastian (SBS) syndromes.

Case Description: We present two interesting cases of renal injury attributed to May-Hegglin Anomaly. The first is a 52-year-old Hispanic female with May-Hegglin Anomaly (MHA) associated with nephropathy and thrombocytopenia complicated by stage 3 chronic kidney disease (CKD) and hypothyroidism. She was found to have a pathogenic MYH-9 heterozygous mutation and she met the clinical criteria for May-Hegglin Anomaly. The patient is not a candidate for kidney biopsy due to low platelets secondary to her May-Hegglin Anomaly. She has been treated with SGLT-2 inhibitors, ARBs for managing her CKD and Synthroid® for hypothyroidism. She continues to have low platelets, proteinuria, and her CKD continues to progress. Our second case highlights a 39-year-old white female with MHA associated with focal segmental glomerulosclerosis, diagnosed at the age of 15 on renal biopsy, thrombocytopenia, and mix connective tissue disorder with rheumatoid arthritis and systemic lupus erythematosus clinical features. She is currently on a treatment regimen of methotrexate, Xeljanz, and IVIG for her rheumatological diseases. Her kidney function has remained stable on ACE inhibitors, HCTZ and as needed loop diuretics for her frequent edema.

Discussion: These cases illustrate the challenges with diagnosing and managing the renal complications associated with MHA due to the MYH-9 gene mutation. The chronic thrombocytopenia in both patients restricts the use of invasive diagnostic procedures such as biopsies that is critical for confirming relation between nephropathy and MHA. This further limit the possibility for more targeted treatment. Thus, these cases stress the importance of genetic testing as a factor in diagnosing and stress the challenge of managing patients with suspected MHA with associated nephropathy and thrombocytopenia. Further studies are needed to improve and understand the management of this rare condition.

TH-PO501

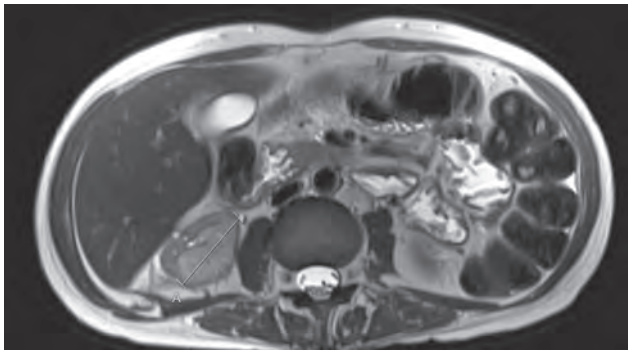
Case Report of a Novel NRIP1 Gene Mutation: Disease Association or Mere Coincidence?

Sabaa Asif, David M. Naimark. *University of Toronto, Toronto, ON, Canada*.

Introduction: Nuclear receptor-interacting protein 1 (NRIP 1) is known for its role in several physiological processes. These include and are not limited to ovulation; mammary gland development; lipid and glucose metabolism in adipose tissue, muscle and liver; regulation of inflammatory processes; maintenance of cognitive function; and cardiac function. Recently, case studies have shown an association between truncating NRIP-1 mutations and CAKUT (Congenital Anomalies of the Kidney and Urinary Tract).

Case Description: A 40-year-old woman presented in 2021, with idiopathic, non-ischemic cardiomyopathy and stage 5 chronic kidney disease (CKD) of unknown etiology. Investigations were inconclusive. Other comorbid conditions included, migraine headaches, anemia and diagnosis of mixed connective tissue disease *versus* fibromyalgia, with positive anti-nuclear antibodies and antinuclear ribonucleoprotein-A antibodies. In late 2023, she was admitted to a hospital with retropharyngeal abscess, and mediastinitis with progression of CKD, requiring initiation of hemodialysis. Prior to admission she had renal imaging as part of kidney transplant evaluation, which showed suspicious renal mass. Magnetic resonance imaging of the kidneys during the admission demonstrated multiple bilateral renal masses. These were confirmed to be lipid-free angiomyolipomas on biopsy. The kidney itself had changes suggestive of chronic hypoperfusion. There were no findings suggestive of any urinary tract abnormalities on imaging. Genetic testing showed a heterozygous c.1203A>C, pArg401Ser, missense mutation of the gene for NRIP1 which is novel.

Discussion: NRIP1 mutations have been associated with different malignant tumors, CAKUT and heart failure. The NRIP1 missense mutation observed in this case could be the etiology of the non-ischemic cardiomyopathy or the first documentation of its association with renal angiomyolipoma. Studies have demonstrated that NRIP1 missense mutations are also present in disease-free controls, hence, further studies are required to validate this association.



Angiomyolipoma of the right kidney.

Hiding in Plain Sight: The Diagnostic Challenge of Autosomal Dominant Tubulointerstitial Kidney Disease

Luke Barr,[1] Lonnie Thach,[1] James J. Paparello,[1] Susan E. Quaggin,[1] Yashpal S. Kanwar,[1] Anthony J. Bleyer.[2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Wake Forest University School of Medicine, Winston-Salem, NC*.

Introduction: Autosomal dominant tubulointerstitial kidney disease (ADTKD) is a group of rare inherited disorders characterized by tubular damage and interstitial fibrosis, bland urinary sediment and normal imaging. Mutations in the *MUC1* gene encoding mucin-1 are one cause. A cytosine insertion within *MUC1* leads to formation of MUC1 frameshift proteins. Deposition of these proteins leads to ADTKD, progressive CKD and early onset ESRD.

Case Description: A 33 year old asymptomatic man was admitted after an elevated serum creatinine of 5.1 mg/dl was found on outpatient labs. There was no history of dysuria, hematuria, NSAID exposure, tobacco use, recurrent UTI, kidney stones or prematurity. While the father's clinical history was unknown, a paternal grandmother and three uncles were on renal replacement therapy. He was hypertensive with labs notable for mild hyperkalemia 5.3 mmol/L, serum bicarbonate 19 mmol/L, BUN 68 mg/dl, serum creatinine 5.15 mg/d and uric acid 10.2 mg/dl. Urinalysis was bland. Renal ultrasound showed a R kidney 10.7 cm, L kidney 8.9 cm, few L simple renal cysts, increased echogenicity and no hydronephrosis. Kidney biopsy showed mild to moderate arteriosclerosis, ATN and moderate tubulo-interstitial disease with 40% tubular atrophy and fibrosis. Initial genetic testing was negative. Through the Rare Inherited Kidney Disease Team at Wake Forest and the Broad Institute of Harvard-MIT, advanced genetic testing identified a *MUC1* mutation, confirming a diagnosis of ADTKD. Ultimately, he progressed to ESRD and is currently being evaluated for transplant.

Discussion: Our case demonstrates a classic presentation of ADTKD-*MUC1* as well as the diagnostic challenges – namely the absence of typical hallmarks of kidney disease like proteinuria, hematuria, serum serologies, diagnostic imaging or pathology. This case highlights the limitation of commercially available genetic testing and the need for improved awareness of these disorders and specialized centers which can help establish the diagnosis. Accurate diagnosis is essential for family planning and prognostication, not only with respect to native kidney disease but post-transplant as well. Only with heightened awareness and identification can our understanding of ADTKD grow and lead to the discovery of early treatment options.

TH-PO503

Chronic Benign Tubular Proteinuria from Compound Heterozygous Mutations in CUBN: A Case Report

Adam Pietrobon,[1,2] Mark Elliott.[1,2] *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]Providence Health Care, Vancouver, BC, Canada*.

Introduction: Proteinuria is a commonly used parameter for predicting decline in renal filtration function. Cubilin, encoded by *CUBN*, is a critical protein involved in low molecular weight protein reabsorption in the proximal tubule. Mutations in *CUBN* lead to Imerslund-Gräsbeck syndrome (IGS), a disorder characterized by vitamin B12 deficiency (and consequences related to that) with or without proteinuria. Recent evidence suggests that C-terminal mutations in *CUBN* may lead to proteinuria without other features of IGS.

Case Description: We report a case of a 47 year-old male with chronic, albumin-predominant, subnephrotic range proteinuria since his teenage years, but preserved eGFR. Neither ACE inhibition nor AT-II receptor blockade reduced his degree of proteinuria. Genetic testing identified three distinct pathogenic mutations in *CUBN* that were confirmed by parental cascade testing to be compound heterozygosity. All mutations were downstream of the vitamin B12-intrinsic factor binding domain of cubilin, two of which conferred stop-gain sequences. The patient had normal vitamin B12 levels and did not exhibit megaloblastic anemia, growth retardation, or any other features of IGS. Renal biopsy was not pursued for this patient as diagnostic clarification was achieved by non-invasive genetic testing alone.

Discussion: This case report presents the first long-term follow-up of a patient with *CUBN* mutations, demonstrating eGFR stability despite chronic proteinuria. We highlight several important lessons. First, not all proteinuria is made equal, and forms of tubular proteinuria can exist without compromising renal filtration function. Second, identifying genetic forms of tubular proteinuria is key to avoiding ineffective interventions (e.g. ACE inhibition, AT-II receptor blockade) and unnecessary invasive procedures (e.g. renal biopsy). Third, the location of *CUBN* mutations dictate phenotypic consequences, with C-terminal mutations leading to proteinuria without vitamin B12 deficiency.

TH-PO504

Cases of Patients with E66Q Mutation Manifesting Zebra Bodies in Various Organs

Hayaki Okamoto, Shunsuke Goto, Keiji Kono, Hideki Fujii. Div of Nephrology, Kobe University Graduate School of Medicine. *Kobe University Graduate School of Medicine, Kobe, Japan*.

Introduction: Fabry disease is a X-linked inherited disorder caused by mutations in the alpha-galactosidase A (GLA) gene, leading to the accumulation of globotriaosylceramide (Gb3) in various organs. The accumulation of Gb3 results in dysfunction of these organs. Although patients with the E66Q mutation have reduced GLA enzyme activity, this mutation is considered a functional polymorphism because Gb3 accumulation is not observed in any organs. We report here cases with the E66Q mutation in which histopathological examination revealed zebra bodies in various organs.

Case Description: A 54-year-old woman was found to have the E66Q mutation from our previous Fabry disease screening study on hemodialysis patients at the age of 46. She initiated hemodialysis therapy at the age of 34, despite her young age, and suffered a cerebral infarction at the age of 44. She also had left ventricular hypertrophy and mild systolic dysfunction. A pathological specimen obtained during cataract surgery showed zebra bodies in the lens epithelial cells. A 34-year-old man, the son of the aforementioned patient, was also found to have the same genetic abnormality (E66Q mutation) at the age of 19 years during a family history survey. He was admitted to our hospital at the age of 33 years for the creation of an arteriovenous (AV) fistula due to progressive deterioration of kidney function. The vascular tissue obtained during the AV fistula surgery showed zebra bodies in both arteries and veins. A myocardial biopsy was performed at the age of 34 years to investigate left ventricular hypertrophy. Optical microscope images showed scattered vacuolar degeneration in cardiomyocytes, and electron microscope images showed zebra bodies in cardiomyocytes. Both patients received enzyme replacement therapy after diagnosis, which improved clinical symptoms such as limb pain and chest pain, as well as laboratory findings such as left ventricular mass and coronary flow reserve.

Discussion: Although known reports suggest that patients with the E66Q mutation do not show tissue Gb3 accumulation, our findings otherwise. These patients exhibited zebra bodies in multiple organs, suggesting Gb3 accumulation. Therefore, we believe there is a possibility that E66Q may not be a functional polymorphism but a pathogenic mutation. Consequently, we suggest that the classification of E66Q should be carefully reconsidered.

TH-PO505

Fishing for Zebras: Catching Fabry Disease with Pretransplant Genetic Testing

Sydney E. Hartsell, Sarah Gilligan, Isaac E. Hall, Duha A. Jweehan, Suayp Oygen, Miklos Z. Molnar, Divya Raghavan. *The University of Utah School of Medicine, Salt Lake City, UT.*

Introduction: Fabry Disease (FD) is a rare X-linked lysosomal storage disorder whose diagnosis can be particularly challenging in women, who often present atypically.

Case Description: A 43-year-old woman with ESRD attributed to hypertension and fibromuscular dysplasia (FMD) presented to renal clinic for pre-transplant evaluation. She had hypertension since age 20, complicated by hemorrhagic stroke at age 33 and an admission for hypertensive urgency at age 34, during which she was told she had FMD based on right renal atrophy and distal right renal artery stenosis, treated with balloon angioplasty. Unfortunately her eGFR declined rapidly over 4 years from 52 to 10 ml/min/1.73m^2 without explanation on serology and "no evidence of fibromuscular dysplasia" or re-stenosis on repeat MRA. She started dialysis in 2019 at age 39. Her medical history was also notable for incidental ischemic strokes seen on imaging, memory impairment, complete heart block in 2022, and systolic heart failure in 2024. Due to the patient's early-onset renal disease (in combination with her cardiac and neurologic history), the transplant nephrologist ordered a kidney gene panel. This revealed a heterozygous, "likely-pathogenic" galactosidase alpha (*GLA*) gene mutation *c.1018T>A (p.Trp340Arg)*, consistent with FD. She was referred to Medical Genetics who elicited a history of hypohidrosis and diarrhea, but no neuropathic pain, skin lesions, vision/hearing impairment, or known family history of FD. However, her son had neuropathy and her brother died young from heart failure. Enzyme levels showed accumulation of globotriaosylsphingosine (LysoGb3) and she subsequently started enzyme replacement therapy. Family testing revealed the same mutation in her daughter.

Discussion: FD demands a high index of suspicion and low threshold for genetic testing in patients with early-onset kidney disease, especially in the setting of cardiac and neurologic manifestations. Panels to identify genetic causes of CKD are now recommended in KDIGO's recent 2024 CKD evaluation guidelines. Patients with FD stand to benefit as more nephrologists gain access to this testing and can cast a wide net to catch heterozygous or atypical cases earlier. Furthermore, ESRD is not too late to test and drastically improve outcomes for patients and their family members.

TH-PO506

Fabry Nephropathy: An Important Phenotype of the Mutation p.R356W (c.1066C>T)

Arquizia M. Albuquerque, Ana Cecília M. Siqueira, Ana Paula Gueiros. *Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil.*

Introduction: Nephropathy is a serious manifestation of Fabry disease. Kidney biopsy (KB) is a valuable tool for diagnosing nephropathy. The aim of this study is to describe renal impairment in three generations of patients with the p.R356W mutation.

Case Description: CASE 1- Male, aged 65, diabetes mellitus for 12 years. Enzyme activity (EA): 0.52 (VR >2.2 umol/L/h); Lyso-GB3: 1.8 (VR < 1.8 ng/mL); Creatinine (Cr) 1.6 mg/dL; proteinuria 2.2 g/24h. KB: Optical microscopy (OM): 4/9 glomeruli with global sclerosis, foamy podocytes, mild tubular atrophy, and interstitial fibrosis, moderate arteriolar hyalinosis, artery with moderate fibrointimal hyperplasia. Electron microscopy (EM): lamellar inclusions in podocytes, thickened capillary loops, podocyte foot process effacement. CASE 2 Female, aged 50. EA: 2.2 (VR1.68-13.3 umol/L/h); Lyso-GB3: 1.6 (VR < 2.0 ng/mL); Cr 0.6 mg/dL; proteinuria 0.2 g/24h; albuminuria 18.5 mg/L. KB OM: segmental sclerosis in 3/47 glomeruli, global sclerosis in 2/47 glomeruli, podocytes with large and vacuolated cytoplasm, interstitial fibrosis (<10%). EM: podocytes with disorganized cytoplasm, foot process effacement containing zebra bodies. CASE 3 Male, aged 31. Lyso-GB3: 2.1 (VR < 0.8 ng/mL); Cr 0.76 mg/dL; proteinuria 0.22 g/24h; urinary albumin/creatinine ratio (ACR) 9.15mg/g. KB: diffuse podocyte vacuolation, preserved tubulointerstitium, arteries with slightly thickened walls. EM: lamellar inclusions in podocytes, with foot process effacement. CASE 4 Female, aged 17. Cr 0.6 mg/dL; ACR 29 mg/g; Lyso-GB3: 0.8 (VR < 1.8 ng/mL). KB OM: Podocyte hypertrophy, artery with mild fibrointimal hyperplasia, tubulointerstitium with no particularities. EM: podocytes with voluminous cytoplasm containing inclusions with myelin figures and zebra bodies and foot process effacement. CASE 5 Male, aged 8. EA: 0.16 (VR 1.68-13.3 umol/L/h), Lyso-GB3: 6.5 (VR < 1.8 ng/mL); Cr 0.4 mg/dL; ACR 4.6 mg/g. KB OM: Discreet podocyte hyperplasia, tubulointerstitial and vascular compartment with no particularities; EM: focal lamellar inclusions in podocytes, endothelium, and tubules; preserved foot process.

Discussion: This study demonstrates the importance of KB in an early diagnosis of Fabry nephropathy and for understanding the phenotypic presentation of the different mutations. This study has demonstrated the tropism of the p.R356W mutation for the kidney.

TH-PO507

MMP1 Levels in Kidney Tissue May Be Related to Kidney Interstitial Fibrosis in Fabry Disease

Aline A. Santana, Regiane S. Cunha, Guilherme Miniskiskosky, Paulo C. Gregório, Rodrigo Hagemann, Fellype Barreto, Andréa M. Stinghen. *Universidade Federal do Parana, Curitiba, Brazil.*

Background: Fabry disease (FD) is a rare disease, linked to the X chromosome and caused by mutations in the *GLA* gene that leads to complete or partial deficiency of the enzyme α-galactosidase (α-GAL). Loss of this enzyme leads to lysosomal accumulation of glycosphingolipids, especially globotriaosylceramide (gb3), with a broad spectrum of clinical manifestations. Matrix metalloproteinase-1 (MMP-1) is a colagenase responsable for insterstitial remodelling, specifically breaking down collagen type I, II, and III. FD patients could have prominent kidney involvement, with progressively worse of renal function caused by fibrosis. Here, we evaluated the MMP-1 presence in renal tissue.

Methods: The study included 6 FD patients diagnosed with the p.G35V missense mutation and 1 control patient. Creatinine and proteinuria levels were evaluated in these patients, and immunohistochemistry for MMP-1 was performed on kidney biopsies.

Results: Female patients (n=5) had creatinine levels 0.78 mg/dL (+- 0.10 mg/dL) and proteinuria 322.0 mg/24h (+- 207.2 mg/24h). Male patient (n=1) shows 0.9 mg/dL of creatinine and proteinuria 400.0 mg/24h. Four of them had stage 1 CKD, while the other two had stage 2 CKD. Analysis of the kidney biopsies showed positive immunostaining for MMP-1 in control patient (Figure 1A) and negative immunostaining for MMP-1 in the glomerular capillary walls for all patients with FD (Figure 1B). MMP-1 interstitial positivity was observed in 4 patients; sparse and discrete form in one, discrete focal form in another one and mild multifocal in 2 patients. Furthermore, 2 patients showed MMP-1 positivity in the tubular epithelium and parietal epithelium. All patients with FD had interstitial fibrosis.

Conclusions: Patients with FD due to the p.G35V mutation have reduced levels of MMP-1, an enzyme related to interstitial kidney fibrosis, even in stages 1 and 2 of CKD.

Funding: Government Support - Non-U.S.

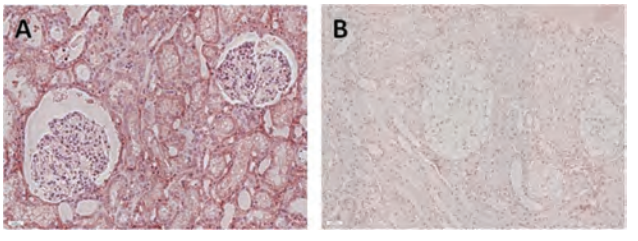

Figure 1 - Images showing MMP-1 immunostaining. (A) Control patient. (B) Male patient with FD. The scale bar indicates 50 μm, magnification 200x.

TH-PO508

Influenza B Triggering Atypical Hemolytic Uremic Syndrome (aHUS) in a Patient with Cobalamin C (CblC) Disease Carrier State and a Complement Factor H (CFH) Mutation

Laura Aponte Becerra, Gilbert W. Moeckel, Deepthi Gunasekaran. *Yale University, New Haven, CT.*

Introduction: AHUS is driven by abnormalities in genes coding for alternative complement pathway regulators triggering increased activity of the membrane attack complex. This causes endothelial damage, platelet adhesion and formation of microthrombi with subsequent thrombocytopenia, intravascular destruction of erythrocytes and acute kidney injury; termed thrombotic microangiopathy (TMA). We report a rare environmental trigger for aHUS in a patient with rare mutations in cobalamin uptake and CFH gene.

Case Description: A 59-year-old woman presented with upper respiratory symptoms and tested positive for Influenza B. Laboratory showed AKI, thrombocytopenia, hemolytic anemia with schistocytes and nephrotic range proteinuria. Creatinine at admission was 2.14mg/dL (from a normal baseline) and peaked at 8.67mg/dL with hyperkalemia requiring hemodialysis. C3 was low. C4, ADAMTS13 activity and Vitamin B12 were normal and methylmalonic acid level was mildly elevated. Acute kidney injury progressed and patient required initiation of hemodialysis. Kidney biopsy showed lobular accentuation of glomeruli, increased matrix deposition, karyorrhectic debris and red blood cell fragments in the mesangium and fibrinoid necrosis of an arteriole. Eculizumab was initiated and six days later renal function recovered, and dialysis was discontinued. Genetic testing revealed heterozygous p. Arg161Gly missense variant in the metabolism

of cobalamin associated C (MMACHC gene) and heterozygous p. Thr724Lys missense variant in the CFH gene classified as a variant of unknown significance.

Discussion: MMACHC gene mutations cause autosomal recessive methylmalonic aciduria and homocystinuria (CblC disease) which rarely presents as aHUS. CblC disease is usually reported in children and none in the carrier state. Additional CFH high-risk haplotype and environmental factors increased the risk for aHUS in this case, with influenza being a known trigger but influenza B being very rare. This case highlights the importance of suspecting aHUS in older adults with identifiable triggers and low threshold to initiate complement blockade.

TH-PO509

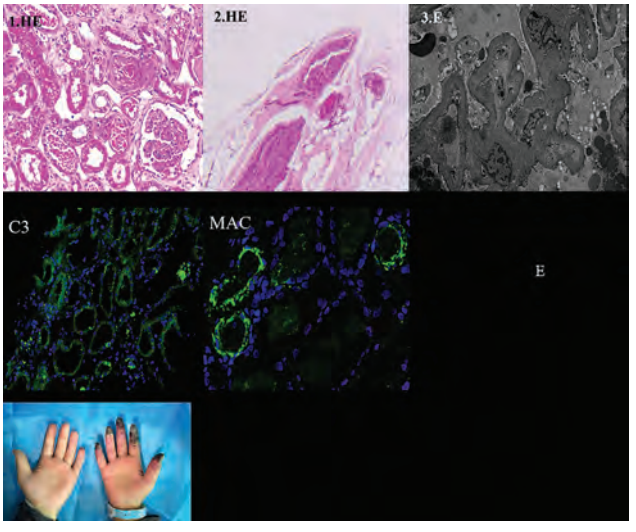
Atypical Hemolytic Uremic Syndrome with Peripheral Gangrene

Ailima Aierken,[1] Gulimire Muhetaer,[1] Shufen Yang,[1] Jing Zhuang,[1] Hong Jiang,[1] Xuefei Tian.[2] *[1]People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China; [2]Yale University School of Medicine, New Haven, CT.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a form of complement-mediated thrombotic microangiopathy (TMA). The clinical symptoms of aHUS can involve multiple organ systems. Few aHUS case reports describe peripheral vascular manifestations.

Case Description: A 27-year-old Chinese male was admitted to the hospital with acute renal failure and thrombocytopenia following a fever. Blood pressure was 145/85 mmHg, with 2.5% peripheral broken red blood cells, LDH at 1024 U/L and normal ADAMTS13 activity. He was diagnosed with TMA. Received hemodialysis, plasma exchange, Rituximab and glucocorticoid therapy. The kidney biopsy revealed TMA. After treatment, he was discharged from dialysis. After 1 month he recurrenced of TMA, began maintenance hemodialysis. After 1 year, exposure to cold weather, the fingertips of his right hand turned cyanotic and painful. The symptoms gradually worsened, leading to necrosis. Laboratory results showed normal platelets, no broken red blood cells, low C3, LDH at 308 U/L, and normal ADAMTS13 activity. Within 3 weeks, the right hand progressed to gangrenous. He has a family history, with two uncles died of kidney failure at around 25 years old. Whole-exome genetic testing revealed a C3 gene mutation (C3: c.640C > T, *p*.P214S), which destabilized the overall spatial structure of the protein. We confirmed the diagnosis of aHUS. Eculizumab treatment was initiated, and the affected finger was amputated. Biopsy of the vascular tissue during surgery revealed intravascular thrombosis. After starting eculizumab, the patient's pain decreased, perfusion near the gangrene area improved.

Discussion: We describe a case of skin involvement associated with C3-associated aHUS, demonstrating that aHUS can affect small peripheral vessels. This case highlights that aHUS lesions can be attributed to TMA, even if TMA may not be fully evident in laboratory tests. The skin gangrene, responded well to eculizumab.



TH-PO510

A Case of Atypical Hemolytic Uremic Syndrome with a Complement Factor I Mutation Triggered by a Femoral Neck Fracture in an Elderly Japanese Patient

Hiroyuki Iwasaki,[1] Hiroaki Io,[1] Toshiki Kano,[1,2] Kunimi Maeda,[1] Yusuke Suzuki.[2] *[1]Juntendo University Nerima Hospital, Nephrology & Blood Purification Center, Nerima-ku, Japan; [2]Juntendo University Faculty of Medicine, Bunkyo-ku, Japan.*

Introduction: Regional and racial differences in the genetic variations of aHUS have also been observed. Complement factor I (CFI) mutations are present in 4–8% of European cases. However, few patients with aHUS with CFI mutations have been reported in Asia, and to our knowledge, there have been no reports of these mutations in Japan.

Case Description: An 83-year-old woman fractured her left femoral neck and was admitted to the orthopedic department of another hospital 2 days before she was referred to our hospital. On admission at the other hospital, her serum creatinine level was found to have increased to 7.23 mg/dL, and she was transferred to our department. Laboratory results revealed hemoglobin levels of 9.2 gm/dL, platelet counts at 7,000/μL, creatinine levels of 8.20 mg/dL, and lactate dehydrogenase at 2838 IU/L. A peripheral blood smear revealed occasional schistocytes with reduced platelets at admission, consistent with HUS. Nine hemodialysis and eight plasma exchange sessions were performed, and the patient was weaned. However, the platelets did not return to their previous levels after plasma exchange. ADAMTS13 activity was 46%, and various examinations were negative for thrombotic thrombocytopenic purpura or secondary TMA. Therefore, she was clinically diagnosed with aHUS and received ravulizumab on day 35 of hospitalization. After the initial induction dose of ravulizumab, the patient's platelet level peaked at 170,000/μL, and there was no further decrease in platelets. The genomic gene sequences confirmed that the patient had a novel heterozygous frameshift mutation in the CFI gene.

Discussion: CFI mutation identified in this patient has not been reported from Japan. Notably, aHUS patients with CFI mutations have a low remission rate of 30-40%, a high mortality rate and a high rate of progression to end-stage renal disease. Ravulizumab treatment was continued in this patient on an outpatient basis, and to date, there has been no recurrence or progression of renal dysfunction for 2 years. Early treatment with plasma exchange and ravulizumab resulted in successful treatment in this case.

TH-PO511

Sex-Specific Modulation of Renal Dopamine Receptor Expression by DRD2 Single-Nucleotide Polymorphisms (SNPs) and Hormonal Factors

Raisha L. Campisi Cadme, Shaun C. Moore, Pedro Alves Soares Vaz de Castro, Hewang Lee, Pedro A. Jose, Ines Armando. *The George Washington University School of Medicine and Health Sciences, Washington, DC.*

Background: The involvement of renal dopamine, through the dopamine D2 receptor (D2R), in maintaining water, electrolyte balance, and blood pressure has a critical role in homeostasis in mammals. We have reported that the D2R is essential in preventing inflammation and kidney injury. In humans, the *DRD2* gene has several polymorphisms. The presence of specific single nucleotide polymorphisms (SNPs), such as rs6276 and rs6277 (*DRD2* SNPs), correlates with decreased D2R expression and activity, and is associated with increased blood pressure and susceptibility to hypertension. Human renal proximal tubule cells (hRPTCs) carrying these *DRD2* SNPs show a proinflammatory and profibrotic phenotype, which differs between sexes and is influenced by hormones in the culture medium. Exploring how hormonal factors modulate these responses could provide insights into sex-specific differences in renal physiology and pathophysiology.

Methods: This study was designed to investigate the factors influencing D2R expression in hRPTCs. We used four different hRPTC lines, genotyped for the absence (WT) or presence of SNPs and categorized by sex (male: M WT, M SNPs; female: F WT, F SNPs). We measured D2R expression levels and investigated the involvement of transcription factors Nurr1, ATF4, and Sp1, and the androgen receptor (AR), all known to bind to the *DRD2* promoter.

Results: D2R expression in male and female hRPTCs was greater in WT than SNPs cells. Expression of Nurr1 and Sp1 was similar in all cell lines. However, there were differences in ATF4 expression. While expressions were similar in F WT and F SNPs cells (1.3±0.1 vs 1.0±0.1; n= 3-5; p=0.199), a notable disparity was observed between M WT and M SNPs (1.0±0.1 vs 2.4±0.1; n= 3-5; p<0.001). AR expression was lower in female WT and SNP cells (0.77±0.09 and 0.8±0.1, respectively) than their male counterparts (1.10±0.10 and 1.56±0.04). Dihydrotestosterone (DHT) (5 nM/24 hr) decreased D2R expression in F WT cells (1.2±0.10 vs. 0.72±0.05; n=10-13; p<0.001) and M WT cells, (0.97±0.06 vs. 0.70±0.090; n=10-13, p<0.001), relative to vehicle treatment. DHT had no effect in cells with SNPs, F or M.

Conclusions: These findings highlight the sex-dependent regulation of renal D2R expression and suggest potential importance of SNPs on gene promoter binding sites and responses to hormones.

TH-PO512

Kidney Disease Due to Caudal Regression Syndrome

Bhaktidevi Makadia, Mercedes Malone, Charles W. Heilig, Brian Li, Irtiza Hasan. *University of Florida College of Medicine, Jacksonville, FL.*

Introduction: Embryonic development, influenced by fetal genetics, maternal health, and environmental factors, plays a pivotal role in shaping long-term health outcomes. Among the myriad anomalies that can arise during this process, Caudal Regression Syndrome (CRS) stands out as a rare condition characterized by developmental abnormalities affecting multiple bodily organs. While infrequent, CRS exhibits a higher prevalence among males and has been linked to maternal diabetes, vascular hypoperfusion, and genetic predispositions. Despite its potential to induce various kidney dysfunctions, CRS often evades prompt identification due to its rarity and the lack of familiarity among healthcare providers. Here, we present a compelling case of a patient with CRS who underwent intricate urological surgeries without prior awareness of her congenital condition.

Case Description: A 21-year-old female sought care at our nephrology clinic for chronic kidney disease and congenital urological issues. Born without an anal opening, she required a colostomy bag and a neo bladder to manage her condition. Furthermore, she had a tethered cord, necessitating complex surgical interventions to ensure her survival into adulthood. Currently, she is managed with a neobladder/nephrostomy tube for urinary elimination. Despite these measures, her GFR has remained in the 30s, with a recent creatinine level of 2.16. Urine analysis revealed significant protein. The patient was unaware of any genetic component to her condition until recommended evaluation by a geneticist to gain further insights into her condition.

Discussion: In this case, CRS poses a distinct challenge since the patient lacks maternal diabetes and has survived into adulthood. The complexity of her medical history highlights the challenges in managing CRS-related complications, especially renal dysfunction. It's crucial to recognize CRS and its impact on kidney health to provide the best possible care. The rarity of CRS underscores the importance of understanding and sharing similar cases to develop suitable treatment approaches. CRS remains a significant cause of renal dysfunction, deserving more research and clinical focus.

TH-PO513

AA Amyloidosis Unveiling Familial Mediterranean Fever in a 65-Year-Old Armenian Man with Arthritis and Immunosuppression History

Sofia Yamada,[1,2] Xavier F. Parada,[3,4] Sphoorthy Pasala,[1,2] Rajesh Anumolu,[1,2] Saif A. Alenizi.[1,2] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]UMass Memorial Medical Center, Worcester, MA; [4]University of Massachusetts Chan Medical School, Worcester, MA.*

Introduction: Familial Mediterranean Fever (FMF) affects certain ethnicities with a higher incidence in males. Caused by MEFV gene mutation, leading to recurrent inflammation. Arthritis occurs in 75% of patients with renal amyloidosis as a complication due to elevated protein production. While colchicine is the mainstay treatment, 5 to 10% of patients may be refractory or encounter adverse effects. Biologic agents serve as a secondary therapy but their efficacy can diminish necessitating alternative treatments

Case Description: A 65 year old Armenian man with a 35 year past medical history of psoriatic arthritis treated with extensive immunosuppressive therapies with refractory symptoms, thalassemia minor, hypertension, and coronary artery disease attributed to JAK inhibitors, status post bilateral total knee arthroplasty 25 years ago. Was admitted for pneumonia and prerenal acute kidney injury with nephrotic range proteinuria. An elevated CH50 suggested hyperfunctioning complements and acute inflammation. Differential diagnoses included infection related glomerulonephritis (IRGN), and adalimumab nephrotoxicity. Kidney biopsy revealed secondary amyloidosis and genetic testing identified heterozygosity for FMF (p.Met694Val and p.VAl726Ala) Classic FMF episodes were absent. Family history revealed possible FMF cases (sister's recurrent abdominal and jaw pain, and a daughter with undiagnosed digestive issues) His father had chronic kidney disease requiring hemodialysis. Treatment with colchicine and IL-1β inhibitors normalized CRP levels and reduced proteinuria maintaining stable renal function

Discussion: While there have been rare cases of AA amyloidosis associated with psoriatic arthropathy, AA amyloidosis is a recognized complication of FMF. Our case reveals an autosomal recessive FMF with two pathogenic variants: p.Val726Ala (mild) and p.Met694Val (severe). Vigilance for thrombotic events is essential due to nephrotic syndrome. Early FMF detection prevents organ damage. Secondary amyloidosis prompted an investigation revealing undiagnosed FMF. Management involves colchicine and IL-1β inhibitors like canakinumab. Adalimumab's efficacy in FMF associated arthritis is noted though previous use on this patient's response was poor. Further research is necessary to refine therapeutic strategies in refractory cases

TH-PO514

A Case of Prolonged Glycosuria Secondary to SLC5A2 Receptor Mutation Affecting theSGLT2

Anzal Jangda, Shivangi Patel. *Morristown Medical Center, Morristown, NJ.*

Introduction: Glycosuria most commonly occurs in diabetics patients but can also be seen in pregnancy, multiple myeloma, secondary to SGLT2 inhibitor use or with any medication that causes proximal renal tubular acidosis for e.g. Tenofovir. Here we present a case of glycosuria secondary to a mutation in the SLC5A2 receptor, encoding the sodium-glucose cotransporter 2 (SGLT2).

Case Description: A 38-year-old with a past medical history of hypothyroidism presented with persistent glucosuria despite normoglycemia on routine lab work. The patient was Initially evaluated by urology for recurrent yeast infections. Subsequent workup was unremarkable, and the patient was referred to nephrology for persistent glycosuria. Patient denied any personal history of diabetes (HBA1c of 5.1%) and Levothyroxine was the only home medication for underlying hypothyroidism. Persistent lab work was notable for normal serum glucose and isolated glucosuria on the urine analysis. Subsequent workup for glycosuria was negative for serum protein electrophoresis (SPEP), free light chains, anti-nuclear antibody (ANA), ruling out concerns for multiple myeloma and connective tissue disease. The patient did not have any electrolyte abnormalities for e.g., hyperphosphatemia, hyperuricemia, or acidosis to suggest proximal Renal tubular acidosis (RTA) or Fanconi's syndrome. Renal ultrasound showed normal kidneys without cysts, hydronephrosis or stones. With work up so far negative for any disease process, there was concern for familial renal glycosuria (FRG). For patient reassurance it was decided to go ahead with genetic testing which confirmed an autosomal dominant/recessive mutation of the SLC5A2 gene. Management primarily involved patient reassurance and dietary modifications including a low carb diet as uncontrolled glycosuria would lead to recurrent yeast infections.

Discussion: This case underlines the importance of considering genetic causes of glycosuria in the absence of diabetes mellitus and other common causes. Accurate diagnosis through genetic testing can spare patients from unnecessary treatments and anxiety associated with a potential misdiagnosis. Additionally, it highlights the significance of genetic counseling and screening for affected individuals, allowing patients to understand their carrier status and potential risk.

TH-PO515

Acute Kidney Failure: An Atypical Presentation of Gordon Syndrome

Hatem Najar, Fitsum T. Hailemariam, Anju Yadav. *Thomas Jefferson University Hospital, Philadelphia, PA.*

Introduction: Gordon syndrome is a rare form of genetic hypertension characterized by hyperkalemia and metabolic acidosis. It is usually diagnosed in teenagers or young adults with normal kidney function. We present a case of a young adult with Gordon syndrome presenting with acute renal failure.

Case Description: A 24-year-old Caucasian male with history of hypertension since he was 16 years old, hyperkalemia, non-adherent to thiazide diuretics presented to the hospital with abdominal pain and vomiting. Family history was significant for early onset hypertension in his brother, father, and paternal grandmother. On arrival blood pressure (BP) was 250/160 mmHg. A comprehensive metabolic panel revealed a creatinine of 9.9 mg/dL, potassium of 3.0 mmol/L, sodium of 136 mmol/L, chloride of 91 mmol/L, CO2 of 18 mmol/L. The complete blood count was significant Hb of 10 g/dL, platelet 87/ mcL. A renal ultrasound revealed increased echogenicity of both kidneys. Detailed serologic work-up for glomerulonephritis was negative. BP was managed with intravenous and oral antihypertensives. Due to persistent azotemia, the patient was initiated on hemodialysis and a kidney biopsy was performed. Kidney biopsy revealed findings suggestive of chronic hypertension, severe arteriolar and arterial intimal thickening, and presence of moderate interstitial fibrosis and tubular atrophy (30-35%). Genetic testing was positive for Kelch Like Family Member 3 (KLHL3) gene identified in heterozygous pattern, which is associated with Gordon syndrome, or Pseudo-hypoaldosteronism, type 2b.

Discussion: We describe an atypical presentation of Gordon syndrome in a young adult presenting with hypokalemia (instead of hyperkalemia) and malignant hypertension leading to dialysis dependent acute kidney injury. The pathophysiology of Gordon syndrome is based on an increased activity of the sodium (Na)-potassium chloride channel. Increased Na reabsorption will induce a state of hypoaldosteronism with hyperkalemia and metabolic acidosis. It is associated with pathogenic variants of the WNK1, WNK2, CUL3 or KLHL 3 genes. Higher suspicion, diagnosis, genetic counselling and management of genetic forms of hypertension are crucial in the prevention of severe complications.

TH-PO516

Increased Risk of Kidney Injury and Early Death from Activating Mutations in the Calcium-Sensing Receptor: A Regional Case Series

Deepika Manoharan,[1,2] Shalabh Srivastava,[1,3] John A. Sayer.[1,2]
[1]Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom; [3]South Tyneside and Sunderland NHS Foundation Trust, Sunderland, United Kingdom.

Introduction: Calcium-sensing receptors (CASR), primarily expressed in the parathyroid glands and kidney tubules, play a key role in calcium homeostasis. Heterozygous activating, or gain-of-function, mutation of the CASR gene causes autosomal dominant hypocalcemia type 1 (ADH1) resulting in severe hypocalcemia associated with inappropriately normal to low parathyroid hormone, hyperphosphatemia, and hypercalciuria. We present 8 patient cases from North East England with this rare condition.

Case Description: Table 1 describes the clinical characteristics including the genetic mutation, biochemistry, and complications in 8 patients with ADH1. All patients were identified to have hypocalcemia at birth or childhood before a formal diagnosis of ADH1 was considered, at which point caution was taken to avoid overcorrection of serum calcium through reduction or complete avoidance of calcium and vitamin D supplementation. However, despite this, 7 out of 8 patients suffered from nephrocalcinosis and/or nephrolithiasis, increasing the risk of recurrent urinary tract infections and renal impairment. 2 out of 8 patients developed kidney failure and suffered from premature death. Other complications such as short stature, dental issues, hypertension, and/or brain calcifications were also noted across all 8 patients.

Discussion: Ectopic calcification, particularly in the kidneys, is a known complication of ADH1. Close monitoring and acceptance of a low serum calcium levels is thought to reduce hypercalciuria and prevent rapid onset of nephrocalcinosis and subsequent renal impairment. However, this case series demonstrates that renal complications in ADH1 is inevitable, despite maintaining 'optimal' serum calcium levels for these patients. Therefore, the use of a novel therapeutic agent, such as a CASR antagonist, may prove to be helpful, and is something we will soon look to offer to these patients as part of a clinical trial.

Table 1: Clinical characteristics of ADH1 patients

Patient	Age, gender, and demographics	CASR gene mutation (heterozygous)	Biochemical profile			Average adjusted Ca2+ (mmol/L)	Renal complications
			Ca2+	PTH	PO4-		
Case 1	57-year-old Caucasian female (deceased)	c.354C>A; p. Asn118Lys	↓	↓	↑	1.83	Nephrocalcinosis Nephrolithiasis UTI ESRF
Case 2	32-year-old Caucasian female (deceased)	c.354C>A; p. Asn118Lys	↓	↓	↑	1.88	Nephrocalcinosis Nephrolithiasis ESRF
Case 3	33-year-old Caucasian female	c.354C>A; p. Asn118Lys	↓	→	↑	1.52	Nephrocalcinosis Nephrolithiasis UTI CKD
Case 4	24-year-old Caucasian female	c.2363T>G; p.Phe788Cys)	↓	↓	↑	1.59	Nephrocalcinosis
Case 5	29-year-old Caucasian male	c.350A>G; p.Gln117Arg	↓	→	↑	1.66

Case 8	38-year-old Caucasian male	c.2495T>C; p.Phe832Ser	↓	→	↑	1.26	Nephrocalcinosis

TH-PO517

OMg! What Links Hypomagnesemia, Kidney Stones, and Arrhythmia

Amara Sarwal, Nirupama Ramkumar, Gurbir S. Sehmbey, Sarah Gilligan.
University of Utah Health, Salt Lake City, UT.

Introduction: Familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC) is an autosomal recessive disease that usually presents during early childhood and is known to be caused by mutations of claudin-16 and claudin-19. We discuss an atypical presentation of an adult patient with kidney stones and hypomagnesemia with genetic testing remarkable for heterozygous mutation in claudin-16 (c235C>G).

Case Description: 23 year old female with history of kidney stones presented to the ED with ventricular fibrillation cardiac arrest. After successful resuscitation, she recovered quickly with intact neurological function. Initial workup revealed low-normal magnesium of 1.7 mg/dL which dropped to 1.5 mg/dL during hospitalization despite 4g of intravenous magnesium per day in addition to oral supplementation. Admission labs were also significant for a calcium of 7.8 mg/dL, albumin of 3.7 mg/dL and serum creatinine of 1.02 mg/dL, which improved during hospitalization. Laboratory values prior to this admission were not available. Medication history was unrevealing for culprit medications, including loop or thiazide diuretics. Urine studies revealed a fractional excretion of magnesium at 16%. Patient was supplemented with magnesium and discharged. During outpatient follow up, a 24 hour urine collection was obtained. She was found to have hypocitraturia, however with a normal urine calcium. Genetic testing was obtained which was negative for pathogenic variants but positive for a variant of unknown significance; a c235C>G heterozygous mutation in claudin-16. Upon outpatient clinic follow up, she continued to require magnesium oxide supplementation, currently at 400mg twice daily, with a corresponding magnesium level of 1.8 mg/dL.

Discussion: FHHNC has over 50 known mutations in the claudin-16 gene, and presents in early childhood leading to progressive kidney failure. Our adult patient had significant renal magnesium wasting during hospitalization that continued as an outpatient, and required ongoing supplementation. Although clinical history and urine magnesium studies were consistent with FHHNC, she did not have hypercalciuria or family history of kidney stones or kidney failure. As genetic testing has become more common in clinical practice, this case highlights the need to critically assess variants of uncertain significance and monitor for any potential clinical manifestations.

TH-PO518

Ceroid Lipofuscin in Renal Tubular Cells in Hermsky Pudlak Syndrome (HPS): An Unexplored Entity

Benjamin Strickland, Juan J. Cintrón-García, Maria M. Picken, Ewa Borys, Kavitha Vellanki. *Loyola University Chicago, Chicago, IL.*

Introduction: HPS is a rare autosomal recessive disorder of lysosomes and lysosome related organelles (LOR) resulting in defective oculocutaneous pigmentation and bleeding diathesis. 11 clinical subtypes have been identified so far with a relatively higher prevalence reported in Puerto Rico. While pulmonary manifestations are well known, the renal component of HPS remains unstudied and under-reported. Here, we report kidney biopsy findings in HPS.

Case Description: A 53 year old male from Puerto Rico with bilateral lung transplant (12/2020) for pulmonary fibrosis related to type 1 HPS and baseline stage G3bA3 CKD presented with SOB and AKI on CKD (increase in baseline serum creatinine from 1.8-2.1 to 4.4 mg/dl) with 3.9 gm/gm albuminuria (baseline 0.57 gm/gm). Urinalysis revealed glucosuria since 2021 with no h/o DM. Kidney biopsy findings revealed acute tubular injury and ceroid lipofuscin deposition in tubular epithelium as shown in Figure 1, similar to prior lung biopsy findings (Figure 1).

Discussion: Renal involvement in HPS is characterized by ceroid lysosomal deposition, yet the incidence/prevalence of biopsy proven kidney involvement is not known. In a report of 49 patients with HPS, 20% had creatinine clearance lower than 90 ml/min/1.73m2 (9 out of 45 patients with available data), the pathophysiology of such a finding neither explained nor explored. To our knowledge, our case is the first to report ceroid disposition in both lung and renal tissue in the same patient.

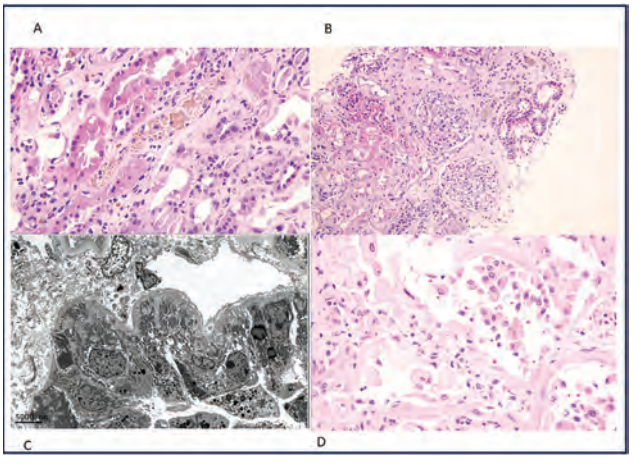

Figure 1: Kidney and lung biopsy findings.
A) H&E section with ceroid tubular deposition.
B) H&E section with mild glomerular mesangial expansion and ceroid tubular deposition.
C) EM section with ceroid tubular deposition.
D) Lung biopsy with ceroid deposition.

TH-PO519

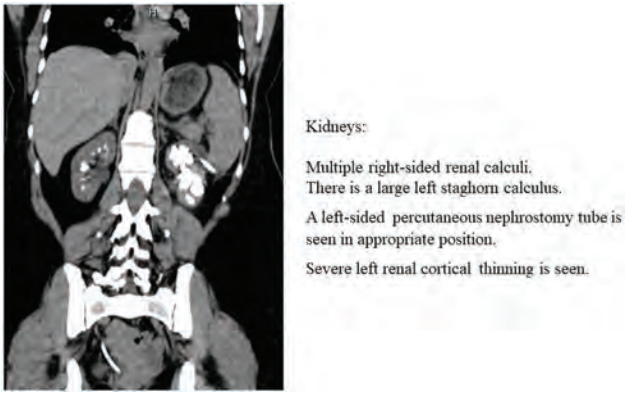
Deafness and Bilateral Staghorn Kidney Stones in a Young Patient

Hoang Anh Nguyen,[1] Sapna Gopal,[1] Anirudh V. Chandra,[1] Anita Kamarzarian,[1] Golriz Jafari,[1] Phuong-Thu T. Pham,[2] Phuong-Chi T. Pham.[1] *[1]UCLA Medical Center Olive View, Sylmar, CA; [2]Ronald Reagan UCLA Medical Center, Los Angeles, CA.*

Introduction: Massive stone formation in a young patient requires a thorough evaluation for the underlying cause. With the advent of genetic testing, rare conditions may be diagnosed.

Case Description: A 36-year-old female is referred for bilateral staghorn calculi and recurrent pyelonephritis. Urological history: lithotripsy and percutaneous nephrolithotomy of left kidney, and cystoscopy with stent placement. Medication: none. Review of systems: deafness since childhood. Family history: noncontributory. Vital signs: blood pressure 126/95 mm Hg, pulse 74, weight 71 Kg, Height 160 cm. Physical examination: within normal limits. Laboratory studies: Serum sodium 134, potassium 3, chloride 111, total CO2 12 mmol/L; blood urea nitrogen 27, creatinine 3.5, glucose 108, calcium 8.6, phosphorus 3.2, magnesium 2.8 mg/dL; total protein 7.9, albumin 3.9 g/dL; parathyroid hormone 82 pg/mL, vitamin D 25 38 ng/mL. Urinalysis: urine pH 7.0 (persistently ≥6.5). Given normal anion gap metabolic acidosis, high urine pH, and hypokalemia, distal renal tubular acidosis (dRTA) type 1 is considered. Serologies for autoimmune disease including ANA, anti-SSA and anti-SSB are negative. Genetic testing reveals homozygous nonsense mutation of ATP6V1B1 gene, encoding H-ATPase, autosomal recessive inheritance.

Discussion: The inherited nonsense mutation of ATP6V1B1 gene is associated with short stature, dRTA, nephrocalcinosis, medullary cysts, hypokalemia, hypokalemic periodic paralysis, and deafness. In the heterozygous state, patients may present with incomplete dRTA, hypercalcemia, and kidney stones. Management includes routine stone management (fluids, potassium supplement as needed). We suspect that the addition of fludrocortisone (in an attempt to acidify the urine) + thiazide diuretic (to both enhenace fludrocortisone efficacy and reduce calciuria) may be beneficial.



TH-PO520

Triple Threat! A Case of Lowe Syndrome with Triple Genetic Mutations

Edward Mwarangu, Uma Mahesh R. Avula, Mohammad Atari, Ramya Krishna Velagapudi, Mohamed Hassanein. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Lowe syndrome (LS), also known as Oculocerebrorenal Syndrome of Lowe (OCRL), is an extremely rare multisystem disorder that primarily affects the eyes, brain, and kidneys. It is inherited in an X-linked manner and is caused by a deficiency of inositol biphosphate 5-phosphatase, localized to the Golgi complex. Here, we report a case with a unique combination of genetic variations in the OCRL, Collagen-4 A3 (COL4A3), and Apolipoprotein-1 (APOL1) genes.

Case Description: A 33-year-old male with a history of congenital cataracts, cerebral palsy, significant growth retardation, and proximal kidney tubular dysfunction, including proteinuria was diagnosed with Lowe syndrome between the ages of 7 and 9. During a routine follow-up his urine protein-to-creatinine ratio increased to 2.23 g/g, and his chronic kidney disease (CKD) progressed, as evidenced by a decrease in Cystatin C estimated glomerular filtration rate from 52 ml/min/1.73m^2 to 46 ml/min/1.73m^2. Genetic testing confirmed the presence of a genetic mutation in the OCRL gene, a heterozygous mutation in COL4A3 gene and a high risk APOL1 allele. In light of these findings, a kidney biopsy was performed, revealing extensive global glomerulosclerosis and segmental thinning of the glomerular basement membrane (GBM) up to 168 nm and lamellated thickening of the tubular basement membranes. He continued to follow up in the nephrology clinic with plan to optimize anti-proteinuric therapy.

Discussion: Lowe Syndrome occurs almost exclusively in males due to mutations in the OCRL gene and has an estimated prevalence of approximately 1 in every 500,000 children. Although not pathognomonic, lamellated tubular basement membranes have been reported in patients with OCRL gene abnormalities which may explain proximal tubular dysfunction. The presence of segmental thinning in the GBM could raise the possibility of early changes secondary to his COL4A3 mutation. To our knowledge, this is the first report of a patient with Lowe syndrome presenting with triple genetic variations. The biopsy enhanced our understanding of the etiology of CKD in this patient.

TH-PO521

Unraveling the Mystery: McCune-Albright Syndrome as a Rare Cause of Fanconi Syndrome and Kidney Failure

Geraldine Boh,[1] Hui-Lin L. Chin,[2] Ru Sin Lim.[1] [1]*Tan Tock Seng Hospital, Singapore, Singapore;* [2]*National University Hospital, Singapore, Singapore.*

Introduction: McCune Albright Syndrome (MAS) is a rare sporadic genetic disorder caused by post-zygotic somatic missense mutations of the *GNAS1* gene characterized by polyostotic fibrous dysplasia, café au lait skin pigmentation, and precocious puberty. Here we present a proband with MAS manifesting with Fanconi syndrome (FS) and eventual kidney failure (KF).

Case Description: A 44-year-old female was referred to Nephrology in 2007 for impaired renal function (Creatinine 136 umol/L, eGFR 42ml/min/1.73m^2). Her medical history included right femur osteoid osteoma, hypophosphatemia, osteoporosis, Grave's disease, and congenital primary amenorrhea. Further work up revealed FS with hypophosphatemia, hypokalemia, hyperchloraemic metabolic acidosis, aminoaciduria (24hr urine total protein 1.3g/day), euglycaemic glucosuria, and a low tubular maximum reabsorption rate of phosphate to glomerular filtration rate (TmP/GFR) ratio implying impaired tubular phosphate reabsorption. Ultrasound kidneys and secondary work up were unremarkable. Renal biopsy was unyielding with non-specific interstitial fibrosis and tubular atrophy. Her kidney function continued to deteriorate necessitating peritoneal dialysis in 2022. In view of idiopathic KF with FS, primary bone marrow failure of unclear cause and endocrinopathies (thyrotoxicosis and primary ovarian failure), genetic testing (whole exome sequencing) was performed. This identified that the proband was mosaic for pathogenic *GNAS* variant (NM:_000516:c.[602G>A];[=],p.(Arg201His)), diagnostic of MAS.

Discussion: This case marks the first instance of MAS presenting with FS and KF to our knowledge. While renal phosphate wasting due to increased FGF-23 level and proteinuria have been reported in MAS, FS and KF are unprecedented, likely mediated by factors apart from FGF-23. We hypothesize that dysfunction of proximal tubule (PT) transporters in MAS relate to elevated circulating cyclic adenosine monophosphate (cAMP) and selective expression of G protein-coupled receptors (GPCRs) in the PT via a gain-of-function in G-protein alpha subunit (Gαs), induced by the GNAS pathogenic variant. Raised cAMP level following chronic Gαs activation may lead to mesangial cell proliferation and hyperfiltration, potentially contributing to KF in MAS. The role of cAMP leading to FS and KF in MAS requires further investigations.

TH-PO522

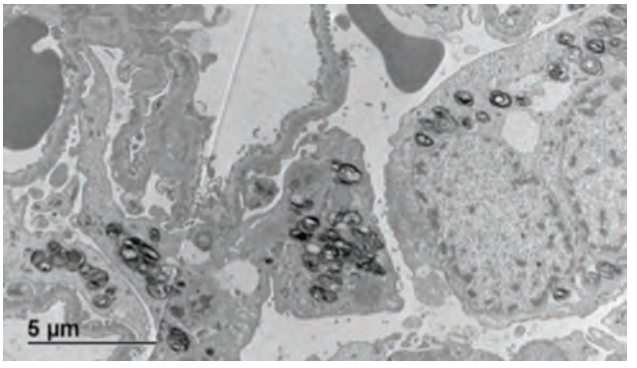
Nail-Patella Syndrome Presenting with Nephrotic Syndrome during Pregnancy

Lucia Facal, Maria Belen Facal, Paula Parnizari, Federico Yandian, Jose Boggia, Gabriela Ottati, Oscar A. Noboa. *Hospital de Clinicas Doctor Manuel Quintela, Montevideo, Uruguay.*

Introduction: We report a rare cause of nephrotic syndrome.

Case Description: A 38-year-old woman with a one-year history of proteinuria, hypoalbuminemia and new headache and blurred vision presented to our clinic at 9 weeks of pregnancy. Physical examination: normotensive, lower limbs edema, Marcus Gunn's sign on right eye, bilateral optic disc edema and serous exudative retinal detachment. Lumbar puncture showed inflammatory CSF. Neoplastic, infectious and systemic autoimmune causes were excluded. A diagnosis of Vogt-Koyanagi-Harada was made and received steroids and azathioprine. Visual acuity slightly improved. She presented with nephrotic syndrome resistant to prednisone, with proteinuria of 8 g/24 hrs., serum albumin 2 g/dl, hypercholesterolemia, Cr 0.3 mg/dl. Renal biopsy revealed non-specific glomerular changes and EM revealed diffuse FPE and myeloid bodies (MBs). *GLA* enzymatic activity was normal and *GLA* sequencing was negative. Exomic sequencing identified a heterozygous pathogenic variant in *LMX1B*. She delivered a healthy baby boy at term. One year after birth: Cr 0.4 mg/dl, serum albumin 4 g/dl and proteinuria 2.6 g/24 hrs. We studied her 22-year-old daughter and found the same variant. She did not show patellar abnormalities but had nail dysplasia.

Discussion: MBs are classically associated but not exclusive of Fabry Disease. The patient had no exposure to silica or drugs. NPS is an autosomal-dominant disease with variable penetrance caused by mutations in *LMX1B*. Our patient presented with patellar hypoplasia, triangular lunulae, reduced sensation to pain and temperature in hands and feet and renal involvement. The risk of preeclampsia in NPS is increased and onset of nephrotic syndrome during pregnancy has been described. This case illustrates the difficulties of diagnosing rare kidney diseases with subtle clinical hints and the importance of EM and sequencing technologies to reach a definitive diagnosis. It is one of the few cases described of NPS and pregnancy.



EM shows MBs in podocytes

TH-PO523

All in the Genes: Chronic Benign Proteinuria Due to CUBN Mutations

Frank Cassavell, Areeba Nayyer, Louis C. Jan, Tanganyika Barnes. *Englewood Hospital and Medical Center, Englewood, NJ*.

Introduction: Proteinuria is common in primary care patients. It can have transient causes such as UTI and heavy exercise or can be persistent. Most forms of persistent proteinuria are caused by damage to the kidney which can be intrinsic as in glomerular diseases or secondary to conditions such as CHF, hypertension, or diabetes. Persistent forms including protein receptor deficiencies can also cause chronic benign proteinuria and do not require treatment. The CUBN gene encodes the cubilin protein which forms a receptor in the proximal renal tubule that plays a key role in blocking excessive protein excretion. Deficiency in the cubilin protein can lead to non-nephrotic range proteinuria without decreased renal function given the lack of associated glomerular disease. We present a case of a patient with chronic, non-nephrotic range proteinuria with normal renal function, found to have the CUBN mutation.

Case Description: A 33-year-old male with a history of mild hypertension treated with 2.5mg lisinopril presented to the nephrology office for evaluation of persistent proteinuria. He had a renal biopsy 15 years prior which showed normal renal cortex by light and electron microscopy. No diagnosis was made or treatment started at that time. His only symptom was slightly foamy urine. Creatinine was 0.99 mg/dl and a 24-hour urine protein collection was significantly elevated at 945 mg/24h, but not nephrotic range. Hepatitis, HIV, and rheumatic disease workup was negative. The patient was started on dapagliflozin for renal protection. At his follow-up visit, a genetic panel showed two very rare heterozygous mutations to the CUBN gene. He was diagnosed with chronic benign proteinuria. Given the low risk for progression to CKD, dapagliflozin and lisinopril were discontinued with plans for one-year follow up.

Discussion: CUBN gene mutations that cause chronic benign proteinuria have been shown to be nondetrimental to kidney function with limited progression to CKD. This case shows the benefit of early genetic testing in cases with isolated, non-nephrotic range proteinuria with normal kidney function through early diagnosis and avoidance of unnecessary treatments or invasive tests such as biopsies. While unlikely, these patients should be followed routinely to screen for worsening renal function.

TH-PO524

Sex Differences in Primary Distal Renal Tubular Acidosis

Viola D'Ambrosio,[1,2] Keith Siew,[2] Rhys Evans,[2] Pietro Manuel Ferraro,[3] Stephen B. Walsh.[2] London Tubular Center. *[1]Universita Cattolica del Sacro Cuore, Rome, Italy; [2]University College London, London, United Kingdom; [3]Universita degli Studi di Verona, Verona, Italy*.

Background: The kidney is one of the most estrogen-responsive organs and an influence of estrogens has been described for several transporters along the renal tubule. Primary distal renal tubular acidosis (dRTA) are rare genetic conditions characterized by impaired urinary acidification in the collecting duct. Our study aimed to investigate phenotypic sex differences in the natural history of primary dRTA.

Methods: We studied 31 genetically confirmed dRTA patients followed at the London Tubular Centre. We undertook a retrospective analysis of prospectively collected clinical, biochemical and radiological data. We used low bone mineral density (BMD) (defined as a Z-score ≤ -2) to assess the severity of osteomalacia.

Results: Baseline characteristics and prevalence of causative mutations are shown in Figure 1. Most patients regardless of sex presented with overt hypercalciuria (60% of women vs 90% of men) but prevalence of nephrolithiasis and nephrocalcinosis was higher in women. Men had a significantly (p value=0.0138) higher decline in annual mean slope of eGFR (-3.3 ± 2.5 mL/min/1.73 m^2) compared to women (-0.5 ± 1.5 mL/min/1.73 m^2) (**Figure 2a**). There was a trend towards higher fractional excretion of phosphate (**Figure2b**) and dyslipidemia in men (**Figure 2c**). Prevalence of low BMD was higher in men (50%) vs women (17%) with low BMD predominantly affecting the lumbar spine.

Conclusions: Men affected by primary dRTA are at increased risk of CKD progression and appear to be more dyslipidemic than women. To our knowledge, this is the first study reporting sex differences in primary dRTA.

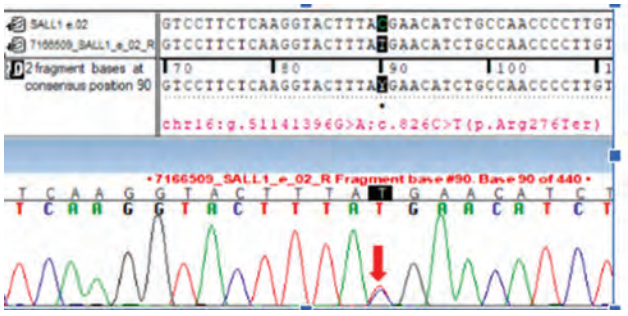
Towne Brocks Syndrome Presenting as ESKD

Aswini P. Patnaik, Nikunj Kishore Rout, Scienthia Sanjeevani, Ashim K. Mahali. *Kalinga Institute of Medical Sciences, Bhubaneswar, India*.

Introduction: Townes Brocks Syndrome (TBS) is rare autosomal dominant disorder with multiple organ involvement with mutation of SALL1 on chromosome 16q12.1. Cardiac and renal abnormalities have been reported infrequently. We present one case with TBS who presented with end stage renal disease. Mutation analysis showed de novo mutation in the SALL1 gene.

Case Description: Proband, 15 years old female presented with anasarca and decreased appetite. She has history of imperforate anus for which operated on 3rd year of life. No significant history in grandparents, parents, siblings. On examination, growth retardation, ear anomaly (overfolding of superior helix of left ear and pre-auricular tag), thumb anomaly (rudimentary Right thumb), flat foot, toe anomaly, atrial septal defect, bilateral sensorineural hearing loss were present. Investigation showed anemia with raised urea and serum creatinine. USG showed both small sized kidneys. Genetic testing confirmed diagnosis with heterozygous nonsense variation of SALL 1gene. Geneting screening of both parents were normal. She was initiated on hemodialysis for renal dysfunction.

Discussion: Malformations related to TBS are usually diagnosed in the neonatal period and less known by adult specialists. Renal anomalies, including functional and structural abnormalities has been resported in 43% of patients. In this case report, typical extra renal manifestations led us to genetic testing and confirming diagnosis of TBS, but uremia was the first symptom to prompt the proband to visit the hospital.



Sanger sequencing

TH-PO526

Patient Satisfaction and Outcomes following a Session with a Genetic Counselor for Kidney Diseases

Megan M. Hager,[1] Quinn P. Stein,[1] Emily Hendricks,[1] Tessa R. Pitman,[1] Mary E. Conway,[1] Cassie Vance,[1] Kelsey Mcqueen,[2] Margaret Westemeyer.[1]
[1]Natera Inc., Austin, TX; [2]PKU foundation, New York, NY.

Background: Limited data exist on patient satisfaction with genetic counseling for kidney disease provided by laboratory genetic counselors (LGCs). Here, we provide survey results designed to examine patient experiences following a Genetic Information Session (GIS) for kidney disease. The survey aimed to understand patient satisfaction and subsequent actions following a GIS. The survey also explored the role of LGCs in improving genetic counseling accessibility to patients, aligning with nephrologists' interest in helping their patients gain access to LGC services to better understand the genetic testing result in the context of their care.

Methods: A 47-question survey was developed based on prior studies and sent to patients via email following a GIS conducted by telephone to review genetic results from the RenasightTM test (a multigene hereditary kidney panel) (Natera, Austin, TX). The collected responses were anonymous and analyzed using simple statistics.

Results: Of 1,667 GIS completed over a 1-year period, 201 responses were recorded. Overall, 95.3% of respondents indicated the GIS was valuable to them. Most respondents (64.7%) felt they had actionable steps to take following the GIS, which included: meeting with a specialist for management of extrarenal problems related to the genetic diagnosis, family planning, seeing a local genetics provider, or sharing results with relatives. Additionally, 78.9% of respondents felt they had the information needed to take additional steps related to their healthcare or family's health following the GIS. 32.9% of respondents indicated they were unable to see a local GC and 52.0% were uncertain if it would be possible to do so.

Conclusions: This is the first study to examine patient satisfaction and outcomes following a GIS for kidney genetics, or to examine LGC service implementation in this context. This study demonstrated that LGCs provided patients with increased access to genetic counseling, valuable information that helped patients and their families navigate their clinical journeys, and acted as a complementary resource/link to providers ordering kidney genetic testing.

TH-PO527

Nephrologists' Views and Experience with Genetic Testing: Developing vs. Developed Countries

Jaison George,[1] Tushar J. Vachharajani,[3] Xiangling Wang.[2] *[1]Kauvery Hospitals, Bangalore, India; [2]Cleveland Clinic, Cleveland, OH; [3]John D. Dingell VA Medical Center & Wayne State University School of Medicine, Detroit, MI.*

Background: Genetic testing has increasingly been utilized in nephrology practice in developed countries, with limited data available on the perspectives of nephrologists from developing countries.

Methods: An online survey was conducted via SurveyMonkey and distributed to practicing nephrologists worldwide through social media, emails, or phone messages.

Results: A total of 297 nephrologists from 28 countries completed the survey, including 230 from developing countries and 67 from developed countries. The majority of respondents from both developing and developed countries reported having ordered genetic testing in their practice (80% vs. 85%, p=0.31). Of those who had ordered genetic testing, 80% from developing countries and 79% from developed countries found it useful (p=0.86). Nephrologists from developing countries expressed more concern about the availability of testing resources compared to colleagues from developed countries (62% vs. 38%, p=0.004). High cost was reported as the leading barrier among nephrologists from both developing and developed countries (64% vs. 61%, p=0.65). Fewer nephrologists from developing countries reported a high level of confidence in interpreting genetic testing results compared to colleagues from developed countries (5% vs. 19%, p=0.00009), while more reported a lack of confidence (47% vs. 22%, p=0.0004).

Conclusions: Renal genetic testing has been considered useful by nephrologists worldwide. There is a pressing need to enhance the availability of testing resources and education in renal genetics, particularly in developing countries. We acknowledge the potential bias of this study, as respondents may have primarily been those interested in genetic testing.

Value of Genetic Testing in a Glomerular Disease Center

Josep Miquel Blasco Pelicano,[1,2] Jordan G. Nestor,[1] Natalie Vena,[1] Kelsie Bogyo,[1] Simone Sanna-Cherchi,[1] Krzysztof Kiryluk,[1] Mariela Navarro Torres,[1] Benjamin Wooden,[1] Andrew S. Bomback,[1] Gerald B. Appel,[1] Jai Radhakrishnan,[1] Pietro A. Canetta.[1] *[1]Columbia University, New York, NY; [2]Hospital Clinic de Barcelona, Barcelona, Spain.*

Background: Integrating genomics into clinical practice is essential for offering high-quality personalized medicine at glomerular disease centers.

Methods: This observational, retrospective study evaluated the clinical usefulness of genetic studies at Columbia University's Glomerular Kidney Disease Center. Over 40 months (7/2020–11/2023), 231 patients with glomerular phenotypes were referred for genetic evaluation. After a multidisciplinary visit by a genetic counselor and a specialized nephrologist, genetic tests were selected individually based on clinical suspicion.

Results: Of the 231 patients, 142 had a biopsy-confirmed glomerular disease, while 89 had a suspected glomerular disease, who never were biopsied. The average age was 43.5 years±16.8, with 54% female and 37% self-reported as white. Main clinical suspicions were collagenopathies (47%), hereditary focal segmental glomerulosclerosis (25%) and complement dysregulation (8%). The most common genetic tests ordered (71%) were large, multi-gene (100+), next generation sequencing panels. Genetic testing results were positive diagnostic (pathogenic or likely pathogenic variants) in 34% (n=79) and positive non-diagnostic (*APOL1* risk alleles) in 9% (n=20) (Figure 1). Among diagnostic results, the most frequent genes were collagen-related (*COL4A3-5*) with 76%, followed by complement genes (*CFH*, *CFI*, *MCP*) and *NPHS1* & *2* (both 4%). Top benefits and clinical implications included prognostic information (47%), therapeutic guidance (42%), familial testing (42%), establishing a genetic diagnosis (34%) and sub-specialty referral (32%).

Conclusions: Multi-disciplinary care integrating genetic evaluation of a glomerular disease referral population provided important benefits for the patients and their families. It is recommended to integrate this approach more broadly, moving forward to a precision medicine in glomerular disease.

TH-PO529

Genome-Wide Survival Study Identifies Variants Associated with Disease Progression in IgA Nephropathy

Xu Linlin, Xu-jie Zhou, Jicheng Lv, Hong Zhang. Professor Zhang's Research Group. *Peking University First Hospital Department of Nephrology Renal Division, Beijing, China.*

Background: IgA nephropathy (IgAN) has a poor prognosis and recent data suggested that almost all of patients may progress to kidney failure within their lifetime. Genetic variations intricately shape disease risks. However, genetic markers associated with the progression of IgA nephropathy have been quite limited.

Methods: We performed genome-wide survival analyses in two independent cohorts and meta-analysis, the PKU-IgAN follow-up cohort containing 1859 IgAN patients and the TESTING cohort containing 279 patients from China. The primary outcome was end-stage kidney disease (ESKD), and the secondary outcome was the combination of ESKD or ≥40% reduction in estimated glomerular filtration rate (eGFR) after diagnostic kidney biopsy. Genome-wide survival analyses were performed on the two cohorts separately, and variants were selected as candidate variants when they had $P < 1\times10^{-5}$ in one cohort and $P < 0.05$ in the other. Functional annotations of candidate variants, expression quantitative trait loci (eQTL) studies, exploration of epigenetic architecture, differential expression of the candidate genes, and the association between genotype and clinical characteristics were conducted.

Results: For the primary outcome, a variant of *SFMBT2* achieved genome-wide significance in the meta-analysis (HR 3.01, $P = 8.24\times10^{-9}$). Two loci, *SLC8A1* (HR 1.90, $P = 2.06\times10^{-7}$) and *MIR548B* (HR 3.19, $P = 5.04\times10^{-7}$) were considered as the candidate loci. For the secondary outcome, three loci, *ESRRG* (HR 3.68, $P = 7.26\times10^{-8}$), *FAM19A5* (HR 1.76, $P = 4.43\times10^{-7}$), and *LINC00583* (HR 3.43, $P = 6.07\times10^{-7}$) were considered as the candidate loci. *SLC8A1*, *SFMBT2*, and *FAM19A5* variants were also associated with the eGFR slope and time-average proteinuria. In addition, the risk allele of *FAM19A5* was associated with the glomerular sclerosis ($P = 4\times10^{-3}$) and the tubulointerstitial damage ($P = 0.03$).

Conclusions: Six candidate loci were significantly associated with prognosis of IgAN. These findings may help characterize molecular mechanisms of progression of IgAN, contributing to the identification of patients at high risk of progression and the development of new therapeutic targets to slow disease progression.

TH-PO530

Immune Checkpoint Molecule B and T Lymphocyte Attenuator and Induces Anti-inflammatory Dendritic Cells in Experimental GN

Bastian Trinsch,[1,2] Paul Diefenhardt,[1,2] Jasper F. Nies,[1,2] Claudio Sierra Gonzalez,[1,2] Manuel Koch,[2] Paul T. Brinkkoetter,[1,2] Bernhard Schermer,[1] Thomas Benzing,[1,2] Sebastian Braehler.[1,2] *[1]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany; [2]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany.*

Background: T cell-mediated inflammation can lead to crescentic glomerulonephritis (GN). T cell receptor signaling requires secondary signals (immune checkpoints) for T cell activation and differentiation. Interference with this signaling might represent a treatment option for GN. In a recent study, we have shown that the immune checkpoint molecule B and T Lymphocyte Attenuator (BTLA) attenuates inflammation in experimental GN. The complex signaling networks involving different immune cell subsets and the binding partner Herpesvirus entry mediator (HVEM), however, remained unclear.

Methods: Nephrotoxic nephritis (NTN) was induced in mice with a cell-specific knock out of BTLA on T cells or dendritic cells. For treatment studies, HVEM coupled to a human Fc-tag (HVEM-Fc) was produced and administered i.v. in wild-type (wt) mice after NTN induction. Readouts included albuminuria and BUN concentration and histological damage on PAS-stained tissue. Immunophenotyping of kidney tissue and renal lymph nodes was performed using IHC, IF, and flow cytometry. A scRNA-sequencing of renal immune cells was performed in wt and BTLA knock out mice with and without induction of NTN.

Results: Compared to wt, BTLA deficiency on dendritic cells led to a reduction of protective cDC1 in kidney tissue and increased numbers of pro-inflammatory T effector cells. The T cell-specific knock out of BTLA, however, led to a decrease of T regulatory cells (Treg) and to infiltration of monocytes and neutrophils. Both mouse lines showed a dysregulation of T cell polarization in renal lymph nodes. Administration of HVEM-Fc reversed this T cell composition and resulted in increasing numbers of renal cDC1 as well as a decreasing number of renal B cells. ScRNA sequencing confirmed overactivation of T cell subsets and altered survival-associated signaling in cDC1.

Conclusions: The necessity of BTLA for the suppression of T effector cells by Tregs is well-established. Our research now reveals the central importance of BTLA in the immunosuppressive function of cDC1 in glomerulonephritis. The potential of HVEM-Fc, functioning as a BTLA agonist and decoy molecule to inhibit inflammatory LIGHT-signaling, opens up exciting possibilities for future treatment strategies in renal inflammatory diseases.

Effects of Multilocus Interaction on IgA Nephropathy in the Chinese Han Population

Dianchun Shi,[1] Wu Yuanyuan,[1] Xueqing Yu,[1,2] Li Ming.[1] *[1]Guangdong Provincial People's Hospital, Guangzhou, China; [2]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. Previous genome-wide association studies (GWAS) have identified multiple susceptibility genes for IgAN, including TNFSF13, ITGAX-ITGAM, FCRL3, ST6GAL1 and CARD9. Gene-gene interaction might have more influence on the susceptibility of IgAN and advance our understanding of the genetic pathogenesis of IgAN. This study aims to investigate the correlation between the gene-gene interaction and IgAN susceptibility.

Methods: A total of 63 single-nucleotide polymorphisms (SNPs) were selected for genotyping by using MassARRAY platform in 1,000 IgAN cases and 1,000 healthy controls. Data quality control and filtering were conducted using PLINK 1.90, and the frequency distribution of genotypes and alleles were calculated. Multifactor dimensionality reduction (GMDR) method was used to analyze the multi-step gene-gene interactions.

Results: The GMDR analysis revealed that the interaction of TNFSF13 (rs4968210), FCRL3 (rs11264793), and ST6GAL1 (rs2284750, rs7634389) was significantly associated with the risk of IgAN (*P*=0.01, *OR*=2.88). In addition, the genotype–phenotype association analysis showed that the interaction of TNFSF13 (rs3803800), FCRL3 (rs11264793, rs7528684), ITGAX (rs11150619) and ST6GAL1 (rs6784233, rs7634389) was associated with eGFR in IgAN patients (*P*=0.01, *OR*=14.03). The TNFSF13 (rs3803800), FCRL3 (rs11264793, rs7528684), ITGAX (rs11150614), and ST6GAL1 (rs7634389) had combined effects on the low density lipoprotein in IgAN patients (*P*=0.01, *OR*=4.81). Furthermore, the interaction of TNFSF13 (rs3803800), FCRL3 (rs11264793, rs7528684), ITGAX (rs7190997) and ST6GAL1 (rs6784233, rs7634389) was also associated with hematuria in IgAN patients (*P*=0.001, *OR*=29.66).

Conclusions: The study suggested that the interaction of ITGAX-ITGAM, TNFSF13, FCRL3 and ST6GAL1 genes might have some influence on the susceptibility to IgAN. Additionally, it may also correlate with the lipid levels, hematuria, and the progression of renal function in patients.

TH-PO532

Dissecting Deregulated Multicellular Programs in IgA Nephropathy

Charlotte M. Boys,[1] Phillip J. McCown,[3] Sean Eddy,[3] Matthias Kretzler,[3] Julio Saez-Rodriguez.[2,1] NEPTUNE Consortium. *[1]UniversitatsKlinikum Heidelberg, Heidelberg, Germany; [2]European Bioinformatics Institute, Cambridge, United Kingdom; [3]University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Our understanding of IgA nephropathy pathogenesis is rich, but incomplete. Emerging single-cell data offers the opportunity for improving our understanding of the disease. The Omnibus of CElls And Nuclei (OCEAN) comprises single nucleus data from 11 living donors from the Michigan Human Kidney Transplant Transcriptomic Atlas study and 120 FSGS, MCD, IgAN, and other kidney disease patients from the NEPTUNE consortium. We present the results from an unsupervised exploratory analysis of this dataset with the aim of studying transcriptomic alterations in primary proteinuric glomerular diseases, with a focus on IgA nephropathy.

Methods: Pseudobulk profiles were generated from OCEAN 10x single nucleus data for each cell type and sample. Candidate ligand-receptor interactions were computed using LIANA+. Exploratory data analysis was performed on the resulting pseudobulk profiles and ligand-receptor features using the multicellular factor analysis framework, resulting in unsupervised "factors" which describe the transcriptomic heterogeneity across all samples including living donors. Factors were associated post-hoc with clinical metadata and cell type compositional information by ANOVA. Further analysis focused on factors best explaining patient heterogeneity in (but necessarily not exclusive to) IgAN.

Results: Our computational analysis disentangles transcriptomic alterations in the tubular compartment associated with GFR loss (p val < 1e-10) and patients age (p val < 1e-8) from other more specific pathological changes. We identify further patterns of transcriptomic dysregulation and cell-cell communication which account for heterogeneity among IgAN patient samples, including a factor associated with parietal epithelial cell expansion and loss of podocytes, accompanied by downregulation of SLIT-ROBO signalling, which was also observed in FSGS.

Conclusions: Analysis of NEPTUNE OCEAN single nucleus data not only provides a description of patient heterogeneity in IgAN and reveals pathogenic alterations in the IgAN transcriptome but, crucially, places these in the wider context of nephrotic syndrome and glomerular disease.

TH-PO533

An Omnibus of Transcripts Integrated from More than One Million Nuclei and Cells of Patients with Kidney Diseases Provides Distinct Insights into Disease Mechanisms

Phillip J. McCown,[1] Edgar A. Otto,[1] Damian Fermin,[1] John R. Hartman,[1] Mathew O. Alaba,[1] Maria Larkina,[1] Michael Arbit,[1] Margaret Helmuth,[1] Brad A. Godfrey,[1] Sean Eddy,[1] Laura H. Mariani,[1] Abhijit S. Naik,[1] Maarten Hoek,[2] Terry Satterfield,[2] Matthias Kretzler.[1] NEPTUNE Consortium. *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Maze Therapeutics Inc, South San Francisco, CA.*

Background: Single nuclear RNA sequencing (snRNAseq) of biopsies affords insight to molecular and cellular pathways in kidneys. In the NEPTUNE consortium, biopsy samples of participants with nephrotic syndrome (NS) have been curated for snRNAseq. While small studies have provided insights using subsets of samples, an omnibus of transcriptional data from numerous samples may aid further discovery and research.

Methods: snRNAseq (n=11) and single cell RNA sequencing (n=47) from kidney biopsies from healthy living donors and transplant recipients in the Michigan HKTTA study were integrated with snRNAseq of 120 biopsies from patients with FSGS, MCD, IgAN, and other kidney diseases enrolled in the NEPTUNE Consortium to identify clusters of cells. Whole genome sequencing data from blood samples of 90 NEPTUNE participants were used to assess APOL1 genotype.

Results: Nuclei and cells (n=1,047,781) resolved into 28 clusters of kidney resident and non-resident cell types, including a novel cluster of transitioning parietal epithelial cells. APOL1 risk alleles were present in 90 participants. Among kidney cell types, we observed the strongest correlation between APOL1 mRNA levels and JAK-STAT activity in podocytes in participants with FSGS with at least one copy of the G1 APOL1 risk allele.

Conclusions: This Omnibus of CElls And Nuclei (OCEAN) from NEPTUNE participants with NS and IgAN is a large set of molecular and clinical data that allows unique analyses that can provide novel insights into mechanisms of kidney diseases

Analysis of Peripheral Blood Mononuclear Cells Single-Cell RNA Sequencing Shows IFN Signaling Activation Contributes to the Pathogenesis of Childhood Nephrotic Syndrome

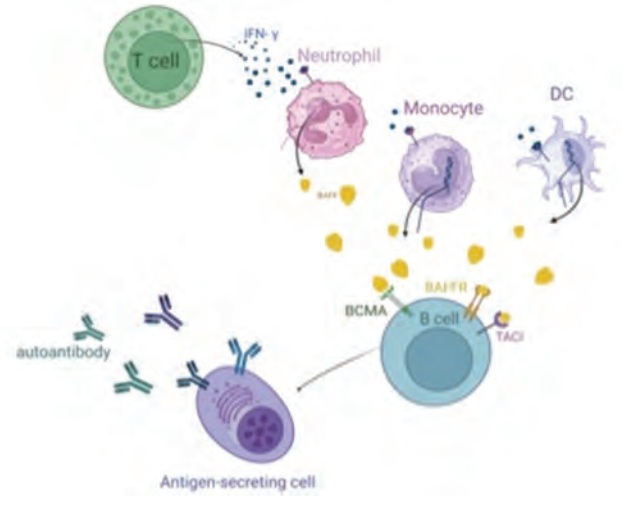
Qiu-yu Li, Fei Liu, Minchao Kang, Linnan Bai, Junnan Wu, Jianhua Mao.
Zhejiang University School of Medicine Children's Hospital, Hangzhou, China.

Background: Idiopathic Nephrotic syndrome (INS) is a prevalent glomerular disease, especially in children. Previous understanding of INS pathogenesis has emphasized T-cell changes and their correlation with cytokine shifts. Accumulating evidence indicates that B-cell dysfunction is also involved in the process. Nevertheless, a gap remains in the comprehensive understanding of the mechanisms and cellular interactions among immune cells in new-onset INS.

Methods: Our study employed single-cell RNA sequencing (scRNA-seq) to characterize immuno-dysfunction in peripheral blood mononuclear cells (PBMCs) obtained from five new-onset INS patients before treatment and post-remission, alongside healthy controls. We identified differentially expressed genes and investigated cell-cell communications across different cell types. We also performed validations.

Results: Through differentially expressed gene analysis across clusters, we observed the activation of interferon-stimulated genes (ISGs) and the enrichment of interferon (IFN)-related pathways. Specifically, we noted increased expression of B-cell activating factor (BAFF) in untreated patients, along with elevated expression of BAFF receptors, particularly B-cell maturation antigen (BCMA) in plasma cells, collaborated by flow cytometry in an independent INS cohort. Furthermore, we identified an increase in the serum level of IFN-γ rather than IFN-α.

Conclusions: Our research provides the first comprehensive exploration of IFN-related pathways in the initiation of INS. These results suggest that IFN-γ activation stimulates the interaction between BAFF and B-cell receptors, triggering autoantibody release and contributing to INS pathogenesis. New insights into the pathogenesis of NS may pave the way for precise therapeutic interventions that target these pathways.



TH-PO535

Single Nucleus Transcriptomic Landscape of Human Glomerular Diseases

Jeong Ho Joo,[1] Sehoon Park,[2] Jeong Seok Lee,[1] Dong Ki Kim.[2]
[1]Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea; [2]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.

Background: Glomerular diseases, often progress to end-stage kidney disease, with each type following a distinct clinical course despite common features. Single-nucleus RNA-seq (SnRNA seq) enabled researchers to capture the gene expression of rare glomerular cells. In this study, we examined the transcriptomic differences among glomerular diseases in glomerular cells.

Methods: We collected snap-frozen kidney biopsy tissues from 6 cases of IgA nephropathy (IgAN), 6 cases of minimal change disease (MCD), 6 cases of PLA2R-Ab positive membranous nephropathy (MN), 3 cases of diabetic kidney disease (DKD), and 7 cases of adjacent normal tissue in renal cell carcinoma. We conducted snRNA seq using kidney tissue, comparing proportions and differentially expressed genes (DEGs) among various diseases. We also subdivided detailed clusters within each cell type and compared specific cell types with the patients' clinical data to assess correlations.

Results: A total of 262,984 nuclei were obtained from 28 subjects with MCD, MN, IgAN, DKD, as well as the control, and UMAP was drawn. Thirteen clusters were identified including glomerular cells. When k-means clustering was performed on DEGs between each condition within each cell types, upregulated DEGs display patterns common to cell types and specific to diseases, whereas downregulated DEGs exhibit patterns specific to cell types and common across various cell types. After subclustering, we identified podocyte with endocytosis feature associated with proteinuria. The module score of marker genes of this cell type significantly increased with higher levels of proteinuria in patients. The proportion of myofibroblasts were increased in glomerular diseases, compared to control group significantly. Additionally, we found that gene expression of myofibroblast was directly associated with kidney function of glomerular diseases.

Conclusions: To our knowledge, our snRNA-Seq data is the largest datasets of biopsy-confirmed human glomerular disease to date. Our results provided novel insights regarding the kidney indwelling cell-specific or disease- specific transcriptomic alterations. The data serve as valuable asset for future investigations into the development of biomarkers or therapeutic targets for glomerular diseases.

TH-PO536

Single-Cell RNA Sequencing Shows How AP-1 Upregulation Affects Different Kidney Cells in the Chronic Progression of Glomerular Diseases

Shuying Li,[1,2] Qilin Chen,[1,2] Li Qiu.[1,2] *[1]Department of Nephrology, Children's Hospital of Chongqing Medical University, Chongqing, China; [2]National Clinical Research Center for Child Health and Disorders, Ministry of Education Key Laboratory of Child Development and Disorders, Chongqing Key Laboratory of Pediatric Metabolism and Inflammatory Disease, Chongqing, China.*

Background: Podocytopathies, resulting from podocyte injury, can lead to proteinuria and often progresses to end-stage renal disease, significantly impacting patient prognosis. Current studies have found that podocyte injury triggers parietal epithelial cell (PEC) activation, proliferation, migration to the capillary tuft, and acquisition of a podocyte phenotype. This process ultimately leads to global glomerulosclerosis and loss of renal function. However, the molecular mechanism underlying this critical process remains unclear.

Methods: We have established a cellular atlas of human glomeruli and kidney tissue from patients with glomerular disease, including 10 pediatric cases and 3 control children using scRNA-seq. Additionally, we conducted in vivo experiments with the AP-1 inhibitor T-5224 in an ADR mouse model.

Results: By rapidly enriching human glomeruli, we constructed a human glomerular cell atlas and identified podocytes with high expression of *NPHS2* and *PLA2R1*. We discovered a group of podocytes expressing AP-1-related genes (*JUNB*, *JUN*, *FOS*, and *FOSB*), designated as AP-1^{high} podocytes. Their existence was confirmed through immunofluorescence and immunohistochemistry. RNA velocity analysis revealed that AP-1^{high} had differentiation potential. Similarly, AP-1^{high} podocytes were also found in the mouse glomerular cell atlas and validated. Reclustering analysis of renal tissue cell atlas from patients with glomerular diseases revealed a group of AP-1^{high} PECs expressing *CCL2* and *ICAM1*. Remarkably, RNA velocity analysis indicated a tendency for AP-1^{high} PECs transform into AP-1^{high} podocytes. Increased expression of AP-1 was observed in connecting tubules, and endothelial cell subsets exhibiting signatures of inflammatory activation linked to chronic kidney disease progression. The critical role of AP-1 was confirmed by treatment with the AP-1 inhibitor T-5224 in mouse model of ADR-induced nephropathy resulting in significant improvement in proteinuria.

Conclusions: Parietal epithelial cells in glomerular diseases are activated and proliferate due to the up-regulation of AP-1, leading to their migration and differentiation into podocytes. The induction and activation of AP-1-related molecules across various cell subsets likely significantly contribute to chronic kidney injury progression and inflammatory activation.

TH-PO537

Kidney Tissue Single-Nucleus Multiomics Analysis of ANCA-Associated Glomerulonephritis Reveals Key Transcriptional Regulation Networks

Shuo Zhang,[1] Lubin Xu,[1] Zheng Huang,[2] Saifu Yin,[3,4] Yun Li,[2] Yanjie Chen,[2] Xini Meng,[2] Ying Wang,[1] Jiaying Li,[1] Yubing Wen,[1] Xixi Zheng,[1] Turun Song,[3,4] Tao Lin,[3,4] Lan Jiang,[2] Limeng Chen.[1] *[1]Department of Nephrology, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China; [2]Beijing Institute of Genomics, Chinese Academy of Sciences and China National Center for Bioinformation, Beijing, China; [3]Department of Urology/Institute of Urology, West China Hospital, Sichuan University, Chengdu, China; [4]Kidney Transplantation Center, West China Hospital, Sichuan University, Chengdu, China.*

Background: We aimed to use single-cell nuclear RNA and chromatin accessibility (ATAC) sequencing on renal biopsy specimens from ANCA-associated glomerulonephritis (AAGN) patients to identify crucial pathways for further mechanistic studies

Methods: We studied five AAGN patients, ten healthy donors, and seven paraneoplastic renal tissues. SnRNA-Seq and snATAC-Seq performed with Universal Droplet-Based Single-Cell Combinational Indexed Sequencing technique. We used the Weighted Nearest Neighbor method for co-dimensional reduction of the multi-omics data, clustering, and cell type annotation via Seurat's Label Transfer method to identify differentially expressed genes and ATAC

Results: The patient group had an average age of 64±6 years, and the clinical manifestations were glomerulonephritis with acute kidney injury and the pathological manifestations of small-vessel vasculitis with crescent formation. Activated parietal epithelial cells (PECs) with high CD44 expression, up-regulated crescent-forming and development potential genes were enriched in AAGN kidneys. SCENIC+ identified E2F3 and BACH1 as core transcription factors (TF) in the regulatory network of activated PECs. Endothelial cell abnormalities were noted in peritubular capillaries (EC-PTCs) with up-regulated genes related to cell junction assembly and angiogenesis. SMAD1 and BACH1 were identified as key TFs of EC-PTC injury. AAGN patients had increased intercellular communication

Conclusions: Our study applied single-cell multi-omics sequencing to AAGN renal biopsies, revealing cell-specific transcriptomes and epigenetic profiles of PECs and EC-PTCs. This work provides insights into new mechanisms and potential therapeutic targets for AAGN

TH-PO538

Integrated Multiomics Analyses and Mendelian Randomization Identify the Macrophage-Endothelial Characteristics of Membranous Nephropathy

Yi Ling, Jianzhong Li. *First Affiliated Hospital of Soochow University, Suzhou, China.*

Background: Membranous nephropathy (MN) is recognized as an autoimmune glomerular disease that may progress to severe end-stage renal disease. In recent years, extensive investigations into molecular characteristics of MN have been conducted at bulk-transcriptome level. However, the single-cell transcriptomic and proteomic features of MN remain to be elucidated. Mendelian randomization (MR) serves as a methodology for establishing causal relationships between exposure factors and outcomes, offering robust evidence to bridge the transition from "associated genes" to "causal genes".

Methods: Transcriptome data of MN glomeruli acquired from GEO databases were analyzed and immune infiltration was delineated. Olink proteomics assessed inflammatory proteins in peripheral blood of MN patients in our cohort. Single-cell analyses were conducted to pinpoint subclusters closely linked to the progression of MN. hdWGCNA was utilized to identify co-expression modules correlated with key subclusters. Finally, bidirectional MR was implemented to select module genes exhibiting causal relationship with MN.

Results: MN patients exhibited an increase in monocyte and M1 macrophage infiltration within glomeruli. scRNA-seq uncovered an increased abundance of pro-inflammatory macrophages expressing *VEGFA* and *CXCL8*, alongside inflammatory endothelial cells (IECs) exhibiting a high level of *CCL2* and *CXCL2* in MN patients with massive proteinuria. The communication between pro-inflammatory macrophages and endothelial cells appeared to be dominated by *VEGFA* and *CXCL8*, while IECs demonstrated an autocrine proclivity for *CCL2* and *CXCL2*. Proteomic analysis showed that inflammatory related proteins, such as MCP1 (CCL2) and IL8 were up-regulated in MN. MR revealed a potential causal relationship between *SLC1A5*, and the occurrence of

MN (OR=1.4, *p*=0.02). Drivers of ferroptosis were significantly enriched in endothelial cells with elevated *SLC1A5*, accompanied by higher expression of *CCL2* and *CXCL2*.

Conclusions: This study elucidated the circulatory and tissue inflammation of MN from a multi-omics perspective and identified pivotal macrophage-endothelial phenotypes and their interactions. MR identified genes with a causal relationship to MN in the phenotype-associated modules, potentially impacted the onset and progression of MN through modulation of endothelial phenotypes.

TH-PO539

Single-Nucleus RNA Sequencing (SnRNA-seq) of Biopsy-Confirmed IgA Nephropathy Reveals Cell-Specific Transcriptomic Alteration

Jeongmin Cho,[1,2] Sehoon Park,[3] Jung Hun Koh,[1] Yaerim Kim,[4] Dong Ki Kim.[3,1]
[1]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Chung-Ang University Gwangmyeong Hospital, Gwangmyeong, Gyeonggi-do, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Keimyung University School of Medicine, Daegu, Republic of Korea.

Background: SnRNA-seq is a valuable method for identifying cell-specific transcriptomic alterations in kidney cells. Our objective was to investigate SnRNA-seq data from biopsy-confirmed IgA nephropathy (IgAN) cases and identify cell-specific alterations in the transcriptome.

Methods: We collected snap-frozen kidney biopsy tissues from 6 cases of IgAN and 7 nephrectomy control cases. The disease control group included 3 cases of diabetic kidney disease, 6 cases of minimal change disease, and 6 PLA2R-Ab positive membranous nephropathy cases. SnRNA-seq was performed on the kidney tissues, and kidney cells were identified through UMAP clustering. We investigated differences in the proportion of kidney cell types and identified differentially expressed genes (DEGs). Additionally, we searched for representative gene loci previously reported in a multiethnic genome-wide association study (GWAS).

Results: We identified transcriptomic profiles of > 50,000 cells from IgAN, with a considerable enrichment of intraglomerular cells. The DEG analysis revealed a high number of DEGs in mesangial cells, fibroblasts, and vascular smooth muscle cells in the IgAN transcriptome compared to the nephrectomy and disease control cases. In the gene set enrichment analysis, the epithelial-mesenchymal transition pathway was enriched in the glomerular cells of IgAN. Among various GWAS loci, ETS1 was the gene significantly highly expressed in the mesangial cells of IgAN, consistent across the compared control groups.

Conclusions: This investigation represents the largest SnRNA-Seq profiling of IgAN kidney cells to date. Notable cell-specific pathways in IgAN were identified. ETS1 may be a kidney-indwelling causal factor for IgAN pathophysiology, considering its significance in both previous GWAS and the current SnRNA-Seq data.

Identification of Cellular Determinants Impacting Mesangial Cells in IgA Nephropathy

Ranjit S. Atwal, Susan E. Quaggin, Hasan H. Munshi, Shana O. Kelley.
Northwestern University, Evanston, IL.

Background: IgA nephropathy is a prevalent glomerulonephritis that frequently develop into end-stage renal disease, impacting over a million patients worldwide. Presently there is no disease-specific therapy, necessitating the development of targeted therapeutic intervention strategies and approaches for early diagnosis. One of the characteristic hallmarks of the disease is the predominant autoimmune complex deposition in the glomerular mesangium. However, the genetic regulators of the preferential accumulation of these IgAN immune complexes on the mesangial cells are not defined.

Methods: Using our magnetic ranking cytometry platform (termed LEAPFROG for large scale phenotypic functional genomics), together with the versatility of genome-scale CRISPR/Cas9 pooled screening across primary mesangial cells and other non-impacted/non-mesangial kidney cell types in parallel, we will identify the cellular surface component(s) driving the predominant accumulation of autoimmune complexes on the mesangial cells. Using our pooled surfaceome libraries, we will systematically profile the impact of individual surface proteins on the sensitivity of galactose-deficient IgA induced IgAN complex deposition. To enrich subpopulation of mesangial cells with either high or low levels of IgAN complex deposit phenotypes, we can functionalize the commercially available monoclonal anti-Gd-IgA1 antibody or the *in vitro* purified IgAN complexes to be useable on our platform. The systematic comparison of next-generation sequencing based guide RNA enrichment of regulators of IgAN complex deposition accumulation on mesangial cells versus the non-mesangial cells is anticipated to enable identification of cellular components regulating the IgAN complex induced proliferation and activation of mesangial cells.

Results: We have completed the lentiviral CRISPR guide RNA library targeting the cellsurfacome. It encompasses 3000 unique surface proteins, with 12,450 unique guides in total. Gererated cosmc knock out DAKIKI cell line for production of galactose-deficient IgA. These reagents, together with the KM55 antibody are being used for phenotypic screening of primary mesangial cells to identify genetic determinants impacting IgA nephropathy.

Conclusions: Use of LEAPFROG-powered CRISPR-cas9 based loss-of-fucnction phenotypic screening is anticipated to identify potentially druggable targets for IgAN.

Investigation of Molecular Insights into the Disease-Specific Pathophysiology of IgA Nephropathy Using Single-Cell RNA Sequencing

Soojin Lee,[1] Gwanghun Kim,[4] Jung Hun Koh,[2] Sehoon Park,[2] Yaerim Kim,[3] Hang-Rae Kim,[4] Dong Ki Kim.[2,4] *[1]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Republic of Korea; [4]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: IgA nephropathy (IgAN) has difficulty in explaining the heterogeneity of its clinical presentation and prognosis as the pathogenesis is not completely elucidated yet. We performed transcriptome profiling of peripheral immune cells of IgAN to explore their role in the pathogenesis of IgAN.

Methods: Peripheral blood mononuclear cells were obtained from 20 IgAN patients and 9 healthy controls. The cells were sorted into B, CD4 T, and CD8 T subsets. Single cell RNA sequencing was performed with NovaSeq6000. The patients were categorized according to the eGFR and proteinuria value. The differentially expressed genes (DEG) were identified. Then, gene ontology analysis was done with ToppGene Suite.

Results: After quality control, 32,742 B cells, 101,637 CD4 T cells, 63,029 CD8 T cells were retained for analysis. Cell clusters were presented in UMAP. (Figure 1) Ninety five genes were commonly upregulated in all subsets of IgAN, including AKT1, JUN and TGFB1. (Figure 2) Compared to control group, severe IgAN group exhibited significant increase in DEG expression; 40, 148, 132 upregulated and 233, 77, 78 downregulated DEGs in B, CD4 T, CD8 T cell subsets, respectively. Downregulated DEGs in B subset were highly enriched in MHC protein complex and antigen binding pathway.

Conclusions: The present transcriptome profiling showed different gene expression profiles according to the severity of IgAN. The study provides new insights into the role of immune cells in understanding the pathogenesis and it may contribute to the investment of the disease specific biomarkers of IgAN.

Unveiling Prognostic Biomarkers in IgA Nephropathy: A Chromatin Accessibility Approach Using Peripheral Immune Cells

Soojin Lee,[1] Gwanghun Kim,[4] Jung Hun Koh,[2] Sehoon Park,[2] Yaerim Kim,[3] Hang-Rae Kim,[4] Dong Ki Kim.[2,4] *[1]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Republic of Korea; [4]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: IgA nephropathy (IgAN), the most prevalent primary glomerulonephritis globally, exhibits heterogeneous clinical presentation and prognosis. The disease's heterogeneity remains enigmatic due to incomplete understanding of pathogenesis. This study employs an epigenetic approach to comprehensively profile peripheral immune cells in IgAN patients, aiming to elucidate their role in disease progression.

Methods: Peripheral blood mononuclear cells were obtained from 57 biopsy-proven IgAN patients and 20 healthy controls and were FACS sorted into B cells, CD4+ T cells, and CD8+ T cells. To explore the role of immune cells in IgAN pathogenesis, we performed Assay for Transposase-Accessible Chromatin (ATAC) Sequencing using NovaSeq 6000. Quality control and normalization process was performed consecutively to identify the differential peaks.

Results: After peak-calling, 65,234 peaks in B cells, 61,007 peaks in CD4+ T cells, and 59,162 peaks in CD8+ T cells, were considered for the differential ATAC-peak selection according to the patient groups. (Figure 1) Differential ATAC-peaks were highest in the CD8+ T cell subset compared to other immune cell populations. Gene ontology analysis showed significant functional differences in CD8+ T cells, when categorized by IgAN progression status. Interestingly, both B and CD4+ T cell subsets displayed significant chromatin accessibility differences, specifically within the ST6GALNAC5 gene locus. (Figure 2)

Conclusions: The present study offers novel insights into the role of immune cells in IgAN pathogenesis. Our findings hold promise for the development of novel, disease-specific biomarkers for improved prognosis assessment in IgAN patients.

Funding: Government Support - Non-U.S.

TH-PO543

Multisystem Alterations in the Mesangium of IgA Nephropathy Mice Using Single-Nucleus RNA Sequencing and Single-Nucleus Assay for Transposase-Accessible Chromatin

Soo-Young Yoon,[1] Dae Kyu Kim,[1] Su Woong Jung,[2] Jin Sug Kim,[1] Ju young Moon,[2] Hyeon Seok Hwang,[1] Kyunghwan Jeong.[1] *[1]Kyung Hee University Hospital, Dongdaemun-gu, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: Immunoglobulin A nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. One of the most prominent features of IgAN is mesangial proliferation with deposition of immune complexes. The role of the immune response in the development of IgAN is well-established. However, the genetics and pathways involved are not yet fully understood.

Methods: Mesangium from ddY mice (8 weeks gddY mice, n=3) and control mice (8 weeks Balb/c mice, m=3) were analyzed from three different system-level perspectives: genome level by single-nucleus assay for transposase-accessible chromatin sequencing (snATAC-seq), transcription level by single-nucleus RNA sequencing (snRNA-seq), and metabolic level by in-silico metabolic flux simulation. 'Pdgfrb', 'Pdgfra', 'Fhl2′ and 'Itga8' were selected as mesangium-specific marker genes prior to analysis.

Results: The study found that there was a proliferation of cells in IgAN compared to the control, as determined through spatial deconvolution of single-nuclei RNA-seq. The cells in the mesangium were rearranged into three subgroups, including two IgAN-specific subgroups and one control-specific subgroup, each with system-level-specific alterations. From an epigenomic perspective, one of the IgAN-specific subgroups revealed a 'positive regulation of cell adhesion' and 'epithelial cell proliferation' compared to the control-specific subgroup. In transcription profile alteration, two IgAN-specific subgroups revealed either upregulation of immune-associated pathways or energy-associated pathways. Metabolic flux changes affected various metabolic pathways, including 'alanine and aspartate metabolism' and 'purine catabolism'. Three metabolic pathways, namely 'beta-alanine metabolism', 'nucleotide metabolism', and 'pyrimidine catabolism', showed multiple simultaneous alterations on all three system levels.

Conclusions: This study provides insight into the key molecular changes that occur during the development of IgAN-associated glomerular injury, particularly in the mesangium of mice.

TH-PO544

Glomerular Dissection Allows High-Throughput RNA Sequencing of Single Podocytes

Najeong Kim,[1] Darshan Jadhav,[1] Nestor H. Garcia,[1] Agustin Gonzalez-Vicente.[1,2] Kidney Precision Medicine Project (KPMP). *[1]Case Western Reserve University, Cleveland, OH; [2]Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Background: Podocytes (POD) are essential for maintaining the integrity of the glomerular filtration barrier. Persistent insult to POD leads to proteinuria and chronic kidney disease. Single nuclei (sn) RNA sequencing (RNAseq) is an important tool in kidney research. As POD represent a small percentage of cells in kidneys, we developed a method to maximize POD recovery.

Methods: Rat glomeruli were microdissected and nuclei suspensions obtained by cellular fractionation. Libraries were prepared with 10X Chromium X technology and sequenced on the Illumina NovaSeq X platform.

Results: Western blots (Fig 1) of 77 glomeruli show enrichment for the slit-diaphragm protein nephrin. We also recovered 22.5 ng RNA from 30 glomeruli with a 28S/18S ratio >1.8. We prepared two sn-libraries, using ~180 (Rat1) and ~90 (Rat2) glomeruli, which yielded 6590 and 1022 sn-transcriptomes, respectively. We quality-controlled and clustered cells in Seurat, and used label transfer from a reference human kidney atlas (PMID: 37468583) to assign cell types (Fig 2). The number of glomerular cells recovered was: POD 1534 (22.2%), parietal epithelial cells (PEC) 96 (1.6%), mesangial cells (MC) 61 (0.9%) and glomerular capillary endothelial cells (EC-GC) 36 (0.5%). The reference atlas contains 2.1% POD, 1.1% PEC, 0.4% MC and 1.3% EC-GC. In addition, the reference atlas recovered on average 73 POD/biopsy, while our pilot study recovered 759 POD/sample.

Conclusions: Collectively, these findings show that our protocol enriches POD proteins and yields high-quality RNA suitable for sequencing. Isolated glomeruli also resulted in a more than tenfold increase in sn-POD transcriptomes per sample compared to kidney biopsies. Further development of this methodology will support high-throughput sequencing of POD with small sample sizes.

Glomerular Transcriptomics Reveal Clinically Relevant Endothelial Disturbances in Idiopathic Nephrotic Syndrome

Sarah K. Nelson-Taylor,[1] Courtney Giannini,[1] Jonathan P. Troost,[4] Tarak Srivastava,[2] Jarcy Zee,[3] Markus Bitzer,[4] Laura Barisoni,[5] Richard J. Johnson,[1] Gabriel M. Cara-Fuentes.[6] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Children's Mercy Kansas City, Kansas City, MO; [3]University of Pennsylvania, Philadelphia, PA; [4]University of Michigan, Ann Arbor, MI; [5]Duke University, Durham, NC; [6]Nationwide Children's Hospital, Columbus, OH.*

Background: There is a growing evidence that the glomerular endothelium is important in podocytopathies presenting as idiopathic nephrotic syndrome (INS). In this study we characterize the expression 10 selected genes associated with glomerular endothelial health and injury in patients with INS.

Methods: N=53 healthy controls and N=153 INS NEPTUNE participants with biopsy proven minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS) and mRNA expression profiling from micro-dissected human glomeruli were included. Gene expression was analyzed according to the histological diagnosis (MCD vs. FSGS) and disease state (relapse/remission). Correlation between gene expression, clinical features (proteinuria, kidney function -eGFR) and validated ultrastructural endothelial (loss of fenestrations, etc.) and podocyte descriptors (foot process effacement, etc.) was performed. Statistical analyses included two-way ANOVA and Pearson correlation.

Results: Endothelial-specific genes related to endothelial health and barrier integrity (NOS3, ESAM, ESM1), glycocalyx injury (HPSE, HYAL1, MMP2, MMP9, ADAMTS1) and cell activation (ICAM1, CAV1) were significantly altered in INS patients (Fig. 1 shows representative results) compared to controls, independent of the histological pattern and disease state. High ICAM1, CAV1 and HPSE expression associated with low eGFR. NOS3 and CAV1 associated with loss of endothelial cell fenestrations, and MMP2 with loss endothelial cell honeycombing appearance. Analysis of gene expression and podocyte descriptors is in process.

Conclusions: Glomerular expression of genes associated with endothelial health is altered in INS, regardless of histological patterns or disease state, and associates with low eGFR and endothelial ultrastructural injury.

Analysis of Glomerular Transcriptomes from Nephrotic Patients Suggests APOL1 Risk Variants Impact Parietal Epithelial Cells

Agustin Gonzalez-Vicente,[1,2] Dana C. Crawford,[1] William S. Bush,[1] Zhenzhen Wu,[2] Leslie A. Bruggeman,[2] Viji Nair,[3] Matthias Kretzler,[3] John F. O'Toole,[2] John R. Sedor.[2] Nephrotic Syndrome Study Network (NEPTUNE) and Kidney Precision Medicine Project (KPMP). *[1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH; [3]University of Michigan, Ann Arbor, MI.*

Background: Two *APOL1* gene variants (G1 and G2), only present in individuals with African ancestry, are linked to increased kidney disease rates. The mechanisms behind this genetic association remain obscure. We hypothesized that individuals with *APOL1* risk alleles have a glomerular transcriptional signature, which could identify candidate disease mechanisms.

Methods: We analyzed glomerular RNASeq transcriptomes from patients with idiopathic nephrotic syndrome, of which 72 had inferred African ancestry (AA) and 152 did not.

Results: Characteristic Direction identified a signature (SIG, 1481 genes), which separated AA patients with *APOL1* risk alleles from those homozygous for reference *APOL1*. Kaplan-Meier (KM) analysis showed that AA patients in the highest tertile of SIG activation scores progressed faster to the composite event of kidney failure or loss of 40% eGFR ($p \leq 0.013$). In addition, we found an association between a gene coexpression metamodule (MM, 437 genes) and the number of *APOL1* risk alleles, which remained significant after adjusting for eGFR and proteinuria. KM analysis showed that AA patients in the highest tertile of MM activation scores were less likely to achieve complete proteinuria remission ($p \leq 0.014$). SIG and MM activation scores did not associate with clinical outcomes in patients without inferred African ancestry. MM and SIG presented 191 common genes, and were both enriched for Epithelial Mesenchymal Transition (EMT) and inflammation terms. Overlap with glomerular cell identity signatures showed that MM predominantly features genes from parietal epithelial cells (PECs) rather than podocytes (PODs).

Conclusions: Concordant with enrichment in EMT genes, PECs could lose their epithelial phenotype while concomitantly driving glomerular scarring. These data suggest *APOL1* nephropathy is mediated by cellular crosstalk, in which PODs expressing G1 or G2 variants have paracrine effects on PECs, perhaps mediated by inflammatory cytokines. Thus, the presence of *APOL1* risk alleles may lead to persistent glomerular inflammation, PEC activation, podocyte loss, and glomerular scarring, thereby accelerating the progression of kidney disease.

TH-PO547

Energy Score Analysis in Immune Cells Linked to Atypical Hemolytic Uremic Syndrome Using Single-Cell Sequencing

I-Ru Chen,[1] Siang-Jyun Tu,[2] Chiu-Ching Huang,[1] Ping chin Lai.[1] *[1]China Medical University Hospital Department of Internal Medicine, Taichung, Taiwan; [2]China Medical University Hospital, Taichung, Taiwan.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, life-threatening thrombotic microangiopathy (TMA) with complex genetic and immunologic factors. Our single-cell sequencing shows a significant correlation between aHUS and immune cell subsets. Energy metabolism is crucial for immune responses, with cells reprogramming upon activation. We hypothesize that energy metabolism genes play a role in aHUS pathogenesis. This study evaluates energy metabolism-related gene expression (Energy Score, ES) in immune cell subpopulations from aHUS patients, unaffected family members, and healthy controls, enabling detailed comparison of aHUS activity and new research avenues.

Methods: We recruited 13 aHUS patients, three unaffected families, and four healthy controls from a medical center in Taiwan. Peripheral blood samples underwent single-cell RNA sequencing (scRNA-seq). The aHUS patients were classified into stable and unstable groups. ScRNA-seq data were processed with CellRanger and analyzed using Seurat in R. Inflammatory genes from the Molecular Signatures Database (MSigDB) were used to compute the energy score (ES) with Seurat's AddModuleScore, enabling detailed analysis of cellular energy metabolism.

Results: Our study assessed Energy Score (ES) in cell subpopulations among aHUS patients, aHUS nuclear families without the syndrome, and healthy controls via transcriptomic analysis. Intermediate monocytes showed the highest ES in aHUS patients, followed by aHUS families, and then healthy controls, with significant differences ($p < 0.0001$). No significant differences were found between aHUS families and healthy controls. Subclusters 1 and 2 of intermediate monocytes had significantly higher ES in aHUS patients compared to others. ES in intermediate monocytes, naïve CD8 T cells, terminal effector CD8 T cells, and non-V delta 2 gamma delta T cells was highest in unstable aHUS patients, followed by stable aHUS patients, aHUS families, and healthy controls.

Conclusions: Our study reveals a link between energy metabolism genes and aHUS severity through single-cell sequencing energy scores. Intermediate monocytes are significant markers of aHUS activity. This suggests energy metabolism genes play a key role in aHUS, warranting further research. These findings could predict disease stability and inform new therapeutic approaches.

TH-PO548

Spatially Resolved Transcriptomic Signature of Relapsing Minimal Change Disease

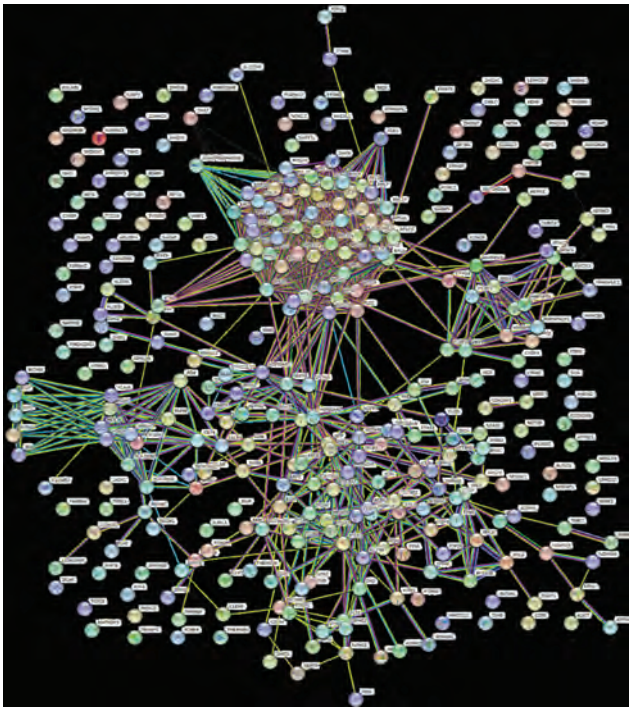
Semin Cho,[1] Jeongmin Cho,[1] Soojin Lee,[2] Sehoon Park,[3] Yaerim Kim,[4] Dong Ki Kim.[3] *[1]Chung-Ang University Gwangmyeong Hospital, Gwangmyeong, Gyeonggi-do, Republic of Korea; [2]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.*

Background: Minimal change disease (MCD) is usually responsive to corticosteroid. However, there are few data regarding the frequently relapsing MCD even after complete remission with previous treatment including corticosteroid. We aimed to investigate the molecular mechanisms of relapsing MCD using spatial transcriptomics.

Methods: We performed spatial transcriptomic profiling using GeoMx Digital Spatial Profiler with formalin-fixed paraffin embedded kidney biopsy specimens from four patients with relapsing MCD and various disease controls (MCD without relapse, focal segmental glomerulosclerosis, membranous nephropathy, diabetic nephropathy, and healthy controls). We compared the gene expression levels of relapsing MCD with the various disease controls in both glomeruli and tubules by DeSeq2 method. Differentially expressed genes (DEGs) were identified, and gene ontology (GO) term annotation and pathway analysis were performed.

Results: A total of 320 DEGs were consistently down-regulated in the glomerulus of relapsing MCD compared to all other various disease controls. Among the 320 DEGs, there are previously known genes that related to the pathogenesis of podocyte disease including NPHS1, NPHS2, and PODXL. GO annotation including cell adhesion molecule binding (GO:0050839), protein-containing complex binding (GO:0044877), MHC class II protein complex binding (GO:0023026) were the most notable annotated domain in the glomerulus of relapsing MCD. On the other hand, no DEG showed significance in the tubules between relapsing MCD and other disease controls.

Conclusions: In this study, we discovered consistently down-regulated DEGs in relapsing MCD compared with the various disease controls through spatial transcriptomics.



TH-PO549

Spatial Transcriptomic Profiling of Glomeruli in FSGS and Minimal Change Disease That Appear Normal on Light Microscopy

Hyung Woo Kim,[1,2] Minsun Jung,[1] Chung Lee,[1] Ga Young Heo,[1,2] Cheol Ho Park,[1,2] Hae-Ryong Yun,[1] Jung Tak Park,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Beom Jin Lim,[1] Seung Hyeok Han.[1] *[1]Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Institute for Innovation in Digital Healthcare, Yonsei University, Seoul, Republic of Korea.*

Background: Distinguishing between minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) based solely on pathological findings is challenging, with no validated biomarkers available for their discrimination.

Methods: Using the GeoMx Digital Spatial Profiler, spatial transcriptomic profiling was performed on formalin-fixed paraffin-embedded kidney biopsy specimens from five patients with MCD and three patients with FSGS (one tip variant and two NOS variants), all of whom presented with nephrotic syndrome. Additionally, we included four control patients from time zero biopsy of kidney recipients. Glomerular regions of interest were selected and outlined by two kidney pathologists using the web interface. For FSGS, glomeruli with and without sclerosis were selected separately. Differential gene expression (DEGs) analyses were conducted by fitting each gene's Q3 normalized expression level using edgeR. Gene ontology (GO) enrichment analyses of DEGs were performed using clusterProfiler.

Results: After excluding genes exhibiting expression levels below 5% of the ROIs in each sample, a final analysis was conducted on the remaining gene expression levels of 13,929 genes. Compared with glomeruli from MCD, normal glomeruli from FSGS exhibited increased expression of *GPR141*, and *DEFB104A* and decreased expression of *BRD2*, *FAM124A*, and *MYADM*. Sclerotic glomeruli from FSGS showed increased expression of *WIPI1* and *CLCN7* and decreased expression of *PODXL*, *NDNF*, *DCN*, and *HTRA1* compared with glomeruli from MCD. When comparing normal and sclerotic glomeruli from FSGS, normal glomeruli showed increased expression of *NPHS2*, *COL4A3*, *ID1*, and *ADAMTSL5*, whereas sclerotic glomeruli showed increased expression of *RPS23*, *RPL27A*, *EEF1G*, and *CRTAP*. Additionally, GO analyses revealed significant enrichment of genes for genes related to various biologic processes when these three phenotypes were compared with each other.

Conclusions: Utilizing digital spatial profiling identified significant differences in the expression profiles between glomeruli in FSGS and MCD that appear normal on light microscopy. Future studies are warranted to validate our findings and evaluate whether the observed genes could serve as discriminative biomarkers between the two phenotypes.

TH-PO550

High-Resolution Morphometry and Spatial Transcriptomics to Reveal Cellular and Molecular Mechanisms of Podocyte Effacement

Tobias Bohnenpoll,[1] Philipp Skroblin,[1] Johannes Pospiech,[1] Anna Guhl,[1] Nils Liebe,[1] Alexander Lomow,[1] Carolin Wiechers,[1] Britta Seip,[1] Menglin Zheng,[1] Michael Helwig,[1] Rüdiger Fritsch,[1] Olivier Radresa,[1] Kristina Kramer,[2] Florian Grimm,[2] Christian A. Wurm,[2] Gerald Donnert,[2] Uwe Andag.[1] *[1]Evotec International GmbH, Göttingen, Germany; [2]Abberior Instruments GmbH, Göttingen, Germany.*

Background: Podocyte injury and effacement precede proteinuria and result in characteristic glomerular lesions associated with focal segmental glomerulosclerosis (FSGS) and other glomerulopathies. These lesions have long been considered distinct disease entities, but their cellular and molecular features remain poorly characterized. Stimulated emission depletion (STED) is a light microscopy technique which provides a unique opportunity to assess podocyte foot process morphology in unprecedented detail. Here, we combine super-resolution STED morphometry and spatial transcriptomics to unravel the cellular and molecular mechanisms underlying podocyte injury and effacement in kidney biopsies from the NURTuRE patient cohort.

Methods: Adjacent thin sections of formalin-fixed, paraffin-embedded biopsies from 18 NURTuRE patients diagnosed with FSGS and other glomerulopathies and 2 healthy living donors were analyzed using STED microscopy (Facility line, Abberior) and spatial transcriptomics (Visium HD, 10x Genomics). Podocyte foot processes and filtration slits were stained for synaptopodin and nephrin, and super-resolution scans were exported for morphometry.

Results: Clinical-grade biopsies were selected to represent patients with early, intermediate, and end-stage disease, maximizing the range of kidney function and proteinuria. High-resolution spatial transcriptomics allowed identification of tissue niches based on the expression of cell type-specific and mechanistic signatures, representing distinct glomerular and tubulointerstitial microenvironments with different cellular composition. Unbiased clustering of spatially and molecularly defined niches stratified glomeruli along the continuum of podocyte injury and glomerular remodeling. Interestingly, glomerular niches were associated with different slit diaphragm lengths and densities, as determined by podocyte STED morphometry, depending on their position along the disease continuum.

Conclusions: Further integration of molecular, morphometric and clinical data has the potential to reveal cellular and molecular mechanisms of podocyte injury and glomerular remodeling and will aid in mechanistic disease understanding.

TH-PO551

Single-Cell Spatial Atlas of Immune and Kidney Cell States in Human Rapidly Progressive Glomerulonephritis

Zeba Sultana, Robin Khatri, Behnam Yousefi, Nikhat Shaikh, Saskia-L. Jauch-Speer, Varshi Sivayoganathan, Hans-Joachim Paust, Thorsten Wiech, Tobias B. Huber, Ulf Panzer, Stefan Bonn, Christian F. Krebs. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Rapidly progressive glomerulonephritis (RPGN) represents the most aggressive form of autoimmune kidney disease and is characterized by the formation of glomerular crescents and the infiltration of immune cells. However, a detailed definition of leukocyte composition, cellular localization and the interactions of immune cells with renal tissue cells leading to the formation of glomerular crescents and loss of renal function is lacking.

Methods: We employed high-dimensional in situ mRNA detection (10x Xenium) to investigate immune cell infiltration and kidney cell reactions in patients with RPGN (ANCA-GN: n= 32; lupus nephritis: n=19; anti-GBM: n=6) and controls (n=6). Based on single-cell RNA-seq and spatial transcriptomics data from kidney samples from the same cohort, we designed a panel consisting of 480 probes for mRNA detection to cover a broad range of immune cells, parenchymal kidney cells and potential drivers of tissue inflammation. We used manual annotation as well as a graph neural network (GNN)-based clustering algorithm to define kidney niches.

Results: Our analysis resulted in a total of 2,899,179 cells from all disease categories and the panel enabled the definition and localization of all major immune and kidney cell types. Gene-expression-based pseudotime analysis from annotated glomeruli provided a trajectory from healthy glomeruli identified most frequently in control samples to severely damaged glomeruli mainly from anti-GBM patients. Patients with ANCA-GN showed glomeruli with all stages of the pseudotime. These analyses define the sequential recruitment of proinflammatory T cells and macrophages into inflammatory niches causing changes in cellular composition and crosstalk between different cell types and resulting in altered transcriptional profiles of epithelial kidney cells leading to crescent formation.

Conclusions: This integrated high-dimensional spatial immune and kidney cell atlas of healthy and RPGN kidneys represents a comprehensive benchmark of the cellular players with their localization and interactions in glomerular pathology. This is the basis for a better understanding of the cellular and molecular mechanisms required to develop targeted therapies in glomerulonephritis.

Single-Cell Spatial Resolution Transcriptomic Profiling in Lupus Membranous Nephritis

Claire Avillach,[1,2] Alessia Giarraputo,[1,2] Ivy A. Rosales,[1,2] Jeremy M. Marcin,[1,2] Nicole L. Brousaides,[1,2] Robert B. Colvin.[1,2] Immunopathology Research Lab.
[1]Mass General Brigham Inc, Boston, MA; [2]Harvard University, Cambridge, MA.

Background: Understanding the molecular pathways involved in membranous lupus nephritis (classV LN) is crucial for identifying diagnostic biomarkers and potential therapeutic targets.

Methods: Spatial transcriptomic technology with cellular resolution was employed to analyze the expression of 1,000 RNAs in kidney core biopsies from patients with classV LN (n=3) and PLA2R-associated membranous nephropathy (PLA2R-MN, n=3). Spatially resolved cells were classified into cell types and differential gene expression analysis was conducted using a negative binomial model.

Results: Spatial single-cell transcriptomic analysis was conducted on 33,195 cells from class V LN samples and 39,127 cells from PLA2R-MN samples. Gene expression analysis revealed a significant upregulation of multiple type I interferon-stimulated genes (ISGs) in lupus nephritis, including IFIMT1, OAS1, STAT1, and IFI27 (Figure1). Increased ISG expression was observed across the main glomerular cell subtypes (podocytes, glomerular endothelial cells, mesangial cells/fibroblasts) as well as in tubular epithelial cells (Figure2). Notably, there was no significant increased expression of interferon (IFN) alpha, beta, gamma genes nor their receptors in lupus nephritis.

Conclusions: In comparison to PLA2-R-MN, class V LN shows activation of the type I IFN pathway. Further studies are needed to determine the role of interferon pathway activation in kidney injury and its use as a possible diagnostic or prognostic biomarker or therapeutic target for class V lupus nephritis.

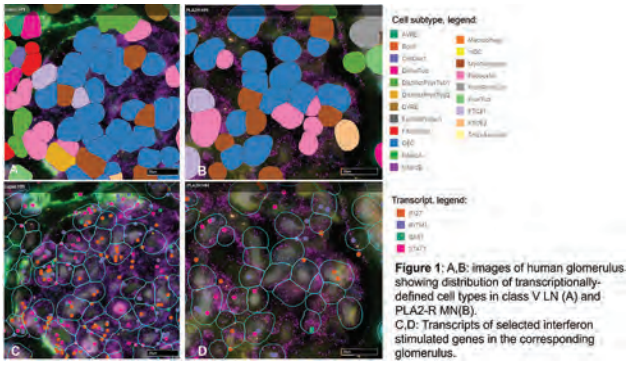

Figure 1: A,B: images of human glomerulus showing distribution of transcriptionally-defined cell types in class V LN (A) and PLA2-R MN(B). C,D: Transcripts of selected interferon stimulated genes in the corresponding glomerulus.

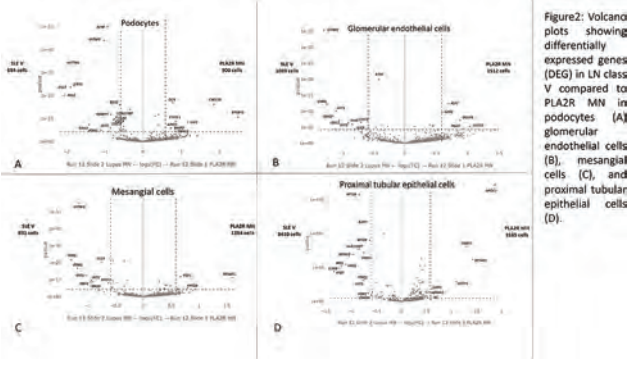

Figure2: Volcano plots showing differentially expressed genes (DEG) in LN class V compared to PLA2R MN in podocytes (A), glomerular endothelial cells (B), mesangial cells (C), and proximal tubular epithelial cells (D).

Glomerular Proteomic Signature in ANCA-Associated Glomerulonephritis

Ivana Stojkic,[1] John P. Shapiro,[2] Asish Thakkar,[3] Salem Almaani.[2]
[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University Wexner Medical Center, Columbus, OH; [3]VA Central Ohio, Columbus, OH.

Background: Crescentic glomerulonephritis (AAGN) is a common manifestation of ANCA-associated vasculitis (AAV) but does not occur in all patients. It is unclear whether the immune pathways driving systemic AAV are similar to the ones that drive AAGN, or whether there are pathways that are specific to the kidneys. To gain more insight into activated disease pathways in AAGN, we performed an agnostic proteomic analysis of glomeruli in patients with AAGN.

Methods: Kidney biopsies from 10 patients with AAGN and 5 controls (transplant donor biopsies) were used. Glomeruli were isolated using laser-capture microdissection, processed, and submitted for LC-MS/MS. Peptides were analyzed for spectral count quantitation. Spectral counts of each disease were compared to control samples and differential abundance analysis was performed using t-tests of log2 transformed peptide counts. Multiple hypothesis testing correction was performed and false discovery rate (FDR) adjusted p-values were used. Significance was defined as an FDR p value of <0.05 AND an absolute log2 fold change >1. Significantly abundant peptides were used for pathway analysis using Reactome.

Results: 105 peptides were significantly upregulated and 331 peptides were significantly downregulated when comparing AAGN vs control (Figure 1). Pathway analysis revealed upregulation of complement peptides, platelet aggregation, and neutrophil degranulation. In addition, several metabolic pathways were downregulated in kidneys of patients with AAGN.

Conclusions: Proteomic analysis of glomeruli from patients with AAGN reveals upregulation of distinct pathways such as the complement system, and downregulation of many metabolic pathways. These pathways can provide insight into the mechanism of kidney injury in AAGN, and aid in development of kidney targeted therapies.

Single Glomerular Proteomics of Crescentic and Noncrescentic Glomeruli

Michael Merchant,[1] Laura Biederman,[4] Michelle T. Barati,[1] Joseph Gaut,[2] Julie Dougherty,[3] Daniel W. Wilkey,[1] Adam E. Gaweda,[1] Jon B. Klein,[1] William E. Smoyer.[3] *[1]University of Louisville School of Medicine, Louisville, KY; [2]Washington University in St Louis School of Medicine, St Louis, MO; [3]Nationwide Children's Hospital, Columbus, OH; [4]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Glomerular crescent formation is characteristic of rapidly progressive glomerulonephritis (RPGN), but the molecular mechanisms of crescent formation are poorly understood. We addressed the hypothesis that proteomic analysis of single crescentic glomeruli compared to unaffected glomerular tissue could reveal differential protein expression and provide mechanistic insight into crescent formation.

Methods: VIPER, a digital imaging platform, was used to annotate and select glomeruli with and without crescents in three different patient biopsies. Single glomeruli were followed through 5µm serial sections on PEN slides for microdissection. Isolated glomerular sections for crescentic and otherwise normal glomeruli (n=3) were analyzed using data independent acquisition (DIA) with a Thermo QE-HF LCMS. DIA data analysis (PeaksX) employed human glomerular and in silico spectral libraries. Single glomerulus datasets (n=6; 3x2) were quantitatively compared by paired and 2-way ttest (unadjusted p<0.05) and functionally characterized by g:Profiler using all proteins to establish differences within (paired) and between (2-way) crescentic and otherwise normal glomeruli.

Results: 1,468 protein groups were detected across all datasets. 21 proteins differentiated crescentic and normal glomeruli with 19 more abundant in crescentic glomeruli. Ontologic analysis of all proteins identified top qualitative terms including cell adhesion (MF), cytoplasmic translation (BP), extracellular space (CC), coronavirus disease (KEGG), and primary focal segmental glomerulosclerosis (Wikipathways enrichment based on the following geneset: CR1, PTPRO, NPHS2, NPHS1, ILK, FYN, MYO1E, PODXL, LIMS1, CD151, MME, ITGA3, SYNPO, TLN1, ITGB1, AGRN, PARVA, DAG1, MYH9, ACTN4,I NF2, COL4A3, LAMA5, UTRN,C OL4A5, VCL, COL4A4, VTN, LAMB2, CD2AP, YWHAQ, PTK2, ITGAV, ITGB3, SCARB2, VIM, KRT8, CTNNB1).

Conclusions: This study demonstrates the ability to get glomerulus specific proteomic data from both crescentic and normal glomeruli from the same biopsy. The proteomic data shows a clear difference between the crescentic glomeruli and the normal glomeruli. Wider application of this technique will allow us to compare different stages of crescent formation as well as crescents in different disease states.

Human Kidney Tissue Proteomics Unveils Complement Factor D Involved in the Pathogenesis of Focal Segmental Glomerulosclerosis

Sahomi Yamaguchi,[1,2] Toshiaki Nakano,[1] Daiki Setoyama,[2] Abhijeet Sonawane,[3] Takaki Iwamoto,[1] Sasha Singh,[3] Masanori Aikawa,[3] Yuya Kunisaki,[2] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Clinical Chemistry and Laboratory Medicine, Kyushu University Hospital, Fukuoka, Japan; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Focal segmental glomerulosclerosis (FSGS) is a clinicopathological syndrome manifested with nephrosis resistant to glucocorticoids. Given the fact that FSGS has unfavorable renal prognosis, efficient therapeutic options targeting specific pathways are sought to be developed. The Columbia classification proposed the 5 variants, namely Collapsing, TIP, Cellular, Perihilar and NOS. Differences in their renal prognosis imply distinct underlying molecular mechanisms, which remains unclear. Here, we aimed to explore factors involved in the pathogenesis of FSGS by comprehensive proteomics with human kidney tissues.

Methods: Kidney tissues from a total of 73 individuals including 23 FSGS patients, healthy and disease controls, were subjected to the analysis using LC-MS/MS-enabled proteomics. Immunohistochemistry and the microarray data from the Nephroseq database were used for validation.

Results: Our proteomics platform identified a total of 4,168 proteins from renal tissue specimens. Comparison of FSGS and healthy control groups identified 175 proteins increased in FSGS, which were enriched in the complement pathway and immune responses by Gene Ontology analysis. These results suggest involvement of the complement system as an underlying mechanism. Furthermore, complement factor D (CFD), which activates the alternative complement pathway, was identified to be significantly elevated in the FSGS group compared to disease control groups. Analysis with immunohistochemistry and gene expression from the Nephroseq database confirmed that CFD was produced mainly in glomeruli, where complement cascades are possibly triggered. Next, we extracted proteins specific for the Columbia variants. Gene Ontology analysis with these factors uncovered that complement pathway was enriched in the Cellular and TIP variants, while endoplasmic reticulum, ribosome, and ferroptosis pathways were in the Collapsing variant, suggesting their different pathophysiology.

Conclusions: Our study provided deeper insights into the recently proposed functional association between FSGS and the complement pathway, offering targeted treatment options. Moreover, the variant-specific molecular background in the Columbia classification will enable us to stratify treatments of FSGS.

TH-PO556

The Glomerular Kinome in Health and Disease

Jonathan C. Haydak, Nanditha Anandakrishnan, Evren U. Azeloglu. Kidney Precision Medicine Project (KPMP). *Icahn School of Medicine at Mount Sinai Department of Medicine, New York, NY.*

Background: Pharmacologically targeting the glomerular kinome is an appealing strategy as existing kinase inhibitors could potentially be repurposed for treating kidney diseases. To this end, we investigated alterations in the glomerular kinome signature in rat models of minimal change disease and hypertensive nephropathy in combination with single-nucleus RNA sequencing (snRNA-seq) from biopsies of patients in the Kidney Precision Medicine Project (KPMP).

Methods: Sprague-Dawley rats were injected with a single dose of 100mg/kg puromycin aminonucleoside (PAN) and studied for 4 weeks with tissue collected at post-injection days 7, 14, 21, and 28. 13-week-old spontaneously hypertensive rats and age- and sex-matched Wistar-Kyoto rats were studied for 5 weeks before harvesting kidneys. Quantitative isobaric tandem mass tag proteomics was performed on isolated glomeruli, with differentially abundant proteins (DAPs) identified using the LIMMA statistical package and correlated with functional measurements such as urine albumin-creatinine ratio. Publicly available KPMP snRNA-seq data was analyzed using Seurat. Pathway analyses on DAPs and differentially expressed genes (DEGs) were performed using Enrichr and Molecular-Biology-of-the-Cell Ontology.

Results: Both rat models showed severe and overlapping perturbations to the glomerular kinome. In PAN rats, alterations in glomerular kinome corresponded to the severity of albuminuria (**Figure 1A**). Enrichment of the top up- and down-regulated kinases showed cytoskeletal dynamics, adhesion, and the Hippo pathway to be significantly impacted. Patient snRNA-seq data from KPMP similarly showed dysregulation of Hippo-related transcripts which correlated with levels of albuminuria (**Figure 1B**).

Conclusions: In albuminuric kidney diseases, the altered kinome and dysregulation of the Hippo pathway may represent common underlying disease mechanisms.

Funding: NIDDK Support, Other NIH Support - NIH T32HD075735

TH-PO557

Expanding the Limits Single Glomerulus Measurements by Targeted, Quantitative Proteomics

Chris Hsu, Mariya T. Sweetwyne, Michael Maccoss. *University of Washington, Seattle, WA.*

Background: As age progresses, the kidney glomeruli can undergo heterogeneous structural changes that affect filtration efficiency and cause kidney dysfunction. To capture these structural changes at the proteomics level, single glomerulus measurements need to be performed to see the spatial heterogeneity that would otherwise be lost in aggregated, bulk kidney or glomerular samples. We aim to improve the sensitivity and sample recovery of a single glomerulus to better profile its molecular heterogeneity.

Methods: Single glomerulus samples were individually dissected from a pool for bulk glomerulus samples from a 7 month old mouse. An optimized acid lysis protocol was performed prior to protein aggregate capture (PAC) and clean-up. A targeted proteomics method was generated from a data-independent acquisition (DIA) library of pooled bulk glomerulus samples. Our targeted list includes peptides from podocyte, glomerular and tubule proteins. Proteomics data on all of the samples were acquired using a targeted method measuring 571 peptides from 500 proteins on an EvoSep running a 30 minute liquid chromatography gradient coupled to a Lumos tribrid mass spectrometer.

Results: We applied our optimized targeted protocol to study 30x single mouse glomeruli compared to bulk glomeruli. Podocyte and glomerular proteins, such as Synaptopodin and Podocin, were enriched in protein abundance, and tubule proteins, such as Uromodulin, were highly depleted in the single glomerulus samples compared to the bulk glomerulus control. To assess heterogeneity of the single glomerulus samples, the coefficient of variation was calculated at the peptide level. A higher coefficient of variation (62%) was observed for the single glomerulus samples compared to the bulk glomerulus samples (20%), demonstrating biological variation of individually measured single glomeruli compared to pooled bulk glomerulus samples.

Conclusions: We developed an effective sample preparation strategy to recover peptides down to the single glomerulus level. Using massively parallel targeted proteomics, we can measure 571 peptides from both single glomeruli and bulk samples with robust quantitation and no missing data. This method allows for the capture of robust individual glomerular proteomes and captures the confounding heterogeneity that accompanies glomerular aging.

TH-PO558

Using Laser Capture Microdissection and Proteomics to Identify Key Components of Metabolic Signaling Pathways in Glomerular Diseases

Marie-Kristin Kroll,[1] Linus A. Volker,[2,1] Martin Höhne,[2,1] Bernhard Schermer,[2,1] Martin Kann,[2,1] Thomas Benzing,[2,1] Paul T. Brinkkoetter.[2,1] *[1]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [2]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: Renal biopsies are classified based on descriptive parameters and validated antibodies. This histopathological assessment does not routinely consider molecular parameters. Here, we aim to unravel the key molecular changes in metabolic signaling pathways to establish a set of molecular markers linked to distinct disease states or response to therapy in glomerular diseases, including MCD and FSGS.

Methods: A technical workflow was established for rodent kidney samples. Glomerular sections of genetically modified mouse models and experimentally treated animals, including the induction of nephrotoxic nephritis (NTN) by serum application, as well as a rodent FSGS model, were isolated by Laser capture microdissection (LCM). Isolated glomerular sections were processed and analyzed using mass spectrometry.

Results: We identified proteins with dissenting regulation within a large-scale proteomics approach using genetically modified and experimentally treated mouse models. The expression patterns of significantly regulated proteins revealed reliable clustering of genetically or experimentally affected mice and control samples. Furthermore, some of

the identified proteins correlated with transcriptome data linked to podocyte damage in rodent models.

Conclusions: Our workflow identified significantly regulated proteins and distinct overlaps with transcriptome data in the glomerular sections of mice with renal impairment. Next, this workflow will be applied to human biopsies of FSGS and MCD patients to identify regulated proteins of interest in a large-scale setup. Following, in a targeted proteomics approach key proteins of metabolic signaling pathways will be analyzed in depth. By combining molecular findings with comprehensive clinical background information, including disease state, progression, and responsiveness to therapy, we aim to define a set of marker proteins allowing a precise molecular characterization of patient biopsies and thereby supporting indications for suitable therapies and drug treatment strategies for MCD and FSGS patients.

TH-PO559

Proteomic Analysis of Glomerular Extracellular Matrix Suggests a Potential Role of Complement in the Pathogenesis of Idiopathic Collapsing Glomerulopathy Associated with APOL1 High-Risk Genotypes

Precil D. Neves,[1] Talita S. Siqueira,[1] Valkercyo A. Feitosa,[1] Andreia Watanabe,[1] Elieser H. Watanabe,[1] Jussara B. Castelli,[2] Natalia G. Gonçalves,[1] Chin J. Lin,[1] Livia B. Cavalcante,[1] Denise M. Malheiros,[1] Lectícia Jorge,[1] Irene L. Noronha,[1] Valdemir M. Carvalho,[2] Luiz F. Onuchic.[1] *[1]Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil; [2]Fleury Laboratory, São Paulo, Brazil.*

Background: The pathogenesis of collapsing glomerulopathy (CG), a highly aggressive nephropathy, remains largely unclear. While a significant fraction of idiopathic CG (ICG) cases is associated with *APOL1* high-risk genotypes (HRG), the differences in pathogenic processes between ICG associated with HRG (ICG+HRG) and with *APOL1* low-risk genotypes (ICG+LRG) are still poorly characterized.

Methods: To identify novel potential differences in molecular pathogenic pathways between ICG+HRG and ICG+LRG, we performed proteomic analyses of glomerular extracellular matrix (ECM) in 4 groups of patients: ICG+HRG (9 cases); non-Mendelian ICG+LRG (8 cases); FSGS-NOS+LRG (5 cases, a disease profile control); and normal kidney tissue (NK, 6 cases, a baseline control obtained from non-affected areas of nephrectomies secondary to malignancy). Glomerular samples were acquired by laser-microdissection. The relative abundance of proteins was compared between groups.

Results: We identified 931 proteins present in at least 60% of the samples of one group. Two hundred of them were classified as ECM proteins. C1QC, CFHR1, and hornerin were detected exclusively in the ICG+HRG group while laminin alpha 2 was detected only in the ICG+LRG group. Moreover, annexin A4, C5, C9, C4b-binding protein alpha chain (C4BPA), Serpin Family B Member 6 (SERPINB6), SERPINB9, and SERPINC1 stood out as displaying greater abundance in ICG+HRG than NK, and C4BPA, COL4A4, COL4A5, laminin beta 2, and nidogen-1 as presenting more abundance in ICG+HRG than FSGS-NOS+LRG. Annexin A4, annexin A6, SERPINB9 and SERPINH1 stood out as displaying greater abundance in ICG+LRG than NK. No difference in abundance was detected between ICG+HRG and ICG+LRG.

Conclusions: Our data showed that ICG+HRG and ICG+LRG presented patterns of glomerular ECM proteins associated with inflammation, immune activation and fibrosis pathways, and suggested a potential involvement of the complement system in the pathogenesis of ICG+HRG.

TH-PO560

Human Tubulointerstitial Responses to Proteinuria Analysed by Proteomics and Laser Capture Microdissection

Lars Nilges, Moritz Lassé, Felicitas E. Hengel, Elion Hoxha, Tobias B. Huber, Nicola M. Tomas, Markus M. Rinschen. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany*.

Background: Proteinuria damages the tubule compartment. Laser capture microdissection (LCM) enables the precise isolation of specific renal tubular segments, allowing for targeted proteomic analysis of the renal tubular interstitium in IgA nephropathy (IgAN) patients. By identifying differentially expressed proteins and molecular pathways associated with tubulointerstitial injury in IgAN, we sought to gain insights into the pathogenesis of this complex renal disease and identify potential therapeutic targets.

Methods: We studied 24 IgAN patients with M1E1 score alongside 10 zero-biopsy controls. Using formalin-fixed paraffin-embedded (FFPE) renal tissue and LCM, we isolated tubular compartments for analysis. Mass spectrometry-based proteomics identified differentially expressed proteins linked to tubulointerstitial injury in IgAN.

Results: Our analysis unveiled a distinct proteomic signature characterized by the upregulation of complement system proteins, including C7, C6, C5, and CFHR1, suggestive of an inflammatory response within the tubular interstitium. This inflammatory milieu is further corroborated by the identification of upregulated IgGs. Our study revealed a profound downregulation of sodium ion transporters, SLC5A1 and SLC4A7, within the tubular interstitium of IgAN patients indicating a significant disruption in tubular function. The marked downregulation of these sodium transporters suggests a pivotal role in the pathogenesis of tubulointerstitial injury, potentially contributing to disease severity and renal dysfunction in IgAN.

Conclusions: Upregulation of proteins associated with the complement system and immune response outside the glomerular compartment indicates a robust inflammatory process. Downregulation of key sodium ion transporters highlights disrupted electrolyte homeostasis and tubular dysfunction. These insights into tubulointerstitial injury in IgAN enhance our understanding of its pathogenesis and identify potential therapeutic targets to improve renal outcomes.

TH-PO561

Analysis of Kidney Biopsies from Patients with Glomerulonephritis Using Imaging Mass Cytometry Reveals Increase in Immune Cells with Associated Dedifferentiation and Injury of Tubular Cells

Marlene Weiss,[1,2] Vijayakumar R. Kakade,[2] Megan L. Baker,[2,4] Tifanny Budiman,[2] Ashish Shelar,[3] Lloyd G. Cantley.[2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Yale University School of Medicine, New Haven, CT; [3]Yale University, New Haven, CT; [4]Yale University Graduate School of Arts and Sciences, New Haven, CT.*

Background: This study was conducted to characterize and develop mechanistic understanding of the tubulointerstitial impact of acute glomerulonephritis. For both ANCA-associated vasculitis (AAV) and Lupus nephritis (LN), there is a lack of patient-targeted therapies.

Methods: 30 FFPE cortex samples from 15 patients (5 with AAV, 5 with proliferating LN, and 5 tumor-remote nephrectomy samples (reference) were analyzed in a Tissue Microarray with imaging mass cytometry (IMC) after staining it with 37 metal-tagged antibody markers. Analysis was performed using scripts in Python and RStudio. Cells were segmented with mesmer, a deep learning platform. Clustering was performed using the Phenograph algorithm.

Results: Analysis of all 30 samples resulted in identification and segmentation of 106,455 cells (37.2% from reference, 31.2% from AAV, 31.6% from LN) with total analyzed tissue areas of 9.7, 5.1 and 5.8 mm^2, respectively. Thirty-nine cell clusters were identified with annotation revealing 17 different cell types. 95.6% of cells were successfully annotated. Total cell counts per mm^2 tissue area showed that reference kidneys had 3.1±1.8% immune cells whereas AAV and LN kidneys contained 28±17% and 21.9±20% immune cells, respectively, including T cells, B cells and macrophages. Analysis of the resident cell types revealed the expected predominance of proximal tubule (PT) cells (38.4±5.2% in reference, 32.7±8.2% in AAV, 30.9±7.5% in LN). Injury markers analyzed included kidney-injury molecule 1 (KIM-1), vimentin, FACL4 (ferroptosis) and pRIPK3 (necroptosis). Initial clustering resulted in 9 different PT clusters, of which 2 were notable for high expression of injury markers. Cells in cluster iPT were increased in both AAV and LN and had high expression of vimentin, pRIPK3 and KIM-1, while cells in cluster aavPT were found only in AAV and had high expression of KIM-1 and FACL4.

Conclusions: AAV and LN kidney samples reveal a marked increase in interstitial immune cells with associated dedifferentiation and injury of resident tubular cells. The tubular injury is highlighted by increased KIM-1, ferroptosis and necroptosis marker expression in injured PT with concurrent downregulation of resident markers Megalin and Aquaporin 1.

TH-PO562

Isotope-Guided Metabolomics Dissects Arginine Metabolism in Proteinuria

Maria Chrysopoulou,[1] Markus Bleich,[3] Nina Himmerkus,[3] Markus M. Rinschen.[1,2] Laboratory of Kidney Omics and Metabolism. *[1]Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark; [2]III Department of Medicine, University Medical Center Hamburg Eppendorf, Hamburg, Germany; [3]Christian-Albrechts-Universitat zu Kiel, Kiel, Germany.*

Background: Proteinuria is a direct outcome of kidney glomerulus injury and an independent risk factor for cardiovascular disease (CVD). Arginine (Arg) metabolism links protein metabolism to renal function and CVD through urea excretion and nitric oxide generation. Due to the many metabolic fates, signals related to Arg metabolism are uninterpretable and its role in proteinuric kidney disease is not completely understood. The aim of this study is to investigate arginine's metabolic fate and interorgan communication in the healthy kidney and proteinuric kidney disease in a systemic way by comprehensive metabolomics and proteomics approaches.

Methods: Compound-heterozygous $Pod^{R231Q/A286V}$ is a mouse model of human hereditary nephrotic syndrome developing progressive proteinuria and leading to focal segmental glomerulosclerosis. *Ex vivo*, isolated and dissected nephron segments from healthy mice (n=4) and isolated tubule and glomeruli suspension from healthy

and Pod$^{R231Q/A286V}$ mice, (n=8), were incubated with $^{13}C_6$-Arg for 60 minutes. Extracted metabolites were analyzed with UHPLC/QQQ-based mass spectrometry targeting Arg-related metabolic pathways. *In vivo*, healthy and Pod$^{R231Q/A286V}$ mice (n=21) were fed with normal and stable isotope-labeled Arg diet for 2 weeks. Metabolites and proteins extracted from 19 metabolically active organs, urine, and plasma were analyzed accordingly.

Results: *Ex vivo,* Arg-derived glutamate, proline and agmatine were detected along the whole nephron, whereas $^{13}C_5$-ornithine and $^{13}C_1$-guanidineacetic acid were mostly formed in the proximal nephron segments. The same Arg metabolic pathways were also confirmed in the tubules and glomeruli suspensions. Proteinuria did not alter Arg metabolism in glomeruli, however, in proteinuric renal tubules, $^{13}C_5$-glutamate, $^{13}C_5$-proline and $^{13}C_1$-guanidineacetic acid were increased. *In vivo*, in proteinuric animals, Arg was accumulated in the liver. Even though total urea levels showed systemic accumulation in all investigated organs and lower excretion in the urine, the relative abundance of newly synthesized urea was decreased. Arg-derived glutamate was increased mostly in the kidneys, demonstrating significant metabolic rewiring across organ borders.

Conclusions: In proteinuria, arginine metabolism shifts from the liver-focused urea formation towards a more global utilization of arginine in the kidney.

TH-PO563

Clinical Impact of Podometrics and Quantitation of Podocyte Parameters in Patients with IgA Nephropathy (IgAN)

Shoko Ochiai, Masao Kikuchi, Koichi Kaikita, Shouichi Fujimoto.
Miyazaki Daigaku, Miyazaki, Japan.

Background: Podocyte loss and resultant nephron loss are common processes in developing glomerulosclerosis and chronic kidney disease. Podometrics for estimating podocyte number, density, glomerular volume and other parameters in kidney biopsies, can be an important toolbox for monitoring glomerular disease. We validated podometrics in patients with IgAN.

Methods: Biopsy-proven IgAN patients with our hospital from 2019 to 2022 were enrolled in this study (n=44, median age 35.5 years [25-57.5], 45.5% male) and podocyte parameters were measured using the technology of Venkatareddy et al. (JASN 2014). Glomerular volume, mean podocyte volume, and podocyte density were measured and divided into two groups, high and low, respectively, to determine their relationship to clinical characteristics. Podocyte parameters were compared between the groups categorized based on the presence or absence of lesion defined by Oxford MEST-C scores (mesangial hypercellularity: M, endocapillary hypercellularity: E, segmental sclerosis or adhesion: S, interstitial fibrosis and tubular atrophy: T, and crescents: C).

Results: Patients with larger glomerular and podocyte volumes were older and had lower eGFR than those with smaller volumes. Patients with lower podocyte density were older, had lower eGFR, and higher UP/Ucr and urinary NAG/Ucr than those with higher. At the time of kidney biopsy, there were no differences in eGFR and UP/UCr between groups in the M, E, and S categories, nor podocyte parameters. However, T1 and T2 had lower eGFR (36.8 vs. 53.8 mL/min/1.73m^2, p<0.05) and higher urinary NAG/Cre (0.0131 vs. 0.0077 IU/mgCr, p<0.05) versus T0. There was no difference in glomerular volume (2.65 v.s. 2.69 x 10^6 μm^3), but podocyte number and density was lower in T1 and T2 (199 v.s. 218 per glomeruli, 162 v.s. 107 per ×10^6 μm^3, respectively). In addition, urinary NAG/UCr was higher (0.0095 v.s. 0.0061 IU/mgCr, p<0.05) and podocyte volume was smaller in C1 and C2 compared to C0 (2905 v.s. 3395 μm^3).

Conclusions: Podometrics correlated well with clinical characteristics and the Oxford classification at the time of kidney biopsy in IgAN patients. Notably, the association between podometrics (evaluating glomeruli) and the T category (presence or absence of tubular lesions) is intriguing and warrants further investigation, including its relationship to prognosis.

TH-PO564

An Unbiased and Automated Approach: Artificial Intelligence (AI)-Based Pipeline for Glomerulosclerosis Scoring in Rodent Models of CKD

Alex Frias Hernandez, Maria K. Ougaard, Ditte M. Jensen, Michael Christensen.
Gubra AS, Horsholm, Denmark.

Background: Glomerulosclerosis is a kidney disease that involves the formation of scar tissue in the glomeruli in patients with chronic kidney disease (CKD). An accurate histopathological evaluation of glomerulosclerosis plays a crucial role in the diagnosis, prognosis and treatment of people suffering from CKD. Several rodent models mimic glomerulosclerosis and aid in preclinical target identification and drug development for CKD. To accelerate the objective and efficient assessment of glomerulosclerosis, we have designed an AI-powered scoring system using deep learning algorithms, adapted to murine and rat CKD models.

Methods: A deep learning model was trained on a large sample test set (4293 glomeruli images) of mouse and rat PAS-stained kidney sections and compared to expert histopathologist-verified manual glomerulosclerosis scoring. AI model performance was validated using an independent kidney sample set from three different mouse models of CKD (adeno-associated virus-mediated renin overexpression (ReninAAV) in uninephrectomized (UNx) db/db mice as a model of diabetic kidney disease, anti-GBM induced nephritis, and adriamycin-induced nephropathy) as well as 5/6 nephrectomy (Nx)-induced CKD in the rat.

Results: Our AI-based method accurately identify and quantify the severity of glomerulosclerosis (ranging from absence to advanced or global sclerosis, scored from 0 to 4) with exceptional sensitivity and specificity in murine and rat kidney sections. It showed promising efficacy in monitoring the progression of glomerulosclerosis not only in murine models (db/db UNx ReninAAV, anti-GBM and adriamycin mice), but also in nephrectomy 5/6-induced CKD model in rats.

Conclusions: Our AI-based glomerulosclerosis scoring method offers unbiased, accurate and automated glomerulosclerosis assessment in rodent models of CKD. The pipeline is optimized to accommodate both mouse and rat kidney sections, highlighting the applicability to the wide range of rodent models of CKD used in preclinical drug discovery.

Urinary Exosomes as Noninvasive Window to Glomerular and Tubular Cells and Their Communication

Sindhu Thiagarajan,[1,2] Janina Kern,[1,2] Nina Sopel,[1,2] Janina Müller-Deile.[1,2]
[1]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany; [2]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany.

Background: Although many renal diseases originate in glomerular unit, subsequent damage of tubular cells may lead to alleviate the disease condition. Exosomes are a type of extracellular vesicles, which play a major role in intercellular communication in many diseases. All cells secrete exosomes which carry nucleic acids, proteins, lipids and metabolites to recipient cells. Our previous studies showed the role of microRNAs in intraglomerular communication as well as their disease specific detection in the urine. However, little is known if such communication can be mediated by exosomes and if they also can serve as non-invasive biomarker.

Methods: Characterization of exosomes from the glomerular and tubular cell lines and patients' urines was performed via nanoparticle tracking analysis to identify size and concentration, electron-microscopic imaging to show intact morphology and appropriate size of the exosomes as well as FACS staining and western blotting to detect common exosome markers. Proteome profiling and proteases activity assay of exosomes from cell culture supernatant and respective "mother cells" was used to characterize internal and external exosome cargo. Cell type specific marker in FACS sorting of exosomes was used to identify the cellular origin of urinary exosomes.

Results: Cell culture and urinary derived extracellular vesicles showed typical exosome size, morphology and marker expression (CD63, CD9, CD81). Proteomics of cell culture derived exosomes and mother cells allowed distinct protein cargo characterization of the exosomes. Proteases activity could be detected on exosome surface derived from glomerular cells. Glomerular cell derived exosomes could be detected and isolated via cell sorting from urines of patients with different glomerular diseases giving a non-invasive material for further characterization as potential biomarker.

Conclusions: Podocyte derived exosomes might deliver cargo to tubular cells on their way of being secreted with the urine where they might serve as non-invasive snapshots of their cell of origin. Size wise exosomes should not be able to pass the glomerular basement membrane in vivo. However, the presence of proteases on exosomes might enable the passage of endothelial cell or even systemic exosomes through the GBM to reach podocytes or even tubular cells.

Funding: Government Support - Non-U.S.

TH-PO566

Patients with IgA Nephropathy (IgAN) or IgA Vasculitis (IgAV) Have Significantly Higher Serum Levels of α1-Microglobulin IgA Complexes

Olivier Lardinois,[1] Leesa Deterding,[1] Jason G. Williams,[1] Patrick H. Nachman.[2]
[1]National Institute of Environmental Health Sciences, Mass Spectrometry Research and Support Group, Research Triangle Park, NC; [2]University of Minnesota, Division of Renal Diseases and Hypertension, Minneapolis, MN.

Background: The cause of IgAN and IgAV remains unknown. Patients with IgAN and IgAV who develop nephritis have elevated levels of circulatory IgA1-containing complexes, which contain galactose-deficient IgA1, IgG antibodies and some unidentified proteins. Identification of the key constituents of these protein-protein complexes and the nature of the chemical bonds within the complexes may lead to better understanding of the pathophysiology of IgAN/V.

Methods: Low and high molecular mass IgA forms were isolated from serum of 32 patients with IgAN/V and 12 healthy controls (HC) by affinity-capture on peptide M agarose beads. Various molecular forms of IgA1 were size-separated by gel electrophoresis. Proteins were visualized by Coomassie blue staining or by Western blotting using appropriate antibodies. The relative abundance of each protein within the complexes was estimated by mass spectrometry using a Tandem Mass Tag (TMT)

quantification approach. A sensitive and efficient method for mapping protein disulfide bonds was used to identify the inter-chain disulfide bonds within the complexes.

Results: Immunoblotting demonstrated 1:1 complexes between IgA and albumin, α1-antitrypsin, or α1-microglobulin. Mapping of protein disulfide bonds demonstrated that 1) complexes of albumin and α1-antitrypsin with IgA monomer are disulfide-bound to penultimate C-terminal cysteine on the tailpiece of IgA and 2) α1-microglobulin is linked to IgA by a non-reducible covalent thioether bond to the same cysteine. Of 146 identified proteins, 86 were robustly quantified in the protein complexes using TMT-based quantification, and 15 showed significantly different levels in patients with IgAN/V and healthy controls. The relative abundance of IgA-α1-microglobulin complexes was significantly higher in patients than HC. The association of IgA-α1-microglobulin complexes level and IgAN had an area under the curve (AUC) value of 0.912 (C.I. = 0.840-0.984), significantly higher than other serum candidate diagnostic biomarkers under investigation.

Conclusions: We confirmed the presence of increased levels of IgA-α1-microglobulin complexes in the serum of patients with IgAN compared to HC. The specificity of the complex for IgAN or IgAV is under investigation. IgA-α1-microglobulin complexes could serve as a non-invasive biomarker of IgAN/V.

Identification of Circulating IgA Targeting Chemical Adducts in Patients with IgA Nephropathy

Sara Alibrandi,[1,3] Paolo Molinari,[1,2] Paolo Cravedi,[1] Emmanuel Zorn.[4]
[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Universita degli Studi di Parma Dipartimento di Medicina e Chirurgia, Parma, Italy; [4]Columbia University, New York, NY.

Background: IgA nephropathy (IgAN) is characterized by IgA accumulation in the mesangial area, leading to inflammation and kidney damage. Despite extensive research into its pathophysiology, the trigger for IgA production remains unclear. We hypothesized that the abnormal IgA levels in IgAN may result from a pathological immune response to post-translational protein modifications. To identify potential targets, we used a high-dimensional ELISA platform to assess IgA reactivity patterns in IgAN patients and controls towards post-translational protein modifications, building on our prior research.

Methods: A total of 28 patients with biopsy-proven IgAN and 22 healthy individuals were enrolled. Serum samples were analyzed using a high-dimensional ELISA platform to assess IgA reactivity to 93 natural chemical adducts. Statistical analyses were performed using Boruta algorithm to identify significant targets.

Results: Among the chemical adducts, carboxymethyl lysine (CML) emerged as a prominent target, with significantly higher IgA reactivity in IgAN patients. This reactivity was confirmed in an independent validation cohort of 15 cases and 15 controls and remained significant after adjusting for total IgA levels. IgG reactivity to CML did not differ between groups. Additionally, a positive correlation was observed between IgA reactivity to CML, serum CML levels and albuminuria in IgAN patients.

Conclusions: This study identifies CML as a potential target of IgA in IgAN. These findings highlight the possibility of using IgA reactivity to CML as a diagnostic biomarker for IgAN and provide new insights into the IgAN underlying mechanisms.

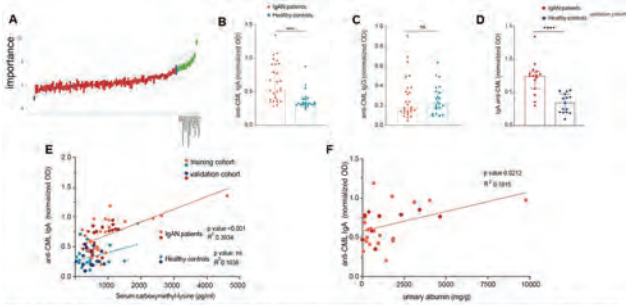

Fig.1: (A) Boxplot of importance distribution of each adduct in Boruta algorithm. Blue boxplots represent a shadow attribute's minimum, average, and maximum Z scores. Z scores of qualities that were rejected and confirmed, respectively, are represented by red and green boxplots. Plasma Testican-2 and MGT5A Are Potential Markers of Membranous Nephropathy

Taesoo Kim,[1,2] Aditya L. Surapaneni,[3,4] Insa M. Schmidt,[5,6] Sahir Kalim,[1,2] Anand Srivastava,[7] Ragnar Palsson,[1,2] Isaac E. Stillman,[8] Morgan Grams,[3,4] Sushrut S. Waikar,[5,6] Eugene P. Rhee.[1,2]
[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]NYU Langone Health, New York, NY; [4]New York University Grossman School of Medicine, New York, NY; [5]Boston Medical Center, Boston, MA; [6]Boston University Chobanian & Avedisian School of Medicine, Boston, MA; [7]University of Illinois Chicago College of Medicine, Chicago, IL; [8]Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Membranous nephropathy (MN) is a rare cause of chronic kidney disease, most of which require biopsy to diagnose. In select cases, serologic assays such as PLA2R antibodies may help diagnose MN where kidney biopsy is contraindicated, but additional specific markers are needed.

Methods: Among 434 individuals who underwent native kidney biopsy adjudicated by 2 expert pathologists, 39 were diagnosed with MN. We examined the associations between the diagnosis of MN and the 6592 plasma protein levels measured by aptamers using linear regression models adjusted for eGFR, proteinuria and demographic factors. Combined cases of normal kidney and thin basement membrane disease served as a control group (n=26). In sensitivity analysis, we evaluated the associations between each plasma protein level and the diagnosis of MN versus all other diagnoses if the reason for biopsy was proteinuria (n=231). For the proteins identified, we examined the kidney expression of the corresponding genes using publicly available single cell RNA sequencing data from the Kidney Precision Medicine Project (KPMP).

Results: Twelve proteins were associated with the diagnoses of MN. Testican-2 ($P=4.0 \times 10^{-11}$) and MGT5A ($P=5.8 \times 10^{-10}$) were the top 2 proteins with significant associations with MN, higher levels of which were associated with a diagnosis of MN. Both Testican-2 ($P=1.2 \times 10^{-8}$) and MGT5A ($P=3.6 \times 10^{-10}$) remained associated with MN in the sensitivity analysis. In KPMP, *SPOCK2* (encodes Testican-2) and *MGAT5* (encodes MGT5A) showed significant enrichment in podocytes (89% and 71% respectively).

Conclusions: These findings identify Testican-2 and MGT5A as candidate plasma markers of MN, both with literature outlining potential biologic relevance. Additional studies should be directed towards external replication.

Funding: NIDDK Support

Unlocking the Role of Transcription Factors in PLCG2 Expression: Implications for Nephrotic Syndrome (NS)

Tarak Srivastava,[1] Daniel P. Heruth,[1] Sean Eddy,[3] Mukut Sharma.[2]
[1]Children's Mercy Kansas City, Kansas City, MO; [2]Kansas City VA Medical Center, Kansas City, MO; [3]University of Michigan, Ann Arbor, MI.

Background: The mechanism of immunopathogenesis of NS in minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) remains unclear. We recently showed elevated expression of a scaffold protein SH3BP2 in MCD and FSGS. SH3BP2 forms a signaling complex with PLCG2, a key enzyme of immune signaling (JCI Insight 2024:e170055) and a candidate gene locus in NS (J Am Soc Nephrol. 2015:1701). To define the role of the SH3BP2/PLCG2 complex in NS we investigated the transcription factors (TFs) regulating PLCG2 expression.

Methods: RNA sequencing data (NEPTUNE consortium) from the glomerular compartment of Control (n=8), biopsy-proven MCD (n=89) and FSGS (n=93) cases were analyzed to (a) identify PLCG2 transcripts and (b) generate a Z-score for each gene for each patient. We used three models to predict TFs regulating PLCG2 expression: JASPAR (jaspar.elixir.no), TFBSpred (michalopoulos.net), and GeneCards (genecards.org). Gene Ontology (GO) analysis was performed using the Panther Knowledgebase (pantherdb.org).

Results: The primary transcript for PLCG2 (ENST00000564138.6; GRCh38.p14) was the most abundant. JASPAR, TFBSpred, and GeneCards predicted 665, 41, and 76

TFs regulating PLCG2, respectively. Data for the 56 TFs identified in more than one dataset were further analyzed. Gene expression for transcription factors IKZF1, MLX, IRF8, POU2F2 and SPI1 increased from Control to MCD to FSGS. Expression of MAX, MEIS2, GLIS2, PKNOX1, ETV2, TFE3, ELF4, SNAI2, ERG, ATF2, NR2C1, KLF9, KLF15, ATF7 and MAZ was significantly different in MCD and FSGS compared to Control. Expression for ETS1, SP1, TFDP1 and MITF was only significantly changed in MCD and that of SMAD5 and GABPA only in FSGS ($p<0.05$ in all comparisons). GO analysis of the 26 transcription factors identified key biological processes including: Developmental (20/26; FDR 8.87E-05), Immune System (11/26; 1.14E-02), Positive Regulation Transcription by RNA PolII (20/26; 6.25E-16) and Negative Regulation of Transcription by RNA PolII (13/26; 2.07E-03).

Conclusions: Identification of these 26 transcriptional regulators of PLCG2 that play a role in Immune System, Regulation of Transcription by RNA PolII and Developmental processes will provide the basis for investigating the role of PLCG2/SH3BP2 complex in the immunopathogenesis of NS and for identifying therapeutic targets.

Establishing Methods to Predict Responsiveness to Steroid Therapy at Disease Onset of Idiopathic Nephrotic Syndrome in Children

Chikage Yajima, Yasuko Kobayashi, Yoko Yamasaki, Takumi Takizawa. *Gunma Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Maebashi, Japan.*

Background: Steroid responsiveness is important in predicting the long-term prognosis of kidney function in children with idiopathic nephrotic syndrome. However, there is no method for predicting steroid responsiveness at disease onset in patients with massive proteinuria. Patients require more than 4 weeks of steroid treatment to diagnose steroid-resistant nephrotic syndrome (SRNS); therefore, complications from refractory edema and side effects of steroid therapy could be severe in SRNS patients. There is an urgent need to establish methods that enable the prediction of patient responsiveness to steroid treatment at disease onset.

Methods: We investigated the activation of αvβ3 integrin and Rho GTPases (RhoA, Rac1, and Cdc42), and cell migration activity utilizing healthy human podocyte cell lines (ciPods). Differentiated ciPods were stimulated with serum obtained from patients with steroid sensitive nephrotic syndrome (SSNS, n=14) and SRNS (n=9) at relapse. Activated αvβ3 integrin expressed on the basement membrane of ciPods was measured using the immunofluorescent antibody method with total reflection illumination fluorescence microscopy. Cell lysates were collected after stimulation with serum to quantify active GTPases using enzyme-linked immunosorbent assay. Cell migration was evaluated using scratch assay.

Results: SRNS relapse serum activated αvβ3 integrin in ciPods, whereas SSNS relapse serum did not induce the activation. Relative fluorescence intensity of active αvβ3 integrin was significantly higher with SRNS serum stimulation than with SSNS serum ($p=0.0012$). The area under the receiver operating characteristic curve was 0.8889, and the cut-off point was 0.166, with 78% sensitivity and 93% specificity. The relative absorbance of active Cdc42, which promotes cell motility, showed no significant difference between SSNS and SRNS stimulation ($p=0.3939$); however, in the migration assay, ciPods tended to migrate faster with SRNS serum stimulation than with SSNS serum stimulation ($p=0.0556$).

Conclusions: The αvβ3 integrin activation level on the ciPods basement membrane surface may be useful in differentiating SRNS from SSNS. The ciPods migration assay can be used supplementally to differentiate between SSNS and SRNS. Further investigations using patient serum samples at disease onset are required.

Presence and Intensity of Leptin Expression in the Kidney in Focal Segmental Glomerulosclerosis: Can It Shed Light on the Pathogenesis and Prognosis of the Disease?

Zeynep Ural. *Kirikkale Yüksek Ihtisas Hospital, Kirikkale, Turkey.*

Background: Focal segmental glomerulosclerosis (FSGS) is a primary glomerulopathy often progressing to chronic kidney failure. It can be primary or secondary to factors like drugs, substance use, sickle cell anemia, HIV, parvovirus B19, genetic factors, and obesity. Leptin, a hormone produced by adipose tissue, binds to receptors in endothelial and mesangial cells, inducing cellular proliferation, extracellular matrix accumulation, and type IV collagen production. These effects of leptin are significant in FSGS pathogenesis. This study evaluates the impact of leptin expression in kidney biopsy on renal survival and differentiation between primary and secondary FSGS.

Methods: Patients with FSGS, followed at Gazi University Faculty of Medicine Hospital's Adult Nephrology Clinic for at least two years and who had undergone diagnostic kidney biopsy, were included. Kidney biopsies were stained immunohistochemically with leptin. Demographic characteristics, clinical and laboratory findings, and medical treatments were recorded. The relationship between immunohistochemical staining and clinical findings was evaluated.

Results: A total of 105 patients were evaluated. 23% were Leptin (-), 62% were Leptin (+), and 15% were Leptin (++). Demographic characteristics were similar across groups. There was no relationship between leptin positivity and body weight. Leptin negativity was significantly associated with a good treatment response, while severe leptin positivity was significantly associated with a poor treatment response (both $p<0.05$). Most patients with secondary FSGS showed severe leptin positivity. Among patients with severe leptin positivity, 92% were non-responsive to treatment, compared to 20% in leptin-negative patients.

Conclusions: The role of leptin in kidney diseases has been known, but no prior study demonstrated leptin expression in glomerular diseases. Our study is the first to show leptin expression in the kidneys of FSGS patients and evaluate disease etiology and prognosis based on expression intensity. Leptin can be a guiding biomarker and therapeutic target in terms of renal survival and treatment response in FSGS. Evaluating leptin expression in the kidney can shed light on pathogenesis, assist in individualized treatment, and provide insights into poor renal prognosis, guiding future studies.

Translational Strategy to Evaluate Urinary Plasminogen as a Targetable Biomarker of Glomerular Diseases

Marina de Cos, Gohar Mosoyan, Jenny Wong, Justina Ray, Steven G. Coca, Kirk N. Campbell. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Given the heterogeneity of glomerular diseases and necessity of kidney biopsies for predictive purposes, non-invasive biomarkers defining mechanisms underlying progression are needed. Our previous work identified plasminogen as a cause of podocyte injury and established a correlation between plasminogenuria and renal dysfunction. Here, we propose a translational strategy to evaluate the plasminogen as a mediator of podocyte damage and the potential utility of plasminogen inactivation, through urokinase-type plasminogen activator (uPA) inhibition, as a protective strategy.

Methods: To evaluate the predictive value of the basal plasminogen, we performed a multicenter cohort study that included 1010 patients from CureGN with biopsy-proven glomerular disease. The main predictor was urine plasminogen at baseline and Cox regression was used to examine ESKD progression. To test uPA inhibition as a protective strategy, we developed a podocyte surface uPA activity assay in immortalized human podocytes, followed by High-Content Image Analysis of the cytoskeleton and focal adhesions by TIRF-Microscopy of podocytes treated with/without human plasminogen and uPA inhibitors.

Results: In the cohort of patients, adjusted Log_2uPlasminogen/Cr was significantly associated with ESKD (HR per doubling Log_2uPlasminogen/Cr 1.31 (95%CI 1.22-1.40), $P < 0.001$). Comparison of the predictive performance of models including Log2uPlasminogen/Cr, Log_2UPCR or both markers showed plasminogen model superiority. In the cell-surface uPA activity assay, amiloride had a IC50 of 8824 nM (5964-12661), compared to Candidates A and B (amiloride derivatives with computationally predicted increased uPA inhibitory activity), whose IC50 were 334.0 nM (249-397) and 643 (385-955). Quantitative high-content image analysis showed that plasminogen treatment resulted in a reduction in cell area and focal adhesions in plasminogen treated cells. Partial rescue was achieved after amiloride cotreatment whereas Candidates A and B completely reversed the phenotype.

Conclusions: Urinary plasmin(ogen) is independently associated with ESKD in patients with glomerular disease. Plasminogen inactivation by uPA inhibition may be a strategy to reduce podocyte damage. Patients most likely to respond to uPA inhibition could potentially be identified using our urinary biomarker approach.

Blood DNA Methylation Is Associated with Histopathological Changes in Patients with Lupus Nephritis

Christine Y. Bakhoum,[1] Patrick C. Demkowicz,[1] Deepika Kumar,[1] Joachim H. Ix,[2] Dennis G. Moledina,[1] Mathieu F. Bakhoum.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]University of California San Diego, La Jolla, CA.*

Background: Approximately 60% of patients with systemic lupus erythematosus (SLE) develop nephritis. Histologically-determined disease classification provides clinically actionable information including administration and intensity of immunosuppression, but requires invasive biopsies. We hypothesized DNA methylation patterns from immune cells would be associated with histopathological changes from kidney biopsy in individuals with lupus nephritis.

Methods: We identified 28 participants from the Yale Kidney Biobank with biopsy-confirmed lupus nephritis. A study renal pathologist graded all kidney biopsies according to the NIH Activity and Chronicity Indices. DNA was extracted from blood buffy coat. DNA methylation was analyzed using Illumina MethylationEPIC V2.0, surveying > 935,000 CpG loci. β-values (percent methylation) were derived using the R Sesame package. We utilized the Bioconductor limma package to determine differentially

methylated loci by overall indices, as well as by each component of disease activity and chronicity. Benjamini-Hochberg method was used for false discovery rate correction.

Results: The cohort was comprised of participants with the following: class I (n=1), class II (n=3), class III (n=5), class III + V (n=3), class IV (n=4), class IV+V (n=1), class V (n=9), and class VI (n=2). The median activity index was 3 (IQR 1, 7). The median chronicity index was 3 (IQR 2, 6.25). In unadjusted analyses, we identified differentially methylated loci ($q < 0.05$) by scores including: fibrinoid necrosis, cellular/fibrocellular crescents, global glomerulosclerosis, fibrous crescents, and total chronicity index (**Table**). After adjustment for age, BMI, sex, and eGFR, loci remained significantly associated with fibrinoid necrosis, cellular/fibrocellular crescents and fibrous crescents.

Conclusions: DNA methylation patterns from immune cells correlate with important histopathologic findings, particularly crescent formation, from kidney biopsy in patients with SLE nephritis.

Funding: NIDDK Support

TH-PO574

Defining NFκβ-Regulated Biomarkers in Lupus Nephritis Patient Serum

Nicholas A. Shoctor, Makayla Brady, Rebecca Lightman, Shweta Tandon, Dawn J. Caster, David W. Powell. *University of Louisville, Louisville, KY.*

Background: Lupus nephritis (LN) is an autoimmune disease that results from glomerular immune complex deposition and subsequent inflammatory events. Prior studies demonstrate that NF-κβ activation contributes to LN pathogenesis. If NF-κβ-regulated proteins contribute to LN, then we hypothesize that some of these proteins are elevated in LN patients' serum relative to healthy donors (HD).

Methods: The Bio-Plex Pro human immune modulator screening panel was used to measure the contents of serum from 28 LN patients and 8 HD controls. Comparisons of protein concentrations between LN patients and HD were performed using Mann-Whitney tests. Comparisons among HD and the LN genotypes were performed using Kruskal-Wallis tests. Associations between protein concentrations and clinical features were determined using Spearman correlation analyses. All results were corrected for multiple comparisons. Logistic regression models were generated for each independent protein and all possible combinations. Receiver operating characteristic (ROC) curves were used to determine the optimal cutoff concentrations for each protein.

Results: Of the 48 NF-κβ-regulated proteins measured, 25 yielded statistically analyzable results. Three of those 25 proteins, IL-2 receptor alpha (IL-2Rα), macrophage colony stimulating factor (M-CSF), and stem cell factor (SCF), were significantly elevated in active LN patients relative to HD. Moreover, serum from patients who were heterozygous for a previously identified NF-κβ-associated LN risk allele, *TNIP1* rs49958881, contained significantly more of each protein than homozygous LN patients or HD. M-CSF and SCF were positively correlated with UPCR. IL-2Rα and SCF were positively correlated with serum creatinine. SCF was negatively correlated with glomerular filtration rate. The best fitting model included IL-2Rα and M-CSF. The optimal cutoff concentrations were 47.8 pg/mL for IL-2Rα, 12.69 pg/mL for M-CSF, and 64.47 pg/mL for SCF.

Conclusions: The central aim of this project was to characterize immune phenotypes associated with NF-κβ in LN. We've identified three NF-κβ-regulated proteins as candidate markers of LN activity that can be obtained relatively non-invasively. Our findings also further characterize approaches to precision medicine by understanding how genetic profiles influence disease progression and response to available therapies.

Retinol Binding Protein 4 Is a Marker for Proteinuria in Humans and Zebrafish

Jan René Haak,[1,2] Cathiana Kolb,[1] Lena Pollinger,[1] Melanie Grosch,[1] Iain A. Drummond,[2] Hermann Haller,[2] Friedhelm Hildebrandt,[3] Mario Schiffer,[1,2] Markus M. Rinschen,[4] Tilman Jobst-Schwan.[1,2] *[1]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [2]Mount Desert Island Biological Laboratory, Salsbury Cove, ME; [3]Division of Nephrology, Department of Pediatrics, Boston Children's Hospital, Harvard Medical School, Boston, MA; [4]Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark.*

Background: A clinical hallmark of glomerular kidney diseases is proteinuria. In humans, proteinuria is described as the urinary albumin-creatine-ratio. The zebrafish is a widely used model in kidney research. However, up to date proteinuria detection in zebrafish requires transgenic lines, because the zebrafish does not possess an albumin orthologue. Although allowing for proteinuria-related kidney research in zebrafish, these transgenic lines may possess altered physiology and lack direct translational potential to human health.

Methods: We performed proteomics on fish water samples of zebrafish larvae with a described glomerular damage phenotype (*magi2a*^{cl604}). We designed and 3D-printed a custom dot blot plate to subject water samples of zebrafish larvae individually housed for 24 hours on a PVDF membrane. Assessment of proteinuria was performed by detecting Rbp4 on the membrane. To induce glomerular damage, different transgenic lines, a chemical induction model and somatic CRISPR knock-out models were used. Additionally, a fluorescent eye assay using the transgenic line *Tg(lfab:VDBP-eGFP)* was performed to compare the performance of the novel assay to a standard zebrafish proteinuria assay.

Results: Using a proteomics approach, we found high abundance of rbp4 in fish water of edema fish compared to control fish. It has been shown before that RBP4 is proteinuria marker in humans as well. Based on that, we developed a dot blot-based assay where fish water is used to quantify proteinuria in individually housed zebrafish larvae by immunodetection of Rbp4. Using four different established models to induce proteinuria in zebrafish, we validated the dot blot-based assay.

Conclusions: We developed a novel proteinuria assay in zebrafish based on the endogenous orthologue of a known human proteinuria marker. This assay allows for individual proteinuria assessment, independent of transgenic zebrafish lines and with a higher physiological relevance. Thereby, we established a novel translational assay that is useful for drug discovery as it is scalable and suitable for high-throughput procedures.

TH-PO576

Expanding the Use of Surface Plasmon Resonance (SPR) for Characterizing Nephritic Factors in Patients with C3 Glomerulopathy (C3G)

Christopher Culek, Cecelia F. Fierce, Carla M. Nester. Molecular Otolaryngology and Renal Research Laboratories. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Nephritic factors (Nefs) are convertase-directed autoantibodies present in up to 80% of C3 glomerulopathy patients.[1] Despite this prevalence and the associated complement dysregulation, there remains much to be learned about Nef characteristics. Previous work used SPR to show Nefs drive disease by stabilizing the convertase and amplifying complement activity.[2] However, this work was unable to characterize patients with Nefs sensitive to regulation by DAF or FH (scenarios evident in our patient population). This deficiency limits our understanding of individual patients and opens the possibility that we are missing populations of Nefs all together. We sought to develop a simple regulator-independent SPR technique that can provide a reproducible half-life of the Nef-convertase interaction.

Methods: C3b was immobilized to an SPR microfluidic chip at 1200RUs. Several concentrations of FB, FD, and IgG were co-injected onto the C3b ligand to form convertase-IgG complexes. The complex dissociated at 37C for 600 seconds (~6-7 half-lives of reagent convertase), to allow total decay of unbound convertase complexes. Then the sensorgram was normalized to 100RUs. The estimated half-life was calculated as the time at which the sensorgram reached 50RUs remaining. We evaluated nine replicates of one polyclonal Nef-positive IgG test subject and five Nef-negative test subjects.

Results: Both the Nef-positive and Nef-negative polyclonal IgG show specificity to the convertase, as previously supported.[3] The Nef-positive stabilization half-life ranged from 2072 to 2084 seconds with a mean of 2080, while the Nef-negative stabilization half-lives ranged from 464 to 598 seconds. The Nef-positive sample had low variability with a SD of only 4.609, and a SE of 1.537. The estimated half-life was independent of the concentration of FB or FD.

Conclusions: This data suggests our approach was able to reproducibly provide an estimated half-life for the Nef-convertase complex. Furthermore, it shows distinct

kinetics between the Nef-positive and Nef-negative autoantibodies. The assay expands the scope of current Nef evaluation by removing the requirement of complement regulator proteins in the kinetic analysis and provides valuable kinetic information for evaluating complement dysregulation in Nef-positive C3G patients regardless of regulator sensitivity.

Establishment of a Human Hybridoma Cell Line That Produces IgG Autoantibody Involved in the Pathogenesis of IgA Nephropathy

Tzu Yu Liu,[1] Ann Chen,[2,3] Shuk-Man Ka.[4] *[1]Graduate Institute of Life sciences, Department of Medicine, National Defense Medical Center, Taipei, Taiwan; [2]Taiwan Autoantibody Biobank Initiative, Hualien Tzu Chi Hospital, Hualien, Taiwan; [3]Department of Anatomical Pathology, Hualien Tzu Chi Medical Foundation, Hualien, Taiwan; [4]Graduate Institute of Aerospace and Undersea Medicine, Department of Medicine, National Defense Medical Center, Taipei, Taiwan.*

Background: IgA nephropathy (IgAN) is an autoimmune disease, also the most common primary glomerulonephritis. Because the pathogenesis underlying IgAN remains largely known, there is still a lack of disease-specific and effective treatment for the renal disease. Recently, there is a key issue in the pathophysiology of galactose deficiency of *O*-glycans on the hinge region of IgA1, which has been considered as a main autoantigen (auto-Ag) involved in the development and progression of IgAN. However, the mechanistic pathways, including: **(1)** resultant production of IgG autoantibody (auto-Ab) against the galactose-deficient IgA1 (Gd-IgA1) auto-Ag triggered by the a auto-Ag; **(2)** subsequent formation of IgG-IgA1 immune complexes (ICs) and their potential in pathogenicity and clinical implications as well as **(3)** the property of the deposition of the ICs in the microenvironment of the glomeruli, in terms of the levels of intensity and distribution, are warranted further investigation.

Methods: To this end, our lab has successfully established exclusively a human hybridoma production platform suitable for preparing human IgG auto-Ab against Gd-IgA1 auto-Ag and the latter proteins. This strategy and the platform rendered a tremendous advantage for us to unravel the pathogenesis involving human IgG auto-Abs and IgA1 auto-Ags in this autoimmune disease towards the understanding of the immune and molecular pathogenesis of IgAN and further translational and clinical research topics. Our preliminary results show that using a SPYMEG human partner cell system and peripheral blood mononuclear cells from IgAN patients.

Results: We first time developed three human hybridoma cell lines from a single (the same) patient with IgAN namely Teddy71 (IgG auto-Ab) and 71D2 and 71C6 (two different IgA1 auto-Ags). In human macrophages and renal mesangial cells, the ICs formed by the human IgG auto-Ab with either of the two distinct human Gd-IgA1 auto-Ags clearly stimulated these cells to produce IL-1β, TNF-α, and IL-6 in significantly different levels, suggesting the nature of auto-Ags itself may also play a key role in resultant inflammatory responses in IgAN.

Conclusions: In consistence with these effects, the ICs containing human IgG auto-Ab and individual IgA1 auto-Ags was able to activate common pathway of complement system *in vitro*.

Ex Vivo Kidney Perfusion as a Model for Recurrent Focal Segmental Glomerulosclerosis

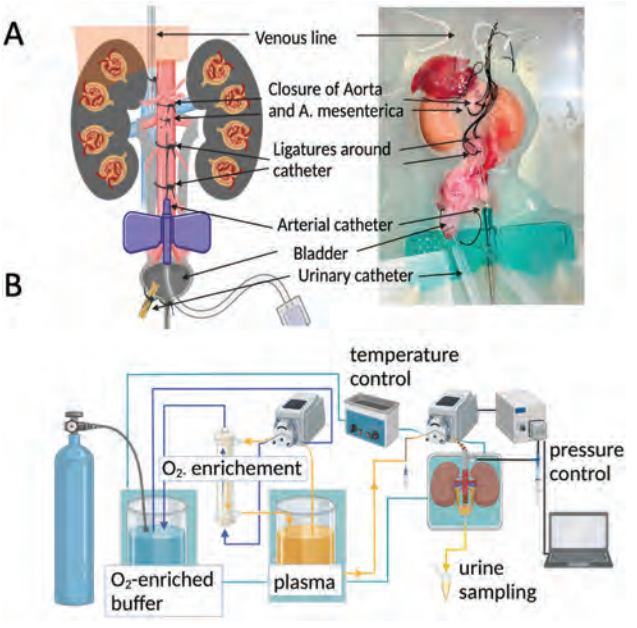
Anne K. Muehlig,[1,2] Fabian Braun,[1,2] Paula F. Rischke,[1] Jun Oh,[1] Sonja Haenzelmann,[3] Manuela Poets,[3] Madelaine Wingerath,[1] Inka C. Homeyer,[1] Oliver Kretz,[1,2] Victor G. Puelles,[1,2] Jan Czogalla,[1,2] Tobias B. Huber.[1,2] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Hamburg Center for Kidney Health, Hamburg, Germany; [3]Universitatsklinikum Hamburg-Eppendorf Zentrum fur Molekulare Neurobiologie Hamburg, Hamburg, Germany.*

Background: Primary focal segmental glomerulosclerosis (FSGS) recurs in about 40%, indicative of a yet unidentified circulating factor. Recently, we detected several novel pathways in an *in vitro* model of podocytes incubated with recurrent (r)FSGS patient sera. To characterize their importance under conditions of intact glomerular integrity, we used *ex vivo* perfusion of mouse kidneys with plasma from rFSGS-patients.

Methods: Kidneys of transgenic podocyte-reporter mice were perfused with plasma from 5 different rFSGS patients and 3 controls (fig 1) (n=20). The glomerular physiology, ultrastructure, protein- and mRNA expression were analyzed using urinanalysis, immunofluorescence, electron microscopy and mRNA bulk sequencing of isolated glomeruli.

Results: Perfusion with rFSGS plasma resulted in an impairment of the filtration barrier, foot process effacement, downregulation of the podocyte marker synaptopodin, remodeling of podocytes and detection of human albumin in the urine of perfused kidneys. mRNA bulk sequencing of glomeruli revealed 802 differentially regulated genes. In rFSGS plasma perfused kidneys integrin b1 and fibronectin were both strongly regulated in the same direction as in rFSGS serum-incubated podocytes in our previous experiments.

Conclusions: *Ex vivo* perfusion with rFSGS plasma resulted in a disruption of the glomerular filtration barrier and was able to recapitulate our previous *in vitro* findings. This study validates ex vivo perfusion of mouse kidneys with human plasma as a model to study rFSGS in the intact cellular architecture. This model represents a valuable tool to identify and target new FSGS pathomechanisms.



Isolated perfused mouse kidneys (A) and perfusion set up (B)

Functional Impact of COL4A3/4A4 Variants in Patients with Nephrotic Syndrome

Jennifer Lai Yee,[1] Veronica Glaser,[1] Damian Fermin,[1] Michelle N. Rheault,[2] Alessia Fornoni,[3] Jacob O. Kitzman.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Minnesota Medical School, Minneapolis, MN; [3]University of Miami, Coral Gables, FL.*

Background: The increasing prevalence of genetic testing in patients with kidney disease has led to the frequent identification of variants in *COL4A3/4A4*, which are vital components of the kidney's glomerular basement membrane. However, the diverse clinical manifestations of these variants remain poorly understood, and the lack of specific functional assays hampers the assignment of variant pathogenicity. We aim to investigate the functionality of *COL4A3/4* in a cell-based collagen trimerization assay and study its impact on disease in a longitudinal observational cohort with nephrotic syndrome (NEPTUNE).

Methods: Patients with a heterozygous *COL4A3/4* variant (n=32 heterozygous, n=1 homozygous) have been identified in the NEPTUNE cohort. We employed an established split luciferase assay to test trimerization (intracellular signal) and secretory effect (extracellular signal) of these variants. We created several known pathogenic, benign, and rare *COL4A3/4* variants found in NEPTUNE and cloned them into the corresponding expression constructs. Intracellular and extracellular NanoLuc luciferase activity was then measured in 293T cells. Finally, we compared these in vitro functional activities with the clinical outcomes of the patients by a descriptive analysis.

Results: Low luciferase activity, either intracellularly or extracellularly, corresponded well to the expression constructs bearing the known pathogenic variants. 3 patients' *COL4A3* variants were successfully cloned and suggested to have a trimerization defect (N=1), secretory defect (N=1), and mild abnormality (N=1 with *APOL1* high-risk genotype) based on intracellular and extracellular luciferase activity. The patient with a variant of trimerization defect had a kidney biopsy showing Alport findings. Both patients with a variant of secretory defect and mild abnormality were pediatric patients with progressive kidney disease (eGFR < 60 at baseline or a 40% loss of eGFR during follow-up).

Conclusions: These findings underscore the potential of the split luciferase assay as an effective functional assay for distinguishing benign and pathogenic *COL4A* variants. This paves the way for future development of the split luciferase as a clinical test to inform the variant pathogenicity and prognosis, and can enable more precise disease classification to foster further research development in NEPTUNE.

TH-PO580

Systematic Classification of WT1 Zinc Finger Missense Mutations Using Multiplex Assays of Variant Effect (MAVEs)

Jennifer Lai Yee, Veronica Glaser, Jacob O. Kitzman. *University of Michigan, Ann Arbor, MI.*

Background: Patients with Mendelian nephrotic syndrome (NS) face a high risk of progressing to end-stage kidney disease. Genetic screening is increasingly accessible and can guide clinical decisions. However, it remains challenging to accurately class variant's pathogenicity. MAVEs are a new category of functional assay that can be applied to many variants at one time in a pooled fashion. Here we apply MAVEs to systematically and prospectively test variants in the zinc finger domains of *WT1*, one of the most common genes underyling Mendelian NS.

Methods: We derived clonal *WT*1 knockout (KO) cell lines from KBM7, a myeloid leukemia cell line that normally expresses *WT1*. We then synthesized a saturation mutagenesis library for *WT1* cDNA, encompasing every possible missense mutation across three zinc-finger motifs (exons 7-9, n=1028 mutations). This library was stably integrated into KBM7 *WT1* KO cells using a lentiviral indcuble expression construct, such that each cell expresses a different *WT1* variant. Because *WT1* loss of function is growth-promoting in KBM7 cells, we performed serial outgrowth of the *WT1* library population for four passages to enrich for loss-of-function mutatinos. We then deeply sequenced the *WT1* library from cells at passage 4 v.s. baseline, and calculated an enrichment score of each mutation.

