Conclusions: The use of an intensive monthly ultrasound surveillance protocol for VA is positively associated with a significantly improved cumulative survival of VA for hemodialysis. By offering the advantage of a timely diagnosis of VA dysfunction enables physicians to perform pre-emptive access corrective procedures improving thus VA patency rates. The establishment of firm conclusions requires the conduction of randomized controlled trials to address to the gap of knowledge and debate regarding VA surveillance.

TH-PO338

The Possibility of Ionic Dialysance as an Index to Predict the Dysfunction of Vascular Access

Haksoo Kim, Soon Bae Kim, Jai won Chang. *Division of Nephrology, Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: Vascular access dysfunction (VAD) in hemodialysis (HD) results in insufficient dialysis dose represented by low Kt/V_{urea} calculated using the serum levels of BUN. If Kt/V_{urea} declines by more than 0.2 without any specific cause, VAD accounts for 70% of the causes. However, the measurement of Kt/V_{urea} in every session of HD is very cumbersome in clinical practice. Ionic dialysance, Kt/V_{ID} calculated by on-line monitoring of conductivity, is easy, non-invasive, able to be measured in every session without cost. Although Kt/V_{ID} was not the same value as Kt/V_{urea}, it was highly correlated with Kt/V_{urea}. The aim of this study is to investigate whether Kt/V_{ID}, instead of Kt/V_{urea}, could be used as an index for the detection of VAD by analyzing the change of Kt/V_{ID} before and after intervention.

Methods: We conducted a retrospective study in 23 patients (M:F=13:10, median of age 71 (IQR 63~80) years, HD duration 80 (43~128) months, AVF:AVG=7:16, DM:non-DM=12:11) underwent 29 times of intervention for VAD between Jan 2017 and Apr 2018. We gathered demographic data and available Kt/V_{ID} in our subjects for 14 days just before and just after intervention by reviewing electronic medical records.

Results: The median age of vascular access was 48 (IQR 20~60) months in this study. The main intervention for VAD was percutaneous transluminal angioplasty (96.5%). Thrombectomy (10.3%) or the insertion of peripheral stent (6.9%) was combined, if needed. Although the change of arterial static intra-access pressure ratio (SIAPR) was not significant, venous SIAPR significantly decreased after intervention (0.613 ± 0.194 vs. 0.399 ± 0.159, $p < 0.01$). The intervention for VAD showed the significant increase in Kt/V_{urea} (1.66 ± 0.29 vs. 1.75 ± 0.28, p=0.044) and in Kt/V_{ID} (1.26 ± 0.30 vs. 1.31 ± 0.30, p=0.038).

Conclusions: Considering the significant increase of Kt/V_{ID} before and after intervention, the reduction of Kt/V_{ID} could be used as an index to require the intervention for VAD. In the future, the analysis of prospectively collected Kt/V_{ID} at every HD session is necessary to define the degree of decrement in Kt/V_{ID} to suggest critical VAD.

TH-PO339

A Noninvasive Method for Assessing Arteriovenous Access Recirculation Using the Crit-Line® Monitor in Hemodialysis Patients: An In Silico Analysis

Vaibhav Maheshwari,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] RRI *[1]Renal Research Institute, New York, NY; [2]Department of Nephrology, Icahn School of Medicine at Mount Sinai, New York City, NY.*

Background: The arteriovenous vascular access is the Achilles' heel of hemodialysis (HD). Access malfunction, often caused by stenosis or thrombosis, results in reduced access flow, increased access recirculation (AR), and lower Kt/V_{urea}. Measurement of access recirculation is a common method to detect fistula problems; however, existing methods are either invasive, costly, or labor intensive. We propose a novel method to measure AR using the Crit-Line® Monitor (CLM), which is non-invasive and free for existing CLM users.

Methods: The proposed method is based on an abrupt increase in ultrafiltration rate (UFR) for a brief period, which will increase the hemoglobin (Hgb) concentration at the dialyzer outlet. When a fraction of this venous return recirculates in the access, we will observe increased Hgb concentration on the CLM. We developed a mathematical model of an extracorporeal dialysis circuit. We perturb the UFR from 10 mL/min (assumed baseline) to 50 mL/min during HD. In the simulations, we start with a known AR and observe the effect of UFR perturbation on CLM-reported Hgb.

Results: At the baseline UFR of 10 mL/min and assumed AR of 10%, when systemic Hgb concentration is 10 g/dL, the CLM Hgb concentration will be 10.04 g/dL. An increase in UFR to 50 mL/min increases the CLM Hgb concentration to 10.23 g/dL. If AR is 20%, the CLM Hgb concentration will be 10.52 g/dL (Figure 1). Per our model, the time required to observe the change in Hgb concentration is less than 3 min. These changes in Hgb concentration can be discerned by the CLM. Systemic Hgb concentration is assumed constant during the simulation period. Based on the described principle, the mathematical expression in Figure 1 can be used to calculate AR.

Conclusions: With a simple UFR perturbation, AR may be measured in every HD session. Our simulation results warrant validation in a clinical study.

$$AR\,[\%] = \frac{(Hgb_1 - Hgb_2)}{Q_b\left(\frac{Hgb_1}{Q_b - Q_{uf,1}} - \frac{Hgb_2}{Q_b - Q_{uf,2}}\right)} \times 100;$$

$Q_{uf,1}$ – Baseline ultrafiltration rate
$Q_{uf,2}$ – Perturbed ultrafiltration rate
Hgb_1 – Baseline hemoglobin concentration
Hgb_2 – Perturbed hemoglobin concentration
Q_b – Arterial blood flow rate

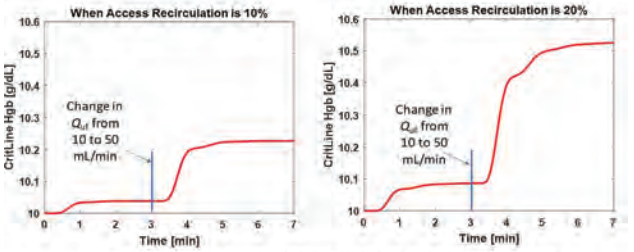

Figure 1: Effect of ultrafiltration perturbation on the hemoglobin concentration.

Ultrasound-Guided Percutaneous Transluminal Angioplasty for Stenosis and Occlusion in Juxta-Anastomosis Arteriovenous Fistula: A Single Center Research Study

Wan Ziming, Hui Gu. *Department of Nephrology, the First Affilicated Hospital of Chongqing Medical University, Chongqing, China*.

Background: Arteriovenous fistula (AVF) is the preferred access for hemodialysis. Percutaneous transluminal angioplasty(PTA) has become a choice for AVF stenosis and ultrasound has been used in PTA more and more frequently.

Methods: In 2016,192 patients underwent PTA in our hospital. Angioplasty was performed using a non-compliant high pressure balloon. The process was visualized by duplex scan. Our inclusion criteria were:1)Stenosises or occlusions were located at juxta-anastomosis:the first 5cm of vein distal to the anastomosis;2)Stenosis was confirmed with conditions:*a*.flow rate is<500ml/min in brachial artery and<200ml/min in fistula during dialysis;*b*.diameter of stenosis is<1.7mm.

Results: 129 patients with 76 males were analyzed.104 of them have AVFs on left arm, and there is one Ulnar-basilic AVF while others are Radial-cephalic AVF. The comparasion of variables are presented in the table. We use Kaplan-meier curve to show the primary and secondary patency rates of patients with stenosis and occlusion respectively. The primary patency rates are better in occlusion(P<0.05), while secondary patency rates have no difference. The primary patency rates are better in patients without diabetes mellitus(P<0.05)while the secondary patency rates had no difference.

Conclusions: For the juxta-anastomosis's stenosis or occlusion, PTA can be used to obtain satisfactory results.

variables comparison

	Before the procedure	After the procedure	p

TH-PO341

Comparison of Peripheral Cutting Balloon vs. Conventional Balloon Angioplasty for Hemodialysis Vascular Access Stenosis: Prospective Randomized Controlled Trial

Masaaki Murakami,[1,2] Kiyoshi Mori,[3] Masashi Mukoyama.[4] *[1]Nephrology, Shizuoka General Hospital, Shizuoka, Japan; [2]nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [3]University of Shizuoka, School of Pharmaceut Sci, Shizuoka, Japan; [4]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan*.

Background: Adequate vascular access is essential for undergoing hemodialysis treatment. Even though clinical success rate of PTA is high, the patency of conventional PTA is relatively low. The cutting balloon which has small blades to create sharp incisions into neointimal hyperplasia is designed to minimize vessel damage. Although few randomized trials have evaluated cutting balloon angioplasty for vascular access, larger study are needed.

Methods: This prospective, randomized single-center clinical trial included patients who had a hemodynamically significant vascular access stenosis within 6 months after the previous procedure. The study was designed to evaluate the efficacy and safety of cutting balloon (cutting balloon group) as compared with conventional balloon angioplasty (conventional balloon group) for the short-time patency cases in the previous treatment. The Kaplan-Meier method was performed to assess the primary and secondary patency of treatment lesion and whole access circuit. A log-rank test was used to evaluate the differences of patency between each group.

Results: One hundred fifty-seven patients provided informed consent and were randomly assigned to undergo cutting balloon angioplasty or conventional balloon angioplasty from December 2012 to November 2017. The clinical success rate was 100% in the both groups. The anatomical success rates were 64.0% in cutting balloon group and 53.9% in conventional balloon group. The primary patency of target lesion was significantly better in the cutting balloon group (28.3%) than in the conventional balloon group (14.1%) at 6 months (P=0.009). The mean pain scale measured using Visual Analogue Scale during the cutting balloon dilation (38.8±25.1) was much lower than the conventional balloon (57.5±28.5) (P<0.001). The average percent stenosis decreased significantly after PTA using the cutting balloon (Δ-49.1%) compared with the conventional balloon (Δ-40.9%) (P=0.0007). Access flow measured by the duplex doppler ultrasonography improved after PTA in both groups. Change in access flow in the cutting balloon group (Δ+308±221) was greater than conventional balloon group (Δ+240±152) (P=0.027).

Conclusions: Our data suggest that cutting balloon angioplasty is effective for patients whose vascular access were short-lived.

TH-PO342

Drug Eluting Balloon Angioplasty in Dialysis Access

Ittikorn Spanuchart, Kenneth D. Abreo, Adrian P. Sequeira, Bakhtiar Amin, Mary A. Buffington, Adrian P. Abreo, Bharat Sachdeva. *Louisiana State University Health Sciences Center, Shreveport, LA.*

Background: Recurrent stenosis is responsible for less than 50 percent patency at 6 months. Neo-intimal hyperplasia (NIH) is driven by hemodynamic factors and barotrauma from angioplasty. Paclitaxel has been shown to reduce NIH. In a RCT, paclitaxel-coated

balloon (Lutonix®) angioplasty compared to conventional angioplasty in AVFs showed better target lesion primary patency (TLPP) at 24 months. We present our data using Lutonix® in the treatment of recurrent stenosis in dialysis accesses.

Methods: This is a retrospective review of all angioplasties from June 1, 2017 to December 31, 2018 done at our hospital. A total of ten patients who underwent Lutnonix® angioplasties after successful conventional balloon angioplasties (< 30% residual stenosis) were included in the study. The target lesion angioplasty free periods before and following Lutnonix® angioplasty were reviewed. Re-interventions requiring angioplasty were clinically driven.

Results: Technical success of target lesion angioplasty was 100% for all angioplasties. The Lutonix® application following conventional angioplasty had a twice longer angioplasty free period compared to conventional angioplasty alone (mean of 320 versus 166 days, respectively) which represents a difference of 154 days, p = 0.04, 95% CI (11, 297). The 6-month TLPP (the index lesion) following Lutonix® angioplasty was 80%. No complications were reported with its use.

Conclusions: Lutonix® application following successful conventional angioplasty appears effective in delaying dialysis access clinically-driven re-stenosis requiring angioplasty. Further longer term studies are required to confirm the effectiveness of the Lutonix® angioplasty and see it is a suitable alternative for stent placement.

TH-PO343

No Increase in All-Cause Mortality from Paclitaxel Coated Balloons (DCB) Used in an Arteriovenous Circuit in Dialysis Patients

Prabir Roy-Chaudhury,[1] Theodore F. Saad,[2] Scott O. Trerotola.[3] on behalf of the Lutonix AV IDE investigators and the Medical Advisory Board *[1]University of North Carolina, Chapel Hill, NC; [2]Nephrology Associates, PA, Newark, DE; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Recent data have suggested an increased mortality in patients treated with paclitaxel balloons (DCB) in the femoropopliteal circulation. In order to assess this issue, in the setting of hemodialysis patients, a post-hoc analysis was performed to describe short (6 month), medium (12 month) and long term (24 month) mortality, in a randomized study on the use of DCB in failing arteriovenous fistulae (AVF).

Methods: 285 patients were enrolled at 23 centers. Patients in both arms received vessel pre-dilatation followed by treatment with either a DCB or a control balloon of similar design to the DCB but without drug (PTA group). Endpoints included 3, 6, 9, 12, 18 and 24 month target lesion primary patency (TLPP), number of interventions required to maintain target lesion patency, and safety endpoints. A special focus of this presentation is a comparison of survival at 6, 12 and 24 months in the two arms of this study.

Results: The DCB and Control (PTA) groups were evenly matched with regard to age, sex, hypertension and smoking. 6 month post intervention primary patency was 71.4% for DCB and 63% in the control (p=NS). There were, however 31.3% fewer interventions at 6 months at the target lesion for the DCB group. A post-hoc analysis documented that there were no significant differences in all cause mortality (see Table) between the DCB and control (PTA) groups at 6 months (6.4% vs 4.2% mortality respectively), 12 months (12.8% vs 9% mortality) and 24 months (23.4% vs 18.1%). p = NS for all analyses.

Conclusions: These data (from the first large prospective randomized trial on the use of DCB in failing AVF) document that the use of DCB in the arteriovenous circuit (failing AVF) does not result in a statistically significant increase in mortality at the short (6 months), medium (1 year) and longer term (2 years) endpoints.

Abstract Withdrawn

TH-PO345

Post-Dialysis Bleeding from AV Fistula (AVF) or Graft (AVG)

Daniel Kushnir, Alon Antebi, Tatiana Tanasiychuk, Jerom Marcuson, Oleg Sura, Amnon Gil, Victor Frajewicki. *Carmel Medical Center, Haifa, Israel.*

Background: AVF is the the preferred access for hemodialysis, and AVG is considered the second best choice. Bleeding from the puncture site after withdrawal of needles is a frequent event in the dialysis unit. The duration of "normal" bleeding time is not well defined. Usually bleeding lasts for up to 10 min, but if this bleeding persists for more than 30 min is considered as prolonged. The purpose of this study was to understand what is considered a normal bleeding time among patients and staff.

Methods: This was a cross-sectional study using a convenient cohort. In this setup, we conducted an anonymous survey in 4 dialysis units (3 hospital based and 1 community located), asking patients, nurses and physicians about issues related with bleeding after needles are removed: the average bleeding time, the difference time between AVF/AVG, the effect of Heparin use on postdialysis hemorrhage, the use of device for bleeding control and the influence of high venous pressure on bleeding.

Results: A total of 92 persons (patients 50%, nurses 38%, physicians 12%) answered the survey. The average bleeding time after a puncture of AVF recorded by patients was 11±7 min and 14±6 with an AVG. This bleeding time was not significantly different from the time defined by nurses (9±7 and 14±4 min) or physicians (8.5±2 and 12±5min). In terms of differences between AVF/AVG, 32% of patients, 26% of nurses and 10% of physicians estimated that there was no difference. Around 30% of the interviewed stated that bleeding may be related to the heparin administration. Use of an hemostatic device was registered by patients in 37%, nurses in 77% and physicians in 90%. Fifty percent of patients thought that bleeding may be related to high venous pressure, as opposed to 88% of the nurses and 100% of the physicians.

Conclusions: Bleeding from the puncture site concern patients, nurses and physicians. Differences of understanding and expectations were appreciated between these groups, showing how much more education must be provided in this field.

TH-PO346

An Endovascular Treatment System for Occluded Native Arteriovenous Fistula

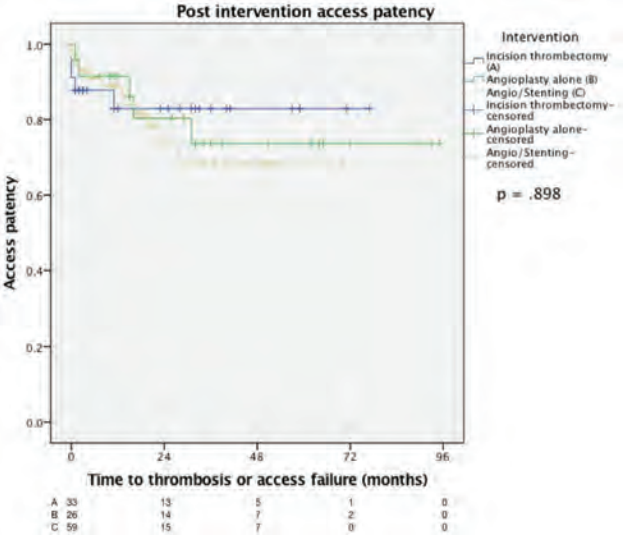
Christopher C. Leo,[1] Jan Swinnen.[2] *[1]National University Hospital, Singapore, Singapore; [2]Westmead Hospital, Sydney, NSW, Australia.*

Background: Westmead Hospital looks after a high number of patients on haemodialysis and because of the superior outcomes achieved with our endovascular techniques in occluded fistulas, from 2005 onwards, all patients who presented with an occluded native arteriovenous fistula (nAVF) to the Western Renal Area institution, were referred to our unit. We have also developed minimally invasive techniques to mature and repair dysfunctional nAVF including techniques to reestablish the flow through a thrombosed nAVF. The aim of this study is to present the techniques and results of the Endovascular Treatment System that we have developed for managing the occluded nAVF.

Methods: The current study is a retrospective chart review on all patients who presented with an occluded nAVF and underwent attempted resuscitation between the 1st January 2005 to 31st of December 2014.

Results: 130 patients were included in the study. Post intervention primary access patency was 83.8% at 6 months, 78.7% at 12 months, 64.6% at 2 years and 59.6% at 3 years. Post intervention assisted access patency in fistulas-in-use was 86.5% at 6 months, 81% at 12 months, 66.8% at 2 years and 61.2% at 3 years. Post intervention secondary patency for all cases was 84.7% at 6 months, 80.2% at 12 months, 66.1% at 2 years and 62% at 3 years. Post intervention secondary patency in fistula-in-use was 91.1% at 6 months, 90% at 12 months, 85% at 2 years and 74.6% at 3 years. Neither access survival nor patency differed significantly when incisional thrombectomy was compared to angioplasty with or without stenting with access survival of 91.2% and 92.5% at 12 months and access patency of 82.9% and 89.7% at 12 months (p = .834 and p =.898 respectively).

Conclusions: In autologous arteriovenous thrombosed fistulae the use of purely endovascular techniques to revive the access is a viable and safe technique to employ in most cases.



TH-PO347

Primary Patency of Single-Needle Puncture for Arteriovenous Fistula Stenosis Resistant to High-Pressure Balloon

Xiao-mei Huang. *Nephrology, the Central Hospital of Wuhan, Tongji Medical College, Huazhong University of Science and Technology, Wuhan Central Hospital, Wuhan, China.*

Background: To evaluate primary patency, safety and Doppler ultrasound data of single-needle puncture (SNP) treatment for AVF stenosis resistant to high-pressure balloon (HPB).

Methods: A retrospective study were conducted from June 2017 to August 2018 that included 83 patients who received PTA for AVF stenosis. Patients were allocated to SNP if AVF stenosis were resistant to HPB. Data collection included AVF stenosis location, stenosis length, percent stenosis, resident inner diameter, balloon pressure,intima thickness, mean access blood flow before and after intervention, complication and primary patency determined by Kaplan-Meier analysis.

Results: I type AVF stenosis (55.4%) were the most in 83 enrolled patients. Sixty-eight patients(81.9%) got technical success with HPB. The remaining 15 patients were allocated to SNP. Ten of 15 patients(88.0%)resistant to HPB got technical success with SNP. There were no significant difference in AVF stenosis location, stenosis length, residual inner diameter and percent stenosis between SNP and HPB. Balloon inflation pressure and inflation times during operation in SNP group (21.9±2.1 atm and 4.4±2.1 times) were higher compared with HPB (15.6±4.5 atm and 1.9±0.6 times). The mean increases in access blood flow after PTA were 578.9±150.8ml/min with SNP and 487.2±100.5ml/min with HPB (p=0.006). Primary patency were similar with SNP and HPB (63.6% v.s.66.5% in the 6th month and 14.5% v.s.7.7% in the 12th month, p=0.65). Intima were thicker in SNP group than HPB group before PTA(1.2±0.3 vs 1.0±0.3,p=0.029), but were similar 6 months after PTA(1.5±0.3 vs 1.3±0.4,p=0.24). No uncontrolled complication endangered AVF occurred.

Conclusions: SNP is a safe option for AVF stenosis resistant to HPB with satisfied primary patency and no more financial burden.

TH-PO348

Risk Factor Profile for Thrombophilia in Patients with ESRD on Maintenance Hemodialysis with Recurrent Arteriovenous Fistula Clotting

Sunnesh Reddy,[1] Venkata A. Yalamanchili,[2] Harini N. Devi,[3] Sarma Pvgk,[4] Sai N. Sameera,[1] Siva K. Vishnubotla,[1] Ram Rapur.[1] *[1]Nephrology, Sri Venkateswara Institute of Medical Sciences, Tirupati, India; [2]Dallas Nephrology Associates, DeSoto, TX; [3]Biochemistry, Sri Venkateswara Institute of Medical Sciences, Tirupati, India; [4]Bio-Technology, Sri Venkateswara Institute of Medical Sciences, Tirupati, India.*

Background: Vascular access is critically important for hemodialysis patients, being both a lifeline and an Achille's heel. Failure of arteriovenous fistula (AVF) has a substantial impact on the patient in terms of economic burden, morbidity and all-cause mortality. Thrombosis is the leading cause of AVF failure accounting for 80-85% of AV access loss. Since limited number of well-established risk factors for access thrombosis are known, in the present study we evaluated the relation between hereditary and acquired thrombotic factors contributing to recurrent AVF thrombosis. We also studied the association between recurrent AVF thrombosis with thrombotic factors in comparison with well-functioning fistulas and its association with ABO blood group, age, gender and diabetes.

Methods: This is a cross-sectional observational study with a total of 100 hemodialysis patients. 50 patients with recurrent AVF failure secondary to access thrombosis served as cases and 50 patients with well working AVFs as controls. Parameters studied are hereditary thrombotic factors- Factor V leiden (G1691A), Factor XIII (val34leu), Prothrombin (G20210A), MTHFR (C677T) by DNR isolation and PCR products and acquired thrombotic factors - Lipoprotein (a), Fibrinogen using immunoturbidimetry, Homocysteine by enzyme recyclic and Anticardiolipin antibody(IgG and IgM) by ELISA method.

Results: In our study hereditary factors were not significantly different between the two groups but acquired factors Lipoprotein (a), Fibrinogen, Homocysteine, Anticardiolipin Antibody IgG and IgM were found to be elevated in patient with recurrent AVF thrombosis when compared to controls (P 0.001). There was significant association between recurrent vascular access thrombosis and non O blood groups (P 0.047). Anemia (Hb < 10 gm/dl) was observed in patients with recurrent vascular access thrombosis when compared to well working fistulas. We did not find a significant association between age, gender and presence of diabetes contributing to recurrent vascular access thrombosis (P 0.826).

Conclusions: Acquired thrombotic factors contribute to recurrent AVF clotting in patients on maintenance hemodialysis. Recurrent AVF thrombosis is more common in non-O blood group and in patients with anemia.

TH-PO349

Coagulation Differences in Dialysis Vascular Access Failure

Danielle Wentworth, Brent J. Portz, Uta Erdbruegger. *University of Virginia Division of Nephrology, Charlottesville, VA.*

Background: Vascular access failure in hemodialysis patients is often caused by access stenosis or thrombosis. Neointimal proliferation and abnormal coagulation play important pathogenetic roles. Currently, no biomarker is available for prediction of access failure leading to stenosis and thrombosis. Sonorehometry is a novel tool assessing blood clot elasticity. We hypothesize blood clot elasticity can be a valuable tool to diagnose vascular access complications in hemodialysis.

Methods: In a cross-sectional study, conventional markers of coagulation including Fibrinogen, platelet count, PT/INR, and aPTT were measured in 21 patients on chronic hemodialysis (for over 3 months). 6 patients had recurrent vascular access failure caused by concurrent thrombosis and stenosis, 9 patients had recurrent access stenosis without thrombosis and 6 patients had functioning access without complications. For each patient, QPlus Cartridge was run on Quantra analyzer to measure coagulation parameters, including Clot Stiffness (CS). Kruskal – Wallis Test was used for in group comparisons and Pearson / Spearman analysis for correlation of fibrinogen level, platelets count and CS.

Results: There was no statistical differences in stiffness parameters in the 3 subpopulations. However, the patients with recurrent vascular access complications caused by Thrombosis/Stenosis had high CS values (figure 1). Numerically higher fibrinogen values were found in patients with vascular access complications.

Conclusions: Hemodialysis patients with recurrent vascular access complications due to thrombosis/stenosis might have higher clot stiffness and signs for a hypercoagulable state explained by the renal failure. A larger cohort needs to be examined to confirm findings and demonstrate that clot stiffness can be utilized to monitor dialysis patients for vascular access complications.

TH-PO350

Antiphospholipid Antibodies Significance in Hemodialysis Patients: A Single-Center Cohort Study

Fatim Camara, Maxime Taghavi, Agnieszka Pozdzik. *Centre Hospitalier Universitaire Brugmann, Brussels, Belgium.*

Background: Antiphospholipid syndrome (APS) is an autoimmune disease caracterized by arterio-venous thrombotic manifestations and persistently positive antiphospholipid antibodies (APAb) as reported in the revised Sapporo classification criteria. The prevalence of APAb in haemodialysed patients is higher compared to the general population. Their role in the occurrence of vascular access thrombosis remains controversial. This study aims to determine the prevalence of APAb and APS and to evaluate their association with vascular access thrombosis and quality of extrarenal purification in haemodialysis patients.

Methods: This is a singler-centre crosse sectional study including 145 haemodialysis patients with available demographic, clinical, biological and immunological parameters (APAb) as well as haemodialysis characteristics. Antiphospholipid biology was defined as persistently positive antibodies (at least 12 weeks apart) without history of clinical manifestation.

Results: The prevalence of antiphospholipid biology (APB) and APS were respectively 17.7% (12/ 117) and 10.3% (6/117). Those patients were younger. Antiphospholipid biology is significantly associated with arterial hypertension and diabetes while the antiphospholipid syndrome with dyslipidaemia. Antiphospholipid biology is a significant risk factor for lower Kt/V independently of type of membrane or haemodialysis modality (conventional haemodialysis versus hemodiafiltration). The APS is associated with vascular access thrombosis. Interestingly, patients with one positive APAb at the screening that were controlled negative during the follow-up were still expose to an increased risk of arterial thrombosis (however this did not reach statistical significance, p = 0,054). These patients were not at risk for vascular access thrombosis.

Conclusions: Despite a small sample size, we report that antiphospholipid syndrome increases the risk of vascular access thrombosis and is an independent risk factor of a lower Kt/V. Our observation underlines the importance of antiphospholipid antiboidies screening in hemodialysis patients and needsmerits to be validated by prospective studies.

TH-PO351

Quantified Vascular Calcification of Vascular Access: Correlation with Coronary Artery Calcium Score and Survival Analysis of Access and Cardiovascular Outcome

Hyunsuk Kim,[2,1] Bom Lee,[1] Houn Jung,[4] Gwangho Choi,[3] Jong-woo Yoon.[2,1]
[1]Chuncheon Sacred Heart Hospital, Chuncheon, GangWon-Do, Republic of Korea; [2]Hallym university, Kidney research institute, Chuncheon, Republic of Korea; [3]Hallym Chuncheon Sacred Heart Hospital, Chuncheon, Please Select, Republic of Korea; [4]Hallym University Medical Center, Chuncheon-si, Republic of Korea.

Background: Vascular calcification (VC) is the major contributor to mortality and morbidity in end-stage renal disease (ESRD) patients. We investigated whether there is a correlation between Coronary artery calcium score (CACS) and quantified vascular calcification score (VCS) of the arm including vascular access and whether VC increases the incidence of intervention and major adverse cardiac and cerebrovascular events.

Methods: ECG gated, non-contrast arm CT scan including vascular access and the coronary vessel was taken. Later, CACS and VCS were measured by using Aquarius Ver. 4.4.12 simulating the Agatston Method. We examined if the subjects with CACS>400 was higher in the group of VC>500, a cutoff of the highest 40% of VC. Survival analysis according to VCS groups was also performed.

Results: In the total 77 patients, there were 44 males (57.1%), and the mean age was 63.9 years. The median vintage of hemodialysis was 49.4 [31.5, 99.2] months. When dividing the patients into two groups based on VCS 500 (lower VCS vs. higher VCS), there were no differences between the 2 groups in sex, age, ESRD etiology, and type of vascular access. However, the HD vintage was significantly older in higher VC group. Median VC and CACS were higher in the higher VC group (VC, 144[75,264] vs. 1058 [713, 3355]; CACS, 21 [0, 171] vs. 552 [93, 2430], P<0.001), and the ratio of the subjects with CACS>400 was higher (17.4% vs. 61.3% P<0.001). Since interventions can occur multiple times in one patient and each intervention is not independent, the Prentice, Williams and Peterson Total Time survival analysis model was used. Intervention Hazard ratio (HR) of the higher VCS group increased by 3.2 times. Additionally, longer duration of hemodialysis and higher magnesium (>2.5 mg/dL) had the lower HR of intervention. Moreover, in the higher VCS group, the HR of MACCE increased 2.3 times.

Conclusions: We quantified the VC and found for the first time that it is associated with CACS. Considering that CACS is closely related to the cardiovascular outcome, VC may also be suggested as a new biomarker to predict the outcome of ESRD patients. Higher vascular calcification increased the risk of access intervention and MACCE.

TH-PO352

Severe but Not Mild Hand Ischemia Is Associated with Poorer Survival in Hemodialysis Patients

Michael Gerrickens,[2] Reshabh Yadav,[2] Rosanne Wouda,[1] Marc Scheltinga.[2]
[1]Zuyderland MC, Heerlen, Netherlands; [2]Maxima MC, Veldhoven, Netherlands.

Background: Some hemodialysis (HD) patients develop hemodialysis access-induced distal ischemia (HAIDI) of the hand that is caused by loss of blood pressure along the heart-hand axis. Anecdotal data suggest that the presence of hand ischemia is associated with poorer patient survival. We hypothesized that patients with severe HAIDI have a worse survival compared to patients with mild or no HAIDI.

Methods: Two patient groups were studied between January 2006 and December 2018 in one Dutch hospital. A control group consisted of patients on stable HD without symptoms or signs of hand ischemia. The experimental group (HAIDI) reported pain and coldness in the dialysis hand in the presence of low digital brachial indices DBIs (normal >0.8, now <0.6). HAIDI patients were graded as mild (Grade I-IIa) or severe (IIb-IV) as suggested by a 2016 consensus meeting. Access flows (Qa) were obtained and potential factors associated with 4-year overall survival were calculated using standard statistical testing.

Results: Age and time on HD tended to be higher in controls (n=45, 24 males; age 73yrs ±12, HD 34months ±26) compared to the HAIDI group (n=49, 26 males; age 68yrs ±16, HD 23months ±28; 0.05<p<0.09). Controls displayed lower Qa and higher DBI (Qa: 1.2L/min ±0.1 vs 1.8L/min ±0.2; DBI 0.80 ±0.2 vs 0.34 ±0.03; both p≤0.001). Interestingly, both Qa and DBI were higher in mild HAIDI (n=26) compared to severe HAIDI (n=23; Qa: 2.4L/min ±0.2 vs 1.1L/min ±0.1; DBI 0.42 ±0.02 vs 0.26 ±0.05; both p=0.005). A total of 43 patients (47%) died during the 4-year follow-up. Overall 2 and 4-year survival were similar in controls and grade I-IIa HAIDI (2-year 79% ±5; 4-year 55% ±6) but lower in grade IIb-IV HAIDI (2-year 58% ±10; 4-year 34% ±10; p<0.028). Following correction for age (HR 1.04 [1.01 - 1.07]), presence of diabetes (HR 2.11 [1.13 - 3.04]) and cardiovascular disease (HR 2.74 [1.48 - 5.09]), low DBI displayed some predictive value for 4-year mortality (HR .99 [.98 - .99], p=0.05)

Conclusions: Severe hand ischemia is associated with poorer survival in HD-patients. Moreover, lower DBI-values have some predictive value for overall mortality, even when correcting for known risk factors.

TH-PO353

Excessively High Fistula Flows in Hemodialysis Patients Possibly Result in an Irreversible Loss of Arterial Remodelling Capacity

Michael Gerrickens,[3] Roel H. Vaes,[1] Vivi Wiersma-van Rijn,[3] Sander Van kuijk,[2] Maarten G. Snoeijs,[2] Bas Govaert,[3] Marc Scheltinga.[3]
[1]St Vincent's Hospital Melbourne, Richmond, NSW, Australia; [2]Maastricht University Medical Centre, Maastricht, Netherlands; [3]Maxima MC, Veldhoven, Netherlands.

Background: Longstanding high flows in hemodialysis access (high flow access, HFA, >2L/min) likely harm hemodialysis patients due to cardiac overload. Flow reduction is advised, especially if hemodialysis access-induced distal ischemia (HAIDI) is also present. Revision using distal inflow (RUDI) effectively reduces flow but high flows often recur. We hypothesized that RUDI would result in shrinking of the brachial artery and dilatation of both the radial artery and greater saphenous (GSV) interponate.

Methods: HFA-patients with a brachial-artery based arteriovenous fistula with high flows (>2L/min) who underwent RUDI between 2011 and 2016 in two Dutch hospitals underwent serial Duplex sonography prior to and 2 and 12 months following RUDI. Volume flow (L/min), diameter (mm) and peak systolic velocity (PSV, cm/s) of the brachial artery, radial artery and GSV were measured. HFA-patients were grouped according to concomitant presence of hand ischemia (HFA-HAIDI), or absence (HFA).

Results: Fifteen patients (54 yr ±16, 10 males; HFA-HAIDI, n=6; HFA, n=9) with a brachial artery HFA undergoing RUDI were studied. Despite an initial decrease in brachial arterial flow followed by a slight increase (preoperative 2.7L/min ±0.3; two months 1.2L/min ±0.2; twelve months 1.5L/min ±0.2; p<.001), brachial artery diameters remained unchanged (7.4mm ±0.5). Proximal radial artery diameters doubled (overall 2.6mm ±.2 to 5.4mm ±1.0, p<.001), albeit less prominent in the HFA-HAIDI-group (+80%) than in the HFA-group (+130%, p=.019). Neither dilatation nor aneurysmatic degeneration were found in the GSV-interponate.

Conclusions: Revision using distal inflow (RUDI) for high flow access (HFA) reduction does not reverse brachial artery dilatation suggesting irreversible structural arterial wall damage possibly contributing to recurrent high flow. Radial artery remodelling is attenuated in HFA-patients previously reporting concurrent hand ischemia, diminishing the likelihood of high flow recurrence in this subgroup. The greater saphenous vein does not dilate within one year following RUDI.

TH-PO354

An Online Ultrafiltration Rate Calculator to Empower Home HD Patients

John W. Agar,[1,2] Dorian R. Schatell.[3]
[1]University Hospital Geelong, Geelong, VIC, Australia; [2]School of Medicine, Deakin University, Geelong, VIC, Australia; [3]Medical Education Institute, Madison, WI.

Background: Despite a 3 decade solute clearance focus, hemodialysis (HD) outcomes correlate more closely with volume factors, especially the rate of change of blood volume. A high ultrafiltration rate (UFR) induces hypotension, hypoperfusion, and functional organ stunning.(1) Thus, a low sessional UFR is critical for circulatory stability. As salt and fluid restriction often manifestly fail to limit interdialytic weight gain**,** HD sessional duration becomes the governing variable to assure a low, safe UFR. While the ideal safe mean maximum per treatment UFR remains in debate, clinical risk increases as the UFR exceeds 6-8 ml/kg/hr, (2) although US guidelines currently recommend a UFR <13ml/kg/hr. Since home HD (HHD) patients can self-adjust their treatment time to ensure a low UFR, we devised an on-line UFR calculator to display the impact of UFR and encourage patients to safely use this flexibility.

Methods: Using the interdialytic weight gain (IDWG), pre-dialysis weight (pre-DW), and intended upcoming treatment time (t), the mean treatment UFR (ml/kg/hr) can be calculated by UFR = (IDWG ÷ pre-DW) ÷ t. This (1) informs impending treatment UFR safety and (2) allows treatment time adjustment to the desired UFR maximum. On-line since 2/2017, an open-access calculator https://www.homedialysis.org/ufr-calculator on the Home Dialysis Central website has facilitated UFR (ml/kg/hr) and 't' flexibility. We have interrogated the site analytics for patterns of use.

Results: Key data (25/2/2016 - 5/5/2019) are shown (attached diagram: Analytics Overview). Rising through 2017–2018, regular use has stabilised in 2019 at 2000–2250 pageviews/week and 0.36 minutes/view. User feedback is uniformly positive. Many HHD patients now routinely use the calculator to adjust their upcoming sessional duration.

Conclusions: HHD patients and professionals can now be empowered to regulate the UFR by durational adjustments based on the UFR calculator. The calculator encourages and empowers flexibility in treatment time and a safer, gentler rate of volume change. McIntye et al: CJASN 2016; 11(4):549-551 Charra et al: Blood Purif 2017; 44:89-97

TH-PO355

Vancomycin and Teicoplanin Clearance During an In Vitro Model of Continuous Venovenous Hemofiltration Using Different Hemofilters

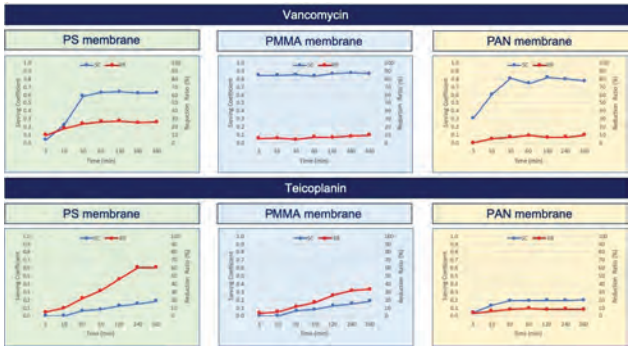
Ilaria Godi,[2] Anna Lorenzin,[1] Silvia De Rosa,[3] Massimo de Cal,[3] Claudio Ronco.[2] *[1]IRRIV, Vicenza, Italy; [2]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy; [3]San Bortolo Hospital, Vicenza, Italy.*

Background: Continuous renal replacement therapies (CRRT) can affect pharmacokinetic behavior of antibiotics. The factors that need to be considered are related to the drug characteristics, CRRT features and patient status. Particularly, the type of membrane can play a major role in drug removal. The aim of this study was to evaluate in an *in vitro* system the convective and adsorptive drug clearance of vancomycin (VAN) and teicoplanin (TEC) during continuous venovenous hemofiltration (CVVH) with polysulfone (PS), polymethylmethacrylate (PMMA) and polyacrylonitrile (PAN) filters.

Methods: VAN and TEC clearance was assessed *in vitro* in blood from healthy donors. Closed circuit simulating CVVH was performed using PS, PMMA and PAN mini-filters at 10ml/min ultrafiltrate and 50 ml/min blood flow rates. The duration of the experiment was of 360 min. Samples were collected at 5, 10, 30, 60, 120, 240 and 360 minutes from in-flow, out-flow and ultrafiltrate line; antibiotic concentrations were measured with biochemistry analyzer. Convective clearance was evaluated in terms of sieving coefficient (SC), and adsorptive clearance was calculated using mass balance analysis.

Results: VAN and TEC blood SC are shown in Fig 1, as well as the reduction ratio of plasmatic concentrations for each membrane. During CVVH using PS, PMMA and PAN membranes, the estimated total adsorbed mass per surface area for VAN was 36.52mg/m2, 11.33mg/m2 and 6.97mg/m2, and for TEC was 98.17mg/m2, 51.33mg/m2 and 9.77 mg/m2, respectively.

Conclusions: Our findings show that during CRRT both convective and adsorptive mechanisms have a role in antibiotics clearance. When dosing patients on CRRT, physicians should take into account not only CRRT flow rate settings and modality but also drug-membrane interaction.



TH-PO356

Application of Individualized Physiologically Based Pharmacokinetic Modeling of Rate Data (iPBPK-R) to Estimate the Effect of Hemodialysis on Nonrenal Clearance Pathways

Yoko Franchetti, Thomas D. Nolin. *University of Pittsburgh, Pittsburgh, PA.*

Background: We previously developed an individualized physiologically-based pharmacokinetic modeling approach using rate data (iPBPK-R) to differentiate contributions of nonrenal metabolic and transport pathways to the disposition of the non-specific probe drug erythromycin. The objectives of the current work were (1) to differentially estimate contributions of nonrenal clearance pathways to erythromycin in patients with ESRD, (2) to investigate the effect of hemodialysis (HD) on these pathways, and (3) to explore the relationship between parameter estimates and uremic toxin concentrations.

Methods: Twelve patients with ESRD received ^{14}C-erythromycin (0.074 mmol IV) pre- and again post-HD and 11 breath samples were collected over 2 hours after each dose. iPBPK-R was applied to measured $^{14}CO_2$ production rates. Eight PBPK parameters were co-optimized between pre- and post-HD periods within patients while activity of CYP3A4 clearance was independently estimated. Inhibitory coefficients of uptake transporters (i.e., OATP) were also estimated. Nonrenal clearance parameter estimates were compared pre- vs post-HD and by gender. As exploratory analysis, the parameter estimates were correlated with uremic solutes and used in hierarchical cluster analysis (HCA). Optimizations were run on the Bridges supercomputer (PSC via NSF XSEDE).

Results: Seven compartments with OATP uptake and CYP3A4 clearance were modeled. Mean relative increase in CYP3A4 clearance pre- vs post-HD within individual patients was 12% which was not statistically significant (p=0.06). However, males had 16% and 19.3% lower median CYP3A4 activity than females pre- (p=0.001) and post-HD (p=0.005), respectively. The estimated inhibition coefficient of uptake transport did not differ between pre- and post-HD (p=0.129). A sub-cluster of two patients with more improved CYP3A4 activity at post-HD (9.4% increase) was identified compared to the other patients (0.59% increase). β-2 microglobulin was inversely correlated with CYP3A4 activity in males pre- (Spearman r=-0.79, p=0.04) but not post-HD.

Conclusions: iPBPK-R is a novel tool to estimate nonrenal clearance parameters within individuals and to explore the effect of HD and uremic toxins on drug disposition in patients with ESRD. Further work is required to validate the i-PBPK-R based results.

TH-PO357

Characterization of Metoprolol and Metabolite Concentrations Pre and Post Hemodialysis: Potential Implications for Intradialytic Hypotension and Post-Dialysis Fatigue

Michael C. Dean, Gabrielle M. Costello, Ernane Souza, Jeremy A. Felton, Balazs Szamosfalvi, Manjunath P. Pai, Amy B. Pai. *University of Michigan, Ann Arbor, MI.*

Background: Previous pharmacokinetic (PK) studies of metoprolol succinate (MPL) were conducted before high-flux HD and did not evaluate post-HD rebound or parent:metabolite (P:M) ratios. Intercompartmental redistribution of antihypertensives may contribute to intradialytic hypotension and post-dialysis fatigue. The aim of this study was to characterize the PK of MPL and α-hydroxymetoprolol during and post-HD.

Methods: Eligible patients were >18 years, on HD 3 days a week for 3.5-5 hours (h), daily dose of MPL 25-200mg, and hemoglobin >9.5 g/dL. Arterio-venous (AV) paired samples were collected prior to HD initiation, 0.5h, 2h, and end of treatment. Post-HD sampling occurred at 0.5, 2, and 4h. Serum samples were assayed by liquid chromatography-tandem mass spectrometry and a non-parametric population PK model was used (PMetrics™ LAPK). T0 samples were analyzed for CYP2D6*4.

Results: Eight patients (5 male, 3 female; Age 59±17 years) were enrolled. The MPL PK data were best fit with a linear, 2-compartment model with absorption rate and fraction absorbed fixed to known values from literature. The model predicted MPL clearance (CL) was relatively unchanged on- and post-HD with a mean (CV) of 46.5 (17.4%) and 41.9 (54.4%) L/h, respectively. AV-dialytic CL was minimal (13.1±8.8% of total CL). The mean volume of distribution (Vd) in central compartment (Vc) decreased: 119.7 (103.2%) L on-HD to 18.4 (128.7%) L post-HD. Mean peripheral compartment Vd (Vp) increased: 17.7 (252.2%) L on-HD to 160.0 (0.0%) L post-HD. Vd changes resulted in significant MPL flux from Vp to Vc on-HD driven by redistribution and from Vc to Vp post-HD due to hemoconcentration. Higher MPL concentrations were seen at 2h on-HD and 4h post-HD. The P:M ratios were variable suggesting phenotypic differences in CYP2D6 activity. Three CYP2D6*4 heterozygotes were identified, but only one showed decreased metabolism based on P:M ratio.

Conclusions: Large changes in Vd due to ultrafiltration drive fluctuating MPL concentrations during and after HD, resulting in highly variable MPL serum concentrations. This may contribute to intradialytic hypotension and/or post-dialysis fatigue. Dialytic CL does not appear to contribute significantly to varying MPL concentration profiles.

TH-PO358

Effect of CKD on the Ex Vivo Metabolism of Δ9-THC into 11-OH-Δ9-THC

Nicholas Tonial,[1] Emily D. Hartjes,[2] Yong Jin (James) Lim,[1] Matthew A. Weir,[2] Brad Urquhart.[2] *[1]University of Western Ontario, London, ON, Canada; [2]Western University, London, ON, Canada.*

Background: Over 40% of chronic kidney disease (CKD) patients experience adverse drug reactions. Cytochrome P450s (CYPs) are major contributors to drug disposition, as they mediate drug metabolism to help facilitate clearance. Rodent models of CKD have shown reduced CYP expression and drug metabolic activity. The use of cannabis for both medicinal and recreational purposes has increased recently and cannabis has been legalized in several regions of the world. While CKD is known to impact the disposition of many drugs, there have been no studies investigating the impact of CKD on the hepatic metabolism of cannabis. This study utilized a rat model of CKD to investigate the impact of CKD on the metabolism of the psychoactive component of cannabis (Δ9-THC) to its primary metabolite 11-OH-Δ-THC. It was hypothesized that CKD would decrease Δ9-THC metabolism.

Methods: CKD was induced in male Wistar rats (n=13) by feeding chow supplemented with 0.5% adenine (n=7) for a total of 42 days while controls (n=6) received standard chow. Blood and organs were collected, and plasma creatinine concentrations were measured utilizing ultraperformance liquid chromatography coupled to mass spectrometry (UPLC-MS). Hepatic microsomal fractions, isolated by differential centrifugation, were incubated with THC (10mM and 20 mM) for 4 minutes, and 11-OH-Δ9-THC concentrations were measured by UPLC-MS, and the metabolite formation rate (pmol/min/mg protein) was calculated.

Results: Plasma creatinine was significantly elevated eleven-fold in adenine-fed rats compared to controls ($p < 0.05$). Metabolite formation rate of 11-OH-Δ9-THC (pmol/min/mg protein) was 30% and 45% higher in CKD samples, when microsomal fractions were incubated with 10 mM and 20 mM, respectively ($p < 0.01$; $p < 0.05$).

Conclusions: Contrary to our hypothesis, this data suggests that CKD results in increased metabolism of Δ9-THC into 11-OH-Δ9-THC. Further analysis, performing Michalis-Menten kinetics will better elucidate the effect of CKD on THC metabolism.

Association Between CYP3A5 SNP rs776746 and Tacrolimus Dose: Single Transplant Center Experience in Southern Chile

Gustavo A. Navarro,[1] Rodolfo Carmona,[1] Marina Leiva Gonzalez,[4] Anita Plaza,[1] Daniel Muñoz,[2] Leopoldo G. Ardiles,[1] Ricardo A. Verdugo,[3] Sergio A. Mezzano,[1] Paola Krall,[1] Claudio Flores.[1] *[1]Universidad Austral de Chile, Valdivia, Chile; [2]Hospital Base Valdivia, Valdivia, Chile; [3]Universidad de Chile, Santiago, Chile; [4]Hospital Intercultural de Nueva Imperial, Temuco, Chile.*

Background: Tacrolimus (TAC) is a common immunosuppresor used in renal transplant (RTx) that requires monitoring to minimize risks. The best marker of TAC exposition is 24 hrs-AUC, but only Co is typically monitored. TAC is metabolized by CYP3A5 that contains a SNP (rs776746 A>G) associated in worldwide cohorts to slow (GG), intermediate (AG) or rapid (AA) TAC metabolism. The aim of this study was 1) to determine the association between rs776746 and TAC doses, 2) to establish if Co had a good correlation with AUC, 3) to analyze the genotype frequencies in Chile and their relationship with the Mapuche (Native Amerindian) ancestry.

Methods: A retrospective study was performed in 57 RTx adults of a single center using TAC of prolonged liberation for more than 3 months. The SNP rs776746 was analyzed by PCR Taqman/sequencing. AUC was determined in 16 patients with the three genotypes (GG/AG/AA). Mapuche ancestry in association to the genotypes was analyzed with the DNA repository in ChileGenómico.

Results: The mean age of the patients was 43 yrs [17-71 yrs], 51% female, 81% RTx with cadaveric donor, median time of RTx was 2.7 yrs. At the time of recruitment, 60% presented C0 between 5-10 ng/ml. We identified 58%, 26% and 16% of subjects with the GG, AG or AA genotype, respectively. The dose/weight (mg/kg) resulted GG=0.06±0.03, AG=0.12±0.05 and AA=0.15±0.05 (mg/kg) that were statistically different between GG-AA and GG-AG ($p<0.001$). The highest correlation between Cx and AUC was C12 ($r=0.97$) and C0 ($r=0.96$), independently of the genotype. The Mapuche ancestry percentage resulted 26% 30% and 37% for GG, AG and AA, respectively ($p<0.0001$).

Conclusions: A high prevalence of the GG genotype was identified, associated to lower requirements of TAC doses, but carriers of at least one A allele duplicated TAC dose. Chilean population has a mixed genetic ancestry and Mapuche ancestry appears to be associated with higher TAC doses, because of higher A allele frequency. Co turns to be an optimal marker of drug exposition. Our results demonstrate the potential clinical value of the CYP3A5 genotype to personalize therapy in Chile, to facilitate post-RTx monitoring, as well as improve credibility of patients TAC adherence. TH-PO360

Mycophenolate Mofetil vs. Cyclophosphamide as Induction Treatment and Mortality in a Series of Cases from the Colombian Caribbean Region with Lupus Nephritis

William A. Peña-Vargas,[2] Gustavo Aroca Martinez,[1] Henry J. Gonzalez Torres,[3] Andres Cadena.[2] *[1]Universidad Simon Bolivar / Clinica de la Costa, Barranquilla, Colombia; [2]Universidad Simón Bolívar, Barranquilla, Colombia; [3]Universidad Simon Bolivar, Barranquilla, Colombia.*

Background: Lupus nephritis (LN) is the most severe complication of systemic lupus erythematosus and induction therapy defines the prognosis of the disease. The type of immunosuppressive therapy (Mycophenolate Mofetil; MMF and Cyclophosphamide; CP) is chosen according to clinical and histological criteria. The objetive was to assessing response to induction therapy with MMF vs CFM and mortality in a number of cases from the Colombian Caribbean region with LN.

Methods: A retrospective analytical study. 423 patients with diagnosis of LN between 2008-2018 were included. Two regimens of immunosuppressive therapy for induction were evaluated in LN: MMF (n = 331); (Dose 2 g / day for 6 months) vs CP (n = 92) (500 mg IV every 15 days for 3 months). Patients were classified according to the criteria of clinical response of ACR (American College of Rheumatology) at: Complete remission (CR), partial remission (PR) and no remission (NR). Furthermore, the mortality associated with MMF vs CFM to 500 weeks (9 years) by Kaplan-Meier estimator was calculated.

Results: All patients, 87% were women, the mean age was 36 ± 13 years. The most common clinical presentation was nephrotic syndrome (70%). Histological class was predominantly proliferative class IV (66%), followed by Class III (23%). Statistically significant proteinuria in 24 hours and creatinine in both treatment groups (MMF vs CFM) ($p <0.05$) difference was found. Regarding the response to induction therapy, 225 (49%) cases NR, 123 (29%) were made and RC 91 (22%) RP. CFM mortality rate (68%) VS MMF (30). There were no statistically significant differences in clinical response and mortality among patient groups, as well as the values of C3, C4 and anti-dsDNA.

Conclusions: In our population, the clinical response in the induction and the mortality rate is similar between the two treatment groups (MMF vs CFM), although the MMF was superior in terms of averages, in response and decreased mortality, but this does not he reached for a statistical difference.

TH-PO361

Fosfomycin Trometamol Administration Enhances Cyclosporine Nephrotoxicity

Juan Antonio Ortega-Trejo,[1,2] Rosalba Pérez-villalva,[1,2] José M. Arreola,[2] Victoria Ramírez,[2] José Sifuentes-Osornio,[2] Norma Bobadilla.[1,2] *[1]Molecular Physology Unit UNAM, Mexico City, Mexico; [2]INCMNSZ, Mexico City, Mexico.*

Background: Urinary tract infection (UTI) is very frequent in renal transplant immunosuppressed patients and the clinicians face the growing increase in antibiotic resistance. Fosfomycin trometamol (Fos) has emerged as a potential UTI treatment, however its influence on calcineurin inhibitors nephrotoxicity (CIN) has not been explored. This study was designed to evaluate the effect of Fos in combination with cyclosporine (CsA) on CIN in the rat.

Methods: Twenty-four male Wistar rats were included and divided into four groups: 1) Control, 2) CsA 15 mg/kg s.c., 3) CsA+Fos 62.5 mg/kg and 4) CsA+Fos 500 mg/kg. Cyclosporinr was daily administered for 14 days, whereas, fosfomycin was starting on day 9 with three doses every 48 h. At the end of the study, functional studies were performed, and tissue samples were obtained.

Results: Table 1

Conclusions: CsA nephrotoxicity was characterized by a significant decrease in RBF and GFR, as well as with a reduction in eNOS, AGT, and AT1R mRNA levels. In CsA+Fos group, greater hypoperfusion, oxidative stress, and increased mRNA levels of pro-inflammatory cytokines were observed. This study shows that Fos increases CsA nephrotoxicity through increasing renal inflammation and alerts us to the combined use of these drugs in the clinical scenario.

Improved Early Treatment Response of Eculizumab with a Patient-Friendly Dosing Scheme in Adult Patients with Atypical Hemolytic Uremic Syndrome

Mendy ter Avest,[1,4] Nicole Van De Kar,[2] Aiko P. De Vries,[3] Dirk jan Moes,[3] Elena Volokhina,[2] Ruben L. Smeets,[2] Roger Brüggemann,[1,4] David M. Burger,[1,4] Jack F. Wetzels,[2] Rob Ter heine.[1,4] the CUREiHUS study group *[1]Pharmacy, Radboud university medical center, Nijmegen, Netherlands; [2]Radboud university medical center, Nijmegen, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Radboud Institute for Health Sciences, Nijmegen, Netherlands.*

Background: With the currently approved dosing schedule of eculizumab in adult aHUS patients (900mg weekly, followed by 1200mg in the fifth week and every 14 days thereafter), exposure is often sub-therapeutic after the first dose, while being supra-therapeutic when starting the maintenance phase. We aimed to develop a dosing strategy to improve early treatment response.

Methods: Pharmacokinetic (PK) and pharmacodynamic (PD) data from 30 aHUS patients were available, consisting of 647 eculizumab time-concentration data and 504 classical pathway (CP) activity levels. PK-PD modeling was performed by means of non-linear mixed effects modeling. The final model was used to investigate alternative dosing strategies through Monte Carlo simulations in 1000 virtual patients to develop a dosing strategy with a higher percentage of patients with a CP activity <10%, without increasing the dose during the initial phase.

Results: A PK-PD model with parallel first order and Michaelis-Menten elimination rates best described the data. The estimates of the model were CL 0.167 L/day (RSE 6%), Vd 7.11 L (RSE 8%), V_{max} 27.7 mg/day (RSE 6%), K_m 20.8 mg/L (RSE 28%). The PK-PD relation was described with an inhibitory Emax model, with an IC50 of 21.3 mg/L (RSE 17.1%). A weight-based loading dose of eculizumab (<60kg: 1500mg, 60-<90kg: 1800mg, 90-<120kg: 2100mg and ≥120kg: 2400mg) on day 1, followed by 1200mg on day 14 and 28 was found to improve treatment. In total, 96.6% of the patients reached the CP target on day 7, compared to 81.3% with standard dosing (Figure 1). This also resulted in a dose reduction of 12.5% compared to the first 28 days of the approved dosing regimen.

Conclusions: A patient-friendly weight-based dosing strategy of eculizumab results in better treatment response during the initial phase at lower costs.

Darunavir Localizes to Cytoplasmic Stress Granules in Human Proximal Tubular Cells

Alan Rosales,[2] Buadi K. Tandoh,[2] Xiaobo Gao,[2] Heidi Karttunen,[2] Michael J. Ross.[1] *[1]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: HIV protease inhibitors (PI) have off-target effects on many cellular pathways data from our laboratory demonstrated that darunavir (DRV), the most commonly used PI, protects renal epithelial cells from HIV-induced injury and inflammatory responses via mechanisms independent of HIV protease. Since the mechanism by which DRV protects kidney cells from injury is poorly understood, we performed studies to identify cellular protein targets of DRV in human renal epithelial cells.

Methods: We used the Direct Magnetic IP/Co-IP Kit to covalently link DRV to NHS-activated magnetic beads. DRV bound– and unbound– beads were incubated with HPT1b whole cell lysate from immortalized human proximal tubular cells (HPT1b). Bound proteins were eluted and analyzed by mass spectrometry. DRV was also covalently linked to NHS-AlexaFluor 488, and cellular localization of DRV-AF488 and stress granule protein G3BP1 were analyzed by fluorescence microscopy.

Results: 52 proteins were identified in all 3 samples from DRV-bound beads at 100-fold or greater abundance than control samples. 23 of the 52 proteins are RNA-binding proteins, most of which are components of cytoplasmic stress granules (SG), including canonical SG proteins G3BP1, G3BP2, and Caprin1. DRV-G3BP1 interaction was confirmed by western blotting of protein eluted from DRV- and control-conjugated beads. To determine if DRV colocalizes with G3BP1 at SG, SG formation was induced in HPT1b cells by incubation with NaAsO2. Fluorescence microscopy localized G3BP1 and DRV-AF488 in the cytoplasm and in cytoplasmic punctae, consistent with SG localization. HIV transduction of HPT1b cells increased G3BP1 punctate staining, demonstrating that HIV induced SG formation. We examined phosphorylation of G3BP1, which promotes SG disassembly. A reduction in p-G3BP1 (Ser149) was observed in HIV transduced HPT1b cells treated with DRV, suggesting that DRV prevents SG disassembly.

Conclusions: These data demonstrate that DRV localizes preferentially to SG in renal epithelial cells. Since SG are intracellular domains that regulate response to stress, DRV may attenuate renal epithelial injury via novel effects upon SG dynamics. Additional studies are needed to determine the role of SG proteins in mediating the protective effects of DRV against kidney injury.

Tenofovir Alafenamide Fumarate (TAF) and Tenofovir (TFV) Have a Different Impact on the Proteome of Proximal Tubular Cells (PTCs)

Hassan Aouad,[1] Bastien Burat,[1] François-Ludovic Sauvage,[1] Marie Essig.[2,1] *[1]INSERM, UMR 1248 IPPRITT, University of Limoges, Limoges, France; [2]APHP, Boulogne Billancourt, France.*

Background: TAF, a new produg of TFV was developed to be less nephrotoxic than Tenofovir Desproxil Fumarate (TDF), by releasing less TFV in the blood. First clinical studies confirmed the low renal toxicity of TAF. However, TAF and TFV respective effects on renal tubular cells have never been compared. The aim of this study was to study the effects of TFV, TAF and ABC (as control nucleosidic inhibitor) on PTC.

Methods: iTRAQ differential proteomic strategy was used to analyse the effects of TFV (287 ng/mL), TAF (215 ng/mL), ABC (4200 ng/mL) or vehicle (water) on LLC-PK1. Cells were exposed for 24h to the different drugs before protein extraction. After proteins digestion by trypsin, peptides were tagged with iTRAQ reagents, then seperated into 12 different fractions by isoelectrofucusing. Generated fractions were analysed using triple TOF 5600+ mass spectrometer (ABSciex).

Results: One hundred sixty-nine proteins were identified in all 5 independent experiments. Among them, 17 were modified by TFV (11 up-regulated and 6 down-regulated), 21 by TAF (10 up-regulated and 11 down regulated) and 17 by ABC (9 up-regulated and 8 down-regulated). Only few proteins were similarly modified by the 3 drugs. ATP synthase-coupling factor 6 and Electron transfer flavoprotein-ubiquinone oxidoreductase were reduced by the 3 drugs whereas testin was increased. TAF and TFV commonly affect the expression of Ras-related protein Rab-1A, U1 small nuclear ribonucleoprotein A, and alter in opposite way the expression of Thymosin beta-10, Polypyrimidine tract-binding protein 1. TFV specifically increased 5 proteins and decreased 3 proteins among them the V-type proton ATPase catalytic subunit A, which is involved in the acidification of cytoplasmic vesicles during membrane trafficking. TAF alone decreased 5 proteins and increased 7 proteins among them megalin, the major protein involved in endocytosis in PTC.

Conclusions: Our results confirmed the different impact of TFV, TAF and ABC on PTC. If the 3 drugs modified the electron chain transport explaining their potential mitochondrial toxicity, TFV seemed to negatively affect the endocytic capacity of PTC whereas TAF may maintain it through the upregulation of megalin. These results are in accordance with clinical data showing a decrease in tubular proteinuria after the switch from TDF to TAF.

Metabolomics Analytic Approach Reveals Global Metabolic Influences by Xanthine Oxidoreductase Inhibitors in a Rat Model of Unilateral Renal Ischemia-Reperfusion Injury

Takashi Tani,[1] Ken Okamoto,[2] Megumi Fujiwara,[1] Akira Katayama,[1] Shuichi Tsuruoka.[1] *[1]Nippon Medical School, Tokyo, Japan; [2]Tokyo University, Bunkyo-Ku, Japan.*

Background: Xanthine oxidoreductase (XOR) inhibitors are clinically applied as anti-gout drugs to inhibit the conversion of xanthine to uric acid by XOR. They reportedly exert an organ-protective effect, especially the potent and selective XOR inhibitors, febuxostat and topiroxostat. We aimed to verify the hypothesis that preservation of tissue high-energy phosphate concentrations contributes to these positive effects in a rat model of unilateral renal ischemia-reperfusion (I/R) injury through global metabolic pathway analysis.

Methods: Six-week-old male Sprague–Dawley rats were orally administrated either 10 mg/kg of febuxostat, 10 mg/kg of topiroxostat, 50 mg/kg of allopurinol, or vehicle 60 min before they were subjected to 30 min of unilateral renal I/R injury. Kidney samples were collected at three time points; before I/R injury (stationary group), 30 min left renal ischemia (ischemic group), 30 min after I/R injury (reperfusion group). Metabolites in kidney lysates were analyzed by HPLC and CE-TOFMS metabolomics.

Results: Metabolomics analysis revealed global impact of I/R injury on metabolic pathways. In XOR-selective-inhibitor-treated groups, tissue concentrations of high-energy phosphates were higher before and after I/R injury, and renal adenine compounds were better preserved throughout I/R injury than in vehicle and allopurinol groups. The XOR-selective inhibitors were also shown to uniquely influence glycolysis, glycogenesis, and the tricarboxylic acid cycle metabolic pathways.

Conclusions: These findings were well in accordance with the proposed hypothesis that the recomposition of high-energy phosphates, such as ATP and ADP, is promoted by the XOR-selective inhibitors via the salvage pathway through blockade of hypoxanthine catabolism, whereas non-specific inhibitory effects of allopurinol on purine/pyrimidine enzymes impede this re-synthesis process. The unique global metabolic alterations by the XOR-selective inhibitors, presumably by a change in the ATP/AMP ratio, acting as an allosteric effector, remained further to be investigated. This study revealed novel findings of the XOR inhibitors' influences on global metabolic pathway, and sheds light on the undetermined physiology of the organ-protective effects of XOR inhibitors.