Results: We observed perfect separation between nonsense and synonymous mutations in functional scores. Missense variants were nearly all deleterious to some extent (89%), with nearly a third of these being equivalently deleterious to a nonsense variant, indicating a strong constraint against coding variation in this key DNA-binding domain. Nevertheless, some mutations have relatively mild effects, especially R435Q, which is also present in apparently unaffected individuals in the general population. Mutations at essential residues that coordinate Zn^{2+} ions were particularly deleterious, comparable to truncating mutations.

Conclusions: The completion of a variant-to-effect map for this region validates the feasibility of extending this approach to the full *WT1* protein. The maps will serve as a freely available 'lookup table' of functional evidence to support the clinical interpretation of newly encountered variants. This approach can improve the accuracy of genetic diagnosis for NS and remove one barrier to future genotype-guided therapies.

TH-PO581

Ex Vivo-Derived Human-Induced Pluripotent Stem Cell (hiPSC) Podocytes from a Patient with Genetic Focal Segmental Glomerulosclerosis with an INF2 Mutation

Victoria Rose, Denise Fink, René Krüger, Johannes Schödel, Mario Schiffer, Janina Müller-Deile. *Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.*

Background: Genetic focal segmental glomerulosclerosis (FSGS) is caused by mutations in podocyte genes related to slit diaphragm formation, actin cytoskeleton or cellular adhesion but knowledge on the consequences of these mutations is limited. Usually genetic FSGS is not responsive to immunosuppression even though partial responses have been documented in some mutations most likely due to direct effects of these agents on podocytes themselves. Patient-specific podocyte models that carry the patient's mutation might help to further characterize the diseased podocyte phenotype and test response to potential treatment options *ex vivo*.

Methods: Human induced pluripotent stem cell (hiPSC)-derived podocytes (hiPSC-Podocytes) were generated by reprogramming dermal fibroblasts, obtained from a human skin punch biopsy, into hiPSCs with subsequent differentiation into podocyte cell type. Healthy donor-derived hiPSC-Podocytes were compared to commonly used conditionally immortalized (ciPodocytes) by bulk RNA sequencing and electron microscopy. Patient-specific hiPSC-Podocytes holding an inverted formin 2 (INF2) mutation were used to assess phenotypical and functional alterations in a personalized manner *ex vivo*.

Results: Compared to ciPodocytes, hiPSC-Podocytes had a higher developed phenotype with better podocyte marker expression, and foot processes. Patient-specific hiPSC-Podocytes showed unbranched and shorter protrusions, loss of podocyte-specific marker and decreased levels of filamentous actin. Furthermore, an increased actin depolymerization rate, altered INF2 cleavage, and other compensatory mechanisms were identified. First treatment experiments with immunosuppressive drugs and actin-modulating agents resulted in improvement of filamentous actin in patient-specific INF2 mutated hiPSC-Podocytes.

Conclusions: Using a patient-specific hiPSC-based model enables investigation of the patient-specific diseased phenotype and response to treatment *in vitro* and allows further studies of podocyte mutations. This will provide valuable insights into patho-mechanisms and may help identify individualized therapeutic strategies. Moreover, patient-derived hiPSCs allow to create patient-specific 3D kidney organoids to study multi-cellular and -structural differences.

Investigating Organoid Characteristics of CoQ10-Deficient Glomerulopathy

Seyoung Yu,[1] Friedhelm Hildebrandt,[2] Heon Yung Gee.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Boston Children's Hospital, Boston, MA.*

Background: Monogenic causes account for 11-30% of steroid-resistant nephrotic syndrome (SRNS) cases in children. Genes involved in the biosynthesis of coenzyme Q_{10} (CoQ_{10}), such as PDSS2, COQ2, COQ6, and ADCK4, are known to cause SRNS and focal segmental glomerulosclerosis (FSGS). CoQ_{10}, located in the mitochondrial inner membrane, is crucial for supporting the electron transport chain in oxidative phosphorylation and for protecting against oxidative stress. While CoQ_{10}-deficient glomerulopathy can be partially treated with CoQ_{10} supplements, the effectiveness of this treatment varies and has limitations. We developed an in vitro model system of CoQ_{10}-deficient glomerulopathies to study drug effects through detailed manipulations, which facilitates a better understanding of the disease and the creation of more effective treatments

Methods: We generated CoQ_{10}-deficient kidney organoids from human induced pluripotent stem cells (iPSCs) using the well-established in vitro induction protocol. To establish CoQ_{10}-deficient human iPSCs, we used synthetically generated gRNAs targeting PDSS2, COQ2, COQ6, ADCK4 along with Cas9 protein. We performed immunostaining and light microscopy analysis to evaluate the extent of their differentiation. We also observed mitochondrial morphology to investigate the phenotypic characteristics due to CoQ_{10} deficiency.

Results: Gene ablation of CoQ_{10}-deficient iPSCs was confirmed through Sanger sequencing. CoQ_{10}-deficient kidney organoids expressed positive kidney markers and successfully differentiated into nephrons. To model glomerulopathy in these organoids, we verified the expression of podocyte markers and confirmed their development using electron microscopy. The podocytes displayed primary processes and cell-cell junctions, resembling the early stages of foot process formation. There were no significant differences in podocyte development between control and CoQ_{10}-deficient kidney organoids. However, examining the ultrastructure of podocytes in CoQ_{10}-deficient kidney organoids revealed abnormal mitochondria, characterized by hyperproliferation and increased size.

Conclusions: In conclusion, we have generated a model of CoQ_{10}-deficient glomerulopathy using kidney organoids, demonstrating abnormal mitochondrial phenotypes. This system provides a valuable platform for testing potential drug therapies and advancing treatment options for this condition.

Comparative Analysis of Human Primary Mesangial Cell Clones: Implications for Experimental Design

Kerstin Ebefors, Alva Johansson, Gayathri Narasimhan, Jenny C. Nystrom. *Goteborgs universitet Sahlgrenska Akademin, Gothenburg, Sweden.*

Background: Mesangial cells (MCs) not only form the central stalk of the glomerulus but are of importance for glomerular cross talk and function. The MCs are central in several glomerular diseases such as IgA nephropathy and diabetic kidney disease and are often used in vitro to reveal molecular mechanisms of onset and progression. Human primary MCs (HMCs) are considered the best option for in vitro studies, but over the years we have observed that there are differences between HMCs from different suppliers (and hence donors) in their phenotype and response to stimuli and/or treatment

Methods: Commercially available HMCs from two different suppliers were cultured and characterized by their expression of mesangial markers (qPCR, western blot, immunofluorescence, mass spectrometry), response to PDGF-BB (proliferation assay, mass spectrometry) and angiotensin 2 (contractility assay). In addition to the commonly used MC markers we put together a list of 144 MC markers, compiled based on 12 recent articles containing omics data, and these markers were used combination with the proteomic data set.

Results: Both clones (HMCv1 and HMCv2) expressed the common MC markers and in the proteomic data set, 70 out of the 144 MC markers were found for both. HMCv1 and 2 and responded with increased proliferation in response to stimulation with PDGF-BB. HMCv1 contracted significantly in response to angiotensin 2, but not HMCv2. Proteomic analysis of HMCv1 and 2 after stimulation with PDGF-BB revealed that HMCv1 was much more responsive than HMCv2 in terms of more differentially regulated proteins and pathways.

Conclusions: In conclusion, we found that there were similarities as well as differences between the two clones of HMCs. Both HMCv1 and HMCv2 behaved as MCs in that they expressed the major MC markers and responded to PDGF-BB stimulation. However, HMCv1 was much more responsive to stimulation with PDGF-BB and angiotensin 2 than HMCv2. These differences could have a major impact on the outcome of experiments performed using these cells, and therefore we suggest to carefully examine the response of the chosen HMC clone to relevant stimulants before conducting experiments on HMCs. In addition, out of our list of 144 MC markers, the clones were found to express 70 and we suggest that these markers can be used as a signature for MCs.

Discovery of Epigenetic Substances for the Treatment of FSGS Using Zebrafish Larvae as an In Vivo Model

Nicole Endlich, Maximilian Schindler. *Universitatsmedizin Greifswald, Greifswald, Germany*.

Background: Podocytes are essential cells of the glomerulus that maintain the size selectivity of the glomerular filtration barrier. Injury to these postmitotic cells is a major cause of FSGS often resulting in end-stage kidney disease. To date, no specific drugs or compounds have been discovered to protect podocytes, underscoring the significant unmet need for drug development. Our group recently established a high-content *in vivo* screening assay to discover potential drugs and compounds to treat FSGS. For this purpose, we used zebrafish larvae that develop a filtering glomerulus within 4 days and we analyzed the effect of epigenetic substances after the induction of FSGS.

Methods: A transgenic zebrafish screening strain expresses the bacterial enzyme nitroreductase as well as the fluorophore mCherry exclusively in podocytes. Furthermore, the expression of a circulating 78 kDa vitamin-D-binding fusion protein with eGFP provides a readout for the integrity of the glomerular filtration barrier in the vasculature. Addition of the prodrug Nifurpirinol (NFP) to the water results in a specific podocyte injury, a loss of mCherry in the glomerulus and a decreased eGFP fluorescence between 4 and 6 days post fertilization (dpf). After 6 dpf, larvae develop proteinuric edema and classical hallmarks of FSGS due to podocyte injury. These readouts were utilized in a rapid, imaging-based screening of an epigenetic drug library as reported in Schindler et al. 2023. Drugs and compounds that prevent a loss of fluorescence or the development of edema were further validated.

Results: The screening of epigenetic drugs revealed that PTACH as well as the substances MN876 and MN119 showed a high potency to alleviate larval FSGS and exhibited a prolonged protective effect on podocytes.

Conclusions: We have identified three promising new drugs/compounds for the treatment of FSGS in zebrafish larvae that are currently under validation in mammalian FSGS models.

Glomerular Disease Caused by Vinyl Carbamate in A/J Inbred Mice: A Novel Model of Membranoproliferative Glomerulonephritis (MPGN)

Athena Y. Gong,[1,2] Lance D. Dworkin,[2] William T. Gunning,[2] Mengxuan Chen.[2] *[1]University of Michigan, Ann Arbor, MI; [2]The University of Toledo Medical Center, Toledo, OH.*

Background: Ethyl carbamate (EC) is a process contaminant in fermented foods and alcoholic beverages. Metabolic conversion of EC generates vinyl carbamate (VC), a carcinogenic metabolite. EC, as a Group 2A probable human carcinogen, and the more potent VC, are known to cause tumors in rodents. However, their effects on the kidney are unknown.

Methods: A/J inbred mice received a single i.p. injection of VC (60 mg/kg). Kidney injury was evaluated. A *post hoc* analysis was performed on a publicly available RNA-Seq transcriptome of kidneys derived from rats treated with fermented wine containing high concentrations of EC.

Results: Beginning 5 weeks post VC injection, mice showed signs of moribund state and were killed. By 12 weeks, a total of 97 of the 240 treated mice had died or were killed. Necropsies of mice revealed evident renal disease, characterized by glomerular lobularization, mesangial hypercellularity and expansion, endocapillary proliferation, and capillary wall thickening by light microscopy. Electron microscopy revealed subendothelial electron-dense deposits, formation of new basement membrane between the interposed cell and endothelium, and extensive podocyte foot process effacement. On immunofluorescent staining, abundant granular mesangial C3 staining was noted along with coarse linear capillary staining, whilst immunoglobulin staining was negative. These changes were highly reminiscent of the pathology of MPGN. In addition, Kyoto Encyclopedia of Genes and Genomes pathway enrichment analyses were performed on differentially expressed genes between high EC-treated and control rats, and showed that complement and coagulation cascades are top predicted biological processes implicated. Furthermore, pathway-based data integration and visualization using Pathview demonstrated that key regulators of complement activation pathways were altered by high EC treatment. Among these, complement factor (CF) D and H, critical positive and negative regulators of the alternative pathway, respectively, were the most affected, with CFD induced by 3.49-fold and CFH repressed by 5.88-fold, underscoring a hyperactive alternative pathway.

Conclusions: VC, a metabolite of EC, induces complement fixation in glomeruli and MPGN in mice. Complement overactivation due to CFD induction and CFH repression may be an underlying pathomechanism.

TH-PO586

Belimumab and Rituximab for the Treatment of Primary Membranous Nephropathy: Initial REBOOT Results

Patrick H. Nachman,[1] Lia Stelzig,[2] Matthew A. Sherman,[3] William T. Barry,[2] Sharon Chung.[4] On behalf of the REBOOT Study Investigators. *[1]University of Minnesota Medical School, Minneapolis, MN; [2]Rho Inc., Durham, NC; [3]National Institute of Allergy and Infectious Diseases, Bethesda, MD; [4]University of California San Francisco, San Francisco, CA.*

Background: Primary membranous nephropathy (PMN) is caused by glomerular immune complex deposition, and 70% of patients produce anti-phospholipase A_2 receptor (PLA_2R) autoantibodies. We hypothesize that treatment with belimumab (BEL) and rituximab (RTX) will enhance memory B cell depletion, curb the re-emergence of autoreactive B cells, and lead to better clinical responses compared to RTX alone.

Methods: REBOOT (NCT03949855) is a two-part, phase 2, multicenter, clinical trial examining the effectiveness of BEL with RTX for the treatment of PMN. Participants (18-75 years) must have detectable serum anti-PLA2R and proteinuria ≥ 4 g/d. Part A is a single arm, open-label, pharmacokinetic study, where all participants receive BEL 200 mg weekly for 52 weeks and RTX 1000 mg at weeks 4 and 6. Participants are followed for complete (CR, proteinuria ≤ 0.3 g/d with serum albumin ≥ 3.5 g/dL) or partial remission (PR, proteinuria < 3.5 g/d with ≥50% reduction from baseline) to week 156. We present the initial clinical results for Part A.

Results: 17 participants (mean age 56 years) started BEL and RTX; 5 stopped BEL prior to week 52 (COVID-19 [n=2]; infection, mood swings, worsening kidney function [1 each]). 9 participants have completed BEL and reached week 104 so far. Table 1 presents baseline characteristics and clinical outcomes. 89% (8/9) achieved CR or PR by week 104. The proteinuria decline, anti-PLA_2R reduction, and serum albumin normalization persisted for 1 year after stopping BEL without additional RTX or other immunotherapy.

Conclusions: A large proportion of evaluable participants have attained PR or CR with BEL and RTX so far. A rapid decline in anti-PLA2R and normalization of serum albumin also occurs. Part A followup continues, and Part B, a randomized, double-blind, placebo-controlled trial comparing BEL with RTX to RTX alone, is enrolling to assess the effectiveness of this treatment strategy.

Funding: Other NIH Support - REBOOT is conducted by the Immune Tolerance Network, which is supported by the National Institute of Allergy and Infectious Diseases (UM1-AI-109565), Commercial Support - Belimumab was provided by GSK plc.

Clinical Outcomes for REBOOT Part A.

Timepoint (# evaluable participants)	Baseline (n=17)	Week 24 (n=13)	Week 52 (n=12)	Week 104 (n=9)
CR or PR (% achieved)	0	23	67	89
Anti-PLA_2R (% detectable)	100	15	17	0
Proteinuria (g/d), median (interquartile range)	11.2 (8.2-16.7)	5.5 (3.7-9.3)	2.1 (1.1-4.9)	1.0 (0.5-2.7)
Serum albumin (g/dL), median (interquartile range)	2.6 (2.3-2.9)	3.6 (3.3-3.7)	4.1 (3.8-4.3)	4.3 (4.2-4.5)
Serum creatinine (mg/dL), mean (standard deviation)	1.2 (0.3)	1.3 (0.4)	1.1 (0.4)	1.2 (0.2)

Anti-PLA2R = anti-phospholipase A2 receptor autoantibody, CR = complete remission, PR = partial remission

TH-PO587

A Phase 1b, Single-Arm, Open-Label Study of Budoprutug, an Anti-CD19 Monoclonal Antibody with Enhanced Antibody-Dependent Cell-Mediated Cytotoxicity (ADCC), in Primary Membranous Nephropathy

Frank B. Cortazar,[1] William Bonificio,[2] Naveen Daryani,[2] Stephen B. Thomas.[2] *[1]New York Nephrology, Vasculitis and Glomerular Center, Albany, NY; [2]Tenet Medicines, Scotch Plains, NJ.*

Background: Membranous nephropathy (MN) is characterized by a histologic pattern of injury caused by autoantibodies directed against podocyte antigens. Targeting B lymphocytes with anti-CD20 monoclonal antibodies has become a preferred therapy for primary MN, but this strategy fails to induce complete remission (CR) in most patients. Budoprutug is an anti-CD19 monoclonal antibody with a broader spectrum of B-cell depletion, including activity against CD19-positive plasmablasts and plasma cells. Here, we present the results of a Phase 1b, open label, dose escalation study of budoprutug in patients with primary MN.

Methods: Eligible patients had primary MN with a history of nephrotic syndrome, received maximally tolerated therapy with a renin-angiotensin system inhibitor for 6 months, and had a urine protein to creatinine ratio (UPCR) of > 2 g/g on two measurements during screening. Budoprutug was administered as 2 bi-weekly doses of 100 or 200 mg six months apart on Days 1,15,169, and 183. The primary objective was safety. Secondary objectives included B-cell levels, anti-phospholipase A2 receptor (anti-PLA2R) antibody (Ab) levels, and changes in proteinuria. The analysis was restricted to patients with at least 48 weeks of follow-up.

Results: Five patients met inclusion criteria, 3 of which were PLA2R Ab positive. All patients achieved complete B cell depletion, with 2 patients reconstituting B-cells before Week 24. Serologic remission was achieved in all anti-PLA2R Ab positive patients over a range of 5 to 18 weeks. Median baseline proteinuria was 4.2 g/g. Three patients achieved complete remission (UPCR ≤ 0.3 g/g, range, 40 to 48 weeks), with a fourth patient achieving a UPCR of 0.33 at week 48. All patients achieved a UPCR < 1 g/g and partial remission. Two patients with 72 week follow up achieved durable CRs ~18 months from initial dosing. Budoprutug was well tolerated with no drug-related serious or Grade ≥3 adverse events.

Conclusions: Treatment with budoprutug resulted in high rates of serologic and clinical remission, suggesting that CD19-targeted B-cell depletion may be a promising approach to the treatment of primary MN. These findings warrant larger studies to confirm the efficacy of budoprutug in MN.

TH-PO588

Randomized Controlled Trial Comparing Rituximab to Mycophenolate Mofetil in Children and Young Adults with Steroid-Dependent Idiopathic Nephrotic Syndrome

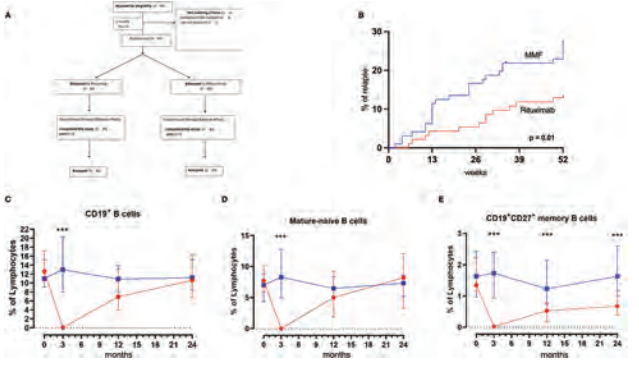
Andrea Angeletti,[1] Gianluca Caridi,[1] Francesca Lugani,[1] Marina Vivarelli,[2] Francesco Emma,[2] Gian Marco Ghiggeri,[1] Manuela Colucci,[2] Antonio Gargiulo,[2] Paolo Cravedi.[3] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Ospedale Pediatrico Bambino Gesu, Roma, Italy; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Steroids induce remission in 90% of children with idiopathic nephrotic syndrome (INS). Some become steroid-dependent (SD) and require the addition of drugs such as calcineurin-inhibitors (CNI), to maintain remission. Considering the toxicity of these drugs, alternative interventions are needed. The anti-CD20 antibody rituximab was effective as a steroid-sparing agent. Mycophenolate mofetil (MMF) is effective in maintaining free-steroid remission, however, studies are limited to a few uncontrolled trials with different doses of MMF.

Methods: This open-label, two-parallel-arm, multi-center, superiority-controlled randomized clinical trial will enroll children with SD-INS maintained in remission with oral glucocorticoids or CNI. Subjects will be randomized to either MMF (1.200 mg/m2) or rituximab (375 mg/m2) infusion. Glucocorticoids will be tapered until complete withdrawal. The primary end-point is to detect as significant at the two-sided p-value of 0.01 with a power >0.8 a reduction in the risk of 1-year relapse. In a sub-cohort of 39 patients (rituximab, n=19; MMF, n=20), we characterized the circulating levels of the B-cell subsets by flow cytometry.

Results: We randomized 160 children and young adults (aged 2–24 years) (**Fig1A**). At 1 year, 12 of 80 (15%) participants who received rituximab experienced relapse versus 30 of 80 (37%) who received rituximab (odds ratio [OR], 2.27; 95% confidence interval [95% CI], 1.20 to 4.29) (**Fig1B**). As expected, there were no significant differences in B-cell subsets between the two arms at baseline. MMF treatment had no significant effect on B cells, while RTX depleted all B-cell subsets. By 1yr, total, transitional and mature-naïve B cells were restored to levels similar to the MMF arm (**Fig.1A-B-C**).

Conclusions: A single dose of rituximab was superior to a single MMF in maintaining remission in children with steroid-dependent and CNI–dependent nephrotic syndrome.



TH-PO589

Updated Results with Povetacicept, an Enhanced Dual BAFF/APRIL Antagonist, in Primary Membranous Nephropathy (RUBY-3 Study)

Arvind Madan,[1] Rajesh Yalavarthy,[2] Dong Ki Kim,[3] Ju young Moon,[4] Inwhee Park,[5] Sreedhar A. Mandayam,[6] Frank B. Cortazar,[7] Sung Gyun Kim,[8] Rupert H. Davies,[9] Amanda M. Enstrom,[9] Heather Thomas,[9] Jiahua Li,[9] Stanford L. Peng,[9] James A. Tumlin.[10,11] *[1]Central Florida Kidney Specialists, Orlando, FL; [2]Western Nephrology, Arvada, CO; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [5]Ajou University School of Medicine, Suwon-Si, Gyeonggi-do, Republic of Korea; [6]The University of Texas MD Anderson Cancer Center, Houston, TX; [7]New York Nephrology Vasculitis and Glomerular Center, Albany, NY; [8]Hallym University Sacred Heart Hospital, Anyang-Si, Gyeonggi-do, Republic of Korea; [9]Alpine Immune Sciences, Inc., Seattle, WA; [10]NephroNet Clinical Trials Consortium, Atlanta, GA; [11]Emory University School of Medicine, Atlanta, GA.*

Background: Inhibition of BAFF and/or APRIL has shown promise in IgA nephropathy (IgAN), lupus, lupus nephritis (LN), and primary membranous nephropathy (pMN), and has the potential to exert a disease-modifying effect. Povetacicept (ALPN-303) is an Fc fusion protein of a variant TACI domain engineered for more potent dual BAFF/APRIL inhibition vs WT TACI or anti-BAFF/-APRIL antibodies. Povetacicept has been associated with on-target reductions in Ig levels and antibody-secreting cells in healthy volunteers. In an initial case report of pMN from the ongoing RUBY-3 study of povetacicept (NCT05732402), immunological remission was achieved at 22 wk, with anti-PLA2R1 levels reduced to below the limit of detection (Tumlin J, et al. Poster TH-PO1125 presented at ASN 2023).

Methods: RUBY-3 is an open-label, multiple ascending dose, ph 1b/2a study of povetacicept 80 or 240 mg SC Q4W for 24 wk, followed by a 28-wk extension; participants meeting prespecified criteria at 48 wk may enter an optional 52-wk extension. Eligible participants are aged ≥18 y with IgAN, pMN, LN, or ANCA-associated vasculitis (biopsy-confirmed diagnosis required for IgAN, pMN, and LN). Participants must be on maximally tolerated ACEi/ARB therapy, with well-controlled BP, and disease-specific immunosuppressive therapy where applicable. Primary objective is safety; secondary objectives include PK, PD, immunogenicity, biomarkers, and efficacy.

Results: As of 1 Mar 2024, 3 participants with pMN have enrolled at the povetacicept dose level of 80 mg SC Q4W; 1 has completed ≥40 wk and 2 have completed <4 wk. Povetacicept has been well tolerated with multiple dosing, with no serious or severe adverse events. In the participant with the longest follow-up, significant reduction in anti-PLA2R1 has continued to be observed following achievement of immunological remission at 22 wk, with levels remaining below the limit of detection. Updated safety, efficacy, PK, and PD findings will be reported at the time of presentation.

Conclusions: In these initial findings, povetacicept demonstrates promising activity in pMN, strongly supporting its further development in autoantibody-associated glomerulonephritis.

CD19 Repopulation and Anti-phospholipase A2 Receptor (PLA2R) following Rituximab in Membranous Nephropathy

Durga Anil K Kanigicherla, Patrick Hamilton, Meshaal M. Shukkur, May K. Thet, Omar S. Ragy. *Manchester Institute of Nephrology and Transplantation, Manchester, United Kingdom.*

Background: Rituximab is used for treatment in PMN. However, remission rates remain modest, and optimal dosing remains uncertain.

Methods: 29 consecutive patients were followed prospectively after rituximab treatment. Clinical markers, Anti-PLA2R, CD19 count (cells/μL) were analysed at 1-week, 2-3-week, 4-6-week, 2-3-month, 4-6-month, 8-10-month, and 12-month.

Results: Features and outcomes are in Table. Remission at 1-year was seen in 15 (52%) patients. All patients had CD19 depletion (<5) between 1-3 weeks. CD19 reconstitution was seen in 6% patients at 4-6 weeks, 25% at 2-3 months, and 60% at 4-6 months. Anti-PLA2R levels reduced at 3 months from baseline but remained at similar level until 12 months. There was significant correlation between CD19 and anti-PLA2R (R=0.89, p= 0.075). Notably, CD19 repopulation preceded rise in anti-PLA2R.

Conclusions: Following rituximab treatment, CD19 levels correlate with anti-PLA2R, repopulation occurs in majority of patients by 4-6 months, and precedes emergence of antiPLA2R. This may explain the modest remission rates in PMN with rituximab and additional dosing at 4-6 months may improve remission.

A Comparative Analysis of Efficacy of Rituximab in Patients with Primary Membranous Nephropathy

Qianwei Zhang, Liyi Xie. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: The efficacy of rituximab in patients with primary membranous nephropathy(PMN) has been confirmed. The study was conducted to analyze the efficacy of rituximab in PMN patients by comparing with supportive and immunotherapy therapy. The optimal treatment strategies for membranous nephropathy were proposed.

Methods: Patients diagnosed with PMN by clinical manifestations of nephrotic syndrome and began initial treatment were divided into four treatment groups: rituximab(RTX); low-dose glucocorticoid with tacrolimus or cyclophosphamide (CTX);supportive treatment. Collecte the data consecutively for 30 months to conduct a single-center retrospective study.

Results: 161 patients underwent the study totally, 93 were male(57.76%) and 68 were female(42.24%). The mean age was 50.50 years old. The mean follow-up time was 17.61 months. The main pathologic types were stage I-II of MN(71.4%). The PLA_2R positive rate in kidney tissue was 78.9%, and it was 62.66% in serum (defined as the PLA_2R titer<20RU/ml). There were no significant differences in age, sex, baseline UTP and eGFR among the four groups(P>0.05). Compared with supportive treatment, remissionin of immunotherapy groups occurred earlier. The decline rate of UTP in the rituximab group was higher than tacrolimus group from 6 months, and the difference was significant at 30 month(μ_{RTX}=91.52%,$\mu_{tacrolimus}$=75.52%,P<0.001). At 12 month and before, the increase rate of ALB was higher in the tacrolimus group. It had a significant difference in the two group at 18 month(μRTX=87.96%,$\mu_{tacrolimus}$=66.98%,P<0.05). The decline rate of UTP in RTX group was lower than that in CTX group at 12 month and before. After 12 month, it was gradually higher in RTX group and showed a significant difference at 24 month(μ_{RTX}=93.45%,μ_{CTX}=64.48%,P<0.001). After 18 month, the eGFR in RTX group decreased by 0.63 ml/min.1.73m^2 compared with baseline data, while it decreased by 8.85, 7.78, 8.55 ml/min.1.73m^2 in tacrolimus, CTX, supportive group respectively.

Conclusions: Rituximab and tacrolimus, cyclophosphamide were all eutherapeutic. Tacrolimus group has better adherence. The efficacy of rituximab had no significant different with other regiments in short term, but the long-term efficacy was better and the kidney function was better protected. In addition, the incidence of adverse events was lower. Therefore, rituximab can be considered as one of the first options for the treatment of the PMN.

TH-PO592

Long-Term Outcome of Adult Patients with Membranous Nephropathy Treated with Rituximab

Maria Jose Vargas-Brochero,[1] Yeshwanter Radhakrishnan,[1] Elisabeth P. Lafaut,[2] Nancy Daniela Valencia-Morales,[1] Miriam Machado,[1] Ladan Zand,[1] Sanjeev Sethi,[1] Maria Jose Soler,[3] Fernando C. Fervenza.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Universiteit Gent Faculteit Geneeskunde en Gezondheidswetenschappen, Gent, Belgium; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: Rituximab (RTX) has become the cornerstone treatment of membranous nephropathy (MN). However, data on hard outcome such as eGFR and progression to end-stage kidney disease (ESKD) are lacking.

Methods: Retrospective cohort study was conducted on MN patients and treated with RTX from January 2000 through December 2022. Clinical outcome were complete remission (CR) [proteinuria ≤0.3 g/24h and serum albumin ≥3.5 g/dl], partial remission (PR)[baseline proteinuria reduction≥50% and proteinuria ≤3.5 g/24h], reduction proteinuria (RP)[baselineproteinuria reduction≥50%], and development of ESKD. Immunological remission (IR) was defined as negative serum PLA2R-Ab.

Results: 90 patients included, 72(80%) were male, and 81(90%) white, with a mean (SD) age of 56.5(14.2) years at RTX initiation. Previous immunosuppression used in 45(50%). Baseline median[IQR]serum creatinine was 1.4 mg/dl [1.09-1.90], albumin 2.8 g/dl [2.2-3.4], and proteinuria 9 g/24h [6.2-11.2]. Nephrotic syndrome was present in 78.9%(71) patients. PLA2R Ab status in serum and/or kidney biopsy was available in 80 (88.9%) and positive in 61 (76.3%) patients. Mean (SE) survival was 17(0.72) years. 87 patients reached clinical response (CR, PR or RP) after a median [IQR] of 6.3 [4.8, 14.8] months. Median [IQR] time to first CR and PR was 21.6[11.8, 41.8] and 6.1[4.3, 13.8] months. Median time to IR was 4.79[95% CI 3.78, 6.34]months. ESKD developed in 3(3.3%) patients. Estimated ESKD-free survival was 100% at 5 years and 96.9% at 10 years.

Conclusions: RTX on MN patients is associated with an excellent long-term renal survival, that compares favorably with historical survival rates using the cyclic corticosteroids/cyclophosphamide regimen.

Figure 1. Proportion of complete remission, partial remission, and reduction of proteinuria ≥50% over time.

Obinutuzumab Is Effective and Safe for Membranous Nephropathy with Very High Risk: A Retrospective Study from China

Duqun Chen,[1] Hui Li,[2] Yuanmao Tu,[1] Youliang Wang,[1] Dandan Qiu,[1] Ke Zuo,[1] Zhen Cheng.[1] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China; [2]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Affiliated Hospital of Nanjing medical University, Nanjing, China.*

Background: Membranous nephropathy (MN) is a common cause of nephrotic syndrome (NS) in adults. Factors considered to place a patient at very high risk for progression include life-threatening complications related to NS and severe renal dysfunction. The present study aimed to explore the efficiency and safety of Obinutuzumab for MN with very high risk in a retrospectively cohort.

Methods: MN patients with serum anti-phospholipase A2 receptor antibody (aPLA2Rab) ≥14RU/ml with very high risk (venous thromboembolic events, n=10, serum creatinine≥1.5mg/dl, n=16) received Obinutuzumab treatment (1g×2) in the National Clinical Medical Research Center for Renal Diseases at Jinling Hospital from October 2022 to November 2023 were retrospectively analyzed. Immunological complete remission is defined as aPLA2Rab<2RU/ml. B cell depletion is defined as CD20+cells<5/ul. All patients were followed more than 6 months.

Results: 26 MN patients including 23 males and 3 females was enrolled in the present study, with a mean proteinuria of 11g/24h at baseline. Complete (proteinuria <0.5g/24h) or partial (proteinuria <3.5g/24h with ≥50% reduction vs baseline) remission was achieved in 35% and 61.5% patients at month 3 and 6 respectively. B cell depletion rate was 100% and 88%, and immunological complete remission was 77% and 85% at month 3 and 6 respectively. aPLA2Rab titers progressively decreased by medians of 99% at month 6 compared to baseline. Obinutuzumab significantly reduced 24-hour proteinuria and increased serum albumin, and immunoglobulin G levels. Estimated glomerular filtration rate was significantly increased by an average of 32% in patients with serum creatinine ≥1.5mg/dl. Venous thrombosis was disappeared in 9 (90%) patients. 16 patients were followed more than 9 months and only one patient failed to response, a remission rate of 94% was achieved at month 9. Infusion-related adverse event was mostly mild. No patients died or progression into end stage kidney disease.

Conclusions: Obinutuzumab is safe and effective in the treatment of membranous nephropathy with very high risk. Large prospective studies are needed to validate these preliminary findings.

Outcomes in Membranous Nephropathy Treated with Intravenous Cyclophosphamide and Oral Prednisolone (Modification of the Modified Ponticelli Regimen): A Single-Centre Experience

David W. Ritter, Jacob A. Lange, David Makanjuola, Nicholas Cole. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: The Modified Ponticelli regime (MPR) is established treatment for membranous nephropathy (MN). We modified this at our centre to use oral Prednisolone 40mg daily (months 1, 3, 5) and intravenous Cyclophosphamide (CP) (single dose at start of months 2, 4, 6). This reduces CP and corticosteroid (CS) exposure as compared to the MPR. We analysed our data to see whether our approach negatively impacted remission and relapse rates.

Methods: Individuals treated with our modified regimen between 2005 and 2024 were identified. Follow-up continued until the most recent clinic visit at our centre, change in immunosuppressive therapy, or death (whichever happened first). Primary outcomes were: partial remission (PR), defined as > 50% drop in proteinuria from baseline AND urine PCR (uPCR) of 30-350 g/mol; complete remission (CR), defined as uPCR <30 g/mol; relapse, defined as recurrence of uPCR >350 g/mol. All were confirmed on at least 2 consecutive samples. An adverse renal outcome was included as a secondary outcome, defined as dialysis-dependence or a >50% decline in GFR from baseline.

Results: 44 individuals commenced our MPR at a median of 4.5 months from diagnosis: 80% were male, 81% were of white ethnicity and the median age was 65 (IQR 58-69) years. 55% were serum PLA2R antibody positive. 39 (87%) completed the full course with a mean total CP dose of 3.1 g (range 1.3-4.5g). The median follow-up period was 1.8 years (IQR.1.0-4.1). 25 (64.1%) achieved remission, and 8 (20.51%) had CR. 7/25 (28%) experienced a relapse during the follow-up period. An adverse renal outcome occurred in 4/14 (29%) of those who did not attain remission, compared to 1/25 (4%) in those who achieved at least PR. The mean rate of eGFR change in those who achieved remission was 2.0 mL/min/year and -9.7 mL/min/year in those who did not ($P < 0.01$).

Conclusions: Our modified MPR achieved comparable remission rates, relapse rates and renal outcomes to those reported with the standard MPR and other regimes that use much higher doses of CP and CS.

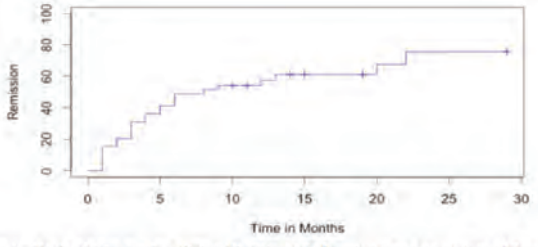

Figure 1 – Kaplan-Meier graph outlining 1st attainment of remission as a percentage of the sample

TH-PO595

Assessing the Rates of Complications in Patients with Membranous Nephropathy Treated with Cyclical Intravenous Cyclophosphamide and Oral Prednisolone: A Single-Centre Experience

Jacob A. Lange, David W. Ritter, David Makanjuola, Nicholas Cole. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: The Modified Ponticelli Regimen (MPR) is an established treatment option for membranous nephropathy (MN). We use a modified MPR at our centre, administering intravenous (IV) Cyclophosphamide (CP) at the start of months 2,4 and 6. Oral Prednisolone 40mg is prescribed daily during months 1,3 and 5 without the use of IV Methylprednisolone. We reviewed whether minimising the dosage of CP and steroids reduces complication rates without compromising on remission rates.

Methods: All patients treated with the modified MPR at our centre were included for analysis. Patients were followed up till either their most recent clinic visit, until they switched immunosuppressive treatment, died or left our locality. We looked at the complications during follow-up, defined as either: leucopenia; severe infection requiring hospitalisation; or hyperglycaemia requiring hospitalisation or insulin initiation.

Results: 44 individuals were identified: 35 (80%) were male; 36 (81%) were of white ethnicity; the median age was 65 (IQR 58-69) years; 2 (5%) had diabetes mellitus. 39 (87%) completed the full course and the mean total CP dose was 3.1 g (range 1.3-4.5g). The median follow-up was 1.8 years (IQR.1.0-4.1). 25/39 (64.1%) achieved remission, 8 of whom (20.51%) reached CR. None became leucopenic, 10 (22.7%) sustained serious infections requiring hospitalisation and 1 (2.3%) needed admission with a hyperglycaemia (blood glucose of 74mmol/L or 1333mg/dL). The infections individuals were admitted with are summarised below, with some patients admitted more than once or with more than one source.

Conclusions: Our modified MPR regime resulted in a comparable remission rate to other studies using a standard MPR (66% for Jha et al. (2007) and 71% for Rao et al. (2019)) but demonstrated a marked reduction in complication rates, particularly in relation to leucopenia and diabetes-related complications: comparative studies using a standard MPR show leucopenia rates of 8.5-42%, infection rates of 25.7-35.7% and hyperglycaemia-related complications of 1.5-40%. Our data suggests that our modified MPR maintains efficacy and reduces treatment-related toxicity.

Infection Type	Respiratory	Gastrointestinal	Urine	Line	Unknown

TH-PO596

Effect of Phospholipase A2 Receptor (PLA2R) Antibody and Inflammatory Factors on Cardiovascular and Thromboembolic Events in Patients with Primary Membranous Nephropathy

Hong Cheng, Nan Ye, Lei Yang, Guo-qin Wang. *Beijing Anzhen Hospital Affiliated to Capital Medical University, Chaoyang-qu, China.*

Background: Primary membranous nephropathy (pMN) is the most likely cause of venous thromboembolic complications in all pathological types of NS, as well as arterial thrombotic events, especially cardiovascular events. What are the high-risk groups for arterial and venous thromboembolic events in patients with pMN? Why are arterial and venous thromboembolic events likely to occur in this population?

Methods: Patients with pMN diagnosed by renal biopsy in our hospital from June 1, 2010 to March 3, 2023 were included. The study outcome was set as a composite of ACS, HF, stroke, arrhythmia, VTE, pulmonary embolism and all-cause mortality.

Results: A total of 433 patients were included, with a median follow-up of 75 months. The proportion of composite endpoint was 8.1%. Univariate analysis showed that the event group had a higher proportion of males, smokers, with hypertension, a previous history of venous thromboembolism, a higher amount of urinary protein, a higher blood PLA2R antibody titer, a higher hsCRP level, and a higher D-dimer and FDP level than the non-event group. Cox proportional hazards model results showed that both high blood PLA2R antibody titer (OR 1.045, 95%CI 1.013-1.078, P=0.006) and high hsCRP levels were independent risk factors for the occurrence of endpoint events (OR 1.057, 95%CI 1.002-1.115, P=0.041). The results of correlation analysis showed that there was a correlation between blood PLA2R antibody titer and hsCRP level (r=0.185, P<0.001), so we inferred that blood PLA2R antibody may lead to endothelial cell injury through an inflammatory mechanism, causing cardiovascular events or thromboembolic events. We initially detected IL-6 levels in the enrolled patients, and the results showed that IL-6 levels were 5.58±4.44pg/ml in the cardiovascular and thromboembolic event groups and 2.95±1.22pg/ml in the non-event group, and the difference between the two groups was statistically significant (p=0.015).

Conclusions: Both high serum PLA2R antibody titer and high hsCRP level are independent risk factors for cardiovascular events or thromboembolic events in patients with pMN, and IL-6 level is significantly increased in the event group, which may suggest that serum PLA2R antibody and inflammation play a role in the mechanism of pMN and provide a basis for our subsequent basic experiments.

TH-PO597

Comparability of Two Anti-phospholipase A2 Receptor (PLA2R) Enzyme-Linked Immunosorbent Assays (ELISAs) in Patients with Primary Membranous Nephropathy

Sean Barbour,[1] Holly Clarke,[2] Eriola Berisha,[3] Audrey Arjomandi,[2] Debbie Chen,[2] William Riboulet,[3] Heather Boston,[3] Sylvie Prot,[3] Daniel C. Cattran,[4] David E. Place.[2] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]Genentech Inc, South San Francisco, CA; [3]F Hoffmann-La Roche AG, Basel, Switzerland; [4]Toronto General Research Institute, University of Toronto, Toronto, ON, Canada.*

Background: In patients with primary membranous nephropathy (pMN), 70-80% have circulating anti-M-type phospholipase A2 receptor (PLA2R) autoantibodies. The EuroImmun (EI) anti-PLA2R (αPLA2R) ELISA is a diagnostic test for pMN used in the ongoing, Phase III MAJESTY clinical trial (NCT04629248), which evaluates the safety and efficacy of obinutuzumab versus tacrolimus in patients with pMN. In the Phase III MEmbranous Nephropathy Trial of Rituximab (MENTOR, NCT01180036), an ELISA developed by Paul Brenchley was used prior to the development of a commercial ELISA. The comparability of the two αPLA2R assays is unknown. Measurement of MENTOR αPLA2R titers using EI-ELISA allows for comparison of outcomes between these B cell depletion clinical trials and informs the MAJESTY protocol design, which uses EI-ELISA.

Methods: Baseline serum samples obtained from MENTOR were analyzed by EI-ELISA. Spearman's rank correlation was used to assess comparability of the EI-ELISA results. For EI-ELISA, αPLA2R+ was defined as ≥14 RU/mL; αPLA2R+ was defined as >40 U/mL by Brenchley ELISA. The median EI-ELISA αPLA2R titer among αPLA2R+ MENTOR study participants was determined and used for stratification of study participants in MAJESTY.

Results: At baseline, αPLA2R titers in MENTOR were highly concordant (r=0.91, P=1.26x10^{-49}) (**Fig 1**). At baseline, 93/130 (71.5%) were αPLA2R+ by the EI-ELISA (≥14 RU/mL) and 96/130 (73.8%) were αPLA2R+ (>40 U/mL) by the Brenchley ELISA, with 96.2% agreement. Among patients who were αPLA2R+ as assessed by the EI-ELISA, the median titer was 175 RU/mL (IQR, 58-394).

Conclusions: The EI-ELISA used in the ongoing MAJESTY study is highly concordant with the Brenchley ELISA. To ensure the two arms in MAJESTY have a comparable proportion of participants who are αPLA2R+, the median EI-ELISA αPLA2R+ titer (175 RU/mL) was used for stratification.

Noninvasive Diagnostic Strategies for Membranous Nephropathy in the NEPTUNE Study

Jarcy Zee,[1,2] Jonathan Hogan,[5] Ahmed Abdullah,[4] Lili Liu,[3] Krzysztof Kiryluk,[3] Laurence H. Beck.[4] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]The Children's Hospital of Philadelphia Research Institute, Philadelphia, PA; [3]Columbia University Vagelos College of Physicians and Surgeons, New York, NY; [4]Boston University Chobanian & Avedisian School of Medicine, Boston, MA; [5]Cabaletta Bio Inc, Philadelphia, PA.*

Background: Clinical practice guidelines recommend that a kidney biopsy is no longer required to confirm a diagnosis of membranous nephropathy (MN) in patients with nephrotic syndrome and a positive test for anti-phospholipase A2 receptor antibodies (PLA2R-Ab). However, the optimal diagnostic strategy for using the different PLA2R-Ab tests and their optimal thresholds for positivity among incident patients with proteinuria is still unknown.

Methods: We used serum samples at or before the first kidney biopsy from NEPTUNE study participants to analyze diagnostic test performance using different combinations and cut-offs of the PLA2R-Ab enzyme-linked immunosorbent assay (ELISA), PLA2R-Ab indirect immunofluorescence (IIF) test, and genetic risk score for diagnosing MN. Secondary analyses included serum samples within 6 months after biopsy but before any immunosuppression use.

Results: N=325 study participants had serum samples on or before the day of kidney biopsy and an additional N=143 had samples within 6 months after biopsy but before any immunosuppression use. N=85 had biopsy-confirmed MN. The combination of ELISA ≥2 RU/mL and positive IIF was the optimal approach, with sensitivity of 0.600, specificity of 1.000, negative predictive value of 0.925, and positive predictive value of 1.000 (Table). Using IIF to confirm only borderline ELISA titers between 2 and 20 resulted in similar sensitivity but specificity of 0.996. In our multiethnic study sample, we did not find improved diagnostic performance with the addition of genetic risk scores.

Conclusions: Given the possibility of false positives by ELISA alone, both ELISA and IIF testing should be performed to establish PLA2R-Ab seropositivity before making a non-invasive diagnosis of PLA2R-associated MN among patients with proteinuria. Further studies in multiethnic populations are needed to assess whether genetic data can augment this approach.

PLA2R-Ab ELISA and IIF diagnostic test characteristics

	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
ELISA ≥2	0.636	0.837	0.443	0.919
ELISA ≥14	0.564	0.996	0.969	0.918
ELISA ≥20	0.527	0.996	0.967	0.912
ELISA ≥2 and IIF+	0.600	1.000	1.000	0.925
ELISA >20 or (20≥ELISA≥2 and IIF+)	0.600	0.996	0.971	0.924
ELISA >20 or (20≥ELISA≥14 and IIF+)	0.564	0.996	0.969	0.918
ELISA >20 and IIF+	0.527	1.000	1.000	0.912

Assessment of Endothelial Dysfunction in Patient with Phospholipase A2 Receptor (PLA2R)-Positive Primary Membranous Nephropathy in Remission

Rishab R. Prabhu,[1,2] Nikhil Vojjala,[1,2] Arun Prabhahar,[5] Joyita Bharati,[4] Ujjwal Gorsi,[5] Pratyaksha Rana,[3] Sunil K. Arora,[5] Raja Ramachandran.[5] *[1]Trinity Health Oakland Hospital, Pontiac, MI; [2]Wayne State University School of Medicine, Detroit, MI; [3]UN Mehta Institute of Cardiology and Research Centre, Ahmedabad, India; [4]Boston Medical Center, Boston, MA; [5]Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: Primary membranous nephropathy (PMN) is associated with endothelial dysfunction. Emerging evidence suggests that this dysfunction persists even after clinical remission. Therefore, we aimed to study the level of endothelial dysfunction in patients with PMN in remission and compare it with healthy controls (HC) and adult podocytopathy patients in remission.

Methods: This prospective cohort study included 60 patients with Phospholipase A2 receptor (PLA2R) positive PMN in remission, all of whom had received immunosuppressive therapy at least six months prior. Endothelial dysfunction was assessed using flow-mediated vasodilation (FMD), nitroglycerin-mediated vasodilation (NMD), and CD4+CD28null T cell levels. These values were then compared with those of healthy controls.

Results: Total of 60 patients with PMN in remission were included in the study. Mean age of the patients was 43.4 years (range: 20-68). Of these, 70% (n=42) were male, and 50% (n=30) had PMN in complete remission. Mean serum creatinine level was 0.873 mg/dl (SD ± 0.2248), the mean 24-hour urinary protein was 0.873 gm/TV (SD ± 0.2248), and the mean serum albumin level was 4.152 mg/dl (SD ± 0.6473). Median FMD in PMN cases, analysed with an FDA-approved brachial analyser, was 7.45% (IQR: 2.925-12.525) (vs 6.45% (IQR=4.525-10.2) in HC (p=0.654), and the median NMD was 7.95% (IQR: 4.5-12.875) in PMN cases versus 5.89% (IQR=3.153-11.88) in HC (p=0.850). Median percentage of CD4+CD28null T cells in the PMN patients was 4.76% (IQR: 2.36-12.18) versus 5.38% (IQR: 2.26-13.09) in HC (p=0.901).

Conclusions: Patients with PMN in proteinuric and serological remission exhibit endothelial dysfunction comparable to that of healthy individuals.

Assessing the Utility and Accuracy of Phospholipase A2 Receptor (PLA2R) Antibody in Membranous Nephropathy: A Systematic Review and Meta-Analysis

Omar S. Ragy,[1] Wessam Abass,[2] Durga Anil K Kanigicherla,[1] Bethany Shinkins,[3] Janine Bestall,[2] Natalie V. King,[2] Paul E. Brenchley,[1] Alison F. Smith,[2] Patrick Hamilton.[1] *[1]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [2]University of Leeds Leeds Institute of Health Sciences, Leeds, United Kingdom; [3]University of Warwick Medical School, Coventry, United Kingdom.*

Background: If used as a first-line triage test to diagnose primary membranous nephropathy, the PLA2R antibody (PLA2R-Ab) test could reduce the proportion of people with nephrotic syndrome needing a kidney biopsy. Evidence to determine an appropriate PLA2R-Ab test threshold, however, is lacking.

Methods: A systematic review of diagnostic accuracy studies was conducted to evaluate serum- or urine-based biomarkers to distinguish primary and secondary membranous nephropathy (MN). We searched for relevant articles in Medline, Embase, Cochrane Library, Scopus, Web of Science, INAHTA, and ClinicalTrials.gov. Cochrane-recommended systematic review and meta-analysis methodology was implemented. QUADAS-2 was used to assess the risk of bias.

Results: Eighty-one studies were eligible for inclusion, and 50 were meta-analyzed stratified by PLA2R-Ab test method using either EUROIMMUN Enzyme-linked immunosorbent assay (ELISA) in 44 studies or EUROIMMUN immunofluorescence test (IF) in 29 studies. The pooled sensitivity and specificity of EUROIMMUN ELISA at a cut-off value of 20 RU/ml were 0.631 (95% CI: 0.546, 0.709) and 0.955 (95% CI: 0.914, 0.977), respectively. The pooled sensitivity and specificity of EUROIMMUN IF at a threshold of 1:10 were 0.705 (95% CI: 0.653 – 0.752) and 0.986 (95% CI: 0.925 – 0.998), respectively. The risk of bias was higher for studies evaluating EUROIMMUN IF compared to the ELISA test. We also explored whether the timing of the index test had an impact on the pooled diagnostic accuracy results; no significant differences were found.

Conclusions: By comprehensively considering the specificity and sensitivity of EUROIMMUN ELISA PLA2R-Ab, we show that 20 RU/mL could be used as an optimal cut-off value to confirm a diagnosis of MN without the need for kidney biopsy.

Type II Glycoengineered Anti-CD20 Antibody MIL62 or Cyclosporine in Chinese Primary Membranous Nephropathy: A Multicenter, Randomized, Open-Label Phase 1b/2 Trial

Zhao Cui,[1] Zhang Yimiao,[1] Heng Li,[3] Hua Zhou,[4] Hong L. Lin,[6] Guangqun Xing,[7] Wei Chen,[8] Wei Liang,[9] Ping Luo,[10] Chen X. Lan,[11] Hui Xu,[12] Yan Zha,[18] Yue Wang,[13] Xing Chen,[14] Zhaohui Ni,[15] Junjun Zhang,[16] Wanhong Lu,[17] Li Hua Zhang,[5] Ming-Hui Zhao,[1] Min Wei,[2] Song Meng,[2] Liang Jinjin,[2] Feng Li.[2] *[1]Peking University First Hospital Department of Nephrology, Beijing, China; [2]Beijing Mabworks Biotech Co Ltd, Beijing, China; [3]The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China; [4]Shengjing Hospital of China Medical University, Shenyang, China; [5]General Hospital of Eastern Theatre Command, Nanjing, China; [6]The First Affiliated Hospital of Dalian Medical University, Dalian, China; [7]The Affiliated Hospital of Qingdao University, Qingdao, China; [8]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [9]Wuhan University Renmin Hospital, Wuhan, China; [10]The Second Hospital of Jilin University, Changchun, China; [11]Affiliated Hospital of Nantong University, Nantong, China; [12]Xiangya Hospital Central South University, Changsha, China; [13]Peking University Third Hospital, Beijing, China; [14]The First Affiliated Hospital of Xiamen University, Xiamen, China; [15]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [16]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [17]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [18]Guizhou Provincial People's Hospital, Guiyang, China.*

Background: A novel glycoengineered type II anti-CD20 antibody, MIL62 with a nearly completely afucosylated N-glycans in Fc region, has demonstrated superior activity compared with rituximab and obinutuzumab in vitro and in vivo, respectively. Last year, we we announced that the 12-week immunological remission rate and 24-week overall remmision rate (ORR) of MIL62 was significantly higher than CsA, meeting the primary endpiont of this study. Here we will update the follow-up data for week 76.

Methods: Eligible patients with pMN diagnosed by kidney biopsy, proteinuria of at least 3.5 g per 24 hours received intravenous MIL62 (two infusions, 600 or 1000 mg each, administered 14 days apart; repeated at 6 months) or Cyclosporine (CsA, starting at a dose of 3.5 mg per kilogram of body weight per day for 12 months). Patients were followed up for up to 104 weeks after initial administration. The primary efficacy outcome was a composite of complete or partial remission of proteinuria and stable eGFR. Safety and anti-PLA2R antibodies were also assessed.

Results: From Feb. 23th, 2022 to Jan. 13th, 2023, a total of 87 patients were randomly enrolled from 19 centers in China. One patient in the MIL62 group discontinued the intervention. As of Apr. 22th, 2024, all the 86 patients had evaluable data at 52 weeks and 75 patients had data at 76 weeks. The complete remission rates (CRR) of MIL62 group and cyclosporine group were 20/60 (33.3%) and 1/26 (3.8%) at 52 weeks (risk difference, 29.5%; 95% CI, 15.5 to 43.5; P=0.003 for superiority), and 23/49 (46.9%) and 0/26 (0.0%) (P<0.001) at 76 weeks. The ORR of MIL62 group and cyclosporine group were 48/60 (80.0%) and 3/26 (11.5%) at 52 weeks (risk difference, 68.5%; 95% CI, 52.5 to 84.4; P<0.001 for superiority), and 35/49 (71.4%) and 2/26 (7.7%) (P<0.001) at 76 weeks. Treatment-related adverse events occurred in 76.7%, 80.6% and 88.5% of MIL62 600mg, MIL62 1000mg and cyclosporine group respectively. No treatment-related death occurred.

Conclusions: MIL62 was superior to cyclosporine in inducing complete or partial remission of proteinuria at 12 months. A phase 3 clinical trial of MIL62 in pMN is ongoing (NCT05862233).

TH-PO602

Characterization of the Immune-Dominant Region on the CysR Domain of Phospholipase A2 Receptor 1 (PLA2R1) Targeted by Autoreactive Memory B Cells

Linda Reinhard,[1] Sara Montagner,[2] Martine Marchant,[2] Zheng Zhou,[2] Marco Catalano,[2] Mariavittoria Iazeolla,[2] Alexandra Lavoisier,[2] Elisabetta Traggiai,[2] Elion Hoxha.[1] *[1]III. Department of Medicine, University Medical Center Hamburg Eppendorf, Hamburg, Germany; [2]Novartis AG, Basel, Switzerland.*

Background: Membranous nephropathy (MN) is caused by PLA2R1-ab in 70-80% of patients. The mechanisms how this highly specific and persistent autoreactive memory response is generated in these patients, remain unclear and all current treatment options for MN are unspecific.

Methods: Using ELISA and Western Blot, the isotypes, affinity and amount of PLA2R1-ab in patients with MN were studied. Circulating memory PLA2R1-specific B cells were isolated from patients with PLA2R1-induced MN and after cloning of the B cell receptors, monoclonal human PLA2R1-ab (PLA2R1-mAb) were produced and used to dissect the epitope binding site. Using inhibition assays, we studied the relevance of this epitope for ab binding and complement activation.

Results: In a cohort of 105 patients with PLA2R1-induced MN, we detected a high affinity IgG4-dominated immune response with expansion of IgG4 memory B cells and plasma blasts. In ca. 1/3 of patients, the PLA2R1 immune response was IgG1-dominant. Four of the five produced human PLA2R1-mAb recognized an overlapping epitope patch on the CysR domain, while the last mAb bound to the CTLD1 domain. PLA2R1-mAb show high affinity (0.2 pM), used different heavy- and light-chain variable region genes and carried high levels of somatic mutations in complementary-determining regions, consistent with antigenic selection. PLA2R1-mAb showed a strong inhibition of serum PLA2R1-ab binding from patients with PLA2R1-induced MN both in vitro and in vivo in a transgenic PLA2R1-specific rat model. In patients with circulating CTLD1-ab, the combination of CysR- and CTLD1-mAb showed an additive inhibitory effect of 85% in vitro and 75% in vivo. PLA2R1-ab positive sera from patients with PLA2R1-induced MN showed strong complement activation in an in vitro complement activity assay. In a competition assay, the PLA2R1-mAb led to abrogation of complement activation by the patients' sera, pointing toward a key functional role for the identified PLA2R1 epitopes in patients with MN.

Conclusions: The detailed characterization of the immune dominant epitope patch on the CysR domain of PLA2R1 targeted by PLA2R1 autoreactive memory B cells will facilitate the development of treatment strategies aimed at depletion of PLA2R1 specific memory B cells and plasma blasts.

Laser Microdissection and Mass Spectrometry: A Reliable Clinical Test for Detection of Membranous Nephropathy (MN) Antigens

Sanjeev Sethi, Jason D. Theis, Benjamin J. Madden, Fernando C. Fervenza, Julie A. Vrana. *Mayo Clinic Minnesota, Rochester, MN.*

Background: MN results from accumulation of antigen (Ag)-antibody (Ab) immune-complexes along the GBM. 13 target Ag have been discovered and include PLA2R, THSD7A, EXT1/EXT2, NELL1, SEMA3B, NCAM1, CNTN1, HTRA1, FAT1, PCDH7, NTNG1, PCSK6 and NDNF, accounting for ~80% of Ag. MN associated with many Ag have distinctive clinicopathologic finding and tissue/serum Ab have been described in all except EXT1/EXT2. As such, it is crucial to accurately identify the Ag in MN. Currently, IHC/IF methods are used to detect PLA2R, THSD7A, NELL1 and EXT1/EXT2. IHC/IF methods do not exist and are not practical for the remaining Ag. We have developed laser microdissection-mass spectrometry methodology (LMD/MS) as a one-stop clinical test for the detection of Ag using paraffin-embedded (FFPE) kidney biopsy tissue.

Methods: For each case, 6 μM thick FFPE sections were mounted on Director slides and H&E stained. Using a Leica Laser Microdissection microscope, the glomeruli were dissected to reach ~250,000 μM² per sample. Proteins were extracted using heat and sonication. Extracted proteins were reduced, alkylated and digested by incubating with trypsin. Resulting peptides were analyzed using an Exploris mass spectrometer connected to a liquid-chromatography system. Resulting MS/MS spectra were processed using three search engines to match the spectra against SwissProt human protein sequence database.

Results: The LMD/MS test was validated in 2 steps: 1) LMD/MS was used to detect the Ag in 75 cases of MN with known Ag. LMD/MS correctly identified the Ag in all 75 cases (100%). 2) LMD/MS was used to identify the Ag in 61 MN cases where the Ag was unknown. LMD/MS identified one of the above Ag in 40 of 61 cases (65.5%) including less common Ag. In 21 cases (34.5%), none of the above Ag were detected. None of the negative controls were positive for any Ag.

Conclusions: LMD/MS is an extremely useful and reliable method for the detection of MN Ag in the clinical laboratory.

LMD/MS showing total spectral counts of MN Ag. Each column represents one MN case; 2 samples from each case are shown. Also shown in the bottom rows are housekeeping proteins actin and vimentin.

TH-PO604

Overview of the Characteristics of a Phospholipase A2 Receptor (PLA2R)-Negative Membranous Nephropathy Cohort

António d. Inácio,[1] Patrícia A. Domingues,[1] Ana D. Piedade,[1] Beatriz B. Mendes,[1] Francisca G. da Fonseca,[1] Julie A. Vrana,[2] Jason D. Theis,[2] Fernando C. Fervenza,[2] Karina Soto,[1] Sanjeev Sethi.[2] *[1]Centro Hospitalar de Setubal EPE, Setubal, Portugal; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Recent insights into target antigens involved in Membranous Nephropathy's (MN) pathophysiology have propelled towards its antigen-based classification. While most are PLA2R-positive, a subset involves a variety of proteins. Antigen identification provides valuable clues regarding underlying disease or exposure, influencing clinical investigation and management. We aimed to characterize a single-center cohort of PLA2R-negative MN through antigen identification.

Methods: Retrospective analysis of all MN cases diagnosed at our Center with negative serum PLA2R titer between 2013-2023. Glomerular laser capture microdissection (LMD) was performed on paraffin-embedded kidney biopsy samples, followed by tandem mass spectrometry (MS) for antigen identification. Clinical data was included for comprehensive analysis.

Results: Of 26 biopsy-proven MN, 14 had negative serum PLA2R. Of those, 11 cases had available tissue sample for LMD/MS. LMD/MS identified a MN antigen in 8 (72.7%) cases. These included: 3 PLA2R (one case with paraproteinemia, other with syphilis and other with no underlying disease); 2 NELL-1 (one with paraproteinemia and other with lung cancer); 1 EXT1/2 (with mixed connective tissue disease and multiple myeloma); 1 HTRA1 (with multiple myeloma and uncharacterized autoimmune disease); 1 NDNF (with thyroid cancer); and 1 THSD7A (had no underlying diagnosis). In 3 (27.3%) cases no antigen was identified by MS. The diagnosis of NELL1, EXT1/EXT2 and THSD7A was confirmed by immunohistochemistry. Time from MN diagnosis to underlying disease diagnosis ranged from >2 years before up to >5 years after. Clinical course and outcomes were widely variable from spontaneous remission to ESKD progression.

Conclusions: More than half of MN cases had negative serum anti-PLA2R antibodies. Our analysis revealed diverse target-antigens involved, reflecting various underlying diseases, and exhibiting different clinical courses. The antigens detected on LMD/MS correlated with the clinical and pathologic findings. We also highlight the sensitivity of LMD/MS in identifying PLA2R, particularly in cases with negative serum measurements. We observed that negative PLA2R IHC staining can be misleading, underlining the need for caution in its interpretation.

TH-PO605

Sparsentan (SPAR) in Pediatric Patients with Rare Proteinuric Kidney Disease: Preliminary Findings from the EPPIK Study

Howard Trachtman,[1] Rosanna Coppo,[2] Nuhira Ahmed Masthan Ahmed,[3] Kenneth V. Lieberman,[4] Alex Mercer,[5] Michelle N. Rheault,[6] Moin A. Saleem,[7] Radko Komers.[3] *[1]University of Michigan, Ann Arbor, MI; [2]Fondazione Ricerca Molinette, Regina Margherita Hospital, Turin, Italy; [3]Travere Therapeutics, Inc., San Diego, CA; [4]Joseph M. Sanzari Children's Hospital of the Hackensack Meridian Health, Hackensack, NJ; [5]JAMCO Pharma Consulting, Stockholm, Sweden; [6]University of Minnesota Medical School, Minneapolis, MN; [7]University of Bristol & Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background: SPAR is a nonimmunosuppressive, dual endothelin angiotensin receptor antagonist (DEARA) approved (US and EU) for adults with IgA nephropathy (IgAN) at risk of rapid disease progression and is being investigated for focal segmental glomerulosclerosis (FSGS). The phase 2 EPPIK study (NCT05003986) evaluates safety and long-term antiproteinuric and nephroprotective effects of SPAR in pediatric patients (pts) with FSGS, minimal change disease (MCD), IgAN, IgA vasculitis (IgAV), and Alport syndrome (AS). We report preliminary findings per individual diagnoses.

Methods: This open-label, single-arm trial examines SPAR safety, efficacy, and pharmacokinetics in ≈30 pts 1-<18 y with FSGS and/or MCD histological patterns (population 1) and ≈27 pts 2-<18 y with IgAN, IgAV, or AS (population 2) over 108 wk and 4-wk safety follow-up. SPAR is given once daily (liquid form, dose adjusted for weight); pts on a renin-angiotensin system inhibitor undergo 2-wk washout before study medication (baseline [BL]). Primary endpoints include safety and efficacy (change in urine protein/creatinine ratio [UP/C]).

Results: At data cutoff (2/15/2024), 34 pts received ≥1 SPAR dose (BL characteristics in **Table**). Over 12 wk, proteinuria (UP/C) decreased by 51% and 27% in pts with MCD and FSGS and 54% and 61% in pts with IgAN/IgAV and AS (**Figure**). SPAR was safe and generally well tolerated.

Conclusions: SPAR is well tolerated in pediatric pts with various glomerular diseases, consistent with adult trials in FSGS and IgAN. Proteinuria decreased in each indication, even in those not previously studied, with about 50% overall reduction over 12 wk of treatment.

TH-PO606

"RESULT" Umbrella Trial in Primary Focal Segmental Glomerulosclerosis/ Minimal Change Disease

Julie Lin,[1,2] An-Qi Hu,[1] Shiguang Liu,[1] Karen Ocwieja,[1] Madhurima Uppara Kowthalam,[1] Arjun S. Channi,[1] Tara C. Hastings,[1] Celine Luscan,[1] Sandrine Turpault,[1] Sagar U. Nigwekar,[3] Manish Maski.[1] *[1]Sanofi, Cambridge, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Primary focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD) continuum is a major cause of nephrotic syndrome among adult and pediatric patients. There is a lack of safe and effective therapies for FSGS/MCD, which is considered to be immune-mediated. We describe the protocol and operational feasibility for the Renal Efficacy Signaling UmbrelLa Trial (RESULT).

Methods: RESULT is an innovative global Phase 2a randomized, placebo-controlled umbrella trial that simultaneously evaluates the safety and efficacy of 3 novel therapies targeting immunological pathways implicated in primary FSGS/MCD: frexalimab (anti-CD40L monoclonal antibody), SAR442970 (anti-OX40L and anti-TNFα bispecific), and rilzabrutinib (BTK-inhibitor). Pts 16-75 years with biopsy-confirmed primary FSGS/MCD, eGFR ≥45 mL/min/1.73 m² and UPCR ≥3 g/g will enter a 12-wk double blind period followed by a 12-wk open-label extension (Fig). Primary endpoint is UPCR reduction from baseline to Wk 12 for each IMP vs pooled placebo. Operational feasibility has been conducted in 132 study sites across 23 countries.

Results: Majority (83%) of investigator responders expressed high interest in the trial, with top reasons being scientific importance (62%) and medical interest for patients (67%). Overall, 79% viewed burden of study procedures as appropriate, and 87% perceived remote study visits as safe. Interviews conducted with 11 affected adults, adolescents, and caregivers confirmed the high burden of disease, need for better therapies, and suitability of trial protocol.

Conclusions: This global RESULT Phase 2a trial utilizes an innovative efficacy signal-seeking master protocol to simultaneously evaluate 3 immunologically active therapies in FSGS/MCD and is the first umbrella trial in nephrology. Operational feasibility and stakeholder feedback demonstrate high scientific and medical interest, as well as appropriateness of trial design and assessments.

TH-PO607

Patient-Reported Outcomes in Adults with FSGS: Sparsentan vs. Irbesartan

Isabelle Ayoub,[1] Mark E. Bensink,[2] Xiaolei Zhou,[3] Jinyi Wang,[3] Wu Gong,[2] Priscila Preciado,[2] Radko Komers,[2] Jula K. Inrig,[2] Michelle N. Rheault,[4] Howard Trachtman.[5] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Travere Therapeutics Inc, San Diego, CA; [3]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC; [4]University of Minnesota Medical School, Minneapolis, MN; [5]University of Michigan, Ann Arbor, MI.*

Background: In the randomized, phase 3 DUPLEX trial (NCT03493685), sparsentan (SPAR), a dual endothelin and angiotensin II receptor antagonist (DEARA), demonstrated a greater sustained antiproteinuric effect compared with irbesartan (IRB), with a favorable safety profile similar to IRB in patients with FSGS. This analysis aimed to evaluate the effect of SPAR compared with IRB on patient-reported outcomes (PROs) in adults with FSGS.

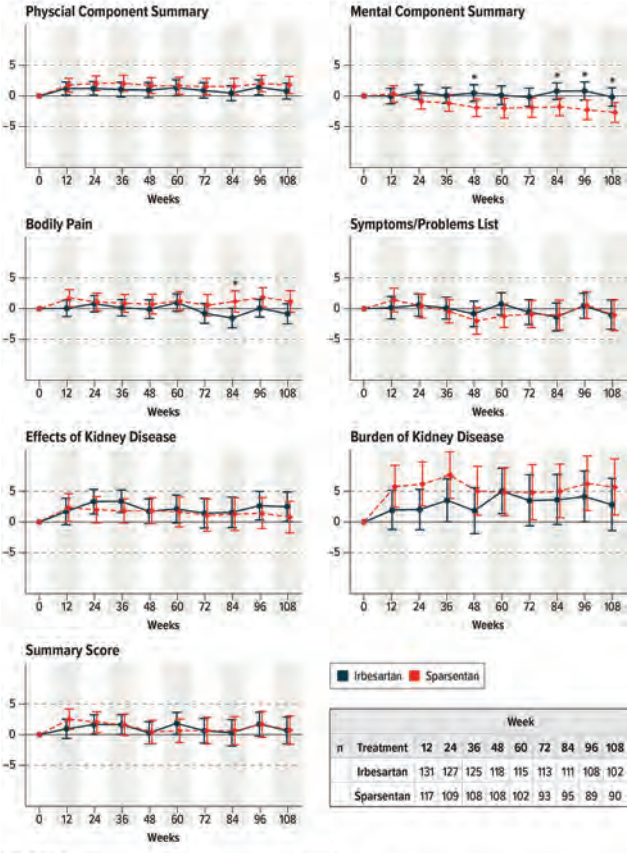
Methods: In the DUPLEX trial, the Kidney Disease Quality of Life-36 (KDQOL-36) questionnaire was administered to adults at baseline and every 12 weeks. Least squares mean changes from baseline in physical component summary, mental component summary, bodily pain, and kidney-targeted subscales were estimated using mixed models for repeated measures. A prespecified threshold change of 5 points was considered clinically meaningful.

Results: Burden of kidney disease scores were clinically meaningfully improved compared with baseline in the SPAR group but not in the IRB group (Figure). Least squares mean changes from baseline scores were stable, if not improved, throughout the 2-year treatment period for SPAR with the exception of mental component summary, which appeared slightly worsened at some timepoints compared with baseline and with IRB.

Conclusions: For adult patients with FSGS, our analysis of PROs from the DUPLEX trial suggests that health-related quality of life was relatively stable over the 2-year treatment period and comparable between SPAR and maximized angiotensin II receptor inhibition with IRB. Further work is needed to better understand the association between PROs and clinical endpoints in FSGS.

Funding: Commercial Support - Travere Therapeutics

Figure. Least Squares Mean Change From Baseline for KDQOL-36 Scores by Treatment and Visit



* $P < 0.05$ for differences between sparsentan and irbesartan.

Note: Summary score is the average of items from the symptoms and problems of kidney disease, effects of kidney disease, and burden of kidney disease scales.

Note: The vertical bars indicate 95% confidence intervals. The dotted lines indicate meaningful changes thresholds. A higher score indicates better HRQOL/functioning.

TH-PO608

Primary FSGS Patient Response to Immunosuppression (IS) and Risk of ESKD

John J. Sim,[1] Mercedes A. Munis,[1] Qiaoling Chen,[1] T. M. Hill,[2] Min Zhuo,[3] Benjamin Lewing,[2] Teresa N. Harrison,[1] Ancilla Fernandes,[2] Asher D. Schachter.[3] *[1]Kaiser Permanente Southern California, Pasadena, CA; [2]Otsuka America Pharmaceutical Inc, Rockville, MD; [3]Visterra Inc, Waltham, MA.*

Background: Primary FSGS is a podocytopathy with variability in response to IS which may affect subsequent outcomes. We compared ESKD outcomes between IS responsive vs non-responsive pts with primary FSGS.

Methods: Retrospective cohort study of Kaiser Permanente Southern California pts (≥18yo) with biopsy confirmed primary FSGS and treated with IS (2010-2021). Treatment response within 8-months was categorized as IS responsive (urine protein to creatinine ratio [UPCR] decline of >50% from baseline AND UPCR ≤3.5g/g) or IS non-responsive. ESKD was defined as treatment with kidney transplant or dialysis. Multivariable Cox proportional hazard models used to estimate hazard ratios (HR) for ESKD. IS was implemented as a time-dependent covariate and Fine-Gray method utilized for the competing risk of mortality.

Results: Among 230 patients treated with IS, 125 (54%) responded to IS. Characteristics of responders vs non-responders were: age 57.4 yrs (vs 57.6), 56% male (vs 51%), 39% White (vs 25%), 30% Hispanic/Latino (vs 30%), 17% Asian/Pacific Islander (vs 24%), 13% Black (vs 22%), mean eGFR 53 (vs 40 mL/min/1.73m²), serum albumin 2.7 (vs 2.9 g/dL), and median UPCR 5.8 (vs 5.3 g/g). Over median follow up of

2.5yrs, 88 patients (38%) progressed to ESKD of which 58pts were IS non-responders. Median time to ESKD was1.8 yrs. Median age at ESKD was 69 yrs. ESKD HR (95% CI) was 0.45 (0.28, 0.73) for IS responders vs non responders. Asian/Pacific Islanders (HR 2.01 [1.05, 3.83]) had the highest risk for ESKD.

Conclusions: We observed a high rate of ESKD within a relatively short time among primary FSGS pts treated with IS. IS non-responders compared to responders had over twice the risk for progression to ESKD.

Figure 1. Cumulative Incidence Curve for ESKD in Treated Primary FSGS

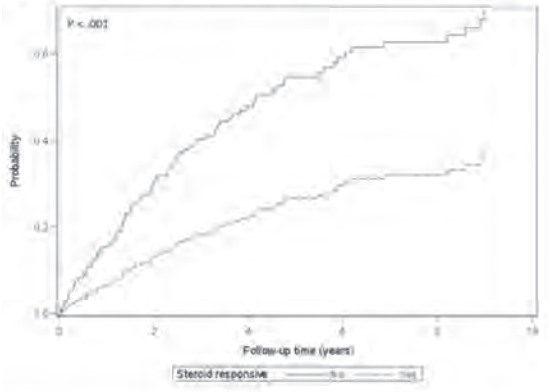


Table 1. Adjusted Hazard Ratio for ESKD among Treated Primary FSGS

Background: FSGS is a common histopathologic lesion in adult patients with nephrotic syndrome. We report on one of the most extensive observational studies of FSGS to identify predictors of long-term outcomes.

Methods: Nine centers enrolled 723 patients with FSGS of primary, genetic, or unknown etiology between 01/01/2000 and 08/01/2021. The GlomCon Research Consortium developed data definitions, collection instruments and study protocol.

Results: Clinical and biopsy characteristics (Table 1) were evaluated based on treatment history. Figure 1 and Table 2 show outcomes at 1, 3, and 5 years and time to events. Several statistically and clinically significant differences exist between immunosuppressive therapy (IST) and no IST groups.

Conclusions: The overall risk of ESKD and death is substantial. Additional analysis is being conducted to identify independent factors (clinical, treatment, and biopsy characteristics) associated with patient outcomes, predictors of IST response, and those most at risk for CKD progression, ESKD, and death.

Funding: Commercial Support - Travere Therapeutics

Clinicopathologic Prognostic Factors to Estimate ESKD in Patients with FSGS

Eun Mi You,[1] Ho Jun Chin.[2,1] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: FSGS can be caused by heterogenous aetiologies with subdivided by primary, secondary, and genetical forms. However, the classification may not provide future outcomes of FSGS. We searched for prognostic markers of any form of FSGS.

Methods: We enrolled a total of 20,404 adult patients who underwent native renal biopsy from 1979 to 2018 in 18 hospitals in Korea. We selected patients with definite segmental sclerosis by light microscopic examination including ≥10 glomeruli and without electron dense deposits by electron microscopic examination. We excluded patients with other forms of pathologic diagnosis except FSGS, with diabetes mellitus, or with follow-up period < 6 months after renal biopsy. We evaluated prognostic factors to estimate the risk of ESRD.

Results: Among 511 patients, GFR <60 ml/min/1.73 m2 was found in 41.5 % of patients and UPCR ≥ 3.0 g/g creatinine in 41.1% of patients. During 117.5 ± 100.1 months of follow-up period, there were 97 (19.0%) patients with incident ESRD. The prognostic factors to incident ESRD were estimated GFR, diastolic blood pressure, year of renal biopsy, glomerular size, amount of global sclerosis (GS) and segmental sclerosis (SS), severity of increase in glomerular matrix, interstitial fibrosis, interstitial inflammation, and tubular atrophy (TA), and presence of artherosclerosis of intrarenal vessels. Adjusted with clinicopathologic factors related to incident ESRD, only pathologic findings of GS, SS, and TA were the independent prognostic factors. AUC by ROC to estimate the event of ESRD by percentage of GS was 0.601 (range; 0.538-0.663, p=0.002) and, by percentage of SS, 0.679 (range; 0.616-0.743, p<0.001). We grouped patients with three pathology categorical variables of a criterion of GS 30.9 %, SS 10.5 %, and moderate degree in severity of TA into 4 groups according to the relative risk to develop ESRD. UPCR was a significant risk factor to estimate ESRD only in a Group 4 with the criterion of 2 g/g creatinine by the Kaplan-Meier test (p=0.034). GFR was not a prognostic factor in any pathology subgroup.

Conclusions: Important prognostic factors to estimate incident ESRD were pathologic findings of GS, SS and TA. Significance of UPCR and GFR as prognostic factors was varied according to pathologic findings. We need to reconsider the criterion of UPCR to initiate immunosuppressive treatment according to pathologic findings at renal biopsy.

Longitudinal Analysis of 100 Biopsy-Confirmed Focal Segmental Glomerulosclerosis: Incidence and Treatment Outcomes of a 10-Year, Single-Center Experience in Saudi Arabia

Sultan Al Dalbhi,[1] Asma M. Alotaibi,[1] Manal E. Alotaibi.[2] *[1]Prince Sultan Military Medical City, Riyadh, Saudi Arabia; [2]Umm Al-Qura University, Makkah, Saudi Arabia.*

Background: This study analyzes trends in biopsy-confirmed Focal Segmental Glomerulosclerosis (FSGS) over a ten-year period and evaluates outcomes of various treatment protocols and amins to identify factors influencing disease progression and disease prognosis.

Methods: A retrospective study of 100 biopsy-confirmed FSGS cases from 2013 to 2022 were analyzed. Hypothetical individual patient data were generated for treatment response, renal function, proteinuria, and quality of life. Statistical methods included trend analysis, survival analysis, and comparative analysis.

Results: The incidence rate of FSGS showed variability over the years, ranging from 2.86% to 21.67%. Notably, the highest incidence rate was observed in 2016 (21.67%). Immunosuppressive therapy and supportive care had higher complete remission rates (33.33% and 48.39%, respectively) compared to steroids (16.67%). All treatment groups experienced a decline in eGFR, with steroids showing the highest mean decline (-14.85 mL/min/1.73 m). Proteinuria reduction was most significant with steroids (-1.83 g/g). Quality of life scores were highest for patients on steroids (mean: 72.64).

Conclusions: This study emphasizes the necessity of individualized treatment strategies for FSGS and highlights the significance of long-term monitoring of patient outcomes.

Table 1: Annual Incidence Rate of FSGS

Year	FSGS Cases	Total Biopsies (Hypothetical)	Incidence Rate (%)
2013	2	70	2.86
2014	3	80	3.75
2015	9	55	16.36
2016	13	60	21.67
2017	8	95	8.42
2018	5	85	5.88
2019	6	90	6.67
2020	2	50	4.00
2021	6	75	8.00
2022	3	60	5.00

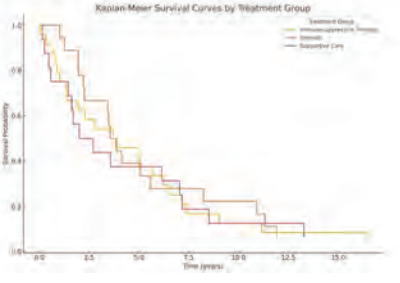
Survival probability over time for different treatment groups (Immunosuppressive, Steroids, Supportive Care).



TH-PO612

Machine Learning-Derived Predictors of Clinical Outcomes in CureGN Participants with FSGS

Mark Elliott,[1] Margaret Helmuth,[2] Abigail R. Smith,[3] Vivette D. D'Agati,[4] Laura Barisoni,[5] Simone Sanna-Cherchi,[4] Daniel C. Cattran.[6] CureGN. *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]University of Michigan, Ann Arbor, MI; [3]Northwestern University, Evanston, IL; [4]Columbia University Irving Medical Center, New York, NY; [5]Duke University, Durham, NC; [6]Toronto General Hospital, Toronto, ON, Canada.*

Background: Focal segmental glomerulosclerosis (FSGS) is a common disease pattern with variable clinical presentations, outcomes, and etiologies, including immune-mediated, adaptive, and genetic. Much of the clinical heterogeneity remains unexplained.

Methods: 722 participants with FSGS have been enrolled with 512 having whole genome sequencing (WGS) data, 276 with centralized biopsy scoring for conventional morphologic parameters, and 226 having both WGS and pathology scoring. Sequential

ridge regression models were performed using: 1) baseline demographic, 2) social determinants of health, clinical, and genetic, 3) pathology morphologic features to predict time to kidney failure defined as two eGFR measurements <15mL/min, dialysis, or kidney transplantation. Ridge regression allows complex modelling while avoiding overfitting. Missing variables were imputed where possible. Discrimination was assessed using integrated area under the curve (iAUC) and variables were ranked by absolute value of standardized coefficients.

Results: Among participants with WGS data, 92 had a high-risk *APOL1* genotype and 32 had monogenic kidney disorders. Model discrimination improved with the stepwise addition of features from model 1 to 3 (iAUC = 0.86, 0.93, 0.95 respectively). Among the 31 most predictive features 14 were protective (1 demographic, 6 clinical, 7 morphologic) and 17 were risk factors (2 demographic, 7 clinical, 1 genetic, 7 morphologic). The top ranked protective factors included high eGFR, high serum albumin, low rates of interstitial fibrosis and tubular atrophy (IFTA), high calcium, diffuse mesangial hypercellularity, high hemoglobin and sodium, tip variant FSGS, and no inflammation in areas of IFTA. Top ranked risk factors included high levels of IFTA, high proteinuria, tubular microcystic changes, hypertension, collapsing variant FSGS, inflammation in areas of IFTA, high levels of segmental and globally sclerosed glomeruli, thrombotic diagnosis, high potassium, edema, high-risk *APOL1* genotype, private health insurance, high levels of arteriosclerosis, black race, use of RAAS inhibitors, and young age at onset.

Conclusions: Machine learning methodologies that integrate a broad range of clinical, genetic, and pathology data allow for the identification of parameters that are predictive of clinical outcome in FSGS.

Role of Neighborhood Disadvantage in Patient Outcomes in Childhood Nephrotic Syndrome in the CureGN Cohort

Elizabeth A. Onugha,[1,7] Abigail R. Smith,[4] Margaret Helmuth,[2] Jill Krissberg,[3] Susan F. Massengill,[5] Chia-Shi Wang,[6] Paul R. Brakeman,[9] Rulan S. Parekh,[10] Sangeeta R. Hingorani.[8] *[1]Baylor College of Medicine, Houston, TX; [2]University of Michigan, Ann Arbor, MI; [3]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Chicago, IL; [5]Wake Forest University School of Medicine, Winston-Salem, NC; [6]Emory University, Atlanta, GA; [7]Texas Children's Hospital, Houston, TX; [8]Seattle Children's Hospital, Seattle, WA; [9]University of California San Francisco, San Francisco, CA; [10]Women's College Hospital, Toronto, ON, Canada.*

Background: Disparities in clinical outcomes in childhood nephrotic syndrome are not completely explained by race and genetics. We aim to examine the influence of residential neighborhood on disease activity and progression in childhood nephrotic syndrome using the Child Opportunity Index (COI).

Methods: CureGN is a prospective cohort study of patients with glomerular diseases diagnosed by biopsy within 5 years prior to enrollment. CureGN pediatric participants with minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) with census tract data were included. COI composite score and subdomain scores in education, health and environment, and social and economic were categorized into quintiles and examined for associations with development of ESKD or 40% decline in eGFR using Kaplan-Meier estimates and log-rank tests.

Results: 371 children (228 MCD; 143 FSGS) with a median follow-up of 5.8 years (IQR 3.4-7.2) were included. Median age at biopsy was 8 years (IQR 4-7); 58% were White, 26% Black, and 12% Hispanic. In the subset of children with FSGS, the probability of progression to kidney failure or 40% decline differed across quintiles of the education domain COI (p=0.02).

Conclusions: In a national cohort of children with nephrotic syndrome, children with FSGS who resided in areas with lower education opportunities had a higher probability of disease progression. Future work will assess potential ways to mitigate the effects of neighborhood opportunities on outcomes.

TH-PO614

Clinical Significance of Immune Deposits and Complement System Activation in Patients with FSGS: Findings from the CureGN Study

Yasar Caliskan,[1] Virginie Royal,[2] Stephan Troyanov,[3] Arnaud Bonnefoy,[4] Clémence Merlen,[4] Mark Schnitzler,[1] John C. Edwards,[1] Krista L. Lentine,[1] Louis-Philippe Laurin.[5] *[1]Saint Louis University, St Louis, MO; [2]Division of Pathology, Hôpital Maisonneuve-Rosemont, University of Montreal, Montreal, QC, Canada; [3]Division of Nephrology, Hôpital du Sacré-Cœur-de-Montréal, University of Montreal, Montreal, QC, Canada; [4]Division of Hematology, Centre Hospitalier Universitaire Sainte-Justine, University of Montreal, Montreal, QC, Canada; [5]Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.*

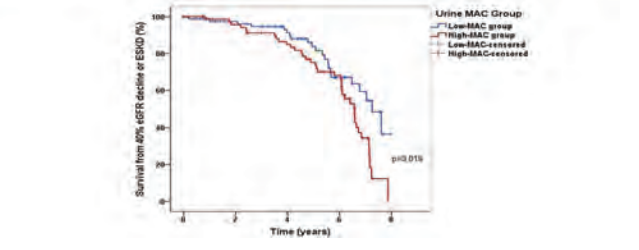
Background: Glomerular IgM and C3 deposits are commonly found in FSGS and assumed to be the result of passive trapping rather than immune mechanisms. The clinical significance of IgM and C3 immunostaining, and their association with complement system activation have not been elucidated yet. We sought to assess the value of immunofluorescence (IF) findings and urinary complement fragments in defining disease activity and progression.

Methods: FSGS patients with available pathology assessment from the CureGN cohort were reviewed and we tested associations of glomerular Igs and C3 staining intensity by IF with the urinary membrane attack complex (sC5b9), proteinuria and time to a composite outcome, defined by kidney failure or 40% eGFR decline. We compared urinary levels of sC5b9 expressed as creatinine and protein ratios.

Results: We analyzed 175 FSGS patients, including 63(36%) incident subjects enrolled within 6 months of pathology review. Glomerular IgM, C3 and IgG deposits were found in 88(50%), 48(27.4%) and 27(15.4%) patients, respectively. 44(91%) and 20(48%) of patients with C3 deposition presented with accompanying IgM and IgG deposition, respectively. C3 deposition was correlated with global sclerosis (r=0.27,p<0.001), interstitial fibrosis and tubular atrophy (IFTA) (r=0.17,p=0.028). In incident patients, urinary sC5b9 levels correlated with total segmental sclerosis (r=0.35,p=0.006) and IFTA (r=0.35,p=0.007). There was no correlation between urinary sC5b9 and the intensity of C3, IgM and IgG staining. IFTA and urinary sC5b9 level at enrollment were independent risk factors for composite outcome (HR 1.92, 95%CI 1.45-2.53,p<0.001 and HR 2.15, 95%CI 1.39-3.33,p<0.001, respectively).(Fig. 1)

Conclusions: In patients with FSGS, a higher urinary level of sC5b9 appears to be associated with eGFR loss independently of proteinuria level. Glomerular C3 deposition was associated with fibrotic lesions which was a predictor of disease progression.

Figure 1. Kaplan Meier survival plot for high urinary membrane attack complex (MAC) group (> median sC5b9 level of 0.075 per proteinuria) versus low MAC group (< median sC5b9 level of 0.075 per proteinuria) (p=0.019).



TH-PO615

Interplay between Immune Deposits, Complement Activation, and APOL1 Renal Risk Variants in Patients with FSGS

Yasar Caliskan,[1] Virginie Royal,[2] Stephan Troyanov,[3] Arnaud Bonnefoy,[4] Clémence Merlen,[4] Mark Schnitzler,[1] John C. Edwards,[1] Louis-Philippe Laurin,[2] Krista L. Lentine.[1] *[1]Saint Louis University, St Louis, MO; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [3]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [4]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada*.

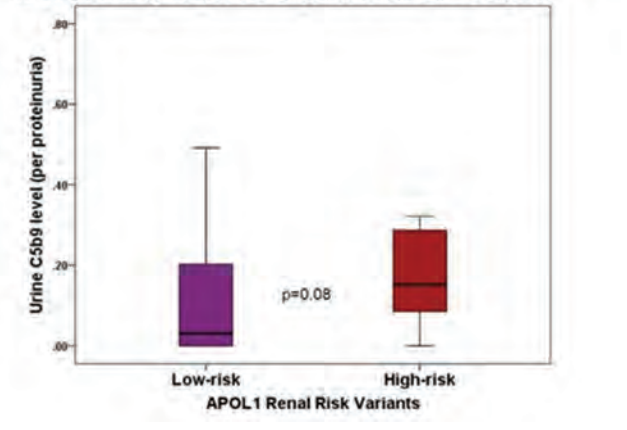
Background: The mechanisms by which *APOL1* renal risk variants (RRVs) carry a worse prognosis in FSGS is debated. Whether glomerular immune deposits and complement activation participate in *APOL1* mediated FSGS is unknown. Using the large CureGN cohort, we evaluated the association *APOL1* RRVs and immunofluorescence (IF) findings and urinary complement fragment measurements (sC5b9).

Methods: We studied the associations of glomerular IgG, IgM and C3 localization and intensity, biopsy findings, urinary sC5b9 and clinical data in CureGN FSGS cohort, regardless of self-reported race. Patients were categorized by two *APOL1* RRVs [high risk (HR)] versus zero to one risk alleles [low risk (LR)] groups. The association between histopathological findings, urinary sC5b9 levels and *APOL1* RRVs were analyzed.

Results: Of 175 participants, 148 (85%) had genetic testing, among whom 31 were HR and 117 were LR participants. The percentage of patients with active disease (UPCR>1 g/g) at enrollment was higher in HR patients compared to LR patients (74% vs 51%, p=0.07). Collapsing FSGS is the dominant type in HR group (45% vs 11%, p<0.001). Mesangial IgG deposition was significantly more frequent in HR group compared to LR group [10 (32%) vs 4 (3%), p<0.001]. Interstitial fibrosis/tubular atrophy and tubular microcystic changes were found at a significantly higher rate in HR group (84% vs 64%, p=0.033; 29% vs 12%, p<0.001, respectively). Urinary sC5b9 levels (median, IQR) were higher in HR patients enrolled within 6 months of biopsy compared to LR group [0.15 (0.08-0.31) vs 0.03 (0-0.20) µg/g, p=0.08] (Fig.1). Proteinuria levels were similar in both groups (p=0.79).

Conclusions: Patients with FSGS and high-risk *APOL1* genotype have more frequent mesangial IgG deposition and a trend towards higher urinary membrane attack complex levels compared to patients with non-risk genotype.

Figure 1. Urine levels of membrane attack complex (sC5b9) per proteinuria were higher in high-risk patients compared to low-risk *APOL1* group.



TH-PO616

Identification of Urinary Biomarkers for Outcome-Associated Digital Pathology Descriptors in Patients with Nephrotic Syndrome

Viji Nair,[1] Jeffrey B. Hodgin,[1] Damian Fermin,[1] Edmond Lee,[1] Laura Barisoni,[2] Matthias Kretzler,[1] Wenjun Ju.[1] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Duke University, Durham, NC.*

Background: Interstitial fibrosis (IF), tubular atrophy (TA) and Mononuclear white blood cells (MWBC) have been shown to be strongly associated with kidney disease outcome in patients with nephrotic syndrome. However, due to the invasive nature of kidney biopsy process, it is impractical to perform repeated assessments hence potentially missing crucial periods for early prognosis and intervention. There is an unmet need to develop non-invasive biomarkers that can represent underlying disease mechanisms and can serve as surrogates for outcome-associated digital pathology descriptors (DPD)s.

Methods: Urine proteomics data (SomaScan assay v4.1), kidney transcriptomic profiles, and DPD including IF, TA, and MWBC of 64 patients with nephrotic syndrome from the NEPTUNE cohort, were integrated to identify urinary protein markers. Statstical methods employed included pearson correlation, linear regression with signifcance set at p ≤0.05. Significance was adjusted for multiple testing. Ingenuity pathway analysis was used to identify enriched canonical pathways. Cox model was used to determine the association of markers with kidney composite endpoint of kidney failure and 40% reduction of GFR.

Results: 274 urine proteins and 2,031 tubulointerstitial genes were identified showing significant correlation with IF (adj. p ≤0.05). Pathway enrichment analysis of IF-correlated genes identified 480 significantly enriched canonical pathways, including interleukin signaling pathways, axonal guidance, STAT3 pathway that have been known as associated with kidney disease progression were among top pathways. Integrating the urine markers and the pathway representing genes, we identified urine protein signatures that predict IF (linear regression, p ≤ 0.05) and a subset of these markers (n=27) also predicted the composite outcome. Similarly, we also identified TA and MWBC associated urinary biomarkers.

Conclusions: We identified pathway representing urine biomarkers that can predict IF and clinical outcomes in patients with NS. Such biomarkers would enable frequent non-invasive pathway-specific disease monitoring, offering the possibility for timely prognosis and targeted treatment. Our finding warrants further validation in larger and independent cohorts.

TH-PO617

A Phase 1 Study in Healthy Adults of the Safety, Tolerability, and Pharmacokinetics of MZE829, an APOL1 Inhibitor, for the Treatment of APOL1-Mediated Kidney Disease (AMKD)

Susan Limb, Victoria Assimon, Janet M. Leeds, Ryan Dick, Cecile Yu, David T. Beattie, Sarah Bronner, Angela Octaviani, Maarten Hoek, Harold S. Bernstein. *Maze Therapeutics Inc, South San Francisco, CA.*

Background: Genetic variants of apolipoprotein L1 (APOL1) are associated with an increased risk of chronic kidney disease and disease progression in individuals of West African ancestry. MZE829 is a highly potent, small molecule inhibitor of APOL1 currently under investigation for the treatment of APOL1-mediated kidney disease (AMKD). We conducted a first-in-human trial to assess the safety, tolerability, and pharmacokinetics of MZE829 in healthy participants.

Methods: The randomized, blinded, placebo-controlled Phase 1 trial evaluated single and multiple ascending doses of MZE829 in healthy participants ages 18 years and older. Assessment of potency and selection of the Phase 1 clinical starting dose were based on the efficacy of MZE829 for reducing albuminuria in a transgenic mouse model of AMKD, where mice homozygous for the APOL1 G2 ($G2_{HOM}$) variant were administered an IFN-γ challenge to elevate APOL1 levels and induce albuminuria. An exposure-response curve from this in vivo pharmacology model was used to assess the minimum anticipated biological effect level and target efficacious exposure range (~EC_{50-98}). Safety and tolerability were evaluated through the assessment of multiple primary endpoints including, the incidence and severity of adverse events, clinically significant abnormalities in laboratory assessments, physical examinations, vital signs, and 12-lead ECGs. Noncompartmental analysis and population pharmacokinetic analysis were used to estimate doses for subsequent patient studies. Selected probes for potential drug-drug interactions were performed to inform use of MZE829 with other medications used in patients with proteinuric kidney disease.

Results: The study is in progress. Final safety and pharmacokinetic results will be presented.

Conclusions: MZE829 is a potent, selective, small molecule APOL1 inhibitor. Phase 1 evaluation in healthy participants demonstrated that safe and well-tolerated doses of MZE829 achieve exposures through the target efficacious range. Trials in patients with AMKD will be conducted to demonstrate clinical proof of concept for proteinuria reduction

Complement Activation Products in Kidneys of Patients with Primary Focal Segmental Glomerulosclerosis

Xiaojie Gong, Jing Huang, Zhao Cui, Ming-Hui Zhao. *Peking University First Hospital Department of Nephrology, Beijing, China*.

Background: Plasma and urinary complement profile of patients with primary focal segmental glomerulosclerosis (FSGS) have provided compelling evidence indicating the participation of complement system in FSGS pathogenesis. However, the profile of complement activation in glomeruli of primary FSGS requires clarification.

Methods: Fifty-four patients with primary FSGS were enrolled. Kidney deposition of complement C1q, MBL, C4d, Bb, C3d and C5b-9 was detected by immunohistochemistry. The correlations between clinical features and glomerular complement deposits were analyzed.

Results: The percentages of glomeruli with positive staining of C1q, C4d, Bb, C3d and C5b-9, and the IOD of MBL were significantly higher in patients with primary FSGS than those in healthy controls (all *P*<0.001). Among FSGS patients in comparison with tip variant, the percentages of C4d positive glomeruli were significantly higher in NOS variant (*P*=0.03), cellular variant (*P*=0.003), and perilihar variant (*P*=0.007); the

percentage of Bb positive glomeruli was significantly higher in cellular variant (*P*=0.02); the percentages of C5b-9 positive glomeruli were significantly higher in NOS variant (*P*=0.001) and cellular variant (*P*=0.001). The percentage of C4d positive glomeruli exhibited positive correlation with the percentage of segmental glomerulosclerosis (r=0.33, *P*=0.02). The percentage of C5b-9 positive glomeruli exhibited negative correlation with eGFR (r=-0.29, *P*=0.04) and positive correlation with the percentage of segmental glomerulosclerosis (r=0.37, *P*=0.008). The percentage of C3d positive glomeruli was significantly higher in the relapse cases than the non-relapse ones (*P*=0.02). The patients with a higher percentage of C5b-9 positive glomeruli had worse kidney prognosis during follow-up (Log-rank, *P*=0.02).

Conclusions: The complement system is activated in primary FSGS, via the classical pathway and alternative pathway. The complement activation was closely related to the pathogenesis of NOS and cellular variant, and correlated with the severity of nephrotic syndrome and kidney outcome. These findings indicate that complement system may actively participate in the mechanism of FSGS.

TH-PO619

Efficacy and Safety of Rituximab in Patients with Focal Segmental Glomerulosclerosis (FSGS): A Single-Center Retrospective Cohort

Amnah T. Kashkari,[1] Nahlah A. Alagla,[1] Hanin S. Aldalham,[1] Gamal Mohamed,[1] Turki Al Hussain,[1] Abeer A. Alkhawlani,[2] Rojina F. Mohamed,[2] Bushra S. Khan,[2] Fawzy M. Abodahab,[2] Ahmed F. Elfar.[1] *[1]King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; [2]Alfaisal University College of Medicine, Riyadh, Saudi Arabia.*

Background: FSGS is a pattern of glomerular lesion which can be primary or secondary. Current therapy is based on FSGS category, avoiding immunosuppressive therapy in non primary-FSGS. Rituximab may be useful in the management, however clinical evidence in adults is limited. Our study assessed the efficacy of Rituximab in adolescents and adults with FSGS.

Methods: We retrospectively reviewed all biopsy proven FSGS from 2010 to 2021. Patients aged ≥ 14 years who received at least one dose of Rituximab were included. Primary outcome was response rate at 3, 6 and 12 months. It was classified as complete or partial remission according to KDIGO criteria.

Results: A total of 30 patients were included. Baseline characteristics are shown in table 1. Response rate (combined complete and partial) at 3, 6 and 12 months was 67 %, 70%, and 69% respectively as in figure 1. At 6 months, 65% of responded patients had B cell depletion. A better response was observed with steroid dependent patients. Median time to first relapse from last Rituximab dose was 11 months with relapse rate of 53%. Regarding safety, mild reactions were reported consistent with the known safety profile of Rituximab.

Conclusions: Our data suggests that Rituximab is effective in FSGS especially those who are steroid dependent. However relapse rate is significant once Rituximab is stopped. To support our result, further studies are needed with larger volume of patients.

Table 1: Baseline Characteristics of 30 Patients with FSGS

	At Diagnosis	At Rituximab Administration
Age (group)	Adolescent 9 (30) Adult 21 (70)	
Age (yrs)	20 (13)	23.5 (14)
Gender	Male 16 (53.3) Female 14 (46.6)	
FSGS classification	Primary 28 (93) Secondary 2 (7)	
Steroid dependent	Dependent 20 (66.6) Resistant 10 (33.3)	
Serum Creatinine (umol/L)	65 (40)	75 (99)
Serum Albumin (g/L)	20 (15)	25 (16)
Urine protein creatinine ratio (mg/mmol)	478.4 (265)	511 (582)

Table 1: results are expressed in N (%) for categorical variables and median (interquartile range) for continues variables

TH-PO620

A Pilot Study on the Efficacy and Safety of Rituximab in the Maintenance of Remission in Adults with Minimal Change Disease

Wang Ling, Xiao Fei, Dai H. Zi. *Department of Rheumatology and Clinical Immunology, Daping Hospital, Army Medical University (Third Military Medical University), Chongqing, China.*

Background: Minimal change disease (MCD) is a common etiology of nephrotic syndrome (NS). Steroid therapy is usually effective, but frequent relapses / steroid-dependent are therapeutic challenges. Rituximab (RTX) has shown promising results in inducing remission of relapsed and refractory MCD in adults, reducing the recurrence rate of the disease and prolonging the recurrence-free time. However, the efficacy and safety of RTX in maintaining the remission of adult-onset MCD have not been reported.

Methods: 12 patients were confirmed by renal biopsy as MCD and received intravenous methylprednisolone (500mg/d, for 3 days) followed by oral methylprednisolone (0.8mg / kg / day). All patients achieved complete remission(CR) within 8 weeks,and then were randomised 1:1 to receive methylprednisolone(n=6) and RTX (n=6, 375mg/m2, intravenous, once weekly, 2 times in total). The methylprednisolone maintenance remission group(MMRG) continued oral methylprednisolone alone, with a reduction of 4 mg every 2-4 weeks. In the RTX maintenance remission group(RMRG), the methylprednisolone was reduced from the 9th week to discontinuation. The total exposure time of methylprednisolone was no more than 9 weeks.

Results: All patients presented with NS with a median urine protein quantification of 10.89 g/24h (5.9, 13.8 g/24h) and a median serum albumin level of 16.7 g/l (13.43, 19.85g/l). Their renal function was normal when MCD was diagnosed. Of the 6 patients with MCD in MMRG, there were three patients of relapsed during glucocorticoid reduction, 1 patient relapsed 1 month after glucocorticoid withdrawal, and 2 patients relapsed 2 months after glucocorticoid withdrawal. The Median duration of sustained remission was 7 months (4.75, 8 months, inter quartile range (IQR)). 6 patients in RMRG during a follow-up of 18.5 months (17, 20.5 months) had no relapse. Compared with the MMRG, the RMRG had significantly longer recurrence-free time (*P*<0.001) and less glucocorticoid exposure(*P*<0.001). No adverse events occurred in all patients.

Conclusions: RTX maybe an effective and safe treatment option for adult patients with first-episode MCD in maintaining disease remission and minimizing glucocorticoid exposure. However, high-quality clinical studies are needed to confirm the efficacy of rituximab in the maintenance of remission in first-episode MCD.

TH-PO621

Plasma Exchange and Rituximab for Prevention of Recurrent FSGS after Previous Graft Loss

Sophie Gharaei,[1,2] Durga Anil K Kanigicherla,[2] Hashim Abbas.[2] *[1]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [2]Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: Primary focal segmental glomerulosclerosis (FSGS) commonly recurs after transplantation, significantly increasing the risk of graft dysfunction, especially in patients with prior graft loss due to recurrent FSGS (rFSGS). Even though therapeutic plasma exchange and rituximab have found increasing use in the treatment of post-transplant recurrence, there is no clear consensus on pre-transplant interventions to prevent recurrence in this patient cohort.

Methods: We conducted a systematic review on the role of prophylactic use of rituximab and plasma exchange to prevent the recurrence of FSGS in patients with prior graft loss due to rFSGS. We analysed the outcomes of 32 patients who had a diagnosis of primary FSGS in their native kidneys, lost one or two prior transplants due to recurrence of FSGS, and received prophylactic treatment with plasma exchange, rituximab or a combination of both.

Results: Table 1 summarises the recurrence rates after different prophylactic treatments, encompassing 32 patients across 11 studies with prior graft loss and re-recurrence. Plasma exchange in isolation (62.5%) was the more common intervention used in these patients, rituximab was used in combination in 25%, and in isolation in 12.5% of patients. Recurrence rates were similar across the three interventions. Overall, 47% experienced recurrence, either immediately or within the first three months after transplantation. 53% remained free of FSGS in the index transplant, with a minimum follow-up of 8 months.

Conclusions: Pre-transplant measures may have a role in the prevention of recurrence of post-transplant FSGS in high-risk patients. The paucity of reliable data available in the literature calls for larger prospective controlled studies to further investigate the effectiveness of pre-emptive plasma exchange and rituximab in preventing this devastating complication in patients with rFSGS.

Prophylaxis (n)	Recurrence (%)	No Recurrence (%)
PE only (20)	9 (45)	11 (55)
RTX only (4)	1 (25)	3 (75)
PE + RTX (8)	5 (63)	3 (37)
Total (32)	15 (47)	17 (53)

Table 1. Rates of rFSGS following prophylactic use of plasma exchange (PE) or rituximab (RTX).

TH-PO622

Obinutuzumab in Children with Kidney Diseases: A Single-Center Experience

Shefali Vyas,[1] Ursula Nath,[2] Benjamin Steinman,[1] Isabel Roberti.[1]
[1]RWJBarnabas Health, West Orange, NJ; [2]University of Delaware, Newark, DE.

Background: Chart review of children with refractory kidney diseases treated with Obinutuzumab. Obinutuzumab an antiCD20 monoclonal antibody developed to overcome rituximab resistance in B-cell malignancies, has demonstrated superior outcomes. Obinutuzumab is proven to be effective in the treatment of active lupus nephritis and membranous nephropathy. There are only 2 peds studies reporting its use in SDNS and MN.

Methods: Chart review was done of children who received Obinutuzumab between 2020 and 2024. All received Obinutuzumab (1000 mg/1.73 m2/dose) and one received Ofatumumab (300 mg/1.73 m2/dose). Indications: adverse reaction or disease relapse after Rituximab; refractory nephropathies to standard therapy (abnormal eGFR or severe proteinuria). Demographic data, etiology of kidney disease, kidney biopsy results, therapies used, eGFR, Urine pr/cr, follow-up time & side effects were collected. Improvement in the degree of proteinuria and/or eGFR changes were reviewed

Results: Total of 46 infusions in 29 patients. Male 52%, Hisp 52%, AA= 27%, C= 7% and other =14%. **Median age** at presentation = 5 yrs. **Etiology**: NS= 22 (76%) [SDNS=13 (59%), SRNS= 41%]; 2 pts post Txp NS (1 FSGS recurrence; 1 de novo MCNS); chronic GN = 5 (17%) (C3GN, SLE, IgAN, C1Q); AIN with AKI=2 (7%). **Biopsy** =25 (96%). **Initial therapy:** All received steroids; Ritx= 20 (69%), CNI (tacro/CSA) = 19 (66%), MMF= 17 (59%), Cytx =7 (30%). **Median age at time** of med =13 yrs, **Median time to respond** = 25 days**. Time of obinutuzumab from diagnosis** 2m-14 years (median 4 yrs). 6 patients received > 2 doses **Proteinuria**: 34 infusions at the time of relapse. Pre-tx no proteinuria =1, mild proteinuria (<2.5 g/g Cr) = 6 ; nephrotic proteinuria (>2.5g/g Cr) = 27. **AKI/CKD** =6 (20%) **ACEi/ARBs**: 48%(14/29) HTN= 24% (7/29) **Post-tx** = 6 patients had mild proteinuria and 1 nephrotic range. (pvalue <0.001) Complete remission of proteinuria was achieved in 75%. **At last follow up:** CKD=5; in all eGFR improved with average 33% post tx. 1 death **Follow up time** (3 to 44 mos; median= 10). Post tx: all patients off steroids and 24% (7/29) off all immunosuppressive therapy

Conclusions: Obinutuzumab was well tolerated in children with various refractory nephropathies. We noted significant reduction in proteinuria and 33% improvement in eGFR. All patients were able to be weaned off the steroids, 75% had complete remission and 24% were off all medications.

TH-PO623

Successful Treatment of Primary FSGS with LDL Apheresis

Anjali B. Nayak,[1] German A. Lozano-Guzman,[1] Raja Dandamudi,[2] Joshua Zaritsky.[1] *[1]Phoenix Children's Hospital, Phoenix, AZ; [2]Washington University in St Louis, St Louis, MO.*

Background: Focal Segmental Glomerulosclerosis (FSGS) remains one of the most common causes of pediatric end stage kidney disease (ESKD). Its treatment remains empiric and is often unsuccessful with significant treatment morbidity. Additionally, recurrence of FSGS is quite common in renal allograft recipients. Therefore we wanted to describe the efficacy and safety of LDL-A in 4 patients with primary FSGS resistant to multi-drug therapy

Methods: Retrospective, single center study. LDL-A was done using the Liposorber LA-15 system, with 12 treatments over 9 weeks. Patients received IV methylprednisolone with the last 6 treatments (Table 1).

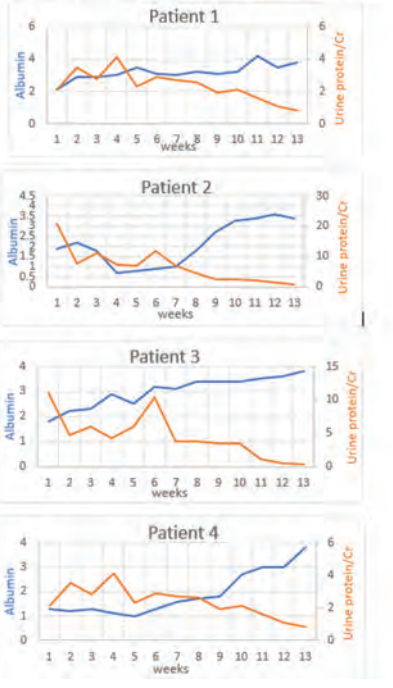
Results: Primary outcomes were measured by either complete remission (CR), or partial remission (PR). CR was a urine protein to creatinine (UPC) of less than 0.5 mg/mg. PR was a UPC between 0.5 mg/mg to 2 mg/mg, and greater than or equal to 50% reduction on proteinuria. Secondary outcomes included improvement in serum albumin. We treated 4 patients with FSGS resistant to multi-drug therapy. All 4 patients responded and went into complete remission. (Pic 1).

Conclusions: All 4 of our patients were able to achieve complete remission of primary FSGS despite a lengthy history of multi-drug resistance. This builds on existing evidence demonstrating the utility of LDL-A in recurrent disease. Although future studies are needed to determine its mechanism of action, LDL-A is a well-tolerated treatment that may become a standard of care in both primary and recurrent FSGS.

Clinical characteristics of patients at baseline

	Patient 1	Patient 2	Patient 3	Patient 4
Age at diagnosis(years)	3	3	5	2
Age at LDL-A treatment	4.5	4.5	5.5	14
Initial treatment course	Steroids, mycophenolate, tacrolimus and rituximab	Steroids, mycophenolate, tacrolimus and rituximab	Steroids, mycophenolate, tacrolimus and rituximab	Steroids, mycophenolate, tacrolimus and rituximab
Post LDL-A course	Went into CR	Went into CR	Went into CR	Went into CR

Figure 1. UPC trend and albumin trend of patients with SRNS during LDL-A treatment and follow up



TH-PO624

Characteristics of Dyslipidemia in Primary Nephrotic Syndromes

Sulaiman M. Alhumaid,[1,2] Hamzah A. Alhamzah,[3] Ali S. Almagooshi,[1] Ahmad M. Samman,[1] Ali M. Alqaraishi,[1] Muhannad Alqudsi.[1]
[1]King Abdulaziz Medical City, Riyadh, Saudi Arabia; [2]King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [3]Imam Muhammad Ibn Saud Islamic University, Riyadh, Saudi Arabia.

Background: Although it is not a criterion for diagnosis, dyslipidemia is frequently found in nephrotic syndrome (NS). Cholesterol, triglyceride, and low-density lipoprotein (LDL) are usually elevated in NS, while high-density lipoprotein (HDL) can be normal or minimally decreased. Mechanisms, treatments, and related medical outcomes of dyslipidemia in NS have been studied in isolation of the underlying disease, hence the comparison of lipid values between primary membranous nephropathy (MN), minimal change disease (MCD), and primary focal segmental glomerulosclerosis (FSGS), is not well recognized.

Methods: Retrospective chart review of patients with NS from 2010-2022. Only patients with primary MN, MCD, and primary FSGS were included. Lipid profile was reported at the time of NS diagnosis and twelve months later. We compared lipid values between three primary NS using Kruskal-Wallis and Mann-Whitney U tests.

Results: There were 409 patients diagnosed with NS. 284 patients were excluded due to insufficient data, secondary NS, or uncontrolled DMII (glycated hemoglobin A1C>8). 125 patients with primary FSGS, MN, or MCD were included. 52=FSGS (41%), 31=MCD (25%), 42=MN (34%). Average age was 32 years, 55=Females (44%), 25=Diabetes Mellitus (DM) (20%), 79=received statin (56%), there was no statistical difference in baseline characteristics between NS groups. After adjustment to serum albumin and urine protein/creatinine ratio, initial cholesterol and triglyceride were similar

in three NS groups (P>0.05), LDL was 216 mg/dL, 201 mg/dL, and 178 mg/dL in FSGS, MCD, and MN respectively p= 0.04 (statistical difference was only in FSGS vs MN group p=0.04), initial HDL was 58 mg/dL, 77 mg/dL, and 50 mg/dL in FSGS, MCD, and MN respectively p=<0.001 (statistical differences were in MCD vs FSGS, and MCD vs MN groups p=0.001, and p=<0.001 respectively). After 12 months follow up, all lipid values were similar in three NS groups regardless of statin use.

Conclusions: After adjustment to primary NS severity, cholesterol and triglyceride values are not significantly different at presentation of MN, MCD, and FSGS. HDL is significantly higher in MCD compared to MN, and FSGS. LDL is significantly higher in FSGS compared to MN. At 12 months follow up, use of statin did not change lipid values in MN, MCD, or FSGS.

TH-PO625

Lipidomics Analysis Reveals Biomarkers for Proteinuria Remission and Disease Progression in FSGS/Minimal Change Disease (MCD) from the NEPTUNE Cohort

Takaya Ozeki,[1,2] Fadhl Alakwaa,[1] Anna V. Mathew,[1] Matthias Kretzler,[1] Laura H. Mariani.[1] NEPTUNE (Nephrotic Syndrome Study Network).
[1]University of Michigan, Ann Arbor, MI; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: FSGS/MCD exhibits significant heterogeneity, presenting a challenge for effective treatment. Assessment of the systemic metabolic changes reflected in circulating lipids and capture of lipid signaling molecules can illuminate this complexity.

Methods: We examined 131 participants with FSGS/MCD from the NEPTUNE cohort, analyzing plasma samples collected within 45 days of kidney biopsy. Lipidomics profiles were obtained through liquid chromatography-mass spectrometry (LC-MS), utilizing in silico tandem mass spectral databases for identification and established normalization method. Rigorous data filtration included the removal of low variance and high missing rate features, missing value imputation, log transformation, and scaling. A Cox-Elastic Net model with 5-fold cross-validation was employed to identify lipids associated with complete remission of proteinuria (CR, UPCR<0.3) and disease progression (40% decline of eGFR or ESKD).

Results: Among the 131 participants, 59.5% had FSGS, 64.1% were adults, and 62.6% were male. Median UPCR level was 1.65, and 31.3% had nephrotic range proteinuria (UPCR>3.5). Median eGFR levels was 84.1 at the sample collection. Over a median follow-up of 51.0 months, 50.0% achieved CR, while 26.2% reached to the composite renal outcomes. We measured 984 plasma lipids, of which 732 met our stringent quality criteria for further analysis. Among these, 37 lipids were associated with CR and 69 with disease progression. Notably, five of them were linked to both outcomes and belong to the Glycerophospholipids, Sphingolipids, and Glycerolipids lipid categories (Table 1).

Conclusions: This lipidomics analysis of FSGS/MCD patients identified specific lipid classes, including Glycerophospholipids, Sphingolipids, and Glycerolipids, as potential biomarkers for proteinuria remission and disease progression. These findings can offer insights into the heterogeneity in FSGS/MCD and suggest avenues for personalized therapeutic interventions. Further mechanistic studies are needed to elucidate the specific roles of these lipid categories in remission of proteinuria and disease progression.

Association of Proteinuria Remission and Its Timing with Kidney Outcomes in Patients with Focal Segmental Glomerulosclerosis

Takehiko Kawaguchi,[1] Toshiyuki Imasawa,[1] Moritoshi Kadomura,[1] Hiroshi Kitamura,[1] Takaya Ozeki,[2] Ritsuko Katafuchi,[3] Kazamasa Oka,[3] Kengo Furuichi,[3] Yoshitaka Isaka,[3] Hiroshii Sato,[3] Hitoshi Sugiyama,[3] Shoichi Maruyama.[2,3] *[1]National Hospital Organization Chibahigashi National Hospital, Chiba, Japan; [2]Nagoya University, Nagoya, Japan; [3]Ippan Shadan Hojin Nihon Jinzo Gakkai, Bunkyo-ku, Japan.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is a leading cause of end-stage kidney disease (ESKD), and proteinuria remission (PR) is associated with improved renal prognosis in patients with FSGS. However, it is unclear whether the timing of PR affects renal outcome.

Methods: Data on 304 patients with biopsy-confirmed FSGS of Japan Renal Biopsy Registry from 2010 to 2013 were analyzed [median age: 52 years; female: 37%; median eGFR: 58 ml/min/1.73m^2; nephrotic proteinuria: 54%; histologic variant: not otherwise specified (NOS) 48%, tip 19%, perihilar 15%, cellular 13%, collapsing 5%]. Patients were divided into 4 groups based on timing of PR (<0.3 g/day) from biopsy: ≦2 months, 2 to 12 months, >12 months, and no PR during follow-up. The primary outcome was a composite of progression to ESKD or all-cause death 5 years after biopsy. Kaplan-Meier curves and multivariable Cox models were used to compare the outcomes among these groups.

Results: One hundred thirty-six patients (45%) achieved PR, with a median time to PR of 4 (interquartile range 2, 13) months (Figure 1). During the median follow-up period of 4.8 years, outcome events occurred in 37 patients (12%). Overall, PR was associated with the primary outcome (adjusted hazard ratio [aHR]: 0.08 [95% confidence interval (CI), 0.02-0.30]). However, no significant difference in the outcome was found among the three groups achieving PR (Figure 2); compared with PR ≦2 months, the aHR for the outcome was 0.87 [95% CI, 0.05-14.2] for PR between 2 and 12 months, 1.04 [95% CI, 0.06-17.6] for PR ≧12 months, and 11.1 [95% CI, 1.38-93.5] for no PR.

Conclusions: Although PR itself has an impact on renal outcomes of FSGS during 5 years, the timing of PR may not predict improved renal prognosis. Specific strategies and interventions to achieve PR should be implemented for better renal outcomes at any clinical stage of FSGS.

Frequency of Adverse Events and Relapses after SARS-CoV-2 Vaccination in Patients with Podocytopathies

Sophia Lionaki,[1,2] Angeliki Sardeli,[1] Marios Papasotiriou,[7] Evangelia Dounousi,[6] Smaragdi Marinaki,[2,8] Kriki Pelagia,[3] Dimitra Gkalitsiou,[4] Vassilios Liakopoulos,[5] Eva P. Andronikidi,[2] Giannakopoulos Panagiotis,[1] Stylianos A. Panagoutsos.[3] *[1]Panepistemiako Geniko Nosokomeio Attikon, Athens, Greece; [2]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [3]Demokriteio Panepistemio Thrakes, Komotini, Greece; [4]Geniko Nosokomeio Athenon Giorgos Gennematas, Athens, Greece; [5]Aristoteleio Panepistemio Thessalonikes, Thessalonike, Greece; [6]Panepistemio Ioanninon, Ioannina, Greece; [7]Panepistemio Patron, Patra, Greece; [8]Laiko General Hospital, Athens, Greece.*

Background: To evaluate the impact, if any, of SARS-CoV-2 vaccination in the clinical course of patients with biopsy-proven podocytopathies.

Methods: This is a multicenter retrospective study of patients with histologically proven minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS), who were vaccinated against SARS-CoV-2. Patients who had developed ESKD prior to vaccine were excluded. Recorded data included adverse events, immunosuppressive regimens and relapses of the primary disease.

Results: Included patients (N=77) patients were 46.1(±17.8) years old and 38(49.3%) were males. Of these, 68(88.3%) patients had received immunosuppression at diagnosis and 80.5% had achieved remission. The time interval from kidney biopsy to vaccination was 69.2(±75.8) months and received 2.9(±0.76) doses. 37.3% of patients were on immunosuppressive therapy at vaccination. 25.3% of patients reported systemic and 31.8% local adverse events associated with vaccination. Among patients on remission at vaccination, 8(10.4%) experienced a relapse of nephrotic syndrome within 3.5 (±2.7) months. Among relapsers, 5 (71.4%%) had MCD.

Conclusions: Patients with podocytopathies in this cohort had a good vaccine safety profile. Among patientson remission 8(10.4%) experienced a relapse of the primary disease after vaccination.

TH-PO628

Prediction of Response to Intensified Immunosuppression in Childhood Steroid-Resistant Nephrotic Syndrome by Multimodal Machine Learning

Franz Schaefer,[1] William Morello,[7] Huy Q. Vo,[6] Anibal Pedraza,[3] Nicola Altini,[4] Moin A. Saleem,[5] Chandra Mohan,[6] Jan U. Becker.[2] *[1]Universitat Heidelberg, Heidelberg, Germany; [2]Universitat zu Koln, Cologne, Germany; [3]Universidad de Castilla-La Mancha, Ciudad Real, Spain; [4]Politecnico di Bari, Bari, Italy; [5]University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom; [6]University of Houston, Houston, TX; [7]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Background: There are no established models to predict the varied response to intensified immunosuppression in steroid-resistant nephrotic syndrome (SRNS). Multimodal machine learning, integrating clinical and genetic data with nephropathology imaging holds great promise to deliver such classifiers with perfect reproducibility. Here, we present such a theranostic classifier based on a multi-centric dataset obtained from the PodoNet registry cohort.

Methods: Data from 201 SRNS patients with available clinical data and whole slide images of kidney biopsies were collected from 14 European pediatric nephrology centres. The clinical input data contained 19 parameters including genetic mutation (yes/no) and eGFR at biopsy; the ground truth theranostic endpoint was treatment response as no (n=114), partial (n=42) and complete remission (n=45) within 6 months as defined by serum albumin and proteinuria changes. We trained our proprietary multimodal MorphSet++ architecture in a weakly supervised fashion. MorphSet++ integrates the clinical data vector from a shallow network at various stages with the transformer-based deep network analysis of the histopathology imaging data. Results are given as means after 5-fold internal cross-validation.

Results: Mean AUC was 80% for complete, 77% for partial and and 81% for no remission. The mean positive predictive value was 89.7, 89.8, 89.3 % and the mean negative predictive value 94.8, 93.4 and 97.6%. Mean sensitivity was 84.2, 67.1, and 98.5% and mean specificity 96.8, 98.4, and 83.9%. Mean balanced accuracy was 90.5%, 82.8%, and 91.2% for no, partial and complete remission, respectively. Adding the results of image analysis improved model performance as compared to clinical/genetic data input alone.t of SRNS.

Conclusions: Our MorphSet++ architecture shows promising results as a theranostic tool to predict response to immunosuppression in SRNS. MorphSet++ allows for rapid up-scaling with additional, larger datasets for even better and more robust performance. This might lead to a re-appraisal of nephropathology in the clinical management of SRNS.

Anti-slit Antibodies on Kidney Biopsy Identify Patients with Steroid-Resistant Nephrotic Syndrome Responsive to Second-Line Immunosuppressant and Hence Have a Good Prognosis

Valentina Raglianti,[1,2] Maria Lucia Angelotti,[2] Luigi Cirillo,[1] Samuela Landini,[1] Viviana Palazzo,[1] Maria Elena Melica,[2] Giulia Antonelli,[2] Carolina Conte,[1] Benedetta Mazzinghi,[1] Francesca Becherucci,[2,1] Paola Romagnani.[1,2] *[1]Azienda Ospedaliero Universitaria Meyer, Firenze, Italy; [2]Universita degli Studi di Firenze, Firenze, Italy.*

Background: Anti-nephrin antibodies have been recently reported in patients with Minimal Change and steroid-sensitive Nephrotic Syndrome (NS), as well as in post-transplant recurrence of Focal Segmental Glomerulosclerosis, supporting an autoimmune etiology in a subset of podocytopathies. We hypothesized that the presence of autoantibodies against slit diaphragm antigens would identify also a subset of patients with steroid resistant NS (SRNS) and explain response to second-line immunosuppressant and hence prognosis

Methods: We evaluated 45 patients with SRNS out of 128 patients with available kidney biopsy samples followed up at Meyer University Hospital IRCCS. By using high-resolution confocal microscopy, we assessed the colocalization between IgG and nephrin staining. To further determine the specificity of the IgG deposition STED microscopy and two different ELISA for anti-nephrin antibodies have been performed

Results: STED microscopy and anti-nephrin ELISA assays suggest that a subset of patients with podocytopathies showed antibodies against either nephrin or non-nephrin slit antigens, i.e. slit antibodies. We observed anti-slit antibodies in 48.5% of non-genetic patients and only in 8.3% of genetic one with SRSN, irrespective of histology lesion patterns. Almost all anti-slit positive patients (92.3%) showed response to second-line immunosuppressive therapy. The only multidrug-resistant anti-slit positive patient reached kidney failure was a diagnosed case of Nail-Patella syndorme. He experienced recurrence after kidney transplantation and anti-slit antibodies have been detected on graft biopsy. Kaplan Meier analysis confirm anti-slit positive patients had a favourable outcome. On the contrary, genetic patient, independently of anti-slit status, and non-genetic anti-slit negative patients, showed poor prognosis at 10 years, both achieving chronic kidney disease and kidney failure

Conclusions: Detection of anti-slit antibodies represents a novel tool for personalized management, by allowing identification of patients more likely to responds to second-line immunosuppressive therapy and have better long term kidney prognosis, i.e. autoimmune podocytopathies

Soluble Angiopoietins in Idiopathic Nephrotic Syndrome

Sarah K. Nelson-Taylor,[1] Colin D. Bauer,[1] Courtney Giannini,[1] Richard J. Johnson,[1] Gabriel M. Cara-Fuentes.[2] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: Idiopathic nephrotic syndrome (INS) is associated with endothelial injury, but its involvement is poorly understood. To gain more insights, we measured soluble (serum) angiopoietins (Ang) 1 and 2 and soluble Tie2, as markers of blood vessel homeostasis, in children with INS.

Methods: We included 17 healthy children, 46 children with steroid sensitive INS (either unbiopsied or with minimal change disease pattern on histology) during relapse and 39 during remission. We measured soluble levels of Ang1, Ang2, and Tie2 in serum using commercially available ELISA kits. Currently, we are analyzing additional patients' samples and estimated total of 70 patients/group by november. Non-parametric tests were used to assess differences among groups and correlation between soluble levels in serum and time to achieve remission in those patients studied during remission. In vitro studies involving immortalized human glomerular cells exposed to healthy and disease sera are in process to test whether INS sera may directly stimulate glomerular endothelial cells to release these soluble biomarkers.

Results: Soluble Ang2 (**Fig. 1a**) and Ang1 levels were higher in patients in relapse and remission than in controls, and higher in those in relapse compared to remission. No differences were found in soluble Tie2 levels between healthy controls and patients. In patients studied during relapse (and with documented time in days to achieve remission), higher soluble Ang2 was associated with slower time to achieve remission (**Fig. 1b**).

Conclusions: INS is associated with alterations of markers of blood vessel homeostasis.

Funding: Private Foundation Support

Peripheral Blood Cell DNA Methylation Can Predict Steroid Response in Nephrotic Syndrome

Samantha J. Hayward, Matthew Suderman, Gavin I. Welsh, Moin A. Saleem. *University of Bristol, Bristol, United Kingdom.*

Background: The majority of children with idiopathic nephrotic syndrome (INS) and adults with Focal Segmental Glomerulosclerosis (FSGS) and Minimal Change Disease (MCD) receive glucocorticoid treatment at diagnosis. Overall, about 10% will not respond to steroid treatment and we have no reliable way of prospectively identifying these patients. DNA methylation (DNAm) is an epigenetic mechanism meaning that it can induce stable but reversible changes in gene expression without any change in underlying DNA sequence. DNAm has shown great potential as a treatment stratification tool in other disease settings. We investigated whether DNAm can predict initial response to steroids in children and young adults with INS.

Methods: Two hundred and eighty one INS patients recruited to the NephroS and NURTuRE cohorts were selected. All patients had been diagnosed with INS ≤ 30 years of age and those who underwent a renal biopsy had a histological diagnosis of FSGS or MCD. Peripheral blood DNAm measurements were generated using the Illumina MethylationEPIC Beadchip (>850,000 CpG sites). Clinical data was used to label patients by their initial response to steroids. Machine learning models were created to predict steroid response from the DNAm data. Models were generated using elastic net following feature filtering, and model hyperparameters were tuned and performance measured within the context of cross validation.

Results: The 281 INS patients had a median age at diagnosis of 5 years (IQR 2-10) and the majority were white (n=198, 71%). The median time between diagnosis and DNAm sample collection was 4 years (IQR 1-10). One hundred and thirty five patients

were sensitive to their first course of steroids and 146 were resistant. The steroid resistant group included patients with known monogenic disease (n=46, 31%). Using the DNAm data, initial response to steroid treatment could be predicted with 70% accuracy and an area under the curve (AUC) of 0.76, (sensitivity 0.79, specificity of 0.60, Figure 1). The final steroid response prediction model contained 14 CpG sites.

Conclusions: We have demonstrated that peripheral blood cell DNAm profiles are a promising predictor of steroid response in INS. Further work to incorporate genetic data into the prediction models is underway and external validation of the results in a separate cohort of patients is required.

Qualitative Findings for Preparing a Clinical Outcomes Assessment Set (COA) for Nephrotic Syndrome (Prepare-NS)

Eloise Salmon,[1] Somayeh Hashemi,[1] Tina Creguer,[1] Courtney N. Hurt,[2] Rebecca Scherr,[1] Yan Zhai,[1] Noelle E. Carlozzi,[1] Jin-Shei Lai,[2] Shikha Wadhwani,[2] John D. Peipert.[2] *[1]University of Michigan, Ann Arbor, MI; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Fluid overload (FO) in nephrotic syndrome (NS) impacts health-related quality of life (HRQOL). Partnering with Food and Drug Administration (FDA), Prepare-NS aims to create and validate COA of FO in NS for use in drug trials over the lifespan. Prepare-NS has developed and debriefed survey items capturing key aspects of FO and its impact on function.

Methods: Individuals with (or caregivers of young children with) focal segmental glomerulosclerosis, minimal change disease, IgM nephropathy, membranous nephropathy, or childhood-onset NS (no biopsy) who had NS edema within 3 months volunteered for interviews on study website. Concept elicitation (CE) by Zoom or phone discussed how FO impacts functioning and other symptoms. Transcripts were coded in NVivo by two independent raters. Recurring themes informed conceptual model development and draft survey items. Additional participants provided feedback on draft items by cognitive debriefing (CogDe).

Results: 32 individuals with NS and 26 caregivers of children with NS completed CE. 6 CogDe interviews analyzed to date. Figure 1 shows demographics. CE themes overall consistent across the lifespan, and among sex, race, and diagnosis groups. Figure 2 shows quotations from CE (by conceptual model domain) and CogDe.

Conclusions: FO in NS over the lifespan impacts multiple HRQOL domains. Validation of survey instruments as COAs in a larger quantitative study is the next phase of Prepare-NS.

	Representative Quotations from Parents/Guardians of Children Ages 2 - 11	Representative Quotations from Individuals Ages 9+
Concept Elicitation		
Physical Function		
Upper Extremity Function	And he couldn't even hold the crayon because his hands were too puffy.	It almost feels like there's something at the bottom of my - like the base of my fingers, like preventing me to like move my hands.
Activities of Daily Living	Putting his shirt on is tough. Putting his socks and shoes on is tough. Bending down to just, like, reach his toes is tough because of the belly.	Sometimes when I swell too much it's for me to put my clothes on because it's hard for me to move
Mobility or Walking	Sometimes she waddles because she gets so big, like a little penguin, like she just waddles around.	Sometimes the swelling would feel like it's getting pushed into my toes and hurt. Enough that I couldn't really walk
Physical Symptom		
Appetite, Thirst, Dietary	She wasn't eating as much. She would say she was full. She would take like one bite, and then, be like "I'm full," you know, "I don't want anything else."...like whenever she swells up.	I didn't really have an appetite at all. I felt like my stomach was full all the time, because of the swelling.
Fatigue	He had very, very low energy, and he would just want to lay around all day.	I just felt like I was drained of energy.
Sleep	He tosses and turns until he's able to find something comfortable sometimes. There are nights where he's moving around so much where he doesn't get the adequate sleep that he needs.	I do get like super tired where I'll stay in bed all day.
Gastrointestinal Diseases	Yeah, when he begins to relapse, he'll have more diarrhea, and then it will quickly turn into constipation.	I go through a lot of times where I am nauseous, and it doesn't really it kind of comes in waves, and I don't really understand where it's coming from, because I don't I don't vomit
Pain, Aches, Cramps, Discomfort	When she was swollen, like all over her body, she was having, like, a pain from every touch on the worst day.	I think the only thing that swelling caused was pain in my feet when I walked. If I was putting weight on my feet, then there was pain
Essential Function		
Breathing	When she was the most swollen that it did seem like her breathing was a little labored because her belly, and everything was so tight.	I just couldn't breathe in all the way because I felt like my stomach was sort of suppressing my lungs.
Urination	[Going]to the bathroom is a big one when he's swollen. He has a really hard time with that because his groin gets so swollen	Just I physically can't pee, because all the swelling
Vision	And her little eyes are so swollen that she can't see very well.	Then I would wake up with my eyes -- my eyes would be swollen out of my face. I mean I couldn't even – I could barely even open my eyes, it was that bad
Cognitive Debriefing		
	When it's at her worst all of these are relevant, every single thing.	I understand the question. It's not repetitive of any of your other questions so far
	That was easy to answer, too, and easy to understand.	All of those questions, all of them. Hitting the nail on the head.
	I can see the relevance of the question. It doesn't necessarily affect my child. But I can see the relevance of the question. I understood the question.	That's a good question. It helps, That helps give you an idea of severity.

TH-PO633

Clinical Characteristics of Young and Elderly Patients with Minimal Change Nephrotic Syndrome

Kodai Furukawa, Shinya Yamamoto, Naoko Yasugi, Hideki Yokoi, Motoko Yanagita. *Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan.*

Background: The clinical features and favorable response to treatment in young patients with minimal change nephrotic syndrome (MCNS) have been reported. However, clinical differences between young and elderly patients remain unclear.

Methods: We evaluated 17 patients diagnosed with MCNS by renal biopsy between January 2019 and December 2023 at our hospital and divided them into two groups: younger (< 65 years) and elderly (≥ 65 years) patients. We collected clinical deta retrospectively.

Results: Of the 17 patients diagnosed with MCNS on renal biopsy, 8 were elderly and 9 were young, with mean ages of 71.7 (median 71.5) and 36.7 (median 34.0) years, respectively. The number of patients diagnosed with acute kidney injury (AKI) at the time of biopsy was higher in the elderly group (7 in the elderly group (87.5%) and 5 in the young group (55.5%)), of whom 6 (75%) in the elderly group had more severe AKI (> stage 2) and 2 (22.2%) in the young group. There was a significant difference between the young and elderly groups ($p < 0.05$). All patients received high doses of steroids (> 0.50 mg/kg body weight/day) as initial treatment, and all patients who responded to treatment achieved complete remission, 6 patients (75%) in the elderly group, and all in the young group. The median time to achieve complete remission was significantly longer in the elderly group (28.0 vs. 9.0 days, $p < 0.05$). In patients who achieved complete remission, there was no significant difference in the following oral steroid doses (0.69 vs. 0.75 mg/kg body weight/day) and the mean urine protein-to-creatinine ratio (10.1 vs. 12.3 g/gCr) at the time of biopsy between the young and elderly groups. The ratios were not significantly different after 12 months of treatment among the 11 patients, excluding 2 elderly patients who underwent dialysis and 3 elderly patients who died during the period due to myocardial infarction, lung cancer, and myelodysplastic syndromes.

Conclusions: We reveal clinical differences between young and elderly patients with MCNS. MCNS in the elderly is associated with more severe AKI and a longer time to achieve complete remission than MCNS in younger patients. When treating elderly patients with MCNS, we should be alert to the complications of steroids and nephrotic syndrome with severe renal impairment, induced by prolonged time to remission.

TH-PO634

Distinctions between C1q Nephropathy and Other Glomerular Diseases with Overlapping Clinical and Pathologic Features

Vanessa Moreno, Yichun Hu, Volker Nickeleit, Harsharan K. Singh, J. Charles Jennette. *The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.*

Background: C1q nephropathy (C1qN) has prominent mesangial C1q immunostaining with varying staining for immunoglobulins. C1qN has overlapping clinical and pathologic features with minimal change disease (MCD), IgM nephropathy (IgMN), focal segmental glomerulosclerosis (FSGS), and class I/II (mesangiopathic) lupus nephritis (MLN). The distinctiveness of C1qN is controversial. C1qN is often considered a variant of MCD and FSGS, or seronegative LN. We compared C1qN demographic, clinical and pathologic features to IgMN, MLN, FSGS and MCD.

Methods: Using data from the UNC Glomerular Disease Collaborative Network, demographic, clinical, and kidney biopsy light microscopy (LM), immunofluorescence (IF) and electron microscopy (EM) data were analyzed from 150 C1qN, 34 IgMN, 104 MLN, 279 FSGS and 115 MCD patients. Diagnosis of C1q nephropathy required C1q staining ≥2+ (scale of 0-4+) with no clinical SLE. Pathology data was prospectively scored at diagnosis. Statistically significant distinctions between C1qN and other glomerular diseases were identified.

Results: As shown in the Table, IF and other pathologic features of C1qN, IgMN, FSGS and MCD are different. Compared to C1qN, these patterns of injury have different LM, EM, demographic and clinical features supporting the possibility of different etiologies and pathogenic mechanisms. C1qN has overlapping IF features with MLN and IgMN but demographic and serologic parameters are different. C1qN has pathologic features overlapping with FSGS and MCD but demographic profile is different.

Conclusions: Compared to IgMN, MLN, FSGS and MCD, C1q nephropathy has different pathologic, demographic and clinical features suggesting different etiology and pathogenesis, and different outcome and response to treatment. The next step with these cohorts is analysis of clinical outcomes and responses to therapy.

Efficacy and Safety of Belimumab in Refractory and Newly Diagnosed Patients with Active Lupus Nephritis: A Real-World Retrospective Observational Study

Ying Ma, Wanhong Lu, Jiping Sun. *Nephrology Hospital of the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: Lupus nephritis (LN), the common manifestation of SLE, continues to be a principal cause of morbidity and mortality. According to 2024 KDIGO guideline, belimumab is recommended as adjunct therapy for active LN. However, the differences in its efficacy and safety between refractory and newly diagnosed active LN are unknown.

Methods: We enrolled active LN patients who initiated belimumab as adjunct therapy in our center between June 2021 and January 2024, and divided them into refractory group and newly diagnosed group according to previous immunosuppressive therapy. Patients were followed up for more than 3 months. Renal manifestation, serologic features, SLEDAI score and steroid dosage were recorded. Efficacy endpoints were complete renal response(CRR) and primary efficacy renal response(PERR)(see BLISS-LN).

Results: A total of 89 active LN patients were selected from 116 LN patients receiving belimumab in our database, among which 42 were in refractory group. At the initiation of belimumab, there is no statistical difference of age, gender, SLEDAI score, renal related markers(proteinuria, serum albumin, eGFR, renal histological classification), and serologic features(positive anti-dsDNA, C3, C4, etc.) between the two groups. Compared with newly diagnosed patients, refractory patients had significantly longer LN duration (P<0.001), lower B-lymphocyte count(P=0.001), and lower dosage of steroids(p=0.003). During the follow-up period, serum albumin, eGFR, C3 and C4 increased, while SLEDAI score, proteinuria and steroids dosage decreased in both groups. The decrease in dosage of steroids were more prominent in newly diagnosed group, with the proportion of patients receiving>7.5 mg/d (prednisone-equivalent dose) steroids reduced from 97.8%(45/46) at initiation to 34.8%(16/46) at last visit. For the refractory active LN patients, the estimated probability of CRR at 3 months was 39.0% and the estimated probability of PERR at 3 months was 48.8%. They were all comparable to newly diagnosed patients by Log Rank test(p=0.137,p=0.623). No difference was found in adverse events rates(p=0.183), time to first renal flare(p=0.792) or RRE(p=0.701).

Conclusions: The add-on treatment with belimumab showed comparable efficacy and safety in refractory and newly diagnosed active LN patients.

Efficacy and Safety of Belimumab in Severe Lupus Nephritis: A Retrospective Single-Center Study

Ailima Aierken,[1] Jing Zhuang,[1] Shufen Yang,[1] Dilina Yalikun,[1] Chengren Xu,[1] Changrong Zhang,[1] Xuefei Tian,[2] Hong Jiang.[1] *[1]People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China; [2]Yale University School of Medicine, New Haven, CT.*

Background: Belimumab is a novel biological agent approved for the treatment of active lupus nephritis (LN), but its efficacy in severe LN has not been fully clarified. This study aimed to evaluate the efficacy and safety of belimumab combined with standard therapy in adult patients with severe active LN compared to standard therapy alone.

Methods: This observational and retrospective single-center study included 36 adult patients with severe active LN. Among them, 18 patients received belimumab combined with standard treatment, while another 18 patients received standard treatment. Demographic, clinical, laboratory, efficacy, and safety variables were collected. Effectiveness was evaluated based on changes from baseline in SLEDAI scores and disease activity markers. Safety data included any adverse event (AE) due to any cause.

Results: The baseline demographic and clinical characteristics of the two groups were similar, with no statistical differences. At week 24, the complete remission rate of renal involvement was significantly higher in the belimumab group compared to the control group (55.6% vs. 33.3%, P = 0.01). The proportion of partial remission of renal involvement was higher in the belimumab group (44.4% vs. 27.8%, P = 0.01). Seven cases of renal involvement in the control group did not reach remission. At week 24, the average SLEDAI score in the belimumab group decreased from 21.67 ± 3.69 at baseline to 6.11 ± 2.423, and the proportion of patients with SLEDAI scores ≤ 4 was higher in the belimumab group than in the control group (38.9% vs. 0%, P = 0.008). At week 24, patients treated with belimumab had a lower proportion of average daily hormone doses (≤ 5 mg/d: 0% vs. 61.6%) compared to the control group. Five patients in the belimumab group required dialysis initially; after treatment, though 2 remained in stage 4 chronic kidney disease, all 5 were off dialysis. The belimumab group was well-tolerated, with an incidence of adverse events similar to the control group. Belimumab did not significantly increase the risk of infection, even during the induction period of LN treatment.

Conclusions: The results of this study indicate that belimumab combined with standard treatment can improve the overall remission rate of severe LN, reduce disease activity, and decrease hormone exposure time while maintaining safety.

TH-PO638

Obinutuzumab for Treatment of Refractory Lupus Nephritis

Tripti Singh,[1] Shelby Gomez,[2] Sarah E. Panzer,[1] Sancia K. Ferguson,[1] Shivani Garg.[1] *[1]University of Wisconsin-Madison, Madison, WI; [2]UW Health, Madison, WI.*

Background: Despite advances, the rates of complete and partial remission remain low in LN. B cell depletion with rituximab has been shown to be effective and is recommended by KDIGO for treatment of refractory LN after verifying adherence to treatment. Obinutuzumab has shown efficacy in addition to mycophenolate mofetil (MMF) in LN. However, the role of Obinutuzumab in refractory LN remains elusive. We studied the efficacy of Obinutuzumab in refractory LN.

Methods: 8 patients with refractory LN were included in the study. Patients received Obinutuzumab 1000 mg, 2 doses, two weeks apart.

Results: Patients included in the study had kidney biopsy with class IV LN (25%), class IV and V LN (25%), class III and V LN (25%) and class II and V LN (25%). Mean age of patients was 29.6 years, 75% were females, 50% were of white race, 13% were Asian race and 38% were Hispanic ethnicity. All patients were on angiotensin convertase inhibitor (ACE-i) or angiotensin receptor blocker (ARB), and 87.5% of patients were on MMF and hydroxychloroquine, 62% were on tacrolimus, and 12.5% on azathioprine. Among this cohort, 75% had been on cyclophosphamide, 50% had been on rituximab, 50% on voclosporin and 37.5% had been on belimumab. Mean duration of follow up was 118 days. After treatment with Obinutuzumab, there was a significant decrease in proteinuria (mean protein: creatinine ratio 2.6 gm/gm vs 1.2 gm/gm, p-value = 0.01, Table 1). There was also significant improvement in mean serum albumin (2.9 gm/dL vs 3.2 gm/dL, p-value 0.03) and serum C4 levels (14 mg/dL vs 17 mg/dL, p-value= 0.02). Additionally, there was a trend in improvement in eGFR (62 ml/min/1.73m^2 vs 71 ml/min/1.73m^2, p-value= 0.19) and serum C3 levels (78 mg/dL vs 87 mg/dL, p-value= 0.23) (Table 1). One patient had shingles 2 months after the Obinutuzumab infusion.

Conclusions: Obinutuzumab therapy along with MMF, HCQ and ACE-i was associated with significant improvement in proteinuria, serum albumin and serum C4 levels in patients with refractory LN. Obinutuzumab could be considered as a treatment option for refractory LN.

Table: Paired t-test to compare Lupus Nephritis parameters pre- and post-Obinutuzumab (8 patients, Median follow-up duration = 118 days)

TH-PO639

Safety and Efficacy of Anifrolumab Therapy to Reduce Proteinuria in APOL1-Associated Lupus Nephritis

James A. Tumlin,[1,2] Lorin M. Sanchez,[1,2] Sharad Virmani,[1,2] Brad H. Rovin.[3,2] NephroNet Clinical Trials Group. *[1]Emory University, Atlanta, GA; [2]NephroNet Clinical Trials Group, Atlanta, GA; [3]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Systemic lupus erythematosus (SLE) is a multiorgan autoimmune disorder that leads to Lupus nephritis (LN) in up to 40% of patients. High type I interferon gene signatures (IFNGS) are present in approximately 80% of patients with LN and are associated with higher rates of treatment failure. Previous studies using the interferon alpha receptor antagonist Anifrolumab to treat Lupus nephritis failed to demonstrate a reduction in UP/Cr at 52 weeks. Because dual expression of APOL-1 "at-risk" alleles in LN is associated with progressive disease, we examined the efficacy of Anifrolumab in LN with varying APOL-1 gene expression.

Methods: Prospective, open-labeled study of 11 patients with confirmed Lupus nephritis with UP/Cr > 500 mg/gm after 6 months of induction immunosuppressive therapy. All patients were maintained on mycophenolate and RAAS therapy for 4 weeks prior to Anifrolumab. All patients were screened for APOL-1 status. Serial UP/Cr and eGFR measurements were collected and reported as Means ± SEM. **Study Inclusion Criteria** 1) APOL-1 testing prior to Anifrolumab infusion; 3) UP/Cr > 500 mg/gm; 5) CKD-Epi eGFR >30 mls/min/1.73M^2 4) and active immunosuppression. **Definitions:** A complete response was defined as UP/Cr < 500 mg/gm after 6 months. A partial response was defined as > 50% reduction from pre-study UP/Cr.

Results: Data from this study are presented in Table-1. Of the 11 enrolled patients 3 had dual APOL-1 at risk alleles and 3 with a single allele. Five patients had no at risk alleles. A six month course of Anifrolumab (300 mg) induced a complete or partial remission in 73% of the total and 66% among dual or single allele LN patients. Both single and dual APOL-1 patients had higher baseline UP/CR compared to wild-type patients. There were no major infections or hospitalizations

Conclusions: Anifrolumab significantly reduced UP/Cr in LN patients with dual, single or no APOL-1 "at risk alleles. Over 60% of dual or single allele LN patients achieved a complete or partial response. Larger studies in this high risk population will be needed to confirm these results.

Comparison between Standard of Care Treatment and Dapagliflozin Added to Standard of Care in Patients with Lupus Nephritis: A Randomized Controlled Trial

Manish Rathi, Niranjan A V, Smita S. Divyaveer, Aman Sharma. *Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: The exploration of sodium-glucose cotransporter-2 inhibitors (SGLT-2i) presents a novel avenue in treating Lupus Nephritis (LN). This study investigates the potential role of adding Dapagliflozin to the SOC treatment in management of LN patients.

Methods: We conducted a randomised controlled open-label study by enrolling 32 newly diagnosed LN patients. Among them, 17 received Dapagliflozin in addition to SOC, while 15 received SOC alone. The patients were followed up monthly for 6 months. The primary outcome was the treatment response at 6 months as per the KDIGO guidelines.

Results: Baseline characteristics revealed no significant demographic differences between the two groups. While both groups exhibited prevalent lupus-related symptoms, the intervention group demonstrated significantly lower mean systolic blood pressure and total protein levels at baseline. At the 6-month follow-up, the clinical response rate in the intervention group was 81.8%, with a trend toward better outcomes compared to the standard of care group (60%) (p 0.425). Frequency of urinary tract infections was higher in the dapagliflozin arm (p 0.31). No significant differences were observed in other parameters between the groups at the 6 months.

Conclusions: In conclusion, this pilot study suggests that the addition of Dapagliflozin to standard care may improve clinical responses in LN with acceptable adverse effects.

Dapagliflozin in Inactive Lupus Nephritis: Preliminary Results of a Cross-Over Trial

Gisele Vajgel, Carlos R. Silva Miranda Filho, Braziliano M. da Silva Júnior, Camila B. Oliveira, Denise M. Costa, Camilla A. de Lima, Paula S. Sandrin-Garcia. *Universidade Federal de Pernambuco, Recife, Brazil*.

Background: Sodium-glucose co-transporter 2 (SGLT2) inhibitors slow the progression of chronic kidney disease (CKD). Lupus nephritis (LN) patients were excluded from the main trials with SGLT2 inhibitors. This trial aims to assess the effect and safety of dapagliflozin in inactive LN patients with residual proteinuria.

Methods: For this cross-over randomized trial, we include adult patients with LN class III, IV (+/-V) without active nephritis but with proteinuria >500mg/24h and ≥ 20ml/min, in the maintenance treatment with a RAAS and MMF<2g/day in stable a dose for at least 4 weeks. We excluded patients with other etiologies of CKD, those with active LN lesions on the recent biopsy (AI>2), use of induction therapy in the last 12 mo. Those included were randomized to receive dapagliflozin 10mg on top of standard of care therapy (SoC) or not. After 24 weeks the groups were switched and those without dapagliflozin received it for the next 24 weeks. Primary endpoint is reduction of proteinuria compared to baseline at 6 and 12 mo. The sample size was calculated for 28 patients enrolled providing 80% power to detect a 25% relative risk reduction in proteinuria (α 0.05).

Results: From 97 screened class III, IV (+/- V) LN patients, we excluded 67 due to active LN, low proteinuria or low eGFR. We included 30 patients that were randomized 14 to start the treatment with dapagliflozin on top of SoC and 16 to remain with the usual therapy for 24 weeks. Eight patients were excluded from the analysis due to new LN flare or lost to f/u. We analyzed the data of 10 patients in the initial dapa+SoC and 12 patients in the initial SoC group after 3 (n=21), 6 (n=21), 9 (n=19) and 12 (n=17) mo. Patients in initial dapa group had a significant decrease in proteinuria after 6 months (1018 to 609mg/day; p=0.017) but increased to 1060mg/day 6 months after the drug withdrawal. This preliminary analysis shows a significant reduction in the proteinuria of –37.3% (+/-38) in patients after 6mo of dapagliflozin as opposed to a 0% (+/-54) for those in the SoC therapy at the end of a 6mo period, p=0.026.

Conclusions: Preliminary results show a significant reduction in residual proteinuria in patients with inactive LN with dapagliflozin without an increase in infections.

Disease Targeting Properties of Voclosporin in Kidney Transplant and Lupus Nephritis Patients

Simon Zhou,[1] Linda M. Rehaume,[1] Ernie Yap,[1] Henry Leher,[1] Lucy S. Hodge,[1] Robert B. Huizinga.[2] *[1]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada; [2]Reformation Consulting Services Inc, Victoria, BC, Canada*.

Background: Voclosporin (VCS), a second generation calcineurin inhibitor, is approved in the United States and Europe for the treatment lupus nephritis (LN) in combination with background immunosuppressive therapy. VCS does not require therapeutic drug monitoring, and is associated with improved glucose, lipid and electrolyte profiles compared to tacrolimus and cyclosporine. VCS demonstrates non-linear selective tissue disposition in animal models, and in renal transplant and LN clinical trials. Pharmacometric modeling was conducted to assess the selective tissue drug disposition relative to systemic drug exposure in patients with renal transplant or LN, comparing with healthy volunteers.

Methods: Individual VCS blood concentration-time measurements were pooled from single and multiple dose ascending studies in healthy volunteers, the Phase IIb PROMISE study in renal transplant patients, and the Phase II AURA-LV and Phase III AURORA 1 studies in LN patients. The VCS blood exposure data were pharmacometrically modelled using a two-compartment model.

Results: In healthy subjects, VCS has comparable central and peripheral volume of distribution (Vc/Vp of 242/272 L/L) and higher elimination than distribution clearance (CL/Q of 43/16 [L/hr]/[L/h]). In transplant patients, VCS has larger peripheral than central volume of distribution (Vc/Vp of 62/2140 L/L), comparable elimination versus distribution clearance (CL/Q of 58/54 [L/hr]/[L/h]) In LN patients, VCS also has larger peripheral than central volume of distribution (Vc/Vp of 34/2120 L/L), slower distribution than elimination clearance (CL/Q of 41/6 [L/hr]/[L/h]).

Conclusions: The larger peripheral volume of distribution indicates selective peripheral tissue uptake of VCS in patients with renal transplant and LN. This is consistent with immunosuppressive activity of VCS in targeted organs relative to blood circulation. The low blood levels of VCS are consistent with the safety profile of VCS compared to other calcineurin inhibitors. Overall, the higher concentration of VCS in affected tissues may account for the efficacy and safety profiles reported in renal transplant and LN patients.

Antiproteinuric Effect and Transient Reduction in Kidney Function of Calcineurin Inhibitors in Hispanic Patients with Lupus Nephritis

Irving G. Ramirez, Mario Alamilla-Sanchez, Valeria Yanez Salguero, Enrique F. Morales Lopez, Martin B. Yama Estrella, Carolina Gonzalez-Fuentes, Karen Hopf, Fani G. Ruiz Rivera, Juan D. Diaz Garcia. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico*.

Background: Systemic lupus erythematosus is an autoimmune disease with common renal involvement. Although current remission inital therapies are effective, a high portion of patients suffer flares or are treatment resistant. Combining immunosuppressants with ICNs may improve clinical response, but scarce data exists for the Hispanic population.

Methods: Patients with SLE and (LN) with persistent proteinuria despite previous immunosuppression and who began a combined regimen, including CNI, were included. 24-hour proteinuria and eGFR by CKD-EPI were assess at 6 and 12 months.

Results: 239 records from patients with LN diagnosis were evaluated, and 42 met inclusion criteria. At 6 months, 40% of the patients obtained complete (CR), and partial response (PR) was reached by 26% of patients. At 12 months, CR and PR were reached by 44% and 32% of patients respectively. A notable reduction in proteinuria was seen at 6 and 12 months compared to baseline (2.89 vs 1.21 g/d, p < 0.001; vs 0.78 g/d, p< 0.001). A transient reduction in eGFR was detected at 6 months (109 vs 104 ml/min/1.73 m^2, p= 0.005), which improved significantly at 12 months (109 vs 117 ml/min/1.73 m^2, p=0.002).

Conclusions: In Hispanic patients with lupus nephritis who previously used immunosuppressor regimes with partial or no response, the addition of a calcineurin inhibitor can be effective. It attains optimal biochemical response rates despite a brief reduction in eGFR that improves without treatment withdrawal.

Therapeutic Effect of Arsenic Trioxide in Human Lupus Nephritis: Results from Network Pharmacology and Ex Vivo Studies

Ruiyan Xie. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong*.

Background: The renal response to standard treatments of lupus nephritis (LN) often remains suboptimal. Preliminary studies showed efficacy of low-dose arsenic trioxide (ATO) in active systemic lupus erythematosus (SLE), but the mechanisms of action are poorly understood.

Methods: Three machine learning approaches and network pharmacology were applied to screen out the predictive targets of differentially expressed genes (DEGs) from human SLE and LN peripheral blood mononuclear cells (PBMCs) and kidney biopsy datasets. Functional enrichment analysis was conducted. The relationship between characteristic genes and inflammatory cell infiltration was further analyzed and validated in ex-vivo experiments.

Results: Twelve predictive intersected DEGs in SLE patients were selected. Functional enrichment analysis showed a strong association between IL-17 signaling pathway and ATO in SLE (p =1.67E-18). Amongst these DEGs, five immunoregulatory genes were further identified by machine learning models, with MMP9 showing the highest AUC (0.942) by ROC curve analysis. Similar results were validated in kidney biopsy and PBMCs from different LN datasets. Our in vitro experiments showed that ATO could downregulate MMP9 and IL17 expression in PBMCs isolated from LN patients (n=5). Ex-vivo studies suggested that ATO may induce apoptosis and inhibit proliferation of CpG-stimulated CD19+ B cells from LN patients.

Conclusions: ATO shows promising effects on B lymphocyte inhibition via downregulation of MMP9, and hence has good potential to be repurposed for the treatment of SLE and LN.

How Global Are the New Lupus Nephritis Guidelines? Evidence Gaps and Underrepresented Groups

Alberto Nordmann-Gomes,[1] Gabriel Cojuc,[2] Adriana Hernández Andrade,[1] Valeria Navarro Sanchez,[1] Juan Carlos Ramirez-Sandoval,[1] Juan M. Mejia-Vilet,[1] Brad H. Rovin.[3] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Recent recommendations for managing lupus nephritis (LN) are based on randomized clinical trials (RCTs). However, these RCTs vary greatly in design and population characteristics. This study aimed to summarize LN RCT data to identify evidence gaps and underrepresented populations.

Methods: We performed a literature review using MEDLINE, CENTRAL, Scopus, and Web of Science to identify all LN RCTs evaluating pharmacologic interventions performed between January 2000 and February 2024. The collected information included variables of study design, selection criteria, studied populations, and study outcomes. Data is summarized by descriptive statistics.

Results: The search strategy identified 1,335 studies of which 71 were selected, with a total population of 8,281 participants. Cyclophosphamide-based regimens were studied in 39 (31.4%) treatment arms, mycophenolic acid analogs (MPAA) in 33 (26.6%), calcineurin inhibitors (CNI) plus standard of care (SoC) in 6 (4.8%), and belimumab plus SoC in 1 (0.8%). The majority of RCTs were multicenter (n=36, 59%), of which 19 (31.1%) were multinational. Most studies were performed in East Asia and the Pacific region (54.1%), followed by North America (24.6%), Europe and Central Asia (26.2%), and Latin America and the Caribbean (22.9%). Tacrolimus plus SoC was exclusively evaluated in Asia while other interventions such as oral cyclophosphamide and belimumab did not include patients from Africa and South Asia. Globally, 86.5% of participants were female. Most participants (55.2%) were Asian, followed by white (28.4%), and only 7.2% were black. ISN/RPS LN classes II and V were evaluated in <10% of RCTs. The definition of the primary efficacy outcome was not standardized among RCTs and only 29 (47.5%) reported severe adverse events. Most guideline-recommended regimens have not been compared against each other.

Conclusions: In light of new recommendations for the management of LN, we make a call to broaden inclusion of underrepresented populations, improve and homogenize study design, and assess unexplored treatment comparisons.

TH-PO646

Urine Epidermal Growth Factor as a Biomarker for Kidney Function Recovery and Prognosis in Glomerulonephritis with Severe Kidney Failure

Alberto Nordmann-Gomes, Adriana Hernández Andrade, Bernardo Juarez Cuevas, María F. Zavala Miranda, Cristino Cruz Rivera, Juan M. Mejia-Vilet.
Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.

Background: Prognostication in glomerulonephritis (GN) with severe kidney failure is critical to evaluate the benefit-to-risk ratio of immunosuppression. This study aimed to evaluate the role of urine epidermal growth factor (uEGF) levels as predictor of kidney function recovery.

Methods: We included 82 subjects with GN and severe kidney failure defined as eGFR ≤30ml/min/1.73m^2 at presentation. Fifty-eight had lupus nephritis (LN) and 24 ANCA-associated vasculitis (AAV). Thirty-five subjects had initial kidney replacement therapy (KRT) requirement. Urine EGF was measured by ELISA and corrected by urine creatinine. The outcomes included time to persistent recovery of eGFR≥30ml/min/1.73m2 and time to recovery of kidney function with dialysis independence in those with initial KRT.

Results: Forty-four (54%) subjects recovered their eGFR ≥30ml/min/1.73m2 with 6-month recovery rates of 93%, 57%, and 0% for subjects in the highest, middle, and lowest uEGF tertile, respectively. Recovery of kidney function was faster and to a higher eGFR in the highest uEGF tertile. The area under the curve (AUC) of uEGF as predictor of recovery was 0.92 (95%CI 0.87-0.98) with a cutoff of 2.60ng/mg having 100% sensitivity to detect all subjects who recovered kidney function above 30ml/min. In the subgroup of subjects with initial KRT, admission uEGF had an AUC of 0.96 (95%CI 0.92-0.99) to detect all subjects who recovered from KRT by 6 months. A uEGF cut-off of 2.0 ng/mg demonstrated 100% sensitivity in detecting all subjects who recovered from KRT within this period.

Conclusions: Urine EGF is a promising biomarker to aid in the prediction of recovery of kidney function in glomerulonephritis with severe kidney function. The addition of uEGF to clinical and histopathological variables may aid therapeutic decisions in these patients.

Early Adoption of Advanced Systemic Therapies in Lupus Nephritis: A Retrospective Analysis

Meghan Weiss, Sawyer A. May. *Spherix Global Insights, Exton, PA*.

Background: Recently, KDIGO and EULAR have issued updated guidelines concerning the management of SLE and LN. These updates advocate for the early use of belimumab and CNIs in the treatment of active LN. Our study delves into US rheumatologists' and nephrologists' strategies for using advanced systemic therapies in LN.

Methods: 1,043 ISN Class III or IV (+/-V) and Class V adult LN patient records were collected in collaboration with 107 US rheumatologists and 90 US nephrologists via an online survey from September to November 2023. These patients had to be in the maintenance phase of treatment and have an eGFR greater than 15 mL/min/1.73m2. This retrospective analysis focuses on the subset of 669 LN patients diagnosed in 2021 or later.

Results: Nearly half (48%) of patients were on an advanced systemic agent during their latest specialist visit, with belimumab being the most commonly prescribed (32%), followed by voclosporin at 12% and rituximab at 4%. Notably, 61% of patients were on oral steroids. About one-third of patients treated with advanced systemic agents for LN received such treatment either before or at the time of diagnosis. Moreover, the majority of patients initiated advanced systemic therapy within six months of diagnosis. There was no discernible difference in the timing of initiation between belimumab, voclosporin, and rituximab by specialists. Upon initiation of belimumab or voclosporin, patients were prescribed an average of 20mg of oral steroids daily. A notable distinction between patient groups was observed in proteinuria levels, with those receiving voclosporin exhibiting higher levels compared to belimumab.

Conclusions: These results underscore a growing emphasis on initiating systemic treatments earlier in the treatment trajectory, yet high doses of steroids remain prevalent. Despite the earlier adoption of advanced systemic therapies, there persists an unmet need for steroid-sparing agents to mitigate the continued reliance on high-dose steroids.

Key Patient Characteristics at Initiation (Means)

Drug	Time from Diagnosis to Initiation	Steroid dose	UPCR	eGFR
Belimumab	Pre-LN diagnosis (n=37)	16.9mg	1.6g	60.4
	Within 6 months of LN diagnosis (n=149)	23.3mg	2.1g	56.2
	>6 months past LN diagnosis (n=113)	12.3mg	1.9g	54.0

TH-PO648

Modeling Chronic Damage in Lupus Nephritis Kidneys Noninvasively

Jorge E. Rojas-Rivera,[1] John P. Shapiro,[1] Juan M. Mejia-Vilet,[2] Valeria Navarro Sanchez,[2] Brad H. Rovin.[1] [1]*The Ohio State University Wexner Medical Center, Columbus, OH;* [2]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico*.

Background: Chronic kidney damage in lupus nephritis (LN) occurs during cycles of inflammation, and healing after treatment. Urine epidermal growth factor (uEGF) correlates well with the histologic chronicity index (CI) and reflects functional tubular mass. We tested models combining uEGF with clinical variables and other putative urine biomarkers to determine whether various levels of chronic damage could be distinguished non-invasively.

Methods: Urine collected at the time of kidney biopsy for LN (n=119) was assessed by ELISAs specific for EGF, complement activation products (C5a, C5b-9, factor Ba) and macrophage-derived CD163, a biomarker of histologic activity in LN. Clinical laboratory tests for serum creatinine (SCr), proteinuria, and complement components C3 and C4 were done. Predictive models to distinguish between no (CI=0) and increasing levels of chronic damage were built by combining urine and clinical markers and were tested using the area under (AUC) the receiver operating characteristic (ROC) curve.

Results: The best models to differentiate between no chronic damage and increasingly higher levels of chronic damage are shown in the Table. The model to predict a CI of 2 or more has the best performance (Figure below Table), but the ability to identify most patients (>80%) with a CI of 4 or greater is still very good (AUC = 0.877, sensitivity = 82%, specificity = 80%). uEGF, serum C3, and uC5b-9 are common to all models.

Conclusions: At LN flare the CI of the kidney can be estimated noninvasively by urine and serum markers. These biomarkers include measures of chronic damage and disease activity consistent with active lesions healing with scarring. Identifying patients with a CI≥4 is important as this level of damage is associated with poor long-term kidney outcome and should prompt treatment with immunosuppressives and nephro-protective therapies. Interestingly, these equations suggest that intra-renal and systemic complement activation may contribute to chronic kidney damage in LN.

AZD1152: Repurposing for Treatment of Lupus Nephritis Driven by the Results of Clinical Trials

Yue Zhao, Shaoshan Liang, Changming Zhang, Ming-chao Zhang, Lang Yue, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing, China*.

Background: Lupus nephritis(LN) is one of the most common and serious complications of systemic lupus erythematosus(SLE). About 20% of LN patients will progress to ESRD within 15 years. The complete remission(CR) rate of LN is not satisfactory. Combination therapy consisting of mycophenolate mofetil, tacrolimus and glucocorticoid achieved a 20% higher CR than conventional therapy. Intrigued by its excellent clinical efficacy, we attempted to discover a new drug which is comparable to combination therapy.

Methods: The Connectivity Map(CMap) database was used for drug repurposing based on the "signature" of combination therapy. And the aurora kinase B(AURKB) inhibitor, AZD1152, was predicted to have similar efficacy as combination regime. The efficacy verification was conducted with MRL/lpr mice. Transcriptome sequencing and functional experiments were performed to reveal and verify the mechanism of AZD1152, respectively. The expression and clinical significance of AURKB were evaluated with lupus-prone mice model and LN patients.

Results: AZD1152 treatment significantly alleviated systemic immune activation and renal injury in MRL/lpr mice. And the efficacy of AZD1152 was comparable to combination therapy. Transcriptome profile demonstrated that AZD1152 could affect local immune-inflammatory pathway in kidney, similar to the combination regime. AURKB, the direct target of AZD1152, was upregulated and expressed in LN renal interstitial infiltrated T cells. The expression levels of AURKB was positively correlated with the activity index(AI) and serum creatinine(Scr) of LN patients. Mechanistic studies indicated that AZD1152 exerts its curative effects mainly through inhibiting AURKB-mediated T-cell proliferation.

Conclusions: This is the first study to illustrate the therapeutic effect of AZD1152 in SLE and renal injury. The comparable efficacy of AZD1152 to combination regime means it is able to further reduce the side effects of drug combination. Our study also revealed the potential of AURKB as a biomarker to predict LN disease activity. In summary, our work proposed a new paradigm for drug discovery which is based on clinical trial proved therapy and approaches of drug repurposing. This strategy is able to accelerate clinical translation process as well as to build bridges between basic scientists and clinical researchers.

7000-Plex Proteomic Screen of Urine for Flare Monitoring and Treatment Response Biomarkers in Active Lupus Nephritis

Chandra Mohan,[1] Kamala Vanarsa,[1] Yewei Ma,[1] Mohammad Daouk,[1] Vinaika Maruvada,[1] Ramesh Saxena.[2] *[1]University of Houston, Houston, TX; [2]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Lupus nephritis (LN) is a major cause of morbidity and mortality in patients with lupus. Since the kidney biopsy is invasive, better, more predictive biomarkers of kidney injury are warranted.

Methods: Clarified urine samples from biopsy proven LN patients with differing degrees of disease activity, and healthy controls, were subjected to a 7000-plex aptamer based proteomic screen. The screening cohort included 15 LN patients with active LN, 6 with inactive LN, 9 healthy controls, and 6 LN patients with serial pre-flare and post-flare urine collections, at an average interval of 3 mo.

Results: Compared to inactive lupus, 605 proteins were significantly differentially expressed in active LN urine (Fig. 1A), with 279 proteins elevated >2-fold at ROC AUC≥0.80. Gene enrichment analysis implicated several functional pathways including receptor-mediated endocytosis, regulation of immune response, GTPase activity, among others. Following treatment, post-flare samples compared to flare samples exhibited 2817 proteins significantly reduced ≥50% (Fig. 1B). Comparing renal flare to pre-flare samples. 398 urine proteins were elevated during flare, with ROC AUC >0.90 and WRS test p-≤ 0.125 (Fig. 1A). A flare response index (FRI) was computed for each urine biomarker, reflecting its fold-change across pre-flare, through flare, to post-flare intervals. Compared to the FRI of urine albumin (6.5), the top 22 urine biomarkers exhibited FRI > 100 (with the highest reaching ~2000).

Conclusions: These studies have identified several novel urine biomarkers of active LN that are highly responsive to renal flares, compared to albuminuria. Further validation studies are warranted.

Funding: Other NIH Support - 1R01AR074096

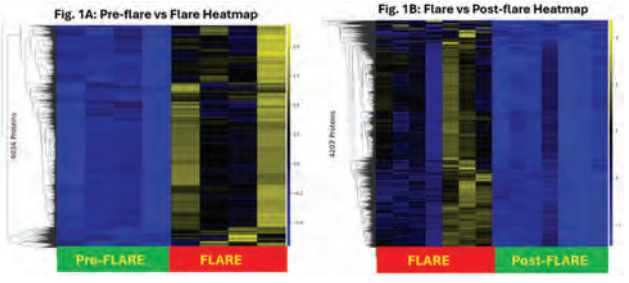

Figure 1. Heatmap representation of urine proteins differentially expressed in lupus nephritis during renal flares compared to pre-flare (A) and renal flare versus post flare following treatment (B), based on hierarchical clustering.

Genetic Regulation of Exhausted and Classic Memory B Cells in Lupus Nephritis: Results from In Vitro Studies and Bioinformatic Analyses

Litong Zhu, Yat Hin Desmond Yap. *Queen Mary Hospital, Hong Kong, Hong Kong.*

Background: Disturbances in exhausted and classical memory B cells are crucial B lymphocyte abnormalities. Genetic dysregulation of exhausted and memory B cells in lupus nephritis remains unclear.

Methods: We analyzed the single cell RNA-seq data of peripheral mononuclear blood cells from the NIH LN dataset (GSE135779) and another published LN single-cell RNA-seq dataset(dbGAP database accession code phs001457.v1.p1). Overlapping differentially expressed genes in exhausted and classical memory B cells from SLE and LN patients were identified, and their expression was validated in B cells obtained from LN patients and healthy controls. GO and KEGG analyses were used to analyze associated pathways. The circulating immune cells in SLE patients were analyzed and their relationship with candidate genes were examined.

Results: IFI44L, XAF1, and MX1 were detected in both exhausted and classical memory B cells, and their increased expression were verified in classical and exhausted memory B cells were obtained from LN patients during remission. Protein protein interaction network of DEGs suggested that STAT1 showed the highest eigenvector centrality. GO and KEGG analyses also suggested that IFI44L, XAF1 and MX1 were involved in distinct biological processes and immune pathways related to SLE and LN. Circulating immune cell analysis revealed significant links between exhausted B cell, neutrophil, and immature B cell.

Conclusions: Altered IFI44L, XAF1 and MX1 expression in exhausted and classical memory B cells may be related to the pathogenesis of SLE and LN.

Proteolytic Rewiring and Signaling through the Human Complement System

Markus M. Rinschen,[1,2] Moritz Lassé,[2] Steffen Thiel,[1] Elion Hoxha,[2] Simon Melderis,[2] Moin A. Saleem,[3] Fatih Demir.[1] *[1]Aarhus Universitet, Aarhus, Denmark; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]University of Bristol Bristol Renal, Bristol, United Kingdom.*

Background: Proteolysis is substantially involved during the manifestation of damage in the kidney in multiple diseases and is pivotal for exacerbation and resolution of inflammatory processes. The human complement system is a prime example for a clinically relevant proteolytic cascade. Systematic lupus erythematosus (SLE) is a severe chronic, inflammatory disease with renal complications, which affects mostly women (>80%).

Methods: We developed a high-throughput, automated analytical workflow for enrichment of N-termini from human EDTA-plasma through negative selection with the mass spectrometry-based "High-sensitivity Undecanal N-TERmini enrichment" (HUNTER) method. We mapped the enriched protease cleavage sites in a variety of clinically relevant populations, including complement inhibitor-treated individuals, SLE and lupus nephritis patients (cross-sectional and longitudinal). Furthermore, in vitro assays for selected proteases and specific activity assays for the human complement system were performed. In addition, we performed serum N-termini enrichment from stable-isotope labeled mice sera to identify proteolytic fragments, which have a lower turnover rate.

Results: We identified > 11 500 protease-generated N-termini in human plasma from more than 150 patients. Most of those N-termini did not correspond to already known fragments and a considerable fraction displayed a substantial alteration in SLE. Additionally, we could identify specific substrates for four central proteases of the human complement system and link this information to our identified N-termini from the human SLE cohorts. We also discovered GFR and proteinuria-associated cleavage products. Some of the identified protein N-termini were clearly linked to renal function, but also to the global activity of the human complement system and could pave the way for potential interventions in the future.

Conclusions: We could identify proteolytic processing events and determine functions of proteolytic modulation in SLE, with implications for lupus nephritis. The data suggest an unanticipated complexity of proteolytic processing throughout the human complement system.

Enlight-LN Registry: Baseline Demographics and Clinical Characteristics of an Initial Cohort of Patients Treated with Voclosporin for Lupus Nephritis in the United States

Niloofar Nobakht,[1] Laura B. Geraldino-Pardilla,[2] Leanna M. Wise,[3] Mohammad Kamgar,[1] Lily Cipolla,[4] Lucy S. Hodge,[4] Keelin Dahl.[4]
[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]Columbia University Irving Medical Center, New York, NY; [3]University of Southern California Keck School of Medicine, Los Angeles, CA; [4]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada.

Background: Voclosporin is approved for adults with active lupus nephritis (LN). In the AURORA 1 and AURORA 2 studies, adding voclosporin to MMF and low-dose glucocorticoids led to significantly earlier and greater reductions in proteinuria while maintaining stable eGFR for up to 3 years. The Enlight-LN registry is designed to characterize the real-world effectiveness and usage patterns of voclosporin in the United States (US). We describe baseline demographics and clinical characteristics of patients currently enrolled in this ongoing, prospective, observational registry.

Methods: The registry is enrolling patients ≥18 years with biopsy-confirmed LN who are initiating or have already initiated treatment with commercial voclosporin within 12 months prior to study consent. Patients receive standard of care according to usual clinical practice. Data are extracted from patient records ~every 3 months up to 36 months and include demographics, disease characteristics, response to therapy and treatment patterns.

Results: Data are available on 123 patients enrolled prior to or on December 31, 2023. Patients ranged in age from 18 to 72 years (median, 33 years); 82.9% were female. Most patients self-identified as White (43.1%) or Black/African American (35.8%); 7.3% were Asian. A total of 35.8% were Hispanic/Latino. Median (range) time since first LN diagnosis was 1.1 (0-26.2) years. The majority of patients (62.6%) had Class III or IV +/- V disease; 32.5% had Class V disease. Median (range) eGFR and SCr were 90 (20-143) mL/min/1.73 m^2 and 0.9 (0-66) mg/dL, respectively. Median (range) UPCR was 2.0 (0-16.8) g/g. A total of 107 patients were on concomitant immunosuppression at voclosporin initiation (most commonly, antimalarials, 72.4%; MMF/mycophenolate sodium, 70.7%; belimumab, 13%). In addition, 58.5% of patients were on steroids and 40.7% on RAAS agents. Three patients were on SGLT-2 inhibitors.

Conclusions: Baseline data on this initial cohort of patients are reflective of the larger LN population in the US, including high percentages of Black and Hispanic and/or Latino patients. Enrollment of additional patients and ongoing data collection will provide valuable insight into the real-world utilization of voclosporin.

Incidence of Adverse Events from SARS-CoV-2 Vaccination and Its Potential Effect on the Outcome of Lupus Nephritis

Angeliki Sardeli,[1] Smaragdi Marinaki,[2,6] Sofia Flouda,[5] Kriki Pelagia,[3] Aliki I. Venetsanopoulou,[4] Evangelia Pantzopoulou,[1] Stylianos A. Panagoutsos,[3] Sophia Lionaki.[1,2] *[1]Panepistemiako Geniko Nosokomeio Attikon, Athens, Greece; [2]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [3]Panepistemiako Geniko Nosokomeio Alexandroupoles, Alexandroupoli, Greece; [4]Panepistemio Ioanninon Reumatologike Klinike, Ioannina, Greece; [5]Panepistemiako Geniko Nosokomeio Attikon, Athens, Greece; [6]Laiko General Hospital, Athens, Greece*.

Background: To investigate the incidence of adverse events associated with SARS-CoV-2 vaccination in patients with lupus nephritis (LN).

Methods: Patients with biopsy-proven LN, who were vaccinated against SARS-CoV-2, were retrospectively studied. Patients who reached ESKD prior to vaccination were excluded. Histopathological class of LN, immunosuppressive regimens for LN, outcome of LN as a result of treatment, the time interval form the diagnostic biopsy to vaccination, the number of vaccine doses, adverse events associated with the vaccine, including systemic and local adverse events were recorded. We also explored the potential of LN relapse after vaccination among patients in remission.

Results: Ninety patients with SLE and renal involvement were included with age of 31(±18) years, of whom 80% were women. Proliferative LN was present in the diagnostic kidney biopsy in 68(77.2%) cases and 91.8% of patients had achieved remission with treatment prior to vaccination. 86.7% of patients were vaccinated with 3(2.75, 3) doses. The median time from diagnosis to vaccination was 59(32-137) months and 70.5% of patients were on immunosuppression at vaccination. 30.5% of patients reported systemic and 36.1% local adverse reactions at the site of administration. Among patients in remission, who were vaccinated, only 1(1.2%) experienced a relapse of LN within 3 weeks of the 1st dose. Three (3.4%) patients who had treatment-resistant disease experienced a worsening of SLE activity after vaccine administration.

Conclusions: In this cohort of patients with a history of LN, SARS-CoV-2 vaccination appears safe, with no effect on the likelihood of disease recurrence among patients who have achieved remission.

TH-PO655

Kidney and Patients Outcomes of Pure Lupus Nephritis: A Nationwide Analysis in Japan

Hidekazu Ikeuchi,[1] Yoichi Imai,[1] Shoichi Maruyama,[2] Hitoshi Sugiyama,[3] Hiroshii Sato,[4] Hitoshi Yokoyama,[5] Keiju Hiromura.[1] *[1]Gunma Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Maebashi, Japan; [2]Nagoya Daigaku, Nagoya, Japan; [3]Kawasaki Ika Daigaku, Kurashiki, Japan; [4]Tohoku Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Sendai, Japan; [5]Kanazawa Daigaku, Kanazawa, Japan*.

Background: Pure membranous lupus nephritis (MLN) generally exhibits a more favorable renal prognosis compared to proliferative lupus nephritis (LN). However, clinical data on pure MLN are limited. This study aims to clarify the renal and patient outcomes, as well as the associated risk factors, of pure MLN in Japan.

Methods: Among 489 adult patients who underwent renal biopsy and were registered as having LN in the Japan Renal Biopsy Registry (J-RBR) from 2007 to 2012, 90 patients with pure MLN were examined in this study. Renal endpoint was defined as a 50% increase in serum creatinine. Risk factors were determined using univariate and multivariate Cox proportional hazards analysis.

Results: The average age at the time of renal biopsy was 43.7±15.1 years, with females comprising 87.8% of the cohort. The average eGFR and urinary protein levels were 90.2±32.7 mL/min/1.73m^2 and 3.36±0.16 g/gCr, respectively. Nephrotic syndrome (NS) was observed in 42.2% of patients. Glucocorticoids (GC) were administered to 84 patients (93.3%), with an average initial dose of 33.5 ± 18.1 mg/day, and 27 patients (30.3%) were treated with GC alone. Tacrolimus was used in 38 patients (42.2%), and cyclosporin A in 14 patients (15.6%). During the median observation period of 62.4 months (IQR, 50.5–81.8), 11 patients (12.2%) reached a renal endpoint and 7 patients (7.8%) died. The 5-year renal and patient survival rates were 90.3% (95% CI, 81.3–95.0) and 93.8% (95% CI, 85.6–97.4), respectively. Univariate analysis showed that eGFR <45 and NS were associated with poor renal outcomes (HR 6.810, P=0.005 and HR 3.789, P=0.049, respectively). Univariate analysis also showed that age ≥45 and eGFR <45 were associated with patient death (HR 6.584, P=0.081 and HR 13.05, P=0.001, respectively). Multivariate analysis revealed that eGFR <45 was an independent risk factor for both poor renal outcomes (HR 5.686, P=0.015) and patient death (HR 8.633, P=0.008).

Conclusions: During a median 5-year observation period, some patients with pure MLN experienced a decline in renal function or death. An eGFR <45 at the time of renal biopsy was identified as a risk factor for both poor renal outcomes and decreased patient survival.

TH-PO656

CKD in Lupus Nephritis: Prevalence and Risk Factors in a Single-Centre Chinese Cohort

Selene Tse Yen Teoh, Yat Hin Desmond Yap, Becky M. Ma, Tak Mao D. Chan. *Queen Mary Hospital, Hong Kong, Hong Kong*.

Background: Despite treatment advances, 10-20% of patients with lupus nephritis (LN) progress to end stage kidney disease (ESKD). Understanding the burden and risk factors of developing chronic kidney disease (CKD) is pivotal in preventing ESKD. We aim to study the prevalence of CKD, defined as estimated glomerular filtration rate (eGFR) <60ml/min/m^2, its evolution over time, and associated risk factors.

Methods: Patients with an incident episode of biopsy-proven LN diagnosed from January 1981 to December 2014 were included, with follow-up censor date February 15 2017. Patients with <2 years of follow-up were excluded. Data were obtained from retrospective review of medical records.

Results: 149 patients with a mean follow up of 15.8±8.5 years were studied; 90% were female and 70.5% had Class III/IV±V LN. Remission (partial or complete) occurred in 83.9% of patients; 56.4% had disease relapse at a median of 3.73 (0.5-27) years after remission. 29.5% developed CKD and 7.4% progressed to ESKD during the study period. Older age, presence of hypertension, an eGFR of <60ml/min, lower C3 and higher dsDNA levels at time of incident biopsy were risk factors for CKD. 24.8% of patients had an eGFR of <60ml/min at the time of incident biopsy, and kidney function improved in over half after treatment, with percentages decreased to 11.7% and 10.7% at 6 months and 1 year respectively. The percentage with eGFR of <60ml/min then increased to 14.1% at 2 years and 14.5% at 5 years. Non-response to treatment, a higher number of flares (2.2±2 vs 1±1.3, p<0.01) and having ≥2 flares were associated with incident CKD during follow-up. Use of mycophenolate mofetil as induction therapy (and continued as maintenance treatment) was associated with reduced risk of CKD development (adjusted OR 0.18, p=0.01). Calcineurin inhibitor use did not differ significantly between those who had or had not developed CKD during follow up (34.1% vs 21.9%, p=0.12). Renin-angiotensin blockers were more commonly used in those with CKD (81.8% vs 61.9%, p=0.02).

Conclusions: CKD is common in patients with LN. Renal impairment at LN flare often improves with treatment, but CKD progresses over time. Efforts to prevent ESKD should focus on modifiable risk factors including optimizing immunosuppressive treatment, prevention of flares, and renoprotective measures.

TH-PO657

Induction Therapy and Kidney Outcomes in Pediatric Lupus Nephritis: A Prospective Study from the Pediatric Nephrology Research Consortium

Melonie A. Phillips,[1] Mahmoud Kallash,[1] Hancong Tang,[1] Steve Rust,[1] Scott E. Wenderfer,[2,3] Tetyana L. Vasylyeva,[4] Jerome C. Lane.[5] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Texas Children's Hospital, Houston, TX; [3]BC Children's Hospital, Vancouver, BC, Canada; [4]Texas Tech University Health Sciences Center, Lubbock, TX; [5]Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Pediatric lupus nephritis (pLN) occurs in 30-50% of children with SLE and is usually more severe compared to adults. Despite that, treatment protocols and outcome data have been limited, mostly constructed using adult studies. In this study, we aim to evaluate the management and outcome of pLN in a large prospective observational multi-center study.

Methods: Patients <21 years of age with new diagnosis of pLN were enrolled at 8 sites across the United States between 2011 and 2019. Induction therapy was determined by the treating practioner. We evaluated 6, 12, and 24-month remission rates, using the American College of Rheumatology guidelines, and kidney outcomes based on induction therapy with Mycophenolate Mofetil (MMF) or Cyclophosphamide (CYC).

Results: Study included 107 patients. The median age at diagnosis was 14 years (range 7-19 years), and 81% of patients were female. Induction treatment varied significantly across institutions, but most patients received MMF (38%) or CYC (21%). 48 patients with proliferative pLN (III, IV, and V + III or IV) received either MMF or CYC. Combined complete and partial remission rates at 6, 12, and 24 months in proliferative pLN with MMF vs CYC induction therapies are listed in table 1. There were no differences in eGFR, proteinuria, or infection rate between CYC vs MMF at 6, 12, or 24 months. Propensity analysis showed that patients with pLN class IV and lower albumin were more likely to receive CYC.

Conclusions: Remission rates and kidney outcomes were similar between children who received induction MMF vs CYC in proliferative pLN. There were significant variations in induction therapy used to manage pLN, which highlights the need for pediatric-focused LN studies to develop standardized treatment regimens and provide equitable care to patients.

Table 1 Combined complete and partial remission rates at 6, 12, and 24 months in proliferative pLN with MMF vs CYC induction therapies

		Combined complete + partial remission rates		
LN class	Induction therapy	6 months	12 months	24 months
III + IV	MMF	54.5% *	80%	71.4%
	CYC	100% *	84.6%	71.4%
Class V mixed	MMF	62.5%	66.7%	33.3%
	CYC	50%	75.0%	66.7%

*p = 0.0297

Single-Center Experience with Exostosin-2 Immunohistochemical Staining in Lupus Membranous Nephropathy

Raghunandan Konda, Vijaya Chelikani, Huma Fatima, Dana V. Rizk, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: In lupus membranous nephropathy (LMN), Exostosin-2 (EXT2) is a potential disease antigen. Compared with EXT2-negative cases, EXT2-positive LMN likely represents a subgroup with favorable kidney biopsy findings with respect to chronicity indices and are less likely to progress to kidney failure. We describe a single center experience of LMN stratified by EXT2 status at initial presentation.

Methods: We conducted a retrospective cohort study of patients with MLN and performed an immunohistochemistry (IHC) study on the kidney biopsy specimen against EXT2. Clinicopathological features in LMN patients with EXT2- positive versus negative IHC staining were compared.

Results: Among 10 LMN patients at initial presentation, 4 were EXT2-positive (40%) and 6 were EXT2-negative (Table 1). Those with EXT2 positivity were all Black females, younger, and had a higher baseline serum creatinine. They all had hematuria and higher proteinuria (including nephrotic-range) at baseline. All EXT2-positive patients had lower chronicity features although 50% had additional proliferative lesions associated with lupus. Electron microscopy revealed a higher rate of subendothelial, mesangial, subepithelial, and intramembranous deposits in EXT2-positive cases.

Conclusions: At our center, 40% of LMN patients had EXT2 positivity comparable to that described in the medical literature. Interestingly, our patients had a higher baseline creatinine, proteinuria, and additional proliferative lesions. However, despite this, their kidney biopsies demonstrated lesser scarring and chronicity features which aligns with the current notion that in EXT positive LMN, the increased secretion of EXT into the glomerular basement membrane (GBM) likely results in increased local synthesis of heparan sulfates which adds to their stability and may offer protection from downstream damaging events.

Table 1: Clinicopathological Features of Exostosin2-Positive and Exostosin2-Negative Lupus Membranous Nephritis at Initial Presentation at UAB

	Exostosin2-Positive (N = 4)	Exostosin2-Negative (N = 6)
Mean age (yr.)	26.5	43
Race		
Black	100%	83.33 %
Hispanic	0%	16.66 %
White	0%	0%
Sex		
Female	100%	83.33 %
Male	0%	16.66 %
Mean serum creatinine (mg/dL)	1.25	0.87
Mean proteinuria (g/g)	6.75	3.70
Proteinuria ≥ 3.5 g/d	75%	66.66%
Hematuria	100%	83.33%
Other autoimmune disease	0%	33% (MCTD, Raynaud's)
Sclerosed glomeruli, %	0-7%	0-30%
IFTA %	5-10%	5-20%
Proliferative features	50%	16.66%
Electron microscopy		
Subepithelial deposits	100%	100%
Intramembranous deposits	100%	83%
Mesangial deposits	0%	17%
Subendothelial deposits	75%	17%
Tubuloreticular inclusion	25%	33%

TH-PO659

Clinical and Outcomes Correlations with Exostosin 1 Positivity Lupus Nephritis

Luiza L. Assis, Luis Yu, Denise M. Malheiros. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Recently, exostosin 1 (EXT1) and exostosin 2 (EXT2), were identified in patients with lupus membranous nephropathy (LMN). Immunohistochemical studies revealed positivity rates from 32.6% to 46%, and these patients present lower chronicity indexes and reduced chronic kidney disease (CKD) progression but are more likely to disclose massive proteinuria at diagnosis. Follow-up results are conflicting, but patients with positive EXT1/EXT2 LMN had a lower incidence of end-stage kidney disease (ESKD) compared to those with negative EXT1/EXT2 LMN. The aim of this study was to assess the prevalence of EXT1/EXT2 in renal biopsies of patients with LMN (class V) and LMN with proliferative component (class III/IV + V), comparing clinicopathologic features at diagnosis and outcomes in patients followed for at least 2 years.

Methods: A retrospective cohort study of patients with membranous lupus nephritis was performed and EXT 1 immunohistochemistry studies on the kidney biopsy specimens were evaluated. (Picture 1). Clinicopathologic features and outcomes of EXT1 positive versus EXT1 negative patients were compared.

Results: Our cohort included 94 patients, of which 34 (36%) were EXT1 positive. According to histological classification, 13 out of 31 (41.94%) patients with LMN were EXT1 positive and 21 out of 63 (33%) patients with LNM associated with proliferation were EXT 1 positive (Picture 2). There were not significant differences between EXT 1 positive and negative groups at the time of renal biopsy, regarding proteinuria and serum creatinine levels, and also activity or chronicity indices on kidney biopsy. A total of 85 patients were followed for a median of 50 months. Patients with EXT1 positive showed significantly higher rates of complete or partial treatment response (p=0.035) and negative anti-DNA antibodies (p=0.01).

Conclusions: The prevalence of EXT1 positivity in LMN was 36% in our cohort. No differences were observed at diagnosis presentation, however, patients with positive EXT1 had better treatment response rates and lower anti-DNA antibodies levels, suggesting a more favorable prognosis for these patients.

TH-PO660

Role of Surveillance Kidney Biopsy in Management of Lupus Nephritis

Mikayla Burrell, Katherine A. Vandenheuvel, Francisco X. Flores, Elif Erkan. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematous. The benefit of early surveillance biopsies to prevent future relapses and to monitor treatment response is not established. In our institution, we implemented surveillance biopsies 6 months after induction therapy. This study aims to assess the value of surveillance biopsies in concordance with the clinical findings in medical management.

Methods: Patients diagnosed with Class III or IV LN on initial kidney biopsy and who had a surveillance biopsy were included in this retrospective chart review. Patients received monthly cyclophosphamide infusions based on NIH protocol or mycophenolate mofetil (MMF) as induction therapy. The clinical history, treatment course, pathology results, and biochemical results were assessed. Proteinuria was determined by urine protein/creatinine mg:mg (UPC) ratio. Estimated glomerular filtration rate (eGFR) was

assessed by the CKiD U25 calculation. LN classification and activity index (AI) was determined by pathology on initial and surveillance biopsies.

Results: Nineteen patients fulfilled inclusion criteria. Seven and 12 patients were initially diagnosed with Class III and Class IV respectively. AI was 8.4±5.6, UPC was 2.57±2.1, and eGFR was 79.09±35 at presentation. LN classification improved in 15 (79%) patients on surveillance biopsy. 16 (84%) patients changed from cyclophosphamide to MMF after the surveillance biopsy, and the other 3 received additional cyclophosphamide or rituximab infusions. Six patients experienced a relapse. Of the patients who switched to MMF, 3 (16%) relapsed. The AI improved in 14 (74%) patients, and mean AI on surveillance biopsy was 1.56. The mean AI on surveillance biopsy was 4.8 and 0.43 between relapsers and non-relapsers respectively ($p<0.05$). Patients who relapsed had a higher LN class (Class III vs Class I/II) on surveillance biopsy in comparison to non-relapsers ($p<0.05$). UPC and eGFR at the time of surveillance biopsy did not predict patient relapse.

Conclusions: The results of surveillance biopsies often guided treatment for patients with LN. The AI and degree of improvement in classification on LN on the surveillance biopsy may be a useful tool in predicting likelihood of LN relapse. We propose that surveillance biopsies should be considered as part of standard care in management of patients with LN.

TH-PO661

Role of Repeat Kidney Biopsy in Lupus Nephritis in a Uruguayan Cohort

Paula Parnizari, Jose Boggia, Leonella Luzardo, Gabriela Ottati, Oscar A. Noboa. *Hospital de Clinicas Doctor Manuel Quintela, Montevideo, Uruguay*.

Background: There is no biomarker that substitutes renal biopsy in assessment of histopathological class, activity, or chronicity in lupus nephritis (LN). We aim to characterize clinical and histological features of repeat biopsies by clinical indication in LN.

Methods: We reviewed the clinical charts and pathology reports of patients with LN and two renal biopsies from a University Hospital in Uruguay.

Results: A total of 20 patients, 18 women were analyzed. Clinical characteristics are shown in Table 1. In 5/9 patients biopsied because of mild clinical changes (hematuria and/or sub-nephrotic proteinuria), pathology revealed severe proliferative forms. Repeat biopsy showed a change in LN class in 80% of the sample, 18.2% to a lower class, 35% to a higher class and 30% had an additional membranous pattern (Class IV+V). There was also an increase in interstitial fibrosis and tubular atrophy (IFTA), 5 vs 20% (p 0.019) and the presence of moderate-severe IFTA was associated with lower eGFR after initial treatment (p 0.009). After repeat biopsy immunosuppression was intensified in 17 patients (85%).

Conclusions: Change in LN class was frequent in this cohort and there was a significant increase in chronic changes in repeat biopsies with a negative impact in renal function. Repeat biopsy by clinical indication is a valuable tool in LN management.

Baseline characteristics according to first and second biopsy

	First biopsy	Second biopsy	p value
Age at time of the biopsy (y), mean (SD)	26.2±11.5	33.1±11.7	<0.0001
Microscopic hematuria and/or proteinuria, n(%)	5 (25)	4 (20)	0.705

TH-PO662

Predictive Value of Chronic Histologic Changes in Lupus Nephritis

Maria C. Cuellar-Gutierrez,[1,2] Jaime Flores-Gouyonnet,[1] Gabriel Figueroa-Parra,[1] Marta I. Casal Moura,[1] Fernando C. Fervenza,[1] Cynthia S. Crowson,[1] Ali Duarte-Garcia,[1] Sanjeev Sethi.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Hospital Del Salvador, Santiago, Chile*.

Background: We aimed to assess the predictive value of the individual components of the NIH chronicity score and the Mayo Clinic Chronicity Score (MCCS) in lupus nephritis (LN).

Methods: LN patients from Mayo Clinic between 1992 and 2023 were included. The earliest kidney biopsy was index date. Follow-up was until July 2023, death or loss follow-up. Biopsy reports were reviewed by a nephropathologist (SS) and chronic lesions reclassified (glomerulosclerosis [GS], interstitial fibrosis [IF], tubular atrophy [TA], arteriosclerosis [AE], and fibrous crescents [FC]). The outcomes were proteinuria <500 mg/day and complete renal response (CRR) within 1-year, end-stage kidney disease (ESKD), and death. We used stratified multivariable proportional hazards regression adjusted for sex and age. P-values <0.05 were statistically significant.

Results: We included 307 patients (median age, 34 years; 75% female; median follow-up, 11 years). The majority had Class III, IV. FC were in 4.9%, AE in 12%. At one year, 47.5% had proteinuria <500 mg/day and 43.4% CRR. Those with grade 2-3 of GS (HR 0.21 [0.09, 0.48] and grade 2-3 IFTA (HR 0.14 [0.05, 0.39] were less likely to achieve proteinuria <500 mg/day. Grade 2-3 of GS (HR 0.19 [0.08, 0.48]) and grade 2-3 IFTA (HR 0.16 [0.06, 0.44] were also less likely to achieve CRR. Similarly, AE (HR 0.44 [0.21, 0.91], for proteinuria <500 mg/day, HR 0.37 [0.16, 0.84], for CRR) was associated with a reduced likelihood of achieving the outcomes. During follow-up, 33 patients died, and 60 developed ESKD. No variables were associated with mortality. Grade 2-3 GS (HR 9.28 [4.91, 17.54], grade 2-3 IFTA (HR 20.10 [10.08, 40.08]), were associated with an increased ESKD (table).

Conclusions: GS, IFTA, AE are independently associated with outcomes in LN. FC is a rare finding. The MCCS included all the chronic histologic elements associated with outcomes in LN.

Table. Hazard ratios of proteinuria<500mg/day, CRR, ESRD, and death for variables.

Element	Prot <500 HR (95%CI)	CRR HR (95%CI)	ESKD HR (95%CI)	Death HR (95%CI)
GS grade 1	0.68 (0.43, 1.08)	0.68 (0.42, 1.10)	1.94 (0.91, 4.13)	1.47 (0.57, 3.77)
GS grade 2-3	**0.21 (0.09, 0.48)***	**0.19 (0.08, 0.48)***	**9.28 (4.91, 17.54)***	2.15 (0.93, 4.98)
IFTA grade 1	**0.57 (0.37, 0.88)***	**0.54 (0.34, 0.86)***	**3.44 (1.70, 6.96)***	1.26 (0.51, 3.12)

TH-PO663

Clinical and Histological Characterization of Several Patients with Lupus Nephritis in Colombia

Maite Hurtado Uriarte, Daniel H. Ducuara, Wilson Suarez, Javier M. Mora Mendez, Andres F. Forero, Maria A. Gomez, Diana C. Sanchez, Angie K. Gonzalez ortiz. *Hospital Clinica San Rafael, Bogotá, D.C., Colombia.*

Background: Lupus Nephritis (LN) is a common and severe manifestation of Systemic Lupus Erythematosus (SLE). The study aims to describe the clinical and histological symptoms and response to treatment in a low-income population.

Methods: Descriptive cross-sectional observational study of patients with LN between 2015 and 2021 at a level 4 hospital in Colombia with renal biopsies.

Results: Ninety-nine patients were described, 72.2% of whom were female with an average age of 32 years. The main presenting syndrome was nephrotic/nephritic (43.4%) and nephrotic (25.3%). The mean SLEDAI was 17. Regarding treatment: The induction regimen included cyclophosphamide (62.4%) and Mycophenolate (34,4%). As for histological classification, 49.5% were class IV and 22.2% IV/V. Crescents were presented in 7%. The median index activity was 2 and a chronicity index was 6. Concerning de outcomes: 5% died during hospitalization and 11.7% within the next year. 29,3% of the patients required treatment at the ICU due to severe malfunction. 18,2% continued with dialysis after discharge from the hospital; of these, 37.5% and 28% continued with dialysis at 6 and 12 months, respectively. Remission at 6 months was 44.1% and 51.6% at 12 months.

Conclusions: A low socioeconomic status population is described with severe clinical and histological LN presentation with infectious and administrative complications that have limited treatment which directly affect mortality and further need of dialysis. This requires the development of public policies in this population to improve short- and long-term outcomes.

TH-PO664

Histologic Predictors of Response and Prognosis in Lupus Nephritis: Why Segmental Sclerosis Should Not Be Part of the Chronicity Index

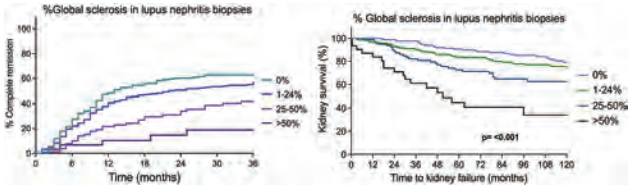
Denisse N. Tinajero Sánchez, Erick Y. Zuñiga Gonzalez, Adriana Hernández Andrade, Valeria Navarro Sanchez, Alberto Nordmann-Gomes, María F. Zavala Miranda, Norma O. Uribe-uribe, Juan M. Mejia-Vilet. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico*.

Background: The current histological chronicity index (CI) is calculated by summing the percentages of glomeruli with global sclerosis (GS) and segmental sclerosis (SS), fibrous crescents (FC), and the percentages of interstitial fibrosis (IF) and tubular atrophy (TA). The study aimed to evaluate the prognostic value of individual histological items in predicting complete response to treatment (CR) and progression to kidney failure (KF)

Methods: This retrospective cohort study included all biopsy-proven LN patients diagnosed between 2008 and 2021 with follow-up ≥36 months. Demographic, laboratory, and histopathological variables were recorded at presentation. The study outcomes were evaluated through time-to-event analyses, including time to CR and time to KF. The best predictive models for CR and KF were constructed using Cox regression analysis and evaluated through Harrell's C statistic

Results: We studied 492 patients with a median follow-up of 99 months (IQR 66-129). The median age was 28 years (IQR 22-37), and 94% were female. Creatinine at presentation was 0.96 mg/dL (IQR 0.67-1.49), proteinuria was 3.4 g/g (IQR 2.0-5.7). Median activity and CI were 4 points (IQR 2-8) and 4 points (IQR 2-6), respectively. Individual items of the CI, except SS, were associated with the time to CR in the univariate analysis, while only interstitial inflammation was associated with time to CR (Figure 1). All activity and chronicity items were associated with time to KF. The best predictive model for KF included GS, FC, IF, and TA (C-statistic 0.74 [0.69-0.78]). The model did not improve with the addition of SS (C-statistic 0.73 [0.69-0.78]). The calculated CI did not improve with the addition of SS (C-statistic 0.72 [0.67-0.76] and 0.71 [0.68-0.76], respectively)

Conclusions: Individual histological items of the activity and CI are variably associated with time to CR and KF. SS is not associated with time to KF, and its inclusion in the calculation of the CI does not improve its predictive value for this outcome



TH-PO665

Assessing Chronicity Index on Kidney Biopsies of Patients with Lupus Nephritis and Its Correlation with Creatinine and Proteinuria at 1-Year Follow-Up

Liliana M. Kassar, Felipe Carvalho Barros Sousa, Karoline W. Silva, Vinícius S. Silveira, José Guilherme R. Gonçalves, Viktoria Woronik, Luis Yu, Cristiane B. Dias, Lectícia Jorge. *Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil*.

Background: Lupus nephritis is a common manifestation of sistemic lupus erithematous and is associated with higher mortality, specially on those who progress to end-stage kidney disease. This study aims to assess chronicity index on initial kidney biopsy as a prognostic factor in lupus nephritis by correlating it to creatinine and proteinuria after 1-year follow-up.

Methods: Patients diagnosed with lupus nephritis between January 2012 and December 2018 were included. Study variables comprised age, gender, creatinine, estimated glomerular filtration rate (eGFR) by CKD-EPI, proteinuria, histological class and chronicity index on renal biopsy.

Results: A total of 253 renal biopsies were performed on the studied period, 86% in women. Mean age was 31 years old (13-70), initial serum creatinine 1.3 mg/dL (0.3-8.0) and final 1.47mg/dL (0.4-13.2). Average eGFR was 58 mL/min (4-156) at the time of kidney biopsy and 82mL/min (4-156) a year later, with average proteinuria going from 1.9g (0.1-10.7) on initial measure to 0.37g (0.04-6.9) after 1 year. Median chronicity index on kidney biopsy was 3 (0-10). Spearman correlation between chronicity index and creatinine after 1 year was 0.538 with $p < 0.001$, and with proteinuria was 0.144 with p 0.047. Chronicity index ≤ 4 was associated with lower proteinuria (p 0.02) and lower creatinine ($p < 0.001$) at 1 year of follow-up.

Conclusions: Patients with high chronicity indices at diagnosis present worse renal function and higher levels of proteinuria during follow-up. Supportive care and degree of immunosuppression in the setting of chronic and irreversible histologic lesions are topics that need more attention in such scenarios.

TH-PO666

Lupus Nephritis Histopathological Classification System: A Questionnaire-Based Survey of the Renal Pathology Society (RPS)

Martina Uzzo,[1,2] Mark Haas,[3] David R. Jayne,[4] Liz Lightstone,[5] Ioannis Parodis,[9] Brad H. Rovin,[6] Surya V. Seshan,[10] Shreeram Akilesh,[7] Agnes B. Fogo,[8] Ingeborg M. Bajema.[2] *[1]Universita degli Studi di Milano-Bicocca Scuole di Specializzazione, Milano, Italy; [2]Universitair Medisch Centrum Groningen Pathologie en Medische Biologie, Groningen, Netherlands; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]University of Cambridge, Cambridge, United Kingdom; [5]Imperial College London Faculty of Medicine, London, United Kingdom; [6]The Ohio State University, Columbus, OH; [7]University of Washington School of Medicine, Seattle, WA; [8]Vanderbilt University Medical Center, Nashville, TN; [9]Karolinska Institutet, Stockholm, Sweden; [10]Weill Cornell Medicine, New York, NY*.

Background: The updated 2018ISN/RPS histopathological classification on kidney biopsy is widely used for prognosis and treatment decisions in lupus nephritis (LN). Due to the success of new targeted agents, there is ongoing discussion about the need for updating existing classification systems. A survey to assess the current use of the 2018ISN/RPS classification system in everyday practice was conducted on behalf of the RPS.

Methods: An online survey was sent between September 27th and October 24th 2023 to active members of the RPS. The survey contained multiple-choice and open-ended questions; results were analyzed anonymously.

Results: 185 of 562 RPS members replied to the questionnaire, mostly pathologists (97%). 120(65%) participants encounter >20 LN biopsies per year, while 13% <10. Nearly 90% discuss biopsy results in multidisciplinary meetings, involving both pathologists and clinicians. The 2018ISN/RPS classification is used in most cases(92%) and 90% of the pathologists include NIH activity/chronicity indices in biopsy reports, although concerns about workload, reproducibility and clinical utility were raised. The average grade on the utility of the 2018ISN/RPS classification and activity/chronicity indexes were 8(IQR 7-9) and 7(IQR-9) on a scale from 0(not useful) to 10(extremely useful). Pathologists rated clinicians' understanding of kidney biopsy reports with an average score of 8(IQR 7-9) on a scale from 0(no understanding) to 10(complete understanding). Suggested improvements of the 2018ISN/RPS classification involved the introduction of new parameters (focus on extraglomerular involvement, laboratory, clinical features), biomarkers (CD68+ staining for endocapillary hypercellularity, EXT1/2 immunostaining), standardization and simplicity. Clearer definitions were requested for class III vs IV, segmental sclerosis vs fibrous crescents, the role of globally sclerosed glomeruli and lupus-like entities.

Conclusions: Our survey shows the 2018ISN/RPS classification is widely used in everyday practice by pathologists, and well known by clinicians. The results obtained by the RPS survey acknowledge the need for ongoing refinement to facilitate targeted treatment decisions, particularly considering evolving phenotypes and therapeutic advancements in LN.

Lupus Navigator Program: Pilot

Abdallah Sassine Geara, Patricia Nogueira De Sa, Stephanie Wirtshafter, Aylin Ergin, Pranav S. Kancherla, Faith Ryu, Himanshi Verma, Kimberly Dequattro. *University of Pennsylvania, Philadelphia, PA.*

Background: SLE disproportionally affects individuals from racial and ethnic minority groups with more than 95% of patients reporting social determinants of health (SDOH) challenges

Methods: We developed a Lupus Navigator Program in an outpatient clinic with 3 phases: 1. Referral: patients identified by the treating physician as having high SDOH challenges based on medical history, compliance, social setting 2. Screening: SDOH survey by volunteer college students 3. Intervention: Medical team implemented an patient-tailored plan

Results: Patients were mainly young black women The top 3 SDOH: visit copays, help with adherence and transportation. The primary SDOH were: transportation, visit copays, and health system navigation. The table summarise the different interventions

Conclusions: This pilot Lupus Navigator Program demonstrated high SODH challenges among individuals with SLE/LN. the next step is to administer this program by a dedicated SLE social worker

Funding: Commercial Support - Aurinia

Global and National Public Awareness and Interest in Glomerular Diseases, 2004-2024

Suryanarayanan Balakrishnan,[1] Charat Thongprayoon,[2] Iasmina Craici,[1] Wisit Cheungpasitporn,[1] Jing Miao.[2] [1]*Mayo Clinic Minnesota, Rochester, MN;* [2]*Mayo Clinic Health System, Mankato, MN.*

Background: Glomerular diseases (GD) significantly impact global health, and public awareness of these conditions is crucial, especially in recent years, as emerging treatments and clinical trials offer patients new opportunities for care. This study investigated public interest in 5 common GD based on Internet search queries.

Methods: We conducted a Google Trends™ search for the terms IgA nephropathy (IgAN), membranous glomerulonephritis (MN), focal segmental glomerulosclerosis (FSGS), lupus nephritis (LN), and diabetic nephropathy (DN) between 1/1/2004 and 5/13/2024. Searching trends were analyzed in both worldwide and the United States.

Results: Over a 20-year review, IgAN showed the most global attention on Google Trends™, whereas MN attracted the least (**Fig. A**). LN demonstrated a rise in interest, peaking at 43 in Mar 2022. In contrast, 4 other diseases, including IgAN, DN, FSGS and MN, experienced noticeable declines in interest (**Fig. B**). Their peak interest search recorded in Apr 2004 for IgAN (100), Jan 2004 for DN (95), May 2004 for FSGS (94) and Feb 2005 for MN (26) (**Fig. E**). Each GD's interest varied across the top 5 countries (**Fig. E**). In the United States, search trends paralleled global pattern, with various search activity across states (**Fig. C-E**).

Conclusions: Despite new treatments and more clinical trials for GD, public interest remains low and unincreased, especially in conditions like MN. This underscores the necessity for heightened awareness to ensure patients benefit from these advancements. The differing interest levels across countries indicate the need for specific public health strategies. There is a crucial need to enhance the availability of accurate information on these diseases through social media and websites to encourage appropriate patient engagement and care.

Podocytic Infolding Glomerulopathy: A Systematic Report of 44 Cases

Zhirang Shen,[1] Changrong Zhang,[1] Jing Zhuang,[1] Yue Qu,[1] Xuefei Tian,[2] Hong Jiang.[1] [1]*People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China;* [2]*Yale University School of Medicine, New Haven, CT.*

Background: Podocytic infolding glomerulopathy (PIG), a newly recognized rare disease entity with unique histopathological features characterized by podocytic cytoplasmic invagination into the glomerular basement membrane (GBM) and presenting as "microsphere" or "microtubule"-like structures visualized under a transmission electron microscope, has attracted increasing attention in recent years. Since PIG was first reported in 1965, the clinical features and pathogenesis of PIG are still poorly understood. Delving into the understanding of PIG, elucidating its etiology, clinical implications, and optimal treatment strategies is needed.

Methods: A total of 1713 kidney biopsies from January 2020 to April 2024 in our kidney center were retrospectively analyzed for PIG screening. The diagnostic criteria for PIG are as follows: Electron microscopy shows microspheres or microtubules associated with podocyte cytoplasm folded into the GBM, along with a complete medical record. Forty-four patients were enrolled in the study.

Results: We reviewed 44 PIG patients, of whom 16 were female (36.4%) and 28 were male (63.6%), with an average age of 40±15.9 years. The median [Min, Max] of 24-hour urine protein quantitation was 2.14[0.0280,8.32]g/24h. The median [Min, Max] of Serum creatinine was 84.0[41.6,688]μmol/l. 43.2% of PIG patients had IgA nephropathy. The pathological results of all patients were consistent with PIG features.

Conclusions: Most PIG patients are complicated with immune system-mediated kidney diseases, such as IgA nephropathy, IgA vasculitis associated nephritis, ANCA-associated glomerulonephritis, etc. However, the pathogenic mechanism of PIG is unknown and needs further study.

Funding: Government Support - Non-U.S.

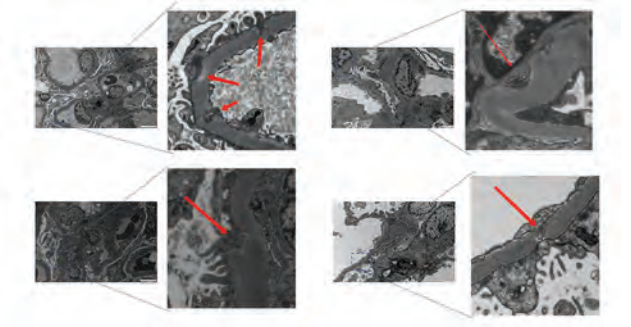

FIGURE 1. Ultrastructure changes of PIG (Arrow: Microspheres in the GBM (→) and podocytes components trapped in the GBM)

Alpha Lipoic Acid-Associated NELL1-Positive Membranous Nephropathy

Mohammed O. Ali,[1] Jignesh Shah,[1,2] Ehsan Shaban.[1] *[1]University of Missouri-Kansas City, Kansas City, MO; [2]University Health Truman Medical Center, Kansas City, MO.*

Introduction: Membranous nephropathy (MN) is one of the leading causes of nephrotic syndrome in adults and involves an autoimmune response against various antigens, such as PLA2R, THSD7A, NELL1, Sema3B, and NCAM1. Notably, there are increased cases of MN triggered by antibodies against NELL1 following exposure to alpha-lipoic acid (ALA) supplements, which are over-the-counter antioxidant supplements for multiple sclerosis, diabetic neuropathy, and schizophrenia. This report presents a case of NELL1-positive MN nephropathy likely caused by exposure to ALA, emphasizing early recognition and good outcomes without immunosuppression.

Case Description: 70-year-old male with diabetes mellitus and hypertension was referred due to concerns about nephrotic syndrome with leg swelling, foamy urine and neuropathic pain. He had been taking 2400 mg of alpha-lipoic acid daily for a year to help with his diabetic neuropathy. Physical examination was notable for bilateral severe pedal edema. Laboratory investigations revealed normal complete blood counts, creatinine, urea, and basic electrolytes. His hemoglobin A1C level was 7%, His albumin level was low at 2.4 g/dl and his cholesterol was elevated at 224 mg/dl, with LDL cholesterol at 120 mg/dl. Urine protein-to-creatinine ratio increased to 6.4 g/g. Additional tests, including serologies for ANA, ANCA, Hepatitis B surface Ag, Hepatitis C Ab, urine protein electrophoresis and serum PLA2R antibodies levels were negative. The kidney biopsy revealed NELL-1 positive Membranous Nephropathy-. Patient underwent age-appropriate malignancy screening with CT chest, abdomen and pelvis which showed no remarkable findings, normal PSA level and a screening colonoscopy was unremarkable. The Patient's NELL-1 positive MN is related to Alpha lipoic acid use, hence it was discontinued, he was on ARB and diuretic at tolerated dose. Three months later, the patient reported resolution of his edema and he is in partial remission of his proteinuria with levels of 2.5 g/g without any immunosupressive agents.

Discussion: ALA has the most substantial evidence of the therapeutic effect in diabetic neuropathy and oxidative stress conditions. Growing data suggests a correlation between MN and (ALA) supplements. The limited literature consists of a few case reports that note the association between lipoic acid and MN and more areas to investigate the pathogenesis behind such correlation.

TH-PO671

Alpha Lipoic Acid- and NELL1-Associated Membranous Nephropathy

William L. Vaughn, Ryan A. Parrish, Indira Chervu. *Wellstar Kennestone Regional Medical Center, Marietta, GA.*

Introduction: Membranous nephropathy (MN) is a leading cause of nephrotic syndrome, representing a spectrum of diseases with a common histological pattern of Immunoglobulin and complement-containing immune deposits in the subepithelial position. 75% of cases are primary to some response to a normal podocyte antigen antigen (of which PLA2R is most common) whereas the other cases are secondary to a systemic process. Neural Epidermal Growth Factor-Like 1 (NELL-1) has been implicated as a target antigen in MN. Alpha Lipoic Acid (ALA), a common over the counter supplement, is often recommended for diabetic neuropathy. We describe a rare case of ALA associated NELL-1 positive MN with complete resolution of proteinuria when the drug was stopped.

Case Description: A 69 year-old female with prediabetes and controlled hypertension presented to clinic for proteinuria in 2022. The patient had no history of CKD. She was prescribed 1200 mg of ALA in October 2020 for peripheral neuropathy. Urinalysis in 2017 was normal. UA in January 2022 revealed an Albumin:Cr 1774 and Serum Creatinine 0.70. 24 hour total protein excretion was 1,625 mg, albumin 1,160 mg and Creatinine clearance of 79. SPEP, UPEP, and Serum Immunofixation were normal. Although the patient had a positive ANA (1:1280), further workup was negative, and rheumatology evaluated the positive lab value to not be clinically significant. Hepatitis panel was negative. Renal biopsy showed segmental membranous nephropathy with diffuse staining for IgG3 and NELL-1. ALA was stopped in June 2022, and in June 2023 there was complete resolution of proteinuria (135 mg 24 hour total protein). She was up to date with all age-appropriate cancer-related screening exams.

Discussion: Recent advances in serologic testing have allowed for a biopsy-sparing approach in diagnosis and treatment of PLA2R associated MN. NELL-1 is the second most common antigen identified in MN. There is an opportunity to expand upon this diagnostic approach to include other target antigens such as NELL-1. ALA associated NELL-1 MN is rarely reported upon in literature. Furthermore, there is only one retrospective review of this association. The growing recognition of the interplay between ALA and NELL-1 MN should prompt research into the unclear mechanism behind how this association occurs. Understanding this relationship will guide intervention to both treat and prevent ALA associated MN.

TH-PO672

What the NELL-1 Does α-Lipoic Acid Have to Do with It?

Khateeb Raza,[1] Andrew Dorst,[2] Salar Alam,[1] Katherine W. Kwon.[1] *[1]Corewell Health Southwest Michigan, Saint Joseph, MI; [2]Michigan State University College of Osteopathic Medicine, East Lansing, MI.*

Introduction: Membranous nephropathy, a common cause of nephrotic syndrome, is characterized by the widespread autoantibody targeting of the glomerular basement membrane and subsequent subepithelial immune complex deposition causing renal impairment. Primary Membranous Nephropathy (PMN) arises from autoantibodies against glomerular podocytes. Phospholipase A2 receptor (PLA2R) remains a predominant target, followed by Thrombospondin type-1 domain containing 7A (THSD7A). Recent studies indicate autoantibodies to Neural Epidermal Growth Factor-like 1 (NELL-1), a non-podocyte target, as a significant emerging cause of PMN. Furthermore, an association between NELL-1-associated PMN and α-lipoic acid (ALA), a common over-the-counter (OTC) antioxidant, is suggested. Herein, a case of NELL-1-positive PMN caused by ALA is described.

Case Description: An 84-year-old male with chronic kidney disease 3b/A3 and type 2 diabetes with peripheral neuropathy was evaluated by nephrology for nephrotic range proteinuria. He notably had a 15-month increase in microalbumin/creatinine ratio from 15 mg/g to 5,410 mg/g, despite therapy with SGLT2i, ARB, and GLP-1. Serum creatinine showed mild fluctuations; his exam remained without stigmata of nephrotic syndrome. Work-up for infectious, autoimmune, or malignant etiologies was unremarkable. Renal biopsy was positive for NELL-1 and negative for PLA2R or THSD7A. An in-depth review revealed an undocumented start of ALA 18 months prior by the patient in attempts to treat neuropathy refractory to maximum gabapentin dosage. Prompt discontinuation of ALA led to improved proteinuria in subsequent labs.

Discussion: NELL-1 PMN induced by ALA supplementation is a rare phenomenon seldom described in literature. Its mechanism, though not fully understood, has been proposed through the activation of autoantibodies. Classically, PMN is treated with immunosuppressive agents. In NELL-1 PMN linked to ALA use, recent literature suggests discontinuation of ALA as sufficient treatment. Contemporary trends have led to the increased use of understudied and under-recognized OTC supplements such as ALA in the treatment of neuropathy. These trends have thus necessitated heightened awareness of potential adverse effects and medication interactions. Timely recognition of adverse effects due to supplements is essential to prevent unnecessary treatment and prompt discontinuation of offending agents.

TH-PO673

Nonsteroidal Anti-inflammatory Drugs (NSAIDs) Associated with NELL1-Positive Membranous Glomerulopathy

Ravi K. Thimmisetty, Karla G. Carias Martinez, George Vasquez-Rios. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: Membranous nephropathy (MN) is the leading cause of nephrotic syndrome in adults. We are presenting a rare case of neural epidermal growth factor-like 1 (NELL-1) caused by NSAIDs.

Case Description: A 49-year-old male with history of hyperlipidemia, DJD and on chronic NSAIDs admitted with complaints of periorbital swelling and generalized body swelling since 2 weeks. Also weight gain of 10 pounds over the last few weeks. h/o recent URI symptoms that resolved quickly. he is taking meloxicam for chronic foot pain and also started taking Artri King for last 2 weeks. vitals were with in acceptable range. on room air. exam shows 1-2+ edema. Labs showed serum Cr of 1.68, nephrotic range proteinuria with random UP/UC ratio 9.52, COVID-19 positive. rest of the labs were acceptable. Biopsy showed Membranous Glomerulopathy, NELL1-Positive. With supportive care, creatinine was 1.05 mg/dl and up/uc is 0.06.

Discussion: NELL1-associated MN is commonly described with malignancy. Our case showed that NSAIDs also contribute for this target antigen associated MN. With in 1-2 months, patient better significantly with supportive care. There is an FDA alert on this Over the counter drug. Need to educate all providers in community not to use Artri King.

TH-PO674

Anti-phospholipase A2 Receptor (PLA2R)-Positive Membranous Nephropathy Triggered by Sunitinib in Patients with Gastrointestinal Stromal Tumor (GIST): A New Association?

Mateus Pascoal, Antony J. Tors, Juliana Hickmann de Moura, Cassiano de Mattos Marques, Elvino J. Guardao barros, Francisco V. Veronese, Luciano Wolffenbuttel. *Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil.*

Introduction: Tyrosine Kinase Inhibitors are classically associated with hypertension and proteinuria due to thrombotic microangiopathy. We report the second case of Membranous Nephropathy associated with anti-PLA2R antibody in the literature, developed shortly after starting Sunitinib, in patients with metastatic GIST.

Case Description: A 55-year-old female was diagnosed with metastatic duodenal GIST in May 2018, and treated with Imatinib 400 mg/day. Oral Sunitinib was started in September 2023 due to disease progression. She developed proteinuria (1450 mg/24 hours) after two doses, leading to treatment discontinuation. Despite that, proteinuria increased to nephrotic levels with urine protein/creatinine ratio (UPCR) of 11 g/g of creatinine. A renal biopsy revealed Membranous Nephropathy and serum anti-PLA2R was positive at 259 UR/ml (<14). The patient was treated with Rituximab, with serologic remission and a marked improvement in proteinuria (UPCR 2.6 g/g of creatinine) shortly after (1 week) completion of treatment.

Discussion: In 2021, Zonoozi et al (BMJ Case Rep 2021;14:e243567) reported a very similar case: proteinuria developed after a few weeks of treatment with Sunitinib in a patient with metastatic GIST that progressed on Imatinib. As in the case reported here, renal biopsy revealed Membranous Nephropathy with serology and tissue IF positive for anti-PLA2R. Both patients were treated with Rituximab, with complete serologic remission. To our knowledge, this is the second case reported of anti-PLA2R Membranous Nephropathy associated with Sunitinib in the literature, coincidentally or not, in patients with GIST. Since there is no known association between Membranous Nephropathy and GIST, and anti-PLA2R antibodies are usually associated with “primary” Membranous Nephropathy, we hypothesize that the Tyrosine Kinase Inhibitor Sunitinib elicited the production of anti-PLA2R antibodies in both cases

TH-PO675

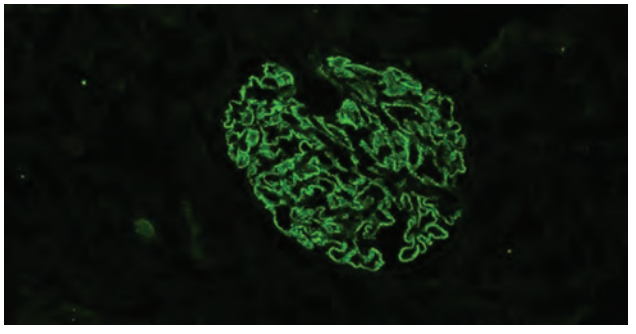
A Case of Primary and Secondary Membranous Nephropathy Associated with a Neuroendocrine Tumor

Wardah Zoha, Maen M. Talib, Ramesh Soundararajan, Mohammed Sadique Hussain, Hasnoor K. Sandhu, Amani Masoud. *Franciscan Health Olympia Fields, Olympia Fields, IL.*

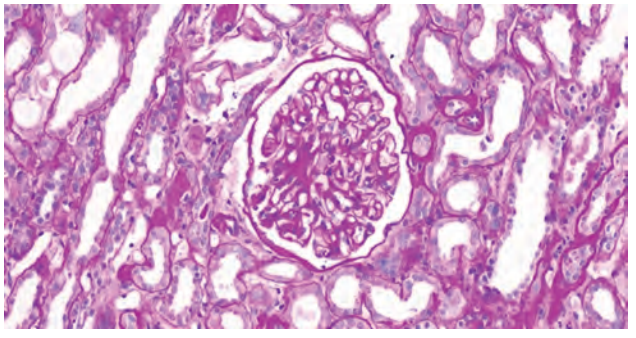
Introduction: Membranous nephropathy (MN) is one of the most common causes of nephrotic syndrome in adults. 80% of MN cases are of primary MN, while 20% are secondary. Primary MN involves a positive antibody for anti-phospholipase A2 receptor (PLA2R). Secondary MN is commonly a result of malignancy, infection or drugs. In this case, we present a patient with biopsy proven PLA2R MN and a new diagnosis of neuroendocrine tumor (NET) yielding a mixed primary and secondary MN diagnosis.

Case Description: A 65 year old man with a medical history of congestive heart failure, chronic kidney disease and tobacco use presented with dark stools and altered mental status. His labs showed hemoglobin 6.4, potassium 8.4, BUN 194 and creatinine 8.9. A computed tomography of the abdomen and pelvis showed multiple enlarged lymph nodes concerning for malignancy. He underwent HD line placement and emergent dialysis was initiated. His mentation improved however his dark stools persisted. He underwent an esophagogastroduodenoscopy which showed an actively bleeding duodenal ulcer that was biopsied. Biopsy results showed a large-cell neuroendocrine tumor (NET). A renal biopsy was then performed which revealed PLA2R positive MN and severe acute tubular injury.

Discussion: The simultaneous occurrence of primary and secondary MN in the setting of NET is rare with only a few cases reported in literature. This unusual presentation does not fit previously accepted classifications of primary versus secondary, but rather shows a combination. Therefore, concurrent workup for age appropriate cancer screening and serum PLA2R levels could be of benefit in patients with a new diagnosis of MN.



IF staining of PLA2R



Thick basement membrane in MN

TH-PO676

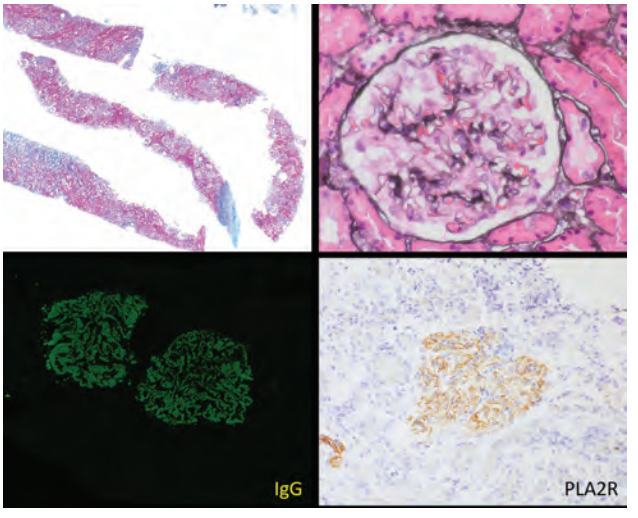
Phospholipase A2 Receptor (PLA2R)-Positive Membranous Nephropathy in a Patient with Negative PLA2R Serology

Irmaris R. Quinones Vargas,[1] Paul B. Avila,[2] J. Pedro Teixeira,[1] Tiffany Caza,[3] Pablo Garcia.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Universidad de San Carlos de Guatemala, Ciudad de Guatemala, Guatemala; [3]Arkana Laboratories, Little Rock, AR.*

Introduction: Recent advances in the understanding of the pathogenesis of membranous nephropathy (MN) led to the identification of several target antigens, including phospholipase A2 receptor (PLA2R). PLA2R antibodies are present in the majority of primary MN cases and have important implications for diagnosis, prognosis, and treatment. Here we present a case of MN negative for PLA2R antibodies but with positive biopsy staining for PLA2R.

Case Description: A 51-year-old man presented to clinic with nephrotic syndrome (NS) with lower extremity edema, serum creatinine 1.1 mg/dL, albumin 0.4 g/dL, 24-h urine protein of 13.2 g, and urine protein-creatinine ratio (UPCR) of 14 g/g. He was recently diagnosed with pulmonary embolism which was felt to be secondary to NS. All serologies, including HIV, hepatitis panel, C3, C4, ANCA, ANA, dsDNA, SPEP, UPEP, free light chains, and PLA2R by immunofluorescence assay (IFA), were negative. A kidney biopsy showed MN with glomerular PLA2R deposition by immunohistochemistry (Figure). He was treated with rituximab 1 g x 2 doses 2 weeks apart. A month later UPCR decreased to 7 g/g and serum albumin increased to 1.4 g/dL.

Discussion: Prior studies have suggested that negative PLA2R serology in patients with previously diagnosed PLA2R-positive MN indicates disease inactivity. However, this case suggests this is not always true. In particular, early in the course of MN PLA2R may be detected on biopsy despite a lack of circulating PLA2R antibodies. For scenarios highly suspicious for MN despite negative initial PLA2R serology, clinicians may consider alternative PLA2R antibody assays (e.g., enzyme-linked immunosorbent assay rather than IFA) as well as definitive biopsy diagnosis.



TH-PO677

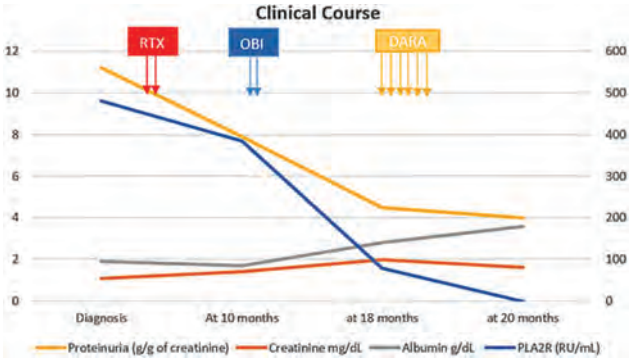
Daratumumab for Anti-CD20-Refractory Membranous Nephropathy

Tammy Yu, Abdallah Sassine Geara. *Penn Medicine, Philadelphia, PA.*

Introduction: Rituximab (RTX) is a cornerstone of therapy for primary membranous nephropathy (MN). However, up to 35-40% of patients do not achieve remission despite depletion of circulating B cells. We discuss a patient with refractory MN who was successfully treated with daratumumab, a plasma cell-directed anti-CD38 monoclonal antibody (mAb).

Case Description: An 80-year-old man presented with anasarca, creatinine (Cr) 1.1 mg/dL, 24-hour urine protein 11.2g, and anti-phospholipase A2 receptor (PLA2R) level 481 relative units (RU)/mL. Kidney biopsy showed subepithelial deposits with basement membrane spikes and diffuse IgG, C3, and PLA2R staining, confirming PLA2R+ MN. He began therapy with RTX 1gx2 in addition to supportive care. At 8 months, he had persistent edema with urine protein to creatinine ratio (UPCR) 11.65 g/g and anti-PLA2R 383 RU/mL. Due to his frailty and age, we elected against treatment with cyclophosphamide (CYC). He was treated with tacrolimus followed by obinutuzumab (OBI) 1gx2. However, despite total depletion of CD19+ B cells, he achieved only partial remission with Cr 2.04 mg/dL, UPCR 7.033 g/g, and anti-PLA2R 78 RU/mL at 6 months. We arranged for daratumumab (DARA) 1800mg weekly injections. At 6 weeks, his edema had resolved, with undetectable PLA2R level, Cr 1.68 mg/dL, and UPCR 4.49 g/g. At 4 months, PLA2R remained undetectable with UPCR 4.03 g/g (Figure 1)

Discussion: Treatment of patients with RTX-resistant MN who are unable to tolerate CYC remains a challenge. Recent reports have demonstrated the potential of newer anti-CD20 mAbs such as OBI for patients with refractory disease. Plasma cell-directed agents like bortezomib or DARA, first approved for B cell malignancies, are now being investigated for autoimmune disease. For our patient, more than 18 months of B cell-depleting therapy led to only partial improvement in PLA2R titers and failed to produce clinical improvement. DARA was able to achieve rapid serologic remission and reversal of his Cr trend, suggesting that anti-CD38 therapy holds promise for multidrug-resistant MN.



Clinical course

TH-PO678

Double Trouble in the Basement! A Case of Phospholipase A2 Receptor (PLA2R)-Associated Membranous Nephropathy with Atypical Anti-glomerular Basement Membrane Disease

Renuka Tolani,[1] Theresa Thurston,[2] Steffi Sathiyaraj,[1] David Lyu,[1] Ziad M. El-Zaatari,[1] Luan D. Truong,[1] Angelina Edwards,[1] Tariq Shafi,[1] Shane A. Bobart.[1] *[1]Houston Methodist, Houston, TX; [2]Texas A&M University System, College Station, TX.*

Introduction: Only a few cases have been reported of concurrent atypical anti-glomerular basement membrane (anti-GBM) disease with membranous nephropathy. Compared to typical anti GBM disease, atypical anti GBM disease is often seronegative, with a mild disease presentation and course. We present a case of concomitant of PLA2R associated membranous nephropathy and atypical anti-GBM disease in a patient with cholangiocarcinoma.

Case Description: A 66-year-old male with type 2 diabetes, hypertension, hyperlipidemia, viral hepatitis C, cirrhosis, and cholangiocarcinoma presented with nephrotic range proteinuria, and worsening bilateral lower extremity edema. Urine studies showed 3+ protein and 13 red blood cells per high powered field and 24-hour urine proteinuria of 14 grams with serum albumin of 2.1 g/dL, and serum creatinine 0.8 mg/dL. (nephrotic syndrome). Serological work-up was negative for ANA, anti-dsDNA, PLA2R, ANCA, rheumatoid factor, and anti-GBM, with normal complements, and no monoclonal gammopathy. A kidney biopsy showed membranous nephropathy with typical light microscopic, immunofluorescent, and electron microscopic changes. In addition, there was atypical anti-GBM disease characterized by a non-circumferential cellular crescent in 1 out of 12 glomeruli, and 2-3+ linear staining for IgG along glomerular basement membrane with 2+ C3, kappa and lambda light chain. There was no tubular basement membrane staining for IgG. The glomeruli demonstrated strong staining for PLA2R, but negative for THSD7A and NELL-1. The patient received rituximab infusion, dapagliflozin, and lisinopril, resulting in remission of proteinuria. Despite intense chemotherapy with cisplatin, gemcitabine and immunotherapy, the malignancy progressed, and he transitioned to hospice care.

Discussion: For our patient, rituximab resulted in remission of proteinuria, but malignancy had progressed. The lack of temporal association is consistent with the biopsy findings of PLA2R -associated membranous nephropathy. While there is not an established guideline, our case demonstrates the utility of rituximab for the management of concurrent atypical anti-GBM disease with membranous nephropathy.

TH-PO679

Unveiling the Enigma: Primary Membranous Nephropathy with Crescent Formation, a Puzzling Rarity

Joy Kumar, Cleris N. Christian, Raafat F. Makary, Irtiza Hasan. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults. Development of crescents in MN is extremely rare (<1%) & is usually associated with a rapidly progressive course to renal failure. We report a case of crescents in primary MN, characterized by positive anti-phospholipase A2 receptor (PLA2R) antibodies with a negative ANCA profile & anti-GBM assay.

Case Description: A 38-year-old male with essential hypertension presented in 2018 with anasarca & hypertensive emergency. Labs showed creatinine (Cr) of 1.1 mg/dl, hypoalbuminemia (serum albumin of 1.4 g/dl), & massive proteinuria (37.13 g/24 hrs). Serum ANCA, ANA, anti-dsDNA, & anti-GBM were negative. Anti-PLA2R was highly positive (280.3 RU/ml). A kidney biopsy with immunofluorescence (IF) & electron microscopy (EM) were consistent with Primary MN (stage 3). IF showed diffuse granular deposits of IgG, C3 & C1q. EM showed subepithelial immune deposits with extensive foot process effacement. No endocapillary proliferation, fibrinoid necrosis, or crescent were seen. Received immunosuppressant (IS) therapy per Dutch protocol, achieving partial remission. In the next 4 years, there were multiple admissions with AKI (Cr ranging between 1.9-3.5 mg/dl), as well as a COVID-19 infection in 2020. A repeat renal biopsy was performed during subsequent readmission with a Cr of 10.6 mg/dl in 2022, which revealed MN with focal crescents (7 cellular/fibro cellular & one fibrous), global sclerosis of 46%, tubular atrophy, & chronic interstitial inflammation. Anti-PLA2R was lower but still elevated (45 RU/ml). No meaningful recovery despite IS therapy, and he progressed to End-Stage Kidney Disease & started on dialysis.

Discussion: The presence of crescents raised suspicion of secondary MN due to infections, neoplasms, etc. However, the lack of secondary MN indicators, negative ANA, anti-dsDNA, ANCA, anti-GBM antibodies, & highly positive anti-PLA2R ab confirmed the diagnosis. Primary idiopathic crescentic MN is rare, with crescent formation likely due to PLA2R immune complex deposition, suggesting MN progression. Although rare, the crescents could also be linked to COVID-19 infection, with no documented cases. Another possibility is the coincidental occurrence of two separate diseases. Recognizing crescents in primary MN is crucial for early & accurate management to prevent progression.

TH-PO680

Rare Coincidence or Secondary Process: Membranous Nephropathy with ANCA-Associated Vasculitis

Leen Al-yacoub, Leal C. Herlitz, Ali Mehdi. *Cleveland Clinic, Cleveland, OH.*

Introduction: Membranous nephropathy (MN) is reported to occur in ANCA-associated vasculitis (AAV) and is usually thought of as secondary. We hereby contrast two cases with AAV both with membranous features one being PLA2R positive suggesting a primary disease process.

Case Description: Case 1: A 70-year-old man with hypertension and chronic sinusitis presented with worsening nasal symptoms, fatigue, poor appetite, and arthralgias. He had severe acute kidney injury requiring dialysis. He had positive C-ANCA/ PR3 antibodies with hematuria and nephrotic-range proteinuria on urinalysis. Kidney biopsy confirmed pauci-immune necrotizing crescentic glomerulonephritis but also showed prominent membranous nephropathy features. Serologic PLA2R testing was negative along with negative tissue PLA2R and Exostosin 1/2 staining. Patient was treated with pulse steroids, plasmapheresis, and oral cyclophosphamide and was able to be liberated from dialysis (Creatinine nadir: 1.2 mg/dL). Proteinuria also trended down from UPCR 7.9 to 3.9 g/g. Due to concern for relapse 3 months into treatment, he was switched over to Rituximab. Remission was achieved after 7 months. Now 2 years after starting rituximab, patient remains in remission (creatinine 1.17mg/dL, UPCR 0.3g/g). Case 2: A 68-year-old female with hypertension and type 2 diabetes presented with generalized edema. She was found to have hematuria, proteinuria, and AKI (creatinine 1.1 mg/dL, baseline 0.7mg/dL). Albumin was 0.9 g/dL with proteinuria of 5.1 g/day. P-ANCA/MPO was positive with kidney biopsy showing pauci-immune crescentic glomerulonephritis along with prominent membranous features. Serologic PLA2R was positive. Patients was treated with pulse steroids and rituximab with serologic and clinical remission within 8 weeks. 5 years after diagnosis patient remains in complete remission (creatinine: 0.68 mg/dL, no hematuria or proteinuria).

Discussion: These cases highlight that MN can occur in the context of AAV. Whether the MN is secondary to AAV is not clear but the PLA2R positive case suggests a seperate primary disease. This patient's presentation with a primarily florid nephrotic syndrome with a mild AKI also suggests that. Rituximab based therapy resulted in remission of both diseases in both cases.

TH-PO681

Thrombotic Microangiopathy and Membranous Nephropathy: A Complicated Paraneoplastic Disorder

Leen Al-yacoub, Jagmeet S. Dhingra, Corey J. Cavanaugh, Leal C. Herlitz, Ali Mehdi. *Cleveland Clinic, Cleveland, OH.*

Introduction: Hematologic malignancies are associated with a myriad of paraneoplastic glomerular pathologies. Various lesions have been described with Mantle cell lymphoma (MCL). We hereby describe a case of concomitant membranous nephropathy (MN) and thrombotic microangiopathy (TMA) in the context of relapsed MCL.

Case Description: A 68-year-old male with history of MCL previously in remission presented with generalized edema. MCL had recently relapsed and patient was set to start Zanubrutinib. He had AKI (Creatinine 2 mg/dL, baseline 1.2), hypoalbuminemia

(1.8 g/dL), nephrotic range proteinuria (13 g/day), normocytic anemia and mild thrombocytopenia. Complements were depleted with a negative serologic workup including PLA2R and THSD7A. Kidney biopsy showed subacute/chronic TMA along with MN. Tissue PLA2R staining was negative. Pathologies were felt to be paraneoplastic and as such lymphoma directed therapy was intensified. Two months later, worsening AKI and anasarca prompted dialysis initiation. Microangiopathic hemolytic anemia and thrombocytopenia were noted along with depleted haptoglobin. Complements remained depleted with elevated sC5b-9 (>2130ng/ml; ref <244ng/ml). Imaging suggested lack of lymphoma response. Along with changing lymphoma therapy, decision was made to initiate eculizumab. This led to liberalization from dialysis (creatinine nadir 1.9 mg/dL) and stabilization of hematologic parameters. Haptoglobin and sC5b-9 also normalized. Attempt at stopping eculizumab after 8 weeks resulted in worsening of kidney and hematologic parameters. Upon restarting eculizumab, things stabilized again. Four months after resuming therapy, kidney function remains stable with improving proteinuria (creatinine 1.9 mg/dL; albumin 3.8g/dL). MCL remains stable.

Discussion: We present a complex paraneoplastic renal pathology of MN and TMA in the context of relapsed MCL. While addressing the underlying malignancy remains the cornerstone of management, given the severity of the presentation eculizumab was successfully used here to stabilize the situation until meaningful hematologic response is achieved. This case highlights that management of these ever-challenging cases needs to be individualized and requires an interdisciplinary approach

TH-PO682

A Case of Membranous Nephropathy Secondary to ANCA-Associated Vasculitis

Chiharu Aizawa,[1] Takuya Fujimaru,[1,2] Futoshi Iwata,[1] Nozomi Kadota,[1] Risa Ishikawa,[1] Yugo Ito,[1] Masahiko Nagahama,[1] Fumika Taki,[1] Motoko Chiga,[2] Eisei Sohara,[2] Shinichi Uchida,[2] Michiko Suzuki.[1] *[1]Sei Roka Kokusai Byoin, Chuo-ku, Japan; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Introduction: ANCA-associated vasculitis (AAV) is sometimes associated with secondary membranous nephropathy (MN). Avacopan, a complement C5a receptor inhibitor, is a drug that can minimize or discontinue corticosteroid doses for AAV. It is unclear whether avacopan, which exerts anti-inflammatory effects through selective C5a receptor antagonism, is useful in the treatment of secondary MN due to AAV.

Case Description: An 80-year-old woman had tested positive for anti-Mycobacterium avium complex antibodies 6 years earlier. She was followed up without treatment because she had no respiratory symptoms. She had been P-ANCA positive for 3 years, but there were no findings suggestive of vasculitis and she was followed up without treatment. She presented to our department with increasing serum creatinine from 0.6 mg/dL to 1.2 mg/dL, severe proteinuria (10 g/gCr), hematuria, and hypoalbuminemia (Alb 2.3 g/dL). Clinically, she was diagnosed with rapid progressive glomerulonephritis with nephrotic syndrome. A renal biopsy was performed and revealed findings of necrotizing crescentic nephritis and MN. Immunofluorescence (IF) staining showed positive IgG4 and MPO-ANCA in the glomerular basement membrane (GBM) but negative anti-PLA2R and anti-THSD7A antibodies. We diagnosed AAV and secondary MN due to MPO-ANCA. We started treatment with prednisolone, rituximab, and avacopan. Prednisolone decreased early. Serum P-ANCA became negative after 1 month of treatment. Seven months later, serum creatinine improved to 1.0 mg/dL, urine protein was 2.8 g/g Cr and serum Alb was 3.9 g/dL.

Discussion: Secondary MN associated with AAV often shows positive MPO-ANCA in the GBM and is negative for IgG4 and anti-PLA2R antibodies in IF staining. However, there have been several case reports of IgG4 predominance. In this case, MPO-ANCA was positive for GBM and was considered secondary MN due to AAV. Avacopan in combination with rituximab and early dose reduction of prednisolone resulted in resolution of P-ANCA, improvement of renal dysfunction, and resolution of proteinuria in this patient. Steroid-sparing therapy with avacopan and rituximab may be effective in secondary MN due to ANCA.

TH-PO683

Anti-brush Border Antibody Disease with Segmental Membranous Nephropathy and Acute Tubular Injury in a Patient with Severe Diabetic Nephropathy

Devansh H. Patel, Deepak Chandramohan, Huma Fatima, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Autoantibody directed to the low-density lipoprotein receptor related protein 2 (LRP2), also known as megalin, is a newly recognized cause of human autoimmune tubular injury. This entity has been termed antibrush border antibody (ABBA) disease or anti-LRP2 nephropathy. LRP2 plays an important role in proximal tubular endocytosis of albumin and other molecules.

Case Description: A 64-year-old male with longstanding diabetes and recurrent AKIs on CKD4A3 presented with symptomatic volume overload and oliguric AKI. He was hypoalbuminemic [Sr albumin 1.5 g/dL] and had high grade proteinuria [UPCR ~ 12.5 g/g] on admission. Extensive serological workup was negative. Kidney biopsy revealed severe diabetes related kidney injury including mesangiolysis and microaneurysmal ruptures, segmental membranous nephropathy [IgG and light chains being 2+], and moderate acute tubular injury. Diffuse, homogenous appearing electron-dense deposits were noted along the TBMs. NELL-1 staining was negative along the GBM; LRP2 staining was positive along the TBM as well as segmentally in the glomeruli [membranous pattern] and along the Bowman's capsule. Patient continues to be dialysis dependent as of now. Immunosuppression was not started given his tenous overall condition.

Discussion: ABBA disease is extremely rare seen in 0.05% of all kidney biopsies. It most commonly afflicts elderly White males; 41% cases have concomitant monoclonal gammopathies. Its co-occurance with severe diabetic nephroapthy is not well ascribed. Acute tubular injury, granular TBM deposits in the proximal tubule, and segmental deposits in the subepithelial region and Bowman's capsule [seen in 80%] are charecteristic. Confirmation warrants positive IF staining for LRP2 within TBM deposits or serologic confirmation of anti-LRP2 antibodies by indirect IF performed on normal human kidney. Prognosis is guarded with 53% progressing to ESKD. Immunosuppression may be warranted in most cases. Our case highlights the importance of considering ABBA disease in the differential when diffuse TBM injury is noted.

TH-PO684

Autologous Stem-Cell Transplant Inducing Autoimmunity Leading to Membranous Nephropathy

Joshua A. Larrazolo, Koyal Jain. *The University of North Carolina at Chapel Hill Department of Medicine, Chapel Hill, NC.*

Introduction: We present a rare case of amyloidosis and autologous stem cell transplant (auto-SCT) two years prior presenting with new nephrotic range proteinuria due to secondary immune complex vasculopathy and membranous nephropathy.

Case Description: A 67-year-old woman with HTN, HLD, AL amyloidosis (diagnosed 4 years ago, treated with CyBorD-Daratumaumab for 1.5 years) presented with worsening proteinuria. Peak proteinuria was 800mg. Auto-SCT was 2.5 years earlier with severe engraftment syndrome (fever, rash, diarrhea) diagnosed by colon biopsy consistent with autologous GVHD treated with prednisone for 2 years, compared to typical 1-2 week therapy, given recurrence of diarrhea with cessation of steroids. Repeat colonoscopy negative for GVHD but inflammatory cecal mass noted while on 5mg Prednisone daily. Prednisone was stopped 4 months prior and patient then noted foamy urine, increased fatigue, mild nausea, intermittent water stools. Lab work showed ACR 3.4g up from 15mg one year ago and UPC 6.4g, moderate hematuria, urine sediment with 1 dysmorphic RBC, stable creatinine 0.97, albumin 2.8, negative ANA, negative anti-PLA2R, positive hepatitis B surface antibody (vaccinated), and negative hepatitis C and CMV. Amyloid noted to be in remission on blood work. Renal biopsy showed membranous nephropathy (stage I-II) and glomerular and arteriolar IgG, IgA, C3, and C1q immune deposits by IF. 40% global and 10% FSGS, minimal glomerular and vascular amyloid deposits, moderate-severe interstitial fibrosis, and tubular atrophy noted. Diagnosis of autoimmune IC type disease with secondary membranous in auto-SCT was made and treatment started with Rituximab and steroids.

Discussion: Autologous GVHD is thought to be similar to autoimmune syndrome and has been documented in the GI tract and skin. Studies have detected autoantibodies after SCT with chronic GVHD, providing evidence for B-cell involvement. Here the proteinuria is driven by membranous nephropathy with polyclonal immune complex deposits. Autoimmunity is likely from ASCT (can happen with infections, e.g. hepatitis B, but it was negative). Steroids and Rituximab can be used to treat auto-SCT-associated antibody mediated autoimmune MN. This case highlights not only a rare presentation but also the importance of repeat biopsy for diagnosing another cause, especially if other markers of amyloidosis are negative and history doesn't support amyloidosis.

TH-PO685

Breaking Barriers: Unconventional Therapy Treats a Challenging Case of Primary Membranous Nephropathy

Md R. Hasan,[1] Ahmed Abdallah,[2] John M. Arthur,[2] Joseph H. Holthoff.[2] *[1]Arkansas College of Osteopathic Medicine, Fort Smith, AR; [2]University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: Membranous nephropathy (MN) is a common cause of nephrotic syndrome, occurring either as primary or secondary. Notably, primary MN is linked to specific antigens, such as phospholipase A2 receptor (PLA2R), which is associated with lower rates of spontaneous remission and a progressive decline in kidney function. Approximately 30% of PLA2R-positive cases may exhibit resistance to conventional treatments like rituximab and cyclophosphamide, prompting the need for innovative therapeutic approaches. We hereby, present a case of treatment-resistant primary MN managed using bortezomib, a medication typically used in myeloma therapy.

Case Description: 44 y.o. male with past medical history of essential hypertension presented to the emergency department with complains of anasarca for 3 weeks. On presentation, he had generalized edema on physical exam. Initial laboratory work up revealed a serum creatinine of 2.5 mg/dl (baseline 1.2 mg/dl), serum albumin of <1 g/dl and a urine protein creatinine ratio (UPCR) showed proteinuria of 12.9 g which was later quantified on

a 24 hour urinary sample as 15 g. We ordered an anti-PLA2R antibody (IgG) titer which was significantly elevated consistent with primary MN. MN was also evident on renal biopsy that was done prior to the antibody results. He was subsequently started on rituximab infusion but unfortunately failed to respond and had persistently elevated anti PLA2R antibodies. Serum CD-19 was undetectable, however, despite achieving complete B-cell depletion he retained high anti-PLA2R antibody levels. We, therefore anticipated plasma cells lacking CD-19 to be the likely source for persistent production of the culprit antibodies and decided to target plasma cells with bortezumab. After two doses of bortezumab, he achieved a gradual reduction in proteinuria as well as anti PLA2R antibodies.

Discussion: For patients with primary MN who do not attain immunologic remission despite B-cell depletion, another hypothesis proposes the existence of long-lived plasma cells that generate anti-PLA2R antibodies. This rationale led to the administration of the proteasome inhibitor, bortezomib, to our patient with PLA2R-positive MN resistant to rituximab. We suggest targeting plasma cells in specific MN cases that remain immunologically active despite successful B-cell depletion with conventional therapies.

TH-PO686

A Case of Severe Membranous Nephropathy Complicated by Chylothorax

Jack Luo, Michael T. Sim, Nasim Wiegley. *UC Davis Medical Center, Sacramento, CA.*

Introduction: Membranous nephropathy (MN) is one of the most common causes of adult-onset nephrotic syndrome (NS). Development of chylothorax is a very rare complication of MN. We present a patient with severe MN, refractory to two first-line immunosuppressive therapy regimens, who developed a chylous pleural effusion, which eventually resolved after the use of cyclophosphamide-based Ponticelli protocol.

Case Description: A 61-year-old White man without any known medical history presented with profound peripheral edema, hypertension, hyperlipidemia, >10 grams per day on 24-hour urine collection, and normal kidney function. Kidney biopsy showed MN with negative PLA2R on tissue staining and serum. A thorough age-appropriate malignancy workup was negative. He was initially treated with rituximab (RTX) infusion 1g x2, followed by initiation of tacrolimus, given minimal response to RTX. He developed progressively worsening shortness of breath, found to have moderate to large right pleural effusion on chest x-ray requiring thoracentesis, with the removal of 1.5L of cloudy white/yellow fluid, with triglyceride (TG) levels of 143 mg/dL. He continued to require monthly thoracentesis. After transitioning to a cyclophosphamide-based regimen with the Ponticelli protocol, he had complete resolution of pleural effusions with partial remission of NS.

Discussion: Chylothorax occurs when the thoracic duct or its tributaries are disrupted, leading to chyle leakage and accumulation into the pleural cavity. The pathophysiology of chylothorax in the setting of MN is not well understood. Proposed theories include increased permeability due to hypoproteinemia or increased lymphatic vessel pressure from severe tissue edema. Immune-mediated damage to lymphatic vessels related to the MN disease process is also a possibility. Further research is needed to elucidate the precise mechanisms underlying this association. Our case underscores the challenges in managing MN and highlights a rare complication of this disease.

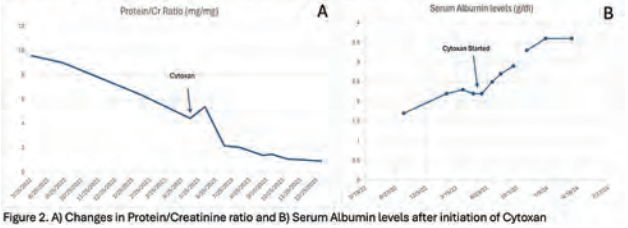

Figure 2. A) Changes in Protein/Creatinine ratio and B) Serum Albumin levels after initiation of Cytoxan

TH-PO687

A Rare Convergence: Suspected Secondary IgA Nephropathy Associated with Dermatomyositis

Jack Luo, Andrea Broka, Kuang-Yu Jen, Nasim Wiegley. *UC Davis Medical Center, Sacramento, CA.*

Introduction: IgA nephropathy (IgAN) is characterized by the accumulation of circulating immune complexes of immunoglobulins and galactose-deficient IgA antibodies in the glomeruli, leading to inflammation and tissue injury. Dermatomyositis, an autoimmune disorder affecting skin and muscles, is rarely linked to kidney manifestations. We present a patient with dermatomyositis who developed sub-nephrotic range proteinuria and microscopic hematuria and was found to have secondary IgAN while on immunosuppressive therapy.

Case Description: A 58-year-old White man with a known history of hypertension, dermatomyositis on Methotrexate 17.5 mg weekly, Tocilizumab 162 mg once a week, and erosive arthritis, presented for evaluation of sub-nephrotic range proteinuria (UPRC 2.5 g/g) with normal kidney function. Initial workup, including ultrasound, complements C3 and C4, and serologic workup for autoimmune disease and chronic infection was negative. Fat pad biopsy was negative for amyloid. Kidney biopsy showed IgAN with the presence of tubuloreticular inclusions on electron microscopy, suggesting a secondary autoimmune nature. He was started on Dapagliflozin, Olmesartan, and Spironolactone with a marked reduction in proteinuria.

Discussion: This case highlights the rare occurrence of secondary IgAN in a patient with dermatomyositis under immunosuppressive therapy. IgAN has been associated with other autoimmune diseases, such as inflammatory bowel disease, celiac disease, and Sjogren's syndrome, but is rarely associated with idiopathic inflammatory myopathies, such as dermatomyositis. Our findings contribute insights into the diverse clinical presentations of idiopathic inflammatory myopathy-associated complications and highlight the need for further studies to evaluate the relationship between idiopathic inflammatory myopathies, such as dermatomyositis, and IgAN.

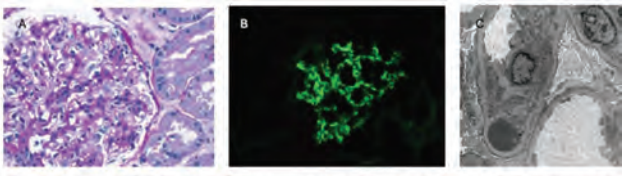

Figure 1: A) Glomerulus with mesangial widening/hypercellularity (PAS, 400X); B) IgA immunofluorescence showing IgA-dominant immune deposits predominantly in the mesangium (200X); C) Electron microscopy reveals paramesangial/mesangial immune deposits (6000X).

TH-PO688

Hypereosinophilic Syndrome with Skin Lesions and Secondary Membranous Nephropathy

Mohamad Bakro, Jee H. Kim, Nitzy N. Munoz Casablanca, Hameeda T. Khan, Aaron S. Stern, Maritza Brown, Hyun Joon Cho. *Mount Sinai Health System, New York, NY.*

Introduction: Hypereosinophilic syndrome (HES) is a rare disorder characterized by persistently high absolute eosinophil count (AEC) (>1500 cells/μL), which leads to organ damage due to cell infiltration. Clinical presentations encompass diverse organ systems, including skin, heart, lungs, and gastrointestinal tract. While uncommon, HES can have renal involvement. Approximately 25-30% of cases of membranous nephropathy (MN) are secondary in nature, with HES being a possible but infrequent cause.

Case Description: A 63-year-old undomiciled male, with a history of alcohol use disorder and evolving hypereosinophilia for over a year, presented for generalized pruritus and a widespread scaly erythematous rash with excoriations. Extensive infectious workup was unremarkable. A bone marrow biopsy ruled out neoplasm, and a skin biopsy showed no evidence of scabies. Despite empiric treatment for scabies and strongyloides, the patient's AEC continued to rise, reaching 13,000 cells/microL. **Laboratory evaluation revealed rising serum creatinine to 5.0 mg/dL and a urine protein-to-creatinine ratio of 3.3.** These findings prompted a kidney biopsy, which demonstrated severe interstitial fibrosis, tubular damage, patchy lymphoplasmacytic interstitial infiltrates, and rare eosinophils. **Electron microscopy** showed mesangial, subepithelial, and intramembranous immune-type deposits. **Immunofluorescence studies revealed IgG and C3 deposits along the glomerular basement membrane, with additional mesangial IgG, IgM, and C3 deposits. Findings were consistent with a diagnosis of secondary MN.** The patient initially showed improvement in kidney function with methylprednisolone followed by a tapering regimen of prednisone. However, during the steroid tapering phase, the patient's renal impairment progressed, ultimately necessitating hemodialysis initiation.

Discussion: HES is a heterogeneous disorder with diverse clinical presentations. Renal involvement, as exemplified by this case, is uncommon but poses significant morbidity with delayed identification and treatment. While the patient initially responded to steroid therapy, kidney disease progression underscores the complexities of managing HES-related renal complications. A review of the literature identified limited case reports of MN associated with HES, highlighting the rarity of this presentation.

TH-PO689

A Child with Exostosin 2-Associated Membranous Nephropathy

Nicole Vegh,[1] Ihor V. Yosypiv.[2] *[1]Louisiana State University, Baton Rouge, LA; [2]Tulane University School of Medicine, New Orleans, LA.*

Introduction: Unlike adults, membranous nephropathy (MN) comprises only 1-2% of childhood nephrotic syndrome. Primary MN is driven by the formation of immune complexes formed by specific antibodies targeting antigens along the subepithelial region of the glomerular basement membrane (GBM). Exostosin 1 and exostosin 2 (EXT1/EXT2) antigens identify a unique form of MN associated with autoimmune disease, such as lupus.

Case Description: A healthy 9-year-old African American boy presented to emergency department for thoughts of suicidal ideation and self harm due to bullying at school. Vital signs and physical examination were normal. Family history was positive for lupus nephritis requiring kidney transplantation. Labs showed normal eGFR, reduced serum albumin (2.5 g/dL), negative ANA, normal C3/C4 complement levels, negative HIV, hepatitis panel, RPR, TB QuantiFERON gold and TSH. Urinalysis (UA) was negative except increased protein to creatinine ratio (5.061 mg/mg). Nephrology started prednisone (2mg/kg/day) treatment of nephrotic syndrome. Lack of remission triggered renal biopsy which showed diffuse global holes and spikes along the thickened GBM, +4 IgG, trace IgA, 3+ C3, 3+ kappa, +3 lambda, EXT2+, global subepithelial and intramembranous electron dense deposits with severe epithelial foot process effacement. Renasight gene panel was negative. A diagnosis of primary EXT2-positive membranous nephropathy was made. *EXT2* encodes glycosyltransferase involved in the chain elongation step of heparan sulfate biosynthesis. Prednisone was stopped and lisinopril was started for nephroprotection. Proteinuria resolved within ~2 months and lisinopril was stopped.

Discussion: This case illustrates that EXT2-positive MN is associated with good short-term clinical outcomes in children. Given that kidney EXT2-positivity is associated with autoimmune diseases, most commonly lupus nephritis, long-term monitoring is required. This case highlights that through identifying specific podocyte antigens, we can tailor individuals' care. Knowledge of the association of EXT2 with lupus nephritis allows for better anticipatory guidance to families.

TH-PO690

THSD7A-Associated Membranous Nephropathy in a Patient with IgA Lambda Myeloma

Saeed Razaq, Khudija Nayab, Frida Rosenblum, Arun Rajasekaran.
The University of Alabama at Birmingham, Birmingham, AL.

Introduction: Membranous nephropathy (MN) is a pattern of glomerular injury caused by autoantibodies binding to specific target antigens, with accumulation of immune complexes along the subepithelial region of glomerular basement membranes. At least 14 target antigens have been identified, accounting for 80%–90% of cases of MN. Thrombospondin type-I domain-containing 7A (THSD7A) was discovered in 2014, but is seen in only 2% cases of MN (both primary and associated with neoplasms). We describe a rare case of THSD7A mediated MN in a patient with concomitant IgA lambda multiple myeloma

Case Description: A 77-year-old male with history of hypertension was admitted with nephrotic syndrome. Cr 1 mg/dL, Sr albumin 1.9 g/dL, and 24 hour urinary protein 6604 mg. SPEP and SIFE revealed 1 IgA lambda monoclonal protein 0.19 mg/dL. Serum PLA2R was negative and serum THSD7A was positive [Mayo Clinic based, titer not available]. Kidney biopsy revealed a membranous pattern of GN with IFTA < 10%. IF: IgG (4+), IgA (4+), IgM (1+), C3 (2+), C1q (trace), kappa LC (3+) and lambda LC (4+) along the capillary loops. Pronase IF was negative. Electron microscopy revealed subepithelial and intramembranous electron dense deposits which were finely granular. Diffuse foot process effacement was noted. PLA2R was negative in the glomeruli while THSD7A IF was positive in the glomeruli. Congo red staining was in kidney biopsy. BM biopsy showed 15% IgA lambda restricted plasma cells. Extensive workup for AL amyloid was negative. A diagnosis of IgA lambda smoldering multiple myeloma was made. Clone based therapy was not initiated and a wait-and-watch approach was implemented. Conservative management including ARBs were started. Patient has now attained complete remission of proteinuria with negative serum THSD7A levels.

Discussion: THSD7A associated MN, in the majority of cases, is a prototypical example of a primary MN, with anti-THSD7A antibodies, predominantly of the IgG4 subclass, directed against THSD7A that is endogenously expressed on podocytes. Disease activity correlates with the titer and trajectory of antibodies and responds to immunosuppression. 16% have a concurrent malignancy; circulating anti-THSD7A antibodies have been reported as a consequence of THSD7A expression by a malignant tumor. Co-occurance with underlying IgA Lambda Smoldering Myeloma has not been reported thus far.

TH-PO691

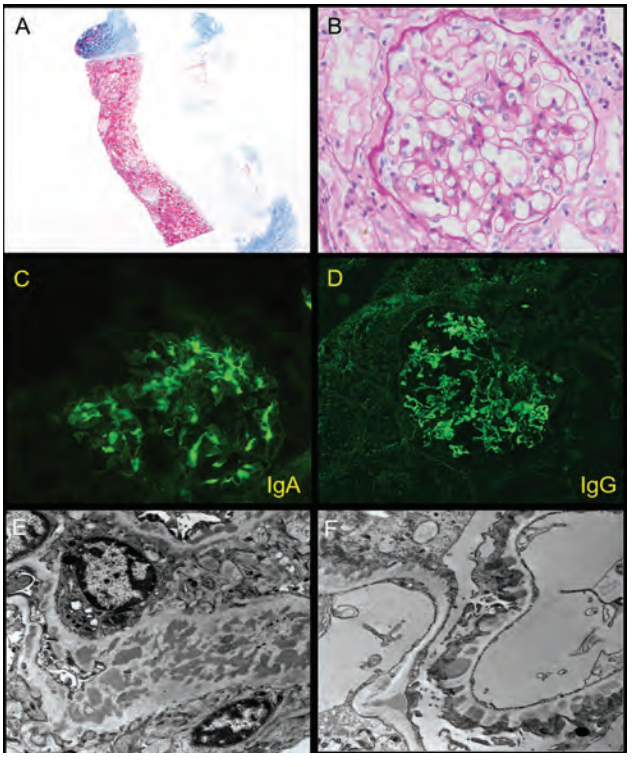
A Postkidney Transplant Patient with Membranous-Like Glomerulopathy with Masked IgG-Kappa Deposits

Paul B. Avila,[1] Ulises Rodriguez Medina,[2] Pooja P. Singh,[2] Namita Singh,[2] Tiffany Caza,[3] Pablo Garcia.[2] *[1]Universidad de San Carlos de Guatemala, Ciudad de Guatemala, Guatemala; [2]University of New Mexico Health Sciences Center, Albuquerque, NM; [3]Arkana Laboratories, Little Rock, AR.*

Introduction: Membranous-like glomerulopathy with masked IgG kappa deposits (MGMIDs) is a novel glomerulonephritis —44% of patients experience worsening kidney disease or ESKD. There is no data on long-term post-kidney transplant (KT) outcomes in patients with MGMID. Here, we present a patient with MGMIDs after KT with four years follow-up after diagnosis.

Case Description: A 47 y/o Hispanic male with ESKD due to membranous nephropathy received DDKT without post-KT complications. He developed worsening proteinuria four years after the KT (2.8 g/g). Thus, he underwent a kidney biopsy, which showed MGMID with concurrent IgA nephropathy (M1 E0 S0 T0 C0). No malignancy, no clones and no bone marrow abnormalities were found. After a multidisciplinary team discussion with the patient, he was started on an ACEi and continued immunosuppressive (IS) therapy (tacrolimus, MMF, and prednisone) with no adjustment to his IS therapy. Four years after his diagnosis, his allograft function remains stable, with an eGFR of 109 ml/min and UPCR of 0.2 g/g.

Discussion: MGMID is a complex disease with no easily identifiable clone, lacks established treatment, and has unclear outcomes. Limited data exists for post-KT MGMIDs. This case highlights the disease remission after ACEi and continuation of his IS therapy, indicating that ACEi, MMF and tacrolimus could play a role in the therapeutic approach. Further studies are needed to understand the disease process and guide our management.



A. No significant interstitial fibrosis
B. Glomerulus with mild mesangial expansion
C. Mesangial IgA staining
D. Capillary loop IgG1 staining
E. Mesangial electron dense deposits.
F. Subepithelial electron dense deposits.

TH-PO692

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits in a Patient with Recent Deceased Donor Kidney Transplant Successfully Treated with Rituximab Monotherapy

Nicholas S. Thorneloe, Alexandra Stewart. *Brooke Army Medical Center, Fort Sam Houston, TX.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMIDs) is a poorly understood monoclonal gammopathy of renal significance. The pathophysiology of this disease remains elusive; though is generally characterized by altered renal function, proteinuria and monoclonal immunoglobulin granular glomerular deposits. Prognosis is poor and treatment without consensus.

Case Description: Patient is a 40-year-old male with history of end stage renal disease due to presumed post infectious C3 glomerular nephritis with secondary focal segmental glomerular sclerosis positive for APOL1; resistant to prolonged steroids. Patient is status post deceased donor kidney transplant in 2022 complicated by delayed graft function with hyperkalemia, hypertension, and secondary polycythemia. Post-transplant patient's creatinine (Cr) nadir was 2.3 with uptrend to 2.8 without proteinuria. Serum immunofixation demonstrated IgA monoclonal protein with kappa light chain specificity, prompting biopsy. Immunofluorescence revealed mesangial deposits of 3+ C3, 1+ C1q, 3+ lambda light chains, 3+ IgG3. Bone marrow biopsy showed hypocellularity without evidence of malignancy. He completed seven of eight doses of Rituximab monotherapy complicated by neutropenia. Renal function improved (Cr 1.9-2.2) and he remained without proteinuria. His recovery course was complicated by severe clostridium difficile infection with acute kidney injury (peak Cr 5.0) one month after completion of Rituximab; likely interfering with optimal renal recovery.

Discussion: Currently therapy for PGNMIDs is without established best practice. Data are from small heterogenous populations with varying intra study combinations of chemotherapy and immunosuppression. The literature supports targeted clonal approach with treatment of underlying hematologic malignancies when relevant. Empiric therapy with some combination of agents such as rituximab, cyclophosphamide, steroids and bortezomib shows promise in those without identifiable clones. It is notable that this patient is without identifiable clonal target and was able to achieve clinical remission with empiric Rituximab monotherapy.

TH-PO693

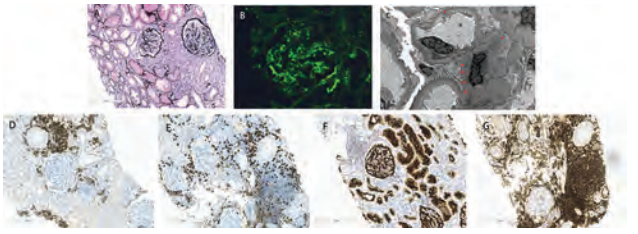
Monoclonal Gammopathy-Associated C3 Glomerulonephritis Secondary to Follicular Lymphoma: A Case Report

Wenjing Cai, Qingying Shi, Chenyu Lei, Xinyi Fu, Anning Xu, Linlin Yuan, Xinling Liang, Zhiming Ye, Zhilian Li. *Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China.*

Introduction: C3 glomerulopathy (C3G) is defined by dominant complement component C3 deposition on kidney biopsy. Monoclonal immunoglobulin-associated C3G (MIg-C3G) is a unique subtype, and lymphoma-associated C3G is rare.

Case Description: A 38-year-old male with a history of hepatitis B virus infection and follicular lymphoma presented with proteinuria, acute kidney injury, and a left neck mass. Renal biopsy revealed C3 glomerulonephritis (C3GN) with lymphoma cell infiltration in the interstitium. Kidney immunohistochemistry showed positive lymphoma (CD19 and CD20) and its subtype follicular lymphoma biomarkers (CD10 and Bcl2). Serum electrophoresis revealed a monoclonal IgM kappa M-spike. Positive autoantibodies to complement C3 convertase and complement factor H indicated complement dysregulation. Treatment with CD20 and CD79b monoclonal antibodies, Zebutinib, and Lenalidomide resolved proteinuria and restored renal function to normal.

Discussion: This case underscores the rarity of follicular lymphoma-associated C3G, with only one previous report in the literature. The patient's diagnosis at a relatively young age without evidence of multiple myeloma or other forms of monoclonal gammopathy of renal significance (MGRS) emphasizes the need for a broad differential diagnosis in glomerulopathies with monoclonal immunoglobulins. The presence of lymphoma cells in the kidney interstitium represents a previously unreported occurrence in patients diagnosed with MIg-C3GN. The patient treated with lymphoma-directed therapy, resolving proteinuria and normalizing renal function, indicating effective B-cell clone treatment.



Kidney histology and immunohistochemistry for general lymphoma and its subtype follicular lymphoma markers. (A) Light microscopy showed a mesangial proliferative pattern of injury with multifocal numerous lymphoma cells infiltration in the interstitium. (B) Immunofluorescence staining showed bright C3 staining along capillary walls and within mesangial areas. (C) Electron Microscopy showed electron-dense deposits in mesangial and endothelial regions (red arrows). (D) CD19. (E) CD 20. (F) CD 10. (G) Bcl2.

TH-PO694

Renal Crystal-Storing Histiocytosis: Transition from Monoclonal Gammopathy of Unknown Significance to Monoclonal Gammopathy of Renal Significance

Kamonluk Rodsom,[1,2] Chutawat Kookanok,[1,3] Wanprapit Noree,[1] Vitchapong Prasitsumrit,[1,2] Tatchaya Kanthajan,[1,4] Ekamol Tantisattamo,[1] Natnicha Jakramonpreeya,[1] Nicha Wareesawetsuwan.[1] *[1]University of California Irvine, Irvine, CA; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]Phramongkutklao College of Medicine, Bangkok, Thailand; [4]Srinakharinwirot University Faculty of Medicine, Bangkok, Thailand.*

Introduction: Crystal-storing histiocytosis (CSH) is a rare condition where immunoglobulins accumulate in histiocytes, causing a variety of manifestations depending on the affected organ systems. We present a case of a man with MGUS which transitioned to MGRS evidenced by renal CSH.

Case Description: A 71-year-old man was diagnosed with MGUS from the workup of normocytic anemia 10 years ago. Urine protein electrophoresis showed a monoclonal spike, serum-free kappa level was 563 mg/dL, and immunofixation showed a κ light chain without corresponding heavy chain and faint IgG κ monoclonal protein. Bone marrow revealed 5-10% of plasma cells. Urinary protein: creatinine ratio (UPCR) had been stable at 400 mg/g of creatinine (Cr). Six years later, he presented with non-nephrotic-range proteinuria. A 24-hour-urine protein was 1,436 mg/day with a stable creatinine of 1.1-1.3 mg/dL. Given the increase in proteinuria with an increase in levels of IgG, kappa light chain, and M-protein and worsening anemia, a kidney biopsy was performed which showed kappa light chain proximal tubulopathy, crystallin type, crystal storing histiocytosis. Segmental glomerulosclerosis**,** with podocyte crystalline inclusions. Low-grade segmental lambda light chain mesangial deposits. Mildly thickened glomerular basement membranes, mild global glomerulosclerosis, arterial and mild arteriolar sclerosis. He has been treated with bortezomib and dexamethasone. His serum Cr is stable at 1.1-1.2 mg/dL and a 24-hour-urine protein decreased to 257 mg/day over 4 years despite without antiproteinuric agents.

Discussion: Our patient had MGUS for 4 years before developing MGRS secondary to renal CSH. Renal involvement in MGUS is usually due to AL amyloidosis, light-chain deposition disease, or chronic kidney disease secondary to paraproteinemia. Nephropathy associated with CSH is extremely rare. Patients diagnosed with MGUS can develop multiple myeloma or other related diseases including MGRS which increases the risk for morbidity and mortality. Therefore, surveillance for transition from MGUS to MGRS is warranted to to early detect and promptly treat for evolving kidney diseases.

TH-PO695

Surviving Fluid Excess: A Rare Case of Collapsing Glomerulopathy with IgM Kappa Monoclonal Gammopathy of Renal Significance

Hira Tahir, Fatima D. Sheikh, Randolph A. Hennigar, Katherine Andrade, Henry Yip. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: Collapsing glomerulopathy (CG) consists of rapid kidney failure and nephrotic syndrome (NS) which can occur with malignancy. Similarly, monoclonal gammopathy of renal significance (MGRS) is a rare renal failure characterized by clonal plasma or B-cells leading to NS from nephrotoxic monoclonal immunoglobulin deposits in the kidney. Our unique case describes collapsing glomerulopathy in IgM kappa deposition disease causing MGRS.

Case Description: A 78-year-old Haitian male with type II diabetes, hypertension, hyperlipidemia and cerebrovascular attack (2019) was referred for poorly controlled hypertension and rising creatinine. Family history included diabetes but no contributing medications or social history. Initial serum creatinine (SCr) of 0.8 mg/dL trended from 1.4 to 4.4 within four months. Urinalysis revealed 100+ protein without hematuria and elevated spot urine microalbumin/Cr of 3484 mg/g and urine protein/Cr of 4.4g. Serum

protein electrophoresis (SPEP) with immunofixation (IFE) had peak in gamma region with IgM kappa but normal kappa/lambda ratio. Otherwise hepatitis B/C, HIV, parvovirus, ANCA, and ANA were negative. Albumin trended 3.7 g/dL to 3.2 g/dL, Hgb 12 g/dL to 8.5 g/dL, cholesterol 145 mg/dL to 216 mg/dL and LDL 66 mg/dL to 135 mg/dL. On subsequent appointments, SBP ranged 150s to 220s mmHg with progression of lower extremity edema. Renal biopsy revealed collapsing glomerulopathy with concurrent IgM Kappa deposits. Hematology evaluation with peripheral blood cytology, bone marrow biopsy and PET/CT imaging diagnosed low-grade monoclonal B-cell lymphocytosis CLL type or B- cell clone causing MGRS. He was treated with rituximab however required dialysis initiation.

Discussion: MGRS is a disease of the kidney, secondary to plasma or B-cell clonal proliferation, requiring treatment to eradicate the offending clone. When plasma or B-cell clones cannot be identified by lab work and bone marrow testing, kidney biopsy can direct treatment. The rapid progression of these diseases warrants prompt diagnosis and treatment to prevent dialysis and furthermore improve prognosis and mortality in this patient population. The rare occurrence of collapsing glomerulopathy simultaneously with IgM Kappa deposition disease warrants further investigation into MGRS treatment protocols.

TH-PO696

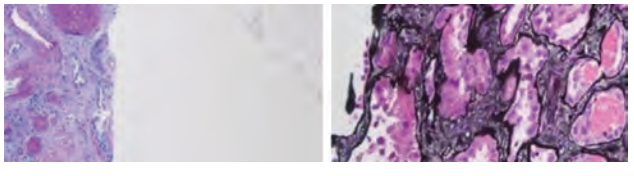
Unveiling the Uncommon: ANCA-Positive IgA Nephropathy

Anvitha Rangan, Mariana Vanoye Tamez, Michael J. Monsour, Syeda M. Sayeed. *Landmark Medical Center, Woonsocket, RI.*

Introduction: Occurrence of antineutrophilic cytoplasmic autoantibodies (ANCA) associated vasculitis (AAV) with immunoglobulin A nephropathy (IgAN) is infrequent. Circulating ANCAs have an underlying role in pathogenesis of this combined entity. We report a rare case of new-onset AAV in a 68-year-old male with IgAN, presenting years after the initial diagnosis of IgAN.

Case Description: A 68-year-old male with stable IgAN was evaluated for epistaxis, hematuria, and purpuric rash over lower extremities occurring over two months. Workup revealed dysmorphic urinary red blood cells, proteinuria, and elevated creatinine (Cr) to 2.62 mg/dl. He also had significantly elevated inflammatory markers and ANCA titers. A repeat kidney biopsy showed fibrinoid necrosis with cellular crescents. Immunofluorescence demonstrated 3+ mesangial IgA deposits. This combination of positive ANCA titers, systemic symptoms, and fibrinoid necrosis provided compelling evidence for a new ANCA-mediated vasculitic process superimposed on IgAN. Intensive corticosteroid therapy was initiated. He then developed an acute diarrheal illness leading to worsening renal failure (BUN/Cr: 243/8.4). Due to rapidly progressive renal failure, cyclophosphamide was started. Plasmapheresis and hemodialysis were eventually required due to minimal renal recovery.

Discussion: Hallmark of ANCA-associated glomerulonephritis is fibrinoid necrosis of the small vessels. ANCA-positive IgAN patients commonly present with extrarenal symptoms as compared to the ANCA-negative IgAN group. Immunotherapy improves renal outcomes and vasculitic symptoms and lowers ANCA titers. It does not reduce the risk of progression to dialysis. Severe proteinuria, advanced age, and low initial eGFR are markers of poor prognosis. IgAN requires regular monitoring of Cr, proteinuria, and changes in symptoms. ANCAs are reported in less than 2% of IgAN patients and may be present during active disease or appear later. ANCAs are pathogenic and not merely biomarkers of AAV. Epitope specificity influences their pathogenicity. These patients have a challenging clinical course. To prevent diagnostic pitfalls, it is essential to repeat kidney biopsy for prompt diagnosis and treatment of ANCA-positive IgAN.



TH-PO697

Triad of Troubles: Rare Confluence of Three Glomerular Diseases

Jessica Boldridge,[1] Ankur Shah,[1] Anthony Chang.[2] *[1]Brown University, Providence, RI; [2]University of Chicago Division of the Biological Sciences, Chicago, IL.*

Introduction: Glomerulonephritis (GN) is an important cause of ESKD contributing to 10-15% of all cases in the United States. IgA nephropathy is the most common cause of GN. Detection is important as delay in treatment can cause significant morbidity with progression to dialysis.

Case Description: A 61 yo female with a PMH of Grave's disease, Sjogren's, Raynauds, extranodal marginal zone lymphoma of the lung treated with rituximab presented initially with hematuria, proteinuria. She had a previous history of IgA vasculitis with renal and skin manifestations including bilateral purpura, hematuria and 0.3g/g proteinuria with preserved GFR. Renal biopsy had shown mild to moderate mesangial expansion, focal endocapillary hypercellularity with fine granular 2+ IgA staining on IF consistent with mesangioproliferative IgAN. She was started on steroids but due to worsening proteinuria and rising Cr she was switched to mycophenolate (MMF) in 2017. This was held in 2021 due to pneumonia. In 2023, she had worsening proteinuria with re-initiation of steroids and MMF. Reiniation of MMF caused anemia, gastrointestinal and infectious complications. A repeat kidney biopsy was performed to assess disease activity and prognosis desmonstrating a single fibrocellular crescent, diffuse mesangial hypercellularity and vacuolated capillary loops with a subepithelial spike formation. There was no significant glomerular staining for IgA. EM demonstrated sub-epithelial electron dense deposits. She was started on rituximab for concomitant membranous glomerulopathy and ANCA vasculitis and avacopan due to her prior steroid complications.

Discussion: We present a rare case of 3 coexisting biopsy proven glomerulopathies in one patient. This is a classic example of Hickam's dictum, an aphorism that notes that the desire to find a single diagnosis for a patients ailments ignores the possibility of multiple co-existing disease states. In this case, the propensity for auto-immunity with her prior sjogrens, graves, and raynauds prompted consideration of multiple syndromes, which was found on biopsy. Treatment of multiple co-existing glomerulopathies is not well described, and our medical decision making was to attempt to apply occam's razor to treatment, using a single treatment strategy that would treat all the co-existing glomerulopathies. This case demonstrates a wide range of medical decision making, highlighting its educational merit.

TH-PO698

Insidious Presentation of IgA Fibrillary Glomerulonephritis

Ayesha Shah, Amna Anees. *Charleston Area Medical Center, Charleston, WV.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare diagnosis, present in 0.5 to 1.4% of native kidney biopsies. Symptoms include proteinuria, hematuria, kidney function impairment, hypertension (HTN), and monoclonal gammopathy. Positive DNAJB9 stain and large, non-branching overlapping fibrils on kidney biopsy confirm the diagnosis. We present a case of FGN in a patient with known chronic kidney disease (CKD).

Case Description: An 80-year-old male with history of CKD stage 3b, HTN, benign prostatic hyperplasia, bladder calculi with obstructive uropathy status post transurethral resection of the prostate, atrial fibrillation on apixaban, and coronary artery disease presented for outpatient nephrology evaluation of elevated creatinine (Cr). He also had proteinuria and microscopic hematuria, ongoing for the past four years. Initially, hematuria was thought to be non-glomerular in nature due to prior urologic history. Patient also had new-onset bilateral lower extremity edema but denied urinary symptoms. His Cr was 1.7 mg/dL (eGFR 39 mL/min), compared to Cr 1.4mg/dL (eGFR 49 mL/min) eight months prior. Urinalysis showed proteinuria, hematuria, and red blood cell casts. Workup was significant for elevated free kappa and lambda light chains without apparent M-spike on protein electrophoresis; urine studies were positive for albumin and alpha-1, alpha-2, beta, and gamma globulins. CT abdomen/pelvis completed six months prior showed only small renal cysts; retroperitoneal ultrasound was significant for bilateral echogenic kidneys. Over the next five months, the patient continued to have lower extremity swelling; Cr at follow-up was 3.2mg/dL. He developed hypocalcemia and hyperphosphatemia. Urological evaluation for post-renal causes, including cystoscopy, was unrevealing. Kidney biopsy was significant for negative Congo red stain and positive DNAJB9 stain. Electron microscopy confirmed FGN, and immunofluorescence was significant for mesangial IgA, IgM, C3, kappa, and lambda staining. The patient was started on systemic steroids and rituximab treatment; he completed two doses of rituximab treatment with improvement in Cr.

Discussion: Our patient had common manifestations of FGN years prior to initial nephrology evaluation, at which point his FGN rapidly progressed prior to rituximab treatment. This case highlights the importance of consideration and timely diagnosis of glomerulonephritis and emphasizes avoiding anchor bias.

TH-PO699

A Unique Case of IgA Nephropathy Associated with Both Immune Thrombocytopenia and Erythrocytosis

Parker Lehmann,[1] Udayan Y. Bhatt,[2] Asish Thakkar.[3] *[1]Idaho College of Osteopathic Medicine, Meridian, ID; [2]The Ohio State University Wexner Medical Center, Columbus, OH; [3]VA Health Care System, Columbus, OH.*

Introduction: Erythrocytosis is characterized by an elevation in hemoglobin and may be primary (typically associated with a mutation in the JAK2 gene) or it may be secondary. Many renal diseases have been associated with erythrocytosis. One association that has become increasingly reported is the association between IgA nephropathy and erythrocytosis. In addition, there have been a few case reports of IgA nephropathy associated with immune thrombocytopenia (ITP). We describe a novel presentation of both erythrocytosis and immune thrombocytopenia associated with IgA nephropathy.

Case Description: A 26yo African American male presented to the Hematology clinic for mild thrombocytopenia. The patient had a positive platelet associated antibody. This resulted in the diagnosis of ITP. The patient was coincidentally noted to have chronic

kidney disease with eGFR of 65cc/min at that time. He subsequently had a climbing hemoglobin and began requiring therapeutic phlebotomy. His erythrocytosis showed no evidence of a JAK2 mutation and a bone marrow biopsy showing a normocellular marrow with an erythroid predominant hematopoiesis but normal megakaryocytes. The diagnosis was idiopathic erythrocytosis. At 36yo, repeat chemistries showed an eGFR of 33cc/min. Because of that, he was referred to nephrology and underwent a renal biopsy that showed IgA nephropathy with moderate interstitial fibrosis and tubular atrophy but without active injury or thrombotic microangiopathy. The patient continued to receive phlebotomy. He was noted to have a normal to occasionally elevated erythropoietin level. Imaging did not show evidence of intrabdominal or renal neoplasms. The patient has not manifested any hemorrhagic complications and his platelet count has continued to be mildly suppressed.

Discussion: IgA nephropathy is the most common primary glomerular disease worldwide. It is diagnosed via biopsy and there are no exact immune markers that definitively suggest IgA nephropathy. However, the presence of hematologic disorders such as ITP and erythrocytosis may also indicate the presence of underlying IgA nephropathy. Our unique case describes IgA nephropathy associated with both ITP and erythrocytosis. Further work is warranted in exploring the pathogenesis of these connected disorders.

TH-PO700

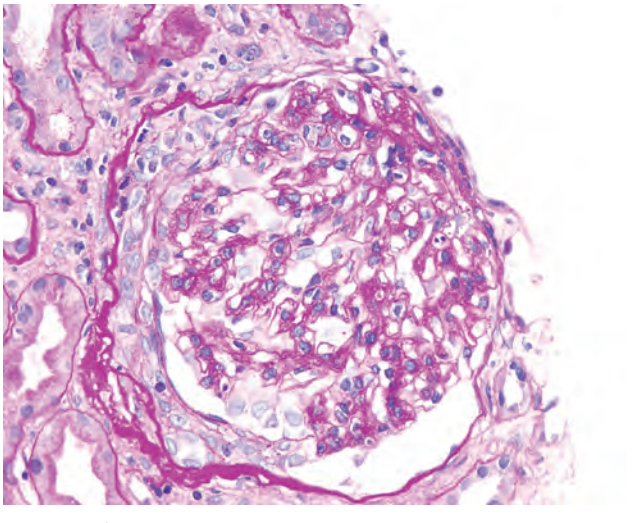
Infliximab-Induced Secondary IgA Nephropathy in a Patient with Rheumatoid Arthritis

Prachi Gajjar,[1] Parth Parmar,[1] Hetvi Gajjar,[2] Sepiya Shrestha,[1] Dhruvil K. Shah,[1] Kashish Magnani.[3] *[1]Trumbull Regional Medical Center, Warren, OH; [2]Pramukhswami Medical College, Karamsad, India; [3]Surat Municipal Institute of Medical Education and Research, Surat, India.*

Introduction: IgA Nephropathy is the most common primary glomerular disease in the world, characterized by the antibody formation against Galactose-deficient IgA1, which gets deposited in the glomerulus. It can be primary or secondary. Secondary causes associated are liver disease, celiac disease, HIV infection and medications like anti-tumour Necrosis Factor α therapy.

Case Description: A 69-year-old male with polyarticular erosive rheumatoid arthritis, atrial fibrillation, hypertension, chronic kidney disease stage 3a with baseline creatinine of 1.5 mg/dL came with a complaint of fatigue and dark urine for a month. His rheumatoid arthritis was well controlled with Infliximab infusions eight weekly for last 10 years. On admission, he had acute kidney injury with five fold rise in creatinine without oliguria. Urinalysis showed microscopic hematuria and moderate proteinuria. Renal biopsy suggested IgA Nephropathy with mesangial proliferation with IgA deposits. Infliximab was stopped, and the patient was given a tapering dose of steroids. After around two months of stable renal function with steroids, rheumatologist resumed Infliximab, which resulted in a similar episode of acute kidney injury, which was again resolved by stopping the medicine. This made it more evident that Infliximab was the culprit behind secondary IgA nephropathy.

Discussion: There have been case reports on Infliximab and other TNFα inhibitors causing secondary IgA Nephropathy. The overall aetiology of medication-induced IgA Nephropathy, along with the underlying autoimmune conditions, is not well understood. One hypothesis suggests antibodies against the glycan structure of TNFα inhibitors lead to interaction with the presence of aberrant IgA1 molecules in the serum, forming large polymeric IgA complexes. More molecular-level studies are needed to get more robust evidence of such an association.



Mesangial Proliferation on PAS stain

TH-PO701

A Rare Case of IgA Vasculitis and Crescentic Glomerulonephritis in a Patient with Cirrhosis

Kevin Zhang, Raphael J. Rosen. Stamford Health Nephrology. *Stamford Hospital, Stamford, CT.*

Introduction: Rapidly progressing glomerulonephritis (RPGN), also known as crescentic glomerulonephritis, is a condition characterized by rapid decline in kidney function over days to weeks. RPGN is characterized by the presence of glomerular crescents seen on kidney biopsy. While most cases of RPGN are pauci-immune glomerulonephritis, less common causes must also be considered. We present an unusual case of RPGN from IgA vasculitis associated with cirrhosis.

Case Description: A 37-year-old man with cirrhosis from alcohol use disorder presented to the emergency department with thrombocytopenia, anemia, and creatinine elevation to 6.1 mg/dL (from a prior baseline of 0.7). Urinalysis demonstrated +4 proteinuria and 3+ hematuria. Of note, he had been diagnosed with leukocytoclastic vasculitis with IgA deposits 4 months prior. On this current admission, his rash had worsened (image 1). He was given pulse dose steroids and renal biopsy was performed, which demonstrated diffuse mesangial and focal endocapillary proliferative and sclerosing glomerulonephritis with membranoproliferative features, focal crescents, and focal necrotizing features. Immunofluorescence demonstrated IgA dominant staining, confirming the diagnosis of crescentic IgA vasculitis. He was treated with cyclophosphamide for RPGN, and his creatinine stabilized.

Discussion: Though IgA nephropathy is the most common glomerulonephritis, crescentic IgA and IgA vasculitis are relatively uncommon. Most patients with cirrhosis who are found to have IgA nephropathy have a mild, secondary form of IgAN. Our patient, in contrast, had extremely severe features of the spectrum of IgA related disorders, including both generalized IgA vasculitis and RPGN from IgAN. In a patient with cirrhosis and acute kidney injury, glomerulonephritis remains on the differential and may be responsive to immunosuppression.

TH-PO702

Sinister Synergy: IgA Nephropathy and Apixaban

Atlee Baker, Gonzalo Matzumura Umemoto. *Washington University in St Louis, St Louis, MO.*

Introduction: IgA nephropathy is the most common glomerulonephritis worldwide, divided into primary and secondary types. Oral anticoagulants have been associated with acute kidney injury, although less well defined. We present a case of IgAN made more severe with the addition of Apixaban.

Case Description: A 75-year-old male with history of recently diagnosed atrial fibrillation on Apixaban, systolic heart failure, and prior EtOH abuse who presented for evaluation of lower extremity edema. He developed rapid onset of stage 3 AKI (sCr 4mg/dL, baseline 1mg/mL) over one month and gross hematuria 1 week prior to presentation. Urinalysis revealed >50 RBCs; UPCR 1.8g/g. Urine microscopy revealed mixed cellular casts. Broad serological work up was negative. C3/C4 levels normal. Infectious work up was negative. US revealed mild liver contour changes concerning for mild cirrhosis. Renal biopsy with findings of IgAN (3+ IgA/C3 in the mesangium and tubular lumen, low mesangial expansion and endocapillary proliferation, no crescents), and numerous RBC casts. Findings were attributed to secondary IgAN with cirrhosis, with other findings suggestive of anticoagulant-related nephropathy. Given the rapid progression of his disease, patient was started on high-dose steroids. Apixaban was held with resolution of hematuria. Patient's renal function subsequently improved and Apixaban was restarted.

Discussion: We present a case of sIgAN complicated by the addition of anticoagulation. Our case is unique as the patient presented with rapidly progressive and

severe renal injury, without characteristic findings of aggressive disease on biopsy. Our case highlights the role that anticoagulation can have worsening glomerular disease.

RBC Casts

TH-PO703

Apixaban-Induced IgA Vasculitis with Nephritis

Tahir A. Jatoi,[1,2] Sandeep R. Sasidharan,[1,2] Rabiya Akram,[1] Mohammad W. Abushawer,[2,1] Fnu Pariya,[1] Arfa Amjad,[1] Subodh J. Saggi,[1] Susan Grossman,[2] Marie-Alex Michel,[2] Moro O. Salifu.[1] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]VA New York Harbor Healthcare System, New York, NY.*

Introduction: Leukocytoclastic vasculitis (LCV), previously called Henoch-Schönlein purpura, is characterized by IgA-dominant immune deposits affecting small vessels and often involves the skin, gastrointestinal tract, joints, and kidneys. Direct oral anticoagulants are an emerging cause of LCV. This is a diagnosis of exclusion. In cases of drug-induced LCV, discontinuation of offending agent is the mainstay of treatment. Steroids may have a role in treating cases with widespread skin involvement. We are presenting a rare case of Apixaban induced leukocytoclastic vasculitis (LCV) with Nephritis

Case Description: 71 y.o. male with PMH of CKD3b, DM, CAD, COPD, HTN, LE DVT with B/L bilateral leg swelling for 6 months, admitted with c/o extensive pruritic rash after being started on Apixaban for 2 weeks. Vital signs and system review were otherwise unremarkable. On PE, he had open skin lesions with draining clear fluid and LE swelling. Labs showed BUN/Creat of 54/2.1, from baseline of 1.6, HGB 11 mg/dl, UA had proteinuria with significant microhematuria, Upcr of 3.7 g/g from 0.5 g/g, IgE levels were elevated 1020, rest of the nephrotic work up was negative. Skin biopsy revealed leukocytoclastic vasculitis. Due to worsening creatinine and proteinuria, renal biopsy was performed, and it showed globally sclerotic glomeruli with moderate interstitial fibrosis and tubular atrophy on light microscopy, IgA staining positive on immunofluorescence with dense deposits in mesangium on electron microscopy. The patient was switched from apixaban to warfarin, and started on prednisone and Mycophenolate Mofetil with a diagnosis of IgA vasculitis and nephritis. Renal function and proteinuria improved.

Discussion: Apixaban is a rare cause of leukocytoclastic vasculitis (LCV). To our knowledge, there are only a few reported cases of LCV due to apixaban in the literature. Our case is the only case of apixaban associated LCV with Nephritis. LCV is a diagnosis of exclusion after infectious, autoimmune, and inflammatory conditions have been excluded. Almost 30% of all cases of LCV are drug-induced. However, anticoagulants are a rare cause of LCV. Our case of apixaban-induced LCV with nephritis highlights a rare complication of a common medication, which is important for physicians to be aware of.

TH-PO704

A Novel Case of IgA Nephropathy and Tubulointerstitial Nephritis in Patients with Crohn Disease Treated with Adalimumab: What Is the Culprit?

Shota Obata,[1] Martine Pollack-Zollman.[2] *[1]Mount Sinai Beth Israel Hospital, New York, NY; [2]Mount Sinai Morningside Hospital, New York, NY.*

Introduction: IgA nephropathy (IgAN) is associated with Crohn's disease (CD) and the use of tumor necrosis factor-alpha inhibitor (TNF-αi). Tubulointerstitial nephritis (TIN) is noted as an extra-intestinal manifestation of CD but is also reported to be caused by the use of TNF-αi. Thus, it is challenging to underpin the culprit of IgAN and TIN among patients with CD treated with TNF-αi. We present a case of IgAN concomitant with TIN in a patient with CD on adalimumab, a TNF- αi.

Case Description: A 21-year-old man with a history of CD treated with adalimumab for six years presented with a sore throat, fever, gross hematuria, and AKI (Cr 3.0 mg/dL from 0.8 mg/dL). Urinalysis revealed numerous WBCs and RBCs, rare eosinophils, negative leukocyte esterase and nitrite, and a urine protein-creatinine ratio of 3.74 g/gCr. Kidney ultrasound showed normal size and echogenicity without hydronephrosis. Immunologic and infectious workups were negative. After hydration, Cr improved to 1.8 mg/dL on discharge. He was referred for kidney biopsy, which revealed IgAN and acute tubular necrosis with acute and chronic interstitial nephritis. Adalimumab was switched to Skyrizi, an interleukin-23 (IL-23) antagonist, and losartan and prednisone 40 mg were initiated. At the last follow-up, Cr improved to 1.32 mg/dL with mild proteinuria of 0.251 g/gCr while on a slow prednisone taper.

Discussion: It is challenging to determine whether CD or TNF-αi induces IgAN and TIN. In our case, extra-intestinal manifestation is unlikely to develop, given the remission of CD. Thus, TNF-αi was switched to IL-23 antagonists in addition to administration of steroids, resulting in improved renal function and resolution of proteinuria. The mechanism of action how TNF-αi causes IgAN and TIN is unknown but may be due to an underlying predisposition to defective IgA1 structure along with altered immune regulation, auto-drug and antibody formation, and/or molecular mimicry, which together leads to immune-complex deposits in the glomeruli. Whether this is a TNF-αi class effect or specific to adalimumab needs to be determined along with the possibility of future research to determine who is at risk. It is important for gastroenterologists treating patients with CD to be aware of this risk, check baseline Cr and urinalysis, and perform regular monitoring.

TH-PO705

Unusual Suspect: Apixaban as a Cause of ANCA-Associated Vasculitis

Navya Reddy Perkit,[1] Mithil Gowda Suresh,[1] Jassimran Singh,[1] Aviraag Vijayaprakash,[1] Helmut G. Rennke,[2] Suzanne G. Martin.[1] *[1]Saint Vincent Hospital, Worcester, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Introduction: Antineutrophilic cytoplasmic antibody (ANCA) vasculitis is a common cause of acute glomerulonephritis in adults, with drug-induced ANCA vasculitis (DIAV) being relatively rare.

Case Description: An 85-year-old female with stage IV chronic kidney disease (CKD), on apixaban for atrial fibrillation, presented with fatigue, weakness, and dyspnea. Exam showed clear lungs and new trace bilateral pitting pedal edema. She had proteinuria, hematuria, and creatinine of 5.41 mg/dL, up from baseline 2.5 mg/dL. Urine protein-creatinine ratio was elevated at 4.5 g/gCr. Renal biopsy indicated chronic-active focal proliferative, necrotizing, and crescentic glomerulonephritis with immune deposits. Serologies showed a high anti-MPO titer of 1:1997, with other autoantibodies negative. Given the elevated anti-MPO titer and biopsy findings, drug-induced ANCA vasculitis was considered. The patient was not on known causative medications. The temporal relationship with apixaban led to its discontinuation and transition to warfain. She received steroids along with two biweekly doses of rituximab which reduced the anti-MPO titer to 1:32 and proteinuria improved to 3 g/gCr.

Discussion: DIAV is a diagnosis of exclusion suggested by high anti-MPO titers, as seen in this case. The rapid improvement after discontinuation of apixaban and two doses of rituximab suggest her ANCA vasculitis was likely due to an offending agent, rather than spontaneous ANCA disease. Apixaban-induced ANCA vasculitis has not been previously reported, though apixaban-induced cutaneous leukocytoclastic vasculitis and drug-induced lupus suggest its potential for autoimmune phenomena. Prompt identification and treatment, including drug discontinuation and immunosuppressive therapy, are crucial for managing DIAV and preventing disease progression. Increased awareness and further research into apixaban-induced DIAV are essential due to its expanding use in CKD patients.

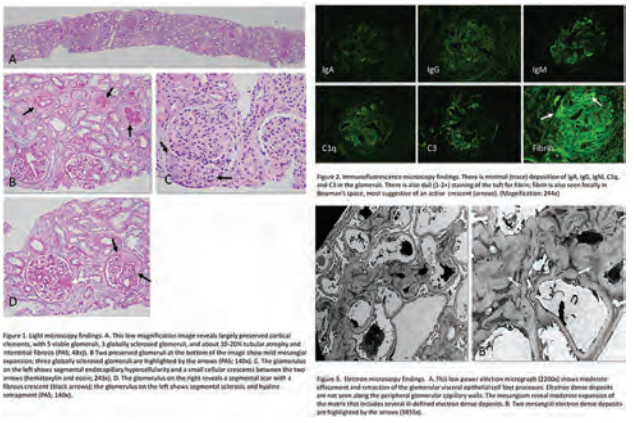

Figure 1. Light microscopy findings. A. This low magnification image reveals largely preserved cortical elements, with 5 viable glomeruli, 3 globally sclerosed glomeruli, and about 10-20% tubular atrophy and interstitial fibrosis (PAS; 40x). B Two preserved glomeruli at the bottom of the image show mild mesangial expansion; three globally sclerosed glomeruli are highlighted by the arrows (PAS; 140x). C. The glomerulus on the left shows segmental endocapillary hypercellularity and a small cellular crescents between the two arrows (hematoxylin and eosin; 240x). D. The glomerulus on the right reveals a segmental scar with a fibrous crescent (black arrows); the glomerulus on the left shows segmental sclerosis and hyaline entrapment (PAS; 140x).

Figure 2. Immunofluorescence microscopy findings. There is minimal (trace) deposition of IgA, IgG, IgM, C1q, and C3 in the glomeruli. There is also dull (1-2+) staining of the tuft for fibrin; fibrin is also seen focally in Bowman's space, most suggestive of an active crescent (arrows). (Magnification: 244x)

Figure 3. Electron microscopy findings. A. This low power electron micrograph (2200x) shows moderate effacement and retraction of the glomerular visceral epithelial cell foot processes. Electron dense deposits are not seen along the peripheral glomerular capillary walls. The mesangium reveal moderate expansion of the matrix that includes several ill-defined electron dense deposits. B. Two mesangial electron dense deposits are highlighted by the arrows (5855x).

TH-PO706

IgA Nephropathy Due to Polycythemia Vera

Sharmilee Vuyyuru, Rajib K. Gupta, Nandakishor Kapa. *University of California Davis, Sacramento, CA.*

Introduction: Polycythemia Vera (PV) can manifest with mutations in the JAK2 gene and affects bone marrow, spleen, and liver. Kidney involvement is rare, but when it occurs, over 50% of cases have glomerular hyperfiltration. We present an unusual instance of PV associated with IgA nephropathy.

Case Description: A 41-year-old male with hypertension (HTN) and PV presented with 24-hour urine protein level of 3.6g and microscopic hematuria. His hemoglobin level was 17.1g/dL, red blood cell count was 6.23m/mm3, and serum erythropoietin level was 8U/l (normal). JAK2-V617F mutation, CALR and MPL were negative. Kidney biopsy showed IgA nephropathy with secondary features like thrombotic microangiopathy (see image 1), segmental fibrinoid necrosis and segmental sclerosis. Serum complements 3 and 4, hepatitis panel, and antibody serologies tested negative. With concern for PV associated IgA nephropathy, bone marrow biopsy and next generation sequencing (NGS) was recommended. Given benefit of sodium glucose co-transporter 2 inhibitors in IgA Nephropathy, and proteinuria, empagliflozin 10mg daily was added to his regimen of losartan 100mg for HTN. On follow up, spot urine protein/creatinine ratio was 1.4g/g, with continued microscopic hematuria.

Discussion: PV associated IgA Nephropathy is rare. A thorough work up should be done for new-onset proteinuria, and kidney biopsy is often indicated. As kidney dysfunction is a later complication and has guarded prognosis, early diagnosis and more awareness is needed to help establish defined therapies.

TH-PO707

Severe IgA Vasculitis Nephritis in Adults: Two Challenging Cases

Assaf Potruch, Momen Abbasi, Roy Abel, Ittamar Gork. *Hadassah University Medical Center, Jerusalem, Israel.*

Introduction: Immunoglobulin A vasculitis (IgAV) in adults is characterized by the combination of skin, gastrointestinal, joint and renal involvement. Yearly incidence is 1-1.8 per 1 million. IgAV nephritis occurs in 45-85% of adults with IgAV, manifesting as acute kidney injury (AKI), active urine sediment and proteinuria. Treatment protocols for severe cases of IgAV nephritis presenting with AKI, nephrotic range proteinuria and crescentic glomerulonephritis (GN) are not validated. We present two cases of severe IgAV nephritis over the span of 2 months.

Case Description: Case I – A previously healthy 54-year-old female presented with a lower limb purpuric rash. A skin biopsy was consistent with IgA vasculitis. Severe terminal ileitis developed, and prednisone 40 mg/d led to symptomatic improvement. Shortly after, proteinuria was noted and increased up to protein/creatinine ratio (UPCR) 6.7 g/g and serum creatinine rose from 0.68 mg/dL to 1.78 mg/dL. Kidney biopsy demonstrated proliferative necrotizing GN with >50% crescents and dominant IgA immune deposits (Figure 1). Methylprednisolone 500 mg/d for 3 days followed by prednisone 60 mg daily and IV cyclophosphamide were started; Proteinuria peaked at a UPCR of 14 g/g Therefore, Rituximab was added, total dose of 2 grams, leading to significant improvement (UPCR 0.5 g/g, creatinine 1.3 mg/dL). **Case II –** A 58-year-old male, with past medical history of diabetes, hypertension and peripheral vascular disease presented with a lower limb purpuric rash. Skin biopsy was consistent with IgAV. Nephrotic syndrome with proteinuria of 6 g/D, leg edema, albumin of 2.6 g/dL and a rise in serum creatinine 0.6 mg/dL to 1.5 mg/dL were observed. Kidney biopsy demonstrated proliferative necrotizing GN with >25% crescents and dominant IgA immune deposits.3 grams IV solumedrol followed by 60 mg/d prednisone, and a total of 6 grams of IV cyclophosphamide were given, with improvement (creatinine to 1.2 mg/dL and UACR below 500 mg/g).

Discussion: Evidence is lacking regarding the optimal treatment of severe IgAV nephritis. The above-described cases presented with severe findings clinically and histologically and responded well to aggressive immunosuppression. Case 1 highlights that Rituximab could be added to our 2nd line treatment options and emphasizes the need for studies in IgAV nephritis treatment.

TH-PO708

CTLA-4 Haploinsufficiency Presenting with IgA Nephropathy

Andrea Broka, Brian Y. Young, Hiba Hamdan, Victoria R. Dimitriades, Kuang-Yu Jen, Nasim Wiegley. *UC Davis Health, Sacramento, CA.*

Introduction: The regulatory mechanisms governing activation and inhibition of the immune response are orchestrated by key molecules. Derangements in CTLA-4 activity can lead to loss of T cell suppression with a resulting hyperinflammatory state, with manifestations of recurrent infections, lymphoproliferation, cytopenias, and liver/lung infiltration.

Case Description: A 25yr South Asian Woman with CTLA4 immune dysregulation syndrome, managed with monthly abatacept (anti CD80/CD86) and IVIg infusions for 5 years, presented with new onset cytopenia, hypertension, acute kidney injury, Cr 3 mg/dL (baseline 1 mg/dl), proteinuria of 1 g/g and an active urine sediment with acanthocytes, red blood cell casts. Serologic workup and cultures were negative. Kidney biopsy showed IgA Nephropathy (IgAN) with 25% crescentic lesions. The etiology of the IgAN was

most likely secondary to her immune dysregulation syndrome, given the concomitant cytopenias and profound upregulation of inflammatory markers, rather than the effect of drug-induced IgAN. Therefore the immunosuppression was escalated. Kidney function initially stabilized, but worsened again, progressing to oliguric AKI-D. She was started on pulse steroids and IV cyclophosphamide. She continues to be dialysis dependent despite these therapies.

Discussion: CTLA-4 haploinsufficiency has been rarely linked with kidney disease, with only a few reports of interstitial nephritis. Our case is the first report of CTLA-4 immune dysregulation associated with glomerulonephritis (GN). Studies have shown that CTLA-4 polymorphisms have a predisposition for GN. This patient's presentation with other autoimmune diseases (cytopenias) and upregulation of systemic inflammatory markers such as CD19 and IL2, it was thought to be more an escape from the abatacept immune regulation, rather than caused by it. This case highlights the first reported IgAN associated with CTLA-4 immune dysregulation syndrome.

TH-PO709

Treatment of Recurrent IgA Nephropathy after Kidney Transplant with Delayed-Release Budesonide

Niloufar Ebrahimi, Yan Chen Wongworawat, Amir Abdi Pour, Sayna Norouzi.
Loma Linda University Medical Center, Loma Linda, CA.

Introduction: IgA nephropathy (IgAN), the most prevalent form of glomerulonephritis worldwide, is characterized by hematuria, proteinuria, and progressive kidney function decline. Currently, there are no clear guidelines on the treatment of recurrent IgAN post-transplant.

Case Description: A 22-year-old Caucasian male with a history of end-stage kidney disease secondary to IgAN status post-kidney transplant two years ago on maintenance therapy with tacrolimus, mycophenolate mofetil, and low-dose steroids presented with hematuria, proteinuria, and declining kidney function. A follow-up biopsy on the transplanted kidney revealed recurrent IgAN with secondary focal and segmental glomerulosclerosis but without signs of acute rejection (Figure 1). Delayed release (DR) budesonide was initiated, and he tolerated the medication well. Figure 2 shows his eGFR and UPCR improvement three months after starting the treatment.

Discussion: The FDA has approved DR budesonide for managing adults with primary IgAN at risk of rapid disease progression. However, transplant patients were excluded from the NefIgArd trial. Our case report suggests future studies on the effects of DR budesonide for treating recurrent IgAN post-transplant.

TH-PO710

Secondary IgA Nephropathy Due to Ketamine-Induced Cirrhosis: A Rare Cause of ESKD in Ketamine Users

Prashant N. Bhenswala,[1,2] Purva D. Sharma.[1,2] *[1]Northwell Health, New Hyde Park, NY; [2]Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Hempstead, NY.*

Introduction: Ketamine abuse is a known cause of hepatobiliary injury and cirrhosis as well as urologic injury possibly resulting from irritation of the urologic system. Chronic ketamine use is also known to cause cystitis, bladder dysfunction, and hydronephrosis. The relationship between cirrhosis and IgA nephropathy is well known and is due to the liver's inability to clear circulating IgA immune complexes. However, little to no reports linking Ketamine-Induced-Cirrhosis (KIC) to IgA nephropathy resulting in kidney failure and end-stage kidney disease needing dialysis have been reported.

Case Description: Our case involves a 26-year-old female with history of ketamine abuse (since age 16), with biopsy proven ketamine-induced liver injury with F1 fibrosis. She presented to the hospital with advanced kidney disease with a serum creatinine of 9 mg/dL, hematuria, and 1gm of proteinuria. Serologic workup was negative. Kidney biopsy was performed that showed focal crescentic and diffuse sclerosing glomerulonephritis consistent with IgA nephropathy with mild activity and severe chronicity. There was severe tubular atrophy and interstitial fibrosis. She was initiated on dialysis and remained dialysis dependent. As a result of her continued ketamine abuse, she was deemed to be ineligible for liver/kidney transplant.

Discussion: Ketamine is a known cause of urologic injury including decreased bladder compliance and volume, hematuria and rarely hydronephrosis and papillary injury. Our patient who was a chronic ketamine user developed progressive IgA nephropathy with crescentic and diffuse sclerosing glomerulonephritis with severe tubular atrophy, causing her to develop end stage kidney disease. This was thought to be secondary to ketamine induced cirrhosis. To the best of our knowledge, this cause of ESRD in ketamine users has not been reported. There should be a low threshold to perform kidney biopsy in ketamine misusers at the earliest onset of kidney disease. Treatment of secondary IgA nephropathy in ketamine users would include cessation of the drug and control of BP and proteinuria. Unfortunately, our patient continued to misuse ketamine and ended up with liver cirrhosis and end stage kidney disease.

TH-PO711

A Rare Clinical Entity: Anti-tubular Basement Membrane Disease

Ubaid Naeem, Vishwajeeth Pasham, Natalie T. Freidin. *Medical University of South Carolina, Charleston, SC.*

Introduction: Acute kidney injury (AKI) is well reported after developing auto antibodies against glomerular basement membrane however very little is published about anti-tubular basement membrane disease (Anti-TBM), an entirely different and rare disease entity, as a cause of AKI.

Case Description: 83-year-old male with a history of Sjogren's syndrome and monoclonal B-cell lymphocytosis was admitted with AKI with a previously normal serum Creatinine(0.9 mg/dl). Urine analysis was significant for microscopic hematuria. His serological workup was positive for ANA, SSA/SSB, MPO with indeterminate ANCA and negative for anti-GBM, IgG4 and Cryoglobulins. He had normal C3, C4 and miniscule population of B-cells on flow cytometry. Rapidly declining kidney function prompted a kidney biopsy and initiation of renal replacement therapy (RRT). His biopsy yielded a diagnosis of anti-TBM, culminating in the initiation of high dose steroids. No anti-TBM antibody levels were sent due to unavailability at our institution. Plasma exchange was also commenced but discontinued due to inconclusive evidence of lung involvement. His renal function recovered without further RRT after two weeks of prednisone 60 mg, followed by a taper to 40 mg along with initiation of Cyclophosphamide 100mg daily.

Discussion: The overall histologic findings of tubulointerstitial nephritis with strong linear proximal tubular basement membrane deposition of IgG and C3 with sparing of glomeruli was diagnostic of anti-TBM disease. Anti-TBM can be of primary or secondary origin. Secondary cases have been reported in association with membranous nephropathy, transplant rejection and urinary infections. Current literature is devoid of any guidelines to monitor disease activity with any markers or treat with any specific immunosuppressive agents. However, anecdotal evidence suggests that plasma exchange, steroids, steroid sparing Immunosuppressive agents and rituximab may have role in the management of anti -TBM. We recommend sending anti -TBM titers, if possible, to monitor the response and to tailor the therapy based on literature review.

A comparison of Anti-TBM vs Anti- GBM vs Anti - ABBA

	Anti-TBM	Anti-GBM	Anti-brush border tubular antibodies disease (ABBA)
Antigen	58-kDA Non collagenous protein	Collagen Type 4a3	LDL-receptor protein-2
Tubular Involvement	+	+	+
Glomerular Involvement	-	+	+
Target Renal Site	Basement membrane of Proximal tubule	Basement membrane of glomeruli	Brush border of tubules
Extra-Renal Involvement	-	+	+/-
IF	Strong Linear IgG/kappa/lambda staining with distal tubules sparing	Linear IgG staining of GBM with focal linear distal tubular staining	Granular staining of brush border of Proximal tubules
EM	No Deposits	Non-specific features of crescentric GN	Segmental sub-epithelial deposits

Fibrillary Glomerulonephritis Associated with Eosinophilic Esophagitis

Ana Paula Gueiros, Janielma S. Laudelino, Denise M. Costa, Italo R. Alves, Thais O. Santos. *Hospital das Clinicas, Recife, Brazil.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare glomerular disease, whose pathophysiology is relatively unclear, and is associated with neoplasms, infectious and autoimmune diseases. Discovering the DNAJ homolog subfamily B member 9 (DNAJB9) has contributed to a better understanding of the pathophysiology and diagnosis of FGN. We report a case of FGN associated with eosinophilic esophagitis (EE), with a challenging diagnosis.

Case Description: A 41-year-old woman, with progressive dysphagia, was diagnosed with EE in 2020. Despite treatment with corticosteroids, her condition worsened, requiring a gastrostomy. She developed renal dysfunction associated with nephrotic syndrome. Tests: creatinine 2.3 mg/dL; serum albumin 2.4 g/dL; proteinuria 7.6g/24h; microscopic hematuria; ANA 1/320; C3 76 mg/dL (normal: 88-165 mg/dL); Other tests were negative, including anti-DNA, anti-Sm, ANCA, serology for hepatitis B and C, HIV and syphilis. Lupus nephritis was suspected and a kidney biopsy was performed. Light microscopy (LM): 3/7 global glomerulosclerosis, 4/7 segmental glomerulosclerosis, discrete mesangial expansion with preserved cellularity and mild interstitial fibrosis and tubular atrophy (IFTA). Positive immunofluorescence (IF) for IgG, C3, kappa and lambda in mesangium and capillary loops. Electron microscopy (EM) was not performed. Treatment was initiated with methylprednisolone and cyclophosphamide. In December 2023, continuing with nephrotic syndrome and renal dysfunction, a new biopsy was performed: LM 35/45 global glomerulosclerosis, discrete, diffuse mesangial matrix expansion and cellularity, severe IFTA; positive IF for the same previous pattern; ME: diffuse thickening of the basement membrane and frequent structured deposits arranged diffusely in the subepithelial, subendothelial, intramembranous and mesangial regions. Deposits averaged 15.6 nm. Immunohistochemistry was performed and was strongly positive for DNAJB9 throughout the glomerular compartment

Discussion: Around 10%-30% of FGN are associated with autoimmune diseases. To our knowledge, this is the first report of FGN associated with EE. We emphasize the importance of EM for the correct diagnosis of glomerulopathies, including FGN. Currently, DNAJB9 is considered an excellent biomarker for FGN and probably a new gold standard for diagnosis

TH-PO713

Rare Case of Fibrillary Glomerulonephritis with Concomitant Acute Interstitial Nephritis Related to Cemiplimab Use

Paras A. Abro, Sheeraz G. Abro, Huma Fatima, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Immune checkpoint inhibitors (ICPI) can cause immune-related kidney injury. Acute tubulointerstitial nephritis (AIN) is commonly caused by ICPIs, although rarely, glomerular injury may also be seen. Fibrillary glomerulonephritis (FGN) is a rare glomerular disorder characterized by the presence of Congo red (CR) negative, non-amyloid fibrillary deposits in the glomeruli. DnaJ homolog subfamily B member 9 (DNAJB9) is a highly sensitive and specific biomarker for FGN. We describe a unique case of FGN accompanied by AIN, hypothesized to be attributable to cemiplimab use.

Case Description: A 63-year-old male with recurrent SCC of the skin treated with cemiplimab (PD-1 inhibitor) presented with non-oliguric AKI. On admission, Sr 13 mg/dL, Sr albumin 4 g/dL, UACR 52 mg/g, and UPCR 513 mg/g. Urinalysis revealed acanthocyturia and RBC casts. The patient had no underlying hypertension or diabetes. Comprehensive serological workup was negative. Kidney biopsy revealed AIN with moderate to severe acute tubular injury and 5-10% IFTA. IF: Trace to 1+ smudgy segmental mesangial staining for IgG, C3, kappa, and lambda. EM revealed mesangial matrix expansion containing segmental nonbranching, randomly arranged fibrillary deposits, ranging in size from 11-17nm in diameter. No usual immune complex deposits or fibrillary deposits were identified along the tubular basement membranes. CR staining was negative. DNAJB9 immunohistochemical staining was positive in the glomeruli. Cemiplimab was discontinued and high-dose glucocorticoids tapered over 6 weeks were given. After 9 weeks, Sr Cr was 2.5 mg/dL with a bland urinalysis.

Discussion: FGN has been associated with malignancy in approximately 9% cases. Given this association, it is recommended to screen patients with FGN for malignancy. Our patient's history of recurrent squamous cell carcinoma may have predisposed him to FGN. Additionally, treatment with cemiplimab, an ICPI, adds complexity due to its potential for drug-induced AIN. While ICPIs are known to cause widespread organ inflammation, isolated AIN are rare, but have been reported. This case underscores the complexity of diagnosing and managing FGN, particularly when present concomitantly with AIN potentially induced by cemiplimab. It also highlights the importance of personalized treatment strategies in managing complex clinical scenarios.

TH-PO714

Rituximab Responsive Relapsing Fibrillary Glomerulonephritis

Sheeraz G. Abro, Paras A. Abro, Huma Fatima, Arun Rajasekaran. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Fibrillary glomerulonephritis (FGN) is seen in 1% of kidney biopsies and is characterized by glomerular deposition of infiltrative fibrils larger than amyloid composed of polytypic IgG lacking Congo red (CR) reactivity. DnaJ homolog subfamily B member 9 (DNAJB9) also known as endoplasmic reticulum-localized DnaJ 4 was discovered is a highly sensitive and specific biomarker. Upto 50% progress to ESKD within a few years of biopsy but the disease course remains highly variable as some patients with sub-nephrotic proteinuria and well-preserved kidney function can have more of a chronic, smoldering course over time.

Case Description: 63-year-old female with past medical history significant for arterial hypertension, morbid obesity, & prediabetes presented with microscopic hematuria & proteinuria. Cr 1.5 mg/dL, eGFR 39 mL/min, Sr albumin 4 g/dl, UPCR 8962 mg/g. Urine microscopy: acanthocyturia & RBC casts. Comprehensive serological workup negative. Kidney biopsy - LM: Moderately expanded mesangium with mild hypercellularity. Capillary basement membranes showed focal & segmental splitting due to the extension of similar material along the capillary loops; 5% IFTA. IF: 2+ smudgy, predominantly mesangial and rare capillary loop staining for IgG, C3 [1-2+], kappa = lambda = 2-3+. EM: Moderately increased mesangial matrix with segmental nodularity, containing randomly arranged, nonbranching, fibrillary deposits, 9-18 nm in diameter. No immune complex deposits or punctate amorphous deposits were identified. CR stain was negative. DNAJB9 IHC stain positive in glomeruli. Patient received 2 courses of Rituximab [each course with 2 doses of 1g spread 14 days apart]. During last follow up, Sr Cr and albumin were normal with UPCR having reduced to 2638 mg/dL. Further Rituximab administration is being based on B-cell reconstitution.

Discussion: There is no standard-of-care treatment for FGN. Rituximab may be the most promising treatment for progressive FGN. In the first prospective clinical trial of rituximab in 11 patients with FGN, investigators observed no significant change in the

eGFR at 12 months. At 1 year, there was an overall ~50% reduction in proteinuria; 3 patients experienced a partial response. Neither treatment nor disease remission status affected DNAJB9 serum levels. Our case highlights the utility of considering use of repeated doses of Rituximab for a select subset of FGN patients.

TH-PO715

Fibrillary Glomerulonephritis with Concurrent Anti-glomerular Basement Membrane Leading to Rapidly Progressive Glomerulonephritis: A Diagnostic Conundrum

Abraham Bell,[1] Gautam Maddineni,[1] Stefan Milutinovic,[1] Isaac Bell,[2] Ibrahim Khambati.[1] [1]*Florida State University, Tallahassee, FL;* [2]*Nova Southeastern University, Fort Lauderdale, FL.*

Introduction: Anti–glomerular basement membrane (anti-GBM) disease is a rare small vessel vasculitis that affects the capillary beds of the kidneys and lungs. It is a well-known significant cause of rapidly progressive glomerulonephritis (RPGN). Conversely, fibrillary glomerulonephritis (FGN) typically presents proteinuria, hematuria and more gradual decline in renal function as compared to a rapid one. Herein, we report a case of anti-GBM disease with finding of FGN on renal biopsy; a rare presentation of both entities existing concurrently.

Case Description: 57-year-old male with a previous medical history significant for hypertension, hyperlipidemia, recently diagnosed CKD stage 3A with previous reported Creatinine of 1.54 a month before admission who presented with complaints of dyspnea, worsening fatigue, sleepiness, and approximately 20-pound weight gain along with decreased urine output. After initial evaluation, the patient was noted to have acute renal failure, evidenced by a creatinine of 13.08 and a BUN of 109. Chest X-ray did not reveal any acute cardiopulmonary findings. The patient subsequently underwent renal biopsy, which revealed glomeruli demonstrating necrosis or cellular/fibrocellular crescent formation. In addition, many glomeruli demonstrated Bowman's capsule disruption and extensive glomerular deposition of DNA JB 9 positive fibrils. As well as having positive anti-GBM antibodies. The patient received treatment with IV Solu-Medrol, which was then transitioned to oral Prednisone 80 mg in conjunction with oral Cyclophosphamide 100 mg. Furthermore, the patient underwent five sessions of plasmapheresis and required initiation on Hemodialysis in the hospital with plans to continue treatment after discharge.

Discussion: Standard of care treatment of anti-GBM disease usually involves the use of prednisone and cyclophosphamide in conjunction with plasmapheresis however, renal prognosis is poor with patient usually requiring initiation of hemodialysis. Similar treatment modalities are used to treat FGN with the clinical presentation of RPGN however, this is largely anectodal with similar renal outcomes. Our case highlights the rare coexistence of these two GNs and the importance of renal biopsy to aid in diagnostic/therapeutic intervention.

TH-PO716

Fibrillary Glomerulonephritis: A Rare Glomerulonephritis with No Definitive Treatment

Htun H. Naing, Daniele Rios Leite. *University of Florida, Gainesville, FL.*

Introduction: Fibrillary glomerulonephritis (FGN) is an uncommon disorder, present in 0.5-1.4% of kidney biopsies. It is mostly seen in Caucasians of 50-60 years of age. It was initially thought to be idiopathic; however, an association with autoimmune disease, malignancy, and HCV infection has been proposed based on recent studies. It typically presents with hematuria, proteinuria, renal function impairment, HTN, and monoclonal gammopathy. For the diagnosis it is required the demonstration of randomly oriented, straight, non-branching, fibrillary deposits with a mean diameter of 20 nm in the mesangium and glomerular capillary walls without microtubule formation and Congo red stain negative. The specific biomarker DNAJB9 can be detected through immunohistochemical stain.

Case Description: A 65-year-old man with medical history significant for lymphoma, tonsillar cancer, prostate cancer, treated HCV, and alcohol use disorder was admitted to the ICU due to alcohol intoxication and pneumonia. He was found to have AKI with microscopic hematuria. His renal function had some improvement initially, with gradual worsening posteriorly, and persistent microscopic hematuria with grade A3 microalbuminuria. He tested negative for ANA, MPO, PR3, anti-GBM, Syphilis, HIV, hepatitis B; C3 and C4 levels were normal. The renal pathology results showed moderate IFTA of 40%, mesangial IgM-dominant immune complex deposition, positive staining for DNAJB9, negative Congo red staining, and haphazardly arranged fibrils within mesangial regions, focally infiltrating the entire width of the GBM, with texture suggestive of fibrillary glomerulonephritis, which was more prominent than the IgM deposition. These results were consistent with FGN. He was found to have a biclonal IgG spike on SPEP, which did not correlate with the findings of IgM deposition. Bone marrow biopsy was normocellular. Cryoglobulin screening was positive. The patient was started on prednisone and ACE-i. His renal function improved but did not return to baseline.

Discussion: Currently, there are no definite treatment guidelines for FGN, and the efficacy of antiproteinuric therapy is unclear. The majority of patients still progress to ESKD, being 40-50% of cases within 2-6 years. Due to the rarity of this condition, further research isneeded for better understanding of the disease process and improvement of treatment outcomes.

TH-PO717

Case of Crescentic Fibrillary Glomerulonephritis with Linear IgG Mimicking Anti-glomerular Basement Membrane Nephritis with Good Response to Treatment

Gedaliah May, Andrew Chandler, Andrew A. Moses, Jordan L. Rosenstock. *Lenox Hill Hospital, New York, NY.*

Introduction: Fibrillary glomerulonephritis (FGN) is an uncommon glomerular disease whose diagnosis depends on electron microscopy (EM) showing fibrillary immune deposits and immunohistochemistry (IH) with DNAJB9 deposits in glomeruli. Light microscopy of FGN can have variable histological patterns, and can rarely present with diffuse crescentic disease which has a very poor prognosis. The deposits on immunofluorescence (IF) are typically described as "smudgy" but can sometimes be pseudo-linear mimicking anti GBM disease. Here we describe a patient with FGN mimicking anti- GBM disease who had a good response to immunosuppressive therapy.

Case Description: The patient is a 31-year-old female with obesity who presented with three weeks of foamy urine, fatigue, and poor appetite. On presentation serum creatinine was 3.0 mg/dL (was 0.5 mg/dl three months prior). Urinalysis showed hematuria and proteinuria and a urine protein/creatinine ratio was 17.3. A kidney biopsy showed diffusely crescentic proliferative glomerulonephritis with fibrinoid necrosis on light microscopy and IF was reported as linear IgG along the glomerular capillaries suspicious for anti-GBM disease. Anti- GBM antibody was negative and the diagnosis of atypical anti- GBM disease was considered. Subsequently, EM revealed diffuse organized fibrillary deposits and later IH showed DNAJB9 positivity in glomeruli. The patient was treated with steroids and intravenous cyclophosphamide. Her creatinine was 1.0 at 6 months follow-up.

Discussion: This case touches on clinical challenges related to crescentic FGN. There can be a challenge in distinguishing crescentic FGN and anti-GBM disease if EM and IH are not immediately available. In our case, atypical anti-GBM disease was considered when her anti-GBM antibody was negative, though this is usually a more indolent disease than typical anti-GBM with either no or only focal crescents. Once a diagnosis was established by EM and IH the optimal treatment regimen remained unclear as there is no clear therapy for crescentic FGN and it has been observed that the prognosis of diffusely crescentic FGN is very poor despite immunosuppression. However, this patient responded well to a course of steroids and cyclophosphamide with a significantly improved creatinine.

TH-PO718

A Cat and a "Full House"

Neha B. Patel, Alana Dasgupta, Isabelle Ayoub, Madeline S. Chung. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: In a patient with constitutional symptoms, positive ANA serologies, and hypocomplementemia, immune complex glomerulonephritis (GN) often suggests lupus nephritis. However, Bartonella endocarditis can mimic this presentation. We detail the case of a 34-year-old man with history of pulmonary valve replacement and cat bite with acute kidney injury (AKI) due to Bartonella endocarditis-related GN.

Case Description: The patient initially presented with upper respiratory symptoms, diarrhea, and AKI, attributed to hypovolemia and NSAID use. AKI worsened despite resolution of symptoms. Further workup revealed elevated rheumatoid factor, positive Epstein-Barr Virus (EBV) IgM, normal complement levels, and negative infectious workup. Kidney biopsy was consistent with IgA nephropathy. Post-discharge, he developed a pruritic rash, assumed to be IgA vasculitis. Twelve days later, he returned with a new pulmonic regurgitation murmur, weight loss, nocturnal fevers, and heart failure symptoms. Both transthoracic and transesophageal echocardiograms were negative for vegetations, but Bartonella IgG titers were elevated. Glucocorticoids resolved symptoms and AKI temporarily, but they recurred post-tapering, prompting transfer to our institution. Repeat serologies showed positive ANCA, low C3 and C4, and high Bartonella titers. Repeat kidney biopsy revealed mesangioproliferative GN with full-house immune complex deposition in the mesangium and also in the subendothelial, subepithelial and intramembranous spaces. Bartonella DNA was detected, leading to hospital readmission for bacteremia and pulmonic valve vegetation. He was treated with antibiotics leading to and then following valve replacement.

Discussion: The differential diagnosis for immune complex glomerulonephritis includes autoimmune disease, malignancy and infection which may often be missed at the time of acute infection due to mild symptoms and a negative infectious workup due to a fastidious and/or slow-growing microbe. Bartonella is most often diagnosed in the later stages of infection with elevated IgG titers rather than IgM and PCR as it is a facultative intracellular bacterium, rarely isolated in culture and only fleetingly found in the blood. When the kidney biopsy shows an immune complex glomerulonephritis, always consider smoldering infections, especially if the patient is immunocompromised or has a history of cardiac valve surgery.

TH-PO719

Diagnosis of Alport Syndrome Requires One More Step after Kidney Biopsy

Dhairya Salvi,[1,2] Pedro A. Pineiro De Jesus.[1,2] *[1]Ascension Providence Rochester Hospital, Rochester, MI; [2]Wayne State University, Detroit, MI.*

Introduction: Alport syndrome is an inherited disorder heterogeneously affecting the basement membrane of the kidney, eyes, and inner ear. It is a diagnostic challenge as symptoms are non-specific, with hematuria being the only evident sign in many cases. The age at presentation and genetic modes of transmission also show significant variation. A kidney biopsy may show non-specific findings making further diagnostic tests necessary.

Case Description: We present a case of a 66-year-old female with a history of long-standing hypertension and WHO class II obesity who was referred to our clinic for CKD stage G2A3 with a baseline creatinine of 0.9 mg/dL. She had microscopic hematuria with 5-9 RBCs on urinalysis and subnephrotic proteinuria with urine protein creatinine ratio of 1.8 g/g. Serological workup for glomerulonephritis was negative. Decision was taken to investigate further with a kidney biopsy which showed epithelial foot process effacement, moderate arteriosclerosis, and glomerulomegaly. thin glomerular basement membrane without any lamellation; Immunofluorescence was negative for antibody or complement deposition. An Alport immunofluorescence showed a normal uninterrupted staining for alpha 5 chain of collagen type IV. Given a family history of CKD, there was still some suspicion of a hereditary disorder. Genetic testing revealed COL4A4 variant suggestive of autosomal dominant Alport syndrome.

Discussion: This patient had hematuria, subnephrotic proteinuria, and CKD which can be attributed to a combination of thin basement membrane nephropathy and hypertensive arteriosclerosis, which was evident on kidney biopsy. The patient did not have eye or ear involvement seen in Alport syndrome. Furthermore, the kidney biopsy did not show any lamellation or splitting of glomerular basement membrane. Despite this, the patient was found to have Alport syndrome based on genetic analysis. This case demonstrates the importance of genetic testing for Alport syndrome despite non-specific findings on kidney biopsy in case of hematuria, progressive kidney disease, and a positive family history.

TH-PO720

Factor B: The "It" Factor in Infection-Related Glomerulonephritis

Jennifer L. Grigsby,[1] Eric Magliulo,[1] David A. Mcmillan,[1] Kirk W. Foster,[2] Prasanth Ravipati.[1] *[1]University of Nebraska Medical Center Department of Internal Medicine, Omaha, NE; [2]University of Nebraska Medical Center Department of Pathology and Microbiology, Omaha, NE.*

Introduction: Infection-Related Glomerulonephritis (IRGN) and C3 Glomerulopathy (C3G) demonstrate considerable clinicopathologic overlap, presenting a diagnostic challenge to clinicians and making selection of an appropriate treatment regimen difficult. We present a case of IRGN which highlights this diagnostic conundrum.

Case Description: A 43-year-old man presented with volume overload, acute kidney injury, 2 grams of proteinuria, and hypocomplementemia without a history or clinical signs of recent infection. Kidney biopsy demonstrated proliferative glomerulonephritis with immune complex deposition with co-dominant staining of C3 and IgG by immunofluorescence. These findings appeared most consistent with a diagnosis of IRGN; however, with primarily subendothelial and mesangial deposits on electron microscopy, lack of infectious history, and a family history notable for chronic kidney disease in multiple relatives, there was concern for familial hypocomplementemia or C3G. His renal function continued to worsen, requiring intermittent hemodialysis and initiation of empiric pulse solumedrol followed by daily prednisone and mycophenolate mofetil. After being discharged, autoantibody testing returned positive for Factor B autoantibodies. Genetic testing otherwise was negative. Given the previously described strong association of Factor B autoantibodies and IRGN, immune suppression was discontinued. Ten weeks after his initial presentation, repeat labs demonstrated resolution of his hypocomplementemia, near resolution of his proteinuria, and return of serum creatinine to normal (0.9 mg/dL).

Discussion: This patient was ultimately diagnosed with IRGN; however, features of his presentation raised concern for C3G. Factor B autoantibodies have been shown to contribute to transient dysregulation of the alternative complement pathway and have been found in a significantly higher proportion of patients with IRGN compared to C3G. This case highlights the utility of diagnostic complement testing, as the positive Factor B autoantibody helped inform the decision to discontinue immune suppression and limit potential related toxicities. Improvement in timeliness and availability of complement testing is needed to aid clinicians faced with diagnostic uncertainty in the realm of C3G.

TH-PO721

Kidney Involvement in Cryoglobulinemia: Not Always Crystal Clear

Raja S. Boddepalli,[1] Vishnupriya Alavala,[1] Lynn D. Cornell,[2] Jason M. Kidd.[1] Virginia Commonwealth University. *[1]Virginia Commonwealth University, Richmond, VA; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Introduction: Cryocrystalglobulinemia (CCG) is a rare variant of type 1 cryoglobulinemia. Renal involvement is rare and associated with plasma cell dyscrasias. In CCG, monoclonal immunoglobulins assemble into crystalline arrays inciting inflammation and causing vasculopathy from pseudo thrombi in renal glomerular capillaries. We present a case of CCG due to monotypic IgG deposits with negative immunofixation (IFE).

Case Description: A 67-year-old male was referred for edema and proteinuria. On presentation, blood pressure was 136/87 mmHg and physical exam was significant for lower extremity edema. Laboratory studies revealed a creatinine of 2.5 mg/dl with no antecedent history of renal failure and spot urine protein to creatinine ratio (UPCR) was 2.5 g/g. Serum and urine IFE were negative. Kidney biopsy showed endocapillary proliferative macrophage-rich glomerulonephritis with intracapillary pseudo-thrombi, intracellular crystals, and monotypic IgG2 Kappa deposits. On electron microscopy, crystals were noted within infiltrating macrophages in glomerular capillary lumens consistent with CCG. (Figure 1) Bone marrow biopsy was unremarkable. He was treated with cyclophosphamide, bortezomib and dexamethasone. Proteinuria persisted and daratunamab was added and serum creatinine improved to 1.8 mg/dl and proteinuria completely resolved 8 months after his initial presentation

Discussion: Our case describes a rare variant of monoclonal gammopathy with renal significance (MGRS) without a detectable circulating monoclonal protein that responded to clone-directed therapy. Kidney biopsy should be pursued in patients with renal insufficiency and proteinuria without abnormal serologies.

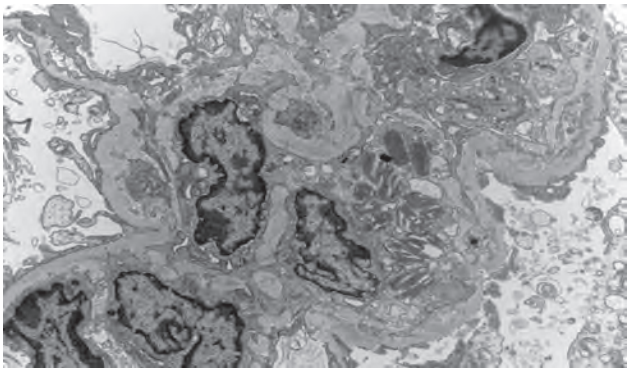

Figure 1: Crystals noted within infiltrating macrophages in glomerular capillary lumens.

TH-PO722

A Periodic Curveball: Collagenofibrotic Glomerulopathy

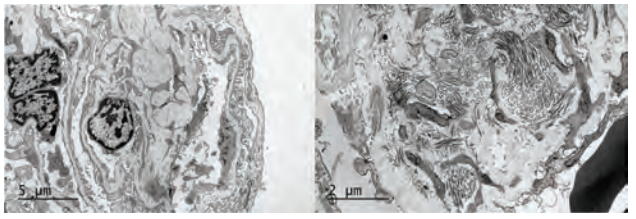
Sydney E. Hartsell, Monica P. Revelo Penafiel, Sarah Gilligan, Gurbir S. Sehmbey, Nirupama Ramkumar. *The University of Utah School of Medicine, Salt Lake City, UT.*

Introduction: Collagenofibrotic Glomerulopathy is a rare idiopathic disease with unknown pathogenesis and no treatment.

Case Description: A 65-year-old man with hypertension and tobacco use disorder was hospitalized after 5 months of fevers, rigors, weight loss, malaise and one week of heavy acetaminophen and ibuprofen use. He was treated for acetaminophen toxicity and received extensive infectious and hematologic workup, which revealed multiple hypermetabolic lymph nodes on PET CT with necrotizing lymphadenitis on biopsy and prostatomegaly with intermittent bleeding on cystoscopy. Nephrology was consulted for microscopic hematuria, spot urine protein:creatinine ratio 524 mg/g, and 117 mg/g albuminuria. Creatinine was 0.9 mg/dL with estimated glomerular filtration rate 90 ml/min/1.73m^2. Serologic workup was negative aside from antinuclear antibody titer of 1:80. Urine microscopy showed acanthocytes. Subsequent renal biopsy showed mesangial and subendothelial deposits of curved fibrils with frayed edges and transverse banding at 60 nm periodicity, consistent with collagenofibrotic glomerulopathy (Figure). Two years later, renal function remains preserved with mild proteinuria and microscopic hematuria. The etiology of his B-symptoms remains unconfirmed. He has been treated with valsartan and dapagliflozin. Rheumatology initiated methotrexate for suspected systemic autoimmune inflammatory syndrome. A recent repeat bone marrow biopsy revealed chronic monomyelocytic leukemia stage 0.

Discussion: Collagenofibrotic glomerulopathy is identified by atypical type III collagen deposition in the mesangium and subendothelium. Limited case reports note hypertension, mild proteinuria, microscopic hematuria and typically preserved renal

function, consistent with this case. Interestingly, this mysterious disease was found amid a mysterious constellation of symptoms. It is classically not linked with extrarenal symptoms at diagnosis, but re-evaluation of known cases should be considered for later development of hematologic or rheumatologic disease.



Electron Microscopy

TH-PO723

An Unusual Presentation of Poststreptococcal Glomerulonephritis (PSGN) in a Patient with Alcoholic Liver Cirrhosis

Aseel Zghayer, Maria M. Picken, David J. Leehey. *Loyola University Chicago Stritch School of Medicine, Chicago, IL.*

Introduction: Post-infectious glomerulonephritis (PIGN) is commonly triggered by streptococcal skin or throat infections and is well-recognized to manifest in childhood. A characteristic feature of PIGN is the activation of the alternate complement pathway, leading to complement overactivation. The typical immunofluorescence pattern seen in PIGN is IgG and C3 deposition. Here, we present an unusual presentation of PIGN in a patient with liver cirrhosis following a recent streptococcal infection.

Case Description: A 54-year-old man, recently diagnosed with alcoholic liver cirrhosis, presented with abdominal pain attributed to an umbilical hernia. He developed oliguric acute kidney injury (AKI) necessitating hemodialysis. During further evaluation, the patient disclosed a history of sore throat, headache, and fever 2 weeks prior to admission. The workup is detailed in Table 1. Kidney biopsy demonstrated PIGN with prominent IgA as well as IgG deposition (Figure 1). After the biopsy, serology for anti-DNAse B was strongly positive, confirming a diagnosis of PSGN. Four weeks later, the C3 level had increased from < 15 to 56 mg/dL, and the patient is off dialysis with a serum creatinine of 2.0 mg/dL.

Discussion: Our patient's very low C3 and normal C4 levels make it highly unlikely that hypocomplementemia was due to a synthetic defect from hepatic cirrhosis. Given that patients with alcoholic liver disease are known to be at increased risk of PIGN, we hypothesize the possibility that our patient had an acute PSGN superimposed on a pre-existing IgA hepatic glomerulopathy. This case underscores the theory that patients with liver cirrhosis may have an impaired ability to clear immune complexes during bacterial infections.

Lab (reference range)	Patient values	Lab (reference range)	Patient values

Oligomeganephronia in a 29-Year-Old Pregnant Woman

Nada Youssef, Prerna Rastogi, Abdullah Thayyil. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Oligomeganephronia (OMN) is a congenital anomaly characterized by reduced nephron number, glomerulomegaly and tubulomegaly. It is a pediatric disease, while late-onset OMN is very rare. We present a case of adult onset OMN at our institute with kidney disease during pregnancy.

Case Description: A 29-year-old female with unexplained stage IV chronic kidney disease (CKD) was referred to us for kidney biopsy. Her clinical history dates to 2019, during a pregnancy, when she was noted to have a creatinine of 1.9 with sub-nephrotic proteinuria. Workup done including complement levels, anti-nuclear and anti-neutrophil cytoplasmic antibodies, myeloperoxidase and proteinase-3 antibody were negative. On physical exam, she had height 64", weight 174 lbs, BMI 29.87 kg/m^2, blood pressure 116/78 mmHg. Cardiac and pulmonary auscultation were normal. She had no edema. She was started on angiotensin receptor blocker. Her kidney function gradually worsened and a kidney biopsy was done in February 2023 showing moderate chronicity with no evidence of an immune complex-mediated process. Supportive measures were continued. As kidney function continued to decline 1 year later, repeat biopsy was done in March 2024 showing findings consistent with histological diagnosis of OMN (images below).

Discussion: OMN is a congenital anomaly characterized by reduced nephron number due to arrested development of metanephric blastema at 14-20-week gestation. Patients are usually born with low birth weight. Early-onset type present at a young age with polyuria, polydipsia, or proteinuria and usually progress to ESRD early in life. Late-onset type is rare; and usually present as asymptomatic proteinuria. Disease pathophysiology is unclear. OMN does not cause any phenotypic characteristics, thus, renal biopsy is crucial for diagnosis. Histologically, OMN is characterized by a reduced number of glomeruli, glomerulomegaly, and tubulomegaly. Over time, histologic changes of fibrosis will be seen. There is no effective treatment for OMN at present. The focus is on supportive measures to reduce glomerular hyperfiltration and delay disease progression.

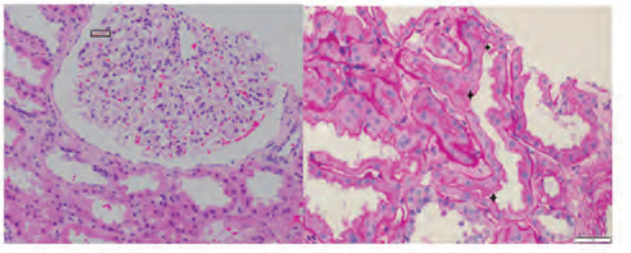

Figure 1 (Left panel): H+E-stained image of the glomerulus. Measurement 315.30 µm. (Right panel): PAS-stained image of a tubule with multiple branch points (Black asterisk). The brush borders are intact and there is no cell exfoliation into the lumen.

Cryoglobulinemic Glomerulonephritis Masquerading as IgA Nephropathy in a Patient with Crohn Disease

Saad A. Alshihri, Gabriel B. Lerner, Adrian Llama, William S. Asch. *Yale University School of Medicine, New Haven, CT.*

Introduction: We report a case of a patient with long standing history of Crohn's presenting with anemia, acute renal failure requiring initiation of dialysis and lower extremity painful rash. Renal biopsy initially suggested IgA nephropathy given history of Crohn's and codominant IgA and IgM, but EM features and serological markers made cryoglobulinemic GN a favorable diagnosis. In this case, we address the diagnostic complexity we came across.

Case Description: This is a 48-year-old Caucasian female who was admitted with anemia, acute kidney injury, and purpuric rash of the lower extremities. Urinalysis revealed red blood cells and nephrotic range proteinuria. Urine sediment showed RBC casts. Renal function rapidly deteriorated requiring initiation of dialysis. Physical exam revealed painful LE purpuric rash, levido reticularis and dorsal foot ulcers. Imaging showed ground glass opacities. Given the rapid decline in renal function and findings suggestive of systemic vasculitis, a renal biopsy was expedited. Biopsy showed focal necrotizing and crescentic glomerulonephritis on LM, IF staining with +1 IgA, IgM and +2 C3 staining. However, there were rare subendothelial and mesangial electron dense deposits with curvilinear substructure on EM suggesting cryoglobulinemic GN. Serological markers came back positive for rheumatoid, borderline low C3 with normal C4 and serum cryoglobulin was positive, with immunofixation showing type 2 mixed cryoglobulins. Broad work up was done to identify an infectious or lymphoproliferative etiology of cryogenesis revealing a positive respiratory culture growing Klebsiella pneumonia on BAL, and pleural nodule biopsy showed organizing pneumonia. The patient was promptly started on pulse steroids, IVIG and PLEX with improvement in skin rash. She continued to require dialysis on discharge, and Rituximab was deferred to the outpatient setting due to active infection.

Discussion: Cryoglobulinemic glomerulonephritis (GN) is a disorder characterized by the deposition of cryoglobulins. Cryoglobulinemic and IgA vasculitis can have multiple similarities in clinical and pathological features. In this case we encountered multiple overlapping clinical and histological findings, but ultimate diagnosis was favorable for cryoglobulinemic vasculitis. The positive rheumatoid and EM findings helped in making the distinction.

TH-PO726

The Cat Scratch That Leaves a Renal Mark: A Bartonella-Associated Glomerulonephritis

David A. Mcmillan, Prasanth Ravipati, Kirk W. Foster, Nathaniel Leonardi, Kathleen Borghoff, Nicolas Cortes-Penfield, Ketki K. Tendulkar.
University of Nebraska Medical Center, Omaha, NE.

Introduction: Chronic infections such as infective endocarditis (IE) and infected implanted devices are known causes of glomerulonephritis (GN). *Bartonella* spp are a leading cause of blood culture-negative IE (BCNE). Due to this a high clinical suspicion is required to make the diagnosis. We present a case of *Bartonella* aortic graft infection related GN.

Case Description: A 63-year-old man with a history of type A aortic dissection with graft repair, was undergoing treatment with cyclophosphamide, bortezomib, and dexamethasone for monoclonal gammopathy of renal significance induced C3 GN. After three months of therapy the patient developed sudden onset shortness of breath. A CT scan showed pseudoaneurysm at the suture line of his previous graft site. Subsequent PET CT scan was concerning for infection corresponding to the small pseudoaneurysm, but blood cultures were negative. TEE showed no vegetations on this prosthetic aortic valve. *Bartonella henselae* serology was positive with IgG >1:1024. His immunosuppression was discontinued and he was initiated on doxycycline 100mg BID and rifampin 300mg BID. Rifampin was discontinued due to poor tolerance. He developed shoulder pain and imaging showed increased size of pseudoaneurysm and surrounding hematoma needing immediate repair. During recovery, he had worsening renal function with creatinine rise from 1.2 mg/dL to 1.7 mg/dL; urine protein to creatinine (PCR) level was elevated at 1.2 mg/mg, and he had microscopic hematuria (>50 RBC/HPF). He underwent kidney biopsy which showed co-dominance of IgM, C3, and C1q with kappa staining. This led to diagnosis of *Bartonella* associated GN and he was initiated on rifabutin along with doxycycline, leading to reduction of PCR to 0.3 mg/mg and Cr to 1.37 mg/dL.

Discussion: *Bartonella* IE and infected implanted devices, as seen in this case, may result in an infection related GN. *Bartonella* IE has been suggested to have clinicopathological differences from IE caused by other bacteria. This includes a higher frequency of crescents along with full-house staining patterns especially IgM and C1q. When diagnosis is uncertain following biopsy physicians should consider obtaining a targeted history of animal exposure and serological workup for *Bartonella* spp. especially in patients with a history of implanted devices or BCNE.

TH-PO727

Cognitive Bias in the Diagnosis of Acute Nephritis: A Case of Complementary Details

Sarah Rokaw,[1] Benjamin A. Wagner,[1] Kavita Mistry,[1] Seymour Rosen,[1] Kambiz Zandi-Nejad,[1] Sylvia E. Rosas,[2,1] Stewart H. Lecker.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Joslin Diabetes Center, Boston, MA.*

Introduction: The etiologies of acute nephritis are characterized by complement levels and systemic versus renal-limited diseases. Both pauci-immune glomerulonephritis (GN) and anti-GBM disease have normal complements and systemic involvement, while lupus nephritis is classically associated with low complements. Nonetheless, studies demonstrating diagnostic sensitivity of complement levels are small and variable.

Case Description: A 33-year-old woman with asthma and prior tobacco use presented with subacute hemoptysis and was found to have acute hypoxic respiratory failure and anemia. Prior to admission, her respiratory symptoms had initially improved with steroids and antibiotics. On presentation, vital signs were remarkable for hypertension and new hypoxia requiring high flow nasal cannula. Physical exam revealed bibasilar rales and 2+ lower extremity edema. Creatinine was at baseline of 0.8 mg/dL with albumin of 3.4 g/dL. Hemolysis labs were positive. Urinalysis revealed 3+ blood and 4+ protein quantified at 3.3 g/g, and sediment demonstrated innumerous RBC casts, WBC casts, and acanthocytes. Bronchoscopy revealed diffuse alveolar hemorrhage. ANA was positive at 1:320 in nuclear homogenous pattern with negative dsDNA and anti-Sm. C3 was slightly low at 83 mg/dL, and C4 was normal. Pulse-dose steroids were initiated, and she received three sessions of plasmapheresis for presumed pauci-immune GN or anti-GBM disease. Additional workup then returned as follows: positive p-ANCA 1:320 with negative MPO and PR3, positive SS-A, negative HIV and hepatitis B/C, negative lupus anticoagulant, and negative antibodies for GBM, anti-PLA2R IgG, cardiolipin, beta-2-glycoprotein, RNP and SS-B. Renal biopsy was delayed for one week due to antecedent NSAID use, though ultimately revealed endocapillary proliferative GN with limited crescent formation and very focal necrosis and immunofluorescence consistent with lupus nephritis.

Discussion: The mildly low C3 was an important diagnostic clue - overlooked due to data mismatch with diagnostic schema. However, the patient met criteria for SLE, which includes a score for low C3 or C4. This case illustrates that a simplified framework of classifying GN must be contextualized both with the sensitivity of available tests and the clinical picture to avoid cognitive bias and diagnostic inaccuracy.

TH-PO728

Does Race Impact Outcomes in Kidney Transplant Recipients with Obesity? A Mate Kidney Analysis

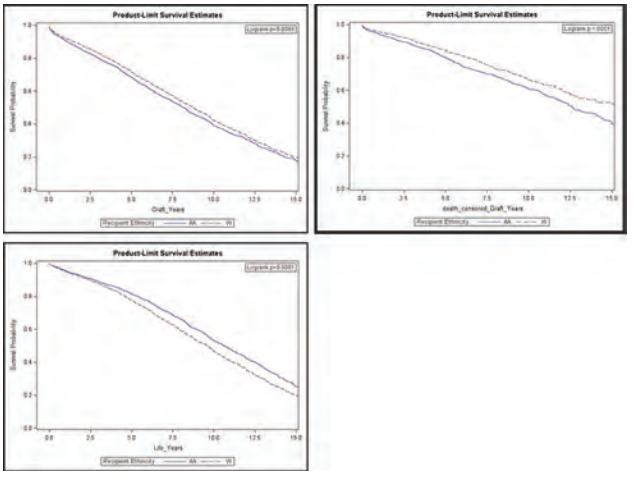
Kalathil K. Sureshkumar,[1] Reem Daloul,[1] Bhavna Chopra,[3] Rita L. McGill.[2] *[1]Allegheny Health Network, Pittsburgh, PA; [2]University of Chicago Pritzker School of Medicine, Chicago, IL; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Epidemiological studies have shown favorable impacts of both high body mass index (BMI) and African American (AA) race on the outcomes in patients on long-term dialysis. A mate-kidney model was used to examine the differential impact of recipient race on the outcomes of obese kidney transplant recipients (KTRs).

Methods: Using OPTN/UNOS database from 2000 to 2023, we identified deceased donors with two adult first-time KTRs who were discordant for recipient race. AA recipients were compared to white recipients for outcomes including transplant hospital length of stay (LOS), delayed graft function (DGF; dialysis in the first post-transplant week), overall graft failure (GF), death-censored GF and patient death. Findings were evaluated with Kaplan-Meier survival plots and McNemar tests.

Results: During the study period, there were 6052 obese recipients who received mate-kidneys from 3026 donors in which one recipient was AA and the other was white. Median hospital LOS did not differ by race. The incidence of DGF was higher in AA KTRs (57.6% vs. 42.5%, p<0.001). Kaplan-Meier analysis showed increased GF and death-censored GF in AA compared to white KTRs but AA recipients had lower patient deaths (figure).

Conclusions: Despite increased risk for DGF and inferior graft outcomes, obese AA recipients had enhanced patient survival compared to their white counterparts. Further work is warranted to investigate the factors that affect the interaction of race and obesity on graft and patient survival.



TH-PO729

Kidney Allograft Nephrectomy Is Associated with Lower Mortality and Improved Repeat Kidney Transplant Rates

Steven Achinger,[1,2] Juan Carlos Ayus,[3] Ambuj Kumar,[1] Athanasios Tsalatsanis.[1] *[1]University of South Florida Morsani College of Medicine, Tampa, FL; [2]Watson Clinic LLP, Lakeland, FL; [3]University of California Irvine, Irvine, CA.*

Background: It has been shown that surgical removal of failed allografts leads to both reduced inflammatory markers and improved patient survival. However, the potential impact of allograft nephrectomy on repeat transplantation is unknown.

Methods: We performed a retrospective cohort study using USRDS data where adult patients with Medicare coverage returning to dialysis after failed kidney transplant between January 1, 1995, and December 31, 2018 were eligible. The index event for the analysis in the comparison group was the date of failure of the first renal allograft. The index event for the analysis in the nephrectomy group was the date of nephrectomy. The primary outcome was time to second transplant. We extracted data on demographics, insurance status and Charlson comorbidity index (using 3 years of hospital claims preceding index event). All analyses were performed using R 4.0.3 package.

Results: Overall, 48,094 patients met the inclusion criteria and 10,117 patients had an allograft nephrectomy. After propensity score matching, 10,117 patients each remained in

the nephrectomy and comparison cohorts **(Table 1)**. Patients in the nephrectomy cohort were more likely to receive a second transplant than patients in the comparison group (HR 1.13; 95% CI:1.07, 1.20; p<0.001) **(Figure 1)**. At 2, 5 and 10 years follow-up, the nephrectomy group had a reduced likelihood of death and a higher likelihood of being alive and having a functional kidney allograft than the comparison group.

Conclusions: Allograft nephrectomy is associated with higher likelihood of repeat kidney transplantation and long term survival with a functioning kidney allograft compared with propensity score matched patients without allograft nephrectomy.

Long-Term Outcomes of BK Viremia in Kidney Transplant Recipients

Sneha Chandrashekar, Srijan Tandukar, Divyash V. Shah, Roy D. Bloom.
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

Background: BK viremia (BKV) occurs in 10-30% of kidney transplant (KT) recipients. It has not been shown to adversely impact short and intermediate term graft and patient outcomes, but long term impact is unknown.

Methods: We included KT alone recipients between 2008 and 2013 without prior history of KT and those who were alive with a functioning graft beyond 90 days of KT. We split the cohort into BK never positive, transient BKV (<140 days) and persistent BKV (≥140 days). Outcomes were graft and patient survival, kidney function, de novo DSA and acute rejection over 10 years of follow up. Survival analysis was performed using Kaplan Meier (KM) analysis.

Results: Among 762 patients, there were 596, 68 and 98 patients in BK never positive, transient BKV and persistent BKV groups respectively. There was no difference in GFR at 10 years (p=0.29), acute rejection (p=0.15) and de novo class I DSA development (p=0.75). De novo class II DSA developed more often in persistent BKV group (p=0.03). On KM analysis, there was no difference in graft (p=0.6) and patient survival (p=0.86).

Conclusions: BKV does not impact long-term outcomes in KT recipients although there is a higher risk of de novo class II DSA development.

Category	BK never positive (N=596)	Transient BK viremia (N=68)	Persistent BK viremia (N=98)	p value

Variation in Quality of Life in Frail, Older Transplant Recipients: Mixed-Methods Results from the Kidney Transplantation in Older People (KTOP) Study

Amarpreet K. Thind,[1,2] Lina Johansson,[2] Michelle Willicombe,[1,2] Edwina A. Brown.[2,1] Kidney Transplantation in Older People Study Investigator Group.
[1]Imperial College London Faculty of Medicine, London, United Kingdom; [2]Hammersmith Hospital, London, United Kingdom.

Background: Demand for kidney transplantation (KT) in older people is increasing. Frailty predicts poorer medical outcomes, but little is known about quality of life (QoL) and lived experiences of KT in frail older people.

Methods: KTOP is a 2-year observational study of patients aged >60 years on the KT waitlist. The mixed methods design used questionnaires and semi-structured interviews to explore QoL experiences. Descriptive and mixed-effect analysis was used for the questionnaires and thematic analysis for the interviews. The qualitative data enabled richer understanding of trends identified from questionnaires.

Results: 210 patients were recruited. 68 were vulnerable/frail of whom 35 underwent KT. 21 were recruited into the qualitative study, 10 of whom underwent KT. After KT, vulnerable/frail participants experienced stabilising of physical QoL (figure), with 81.3% reporting improved treatment satisfaction and less illness intrusion (68.8%). However, mental QoL declined (figure) and 58.8% reported worse symptom burden after KT. Qualitative themes revealed KT as physically and emotionally demanding (table). Time free from dialysis was valued yet challenged by unchanging frailty and unexpected burdens of KT. Family/social networks, spiritual beliefs, and positive mindset enabled coping with KT.

Conclusions: Vulnerable/frail older people have mixed QoL changes after KT. Determining expectations of KT and individual personal and socio-cultural resources, are integral to discussions and decision making around KT listing.

Figure. Predicted quality of life changes in vulnerable/frail participants on the waitlist and following transplantation.

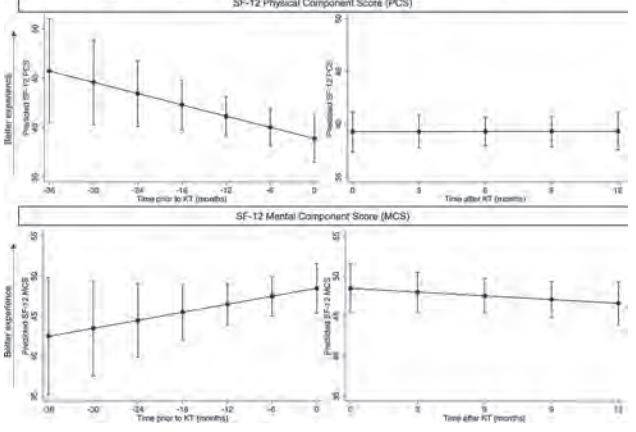

Table 1. Qualitative themes and subthemes encompassing quality of life.

Time point	Themes: subthemes		
Waitlist on dialysis	**Burden of dialysis** • *Physical impact* • *Emotional impact* • *Compromised quality of life*	**Living with frailty** • *Physical impact* • *Emotional impact*	**Personal & socio-cultural resources** • *Coping mindset* • *Faith as a source of resilience* • *Family involvement*

TH-PO732

A Multimodal Aftercare Intervention Improves Outcome after Kidney Transplantation: Results of the KTx360° Aftercare Program Using Claims Data

Lars Pape,[1] Mario Schiffer.[2] The KTx360° Research Group. *[1]Universitatsklinikum Essen, Essen, Germany; [2]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany*.

Background: The after-care treatment project KTx360° aimed to reduce graft failure and mortality after kidney transplantation (KTx).

Methods: The study was conducted in the study centers Hannover, Erlangen and Hannoversch Muenden from May 2017 to October 2020 under the trial registration ISRCTN29416382. The program provided a multimodal aftercare program including specialized case management, telemedicine support, psychological and exercise assessments, and interventions. For the analysis of graft failure, which was defined as death, re-transplantation or start of long-term dialysis, we used longitudinal claims data from participating statutory health insurances (SHI) which enabled us to compare participants with controls. To balance covariate distributions between these nonrandomized groups we used propensity score methodology, in particular the inverse probability of treatment weighting (IPTW) approach.

Results: In total, 930 adult participants were recruited at three different transplant centres in Germany, of whom 320 were incident (enrolled within the first year after KTx) and 610 prevalent (enrolled >1 year after KTx) patients. Due to differences in the availability of the claims data, the claims data of 411 participants and 418 controls could be used for the analyses. In the prevalent group we detected a significantly lower risk for graft failure in the study participants compared to the matched controls (HR=0.13, 95% CI=0.04-0.39, p=0.005, n=389), whereas this difference could not be detected in the incident group (HR=0.92, 95% CI=0.54-1.56, p=0.837, n=440).

Conclusions: Our findings suggest that a multimodal and multidisciplinary aftercare intervention can significantly improve outcome after KTx, specifically in patients later after KTx. For evaluation of effects on these outcome parameters in patients enrolled within the first year after transplantation longer observation times are necessary.

TH-PO733

Pain Interference and Social Participation among Kidney Transplant Recipients

Maria G. Pucci,[1] Sambea Cochrane,[1] Janine Farragher,[2] Susan J. Bartlett,[3,4] Doris Howell,[5] Madeline Li,[6] John D. Peipert,[7,8] Istvan Mucsi.[1] *[1]Multi-Organ Transplant Program, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Department of Occupational Science and Occupational Therapy, Temerty Faculty of Medicine, University of Toronto, Toronto, ON, Canada; [3]Centre for Outcomes Research and Evaluation, McGill University Health Centre, Montreal, QC, Canada; [4]Division of Clinical Epidemiology, Department of Medicine, McGill University, Montreal, QC, Canada; [5]Princess Margaret Cancer Research Institute, Toronto, ON, Canada; [6]Psychosocial Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada; [7]Department of Medical Social Sciences, Northwestern University, Feinberg School of Medicine, Chicago, IL; [8]Northwestern University Transplant Outcomes Research Collaborative, Comprehensive Transplant Center, Feinberg School of Medicine, Chicago, IL.*

Background: Bodily pain can be linked to poor quality of life (QOL) and limited social participation. Social participation, defined as the ability to perform one's usual social roles and activities, is a patient-valued QOL domain often restricted in kidney transplant recipients (KTRs). Our objective was to explore the association between pain interference (PI) and social participation (SP) among KTRs.

Methods: We analyzed cross-sectional data from a convenience sample of adult KTRs at Toronto General Hospital. PI and SP were assessed using Patient-Reported Outcome Measurement Information System (PROMIS) computer adaptive testing (CAT). We defined moderate/severe PI as a T-score > 60 and low SP as a T-score < 45. We used Spearman correlation analysis to explore the relationship between SP and PI and employed multivariable linear and logistic regression to further examine the association, after adjusting for covariables (age, sex, marital status, racialized status, comorbidity, hemoglobin, albumin, eGFR, months since transplant, depression, and fatigue). Multiple imputation was used to address missing data.

Results: The mean (SD) age of the 282 participants was 52 (14) years, 62% were male, 59% were white. The median (IQR) months since transplant was 37 (120). The mean (SD) SP and PI scores were 52 (9) and 50 (10), respectively. A moderate negative correlation existed between SP and PI (rho= -0.55, p<0.001). This association remained significant in multivariable linear regression analysis after adjusting for covariables (ß= -.253, p<0.001; 95% CI: -.340 – -.165). Participants with moderate/severe PI were more likely to report low SP compared to those with no or mild PI in multivariable logistic regression analysis after adjusting for covariables (OR= 5.16, p= 0.001; 95% CI: 1.93 – 13.8).

Conclusions: KTRs experiencing significant PI reported more limited SP than those with low PI. Future studies should assess the impact of pain and pain management on social health following transplantation.

Funding: Private Foundation Support, Government Support - Non-U.S.

TH-PO734

Symptom Recovery after Kidney Transplantation

Ana M. Samudio,[1] Crystal Huang,[1] Katalin Groe,[1] Nolan J. Marblestone,[1] Susan J. Bartlett,[2,3] Doris Howell,[4] Madeline Li,[4] John D. Peipert,[5,6] Istvan Mucsi.[1] *[1]University Health Network, Toronto, ON, Canada; [2]McGill University Health Centre, Montreal, QC, Canada; [3]McGill University, Montreal, QC, Canada; [4]Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada; [5]Northwestern University Department of Medical Social Sciences, Chicago, IL; [6]Northwestern University Comprehensive Transplant Center, Chicago, IL.*

Background: We report physical and psychological symptom severity and frequency among incident kidney transplant (KT) recipients using Patient Reported Outcomes Measurement Information System (PROMIS) computer adaptive tests (CAT).

Methods: Longitudinal convenience sample of incident (<30 days post-transplant) adult KT recipients, recruited 2021-2024. Participants completed PROMIS CATs at baseline, biweekly for 3 months, and monthly thereafter. PROMIS T are standardized to a mean of 50 and standard deviation (SD) of 10, corresponding to the U.S. general population mean. Scores > 60 or <= 40 indicate moderate-severe symptom severity or function impairment, respectively.

Results: Of 133 participants, 84(63%) were male, 69(58%) were white, 43(35%) had diabetes, and mean(SD) age was 51(15) years. Median (interquartile range) time after transplant at enrolment was 5(3,8) days. At baseline, all domain T-scores were worse than the U.S. population mean and improved significantly by week 12. At week 12, domain T-scores neared the U.S. population mean (Table 1). Mean T-scores at week 24 were similar to week 12, except physical function and pain interference, which showed significant further improvement. At week 0, the proportion of patients scoring moderate-severe symptom severity or function impairment: fatigue 36%, sleep disturbance 32%, physical function 52%, pain interference 48%, anxiety 36%, and depression 18%. At week 12, the proportion of patients scoring moderate-severe symptom severity or

function impairment: fatigue 7%, sleep disturbance 14%, physical function 12%, pain interference 10%, anxiety 11%, and depression 10%. All proportions were significantly lower at week 12 vs week 0, except for depression.

Conclusions: A majority of KT recipients will experience moderate-severe symptom severity or function impairment immediately post-transplant. By week 12, most improve significantly and near levels seen in the U.S. general population. Findings highlight need for systematic symptom screening and support early after kidney transplant.

Inflammatory Markers in Patients with ESKD on Maintenance Hemodialysis, Hemodiafiltration (HDF), and Early Postkidney Transplant Patients and Their Relation to Quality of Life (SGA Score)

Magdy ElSharkawy, Hesham M. Elsayed, Aber H. Baki, Abdelrahman A. Elbraky, Mohamed A. Abd El-Mohsen, Meryhan O. El-Rayes. Dept of Internal Medicine and Nephrology. *Ain Shams University Faculty of Medicine, Cairo, Egypt*.

Background: Patients with end-stage renal disease (ESRD) needing renal replacement therapy is estimated about 7 million worldwide. Hemodiafiltration (HDF) yields an increased overall solute clearance compared with hemodialysis (HD). Kidney transplantation offers an improved quality of life in comparison to dialysis. In ESRD, inflammation has become recognized. High-sensitivity C-reactive protein (Hs-CRP) is a biomarker of inflammation which plays a key role in atherosclerosis.A growing amount of information is emerging about MicroRNAs in the regulation of renal fibrosis. We studied inflammatory markers and quality of life (QOL) in different renal replacement modalities.

Methods: A cross-sectional study was conducted on 75 patients;25 patients with ESRD on HD,25 patients with ESRD on HDF and 25 early post-renal transplant patients. Moreover, 10 healthy controls were added to get to the normal gene expression of the studied MicroRNA 'serum miR-223'.Inflammatory biomarkers (Hs-CRP, serum miR-223) were withdrawn and subjective global assessment (SGA) was applied.

Results: Hs-CRP was significantly higher in HD patients; median 14.2 (7.4 - 16.9 mg/L) than HDF; median 6.3 (4.1 - 14.3 mg/L) and post renal transplant patients median 5.2 (3.3 - 8.6 mg/L) **(P= 0.003)**. Serum miR-223 showed down-regulation in dialysis patients; HD and HDF. This down-regulation improved in post renal transplant patients (approaching readings of the healthy control group) with highly significant differences between dialysis and post-transplant groups **(P= 0.000)**. Post renal transplant patients had better quality of life;SGA score A (normal)= 100%, in comparison with dialysis groups of patients. Moreover, when comparing SGA in both dialysis modalities, HDF group of patients had better quality of life as 76% of them had normal nutritional status (SGA score A) in comparison with the HD group who had only 32% patients with SGA score A (normal) with highly significant statistical differences between the 3 groups **(P= 0.000).**

Conclusions: Kidney transplantation offers improved quality of life for ESRD patients in comparison to dialysis. Moreover, for patients on dialysis, HDF modality demonstrates a beneficial effect on QOL in comparison to HD.

TH-PO736

Effect of a Lifestyle Intervention on Sleep and Fatigue in Kidney Transplant Recipients: A Predefined Analysis of the Active Care after Transplantation (ACT) Randomized Clinical Trial

Tim J. Knobbe,[1,2] Daan Kremer,[1,2] Frederike J. Bemelman,[3] Stefan P. Berger,[1,2] Gerjan Navis,[1,2] Stephan J. Bakker,[1,2] Eva Corpeleijn.[1,2] *[1]Rijksuniversiteit Groningen, Groningen, Netherlands; [2]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [3]Amsterdam Universitair Medische Centra, Amsterdam, Netherlands*.

Background: Improving lifestyle may be a promising target to improve sleep quality and reduce fatigue among kidney transplant recipients (KTR). We assessed whether a lifestyle intervention, proven to enhance physical functioning, improves sleep and reduces fatigue among KTR.

Methods: We performed a predefined analysis of the Dutch multicenter randomized controlled Active Care after Transplantation (ACT) study (NCT01047410). KTR were randomized into exercise intervention, exercise + diet intervention, or usual care. Exercise intervention included three months supervised exercise with 15 months lifestyle coaching. For the exercise + diet group, this was supplemented with 15 months dietary counselling. Sleep and fatigue were assessed by KDQOL-SF and CIS20R questionnaires. Multilevel general linear mixed model analyses were performed.

Results: We included 146 KTR (36% female, mean age 54±13 years); 57 received exercise intervention, 45 exercise + diet intervention and 44 usual care. At 15 months, both arms showed no statistically significant effect on sleep quality (**Figure 1a**), with a mean difference in estimated marginal means (EMM) from baseline, compared with control, of +1.7 (95%CI -2.8, +6.2) for the exercise intervention group (P=0.47) and +4.0 (95%CI -0.9, +8.8) for the exercise + diet group (P=0.11). Regarding fatigue severity, no statistically significant effect was observed at 15-months (**Figure 1b**), with a mean difference in EMM from baseline, compared to the control, of -1.4 (95%CI -7.0, +4.2) for the exercise intervention group (P=0.62) and -0.2 (95%CI -6.2, +5.8) for the exercise + diet intervention group (P=0.94).

Conclusions: Although the lifestyle intervention had previously been shown to improve physical functioning, there was neither a significant treatment effect on sleep nor on fatigue. Improving lifestyle – important as it may be – may not be a panacea for KTR. Addressing sleep and fatigue in this population requires a specific, dedicated approach.

Primary Care Utilization by Kidney Transplant Recipients

Long Qian,[1] Sophia Faulkner,[1] Yu Yamamoto,[1] Sarthak Virmani,[2] Francis P. Wilson,[1] Sherry Mansour.[1] *[1]Yale University, New Haven, CT; [2]University of Virginia, Charlottesville, VA*.

Background: While most kidney transplant recipients (KTRs) receive consistent outpatient care from nephrologists, the extent to which they access primary care providers (PCPs) is unknown, as is whether receiving primary care affects clinical outcomes.

Methods: We used the electronic medical record data of Yale New Haven Hospital from 2016 to 2020 to investigate patterns of PCP exposure among KTRs and factors associated with PCP exposure. We used a multivariable cox regression analysis adjusting for demographics and clinical factors to assess the association between seeing a PCP and all-cause mortality.

Results: A total of 844 KTRs were included with a median follow-up time of 3.16 (IQR:1.55, 4.84) years. Median age was 54 (IQR: 42, 63) years; 311 (37%) were female; 244 (29%) identified as Black and 125 (15%) identified as Hispanic. 33% of KTRs had at least one PCP visit after transplantation during our study period but within 1 year after transplantation, only 15% saw a PCP. Those seen by a PCP were slightly older [56 (47, 64) vs. 53 (42, 63) years, p=0.08], and more likely to be female (61 (47%) vs. 250 (35%), p=0.01] and diabetic [75 (57%) vs. 56(43%), p=0.01]. Additionally, being female and diabetic were independently associated with, respectively, a 66% and 69% higher odds of seeing a PCP (aOR: 1.66 (95%CI:1.13-2.42 and aOR:1.69 (95%CI: 1.15-2.49)]. During our study follow up, 98 (12%) of KTRs died. Seeing a PCP within the first year was not significantly associated with all-cause mortality (aHR 0.74 (95%CI: 0.17-3.19).

Conclusions: Only a small proportion of KTRs are seen by a PCP post-transplant. There were certain factors associated with higher odds of PCP exposure, but overall PCP exposure was not associated with all-cause mortality. Further investigations are needed to evaluate if PCP exposure may improve outcomes in KTRs.

TH-PO738

Impact of Diabetes on Physical Function Recovery following Kidney Transplantation

Jad Fadlallah, Eliana Barbuzzi, Fabiha Razzak, Caroline Carruthers, Christina Commisso, Nishat F. Syeda, Nathaniel Edwards, Heather Ford, Istvan Mucsi. Kidney Health Education and Research Group. *University Health Network, Toronto, ON, Canada*.

Background: Diabetes mellitus (DM) can impair post-operative recovery. We assess the association of DM with recovery of physical function over time among incident kidney transplant (KT) recipients using the Patient Reported Outcome Measurement Information System (PROMIS) physical function computer adaptive test (PF-CAT).

Methods: Longitudinal convenience sample of incident (<30 days post-transplant) adult KT recipients recruited in 2021-2024. Demographic information was self-reported, clinical data extracted from health records. Participants completed PROMIS PF-CAT at baseline, biweekly for 3 months, and then every four weeks up to 6 months on an electronic data capture platform. PROMIS PF-CAT is scored on a T-score metric (20-80, higher scores=better physical function). Linear mixed-effect models with random intercepts were used to compare PF recovery between DM and non-DM (NDM) KT recipients. The model included the interaction between time and diabetes status, representing the average difference in PF over time, adjusting for age, sex, education, socioeconomic status, BMI and significant anxiety or depression symptoms at baseline. Individual clinically significant improvement in PF was assessed in a time-to-event analysis, with the use of log-rank tests and Cox proportional-hazards model adjusting for mentioned covariates. The primary event was defined as reaching a T-score ≥50.

Results: Of 110 participants, 71(65%) were male, 62(56%) were white, 36(33%) had DM, mean(SD) age was 51(15) years and median[IQR] time since transplantation at enrollment was 4[3; 7] days. DM had significantly lower PROMIS PF over time (ref:NDM, coeff, -0.19; 95%CI, -0.33 to -0.05). At baseline, mean(SD) scores in DM(n=36) vs NDM(n=74) were 39(10) vs 39(8). At 12w, scores in DM(n=11) vs NDM(n=33) were 45(6) vs 47(6). At 24w, scores in DM(n=11) vs NDM(n=30) were 48(5) vs 51(6). The cumulative incidence of the event was 25 in NDM vs 5 in DM, p=0.02. This association remained significant after adjusting for covariates (ref: NDM, HR, 0.33; 95%CI 0.11 to 0.95, p=0.04).

Conclusions: KT recipients with DM demonstrated less significant improvements in PF over 6 months compared to NDM. KT with DM may need extra support for their PF, such as prehabilitation or post-transplant rehabilitation.

Diabetes Distress Is High and Negatively Affects Diabetes Control in Kidney Transplant Recipients (KTR): A Prospective Study

Aleksandra Kukla, Sukhdeep S. Sahi, Aleksandar Denic, Corey Kurek, Ravinder Jeet Kaur, Afsana Ansari Shaik, Byron H. Smith, Tayyab S. Diwan, Mark D. Stegall, Yogish C. Kudva. *Mayo Clinic Minnesota, Rochester, MN*.

Background: Impact of diabetes distress (DDS) on type 2 diabetes (T2D) control in KTR is unknown. Validated T2D DDS questionnaire includes emotional, physician-related, management related, and interpersonal distress components (17 points). Total scores>2 and ≥3 in each component indicate moderate and severe DDS, respectively.

Methods: We prospectively assessed DDS in 21 KTR at mean time of 2.1 (1.5) y post KT. Glucose control was assessed by Continuous glucose monitoring (CGM) metrics (Dexcom G6) worn for ten days and HbA1C.

Results: Table 1 depicts demographics and Figure 1 glucose metrics. Treatment regimens: Median DDS scores were 7 (IQR 5,13), 4 (IQR4,4), 8 (IQR 5,11), and 3 (IQR 3,5) for emotional, physician, treatment regimen, and interpersonal subscale, respectively. CGM metrics showed mean time in range (TIR; goal>70%) of 42.6 (25.2) %, and mean time in hyperglycemia of 57.4 (25.2) %. Treatment distress correlated with higher mean glucose (rs=0.44; p=0.04) and lower TIR (rs=-0.45; p=0.04) and higher HbA1c (latter in pts with no anemia) (rs=0.62; p=0.003). No correlation was found between HbA1c and CGM metrics.

Conclusions: KTR with T2D experience high DDS, which negatively impact glucose control. Efforts should be focused on reducing treatment burden.

SGLT2 Inhibitors in Kidney Transplant Recipients: A Pharmacist-Led Clinic in a Predominantly Hispanic and American Indian Population

Raja Ravender, Ngoc-Yen Pham, Namita Singh, Pablo Garcia, Christos Argyropoulos, Pooja P. Singh. *University of New Mexico Health Sciences Center, Albuquerque, NM*.

Background: SGLT2 inhibitors have been shown to help modify disease progression for diabetes and CKD. Kidney transplant recipients (KTRs) were excluded from major RCTs utilizing these drugs. Here we describe kidney outcomes and adverse events among KT recipients in New Mexico (NM).

Methods: This is a single-center retrospective chart review of KTRs in NM who were started on SGLT2 inhibitors from May 2019 through June 2023, and followed for one year after initiation of therapy. Diabetes management was done primarily by a clinician pharmacist-run clinic. The primary objective reviewed adverse events in immunocompromised people and the secondary objectives reviewed eGFR, proteinuria, HCT, and HgA1C.

Results: We included 49 KTRs in this cohort, 24% American Indian, 16.3% non-Hispanic White, 46.9% Hispanic White, 4% Asian, 2% Black, 2% Native Hawaiian, and 4.8% unreported. 81.6% of patients were started on Empagliflozin, with 84.8% started on SGLT2 inhibitors for diabetes management and 27.1% for other causes. In one year 8.9% of patients had a urinary tract infection (UTI), with 4% having two UTIs and one requiring IV antibiotics to treat the UTI twice. One patient had a metatarsal amputation and the SGLT2 inhibitor was discontinued. Only 6% of patients were taken off the medications due to either adverse events or other reasons. No patients experienced ketoacidosis or a thrombotic event such as DVT. After adjusting for age, gender, and ethnicity there was a reduction of UACR (6mg/g per month) and UPCR (15 mg/g) per month of therapy. At 12 months there was an estimated 35% reduction in proteinuria with no significant change in the eGFR or HCT.

Conclusions: SGLT2 inhibitors are a safe therapy among immunocompromised transplant recipients. A few patients in our study were taken off therapy due to an adverse event. The reduction in proteinuria was similar to what was seen in major RCTs. Using an interdisciplinary approach with the help of clinical pharmacists, quality of care delivered is greatly improved in this vulnerable population of patients who require comprehensive care due to their multiple comorbidities.

	EGFR	HCT	UPCR
Change in the lab per month of therapy	0.15 +/- 0.16 ml/min/1.73m2/month	0.08 +/- 0.18 %/month	-14.6 +/- 5.8 mg/mg/month
P Value	0.38	0.66	0.0127

A Prospective Observational Study to Assess the Efficacy of a SGLT2 Inhibitor (Dapagliflozin) in Kidney Allograft Recipients with Diabetes Mellitus

Avishek Naskar. *Kolkata Kidney Institute, Kolkata, India.*

Background: Cardiovascular disease is a major cause of graft loss and mortality in renal transplant patients, who may be benefited from SGLT2 inhibitors. But, they are not routinely recommended and few studies of their use in renal transplant patients have been published.

Methods: In this 12 months study, 100 renal transplant patients with both pre-existing and post transplant diabetes mellitus, visiting out patient department, were included. Half of them received dapagliflozin 10mg along with their ongoing anti-diabetic medicines and the others continued their already ongoing medicines, with dose adjustment according to HbA1c. Fasting and post-prandial blood glucose, glycated hemoglobin (HbA1c) and creatinine and urine for routine examination and albumin-creatinine ratio (ACR) were tested at baseline and at 3, 6 and 12 months during routine follow-up visit.

Results: There was no significant statistical difference in the mean reduction of HbA1c (0.72% in dapa group, 0.86% in non-dapa group), as well as mean reduction of urine ACR between the 2 groups. No significant change in eGFR was found at 12 months. There was no episode of acute kidney injury observed, other than in patients requiring hospitalization. The frequency of urinary tract infection (UTI) (12% in both the groups) as well as genital infections were not statistically different (8% in dapa group, 6% in non-dapa group). Dapagliflozin was discontinued in 4% patients with UTI, for recurrence, but none in those with genital infections. No patient suffered rejection, ketoacidosis or hypotension.

Conclusions: Dapagliflozin lead to a modest reduction of HbA1c, but had less potent anti-proteinuric action. It was not associated with significant allograft dysfunction, and had similar frequency of adverse effects like that of other anti-diabetic medications.