TH-PO366

Renoprotective Effects of Phosphodiesterase 5 Inhibitor in Models of CKD with Hypertension and Nephrotic Syndrome

Yuji Hotta,[1] Natsumi Tomita,[1] Aya Naiki-Ito,[2] Mayu Yoshikawa,[1] Tomoya Kataoka,[3] Satoru Takahashi,[2] Kazunori Kimura.[1,3] *[1]Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [2]Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [3]Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.*

Background: Phosphodiesterase (PDE) 5 inhibitor has a renoprotective effect. PDE5 expression in glomeruli is confirmed, but its role has been unclear. In this study, we assessed the effects of tadalafil (Tad), a PDE5 inhibitor, using two renal dysfunction models, chronic kidney disease (CKD) with hypertension and nephrotic syndrome.

Methods: ***1) CKD model.*** We used Dahl salt-sensitive rats with hypertension and CKD induced by a high-salt diet. The rats were divided into normal salt, high salt, and Tad 1- and 10-mg/kg treatment groups. After 8 weeks of treatment, we analyzed kidney function, blood pressure, and histopathological changes. ***2) Nephrotic syndrome model.*** A nephrotic syndrome model was created with Wistar-ST rats by adriamycin (ADR) injection. The rats were divided into control, ADR, and ADR+Tad 10 mg/kg groups. After 2 or 4 weeks of treatment, urinary protein and serum albumin levels were evaluated.

Results: ***1) CKD model.*** High-salt diet induced kidney dysfunction and severe hypertension. Tad 10 mg/kg treatment prevented increases in serum creatinine (SCr) and urinary protein levels and hypertension (Fig. 1). Tad 1 mg/kg treatment significantly prevented the increase in SCr and urinary protein levels, but not hypertension. Histopathological analysis revealed that Tad treatment attenuated glomerular injury. ***2) Nephrotic syndrome model.*** ADR injection induced high urinary protein level and low serum albumin level. Tad treatment attenuated proteinuria at 2 and 4 weeks and reduction of serum albumin level at 4 weeks.

Conclusions: This study suggests that Tad treatment is effective for both CKD and nephrotic syndrome. The improvement might be induced by the effects against glomerular impairment, particularly podocyte injury.

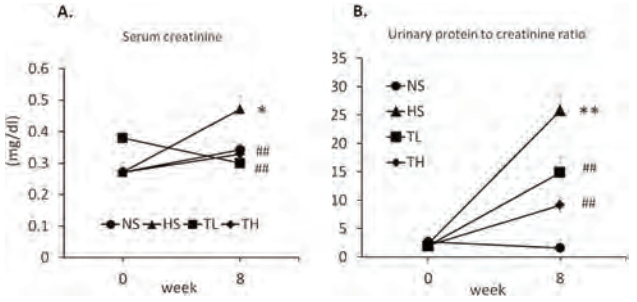

Fig. 1 SCr (A) and urinary protein to creatinine ratio (B) in CKD model. NS, normal salt; HS, high salt; TL, HS+tadalafil (1 mg/kg/day); TH, HS+tadalafil (10 mg/kg/day; n=5–7). *P<0.05; **P<0.01, versus NS; #P<0.05; ##P<0.01, versus HS.

TH-PO367

SNF472 Is More Efficacious In Vivo Than Its 4,6-bisPEGylated Derivative in Inhibiting Vascular Calcification in Rats

Miquel D. Ferrer,[1,2] Maria del mar Perez,[1] Firas Bassissi,[1] Joan Perelló,[1,2] Carolina Salcedo.[1] *[1]Sanifit Therapeutics, Palma, Spain; [2]Universitat de les Illes Balears, Palma, Spain.*

Background: Vascular calcification (VC) is a major contributor to increased morbidity and mortality in Chronic Kidney Disease patients undergoing dialysis. Although VC is a multifactorial process, the final common pathway is deposition of solid hydroxyapatite (HAP) within the arteries. SNF472, salt of InsP6, is a selective calcification inhibitor that interferes in the formation and growth of ectopic HAP. SNF472 is currently being developed for the treatment of calciphylaxis in patients on dialysis. Inositol-1,2,3,5-tetraphosphate-4,6-bisPEG$_{100}$ (InsP4bisPEG) is an inositol phosphate derivative resulting from the PEGylation of inositol tetraphosphate (InsP4) with polyethylene glycol (PEG) 100. The aim of this study was to compare the relative bioavailability and *in vivo* efficacy in the inhibition of calcification of subcutaneous (s.c.) InsP4bisPEG and SNF472 at equimolar doses in rats.

Methods: S.c. pharmacokinetics (PK) of InsP4bisPEG and SNF472 were assessed in male Sprague Dawley rats after a single administration. Plasma samples were obtained and analyzed. The *in vivo* efficacy was evaluated in 24 male Sprague Dawley rats, divided into three groups of eight rats receiving placebo (NaCl 0.9%) or equimolar doses (36 μmol/kg) of SNF472 or InsP4bisPEG. Vascular calcification was induced by 3 consecutives daily s.c. administrations of 150 kIU/kg vitamin D3, starting on day 1. Rats were sacrificed 5 days after induction of calcification, and aorta was collected for calcium analysis.

Results: The plasma C_{max} of InsP4bisPEG was 9.8 μM, at a t_{max} of approximately 30 minutes. AUC_{0-t} was 13.1 μmol/h/L and the terminal half-life ($t_{1/2}$) was 46 min. SNF472 showed a plasma C_{max} of 7.4 μM at around 15 min, with an AUC_{0-t} of 2.5 μmol/h/L and a terminal $t_{1/2}$ of 17 min. SNF472 treated animals presented significantly lower calcium levels in aorta, which were 38% and 55% lower than placebo and InsP4bisPEG treated animals, respectively.

Conclusions: InsP4bisPEG is more bioavailable than SNF472 and presents a longer plasma half-life. However, SNF472 is more efficacious inhibiting aorta calcification than this InsP6 PEGylated derivative in an *in vivo* vitamin D3 rat model at 36 mmol/kg. This is probably due to the larger affinity of SNF472 for HAP crystals.

TH-PO368

An Open-Label, Single-Dose, Parallel-Group Study to Evaluate the Effects of Renal Impairment on the Pharmacokinetics of ELX-02: Results from Subjects with Mild and Moderate Renal Impairment

Gregory Williams. *Eloxx Pharmaceuticals, Inc, Waltham, MA.*

Background: ELX-02 is an investigational synthetic eukaryotic ribosomal selective glycoside (ERSG) that induces read-through of nonsense mutations through interaction with the ribosome resulting in full-length functional proteins. ELX-02 is being developed as a therapy for genetic diseases caused by nonsense mutations such as nephropathic cystinosis and polycystic kidney disease. It is well established that kidney disease is characterized by multiple physiologic effects, which induce clinically significant changes in pharmacokinetics.

Methods: Eloxx Pharmaceuticals, Inc. is presently conducting a Phase 1 study designed to determine the effect of various severities (i.e., mild [eGFR 60-89 mL/min/1.73m^2], moderate [eGFR 30-59 mL/min/1.73m^2], and severe eGFR [<30 mL/min/1.73m^2, not requiring dialysis] of renal impairment, compared to a control group with normal renal function [eGFR ≥ 90 mL/min/1.73m^2) on the PK of ELX-02 after a single dose of 1 mg/kg. Six subjects are planned to be enrolled in each category of renal failure, and 6-8 subjects enrolled in the control group.

Results: To date, treatment of subjects with mild and moderate renal impairment has been completed. In subjects with mild renal impairment the mean eGFR at baseline was 74.7 mL/min/1.73m^2, C_{max} was 2,993 ng/mL, T_{max} was 1.1 hr, AUC_{0-inf} was 16,999 ng*h/mL, $t_{1/2}$ was 3.3 hr, and Cl/F was 4.4 L/h. In the moderate group the mean baseline eGFR was 41.7 mL/min/1.73m^2, C_{max} was 3,688 ng/mL, T_{max} was 1.3 hr, AUC_{0-inf} was 35,172 ng*h/mL, $t_{1/2}$ was 6.5 hr, and Cl/F was 2.4 L/h. These results indicate that the degree of renal impairment has effects on the PK of ELX-02, with an increase in C_{max}, T_{max}, AUC, and $t_{1/2}$ and a decrease in Cl/F in subjects with moderate renal impairment when compared to subjects with mild renal impairment. No adverse events have been reported in this study.

Conclusions: Results from the severe and control groups will be available at the meeting. Based on the preliminary results available to date, ELX-02 can be used safely in patients with renal dysfunction and dose adjustments may be considered for patients with varying degrees of renal impairment. These results support the continued development of ELX-02 for the potential treatment of nonsense mutation mediated kidney diseases.

TH-PO369

Effect of Moderate Hepatic Impairment on Pharmacokinetics of Vadadustat, an Oral Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor (HIF-PHI)

Ajit B. Chavan, Susan K. Paulson, Leontia Burke, Rishikesh Sawant, Brian Schwartz, Emil deGoma. *Akebia Therapeutics Inc., Cambridge, MA.*

Background: Vadadustat is an oral HIF-PHI in development for the treatment of anemia due to chronic kidney disease. Vadadustat is primarily metabolized to O-glucuronide by UPD-glucuronosyltransferases (UGTs). The predominant UGT involved in the metabolism of vadadustat is UGT1A9, which is expressed in the liver and kidney. Therefore, the role of hepatic impairment in vadadustat clearance was evaluated.

Methods: This phase 1, open-label, parallel-group, single-dose study evaluated pharmacokinetics (PK) of 450 mg vadadustat in adults (18-70 y) with moderate hepatic impairment (Child-Pugh Class B) versus those with normal hepatic function. Blood samples were collected pre-dose and up to 72 h post-dose. Primary endpoints were area under the curve from dosing to last concentrations (AUC_{last}) and to infinity (AUC_{inf}) as well as maximum concentration (C_{max}); additional PK parameters included time to C_{max} (T_{max}) and half-life ($t_{1/2}$). Safety and tolerability were assessed throughout the study.

Results: All 16 enrolled participants completed the study (hepatic impairment, n=8; normal, n=8). Demographics were similar between groups (overall: 100% white, 62.5% female, mean age 59.2 y). Vadadustat plasma exposure (AUC) was slightly higher in the hepatic impairment group, whereas C_{max} was generally similar between groups (Table). Point estimates of the hepatic impairment:normal geometric mean ratios (90% CI) for AUC_{last}, AUC_{inf}, and C_{max} were 1.05 (0.82-1.35), 1.06 (0.82-1.36), and 1.02 (0.79-1.32), respectively. Mean elimination half-life was 5.8 h in the normal group and 7.8 h in the hepatic impairment group. Treatment-emergent adverse events (TEAEs) were reported by 1 participant in the hepatic impairment group and 2 in the normal group. Most TEAEs (86% [6/7]) were mild in severity; none were severe.

Conclusions: In this study, moderate hepatic impairment did not significantly impact vadadustat systemic exposure. A single dose of 450 mg vadadustat was generally well tolerated by participants with both normal and moderately impaired hepatic function.

Funding: Commercial Support - Akebia Therapeutics, Inc.

Hepatic Function Status	$AUC_{0\text{-}last}$ (h*μg/mL)	$AUC_{0\text{-}inf}$ (h*μg/mL)	C_{max} (μg/mL)	T_{max} (h)	$t_{1/2}$ (h)
Moderate Impairment (n=8)	432 (35.4)	436 (35.6)	52.9 (22.2)	2.0 (1.0-4.0)	7.8 (32.6)

TH-PO370

A Systematic Meta-Analysis on Interspecies Differences in Renal Drug Clearance

Katja Jansen,[1] Carla Pou casellas,[4,5] Kimberley Wever,[2] Lucianne Groenink,[1] Rosalinde Masereeuw.[3] *[1]Utrecht University, Utrecht, Netherlands; [2]Radboud university medical centre, Nijmegen, Netherlands; [3]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands; [4]University Medical Center Utrecht, Utrecht, Netherlands; [5]Hubrecht Institute, Utrecht, Netherlands.*

Background: Various animal models are used to study drug efficacy and safety prior to approval for human use. Renal clearance (CLr) is a standard pharmacokinetic measure, for which animal data is extrapolated to humans by allometric scaling, using exponents of 0.55-0.75. It is worth noting that the physiological system of waste removal is designed to exactly meet the demand set by metabolic rate, which in turn scales with body weight to the power of 0.75 (Kleiber's law). Thus, human CLr should be predictable based on body weight by scaling with 0.75. The exponents used in literature aim for best fit, thus deviations from 0.75 might result from biological interspecies differences. Using the allometric exponent of 0.75, our study aimed at quantifying interspecies differences in renal drug clearance. To find possible mechanistic explanations for these differences, we related them to the physicochemical properties of drugs.

Methods: Using PubMed and EMBASE, we systematically reviewed literature on human and animal CLr measures for 20 renally excreted drugs. Based on the human data and simple allometric principles, we calculated the CLr value expected for the respective animal body weight. Subsequently, average fold errors (AFEs) were calculated as the ratio between the literature-derived CLr values and the expected CLr values. Finally, we quantified mean differences (MDs) in AFEs between animals and humans.

Results: Based on 264 included studies, we calculated AFEs ranging from 0.45-3.05 for mice, 0.77-3.34 for rats, 0.28-1.61 for rabbits, 0.27-3.4 for dogs, 0.57-1.78 for monkeys and 1.01-1.31 for humans. Comparing animal to human AFEs, we determined for all drugs an average MD [95% CI] of 0.01 [-0.23, 0.26] for mice, 0.47 [0.17, 0.77] for

rats, 0.17 [-0.12, 0.45] for rabbits, 0.23 [-0.13, 0.56] for dogs and -0.08 [-0.33, 0.16] for monkeys. Only for rats, the overall effect size was significantly different from humans. Subgroup analyses showed no clear relation to physicochemical drug properties.

Conclusions: In general, animal models are good predictors for human drug clearance using simple allometry. However, rats (the most popular animal model) significantly overestimate human CLr, which could explain the exponent deviation in literature and suggest that rat models should be used with caution.

Drugs Applied to Kidney Patients May Interact with Uremic Toxins for Renal Excretion

Rosalinde Masereeuw,[1] Silvia M. Mihaila,[2] Marianne C. Verhaar,[2] Dimitrios Stamatialis,[3] Karin G. Gerritsen.[2] *[1]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands; [2]University Medical Center Utrecht, Utrecht, Netherlands; [3]University of Twente - Faculty of Science and Technology, Enschede, Netherlands*.

Background: Organic anion transporters (OATs) are involved in the tubular secretion of protein-bound uremic toxins (PBUT). In CKD, excretion of PBUTs is compromised leading to their accumulation, exacerbating CKD and contributing to uremic complications. Recently, we showed that conditionally immortalized proximal tubule epithelial cells (ciPTECs) expressing OAT and cultured on biofunctionalized membranes, actively secrete PBUTs [1,2]. However, OAT1 also handles a wide range of drugs. Here, we investigated the interaction between drugs commonly prescribed to CKD patients and PBUTs for OAT1-mediated transport, using indoxyl sulfate (IS) as prototype PBUT.

Methods: A panel of 9 drugs was screened for interactions in ciPTECs-OAT1 monolayers in the presence (+) and absence (-) of IS, at a uremic concentration (110 μM). To evaluate OAT1 function, fluorescein was used as substrate and its uptake was measured using a multi-plate reader.

Results: Our results show that ACE-inhibitors and cimetidine have either no or a slight effect at non-therapeutical concentrations on OAT1-mediated fluorescein uptake. On the contrary, ATII-inhibitors, statins and furosemide significantly reduced fluorescein uptake, with the highest potency for ATII-inhibitors. This trend was maintained in presence of IS, suggesting that these drugs could negatively influence secretion of PBUTs by ciPTECs (**Table 1**).

Conclusions: Drugs commonly used by kidney patients may compromise endogenous waste product clearance. Further studies should address the transepithelial excretion of PBUTs in the presence of drugs. A similar evaluation in CKD patients would validate our findings. 1. Jansen J, *et al*, Sci. Rep. 6:26715, 2016; 2. Nieskens TTG, *et al*, AAPS J. 18: 2, 2016

Kidney-Targeted Drug Delivery via Chitosan-Modified Liposome

Ping Xia,[2,1] Wei Li,[2,1] Yao Zhou,[3] Wei Sun,[1] Kun Gao.[1] *[1]Nephrology Division, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China; [2]Nanjing University of Chinese Medicine, Nanjing, China; [3]Xuzhou Medical University, Xuzhou, China*.

Background: Regarding kidney disease therapy, extra-renal effects, the inactivation of drug before reaching kidney or altered distribution due to the pathophysiology of diseases limit some medication widely use. The specific delivery or selective activation in kidney maximizes therapeutic effectiveness and minimizes toxic side effects. The improvement of the pharmacokinetic profile should be accomplished by drug targeting strategies. Liposome is single-layer or multi-layered vesicles composed of ordered lipid bilayers with an aqueous phase inside. Selective delivery of drugs in liposomes has been used clinically to treat some diseases because of their excellent biocompatibility, wide range of drug loading and low toxicity. They can increase the stability and solubility of the drug, give drug delivery and sustained release drug characteristics, and effectively improve the drug bioavailability. In this study, we evaluated the safety and effectiveness of chitosan-modified liposome as a kdiney-trageted delivery system.

Methods: To establish chitosan-modified liposome delivery system, liposomes were prepared by thin-film methods and post-insertion technology was performed to achieve chitosan modification. The morphology was confirmed by scanning electron microscopy (SEM) and transmission electron microscopy (TEM). To study the safety of this system, the cellular viability of human renal tubular epithelial cells, HK-2, was evaluated by cell proliferation kit. Drug release from the nanocomplex was analyzed at pH 7.4,6.8 and 5.0 using the dialysis method. To investigate the specific kidney-targeted delivery, the vector and its modified liposome was injected into mice and the distribution was analyzed by fluorescence imaging.

Results: Zeta potential of liposome pre- and post- chitosan modification confirmed the success of the reaction. The drug-loading system was spherical-like nanoparticles with an average particle size of (48.49±0.61) nm. The *in vitro* release results showed the nanoparticles had no burst release under physiological pH conditions. Near-infrared fluorescence imaging indicated that the system could be effectively distributed to the kidney. Furthermore, this system had no obvious toxicity to renal tubular epithelial cells.

Conclusions: The chitosan-modified liposome is expected to achieve renal targeted drug delivery and the drug-loading system is safe and stable.

Screening for Effective Components of Tripterygium wilfordii Hook F for the Treatment of Diabetic Nephropathy Based on Computer Simulation

Lengnan Xu, Yonghui Mao, Ban Zhao. Department of Nephrology, Beijing Hospital, National Center of Gerontology *Beijing Hospital, Beijing, China*.

Background: Triptergium wilfordii Hook F (TwHF), is commonly used in the management of many renal diseases through antiinflammation and immunosuppressive in traditional Chinese medicine. How to reduce the toxicity of TwHF without affecting its efficacy has always been an important research issue. In this study, we used evidence-based research to detail the natural ingredients isolated from TwHF, referenced a gene library when screening for components effective in the management of diabetic nephropathy (DN) and provide a scientific foundation for the development of novel drugs for treatment of this condition.

Methods: CNKI, Wanfang, VIP, Pubmed and relevant databases were used to retrieve and summarize the components of TwHF. All data analyses were carried out using the Discovery Studio 4.5 System, and the Systemdockonlinedockingmethod platform to find active small molecules and effector proteins, and then using online big data to screen for genetic information relevant to DN.

Results: A total of 370 compounds classed into 4 main categories(36 sesquiterpenes, 93 diterpenes, 133 triterpenes and 106 alkaloids) obtained. A total of 46 small molecules were found to be biologically active constituents of TwHF in the setting of DN, mainly affecting the inflammatory response through PI3K-Akt and Jak-STAT pathways. 4 small molecules (Triptonoditerpenic Acid, Regeol C, Demethylzeylasteral and Demethylzeylasterone) mainly affected the inflammatory response. Through screening DN genes, 7 target proteins(VDR, JAK1, JAK2, JAK3, PPARG, MARK14, TGFBR1) were found to have high correlation scores.

Conclusions: The emergence of network pharmacology has completely altered the research approach towards novel drug development and has greatly compensated for a lack of experimental capabilities. We first report tripterygium glycosides to act on VDR. Further experimentation can confirm the accuracy of target and molecular networks as well as effective components of TwHF.

Additive Renoprotective Effects of Angiotensin Converting Enzyme Inhibition and Nitro Fatty Acid (CXA-10) Combination

Aaron J. Polichnowski,[1] Anil K. Bidani,[2] Geoffrey A. Williamson,[3] Jeffrey S. Finman,[5] Michael Mcalexander,[5] Karen A. Griffin,[4] Robert N. Willette,[5] Diane K. Jorkasky.[5] *[1]East Tennessee State University, Johnson City, TN; [2]Loyola University Med Ctr and Hines VA Hospital, Maywood, IL; [3]Illinois Institute of Technology, Chicago, IL; [4]Loyola University Medical Center Hines VA Hospital, Maywood, IL; [5]Complexa, Inc., Berwyn, PA*.

Background: Underlying pathogenic mechanisms in chronic kidney disease (CKD) include chronic inflammation, oxidant stress, and matrix remodeling associated with dysregulated NF-κB, NRF2 and SMAD signaling pathways, respectively. During CKD progression these pathogenic mechanisms overwhelm endogenous cytoprotective mechanisms mediated by nitro fatty acids (NO_2-FA) that act through posttranslational protein modification to limit inflammation and oxidant stress.

Methods: To restore cytoprotective balance, we evaluated the effects of chronic treatment with CXA-10 (10-nitro-9(E)-octadec-9-enoic acid), a nitro fatty acid, in a reduced renal mass (RRM) – high salt rat model of progressive CKD. Five treatment groups were examined (Control, CXA-10 (1.25 and 3.75 mg/kg, p.o.), enalapril and enalapril + CXA-10), for a 3-week dosing period that commenced 4 weeks following RRM.

Results: Enalapril significantly attenuated the increase in mean arterial pressure (MAP) and mildly blunted proteinuria, non-significantly. Similarly, the low dose of

CXA-10 non-significantly attenuated proteinuria but had no effect on the increase in MAP. In a two-factor analysis model, both CXA-10 and enalapril treatment significantly blunted the increase in proteinuria (p= 0.048 and 0.045, respectively). The combination of enalapril and CXA-10 (1.25 mg/kg) did not further alter MAP more than enalapril alone, but significantly reduce proteinuria after 3 weeks of treatment when compared to Control (-12% vs. 30%). Treatment with CXA-10 alone (1.25mg/kg & 3.75 mg/kg) maintained renal blood flow (RBF) at pretreatment levels. Based on a histopathologic analysis, none of these short-term treatment regimens (3 weeks) altered the moderate glomerulosclerosis and mild renovascular injury observed in the model.

Conclusions: The results suggest that the combination of enalapril and CXA-10 may exert additive MAP-dependent (enalapril) and MAP-independent (CXA-10) effects to limit increases in proteinuria without compromising renal perfusion.

Rhein Reverses miR-34a-Mediated Autophagy in D-Galactose-Induced Renal Aging Rats via the Regulation of Gut Microbiome

Yue Tu,[1] Buhui Liu,[2] Yigang Wan.[2] Nanjing University of Chinese Medicine *[1]Nanjing University of Chinese Medicine, Nanjing, China; [2]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China*.

Background: The alterations of gut microbiota in composition, diversity and functional features have a close relationship with aging-associated pathologies, including renal aging. microRNAs (miRNAs)-mediated autophagy also has an important role in aging. Recently, traditional Chinese herbal medications have been reported to possess potent anti-aging activities. Rhein is a bioactive constituent of rhubarb, derived from the root of *Rheum palmatum* with the anti-aging pharmacological effect. But the characteristics of gut microbiome and its relationship with miRNAs-mediated autophagy of rhein in anti-renal aging are unknown.

Methods: Forty rats were divided into Normal (N), Model (M), Rhein (R) and Vitamin E (VE) groups. D-galactose (D-gal) was used to induce renal aging. The appropriate doses of rhein, VE and distilled water were administrated with oral, respectively. All rats were sacrificed after 8 weeks treatments. Blood serum, fecal samples and kidneys were collected for the detection of various indicators. The characteristics of gut microbiome were determined by 16S rDNA Sequencing. Serum concentrations of uremic toxins indoxyl sulfate (IS), p-cresol sulfate (pCS) and trimethylamine oxide (TMAO) were detected by ELISA. miR-34a expression level was detected by RT-PCR. The senescence-associated-β-galactosidase (SA-β-gal) staining was observed. The aging-related protein expressions of Klotho, p53 and p21, as well as the protein expressions of autophagy markers, Beclin-1, LC3 I/II, p62, and Atg12 were detected by Western Blot.

Results: Results showed that, the structure and diversity of gut microbiota in 4 groups were different. Rhein and VE could reverse the abundance of some genus changed significantly in M group when compared with N group. Rhein and VE could notably decrease the increased IS, pCS and TMAO in M group. Rhein and VE markedly alleviated the up-regulation of miR-34a in M group. In addition, rhein and VE could attenuate strong positive staining for SA-β-gal, and reverse the significantly changed aging-related protein expressions and autophagy markers in M group.

Conclusions: This study proved rhein, similar to VE, could alleviate renal aging via regulating gut microbiome and miR-34a-mediated autophagy. Thus, targeting gut-kidney axis and miRNAs-mediated autophagy may provide new strategies in age-associated renal damage of the elderly patients.

Hyperoside Ameliorates Renal Tubular Epithelial Cells Ageing Induced by D-Galactose via Regulating m^{6}A Modification of TFEB mRNA

Buhui Liu,[1] Yue Tu,[2] Yigang Wan.[3] *[1]Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjng, China; [2]Nanjing University of Chinese Medicine, Nanjing, China; [3]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China*.

Background: The kidney is a typical organ that undergoes age-related tissue injury, however, there is little information on therapeutic effects underlying age-associated renal damage. Hyperoside (HYP), a component of *Abelmoschus manihot*, is reported to be useful for preventing premature ageing induced by D-galactose (D-gal). But its potential mechanisms remain unclear. N6-methyladenosine (m^{6}A) mRNA modification plays a critical role in transcription factor EB (TFEB) discovered as a master regulator of autophagic function. We thereby aimed to determine whether HYP alleviates D-gal-induced renal ageing by targeting autophagic activity and m^{6}A modification of TFEB mRNA, compared to vitamin E (VE).

Methods: Renal proximal tubular epithelial cells of rats (NRK-52E cells) were divided into the normal, the D-gal model, the low dose of HYP, the high dose of HYP and the VE groups, and treated by the different measures, respectively. More specifically, NRK-52E cells in each group were separately treated by 1% FBS or D-gal (100 mM) or D-gal (100 mM) + HYP (5 mg/L) or D-gal (100 mM) + HYP (10 mg/L) or D-gal (100 mM) + VE (50 mg/L). After intervention for 24 h, firstly, effects of D-gal on the mRNA levels of m^{6}A and TFEB; the ageing-related protein expression levels of Klotho, P27, P16, IL-1, TGF-β and MCP-1; SA-β-gal staining and LC3 Lentiviral transfection in NRK-52E cells were detected, respectively. Secondly, effects of D-gal, HYP and VE on activation of NRK-52E cells proliferation were investigated. Finally, effects of HYP and VE on the mRNA levels of m^{6}A and TFEB; the ageing-related protein expression levels; SA-β-gal staining and LC3 Lentiviral transfection in NRK-52E cells exposed to D-gal were examined severally.

Results: For NRK-52E cells, D-gal induced the low mRNA levels of m^{6}A and high mRNA levels of TFEB, and caused ageing and autophagy. The co-treatment of HYP at the high dose and D-gal significantly ameliorated the ageing-related protein expression levels and LC3 protein expression. In addition, the co-treatment of HYP at the high dose and D-gal obviously increased the mRNA level of m^{6}A and decreased the TFEB level. The VE group has the similar changes as HYP at the high dose.

Conclusions: We clarified that HYP and VE could improve D-gal-induced renal tubular cellular ageing by reducing autophagic activity and increasing m^{6}A modification of TFEB mRNA.

TH-PO377

5-HT$_{1F}$ Receptor Mediates Renal Vascular Homeostasis and Mitochondrial Biogenesis

Tess Dupre, Rick G. Schnellmann. *University of Arizona, Tucson, AZ*.

Background: Acute kidney injury (AKI) is a disease with no treatment options. After AKI, there is a marked reduction in renal vasculature. Thus, promoting vascular recovery following AKI could facilitate renal repair as the vasculature is responsible for carrying oxygen and nutrients to extravascular tissues. Our laboratory has shown that stimulating mitochondrial biogenesis (MB) through the 5-HT$_{1F}$ receptor stimulates recovery from AKI. In contrast, 5HT$_{1F}$ receptor knockout mice have decreased MB, vascular content, and poor renal recovery. Importantly, induction of MB has been linked to increased angiogenesis. Thus, we hypothesized that the 5HT$_{1F}$ receptor mediates MB and plays a role in vascular homeostasis in renal endothelial cells.

Methods: Primary human glomerular endothelial cells (HEC) and mouse glomerular endothelial cells (MEC) were treated with the 5-HT$_{1F}$ receptor agonists 300nM LY344864 or 100 nM lasmiditan for 24 or 72h. Branching morphogenesis and wound healing were assessed via matrigel and scratch migration assays, respectively. Mitochondrial biogenesis was assessed by enumerating mitochondra via electron microscopy analysis.

Results: Treatment of HEC and MEC with LY344864 or lasmiditan induced MB, as evidenced by increased mitochondrial number in comparison to vehicle treated cells. HEC that were treated with lasmiditan or LY344864 exhibited increased migratory capacity, as evidenced by increased endothelial branching (matrigel migration assays) and increased would healing (scratch closure).

Conclusions: Stimulation of 5-HT$_{1F}$ receptor with LY344864 and lasmiditan induces MB in HEC and MEC, and 5-HT$_{1F}$ receptor mediates angiogenic pathways. We propose that inducing MB in endothelial cells after AKI could restore vascular function and stimulate renal repair and recovery.

TH-PO378

Activation of the Keap1/Nrf2 Pathway Increases GFR by Increasing Glomerular Effective Filtration Area Without Affecting the Afferent/Efferent Arteriole Ratio

Kengo Kidokoro,[2] Hajime Nagasu,[2] Minoru Satoh,[2] Colin J. Meyer,[1] Naoki Kashihara.[2] *[1]Reata Pharmaceuticals, Irving, TX; [2]Kawasaki Medical School, Kurashiki, Japan*.

Background: The Keap1/Nrf2 pathway regulates various cytoprotective, anti-inflammatory, and antioxidant genes. Nrf2 activator, Bardoxolone methyl (BARD), increases the estimated glomerular filtration rate (eGFR) in patients with diabetic kidney disease (DKD). Moreover, BARD improved renal function in DKD patients, as revealed through the assessment of inulin clearance, the gold standard for measuring the GFR. These findings indicate that the Keap1/Nrf2 pathway is largely involved in the regulation of the GFR; however, the precise underlying mechanisms are yet unclear. This study aimed to pharmacologically and genetically investigate the mechanisms underlying the regulation of the GFR by the Keap1/Nrf2 pathway via multiphoton microscope (MPM) imaging in vivo.

Methods: C57BL/6 (Control), Nrf2-knockout (Nrf2-KO), and Nrf2-activated Keap1-knockdown mice (Keap1-KD) were used herein and treated with the synthetic terpenoid RTA dh404 (RTA, 10 mg/kg/day by gavage) for 1 week. Single-nephron GFR (SNGFR), the diameter of the afferent/efferent arterioles and glomerular permeability were evaluated using MPM. Intracellular calcium in response to ATP and angiotensin II stimulation and the effect of RTA on [Ca2+]i were evaluated using Fluo 4 and Fura red in cultured mesangial cells and podocytes. Production of reactive oxygen species and nitric oxide (NO) availability were assessed using CellROX® Deep Red and diaminofluorescein-FM diacetate (DAF-FM DA) upon the exposure to these stimuli.

Results: SNGFR was significantly higher in Keap1-KD mice than in the control group (9.13±0.55 vs 4.40±0.39 nl/min, p<0.05). RTA administration increased the SNGFR in the control mice but not in Nrf2-KO mice (6.00±0.40 vs 4.66±0.35 nl/min, p<0.05). The glomerular afferent/efferent arteriole ratio was not altered significantly in all groups. RTA treatment did not affect the glomerular permeability of albumin and 40 kDa dextran. RTA treatment inhibited calcium influx into cultured podocytes and mesangial cells induced by angiotensin II or ATP, thereby affecting contractile responses. Oxidative stress and NO bioavailability were also ameliorated with upon RTA treatment.