TH-PO742

SGLT2 Inhibitors Reduce the Rate of Decline in the Estimated Glomerular Filtration Rate of Kidney Transplant Patients with Recurrent or De Novo Glomerulonephritis

Hyuk yong Kwon, Sung Hyun Son, Jin M. Kong. *Nephrology, Department of Internal medicine, BHS-Hanseo Hospital, Busan, Republic of Korea.*

Background: Although recurrent or de novo glomerulonephritis (GN) after kidney transplantation (KT) is one of the main causes of renal allograft failure, no effective treatment is currently available. Recent evidences indicate the beneficial effects of sodium-glucose cotransporter 2 inhibitors (SGLT2i) in delaying the progression of a broad range of chronic kidney diseases, including GN.

Methods: Twenty-seven patients with biopsy-proven GN of the renal allograft were treated with SGLT2i at a median of 16.3±8.4 years post-transplant and were prospectively followed. IgA nephropathy was the most common (n=18), followed by focal segmental glomerulosclerosis, membranous nephropathy, and minimal change disease (n=2 each), and others (n=3). The baseline mean eGFR was 57±26 mL/min/1.73 m^2. The baseline mean urine protein-creatinine ratio (U-PCR) was 689±536 mg/g. The primary outcomes were the changes in proteinuria from baseline to 6 and 12 months, and the change in the eGFR slope before (-12 to 0 months) and after (3 to 15 months) the initiation of SGLT2i. The secondary outcomes were changes in body weight (BW), systolic blood pressure (SBP), and doses of antihypertensives. Adverse reactions were closely monitored.

Results: The post-SGLT2i follow-up period was 23.9 (median) ±15.0 months. The eGFR slope improved from -5.67±7.77 ml/min/1.73 m^2/year [before SGLT2i] to -0.38±17.19 [after SGLT2i] (P=0.006, paired t-test). The U-PCR did not change significantly. BW decreased significantly at 3 months and was maintained thereafter. SBP did not change significantly, but the number of antihypertensives decreased. There were no cases of acute pyelonephritis, acute kidney injury, or other adverse reactions attributable to SGLT2i.

Conclusions: SGLT2i slowed the decline in eGFR in patients with GN of the renal allograft and was well-tolerated. Our preliminary results warrant confirmation by further studies with a larger number of patients and prolonged follow-up.

TH-PO743

Benefits of Glucagon-Like Peptide 1 Receptor Agonists in Kidney Transplant Recipients

Oscar A. Garcia Valencia,[1] Sukhdeep S. Sahi,[1] Jie Na_,[1] Byron H. Smith,[1] Pooja Budhiraja,[2] Tayyab S. Diwan,[1] Naim S. Issa,[1] Aleksandar Denic,[1] Ahmed Abdelrheem,[1] Hani Wadei,[3] Yogish C. Kudva,[1] Aleksandra Kukla.[1]
[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic Arizona, Scottsdale, AZ; [3]Mayo Clinic in Florida, Jacksonville, FL.

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RA) showed improved outcomes in patients with type 2 diabetes (DM2), however limited studies exist in kidney transplant recipients (KTR).

Methods: We retrospectively studied patient and allograft outcomes in KTR treated with GLP-1 RA for at least 12 months vs a reference group (DM2 with not treated with GLP-1 RA).

Results: Demographics of both cohorts are presented in Table 1. The mean (SD) follow-up for GLP-1 RA and reference group was 6.9 (4.4) and 6.8 (4.2) years, respectively. The use of GLP-1 RA was associated with significantly better survival (p=0.03); Fig. 1, improved mean urine albumin/creatinine ratio (decreased by 31 mg/g/year vs increased by 20.47 mg/g/year; p <.001), eGFR (increased by 0.52 mL/min/BSA/y vs decreased by 1.56 mL/min/BSA/y, p= 0.044) and triglycerides (decreased by 2.17 mg/dl/y and decreased by 2.3 mg/dl/y; p=.04) in GLP1RA treated patients versus not, respectively.

Conclusions: GLP1RA may potentially improve survival and may positively impact kidney endpoints. Limitations include the retrospective study design and potential bias related to patient selection for GLP-1 RA therapy. Prospective studies with patient survival and renal endpoints are needed.

Table 1: Baseline characteristics for treatment and reference group

Baseline Characteristics	GLP-1 RA treatment group (n=77)	Reference group (N=2094)	p-value
Female sex, N (%)	30 (39)	711 (34)	0.39
Age at transplant, years	57.9 (9.5)	60.8 (9.5)	0.015
BMI at transplant, kg/m2/BSA	32.1 (4.3)	30.1 (5.1)	0.002
Race, N (%)			0.02

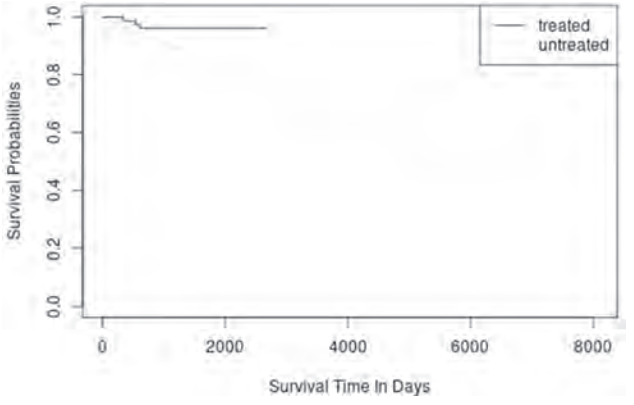
White	42 (54.5)	924 (44.1)	
American Indian/Alaskan Native	2 (2.6)	175 (8.4)	
Asian	3 (3.9)	98 (4.7)	
Other	12 (15.6)	565 (27)	
Age at GLP-1 RA start, years	62.0 (9.4)	NA	NA
Baseline MACE events			NA
Heart Failure, N (%)	22 (28.5)	NA	
Myocardial Infarction, N (%)	7 (9.1)	NA	
Stroke, N (%)	7 (9.1)	NA	
Time between transplant and GLP-1 RA start, years	4.1 (4.3)	NA	NA
Serum creatinine at transplant, years	1.4 (0.4)	1.5 (0.7)	0.21
eGFR at transplant, mL/min/1.73 m^2	41.9 (14.4)	40.9 (15.2)	0.59
Albumin/creatinine ratio at transplant, mg/gm,	187.6 (226.2)	93.8 (161.4)	0.03
Hba1c at transplant, %	7.2 (1.5)	7.0 (1.4)	0.56
Triglycerides at transplant, mg/dl	165.6 (118.8)	171.6 (116.6)	0.71



TH-PO744

Evaluating the Impact of Multiple Kidney Retransplants on Post-transplant Outcomes: An Analysis of the OPTN/UNOS Database

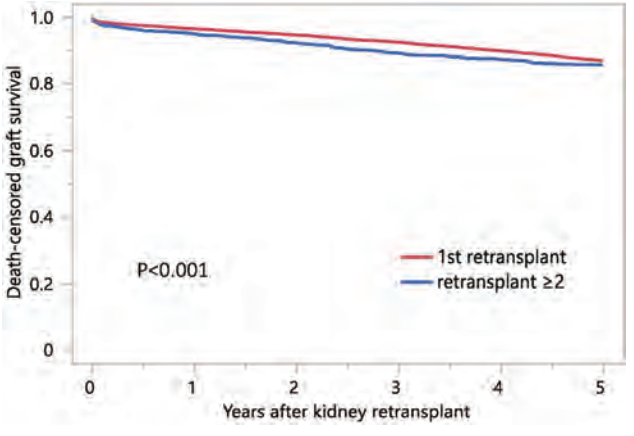
Oscar A. Garcia Valencia,[1] Charat Thongprayoon,[1] Jing Miao,[1] Iasmina Craici,[1] Napat Leeaphorn,[2] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Kidney transplantation offers a valuable therapeutic option for patients esperiencing graft failure after their initial transplant. There is a increasing trend of patients undergoing multiple retransplants however the impact of these subsequent procedures remains understudied. This study evaluated the assocaition between the number of kidney retransplants and patient outcomes.

Methods: Using the OPTN/UNOS database, we identified all kidney-only retransplants in the United States from 2010 to 2019. We categorized them into two groups: those with a first kidney retransplant and those with two or more. The study analyzed the association between multiple retransplants and outcomes such as death-censored graft failure, patient mortality, and acute rejection through Cox proportional hazard and logistic regression analyses.

Results: Of the 17,433 recipients of kidney retransplants included, 15,821 (91%) received one retransplant, while 1,612 (9%) underwent two or more. The latter group tended to be younger, more frequently white, had higher PRA levels, used public insurance, and attained higher education levels. However, they had a lower prevalence of DM and total HLA mismatch compared to individuals with a single kidney retransplant. Multivariate analysis revealed that multiple retransplants significantly increased the risk of death-censored graft failure and acute rejection, albeit it did not significantly impact patient mortality.

Conclusions: Patients undergoing multiple kidney retransplants face a higher risk of graft failure and rejection compared to those with a single retransplant. These findings highlight the need for tailored management and surveillance strategies to improve outcomes for patients receiving multiple kidney retransplants.



TH-PO745

Treatment with Cinacalcet Post Kidney Transplant Does Not Confer Clinically Meaningful PTH Suppression Compared with No Treatment

Emily K. O'Leary, Erin Biggs, Michele Mccloskey, Jorge C. Garces, Juan Carlos Q. Velez, Terrance J. Wickman. *Ochsner Health, New Orleans, LA.*

Background: Cinacalcet is a calcimimetic used to treat secondary hyperparathyroidism (SHP) of end-stage kidney disease (ESKD) that fails to achieve adequate parathyroid hormone (PTH) suppression with calcitriol or other vitamin D analogs. However, their role to control persistent PTH after kidney lacks supporting evidence. We hypothesized that the use of calcimimetics provides no meaningful difference in PTH level after kidney transplant when compared with calcitriol or other vitamin D analogs or no therapy at all.

Methods: A retrospective chart review was performed searching for adults with a diagnosis of SHP who received a kidney transplant at Ochsner Health between 2018 and 2022. SHP was defined by ICD code. We excluded those with parathyroidectomy, dual organ transplant or missing data. We compared 6-month post-transplant PTH amongst patients being treated with cinacalcet, cinacalcet and calcitriol, calcitriol, or no treatment, by linear regression.

Results: 226 patients were included, mean age was 51 (20-78), mean BMI was 30 (19-47), 43% women, and 56% Black. 93% had hypertension, 39% had diabetes. All treatment groups showed a statistically significant decrease in PTH 6 months after transplant, as expected. Mean post-transplant PTH for those on cinacalcet, cinacalcet and calcitriol, calcitriol, and no treatment were 272, 208, 320, and 277 pg/mL, respectively. Adjusting for age, pre-transplant PTH, type of donor, delayed graft function, and dialysis before transplant, we observed no difference in mean PTH after transplant in patients treated with cinacalcet alone compared to the no treatment group (p=0.21); however, we observed a lower mean post-transplant PTH with those treated with calcitriol alone (p=0.0007).

Conclusions: Use of cinacalcet after kidney transplant was not associated with a clinically significant difference in PTH suppression when compared to cinacalcet and calcitriol, calcitriol, or no treatment. Our findings suggest that calcimimetics may not be beneficial for the treatment of SHP after kidney transplant.

TH-PO746

Nonadherence to Immunosuppressive Medications in Kidney Transplant Recipients: A Systematic Scoping Review

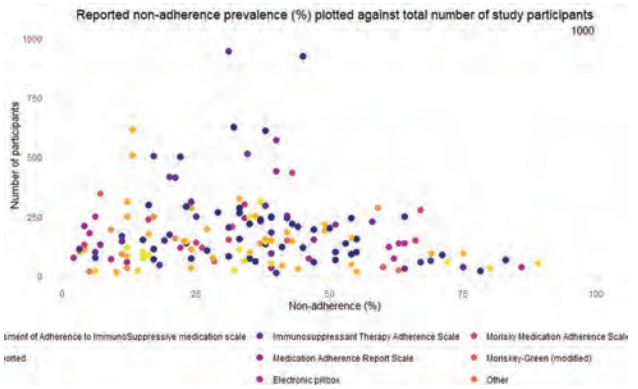
Michael Corr,[1] Andrew I. Walker,[2] Alexander P. Maxwell,[1] Gareth J. McKay.[1] *[1]Queen's University Belfast, Belfast, United Kingdom; [2]Northern Ireland Foundation Programme, Belfast, United Kingdom.*

Background: Rejection and graft failure remain common in transplant recipients. Non-adherence to immunosuppressive medications is considered a major contributor to reduced long-term graft survival, particularly in younger people. Improved clinical practice based on adherence studies has been minimal. Our aim was to increase understanding of non-adherence to immunosuppressive medications following kidney transplantation and identify research gaps to inform future studies.

Methods: Joanna Briggs' Institute Methodology used. MedlineALL, Embase, Web of Science Core Collection and Scopus databases searched January 2000 through December 2023. Abstract and full text review undertaken independently by two reviewers. Data collated using a pre-designed extraction tool.

Results: 359 articles met the inclusion criteria. Non-adherence was commonly defined using self-reported questionnaires. Prevalence of non-adherence varied widely. There was little correlation between method of measurement and reported rates of non-adherence (Figure 1). Despite younger age being identified as a risk factor for non-adherence, reported prevalence did not differ significantly in studies reporting prevalence in children, adolescents, or young adults vs. older adults (33.5% vs. 34.0%). Interventional studies to improve adherence are heterogenous, often report small effects and limited by the lack of gold-standard methods to measure adherence.

Conclusions: Despite increasing research in the field, evidence to support measures to improve non-adherence in kidney transplant recipients remains weak. Future studies should consider a common definition of non-adherence to enable robust comparisons to be made e.g. using the Basel Assessment of Adherence to Immunosuppressive Medication Scale (BAASIS). We recommend validation of existing tools and interventions in larger cohorts rather than further single-centre studies to improve the evidence-base to address this important clinical problem.



TH-PO747

Using Artificial Intelligence to Improve Tacrolimus Dosing in Kidney Transplant Patients

Sean A. Perez,[1] Mingjia Huo,[4] Linda Awdishu,[3] Hayden H. Pour,[2] Janice Kerr,[3] Pengtao Xie,[4] Adnan A. Khan,[2] Kristin Mekeel,[1] Shamim Nemati.[2]
[1]University of California San Diego Department of Surgery, La Jolla, CA; [2]University of California San Diego Department of Medicine, La Jolla, CA; [3]University of California San Diego, Skaggs School of Pharmacy and Pharmaceutical Sciences, San Diego, CA; [4]University of California San Diego Department of Electrical and Computer Engineering, La Jolla, CA.

Background: Tacrolimus (FK) is a mainstay of post-transplant immunosuppression with a narrow therapeutic window. Achieving therapeutic FK trough concentrations in the immediate post-operative period is challenging due to changing perioperative physiology and pharmacokinetics resulting in variable day to day exposures. We developed a machine learning (ML) model to predict the next day FK concentration and guide dosing to prevent persistent over- or under-dosing.

Methods: Retrospective data was extracted for adult kidney and/or liver transplant recipients from January 2016 to December 2023. Patient demographics, vital signs, laboratory values, diet, and medications were utilized to build the model. Data was randomly split 70%/15%/15% for training, validation, and test sets. XGBoost, traditional Recurrent Neural Network, and Long Short-Term Memory models were evaluated for best fit given the complexity of relationships and time dependency.

Results: 1126 (706 kidney, 420 liver) transplant recipients were included in the study with a median (IQR) age of 58 (47-65) years, 51% white race, with FK daily dose of 4.0 (1.5 – 8.0) mg and concentration of 8.38 (5.9-10.3) ng/mL. The XGBoost model achieved a Mean Absolute Error (MAE) of 1.916 when predicting the next day's FK concentrations. Figure 1 depicts the model's ability to predict underdosage or overdosage—using a target concentration of 10-13 ng/mL, via 3-class classification task. Overall, the model achieved accuracy of 0.73 with average F1-score of 0.58, F1-score 0.85 for predicting underdosing, and area under the curve of 0.67.

Conclusions: Machine learning accurately predicts next day FK concentrations which may improve precision dosing. Future directions include clinical implementation and evaluation and development of decision support for dosing recommendations.

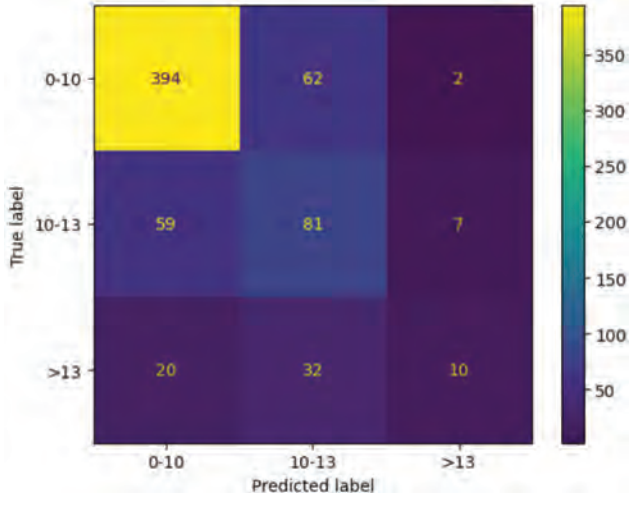


Figure 1. XGBoost 3-class classification task.

Real-World Data of Tacrolimus Drug Levels in Ultra-long Kidney Transplant Survivors

Chung Hee Baek, Hyosang Kim. *Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.*

Background: Maintaining tacrolimus trough drug levels of more than 5ng/ml decreases the risk of de novo donor-specific antibodies. However, for ultra-long kidney transplant survivors, the evidence of appropriate tacrolimus levels is rare. Therefore, we investigated real-world data on tacrolimus drug levels of ultra-long kidney transplant survivors in a high-volume medical center.

Methods: Our center started kidney transplantation in 1990. Among 1375 patients who received kidney transplants in our center from 1990 to 2002, 606 kidney allografts survived more than 20 years. We identified 155 kidney transplant recipients who administered tacrolimus continuously from 15 to 20 years after kidney transplantation and analyzed tacrolimus drug levels and clinical outcomes.

Results: The mean tacrolimus trough drug levels between 15 and 20 years after kidney transplantation was 3.94 ng/mL ± 1.52 (range 1.13 – 7.70, median 3.61). After 20 years of kidney transplantation, 11 cases of rejection and 19 cases of graft failure occurred. When analyzing three groups according to the tacrolimus drug levels (<3ng/ml, 3-5ng/ml, >5ng/ml), there were no significant differences in the incidence of rejection (10.2% in <3ng/ml group, 7.4% in 3-5ng/ml group and 2.6% in >5ng/ml group, P = 0.392) and graft failure (16.4% in <3ng/ml group, 11.8% in 3-5ng/ml group and 7.9% in <5ng/ml group, P = 0.486). However, the >5ng/ml group showed the lowest rejection and graft failure incidence without statistical significance. When analyzing two groups according to the tacrolimus drug levels (<5ng/ml group and ≥5ng/ml group), there were also no significant differences in rejection and graft failure.

Conclusions: Very low and high tacrolimus drug levels did not show different graft outcomes in ultra-long kidney transplant survivors. However, it seems that tacrolimus drug levels >5ng/ml are not related to poor outcomes compared to physicians' worries about calcineurin inhibitor toxicities. Well-designed, randomized prospective studies are necessary for more appropriate use of tacrolimus in ultra-long kidney transplant survivors.

TH-PO749

Comparison of Extended-Release and Immediate-Release Tacrolimus for Preventing De Novo Human Leukocyte Antigen (HLA) Sensitisation in Patients with Failed Allografts

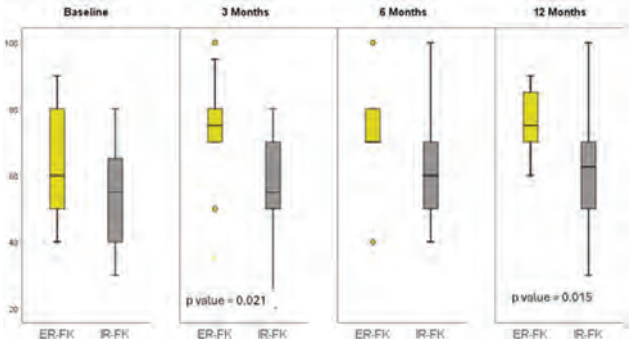
Tina E. Thomson, Michelle Willicombe. *Imperial College London, London, United Kingdom.*

Background: No consensus exists for maintenance immunosuppression in patients returning to dialysis following allograft failure. De novo HLA is undesirable for those suitable for retransplantation. Continuation of low dose tacrolimus may provide protection against broadening sensitisation, but it has a narrow therapeutic index. The use of extended release (ER-FK) preparations may enable better adherence less complications.

Methods: This is an interim analysis of a prospective study, randomising patients to either receive ER-FK or immediate release IR-FK to achieve a trough level of 3-5ng/ml. The primary end point was dnHLA development at 2 yr post-failure. Additional clinical variables, included screening for medication adherence (BAASIS©) and quality of life measures (QoL) (ED-5D-5L) at baseline, 3,6,12,18,24 months.

Results: There was no difference in baseline characteristics of 35 patients with at least 1yr follow-up. At 6 months, 42% of patients had developed dnHLA which increased to 54% by 1yr, with the corresponding number of DSA being 23% and 34%; no differences were seen between the ER-FK and IR-FK groups. Adherence scores were low overall, and significantly lower in IR-FK group at 3 months (p=0.02). 25% of the IR-FK group had a trough level <3 at any time point compared with 8% of the ER-FK (p=0.26). Despite randomisation, baseline QoL measures were lower in the IR-FK, which were reflected in the self-reported health visual analogue scale Figure 1. IR-FK group had significantly worse diabetic control (p=0.009) and also higher CRP (p=0.026). Infection-related admissions were significantly higher with IR-FK(p=0.05). 4 patients died. 5 have been retransplanted.

Conclusions: We found no difference in dnHLA by FK preparation, but 'sub-therapeutic' levels were more frequent with IR-FK. There was a significant burden of poor QoL measures, which correlated with co-morbidity and may confound both HLA responses and adherence. Multiple considerations are likely required to reduce dnHLA in patients with failed allografts.



TH-PO750

Incidence of Thrombotic Microangiopathy in Kidney Transplant Recipients Who Received Tacrolimus: A Multicenter Retrospective Study

Ahmad Matarneh, Sundus Sardar, Rafael Portela, Gurwant Kaur, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Thrombotic microangiopathy (TMA) is a severe condition characterized by thrombocytopenia, hemolytic anemia, and acute kidney failure. TMA can be triggered by infections, medications such as calcineurin inhibitors, and genetic complement defects. In kidney transplant recipients, TMA can lead to graft failure, morbidity, and mortality. Our study aims to identify the incidence of TMA in kidney transplant recipients on tacrolimus versus those not on tacrolimus, and to assess outcomes including transplant rejection, graft failure, and mortality risk.

Methods: We conducted a retrospective multi-center cohort study using TriNetX. We identified 1,252 post-renal transplant recipients on tacrolimus and 290 not on tacrolimus. Survival rates after developing TMA were analyzed over 5 years. Secondary endpoints included the incidence of kidney transplant failure in recipients who developed TMA on tacrolimus compared to those not on tacrolimus, and the risk of graft failure, mortality, and TMA incidence over 5 years.

Results: TMA occurred in 40.3% of kidney transplant recipients on tacrolimus, compared to 24.4% in the non-tacrolimus group (RR=0.613, 95% CI 0.495-0.760). The 5-year risk of developing TMA was higher in patients on tacrolimus (0.7% vs. 0.2%, P=0.0). Survival probability was 36.1% in tacrolimus patients with TMA, compared to 77.3% in non-tacrolimus patients (RR=0.379, 95% CI 0.291-0.495). The risk of graft rejection over 5 years was higher in patients on tacrolimus with TMA (43.1% vs. 16.95%). The risk of kidney graft failure over 5 years was higher in tacrolimus patients with TMA (38.6% vs. 24.1%, RR=0.624). Kidney transplant recipients on tacrolimus with TMA had a survival rate of 98.4% compared to 99.2% in the other group (Hazard ratio 0.387, 95% CI 0.329-0.453). Our study shows a significant difference in TMA incidence in kidney transplant recipients on tacrolimus compared to those not on tacrolimus (P=0.053). There is a higher risk of graft rejection in patients on tacrolimus who develop TMA.

Conclusions: 1. Tacrolimus appears to be an independent risk factor for TMA in kidney transplant recipients. 2. The risk of graft rejection is higher in patients on tacrolimus who develop TMA. 3. The survival rate in kidney transplant recipients who developed TMA was less in those who recieved tacrolimus.

TH-PO751

Safety and Efficacy of Weight-Based MMF (Cellcept) Dosing in Kidney Transplant Recipients: A Quality Improvement Study

Aidan Gangji,[1,2] Wilma M. Hopman,[1] Jessy Donelle,[1] Melana Felske,[1] David C. Holland,[1,3] M. Khaled Shamseddin.[1,3] *[1]Kingston Health Sciences Centre, Kingston, ON, Canada; [2]Queen's University Faculty of Health Sciences, Kingston, ON, Canada; [3]Queen's University, Kingston, ON, Canada.*

Background: Mycophenolate mofetil (MMF) reduces the risk of acute rejection (AR) in kidney transplant recipients (KTRs) and improves post-transplant graft survival. MMF is usually prescribed in fixed doses (2 gm/day). Due to its side effects, MMF doses often require reduction. Weight-based MMF dosing (10-16 mg/kg/day) was correlated with therapeutic level in Asian KTRs. We are aiming to evaluate the safety and efficacy of weight-based MMF dosing at 15 mg/kg/day, adopted by our program in September 2021.

Methods: This is a single center retrospective quality improvement study evaluating the safety and efficacy of weight-based MMF dosing at 15 mg/kg/day, compared with non-weight-based doses (≤ 2 gm/day), to reduce the risk of MMF-associated side effects including leukopenia (WBC ≤ 3.5), BK- and/or CMV-viremia, while monitoring the risk of AR associated with reduced MMF doses. All KTRs followed in our kidney transplant clinic at Queen's University between September 1, 2021, and August 31, 2023, were included.

Results: 230 KTRs [Age 56.9±14.4 years, Female (36.1%), Caucasian (87.8%)] were included. By August 31, 2023, 112 (48.7%) patients were on MMF. 18 patients were on weight-based doses (15.9 (14.9-18.1) mg/kg/day). 17 patients were on fixed doses (20.7 (17.2-26.2) mg/kg/day). 68.8% of MMF patients were on reduced doses (14.4 (10.4-14.4) mg/kg/day) due to adverse effects, most notably leukopenia (25%) and BK-viremia (18%). At the end of the study, leukopenia, BK- and CMV-viremia were active in 4 (1.7%), 7 (3%) and 1 (0.4%) of all patients, respectively and none of them were on weight-based MMF doses. Median eGFR of MMF patients was higher than non-MMF patients (58 vs. 53 ml/min per 1.73 sm; P 0.37), and it was better among patients on weight-based MMF doses compared with fixed (68.5 vs. 51; P 0.035) and reduced doses (58; P 0.26).

Conclusions: Snapshot data showed a low rate of leukopenia, BK- and CMV-viremia/infection, likely due to effective MMF dose reduction. Further analysis will be done through our next retrospective cohort study to evaluate the outcomes of weight-based dosing.

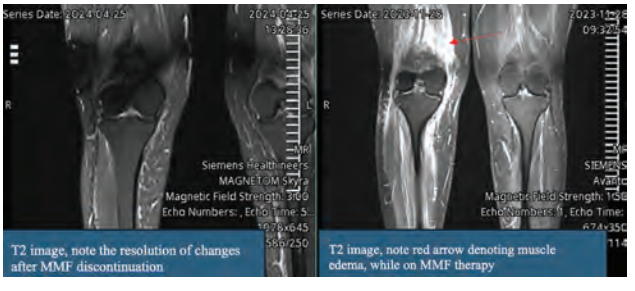
Sickle Cell Pain Crisis or Something Else? A Painful Journey of a Kidney Transplant Patient

Waseem Umer, Essa Abuhelaiqa, Mohamad M. Alkadi. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Mycophenolate (MMF) is an essential medication in transplant care, yet one should be vigilant of the uncommon adverse effects of such agents. We describe a rare side effect of migratory arthralgias and myalgia related to MMF in a post-renal transplant patient.

Case Description: A 44-year-old lady with past medical history of sickle cell trait, type I diabetes mellitus complicated by diabetic nephropathy, status post preemtive live-related kidney transplant in October 2023. She was maintained on a steroid-free regimen with MMF and tacrolimus. Following discharge, she visited the emergency room multiple times with joint pain and swelling at different sites, including the left shoulder and wrist, right thigh and knee. Each time she was diagnosed with sickle cell pain crisis and discharged after symptoms improvement. Tacrolimus levels were within target range, and extensive workup including workup for rheumatological and infectious causes, was unremarkable. An MRI of the leg was performed, which showed extensive muscular edema of distal right thigh, knee, and leg regions with no evidence of avascular necrosis or osteomyelitis (Figure1). These findings prompt us to investigate medication-related adverse effects; hence, MMF was discontinued. Surprisingly, two days later, the patient's symptoms improved significantly. Upon follow-up, three months later, a repeat MRI of the leg showed near total resolution of the right lower limb muscular oedema, with no recurrence of symptoms.

Discussion: Migratory polyarthritis with myalgias is a rare and usually forgotten side effect of MMF. In 2002, Bart et al. first described an inflammatory reaction in two patients with Wegner's granulomatosis treated with MMF, characterized by fever, arthralgia and myalgia, these symptom resolved within 48hrs of MMF discontinuation 1. This was followed by several other reports, all of which described a pro-inflammatory reaction in the form of migratory polyarthralgia related to MMF. 2 3,4,5,6 In conclusion, a nephrologist should be informed about rare MMF-related side effects, and early intervention should be considered to prevent long-term complications.



TH-PO753

Alfalfa-Induced Acute Cellular Rejection in a Kidney Allograft

Ryan Cullen, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Tacrolimus is an immunosuppressant used in solid organ transplants. Tacrolimus has known drug-drug interactions with a variety of prescripation medications, as well as foods, food extracts, and over the counter supplements. These interactions can cause subtherapeutic or supratherapeutic levels of tacrolimus resulting in suboptimal immunosuppression or nephrotoxicity. We present a case of acute cellular rejection in a renal allograft caused by a drug-drug interaction between tacrolimus and an alfalfa supplement.

Case Description: 56 year old female with history of ESKD secondary to IgA nephropathy, s/p LDKT 1997, DDKT 2015 who presented with subacute cough, poor appetite, and fatigue. She recently returned from a four week trip to Mexico, prior to this she started taking an alfalfa supplement. She denied missing doses of her immunosuppressants tacrolimus and mycophenolic acid. Physical exam was unremarkable. Labs notable for Cr 3.09mg/dL (baseline 0.70-0.80mg/dL), CK normal, UA with bland sediment, UPCR 0.45g/g, Ur Na 29mmol/L, FENA 3.4%. Retroperitoneal US showed increased cortical thickness and mild hydronephrosis of left renal allograft. CT abdomen/pelvis showed perinephric inflammation and mild collecting system dilatation of left renal allograft. She was started on IV fluids but no change in Cr after 24 hours. Further studies showed a tacrolimus level < 1.5 ng/mL, negative CMV DNA, and negative BK DNA. Foley catheter was placed, repeat renal allograft US showed improved hydrouerteronephrosis but no change in Cr. Renal allograft biopsy showed Banff 1B acute cellular rejection, C4D staining negative. Patient was treated with a 3 day course of pulse-dose steroids followed by prednisone taper. She was resumed on her tacrolimus and mycophenolic acid. The alfalfa supplement was discontinued. She was counseled to avoid OTC supplements in the future.

Discussion: Adverse interactions between tacrolimus and other medications have been previously reported, as well as interactions between tacrolimus and foods including grapefruit juice, clementine, tumeric, and cranberry extract. To our knowledge, this is the first reported case of an alfalfa supplement interfering with the metabolism of tacrolimus, resulting in subtherapeutic levels and acute cellular rejection in a kidney allograft. This case demonstrates the importance of counseling patients on the potential harms of over the counter supplements.

TH-PO754

Importance of the Use of Omeprazole and Famotidine in the Development of Chronic Dysfunction of the Kidney Transplant

Milosz Miedziaszczyk, Ilona Idasiak-Piechocka. *Uniwersytet Medyczny im Karola Marcinkowskiego w Poznaniu, Poznan, Poland.*

Background: Tacrolimus is metabolized in the liver with the participation of the CYP3A4 and CYP3A5 enzymes. Proton pump inhibitors are used in kidney transplant patients to prevent duodenal and gastric ulcer disease due to glucocorticoids. Omeprazole, unlike famotidine, is a substrate and inhibitor of the CYP2C19, CYP3A4, CYP3A5 enzymes. The aim of the study is to compare the effect of omeprazole and famotidine on the tacrolimus concentration and risk of developing chronic dysfunction of the kidney transplant.

Methods: A randomized, non-blinded study was conducted in 24 adult patients with stable kidney transplant function who received a standard triple immunosuppression regimen. Patients were assigned to the study group (n=12) additionally receiving omeprazole (20 mg) or the control group (n=12) receiving famotidine (20 mg). At the time of qualification and during follow-up visits, tacrolimus blood concentration and selected laboratory tests were performed. Statistical analysis was performed using the MedCalc system.

Results: A single administration of omeprazole increased tacrolimus concentrations. AUC0-6 amounted to 63.07±19.46 ng×h/mL (day 2) vs 54.23±10.48 ng×h/mL (day 1), (p=0.0295). Conversely, no significant changes were observed for famotidine. The value of creatinine concentration did not change significantly after three years in the study group (1.53±0.50 vs 1.70±0.72, p=0.5071) and in the control group (1.54±0.25 vs 1.50±0.49, p=0.1953). The difference in creatinine concentration values between the groups after three years was not significant (1.70±0.72 vs 1.50±0.49, p=0.6891). The value of tacrolimus concentration in the blood increased after a year in the study group (3.41±1.36 vs. 2.44±1.30, p=0.0101). A reduction in tacrolimus dosage was observed after three years in the study group (3.56±1.75 vs 2.78±1.00, p=0.0440) and in the control group (2.72±0.84 vs 2.10± 0.48, p=0.0051). In one patient in the study group and in the control group, the kidney transplant was rejected due to infection. Both patients are treated with hemodialysis.

Conclusions: Omeprazole significantly increases blood exposure of tacrolimus after single administration and after one year from administration the drug. There was no effect of famotidine or omeprazole on the function of the kidney transplant. ClinicalTrials.gov identifier: NCT05061303.

TH-PO755

Impact of Probiotic Supplementation on Kidney Transplantation Outcomes

Yookyung Jang, Young Eun Choi, Tai yeon Koo, Sewon Oh, Sang-Kyung Jo, Ko Yoon Sook, Lee Hee Young, Myung-Gyu Kim. *Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: The effect of probiotic supplementation on kidney transplantation (KT) outcomes has limited evidence, leading to an unclear understanding of the potential advantages and disadvantages in KT recipients. This study aims to explore the effects of probiotic supplementation on KT outcomes.

Methods: We conducted a retrospective analysis of medical records from 354 KT recipients at Korea University Anam Hospital between January 2010 and December 2020. Only patients who had taken probiotics within 1 year post-KT were included, and transplant outcomes, including graft function, infections, and cardiovascular events, were evaluated 1-3 years after KT.

Results: Of the 354 recipients (mean age: 48.03 years; 31.64% female), 97 received probiotics during the study period, with 36 taking them for >3 months. Probiotic types included Lactobacillus spp. (45.4%), Bacillus subtilis (14.4%), and others (40.2%). The average duration of supplementation was 104.8 days. The probiotics group showed no significant difference in eGFR at 1 and 3 years compared with the non-probiotics group. CMV viremia occurred in 80 patients, with a higher incidence in the probiotics group (35.1 vs. 14.0%). No significant differences were reported in BK viremia or COVID-19 infection. During the study period, 116 patients received antibiotics for >1 week, and the prevalence of bacterial infection was no significantly difference between the two groups. In addition, 15 patients experienced new-onset cardiovascular disease, with no significant difference between the groups. Propensity score matching, employed to address baseline differences between groups also revealed that probiotic supplementation was only significantly associated with the development of CMV viremia, suggesting a potential immunomodulatory effect of probiotics on T-cell function and CMV infection.

Conclusions: This study identified a notable association between probiotic use and CMV viremia after KT. Large-scale prospective studies are needed to comprehensively understand the impact of probiotics on immunocompromised patients and to obtain sufficient evidence for both their safety and effectiveness.

TH-PO756

Recurrence of Anti-nephrin Antibodies Associated Nephrotic Syndrome after Kidney Transplantation

Iman W. Chaudhry, Tariku T. Gudura, Emilio D. Poggio, Kristen Tomaszewski, Itunu O. Owoyemi. Cleveland Clinic Foundation. *Cleveland Clinic, Cleveland, OH.*

Introduction: Minimal change disease (MCD) and focal segmental glomerulosclerosis are podocytopathies characterized by damage to the glomerular basement membrane, leading to nephrotic syndrome. Anti-podocyte antibodies have been proposed as potential circulating factors damaging nephrin, a component of the slit diaphragm. We report a case of recurrent MCD after kidney transplantation associated with anti-nephrin antibodies.

Case Description: A man in his 50s with end stage kidney disease (ESKD) secondary to biopsy proven minimal change disease, treated with steroids, received a deceased donor kidney transplant. He presented eight weeks post-transplant with complaints of shortness of breath and decreased urine output. Labs at presentation were significant for BUN 56 mg/dL, creatinine 1.97 mg/dL (baseline 1.3–1.5 mg/dL), total protein 3.9 g/dL, serum albumin 1.8 g/dL, and urine protein to creatinine ratio (UPCR) of 8.65 mg/mg. Secondary work up for nephrotic range proteinuria was done and was negative. His hospital course was complicated by hemorrhagic shock due to gastrointestinal bleed from an ulcer. He tested positive for H. pylori and was treated. He clinically improved with bleed resolution however nephrotic syndrome persisted prompting a transplant kidney biopsy. Biopsy showed diffuse podocyte foot process effacement with finely granular podocyte staining for IgG. IgG/nephrin immunofluorescence showed overlap of clustered nephrin with punctate IgG, indicative of anti-nephrin antibodies. He received two doses of rituximab 1000 mg with significant reduction in UPCR to 0.95 and serum albumin increase to 3.3 g/dL. Kidney function improved to baseline.

Discussion: In kidney transplant patients, with recurrence of nephrotic syndrome, anti-nephrin antibodies should be considered as a possible contributing etiology. Response to rituximab in this case suggests that B cell targeted therapy may be a reasonable approach of treatment for patients with anti-nephrin associated MCD post-transplant. Interestingly, MCD has been associated with chronic infections. Our patient had H. Pylori infection which was treated prior to B cell therapy. It is unclear how significant that may have been. The role of underlying cause of MCD and anti-nephrin antibodies still needs further exploration.

TH-PO757

Preemptive Kidney Transplantation Trends in Lupus

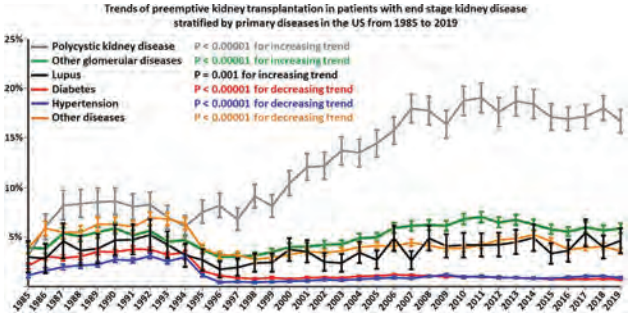
Gabriel Contreras,[1] Javier Pagan,[1] Tali Elfassy,[1] Miguel A. Bandes,[1] Nicolas Bustamante,[2] Mariella O. Goggins,[1] Laura Aponte Becerra,[3] Jair Munoz Mendoza,[1] Yelena Drexler,[1] Shawn Alonso,[1] David Roth.[1] *[1]University of Miami Miller School of Medicine, Miami, FL; [2]Universidad de Ciencias Medicas, San Jose, Costa Rica; [3]Yale University School of Medicine, New Haven, CT.*

Background: The proportion of patients with lupus approaching end-stage kidney disease (ESKD) and undergoing preemptive kidney transplantation (PKT) is <5%, due to concern for poor outcomes. In this study, we describe PKT trends in lupus versus non-lupus patients from 1985 to 2019. We also describe all-cause mortality rate in lupus and non-lupus patients undergoing PKT.

Methods: We included 3,035,161 incident ESKD patients with adequate records in the USRDS. Patients were stratified by their primary diagnosis of ESKD into 6 groups: lupus, polycystic kidney disease (PKD), glomerular diseases excluding lupus (GD), diabetes mellitus (DM), hypertension (HTN), and other diseases (OD). PKT trends were assessed with the Cochran-Armitage test.

Results: Of 33,415 lupus and 3,001,746 non-lupus incident ESKD patients, 1,234 (3.69%) and 68,326 (2.28%) underwent PKT. Lupus versus non-lupus patients undergoing PKT were younger (41 vs. 49 years), more often women (82% vs. 42%), and more frequently received living donor kidneys (64% vs. 52%). PKT trends increased from 1985 to 2019 in the lupus (3.02% to 4.65%, p=0.001), PKD (3.14 to 16.71%, p<0.001), and GD (3.94% to 5.90%, p<0.001) groups and decreased in the DM (2.11% to 0.71%, p<0.001), HTN (1.15% to 0.92%, p<0.001) and OD (3.89% to 3.60%, p<0.001) groups. Among lupus patients, PKT trends increased in those ≥ 50 years of age (1.18% to % 6.73, p<0.001), women (3.11% to 4.83%, p=0.002), Caucasian-Americans (3.78% to 5.26%, p<0.001), and Asian-Americans (0% to 10.61%, p<0.001). Among PKT patients, the mortality rate (per 100 patient-years) was similarly low in lupus (2.59), GD (2.62), PKD (2.20) and OD (2.99) patients, but significantly higher in HTN (6.39) and DM (6.49) patients.

Conclusions: In patients approaching ESKD, PKT trends have increased from 1985 to 2019 in patients with lupus, PKD and GD, most notably in PKD patients. Mortality rates are similarly low in lupus, GD, and PKD patients undergoing PKT.



TH-PO758

Outcomes after Kidney Transplantation in ANCA-Associated Vasculitis

Benoit Brilland,[1] Marine Dekervel,[1] Priscille Traversat,[1] Antoine Thierry,[11] Leonard Golbin,[3] Dominique Bertrand,[12] Emilie Cornec-Le Gall,[4] Giorgina B. Piccoli,[5] Assia Ilham Djema,[6] Nicolas Henry,[7] Agnes Duveau,[1] Dany Anglicheau,[8] Valerie Chatelet Pouliquen,[9] Sophie Caillard,[10] Fabien Duthe,[11] Philippe Gatault,[2] Jean Francois Augusto.[11] Spiesser Group. *[1]CHU Angers, Angers, France; [2]CHU Tours, Tours, France; [3]CHU Rennes, Rennes, France; [4]CHU Brest, Brest, France; [5]Centre Hospitalier du Mans, Le Mans, France; [6]Centre Hospitalier de Cholet, Cholet, France; [7]CH Laval, Laval, France; [8]Assistance Publique - Hopitaux de Paris, Paris, France; [9]Centre Hospitalier Universitaire de Caen Normandie, Caen, France; [10]CHU Strasbourg, Strasbourg, France; [11]Centre Hospitalier Universitaire de Poitiers, Poitiers, France; [12]CHU Rouen, Rouen, France*.

Background: ANCA-associated glomerulonephritis (AAV-GN) frequently leads to end-stage kidney disease (ESKD), requiring replacement therapy with dialysis or kidney transplant (KT). Few large studies evaluated the outcome of these patients after KT. Our aim was to describe, in comparison with a control group, the occurrence of delayed graft function, graft failure, relapse, acute rejection, death; and to study the risk factors associated with these events.

Methods: This was a retrospective, multicenter (8 French centers), observational study including patients who received a KT between 2005 and 2023 for ESKD secondary to AAV-GN. Each vasculitis case receiving a KT was matched with 2 controls, matched on gender, center, recipient age (± 5 years) and transplant period (± 1 year). Event-free survival and the associated risk factors were analyzed.

Results: 474 patients were included, including 158 with AAV-GN and 316 control patients. The median post-KT follow-up for vasculitis patients was 5.3 years. There was no difference in the occurrence of DGF between the groups (17.9 vs 18.3 %, p = 1.0). In multivariable analysis, graft survival tended to be lower in the AAV-GN group compared to the controls (76% vs 81% at 10 years, p = 0.057, **Figure 1A**). 11 patients experienced a relapse after KT. ANCA positivity at the time of transplantation appeared to be correlated with relapse. There was no difference in the incidence of acute rejection between the groups (p = 0.4). In multivariable analysis, overall survival was not significantly lower in AAV-GN patients compared to controls (60% vs 72% at 10 years, p = 0.13, **Figure 1B**).

Conclusions: Kidney transplantation is a valuable option for patients with AAV-GN: the relapse rate is low, and the occurrence of acute rejection is comparable to a population of control patients. However, in AAV-GN, graft survival appears to be poorer when compared to control patients.

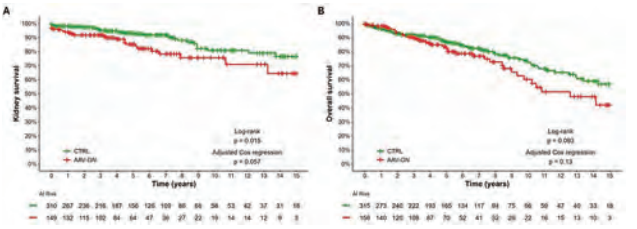


Figure 1. Kidney (A) and overall (B) survival after kidney transplantation.

TH-PO759

Outcomes after Kidney Transplantation in Anti-glomerular Basement Membrane Disease

Benoit Brilland,[1] Priscille Traversat,[1] Marine Dekervel,[1] Philippe Gatault,[11] Antoine Thierry,[10] Emilie Cornec-Le Gall,[3] Leonard Golbin,[2] Agnes Duveau,[1] Giorgina B. Piccoli,[4] Assia Ilham Djema,[5] Nicolas Henry,[6] Dany Anglicheau,[7] Valerie Chatelet Pouliquen,[8] Sophie Caillard,[9] Fabien Duthe,[10] Dominique Bertrand,[12] Jean Francois Augusto.[1] Spiesser Group. *[1]CHU Angers, Angers, France; [2]CHU Rennes, Rennes, France; [3]Centre Hospitalier Regional et Universitaire de Brest, Brest, France; [4]Centre Hospitalier du Mans, Le Mans, France; [5]Centre Hospitalier de Cholet, Cholet, France; [6]CH Laval, Laval, France; [7]Assistance Publique - Hopitaux de Paris, Paris, France; [8]Centre Hospitalier Universitaire de Caen Normandie, Caen, France; [9]CHU Strasbourg, Strasbourg, France; [10]Centre Hospitalier Universitaire de Poitiers, Poitiers, France; [11]CHU Tours, Tours, France; [12]CHU Rouen, Rouen, France*.

Background: Anti-glomerular basement membrane antibody disease-associated glomerulonephritis (GBM-GN) frequently leads to end-stage kidney disease (ESKD), requiring replacement therapy with dialysis or kidney transplant (KT). Few studies evaluated the outcome of these patients after KT. Our aim was to describe, in comparison with a control group, the occurrence of the following events: delayed graft function recovery, graft survival, relapse, acute rejection, overall survival; and to study the risk factors associated with these events.

Methods: This was a retrospective, multicenter (8 French centers), observational study including patients who received a KT between 2005 and 2023 for ESKD secondary to GBM-GN. Each vasculitis case receiving a KT was matched with 2 controls, matched on gender, center, recipient age (± 5 years) and transplant period (± 1 year). Event-free survival and the associated risk factors were analyzed.

Results: 165 patients were included, including 55 with GBM-GN and 110 control patients. The median post-KT follow-up for vasculitis patients was 8.3 years. There was no difference in the occurrence of DGF between the groups (22.2 vs 18.3%, p = 0.61). In multivariable analysis, there was no difference in graft survival when comparing both groups (80% vs 81% at 10 years, p = 0.7) (**Figure 1A**). Only one patient experienced a relapse after KT (being anti-GBM negative at the time of transplantation). There was no difference in the incidence of acute rejection between the groups (p = 0.3). In multivariable analysis, there was no difference in overall survival when comparing both groups (87% vs 85% at 10 years, p = 0.3) (**Figure 1B**).

Conclusions: Kidney transplantation is a valuable option for patients with GBM-GN: outcomes are similar to those of a matched population with similar occurrence of acute rejection, graft loss or death.

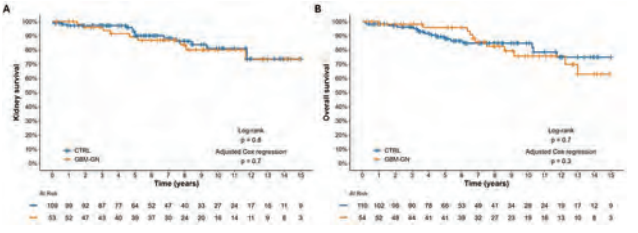

Figure 1. Kidney (A) and overall (B) survival after kidney transplantation.

Acute Rejection and Relapse of Native Disease in Kidney Transplant Recipients with ESKD from ANCA-Associated Vasculitis: Insights from a Single-Center Study

Nada Youssef, Melissa L. Swee, Sarat C. Kuppachi. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a rare systemic autoimmune disease characterized by necrotizing inflammation of small blood vessels leading to end-organ damage. Up to 40% of AAV patients progress to end-stage kidney disease (ESKD), necessitating renal replacement therapy. The long-term outcomes of patients with AAV after renal transplantation are not well described. Our study aims to evaluate biopsy proven acute rejection (BPAR) and relapse of AAV following transplantation at our center.

Methods: We retrospectively reviewed all patients with ESKD secondary to AAV who underwent a kidney transplant at the University of Iowa between January 2000 and October 2023. 33 kidney transplants were completed in 30 patients.

Results: Among the 33 transplant episodes, 18 grafts were from deceased donors, 3 from living unrelated donors, and 12 from living related donors, including an identical twin. 3 patients (9%) developed AAV relapse between 4 and 117 months after transplantation and, all had p-ANCA sub-type of AAV. None required dialysis or lost their graft. 9 patients (27%) developed BPAR between 2 and 178 months after transplant. Of these, 5 had p-ANCA, 2 c-ANCA, and 2 had unknown sub-types. 5 of the 9 developed graft failure requiring dialysis (15%). 3 patients died with functioning graft, 1 after rejection treatment, 1 after relapse of AAV and one of non AAV disease (42, 92 and 120 months after transplant).

Conclusions: Our data indicates transplant and overall survival rates in patients with ESKD secondary to AAV are comparable to those receiving kidney transplants for ESKD due to other causes. AAV relapse after kidney transplantation is uncommon but appeared exclusively in patients with the p-ANCA subtype and those who received IL-2RA or no induction. Kidney transplantation remains a viable and effective treatment option for these patients and larger database analysis are necessary to better characterize those at risk for disease relapse and BPAR.

	All Patients (n=30)	Patients with Relapse (n=3)

Two Cases of Recurrence Immediately after Living Donor Kidney Transplantation for ANCA-Associated Vasculitis (AAV)

Yusuke Shimanaka, Aya Kaito, Tetsuro Takeda. *Dokkyo Medical University Saitama Medical Center Department of Nephrology, Saitama, Japan.*

Introduction: Rituximab, the standard treatment for AAV, reduces B cells and suppresses antibody production, thus contributing to the prevention of AAV recurrence. The two cases presented here are precious cases of recurrent AAV immediately after kidney transplantation (KT).

Case Description: [Case 1] A 24-year-old woman diagnosed with AAV 7 years ago, was treated with steroid pulse therapy, plasma exchange, and rituximab, but her renal function declined, and she was introduced to hemodialysis four years ago. MPO-ANCA remained positive, and a blood group-mismatched living donor KT was performed with her aunt as donor. On postoperative day 8, serum creatinine worsened to 2.16 mg/dL and kidney biopsy revealed tuft necrosis. She was considered to have recurrent AAV and creatinine improved to 1.57 mg/dL with steroid pulse and plasma exchange. Repeat biopsy after KT showed still tuft necrosis and fibrocellular crescents. After administration of avacopan, creatinine remained at 1.5-1.7 mg/dl. [Case 2] A 23-year-old woman diagnosed with AAV 18 months ago, was treated with steroid pulse therapy and rituximab, but kidney biopsy showed devastated glomeruli and fibrous crescents, and hemodialysis was introduced. MPO-ANCA remained positive, and a blood group-matched living donor KT was performed with her mother as donor. On postoperative day 4, creatinine deteriorated to 3.34 mg/dL and biopsy showed focal fibrinoid necrosis and cellular crescents. She was diagnosed to have recurrent AAV and was treated with steroid pulse, plasma exchange, cyclophosphamide pulse, and abacopan. Proteinuria and hematuria resolved, and creatinine improved to 1.49 mg /dL.

Discussion: The recurrence rate of AAV after KT is reported to be about 10%, and even if recurrence occurs, treatment is successful with intensified immunosuppressive therapy, making KT highly beneficial. ANCA antibody titer before KT does not affect the recurrence rate, so KT should not be postponed because of ANCA positivity. However, KT within one year of remission is associated with increased mortality. Among cases presenting with RPGN, relapse is reported to be more common in ANCA-positive cases than in non-positive cases. The fact that AAV recurred immediately after administration of rituximab, also used in KT, suggests that the MPO-ANCA-producing cells may have already changed from B cells to plasma cells.

Changing the Tides in Hawaii: Recurrent IgA Nephropathy in an Isograft on the 70th Anniversary of the First Successful Twin Transplantation

Chinnawat Arayangkool, Akiko Tokunaga, Lisa Kim. *University of Hawai'i System, Honolulu, HI.*

Introduction: IgA nephropathy (IgAN) is the most common primary glomerulopathy globally and also most common to recur after transplantation. While a pediatric screening program for IgAN is not standard in the United States, it is routine in several Asian countries. We report a case of presumed recurrent IgAN in a monozygotic twin and question the status quo for screening in Hawaii.

Case Description: A 36-year-old Asian male with history of living related renal transplant (LRRT) from twin brother underwent allograft biopsy for increasing proteinuria and hematuria. Serum creatinine (SCr) and eGFR were stable (Chart 1). Four years prior he presented to his PCP with tension headaches and found hypertensive 191/99 mmHg, SCr 6.0 mg/dL with eGFR 11 mL/min/1.73m(2). His brother was confirmed as a monozygous twin without hypertension, proteinuria or hematuria. LRRT was performed 18 months after initial presentation. He received basiliximab induction and tacrolimus with immediate graft function and discharged on post op day 4. One year post transplant immunosuppression was weaned off. The allograft biopsy showed no evidence of acute cellular or antibody-mediated rejection but was consistent with recurrent IgAN (MEST-C score M1, E0, S0, T0, C0). Mycophenolate mofetil was started with decrease in proteinuria. Two years post donation his brother continued without proteinuria or hematuria.

Discussion: In 1954, the first twin transplantation or "isograft" was considered a success after 8 year graft survival. Yet, in the following 70 years there remain uncertainties about prevention of recurrent disease, especially IgAN. Our case exemplifies the need for earlier detection and prevention of end stage kidney disease in early adulthood. Further studies are warranted in a high multi-ethnic Asian population like Hawaii to assess the benefit of a screening program for IgAN.

TH-PO763

Successful Kidney Transplantation in Dent Disease

Adnan Barazi, Kalathil K. Sureshkumar. *Allegheny Health Network Graduate Medical Education, Pittsburgh, PA.*

Introduction: Dent disease is a rare X-linked recessive condition due to inactivating mutation in CLCN5 or OCRL1 gene resulting in proximal tubular dysfunction that primarily affects young men characterized by low molecular weight (LMW) proteinuria, hypercalciuria, recurrent kidney stones, nephrocalcinosis and progressive kidney failure. Only ~ 250 families have been identified with these mutations. We present a patient with Dent disease from CLCN5 mutation and kidney failure who underwent successful kidney transplantation from a living donor.

Case Description: A 51-year-old male with long-standing proteinuria, recurrent kidney stones, progressive chronic kidney disease (CKD) on peritoneal dialysis for 2 years with kidney biopsy evidence for secondary focal segmental glomerulosclerosis was evaluated for kidney transplantation. His brother also was experiencing recurrent kidney stones and CKD. Genetic test on the patient revealed mutation in CLCN5 gene consistent with Dent disease type 1. Patient was not sensitized, IgG negative for CMV but positive for EBV and underwent living unrelated kidney transplantation from a 4 HLA mismatched donor who was IgG negative for CMV and positive for EBV. Thymoglobulin was used for induction followed by tacrolimus/mycophenolic acid maintenance. Patient received infection prophylaxis with acyclovir, nystatin and trimethoprim-sulfamethoxazole. There was prompt allograft function (figure1).

Discussion: Our case illustrates the importance of genetic testing especially in young patients with family history of kidney disease. This will help in arriving at correct diagnosis and to advise genetic screening of immediate family members. Since end-organ damage in Dent disease is renal-limited, kidney transplantation is curative. Female family members are carriers, can have low grade LMW proteinuria and could develop future mild kidney failure. Caution should be used while evaluating female family members as potential living donors.

Typical! Atypical Hemolytic Uremic Syndrome (aHUS) Overlooked in Malignant Hypertension and Thrombotic Microangiopathy: Case Reports and Clinical Implications

Norhan Elsayed, Michael Allevato, Brian R. Stephany, Raviprasenna K. Parasuraman. *University of Michigan, Ann Arbor, MI.*

Introduction: Thrombotic microangiopathy (TMA) is a clinicopathologic manifestation of atypical HUS (aHUS) and often overlooked in patients with malignant hypertension (MH) leading to a delay in diagnosis. Prompt diagnosis of aHUS can significantly improve patient outcomes, especially in the setting of kidney transplantation where recurrent disease can occur rapidly in the allograft. Here we describe two cases of patients with severe HTN and TMA: one where aHUS was diagnosed and managed with eculizumab prior to kidney transplantation and one where the diagnosis was masked by other clinical features and ultimately resulted in recurrence after transplant.

Case Description: Case 1: A 34 y/o woman with CKD due to Class IV lupus nephritis presented with hypertensive emergency with native kidney biopsy also showing features of TMA. Genetic testing for aHUS revealed variants of unknown significance in CD46 (membrane co-factor protein). She later underwent a renal transplant with immediate graft function, but soon after developed allograft dysfunction with hematological features of TMA confirmed by biopsy. Other causes of TMA were ruled out leading to a diagnosis of aHUS. She was treated with eculizumab emergently and had normalization of allograft function. Case 2: A 32 y/o woman presented with hypertensive emergency and cardiomyopathy during the postpartum period and was found on biopsy to have chronic TMA. Genetic testing revealed a homozygous variant in the CFI gene, a variant of unknown significance in the THED gene, and a homozygous deletion of CFHR3-CFHRI. She was treated with eculizumab prior to transplantation and had a stable post-transplant course without recurrent disease.

Discussion: It can be challenging to determine whether TMA is due to MH or underlying aHUS caused by derangement in the alternative complement pathway. It has been estimated that 20% of MH patients who require hospital admission have TMA features and 60% of these patients may have underlying aHUS when genetic testing was performed. We believe it is crucial to obtain genetic testing for aHUS in patients with severe HTN and TMA to help distinguish these conditions and improve patient outcomes by making the diagnosis of aHUS, guiding treatment options, facilitating genetic counseling and preventing recurrence of TMA in renal allografts.

Successful Use of Eculizumab for Prevention of Atypical Hemolytic Uremic Syndrome Recurrence in a Pregnant Kidney Transplant Recipient with CFH Gene Mutation: A Case Report and Literature Review

Somaya Zahran,[1] Thomas Nodzynski,[2] Catherine Matte,[3] Shaifali Sandal,[1] Tiina Podymow,[1] Marcelo Cantarovich.[1] [1]*McGill University, Montreal, QC, Canada;* [2]*Hopital general du Lakeshore, Pointe-Claire, QC, Canada;* [3]*Anna Laberge Hospital, Montreal, QC, Canada.*

Introduction: Eculizumab is a humanized monoclonal antibody targeting C5, used in the treatment of atypical hemolytic uremic syndrome (aHUS). It is accepted as maintenance therapy for the prevention of recurrent aHUS post kidney transplant (KTx), however, clinical experience with its use during pregnancy is limited.

Case Description: 36-year-old woman with history of end stage renal disease secondary to aHUS with confirmed complement factor H gene mutation was treated with hemodialysis, plasmapheresis, rituximab and vincristine. She received a standard-criteria deceased donor KTx in 2013. Eculizumab was administered in the perioperative period at a dose of 1200 mg IV, followed by 1200 mg Q1W for 2 weeks, and then Q2W thereafter as maintenance therapy. In 2016, she had a planned pregnancy during which eculizumab was continued. Biomarkers of hemolysis and kidney function were closely monitored. Despite the development of pre-eclampsia resulting in preterm delivery at 33W, the patient delivered a healthy infant and had well-preserved allograft function with no aHUS recurrence. 8 years later, no complications are observed and her child is developing normally. Pubmed search was conducted for reports of prophylactic use of eculizumab in aHUS pregnant KTx recipients between 1993 and 2024. 35 articles were found, of which, three fulfilled our criteria (table 1).

Discussion: Although eculizumab is considered safe during pregnancy, its use in pregnant KTx recipients is rare given the lack of relevant pharmacological data and unknown long-term effects on the offspring. We report for the first time, 8-year follow up favorable maternal and fetal outcomes and provide a literature review of similar cases. We conclude that maintenance eculizumab is a plausible option for prevention of aHUS recurrence in pregnant women who received KTx. Close monitoring of hemolytic markers and kidney function is recommended to ensure early detection and management of complications.

Article	# of cases	Patient characteristics	Genetic testing	Pre-conception immunosuppression	Eculizumab dose			Monitoring during pregnancy	Pregnancy complications	Pregnancy outcome

TH-PO766

The Secret Ingredient for Isolated Kidney Transplantation with Primary Hyperoxaluria: A Case Report

Sarah Hryzak,[1] Christopher R. Showers,[1] Zahra Ahmad,[2] Olivia Atlas,[1] Katie Hummel,[1] Samir Abu Gazala,[1] Sabiha M. Hussain.[1] [1]*Hospital of the University of Pennsylvania, Philadelphia, PA;* [2]*University of Pennsylvania, Philadelphia, PA.*

Introduction: Primary hyperoxaluria is defined by a group of autosomal recessive conditions that cause alteration of oxalate metabolism leading to complications such as kidney failure. Simultaneous liver-kidney transplantation (SLKT) has been the treatment of choice for primary hyperoxaluria however newer therapies with RNA interference (RNAi) may offer alternative options. Here we outline both the utilization of RNAi therapy as well as specifics of perioperative kidney replacement therapies for successful isolated kidney transplant (KT).

Case Description: 25-year-old with hypertension diagnosed with primary hyperoxaluria at nine months old experienced multiple kidney stones and eventually progressed to advanced kidney disease. She was treated with pyridoxine with reduction in nephrolithiasis. She then received Lumasiran injections for 23 months prior to receiving KT. Plasma oxalate levels were monitored and a level of ≤20umol/L was targeted prior to KT. To achieve this, one week prior to KT, patient underwent daily four-hour hemodialysis sessions for five consecutive days to optimize oxalate clearance. She then underwent isolated living-unrelated KT with immediate graft function followed by three consecutive days of hemodialysis (Figure1). Patient was induced with thymoglobulin and maintained on tacrolimus, mycophenolate and prednisone. She required no further treatments and continues to have excellent allograft function with creatinine of 1.2mg/dL seven months post KT.

Discussion: Primary hyperoxaluria is a devastating disease that for decades has been treated with SLKT. This case highlights the ability to avoid dual organ transplantation and provides granular details of perioperative renal replacement management utilized for a successful KT. By continuing to expand our knowledge on treatment for primary hyperoxaluria, we can reduce risks associated with multi-organ transplantation as well as increase organ availability worldwide.

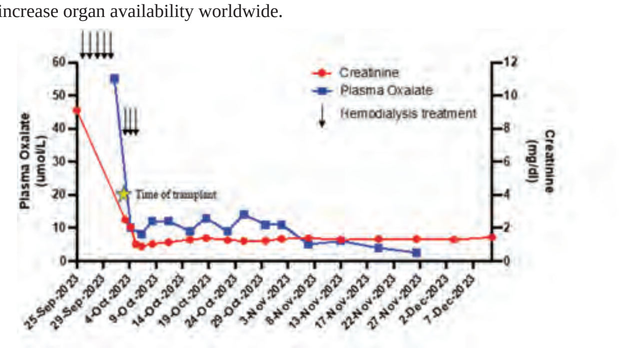

Figure 1 Measured serum creatinine levels (mg/dl) and plasma oxalate levels (umol/L) before, during, and after time of isolated kidney transplantation with timing of dialysis treatments outlined.

TH-PO767

Less Is More: A Case of Isolated Kidney Transplantation with Lumasiran in Primary Hyperoxaluria Type 1

Alissa A. Ice, Muhammad J. Azam, Anthony J. Langone. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Primary hyperoxaluria type 1 (PH1) is a rare autosomal recessive disorder of hepatic glyoxylate metabolism. Consequently, it results in the overproduction of oxalate causing nephrolithiasis, nephrocalcinosis, and CKD. In the setting of kidney failure, generally simultaneous liver and kidney transplantation is recommended. Given the pathophysiology with high risk for recurrent allograft involvement and previous lack of effective therapies, there are very few cases of kidney-only transplantations in these patients. We present an exceedingly rare case illustrating the essential role of lumasiran, a small interfering RNA agent, in PH1 kidney-only transplantation.

Case Description: A 41 year old male with PH1 and subsequent ESRD, HTN, developmental delay, and history of a resected paraganglioma underwent a deceased kidney donor transplantation. Notably, he developed nephrolithiasis at the age of 13 and underwent lithotripsy at age 26 prior to his PH1 diagnosis. Hemodialysis and lumasiran were initiated three years prior to his transplantation, with plasma oxalate levels ranging between 13-65 mcmol/L during this timeframe. He received alemtuzumab and solumedrol induction with immediate graft function followed by maintenance tacrolimus, mycophenolate, and prednisone. In addition to hyperhydration, low oxalate diet, and pyridoxine, he was continued on his lumasiran injections. Within the first month posttransplantation, his plasma oxalate level became undetectable and creatinine was 0.9.

Discussion: PH1 is characterized by a mutation in the alanine glyoxylate aminotransferase gene, which encodes for the hepatic peroxisomal enzyme AGT and results in increased glyoxylate production and thus oxalate. The first drug to treat PH1, lumasiran, was FDA approved in 2020, targeting glycolate oxidase and thereby decreasing oxalate synthesis. Although it does not affect the systemically stored oxalate release, this case highlights the favorable decline in plasma oxalate levels even without prophylactic posttransplantation dialysis that a few cases have employed. This clinical vignette illustrates that patients with PH1 can receive a successful kidney transplant without a concomitant liver transplant in the setting of aggressive medical management, including the novel agent, lumasiran.

TH-PO768

Clinical Characteristics and Outcomes of Kidney Transplantation in Patients with Autosomal Dominant Polycystic Kidney Disease

Jin Hyeog Lee, Sung Jin Moon. *Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea.*

Background: Kidney transplantation (KT) is the best treatment for autosomal dominant polycystic kidney disease (ADPKD). We aimed to investigate clinical characteristics and outcomes of KT in ADPKD patients compared to those in non-ADPKD patients.

Methods: We retrospectively analyzed KT recipients in two Korean transplantation centers A propensity score-mactching and Cox regression analysis were used to assess the clinical outcomes of ADPKD compared to non-ADPKD and prognostic factors influencing outcomes in ADPKD.

Results: Among a total of 4,452 KT patients, 189 (4.2%) were ADPKD patients. In both groups, living-donor KT were more common than deceased-donor KT. The ADPKD group had a 4.09-fold higher risk of post-transplant diabetes mellitus and a 1.65-fold higher risk of post-transplant infection compared to the non-ADPKD group; however, it had similar risk of rejection, graft failure, and mortality. In the ADPKD group, kidney volume decreased after KT irrespective of kidney volume status, while size of hepatic cyst increased. Either kidney volume or nephrectomy of native kidneys was not associated with risk of infection, graft failure, or mortality in the ADPKD group.

Conclusions: ADPKD patients have a higher risk of post-transplant diabetes mellitus and infection than non-ADPKD patients without a significant impact of kidney volume or nephrectomy on post-transplant outcomes.

A Case of Omeprazole-Associated Tubular Disease with Subsequent Kidney Transplant

Christopher B. Gitter, Badi Rawashdeh, Anna R. Gaddy. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Anti-tubular basement membrane (anti-TBM) antibody disease is an extremely rare disease characterized by the direct exposure of the renal tubular cell basement membrane, focused in the proximal tubule. Diagnosis is one of exclusion and treatment is generally similar to that of anti-glomerular basement membrane disease. Only one case of anti-TBM disease undergoing transplant has been reported.

Case Description: A 50 year old male presented to a tertiary care center for orthostatic hypotension and was found to have worsening of prior AKI. In the year prior to presentation, patient underwent extensive workup for esophageal dysmotility and was started on omeprazole three months prior to admission. One month prior to admission, patient presented to outside hospital for rash and AKI and was diagnosed with acute interstitial nephritis (AIN) with "unusual linear C3 deposition along basement membrane" attributed to omeprazole therapy. Physical exam showed diffuse macular rash and purpuric lesions on lips. Urinalysis demonstrated mild proteinuria, without hematuria or casts. Patient underwent native kidney biopsy which demonstrated extensive acute interstitial nephritis with linear IgG and C3 immunofluorescence staining of the tubular basement membranes. The patient underwent plasma exchange and was started on cyclophosphamide plus glucocorticoids. Clearance remained poor and the patient required maintenance dialysis. Due to polyuria, glucosuria, and orthostasis, the patient required high dose fludrocortisone and salt tablets and ultimately underwent bilateral renal artery glue embolization in an attempt to minimize wasting. Ultimately, the patient underwent uncomplicated deceased brain death kidney transplant, where graft biopsy was performed prior to anastomoses. Methylprednisone and anti-thymocyte were used

for induction, with maintenance regimen of tacrolimus, mycophenylate mofetil, and prednisone started prior to discharge.

Discussion: Initial patient presentation remained consistent with AIN, however his continued polyuria likely was a result of extensive proximal tubular damage as demonstrated on biopsy. This case may represent the second case of successful kidney transplant in a patient with this disease presentation. Repeat graft biopsy as follow-up for kidney transplant may be beneficial in understanding further disease presentation and progression.

TH-PO770

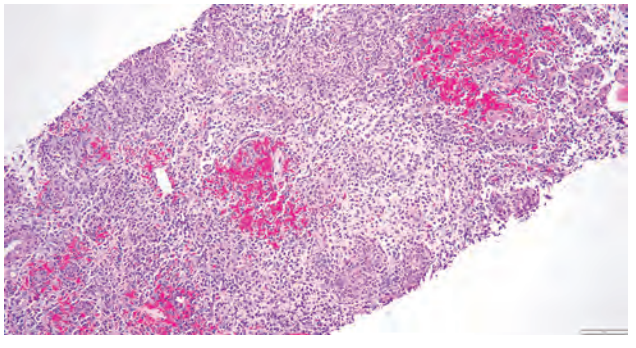
Post-transplant Granulomatous Tubulointerstitial Nephritis (GIN)

Fausto R. Cabezas, Andrea Roche-Recinos, Subodh J. Saggi, Yihe Yang.
SUNY The State University of New York, Albany, NY.

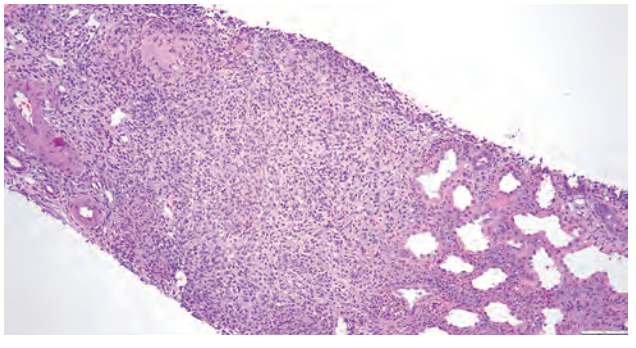
Introduction: GIN is identified in less than 1% of allograft biopsies. We describe a case of GIN contributing to graft failure.

Case Description: A 69-year-old man with ESKD of unknown etiology & liver failure from concomitant hepatitis B/C infection received a Simultaneous Liver-Kidney Transplant in 2017. He previously underwent a Living Unrelated Kidney Transplant in 2007. Recently, Serum creatinine (sCr) increased from 2.9 mg/dl to 4.3 mg/d with nephrotic range proteinuria (UPCR 6.0 GR/GR) and urinalysis showing pyuria (WBC 49) with no hematuria. He required hemodialysis given declining allograft function. An allograft biopsy (Images) showed acute pyelonephritis with non-necrotizing granulomata and negative AFB stain. Occasional collapsing lesions are identified in the glomeruli. And recurrent diabetic nephrosclerosis was also identified. We were unable to prove active tuberculosis infection.

Discussion: GIN is commonly associated infectious agents in up to 60% of cases. The etiology GIN in this patient is likely multifactorial. His second post-transplant course was complicated with recurrent urinary tract infections, antibody mediated rejection, and most recently, an episode of cellular mediated rejection treated with corticosteroids and thymoglobulin. However, granulomata in the interstitium rarely cause nephrotic range proteinuria. The observed proteinuria is attributed to collapsing lesions and concurrent diabetic kidney disease. De novo collapsing lesions, which can appear in 10-20% of kidney allografts, are linked to several risk factors including: high-risk ApoL1 genotype, viral infections such as HIV, SARS-CoV-2, CMV, EBV and BK virus, recent or active rejection, and acute vaso-occlusion.



Allograft biopsy. H&E stain, 200x magnification.



TH-PO771

Trends in 1-Year Outcomes among Kidney Transplant Recipients, by Time since Transplant

David T. Gilbertson,[1,2] James B. Wetmore,[1,2] Jiannong Liu,[1] Nicholas S. Roetker,[1] Kirsten L. Johansen.[1,2] *[1]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Trends in 1- and 5-year outcomes after kidney transplant (KTx) have improved over the last 20 years, trends that could be driven in part by increasing prevalence of long-term KTx survivors over time. We examined trends in rates of 1-year death and graft loss among KTx recipients, overall and by time since KTx.

Methods: We selected point prevalent deceased-donor KTx recipients on Jan 1 of each year, 2000-2019. In each cohort, we examined 1-year death and death-censored graft loss rates. We estimated unadjusted and adjusted rates overall and by time since KTx. Adjustors were age, sex, race, ESKD cause and pre-KTx dialysis vintage.

Results: Before adjustment, patient survival showed little change over time, whereas adjusted analyses show improvement (Fig 1). Death-censored graft loss improved over time, regardless of adjustment. Fig 2 shows adjusted 1-year death (top) and graft loss (bottom) rates by time since KTx, for 2000, 2010 and 2019. After 2 years post-KTx, death and graft loss rates increased by time since transplant, as expected. However, rates of both outcomes were lower in 2010 and 2019 relative to 2000, irrespective of the years since transplant.

Conclusions: Adjusted rates of death and death-censored graft loss in the year following KTx have improved over time, an important finding given that older patients and those with more comorbidities are now more likely to receive a KTx than in the past. Adjusted outcomes are better in 2019 than in 2000, irrespective of the time since KTx.

TH-PO772

Comparative Survival Outcomes of Kidney Transplantation vs. Ongoing Dialysis in Extremely Elderly Patients: A Matched-Pair Study

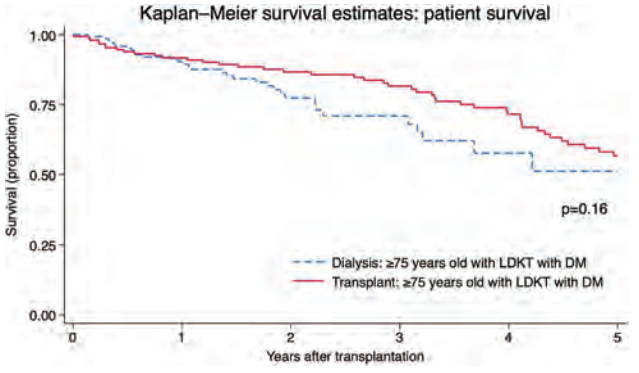
Napat Leeaphorn,[1] Rose Mary Attieh,[1] Oscar A. Garcia Valencia,[2] Wisit Cheungpasitporn,[2] Tambi Jarmi.[1] *[1]Mayo Clinic Florida, Jacksonville, FL; [2]Mayo Clinic Minnesota, Rochester, MN.*

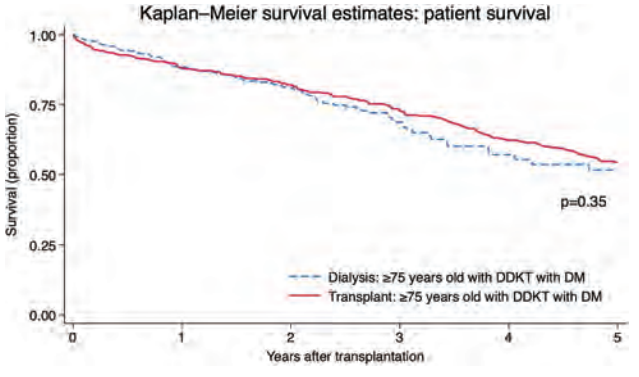
Background: Limited data exists on the outcomes of kidney transplantation (KT) in extremely elderly patients.

Methods: Using the OPTN database between 2005 and 2019, elderly recipients who were on dialysis before KT were stratified into two groups: 70-74 and ≥75 years old. These recipients were then exactly matched to waitlisted dialysis patients by age at the start of dialysis, race, diabetes status, functional status, and duration on inactive status while on the waitlist (WL). Propensity matching was used for the remaining variables.

Results: Recipients aged 70-74 had a 37% lower risk of death compared with WL candidates of the same age (HR=0.63, p<0.001). This age group benefited from KT regardless of their diabetes status and transplant type. Recipients aged ≥75 had an overall 20% lower risk of death compared with WL candidates (HR=0.80, p=0.001). However, no significant difference in mortality risk was observed in diabetic patients within this age group (HR=0.85, p=0.15). When analyzed by transplant type, there was a trend towards reduced mortality in diabetic living donor KT recipients aged ≥75, though it did not reach statistical significance (HR=0.72, p=0.16). No difference in mortality was found for diabetic deceased donor KT recipients aged ≥75 compared to those on the WL (HR=0.89, p=0.35).

Conclusions: KT provides a significant decrease in mortality risk compared to dialysis among individuals aged 70-74 with ESRD on the WL, as well as non-diabetic patients aged ≥75. However, the advantage of KT becomes less evident in diabetic patients aged ≥75, particularly those without living donors.





TH-PO773

Kidney Transplant Outcomes in Patients with BMI of 35 or Greater: Should We Be Doing More? A Single-Center Experience

Arjun Sabharwal, Arif Khwaja, Jacob W. Whatmore. *Northern General Hospital Sheffield Kidney Institute, Sheffield, United Kingdom.*

Background: Obesity remains a key barrier to access to kidney transplantation. Large registry data shows that whilst obese patients have poorer graft survival compared to those with a normal BMI, they still have a survival advantage when compared to outcomes on dialysis. However, it is not clear whether there are similar outcomes in smaller transplant centers. We therefore conducted a single-center audit evaluating transplant outcomes in patients with BMI ≥ 35 at the time of transplant at the Sheffield Kidney Institute, UK from 2010-2023.

Methods: This single center, retrospective study looked at death censored graft survival, medical and surgical complications for a total of 53 patients who were transplanted from 2010 to 2023 with a BMI ≥ 35 kg/m2 at the time of transplant.

Results: A total of 53 transplants were done in the time period in patients with a BMI ≥ 35. The recipient mean age was 58 years (SD 10.7) with a mean BMI of 36.8 kg/m2 (Range: 35-40.9) at the time of transplant. Most common primary disease was IgA Nephropathy(n=11) followed by Diabetic Nephropathy (n=8). Graft failure was observed in 10 patients (18.8%) and 13 (24.6%) died with a functioning graft out of a total 53 transplants. In the 38 patients who had at least 5 years follow up, 23 (60.6%) had a functioning graft and there were 6 graft failures (15.8%) over a median follow up of 6.29 years. Average eGFR for those with functioning grafts were 53.9 ml/min/1.73m2 with a mean graft survival age of 6.8 years. In terms of medical complications 6 (11.3%) had a biopsy proved rejection, 28 (52.8%) had a delayed graft function, post-transplant CMV was seen in 3 patients. New onset diabetes after transplant was observed in 11(28.9%) patients. Six % of grafts failed in the first 3 months. Wound infection was the most common surgical complication n=8 (15.1%) and the average length of stay in hospital was 7.8 days. Readmission rates within 30 days were n=11(20.7%).

Conclusions: Patients with BMI ≥ 35 do have increased medical and surgical complications including NODAT, delayed graft function and wound infection but can be successfully transplanted. Careful patient selection and optimisation may further improve transplant in obese recipients. Patients in smaller centres should not be denied transplantation based on BMI alone and a thorough assessment by the surgeon should be done for them.

TH-PO774

Outcomes among Hispanic Kidney Transplant Recipients Including Non-US Citizens

Sixto G. Giusti, Susana Arrigain, Rocio Lopez, Marco Ramos, Marko A. Karakadze, Lilia Cervantes, Jesse D. Schold, Elizabeth A. Pomfret. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

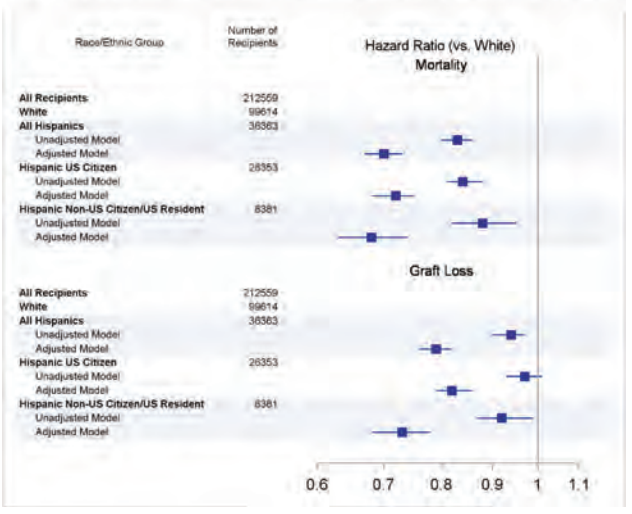
Background: Hispanics experience a faster progression of CKD to kidney failure compared to non-Hispanic Whites (NHW). They are also less likely to receive pre-dialysis nephrology care, be referred for transplant evaluation, be listed for transplant, and receive a transplant. This study compares transplant outcomes between Hispanic individuals and NHW, to demonstrate the benefit of increasing access to transplantation to this patient population.

Methods: We evaluated kidney transplant recipients from 2010-2021 using the SRTR data. For the main outcomes we compared time to post-transplant patient mortality and graft failure between Hispanic and NHW recipients using Cox proportional models adjusted for donor and recipient characteristics.

Results: Among 212,559 kidney recipients, 17% were Hispanic and 47% were NHW. Among Hispanics, 27.5% were non-US citizens. Hispanic recipients were younger than NHW recipients (mean age 48.8+14.1 vs. 53.5+14.0). The average wait list months for Hispanics was 18.4 compared to 12.7 for NHW recipients. 28% of Hispanics had private health insurance compared to 42% of NHW. In adjusted models, Hispanics had a lower HR of death and graft failure compared to NHW recipients (HR=0.70, 95 % CI: 0.67, 0.73, and HR=0.79, 95% CI: 0.76, 0.82, respectively). We found similar results when comparing Hispanic non-US citizens to NHW recipients (HR=0.68, 95 % CI: 0.63, 0.74, and HR=0.73, 95% CI: 0.68, 0.78; Figure 1).

Conclusions: Despite many social and economic challenges and irrespective of citizenship status, Hispanic transplant recipients had a lower HR of death and better graft survival compared to NHW transplant recipients. Future studies that focus on reducing disparities throughout the transplant process and improve access to transplantation in this population are warranted.

Figure 1. Unadjusted and Adjusted Hazard Ratios of Mortality and Graft Failure



TH-PO775

Death and Kidney Failure in 3-Year Survivors of Kidney Transplantation: Influence of Prior Changes in eGFR

Finnian R. McCausland,[1,2] Martina M. McGrath,[1,2] Brian Claggett,[1,2] Edgar L. Milford,[1,2] Andrew S. Levey,[3] Marc A. Pfeffer.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Tufts Medical Center, Boston, MA.*

Background: Kidney transplant recipients (KTRs) continue to experience high rates of allograft failure and death. We explored if changes in eGFR between the first and third year post-transplant could identify patients at higher risk for subsequent allograft failure and death.

Methods: From 149,058 adult KTRs in the UNOS database who received a first kidney transplant from 2009-2019, we included 109,198 who survived to 3 years post-transplant with a functioning allograft and available baseline and follow-up (1- and 3-year post-transplant) serum creatinine. We calculated eGFR using the 2021 CKD-EPI equation and used Cox models, landmarked at 3-year post-transplant, to explore the association of eGFR decline (<0, 0-<5, and ≥5 mL/min/1.73m^2/year) with subsequent development of the composite of allograft failure or death (median follow-up 3.5 yrs). Models were adjusted for age, sex, race, diabetes, BMI, baseline eGFR, graft vintage, and donor status (living/cadaveric).

Results: During the two-year exposure period, 50,796 (44%), 33,611 (31%), and 24,791 (23%) experienced eGFR decline <0, 0-<5, and ≥5 mL/min/1.73m^2/year, respectively. Patients in the highest category of eGFR decline were more likely to be younger, female, Black, diabetic, received a cadaveric donor, have lower BMI, yet higher baseline eGFR. Overall, beginning 3 years post-transplant, 31,302 (23%) of patients developed allograft failure or death. Compared with eGFR decline <0, patients experiencing an annual decline >5 mL/min/1.73m^2 had a 2.6-fold (HR 2.62; 95%CI 2.55, 2.70) higher adjusted risk of allograft failure or death (Table 1).

Conclusions: In a contemporary cohort of KTRs, who survived at least 3 years post-transplant, rates of subsequent allograft failure and death remain unacceptably high. An eGFR decline >5 mL/min/1.73m^2/year in the prior two years is an easily calculable metric and identifies patients at markedly higher risk of future allograft failure and death.

	Category of annualized eGFR decline		
	<0 ml/min/1.73m^2	0-<5 ml/min/1.73m^2	≥5 ml/min/1.73m^2

TH-PO776

Model-Based Inference of the Living-to-Deceased-Donor Ratio among Living Kidney Transplant Patients in the United States

David J. Joerg,[1] Doris H. Fuertinger,[1] Benjamin E. Hippen,[2] Peter Kotanko.[3,4] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Global Medical Office, Fresenius Medical Care, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: In the United States, statistics on the proportions of incident kidney-transplant patients with living-donor (LD) or deceased-donor (DD) kidneys are available via the Organ Procurement & Transplantation Network (OPTN) database. However, data on the prevalent patient population with an LD/DD kidney transplant is not widely available, as longer-term follow-up and outcomes reporting is not uniform. As DD kidney transplants are more common than LD transplants but also result in inferior mean long-term patient and graft survival, the prevalent population of patients with a functioning transplant by donor-type is likely different from the incident transplant population.

Methods: Using a two-compartment modeling approach capturing transplantation, graft failure and mortality by donor-type, we inferred a range for the LD proportion in 2020. Rates for modelled processes were sourced from the US Renal Data System's Annual Data Report 2023. A multitude of model simulations (N = 100,000) were performed, initialized with LD proportions ranging between 0% and 100% in 2001, reflecting the uncertainty about past prevalent proportions (Fig. 1a,b). The model then simulated kidney-transplant patient numbers by donor type until 2020.

Results: Model simulations converged towards an LD proportion of 44% ± 3% (mean ± sd.) in 2020 (Fig. 1c), a relatively narrow band compared to the wide range of initial proportions. This is because of mean patient and graft survival times being shorter than the simulation period (19 y). Thus, final proportions are dominated by the balance of incidence, graft failure and mortality in the preceding years.

Conclusions: Modeling results suggest that the proportion of prevalent patients in the U.S. with a functioning graft from a living donor is 45%. Based on these results, the long-term care workforce might be faced with both (a) "long-graft-survivor" living donor recipients disproportionately represented in the prevalent transplant population, and (b) a higher volume of patients with earlier graft failure after deceased donor transplants.

Funding: Commercial Support - Fresenius Medical Care

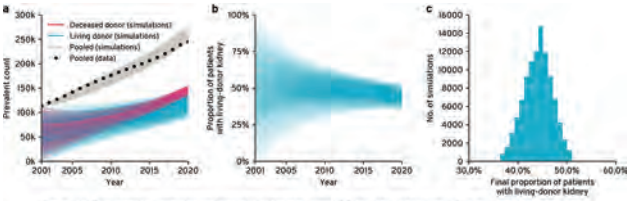

Figure 1: (a) Total counts of transplant patients with a deceased-donor (DD, red) and living-donor (LD, blue) kidney transplant according to the simulation model; different simulation curves correspond to different initial conditions with varying initial LD proportion (see panel b). Pooled (LD+DD) counts shown for simulations (gray), compared against data (dots) from the USRDS Annual Data Report 2023 (Reference Table D.9). (b) Living-donor proportion for the model simulations shown in panel a. Panels a and b show 1,000 simulations for visual clarity. (c) Distribution of final (2020) living-donor proportions in model simulations. (N = 100,000 simulations)

TH-PO777

Impact of Donor Sex on Graft Outcome in Deceased Donor Kidney Transplantation

Thei S. Steenvoorden, Liffert Vogt, Marc Hilhorst, Frederike J. Bemelman, Jesper Kers, Hessel Peters-Sengers. *Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Clinically relevant differences between human sexes have been made apparent in many diseases, but studies in kidney transplantation have been producing varying results. Because of recent insight in the possibly fundamental differences between grafts donated after brain death (DBD) and after circulatory death (DCD), we postulated that it is important to look at the effects of donor and recipient sex for donor types individually.

Methods: We requested data from the national renal replacement registry of the Netherlands and the Scientific Registry of Transplant Recipients (SRTR, United States). We used cumulative incidence competing risk (CICR) analyses treating recipient death as competing event, and confounder-adjusted cause-specific cox-regression analyses to determine the association of donor sex and donor-recipient sex matching with death-censored graft loss (DCGL) in DBD and DCD.

Results: In the Dutch cohort (2010-2024), there were 988 female DBD and 848 male DBD donors, CICR showed that DCGL was more common in grafts from female donors than in male donors (Figure A). Cerebrovascular accident was more common in female donors and donor age was higher than in male donors. After covariate adjustment, the adjusted hazard ratio (aHR) for female DBD donors was 1.43 (95% CI: 1.08–1.88; reference male DBD donors, p=0.013). This association was independent of recipient sex and weight mismatching. There were no differences in DCGL between the grafts from 1031 female and 1619 male DCD donors (Figure B). In a preliminary external validation of these findings in data from the SRTR (DBD N = 112,873, DCD N = 38,289), female

donor sex also had a differential impact on DCGL in DBD and DCD. Driving factors explaining these between-sex differences will be analyzed in both cohorts together with kidney biopsy data.

Conclusions: Donor sex has a differential impact on outcome specific to donor type.

Incidence of death-censored graft loss with competing risk recipient death.

TH-PO778

Patient and Graft Survival Rates at 5 Years following Kidney Transplant at the National Transplantation Center in Ethiopia

Solomon T. Amade. *Saint Paul Hospital Millennium Medical College, Addis Ababa, Ethiopia.*

Background: In Ethiopia living donor kidney transplantation was started in September 2015 at the National Transplantation Center. The center was established in Saint Paul Hospital Millennium Medical College (SPHMMC) in collaboration with the Ethiopian Federal Ministry of Health and Michigan University. One year death censored graft survival rate was 98.5%. This study was conducted to determine five-year patient and graft survival among the cohort of recipients operated from September1 2015 to November 15 2018.

Methods: A retrospective study of the cohort was conducted. Recipient and donor data were collected from the medical records using a structured printed tool. The collected data were entered and analyzed using IBM SPSS statistics version 29.0.2.0. Five-year graft and patient survival rates were determined. Predictors of five year patient and graft survival were identified using logistic regression. Ethical clearance was obtained from the institutional review board of SPHMMC. Data collection took place from November 15 to December 12 2023.

Results: Ninety two recipients were included. Mean ± SD age was 34.07 ± 11.26 years. Sixty-four (68.8%) were male. Mean ± SD age of donors was 34.9 ± 11.9 years. All except 9 (9.8%) were related to the recipient. Basiliximab was the induction regimen for 93.5%. Tacrolimus, MMF and prednisolone were maintenance immunosuppressive for 95% of recipients. Five year patient survival was 83.7%. Age ≥ 40 years, longer duration of post-op admission, serious infection during follow-up, graft rejection and graft biopsy predicted significantly reduced five year patient survival. OR (95% CI) were 0.19 (0.05-0.77), 0.92 (0.86 - 0.99), 0.06 (0.01 - 0.47), 0.14(0.03-0.64) and 0.21(0.06 - 0.74) respectively. Tertiary education predicted better five year patient survival OR (95% CI) 6.73(1.16-39.09). Five year death censored graft survival was 90%. Donor 24 hour urinary protein level, record of graft rejection and number of hospital admissions predicted reduced five-year death censored graft survival with OR (95% CI) of 0.98 (0.96 – 0.99), 0.01(0.001-0.1) and 0.39 (0.22 – 0.71) respectively.

Conclusions: Five year survival rate of recipients at the National Transplantation Center of Ethiopia is acceptable. The death censored graft survival rate at five years is comparable to those in developed regions.

TH-PO779

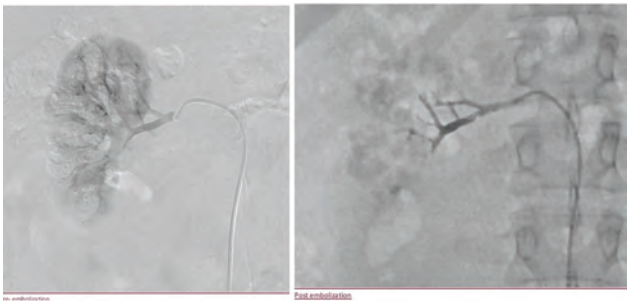
Residual Native Kidney Function after Kidney Transplant (KT): Unusual Complications

Abdallah Abdelrazeq, Swati Rao, Ziv J. Haskal, Jeanne Kamal. *University of Virginia, Charlottesville, VA.*

Introduction: Bartter syndrome, affects 1 in 1,000,000, presents challenges in KT recipients with residual native renal function. We present the clinical course of a KT recipient with suspected Bartter syndrome.

Case Description: 26-year-old man with CKD V underwent a preemptive deceased donor KT. Kidney biopsy (bx) 7 years ago revealed interstitial nephritis with moderate fibrosis and tubular atrophy, attributed to prolonged NSAID use. He had persistent hypokalemia requiring supplementation. Post-transplant, he experienced slow graft function (SGF), serial allograft bx showed acute tubular injury. He received thymoglobulin induction and a calcineurin-inhibitor (CNI)-based maintenance immunosuppression regimen. Due to ongoing SGF with nadir creatinine (Cr) of 4, he was switched to a CNI-free regimen with Belatacept. His electrolyte profile showed hypokalemia, and a significant urine output of 3-5 L/day, requiring scheduled fluid administration after which Cr improved but plateaued at 3. Technetium-99m mercaptoacetyltriglycine perfusion scan (MAG3) with split function analysis showed a 32.6% contribution from native kidneys. raising suspicion of Bartter syndrome, with preserved native output leading to chronic hypovolemia and allograft dysfunction. Following multidisciplinary discussion, including the patient's input, native right renal artery embolization with 10 mL of Visipaque 270 was performed 9 months post-transplant. Procedure was tolerated well. Cr, 1 month after, improved to 2.9, with long term follow-up awaited.

Discussion: Residual kidney function in tubulointerstitial, salt-wasting diseases can challenge KT, impending allograft function. In such disease, timing of KT is crucial. Delaying until no residual renal function or considering preemptive native nephrectomy may minimize allograft failure risk. Native kidney embolization is a minimally invasive alternative to nephrectomy, though its efficacy remains unproven in KT. We plan to update MAG3 to assess left native kidney function and consider contralateral embolization.



Selective Native Renal Artery Embolization:Radiological Procedure

TH-PO780

Fistula Ligation after Kidney Transplant: Yes or No?

Farah M. Ahmed,[1] Rosa M. Montero.[2,1] *[1]St George's University of London, London, United Kingdom; [2]St George's University Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: Cardiovascular disease (CVD) accounts for 30-35% of all-cause mortality in kidney transplant recipients (KTR) causing 25% of deaths 1-year post-transplant. Arteriovenous Fistulas(avf) have been shown to contribute to CVD progression with up to 42% of ESRD patients on dialysis developing Heart Failure and Pulmonary Hypertension. We report our experience with avf ligation in KTR.

Methods: A single centre retrospective observational study of all KTR with existing avf at the time of their transplant between 1983-2023 were included. Demographic and clinical outcome data was collected from electronic patient records including dates of avf formation and ligation, echocardiogram (echo) details at baseline and post-transplant. All KTR were categorised into 4 groups according to EF; group 1 <35%, group 2 36-49%, group 3 50-54%, group 4 ≥55% according to British Society of Echocardiography classification. Paired t-tests and ANOVA were used to perform statistical analysis with a $p<0.05$ significant level.

Results: 340 KTR from 1983- 2023 had avf in our centre. 214 Male, 126 female with a median age 63yrs (25-88yrs). 122 White, 80 Black, 97 Asian, 6 Chinese, 24 Other, 11 Unknown. 142 (42%) had avf ligation of which 17 KTR previously had >1 avf ligated leaving 116 KTR with avf ligated in total (73Male, 43Female). 20% (23/116) died unrelated to the procedure. Median time avf duration 9yrs (1-41yrs), median time post-KT avf ligation 5yrs (0-21yrs). 52% (61/116) had pre-KT echo classified according to EF: Group 1 had 1 KTR, Group 2: 5, Group 3: 8 Group 4 47. 20 KTR had a subsequent echo post ligation. 55% (11/20) had pre and post echo with 6 KTR showing an improvement moving from group 3 to 4(5) and group 2 to 4(1) in this small sample ($p=0.06$). Creatinine significantly improved pre-post KT ($p<0.001$). The changes were not related to the type of avf.

Conclusions: Many KTR did not meet the criteria for echo pre- transplant work-up leading to a smaller cohort. 11 KTR had an echo after avf ligation. An insignificant trend towards improvement in EF was seen despite the small sample size. Given the lack of guidance in this area consideration should be given to performing an echo 1 year after ligation to determine whether there is any improvement in cardiac function given the high cardiovascular morbidity and mortality of KTR.

TH-PO781

Venous Outflow Obstruction: A Rare Cause of Shock in a Recent Kidney Transplant Patient

David Wilhelm, Saed Shawar. *Vanderbilt University, Nashville, TN.*

Introduction: There are four recognized types of shock: distributive, cardiogenic, hypovolemic, and obstructive. Septic shock is the most common among ICU patients, while obstructive shock is rare. We present a case of venous outflow obstruction causing shock in a recent kidney transplant patient.

Case Description: A 64-year-old female with end-stage kidney disease (ESKD) secondary to diabetes and hypertension, who had undergone a living-related kidney transplant with immediate graft function, was readmitted one week later with fatigue, lightheadedness, significant right greater than left lower extremity swelling, acute kidney injury, and shock. A full workup for shock revealed no evidence of infectious, cardiologic, or endocrinologic causes. A CT scan of the chest, abdomen, and pelvis without contrast showed no acute chest abnormality but identified a hyperdense area in the right external iliac vein, raising concerns for deep vein thrombosis. Additionally, it showed a narrowed right common iliac vein and inferior vena cava (IVC). A CTA of the pelvis with bilateral lower extremity runoff revealed right greater than left edema and no venous enhancement in the right iliac vein. Interventional radiology performed venography and found an atretic right common iliac vein and IVC with multiple collaterals. Venoplasty and stent placement were performed, extending from the IVC to the right external iliac vein. The patient's hypotension resolved upon relief of the venous obstruction, and she experienced significant improvement in lower extremity swelling.

Discussion: This case represents a rare cause of shock. Although the patient was treated with broad-spectrum antibiotics, a thorough infectious workup was negative. Further evaluation for other causes of shock was also unremarkable. The patient's shock resolved with relief of the obstruction, indicating this as the primary etiology. The cause of venous obstruction in this patient was unknown. Risk factors for venous stenosis include thrombotic and non-thrombotic etiologies. Non-thrombotic causes include extrinsic vein compression or obstruction related to an intraluminal device. For ESKD patients, vein stenosis related to the presence of a dialysis catheter is a specific etiology to consider. In summary, this case of venous outflow obstruction highlights the importance of maintaining a broad differential diagnosis in patients presenting with shock.

TH-PO782

Patient Review of Informed Consent Form as Best Practice in Clinical Trial Design

Devra Densmore. *Elevate Advocacy, Chicago, IL.*

Background: The informed consent form (ICF) is one of the most important documents in a clinical trial, because it contains all essential and relevant information on both what will happen within a study and what is expected and provided to a study participant. However, rigorous reviews by members of the patient population being studied are not done consistently in the study design and development process. Our objective was to optimize readability and understandability of patient-facing clinical study materials for kidney transplant-related interventional clinical trial by facilitating asynchronous review of informed consent form (ICF) by global panel of kidney transplant patients and advocates.

Methods: Three separate asynchronous 10-day reviews of draft ICF were provided to individual (3) global patient reviewers via a secure online platform in August, October, and December 2023.

Results: Elevate Advocacy, in partnership with one of its sponsor clients, facilitated three separate reviews by three global patients and advocates who had experience with post-kidney transplant complications. Although the three reviewers were from different countries, racial and ethnic backgrounds, trial experience (e.g., naive vs experienced), sexes, and ages, 68% of their comments and suggestions were independently aligned. In total, 183 comments, questions and suggestions were provided on a 19-page draft ICF. An in-depth review of all comments was conducted to understand what feedback should be incorporated into the ICF (50%). Recommendations included: ● A schematic design of the study visits, dosing schedule, and timeline ● A pronunciation guide for the study drug ● Language that was universally understood by global audiences ● Formatting changes of dense text into sections and bulleted lists

Conclusions: Patients and advocates can provide valuable insights and feedback on patient-facing study materials to make them more understandable for clinical trial participants. Patient-facing study materials review can be a safe, low-cost, and highly valuable exercise that benefits both the study and the study participants. To be most successful, reviews should be iterative and allow enough time for patient reviewers to provide feedback (7-10 days), internal program teams to analyze and discuss the incorporation of comments into the ICF, and internal review committees to determine if template changes should be made.

TH-PO783

Unique Case of Hemosiderosis-Induced Ascites in Kidney Transplant Recipient

Mansoor Ahmed, Sakil A. Bhuiyan, Navdeep Kaur, Rula A. Abdulrahman, Farah Daccueil. *Stony Brook University, Stony Brook, NY.*

Introduction: Iron overload or hemosiderosis is often a frequent complication from intermittent blood transfusions. Anemia of end stage kidney disease (ESKD) is managed with IV iron and erythropoietin stimulating agents (ESAs) and these patients are at risk of iron overload, especially those with increased dialysis vintage. Here we describe a unique case of recurrent ascites caused by secondary hemosiderosis in a kidney transplant recipient who was on Peritoneal Dialysis (PD) for 12 years.

Case Description: A 61-year-old female with ESKD secondary to presumed Hypertension underwent 2nd deceased donor renal transplant(DDRT) in 2023. She was on PD from 2011 to 2023. She required 8 units of PRBC's peri-operatively. Nadir creatinine 0.77 mg/dl. Post-transplant course complicated with COVID PNA, transplant renal artery stenosis requiring stent placement. She developed ascites three months post-transplant requiring frequent large volume paracentesis which was contributed to hepatic congestion in setting of heart failure with preserved ejection fraction (HFpEF). Seven months post-transplant she developed AKI in setting of E.coli bacteremia, CMV viremia and a transplant renal biopsy was performed showing focal endothelialitis, suggesting T cell mediated rejection, CMV nephritis and renal hemosiderosis and about 40% IFTA. Labs also showed iron levels of 15, Ferritin of 1400, TSAT 27%, AST/ALT normal, with elevated ALP 130. MRI liver was done which showed mild diffuse gain of signal in liver and spleen. A liver Biopsy was also performed which showed nodular regenerative hyperplasia and 1-2+ iron staining in Kupffer's cells + hepatocytes and no evidence of fibrosis. Given liver biopsy findings and multiple transfusion history, it can be hypothesized that recurrent ascites was likely to secondary hemosiderosis rather than HFpEF. Patient's AKI recovered with treatment of underlying infection. Of recent, she has not required paracentesis.

Discussion: Here we describe an interesting case of a transplant patient with high dialysis vintage who developed recurrent ascites due to renal hemosiderosis. It is possible that long term IV iron exposure and multiple transfusions immediately post-transplant lead to secondary hemosiderosis. Long term PD could be contributing to development of ascites as well.

TH-PO784

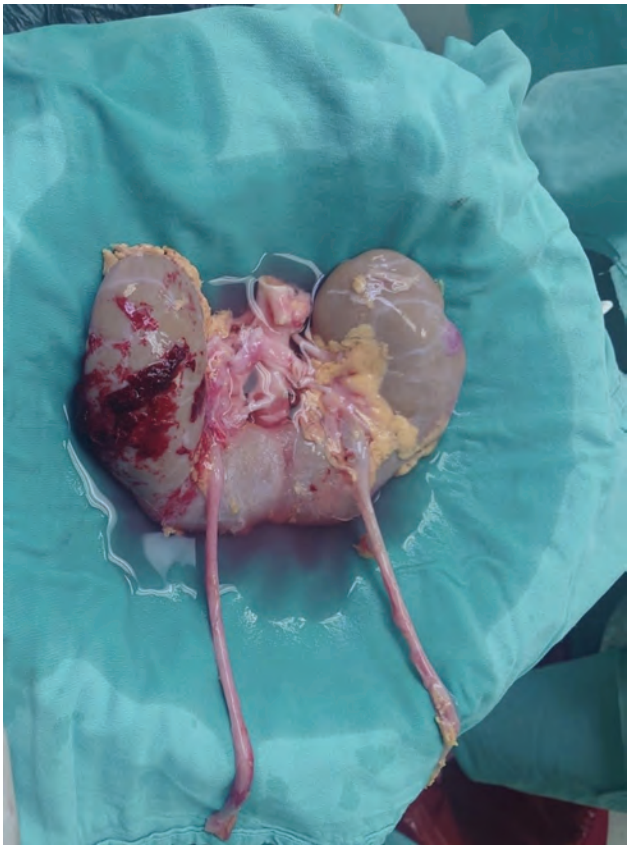
Case Report of First Kidney Transplant in Mexico Using Horseshoe Kidney from a Cadaveric Donor in a Single Recipient

Joary Vargas Santana, Asdrubal Guevara-Charles, Marco A Hernández-Guedea, Mara C. Olivo Gutierrez, Allina P. Flores Mendoza. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.*

Introduction: Horseshoe kidneys are the most common fusion defect of the kidneys, with a reported frequency of approximately 1:500. They are characterized by anomalies in the position, rotation and vascular supply of the kidney.

Case Description: The recipient was a 51-year-old female patient, with a history of chronic kidney disease of unknown etiology diagnosed in 2012, she received a first kidney transplant from a deceased donor in 2014. She entered to transplant protocol for a 2nd kidney transplant in 2019 with eGFR CKD EPI 13 ml/min/1.73m^2. A horseshoe kidney transplant with 2 arteries and 2 veins per kidney, a infraumbilical laparotomy approach was performed, bloc implant with arterial anastomosis to the right common iliac artery and venous anastomosis to the infrarrenal cava, induction immunosuppression was with thymoglobulin and methylprednisolone. She presented spontaneous uresis after graft reperfusion, she was discharged on March 12, 2024, with creatinine 0.4 mg/dl.

Discussion: There is little evidence of related cases of kidney transplant associated with horseshoe kidney, there are case reports that show en bloc transplantation to 2 recipients, unlike our case that includes a single recipient. Currently considered technically and biochemically successful, long-term surveillance continues to assess graft survival and whether there are complications associated with using this type of graft with anatomical variant, since they have been associated with associated syndromes and subsequent malignancy.



TH-PO785

Prevalence and Correlates of Hepatic Steatosis and Fibrosis in Patients with CKD before Kidney Transplantation: A Retrospective Cohort Study

Carlo Alfieri,[1,2] Rosa Lombardi,[1,2] Anna Regalia,[1] Simona Verdesca,[1] Mariarosaria Campise,[1] Emilietta Brigati,[1] Margherita Di Naro,[1] Anna Sikharulidze,[1] Giuseppe Castellano,[1,2] Paolo Molinari.[1] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: Metabolic dysfunction associated steatotic liver disease (MASLD), is closely linked to CKD and increases the risk of hepatic fibrosis and cardiovascular damage. MASLD is common in the general population but data on dialysis patients is limited. We aim to assess the prevalence of MASLD and related factors in kidney transplant patients at the time of list admission.

Methods: We studied 531 kidney transplant patients (age 49±13, 59% male) from 2010-2020. We noted their data at admission. Hepatic steatosis (HS) was gauged by hepatic steatosis index (HSI), with >36 as pathological (HSI+). Advanced fibrosis (>F3) was assessed by Fibrosis-4 index (FIB4), with >1.3 and >2.66 as borderline and pathological (FIB4+), and the NAFLD Fibrosis Score (NFS), with >-1.455 and >0.676 as borderline and pathological (NFS+).

Results: In our study, 67.2% of patients had hemodialysis. At evaluation, 8.8% had diabetes, 15% were obese, and 37.5% had steroid treatment history. Glomerulonephritis and polycystic kidney disease caused nephropathy in 20% and 18% of cases, respectively. HSI, FIB4, and NFS averages were 32.9±6.01, 1.25±1.07, and -1.75±1.5. FIB-4 and NFS correlated strongly (r=0.65, p<0.0001). HS by HSI+ was in 27.5% of patients, while hepatic fibrosis by FIB4+ and NFS+ was in 32.8% and 39.3% of patients. HSI+ patients were older with higher BMI, glucose, and urea levels. FIB4+ and NFS+ patients were older with higher glucose and CRP levels. NFS+ patients had higher BMI. These results confirm the concordance between the two fibrosis markers. In multivariate analysis, BMI and urea were independent risk factors for hepatic steatosis by HSI, while age and CRP were independent risk factors for hepatic fibrosis by both FIB4+ and NFS+.

Conclusions: Our data reveals a high occurrence of MASLD in patients awaiting kidney transplants, particularly in older, overweight individuals. Inflammatory parameters independently predicted hepatic fibrosis, suggesting their potential role. FIB4 and NFS showed a strong correlation, validating their use as fibrosis markers. Future research could shed light on the causes, risk factors, and impacts of HS and fibrosis on kidney transplant outcomes.

TH-PO786

Association between Noninvasive Liver Biomarkers and Graft Outcomes in Kidney Transplant Recipients

Jaeyun Lee, Chung Hee Baek, Hyosang Kim, Chan-Young Jung. *Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.*

Background: Though studies have suggested that metabolic risk profiles may be prognostic factors in kidney transplant recipients (KTRs), the prognostic significance of fatty liver severity, a known surrogate of metabolic risk, in KTRs has not been previously investigated. This study aimed to evaluate the association between non-invasive liver biomarkers and graft outcomes in KTRs.

Methods: Patients who underwent deceased or living donor kidney transplantation (KT) between January 2000 and December 2022 were collected. Hepatic fibrosis burdens of KTRs were assessed using the Fibrosis-4 (FIB-4) score and the non-alcoholic fatty liver disease fibrosis score (NFS), one month after KT. The primary outcome was a composite of 50% estimated glomerular filtration rate (eGFR) decline and graft failure. Secondary outcomes included individual outcomes of 50% eGFR decline, graft failure, and acute rejection including both cellular and antibody-mediated rejection.

Results: A total of 3,092 patients were grouped into three categories according to FIB-4 scores. During a mean follow-up of 6.0 years, the composite outcome occurred in 519 (2.8/100 person-years) patients. For the secondary outcomes, incidence rates for 50% eGFR decline, acute rejection, and graft failure were 2.3, 2.3, and 1.5 per 100 person-years, respectively. The cumulative incidences of all outcomes were higher in patients with higher FIB-4 scores (all P <0.05; Fig 1). In multivariate Cox models, the highest score group (FIB-4≥2.67) had a 2.05-fold (95% confidence interval [CI], 1.44-2.91; P<0.001) higher risk of the composite outcome compared to the lowest score group (FIB-4<1.30). The highest score group showed higher risk of the secondary outcomes compared to the lowest score group, with risk ratios of 1.75 (95% CI, 1.16-2.66), 1.62 (95% CI, 1.06-2.46), 2.23 (95% CI, 1.43-3.46). Similar findings were observed for NFS.

Conclusions: Higher liver fibrosis scores were associated with unfavorable graft outcomes in KTRs.

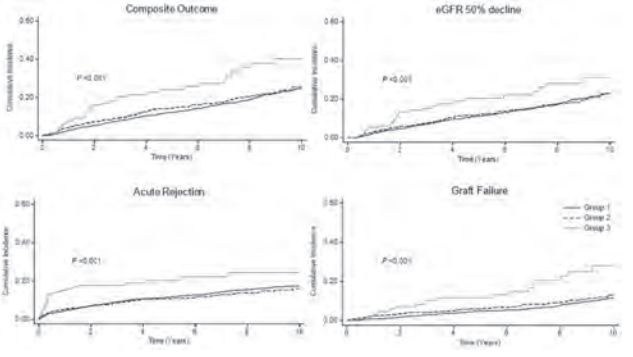


Figure 1. Cumulative incidence of graft outcomes according to FIB-4 score

TH-PO787

Association between Kidney Allograft Fibrosis and Magnetic Resonance Elastography-Derived Stiffness in Kidney Transplant Recipients

Pantipa Tonsawan, Kattareeya Jandaboot, Ubonrat Toimamueang, Pakorn Kiatsopit, Ukrit Rompsaithong, Julaluck Promsorn. *Khon Kaen University, Nai Mueang, Thailand.*

Background: Kidney biopsy remains the gold standard for assessing fibrosis. However, it is an invasive procedure and leads to significant complications. Magnetic resonance elastography (MRE) has been evaluated as an alternative method for evaluating fibrosis, but the results are still inconclusive. Herein, we aimed to determine the association between MRE-derived whole stiffness and interstitial fibrosis and tubular atrophy and urinary transforming growth factor (TGF) beta.

Methods: We conducted a cross-sectional study involving adult kidney transplant patients who required kidney biopsy. Enrolled patients underwent evaluation using two-dimensional gradient-echo MRE within 2 days prior to biopsy, enabling the determination of MRE-derived whole kidney stiffness through computer-assisted techniques. Urinary TGF beta was collected at the biopsy date and measured by ELISA. Pathological results were classified according to the Banff classification system. Correlations between MRE-derived whole kidney stiffness, histologic fibrosis, and urinary TGF beta were analyze.

Results: 21 patients were calculated for interim analysis. Majority were deceased donor kidney transplant patients (90.5%). Median transplant vintage was 8.6 years (interquartile range [IQR] 3.8-11.1 years) with a median estimated glomerular filtration rate of 36.6 ml/min/1.73 m^2 ([IQR] 24.3-49.6 ml/min/1.73 m^2). Most common biopsy indication was allograft dysfunction. We found that mean MRE-derived whole kidney stiffness was a significant negative correlation to the overall nephron fibrosis and ct scores

(*Rho* = -0.48, p=0.03, *Rho* = -0.47, p=0.03, respectively). In addition, there was a trend to negatively associate ci and cv scores and whole kidney stiffness. However, MRE-derived kidney stiffness did not show a significant correlation with urine TGF beta.

Conclusions: MRE-derived whole kidney stiffness correlates with nephron fibrosis, suggesting that MRE could offer a promising alternative for fibrosis evaluation in kidney transplant recipients.

Radiomic Texture Features in CT Images of Kidneys in Ventilated Deceased Donors Predict Delayed Graft Function

Fayzan Ali,[1] Edwin Baldelomar,[2] Jennifer R. Charlton,[3] Richard L. Wahl,[2] Gary F. Marklin,[4] Kevin M. Bennett.[2] *[1]Saint Louis University School of Medicine, St Louis, MO; [2]Washington University in St Louis School of Medicine Mallinckrodt Institute of Radiology, Saint Louis, MO; [3]University of Virginia Department of Pediatrics, Charlottesville, VA; [4]Mid-America Transplant, St. Louis, MO.*

Background: Kidney transplants are a life-saving resource for ~25,000 patients each year. 80% of allografts come from deceased donors. The success of kidney transplants is affected by variable organ quality and recipient factors. However, there is no method to reliably predict which kidneys will be successful. We investigated the use of contrast-enhanced Xray-CT images of the kidneys in ventilated deceased donors, acquired during assessment for cardiovascular function. We hypothesized that radiomic features from CT images of deceased donors under ventilation, scanned before the kidneys are removed, associate with transplant outcomes measured by delayed graft function (DGF) after transplant in recipients.

Methods: We acquired CT images of 102 (65M, 37F) ventilated, brain-dead donors at a single organ procurement organization (1/2019-6/2019). Scans were acquired with a Siemens 64-slice Somatom and Optiray 350 contrast. The primary outcome was DGF defined as need for dialysis within a week after transplant, obtained from the Scientific Registry of Transplant Recipients. Donors of all transplanted kidneys were included. Donors whose kidneys were not transplanted were excluded. Texture features (n=64) were extracted from three image slices of each kidney using Lifex. ANOVA was performed with a Bonferroni correction to determine significant prediction of DGF (p<0.01).

Results: Two image texture features, Grey Level Co-occurrence Matrix (GLCM) Contrast and GLCM Cluster Prominence, predicted DGF. These features measure heterogeneity and may reflect microvascular ischemia. Significantly higher GLCM Contrast and Cluster Prominence were observed in both cortex and medulla in kidneys with DGF (p<0.01).

Conclusions: Two radiomic features in CT images of kidneys in ventilated deceased donors were highly predictive of DGF. With further validation, this approach could provide a sensitive, individualized measure of deceased donor kidneys to improve functional assessment resulting in transplantation. It could also enable studies of optimal donor management to improve allograft function.

Relationship between Parenchymal Stiffness and Kidney Fibrosis in Kidney Transplant Recipients

Kohei Unagami,[1,2] Ayaka Saitoh,[1,2] Toshihito Hirai,[1] Kazuya Omoto,[1,2] Tomokazu Shimizu,[1,2] Junichi Hoshino,[1] Toshio Takagi,[1] Hideki Ishida.[1,2] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Yochomachi Clinic, Shinjuku-ku, Japan.*

Background: Transplant kidney biopsy has been the method for evaluating interstitial fibrosis and tubular atrophy (IF/TA) of renal allografts. However, its invasiveness, limited sequency and quantitation are shortcomings. Transient elastography (TE) is a device primarily used for measuring liver cirrhosis under ultrasound. TE may have shown promise for assessing transplanted kidney located in the iliac fossa unlike own kidneys, which are located deep from the body surface. We investigated the parenchymal stiffness of renal allografts in kidney transplant recipients and its correlation with renal allograft fibrosis and renal function.

Methods: A total of 455 recipients who underwent kidney transplantation between 2001 and 2023 were included in this study. All recipients underwent TE using FibroScan®expert630 (Echosense Paris, France) (Figure1). TE measured parenchymal stiffness in a volume approximating a cylinder of 25-55 mm in length.

Results: Parenchymal stiffness measurement was successful in 450 of 455 patients (98.9%). The median stiffness of renal allograft parenchyma was 46.7 kPa. Correlations with TE median values, recipients' serum creatinine levels, eGFR, and IFTA showed statistically significant differences (p <0.01 in each). Further division into two groups (eGFR >40 and ≦40) revealed significant differences in allograft kidney age, renal allograft parenchyma, and recipients' hemoglobin levels (p <0.01).

Conclusions: Renal function deterioration and IF/TA progression exhibited a robust correlation with renal allograft parenchyma by TE. TE is non-invasive, exhibits excellent reproducibility and rapidity, and is considered highly valuable for quantitative evaluation of IF/TA.

Venous Excess Ultrasound (VExUS) and Lung Ultrasound (LUS) in Post-transplant (PosKTx) Volume Assessment (VA): Is There a Place for Them?

Haridian Sosa Barrios,[1,2] Irene Minguez,[1] Victor Burguera,[1] Cristina Galeano,[1] Sandra Elias,[1] Miriam Roncal Redin,[1] Jorge Sánchez,[1] Raquel Moreno Garcia,[1] Milagros Fernandez-Lucas,[1,2] Maite Rivera Gorrin.[1,2] Grupo de Nefrología Diagnóstica e Intervencionista de la Sociedad Española de Nefrología (GNDI). *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Universidad de Alcala, Alcala de Henares, Spain.*

Background: VA in the posKTx period reduces morbidity and mortality, saving resources.LUS, VExUS and bioimpedance (BIA) are volume evaluation methods on the rise.

Methods: Prospective single-center study (4-12/23):31 pts (Group1) VA days+1 and +7 (LUS, VExUS, BIA and physical examination (PE) vs 40 previous KTx (Group 2) assessed clinically.

Results: Characteristics in table 1. No differences at baseline or evolution (delayed function, RRT, hospitalization or cardiovascular events (CVE) nor weight gain day+1, although there were 6 acute pulmonary edema in group 2 (post-KTx) and only 2 post-discharge in group 1. BIA not correlated with PE (p 0.022). VExUS score and BIA did not correlate. BNP and Ca125: 88% with CVE had elevated BNP and 22% high Ca125. Of those requiring HDx, 85.7% had elevated BNP and 14.2% risen Ca125. VExUS score: Day+1 VExUS1 (3): 50% elevated BNP but normal Ca125. VExUS 2 (1) elevated Ca125 + BNP. VExUS 3 none. Day+7 VExUS1 (4): 75% elevated BNP and 25% elevated Ca125. VExUS+LUS detected hypervolemia with normal PE (3 mild edema

and VExUS 1-2, 9 pathological LUS without clinical edema or only mild), although not significantly. VExUS modified treatment in 77.6% day+1 and 30% day+7: **day 1-->** *No* 7 (22.6%), *reducing iv fluids 71%*; *reducing iv fluids+diuretics* 1, *lower limb edema due to lymphocele* 1.D**ay 7-->** *No* 19 (70.1%), *reducing iv fluids* 2, *stopping iv fluids* 2, HDx 1, *other findings* 3 (2 *retroperitoneal bleedings and 1 perirrenal haematoma).*

Conclusions: LUS+VExUS outperformed PE for accurate management of posKTx volume, detecting hypervolemia early and modifying the therapeutic attitude up to almost 78% of cases. BIA correlated poorly with volume status in these patients.

Carboxyhemoglobin and Smoking Status in Kidney Transplant Recipients

Sovia Salamah,[1] Antonio W. Gomes Neto,[1] Firas F. Alkaff,[1,2] Jenny E. Kootstra-Ros,[1] Daniel J. Touw,[1] Casper F. Franssen,[1] Stephan J. Bakker.[1]
[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Universitas Airlangga Fakultas Kedokteran, Surabaya, Indonesia.

Background: Smoking is a risk factor for graft failure and death in kidney transplant recipients (KTRs). Nicotine addiction complicates quitting and self-reported smoking status is unreliable. Urinary cotinine is the gold standard for identifying active smokers, but is costly, infrequently measured, and prone to false positivity in nicotine patch or gum users. We aimed to investigate carboxyhemoglobin (COHb) as a potential biomarker for assessing smoking in KTRs.

Methods: We used data from KTRs in the TransplantLines Biobank and Cohort. Smoking status was determined by a questionnaire. Urinary cotinine was measured with Enzyme Multiplied Immunoassay Technique (LLQ 100 µg/L) and plasma COHb was obtained from blood gas analysis. The ROC curve evaluated the diagnostic performance.

Results: Among 404 KTRs (mean age 56 ± 13 years, 43% female, median time post-transplant 89 months [interquartile range (IQR) 36-157]), the prevalence of KTRs with urinary cotinine > 100 µg/L was 15.1%, and the median COHb was 0.92% [IQR 0.82-1.14%] **(Table)**. COHb was strongly correlated with urinary cotinine (R=0.61; P<0.001). The area under the curve (AUC) of urinary cotinine and COHb was comparable **(Figure)**. Using the Youden index, the COHb cut-off was 1.5%. With this cut-off, the specificity and sensitivity of COHb were 94% and 72%, respectively.

Conclusions: Carboxyhemoglobin, which is more accessible than urinary cotinine, is just as effective in identifying smoking in KTRs.

Urinary cotinine and COHb of KTRs according to their answer on smoking questionnaire.

	Total N=404	Non-smoker N=107	Ex-smoker N=153	Smoker N=36	Unknown N=28	P-value
Detectable urinary cotinine concentration, n (%)	61 (15.1%)	3 (1.6%)	19 (12.4%)	32 (88.9%)	7 (25%)	<0.001

Serum Metalloproteinase-8 (MMP-8) and Tissue Inhibition of Metalloproteinase-1 (TIMP-1) Pretransplant Levels Predict Early Graft Function after Kidney Transplantation

Kadri Hendrikson,[1,2] Ilkka Helanterä,[1] Seppo Meri,[2] Timo Sorsa,[2] Fernanda Ortiz.[1] *[1]Helsingin Seudun Yliopistollinen Keskussairaala, Helsinki, Finland; [2]Helsingin Yliopisto, Helsinki, Finland.*

Background: Matrix metalloproteinases (MMPs) have a major role in the degradation of components of the extracellular matrix, which results in tissue remodeling. Particularly MMP-8, released by polymorphonuclear neutrophils, has a role in mediating inflammation and kidney fibrosis. Tissue inhibitor of metalloproteinase-1 (TIMP-1) is a natural inhibitor of MMP-8. MMPs have been suggested as a possible common pathway for chronic allograft nephropathy. MMP-8 role in renal transplantation has not been described.

Methods: We prospectively recruited 60 patients waitlisted for kidney transplantation. Patients were divided into 3 groups based on the graft function after surgery: delayed graft function (DGF: need of dialysis), immediate (IGF), and slow graft function (SGF: creatinine concentration over 2,2 mg/dl after 7 d pop). Follow-up data was obtained from the Finnish Transplant Registry. MMP-8 and TIMP-1 were measured in the serum from 59 patients obtained before transplant surgery. MMP-8 levels were determined by time-resolved immunofluorometric assay (IFMA), and TIMP-1 levels by ELISA. Mann-Whitney-U test was used to investigate differences across groups.

Results: MMP-8 concentration was highest and TIMP-1 the lowest in DGF, although not statistically different across DGF, SGF, and IFG (p=0.072 and p=0.060 respectively), but the MMP-8/TIMP-1 ratio was the highest in DGF group (p=0.029). We identified four outlier values, particularly in patients over 70 years old, without any other distinct characteristics explaining the high values. After removing outliers, MMP8 was statistically significantly higher in DGF than IGF (p=0.029). TIPM-1 concentration was lower in DGF (p=0.075) and MMP-8/TIPM-1 ratio was the highest in DGF vs IGF (p=0.014).

Conclusions: High pre-transplant concentrations of pro-inflammatory marker MMP-8 and lower TIMP-1 are related to delayed graft function.

Urine Epidermal Growth Factor as a Potential Biomarker of Functional Kidney Mass for the Evaluation of Kidney Transplant Donors and Recipients

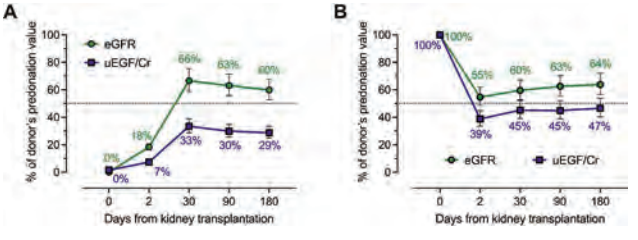
Adriana Hernández Andrade, Bernardo Juarez Cuevas, Valeria Navarro Sanchez, Jesus A. Sanchez Ramirez, Alberto Nordmann-Gomes, María F. Zavala Miranda, Cristino Cruz Rivera, Luis E. Morales-Buenrostro, Juan M. Mejia-Vilet.
Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.

Background: Serum creatinine (SCr) and the estimated glomerular filtration rate (eGFR) are limited biomarkers of kidney function. A kidney donor "loses" approximately 50% of the kidney mass, still, post-procedure SCr and eGFR recover to a value ≥60-70% baseline. The study aimed to evaluate urine epidermal growth factor (uEGF) as a better biomarker of kidney mass.

Methods: We recruited 32 donor/receptor pairs and obtained their pre-donation/pre-transplantation demographics, and kidney function tests. After the kidney donation/transplantation procedure, we collected blood and urine samples on days 2, 30, 90, and 180. The course of uEGF and eGFR were evaluated by linear mixed models and expressed as a percentage of the baseline kidney donor values.

Results: Kidney donors had a median age of 38 years (IQR 32-54), and 24 (75%) were female. Kidney recipients' median age was 36 years (IQR 29-46), 18 (56%) were male, 18 (56%) had kidney failure from an unknown cause, and 8 (25%) from glomerular disease. 27 (84%) corresponded to a first transplant and 5 (16%) to a second transplant. The baseline eGFR in kidney donors decreased immediately post-donation and then stabilized at 60-64% of their baseline eGFR from day 30. Conversely, uEGF decreased post-donation and stabilized at 45-47% of their baseline uEGF (closer to the theoretically 50% decrease after donation) (Figure 1B). In kidney recipients, the eGFR increased to a peak of 66% of the baseline eGFR of their kidney donor and remained at 60-63% over follow-up. Interestingly, uEGF in the kidney recipient remained at 29-33% of the baseline level of the kidney donor. Urine EGF (but not eGFR) in the recipient correlated with the allograft volume estimated by CT scan.

Conclusions: Urine EGF is a potential biomarker of functional kidney mass to be used for the evaluation of kidney donors and kidney recipients. uEGF levels are better approximate to the theoretical 50% "loss" of kidney mass that occurs after donation.



TH-PO794

Urinary Podocin as a Noninvasive Marker of Kidney Injury in New-Onset Diabetes after Kidney Transplantation

Adriana A. Rezende,[1] Ony A. Galdino,[1] Mabelle A. De Lima,[2] Mauricio G. Pereira,[2] Jose B. Almeida,[1] Marcela Ururahy,[1] Karla Souza.[1] *[1]Universidade Federal do Rio Grande do Norte, Natal, Brazil; [2]Universidade Potiguar, Natal, Brazil.*

Background: New-onset diabetes after transplantation (NODAT) is a serious metabolic complication that leads to decreased survival of renal allograft transplantation. However, currently, there is no early marker to assess kidney injury in NODAT. Given that podocytes are the primary targets of kidney injury, proteins from these cells are potential early markers of kidney dysfunction in NODAT. Among these podocyte proteins, podocin is an important molecule that maintains the integrity of the glomerular filtration barrier, which is negatively regulated in the case of kidney injury. Therefore, the aim of the study was to evaluate the potential of urinary podocin as a non-invasive marker of kidney injury in NODAT.

Methods: Thirty-eight kidney transplant (KTx) patients, who were 6 months post-KTx and aged above 19 years, without a history of segmental and focal glomerulosclerosis or *Diabetes mellitus*, were recruited. Patients were divided into 2 groups according to the diagnosis of NODAT [non-NODAT (n=20) and NODAT (n=18) groups]. Fasting blood glucose, glycated hemoglobin, serum creatinine, urinary albumin/creatinine ratio (ACR), and estimated glomerular filtration rate (eGFR) were determined. Podocin was measured by western blot from urinary extracellular vesicles, previously isolated by ultracentrifugation. Podocin band density was normalized by urinary creatinine.

Results: An increase in fasting blood glucose ($p < 0.001$) and HbA1c levels ($p < 0.001$) was observed in the NODAT group. Additionally, ACR and serum creatinine levels were elevated in the NODAT group compared to the non-NODAT group ($p < 0.001$, for both). In contrast, eGFR values decreased in the NODAT group compared to the non-NODAT group ($p = 0.003$). Increased urinary podocin was found in the NODAT group compared to the non-NODAT group ($p < 0.001$). Furthermore, urinary podocin was observed to be a predictor of low eGFR <60 mL/min/1.73 m² [Area Under the Receiver Operating Characteristic (AUROC) = 0.844; p = 0.032].

Conclusions: This study is the pioneer to show an increase in urinary podocin in NODAT patients. These results associated with the ones obtained in the AUROC analysis and for the eGFR suggest that urinary podocin can become a potential marker in the early detection of kidney injury in the NODAT.

TH-PO795

Urinary Nephrin and Podocin Levels as Potential Predictors of Reduced Glomerular Filtration Rate after Kidney Transplantation

Karla Souza,[1] Ony A. Galdino,[1] Mabelle A. De Lima,[2] Mauricio G. Pereira,[2] Jose B. Almeida,[1] Marcela Ururahy,[1] Adriana A. Rezende.[1]
[1]Universidade Federal do Rio Grande do Norte, Natal, Brazil; [2]Universidade Potiguar, Natal, Brazil.

Background: Nephrin and podocin could be associated with early podocyte injury, leading to alterations in the glomerular filtration barrier that may result in a reduced glomerular filtration rate (GFR) after kidney transplantation (KTx). Therefore, the aim of this study was to investigate whether the increase in urinary levels of nephrin and podocin is associated with low GFR post-KTx.

Methods: Forty KTx patients aged above 19 years, without a history of segmental and focal glomerulosclerosis or *Diabetes mellitus* were recruited. Urinary albumin/creatinine ratio (ACR), estimated GFR (eGFR), and serum creatinine were determined. Nephrin and podocin were measured by western blot from urinary extracellular vesicles isolated by ultracentrifugation. All analyses were performed in patients at 3, 6, 9, and 12 months post-KTx.

Results: An increase in ACR and a decrease in eGFR were observed at 12 months compared to 3 months post-KTx. No differences were found in serum creatinine levels. A linear mixed effects model was employed to investigate the association between urinary nephrin and podocin levels with low GFR post-KTx, using eGFR as the dependent variable. The model considered the 12-month follow-up as the fixed effect and included nephrin and podocin as covariates. This analysis indicated an association between urinary nephrin [3 months ($p<0.001$), 6 months ($p=0.031$), 9 months ($p=0.029$), and 12 months ($p=0.006$)] and podocin [3 months ($p<0.001$), 6 months ($p=0.001$), 9 months ($p=0.012$), and 12 months ($p=0.014$)] with the reduction of eGFR. To determine if urinary nephrin and podocin could predict low GFR post-KTx, an Area Under the receiver operating Characteristic (AUC) analysis was performed. It was observed that urinary nephrin [3 months (AUC=0.984,$p=0.001$), 6 months (AUC=0.999,$p<0.001$), 9 months (AUC=0.929,$p=0.001$), and 12 months (AUC=0.857,$p=0.005$)] and podocin [3 months (AUC=0.900,$p=0.005$), 6 months (AUC=0.999,$p<0.001$), 9 months (AUC=0.999,$p<0.001$), and 12 months (AUC=0.913,$p=0.001$)] were predictors of low eGFR.

Conclusions: The results demonstrate an association between urinary nephrin and podocin and low GFR. Moreover, the high AUC values found during patient follow-up indicate that these urinary proteins are potential predictors of low GFR post-KTx.

Next-Level Approach to Antibody-Mediated Rejection and T Cell-Mediated Rejection Diagnosis in Kidney Transplantation: Dynamic Duo of Urine CXCL10 and Donor-Derived Cell-Free DNA

Daniel Fantus,[1,2] Sílvia Casas,[5] Narin S. Tangprasertchai,[5] Thierry Viard,[5] Justin Belair,[2] Chee Loong Saw,[4] Claude Daniel,[4] Julie Ho.[3] *[1]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [3]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [4]McGill University Health Centre, Montreal, QC, Canada; [5]CareDx Inc, Brisbane, CA.*

Background: Biopsies are required to diagnose rejection but they are invasive and difficult to use for monitoring. While there is evidence that donor derived cell free DNA (dd-cfDNA) performs well as a biomarker of antibody-mediated rejection (AMR), its ability to identify T cell mediated rejection (TCMR) remains unclear. In contrast, urine CXCL10 is a well-characterised biomarker of tubulitis. Due to these complementary properties, we hypothesized that use of these 2 biomarkers together would improve the diagnosis of rejection phenotypes marked predominantly by tubulitis, particularly TCMR.

Methods: A single center exploratory study was conducted whereby 126 transplant biopsies (with paired plasma and urine) were selected. Banff criteria were followed to generate the following diagnostic categories: AMR (n=20), low and high grade TCMR (n=17) and normal histology (n=43). Urine CXCL10 was measured using the Meso Scale V-Plex assay. Cell free DNA was extracted from EDTA plasma samples and percent donor derived cell free DNA calculated using the CareDx AlloSeq cfDNA kit.

Results: The AUC for AMR (versus normal) was 0.952 (0.893-1000) using dd-cfDNA. In contrast, the AUC for AMR was 0.595 (0.469-0.722) using urine CXCL10 and increased to 0.969 (0.923-1.000) when dd-cfDNA was added ($p=1.71X10^{-8}$). For high grade TCMR, AUC using dd-cfDNA was 0.762 (0.562-0.963). AUC using urine CXCL10 was 0.681 (0.474-0.888) and increased to 0.792 (0.585-1.000) when dd-cfDNA was added (p=0.16). For low grade TCMR, AUC was 0.577 (0.442-0.711) using dd-cfDNA. AUC was 0.595 (0.424-0.767) using urine CXCL10 and increased to 0.652 (0.473-0.832) (p=0.32) when dd-cfDNA was added.

Conclusions: Urine CXCL10 is a weaker diagnostic biomarker of AMR compared to dd-cfDNA. In contrast, when evaluating TCMR, there was no clear advantage of one biomarker over the other, though their combination may improve diagnosis. These findings require prospective multi-center studies.

TH-PO797

Urinary Basigin/CD147 Is a Useful Marker of Acute T Cell-Mediated Rejection in Kidney Transplant Recipients

Makoto Tsujita. *Masuko Kinen Byoin, Nagoya, Japan.*

Background: Acute T cell-mediated rejection (ATCMR) is one of the severe problems following kidney transplantation. However, no reliable marker of it is currently available in Japan.

Methods: This cross-sectional study was performed at Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital to determine whether serum or urinary Basigin/CD147 worked as an effective marker of ATCMR from 2016 to 2018. Serum and urinary samples were obtained when episode graft biopsies were done.

Results: A total of 46 kidney transplant recipients received graft biopsies. Three of them missed serum and urinary samples and three in ATCMR were on post-rejection treatment. Graft biopsy results revealed ATCMR in 12 of them, calcineurin inhibitor nephrotoxicity (CNIN) in 9, chronic active antibody-mediated rejection (CAAMR) in 9, BK nephropathy, recurrence IgA nephropathy, necrotic glomerulonephritis, and infection-related glomerulonephritis in one each, and others in 6. Urinary Basigin/CD147 levels in patients with ATCMR group (690.1 ± 247.0 pg/gCre) were notably greater than those in patients with CAAMR (242.2 ± 86.1 pg/ gCre) and CNIN groups (351.6 ± 117.0 pg/ gCre). ($P < 0.001$)(Figure1) No statistical difference in serum Basigin/CD147 levels was observed between those groups. At an urinary Basigin/CD147 of 631.5 pg/gCre, sensitivity, and specificity of 75% and 84%, respectively, were reached for diagnosing acute rejection with an area under the curve of 0.80.(Figure2)

Conclusions: Urinary Basigin/CD147 was correlated with tubulointerstitial damage and might be a potential marker for ATCMR in kidney transplant recipients. Further study will be needed to clarify the effectiveness of Basigin/CD147.

Noninvasive Urine Epigenomics Identifies Allograft Pathology in Kidney Allografts

Essa Abuhelaiqa,[1,2] Mohamad M. Alkadi,[1,2] Aziz Belkadi,[2] Gaurav Thareja,[2] Thangamani Muthukumar,[3] Hassan A. Al-Malki,[1,2] Manikkam Suthanthiran.[3] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Weill Cornell Medicine - Qatar, Doha, Qatar; [3]Weill Cornell Medicine, New York, NY.*

Background: Development of noninvasive assay as a diagnostic alternative to allograft biopsy in kidney transplantation is critical and has the potential of prompt diagnosis and treatment of allograft dysfunction. We aim to detect kidney pathology via recognition of associated methylation signatures and cellular profiles in urine, hypothesizing that different disease states lead to unique and measurable epigenetic and cellular changes.

Methods: Urine samples were obtained at time of for-cause kidney allograft biopsy of 138 kidney allograft recipients. Urinary pellet DNA was processed with the Infinium MethylationEPIC kit and categorized into "phenotypes" from biopsy findings. The resulting methylation data was filtered with the "ewastools" package in R. Average cellular composition for each phenotype was generated through a reference atlas and deconvolution algorithm from the literature. Differentially methylated regions (DMR) were compared between non-rejection (NR) and acute rejection (AR) specimens via the chip analysis methylation pipeline package.

Results: From a total of 138 unique samples and 11 technical replicates, methylation data for 650,719 CpG sites per analyte was available after filtering. Deconvolution analysis demonstrated immune cell predominance in AR and micro-vascular injury, particularly neutrophils, with only BKVN samples showing relative renal cell prevalence. Borderline samples showed a cellular profile intermediate between NR and AR. DMR analysis yielded a panel of 197 genes containing differentially methylated CpG sites between AR and NR samples.

Conclusions: Epigenomic analysis of urine is a feasible modality to assess graft health, with cellular composition and DMRs acting as surrogate biomarkers.

Funding: Government Support - Non-U.S.

Urinary Metabolite Constellation Also Detects Very Early Post-transplant Rejection in Living Donor Kidney Recipients

Miriam C. Banas,[1] Katharina Wiesner,[1,3] Bernhard Banas,[1] Andrew Robertson,[2] Amauri Schwäble Santamaría,[2] Simone Mark,[2] Eric Schiffer.[2]
[1]Universitatsklinikum Regensburg, Regensburg, Germany; [2]Numares AG, Regensburg, Germany; [3]Barmherzige Brüder, Regensburg, Germany.

Background: Kidney transplantation is the preferred treatment for end stage kidney disease, offering improved survival rates and quality of life compared to dialysis. However, acute allograft rejection remains a significant complication, necessitating accurate diagnosis for timely intervention. Standard serum creatinine monitoring lacks specificity, leading to unnecessary biopsies and missed subclinical rejection. Previously we published a novel metabolom-based urinary non-invasive test for the detection of renal allograft rejection (Banas M et al., EBioMedicine, 2019).

Methods: In this study, conducted as part of the UMBRELLA study, n=682 urine samples from 109 transplant recipients were analyzed using a recently introduced urine metabolite constellation of alanine, citrate, lactate, and urea. Parameters (n=29) such as induction therapy, warm ischemia time, and donor type were examined for their impact on the test's performance to identify biopsy confirmed rejection in the first 14 days post-transplant.

Results: Univariate analysis identified 10 significant confounders, particularly the influence of deceased organ donation on metabolic urine profiles. Multivariate analysis confirmed the relevance of parameters related to living donation and highlighted warm ischemia time as an independent factor affecting metabolite profiles. Subgroup analysis directly testing the performance of the rejection score revealed living donor recipients as the most accurately discriminated subgroup with an AUC of 0.720 (95% CI 0.62-0.82), followed by those with short (<30 min) warm ischemia times 0.702 (95% CI 0.61-0.79). Clinical observations supported these findings, with anomalies in the urine metabolite test often correlating with clinical complications.

Conclusions: The study underscores the importance of considering donor type and ischemia times when interpreting metabolomics data for rejection monitoring in kidney transplant recipients. Understanding these factors could enhance the accuracy of non-invasive rejection detection methods, facilitating timely intervention and improving patient outcomes.

TH-PO800

Time Course of Glycolytic Control Protein Expression in Urinary Extracellular Vesicles (UEV) of Deceased Donor Kidney Transplant Recipients

Po Yee Mia Leung,[1,2] Alison S. Graver,[1,2] Marina Katerelos,[2] John B. Whitlam,[1,2] David A. Power,[1,2] Peter F. Mount.[1,2] *[1]Faculty of Medicine, Dentistry and Health Sciences, University of Melbourne, Melbourne, VIC, Australia; [2]Department of Nephrology, Austin Health, Melbourne, VIC, Australia.*

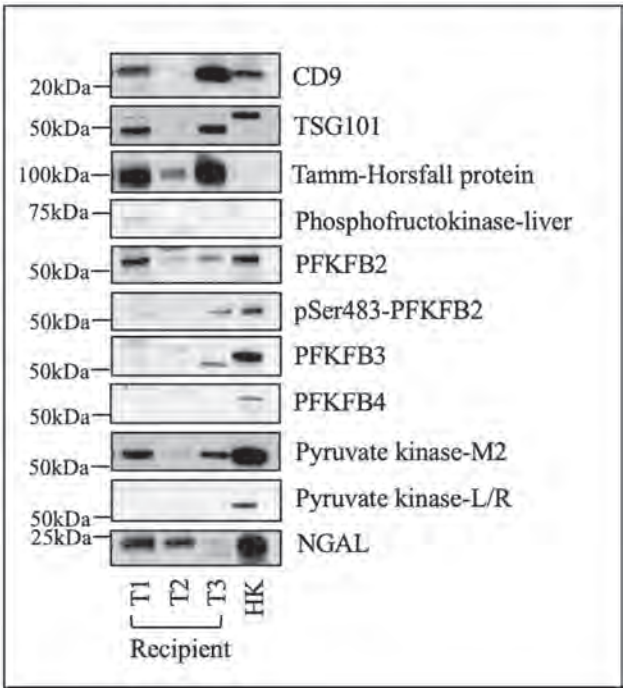
Background: An important switch to increased glycolysis has been demonstrated in experimental ischaemia-reperfusion injury. We aimed to measure expression of glycolytic control proteins contained in UEV as a marker for changes in renal glycolysis following deceased donor kidney transplantation.

Methods: In this prospective observational study, urine samples were collected from deceased donor kidney transplant recipients prior to (T0) and after transplant at days 1-3 (T1), 5-10 (T2) and 70-100 (T3). UEV were separated by differential ultracentrifugation and characterized by expression of CD9, TSG101 and THP. Proteins were analysed by immunoblotting and included PFK-L, PFKFB2, pSer483-PFKFB2, PFKFB3, PFKFB4, PK-LR, PK-M2 and NGAL. Densitometry was normalized to urine creatinine, then compared via repeated measures one-way ANOVA.

Results: 29 urine samples from 8 subjects were included. Three were anuric at T0. PFK-L was not detected. There were no statistically significant changes in expression of PFKFB2, pSer483-PFKFB2, PFKFB3, PFKFB4 and PK-M2 over time. Expression of PFKFB2 and PK-M2, however, was seen in 8/8 subjects at T1 and persisted in 7/8 subjects at T3. PK-LR was detected in 4/5 samples at T0 and not thereafter (p=0.0010). NGAL was detected in 4/5 subjects at T0 and in 8/8 at T1-3, with expression measured by densitometry reducing over time (p=0.043).

Conclusions: Regulation of glycolytic control in the early post-transplant period is poorly understood. We identified changes in PFKFB2 and PK-M2 immediately post-transplant, which persists over time. PFKFB2 and PK-M2 have been associated with increased glycolysis, including aerobic glycolysis. Future studies will focus on the way this can be used to monitor kidney transplants.

Figure 1 - Representative Western blots of one recipient with UEV at time points T1, T2 and T3 (anuric at T0). Human kidney lysate (HK) was the positive control.



TH-PO801

Single-Center Observational Study of Torque Teno Virus in Mainly Steroid-Free Adult and Pediatric Kidney Transplant Recipients

Ann-Maria Gramkow,[1] Helle C. Thiesson,[1,2] Maja Nørgaard,[3] Pernille Koefoed-Nielsen,[3] Randi Berg.[3] *[1]Odense Universitetshospital, Odense, Denmark; [2]Syddansk Universitet Det Sundhedsvidenskabelige Fakultet, Odense, Denmark; [3]Aarhus Universitetshospital, Aarhus, Denmark.*

Background: Torque Teno Virus (TTV), an apathogenic single-stranded anellovirus, is prevalent in solid organ transplant recipients. Evidence suggests that its replication varies with immunosuppression after transplantation. This study investigates TTV correlations with rejection and infections in kidney transplant recipients and assesses the impact of steroid-free versus steroid-containing therapy. It explores individual TTV trajectories over time and compares TTV dynamics and levels between adult and pediatric recipients.

Methods: We prospectively collected 1704 samples from 310 adults and 20 pediatric recipients after transplantation. All recipients received tacrolimus and mycophenolate mofetil; 27% also received prednisolone, while the remainder were steroid-free. TTV was quantified with an in-house rtPCR assay. Cox regression models assessed TTV's association with rejection and infections, while mixed effects linear regression models analyzed other outcomes.

Results: We observed a decreased hazard ratio for rejection (HR 0.90, 95% CI: 0.82-0.99) with increasing TTV load but no association with infections (HR 1.00, 95% CI: 0.97-1.03). TTV levels were 0.66 (95% CI: 0.42-0.90) log10 copies/ml higher in recipients receiving prednisolone than those not receiving prednisolone ($p<0.001$). Stratification by TTV levels at transplantation revealed significant differences in levels over time: 2.51 (95% CI: 2.32-2.69) log10 copies/ml in the first tertile, 4.32 (95% CI: 4.02-4.62) in the second, and 5.02 (95% CI: 4.77-5.26) in the third. TTV peaked three months post-transplantation, then declined to stabilize, with no significant differences between adult and pediatric recipients.

Conclusions: We observed decreasing TTV levels correlated with increased rejection risk, but no association with infections. Notably, steroid use increased TTV levels, suggesting caution extrapolating TTV thresholds established from steroid-based regimens on steroid-free populations. Recipients with low TTV levels at transplantation maintained this trend over time. Further research is warranted to explore individual TTV trajectories. No differences in TTV level or dynamic were observed between adult and pediatric recipients, supporting the applicability of TTV in pediatric recipients.

TH-PO802

Assessing Stability of Donor-Specific Antibodies (DSA) in Relation to Changes in Donor-Derived Cell-Free DNA: A Retrospective Cohort Study

Bradley Hyman. *Memorial Hermann Texas Medical Center, Houston, TX.*

Background: Focus of renal transplant recipients has turned toward prolonging the life of the graft. Donor-derived cell-free DNA (dd-cfDNA), is now validated for the assessment of allograft injury in transplant recipients. Given the relatively new use, the relevance of persistently elevated levels of dd-cfDNA remains unknown. In this study, we compare patients with and without sustained elevation above 1% for more than 12 months and their relationship with transplant biomarkers.

Methods: This retrospective cohort study included all patients managed at UTHealth, University of Texas at Houston. In routine clinical care, post-transplant patients are seen in clinic every 3 months after the acute post-transplant period. At each visit, blood and urine tests were performed. Estimated glomular filtration rate (eGFR) was calculated using the Chronic Kidney Disease in Children Under 25 (CKiD U25) equation. Data were de-identified prior to analysis.

Results: From 2017 to 2023, a total of unique 61 pediatric renal transplant recipients were followed at the UTHealth transplant clinic. We excluded patients who had undergone combined visceral organ transplant (n=4) and those with less than 4 dd-cfDNA values reported by the end of the study period (n=14). Among the 43 patients included in the analysis, 10 patients experienced persistently elevated dd-cfDNA levels, >=1.0% for at least 12 months. No differences were noted when comparing baseline characteristics, cause of ESRD, or transplant source between the two groups. Comparing between the two groups, for those with dd-cfDNA level >1.0% for more than one year, there was a difference in DSA data. For those who met the defined threshold, DSA presence was increased (OR 4.03, 95% CI, 0.81 to 20.0, p value 0.088). Further analysis of DSA classes showed increased presence of Type A and B (OR 22.2 and 55.7, respectively, p-value <0.001). After controlling for months from transplant, sustained elevation of dd-cfDNA levels was an independent risk factor for presence of DSA.

Conclusions: To our knowledge, this is the first pediatric study evaluating sustained elevation of dd-cfDNA levels and its association with DSA. Obtaining dd-cfDNA levels during these visits can easily be performed and could provide supplemental information for the continued monitoring and management of renal transplant recipients.

TH-PO803

Discovery and Validation of a Kidney Rejection Prediction Model Using Urinary CXCL9 and CXCL10

Kenny W. Chen,[1] Lihui Zhao,[1] Sookhyeon Park,[1] Sujay D. Paudel,[1] Ronnie Lacombe,[2] Steven Kleiboeker,[2] John J. Friedewald.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Eurofins Viracor BioPharma Services, Lenexa, KS.*

Background: Urinary chemokines (CXCL9 + CXCL10) have shown to be non-invasive biomarkers in diagnosing kidney rejection. We aim to discover and validate a rejection prediction model combining the two by assessing the diagnostic performance in two independent cohorts.

Methods: We analyzed 638 biopsy paired urine samples paired from the CTOT-08 trial for discovery and then samples from an internal study cohort as a validation. We fit univariate logistic regression models using urine CXCL9 and CXCL10 normalized to urine creatinine and a logistic regression model with both to predict kidney rejection. AUC was used to evaluate the model's diagnostic performance.

Results: The univariate logistic model with CXCL9 had an AUC of 0.694 while the univariate model with CXCL10 had an AUC of 0.634. In the logistic model with both CXCL9 and CXCL10, the AUC was 0.678. In the validation cohort, the univariate model with CXCL9 had an AUC of 0.674, the univariate model with CXCL10 had an AUC of 0.677 and the model with both had an AUC of 0.678.

Conclusions: Incorporating urinary biomarkers CXCL9 and CXCL10 into prediction models to monitor kidney rejection resulted in moderately high diagnostic value (AUC: 0.63 – 0.68). This performance held in the external validation cohort. The combination of both biomarkers did not significantly improve model performance.

TH-PO804

Impact of Donor-Derived Cell-Free DNA Testing on Patient and Graft Outcomes

Fawad Shuaib,[1] Ana L. Castellanos,[1] Sravanthi Paluri,[1] Lauren Schumacher,[1] Olivia Philippart,[1] Jesica Yau,[2] Hasan Fattah.[1] *[1]University of Kentucky, Lexington, KY; [2]CareDx Inc, Brisbane, CA.*

Background: The objective of this study was to compare outcomes in cohorts of patients with and without donor-derived cell-free DNA (dd-cfDNA) testing.

Methods: This is a single center retrospective cohort study of kidney transplant recipients (KTRs) comparing a historical cohort of patients transplanted from 2015-2017 without dd-cfDNA testing and cohort of patients transplanted from 2019-2022 with dd-cfDNA testing. Outcomes included BPAR, DSAs, death censored graft loss, death, and renal function at 1 year.

Results: 408 KTRs were included in the analysis. There were significantly more patients with DGF and DCD donor type in the dd-cfDNA cohort (Table 1). At 1-year post-transplant, there was no significant difference in DSAs (7.4% vs 8.3%; p=0.75) or BPAR (6.5% vs 7.8%, p=0.621) between the two groups. Statistical analysis on death-censored graft loss and patient death was not performed due to few KTRs reaching these

outcomes (Table 2). Serum creatinine and eGFR at 1-year was not significantly different between the two cohorts, whereas there was significantly less proteinuria in the historical cohort (7.5% vs 13.6%, p=0.044). When stratifying the dd-cfDNA cohort by results ≥ 0.5% vs <0.5% at 3 months and 1 year, there was significantly more BPAR seen in the ≥ 0.5% dd-cfDNA cohort.

Conclusions: There was no difference in most outcomes between the two cohorts, except for more proteinuria in the dd-cfDNA cohort. This result is limited due to higher proportion of KTRs with DGF and DCD donor type in the dd-cfDNA cohort. Assessing effectiveness of dd-cfDNA monitoring was limited to 1 year follow up period in our study. The impact of dd-cfDNA testing frequency on patient-centered outcomes remains unknown. Further studies are needed to study the ideal testing frequency impact on such outcomes.

Selective Implementation of Belatacept (Bela) Every Other Month as a Standard Care Option with the Use of Donor-Derived Cell-Free DNA (dd-cfDNA) Testing

Jae H. Son, Ryan Fields, Geeta Karadkhele, Michael Hurtik, Payaswini Vasanth, Christian Larsen. *Emory University, Atlanta, GA.*

Background: The goal of this study is to safely transition selected kidney transplant recipients who are 24 months post-transplant to an every-other-month Bela regimen using dd-cfDNA monitoring.

Methods: A cohort of 13 patients was included. Inclusion criteria were at least 24 months post-transplant, off calcineurin inhibitors for a minimum of 6 months, free from acute cellular rejection or donor-specific antibodies, and stable renal function for ten months. Increased monitoring for q2 months Bela included dd-cfDNA approximately monthly for six months, then every month until one year after the transition, followed by every six months.

Results: dd-cfDNA was used to detect cell death, which is not rejection-specific. Creatinine values from 180 days before the beginning of cfDNA were used to help establish a baseline. In the study, the Subjects' creatinine (Cr) was stable. Two subjects experienced a concerning increase in cfDNA that was not associated with increased Cr. cfDNA levels and returned to baseline. Two subjects had a short interval of noncompliance with MMF without overt signs of rejection. One was advised to return to the standard regimen but refused. Cr remained at baseline.

Conclusions: Bela preserves renal function, reduces DSA formation, and improves long-term survival. Standard monthly infusions lead to significant costs, monthly travel, and frequent healthcare encounters for life. In the current climate, the institution that provides this service facilitates crucial care coordination (recurrent scheduling, extensive tracking, etc.) with a strained infusion capacity for an ever-growing population. We have found that q2 monthly Bela with cfDNA monitoring is a safe alternative to monthly infusions. This regimen mitigates the risk of rejecting futile biopsies, improves compliance, and decreases the financial burden of healthcare.

TH-PO806

Use of Donor-Derived Cell-Free DNA and Gene Expression Profiling to Facilitate Belatacept Monotherapy in Kidney Transplant Recipients

David Wojciechowski,[1] Juan D. Salcedo Betancourt,[1] Morgan Marsh,[1] Cyrus Feizpour,[3] Hwarang S. Han,[2] Laila S. Lakhani,[1] Swee-Ling Levea,[1] Lee E. Anderson.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]The University of Texas at Austin, Austin, TX; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: Donor-derived cell-free DNA (AlloSure) levels <1.0 % and gene expression profiling (AlloMap) score <11.5 help discriminate immune quiescence from acute rejection. We investigated their utility in weaning to belatacept monotherapy.

Methods: Between December 2022 and April 2024, we enrolled adult kidney recipients on belatacept immunosuppression with stable renal function (eGFR >40 mL/min/1.73m2) and absent Donor-Specific Antibodies (DSA) into a 12-month prospective, single-center, interventional pilot study. AlloSure, AlloMap, serum creatinine, spot urine protein, and DSA were measured at monthly infusion visits. Patients deemed clinically stable (eGFR <20% lower than baseline, absence of biopsy-proven rejection) and immune quiescent (absence of de novo DSA, AlloMap <11.5, AlloSure <1.0 % or >0.5% without a change >61% from baseline) underwent immunosuppression tapering. Outcomes included biopsy-proven rejection, allograft/patient survival, change in eGFR, proteinuria or de-novo DSA development, and percentage of patients weaned to belatacept monotherapy.

Results: We analyzed the first 19 patients who completed at least 6 months of follow-up. Subjects were predominantly male (n=14) with a mean age of 56 years. Mean eGFR in mL/min/1.73m2 was 72.84 ± 19.04 SD at enrollment and 70.47 ± 18.59 SD at 6 months. The most common agents used with belatacept were prednisone + mycophenolate (n = 16), prednisone + everolimus (n = 2) or sirolimus (n=1). Mean AlloSure and AlloMap throughout were 0.27% ± 0.25 and 11.29 ± 1.99 respectively. 5 patients (26%) were weaned off prednisone, and 2 were weaned entirely off prednisone and mycophenolate. There was 100% patient and graft survival, with no biopsy-proven rejection, nephrotic proteinuria, or DSA development.

Conclusions: Despite having AlloSure <1%, the mean AlloMap score was above the reported threshold shown to discriminate rejection from quiescence. We hypothesize that patients on belatacept-based immunosuppression have higher AlloMap scores even if immune quiescent, as prior studies primarily included patients on tacrolimus-based immunosuppression. Higher cutoffs may be necessary for this population. Investigation is ongoing to test this hypothesis in our cohort.

Histopathological Discordance with Sequentially Rising Donor-Derived Cell-Free DNA

Andrew Slater, William L. Clapp, Alfonso Santos, Amer A. Belal. *University of Florida, Gainesville, FL.*

Introduction: Plasma donor-derived cell-free DNA (dd-cfDNA) fraction is a promising, non-invasive predictive tool for allograft kidney rejection. An elevated dd-cfDNA fraction when combined with HLA de novo donor-specific antibody (dnDSA) can further be used to predict ABMR. We discuss a case where the dd-cfDNA and dnDSA inform decisions to seek a biopsy that is ultimately inconsistent with the predictive models for ABMR.

Case Description: A 73-year-old male with ESKD due to Type 2 diabetes had a living, unrelated kidney transplant (KT). There were no pre-formed anti-HLA antibodies, and HLA A-B-DR mismatch was 2-2-1. Induction was with basiliximab. He started tacrolimus (TAC), mycophenolate (MMF) 750 mg BID and prednisone. Two months post KT, MMF was reduced to 500 mg BID due to leukopenia. Three months post KT, MMF was paused for neutropenic fever and then resumed at 250 mg BID. He developed low titer BK viremia. TAC trough goal was reduced to 4-6 mcg/L. The prednisone dose was reduced from 10 mg to 5 mg daily. The patient began serial checks of dd-cfDNA, with a dd-cfDNA fraction of 0.19%. 13 months post KT, the repeated dd-cfDNA fraction increased to 0.28% with a new finding of a single dnDSA, DQ2 (8000MFI). Although he had stable creatinine without proteinuria, there was concern for subclinical acute rejection. An allograft biopsy showed mild glomerulitis without evidence of acute rejection but with findings of mild glomerulitis. There was concern for microvascular injury of immunologic causes, so serial measurement of dd-cfDNA and dnDSA continued. 16 months post-KT, the dd-cfDNA rose to 2.1%. Although creatinine remained stable without proteinuria, a second kidney biopsy was done. There was focal, minimal peritubular capillary staining for C4d without morphological evidence of rejection. 28 months post-KT, creatinine has remained stable without proteinuria.

Discussion: Although novel tools exist in predicting allograft kidney rejection, they are imperfect and require careful interpretation and application. There was marked discordance between the probability of active rejection, as indicated by the combination of elevated and sequentially rising fractions of dd-cfDNA and dnDSA, and the absence of histological, immunofluorescence, and electron microscopic evidence of rejection on two kidney allograft biopsies 4 months apart.

TH-PO808

Transcriptomic Analysis of Kidney Allograft Biopsies May Allow Early Detection of Rejection, Precise Rejection Typing, and Dynamic Treatment Monitoring

Thomas Schachtner, Vila S. Angheloiu, Lukas Weidmann, Dusan Harmacek, Britta George, Elena Rho, Ariana Gaspert, Seraina C. Von Moos. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: The 2022 Banff Meeting Report suggests that biopsy-based transcripts related to antibody-mediated rejection (AMR) could substitute for microvascular inflammation (MVI). In addition, transcriptomic analysis may (1) detect molecular signatures associated with rejection earlier than traditional histopathologic methods, (2) distinguish between different types of rejection more accurately, and (3) provide more quantifiable measures of treatment responses. Studies with follow-up biopsies, however, are needed to test the performance of biopsy-based transcript analysis for these aims.

Methods: From 2018 to 2023, we examined 62 kidney transplant recipients and 139 kidney allograft biopsies evaluated by histology and the Molecular Microscope Diagnostic System (MMDx). The 62 biopsy series were analyzed regarding (1) the time of rejection diagnosis, (2) the type of rejection, and (3) the response to treatment.

Results: 20, 5, 8, and 29 of the initial biopsies showed histologic AMR/DSA-negative MVI, TCMR, mixed AMR/TCMR, and no AMR/TCMR (including 8 probable AMR cases), respectively. Molecular AMR, TCMR, and mixed AMR/TCMR were detected in 17, 4, and 8 of the initial biopsies, respectively. Follow-up biopsies were obtained at a median of 9 months (IQR 4,18) after the initial biopsy. With the MMDx, AMR was detected sooner in 8 cases (including 3 probable AMR cases by histology), which was verified histologically by the follow-up biopsy. There were 3 cases of histologic TCMR with mixed molecular AMR/TCMR and 2 cases of histologic AMR with mixed molecular AMR/TCMR. Follow-up biopsies verified the presence of mixed AMR/TCMR in all 5 cases by histology. Using transcriptomic analyses, treatment responses were observed in 1 early active AMR and 3 mixed AMR/TCMR cases (by rejection classifier scores) but not by histology. 5 of 20 histologic AMR cases (25%) showed no molecular AMR signature throughout the biopsy series.

Conclusions: Biopsy-based transcript diagnostics can help detect rejection sooner and identify rejection types more precisely, which might reduce the need for repeat biopsies and support treatment decisions. Molecular diagnostics may also allow clinicians to measure treatment outcomes more comprehensively through follow-up biopsies.

TH-PO809

Pretransplant Inflammatory Biomarkers Predict Death-Censored Graft Failure after Kidney Transplantation

Elizabeth C. Lorenz,[1] Byron H. Smith,[2] Amanda L. Tapia,[2] Walter Park,[2] Mark D. Stegall.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Pre-transplant inflammatory biomarkers have previously been associated with adverse kidney transplant (KT) outcomes, including delayed graft function and acute rejection. The goal of this study was to determine if pre-KT inflammatory biomarkers are also associated with graft failure after KT.

Methods: We retrospectively measured inflammatory biomarker levels in serum collected up to 1 year prior to KT in recipients transplanted at Mayo Clinic in Rochester, Minnesota between 1/2006-12/2018. The following biomarkers were chosen based on their association with medical risk across multiple patient populations: interleukin-15 (IL-15), IL-1β, monocyte chemoattractant protein-1 (MCP-1), growth differentiation factor-15 (GDF-15), IL-6, monokine induced by gamma interferon/chemokine (C-X-C motif) ligand 9 (MIG/CXCL9), soluble FAS (sFAS), soluble tumor necrosis factor receptor-1 (sTNF-R1), and TNFα. Biomarker levels were normalized with Z-transformation. Kaplan-Meier estimation and Cox regression were used to examine the relationship between biomarkers and death-censored graft failure.

Results: Our cohort consisted of 1,595 KT recipients with a mean age of 52.0 ± 14.2 years; 62.9% were male and 83.2% were White. Over a mean follow-up of 7.4 ± 3.9 years, 10.4% of patients (n=166) experienced death-censored graft failure. Higher pre-KT levels of soluble tumor necrosis factor receptor-1 (sTNF-R1) were significantly associated with death-censored graft failure after adjusting for other biomarkers (HR 1.4 per standardized log-value, 95% CI 1.2-1.7, p=0.0006).

Conclusions: Pre-KT activation of TNF pathways may contribute to graft failure following KT. Measuring pre-KT serum concentrations of sTNF-R1 may help to risk stratify and manage patients undergoing KT.

Pediatric Transplantations: Clinical and Training Perspectives Based on a Survey of Pediatric Transplant Fellows

Nikhil Nair,[1] Mignon McCulloch,[2] Rupesh Raina.[3,4] *[1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Red Cross War Memorial Children's Hospital, Rondebosch, South Africa; [3]Cleveland Clinic Akron General, Akron, OH; [4]Akron Children's Hospital, Akron, OH.*

Background: The aim of this survey was to identify the satisfaction and shortcomings that pediatric transplantation fellows have with their education. Additional aims included the identification of strategies and modalities to better improve transplant education during fellowship.

Methods: An online Qualtrics survey composed of 29 questions available in Enlgish and Spainish was distributed to pediatric transplant fellows through various international pediatric and transplant associations. The responses of the online survey was entered into the Microsoft Excel and analysis was performed using SPSS version 22.

Results: A total of 237 physicians responded to the survey with a diverse distribution participants from Europe(38.4%), Asia(30%), the Americas(27.2%), Africa(2.1%) and Ocenaina(2.1%). In regard to overall education, most patients felt they were adequately educated on the important aspects of pre and post transplant care. Content areas fellows felt they were more lacking in education included transition protocols from paediatrics to adult care post transplantation(12.2%), immuno-suppression regimens post-transplantation(10.6%), and side-effects of different immunosuppression regimens post-transplantation(10.6%). In regards to improving the fellow education process, the formats fellows felts were most likely to help included, discussions of fellow's cases(88.8%), short presentations with open questions(69.2%) and Pro/con discussions(57.0%). Overarching competencies that warranted inclusion and emphasis according to fellows included critical thinking(80.6%), problem solving(76.6%) and leadership skills(69.6%).

Conclusions: This survey provides valuable information in regard to the quality of training and knowledge base from a diverse group current/former pediatric fellows from around the world. The majority of fellows are getting good to above average education for the majority of content areas they are expected to know over the course of their fellowship. Despite this there are still key foundational areas in immunosuppression and post transplant management that can use investigation for new methods for delivery information. The fellows who responded to this survey identified several promising methods for developing new educational content to serve as the foundation for discussion for the development of updated training guidelines.

TH-PO811

Pediatric Kidney Transplant and BK Viral Infection: A Single-Center Retrospective Analysis of Interventions and Outcomes

Raja Dandamudi,[1,2] Kevin T. Barton,[1,2] Vikas R. Dharnidharka.[1,2]
[1]Washington University in St Louis, St Louis, MO; [2]St. Louis Children's Hospital, St Louis, MO.

Background: In a single-center cohort of pediatric renal transplant patients, we investigated BK virus-associated nephropathy (BKVN) incidence, management strategies, and clinical outcomes.

Methods: We analyzed kidney transplant patients from Jan 2009 to Dec 2022. Ureteral stents placed during transplantation removed in 4-6 weeks. Recipients had monthly urine and plasma PCR screening for BK virus for the first 12 months and during rejection treatment.

Results: Among 101 patients, 17 (16.8%) had BK viruria, 15 (14.9%) had presumptive BKVN (DNAemia >10,000 copies/mL), and 15 (14.9%) had probable BKVN (DNAemia 1,000-10,000 copies/mL), with 4 showing blip DNAemia. Median time to BK viruria was 48 days post-transplant and 141 days for BK viremia. Of the 15 patients with presumptive BKVN, 11 (73.3%) were male; 10 (66.6%) were white, 4 (26.7%) African American, and 1 (6.7%) other. Mean age at transplantation was 11.6 years (range 2.4-18.4); 11 (73.3%) received kidneys from deceased donors. 10 patients had IVIg monthly at 500 mg/kg for 6 months. Before IVIg, mean urinary BKV DNA was 232 million ± 574 million copies/mL, and plasma load was 171,945 ± 428,810 copies/mL. At diagnosis, mean serum creatinine peaked at 1.3 mg/dL (baseline 0.85 mg/dL). Post-treatment, mean serum creatinine improved to 0.95 mg/dL, and plasma BKV DNA load decreased to 312 ± 788 copies/mL. 7/10 had non-quantifiable plasma loads. One IVIg-allergic patient received leflunomide alone, clearing BK viremia from 160,000 to non-quantifiable levels, with creatinine improving from 1.6 to 1 mg/dL. 4 patients received 10 monthly doses of IVIg but did not clear DNAemia and then received leflunomide. Two cleared BK virus (mean 27,900 copies/mL to undetected) with creatinine improving (2.02 to 1.14 mg/dL). Two non-responsive patients received low-dose IV cidofovir (0.5-0.75 mg/kg/dose) for six doses. Despite BK viral level improvements (28,000 to 15,000 copies/mL), viremia clearance was unsuccessful, with minimal creatinine improvement (1.45 to 1.2 mg/dL).

Conclusions: At our center, IVIg seems to be an effective treatment for persistent BKVN after failed reduction in immunosuppression. IVIG was effective in 70% of cases, while leflunomide alone or following IVIG was effective in 60%. The addition of cidofovir for those resistant to IVIG and leflunomide was not successful.

TH-PO812

Probability of Kidney Transplant in the Pediatric ESKD Population by Residence Type

Lucas Barrett, Morgan B. Swanson, David Axelrod, Lyndsay Harshman.
University of Iowa Health Care, Iowa City, IA.

Background: Rurality is a commonly cited barrier to care in pediatric nephrology. Utilization of healthcare by pediatric chronic kidney disease (CKD) patients has been shown to be largely centralized, with more than 86.6% of hospitalized pediatric CKD patients being cared for in urban teaching hospitals in one study. Access to care is a particular problem in CKD as it is a progressive disease that often leads to end-stage kidney disease (ESKD) requiring dialysis and/or kidney transplantation (KT). The goal of this study is to estimate the effect of rural or micropolitan residence, compared to urban residence, on probability of KT in patients with pediatric ESKD in the United States (US).

Methods: We performed an observational cohort study using the US Renal Data System (USRDS) to identify pediatric (< 18 years) ESKD patients who have their first ESKD service between 2000 and 2019 and classify them using ZIP codes to rural, micropolitan, or urban residence at time of first ESKD service. Stabilized inverse probability of treatment weighting (IPTW) was used to balance rural, micropolitan, and urban groups based on their baseline covariates. Weighted Cox regression was used to calculate the hazard ratio of experiencing KT for rural and micropolitan patients compared to urban. Sensitivity analyses were run using time-varying residential status, mean and median imputation for missing calculated panel reactive antibody percentage and competing risks regression.

Results: The final cohort of 14,404 pediatric (<18 years old) patients had 12,390 patients (86.0%) with urban residence, 1,095 patients (7.6%) with micropolitan residence, and 919 patients (6.4%) with rural residence. Of the cohort, 13,316 patients underwent kidney transplantation and 369 died prior to transplantation. Cox regression showed a non-significant decrease in probability of transplantation for patients who had rural (HR = 0.95, 95% CI = 0.86, 1.06) and micropolitan (HR = 0.99, 95% CI = 0.91, 1.07) residence compared to urban residence. Sensitivity analyses had similar results.

Conclusions: Despite differences in healthcare resources between rural, micropolitan, urban areas in the US, once children receive their first ESKD service we did not identify a difference in probability of receiving KT based on rurality of residence.

TH-PO813

Linear Growth after Pediatric Kidney Transplant: Factors Influencing Catch-Up Growth in a Retrospective Cohort

Patrick Ribeiro, Paula S. Campelo, João Victor R. Borges, Leonardo P. Stakonski, Marcos K. Hesler, Marco A. De Barros, Lucimary D. Sylvestre, Maria H. Peralta, Andrea N. Moreno-Amaral. *Pontificia Universidade Catolica do Parana, Curitiba, Brazil.*

Background: Children with chronic kidney disease often face growth deficits due to electrolyte, nutritional, and hormonal issues. Kidney transplantation (KT) can enhance growth, but catch-up growth (CUG) to expected height for age is not always achieved. Understanding post-transplant (PT) growth is vital for optimizing interventions, such as growth hormone (GH) use, which is limited in Brazil. Therefore, this study aims to identify the prevalence and factors associated with sufficient CUG in children who underwent KT.

Methods: This retrospective cohort study at a tertiary pediatric nephrology center in Brazil included patients under 18 who had KTs between 2010 and 2023. Data were collected from medical records. Sufficient CUG was defined as an increase in height standard deviation score (SDS) ≥ 0.5 SD from pre-transplant to 2 years PT. Weight, height SDS and BMI-for-height-age SDS were compared using ANOVA for repeated measures, followed by Bonferroni post hoc tests for normally distributed variables, and the Friedman test with Bonferroni-adjusted significance level post hoc analysis for non-normal variables. Logistic regression was used to identify pre-transplant factors associated with CUG, with significance set at 5%.

Results: The sample included 27 patients (mean age 9.4 years, 81.5% male). Dialysis modalities included peritoneal (44.4%), hemodialysis (29.6%), and both (18.5%). Uropathy was the main etiology (51.9%). None used GH during follow-up. Preemptive transplants accounted for 7.4%. KT significantly improved weight ($p<0.001$), height SDS ($p<0.024$), and BMI-for-height-age ($p<0.002$), with more pronounced gains in the first 6 months. Improvements stabilized between 6 months and 1 year. Among the 22 patients who followed up to 2 years, sufficient CUG was observed in 18.2%. Univariate and multivariate analyses found no significant associations between the pre-transplant characteristics and CUG.

Conclusions: KT significantly improved height and weight, though only a small proportion achieved sufficient CUG after 2 years. Larger studies are needed to identify factors involved in CUG and optimize interventions.

TH-PO814

BMI in Pediatric Kidney Transplant Candidates: Association with Neurodevelopmental Outcomes

Lidan Gu,[1] Danielle M. Glad,[2] Christopher J. Anzalone,[3] Finola E. Kane-Grade,[4] Michael D. Evans,[1] Sarah J. Kizilbash.[1] *[1]University of Minnesota Medical School, Minneapolis, MN; [2]Medical College of Wisconsin, Milwaukee, WI; [3]Boston Children's Hospital, Boston, MA; [4]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Recent studies indicated that both low and high body mass index (BMI) in pediatric kidney transplant patients is linked to higher graft failure and mortality risk (al Tamimi et al., 2023; Bonthuis et al., 2023; Winnicki et al., 2018). However, the interaction of BMI, neurocognitive outcomes, and transplant outcomes has not been explored. This study aimed to evaluate the association between BMI, neurocognitive outcomes, and transplant outcomes.

Methods: A retrospective study was completed for 75 patients aged 3 to 17 years who completed pre-transplant neuropsychological evaluations at University of Minnesota Medical Center between 2010 and 2022. Neurocognitive outcome variables include Full Scale IQ, Verbal Comprehension, Nonverbal Reasoning, Working Memory, and Processing Speed. Medical (i.e., pre-transplant BMI, eGFR 1 year and 5 years post-transplant) and demographic variables were retrieved from the electronic medical records. Based on the CDC guideline, patients were categorized to underweight, normal, overweight, and obese groups. Analysis of Variance was used to exam the effect of BMI category on neurocognitive outcomes. Spearman correlations examined the correlation between BMI z scores, neurocognitive performance, and eGFR at 1 and 5 years.

Results: The mean age at the time of neuropsychological evaluation was 11.7 years (SD=3.6). The mean age at kidney transplant was 13.3 (SD=3.6). The mean BMI z score was 0.2 (SD=1.2). Within the 75 patients, 7 (9.3%) were underweight, 45 (60.0%) were normal, 12 (16%) were overweight, and 11 (14.7%) were obese. There was a significant effect of BMI category on Working Memory performance ($F(3)=2.82$, $p=0.045$). Patients with normal BMI had higher Working Memory performance than patients who were underweight or overweight. There was no significant effect of BMI category on other neurocognitive outcomes (p values ranged from 0.197 to 0.60). Pre-transplant BMI z scores were not significantly associated with eGFR at 1 year or 5 years post-transplant.

Conclusions: Our study found that pre-transplant body mass index (BMI) was associated with pre-transplant working memory in pediatric kidney transplant candidates. The findings highlight the importance of a multidisciplinary approach to managing medical and neurocognitive factors to ensure optimal outcomes in this population.

TH-PO815

Decreasing Trends in Pediatric Kidney Transplantation in Mexico, 2007-2023

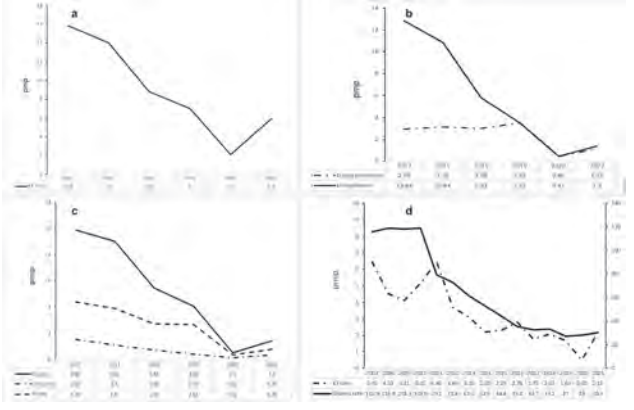
Ana E. Oliva,[1] Jochen G. Raimann,[2] Ariella E. Mermelstein,[2] Andrea Nandorine Ban,[2] Yuridia Plascencia,[3] Mara Medeiros,[4] Araceli Cisneros,[5] Jonathan Chavez,[1,6] Guillermo Garcia-Garcia.[6] *[1]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; [2]Renal Research Institute, New York, NY; [3]Hospital de Pediatria Centro Medico Nacional de Occidente, Guadalajara, Mexico; [4]Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico; [5]Hospital San Javier, Guadalajara, Mexico; [6]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico*.

Background: Kidney transplantation (KT) is the most preferable therapy for children with end-stage kidney disease (ESKD). There is a paucity of information on temporal trends of KT in children in Mexico. We analyzed data of KT in children < 18 years between 2007-2023, to determine the presence of inequalities in access to KT.

Methods: In this retrospective study of pediatric ESKD patients receiving KT, we analyzed data from the national transplant center database between 2007- 2023. Transplant rates are presented by insurance status and donor type and standardized to the general population in the respective age segment as per million population (pmp). In the absence of a national dialysis registry, we estimated trends of dialysis prevalence based on data from the Jalisco state registry.

Results: We analyzed a total of 5,123 KT patients. The median age was 14 years (IQR 12 to 16), 57% males, and 71% were recipients from living donors. 32% were uninsured, 61% had public and 8% private insurance. Annual KT rates decreased steadily from 15.8 pmp in 2007 to 7.0 pmp in 2019, and further to 2.1 pmp during the COVID-19 pandemic, mainly in those with living donors (12.8 pmp to 3.5 pmp). The decrease was independent of health insurance status (**Fig a to c**). Consistently, in Jalisco KT rates dropped from 6.45 pmp in 2007 to 1.66 pmp in 2019 accompanied by a decrease in dialysis prevalence from 115.9 pmp in 2008 to 27.0 pmp in 2019 (**Fig d**).

Conclusions: Pediatric kidney transplant rates in Mexico have consistently decreased over the last 17 years, independent of health insurance status. Based on the results from Jalisco the drop is accompanied by a decrease in the number of dialysis patients. It remains to be evaluated if the decrease is caused by limited access to dialysis treatment or due to decreases in the prevalence of ESKD.



Pediatric kidney transplantation rates

TH-PO816

Safety and Efficacy of Selective Plasma Exchange vs. Conventional Plasma Exchange in Pretransplant Desensitization of ABO-Incompatible Kidney Transplantation

Takahiro Inoue,[1,2] Norio Hanafusa,[1] Yuki Kawaguchi,[1] Kohei Unagami,[1] Junichi Hoshino,[1] Hideki Ishida,[1] Toshio Takagi,[1] Ken Tsuchiya.[1] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Tsukuba Kidney Clinic, Tsukuba, Japan*.

Background: Selective Plasma Exchange (SePE) is a new simple PE modality that uses a membrane plasma separator with a smaller pore size compared to conventional plasma separators and enables removal of small and medium-sized molecules without removing larger substances such as coagulation factors. Conventional PE (CPE) supplemented with fresh frozen plasma (FFP) is performed preoperatively to reduce the risk of bleeding, but adverse events associated with FFP are common. Since July 2022, our institution has started SePE as a desensitization method before ABO-incompatible kidney transplantation.

Methods: This is a single-center, retrospective cohort study of patients undergoing ABO-incompatible kidney transplantation from January 2020 to April 2024. Seventy-five patients underwent apheresis for antibody removal prior to kidney transplantation and were divided into two groups: one undergoing CPE with FFP and the other undergoing SePE. The safety and efficacy of both groups were compared.

Results: In the CPE group, adverse events were observed in 17 cases, including four instances of anaphylactic shock. In the SePE group, hypotension was observed in five cases, but no serious adverse events were reported. Except for one case, preoperative antibody levels in both groups were reduced to less than 32 times the target. Although the surgical time was longer for the CPE group, there was no significant difference in intraoperative blood loss between the two groups.

Conclusions: Both groups showed adequate antibody removal, whereas the incidence of adverse events in the pretransplant desensitization of ABO-incompatible kidney transplantation was lower in the SePE group compared to the CPE group.

Clinical features and Outcome between SePE group and CPE group

Patients undergoing kidney transplantation(N = 75)	SePE(N = 48)	CPE(N = 27)	P value
Age, years.	51.1 ± 13.1	49.2 ± 13.8	0.568
IgM (initial titers at admission)	16.0 (8.0-16.0)	16.0 (8.0-32.0)	0.152
IgM(titers at transplantation)	2.0 (2.0-4.0)	1.0 (1.0-2.0)	0.006
IgG (initial titers at admission)	8.0 (2.0-16.0)	64.0 (32.0-128.0)	0.017
IgG(titers at transplantation)	2.0 (2.0-4.0)	4.0 (2.0-16.0)	0.007
Surgical operating time, min.	234.5 (213.0-280.0)	274.0 (243.0-316.0)	0.015
Total blood loss, ml.	200.0 (93.8-298.0)	150.0 (80.5-292.5)	0.811
Patients experiencing adverse events during PE, n.%	5 (10.4)	17 (63.0)	<0.001
Anaphylactic shock, n. %	0 (0)	4 (14.8)	0.027

TH-PO817

Effects of Desensitization Therapy on Acute Rejection and Graft Function in Patients Who Are Hyperimmunized after Receiving a Living-Donor Kidney Transplant

Caren D. Castro,[1,2] Jorge Andrade-Sierra,[3,1] Hugo L. Reynoso de la Torre,[1,2] Enrique Rojas-Campos,[1,2] Luis Alberto Evangelista-Carrillo,[1,2] Mauricio Carvallo Venegas,[1,2] Adriana Banda Lopez,[1,2] Jose Ignacio Cerrillos,[1,2] Miguel Medina Perez,[1,2] Diana Laura Muñoz.[1,2] *[1]Instituto Mexicano del Seguro Social. UMAE-Centro Medico Nacional de Occidente. Depto Nefrologia y Trasplantes, Guadalajara, Mexico; [2]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico; [3]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico*.

Background: Desensitization therapy may enhance the probability of successful kidney transplantation (KT) and ensure long-term survival for hyperimmunized patients.

Methods: A retrospective cohort included 38 patients ≥18 years with a positive DSA flow crossmatch test. (January 2018 to December 2022). All patients received pre-transplant desensitization using plasmapheresis (PF), immunoglobulins (IG), rituximab (RTX) and maintenance immunosuppressive consisting of mycophenolic acid, prednisone, tacrolimus (TAC) and thymoglobulin. The occurrences of infectious and acute rejection (AR) episodes were registered.

Results: The function of the graft at 12 months was 80 ± 28.5 ml/min/1.73m2 and AR rate was 18.4% (7 patients). The MFI class I of the patients who developed AR was 7001 ± 1269 (p= 0.17), and MFI class II 7083 ± 3264 (p=0.58). Two patients developed hyperacute rejection, both positive in DSA flow crossmatch class II, with a MFI DSA class I 6782 ± 1639 and class II of 8958 ± 5828. The first patient with positive antigen B and DR, and the second patient with positive antigen for C and DR. 36.5% patients had urinary tract infection (UTI), with a cumulative number of UTI events of 27. Four patients developed respiratory tract infections (10.5%), death was reported in 2 of them due to the infection.

Conclusions: The main risk factors were the number of match class II antigens and serum tacrolimus levels at 6 months. The hyperimmunized patients can have an opportunity and access a high-risk transplant, with successful results.

Demographic Characteristics of the Population

Age (years)	31 (IQR, 28-35)
Male-gender (%)	23 (60.5%)
Dialysis Time, (years)	3 (IQR, 1-6)
DSA, MFI (SD)	
Class I	6725 ± 4763
Class II	9764 ± 4473
Transplant n (%)	
First	11 (28.9%)
Second	27 (71.1%)
Acute rejection n (%)	7 (18.4%)
Rejection type n (%)	
Antibody-mediated rejection	7 (100%)
Acute T-cell–mediated rejection	0 (0%)
Crs at discharge (mg/dL)	1.06 ± 0.69
CrS at 3 months (mg/dL)	1.18 ± 0.51
CrS at 12 months (mg/dL)	1.33 ± 0.69
Infections	
UTI	15 (39.4%)
CMV	0
Respiratory tract infection	4 (10.5%)
BK virus	0

DSA: Donor specific antibody, CrS: serum creatinine, UTI: urinary tract infection, CMV: cytomegalovirus.

Successful Eculizumab-Based Desensitization in ABO-Incompatible Living Donor Kidney Transplantation

Ga Young Heo, Minsun Jung, Honglin Piao, Hyun-Jeong Kim, Hyung Woo Kim, Juhan Lee, Kyu ha Huh, Beom Seok Kim, Jaeseok Yang. *Yonsei University, Seoul, Republic of Korea*.

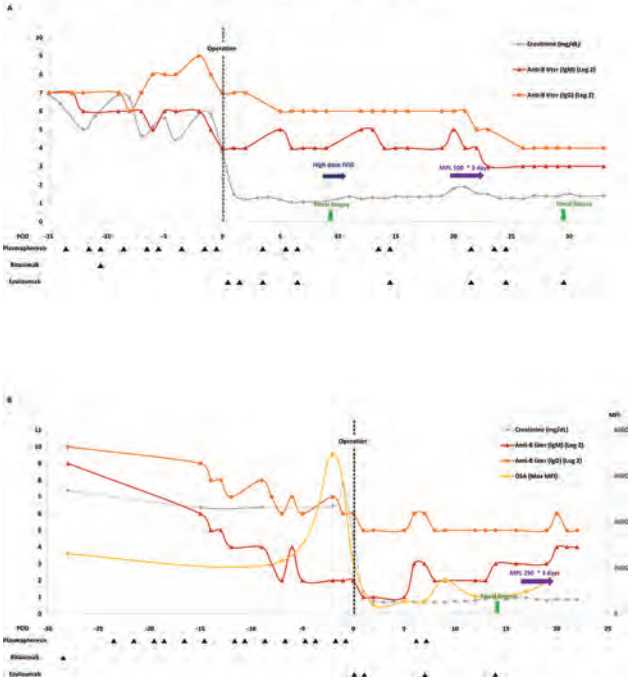
Background: High titers of anti-ABO antibodies in some patients are refractory to standard desensitization, leading to loss of KT opportunities or AMR.

Methods: Eculizumab-based desensitization was used to rescue high-titer ABOi KT patients refractory to plasmapheresis/rituximab-based desensitization.

Results: Initial titers of anti-ABO IgG antibodies in the two patients were 1:512 and >1:1024; the final pre-transplant titers after desensitization were 1:128 and 1:64. Both patients received eculizumab from the day of KT to two or four weeks post-KT and maintained stable renal function up to one-year without overt complications, despite early episodes of suspicious AMR or borderline TCMR. Molecular phenotype analysis of allograft biopsies using the B-HOT gene panel revealed that gene expression patterns in the ABOi KT with eculizumab group overlapped with those in the ABOi KT with AMR group more than in the ABOi KT without AMR group, except for complement pathway-related gene expression.

Conclusions: Short-term eculizumab-based desensitization therapy is promising for rescuing ABOi KT recipients with unacceptably high anti-ABO antibody titers refractory to plasmapheresis-based desensitization therapy.

Figure 1. Clinical courses of patients in the eculizumab group. **(A)** Case 1 and **(B)** Case 2.



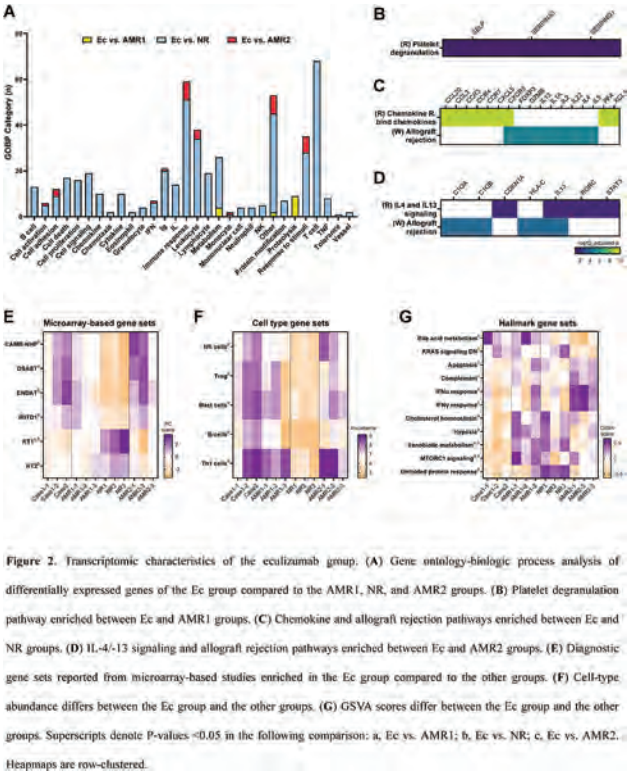


Figure 2. Transcriptomic characteristics of the eculizumab group. **(A)** Gene ontology-biologic process analysis of differentially expressed genes of the Ec group compared to the AMR1, NR, and AMR2 groups. **(B)** Platelet degranulation pathway enriched between Ec and AMR1 groups. **(C)** Chemokine and allograft rejection pathways enriched between Ec and NR groups. **(D)** IL-4/-13 signaling and allograft rejection pathways enriched between Ec and AMR2 groups. **(E)** Diagnostic gene sets reported from microarray-based studies enriched in the Ec group compared to the other groups. **(F)** Cell-type abundance differs between the Ec group and the other groups. **(G)** GSVA scores differ between the Ec group and the other groups. Superscripts denote P-values <0.05 in the following comparison: a, Ec vs. AMR1; b, Ec vs. NR; c, Ec vs. AMR2. Heapmaps are row-clustered.

Is Induction Therapy with Basiliximab Mandatory in Kidney Transplant Recipients with a Low Immunological-Risk Profile?

Florian Lacave, Arnaud Devresse, Christophe de Terwangne, Guillaume Fernandes, Tom Darius, Antoine Buemi, Eric Goffin, Nada Kanaan. *Cliniques universitaires Saint-Luc, Bruxelles, Belgium*.

Background: Induction therapy with basiliximab is recommended in kidney transplant (KT) recipients with a low immunological risk (LIR) profile. Whether basiliximab is associated with a decreased risk of acute rejection (AR) and graft loss is controversial.

Methods: In our institution, LIR patients (absence of anti-HLA antibodies before KT) are inducted with basiliximab in case of living-donor KT (LDKT) while deceased-donor KT recipients (DDKT) receive no induction. Maintenance immunosuppression is similar, including a combination of tacrolimus, mycophenolate and steroids. In this single-center retrospective study, all adult LIR patients who underwent KT between 01/01/2015 and 12/31/2022 (excluding ABO-incompatible and multiorgan transplantations) have been included.

Results: Of the 471 patients included, 354 received a DDKT (DDKT group) and 117 a LDKT (LDKT group). Patients from the DDKT group were more frequently male, older and received fewer preemptive KT compared to those from the LDKT group. The median (IQR) number of HLA A-B-DR mismatches was 3 (2-3) and 2 (2-4) in the DDKT group and the LDKT group, respectively. Survival free from treated AR was similar in both groups at 6 months, 1 year and 5 years (Figure 1), as was 5-year survival without reaching a composite endpoint of treated AR or graft loss. At 5 years, the incidences of graft loss (p= 0.074) and death (p=0.6) were similar in the DDKT group vs LDKT group.

Conclusions: Induction therapy with basiliximab showed no benefit regarding the risk of treated AR or graft loss within 5 years post-KT compared with a strategy without induction therapy in patients with a LIR profile.

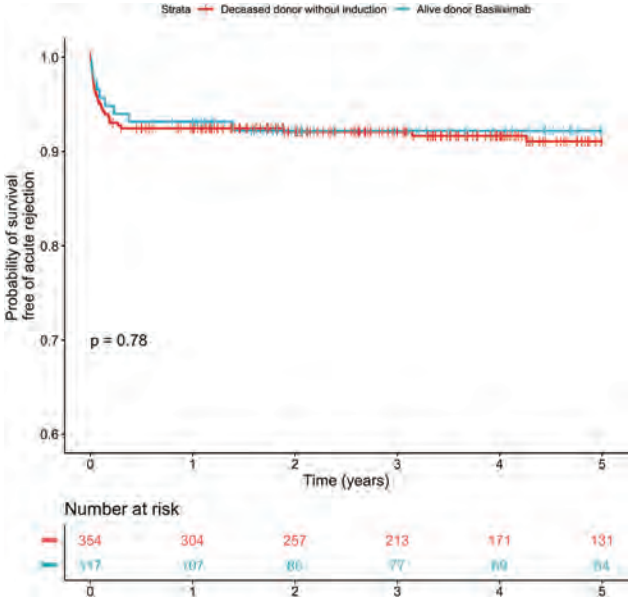

Figure 1 : Treated acute rejection-free survival in the 5 years after kidney transplantation.

Rabbit Anti-thymocyte Globulin Induction (rATG) in Older Adult Kidney Transplant Recipients

Brandon L. Trollinger,[1] Rachel Cartus,[3] Nada Alachkar,[2] Heather Carberry,[2] Divyanshu Malhotra,[2] Laura Lees,[1] Benjamin Philosophe,[2] Sara Strout,[1] Daniel C. Brennan.[2] *[1]The Johns Hopkins Hospital, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Keck Medicine of USC, Los Angeles, CA.*

Background: Deceased donor kidney transplants are increasingly performed in older patients. There are limited published efficacy and safety data of rATG use in this population, particularly in those ≥75 years old.

Methods: This is a single center, real-world retrospective cohort study of 445 first-time kidney-only DDKT recipients ≥40 yo who received rATG induction. Patients were age-stratified: 40-64 yo (middle age, MA), 65-74 yo (older, O), ≥75 yo (oldest old, OO). Dosing, baseline characteristics, efficacy and safety outcomes were analyzed using Kruskal-Wallis or Fisher's exact tests.

Results: The cohorts (MA: n=284, O: n=133, OO: n=28) showed imbalances in baseline characteristics: race, sensitization, weight and estimated posttransplant survival/ kidney donor profile indices (Figure 1). Median rATG dose (mg/kg) decreased with increasing age (MA: 5.0, O: 4.5, OO: 3.1, p<0.01) with lower rejection rates. Death, early cytomegalovirus viremia, cardiovascular events and cancer rates were higher in the older cohorts, but death-censored graft failure and infection were not (Figure 2).

Conclusions: Lower rATG doses effectively prevented rejection with similar graft survival rates in older patients. However, adverse event rates remain higher in these cohorts.

TH-PO821

Anti-thymocyte Globulin (ATG) vs. Interleukin-2 Receptor Antagonist (IL-2 RA) in Low Immunologic-Risk Kidney Transplant Recipients

Pamela M. Prado Lozano, Jose H. Cano Cervantes, Mayra M. Matias Carmona, Citlali Fernandez Vivar, Carolina Gonzalez-Fuentes, Jose L. Torres Cuevas, Martin B. Yama Estrella, Nicte Alaide R. García, Martin O. Carbajal, Ydris Z. Rosillo-Salgado. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico*.

Background: KDIGO recommends IL2-RA as first line induction therapy and a lymphocyte-depleting agent for kidney transplant recipients (KTR) at high immunologic risk. Although, depleting agents reduce acute rejection they also increase the risk of infections and malignancies. However, the evidence is controversial.

Methods: Patients were allocated to receive IL2-RA or rATG as induction in a 1:1 ratio. Inclusion criteria: ≥18 years old, LIR – KTR. LIR was defined as PRA <30%,1st kidney transplant from living donor with ABO compatibility. PBL subsets, C3 and IgG determinations were obtained pre-transplant, 7 days and 3 months after. CMV and BK viral loads obtained as per protocol and allograft biopsies performed at 3 and 12 months. All received maintenance with Mycophenolic Acid, Tacrolimus and prednisone. Prophylaxis with Trimethoprim – Sulfamethoxazole was given to all and Valganciclovir to those with moderate-high risk for CMV. Primary outcome: measure the effect of rATG compared to IL2-RA as induction for LIR-KTR in PBL subsets, C3 an IgG levels at 7 days and 3 months after transplant. Secondary outcomes: evaluate the incidence of BPAR and infections.

Results: 24 patients were analyzed, 14 received IL2-RA. There was a significant decrease in PBL subsets at 7 days post-transplant in the rATG group. CD4 418 cel/µl (285 – 788 cel/µl) vs 30 cel/µl (2 – 58 cel/µl) p = 0.0002, CD8 58 cel/µl (3 – 108 cel/µl) vs 291 cel/µl (116 – 483 cel/µl) p=0.011; CD4/CD8 ratio 1.8 (1.48 – 2.82) vs 0.76 (0.36 – 0.76) p=0.0002, and NK cells 85 cel/µl (74 – 113.5 cel/µl) vs 34 cel/µl (8 – 65 cel/µl p=0.045). This difference was sustained by month 3 in the CD4 count (935 ± 440 cel/µl vs 228 ± 136 cel /µl, p= 0.002) and CD4/CD8 ratio (0.96 ± 0.65 cel/µl vs 1.79 ± 0.33 cel/µl, p = 0.008); with no difference in CD8, NK cells, C3 and IgG at this point. The IL2-RA group showed significant decrease in CD4 and NK cells by day 7; sustained until month 3 for CD4. During follow up, 1 patient in the IL2-RA group presented an ITU and 1 in the rATG early CMV infection. There was 1 BPAR in IL2-RA vs none in the rATG.

Conclusions: rATG is associated with prolonged CD4 suppression but no CD8, what probably lessens the adverse effects, while improving allograft survival.

TH-PO822

Impact of Delayed Graft Function on Kidney Transplant Outcomes

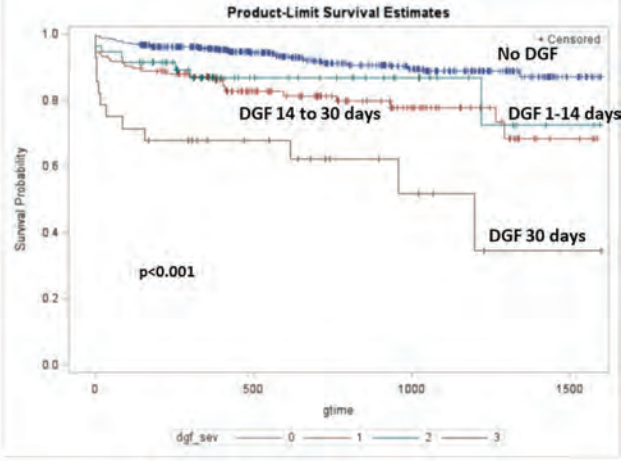
Mary Show, Mona D. Doshi. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Delayed graft function (DGF) is a frequent complication following deceased donor kidney transplant. The revised allocation policy mandates a wider geographical distribution of kidneys from deceased donors resulting in prolonged cold time and higher rates of DGF. Our study explores the impact of duration of DGF on graft function and survival.

Methods: We reviewed records of 687 patients who received deceased donor kidney transplant (DDKT) from 2020 to 2023 at the University of Michigan Transplant Center. Patients were grouped based on occurrence of DGF (need for dialysis within 7 days of transplant) and duration (0-14, 15-30, and >30 days). We compared donor, and recipient characteristics across 4 groups. Graft outcomes across 4 groups were compared via serum creatinine at last follow-up and also via Kaplan-Meier Survival Curves. Cox proportional hazard models were constructed to account for donor and recipient factors for graft loss.

Results: Of the 687 DDKT, 466 (68%) had no DGF and 221 (32%) developed DGF. Of 221 patients with DGF, 135 (61%) required dialysis for <14 days, 58 (26%) for 15-30 days, and 28 (13%) for more than 30 days. Donor risk factors that were associated with severe DGF include donation after cardiac death, death by anoxia, history of hypertension, and diabetes mellitus (p<0.05). Recipient risk factors for severe DGF include usage of anticoagulation, and Midodrine, African American race, and history of diabetes (p<0.05). Serum creatinine varied across 4 groups and was lowest among patients with no DGF and highest among patients with most severe DGF (1.1±0.6, 1.7±0.6, 2.3±0.9 and 2.4±1.4 mg/dL; p<0.001). Graft survival varied across 4 groups and was lowest among recipients requiring dialysis for more than 30 days (see Figure 1, p<0.001). On multi-variate analyses, severity of DGF, donor age and donor history of diabetes were associated with graft loss.

Conclusions: Duration of DGF has a negative impact on graft function and survival. New strategies are needed to improve organ preservation and manage patients after transplant to reduce the duration of DGF and subsequently graft loss.



TH-PO823

Single-Center Short-Term Outcomes in Recipients of Deceased Donor Kidneys with AKI

Barbara A. Greco, Kenneth Brand, Boonyanuth N. Maturostrakul. *Baystate Medical Center, Springfield, MA.*

Background: Previous reports suggest that long term outcomes in recipients of deceased donor kidneys (DDKT) from donors with acute kidney injury (AKI) are comparable to those without AKI. We report short term outcomes in 20 recipients of AKI donor kidneys compared to 20 recipients of kidneys without AKI to provide insight into optimal deceased donor acceptance criteria.

Methods: We reviewed data on 40 consecutive recipients of DDKT done at the Baystate Transplant Program between October 2023 and March of 2024. Twenty of these were from donors with AKI defined as terminal creatinine (Cr)> 1.5 times admission Cr. We used UNET data to collect demographics, KDPI, DCD criteria, terminal creatinine and urine output, and pre-implantation biopsy findings. Cold ischemia time (CIT) was obtained from the OPO. Recipient outcomes were evaluated as part of quality review.

Results: The mean age and KDPI of recipients of AKI vs. standard kidneys was 58.2 vs.59.7 years and 70.15 (43-98) vs. 76.2 (49-98), respectively. AKI kidney donor age was higher, 61.8 vs. 51.1 years, with a similar number of DCD donors in each group (9 vs. 10). CIT was higher in the AKI donor group: 1436 vs. 1215 min. LOS was comparable between groups: 8 vs. 8.5 days (excluding 1 recipient of an AKI kidney who remains hospitalized). More than twice as many recipients of AKI kidneys had DGF (13/20) vs. nonAKI (6/20). Mean Cr at 3 months for recipients of AKI vs. nonAKI kidneys were 2.42 and 2.26 mg/dl, respectively, and 45% vs. 44% had Cr>2 mg/dl at 3 months. Two recipients of AKI donors remained dialysis-dependent at 3 months post-transplant. These patients had significant post-transplant complications. For-cause allograft biopsies in 2/8 AKI recipients and 4/12 recipients of nonAKI donors revealed acute rejection. At 4 months post-transplant, 4 recipients of AKI donor kidneys vs none from nonAKI donors have been referred for retransplantation due to poor allograft function.

Conclusions: Our single-center, short-term outcomes in 40 DDKT recipients are concordant with prior reports that kidneys from donors with AKI have similar allograft functional outcomes with no increase in rejection rate. Accepting kidneys from deceased donors with AKI can increase rates of transplantation but at the cost of more DGF and graft failures.

TH-PO824

Risk Factors for Death-Censored Graft Loss and Death in Kidney Transplant Recipients with Delayed Graft Function

Krutika P. Chauhan, Qingyuan Tan, Siobhan Sutcliffe, Su-Hsin Chang, Tarek Alhamad, Massini Merzkani. *Washington University in St Louis, St Louis, MO.*

Background: Delayed Graft Function (DGF) independently causes a significant reduction in graft survival. Very few studies have analyzed the risk factors for graft loss and death in recipients.

Methods: We used the Organ Procurement and Transplantation Network (OPTN) data for solitary kidney transplants from 1/1/2000 to 12/31/2023. We included adults with solitary ABO-compatible kidney transplants who were on dialysis before the transplant. We limited the study population to people who had delayed graft function, defined as requiring dialysis during the first week after transplantation. Our outcomes were death-censored graft loss (DCGL) and death with functioning graft. Multivariable Cox regression was done to evaluate the association of risk factors and adjusted for recipient, donor, and transplant characteristics.

Results: There were 72,992 solitary deceased kidney transplants with DCGL 23% and death 20.1%. Risk factors for increased DCGL were younger age (aHR=0.79 95% CI 0.78-0.80), lower donor BMI (aHR=0.94 95%CI 0.93-0.95), African American recipient (aHR=1.25 95%CI 1.20-1.29), and donor (aHR=1.09 95%CI 1.04-1.15), history of smoking (aHR=1.19 95% CI 1.15-1.23), and extended criteria donor (aHR=1.25; 95% CI 1.19-132) (Fig 1A) Risk factors for increased risk for death with functional graft were higher recipient age (aHR=1.56 95% CI 1.54–1.59), recipient gender male (aHR=1.06 95% CI 1.02-1.10), higher recipient BMI (aHR=1.03 95% CI 1.01–1.04), history of smoking (aHR=1.16 95% CI 1.12-1.21), and ECD (aHR=1.14 95% CI (1.07–1.20) (Fig 1B)

Conclusions: Recipients of DGF have unique risk factors for DCGL and death, emphasizing the need for closer follow-up and monitoring of this group. Additional prospective studies are essential for patient and graft survival.

Delayed Graft Function Equally Worsens Early Outcomes in Kidney Recipients from Donation after Circulatory Death vs. Brain Death Donors

Angela L. Zhou, Suseela A. Raj, Ekaterina Fedorova, Jacqueline Garonzik Wang, Didier A. Mandelbrot, Brad C. Astor, Sandesh Parajuli. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: While delayed graft function (DGF) is more common after donation after circulatory death (DCD) vs donation after brain death (DBD) kidney transplantation, we sought to determine if risk factors for DGF and post-transplant outcomes differ across donor type.

Methods: We studied all adult kidney deceased donor recipients (DDKTR) transplanted between 2005-2019 at UW Health Transplant Center, stratified by donor type (DBD vs. DCD). DGF was defined as dialysis within the first week after transplantation. Outcomes of interest included DGF, acute rejection (AR), one-year uncensored (GF) and death-censored graft failure (DCGF).

Results: Among 2543 DDKTs, 804 (31%) were DCD. In DBD recipients, older donor age, higher terminal creatinine, higher KDPI, right kidney, prolonged cold ischemia time (CIT), higher recipient BMI, and depleting induction agent were associated with higher risk for DGF, while female recipient and preemptive transplant were protective. Similarly, among DCD, older donor age, female donor, higher donor and recipient BMI, and depleting induction were associated with increased risk, while female recipient and preemptive transplant were protective. While DGF was significantly associated with higher risk for AR and GF, these associations did not differ significantly between DBD and DCD in adjusted models: AR (HR: 2.22 in DBD vs 2.37 in DCD; p-interaction=0.65); GF (3.04 vs 2.56; p-interaction=0.47). There were no adjusted DCGF to compare.

Conclusions: Several factors differ between DBD and DCD for risk of DGF. However, early outcomes were similarly worsened in both groups.

TH-PO826

Delayed Graft Function among Simultaneous Pancreas-Kidney Transplant Recipients Is Associated with an Increased Risk of Urinary Tract Infections and Kidney Rejections

Sofia Nehring Firmino, Ekaterina Fedorova, Eman Alshaikh, Dixon Kaufman, Jon S. Odorico, Didier A. Mandelbrot, Brad C. Astor, Sandesh Parajuli. *University of Wisconsin-Madison, Madison, WI.*

Background: Kidney delayed graft function (K-DGF) is associated with various detrimental outcomes among simultaneous pancreas and kidney (SPK) recipients. However, its potential risk associated with infection and rejection remains unclear.

Methods: We compared recipients with K-DGF to those without K-DGF among all adult SPK recipients transplanted at our center between 01/2010 and 12/2022 who had pancreas graft survival of more than 2 weeks. Outcomes of interest included urinary tract infections (UTI) and pneumonia, along with pancreas and kidney graft rejections, within one-year post-transplant.

Results: 543 SPK recipients were included, of whom 47 (9.5%) developed K-DGF. A total of 89 recipients had UTI, 33 had pneumonia, 77 had pancreas rejection and 21 had kidney rejection within one-year post-transplant. Recipients with K-DGF experienced a higher incidence of UTI. This association remained after adjustment for baseline characteristics (adjusted Hazard Ratio [aHR]: 3.06; 95% CI: 1.46-6.42; p=0.003). Similarly, K-DGF was associated with increased risk for kidney rejection in an unadjusted and adjusted models (aHR: 5.47; 95% CI: 1.98-15.1, p=0.001). K-DGF was not associated with pneumonia or pancreas rejection.

Conclusions: K-DGF among SPK recipients is associated with an increased risk for UTI and kidney allograft rejection, likely related to dysregulation of the immune system. Close monitoring and appropriate management are warranted in these unique patient populations.

Impact of Modified Delayed Graft Function (DGF) Biopsy Protocol on Patient and Allograft Outcomes: A Retrospective, Single-Center Study

Swarna laxmi Umapathy,[1] Jae H. Son,[1] Jayden Eccleston,[1] Karthiga Vasudevan,[2] Abinaya Rajendran,[4] Ryan Demartino,[3] Payaswini Vasanth.[1] *[1]Emory University, Atlanta, GA; [2]Georgia Department of Public Health, Atlanta, GA; [3]Emory Healthcare, Atlanta, GA; [4]Pondicherry Institute of Medical Sciences, Pondicherry, India.*

Background: The traditional DGF biopsy protocol (defined as weekly biopsy until resolution of DGF) was modified by delaying the first biopsy until two weeks post-transplantation, with subsequent biopsies performed only if indicated. Our Study seeks to evaluate the impact of implementing a modified DGF biopsy protocol on patient and allograft outcomes.

Methods: We conducted a retrospective analysis of kidney transplant recipients with DGF 2021-2023, comparing outcomes between those managed under the traditional and modified protocols

Results: 450 patients who had DGF in 2021-2023 were included in this Study. Results are outlined in Table 1. In 2021, under the traditional biopsy protocol, 19 patients (14%) experienced rejection, with the majority having borderline results, and some showing v1 lesions that were not treated due to DGF recovery. In 2022 and 2023, with the new biopsy protocols, 23 (14%) and 13 (8%) experienced rejection, with the majority having borderline results and only a few needing clinically significant treatment. Technical, vascular issues and recurrent disease resulted in graft failure and was unrelated to DGF.

Conclusions: Implementing the new protocol significantly reduced early DGF biopsies without negatively impacting patient and allograft outcomes. Moreover, this change led to significant cost savings, with each biopsy costing approximately $3000, alongside reductions in length of stay and readmission rates associated with biopsy procedures. These findings underscore the efficacy of protocol adjustment in enhancing both the clinical and economic aspects of post-transplant care.

	2021	2022	2023

Does Early Belatacept Conversion in Delayed Graft Function Preserve Allograft Function?

Jasmine Zahid, Rehan Ansari, Ronald Michael Hofmann. *Trinity Health Michigan, Grand Rapids, MI.*

Background: Calcineurin inhibitors (CNIs) remain the cornerstone of immunosuppression in renal transplantation. However, there remain concerns regarding CNI induced nephrotoxicity. Belatacept is an alternative to nephrotoxic CNIs and has been FDA approved for immunosuppression in renal transplantation since 2011. The purpose of this case series is to identify short-term outcomes of early belatacept conversion in prolonged delayed graft function (DGF).

Methods: DGF includes patients who required dialysis within the first 2 weeks post-transplant. Early Belatacept conversion occurs within the first 6 months post-transplant. Charts were individually audited for data collection. Demographic data included age, gender, race, BMI, history of diabetes, and new onset diabetes after transplantation,

HLA mismatch, KDPI, cPRA, EBV, CMV, BK virus, donor type, prior transplants, pre-transplant dialysis dependence, dialysis length, biopsy, steroid use, neutropenia. Outcomes included creatinine, GFR, PTLD, infections and withdrawal from dialysis. SPSS was used for statistical analysis.

Results: This case series included 19 patients. Transplantation occurred from 2012-2023. Patient demographics are Figure 1. Patients had a statistically significant improvement in creatinine and GFR in 6 months. Additional complications included new onset diabetes after transplantation and acute cellular mediated rejection in 1 patient each. All patients were weaned off dialysis except one. No patients developed PTLD.

Conclusions: This case series suggests early conversion to Belatacept in DGF results in preserved short-term graft function. This case series adds to the current literature suggesting that the long term outcomes of Belatacept warrants further study.

Pre and Post-conversion GFR

	Pre-conversion GFR	Post-conversion GFR
Median [25th, 75th percentile]	13.5 [6.0, 25.5]	35.5 [26, 42.5]
Mean ± SD	16.4 ± 10.7	34.3 ± 11.0

Extended Experience of Belatacept Conversion in Kidney Transplant Patients with Chronic Active Antibody-Mediated Rejection

Dhiren Kumar, Louiza Azzouz, Irfan A. Moinuddin, Gaurav Gupta.
Virginia Commonwealth University, Richmond, VA.

Background: Chronic active antibody mediated rejection (cABMR) is a major cause of kidney transplant (KT) loss. Current therapies have unclear efficacy and side effects. We have previously presented our experience with belatacept conversion with an improved eGFR compared to propensity matched controls (Kumar et al, Transplantation 2021). Here we present our extended experience with clinical outcomes and graft survival.

Methods: 55 patients with biopsy-proven cABMR were converted to belatacept with a modified tacrolimus taper performed over 12 weeks. 46/55 (84%) patients underwent biopsies between 6-12 months post-conversion and 32/55 (58%) also underwent paired transcriptome analysis using the molecular microscope (MMDx; ATAGC). We followed eGFR, graft survival and evaluated predictors of graft survival.

Results: Patients (mean age: 44years) were converted from tacrolimus to belatacept at a median of 29 months post-KT. At conversion, the cohort had low mean GFR of 44.6±22ml/min/1.73m2 and high mean chronicity scores (CI+CT) of 2.55±1.31. The mean decline in eGFR for the 12 months prior to conversion was -0.89±2.5ml/min/1.73m2 which then stabilized/improved to 1.37±2.9 ml/min/1.73m2 (p=0.002) 12 months after conversion. 53/55 (96%) of patients had less than 30% decline in GFR at 12-months. A paired histologic and MMDx comparison of pre and post-biopsies showed no worsening in microvascular inflammation (G+PTC), chronicity scores (CI+CT) and molecular ABMR scores. Overall, at a median follow up of 58 months (IQR:39-66), death censored graft survival was 67% and patient survival was 87%. Those with graft loss had a significantly lower GFR at conversion (36±16ml/min/1.73m2 vs 49±23ml/min/1.73m2; p=0.03). The area under the curve (AUC) for GFR at conversion was 0.69 (95% [CI] 0.55 to 0.80; p=0.01) for predicting graft failure. A GFR cutoff value of less than 30ml/min/1.73m2 had a specificity of 76% and sensitivity of 55%.

Conclusions: In this largest and extended report on belatacept conversion for cABMR with associated low GFR and high chronicity in patients who were otherwise not candidates for additional intensive immunosuppressive therapies, showed both short and long-term stability in renal function. Extended graft survival was seen in patients who had higher GFR at the time of conversion.

TH-PO830

Human Leukocyte Antigen (HLA)-Incompatible Kidney Transplantation Shows Similar Outcomes Compared with HLA-Compatible Kidney Transplantation after Early Rejection

Youn sik Oh,[1] Ji Won Min,[4] Sik Lee,[3] Jaeseok Yang,[2] Myoung soo Kim,[2] Mingyu Kim,[1] Jeong-Hoon Lim,[1] Hee-Yeon Jung,[1] Sun-Hee Park,[1] Chan-Duck Kim,[1] Yong-Lim Kim,[1] Jang-Hee Cho.[1] KOTRY Study Group.
[1]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [3]Jeonbuk National University Hospital, Jeonju, Jeollabuk-do, Republic of Korea; [4]The Catholic University of Korea Seoul St Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.

Background: HLA-incompatible (HLA-i) kidney transplantation (KT) constitutes a high-risk group with an increased risk of rejection and graft failure. We investigated the differences in short- and long-term outcomes of HLA-i KT compared to HLA-compatible (HLA-c) KT.

Methods: Patients with living donor KT were enrolled from a prospective nationwide cohort in Korea. HLA-i KT was defined as a desensitized transplantation with complement-dependent cytotoxicity (CDC) or flow-cytometric (FCM) crossmatch positivity. The primary outcome was a composite of acute rejection, graft failure, and patient death. The association between acute rejection and HLA types was analyzed. The trough levels of tacrolimus compared between HLA-i and HLA-c KT groups.

Results: A total of 3692 KT recipients were enrolled and 466 (12.6%) patients received HLA-i KT. Kaplan-Meier curve revealed that HLA-i KT showed higher acute rejection, graft failure, and the composite than HLA-c KT (P<0.05). The HLA-i group is associated with a higher risk of the composite (adjusted HR [aHR] 1.57; 95% CI 1.34-1.79; *P*<0.001) (Table 1) and acute rejection (aHR 1.56; 95% CI 1.37-2.88; *P*<0.001) (Table 2) than the HLA-c group during the 1st year after KT. However, 1 year after KT, all the transplant outcomes did not differ between the two groups. Logistic regression analysis showed that antibodies against HLA-DR were significantly associated with an increased risk of acute rejection (OR 1.93; 95% CI 1.14-3.28; P=0.015). Tacrolimus trough levels of the HLA-i and HLA-c groups showed no difference at 1 year after KT (6.3±2.2 vs. 6.4±2.3 ng/mL, respectively) and thereafter.

Conclusions: HLA-i KT showed worse transplant outcomes until 1 year after transplantation. However, HLA-i KT after the early period had non-inferior graft and patient survival results compared to HLA-c KT.

Tocilizumab in the Treatment of Allograft Rejection in an HIV-Positive Kidney Transplant Recipient

Kavindya Wickramasinghe,[1] Joseph D. Nguyen,[1] Joel D. Murphy,[2] William F. Glass,[3] Swati Rao.[4] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]Arkana Laboratories, Little Rock, AR; [3]University of Virginia Department of Pathology, Charlottesville, VA; [4]University of Virginia, Charlottesville, VA.*

Introduction: Chronic active antibody-mediated rejection (CAAbMR) in kidney transplant recipients (KTRs) is a major cause of late graft loss and responds poorly to standard-of-care (SOC) immunosuppression (steroids, IVIG, plasmapheresis). Recently, tocilizumab (TCZ), an IL-6 receptor antagonist affecting multiple pathways involved in B-, T-, and plasma cell activity, has been utilized in the treatment of CAAbMR. However, escalating immunosuppression in patients with chronic infections, such as HIV and HBV, can increase the risk of viral reactivation. We report a successful case of TCZ used to treat refractory allograft rejection in a KTR with chronic HIV and HBV.

Case Description: A 56-year-old male with well-controlled HIV and HBV, with ESKD from HIV nephropathy, received a deceased donor kidney transplant in 2016. After enjoying good allograft function for 5 years, he developed proteinuria (1 g/d) with low-level donor specific antibodies. Kidney biopsy demonstrated CAAbMR (fig. 1a/b). As the patient demonstrated no response to SOC treatment (fig. 1c/d), he was started on TCZ. During the 1-year treatment course, serial monitoring of HIV and HBV was conducted. He did not develop viremia and CD4 count remained over 200 cells/mm^3. One episode of cellulitis was treated with IV antibiotics. The Cr remains 1 mg/dl, proteinuria has improved (0.3 g/d), and the allograft biopsy shows improvement in CAAbMR (fig. 1e/f).

Discussion: As with all immunosuppressive medications, TCZ use in KTRs has been associated with infections. Extrapolating from the safety of short-term TCZ in HIV patients during the COVID-19 pandemic, we opted for long-term TCZ for treatment of refractory CAAbMR in our patient, with serial viral load monitoring. To the authors' knowledge, this is the first case report demonstrating the successful use of TCZ in a KTR with HIV and HBV.

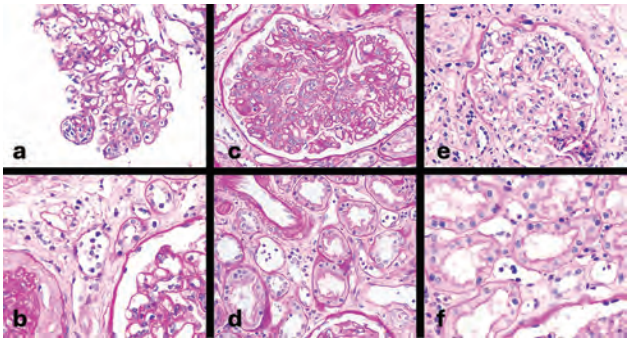

Figure 1. Biopsy after SOC therapy for CAAbMR showing lack of efficacy (g3,ptc3,cg1). Biopsy after 6 months (c/d) and 12 months (e/f) of TCZ showing improvement (g2,ptc2,cg1b) and minimal IFTA.

TH-PO832

Systemic Thrombotic Microangiopathy Induced by Antibody-Mediated Rejection in a Highly Sensitized Kidney Transplant Recipient

Gilad S. Guez, Beatrice P. Concepcion, Michelle A. Josephson, Sambhavi Krishnamoorthy, Patrick Cunningham, Yousuf Kyeso. *University of Chicago Pritzker School of Medicine, Chicago, IL.*

Introduction: Atypical HUS (aHUS) is a form of thrombotic microangiopathy (TMA), which is defined by thrombocytopenia, microangiopathic hemolytic anemia, and acute kidney injury. aHUS is caused by uncontrolled activation of the alternative pathway of the complement cascade, and can be due to a variety of causes, such as genetic defects in complement related factors or acquired autoantibodies to complement regulators. Here we present a unique case of aHUS post kidney transplant in a highly sensitized recipient.

Case Description: A 38 year old female with history of ESRD secondary to bilateral ureteral reflux disease, presented for deceased donor kidney transplantation. The patient was highly sensitized with panel reactive antibody of 100% due to history of blood transfusions and pregnancy. She underwent desensitization while on the waiting list with eight sessions of plasmapheresis and replacement IVIG. This resulted in a flow negative T and B cell crossmatch kidney transplant offer with pre-existing class I and II donor specific HLA antibodies (DSAs). On post-operative day 1, she developed acute kidney injury, acute anemia, thrombocytopenia, and schistocytes were found on the blood smear. Additional labs showed low C3, elevated LDH, and undetectable haptoglobin level. ADAMTS13 functional assay was 54%. aHUS was suspected, and patient was immediately started on eculizumab. Subsequent kidney biopsy showed evidence of microangiopathy with focal C4d positivity. Hematologic markers improved within 24-48 hours after initiation of eculizumab, as did renal function. Follow up genetic testing revealed homozygous CFHR1 deletion.

Discussion: This case illustrates an early development of acute antibody mediated rejection manifested as systemic TMA post kidney transplantation. This process was likely triggered by the presence of DSAs in the setting of homozygous CFHR1 deletion, and promptly responded to eculizumab. This case supports the use of pre-transplant genetic testing to stratify patients who are at high risk for developing post-transplant TMA, and such can help guide the decision-making process of peri-operative use of eculizumab.

Clinical Outcomes of Antibody-Mediated Rejection with or without Anti-human Leukocyte Antigen (HLA) Donor-Specific Antibody

Byounghwi Ko, Minsun Jung, Juhan Lee, Jaeseok Yang. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Antibody-mediated rejection (ABMR) is a major cause of late kidney allograft loss. It is increasingly recognized that histologic ABMRs without detectable donor-specific antibodies (DSA) can occur. Several studies have examined the prognosis of DSA-negative ABMR; however, there remains a need for further evidence.

Methods: From a single-center, retrospective study conducted from 2006 to 2021, 2,498 kidney transplant patients were screened, and 1,483 were available for at least one renal biopsy. Of these, 290 patients with biopsy-proven T-cell mediated rejection (TCMR) or ABMR were included in the study. The patients were categorized into TCMR, DSA-positive ABMR, and DSA-negative ABMR groups. DSAs were measured between the six months before and after the biopsies. The primary outcome was death-censored graft failure, and the secondary outcome was death-uncensored graft failure.

Results: The incidences for death-censored graft failure of TCMR, DSA-positive ABMR, and DSA-negative ABMR were 4.56, 4.98, and 6.23 per 100 patient-years. Over a median follow-up period of 5 years, death-censored graft failure occurred in 94 (32.4%) patients, with an incidence of 5.87 per 100 person-years. Compared with the TCMR group, the fully adjusted hazard ratios (HR) with 95% confidence intervals (CI) for death-censored graft failure were 1.28 (0.74-2.23) for the DSA-positive ABMR group and 1.67 (0.89-3.11) for the DSA-negative ABMR group. Furthermore, for death-uncensored graft failure, the DSA-negative group had a significantly higher risk compared with the TCMR group (HR, 1.88; 95% CI, 1.06-3.32), whereas the risk did not differ between the DSA-negative and DSA-positive group.

Conclusions: DSA-negative ABMR showed a significantly higher risk for death-uncensored graft failure compared with TCMR, with a similar risk as DSA-positive ABMR. Validation study using a Korean nationwide kidney transplant cohort is ongoing together with exploration of specific causes of DSA-negative ABMR.

TH-PO834

A Descriptive Study of a New Mexico-Based Kidney-Allograft Biopsy Registry

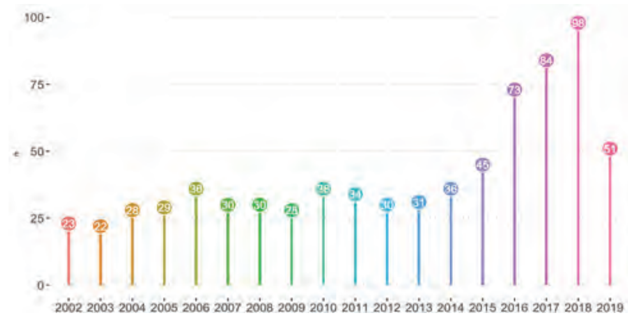
Saeed K. Shaffi. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: A kidney biopsy provides crucial information regarding allograft health. The diagnoses encountered on kidney allograft biopsies at the University of New Mexico Health Sciences Center have not been systematically studied. Additionally, the frequency of multiple pathologies in a single biopsy report is unknown. Therefore, we performed a retrospective review of the allograft biopsies to describe the frequency of diagnoses from this allograft biopsy registry.

Methods: The kidney biopsy registry was established using natural language processing (NLP) to extract diagnoses from biopsy reports, covering the period from January 2002 to June 2019. We identified kidney allograft biopsies, described the frequency of diagnoses, and, for common diagnoses, explored the presence of other pathologies. Results were reported as n (%) or Median (IQR), as appropriate.

Results: A total of 742 allograft biopsies were performed. The number of biopsies increased over the years (Fig. 1). The median biopsy age was 43 years (IQR 22–58). The most frequent diagnoses were acute T-cell mediated rejection (acute-TCMR), transplant glomerulopathy, and acute tubular necrosis (Fig. 2a). Acute tubular necrosis was the most common accompanying diagnosis in patients with acute TCMR and transplant glomerulopathy, respectively.

Conclusions: We analyzed a large number of allograft biopsies using NLP and described the diagnoses encountered in this population.



The number of biopsies performed each year.

Intestinal Microbiome and Acute Rejection of the Transplanted Kidney: Results of Single-Center, Case-Control Study

Marcin Adamczak,[1] Patrycja Pokora,[1] Mariusz Kaczmarczyk,[2] Damian Gojowy,[1] Anna Wierzbicka-Wos,[2] Danuta Cembrowska-Lech,[2] Aureliusz Kolonko,[1] Igor I. Loniewski,[3,2] Andrzej Wiecek.[1] [1]*Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland;* [2]*Sanprobi sp. z o.o, Szczecin, Poland;* [3]*Department of Biochemical Science, Faculty of Health Sciences, Pomeranian Medical University, Szczecin, Poland.*

Background: Kidney transplantation (KTx) is the preferred form of renal replacement therapy. Acute rejection of transplanted kidney (AR) shortly after KTx may impair long-term survival of the kidney graft and the recipients. The relationship between gut microbiota and kidney rejection remains underexplored. This study aimed to investigate the relationship between gut microbiome and the risk of AR shortly after KTx.

Methods: In this single-center, retrospective case-control study, 10 patients with biopsy proved AR shortly after KTx (mean age 44.7 ± 12.3 years; 8M/2F) were matched by sex and age with 20 patients without AR during one year follow up after KTx (mean age 43.7 ± 10.7 years; 16M/4F). Stool samples were collected 4-7 days after KTx for microbiome analysis using Illumina shallow shotgun sequencing. Bioinformatic analysis included taxonomic and functional profiling, with predictive modeling performed using a random forest model. Model performance was evaluated using receiver operating characteristic (ROC) curves and area under the curve (AUC).

Results: No significant differences in clinical characteristics or microbiota diversity were observed between two groups. Differential abundance analysis identified *Bacteroides dorei/vulgatus* and *Clostridium* as differentially abundant in AR patients, but no consistent taxonomic markers were found. Predictive models varied in performance, with functional KEGG pathway profiles showing the highest predictive value (AUC = 0.740). Key metabolic pathways implicated included lipid metabolism (e.g., sphingolipid metabolism, glycerophospholipid metabolism, and secondary bile acid biosynthesis), glycan biosynthesis, and terpenoid and polyketide metabolism.

Conclusions: 1. No universal taxonomic gut microbiota marker of AR was identified. 2. Functional profile of the gut microbiome may be related with AR, with specific metabolic pathways 3. These findings suggest a role for immunomodulation, inflammation, and metabolic regulation in AR, highlighting the need for further research to understand these associations and their impact on kidney transplant outcomes.

TH-PO836

Gender Inequities Persist in National Institutes of Health Funding for Nephrology Research

Karima Wehbe,[1] Wafaa M. Khaled,[1] Hay Me Me,[2] Kenar D. Jhaveri,[3] Rose Mary Attieh.[3,4] [1]*American University of Beirut, Beirut, Lebanon;* [2]*Mayo Clinic Arizona, Scottsdale, AZ;* [3]*Northwell Health, Great Neck, NY;* [4]*Mayo Clinic in Florida, Jacksonville, FL.*

Background: Gender inequity remains pervasive in the medical community, with women significantly underrepresented in access to extramural funding opportunities. We aimed to assess gender disparities in National Institutes of Health (NIH) awards for nephrology research within the 40 highest-funded academic university hospitals in the United States between 2017 and 2020.

Methods: Data on funding for nephrology research were retrieved from the NIH Principal Investigator (PI) database records. Only new awards were considered. Grants were identified by specifying the corresponding fiscal year (2017-2020), award type "new", and NIH spending category "kidney disease". For each grant, the type, amount of funds, and gender of the PI were recorded.

Results: Between 2017 and 2020, the NIH awarded 1472 new grants for research on kidney disease. 40 academic medical centers received the majority of grants (776 grants, 52.7% of total). Within these institutions, male PIs were awarded 475 grants (61.2%), totaling $193,787,257. Female PIs received 301 grants (38.8%), totaling $108,102,109 (**Table 1**). The difference in NIH funding between male and female PIs across all grant types was statistically significant, favoring male PIs (95% CI: [-89,812; -24,258]; p-value < 0.001). However, this imbalance was not observed across the 10 most commonly awarded grant types (p-value >0.05 for all).

Conclusions: Gender inequities in NIH funding remain in nephrology. Further research is warranted to understand their root cause and to explore strategies aimed at empowering women in the field to successfully secure funding.

Women as Leaders in Nephrology Research: Have We Bridged the Gender Gap?

Darshil K. Jhaveri,[1] Kiran Munir,[2] Kenar D. Jhaveri,[2] Rose Mary Attieh.[2,3] [1]*Herricks Union Free School District, New Hyde Park, NY;* [2]*Northwell Health, Great Neck, NY;* [3]*Mayo Clinic in Florida, Jacksonville, FL.*

Background: Significant efforts have been made in the field of nephrology to advocate for the professional development and inclusion of women. However, it remains unclear whether these efforts have materialized. We aimed to assess the current state of research leadership among women in nephrology by analyzing gender disparities in original research output and in number of citations per article across key nephrology subspecialties.

Methods: Abstracts accepted for oral presentation at the American Society of Nephrology (ASN) Kidney Week meetings 2017-2020 were reviewed to capture impactful nephrology research. A subset focusing on glomerular diseases (GN), transplant, and onconephrology was selected. The gender of the first or last author (FLA) was recorded. Public databases (PubMed, Web of Science, and Google Scholar) were interrogated to find corresponding articles. The number of citations per article was analyzed for academic influence.

Results: 336 abstracts were screened. 50.6% (N=170) had male-only FLA and 49.4% (N=166) had at least 1 female FLA (**table 1**). 75.9% of abstracts (N=129) with male-only FLAs were eventually developed into full articles vs 84.9% (N=140) of abstracts with at least 1 female FLA. There was a very strong correlation between FLA gender groups on the abstract and on the full article (p-value<0.001), and no significant inter-group difference in any of the following: average number of abstracts having corresponding articles with FLAs of same gender group (p=0.32), average number of abstracts having corresponding articles with FLAs of the opposite gender group (p=0.85), average number of abstracts which did not result in a full article (p=0.35). In addition, we found no statistically significant difference in the median number of citations per article between FLA gender groups (95% confidence interval [CI] [-5;5]; p-value 0.97) (**table 2**).

Conclusions: This is the first report to demonstrate that male and female researchers in nephrology now exhibit comparable academic performance and influence. While our findings are encouraging, women in the field still face numerous obstacles, and the road to true and sustainable gender equity remains long.

TH-PO838

Gender and Geographical Differences in International Nephrology Guideline Authorship: A Comparison of the US, UK, and International Nephrology Guidelines, 2009-2024

Ohm S. Tripathi. *University of Connecticut, Storrs, CT.*

Background: In Nephrology, there is an underrepresentation of women as first and senior authors as well as in leadership positions. We evaluated the trends in gender and geographical differences in the guideline writing groups of the KDIGO, KDOQI, Renal association, UKKA, and ISPD from 2009 to 2024.

Methods: We extracted all guidelines authors from 2009 to 2024, assessed their gender from publicly available profiles, and compared differences based on chair position, workgroup, and specific societies. Stratified and trend analyses were performed using $\chi 2$ and average annual percentage change. We analyzed various countries' representation among different guidelines.

Results: A total of 14 KDIGO, 22 KDOQI, 12 Renal Association, 22 UKKA, and 9 ISPD guidelines were analyzed. There were 831 authors (37.3% women vs 62.8% men, p<0.05), KDIGO (203 authors [26.1% women vs 73.9% men, p <0.05]), KDOQI (185 authors [34.1% women vs 65.9% men, p <0.05]), Renal Association (91 authors [41.8% women vs 58.2% men, p=0.54]), UKKA (278 authors [42.5% women vs 57.5% men, p<0.05]) and ISPD(74 authors [41.9% women vs 58.1% men, p=0.39]). There were 23 women chairs KDIGO (3 authors [10.7 % women vs 89.3% men, p <0.05]), KDOQI (15 authors [42.9% women vs 57.1% men, p =0.30]), Renal Association (3 authors [50% women vs 50% men, p=1]), and UKKA (2 authors [25% women vs 75% men, p=0.13]). The US had the highest numbers of authors in KDIGO (72) and KDOQI (174) while the UK (23) had the highest authors contribution in ISPD.

Conclusions: There is a significant disparity in the inclusion of women on all the international nephrology guidelines as chair and as authors. Further advocacy is required to promote equity, diversity, and inclusion in our nephrology guidelines globally. The US and UK contribute most to the guidelines. KDIGO had the most diverse country representation.

TH-PO839

Assessing Diversity and Inclusion in Nephrology Journal Editorial Leadership: EDI-N Study

Jingyao Zhang,[1] Rhea Gandhi,[1] Tushar Chopra,[2] Vineet Gupta,[1] Rakesh Malhotra.[1] *[1]University of California San Diego, La Jolla, CA; [2]University of Virginia, Charlottesville, VA.*

Background: Understanding and promoting diversity within editorial boards is crucial for advancing equity, fostering scholarly inclusivity and addressing bias in academic publishing. Here, we investigated the self-identified gender and race/ethnicity diversity within the editorial boards of nephrology journals.

Methods: A brief survey consisting of ten questions was electronically disseminated to editors, including editors in chief, deputy, associate, assistant, and section editors, as well as editorial board members, across 23 nephrology journals via REDCap. The survey aimed to gather self-reported demographic details such as gender, age, ethnicity, geographical location, editorial board position, and educational background. A follow-up reminder email was sent twice, each with a one-week gap to enhance response rates. Summary statistics were used for data analysis.

Results: Out of 1095 members, 367 (34%) respondents completed the survey. Among these, 58% were male, and 42 % were female. There were significant differences among gender representation (P<0.01) in journals leadership position with only 8.3% of Editor-in-Chief positions held by women. Regarding race/ethnicity, a majority of editorial board members were White (66.7%), followed by those identifying as Asian (10.7%) and South Asian (10.7%). Blacks and Hispanics constitute only 2.2% and 4.9% of editorial members, respectively. Editorial-in-Chief positions were predominantly held by White individuals (71%) followed by South Asians (17%). There was no reported Black and Hispanic individuals in Editor-in-Chief positions. Only 10 % of early career investigators with age less than 40 and 19% with degree outside of medicine were part of the editorial board.

Conclusions: This analysis reveals a significant underrepresentation of women and minorities in leadership positions within nephrology editorial boards. Journal should implement strategies for greater diversity and representation in editorial boards.

Funding: Other U.S. Government Support

TH-PO840

Modeling Diversity in Diabetic Kidney Disease Clinical Trials Using Real-World Data

Andrew M. Bevan,[1] Davide Garrisi,[2] Sarah D. Stump,[3] Carmichael Angeles.[3] *[1]PPD, Part of Thermo Fisher Scientific, Cambridge, United Kingdom; [2]PPD, Part of Thermo Fisher Scientific, Milan, Italy; [3]PPD, Part of Thermo Fisher Scientific, Wilmington, NC.*

Background: The FDA places emphasis on studying clinically relevant trial populations but does not address how to define these. The authors previously reported underrepresentation of people of African descent in lupus nephritis trials, but this has not been investigated in more common renal disorders such as diabetic kidney disease (DKD). The study aims to compare demographics of individuals with DKD from a large electronic health record (EHR) database with completed US-only DKD trials and propose statistical parameters for cohort sizes to support DKD trial planning.

Methods: Data was obtained from the TriNetX Analytics Network containing EHRs from >150 million individuals in the US. Demographics (gender, race, ethnicity) were assessed for those with an ICD-10-CM code E11.22 Type 2 Diabetes Mellitus with DKD in the last 5 years that did not also have an ICD-10-CM code N18.6 ESRD. Binomial confidence intervals were calculated to define demographic cohort sample sizes for clinical trials. Data were compared to average proportions of demographic cohorts in completed US-only DKD trials reported in clinicaltrials.gov.

Results: Real-world Data: 583,660 individuals met eligibility, gender distribution (50.2% Male, 45.4% Female, 4.4% Unknown), race distribution (62.8% White, 19.8% Black or African American, 4.0% Asian, 13.4% Other/Unknown), ethnic distribution (73.5% Non-Hispanic or Latino, 6.9% Hispanic or Latino, 19.6% Unknown). **Clinical Trials:** 9 DKD clinical trials were evaluated (956 subjects). Gender was reported for 9 trials (Male 64.8%, Female 35.2%). Race was reported for 6 trials (813 subjects), 77.4.% White, 18.2% Black or African American, 2.0% Asian, 2.3% Other/Unknown. Ethnicity was reported for 3 trials (549 subjects), 64.4.% Non-Hispanic/Latino, 35.6% Hispanic/Latino. **Cohort Modelling:** Based on an analysis of binomial confidence intervals, a US DKD trial of 100 subjects would be considered statistically representative ($p < 0.05$) of the TriNetX population if it included a range of 40-60 Male, 35-55 Female, 53-72 White, 13-29 Black or African American and 13-29 Hispanic/Latino patients.

Conclusions: Our data shows underrepresentation of non-white and female patients in US-only DKD trials compared to the TriNetX DKD population. Large EHR databases are one method to determine "real-world" demographics to support the planning of "representative" trial cohorts.

TH-PO841

Designing Equitable Care for Kidneys (DECK): Community-Based Interventions for Addressing Social Determinants of Health and Kidney Disease Risk Factors

Amber Paulus. *Virginia Commonwealth University School of Medicine, Richmond, VA.*

Background: Health disparities in kidney disease are often attributed to higher rates of risk factors such as diabetes and hypertension among minority groups. While research has extensively focused on clinical risk factors, little is known about the intersection of chronic kidney disease (CKD) risk and unmet social determinants of health (SDOH) needs.

Methods: The DECK Pilot Study, guided by the Equitable Diagnosis Pathway (EDP) model for chronic kidney disease, selected Richmond's East End for community-based screenings. The EDP model informed our intervention to address the silent nature of CKD, as 9 in 10 individuals are unaware of their condition until it is advanced. Using the CDC's Social Vulnerability Index (SVI) and HOLC ratings, we identified the East End for its high social vulnerability and history of redlining. This data-driven approach aims to identify and address CKD risk and unmet social needs to slow disease progression.

Results: Based on U.S. Census data, Richmond, VA has over 225,000 residents, of which 54.8% are non-White. Analysis revealed the East End has a high burden of CKD risk factors, including diabetes, hypertension, and obesity. The Dialysis Facility Report indicated 75% of dialysis patients in Richmond are Black, compared to 22% White. Additionally, 19% of individuals with ESRD in Richmond did not receive pre-dialysis nephrology care, and 5% to 12% of those starting dialysis lacked medical coverage, compared to 3% to 7% statewide. Diabetes is the major cause of kidney disease in Richmond, emphasizing the need for early detection and intervention.

Conclusions: The DECK Pilot Study demonstrates the critical need for integrating community-based interventions to address both medical and social determinants of kidney health. DECK serves as a model for enhancing kidney health equity and can be replicated in other underserved communities to reduce health disparities and improve care quality.

Funding: Private Foundation Support

TH-PO842

Promoting Kidney Health Equity through Kidney Disease Screening and Awareness Program at University of Virginia

Morgan Greig,[1] Joseph D. Nguyen,[1,2] Monarch Shah,[1] Rakesh Malhotra,[3] Tushar Chopra.[1] *[1]UVA Health, Charlottesville, VA; [2]University of Virginia School of Medicine, Charlottesville, VA; [3]University of California San Diego Department of Medicine, La Jolla, CA.*

Background: Kidney Disease Screening and Awareness Program (KDSAP) at University of Virginia (UVA) aims to promote kidney health awareness and improve outcomes among vulnerable populations. Our community health events employed questionnaires and screening tests to assess community prevalence and awareness of hypertension (HTN), diabetes (DM), and isolated proteinuria among participants based on self-reported race and gender.

Methods: Self-reported race, gender, and screening results were obtained from the KDSAP at UVA database from 2022 to 2024. Reported race was White, Black, Asian, Hispanic, or Latin(o). Reported gender was male, female, or other. Positive HTN screen was defined as blood pressure above 130/80 mm Hg, positive DM screen was defined as fasting blood glucose ≥126 mg/dL, and positive proteinuria screen was defined as urine albumin creatinine ratio (UACR) above 30 mg/g. A patient-reported screening questionnaire obtained the percentage of participants unaware of their condition.

Results: Of the 92 patients in the KDSAP database, the frequency of a positive screening test was 48.9% for HTN, 10.1% for DM, and 32.2% for proteinuria. Positive HTN screening rate was particularly prevalent among self-reported males (52.8%), Blacks (64%), and Asians (64.7%), with unawareness rates of 67.9%, 25%, and 81%, respectively (Table 1). Positive proteinuria screen rate was 30-40% amongst males, females, whites, and blacks, and approximately 80-100% of total participants were unaware of proteinuria.

Conclusions: In summary, the majority of patients screened positive on at least one test, and many of these patients were unaware of their condition. Our data suggests that there are significant cultural and socioeconomic barriers to care that prevent vulnerable populations from taking advantage of preventive interventions, both medical and educational, for chronic conditions such as HTN, DM, and CKD. We improved patient awareness and provided educational materials with the goal of leading to positive behavioral changes. Our study highlights the need for long-term primary care and nephrology follow-up for patients who screened positive.

Supporting the Participation of Latinx Individuals in Dialysis Research

Katherine M. Rizzolo,[1] Jennifer E. Flythe,[2] Lilia Cervantes.[3] *[1]Boston Medical Center, Boston, MA; [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Despite their disproportionate burden of kidney disease, the Latinx population is underrepresented in kidney research. Culturally concordant community health workers (CHWs) with shared lived experience have increased Latinx patient representation in cancer research, but less is known about enhancing Latinx representation in kidney research. Our study aims to fill the knowledge gap about optimal strategies for supporting the participation of Latinx individuals in kidney research, through the lived experience of adult Latinx people with kidney disease and CHWs who are involved in the recruitment of Latinx individuals for research.

Methods: We conducted a qualitative study with adult Latinx dialysis recipients and CHWs via semi-structured interviews assessing barriers/ facilitators to research participation. Interview transcripts were analyzed inductively for themes, coding followed thematic analysis and consensus on themes and sub-themes was reached.

Results: Patient participants (n=6) had a mean age of 56.2 years, 50% were women with 6.3 year average dialysis vintage. CHW participants (n= 9) had a mean age of 44.5 years, 77.8% were women, and 66.7% identified as Latinx. Participants described four themes (table): 1) Community relationships are key to trust building 2) Key elements to building rapport 3) Motivations to participate in a research study and 4) Barriers to participation and retention. Key areas to enhance recruitment and retention are researcher accountability (i.e. returning research findings to the community), valuing the patient voice and lived experience, and addressing social needs and language barriers that may de incentivize participation.

Conclusions: Our study indicates that relationship building and establishing trust in a community is critical for Latinx research participants. The strategies identified in this study will generate insights into augmenting diversity in future kidney research, an essential step toward achieving health equity.

Funding: Private Foundation Support

Theme and sub-themes	Patient illustrative quote	CHW illustrative quote
Community relationships are key to trust building		
Language/culture concordance Improve connection Equal footing/lack of power dynamic Community partnership Understanding lived experience	Before talking about the study, before talking about the protocols and everything, you make a connection …So that the person feels that they are important to you, not that you arrive and impose on them like, "Oh, I am the worker." No, feel that they are above you, that you are there because you need them in the research, not them needing you. (PT4)	I think a lot of people rightly so have hesitations about research. And so, I think the more that we can get involved in the community in a way that is genuine and not like, hey, here's our study like do it. But just really making genuine connections is a really important first step. (CHW15)
Key elements to building rapport		
Warmth and curiosity of interviewer Sincerity and caring about the individual In-person preferred over phone Interviewers encourage active participation and confidence	The sincerity regarding the person who is going to invite you, or honesty is what matters most because I think that if you invite me, you're not going to invite me to something where I'm going to get harmed, because someone aware that there will be some harm would automatically reject participation. (PT2)	When you're doing a program specifically for Latinos, and you can connect with them and teach them that it's important what they have to say, I noticed that it would make them more willing to talk, and they felt more comfortable, too. So, a person who is outgoing, friendly, obviously, and curious to learn from people. (CHW2)
Motivations to participate in a research study		
Research helping community Learning about disease Personal health benefit Compensation	It wasn't even about the money. It's just the knowledge. I'm a mother, I'm a sister, I'm a daughter, I'm a pet owner and I'm needed… I wanna live, I wanna be able to see my grandkids. (PT9)	I would say the biggest thing that has helped me get Latinos to respond is by being sincere about the fact that their information is going to help someone. (CHW6)
Barriers to participation and retention		
Not feeling heard or valued Social needs and language barriers Lack of clarity of the study expectations Lack of study team accountability or follow up	Information on any topic or any information or study, that's very important to be well informed to know what you're doing, what you're going to receive, or what you're going to share with the next patients, what you can give them in your case. (PT4)	I think it is very important that we are clear that sometimes there are no benefits for the patient or that it will not impact the care they are receiving from the hospital…I think sometimes there is no direct connection and there is no trust either, that they don't know exactly what their participation involves and why we are interested in knowing anything about their experience. (CHW13)

A Qualitative Study of Chinese American Knowledge and Perceptions about Kidneys and Kidney Diseases

Michelle M. Richardson,[1,2] Abigail Lebovitz,[2] Klemens B. Meyer,[3,2] Tamara Vesel.[3,2] *[1]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [2]Tufts University School of Medicine, Boston, MA; [3]Tufts Medical Center, Boston, MA.*

Background: Asian Americans have a higher risk of early chronic kidney disease (CKD) compared to other racial groups in the United States (US) and were the only group without a decrease in end-stage renal disease prevalence from 2019-2021 [USRDS 2023 Annual Report, United States Renal Data System]. Timely identification and treatment of CKD is crucial to prevent or delay disease progression. Evaluating kidney health and disease knowledge can shape culturally sensitive education to reduce disease prevalence.

Methods: Our community partner conducted semi-structured, 1:1 interviews of elders without kidney disease from 12/2023-2/ 2024. Iterative multi-stage thematic analyses identified key concepts and themes.

Results: Of nine participants, 89% were female, all were born in China, lived in the US an average of 19 years, and over half had at least a high school education. Eight interviews were in Cantonese and one in Taishanese. Half of participants knew someone with kidney disease. Baseline knowledge was high and included: knowing the importance of kidneys for overall health and survival; the role of kidneys in hormone regulation,

fluid balance, and detoxification; the relationship between kidneys and the urinary system; and recognizing "silent" disease progression. Additional themes arose at the intersection and divergence of traditional Chinese medicine and western medicine concepts of CKD including: relationship of kidney disease with sexual health, the term "kidney deficiency", and the consideration of mood and mindset when understanding disease. Lastly, concern over lack of individual and population knowledge surrounding kidney health and CKD was prevalent and many were curious and enthusiastic to learn more about the kidneys and identifying CKD.

Conclusions: Overall, our participants' knowledge of the kidneys was advanced. There are important cultural considerations within Eastern and Western medicine that clinicians should be aware of when providing CKD education and care. Chinese American individuals have distinctive perspectives and understanding of kidney health and disease that should be acknowledged to provide high quality, culturally respectful disease education and health care.

Creating a Bilingual Community Advisory Board to Promote Kidney Research and Academic-Community Collaborations

Michelle M. Osuna-Diaz, Tessa K. Novick. *The University of Texas at Austin Dell Medical School, Austin, TX.*

Background: Little is known about best practices for establishing a bilingual community advisory board to promote academic-community collaborations.

Methods: We created a community advisory board composed of nephrology providers, researchers, people with kidney disease, and community-based organizations representing Hispanic/Latine and Black/African American populations. We held ten virtual board meetings in Spanish with live interpretation, then conducted a focus group to assess (1) strengths and challenges, and (2) recommendations for improvement and sustainability. We described the process of board creation, meeting agenda items, and thematic analysis of focus group content.

Results: The board included 17 members with diverse representation. Agenda items included: establishment of mission and member responsibilities, selection of leadership, review of a grant proposal, and provision of small grants to members to conduct research that promoted the board's mission. Live virtual interpretation increased sense of inclusivity and connection. Challenges included incomplete understanding of the purpose of collaboration, lack of trust, and lack of sustainable funding. Recommendations included community fiscal sponsorship and teambuilding activities to promote trust.

Conclusions: Bilingual community advisory boards promote academic-community collaboration.

TH-PO846

Associations of Risk and Protective Factors with Kidney Outcomes among American Indians: The Strong Heart Family Study

Reya H. Mokiao,[1,2] Kristen E. Carlin,[2] Jason F. Deen,[1] Jason G. Umans,[3,4] Bessie A. Young,[1] Amanda M. Fretts.[5] *[1]University of Washington School of Medicine, Seattle, WA; [2]Seattle Children's Research Institute, Seattle, WA; [3]MedStar Health Research Institute, Hyattsville, MD; [4]Georgetown University, Washington, DC; [5]University of Washington School of Public Health, Seattle, WA.*

Background: Kidney disease disproportionately affects American Indians (AI) compared to White individuals, and it is important to explore modifiable risk factors as potential areas for intervention. The objective of this study was to explore the associations of kidney disease risk factors, achievement of the American Heart Association's (AHA) Life's Essential 8 (LE8), and social support with low estimated glomerular filtration rate (eGFR) and albuminuria among AI in the Strong Heart Family Study (SHFS).

Methods: The study population included participants from the SHFS, a longitudinal study of cardiovascular disease (CVD) among AIs from 12 tribes (n=1956, age 39 ± 16 years, 61% female, 13% with diabetes (DM)). Participants completed baseline (2001-2003) and follow-up (2007-2009) exams. The primary exposures were prevalent DM, obesity, hypertension, dyslipidemia, CVD, smoking, diet, physical activity, a modified LE8 score (smoking, body mass index (BMI), lipids, glucose, blood pressure, physical activity, and diet), and social support as risk/ protective factors. The primary outcomes were: 1) incident albuminuria (albumin to creatinine ratio 30mg/g or greater); 2) incident low eGFR (eGFR < 90 ml/min/1.73m^2 using the 2021 CKD-EPI Creatinine equation). Generalized estimating equations were used to examine the association of all exposures with outcomes.

Results: In this relatively young cohort of AI, kidney disease risk factors were common. Based on LE8 scores, 14%, 71% and 15% had low, moderate, and optimal CVD health respectively. At follow up, 10% had incident albuminuria and 8% had incident low eGFR. Higher BMI (OR 1.04, 95%CI 1.01, 1.07, p<0.01) and DM (OR 2.94, 95%CI 1.84, 4.67, p< 0.0001) were associated with incident albuminuria. Those with moderate (0.57, 95%CI 0.39, 0.84, p<0.01) and high (OR 0.30, 95%CI 0.16, 0.58, p<0.001) compared to those with low CVD health based on LE8 scores had decreasing odds of incident albuminuria. None of the exposures were associated with incident low eGFR.

Conclusions: Although kidney disease risk factors were prevalent among the SHFS cohort, adherence to the AHA's LE8 was associated with lower odds of incident albuminuria. Preventative interventions that promote and facilitate adherence to healthy behaviors, like LE8, may improve cardiovascular and kidney health among AIs.

Funding: Other NIH Support - The Strong Heart Study has been funded in whole or in part with federal funds from the National Heart, Lung, and Blood Institute, National Institute of Health, Department of Health and Human Services, under contract numbers 75N92019D00027, 75N92019D00028, 75N92019D00029, & 75N92019D00030. APOL1 Genotyping, Knowledge, and Attitudes among African American Patients: Building a Cohort in a Midwestern US Urban Community

Krista L. Lentine,[1] Marie D. Philipneri,[1] Aliza Anwar Memon,[1] John C. Edwards,[1] Amy Mosman,[1] Kana Miyata,[1] Fadee Abu Al Rub,[1] Amber Carriker,[4] Barry I. Freedman,[2] Rengin Elsurer Afsar,[1] Baris Afsar,[1] Anthony N. Muiru,[3] Chi-yuan Hsu,[3] Yasar Caliskan.[1] *[1]Saint Louis Univ, St. Louis, MO; [2]Wake Forest, Winston Salem, NC; [3]UCSF, San Francisco, CA; [4]Mid-America Transplant, St. Louis, MO.*

Background: While some past studies assessed interest in apolipoprotein L1 (*APOL1)* genotyping among focus groups, few studies examine attitudes and knowledge combined with the opportunity to receive individual genotyping.

Methods: We offered *APOL1* genetic testing and surveyed knowledge, attitudes and concerns related to *APOL1* testing and kidney risk management among self-identified African American patients (NCT05656261) including 3 mo. follow-up (**Fig 1A**).

Results: Among 263 participants with genotyping results to date (Jan 2019–March 2024), 16% had high-risk genotypes (2 *APOL1* RRVs) and 84% were low-risk (0/1 RRV). Median $eGFR_{2021}$ was 47.7 in *APOL1* low-risk vs. 42.2 ml/min/1.73 m^2 in high-risk groups. 50.7% of low-risk and 54.8% of high-risk groups reported family members with kidney problems. 24% of the 2 RRV group rated their overall health as poor to very poor, vs. 10% of the 0/1 RRV group. At baseline, 86% reported they would want *APOL1* testing for their family members. However, only 9.5% accepted formal genetic counseling beyond study-related education. Participants reported a variety of behavior changes may follow genotyping information (**Fig 1B**). The proportion who might worry about a high-risk genotype was lower at 3 mo. (18% vs 23%). 90% agreed to future research.

Conclusions: Self-identified African American patients at a Midwestern medical center report a high family history of kidney disease and were receptive to individual *APOL1* genetic testing, not only in theory, but by participating in testing. Ongoing research is needed to define the interplay of genetic and environmental factors underlying kidney risk in this population.

Who Receives Kidney Disease Education? An Analysis of Patients with ESKD

Ron Preblick,[1] Praveen Kumar Potukuchi,[1] Jessica Voss,[1] Cynthia Gutierrez,[2] Danielle Acquaviva,[2] Mona Kelkar,[2] Yu Hong,[2] Amy D. Waterman.[3]
[1]Genzyme Corporation, Cambridge, MA; [2]Genesis Research LLC, Hoboken, NJ; [3]Houston Methodist Hospital, Houston, TX.

Background: While kidney disease education (KDE) is linked to improved outcomes for ESRD patients, disparities in uptake exist. We evaluated the association of KDE with social determinants of health (SDOH) among 519,902 patients with ESRD.

Methods: This retrospective cohort study was conducted using data from Medicare-linked US Renal Data System (USRDS), the Agency for Healthcare Research and Quality (AHRQ) SDOH database, and the Robert Graham Center's calculated social deprivation index (SDI). Included patients had a CMS2728 fill date between Jun 30, 2011 and Sept 30, 2019, an ESRD diagnosis ±30 days of the fill date, and ≥1-year pre-index activity. KDE status was assessed in the 2-year pre-index period. Baseline characteristics were assessed using CMS2728 and Medicare claims. Neighborhood variables were linked at the zip code level. Post-index ESRD treatments were assessed during a variable follow-up period. Univariate logistic regression was used to test SDOH differences between KDE and non-KDE patients.

Results: Of the patients identified, 7,838 received KDE (1.5%). Most received individual KDE (75.6% vs group [23.1%] or both [1.3%]), with mean of 1.6 sessions (SD 1.2). Most received KDE in stage 4 (85.6%), followed by stages 5 (13.1%) and 3 (1.3%). Black patients were less likely to receive KDE (Odds Ratio [OR] 0.92 vs White patients [95% confidence interval 0.87-0.97]), as were Hispanic patients (OR 0.72 vs non-Hispanics [0.67-0.79]). Patients who were in the most vulnerable quartile of the SDI were less likely to receive KDE than those in higher quartiles (OR 0.68; 95% CI, 0.64-0.79). Similar results were seen across SDOH factors (**Figure**). Throughout the post-index period, patients in the KDE group were more likely than non-KDE patients to receive peritoneal dialysis (28.1% vs 17.3%) and/or kidney transplants (4.4% vs 2.4%).

Conclusions: Identifying factors associated with KDE disparities may provide opportunities to increase utilization and improve outcomes.

Long-Term Effects of Structural Racism on Kidney Health: Redlining in Atlanta

Jennifer L. Bragg-Gresham,[1] Linda Fraunhofer,[2] Ana Laura Licon,[1] Tiffany C. Veinot,[3] Jennifer L. Ennis,[2] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]Laboratory Corporation of America Holdings, Burlington, NC; [3]University of Michigan School of Information, Ann Arbor, MI.*

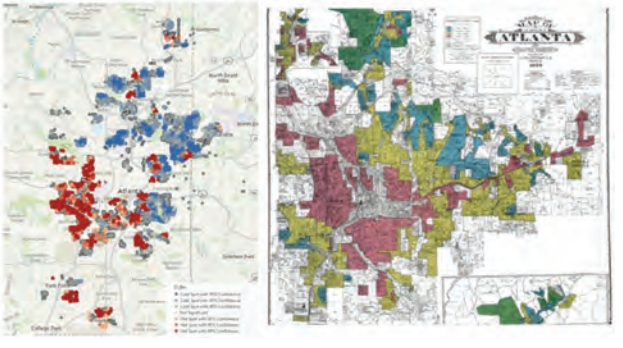
Background: In 1938, the Home Owners' Loan Corporation (HOLC) produced a map of Alanta, GA, as a safety investment guide for mortgage lenders. Areas labeled "hazardous" reinforced racial residential segregation with lasting patterns of continuing inequality. We hypothesize that individuals residing in "less desirable" neighborhoods continue to face challenges contributing to the risk of kidney disease.

Methods: Using Labcorp's most recent kidney disease laboratory tests (~25K, 2021-2024) from individuals residing in previously mapped HOLC districts in Atlanta, GA, we spatially joined results to each grade (A: Best [Blue], B: Desirable [Green], C: Declining [Yellow], and D: Hazardous [Red]). Kidney disease was defined by either an eGFR <60 ml/min/1.73m^2 or a UACR ≥30 mg/g. Hot spot analysis was conducted employing the Getis-Ord Gi*. Logistic regression assessed the odds of kidney disease by HOLC grade, adjusted for age, sex, and current Area Deprivation Index (ADI).

Results: Individuals living in HOLC-A & B neighborhoods were older with a higher proportion of females than those in HOLC-C & D. The prevalence of CKD and current ADI were higher within each successively worse HOLC grade (CKD from 5.3%-13.2% and ADI from 1-3.6). The odds of kidney disease was significantly higher for all HOLC grades compared to grade A (B: OR=1.9, C: OR=2.9, and D: OR=3.7, all p<0.0001). Current day ADI was associated with 13% higher odds of CKD per 1 higher ADI score, p<0.0001.

Conclusions: Significant positive associations were seen between historically redlined areas of Atlanta and the odds of kidney disease. It is imperative to determine the mechanisms underlying these observations and to develop place/person-centered intervention programs to mitigate the effects of these disparities. Future work will assess the causal impact of current day social determinants of health in these geographic areas, including measures of housing, food insecurity, access to healthcare, climate/temperature, and air pollution.

Figure: Current Day Hotspot Map of CKD Compared to 1938 Redlining Map of Atlanta



TH-PO850

Navigating the Distinct Needs of English- and Spanish-Speaking Patients with Kidney Diseases

Kimberly Vasquez, Brittany S. Christian, Jenny I. Shen. *Harbor-UCLA Medical Center, Torrance, CA.*

Background: Latinx patients have a high burden of chronic kidney disease (CKD) and face barriers such as limited health literacy, mistrust of health providers, and communication issues. Patients of lower socioeconomic status face similar barriers,

regardless of their ethnicity. We sought to explore the experiences of patients with CKD who receive care at a US safety-net hospital as well as the potential challenges of introducing a peer mentoring program to support these patients.

Methods: We conducted 8 focus groups of 33 adult patients and 27 caregivers who receive CKD care at a safety-net hospital in California. Patients either spoke English or Spanish. Transcripts were analyzed thematically.

Results: The median age of participants was 50. 60% were women; 40% Spanish-speaking. All had low enough income to qualify for Medicaid. The themes identfied were 1) the need for more information and better communication, 2) the emotional toll of CKD, and 3) lack of trust (Table). To increase awareness of exisiting peer mentoring programs, patients suggested direct text messages, personalized calls, interactive introductory videos, and having doctors introduce the program during clinic visits.

Conclusions: Participants described their kidney disease journey as a labyrinth with emotional distress for themselves and their caregivers. Peer mentors can address barriers of lack of emotional support, communication, and health literacy. Multi-faceted approaches to raising awareness of peer mentoring programs are needed to encourage participation in peer mentoring programs.

Illustrative Quotes

Theme	Quote
Lack of clear information and communication	"You come [to clinic] and you ask, what happened, something is going on...because you don't know the reason why. It has to be from something."
	"I did know [about living with dialysis], not until now [at this focus group] that I talked to the woman explaining about her situation, I am like wow, she has [been on dialysis] a long time and has been surviving."
Emotional toll of CKD	"Your body is fighting against you, and you don't know why, you don't know what to do, and nobody knows what to do with you. I am living in an underlying fear because I don't know what is going to happen... so abruptly my life changed."
	"Every time I wake up, I am grateful to God I am not dead because I was feeling really bad."
Lack of trust	"The doctor told me why you are taking this medicine? its damaging more your kidneys. You were not supposed to be taking this medicine, when he gave me those pills... He told me the contrary."
	"Every time I come in clinic it's a different doctor and they tell me something different. Do they really know what's going on?"

TH-PO851

Sex- and Age-Related Differences in the Prevalence of the Cardiovascular-Kidney-Metabolic Syndrome among US Adults, 1999-2020: An Analysis of the NHANES Survey

Bernhard M. Schmidt, Samira Soltani, Johann Bauersachs, Kai M. Schmidt-Ott, Anette Melk, Zhejia Tian. *Medizinische Hochschule Hannover, Hannover, Germany*.

Background: The cardiovascular-kidney-metabolic (CKM) syndrome is defined as the intricate interplay among metabolic risks, chronic kidney disease (CKD) and the cardiovascular system. The deteriorating CKM syndrome contributes to untimely morbidity and mortality. We aim to characterize sex and age related differences in the prevalence of CKM syndrome.

Methods: We used cross-sectional data provided by National Health and Nutrition Examination Survey (NHANES), representative of the non-institutionalized civilian population of the United States. We included non-pregnant participants aged 18 or older between 1999 and 2020 in our analysis. Prevalence was analyzed overall and by population subgroup (including age, sex, and race/ethnicity), and was weighted to be nationally representative.

Results: A total of 32848 US adults were included in our study from 1999 to 2020 (weighted mean age, 47.3 years; women, 51.3%). 7.9% of US adults were at stage 0 without any CKM risk factors, with the majority being female, comprising 64% of this subgroup. A higher percentage of younger participants were categorized in this group, with 74.9% being under the age of 45. 18.3% of US adults encountered issues related to excess or dysfunctional adiposity without other metabolic risk factors or CKD (stage 1). The distribution between sexes was similar. Over half of the US adult population (56.5%) exhibited either metabolic risk factors, CKD, or a combination of both (stage 2). Older individuals were more prevalent in stage 2, with 41.1% between the ages of 45-64 and 20.4% aged 65 or older. Females aged 65 or older showed a significantly higher prevalence across almost all metabolic risk factors and CKD compared to men. Between 1999 and 2020, the CKM features increased with decreasing prevalence of CKM stage 0 (*P* for trends =0.0018) in females (*P* for trends =0.0039) and to a leser extent in males (*P* for trends =0.031).

Conclusions: Our findings illustrate an exceptionally high and increasing prevalence of CKM syndrome among US adults. Especially elderly women are overrepresented in the high risk group of stage 2 patients. Intense preventive measures should explicitly focus on this group of female patients

TH-PO852

Association and Contribution of Gender-Related Characteristics to Prevalence of CKD in Women and Men in a Multiethnic Population

Taryn G. Vosters,[1] Vianda S. Stel,[1] Liffert Vogt,[1] Kitty J. Jager,[1] Frans J. van Ittersum,[2] Bert-Jan Van den Born,[1] Irene van Valkengoed.[1] *[1]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands*.

Background: In chronic kidney disease (CKD), prevalence differences between sexes have been reported. While biological factors have been investigated, research on sociocultural factors is scarce. We explore the extent gender-related characteristics associate with, and contribute to, CKD prevalence in women and men in a multi-ethnic population.

Methods: Cross-sectional analyses were performed on data of 12,221 women and 8,930 men aged 18-70 years across six ethnic groups from the HELIUS Study. Using age-, education-, and ethnicity adjusted Poisson regression, we determined associations between time spent on housework; primary earner status; employment status; and occupational segregation, and CKD. Population Attributable Fractions estimated the contribution to CKD and the extent traditional CKD risk factors explained these contributions.

Results: In women, associations with CKD were found for doing little housework, part-time work, and unemployment. In men, primary-earnership and unemployment were associated. Associations aligned across ethnic groups. Estimated contributions ranged from 1.8% for women doing little housework to 26.5% for part-time employment and 12.1% for unemployment to 37.5% for primary-earnership in men, and were hardly explained by risk factors.

Conclusions: In our study, gender-related characteristics are associated with CKD in women and men across ethnic groups. Contributions to population prevalence may hardly be explained by CKD risk factors.

TH-PO853

Intersection of Race, Age, and Mortality in Young Adults in the United States Renal Data System

Neha D. Pottanat,[1,2] Marciana Laster,[1,2] Jaya S. Parulekar,[1] Mengyu Di,[3] Jade Buford,[3] Rachel E. Patzer.[1,3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [3]Regenstrief Institute Inc, Indianapolis, IN*.

Background: Adults 18-44 years with end-stage kidney disease (ESKD) demonstrate heterogeneity in mortality and transplant waitlist access when categorized by race-ethnicity. Young adults have intensified disparities, but the age cut-off is unknown. Patients between 18-26 years experience changes in insurance status and executive functioning, as it relates to health self-management and transitioning to adult care. Our goal is to compare racial-ethnic disparities in adults <26 years to 26-44 years.

Methods: Incident patients receiving dialysis were identified using USRDS data from 2015-2020. Cox proportional hazard models adjusted for covariates were used to examine the relationship between race-ethnicity and mortality within each age category.

Results: Baseline characteristics of ESKD patients are described for each age category (**Table 1**). Non-Hispanic Black, non-Hispanic Asian, and Hispanic patients had a lower risk of mortality when compared to the reference group of non-Hispanic White patients in crude and adjusted analyses (**Table 2**). When stratified by age, these findings persisted amongst all racial-ethnic categories in patients 26-44 years old. However, in those <26 years, non-Hispanic Black patients had increased risk of mortality in crude analysis (HR 1.41, 95% CI 1.22-1.63) with attenuation upon adjustment. The lower risk of mortality noted in Hispanic and non-Hispanic Asian patients remained within this age group.

Conclusions: This study emphasizes that disparities in mortality within the non-Hispanic Black dialysis population are age dependent. This is consistent with prior research suggesting a "survival advantage" may not be present in younger non-Hispanic Black adults. Further research is needed to define critical ages when disparities in outcomes become apparent.

Table 1: Baseline characteristics of ESKD patients (2015-2020) by age category

Variable	Level	Age 18-25 N =8277 (9.47)	Age 26-44 N = 79134 (90.53)
Sex	Female	3835 (46.33)	32099 (40.56)
	Male	4442 (53.67)	47035 (59.44)

TH-PO854

Sex-Free Estimation of eGFR Preferentially Reclassifies Women as Having Better Kidney Function

Inga Steinbrenner,[1] Anna Kottgen,[1] Elke Schaeffner,[2] Kai-Uwe Eckardt,[3,4] Ulla T. Schultheiss.[1,5] *[1]Institute of Genetic Epidemiology, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany; [2]Institute of Public Health, Charité – Universitätsmedizin Berlin, Berlin, Germany; [3]Department of Nephrology and Hypertension, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen-Nürnberg, Germany; [4]Department of Nephrology and Medical Intensive Care, Charité, Berlin, Germany; [5]Department of Medicine IV, Nephrology and Primary Care, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany.*

Background: Chronic kidney disease (CKD) is staged based on estimated glomerular filtration rate (eGFR, G categories) and urinary-creatinine-to-albumin-ratio (UACR; A categories). Using the cystatin-C based CKD-EPI equation (CKD-EPI) to estimate GFR, women are more likely to be diagnosed with CKD, while men have higher incidence of kidney replacement therapy (KRT). This discrepancy could stem from an overestimation of CKD prevalence and severity on eGFR equations in women, or a slower CKD progression in women compared to men. Pottel et al. introduced a cystatin C-based eGFR equation (EKFC) no longer requiring sex information showing less bias compared to measured GFR than previous equations. We therefore assessed reclassification of CKD stages in >5,000 participants diagnosed with CKD in the German CKD (GCKD) study with the EKFC compared to the CKD-EPI equation in a sex-specific manner.

Methods: The GCKD study's main inclusion criteria were an eGFR between 30-60 or >60 mL/min/1.73m² in the presence of a UACR >300 mg/g. Of 5,217 participants, 91.5% fulfilled the criteria of decreased eGFR, while 8.5% were enrolled based on UACR. Cystatin C was measured from baseline serum samples using a particle-enhanced turbidimetric immunoassay (Tina-quant, Roche). The CKD-EPI and EKFC equations were used to estimate GFR. Reclassification of proportions by sex using the KDIGO G stages was done by comparing the CKD-EPI equation with the EKFC equation.

Results: Among 5,161 participants (60% men), clear sex-specific differences were detected when applying the EKFC equation: compared to the CKD-EPI equation, women in G3a/b were 2-4.5 times more likely to be reclassified to a "milder" G category of CKD (**Table**).

Conclusions: The observed reclassification of women is consistent with the lower incidence of KRT in women and may help to resolve the apparent discrepancy of higher CKD prevalence yet lower KRT incidence observed with previous equations. Future studies should assess the relationship between EKFC estimates and CKD progression.

CKD-EPI \ EKFC		normal or high (G1)	mildly decreased (G2)	mildly to moderately decreased (G3a)	moderately to severely decreased (G3b)	severely decreased (G4)	kidney failure (G5)	N	reclassified N (%)
Men									
G3a	mildly to moderately	0	6.1%	93.9%	0	0	0	902	55 (6.1%)
G3b	moderately to severely	0	0	19.9%	80.1%	0	0	988	197 (19.9%)
Women									
G3a	mildly to moderately	0	27.5%	72.5%	0	0	0	556	153 (27.5%)
G3b	moderately to severely	0	0	39.8%	60.2%	0	0	646	257 (39.8%)

Excerpt: Reclassification of G categories by sex in GCKD study participants in G3a/b by the cystatin C-based EKFC eGFR equation without sex and cystatin C-based CKD-EPI eGFR equation including sex.

TH-PO855

High Prevalence and Inequities in Unmet Social Risk in Diverse Urban Patients on Hemodialysis

Wenchy Tan,[1] Huei Hsun Wen,[1] Lin-Chun Wang,[2] Zijun Dong,[2] Lela Tisdale,[2] Stephan Thijssen,[2] Peter Kotanko,[2] Girish N. Nadkarni,[1] Lili Chan.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Renal Research Institute, New York, NY.*

Background: Health-related social risks (SR) are associated with adverse health outcomes amongst patients with kidney disease. We aimed to identify and analyze SR in a diverse population of hemodialysis (HD) patients.

Methods: We prospectively surveyed SR related to insecurity of housing, food, transportation, and utilities in HD patients from five New York centers, using the AHC Health-Related Social Needs Screening Tool (AHC-HRSN). The presence of unmet SR was compared across self-reported race/ethnicity. Patient demographics (age, gender, education level, employment status, marital status, and income) were assessed for their association with the odds of having any unmet SR using logistic regression. A two-tailed p-value <0.05 was considered statistically significant.

Results: Among 324 consented patients, 144 (44%) had at least one unmet SR (Fig. 1A). Food insecurity differed significantly across race/ethnicity groups ($p = 0.017$). While lower proportions of Whites reported experiencing any unmet SR (35%) compared to Hispanics (63%), Blacks (59%), and Asians (43%), this difference was not statistically significant ($p = 0.097$). Having a college degree or above (OR: 0.64, 95% CI: 0.410 – 0.996) and older age (OR: 0.98, 95% CI: 0.967 – 0.996) were each associated with significantly lower odds of having any SR (Fig. 1B). No significant association was observed between SR and gender, employment status, and marital status after adjusting for patient demographics (Fig. 1C).

Conclusions: This study uncovered disparities in SR factors across different demographic categories, including race/ethnicity and education levels. The overall high burden of unmet SR indicates a need for improved screening and referrals.

TH-PO856

"Life Is Either You're Going into a Storm, Going through a Storm, or Coming out of One": Narrative Interviews with Younger Adults on Dialysis in Baltimore City

Yordanos Tesfai,[1] Deirdre Petkiewicz,[2] Kennedy A. Brown,[2] Deidra C. Crews,[3] Kathryn Taylor.[2] *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins Medicine, Baltimore, MD.*

Background: Racial disparities in survival with kidney failure are most pronounced among younger adults on dialysis, particularly those living in disinvested urban communities. We lack understanding of how younger Black adults on dialysis living in these communities frame their own narratives, navigate their environment to preserve functioning, or the role of dialysis in that work. Narratives can inform interventions to advance health equity in dialysis.

Methods: We are conducting narrative (unstructured) interviews with younger adults on dialysis in Baltimore City to explore their lived experience on and off dialysis. We are recruiting a purposive sample of adults age 18 to 45 years who are receiving dialysis from a facility in Baltimore City, excluding adults who initiated dialysis before age 18. We aim to enroll 15 participants and complete data analysis by October 2024. We will conduct member checking via focus groups when enrollment is complete. We present preliminary analysis of interviews with the 8 participants we have enrolled to date. Interviews were audiorecorded and transcribed, and we used F4Analyze to code qualitative data. Three study members independently conducted reflexive thematic analysis of study interviews and discussed preliminary codes and themes.

Results: All participants self-identified their race as Black or African American and their ethnicity as non-Hispanic; 6 (75%) identified as male. Preliminary codes and supporting quotes (Table 1) illuminate how participants creatively leveraged psychological and available social resources to navigate life as a person on dialysis.

Conclusions: Multiple targets exist for interventions to eliminate racial survival inequities among younger adults on dialysis in disinvested urban communities.

Funding: Other NIH Support - NIH/NIMHD P50MD0173XX

Preliminary Codes	Supporting Quotes
Trying to process	The physical is draining. But depression is real....just kind of realizing this is my life now. Where I'm going to in-center three days a week, and I'm sitting in a room with mostly older folks, because I'm 35 at this time...Trying to process all that's going through, what does it mean for your life? What does it mean going forward? (Participant 6)
Strategies: Prioritizing multiple responsibilities and tasks/ adjusting to fluctuating energy levels	Really the biggest transition was trying to find time for everything. And then also managing that along with energy levels...when I get out of dialysis on a Tuesday and a Thursday, I'm wiped. I've woken up at 7:00, went to work, worked all day...Trying to figure out what are the important priorities for getting things done. For me, it's making sure that there's food in my house, dinner is made, making sure that it's not in shambles completely. And then making sure that my mom's okay, because she is needing a lot more help now than previously. (Participant 1)
Strategies: Negotiating with clinicians for person-centered care	...every year they have this yearly action plan they're supposed to give to the patients and I told my doctor that we're not going to do this on the floor. I don't feel comfortable. I've always said that. So he goes and says, well, he didn't want to do telehealth...And then he goes and says, "Well, you can come up here on Tuesday." Well, in my head I'm like, I live in West Baltimore. I'm not coming across town just to meet with you for 15 minutes for you to tell me the same thing you told me last year...So I didn't show up. Time went by..."Well, I'm going to start the paperwork to have you discharged." So you're going to discharge me because I don't want to meet with you– So it took for me to say something to call the, you know, 1-800 number for them to come back and say, "Hey, won't you just do it in the observation room," which nobody else is in there but one person. (Participant 5)
Survival resources: People try to take advantage of you	So it's like I found myself, here recently, I found myself getting this young lady to come. I thought she was going be here to help me. That's not the case. It's like she's taking advantage of me, and you run into that at times. Not all dialysis patients, because some people have their family and friends and things like that, but for some reason, I ran into this brick wall and I can't get her to move out...Or when we talk, it turns into a argument on her part, and the one day she jumped up in my face and I felt threatened. So now, I have sleep with a butcher knife underneath my pillow and a empty soda bottle, glass bottle, by my bedside. (Participant 7)
Survival resources: I didn't have anyone to guide me	I spent a month in the hospital and then two months in [a skilled nursing and rehabilitation facility]...So that's three months altogether. I got kicked out of the house where I was living too, at the time, because I didn't have no rent and had no money. I wasn't getting disability yet. So, I was working part time on dialysis, not on disability or nothing. Again, I didn't have anybody to guide me, like "Hey, man, you're on disability. Let me take you to Social Security." Because I was on my own on the street. (Participant 2)
Reframing the situation: You have to see the world as it is	It just doesn't make sense to keep perceiving the world and the way that you think it should be. You have to deal with things the way it is and then work from there. Somebody told me, I remember who it was, I'll never forget this, "Life is either you're going into a storm, going through a storm or coming out of one."...Like, that's life. And you're going to have to learn how to put on your raincoat, put on your boots and just deal with it. And I mean, I just had to deal with it. I mean, is it resilience? I guess. (Participant 2)
Reframing the situation: You have to have some kind of hope	My uncle just passed, and the one thing that I believe that why he passed is that he didn't have something to look forward for...You have to have some kind of hope, something that you want to strive for...You got to have something to go for to keep you moving because if not, you just sit still and just, you just die. (Participant 8)

TH-PO857

Motivation Associates with Dialysis Treatment Adherence in African American Patients

Marylou Wallace,[1] Julianna Forbess,[1] Meaghan S. Roche,[2] Heather L. Prigmore,[1] Robert Greevy,[1] Marquetta L. Faulkner,[3] Hilary A. Tindle,[1] Devika Nair,[1] Rachel B. Fissell,[1] Kerri L. Cavanaugh,[1] Ebele M. Umeukeje.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Henry Ford Health System, Detroit, MI; [3]Meharry Medical College, Nashville, TN.*

Background: African Americans (AA) comprise 33% of end-stage kidney disease (ESKD) patients, and are more likely to be nonadherent to in-center hemodialysis (HD) compared to Whites. Motivation-based factors informed by self-determination theory (SDT) associate with medication adherence. However, the association with HD treatment adherence in AA is unknown.

Methods: In a multi-site prospective study, motivation was assessed via SDT surveys: Autonomous Regulation [(AR) range: 1-7], Health Care Climate Questionnaire [(HCCQ) range: 1-7], and Perceived Kidney Disease Self-Management Scale [(PKDSMS) range: 8-40] Higher scores indicate better 'attitudes', perception of autonomy support from providers, and self-efficacy, respectively. Nonadherence was reported as mean proportion of missed HD minutes and shortened (i.e.,>15 minutes less than prescribed HD) and missed HD sessions over 3-month post-baseline survey period. Mean number of sessions was standardized to 36.

Results: Among 210 AAs on HD for at least 90 days (56.2% male; mean age 56 (±13.8), about one-third had a high school education or less, an annual income of $10,000 or less, and lived alone. Mean number of missed and shortened HD sessions per 36 sessions was 1.8 (±3.24) and 3.24(±5.04) respectively. All SDT scores significantly associated with shortened HD sessions; AR being the strongest. Higher PKDSMS scores were inversely and significantly associated with all measures of HD non-adherence **(Table 1).**

Conclusions: SDT measures were associated with HD adherence. Optimizing patients' attitudes may be most effective for improving nonadherence due to shortened HD. Enhancing patients' self-efficacy may significantly impact nonadherence for shortened and/or missed HD. Future research will target better understanding of underlying factors affecting patients' attitudes and self-efficacy to inform motivational strategies for improving HD adherence and kidney health equity.

Funding: NIDDK Support

Table 1

	Missed minutes	Missed minutes	Missed HD sessions	Missed HD sessions	Shortened HD sessions	Shortened HD sessions

TH-PO858

Apathy, Depression, and Hemodialysis Adherence in African American Patients

Meaghan S. Roche,[1] Marcus G. Wild,[2] Ratib T. Mahfouz,[1] Amulya Rajagopal,[1] Luis G. Osorio,[1] Javad Najjar Mojarrab,[1] Queen Henry-Okafor,[3] Toddra Liddell,[2] Rachel B. Fissell,[2] Devika Nair,[2] Heather L. Prigmore,[2] Robert Greevy,[2] Kerri L. Cavanaugh,[2] Hilary A. Tindle,[2] Ebele M. Umeukeje.[2] *[1]Henry Ford Health System, Detroit, MI; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University School of Nursing, Nashville, TN.*

Background: African Americans (AAs) have a four-fold higher prevalence of end-stage kidney disease (ESKD), high depression risk, and poor adherence to in-center hemodialysis (HD) compared to Whites. Depression and Apathy, and their association with HD adherence, are greatly understudied in AAs.

Methods: Validated surveys assessing depressive symptoms (Center for Epidemiologic Studies Depression scale, [range:0-30], higher scores indicating more depressive symptoms) and trait apathy (Apathy Evaluation Scale, [range:7-28], higher scores indicating less apathy), were administered to a multi-site cohort of AAs at 3 HD clinics. Nonadherence was defined as mean proportion of shortened HD sessions (i.e.,>15 minutes less than prescribed HD), and missed HD sessions over the 3-month post-baseline survey period; and mean number of missed/shortened sessions standardized to 36 sessions.

Results: AAs (N = 210; mean age 56; 56% male) had been on HD for at least 90 days. About one-third had a high school education or less; earned $10,000 /year or less; and lived alone. Mean number of missed and shortened HD sessions per 36 sessions was 1.8(±3.24) and 3.24(±5.04) respectively. Prevalence of significant depressive symptoms was 29.0%. Higher depressive symptoms (Fig.1) (r= 0.23; p = 0.001) and more apathy (r= -0.15; p = 0.029) correlated with shortened HD but not missed HD sessions.

Conclusions: Higher depressive symptoms and more apathy correlated with more shortened sessions in AAs on HD. Motivational strategies to reduce depressive symptoms and apathy, may be a novel way to improve adherence to HD among AAs, curb racial disparities, and promote kidney health equity.

MoVE TRIAL Protocol: MotiVational Strategies to Empower African American Patients to Improve Dialysis Adherence

Anita Medepalli,[1] Marylou Wallace,[2] Zuri N. St. Julien,[3] Julianna Forbess,[2] Heather L. Prigmore,[2] Robert Greevy,[2] Sarah J. Schrauben,[4] Devika Nair,[2] Rachel B. Fissell,[2] Julia Lewis,[2] Kerri L. Cavanaugh,[2] Kenneth A. Resnicow,[5] Ruth Q. Wolever,[2] Ebele M. Umeukeje.[2] *[1]Mercer University, Macon, GA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of Missouri-St Louis, St Louis, MO; [4]University of Pennsylvania, Philadelphia, PA; [5]University of Michigan, Ann Arbor, MI.*

Background: Compared to Whites, African Americans (AA) have a four-fold higher prevalence of end-stage kidney disease (ESKD) and higher hemodialysis (HD) treatment non-adherence rates. We pilot-tested (NCT05003115) and confirmed *feasibility* of culturally tailored motivational interviewing (MI) to improve HD adherence in AA. We describe our efficacy trial protocol (NCT05735743) and hypothesize that the intervention improves HD adherence.

Methods: Multi-site, 2-arm, parallel group (MI vs. Usual Care) RCT of ≥ 18 years old, AA HD patients (n=150, 2:4:2 stratified block randomization), who missed or shortened ≥1 session by ≥15 minutes/2 months before enrollment. Trained health coaches (HC) conduct MI sessions. Intervention fidelity is assessed pre-enrollment and mid-RCT, via MI Treatment Integrity Scale. MI patients receive 6 sessions in 8 weeks, culturally tailored to prioritize AA patient-identified contributors to nonadherence, including racial identity (Fig 1). Survey completion and EMR abstraction occur at baseline, 8, and 24 weeks; adherence data is abstracted to week 24. Primary and secondary outcomes are proportions of missed HD minutes at 8 and 24 weeks, respectively.

Results: IRB approval was obtained. Manual of procedures, intervention manual, and study charter were developed. HC received protocol, logistics, and further MI training. Enrollment was launched upon DSMB and site approval. RCT activities are ongoing.

Conclusions: Findings will determine *efficacy* of culturally tailored MI on improving HD adherence in AA. Improved HD adherence will reduce morbidity, mortality, healthcare costs, and racial disparities in ESKD.

TH-PO860

The Lived Experiences of African American and Latinx Individuals with CKD Using Photo Elicitation

Sadia Anjum Ashrafi,[1] Norman A. Hernandez,[2] Laura Quintero Silva,[2] Katherine Hopkins,[2] Michelle Martinez,[2] Maya Ordaz,[2] Minakshi Raj,[2] Andiara Schwingel.[2] *[1]University of Illinois Chicago College of Medicine, Chicago, IL; [2]University of Illinois Urbana-Champaign, Urbana, IL.*

Background: Chronic Kidney Disease (CKD) disproportionately affects the lives of African Americans and Latinx, but there remains a knowledge gap about their lived experiences. Therefore, the US healthcare system struggles to address their needs, leading to poorer health outcomes among these populations. This study aims to uncover the lived experiences of African American and Latinx individuals with CKD using a participatory approach to guide the delivery of optimal health care.

Methods: This study employed the photo elicitation technique with 20 individuals with CKD (African Americans = 15 and Latinx = 5). Each participant shared five photos that symbolized their CKD journeys and subsequently discussed these photos during individual Zoom interviews, either in English or Spanish, based on their preferences. The interviews were transcribed verbatim, cleaned, coded, and subjected to reflexive thematic analysis.

Results: The analysis of both photos and interview transcripts revealed four key themes. Theme 1 explored "*The Burden of CKD: Physical Challenges, Limited Lifestyle, and Emotional Stress*," revealing the profound impact of CKD on patients' physical, social, and emotional well-being throughout their journey. Theme 2, "*Navigating CKD with Positivity and Support*," investigated how participants maintained psychological resilience and received support from their surroundings despite the challenges they faced. Theme 3, "*Systemic Challenges in the Journey*," addressed the systemic barriers encountered by participants, such as financial constraints, communication barriers, systemic racism within the kidney care system, and limited access to care. Lastly, Theme 4, "*Building Bridges in the Kidney Community*," underscored participants' endeavors to combat CKD within their communities through advocacy and outreach efforts.

Conclusions: These findings emphasize the requirement for a healthcare approach that is more inclusive and equitable, addressing the specific needs and obstacles encountered by these populations. This will lead to improved health outcomes for African American and Latinx individuals with CKD.

TH-PO861

Historical and Contemporary Burden of ESKD among Torres Strait Islander People of Australia, 1963-2022

Jaquelyne T. Hughes, Katie Cundale, Shahid Ullah, Karla J. Canuto. *Flinders University College of Medicine and Public Health, Adelaide, SA, Australia.*

Background: Zenadh (Torres Strait Islander) people are the First Peoples of the lands and waterways of the Torres Strait in Australia. Zenadh people have been oppressed by colonisation and systemic racism for many years, experiencing sustained barriers to healthcare and optimal health outcomes. Today, Zenadh people live with inequitable rates of advanced diabetes and kidney disease. To best advocate for health equity change, Tribal Elders sought to describe the patterns, modality, and outcomes of kidney replacement therapy (KRT) among Zenadh people to inform health-improving actions.

Methods: Data was extracted from the Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry that included demographic details (age, sex, location), primary disease, comorbidities, and treatment modality. Adults (≥18 years) who commenced KRT in Australia between 1963 and 2022 were included, and we describe patients with the ethnicity identifier of "Torres Strait Islander". The research and its conduct was approval by Maluilgal Tribal Governance and an Indigenous Health Ethics Committee.

Results: A total of 453 Zenadh adults received KRT during 1963-2022, with an average commencement age of 54 (SD=12.3) years and 55% were female. The most recent decade accounted for 42% (190/453) of KRT initiation, and the majority of patients overall were resident of Queensland (92%, 418/453). Diabetic kidney disease was the primary kidney disease in most patients (75%, 341/453). Forty-seven (10%) transplants occurred since 1978. For Zenadh patients still alive at 31 December 2022, satellite and hospital haemodialysis were the two most common KRT modalities (51% and 26%, respectively), and transplantation was 9%.

Conclusions: This analysis presents, for the first time, data specific to the treatment of kidney failure for Zenadh people who have lived across Australia during 1963-2022. This first look into the historical and contemporary burden of kidney disease establishes baseline health statistics from which health improving actions can be progressed and health systems held accountable for equity and change.

TH-PO862

Improving Transplantation Equity in Australia: The National Indigenous Kidney Transplantation Taskforce

Jaquelyne T. Hughes,[1,2] Katie Cundale,[3,4] Stephen P. McDonald.[3,5] *[1]Flinders University College of Medicine and Public Health, Adelaide, SA, Australia; [2]Royal Darwin Hospital Division of Medicine, Darwin, NT, Australia; [3]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [4]South Australian Health and Medical Research Institute Limited, Adelaide, SA, Australia; [5]The University of Adelaide Adelaide Medical School, Adelaide, SA, Australia.*

Background: In Australia, Aboriginal and Torres Strait Islander people experience inequitably high rates of kidney failure yet significantly lower rates of transplantation. The Australian Government recognised this disparity and funded the establishment of the National Indigenous Kidney Transplantation Taskforce (NIKTT). The NIKTT is the

first of its kind: in Australia, and other colonised countries, little coordinated effort has been made from government-led initiatives to truly change transplantation access and outcomes for Indigenous peoples.

Methods: The NIKTT was created to drive the development and implementation of initiatives that targeted gaps in access to care for Aboriginal and Torres Strait Islander kidney patients, facilitating improved transplant waitlisting. The NIKTT did this by: (1) implementing enhanced clinical data collection on waitlisting; (2) trialling a range of locally developed and led service models; and (3) evaluating cultural bias initiatives in Australia. To best inform Taskforce action, the NIKTT created a national network of Aboriginal and Torres Strait Islander consumers and established Indigenous Reference Groups at transplant units around the country.

Results: Over three years, the NIKTT found that: (1) While there was an increase in the number of Aboriginal and Torres Strait Islander people activated on the waitlist, waitlisting and transplantation remain inequitable in Australia. Data suggests that late initiation of work up, along with clinician-perceived barriers such as obesity and non-adherence, could contribute to this disparity; (2) Models of care that work best to increase the rate of placement on the waitlist include outreach assessment clinics, patient navigator programs, Indigenous Reference Groups, and context-specific educational resources; and (3) Increasing the Aboriginal and Torres Strait Islander renal workforce, tailoring models of care to local contexts, and improving institutional safety through policies and funding could meaningfully improve the safety of services.

Conclusions: The development of a national Taskforce was critical to provide a focal point to drive real change in Australia. Targeted clinical, policy, and consumer activity within the NIKTT has confirmed increased waitlisting, but further time and funding is needed to appreciate the impact on transplantation and outcomes.

TH-PO863

Responses from Arabic-Speaking Caregivers of Youth with Chronic Conditions to the Health Care Transition Readiness Starx Questionnaire

Peter Said, Yara Abumohsen, Maria E. Ferris. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Successful healthcare transition (HCT) is vital for youths with chronic conditions shifting from pediatric to adult care. A USA cohort revealed a preference among youths for health information from caregivers. Assessments of HCT readiness using the STARx Questionnaire inform customized interventions. However, there is a lack of studies on Arabic-speaking dyads. Our hypothesis explores potential differences in HCT readiness scores among youth with chronic conditions.

Methods: The STARx Questionnaire underwent translation/back-translation into Arabic. Ethics approval was obtained from the University of North Carolina at Chapel Hill and Zagazig University, Egypt. We enrolled youths with chronic conditions and their caregivers.

Results: We included 107 youth/caregiver dyads, with 60% male youths, averaging 13.3±1.2 years. Diagnoses comprised 24% Kidney disease, 33% thalassemia, and 43% diabetes mellitus. The median medication count was 2 (range 0-4). Total Caregiver STARx scores positively correlated significantly with youth's age (Pearson r=0.31, Figure 1). While total STARx scores significantly correlated between caregivers and youths (Pearson r=0.18, Figure 1), caregivers scored substantially lower (51±5) than youths (54±5, p=1.35E-07, paired t-test). Lower caregiver scores were observed in disease knowledge and self-management domains, with caregivers outperforming youths in provider communication (Table 1).

Conclusions: Arabic-speaking caregivers scored lower in HCT readiness (total, disease knowledge, and self-management), while youths scored lower in healthcare communication. Ambiguity exists whether youths overestimate their skills in disease knowledge and self-management. Further investigation of the caregiver-youth gap in provider communication is needed to enhance youths' skills and perceptions.

Table 1: Total and 3 sub-domain STARx Questionnaire scores of youths and caregivers and paired t-test

	Youth		Caregiver		p-value
Parameter	Average	St. Dev	Average	St. Dev	
Total (90 points)	54	5	51	4	<0.0001
Disease knowledge (20 points)	15	1	10	2	<0.0001
Self-management (25 points)	15	2	13	2	<0.0001
Provider communication (20 points)	12	2	15	2	<0.0001

TH-PO864

Equity in Kidney Transplant Allocation: Graft Survival Outcomes for Blood Group B Recipients from A2/A2B- and ABO-Compatible Donors

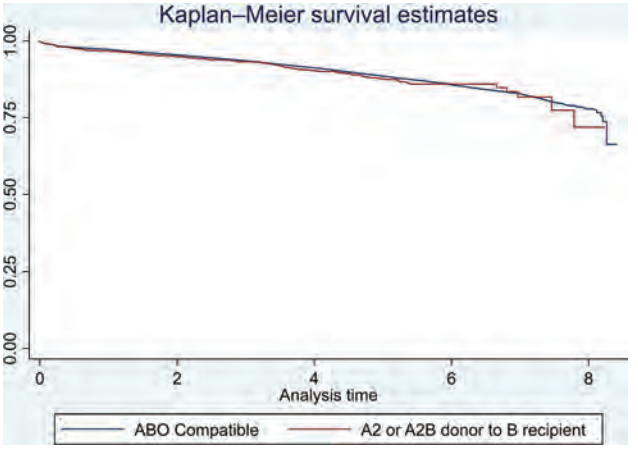
Hatem Ali,[1] Ahmed Daoud,[2,3] Tibor Fulop.[2] *[1]University Hospitals North Midlands, Stoke on Trent, United Kingdom; [2]Medical University of South Carolina, Charleston, SC; [3]Cairo University Medical School, Cairo, Egypt.*

Background: Disparities in kidney transplant allocations affect blood group B candidates, who are predominantly from minority groups. Prior studies have indicated successful outcomes from transplanting kidneys from donors with non-A1/non-A1B (A2/A2B) subtypes to blood group B recipients.

Methods: This retrospective cohort study utilized the United Network for Organ Sharing (UNOS) database, covering the period from January 1, 2015, to June 1, 2022, with follow-up data until June 1, 2023. The study included 110,826 adult deceased kidney donor transplant recipients, of which 109,353 (98.24%) received ABO-compatible transplants. We compared graft survival between blood group B recipients receiving kidneys from A2B or B group donors (incompatible group) and those receiving ABO-compatible kidneys. Covariates such as donor age, sex, ethnicity, BMI, hypertension, diabetes, transplant factors (PRA, HLA mismatch, cold ischemia time), and recipient factors (age, sex, ethnicity, cause of renal failure, BMI, dialysis prior to transplant, number of previous transplants) were adjusted for in the analysis.

Results: Our findings show no significant difference in graft survival between the ABO-compatible and incompatible groups, with a hazard ratio of 1.08 (95% CI: 0.91-1.27; p=0.345). This suggests equivalent outcomes in both groups, supporting the viability of expanding donor eligibility criteria to include A2/A2B donors for blood group B recipients.

Conclusions: The study supports the ongoing efforts to improve equity in kidney transplant allocations through broader use of A2/A2B donors for blood group B recipients, particularly benefiting minority populations. This could potentially mitigate disparities in transplant access and outcomes for this group, aligning with changes implemented in the kidney allocation system (KAS). Further research is needed to explore the long-term impacts of these policy changes on transplant equity.



TH-PO865

Tears of the Nile: Unraveling the Tragedy of Kidney Transplant Recipients in Sudan during Wartime

Lina Alatta,[1,2] Amira Mohamed,[2,3] Anmar Homeida.[2,4] *[1]New York Presbyterian Queens, Flushing, NY; [2]Sudanese American Physicians Association (SAPA), Plano, TX; [3]Montefiore Medical Center, New York, NY; [4]New York University, School of Global Public Health, New York, NY.*

Background: In 1974, Sudan achieved its first renal transplantation, but progress stalled for twenty-five years. However, in 2000, a transformative initiative led by Sudanese expatriate surgeons and local nephrologists, with support from visiting teams from England, revitalized kidney transplantation in Sudan. Currently, Sudan has four functioning transplant centers, including a specialized pediatric unit in Khartoum. Despite challenges like political instability and healthcare underinvestment, studies are shedding light on obstacles faced by transplant patients, such as financial constraints and limited post-transplant care Following the onset of the conflict in Sudan on April 15, 2023, the healthcare system experienced considerable strain and depletion of already limited resources. Prior to the outbreak of war in Sudan, the estimated population of living transplant recipients stood at approximately 4500. Kidney transplant recipients rely on immunosuppressive medication to sustain graft viability. However, interruptions in medication availability and follow-up care markedly increase vulnerability to infections and the risk of transplant rejection

Methods: Data were collected from published research, social media, and medical personnels

Results: Kidney transplant recipients faced a disruption in access to immunosuppressive medications, as the primary pharmacy serving these patients was in Ahmed Gassim Hospital. There is a lack of clear data regarding the incidence of infections or transplant rejection cases, as well as the number of patients requiring hospitalization or dialysis.

Conclusions: The findings highlight the severe impact of wartime conditions on kidney transplant recipients in Sudan, emphasizing disruptions in accessing vital medications and follow-up care. To assist kidney transplant patients in conflict zones like Sudan, the international community should prioritize strengthening health infrastructure, providing training programs for healthcare professionals, and establishing financial aid mechanisms. Additionally, promoting robust organ donation initiatives, fostering research and data collection, building collaborative networks, and utilizing telemedicine for remote support are essential steps. These efforts aim to improve the resilience and sustainability of kidney transplant programs, ultimately enhancing patient outcomes and quality of life.

TH-PO866

Barriers to Familial Consent in Deceased Organ Donation among Racialized and Indigenous Communities in Canada: A Qualitative Study

Simran Sandhu,[1] Jagbir Gill,[1,3] Reetinder Kaur.[2] *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]Providence Research, Vancouver, BC, Canada; [3]Division of Nephrology, The University of British Columbia, Vancouver, BC, Canada.*

Background: In Canada, over 3700 people are on the organ transplant list, with deceased donor kidney transplants making the majority of transplants completed annually. Despite the increasing numbers of transplants, populations marginalized by race and ethnicity have lower rates of organ donation registration and are less likely to consent to donation. Gaining insight into barriers to providing consent is critical in developing strategies to address disparities. This study aimed to identify barriers to familial consent among members of racialized and Indigenous communities.

Methods: 48 participants were recruited through community-based organizations in British Columbia (BC) and included BC residents, aged over 19, who spoke English. 31 participants completed interviews and 17 completed focus groups. Participants were oversampled for members of racialized and Indigenous communities. A case vignette was used to collect data with data analyzed using summative content analysis.

Results: Four overarching barriers were identified: 1) system-level; 2) community-based; 3) related to decision-making; and 4) informational. System-level barriers highlighted mistrust of Canadian healthcare institutions, perceived coercion, and the role of language in consent. Community-based barriers involved ideas around the deceased body, funeral, afterlife, and general perceptions of organ donation. Decision-making was affected by family dynamics and donor and recipient identity. Informational barriers such as age eligibility also influenced consent. Facilitators to address barriers include culturally diverse resources, increasing community knowledge, and providing language, cultural, and religious support to build trust and facilitate discussions.

Conclusions: This study highlights barriers and modifiable determinants to familial consent in deceased organ donation among members of racialized and Indigenous communities. Although it examines barriers to familial consent for all organ donation, findings are of significant relevance to kidney care, as patients waiting for kidney transplants constitute the majority of patients on transplant waitlists. Education and engagement initiatives must be targeted at the health system and community levels to fully address barriers to consent and reduce racial and ethnic disparities in organ transplantation.

TH-PO867

Kidney Transplantation and Health Equity in ESKD Survival

Paul T. Williams. *E O Lawrence Berkeley National Laboratory, Berkeley, CA.*

Background: Recently, the OPTN mandated race-neutral equations to estimate kidney function, and to retroactively apply the results to credit Blacks for the wait time that would have been accrued. This will likely decrease the proportion of White ESRD patients receiving deceased donor kidneys. Because the risks for mortality and ineligibility due to deteriorating health are greater in Whites than non-Whites, the OPTN policy changes could increase racial health disparities in ESRD survival.

Methods: Age- and sex-adjusted 2-year, 5-year, and 10-year survival rates from the 2021 United States Renal Data System ESRD cohort were used to estimate the effects of deceased donor kidney re-assignment on racial health equity in ESRD patients. Overall survival calculated as the weighted average of 2-year survival for dialysis, deceased donor, and live-donor transplant patients.

Results: Two-year survival was substantially lower in White than Black ESRD patients as originally allocated (70.6% vs. 77.1%). Each 10% in deceased donor kidneys diverted from non-Black to Black recipients increased Black survival by 0.518% whilst decreasing White survival by 0.194%, further increasing Black-White health inequity. Conversely, re-allocating most of the 8853 deceased donor transplants originally allocated to non-White to White dialysis patients would theoretically eliminate White-Black inequity in 2-year survival (73.4% vs. 74.8%). Although this would decrease 2-year survival in non-Whites, all would continue to survive better than Whites.

Conclusions: Increasing deceased donor kidney transplants to Blacks from non-Blacks is projected to increase Black-White survival disparities, contrary to the pursuit of health equity. Alternatively, deceased donor kidneys could be assigned by treating patients equally regardless of race, as has been the American ideal.

TH-PO868

Medical Mistrust Predicts Lower Likelihood of Wait-Listing in Kidney Transplant Candidates

Miriam E. Velez-Bermudez,[1] Yuridia Leyva,[1] Chethan M. Puttarajappa,[3] Arjun L. Kalaria,[3] Yiliang Zhu,[1] Yue-Harn Ng,[2] Amit D. Tevar,[3] Mary Amanda Dew,[3] Larissa Myaskovsky.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]University of Washington School of Medicine, Seattle, WA; [3]UPMC, Pittsburgh, PA.*

Background: The kidney transplant fast track (KTFT) program was implemented within a large, single-center urban transplant center to reduce patient burden and streamline the kidney transplant (KT) evaluation process. KTFT aimed to improve the KT evaluation process for all patients, regardless of socioeconomic resources, and reduce the waitlisting disparity between White and Black patients. In this prospective cohort study of patients who underwent KTFT, we examined whether sociocultural factors (e.g., medical mistrust; discrimination & racism in healthcare; trust in physician) predicted the likelihood of KT waitlisting.

Methods: Patients who were referred to KT evaluation were recruited into KTFT starting in 2015. Baseline characteristics were collected during a pre-KT evaluation interview. Participants' medical records were reviewed through 08/2022 for waitlist status. We used Fine-Gray proportional hazards models to examine how sociocultural factors uniquely predicted likelihood of waitlisting, controlling for demographics and clinical factors.

Results: The final sample of KTFT patients included 1107 participants (782 Non-Hispanic White, 243 Non-Hispanic Black, 82 Other). We found that medical mistrust (subdistribution hazard ratio [SHR] = 0.79, 95% CI: 0.70, 0.90) and Black race (SHR = 0.70, 95% CI: 0.55, 0.90) lowered likelihood of waitlisting. After controlling for demographic and clinical factors, the effect of Black race on waitlisting went away, but the influence of medical mistrust on waitlisting was maintained (SHR = 0.86, 95% CI: 0.75, 0.99).

Conclusions: In a cohort of patients who underwent a clinic-level intervention that streamlined the KT evaluation process, we found that medical mistrust, not race, was associated with reduced likelihood of KT waitlisting. These findings suggest that working to reduce KT disparities may involve targeting sociocultural factors that explain race differences, rather than targeting race itself. Such interventions may need to involve targeting multiple levels within the healthcare system (e.g., clinic-level and provider-level intervention) instead of exclusively focusing on a single level.

TH-PO869

Racial Disparities in Inpatient Outcomes for Patients with Renal Cell Carcinoma

Iskandar Berbari, Fayaz A. Khan, M Kenan Rahima, Madelyn Durhman. *TriHealth Inc, Cincinnati, OH.*

Background: Healthcare disparities persist, reflecting variations in health outcomes, access, and quality among racial groups. Understanding these disparities is essential for improving healthcare equity.

Methods: We queried the National Inpatient Sample 2017-2020 for adult patients of different races hospitalized with Renal cell carcinoma (RCC) using ICD-10 codes. The primary outcome was inpatient mortality. The secondary outcomes were intubation, length of stay (LOS), and hospital cost. Multivariable logistic, linear, and Poisson regression analyses were used to estimate clinical outcomes with a p-value < 0.05 was significant.

Results: Total 361060 RCC hospitalizations, mean age 65.6 years, 64.7% male. Caucasians were the largest group, followed by Blacks. Blacks had the highest rates of AKI, CKD, dialysis indicating more severe renal impairment. Clinical characteristics are listed in Figure 1. Blacks have the highest rates of intubation, LOS, and inpatient mortality. Hispanics incurred the highest total costs. Clinical outcomes are shown in Figure 2.

Conclusions: Data suggest significant racial disparities in inpatient admissions and outcomes of RCC. A lower rate of hospitalization among Blacks, despite higher incidence may be due to decrease access to healthcare, poor awareness, socioeconomic factors, reporting biases. Targeted interventions are needed to address these disparities, including improved access to healthcare, better management of comorbid conditions, and aggressive follow-up care, particularly for high-risk groups like Blacks.

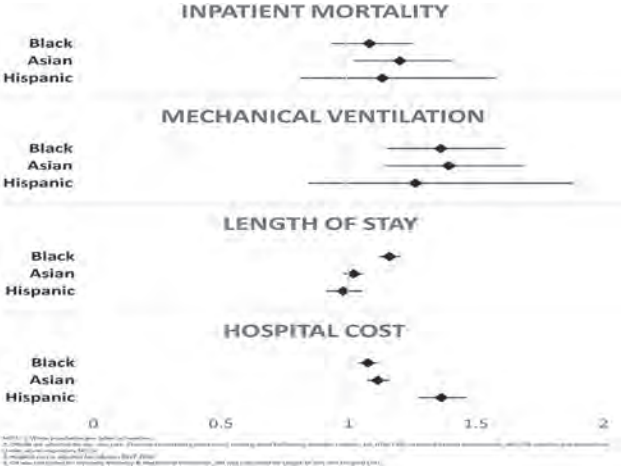

Figure 2

TH-PO870

Racial Disparities in Adverse Cardiovascular and Cerebrovascular Events among Patients with Renal Cell Carcinoma

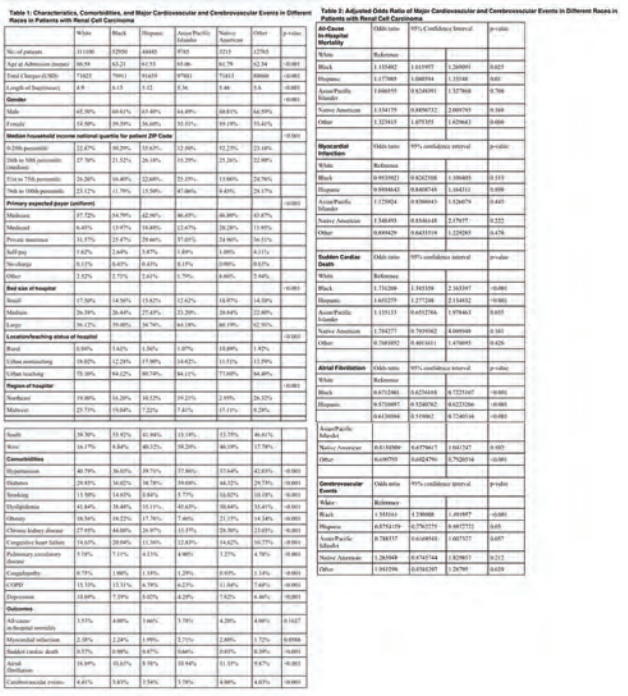
Sobia Mansoor,[1] Kanishka Uttam Chandani,[1] Siddharth P. Agrawal,[1] Sahil Bhargava,[2] Maharshi Raval,[1] Sajid Siddiq,[1] Ahmed Nadeem,[1] Michael J. Monsour.[1] *[1]Landmark Medical Center, Woonsocket, RI; [2]Smt NHL Municipal Medical College, Ahmedabad, India.*

Background: Renal cell carcinoma (RCC) is the most prevalent urogenital malignancy and the 13th leading cause of cancer-related mortality. Treatment advances, including ICIs, have improved overall survival (OS). We aim to study racial disparities in major cardiovascular and cerebrovascular events (MACCE) among RCC patients.

Methods: ICD-10 codes were used to identify RCC patients from the NIS 2016–2020 database. MACCE included all-cause in-hospital mortality (ACIHM), acute myocardial infarction (AMI), atrial fibrillation (AF), cerebral events, and sudden cardiac death (SCD). Baseline characteristics and MACCE were compared using chi-square for categorical or ANOVA for continuous data (statistical significance determined p-value<0.05), with results stratified by patient's race.

Results: 434,260 patients were identified: 71.65% (311,100) White, 12.19% (52,950) Black, 10.23% (44,445) Hispanic, 2.25% (9,785) Asian/Pacific Islander, 0.74% (3,215) Native American, and 2.93% (12,765) were of other races. When compared to White patients, ACIHM and SCD were significantly higher in Black patients with an adjusted odds ratio (aOR) of 1.13 (95% CI 1.01-1.26, p=0.025) and Hispanics (aOR of 1.17, 95% CI 1.04-1.33, p=0.01). Cerebral events were higher in Black patients (aOR of 1.35, 95%CI 1.23-1.49, p<0.001) and lower in Hispanics (aOR 0.87, 95%CI 0.77-0.98, p=0.03). Most racial groups were noted to have lower aORs of AF as compared to white patients.

Conclusions: The study noted that cerebral events were higher in black patients, and ACIHM and SCD were considerably higher in black and Hispanic patients. The findings underscore the need for equitable access to healthcare and further research regarding the epigenomic factors involved.



TH-PO871

Demographics and Trends of Uropathy-Associated Mortality in the United States, 1999-2020

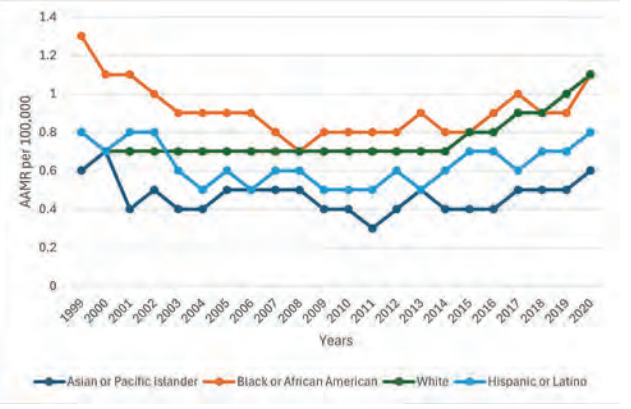
Badar U Din Shah,[1] Muhammad Talha Shaukat,[2] Wania Rehman,[2] Malik S. Hayat,[2] Muhammad Imaz Bhatti,[2] Aleenah Mohsin,[3] Aqeeb Ur Rehman.[4]
[1]Geisinger Medical Center, Danville, PA; [2]King Edward Medical University, Lahore, Pakistan; [3]Brown University, Providence, RI; [4]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL.

Background: Uropathy/ obstructive uropathy is a progressively growing cause of mortality and morbidity in the United States. In this study, we aimed to analyze trends of uropathy-related mortality in the US from 1999-2020. Understanding the epidemiology and trends would help guide in better management and consequently improve outcomes.

Methods: Data was extracted from the Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiological Research (CDC WONDER) database from 1999-2020. Age-adjusted mortality rate (AAMR) per 100,000 individuals and annual percent changes (APC) with 95% Confidence Intervals (CI) were calculated using Joinpoint regression analysis. Data were also stratified to account for gender, race, locale and patient population.

Results: A total of 56,521 uropathy-related deaths were identified from 1999-2020. There was an overall decline in the AAMR from 1990 to 2011 followed by a gradual rise from 2011 to 2020 with an APC of -1.7457 and 5.6503 respectively. The analysis revealed significant disparities in mortality rates among different demographic groups. The mortality rates were found to be higher in male patients (AAPC:0.08% (95% CI -0.63 to 0.79)) and white/non-Hispanic patients (AAPC:1.5% (95 % CI 0.84 to 2.26)). There was no statistically significant difference between the mortality rates of metropolitan (AAPC:1.24% (95% CI 0.5845 to 1.8938) and non-metropolitan areas (AAPC: 1.29% (95% CI 0.33 to 2.45)). A higher proportion of uropathy-related mortality occurred in the Southern regions of the country and most deaths occurred among the in-patient population.

Conclusions: Though there has been an overall decline in mortality associated with uropathy from 1999-2011, a progressively rising trend from 2011 highlights the need for targeted research and interventions to address demographic disparities and regional healthcare inequities.



Uropathy associated mortality trends across different races

TH-PO872

Association of Intravenous vs. Oral Iron Therapy with Risk of Infectious Outcomes in Patients with CKD

Prabin Shrestha,[1] Keiichi Sumida,[1] Fridtjof Thomas,[1] Satya Surbhi,[1] Abu Mohd Naser,[2] Elani Streja,[3] Connie Rhee,[3] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,4] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]The University of Memphis, Memphis, TN; [3]University of California Irvine, Irvine, CA; [4]VA Memphis Healthcare System, Memphis, TN.*

Background: Iron replacement therapy (IRT) is a core component of anemia management in chronic kidney disease (CKD), but its long-term safety remains unclear. Intravenous (IV) IRT has been linked to increased risk of bacterial infections, but the evidence is inconclusive. We investigated the association of IV vs oral IRT with infectious hospitalization and infectious mortality.

Methods: In a national cohort of US Veterans, we identified 18,307 incident new users of IRT with eGFR <60 mL/min/1.73m^2 at baseline (N=17,428 on oral and 879 on IV iron). We used propensity score overlap weighting to account for differences in baseline characteristics associated with the use of IV vs oral iron. We examined the association of IV vs oral IRT with the incidence of the composite outcome of infectious hospitalization or infectious mortality in competing risk regression models, with non-infectious mortality as the competing event.

Results: The overall mean (SD) age was 73±10 years, 97% were male, 75% were white, and the baseline eGFR, hemoglobin and ferritin levels were 43±13 ml/min/1.73m^2, 10.6±1.8 gm/dL and 78 mcg/l (25th-75th pctl: 26-212), respectively. There were 4,580 cases of the composite infectious outcome (event rate **98.41**/1000PY; 95% CI **95.56-101.27**) over a median follow up of **2.12** years. IV IRT (vs oral IRT) was associated with higher crude risk of infection (Figure 1), but the association became statistically non-significant after PS weighting (subhazard ratio, 1.09; 95% CI 0.90-1.32; p-value 0.4) (Figure 1).

Conclusions: In this comparative effectiveness study, IV IRT was associated with similar risk of infectious outcomes as oral IRT.

Funding: Veterans Affairs Support

Composite outcome of infectious hospitalization or infectious mortality

Iron Therapy		PS overlap Weighting	
	Event rate per 1000PY (95% CI)	SHR (95% CI)	P-value
IV (N=879)	152.39 (133.39, 171.40)	1.09 (0.90, 1.32)	0.4

IHOPE: A Randomized, Open-Label, Positive-Controlled, Multicenter Study to Evaluate the Efficacy and Safety of Oral Iron Polysaccharide Complex in Patients on Hemodialysis

Renhua Lu,[1] Haijiao Jin,[1] Juan Cao,[2] Hua Li,[3] Xiaoxia Wang,[4] Yinghui Qi,[5] Qiu Li,[6] Xudong Cai,[7] Bin Song,[8] Na Li,[9] Lianglan Shen,[10] Lili Wang,[11] Xiaoping Wang,[12] Zhaohui Ni.[1] *[1]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [2]Taixing People's Hospital, Taixing, China; [3]Shaw Hospital Affiliated to Zhejiang University School of Medicine, Hangzhou, China; [4]Tongren Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [5]Shanghai Punan Hospital of Pudong NEW District, Shanghai, China; [6]The First People's Hospital of Shuangliu District, Chengdu, Chengdu, China; [7]Ningbo Traditional Chinese Medicine Hospital, Ningbo, China; [8]Deyang People's Hospital, Deyang, China; [9]Jinan Zhangqiu District People's Hospital, Jinan, China; [10]Nantong First People's Hospital, Nantong, China; [11]Shandong Province Qianfoshan Hospital, Jinan, China; [12]Central Hospital Affiliated to Shandong First Medical University, Jinan, China.*

Background: The IHOPE study (ChiCTR 2000031166) evaluated the efficacy and safety of iron polysaccharide complex (a novel oral trivalent iron preparation) in individuals receiving hemodialysis (HD) in China.

Methods: IHOPE was a randomized, open-label, positive-controlled, non-inferiority, multicenter study conducted at 12 sites across China. Participants aged 18-75 years who were receiving HD ≥3 months with hemoglobin (Hb) levels ≥100–<130g/L, transferrin saturation (TSAT) ≥20–≤50% or serum ferritin (SF) ≥100–≤500 μg/L, and who had received recombinant human erythropoietin or iron therapy within 12 weeks prior to enrollment, were recruited. Following a 4-week screening period, patients were randomized 1:1 to the experimental group (iron polysaccharide complex 150 mg twice daily orally) or a control group (iron sucrose injection 100 mg 2-weekly IV) for 24 weeks. The primary outcome was the TSAT at 12 weeks of treatment. Secondary outcomes included the TSAT and Hb after 24 weeks of treatment. Safety outcomes included recorded adverse events (AEs) and severe adverse events (SAEs). Non-inferiority for TSAT was assessed using confidence interval methods, with a non-inferiority margin of 7%.

Results: 193 adults of mean (SD) age 55.3 (11.66) years were randomized to the experimental group (n = 96) or control group (n = 97); 62.2% were male. At 12 weeks, TSAT in the expertimental group was 32.3% (95% CI 29.39–35.19%) demonstrating non-inferiority to the control group – in whom TSAT was 33.4% (95% CI 30.95–35.77%). At 24 weeks, TSAT values were 29.4% (95% CI 26.71–32.18%) in the experimental group and 32.6% (95% CI 29.68–35.45%) in the control group, again showing non-inferiority. Hb levels at 24 weeks were also comparable between the experimental and control groups (114.6 ± 11.81 g/L vs 117.4 ± 13.89 g/L; *P* = 0.166). AEs and SAEs were reported in 56.3% and 15.6% of patients, respectively in the experimental arm, and 47.4% and 13.4%, respectively in the control arm, with no new safety concerns identified.

Conclusions: Orally administered iron polysaccharide complex is an effective, well-tolerated treatment, demonstrating non-inferiority to intravenous iron sucrose in managing anemia among Chinese individuals receiving HD.

TH-PO874

Overexpression of the Iron Regulatory Hormone Erythroferrone Mitigates Anemia and Enhances Kidney Function in a Mouse Model of CKD

Brian Czaya, Elizabeta Nemeth, Tomas Ganz. *Center for Iron Disorders, David Geffin School of Medicine, University of California Los Angeles, Los Angeles, CA.*

Background: Most CKD patients develop anemia because of combined effects of relative erythropoietin deficiency, iron restriction caused by increased levels of the iron-regulatory hormone hepcidin, as well as absolute iron deficiency. Erythropoietin-stimulating agents (ESAs) and iron supplementation mitigate anemia in CKD, but patients often become hyporesponsive to the treatment, requiring higher doses of these drugs. Increasing ESA doses may heighten risks of thrombosis and cardiovascular mortality, highlighting the need for alternative strategies. Erythroferrone (ERFE) is a hormone produced by erythroblasts in response to EPO, and functions as a physiological suppressor of hepcidin to facilitate iron mobilization for erythropoiesis. In CKD, diminished marrow erythroblasts and inadequate EPO concentrations contribute to decreased ERFE production, likely further increasing hepcidin. Exploring the potential therapeutic use of ERFE in CKD, we tested the impact of augmented ERFE on systemic iron homeostasis, hypoxia, inflammation, and kidney function.

Methods: Transgenic mice with erythroid overexpression of ERFE (ERFE-Tg) have similar iron stores to wild-type littermates (WT) at weaning but become iron-overloaded as they age. To prevent early iron overload prior to CKD, we placed ERFE-Tg at weaning on low iron (4 ppm) diet for 4 weeks. WT mice were fed iron-replete diet. At 8 weeks of age, male ERFE-Tg and WT were then fed identical 0.2% adenine-rich diet containing 100 ppm iron for 8 weeks to induce CKD.

Results: At 16 weeks, both WT and ERFE-Tg developed CKD and anemia, but ERFE-Tg had higher hemoglobin, MCV and serum iron, as well as a lower ratio of serum hepcidin to liver iron content, indicating effective suppression of hepcidin by ERFE even in the setting of CKD. Systemic hypoxia as reflected by serum VEGF levels was also reduced in ERFE-Tg, indicating improved tissue oxygenation. Furthermore, although systemic and kidney inflammation (TNFa, IL1b, IL6) were similar between WT and ERFE-Tg, kidney function (BUN and serum creatinine) was less impaired in ERFE-Tg.

Conclusions: Our study demonstrates that despite chronic inflammation, ERFE overexpression in adenine-induced nephropathy improves CKD-associated anemia, hypoxia and kidney function. These data indicate that therapeutic augmentation of ERFE could provide multiple benefits in CKD.

TH-PO875

Effects of Interleukin-6 Inhibition with Clazakizumab on Anemia and Iron Parameters in Patients with Kidney Failure

Brendon L. Neuen,[1] Myles Wolf,[2] Benjamin P. Catanese,[2] Mark A. Heise,[4] Pierluigi Tricoci,[4] Anna Marie Chang,[4] Glenn M. Chertow.[3] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]Duke University School of Medicine, Durham, NC; [3]Stanford University School of Medicine, Stanford, CA; [4]CSL Behring LLC, King of Prussia, PA.*

Background: Inflammation contributes to anemia and erythropoietin stimulating agent resistance in patients with kidney failure. Clazakizumab is a high affinity humanized monoclonal antibody that targets the interleukin-6 (IL-6) ligand and inhibits downstream IL-6 function. We recently reported an approximate 90% reduction in high-sensitivity C-reactive protein (hs-CRP) in patients receiving dialysis with a history of cardiovascular disease and/or diabetes. We sought to evaluate the effect of clazakizumab on anemia and iron parameters.

Methods: The Phase 2b component of the POSIBIL$_6$ESKD Phase 2b/3 trial evaluated the effect of clazakizumab (2.5mg, 5mg, 10mg) or placebo administered every 4 weeks. The primary efficacy endpoint was the placebo-adjusted change in hs-CRP at 12 weeks. We prespecified as secondary endpoints the effects of clazakizumab on hemoglobin (Hb), iron parameters, and hepcidin, using mixed effects models for repeated measures.

Results: Among 127 participants, overall mean ± SD Hb and TSAT, median (25%, 75% range) ferritin and hepcidin were 10.7 ± 1.4 g/dL, 31 ± 11.7%, 1267 (735, 1598) μg/L and 232 (150, 306) ng/mL, respectively. The mean increase in Hb was 0.6 ± 1.5, 1.0 ± 1.3, 1.0 ± 1.4 g/dL at 12 weeks relative to baseline in the 2.5, 5, and 10 mg clazakizumab groups, respectively, compared with 0.4 ± 1.3 g/dL with placebo. These differences were not statistically significant. Clazakizumab significantly increased transferrin saturation and reduced hepcidin across all studied doses versus placebo, and had no clear effect on ferritin (**Figure**).

Conclusions: Through anti-IL6 effects, clazakizumab may improve iron utilization and contribute to anemia correction in patients receiving dialysis. Larger and longer-term data from the ongoing Phase 3 study will provide additional insights.

TH-PO876

Impact of Changes in Hemoglobin on Health-Related Quality of Life in Dialysis Patients

Thomas S. van Lieshout,[1,2] Esmee Driehuis,[1,3] Osman Mahic,[3,4] Brigit C. van Jaarsveld,[1] Alferso C. Abrahams.[3] DOMESTICO Study Group.
[1]Amsterdam UMC Locatie VUmc, Amsterdam, Netherlands; [2]Noordwest Ziekenhuisgroep, Alkmaar, Netherlands; [3]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [4]Julius Centrum voor Gezondheidswetenschappen en Eerstelijns Geneeskunde, Utrecht, Netherlands.

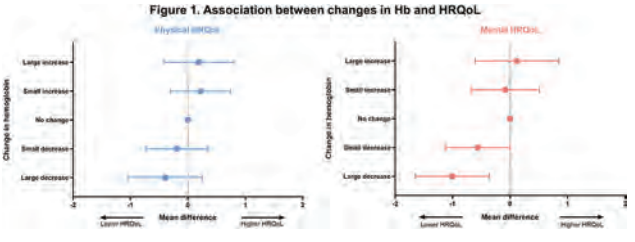
Background: Anemia is a common complication among dialysis patients and has a negative impact on health-related quality of life (HRQoL). Higher levels of hemoglobin (Hb) are associated with better HRQoL but also with an increased risk of adverse events like stroke. The optimal target level for Hb remains subject of debate and an individual approach is proposed. To develop this, changes in Hb are of additional importance. However, the impact of changes in Hb levels on HRQoL are unclear. Therefore, we investigate the impact of changes in Hb on HRQoL during the first 24 months of dialysis.

Methods: Dialysis patients (n=1718), included in the prospective Dutch nOcturnal and hoME dialysis Study To Improve Clinical Outcomes (DOMESTICO), were studied. Change in Hb was categorized into no change (-0.5; 0.5 g/dL), small increase (0.5; 2.0 g/dL), large increase (> 2.0 g/dL), small decrease (-2.0; -0.5 g/dL), and large decrease (<-2.0 g/dL). HRQoL was measured with the 12-item Short Form Health Survey (SF-12), containing two summary scores, reflecting physical and mental HRQoL. Data were analyzed using linear mixed models and generalized linear models, both adjusted for confounders.

Results: Mean age at initiation was 63.8 years (SD 14.5) and 75.3% of the patients started with hemodialysis. The mean Hb level during the first 24 months of dialysis was 10.8 g/dL (SD 1.6). Patients with an increase or decrease in Hb showed no difference in physical HRQoL compared to patients with stable Hb over time (Figure 1). A large decrease in Hb was associated with lower mental HRQoL over time, with a mean difference of -1.01 (95% CI -1.65;-0.36). An increase of Hb did not impact mental HRQoL (Figure 1).

Conclusions: This study shows that a decrease in Hb has a negative impact on mental HRQoL compared to no change in Hb. Hb changes were not associated with physical HRQoL. These findings indicate that physicians should not focus on increasing Hb levels but rather on preventing a decrease when it comes to HRQoL. Such an approach could help in adjusting present guidelines with the goal to induce less adverse events and improve cost-effectiveness.

Figure 1. Association between changes in Hb and HRQoL



TH-PO877

Associations of Anemia and Iron Parameters with Fatigue in Persons with and without Kidney Diseases

Lucile Parker Gregg,[1,2] Christine Vu,[3] Aaron R. Perkins,[3] Hui Yang,[3] Sankar D. Navaneethan,[1,4] Carlos A. Alvarez.[3] *[1]Baylor College of Medicine, Houston, TX; [2]VA Center for Innovations in Quality Effectiveness and Safety, Houston, TX; [3]Texas Tech University Health Sciences Center, Dallas, TX; [4]Michael E DeBakey VA Medical Center, Houston, TX.*

Background: Low estimated glomerular filtration rate (eGFR) is associated with anemia and absolute and functional iron deficiency. Hemoglobin and biomarkers of iron stores are associated with fatigue, but it is unclear if an eGFR <60 mL/min/1.73 m^2 modifies these relationships.

Methods: Using data from the National Institutes of Health All of Us cohort, we identified individuals who answered the self-reported fatigue item over the last 7 days at cohort enrollment, with fatigue defined as any fatigue (*i.e.*, mild, moderate, severe, or very severe) *vs.* none. We limited the sample to individuals who had a hemoglobin, ferritin, and/or transferrin saturation (TSAT) level within 1 year of cohort enrollment. Ferritin <30 ng/mL (consistent with KDIGO guidelines) or TSAT <20% identified patients with likely absolute iron deficiency. Multivariable logistic regression evaluated the associations of hemoglobin, ferritin, and TSAT levels with fatigue, adjusting for age, sex, race, and ethnicity, with multiplicative interaction terms to assess if an eGFR <60 mL/min/1.73 m^2 modified these associations.

Results: Of 19,310 individuals included in the cohort, fatigue was present in 16,587 (86%). Compared to those without fatigue, patients with fatigue had lower median (IQR) hemoglobin, 10.5 (8.8, 12.2) *vs.* 10.7 (8.8, 12.6) g/dL, *P*<.0001, and lower TSAT, 21 (13, 30) *vs.* 23 (15, 32), *P*<.0001 (**Figure A**). Those with fatigue were also more likely to have hemoglobin <10 g/dL (40% *vs.* 31%, *P*<.0001), ferritin <30 ng/mL (32% *vs.* 29%, *P*=.003), and TSAT <20% (56% *vs.* 48%, *P*<.0001). Fatigue was present in 7,164 (85%) of those with an eGFR ≥60 and 5,243 (86%) with an eGFR <60 mL/min/1.73 m^2. Hemoglobin <10 g/dL was associated with higher odds of fatigue in those with an eGFR <60 but not in those with an eGFR ≥60 mL/min/1.73 m^2, interaction *P*<.0001 (**Figure B**).

Conclusions: Hemoglobin <10 g/dL was associated with fatigue in those with an eGFR<60 but not ≥60 mL/min/1.73 m^2, possibly related to differences in the physiology of oxygen delivery and utilization in kidney disease. The presence of kidney disease limits the use of ferritin and TSAT levels to identify iron deficiency and may affect these associations.

TH-PO878

Exploring the Interplay of Inflammation, Eryptosis, and Anemia in ESKD

Andrea N. Moreno-Amaral,[1] Erika S. Dias,[1] Júlia B. Monte-Alegre,[1] Beatriz Akemi K. Van Spitzenbergen,[1] Gabriela B. Andrade,[1] Vitor A. Brugnolo-Santos,[1] Yuri D. Ozogovski,[1] Gabriela Ferreira Dias,[2] Nadja Grobe,[2] Peter Kotanko,[2] Thyago P. Moraes.[1,3] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Most ESKD patients have some degree of chronic inflammation, which heightens infection risk, elevates pro-inflammatory cytokines, and augments uremic solute accumulation. These events could exacerbate anemia by premature death (eryptosis) of red blood cells (RBC). This study aimed to explore the link between eryptosis, cytokines, and hemoglobin levels (HB) in ESKD dialytic patients.

Methods: Serum from 41 ESKD dialytic patients was analyzed using ELISA for IL-6, IFN-g, TNF-a, and IL-1b. RBC from peripheral blood were annexin-V labeled to assess phosphatidylserine (PS) expression. A nonparametric Spearman test was used to analyze the correlation between the variables, while simple linear regression was employed to quantify the slope and intercept of these relationships.

Results: Figure 1 – As expected, Hb levels correlated inversely with the cytokines INF-g (A, p<0.01) and IL-1b (B, p<0.03) but not with IL-6 (C, p<0.07) and TNF-a (D, p<0.06). Higher PS expression was correlated with lower Hb levels (E, p<0.001). Additionally, significant inverse correlations were observed between PS expression and IFN-g (F, p<0.001), IL-1b (G, p<0.001), and IL-6 (H, p<0.001). However, no significant correlation was found between PS exposure and TNF-a (I, p<0.55).

Conclusions: The results showed a link between low Hb levels and high cytokine concentrations, connecting inflammation with anemia. A significant inverse correlation was also seen between high PS expression and low Hb levels and between PS expression and the cytokines INF-g, IL-1b, and IL-6. These findings imply an association between eryptosis, renal anemia, and inflammation in these patients. This underscores the importance of addressing inflammation and eryptosis to manage anemia, potentially reshaping clinical approaches.

Association of Erythropoietin Resistance with Sleep Apnea Syndrome and Prognosis in Patients on Maintenance Hemodialysis

Yasuhiro Mochida, Kunihiro Ishioka, Machiko Oka, Hidekazu Moriya, Takayasu Ohtake, Yusuke Tsukamoto, Sumi Hidaka. *Shonan Kamakura Sogo Byoin, Kamakura, Japan.*

Background: Nocturnal intermitted hypoxia with sleep apnea syndrome (SAS) is known to stimulate erythropoietin (EPO) production and is associated with prognosis in populations without kidney dysfunction. However, it remains unresolved whether SAS severity is related to EPO production, EPO resistance, and cardiovascular events in patients with end stage kidney disease. In this study, we investigated the association between SAS severity and EPO resistance in hemodialysis patients.

Methods: We investigated the association between the nocturnal 3% oxygen desaturation index (3%ODI) and the EPO resistance index (ERI) in 134 hemodialysis patients who underwent overnight pulse oximetry at Shonan Kamakura General Hospital from December 2012 to April 2013. After evaluating overnight pulse oximetry, these patients were divided into 4 groups (low or high 3% ODI and ERI levels) and followed up to investigate major adverse cardiovascular events (MACEs) for about 8 years until April 2021. MACEs included cardiac events, cerebrovascular events, peripheral artery disease events, and cardiovascular death. The association between 3% ODI and ERI was investigated by multiple linear regression analysis with covariants: age, sex, duration of hemodialysis, history of diabetes mellitus, systolic blood pressure, and serum of albumin, c-reactive protein, beta-2 microglobulin, phosphate, and parathyroid hormone. The cumulative incidence of MACEs across the groups was assessed using the log-rank test for trend with Kaplan-Meier curve.

Results: The baseline characteristics of 134 patients were as follows: the median age was 67 years, 37.3% were diabetic, and the median duration of HD was 69 months, median 3% ODI was 11.3 %, median ERI was 8.94. 3% ODI was independently associated with ERI (beta co-efficient = -1.2%, p=0.002) by multiple linear regression analysis. The Highest incidence of MACE was shown in the group with high 3% ODI and high ERI compared with low 3% ODI and low ERI (p for trend=0.01, hazard ratio=2.43).

Conclusions: Hemodialysis patients with hypoxemia were associated with lower ERI than patients without hypoxemia. However, it should be noted that patients with nocturnal hypoxemia had a higher likelihood of developing cardiovascular disorders, especially in those with high EPO resistance.

TH-PO880

Reduced Flippase Activity in the Early Life of Mature Erythrocytes Is Associated with Their Shortened Lifespan in Renal Anemia

Momoko Seki, Nobuto Arashiki, Shun Manabe, Hiroshi Kataoka, Ken Tsuchiya, Junichi Hoshino, Fumio Nakamura. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.*

Background: The lifespan of mature erythrocytes in renal anemia patients is shortened (approximately 70 days) compared to that of healthy individuals (120 days), but its pathogenesis is unclear. Previously, we reported that in healthy senescent erythrocytes decreased intracellular K^+ and ATP levels, and flippase molecule ATP11C, lead to decreased flippase activity, resulting in increased phosphatidylserine (PS) exposure, a removal sign for macrophages (Seki M, 2020). Our recent investigations have revealed that senescent erythrocytes from renal anemia patients also exhibited decreased flippase activity, leading to PS exposure, mainly due to K^+ loss. This study demonstrated that senescent erythrocytes in patients were younger than the senescent erythrocytes in healthy individuals. We additionally conducted a quantitative proteome analysis of the membrane proteins obtained from young and senescent erythrocytes of patients to identify candidates involved in K^+ loss.

Methods: Erythrocytes from patients undergoing maintenance hemodialysis and from healthy volunteers were fractionated into young (light) and senescent (heavy) populations using a Percoll-density gradient according to our previous report. HbA1c was measured in fractionated erythrocytes as a marker of their age. We conducted a quantitative MS/MS using the Tandem Mass Tagging labeling system on membrane proteins from young and senescent erythrocytes of renal anemia patients (n=3).

Results: Although the number of senescent erythrocytes in patients bore a similarity to that of healthy humans, HbA1c levels in the heavy fractions of patients were lower than levels in healthy individuals. The proteomic analysis of patients' membranes presented oxidation-modified Transient Receptor Potential Melastatin 2 (TRPM2), an oxidation-sensitive calcium channel, and a sufficient amount of Piezo1, a mechanosensitive calcium channel. Both are potent contributors to activate calcium-dependent K^+ leakage (Gardos effect).

Conclusions: In the early life of mature erythrocytes in renal anemia patients, reduced flippase activity causes PS exposure due to K^+ loss. We identified two responsible candidates for K^+ leakage, TRPM2 and Piezo1, which could serve as novel therapeutic targets for renal anemia.

Mitochondrial Dysfunction in FOXD1 Lineage Cells Has a Key Role in the Development of Anemia Associated with CKD

Hanako Kobayashi,[1,2] Volker H. Haase.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Anemia is one of the common complications of chronic kidney disease (CKD) diminishing quality of life and increasing cardiovascular mobility and mortality in affected patients. Inadequate production of renal erythropoietin (EPO) is the main cause of CKD-associated anemia. EPO is produced in perivascular fibroblast-like cells which are derived from FOXD1 lineage cells and are regulated by hypoxia-inducible factor-2 (HIF-2). Despite recent advances in understanding EPO regulation, the mechanisms for the loss of EPO production are ill-defined. Perivascular fibroblast-like cells are viewed as quiescent; however, they can rapidly proliferate, migrate, and produce extracellular matrix in kidney disease. The role of metabolic regulation in this process is only incompletely understood. Mitochondria (mt) are essential for cellular metabolism, and mt dysfunction is a common feature of acute and chronic kidney diseases. However, the function of mt in perivascular fibroblast-like cells is largely unknown.

Methods: To investigate mt function in renal stroma, we generated and analyzed mice with interstitial cell-specific deficiency of mt transcription factor A (TFAM) using *FoxD1-cre* transgenic mice (*FoxD1-Tfam*$^{-/-}$). TFAM is required for the transcription of mt genes and mt DNA replication and is thus essential for the maintenance of mt mass and function.

Results: We demonstrate that suppression of mt mass in renal stroma results in progressive renal failure, characterized by elevated BUN, tubulointerstitial fibrosis, and glomerulosclerosis. Single cell RNA sequencing of *FoxD1-Tfam*$^{-/-}$ interstitial cells demonstrated increased expression of genes involved in amino acid metabolism and ATF4-mediated stress responses. Furthermore, *FoxD1-Tfam*$^{-/-}$ mice developed anemia, characterized by relative EPO deficiency in response to hypoxia or treatment with HIF stabilizing agents. This was due to the inability to stabilize HIF-2α in *Tfam*$^{-/-}$ stroma.

Conclusions: In summary, we have developed a novel genetic mouse model of slowly progressive CKD-associated anemia that mimics human disease. Our data suggest that mt in renal stroma play a critical role for the maintenance of normal kidney function and homeostasis.

Protein-Bound Uremic Solute 3-Carboxy-4-Methyl-5-Propyl-2-Furanpropanoic Acid (CMPF) Induces Eryptosis through a Piezo1-Dependent Pathway

Beatriz Akemi K. Van Spitzenbergen,[1] Erika S. Dias,[1] Júlia B. Monte-Alegre,[1] Gabriela B. Andrade,[1] Vitor A. Brugnolo-Santos,[1] Yuri D. Ozogovski,[1] Gabriela Ferreira Dias,[2] Nadja Grobe,[2] Peter Kotanko,[2,3] Andrea N. Moreno-Amaral.[1] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The uremic solute 3-Carboxy-4-methyl-5-propyl-2-furanpropionate (CMPF) exhibits structural resemblances with Jedi1, a known chemical activator of the mechanosensitive ion channel Piezo1. Therefore, we hypothesized that activation of Piezo1 on red blood cells (RBC) may promote eryptosis, i.e., premature RBC death in uremia (Kotanko, FASEB Bioadv. 2022). Our aim was to further probe into that hypothesis.

Methods: Isolated RBC from six healthy individuals were either pre-treated or left untreated with the Piezo1 inhibitor GsMTx-4 (5 min). This step was followed by 30 min incubation with CMPF or Jedi1 (both 87 mM). Subsequently, we stimulated

Piezo1 by challenging RBC for 5 min with either hypotonic (NaCl 6g/L) or isotonic (9 g/L) saline. After centrifugation, RBC pellets were stained with Annexin-V to assess phosphatidylserine (PS) exposure on the RBC membrane and with Fluo-4AM to quantify intracellular calcium (icCa2+). Both signals report eryptosis pathways were measured by flow cytometry.

Results: Table 1: When challenged with hypotonic saline, both Jedi1 and CMPF increased PS exposure and $icCa^{2+}$. In contrast, in the presence of isotonic saline, CMPF, but not Jedi1, increased PS and $icCa^{2+}$. These effects were prevented by 5-min pre-incubation with GsMTx-4.

Conclusions: Our results support the notion that CMPF, a uremic toxin, activates Piezo1 on RBC and, through that pathway, promotes eryptosis. Further investigation is warranted to determine whether and to what extent this effect aggravates anemia in kidney patients.

Experimental Condition	NaCl 6 g/L		NaCl 9 g/L	
	% PS exposure (MFI)	% icCa2+ (MFI)	% PS exposure (MFI)	% icCa2+ (MFI)
Control (DMSO 0.12% in PBS+4% HSA)	5.3 ± 1.4	21.1 ± 1.8	3.8 ± 1.1	14.1 ± 3.1

Prescribing Practices of Erythropoiesis-Stimulating Agents in Dialysis-Dependent and Nondialysis-Dependent CKD

Rammdeep Saini,[1,2] Keigan More,[1,2] Jo-Anne S. Wilson,[1,2] David Clark,[1,2] Amanda J. Vinson,[1,2] Karthik K. Tennankore.[1,2] *[1]Dalhousie University, Halifax, NS, Canada; [2]Nova Scotia Health Authority, Halifax, NS, Canada.*

Background: Anemia is a common complication of CKD. Erythropoiesis-stimulating agents (ESAs) have been used to treat CKD-associated anemia but are associated with increased risk of stroke, cancer progression and recurrence. There are no clear guidelines on ESA use for CKD patients with stroke, active or prior malignancy. Our objective was to assess the practice patterns and hemoglobin targets of Canadian Nephrologists and other Nephrology prescribers for ESA use in CKD patients with stroke or malignancy.

Methods: We developed a cross-sectional, online survey to assess the anemia practice patterns of Canadian nephrologists, nephrology trainees, pharmacists and nurse practitioners. Survey design was done using a modified-Delphi process. The survey was nationally disseminated to members of the Canadian Society of Nephrology from March to May, 2024. Descriptive statistics were used to characterize hemoglobin targets and perceptions of "comfort" in prescribing across practitioners.

Results: Survey response rate is 16.3% (88/540). In general CKD patients, a hemoglobin target of 95-115 g/L was most common (50.0%). In CKD patients with history of stroke, 90-105 g/L and 95-115 g/L were the most common targets (both 27.3%). In CKD patients with active or previous malignancy, 90-105 g/L was the most common target (27.3% and 25.0%, respectively). Figure-1 shows Likert scale ratings for ESA prescribing comfort in different CKD populations. Differences were observed for comfort in prescribing. Final survey results will be available in June 2024.

Conclusions: This study highlights that there are a wide range of hemoglobin targets that are used, especially among those with active or prior malignancy and informs the need for better evidence for hemoglobin targets among CKD patients with malignancy or stroke.

Question	Median Rating	Interquartile Range	P
I am comfortable with prescribing ESAs in patients with dialysis dependent or non-dialysis dependent CKD	5	4-5	–
I am comfortable with prescribing ESAs in dialysis dependent or non-dialysis dependent CKD patients with history of stroke	4	3-4	<0.001
I am comfortable with prescribing ESAs in dialysis dependent or non-dialysis dependent CKD patients with an active malignancy	3	2-4	<0.001
I am comfortable with prescribing ESAs in dialysis dependent or non-dialysis dependent CKD patients with history of previous cancer	4	3-4	<0.001

Figure-1: Likert Scale Ratings for ESA Prescriber Comfort in CKD Populations. Likert Rating: 1-Strongly Disagree, 2-Disagree, 3-Neither Agree nor Disagree, 4-Agree, 5-Strongly Agree. Comfort levels between general CKD patients versus other populations were compared.

TH-PO884

Association of Erythropoietin Resistance Index with Interleukin-6 among Patients Undergoing Conventional and Extended-Hours Haemodialysis

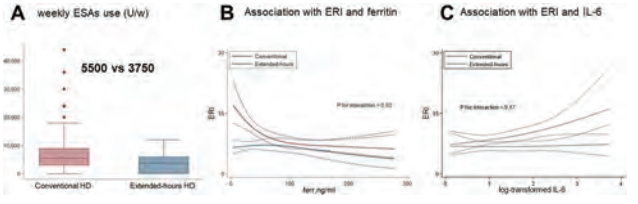
Nobuhiro Nishibori, Takumi Yamada, Masaki Okazaki, Takahiro Imaizumi, Shoichi Maruyama. *Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan.*

Background: Extended-hours hemodialysis (HD) has better clinical outcomes than conventional HD. In patients with maintenance HD, high level of the erythropoietin resistance index (ERI) is known as the factor of high mortality. Previous studies have reported that Extended-hours HD is associated with lower ERI levels, but the mechanism is unkouwn.

Methods: We performed a cross-sectional study of patients with extended-hours HD or conventional HD between January and March 2020. ERI was calculated by dividing weekly erythropoiesis-stimulating agents (ESAs) use by body weight (BW, kg) and hemoglobin (Hb, g/dL). Blood interleukin-6 (IL-6) levels were measured by ELISA kit (HS600C, R&D). Linear and non-linear associations between ERI, ferritin and IL-6 levels were examined across dialysis modalities.

Results: A total of 364 participants (176 with extended-hours HD and 188 with conventional HD) were included in the analysis. The mean age was 66 vs 72 years, percentage of men was 68 vs 62%, and the mean Hb was 11.1 vs 11.2 g/dL. Extended-hours HD was associated with lower weekly ESAs use (FigureA). Multivariable linear regression analysis showed that extended-hours HD was associated with lower weekly ESAs use; -3800 U/week (95% confidence interval (CI); -5300 to -2300). In Figure B, restricted cubic spline (RCS) function indicated that extended-hours HD was associated with lower ERI, especially in hypoferritinic conditions (*P* for interaction <0.01). In conventional HD group, ERI is increased with elevation of IL-6 levels, on the other hans, in extended-hours HD group, ERI appears to remain unchanged despite increased IL-6 levels (FigureC).

Conclusions: The patients with extended-hours HD had lower ERI than those with the conventional HD group, especially in hypoferritinic conditions. In extended-hours HD group, higher IL-6 levels tended not to be associated with higher ERIs, which may contribute to better clinical outcomes in patients on extended-hours HD.



TH-PO885

Role of Iron Sequestration in the Development of Anemia of CKD: Implications for Treatment Resistance

Chantalle A. Campbell, Jade Matthews balcombe, Hannah G. Federman, Heba Elsayed, Kanza Baqai, Edwin Patiño, Mary E. Choi, Oleh M. Akchurin. *Weill Cornell Medicine, New York, NY.*

Background: Anemia is a common complication of CKD, and iron supplementation is the recommended first line of therapy. The efficacy of oral iron therapy in CKD is unsatisfactory, likely owing, at least in part, to elevated hepcidin. Hepcidin induction might limit iron availability for erythropoiesis through either reduced intestinal absorption or by enhanced sequestration. However, the relative contribution of iron malabsorption vs. sequestration to anemia of CKD remains unclear.

Methods: CKD was induced in 8-week old wild type (WT) and macrophage-specific (*LysM*-Cre) ferroportin (*Fpt*) knockout (KO) mice using a 0.2% adenine diet for 8 weeks. We used oral carbonyl iron, iron sulfate, and iron citrate in doses comparable to those used in CKD patients. Iron content was quantified in the bone marrow, spleen, and liver by staining, a bathophenanthroline-based colorimetric method, and by MRI. Tissue ferritin was assessed by immunoblotting.

Results: WT CKD mice developed anemia and their serum hepcidin was 3-fold higher than in healthy mice. There was a marked increase in the number of iron-positive cells in the bone marrow (Fig.) and a 2-fold increase in the spleen of WT CKD mice compared to healthy mice. Liver ferritin was induced in untreated WT CKD mice. Macrophage-specific *Fpt* KO CKD mice had more severe anemia and further increase of iron stores in the bone marrow, spleen, and liver, compared to WT CKD mice. Oral iron supplementation improved hemoglobin in WT CKD mice by 20.8% but increased hepcidin by 1.5-fold, spleen iron content by 74.8% and liver iron content by 12.5-fold compared to untreated CKD mice.

Conclusions: In this model of CKD, we observed iron sequestration in the bone marrow, spleen, and liver in the absence of iron therapy. Oral iron supplementation further enhanced iron sequestration, disproportionate to the alleviation of anemia in CKD mice. Sequestered iron remained partially mobilizable via incompletely suppressed ferroportin.

Bone marrow iron staining by Perls Prussian blue in healthy mice and in mice with untreated CKD after 8 weeks of control or adenine diet.

TH-PO886

Iron Sequestration in Kidney Macrophages Is Essential for Protecting Proximal Tubules from Iron Overload during Iron Therapy in CKD

Hannah G. Federman,[1] Chantalle A. Campbell,[1] Heba Elsayed,[1] Divya Bhatia,[1] Mary E. Choi,[1] Francesca Vinchi,[2] Oleh M. Akchurin.[1] *[1]Weill Cornell Medicine, New York, NY; [2]New York Blood Center, New York, NY.*

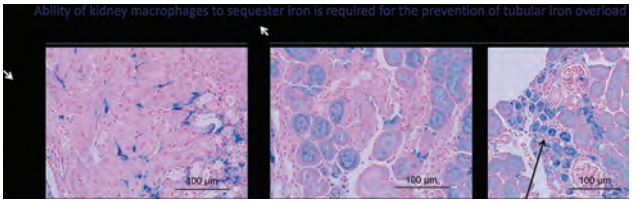
Background: Chronic kidney disease (CKD) affects 10-15% of the adult U.S. population. Iron supplementation is very common in patients with CKD, and may lead to organ iron overload, rising concerns about nephrotoxic effects of iron. However, intrarenal iron trafficking during iron supplementation in CKD has not been delineated, making it difficult to account for renal effects of iron in CKD patients.

Methods: CKD was induced in 8-week old wild type (WT) and myeloid-specific (*LysM*-Cre) ferritin heavy chain knockout mice (*Fth1*$^{M\phi}$-KO) by 8 weeks of adenine diet. Iron dextran was administered intraperitoneally once a week, 500 mg/kg/dose. Kidney tissues were assessed by histology as well as processed for single cell suspensions via collagenase digestion immediately upon harvest, and analyzed by flow cytometry. Furthermore, proximal tubular epithelial cells (pTEC) and kidney macrophages were isolated using CD133 and CD11b magnetic microbeads.

Results: In pTEC of untreated WT CKD mice, ferritin heavy and light chain proteins were induced while labile iron pool was reduced, compared to healthy WT mice. Expression of transferrin receptor 1 (TfR1), a major iron importer, was reduced in pTEC of untreated CKD mice compared to controls. Iron suppementation resulted in iron accumulation within kidney macrophages in WT CKD mice while sparing pTEC, as assessed by Perls iron stain of kidney tissues and sorted kidney macrophages. In *Fth1*$^{M\phi}$-KO CKD mice supplementaed with iron, the distribution of iron within the kidney was vastly different from the WT: iron was accumulating primarily in pTEC, with especially massive iron content seen within atrophic tubulues in the areas of fibrosis (Figure).

Conclusions: Kidney macrophages are indespensable for preventing tubular iron overload during iron supplementation in CKD. Modifying iron-scavenging ability of kidney macrophages may represent a novel renoprotective strategy in CKD.

Funding: NIDDK Support



Iron accumulation in wild type and myeloid-specific ferritin heavy chain knockout mice with adenine-induced CKD treated with iron dextran supplementation.

TH-PO887

Safety and Effectiveness of Erythropoietin vs. Roxadustat for Anemia in Hemodialysis-Dependent Peridialytic CKD Patients: An Observational, Retrospective, Matched, Real-World Study

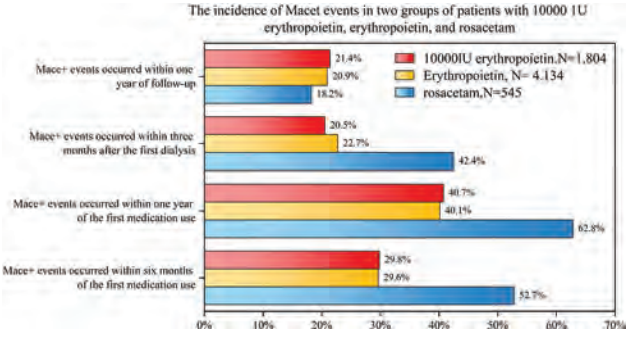
Li H. Wang. *The Second Hospital of Tianjin Medical University, Tianjin, China.*

Background: Current evidence remains elusive about the efficacy and safety of erythropoietin *versus* roxadustat for anemia treatment in the peridialytic period.

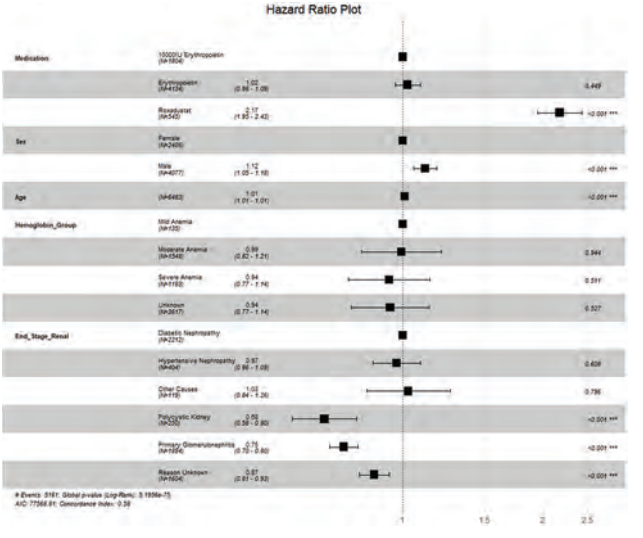
Methods: This study extracted longitudinal data from a metropolis-wide hospitals-based database Tianjin Healthcare and Medical Big Data Platform. Subjects with CKD stage G5 and anemia (hemoglobin <100 g/L) who had received treatment with erythropoietin or roxadustat between January 1, 2015 and December 31, 2021.

Results: Of 40,324 patients who were included and treated with erythropoietin and erythropoietin 10,000 IU were matched to 545 patients treated with roxadustat. Significant differences were observed in the rates of MACE+ events as well as cardiocerebrovascular events.

Conclusions: Erythropoietin, particularly erythropoietin 10,000 IU, improved hemoglobin response and exhibited better cardiovascular safety, as compared with roxadustat, in patients with anemia who had hemodialysis-dependent CKD in the peridialytic period.



The rates of MACE+ events within 6 and 12 months of treatment initiation, within 3 months of hemodialysis initiation and during 12 months of follow-up among patients who were treated with roxadustat, erythropoietin, or erythropoietin 10,000 IU



COX regression analysis showed that receipt of roxadustat was associated with an approximately two-fold increase in the risk of MACE+ *versus* erythropoietin 10,000 IU (HR=2.17, 95% CI 1.95-2.43; *P*<0.001).

TH-PO888

Pegmolesatide for the Treatment of Anemia in Patients with CKD Undergoing Dialysis: Insights from a Randomized Active-Controlled Phase 3 Study

Jianghua Chen,[1] Linghui Zhou,[2] Minghao Guo,[3] Hongguang Zheng,[4] Deqiong Xie,[5] Zhizhen Hu,[6] Weili Luo.[6] *[1]The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China; [2]The First Affiliated Hospital of Xiamen University, Xiamen, China; [3]The First Affiliated Hospital of Xinxiang Medical University, Xinxiang, China; [4]General Hospital of Northern Theater Command, Shenyang, China; [5]Second People's Hospital of Yibin, Yibin, China; [6]Jiangsu Hansoh Pharmaceutical Co Ltd, Lianyungang, China.*

Background: Pegmolesatide, a novel long-acting pegylated erythropoietin mimetic peptide, has proved comparable efficacy and safety with epoetin alfa based on a randomized, multicenter, open-label, non-inferiority phase 3 study (NCT03902691). This post-hoc analysis aims to explore further benefits of pegmolesatide for the treatment of anemia patients on dialysis.

Methods: A total of 372 chronic kidney disease (CKD) patients undergoing dialysis were randomized (2:1) to receive pegmolesatide or epoetin alfa for 52 weeks. Post-hoc analysis was conducted to assess the proportions of patients across various hemoglobin (Hb) ranges during the efficacy evaluation period.

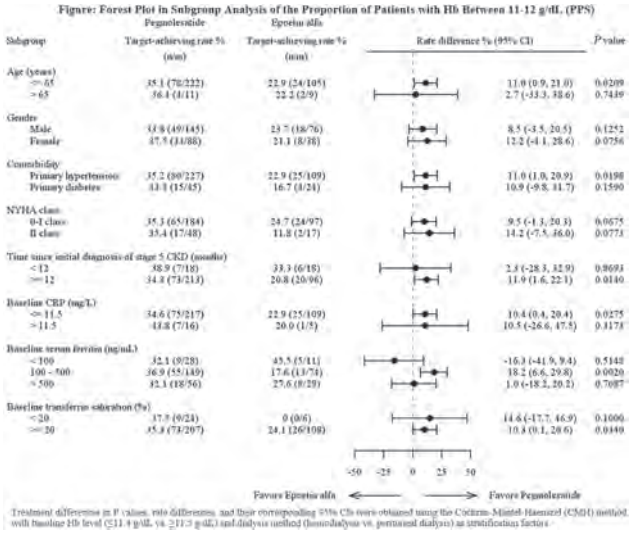
Results: A larger proportion of patients on pegmolesatide achieved mean Hb≥11 g/dL compared to those on epoetin alfa (63.9% vs. 44.7%, *P*=0.0003). More patients receiving

pegmolesatide maintained their Hb levels within the target ranges of 11-12 g/dL (35.2% vs. 22.8%, *P*=0.0164) and 11-13 g/dL (57.5% vs. 36.8%, *P*=0.0002) compared to those receiving epoetin alfa. In subgroups of baseline characteristics with age ≤65 yrs., primary hypertension, stage 5 CKD≥12 months, CRP≤11.5 mg/L, serum ferritin between 100-500 ng/mL, and transferrin saturation≥20%, pegmolesatide also showed greater effect in maintaining Hb levels between 11-12 g/dL (Figure). Similar findings were observed in these subgroups for the target range of 11-13 g/dL. The incidences of treatment related adverse events of particular interest, including hypertension (4.5% vs. 6.5%), hepatotoxicity (0.8% vs. 2.4%) and hyperkalaemia (2.4% vs. 4.0%), were numerically lower in the pegmolesatide group.

Conclusions: Pegmolesatide demonstrated a stronger likelihood of maintaining Hb levels within guideline-recommended ranges and potentially provided a more favorable safety profile compared to epoetin alfa.

Funding: Commercial Support - Jiangsu Hansoh Pharmaceutical Co Ltd

Figure: Forest Plot in Subgroup Analysis of the Proportion of Patients with Hb Between 11-12 g/dL (PPS)



Treatment difference in P values, rate differences, and their corresponding 95% CIs were obtained using the Cochran-Mantel-Haenszel (CMH) method with baseline Hb level (≤11.4 g/dL vs. ≥11.5 g/dL) and dialysis method (hemodialysis vs. peritoneal dialysis) as stratification factors.

TH-PO889

Hepcidin Is a Potential Predictor Marker for Anemia Progression in Patients on Hemodialysis

Hiroki Uchida, Ryo Kurimoto, Miho Suzuki, Akiko Kudo, Takeshi Nakata, Akihiro Fukuda, Hirotaka Shibata. *Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan*.

Background: Higher hepcidin levels observed in patients on hemodialysis cause functional iron deficiency and erythropoiesis-stimulating agent hyporesponsiveness, which may result in anemia; however, the impact of hepcidin elevation on anemia in patients on hemodialysis remains unclear. This study assessed the association between hepcidin-25 and hemoglobin (Hb) levels in patients on hemodialysis.

Methods: This observational study included 44 outpatients on hemodialysis with 251 available blood test results between April and November 2023. Erythropoiesis-stimulating agents and hypoxia-inducible factor prolyl hydroxylase inhibitors were administered in 40 and 2 patients, respectively, whereas 2 patients did not receive anemia treatment. Transferrin saturation and Hb, ferritin, and serum hepcidin-25 levels were measured every month, and the association of same-month hepcidin-25 and Hb levels were assessed. Whether the hepcidin-25 levels predicted future anemia and changes in Hb levels was determined by assessing the associations of hepcidin-25 with the next-month Hb level and the changes in Hb level after 1 month.

Results: Hepcidin-25 levels, although not associated with the same-month Hb levels ($\rho = -0.0377$, $P = 0.5528$; Fig. 1), exhibited significant negative association with the next-month Hb levels ($\rho = -0.2171$, $P = 0.0005$; Fig. 1) and the changes in Hb levels ($\rho = -0.1349$, $P = 0.0326$; Fig. 2). Furthermore, Hb levels in the next month declined in patients with hepcidin-25 levels of >70 ng/mL (Fig. 3).

Conclusions: Our analyses demonstrated that hepcidin levels were useful in predicting anemia progression within a month in patients on hemodialysis. A hepcidin level of >70 ng/mL predicted anemia progression, suggesting the requirement for intensified anemia treatment in these patients on hemodialysis.

Recombinant Human Erythropoietin (rhEPO)-Fc for Renal Anaemia in Chinese Patients on Haemodialysis: A Multicentre, Randomised, Open-Label, Phase 3 Study

Liangying Gan,[1] Ling Tong,[2] Chun Yang,[2] Li Zuo.[1] Fc-Acts Study Group. *[1]Peking University People's Hospital, Beijing, China; [2]Sichuan Luzhou Buchang BIO-Pharmaceutical Co., Ltd., Beijing, China*.

Background: Recombinant human erythropoietin (rhEPO) Fc fusion protein (rhEPO-Fc) has been developed to prolong the plasma half-life and improve the biological activity of EPO. The efficacy and safety characteristics of rhEPO-Fc have not been investigated in renal anaemia patients.

Methods: This was a multicentre, randomised, open, positive drug controlled, phase 3 trial conducted at 45 hospitals in China (NCT05359068). After a 6-week screening period, eligible patients were randomised (2:1) to receive rhEPO-Fc initiated at 18 μg/kg once a week or rhEPO initiated at 1500 IU two to three times a week or 3000 IU twice a week for 28 weeks. Eligible patients were enrolled to the consecutive 24-week extended treatment period. The primary outcome was the change in mean haemoglobin (Hb) from baseline between week 21 and week 28. Efficacy was analysed in full analysis set (FAS) and per protocol set (PPS). Safety was assessed in all patients who received at least one dose of the investigational drugs.

Results: Between 31 May 2021 and 27 June 2023, 356 patients received rhEPO-Fc and 178 received rhEPO injection. The rhEPO-Fc treatment group resulted in a significantly greater least-square mean (LSM) of the mean Hb changes between week 21 and week 28 from baseline in the FAS and PPS populations: inter-group LSM difference of 3.96 (95% CI 3.02 to 4.89; P<0.001) and 2.27 (0.60, 3.95; P=0.008), respectively. The incidence of adverse drug reaction (ADR) in the rhEPO-Fc group was slightly lower compared with the rhEPO group (39.2% vs 40.2%). The percentage of patients with dose adjustment due to treatment emergent adverse events (TEAEs) in the rhEPO-Fc group was statistically significantly lower compared with that of the rhEPO group (0.0% vs 2.2%; P<0.05). Two patients in the rhEPO-Fc group and 4 patients in the rhEPO group died due to TEAEs that were considered not related to the investigational drugs.

Conclusions: The efficacy of rhEPO-Fc was not inferior to that of rhEPO in maintaining Hb in Chinese hemodialysis patients with anaemia and was generally well tolerated.

Association of Anemia (Hemoglobin <13 g/dL in Men and <12 g/dL in Women) with Long-Term Kidney Prognosis in Patients with ADPKD: Insights from Time Series Analyses

Hiroshi Kataoka, Toshio Mochizuki, Shun Manabe, Yusuke Ushio, Momoko Seki, Ken Tsuchiya, Kosaku Nitta, Junichi Hoshino. *Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan*.

Background: Hemoglobin (Hb) levels are generally higher in autosomal dominant polycystic kidney disease (ADPKD) compared to other kidney diseases, but the prognostic role of anemia in ADPKD is not well understood. Prognostic factors for kidney outcomes can vary with the length of follow-up periods, making it crucial to understand the time-series changes and integrals of pseudo-R^2 values for kidney risk factors.

Methods: We enrolled 553 ADPKD patients. Renal outcome was defined as a 50% reduction in estimated glomerular filtration rate or initiation of renal replacement therapy. Survival analyses and logistic regression analyses for generating time-series pseudo-R^2 values were conducted. The integrated values of the pseudo-R^2 values from the 1st year to the 17th year (1Y–17Y Integrals) were calculated to determine the optimal Hb cut-off points for long-term renal prognosis.

Results: Multivariable Cox analyses indicated that anemia (Hb 1 g/L decrease, P=0.0004) was associated with kidney disease progression. To determine the anemia cut-off for kidney prognosis, pseudo-R^2 values for Hb <12 g/dL showed the highest 1Y–17Y integrals of 1.88 among all anemia cut-offs. These values peaked at 0.2401 two years after baseline and had the highest end value of 0.0721 at 17 years. Therefore, Hb <12 g/dL was identified as a key indicator of long-term kidney prognosis in ADPKD patients. Similar sex-specific analyses revealed different anemia cut-offs: Hb <13 g/dL in men and Hb <12 g/dL in women.

Conclusions: The 1Y–17Y Integrals of the pseudo-R^2 values for kidney prognosis contributed to determining the cut-off points of the anemia according to the sex difference.

A Randomized Controlled Trial to Evaluate the Efficacy of Roxadustat Dosing Regimens in Patients with CKD and Anemia on Dialysis

Yan Tu,[1] Bi-Cheng Liu,[1] Cuihua Huang,[3] Zhang Yuchen,[3] Shuting Pan,[2] Wei Niu.[4] *[1]Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, China; [2]Clinical Biometrics, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China; [3]Medical Affairs, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China; [4]Clinical Development, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China*.

Background: It is unknown how roxadustat dose frequency reduction impacts hemoglobin (Hb) maintenance in patients with CKD anemia. We report here on Part 2 of a Phase 4 study (NCT04059913) which evaluated efficacy (Hb maintenance) and safety of three roxadustat dosing frequencies (once weekly [QW], twice a week [BIW], thrice a week [TIW]) in Chinese CKD anemia patients on dialysis after Hb correction in Part 1 (2023 ASN TH-PO981).

Methods: Eligible patients from Part 1 (Weeks 19 and 21 Hb ≥105 g/L and 4-week change in Hb >−10 g/L) were randomized to roxadustat QW, BIW or TIW. Frequency increases were permitted if needed. Non-inferiority testing was used for full analysis set (FAS) and per protocol set (PPS) analyses: 1) BIW vs. TIW and 2) QW vs. TIW (non-inferiority margin [NIM]=10 g/L). The primary endpoint was least-squares mean (LSM) Hb averaged at Weeks 33–37.

Results: A total of 178 patients were included: 175 patients in FAS (TIW: 61; BIW: 59; QW: 55) and 169 patients in PPS (TIW: 60; BIW: 57; QW: 52). Demographics were comparable across arms. Mean (SD) baseline Hb were 115.0 (6.1) g/L (TIW), 115.4 (6.5) g/L (BIW) and 114.4 (5.7) g/L (QW). In the PPS, the Hb LSMs [95% CI] at weeks 33-37 were 108.3 [105.7, 110.9] g/L (TIW), 107.1[104.4, 109.7] g/L (BIW), and 106.3 [103.6, 108.9] g/L (QW) (differences: −1.2 [95% CI: −4.4, 1.9] g/L [BIW vs. TIW]; −2.0 [95% CI: −5.3, 1.2] g/L [QW vs. TIW]). The lower 95% CI limit was >−10 g/L (NIM margin) for each comparison. FAS and PPS results were consistent. Around 90–95% TIW patients maintained TIW dosing, while 69.5–76.3% BIW and only 30.9–32.7% QW patients maintained their dose frequency. TEAEs occurred in 81.1% (TIW), 78.3% (BIW), and 63.4% (QW) of patients.

Conclusions: Non-inferiority was established between roxadustat BIW vs. TIW and QW vs. TIW. However, a proportion of patients in QW and BIW arms required dose frequency increases to maintain Hb. The clinical benefit of reducing roxadustat dose frequency is limited and should be carefully evaluated.

TH-PO893

Single-Centre Prospective Study of Indigenously Developed Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor (HIF-PHI) (Desidustat) for Treatment of Renal Anemia

Krishnaswamy Sampathkumar, Krishna Priya, Biju Dennis. *Meenakshi Mission Hospital and Research Centre, Madurai, India*.

Background: Anemia in dialysis patients impairs quality of life and leads to adverse cardiovascular outcomes. Standard treatments for CKD-associated anemia include EPO analogues and iron supplementation. Desidustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI), was recently approved in India for treating anemia in CKD patients. This study aims to evaluate the efficacy and safety of Desidustat in patients with dialysis-dependent CKD anemia.

Methods: This single-center, prospective study enrolled 68 dialysis-dependent CKD patients with anemia. Patients received Desidustat (Oxemia®) either twice or thrice weekly, depending on their hemoglobin (Hb) levels, and were monitored monthly. Supplemental treatments included iron, vitamin B12, and folic acid as needed. The primary endpoint was the efficacy of Desidustat in increasing Hb levels, while the secondary endpoint assessed its safety profile.

Results: The study cohort consisted of 68 patients, 47 (69.11%) male, with a mean age of 56 ± 11.5 years. The majority, 66 (97%), were on maintenance hemodialysis (MHD) twice weekly, while 2 (3%) were on thrice weekly schedules. Desidustat was administered to 35 (51.4%) patients thrice weekly and to 31 (45.6%) patients twice weekly. Among the participants, 40 (58.8%) were EPO-naïve, and 28 (42.8%) had switched from EPO therapy. Significant improvements in Hb levels were observed following Desidustat treatment ($p<0.05$). Pre-treatment Hb was 7.78 gm/dl, increasing to 8.27 gm/dl after 1 month, 8.71 gm/dl after 2 months, 9.22 gm/dl after 3 months, and 9.94 gm/dl after more than 3 months, with a mean treatment duration of 11.8 ± 6.7 months. Both EPO-naïve patients and those who switched from EPO showed comparable increases in Hb levels. Background therapy included oral iron for 12 (17.6%) patients, intravenous (IV) iron for 52 (76.4%) patients, and vitamin B12 supplementation. Adverse events included mild hyperkalemia in 6 patients and vomiting in 2 patients, both managed appropriately.

Conclusions: This study demonstrates that Desidustat is an effective and safe alternative for treating anemia in dialysis-dependent CKD patients. Given its oral administration Desidustat offers a convenient alternative to injectable EPO therapies

TH-PO894

Evaluating Therapeutic Potential and Safety Profile of Desidustat for Anaemia Management in Patients with CKD: A Prospective, Open-Label, Single-Centre Study

Dinesh Khullar, Abhishek Singh, Deepak Kumar, Sahil Bagai, Kulwant Singh, Rahul Grover. *Max Super Speciality Hospital, Saket, Delhi, India*.

Background: Anemia is one of the common, most prevalent and challenging complications of chronic kidney disease (CKD). Desidustat (Oxemia®), a hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI), is a promising oral alternative to injectable erythropoiesis-stimulating agents (ESAs) for the treatment of anaemia in patients with CKD. Desidustat is approved in India for adults with CKD who are either not on dialysis or on dialysis. Here we aim to evaluate the real life effectiveness and safety profile of Desidustat in managing anemia among patients with chronic kidney disease (CKD).

Methods: This is a prospective single center analysis of Patient suffering from CKD –Anemia treated with Newer HIF PHIv-Desidustat. In this study Patients were on 100 mg Desidustat three times in a week. Primary end point was to observe rise in Hb from baseline to 24 weeks. Other secondary were safety and rise of Hb between different subgroup. Dose adjustments based on the haemoglobin levels at each follow up.

Results: Sixty four (n=64) patients median (IQR) age 60(18.5) years, n=37(57.8%) were female. Majority of the patients were suffering from CIN (21, 32.8%), DKD (15, 23.4%) and CGN (13, 20.3%). 33 (51.5%) were on HD, one patients on PD and 30 (46.8%) were Pre Dialysis patients. Out of 64 Patients, 43(67.2%) patients were EpO switched and 21(32.8%) were EpO naïve patients. There was statistically significant improvement in mean Hb (figure 1). In different category of EpO naïve Switched from EpO, DD vs ND rise of Hb was comparable. Among the safety parameters, the change in serum potassium value from baseline to the end of 24 weeks was within the normal range, with minimal change (p=0.856). The adverse events were observed in (n=5, 7.8%) patients; including VA stenosis(n= 1,1.6%), MGUS(n= 1,1.6%), Vascular Thrombosis(n= 1,1.6%), IE(n= 1,1.6%), and MACE death(n= 1,1.6%).

Conclusions: The study shows desidustat is significantly effective in improvement of Hb levels in both EPO exposed and naïve patients with CKD anaemia. The oral administration further improves the compliance of the patients.

TH-PO895

Real-World Experience of Hypoxia-Inducing Factor-Prolyl Hydroxylase Inhibitor Desidustat for Anemia in Dialysis-Dependent CKD

Aswini P. Patnaik, Nikunj Kishore Rout, Ashim K. Mahali, Scienthia Sanjeevani. *Kalinga Institute of Medical Sciences, Bhubaneswar, India*.

Background: Anemia poses a significant challenge in the management of End-stage kidney disease (ESKD), leading to a diminished quality of life in affected individuals. Patients with ESKD have a relative deficiency of Eryhtopoetin (EpO) andErythropoetin analogues are a standard of care for such patients. Desidustat is a of Hypoxia Inducing Factor Prolyl Hydroxylase Inhibitor (HIF –PHI) thatendogenously increases the EpO production. We studied the real world effectiveness of Desidustat, in ameliorating anemia among ESKD patients undergoing maintenance hemodialysis.

Methods: Observational cohort data were collected data of 65 ESKD patients, aged >18 years on maintenance hemodialysis with hemoglobin levels <10g/dL. Patients with iron deficiency anemia, known bleeding disorders, recent red blood cell transfusions, or concurrent cancer were excluded. Initially, all patients received 100 mg of Desidustat thrice weekly, with subsequent dose adjustments based on individual responses.

Results: The patients had a mean age of 50.35±12.94 years with 45 being male. Of all patients, 41 (63%) were EpO naïve and others were switched from EpO. After 3 months, only 6 patients exhibited a positive response to the initial Desidustat regimen, necessitating a dose escalation to 150 mg. thrice weekly. Following this, 47 out of 65 patients showed significant improvements in hemoglobin levels after 3 months. However, 18 patients (27.6%) did not respond to Desidustat treatment. The mean hemoglobin level before Desidustat initiation was 8.13±0.77 g/dl and after 24 weeks of Desidustat therapy, the mean hemoglobin level rose to 8.73±0.97 g/dl, with a statistically significant p-value of <0.001. There were no major adverse events during the follow-up duration.

Conclusions: Desidustat demonstrated effectiveness in increasing Hb levels in around 3/4th of ESKD patients undergoing MHD. However, starting at 150mg thrice weekly seems to be more beneficial in our population

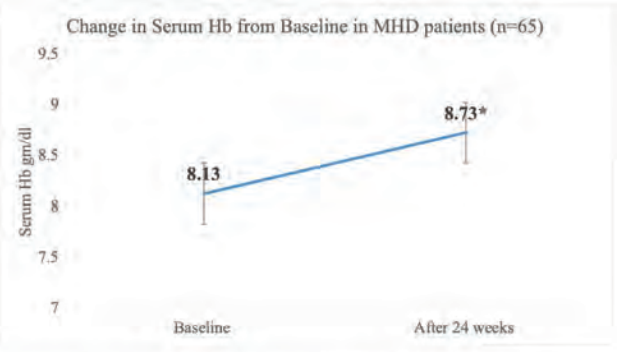

Figure 1: Change in Serum Hb from baseline to 24 weeks (* p<0.01)

TH-PO896

First-in-Human Study of Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor (HIF-PHI) AND017 in Healthy Participants

Yusha Zhu, Ping Du, Qi Zhu. *Kind Pharmaceuticals LLC, Redwood City, CA.*

Background: AND017 is a novel oral HIF-PHI independently developed by Kind Pharmaceuticals LLC. The first-in-human study of AND017 was performed among healthy subjects in Australia to evaluate the safety, pharmacokinetics, and pharmacodynamics of AND017 (NCT04751539).

Methods: This Phase I, randomized, double-blinded, placebo-controlled study consisted of two parts: a single ascending dose (SAD) part followed by a multiple ascending dose (MAD) part. In the SAD part, doses of 1, 4, 10, 20, 30, and 50 mg AND017 or placebo were assessed in 6 consecutive cohorts; In the MAD part, doses of 4, 10, 20 and 30 mg AND017 or placebo were administered daily for 10 days and assessed in 4 consecutive cohorts. After each cohort, a Safety Review Committee (SRC) reviewed blinded cumulative safety data to determine the safety of the study dose before proceeding to the next dose cohort.

Results: A total of 78 subjects were enrolled in the study- 46 subjects in the SAD part and 32 subjects in the MAD part. All subjects were included in the PD and safety analysis set; all 58 subjects dosed with AND017 were included in PK analysis set. Subjects in all treatment groups were of similar demographic and baseline characteristics. AND017 was absorbed quickly with a median T_{max} of 2-4.5 h after single and multiple dose administration. There was no tendency toward a change in T_{max}, half-life, volume of distribution and clearance across the dose range investigated. AND017 steady state reached by 6 days dosing, with an approximate 1.2 to 1.6-fold accumulation after 10 days of administration. Dose proportionality in AND017 exposure was observed after single (1 to 50 mg) and multiple (4 to 30 mg) dosing. In the PD analysis, $E_{max,EPO}$, baseline-corrected $E_{max,EPO}$, $AUEC_{0\text{-}24,EPO}$, and baseline-corrected $AUEC_{0\text{-}24,EPO}$ of erythropoietin (EPO) showed obvious dose dependence. The increase in EPO was significantly associated with the PK exposure. The most frequently reported treatment related adverse events in the SAD part were dizziness, headache, and fatigue occurred in 2 subjects of AND017 cohorts each; in the MAD part, headache occurred in 2 subjects of AND017 cohorts and 1 subjects of placebo cohort.

Conclusions: AND017 appeared to be safe and well tolerated when administered to healthy adult subjects at oral doses ranging from 1 mg up to 50 mg in the SAD part and 4 mg up to 30 mg in the MAD part.

TH-PO897

Effect of Food on the Pharmacokinetics of AND017 in a Phase I Study

Yusha Zhu,[1] Hua Zhang,[2] Ping Du,[1] Qi Zhu,[1] Liyan Miao.[2]
[1]Kind Pharmaceuticals LLC, Redwood City, CA; [2]The First Affiliated Hospital of Soochow University, Suzhou, China.

Background: AND017 is a novel hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) independently developed by Kind Pharmaceuticals LLC and is an emerging new option of treatment for anemia due to chronic kidney disease (CKD). The effect of food on the pharmacokinetics (PKs) of AND017 was investigated in a Phase I study (NCT04712500).

Methods: This is a Phase I, randomized, open-labeled, two-sequence, two-period, crossover study conducted among healthy non-elderly volunteers in China. The primary objective was to evaluate the effect of food on the PKs of a single oral dose of 10 mg of AND017. The study consisted of two periods with a 5-day washout in between. Healthy volunteers were randomized at 1:1 to receive a single dose of 10 mg AND017 under fasted (sequence A) or fed conditions (sequence B) in the first study period. After a 5-day washout, volunteers received another single dose of 10 mg of AND017 under fed (sequence A) or fasted (sequence B) conditions in the second study period. PK samples were collected at pre-dose, 0.5, 1, 1.5, 2, 3, 4, 5, 6, 7, 8, 10, 12, 24, 48, and 72 h post-dose

after each dose. Safety was assessed by monitoring adverse events (AEs), clinical laboratory tests (hematology, chemistry, urinalysis, and coagulation), vital signs, 12-lead ECGs, and physical examinations.

Results: In the study, a total of 14 healthy volunteers were enrolled with similar demographics and baseline characteristics. There were no significant differences in the PK parameters when AND017 was administered under fed and fasted conditions, except for a 20% reduction of C_{max} under fed condition compared to the fasted condition; the geometric mean ratio (fed/fasted) and 90% CI for C_{max} and $AUC_{0\text{-}inf}$ were 79.61% (73.40,86.34) and 99.93% (96.31,103.68) respectively. In the safety analysis, a total of 7 volunteers reported 12 TEAEs, among which 4 TEAEs reported by 3 volunteers were determined to be treatment-related, which were alanine aminotransferase increased, diastolic pressure decreased, triglycerides high, and creatine kinase increased, with each reported once and CTCAE grade ≤2. No AE leading to discontinuation or SAE occurred in the study.

Conclusions: In summary, a single dose of AND017 at 10 mg administered alone or in combination with food was generally safe and well-tolerated in healthy non-elderly volunteers. The study supports the safe use of AND017 under fed or fasted conditions.

TH-PO898

Safety and Efficacy of AND017, a Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor (HIF-PHI), in Patients with Nondialysis-Dependent CKD (NDD-CKD)

Yusha Zhu,[1] Li Zuo,[4] Xiaoqiang Ding,[5] Suzanne Wilson,[1] Ping Du,[1] Qi Zhu,[1] Geoffrey A. Block,[3] Pablo E. Pergola.[2] *[1]Kind Pharmaceuticals LLC, Redwood City, CA; [2]Renal Associates PA, San Antonio, TX; [3]US Renal Care, Dallas, TX; [4]Peking University People's Hospital, Beijing, China; [5]Zhongshan Hospital Fudan University, Shanghai, China.*

Background: AND017, a novel HIF-PHI, was investigated in a Phase II study in patients with NDD-CKD in the US and China (NCT05035641).

Methods: Patients with NDD-CKD and hemoglobin (Hb) ≥7.5 and <10.0 g/dL were randomized at a 1:1:1:1 ratio to AND017 8 mg, 12 mg, 16 mg or placebo three times weekly (TIW) during the first 5-weeks treatment (Fixed-dose Period, no dose adjustment allowed). At the end of the Fixed-dose period (Week 6), patients who met the pre-defined criteria were re-randomized at a ratio of 1:1 to continue the TIW dosing schedule or switch to a once-weekly (QW) dosing schedule and entered the 8-week Titration Period. During this period, the doses of the study drug were adjusted to maintain Hb within the range of 10.0-11.0 g/dL inclusive. The primary objectives were to evaluate the safety and efficacy of AND017 by assessing the rate of rise in Hb at Week 6.