Conclusions: The Keap1/Nrf2 pathway plays a pivotal role in regulating GFR and presumably mediates the effects of BARD on GFR.

TH-PO379

PEGylation of Inositol Hexaphosphate (InsP6) Decreases Its Binding Affinity for Hydroxyapatite and Its Capacity to Inhibit Plasma Calcification In Vitro

Maria del mar Perez,[1] Miquel D. Ferrer,[1,2] Joaquin Ortega-Castro,[2] Firas Bassissi,[1] Joan Perelló,[1,2] Carolina Salcedo.[1] *[1]Sanifit Therapeutics, Palma, Spain; [2]Universitat de les Illes Balears, Palma, Spain.*

Background: Vascular calcification (VC) is a major contributor to increased morbidity and mortality in Chronic Kidney Disease patients undergoing dialysis. Although VC is a multifactorial process, the final common pathway is deposition of solid hydroxyapatite (HAP) within the arteries. SNF472, a salt of InsP6, is a selective calcification inhibitor that interferes in the formation and growth of ectopic HAP. SNF472 is currently being developed for the treatment of calciphylaxis in patients on dialysis. Inositol-1,2,3,5-tetraphosphate-4,6-bisPEG$_{100}$ (InsP4bisPEG) is an inositol phosphate derivative resulting from the PEGylation of inositol tetraphosphate (InsP4) with polyethylene glycol (PEG) 100. Our aim was to study the binding affinities of SNF472, InsP4bisPEG and InsP4 for the HAP surface, and its relationship with their *in vitro* efficacy by inhibiting calcium phosphate crystallization.

Methods: To evaluate the adsorption binding affinity (E_{ads}) of SNF472, InsP4bisPEG and InsP4 to the HAP crystal surface, computational studies were performed using Density Functional Theory calculations with DMOL3 (MS2016). The in vitro efficacy of InsP4bisPEG and InsP4 was evaluated using a pharmacodynamic assay to measure the plasma calcification potential using a previously validated spectrophotometric method, and compared to SNF472 in the 0-100 μM range.

Results: Molecular modelling revealed that SNF472 binds to the HAP surface with higher affinity than InsP4bisPEG, as revealed by their relative energies of absorption taking InsP4 as reference (ΔE_{ads}=-110 kcal/mol for SNF472 and ΔE_{ads}=-41.1 kcal/mol for InsP4bisPEG). These results are correlated with the inhibition potencies observed in the human plasma HAP crystallization assay. EC_{50} was 2.2 μM, 3.8 μM and 8.5 μM, for SNF472, InsP4bisPEG and InsP4, respectively.

Conclusions: SNF472 shows the highest binding affinity and the highest in vitro potency in the inhibition of HAP crystallization in human plasma, which is concordant with the larger electrostatic interactions between SNF472 and HAP, since it is a more charged molecule.

Antisense Oligonucleotides Target Proximal Tubular Epithelial Cells in Kidney

Sabrina Markert,[2] Andreas Hofmeister,[1] Dana K. Stenzel,[3] Joachim Hoyer,[4] Holger Garn,[1] Ivica Grgic.[1] *[1]Philipps-University Marburg, Marburg, Germany; [2]Philipps Universität Marburg, Marburg, Germany; [3]Internal Medicine and Nephrology, Philipps-University Marburg, Marburg, Germany; [4]Marburg Philipps-University, Marburg, Germany.*

Background: Developing, refining and deploying new drugs to target specific molecules in cell types and tissues of interest is crucial for advancing towards precision medicine. Antisense oligonucleotides (ASO) are chemically synthesized, short DNA oligomers that can be applied to target specific mRNAs via hybridization and degradation, thus resulting in a reduced synthesis of related proteins. Recent data suggest that newer, more stable and effective generations of ASO may be of therapeutic value, including in humans. However, our understanding of the biodistribution and efficacy of systemically delivered ASO in organs is insufficient.

Methods: Here, we investigated the distribution, cell incorporation and gene knockdown efficiency of ASO specifically in kidney cells *in vitro* and *in vivo* using an unbiased approach.

Results: First, we designed and generated several eGFP-specific LNA Gapmer-type ASO and tested for eGFP knockdown potency *in vitro*. Promising candidates were amplified and then used in two transgenic mouse models of ubiquitous, constitutive eGFP-expression. EGFP-mice were i.p. injected with ASO directed against eGFP or control ASO for five to ten days, sacrificed and organs harvested for analyses. Comprehensive immunohistological studies in kidney using cell-specific staining techniques found distinct and robust eGFP suppression in proximal tubular epithelial cells (PTEC) but not in other renal cell types including the TAL, collecting duct, interstitium and endothelial cells. To study the biodistribution and dynamics of systemic ASO in more detail, we administered fluorophore-labeled ASO to wildtype mice and found overwhelming ASO enrichment in PTEC, suggesting highly preferential ASO incorporation in this segment of the nephron. In line, temporary exposure of mammal PTEC to labeled ASO *in vitro* resulted in rapid and sustained increases in intracellular fluorescence, indicating efficient ASO uptake by PTEC.

Conclusions: In summary, our data provide strong evidence for a differentiated biodistribution and cellular internalization of ASO in renal tissue with systemic delivery, implicating important differences in ASO-mediated knockdown efficacy and favoring, overall, PTEC as potential target cells. This disparity in ASO accessibility and hence expectable impact needs to be considered when defining therapeutic targets in kidney.

Application of the Kidney Failure Risk Equation to an Electronic Health Record-Based CKD Registry

Salman Ahmed,[1] Mallika L. Mendu,[1] Gary C. Curhan.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: The Kidney Failure Risk Equation (KFRE), utilizes age, sex, estimated glomerular filtration rate (eGFR), and urine albumin to creatinine ratio (UACR), to predict progression to End Stage Renal Disease (ESRD). Application of the KFRE to an electronic health record (EHR)-based chronic kidney disease (CKD) registry enables ESRD risk stratification across a CKD population.

Methods: Cross-sectional study of 57,385 patients included in the Partners Healthcare System (PHS) CKD registry (dialysis and transplant patients were excluded). Multivariate logistic regression analyses were conducted to identify factors associated with: UACR testing; arteriovenous fistula (AVF) and placement; kidney transplant referral; and completion of advance directives.

Results: 17,266 (30%) patients had all variables required for KFRE; 40,119 (70%) patients lacked UACR. Factors associated with UACR testing were diabetes, hypertension, obesity, and being seen by an in-network nephrologist. In the highest KFRE risk stratum (≥ 40% risk of ESRD within two years; N=515), 35 (6.8%) patients had an AVF; 64 (12.4%) patients had been referred for transplantation; and 61 (11.8%) patients had advanced directives. Factors associated with not having an AVF were older age, female sex, and fewer visits to an in-network nephrologist. Factors associated with lack of transplant referral were older age, higher eGFR, and not having a PHS nephrologist. Factors associated with lack of advance directives were younger age, male sex, not having a PHS Primary Care Provider, and KFRE stratum of lowest (<3% risk) or low (3-9.9% risk).

Conclusions: The KFRE stratifies risk of ESRD; however, 70% of our patients with CKD lack UACR testing. Institution-wide UACR testing will facilitate care optimization. Our findings enable targeted care of sub-populations to improve care delivery and transition to ESRD.

Funding: NIDDK Support

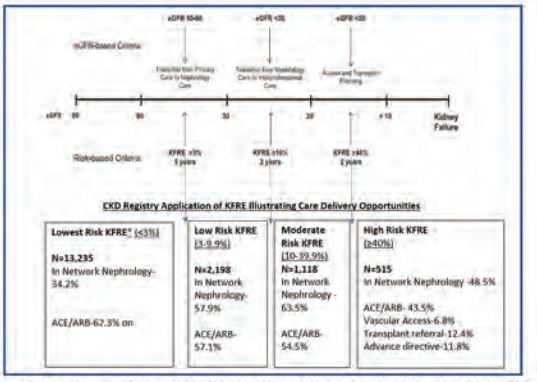

Figure 1: Risk stratification adapted from Tangri NDT 2017, with performance on metrics per stratum applied to PHS CKD Registry. *2 year risk of ESRD from Kidney Failure Risk Equation (KFRE). Abbreviations. ACE/ARB: angiotensin converting enzyme inhibitor / angiotensin receptor blocker.

A Predictive Model for Progression of CKD to Kidney Failure Using an Administrative Claims Database

Ajay Sharma,[1] Paula J. Alvarez,[2] Steven D. Woods,[2] Jeanene Fogli,[2] Dingwei Dai,[1] Rajesh Mehta.[1] *[1]Healthagen Outcomes, division of CVS Health, New York, NY; [2]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA.*

Background: To develop and validate a predictive model to identify patients (pts) with chronic kidney disease (CKD) Stage 3 or 4 at high risk for progression to kidney failure (KF) over a 24-mo period.

Methods: A predictive model was developed and validated utilizing a retrospective claims database of CKD Stage 3 or 4 patients from a large US payer. The study covered 36 mo with a 12-mo (2015) baseline period and 24-mo (2016–2017) prediction period. All pts were ≥18 yrs of age without dialysis or kidney transplant and had 36 months of enrollment. KF was defined as: eGFR <15 mL/min/1.73 m^2; or dialysis; or kidney transplant; or one diagnosis (ICD-10-CM: N18.5, N18.6) in prediction period. Multivariate logistic regression was used to develop a model estimating the 2-yr probability of KF as a function of baseline covariates. Area under receiver operating characteristic (ROC) curve (AUC), calibration, gain and lift charts of the validation sample were used to assess the predictive model performance.

Results: Of the 74,114 pts studied, 2476 (3.34%) had incident KF in the prediction period (**figure**). The predictive model included age, gender, CKD Stage, hypertension (HTN), diabetes mellitus (DM), congestive heart failure (CHF), peripheral vascular disease (PVD), anemia, hyperkalemia (HK), and poor RAAS inhibitors adherence. The strongest predictors were CKD Stage (4 vs 3), HTN, DM and HK. The ROC curve and calibration analyses in the validation sample showed good predictive accuracy (AUC=0.834) and good calibration.

Conclusions: This predictive model provides a good level of accuracy in identifying CKD pts at high risk of progressing to KF up to 2 yrs in advance in a national health plan with over 10 million lives. Early identification using this model could potentially lead to improved health outcomes and reduce health care expenditure.

TH-PO383

Prognostic Score for Chronic Renal Disease in Patients with Lupus Nephritis

Myriam K. Perez,[2] Jineth L. Diaz villar,[2] Angela M. Cordoba hurtado,[1] L. M. Perez-Navarro,[2] Virgilia Soto,[3] Rafael Valdez-Ortiz.[2] M *[1]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico; [2]Hospital General de México Dr. Eduardo Liceaga, México, Mexico; [3]INC Ignacio Chavez, Mexico City, Mexico*.

Background: There is currently a prognostic score of progression to chronic kidney disease (CKD) in patients with lupus nephritis (LN), this tool evaluates: cellular and fibrous crescents; activity and chronicity index; glomerular sclerosis; interstitial fibrosis; nephrotic syndrome and glomerular filtration rate. The resulting data divides the population at low risk; moderate; and severe risk. The objective of this study was to apply this score to Mexican patients with LN and to predict their progression to CKD.

Methods: Study of ambilective cohort of patients with NL of the HGM from August 2012 to August 2017, in which the prognostic score was applied. Descriptive statistics and survival analysis were performed with Cox regression, with 95% CI, considered a value of $p < 0.05$ as statistically significative.

Results: 141 patients were analyzed; we found a mean age of 32.01±10.95 years, 73% (103) women. According to the ISN/RPS class IV (38%) and class IV+V (34%) were identified and classes II, III, III+IV and V were presented with frequency of 11% or less. The score stratified 54% (76) patients in the low risk; 43% (60) moderate; and 3% (4) severe. During the follow-up at 6 months, 29 patients (26%) presented total remission (RT); 42% (48) partial remission (PR); and 32% (36) without remission (SR). Progression to CKD was observed in 19% of patients with (RT), in 37% with (RP) and in 44% (SR), ($p < 0.05$). For terminal CKD (ERCT) no significant differences were observed (patients with RT 20%, RP 27% and SR 53%, $p = 0.15$). According to the score, 15 (22%) of the patients with low risk presented progression to CKD, unlike 33 (73 %) of those with moderate risk, and 4 (100%) with high risk ($p < 0.001$). Progression to ERCT was observed in 3 (4%) patients with low risk, 27 (45%) moderate risk and 1 (20%) patient with high risk ($p < 0.001$).

Conclusions: The results show that the application of this prognostic score in Mexican patients with LN is useful to predict the progression to CKD and ESRD regardless of the response to treatment.

TH-PO384

Prediction Model from Big Data for Rapid GFR Decline in CKD Patients by Machine Learning Technique

Daijo Inaguma,[1] Ryosuke Yanagiya,[2] Akira Koseki,[3] Toshiya Iwamori,[3] Michiharu Kudo,[3] Yukio Yuzawa.[1] *[1]Nephrology, Fujita Health University School of Medicine, Toyoake, Japan; [2]Medical Information Systems, Fujita Health University School of Medicine, Toyoake, Japan; [3]IBM, Tokyo, Japan*.

Background: Recent studies have focused on kidney function trajectory because it might be related to the incidence of cardiovascular (CV) disease and all-cause mortality. We aimed to investigate risk factors for rapid GFR decline and create a machine learning-based predictive model by using one big hospital database.

Methods: We used a database derived from the Fujita Health University Hospital. Medical data were available for 120,689 eGFR-recorded patients in this study. Among them, 21,198 patients met the CKD criteria. Rapid GFR decline in patients with CKD was defined as eGFR decline of ≥30% per 2 years; we used average eGFR of past 90 days to avoid temporal spikes of measurements. We then selected unique 5,818 CKD patients with rapid GFR decline, from which 10,093 samples of rapid GFR decline were obtained. We built a prediction model to classify rapid GFR decline using machine learning algorithms including logistic regression, decision tree, and random forest. We used explanatory variables including 90-day past data of eGFR, proteinuria, serum creatinine (Cr), blood pressure, body mass index, sex, and age. Among those longitudinal data, we used average, standard deviation (SD), and exponentially smoothed average (ESA) to form explanatory variables for the prediction model. Contribution to rapid GFR decline was examined by weight of each variable.

Results: We used serial 10,093 data each from 5,818 CKD patients with rapid GFR decline and without rapid GFR decline for the prediction model. There were no significant differences in age and sex between the two groups. Mean proteinuria, ESA of proteinuria, SD of serum Cr, ESA of serum Cr, and SD of Hematocrit were associated with rapid GFR decline in the random forest model. Moreover, the random forest model predicted rapid GFR decline with an accuracy of 0.75 (area under the curve). Meanwhile, area under the curves for predicting rapid GFR decline were 0.69 and 0.69 in the logistic regression and decision tree models, respectively. By the decision tree analysis, the incidence of rapid GFR decline was 90% if the following criteria were fulfilled: 4+ or more of mean urine protein; ≤1.33 ESA of serum Cr; ≤1.03 SD of hemoglobin.

Conclusions: The random forest model by machine learning could be useful to identify patients with rapid GFR decline in real world clinical setting.

TH-PO385

Discovery of CKD Patient Subgroups by Consensus Clustering: The CRIC Study

Zihe Zheng,[1] Sushrut S. Waikar,[2] Wei Yang,[1] Tariq Shafi,[3] Chi-yuan Hsu,[4] Francis P. Wilson,[5] Jing Chen,[6] Amanda H. Anderson,[7] Ana C. Ricardo,[8] Tamara Isakova,[9] Hernan Rincon-Choles,[10] Radhakrishna R. Kallem,[1] Harold I. Feldman,[1] J. R. Landis.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Harvard Medical School, Boston, MA; [3]University of Mississippi Medical Center, Jackson, MS; [4]University of California San Francisco, San Francisco, CA; [5]Yale School of Medicine, New Haven, CT; [6]Tulane School of Medicine, New Orleans, LA; [7]Tulane University, New Orleans, LA; [8]University of Illinois at Chicago, Chicago, IL; [9]Feinberg School of Medicine, Northwestern University, Chicago, IL; [10]Cleveland Clinic, Cleveland, OH*.

Background: CKD is a heterogeneous condition with multiple underlying causes, risk factors, and outcomes. Consensus clustering may reveal CKD subgroups with different risk profiles of adverse outcomes.

Methods: Among 2696 participants in the prospective CRIC Study, we performed unsupervised consensus clustering with K-means, without using outcome information, on 72 baseline characteristics of traditional and novel factors to discover patient subgroups. We calculated the standardized difference of all predictors across subgroups, and used the cut-off of ±0.3 to show key features. We examined the associations of each subgroup with ESRD, cardiovascular diseases (composite of heart failure, MI, stroke and PAD), and death.

Results: Three unique CKD subgroups, identified using only baseline factors, were associated with low (Cluster1, N=1203), medium (Cluster2, N=1098), and high (Cluster3, N=395) risks of the outcomes (**Fig 1**). Patients in cluster 1 (lowest risk) had lower bone & mineral, diabetes, cardiac, and obesity markers, greater eGFR, and used fewer medications. Patients in cluster 2 had higher diabetes and obesity markers, and used more medications. Patients in cluster 3 (highest risk) had higher bone & mineral (except for lower serum calcium), cardiac (except for lower serum CO_2), inflammation (except for lower serum albumin), and kidney markers (except for lower eGFR) (**Fig 2**).

Conclusions: Consensus clustering discovered distinct subgroups of CKD patients with distinguishing patterns of baseline clinical and laboratory factors yielding markedly different risks of important clinical outcomes. Specific biomarkers featuring high-risk CKD subgroup could provide potential treatment targets.

Optimizing Machine Learning Methods for Clinical Outcome Prediction

Qian Liu,[1] Abigail R. Smith,[1] Laura H. Mariani,[2,1] Jarcy Zee.[1] [1]*Arbor Research Collaborative for Health, Ann Arbor, MI;* [2]*University of Michigan, Ann Arbor, MI.*

Background: Machine learning (ML) is useful to identify novel biomarkers and predict clinical outcomes, especially when predictors outnumber patients, but model building procedures are underutilized. We compared two ML methods and the impact of pre-specifying covariate functional forms on predictive accuracy and variable importance using data from NEPTUNE, a prospective cohort study of glomerular disease patients.

Methods: The sample was split into training (70%) and validation (30%) sets. Ridge regression and random forest models were developed in the training set to predict time to two clinical outcomes: disease progression (ESRD or ≥40% eGFR decline with last eGFR <60) and complete remission of proteinuria (UPCR <0.3), with and without categorizing continuous covariates to accomodate non-linear associations with outcomes. Predictors included 56 demographic/clinical characteristics, which were ranked by variable importance. Discrimination was estimated in the validation set using integrated area under the curve (iAUC).

Results: Using pre-specified covariate functional forms in ridge regression increased iAUC from 0.68 to 0.74 for the progression outcome, but had little impact for remission (0.79 vs. 0.78; Fig) or the random forest method for both outcomes. iAUCs from random forest were higher than those from ridge for progression but not remission. After pre-specifying functional forms in ridge regression, variable importance ranks increased for some known risk factors: rank of UPCR for predicting remission rose from 48 to 5 and rank of eGFR for predicting progression rose from 52 to 1. Other important predictors were disease diagnosis, age, and immunosuppression use for remission and disease diagnosis, race, and hypertension for progression.

Conclusions: For ML methods assuming linear associations, like ridge regression, pre-specifying covariate functional forms is important for predictive accuracy and detecting important predictors. Different ML methods may improve prediction for different outcomes. Higher ranking of known risk factors improves face validity in prediction models and may have positive implications for external validation performance.

Study on Glomerular Filtration Rate Equation Using Ensemble Learning and Linear Regression

Xun Liu,[1] Linsheng Lv,[1] Yuqiu Ye,[2] Shaomin Li,[1] Wentao Hu.[2] [1]*The Third Affiliated Hospital of Sun-Yat-Sen University, Guangzhou, China;* [2]*Department of Nephrology, The Third Affiliated Hospital of Sun Yat-sen University, Guangdong, China, Guangzhou, China.*

Background: Accurate estimating glomerular filtration rate (GFR) is crucial both in clinical practice and epidemiological survey. We incorporated semi-supervised learning technology to improve GFR estimation performance.

Methods: Data from patients with CKD and healthy people who were examined by radionuclide renal dynamic imaging or dual plasma DTPA in the Tianhe and Lingnan districts of The Third Affiliated Hospital of Sun Yat-sen University from January 2012 to April 2018 including baseline indicators, laboratory indicators, Kidney color Doppler ultrasound results, medication status. A total of 1,732 CKD patients and healthy people who had ECT examinations were included, of which 932 patients in Tianhe District used data as modeling data, and other 400 patients in Tianhe District as an internal validation data set, 400 patient data from Lingnan districts and outpatient department was used as the external validation data set. In the modeling group, the conventional data is modeled by linear regression and ensemble learning method, and then the verification group data is imported into the model to judge the prediction performance. We use internationally accepted bias, precision and accuracy comprehensively evaluate the predictive the model effectiveness and use the bootstrap method to calculate the 95% confidence interval and select the optimal model.

Results: A total of 1,732 CKD patients and healthy people were included in the study. The mean age was 57.15±13.56 years, and the mean GFR (mGFR) was 87.01±37.63 ml/min/1.73 m^2. The newly revised CKD-EPI equation using smooth linearity (N-Spline technique) is superior to the equations modeled by traditional linear regression methods in terms of precision ($p < 0.001$). In terms of accuracy and precision, the XGboost model equation is superior to the linear regression equation of the same variable ($p<0.05$). Compared with the 4-variable revision CKD-EPI model, the 15-variable, 3-variable XGboost model improved in bias, but it was not statistically significant; it was better in accuracy and precision ($P<0.05$). Compared with the widely used eGFR model (4 and 6 variable MDRD models), the bias, accuracy and precision of the 4-variable revision CKD-EPI model were better ($P<0.05$).

Conclusions: The ensemble learning model can optimize the predictive performance of the GFR model.

TH-PO388

Improving Glomerular Filtration Rate Estimation by Semi-Supervised Learning: A Development and External Validation Study

Xun Liu,[1] Linsheng Lv,[1] Yuqiu Ye,[2] Shaomin Li,[1] Wentao Hu.[2] [1]*The Third Affiliated Hospital of Sun-Yat-Sen University, Guangzhou, China;* [2]*Department of Nephrology, The Third Affiliated Hospital of Sun Yat-sen University, Guangdong, China, Guangzhou, China.*

Background: Accurate estimating glomerular filtration rate (GFR) is crucial both in clinical practice and epidemiological survey. We incorporated semi-supervised learning technology to improve GFR estimation performance.

Methods: Databases of AASK, CRIC and DCCT studies were pooled together for model development, whereas MDRD and CRISP studies for model external validation. The pooled development data set contained 2,719 participants, whereas the pooled external validation data set contained 1,952 participants. 4,829 participants only without GFR records but all other information available were pooled into an unlabeled data set for semi-supervised learning. New Predictors & Established Predictors : Serum creatinine, Age, Sex, Black race, Diabetes status, Hypertension and Body Mass Index. GFR measured as the urinary clearance of ^{125}I-iothalamate. The revised CKD-EPI creatinine equations was selected as benchmark for performance comparisons. The proposed semi-supervised model was essentially an artificial neural network developed by Ladder Network algorithm. Head-to-head performance comparisons were conducted between revised equations and semi-supervised models from 4-variable to 7-variable.

Results: In each independent variables combination, the semi-supervised models consistently achieved superior results in all 3 performance indicators compared with corresponding revised CKD-EPI equations in the external validation data set. When selecting one representative revised equation and semi-supervised model for further comparison, compared with revised 4-variable CKD-EPI equation, the 7-variable semi-supervised model performed less biased (mean of difference: 0.03 [-0.28, 0.34] vs 1.53 [1.28, 1.85], $P < 0.001$), more precise (interquartile range of difference: 7.94 [7.37, 8.50] vs 8.28 [7.76, 8.83], $P = 0.1$) and accurate (P30: 88.9% [87.4%, 90.2%] vs 86.0% [84.4%, 87.4%], $P < 0.001$.

Conclusions: The superior performance of the semi-supervised models during head-to-head comparisons supported the hypothesis that semi-supervised learning technology could improve GFR estimation performance. The semi-supervised model still requires extra and careful validation, and further improvement is expected by integrating more cohort data.

Development of the Deep Neural Network for Estimating Glomerular Filtration Rate

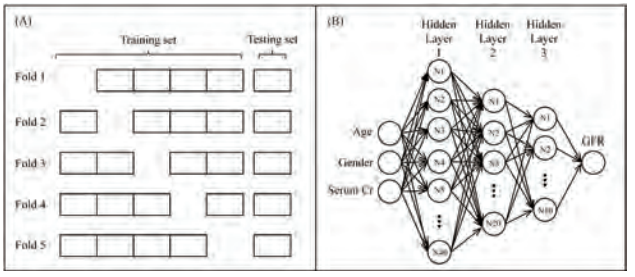
Jae Won Yang,[1] Jun Young Lee,[1] Jae seok Kim,[1] Minseob Eom,[2] Moonhee Chai,[1] Seung-Ok Choi,[1] Jin-Jae Jeong.[1] [1]*Wonju Christian Severance Hospital, Wonju, Kangwon do, Republic of Korea;* [2]*Yonsei Univ. Wonju College of Medicine, Wonju, Republic of Korea.*

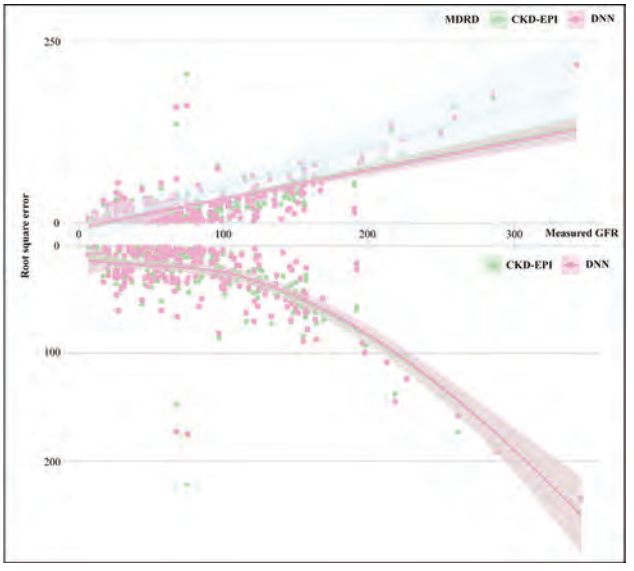
Background: A variety of calculation formulas to estimate glomerular filtration rate (GFR) have been developed for decades. Recently, modern clinical medicine has been trying to use a deep neural network (DNN) in various clinical fields. Thus, we aimed to use DNN model for estimating GFR in the study.

Methods: A total of 241 patients with chronic kidney disease were enrolled in the study. All participants had technetium-99m diethylenetriaminepentaacetic acid (^{99m}Tc-DTPA) renogram to obtain the standard value of GFR. We measured serum creatinine levels from all participants and calculated GFRs using various formulas such as MDRD and CKD-EPI. Furthermore, we developed a DNN model with three hidden layers. The first, second, and third hidden layers included 40, 20, and 10 nodes respectively. We compared GFR values of MDRD, CKD-EPI, and DNN model against standard GFR values from renogram in various statistical ways.

Results: The mean differences of GFR value from MDRD, CKD-EPI, and DNN methods with standard GFR were 2.35, 2.86, and 1.87 mL/min respectively. The mean root-mean-square-error values of MDRD, CKD-EPI, and DNN methods against standard GFR were 19.45, 18.9, and 16.78 (mL/min)^2 respectively suggesting that the GFR values of DNN model are closest to standard GFR values. When estimating the accuracy in classifying CKD stages, the degree of accuracy of MDRD, CKD-EPI, and DNN methods were 83.0, 84.3, and 85.1% respectively suggesting that the DNN model is the most accurate method in classifying CKD stages.

Conclusions: GFR measurement using DNN model is believed to be useful and accurate.





TH-PO390

Comparison of Standard and Age-Adapted GFR Criteria for Determination of CKD Prevalence

Arnar J. Jonsson,[1,2] Sigrún H. Lund,[3] Runolfur Palsson,[1,2] Olafur S. Indridason.[1]
[1]Landspitali - The National University Hospital of Iceland, Reykjavík, Iceland; [2]University of Iceland, Reykjavík, Iceland; [3]deCODE genetics, Reykjavík, Iceland.

Background: Inclusion of age-adapted GFR criteria in the definition of chronic kidney disease (CKD) has been proposed to avoid overdiagnosis in the elderly and underdiagnosis in the young. The aim of this study was to estimate the prevalence of CKD based on age-adapted glomerular filtration rate (GFR) criteria compared with a standard cut-off GFR value of 60 mL/min/1.73 m^2.

Methods: In this retrospective study, we obtained all serum creatinine (SCr) values and urine protein measurements from every clinical laboratory in Iceland in 2008-2016. Clinical information, including ICD-10 diagnosis codes, was retrieved from nationwide electronic medical records. Estimated GFR was calculated from SCr using the CKD-EPI equation. CKD was defined as presence of kidney damage, either proteinuria or ICD-10 diagnosis codes indicating kidney disease, or reduced eGFR for ≥3 months. The definition of reduced eGFR was <60 mL/min/1.73 m^2 according to the standard KDIGO criteria, whereas the age-adapted eGFR definition was <75 mL/min/1.73 m^2 for age <40 years, <60 mL/min/1.73 m^2 for 40-65 years and <45 mL/min/1.73 m^2 for age ≥65 years.

Results: We obtained 2,120,232 SCr values for 218,437 individuals. The median age was 46 (range, 18-107) years; 47% were men. The age-adjusted mean annual prevalence of CKD per 100,000 men and women, respectively, was 4420 (95%CI, 4370-4470) and 5500 (95%CI, 5440-5550) using standard GFR criteria, compared with 2844 (95%CI, 2805-2883) and 3232 (95%CI, 3190-3274) using age-adapted criteria. In men, the prevalence per 100,000 using standard vs age-adapted GFR criteria was 505 vs 591 in the age group 18-44 and 54,454 vs 31,958 in the age group 85+. In women, the prevalence per 100,000 was 908 vs 1078 and 48,868 vs 26,157 for the same age groups, respectively (Figure 1).

Conclusions: Compared with the conventional GFR cut-off, age-adapted GFR thresholds for definition of CKD yield a slightly higher prevalence in the young age groups, but a markedly lower prevalence among older people.

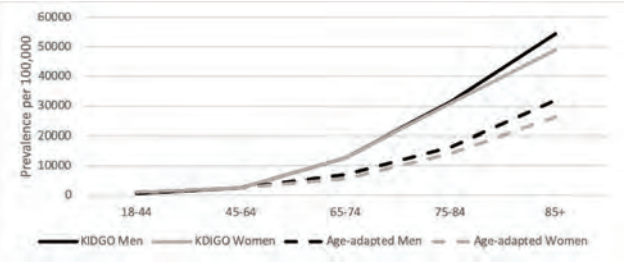


Figure 1. *Prevalence of CKD per 100,000 by sex (men black, women gray), age groups and diagnostic criteria.*

Normalizing Urine Albumin to Urine Creatinine, Osmolality, or Not at All: Insights from NHANES

Jacob J. Koopman,[3] Joachim H. Ix,[1] Rebecca Scherzer,[2] Michael Shlipak,[5] Sushrut S. Waikar.[4] *[1]UCSD, San Diego, CA; [2]UCSF, San Francisco, CA; [3]Leiden University Medical Center, Den Haag, Netherlands; [4]Harvard Medical School, Boston, MA; [5]San Francisco VA Medical Center, San Francisco, CA.*

Background: The concentration of urinary metabolites and proteins such as albumin is influenced by water excretion and urinary concentration, which varies across individuals and diurnally within individuals. To account for this variability, measures like albuminuria are often reported as normalized ratios. We hypothesized that the method of expressing urinary albumin – whether as a raw concentration or normalized to urine creatinine or osmolality – would influence observed associations with mortality due to confounding from determinants of urine creatinine excretion and osmolality, such as muscle mass, solute intake, and concentrating ability of the kidney.

Methods: We used data from the National Health and Nutrition Examination Survey 2009-2010 to model associations of albuminuria with mortality using Cox proportional hazards models. We used measurements on spot urine samples from 5,641 adults (age 42 ± 17 yrs) who had follow-up information on vital status (377 deaths) over 6 years.