Results: A total of 113 patients were enrolled: placebo (28), 8 mg (28), 12 mg (29), and 16 mg (28). Treatment-emergent adverse events occurred in 69.41% in the pooled AND017 group versus 64.29% in the placebo group while treatment-related adverse events occurred in 11.76% in the pooled AND017 group versus 3.57% in the placebo group. A total of 6 patients from AND017 dose groups experienced serious adverse events (SAEs), none of which were assessed as related to the study drug. Compared to the placebo group, the mean rate of rise in Hb (g/dL/week) from baseline to Week 6 was significantly higher in all the AND017 dose groups ($p<0.0001$). Change from baseline in Hb at Week 6 was 1.44 g/dL, 2.03 g/dL, 2.51 g/dL in AND017 8 mg, 12 mg, and 16 mg group, respectively, and -0.21 g/dL in the placebo. The cumulative response rates (Hb ≥10.0 g/dL and increase from baseline ≥1.0 g/dL during the entire treatment period) were higher in all AND017 dose and dosing frequency groups, 100% and 90% for the pooled AND017 TIW group and QW group, respectively, compared to 40% in the placebo.

Conclusions: AND017 was safe and well tolerated in patients with NDD-CKD and anemia. AND017 effectively increased Hb level in a dose-dependent manner starting at 8 mg TIW within the first 5-week Fixed-dose period and maintained Hb within 10.0-11.0 g/dL at both TIW and QW dosing frequency in the following 8-week Titration period.

TH-PO899

Real-World Evidence of Vadadustat in Patients with Anemia and CKD: Interim Results from Postmarketing Surveillance (VIOLET Survey) in Japan

Kiichiro Ueta,[1] Kenichi Nishimura,[1] Kazuyo Sasaki,[1] Jing Bi,[1] Takafumi Hashimoto,[1] Yuki Seto,[1] Masaomi Nangaku.[2] *[1]Mitsubishi Tanabe Pharma Corporation, Tokyo, Japan; [2]The University of Tokyo, Tokyo, Japan.*

Background: Vadadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor. We report the interim results of ongoing post-marketing surveillance (PMS) in Japanese patients with anemia in CKD receiving vadadustat.

Methods: This 2-year, prospective, observational, multicenter PMS evaluated the safety and effectiveness of vadadustat in clinical practice. Patients with anemia in CKD who had not been treated with vadadustat were enrolled. The occurrence of adverse drug reactions (ADRs) and hemoglobin levels, etc., were evaluated for the interim analysis up to June 2023. ADRs of special interest included hepatic impairment, thromboembolism, hypertension, cardiovascular events excluding thromboembolism, malignant tumor, retinal hemorrhage, and progression of autosomal dominant polycystic kidney disease.

Results: A total of 1847 patients (non-dialysis (ND): 1233; peritoneal dialysis (PD): 142; hemodialysis (HD): 472) were included in safety analysis. The proportion of patients switched from erythropoiesis-stimulating agents was ND: 12.08%, PD: 33.80% and HD: 42.16%, respectively. The median duration for vadadustat treatment was ND: 182 days, PD: 182 and HD: 138 days. ADRs and serious ADRs occurred in 10.94% and 3.41% (overall), 10.30% and 2.92% (ND), 12.68% and 5.63% (PD) and 12.08% and 4.03% (HD), respectively. The most common ADR were ND: diarrhea (0.89%), PD: diarrhea (2.11%) and decreased appetite (2.11%), and HD: nausea (2.54%), respectively. There were no ADRs of special interest with incidence > 2%. The hemoglobin values (g/dL, mean ±SD [n]) at baseline and 1 year after the treatment were 10.10±1.16 [1198] and 11.23±1.39 [434] (ND), 10.57±1.32 [142] and 11.17±1.36 [40] (PD), and 10.10±1.38 [471] and 10.83±1.30 [109] (HD), respectively. The mean dose of vadadustat (mg/day) 1 year after the treatment were 321.7 (ND), 373.1 (PD) and 386.9 (HD). The latest interim results up to June 2024 will be presented at Kidney Week 2024.

Conclusions: Any new safety concerns beyond those already described in the package inserts were not identified in the interim analysis of PMS.

Framework to Assess the Benefits and Risks of Treatments and Dosing Regimens for Anemia of CKD

Kevin Dykstra, Todd E. Minga, Bryce S. Foote, Zhiqun Zhang, Pamela C. Navarro Gonzales, Steven K. Burke. *Akebia Therapeutics Inc, Cambridge, MA.*

Background: Vadadustat (VADA) is an oral HIF prolyl hydroxylase inhibitor approved for treating anemia in adults with CKD on dialysis. VADA stabilizes HIF, stimulates endogenous EPO production, increases iron mobilization and RBC production. It is approved for use in 38 countries. The recommended starting dose for VADA is 300mg QD, with dose adjustments between 150-600mg to maintain Hb levels within target range. Alternative dosing regimens may be beneficial based on patient characteristics or preferences. We developed a framework to balance benefits and risks of VADA treatment with different treatment regimens.

Methods: The framework was developed by first identifying and ranking treatment attributes associated with any treatment for CKD-related anemia including efficacy, safety, and tolerability outcomes. An importance value (0-100) was assigned to each attribute. Specific outcome measures and relevant responses associated with each attribute were identified. Weights for each response within an attribute were elicited. The result was the benefit-risk framework in which a given treatment regimen could be assigned a net benefit or clinical utility score based on its performance in the benefit-risk framework, with the utility scores ranging from 0-100 after normalization.

Results: We identified and ranked 7 attributes (1 efficacy, 4 safety, and 2 tolerability/convenience) that contribute to the overall utility of a treatment for CKD anemia. Overall, efficacy (transfusion avoidance) contributed 25% to the utility score, while safety attributes (incidence of MACE, thromboembolic events, hospitalization for HF, and vascular access thromboses) contributed 60% of the net benefit; tolerability and convenience contributed the remaining 15% of utility. When combined with mathematical models predicting the probability of a given response for each attribute, the expected benefit-risk tradeoff for that regimen could be calculated and compared against alternative treatments or dosing regimens.

Conclusions: This benefit-risk framework will be used to identify and optimize treatment regimens for VADA in comparison to the standard of care (ESAs).

On-Treatment Analyses of Cardiovascular Safety in the Vadadustat Phase 3 Program

Wolfgang C. Winkelmayer,[1] Steven K. Burke,[2] Glenn M. Chertow,[3] Kevin Dykstra,[2] Kai-Uwe Eckardt,[4] Mark Koury,[5] Wenli Luo,[2] Todd E. Minga,[2] Eldrin F. Lewis.[3] *[1]Baylor College of Medicine Margaret M and Albert B Alkek Department of Medicine, Houston, TX; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Stanford University School of Medicine, Stanford, CA; [4]Charité–Universitätsmedizin Berlin, Berlin, Germany; [5]Vanderbilt University Medical Center, Nashville, TN.*

Background: Vadadustat (VADA) is an oral HIF-PHI for treating anemia in CKD. In the Phase 3 clinical program ($INNO_2VATE$: incident dialysis-dependent [DD]-CKD or prevalent DD-CKD; PRO_2TECT: ESA-untreated and ESA-treated non-DD [NDD]-CKD), VADA demonstrated noninferiority (HR=1.25 threshold) to darbepoetin alfa (DA) for MACE risk in DD-CKD (HR: 0.96, 95% CI, 0.83 to 1.11) but not NDD-CKD (HR: 1.17, 95% CI, 1.01 to 1.36) in primary ITT analyses. We conducted on-treatment analyses taking PK/PD profiles into account to better understand MACE risk.

Methods: The primary safety endpoint was time to first MACE (all-cause mortality, nonfatal MI, nonfatal stroke). Secondary safety endpoints were time to expanded MACE (MACE plus hospitalization for either heart failure or major thromboembolic event), CV MACE, CV mortality, and all-cause mortality. We adjusted on-treatment time at risk to include time to last treatment drug administration plus 28 days plus dosing frequency to account for PK/PD differences (VADA vs DA). For considering dosing frequency, we added 1 day for VADA and variable days (7-28 days) for DA.

Results: INNO$_2$VATE trials randomized 3902 patients (VADA=1947, DA=1955); PRO$_2$TECT trials randomized 3476 patients (VADA=1739, DA=1732). In the on-treatment analysis of DD-CKD, the risk of MACE was similar between treatment groups, consistent with results from ITT analyses (**Figure**). In the on-treatment analysis of NDD-CKD, the risk of MACE was similar between groups, and similar to results derived from the ITT analyses, inclusive of crossing the non-inferiority threshold. On-treatment analyses of secondary safety endpoints for DD-CKD and NDD-CKD populations were similar to their respective ITT analyses.

Conclusions: On-treatment dose-frequency-adjusted analyses address imbalances in PK/PD profiles and effective treatment duration between comparators and can complement results derived from ITT analyses.

Major Adverse Cardiovascular Events (MACE) in Patients Randomly Assigned to Vadadustat vs. Darbepoetin Alfa during the 3 Months after Dialysis Initiation

Wolfgang C. Winkelmayer,[1] Steven K. Burke,[2] Glenn M. Chertow,[3] Kai-Uwe Eckardt,[4] Eldrin F. Lewis,[3] Wenli Luo,[2] Todd E. Minga,[2] Mark J. Sarnak.[5]
[1]Baylor College of Medicine, Houston, TX; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Stanford University School of Medicine, Stanford, CA; [4]Charite Universitatsmedizin Berlin, Berlin, Germany; [5]Tufts University School of Medicine, Boston, MA.

Background: Trials and registries usually do not capture events during the weeks following dialysis initiation, when cardiovascular event rates and mortality are particularly high. The PRO$_2$TECT trials compared vadadustat (VADA), an oral HIF-PHI, and the ESA darbepoetin alfa (DA), in patients with non–dialysis-dependent (NDD)-CKD (ESA-untreated [NCT02648347] and ESA-treated [NCT02680574]). Many PRO$_2$TECT patients progressed to kidney failure and initiated dialysis, thus providing an opportunity to study this vulnerable incident dialysis period.

Methods: The PRO$_2$TECT Ph 3 trials randomized 3476 patients with anemia and NDD-CKD 1:1 to VADA or DA. This post-hoc analysis anchored baseline at dialysis initiation and followed patients for up to 90 days. We estimated cumulative incidences and rate ratios (RR) with 95% confidence intervals (CI) of MACE (all-cause mortality, nonfatal MI, nonfatal stroke) and expanded MACE (MACE plus hospitalizations for either heart failure or a thromboembolic event). We also described event rates in 30-day intervals for 90 days after dialysis initiation.

Results: 527 patients randomized to VADA and 539 patients randomized to DA initiated dialysis. The median [25th, 75th percentile] time since trial enrolment was 255 [122, 448] days in the VADA and 268 [142, 483] days in the DA group. In the first 90 days after dialysis initiation, 50 patients (9.5%) in the VADA group and 55 patients (10.2%) in the DA group had a MACE (RR=0.93; 95% CI: 0.65-1.34]). During the same time, 57 patients (10.8%) in the VADA group and 67 patients (12.4%) in the DA group had an expanded MACE (RR=0.87; 95% CI, 0.62-1.21). Incidence of expanded MACE was highest in the 30 days after dialysis initiation (Table), where most events were deaths.

Conclusions: Rates of MACE and expanded MACE within the first 90 days of dialysis initiation were similar among patients randomized to VADA vs. DA. The majority of these events occurred in the first 30 days after dialysis initiation.

Funding: Commercial Support - Akebia Therapeutics, Inc.

Expanded MACE After Dialysis Initiation

	Vadadustat N=527 n (%)	Darbepoetin alfa N=539 n (%)
1-30 days after dialysis initiation	36 (6.8)	40 (7.4)
>30-60 days after dialysis initiation	8 (1.51	14 (2.6)
>60-90 days after dialysis initiation	6 (1.1)	8 (1.5)

TH-PO903

Projected Long-Term Cost Savings with Roxadustat, a Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor (HIF-PHI), among Patients on Hemodialysis: Insights from a 100-Week Longitudinal Study

Satoshi Funakoshi, Jyunichiro Hashiguchi, Shinichi Abe, Kenji Sawase, Mayu Iwata. *Nagasaki Kidney Center, Nagasaki, Japan.*

Background: HIF-PH inhibitors are attracting attention for their novel mechanisms of action. However, the cost of the starting dose of HIF-PH inhibitors is considerably higher than biosimilar ESA, and it may limit the use of them. Nevertheless, HIF-PH inhibitors demonstrate targeting capabilities across numerous genes, hinting at potential advantages extending beyond just anemia alleviation.

Methods: Seventy-two hemodialysis (HD) patients receiving 9000 U/week of EPO were transitioned to roxadustat thrice weekly at 100 mg doses, titrated to maintain hemoglobin (Hb) levels between 10 to 12 g/dL. During the titration of roxadustat dosage, we carefully observed ferrokinetic and administered iron supplementation as necessary.

Results: The initial dose of roxadustat was approximately 261 mg/week, equivalent to about 4,000 yen/week, well above EPO's cost of about 2,600 yen/week. Over time, the dose of roxadustat gradually decreased, and as shown in the figure, after 60 weeks, the cost of roxadustat was almost equal to that of EPO. during 100 weeks, the dose/cost of roxadustat decreased to about 60% from the initial dose. At the same time, GNRI decreased slightly from 92 ± 12.4 to 87 ± 8.9 and CRP increased from 0.3 ± 0.14 mg/dL to 0.8 ± 0.14 mg/dL, but without statistical significance. No serious adverse reactions were reported.

Conclusions: Roxadustat, HIF-PH inhibitors, demonstrated the dose / cost reductions over long-term use. Given their reported cost-sparing advantages, HIF-PH inhibitors emerge as effective alternatives to ESA for managing anemia in HD patients. The observed reduction in cost over time subsequent to switching from EPO to roxadustat suggests underlying factors beyond nutritional and inflammatory statuses. Hence, further investigation into this phenomenon is warranted.

A Prospective Single-Center Study on Desidustat, a Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor (HIF-PHI), in the Management of Anemia in Dialysis-Dependent CKD

Arun Kumar Narayana. *Apollo Hospital Seshadripuram, Bengaluru, India.*

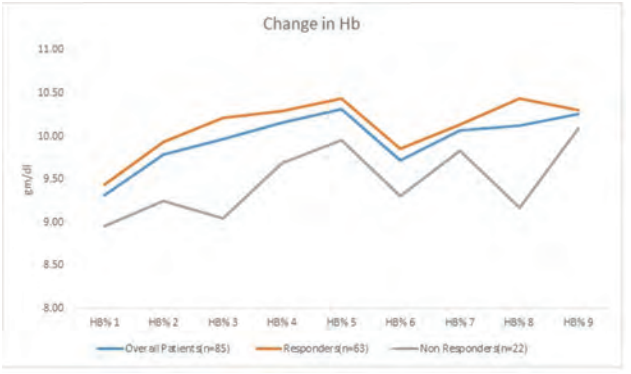
Background: Erythropoietin analogous is the backbone of the treatment of dialysis-dependent CKD –Anemia. Recently in India, Desidustat (Oxemia®) a HIF PHI approved by DCGI in dialysis-dependent and Non dialysis-dependent CKD Anemia. The current study enroutes the outcome of the usage of desidustat in DD-CKD Anemia patients.

Methods: We analyzed data of patients who were receiving Desidustat 100 mg thrice weekly for correction of Anemia at our center. Patients were followed up regularly for Anemia parameters.

Results: In the current study, we enrolled data from 85 patients at our center. The majority of 61 (71.7%) were male, and 24 (28.2%) were female. The mean age of participants was 51.27±14 years. The majority, 66 (77.6%), belong to the middle socioeconomic background. All the patients analyzed received three-time maintenance hemodialysis at our center. Patients with ESRD 71 (83.5%), hypertension 83 (97.6%), diabetic nephropathy 42 (49.4%), PVD 3 (3.5%), Alport syndrome 1 (1.1%), and CVD 1 (1.1%). The baseline serum creatinine of the patients was 6.4±1.5 mg/dl. Serum Iron 29.51±7.94, TSAT 25.06 ± 6.9, and Serum Ferritin 89.34 ± 39.19. In the present study, out of 85 patients, 63 (74.1%) responded with the treatment of anemia, while 22 (25.6%)

showed a low rise in Hb with desidustat treatment, as shown in figure 1. In the present study, out of 85 patients, 10 (11.7%) underwent renal transplantation and 3 (3.5%) expired. The reason for low Hb in 22 patients can be due to iron depletion. Gastrointestinal ADRs were observed with Desidustat therapy, which was treated appropriately.

Conclusions: The treatment of dialysis-dependent CKD anemia with Desidustat showed a promising response rate. Ensuring adequate iron repletion is crucial for optimizing the response to HIF-PHI treatment



TH-PO905

Impact of Roxadustat Kinetic Pharmacodynamics on Starting Dosage for Anemia in Dialysis-Dependent (DD) and Nondialysis-Dependent (NDD) Patients with CKD

Chenhui Deng,[1] Ping Liu,[1] Yiqing Wu.[2] *[1]Clinical Pharmacology Department, Linking Truth Technology Co., Ltd, Beijing, China; [2]Medical Affairs, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China.*

Background: We evaluated the impacting factors on roxadustat pharmacodynamics, and simulated relevant dosing regimens based on the established kinetic-pharmacodynamic (K-PD) model to support the starting dose optimization in Chinese CKD anemia patients.

Methods: The analysis included 9964 hemoglobin (Hb) data from 992 Chinese patients in 6 Phase 2/3/4 clinical studies. Based on the established K-PD model, Hb levels in these patients at standard or 1–step lower starting dosing regimen were simulated following 52 weeks of three times weekly administration. Dose adjustment was allowed based on Hb levels at Week 4 and later to maintain Hb levels within 10.5-12.0 g/dL.

Results: The Hb profiles in CKD anemia patients were well described with a cell lifespan model. Body weight, subject type (DD/NDD), and prior erythropoietin (EPO) dose (≥ or <10,000 IU/wk) were significant covariates for roxadustat dose at half of the maximum stimulation (ED_{50}); the effect of CKD stage (3&4) on ED_{50} in 1 Phase 4 study (NDD) was also included in the final model. For NDD CKD stage 3&4 patients, erythropoiesis-stimulating agent (ESA)-naïve DD patients, and ESA-treated DD patients with prior EPO dose <10,000 IU/wk, following the 1–step lower starting dose, adequate efficacy (10.5 g/dL≤ Hb <12.0 g/dL) could still be maintained and proportions of patients with high Hb levels (Hb ≥13.0 & Hb ≥12.0 g/dL) could be further reduced compared to the standard starting dose. For NDD CKD stage 5 patients, at the standard starting dose, a higher proportion of patients had an increase in Hb levels of 1-2 g/dL within the first 4 weeks without obvious increase in proportions of patients with high Hb levels, compared to the 1–step lower starting dose. For ESA-treated DD patients with prior EPO dose ≥10,000 IU/wk, at the standard starting dose, a higher proportion of patients maintained adequate efficacy for the first 8 weeks without obvious increase in proportions of patients with high Hb levels, compared to the 1–step lower starting dose.

Conclusions: For NDD CKD stage 5 patients and ESA-treated DD patients with prior EPO dose ≥10,000 IU/wk, the standard starting dose can be maintained. For NDD CKD stage 3&4 patients, ESA-naïve DD patients, and ESA-treated DD patients with prior EPO dose <10,000 IU/wk, the 1–step lower starting dose may be considered.

TH-PO906

Efficacy of Desidustat in Increasing and Maintaining Hemoglobin Levels in Anemic Patients with CKD

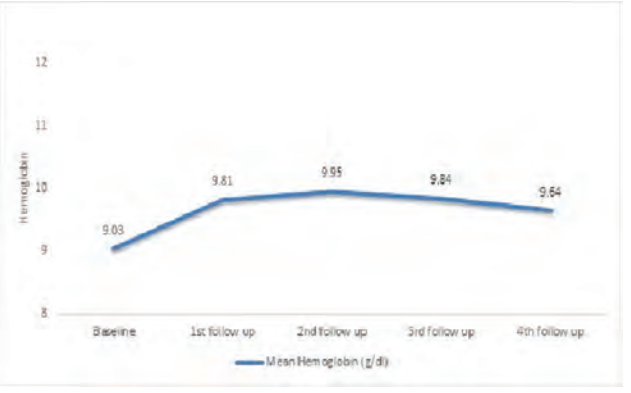
Manish R. Balwani. *Saraswati Kidney Care Center, Nagpur, India.*

Background: Desidustat, a novel hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor, offers a promising therapeutic approach by stimulating endogenous erythropoietin production and promoting red blood cell production. The study aims to contribute valuable insights into the potential therapeutic role of Desidustat in improving hemoglobin parameter in anemic - CKD patients.

Methods: This is a retrospective single centre, open label interventional study. Patients diagnosed with anemic CKD were enrolled into this study. The patients underwent desidustat therapy at a dosage of 100 mg thrice a week for the management of anemia associated with CKD. Regular follow -ups were conducted to monitor anemia and to ensure safety. In addition to anemia management, patients received standard treatment as per naive cause of CKD. Difference in hemoglobin parameter was analysed comparing the measurement at baseline to 4th follow up visit.

Results: Total of 79 patients were included into study, 43(54.4%) male and 36(45.6%) female (Mean age 54.62 ± 13.99). In these 79 patients, 42(53.2%) were having diabetes mellitus, 67(84.8%) were having hypertension, 21(26.5%) were having glomerulonephritis, 19(24.1%) were having diabetic retinopathy and 28(35.4%) were having diabetic nephropathy as a concomitant disease. 28(35.4%) patients were on regular maintenance haemodylasis and 51(64.5%) were on iron supplement as per their requirement. Following treatment with desidustat, significant improvements in mean hemoglobin levels were observed at each follow-up visit (P value <0.05). There were no any reported adverse events during the treatment follow-up period.

Conclusions: This study demonstrates the effectiveness of desidustat in improving significant hemoglobin levels in anemic CKD in both dialysis dependent and independent patients. A well designed, long duration, randomized controlled trial will further help in establishing this concept.



Mean rise in Hb($p<0.05$)

Safety and Efficacy of Vadadustat in Erythropoiesis-Stimulating Agent-Naïve Patients New to Dialysis Who Have CKD-Related Anemia

Glenn M. Chertow,[1] Steven K. Burke,[2] Eldrin F. Lewis,[1] Wenli Luo,[2] Todd E. Minga,[2] Mark J. Sarnak,[3] Kai-Uwe Eckardt.[4] *[1]Stanford University School of Medicine, Stanford, CA; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Tufts Medical Center, Boston, MA; [4]Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Vadadustat (VADA) is an oral HIF-PHI for treating anemia in CKD. In the phase 3 incident $INNO_2VATE$ trial in patients new to dialysis, VADA was noninferior to the ESA darbepoetin alfa (DA) for hemoglobin (Hb) efficacy, with a similar safety profile. Since this trial enrolled patients with and without prior ESA use, post hoc analyses of patients previously naïve to ESAs were conducted to better understand efficacy and safety of VADA in this subgroup.

Methods: A post hoc analysis of the incident $INNO_2VATE$ trial (N=369; NCT02865850) assessed the efficacy and safety of VADA compared to DA in ESA-naïve patients. Primary and secondary efficacy endpoints were mean change in Hb from baseline to the primary (PEP, weeks 24-36) and secondary (SEP, weeks 40-52) evaluation periods, respectively (noninferiority margin [lower bound of the 95% CI] of –0.75 g/dL). Other endpoints included the proportion of patients requiring ESA rescue and those with Hb levels >12g/dL and <9g/dL. Treatment-emergent adverse events (TEAEs), serious AEs (SAEs), and TEAEs leading to death were reported as safety endpoints.

Results: In the incident $INNO_2VATE$ trial, 192 patients were ESA naïve (VADA, n=89; DA, n=103). A majority (VADA, n=58 [65.2%]; DA, n=66 [64.1%]) had Hb <9.5 g/dL. In ESA-naïve patients, VADA was noninferior to DA for Hb efficacy during the PEP (LS mean treatment difference, -0.13; 95% CI, -0.44 to 0.18) and SEP (LS mean treatment difference, 0.05; 95% CI, -0.30 to 0.40). ESA rescue therapy was similar, with 9.0% and 10.6% (PEP) and 6.2% and 7.2% (SEP) of patients receiving it in the VADA and DA groups, respectively. Hb excursions >12.0 g/dL were more common in the VADA group (PEP, 25.6%; SEP, 30.4%) than the DA group (PEP, 18.9%; SEP, 21.2%). Hb concentrations <9.0 g/dL were seen with similar frequency in the VADA and DA groups during the PEP (VADA, 23.1%; DA, 18.9%) and SEP (VADA, 24.6%; DA, 28.2%). Safety endpoints were seen with similar frequency between treatment groups: TEAEs (VADA, 79.5%; DA, 86.3%), SAEs (VADA, 51.1%; DA, 57.8%), TEAEs leading to death (VADA, 11.4%; DA, 9.8%).

Conclusions: In this post hoc analysis of ESA-naïve patients new to dialysis with CKD-related anemia, VADA was noninferior to DA for efficacy and had a similar safety profile.

TH-PO908

Long-Term Safety of Vadadustat for Treatment of Anemia-Related CKD in Phase 3 Trials

Glenn M. Chertow,[1] Steven K. Burke,[2] Kai-Uwe Eckardt,[3] Mark Koury,[4] Wenli Luo,[2] Todd E. Minga,[2] Eldrin F. Lewis.[1] *[1]Stanford University Department of Medicine, Stanford, CA; [2]Akebia Therapeutics Inc, Cambridge, MA; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Vadadustat (VADA) is an oral HIF-PHI for treating anemia in CKD. In a safety analysis from the VADA phase 3 clinical program, VADA had a similar safety profile to darbepoetin alfa (DA) over the course of treatment with respect to treatment-emergent adverse events (TEAEs) and TEAEs of special interest (TEAESIs), including cardiovascular, hepatic, retinal, and neoplasm-related AEs. The present analysis evaluated the long-term safety of VADA compared with DA in patients from the phase 3 VADA clinical program.

Methods: Safety data were pooled from four global phase 3 trials that compared the safety and efficacy of VADA and DA in patients with CKD ($INNO_2VATE$: incident dialysis-dependent [DD]-CKD [NCT02865850] or prevalent DD-CKD [NCT02892149]; PRO_2TECT: ESA-untreated [NCT02648347] or ESA-treated [NCT02680574] with non-DD [NDD]-CKD). We compared the long-term (≥2 years) risk of TEAESIs and serious TEAESIs for each treatment arm. TEAESIs were grouped by medical topic. Rate ratios and 95% CIs were calculated for each TEAESI to evaluate potential differences between treatment arms.

Results: In the global phase 3 program, 2634 patients had ≥2 years of treatment and follow-up (VADA, n=1305, total patient years [PY]=3426.7; DA, n=1329, total PY=3512.4). Baseline characteristics were similar. TEAESIs were observed in 625 (47.9%; 42.2 events per 100 PY) and 696 (52.4%; 46.2 events per 100 PY) patients treated with VADA and DA, respectively (**Figure**). The frequency of serious TEAESIs was similar between VADA (259 patients [19.8%]; 12.3 events per 100 PY) and DA (292 patients [22.0%]; 14.5 events per 100 PY).

Conclusions: The long-term (≥2 years) safety profile of VADA was similar to DA in a pooled population of patients with DD- or NDD-CKD-related anemia.

Funding: Commercial Support - Akebia Therapeutics, Inc.

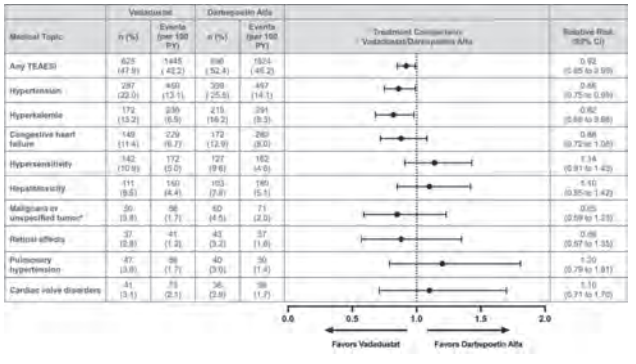

Figure. TEAESIs During Long-term Treatment. *Clear cell renal carcinomas were reported in 2 (0.2%) patients in the VADA group and 2 (0.2%) patients in the DA group.

TH-PO909

Single-Center 1-Year Experience with the Hypoxia-Inducible Factor-Prolyl Hydroxylase Inhibitor Desidustat (Oxemia) in Dialysis- and Nondialysis-Dependent Patients with CKD and Anemia

Vishal Saxena. *BLK Max Hospital, New Delhi, India.*

Background: Chronic Kidney Disease (CKD)-induced anemia results from a deficiency of erythropoietin. Recently, Desidustat, a HIF-PHI, approved in India, has shown promise in correcting anemia in both dialysis-dependent and non-dialysis-dependent CKD patients. This study presents a retrospective analysis of Desidustat usage in CKD anemia patients.

Methods: This retrospective analysis was conducted at BLK Max Hospital, New Delhi. Patients diagnosed with CKD received Desidustat at doses of 100 mg, thrice weekly, with regular monitoring of hemoglobin levels. Subjects with diabetic nephropathy, ADPKD, and a history of malignancy were excluded. The Desidustat dose was adjusted to maintain hemoglobin levels of 11-12 gm/dL.

Results: We enrolled 45 patients: 17 (37.7%) with CKD stage 3, 5 (11.1%) with CKD stage 4, 12 (26.6%) with CKD stage 5, and 11 (24.4%). Of these, 24 (53.4%) were male and 21 (46.6%) female. The majority (34, 75.5%) were non-dialysis-dependent, while 11 (24.4%) were dialysis-dependent. Hypertension was present in 40 (88.8%), diabetes in 11 (24.4%), hypothyroidism in 8 (17.7%), and hyperthyroidism in one patient. All patients received Desidustat thrice weekly with intravenous iron supplementation. Most patients (43, 95.5%) received 100 mg, one patient received 125 mg (2.2%), and another 150 mg (2.2%). The mean serum creatinine was 4.48 ± 1.28 mg/dL, eGFR was 23.17 ± 8.13 mL/min/1.73m2, and mean transferrin saturation (TSAT) was 21.21 ± 9.65%. The mean baseline hemoglobin was 10.28 ± 1.8 g/dL, which increased to 13.5 ± 1.7 g/dL by the end of the study ($p<0.05$, one-way ANOVA). Compliance with Desidustat was high, and no thrombosis, fistula failure, treatment failure, or hyperkalemia associated with HIF-PHI treatment was observed. Mild adverse events such as decreased appetite, vomiting, and generalized body weakness were transient and self-resolved.

Conclusions: Desidustat showed promising outcomes in improving hemoglobin levels in CKD-related anemia. Long-term data suggest that Desidustat is a safe alternative to erythropoietin analogues.

Pharmacovigilance Analysis of the US Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) Events for Belzutifan

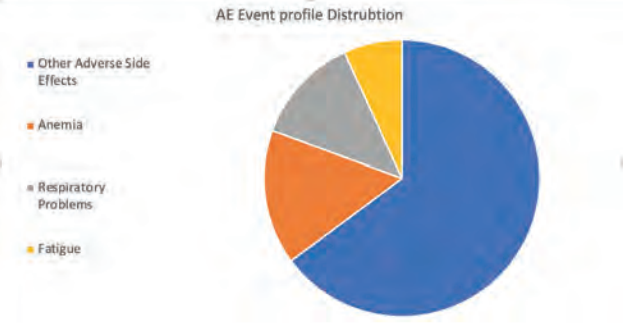
Abraham Bell, Stefan Milutinovic, Gautam Maddineni, Meloney Oliveira. *Florida State University, Tallahassee, FL.*

Background: Belzutifan is an anti-cancer medication used for the treatment of on Von Hippel–Lindau (VHL) disease-associated renal cell carcinoma. Belzutifan is a hypoxia-inducible factor-2 alpha (HIF-2α) inhibitor. The adverse effects reported with belzutifan use include, but not limited to, fatigue, anemia, dyspnea and acute kidney injury (AKI).

Methods: We explored belzutifan's reported adverse events using the FDA Adverse Reporting System (FAERS). We analyzed data that was used in the initial study to approve belzutifan from late 2021 until May 2024.

Results: A total of 731 adverse events were reviewed. The most common side effect reported was anemia in 115 cases (14.9%). The second most common side effect were respiratory problems (both hypoxia and dyspnea) reported in over 92 cases (12.6%). The third most common side effect was fatigue, which was present in over 50 cases (6.8%). Among all adverse effects, over 543 (24.3%) were classified as severe cases that required hospitalization. Of those 543 cases, over 62 (8.5%) resulted in death.

Conclusions: The side effects of belzutifan that were commonly reported in FAERS include fatigue, anemia and respiratory complaints. According to the LiteSpark study (1), the most common side effect was anemia, reported in over 25 percent of the patient cohort. According to our results that was also present amongst the most common side effects as well. With the new approval of this drug for the treatment of advanced RCC in the setting of VHL disease, it is crucial that there is ongoing monitoring and reporting of adverse events and safety monitoring as it is used to treat patients.



Adverse event profile distrubution by cases of FAERS

TH-PO911

Pharmacovigilance Analysis of the US Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) Events for Daprodustat

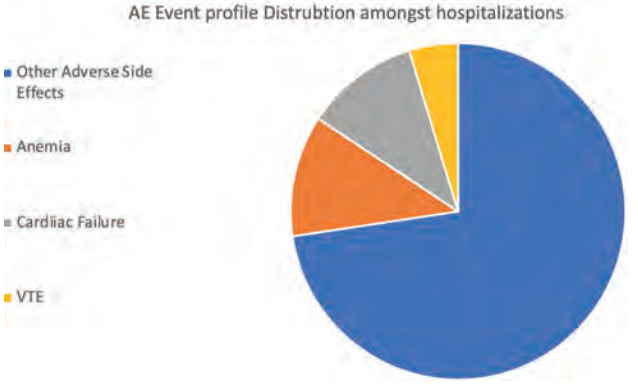
Abraham Bell,[1] Gautam Maddineni,[1] Stefan Milutinovic,[1] Isaac Bell,[2] Meloney Oliveira.[1] *[1]Florida State University, Tallahassee, FL; [2]Nova Southeastern University, Fort Lauderdale, FL.*

Background: Daprodustat was granted approval by the U.S. Food and Drug Administration on February 1st, 2023, marking it as the inaugural oral therapy for anemia induced by chronic kidney disease in adult patients undergoing dialysis for a minimum of four months. Notably, daprodustat carries a black box warning due to the heightened risk of thrombotic vascular events, myocardial infarction, cerebral vascular events, and mortality.

Methods: The adverse events associated with daprodustat were examined by utilizing the FDA Adverse Event Reporting System (FAERS). Our analysis encompassed data spanning from February 2023 to March 31st, 2024.

Results: A comprehensive review of 575 reported cases revealed that 318 cases necessitated hospitalization due to the severity of the adverse effects, with 147 reported fatalities. Notably, the most frequently reported event among hospitalized patients was a reduction in hemoglobin levels subsequent to the initiation of daprodustat (37 cases). The second most commonly reported event was cardiac failure, encompassing both new onset and acute exacerbation of chronic heart failure (35 cases). Additionally, venous thromboembolism (VTE) was reported in 15 cases.

Conclusions: FAERS analysis has highlighted anemia, acute exacerbation of heart failure, and venous thromboembolism as noteworthy adverse effects associated with daprodustat. Given its status as a novel medication, it is imperative to conduct further research and implement vigilant monitoring whilst on treatment with daprodustat.



FAERS Adverse event proflie amongst hospitalizations (severe cases)

Reversible Central Hypothyroidism Associated with Roxadustat in Patients Undergoing Hemodialysis

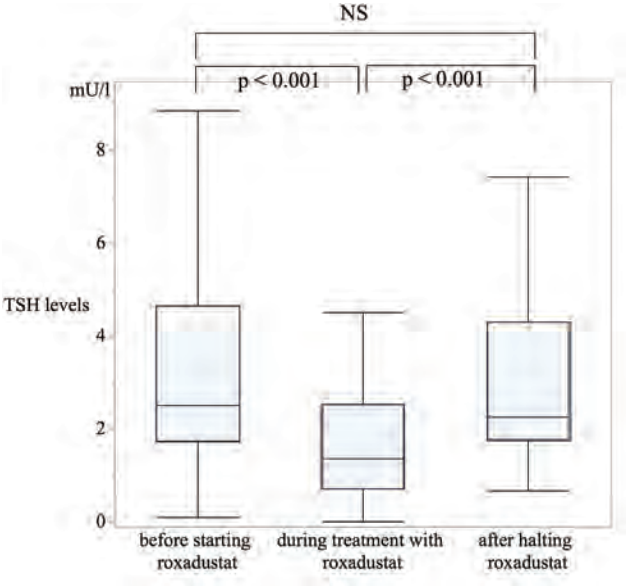
Emiko Otsuka,[1] Mineaki Kitamura,[1] Shinichi Abe,[2] Satoshi Funakoshi,[2] Tomoya Nishino.[1] *[1]Nagasaki Daigaku Byoin, Nagasaki, Japan; [2]Nagasaki Kidney Center, Nagasaki, Japan.*

Background: More than 90% of patients undergoing hemodialysis suffer from anemia. The conventional treatments involve the use of erythropoiesis-stimulating agents (ESAs) and iron supplementation. Recently, hypoxia-inducible factor-prolyl hydroxylase inhibitors (HIF-PHIs) have emerged as an alternative therapy for renal anemia. As roxadustat, one of HIF-PHIs, has been widely used, there have been several reports on central hypothyroidism associated with roxadustat. However, the prevalence and reversibility of roxadustat-associated central hypothyroidism in patients undergoing hemodialysis remain unclear.

Methods: We conducted a retrospective study at a single center. We included patients undergoing hemodialysis who were initially administered with roxadustat but later transitioned to ESA, and measured TSH, FT4, FT3 before, during, and after halting roxadustat treatment at the Nagasaki Renal Center from February 2020 to August 2023. We analyzed TSH, FT4, and FT3 levels in three periods: before starting roxadustat, during treatment with roxadustat, and after the discontinuation of roxadustat treatment. The Friedman test and the Bonferroni post hoc test were used to analyze.

Results: We analyzed 51 patients (mean age: 72.3 ± 10.7 years and 58.8% male). During the treatment, TSH significantly decreased from 2.46 (1.60–4.51) mU/l to 1.36 (0.72–2.41) mU/l(P<0.001) and FT4 decreased from 1.11 (0.97–1.24) mU/l to 0.92 (0.71–1.03) mU/l (P<0.001). After cessation, TSH and FT4 subsequently recovered to 2.56 (1.78–4.63) mU/l(P<0.001) and 1.05 (0.93–1.17) mU/l (P<0.001) (Figure). There were no significant differences in FT3 at the three points.

Conclusions: Roxadustat causes reversible central hypothyroidism in patients undergoing hemodialysis.



TH-PO913

Cutoff Value of Erythropoiesis-Stimulating Agent Resistance Index at Which Iron Replacement Therapy Is Expected to Be Effective

Chie Ogawa,[1,2] Ken Tsuchiya,[3,2] Taku Morito,[1] Hiroaki Io,[4] Kunimi Maeda.[1,2] *[1]Maeda Institute of Renal Research, Kawasaki, Japan; [2]Biomarker Society, INC, Kawasaki, Japan; [3]Department of Blood Purification, Tokyo Women's Medical University, Tokyo, Japan; [4]Juntendo Nerima Hospital, Tokyo, Japan.*

Background: Erythropoiesis stimulating agents (ESAs) in the treatment of renal anemia have provided tremendous long-term success, but the current problem is resistance to them. A number of causative factors can be cited, but the biggest concern is the issue of iron supply for iron deficiency and the lack of a useful iron indicator. Therefore, we investigated ESA resistance index (ERI) levels and the effects of oral iron replacement therapy (OIRT) in hemodialysis (HD) patients.

Methods: This study involved 81 courses in 67 HD patients with CRP< 0.3mg/dL who received OIRT. OIRT was performed for patients with serum ferritin <60 ng/mL and Hb <12 g/dL and continued for at least seven months(M7). The dose of darbepoetin alfa (DA) was adjusted to a target Hb level of 10–12 g/dL in accordance with the Japanese guidelines. The relationship of efficacy to changes in erythrocyte- and iron-related factors as well as baseline (M0) data was examined. Effective group was when (1) Hb increased by ≥1 g/dL or to >12 g/dL without an increase in DA, and (2) the DA dose was decreased. ERI = Weekly DA dose (μg) x 200/Hb level (g/dL)/body weight(kg).

Results: There were no significant differences in erythrocyte- and iron-related factors between the effective and ineffective groups at M0, and only the ERI was significantly higher in the effective group (9.0±7.6 vs 4.0±2.5, p=0.01). ROC curve analysis with efficacy as the endpoint showed a ERI cut-point value of ≥7.8 (sensitivity; 51.5%, specificity; 93.3%, AUC; 0.78, 95% CI; 0.66–0.90). In patients with an ERI ≥ 7.8, there were only 1 invalid cases. ERI showed significant monthly decreases down from M1 to 4 and maintained a constant value thereafter in effective group, whereas no significant change in ineffective group, and ERI was no significant difference between the groups at M7(4.9±3.8vs 3.8±2.8, p=0.32,). In effective group, red blood cell (RBC) counts and mean hemoglobin content (MCH) showed a significant increase. Serum ferritin significantly elevated at similar levels in both groups.

Conclusions: This study showed a decrease in ERI, and an increase in RBC and MCH in the effective group, suggesting that the proliferation of RBC and the production of hemoglobin were suppressed due to iron deficiency. Thus, iron replacement therapy may be effective in HD patients with CRP<0.3mg/dL and ERI≥7.8.

Hemoglobin Rate of Rise during Initial Treatment in Nondialysis-Dependent Patients with CKD and Anemia: Secondary Analysis of a Randomized Controlled Study

Ping Li,[1] Cuihua Huang,[2] Xiaoyan Xia,[2] Shuting Pan,[3] Guangyan Cai,[1] Xiangmei Chen.[1] *[1]Department of Nephrology, First Medical Center of Chinese PLA General Hospital, Nephrology Institute of the Chinese People's Liberation Army, National Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Disease, Beijing, China; [2]Medical Affairs, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China; [3]Clinical Biometrics, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China.*

Background: Clinical guidelines recommend a rate of rise (RoR) in hemoglobin (Hb) for chronic kidney disease (CKD) patients with anemia of 10-20 g/L/month, not exceeding 20 g/L/month during correction phase. We conducted a secondary analysis of a randomized study (ChiCTR2100045359) to evaluate RoR in Hb during the initial 8 weeks'treatment in non-dialysis CKD patients with anemia receiving a weight-based standard (<60/≥60 kg: 70/100 mg three times per week [TIW]) or lower (<60/≥60 kg: 50/70 mg TIW) starting dose of roxadustat.

Methods: This secondary analysis used existing data of a previous randomized study (primary results presented at ASN 2023 TH-PO1157). Patients treated with roxadustat who had at least one post-baseline Hb value were included. RoRs in Hb every 4 weeks and its distribution (ideal: 2.5-5 g/L/week; high: >5 g/L/week) during initial treatment (weeks 0–8) were evaluated.

Results: A total of 249 patients (126 in lower starting-dose and 123 in standard starting-dose arms) were included. Overall baseline Hb was 89.9±6.9 g/L. Patients in the lower-dose arm experienced slower ROR (g/L/week) in Hb during weeks 0–4 (3.3 [3.0] vs. 4.7 [3.2], P=0.0003) and weeks 0–8 (2.6 [1.9] vs. 3.3 [1.7], P=0.0024) compared to the standard-dose arm (Table). In the lower-dose arm, there were fewer patients with Hb RoR >5 g/L/week (4.8% [6/124] vs. 11.6% [14/121], P=0.0278), more patients with Hb RoR <2.5 g/L/week (45.2% [56/124] vs. 28.1% [34/121], P=0.0029), and a similar patients with Hb RoR 2.5–5 g/L/week during weeks 0-8 (50.0% [62/124] vs. 60.3% [73/121], P=0.0996) compared to the standard-dose group.

Conclusions: Both lower and standard starting doses of roxadustat corrected anemia with an ideal RoR in Hb for non-dialysis CKD patients during initial treatment. Patients receiving the lower starting dose had a slower RoR and fewer patients with high RoR.

Rate of rise in Hb during initial treatment

Statistic	Overall		CKD Stage 3-4		CKD Stage 5	
	Lower (n=126)	Standard (n=123)	Lower (n=77)	Standard (n=72)	Lower (n=49)	Standard (n=51)
Weeks 0-4, Mean (SD)	3.3 (3.0)	4.7 (3.2)	3.5 (3.0)	5.3 (3.1)	2.9 (2.9)	3.9 (3.1)
Difference, 95% CI	-1.4 (-2.2, -0.7)		-1.9 (-2.9, -0.8)		-0.9 (-2.2, 0.3)	
Weeks 4-8, Mean (SD)	2.1 (2.7)	1.6 (3.4)	2.1 (2.7)	1.0 (3.5)	2.0 (2.8)	2.6 (3.1)
Difference, 95% CI	0.4 (-0.4, 1.2)		1.0 (-0.0, 2.1)		-0.5 (-1.7, 0.7)	
Weeks 0-8, Mean (SD)	2.6 (1.9)	3.3 (1.7)	2.8 (1.8)	3.3 (1.8)	2.3 (2.1)	3.2 (1.7)
Difference, 95% CI	-0.7 (-1.2, -0.3)		-0.6 (-1.2, -0.1)		-0.8 (-1.6, -0.1)	

CI, confidence interval; CKD, chronic kidney disease; Hb, hemoglobin; SD, standard deviation.
Rate of Rise is defined as a slope from a linear regression model estimated using Hb values in the given time period.
Treatment comparisons were performed using Analysis of Covariance, taking baseline Hb and baseline estimate glomerular filtration rate as covariates.

TH-PO915

Hemoglobin Variability in Nondialysis-Dependent Patients with CKD and Anemia: Secondary Analysis of a Randomized Controlled Study

Ping Li,[1] Cuihua Huang,[2] Shirui Tang,[2] Shuting Pan,[3] Guangyan Cai,[1] Xiangmei Chen.[1] *[1]Department of Nephrology, First Medical Center of Chinese PLA General Hospital, Nephrology Institute of the Chinese People's Liberation Army, National Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing Key Laboratory of Kidney Disease Research, Beijing, China; [2]Medical Affairs, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China; [3]Clinical Biometrics, FibroGen (China) Medical Technology Development Co., Ltd., Beijing, China.*

Background: In a previous randomized study, a smaller absolute value of the rate of hemoglobin (Hb) change was seen during 16-weeks' treatment for non-dialysis patients with chronic kidney disease (CKD) and anemia receiving a lower roxadustat starting dose (<60/≥60 kg: 50/70 mg three times per week [TIW]) compared to the standard starting dose (<60/≥60 kg: 70/100 mg TIW), indicating less temporal Hb variability with a lower starting dose of roxadustat (previously published, ASN 2023 TH-PO1157). We conducted a secondary analysis of this study to evaluate Hb variability in both arms by non-temporal methods.

Methods: This was a secondary analysis of study ChiCTR2100045359. Patients treated with roxadustat and with at least one non-missing post-baseline Hb value were included. Hb variability was measured throughout the entire treatment period (16 weeks) by typical non-temporal methods: standard deviation (SD), coefficient variation (CV), and residual SD of Hb. The proportion of patients who achieved Hb treatment targets of 110–130 and 100–130 g/L averaged over weeks 12-16 was counted.

Results: A total of 249 patients were included (126 in lower starting-dose and 123 in standard starting-dose arms). Overall baseline Hb was 89.9±6.9 g/L. More patients in the standard-dose arm achieved the Hb treatment targets of 110–130 g/L (lower, 50.8% [64/126]; standard, 68.3% [84/123]; odds ratio [OR] [95%CI]: 0.54 [0.31, 0.94], P=0.0293), and 100–130 g/L (lower, 69.8% [88/126]; standard, 86.2% [106/123]; OR [95%CI]: 0.42 [0.20, 0.88], P=0.0217) averaged over weeks 12–16. Patients in the lower-dose arm had significantly less SD of Hb (lower, 11.1 [4.2] g/L; standard, 12.4 [4.1] g/L; difference [95%CI]: -1.4 [-2.4, -0.4] g/L, P=0.0078), and less residual SD of Hb (lower, 7.9 [4.0] g/L; standard, 9.1 [4.1] g/L; difference [95%CI]: -1.2 [-2.3, -0.2] g/L, P=0.0195). The CV of Hb was also less for the lower-dose arm, but the difference was not significant (lower, 10.8% [4.0%]; standard 11.4% [3.7%]; difference [95%CI]: -0.8% [-1.7%, 0.1%], P=0.0651).

Conclusions: More patients treated with the standard starting dose of roxadustat achieved Hb treatment targets at weeks 12–16. However, Hb variability during the 16-week treatment period was less for patients receiving the lower starting dose.

TH-PO916

Association of Hemoglobin Level with Mortality and Its Effect Modifiers in Patients Undergoing Maintenance Hemodialysis: A Nationwide Cohort Study

Takaaki Kosugi,[1] Takeshi Hasegawa,[2] Takahiro Imaizumi,[3] Hiroki Nishiwaki,[4] Hirokazu Honda,[5] Yasuhiko Ito,[6] Kazuhiko Tsuruya,[1] Masanori Abe,[7] Norio Hanafusa,[9] Takahiro Kuragano.[8] *[1]Department of Nephrology, Nara Medical University, Kashihara, Japan; [2]Institute of Clinical Epidemiology, Showa University, Tokyo, Japan; [3]Department of Advanced Medicine, Nagoya University Hospital, Nagoya, Japan; [4]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [5]Division of Nephrology, Department of Medicine, School of Medicine, Showa University, Tokyo, Japan; [6]Department of Nephrology and Rheumatology, Aichi Medical University, Nagakute, Japan; [7]Division of Nephrology, Hypertension and Endocrinology, Department of Internal Medicine, Nihon University School of Medicine, Tokyo, Japan; [8]Division of Kidney and Dialysis, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan; [9]Department of Blood Purification, Tokyo Women's Medical University, Tokyo, Japan.*

Background: The optimal range of hemoglobin (Hb) levels in patients on hemodialysis (HD) remains controversial. This study aimed to investigate the association between Hb levels and mortality in patients on HD, and to explore the potential factors modifying this association using the latest nationwide database in Japan.

Methods: This observational study utilized a nationwide database from the Japanese Renal Data Registry spanning from 2019 to 2021. This study included 265,779 patients who underwent HD thrice a week. The exposure of interest was the Hb level, which was categorized into six groups: <9.0, 9.0–9.9, 10.0–10.9, 11.0–11.9, 12.0–12.9, and ≥13.0 g/dL. The primary outcome was all-cause mortality. A multivariable Cox regression analysis was performed. The nonlinear relationship between Hb levels and outcomes was investigated using restricted cubic spline analysis. Subgroup analysis was performed to explore the potential factors modifying the association between Hb levels and all-cause mortality. Missing values were imputed using multiple imputations by chained equations.

Results: During a median follow-up period of 24 months, 45,734 patients died. Compared to the reference Hb category of 10–10.9 g/dL, the risk of all-cause mortality was higher in the Hb categories of <9.0, 9.0–9.9, and ≥13 g/dL with the adjusted hazard ratios (95% confidence intervals) of 1.24 (1.20–1.29), 1.09 (1.06–1.12), and 1.19 (1.14–1.25), respectively. Restricted cubic spline analysis also showed a U-shaped relationship between Hb level and mortality. The subgroup analysis indicated that the Hb category of 12.0–12.9 g/dL was associated with increased mortality risk in patients on dialysis for ≥10 years and those with a history of cerebral infarction.

Conclusions: Hb levels of <10.0 and ≥13.0 g/dL were significantly associated with an increased risk of mortality compared with an Hb level of 10.0–10.9 g/dL in patients undergoing HD. An Hb level of ≥12.0 g/dL was also associated with an increased risk in patients on dialysis for ≥10 years and those with a history of cerebral infarction.

TH-PO917

Treatment of Clinically Meaningful Anemia by Prescriber Type in Nondialysis-Dependent CKD Patients in the United States

Jeffrey Petersen,[1] Junjie Ma,[1] Carol Moore,[1] Matthew R. Weir,[2] Jeffrey S. Berns,[3] Robert D. Toto.[4] *[1]Amgen Inc, Thousand Oaks, CA; [2]University of Maryland School of Medicine, Baltimore, MD; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Anemia management in patients with non-dialysis dependent chronic kidney disease (NDD-CKD) remains suboptimal due to a lack of data to further understand the potential barriers. This study investigated anemia treatment patterns by prescriber type in NDD-CKD patients with clinically meaningful anemia (hemoglobin [Hb] < 10 g/dL).

Methods: This retrospective cohort study used the Optum electronic health record database (Jan 2015–Dec 2022) to describe the treatment of NDD-CKD anemia with red blood cell transfusion (RBCT), intravenous (IV) iron, or erythropoiesis stimulating agents (ESAs). Inclusion criteria included: age ≥ 18 years at CKD diagnosis, stage 3–5 CKD, ≥ 2 Hb measurements < 10 g/dL, and treatment-naïve for anemia. The date of first Hb result < 10 g/dL was the index date for anemia diagnosis. Temporal trends of anemia treatment patterns were analyzed and stratified by prescriber type.

Results: Overall, 88,917 NDD-CKD patients (mean [SD]: age, 73.9 [10.5] years; baseline Hb, 9.1 [0.6] g/dL) were included. During the follow-up (median [25th–75th percentile], 1.34 [0.50–2.94] person years), two-thirds of patients received no treatment. Among patients prescribed treatment at the index date, 20% received RBCT, 7% IV iron, and 8% an ESA; after index, 23% received RBCT, 9% IV iron, and 13% ESAs, alone or in combination. Among patients treated at index, 8% and 4% continued to receive treatment at 1- and 2-year follow-up, respectively. At 3 months, 61% and 30% of patients received RBCT or ESAs, versus 39% and 62%, respectively, at 1 year (Fig A). Among the 5 most common prescriber types, internists, surgeons, and oncologists prescribed RBCT to ~60% and nephrologists to 28% of patients (Fig B). ESAs (epoetin alfa and darbepoetin alfa combined) were prescribed to 25% and 50% of patients by oncologists and nephrologists, respectively.

Conclusions: A large proportion of NDD-CKD patients with clinically meaningful anemia remained untreated. RBCT was the most common initial treatment versus ESAs which increased with longer follow-up. Treatment patterns varied by prescriber type with nephrologists prescribing ESAs most frequently.

Clinical Implementation Framework of Anemia Control Model in Singapore

Jasmine Ion Titapiccolo,[1] Milind Nikam,[2] Nandakumar Mooppil,[2] Tripti Singh,[2] Andrea Gualdoni,[3] Jeffrey L. Hymes,[4] John W. Larkin,[4] Len A. Usvyat,[4] Francesco Bellocchio,[1] Luca Neri,[1] Julianna Yeung.[3] *[1]Fresenius Medical Care AG, Bad Homburg, Germany; [2]Fresenius Medical Care AG, Singapore, Singapore; [3]Fresenius Medical Care AG, Hong Kong, China; [4]Fresenius Medical Care AG, Boston, MA.*

Background: The efficacy and safety of the Anemia Control Model (ACM) in Europe is well documented. Since 2021, ACM was piloted and implemented in Singapore. We sought to report the uptake and outcomes of ACM in the first two years of clinical implementation.

Methods: Our clinical implementation framework was based on incremental piloting and expanding the use of ACM progressively in additional clinics (Fig 1). We evaluated hemoglobin (Hb) target achievement over 12-months follow up.

Results: In a preclinical feasibility analysis ACM accurately predicted Hb levels (mean absolute error=0.66). We piloted ACM in three clinics for usability and clinical performance and gradually expanded in the full network over two years. Doctors assessed 6597 suggestions generated by ACM (52% were accepted). ACM target achievement was higher in patients treated according to ACM suggestion (p<0.05) (Fig 2).

Conclusions: Despite improved target achievement, the uptake of ACM suggestions in clinical practice is still partial. More research should be conducted in advancing clinical implementation framework of artificial intelligence so that this technology can be more effectively utilized in clinical practice.

Funding: Commercial Support - Fresenius Medical Care, Private Foundation Support

TH-PO919

Association of CKD with Sarcopenia: A Population-Wide Study

Mackenzie R. Alexiuk,[1,2] Silvia J. Leon Mantilla,[3] Hailey V. Hildebrand,[4] Clara Bohm,[4,3] William Leslie,[4,5] Navdeep Tangri.[4,3] *[1]University of Manitoba Department of Community Health Sciences, Winnipeg, MB, Canada; [2]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [3]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [4]University of Manitoba Department of Internal Medicine, Winnipeg, MB, Canada; [5]St Boniface General Hospital, Winnipeg, MB, Canada.*

Background: Sarcopenia, defined as the loss of muscle mass, is a growing public health concern and is an underrecognized problem in adults with Chronic Kidney Disease (CKD). The diagnosis of sarcopenia can be made via measurement of appendicular lean mass index (ALMi, indexed to height by m^2), traditionally obtained through whole-body dual-energy X-ray absorptiometry (DXA) scans, however these are not frequently performed. As a result, large population-based studies examining the relationship between CKD and sarcopenia are lacking.

Methods: Using Manitoba longitudinal administrative health data, we identified adults who had at least one DXA scan linkable to serum creatinine values within 365 days, between 2007 and 2022. Serum creatinine was used to calculate estimated glomerular filtration rate, and estimated ALMi (eALMi) was calculated through central DXA scans via a previously developed algorithm. Linear, logistic, and Cox proportional hazards models were executed to examine the relationship between CKD, sarcopenia, and adverse clinical outcomes.

Results: Our cohort contained 24,660 individuals (64.4 ± 12.5 years, 84.4% female), with 3,204 individuals (13.0%) having eALMi indicating sarcopenia. 22,648 individuals (91.8%) had eGFR ≥ 60, and 2,012 (8.2%) had eGFR < 60. After adjustment for age, sex, estimated central mass index, and comorbid conditions, the presence of eGFR < 60 was associated with higher odds of sarcopenia (OR: 1.39; 95% CI: 1.16–1.67). In individuals with two DXA scans (n=2,985), eGFR < 60 at baseline was associated with a larger decline in eALMi compared to individuals with preserved eGFR (OR: 1.61; 95% CI: 1.05–2.45). Both sarcopenia and declining eALMi were also associated with adverse clinical outcomes including hospitalization and emergency room visits, home care use, long-term care use, and all-cause mortality.

Conclusions: Our results show that CKD is associated with sarcopenia and leads to more rapid declines in appendicular lean mass over time. These findings further validate our central DXA based measurement of eALMi and sarcopenia and highlight the importance preservation of muscle mass in individuals with CKD, especially in those with reduced eGFR.

Low Skeletal Muscle Area Measured by CT Is Associated with Osteoporosis in Patients on Hemodialysis

Hwajin Park. *The Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.*

Background: There are few studies to address the association of muscle and bone in dialysis patients and most of the previous studies assessed skeletal muscle mass with BIA and DXA. Whereas, we selected abdominal CT scans as assement tools for SMA because of an advantage of guaranteeing high accuracy and reproducibility. Thus, the purpose of this study is to examine the association between SMA measured by abdominal CT and BMD, and to investigate the risk of occurrence of osteoporosis with low measured SMA values.

Methods: We included 87 patients who underwent abdominal CT and BMD within 3 months after initial HD date at Daejeon St. Mary's hospital between January 2018 and September 2021. We used an abdominal CT image exported at the upper endplate of L3 transverse section and SMA was calculated by the open-source software program developed by Samsung Medical center of Korea in 2018. The BMD was measured by DEXA. All patients were divided into four SMA groups according to the interquartile ranges of measured SMA values to compare the impact of SMA groups on the osteoporosis occurrence.

Results: The mean SMA in all patients was 122.92 cm^2, and significantly higher in men (137.22 ± 26.48) than in women (106.88 ± 22.98). The positively correlated factors with both BMD were Sex(male), BMI, SMA, VFA. In multivariate regression analysis, the independent factor that most significantly affected with each BMD was the SMA ($\beta = 0.314$, $\beta = 0.974$). The risk for osteoporosis more increased as the subjects belong to the lower SMA groups (Very low SMA group; OR = 40.11, $p < 0.001$).

Conclusions: Low skeletal muscle area assessed by abdominal CT independently increases risk of osteoporosis occurrence in hemodialysis patients.

Figure 1. Correlation between SMA and lumbar spine BMD. (B) Correlation between SMA and proximal femur BMD.

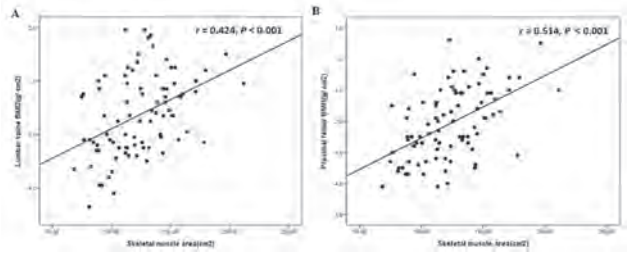

Table 4. Comparison of baseline clinical parameters among four SMA groups based on the interquartile ranges of measured SMA values.

	High SMA	Moderate SMA	Low SMA	Very low SMA	
	SMA ≥ 75 percentile (N = 22)	50 percentile ≤ SMA < 75 percentile (N = 22)	25 percentile ≤ SMA < 50 percentile (N= 21)	SMA < 25 percentile (N=22)	*p*-value
Age(years)	59.91 ± 10.98	67.14 ± 16.90	66.76 ± 12.38	67.73 ± 13.47	0.197
Sex Male, n(%)	18(81.8)	17(77.3)	8(17.4)	3(13.6)	< 0.001
BMI(kg/m^2)	27.58 ± 4.22	24.40 ± 3.12	22.78 ± 2.81	22.88 ± 6.97	0.003
Lumbar spine BMD (g/cm^2)	-0.65 ± 1.03	-0.77 ± 1.51	-1.51 ± 1.56	-2.26 ± 1.36	0.001
Proximal femur BMD(g/cm^2)	-1.39 ± 1.04	-1.69 ± 1.02	-2.46 ± 1.00	-2.81 ± 0.88	< 0.001

TH-PO921

Creatinine Filtration as an Indicator of Muscle Mass and Functional Status in Older Adults

Jacquelyn Ferguson,[1] Andrew S. Levey,[4] Lesley A. Inker,[4] Pranav S. Garimella,[3] Shoshana Ballew,[6] Tatsufumi Oka,[5,4] O. Alison Potok.[3,2] *[1]University of Vermont The Robert Larner MD College of Medicine, Burlington, VT; [2]San Diego Veterans Affairs Healthcare system, La Jolla, CA; [3]University of California San Diego, La Jolla, CA; [4]Tufts Medical Center, Boston, MA; [5]Osaka Daigaku, Suita, Osaka, Japan; [6]NYU Langone Health, New York, NY.*

Background: Low muscle mass is associated with frailty and mortality in older adults. Estimated creatinine (Cr) filtration, defined as the product of serum Cr by cystatin C-based glomerular filtration rate (eGFRCys) in mg/day/1.73m^2, has been associated with frailty and mortality. We hypothesized that lower Cr filtration would be associated with poor functional status and decreased muscle mass on imaging, in both men and women.

Methods: In the Health Aging Body Composition study, 2804 (91% of HABC) well-functioning community-living elders (aged 70-79) had serum Cr, cystatin C, functional status defined by the HABC physical performance battery HABCPPB (score 0=worst; 4=best), and appendicular lean mass (aLM) and fat free mass (FFM) on dual-energy X-ray absorptiometry (DXA). CKD-EPI 2012 and 2021 equations were used to calculate eGFRCys and eGFRCr-Cys respectively. Participants were stratified by sex and divided into Cr filtration tertiles. The association of Cr filtration with outcomes was assessed by linear regression.

Results: Mean(SD) age was 74(3) years, eGFRCr-Cys was 74(17) mL/min/1.73m^2, Cr filtration was 1049(246) mg/day/1.73m^2. Mean HABCPPB score, aLM and FFM were 2.3(0.5)points, 24(4) and 57(7)kg in men, and 2.1(0.5)points, 17(3) and 41(6)kg in women, respectively. Men and women in the highest vs lowest Cr filtration tertile walked faster (1.1(0.4) vs. 1.0(0.5)m/s for men; 1.0(0.4) vs. 0.8(0.5)m/s for women), and had stronger grip (40(8) vs. 35(7)kg for men; 24(6) vs. 21(5)kg for women). Higher Cr filtration (per SD) was associated with significantly better HABCPPB performance, higher aLM and FFM in both sexes (Table).

Conclusions: Higher Cr filtration was associated with better functional status, higher aLM and FFM in both men and women. These findings suggest it might be used clinically as a measure of muscle mass and function in older adults.

Funding: NIDDK Support

Association of Cr filtration (per SD) with functional status and with body composition, stratified by sex.

Clinical and Nutritional Variables Associated with Hospital Stay Days in Older Adults with CKD

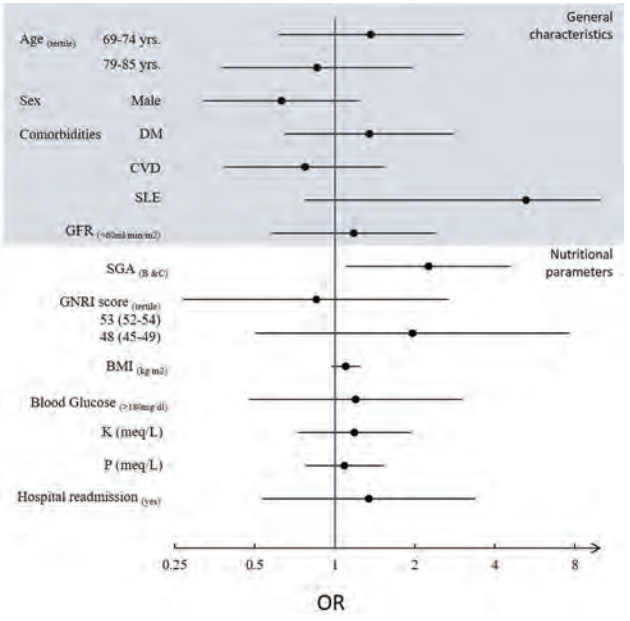
Sonia Lopez-Cisneros,[1] Samuel Ramos-Acevedo,[2] Ailema Janeth G. Ortiz,[3] Angeles Espinosa-Cuevas.[4] *[1]Instituto Nacional de Geriatria, Ciudad de Mexico, Mexico; [2]Mc Master University, Hamilton, ON, Canada; [3]Instituto Nacional de Pediatria, Mexico City, Mexico; [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: Malnutrition in hospitalized patients with chronic kidney disease (CKD) is a prevalent condition that is related to mortality, higher costs, and prolonged hospital stays, as well as higher hospital readmissions. The relationship between specific nutritional parameters and the days of hospital stay in our population with chronic kidney disease (CKD) has been little explored. We aimed to evaluate the association of days of hospital stay with different nutritional parameters and determine their relationship with hospital readmission.

Methods: Data was analyzed from the database of a retrospective cohort from 2007 to 2021 of patients with CKD who received nutritional care from our service. We included patients >60 years, both sexes, with at least one serum albumin, weight, and height record. Patients with terminal cancer, treatment with some renal replacement therapy, or with missing data were excluded.

Results: 419 patients were analyzed; those with longer days of hospital stay (>seven days) decreased serum albumin concentrations, and so did those with CKD stages 3Gb – 5, as well as lower scores in geriatric nutritional risk index (GNRI). Any degree of malnutrition assessed with the subjective global assessment was associated with a greater probability of prolonged stays (Table 1). No significant associations with hospital readmission were observed.

Conclusions: the detection and classification of malnutrition were related to longer days of hospital stay in patients with CKD.



TH-PO923

Creatinine Filtration as a Novel Index of Muscle Mass and Adverse Outcomes among Older Adults

Tatsufumi Oka,[1,2] Juan J. Carrero,[3] Shoshana Ballew,[4,7] Edouard Fu,[5] Yingying Sang,[4] Marie Evans,[3] Junichi Ishigami,[6] Lesley A. Inker,[2] Morgan Grams,[4] Josef Coresh,[4,7] Andrew S. Levey.[2] *[1]Osaka University Graduate School of Medicine, Suita, Japan; [2]Tufts Medical Center, Boston, MA; [3]Karolinska Institutet, Stockholm, Sweden; [4]New York University Grossman School of Medicine, New York, NY; [5]Leids Universitair Medisch Centrum, Leiden, Netherlands; [6]Johns Hopkins University Center for Health Security, Baltimore, MD; [7]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Low muscle mass is common among older adults and associated with poor prognosis. Quantifying muscle mass is challenging in routine clinical practice. We previously proposed estimated glomerular filtration of creatinine (eGFcr), the product of serum creatinine (Scr) times estimated GFR using serum cystatin C (Scys) (eGFRcys), as a practical index of muscle mass in older adults, and showed an inverse association with all-cause mortality (Ballew SH, et al. *JASN* 2023). The association of eGFcr with other clinical outcomes remains uncertain.

Methods: Using data from the SCREAM (Stockholm CREAtinine Measurements) project, a health care utilization cohort in Stockholm, we analyzed 82,154 adults aged ≥65 years who had same-day tests for Scr and Scys. We examined the associations of eGFcr with all-cause and cardiovascular mortality using sex-specific Cox regression models. The associations with recurrent outcomes (hospitalizations, infection, acute kidney injury, myocardial infarction or stroke, and heart failure) were examined using sex-specific negative binomial regression.

Results: At baseline, mean (SD) age and eGFRcys were 75 (8) years and 55 (24) mL/min/1.73 m^2 in men and 78 (9) years and 53 (23) mL/min/1.73 m^2 in women, respectively. During follow-up (median, 3.9 years), a lower quintile of eGFcr was significantly associated with a higher risk of all-cause mortality in men (hazard ratio [HR] in the lowest quintile [vs. the highest quintile], 3.74; 95% confidence interval [CI], 3.48–4.03) and in women (HR, 3.34; 95% CI, 3.09–3.60), and cardiovascular mortality in men (HR, 2.88; 95% CI, 2.50–3.32) and in women (HR, 2.92; 95% CI, 2.50–3.41) in multivariable models. A consistent monotonic association was observed in each recurrent outcome (P_{trend} <0.001) (Figure).

Conclusions: Lower eGFcr was associated with a higher risk of multiple adverse outcomes among community-based older adults. We suggest evaluating the clinical utility of assessing eGFcr in clinical and research settings.

TH-PO924

Risk Factors of CKD Progression in Elderly Patients by Stratified Analysis from 60s to 80s

Takahito Moriyama, Yuta Kimura, Rie Suzuki, Yoshitaka Miyaoka, Yoshihiko Kanno. *Tokyo Ika Daigaku, Shinjuku-ku, Japan.*

Background: The recent high care and the managements for elderly patients have been improving their problems about the lower quality of life with malnutrition, frail, cognitive dysfunction, and others. Those approaches might also change the CKD progression and risk factors. This study analyzed 7 years renal prognosis and the risk factors for progression by the stratified analysis from 60s to 80s of CKD patients.

Methods: The 328 elderly CKD out-patients who were visited our institution in January 2017 were divided into three groups according to the age of 60s, 70s, and 80s. The clinical and laboratory findings, and medication [renin angiotensin systems (RAS) inhibitors, statins, and any diuretics] were compared among these three groups, and the renal survival until end stage kidney disease (ESKD) and/or 50 % decrease of eGFR was analyzed by the Kaplan-Meier method and log-rank test. The risk factors for CKD progressions were analyzed by the univariate and multivariate Cox regression analysis in each 60s, 70s, and 80s.

Results: The sex distributions, mean arterial pressure (MAP), and body mass index (BMI) were similar among three groups (60s/70s/80s; MAP: 94.8/92.7/93.2 mmHg, p=0.196, BMI: 24.8/23.8/23.8 kg/m^2, p=0.054). Hemoglobin (Hb) and serum albumin were significant lower according to the ages (Hb: 12.6/12.0/11.7 g/dL, p<0.001, albumin: 3.9/3.8/3.7 mf/dL, p=0.005), but the eGFR (31.3/31.1/31.8 mL/min/1.73m^2, p=0.106) and other laboratory factors were similar among three groups. The administrations of RAS inhibitors and statins were similar, but any diuretics were significantly higher according to the age (28.0/31.6/47.7 %, p=0.01). The renal survival rates were similar among three groups (68.0/58.6/59.1%, p=0.149). The univariate and multivariate analysis indicated that CKD stage and the amount of proteinuria was the significant risk factors in any ages, and the other risk factors were higher BMI in 60s [hazard ratio (HR): 1.47, 95% confidence interval (CI): 1.07-2.02, p=0.017], and lower Hb in 70's (HR: 1.68, 95% CI: 1.28-2.21, p<0.001), but any medications were not related.

Conclusions: These results indicated that we should pay attention to CKD stage and the amount of proteinuria in any elderly CKD patients. Moreover, we should also pay attention to obesity in 60s and anemia in 70s to prevent form progression of CKD.

TH-PO925

Impact of the Kidney-Metabolic Pattern on Multimorbidity and Mortality among Elderly Inpatients in China

Mengjing Wang, Jing Chen. *Huashan Hospital Fudan University, Shanghai, China.*

Background: As populations age globally, multimorbidity has emerged as a significant challenge, complicating medical decision-making and deteriorating health outcomes. Chronic kidney disease (CKD) is a common condition among the aging population, yet its role and influence on elderly multimorbidity are seldom reported. This study aims to enhance the management and standardization of medical data and chronic disease diagnoses among elderly inpatients in China, investigating the prevalence and patterns of multimorbidity, with a specific focus on CKD-associated multimorbidity patterns and their prognosis.

Methods: Our study conducted a cross-sectional analysis using a large dataset from a single center, maintained by the comprehensive hospital at Fudan University, Shanghai, China. Data were collected from the electronic medical records system for patients aged over 60 years at Huashan Hospital, Fudan University, between January 1, 2013, and January 1, 2019.

Results: Our database included 163,626 elderly inpatients with a mean age of 69.8±0.1 years. The number of morbidities was positively associated with mortality. 80.7% of patients with CKD had other comorbidities. Factor analysis revealed four multimorbidity patterns in the elderly inpatients, named the "Kidney-metabolic" pattern, "Cerebro-vascular" pattern, "Cardio-pulmonary" pattern, and "Thyroid-digestive" pattern. The "Kidney-metabolic" pattern, characterized by CKD, Hypertension, Diabetes, and Lipid disorders, exhibited the highest prevalence at 13.3%. All four multimorbidity patterns were significantly positively associated with increased mortality. However, the

impact of the "Kidney-metabolic" pattern on mortality was the only one that significantly increased with age. Among patients with the "Kidney-metabolic" pattern, the odds ratios (OR) for mortality in those aged 80-89 and ≥90 years were 11.469 (95% CI: 9.066-14.508) and 49.237 (95% CI: 37.455-64.724), respectively, compared to those aged 60-69 years.

Conclusions: CKD plays a critical role in the multimorbidity of the elderly. The "Kidney-metabolic" pattern, the most prevalent among the elderly, significantly heightened mortality risk, particularly in the oldest cohorts. Clinical practices should prioritize the management of CKD and associated metabolic diseases within multimorbid contexts to reduce mortality and promote healthy aging.

Aortic Valve Alterations in Dialysis-Initiating Patients: Patient Background and Prognosis

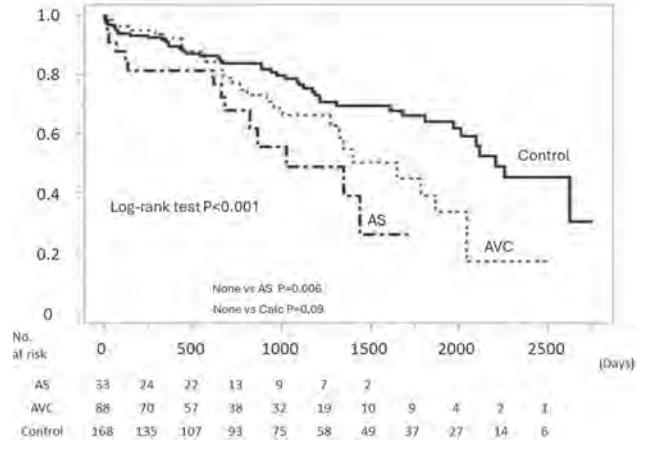
Mineaki Kitamura,[1,2] Tomoya Nishino.[1] *[1]Nagasaki Daigaku Byoin, Nagasaki, Japan; [2]Nagasaki Minato Medical Center Shimin Byoin, Nagasaki, Japan.*

Background: Aortic stenosis (AS) is a critical complication in patients undergoing, and aortic valve calcification (AVC) is considered a culprit lesion. However, little is known regarding aortic valve changes in dialysis-initiating patients, as past studies focused on those undergoing maintenance dialysis. We aimed to elucidate the relationship between AVC, AS, and patient survival following dialysis initiation.

Methods: Patients initiating dialysis between 2016 and 2023 were included. Echocardiograms assessed aortic valve changes, defining AS with a maximum trans-aortic velocity > 2.0 m/s. Patients were categorized into AS, AVC only, and control groups and followed up until February 2024. Multivariable logistic regression and Cox regression were used.

Results: We included 289 patients (mean age: 71.8 ± 12.2 years, 65.3% male, HD: PD=275:14). Aortic valve changes were identified in 121 patients (42%), with 33 patients (11%) meeting AS criteria. The mean ages for the AS, AVC only, and control groups were 79.1±8.9, 75.9±9.2, and 68.3±12.9, respectively (P<0.001). Multivariable logistic regression identified age as the sole factor associated with aortic valve changes (P<0.001). During a median follow-up of 718 (interquartile range 307-1353) days, 88 patients died. The log-rank test revealed significantly worse outcomes in the AS group. Even adjusted multivariable Cox regression indicated that AS was an independent death risk factor post-dialysis initiation (HR: 1.95, 95% CI: 1.06–3.59, P=0.04). However, aortic valve changes (AS + AVC only) were not a significant death risk (HR: 1.51, 95% CI: 0.95–2.39, P=0.08).

Conclusions: AS and AVC are associated with age in patients initiating dialysis. However, AVC only was not a risk factor for death, suggesting that risk factors related to AS, such as serum phosphate levels, should be strictly controlled following dialysis initiation.



Kaplan–Meier curves for aortic stenosis (AS), aortic valve calcification (AVC), and Control groups.

TH-PO927

Effect Modification of Familial Longevity on the Association between Cardiovascular Disease and Kidney Dysfunction

Laith Alzyood,[1,2] Tina Gao,[2] Sanish Sathyan,[2] Sandra Aleksic,[2] Sofiya Milman,[2] Michal L. Melamed,[3] Wei Chen.[2] *[1]Montefiore Medical Center, New York, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]New York University, New York, NY.*

Background: Chronic kidney disease (CKD) is among the strongest risk factors for cardiovascular disease (CVD) and mortality. Familial longevity may protect from age-related diseases. We hypothesized that familial longevity modified the association between CKD and CVD in older adults.

Methods: LonGenity is a cohort study of community dwelling Ashkenazi Jewish adults aged 65-94 years that aims to identify genetic determinants of familial longevity by comparing offspring of parents with exceptional longevity (OPEL, n=427) with offspring of parents with usual survival (OPUS, n=404). Exceptional longevity was defined as living past the age of 95 years. GFR was estimated using serum creatinine and CKD-EPI equation. Prevalent CVD was defined as a composite of myocardial infarction, coronary artery bypass graft, percutaneous intervention, or stroke. Multiple logistic regression was used to examine the cross-sectional association between eGFR and CVD. Effect modification with familial longevity (OPEL vs. OPUS) was tested using a first-order interaction term and stratified analyses.

Results: Mean age was 76±7 years, 57% were women, 9% had diabetes, 44.5% had hypertension, and 14.6% had CVD. Mean eGFR was 73 and 69 ml/min/1.73m2 in OPEL and OPUS, respectively. Familial longevity did not significantly modify the association between eGFR and CVD (p for interaction=0.99). In stratified analyses, after adjusting for age, sex, physical activity, hypertension, diabetes, and body mass index, the odds ratio for having CVD was 0.94 (95% CI: 0.84-1.04) for every 5 mL/min/1.73m2 higher eGFR among OPEL and 0.94 (95% CI: 0.86-1.02) for OPUS.

Conclusions: In this unique cohort, we found that familial longevity did not significantly modify the association between eGFR and CVD prevalence. Further studies are needed to examine whether kidney disease predicts the incidence or progression of CVD.

Development of a Prognostic Risk Score to Predict Early Mortality in Incident Elderly Japanese Patients on Hemodialysis

Hirokazu Okada,[1] Ken Sakai,[2] Ichiei Narita,[6] Toshiki Moriyama,[5] Yoshitaka Isaka,[5] Kei Fukami,[3] Eiichiro Kanda,[4] Naoki Kashihara.[4] *[1]Saitama Ika Daigaku, Iruma-gun, Japan; [2]Toho Daigaku, Ota-ku, Japan; [3]Kurume Daigaku Igakubu Daigakuin Igaku Kenkyuka, Kurume, Japan; [4]Kawasaki Ika Daigaku, Kurashiki, Japan; [5]Osaka Daigaku, Suita, Japan; [6]Niigata Daigaku, Niigata, Japan.*

Background: Information of short-term prognosis after hemodialysis (HD) introduction is important for elderly patients with chronic kidney disease (CKD) and their families choosing a modality of renal replacement therapy. Therefore, we developed a risk score to predict early mortality in incident elderly Japanese hemodialysis patients.

Methods: We analyzed data of incident elderly HD patients from a nationwide cohort study of the Japanese Society for Dialysis Therapy Renal Data Registry (JRDR) to develop a prognostic risk score. Candidate risk factors for early death within 1 year was evaluated using multivariate logistic regression analysis. The risk score was developed by summing up points derived from parameter estimate values of independent risk factors. The association between risk score and early death was tested using Cox proportional hazards models. This risk score was validated twice by using an internal validation cohort derived from the JRDR and an external validation cohort collected for this study.

Results: Using the development cohort (n=2,000), nine risk factors were retained in the risk score: older age (>85), yes=2, no=0; sex, male=2, female=0; lower body mass index (<20), yes=2, no=0; cancer, yes=1, no=0; dementia, yes=3, no=0; lower creatinine (<6.5 mg/dL), yes=1, no=0; lower albumin (<3.0 g/dL), yes=3, no=0; normal or high calcium (≥8.5 mg/dL), yes=1, no=0; and higher C reactive protein (>2.0 mg/dL), yes=2, no=0. In the internal and external validation cohorts (n=739, 140, respectively), the medium- and high-risk groups (total score, 6 to 10 and 11 or more, respectively) showed significantly higher risk of early death than the low-risk group (total score, 0 to 5) (p<0.001).

Conclusions: We developed a prognostic risk score predicting early death within 1 year in incident elderly Japanese HD patients, which may help detect elderly patients with a high-risk of early death after HD introduction.

TH-PO929

Serum Uric Acid and the Risk of Cardiovascular and All-Cause Mortality in Community-Dwelling Older Adults

Antonios Douros, Muhammad Barghouth, Nina Mielke, Natalie Ebert, Elke Schaeffner. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Several observational studies have shown moderate-to-strong associations between serum uric acid (SUA) and the risk of adverse cardiovascular outcomes and death. However, data on these associations among older adults are scarce. This is an important knowledge gap given the common use of SUA lowering drugs in this group, which are associated with several toxicities. Thus, we conducted a preliminary assessment of the association between SUA and the risk of cardiovascular and all-cause mortality among older adults.

Methods: We conducted a population-based prospective cohort study using data from the Berlin Initiative Study (BIS) linked to administrative healthcare data. Participants were followed from cohort entry until the occurrence of a study outcome or two years after their last individual visit, whichever occurred first. We created four exposure groups based on quartiles of SUA distribution at cohort entry – from low to high in mg/dL: Q1 [1.7,4.8], Q2 (4.8,5.8], Q3 (5.8,6.8], Q4 (6.8,13.0] – and used an intention-to-treat exposure definition (Q2 as reference group). Cox proportional hazards model estimated age- and sex-adjusted hazard ratios and 95% confidence intervals of cardiovascular and all-cause mortality.

Results: Overall, 2058 of the 2069 BIS participants were included. Mean age was 80 years, 53% were female, and the mean eGFR was 58 mL/min/1.73m^2. BIS participants with high SUA levels (Q4) were more likely to be male, obese, smokers, and to have prior cardiovascular or chronic kidney disease than those with lower SUA levels (Q1-Q3). During a median follow-up of 8 years, Q1 and Q3 were not associated with the risk of either outcome, when compared to Q2 (Table). Q4 was associated with a numerical, statistically non-significant increase in the risk of cardiovascular mortality and with a 30% increased risk of all-cause mortality, compared to Q2.

Conclusions: Our prospective cohort study suggests that high SUA is associated with the risk of all-cause, but not with cardiovascular mortality in older adults.

Patient Activation Impacts Physical Activity in Older Adults with CKD

Karan K. Mirpuri,[1] Christopher N. Roach,[2] Emily M. Woodall,[2] Heather L. Prigmore,[2] Robert Greevy,[2] Daniel Cukor,[3] Warren D. Taylor,[2] Ebele M. Umeukeje,[2] Rachel B. Fissell,[2] Kerri L. Cavanaugh,[2] Devika Nair.[2] *[1]Washington University in St Louis, St Louis, MO; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Rogosin Institute, New York, NY.*

Background: Older adults with Stage 3B-5 chronic kidney disease (CKD) experience high mortality due to cardiovascular disease. Though physical activity reduces cardiovascular risk, most older adults with CKD are sedentary. The few physical activity interventions for this group face high drop-out, potentially because they do not target factors that strongly impact activity. We tested whether Patient Activation, a modifiable psychological construct of knowledge, confidence, and skill, associates with physical activity frequency in older adults with CKD to explore its utility as an intervention target.

Methods: In a cross-sectional multi-site study, we collected validated psychological (including Patient Activation Measure-13 (PAM-13); 0-100, Levels 1-4) and physiologic (including Montreal Cognitive Assessment, Physical Frailty Phenotype) factors. Physical activity was measured with the first question of the validated Exercise Vital Sign, a report of the average days/week of moderate-to-vigorous physical activity. Comorbidities were obtained from the medical record.

Results: In 231 older adults with Stage 3B-5 CKD (median age 69, 46% women, 26% Black), median PAM-13 was 65.50 (Interquartile Range (IQR) [55.60, 75]). Higher Activation associated with more frequent days of moderate-to-vigorous physical activity. Adjusting for demographics, hemoglobin, body mass index, cognition, comorbidities, instrumental support, depression, anxiety, literacy, pain, and fatigue, a 19.4 point, or 1 IQR difference in PAM-13 associated with a 0.83 (95% Confidence Interval (CI) [0.36, 1.31]; p<0.001) increase in activity days. On average, frailty associated with fewer activity days, -1.89 (95% CI [-3.07, -0.71]); p<0.01).

Conclusions: Older adults with CKD reporting higher Activation also reported more frequent moderate-to-vigorous physical activity, independent of many conceptually relevant covariates.

Concentric vs. Eccentric Cycling: Effects of Progressive Training in Older Patients with CKD: A Randomized Trial

Chien Yao Sun,[1,3] Chia-Ter Chao,[2] Yu T. Chang.[1] *[1]National Cheng Kung University, Tainan, Taiwan; [2]National Taiwan University Hospital, Taipei, Taiwan; [3]University of California San Francisco Department of Medicine, San Francisco, CA.*

Background: Sarcopenia is common in CKD patients and leads to negative clinical outcomes. Eccentric cycling, which involves muscle lengthening under load, offers benefits like lower energy cost and perceived exertion, enabling higher intensity training. This study evaluates the effectiveness of a novel eccentric cycling (ECCcyc) intervention to reverse sarcopenia in older CKD patients.

Methods: Patients over 55 years with confirmed CKD were randomized into three groups: ECCcyc exercise, concentric cycling (CONcyc), or exercise education control. They completed 24 sessions over eight weeks, three times per week, for 20-30 minutes each on a stationary bike. Training was at RPE 13, starting at 50% of maximal cardiopulmonary output, with weekly increases of 5-10%. Efficacy (body composition, performance, cardiopulmonary fitness) was assessed at baseline and after intervention using the GEE statistical method.

Results: Thirty-one CKD patients were assigned to ECCcyc (11), CONcyc (10), and control (10) groups. Post-24 sessions, significant improvements were seen in the ECCcyc group in physical function, cardiopulmonary capacity, and quality of life. Skeletal muscle percentage increased by 3.4% in ECCcyc, while CONcyc and control groups declined by 4.4% and 4.1%, respectively (group-time interaction P<0.001). Knee strength rose from 26.2 to 30.1 kg (+14.9%) in ECCcyc, compared to 22.5 to 24.3 kg (+8.0%) in CONcyc, and decreased from 23.6 to 23.5 kg (-0.4%) in the control group. Peak oxygen consumption increased by 16.8% in ECCcyc and 15.7% in CONcyc, but decreased by 11.2% in the control group (P<0.001). The 6-minute walking distance increased by 6.5% in ECCcyc, 10.7% in CONcyc, and 3.8% in the control group (P<0.001).

Conclusions: This study provides promising evidence for the feasibility of a novel cycling modality to reverse sarcopenia in older CKD patients.

Evaluating Decision-Making Capacity in Elderly Patients with ESKD on Hemodialysis

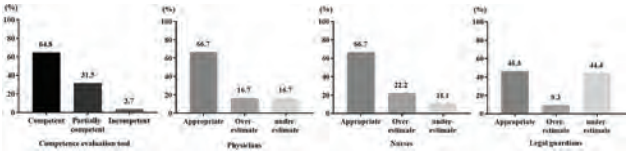
Byung chul Yu, Soo Jeong Choi, Moo Yong Park, Jin kuk Kim. *Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea.*

Background: Although the act on decisions on life-sustaining treatment including hemodialysis (HD) came into force in Korea, there is no specific mention to the assessment of the patient's decision-making capacity (DMC). We compared assessments of DMC of elderly patients with end-stage kidney disease (ESKD) on HD as provided by attending physicians, nurses, legal guardians, and a competence assessment tool.

Methods: The DMC of the 94 elderly patients aged 65 and more with ESKD on HD were assessed by physicians (n = 5), nurses (n = 18), legal guardians (n = 94), and the Korean version of the Capacity-to-Consent Screen (K-CCS) as an assessment tool. We analyzed the agreement between intuitive assessments by participants and objective assessments using K-CCS for patients' DMC.

Results: The mean age and dialysis vintage of the patients were 70.2 years and 15.1 years, respectively. The concordance with capacity assessed using the K-CCS was higher in physicians- and nurses- compared with legal guardians-rated capacity (64.8% both vs. 46.3%, p = 0.003). Compared to the capacity assessed by K-CCS, legal guardians tended to underestimate the capacity (Figure 1). While physician-rated capacity showed a good agreement (α = 0.634) with the assessments using the K-CCS, assessments by nurses and legal guardians showed a moderate agreement (α = 0.580 and 0.479, respectively). A good agreement between the competence assessments of the nurses versus those of the physicians (α = 0.768), but a moderate agreement between the assessments of the physicians and nurses versus those of the patients' legal guardians (α = 0.452 and 0.447, respectively), was observed.

Conclusions: Although the intuitive assessments by nephrologists showed a good agreement with the objective evaluation using assessment tools, one-third of their assessments were inaccurate. Particularly, the tendency of legal guardians to underestimate patients' DMC raises concerns about limiting patients' autonomy. Actively utilizing competence assessment tools may help in accurately evaluating DMC of elderly patients with ESKD on HD.



Comparison of the decision-making capacity of patients assessed by the competence evaluation tool with intuitive assessments by participants

TH-PO933

Clinical Outcomes between Planned and Unplanned Hemodialysis in Elderly Patients

Woo Yeong Park,[1] Jang-Hee Cho,[2] Byung chul Yu,[3] Sang Heon Song,[4] Jae Won Yang,[5] Sungjin Chung,[6] Young Youl Hyun,[7] Eunjin Bae,[8] In O Sun,[9] Hyunsuk Kim,[10] Won Min Hwang,[11] Sung Joon Shin,[12] Soon hyo Kwon,[13] Kyung Don Yoo,[14] Yu Ah Hong.[15] The Korean Society of Geriatric Nephrology (KSGN). *[1]Division of Nephrology, Department of Internal Medicine, Keimyung University Dongsan Hospital, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, Kyungpook National University Hospital, School of Medicine, Kyungpook National University, Daegu, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea; [4]Division of Nephrology, Department of Internal Medicine, Pusan National University Hospital, Busan, Republic of Korea; [5]Division of Nephrology, Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; [6]Division of Nephrology, Department of Internal Medicine, Yeouido St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Seoul, Republic of Korea; [7]Division of Nephrology, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [8]Division of Nephrology, Department of Internal Medicine, Gyeongsang National University Changwon Hospital, Changwon, Republic of Korea; [9]Division of Nephrology, Department of Internal Medicine, Presbyterian Medical Center, Jeonju, Republic of Korea; [10]Division of Nephrology, Department of Internal Medicine, Hallym University Chuncheon Sacred Heart Hospital, Hallym University College of Medicine, Chuncheon, Republic of Korea; [11]Division of Nephrology, Department of Internal Medicine, Konyang University Hospital, Daejeon, Republic of Korea; [12]Division of Nephrology, Department of Internal Medicine, Dongguk University Ilsan Hospital, Dongguk University School of Medicine, Goyang, Republic of Korea; [13]Division of Nephrology, Department of Internal Medicine, Soonchunhyang University Seoul Hospital, Seoul, Republic of Korea; [14]Division of Nephrology, Department of Internal Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea; [15]Division of Nephrology, Department of Internal Medicine, Daejeon St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Daejeon, Republic of Korea.*

Background: The initial mortality rate of hemodialysis (HD) is high in elderly patients with end-stage renal disease (ESRD). However, the clinical outcomes between unplanned and planned HD treatment among them and prognostic factors are not clear.

Methods: We analyzed 2,373 patients aged ≥70 years starting HD. We investigated patient survivals between unplanned and planned HD in elderly ESRD patients and risk factors for mortality.

Results: Unplanned HD patients were older, had a higher dementia, congestive heart failure (CHF) and activities of daily living dependency, lower BMI, hemoglobin, albumin, hypertension and diabetes. However, there were no significant differences in the proportion of ischemic heart disease, cerebrovascular accident, in the hospitalization history prior to HD initiation between planned and unplanned HD. The proportions of catheter use at dialysis initiation and maintenance vascular access were significantly higher in the unplanned HD patients than in the planned HD patients. In Kaplan-Meier analysis, unplanned HD patients showed significantly lower patient survival rate than planned HD patients. In multivariate cox regression analysis, male, older age at dialysis initiation, lower BMI, CHF, uncontrolled malignancy, lower activities of daily living dependency, hospitalization prior to HD, catheter use as a maintenance vascular access and lower serum albumin level were significantly associated with a higher risk of all-cause mortality.

Conclusions: In elderly ESRD patients, unplanned HD using catheter as maintenance dialysis has a poor prognosis, so it is necessary to plan the appropriate vascular access in elderly patients.

Comparison of the Expression Levels of Senescence Genes between Human Normal Kidney Cells and Kidney Tumor Cells According to Age

Woo Yeong Park, Yaerim Kim, Jin hyuk Paek, Kyubok Jin, Seungyeup Han. *Division of Nephrology, Department of Internal Medicine, Keimyung University School of Medicine, Keimyung University Dongsan Hospital, Daegu, Republic of Korea.*

Background: Although most carcinogenic mutations induce senescence, senescence-induced cell-cycle arrest can prevent mutations, resulting in the suppression of tumorigenesis. On the contrary, the senescence-associated secretory phenotype also contributes to a pro-inflammatory and growth-stimulatory microenvironment that can promote tumor development. Despite their potential correlation, the relationship between tumor- and aging-related transcriptional changes is largely unknown.

Methods: We integrated three datasets in publicly available bulk and single-cell RNA-seq: Gene Expression Omibus (GSE207493, GSE159115, GSE131685), and applied new senescent gene set in CellAge and SenMayo to our dataset. We classified them into younger and older age groups to compare senescent gene expression patterns in normal kidney and kidney tumor cells based on the age. The study aims to investigate the differences in expression patterns of senescence genes between them.

Results: We clustered normal kidney and kidney tumor cells in the UMAP plot. Kidney tumor was located on the proximal tubule. We compared senescent gene expression levels between normal kidney and kidney tumor cells, focusing on differences between younger and older age groups. ACTB and GAPDH were in the control group, and the expression of representative senescent genes p21 (CDKN1A), p16 (CDKN2A), and p53 (TP53) was confirmed. Among them, the expression difference in CDKN1A was found to be greater in kidney tumor cells than in normal kidney cells. I applied the new senescent gene set, and CTSS, G0S2, S100A11, NEAT1, and SERPINA1 showed similar patterns. This suggests that in kidney tumors, the difference in expression of senescent genes becomes greater with older age.

Conclusions: Kidney tumorigenesis might be associated with senescent genes. This result can serve as a basis for future studies on the role of aging and senescence in human kidney malignancies.

Integrating Palliative Care Consultation into a Hemodialysis Unit: A Pilot Study

Natanong Thamcharoen,[1] Pagaporn Asavapujanamanee,[2] Jeerath Phannajit,[1] Paweena Susantitaphong,[1,3] Kearkiat Praditpornsilpa.[1,3] *[1]King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Benchakitti Park Hospital, Bangkok, Thailand; [3]Chulalongkorn University, Bangkok, Thailand.*

Background: Patients on hemodialysis(HD) are rarely engaged in advance care planning(ACP), resulting in frequent use of invasive treatments that are futile at the end of life. This study aims to assess the impact of integrating palliative care consultations on ACP in a HD unit.

Methods: This single-center, prospective cohort study was conducted at Benchakitti Park General Hospital HD Unit in Bangkok, Thailand. Patients on chronic HD were screened, those who met any of the following criteria were enrolled:Older than 80 years, advanced organ failure, metastatic cancer, and Palliative Performance Score ≤ 40. The enrolled patients were referred to a palliative care specialist if the primary nephrologist agreed (palliative care group, PC); otherwise, they received routine care(routine care group,RC). The study compares these 2 groups for the number of ACP or code status discussions and treatments received at the end of life.

Results: One hundred and twenty-two patients were screened, 45 patients(36.9%) were enrolled and followed for 18 months. Mean age was 81.5±9.3 years. As shown in Table1, 10 out of 45 patients (22.2%) were referred to a palliative care specialist, while 35 patients received routine care. ACP was discussed in all patients in PC group, while none in the RC group had the discussion. Seven patients(70%) in PC group chose DNR/DNI. During the follow-up, 10 out of 45 patients(22.2%) died. Of those who died, 5 out of 8 patients(62.5%) in the PC group received comfort care at the end of life, while 1 out of 2 patients in the RC who died received comfort care. One patient in PC group who chose DNR/DNI initially had full resuscitation and died. Three patients in the PC group had planned HD withdrawal and died at home.

Conclusions: Significant numbers of patients on chronic HD require palliative care. Integrating palliative care to HD unit can assist patient with ACP. Patients who had palliative care consult had code status addressed more and received less aggressive care at the end of life.

Outcomes	Palliative care, PC group (N = 10)	Routine care, RC group (N = 35)

Prognostic Awareness among Patients with ESKD and Care Partners: Preliminary Themes from Semistructured Interviews

Annie Liu,[1,2] Amanda J. Reich,[3,2] Joshua R. Lakin,[4,2] Sahir Kalim.[1,2]
[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Dana-Farber Cancer Institute, Boston, MA.

Background: End stage kidney disease (ESKD) patients have shown limited prognostic awareness and less is known about their care partners. With older adults on dialysis and care partners being a crucial support source, we aimed to characterize various domains of prognostic awareness among patient-care partner dyads to inform the future delivery of goal concordant care.

Methods: We conducted 12 initial semi-structured interviews with ESKD patients on hemodialysis at a Boston hospital and their care partners using an interview guide developed by our research team (comprised of nephrologists, palliative care physician, and qualitative researcher). Qualitative analysis of audio-recorded, de-identified, transcribed interviews was performed. Inductive codes were identified based on Antonovsky's sense of coherence model.

Results: Analysis of 12 interviews (7 patients and 5 care partners) with a median duration of 33 minutes (19-40 minutes) revealed two preliminary themes: (1) Prognosis perception: Care partners viewed patient prognosis as time before death and shorter in duration than the patients. (2) Prognostic information preferences: Patients preferred prognostic information focused on changes in physical function, whereas care partners sought information on time remaining and expected end of life symptoms.

Conclusions: Preliminary data from this exploratory study suggest differing prognostic information needs within the dyads, possibly due to their distinct roles and responsibilities.

Participant sociodemographic and clinical characteristics

	Patient (n=7)	Care partner (n=5)
Age (years)	M=74 (67-84)	M=53 (38-65)

Kidney Palliative Care in the Outpatient Setting

Samantha L. Gelfand,[1,2] Kate Sciacca.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Dana-Farber Cancer Institute, Boston, MA.*

Background: Patients with advanced kidney disease have notable unmet palliative care needs that can affect quality of life, coping, and caregiver distress. In the United States, most outpatient specialty palliative care is devoted to patients with cancer. Few patients with advanced kidney disease have access to outpatient longitudinal palliative care. At our tertiary academic medical center, an interprofessional specialty palliative care team called KidneyPal has operated in the inpatient setting since 2019. KidneyPal developed the KidneyPal Outpatient Program (KPOP) to define and meet the palliative care needs of seriously ill outpatients with kidney disease.

Methods: We conducted a manual chart review of electronic medical records of patients seen in KPOP from October 2022-October 2023. We maintained a panel that lists all patients who have received care from KidneyPal in both inpatient and outpatient settings.

Results: Over one year, we convened 48 half-day KPOP clinic sessions. Half of these clinic sessions were staffed by a physician and nurse practitioner together, and half by the nurse practitioner alone. An average of 2.8 patients were seen per clinic session (range 0-6). A total of 138 visits occurred for a total of 63 unique patients. Mean patient age was 71.1 (range 23-91 years). Nineteen patients (30%) died during this period. Thirty-one patients (49%) were also cared for during hospitalization by the inpatient branch of the KidneyPal team. Thirteen patients (20%) elected conservative kidney management over dialysis for the treatment of kidney failure. Eleven patients (17%) received > 1 opioid prescription for the treatment of severe refractory pain.

Conclusions: Outpatient kidney palliative encompasses symptom management and decision support regarding treatment options for kidney failure. The patient population was seen in outpatient kidney palliative care is older and experiences high mortality rates. A substantial proportion may opt for conservative kidney management over dialysis if offered the choice. Approximately half of patients who received outpatient longitudinal palliative care in the clinic experienced hospitalizations during which they required inpatient palliative care consultation as well. Models of kidney palliative care should consider including outpatient resources to enhance care continuity and longitudinal relationships.

TH-PO938

Comprehensive Geriatric Assessment (CGA) and Optimisation Services before Kidney Transplantation in Older Potential Recipients: Results from the First UK-Wide Transplant Centre Survey Study

John Holland,[1,2] Judith S. Partridge,[1,2] Antonia Cronin.[1,2] *[1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]King's College London, London, United Kingdom.*

Background: In the UK, as elsewhere, chronic kidney disease (CKD) is more prevalent in older people. Kidney transplant is the treatment of choice for End-Stage-Kidney Disease (ESKD). As the number of patients aged over 60 with advanced CKD increases, the demand for transplants in this cohort will inevitably increase. Frailty, multimorbidity and cognitive impairment are seen frequently in old age and are associated with poorer transplant outcomes. CGA is a multidimensional multidisciplinary methodology that has demonstrated benefit at systematic review level in modifying outcomes relating to these factors. This national survey aims to describe availability of CGA and optimisation services across the UK, assess attitudes and beliefs on CGA among transplant clinicians and investigate practice relating to assessment and documentation of mental capacity prior to transplant listing.

Methods: A 21-question electronic survey was developed on the SurveyMonkey platform using established healthcare survey methodology including focus groups, piloting, and research-specific question design. Lead transplant clinicians at each of the UK's 23 transplant centres were contacted by email and invited to participate using a protected survey link between 24/04/24-15/05/24

Results: A 100% response rate was obtained (23/23). Most respondents reported that frailty (13/19) and cognitive impairment (9/18) in potential transplant recipients over 60 were not adequately addressed by current NHS services.17/19 (89%) of respondents were in favour of using CGA in this population though only 3 units offered CGA. Lack of funding (13/18) and clinical evidence (12/18) were reported as key barriers to implementing CGA services. Most respondents reported their unit lacked robust methods of assessing (10/18) and documenting (10/18) mental capacity of potential transplant recipients prior to listing.

Conclusions: Our nationwide survey shows that at present frailty, multimorbidity and cognitive impairment in older potential kidney transplant recipients are not being adequately addressed in the UK. An overwhelming majority of respondents were in favour of making CGA accessible to this group. Research is underway to develop a transplant-specific CGA to improve access to and outcomes from kidney transplant in this patient cohort.

TH-PO939

Polypharmacy and Potentially Inappropriate Medications among Elderly Patients with Advanced Stage G5 CKD

Masahiko Yazawa,[1] Hiroki Nishiwaki,[2,3] Minoru Murakami,[9] Yosuke Saka,[11] Kenichiro Koitabashi,[8] Masahide Furusho,[10] Yoshihiko Raita,[6] Hiroo Kawarazaki,[4] Hideaki Shimizu,[7] Takeshi Hasegawa,[5] Yugo Shibagaki,[1] Sho Sasaki.[12] Japanese InvestigatOrs with Innovative NeTwork about Kidney Disease (JOINT-KD). *[1]St. Marianna University School of Medicine, Kawasaki, Japan; [2]Showa Daigaku Fujigaoka Byoin, Yokohama, Japan; [3]University of Illinois at Chigo Division of Nephrology, Chicago, IL; [4]Teikyo University Hospital, Mizonokuchi, Kawasaki, Japan; [5]Showa Daigaku, Shinagawa-ku, Japan; [6]Okinawa Chubu Hospital, Naha, Japan; [7]Daido Byoin, Nagoya, Japan; [8]Inagi Shiritsu Byoin, Inagi, Japan; [9]Saku General Hospital, Saku, Japan; [10]Kagoshima Medical Center, Kagoshima, Japan; [11]Kasugai Shimin Byoin, Kasugai, Japan; [12]Kyoto Daigaku Igakubu Fuzoku Byoin, Kyoto, Japan.*

Background: The American Geriatrics Society identifies Beers Criteria and potentially inappropriate medications as medication use–related issues among the elderly. Patients with chronic kidney disease (CKD) experience polypharmacy when managing multiple conditions according to clinical practice guidelines. However, a standardized description of polypharmacy and Beers Criteria–listed medications (BCLM) among elderly patients with non-dialysis-dependent CKD stage G5, defined as an estimated glomerular filtration rate (eGFR) < 15 mL/min/1.73 m², is lacking.

Methods: This multicenter cross-sectional study of eight teaching hospitals in Japan included elderly (≥65 years old) and non-elderly patients with non-dialysis-dependent CKD stage G5. Study candidates were enrolled from April to June 2013, and their total daily number of regular oral medications was recorded. Super-polypharmacy was defined as ≥10 medications. Medication issues, including BCLM, were compared between groups. A multivariable logistic regression analysis was done to analyze factors related to super-pharmacy and BCLM use.

Results: Of the 600 participants, 412 were elderly. The mean age and eGFR of the elderly group were 76.8±7.0 years and 10.8 mL/min/1.73 m^2, respectively. Total medications were significantly higher in the elderly versus non-elderly group (9.2±3.8 and 8.4±3.6, respectively; p=0.001). Super-polypharmacy was more prevalent in the elderly versus non-elderly group (47% vs. 37%, respectively; p=0.042). Regarding BCLM, fewer elderly participants used insulin and potassium-sparing agents, whereas significantly more elderly participants took proton pump inhibitors and hypnotics. The logistic regression analysis revealed that age, welfare public assistance, hypertension, cardiovascular disease, and diabetes were significantly associated with super-polypharmacy. The BCLM analysis identified age as negatively associated with BCLM use.

Conclusions: Almost half of elderly patients with non-dialysis-dependent CKD stage G5 had super-polypharmacy. Age was significantly associated with polypharmacy but less associated with BCLM use. Although this vulnerable population requires many medications, nephrologists might pay attention to using PIMs.

TH-PO940

Age-Related Changes in Nephrons and Podocytes: A Morphometric Study of Japanese Autopsy Kidneys

Eisuke Kubo,[1] Kotaro Haruhara,[1] Takaya Sasaki,[1] Yusuke Okabayashi,[1] Go Kanzaki,[1] John F. Bertram,[3] Akira Shimizu,[2] Nobuo Tsuboi,[1] Takashi Yokoo.[1] *[1]Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; [2]Nihon Ika Daigaku, Bunkyo-ku, Japan; [3]Monash University, Melbourne, VIC, Australia.*

Background: Glomerular filtration rate (GFR) declines with age. However, how the number and size of nephrons and podocytes changes with age or age-related GFR decline is not fully elucidated.

Methods: Fifty autopsy kidneys without apparent kidney disease were studied. Subject age ranged from 28 to 85 years. The total number of non-sclerotic glomeruli (NSG) per kidney was estimated using design-based stereology. Podocyte number per glomerulus and glomerular and podocyte volumes were estimated using model-based stereology. Correlations between these parameters, age and estimated GFR without adjustment for body surface area (eGFR) were assessed using linear regression analysis.

Results: The median number of NSG was 421,547 per kidney and median podocyte number per glomerulus was 492. The loss of NSG averaged 9,040 per year (Fig A), and the total number of podocytes per kidney declined at a rate of 5.57 million per year (Fig B). Given that an average of 9,040 NSG were lost each year, the glomerulosclerosis-associated podocyte loss was estimated as a median of 4.4 million (IQR, 3.5×106–5.0×106) per kidney per year. The number of podocytes lost in each NSG per year was 2.7 (median, IQR 1.2–6.8). Both the number of NSG and total podocyte number per kidney were positively correlated with eGFR. Interestingly, despite the fact that both glomerular and podocyte numbers decreased with aging or eGFR decline, neither glomerular volume nor podocyte volume changed with age (Fig C and D) or eGFR.

Conclusions: This study is the first to quantitatively estimate nephron and podocyte morphometric indices associated with age and age-related GFR decline in the same population. These results suggest that a reduced number of nephrons and podocytes, and a lack of size compensation for these decreases, are characteristic morphological features of aging kidneys.

Age-Related Downregulation of TFEB Activity in Proximal Tubules Affects Systemic Lipid Metabolism and Causes Apolipoprotein A4-Related Amyloidosis

Jun Nakamura, Takeshi Yamamoto, Tomoko Namba-Hamano, Atsushi Takahashi, Jun Matsuda, Satoshi Minami, Shinsuke Sakai, Sho Matsui, Hideaki Kawai, Takuya Kubota, Yoshitaka Isaka. *Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan.*

Background: Transcription factor EB (TFEB) is important for longevity in *Caenorhabditis elegans* and age-related deterioration of several organs in mice. However, the role of TFEB in proximal tubules remains unknown.

Methods: We investigated TFEB nuclear translocation in mouse kidneys and human kidney biopsy samples. We generated TFEB proximal tubular epithelial cell (PTEC)-conditional knockout mice (TFEB cKO mice). Wild-type mice and TFEB cKO mice were bred for up to 24 months to elucidate the role of TFEB in PTECs of aged mice.

Results: TFEB nuclear translocation in PTECs was decreased in aged mice and older patients. Surprisingly, amyloid fibrils were prominently deposited in the glomeruli and the interstitium of several aged TFEB cKO mice. To identify amyloidogenic proteins, we isolated glomeruli by laser-capture microdissection and subject the sample to proteomics. Proteomic analyses indicated that apolipoprotein A4 (ApoA4) was the primary candidate. Indeed, ApoA4 was highly positive, corresponding to the distribution of amyloid deposits, and the hepatic *Apoa4* mRNA was increased. We found that hepatic steatosis was more severe in aged TFEB cKO mice, which may upregulate hepatic ApoA4, as previously reported. In addition, we verified white adipose tissue hypertrophy and increased circulating free fatty acids in aged TFEB cKO mice. These indicate that TFEB deficiency in PTECs of aged mice causes metabolic disorders. To further elucidate the role of TFEB in PTECs, we performed scRNA-seq analyses of the kidneys. The scRNA-seq analyses showed that both oxidative phosphorylation (OXPHOS) and lysosome pathways were downregulated in the PTECs of aged TFEB cKO mice. Electron microscopy revealed that the number of mitochondria-lysosome-related organelles, which are involved in mitochondrial quality control dependent on lysosomal function, was increased in the PTECs of aged TFEB cKO mice. Reflecting these results, succinate dehydrogenase staining, indicative of mitochondrial function, was also deteriorated in the PTECs of aged TFEB cKO mice.

Conclusions: TFEB deficiency in PTECs of aged mice induces metabolic disorder due to dysfunction of both OXPHOS and lysosome pathways, likely contributing to ApoA4-related amyloidosis.

TH-PO942

PRDM16 Attenuates Glomerular Aging by Upregulating Autophagy of Podocytes

Ben Tang, Qian Yuan, Chun Zhang. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Aging leads to age-related glomerulosclerosis and a decline in GFR, manifested by the loss and reduced density of podocytes. As terminally differentiated cells, podocytes have high autophagic activity to maintain cellular homeostasis. Reduced autophagy in podocytes results in their damage and accelerates aging. Previous research by our group found that PR domain-containing 16 (PRDM16) expression decreases in damaged podocytes; however, the role of PRDM16 in podocyte aging and its relationship with autophagy levels remain unclear.

Methods: We investigated the function and mechanism of PRDM16 in natural aging animal models and immortalized human podocytes cell line models to provide a theoretical basis for targeted delay of podocyte aging. The mouse models included 24-month-old wild-type mice with PRDM16 lenti-virus injected into the renal cortexand and naturally aging mice withSelective knockout of PRDM16 in podocytes($PRDM16^{Flox}$/$NPHS2^{Cre}$) mice, supplemented by various morphological and molecular biology tests. The cellular model used an immortalized human podocyte line treated with adriamycin and X-ray irradiation, supplemented by various morphological and molecular biology tests, to confirm that PRDM16 regulates autophagy levels and thereby affects podocyte aging.

Results: In aged mice kidney, podocyte damage and sclerosis worsen, and PRDM16 expression decreases in podocytes. In podocytes aged by adriamycin or X-ray irradiation, both transcription and translation levels of PRDM16 are reduced. In vivo, localized overexpression of PRDM16 in the renal cortex significantly reduces proteinuria levels in aged mice, improves autophagic flux, and protects podocyte function. Conversely, Specific knockdown of PRDM16 in podocytes in vivo further reduces autophagy and exacerbates podocyte damage, sclerosis, and aging in elderly mice. In vitro, overexpression of PRDM16 effectively restores autophagic flux stimulated by radiotherapy and alleviates podocyte aging while knocking down PRDM16 impairs autophagic function and exacerbates aging in podocytes. In podocytes, overexpression of PRDM16 increases the expression of the key autophagy gene ATG4A, while knocking down PRDM16 reduces ATG4A expression levels.

Conclusions: Upregulating PRDM16 can restore autophagic flux by increasing ATG4A expression, thereby delaying podocyte aging and improving glomerulosclerosis.

TH-PO943

Loss of Kidney Microvasculature during Aging Is Dependent on Several Pathways: A Study in African Turquoise Killifish

Anastasia Paulmann,[1,2] Matthew Cox,[1] Laura L. Beverly-Staggs,[1] Cory P. Johnson,[1] Hannah Somers,[1] Hermann Haller.[1,2] Haller Lab. *[1]Mount Desert Island Biological Laboratory, Salsbury Cove, ME; [2]Medizinische Hochschule Hannover, Hannover, Germany*.

Background: It has been proposed that age-related kidney dysfunction and chronic kidney disease are closely associated with the loss of microvasculature, microvascular rarefaction. However, microvascular rarefaction has not been studied in an aging model and the underlying mechanisms are unclear.

Methods: We analyzed vascular density of aging kidneys in a novel aging model, African turquoise killifish (Nothobranchius furzeri), with natural lifespan of 4-6 months and phenotypical signs of aging. We tested the effects of aging on microvascular structure in different organs (kidney as well as heart and liver). Microvascular density was analyzed by histology, immunostaining and in-situ hybridization. We further used single nuclei RNA sequencing (snucRNAseq).

Results: We were able to observe a significant reduction of the kidney microvasculature in aged kidneys. The loss of vascular density was most prominent in the kidney (63.3%), followed by heart (53.35%) and liver (49.2%). We observed a significant change in gene expression in molecular pathways of endothelial cell differentiation and metabolism.

Conclusions: Our results provide a better understanding of microvascular loss and allow the identification of novel treatment targets to prevent microvascular loss in aging kidneys.

TH-PO944

Cross-Talk of Tet2 and Autophagy Promotes Senescence and Kidney Aging

Xinyue Mao,[1,2] Lu Li,[1,2] Xiaoyan Li,[1,2] Xia Zhou,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN*.

Background: Kidneys are highly susceptible to the aging process. In renal aging, a complex interplay of genetics, epigenetics, and cellular dysfunction leads to a decline in renal function. Dysregulation of DNA methylation is a prominent feature of aging. However, the role of the ten eleven translocation (Tet) enzymes, which oxidize 5-methylcytosines (5mCs) and promote locus-specific reversal of DNA methylation, in senescence and kidney aging is largely unknown.

Methods: We performed Western blot, qRT-PCR, immunoprecipitation (IP), GST pull-down assay, reduced representation bisulfite sequencing (RRBS) and methylation-specific PCR (MSP) to investigate a crosstalk of Tets and autophagy in renal tubular cells upon induction of senescence and aged kidneys upon treatment with autophagy inhibitor or Tets activator.

Results: The proteins of Tets family members (Tet1, Tet2 and Tet3) were decreased in senescent renal tubular cells and in aged kidneys, but not their mRNAs, compared to the controls. Treatment with the autophagy inhibitor (lys05) but not the proteasome inhibitor (MG132) only blocked the downregulation of Tet2 protein but not Tet1/3 upon induction of senescence. Treatment with lys05 also increased the Tet2 protein levels in aged kidneys. We found that Tet2 interacts with ATG7, but not other autophagy proteins. Knockdown of ATG7 with siRNA also blocked senescence mediated Tet2 downregulation. Tet2 directly binds to ATG7 as examined with purified GST pull-down assay. We defined the domain of Tet2 that interacts with ATG7 with Tet2 truncated constructs. We further found that AMPK mediated Tet2 phosphorylation could decrease the interaction between Tet2 and ATG7, blocking autophagy mediated Tet2 downregulation in senescent renal tubular cells. By performing RRBS, we identified three autophagy-related genes (PIK3C2B, PIK3C3 and PIK3CA), which were hypermethylated in senescent renal tubular cells as examined by MSP. Treatment with Tet2 activator AA increased the expression of PIK3C2B, PIK3C3 and PIK3CA but decreased two senescence markers, p16 and p21, supporting a direct role of Tet2 in the regulation of autophagy and senescence.

Conclusions: Tet2 is recognized as a substrate of autophagy, and is subjected to autophagy protein ATG7 mediated degradation. The downregulation of Tet2 increased the methylation of autophagy-related genes in senescent renal tubular cells and aged kidney.

TH-PO945

Role of Podocyte Ceramide Synthase 6 and C16 Ceramide in Aging-Related Kidney Changes in Marmosets

Yihan Yuan,[1] Qinyue Wang,[1,2] Qingwei Zhao,[1] Hak Joo Lee,[1,3] Ian M. Tamayo,[1] Esmeralda Trevino,[1] Balakuntalam S. Kasinath,[1] Daohong Zhou,[1] Kumar Sharma,[1,3] Guanshi Zhang.[1,3] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Columbia University, New York, NY; [3]Audie L Murphy Memorial Veterans' Hospital, San Antonio, TX*.

Background: The marmoset, a nonhuman primate, has been established as a valuable model for studying the aging kidney. Aged marmosets' kidneys exhibit glomerulosclerosis, tubular fibrosis, and an increased urinary albumin to creatinine ratio. Signaling pathways related to protein synthesis and fibrosis were activated in the kidneys of these aged marmosets. Matrix-assisted laser desorption/ionization-mass spectrometry imaging (MALDI-MSI) analysis has revealed alterations in lipid profiles within the glomeruli of aging mouse kidneys, with a particular accumulation of ceramides (Cer) in the aging kidney. However, the role of Cer metabolism in the progression of aging-related renal changes in marmosets remains unclear.

Methods: We investigated the lipid profile in glomeruli *in situ* using MALDI-MSI-based spatial metabolomics (spatial resolution: 20 μm). The study included young male and female (around 3 years; n=4/gender), aged male and female (around 16 years; n=5/gender) marmosets from the Southwest National Primate Research Center. A targeted list of lipids involved in ceramide metabolism was extracted from the glomeruli of young and aged marmosets for comparisons. The protein level of Cer synthase 6 (CERS6) in kidney cortical tissues was measured using western blotting. Given that CERS6 is specifically expressed in podocytes of human kidneys according to single-cell transcriptomics, immunofluorescence (IF) staining was employed using anti-synaptopodin (a podocyte marker) and anti-CERS6 antibodies.

Results: Univariate and multivariate analyses revealed significant changes in lipid species involved in Cer metabolism within the glomeruli of aging marmosets. Notably, C16 Cer accumulated in the glomeruli of aged marmosets. The enzyme CERS6, which biosynthesizes C16 Cer, was significantly elevated in the kidney cortex of aging marmosets compared to young controls. IF demonstrated that CERS6 was specifically expressed in podocytes of marmoset kidneys and its expression increased with age.

Conclusions: These findings indicate dysregulation of Cer metabolism in the glomeruli (e.g., podocytes) of aging marmoset kidneys. This provides valuable insights into potential therapeutic targets and enhances our understanding of the pathological and metabolic changes associated with renal aging.

Characterization of Aging-Associated Renal Phenotypes in Renal Tubular Cell-Specific NFAT5 Knockout Mice

Kosuke Maruyama, Yuichiro Izumi, Makoto Ono, Yutaka Kakizoe, Takashige Kuwabara, Masashi Mukoyama. *Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan*.

Background: The number of patients with chronic kidney disease (CKD) and hypertension is increased with age; however, it is not clearly defined why and how aging causes renal dysfunction and hypertension. Nuclear factor of activated T-cells 5 (NFAT5) is a transcription factor that is activated upon hypertonic conditions as observed in the renal medulla. Genome-wide association study has suggested that NFAT5 variants are associated with the elevation of blood pressure. We have shown that the renal tubular cell-specific NFAT5 conditional knockout (KO) mice exhibit salt-sensitive hypertension, while the mice exhibit impaired urine concentrating ability and are susceptible to renal fibrosis. These phenotypes resemble aging-associated renal dysfunction, i.e., urine concentrating disorder, salt-sensitive hypertension, and renal fibrosis. We therefore investigated the possible involvement of NFAT5 in aging-related changes of the kidney.

Methods: Aged NFAT5 KO mice (18 months old) were characterized in terms of aging-related renal phenotypes and compared with wild type (WT) mice. Kidney function was evaluated by serum creatinine. Gene expressions of senescence-associated secretory phenotype (SASP)-related factors (IL-6, IFNγ, TGF-β1, CDKN1A (p21), CDKN2A (p16), COL1A1, PAI-1, MMP3) were examined by real-time PCR. Renal fibrosis was evaluated by AZAN staining.

Results: Gene expressions of SASP-related factors were significantly increased in KO mice compared with WT mice. KO mice exhibited renal atrophy and fibrosis in the medulla. Serum creatinine was significantly higher in KO mice than in WT mice.

Conclusions: These results suggest that renal tubular NFAT5 protects against the progression of aging-associated chronic kidney disease.

TH-PO947

Vitamin D Receptor Deficiency Promotes Premature Aging by Inducing Pericytes and Microvessel Loss

Xujiao Chen. *Huashan Hospital Fudan University, Shanghai, China.*

Background: Aging is a complex process influenced by a variety of factors and demonstrates organ-specific characteristics. A common hallmark of pathological changes across various organs is the decline in microvascular density. However, the molecular mechanisms governing organ-specific microvascular decline and aging are still not well understood. Vitamin D receptor (VDR) plays a crucial role in maintaining vascular health, and its deficiency is associated with numerous age-related diseases. Nonetheless, whether VDR regulates the aging process via microvascular pathways remains unreported.

Methods: We extracted data in the Tabula Muris Senis database, and analyzed the changes in the expression of VDR with age. The VDR knockout mice was established and the changes of kidney, bone, heart, liver, lung, muscle, skin, spleen, and other tissues and organs at the age of 3 to 12 months in aging related indicators at the functional, histological and molecular biological levels were obeserved. Single cell RNA sequencing was performed in the kidneys of 6-month-old wild type and VDR knockout mice, while RNA velocity and pseudo-time analysis were used to simulate the dynamic changes of cell. adeno-associated virus (AAV) transfection technology was mainly used to carry out in vivo research in mice. Kidney pericyte-specific VDR knockdown and overexpress model were established to validate the function of pericyte in kidney aging. Finally, the effect of VDR on pericytes angiogenesis was investigated through 3D co-culture of pericytes and endothelial cells.

Results: In this study, we demonstrate that VDR deficiency leads to premature aging, prominently affecting the kidneys. Using single-cell RNA sequencing, we identified pericytes as the most significantly altered cell subtype within the kidney in VDR knockout mice. Further analysis revealed a marked decrease in pericytes and microvessels in both VDR knockout and kidney pericyte-specific VDR knockdown mice. Notably, an augmented pericyte-myofibroblast differentiation was observed, suggesting a potential mechanism underlying the observed microvascular dysfunction in the absence of VDR, which contributed to the aging process.

Conclusions: Our investigation into the role of VDR in the decline of pericytes and microvessels throughout the aging process holds the potential to unveil novel therapeutic strategies for delaying multi-organ aging.

ZFYVE21 Sustains Akt-Endothelial Nitric Oxide Synthase (ENOS) Signaling to Promote Vascular Barrier Function in the Kidneys during Aging

Dan Jane-wit. *Yale University School of Medicine, New Haven, CT.*

Background: We previously identified ZFYVE21 as a Rab5 effector in ECs. ZFYVE21 is a zinc finger-containing protein implicated in cell motility whose functions *in vivo* are unknown. In cultured human endothelial cells (ECs), we previously observed that ZFYVE21 localized to Rab5+ vesicles where it modulated PI(3,4,5)P3 content to enable Akt activation. As part of these studies, we incidentally observed that ZFYVE21 was highly expressed in glomerular ECs as well as peritubular capillaries. These observations prompted us to examine ZFYVE21 in Akt-mediated ENOS activity, a pathway critical for homeostasis of vascular barriers.

Methods: We used gene targeting to generate endothelial cell (EC)-specific ZFYVE21 KO reporter mice where ECs were labeled with GFP while other cells expressed RFP. We performed whole blood chemistries and inulin clearance measurements in mice. We analyzed human and mouse kidney tissues using I.F., in situ hybridization, Western blots, co-immunoprecipitations, and electron microscopy. We performed live cell imaging studies using mutant reporter constructs.

Results: We found that ZFYVE21 levels significantly decline in ECs in aged human and mouse kidneys. To investigate attendant effects, we analyzed EC-specific ZFVYE21$^{-/-}$ reporter mice. ZFYVE21 EC$^{-/-}$ mice developed accelerated aging phenotypes including reduced ENOS activity, failure to thrive, and renal insufficiency; and kidneys from ZFYVE21 EC$^{-/-}$ mice showed interstitial edema and glomerular EC injury. ZFYVE21-mediated phenotypes were not programmed developmentally as loss of ZFYVE21 in ECs during adulthood phenocopied its loss prenatally, and a nitric oxide donor normalized kidney function in adult hosts. Using live cell imaging and human kidney organ cultures, we found that, in a Rab5- and Akt-dependent manner, ZFYVE21 reduced vesicular levels of inhibitory caveolin-1 and promoted transfer of Golgi-derived ENOS to a perinuclear Rab5+ vesicular population to functionally sustain ENOS activity.

Conclusions: Our work defines a ZFYVE21-mediated trafficking mechanism sustaining ENOS activity and demonstrates the relevance of this pathway for maintaining kidney function with aging.

Relationship between Psychological Resilience and Health Outcomes in Older Adults with Advanced CKD

Brett Burrows,[1] Anika Lucas,[1,2] C. Barrett Bowling,[1,2] Rasheeda K. Hall.[1,2]
[1]Duke University School of Medicine, Durham, NC; [2]Durham VA Health Care System, Durham, NC.

Background: Resilience, defined as the ability to recover from stressful events, is important for healthy aging. However, resilience has not been well studied in older adults with advanced chronic kidney disease (CKD), a subpopulation at high risk of stress due to wavering health status. Towards a goal of improving or maintaining resilience in older adults with advanced CKD, there is a need to identify factors related to resilience. We aimed to examine the association of depressive symptoms, physical activity (PA), and community mobility with psychological resilience.

Methods: This cross-sectional study surveyed 30 older adults (≥55 years of age) with advanced CKD (eGFR<30 ml/min/1.73m^2) seen at a routine nephrology visit to assess the potential correlation (Pearson's correlation coefficient) between psychological resilience and depressive symptoms, PA levels, and community mobility. Psychological resilience was assessed by the Resilience Scale (scores range 25 to 175, cut-offs: ≤120= low resilience, 121-145= moderate resilience, ≥146= high resilience). Depressive symptoms were assessed by the Center for Epidemiological Studies Depression (CESD) (higher scores indicate greater depressive symptoms). PA was measured by the PA Scale for the Elderly (PASE) (higher scores indicate increased PA) and community mobility was measured by the Life-space Assessment (LSA) score (higher scores reflect greater mobility).

Results: Mean (SD) age was 73.0 (9.8) years, 56.7% were female, 56.7% were Black race, and participation rate was 85.7%. The majority reported low to moderate levels of resilience (60%), with a mean (SD) of 138.0 (21.4). Participants also reported low levels of PA (mean= 71.2, SD= 72.8) and community mobility (mean= 58.6, SD= 26.7), and elevated depressive symptoms (mean= 13.9, SD= 9.9). The CESD had the strongest correlation (r= -.82 (p< 0.001)) to psychological resilience, with both the PASE and the LSA displaying moderate strength correlations (r= .38, p= 0.04; r= .47, p< 0.01, respectively).

Conclusions: The majority of participants had low to moderate levels of resilience. We found that depressive symptoms had a strong inverse correlation with psychological resilience. Future studies should examine the underlying mechanisms of this relationship and potential therapies to promote resilience among older adults with advanced CKD.

TH-PO950

Impact of Frailty on Performance of the Kidney Failure Risk Equation Using Creatinine- and Cystatin C-Based eGFR

Heather Walker, Michael K. Sullivan, Bhautesh D. Jani, Katie I. Gallacher, Patrick B. Mark. *University of Glasgow College of Medical Veterinary and Life Sciences, Glasgow, United Kingdom.*

Background: There is a high prevalence of frailty in people with chronic kidney disease (CKD). Frailty is associated with increased risk of mortality. Risk predictions equations, such as the kidney failure risk equation (KFRE) can guide management. Consideration of the competing risk of mortality on risk of future need for kidney replacement therapy is important. Decline in muscle mass in frail people may impact accuracy of creatinine-based eGFR. Using Cystatin C based eGFR (eGFRcys) or combined creatinine and Cystatin C eGFR (eGFRcrcys), may improve risk stratification of future kidney failure. We assessed the impact of frailty on performance of KFRE using eGFRcr, eGFRcys and eGFRcrcys in the UK Biobank research cohort.

Methods: Adults with CKD G3-5 (eGFR<60mL/min/1.73m^2 by any of eGFRcr, eGFRcys and eGFRcrcys) were studied. Frailty was assessed by the Fried, Rockwood and laboratory frailty indices. The outcome was kidney failure, i.e.long-term dialysis or kidney transplantation. KFRE performance at 2- and 5-years was assessed.

Results: 24,489 participants were studied; 8,533 (34.8%) had frailty by at least one frailty measure. The frail group had a mean age of 62.4 years (SD 5.7), 57% were female and mean eGFRcr 67.7ml/min/1.73m^2 (SD 17.7) compared to mean age 63.1 years (SD 5.6), 52% female and mean eGFRcr 64.5 ml/min/1.73m^2 (SD 14.8) in the non-frail group (all p<0.001). The frail group had higher discrepancy between eGFRcys and eGFRcr compared to the non-frail (-15.8 vs -6.9 ml/min/1.73m^2, p<0.001). There were 312 (1.27%) kidney failure and 1,471 (6.01%) death events within 5-years. Discrimination power of KFRE was good in individuals with and without frailty (AUC ≥0.87 across all frailty measures and eGFR equations). A higher risk of kidney failure was demonstrated in frail compared to non-frail groups with increased divergence between Kaplan-Meier and Aalen-Johansen cumulative incidence curves suggesting greater impact of the competing risk of death in the frail group.

Conclusions: KFRE adequately predicts kidney failure risk in individuals with frailty. GFR estimated using equations containing Cystatin C does not impact performance. Further work developing models considering competing risk of death may refine the risk of kidney failure in individuals with frailty.

Association between Urine Albumin and Estimated Glomerular Filtration Rate with Incident Frailty in Healthy Older Adults: Secondary Analysis of the ASPREE Trial Cohort

Elisa K. Bongetti,[1,2] Anna Wilkinson,[3,4] James B. Wetmore,[5] Anne M. Murray,[6] Robyn L. Woods,[3] Sara E. Espinoza,[7] Michael E. Ernst,[8] Michelle A. Fravel,[8] Suzanne G. Orchard,[3] Le T. Thao,[3] Joanne Ryan,[3] Rory Wolfe,[3] Kevan Polkinghorne.[1,2] *[1]Department of Nephrology, Monash Health, Melbourne, VIC, Australia; [2]Monash University Department of Medicine, Clayton, VIC, Australia; [3]School of Public Heath and Preventative Medicine, Monash University, Melbourne, VIC, Australia; [4]Disease Elimination, Burnet Institute, Melbourne, VIC, Australia; [5]Division of Nephrology, Hennepin Healthcare, Minneapolis, MN; [6]Berman Center for Outcomes and Clinical Research and Department of Medicine, Hennepin Healthcare Research Institute, and Department of Medicine, Geriatrics Division, Hennepin Healthcare Minneapolis, Minneapolis, MN; [7]Center for Translational Geroscience, Department of Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; [8]Department of Pharmacy Practice and Science, College of Pharmacy; and, Department of Family Medicine, Carver College of Medicine. The University of Iowa, Iowa City, IA.*

Background: Identifying risk factors for frailty may facilitate early diagnosis and intervention to preserve functional status. The association between estimated glomerular filtration rate (eGFR) and albuminuria (spot urine albumin to creatinine ratio, UACR) with incident frailty in generally healthy older individuals is unclear. This study aimed to investigate whether abnormal kidney function is associated with incident frailty assessed by the modified Fried frailty phenotype (FP), and, separately, a deficit accumulation frailty index (FI).

Methods: This was a secondary analysis of 16,965 non-frail older adults aged ≥65 years in the ASPirin in Reducing Events in the Elderly (ASPREE) randomised trial cohort. Primary exposures were UACR, and eGFR calculated with the Chronic Kidney Disease Epidemiology Collaboration 2021 equation. Missing data in the FP was managed with multiple imputation. The primary outcome was time to incident frailty, analysed using multivariable adjusted discrete time survival analyses.

Results: The mean age was 75.0 ± 4.5 years, median eGFR 78.5mL/min/1.73m^2 (IQR 67.5, 89.3), and the median UACR was 0.80 mg/mmol (IQR 0.50, 1.50). In analyses using the FP, 950 people developed frailty over a median follow-up of 4.7 years (IQR 3.0, 5.0). Using the FI, 2,338 developed frailty over a median of 4.0 years (IQR 3.0, 5.0). The relationships between eGFR and both incident FP and FI was non-linear, such that an eGFR <45 or ≥75mL/min/1.73m^2 was significantly associated with an increased risk of incident frailty. For every doubling of baseline UACR, risk of incident frailty increased by 4% using the FP (HR: 1.04, 95%CI:1.02-1.07) and the FI (HR: 1.04, 95%CI:1.01-1.07).

Conclusions: In older adults, doubling of UACR, even at very low levels, was independently associated with incident frailty. Both low and high eGFR were associated with increased risk of incident frailty.

TH-PO952

Impact of Y-Chromosome Loss on Age-Related Gene Expression

Jose L. Agraz, Parker C. Wilson. Wilson Lab. *University of Pennsylvania, Philadelphia, PA.*

Background: Loss of Y chromosome (LOY) is associated with compromised DNA repair, increased inflammation, and diminished immune surveillance. Single-cell RNA sequencing (scRNA-seq) elucidates the impact of LOY in the kidney, which may provide insight into how LOY heightens susceptibility to chronic kidney disease (CKD), acute kidney injury (AKI) and renal cancer. This study analyzes a large scRNA-seq dataset from the Kidney Precision Medicine Project (KPMP) to examine the effects of aging and LOY in different kidney cell types.

Methods: The KPMP dataset comprised 174 participants: 87 males, 85 females, and 2 individuals with an unspecified sex, aged 20 to 89. These data include samples from healthy individuals (n=55) and patients with CKD (n=82), AKI (n=33), and diabetes mellitus without CKD (n=3). scRNA-seq raw data was realigned, preprocessed to remove doublets, and integrated using scvi-tools. LOY cells were genotyped based on the lack of Y chromosome transcripts in cells meeting prespecified filters. Differential expression was compared between groups using scanpy.

Results: We observed significant age-related changes in gene expression among multiple kidney cell types. In aged men, *TTTY14* and *USP9Y* (Y chromosome transcripts) were significantly decreased in healthy proximal tubule (PT) and injured PT subsets, parietal epithelial cells, and distal nephron cell types. Cell types with the highest proportion of LOY were injured subsets of proximal tubule: PT_MT (22%), PT_PROM1 (17%), and PT_VCAM1 (13%). LOY in PT was associated with enrichment of multiple pathways, including calcium reabsorption, immune response, and metabolic pathways.

Conclusions: LOY significantly impacts gene expression in PT of aging males. Elevated LOY in PT cell types correlates with enrichment of pathways linked to calcium reabsorption, immune response and metabolic pathways. These data suggest LOY contributes to cellular dysfunction and may predispose men to kidney disease.

Exploring the Therapeutic Strategy of Low-Intensity Pulsed Ultrasonography in Age-Related CKD

Shing-Hwa Liu,[1] Chih-Kang Chiang,[1] Ting-Yu Chang,[1] Cheng-Tien Wu.[2] *[1]National Taiwan University, Taipei, Taiwan; [2]China Medical University, Taichung, Taiwan.*

Background: The global population is entering an aging stage. The prevalence of chronic kidney disease (CKD) in people ≥65 years old is much higher than that of people under 65 years old. Ultrasound has been a useful diagnostic tool for a long time. Non-invasive low-intensity pulsed ultrasound (LIPUS) has been found to be a method for treating diseases, such as neurological or bone diseases. Our team's studies also found that LIPUS could effectively alleviate the renal dysfunction in AKI and CKD mouse models. The preventive or therapeutic strategies for age-related CKD still need to be clarified or developed. Here, we evaluated the interventional potential of LIPUS on CKD progression in a naturally aging mouse model.

Methods: Male C57BL/6 mice with the age of 3 (young control), 12, and 24 months (human age equivalent: about 20, 42.5, and 69 years, respectively) were tested. LIPUS with condition of 3 MHz, 0.1 W/cm^2, 20 min daily was applied to the kidney of aged mice for one month. The biochemical analysis in the serum, histological examination in the kidney, and protein expression for senescence-related signaling molecules in the kidney were determined.

Results: In naturally aged mice, the serum creatinine and cystatin C, but not BUN, levels were significantly increased in mice with 24-month-old ($p<0.05$, n=6), but not 12-month-old ($p>0.05$, n=6), compared to the young control mice (3-month-old), which could be significantly reversed by LIPUS stimulation ($p<0.05$, n=6). The periodic acid-Schiff stain and Masson's trichrome stain showed that there were histological changes and collagen deposition, respectively, in aged mice with 24-month-old ($p<0.05$, n=6), which could be significantly reversed by LIPUS stimulation ($p<0.05$, n=6). The protein expression levels of senescence markers including senescence-associated secretory phenotype (SASP)-related signals (p53, p21, GATA-4, NFκB, TGFβ, IGFBP3, and PAI-1) increased in the kidneys of aged mice ($p<0.05$, n=6). LIPUS treatment significantly prevented the increased senescence signals in the kidney of aged mice ($p<0.05$, n=6).

Conclusions: These findings suggest that cell senescence in the kidney may contribute to the CKD progression in naturally aged mice. LIPUS is capable of inhibiting the renal cell senescence in the aging kidney and may have potential for treating age-related CKD.

Mary1 Increases Adenosine Triphosphate and Decreases Collagen-1 in Renal Cortices of Aged Mice

Kai W. Mcalister,[1] Jaroslav Janda,[1] Paul Victor Santiago Raj,[1] Austin D. Thompson,[1,2] Rick G. Schnellmann.[1,3] *[1]The University of Arizona College of Pharmacy, Tucson, AZ; [2]Southwestern Environmental Health Sciences Center, Tucson, AZ; [3]Southern Arizona VA Health Care System, Tucson, AZ.*

Background: Kidney disease remains a leading cause of death in the United States and its prevalence is on the rise. One of the greatest risk factors for the development of kidney disease is aging. Unfortunately, little is known regarding prevention of the debilitating effects of renal aging. Renal aging is characterized by increased mitochondrial dysfunction and fibrogenic mediators, which have been linked to various metabolic and renal impairments, such as diabetes, obesity, cardiovascular disease, and chronic inflammation. Mary1 is an experimental therapeutic that induces mitochondrial biogenesis (MB) and restores renal function in a mouse model of AKI. We hypothesized that treatment with Mary1 may decrease markers of renal dysfunction during aging.

Methods: Mice were divided into three groups: 1) young (10-week-old) mice treated with vehicle control [saline + 0.1% DMSO], 2) aged (25-month-old) mice treated with vehicle control, and 3) aged mice treated with Mary1 [0.3 mg/kg] (n=6-8/group). Each group was further divided into subgroups and treated for 1) 3 weeks or 2) 16 weeks. Following treatment, kidneys were harvested, and cortical tissue was used for immunoblotting and RT-PCR.

Results: For the 3-week treatment group, Mary1-treated aged mice exhibited a 35% reduction in renal cortical collagen-1 mRNA, and a 61% reduction in collagen-1 protein

compared to vehicle-treated aged mice. For the 16-week group, Mary1-treated aged mice exhibited a 46% reduction in renal cortical collagen-1 mRNA, and a 35% reduction in collagen-1 protein compared to vehicle-treated aged mice. Additionally, Mary1 treatment increased renal cortical ATP by 73% compared to aged mice that received vehicle, reaching levels comparable to that in young mice in the 3-week treatment group. While Mary1-treated aged mice exhibited a 33% increase in renal cortical collagen-1 mRNA, there was a persistent 35% reduction in collagen-1 protein compared to vehicle-treated aged mice in the 16-week group.

Conclusions: These results show the therapeutic potential of Mary1 in ameliorating age-related renal cortical mitochondrial dysfunction and fibrosis. Further research is needed to determine the mechanism by which Mary1 achieves these therapeutic effects.

Decrements in Lower-Body Muscle Power Are Associated with Impaired Physical Function in Patients on Hemodialysis

Natalie A. Macheret,[1] Drake Dillman,[2] Sharon M. Moe,[2] Sharon L. Karp,[2] Kenneth Lim,[2] Eliott Arroyo.[1] *[1]Wake Forest University, Winston-Salem, NC; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Patients with chronic kidney disease (CKD) commonly suffer from poor physical function and decreased quality of life. Muscular power—the product of force and velocity of contraction—is a significant predictor of physical function in healthy older adults. However, the role of muscle power in regulating physical function in CKD is unclear. Herein, we sought to examine the relationship between muscular power and physical function in individuals with advanced CKD on hemodialysis (HD).

Methods: This cross-sectional study used data from the Musculoskeletal Function, Imaging and Tissue Resource Core (FIT Core) study cohort at the Indiana Center for Musculoskeletal Health. Participants completed a comprehensive battery of objective and self-reported physical function assessments. Muscle power was estimated from the sit-to-stand test using a validated equation and adjusted for body mass (relative power) and leg muscle mass (specific power). Multiple linear regression analysis was used to assess the association between relative muscle power and physical function outcomes.

Results: Group comparisons between patients on HD (n=44, 54.5% men, age=50±14 y) and healthy controls (n=50, 62% men, age=52±14 y) showed that the HD group had a greater prevalence of diabetes (p<0.001), but no significant differences in age, sex, or race. Patients on HD exhibited significant decrements in both relative (3.0 [0.8] W/kg versus 3.9 [1.2] W/kg in controls; p<0.001) and specific (14.5 [3.4] W/kg versus 17.8 [5.3]; p<0.001) muscle power, even after adjusting for age, sex, diabetes, smoking status, cardiovascular disease, and race. Relative muscle power in patients on HD was significantly associated with the short physical performance battery (SPPB) score (β=1.5, p<0.001) and with the physical function subscale of the Short Form 36 Health Survey (SF36 PF-10) score (β=13.0,p=0.006) after adjusting for covariates.

Conclusions: Patients on HD exhibit significant decrements in both relative and specific lower body muscle power, which indicates that these decrements are not a result of muscle atrophy alone. The decline in muscle power is independently associated with both objective and self-reported measures of physical function. Further research is needed to validate the prognostic utility of muscle power in patients on HD.

Association between Electrical Impedance Vectors and Sarcopenia in Patients with CKD

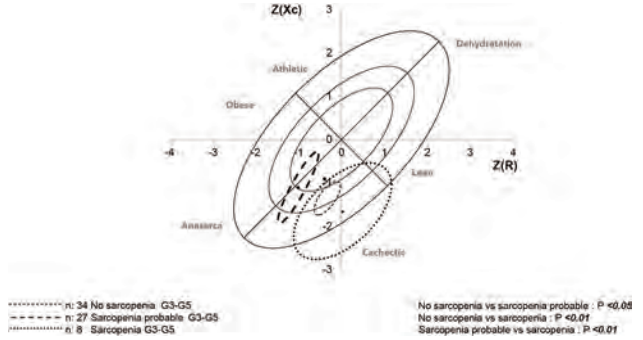
Ailema Janeth G. Ortiz,[1] Laura F. Rosales Arreola,[2] Ana Callejas,[2] Paola V. Miranda,[2] Sonia Lopez-Cisneros,[3] Angeles Espinosa-Cuevas.[2] *[1]Instituto Nacional de Pediatria, Mexico City, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [3]Instituto Nacional de Geriatria, Ciudad de Mexico, Mexico.*

Background: Sarcopenia, characterized by the progressive loss of muscle quality and quantity, affecting quality of life, commonly occurs in patients with Chronic Kidney Disease. Bioelectric Impedance (IBE) and IBE Vectors (VIBE) allow the identification of decreased muscle mass and might identify patients with sarcopenia. We aimed to identify the association between VIBE and sarcopenia in patients with CKD (G3-G5) and HD.

Methods: This cross-sectional study included adult patients over 18 years with ESRD and replacement treatment. Bioelectrical impedance measurements were performed, and body composition was evaluated. The EWGSOP2 criteria were used to diagnose sarcopenia.

Results: The prevalence of sarcopenia was 11.6% in CKD (G3-G5) and 14.8% in HD. VIBE patterns indicated that sarcopenia was located outside the tolerance ellipses in the right quadrant in both groups ($p < 0.05$). In the HD population, the phase angle and Impedance Ratio (IR) were lower in patients with CKD on HD (p 0.03). In CKD (G3-G5), age was higher in the sarcopenia group ($p < 0.05$), and they had DM (p 0.03) and lower creatinine concentration (p 0.02).

Conclusions: The results suggest that VIBE, phase angle, and IR could be helpful tools for identifying sarcopenia in patients with CKD and HD. These measurements could provide valuable information for the early detection and management of sarcopenia in this population.



TH-PO957

Nutritional Status and Sleep Quality in Adult Patients with CKD

Ailema Janeth G. Ortiz,[1] Norberto Rodriguez Gonzalez,[5] Ingrid Mendoza Mayorga,[4] Samuel Ramos-Acevedo,[3] Sonia Lopez-Cisneros,[2] Angeles Espinosa-Cuevas.[4] *[1]Instituto Nacional de Pediatria, Mexico City, Mexico; [2]Instituto Nacional de Geriatria, Ciudad de Mexico, Mexico; [3]McMaster University, Hamilton, ON, Canada; [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [5]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: Sleep and appetite disorders share common mechanisms and have been shown to impact metabolic disorders in the general population. Patients with chronic kidney disease (CKD) often experience sleep disturbances, but whether these are associated with their nutritional status is unknown. We aimed to determine the relationship between measures of nutritional status and sleep quality in adult patients with non-dialysis-dependent CKD.

Methods: Cross-sectional cohort study including adult patients with estimated glomerular filtration rate (eGFR)<60 ml/min/1.73m2 attending nephrologist consultations. Patients with amputations or metallic plates, diagnosed psychiatric disorders, and using medications with a direct effect on sleep were excluded. All patients responded to the Pittsburgh sleep quality questionnaire (PSQI) and underwent a full nutritional assessment including subjective global assessment (SGA), bioelectrical impedance, anthropometry, and 24-hour recall. Multivariate regression was used to analyze the associations between measures of nutritional status and sleep quality (Odd Ratios with 95% confidence intervals).

Results: A total of 106 participants, median age 52 (38-66) years. Hypertension was present in 62% of participants and diabetes in 46%. The majority (75%) of participants presented poor sleep quality (PSQI ≥5), and a total of 35% were considered malnourished (SGA>1). Compared to well-nourished patients, malnourished patients were more likely higher systolic blood pressure, lower serum albumin, and lower eGFR, ($p<0.05$ for all). No significant differences in age, gender, comorbidities, or dietary energy intake were observed. Malnourished patients also reported higher PSQI scores (worse sleep quality, median score 10 vs 7, $p <0.01$). In multivariable logistic regression adjusting for age, sex, eGFR, energy intake, and comorbidities, the Odds of malnutrition increased by 18% (OR 1.18, 95% CI 1.04 to 1.33) for unit increase in PSQI).

Conclusions: Most patients with non-dialysis dependent CKD reported poor sleep quality, and its severity was associated with the presence of malnutrition as assessed by SGA.

TH-PO958

Sarcopenia in Patients on Hemodialysis in Brazil: Results of the SARC-HD Study

Heitor S. Ribeiro,[1] Marvery P. Duarte,[1] Otavio Nobrega,[1] Fábio A. Vieira,[1] Maryanne Silva,[2] Dário R. Mondini,[11] Bruna Maggi Sant'Helena,[12] Henrique S. Disessa,[3] Angélica N. Adamoli,[10] Daiana C. Bundchen,[7] Rodrigo d. Krug,[4] Antonio Jose Inda-Filho,[9] Carla M. Avesani,[5] Barbara P. Vogt,[8] Maycon M. Reboredo.[6] SARC-HD Study Group. *[1]Universidade de Brasilia Faculdade de Ciencias da Saude, Brasilia, Brazil; [2]Universidade Estadual Paulista Julio de Mesquita Filho, Botucatu, Brazil; [3]Universidade Estadual Paulista Julio de Mesquita Filho, Bauru, Brazil; [4]Universidade de Cruz Alta, Cruz Alta, Brazil; [5]Karolinska Institutet, Stockholm, Sweden; [6]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil; [7]Universidade Federal de Santa Catarina, Ararangua, Brazil; [8]Universidade Federal de Uberlandia, Uberlandia, Brazil; [9]Centro Universitario ICESP, Brasilia, Brazil; [10]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [11]Universidade Estadual de Campinas, Campinas, Brazil; [12]Faculdade IELUSC, Joinville, Brazil.*

Background: Sarcopenia is a common feature of patients on hemodialysis and is strongly associated with adverse clinical outcomes, but its epidemiology in middle-income countries remains underexplored. We described the prevalence and risk factors for sarcopenia in patients on hemodialysis in Brazil.

Methods: Baseline data from the SARC-HD multicenter study was analyzed. Muscle strength was assessed by handgrip; muscle mass by calf circumference; and physical performance by gait speed. Sarcopenia diagnosis and staging were based on the revised EWGSOP2 as probable, confirmed, and severe sarcopenia. Prevalence rates were compared among clinical and sociodemographic characteristics and risk factors analyzed.

Results: 983 patients (median 59 years; 40% female) from 19 Brazilian dialysis centers were enrolled. Prevalences of probable, confirmed, and severe sarcopenia were 12%, 9%, and 5%, respectively. The prevalence of sarcopenia increased with advancing age groups, ranging from 7% to 45% in males and from 4% to 21% in females. After adjustment for confounders, male sex (odds ratio [OR]:1.7, 95% confidence interval [CI]:1.1–2.7), older age (OR:3.4, 95%CI:2.2–5.4), white ethnicity (OR:1.8, 95%CI:1.2–2.8), hemodiafiltration treatment (OR:1.6, 95%CI:1.1–2.4), and catheter access (OR:1.6, 95%CI:1.0–2.4) were the main risk factor for sarcopenia; however, overweight (body mass index ≥25.0 kg/m^2) was a protective factor (OR:0.3, 95%CI:0.2–0.4).

Conclusions: Any stage of sarcopenia was found in one out of four patients on hemodialysis. Male sex, older age, white ethnicity, hemodiafiltration treatment, and catheter access were risk factors for presenting sarcopenia. Our findings enhance the understanding of sarcopenia in patients on hemodialysis in Brazil.

Association of Phase Angle with Cardiorespiratory Fitness and Physical Function in Patients on Maintenance Hemodialysis

Robbie L. Grace,[1] Drake Dillman,[2] Nolan Groninger,[2] Sharon M. Moe,[2] Sharon L. Karp,[2] Kenneth Lim,[2] Eliott Arroyo.[1] *[1]Wake Forest University, Winston-Salem, NC; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Phase angle (PhA) is a surrogate measure of cellular health and integrity of the cell membrane derived via bioelectrical impedance analysis. PhA has been shown to be predictive of muscle strength and physical function in healthy older adults. Herein, we sought to examine the relationship of PhA with cardiorespiratory fitness and physical function in patients on maintenance hemodialysis (HD).

Methods: This exploratory cross-sectional study used pooled data taken from previous trials conducted in the Division of Nephrology & Hypertension at the Indiana University School of Medicine. Participants completed a comprehensive battery of physical function assessments and a cardiopulmonary exercise test. Body composition and PhA were measured using bioelectrical impendence spectroscopy at a current frequency of 50 kHz. Multiple linear regression analyses were used to assess the association of PhA with peak oxygen uptake (VO_2Peak) and physical function outcomes.

Results: Group comparisons between patients on HD (n=27, 59% men, age=52 [12] y) and healthy controls (n=13, 38.5% men, age=53 [9] y) showed differences in race (p<0.001), however no differences in age, sex, or BMI. Patients on HD had a lower PhA (5.0 [1.4]°) compared with the controls (5.9 [0.6]°, p=0.005), even after adjusting for age, sex, and race (p=0.002). The HD group also had a lower short physical performance battery (SPPB) score (11 [8.3-12] versus 12 [12-12], p=0.002) and lower VO_2Peak (13.4 [3.7] mL*kg^{-1}*min^{-1} versus 30.7 [0.6] mL*kg^{-1}*min^{-1}; p<0.001) compared with the controls. PhA in patients on HD was significantly associated with VO_2Peak (β=1.18, p=0.022) and SPPB score (β=0.92, p=0.006) on univariate regression. After adjusting for age, PhA remained significantly associated with SPPB score (β=0.71, p=0.032); however, it was no longer associated with VO_2Peak (β=1.01, p=0.055).

Conclusions: Patients on HD exhibit significant declines in PhA that are comparable with those observed in older (65+ years) adults and are associated with impaired physical function. Further prospective studies are needed to determine whether changes in PhA as kidney function declines are predictive of physical function decline in this vulnerable population.

Exercise and Physical Activity for People with CKD: A National Survey of Nephrologist Practice Patterns in Saudi Arabia

Enad A. Alsolami, Sami A. Alobaidi. *University of Jeddah, Jeddah, Saudi Arabia.*

Background: A variety of health benefits are associated with physical activity in individuals with chronic kidney disease. The aim of this study was to examine nephrologist practice patterns concerning exercise and physical activity (PA) in CKD patients.

Methods: This is an online cross-sectional survey study that was conducted between June 2023 and May 2024 in Saudi Arabia. Nephrology fellow, specialists, and consultants in Saudi Arabia formed the study population.

Results: A total of 96 physicians participated in this study. Only 9.4% of renal units have exercise programs available to patients. These programs are available mainly for advanced CKD (pre-dialysis) and in-center hemodialysis patients. The major barriers to initiating or expanding exercise programs at their centers are a lack of motivation/interest from front-line staff (55.2%), lack of interest from management (48.3%), and no funding (47.1). Around 56.2% of respondents ask patients about their level of physical activity. Additionally, 64.6% give patients specific advice on how to increase their level of physical activity. For the types of exercise most beneficial for people with CKD, 90.6% recommend walking. Around 34.4% of respondents believe that physiotherapists should take ownership in providing exercise counselling and resources to people with CKD. The majority agreed or strongly agreed to recommend exercise in patients with CKD (76.0%). The mean attitude score for the study participants was 32.1 (SD: 3.9) out of 40 (equal to 80.3%); which demonstrates positive attitude towards recommending exercise for CKD patients.

Conclusions: This study highlights a critical gap in the availability of exercise programs for CKD patients. Key barriers include lack of interest by staff and management and funding issues. In spite of these barriers, a majority of physicians acknowledge the role of exercise in CKD patients and advice regarding physical activity on a frequent basis. It suggests recommendations in order to expand the programs, including increasing staff motivation, securing management support, and getting funding for exercise programs and identifying the role of physiotherapists in exercise counselling for CKD patients.

Sarcopenia Index Is Associated with the Risk of Stroke in Middle-Aged and Older Chinese Adults: A Retrospective Cohort Study from the China Health and Retirement Longitudinal Study

Haofei Hu,[1,2] Zhiming Ye.[1] *[1]Guangdong Provincial People's Hospital, Guangzhou, China; [2]Shenzhen Second People's Hospital, Shenzhen, China.*

Background: The sarcopenia index (SI), calculated as the serum creatinine divided by the serum cystatin C, multiplied by 100, is recommended for predicting sarcopenia. However, limited evidence exists regarding its association with incident stroke. The aim of this study was to assess the relationship between SI and the risk of stroke in middle-aged and older adults.

Methods: This study utilized a retrospective cohort design, enrolling a total of 7842 participants who met the inclusion criteria from the China Health and Retirement Longitudinal Study (CHARLS) between 2011 and 2012. The study utilized the Cox proportional-hazards regression model to investigate the correlation between baseline SI and the risk of stroke. To identify the non-linear relationship between SI and stroke, a Cox proportional hazards regression with cubic spline function and smooth curve fitting technique was employed. Additionally, various sensitivity and subgroup analyses were performed.

Results: The mean age of the participants was 59.97 ± 10.06 years, with 3607 (46.0%) being male. The average baseline SI was 78.53 ± 17.43. Over a median follow-up period of 7.0 years, 938 (11.96%) individuals experienced a stroke. The multivariate Cox proportional hazards regression model revealed a negative association between SI and stroke risk (HR=0.995, 95% CI: 0.991-0.999). A non-linear relationship between SI and incident stroke was identified, with an inflection point at 70.0 for SI. Each 1 unit increase in SI to the right of the inflection point corresponded to a 0.9% decrease in stroke risk (HR=0.991, 95% CI: 0.985-0.997). However, when the SI was lower than 70.0, the connection was not significant (HR: 1.006, 95% CI: 0.994-1.017). The robustness of our results was confirmed through sensitivity and subgroup analyses.

Conclusions: This study provides evidence of a negative and non-linear correlation between SI and stroke risk in middle-aged and older adults in China. When the SI exceeded 70.0, a significant negative association with stroke risk was observed. Maintaining an SI level above 70.0 may contribute to a notable reduction in the risk of stroke.

Determining the Feasibility and Acceptability of a Culturally Tailored Lifestyle Intervention to Improve the Health of Hispanic and Native American Kidney Transplant Recipients

Miriam E. Velez-Bermudez, Claudia M. Rice, Shoshana Adler Jaffe, Yuridia Leyva, Elizabeth Y. Jimenez, Yiliang Zhu, Pooja P. Singh, Christos Argyropoulos, Mark L. Unruh, Larissa Myaskovsky. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Our team conducted a culturally-tailored diet and exercise clinical pilot trial with kidney transplant (KT) recipients, integrating lifestyle changes into post-KT care prior to discharge from KT surgery. We purposely recruited a diverse sample of KT recipients to test the pilot study's feasibility and acceptability.

Methods: Patients were randomized into usual care (UC) or the intervention arm 2-5 days after KT surgery and prior to discharge. Physical activity for all participants was measured with an activPAL accelerometer. Participants were instructed to wear the activPAL for one week, at four time points throughout the 12-month study period. Intervention participants received a customized exercise and nutrition plan tailored by a physical therapist (PT) and registered dietitian nutritionist (RDN). Feasibility was determined by recruitment/retention rates and intervention activity adherence. Acceptability was assessed by satisfaction ratings (3-month follow-up) and interviews (6-month follow-up).

Results: Forty-nine patients were approached, 23 (47%) agreed to participate, and three (13%) subsequently withdrew from the study. The final sample consisted of 20 patients (11 Intervention, 9 UC; 9 Hispanic, 7 Native American, 4 Other). Eighty-two percent of the intervention participants wore the activPAL at all four follow-ups versus 67% of the UC participants. Among intervention arm participants, per-protocol adherence to the PT and RDN visits was 78% and 82%, respectively. Intervention arm participants' responses to surveys and interviews demonstrated intervention acceptability, ease of participation, and overall satisfaction with the intervention.

Conclusions: This pilot effectively delivered a lifestyle intervention to a diverse sample of KT recipients, demonstrating good retention and adherence to the intervention and activity monitoring components. The PT and RDN components were well-received by participants, who also reported satisfaction with the intervention. This study is a vital step to creating a large-scale lifestyle intervention that addresses the post-KT diet and exercise needs of Hispanic and Native American recipients.

Distribution of Sedentary Time during the 24-Hour Day in Adults with CKD

Mary Hannan,[1] Arissara Sawatpanich,[1] Emily Kringle,[2] Eleanor Rivera,[1] Ardith Z. Doorenbos,[1] James P. Lash.[1] *[1]University of Illinois Chicago, Chicago, IL; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Adults with CKD spend over 60% of their waking time sedentary, but less is known about when during the 24-hour day most sedentary time occurs. We examined distribution of within-day sedentary time among adults with CKD and explored differences by demographic and health characteristics.

Methods: This is a secondary analysis of baseline data (n=21) from a feasibility study evaluating a sedentary-reducing intervention in adults with CKD. Sedentary behavior was evaluated with the activPAL inclinometer. Waking sedentary time (sleep time removed) was examined during four time periods, and distribution was explored by gender, employment status, and CKD Stage with independent samples t-tests.

Results: Mean age was 59.7 yrs., 76% were women, 57% were employed, and 86% had CKD Stage 3. Mean waking sedentary time was 11.75 hours/day. Most sedentary time occurred in the afternoon and evening. Men, those who were retired, and those with CKD Stage 4 each had the highest amount of sedentary time occur in the evening. Women, those who were employed, and those with CKD Stage 3 each had the highest amount of sedentary time occur in the afternoon.

Conclusions: Adults with CKD tend to accumulate their sedentary time during the afternoon and evening. These exploratory findings support that sedentary-reducing interventions for those with CKD should focus on reallocating sedentary time to non-sedentary activities that are feasible during the afternoon and evening. Funding for this research was provided through a research grant from the American Nephrology Nurses Association (ANNA). Findings of the study do not necessarily reflect the opinions of ANNA. The views expressed herein are those of the authors and no official endorsement by ANNA is intended or should be inferred.

TH-PO964

Sleep Quality and Symptom Experience in CKD

Roseanne E. Billany,[1] Ella C. Ford,[2] Gurneet K. Sohansoha,[1] Courtney J. Lightfoot,[1] Alice C. Smith.[1] *[1]University of Leicester College of Life Sciences, Leicester, United Kingdom; [2]Leeds Beckett University, Leeds, United Kingdom.*

Background: Poor sleep quality is common in chronic kidney disease (CKD). Understanding how symptoms (Sx) relate to sleep could help identify people who experience, or are at risk of experiencing, poor sleep quality. We explored the relationship between sleep quality and Sx experienced in people with living with CKD and their significant others (SO).

Methods: People living with CKD and their SO were invited from nine hospital sites in England to complete an online survey including the Pittsburgh Sleep Quality Index (PSQI) and the Kidney Symptom Questionnaire (KSQ). Data were analysed using multiple regression (adjusted for age and sex), χ^2, and Mann-Whitney U as appropriate.

Results: 291 CKD (age 60±14 years; 54% male; 173 (59%) non-dialysis; 66 (23%) kidney transplant; 52 (18%) dialysis [haemo and peritoneal]), and 47 SO (age 63±11 years; 32% male) had complete data. The proportion of participants with poor sleep was greater in CKD than in SO (60% vs 45%, respectively; p=.046). The median number of Sx experienced by people with CKD was higher than in SO (5 vs 2; p=.001). There was a significant association between sleep quality and number of Sx in CKD in univariate analysis and after adjustment (both p<.001). In a multivariable model, loss of appetite, pain, weakness, restless legs syndrome, and feeling cold were significantly associated with poorer sleep quality (Table 1).

Conclusions: We found relationships between experiencing CKD-related Sx and poorer sleep quality in CKD. Optimal CKD management should include assessment of both Sx burden and sleep quality; a bi-directional relationship is likely. Multi-disciplinary teams and sleep services should work together to provide relevant information, and/or referrals to optimise sleep and Sx management and improve quality of life.

Table 1: Multivariable model exploring the contribution of symptoms experienced to sleep quality measured by the PSQI in people living with CKD

Symptom Experienced	B	CI	β	p
Itching	0.26	(-0.65, 1.17)	0.03	0.571
Loss of appetite	1.69**	(0.71, 2.67)	0.20**	0.001
Pain in bones/joints	1.06*	(0.07, 2.06)	0.14*	0.036
Poor concentration/alertness	0.78	(-0.23, 1.79)	0.10	0.129
Loss of libido	0.13	(-0.79, 1.05)	0.02	0.777
Loss of muscle strength/power	1.42*	(0.39, 2.45)	0.18*	0.007
Shortness of breath	-0.45	(-1.40, 0.49)	-0.06	0.345
Cramp/muscle stiffness	-0.26	(-1.24, 0.71)	-0.03	0.598
Restless legs	0.96*	(0.03, 1.88)	0.12*	0.043
Feeling cold	1.02*	(0.07, 1.96)	0.13*	0.036
Need to urinate more often	0.80	(-0.06, 1.67)	0.10	0.069

Association between Sleep Hours and Incidence of Kidney Failure: Findings from the National Health and Nutrition Examination Survey, 2005-2018

Yoshihisa Miyamoto, Alain K. Koyama, Ryan Saelee, Fang Xu, Ibrahim Zaganjor, Stephen J. Onufrak, Meda E. Pavkov. *Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Sleep duration may be associated with chronic kidney disease (CKD) and its progression. However, few studies have examined the association between sleep duration and kidney failure incidence.

Methods: We used data from the National Health and Nutrition Examination Surveys (2005–2006 through 2017–2018) linked to the United States Renal Data System to assess the association between self-reported sleep duration and three outcomes: incidence of kidney failure, all-cause death, and the composite of the two. We followed adults aged ≥20 years from the interview date until the date of kidney failure, death, or December 31st, 2018, whichever occurred first. We used multivariable Cox regression models to estimate hazard ratios (HRs) with 95% confidence intervals (CIs) to adjust for demographics, eGFR, log of urine albumin creatinine ratio, diabetes, and hypertension.

Results: Among 27,498 adults who met the inclusion criteria, 1,544 (4.4%) reported a sleep duration of <5 hours, 2,497 (7.8%) reported ≥5 to <6 hours, 5,828 (20.7%) reported ≥ 6 to <7 hours, 14,202 (55.4%) reported ≥ 7 to <9 hours and 3,427 (11.6%) reported ≥ 9 hours. The mean age was 47 years; 48% were men and 66.7% were non-Hispanic White, 11.4% were non-Hispanic Black. The median observational period was 6.2 years. Compared to ≥7 to <9 hours of sleep, sleep durations < 5 hours, ≥ 5 to <6 hours and ≥9 hours were associated with higher risk of the composite events (adjusted hazard ratio, 1.67 [95% CI, 1.34-2.08], 1.34 [1.14-1.56], and 1.50 [1.31-1.71], respectively). Similarly, sleep durations < 5 hours and ≥ 9 hours were associated with higher risk of kidney failure (adjusted hazard ratio, 1.44 [95% CI, 0.85-2.42] and 1.64 [0.83-3.21], respectively) although not statistically significant due to low number of events.

Conclusions: Both shorter and longer sleep duration may be associated with higher risk of kidney failure and death.

TH-PO966

Effect of a Low-Protein Diet Supplemented with Ketoanalogues on Body Composition and Hand Grip Strength of Elderly Mexican Patients with CKD Attending a Nutritional Care Center

Nadia I. Aldana Solis,[1] Abril G. Espinoza,[2] Julia Nava,[1] Adriana Salinas Rico,[1] Araceli Aguilar Gamiño,[1] Sara De La Rosa Diez,[1] Joel D. Kopple.[3] *[1]Fresenius Kabi Mexico SA de CV, CDMX, Mexico; [2]Fresenius Kabi Mexico SA de CV, Tijuana, Mexico; [3]The Lundquist Institute, Torrance, CA.*

Background: Chronic kidney disease has become one of the significant causes of mortality in the world. Nutritional therapy is one of the cornerstones of conservative management. Elderly subjects with CKD are considered a frail population. An LPD supplemented with keto analogs and adequate energy supply could be an option for treatment to avoid or differ dialysis and maintain a good nutritional status and muscle strength.

Methods: This was a retrospective analysis of 60 patients with CKD stages 3b-5. The data were collected from the database of one Fresenius Kabi CEAN center in Mexico City. The study included nondiabetic and diabetic patients who were ≥65 years old. Each patient was prescribed a sk-LPD individualized according to the patients GFR level, nutritional status, and specific tastes. Biochemical, body composition, HGS, and nutritional screening parameters were compared between baseline and at a six-month interval.

Results: The patient population was 41.7% female and 43.3% diabetic. At the onset of dietary treatment, according to the BMI criteria, 41.7% were normal weight; 43.3% were overweight, and 15% obese. After six month's treatment, 45% were normal weight, 38.3% were overweight, and 16.7% obese (change in weight status: p=NS). Fat mass tended to decrease from 37.2±10.0 to 35.5±8.9% p=0.32; lean body mass did not change, 47.5±16.1% to 48.4±17.0% p=0.76; and phase angle tended to decrease although not significantly, 4.49±2.37 to 4.02±0.73, p=0.080. HGS was maintained 21.6 ±7.6 to 21.7 ±8.0 kg p=0.109. Serum urea nitrogen (SUN) decreased at six months from 47.9±21.8 to 33.7±17.2 mg/dL, p<0.001. Serum albumin was maintained, 4.14±0.40 to 4.14±0.40 g/dL, p=0.722, eGFR increased from 25.0±10.3 to 29.4±13.0 ml/min/1.73 m^2 p=0.042.

Conclusions: The major decrease in SUN during the study suggests at least fair to good adherence to the prescribed diets. No significant changes were noticed in anthropometric, biochemical, HGS and other nutritional characteristics during this six-month interval, suggesting that the sk-LPD treatment maintained nutritional status in these older stage 3b-5 CKD patients.

TH-PO967

Maternal Ketosis during Gestation: Implications for Fetal Kidney Development and Long-Term Kidney Health

Oded Volovelsky, Yaniv Makayes, Morris Nechama. *Hadassah University Medical Center, Jerusalem, Israel.*

Background: Maternal ketosis is a metabolic state that can be encountered during normal pregnancy, gestational diabetes, and due to the growing popularity of ketogenic diets. While ketone bodies in the physiological range facilitate energy supply to the fetus, emerging data suggest potential adverse fetal outcomes of increased ketosis. This study investigates the impact of maternal ketosis during gestation on fetal kidney development and nephrogenesis, a critical determinant of lifelong renal health.

Methods: Two murine models evaluated the effects of maternal ketosis on kidney development: a ketogenic diet regimen and exogenous beta-hydroxybutyrate (BHB) supplementation in drinking water. Nephron endowment was quantified in adulthood, and renal function was assessed by blood urea levels. Nephron progenitor cells were isolated via fluorescence-activated cell sorting from transgenic reporter mice, and RNA-sequencing analyzed transcriptomic profiles. Alterations in gene expression pathways were validated through immunofluorescence, western blot, and qPCR.

Results: Both maternal ketosis models exhibited significantly reduced nephron endowment at birth and adulthood compared to the control group, indicative of impaired nephrogenesis. The reduction in nephron number in the ketogenic group was associated with compromised long-term renal function in adulthood, as was measured by elevated blood urea levels. Transcriptomic analyses revealed decreased proliferative capacity of nephron progenitors, with downregulation of the MYC pathway and concomitant upregulation of inflammatory response genes. These findings were consistently validated across multiple complementary techniques.

Conclusions: This study provides compelling evidence that maternal ketosis during gestation adversely impacts fetal kidney development and long-term renal function. Reduced nephron progenitor proliferation, decrease MYC expression and heightened inflammatory signaling, emerges as an underlying mechanism. These findings underscore the importance of monitoring and managing maternal ketosis to protect fetal nephrogenesis and lifelong kidney health.

TH-PO968

Patient Self-Management of Kidney Diseases: A Health Care Staff Perspective

Naeema A. Patel, Matthew Graham-Brown, Alice C. Smith, Courtney J. Lightfoot. *University of Leicester College of Life Sciences, Leicester, United Kingdom.*

Background: Self-management is an important component of care for people with chronic kidney disease (CKD). Effective self-management has the potential to improve health outcomes, but evidence-based resources to support people with non-dialysis CKD to self-manage are lacking. Healthcare professionals (HCPs) are critical for the uptake and adoption of self-management resources in clinical practice. This qualitative study explored professional stakeholders' views on current practices of self-management education and support and the requirements for effective resources to be used in routine care

Methods: Semi-structured interviews with kidney HCPs and service managers were conducted to explore CKD education and self-management support. Interviews were audio recorded and transcribed verbatim. Data were analysed using thematic analysis.

Results: 42 participants, including 20 nephrologists, 6 kidney nurses, 10 allied health professionals, and 6 service managers in kidney care and quality improvement were interviewed. Four overarching themes were identified: **Lack of prioritisation of self-management education and practices** (perceived that self-management is overlooked in CKD and lacks priority in current practices) **Personalised and responsive approach to CKD** (considering the need to take a patient-centred approach to care and understanding self-management in CKD to other multiple long-term conditions) **Perceived features of successful self-management** (identifying key effective strategies for self-management resources and support) **Considerations around health equity** (Adapting interventions to improve equity and accessibility for underserved groups)

Conclusions: The findings highlight the need for patient education and evidence-based self-management resources. HCPs should prioritise patient knowledge and understanding of kidney disease, tailor resources to individual needs, and improve equity for underserved groups. These findings can be used to support the design and delivery of healthcare resources to optimise and increase uptake.

TH-PO969

Depressive Symptoms and RANKL/OPG in Hemodialysis

Heejeong Kim, Dong-Young Lee. *Department of Internal Medicine, Veterans Healthcare Service (VHS) Medical Center, Seoul, Republic of Korea.*

Background: Depression and osteoporosis are prevalent in dialysis patients. Denosumab and romosozumab similarly block RANKL. While RANKL causes bone resorption after binding RANKL, binding with OPG inhibits bone resorption. A recent

mice study, denosumab improved depressive-like phenotype by inhibiting RANKL. OPG was linked to depression. This study aimed to explore the association of depressive symptoms with RANKL/OPG in HD patients.

Methods: We conducted a cross-sectional study involving 172 HD patients, measuring plasma RANKL, OPG levels. Logistic regression analysis was performed to evaluate the effect of RANKL and OPG on the depressive symptoms.

Results: The depressive symptoms were observed in 90(52.3%) subjects. RANKL tertile 3 had negative association with BDI score(β-4.527, 95% CI -8.310~-0.743) in univariate analysis. This association persisted after multivariate adjustments(β-5.603, 95% CI -9.715~-1.491) in linear regression. In logistic regression between RANKL tertiles and depressive symptoms, RANKL tertile 3 had significantly lower unadjusted OR (0.40, 95% CI 0.19~0.86), and multivariate-adjusted OR (0.31, 95% CI 0.12~0.82) for depressive symptoms.

Conclusions: OPG wasn't significantly associated with depressive symptoms. Higher plasma RANKL levels were associated with lower depressive symptoms in HD patients.

Odds ratios of plasma RANKL, OPG, and RANKL/OPG ratio for depressive symptoms

	OR (95% CI) Unadjusted	P value	OR (95% CI) Adjusted	P Value

Association of Cardiovascular-Kidney-Metabolic Syndrome with Cognitive Decline and Dementia: The ARIC Study Insights

Peichen Xie, Yiqin Wang, Wei Chen. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*.

Background: Cardiovascular-kidney-metabolic(CKM) syndrome is a prevalent health concern, while its impact on cognitive function has not been extensively studied.

Methods: We conducted a prospective analysis with Atherosclerosis Risk in Communities (ARIC) study data. CKM risk was assessed with the PREVENT™ Calculator and cognitive function was evaluated using *z* score from different cognitive function tests at Visit 2 and Visit 4. Dementia cases were identified through a combination of assessments and hospital records, with analyses adjusted for demographics and vascular risks during Visit 5.

Results: Our study included 10,960 participants with a mean age of 56.9±5.7 years. A robust inverse relationship was observed between cognitive function and CKM risk, with the inflection point at 6.381% CKM risk for the global *z* score. The risk of dementia increased with higher CKM risk (HR 1.14, 95% CI 1.13-1.16). Notably, male participants exhibited a comparatively reduced risk of dementia (HR 0.72, 95% CI 0.63-0.82). A subsequent sensitivity analysis, utilizing baseline data from Visit 4 (n=4644), confirmed these results.

Conclusions: Our findings indicate a significant link between CKM risk and cognitive decline, suggesting the importance of CKM syndrome management in preventing cognitive impairment and dementia.

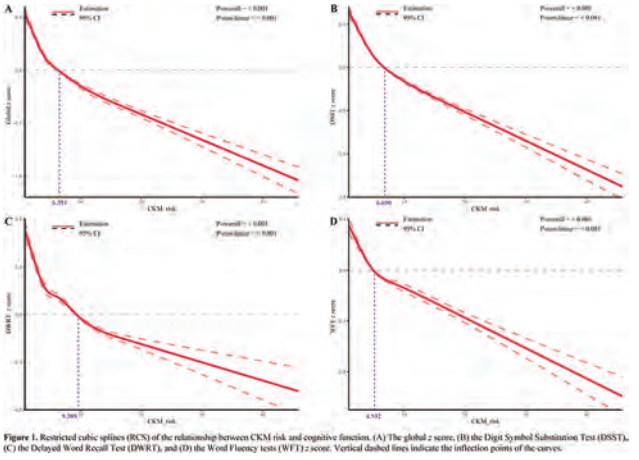

Figure 1. Restricted cubic splines (RCS) of the relationship between CKM risk and cognitive function. (A) The global *z* score, (B) the Digit Symbol Substitution Test (DSST), (C) the Delayed Word Recall Test (DWRT), and (D) the Word Fluency tests (WFT) *z* score. Vertical dashed lines indicate the inflection points of the curves.

RCS of CKM risk and cognitive scores

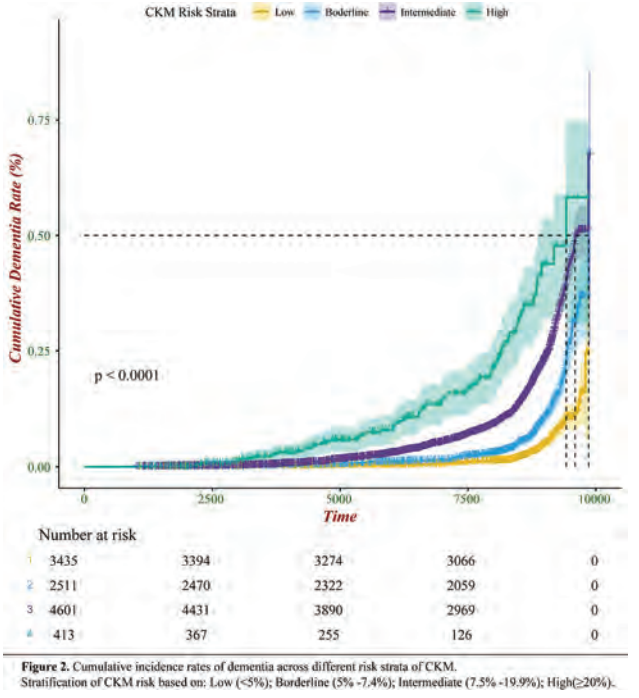

Figure 2. Cumulative incidence rates of dementia across different risk strata of CKM. Stratification of CKM risk based on: Low (<5%); Borderline (5% -7.4%); Intermediate (7.5% -19.9%); High(≥20%).

TH-PO971

Age-Specific Relationship between Insulin Resistance and Obesity: A Machine Learning-Based Interpretation

Sewon Oh, Yookyung Jang, Young Eun Choi, Tai yeon Koo, Myung-Gyu Kim, Sang-Kyung Jo. *Korea University, Seongbuk-gu, Republic of Korea*.

Background: There has been a threefold surge in the global prevalence of obesity over the last four decades. Obesity is related to the increased risk of cardiovascular and kidney disease. Obesity in the elderly exhibits distinct features, such as sarcopenia and an increased visceral fat mass. We investigate the risk factors for obesity according to age by developing machine learning (ML) model.

Methods: We performed ML analysis on 3768 individuals whose age was over 18 from the 2021 Korea National Health and Nutrition Examination Survey dataset. ML predicted individual body mass index (BMI) values, and the predictive values were labeled into normal (BMI<25 kg/m^2) and obese (BMI>25 kg/m^2). Through 5-fold cross-validation, the performance and SHapley Additive exPlanations (SHAP) values, representing the feature importance in each sample, were calculated in the test set of every fold and collected.

Results: The Light Gradient Boosting Machine demonstrated reliable prediction, yielding an area under ROC curve of 0.813 (higher than other ML algorithms) and an error of 2.199±1.654. SHAP analysis revealed high importance for Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) and fasting insulin, displaying an

increasing trend with higher BMI (Figure 1.a). Important indicators were followed by, systolic blood pressure, alanine-transaminase, uric acid, HDL-cholesterol, hypertension, age and occupation. Age showed the highest interaction with the impact of HOMA-IR. A dependence plot (Figure 1.b) illustrated that the impact of high HOMA-IR on BMI was higher in younger adults compared to older adults. A significant disparity in obesity ratio between HOMA-IR>5 and HOMA-IR<5 was observed, particularly pronounced in individuals under 50 years.

Conclusions: While HOMA-IR is recognized for its significance in BMI and diabetic diseases, this study highlights its prominence over other known BMI-related features. The analysis showed that younger ages with high insulin resistance is more vulnerable to obesity compared to older adults.

TH-PO972

Combination of Hyperuricemia and Obesity Is an Independent Risk for CKD in the Young Population

Akihiro Kuma, Yasuyuki Mimura, Masayoshi Nanami, Takahiro Kuragano. *Department of Cardiovascular and Renal Medicine, Hyogo Medical University, Nishinomiya, Japan.*

Background: Recent studies have shown a significant relationship between hyperuricemia and kidney disease. However, managing serum uric acid (SUA) levels in incident chronic kidney disease (CKD) remains challenging. This study investigated the appropriate SUA management in incident CKD to prevent kidney dysfunction in the general population.

Methods: This retrospective observational study included Japanese aged 20–60 years who underwent a health examination during 2009–2014. Participants with an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 or proteinuria ≥1+ in 2009 were excluded. Incident CKD was defined as eGFR <60 mL/min/1.73 m^2 or proteinuria 5 years later. Receiver operating characteristic (ROC) curve analysis was performed to determine the SUA cutoff value for incident CKD. The risk of incident CKD (odds ratio [OR] and confidence interval [CI]) was analyzed using logistic regression analysis. Propensity score matching based on the SUA cutoff value was performed to exclude biases related to participant covariances.

Results: Of 16,708 recruited participants, 8,702 were eligible. Mean age, eGFR, and SUA were 41.4 years, 81.1 mL/min/1.73 m^2, and 6.0 mg/dL, respectively. A total of 728 (8.4%) participants developed CKD. Based on the ROC analysis, the SUA cutoff value for incident CKD was 6.6 mg/dL. High SUA level (≥6.6 mg/dL) combined with obesity (body mass index ≥25 kg/m^2) was a significant risk for incident CKD in participants aged <40 years (OR=2.18, 95% CI 1.10–4.31) but not if without obesity (OR=0.69, 95% CI 0.40–1.18). SUA level was significantly associated with obesity status (P=0.009). In participants aged ≥40 years, high SUA level was a risk factor for incident CKD, regardless of obesity status (OR 1.32, 95% CI 1.07–1.63). In participants aged <40 years with obesity and high SUA level, the difference in 5-year eGFR slope between participants with <6.6 mg/dl of SUA and those with ≥6.6 mg/dL (5-year later) was +0.80 mL/min/year (P=0.0002).

Conclusions: In the population aged <40 years, SUA of ≥6.6 mg/dL combined with obesity was an independent risk for incident CKD 5 years later. Lowering SUA to <6.6 mg/dL may attenuate eGFR decline.

TH-PO973

Role of Normal Protein Catabolic Rate (nPCR) in Predicting Weight Loss among Patients on Hemodialysis Treated with Tirzepatide

Jyunichiro Hashiguchi, Shinichi Abe, Satoshi Funakoshi, Mayu Iwata, Kenji Sawase. *Nagasaki Kidney Center, Nagasaki, Japan.*

Background: Tirzepatide, a novel dual GLP-1/GIP receptor combination, shows promising potential for treating type 2 diabetes mellitus (T2DM) by inducing weight loss, albeit with variable efficacy among individuals. In HD patients, establishing appropriate dry weight (DW) parameters is crucial, as spontaneous weight fluctuations are uncommon. This study aims to identify optimal parameters for setting DW in patients undergoing HD on tirzepatide treatment.

Methods: Twenty-three stable type 2 diabetic patients undergoing outpatient maintenance HD, already on existing GLP-1 receptor agonists, were enrolled. Mean age was 63.8 years, with 18 males and 5 females, and mean dialysis history of 5.6 years. Patients transitioned from existing GLP-1 receptor agonists to tirzepatide, with the correlation between the rate of DW reduction, clinical symptoms, and changes in various nutritional indices assessed over a 6-month period.

Results: Mean DW decreased significantly from 72.7kg to 70.3kg over 6 months, with an average weight loss of -2.6kg (-3.9%). Notably, a considerable variation in weight change was observed (standard deviation: 2.28; coefficient of variation: -0.851). Among nutritional indices, only nPCR demonstrated a significant correlation with weight loss (r=-0.44, p=0.04), indicating greater weight loss in patients with decreased nPCR (Figure).

Conclusions: While serum phosphorus and potassium levels are commonly used to estimate appetite and food intake in hemodialysis patients, they did not exhibit significant correlation with changes in body weight. Conversely, nPCR, reflecting dietary protein intake, showed the strongest correlation with weight changes during tirzepatide administration. Monitoring nPCR can enable early detection of appetite loss and facilitate adjustments in DW, potentially mitigating complications like pulmonary congestion and pleural effusion associated with tirzepatide use in HD patients.

Causal Effect of Kidney Function on Lipid Metabolism: An Integrated Population-Scale Observational Analysis and Mendelian Randomization Study

Minsang Kim, Jeongmin Cho, Sehoon Park. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Additional investigations into the causal effects of kidney function on various metabolites, particularly lipoprotein lipids in detailed subfractions of lipoprotein particles, in the general population are warranted.

Methods: This study included cross-sectional observational and Mendelian randomization (MR) analyses. For both analyses, 157,541 participants aged 40–69 years from the UK Biobank cohort were included. The estimated glomerular filtration rate (eGFR) was the exposure, and the outcome was each of the 178 metabolites from recently updated metabolomics data, including detailed lipoprotein components within 14 subclasses of lipoproteins. Observational analysis was performed using multivariable linear regression analysis. Genetic instruments for eGFR were developed from the Chronic Kidney Disease Genetics genome-wide association study meta-analysis results, which comprised 567,460 individuals of European ancestry. A two-sample MR analysis was performed using the random-effects inverse variance weighted method as the main MR method.

Results: In the integrated results of the observational and MR analyses, 26 metabolites were causally associated with eGFR (Figure 1). A lower eGFR causally decreased lipoprotein components of high-density lipoprotein (HDL) and several of its subclasses, particularly medium HDL. Conversely, a lower eGFR causally increased triglycerides (TG) levels in smaller-sized very low-density lipoprotein (VLDL) and intermediate-density lipoprotein, as well as increased lipoprotein particle concentrations and total lipids in small VLDL.

Conclusions: Decreased kidney function causally aggravates lipoprotein lipid profiles; therefore, clinicians should closely monitor the lipid profiles of individuals with impaired kidney function.

Weight-Loss Interventions in Patients with Overweight/Obesity and CKD

Ryan Chang, Livia A. Frost, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Obesity is an independent risk factor for progression of chronic kidney disease (CKD). We conducted a systematic review and meta-analysis to evaluate the effects of weight loss interventions in patients with non-dialysis-dependent CKD.

Methods: We searched Embase, Web of Science, Cochrane, and MEDLINE for randomized controlled trials (RCTs) and pre-specified and post-hoc analyses of RCTs that examined surgical, lifestyle, and pharmacologic interventions in adult patients with CKD and overweight or obesity. We used Cochrane RevMan to perform a random-effects meta-analysis comparing each intervention to its respective control. Weighted mean differences (with 95% confidence intervals) were calculated for various kidney outcome measures.

Results: We included 32 studies (from a total of 12,175 studies identified during search). 3 examined surgical interventions, 15 examined lifestyle interventions, and 14 examined pharmacologic interventions (9 of which were GLP-1 agonists). Lifestyle changes were associated with improvements in eGFR, rate of eGFR change, BMI, and weight (Figure). Surgery was associated with significant reductions in weight, BMI, and HbA1c, but no improvements in kidney parameters. Both GLP-1 agonists and other medications were associated with weight loss, but only GLP-1 agonists improved eGFR, rate of eGFR change, and HbA1c. Surgical and lifestyle interventions also improved proteinuria, while some GLP-1 agonist trials demonstrated improvements in urine albumin-creatinine ratio.

Conclusions: Weight loss interventions, particularly lifestyle-based and GLP-1 agonists, may confer improvements in kidney function. Larger trials examining kidney outcomes in patients with obesity and CKD are needed to fully elucidate the benefits of such interventions.

Intervention Type	Outcome	Number of Trials; Patients	Effect Size	95% Confidence Interval	I-squared
Lifestyle	Change in eGFR	9; 6462	0.55 mL/min/1.73 m^2	0.12, 0.97	0%

Health Trajectories of Adults with ESKD and Obesity Who Are Trying to Lose Weight

Dahlia Stott,[1] Bengucan Gunen,[1] Stephen Chien,[1] Brandy-Joe Milliron,[1] Ann C. Klassen,[1] Lucy Robinson,[1] Jason Cobb,[2] Alden M. Doyle,[3] Meera N. Harhay.[1] *[1]Drexel University, Philadelphia, PA; [2]Emory University, Atlanta, GA; [3]University of Virginia, Charlottesville, VA.*

Background: Adults with ESKD and obesity (i.e., body mass index ≥30 kg/m^2) have reported numerous barriers to healthy weight loss, limiting access to transplantation. Weight loss in ESKD patients may also indicate frailty or sarcopenia. Knowledge gaps persist about predictors of healthy weight loss in adults with ESKD and obesity.

Methods: In our longitudinal cohort study, we are assessing predictors of weight, body composition (using bioimpedance spectroscopy), anthropometry, and functional trajectories among adults with ESKD and obesity who are trying to lose weight. In this preliminary analysis, we compare dietary quality, health literacy, and 3-month changes in fat free mass, waist circumference, and physical function of participants who did and did not achieve weight loss using t-tests and Mann-Whitney U tests, as appropriate.

Results: Among 34 participants with longitudinal data to date, 41% lost weight at 3 months (mean loss 2 kg, SD 1.74 kg). Mean participant age was 57 years; 47% were female, and 94% identified as non-Hispanic Black. No participants were taking weight loss medication at baseline. Participant characteristics, dietary intake, and health literacy were similar between those with and without weight loss. Participants who lost weight were more likely to lose waist circumference but had similar changes in fat free mass and physical function as those without weight loss (Table).

Conclusions: Less than half of participants achieved desired weight loss at 3 months. Those who lost weight had similar baseline dietary quality and health literacy but were more likely to lose waist circumference than those who did not lose weight. Fat free mass and functional status changes were observed with and without weight loss.

Funding: NIDDK Support

TH-PO977

Impact of Bariatric Surgery on Metabolic and Lithogenic Risk Factors in Patients with Morbid Obesity

Sofia San Román, Gustavo Bruno, Lucía Fernández Talice, Gabriela Ottati, Pilar Portas, Mariela Garau, Oscar A. Noboa. *Universidad de la Republica Uruguay, Montevideo, Uruguay.*

Background: Obesity and metabolic syndrome are risk factors for kidney stones. Bariatric surgeries, Roux-en-Y gastric bypass (RYGB) and sleeve gastrectomy (SG), are options for the management of obesity. Despite the many positive metabolic outcomes, RYGB is also associated with higher risk of kidney stones after surgery. The aim of this study is to determine the modification of lithiasis risk factors in obese patients post-bariatric surgery.

Methods: Descriptive, observational and prospective study analyzing lithogenic factors before and 6 months after bariatric surgery. Wilcoxon signed-rank test was used to assess median differences. Ethical approval was obtained

Results: 25 patients (24 womens), mean age was 43.3 (±10.6) years. RYGB was performed in 16 and SG in 9. The initial BMI was 47 kg/m ^{2} (38.0 - 70.4 kg/m^2). The post BMI was 30.6 kg/m^2 (22 - 50 kg/m^2). In the pre-bariatric study, 10 patients had oxaluria higher than 40 mg/day, with a mean of 37.1 ± 17.5 mg/day, 7 had calciuria higher than 250 mg/day, with a mean of 195.7 ± 148.9 mg/day, 15 had uricosuria higher than 600mg/day, with a mean of 706.9 ± 290.7 mg/day, 10 had citraturia less than 300mg/day, with a mean of 514.8 ± 408.5 mg/day, and 10 had magnesiuria less than 73mg/day with a mean of 88.7 ± 46.2 mg/day. 15 had parathyroid hormone (PTH) levels higher than 68pg/mL, with a mean of 83.8 ± 38.4 pg/mL with normocalcemia, 11/15 with hypovitaminosis D. Postoperatively, significant reductions were seen in hyperuricosuria present in 6/25 patients, with a mean of 498.9 ± 194.2 mg/day, p: 0.005, and hypomagnesuria present in 5/25, with a mean of 120.8 ± 68.8 mg/day, p: 0.021. Mean oxaluria was 33.9 ± 25.6mg/day, decreasing in 6/10 patients with preoperative hyperoxaluria and new onset in 3 patients, with no differences based on the type of surgery. Citraturia and calciuria showed a non-significant decrease. Among the 15 patients with elevated (PTH) levels preoperatively, only 6 remained elevated postoperatively, 4 with persistent hypovitaminosis D. Additionally, 3 patients developed postoperative hyperparathyroidism.

Conclusions: Morbid obesity presents significant lithogenic risk factors. Bariatric surgery modifies these factors, particularly reducing hyperuricosuria and increasing hypomagnesiuria

TH-PO978

Dynamics of Changing Nutritional Status following Kidney Transplantation

Diana Sukackiene,[1,2] Marius Miglinas.[1,2] *[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]Center of Nephrology, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania.*

Background: Kidney transplantation (KTx) is the optimal treatment for end-stage renal disease (ESRD) which improving patient survival, yet nutritional and metabolic disorders in patients both before and after KTx are an important clinical and scientific problem. Our study aimed to assess the nutritional status and body composition of candidates for kidney transplantation before the surgery and 12 months after it, to analyse the changes.

Methods: Prospective, observational study was conducted in a tertiary reference hospital. The nutritional status of the patients was assessed by performing laboratory tests, anthropometric measurements, and body composition analysis by using the Bioelectrical Impedance Analysis (BIA), measuring the handgrip strength (HGS), and filling out malnutrition (MN) screening tools on the day of KTx, 6 and 12 months after it.

Results: A total of 98-kidney transplant patients (mean age of 43 [20;60] years, 55 % male, 10 % with diabetes) were included. 52 % of the subjects were overweight or obese before KTx and only 4 % had BMI less than 18.5 kg/m^2 . The baseline screening showed the prevalence of malnutrition prior to the KTx ranged from 7 to 40 %, depending on the screening questionnaire. When assessing the nutritional risk after KTx - the frequency of a low or mild risk of MN is reduced, and more patients achieve a good nutritional status and subsequently lose the risk of MN (87–98%). In the female population, HGS significantly decreased when assessed before KTx and after 6 months (26.2 ± 6 kg and 24.1 ± 6 kg, $p < 0.01$), as well as after 12 months (26.2 ± 6 kg and 24.2 ± 6.7 kg, $p < 0.01$). In men, a significant decline in HGS was observed only after 6 months (46.3 vs 44.1 kg, $p < 0.01$) A decrease in the muscle mass was found in 8% of males 6 months after the surgery, and in 4% of females 12 months after the surgery. This reduction in the muscle mass leads to a significant loss of fat free mass. During the 1-year follow up period we observed a significant increase in body weight (77.6 ± 17.6 kg vs 79.1 ± 18.3 kg), waist circumference (92.6 ± 15 cm vs 96.7 ± 16.2 cm), fat mass (14.4 [1.8-56.9] kg vs 17.3 [2-51.8] kg).

Conclusions: Kidney transplantation leads to changes in body composition that favor increasing body weight driven by fat mass accumulation, increased waist circumference and lean body mass loss.

Clenbuterol-Associated Rhabdomyolysis: A Rare Case Report

Parth Parmar,[1] Prachi Gajjar,[1] Hetvi Gajjar,[2] Dhruvil K. Shah,[1] Pratik Gyawali,[1] Sepiya Shrestha,[1] Kashish Magnani.[3] *[1]Trumbull Regional Medical Center, Warren, OH; [2]Pramukhswami Medical College, Karamsad, India; [3]Surat Municipal Institute of Medical Education and Research, Surat, India.*

Introduction: Clenbuterol is a beta-2 agonist medication used by fitness enthusiasts for anabolic and lipolytic effects. It has been obtained from illegal markets since it was banned by the US FDA. It carries the risk of severe adverse effects such as myocardial infarction, death and others.

Case Description: We present a case of a 43-year-old male who was involved in bodybuilding. He presented to the hospital with complaints of red urine for a day after using Clenbuterol in higher doses and an extensive workout session at the gym. On admission, laboratory findings showed serum creatine kinase levels of 66,000 U/L and red urine without red blood cells in urinalysis, suggesting the diagnosis of rhabdomyolysis. He survived no fractures or muscle injuries recently. He maintained adequate urine output and normal serum creatinine levels throughout his hospital stay. With intravenous hydration, laboratory serum creatine kinase values trended down to normal. The patient was discharged and advised that the US FDA does not recommend Clenbuterol in the United States for any use in humans or animals.

Discussion: Clenbuterol is an illegally available illicit drug used by fitness enthusiasts. Case reports regarding rhabdomyolysis in humans after illicit use are limited. Proper education regarding Clenbuterol and its serious adverse effects, including death, is needed among fitness enthusiasts. Physicians must also keep a differential diagnosis of rhabdomyolysis due to Clenbuterol in young athletes.

Effects of Intradialytic Aerobic Exercises on Mitochondrial Biogenesis Markers in Patients Undergoing Hemodialysis

Denise Mafra,[1,2] Livia D. Alvarenga,[2] Ludmila F. Cardozo,[1] Marcelo Ribeiro-Alves,[3] Jessyca S. Brito.[2] *[1]Universidade Federal Fluminense, Niteroi, Brazil; [2]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [3]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil.*

Background: Chronic kidney disease (CKD) patients commonly have impaired mitochondrial biogenesis and antioxidant defenses. Therefore, gene transcription factors involved with mitochondrial function, such as the peroxisome proliferator-activated receptor gamma 1 alpha coactivator (PGC-1α), the nuclear respiratory factor-1 gene (NRF1) and the mitochondrial transcription A (TFAM), may have its expression modified in patients with CKD. Furthermore, nuclear factor erythroid 2-related factor 2 (Nrf2), an important antioxidant transcription factor, and antioxidant enzymes such as NQO1: NAD(P)H: quinone oxidoreductase-1 (NQO1) are downregulated in CKD patients contributing to oxidative stress. Thus, the study aimed to evaluate the effects of an aerobic intradialytic exercise program on the expression of mitochondrial function markers and antioxidant function in hemodialysis (HD) patients.

Methods: This was a longitudinal crossover clinical trial that included 18 HD patients [61.1% men; 44 (12.2) years; 23.7 (3.9) kg/m^2; dialysis vintage = 17.2 (20.2) months]. Patients were randomized into 2 groups: exercise and control (usual care). The physical exercise program was individualized and performed on an adapted stationary bicycle, consisting of heating (5 minutes), 35 minutes of aerobic training at target heart rate, and cool down (load reduction for 5 minutes), monitored thrice weekly for 3 months. After this, there was one month of washout, crossover, and another 3 months of intervention. Peripheral blood mononuclear cells were isolated and processed to evaluate PGC-1α, NRF1, TFAM, Nrf2, and NQO1 mRNA expression by RT-qPCR.

Results: After the intradialytic exercise program intervention, there was no significant change in the mitochondrial parameters evaluated (PGC-1α, TFAM, and NFR1) nor in the parameters related to antioxidant defenses (Nrf2 and NQO1). Interestingly, a positive correlation was found between PGC-1α and Nrf2 mRNA expression ($r=0.38$ $p=0.04$) and between TFAM and NRF1 ($r=0.45$, $p=0.00$) at baseline.

Conclusions: Three months of interdialytic aerobic exercise was insufficient to modulate significantly mitochondrial biogenesis markers or increase antioxidant defenses.

TH-PO981

Association between Kidney Function and Comprehensive Frailty in Elderly Japanese Community-Dwelling Adults

Tatsunori Toida, Akiko Kamimura, Toshiyuki Atsumi, Yasuyuki Kourogi. *Kyushu University of Medical Science, Nobeoka, Japan.*

Background: The Japanese government has implemented a new screening program to prevent the worsening of comprehensive frailty in older adults, and a new frailty assessment questionnaire for medical check-ups of old-old adults aged ≥75 years (QMCOO) has been developed starting in 2020. Few detailed studies have investigated renal function as a risk factor for comprehensive frailty. Therefore, this study examined the association between renal function and comprehensive frailty using the QMCOO score in Japanese community-dwelling elderly.

Methods: Between April 2020 and March 2021, 4621 participants (mean age: 80.1 years; 39.5% male) underwent annual health check-ups in Nobeoka City, Miyazaki Prefecture, Japan. Subjects were divided into four groups based on their estimated glomerular filtration rate (eGFR): G4+5 (<30 mL/min/1.73m^2, n=106), G3b (30–44 mL/min/1.73m^2, n=473), G3a (45-59 mL/min/1.73m^2, n=1477), and G1+2 (≥60 mL/min/1.73m^2, n=2526). Associations between the eGFR groups and comprehensive frailty assessed using a cutoff score of 3/4 for the QMCOO (Geriatr Gerontol Int. 2023, 23,437) were examined. Physical, oral, nutritional, cognitive, and social frailty subdomains were also investigated. In a longitudinal analysis, the G1+2 group served as a reference to

investigate the incidence of comprehensive frailty during the following year among participants without frailty at baseline (n=2398) using logistic regression models to examine odds ratios adjusted for potential confounders.

Results: In this cross-sectional study, the frequency of comprehensive frailty increased with worsening renal function (G1+2: 21.5%; G3a: 23.2%; G3b: 32.8%, G4+5: 38.7%). The results were similar for the physical, oral, nutritional, and cognitive subdomains though no association between renal function and social frailty was identified. In the longitudinal study, a G4+5 eGFR was significantly associated with new-onset comprehensive frailty (G3a: odds ratio (OR): 0.83, 95% confidence interval (CI): 0.62–1.10; G3b: OR: 0.69, 95% CI: 0.43–1.09; G4+5: OR: 2.37, 95% CI: 1.10-5.20).

Conclusions: A decline in renal function in older adults may be a risk factor for comprehensive frailty.

TH-PO982

Estimating Glomerular Filtration Rate: Is There Any Role of Including Lipids and Hemoglobin A1c (Hb A1c) in Patients with Cardiovascular Disease?

Madhab Ray.[1,2] Healthy Heart Initiative Study Group. *[1]University of California Davis, Davis, CA; [2]Tufts Medical Center, Boston, MA.*

Background: Estimation of Glomerular Filtration Rate (GFR) is a cornerstone in practice of nephrology and modern medicine. Over the last few decades, the estimation process has gone through multiple iterations with combinations of different potential predictor variables. Most commonly used CKD-Epi formula incorporates five variables: age, sex, race, body surface area and serum creatinine levels. However, there are potentially some unmeasured variables which, in a given clinical context may add predictive accuracy.

Methods: Four thousand schoolteachers were recruited in Calcutta, India for cardiovascular disease (CVD) risk assessment and evaluation of kidney function with joint approval from Tufts University IRB, Boston, and the local Ethics Committee, Calcutta. GFR was estimated with CKD-Epi model. To explore any potential unmeasured variables for GFR regression analyses were performed with traditional CVD risk factors: lipid panel for dyslipidemia and Hb A1c for diabetes mellitus.

Results: The mean age of the participants was 44 years with 41% male. Estimation of renal function with eGFR revealed most of the study population had CKD G2 (n = 125, 52%) followed by G1 and G3 (n = 53, 22% each). Six participants had CKD G3B while number of participants in G4 and G5 were one in each category. Univariate analyses showed considerable association of GFR with total cholesterol, HDL, triglycerides and Hb A1C. A multivariable regression model showed significant association with HDL and Hb A1 C when adjusted for total cholesterol and triglycerides.

Conclusions: In patients with CVD and diabetes mellitus incorporating Hb A1 C level may potentially improve accuracy of estimated GFR by CKD-Epi model. It is important for the clinicians to remain cognizant of the possibility of inflated GFR in presence of diabetes mellitus with high Hb A1C. Similar adjustment, although to a lesser extent, may be necessary for HDL level. While elevated HB A1 C level may increase GFR by its glycosuric effect the mechanism by which HDL may influence GFR is not entirely clear at this point.

Multivariable linear regression model with HDL and Hb A1C for eGFR

	Estimate	95% CI	P value
Intercept	88.6	72.52 — 104.66	<0.001
Cholesterol	-0.03	-0.11 — 0.05	0.5
HDL	-0.55	-0.81 — - 0.28	<0.001
Triglycerides	0.03	-0.02 — 0.08	0.18
HB A1C	1.99	0.17 — 3.81	0.03

TH-PO983

Association between Potential Renal Acid Load and 10-Year Mortality in Patients on Hemodialysis

Mai Tanaka, Hideyuki Kabasawa, Michihiro Hosojima. *Department of Clinical Nutrition Science, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Dietary intake has long been known to influence acid-base balance. Recently, higher dietary acid load (DAL) has been reported to be associated with increased risk of incidence and progression of chronic kidney disease. However, the association between DAL and mortality in patients on maintenance hemodialysis (MHD) has not been evaluated. In this study, we investigated the association between DAL and mortality and analyzed the kinds of food that affect DAL in Japanese patients on MHD.

Methods: We retrospectively analyzed baseline laboratory data, self-administered diet history questionnaire results, and 10-year mortality rates in 44 patients (26 men, 67.9±10.4 years) on MHD who participated in a randomized, double-blind, crossover pilot trial of rice endosperm protein supplementation which was conducted in 2013. DAL was estimated from nutrition intake using potential renal acid load (PRAL). Patients were divided into tertiles according to PRAL score to explore its association with all-cause mortality. Cox proportional hazards regression with adjustment for age and sex was performed to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for all-cause mortality. In addition, multivariable logistic regression was performed to estimate odds ratios (ORs) for the kinds of food that significantly affected PRAL score.

Results: During the 10-year observation period, a total of 19 patients (43%) died. Mean PRAL score was 11.0 mEq/L. A higher PRAL score was significantly associated with higher all-cause mortality. The multivariable-adjusted HR for all-cause mortality in the highest tertile compared with the lowest tertile of PRAL score was 3.88 (95% CI, 1.10-13.61). Multiple logistic regression analysis showed a significant association between higher PRAL score and lower intake of green and yellow vegetables (OR, 5.40; 95%CI, 1.37-21.26) and fruits (OR, 4.76; 95% CI, 1.30-16.76).

Conclusions: Our findings suggested that high PRAL score is positively associated with all-cause mortality in patients on MHD. Low intake of fruits and vegetables would increase PRAL score and might affect the risk of mortality in Japanese patients on MHD. Further studies, including prospective ones, are needed to confirm whether DAL affects mortality in patients on MHD.

TH-PO984

Prevalence of Visual Impairment and Effects on Quality of Life (QoL) in a Population of Inner-City Patients with ESKD

Wen Huang, Sasha E. Gerard, Mariana S. Markell. *SUNY Downstate Health Sciences University College of Medicine, Brooklyn, NY.*

Background: Kidney disease is often associated with eye disease. We investigated the prevalence of visual impairment and impact on QOL in an inner city population of pts with ESKD.

Methods: A random convenience sample of 13 hemodialysis and 13 kidney transplant pts were surveyed face to face regarding their visual ability utilizing general vision-related questions and the National Eye Institute Visual Function Questionnaire (NEI VFQ-25).

Results: Mean age was 61.8±2.5yrs, 15 male (58%), 22 (85%) identified as Black, 59% (13) made <$40K/yr. 41% (10/24) rated their vision as fair to poor. Higher income was associated with better vision related mental health (r=0.6, p=0.005), despite no association with personal vision rating. Mean HbA1c was 6.2±0.2, range 4.7-8.8. Higher HbA1c was associated with eye discomfort (r=0.68, p<0.001), difficulty seeing at night (r=0.44, p=0.03), inability to accomplish tasks (r=-0.45, p=0.03), limitation due to optic pain or discomfort (r=-0.63, p=0.01), being more likely to stay home (r=-0.51, p=0.01) and feeling less control (r=-0.59, p=0.002). Pts who stayed home were also more likely to report no longer reading the newspaper or doing close activities (r=-0.61, p=0.002), being unable to read street signs (r=-0.59, p=0.002), find things (r=-0.77, p<0.001) or use stairs (r=-0.77, p=0.001). They also reported difficulty judging facial reactions (-0.69, p<0.001), frustration (r=0.85, p<0.001), inability to work (r=0.74, p<0.001), increased dependency (r=-0.78, p<0.001), decreased mental health (r=0.84, p<0.001) and decreased social interactions (r=0.78, p<0.001). There was no difference between dialysis and txp pts or males and females.

Conclusions: In our population: 1. Almost half of pts rated their vision as fair to poor 2. Pts with higher income had better adjustment to visual limitations. 3. Higher HbA1c was associated with more symptoms, decreased social interaction, and feeling less control. 3. Limited vision patients reported stopping normal daily activities, inability to work, decreased mental health and increased dependency. 4. Visual impairment has far reaching impact on QoL in pts with ESKD and may be overlooked given other medical issues. Decreased visual function should be recognized and addressed early in the course of kidney disease, with targeted support provided for the already visually impaired.

TH-PO985

Impact of Fatty Acid Desaturase 1 on CKD via Very Low-Density Lipoprotein-Associated Metabolites: A Drug Target-Related Mediation Mendelian Randomization Study

Lei Chen, Wanxin Tang. *West China Hospital of Sichuan University, Chengdu, China.*

Background: Metabolic dysregulation plays a crucial role in chronic kidney disease (CKD). Identifying new targets for CKD through metabolites and their regulatory genes requires further investigation.

Methods: A total of 233 metabolites from GWAS Catalog with $P < 5 \times 10^{-8}$ were utilized for Mendelian randomization with CKD. External validation was conducted from UK Biobank. Cis-eQTL of genes related to VLDL were selected for Mendelian randomization with CKD and metabolites. The total effect of the fatty acid desaturase 1 gene (*FADS1*) on CKD and metabolite-mediated effects were calculated. Bulk RNA-seq were used to validate *FADS1* expression in the kidney tissues of patients with CKD.

Results: The cholesteryl esters to total lipids ratio in medium VLDL (OR = 0.84 [0.77–0.92]; P.adj = 0.039) and total cholesterol to total lipids ratio in small VLDL (OR = 0.84 [0.77–0.91]; P.adj = 0.003) were protective factors for CKD, whereas the triglycerides to total lipids ratio in small VLDL (OR = 1.18 [1.09–1.27]; P.adj = 0.009) and the triglycerides to total lipids in very small VLDL (OR = 1.19 [1.10–1.27]; P.adj < 0.001) were risk factors. They mediated the risk of CKD by *FADS1* (OR = 1.11 [1.06–1.17]; P.adj = 0.001), and mediation effects of 21.17%, 10.43%, 23.52%, and 29.96% were obtained. The differential expression of *FADS1* was observed in the kidney tissues of patients with CKD.

Conclusions: *FADS1* is a risk factor for CKD and a novel therapeutic target. Four metabolites mediate the detrimental effect of *FADS1* in CKD.

TH-PO986

Lipoprotein (a) and Kidney Function: A Correlation Study

Xinyi Fu, Chenyu Lei, Anning Xu, Linlin Yuan, Wenjing Cai, Qingying Shi, Xinling Liang, Zhiming Ye, Zhilian Li. *Department of Nephrology, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China.*

Background: Recent evidence implicates Lipoprotein(a) [Lp(a)] as a potent atherogenic factor, surpassing LDL in its cardiovascular risk. Despite this, the dynamics of plasma Lp(a) levels across varying stages of renal function, as defined by estimated Glomerular Filtration Rate (eGFR), remain inadequately explored. This retrospective study aims to investigate the relationship between plasma Lp(a) concentrations and renal function, utilizing a large patient cohort.

Methods: Between January 2019 and December 2022, data from 141,376 patients at Guangdong Provincial People's Hospital, including renal function parameters and lipid profiles, were analyzed. Lipid markers studied encompassed Lp(a), triglycerides (TG), total cholesterol (TC), HDL-C, LDL-C, Apo A1, and Apo B. Patients were stratified into five groups per eGFR levels aligning with chronic kidney disease stages (KDIGO guidelines). Plasma Lp(a) levels were compared across these groups through the Kruskal-Wallis test, with statistical analyses performed using SPSS version 22.0.

Results: The median plasma Lp(a) concentration in the study population was 166.0 mg/L (IQR: 91.0 - 346.0 mg/L). Importantly, the median plasma Lp(a) levels (IQR) showed a progressive increase across the five eGFR groups, as follows: eGFR ≥ 90 mL/min/1.73 m^2 : 153.0 (85.0, 313.0) mg/L;eGFR 60-89 mL/min/1.73 m^2: 172.0 (95.0, 351.0) mg/L;eGFR 30-59 mL/min/1.73 m^2: 203.0 (107.0, 422.0) mg/L;eGFR 15-29 mL/min/1.73 m^2: 235.0 (125.0, 469.0) mg/L;eGFR < 15 mL/min/1.73 m^2 : 260.5 (148.0, 460.0) mg/L. Statistical analysis revealed a highly significant difference in Lp(a) levels among the groups (p< 0.01), with pairwise comparisons also demonstrating statistically significant differences between each group (p < 0.01). Notably, this trend was not observed for other lipid markers including LDL-C and ApoB.

Conclusions: Our findings underscore a clear association between plasma Lp(a) concentrations and renal function decline. As eGFR decreases, there is a discernible rise in plasma Lp(a) levels, highlighting its potential role in renal dysfunction progression.

TH-PO987

Trend Analysis of Kidney Failure and Metabolic Syndrome-Related Mortality, 1999-2020

Mohammad Ammar ur Rahman,[1] Ahmed J. Chaudhary,[2] Jawad Ahmad,[2] Saleha Azeem,[1] Luqman Munir,[1] Amna Khalid.[1] *[1]King Edward Medical University, Lahore, Pakistan; [2]Detroit Medical Center, Detroit, MI.*

Background: End-stage renal disease which manifests as renal failure is one of the leading causes of death in America and when combined with a comorbidity like metabolic syndromes, has reasonable prevalence. Minor metabolic syndromes including lipomatosis, lipodystrophy, and tumor lysis syndrome increase the complications of renal failure by interfering with the function of the already diseased kidney to a greater extent which is often the underlying pathology. The goal of this study is to explore the trends of mortality due to renal failure when combined with various minor metabolic syndromes like lipomatosis, lipodystrophy, and tumor lysis syndrome from 1999 to 2020 using the age-adjusted mortality rates to target inconsistencies in various epidemiological groups. These metabolic syndromes affect the overall survival outcome of patients with end-stage renal disease leading to worse outcomes.

Methods: We analyzed Death Certificates from the Centers for Disease Control and Prevention (CDC) Wide Ranging Online Data for Epidemiological Research (WONDER) database from 1999-2020. AAMR per 1,000,000 people and annual percent change (APC) with a 95% confidence interval were determined. We then used the Joinpoint Regression Program to obtain trends amongst demographic (race, ethnicity, gender, age) groups.

Results: There has been a steady rise in mortality from 1999 to 2015 with an annual percent change (APC) of 4.47 but from 2015 onward, a steep rise in mortality with an APC of 17.67 has been observed. Overall mortality for males has been higher and steady but APC for females followed an interesting trend as it declined from 2003 to 2007 but has risen since. African Americans have consistently had worse outcomes as APC since 1999 has been in the high 20s with it dropping down in the early to mid-2000s. South census region has crept up to be the region most affected which until 2012 was the Midwest.

Conclusions: Renal failure and metabolic syndromes-related mortality have experienced an uprise in the United States in recent years. Persistent demographic and geographic disparities in renal failure and associated metabolic syndromes' mortality underscore the need for further investigation and intervention.

TH-PO988

Prevalence of Hyperuricemia and Its Correlation with Metabolic Syndrome in Young Adults: A Cross-Sectional Study in Eastern China

Bohan Lu.[1,2] Dept of Nephrology, Renji Hospital, Shanghai Jiaotong University School of Medicine. *[1]Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Ningbo Hangzhou Bay Hospital, Ningbo, China.*

Background: Hyperuricemia (HUA) has emerged as a significant metabolic disease, particularly in young population with metabolic syndrome (MS). The purpose of this study was to study the prevalence of HUA and its correlation with metabolic syndrome among young adults in a coastal city of eastern China.

Methods: It was a cross-sectional study conducted in adults undergoing routine healthy checkup. Anthropometric data and serological parameters were collected and in related to serum uric acid (SUA) concentration and prevalence of HUA.

Results: A total of 9,196 adults with mean age of 34.3 ± 11.8 years old and 75.2% of males were recruited. Mean SUA level was 371.8 ± 95.6 mmol/l and overall HUA prevalence was 31.3%. SUA level was higher and HUA was more common in younger males, as well as in those with MS (OR: 3.07; 95% CI: 2.78 - 3.39) demonstrated by using the univariable binary logistic regression analysis model. The multivariable binary logistic regression analysis revealed that male (OR: 3.74; 95% CI: 3.12 - 4.48), young age (OR: 1.22; 95% CI: 1.19 - 1.26), low estimated-glomerular filtration rate (OR: 2.45; 95% CI: 2.11 - 2.84), high body mass index (OR: 2.31; 95%CI: 2.06 - 2.60), hypertension (OR: 1.18; 95% CI: 1.04 - 1.32), high serum triglyceride (OR: 2.08; 95%CI: 1.81 - 2.37), and low serum high-density lipoprotein cholesterol (OR: 1.33; 95% CI: 1.15 - 1.55) were independent risk factors associated with HUA prevalence.

Conclusions: SUA level increased and HUA was common in young adults. Male, young age, reduced kidney function, combined with MS and more MS components were associated with prevalence of HUA.

TH-PO989

Association of Zinc Deficiency with Abdominal Fat and Muscle Mass Areas in Patients on Hemodialysis

Junko Ishida,[1] Nao Muramoto,[1] Masako Tanaka,[1] Yoshiteru Yamada,[2] Mayumi Yamada,[2] Ai Asano,[2] Teppei Matsuoka,[2] Akihiko Kato.[3]
[1]Kinjo Gakuin University, Nagoya, Japan; [2]Taiseikai Medical Corporation, Ogaki, Japan; [3]Hamamatsu University Hospital, Hamamatsu, Japan.

Background: Zinc (Zn) deficiency is highly prevalent in hemodialysis (HD) patients. However, the relationship between Zn deficiency and body muscle and fat masses remains to be clarified in HD patients. So, we aimed this study to examine the relationship between serum Zn levels and anthropometric parameters in HD patients in a cross-sectional design.

Methods: We measured abdominal muscle area (AMA), subcutaneous fat area (ASFA) and visceral fat area (AVFA) on transverse slice of computed tomography (CT) at L3 to L4 of vertebral bodies in 287 patients who had been undergoing regular HD for more than 2 years (median age: 69.0 years old, M/F = 200/87, diabetes (DM)/non-DM = 87/200). We adjusted these parameters by height square. This study was approved by the Institutional Ethics Committee of Kinjo Gakuin University and supported by JSPS KAKENHI(JP20K10391).

Results: Serum Zn was lower than the reference range (80~130 μg/dL) in almost of the patients (97%). Median Zn level was significantly lower in non-DM patients (56.0 [51.0-62.0] μg/dL) when compared with DM patients (58.0 [53.0-66.0] μg/dL) (p<0.05). Zn deficiency (<60 μg/dL) was found in 64.5% of non-DM patients and 54.0% of DM patients, respectively. AMA, ASFA, AVFA were significantly lower in non-DM than in DM patients (p<0.05) (Table). There was a significant and positive correlation between serum Zn and AMA in non-DM patients (r=0.185, p<0.01), but not in DM patients. Serum Zn was also significantly and negatively correlated with ASFA, but not with AVFA in DM and non-DM groups. Multiple regression analyses revealed that serum Zn was a significant determinant of AMA and ASFA.

Conclusions: Our findings suggested that Zn deficiency is associated with abdominal muscle wasting, while with accumulation of subcutaneous fat mass in non-DM HD patients.

Funding: Other NIH Support - This work was supported by Grant-in-Aid for Scientific Research "JSPS KAKENHI" Grant Number JP 20K10391

Abdominal anthropometric parameters in non-DM and DM patients

Primary disease	Non-DM	DM	P value
N	200	87	
Age (years)	70.0 (59.0 - 78.0)	68.0 (55.0-73.0)	N.S.
HD vintage (years)	10.6 (4.9 - 19.7)	5.9 (2.9-9.0)	< 0.05
AMA (cm2/m2)	33.09 (27.66 - 39.23)	35.31 (30.11 - 41.54)	< 0.05
ASFA (cm2/m2)	35.17 (22.09 - 56.14)	43.60 (32.40 - 61.19)	< 0.01

Early Evidence of Tendon Dysfunction in a Rat Model of CKD

Christopher Hayden,[1] Natalie K. Gilmore,[1] Baback Roshanravan,[2] Keith Baar.[1] *[1]University of California Davis, Davis, CA; [2]University of California Davis School of Medicine, Sacramento, CA.*

Background: Spontaneous tendon ruptures are debilitating injuries that are disproportionately high in individuals with chronic kidney disease (CKD). Despite this, almost no data exists regarding CKD-related tendon pathology. Thus, we used a rat model of CKD to determine whether tendon mechanics are altered by CKD.

Methods: Sprague-Dawley rats (n=32, 50% female, age=8wk) were equally divided into a control group (CON) and a group fed chow with 0.25% adenine to induce CKD. After 8wk, blood markers for CKD were evaluated, and Achilles and tibialis anterior (TA) tendons were collected. Tendons were then tested in tension to failure using a single-column tensile tester with a 100N load cell. Maximum tensile load (MTL), failure stress, Young's modulus, and cross-sectional area (CSA) were determined. The strongest of each tendon for every animal was used in analysis. The effect of CKD was evaluated for each tendon by two-way ANOVA (main and interaction effects: CKD and sex).

Results: CKD was confirmed through elevated creatinine (1.99 vs 0.61mg/dL, CKD vs CON, P=0.001), blood urea nitrogen (93.4 vs 21.4mg/dL, P<0.001), kidney mass (2.7 vs 1.25g, P<0.001), and lower hematocrit levels (34 vs 47%, P<0.001). Final body weight did not differ for the females (282 vs 284g, P=0.9), but the CKD males were lighter than controls (438 vs 585g, P<0.001). The failure stress of TA tendons was significantly lower in CKD vs CON (18.8 vs 24.8 mPa, P=0.039). There were no statistically significant differences in MTL, modulus, or CSA (p>0.097) or for any parameter for the Achilles (P=0.73). Sex did not modify the effects of CKD (P=0.86).

Conclusions: We demonstrate that, early in the development of CKD in rats, TA tendons failed at a lower stress. These results along with the finding that there were no differences in CSA between groups suggest that CKD diminishes tendon material properties. To our knowledge, this is the first direct evidence of changes in tendon mechanics caused by kidney disease, providing a model for further evaluating mechanisms and interventions.

Gut Microbe-Derived Metabolite Phenylacetylglutamine and Risk of CKD Progression

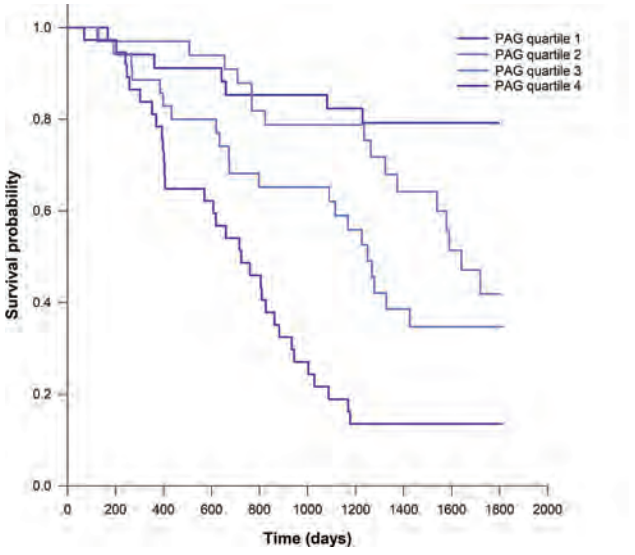
Evelyn Cheng,[1] Ting-yun Lin,[2] Szu-Chun Hung.[2] *[1]University of Washington, Seattle, WA; [2]Taipei Tzu Chi Hospital, Taipei, Taiwan.*

Background: Phenylacetylglutamine (PAG) is a gut microbe-derived metabolite from dietary phenylalanine. High PAG levels have been associated with overall mortality and cardiovascular disease in patients with CKD. However, potential associations of PAG with the risk of progression to kidney failure in patients with CKD remains unclear.

Methods: We prospectively followed 152 non-dialysis patients with CKD stages 3–5 and a measurement of plasma PAG. The primary outcome was a composite of progression of kidney disease (defined as a sustained decrease in eGFR of ≥40% from baseline, initiation of maintenance dialysis, kidney transplantation, or death from renal causes).

Results: Participants had a mean age of 66 years; 41.4% were women; 39.5% had diabetes; and the median eGFR was 23 mL/min/1.73 m2. Participants with higher PAG were more likely to have a significantly lower eGFR (P <0.001). During a median follow-up of 3.3 years, progression of kidney disease occurred in 76 (50%) participants. Higher PAG was associated with a significantly increased risk of the composite outcome after controlling for demographics, comorbidities, and proteinuria (hazard ratio, 1.79; 95% CI, 1.27–2.54). However, the association was attenuated and statistically insignificant after adjustment for eGFR.

Conclusions: Our findings suggest the relevance of PAG in the progression of kidney disease. Whether PAG is simply a marker of kidney dysfunction or, in contrast, whether PAG actively alters the course of CKD needs to be investigated.



PAG and CKD progression. Kaplan–Meier survival curve. Quartiles of serum PAG.

	Model 1		Model 2		Model 3	
	HR (95% CI)	*P* value	HR (95% CI)	*P* value	HR (95% CI)	*P* value
PAG (Ln)	2.47 (1.86–3.29)	<0.001	1.79 (1.27–2.54)	0.001	1.25 (0.86–1.93)	0.229

Gut Microbe-Derived Metabolite Trimethylamine N-oxide and Risk of CKD Progression

Evelyn Cheng,[1] Ting-yun Lin,[2] Szu-Chun Hung.[2] *[1]University of Washington, Seattle, WA; [2]Taipei Tzu Chi Hospital, Taipei, Taiwan.*

Background: Trimethylamine N-oxide (TMAO) is derived from gut microbial metabolism of dietary L-carnitine, phosphatidylcholine, and choline. Higher TMAO have been associated with increased risk of cardiovascular diseases. However, the potential relevance between TMAO and kidney function decline in patients with CKD remains unclear.

Methods: We prospectively followed 152 participants with CKD stages 3–5. Measurement of plasma TMAO was done by liquid chromatography-mass spectrometry at baseline. The primary outcome was defined as a composite of progression of kidney disease (sustained decline in eGFR of ≥40% from baseline, initiation of dialysis, or death from renal causes). Additionally, we performed logistic regression to determine the probability of slow and fast eGFR decline (≤3 versus >3 ml/min/year) with plasma TMAO as the main predictor.

Results: Participants with higher TMAO were more likely to have a significantly lower eGFR. Higher TMAO was significantly associated with an increased risk of the composite outcome after adjustment for demographics, comorbidities, proteinuria, and the use of ACEI/ARB (hazard ratio, 1.48; 95% CI, 1.21–1.97). However, the association was attenuated and statistically insignificant after adjustment for eGFR. Higher TMAO was significantly associated with increased odds of fast eGFR decline after adjustment for eGFR, proteinuria, and other confounding characteristics (odds ratio, 2.35; 95% CI, 1.31–4.22). In addition, gut microbial analyses showed that compared to slow eGFR decliners, fast eGFR decliners had a significantly higher abundance of *Ruminococcus* and *Collinsella*, which have been implicated as TMA-producing bacteria in previous studies.

Conclusions: TMAO is associated with fast eGFR decline in patients with CKD. Whether the gut microbiota contributes to the progression of CKD needs further investigations.

Cox proportional hazard survival analysis

	Model 1		Model 2		Model 3	
	HR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value

Metabolome Biomarkers of CKD Progression in SPRINT Participants

Yunus Ozekin,[1] Zhiying You,[1] Kristen L. Nowak,[1] Berenice Y. Gitomer,[1] Anna Jovanovich,[2] Michel Chonchol.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Bozeman Health, Bozeman, MT.*

Background: Understanding circulating metabolome patterns in relation to kidney disease progression may facilitate the identification of novel biomarkers and development of targeted interventions for CKD progression.

Methods: Untargeted metabolomics of baseline plasma samples from 700 Systolic Blood Pressure Interventional Trial (SPRINT) participants with CKD was performed using UPLC-MS/MS. Bioinformatic analysis was performed using the MetaboAnalyst 6.0 workflow. The association between 35 metabolites and the primary kidney outcome in SPRINT (≥50% decrease in eGFR or development of ESKD requiring dialysis or kidney transplantation) was assessed using Cox proportional hazards models.

Results: Baseline characteristics are summarized in Table 1. There were 1686 metabolites with standardized measurements at baseline. 234 compounds were upregulated and 27 were downregulated (p<0.05, abs(fold change) >1.5) (Fig. 1). The associations of the top 35 metabolites with the CKD composite outcome in SPRINT are shown in Fig. 2.

Conclusions: Among patients with CKD, novel metabolites derived from untargeted metabolomic profiling were independently associated with kidney disease progression outcomes.

Metabolites Associated with Inflammatory Proteins in the AASK Study

Teresa K. Chen,[1,2] Aditya L. Surapaneni,[3] Michelle M. Estrella,[1,2] Lawrence J. Appel,[4] Wassim Obeid,[4] Chirag R. Parikh,[4] Morgan Grams.[3]
[1]University of California San Francisco, San Francisco, CA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]New York University, New York, NY; [4]Johns Hopkins University, Baltimore, MD.

Background: Inflammation is associated with greater risk of adverse outcomes, including CKD progression, CVD, and mortality, and may also be impacted by the metabolic milieu. Using an untargeted metabolomics approach, we identified metabolites associated with 9 inflammatory proteins (TNFR1, TNFR2, TNF-α, IFN-γ, IL-6, IL-8, IL-10, UMOD, EGF) in the African American Study of Kidney Disease and Hypertension (AASK).

Methods: Among 491 AASK participants (37% female, mean age 54 y and GFR 45 mL/min/1.73m^2, median UPCR 91 mg/g), we measured 812 serum metabolites by untargeted mass spectrometry (Metabolon) at study baseline and serum proteins by targeted immunoassays (MesoScale Discovery) at baseline, 12- and 24-months. Using multivariable linear regression, linear mixed-effects, and Cox PH models, we evaluated associations of metabolites with proteins at baseline, over time, and with ESKD risk, respectively. We used Metaboanalyst to identify enriched metabolomic pathways for each protein.

Results: At baseline, 367 associations between metabolites and inflammatory proteins were significant after Bonferroni correction: with more positive associations for TNFR1 (97%), TNFR2 (97%), IL-8 (77%), and IL-10 (100%); more negative associations for UMOD (80%) and EGF (97%); and variable for TNF-α, IFN-γ, and IL-6. Enriched pathways differed across inflammatory proteins (**Table**). For TNFR1 and TNFR2, these included inositol phosphate metabolism, ascorbate and aldarate metabolism, and tryptophan metabolism. Several metabolites were associated with changes in TNFR1, TNFR2, TNF-α, IL-8, UMOD, or EGF. Higher levels of tigylcarnitine and N2,N5 diacetylornithine were associated with 2-year increases in TNFR1 and/or TNFR2, and notably of ESKD (**Figure**).

Conclusions: Using an untargeted approach, multiple metabolites were cross-sectionally and longitudinally associated with inflammatory proteins.

Urine Metabolome and CKD Progression in African American Patients

Changwei Li,[1] Ruiyuan Zhang,[1] Morgan Grams,[2] Tanika Kelly,[3] Jing Chen,[4,1] Jiang He.[1]
[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [2]New York University Grossman School of Medicine, New York, NY; [3]University of Illinois System, Urbana, IL; [4]Tulane University School of Medicine, New Orleans, LA.

Background: Urine samples of chronic kidney disease (CKD) patients may contain unique metabolite profiles for CKD progression. However, urinary metabolomic study of CKD progression, particularly among African American (AA) patients, has not been well studied. We aimed to identify novel urinary metabolites associated with CKD progression in AA participants of the Chronic Renal Insufficiency Cohort (CRIC).

Methods: Metabolites were measured from baseline 24-hour urine samples of 1,513 AA participants of the CRIC, using an untargeted approach. After quality control, 1,350 metabolites were analyzed. CKD progression was defined as the onset of end-stage renal disease or a 50% reduction in estimated glomerular filtration rate (eGFR). Associations of metabolites with CKD progression were examined by a base model adjusting for age, sex, study site, smoking, drinking, body mass index, systolic blood pressure, diabetes, cardiovascular disease, and APOL1 risk alleles, and two models sequentially adding urine protein creatinine ratio and eGFR. Metabolites with a false discovery rate corrected q <0.05 were deemed significant. For metabolites with unknown identities, we performed genome-wide analyses to identify genes associated with them.

Results: A total of 569, 287, and 14 metabolites were significantly associated with the risk of CKD progression in the three models, respectively (**Figure**). Among the 14 metabolites identified in the fully adjusted model, *guanidinosuccinate*, a uremic toxin, was most significant, with one standard deviation increase associated with 1.31 (95% confidence interval: 1.18-1.45, q=2.25×10^{-4}) times higher risk of CKD progression. While many known metabolites were previously linked to eGFR, two metabolites, *2-amino-2-methyl-1-propanol (AMP)* and *N2,N6-diacetyllysine*, showed novel associations with CKD progression. Moreover, unknown metabolite X-25422 showed significant associations with *ASNS* and *ASPG*, two genes involved in asparagine synthesis and metabolism.

Conclusions: We identified 14 urinary metabolites associated with CKD progression among African Americans.

Genome-Wide DNA Methylation Association Study Identifies DNA Methylation Associated with ESKD

Xiaohong Zhou. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: End stage renal disease (ESRD) is a leading cause of morbidity and mortality worldwide. It has been increasingly appreciated that epigenetic changes, such as DNA methylation, play an important role in kidney disease.

Methods: Here, using Illumina Infinium EPIC arrays, we performed an epigenome-wide association study (EWAS) of DNA methylation in two ESRD cohorts from China (460 ESRD cases and 196 controls with CKD) and Singapore (229 ESRD cases and 508 controls with T2D).

Results: Through a meta-analysis of the association evidences from the two cohorts, we discovered 2400 differentially methylated probes or CpG sites (DMP) whose DNA methylation levels were associated with ESRD at genome wide significance (P < 1.29e-8), with 39% ~ 72% of which were found to be associated with estimated glomerular filtration rate (eGFR) by several EWAS analyses of eGFR. The 2400 DMPs were mostly located in transcriptionally active enhancers, and 42.7% of them were found to be associated with transcriptomic changes according to published eQTM datasets. By interrogating these 2400 DMPs with the genomic functional information for blood, kidney and muscle tissue, we identified 3788 target genes whose transcriptions may be influenced by these DMPs. The enrichment analysis of these target genes revealed the pathways and GO terms related to immunity and inflammation, endocrinology and metabolism, particularly autophagy process, B cell receptor signaling and insulin resistance.

Conclusions: Our findings have not only discovered ESRD associated DNA methylation variations that can be used as biomarkers for ESRD, but also highlighted certain biological processes that are involved in kidney disease progression to ESRD.

Mendelian Randomization Reveals a Causal Relationship between the Effects of Gut Microbiota and Progression of CKD

Chiehlun Yang. *Xiamen Chang Gung Hospital, Xiamen, China.*

Background: To reveal the causal relationship between gut microbiota and the progression of Chronic Kidney Disease (CKD) using Mendelian Randomization (MR).

Methods: A two-sample MR Analysis combined with Genome-Wide Association Studies (GWAS) data was used to evaluate the potential impact of 195 bacterial groups on CKD progression. Inverse Variance Weighted (IVW) method was used as the main analysis tool. Robustness was verified by weighted median, MR-Egger regression, MR-PRESSO detection and Model-Based Estimation (MBE). The Bonferroni correction method was used to adjust the risk of false positives in multiple comparisons.

Results: MR Analysis showed that *Desulfovibrionales, Eubacterium eligens, Desulfovibrionaceae, Mucoraceae UCG-002, Proteobacteria, and Clostridium* increased significantly with CKD risk ($P<0.05$). Sensitivity analysis showed that the main MR Analysis results were robust.

Conclusions: This study provides evidence of a causal relationship between the gut microbiota and the progression of CKD, and in particular an increased abundance of *Desulfovibrionales* is associated with an increased risk of CKD. These findings reinforce the important role of gut microbes in the pathogenesis of CKD and provide directions for future research and potential clinical interventions.

TH-PO998

Identification of Modifiable Risk Factors for Incident CKD via an Exposome-Wide Association Study

Yang Gyun Kim,[1,2] Sanghyuk Jung,[2] Su Woong Jung,[1] Ju young Moon,[1] Sangho Lee,[1] Dokyoon Kim.[2,3] *[1]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Biomedical Informatics, University of Pennsylvania, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) has no specific treatment, making the control of modifiable risk factors crucial in mitigating kidney disease and related complications. This study aimed to clarify the variable modifiable factors associated with incident CKD.

Methods: We analyzed 351,123 European participants from the UK Biobank who had not been diagnosed with CKD. An exposome-wide association study was conducted with 271 modifiable factors to find associations with incident CKD. Genetically high-risk patients were defined as those having a high polygenic risk score for CKD stage 3 or higher, based on a large-scale genome-wide association study from CKDGen Consortium.

Results: The mean age of subjects was 57.33±7.94 years. CKD occurred in 12,259 cases over a median follow-up period of 11.85 years. Of the 271 risk factors, 155 were significantly associated with incident CKD: 63 factors were protective, while 92 factors had detrimental effect on disease development (Figure 1). When dividing the factors into five main domains- lifestyle, environmental, psychological, socio-economic status, and physical components- 66.24%, 27.27%, 61.76%, 85.19%, and 72.41% significantly contributed to developing CKD in each domain, respectively. Higher physical activity, better pulmonary function, and more coffee intake were the strongest protective factors against the development of CKD, whereas frequent chest pain, physical restriction, and low satisfaction were the highest risk factors. This pattern was consistent across the different CKD genetic risk groups.

Conclusions: This study identified critical modifiable risk factors for incident CKD development. Even for individuals with a high genetic risk, managing these risk factors can effectively reduce the likelihood of developing CKD.

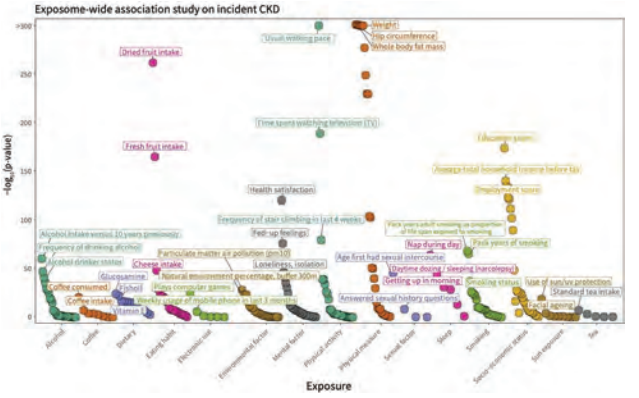

Figure 1

TH-PO999

Effects of Body Mass Index on Rapid Kidney Function Decline: A Two-Sample Mendelian Randomization Study

Haofei Hu,[1,2] Zhiming Ye.[1] *[1]Guangdong Provincial People's Hospital, Guangzhou, China; [2]Shenzhen Second People's Hospital, Shenzhen, China.*

Background: Observational studies have reported an association between body mass index (BMI) and a decline in renal function, but the causal relationship between BMI and renal function decline has not been established. The objective of the study was to use the two-sample Mendelian randomization (MR) approach to evaluate the causal impact of BMI on rapid renal function decline.

Methods: We obtained the instrumental variables for BMI from a meta-analysis of genome-wide association studies (GWAS) that included approximately 700,000 individuals of European descent. To obtain summary statistics data for rapid renal function decline, we used data from a previously published meta-analysis of GWAS that included over 270,000 individuals. Two criteria were used to determine the rapid renal function decline: a decline of 3 mL/min/1.73m^2/year or more in estimated glomerular filtration rate (eGFR) ("Rapid3"), and a drop of 25% or more in eGFR and an eGFR below 60 mL/min/1.73m^2 at follow-up among individuals with eGFR of 60 mL/min/1.73m^2 or more at baseline ("CKDi25). We employed several filtering steps to select robust genetic instruments associated with BMI. Our primary analysis utilized the inverse variance weighted (IVW) method, with additional MR methods including weighted median, MR-Egger, and MR Pleiotropy RESidual Sum and Outlier test.

Results: We utilized a set of 491 single nucleotide polymorphisms (SNPs) as instrumental variables in this MR study. Our findings showed that genetically predicted higher BMI was significantly associated with an elevated risk of rapid renal function decline, as determined by the IVW method for CKDi25 [OR = 1.33, 95% CI = 1.22-1.44, $P = 1.54 \times 10^{-11}$] and Rapid3 [OR = 1.15, 95% CI = 1.09-1.22, $P = 7.99 \times 10^{-7}$]. The results of both the MR Egger regression analysis and the weighted median method were consistent with the primary analysis. In addition, the effect estimate remained stable even after eliminating SNPs that were connected to confounding factors, and the "Leave-one-out" analysis validated the consistency of our findings. Notably, the absence of heterogeneity and directional pleiotropy was suggested by our results.

Conclusions: The results of the MR analysis suggest that there may be a causal relationship between BMI and a higher risk of renal function decline.

CKD as a Mediator of the Associations between Adiposity and Cardiovascular Diseases

Killian Donovan, Rebecca J. Sardell, William G. Herrington, Natalie Staplin. Renal Studies Group. *University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom.*

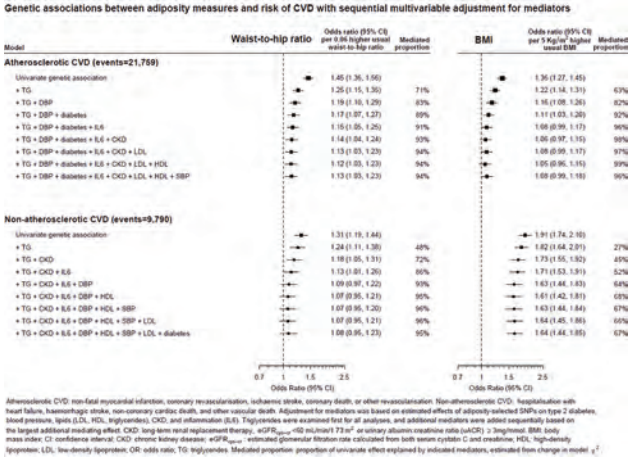
Background: Adiposity is associated with atherosclerotic and non-atherosclerotic cardiovascular diseases (CVDs). These associations are not fully explained by traditional cardiovascular risk factors. Genetic epidemiological methods can be used to estimate the mediating effects of risk factors including chronic kidney disease (CKD) on cardiovascular outcomes.

Methods: Data from 288,984 UK Biobank participants were used to estimate the relevance of genetically-predicted waist-to-hip ratio (WHR, central adiposity) and body-mass index (BMI, general adiposity) to risk of CVDs, both atherosclerotic (aCVD) and non-atherosclerotic (nCVD). Genetic analyses employed Mendelian Randomisation (MR) and data from 394 WHR and 773 BMI-associated loci. To explore how adiposity causes

CVDs, multivariable MR models were constructed adjusting for the genetic associations between these loci and mediators including blood pressure (BP), lipids, diabetes status (DM), inflammatory markers and CKD.

Results: 21,759 (7.5%) participants had aCVD and 9,790 (3.4%) participants had nCVD. Genotype-predicted WHR and BMI were both associated with increased risk of aCVD and nCVD (Fig 1). TGs, diastolic BP, and DM were the top mediators for aCVD explaining ~90% of both BMI and WHR associations (Fig 1). Adding CKD to this model did not significantly increase the explained effect. TGs, CKD and inflammation (IL-6) were the top mediators for nCVD, together explaining 86% of WHR associations and 52% of BMI associations (Fig 1).

Conclusions: MR suggests that any mediating effect of CKD on the effects of adiposity on risk of aCVD is small (particularly when compared to the mediating effects of TGs, BP and DM). Conversely, CKD is likely to be an important mediator of effects of central adiposity (WHR) on risk of nCVD. The effects of general adiposity (BMI) on nCVD appear to be only partly explained by CKD, inflammation, BP and lipids.



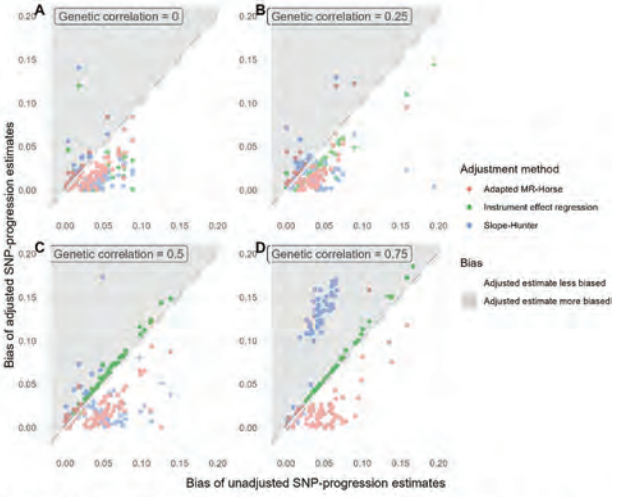


Figure 1: Bias of estimated SNP effects on CKD progression in simulated GWAS of CKD progression, with and without adjustment, in scenarios with increasing correlation between SNP effects on CKD incidence and CKD progression. With increasing genetic correlation, existing adjustment methods yield more biased results (gray shaded areas). MR-Horse adjusted estimates are consistently less biased than unadjusted estimates.

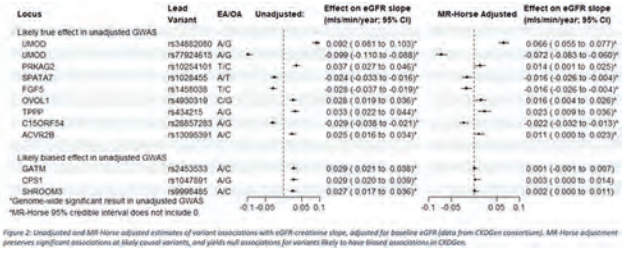

Figure 2: Unadjusted and MR-Horse adjusted estimates of variant associations with eGFR-creatinine slope, adjusted for baseline eGFR (data from CKDGen consortium). MR-Horse adjustment preserves significant associations at likely causal variants, and yields null associations for variants likely to have biased associations in CKDGen.

TH-PO1001

A Bayesian Method to Reduce Selection Bias in Genetic Association Studies of CKD Progression

Killian Donovan. Renal Studies Group. *University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom.*

Background: The rate of progression of CKD has high inter-patient variability. Genetic differences are responsible for some of this variation, but GWAS results have been inconsistent. This may be due to selection bias arising when GWAS participants are selected based on kidney function. Such bias is apparent in the results of existing studies. Current methods to address this bias are predicted to fail in the setting of CKD due to high genetic correlation between incident CKD and rate of CKD progression.

Methods: We adapted a Mendelian Randomization method (MR-Horse) for unbiased estimation of SNP associations with CKD progression in the setting of correlated SNP effects on disease incidence and progression (the hypothesized genetic architecture of CKD). We applied this method and others to simulated GWAS of traits with different genetic architectures. We then applied these methods to GWAS results from the CKDGen Consortium, and evaluated their effects on SNP-progression estimates at loci with known significant effects on progression and at loci with likely biased associations.

Results: Our method reduced the bias of simulated SNP-progression effect estimates, including in situations with high genetic correlation where other methods failed (Fig 1). Power and type 1 error rate were comparable to other methods. In CKDGen data (Fig 2), our method attenuated associations at loci with likely biased associations with CKD progression, whilst preserving associations at loci with likely real direct effects on progression.

Conclusions: GWAS of CKD progression are affected by selection bias, and this can be reduced by an adaptation of the MR-Horse method.

Differential DNA Methylation in CKD with Particular Reference to APOL1

Suri Guga,[1] Dalvir Kular,[1] Samantha J. Hayward,[4] Moin A. Saleem,[4] Kate Bramham,[1,3] Ania B. Koziell.[1,2] *[1]King's College London, London, United Kingdom; [2]Evelina London Children's Hospital, London, United Kingdom; [3]King's College Hospital NHS Foundation Trust, London, United Kingdom; [4]University of Bristol, Bristol, United Kingdom.*

Background: Individuals of African descent are generally at increased risk of CKD and specific variants of the *APOL1* gene play a significant role. However, not all high risk cases progress to CKD suggesting other factors such as co-variants and environmental/ epigenetic modifiers may contribute. The study examined the role of whole genome DNA methylation (DNAm) on CKD, including its impact on both baseline glomerular filtration rate (eGFR) and rate of change in eGFR. Additionally, the study explored whether differntial DNAm might also explain the differing phenotypes associated with high-risk *APOL1* genotypes with no protective allele detected.

Methods: Genome-wide DNAm data from the Genetic Epidemiology Network of Arteriopathy (GENOA) was analysed. Phenotypic evaluation including CKD status together with *APOL1* risk variant genotype identified 1,394 cases suitable for study. CKD was defined as estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73 m2 and urine albumin-creatinine ratio (uACR) > 30 ug/mg. Bioinformatics tools were used for DNA methylation (DNAm) analysis controlling for age, cell type, BMI, gender and smoking. EWAS and linear regression analysis was performed on CKD and non-CKD cases. The relationship between *APOL1* DNAm on baseline eGFR was analysed used linear regression and a mixed-effects model used to analyse the association between DNAm with change in eGFR.

Results: Analysis DNAm in CKD vs non-CKD showed significant differences at 3 CpG islands ($p < 0.05$). Whole genome DNAm analysis of high risk *APOL1* CKD *vs.* high risk non-CKD cases identified a unique CpG signal as significantly differentially methylated ($p < 0.05$).. Mixed-effect model analysis detected an association between DNAm and longitudinal eGFR change ($p < 0.05$). Lastly, linear regression analyses, adjusted for age and the interval between examinations, identified differential DNAm at another unique CpG. No difference in DNAm was detected in high risk genotype *vs.* low risk APOL1 genotype cases with or without CKD.

Conclusions: The findings suggest that differential DNAm may contribute to CKD. Additionally, APOL1 DNAm appears associated with CKD development. It might also in part explain why some high risk APOL1 genotype cases develop CKD and others do not. Epigenetic markers could aid in understanding the pathogenesis of CKD and suggest novel avenues for targeted interventions.

TH-PO1003

SLC6A19 (BOAT1) Allelic Series: Loss of Function Is Associated with Improved Kidney Function

Sahar V. Mozaffari, Yannan Xi, Laura Sanman, Julie Ullman, Susan Limb, Maarten Hoek, Karol Estrada, Robert R. Graham. *Maze Therapeutics Inc, South San Francisco, CA.*

Background: Chronic kidney disease (CKD) remains a significant health burden despite recent advances in care, including development of inhibitors of the sodium-dependent glucose transporter SLC5A2 (SGLT2). A burden test incorporating predicted loss of function (pLOF) and rare missense variants (MAF <1%) identified SLC6A19 as among the strongest effects in the genome for improved kidney function (UK biobank: serum creatinine, beta = -0.13, p = 4.58e-35). The gene SLC6A19 encodes the protein BoAT1, a sodium-dependent neutral amino acid transporter involved in the uptake of free amino acids from the diet and minimizing loss of amino acids via the urin

Methods: Here, we built an allelic series of variants that impact SLC6A19 function or expression levels composed of aggregated pLOF and rare predicted damaging missense variants, a known hypomorphic missense variant (D173N, rs121434346), and an eQTL variant (rs11133665). We then tested these variants for an association to biomarkers of kidney function and disease risk across multiple biobanks.

Results: A meta-analysis for serum creatinine, a marker of kidney function, was performed across multiple large-scale datasets (UK Biobank, deCODE, CKDGen: > 600,000 individuals). The hypomorphic variant D173N (rs121434346) is associated with decreased serum creatinine (beta: -0.15, p: 7.2e-24) in deCODE and UK Biobank meta-analysis. Aggregated UK Biobank pLOF variants (beta: -0.15, p: 1.02e-04) and missense variants (MAF<0.001) (beta: -0.08, p-value: 3e-13) are associated with decreased serum creatinine. Consistent results for the SLC6A19 allelic series were obtained for estimated glomerular filtration rate (eGFR) and serum cystatin C, suggesting loss of function of SLC6A19 is associated with improved markers of kidney function.

Conclusions: An allelic series of functional SLC6A19 variants is robustly associated with serum and urine markers related to kidney function, with loss of function of SLC6A19 conferring reno-protection, and suggests inhibition of SLC6A19 is a potential therapeutic approach for CKD.

Genome-Wide Association Study on Creatinine Clearance in the Lifelines Cohort Study

Anna D. Argoty-Pantoja, Peter J. Van der Most, Amarens van der Vaart, Harold Snieder, Martin H. De Borst. *University of Groningen, University Medical Center Groningen, Groningen, Netherlands.*

Background: Genome-wide association studies (GWAS) for kidney function have mainly focused on creatinine-based glomerular filtration rate (eGFR). However, variation in muscle mass reduces the accuracy of the eGFR. Creatinine clearance is able to assess kidney function independently of muscle mass. Our aim was to identify genes influencing creatinine clearance as an alternative phenotype of kidney function. In addition, we aimed to analyse overlap of creatinine clearance loci with eGFR loci.

Methods: We performed a GWAS on creatinine clearance and eGFR (creatinine-based CKD-EPI 2009) in 58,976 individuals of European descent from the Lifelines Cohort Study. Genetic correlation between phenotypes and heritability was estimated using linkage disequilibrium score regression. In addition, we performed expression Quantitative Trait Loci (eQTL) analyses.

Results: We identified 16 independent loci for creatinine clearance with 21 genome-wide significant lead single nucleotide polymorphism (SNPs) ($P < 5x10^{-8}$). In addition, we found 65 loci for eGFR with 95 lead SNPs. Two new SNPs, not previously related to eGFR in CKDGen were discovered (rs146465192: EAF = 0.01, $P = 3.38x10^{-09}$; rs117014836: EAF = 0.02, $P = 5.42x10^{-09}$). Both SNPs were also associated with eGFR (rs146465192: $P = 1.34x10^{-08}$; rs117014836: $P = 3.64x10^{-07}$) in our analysis. The variant rs117014836 was associated with expression levels of *AGPAT4* gene in blood (eQTL $P = 6.54x10^{-6}$). The common SNP heritability of creatinine clearance was 12%. We observed a high genetic correlation between creatinine clearance and eGFR (rg = 0.77).

Conclusions: We found two new SNPs, one of which influenced blood expression of *AGPAT4* gene, which plays a crucial role in modulating the diversity of fatty acid chains. This supports the role of lysophospholipid metabolism in impaired kidney function.

TH-PO1005

A Comprehensive Report on Patients with CKD in the CDC NHANES Cohort, 2001-2020

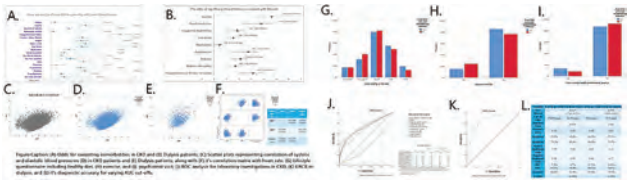
Muhammad Sohaib Asghar.[1,2] Chad K. Brands (AdventHealth Sebring Internal Medicine Residency Program). *[1]AdventHealth Sebring, Sebring, FL; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: This study is a comprehensive review of the Centers for Disease Control and Prevention (CDC) National Health and Nutrition Examination (NHANES) databases. The primary objectives were to ascertain patterns of demographic and clinical data among chronic kidney disease (CKD) and dialysis patients.

Methods: This study examines participants from the CDC NHANES database to identify the population diagnosed with chronic kidney disease or dialysis patients in the past 12 months. The total cohort of 51,743 patients were included in each group, i.e., CKD group included 1509 patients (out of which 173 patients have received dialysis in the past 12 months), while non-CKD group included 50,234 patients.d. Exclusion criteria included age ≥85 years of age (n=624), pregnancy (n=1375), and history of malignancy (n=5575).

Results: The mean age of study participants (n=51,743) was 48.50 ±17.43 years. Age is significantly higher in CKD group but there was no difference in dialysis versus non-dialysis patients (P=0.833). There is no gender predisposition in CKD patients however, males were more likely to undergo dialysis with 13.3% vs 9.8% in females (P=0.032). Among racial differences, Non-hispanic whites are predominantly affected by CKD (37.0%) followed by non-hispanic blacks (29.3%) but non-hispanic blacks are mostly undergoing dialysis (48.6% vs 17.3%). BMI (kg/m^2) was significantly higher in CKD group (P<0.001), but lower in dialysis group (P=0.039). Among urinary complaints, history of kidney stones is prevalent in CKD patients (7.7% vs 2.6%, P<0.001). Frequent coexisting comorbidities were congestive heart failure (OR: 9.8), diabetes (OR: 5.4), Coronary artery disease (OR: 5.0), and hypertension (OR: 4.7). UACR (>30 mg/g) is able to categorize CKD patients (**AUC**: 0.73), at a sensitivity of *44.9%* and a specificity of *88.8%*.

Conclusions: Certain clinical factors were identified as highly associated with CKD, as disseminated by the NHANES database findings.



TH-PO1006

Patient-Centered Outcomes of Advanced CKD Treated with Conservative Management vs. Dialysis: A Substudy of the Prospective NIH OPTIMAL Cohort

Amy S. You,[1] Yoko Narasaki,[1] Alejandra Novoa Vargas,[1] Lisa Le,[1] Danh V. Nguyen,[2] Kamyar Kalantar-Zadeh,[3] Connie Rhee.[1] *[1]University of California Los Angeles, Los Angeles, CA; [2]University of California Irvine, Irvine, CA; [3]Harbor-UCLA Medical Center, Torrance, CA.*

Background: While dialysis has been the treatment paradigm among advanced CKD patients ineligible for/unlikely to receive transplantation, it may not improve HRQOL among certain subgroups (elderly, multi-morbid), which has motivated interest in conservative management (CM) as an alternative patient-centered treatment option.

Methods: In a subcohort of 53 participants from the ongoing multicenter prospective NIH OPTIMAL study comparing CM vs. dialysis preparation on the longitudinal trajectory of HRQOL, physical performance/activity, symptom burden, and nutrition in stage 4-5 CKD patients, we examined baseline patient-centered outcomes data collected using validated instruments.

Results: Short Form 36 data showed low (worse) PCS (median [IQR] 41 [28, 52]) and MCS (median [IQR] 56 [47, 59]) scores. Short Physical Performance Battery data showed relatively low physical performance (median [IQR] 9 [7, 11]). Human Activity Profile data showed low self-reported activity (50% with low Adjusted Activity Score <53). Dialysis Symptom Index data showed high symptom burden (median [IQR] 25 [15, 30]). The most prevalent symptoms included feeling tired/lack of energy (60%), dry skin (60%), and trouble staying asleep (51%).

Conclusions: Baseline data from the NIH OPTIMAL cohort showed low HRQOL, low physical performance/activity, and high symptom burden in advanced CKD patients undergoing CM vs. dialysis preparation.

Assessing the Quality of Care for People with CKD: A Systematic Review and Meta-Analysis

Daniel B. Ketema,[1,2] Hannah Wallace,[1,3] Brendon L. Neuen,[1] Sradha S. Kotwal,[1] Paul E. Ronksley,[4] Sunil Badve,[1] Vlado Perkovic,[2] Martin P. Gallagher,[1,2] Rohina Joshi,[5,1] Min Jun.[1,2] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]University of New South Wales Medicine & Health, Sydney, NSW, Australia; [3]Western Health, Footscray, VIC, Australia; [4]University of Calgary Department of Community Health Sciences, Calgary, AB, Canada; [5]University of New South Wales Medicine & Health, Sydney, NSW, Australia.*

Background: Effective strategies for managing CKD are available, but the extent to which implementation of these strategies is consistent with guideline recommendations is uncertain. We aimed to synthesize available data on the quality of CKD care globally.

Methods: EMBASE, PubMed, and CINAHL were systematically searched (inception–2023) for observational studies reporting on the quality of CKD care across domains related to patient monitoring (eGFR, albuminuria), appropriate medication use (ACEIs, ARBs, statins, NSAIDs), and treatment targets (BP, HbA1c) according to management recommendations in international CKD guidelines. Pooled estimates (95% CI) of the percentage of patients who met the quality indicators for CKD care were obtained using random effects meta-analysis.

Results: 58 studies across 22 countries, including a total of 2,969,039 patients with CKD, were included. The reporting of and adherence to quality indicators for CKD care varied substantially across the included studies (Figure 1). Summary estimates of the percentage of CKD patients who met key indicators showed that (1) eGFR was monitored in 81% (75–87%) of patients, albuminuria in 47% (40–54%) and BP in 90% (84–95%); (2) ACEIs/ARBs were prescribed in 56% (51–62%), statins in 56% (48–64%), and NSAIDs withheld in 81% (77–86%) and (3) a BP target of ≤140/90 mmHg was achieved in 56% (48–64%) patients.

Conclusions: Current evidence suggests substantial variation in the reporting and quality of CKD care. Concordance with guideline recommendations varied across quality indicators and patient groups, with opportunities for considerable improvement, particularly albuminuria testing. Effective quality improvement strategies to address gaps in CKD care, along with systematic approaches for monitoring care quality, are needed.

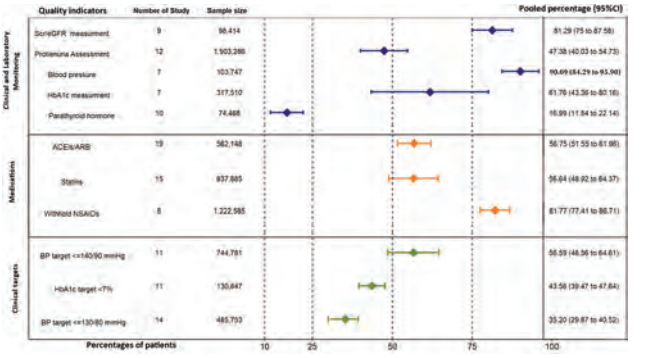

Figure 1: Forest plot summarising the percentage of patients with CKD who met the quality indicators for CKD care

Health Insurance Status since the Affordable Care Act among US Adults with and without CKD

Jenna Kiryakos,[1] Tiffany C. Veinot,[2] Yun Han,[1] William H. Herman,[1] Hal Morgenstern,[4] Yoshihisa Miyamoto,[3] Rajiv Saran,[1] Jennifer L. Bragg-Gresham.[1] *[1]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [2]University of Michigan School of Information, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of Michigan School of Public Health, Ann Arbor, MI.*

Background: Adults without health insurance are more likely to delay care due to costs, including preventive care and services for acute and chronic illnesses. In 2010, the Affordable Care Act (ACA) was implemented to reduce the number of uninsured individuals under age 65 through health insurance exchanges, the dependent coverage provision, Medicaid expansion, and other policy changes. As health care coverage is important for optimal management of chronic kidney disease (CKD), we sought to examine the proportion of adults who lack health care coverage by CKD status.

Methods: We included 38,119 participants from the National Health and Nutrition Examination Survey (NHANES, 2001–March 2020) aged 18–64 years. CKD was defined by the presence of albuminuria (urine albumin to creatinine ratio – UACR ≥30 mg/g) or estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m^2. Lack of health care coverage was defined by a response of "No" to the NHANES question "Are you covered by health insurance or some other kind of health care plan?". The proportion of adults without health insurance by CKD status was age-standardized to the 2010 U.S. Census population for adults ages 18–24, 25–44, and 45–64.

Results: The sample included 3,967 participants with CKD and 34,152 participants without CKD. The mean age of the entire sample was 40.7 and 50% were male. For both those with and without CKD, prevalence of lack of health insurance increased from 2001-2004 to 2009-2012 (p=0.01), then declined (p<0.001). The decline corresponded with the implementation of the ACA (Figure). Age-standardized trends were similar to crude rates.

Conclusions: Since 2009-2012, coinciding with the ACA implementation, there has been a decrease in the proportion of US adults without health insurance. This trend was present in adults with or without CKD; however, the percentage of persons lacking health insurance tended to be higher among those with CKD.

TH-PO1009

Health-Related Social Needs and CKD in Medicare Advantage Beneficiaries

Lindsay Bengtson,[2] Anny C. Wong,[2] Alexandra Rothenburger,[2] Zackery R. White,[1] Amanda Terry,[1] Halima Ahmadi-Montecalvo,[1] Bonnie M. Donato.[2]
[1]Unite Us, New York, NY; [2]Boehringer Ingelheim International GmbH, Ingelheim, Germany.

Background: The impact of health-related social needs (HRSNs) on patient outcomes has been established; however, there is limited research regarding HRSNs and chronic kidney disease (CKD). This study addresses this gap by identifying HRSN predictors of CKD diagnosis at stage 3 vs. stages 1 or 2 and examining the association between HRSNs and concordance with guideline-recommended CKD management in the year following diagnosis.

Methods: A retrospective database analysis was conducted of Medicare Advantage beneficiaries newly diagnosed with CKD stages 1-3 from January 2020 to October 2022. Patients' HRSNs were identified using Unite Us' Social Needs System (SNS), a proprietary index leveraging public and consumer data to identify individual-level social risk. Logistic regression assessed the effect of HRSNs on the likelihood of diagnosis at stage 3 vs. stages 1 or 2. Logistic and linear regression examined the effect of HRSNs on healthcare utilization (HCU) and CKD management in the year following diagnosis, adjusted for CKD stage. Analyses were adjusted for age, sex, race/ethnicity, urbanity, comorbidities, and baseline HCU.

Results: A total of 6,053 individuals with CKD were included (median age 76 years; 97% English-speaking; 54% female; 84% White, non-Hispanic). CKD stage at diagnosis varied: stage 1 (2%), stage 2 (18%), and stage 3 (80%). Identified HRSNs included a lack of internet access (15%), food insecurity (10%), and financial insecurity (8%). While individuals with HRSNs tended to be diagnosed at stage 3 vs stage 1 or 2, differences were not statistically significant. Women (OR: 1.34; CI: 1.17-1.54, p<0.01) and older individuals (OR: 1.04; CI: 1.02-1.65, p<0.01) were more likely to be diagnosed at stage 3 than stages 1 or 2, while those with proteinuria (OR: 0.49; CI: 0.35-0.68, p<0.01) or living in rural counties (OR: 0.72; CI: 0.61-0.84, p<0.01) were less likely. In the year following diagnosis, patients with financial insecurity, versus those without, had an increased number of ER visits (β: 0.15; CI: 0.01-0.29, p=0.01) and were less likely to receive diabetes education (OR: 0.40; CI: 0.16-0.97, p=0.04).

Conclusions: These findings emphasize that specific HRSNs impact CKD management and present opportunities for targeted interventions to address HRSN barriers to care for individuals with CKD.

Evaluating the Clinical, Socioeconomic, and Environmental Impact of Guideline-Directed Therapy in the United States: An IMPACT CKD Analysis

Navdeep Tangri,[1] Cole Wyman,[2] Naveen Rao,[2] Jieling Chen,[3] Stacey Priest,[4] Stephen Brown,[4] Aleix Cases,[5] Steven J. Chadban.[6] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; [3]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD; [4]EVERSANA, Burlington, ON, Canada; [5]Hospital Clinic de Barcelona, Barcelona, Spain; [6]Royal Prince Alfred Hospital, Camperdown, NSW, Australia.*

Background: Chronic kidney disease (CKD) is underdiagnosed and undertreated in the United States (US) despite evidence that therapies can delay disease progression and reduce clinical events. This study aims to illustrate the impact of improved adherence to therapies recommended for patients with CKD (i.e., guideline-directed medical therapy [GDMT]) on clinical, socioeconomic, and environmental outcomes to inform policy decisions.

Methods: The US population was simulated for 25-years (baseline: 2022; simulated years: 2023-2047) using the IMPACT CKD model. Two scenarios were compared: 75% adherence to GDMT vs. current practice as observed. GDMT included glucose and lipid lowering, antihypertensive, and lifestyle interventions. It was assumed that patients diagnosed with CKD could be treated with multiple therapies per guideline eligibility and that there would be no changes to guidelines or CKD detection rate over the time horizon. Treatment effects on estimated glomerular filtration rate (eGFR) decline, cardiovascular events, and acute kidney injury (AKI) events were assumed to be multiplicative.

Results: Improved adherence to GDMT was associated with a 32% decrease in dialysis due to delayed disease progression. Reductions were projected in myocardial infarction, stroke, hospitalized heart failure, AKI, and death by 21%, 17%, 24%, 9%, and 5%, respectively. Renal replacement therapy (RRT) and total CKD costs were projected to decrease by 25% and 5%, respectively. Freshwater consumption, fossil fuel depletion, and carbon emissions due to RRT were also projected to decrease by 28%. Furthermore, reductions in disease progression and death also contributed to improvements in projected net workdays, gross domestic product, full-time equivalents, and tax revenue among employed patients and caregivers. The benefits of improved adherence to GDMT were seen after six years. Similar trends were observed with a 10-year time horizon but with smaller magnitude.

Conclusions: This study predicted significant clinical, socioeconomic, and environmental benefits with improved adherence to GDMT. These findings underscore the importance of policy action to improve adherence and actualize the potential of effective therapies to mitigate CKD burden.

Comorbidity Prevalence among Patients with CKD: Insights from the National Health and Nutrition Examination Survey (NHANES)

Doris H. Fuertinger,[1] David J. Joerg,[1] Felix J. Meigel,[1] Peter Kotanko.[2,3]
[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In the past decade, obesity and various other conditions that can cause chronic kidney disease (CKD) were on the rise. We used data from the National Health and Nutrition Examination Survey (NHANES) cycles 2007-2008 and 2017-2018 to quantitate the changes in diabetes mellitus (DM), overweight, obesity and heart failure (HF) in different CKD risk categories.

Methods: We stratify the NHANES population into KDIGO risk categories based on albuminuria and creatinine measurements (both serum and urine). Additionally, we assess the prevalence of obesity, HF, and DM by stratifying the NHANES population by body mass index (overweight: BMI 25-30, obesity: BMI >30 kg/m^2), self-reported diagnosis of DM as well as fasting glucose or HbA1c levels and HF. We analyze patients for whom complete information on CKD and DM, obesity, and HF was reported.

Results: The percentage of CKD patients that are overweight has slightly declined for all CKD risk categories during the considered decade 2007/2008-2017/2018 (very high risk: 30% to 29%). This is contrasted by a pronounced increase in obesity over all CKD risk categories (very high risk: 43% to 54%), see Fig. 1. The proportion of CKD patients having DM markedly increased in the very high risk group (46% to 57%), but showed only a slight increase in the high risk category (40% to 42%). HF among CKD patients showed a stagnant or declining trend in the high risk categories (13% to 13% and 24% to 20%).

Conclusions: NHANES data suggest a pronounced upward trend in the proportion of CKD patients suffering from DM and obesity and a stagnant trend in CKD patients suffering from HF and overweight. The analysis is limited by the fact that CKD measurements and self-reported diagnoses are not available for all NHANES participants.

TH-PO1012

Evaluation of the SGLT2 Inhibitor Dapagliflozin as an Alternative Treatment of Kidney Impairment in a 5/6 Nephrectomy Model Associated with Obesity

Desiree R. Bernardo,[1] Daniele Canale,[1] Mariana M. Nascimento,[1] Maria H. Shimizu,[1] Antonio C. Seguro,[1] Ana Carolina de Braganca,[3] Rildo A. Volpini.[3,2]
[1]Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil; [2]Universidade de Sao Paulo Faculdade de Medicina de Ribeirao Preto, Ribeirao Preto, Brazil; [3]Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.

Background: Chronic kidney disease is a global health burden, characterized by functional and structural renal changes as decreased GFR, inflammation and fibrosis. Obesity is a chronic disease directly related to diabetes mellitus and hypertension, the main disorders responsible for the progression to end-stage kidney disease. Lately, the alternative use of SGLT2 inhibitors has been offering new perspectives for the treatment of kidney diseases, regardless their glucosuric effects. We evaluated the effects of dapagliflozin (DAPA) as an alternative treatment on renal impairment in an obesity-associated 5/6 nephrectomy (Nx) model.

Methods: We followed male wistar rats during a 100-day protocol. On day 40, all the rats were submitted to Nx surgery and followed up until the end of the protocol. The animals were divided into four groups according to the diet: standard (N); hyperlipidic (N+H); standard+DAPA (N+D); and hyperlipidic+DAPA (N+H+D). DAPA (50 mg/kg diet) was offered from the 1st day after Nx surgery. We evaluated anthropometric data, biochemical parameters, GFR, renal protein expression of SGLT1 and GLUT2, as well as renal tissue levels of SGLT2, TGF-β, collagen 3 (COL-3) and MCP-1 by ELISA.

Results: N+H animals presented a lower GFR, increased anthropometrical and metabolic parameters, and enhanced renal tissue levels of TGF-β, COL-3 and MCP-1. N+H+D showed improved renal function, metabolic parameters, and a restoration of plasma glucose levels. Most importantly, treatment with dapagliflozin prevented the renal expression of TGF-β, COL-3 and MCP-1 in this obesity-associated Nx model. The results are described in Figure 1 (Table 1).

Conclusions: The use of dapagliflozin prevented the renal fibrosis formation and inflamation observed in our 5/6 nephrectomy model associated with obesity. Financial support: FAPESP 2022/07409-0, 2023/06387-6.

Racial Disparities in SGLT2 Inhibitor (SGLT2i) and Glucagon-Like Peptide 1 Receptor Agonist (GLP-1 RA) Use in the US Military Health System (MHS)

James D. Oliver,[1] Robert Nee,[1,2] Hava Marneweck,[4] Amanda Banaag,[4] Fang Xu,[3] Alain K. Koyama,[3] Yoshihisa Miyamoto,[3] Meda E. Pavkov,[3] Tracey L. Koehlmoos.[1] *[1]Uniformed Services University of the Health Sciences, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]Henry M Jackson Foundation for the Advancement of Military Medicine Inc, Bethesda, MD.*

Background: Recent studies have indicated racial disparities in the use of SGLT2i and GLP-1 RA, novel diabetes mellitus (DM) therapies that have been shown to reduce chronic kidney disease (CKD) progression and cardiovascular morbidity and mortality. We evaluated whether such disparities exist in the MHS, a universal payer system with fewer barriers to health care access.

Methods: We extracted data for 2,989,368 non-pregnant adults in 2019. Diagnoses of type 2 DM and CKD were based on ICD-10 codes, labs, and medications. Adjusted odds ratios (aOR) for medication use were calculated by multivariable logistic regression.

Results: The DM population was 180,625 (6.0%), of whom 68,747 (38.1%) had CKD (median age 60 years, 47.2% female; 32.5% White, 17.7% Black, 5.1% Asian/Pacific Islander, 0.5% Native American/Alaska Native [NA/AN], 3.1% Other, 11.4% Unknown, and 29.7% Missing). Use of an SGLT2i or GLP-1 RA was 13.1% and 12.5%, respectively (Table) and was higher in White adults than in other races except NA/AN. After adjustment for age, sex, socioeconomic status, and comorbidities (CKD, hypertension, heart disease, heart failure, obesity), aOR of using either medication was significantly lower in all racial groups except NA/AN compared to White adults.

Conclusions: In the MHS, a universal payer system with minimal barriers to access, use of an SGLT2i or GLP-1 RA was significantly lower in most non-White adults. Further investigation may be required to determine the factors behind the prescription differences and possible mitigation strategies. *The views expressed in this abstract are those of the authors and do not reflect the official position of the Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., the Department of Defense, the Department of Health and Human Services, or the U.S. government.*

SGLT2 Inhibitors and Mortality Risk in Individuals with Advanced CKD

Rochell Issa,[1] Mirela A. Dobre,[2] Mohamed Makhlouf,[2] Lavinia A. Negrea,[2] Andrei Brateanu.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]University Hospitals, Cleveland, OH.*

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) have been shown to reduce all-cause mortality in type 2 diabetes. It is unknown whether this beneficial effect is maintained in advanced CKD stages 4-5D, irrespective of diabetes status.

Methods: In this retrospective cohort study of electronic health records from the TriNetX Analytics Network, we aimed to assess the associations of SGLT2i with all-cause mortality compared to usual care without SGLT2i medications in patients >65 years with CKD 4-5D. The hazard ratios (HRs) and 95% confidence intervals (CIs) of all cause mortality were calculated for the 6-month, 1 and 5 year follow-up by comparing propensity score-matched patient groups.

Results: The study population included 40,000 patients with CKD stages 4-5D who were prescribed SGLT2i or usual care without SGLT2i. Compared with non-SGLT2i users, patients with CKD 4 or 5 pre-dialysis (mean age 74.8± 6.2 years, 48% female), or CKD 5D (mean age 73.3±5.8 years, 42% female) taking SGLT2i had lower risk for all-cause mortality, consistent across CKD stages and time points (Table).

Conclusions: The use of SGLT2i was associated with a significant lower all-cause mortality risk in patients with advanced CKD stages 4, 5, or 5D.

Cost-Effectiveness of Empagliflozin in CKD in a Real-World US Population

Satabdi Chatterjee,[1] Neda Al Rawashdh,[2] Pablo Anaya,[2] Anastasia Uster,[4] Anna R. Aguirre Mazo,[4] Mafalda Ramos,[3] Laetitia Gerlier,[5] Mark Lamotte.[3]
[1]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [2]IQVIA Inc, Falls Church, VA; [3]Th(is)2modeling, Asse, Belgium; [4]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [5]IQVIA Belgium, Zaventem, Belgium.

Background: Studies have established the cost-effectiveness of empagliflozin (EMPA) on top of standard of care (SoC) in patients similar to the EMPA-KIDNEY population (wide range of patients with CKD, with or without diabetes) and have shown benefits of timely EMPA initiation from a US payer perspective. In the current study the cost-effectiveness of EMPA and the consequences of delaying EMPA, in a real-world population of patients with CKD was assessed.

Methods: Using a patient-level state transition model that defined health states by KDIGO categories, simulated patients were tracked over a lifetime horizon. 2020 US Renal Data System data were used to populate demographics, CKD stages (40.3% G1, 19.8% G2, 28.6% G3a, 7.9% G3b, 2.4% G4, 1.0% G5), and comorbidities (e.g., 51.7% diabetes, 61.2% cardiovascular disease). The model used published cohort studies to predict disease progression, complications, and death; EMPA-KIDNEY trial data for treatment effects; and literature for drug costs, complication, and adverse events management costs and utilities. Life years (LY), quality-adjusted LY (QALY), and incremental cost-effectiveness ratios (ICERs) were estimated at a willingness to pay (WTP) threshold of $150,000/QALY. Scenario analyses compared delaying initiation of EMPA by 1, 3, and 5 years vs. SoC alone with the base case (no EMPA delay).

Results: In base case analyses, use of EMPA+SoC delayed disease progression to ESKD or death by 1.21 years, and resulted in 0.50 LYs and 0.47 QALYs gained vs. SoC only. The increased effectiveness came with higher costs for both payers ($20,393 for commercial payers and $42,152 for Medicare), however, ICERs ($43,898/QALY for commercial and $90,737/QALY for Medicare) were cost-effective at the WTP threshold. Delaying EMPA initiation reduced the clinical benefits and increased the incidence of progression to ESKD and the need to initiate kidney replacement therapy; a longer delay in initiation further reduced benefits. Additionally, delaying EMPA therapy did not result in significant savings to either commercial or Medicare payers.

Conclusions: Findings confirm the cost-effectiveness of EMPA in a real-world population of individuals with CKD for US commercial and Medicare payers, and provide evidence of benefits with timely initiation of EMPA.

Association between Environmental Factors and Kidney Diseases: A Nationwide Population-Based Study

Semin Cho,[1] Jeongmin Cho,[1] Soojin Lee,[3] Sehoon Park,[2] Kyungdo Han,[5] Dong Ki Kim,[2] Yaerim Kim.[4] *[1]Chung-Ang University Gwangmyeong Hospital, Gyeonggi-do, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Eulji University Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea; [4]Keimyung University Daegu Dongsan Hospital, Daegu, Republic of Korea; [5]Soongsil University, Dongjak-gu, Seoul, Republic of Korea.*

Background: It is well known that various environmental factors including air pollution increase the risk of kidney disease. We aimed to elucidate the risk of chronic kidney disease according to the indoor air quality and urinary volatile organic compounds (VOCs) using data from the Korea National Health and Nutrition Examination Survey (KNHANES).

Methods: The ratio of indoor and ambient PM2.5 and urine creatinine-corrected VOCs concentration were extracted from the KNHANES VIII (2019-2021) dataset. CKD was defined as estimated glomerular filtration rate (eGFR) less than 60 mL/min/1.73m^2, and the association between environmental factors and CKD was analyzed through multiple linear regression model.

Results: A total of 1,319 participants was analyzed in this study. The highest quartile of indoor and ambient PM2.5 ratio was associated with increased risk of CKD (odds ratio(OR), 4.28; 95% confidence interval(95% CI), 1.43-12.75) after adjustment of age, sex, comorbidities, and window opening status. The urinary concentration of several VOCs (3,4MHA [3,4-Methylhexanoic Acid], PGA [Phenylglyoxylic Acid], MA [Maleic Acid], DHBMA [Dihydroxybenzene Mercapturic Acid]) have been found to have statistically significant association with reduced kidney function. ([3,4MHA] OR, 5.86; 95% CI, 1.30-26.45; [PGA] OR, 14.30; 95% CI, 1.53-133.78; [MA] OR, 5.38; 95% CI, 1.03-28.12; [DHBMA] OR, 4.14; 95% CI, 0.77-22.21).

Conclusions: In this cross-sectional study, the indoor air quality of PM2.5 relative to the concentration of PM2.5 in the ambient air was associated with the deterioration of kidney function and urinary VOCs concentration showed the association with declined kidney function which could be used to be a predictive marker of CKD.

International Patterns of Low eGFR in Population-Based Surveys of Working-Age Adults: Disadvantaged Populations eGFR Epidemiology (DEGREE) Study

Ben Caplin,[1] Charlotte E. Rutter,[2] Neil Pearce.[2] DEGREE Study Group.
[1]University College London Research Department of Renal Medicine, London, United Kingdom; [2]London School of Hygiene & Tropical Medicine, London, United Kingdom.

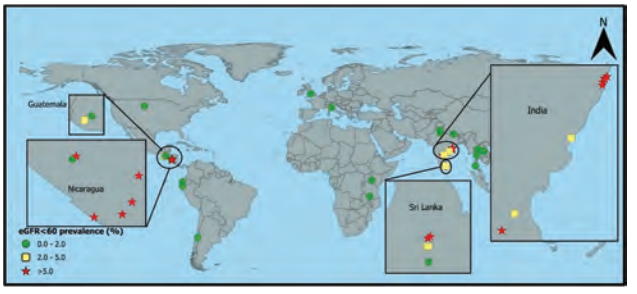
Background: The Disadvantaged Populations eGFR Epidemiology study was designed to gain insight into the burden of chronic kidney disease (CKD) of undetermined cause (CKDu) by using standard protocols to estimate the general-population prevalence of low estimated glomerular filtration rate (eGFR).

Methods: We estimated the age-standardised prevalence of eGFR<60mL/min/1.73m^2 not due to common, known causes of CKD (eGFR<60$_{[absent\ HT,\ DM,\ high\ ACR]}$) by excluding participants with self-reported or measured hypertension or diabetes, or an ACR>300mg/g or equivalent in population-representative surveys of working-age adults, stratified by sex and rural-urban classification. Included studies either were designed to estimate CKDu burden or were re-analyses of regional or national surveys and were conducted either in areas where CKDu was reported to be endemic or in areas with proposed CKDu risk factors, alongside two high-income reference datasets.

Results: There were 61306 participants from 43 areas across 14 countries. A high prevalence (>5%) of eGFR<60$_{[absent HT, DM, high ACR]}$ was generally only observed in rural men. Rates were highest in Andhra Pradesh, India, and Northwest Nicaragua. Of the areas considered, prevalence in rural men was low outside of Central America and South Asia; including areas of Kenya, Italy, Malawi, Peru, Chile, Ecuador, and Thailand (as well as England and the USA).

Conclusions: Although there are limitations in terms of comparability of study populations, study timing, lack of individual-level exposures, and absent data in many regions, this work is the first attempt to estimate the burden of CKDu around the world. Clusters of disease may exist elsewhere, but to date there is evidence consistent with a high general-population burden of CKDu in Central America and South Asia.

Funding: Government Support - Non-U.S.



eGFR<60: Age-standardised rural male prevalence of eGFR<60$_{[absent HT, DM, high ACR]}$ in mL/min/1.73m^2. NB: USA includes both rural and urban. The authors take a neutral position with respect to territorial clams on the map.

Time-Updated eGFR Variability Is Associated with Mortality, Cardiovascular Disease, and ESKD in Patients with CKD: The CRIC Study

Hiroki Nishiwaki,[1,3] Celestin Missikpode,[1] Ana C. Ricardo,[1] Wei Yang,[4] Amanda H. Anderson,[2] James P. Lash,[1] Tanika Kelly.[1] CRIC Study Investigators. *[1]University of Illinois Chicago, Chicago, IL; [2]Tulane University, New Orleans, LA; [3]Showa University Fujigaoka Hospital, Yokohama, Japan; [4]University of Pennsylvania, Philadelphia, PA.*

Background: Previous reports have identified increased estimated glomerular filtration rate (eGFR) variability, measured during a single ascertainment window, as a risk factor for CVD and all-cause mortality. We hypothesized that repeated measures of eGFR variability over multiple ascertainment windows would display stronger associations with common CKD sequelae when compared to analysis methods investigating only a single measure.

Methods: To test our hypothesis, we leveraged longitudinal data from 4,224 participants of the Chronic Renal Insufficiency Cohort (CRIC). eGFR variability was estimated as the coefficient of variation of eGFR measured at 3 consecutive annual follow-up visits, starting at baseline and estimated repeatedly in one-year sliding windows. Associations of eGFR variability with all-cause mortality, CVD, and CKD were tested using two statistical models: Cox proportional hazards models that included baseline covariables and eGFR variability measured during the first ascertainment window (baseline model) and marginal structural models that included repeated measures of eGFR variability and covariables (time-updated model).

Results: The 4,224 CKD patients contributed a total of 39,024 person-years of follow-up time, with a median participant follow-up time of 5.9, 6.1, and 8.3 years for CVD, ESKD and all-cause mortality, respectively. In the baseline and time-updated multivariable adjusted analyses, each standard deviation increase in eGFR variability was associated with respective, 1.04-fold (95%CI:0.96-1.13) and 1.78-fold (95%CI:1.50-2.11) increased risks of CVD, 1.08-fold (95%CI:0.99-1.18) and 2.20-fold (95%CI:1.76-2.75) increased risks of ESKD, and 1.15-fold (95%CI:1.08-1.23) and 1.56-fold (95%CI:1.35-1.81) increased risks of all-cause mortality.

Conclusions: Time-updated analyses revealed markedly larger effect sizes compared to the baseline model, highlighting the potentially important role of this measure in common CKD sequelae.

GFR Estimation Errors and Association with Outcomes in CKD

Maria Clarissa Tio,[1] Xiaoqian Zhu,[1] Yoshitsugu Obi,[1] Timothy E. Yen,[1] Michael E. Hall,[1] Neville R. Dossabhoy,[1] Tariq Shafi.[2] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Houston Methodist, Houston, TX.*

Background: Estimated GFR (eGFR) can often be significantly different from measured (mGFR). The clinical implications of large errors in eGFR on risks of outcomes in CKD are unknown.

Methods: Using the Chronic Renal Insufficiency Cohort, a multi-center, prospective cohort of persons with CKD, we analyzed 1,423 participants with mGFR (urinary clearance of iothalamate). We calculated eGFR using the CKD-EPI 2021 creatinine equation. We defined large errors as eGFR that was 15% higher or lower than mGFR. We evaluated the association of large errors, compared to no errors, with outcomes using Fine-Gray subdistribution hazard models for kidney failure with death as a competing risk and Cox proportional hazards models for death, and first occurrence of hyperkalemia, hyperphosphatemia, and anemia. All models were adjusted for age, sex, and race/ethnicity. Data were provided by NIDDK CR, a program of the NIDDK.

Results: Mean age was 56 years, 44% were women, and 37% were Black participants. 776 (55%) participants had large errors: 428 (30%) had mGFR > eGFR and 242 (17%) had mGFR < eGFR. Those with mGFR < eGFR tended to be of White or Hispanic race/ethnicity, have diabetes, and have a higher systolic blood pressure and body mass index. mGFR > eGFR (underestimation) was associated with lower risk of death (HR=0.73; 95%CI: 0.65-0.82), hyperphosphatemia (HR=0.68; 95%CI: 0.49-0.94), and anemia (HR=0.84; 95%CI: 0.73-0.97), with trends toward lower risk of kidney failure and hyperkalemia (Table 1). Conversely, mGFR < eGFR (overestimation) was associated with increased risk of kidney failure (HR=1.22; 95%CI: 1.11-1.35) and anemia (HR=1.39; 95%CI: 1.16-1.66), with trends toward increased risk of death, hyperkalemia, and hyperphosphatemia (Table). Every 10 mL/min/1.73 m^2 increase in bias (eGFR-mGFR) was significantly associated with an increased 22% risk of death, 19% risk of kidney failure, 20% risk of hyperkalemia, 18% risk of hyperphosphatemia, and 18% risk of anemia (Table).

Conclusions: Among persons with CKD who have large differences between mGFR and eGFR, risks of adverse outcomes track closer to mGFR than eGFR.

Funding: Other NIH Support - U54GM11542

Table 1

Exposure		All-Cause Death	Kidney Failure	Hyperkalemia	Hyperphosphatemia	Anemia
Large Error	No large error	ref	ref	ref	ref	ref
	mGFR >eGFR	0.73 (0.65, 0.82)*	0.88 (0.74, 1.04)	0.89 (0.69, 1.13)	0.68 (0.49, 0.94)**	0.84 (0.73, 0.97)**
	mGFR < eGFR	1.37 (0.99, 1.88)	1.22 (1.11, 1.35)*	1.25 (0.99, 1.58)	1.08 (0.87, 1.34)	1.39 (1.16, 1.66)*
Bias (eGFR-mGFR)		1.22 (1.12, 1.34)*	1.19 (1.09, 1.31)*	1.20 (1.11, 1.29)*	1.18 (1.09, 1.28)*	1.18 (1.12, 1.24)*

mGFR > eGFR is defined as mGFR > 1.15*eGFR.
mGFR < eGFR is defined as mGFR < 0.85*eGFR.
eGFR-mGFR is the absolute difference between a participant's eGFR and mGFR divided by 10. Sample interpretation: each 10 unit increase in the difference between eGFR and mGFR is associated with a 22% increased risk of death.

Outcomes and Risk Factors of Widened Difference in Estimated Glomerular Filtration Rate by Creatinine or Cystatin C: Adjust Model Development with More than 300,000 UK Biobank Participants

Min Woo Kang, Yong Chul Kim, Kook-Hwan Oh, Dong Ki Kim, Sehoon Park. *Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: Recent studies have highlighted the significance of discrepancies between cystatin C-based(eGFRcys) and creatinine-based(eGFRcr) CKD-EPI eGFR. This study explores the implications of differences between eGFRcys and eGFRcr(eGFRdiff) on clinical outcomes and develops an adjusted model using eGFRcr and variables.

Methods: Using data from the UK Biobank cohort of 343,854 participants, we stratified them into three groups based on eGFRdiff: lower(eGFRcys-eGFRcr<-15), middle(-15≤eGFRcys-eGFRcr≤15), and upper(eGFRcys-eGFRcr>15). We analyzed the risks of death, MI, and ischemic stroke in the eGFRdiff<-15 and eGFRdiff>15 groups using Cox regression models. Logistic regression identified variables associated with eGFRdiff. And we developed and validated a regression model using eGFRcr and associated variables to approximate eGFRcys.

Results: Individuals with eGFRdiff<-15 had increased risks of death (HR:1.37[1.30-1.44]), MI (HR:1.23[1.15-1.33]), and ischemic stroke (HR:1.19[1.08-1.31]). Variables associated with eGFRdiff<-15 included high waist/hip circumference, high body weight, low fat-free mass, high total food intake, low protein intake, diabetes, and larger kidney volumes. A regression model was developed using eGFRcr, sex, age, height, weight, and BMI. In the validation set, this model achieved an adjusted R^2 of 0.47, improved from the initial R^2 of 0.32 between eGFRcys and eGFRcr. The adjusted model improved clinical outcome prediction.

Conclusions: This study confirmed that eGFRdiff<-15 is associated with increased risks of clinical outcomes and identified factors associated with eGFRdiff. We developed an adjusted model, demonstrating superior clinical outcome association.

Vector Field Model of CKD Stage and Its Directional Derivative Mathematically Enable Accurate Kidney Prognosis Prediction

Eiichiro Kanda,[1] Bogdan I. Epureanu,[2] Taiji Adachi,[3] Tamaki Sasaki,[1] Naoki Kashihara.[1] *[1]Kawasaki Ika Daigaku, Kurashiki, Japan; [2]University of Michigan, Ann Arbor, MI; [3]Kyoto Daigaku, Kyoto, Japan.*

Background: Chronic kidney disease (CKD) is the cause of end-stage kidney disease (ESKD), cardiovascular disease, and death, and is categorized into 18 stages on the basis of the estimated glomerular filtration rate (eGFR) and proteinuria. It is difficult to accurately predict CKD progression, because CKD stage cannot be mathematically analyzed in terms of scale and cut-off values. In this study, we determined whether CKD stage transformed into a vector field accurately predicts ESKD risk (CKD vector field model).

Methods: The distance from stage G1 A1 to a patient's current stage in terms of on eGFR and proteinuria was defined, r. The model was constructed to reflect ESKD risk on the basis of systematic review of large cohort studies: ESKD risk=exp(r). Then, the model was validated using data from a cohort study of CKD patients in Japan followed up for three years (n=1,564). Moreover, the directional derivative of the model was developed as an index of CKD progression velocity.

Results: Cox proportional hazards models showed the exponential association between r and ESKD risk (p<0.0001). The CKD potential model more accurately predicted ESKD with the areas under the receiver operating characteristic curves adjusted for baseline characteristics 0.81 (95% CI 0.76, 0.87) than CKD stage 0.59 (95% CI 0.54, 0.63) (p<0.0001). Moreover, the directional derivative of the model better predicted the ESKD risk 0.77 (95% CI 0.71, 0.83) than eGFR slope 0.53 (95% CI 0.47, 0.60) (p<0.0001).

Conclusions: Those results indicated that the vector field model mathematically unifies CKD stage and eGFR slope and enables the accurate estimation of CKD progression.

Impact of the CKD-EPI 2021 Equation on the Classification of CKD in Older Australian Adults

Elisa K. Bongetti,[1,2] Rory Wolfe,[3] James B. Wetmore,[4] Anne M. Murray,[5] Robyn L. Woods,[3] Michelle A. Fravel,[6] Mark Nelson,[7] Nigel Stocks,[8] Suzanne G. Orchard,[3] Kevan Polkinghorne.[2,1] *[1]Monash University Department of Medicine, Clayton, VIC, Australia; [2]Department of Nephrology, Monash Health, Melbourne, VIC, Australia; [3]Monash University, School of Public Health and Preventative Medicine, Melbourne, VIC, Australia; [4]Division of Nephrology, Hennepin Healthcare, Minneapolis, MN; [5]Berman Center for Outcomes and Clinical Research and Department of Medicine, Hennepin Healthcare Research Institute, and Department of Medicine, Geriatrics Division, Hennepin Healthcare, Minneapolis, MN; [6]Department of Pharmacy Practice and Science, College of Pharmacy; The University of Iowa, Minneapolis, MN; [7]University of Tasmania Menzies Institute for Medical Research, Hobart, TAS, Australia; [8]Adelaide Medical School, Discipline of General Practice, Adelaide, SA, Australia.*

Background: A recalibrated version of CKD-EPI$_{2009}$, without a race coefficient, was released in 2021 (CKD-EPI$_{2021}$). This updated equation, implemented in the US, can result in the reclassification of chronic kidney disease (CKD) stage in a significant proportion of individuals. The aim of this study was to investigate the clinical impact of transitioning from the 2009 CKD-EPI (CKD-EPI$_{2009}$) to the 2021 CKD-EPI (CKD-EPI$_{2021}$) estimated glomerular filtration rate (eGFR) equation in generally healthy older Australians.

Methods: This was a prospective cohort study using data from 16,244 Australian community-dwelling adults aged ≥70 years, in the ASPirin in Reducing events in the Elderly (ASPREE) study cohort. Baseline characteristics and long-term health outcomes were compared in participants who were reclassified to a different chronic kidney disease (CKD) stage with CKD-EPI$_{2021}$ versus those with unchanged classification.

Results: With CKD-EPI$_{2021}$, baseline eGFR increased by a median of 3.8 mL/min/1.73m^2 (interquartile range [IQR] 3.3, 4.4) resulting in the reclassification of 3,106 (20%) participants to a less advanced CKD stage and the reduction in the prevalence of CKD from 17% to 12%. Over a median follow-up period of 6.5 years (IQR 5.4, 7.9), there was no difference in disability-free survival (HR: 0.94, 95%CI:0.84-1.05), mortality (HR: 0.90, 95%CI:0.78-1.03), major cardiac events (HR: 0.94, 95%CI:0.79-1.13), or hospitalisations for heart failure (HR: 1.00, 95%CI:0.67-1.49) in reclassified, versus non-reclassified, participants.

Conclusions: Implementing CKD-EPI$_{2021}$ would raise eGFR by a median of nearly 4 ml/min/1.73m^2, substantially reducing the proportion of older Australian adults classified as having CKD with no difference in long-term health outcomes among reclassified people. Transitioning to using the CKD-EPI$_{2021}$ may result in a significant reduction in nephrology referrals in generally healthy, older adults.

Associations of Epigenetic Age Acceleration and Kidney Function in the Bogalusa Heart Study

Brenna J. Kirkpatrick,[1] Tanika Kelly,[1] Changwei Li,[2] James P. Lash.[1]
[1]University of Illinois Chicago College of Medicine, Chicago, IL; [2]Tulane University, New Orleans, LA.

Background: Chronic kidney disease (CKD) is an age-related condition associated with significant morbidity and mortality that affects approximately 14% of the US population. As the average age in the US increases, it is critical to identify factors that may predispose individuals to heightened risk of kidney dysfunction. Epigenetic age acceleration (EAA), defined as the difference between chronological age and a composite DNA methylation-derived age, has emerged as a robust predictor of numerous health conditions. Multiple EAA measures have been validated, each with its own physiologic implications. We hypothesized that accelerated epigenetic aging is associated with baseline kidney function and its prospective decline in the Bogalusa Heart Study (BHS).

Methods: We examined associations between four EAA measures (intrinsic EAA [IEAA], extrinsic EAA [EEAA], PhenoAA, and GrimAA) and kidney function in BHS, a longitudinal, prospective study aimed at characterizing cardiometabolic risk factors across the lifespan. Kidney function was assessed as estimated glomerular filtration rate (eGFR), calculated using the race-free CKD-EPI creatinine-based equation. Multiple logistic regression was used to examine cross-sectional associations of EAA with the discrete reduced kidney function outcome (eGFR < 60 mL/min/1.73 m^2) at the most recent study visit (N=1,249). For participants with repeated kidney function measurements, multiple logistic mixed effects models were used to assess associations of baseline EAA and progression to the reduced kidney function outcome (N=965). Cross-lagged panel models were constructed to examine directionality of associations between EAA and kidney function at two time points (N=676).

Results: At baseline, each standard deviation increase in EEAA, GrimAA, and PhenoAA conferred significant 1.73, 1.55, and 1.46 increased odds of reduced kidney function, respectively (P=2.11 X 10-3, 0.04, 0.03, respectively). Likewise baseline EEAA and GrimAA were prospectively associated with 2.03 and 3.50 increased odds of incident kidney function decline (P=0.02 and 2.88 X 10-3, respectively). Path coefficients from baseline EEAA and GrimAA to follow-up eGFR were statistically significant.

Conclusions: Our findings implicate accelerated epigenetic aging as a novel predictor of kidney function decline.

Associations of Proteinuria Trajectories with Kidney Failure and Death in Patients with CKD

Avi G. Aronov,[1] Ashish Verma,[2] Ana C. Ricardo,[1] Tanika Kelly,[1] Sushrut S. Waikar,[2] James P. Lash,[1] Anand Srivastava.[1] CRIC Study. *[1]University of Illinois Chicago, Chicago, IL; [2]Boston Medical Center, Boston, MA.*

Background: Despite repeating proteinuria measurements multiple times during the clinical course of a patient with chronic kidney disease (CKD), clinicians may overlook the significance of temporal patterns of proteinuria. In addition, it is unclear whether proteinuria trajectories identify sub-populations with varying risks of adverse clinical outcomes.

Methods: We used group-based trajectory modeling to identify proteinuria trajectories based on annual urine protein-to-creatinine ratio (UPCR) measurements in 3209 participants of the Chronic Renal Insufficiency Cohort Study who were alive and did not reach end-stage kidney disease (ESKD) within 3 years of study entry. Multivariable-adjusted Cox proportional hazards models tested the associations of UPCR trajectories with ESKD and death in those who survived beyond the 3rd annual visit.

Results: Trajectory analyses identified 4 discrete groups based on annual UPCR measurements: low-slowly rising (n=1528), high-slowly rising (n=1363), regressing (n=114), and rapidly rising (n=204) (**Figure 1A**). Compared to the low-slowly rising proteinuria trajectory group, participants in the other proteinuria trajectory groups had lower socioeconomic status, a greater prevalence of comorbid conditions, and lower eGFR. During a median follow-up of 8.6 years, 547 participants progressed to ESKD, and 836 participants died. Compared to the low-slowly rising group, all proteinuria trajectory groups were associated with higher risks of subsequent ESKD, but only the high-slowly rising group was associated with a higher risk of death (**Figure 1B**).

Conclusions: Trajectories of repeated proteinuria measurements identify subgroups of patients with CKD that have increased risks of ESKD and death independent of known risk factors.

Funding: NIDDK Support, Other NIH Support - NHLBI

TH-PO1025

Panel Estimated Glomerular Filtration Rate: Statistical Considerations for Maximizing Accuracy in Diverse Clinical Populations

Nora F. Fino. CKD-EPI. *University of Utah Health, Salt Lake City, UT.*

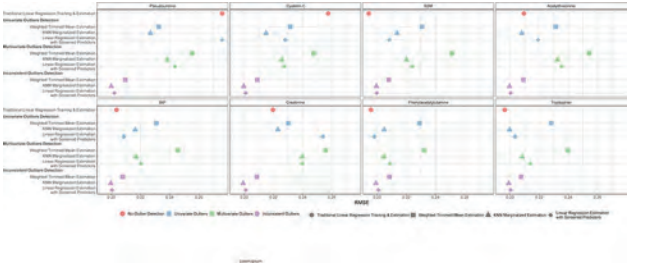
Background: Accuracy of eGFR is limited by non-GFR determinants that affect creatine or cystatin C. We hypothesized that a panel eGFR that incorporates multiple filtration markers with unrelated non-GFR determinants could further improve eGFR accuracy, but methods for robust estimation that can accommodate anomalous values of some filtration markers are required for optimal accuracy. Here, we evaluated methods for estimating GFR based on multiple markers in applications with higher rates of anomalous predictors.

Methods: We detected anomalous predictors in the application data using 3 approaches: univariate outliers, multivariate outliers, and inconsistencies among predictor markers. After removing anomalous predictors, we also compared 3 approaches for robust estimation: weighted trimmed mean prediction, linear model with K-nearest neighbors (KNN) marginalized estimation, and linear regression with screened predictors estimation. Using statistical simulation to emulate applications with increased anomalous predictors, we compared these approaches using Root Mean Square Error (RMSE). As proof of concept, we evaluated these methods in an initial panel of 8 markers (5 metabolites and 3 low molecular weight proteins) in 3,554 participants from 9 diverse studies.

Results: Figure displays RMSE for each strategy. For example, when 10% of pseudouridine values were anomalous using the univariate and multivariable outliers perspective and applying the three robust estimation approaches, RMSEs were 0.227 - 0.276 and 0.238-0.255, respectively. However, when considering inconsistent outliers with linear regression with screened predictors estimation, the RMSE was 0.196. Results using other markers are similar.

Conclusions: We found that focusing on markers with consistent predictors yields robust GFR estimates in application populations with substantial levels of anomalous predictors. Our findings demonstrate that even in cases where a subset of markers appears to be anomalous for a particular patient, accurate and unbiased estimates remain feasible.

Funding: NIDDK Support



TH-PO1026

Intraindividual Difference between Cystatin C- and Creatinine-Based eGFR Is Associated with All-Cause and Cardiovascular Mortality: The Fukuoka Kidney disease Registry (FKR) Study

Hiromasa Kitamura,[1,2] Shigeru Tanaka,[1] Hiroto Hiyamuta,[3] Hiroaki Ooboshi,[1] Kazuhiko Tsuruya,[4] Takanari Kitazono,[2] Toshiaki Nakano.[2] *[1]Fukuoka Shika Daigaku, Fukuoka, Japan; [2]Kyushu Daigaku, Fukuoka, Japan; [3]Shakai Iryo Hojin Seitetsu Kinen Yawata Byoin, Kitakyushu, Japan; [4]Nara Kenritsu Ika Daigaku, Kashihara, Japan.*

Background: Estimated glomerular filtration rate (eGFR) based on serum creatinine (eGFRcr) and serum cystatin C (eGFRcys) are widely used to evaluate kidney function in patients with chronic kidney disease (CKD). Discrepancies between these measurements are not uncommon and have been linked to adverse outcomes such as death and cardiovascular events. Despite this, research on these discrepancies and their association with outcomes in Japanese patients with CKD is limited, highlighting a major gap in the collective understanding within this community.

Methods: We examined 4,244 patients with non-dialysis-dependent CKD who participated in the Fukuoka Kidney disease Registry (FKR) Study, a multicenter prospective cohort study. Patients were categorized into three groups based on eGFRdiff (calculated as eGFRcys – eGFRcr, mL/min/1.73m^2): G1 (<0), G2 (0–10), and G3 (>10). The associations between eGFRdiff and both all-cause and cardiovascular mortality were investigated using Cox proportional hazards models.

Results: During the 5-year follow-up period, 418 patients (9.8%) died from all causes, and 101 patients (2.4%) died from cardiovascular causes. Compared to G3, the multivariable-adjusted hazard ratios (HRs) and their 95% confidence intervals (CIs) for all-cause mortality were 2.67 (1.98–3.59) for G1 and 1.71 (1.25–2.33) for G2. For cardiovascular mortality, the HRs (95% CIs) were 2.48 (1.38–4.46) for G1 and 1.20 (0.63–2.30) for G2.

Conclusions: Lower eGFRdiff values are associated with poor outcomes in terms of both all-cause and cardiovascular mortality in patients with non-dialysis-dependent CKD.

TH-PO1027

Kidney Function Variability Independently Predicts CKD Progression

Richard L. Amdur,[1,2] Mark J. Butler,[1,2] Jia Hwei Ng.[1,2] *[1]Northwell Health, New Hyde Park, NY; [2]Feinstein Institutes for Medical Research, New Hyde Park, NY.*

Background: Kidney function variability (KFV) was an independent predictor of renal and cardiovascular outcomes in 15 prior studies since 2009. Here, we test three measures of KFV in a large patient sample in a US healthcare system to determine the optimal definition of KFV for predicting renal outcomes.

Methods: Using EHR data from 2016-2023 in a large hospital system in the northeastern US, we selected patients who had an inpatient admission and at least 4 serum creatinine (Scr) measurements over 18 months (baseline) and baseline eGFR > 30 ml/min/1.73 m2. We calculated eGFR slope and variability during this baseline period and examined renal outcomes for patients with 3 or more Scr measures over at least 6 and up to 80 months of follow-up. Renal outcomes included 25% eGFR decrease from baseline mean and entry into stage 4 CKD. We used quintiles of KFV as measured by standard deviation (SD), coefficient of variation (CV), and non-linearity (NL; deviation from the individual patient's regression line of monthly minimum eGFR x year). We used Cox proportional hazard models with covariates age, race, sex, baseline mean eGFR, baseline slope of eGFR, baseline comorbidities and baseline anti-diabetic or anti-hypertensive medication class, to examine the independent predictive value of each KFV measure on renal outcomes, with censoring at death or the end of the study period.

Results: 99,964 patients qualified for inclusion (mean age 62, mean baseline eGFR 82, 57% female, 17% Black, 6% Asian, 13% Hispanic, 28% with DM). 15.1% of patients had 25% eGFR drop, and 5.5% reached CKD stage 4. In Cox models adjusted for demographics, comorbidities, medications, and baseline eGFR slope and mean, all three KFV measures were significant independent predictors of both renal outcomes (all p<.0001), but the strongest effect was for CV. After adjusting for covariates, each 1-quintile increase in baseline eGFR-CV was associated with a 12% increase in hazard of 25% eGFR decline (95% ci 10-13%, p<.0001) and a 15% increase in hazard of reaching stage 4 CKD (95% ci 13-18%, p<.0001) during follow-up.

Conclusions: KFV is a powerful independent predictor of CKD progression even after accounting for baseline level and slope of eGFR and other covariates, and since it is easily obtainable, it should be considered for use in future risk stratification algorithms. CV appears to be the best measure of KFV.

TH-PO1028

Impact of Adoption of European Kidney Consortium Equation (EKFC) on CKD Prevalence and CKD Staging in Older Irish Adults

Meera Tandan,[1] Leonard Browne,[1] Austin G. Stack.[1,2] National Kidney Disease Surveillance System and Quality Assurance Programme. *[1]University of Limerick, Limerick, Ireland; [2]Health Service Executive, Dublin, Ireland.*

Background: The Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation tends to overestimate glomerular filtration rate (GFR) and has limitation in younger and older age groups, while the European Kidney Function Consortium (EKFC) full-age spectrum (FAS) correct for these problems and provide better performance in estimating GFR. We compared the 2017 EKFC- FAS(Scr-CysC) equation with 2012 CKD-EPI(Scr-CysC) for estimating CKD prevalence and staging in a national representative sample of older Irish adults.

Methods: We utilised data from The Irish Longitudinal Study on Ageing (2009-2011), for participants aged 50 to 79 years with complete measurement of serum creatinine (Scr) and Cystatin-C (CysC). Using 2017 EKFC- $FAS_{(Scr\text{-}CysC)}$ and 2012 CKD-$EPI_{(Scr\text{-}CysC)}$, equations eGFR was calculated. CKD was defined as eGFR below 60 ml/min/1.73m^2. Median eGFR, CKD prevalence, concordance correlation coefficient (CCC), and impact of EKFC equation on GFR category reclassification was examined.

Results: A total of 5,092 participants (53.3% women), median age 61 years were included. CKD prevalence varied significantly from 10.8% (9.9% – 11.8%) using 2021 CKD-$EPI_{(Scr\text{-}CysC)}$ to 16.7 % (15.5 - 17.9%) with the 2017 EKFC- $FAS_{(Scr\text{-}CysC)}$ equation. The corresponding numbers of CKD increased from 114,867 to 176,439 individuals respectively. The median eGFR for 2021 CKD-$EPI_{(Scr\text{-}CysC)}$ was 82.1 ml/min/1.73m^2 and 2017 EKFC- $FAS_{(Scr\text{-}CysC)}$ was 74.5 ml/min/1.73m^2, P<0.001). The net reclassification was 23.1 % based on 2017 EKFC- $FAS_{(Scr\text{-}CysC)}$ equation compared to CKD-EPI 2012 $_{(Scr\text{-}CysC)}$ and was towards more worsening CKD stage. The CCC between 2012 CKD-$EPI_{(Scr\text{-}CysC)}$ and 2017 EKFC- $FAS_{(Scr\text{-}CysC)}$ was 0.88 (95% CI, 0.88 - 0.89).

Conclusions: CKD prevalence varies according to eGFR equation with substantially higher numbers of CKD predicted by the European Kidney Function Consortium than CKD-EPI equations. This has direct implications on healthcare planning, resource allocation, and rates of referral to specialist nephrology services in Ireland.

Circulating Very Long-Chain Saturated Fatty Acids and Incident CKD: A Meta-Analysis of Prospective Cohort Studies

Benjamin Lidgard, Amanda M. Fretts, Rozenn Lemaitre. Fatty Acids Outcomes Research Consortium. *University of Washington, Seattle, WA.*

Background: Chronic kidney disease (CKD) is a global health problem whose prevalence is expected to increase. Identification of novel risk factors for CKD may lead to improved outcomes. Saturated fatty acids (SFAs) have been posited as contributors to CKD risk. We performed a meta-analysis of de-novo analyses which were undertaken in 12 contributing cohorts using a harmonized protocol to evaluate the associations of SFA with incident CKD.

Methods: SFAs were measured in 12 cohorts in the Fatty Acids Outcomes Research Consortium (FORCE), yielding a sample size of 17,838 participants with eGFR >60 mL/min/1.73 m2 across 9 countries. Associations between each SFA (16:0, 18:0, 20:0, 22:0, and 24:0) and incident CKD (defined as an eGFR <60 mL/min/1.73 m2 and ≥25% decrease from baseline) were assessed by Cox or Poisson regressions, adjusted for multiple potential covariates. Results were pooled using inverse variance weighted meta-analysis.

Results: In total, 2,548 participants across the 12 cohorts developed CKD during follow-up. After adjustment for multiple covariates, higher concentrations of SFA 18:0 were associated with significantly decreased risk of incident CKD (RR per interquintile range of SFA 18:0 0.86, 95% CI 0.78 to 0.95, P=0.003, I2=0.00%) (Figure). SFA 18:0 was associated with slower annual decline in eGFR and less risk for ≥40% decline in eGFR from baseline in sensitivity analyses.

Conclusions: In this meta-analysis of harmonized de-novo analyses among 12 cohorts across 9 countries (including 17,838 participants without baseline CKD), higher circulating levels of SFA 18:0 were consistently associated with decreased risk for incident CKD. Future work may be indicated to assess mechanisms by which SFA 18:0 may exert kidney-protective effects, and how circulating SFA 18:0 levels may be altered.

TH-PO1030

Patients with CKD with Wide Fluctuations in Plasma Uric Acid Levels Are Prone to Have Faster Decline in eGFR and High Chance of Orthopedic Admissions

Hiroshi Tanaka. *Mihara Red Cross Hospital, Mihara, Japan.*

Background: Plasma uric acid level is known to be associated not only with gouty attacks and urolithiasis but also with CKD progression and higher cardiovascular mortality. In some CKD patients, plasma uric acid levels are occasionally found to be widely fluctuated; the clinical significance of those fluctuations has not been extensively studied. In the era of growing numbers of elderly population, this fluctuation might be associated with unfavorable patient prognosis such as orthopedic admissions.

Methods: A hospital-wide study with all the laboratory data for a period of 4 years and 2 months was conducted. Non-dialysis patients with an age 18 or more in whom the eGFR slope was calculated over 731 days or more, with a median eGFR < 60 mL/min/1.73m^2, and with at least 3 uric acid measurements, were included in the study. Uric acid level fluctuations were analyzed by 3 parameters: standard deviation (SD), coefficient of variation (CV) and interquartile range (IQR). Hospital admission records were retrieved over 52 months following the above survey period of uric acid fluctuations.

Results: A total of 1,103 patients met the inclusion criteria. Those with wide fluctuations in plasma uric acid (i.e., those who had the widest quartile in CV) had faster eGFR decline than patients in the narrower 3 quartiles (-2.67 +- 5.74 vs -1.01 +- 2.55 mL/min/1.73m^2/yr, P<0.0001; Because a virtually identical trend was confirmed also in analyses with SD and IQR, CV will be used thereafter). Hyperuricemic patients (i.e., patients with higher-than-median plasma uric acid level) had faster eGFR decline compared with normouricemic patients (-2.61+- 6.30 vs -1.02 +- 3.31 mL/min/1.73m^2/yr, P=0.0015). The eGFR decline was even faster in widely-fluctuated hyperuricemic patients compared with the rest (eGFR decline: -3.65 +- 6.30 vs -1.66 +- 4.99 mL/min/1.73m^2/yr, P<0.0001). Interestingly those who had wide fluctuations in uric acid level were found to have significantly higher risk of orthopedic admissions in the following 52 months compared with those with narrow fluctuation (14.9% vs 9.1%; chi-squared test, P=0.020).

Conclusions: Wide fluctuation in plasma uric acid level is associated with faster eGFR decline and risk of orthopedic admissions.

Prediction of Medication Therapy Problems in Patients with Moderate-to High-Risk CKD

Melanie R. Weltman,[1,2] Alaa A. Alghwiri,[2] Zhuoheng Han,[2] Linda-Marie U. Lavenburg,[2] Thomas D. Nolin,[1,2] Jonathan G. Yabes,[3,4] Yi-Fan Chen,[3] Manisha Jhamb.[2] *[1]University of Pittsburgh School of Pharmacy, Pittsburgh, PA; [2]University of Pittsburgh Division of Renal-Electrolyte, Pittsburgh, PA; [3]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [4]University of Pittsburgh Department of Biostatistics, Pittsburgh, PA.*

Background: Patients with chronic kidney disease (CKD) are at risk of medication therapy problems (MTP) due to high comorbidity and medication burden. Using data from the Kidney Coordinated HeAlth Management Partnership (K-CHAMP) trial, we used machine learning to build a predictive model to identify MTP high-risk patients with CKD in the primary care setting.

Methods: We used baseline data from patients enrolled in the intervention arm of the K-CHAMP trial, completed May 2019 to July 2022, which tested a population health management strategy, including medication management, for improving CKD care. The dataset was divided into 80% training and 20% testing subsets. The area under the ROC curve (AUROC) was used to assess classification accuracy in distinguishing between patients with and without MTP. Eight candidate models were considered, and the top three performing models (Random Forest, Support Vector Machines, and Gradient Boosting), based on cross-validated AUROC on training data, underwent further refinement. The model with the highest AUROC in the testing set, while considering the bias/variance trade-off, was selected as the best-performing model.

Results: Among 730 patients who received medication review at baseline, 566 (77.5%) had at least 1 MTP. Key demographics were mean age 74 years, 55% females, 92% White, 64% with diabetes, and the mean number of medications was 5.8 at baseline. The Random Forest model had the best performance on the testing set with AUROC 0.72, sensitivity 0.80, and specificity 0.64. The five most influential variables, ranked in descending order of importance for predicting individuals with MTP, were diabetes status (yes/no), HbA1C level, UACR level, age, and number of comorbidities.

Conclusions: The Random Forest model provided the highest performance in predicting MTP for patients with moderate-to high-risk CKD. Future work will focus on developing a user-friendly online tool aimed at identifying patients who may benefit most from pharmacist-led medication management.

Long-Term Use of Proton-Pump Inhibitors Is Associated with Rapid Progression to ESKD in Patients with CKD: A Korean Nationwide Study

Harin Rhee. *Pusan National University School of Medicine, Busan, Republic of Korea.*

Background: Proton pump inhibitors (PPIs) are one of the most widely used drugs worldwide. Nevertheless, it has long been debated whether PPIs are associated with disease progression in patients with chronic kidney disease (CKD).

Methods: Using the Korean Health Insurance Review and Assessment (HIRA) database encoded in the Observational Medical Outcomes Partnership – Common Data Model (OMOP-CDM) version 5.3, a total of 34,656 patients with CKD stage 3 or 4 initiating PPIs or H2 receptor antagonists (H2RAs) for more than 90 days were assembled from 2012 through 2021. ESKD progression was defined as the initiation of kidney replacement therapy (hemodialysis, peritoneal dialysis, or kidney transplantation) for more than three months. The observation period was three years, and we calculated the incidence rate (IR) as 100 person-years (PYs) in the 1:1 propensity score-matched model.

Results: After 1:1 propensity score matching, we retrieved a total of 19,438 CKD stage 3 or 4 patients initiated PPIs or H2RA for more than three months. In all, 66.3% were CKD stage 3, 44.5% were aged over 75 years, 59.8% were male, and 68.3% had diabetes. During the mean follow-up of 1.2 years, ESKD progression was observed in 2,327 patients, and it was more frequent in PPI users (IR, 10.5/100PYs) compared to H2RA users (IR, 9.2/100PYs; incidence rate ratio (IRR), 1.19(1.07-1.32)). In the subgroup analysis, ESKD progression was more prominent in CKD stage 3 patients (PPI, 5.7 /100 PYs; H2RA 4.2/ 100 PYs; IRR 1.40(1.12-1.69)) than in CKD stage 4 (PPI, 19.8/100 PYs; H2RA 19.34 /100 PYs; IRR 1.03(0.91-1.18)), and non-diabetic CKD 3 or 4 patients (PPI, 7.7/100PYs; H2RA, 6.3/100 PYs; IRR, 1.32(1.07-1.64)) than in diabetic CKD 3 or 4 patients (PPI, 11.7/100PYs; H2RA, 10.80/100 PYs; IRR, 1.12(0.99-1.26)).

Conclusions: In CKD stage 3 or 4 patients, the use of PPIs for more than three months is associated with a 19% higher risk of ESKD progression, and the risk is more prominent in non-diabetic and earlier-staged CKD patients.

TH-PO1033

Association of Glucose Variability with Coronary Artery Calcium Score in Patients with Nondialysis-Dependent CKD: Findings from KNOW-CKD

Dong Hoon Kang, Jong Hyun Jhee, Byounghwi Ko, Cheol Ho Park, Ga Young Heo, Hyung Woo Kim, Jung Tak Park, Seung Hyeok Han, Shin-Wook Kang, Tae-Hyun Yoo. *Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Coronary artery calcification (CAC) is common in patients with chronic kidney disease (CKD) and predicts the risk of cardiovascular disease. Glucose variability has been implicated as an independent risk factor for adverse cardiovascular outcomes in various populations. We investigated whether glucose variability is associated with CAC prevalence and progression in patients with non-dialysis CKD.

Methods: We used a prospective cohort of Korean patients with CKD. CAC score was measured at baseline and 4-year with Agatston units and fasting blood glucose was measured at baseline, 6-month, and 1-year. Glucose variability was defined as the standard deviation of three fasting blood glucose measurements. CAC prevalence was

defined as a baseline CAC score greater than zero and CAC progression was defined as an annual CAC percentage change of 15% or greater.

Results: Of the total of 1,518 patients, mean age was 53.5 years and 39.9% were men. According to four glucose variability group stratified by quartile, the prevalence of CAC was 37.6%, 38.9%, 52.0% and 76.3% for each group (Q1 vs Q4, prevalence ratio 1.35, 95% CI 1.08–1.69, *p*=0.009). In overall patients, higher glucose variability was associated with a higher risk of CAC progression (Q1 vs Q4, relative risk 1.85, 95% CI 1.20–2.87, *p*=0.005). In a subgroup analysis stratified according to the presence of diabetes, association was only observed in non-diabetic CKD patients (non-diabetic Q1 vs Q4, relative risk 2.01, 95% CI 1.12–3.62, *p*=0.02; diabetic CKD Q1 vs Q4, relative risk 1.31 (0.37–4.64), *p*=0.68).

Conclusions: In non-dialysis CKD patients, higher glucose variability was associated with a higher prevalence of CAC, and in non-diabetic CKD patients, higher glucose variability was associated with CAC progression.

Funding: Government Support - Non-U.S.

	Prevalence of Coronary artery calcification (N=1518)			Progression of Coronary artery calcification (N=959)		
Glucose variability group	No. of events (%)	Prevalence ratio (95% CI)	P value	No. of events (%)	Odds ratio (95% CI)	P value
Q1	143 (37.6%)	1.0	–	71 (29.6%)	1.0	–

Association between Weight Change and Estimated Glomerular Filtration Rate Decline in a Middle-Aged Population

Niloofar Deravi,[1] Azra Ramezankhani,[1] Mohammad Rahmanian,[1] Parto Hadaegh,[1] Alireza Esteghamati,[2] Fereidoun Azizi,[1] Farzad Hadaegh.[1]
[1]Shahid Beheshti University of Medical Sciences Research Institute for Endocrine Sciences, Tehran, Tehran, Islamic Republic of Iran; [2]Tehran University of Medical Sciences, Tehran, Tehran, Islamic Republic of Iran.

Background: Little is known about the impact of weight change on the estimated glomerular filtration rate (eGFR) decline. We examined the association between weight changes and eGFR decline risk among middle-aged Iranians, participating in the Tehran Lipid and Glucose Study cohort.

Methods: A total of 4,748 individuals aged ≥30 years were selected. We defined weight change as difference in body weight during 3 years. The outcome was an eGFR decline of ≥30% and ≥40%. Cox regression models were utilized to calculate multivariable hazard ratios (HRs, 95% confidence interval (CI)) for different body weight changes (>10% weight loss; 5% to 10% weight loss; -5% to 5% weight change (reference group); 5% to10% weight gain; >10% weight gain).

Results: After a median follow-up of 9.4 years, there were 498 and 144 cases of eGFR decline of ≥30% and ≥40%, respectively. Individuals with a weight gain of ≥10% had a 71% higher risk (1.71, 1.15-2.55) for eGFR decline of ≥30%; the comparable value for eGFR decline of ≥40% was 2.85 (1.46-5.57). Those with a 5%-10% weight loss had higher risk for eGFR decline of ≥30% [(1.30 (0.98-1.72), P=0.06]; and an 86% (1.86, 1.18-2.93) higher risk for ≥40% eGFR decline. The impact of weight gain was more prominent among hypertensive individuals for eGFR decline of ≥30% (P for interaction=0.007). In a sensitivity analysis, among those with eGFR>60 ml/min per 1.73 m2 and without eGFR decline during weight change period, weight gain of >10% was associated with a 53% higher risk of eGFR decline ≥30% (1.53 (0.99-2.37).

Conclusions: Among the middle-aged Iranian population, there was significant association between both weight gain and weight loss with subsequent eGFR decline. Our results underscore the clinical importance of monitoring weight as a factor in renal risk assessment.

Analysis of the Relationship between Body Mass Index and Kidney Function Decline in a Middle-Aged Japanese Population

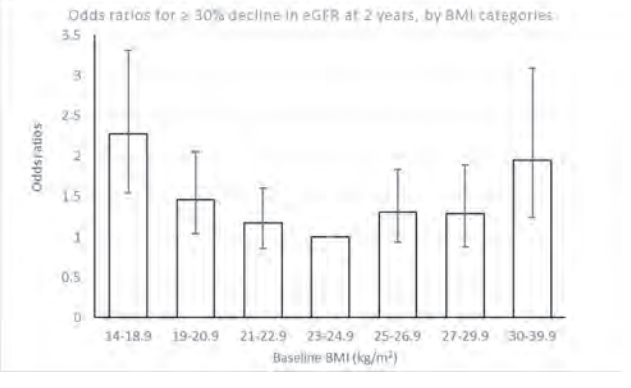
Miki Nakamura, Chiho Yamazaki, Keiju Hiromura, Kei Hamazaki.
Gunma Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Maebashi, Japan.

Background: The number of dialysis patients in Japan is increasing every year. In patients with chronic kidney disease, both obesity and underweight are reported to be risks for renal function decline. On the other hand, in the general population, obesity is a risk factor, but the relationship between underweight and renal function decline has not been well studied. Therefore, we aimed to analyze the relationship between body mass index (BMI), especially underweight, and renal function decline using health checkup data from Gunma prefecture, Japan.

Methods: We studied National Health Insurance beneficiaries aged 40 to 74 in Gunma who underwent health checkups in FY 2018 and 2020 and had usable estimated glomerular filtration rate (eGFR) and BMI data. We excluded those who self-reported receiving dialysis or had a BMI < 14 kg/m^2 or ≥ 40 kg/m^2. The outcome was defined as an eGFR decline rate of ≥ 30% over 2 years. Baseline BMI was classified into 7 categories, and odds ratios (OR) and 95% confidence intervals (95% CI) were calculated by logistic regression analysis.

Results: 64,970 individuals were included in the analysis. In a model adjusted for age, sex, smoking, alcohol consumption, blood pressure, hemoglobin A1c, and lipid profile, BMI and renal function decline showed an inverse J-shaped relationship, with underweight (BMI = 14.0-18.9 kg/m^2, OR [95% CI] 2.27 [1.55-3.31]) posing a higher risk of renal function decline compared to obesity (BMI = 30.0-39.9 kg/m^2, OR [95% CI] 1.95 [1.24-3.09]). Similar trends were seen across subgroups by sex, age, urinary protein presence, baseline eGFR, and diabetes, especially among those with negative urinary protein and non-diabetic status.

Conclusions: In the middle-aged and elderly general population, both obesity and underweight were shown to be risk factors for renal function decline. To prevent the need for dialysis, intervention is necessary for underweight groups who are not targeted for health guidance.



TH-PO1036

Periodontal Disease, Its Treatment, and the Risk of Kidney Failure among US Veterans

Nilang G. Patel,[1,2] Scott Silvey,[2,1] Jasmohan S. Bajaj.[1,2] *[1]VA Richmond Medical Center, Richmond, VA; [2]Virginia Commonwealth University Department of Internal Medicine, Richmond, VA.*

Background: Association of periodontal disease(PD) on incidence and progression of CKD is unknown.

Methods: Retrospective study conducted on veterans eligible for continuous and comprehensive dental care from 2009-2014. Veterans with a baseline eGFR > 60 ml/min/1.73m^2 were followed from the date of their initial comprehensive dental exam until the end of 2019. Patients divided into three groups: Periodontal disease (PD), Periodontal disease with treatment (PT) and no periodontal disease (no-PD). The composite outcome included: incident CKD, a 40% drop in eGFR, transplant/dialysis, or death.

Results: 86,376 veterans (age 57.17±12.59, 91.4% male) were included in the final cohort. 12,172(14.1%) had untreated PD, 20,283 (23.5%) had PT and 53,921 (62.4%) had No-PD. The median follow-up was 7.39 yrs. Table 1 shows baseline characteristics and outcomes. Upon analyzing the primary composite outcome, PD patients had significantly increased risk over time(HR,1.18 [1.12-1.24], p<0.001), as did PT patients (HR:1.05 [1.01-1.09], p=0.02) (Fig. 1). After adjusting all covariates, PD associated with higher rates of the composite outcome (aHR:1.08 [1.01-1.15], *p*=0.025), while the PT was no longer statistically significant.

Conclusions: Untreated periodontal disease is linked to an increased Incident CKD and CKD progression. Treated PD associated with better outcomes.

Funding: Veterans Affairs Support

CKD and Infection Risk: A CKD Prognosis Consortium Study

Junichi Ishigami, Keiichi Sumida. CKD Prognosis Consortium.
CKD Prognosis Consortium, New York, NY.

Background: Infectious disease is a major cause of hospitalization in people with CKD yet it has not been systematically studied across stages of CKD.

Methods: We analyzed data on 2,958,633 individuals (mean age 49 yrs, 59% female, 19% diabetes, mean eGFRcr (CKD-EPI 2021), 93 ml/min/1.73m^2) from 45 cohorts in the CKD Prognosis Consortium to examine the association of eGFRcr and ACR with the risk of hospitalization with infection. Outcomes were ascertained through ICD-9 and 10 codes on hospital discharge records relevant to acute infections (i.e., upper and lower respiratory tract, urinary tract, skin and soft tissue, musculoskeletal, gastrointestinal tract, genital, nervous system, cardiovascular system infections, and sepsis). Follow-up was censored at December 31, 2019, and therefore COVID-19 infection was not assessed. Multivariable Cox models were used to estimate HRs.

Results: During follow-up, 195,040 had a hospitalization with infection (IR, 140.3 [89.4-202.5] per 10,000 person-yrs). In Cox models, compared to eGFRcr 90-105 and ACR <10, lower eGFRcr and higher ACR were each incrementally associated with an increased risk of infection, including in eGFRcr 45-59 and ACR 10-29 (adjusted HRs [95% CI], 1.46 [1.41-1.51] and 1.41 [1.35-1.47], respectively; far right column and bottom row in **Figure**). High eGFRcr ≥105 was also associated with the risk of hospitalization with infection (1.33 [1.27-1.39]). The cross-category analysis revealed that the association of eGFRcr and ACR was independent of each other, with the highest risk observed in eGFRcr <30 and ACR ≥300 (5.92 [5.37-6.53] vs. eGFRcr 90-105 and ACR <10). These findings were consistent across infection subtypes.

Conclusions: Lower kidney function and higher albuminuria were independently associated with a higher risk of infection. The risk was substantially elevated even in mild to moderate CKD, with the highest risk seen in the most advanced stage of CKD. Infection prevention measures should target individuals across all CKD stages, and are particularly important for those with low eGFR and elevated ACR.

Funding: NIDDK Support, Private Foundation Support

Association of Water Intake with Incident CKD in the UK Biobank Study

Hyung Woo Kim,[1,2] Ga Young Heo,[1,2] Cheol Ho Park,[1,2] Jung Tak Park,[1] Seung Hyeok Han,[1] Tae-Hyun Yoo,[1] Shin-Wook Kang.[1] *[1]Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Institute for Innovation in Digital Healthcare, Yonsei University, Seoul, Republic of Korea.*

Background: Water intake has been suggested as a preventive strategy for chronic kidney disease (CKD). Nevertheless, there is a lack of evidence to suggest that higher water intake may be beneficial in the prevention of CKD.

Methods: This prospective, population-based cohort study enrolled participants without a history of CKD from the UK Biobank. Participants with heart failure, valvular heart disease, or a history of diuretic use were excluded. The main exposure was total daily fluid intake including water, tea, and coffee. Inverse probability of treatment weighting (IPTW) based on propensity scores was used to build groups with different amount of daily fluid intake. The primary outcome was the newly diagnosed CKD and the risks were estimated by Cox regression models.

Results: Among 286,139 participants (median age, 57 years; men, 48.2%; median estimated glomerular filtration rate, 97.9 ml/min/1.73 m^2), 6,816 (2.4%) cases of incident CKD occurred. Participants were categorized into five groups according to the amount of daily fluid intake: <1.5 L/d (n=117,555), 1.5 to 2.0 L/d (n=87,613), 2.0 to 2.5 L/d (n=48,845), 2.5 to 3.0 L/d (n=19,026), and ≥3.0 L/d (n=13,100). Compared with participants who intake 1.5 to 2.0 L/d of fluid, the respective hazard ratios (95% confidence intervals) for those with <1.5 L/d, 2.0 to 2.5 L/d, 2.5 to 3.0 L/d, and ≥3.0 L/d were 1.06 (1.01-1.13), 1.06 (0.98-1.14), 1.04 (0.93-1.16), and 1.26 (1.11-1.43), respectively.

Conclusions: The relationship between fluid intake and the development of CKD appears to be non-linear. The findings of this study indicate that consuming a high volume of fluid may not be associated with a reduced risk of incident CKD.

TH-PO1039

Subclinical Liver Fibrosis and Associated Risk Factors and Clinical Outcomes in CKD: The CRIC Study

Jing Chen, L. Lee Hamm, Cong Zhao, Siyi Geng, Lucy Van Dyke, Sydney L. Richardson, Layla H. Wright, Grace S. Morley, Rebecca J. Owens, Geetika Gorrepati, Allison N. Marshall, Vecihi Batuman, Jiang He. *Tulane University, New Orleans, LA.*

Background: Metabolic abnormalities associated with CKD may lead to liver fibrosis. We studied the incidence, risk factors, ASCVD, and mortality associated with subclinical liver fibrosis in CKD patients.

Methods: This analysis included 3,485 CKD patients from the Chronic Renal Insufficiency Cohort (CRIC) Study, excluding those with missing values. The mean follow-up was 8.2 years. The validated FIB-4 index (age × AST / (PLT × $\sqrt{}$ALT) evaluated subclinical liver fibrosis (defined as a FIB-4 >3.25). CVD and death events were adjudicated by two physicians. Cox proportional hazards models with backward selection examined risk factors for incident liver fibrosis, including CVD risk factors, eGFR, uACR, and biomarkers (inflammation, mineral bone disorder, fibrosis, and NT-proBNP). The models also assessed the link of FIB-4 with ASCVD and all-cause mortality.

Results: The average age was 62 for those with FIB-4 > 3.25 and 57 for those with FIB-4 ≤ 3.25. The age-adjusted incidence was 14.0 per 1000 person-years (17.5 for men and 10.1 for women). Multivariable-adjusted hazard ratios (HR) and 95% CI for liver fibrosis and risk factors are shown in **Table**. HR (95% CI) for one SD higher FIB-4 were 1.06 (1.02, 1.11) for ASCVD and 1.07 (1.03, 1.10) for all-cause mortality, adjusted for confounders including eGFR and uACR.

Conclusions: This study indicates that age, male, mineral bone disorder, inflammation, fibrotic factors, and volume overload are independently associated with risk of subclinical liver fibrosis. Additionally, liver fibrosis was associated with ASCVD and all-cause mortality. Further studies are needed to assess liver fibrosis and related interventions in CKD.

Association of Pancreas Fat Fraction with Adverse Kidney and Cardiovascular Outcomes

Philip K. Thomas,[1] Celestin Missikpode,[1] Ashish Verma,[2] Runqi Zhao,[2] Sophie E. Claudel,[2] Insa M. Schmidt,[2] Petter Bjornstad,[3] Brian Layden,[1] James P. Lash,[1] Sushrut S. Waikar,[2] Anand Srivastava.[1] *[1]University of Illinois Chicago, Chicago, IL; [2]Boston University, Boston, MA; [3]University of Washington, Seattle, WA.*

Background: Pancreas fat accumulation has been associated with impaired glucose metabolism and stimulation of inflammation. The associations of pancreatic fat fraction (PFF) with adverse outcomes remain understudied.

Methods: We estimated baseline predicted PFF (pPFF) from abdominal MRI in 29464 participants of the UK Biobank. Since the initial imaging visit occurred 9.3 [IQR 8.2,10.2] years after the baseline visit, we calculated annual change in PFF using linear regression in 337 participants who underwent repeat imaging 2.8 [IQR 2.2,4.8] years after the initial scan. We back-calculated pPFF by adding this change to each participant based on the time between the baseline visit and initial MRI visit assuming linear change in PFF over time. Multivariable-adjusted proportional hazards models tested associations of pPFF with incident chronic kidney disease (CKD), cardiovascular disease (CVD), and death.

Results: Participants had a mean ± SD age of 56 ± 8 years, mean eGFR of 98 ± 13 mL/min/1.73m^2, median [IQR] albuminuria of 5.7 [3.5,9.2] mg/g, and median pPFF of 4.7 [1.6,10.3]%. During a median follow-up of 13.8 years, there were 573 incident CKD events, 1049 incident CVD events, and 471 deaths. In fully adjusted models, participants in the 2nd and 3rd tertiles of pPFF each had a 1.58-fold increased risk of incident CKD compared to the 1st tertile, respectively (**Figure 1A**). The association of pPFF with incident CKD was non-linear (Non-linear P<0.001, **Figure 1B)**. pPFF was not associated with incident CVD or death.

Conclusions: Higher pPFF levels are associated with increased risk of incident CKD but not CVD or death. Future studies should investigate whether reducing pancreas fat decreases the risk of incident CKD.

Association of IgG Glycosylation with Kidney Markers and CKD Progression

Ulla T. Schultheiss,[1,2] Elena Butz,[1] Ivan Gudelj,[3,4] Barbara Radovani,[3] Anna Kottgen,[1] Peggy Sekula.[1] GCKD Study Investigators. *[1]Universitatsklinikum Freiburg, Freiburg, Germany; [2]Synlab MVZ Humangenetik Freiburg GmbH, Freiburg, Germany; [3]University of Rijeka, Faculty of Biotechnology and Drug Development, Rijeka, Croatia; [4]Genos Glycoscience Research Laboratory, Zagreb, Croatia.*

Background: Glycosylation profiles of immunoglobulin G (IgG) has been associated with kidney function and chronic kidney disease (CKD) in the general population but has not been explored in CKD cohorts. Glycans, like galactose, modulate immune responses and may impact kidney diseases. Our aim was to identify glycosylation patterns associated with kidney function markers and CKD progression to kidney failure (KF) and mortality among CKD patients.

Methods: Plasma samples from 4819 German CKD (GCKD) study participants were analyzed for 24 IgG glycans. This abstract focuses on 12 traits derived from these measurements, related to either complete or partial glycosylation patterns. Linear and Cox regression models, adjusted for confounders, evaluated associations with eGFR, UACR, KF, and mortality. A significance threshold of p=0.0021 (0.05/24) was used.

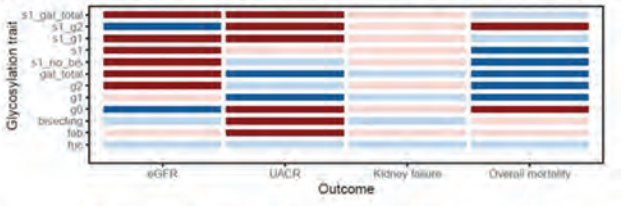
Results: The study included 460 participants reaching KF and 607 died during 6.5-years follow-up. Mean age was 60.1 years, with 39.8% females, median UACR of 50.8 mg/g, and median eGFR of 49.4 mL/min/1.73m^2. Most glycosylation patterns showed significant results, none were associated with KF, e.g. an increase of one standard deviation total galactosylated IgG (gal_total) was significantly associated with a 0.045 mL/min/1.73m^2 increase in eGFR and a 0.11 mg/g decrease in UACR. Higher levels of gal_total were linked to a lower risk of mortality (Hazard Ratio 0.72), indicating a protective effect. Similar protective effects were observed for s1, s1_no_bis, g2, and g1, while harmful associations were found for s1_g2 and g0.

Conclusions: Our study shows that certain patterns of glycosylation in IgG N-glycans are associated with kidney function and mortality. Galactosylation and specific sialylation patterns are linked to better kidney function and lower mortality, while agalactosylation

and specific ratios of sialylation are associated with poorer kidney function and higher mortality. Ongoing analyses will further explore these associations.

Funding: Government Support - Non-U.S.

Figure: Association of the 12 derived IgG glycans with eGFR, UACR, kidney failure, and mortality.



Legend: s1_gal_total=monosialylated and total galactosylated IgG, s1_g2=monosialylated and digalactosylated IgG, s1_g1= monosialylated and monogalactosylated IgG, s1=monosialylated IgG, s1_no_bis=monosialylated IgG without bisecting N-acetylglucosamine in IgG N-glycome, gal_total=total galactosylated IgG, g2=digalactosylated IgG, g1=monogalactosylated IgG, g0=agalactosylated IgG, bisecting=bisecting N-acetylglucosamine in IgG N-glycome, fab=Fab glycosylated IgG, fuc=fucosylated IgG. g0, g1, g2, gal_total, s1, s1_no_bis, bisecting, and fuc levels are derived in relation to the total IgG N-glycome. s1_g1, s1_g2, s1_gal_total, and fab levels are derived in relation to g1, g2, and gal_total respectively.

TH-PO1042

Empagliflozin Dosage and Albuminuria Reduction in CKD

C. E. Cervantes, Dustin Le, Mohamad A. Hanouneh. *Johns Hopkins University, Baltimore, MD.*

Background: Exploratory analysis from EMPA-REG trial revealed empagliflozin significantly reduces albuminuria compared to placebo. Yet, no study has examined if there's a correlation between albuminuria reduction and varying dosage.

Methods: We conducted a retrospective study on CKD patients with UACR > 30 mg/g, dividing them into two groups: group one received empagliflozin 10 mg daily and group 2 received empagliflozin 25 mg daily, with primary goal of assessing the proportion of patients achieving >50% reduction in UACR from baseline.

Results: 163 patients were included, 94 (58%) were on group 1 with mean eGFR 43.2 ml/min per 1.73m2 and median UACR 399 mg/g, and 69 (42%) were on group 2 with mean eGFR 51.0 ml/min per 1.73m2 and median UACR 666 mg/g. At baseline, 126 (77.3.%) were on RAAS blockade, and 131 (80.3%) had type 2 diabetes. After 6 months, a reduction of > 50% in albuminuria was noted in 46% of patients in group 1, while in group 2, this figure rose to 68% [with a p-value of 0.01 and an OR of 2.46 (95% CI: 1.24 to 4.9)] (Figure 1A). When we looked at percent albuminuria reduction adjusted for baseline covariates, despite noting a greater reduction in group 2 (54%, 95% CI 41 to 67) compared to group 1 (45%, 95% CI 36 to 55), the difference was 9.2% (95% CI: -0.16 to 22.7) and was not statistically significant (Figure 1B). At 6-months, the mean difference in eGFR was –2 ml/min per 1.73m2 (SD 5.7) in group 1 and -2.7 ml/min per 1.73m2 (SD 7.7) in group 2, with no discernible variance between the two groups following adjustment for baseline eGFR and baseline covariates [the difference was -0.38 (95% CI: -2.49 to 1.74)]. At 6-months, the average difference in serum potassium was –0.1 mmol/L (SD 0.4) in both groups with no difference between the two groups after adjustment for baseline serum potassium level and baseline covariates [0.00 (95% Cl: -0.11 to 0.11].

Conclusions: Higher dose of empagliflozin led to more reduction in albuminuria among CKD patients, without a significant change in eGFR or serum potassium levels compared to the lower dose.

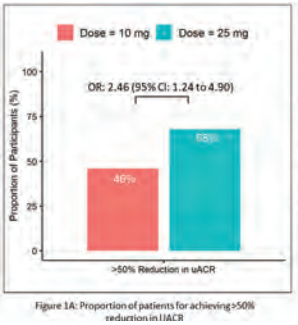


Figure 1A: Proportion of patients for achieving >50% reduction in UACR

TH-PO1043

Effects of Empagliflozin on Health Care Use and Quality of Life in CKD in the United Kingdom: Results from EMPA-KIDNEY

Junwen Zhou, Borislava N. Mihaylova. On behalf of the EMPA-KIDNEY Collaborative Group. *Health Economics Research Centre, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom.*

Background: In EMPA-KIDNEY, empagliflozin reduced the risk of the primary composite outcome of kidney disease progression or cardiovascular death in patients with chronic kidney disease at risk of progression. We aimed to estimate the effects on within-trial healthcare use and health-related quality of life (QoL).

Methods: 6609 participants were randomly assigned to empagliflozin 10 mg daily or placebo and followed for a median of 2.0 (IQR 1.5-2.4) years. We estimated the effects of allocation to empagliflozin on healthcare use and costs (2022 UK£), including hospital admissions, concomitant medications, and kidney replacement therapy, and on QoL using shared parameter (analyzing outcomes together with time to death) or negative binomial models. These models informed estimates of the net effects of empagliflozin on healthcare use and costs and quality-adjusted life years (QALYs) over 2.5 years using 3.5%/year discount rate.

Results: Allocation to empagliflozin resulted in fewer hospital admissions (hazard ratio 0.86, 95% confidence interval 0.78-0.95). There were fewer days on (rate ratio (RR) 0.98, 0.95-1.00) and lower cost of (RR 0.90, 0.85-0.96) concomitant medications. Only a small number of participants initiated kidney replacement therapy and there was no statistically significant difference in these costs (RR 0.74, 0.33-1.69). Overall over 2.5 years, the estimated net cost of healthcare use was £353 (8-698) and additional QALYs were 0.016 (0.001-0.032) per participant allocated empagliflozin (Table).

Conclusions: In EMPA-KIDNEY and based on UK costs, allocation to empagliflozin over 2.5 years reduced other healthcare related costs, offsetting about two-thirds of empagliflozin costs. Ongoing post-trial follow-up will provide useful information on longer-term effects.

Funding: Commercial Support - EMPA-KIDNEY was funded by a grant to the University of Oxford from Boehringer Ingelheim and Eli Lilly.

Effects of empagliflozin on healthcare use and quality-adjusted life years (QALYs) over 2.5 years in EMPA-KIDNEY

Validation of Impact Using SGLT2 Inhibitor in Changes of Body Weight and Serum Albumin for Elderly Patients with CKD: A Retrospective Observational Study

Honami Honjoh, Takahito Moriyama. *Tokyo Ika Daigaku, Shinjuku-ku, Japan.*

Background: Elderly Chronic Kidney Disease (CKD) patients have a high frequency of frailty. These definitions include body weight (BW) loss and decreasing serum albumin, perceived as critical changes suspecting nutrition disorder. Although recent studies have shown that Sodium-glucose cotransporter 2 inhibitors (SGLT2Is) have improved renal surviva, the impact of SGLT2Is on nutrition status in elderly CKD patients is not well understood.

Methods: This retrospective observational study was conducted on CKD patients who were treated with SGLT2I at our department from 2020 to 2023. From these 207 patients, 94 patients whose serum creatinine (Cr), serum albumin, and BW had been fully measured at the three time points (baseline and at one year before and after treatment) were included. eGFR slopes and the % change of serum alb and BW were calculated from a one-year period before baseline and a one-year period after treatment, respectively.

Results: The characteristics of 94 patients) were mean age 65.1±15.6 (≥65 years old: 58.5%), female 21 (22.3%), diabetes 37 (39.4%), hypertension 86 (91.5%), ischemic heart disease 19 (14.7%), mean eGFR 40.9±23.1 mL/min/1.73 m 2. Overall, eGFR slope was not changed between before and after treatment (before treatment -0.173 mL/min/

1.73m2/month, after treatment -0.22 mL/min/1.73m 2 /month, p=0.83). % BW was significantly decreased after administration [-0.0 (-0.28 to 2.1) %/year vs -2.0 (-0.43 to 0.0) %/year, p < 0.001], though serum albumin was not changed (p=0.13). Elderly pstients had more severe CKD, lower BMI, more frequent ischemic heart disease, less use of inhibitors of renin angiotensin-aldosterone systems, and lower baseline eGFR compared with not elderly patients. In high-risk group, which had the decreasing changes in both % BW and % albumin between before and after treatment, the eGFR was significantly lower (p=0.016). The predictors for BW loss and decreasing serum alb were baseline lower albumin level [odd ratio (OR) 7.22 (1.17- 44.7), p = 0.033 and more severe CKD stage 2.44 (1.05-5.67), p = 0.037].

Conclusions: It was suggested that the lower the serum albumin level and the more severe CKD stage, the more likely BW and serum albumin will decrease in this study. Further evaluation is required to determine whether these changes are associated with malnutrition.

TH-PO1045

Increasing Use of SGLT2 Inhibitors in Patients with CKD and Heart Failure through Physician Education and Outreach Reduces Inpatient Admissions in a Value-Based Care Model

Katherine W. Kwon, Roy G. Marcus, Douglas Eckhardt, Jie Pu, Robert Pardini, Nirav Vakharia. *Panoramic Health, Tempe, AZ.*

Background: We developed a quality improvement project to increase the uptake of SGLT2i therapy in patients with comorbid chronic kidney disease and heart failure (CKD/HF) participating in a value-based care model with Panoramic Health.

Methods: Patients with CKD/HF and SGLT2i penetration were identified using data from both claims and electronic medical records (EMR). A prescription was defined as at least one prescription written within the past year, or an SGLT2i on the EMR medication list. We then undertook several interventions to increase appropriate prescribing rates. After executing a physician survey to gauge baseline knowledge, we conducted physician education about the efficacy and safety of SGLT2i medications. The Panoramic Health pharmacy team identified patient candidates and notified physicians prior to their next scheduled appointment. Practice-level SGLT2i prescribing rates were reported monthly to practice leaders. Outcomes metrics included SGLT2i prescriptions and inpatient admissions, expressed as admissions per 1000 patients (IP/1K).

Results: The initial rate of SGLT2i utilization in the target population was 16.1%. After five months of the described interventions, rates increased to 24.5% across participating Panoramic Heath partner practices, with some practices achieving rates as high as 50%. All-cause hospital admissions remained, on average, 11% lower (IP/1K of 964 vs. 1070) in patients prescribed an SGLT2i compared to those who were not. This trend persisted as the proportion of patients receiving SGLT2i increased. We also tracked physician responses to pharmacist outreach. 19.7% of messages led to a new prescription. The most common reasons given for not prescribing were “defer to PCP,” “frequent UTIs” and “does not meet criteria.”

Conclusions: SGLT2i prescribing rates are an important metric in any value-based program. While this simple intervention has a near-immediate impact on inpatient admissions, uptake has been slow. Our physician partners responded to education delivered by peers and directed outreach on individual patients. However, therapeutic inertia and concern for potential side effects continue to pose challenges to increased adoption.

Targeted Clinician Emails to Promote SGLT2 Inhibitor Re-initiation after Discontinuation for Remediable Side Effects

Sarah F. Sanghavi,[1,2] Neha Deval,[3] Ethan Nguyen.[1] *[1]VA Puget Sound Health Care System Seattle Division, Seattle, WA; [2]University of Washington, Seattle, WA; [3]Sea Mar Community Health Centers, Seattle, WA.*

Background: Despite well-established efficacy in decreasing progression of kidney disease, SGLT2i therapy is discontinued in up to 60% of patients at 2 years. The purpose of this study was to identify veterans who had indications for SGLT2i reinitiation and remediable side effects. We then performed an intervention designed to educate the discontinuing clinician and resume therapy.

Methods: We identified patients from the VA Puget Sound Healthcare System who had a prescription for an SGLT2i discontinued between 1/1/2019 and 2/1/2023. Charts were manually reviewed to determine the reason for discontinuation and indications for therapy. Indications were defined as CAD or CHF, albuminuria > 30 mg/g, and eGFR < 60 ml/min. If the reason for discontinuation was remediable, patient specific e-mails were sent to the primary care provider or the discontinuing clinician outlining the reason for discontinuation and rationale for a second trial of the medication.

Results: The medical records of 805 veterans who discontinued therapy within the 4-year period were reviewed. After removal of records for discontinuation due to death or transfer to another VA, 435 records remained. The most common causes for discontinuation were genital infection (62), urinary frequency (60), volume depletion (53), decline in eGFR (30), and GI symptoms (23). We identified 99 patients with an indication to resume SGLT2i therapy and remediable side effects. Within 3 to 9 months of clinician e-mail notification, 26/99 veterans had resumed treatment.

Conclusions: We found that 23% of veterans who discontinued SGLT2i therapy had an indication for treatment and remediable side effects. Targeted e-mails to clinicians resulted in resumption of medication in 26% of veterans within 3-9 months of notification suggesting benefit of the intervention. Longterm data are needed to determine if this effect is durable.

TH-PO1047

Effects of Empagliflozin on Serum Uric Acid and Gout in CKD

Kaitlin J. Mayne. The EMPA-KIDNEY Collaborative Group. *University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom.*

Background: Sodium-glucose co-transporter-2 (SGLT2) inhibitors reduce serum uric acid and may reduce the risk of gout in patients with diabetes and/or heart failure, but randomized evidence in patients with CKD is lacking.

Methods: EMPA-KIDNEY compared empagliflozin 10 mg daily with placebo in 6609 patients with CKD (Clinicaltrials.gov: NCT03594110). Eligible patients had an eGFR of 20 to <45; or 45 to <90 mL/min/1.73m^2 with ≥200 mg/g albuminuria. Serum uric acid measured at randomization, 2 and 18 months was analyzed using a mixed model repeated measures approach including interaction terms to estimate subgroup-specific effects with calculation of heterogeneity or trend statistics. In exploratory analyses, first and total gout events were analyzed in Cox regression models with the Andersen-Gill extension for total events. All models were adjusted for age, sex, region, eGFR, uACR and diabetes status.

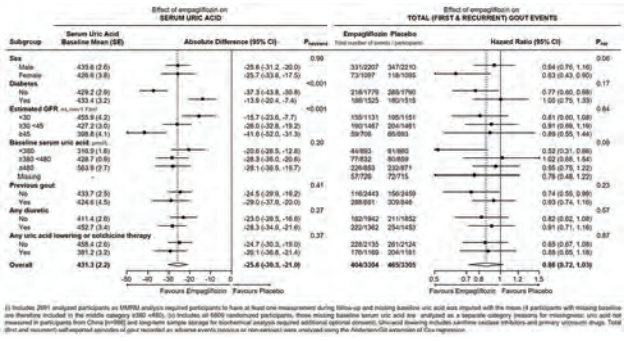
Results: Mean±SD baseline serum uric acid was 431.3±113.5 μmol/L. Empagliflozin reduced serum uric acid (study average between-group difference [95% CI] -25.6 [-30.3, -21.0] μmol/L). Uric acid lowering was greater in participants without diabetes (heterogeneity P<0.001) and at higher eGFR (trend P<0.001; Figure). During 2 years’ median follow-up, there was no significant effect of empagliflozin on risk of gout events alone (whether analyzing first or all occurrences, Table) which was consistent across subgroups including by baseline diabetes, eGFR and uric acid concentration (heterogeneity P all >0.1).

Conclusions: In EMPA-KIDNEY, empagliflozin modestly reduced serum uric acid with greater effects at higher eGFR and in those without diabetes, but did not significantly reduce episodes of gout.

Funding: Commercial Support - EMPA-KIDNEY trial funding from Boehringer Ingelheim & Eli Lilly

Effects of empagliflozin versus placebo on gout

	Empagliflozin n/N	Empagliflozin Rate per 1000 patient-years	Placebo n/N	Placebo Rate per 1000 patient-years	Hazard Ratio (95% CI)
First occurrence of gout	278/3304	45.7	317/3305	52.3	0.87 (0.74-1.02)
All occurrences of gout	404/3304	62.2	465/3305	71.7	0.86 (0.72-1.03)
First occurrence of gout or new initiation of xanthine oxidase inhibitor, primary uricosuric agent or colchicine in participants not on such therapy at randomization	261/2135	66.3	314/2124	81.8	0.81 (0.69-0.96)



Effects of empagliflozin versus placebo on serum uric acid and gout in subgroups defined by baseline characteristics

TH-PO1048

Patient-Level Factors Associated with the Prescription of SGLT2 Inhibitors in Patients with CKD

Angela M. Victoria Castro, Lisa Chan, Bashar A. Kadhim, Justin A. Dower, Rema Elmostafa, Sherry Mansour. *Yale University School of Medicine, New Haven, CT.*

Background: Sodium/glucose cotransporter 2 inhibitors (SGLT2i) are a valuable therapy in patients with chronic kidney disease (CKD). However, since approval by the Food and Drug Administration, they have not gained widespread use in CKD patients. In this study, we aimed to evaluate the patient-level factors associated with SGLT2i prescription within the Yale New Haven Health System.

Methods: This is a retrospective study of patients with CKD and eGFR ≥20mL/min/1.73m2, treated in the inpatient or outpatient setting from 2021 to 2024. We used a multivariable logistic regression model to estimate the adjusted odds ratios (aOR) to identify factors associated with SGLT2i perscription. We adjusted for sociodemographic and clinical factors.

Results: Out of a total of 352,408 eligible patients with CKD, 5,728 (1.6%) were prescribed SGLT2i. Patients who received a prescription were more likely older (median (IQR) 70 (60-78) vs. 62 (48-73) years, p<0.001), male (61% vs. 42%, p<0.001), Black (19% vs.12%, p<0.001) and retired (50% vs. 33%, p<0.001) as compared to those who did not receive an SGLT2i. The most frequent specialties prescribing SGLT2is were Internal Medicine (35%) and Cardiology (31%), with only 3% of perscriptions by Endocrinologists and 1% by Nephrologists. Among Hispanic and Black CKD patients, only 1% and 2% respectively were prescribed SGLT2is. Native American (aOR 0.36, 95%CI 0.26-0.52), Black (aOR 0.49, 95%CI 0.45-0.52), and Asian (aOR 0.62, 95%CI 0.52-0.73) patients were 64%, 51%, and 38% less likely to get prescribed SGLT2is as compared to White CKD patients, respectively. Similarly, patients with Medicaid (OR 0.81, 95%CI 0.75-0.88) were 19% less likely to be perscribed as compared to the ones with comercial insurance. Patients unable to work due to disability (OR 0.36, 95%CI 0.33-0.40) and unemployed (OR 0.62, 95%CI 0.57-0.68) were also 64% and 38% less likely to be prescribed an SGLT2i, respectively, when compared with employed patients.

Conclusions: In this preliminary analysis of patient-level factors, we found that there is suboptimal use of SGLT2is in the CKD population and that social determinants of health impact the prescription of these medications. There is a need for further evaluation of interventions to promote the use of SGLT2is in CKD patients with emphasis on health equity for all.

TH-PO1049

Benefits of Dapagliflozin in Slowing eGFR Decline in Patients with Different Rates of eGFR Loss

Niels Jongs,[1] Peter Rossing,[2,3] David Sjostrom,[4] Glenn M. Chertow,[5] Robert D. Toto,[6] David C. Wheeler,[7] Hiddo J. Heerspink.[1,8] *[1]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [2]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [4]Late-stage Development, Cardiovascular, Renal, and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [5]Departments of Medicine and Epidemiology and Population Health, Stanford University School of Medicine, Stanford, CA; [6]Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [7]Department of Renal Medicine, University College London, London, United Kingdom; [8]The George Institute for Global Health, Sydney, NSW, Australia.*

Background: Inclusion of patients likely to experience a loss of estimated glomerular filtration rate (eGFR) is required to detect a kidney protective treatment effect in clinical trials. This is usually achieved by enrolling patients with high levels of albuminuria. However, not all patients with elevated albuminuria show a progressive loss of kidney function. eGFR slope before the trial may better predict whether patients experience a loss in eGFR during a clinical trial. We assessed the effect of dapagliflozin on eGFR slope according to patient eGFR slope prior to inclusion in the DAPA-CKD trial (pre-inclusion eGFR slope).

Methods: We recorded eGFR data for ≤2 years from electronic medical records for 4304 patients with CKD before enrollment in DAPA-CKD, a randomized, placebo-controlled trial of dapagliflozin. We used linear regression to estimate within-patient pre-inclusion eGFR slopes. We evaluated the association of pre-inclusion eGFR slope with total (randomization to end-of-treatment) and chronic (Week 2 to end-of-treatment) eGFR slopes using a two-slope linear mixed-effects model. The composite kidney endpoint was defined as sustained ≥50% eGFR decline, end-stage kidney disease, or death from kidney causes.

Results: In total, 870 (20.2%) patients with ≥3 historical eGFR measurements were evaluated (mean pre-inclusion eGFR slope [SD]: −6.15 [6.1]). The benefit of dapagliflozin in reducing the total (p-interaction: 0.018) and chronic (p-interaction: 0.022) eGFR slopes was more pronounced in patients with steeper pre-inclusion eGFR slopes (rapid progressors; **Figure**). The effect of dapagliflozin compared to placebo on the composite kidney endpoint was also more pronounced in rapid progressors (p-interaction: 0.023).

Conclusions: Determination of pre-trial eGFR slope may help to identify patients with CKD at higher and lower risks of progression and those more or less likely to benefit from a targeted intervention to slow kidney function loss.

Implications of Acute GFR Change for the Effect of SGLT2 Inhibitors on Long-Term End Points

Ransmond O. Berchie,[1] Lesley A. Inker,[2] Hiddo J. Heerspink,[3] Tom Greene.[1] *[1]University of Utah Health, Salt Lake City, UT; [2]Tufts University, Medford, MA; [3]Universiteit Groningen Afdeling Gezondheidswetenschappen, Groningen, Netherlands.*

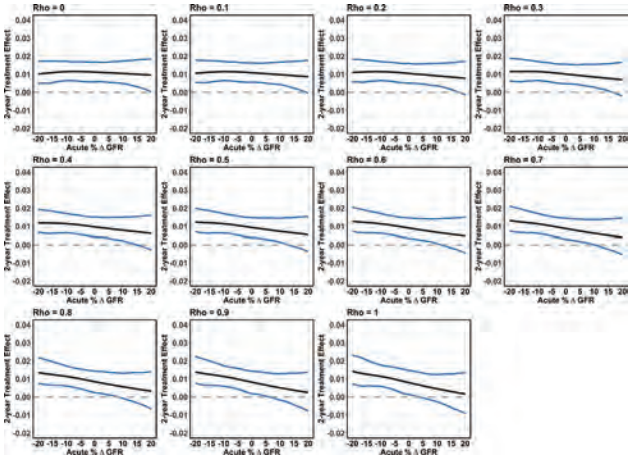
Background: Several studies have reported that chronic kidney disease (CKD) patients often experience a substantial decline in glomerular filtration rate (GFR) within 1 month after initiating treatment with sodium-glucose cotransporter-2 inhibitors (SGLT2i). Our goal is to determine, to the extent possible from the data, how the expected effect of SGLT2i on the time to kidney failure is modified by knowledge of the acute GFR change (ΔGFR) after starting SGLT2i.

Methods: We used a Johnson SU model for the distribution of ΔGFR within the SGLT2i and control groups and a Fine-Grey model with cubic splines to relate ΔGFR to the time to kidney failure with death as a competing risk for 3 clinical trials: DAPA-CKD, EMPA-REG, and CREDENCE. Then, using the modern causal inference framework of principal stratification, we specified the unobservable correlation ρ between ΔGFR under the SGLT2i and control treatments as a sensitivity parameter. This allowed us to define the distribution of ΔGFR under the control consistent with an observed ΔGFR with the SGLT2i and thereby estimate the effects of SGLT2i on the time to kidney failure conditional on ΔGFR across different possible values for ρ.

Results: Across all values of ρ, we find no evidence that negative acute GFR changes after SGLT2i initiation indicate an adverse effect or reduction in the benefit of SGLT2i on kidney failure. Moreover, for ρ≥0.7, we observe a trend suggesting that more negative acute changes signify a greater benefit of SGLT2i on the time to kidney failure.

Conclusions: The findings suggest that larger than average GFR reductions 1 month after initiating SGLT2i do not signify reduced benefit on kidney failure and may indicate therapeutic effectiveness.

Funding: Private Foundation Support



The Figure shows the impact of ΔGFR on the estimated effect of SGLT2i treatment on the probability of kidney failure by 2 years.

Real-Life Experience on the Effect of SGLT2 Inhibitors vs. Finerenone vs. Combination on Albuminuria in CKD

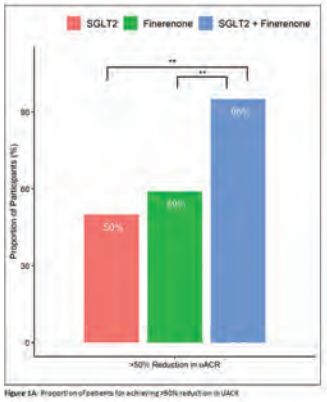
Mohamad A. Hanouneh, Dustin Le, Christina L. Tamargo, Bernard G. Jaar, C. E. Cervantes. *Johns Hopkins University, Baltimore, MD.*

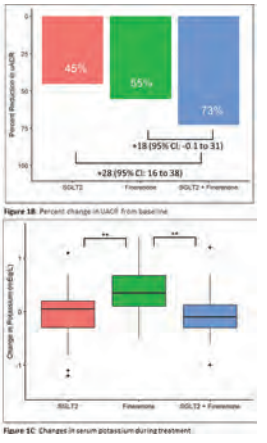
Background: Recent progress in treating CKD include utilizing SGLT2 inhibitors and selective mineralocorticoid receptor antagonists, finerenone. This real-world experience retrospective study examines the effects of these treatments, individually and in combination on CKD patients.

Methods: 98 adults patients with CKD, an eGFR 25 to 90 ml/min per 1.73 m2 and a urine albumin/creatinine ratio (UACR) > 30 mg/g were included. The patients were divided into 3 groups with 8 months follow-up: group one (N=52) treated with SGLT2 inhibitors, group two (N=22) treated with finerenone, and group three (N=24) treated with combination therapy- SGLT2i inhibitors for the first 4 months then finerenone was subsequently added. The primary outcome was the percentage of patients achieving >50% reduction in UACR from baseline.

Results: For all patients, the mean eGFR was 51.0 ml/min per 1.73m2, and median UACR was 580 mg/g. After 8 months, >50% decrease in albuminuria was achieved in 96% of patients in group 3, compared to 50% in group 1 and 59% in group 2 (P-values <0.01 and <0.01 respectively) (Fig 1A). When we assessed percent albuminuria reduction adjusted for baseline covariates, there was a significant difference comparing group 1 (45%, 95% CI [32,58]) to group 3 (73%, 95% CI [53,92]) with difference reduction of 28% (95% Cl [16,38], p-value < 0.01) (Fig 1B). Despite observing a substantial reduction in albuminuria in group 3 compared to group 2, the difference was 18% (95% Cl: [-0.1,31]) and did not reach statistical significance (p-value 0.07) (Fig 1B). There was a significant change in mean potassium levels in group 2 (+0.4 mmol/L) compared to either group 1 (0.0 mmol/L, p-value: < 0.01) or group 3 (-0.01 mmol/L, p-value: < 0.01) (Fig 1C). However, there was no difference comparing group 1 and 3 (Fig 1C).

Conclusions: In this real-world experience, the combination of SGLT2 inhibitors and finerenone in CKD patients was associated with a significant reduction in UACR, without an increased risk of hyperkalemia.





TH-PO1052

Effects of Zibotentan Alone and in Combination with Dapagliflozin on Fluid Retention in Patients with CKD

Johannes D. Smeijer,[1] Magnus Åstrand,[2] Anne-Kristina Mercier,[2] Peter J. Greasley,[3] Philip D. Ambery,[4] Hiddo J. Heerspink.[1,5] Investigators of ZENITH-CDK Clinical Trial. *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Clinical Pharmacology and Quantitative Pharmacology, Clinical Pharmacology and Safety Sciences, R&D, AstraZeneca, Gothenburg, Sweden; [3]Research and Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [4]Clinical Late Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [5]The George Institute for Global Health, Sydney, NSW, Australia.*

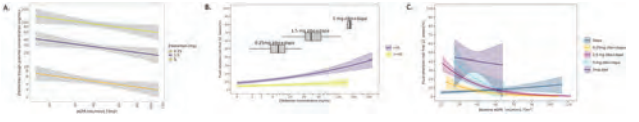
Background: Endothelin receptor antagonists (ERAs) effectively reduce albuminuria but are limited by fluid retention risk, particularly in patients with chronic kidney disease (CKD). Combining ERAs with sodium-glucose cotransporter 2 (SGLT2) inhibitors, which have diuretic effects, offers a promising strategy to mitigate fluid retention. In this post-hoc analysis of the ZENITH-CKD trial, we assessed fluid dynamics in patients with CKD treated with the ERA zibotentan alone, and in combination with the SGLT2 inhibitor dapagliflozin

Methods: In ZENITH-CKD, 508 patients with CKD (eGFR ≥ 20 mL/min/1.73 m2 and a urinary albumin-to-creatinine ratio (UACR) of 150–5000 mg/g) were randomized to treatment with placebo, dapagliflozin 10 mg plus placebo, zibotentan (0.25, 1.5 or 5 mg) plus dapagliflozin 10 mg and zibotentan 5 mg plus placebo. We evaluated correlations between changes in fluid retention markers and bioimpedance-measured extracellular fluid (ECF) in response to zibotentan treatment. We used Cox proportional hazards regression to assess the association between zibotentan/dapagliflozin treatment, baseline characteristics, and fluid retention, as well as the relationship between zibotentan plasma exposure and fluid retention.

Results: After 3 weeks of treatment with zibotentan 0.25, 1.5 or 5 mg plus dapagliflozin 10 mg, changes in body weight, BNP, and hemoglobin were independently associated with changes in ECF. Higher doses of zibotentan significantly increased the risk of fluid retention compared to dapagliflozin alone (zibotentan 5 mg HR 9.13 [95%CI 3.40, 24.49]). The hazard ratio attenuated when zibotentan was combined with dapagliflozin (HR zibotentan/dapagliflozin 5/10 mg 3.61 (95%CI 1.26,10.33) and zibotentan/dapagliflozin 0.25/10 mg HR 0.99 (95%CI 0.37, 2.63). The risk of fluid retention increased with higher zibotentan exposure and lower eGFR.

Conclusions: High doses of zibotentan increased the risk of fluid retention which could be reduced with lower doses and addition of dapagliflozin. This risk was more pronounced at lower eGFR which highlights the need for combined use of low zibotentan doses and dapagliflozin in advanced CKD.

Funding: Commercial Support - The ZENITH-CKD trial was sponsored by AstraZeneca



TH-PO1053

Cumulative Effects of Aldosterone Synthase and SGLT2 Inhibition on Albuminuria in People with CKD

Peter Rossing,[1] Sibylle J. Hauske,[2] Lisa Cronin,[3] Hiddo J. Heerspink,[4,5] Juliane Meyerhoff,[2] Shimoli Shah,[3] Zhichao Sun,[3] Dick de Zeeuw,[4] Katherine R. Tuttle.[6] On behalf of the ASi in CKD Group. *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [3]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [4]University Medical Centre Groningen, Groningen, Netherlands; [5]The George Institute for Global Health, Sydney, NSW, Australia; [6]Providence Inland Northwest Health, Spokane, WA.*

Background: A phase II trial reported efficacy and safety of the aldosterone synthase inhibitor (ASi) BI 690517 in chronic kidney disease (CKD) showing significant albuminuria reduction with or without empagliflozin (EMPA) in the background. This *post hoc* analysis estimates the cumulative effects of ASi and EMPA 10mg on urine albumin:creatinine ratio (UACR) vs ASi alone.

Methods: Participants receiving a maximally tolerated dose of a renin-angiotensin system inhibitor were first randomized (R1) to an 8-week run-in period to receive EMPA 10mg daily or $EMPA_{PBO}$, followed by a second randomization (R2) to a 14-week treatment period to receive ASi (3, 10, or 20mg daily) or ASi_{PBO}. For the run-in period, EMPA effects were assessed by pooling participants into EMPA vs $EMPA_{PBO}$ groups, regardless of ASi dose levels at R2. Randomized ASi dose groups on top of EMPA/$EMPA_{PBO}$ were assessed from R2 to 14 weeks. R2 served as the baseline reference time point and mixed-effect model for repeated measures (MMRM) was used to assess change in UACR. Cumulative

effects of both ASi and EMPA were calculated by adding UACR changes from R1 to R2 and R2 to the end of treatment period.

Results: UACR data were available from 249 participants who were randomized at R1 to receive EMPA 10mg and 254 who received $EMPA_{PBO}$. Estimated cumulative effects on UACR reduction from R1 to week 14 were larger with EMPA+ASi 10mg (-61%) compared to ASi 10mg alone (-40%) and vs $EMPA_{PBO}$+ASi_{PBO} (-3%) (**Table**).

Conclusions: Meaningfully larger UACR reductions across all ASi doses were achieved in participants with CKD who received both active components of EMPA+ASi compared to treatment with either ASi or EMPA alone. Combination of ASi with SGLT2 inhibitors is a promising, novel therapy strategy that may afford superior benefits over AS or SGLT2 inhibition alone and will be tested further in a phase III clinical trial.

TH-PO1054

Insulin Glargine and SGLT2 Inhibitors Have Higher Risk of Major Adverse Cardiovascular Events (MACE) Compared with Glucagon-Like Peptide 1 Receptor Agonists (GLP-1 RAs) in a National Cohort of Veterans with Type 2 Diabetes (T2D) and CKD

Niharika Katkam,[1,2] Amara Sarwal,[1,2] Sydney E. Hartsell,[1,2] Ravinder Singh,[1,2] Guo Wei,[1,2] Robert E. Boucher,[1,2] Akhil Ramanujam Chakravartula,[1,2] Jincheng Shen,[1,2] Mckenna R. Nevers,[1,2] Stavros Drakos,[1,2] Tom Greene,[1] Srinivasan Beddhu.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Insulin glargine(IG) is commonly used for glycemic control in persons with T2D and CKD. However, there is limited data on direct comparisons between IG and newer agents like GLP1-RA and SGLT2i on MACE in CKD.

Methods: We used an active comparator, new user design to compare the effects of initiating IG, GLP1-RA, or SGLT2i on MACE between 1/1/18 to 12/31/21 in veterans with T2D on metformin. Prescriptions for these agents between 1/1/08 to 1/1/18 was an exclusion. Follow-up was until 3/31/23. Application of inverse probability weighting(IPW) for each of the pairwise comparisons resulted in balance of baseline variables including demographics, comorbidity, duration of T2D, BP, BMI, A1C, eGFR and meds. MACE was defined as ER visit/ hospitalization for MI, stroke or HF. IPW Cox models with further adjustment for baseline covariates, were used to related the three drug initiation groups to MACE, all-cause mortality(ACM) or composite of MACE/ACM in those without and with CKD (eGFR < 60).

Results: 33.7% were initiated on IG, 13.7% on GLP1-RA, and 52.6% on SGLT2i. 16.5% had CKD. We observed 15461 MACE events/ 352837person-years in non-CKD and 5304 events/ 61578person-years in CKD.11325 deaths/ 377116person-years in non-CKD and 3943 deaths/70343person-years in CKD. IPW Cox model results are summarized in Table.

Conclusions: In CKD, initiation of IG was associated with higher risk of MACE and ACM compared to GLP1-RA and higher risk of ACM compared to SGLT2i. Compared to GLP1-RA, SGLT2i had higher risk of MACE in CKD. Randomized controlled trials comparing SGLT2i and GLP1-RA in CKD are warranted.

Funding: NIDDK Support, Other NIH Support - NIA, Veterans Affairs Support

MACE	Non-CKD HR (95% CI)	CKD HR (95% CI)
IG vs GLP1-RA	1.27 (1.19, 1.34)	1.14 (1.04, 1.25)
IG vs SGLT2i	1.10 (1.05, 1.14)	1.03 (0.96, 1.11)
SGLT2i vs GLP1-RA	1.16 (1.09, 1.23)	1.13 (1.03, 1.24)
MACE/ ACM		
IG vs GLP1-RA	1.44 (1.37, 1.51)	1.25 (1.16, 1.36)
IG vs SGLT2i	1.28 (1.24, 1.32)	1.18 (1.11, 1.25)
SGLT2i vs GLP1-RA	1.13 (1.07, 1.19)	1.08 (1.00, 1.18)
ACM		
IG vs GLP1-RA	1.72 (1.60, 1.85)	1.42 (1.27, 1.58)
IG vs SGLT2i	1.59 (1.51, 1.67)	1.43 (1.32, 1.56)
SGLT2i vs GLP1-RA	1.11 (1.03, 1.19)	1.01 (0.89, 1.13)

TH-PO1055

Insulin Glargine Compared with Glucagon-Like Peptide 1 Receptor Agonists (GLP-1 RAs) or SGLT2 Inhibitors Is Associated with Higher Risk of Alzheimer Disease and Alzheimer Disease-Related Dementias (AD/ADRD) in CKD

Amara Sarwal,[1,2] Guo Wei,[1,2] Ravinder Singh,[1,2] Sydney E. Hartsell,[1,2] Adam Bress,[1,2] Catherine G. Derington,[1,2] Robert E. Boucher,[1,2] Mckenna R. Nevers,[1,2] Niharika Katkam,[1,2] Augustine Takyi,[1,2] Akhil Ramanujam Chakravartula,[1,2] Jincheng Shen,[1,2] Tom Greene,[1] Srinivasan Beddhu.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: It is unknown whether the risk of AD/ADRD is related to the use of insulin glargine (IG), GLP1-RA or SGLT2i in persons with T2D and CKD.

Methods: Using VA Informatics and Computing Infrastructure (VINCI) platform, we conducted an active comparator, new user design study to compare the effects of initiating IG, GLP1-RA, or SGLT2i on AD/ADRD between 1/1/18 to 12/31/21 in veterans with T2D on metformin and without AD/ADRD at baseline (N= 155,481). Prescriptions for these agents anytime between 1/1/08 to 1/1/18 was an exclusion. Follow-up was until 3/31/2023. Generalized propensity score based inverse probability weighting (IPW) was employed to control confounding in the observational data and facilitate comparisons among the three drug classes. In IPW Cox models, drug classes were related to time to the first diagnosis of AD/ADRD (defined by ICD-10) in those without and with CKD (eGFR <60).

Results: 33.2% were initiated on IG, 12.8% on GLP1-RA and 53.0% on SGLT2i. 16% had CKD. There were 2970 AD/ADRD events over 361410 patient-years in non-CKD and 3946 AD/ADRD events over 64806 patient-years in CKD patients. In IPW Cox regression, IG had higher risk of AD/ADRD when compared to GLP1-RA and SGLT2i (Figures).

Conclusions: In both non-CKD and CKD subgroups, IG is associated with higher AD/ADRD risk when compared to SGLT2i and GLP1-RA whereas SGLT2i and GLP1-RA had similar risk.

TH-PO1056

Comparative Effectiveness of Semaglutide, Liraglutide, and Dulaglutide for All-Cause Mortality in Type 2 Diabetes (T2D) with and without CKD: An Emulated Clinical Trial Observational Study

Amara Sarwal,[1,2] Guo Wei,[1,2] Sydney E. Hartsell,[1,2] Ravinder Singh,[1,2] Mckenna R. Nevers,[1,2] Niharika Katkam,[1,2] Augustine Takyi,[2] Akhil Ramanujam Chakravartula,[2] Jincheng Shen,[1,2] Srinivasan Beddhu.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Compared to placebo, semaglutide, liraglutide and dulaglutide reduced the risk of CV events and CV death. However, there is a paucity of data on comparative effectiveness of these agents versus each other. Therefore, we examined the comparive risk of all-cause mortality (ACM) of these agents in a national cohort of veterans with T2D.

Methods: We used the active comparator, new user study design to compare the effect of initiating on semaglutide, liraglutide or dulaglutide on ACM in veterans with T2D on metformin who initiated any one of these three between 01/01/2018 to 12/31/2021 (N=22145). Those with previous use of these agents were excluded. Administrative censor date was 03/31/2023. ACM data were obtained from VA CDW which is also updated with national vital statistics. Generalized propensity score based inverse probability weighting (IPW) was employed to balance baseline variables across the three classes. In IPW Cox models, the study drug classes were related to the risk of mortality in those without and with CKD (eGFR < 60).

Results: 49.1% were initiated on semaglutide, 24.6% on liraglutide and 25.0% on dulaglutide. Mean age was 64 ±11 years, 9% were female and 16.5% were Black. Mean eGFR 81 ± 20. 17.2% had CKD. There were 1081 deaths/54727 years of follow-up in non-CKD and 489 deaths/10606 years in CKD subgroups. In non-CKD subgroup, both dulaglutide and semaglutide had higher hazard of ACM compared to liraglutide whereas dulaglutide and semaglutide had similar hazard (Figure). In CKD subgroup, hazard of ACM was similar across the three pairwise comparisons.

Conclusions: In the non-CKD subgroup, liraglutide had lower hazard of mortality compared to either dulaglutide or semaglutide. However, in the CKD subgroup, all three agents had similar risk of mortality.

Risk of Gastroparesis Is Higher with Glucagon-Like Peptide 1 Receptor Agonists (GLP-1 RAs) but Risk of Death Is Higher with Insulin Glargine in Veterans with Type 2 Diabetes and CKD

Amara Sarwal,[1,2] Ravinder Singh,[1,2] Guo Wei,[1,2] Sydney E. Hartsell,[1,2] Robert E. Boucher,[1,2] Mckenna R. Nevers,[1,2] Niharika Katkam,[1,2] Augustine Takyi,[1,2] Akhil Ramanujam Chakravartula,[1,2] Jincheng Shen,[1,2] Srinivasan Beddhu.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: There is a paucity of data on the risk of gastroparesis risk with GLP1-RA compared to insulin glargine (IG) or SGLT2i in T2D with CKD.

Methods: We used the active comparator, new user design to emulate a trial to compare the effects of IG, GLP1-RA or SGLT2i in veterans with T2D on metformin without baseline GI comorbidities who initiated one of these three agents for the first time between 01/01/18 to 12/31/21. Administrative censor date was 03/31/23. Generalized propensity score based inverse probability weighting (IPW) was employed to control confounding and facilitate comparisons among the drug classes. In IPW Cox models, the study drug classes were related to the risk of gastroparesis and death in those without (N=119945) and with CKD (eGFR < 60, N=23027).

Results: In the CKD cohort, 36% were initiated on IG, 15% on GLP1-RA and 49% on SGLT2i. In IPW Cox regression, IG had a decreased risk of gastroparesis although had a higher risk of death when compared to GLP1-RA (Figures). IG was associated with increased risk of both outcomes when compared to SGLT2i. SGLT2i had a lower risk of gastroparesis and similar risk of death compared to GLP1-RA. Similar trend was seen in the non-CKD subgroup, although SGLT2i was had a higher risk of death compared to GLP1-RA.

Conclusions: As the risk of death with IG is higher, concern for gastroparesis should not prohibit prescription of GLP1-RA over IG in people with T2D and CKD.

SGLT2 Inhibitors, Glucagon-Like Peptide 1 (GLP-1) Receptor Agonists, and the Risk of Hypokalemia and Hyperkalemia in a National Cohort of Veterans with Type 2 Diabetes

Akhil Ramanujam Chakravartula,[1,2] Sydney E. Hartsell,[1,2] Amara Sarwal,[1,2] Guo Wei,[1,2] Mckenna R. Nevers,[1,2] Robert E. Boucher,[1,2] Niharika Katkam,[1,2] Augustine Takyi,[1,2] Jincheng Shen,[1,2] Tom Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: As SGLT2i are osmotic diuretics, they might increase the risk of hypokalemia and decrease the risk of hyperkalemia compared to other glycemic agents such as GLP1-RA or insulin glargine (IG).

Methods: Using the VA Informatics and Computing Infrastructure (VINCI) platform, in an active comparator new user design study, we compared the effects of IG, GLP1-RA, or SGLT2i on the risk of hypo and hyperkalemia. We identified veterans with T2D on metformin who initiated one of these 3 agents of interest for the first time between 1/1/18 to 12/31/21. We excluded those with prior prescriptions for these agents between 1/1/08 to 1/1/18. Index date was defined as the first date one of these agents were prescribed. Baseline demographics, BP, BMI, comorbidity, medications, lab data including eGFR and A1C were extracted. Follow-up was until 3/31/2023. Hyperkalemia and hypokalemia were identified using diagnostic codes. We used generalized propensity score based inverse probability weighting (IPW) to balance baseline variables across the study drug classes. IPW cox regression models related study drug class to outcomes.

Results: The study included 161,405 participants who were 64.9±10.8 years old, 94.6% male, 18.6% black at baseline with mean eGFR of 80± 20ml/min/1.73m^2 and 16.5% with baseline eGFR <60 ml/min/1.73m^2. There were 9,745 hyperkalemic events over 430,841 years of follow up, and 8,455 hypokalemic events over 433,548 years of follow up. The figure shows weighted cox model results of event rates and hazard ratio by pairwise drug comparison.

Conclusions: In veterans with T2D, IG is associated with a higher risk of both hyper- and hypokalemia compared to GLP1-RA or SGLT2i. Both SGLT2i and GLP1-RAs had similar risk of hypo or hyperkalemia.

TH-PO1059

Does CKD Modify the Effects of Glucagon-Like Peptide 1 Receptor Agonists (GLP-1 RAs) and SGLT2 Inhibitors on Weight Loss?

Shalini Kasera,[1] Sydney E. Hartsell,[1,2] Guo Wei,[1,2] Ravinder Singh,[1,2] Mckenna R. Nevers,[1,2] Amara Sarwal,[1,2] Akhil Ramanujam Chakravartula,[1] Niharika Katkam,[1] Srinivasan Beddhu.[1,2] *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: It is unknown whether weight loss resulting from a GLP1-RA or SGLT2i is modified by the presence of CKD.