Results: Median estimated glomerular filtration rate was 97 (range, 7-170) ml/min/1.73m^2, and median albumin:creatinine ratio was 5.9 (range 0.3-13,788) mg/g. The Table shows the associations of albuminuria with the risk of death. The strongest association was observed with urine albumin after multivariable adjustment for urinary creatinine.

Conclusions: While all methods of modeling urine albumin showed that elevated levels were independently associated with mortality, we found that associations were stronger when *adjusted* rather than *normalized* for urine creatinine and osmolality. Normalizing urinary biomarkers to urine creatinine may not be the optimal approach to distinguish urinary biomarker associations with health outcomes.

	Q1	Q2	Q3	Q4
Urine albumin	-	1.78 (1.06-2.98)	1.68 (1.12-2.51)	2.12 (1.33-3.37)
Urine albumin:creatinine ratio	-	1.24 (0.74-2.07)	1.62 (1.08-2.43)	2.51 (1.60-3.92)
Urine albumin:osm ratio	-	0.82 (0.53-1.27)	1.53 (0.94-2.50)	1.85 (1.23-2.79)
Urine albumin, adjusted for urine creatinine	-	2.30 (1.33-3.99)	2.42 (1.50-3.91)	3.14 (1.86-5.30)
Urine albumin, adjusted for urine osm	-	2.10 (1.22-3.62)	2.19 (1.34-3.56)	2.80 (1.68-4.65)

Multivariable-adjusted (MV) hazard ratios (95% confidence intervals) for different measures of urinary albumin quartiles and the risk of death. Models were adjusted for age, sex, race/ethnicity, hypertension, cardiovascular disease, diabetes mellitus, body mass index, and estimated glomerular filtration rate.

TH-PO392

Conversion of Urine Protein-Creatinine to Albumin-Creatinine Ratio for Use in CKD Risk Equations

Keiichi Sumida, Girish N. Nadkarni, Kevan Polkinghorne, Hiddo J. L Heerspink. *CKD Prognosis Consortium, Baltimore, MD.*

Background: Urine albumin-creatinine ratio (ACR) is a core component of CKD staging and used in equations to predict adverse outcomes. However, many cohorts and health systems preferentially measure urine protein-creatinine ratio (PCR) rather than ACR. These assays measure different protein components and the degree to which levels of PCR may be convertible to ACR is untested.

Methods: Cohorts in the CKD Prognosis Consortium with outpatient measures of PCR and ACR performed <90 days apart were included in the development of an equation for conversion of PCR to ACR using linear regression. Analyses were performed using all available data within individual cohorts, accounting for multiple records per person. Data were then meta-analyzed using random effects and linear splines to model log-PCR with a knot at 500 mg/g.

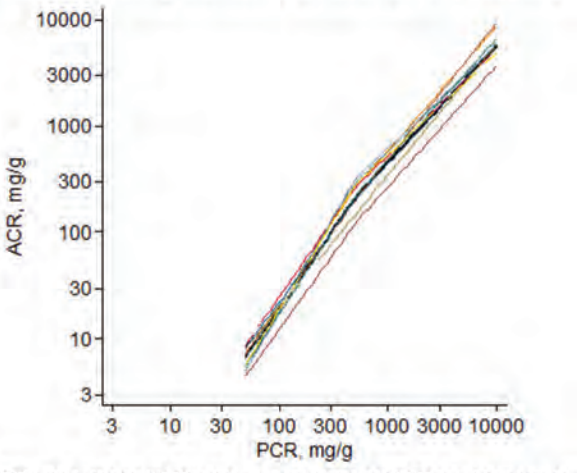
Results: There were 11 cohorts (2 general population, 3 high cardiovascular risk, 6 CKD cohorts) with 34,708 participants included from North America, Europe, and Japan. Average age was 58 years (SD, 16), 50% were female, and 7.4% were black. Median ACR was 181 mg/g (IQR, 51-304), and median PCR was 373 mg/g (152-654). There was no relationship between ACR and PCR at PCR <50 mg/g; thus, these values were excluded in the development of the equation. Above PCR 50 mg/g, there was a log-linear relationship with a slightly shallower slope at PCR >500 mg/g (p<0.001; footnote of figure; median

RMSE 0.83). Relationships between PCR and ACR were similar across cohorts (Figure), as well as demographics, and hypertension, cardiovascular disease, and diabetes status.

Conclusions: Guidelines recommend measurement of ACR. However, when ACR is not available, we developed an equation to convert PCR levels >50mg/g to ACR for use in risk equations. Lower levels of PCR were not amenable to harmonization.

Funding: NIDDK Support, Private Foundation Support

Figure: Relationship between PCR and ACR in 11 cohorts



ACR=EXP(1.486702*LN(MIN(PCR,500)/200)+1.105372*LN(MAX(PCR,500)/500)+3.99156)

TH-PO393

High-Normal Albuminuria Is Strongly Associated with Incident CKD in a Nondiabetic Population with Normal Kidney Function

Aiko Okubo,[1,2] Ayumu Nakashima,[2] Shigehiro Doi,[2] Toshiki Doi,[2] Toshinori Ueno,[2] Kazuya Maeda,[2] Takao Masaki.[2] *[1]Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Hiroshima University Hospital, Hiroshima, Japan.*

Background: Several studies have reported that high albuminuria within the normal range (high–normal albuminuria) is associated with chronic kidney disease (CKD). This study aimed to clarify the association between high–normal albuminuria and the risk of incident CKD, particularly in a nondiabetic population with normal kidney function.

Methods: A 10–year follow–up, retrospective cohort study was preformed involving 317 Japanese men (mean age, 42 years) with an eGFR ≥ 90 mL/min/1.73 m^2 and urine albumin-to-creatinine ratio (UACR) < 30 mg/gCr. Patients were free of diabetes mellitus. We calculated the cut–off value of the UACR from receiver–operating characteristic curves, and the value of ≥ 7.0 mg/gCr was defined as high–normal albuminuria. Multivariate stepwise analysis and logistic regression approaches were used to assess independent predictors of the incidence of CKD.

Results: Twenty–nine (9%) participants developed CKD through 10 years of follow–up. At the baseline examination, blood pressure, the UACR, and BUN values were higher in participants who developed incident CKD than in those with normal renal function. After adjustment for confounders, high–normal albuminuria was associated with an increased risk of incident CKD. Logistic regression analyses showed that subjects with a UACR ≥ 7.0 mg/gCr had an increased risk of new–onset CKD 10–years later compared with a UACR < 7.0 mg/gCr (odds ratio, 16.61; 95% confidence interval, 6.45–42.78; $P < 0.01$]. This difference persisted after adjustment for age, BMI, hypertension, smoking status, and dyslipidemia.

Conclusions: High–normal albuminuria is associated with incident CKD in a nondiabetic population with normal kidney function.

TH-PO394

eGFR Trajectory in Old Age

Elke Schaeffner,[1] Natalie Ebert,[1] Markus van der Giet,[1] Martin K. Kuhlmann,[3] Peter Martus,[2] Nina Mielke,[1] Alice Schneider,[1] Doerte Huscher.[1] *[1]Charité-Universitätsmedizin Berlin, Berlin, Germany; [2]UKT Tübingen, Tübingen, Germany; [3]Vivantes Klinikum im Friedrichshain, Berlin, Germany.*

Background: Longitudinal data about the natural course of estimated glomerular filtration rate (eGFR) among older adults over several years are scarce. The Berlin Initiative Study (BIS) aims to fill this gap by evaluating repeat assessments of eGFR over time and potential risk factors for GFR decline in older adults.

Methods: The BIS is a prospective population-based cohort study initiated in 2009 whose participants are members of a German insurance company with the biggest fraction of older adults. Participants were interviewed face-to-face biannually using a standardized questionnaire recording clinical, laboratory and patient reported outcomes. eGFR was calculated with the $BIS2_{(crea/cysC)}$ formula. The course of eGFR was analyzed with a linear mixed-effects model, comprising age, sex, diabetes mellitus (DM), smoking status, body mass index (BMI), systolic blood pressure (sysBP), albumin-creatinine ratio (ACR), serum creatinine, cystatin C, ACE inhibitors, AT1 antagonists, NSAID, number of regular drugs, and myocardial infarction (all time-dependent), applying multiple imputation for missing data.

Results: As of May 06, 2019, 2,069 participants (47.4% male, mean age 80.4 years at inclusion) were followed for a median of 6.0 years. Of those, 1,699 (82%) had at least 2 eGFR assessments. We observed higher eGFR values in men. Crude linear regression lines of the eGFR course suggested a continuous decline, which decreased with rising age. In the mixed linear effects model, age, sex, BMI, myocardial infarction, current smoking, sysBP, use of sartanes and the number of regular drugs had a significant impact on eGFR.

Conclusions: Taking into account the potential impact of clinical, therapeutically and behavioral variables, we still observed an age-dependent decrease of eGFR, suggesting a naturally declining course in older age. The mixed model reveals that the expected mean eGFR for men aged ≥79 and women ≥78 is below 60, defining deficient kidney function when using the current classification system.

TH-PO395

Sex Differences in the Risk of ESKD and Death Among Patients with Moderate to Advanced CKD Followed Up in Renal Clinics

Roberto Minutolo,[1] Francis B. Gabbai,[2] Luca De Nicola.[3] *[1]Nephrology, University of Campania, Naples, Italy; [2]Medicine, VA San Diego Healthcare System and University of California at San Diego, San Diego, CA; [3]University of Campania, Napoli, Italy.*

Background: Data on sex-specific differences in the epidemiology of CKD may help nephrologists to better tailor treatments for their patients. However, studies evaluating the association of sex with CKD progression have provided conflicting results.

Methods: We pooled four observational cohort studies including consecutive CKD patients (not dialysis/transplant) under stable Nephrology care for >6 months. Out of 3,212 unique patients, we selected 1,311 men and 1,024 women with eGFR<45 mL/min/1.73m^2. Primary outcome was ESKD (chronic dialysis or renal transplantation); all-cause mortality and eGFR decline were secondary outcomes. We used multivariable Cox proportional hazard analysis to estimate relative risk of ESKD and all-cause mortality, and linear mixed models to estimate the rate of eGFR decline.

Results: Age (67±14 y), systolic BP (139±20 mmHg), use of RAS inhibitors (69%), antihypertensive drugs (2.3±1.2) and statins (30%) were similar in men and women. Compared to men, women had lower eGFR (26±11 vs 28±10 mL/min/1.73m^2, P<0.001) and lower proteinuria (0.45 g/d IQR 0.14-1.10 vs 0.69 g/d, IQR 0.19-1.60, P<0.001). During a median follow-up of 4.2 years, 757 developed ESKD (307 women) and 471 died (196 women). Table reports the adjusted risk (HR and 95%CI) of ESKD and all-cause mortality overall and by CKD stages. We found a significant interaction between sex and proteinuria with the risk of ESKD in men becoming significantly greater at a level of proteinuria ≥0.5 g/d. Rate of eGFR decline (mL/min/year) was greater in men than in women (2.1 95%CI 2.0 -2.2 vs 1.8, 95%CI 1.7-1.9, P<0.001) with no difference across CKD stages (P=0.28). The difference in slopes between men and women was progressively larger with proteinuria levels ≥0.5 g/d (P=0.04).

Conclusions: Our study highlights an excess of renal risk in men possibly related, at least in part, to the higher levels of proteinuria in men compared to women.

	Overall	CKD stage 3B (eGFR 30-45)	CKD stage 4 (eGFR 15-29)	CKD stage 5 (eGFR<15)
ESKD: Women	Reference	Reference	Reference	Reference
Men	1.50 (1.27-1.77)	1.52 (1.03-2.24)	1.58 (1.25-1.99)	1.41 (1.09-1.83)
Mortality: Women	Reference	Reference	Reference	Reference
Men	1.32 (1.07-1.62)	1.49 (1.09-2.02)	1.19 (0.89-1.60)	1.27 (0.72-2.26)

Performance of Creatinine-Based GFR Estimates in Patients on Ritonavir-Boosted Protease Inhibitors

Juhi Chaudhari,[1] Christina M. Wyatt,[2] Shiyuan Miao,[1] Zipporah Krishnasami,[6] Andrew S. Levey,[1] Michael J. Ross,[5] Lene Ryom,[7] Amanda Mocroft,[4] Laurence Brunet,[3] Jennifer S. Fusco,[3] Lesley Inker.[1] *[1]Tufts Medical Center, Boston, MA; [2]Duke University School of Medicine, Durham, NC; [3]Epividian, Inc., Durham, NC; [4]University College London, London, United Kingdom; [5]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [6]Medical University of South Carolina, Charleston, SC; [7]CHIP, Department of infectious diseases, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.*

Background: The pharmacoenhancer ritonavir has been shown to inhibit tubular transport of creatinine *in vitro*. We aimed to determine whether use of ritonavir-boosted protease inhibitors (PI/r) affects the performance of creatinine-based GFR estimates.

Methods: We previously measured GFR (mGFR) in 200 HIV-positive adults on stable antiretroviral therapy using plasma iohexol clearance. We evaluated performance of the CKD-EPI creatinine equation (CKD-EPI$_{cr}$), MDRD Study equation, and Cockcroft-Gault creatinine clearance (indexed to 1.73m^2 body surface area) versus mGFR. We compared bias (median difference between mGFR and estimated GFR) and accuracy (percent of estimates within 30% of mGFR, with large errors indicated by 1-P$_{30}$). Statistical significance of the differences in bias and accuracy were tested by Wilcoxon two-sample test and chi-square test, respectively.

Results: 73% of the population was male, 52% of Black race, and 34% over the age of 50 years. 61% were virologically suppressed and 44% were on a PI/r. No participants were taking other antiretrovirals known to inhibit creatinine secretion. The CKD-EPI$_{Cr}$ equation performed better than other equations. There were no clinically or statistically significant differences in the performance of any equation between the PI/r and no-PI/r groups (Figure).

Conclusions: Use of PI/r did not have a significant impact on the performance of creatinine-based GFR estimates as compared to mGFR. Declines in eGFR with the use of PI/r may reflect real changes in kidney function.

CKD Prevalence in the US Military Health System (MHS) by Laboratory vs. ICD-9 Coding

James D. Oliver,[1,2] Robert Nee,[1,2] Lindsay Grunwald,[3] Amanda Banaag,[3] Meda E. Pavkov,[4] Nilka Rios Burrows,[4] Tracey L. Koehlmoos,[2] Eric S. Marks.[2] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services University of the Health Sciences, Bethesda, MD; [3]Henry M. Jackson Foundation, Bethesda, MD; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Epidemiological analysis of CKD is limited by variable definitions of CKD and accuracy of the diagnosis in the medical record. We report here on CKD prevalence by laboratory and coding data in the MHS Data Repository (MDR), a large database for a universal system of coverage of US active-duty military, retirees, and family members, with demographics similar to that of the US general population.

Methods: Patient data for age ≥ 18 from Fiscal Year (FY) 2006-15 were extracted from the MDR. CKD diagnosis was based on either ICD-9 codes or from labs (CKD-EPI eGFR < 60 mL/min/1.73m^2, uPCR ≥ 0.15 g/g, or uACR ≥ 30 mg/g). Code+ was defined as ≥ 1 inpatient or ≥ 2 outpatient CKD codes during the FY. Two definitions of Lab+ were used: 2Lab+ (gold standard) was defined as the most recent labs in the FY being persistently abnormal over ≥ 3 months. 1Lab+ was defined as any abnormal lab during the FY. Code+ and 1Lab+ were compared to 2Lab+ by sensitivity/specificity, chi-square, Cohen's kappa, and McNemar's test.

Results: For FY2015, data from 3,360,305 patients were analyzed (mean age = 37.6±15.6). 969,873 (28.9%) had labs. Among patients with labs, 2Lab+CKD prevalence was 2.5% overall and increased to 9.7% for age ≥ 60. 1Lab+CKD prevalence was 9.9% overall and increased to 31.5% for age ≥ 60. Code+CKD prevalence was 2.8% overall and 4.8% in patients with labs. Only 54.8% of 2Lab+ were also Code+. 1Lab had a Positive Predictive Value (PPV) = 0.25 and a Negative Predictive Value (NPV) = 1.0 for 2Lab (Table). Code had a PPV = 0.28 and a NPV = 0.99 for 2Lab. For age ≥ 60, PPVs were higher for both 1Lab+ (0.31) and Code+ (0.47).

Conclusions: Based on ICD-9 codes, provider awareness of CKD in the MHS is low. Use of a single lab value significantly overestimates CKD prevalence and has a poor PPV compared to repeat measures. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Departments of Army/Navy/Air Force, Department of Defense, Department of Health and Human Services, or the US Government.

State-Level Kidney Disease Surveillance Using Medicaid Data in Michigan and California

Zubin J. Modi,[1] Yiting Li,[1] Xiaosong Zhang,[1] Delphine S. Tuot,[2] Meda E. Pavkov,[3] Nilka Rios Burrows,[3] Neil R. Powe,[2] Debbie S. Gipson,[1] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of California, San Francisco, San Francisco, CA; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Medicaid provides health insurance for low-income individuals, including children. Coverage varies by state. We examined the feasibility of using state-level Medicaid data for chronic kidney disease (CKD) surveillance in a disadvantaged, low income, and younger US population.

Methods: The 2012 Medicaid Analytic eXtract data for the states of Michigan (MI) and California (CA) were evaluated. Patients with >3 months of Medicaid eligibility ≥1 claim were included. CKD was defined by two outpatient or one inpatient ICD-CM diagnosis codes. Descriptive analyses were conducted for children (age <22) and adults (age ≥ 22).

Results: The study population for MI (n=1,700,044) included 989,834 (58%) children and for CA (n=7,457,920) included 3,661,569 (49%) children. CKD was diagnosed in 0.9% of children (9,160) and 3.7% of adults (26,580) in MI, and 0.7% of children (24,090) and 3.0% of adults (114,183) in CA. There was geographic variation in prevalence of diagnosed CKD (Figure 1). Higher proportions of diabetes (DM) and hypertension (HTN) were seen in those with CKD (vs. non-CKD) in MI (DM: children 3.9% vs. 0.7%, adults 41.3% vs. 11.7%; HTN: children 7.6% vs 0.6%, adults 62.4% vs 17.2%) and CA (DM: children 2.2% vs. 0.4%, adults: 40.6% vs. 7.9%; HTN: children 6.6% vs. 0.2%, adults 47.7% vs. 11.1%). Emergency department use was higher among CKD patients (vs. non-CKD) in both MI (children 59.4% vs. 40.5%; adults 65.9% vs.40.9%) and CA (children 49.8% vs. 28.8%; adults 41.6% vs. 21.4%).

Conclusions: We demonstrate the feasibility of utilizing Medicaid data from two states for CKD surveillance efforts. There is substantial geographic variation of diagnosed CKD in both MI and CA with higher prevalence mostly in urban areas. Children and adults with CKD had a higher prevalence of comorbidities and ED use compared to those without CKD. This work serves as a foundation for future analyses of other state and longitudinal data to guide upstream disease prevention and management for a young and socioeconomically disadvantaged population.

Prevalence of Chronic Kidney Disease (per 1000 patients) in Michigan (A) and California (B), by county

TH-PO399

Forecasting Future Growth in CKD in the Irish Population: 2005-2024

Austin G. Stack,[1,2] George S. Mellotte,[3] Cécile Couchoud,[4] Leonard Browne.[2]
[1]Division of Nephrology, University Hospital Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [3]St James Hospital, Dublin, Ireland; [4]Biomedicine Agency, Saint Denis La Plaine, France.

Background: Although chronic kidney disease (CKD) is common in the Irish health system, few data exist on longitudinal trends and future growth. To better inform strategic planning of renal services, we determined future trends in CKD burden in the Irish population.

Methods: Data from the National Kidney Disease Surveillance System (NKSS) determined age and sex standardised prevalence of CKD among adults > 18 yrs, in Midwest and Northwest regions from 2005-2014. CKD was defined as eGFR <60 ml/min per 1.73 m^2 using the CKD-EPI equation. Four forecasting models (naive with trend, exponential smoothing, Holt's linear trend, and autoregressive integrated moving average (ARIMA)) estimated future prevalence of CKD beyond 2015 to 2024. The population at risk was derived from national census data in 2006 and 2011.

Results: Study included 478,251 participants, average age 55.5 (18.8) years with 53% female. From 2005 to 2014, overall prevalence increased significantly from 6.72% (95% CI 6.71-6.74%) to 7.73% (7.71-7.46%), with significantly greater increases for men [5.81 (5.78,5.85) to 7.28 (7.25,7.32), p< 0.001)] than for women [7.62% (7.59,7.66%) to 8.15 (8.12,8.19)]. The largest growth occurred in the elderly age 75+, p-value <0.001, while prevalence fell in all other age groups, p value <0.001 for each. By 2024, overall prevalence was predicted to increase to 9.20 % (95% PI 8.66, 9.75); men 9.40% (95% PI: 8.81, 9.99); and women 9.06 % (95% PI: 8.31, 9.80).

Conclusions: In line with current trends, we forecast continued growth in CKD burden up to 2024. These are driven principally by increases in the elderly. Given the risk implications on rates of kidney failure, morbidity and mortality, actionable policies that promote better CKD prevention and treatment strategies should be vigorously pursued.

TH-PO400

The Prevalence, Awareness, and Treatment of CKD in Korean Adults

Kyeong Min Kim. *Eulji medical center, Daejeon, Republic of Korea.*

Background: Chronic kidney disease (CKD) is a global public health problem, and its prevalence has dramatically increased with an increasing old aged and their chronic diseases. It is known that the rate of recognition and treatment of chronic renal failure is very low. But there is a lack of data on prevalence, awareness, treatment of CKD that is representative of the Korean population. Our objective was to investigate the prevalence, awareness and treatment in Korean CKD patients.

Methods: Among adults aged ≥19 years who participated in the Korea National Health and Nutrition Examination Survey (KNHANES) between 2013 and 2014, a total of 15,568 subjects were analyzed. CKD prevalence was defined as an eGFR < 60mL/min/1.73m2 or spot urine albumin to creatinine ratio ≥ 30 mg/g.

Results: A total of 9,550 incident CKD patients between 2013 and 2014 were included in the analysis. The prevalence of CKD was 8.66%. Of the total patients, 341 patients (3.78%) were in the stage 1 of CKD, 316 patients (2.52%) in the stage 2, 311 patients (2.15%) in the stage 3, 15 patients (1.16%) in stage 4 and 4 patients (0.04%) in the stage 5. The rate of awareness and the treatment of CKD were 2.19% and 1.35%, respectively.

Conclusions: In this nationally representative KNHANES data, very low awareness and treatment observed for Korean patients with CKD. And we analyzed the prevalence of chronic kidney disease in Korean adults using the most up-to-date data available. The present findings provide meaningful epidemiological data.

Table 1. Awareness of CKD in South Korea

Diagnosis of CKD by Doctor	Non-CKD	CKD	Total
None	8029(96.5)	906(94.28)	8935(96.27)
Yes	9(0.11)	21(2.19)	30(0.32)
Unknown or unresponsive	282(3.39)	34(3.54)	316(3.4)
Total	8320(100)	961(100)	9281(100)

TH-PO401

Histopathologic and Demographic Features Associated with ESRD and Death

Tae-Hwi Schwantes-An, Ranjani N. Moorthi, Carrie L. Phillips, Michael T. Eadon. *Indiana University School of Medicine, Indianapolis, IN.*

Background: The ability to stratify risk for developing end-stage renal disease and death in those who undergo a kidney biopsy allows us to better prognosticate patients who are at higher risk. We hypothesize that histopathologic features in kidney biopsy specimens augment risk stratification for ESRD and death over and above a fully adjusted demographic and clinical model.

Methods: Data from 2,720 individuals who underwent a kidney biopsy from 2001 to 2015 from the Biobank Biopsy Cohort of Indiana were obtained. Natural language processing facilitated annotation of histopathologic features and discrete clinical data was added using bioinformatics methods. Primary outcome was defined as time to ESRD or death, whichever occurred earlier. Censoring was done at 5 year follow up. Using Cox proportional hazard models, we studied relationship between demographic variables, comorbidities, baseline clinical features, primary diagnosis, and histopathologic features.

Results: Within 5 years of biopsy, 625 (23.0%) patients reached the primary endpoint of ESRD or death. Survival analysis with demographic and clinical variables as covariates and stratification by baseline renal function, showed following histopathologic features stratifying risk for the primary outcome, glomerular obsolescence (Hazard Ratio 1.81, 95% CI, 1.42 to 2.32, Pvalue < 0.001), interstitial fibrosis and tubular atrophy (HR 1.61, 95% CI, 1.30 to 2.0, Pvalue < 0.001), arteriolar hyalinosis (HR 1.46, 95% CI, 1.15 to 1.85 Pvalue < 0.01), and nodular mesangial sclerosis (adjusted HR 1.44, 95% CI, 1.15 to 2.82 Pvalue <0.01).

Conclusions: Histopathologic features on kidney biopsy specimens further augmented risk prediction for ESRD and death when compared to models with demographic and clinical variables alone. Inclusion of histopathologic features in ESRD and death risk models facilitates improved prognostication.

The Histological Spectrum of CKD in HIV-Infected Black Patients: A Single-Centre Experience

Ugochi C. Onu,[1] Dwomoa Adu,[2] Akinlolu O. Ojo,[3] Ifeoma I. Ulasi.[4] H3Africa Kidney Disease Research Network *[1]University of Nigeria Teaching Hospital Enugu, Enugu, Nigeria; [2]University of Ghana, Accra, Ghana; [3]University of Arizona Health Sciences, Tucson, AZ; [4]College of Medicine, University of Nigeria, Enugu, Nigeria.*

Background: HIV infection has become one of the world's most serious health and developmental challenge affecting 36.9 million people. Kidney disease is the 4th most common cause of death among HIV-infected patients. HIV-Associated Nephropathy (HIVAN) has been documented as the most common cause of chronic kidney disease (CKD) in HIV-1seropositive patients. Although 9% of world's HIV-infected patients live in Nigeria, data on spectrum of kidney diseases affecting HIV-infected patients are still paltry. The study was undertaken to determine the histological spectrum of CKDs in HIV-infected patients.

Methods: Fifty-eight adequate biopsy samples from 72 adult HIV- infected patients with ≥stage 3 CKD who underwent real time ultrasound guided kidney biopsy between April 2016 and August 2018 were studied using light microscopy and immunohistochemistry. Patients having diabetes mellitus, other viral infections, obstructive uropathies, other systemic diseases with renal involvement and malignancies were excluded.

Results: There were 25 (43.1%) males and 33 (56.9%) females. Participants were aged 21-65 years. Mean age was 43.86± 9.83years. Forty-three (74.1%) patients had WHO clinical asymptomatic disease. Only 9/58(15.5%) patients had CD4 cell count < 200 cells/mm^3. Histology showed 13(22.4%) HIVAN, 8(13.8%) normal histology and 37(63.8%) non-HIVAN lesions including: 12(20.7%) FSGS (NOS), 7(12.1%) focal global glomerulosclerosis, 6(10.3%) chronic interstitial nephritis, 4(6.9%) minimal chronic damage, 4(6.9%) arterionephrosclerosis, 3(5.2%) FSGS (cellular variant) and 1(1.7%) BK-virus nephropathy.

Conclusions: Although HIVAN remains the predominant histology finding in HIV-infected patients with CKD, its prevalence in this study is less than previous reports emphasizing the need for kidney biopsy for accurate diagnosis of CKD in HIV-infected patients.

TH-PO403

Clinical and Pathological Characterization of Patients with ESKD from a Potential Mexican CKD of Undetermined Etiology (CKDu) Hotspot

Sofía De Arrigunaga,[1] Marco A. Ascencio Martinez,[1] Laura Crespo Ortega,[1] Gregorio Villarreal,[1] Gregorio T. Obrador,[1] Antonio Villa,[1] Diego J. Aguilar-Ramirez,[2] Magdalena Madero.[3] *[1]Universidad Panamericana, School of Medicine, Mexico City, Mexico; [2]University of Oxford, Oxford, United Kingdom; [3]Instituto Nacional de Cardiologia, Mexico, Mexico.*

Background: Mesoamerican nephropathy (MeN) – the chronic kidney disease of unknown etiology (CKDu) identified in Central American hotspots – affects mostly young, male farmers without traditional risk factors (TRF) for kidney disease. To date, CKDu hotspots have not been described in Mexico. Between 1991 and 2018, 57 patients from a sugarcane region in Tierra Blanca, Veracruz (Mexico) were referred to our Institution for kidney transplantation. The aim of this study was to identify the clinical characteristics and risk factors for CKDu in these patients and compare their histopathological findings with others previously reported.

Methods: Sociodemographic, clinical, laboratory and pathological data were collected from medical records. Patients were categorized as having TRF for CKD (diabetes mellitus and/or hypertension) or not (CKDu). Descriptive statistics were used and multivariate logistic regression models were built to identify CKDu associated risk factors.

Results: The mean age of the 57 patients was 26.9 ± 9.7 years, 70% were male, and 44% farmers. Mean BMI was 23.0 ± 4.17, and 39% had a positive family history for CKD. Thirty (53%) patients met CKDu criteria. In the multivariate logistic regression model, agricultural work and family history of CKD were independent risk factors for CKDu, while high BMI conferred protection. Of the six patients who underwent kidney biopsy, 5 showed atrophy, mild sclerosis, tubulointerstitial nephritis, and inflammatory infiltrate, all compatible with previously reported MeN findings.

Conclusions: The clinical and pathological characteristics of this group of patients suggest that Tierra Blanca, Veracruz (Mexico) may be a potential CKDu hotspot. This conclusion is further supported by another study done by our group that showed a high prevalence of CKDu in this region. Further research is needed to confirm our findings.

Characteristic	OR (CI 95%)	p
Age in years	0.99 (0.9 - 1.0)	0.75
Sex	0.96 (0.2 - 4.5)	0.96
BMI (kg/m^2)	0.81 (0.8 - 1.0)	0.03
Agriculture work	4.61 (1.0 - 21.3)	0.05
Family History of CKD	4.56 (1.2 - 17.7)	0.03

Table 1. Logistic regression model for CKDu

TH-PO404

Biomarkers and CKD Progression: Avoiding Pitfalls in Methodology

Ibrahim Ali,[2] Sara T. Ibrahim,[3] Rajkumar Chinnadurai,[2] Maarten W. Taal,[1] Philip A. Kalra.[2] *[1]University of Nottingham, Nottingham, United Kingdom; [2]Salford Royal Hospital NHS Foundation Trust, Manchester, United Kingdom; [3]Alexandria University, Alexandria, Egypt.*

Background: Many studies that report biomarkers predictive of CKD progression share a key pitfall: poor characterisation of patients' progression, due to a lack of eGFR values and a short follow-up time. We apply a 2-stage method to robustly categorise patients with linear CKD progression for an upcoming biomarker study.

Methods: We included 2038 CKD patients in the Salford Kidney Study, with a total of 66455 outpatient eGFR values. Stage 1: Delta (Δ) eGFR (±ml/min/1.73m^2/yr) for each patient was calculated by linear regression. ΔeGFR ≤-3ml/min/1.73m^2/yr defined rapid progressors (RP); -0.5 to +1m/min/1.73m^2/yr defined stable progressors (SP). Stage 2: We assessed the eGFR-time graphs of RP and SP using our hospital e-records. Patients were selected if they had a clear, linear pattern of progression. To validate our method, we analysed plasma levels of KIM-1 and NGAL, biomarkers shown to be predictive of ESRD, in RP and SP, expecting higher levels in RP at stages 1 and 2.

Results: By linear regression alone, there were 388 RP and 458 SP. Stage 2 refined this group by unmasking non-linear progression, excluding 22% of RP and 33% of SP in the process (see figure). Median ΔeGFR in the final RP group was -4.69ml/min/1.73m^2/yr (IQR -5.86 to -3.65) and 0.09ml/min/1.73m^2/yr (IQR -0.53 to 0.93) in SP; p<0.001. Median number of eGFR values per patient was 23 in both groups (IQR 15-35 in RP; 15-39 in SP). Median follow-up was 52months (IQR 36-73) in RP and 78months (IQR 56-112) in SP. KIM-1 and NGAL levels were higher in RP than SP in stage 1 (p<0.001), and also higher in the refined stage 2 group, but significant for only NGAL, p=0.02.

Conclusions: We believe we are the first to combine linear regression and eGFR-time graphs to precisely stratify patients based on their ΔeGFR. Our method, aided by a cohort with multiple eGFR values and long follow-up, should help yield improved insights between measured biomarkers and specific, linear patterns of CKD progression.