Methods: In an active comparator, new user study, we examined the effects of CKD status on weight loss in veterans with T2D on metformin who began insulin glargine (IG), SGLT2i or GLP1-RA from 1/1/18 to 12/31/21. Index date was the date of initial drug prescription. Outpatient weight closest to the index date and within 1 year prior was defined as baseline weight. Weight change after drug initiation was defined as the difference between baseline weight and an average of all outpatient weights across 6 month intervals after the index date up to 24 months. Follow-up was until 3/31/2023 or 24 months after index date, whichever was earlier. Inverse probability weights (IPW) for each pairwise drug comparison resulted in balance of baseline variables across the drug classes. In IPW mixed effects models, study drug classes were related to weight change at 24 months in pairwise comparisons in non-CKD and CKD (eGFR <60) subgroups. Effect modification was tested by comparing the regression coefficients for each of the pairwise comparisons in non-CKD and CKD subgroups.

Results: Out of 148,920 included veterans, 5.4% were female, 76.1% were white with mean age 64.9±10.7 years, baseline eGFR 80±20 and 16.7% with CKD. The figure shows weight loss at 6 month intervals by drug class and CKD status and the table shows mixed effects model results.

Conclusions: Patients lost significantly more weight on GLP1-RA or SGLT2i compared to insulin glargine, but there was minimal difference in weight change at 2 years between SGLT2i and GLP1-RA. CKD status did not modify weight loss on SGLT2i or GLP1-RA.

Funding: NIDDK Support, Other NIH Support - NIA, Veterans Affairs Support

Pairwise Comparison	Weight Difference at 24 Months (pounds) in Non-CKD Subgroup	Weight Difference at 24 Months (pounds) in CKD subgroup	Interaction P-Value for CKD Status on Drug-Based Weight Change
IG v. GLP1-RA	6.82(6.41, 7.22)	6.98(6.10, 7.87)	0.74
IG v. SGLT2i	6.13(5.80, 6.46)	6.09(5.40, 6.79)	0.93
SGLT2i v. GLP1-RA	0.69(0.32, 1.06)	0.89(0.09, 1.70)	0.65

Effects of Glucagon-Like Peptide 1 Agonists (GLP-1 RAs) on Ectopic Fat Deposition in CKD: A Pilot and Feasibility Study (GLIMP)

Ragibe Gulsah Dilaver,[1] Rachelle Crescenzi,[3] Rengin Elsurer Afsar,[2] Jorge Gamboa,[1] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Department of Medicine, Nashville, TN; [2]Saint Louis University Department of Internal Medicine, St Louis, MO; [3]Vanderbilt University Medical Center, Nashville, TN.*

Background: Ectopic fat deposition, including intermuscular adipose tissue (IMAT), is associated with metabolic derangements such as insulin resistance (IR) and inflammation in patients with CKD. GLP-1RA reduces ectopic fat deposition in patients with type 2 diabetes and obesity. In a pilot and feasibility study, we aimed to test whether dulaglutide administration decreases IMAT accumulation and improves physical performance in patients with stage 3-4 CKD.

Methods: We prospectively enrolled 7 patients with stage 3-4 CKD serving as their own controls. Dulaglutide (1.5 mg/week) was administered for 12 weeks. IMAT accumulation in the quadriceps muscle using magnetic resonance imaging, biochemical markers including markers of inflammation and insulin resistance, and physical performance were measured before and after administration.

Results: Participant demographics were as follows: age 59 ± 8 years, BMI 31.4 ± 4.1 kg/m2, 57.1% female, and baseline eGFR 31.7 ± 9.0 mL/min/1.73m2. Two patients had type 2 diabetes. IMAT accumulation was 0.104 ± 0.041 before treatment and 0.095 ± 0.033 after treatment (p = 0.69), **(Figure 1)**. BMI levels were significantly lower after the treatment (p < 0.001). There were no statistically significant differences in HbA1c, Hs-CRP, total cholesterol, triglyceride concentrations, short physical performance battery test scores before and after treatment **(Table 1).** Medication was well tolerated except one participant stopped early due to nausea and one due to injection site drug reaction.

Conclusions: In this pilot and feasibility study in patients with stage 3-4 CKD, 12 weeks of dulaglutide administration decreased IMAT accumulation numerically but the difference did not reach statistical significance. The medication was well tolerated. Larger studies are needed to examine the metabolic effects GLP-1RAs in patients with CKD.

Trial Design and Baseline Characteristics from REMODEL: A Mechanistic Study of Semaglutide vs. Placebo in People with Type 2 Diabetes and CKD

David Cherney,[1] Petter Bjornstad,[2,3] Milenta M. Chacko,[4] Thomas P. Gunnarsson,[5] Jeffrey B. Hodgin,[6] Matthias Kretzler,[6] Nicolas Belmar,[5] Menno Pruijm,[7] Philip A. Schytz,[5] Katherine R. Tuttle.[2] *[1]University Health Network, Toronto, ON, Canada; [2]University of Washington, Seattle, WA; [3]University of Colorado Anschutz Medical Campus, Aurora, CO; [4]Novo Nordisk GBS India, Bangalore, India; [5]Novo Nordisk A/S, Bagsvaerd, Denmark; [6]University of Michigan Michigan Medicine, Ann Arbor, MI; [7]Universite de Lausanne, Lausanne, Switzerland.*

Background: Type 2 diabetes (T2D) is the leading cause of chronic kidney disease (CKD) and kidney failure globally. Semaglutide, a glucagon-like peptide-1 receptor agonist, reduces risks of major kidney, cardiovascular, and mortality outcomes in people with T2D and CKD as shown in the FLOW trial. Despite the clinical benefits, the precise kidney-specific mode-of-action (MoA) of semaglutide remains unclear.

Methods: REMODEL is a 52-week phase 3b trial investigating the kidney-specific MoA for semaglutide (once-weekly subcutaneous 1.0 mg) vs. placebo in people with T2D and CKD (Figure 1). Primary endpoints are magnetic-resonance imaging (MRI)-based measures of changes in kidney oxygenation, global kidney perfusion, inflammation and fibrosis. A subset of participants opted to undergo sequential kidney biopsies both at baseline and at the end of treatment for tissue-based interrogation including single nucleus transcriptomics, pathology, and morphometric examination.

Results: REMODEL enrolled 106 participants across 8 countries (Table 1). All participants were prescribed concomitant medications at baseline with 98.1% using RAAS inhibition, and 38.7% using SGLT2i. Baseline kidney biopsies were performed in 33 participants with characteristics similar to the entire cohort.

Conclusions: REMODEL will comprehensively assess multiple proposed physiological pathways for the kidney-specific MoA of semaglutide and will help elucidate kidney-specific benefits seen in the FLOW trial. The REMODEL trial has successfully enrolled a representative population of people with T2D and CKD, ensuring the generalizability and clinical relevance of the findings.

TH-PO1062

Effect of Spironolactone on Long-Term Outcomes in Patients with CKD

Tz-Heng Chen,[1,2] Shuo-ming Ou,[1,3] Yuan-Chia Chu,[1] Der-Cherng Tarng.[1] *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan; [3]National Institutes of Health, Bethesda, MD.*

Background: Steroidal mineralocorticoid receptor antagonists (MRAs) have been shown to reduce mortality in patients with heart failure with reduced ejection fraction, while also effectively treating resistant hypertension and lowering proteinuria. However, the effects of steroidal MRAs on patients with chronic kidney disease (CKD) remain uncertain. This study aimed to investigate the impact of spironolactone on long-term outcomes among CKD patients.

Methods: In a retrospective cohort study, we identified patients with CKD stage 3–5 from January 1, 2011, to June 30, 2023. The patients were divided into spironolactone user and nonuser groups. We matched each spironolactone user to two nonusers according to propensity scores. The outcomes of interest included end-stage renal disease (ESRD), major adverse cardiovascular events (MACEs), all-cause mortality, and severe hyperkalemia. MACEs were defined as a composite of nonfatal stroke, nonfatal myocardial infarction, and cardiovascular death.

Results: After propensity score matching, 2,711 spironolactone users and 5,422 nonusers were included in the analyses. Compared with nonusers, the spironolactone users exhibited higher risks of all-cause mortality (adjusted hazard ratio [aHR], 1.23; 95% confidence interval [CI], 1.10–1.37) and severe hyperkalemia (aHR, 1.44; 95% CI, 1.23–1.68). However, there was a lower risk of MACEs (aHR, 0.89; 95% CI, 0.81–0.98), primarily due to a significant reduction in stroke risk (aHR, 0.78; 95% CI, 0.70–0.87). The risk of ESRD was similar between the two groups (aHR, 1.07; 95% CI, 0.84–1.37).

Conclusions: In patients with CKD, spironolactone use was associated with increased risks of all-cause mortality and severe hyperkalemia, and a reduced risk of MACE, primarily driven by a decrease in stroke risk. The risk of ESRD remained unchanged.

Risks of end-stage renal disease, major adverse cardiovascular events, all-cause mortality and severe hyperkalemia between spironolactone users versus matched nonusers

	Spironolactone users			Spironolactone nonusers

TH-PO1063

Effect of the RAS Inhibitors on Kidney Outcomes in Patients with Advanced CKD: A Systematic Review and Meta-Analysis

Kavita Jintanapramote, Rathanon Leevongsakorn, Anan Chuasuwan. *Bhumibol Adulyadej Hospital, Bangkok, Thailand.*

Background: Chronic kidney disease (CKD) is a global health concern, with Renin-Angiotensin System inhibitors (RASi) playing a crucial role in slowing CKD progression. However, the efficacy and safety of advanced CKD (eGFR <30 ml/min per 1.73 m^2) are still controversial. This study aims to evaluate the impact of RASi on kidney function and outcomes in this specific population.

Methods: We conducted a literature search in MEDLINE, Scopus, and the Cochrane Central Register of Controlled Trials until September 2023 in search of studies comparing the effects of receiving RASi versus non-receiving RASi in advanced CKD patients on kidney progression, all-cause mortality, major adverse cardiovascular events (MACEs), hyperkalemia, and heart failure.

Results: A total of ten studies, including 60,212 participants, were included. Analysis revealed no statistically significant difference in kidney progression [risk ratio (RR) 1.08 (95% CI: 0.95-1.23)] or MACEs [RR 0.95 (95% CI: 0.81–1.0)] between receiving RASi and non-receiving RASi. However, a significant decrease in all-cause mortality was observed in patients receiving RASi [RR 0.88 (95% CI: 0.79–0.98)]. Conversely, the analysis indicated a significant increase in adverse events in RASi usage, including hyperkalemia [RR 1.29 (95% CI: 1.15–1.43)] and heart failure [RR 1.35 (95% CI: 1.16–1.56)].

Conclusions: The use of RASi in advanced CKD has shown benefits in reducing all-cause mortality without exacerbating kidney disease progression. However, employing RASi may also lead to complications such as hyperkalemia and potential heart failure, necessitating caution and diligent monitoring.

TH-PO1064

Impact of Renin-Angiotensin-Aldosterone-System Inhibition on Advanced CKD: A Retrospective Observational Study

Lukas Westermann,[1] Janis M. Nolde,[1] Frederic Arnold,[1,2] Thomas Welte.[1]
[1]Department of Medicine IV, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany; [2]Institute for Microbiology and Hygiene, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany.

Background: Therapeutic renin-angiotensin-aldosterone system inhibition (RAASi) slows chronic kidney disease (CKD) progression in mild and moderate CKD, but was thought to be unfavorable in advanced CKD. In contrast, recent data from a randomized controlled trial demonstrated that RAASi does not modulate kidney function decline in advanced CKD. Due to limited real-world data, this study investigates effects of RAASi on kidney function decline in advanced CKD in a comparably large cohort.

Methods: This single-center retrospective observational study presents data from 951 individuals with advanced CKD (estimated glomerular filtration rate [eGFR] 15-30 ml/min/1.73 m^2) treated with or without RAASi, incorporating 1.298 treatment intervals over a median follow-up period of 19 months (interquartile range: 8-44). The primary endpoint was defined as time to manifestation of ESRD (eGFR <15 ml/min/1.73 m^2) and was analyzed using interval- and right-censored datasets. Patients receiving RAASi were compared to those not receiving RAASi using univariate and covariate-adjusted time-to-event analysis. Covariate-adjusted hazard ratios (HR) were estimated for covariates comprised of several discrete (sex, CKD diagnosis) and continuous variables (year of inclusion, age, eGFR, urin-protein-creatinine-ratio [UPCR], BMI, mean arterial pressure, hemoglobin and serum potassium), applying multivariate parametric regression models.

Results: Univariate time-to-event analysis revealed a statistically significant yet clinically negligible difference in the median time to ESRD between the RAASi vs. non-RAASi group (p<0.001), with 7.0 years [95% CI: 4-NA] vs. 7.19 years [95% CI: 5.62-NA], respectively. Covariate adjusted analysis did not confirm an association of RAASi and kidney function decline (HR 0.90 [95% CI: 0.65-1.24], p=0.506). Higher eGFR (HR 0.75 [95% CI: 0.72-0.78], p<0.001) was associated with slower kidney function decline. Increased UPCR (HR 1.18 [95% CI: 1.12-1.24], p<0.001) was associated with faster kidney function decline.

Conclusions: RAAS inhibition is not associated with slower kidney function decline in advanced CKD. This study supports the continuation of therapeutic RAAS inhibition in advanced CKD, if clinically indicated. **FA and TW contributed equally.*

Mineralocorticoid Receptor Antagonist (MRA) Use Patterns following Potassium Binder Initiation: Insights from the DEMONSTRATE Database

Hans Furuland,[1] Anders Larsson,[1] Milica Uhde,[2] Matilda Almstedt,[2] Thomas Cars,[2] Maria K. Svensson.[1] *[1]Uppsala Universitet, Uppsala, Sweden; [2]CLS Vifor, Uppsala, Sweden.*

Background: Hyperkalemia (HK) is a common in chronic kidney disease (CKD). Mineralocorticoid receptor antagonists (MRAs) provide significant cardiovascular and renal benefits but can exacerbate HK. HK often leads to the reduction or discontinuation of MRA therapy. This study aims to investigate the treatment pattern of MRA following initiation of treatment with potassium binders.

Methods: From the DEMONSTRATE database (six regions in mid-Sweden) patients with at least one pharmacy dispensation of first (sodium polystyrene sulfonate, SPS) or second-generation (patiromer or sodium zirconium cyclosilicate, SZC) potassium binders between 2005 and 2022 were selected, prescriptions were estimated and treatment episodes were established.

Results: 2,146 and 280 patients were treated with MRA and initiated first and second-generation K+ binders. The second-generation users tended to have a higher comorbidity profile. 26% had an overlapping comorbid profile of hypertension, heart failure, diabetes mellitus and CKD. Persistence to potassium binder treatment was higher among second generation users; median persistence was 87.5 and 112.5 days for first and second generation respectively. After 120 days 33% had discontinued MRA and after 240 days more than 50% (Figure 1).

Conclusions: MRA-treated patients had a high comorbidity profile and compared to the first-generation potassium binders, patients initiating second generation potassium binders had more comorbidities and longer K+ binder treatment duration. Overall, potassium binder users still dose reduced MRA to a large degree. Whether second generation binders lead to more persistent MRA use remains to be elucidated.

Effect of Ultrasound Renal Denervation in Patients with CKD: A Matched-Controlled Analysis of the RADIANCE Clinical Trial Program

Roland E. Schmieder,[1] Michel Azizi,[2] Debbie L. Cohen,[3] Samantha Rogers,[4] Maureen Mcguire,[4] Candace Mcclure,[5] Ajay J. Kirtane.[6] *[1]University Hospital Erlangen, Erlangen, Germany; [2]Universite Paris-Descartes, Paris, France; [3]University of Pennsylvania, Philadelphia, PA; [4]Recor Medical, Palo Alto, CA; [5]North American Science Associates Inc, Minneapolis, MN; [6]Columbia University Irving Medical Center, New York, NY.*

Background: In CKD patients, hyperactivation of the sympathetic nervous activity exacerbates hypertension. Ultrasound renal denervation (uRDN), known to decrease SNS activity, has been shown to lower blood pressure (BP) in hypertension patients. In addition, pilot studies indicate that uRDN could lower BP among CKD patients.

Methods: The RADIANCE clinical program included 3 randomized controlled studies that compared uRDN to sham control in 506 mild-to-moderate and resistant hypertensive patients. Patients were eligible for randomization if daytime ambulatory BP (dABP) was ≥135/85 mmHg after a 4-week stabilization/washout period and eGFR was ≥40 ml/min/1.73m^2. In a matched analysis, the BP response 2 months after uRDN or sham was compared between patients with eGFR<60 (CKD n=28: 16 uRDN and 12 sham) and patients with eGFR ≥60 (non-CKD n=28: 16 uRDN and 12 sham) who were matched on cohort, treatment arm, sex, race, age (± 8 years), and baseline daytime ambulatory systolic BP (dASBP) (±15mmHg).

Results: In this cohort, 79% were men; 21% were black; and average age was 59 years. At baseline, dABP was 150.8/93.5±10.4/7.0 mmHg vs. 153.4/94.0±9.9/7.8 mmHg (p=0.333), median antihypertensive medications defined daily dose was 2.0 vs 2.5 (p=0.565), and eGFR was 53.2±4.9 vs. 77.6±12.2 ml/min/1.73m^2 (p<0.001) in CKD vs. non-CKD patients, respectively. At 2-months, there were no differences in changes in dASBP from baseline -7.7±18.7 mmHg vs. -8.7±11.3 or office systolic BP -7.6±19.4 vs. -5.1±17.9 in CKD vs. non-CKD, respectively. Changes in eGFR at 2 months were CKD: +7.4±11.0 vs. non-CKD + 2.2±9.6 (baseline-adj p=0.804). Results were similar when comparing the patients with uRDN only: neither dASBP nor office BP differed between CKD and non-CKD patients. Among CKD only patients, the mean difference in dASBP reduction between uRDN and sham at 2-months was -11.1 mmHg (95% CI: -25.3, 3.1; p adj=0.119) and diastolic ambulatory BP -8.0 mmHg (95% CI: -16.4, 0.3; p adj=0.007).

Conclusions: Among patients with mild CKD in the RADIANCE trials, uRDN reduces BP to the same magnitude in both CKD and non-CKD patients while eGFR was not adversely affected. This analysis supports the use of uRDN in patients with uncontrolled RDN who have stage 3 CKD (40-60 ml/min/1.73m^2).

TH-PO1067

The Acute Kidney Function Change with Fenofibrate Is Not Damaging: A Post Hoc Analysis of the FIELD Trial

Alexandra Gallagher,[1,2] Rachel L. O'Connell,[2] George Mangos,[1,4] Brendan Smyth,[1,2] Anthony C. Keech,[5,2] Meg Jardine.[3,2] The FIELD Investigators. *[1]St George Hospital Department of Renal Medicine, Kogarah, NSW, Australia; [2]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [3]Concord Repatriation General Hospital, Concord, NSW, Australia; [4]University of New South Wales Medicine & Health, Sydney, NSW, Australia; [5]Department of Cardiology, Royal Prince Alfred Hospital, Sydney, NSW, Australia.*

Background: Several agents known to protect against chronic kidney disease have been associated with an initial decline in the estimated Glomerular Filtration Rate (eGFR). Studies on sodium-glucose cotransporter-2 inhibitors have shown that these initial eGFR dips are not harmful, although the analyses were conducted after randomization. Fenofibrate, on the other hand, leads to an acute, reversible eGFR decline through non-glomerular mechanisms. In a trial where the acute eGFR response to fenofibrate was assessed before randomization, the aim was to test whether this initial acute eGFR decline could predict potential benefits.

Methods: The FIELD trial randomised adults to fenofibrate or placebo. All participants were exposed to an active run-in. The Acute Fenofibrate Response (AFR) was measured and categorised as nil, mild, moderate, or large (increase/no change, 0-10%, 10-20%, >20% eGFR decline). Subgroup analyses were conducted for several cardiovascular outcomes, mortality, a clinical kidney endpoint (doubling serum creatinine, eGFR <15ml/min/1.73m^2, renal related death, or kidney replacement therapy), and total (baseline to study close) and chronic (4 months post-randomisation to study close) eGFR slopes, with heterogeneity assessed using a test of trend.

Results: In 9777 participants, fenofibrate therapy did not reduce coronary events with no evidence of treatment modification by acute eGFR decline category (overall HR 0.89 [95% CI 0.75 to 1.05]); nil, mild, moderate, and large acute decline: 1.08, 0.77, 1.02 and 0.82 respectively, p-trend 0.997). AFR category did not predict harm for clinical kidney, total cardiovascular events (Figure 1) nor for total microvascular events, or all-cause mortality (p-trend 0.46 and 0.95, respectively). Subgroups of greater AFR experienced more improvement on chronic eGFR slope, and the reverse trend for total slope (p-trend <0.0001 and 0.01, respectively).

Conclusions: There was no evidence that greater acute eGFR decline leads to fenofibrate-associated harm for a range of clinically meaningful endpoints.

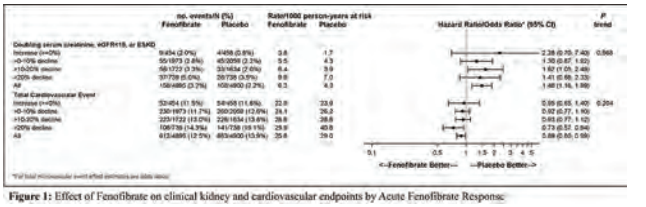

Figure 1: Effect of Fenofibrate on clinical kidney and cardiovascular endpoints by Acute Fenofibrate Response

Association of Fibrate Use with Greater Survival Independent of Baseline Kidney Function and Albuminuria

Rina Takahashi,[1] Jenny I. Shen,[1] Diana Tran,[1] Ibrahim Elali,[1] Tiane Dai,[1] Keiichi Sumida,[2] Fridtjof Thomas,[2] Connie Rhee,[3] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]The Lundquist Institute, Torrance, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA.*

Background: Fibrate use can result in an acute increase in serum creatinine, making assessing long-term outcomes associated with fibrates difficult. Additionally, some studies reported no change, and others showed improved mortality with fibrate use. This study aims to examine the association of fibrate use with death independent of changes in serum creatinine levels in a large national cohort of United States (US) Veterans with long follow-ups.

Methods: A retrospective cohort study was conducted to examine the association of de novo prescription of fibrate medications during the baseline period with death over 14 years. Patients (n=688,382) were selected from Veterans Administration (VA) research databases if they had data on albuminuria from 2004 to 2006. Associations were examined in Cox proportional hazard models adjusted for demographics, major comorbidities, and laboratory data, including baseline estimated glomerular filtration rate (eGFR), albuminuria, and medications.

Results: We identified 58,773 incident new fibrate users. The overall mean (SD) age was 59 (13) years, with 6.6% female, 17.9% Black, and 7.0% Hispanic, and baseline triglycerides of 119 (81, 181) mg/dl (users 334 (228, 497), non-users 112 (79, 163)) mg/dl. Fibrate users were more likely to be male, White, current smokers, and had higher frequencies of comorbidities. Fibrate use (vs. non-use) was associated with a lower risk of death (Hazard ratio (HR): 0.91, 95% confidential interval [CI]: 0.89-0.93).

Conclusions: In this large national cohort of US Veterans with long follow-up, fibrate use was associated with a lower risk of death independent of baseline renal function and albuminuria. Further studies are needed to corroborate the potential benefits of fibrate on survival.

Kidney Safety of Prescribed Oral Fibrates in Veterans without CKD

Rina Takahashi,[1] Jenny I. Shen,[1] Diana Tran,[1] Ibrahim Elali,[1] Tiane Dai,[1] Keiichi Sumida,[2] Fridtjof Thomas,[2] Connie Rhee,[3] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]The Lundquist Institute, Torrance, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA.*

Background: Prescribing fibrate medications can result in an acute increase in serum creatinine, making assessing renal outcomes associated with fibrates difficult. There is limited research on certain renal outcomes, and past studies have mixed results. This study aims to examine the association of fibrate use with incident chronic kidney disease (CKD) and incident end-stage renal disease (ESRD) in a large national cohort of veterans of the United States (US) who have long follow-ups.

Methods: A retrospective cohort study examined the association of de novo prescription of fibrate medications during the baseline period with incident CKD and ESRD over 14 years. Patients (n=688,382) were selected from VA databases if they had albuminuria data from 2004 to 2006. Cox proportional hazard models (Model 2-6) and Fine-Gray competitive risk models (Model 7, competing events: ESRD, death) were used and adjusted for demographics, major comorbidities, labs, baseline estimated glomerular filtration rate (eGFR), albuminuria, and medications.

Results: We identified 58,773 incident new fibrate users. The overall mean (SD) age was 59 (13) years, with 6.6% female, 17.9% Black, and 7.0% Hispanic, and baseline triglycerides of 119 (81, 181) mg/dl (users 334 (228, 497), non-users 112 (79, 163)) mg/dl. Fibrate users were more likely to be male, White, current smokers, and had higher frequencies of comorbidities. Fibrate use (vs. non-use) was associated with a higher risk of CKD (Model 6, Hazard ratio (HR): 1.21, 95% confidential interval [CI]: 1.19-1.24) but with a lower risk of ESRD (Model 6, HR: 0.80, 95% CI: 0.71-0.92). Fine-gray models showed similar results (Model 7).

Conclusions: In this large national cohort of US Veterans with long follow-up, fibrate use was associated with a higher risk of incident CKD but a lower risk of ESRD. Further studies are warranted to corroborate the potential benefits of fibrate on kidney function.

TH-PO1070

Examining the Associations between Incident Niacin Therapy and Kidney Outcomes

Rina Takahashi,[1] Thuy-Anh Bui,[4] Ibrahim Elali,[1] Diana Tran,[1] Keiichi Sumida,[2] Fridtjof Thomas,[2] Ramanath B. Dukkipati,[1] Anuja P. Shah,[1] Connie Rhee,[3] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]The Lundquist Institute, Torrance, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA; [4]University of California Irvine, Irvine, CA.*

Background: Despite the favorable data shown in studies of niacin, a lipid-lowering medication that can lower triglycerides and improve other risk factors for renal outcomes, its effect on long-term outcomes remains to be determined. This study aims to examine the associations of niacin therapy with incident chronic kidney disease (CKD) and end-stage renal disease (ESRD) in patients with normal renal function.

Methods: In a nationwide historical cohort of 1,139,630 US Veterans with normal baseline eGFR, we examined the association of de novo prescription of niacin from 2004 to 2006 with incident CKD (defined as eGFR <60 ml/min/1.73m2 on two occasions, separated by ≥90 days) and ESRD during the 14-year follow-up. Associations were examined in Cox proportional hazard models adjusted for demographics, major comorbidities, and laboratory measurements. Prescription time-distribution matching was used to control for survival bias.

Results: We identified 133,450 new users of niacin. Overall, patients (n=1,139,630) had a mean (standard deviation; SD) age of 60 (13) years, with 6% female, 78% White, 16% Black, and 6% Hispanic. Niacin users were more likely to be male, White, current, or former smokers, with higher frequencies of comorbidities. Niacin use (vs. non-use) was associated with a higher risk of CKD (Hazard ratio [HR]: 1.16, 95% confidential interval [CI]: 1.15-1.17) but a lower risk of ESRD (HR: 0.85, 95% CI: 0.79-0.92).

Conclusions: In a large national cohort of US Veterans with normal kidney function, niacin use was associated with a higher risk of incident CKD but a lower risk of ESRD. Additional studies are warranted to examine the potential effect of niacin on renal function.

TH-PO1071

Association of Prescribed Bicarbonate Therapy with Incident Kidney Failure in Veterans with CKD

Diana Tran,[1] Rina Takahashi,[1] Ibrahim Elali,[1] Jenny I. Shen,[1] Ramanath B. Dukkipati,[1] Anuja P. Shah,[1] Prabin Shrestha,[2] Fridtjof Thomas,[2] Keiichi Sumida,[2] Connie Rhee,[3] Kamyar Kalantar-Zadeh,[1] Csaba P. Kovesdy.[2] *[1]The Lundquist Institute, Torrance, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA.*

Background: Treatment of metabolic acidosis may delay the renal function decline in patients with chronic kidney disease (CKD), but the effects of bicarbonate on CKD progression to end-stage renal disease (ESRD) in unselected populations with all stages of CKD remain unclear. We examined the association of bicarbonate use with incident ESRD in a large national cohort of United States (US) Veterans.

Methods: In a cohort of 50,540 patients with incident CKD (eGFR <60 mL/min/1.73m^2), we examined the association of de novo bicarbonate prescription with incident ESRD (defined as initiation of renal replacement therapy) during the 14-year follow-up using Cox proportional hazard models adjusted for demographics, major comorbidities, baseline eGFR, urine albumin-creatinine ratio (UACR), and use of renin angiotensin-system inhibitors. Additionally, propensity score (PS) overlap weighting, inverse probability of treatment weighting (IPTW), and PS matching were used to reduce confounding.

Results: We identified 11,896 incident bicarbonate users. Overall mean age was 65, with 3.0% female, 15.3% Black, and 5.5% Hispanic, baseline serum bicarbonate of 24.2±4.4 (users 20.2±3.7, non-users 26.1±3.4) mEq/L, and eGFR of 35.5±11 mL/min/1.73m^2. Bicarbonate users were more likely to be male, Black, current smokers, had higher frequencies of diabetes and liver disease, and lower eGFR compared to non-users. Bicarbonate use (vs. non-use) was associated with a higher risk of incident ESRD in the fully adjusted model (HR: 1.48, 95% CI: 1.38-1.60), PS overlap weighting (1.41, 1.29-1.55), IPTW (1.24, 1.19-1.29), and PS matching (1.72, 1.61-1.85).

Conclusions: In this large national cohort of US Veterans with long follow-up, bicarbonate use was associated with a higher risk of incident ESRD. Further studies are needed to test the effects of bicarbonate replacement on CKD progression.

Effect of Sodium Bicarbonate on Blood N-terminal Pro B-type Natriuretic Peptide (NT-proBNP) and Fetuin Levels: A Secondary Analysis of the VA-Bicarb Trial

Paola Gudino,[1] Seiji Koike,[2] Jodi A. Lapidus,[2] Daniela A. Arrieta-Asmadt,[3] Mirela A. Dobre,[4] Matthew K. Abramowitz,[5] Thomas H. Hostetter,[6] Alfred K. Cheung,[3] Wei Chen,[5] Michal L. Melamed,[7] Kalani L. Raphael.[3]
[1]New York City Health and Hospitals Corporation, New York, NY; [2]Oregon Health & Science University, Portland, OR; [3]University of Utah Health, Salt Lake City, UT; [4]University Hospitals, Cleveland, OH; [5]Albert Einstein College of Medicine, Bronx, NY; [6]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [7]New York University, New York, NY.

Background: NaHCO3 is often used to treat metabolic acidosis in chronic kidney disease (CKD). However, NaHCO3 has been hypothesized to cause fluid retention and increase risk of vascular calcification. We conducted a secondary analysis of the VA-Bicarb Trial to determine the effect of NaHCO3 on blood N-terminal pro-b-type natriuretic peptide (NT-proBNP) and fetuin levels.

Methods: NT-proBNP and fetuin were measured from stored samples of participants in the VA-Bicarb Trial, a six-month, double-blind, randomized, placebo-controlled NaHCO3 trial of 74 US Veterans with stage 2-4 CKD attributed to diabetes. Measurements were performed at baseline, month-3, and month-6. Generalized linear mixed effects models were fit and a series of hypothesis tests were performed to globally asses differences in biomarker trajectory between treatment groups as well as intergroup differences at each visit. Additionally, we analyzed intragroup biomarker variations at each visit relative to the group baseline values.

Results: The mean (SD) age was 72 (8) years, 72 (97%) male, and 64 (87%) non-Hispanic White. Mean (SD) eGFR was 56 (20) ml/min/1.73m^2 and median (IQR) urinary ACR was 121 (58, 370) mg/g. Median (IQR) NT-proBNP was 81 (48, 219) pg/mL and mean (SD) fetuin was 840 (187) µg/mL. Fetuin decreased in both the NaHCO3 and placebo groups at month-3; month-6 values returned to near baseline levels in both groups (Figure 1A). There was no significant change in NT-proBNP levels in either group during follow-up (Figure 1B). Overall, there was no statistically significant difference in NT-proBNP or fetuin between the groups.

Conclusions: Among US Veterans with stage 2-4 CKD attributed to diabetes, treatment with NaHCO3 had no effect on blood NT-proBNP or fetuin levels.

Proteinuria Outcomes of Tenofovir Alafenamide Fumarate (TAF) vs. Tenofovir Disoproxil Fumarate (TDF) Regimens for Treatment of HIV, HBV, and HIV PrEP: A Systematic Literature Review and Meta-Analysis

Xi Liang,[1] Kyu Yun Park,[1] Haeseon Lee,[1] Nathorn Chaiyakunapruk,[1] Tara Dhippayom,[3] Rachel Rogers,[2] Amy R. Weinberg,[2] Julia Green,[2] Aileen Chi,[2] Connor W. Willis.[1] *[1]University of Utah Health, Salt Lake City, UT; [2]Gilead Sciences Inc, Foster City, CA; [3]The Prince Royal's College, Chiang Mai, Thailand.*

Background: TDF and TAF are tenofovir's prodrugs. TAF has improved renal safety and comparable efficacy to TDF. Monitoring proteinuria biomarkers is crucial for early kidney damage detection. We aimed to comprehensively synthesize evidence on proteinuria outcomes of TDF and TAF regimens.

Methods: We systematically reviewed RCTs comparing TDF vs. TAF for pre-exposure prophylaxis (PrEP), treatment of human immunodeficiency virus (HIV-1), hepatitis B virus (HBV), and HIV/HBV. We searched PubMed, EMBASE, Web of Science, and Cochrane Trial Registry from inception to 12/6/2023. The outcomes were pooled using mean % change differences with 95% CI. The heterogeneity was assessed using I^2 test. Subgroup analyses were based on baseline eGFR and prior treatment.

Results: Out of 9,014 studies, 10 RCTs reported urine protein to creatinine ratio (UPCR), 12 RCTs reported urine albumin to creatinine ratio (UACR), 15 RCTs reported retinol-binding protein to creatinine ratio (RBPCR), and 16 RCTs reported β_2-macroglobulin to creatinine ratio (β_2MCR). TAF showed improved proteinuria compared to TDF, with a magnitude of improvement increasing over time. This trend was consistent across all subgroup analyses.

Conclusions: Proteinuria outcomes significantly improved with TAF compared to TDF, which became more pronounced over time. This supports using TAF regimens across indications.

Association between Urate-Lowering Therapy and Kidney Failure in Patients with CKD

Agathe Mouheb,[1,5] Oriane Lambert,[2] Natalia Alencar de Pinho,[2] Christian Jacquelinet,[3] Maurice Laville,[9] Christian Combe,[4,8] Denis Fouque,[10,9] Luc Frimat,[6,11] Ziad Massy,[7,12] Solene M. Laville,[1,5] Sophie Liabeuf.[1,5]
[1]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [2]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [3]Agence de la biomedecine, La Plaine Saint-Denis, France; [4]Centre Hospitalier Universitaire de Bordeaux Groupe hospitalier Sud, Bordeaux, France; [5]Universite de Picardie Jules Verne, Amiens, France; [6]Centre Hospitalier Regional Universitaire de Nancy, Nancy, France; [7]Association pour l'Utilisation du Rein Artificiel dans la région parisienne (AURA), Paris, France; [8]INSERM, U1026, Université Bordeaux Segalen, Bordeaux, France; [9]Université de Lyon, CarMeN INSERM1060, Lyon, France; [10]Nephrology department, Lyon South Medical Center, Lyon, France; [11]Universite de Lorraine Laboratoire Adaptation Mesure et Evaluation en Sante Approches Interdisciplinaires, Vandoeuvre-les-Nancy, France; [12]Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France.

Background: Hyperuricemia is a hallmark of gout and a suspected risk factor for the progression of chronic kidney disease (CKD). However, the impact of urate-lowering therapy (ULT) on CKD progression is subject to debate. The objective of the present study was to evaluate the association between ULT prescription and the progression of kidney disease in patients with CKD.

Methods: CKD-REIN is a French, nationwide, prospective cohort of 3,033 nephrology outpatients with a confirmed diagnosis of CKD (eGFR<60 mL/min/1.73 m²). Prescriptions of ULT drugs (allopurinol or febuxostat), and patient's characteristics were recorded prospectively during follow-up. Propensity score-matched, cause-specific Cox proportional hazards regression models were used to assess the association between incident ULT use and CKD progression (defined primarily as the initiation of kidney replacement therapy (KRT) but also in other ways).

Results: Among the patients included in the cohort, 337 started ULT and were matched with a ULT non-user. The characteristics of the matched patients were balanced. The median age of the patients was 71 years, the mean eGFR was 30 mL/min/1.73 m², the mean uricemia was 494 µmol/L, and 65% were receiving diuretics. Over a median follow-up of 3.2 [1.9-4.2] years, 136 patients started KRT (incidence rate [95% confidence interval (CI)]: 7.6 [6.3–8.8] per 100 person-years), among whom 66 patients initiated ULT. Our analysis did not reveal a significant association between ULT prescription and the occurrence of KRT (HR [95%CI]: 0.89 [0.67 – 1.20]). Regardless of the definition considered, CKD progression was not significantly associated with ULT prescription.

Conclusions: Real-world data from the CKD-REIN cohort show that ULTs do not slow the progression of CKD. Thus, in patients with asymptomatic hyperuricemia, ULT should not be prescribed for the purpose of slowing down CKD progression.

TH-PO1075

Efficacy and Safety of SEL-212 in Patients with Refractory Gout and CKD: A Post Hoc Analysis from the Two Phase 3 DISSOLVE Studies

Puja Khanna,[1] Richard J. Johnson,[2] Rehan Azeem,[3] Aletta Falk,[4] Bhavisha Desai,[3] Hugues Santin-Janin,[5] Herbert Baraf,[6,7] Alan J. Kivitz.[8] *[1]Division of Rheumatology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Division of Renal Diseases and Hypertension, University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Sobi, Waltham, MA; [4]Sobi, Stockholm, Sweden; [5]Sobi, Basel, Switzerland; [6]The Center for Rheumatology and Bone Research, Rheumatology, Wheaton, MD; [7]The George Washington University, Rheumatology, Washington, DC; [8]Department of Rheumatology, Altoona Center for Clinical Research, Duncansville, PA.*

Background: Chronic kidney disease (CKD) is common in patients with gout, especially in patients with chronic refractory gout (CRG), but evidence on the management of gout in these patients is limited (Stamp LK, et al. *Nat Rev Rheumatol* 2021;17:633). Here, we present Phase 3 efficacy and safety data on the investigational uricase-based therapy SEL-212 in patients with CRG and CKD.

Methods: DISSOLVE I (NCT04513366) and DISSOLVE II (NCT04596540) investigated the efficacy and safety of SEL-212, a two-component infusion therapy of pegadricase (a pegylated uricase) and immune-tolerizing nanoparticles containing sirolimus in the treatment of CRG. Two doses of SEL-212 or placebo were administered every 28 days for up to 6 treatment periods (TPs) in DISSOLVE II, or up to 12 TPs in DISSOLVE I. The primary endpoint was serum uric acid reduction below 6 mg/dL for at least 80% of the time during TP6. Secondary endpoints assessed sUA reduction and related outcomes. In this *post hoc* analysis, efficacy and safety data from both studies were pooled and outcomes in patients with CKD stage 3 at baseline were analyzed using the Mantel-Haenszel test with randomization of tophus presence (yes/no) with a two-sided error rate of α=2.5% to account for the two comparisons of study drug against placebo.

Results: Among 265 patients in DISSOLVE I and II, 61 had CKD stage 3. The proportion of patients with CKD stage 3 who met the primary endpoint was broadly comparable to the overall population: 52% vs 51% in the high dose treatment arm, 61% vs 43% in the low dose arm, and 10% vs 8% in the placebo arm. Mean glomerular filtration rates were stable in both arms from baseline to TP6 (Fig. 1).

Conclusions: Data from DISSOLVE I and II endorsed the efficacy and safety of SEL-212 in patients with gout refractory to conventional therapy with CKD stage 3. Further studies are needed to establish the use of this novel combination product in refractory gout with end-stage kidney damage.

Funding: Commercial Support - Sobi and Selecta Biosciences, Inc

Effect of Different Erythropoiesis-Stimulating Agents on Mortality and Kidney Disease Progression among Nondialysis-Dependent Patients with CKD

Sungjin Chung, Eun Sil Koh. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Erythropoiesis-stimulating agents (ESAs) are commonly prescribed to treat anemia in both dialysis-independent and -dependent chronic kidney disease (CKD) patients. However, the clinical outcomes, particularly mortality, associated with short- and long-acting ESAs remain debated. This study investigates the prognostic implications of ESA type in a large cohort of non-dialysis CKD patients.

Methods: Using the Korean National Health Insurance Service cohort database, we analyzed data from 166,673 subjects treated with epoetin α, darbepoetin, or methoxy polyethylene glycol-epoetin β (MPGB) between 2002 and 2021, with follow-up until December 31, 2022. The primary outcomes were all-cause mortality, a decline of over 40% in estimated glomerular filtration rate (eGFR), or initiation of dialysis.

Results: During the follow-up period, patients receiving darbepoetin or MPGB had a significantly lower risk of renal composite outcomes compared to those receiving epoetin α (HR 0.523, 95% CI 0.489-0.561 and HR 0.266, 95% CI 0.246-0.288, respectively). However, darbepoetin use was associated with a significantly higher risk of all-cause death (HR 1.119, 95% CI 1.053-1.190), while MPGB use showed a significantly lower risk (HR 0.928, 95% CI 0.873-0.986) compared to epoetin α. Excluding subjects with missing hemoglobin data, those treated with MPGB who achieved optimal hemoglobin levels (10.0-10.9 g/dL) demonstrated a higher risk of all-cause death compared to those treated with epoetin α.

Conclusions: The use of longer-acting ESAs in non-dialysis CKD patients may be associated with a reduced risk of kidney disease progression compared to short-acting ESAs. However, longer-acting ESAs may also be linked to an increased mortality rate, particularly among patients achieving optimal hemoglobin levels with MPGB.

Health Effects (Renal) of Extra Strength Avmacol (HEROES) Study: Interim Update from the Phase 2 Randomized Double-Blind Placebo-Controlled Trial

Yves T. Wang, Sharvari A. Sonawane, Allison J. Stewart, Rita Ghimirey, Timothy J. Beane, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Progression of chronic kidney disease (CKD) is associated with increased oxidative stress (OS). The common null allele of the glutathione S-transferase µ-1 (*GSTM1*) gene, which encodes an antioxidant enzyme and is a downstream target of nuclear factor erythroid 2-related factor 2 (Nrf2), has been shown to be associated with elevated oxidative stress and increased risk of CKD progression in clinical studies. We hypothesize that upregulating antioxidant enzymes by activating the Nrf2 pathway via supplementation with sulforaphane (SFN) would decrease markers of OS and inflammation and slow CKD progression. We are testing this hypothesis using Avmacol Extra Strength (ES) in a Phase 2 randomized double-blind placebo-controlled safety and feasibility trial.

Methods: Adult subjects with CKD Stage 3-4 (eGFR 15-60 mL/min/1.73m^2) and progressive GFR decline are recruited from the Kidney Clinic at the University of Rochester Medical Center. Subjects are randomized to take 4 tablets daily of either Avmacol ES or a matching placebo for 6 months. Blood and urine are obtained for markers of OS and inflammation at baseline, and at 1, 3, and 6 months, in addition to standard of care clinical labs. *GSTM1* genotype is also determined.

Results: As of May 1, 2024, 59 subjects have enrolled and completed a baseline visit, of which 28 have completed the 6-month study. By RT-PCR genotyping, 27 have at least 1 active *Gstm1* allele (1/0 or 1/1, 45.8%). In total, there have been 149 reported side effects (SEs), including 101 related to the gastrointestinal (GI) system, and 3 serious adverse events (SAEs), all GI-related. While 1 arm of the study has a slightly higher proportion of subjects without any SEs (21.2% vs. 12.0%), the number of SEs per subject with at least 1 SE is similar (2.5 vs 2.7). One subject with a GI SAE was discontinued from the study due to safety concerns, while another 7 subjects have voluntarily withdrawn from the study.

Conclusions: As of this interim report, there is no significant difference in SE or SAE rate between the arms of the study, with most being relatively mild. The *GSTM1* genotypes of the study participants are within the expected proportions. This study is on pace to complete recruitment (100 subjects total) in ~6 months.

Hyperkalemia Treatment Strategies by Specialty in the TRACK Study: Interim Analysis

Meredith S. Bishop,[1] Judith Hsia,[2] Linda F. Fried,[3] Jordi Bover,[5] Javed Butler,[6] Pietro Manuel Ferraro,[7] Markus P. Schneider,[8] Navdeep Tangri,[9] Wolfgang C. Winkelmayer,[4] Nitin Shivappa,[1] Anna-Karin Sundin,[1] Hungta (Tony) Chen,[1] Marc P. Bonaca.[2] *[1]AstraZeneca Pharmaceuticals LP, Wilmington, DE; [2]University of Colorado System, Denver, CO; [3]University of Pittsburgh, Pittsburgh, PA; [4]Baylor College of Medicine, Houston, TX; [5]Hospital Universitari Germans Trias i Pujol, Badalona, Spain; [6]Baylor Scott & White Health, Dallas, TX; [7]Universita degli Studi di Verona, Verona, Italy; [8]Friedrich-Alexander-Universitat Erlangen-Nurnberg Medizinische Fakultat, Erlangen, Germany; [9]University of Manitoba, Winnipeg, MB, Canada.*

Background: We compared baseline treatment strategies by healthcare provider (HCP) specialty from TRACK, a prospective, observational study designed to address the evidence gap regarding HCP decision making in patients with hyperkalemia (HK).

Methods: TRACK enrolled adults with serum potassium (sK^+) >5.0 mmol/L and recorded HCP management decisions for 12 months. HCPs were asked, but not required, to record their specialty. An interim analysis was conducted when 600 enrolled participants had completed 6 months. Initial treatment strategy by specialty was compared using Fisher's exact or Pearson's Chi-squared tests. Treatment objectives and planned treatment duration were analyzed descriptively.

Results: Participants (N=1330) were enrolled (July 2022–December 2023) in the USA and Europe (mean age, 68±14 years; female, 31%; mean sK^+, 5.6±0.5 mmol/L; estimated glomerular filtration rate, 28±21 mL/min/1.73 m^2). In total, 55% had chronic kidney disease (CKD) without heart failure (HF), 29% had CKD and HF, and 6% had HF without CKD. Overall, nephrologists managed 597 (45%) participants, 327 (25%) had another specified specialty (237 cardiologists), and the HCP specialty was not specified for 30%. Nephrologists were more likely to plan for indefinite treatment, cite CKD guideline compliance as an objective, and prescribe a low K^+ diet (Table; P<0.0001); less likely to manage renin-angiotensin-aldosterone system inhibitor therapy as an initial strategy and more likely to manage K^+ binder therapy (both P<0.0001).

Conclusions: HCP specialty affected HK management approaches, possibly reflecting differences in specialty guidelines.

Funding: Commercial Support - AstraZeneca

Weight-Based Sliding Scale vs. Fixed-Dose Loop Diuretics for Fluid Overload in CKD: A Retrospective Analysis

Sameen Aamer,[1] Katelin Gardonis,[1] Andrey Vavrenyuk,[2] Randa Abd Algayoum,[3] Swati Arora.[1] *[1]Allegheny General Hospital, Pittsburgh, PA; [2]University of Wisconsin-Madison, Madison, WI; [3]Garden City Hospital, Garden City, MI.*

Background: Managing fluid overload in chronic kidney disease (CKD) patients is challenging. Fixed doses of loop diuretics often lead to complications such as frequent hospitalizations due to volume overload or pre-renal acute kidney injury (AKI). While weight-based loop diuretic adjustments have reduced hospitalizations in heart failure patients, this approach has not been specifically studied in CKD patients.

Methods: A single-center retrospective study (n=80) from June 2020 to July 2022 compared clinical outcomes between forty patients on fixed-dose loop diuretics (FDD) and forty on weight-based sliding scale loop diuretics (SSD).

Results: The demographics of both groups were similar, except that SSD patients were older (mean age 64.15 vs. 56.28, p = 0.04) and predominantly white (81%), while FDD patients were more likely to be Black (30%, p = 0.03). Linear modeling revealed that SSD significantly predicted better blood pressure (BP) control, with FDD patients having 7.95 mmHg higher BP (β = 7.95, t(246) = 2.19, p = 0.03). Hierarchical generalized linear modeling showed a 57% variance in volume between groups, with SSD patients being 46% less likely to develop hypervolemia over time (OR = 0.54, 95% CI [0.37, 0.80], p = 0.03) compared to FDD patients, who were 8% less likely to develop hypervolemia over time (OR = 0.92, 95% CI [0.71, 1.20], p = 0.03). Patients on FDD had higher hospitalization rates (43.4%) compared to 18.5% for those on SSD (p = 0.03). Clinical outcomes are shown in Table 1.

Conclusions: This study highlights the benefits of sliding scale loop diuretics for managing fluid overload in CKD patients, leading to fewer hospitalizations and improved volume control over time. Further research is needed to validate and expand upon these findings.

TH-PO1080

Effects of Pediococcus acidilactici GKA4 Supplementation on Proinflammatory Cytokines in Early-Stage CKD

Wen-Ching Yang, Hui-Min Hsieh, Jun-Peng Chen, Yun-Yu Chen, Po-Hsin Pai, Cheng-Hsu Chen. *Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Chronic kidney disease (CKD) commonly results in elevated levels of proinflammatory cytokines such as TNF-α and IL-6. Although probiotics may modulate these markers in advanced CKD, their effects on early-stage CKD (ECKD) are unclear. This study explored the impact of a specific probiotic on these cytokines in patients with ECKD.

Methods: In this randomized, double-blinded, placebo-controlled trial, individuals with CKD stages G2–3a (eGFR 45–89 mL/min/1.73 m^2; ages 20–90 years) were enrolled. Participants were randomly allocated to a probiotic group (Pediococcus acidilactici GKA4) or a control group (placebo) for a six-month treatment period. TNF-α and IL-6 levels were measured in the serum and urine by ELISA, with urinary values adjusted for urine creatinine. Differences between groups were assessed using generalized estimating equations (GEEs).

Results: Eighty patients (median age 57 years; median eGFR 64.1 mL/min/1.73 m^2) were included in the intention-to-treat analysis, with 40 patients in each group. No significant differences between the groups in serum and urinary IL-6 or serum TNF-α levels were observed. However, there was a significant decrease in urinary TNF-α levels adjusted for urine creatinine (TNF-α/Cr) in the probiotic group compared to the control group ($p = 0.017$).

Conclusions: Although probiotic supplementation did not alter serum TNF-α or IL-6 levels, it modulated urinary TNF-α excretion in ECKD patients. Further studies with a larger population are required to confirm the findings.

Table 1. Generalized estimating equation (GEE) analysis of cytokines between the two groups

	β	SD	95% Confidence interval	p value
Serum measurement				
IL-6 (pg/mL)	-0.061	0.303	(-0.654, 0.532)	0.841
TNF-α (pg/mL)	-0.283	0.389	(-1.045, 0.480)	0.467
Urinary measurement				
IL-6/Cr (pg/mg)	0.001	0.003	(-0.006, 0.007)	0.866
TNF-α/Cr (pg/mg)	-0.007	0.003	(-0.013, -0.001)	0.017*

Prognostic Enrichment Using the Klinrisk Model: Insights from Landmark Kidney Disease Clinical Trials

Brendon L. Neuen,[1,2] Thomas W. Ferguson,[3,4] Meg Jardine,[5,2] Bruce Neal,[6,2] Vlado Perkovic,[7,2] George L. Bakris,[8,9] Rajiv Agarwal,[10] Patrick Schloemer,[11] Alfredo E. Farjat,[11] Niels Jongs,[12,13] Hiddo J. Heerspink,[12] David C. Wheeler,[14,15] Glenn M. Chertow,[16] Navdeep Tangri.[3,4] *[1]Royal North Shore Hospital, St Leonards, NSW, Australia; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]University of Manitoba Department of Internal Medicine, Winnipeg, MB, Canada; [4]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [5]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [6]University of New South Wales Medicine & Health, Sydney, NSW, Australia; [7]University of New South Wales, Sydney, NSW, Australia; [8]University of Chicago Pritzker School of Medicine, Chicago, IL; [9]University of Chicago Division of the Biological Sciences, Chicago, IL; [10]Indiana University School of Medicine, Indianapolis, IN; [11]Bayer AG, Leverkusen, Germany; [12]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [13]Rijksuniversiteit Groningen, Groningen, Netherlands; [14]University College London, London, United Kingdom; [15]National Institute for Health and Care Research, London, United Kingdom; [16]Stanford University School of Medicine, Stanford, CA.*

Background: Patients with macroalbuminuria (KDIGO stage A3) experience high rates of CKD progression and cardiovascular events. Identifying patients with lesser degrees of albuminuria who also experience high kidney and cardiovascular event rates could enhance access to, and improve efficiency of, CKD-focused clinical trials.

Methods: We applied the Klinrisk model, a validated machine learning model incorporating routinely collected laboratory data, to patients with uACR ≥30 mg/g who were evaluated for participation in the CANVAS Program, CREDENCE, FIDELIO, FIGARO and DAPA-CKD trials but who failed screening due to albuminuria levels below the randomization threshold. We examined 2-year incidence of CKD progression (40% decline in eGFR or kidney failure) in different uACR categories, stratified by Klinrisk score (low, intermediate, and high risk indicating <2%, 2–10%, and >10% 2-year risk of CKD progression, respectively). We subsequently reviewed screen failure data from the CREDENCE, FIDELIO and DAPA-CKD trials to determine what proportion of individuals with uACR 30–300 mg/g could have been enrolled using a Klinrisk-informed approach.

Results: Across the included trials, the incidence of CKD progression among participants with uACR 30–300mg/g (KDIGO stage A2) was highly variable across risk categories, ranging from 1.1 to 9.7% in those classified as low vs. high risk by the Klinrisk model, respectively. Compared to participants with uACR 300-1000 mg/g, event rates were similar or higher for participants with uACR 30-300mg/g classified as high-risk based on the Klinrisk model. 24 to 36% of participants who screen failed due to A2 albuminuria in the CREDENCE, FIDELIO and DAPA-CKD trials were classified as high risk with the Klinrisk model.

Conclusions: Extending recruitment to patients with uACR 30-300mg/g at high-risk based on the Klinrisk algorithm could facilitate recruitment for CKD progression trials without affecting event rates. Prognostic enrichment using Klinrisk has the potential to accelerate drug development in CKD by enabling more inclusive and efficient clinical trials.

TH-PO1082

Composite Primary Outcome Variables in Nephrology Clinical Trials

Steven Fishbane, Pratap Kumar Upadrista, Hitesh H. Shah. *Northwell Health Division of Nephrology, Great Neck, NY.*

Background: Clinical trials use one or more primary outcome variables to assess results. The type of outcome selected can affect sample size needed and interpretation of results. Composite endpoints have been increasingly popular in nephrology trials. Although potentially beneficial, composites have also been criticized for leading to potentially misleading results. In this analysis we studied nephrology trials with a special emphasis on composite outcomes and the component variables from which the composites were constructed.

Methods: We searched nephrology trials published in major medical and nephrology journals between 1/1/2019 – 12/31/2023. Only articles based on primary trials were used; post hoc or other secondary analyses were excluded. For each publication a reviewer assessed the primary outcome as well as study characteristics and results. For each study that used composite primary outcomes (CPO), the individual component results were analyzed.

Results: 183 studies were analyzed, of which the primary endpoint was a single outcome variable in 123 (67.2%), co-primary variables in 28 (15.4%) and CPO in 32 (17.4%) (Table). With CPOs, the mean number of individual component variables was 3.4±1.6. Studies with CPOs had larger sample sizes (<0.0001) and were significantly more likely to have positive study results (p=0.03, Table), with 50% of the CPO component variables having positive results. We found no association between the

number of component variables and likelihood of positivity of the overall CPO. Trials with CPO were more likely to be published in medical than nephrology journals 25/70 (35.7%) vs. 7/113 (6.2%), p<0.0001. Reporting of CPO was frequently associated with failure to provide results for the composite's individual component variables (42.9%).

Conclusions: Nephrology trials commonly utilize composite primary endpoints. In this study we describe the impact on study results, the quality of reporting of CPOs and note how these endpoints can alter the interpretation of studies.

TH-PO1083

Examining the Association between Quality of Life and Functional Status in African American Adults with CKD in Southeast Wisconsin: A Cross-Sectional Study

Mukoso N. Ozieh,[1,2] Aprill Dawson,[1] Leonard E. Egede.[1] *[1]Medical College of Wisconsin Department of Medicine, Milwaukee, WI; [2]VA Milwaukee Healthcare System, Milwaukee, WI.*

Background: CKD is a burdensome disease and quality of life (QOL) independently predicts morbidity and mortality in patients with CKD. The aim of this study was to examine the association between quality of life and functional status in African American adults with chronic kidney disease in southeast Wisconsin.

Methods: Three hundred African American adults were recruited from southeast Wisconsin, United States in 2020. Individuals aged 21 and older with a diagnosis of chronic kidney disease were eligible to participate. CKD diagnosis was based on self-report and laboratory diagnosis based on estimated glomerular filtration rate (eGFR) in ml/min/1.73m2 using CKD-EPI 2021. Quality of life was based on the physical component score (PCS) and mental component score (MCS) and functional status was based on the EQ-5D-3L which comprises 5 dimensions: mobility, self-care, usual activities, pain/discomfort and anxiety/depression and the EQ visual analog scale (VAS) scores which range from 0 to 100, where 100 is the best possible health state. Unadjusted and adjusted models were performed using the QOL components and the five dimensions of functional status as the dependent variables adjusting for relevant covariates.

Results: In this cross-sectional study of 300 African American adults, the mean age was 51.9 ± 12.5 for CKD on dialysis (CKD-D) and 60.3 ± 11.4 non-dialysis dependent CKD (CKD-ND). Mean eGFR for CKD-D was 7.8 ± 6.7 and 50.8 ± 22.6 for CKD-ND. We found significant associations for CKD-ND status and EQ pain/discomfort (β = 0.52, p < 0.01). BMI was an independent correlate for PCS (β = 0.25, p <0.01), EQ VAS (β = -7.5, p <0.01), EQ mobility (β = 0.41, p <0.01), EQ self-care (β = 0.37, p <0.01), EQ usual activities (β = 0.35, p <0.01), and EQ anxiety/depression (β = 0.41, p <0.01). Employment was an independent correlate for EQ VAS (β = 9.69, p <0.01), EQ self-care (β = -0.48, p <0.01), EQ usual activities (β = -0.67, p <0.01), and EQ anxiety/depression (β = -0.49, p <0.01). We did not significant associations for CKD-ND status and mcs (β = -0.61, p 0.07).

Conclusions: Future studies exploring the direct and indirect pathways to understand the relationship between functional status and CKD-ND are needed in order to develop novel interventions to address and improve QOL and functional status in adults with CKD.

Calcineurin Inhibitors Cause Kidney Fibrosis by Inactivating Pyruvate Dehydrogenase and Disrupting Energy Metabolism in Proximal Tubule Cells

Yasuhiro Oda,[1] Hiroshi Nishi,[1] Teruhiko Yoshida,[2] Jeffrey B. Kopp,[2] Masaomi Nangaku.[1] *[1]The University of Tokyo Graduate School of Medicine, Bunkyo, Japan; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Arteriolopathy is regarded as a hallmark of chronic calcineurin inhibitor (CNI) nephrotoxicity, but whether tubular cells play a causative role in the development of chronic CNI nephrotoxicity is not fully understood. Calcineurin was recently shown to directly dephosphorylate and activate pyruvate dehydrogenase (PDH), a gatekeeper of the TCA cycle. We hypothesized that 1) CNIs disrupt mitochondrial energy metabolism by decreasing the activity of PDH in energy-demanding proximal tubule cells (PTCs) in the kidneys and 2) the dysregulated mitochondrial metabolism causes cellular senescence, thereby contributing to kidney fibrosis.

Methods: Primary human renal proximal tubule epithelial cells (RPTECs) were cultured with cyclosporin A (CsA) or tacrolimus. Chronic CNI nephrotoxicity mouse model was created by feeding low-salt diet and administering 30 mg/kg/day CsA to ICR mice for up to 4 weeks.

Results: Single-nucleus RNA-seq showed that genes associated with oxidative phosphorylation were significantly downregulated in PTCs of chronic CNI mouse model compared to PTCs of its control mouse (FDR < 0.001, gene set enrichment analysis). CsA administration increased the ratio of KIM-1+ PTCs with an upregulated expression of genes associated with cellular senescence and TGF-β signaling. In primary human RPTECs cultured with CsA or tacrolimus, the amount of phosphorylated, inactivated PDH was increased, and PDH activity was decreased. Mitochondrial oxygen consumption was decreased in primary human RPTECs cultured with CsA or tacrolimus, and this decrease was ameliorated by lentiviral overexpression of PDP1, an endogenous phosphatase and activator of PDH. The level of senescence-associated β-galactosidase and senescence-associated gene expression was increased in primary human RPTECs cultured with CsA. Administering dichloroacetic acid, an activator of PDH, to chronic CNI nephrotoxicity mouse model alleviated the increase in both immunohistochemical staining of type I collagen in the kidneys and the upregulated expression of senescence-associated genes caused by CsA administration.

Conclusions: To our knowledge, this is the first study to show that CNIs disrupt energy metabolism by inactivating PDH in PTCs and that activating PDH ameliorates dysregulated energy metabolism as well as kidney fibrosis.

Renal Tubule-Specific Deletion of Aldosterone Synthase CYP11B2 Improves 2-Kidney, 1-Clip-Induced Ischemic Nephropathy, and Renovascular Hypertension in Mice

Ziwei Fu,[1,2] Changjiang Zou,[1,2] Tianxin Yang.[1,2] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT.*

Background: Although the intrarenal renin-angiotensin system (RAS) has been well established, evidence for intrarenal generation of aldosterone (Aldo) is scarce and therefore Aldo is often omitted in the intrarenal RAS. The co-expression of renin and its receptor (pro)renin receptor (PRR) in the collecting duct (CD) constitutes a key component of the intrarenal RAS.

Methods: In the present study, mice carrying inducible Pax8-rtTA-LC1-Cre were crossed with CYP11B2 floxed mice to generate a novel mouse model of renal tubules-specific deletion of CYP11B2 (RT CYP11B2 KO), born at the expected Mendelian ratio without noticeable developmental abnormalities. CD-specific deletion of PRR (CD PRR KO) or renin (CD renin KO), RT CYP11B2 KO mice and related floxed mice were subjected to sham or 2K1C procedure, followed by radiotelemetry analysis of blood pressure (BP), renal injury, and indices of the Aldo, as well as the expression of subunits of ENaC.

Results: Clipping-induced hypertension and renal injury were both attenuated in RT CYP11B2 KO mice as compared with floxed controls (MAP on day 24: Floxed/2K1C 151.2±4.9 mmHg vs. RT CYP11B2 KO/2K1C 135.3±3.6 mmHg, n=7, p < 0.05) (urinary albumin/creatinine:Floxed/2K1C69.7±4.8mg/gvs.RTCYP11B2KO/2K1C34.2±3.8mg/g, n=7, p < 0.01). Clipping-induced upregulation of renal fibronectin and α-SMA was blunted in RT CYP11B2 KO mice by 54% and 50%, respectively. Similarly, clipping induced paralleled increases in renal mRNA expression of IL-1β, TNF-α, MCP-1 and TGF-β1 were all blunted in RT CYP11B2 KO mice. The protective phenotype of RT CYP11B2 KO mice were paralleled with suppressed urinary Aldo level (urinary Aldo excretion: Floxed/2K1C 9.8±0.7 ng/24h vs. RT CYP11B2 KO/2K1C 2.2±0.3 ng/24h, n=7, p < 0.01). In contrast, clipping-induced enhancement of circulating Aldo remained unchanged between the genotypes. Moreover, renal medullary α-ENaC mRNA expression was elevated by clipping in floxed mice, which was blunted by 51% in RT CYP11B2 KO mice. CD PRR KO mice and CD renin KO mice exhibited similar improvements in renal injury and hypertension, which was paralleled with suppressed intrarenal Aldo levels.

Conclusions: Together, these results provide genetic evidence for pathogenic role of intrarenal Aldo in renovascular hypertension and ischemic nephropathy.

Cell-Specific Role of Platelet-Derived Growth Factor Subunit B (PDGF-B) in Kidney Fibrosis

Barbara M. Klinkhammer,[1] Eva M. Buhl,[2] Tim Caspers,[1] Dickson W. Wong,[1] Michaël Goedertier,[3] David Laurin Hölscher,[4] Roman D. Bülow,[1] Peter Boor.[1,2]
[1]Institute of Pathology, RWTH Aachen University Hospital, Aachen, Germany; [2]Electron Microscopy Facility, RWTH Aachen University Hospital, Aachen, Germany; [3]Institute for Computational Genomics, RWTH Aachen University Hospital, Aachen, Germany; [4]Division of Nephrology and Immunology, RWTH Aachen University Hospital, Aachen, Germany.

Background: Kidney fibrosis is a critical pathological process in progressive kidney diseases. Platelet-derived growth factor (PDGF) has been implicated in the development and progression of kidney fibrosis, yet the exact cellular origins remain unclear.

Methods: Three transgenic mouse lines were generated with cell-specific *Pdgfb* deletion in platelets, fibroblasts or epithelial cells. Spontaneous phenotypes were analyzed in young and aged male and female animals. Kidney fibrosis was induced by unilateral ureteral obstruction, ischemia-reperfusion injury or 0.2% adenine diet. Kidney function was analyzed by blood and urine analysis and perfused kidneys were investigated with histological, immunohistochemical, and immunofluorescence stainings, molecular biology and protein biochemical analyses.

Results: Mice with megakaryocyte- and platelet-specific *Pdgfb* deletion exhibited neither a spontaneous kidney phenotype nor altered fibrosis development in disease models, challenging the conventional understanding of fibrosis as wound healing, in which "platelet-derived" growth factors play a major role. PDGF-B, and its receptor PDGFR-β, are expressed by mesenchymal cells in the kidneys, and some studies suggested potential autocrine effects. Deletion of *Pdgfb* in mesenchymal cells had no effects on normal development, aging or disease model progression, suggesting negligible effects of autocrine signaling in the kidney. In contrast, mice with *Pdgfb* deletion in kidney tubular epithelial cells exhibited smaller kidneys with reduced interstitium, particularly in the medulla, without compromising overall development or physiological kidney function, even at advanced ages. Furthermore, in three distinct models featuring tubular injury from various causes, mice lacking *Pdgfb* in tubular cells displayed significantly reduced fibrosis. The diminished paracrine PDGF-B/PDGFR-β signaling between tubules and peritubular fibroblasts led to decreased activation and proliferation of peritubular PDGFR-β+ cells, ultimately altering the profibrotic niche in the interstitium.

Conclusions: Our findings unveil a PDGF-driven molecular mechanism of paracrine cellular crosstalk mediating the transition from tubular injury to interstitial fibrosis.

ADAMTS12 Promotes Fibrosis by Cleaving HMCN1, Enabling the Activation and Migration of Injury-Responsive Fibroblasts

Lars Koch,[1] Konrad Hoeft,[1] David Schumacher,[1] Ling Zhang,[1] Maria Tanzer,[2] Felix Schreibing,[1] Qingqing Long,[1] Barbara M. Klinkhammer,[3] Carla S. Schikarski,[1] Sidrah Maryam,[1] Sarah Krieg,[4] Fabian Peisker,[1] Gideon J. Schaefer,[1] Sylvia Menzel,[1] Benjamin D. Humphreys,[5] Peter Boor,[3] Rafael Kramann.[1,6] Dept of Medicine 2 (Nephrology, Rheumatology, Clinical Immunology, Hypertension), RWTH Aachen University. *[1]Department of Medicine 2 (Nephrology, Rheumatology, Clinical Immunology and Hypertension), RWTH Aachen University, Aachen, Germany; [2]The Walter and Eliza Hall Institute of Medical Research, Melbourne, VIC, Australia; [3]Department of Pathology, RWTH Aachen University, Aachen, Germany; [4]Institute of Biochemistry and Molecular Biology, RWTH Aachen University, Aachen, Germany; [5]Institute of Biochemistry and Molecular Biology, RWTH Aachen University, St. Louis, MO; [6]Department of Internal Medicine, Nephrology and Transplantation, Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Fibrosis is the uncontrolled replacement of parenchymal tissue with extracellular matrix (ECM) following tissue injury, which impairs organ function. Myofibroblast, which mainly originate from a small perivascular progenitor population marked by Gli1, are considered the major source of ECM deposition. Following injury, they proliferate, migrate to the interstitium, and differentiate into myofibroblasts.

Methods: We conducted genetic fate-tracing to analyze gene expression in Gli1+ cells after unilateral ureteral obstruction (UUO). *Adamts12*$^{-/-}$ and wild-type (WT) mice were subjected to UUO and myocardial infarction (MI) surgeries to assess fibrosis, ejection fraction, and spatial gene expression using 10X Visium spatial transcriptomics. *In vitro*, human renal PDGFRB+ fibroblast cell lines with CRISPR-mediated ADAMTS12 knockout (KO) and lentiviral overexpression of catalytically active and inactive ADAMTS12 were analyzed using bulk RNA sequencing and live-cell imaging. ECM expression of WT and ADAMTS12-KO fibroblasts was characterized by mass spectrometry. Digestion assays and siRNA knockdown assessed the interaction of ADAMTS12 and HMCN1.

Results: *Adamts12* was identified as top upregulated gene in Gli1+ fibroblast progenitor cells following UUO. In UUO and MI models, *Adamts12*$^{-/-}$ mice exhibited reduced fibrosis and preserved left ventricular ejection fraction post-MI. Spatial transcriptomics post-MI confirmed depletion of injury-response fibroblasts in *Adamts12*$^{-/-}$ mice. *In vitro*, PDGFRb+ fibroblasts expressing catalytically active ADAMTS12 showed a distinct injury-response fibroblast signature and increased migration-associated genes. Live-cell imaging confirmed accelerated cell migration by active ADAMTS12. Mass spectrometry revealed accumulation of HMCN1 in ADAMTS12-KO cell ECM. Digestion assays confirmed HMCN1 cleavage by ADAMTS12, a hitherto unknown ADAMTS12 substrate. Enhanced fibroblast migration with cleaved HMCN1 was validated by siRNA knockdown and live-cell imaging.

Conclusions: We identified ADAMTS12 as a critical checkpoint in fibrosis, that controls fibroblast migration and activation via cleavage of a hitherto unknown substrate, HMCN1.

CAPG as a Novel Therapeutic Target in Kidney Fibrosis via Transforming Growth Factor (TGF)-β Signaling by Mediating Smad4 and CBP Interaction in Fibroblasts

Sixiu Chen,[1] Meng Zhang,[1] Tao Zhang,[2] Joseph V. Bonventre,[3] Wei Chen.[1]
[1]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Sun Yat-sen University Zhongshan School of Medicine, Guangzhou, China; [3]Brigham and Women's Hospital, Boston, MA.

Background: Fibroblast-to-myofibroblast transition is a key event in renal fibrosis (RF). However, the mechanisms remain unclear. Using single-cell RNA sequencing (scRNA-seq) from a public dataset (GSE180420), we identified that elevated expression of CAPG, a member of the gelsolin family, is associated with fibroblast activation. This study aims to investigate the role and mechanism of CAPG in RF.

Methods: We generated *Capg* knockout (*Capg*$^{-/-}$) and heterozygous (*Capg*$^{+/-}$) mice and utilized folic acid (FA) and unilateral ischemia-reperfusion injury with contralateral nephrectomy (uIRIx) models. scRNA-seq was performed on the FA model. Renal fibroblasts (NRK-49F) were transfected with CAPG-siRNA and CAPG-overexpressing (CAPG-OE) lentivirus. CUT&Tag sequencing identified CAPG-regulated pathways while immunoblotting, immunofluorescence (IF), immunoprecipitation (IP), and chromatin immunoprecipitation (ChIP) were conducted for further analysis.

Results: CAPG expression was significantly elevated in CKD patient kidney tissues compared to healthy controls and correlated with the degree of fibrosis. CAPG levels progressively increased post-FA injection. CAPG deficiency significantly reduced renal fibrosis, as evidenced by histological analysis, and reduced expression of extracellular matrix (Figure 1). scRNA-seq revealed CAPG expression predominantly in fibroblasts in fibrotic kidneys, with IF confirming nuclear localization in fibroblasts. CUT&Tag sequencing indicated CAPG-binding genes are enriched in TGF-β signaling, sharing similar binding sites with Smad proteins. IP confirmed CAPG and CBP interactions with Smad4 in NRK-49F cells. Quantitative IP demonstrated TGF-β-induced interaction between Smad4 and CBP, which was inhibited by CAPG knockdown. ChIP confirmed co-localization of CAPG and Smad4 at *Col1a1* promoter region, with ChIP-qPCR showing increased CBP enrichment at *Col1a1* promoter in CAPG-OE cells compared to controls.

Conclusions: CAPG is upregulated following kidney injury and promotes the interaction between Smad4 and CBP, thereby activating the TGF-β pathway. This leads to fibroblast activation and progression of RF, suggesting CAPG as a potential therapeutic target for RF.

Targeting Long Noncoding RNA MALAT1 Preserves Endothelial Cell Integrity and Protects against Kidney Fibrosis

Qiao Zhao,[1] Loïs van der Pluijm,[1] Daniel Peled,[2] Juliette A. de Klerk,[1] Roderick Slieker,[1] Leen M. 't Hart,[1] Wendy Stam,[1] Jacques Duijs,[1] Angela Koudijs,[1] Joris I. Rotmans,[1] Anton J. Van Zonneveld,[1] Coen van Solingen,[2] Roel Bijkerk.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]NYU Langone Health, New York, NY.*

Background: Loss of integrity of the peritubular capillary network is directly associated with the development of kidney fibrosis and chronic kidney disease. Here, we aimed to identify long non-coding RNAs (lncRNAs) that could serve as a target to maintain vascular integrity and decrease kidney fibrosis.

Methods: We induced vascular injury and kidney fibrosis by ischemia-reperfusion injury (IRI) and unilateral ureteral obstruction (UUO) in VE-cadherin-ERT2;tdTomato mice to label and trace endothelial cells (ECs). Subsequently, we sorted Tomato-positive ECs by FACS and profiled for differentially expressed lncRNAs. We reprocessed transcriptomic datasets to assess kidney and circulating *MALAT1* levels in patients with kidney fibrosis.

Results: In IRI and UUO, we found 417 and 587 lncRNAs differentially expressed (>2-fold, $p<0.05$) in the VE-cadherin-derived tomato-positive ECs, respectively. We identified the conserved lncRNA *MALAT1* to be increased in ECs in both UUO (7.42-fold) and IRI (2.38 fold). Subsequent gapmer-mediated knockdown of *MALAT1* in the UUO model protected against the development of kidney fibrosis, as illustrated by a ~50% decrease in collagen deposition and a concomitant decrease in interstitial α-SMA positive cells. This protective effect was associated with an increase in capillary density and reduced endothelial to mesenchymal transition. Transcriptomic analysis of kidney ECs isolated using FACS from gapmer-*MALAT1* treated animals demonstrated that *MALAT1* knockdown increased ECM-receptor and cell-cell interaction. Indeed, using the microvessel-on-a-chip platform and transendothelial electric resistance assays, we demonstrated that silencing *MALAT1* resulted in increased barrier function, less vascular leakage and a decreased angiogenic response. In addition, *MALAT1* knockdown in ECs decreased focal adherens junctions and maintained normal VE-cadherin distribution. Lastly, we found both kidney and circulating *MALAT1* levels to be increased in patients with fibrotic kidney disease compared to healthy controls.

Conclusions: Taken together, we demonstrated that targeting *MALAT1* preserves endothelial cell function and kidney health and may provide novel strategies to counteract the development of fibrosis.

Repression of Frmd6 Expression by miR-17/-20a in the Renal Epithelium Mitigates Interstitial Fibrosis

Debora Malta C.S Santos,[1] Maliha Tayeb,[1] Andrew J. Bodnar,[1] Christopher L. O'Connor,[2] Huanqing Zhang,[2] Corynn Appolonia,[1] Brittney M. Rush,[1] Roderick J. Tan,[1,3] Arohan R. Subramanya,[1] David L. Turner,[2] Markus Bitzer,[2] Jacqueline Ho.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Michigan, Ann Arbor, MI; [3]Pittsburgh Center for Kidney Research, Pittsburgh, PA.*

Background: Chronic kidney disease (CKD) is characterized by a progressive decline in kidney function, and renal fibrosis is an essential part of the pathophysiological mechanism underlying disease progression. In this study, we investigated the role of the *miR-17~92* microRNA (miRNA) cluster in renal fibrosis. This cluster generates a single polycistronic primary transcript that yields six mature miRNAs (*miR-17*, *-18a*, *-19a*, *-19b*, *-20a*, and *-92a*).

Methods: Unilateral ureteral obstruction (UUO) and acute kidney injury (AKI) to CKD model were used as models of renal fibrosis. To investigate the potential role of *miR-17~92* as an anti-fibrotic molecule, genetic mouse models of inducible Pax8 lineage-specific deletion (*imiR-17~92*^{EpiLOF}) and gain-of-function (*imiR-17~92*^{EpiGOF}) of *miR-17~92* were generated. Protein expression was assessed by immunostaining in mouse kidneys and human nephrectomy samples from the PRECISE cohort, which includes patients with CKD stages 1 and 2. PAR-CLIP was performed in the human proximal tubular epithelial cell line HK2 treated or not with TGFβ1 to identify potential *miR-17~92* targets, which were then validated by dual luciferase reporter assays in HEK293 cells. HK2 cells were transfected with either an empty vector or a vector containing the *Frmd6 cDNA*.

Results: *miRs-17*, *-18a*, and *-20a* were upregulated in UUO and the AKI to CKD model. Interestingly, UUO-induced fibrosis was exacerbated in *imiR-17~92*^{EpiLOF} mice but ameliorated in *imiR-17~92*^{EpiGOF} mice. *Frmd6*, an activator of Hippo signaling, was identified as a novel *miR-17/-20a* target. Frmd6 was increased in the tubular epithelium of obstructed *imiR-17~92*^{EpiLOF} kidneys compared to controls. Furthermore, augmented Frmd6 was associated with regions of human nephrectomy samples with increased collagen III deposition. Finally, overexpression of Frmd6 in HK2 cells resulted in increased expression of the COPII secretory pathway component, Sec31, and was accompanied by elevated secretion of collagen III in conditioned media.

Conclusions: Together, our findings indicate that the epithelial-derived *miR-17~92* limits collagen deposition during renal fibrosis by regulating Frmd6 expression.

ACSM3 Protects Kidney Aging and Fibrosis by Cellular Senescence via Histone Acetylation

Yiting Wu,[1,2] Liang Ma,[1,2] Ping Fu.[1,2] *[1]Sichuan University, Chengdu, China; [2]Kidney Research Institute, Division of Nephrology, West China Hospital of Sichuan Univeristy, Chengdu, China.*

Background: Cellular senescence is associated with renal disease progression. Accelerated tubular cell senescence promotes the pathogenesis of renal fibrosis caused by natural aging and disease.

Methods: Proteomic analysis and IHC staining were made to show Acsm3 expression. Acsm3 KO and overexpressed(AAV) mice were performed UUO surgeries. Renal fibrosis was measured by qPCR and Western Blot. SA-β-gal staining and γH2AX IHC staining was used to check senescence. IF staining was to locate Acsm3.

Results: Cellular senescence happened in both elderly mice and UUO mice. Acsm3 is the No.1 increased protein in elderly mice via proteomic sequencing. ACSM3 was positively correlated with age and eGFR. The KO of Acsm3 could induce renal fibrosis with increased α-SMA etc. Senescence was increased with growth SA-β-gal and γH2AX. Overexpressing Acsm3 by AAV, the fibrosis and senescence became less. H3K27AC was the most significant histone modification among others. Locating ACSM3 in cell mitochondria, there was an ACSM3 nuclear translocation treated with TGF-β. Overexpression of ACSM3 can reduce acetyl-CoA in the nucleus.

Conclusions: Acsm3 may be a protector for renal fibrosis by inhibiting cellular senescence of tubular epithelial cells. The underlying mechanism may be the histone acetylation modification.

Transient DNA Damage in Proximal Tubules Accelerates Kidney Aging

Masanobu Takasu,[1] Seiji Kishi,[1] Yuhei Kirita,[2] Kengo Kidokoro,[1] Tamaki Sasaki,[1] Naoki Kashihara,[1] Motoshi Hayano.[3] *[1]Kawasaki Ika Daigaku, Kurashiki, Japan; [2]Kyoto-fu, Kyoto, Japan; [3]Keio Gijuku Daigaku, Minato-ku, Japan.*

Background: As global aging, it is crucial to investigate how aging impacts organ functions. CKD is increasingly prevalent among older populations. Research shows that kidney function gradually declines until age 40, after which the deterioration accelerates (J Am Geriatr Soc, 1985; Nephrol Dial Transplant, 2006). This underscores the role of aging in elevating kidney disease risk. However, the reasons behind the rapid decline in kidney function post-40 and the impact of early adult lifestyle choices on later kidney health remain unclear. Our previous studies with ICE (Inducible Changes in Epigenome) mice (Hayano et al, Cell, 2023), motivate this investigation into how DNA stress contributes to kidney aging.

Methods: We developed ICE mice by crossing I-PpoI$^{STOP/+}$ mice with Cre$^{ERT2/+}$ mice. The enzyme I-PpoI only causes DNA double-strand breaks during tamoxifen administration, which are repaired via the DNA damage repair pathway. We fed 4 to 6 month-old ICE mice a tamoxifen-enriched diet for three weeks and euthanized them at 14 months. We then conducted a thorough examination of their kidney function, including histology, snRNA sequencing, qPCR, and WB analysis.

Results: Histological evaluation showed no significant changes in interstitial fibrosis between ICE and control mice. However, snRNA sequencing revealed an increase in the proximal tubules of ICE mice expressing Kim-1 and Vcam-1, markers of failed repair. Increased expression of VCAM-1 at the protein level was also confirmed by WB and immunostaining. We also observed heightened expression of p21 and upregulation of the DNA repair gene Mgmt, indicating genomic instability and progressive cellular senescence in the proximal tubules. Assessments of whole kidneys showed no changes in mitochondrial number, and single-cell analysis indicated no significant differences in mitochondrial function.

Conclusions: Our findings suggest that even brief, transient DNA damage, though repaired, can have long-term effects on kidney health, particularly in the proximal tubules. These tubules exhibit signs of DNA instability and accelerated cellular senescence, which may increase their vulnerability to external damage. This vulnerability underscores the susceptibility of the proximal tubules to DNA damage and could explain the diminished recovery from acute kidney injury observed in older individuals.

TH-PO1093

Glycolysis-Induced Advanced Glycation End Products Promote Tubular Senescence and Maladaptive Kidney Repair after Ischemic Injury

Qingqing Wei,[1] Zheng Dong.[1,2] *[1]Augusta University Department of Cellular Biology and Anatomy, Augusta, GA; [2]Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.*

Background: Maladaptive kidney repair is accompanied by the metabolic switch to glycolysis. In our study, specific knockout of renal tubule PKM2 (PKM2-KO), a key enzyme in glycolysis, ameliorated maladaptive kidney repair after ischemic injury.

Methods: In PKM2-KO mouse kidneys, we observed higher levels of GSH, likely due to the metabolic flux shift to the pentose phosphate pathway (PPP), a branched pathway producing NADPH and GSH. One consequence of this metabolic shifting could be the neutralization of methylglyoxal (MG, a major by-product of glycolysis) by PPP-derived GSH. MG is a reactive carbonyl species, which binds to various biomolecules (e.g. proteins, nucleic acids, and lipids) to form advanced glycation endproducts (AGEs), causing cellular dysfunction such as senescence in renal tubular cells.

Results: Consistently, we found that senescence was significantly induced in kidneys after 30 minutes ischemia and 2 weeks of reperfusion, showing higher SA-b-Gal staining and P16 expression (senescence markers). Meanwhile, there was dramatic AGEs induction, as demonstrated by the immunoblots and immunohistochemical staining in kidneys. PKM2-KO significantly suppressed the induction of P16 and AGEs. In cultured renal proximal tubular cells, MG induced P16 and promoted the expression of fibronectin after TGF-b1 treatment. Furthermore, AG1, an activator of the key enzyme glucose 6 phosphate dehydrogenase in PPP, enhanced wound healing in a scratch wound model of cultured renal proximal tubular cells.

Conclusions: In conclusion, these data suggest that metabolic switch to glycolysis may induce MG/AGEs in proximal tubule cells, exacerbating the senescence to promote maladaptive kidney repair.

p38 Phosphorylation in Proximal Tubular Cells Induces Quiescence-to-Senescence Transition and Kidney Fibrosis

Yohei Iwashige,[1] Ryo Yamada,[1] Takuya Morinishi,[1] Koji Muro,[1] Shigenori Yamamoto,[1] Yasuhiro Yamada,[2] Motoko Yanagita.[1] *[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan; [2]Tokyo Daigaku, Bunkyo-ku, Japan.*

Background: Phosphorylation of p38 (p-p38) has been reported in kidney injury models and is known to induce cellular senescence *in vitro*. However, how p-p38 contributes to kidney injury has not been fully elucidated.

Methods: We established transgenic mice (PT-MKK6EE mice) and cell lines (MKK6EE HK-2) that can induce doxycycline (Dox)-induced constitutive p38 phosphorylation in proximal tubular cells (PTCs). The contribution of p-p38 in the induction of cellular senescence and fibrosis was examined in these mice and cell lines.

Results: Wild-type mice showed p-p38 expression in injured PTCs in ischemia-reperfusion (IR) and ureteral obstruction models. Ki67 expression was suppressed in p-p38 positive PTCs, suggesting a link between p-p38 and cell cycle arrest *in vivo*. In PT-MKK6EE mice, Dox treatment induced p38 phosphorylation in PTCs, where Cyclin D1 expression was completely suppressed and Kim-1 expression was strongly induced. When IR injury model was induced in PT-MKK6EE mice, Ki67-positive cells in PTCs was significantly decreased, supporting the hypothesis that p-p38 induces cell cycle arrest *in vivo*. Furthermore, after long-term observation without injury, a subpopulation of p-p38-induced PTCs exhibited cytoplasmic lysosomal accumulation and a pro-inflammatory phenotype, indicating a phenotype similar to cellular senescence. Additionally, αSMA-positive myofibroblasts appeared around p-p38-induced PTCs, suggesting that p-p38 in PTCs induces kidney fibrosis. In MKK6EE HK-2 cells, Dox treatment induced p38 phosphorylation and inhibited cell proliferation. At the same time, Dox treatment decreased Cyclin D1 expression and increased p21 and p27 expression, together with the reduction of Skp2, an E3 ligase of p21 and p27, consistent with cellular quiescence, known as the G0 phase. Long-term observations revealed cytoplasmic lysosomal accumulation and a pro-inflammatory phenotype in p-p38 induced cells *in vitro*.

Conclusions: We revealed a novel mechanism by which p-p38 induces G0 cell cycle arrest by increasing p21 and p27 expression and decreasing Skp2 expression *in vitro*. Furthermore, prolonged p-p38 expression induces quiescence-to-senescence transition both *in vivo* and *in vitro*. In addition, p-p38-induced senescent PTCs *in vivo* affect the surrounding microenvironment and induce kidney fibrosis.

TH-PO1095

TEAD1 Regulates Tubular Epithelial-Cell Dedifferentiation and Kidney Fibrosis

Melanie Tran, Baihai Jiao, Hao Du, Yanlin Wang. *University of Connecticut School of Medicine, Farmington, CT.*

Background: A prominent pathological feature of chronic kidney disease (CKD) is renal fibrosis, which is characterized by excessive accumulation of extracellular matrix (ECM). In fibrosis, tubular epithelial cells (TECs) undergo dedifferentiation leading to reduced expression of characteristic epithelial markers and increased expression of mesenchymal markers. Despite recent advances in our understanding of the mechanisms of renal fibrosis, the molecular mechanisms remain poorly understood. In this study, we examined the role of TEA domain family member 1 (TEAD1) in regulating TEC dedifferentiation during the development of CKD.

Methods: Cultured TECs were used to examine the role of TEAD1 in regulating TEC dedifferentiation, G2/M cycle arrest, and cellular senescence. Proximal tubule-specific TEAD1 knockout ($TEAD1^{PKO}$) mice were generated by crossing TEAD1 floxed mice with PEPCK-Cre mice. Ten-week-old male $TEAD1^{PKO}$ mice and $TEAD1^{f/f}$ ($TEAD1^{CON}$) mice were intraperitoneally injected with folic acid (250 mg/kg) or vehicle (0.3mM $NaHCO_3$) to induce renal fibrosis. Blood and kidneys were collected at 14 days for analysis of kidney function, TEC dedifferentiation, inflammation, fibroblast activation, collagen deposition and fibrosis.

Results: In cultured TECs, knockdown of TEAD1 using shRNA promoted TEC dedifferentiation and ECM protein production. Additionally, knockdown of TEAD1 markedly induced p-H3 and p21 levels indicating G2/M cycle arrest which was associated with increased senescence-associated β-galactosidase activity. In contrast, overexpression of TEAD1 prevented tubular cell dedifferentiation and ECM protein production, and markedly reduced p-H3 and p21 expression. *In vivo*, TEAD1 expression was significantly induced in kidneys of mice with folic acid injury. Following folic acid injury, $TEAD1^{PKO}$ mice exhibited kidney dysfunction as reflected by higher BUN levels compared with $TEAD1^{CON}$ mice. Moreover, $TEAD1^{PKO}$ mice had increased inflammatory cytokines, enhanced fibroblast activation and upregulated total collagen deposition and ECM proteins, which was associated with p-H3 and p21 induction compared with $TEAD1^{CON}$ mice.

Conclusions: Taken together, our results indicate that TEAD1 plays an important role in regulating TEC dedifferentiation and fibrosis. Therefore, targeting TEAD1 could represent a novel therapeutic approach for attenuating CKD progression.

TH-PO1096

ELF4 in NK Cells Is an Important Mediator of Fibroinflammation in Mice and Patients

Chenyu Li, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Inflammation plays a key role in tissue fibrosis. However, the pathways that orchestrate the inflammatory response are poorly understood. Using genome-wide comparative transcriptomics, we identified ELF4 as a conserved transcription factor upregulated in mouse kidney fibrosis models and human chronic kidney disease (CKD) samples.

Methods: We analyzed gene expression profiles of kidneys from five mouse fibrosis models and human CKD samples to identify conserved transcriptional regulators. The functional role of the identified transcription factor ELF4 was studied using genetic modified mice, single cell RNA-seq, chromatin immunoprecipitation and in vivo antibody mediated cell-depletion and cytokine neutralization.

Results: Overlap analysis of differentially expressed genes identified ELF4 as a conserved upregulated transcription factor in kidney fibrosis. Mice with genetic deletion of ELF4 were protected from folic acid induced kidney fibrosis, showing reduced collagen accumulation and expression of pro-fibrotic genes. Single cell RNA-seq and immunofluorescence indicated that ELF4 was primarily expressed by NK cells in the mouse kidney. ChIP-seq and scRNA-seq revealed that ELF4 directly regulates IFNG expression in NK cells. In vivo, loss of ELF4 reduced IFNG expression by NK cells and altered macrophage polarization in an IFNG dependent manner, which further confirmed by NK cell depletion and IFNG neutralization experiments. Antisense oligonucleotide mediated ELF4 knockdown also protected mice from kidney fibrosis, recapitulating the genetic deletion phenotype. Moreover, in vitro studies showed that ELF4 knock out macrophages had normal IFNG response, indicating an indirect regulation of macrophages by ELF4 in vivo.

Conclusions: We identified ELF4 as a conserved transcription factor induced in kidney fibrosis. ELF4 expressed by NK cells directly regulates IFNG expression and indirectly alters macrophage polarization and fibrogenesis. Inhibiting ELF4 expression might provide new therapeutic opportunities for kidney fibrosis.

Itaconate Serves as a Urinary Biomarker and an Inhibitor of Chronic Kidney Inflammation

Qian Yuan, Xie Yaru, Chun Zhang. *Huazhong University of Science and Technology Tongji Medical College Union Hospital, Wuhan, China.*

Background: Inflammation plays a pivotal role in the pathogenesis of chronic kidney diseases (CKD), serving as a predominant pathological alteration and a key driving force. The identification of a noninvasive biomarker for renal inflammation holds significant implications for elevating the progression of CKD. Notably, the correlation between phenotypes and metabolite levels surpasses that observed for proteins and genes, highlighting the growing attention towards exploring metabolites as biomarkers for human diseases. Therefore, this study aims to investigate noninvasive metabolic biomarkers of renal inflammation.

Methods: Metabonomics analysis was used to identify key differential metabolites in urine samples from CKD patients and healthy individuals. The correlation between urinary itaconate levels measured by LC-MS/MS and renal inflammation was investigated. Furthermore, the mechanism underlying the upregulation of itaconate was explored using single-cell sequencing, Western Blot, qRT-PCR, and ChIP assays. To explore the role of itaconate in the progression of CKD, *IRG1* global knockout mice and macrophage specific *IRG1* deletion mice were generated, and were subjected to bilateral ischemia reperfusion (bIRI) surgery.

Results: Through metabonomics and LC-MS/MS analysis, we found that urinary itaconate was elevated in patients and mice with CKD, and positively correlated to renal inflammation and the decline of renal function. Mechanistically, the IL-1β signaling pathway activates the transcription factor AP-1, thereby upregulating the expression of IRG1, which encodes the enzyme responsible for catalyzing itaconate production through direct binding to its promoter in macrophages. Furthermore, renal cytokines and alternative M2 macrophages accumulation, as well as the development of renal fibrosis induced by bIRI were aggravated by global *Irg1* knockout and macrophage specific *Irg1* knockout.

Conclusions: Our findings not only provide a noninvasive biomarker of chronic renal inflammation but also elucidate the role and mechanism of itaconate in CKD.

Identification of Gut Microbiota Involved in the Production of Uremic Toxins in Patients with CKD

Takafumi Toyohara,[1] Shun Watanabe,[1] Koichi Kikuchi,[1] Takehiro Suzuki,[1] Tetsuhiro Tanaka,[1] Takaaki Abe.[1,2] *[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Tohoku University Graduate School of Biomedical Engineering, Sendai, Japan.*

Background: Modulating the gut microbiota is a promising therapeutic strategy for chronic kidney disease (CKD) because uremic toxins derived from gut microbiota accumulate in CKD patients and worsen their prognosis. However, the specific gut bacterial species involved in the production of uremic toxins in CKD patients have not been sufficiently elucidated. This study aimed to identify gut bacteria that either produce or inhibit uremic toxins.

Methods: Serum levels of gut microbiota-derived uremic toxins (Indoxyl sulfate (IS), Phenyl sulfate (PS), *p*-Cresyl sulfate (*p*CS), trimethylamine N-oxide (TMAO)) were measured in 101 CKD patients attending Tohoku University Hospital. Additionally, the gut microbiota composition was analyzed by 16S rRNA gene sequencing. Multiple regression analysis was conducted with the uremic toxins as dependent variables and bacterial composition and eGFR as explanatory variables to identify significant bacteria independent of kidney function as a confounder.

Results: Analysis of patient stool samples identified 585 bacterial species at the genus level. Multiple regression analysis revealed significant correlations between uremic toxins and gut microbiota in 21 combinations. Notably, two species showed a strong positive correlation with *p*CS, and two showed a strong negative correlation. At the species level, *Clostridium fessum*, *Veillonella parvula*, and *Enterocloster bolteae* were negatively correlated with *p*CS. When these three species were administered to adenine-induced renal failure mice, only *Veillonella parvula* significantly reduced *p*CS levels ($P = 0.0079$).

Conclusions: This study identified bacterial species correlated with blood *p*CS levels in renal failure patients. Among these species, *Veillonella parvula* significantly reduced the *p*CS level in a renal failure mouse model. These findings suggest that modulating specific bacterial species could lead to new therapeutic strategies for CKD, improving patient outcomes through gut microbiota or dietary intervention.

Small Molecule Inhibitor of Gut Microbial Choline Trimethylamine Lyase Reduces Serum Trimethylamine N-oxide and Slows the Loss of Kidney Function in a Rat Model of CKD

Jerry Buysse, Jun Shao, Robert Matunas, Camilla V. Simpson.
Zehna Therapeutics, Inc., Los Altos, CA.

Background: Gut microbial choline trimethylamine (TMA) lyase (CutC) plays a key role in the formation of TMA, a precursor of trimethylamine *N*-oxide (TMAO) that is both a cause and driver of CKD. Here we describe the pharmacological effects of small molecule CutC inhibitor ZTx102 on serum TMAO level and kidney function in an adenine-induced rat model of CKD.

Methods: CKD was induced and maintained in rats by adding 0.25% adenine to a standard chow diet supplemented with 0.5% choline in the drinking water. The small molecule CutC inhibitor, ZTx102, an orally administered colon directed formulation, was administered at doses of 1.25 and 12.5 mg/kg of body weight, once a day, during the maintenance phase. The controls received matching placebo, once a day. Serum TMAO was quantified using LC-MS/MS. Kidney function was assessed by serum levels of creatinine and eGFR.

Results: Adenine and choline supplementation increased serum levels of TMAO and creatinine in rats. Oral administration of ZTx102 as a colon directed formulation resulted in rapid and sustained reduction of serum TMAO to the normal range during the maintenance phase of the study. ZTx102 significantly reduced serum levels of creatinine (0.8 mg/dL in 12.5 mg/kg ZTx102 vs. 1.5 mg/dL in placebo; P<0.001). ZTx102 significantly slowed eGFR decline (0.96 mL/min in 12.5 mg/kg ZTx102 vs. 0.64 mL/min in placebo; P<0.05). In addition, ZTx102 reduced serum N-terminal prohormone of brain natriuretic peptide (5.6 pg/mL in 12.5 mg/kg ZTx102 vs. 112.2 pg/mL in placebo; P<0.0001), a biomarker of myocardial stress and early heart failure.

Conclusions: The small molecule CutC inhibitor ZTx102 is effective in normalizing elevated serum levels of TMAO and slowing the loss of kidney function in a rat model of CKD when administered as a colon directed formulation. Reduction of serum TMAO level by the CutC inhibitor ZTx102 may provide a potential new approach to slow disease progression in persons with CKD.

Depletion of the Gut Microbiota Modulates Metabolome and Immune Profiles in Experimental CKD

Alex Yarritu,[1] Wibke Anders,[1] Sakshi Kamboj,[2] Sara A. Hassan,[1] Carina Hoffmann,[1] Ariana Rauch,[1] Franziska Fuckert,[1] Johannes Holle,[1] Hendrik Bartolomaeus,[1] Wolfram Gronwald,[2] Nicola Wilck.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Universitat Regensburg, Regensburg, Germany.*

Background: Chronic Kidney Disease (CKD) disrupts the gut microbiome, leading to the production of uremic toxins that impaired kidneys fail to excrete. These toxins potentially increase immune cell activation and senescence, promoting chronic inflammation and exacerbating CKD progression. The exact mechanisms by which gut-derived uremic toxins modulate these alterations remain poorly understood. We hypothesize that microbiome depletion reduces uremic toxin accumulation and immune activation, thereby slowing CKD progression.

Methods: Experimental CKD was induced in 129Sv mice by 5/6 nephrectomy (STNx). Mice were given a non-absorptive antibiotic (Abx) cocktail in drinking water for microbiota depletion or control (Ctrl) throughout the 13-week study period. Plasma, feces, and urine were collected longitudinally to explore metabolite dynamics and CKD progression using untargeted Nuclear Magnetic Resonance (NMR), followed by a targeted approach.

Results: Measurement of 16S gene abundance confirmed the suppression of intestinal microbial load in Abx groups. 16S sequencing of fecal samples showed alterations of bacterial taxa by STNx, with some taxa being reminiscent of human CKD. Abx-STNx mice showed improved kidney function compared to STNx (FITC-sinistrin GFR 113.2 ± 57.21 µl/min vs. 53.32 ± 41.05 µl/min; p = 0.0028). Abx-STNx mice exhibited reduced systemic inflammation, with lower plasma C-reactive protein levels (56.88 ± 16.21 µg/L vs. 78.57 ± 16.57 µg/L; p = 0.0024). Untargeted NMR analysis identified a unique metabolite profile, with higher accumulation of 36.8% the detected metabolome in STNx (p = 0.05) compared to only 18.2% in Abx-STNx (p = 0.05), suggetsing that half of the metabolite accumulation in CKD is microbiome-dependent. To further explore the mechanistic link between metabolite accumulation and inflammation, we assessed the aryl hydrocarbon receptor (AhR)-activating potential. Moreover, organ-specific (blood, spleen, heart, intestine) immune cell composition was analyzed.

Conclusions: Microbiome depletion in experimental CKD improves kidney function. Abx impacted plasma metabolite profiles, leading to reduced inflammation. These proof-of-concept experiments underscore the microbiome as treatment target for in CKD.

Proximal Tubular Function Is Independent of Glomerular Filtration Rate

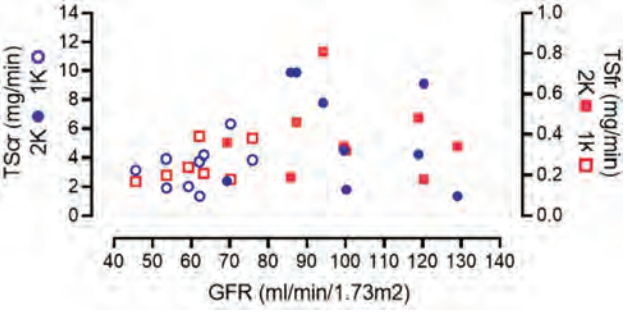
Magdalena Madero,[1] Ana K. Fernandez Yepez,[1] Guadalupe M. Montesinos Ojeda,[1] Alan J. Guzmán Portillo,[1] Aurora I. Estrada Escamilla,[1] Francisco Perez Allende Perez,[1] Bernardo Rodriguez-Iturbe.[1,2] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Ciudad de Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: Tubular function is not routinely evaluated in kidney donors in the assumption that glomerular filtration rate (GFR) offers adequate representation of overall kidney health

Methods: We studied in kidney donors the response of cationic organic transporters (COT) with an oral dose of 5g of creatinine (cr) and anionic organic transporters (AOT) with an intravenous dose of 1mg/kg of furosemide (fr). Previous studies had shown that these doses resulted in maximal stimulation of CAT and AOT, respectively, without significant changes in GFR. Studies were done in 10 kidney donors (age 20-51 years; 3 females) before (2 kidneys or 2K) and 3 months after nephrectomy (1 kidney or 1K). GFR (iohexol), serum and urine cr (autoanalyzer) and urinary fr (HPLC) concentrations were determined in hourly blood and urine collections obtained 5 hours after the administration of cr and fr. Water diuresis was maintained during the studies and complete bladder emptying was determined by ultrasound. Tubular secretion of cr (TScr) was estimated as the subtraction of filtered creatinine (GFR x serum cr) from the urinary creatinine excretion (Ucr x Uvolume) and tubular secretion of furosemide (TSfr) = Ufr x Uvol. Data given are mean±95%CI

Results: First hour TScr and TSfr in the first hour (2K-TScr= 5.47±2.57 mg/min; 2K-TSfr= 0.39±0.123 mg/min) were 3-4 fold higher (p<0.01) than in subsequent hours when they remained essentially stable. The 1K responses were lower than the 2K responses, but also maximal in the first hour, (1K-TScr 3.38±0.981; 1K-TSfr 0.25±0.068) and stable afterwards. As There were no correlations between TScr or TSfr with the GFR in 2K or 1K studies (Figure 1) and no consistent changes between 2K and 1K studies in the relation between GFR and TScr or TSfr

Conclusions: The data show that stimulated functional responses of OCT and OAT in kidney donors, neither pre nor post-nephrectomy, are related to GFR and deserve evaluation of their prognostic relevance.



TH-PO1102

Cell Cycle Arrest and CCN2 Expression in Proximal Tubular Epithelial Cells in a Mouse CKD Model

Wakako Kosakai,[1] Tetsuya Sato,[2] Tsutomu Inoue,[1] Daichi Fukaya,[1] Hiroaki Amano,[1] Hirokazu Okada.[1] *[1]Saitama Ika Daigaku, Iruma-gun, Japan; [2]Saitama Ika Daigaku, Hidaka-shi, Japan.*

Background: Proximal tubular epithelial cells (PTECs) enter the M phase in response to injury, after which a subset of the cells undergo G2/M arrest and acquire a pro-fibrotic phenotype (PFP), expressing CCN2 and TGF-β. Alternatively, other reports indicate G1/S arrest resulting in a PFP. To investigate the relationship between the cell cycle of PTECs and the PFP, we used a unilateral renal ischemia-reperfusion injury (IRI) model.

Methods: We reanalyzed the publicly available data for scRNA-seq from IRI, extracting only the PTEC data (cont. 7,315 cells; IRI 1, 3, 14 days; 2,689 cells: Nat. Commun. 13 (1): 4018). Furthermore, we performed studies in IRI model established using F1 mice generated by crossing Fucci2aR mice with γ-glutamyltransferase-Cre mice, allowing visualization of the cell cycle by fluorescence (G1 = Cherry, S/G2/M = mVenus). We also used cultured renal tubular epithelial cells (HK-2 cells).

Results: Reanalysis of scRNA-seq data revealed that the proportion of PTECs in the G2/M phase in fibrotic kidneys was similar to that in normal kidneys, with a minor increase in the acute phase (10.3% normal vs. 12.2% at 3 days, 8.7% at 14 days post-fibrosis). In F1 mice, mVenus-positive cells increased sharply after IRI, but declined from a peak at 3 days (2.3 ± 2.1%) to less than 1% by day 7 (0.8 ± 1.1%) with no further increase observed, despite progressive fibrosis. Mimicking IRI in HK-2 cells by transiently inducing G1/G0 arrest via a hypoxia/glucose-free medium followed by re-oxygenation and the addition of growth media led to transient cyclin-dependent kinase 1 upregulation and progression into the S/G2 phase. However, as the cell density increased,

p21/p27 expression increased, with the proportion of G1/G0 PTECs increasing again by 72 h. These re-arrested G1/G0 cells exhibited increased TGF-β and CCN2 expression. Higher cell densities tended to further enhance CCN2 expression.

Conclusions: While G2/M arrest has been highlighted in the PFP, our findings suggest that G1/G0-arrested PTECs can also acquire this phenotype. In injured kidneys, the proportion of G1/G0-arrested PTECs exceeded that observed in the G2/M phase. Although the importance of PTECs in chronic kidney disease progression is undisputed, further studies should consider cells in all cell cycle states rather than limiting their focus to particular phases.

Inhibition of Hyaluronan Synthesis or Hyaluronan-CD44 Interaction Attenuates Kidney Inflammation and Fibrosis in NZB/W F1 Mice

Tak Mao D. Chan, Cheuk Yin Wong, Yuesong Xu, Susan Yung. *Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong, Hong Kong.*

Background: Lupus nephritis (LN) is characterized by immune-mediated kidney injury, and it is an important cause of acute kidney injury and chronic kidney disease. Hyaluronan (HA) is a non-sulfated glycosaminoglycan implicated in tissue inflammation and fibrosis through binding to its cell surface receptor, CD44. We previously demonstrated that in patients with LN the circulating HA level correlated with the severity of chronic kidney damage as demonstrated in kidney biopsies. This study investigated the effect of 4-methylumbelliferone (4-MU), a specific inhibitor of HA synthesis, and anti-CD44 antibody, on disease manifestations and kidney fibrosis in an animal LN model of NZB/W F1 mice.

Methods: HA expression was investigated in female NZB/W F1 mice showing proteinuria. In the first study, mice were randomized to receive either vehicle (Arabic Gum) or 4-MU in Arabic Gum for 12 weeks. In the second study, mice were randomized to receive either anti-CD44 antibody or Control IgG for 4 weeks and parameters related to kidney inflammation and fibrosis were assessed in both studies.

Results: As disease progressed, mice treated with Arabic Gum or Control IgG showed glomerulosclerosis and neighboring glomerular hypertrophy, tubular dilation with flattening of epithelial cells, tubular protein casts and periglomerular and tubulo-interstitial mononuclear cell infiltration that included $CD3^+$ and $CD4^+$ T cells, $CD19^+$ B cells and macrophages. Also, HA expression increased in the interstitium and periglomerular area, accompanied by increased CD44, TGF-β1, IL-1β, MCP-1, α-smooth muscle actin, fibronectin, collagen, VCAM-1, and NGAL expression. Treatment of mice with either 4-MU or anti-CD44 antibody preserved normal kidney histological structure, which was associated with reduced expression of mediators of tubulo-interstitial fibrosis and mononuclear inflammatory cell infiltration.

Conclusions: The findings suggest that HA plays a key role in the pathogenesis of inflammation and fibrosis in LN, and suppression of HA synthesis or its interaction with CD44 may have therapeutic implications.

TH-PO1104

Inhibition of Hyaluronan Synthesis Attenuates Tubulointerstitial Inflammation and Fibrosis in Murine Unilateral Ureteral Obstruction Model of CKD

Yuesong Xu, Susan Yung, Tak Mao D. Chan. *Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong SAR, Hong Kong.*

Background: Chronic kidney disease (CKD) is a major global issue resulting in considerable morbidity and mortality. Irrespective of the primary etiology, tubulo-interstitial fibrosis is the predominant pathogenic process in CKD progression to end-stage kidney disease, but the underlying mechanism remains obscure. Hyaluronan (HA) is a ubiquitous component of the extracellular matrix and is implicated in tissue inflammation and fibrosis. HA is synthesized by three enzymes, namely HA synthase (HAS), I, II and III. We investigated the roles of HAS I, II and III in tubulo-interstitial inflammation and fibrosis in a murine model of unilateral ureteral obstruction (UUO).

Methods: UUO or Sham operation (Control group) was performed on 10-week old male wild-type (WT) and HAS I, III or I/III knockout (KO) mice, and sacrificed 14 days after UUO and the kidneys were harvested to investigate histopathology and expression of mediators relating to inflammation, fibrosis and tubular injury.

Results: Compared to WT Sham mice, WT mice with UUO showed increased tubulo-interstitial HA expression, and HAS I, II and III gene expression was increased by 360.70±82.95-fold, 91.91±14.6-fold and 3.96±0.37-fold respectively (p = 0.0020, <0.0001 and 0.0022 respectively). Increased HA expression was accompanied by tubular atrophy, immune cell infiltration, and increased expression of KIM-1, TNF-α, CCL-2, α-smooth muscle actin, fibronectin and collagen III (p<0.05, for all). HAS I, III and I/III KO mice with UUO showed reduced immune cell infiltration, tubular atrophy and mediators of renal tubular injury, inflammation and fibrosis, and reduced HA expression, compared to WT UUO mice. HAS I KO was associated with more marked reduction in the expression of inflammatory and fibrotic mediators.

Conclusions: Our findings suggest that HA and HAS I, II, and III may have distinct roles in mediating tubulo-interstitial inflammation and fibrosis in murine UUO CKD model.

TH-PO1105

TGFBR1 Inhibition Attenuates Expansion of Maladaptive Tubule Cells and Ameliorates Kidney Function Decline in the Adenine Nephropathy Mouse Model of CKD

Shawn S. Badal,[1] Jay Kuo,[1] Seamus Ragan,[1] Mark McConnell,[1] Reza Amirzadeh,[1] Mariam O. Oyinlola,[1] Charles Nieh,[1] Ralph Gruber,[3] Johannes Nordlohne,[2] Tobias Bohnenpoll,[2] N. Eric Olson.[1] *[1]Chinook Therapeutics Canada Inc, Vancouver, BC, Canada; [2]Evotec SE, Hamburg, Germany; [3]Novartis AG, Basel, Switzerland.*

Background: CKD is increasing worldwide and there is an urgent need for new therapies designed against molecular endotypes of CKD. Recently, a distinct population of maladaptive tubule (MT) cells with a unique molecular phenotype have been linked to more rapid ESRD progression and fibrosis, inflammation and tissue injury in CKD. Here, we characterize an in vivo model of renal impairment and evaluate if inhibition of TGF-β1 signaling attenuates MT cell accumulation, fibrosis, and renal function loss.

Methods: CD1 mice were randomized to control, 0.15% adenine diet or adenine diet with ALK5 inhibitor (ALK5i, SB-525334) equivalent to 60mg/kg in chow. Mice were sacrificed 4 weeks after diet initiation for endpoint analysis. Plasma and serum were collected for creatinine and blood urea nitrogen (BUN) analysis. Kidneys were harvested for assessment of fibrosis (PSR), tubular atrophy (LTL), MT marker (VCAM1) and tubular injury (PAS). Nuclei extracted from flash frozen kidneys were fixed, and barcoded libraries were prepared for single nucleus RNA-Seq.

Results: Creatinine (0.30±0.03 vs. 0.20±.01 mg/dL, p<0.05) and BUN (46.6±8.9 vs. 28.3±5.4, p<0.001) were elevated in adenine and attenuated in ALK5i animals. PSR stain (28.3±5.49 vs 4.5±2.08 %, p<0.0001) and tubular injury (20.7±3.9 vs 9.1±4.0 a.u., p<0.0001) increased following adenine diet and attenuated in ALK5i group. LTL+/VCAM1- (healthy PT), decreased in adenine diet and restored following ALK5i inhibition (13.8±6.0 vs 29.8±5.6 %, p<0.0001). LTL-/VCAM+ cells (MT cells), increased in adenine diet, and decreased after ALK5 inhibition (32.9±4.4 vs 19.3±4.5 %, p<0.0001). snRNA-Seq revealed significant expansion of MT cells with adenine diet and failed repair cells were dominant in the adenine samples compared to control (33% FR vs 0.9% FR).

Conclusions: Inhibition of TGF-β1 pathway attenuates MT cell accumulation in adenine model determined by sn-RNA-Seq and tubular staining for VCAM1 and LTL. ALK5i prevented adenine-induced tubular injury and atrophy, reduced fibrosis and kidney function loss. This study confirms induction of MT cells in the adenine model and as proof of concept that pharmacological intervention can impact accumulation of MT cells in a model of CKD.

TH-PO1106

Histone Demethylase Inhibitor, GSK-J4, Suppresses Tubulointerstitial Fibrosis in CKD

Imari Mimura, Fumiaki Tanemoto, Masaomi Nangaku. *Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan.*

Background: Epigenetic modifications including histone modifications in the kidney have recently been reported to contribute to the progression of renal fibrosis. We have previously reported that one of histone modification inhibitors suppressed renal fibrosis by decreasing open chromatin region. Another histone modifier inhibitor, GSK-J4, is known to inhibit KDM6b (lysine demethylase 6b) which demethylates H3K27me3, resulting in the increase in H3K27me3, a repressive mark of histone modification. We investigated how GSK-J4 affected renal fibrosis.

Methods: We performed in vitro experiments using normal rat kidney interstitial fibroblast cells (NRK49F) stimulated by transforming growth factor-beta (TGF-β) with or without exposure to GSK-J4. To identify the downstream target genes of GSK-J4, we performed comprehensive RNA-seq under normal condition and TGF-β stimulation with and without GSK-J4. In addition, we also performed RNA-seq using siRNA of KDM6b to identify the downstream targets of KDM6b because GSK-J4 inhibited KDM6b.

Results: We confirmed that fibrosis-promoting genes including Ccn2 (cellular communication network factor2), also known as Ctgf (connective tissue growth factor), were inhibited by GSK-J4 in NRK49F under TGF-β stimulation. As a result of RNA-seq, we identified 113 downstream target genes of GSK-J4 that were upregulated by TGF-β and downregulated by GSK-J4. After siRNA knockdown of KDM6b with TGF-β stimulation, we identified 26 genes whose expression was upregulated by TGF-β but downregulated by knockdown of KDM6b. We compared the downstream genes of GSK-J4 to those with siRNA of KDM6b, and we identified seven genes commonly. Among them, Acta2 (alpha SMA; alpha smooth muscle actin), a fibrotic marker whose expression increases as renal

fibrosis progresses, was suppressed by GSK-J4 treatment, which prevented KDM6b from demethylating H3K27me3 and increases H3K27me3, resulting in the reduction of renal fibrosis.

Conclusions: GSK-J4 inhibited renal fibrosis by modulating H3K27me3 via KDM6b on fibrosis-related genes including Acta2. It is important to elucidate the epigenetic molecular mechanisms that accompany the progression of renal fibrosis, as this will lead to the discovery of new therapeutic targets in CKD.

TH-PO1107

Characterization of the Mouse Adenine Nephropathy Model: Kidney Proteomic Profiling

Srinath Jagarlapudi, Simone Romoli, Chang J. Zou, Rose A. Keenan, Charles Halsey, Jeffrey A. Culver, Jeffrey Morin, Dinesh K. Hirenallur-Shanthappa, Denis Feliers. *Pfizer Cambridge, Cambridge, MA*.

Background: Most models of chronic kidney disease in mice do not show a robust inflammation/fibrosis response. In this study, we sought renal injury and function in mice fed an adenine-rich diet.

Methods: Ten weeks-old C57Bl/6 mice were fed an adenine-rich diet (0.15%) for 6 weeks. Noninvasive renal oxygen content, renal stiffness and transcutaneous glomerular filtration rate (GFR) were determined at the end of the experiment. Tubular integrity was measured using the furosemide test and correlated with histology and expression of tubular injury biomarkers. The remaining kidneys were harvested, and proteomics analysis was performed on the cortical fraction.

Results: In adenine-fed mice, we observed a progressive reduction in GFR, which reached ~30% of the initial value at 6 weeks. Renal oxygenation was reduced, and renal stiffness was increased in the adenine-fed mice. Histology showed a significant increase in tubular degeneration, inflammation and fibrosis, the latter correlating well with renal stiffness. Adenine-fed mice had an impaired response to furosemide, suggesting a disruption of tubular integrity. Nephron segment-specific injury marker analysis showed that the proximal tubules, cortical thick limb of the loop of Henle and distal tubules were injured in this model. Proteomic analysis showed a massive increase in pathways associated with extracellular matrix expansion, inflammation and complement cascade, while pathways associated with TCA cycle and respiration, transport activity, amino acid metabolism and peroxisomal lipid metabolism were downregulated.

Conclusions: An adenine-rich diet causes a progressive loss of renal function that is associated with a significant increase in tubular injury, fibrosis and inflammation, and a reduction in tubular transport activity and energy metabolism. Therefore, adenine causes chronic renal failure in mice, which manifests as progressive renal insufficiency and metabolic abnormalities that are similar to those seen in patients with chronic kidney disease.

TH-PO1108

Adenine-Induced Mouse Model of CKD Shows Rapid Development of Impaired Kidney Function, Anaemia, Muscle Wasting, and Persistent Kidney Fibrosis following Diet Reversal

Maria K. Ougaard, Frederikke E. Sembach, Michael Christensen. *Gubra, Hørsholm, Denmark.*

Background: Translational rodent models are essential to identify more efficacious treatment options for patients with chronic kidney disease (CKD). However, most preclinical CKD models do not demonstrate impaired kidney function as determined by decreased glomerular filtration rate (GFR). Here, we characterized the adenine diet-induced (ADI) mouse model of CKD for functional, biochemical and histological hallmarks of CKD.

Methods: Male C57BL/6j mice (11 wks. old) were randomized into study groups (n=8-10/group) based on body weight. ADI mice received a control (ctrl) diet from study day -2 and a CKD-inducing diet 0.2% adenine for up to 5 weeks, while control mice received a ctrl diet served as healthy controls (CTRL mice). All groups received oral vehicle dosing once daily from day 1 until termination. Transdermal GFR (tGFR), urine albumin-to-creatinine ratio (uACR), and plasma cystatin C (pCyC) were evaluated at week 3 and 5. Blood was collected for haemoglobin analysis, and gastrocnemius muscle and kidney tissue were sampled and weighed. Kidneys were processed for histological evaluation of markers of macrophage infiltration (F4/80) and fibrosis (Col1a1). In parallel study, ADI mice (3 weeks on ADI diet) were switched to control diet for 2 weeks (diet reversal) to test for spontaneous regression of kidney biomarker and histological changes (uACR, pCyC, F4/80, Col1a1).

Results: Compared to controls, ADI mice showed a significant tGFR decline correlating with increased pCyC levels and marked albuminuria at 3 and 5 weeks after adenine diet-induction. At termination, ADI mice showed significantly decreased haemoglobin and gastrocnemius muscle weight compared to CTRL mice. Furthermore, Quantitative histomorphometric analyses revealed development of renal fibrosis and macrophage infiltration in ADI mice. While diet reversal improved uACR, pCyC, renal fibrosis and macrophage infiltration remained significantly increased in ADI mice.

Conclusions: ADI mice rapidly develop functional, biochemical, and histological hallmarks of CKD complicated by anaemia and muscle wasting. Collectively, the ADI mouse model is highly applicable in preclinical target and drug discovery for CKD.

Cluster of Differentiation-14 Contributes to Tubulointerstitial Inflammation in a Murine Model of CKD

Vivian Wei, Jing Yu. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong*.

Background: Chronic kidney disease (CKD) is characterized by progressive tubulo-interstitial fibrosis and tubular atrophy leading to irreversible deterioration of kidney function. Low-grade persistent inflammation drives CKD progression, but the underlying mechanism remains obscure. CD14 is a GPI-anchored glycoprotein that is predominantly expressed on myeloid cells. Secretion of pro-inflammatory cytokines by macrophages is CD14-dependent. We previously demonstrated that CD14 expression was increased in proximal tubular epithelial cells (PTEC) and interstitium in kidney biopsies of patients with CKD. This study investigated the role of CD14 in kidney inflammation in a murine model of CKD.

Methods: CKD was induced in male wild-type (WT) and CD14 knockout (KO) mice by feeding with casein-based chow containing 0.2% adenine for 8 weeks, after which time kidneys were harvested to assess the expression of mediators of inflammation and kidney injury. Mice fed casein-based chow served as non-CKD controls. The role of CD14 in inflammatory processes was investigated in HK-2 cells that either overexpressed CD14 or were deficient in CD14 expression.

Results: CD14 gene expression increased by 17.66 ± 5.64-fold in WT CKD mice compared to non-CKD WT mice, and was predominantly localized to PTEC and the interstitium. Increased CD14 expression was accompanied by proteinuria and increased mediators of inflammation and tubular injury including IL-6, TNF-α, MCP-1, TGF-β1, NGAL and KIM-1. CD14 KO mice with CKD showed significantly reduced expression of pro-inflammatory and pro-fibrotic cytokines and markers of tubular injury, accompanied by reduced proteinuria ($p<0.05$, for all). HK-2 cells overexpressing CD14 showed increased IL-6, IL-8 and MCP-1 secretion compared to non-transfected cells, and LPS stimulation further augmented cytokine secretion. CD14-deficient HK-2 cells showed significantly reduced IL-6, IL-8 and MCP-1 secretion compared to non-transfected cells.

Conclusions: Our data suggest that CD14 contributes to tubulo-interstitial inflammation in murine adenine-induced CKD and may regulate pro-inflammatory cytokine secretion in PTEC.

Single-Nucleus RNA Sequencing of AKI to CKD Transition: Novel Perspectives on Leptospirosis Kidney Disease

Yuehan Lu,[1,3] Li-Fang Chou,[1,2] Huang-Yu Yang,[1,3] Chih-Wei Yang.[1,3]
[1]Kidney Research Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Graduate Institute of Biomedical Sciences, Department of Microbiology and Immunology, Department of Biochemistry, Chang Gung University, Taoyuan, Taiwan; [3]Department of Nephrology, Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Background: Leptospirosis is a widespread zoonotic disease. Prior cohort studies highlight that acute *Leptospira* infection leads to chronic kidney disease(CKD). This study investigates the transition from acute kidney injury (AKI) to CKD due to *Leptospira* infection.

Methods: 1. Mouse model for leptospiral kidney disease. 2.Transcriptome-wide changes and single-nucleus RNA sequencing(snRNA-seq) in infected kidneys.

Results: The study examined the pathogenic mechanisms from acute to chronic phases during leptospirosis progression. Infected mice showed kidney injury and bacterial adherence to the renal tubules by day 28 post-infection. Renal pathology revealed tubular degeneration, inflammation, and fibrosis characteristic of CKD. Transcriptome profiling identified 714 and 1089 differentially expressed genes at days 7 and 28 postinfection, respectively, which enriched in pathways related to cell activation and innate immune response. Hierarchical clustering identified immune-related genes like *LBP*, *FCGR1*, *SYK*, *IL33*, *COLLA1*, *IRF7*, *NCF1*, and *TLR2*, highlighting roles in immune response regulation and fibrogenesis. SnRNA-seq characterized renal cell states to identify 33 distinct clusters, including various renal cell types. Normal proximal tubular cells (PTCs) decreased on the 7th day postinfection, with an increment of injured PTCs with a potential marker Kynu. Initially, fibroblast numbers increased in the infected group, suggesting early fibrosis development. By day 28, immune cell populations grew, indicating their role in chronic *Leptospira* kidney disease.

Conclusions: *Leptospira* infection disrupts normal kidney cell composition, particularly affecting proximal tubules. Early infection stages revealed a rise in fibroblasts. As infection progresses, immune cell populations increase, indicating their involvement in CKD pathophysiology.

Emx2 Regulates Ciliogenesis by Controlling Prostaglandin Production

Thanh Khoa Nguyen, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

Background: Cilia serve important homeostasis roles in fluid flow and sensing to maintain a healthy kidney, and cilia defects have been linked to chronic kidney diseases. Renal multiciliated cells (MCCs) are an aberrant ciliated cell type found in several human kidney pathological states.

Methods: Here, we hypothesized *empty spiracles homeobox gene 2 (emx2)* is important for cilia development in monociliated cells and MCCs. Utilizing several *emx2* deficient models, we performed *in situ* hybridization, renal clearance assays and immunohistochemistry to assess cilia development and function. We studied the relationship between *emx2* and known regulators of the prostaglandin biosynthesis in the kidney such as *ppargc1a*, its downstream targets *ptgs1* and the prostaglandin molecule PGE_2 through a series of qualitative, quantitative and rescue experiments. Finally, we assessed renal basal body functions and performed rescue experiments with PGE_2 in *emx2* deficient models.

Results: We discovered that *emx2* is expressed across ciliated tissues, such as the otic vesicle, nasal placode and renal MCCs. Our *emx2* deficient models displayed reduced cilia development in nephrons, Kupffer's vesicle, neuromasts and the ear. Furthermore, *emx2* deficient embryos displayed a significant reduction in the number of renal MCCs and kidney functional defects including delayed renal clearance, which was associated with pericardial edema. Interestingly, *emx2* deficiency reduced *ppargc1a* and *ptgs1* expression, and the provision of transcripts encoding *ppargc1a* or *ptgs1*, or the supplement of endogenous PGE_2, was sufficient to partially rescue cilia length, intensity and number of ciliated basal bodies. Lastly, we discovered that *emx2* deficiency led to aberrantly positioned basal bodies in the nephron tubule epithelium, which was successfully rescued with PGE_2.

Conclusions: Taken together, our study revealed that *emx2* is an essential regulator of cilia development across tissues through the modulation of prostaglandin biosynthesis.

Complement C5aR-Mediated Tubular Mitochondrial Dysregulation in Kidney Ischemia-Reperfusion Injury-Induced AKI to CKD

Jingyuan Ma, Wai Han Yiu, Yuchen Feng, Kar Neng Lai, Sydney Tang. *The University of Hong Kong, Hong Kong, Hong Kong.*

Background: Activation of C5a/C5aR axis contributes to the progression of kidney ischemia-reperfusion injury (IRI), but the mechanisms remain unclear. Potential harm to mitochondrial homeostasis can cause biological disturbances, the production of reactive oxygen species and ultimately cell death and kidney dysfunction. In this study, we aim to explore the role of tubular C5aR1 on mitochondrial homeostasis during IRI-induced acute kidney injury (AKI) to chronic kidney disease (CKD).

Methods: Tubule-specific C5aR1 knockout mice ($C5aR1^{lox/lox}$, KspCre; KO) and their littermates without Cre allele ($C5aR1^{lox/lox}$; WT) were subjected to kidney bilateral ischemia/reperfusion injury (BIRI) and sacrificed 7 days later. Kidney damage was assessed by evaluating kidney function, histopathological changes and expression levels of pro-inflammatory, fibrotic, oxidative stress, apoptotic and mitochondrial function related markers.

Results: C5aR1 KO mice exhibited significant decrease in serum BUN and creatinine levels and showed a markedly reduction in the expression levels of kidney injury marker Kim1 and NGAL in the 7-day BIRI model compared to WT controls. Along with the improvement in kidney function, the number of apoptotic tubular cells and cleaved caspase-3 expression were reduced, resulting in less tubular injury in KO mice. The expression levels of inflammation and fibrosis markers were significantly decreased in kidney tissues of KO mice after BIRI. Mitochondrial function was improved with a decrease in oxidative stress markers (NOX2 and 8-OHdG) and an increase in mitochondrial DNA copy number (ND1) and biogenesis (PGC1α) in KO mice after BIRI.

Conclusions: Tubular deficiency of C5aR1 mitigates IRI-induced kidney damage and apoptosis by reducing mitochondrial dysfunction and oxidative stress. Funding: Research Grants Council of Hong Kong (General Research Fund, grant no. 17108222), Hong Kong Society of Nephrology Research Grant (2021)

Purinergic Calcium Signaling Drives Tubulointerstitial Cross-Talk in Kidney Diseases

Andreja Figurek,[1] Nevena Jankovic,[1] Sarah Kollar,[1] Andrew Hall.[1,2] *[1]Insitute of Anatomy, University of Zurich, Zurich, Switzerland; [2]Department of Nephrology, University Hospital Zurich, Zurich, Switzerland.*

Background: Chronic kidney disease (CKD) is a major global health problem with limited treatment options. In response to injury proximal tubules (PTs) release factors that activate surrounding fibroblasts to a pro-fibrotic phenotype, which then drives progressive organ damage. Identifying signaling mechanisms between PTs and fibroblasts could reveal new targets for therapeutic intervention. Calcium is a vital intracellular second messenger that regulates many processes, but the nature of calcium signaling in renal fibroblasts was previously not well understood.

Methods: Multiphoton imaging of the kidney *ex vivo* and *in vivo* in transgenic mice expressing a calcium reporter in renal fibroblasts; confocal imaging of calcium activity in normal rat kidney fibroblasts *in vitro*; histological analysis in fixed tissue.

Results: Interstitial fibroblasts in the kidney display spontaneous calcium transients that originate in processes before spreading across the cell, and which markedly increase in frequency in models of acute tubular injury (cisplatin toxicity) and CKD/renal fibrosis (unilateral ureteric obstruction – UUO). Exposing fibroblasts to UDP or synthetic agonists of its target receptor P2Y6 produced acute rises in intracellular calcium. P2Y6R activation also stimulated fibroblast proliferation and migration, and expression of pro-fibrotic markers *in vitro*. In mice exposed to UUO, affected kidneys showed P2Y6R transcriptional up-regulation and knock out or pharmacological inhibition of the P2Y6R decreased fibroblast proliferation, myofibroblast activation, macrophage proliferation, and collagen 1 expression. Moreover, blocking the P2Y6R decreased fibroblast and macrophage proliferation, and myofibroblast activation in another well-established model of CKD (folic acid nephropathy).

Conclusions: We provide evidence that purinergic mediated calcium signaling mediates tubulo-interstitial cross-talk in CKD and that the P2Y6R could represent a therapeutic target.

TH-PO1114

Kidney Phenotype of Fosl2 Knockout Mice

Marta Ribagorda Bermejo,[1,2] Aranzazu Pintor Chocano,[3] Maria Dolores Sanchez-Nino,[1,2] Alberto Ortiz.[1,2] Group of Nephrology, Vascular Pathology, and Hypertension. *[1]Instituto de Investigacion Sanitaria de la Fundacion Jimenez Diaz, Madrid, Spain; [2]Universidad Autonoma de Madrid Facultad de Medicina, Madrid, Spain; [3]Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain.*

Background: Fosl2 is a member of the AP-1 transcription factor family that plays a role in processes such as fibrosis and inflammation. Fosl2 overexpression induced fibrosis and inflammation in multiple organs, being used as a spontaneous model of systemic sclerosis. Fosl2 deficiency decreased the severity of fibrotic and inflammatory processes. However, the role of Fosl2 in kidney disease is unknown.

Methods: In kidney transcriptomics analyses, we found Fosl2 to be upregulated in a murine cisplatin and folic acid-induced acute kidney injury models. To characterize the role of Fosl2 in kidney injury, we generated renal proximal tubule-specific Fosl2 knock-out mice ($Fosl2^{\Delta tub}$). The kidney phenotype of $Fosl2^{\Delta tub}$ mice was characterized by real-time qPCR, immunohistochemistry and Western blotting and primary cell culture.

Results: Contrary to expectations, deletion of Fosl2 in proximal tubular cells led to a pathological kidney phenotype in 3-month-old mice. While serum creatinine and urea levels were similar to WT mice, $Fosl2^{\Delta tub}$ mice displayed an increased kidney expression of Ngal, an early marker of kidney injury and of pro-inflammatory cytokines in association with higher immune cell infiltration. Moreover, there was evidence of an early fibrotic phenotype (*fibronectin 1* and *cpt1a* mRNA and Sirius Red staining) and of decreased nephroprotective factor (e.g., *klotho*) expression. In concordance with these results, in primary renal tubular cell culture, there was an increase in pro-inflammatory cytokines and fibrotic markers and a decrease in nephroprotective factors.

Conclusions: Fosl2 deficiency in mouse proximal tubular kidney cells causes subclinical kidney injury. These results highlight the versatility of Fosl2 roles in different tissues and cell types and open a new range of investigation lines for the treatment of kidney disease.

Vitamin C Alleviates Kidney Interstitial Fibrosis by Reducing TET2-Mediated SOCS3 m5C Modification

Junjun Luan, Yonghe Zhang, Feifei Miao, Hua Zhou. *Shengjing Hospital of China Medical University, Shenyang, China*.

Background: Methylcytosine dimethoxygenase-2 (TET2) has recently been identified as an 'eraser' of 5-methylcytosine (m^5C) to participate in RNA methylation and chronic kidneyn diseases. Studies have shown that Vitamin C (VC) can directly enhance the catalytic activity of TET enzyme. However, the role of TET2 in renal interstitial fibrosis remains unknown. This study we aimed to clarify whether upregulated TET2 by VC alleviates renal interstitial fibrosis and explore its underlying mechanism.

Methods: ICR mice were randomly divided into 4 groups: normal control (NC), folic acid (FA, FA was peritoneally injected to mice), FA+ early VC (prophylactic VC treatment once a day and 4 days before folic acid injection for 34 days, and FA+ late VC (delayed VC treatment after AKI induction for 28 days). Serum creatinine (Scr), and blood urea nitrogen (BUN) were examined. Histological damages were evaluated. TET2, suppressor of cytokine signaling 3(SOCS3), profibrotic proteins α-smooth muscle actin (α-SMA), and fibronectin (FN) were also analyzed. The m^5C level of SOCS3 mRNA was detected by MeRIP-qPCR. *In vitro* study, the HK2 cells were transfected with TET2 siRNA, VC and hTGF-β1 to repeat the associated tests in vivo. The m^5C% of total RNA from different groups of HK2 cells was determined using the m^5C ELISA kit.

Results: In FA mice, Scr and BUN were increased on day 2 and returned to the baseline by day 30; tubular injuries and interstitial fibrosis were seen on PAS and Masson staining; α-SMA and FN were overproduced. Renal TET2 was decreased and SOCS3 was increased. The m^5C level of SOCS3 mRNA was increased. In FA+ early VC mice and FA+ late VC mice, the level of SOCS3 and profibrotic α-SMA and FN were reverted by activating TET2. Importantly, the m^5C level of SOCS3 mRNA was decreased. The same change directions to FA mice of SOCS3 and profibrotic proteins were seen in HK2 cells transfected with TET2 siRNA and cells stimulated by hTGF-β1; total m^5C level in those cells was increased. Another side, the upon changes in HK2 cells by hTGF-β1 stimulation were reverted by VC treatment.

Conclusions: Vitamin C agonism of TET2 can alleviate renal interstitial fibrosis by reducing SOCS3 expression through m^5C methylation modification.

Niraparib, an FDA-Approved Poly-(ADP-Ribose) Polymerase (PARP) Inhibitor Is Renoprotective against Cisplatin Nephrotoxicity in Ovarian Tumor-Bearing Mice

Mira Noh, Amritha Kannan, Babu J. Padanilam. *Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Cisplatin is one of the most commonly used drugs for the treatment of many solid cancers. However, its dose-limiting side effect is nephrotoxicity, leading to acute kidney injury and chronic kidney disease. We previously demonstrated that genetic or pharmacological suppression of poly(ADP-ribose) polymerase 1 (PARP1) protects against cisplatin nephrotoxicity. PARP1 inhibitors such as olaparib, niraparib, and rucaparib are currently FDA-approved for the treatment of ovarian cancer. In this study, we investigated the effect of niraparib on cisplatin nephrotoxicity in an ovarian tumor-bearing model.

Methods: OVCAR3, ovarian cancer cell line cells, bearing mice were established in athymic nude mice and the animals were treated with saline (vehicle), 8 mg/kg cisplatin (once a week), or cisplatin plus 10 mg/kg niraparib (daily).

Results: We found that PARP1 inhibition attenuated kidney cell death and tissue damage, preserving renal function during cisplatin treatment in ovarian tumor bearing mice. Furthermore, inhibition of PARP1 attenuated cisplatin-induced inflammation and renal interstitial fibrogenesis.

Conclusions: Taken together, these results demonstrate that the FDA-approved PARP inhibitor, niraparib can protect efficaciously against renal tubular cell death during cisplatin nephrotoxicity in tumor bearing mice and could be developed as potential therapeutic agents to improve cisplatin nephrotoxicity.

Regulation of Kidney Fibroblast Functions by Palladin-MRTF Circuit in Response to TGF-β1

Naoki Yamamoto, Norihiko Sakai, Yuta Yamamura, Ichiro Mizushima, Shinji Kitajima, Akinori Hara, Miho Shimizu, Takashi Wada, Yasunori Iwata. *Kanazawa Daigaku, Kanazawa, Japan*.

Background: Kidney fibrosis is the common mechanism resulting in chronic kidney disease. We previously clarified myocardin-related transcription factor (MRTF) – serum response factor (SRF) signaling drives renal fibroblast activation and focal adhesion formation consisting of integrins through actin cytoskeleton reorganization. Thus far, it has been reported that actin-associated proteins (AAPs) regulate actin filament assembly and disassembly. However, it has yet to be understood whether AAPs relates to the pathogenesis of the fibrosis. Here, we investigated whether AAPs contributed to the renal fibroblasts (RFBs) activation and focal adhesion formation through actin cytoskeleton reorganization.

Methods: Cultured renal fibroblasts were used to examine transforming growth factor (TGF)-β_1-dependent AAPs. Of these AAPs, palladin was selected for further investigation. The effects of palladin on actin polymerization and MRTF-SRF signaling were evaluated in TGF-β_1-stimulated renal fibroblasts (RFBs) treated with paladin siRNA. In addition, palladin expression was evaluated with siRNA targeting MRTF-A/-B. Furthermore, expressions of α1 chain of type I procollagen (COLIAI), α-smooth muscle actin (αSMA), and integrin α11/β1 were explored with siRNA targeting palladin.

Results: Palladin was significantly upregulated in RFBs with TGF-β_1 stimulation. Palladin knockdown suppressed actin polymerization and MRTF-SRF signaling induced by TGF-β_1 whereas palladin expression was suppressed by siRNA targeting MRTF-A/-B. These results suggested that the amplification loop was created between palladin and MRTF-SRF signaling. In addition, the treatment of RFBs with siRNA targeting palladin attenuated COLIAI and αSMA. In addition, integrin α11/β1 expression induced by the stimulation with TGF-β_1 was also suppressed by palladin knockdown. Finally, the inhibition of integrin α11/β1 expression reduced MRTF-SRF signaling and expressions of COLIAI and αSMA.

Conclusions: TGF-β_1-induced amplification loop between palladin and MRTF-SRF signaling mediates renal fibroblast activation and focal adhesion formation, resulting in the upregulation of extracellular matrix expression.

TH-PO1118

Protective Effect of Targeted Inhibition of Cathepsin S Activity on CKD

Jiayi Zhou, Haiyan Fu. *State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Renal Division, Nanfang Hospital, Southern Medical University, Guangzhou, China*.

Background: Chronic kidney disease (CKD) is a public health issue characterized by vascular rarefaction, marked by reduced capillary density. The molecular mechanisms underlying endothelial cell injury and loss remain unclear. Cathepsin S (CTSS), a lysosomal protease involved in degrading damaged proteins, has been linked to various diseases. However, its role in vascular rarefaction in CKD is not understood. Previous research indicated that limonin, a compound known for its protective effects against acute kidney injury, might also protect against CKD.

Methods: We used a bilateral ischemia-reperfusion injury (IRI) model to induce CKD in mice and generated CTSS knockout mice. LY3000328, a specific CTSS inhibitor, was administered three days before IRI. We conducted molecular pathology studies on human umbilical vein endothelial cells (HUVECs) in vitro and screened small molecule inhibitors of CTSS from a natural product library. Molecular docking studies assessed the binding affinity between CTSS and limonin, which was validated by microscale thermophoresis (MST) and cellular thermal shift assays (CETSA). Both in vivo and in vitro studies were performed.

Results: CTSS expression and enzyme activity were significantly upregulated in CKD animal models. CTSS knockout and inhibition of CTSS in vivo restored capillary density and reduced renal fibrosis after IRI. Pathologically, CTSS in renal vascular endothelial cells translocated into the nucleus and targeted the degradation of the MCM 2-7 complex, inhibiting the G1/S transition in endothelial cells. This impaired repair mechanisms and worsened CKD progression. Limonin was identified as a natural inhibitor of CTSS. Molecular docking showed a strong binding affinity between CTSS and limonin, confirmed by MST and CETSA. In vitro, limonin bound to CTSS's active center, inhibiting MCM 2-7 complex degradation and promoting the G1/S transition in endothelial cells. In vivo, limonin significantly reduced vascular rarefaction and renal fibrosis.

Conclusions: CTSS plays a critical role in CKD by inhibiting HUVEC cell cycle progression through enzymatic hydrolysis of the MCM 2-7 complex. Targeting CTSS activity offers a novel therapeutic strategy for CKD. Limonin effectively inhibits CTSS, promotes the G1/S transition in HUVECs, alleviates renal fibrosis, and shows promise for clinical application in CKD treatment.

Elucidation of the Renoprotective Effects of SGLT2 Inhibitors in Nondiabetic CKD

Akira Hirano, Kengo Kidokoro, Seiji Kishi, Hajime Nagasu, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Ika Daigaku, Kurashiki, Japan.*

Background: In the DAPA-CKD trial, dapagliflozin, an inhibitor of Sodium Glucose Cotransporter 2 (SGLT2), has shown the renoprotective effects in patients with chronic kidney disease (CKD), regardless of type 2 diabetes status. Previously, we demonstrated that the involvement of the tubuloglomerular glomerular feedback (TGF) mechanism mediated by the adenosine/adenosine A1 receptor pathway in the pathogenesis of glomerular hyperfiltration in type 1 diabetic mice (Circulation 2019), and observed that SGLT2 inhibition alleviated glomerular hyperfiltration in those mice. However, the renoprotective mechanisms of SGLT2 inhibitor in non-diabetic CKD remain unclear. The aim of this study is to verify the contribution of SGLT2 as an important factor in compensatory glomerular filtration, throughing mechanisms such as increased glucose load to the remnant nephrons due to a decrease in the number of nephrons, enhanced Na^+ reabsorption through SGLT2 and reduced Na^+ delivery to the macula densa.

Methods: Male C57BL/6 mice were subjected to infarction-inducing 5/6 nephrectomy (Nx) to establish a CKD model. The experimental groups comprised a control group, a 5/6Nx group, and a 5/6Nx group treated with an SGLT2 inhibitor for one week. Single Nephron Glomerular Filtration Rate (SNGFR) was measured using in vivo imaging techniques. Additionally, Proximal tubular reabsorption of 2-NDBG (2-deoxy-2-[(7-nitro-2,1,3-benzoxadiazol-4-yl) amino]-D-glucose) injected transarterially via catheter was also evaluated in vivo. The urinary excretion of adenosine, which is a vasoconstrictive factor of TGF, was quantified.

Results: SNGFR was significantly increased in 5/6Nx group compared to the control group. Additionally, the 5/6Nx group exhibited increase in the uptake of 2-NBDG relative to the control group, whereas the group receiving SGLT2 inhibitor treatment displayed reduction in uptake. Moreover, the SGLT2 inhibitor treatment group exhibited augmentation in the urinary excretion of adenosine in comparison to the 5/6Nx group. Adenosine A1 receptor antagonist administration cancelled the inhibitory effect of SGLT2 inhibitors on hyperfiltration.

Conclusions: Increased glucose uptake via SGLT in the proximal tubule initiates the TGF that leads to hyperfiltration of residual nephrons in non-diabetic CKD.

TH-PO1120

Sabizabulin Ameliorates Kidney Fibrosis by Inhibition of Myofibroblast-Specific Beta Tubulin 3

Yoichiro Ikeda, Masaomi Nangaku. *Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan.*

Background: Tubulointerstitial fibrosis is the hallmark of pathological changes found in the kidneys of CKD patients irrespective of the etiologies. A variety of investigations have been conducted to elucidate the mechanisms of progression to CKD to end-stage kidney diseases so far, but still substantially effective remedies to prevent CKD are limited and not clinically applied. Beta tubulin3 (TUBB3) is specifically expressed in neurons in normal settings, but we found that it is expressed specifically in interstitial cells in kidneys with tubulointerstitial fibrosis. Then we investigated if the intervention of expression of TUBB3 affects the tubulointerstitial fibrosis in kidney in the setting of CKD by using TUBB3-specific inhibitor sabizabulin.

Methods: 10T1/2 cells and mouse primary fibroblasts were used for the fibrogenic assays in vitro by an addition of TGF-beta. Standard C57BL/6 mice were used for the analysis in vivo by doing unilateral ureteral obstruction (UUO) under treatments with TUBB3 inhibitor sabizabulin or vehicle.

Results: Mouse primary fibroblasts, considered as a model of fibroblasts or pericytes, expressing low levels of TUBB3 at baseline, increase fibrogenic responses when stimulated by TGFb, and TUBB3 inhibitor significantly reduced their responses. (aSMA reduction by 40%) Knockdown of TUBB3 by siRNA also showed its significant reduction. (aSMA reduction by 60%) 10T1/2 cells, considered as a model of myofibroblasts, express high levels of TUBB3 at base line, and show strong fibrogenic phenotypes. Sabizabulin reduces fibrogenic responses significantly in a dose dependent manner. (aSMA reduction by up to 70%) UUO mice develop kidney fibrosis in the kidney with a ligation in a time dependent manner. TUBB3 expression is significantly elevated accordingly by UUO, and TUBB3 inhibitor successfully reduced the total TUBB3 expression in UUO kidney in a dose dependent manner. (up to 70%) Surprisingly, histological changes in UUO were significantly suppressed by sabizabulin. Fibrogenic responses were also attenuated by sabizabulin (aSMA reduction by 50%)

Conclusions: Sabizabulin was shown to be effective to ameliorate kidney fibrosis in virto and in vivo. It could be a potential treatment option for CKD.

Funding: Government Support - Non-U.S.

TH-PO1121

Dicarboxylic Acids Protect against CKD

Rebecca M. Uhlean, Katherine Pfister, Sunder Sims-Lucas, Debora Malta C.S Santos. *University of Pittsburgh, Pittsburgh, PA.*

Background: Chronic kidney disease (CKD) affects 30 million people in the US and over 800 million people worldwide. Treatment for end-stage renal failure is largely limited to renal transplant or lifelong dialysis, creating an urgent need for new therapies. We have shown that dicarboxylic acids are protective against acute kidney injury (AKI) in the proximal tubule via hypersuccinylation of mitochondrial and peroxisomal proteins, thereby bolstering peroxisomal fatty acid oxidation over mitochondrial FAO. In this study we aimed to determine whether this mechanism could be leveraged to protect against fibrotic damage due to chronic kidney injury, which we model using Unilateral Ureteral Obstruction (UUO) surgery.

Methods: Wild-type male B6/129 mice were procured from Jackson Laboratories and the experimental group fed with an 10% 8-chain dicarboxylic acid (DC_8, suberic acid) diet. Both the experimental and the control groups underwent UUO surgery, whereby the ureter of one kidney was obstructed for three days before both kidneys were harvested. Each kidney was split into four pieces as follows – 1. histological and immunohistochemical staining; 2. fatty acid oxidation analysis; 3. succinylome analysis using targeted mass spec; 4. snap-frozen for validation and downstream analysis of fibrosis, as well as peroxisomal and mitochondrial signaling.

Results: As previously shown, there was hypersuccinylation in the DC_8-treated animals compared to control fed animals. This was accompanied with corresponding upregulation of peroxisomal FAO specifically in the collecting ducts, which was confirmed by targeted mass spec. Supplementation of DC_8 showed marked protection in the collecting ducts, with decreased dilation and tubular epithelial shedding compared to controls. There was also a decrease in the dilation of the renal pelvis in DC_8 treated animals. Further to this immunohistochemical staining showed a decrease in fibrotic markers in the kidneys of DC_8-fed animals

Conclusions: Taken together this suggests that DC_8 is protective against collecting duct damage and fibrotic changes that occur in CKD. This expands the utilization of DC8 therapy beyond the acute setting and into fibrosis and chronic kidney disease.

Funding: NIDDK Support

Gain-of-Function Mutation in PDE3A Limits Renal Signs of CKD

Olena Potapenko,[1,2] Theda U. Bartolomaeus,[2] Fiona Spindler,[1] Michael Bader,[2] Anastasiia Sholokh,[2] Reika Langanki,[2] Eremire Vila,[1] Sofia K. Forslund,[2] Enno Klussmann,[2] Lajos Marko.[2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Max-Delbruck-Centrum fur Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.*

Background: Hypertension is a major risk factor for the development of chronic kidney disease (CKD). Hypertension and brachydactyly syndrome is caused by gain of function mutations in the phosphodiesterase 3a (*PDE3A*) gene and leads – if untreated – to stroke and premature death. However, patients hardly develop end-organ damage. Here, we investigated the effect of the *PDE3A* gene mutations on renal manifestation in a rat model of CKD.

Methods: PDE3A-activating (Δ3aa), litter-mate wild-type (WT) and PDE3A-deleted (functional DEL) rats were generated and CKD was induced by bilateral renal ischemia through clamping renal arteries for 45 minutes. Four weeks after surgery kidneys were harvested for histological and gene expression analyses. Blood pressure was continuously measured by telemetry for 1 week before and 3 weeks after renal ischemia.

Results: Serum creatinine and cystatin C levels were elevated 4 weeks after CKD induction in all 3 groups of rats which underwent CKD-inducing surgery in comparison to values before surgery or values of sham-operated animals. However, no difference could be observed between the groups. Δ3aa rats had significantly higher, and functional DEL significantly lower systolic blood pressure than WT rats (142 vs 121 and 115 mmHg, respectively) which was not affected by the CKD induction. CKD induction led to a reduction of the area of the Bowman's capsule ($p<0.05$) and the glomerular capsule area ($p=0.0536$) in WT but not in the Δ3aa rats. CKD induction led to increased media-to lumen ratio of renal arteries in WT rats but not in Δ3aa rats. Additionally, induction of CKD led to significant renal fibrosis in the kidneys of both WT and Δ3aa rats. However, the fibrotic area in kidneys of Δ3aa rats was less than that of the WT rats. The expression of genes involved in fibrosis showed similar trends in WT and Δ3aa rats.

Conclusions: Our data show that gain-of-function mutation of *PDE3A* limit the development of CKD-induced renal changes arguing that PDE3A modulation can be a useful approach for prevention of hypertension-associated CKD.

Funding: Government Support - Non-U.S.

TH-PO1123

Involvement of Calcium (Ca)-Sensing Receptor in the Development of Interstitial Fibrosis

Akira Kurosawa, Kaori Takayanagi, Masaaki Terao, Shunsuke Takahashi, Akito Maeshima, Hajime Hasegawa. Dept of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University. *Saitama Ika Daigaku Sogo Iryo Center, Kawagoe, Japan.*

Background: The function of the calcium-sensing receptor (CaSR) in the kidney have not been well understood. We previously reported that the expression of CaSR significantly decreases with the progression of renal interstitial fibrosis. In this study, we administered etelcalcetide (ETL), a CaSR agonist, to a renal fibrosis model to analyze the relationship between CaSR and renal fibrosis.

Methods: We created a renal fibrosis model using 8-week-old Sprague-Dawley rats with unilateral ureteral obstruction (UUO). The rats were sacrificed on the seventh day after ureteral ligation, and samples were collected. Some UUO rats were subcutaneously administered ETL at a dose of 0.5 mg/kg/day. The rats were divided into three groups: Sham (n=8), UUO (n=9), and UUO+ETL (n=10). We conducted blood biochemical tests, evaluated fibrosis using ED-1 staining, αSMA staining, Azan staining, and Picro-Sirius Red (PSR) staining, and compared mRNA expression levels of molecules related to fibrosis, repair, and regeneration using RT-PCR.

Results: CaSR expression significantly decreased due to UUO, but immunohistochemistry and mRNA expression analysis confirmed partial recovery of CaSR expression with ETL administration. Azan staining and PSR staining demonstrated a significant reduction in fibrosis with ETL treatment in UUO rats. ED-1 and αSMA staining revealed a significant decrease in positive areas with ETL administration. Furthermore, ETL treatment significantly increased BMP-7 mRNA expression compared to the UUO group.

Conclusions: ETL partially restored reduced CaSR expression in the kidney, improved renal fibrosis, and inhibited the accumulation of extracellular matrix. The involvement of BMP-7 suggests that CaSR agonists could be a novel therapeutic approach for inhibiting renal fibrosis.

TH-PO1124

Effects of Particulate Matter on CKD: Inflammation, Oxidative Stress, and Fibrosis in Animal Model

Duk-Hee Kang, Chor ho Jo, Dal-Ah Kim. *Ewha Womans University College of Medicine, Seoul, Republic of Korea.*

Background: The exposure to particulate matter (PM) is regarded to be associated with respiratory, cardiovascular, and kidney diseases based on epidemiological analysis. However, there are no studies investigating the causative role of PM in the kidney disease. The activation of endoplasmic reticulum (ER) stress, NLRP3 inflammasome, and oxidative stress are the key mechanisms of renal injury. This study is undertaken to explore the effects of artificially manufactured PM (APM) on the kidneys of animal model of CKD, unilateral ureteral obstruction (UUO).

Methods: Male Sprague-Dawley rats were divided into four groups: Normal control, APM (5 mg/kg, administration for 3 or 5 times via Intratracheal instillation), UUO, and UUO+APM. BUN, proteinuria, renal histology including macrophage marker ED-1 expression, and the markers of ER stress (GRP78, ATF4, CHOP, and cleaved caspase-1), NLRP3 inflammasome (NLRP3 and ASC), oxidative stress (nitrotyrosine, SOD2, catalase, and GPx1) and renal fibrosis (F4/80, α-SMA, and osteopontin) in the kidneys were analyzed at 9 or 14 days of APM exposure.

Results: UUO increased BUN, tubulointerstitial fibrosis, and expression of GRP78, ATF4, CHOP, and NLRP3, ASC, cleaved caspase-1. Markers of renal fibrosis are upregulated with an increased nitrotyrosine and reduced SOD2, catalase, and GPx1 in UUO group. In APM+UUO group, ED-1, GRP78, CHOP expression was increased in 9 and 14 days, and NLRP3, cleaved caspase-1, F4/80, and osteopontin were upregulated in 14 days. In normal rats, APM also increased the expression of ATF4, cleaved caspase-1 and NLRP3 with an imbalance of oxidative stress and increased expression of F4/80 and osteopontin.

Conclusions: Exposure to APM resulted in an enhanced expression of markers of renal inflammation, ER stress, oxidative stress, NLRP3 inflammasome, and fibrosis in both normal and UUO rat models. These findings suggest a potential causative role of PM in kidney disease in subject with normal renal function and CKD.

TH-PO1125

Effects of Long-Term Electronic-Cigarette (E-cig) Aerosol Exposure and Kidney Health in Mice

Amna Raja,[1] Morgan E. Poindexter,[2] Christina Awada,[1] Judith T. Zelikoff,[1] Edgar A. Jaimes.[3] *[1]New York University Grossman School of Medicine, New York, NY; [2]University of California Davis, Davis, CA; [3]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: The link between nicotine/cigarette smoke and chronic kidney disease (CKD) is well-established. In contrast, the relationship between E-cigarette (e-cig) use and kidney injury, is relatively unknown. The aim of this toxicological study was to examine whether inhalation exposure of healthy adult mice to e-cig aerosols, with and without nicotine, produces gene expression changes linked to kidney injury.

Methods: 7-8-week-old FVB/NJ mice were exposed to either: 1) filtered air (control); 2) PG/VG (1:1); or 3) PG/VG (1:1) + Nicotine (24 mg/ml) for 3-mo (5d/wk). RNA was extracted from the kidney and bulk RNAseq was performed, followed by RNAseq libraries preparation with TruSeq Stranded Total RNA kit (Illumina). Libraries were sequenced and aligned against the mouse genome. Differential gene expression analysis was performed with DESeq2 R/Bioconductor package. Ingenuity Pathway Analyses (IPA) was then used to comprehensively analyze the differentially expressed genes (DEGs) in order to infer the underlying causes of the observed fold-changes and predict downstream health events.

Results: Inhalation exposure of mice to PG/VG + nicotine resulted in gene expression changes in 61 genes, compared to the air control group; only 7 genes were differently expressed in the PG/VG group, compared to control. Changes in kidney injury-related genes (i.e., *Adrb3, Ca4, Ca3, Lep, Mfsd2a, Adipoq, Angptl4, Cd1d*) were observed in the kidneys of mice exposed to PG/VG + Nic aerosol, compared to filtered air controls. IPA analysis revealed that gene expression changes observed in PG/VG + Nic exposed mice are related to transcription regulation, adipogenesis and circadian rhythm signaling pathways. Organismal injury, nutritional disease and connective tissue disorders were the top diseases based on gene expression changes. In contrast, mice exposed to PG/VG aerosol, without nicotine demonstrated an upregulation of kidney-injury related genes (i.e., *Upk2*, and *Myc*), compared to the control group.

Conclusions: This study indicates that long-term, repeated exposure of adult male mice to e-cig aerosols alters the expression of kidney-injury related genes. This groundbreaking study and overlooked research area demonstrates the kidney as a target of e-cig use, and opens the door for further research concerning the impact of e-cig use on kidney health.

Sex-Dependent Effects of Whole-Life Arsenic Exposure and High-Fat Diet on the Kidney Proteome

Timothy Cummins,[1] Joshua S. Carty,[2] Michelle T. Barati,[1] Adam E. Gaweda,[1] Daniel W. Wilkey,[1] J. C. States,[1] Jon B. Klein,[1] Michael Merchant.[1] *[1]University of Louisville School of Medicine, Louisville, KY; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: The Agency for Toxic Substances and Disease Registry (ATSDR) Substance Priority List ranks Arsenic (As) the number one priority. Environmental exposure to As as well as western high fat diets are global concerns for developed and developing nations. High-fat diet co-morbidities including diabetes, kidney disease, hypertension and cardiovascular disease likely modify pathologic mechanisms of As renal toxicity. We addressed the hypothesis that a proteomic approach to study whole life exposure to sodium arsenite (As_i) in male and female mice fed a high fat diet could reveal proteins and mechanistic pathways important to understanding As_i toxicity.

Methods: Cortical kidney lysates from four groups of male and female mice (n=3/group) were compared using a proteomic approach. Groups included (A) mice exposed to 0 or (B) 100 ppb As_i in drinking water from conception, and fed (C) normal or (D) high-fat chow diet for 21 weeks post weaning at 3 weeks. Univariate and multivariate methods were used to compare protein abundances ($q<0.05$) and identify As_i, sex-based or diet-induced effects on the kidney. Immunohistochemistry and immunoblot confirmation assays indicated potential proteins associated with kidney dysregulation as a function of As_i exposure, sex-based differences and diet.

Results: 2931 kidney proteins were identified, 107 were increased and 94 were decreased (log2FC1) in females vs males after multiple testing correction. Multivariate PLSDA and clustering methods defined differences dominated by sex>diet>>As_i. 2-way ANOVA identified As-exposure regulation of glomerular proteins important for podocyte function, and proximal and distal tubular proteins including As_i up-regulation of aquaporin-3 in females only. Histologic analysis identified arsenic-associated focal degenerative tubule cell toxicity in males and female. Overall, informatics analyses indicated sex, diet, and As_i proteome differences appear to impact multiple biological components such as RNA binding, mitochondria function, and energy metabolism.

Conclusions: Renal proteome studies of sexual dimorphic responses in As_i and high-fat diet exposures indicate potential for sex- and As_i-dependent markers of diet induced kidney damage.

Male Mice Have Increased Expression of Renal Genes Linked to Kidney Disease Compared with Gene Expression in Female Mice

G. R. Crislip, Michelle L. Gumz. *University of Florida, Gainesville, FL.*

Background: Men are at increased risk of reaching kidney failure sooner than women, even though less men have chronic kidney disease (CKD) compared to women. Gene expression profiles have linked inflammaiton and fibrosis as contributors to CKD on a molecular level. Kidney function is influenced by circadian rhythms, therefore, consideration of the time of day is warranted. Both humans and mice are diurnal, however, mice are nocturnal and are active during the night. We hypothesized that male young adult mice will have up-regulated expression of genes that are linked to CKD progression compared to female mice.

Methods: We used six-month-old male and female control mice on a C57BL/6 background. Kidneys were harvested at zeitgeber time (ZT) 0 or ZT12, at the beginning of the inactive and active periods for mice. RNA was isolated from the renal medulla and prepared for RNA sequencing (5-9 pooled samples for males, 4-8 for females). Differential gene expression was analyzed using DESeq2 (abs(log2(FC)) ≥ 1.0 and FDR-corrected P-value ≤ 0.05). Qiagen ingenuity pathway analysis was performed.

Results: At ZT0, there were 469 differentially expressed genes between males and females. There were 525 differentially expressed genes at ZT12. Interestingly, genes linked to kidney damage are down-regulated in females at both time points compared to males. The kidney injury molecule, Havcr1, was down-regulated in females compared to males only at ZT0 (log2(FC)=-2.4; P=0.04). However, renal inflammation pathways were up-regulated in females. Cxcr4 was one of the contributors to this finding, which is a gene that promotes infiltration of inflammatory cell to the inflammation site. Cxcr4 was only found to be up-regulated in female mice at ZT0 (log2(FC)=1.3; P=0.01). The anti-aging protein Klotho (Kl) was surprisingly down-regulated in females compared to age-matched males at both time points (log2(FC)=1-1.2; P<0.001).

Conclusions: In conclusion, female mice have down-regulated expression of genes that are linked to the development of CKD compared to males. More of these CKD-related genes were found to be differentially expressed at the beginning of the inactive period vs. active period of the mice. There is evidence that females have up-regulation of genes that promotoe renal inflammation. This finding is interesting as women are more likely to develop immune-related kidney diseases compared to men.

Sodium Bicarbonate Treatment Promotes Hypoxia and Insulin Resistance in Rats

Paul O'Connor, Elinor Mannon. *Augusta University, Augusta, GA.*

Background: The Use of Bicarbonate in Chronic Renal Insufficiency (UBI) study, found that the relationship between serum bicarbonate and HOMA-IR in patients treated with sodium bicarbonate is non-linear. That is, while HOMA-IR decreased in patients with serum bicarbonate between 24-28mmol, HOMA-IR increased in patients with levels above 28mmol/L. The mechanisms underlying the divergent responses in the UBI study remain unclear. Chronic intermittent hypoxia has been reported to promote loss of insulin sensitivity. As metabolic alkalosis from high serum bicarbonate may slow respiratory rate, in the current study we hypothesized that sodium bicarbonate treatment may promote hypoxia and insulin resistance in rats with CKD

Methods: Male Sprague Dawley rats were used (n=9-3 per group). Rats underwent either surgical incision 5/6 nephrectomy surgery or sham surgery and were allowed to recover for 8 weeks before performing a baseline insulin tolerance test (ITT). Rats were then randomly divided into treatment groups to receive either 0.1M $NaHCO_3$ in the drinking water (Bicarbonate treatment) or tap water 2 weeks. At the end of the treatment period, blood was collected from the tail vein for analysis (PrimeVet blood gas analyzer) and a repeat ITT performed

Results: Rats in the CKD group had significantly higher plasma creatinine and BUN when compared to rats in the sham group (p<0.01). Plasma HCO_3- was significantly elevated in both sham and CKD bicarbonate treated rats compared to rats receiving tap water (P=0.02). Consistent with bicarbonate treatment promoting hypoxemia and tissue hypoxia, plasma lactate was significantly elevated in both sham and CKD bicarbonate treated rats when compared to rats receiving tap water (p=0.02). Hematocrit and total hemoglobin also tended to be elevated following bicarbonate treatment. Fasted glucose levels were significantly elevated in both sham and 5/6 Nx rats following bicarbonate treatment (p=0.01). ITT identified reduced insulin sensitivity in both sham and 5/6 Nx rats following 2 weeks of bicarbonate, but not tap water treatment.

Conclusions: Our data indicate that bicarbonate loading can promote both hypoxia and worsen insulin sensitivity in rats. We speculate that increases in HOMA-IR in CKD patients receiving bicarbonate with plasma HCO_3- above 28mmol/L may be due to insulin resistance secondary to pH mediated decreases in respiratory rate and intermittent hypoxemia.

Kidney Protection during the AKI to CKD Transition: Post-translational Modifications Drive Peroxisome Activity and Cytoskeletal Rearrangements

Katherine Pfister.[1,2] [1]*University of Pittsburgh, Pittsburgh, PA;* [2]*UPMC, Pittsburgh, PA.*

Background: Acute Kidney injury (AKI) is an unfortunately frequent disease without an effective treatment. In many cases, AKI can progress to Chronic Kidney Disease (CKD) and in the worst-case scenario, End Stage Renal Disease (ESRD). To attenuate these transitions, we need a better understanding of the cellular mechanisms underlying damage and physiological changes as disease progresses. The most pronounced effect of AKI is on the Proximal Tubule Epithelial Cells (PTECs) which have the highest metabolic activity and are therefore most susceptible to damage after ischemia, sepsis, or transplant stress. This damage causes not only an increase in radical oxygen species and genetic reprogramming but also a significant change in the landscape of posttranslational modifications (PTMs).

Methods: With our collaborators, we performed targeted mass spectrometry and data-mining to understand the progressive changes in untreated AKI to CKD in murine kidneys. Following our recently published study on the protective effects of upregulated peroxisomal fatty acid oxidation (FAO) through dicarboxylic acid diet supplementation, we analyzed the long-term effects of Suberic Acid (DC8) on the AKI to CKD transition. Large classes of proteins can be modulated rapidly and reversibly through the activity of enzymes that ligate Posttranslational Modifications (PTMs) and we developed a list of candidate proteins that are significantly altered in DC8-fed mice exposed to a CKD model of injury.

Results: We chose to focus on the relationship between peroxisomal FAO enzymes and the resulting cytoskeletal changes that drive the fibrotic phenotype indicative of CKD. We identified a list of actin-binding proteins that are specifically succinylated at key residues when the DC8 treated mice are subjected to an *in vivo* model for CKD and we propose that the increased peroxisomal FAO has long-term protective effects maintaining the epithelial profile of PTECs after injury, preventing cell shedding, tubular collapse, and increased fibrotic scarring that are signs of worsening CKD and ESRD.

Conclusions: By understanding the cellular mechanisms of the AKI to CKD transition we can promote directed clinical trials to lessen the number of patients on lifetime dialysis and those requiring kidney transplants worldwide.

Extra Domain A-Spliced Fibronectin Variant Contributes to Tubulointerstitial Fibrosis in CKD

Susan Yung, Yuesong Xu, Max Tung, Rafter Y. Wu, Tak Mao D. Chan. *Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong, Hong Kong.*

Background: Chronic kidney disease (CKD) is characterized by progressive tubulo-interstitial fibrosis and tubular atrophy, leading to kidney failure. There is no effective treatment for kidney fibrosis. Fibronectin (native FN) is a large glycoprotein present in all tissues, and its accumulation in the tubulo-interstitium is a feature in progressive tubulo-interstitial fibrosis. Also, the extra domain A-spliced variant of FN isoform (EDA-FN) is enriched in fibrotic lesions. This study investigated the role of EDA-FN in the pathogenesis of tubulo-interstitial fibrosis in CKD.

Methods: CKD was induced in wild-type (WT) and EDA-FN knockout (KO) mice by feeding with casein-based chow containing 0.2% adenine for 12 weeks, and mice fed casein-based chow served as controls. Mice were sacrificed and kidneys were harvested to assess histopathological changes and expression of mediators of inflammation and fibrosis. In vitro studies were performed on proximal renal tubular epithelial cells (PTEC).

Results: Compared with WT casein-fed mice, WT CKD mice showed proteinuria, tubular atrophy, increased EDA-FN expression, and increased gene and protein expression of native FN, collagen type I and III, and α-smooth muscle actin ($p < 0.05$, for all). EDA-FN KO CKD mice showed comparable proteinuria as WT CKD mice, but less severe kidney histopathological features with reduced immune cell infiltration and decreased expression of fibrosis mediators. Under physiological condition, EDA-FN was not expressed by PTEC. Exposure to TGF-β1, IL-1β, but not IL-6, IL-8 or MCP-1, induced EDA-FN in PTEC, which was mediated in part through PI3K and p38 MAPK phosphorylation. Incubation of PTEC with EDA-peptide increased native FN, collagen I and SNAIL expression and IL-6, IL-8 and MCP-1 secretion.

Conclusions: Our data showed that murine adenine-induced CKD had increased tubulo-interstitial EDA-FN expression, which participated in the pathogenesis of chronic tubulo-interstitial inflammation and fibrosis.

The Actin and Microtubule Network Regulator WHAMM Is Identified as a Key Kidney Disease Risk Gene

Dhanunjay Mukhi,[1] Kolligundla L. Prasanna,[1] Tomohito Doke,[1] Magaiver A. Silva,[1] Hongbo Liu,[1,2] Matthew Palmer,[1] Katalin Susztak.[1] Susztak Group.
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Rochester Medical Center, Rochester, NY.

Background: Nearly 850 million people suffer from kidney disease across the globe, yet the molecular mechanisms remain elusive. Recent genome-wide association studies identified genetic variants at more than 800 loci responsible for kidney dysfunction, however, target genes, target cell types, and underlying pathways remain poorly understood.

Methods: We utilized a comprehensive gene prioritization strategy involving multiple genetic evidence (kidney expression and methylation quantitative trait (eQTL & meQTL), allele-specific expression, snATAC-seq, Bayesian colocalization, and SMR, etc.) to identify the Wasp homolog associated with actin, membranes, and microtubules (*WHAMM*) as a causal gene for kidney dysfunction on chromosome 15. We obtained WHAMM genetic knockout mice and analyzed at baseline and after induction of acute kidney injury, chronic kidney disease by folic acid injection, and unilateral ureter obstruction (UUO). Serum creatinine, BUN, and cystatin C levels were measured. Gene expression and protein levels were measured by real-time PCR, western blotting, and immunofluorescence. Primary kidney tubule epithelial cells were analyzed for cytoskeleton changes, ASC-speckle formation, and cell death by confocal microscopy imaging. Autophagy was assessed by LC3 turnover at baseline and after induction of starvation, and cisplatin. We employed cytoskeletal inhibitors in both in vitro and in vivo studies to demonstrate the role of WHAMM in kidney disease.

Results: Here we show that nucleotide variants on chromosome 15 are not only associated with kidney dysfunction but also regulate the expression of *WHAMM*. *WHAMM* expression is higher in mice and patients with chronic and acute kidney disease. Genetic knockout of *Whamm* appeared healthy at baseline but showed less injury following cisplatin, folic acid, and unilateral ureteral obstruction. In vitro cell studies indicated that WHAMM controls cell death by regulating actin-mediated cytochrome c release from mitochondria and the formation of ASC-speckles. Pharmacological inhibition of actin dynamics was able to mitigate kidney disease development in experimental models.

Conclusions: Our study identifies a key role of *WHAMM* in the kidney disease development and the pharmacological modulation of this pathway as a potential therapeutic approach.

Eculizumab Therapy and Kidney Recovery in SARS-CoV-2-Induced Complement-Mediated Thrombotic Microangiopathy (CM-TMA)

Zeyad J. Rifai, Heather Rowe, Nirali B. Ramani. *Southern Illinois University School of Medicine, Springfield, IL.*

Introduction: Thrombotic Microangiopathies (TMA) have a diverse pathogenesis, featuring microangiopathic hemolytic anemia, thrombocytopenia, end-organ injury, affecting renal microvasculature via microthrombi formation. Advancements in complement biology have introduced targeted therapies like Eculizumab, interrupting the terminal complement pathway mitigating microvascular thrombotic endothelial damage.

Case Description: 60-year-old male, hospitalized for chest pain secondary to uncontrolled hypertension with a negative cardiac workup, and incidental SARS-CoV-2 infection, returned three weeks later with a two-week history of malaise and reduced urine output. He denied infectious, or gastrointestinal symptoms. Investigation revealed a creatinine of 4.09 mg/dL (baseline 0.9 mg/dL). UA with proteinuria and 50 RBC/HPF. Paraproteinemia and autoimmune workup including anti-GBM, ANCA, Lupus serology, Lupus Anticoagulant, Antiphospholipid antibody, C3/C4/CH50 complement, Factor H level and Factor H autoantibody were unremarkable. ADAMSTS-13 activity was not supportive of TTP, Coombs Test was negative. Given a negative stool culture and deteriorating renal function (peak creatinine 5.32 mg/dL), suspicion for CM-TMA increased, prompting pursuit of a renal biopsy to guide management. Light microscopy revealed acute to subacute TMA with secondary acute tubular injury confirming our suspicion of CM-TMA. He was established with an outpatient dialysis center and hematology for Eculizumab infusions. The patient suffered cardiac arrest during a dialysis session requiring hospitalization delaying his Eculizumab infusions. The cardiac arrest was attributed to an anaphylactic reaction to intradialytic iron infusion. He eventually began his Eculizumab regimen; clinical course is highlighted by discontinuation of dialysis four months after renal insult. He maintains routine follow-up with nephrology and hematology clinic for maintenance Eculizumab infusions.

Discussion: Although genetic analysis was inconclusive, a 'first-hit' mutation predisposing to complement dysregulation coupled with SARS-CoV-2 as a 'second-hit' remains a likely pathogenesis. There are no current guidelines describing the length of Eculizumab therapy in this particular case. Our aim is to emphasize the importance of standardizing the duration of Eculizumab therapy, particularly in the absence of autoantibodies or familial history.

Mortality among Patients on Hemodialysis Who Received Heterologous and Homologous COVID-19 Vaccine Regimens in Thailand

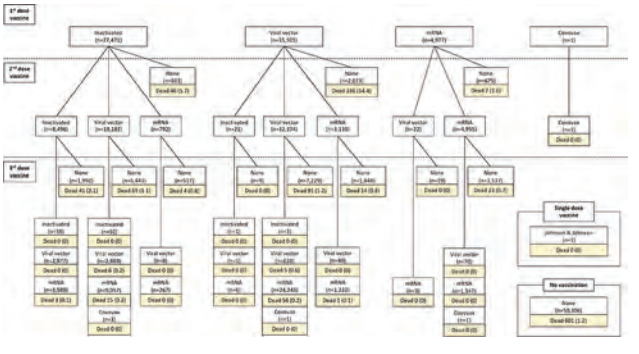
Pattharawin Pattharanitima,[1] Suthiya A. Anumas,[1] Manoch Rattanasompattikul,[2] Thatsaphan Srithongkul,[3] Sukit Raksasuk,[3] Suchai Sritippayawan.[3]
[1]Thammasat University Hospital, Khlong Nueng, Thailand; [2]Golden Jubilee Medical Center, Nakorn Pathom, Thailand; [3]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.

Background: Although studies showed the effectiveness of a 2-dose homologous regimen, it was impractical in Thailand due to limited vaccine supply. Consequently, heterologous vaccine regimens were implemented. This study aims to evaluate the mortality rate and risk factors for mortality in maintenance hemodialysis (HD) patients who received various vaccine regimens.

Methods: We retrospectively reviewed the data of patients receiving HD in Thailand from January 2021 to December 2022. The demographic, vaccination history, SARS-CoV-2 test results, and other laboratory data were retrieved from the Department of Medical Sciences and Thailand RRT registry. Mortality was defined as death within 30 days after a positive RT-PCR or rapid antigen test for SARS-CoV-2.

Results: Among 121,761 HD patients, 71,455 (58.7%), 67,953 (55.8%), and 46,288 (38.0%) patients received 1,2 and 3 vaccine doses, respectively (Figure 1). Of these, 8,836 (40.9%) and 44,900 (97.0%) patients received heterologous vaccines for their first 2 and 3 doses. The most common regimens were viral vector (VV)-VV-mRNA (33.9%), inactivated (IA)-VV-mRNA (12.7%), and VV-VV (10.2%), with mortality rates of 0.2%, 0.2%, and 1.3%, respectively. The mortality was 601 (1.2%) and 667 (0.9%) among unvaccinated and vaccinated patients (P <0.001), and 0.7% and 6.0% among who tested negative and positive for SARS-CoV-2 (P <0.001). Multivariate analysis showed that female, age ≥50 years, no vaccination, single-dose VV and IA vaccination, high BMI, admission to advanced care wards, and requirement for high oxygen therapy were risk factors for mortality. The VV-VV-mRNA regimen was a protective factor.

Conclusions: This study showed that a single dose of VV and IA vaccines was associated with higher mortality compared to the mRNA-mRNA regimen, while the VV-VV-mRNA vaccine was a protective factor. The mortality in patients who received other vaccine regimens was comparable to those who received the mRNA-mRNA regimen.



TH-PO1135

Circulating ACE2 Activity and Gas6 Are Increased in Patients Diagnosed with COVID-19

Irene Martínez Díaz,[1] Ander Vergara,[1] Antonio Cano Camara,[1] José T. Ortiz Pérez,[3] Adria Fernandez Diaz,[3] Carmen Llorens Cebrià,[1] Sara Nunez-Delgado,[1] Jordi Vilardell,[1] Pablo García de Frutos,[2] Albert Morales,[2] Conxita Jacobs Cachá,[1] Maria Jose Soler.[1] Nephrology and Transplantation Group. *[1]Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Hospital Universitari, Vall d'Hebron Barcelona Hospital Campus,. Nephrology and Transplantation Research Group, Barcelona, Spain; [2]Instituto de Investigaciones Biomédicas de Barcelona (IIBB)-Consejo Superior de Investigaciones Científicas (CSIC), Barcelona, Spain; [3]Department of Cardiology, Cardiovascular Institute, Hospital Clínic de Barcelona, Fundació Clinic per la Recerca Biomédica, Universitat de Barcelona, Barcelona, Spain*.

Background: The angiotensin converting enzyme 2 (ACE2) is the cell entry receptor for SARS-CoV-2. SARS-CoV2 participates in ACE2 shedding from cell membrane, increasing soluble ACE2. ACE2 has been shown to cooperate with the receptor AXL, internalizing SARS-CoV-2. The present study aims to evaluate if the circulating ACE2 activity and the serum levels of AXL and its ligand Gas6 are related with the disease prognosis.

Methods: During the first wave of COVID-19 pandemic, first emergency attendance serum samples were collected from 1519 COVID-19 patients diagnosed at two centers. Age, sex, comorbidities and clinical and analytical variables were collected from the patient's records. Patients that were admitted to intensive care unit, required mechanical ventilation or died due to COVID-19 were considered severe patients. Serum ACE2 activity was measured by fluorescence enzymatic activity assay while Gas6 and sAXL by ELISA.

Results: Patients with severe COVID-19 were older and presented more comorbidities (Table 1). Circulating ACE2 activity and Gas6 levels were increased in 0.43ng/µL and in 5ng/mL respectively (95%IC:0.32–0.54, p<0.001; 95%IC:3.44–6.56, p<0.001) in patients that afterwards developed severe COVID-19 (Table 1). However, we found no differences in levels of sAXL between patients with severe and non-severe COVID-19. A logistic regression model adjusted by age, sex, diabetes, hypertension, obesity, cardiovascular disease and chronic kidney disease identified that high circulating ACE2 activity and high Gas6 levels were independently associated with worse SARS-CoV2 disease (OR:2.5, 95%CI:2.02–3.25, p<0.001; OR:1.0, 95%CI:1.01–1.04, p<0,001, respectively).

Conclusions: Elevated circulating ACE2 activity and GAS6 at admission to the Emergency Department are a risk factor for severe COVID-19 disease. In contrast, sAXL levels are not related to the severity of the disease.

Funding: Private Foundation Support, Government Support - Non-U.S.

Table 1. Comparison of demographic, clinical features and circulating ACE2 activity, Gas6 and AXL between non-severe and severe COVID-19 patients. *a Cardiovascular disease is defined as a history of heart disease, pericarditis, cardiac arrhythmia, heart failure, stroke or peripheral arterial disease. b: circulating ACE2 activity was measured in relative fluorescence units (RFU/s) adjusted using a standard curve with known ACE2 concentrations. $ Mann Whitney Test # Chi² Test*

Kidney Function in Children and Adults Hospitalized with Coronavirus Disease in 2019: Relationship with Urinary Biomarkers and Genetic Polymorphisms

Elba O. Medina Hernandez,[1] Enrique J. Robiou Vivero,[1] Rafael Valdez-Ortiz,[1] Mara Medeiros.[2] *[1]Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; [2]Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico*.

Background: The kidneys are commonly affected in COVID-19; we can see abnormal dipstick or acute kidney injury; NGAL and Cystatin C increase after kidney injury. Recognition of AKI is sometimes late; identification would help to improve the outcome

Methods: Prospective cohort study (July-September 2020), patients of any age hospitalized for COVID-19. Upon admission and discharge, blood chemistry, urianalysis, NGAL, Cystatin C and APOL1 gene were evaluated

Results: 159 patients were included. In children initial vs final cystatin C; median 26.88vs8.45, regarding initial vs final NGAL, median 7.48vs2.38. In adults Cystatin C initial vs final had a median 79.57vs32.97, NGAL initial vs final 31.74vs17.23. APOL1 variant was found in two adults and one child

Conclusions: Children had lower AKI and mortality than adults. Urinary cystatin C was higher at the admission, but the change was significant only in adults. We found no relationship between genetic variants of APOL1 and the severity of kidney damage

Funding: Government Support - Non-U.S.

Impact of the COVID-19 Pandemic on Health Care for People with Rare Diseases in Germany (SCOPE-RD)

Lukas Völkel,[1,4] Lucas R. Fahrenschon,[2] Julia Fleck,[2] Martin Mücke,[2] Melanie May,[3] Immo Zech,[3] Annette D. Wagner.[1] *[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Universitatsklinikum Aachen, Aachen, Germany; [3]Kyowa Kirin Niederlassung Deutschland, Dusseldorf, Germany; [4]Boehringer Ingelheim International GmbH, Ingelheim, Germany*.

Background: The Covid-19 pandemic has profoundly impacted healthcare worldwide, affecting vulnerable groups such as patients with rare diseases. This study aims to analyze the influence of the Covid-19 pandemic on the healthcare of patients with rare diseases in Germany.

Methods: In order to assess the impact of the pandemic on people with rare diseases in Germany, a retrospective cross-sectional study was conducted using performance data from the statutory health insurance (SHI). The study was conducted in a stepwise approach, comprising 1) a systematic literature review, 2) expert discussions, 3) feasibility analyses and 4) a main analysis. The anonymized SHI claims data set with information on around 9 million people insured was used in this study. Observation period was 2017 to 2022. All 16 indications to be analysed were compared with each other in terms of successful annual diagnoses and other key figures collected. The dataset provided information on feasibility, demographics, work ability, healthcare resource utilisation, burden of disease, top 50 outpatient-, inpatient-, DRG-, OPS-, EBM- and ATC-codes and costs incurred.

Results: The sample drawn from the database contains almost 5 million individuals. In total 14,912 patients were identified within six years with an average age of 59.9. Patient numbers increased over time, but showed a decline in 2020 (2%). 10 of 16 diseases showed less documented patients compared to 2019. The annual diagnoses of all summarised indications showed an increasing trend. The absolute number of diagnoses only fell between 2019 and 2020, before rising sharply again in 2021. The annual mortality rates were between 5.6 and 7.1 per cent. An increase of one percentage point from 2020 was observable. Total patient counts and prevalence rates could be a hint to underline the assumption that less cases were identified due to the pandemic situation and less contacts of healthcare providers. In 7 subgroups the prevalence rates were in ranges as expected, in 5 subgroups the prevalence rates were over- or underestimated.

Conclusions: This study focuses on methodology's complexity and provides insights into the epidemiology and patient characteristics of 16 rare diseases. Initial results indicate that these vulnerable groups were significantly affected by the Covid-19 pandemic.

Survival of COVID-19 Infection after Integrated Resource Planning Vaccination among Thai Patients on Hemodialysis: An Observational Cohort Study

Manoch Rattanasompattikul,[1,2] Suchai Sritippayawan,[2,3] Sukit Raksasuk,[2] Pattharawin Pattharanitima,[4] Thatsaphan Srithongkul.[2,3] *[1]Golden Jubilee Medical Center, Faculty of Medicine Siriraj Hospital, Phutthamonthon District, Thailand; [2]Nephrology Division, Department of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]The Nephrology Society of Thailand, Bangkok, Thailand; [4]Nephrology Unit, Department of Medicine, Faculty of Medicine, Thammasat University, Pathumtani, Thailand.*

Background: In response to the pressing issue of limited vaccine supply and initial vaccine source acceptance, heterologous vaccination schedules were adopted, and integrated resource planning (IRP) and management were implemented. This study aims to estimate the change in odds of COVID-19 death following the Thai-IRP vaccination model in maintenance hemodialysis (MHD) patients.

Methods: An authorized committee thoroughly reviewed the data of patients receiving MHD admitted due to COVID-19 from January 2020 to December 2021. The sources of the databases for analysis are described in **Figure 1**. Conditional logistic regression was a fully adjusted model for mortality by dose and each type of vaccine.

Results: In total, 5824 MHD patients were identified with COVID-19 infection (53% male; mean age 58± 14 years). The mortality rate was 7% (N =409), with the underlying disease of diabetes and hypertension (17%), only diabetes (21%), and only hypertension (42%). Covariates associated with mortality in subgroups of the population at risk were significant with age ≥ 60 years, highest BMI and lowest nPNA, crude odds ratio (ORs) [95% CI] were 1.90 [1.54, 2.34], 1.65 [1.29, 2.13] and 1.77 [1.22, 2.56], respectively. The ORs focusing on the mortality outcome of various vaccinations showed that two doses of each vaccine type decreased mortality. The single dose of inactive SARSCoV-2 virus vaccines and ChAdOx1 nCoV-19 vaccine demonstrated increased ORs in the fully adjusted model (2.15 [0.82, 5.67] and 2.22 [1.17, 4.20]).

Conclusions: Our study underscores that age (≥ 60 years old), highest BMI, and lowest nPNA are associated with death in severe acute respiratory syndrome coronavirus two infections. Notably, the Thai-IRP model vaccination demonstrates a clear benefit from the first vaccination dose compared with no vaccine group in each type of vaccine, except the ChAdOx1 nCoV-19 vaccine, which showed an adverse outcome from the first vaccination dose.

Fear of COVID-19 after Vaccination Dissemination and Its Relationship with Multidimensional Health Literacy among Patients on Maintenance Hemodialysis

Atsuro Kawaji,[1] Ryohei Inanaga,[2,4] Takumi Toishi,[1] Masatoshi Matsunami,[1] Tomo Suzuki,[2,1] Tatsunori Toida,[2,3] Noriaki Kurita.[2] *[1]Kameda Medical Center, Kamogawa, Japan; [2]Fukushima Kenritsu Ika Daigaku, Fukushima, Japan; [3]Kyusyu University of Medical Science, Nobeoka, Japan; [4]Shinyurigaoka Sogo Byoin, Kawasaki, Japan.*

Background: A worldwide increase in anxiety due to the COVID-19 pandemic has been suggested to contribute to unhealthy lifestyle habits and depression among patients undergoing hemodialysis (HD). However, the degree of fear of COVID-19 after vaccination dissemination remains to be quantified. In addition, the independent impact of high-order health literacy (HL) on fear of COVID-19 has not been adequately investigated.

Methods: This was a multicenter cross-sectional study conducted in 2022 after the vaccination against COVID-19 became widely available in Japan. The subjects were adults receiving in-center HD. The exposure was multidimensional HL measured by the 14-item Functional, Communicative, and Critical Health Literacy scale. The outcome was the fear of COVID-19 measured by the 7-item Japanese version of the Fear of COVID-19 scale (FCV-19S; total score range 7-35 pts: higher scores indicate stronger fear). Differences in FCV-19S scores among the HD patients and those among Japanese adults in April 2020 (i.e., the beginning of the endemic) reported in the development paper were compared using the unpaired t-test. The association between multidimensional HL and FCV-19S scores was estimated using a multivariable-adjusted general linear model.

Results: In total, 446 HD patients were analyzed. Of these, 431 (96%) and 9 (2%) had received three and two doses of vaccination, respectively. Their FCV-19S scores were significantly lower than those of the general population at the beginning of the endemic ($P < 0.001$; mean difference -4.4 [95% confidence interval (CI): -5.1 to -3.7]; standardized effect size [ES] 0.77). Higher functional HL was associated with less fear (per 1-pt higher: -1.0 [95% CI: -1.7 to -0.3]; standardized ES -0.18). In contrast, higher critical HL was associated with stronger fear (per 1-pt higher: 2.0 [95% CI: 0.9 to 3.2]; standardized ES 0.36). Communicative HL was not associated with fear.

Conclusions: Even after widespread of vaccination, patients' fear due to low functional HL can be reduced by providing health information in an easy-to-understand manner. For patients with skepticism to correct information and strong fear due to excessive critical HL, honest explanations by healthcare providers may be important.

Proenkephalin in Critically Ill Patients with COVID-19

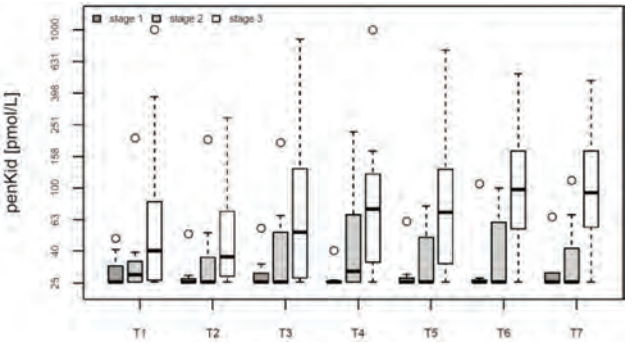
Marlies Ostermann,[1] Oliver Hartmann,[3] Janin Schulte,[3] Fabiola D'Amato,[1] Kyma M. Vas,[1] Shelley Lorah,[1] Gillian Radcliffe,[1] Nuttha Lumlertgul.[2] Sphingotec Penkid and GSST Research Team. *[1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [3]SphingoTec GmbH, Hennigsdorf, Germany.*

Background: There is growing evidence for proenkephalin A 119-159 (penKid) as an accurate biomarker to estimate kidney function and detect acute kidney injury (AKI) in various patient cohorts but its role in critically ill patients with COVID-19 has not been described.

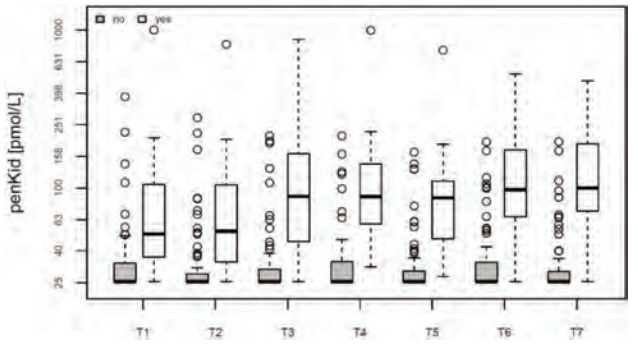
Methods: We recruited critically ill adult patients with COVID-19 admitted to the intensive care unit (ICU) in a University Hospital in London, UK, between August 2020 and January 2022 and measured plasma penKid levels daily for up to seven days. PenKid was compared in patients with and without AKI according to Kidney Disease Improving Global Outcomes (KDIGO) criteria and analyzed for prediction of need for renal replacement therapy (RRT).

Results: Ninety-one critically ill adult patients (34 females, 57 males; mean age 51 years; mean SOFA score 6) were admitted to the ICU. Sixty patients (66%) required mechanical ventilation, 36 patients (40%) had AKI at enrolment of whom 21 received RRT. Twenty-eight day mortality was 15.4%. Among the survivors, six patients (8%) were RRT dependent on day 28. During the first week after enrolment, plasma penKid was increased with stages of AKI and highest penKid levels were observed in patients receiving RRT (Figure 1). Plasma penKid on day 1 at ICU identified patients who were RRT dependent on day 28 (Figure 2).

Conclusions: In critically ill adults with COVID-19, penKid is a measure of kidney function, diagnoses AKI and predicts RRT dependence at 28 days.



penKid by AKI stage



penKid by RRT dependency on day 28

AKI in COVID-19 Associated Respiratory Failure (C-19RF) and Other Etiologies: Implications for Distinction in Clinical Characteristics, a Retrospective Analysis of the NU SCRIPTS Study

Jackson Rajendran, Carlos Valladares, Song Peng Ang, Bryan D. Gregory, Jose I. Iglesias, Maya Iglesias. *RWJBarnabas Health, Toms River, NJ.*

Background: Differences in the development of AKI in patients with C-19RF and other causes of severe respiratory failure (RF) may exist, which could have implications for clinical management. We retrospectively analyzed the NU SCRIPTS data to compare AKI's clinical characteristics and outcomes in C-19RF patients and RF attributable to other causes.

Methods: We evaluated 368 mechanically ventilated patients (pts.) from the NU SCRIPT study. AKI was defined as a ≥ 0.3mg/dl increase in serum creatinine within 48 hrs. Clinical and laboratory values obtained on admission were analyzed. We employed stepwise forward logistic analysis (LR) to determine those variables associated with C-19RF. In addition, we used logistic regression analysis LR to compare independent predictors of mortality in C-19RF and RF pts. Those variables found to be statistically significant in univariate analysis ($p < 0.05$) were included in the LR analysis.

Results: A total of 250 pts developed AKI, consisting of 81 patients with C-19RF and 169 RF pts. There was no significant difference in mortality between C-19RF and RF groups (43 vs 47%). Likewise, there was no difference between groups in the need for renal replacement therapy. Stepwise LR demonstrated that increased days on mechanical ventilation, non-Caucasian race, hemoglobin, and increased platelet white blood cell ratio (Plt./WBC) were associated with C-19RF. LR demonstrated that SOFA score, higher O2 saturation and a higher Plt./WBC were associated with increased mortality in C-19RF patients. In contrast, in the RF pts. increased age, Sofa score, vasopressor requirement, and the need for renal replacement therapy were independently associated with mortality.

Conclusions: There are significant differences in clinical outcomes between C-19RF and RF pts developing AKI. These findings suggest a different clinical course and phenotype in the groups. These findings emphasize tailored management strategies based on respiratory failure etiology for better outcomes in C19RF and RF populations.