TH-PO405

Evaluation of Kidney Fibrosis Based on Imaging and Histologic Analysis

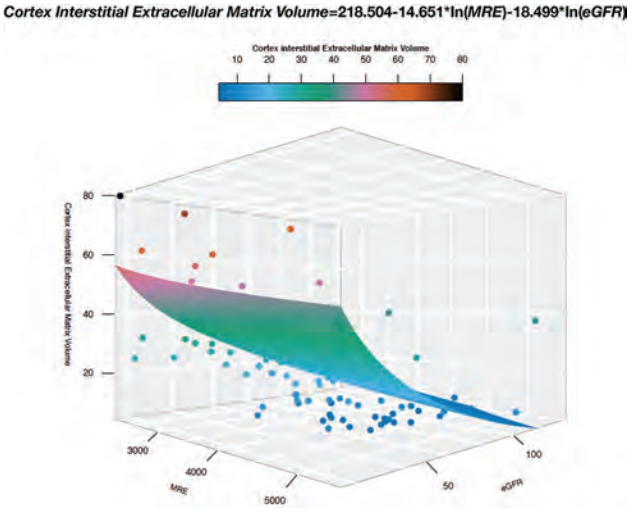
Jiong Zhang,[1] Tang Xiong,[2] Xiaoshuang Liu,[4] Long jiang Zhang,[3] Zhihong Liu.[1] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [2]Nangjin University, Nanjing, China; [3]Jinling Hospital, Nanjing, China; [4]Ping An Health Technology, Beijing, China.*

Background: Increased institial extracellular matrix (EM) and peritubular capillary (PTC) dropout are two key pathologic features of the fibrosing kidney. There is absence of multiple dimensional pictures to show fibrotic kidney from function, imaging and morphology.

Methods: We derived a represented model for EM ratio and PTC densities using intravoxelincoherent motion diffusion weighted imaging (IVIM-DWI), magnetic resonance elastography (MRE) and glomerular filtration rate (estimate GFR). 97 patients with chronic kidney diseases from stage 1 to 4 were studied. EM ratio and kidney microcirculation were evaluated by pathology. A multi-dimensions perspective and relationship of kidney fibrosis based on histology, imaging and GFR were established. Multiple linear regression models were performed.

Results: The cortex EM ratios were linear with the nature logarithm of MRE and eGFR, which were both negatively associated with EM ratios. The best fitted model was as below: EM ratio=218.504-14.651×In(MRE)-18.499×In(eGFR) The lower of eGFR and MRE, there were higher of CEMR (Figure 1). The PTC densities were linear with DWI-Fraction and eGFR, which were both positively related with PTC. The best fitted model was as below: PTC density=17.914+9.403×(DWI-Fraction)+0.112×eGFR The lower of eGFR and DWI-Fraction, there were lower of PTC (Figure 2).

Conclusions: Our study firstly provides histological evidences to support that IVIM-DWI and MRE can effectively evaluate the EM ratio and PTC density. These findings delineate the multi-dimensional picture of kidney fibrosis.



TH-PO406

Reproducibility of the SOMAscan Proteomic Assay in CKD: A Pilot Study in the Chronic Renal Insufficiency Cohort (CRIC) for the CKD Biomarkers Consortium

Ruth F. Dubin,[1] Rajat Deo,[2] Yue Ren,[2] Haochang Shou,[2] Harold I. Feldman,[2] Eugene P. Rhee,[3] Josef Coresh,[6] Paul L. Kimmel,[4] Peter Ganz.[5] *[1]UCSF, San Francisco, CA; [2]University of Pennsylvania, Philadelphia, PA; [3]Massachusetts General Hospital, Newton, MA; [4]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [5]University of California, San Francisco, San Francisco, CA; [6]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD.*

Background: The Slow Off-rate Modified Aptamer proteomic assay (SOMAscan) is a transformative tool used increasingly in medical research as it affords the opportunity to measure 4,933 unique proteins in 150µl of plasma. In prior studies, mostly outside of the setting of chronic kidney disease (CKD), these assays have low levels of analytical variability, with median inter- and intra-assay coefficients of variation (CV) of 4–6%. Whether the biochemical alterations present in CKD impact the assay's precision is unknown. We examined the reproducibility of these assays in participants with CKD.

Methods: Cryopreserved blinded split duplicate plasma samples from 24 CRIC participants were assayed at SomaLogic (Boulder, CO). Among these 24, 8 were from each of CKD Stages IIIa, IIIb, and IV. Within each stage, 4 had diabetes, and 4 had history of CVD. Using the SOMAscan v.4, 4933 unique proteins were quantified in each paired sample in fluorescent units.

Results: Prior to unblinding, 1 sample was excluded for having a technical error. For the remaining 23 paired samples, the median intra-assay CV for all proteins was 7%; 95.6% of all 4,993 proteins had CV ≤10% and 99.8% had a CV ≤20%. The distribution of CV's did not differ by CKD stage (Figure).

Conclusions: Measurement of 4,993 unique proteins with SOMAscan in plasma samples of patients with CKD was achieved with low levels of analytical variability. These data demonstrate that the SOMAscan assay is suitable for large-scale proteomic studies of individuals with CKD.

TH-PO407

The Association Between FIB-4 Index and the Prevalence of CKD: The Fukuoka Kidney Disease Registry Study

Masatoshi Hara,[1] Shigeru Tanaka,[2] Kumiko Torisu,[2] Masanori Tokumoto,[4] Kazuhiko Tsuruya,[3] Hiroaki Ooboshi,[5] Toshiaki Nakano,[2] Takanari Kitazono.[6] *[1]Division of Internal Medicine, Fukuoka Dental College, Tamura, Sawara-ku, Fukuoka, Japan; [2]Kyushu University, Fukuoka, Japan; [3]Nara Medical University, Kashihara, Japan; [4]Department of Internal Medicine, Fukuoka Dental College, Sawara-ku, Japan; [5]Fukuoka Dental College, Fukuoka, Japan; [6]Department of Medicine and Clinical Science, Fukuoka, Japan.*

Background: Growing evidences have shown that non-alcoholic fatty liver disease (NAFLD) associates with chronic kidney disease (CKD). Liver biopsy is the gold standard for assessing the severity of NAFLD. However it is difficult to be used as a routine screening tool due to its possible risk. Therefore non-invasive assessments to evaluate NAFLD by combining clinical and routine laboratory parameters have been developed. One of such assessments, Fibrosis-4 (FIB-4) index, defined as as [age (years) × AST (U/L)/[platelet count (10^9/L) × √ALT (U/L)], has shown a good correlation with historical severity of NAFLD. However, it is still unclear whether FIB-4 index associates with CKD.

Methods: In this cross-sectional study, we included 3,197 CKD patients who participated in an ongoing prospective study, the Fukuoka Kidney disease Registry Study. We evaluated the association between FIB-4 index and either the prevalence of estimated glomerular filtration rate (eGFR)<60 ml/min/1.73 m² or urinary albumin creatinine ratio (UACR)≥30 mg/g. Patients were divided into quartiles according to their baseline FIB-4 index levels: quartile (Q) 1, <1.12; Q2, 1.12–1.66; Q3, 1.67–2.30; and Q4, ≥2.31. The association between FIB-4 index levels and the prevalence of eGFR<60 ml/min/1.73 m² or UACR≥30 mg/g was estimated using the logistic regression analysis.

Results: In this study, 2464 (77.0%) patients were eGFR<60 ml/min/1.73 m², and 2433 (76.1%) showed UACR≥30 mg/g. FIB-4 index was negatively correlated with eGFR levels (r = -0.38, P<0.001), whereas there was no correlations with UACR levels (r = 0.014, P = 0.42). The multivariable-adjusted odds ratios (ORs) and 95% confidence intervals (CIs) for prevalence of eGFR<60 ml/min/1.73 m² were 1.25 (0.92–1.71), 1.50 (1.04–2.16), and 1.85 (1.18–2.89) in Q2, Q3, and Q4, respectively, compared with patients in the lowest category (Q1) (P for trend = 0.005). Every 0.1 increment in FIB-4 index was associated with a 1.03-fold (95% CI 1.01–1.05) increased prevalence of eGFR<60 ml/min/1.73 m² after adjusting for the potential confounding factors.

Conclusions: Higher FIB-4 index was associated with higher ORs of eGFR<60 ml/min/1.73 m². Further follow-up study is needed to determine whether FIB-4 index predicts the development and progression of CKD.

TH-PO408

Association of Serum Uromodulin with Mortality, Cardiovascular Disease, and Kidney Function Decline in CKD Patients: The GCKD Study

Dominik Steubl,[1,2] Markus P. Schneider,[3] Heike Meiselbach,[4] Jennifer Nadal,[11] Turgay Saritas,[9] Vera Krane,[5] Claudia Sommerer,[10] Seema Baid-Agrawal,[7] Anna Kottgen,[6] Kai-Uwe Eckardt,[8] Juergen E. Scherberich.[12] *[1]Klinikum rechts der Isar, Munich, Germany; [2]Division of Nephrology, Tufts Medical Center, Boston, MA; [3]Klinikum Nuremberg, Nuremberg, Germany; [4]Nephrology and Hypertension, Erlangen, Germany; [5]University of Wuerzburg, Wuerzburg, Germany; [6]Medical Center - University of Freiburg, Freiburg, Germany; [7]Sahlgrenska University Hospital, University of Gothenburg, Gothenburrg, Sweden; [8]Charité – Universitätsmedizin Berlin, Berlin, Germany; [9]Nephrology, RWTH Aachen, Aachen, Germany; [10]University Hospital of Heidelberg, Heidelberg, Germany; [11]IMBIE, Bonn, Germany; [12]University Munich Klinikum Muenchen Harlaching, Muenchen Gruenwald, Germany*.

Background: Uromodulin is exclusively produced by tubular cells and released into both urine and serum. Lower sUMOD has been associated with end-stage renal disease (ESRD) in Chinese chronic kidney disease (CKD) patients and with higher risk for mortality in patients undergoing coronary angiography. The association of sUMOD with mortality, cardiovascular (CV) events and ESRD in Caucasian CKD patients is unknown.

Methods: We measured sUMOD in 5143 participants enrolled in the German Chronic Kidney Disease (GCKD) study. The associations of baseline sUMOD with all-cause mortality, major adverse CV events (MACE; a composite of fatal CV event, non-fatal myocardial infarction or stroke, or incident peripheral vascular disease) and ESRD (dialysis or transplantation) were evaluated using multivariable Cox regression analysis, adjusting for demographics, estimated glomerular filtration rate (eGFR), albuminuria, CV risk factors and medication.

Results: The mean age was 60±12 years, 60% were male. sUMOD level was 98±60 ng/ml, eGFR was 47±17 ml/min/1.73 m^2 and 78% had eGFR<60 ml/min/1.73 m^2. Patients in the lower sUMOD quartiles had lower eGFR and higher albuminuria. Prevalent diabetes, hypertension, coronary artery disease and stroke at baseline were more frequent in lower sUMOD quartiles. During a follow-up of 4 years, 319 patients died, 398 developed MACE and 216 ESRD (Table 1). In multivariable analysis, higher sUMOD was significantly associated with lower hazard for mortality (HR 0.572, 95%-CI [0.377-0.869] for the highest versus lowest quartile), MACE (HR 0.632 [0.445-0.898]) and ESRD (HR 0.238 [0.103-0.547], Table 1).

Conclusions: Higher sUMOD is independently associated with lower risk for mortality, CV events and ESRD in Caucasian CKD patients. A better understanding of the underlying mechanisms may lead to therapies offering both renal and CV protection in CKD patients.

Association Between Urinary A Megalin and Metabolic Syndrome in Japanese Adults

Keiko Kabasawa,[2] Michihiro Hosojima,[2] Yumi Ito,[2] Hiroyuki Kurosawa,[3] Hideyuki Kabasawa,[2] Yoshiaki Hirayama,[3] Kazutoshi Nakamura,[2] Akihiko Saito,[2] Kazuo Matsushima,[1] Junta Tanaka,[2] Ichiei Narita.[2] *[1]Yukiguni Yamato Hospital, Minamiuonuma, Japan; [2]Niigata University, Niigata, Japan; [3]Denka Seiken Co., Ltd, Gosen, Japan.*

Background: Metabolic syndrome (MetS) is a risk factor for chronic kidney disease (CKD). Megalin is an endocytic receptor in proximal tubule epithelial cells that mediates the endocytosis of glomerular-filtered toxic substances and is recognized as a potential therapeutic target for MetS-related CKD. Although microalbuminuria is a well-known marker of MetS-related CKD, markers for its early detection remain unestablished. Thus, in this study, we assessed the association of urinary biomarkers including ectodomain (A-megalin) and full-length (C-megalin) forms of megalin with MetS in Japanese adults.

Methods: Among 348 subjects (184 men; average age 61.3 years old) with urine albumin-to-creatinine ratio (ACR) < 300 mg/g on health check examination, urine biomarkers including A-megalin, C-megalin, ACR, α_1-microglobulin (a1M), β_2-microglobulin, *N*-acetyl-β-D-glucosaminidase, and podocalyxin were assessed cross-sectionally. MetS scores were adopted from National Cholesterol Education Program (third revision) of the Adult Treatment Panel criteria modified for Asians; subjects with ≥3 components were diagnosed as having MetS.

Results: Subjects included 97 patients with MetS, 20 with diabetes, and 134 with hypertension; median body mass index, estimated glomerular filtration rate (eGFR) and ACR were 22.6 kg/m^2, 74.4 mL/min/1.73 m^2, and 7.5 mg/g, respectively. MetS scores were positively correlated with urinary A-megalin, ACR, and a1M in Spearman's partial correlation analysis, adjusted for sex and age (r = 0.12, 0.25, and 0.13, respectively). In multivariable logistic regression analysis, higher urinary A-megalin was positively associated with MetS even after adjustment for age, sex, diabetes, hypertension, ACR and eGFR (adjusted odds ratio of MetS for elevated quartile of A-megalin: 1.37, 95% CI: 1.06-1.77, P = 0.01).

Conclusions: Urinary A-megalin was independently associated with MetS in a Japanese adult population. Further longitudinal studies are needed to confirm the association of urinary A-megalin with the development and progression of MetS-related CKD.

TH-PO410

The Association Between Urinary Neutrophil Gelatinase-Associated Lipocalin and Renal Prognosis in Patients with CKD

Naohiko Fujii. *Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan.*

Background: Urinary neutrophil gelatinase-associated lipocalin (uNGAL) is a new biomarker for renal tubular damage. Significant associations between uNGAL and renal prognosis have been reported in many papers; however, it may often be affected by urinary tract infection (UTI), and its cut-off value in patients with chronic kidney disease (CKD) has not been well established. The aims of our study were to investigate the association between uNGAL and renal prognosis in CKD and to explore the cut-off value specific for patients with CKD.

Methods: This was a retrospective observational cohort study at a single hospital in Japan. We included adult patients with the estimated glomerular filtration rate (eGFR) of 10 to 70 mL/min/1.73m^2 from Jan 2017, who had at least one measurement of uNGAL. We used baseline uNGAL adjusted for urinary creatinine (Cr) as an exposure variable and divided the patients into quartiles. The renal outcome was defined as a 30% increase in serum Cr from baseline values. UTI was determined by baseline urinalysis. We performed survival analyses for the renal outcome, by using the Cox proportional hazards model including restricted cubic spline (RCS) curves. We also performed longitudinal analyses for eGFR decline using the mixed effects model. All statistical analyses were done using STATA 13.1.

Results: In total, 195 patients with CKD were included. Mean age and eGFR at baseline were 70.6 years and 32.3 mL/min/1.73m^2, respectively. The median [interquartile range (IQR)] of baseline uNGAL and urinary protein to Cr ratio (uPCR) were 71 [21 - 219] ug/gCr and 0.71 [0.18 - 2.53] g/gCr, respectively. Patients with UTI showed significantly higher uNGAL at baseline than those without (226 [90 - 429] vs. 42 [15 – 123]). During the mean follow up of 171 days, there were 59 renal events. The Kaplan-Meier curve indicated a gradual risk escalation towards the upper quartiles of uNGAL. The adjusted hazards ratios of uNGAL quartiles were 2.8 [0.8 - 10.2], 4.9 [1.3 - 18.7], and 4.2 [1.0 - 17.2] in Q2, Q3, and Q4, respectively. The RCS curves suggested a significantly higher risk at 73.6 ug/gCr or greater. The eGFR slope, however, was comparable among Q1-4, while proteinuria was significantly associated with a greater reduction in eGFR.

Conclusions: A single measurement of uNGAL greater than 73.6 was associated with poor renal outcome. UTI may partially explain its limited prognostic value in clinical practice.

TH-PO411

Plasma Biomarkers and the Association with Kidney Outcomes in African Americans with High-Risk Apolipoprotein L1 Variants

Kinsuk Chauhan,[1] Divya A. Verghese,[1] Shikha Wadhwani,[2] Neha Debnath,[1] Lili Chan,[1] Girish N. Nadkarni,[1] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: The high-risk Apolipoprotein L1 (*APOL1*) genotype is associated with incident and progressive chronic kidney disease (CKD) in people of African ancestry. Previous studies have demonstrated that suPAR is associated with CKD in individuals with the APOL1 high-risk genotype. We assessed the associations of suPAR and other plasma biomarkers with CKD in this population.

Methods: We measured plasma suPAR, IL-18, MCP-1 and YKL-40 in 498 Bio*Me* Biobank participants with a high-risk *APOL1* genotype. Using multivariable Cox Regression, we determined the association of these biomarkers with a composite kidney outcome of ESRD or ≥ 40% sustained decline in eGFR during the follow-up period using sequentially adjusted models.

Results: Among 498 participants, median age was 56 years, 67.7% were female and baseline eGFR was 83.3 ml/min/1.73 m^2. 80 of the 498 (16.1%) experienced the composite outcome over a median of 5.9 years. After adjusting for demographics, comorbidities, medications, and eGFR, suPAR (adjusted HR 1.9 per doubling, 95% CI 1.2-3), IL-18 (adjusted HR 1.4 per doubling, 95% CI 1.1-1.9), MCP-1 (adjusted HR 1.6 per doubling, 95% CI 1.1-2.1), and YLK40 (adjusted HR 1.3 per doubling, 95% CI 1.1-1.5) were associated with increased risk of the composite kidney outcome (**Figure** left panel). After adjustment for 3 previously measured biomarkers (plasma TNFR1, TNFR2 and KIM-1), however, the independent associations between all 4 biomarkers and the kidney outcome were attenuated (**Figure** right panel).

Conclusions: Plasma suPAR, IL-18, MCP-1 and YLK40 were individually associated with kidney function decline or ESRD in individuals with high-risk *APOL1* genotype. However, the relevance of these biomarkers in the setting of other commonly measured biomarkers is unclear.

Attenuation of Estimated Glomerular Filtration Rate Decline After Arteriovenous Fistula Creation in Pre-Dialysis

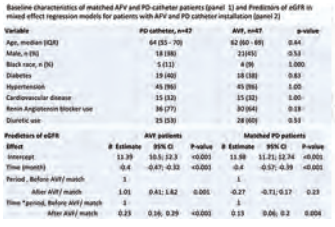
Marie-Eve Dupuis,[1] Louis-Philippe Laurin,[1] Naoual Elftouh,[1] Vincent Pichette,[1] Remi Goupil,[2] Jean-Philippe Lafrance,[1] Annie-Claire Nadeau-Fredette.[1] *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

Background: Arteriovenous fistula (AVF) placement has been associated with potential attenuation of eGFR decline. Uncertainty remained as to whether this association is specifically related to AVF or rather involves confounding such as natural change in eGFR decline. We sought to assess CKD-EPI eGFR changes before and after AFV creation using a comparator group of peritoneal dialysis (PD) oriented patients.

Methods: This observational study included incident patients followed in a CKD clinic between 2000 and 2017. Patients with AVF placement were matched 1:1 (using age, sex, race, diabetes and eGFR) with patients who underwent PD catheter installation. Time zero/match-point was defined by AVF creation date (AVF group) or date when eGFR was closest to their 'AVF-pair' eGFR at time of AVF creation (PD-matched group). Mixed effect linear regression models were built to predict eGFR in the AVF and PD-matched groups. Estimated-GFRs were calculated using the CKD-EPI equation.

Results: Baseline characteristics of the 47 patients with AVF and 47 patients with PD catheter installation were globally similar. Median eGFR at time of AVF creation was 11.4 ml/min/1.73m^2 (and 11.9 ml/min/1.73m^2 in matched PD group). Predicted eGFR decreased by 0.4 ml/min per month in both groups. There was an attenuation in eGFR decline each additional month after AVF creation/match-point (*B* 0.23, p<0.001 AVF group, *B* 0.13, p<0.001 PD matched group). However, the period after AVF creation (or match-point) was associated with a fixed increase in predicted eGFR only for the AVF group (*B* 1.01, p<0.001).

Conclusions: In this matched cohort study, placement of AVF was associated with an increase in predicted eGFR in the AVF group only. There was however, an attenuation of monthly eGFR decline in both groups with progression of advanced CKD. Overall, this study supports other findings suggesting a contribution of AVF in the stabilisation of eGFR decline.



Baseline characteristics of matched AFV and PD-catheter patients (panel 1) and Predictors of eGFR in mixed effect regression models for patients with AFV and PD catheter installation (panel 2)

Variable	PD catheter, n=47	AVF, n=47	p-value

TH-PO413

Prevalence of Kidney Failure Among Adult Population in Madagascar

Ranivoharisoa E. Mikkelsen,[1] Antso hasina Raherinandrasana,[2] Ziad Massy,[3] Julio Rakotonirina,[2] Harilalaina W. Randriamarotia.[1] Befelatanana Neprology's Team *[1]University Hospital of Befelatanana, Antananarivo, Madagascar; [2]University Hospital of Care and Public Health Analakely, Antananarivo, Madagascar; [3]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France.*

Background: Kidney Failure becomes a public worldwide health problem mainly in a developing country. Few data is available in most of countries in Africa to specify the prevalence of CKD. We assessed the prevalence and risk factors of kidney failure among population in Madagascar.

Methods: We conducted a randomized, multicenter, cross sectional study among four provinces in the Island. It includes Tananarive, Majunga, Fianarantsoa and Tamatave. Kidney function was evaluated by capillary creatinine using strip test and creatinine meter. We defined kidney failure if the glomerular filtration rate calculated with the Equation of Chronic Kidney Disase Epidemiology was under than 60ml/mn/1,73m2. Cluster sample was used to characterise the study population.

Results: A total of 808 patients were included. Prevalence of kidney failure was 12.5%. Mean age was 38 years old (+/-15). Sex-ratio was 0,84. Patients were aged 25-55 years old in 62,1%. Normal socioeconomic class was found in 64% of the cases. Hypertension and diabetes were identified respectively in 30,3% and 7,7% in studied population. During screening, mean creatinine level was 99µmol/l (+/-25) and mean post prandial glycemia was 1,16g/dl (+/-0,3). According to KDIGO classification, patients were classified in Stage 3, 4 and 5 of CKD respectively in 10,76%(N=87), 0,7 % (N=6) and 1% (N=8). In mono variable analysis, kidney failure was related with gender (p =0,078), age(p =0,0001), socioeconomic class (p=0,005), familial back ground of hypertension (p =0,04), personnel back ground of hypertension (p <0,0001) and diabetes (p =0,05), the level of blood pressure during examination (p=0,088), glycemia (p = 0,003) and body mass index (p = 0,003). In Multiple variable analysis, it was related with female gender (OR =0,57; IC =0,35-0,92), age > 54 years old (OR =14,04; IC =5,25-37,5), rich socio economic class(OR =2,8; IC =1,03-7,81), overweight (OR =2,5; IC =1,08-4,92) and obesity (OR =2,5; IC =1,13-5,73)

Conclusions: This is the first study in Africa which evaluates the kidney failure by using creatinine strip test. The prevalence is high compare another african countries. Almost of the patients were seen lately over Stage 3 of CKD requiring a specialized medical follow-up. Prevention of all risk factors should be first of all the best solution.

TH-PO414

Estimated Glomerular Filtration Rate and Incidence of Major Surgery: A Population-Based Cohort Study

Tyrone Harrison, Matthew T. James, Kelly B. Zarnke, Zhihai Ma, Shannon M. Ruzycki, Brenda Hemmelgarn. *University of Calgary, Calgary, AB, Canada.*

Background: Approximately 1 in 9 Canadian adults have a surgical procedure each year, however whether the rates of major surgical procedures vary by level of estimated glomerular filtration rate (eGFR) is unknown. We aimed to quantify the incidence of major surgery by varying degrees of impaired kidney function.

Methods: We identified 1,455,565 adults in Alberta, Canada that had at least one outpatient serum creatinine measure or were in receipt of chronic dialysis between 2008 and 2009. As in prior studies, incident major surgical procedures were identified and categorized into 13 major surgical subtypes using procedure codes and physician claims; major surgery was defined by requiring hospital admission for at least one day. Surgical subtypes included musculoskeletal, intra-abdominal, lower urologic/gynecologic, head and neck, vascular, skin and soft tissue, cardiac, breast, neurosurgery, retroperitoneal, thoracic, anorectal, and ophthalmologic. Only the first event per surgical subtype was included. Patients were followed from January 1 2010 to December 31 2016, and were censored at kidney transplantation, outmigration or death. Incidence rates by eGFR strata were estimated using negative binomial regression and adjusted for age, sex, income, location, proteinuria, and comorbidity.

Results: The median age of the cohort was 51.6 years (IQR 39.4, 63.4) with the majority female (57.0%). Most patients had an eGFR ≥60mL/min/1.73m^2 (92.2%), with 0.1% having an eGFR <15mL/min/1.73m^2 not on dialysis. Over a median follow up of 7.00 years, musculoskeletal surgeries were the most common across all eGFR strata, with adjusted incidence rates between 9.48 per 1000 person-years (95%CI: 9.39, 9.56) for those with eGFR ≥60mL/min/1.73m^2 and 74.81 per 1000 person-years (95%CI: 65.60, 85.32) for dialysis patients. Similar trends of increasing surgical incidence for those with lower eGFR were noted for all surgical types except for breast and lower urologic/gynecologic.

Conclusions: In a large population-based cohort, incidence rates of major surgical procedures increased with decreasing eGFR, and were highest among dialysis-dependent patients. Further research is needed to investigate whether differences exist in perioperative outcomes and costs for those with varying degrees of kidney function.

TH-PO415

Clinical Significance of Creatinine Variability and Its Impact on Cardiovascular Outcomes in the General Population

Soojin Lee,[1] Min woo Kang,[1] Semin Cho,[1] Yaerim Kim,[1] Jung Pyo Lee,[2] Chun Soo Lim,[2] Kwon Wook Joo,[1] Yon Su Kim,[3] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Linear decline of glomerular filtration rate (GFR) is associated with aggravating the patient outcomes. Serum creatinine, which is commonly used for estimating GFR, often fluctuates throughout the serial measurement. The clinical significance of creatinine fluctuation among the general population whose renal function is prior to chronic kidney disease (CKD) development had not been demonstrated yet. Thus, we investigated the study to evaluate the impact of creatinine variability on patient outcomes.

Methods: A nationwide retrospective cohort study was performed using the database of Korean National Health Insurance System. Adult patients who received national health screening program and measured creatinine for ≥3 times between 2012 and 2016 were considered. Those who previously developed CKD were excluded. The variability of creatinine values were presented with variability independent of mean (VIM). The patients were classified into quartiles of the VIM and Q4 presented highest variability of creatinine. Then, the risks of myocardial infarction (MI), stroke and death were assessed according to the extent of variability.

Results: During the median follow up of 3.27 years, 3,509,899 participants were examined for association of creatinine variability and cardiovascular outcomes.

Participants with higher creatinine variability were significantly associated with elevated risk of MI (hazard ratio (HR) (95% confidence interval (95% CI)) 1.11 (1.04-1.18), stroke (HR (95%CI) 1.06 (1.00-1.13)) and death (HR (95%CI) 1.15 (1.09-1.21)), compared to those with the lowest quartile of creatinine variability.

Conclusions: Increased creatinine variability exhibited association with elevated risk of MI, stroke and death. In general population, whose renal function is prior to CKD development, monitoring of creatinine variability needs to be considered as the parameter of predicting the adverse outcomes, in addition to the decline of GFR.

TH-PO416

Progressive Kidney Failure: An Overlooked Feature of Down Syndrome

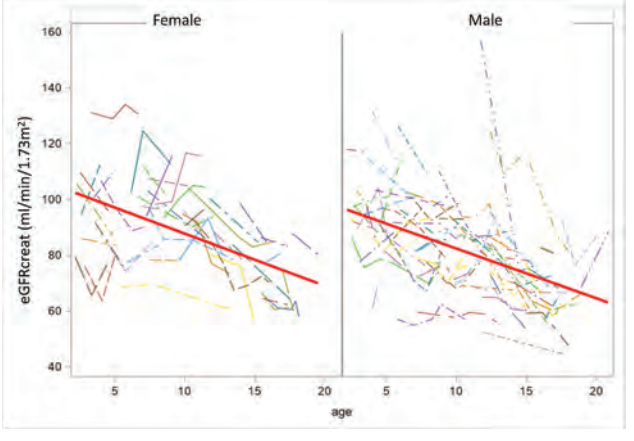
Arend Bokenkamp,[1] Marieke M. Chatelion counet,[6] Emil Den bakker,[2] Michel E. Weijerman,[3] Hans Pottel,[4] R. N. Van der plas,[7] Chantal J. Broers.[5]
[1]Pediatric Nephrology, Amsterdam University Medical Center, Amsterdam, Netherlands; [2]VUMC, Duivendrecht, Netherlands; [3]Alrijne Hospital, Leiderdorp, Netherlands; [4]KULeuven, Kortrijk, Belgium; [5]Amsterdam UMC, location VUMC, Amstelveen, Netherlands; [6]Amsterdam University Medical Center, Amstelveen, Netherlands; [7]AUMC, Amsterdam, Netherlands.

Background: Life expectancy of patients with Down syndrome (DS) has increased significantly in the last decades. DS is associated with a fourfold risk of urinary tract abnormalities, still data on renal dysfunction in DS patients are conflicting. The present study was set out to assess kidney function in a large pediatric tertiary DS clinic.

Methods: Retrospective analysis of data collected during routine visits at the DS clinic of VU medical center. All patients aged between 2 and 18 years in whom serum creatinine had been measured were eligible for inclusion. Exclusion criteria were glucocorticosteroid use, neuromuscular disease or primary referral to a nephrologist or urologist. Kidney function was assessed using the full-age spectrum equations, i.e. $eGFR_{crea}$= (107.3/[sCr (mg/dL)/Q (age- or height-based normal value)]) and $eGFR_{cys}$= (107.3/sCys (mg/L)/0.82). In a subgroup of 74 patients, a total of 374 serial creatinine measurements were analyzed by linear mixed modelling.

Results: Serum creatinine was available in 189 patients (63% boys), aged 10.8 ± 5.0 years, cystatin C in 143 (64% boys). Mean $eGFR_{crea}$ was 83.6 ± 16.7 mL/min/1.73m^2, mean $eGFR_{cys}$ 87.3 ± 12.0 mL/min/1.73m^2. Based on $eGFR_{crea}$, 32% of patients had CKD stage 1, 62% stage 2 and 6% stage 3. There was no relation between kidney function and co-morbidity (i.e. celiac disease, congenital heart disease, hypothyroidism and history of leukemia). Serial measurements showed a significant decline of $eGFR_{crea}$ (slope -2.01ml/min/1.73m^2/yr [95%CI -2.99 to -1.04] (p = 0.0001).

Conclusions: Mildly to moderately impaired renal function is a common finding in children with Down syndrome. The progressive loss of GFR is troublesome and calls for regular monitoring of kidney function both in children and in adults with DS to identify potentially treatable risk factors for disease progression such as hypertension and microalbuminuria.



Serial measurements of $eGFR_{crea}$

TH-PO417

Incidences of ESKD and Death Before ESKD Among US Veterans with New-Onset CKD

Guofen Yan,[1,2] Tom Greene,[3] Robert Nee,[4] Alfred K. Cheung,[3,2] Mohammed N. Oliver,[5] Wei Yu,[1] Keith C. Norris.[6]
[1]University of Virginia, Charlottesville, VA; [2]Veterans Affairs Salt Lake City Healthcare System, Salt Lake City, UT; [3]University of Utah, Salt Lake City, UT; [4]Walter Reed National Military Medical Center, Vienna, VA; [5]Virginia Department of Health, Richmond, VA; [6]UCLA, Marina Del Rey, CA.

Background: Epidemiologic data on competing-risk events of progressing to ESKD or dying before ESKD are mixed due to prevalent cohorts used. Using a recently constructed national incident CKD cohort, we report the 5-year incidence of these two events following new CKD onset by demographics, kidney function and comorbid conditions.

Methods: The cohort included 534,972 subjects with new onset CKD (stage 3-5) between 2002 and 2011 in the U.S. Veteran Affairs database. CKD onset was determined by two eGFRs (based on CKD-EPI equation) <60 mL/min/1.73 m^2 at >90 days apart. We excluded subjects in the database who had <2 years before the first eGFR<60 or had prior ESKD. As such, the index date identified was very close to new onset CKD. All subjects were followed for 5 years.

Results: The three groups had similar mean eGFRs at onset (range 49-50 ml/min/1.73m^2) and gender distributions (97-98% male). Blacks had younger onset age (mean 67 yrs) than Hispanics (71 yrs) and whites (74 yrs). Over the course of 5 years after onset, approximately two-thirds of the initial cohort remained alive in pre-ESKD, with Blacks having a lower percentage (65%) than Hispanics and Whites (68%). Among the one-third who progressed, Blacks and Hispanics had greater percentages who progressed to ESKD than Whites (10%, 7%, and 2%, respectively), whereas they had smaller percentages of dying before ESKD (25%) than Whites (30%). Males were more likely than females to develop these two events. The relative likelihood of the two events also varied by age and eGFR stage (Table), as well as comorbidities such as diabetic and hypertensive status and cardiovascular diseases (not shown).

Conclusions: Improving outcomes for patients with CKD could be more effective by identifying risk factors associated with differential risks of developing ESKD and dying before ESKD.

Survival of Patients with CKD Stages 1-5 in Iceland

Arnar J. Jonsson,[3,1] Sigrún H. Lund,[2] Runolfur Palsson,[3,1] Olafur S. Indridason.[3]
[1]University of Iceland, Reykjavík, Iceland; [2]deCODE genetics, Reykjavík, Iceland; [3]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland.

Background: Studies on survival of patients with chronic kidney disease (CKD) employing the KDIGO definition and classification system with repeated serum creatinine (SCr) and proteinuria measurements are scarce. The purpose of this study was to estimate hazard ratio (HR) for death in patients with CKD stages 1-5 in Iceland.

Methods: In this retrospective study, we obtained all SCr values and urine protein measurements from every clinical laboratory in Iceland in 2008-2016. Clinical information, including ICD-10 diagnosis codes, was retrieved from nationwide electronic medical records. Estimated glomerular filtration rate (eGFR) was calculated from SCr using the CKD-EPI equation. CKD was defined as presence of kidney damage, either ICD-10 diagnosis codes indicating kidney disease or proteinuria, or as eGFR <60 mL/min/1.73 m^2 for ≥3 months. Cox regression was used for survival analysis with CKD stage as a time-dependent variable and adjustments for age at study entry, sex, number of SCr measurements, initial eGFR, multiple co-morbid conditions and by CKD detection criteria, i.e. proteinuria, kidney specific diagnosis or reduced eGFR, either by a single criterion or various combinations.

Results: We obtained 2,120,232 SCr values for 218,437 individuals and information on proteinuria for 84,364 individuals. A total of 4972 had persistent proteinuria, 5286 had kidney disease diagnoses and 20131 had eGFR <60 mL/min/1.73 m^2. The median age was 46 (range, 18-107) years and 47% were men. Compared with individuals without CKD, the hazard ratios (95%CI) for patient survival were 10.39 (7.62-14.17), 3.92 (3.18-4.85), 1.43 (1.31-1.56), 2.00 (1.83-2.20), 3.15 (2.78-3.57) and 11.18 (8.96-13.95) for CKD stages 1, 2, 3a, 3b, 4 and 5, respectively.

Conclusions: This nationwide study on survival of patients with CKD, incorporating kidney disease diagnoses and numerous urine protein and SCr values over time, suggests increased risk of death for all CKD stages. While this finding supports current criteria for definition of CKD, a more detailed analysis of the influence age is needed.

TH-PO419

eGFR Decline in Patients with CKD and at Risk for CKD by Age, Gender, and Race/Ethnicity in Two Large Health Systems

Susanne B. Nicholas,[1] Ning Li,[1] Kenn B. Daratha,[2] Obidiugwu Duru,[1] Cami R. Jones,[2] Jenny I. Shen,[3] Radica Z. Alicic,[2,4] Sterling McPherson,[2,4] Katherine R. Tuttle,[2,4] Keith C. Norris.[1] CURE-CKD Registry Study Team
[1]David Geffen School of Medicine, Los Angeles, CA; [2]Providence St. Joseph Health, Spokane, WA; [3]LaBiomed at Harbor-UCLA, Torrance, CA; [4]University of Washington School of Medicine, Spokane, WA.

Background: Comparisons in eGFR decline in patients with CKD and At-risk for CKD have not been described. We completed an analysis of eGFR trajectories (eGFR-T) in CKD and At-risk for CKD patients from the UCLA-PSJH CKD Registry.

Methods: The cohort: >2.6 million adults (2006-2017) based on labs and/or diagnoses of CKD, hypertension (HTN), diabetes mellitus (DM), or pre-DM from administrative codes. We analyzed CKD (N=84,150) and At-risk CKD (N=807,211) patients with ≥3 eGFRs ≥15ml/min/1.73m^2 followed for an average (SD) of 5.4±2.4years. We identified non-decliners, moderate and severe decliners (<2mL; 2-5mL and >5mL/min/1.73m^2/year), by least-squares fit for individual eGFR-T. Linear mixed effects (LME) models compared eGFR-T in moderate and severe decliners across gender and race/ethnicity groups, stratified by CKD vs. At-risk for CKD.

Results: Most patients were 45-64 yrs (41%), female (56%) and White Non-Latino (83%). CKD vs. At-risk CKD patients were ≥65years (72% vs 36%), and had more DM (18% vs 106%) and HTN (25% vs 18%), p<0.001. Severe (vs. non- and moderate-) decliners had higher baseline eGFR and 27% of At-risk CKD progressed to eGFR <60ml/min/1.73m^2). eGFR-T were steepest for CKD 18-44 yrs: -5.22 (95%CI= -5.38, -5.11) and At-risk patients 18-44 yrs: -4.16 (95% C= -4.18, -4.14) vs. other age groups, p<0.001. In LME bivariate analyses, eGFR slopes differed by age, gender and race/ethnicity for all decliners. Specifically, annual change in eGFR was lowest in patients >45 yrs (p<0.001) and declined in female>male CKD (p=0.025) and At-risk CKD (p<0.001) patients. eGFR-T were steepest for CKD American Indian/Alaska Native (p=0.007) and At-risk Native Hawaiian/Pacific Islander (p<0.001) vs. White Non-Latino. Similar results were obtained in fully adjusted LME models.

Conclusions: Patients with CKD are older, have more DM and HTN, lower baseline eGFR and more rapid renal function decline compared to At-risk CKD patients. CKD and At-risk CKD severe decliners were youngest, with the highest baseline eGFR. The study results suggest a subset of young patients with high baseline eGFR may be important to target to prevent rapid renal function decline.

Progression of Kidney Disease in Patients with CKD of Undetermined Etiology in Sri Lanka: Disease Natural History and Association with Water Source

Pasan M. Hewavitharane,[1] Shuchi Anand,[2] Rohana Chandrajith,[3] Nishantha Nanayakkara,[4] Kalinga T. Silva,[3] Penny Vlahos.[5] *[1]General hospital (Teaching), Kandy, Sri Lanka., Anuradhapura, Sri Lanka; [2]Stanford University, Stanford, CA; [3]University of Peradeniya, Peradeniya, Sri Lanka; [4]Teaching Hospital, Kandy, Kandy, Sri Lanka; [5]University of Connecticut, Groton, CT.*

Background: Chronic kidney disease of unknown etiology (CKDu) is occurring at high rates in Sri Lanka, without an identified cause or risk factors for progression. Prior GIS mapping and case-control studies have implicated shallow water well use as potentially causative, since water here could communicate with irrigated fields. We recruited a cohort of patients with CKDu from an endemic region in Sri Lanka to determine 1) natural history of disease, and 2) identify any modifiable risk factors for disease progression, with the hypothesis that persons experiencing faster progression may have ongoing or higher dose exposure to the putative causative agent(s).

Methods: We recruited 302 persons with CKDu, with the clinical criteria: CKD-EPI eGFR < 60 ml/min/1.73m2 on two tests at least 3 months apart, none to trace proteinuria on urine dipstick, and no self-reported diagnosis of diabetes. In addition to extensive baseline questionnaire and groundwater sampling, we undertook quarterly IDMS-calibrated serum creatinine testing. We used linear mixed models to test the association of three putative risk factors with eGFR decline over time, accounting for age and sex.

Results: Over a median follow up 9.8 (25th-75th percentile 9.6, 10.7) months, 293 participants provided at least one serum test for eGFR assessment, with median eGFR slope -0.68 (25th-75th percentile -3.14 to 1.00) ml/min/1.73m2/year. 48 (16.4%) participants experienced eGFR decline > 5 ml/min/1.73m2/year. Participants who had never used water from a dug well had slower decline (eGFR slope 6 ml/min/1.73m2 higher (95%CI: 0.3-12.3 ml/min/1.73m2, p value: 0.04) (Figure 1).

Conclusions: Kidney function decline in surviving patients with CKDu in Sri Lanka is slow. No exposure to dug well water was associated with slower decline, and could be investigated as potential cause(s) or disease modifiers.

Urinary Molybdenum Levels and CKD: National Health and Nutrition Examination Survey (1999–2016)

Joo Hong Joun,[4] Jeonghwan Lee,[1] Lilin Li,[2] Jung Pyo Lee.[3] *[1]Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Boramae Medical Center, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Preliminary Medicine Courses, Seoul National University, Seoul, Republic of Korea.*

Background: Molybdenum is both a metal and a micronutrient needed for enzymatic reactions in the carbon, sulfur, and nitrogen metabolism. However, their effects on kidney functions are not well investigated. We aimed to investigate the association of urinary molybdenum levels with chronic kidney disease (CKD) according to increased urinary albumin-to-creatinine ratio (ACR), decreased glomerular filtration rate (GFR), and composite outcomes.

Methods: Population-based cohort study. A total of 16,294 adult aged above 18 years old participants, who participated in the NHANES surveys over 18 years, were enrolled. We used multivariable linear regression adjusting age, sex, ethnicity, diabetes mellitus, hypertension, and body mass index to analyze the association between log-transformed standardized (standard deviation converted to 1) urinary molybdenum levels and urinary ACR and GFR. The association between log-transformed standardized urinary molybdenum levels and CKD was investigated by multivariable logistic regression methods. CKD was defined as three categories; urinary ACR above 30 mg/g (CKD_ ACR30), GFR below 60 ml/min/1.73m2 (CKD_GFR60), and composite of CKD_ACR30 or CKD_GFR60 (CKD_ACR30GFR60).

Results: Mean age of participants was 47.1 ± 19.3 years old, and male participants were 7,978 (49.0%). Mean urinary ACR was 42.6 ± 326.5 mg/g and GFR was 94.4 ± 24.7 ml/min/1.73m^2. Diabetic patients were 2,162 (13.3%) and participants with hypertension were 6,314 (38.8%). Number of patients with CKD_GFR60, CKD_ACR30, and CKD_ ACR30GFR60 was 1,401 (8.6%), 1,983 (12.2%), and 2,922 (17.9%). Log-transformed standardized urinary molybdenum levels were significantly associated with the GFR (β = 3.093, P-value < 0.001), but not with urinary ACR (β = 2.761, P-value = 0.289). Prevalence of CKD_GFR60 and CKD_ACR30GFR60 decreased significantly according to the increased urinary molybdenum levels (P-value < 0.001 and 0.03, respectively).

Conclusions: Urinary molybdenum levels are positively correlated with GFR, risk of CKD (CKD_GFR60 and CKD_ACR30GFR60) decreased according to the increased urinary molybdenum levels.

A Newly Recognized Endemic Region of CKD of Undetermined Etiology in South India: The Tondaimandalam Nephropathy

Sreejith Parameswaran,[1] Sitanshu S. Kar,[2] Priyamvada P. S,[2] Sumit Mohan,[4] Jai Radhakrishnan.[3] *[1]JIPMER, Ponidcherry, India; [2]JIPMER, Puducherry, Puducherry, India; [3]Columbia University Medical Center, New York, NY; [4]Columbia University, New York, NY.*

Background: There are some regions with high incidence of unexplained CKD, referred to as CKD of Undetermined etiology (CKDu), predominantly affecting underprivileged farming populations in tropical climates in Sri Lanka & Latin America. Similar CKD cluster was reported from Andhra Pradesh, India. Many patients exhibiting characteristics of CKDu seek treatment at our tertiary care center in South India & we explored whether a similar burden of CKDu exist in our region as well.

Methods: All consecutive incident adults with CKD per KDIGO criteria presenting to the renal clinic between 1st January 2015 and 31st December 2018 were prospectively recruited in this observational study. Case definition of CKDu by WHO was used.

Results: Among 2440 patients with CKD, 75.3% were male & mean age 50.8 (±13.6) yrs. 56% patients were from Villupuram & Cuddalore districts of Tamil Nadu state (Figure 1). Approx. 50% patients reported working on sugarcane, peanut & rice paddy farms. 65.7% had family income < INR 5000 (USD$77) per month. Diabetic Nephropathy was the cause of CKD in 21.7%, Hypertensive Nephrosclerosis in 14.5% & Chronic Glomerulosclerosis in 3.1%. The single largest diagnostic category was CKDu - 56.2%. CKDu contributed a significantly higher proportion of kidney disease among farmers, agricultural & other unorganized laborers; the proportion of CKDu was significantly higher among the uneducated patients & in the lower income group.

Conclusions: We define a new endemic area of CKDu (Tondaimandalam) in Tamil Nadu, India, accounting for 56.2% of CKD.

Associations Between Long-Term Ambient $PM_{2.5}$ Exposure and Prevalence of CKD: An Analysis Based on the China National Survey of CKD

Jinwei Wang,[1] Jing Huang,[2] Guoxing Li,[3] Ming Hui Zhao,[4] Luxia Zhang.[5,6]
[1]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [2]Department of Occupational & Environmental Health Sciences, Peking University School of Public Health, Beijing, China; [3]Department of Occupational & Environmental Health Sciences, Peking university, Beijing, China; [4]Peking University First Hospital, Beijing, China; [5]Peking University Institute of Nephrology, Beijing, China; [6]Center for Data Science in Health and Medicine, Peking University Health Science Center, Beijing, China.

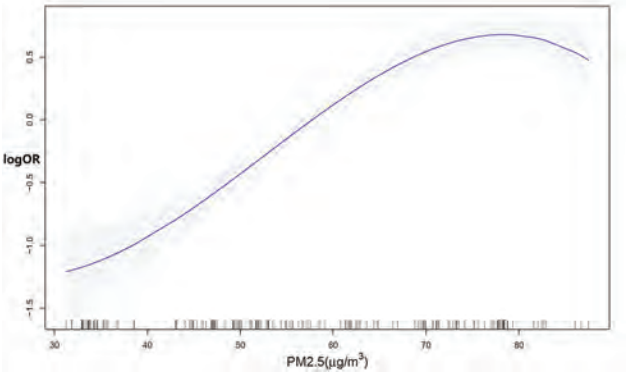
Background: Our aim is to explore the associations between long-term exposure to ambient $PM_{2.5}$ and prevalence of chronic kidney disease (CKD) based on the China National Survey of CKD.

Methods: A sample of 47,204 people representing general adult population in China were recruited from January 2007 to October 2010. Annual exposure to satellite derived $PM_{2.5}$ (obtained from the Aerosol Optical Depth Database) prior to the survey date (2 years range) was estimated at each participant's address using validated satellite-based spatiotemporal model with 10km×10km resolution. Participants with estimated glomerular filtration rate <60 mL/min/1.73 m^2 and/or urinary albumin creatinine ratio≥30mg/g were defined as CKD. Generalized additive mixed effects models were used to estimate the associations, and the influence of the potential modifiers were also analyzed.

Results: The overall prevalence of CKD was 10.8%. Two-year mean $PM_{2.5}$ concentration was 57.41 μg/m^3, with a range from 31.25 to 87.49 μg/m^3. Per 10 μg/m^3 increase in $PM_{2.5}$ was positively associated with the prevalence of CKD with adjusted OR of 1.33 (95%CI: 1.25, 1.41). The exposure-response curve showed relatively steep at low levels of exposure and flattened out at higher exposures (Figure). Similar findings were detected for albuminuria. Stratified analyses indicated the associations were stronger in the smokers than non-smokers, in the young people versus the elderly, and were stronger in participants without comorbid diseases than those with comorbid diseases including diabetes, hypertension, obesity, and cardiovascular history.

Conclusions: This study showed a significant association between long-term $PM_{2.5}$ exposure with broad range and increased prevalence of CKD in the national representative general population.

Funding: Government Support - Non-U.S.



The exposure-response curve between long-term exposure to ambient $PM_{2.5}$ and prevalence of CKD

TH-PO424

Incident CKD over 4 Years in a Population-Based Study of Apparently Healthy Young Adults at Risk of Mesoamerican Nephropathy (MeN)

Marvin A. Gonzalez,[1,2] Armando B. Camacho,[2] Dorothea Nitsch,[3] Neil Pearce,[3] Ben Caplin.[1] *[1]UCL, London, United Kingdom; [2]Research Center on Health, Work and Environment at National Autonomous University of Nicaragua, Leon, León, Nicaragua; [3]London School of Hygiene and Tropical Medicine, London, United Kingdom.*

Background: MeN has led to the death of tens of thousands of young adults across rural Central America. We recently reported eGFR decline of over 30mL/min/1.7m^2 over 2 years among substantial numbers of apparently healthy young adults from rural communities in northwest Nicaragua[1]. The consequences of this early loss of eGFR is not known.

Methods: The original 350 participants (a rural, population-based sample, aged 18-30 years, male:female ratio 3:1, without reported diabetes, hypertension or CKD) from the study have been followed-up annually for a further 2 years. An additional 417 men and women (ratio 1:1) were recruited in October 2018. Serum creatinine was measured at UNAN-León after each study visit and eGFR was calculated by CKD-EPI formula. *de novo* CKD was defined as those participants from the original cohort with an eGFR≥60mL/min/1.7m^2 at baseline who developed an eGFR <60mL/min/1.7m^2 on at least two serial measurements without recovery.

Results: Across all participants (mean age 24.8 years) at baseline 87% of men and 95% of women had an eGFR≥90mL/min/1.7m2, but despite excluding those self-reporting CKD, 2.9% of males had an eGFR<60mL/min/1.7m^2. In the original cohort, 90% participants attended ≥2 of the 7 study visits. eGFR varied substantially visit-to-visit such that 42% of men (Figure) and 54% of women had an eGFR<90mL/min/1.7m^2 at some point during the 4-year follow-up. Furthermore, among men (but not women), 11% had an eGFR<60mL/min/1.7m^2 (at ≥1 visit), 3.8% developed *de novo* CKD, and 0.8% (n=2) died from kidney failure over the follow-up.

Conclusions: Within person eGFR varies substantially in this population at high-risk of MeN. This likely reflects important biological effects, as well as analytical variation, making longitudinal studies critical for disease insight. Nonetheless there is both a substantial loss of eGFR and unprecedented rates of incident CKD among young men in the region. 1. Gonzalez-Quiroz et al. *JASN* 2018

Electron Microscopic Description of a Sensitive Diagnostic Proximal Tubular Lysosomal Lesion in Patients with CINAC/CKDu/MeN and Calcineurin Inhibitor Nephrotoxicity

Benjamin A. Vervaet,[2] Cynthia C. Nast,[1] Gerd Schreurs,[2] Channa Jayasumana,[3] Frank Roels,[9] Chulani A. Herath,[4] Nika Kojc,[5] Anne S. Rodrigo,[4] Swarnalata Gowrishankar,[6] Christiane I. Mousson,[10] Rajeewa T. Dassanayake,[7] Carlos M. Orantes,[8] Patrick C. D'Haese,[2] Marc E. De Broe.[2] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]University of Antwerp, Antwerp, Belgium; [3]Faculty of Medicine, Anuradhapura, Sri Lanka; [4]Sri Jayawardenepura General Hospital, Colombo 5, Sri Lanka; [5]Medical faculty Ljubljana, Ljubljana, Slovenia; [6]Apollo Hospitals, Hyderabad, Hyderabad, India; [7]General hospital Polonnaruwa Sri Lanka, Polonnaruwa, Sri Lanka; [8]National Direction of Non-communicable diseases of Ministry of Health, San Salvador, El Salvador; [9]Ghent University, Gent, Belgium; [10]University Hospital Dijon, Dijon, France*.

Background: In Sri Lankan CINAC patients, we observed a constellation of proximal tubular cell findings including cellular/tubular atrophy, cell fragment shedding and the presence of an increased number of enlarged lysosomes. Here we define the EM lysosomal phenotype and evaluate its presence in CINAC/MeN/CKDu cases and controls.

Methods: Renal biopsies (18 Sri Lanka, 10 El Salvador, 1 India, 3 France) of patients with a diagnosis of CINAC (CKD 1-3A, 3B) were examined by electron microscopy (EM) in comparison to renal biopsies of normal kidneys at implantation, patients with calcineurin inhibitor (CNI) toxicity (n=17), proteinuric nephropathies (n=15), light chain disease (n=4), cases on nephrotoxic drugs (lomustine, clomiphene, lithium, tenofovir, cisplatinum) and patients with reduced renal function of various causes (n=20).

Results: The aberrant lysosomal phenotype can be defined as enlarged (>1.2μm) and dysmorphic with a light-medium electron-dense matrix containing dispersed dark electron-dense non-membrane bound "aggregates". Clusters of 4-6 smaller lysosomes with the same features could be observed. No cristae or other features of mitochondria, autophagic vacuoles, lipofuscin/ceroid droplets, peroxisomes, myeloid bodies or laminated inclusions were observed. Patients with CNI nephrotoxicity and several nephrotoxic cases (lomustine, clomiphene, lithium) and a subset light chain disease patients, all conditions directly or indirectly linked to calcineurin inhibition, presented the same lesions. We present an image set of the consistency of the diagnostic lysosomal lesion versus similar non-diagnostic features.

Conclusions: A rather sensitive constellation of lysosomal lesions in renal proximal tubular cells was detected associated with CINAC/CKDu/MeN and CNI nephrotoxicity in several countries, suggesting a common pathomechanistic paradigm where CINAC patients are experiencing a tubulotoxic mechanism similar to CNI nephrotoxicity.

MicroRNA Profiling of Urinary Exosomes to Identify Appropriate Housekeeping Genes and Early Biomarkers of CKD in Humans

Swasti Tiwari,[1] Manju Kumari,[1] Bhuvnesh Rai.[2] *[1]Sanjay Gandhi PGI, Lucknow, India; [2]SGPGIMS, Lucknow, India*.

Background: In the last decade or so the CKD mortality increased by almost 30%, with diabetic kidney disease increased by 40% throughout the globe. Regular screening for kidney disease onset can lessen this burden. The potential of urinary exosome (UE) as a non-invasive source for kidney disease biomarkers has gained enormous research attention. However, the lack of optimal endogenous control for normalizing gene-expression in UE limits its translation into clinical practice.

Methods: Using microarray, we compared the microRNA profile of UE from early kidney disease subjects [with and without diabetes, serum creatinine < 2.0 mg/dl) with matched healthy controls. taqman-based RT-PCR was done for validation

Results: Around fifteen hsa-miRs were found constitutively expressed across the three groups. Out of these, four abundant miRs were validated by TaqMan-based RT-PCR (n=10-20/group). Also, we found twenty-seven differentially expressed miRs in the UE among the three groups. Pathway analysis revealed VEGF signaling, focal adhesion, and cytokine-cytokine receptor interaction pathways as major targets of the differentially expressed miRs. Among the the differentially expressed miRs, miR-200c-3p, let-7b-3p, miR-6812 and miR-320 were validated by TaqMan-based RT-PCR (n=10-20/group). Also, the target gene prediction of ten novel miRs, identified in the UE, was done using the bioinformatic approach.

Conclusions: In conclusion, we have identified miRs in UE with the potential to serve as 1) kidney disease biomarkers and, 2) endogenous controls, for normalizing miRNA expression in urinary exosomes in kidney disease subjects. Funded by ICMR

Clinical Considerations Surrounding CKD of Undetermined Etiology (CKDu): Expert Consensus from the Third International Workshop on CKDu

Nathan H. Raines,[1] Guillermo Hidalgo,[3] Nelson B. Garcia salazar,[8] Chulani A. Herath,[2] Ramon Garcia-Trabanino,[5] Gangadhar Taduri,[4] Ever O. Cipriano,[9] Susan R. Mendley,[6] Ricardo Correa-Rotter.[7] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Sri Jayawardenepura General Hospital, Colombo 5, Sri Lanka; [3]Eastern Carolina University, Greenville, NC; [4]Nizams Institute of Medical Sciences, Hyderabad, India; [5]Centro de Hemodialisis, San Salvador, El Salvador; [6]NIDDK/NIH, Bethesda, MD; [7]Institutor Nacional de la Nutricion, Mexico City, Mexico; [8]MINSA - SILAIS Chinandega, León, Nicaragua; [9]Instituto Guatemalteco de Seguridad Social, Guatemala, Guatemala.*

Background: CKDu is a term that describes a pattern of endemic, non-diabetic, non-hypertensive kidney diseases characterized by reduced GFR without nephrotic range proteinuria or features of glomerulonephritis. It has been described most extensively in rural communities in Mesoamerica, Sri Lanka, and India, although the global extent is unknown. The underlying etiology or etiologies of CKDu remains incompletely understood, and there are no consensus guidelines for CKDu management.

Methods: The Third International Workshop on CKDu was held March 20-22, 2019 in San Jose, Costa Rica. Our working group, comprised of clinicians who care for CKDu patients in Sri Lanka, India, and Mesoamerica as well as CKDu researchers, developed an expert consensus on the on clinical features and management of the disease.

Results: While there are many similarities in the clinical aspects of CKDu in India, Sri Lanka, and Mesoamerica, there are notable differences as well. Individuals affected in Mesoamerica are younger (aged 20-40 as opposed to 20-60). Both regions show a high male-to-female ratio, and familial concordance. Affected individuals largely live in poverty. Most work in agriculture and live in rural areas, although not all. Hypokalemia, hyponatremia, minimal proteinuria, and sterile pyuria are highly prevalent. Individuals in Central America but not India or Sri Lanka can have hyperuricemia and urate crystalluria. Early biopsies demonstrate tubulointerstitial nephritis with a lymphocytic infiltrate. Both regions describe AKI episodes which may or may not be associated with CKDu. Clinical management in early stages of CKDu focuses on appropriate hydration with clean water, minimization of exposure to heat and agrichemicals, and correction of electrolyte disturbances. Timely diagnosis and establishment of nephrology care appears to improve outcomes.

Conclusions: More studies on the clinical aspects and management of CKDu are desperately needed; to date there is little published guidance for clinicians and health care policymakers. Nevertheless, based on our experience there are concrete actions which can be taken by both healthcare providers and governments to care for people affected by CKDu.

Association of Urine Biomarkers of Kidney Tubule Health with Incident CKD in the REGARDS Cohort

Michael Shlipak,[1] Joachim H. Ix,[7] Ronit Katz,[11] Sushrut S. Waikar,[3] Jason H. Greenberg,[4] Susan L. Furth,[5] Joseph V. Bonventre,[6] Sarah J. Schrauben,[2] Paul L. Kimmel,[8] Chirag R. Parikh,[13] Vasan S. Ramachandran,[14] Harold I. Feldman,[2] Jeffrey R. Schelling,[12] Steven G. Coca,[15] Mark J. Sarnak,[9] Orlando M. Gutierrez.[10] *[1]San Francisco VA Medical Center, San Francisco, CA; [2]University of Pennsylvania, Philadelphia, PA; [3]Harvard Medical School, Boston, MA; [4]Yale University, Woodbridge, CT; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]Brigham and Women's Hospital, Boston, MA; [7]UCSD, San Diego, CA; [8]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [9]Tufts Medical Center, Boston, MA; [10]UAB School of Medicine, Birmingham, AL; [11]University of Washington, Seattle, WA; [12]Case Western Reserve University, Cleveland, OH; [13]Johns Hopkins University, Baltimore, MD; [14]Boston University School of Medicine, Framingham, MA; [15]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Novel biomarkers have been identified that associate with the onset or progression of CKD in specific populations. Within the Reasons for Geographic and Racial Differences in Stroke (REGARDS) Study, we evaluated whether 5 proteins, measured in stored urine specimens, were associated with the subsequent development of CKD among persons without diabetes at baseline.

Methods: The REGARDS Study recruited Black and White participants from the continental US with emphasis on the Southeast US stroke belt. Candidate participants for this ancillary study had a baseline estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73m2, had a stored urine specimen from baseline, and eGFR repeated at the follow-up visit 9 years later. Incident CKD was defined as the onset of an eGFR <60 ml/min/1.73m2 and a ≥40% decline in eGFR. The case-cohort design included a subcohort of 493 individuals, among whom 57 developed incident CKD, and 431 additional cases of incident CKD. Weighted multivariable proportional hazards analyses modeled biomarkers both as continuous variables (log2) and in quartiles.

Results: The mean age of the subcohort was 63±8 years, 58% were women, and 30% were Black; mean (SD) eGFR was 89±14 ml/min/1.73m2 and median (IQR) albumin-to-creatinine ratio was 6.1 (4.2- 9.7) mg/g. In unadjusted models, only higher urine EGF was associated with incident CKD (HR per two-fold increment 1.20; 95% CI: 1.02-1.41); this

association was attenuated after adjustment. No other biomarker approached statistical significance in any analysis (Table).

Conclusions: Among REGARDS Study participants without diabetes or CKD at baseline, none of the 5 urine biomarkers studied was independently associated with incident CKD

Longitudinal Follow-Up and Outcomes for Patients with CKD in China: Results from the C-STRIDE Study

Jinwei Wang,[1] Luxia Zhang,[2,4] Ming Hui Zhao.[3,5] C-STRIDE study group *[1]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [2]Peking University Institute of Nephrology, Beijing, China; [3]Peking University First Hospital, Beijing, China; [4]Center for Data Science in Health and Medicine, Peking University Health Science Center, Beijing, China; [5]Peking-Tsinghua Center for Life Sciences, Beijing, China*.

Background: We aimed to evaluate the longitudinal prognosis of chronic kidney disease (CKD) in China by comparing incidence rates of end-stage kidney disease (ESKD), cardiovascular disease (CVD) and death.

Methods: Totally, 3,700 participants of the C-STRIDE study, an ongoing cohort study with stage 1-4 CKD, were included. The outcomes were occurrence of ESKD, CVD, and death. Crude incidence rates were computed and expressed as the number of events per 100 patient-years. Cumulative incidence curves were depicted for the outcomes and stratified by age, eGFR and ACR, with the adjustment for other risk factors. Fine and Gray model was used in computing the cumulative incidence of ESKD and CVD.

Results: The participants were 49.9±14.3 years, with 58.2% of male, 70.6% with eGFR<60ml/min/1.73m2 and 55.5% with ACR≥300mg/g. After a median follow-up of 5 years, the crude incidence rate of ESKD was about two times that of CVD (3.14/100 patient-years vs. 1.77/100 patient-years) and three times that of death (3.14/100 patient-years vs. 0.92/100 patient-years). The cumulative incidence of ESKD was significantly higher among those aged<55 years than the counterparts, while adverse situations were observed for CVD and death (all p-values<0.05). Higher cumulative incidence rate of ESKD was observed in those with eGFR<60ml/min/1.73m2 and ACR≥300mg/g, while much smaller gaps were detected for cumulative incidence rates of CVD and death (Figure).

Conclusions: Our study found a higher rate of ESKD than CVD or death in a prospective cohort study of patients with CKD in China. Advanced age was shown as protective factors for the risk of ESKD, while reduced eGFR and presence of albuminuria exacerbate the risk of ESKD, compared with their effect on the risk of CVD and death.

Associations of Plasma YKL-40 with Kidney Disease Progression, Mortality, and Histopathologic Lesions in Native Kidney Biopsies

Insa M. Schmidt,[1] Anand Srivastava,[2] Ragnar Palsson,[6] Venkata Sabbisetti,[3] Isaac E. Stillman,[7] Helmut G. Rennke,[3] Astrid Weins,[5] Sushrut S. Waikar.[4] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Brigham and Women's Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]Brigham & Women's Hospital, Boston, MA; [6]Harvard, Belmont, MA; [7]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: YKL-40 is a chitinase-like protein and important regulator of renal tissue injury and apoptosis. We evaluated the association of plasma YKL-40 with progression to ESRD and all-cause mortality among patients with diverse kidney diseases. Furthermore, we tested whether YKL-40 is associated with specific clinicopathologic diagnoses and histopathologic lesions in human kidney biopsies.

Methods: We measured plasma YKL-40 levels in 490 participants of the Boston Kidney Biopsy Cohort—a prospective cohort study of patients undergoing native kidney biopsies. Biopsies were reviewed by renal pathologists and adjudicated for histopathologic findings. Cox proportional hazard models tested the association between YKL-40 and the risks of progression to ESRD and all-cause mortality. Multivariable linear regression models were used to assess the relationship between YKL-40, histopathologic lesions, and clinicopathologic diagnoses. Models were adjusted for age, race, sex, diagnosis, proteinuria, and eGFR.

Results: YKL-40 correlated positively with proteinuria and inversely with eGFR (r=0.27, r=-0.51; p<0.0001, respectively). During a median follow-up time of 25 months, higher YKL-40 levels were independently associated with an increased risk for progression to ESRD (adjusted HR per 1-SD increase of natural log-transformed YKL-40=1.59, 95%CI (1.10-2.31)) and all-cause mortality (adjusted HR=2.28, 95%CI (1.44-3.62)). YKL-40 levels were significantly higher in non-proliferative glomerulopathies (adjusted β=0.48 [ref=normal or thin basement membrane], 95%CI (0.16-0.79), p=0.003) and significantly associated with more severe arterial sclerosis (adjusted β=0.16 [ref=no sclerosis], 95%CI (0.005,0.32), p=0.043).

Conclusions: YKL-40 is independently associated with increased risks of all-cause mortality and progression to ESRD in patients with a diverse spectrum of kidney diseases. Higher levels of YKL-40 were seen in non-proliferative glomerulopathies and biopsies with more severe arterial sclerosis.

TH-PO431

Urinary Calprotectin, Neutrophil Gelatinase Associated Lipocalin (NGAL), and KIM-1 in the Differentiation of Inflammatory vs. Noninflammatory CKD

Felix S. Seibert, Timm H. Westhoff. *University Hospital Marien Hospital Herne, Herne, Germany*.

Background: It has been demonstrated that urinary neutrophil gelatinase-associated lipocalin (NGAL) and calprotectin are helpful biomarkers in the differentiation of intrinsic and prerenal acute kidney injury. The present cross-sectional study investigates, whether urinary biomarkers are able to differentiate primarily inflammatory from non-inflammatory entities in chronic kidney disease (CKD).

Methods: Urinary calprotectin, NGAL and kidney injury molecule-1 (KIM-1) concentrations were assessed in a study population of 143 patients with stable CKD and 29 healthy controls. Stable renal function was defined as an eGFR fluctuation 5ml/min/1.73m2 in the past 12 months. Pyuria, metastatic carcinoma and renal transplantation were regarded as exclusion criteria. Diabetic nephropathy, hypertensive nephropathy, and polycystic kidney disease were categorized as "non-inflammatory renal diseases", whereas glomerulonephritis and vasculitis were regarded as "inflammatory renal diseases".

Results: Urinary calprotectin and NGAL concentrations significantly differed between CKD and healthy controls (p<0.05 each), whereas KIM-1 concentrations did not (p=0.84). Urinary calprotectin concentrations were numerically highest in glomerulonephritis/vasculitis (155.7 ng/ml), NGAL concentrations in diabetic and hypertensive nephropathy (18741 pg/ml), and KIM-1 concentrations in polycystic kidney disease (1556 pg/ml). However, the three biomarkers did neither show significant differences in-between the individual entities, nor the two categories of inflammatory vs. non-inflammatory renal diseases (calprotectin 155.7 vs. 96.99 ng/ml; NGAL 14896 vs. 11977 pg/ml; KIM-1 1388 vs. 1009 ng/ml; p>0.05 each).

Conclusions: The urinary biomarkers calprotectin, NGAL and KIM-1 have no diagnostic value in the differentiation of inflammatory vs. non-inflammatory etiologies of CKD.

TH-PO432

A Phase 1 Randomized, Double-Blind, Placebo-Controlled, Cohort Dose-Escalation Study of a Human Monoclonal Antibody to IL-6 in Patients with CKD

Kristen L. Nowak,[1] Michel Chonchol,[1] Rahul Kakkar,[2] Matt Devalaraja,[2] Larry Lo,[2] Douglas F. Kling.[2] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Corvidia Therapeutics, Waltham, MA.*

Background: Chronic systemic inflammation is highly prevalent in patients with CKD (measured as an elevated high-sensitivity C-reactive protein [hsCRP]) and independently associated with cardiovascular events and mortality. Use of an interleukin-6 (IL-6) blocker to suppress inflammation represents a potential new paradigm to reduce cardiovascular risk in patients with CKD.

Methods: COR-001 is a fully human monoclonal antibody against IL-6. A phase I trial of COR-001 was conducted in patients with moderate-to-severe non-dialysis dependent CKD (estimated glomerular filtration rate [eGFR] 20-60 ml/min/1.73 m^2) and evidence of chronic inflammation (hsCRP] level >2 mg/L over two consecutive measurements). Three cohorts of n=4 (3:1 active vs. placebo) were randomized in a blinded fashion to a single dose of COR-001 (5 mg, 15 mg, and 50 mg subcutaneous injection) and followed for 12 weeks for safety, and pharmacokinetic and pharmacodynamics assessments.

Results: Participants were 67±11 years with a baseline eGFR of 40±13 ml/min/1.73 m^2 and hsCRP of 5.1±2.6 mg/L. Throughout the 12-week study period, dose escalation was approved and all adverse events were within the expected range for a CKD population selected based on the presence of inflammation. hsCRP levels were substantially reduced with COR-001 treatment. 100% of participants achieved suppression of hsCRP to < 2mg/L with the 15 mg and 50 mg dose, and several subjects had undetectable levels of hsCRP with the 50 mg dose (Figure). No SAEs were reported in any cohort. The pharmacokinetic data suggested a half-life of 38-52 days in these patients.

Conclusions: IL-6 inhibition with COR-001 was safe and highly effective at suppressing hsCRP over a long period with a single injection, in adults with moderate-to-severe CKD and evidence of chronic inflammation.

A Meta-Analysis of Placebo-Controlled Randomized Clinical Trials of Octreotide-LAR in Autosomal Dominant Polycystic Kidney Disease

Satyanarayana R. Vaidya, Ajai S. Rajabalan, Frederic F. Rahbari-Oskoui. *Emory University School of Medicine, Atlanta, GA.*

Background: Autosomal Dominant polycystic kidney disease (ADPKD), is the most common hereditary disease of the kidneys, characterized by tubular epithelial cell proliferation (ECP) and fluid secretion (FS) leading to cystic kidney enlargement and progressive renal failure in most cases. Cyclic adenosine monophosphate (cAMP) pathway has been clearly implicated in both ECP and FS. Somatostatin and its synthetic analogues have shown to inhibit invitro adenyl cyclase activity in vitro and slow cyst growth both in few underpowered studies in either early or more advanced stages of ADPKD. This project aimed to evaluate the efficacy of Octreotide-LAR on disease progression based on a meta-analysis of published literature, across all stages of CKD due to ADPKD.

Methods: All placebo-controlled randomized trials (RCT) of Octreotide-LAR (OLAR) in ADPKD were identified through a search using the PubMed, EMBASE, and Cochrane Central Register of Controlled Trials databases. A meta-analysis of efficacy (rate of cyst growth and kidney function decline) and safety outcomes was performed. Participants in those trials were adults, with clinical and ultrasound diagnosis of AKPKD with glomerular filtration rate (GFR) of ≥15 ml/min/1.73 m2, with exclusion of diabetics and poorly controlled hypertension (BP> 180/110 mmHg). Outcomes were mean Total kidney volume (TKV) and decrease in Gfr (Ideally you want an annualized rate of eGFR decline) and were compared by using Standard mean difference (SMD).

Results: Four RCTs fulfilled the inclusion criteria, yielding 445 patients. Compared to placebo, OLAR showed a significant reduction of TKV, SMD -0.41 [95% confidence intervals CI -0.69 to -0.12], p=0.005 but a comparable mean reduction in Gfr SMD 0.01 [95% CI -0.17 to 0.20], p=0.90 and rate of adverse events RR (risk ratio) 1.46 [0.82 to 2.61], p=0.20.

Conclusions: OLAR delays the cyst growth across all stages of kidney disease in ADPKD, without a clear beneficial effect on kidney function, or a significant difference in adverse outcomes. Longer follow up is required to elucidate a potential beneficial role of OLAR on kidney function.

Protein-Bound Uremic Toxins Lowering Effect of Sevelamer in Pre-Dialysis CKD Patients with Hyperphosphatemia: A Randomized Controlled Trial

Kullaya Takkavatakarn,[1] Pongpratch Puapatanakul,[1] Pajaree Chariyavilaskul,[2] Pisut Katavetin,[1] Kearkiat Praditpornsilpa,[1] Somchai Eiam-Ong,[1] Paweena Susantitaphong.[1] *[1]Division of Nephrology, Department of Medicine, King Chulalongkorn Memorial Hospital, Chulalongkorn University, Bangkok, Thailand; [2]Department of Pharmacology, Chulalongkorn University, Bangkok, Thailand.*

Background: P-cresol (pCS), the protein-bound uremic toxins, is strongly associated with cardiovascular events and mortality in chronic kidney disease(CKD). However, effectively therapeutic reduction of this toxin is still limited. This is the first study to evaluate the pleiotropic effects of sevelamer on decreasing of pCS in predialysis CKD patients with hyperphosphatemia.

Methods: This was a randomized controlled trial comparing sevelamer with calcium carbonate in predialysis CKD patients with persistent hyperphosphatemia. After 2 weeks of run-in period, patients were randomly assigned to receive either daily 2,400 mg of sevelamer (n=12) or 3,000 mg of calcium carbonate (n=12) for 12 weeks. Plasma pCS, high sensitivity C-reactive protein (hs-CRP), lipid profiles and renal function were evaluated at baseline and 12 weeks after treatment. The study was registered with the Thai Clinical Trials Registry (TCTR20181018003).

Results: The baseline characteristics were not different. The significant reduction of log plasma pCS, hs-CRP, LDL-cholesterol, and serum phosphate were demonstrated in sevelamer group, whereas non-significant changes were observed in calcium carbonate group (Table1). Interestingly, there was significantly greater renal function progression in calcium carbonate group comparing with sevelamer group (mean difference of eGFR -2.71±1.04 mL/min/1.73m^2, p=0.018).

Conclusions: This is the first study to demonstrate benefit effect of sevelamer on decreasing pCS and retarding renal impairment in predialysis CKD patients with hyperphosphatemia. These effects of sevelamer might be considered as treatment for slowing CKD progression and decreasing the risk of cardiovascular events in CKD patients.

TH-PO435

Utility of D-Serine in the Estimation of GFR and the Diagnosis of Kidney Diseases

Atsushi Hesaka,[1,2] Shinsuke Sakai,[4] Masaru Horio,[2] Yoshitaka Isaka,[2] Tomonori Kimura.[1,3] *[1]KAGAMI Project, National Institute of Biomedical Innovation, Health and Nutrition (NIBIOHN), Ibaraki, Japan; [2]Osaka University Graduate School of Medicine, Ashiya, Japan; [3]Reverse Translational Project, Center for Rare Disease Research, National Institute of Biomedical Innovation, Health and Nutrition (NIBIOHN), Ibaraki, Japan; [4]Osaka University, Suita, Japan.*

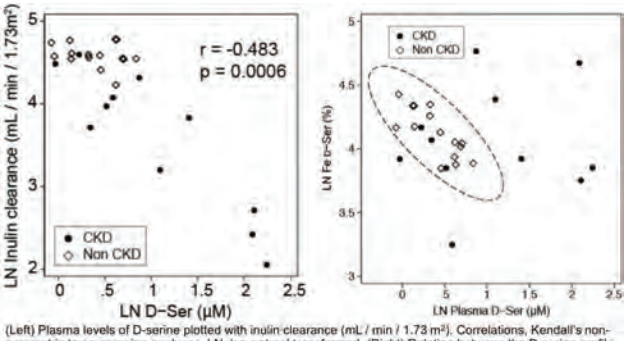
Background: Glomerular filtration ratio (GFR), measured by inulin clearance, is rarely used in clinics due to its methodological complexity. As a replacement, estimated GFR (eGFR), calculated from either serum creatinine or serum cystatin C, is widely used currently, but it has some limitations such as the accuracy. D-Amino acids, long-term undetected enantiomers of L-amino acids, is now emerging as a potential biomarker

especially in kidney diseases. Here we investigated the potential of D-serine as a biomarker for kidney function and diseases.

Methods: Inulin clearance and chiral amino metabolomics were simultaneously performed in 11 CKD patients and 15 non-CKD participants. The association between chiral amino acids and clinical parameters was analyzed using either unsupervised principal component analysis (PCA) or supervised orthogonal partial least squares (OPLS) analysis. Additionally, D-serine was monitored in one patient with systemic erythematous lupus nephritis during its recovery phase.

Results: The plasma level of D-serine correlated well with the actual GFR, and this correlation was compatible with those of serum creatinine and cystatin C. Fractional excretion (Fe) of D-serine in non-CKD was much higher than those of L-serine, but its variance was maintained within a certain limited range. Although Fe of D-serine was uncorrelated with GFR, it reflected the presence of CKD. The combination of plasma and Fe of D-serine effectively separated the CKD from non-CKD participants. This concept was exemplified in a patient with SLE, in which the combination of plasma and Fe of D-serine well-reflected its recovery phase.

Conclusions: D-serine would benefit patients with kidney diseases via accurate estimation of GFR and estimation of disease activities.



(Left) Plasma levels of D-serine plotted with inulin clearance (mL / min / 1.73 m²). Correlations, Kendall's non-parametric tau regression analyses. LN, log-natural transformed. (Right) Relation between the D-serine profile (plasma level and Fe) and CKD. The dotted-eclipse represents 95% confidence interval of non-CKD.

High Serum Adiponectin Is Associated with Renal Outcome in CKD: Results from the KNOW-CKD Study

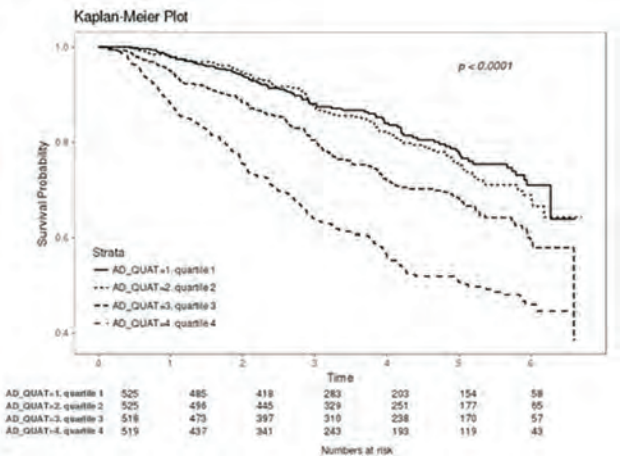
Su hyun Song,[1] Hong sang Choi,[1] Chang Seong Kim,[1] Seong Kwon Ma,[1] Curie Ahn,[2] Soo Wan Kim,[1] Eun Hui Bae.[3] Chonnam National University Medical School *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Chonnam National University Hospital, Gwangju, Republic of Korea*.

Background: Adiponectin, a peptide hormone secreted from adipocytes, exerts anti-inflammatory, anti-diabetic, anti-atherogenic properties. Paradoxically, serum adiponectin levels are increased in patients with end-stage renal disease, and those patients are featured with chronic inflammation, increased insulin resistance and increased cardiovascular risk. We aimed to determine the relationship between serum adiponectin levels and renal outcome in chronic kidney disease (CKD) patients.

Methods: This prospective longitudinal study included 2087 CKD patients from the KNOW-CKD study (KoreaN Cohort Study for Outcomes in patients With Chronic Kidney Disease). Patients were divided into quartiles according to their serum adiponectin levels. The composite renal outcome was defined as one or more of the followings: initiation of dialysis or transplantation, a two-fold increase in baseline serum creatinine level, or a 50% decline in the estimated glomerular filtration rate (eGFR) during the follow-up period. A Cox proportional hazard ratio model was applied to analyze the relationship between composite renal outcome and serum adiponectin levels.

Results: Mean patient age was 53.5 ± 12.2 years, and 1273 (61%) were men. The eGFR was 50.4 ± 30.2 ml min^{-1} 1.73 m^{-2}. Mean values of each quartile of serum adiponectin were 2.9 ± 1.4, 7.2 ± 1.2, 12.7 ± 2.0 and 26.1 ± 9.6 μg/ml. Serum adiponectin level was inversely associated with body mass index and eGFR. In multivariate regression models, an association was found between the highest quartile of serum adiponectin and increased risk of composite renal outcome (HR, 1.336; 95% CI 1.029-1.734).

Conclusions: A high serum adiponectin level is independently associated with poor renal outcome, which suggests the potentially adverse role of adiponectin in CKD progression.



Kaplan-Meier survival curve according to serum adiponectin quartile groups.

Deoxycholic Acid and Mortality, ESRD, and Cardiovascular Events in Patients with CKD

Rebecca Frazier,[8] Xuan Cai,[9] Jungwha Lee,[8] Anna J. Jovanovich,[1] Jing Chen,[2] Rajat Deo,[11] James P. Lash,[3] Amanda H. Anderson,[4] Alan S. Go,[10] Tariq Shafi,[5] Harold I. Feldman,[11] Eugene P. Rhee,[6] Michel Chonchol,[7] Makoto Miyazaki,[12] Tamara Isakova.[8] *[1]Denver VA / University of Colorado, Denver, CO; [2]Tulane School of Medicine, New Orleans, LA; [3]University of Illinois at Chicago, Chicago, IL; [4]Tulane University, New Orleans, LA; [5]University of Mississippi Medical Center, Jackson, MS; [6]Massachusetts General Hospital, Newton, MA; [7]University of Colorado, Aurora, CO; [8]Feinberg School of Medicine, Northwestern University, Chicago, IL; [9]Northwestern University, Chicago, IL; [10]Kaiser Permanente Northern California, Oakland, CA; [11]University of Pennsylvania, Philadelphia, PA; [12]University of Colorado-Denver, Aurora, CO*.

Background: Deoxycholic acid (DCA), a secondary bile acid, is elevated in patients with chronic kidney disease (CKD) and has been linked to vascular calcification in this population. There have not been studies examining the relationship between DCA and adverse events in CKD patients.

Methods: Using data from the prospective Chronic Renal Insufficiency Cohort Study, we analyzed the association between fasting serum DCA levels and death, end-stage renal disease (ESRD), ESRD-censored death and cardiovascular (CV) events in 3147 participants with CKD. We used Tobit regression to determine predictors of high DCA and Cox regression to determine the association between DCA and outcomes.

Results: The average age of participants was 58.9 ± 10.7 years, 40.6% were black, 48.0% had diabetes, and the mean eGFR was 42.5 ± 16.0 ml/min/1.73m^2. The independent predictors of elevated DCA were increased age and non-use of statins. Cox regression showed a U-shaped association between log-transformed DCA levels and outcomes. After adjustment, DCA values above the transition points were significantly associated with death, ESRD and ESRD-censored death (HR 1.23, 95% CI 1.04-1.45; HR 1.73, 95% CI 1.13-2.66; HR 1.23, 95% CI 1.00-1.50 respectively). DCA values below the transition points were significantly associated with ESRD (0.87, 95% CI 0.78-0.96). There was no association between DCA and CV events.

Conclusions: DCA is associated with death, ESRD and ESRD-censored death in a U-shaped distribution. DCA levels above the transition points are associated with death, ESRD-censored death, and ESRD in CKD patients, while values below the transition points are associated with ESRD.

Differences in Urinary Potassium and Acid-Base Handling in African American vs. Non-African American CKD Patients

Victoria T. Vo,[1] Saurabh Chawla,[2] Cameron J. Menezes,[2] Benjamin S. Ko,[2] Elaine M. Worcester,[2] Fredric L. Coe,[2] Anna L. Zisman.[2] *[1]Nephrology, University of Chicago, Chicago, IL; [2]University of Chicago, Chicago, IL.*

Background: African American (AA) patients with chronic kidney disease (CKD) have faster progression to end stage renal disease (ESRD) than non AA CKD patients. The underlying etiology is multifactorial related to genetics (APOL1), renal disease pathology, co-morbidities or underlying physiologic differences. Physiologic differences include potassium (K+) and acid/base metabolism within the CKD population, specifically racial differences between AA and non AA patients with CKD. Correction of metabolic acidosis in CKD patients has shown to slow progression of CKD, but few studies have examined differences between acid/base metabolism in AA and non AA. No studies have examined differences in urinary K+ excretion in these populations but studies that have shown AA CKD patients maintain lower serum K+ compared to non AA CKD patients. Our object is to identify differences in K+ handing and acid/base metabolism in AA vs non AA CKD patients

Methods: We studied a cohort of 107 patients with CKD Stage 3-5 who had collected 24-hr urine and serum studies as part of routine clinical care between 2009-2018

Results: Urinary K+ excretion in AA patients was much lower (50±3 mEq and 38±5 mEq, early and late CKD respectively; p<0.05) compared to non AA patients (64±3 mEq and 77±7 mEq, early and late CKD respectively; p value <0.01). Examination of acid/base metabolism using "GI anion", a measure of net dietary alkaline load, found late stage CKD non AA male patients had more urinary alkali excretion (71±12, p value <0.01) compared to early stage non AA patients (27±5) and all stages of AA patients (32±4 and 25±7 mEq, early and late CKD respectively). Also, within each CKD stage, protein catabolic rate (PCR) in non AA patients was much higher (1.00±0.03 and 1.03±0.07, early and late CKD respectively; p value <0.01) than AA patients (0.8±0.03 and 0.71±0.04, early and late CKD respectively).

Conclusions: AA patients with CKD handle K+ excretion and acid/base metabolism differently than non AA patients. The mechanism and impact of these racial disparities in CKD warrant further investigation.

Association Between Income Disparities and Risk of CKD: A Nationwide Cohort Study of 7 Million Adults in Korea

Shin-Wook Kang,[2] Chan-Young Jung,[2] Byounghwi Ko,[2] Wonji Jo,[2] Tae ik Chang.[1] *[1]Department of Internal Medicine, National Health Insurance Service Medical Center, Ilsan Hospital, Gyunggi-do, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Income disparities may have bearing on public health problems. However, longitudinal studies of the relationship between income level and incident chronic kidney disease (CKD) are scarce.

Methods: To examine the association between income level and incident CKD in healthy adults with normal baseline kidney function, we studied the association between income level categorized into deciles and incident CKD in a national cohort comprised of 7.4 million adults who underwent National Health Insurance Service health examinations between 2009–2015 with baseline estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73m^2. Incident CKD was defined as *de novo* development of eGFR <60 mL/min per 1.73m^2 (model 1) or ≥25% decline in eGFR from the baseline values accompanied by eGFR <60 mL/min/1.73m^2 (model 2).

Results: During a median follow-up of 4.8 years, there were a total of 122,032 (1.65%) and 55,779 (0.75%) incident CKD events based on model 1 and 2 definitions, respectively. Compared with income levels in the sixth decile, there was an inverse association between lower income level and higher risk of CKD up to fourth decile, above which no additional reduction (model 1) or slightly higher risk of CKD (model 2) was observed at higher income levels. The multivariable-adjusted hazard ratios (95% confidence interval) from the lowest to fourth deciles were 1.30 (1.26-1.33), 1.16 (1.13-1.19), 1.07 (1.05-1.10), and 1.06 (1.03-1.09) in model 1 and 1.32 (1.27-1.37), 1.18 (1.14-1.22), 1.08 (1.04-1.13), and 1.05 (1.01-1.09) in model 2, respectively. These associations persisted across various subgroups of age, sex, and comorbidity status.

Conclusions: In this large nationwide cohort, lower income levels were associated with higher risk of incident CKD.

TH-PO440

Implications of Different Methods for Calculating Time to Percentage in eGFR Decline Outcomes

Jarcy Zee,[1] Qian Liu,[1] Maria Larkina,[2] Abigail R. Smith,[1] Jonathan P. Troost,[2] S.M. Bagnasco,[3] Matt G. Sampson,[2] Laura Barisoni,[4] Laurence H. Beck,[5] Brenda W. Gillespie,[2] Debbie S. Gipson,[6] Laura H. Mariani,[2] Wenjun Ju,[2] Viji Nair.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]The Johns Hopkins School of Medicine, Baltimore, MD; [4]Duke University, Durham, NC; [5]Boston University Medical Center, Boston, MA; [6]University of Michigan Mott Children's Hospital, Ann Arbor, MI.*

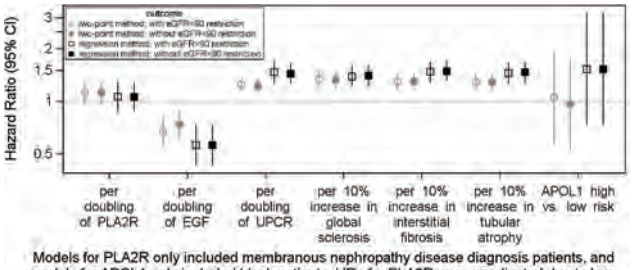
Background: Multiple methods for calculating time to 40% eGFR decline outcomes may differentially characterize kidney disease progression. We compared the traditional "two-point method" (using baseline eGFR to determine the decline threshold and first subsequent eGFR lower than the threshold for the event time) to a "regression method" (fit a regression line to all eGFRs to calculate the threshold and event time), with and without an additional restriction that eGFR<90 at the event time.

Methods: NEPTUNE is a multi-site observational cohort study of patients with glomerular disease. Based on subsets of N=605 patients with available data, we used Cox models to estimate effects of morphologic damage (interstitial fibrosis, tubular atrophy, global sclerosis), urine biomarkers (epidermal growth factor [EGF], urine protein creatinine ratio [UPCR]), serum anti-Phospholipase A2 receptor (PLA2R), and apolipoprotein L1 (APOL1) genotype on time to 40% eGFR decline (or end-stage renal disease) across different methods, adjusted for patient demographic and clinical characteristics.

Results: The regression method and additional restriction of eGFR<90 yielded lower event rates, the latter especially for patients with high eGFR at study enrollment. Effect estimates using the regression method were similar or greater in magnitude (i.e., away from the null) for most predictors [Fig]. Effect estimates with and without the eGFR<90 restriction were similar.

Conclusions: The regression method can facilitate detection of smaller exposure effects. Given a previous study showing increased accuracy of the regression method over the two-point method, we recommend the regression method for calculating time to percent eGFR decline to increase accuracy of effect estimates. The eGFR<90 restriction can capture at least mild loss of kidney function at the event time, which may be needed when hyperfiltration at baseline is a concern.

Funding: NIDDK Support



Models for PLA2R only included membranous nephropathy disease diagnosis patients, and models for APOL1 only included black patients. HRs for PLA2R were unadjusted due to low number of outcome events. HRs for others were adjusted for patient age, race, sex, disease diagnosis, eGFR, UPCR, and medication use (immunosuppression and RAAS blockade), unless the number of events was limited, in which case backward selection was used to select adjustment variables.

Aldosterone Antagonists for Preventing the Progression of CKD: An Updated Cochrane Review

Edmund Y. Chung,[1] Suetonia Palmer,[2] Giovanni F. Strippoli.[3] *[1]NSW Northern Sydney Health District, Lindfield, NSW, Australia; [2]University of Otago, Christchurch, New Zealand; [3]University of Bari, Bari, Italy*.

Background: Angiotensin-converting enzyme inhibitors (ACEi) and angiotensin receptor blockers (ARB) reduce proteinuria and retard the progression of chronic kidney disease (CKD), though resolution of proteinuria may be incomplete. We evaluated whether addition of an aldosterone antagonist may further prevent progression of CKD.

Methods: We searched the Cochrane Kidney and Transplant Register of Studies through to 3 September 2018 for randomized controlled trials comparing aldosterone antagonists to standard care or placebo in patients with proteinuric CKD. Two independent authors extracted data for end-stage kidney disease (ESKD), major cardiovascular events, mortality, proteinuria, glomerular filtration rate (GFR), blood pressure, hyperkalemia, acute kidney injury (AKI), and gynecomastia. Risk of bias was assessed using the Cochrane tool. Evidence certainty was evaluated using GRADE.

Results: Forty-three studies (5171 participants) were eligible. Risk of bias in the evaluated methodological domains was unclear or high risk in most studies. Aldosterone antagonists had uncertain effects on risk of ESKD (2 studies, 84 participants, risk ratio [RR] 3.00, 95% confidence interval [CI] 0.33 to 27.65, *very low certainty evidence*), mortality (3 studies, 421 participants, RR 0.58, 95%CI 0.10 to 3.50, *low certainty evidence*), cardiovascular events (3 studies, 1067 participants, RR 0.95, 95%CI 0.26 to 3.56, *low certainty evidence*) and GFR (12 studies, 861 participants, MD -2.25 ml/min/1.73 m^2, 95%CI -4.76 to 0.25, *low certainty evidence*); may reduce proteinuria (14 studies, 910 participants, standardized mean difference [SMD] -0.53, 95%CI -0.86 to -0.19, *very low certainty evidence*) but probably increases risk of hyperkalemia (17 studies, 2683 participants, RR 2.10, 95%CI 1.42 to 3.13, *moderate certainty evidence*), AKI (4 studies, 1088 participants, RR 2.02, 95%CI 1.02 to 4.02, *moderate certainty evidence*) and gynecomastia (4 studies, 281 participants, RR 5.14, 95% CI 1.14 to 23.23, *moderate certainty evidence*) compared to standard care or placebo.

Conclusions: Aldosterone antagonists when added to ACEi or ARB (or both) may reduce proteinuria but have uncertain effects on death, major cardiovascular events or ESKD and may incur excess hyperkalaemia, acute kidney injury and gynecomastia.

Comprehensive Profiling of the Clinical Nephropathies in Participants of the H3Africa Kidney Disease Research Network Project Cohort Study

Yemi R. Raji,[1] Titilayo O. Ilori,[2] Shikhar Kumar,[3] Manmak Mamven,[8] Rulan S. Parekh,[4] Rasheed A. Gbadegesin,[5] Babatunde L. Salako,[6] Dwomoa Adu,[7] Akinlolu O. Ojo.[9] H3Africa Kidney Disease Research Network *[1]University of Ibadan and University College Hospital, Ibadan, Oyo State, Nigeria, Ibadan, Nigeria; [2]Emory University School of Medicine, Chandler, AZ; [3]The university of arizona, Tucson, AZ; [4]The Hospital For Sick Children, Toronto, ON, Canada; [5]Duke University Medical Center, Durham, NC; [6]University of Ibadan, Ibadan, Nigeria; [7]University of Ghana, Accra, Ghana; [8]Medicine, University of Abuja, Abuja, Nigeria; [9]University of Arizona Health Sciences, Tucson, AZ.*

Background: It is estimated that more than greater than 50 million African Blacks have Chronic Kidney Disease (CKD) due to clinically defined nephropathies. A significant fraction of these will progress to ESRD. Despite the high rate of CKD progression among individuals of African ancestry, the molecular and clinical factors underlying this high burden is not completely understood. The ongoing H3Africa Kidney Disease Cohort study aims to evaluate the independent contribution of risk variants in the *APOL1* genes to the progression of clinically defined nephropathies among 3,000 African Blacks. This abstract described the baseline characteristics of the participants of the study

Methods: A longitudinal study of 3,000 African black with clinical defined nephropathies. It involves baseline and follow up visits. At the baseline, relevant clinical information was obtained while blood and urine specimens were collected for the assays. Biological specimens were processed, stored, packaged and shipped to the central repository for analysis. Information obtained from participants were demographics, contact information and medical history and blood was collected for DNA, RNA, whole blood, serum creatinine, full blood count and anthropometric measures. Where clinically indicated a kidney biopsy was performed and kidney tissue examined histologically.

Results: A total of 2,192 participants were included in this analysis, and the clinical nephropathies include hypertensive nephropathy 1194 (54.5%), diabetic nephropathy 558(25.5%), sickle cell nephropathy 63(2.9%) and CKD of unknown aetiology 377(17.2%). The mean age among participants were 53.84±14.41, 58.92±11.46, 35.24 ±13.67 and 37.08 ±15.97years for hypertyensive, diabetic and sickle cell nephropathies and CKD of unknown aetiology respectively. Albumin-Creatinine Ratio was higher among participants with CKD of unknown aetiology (165.09±302.49mg/Mmol) and sickle cell nephropathy (109.13±111.18mg/mMol) compared to hypertensive nephropathy 62.68±184.32mg/mMol) and diabetic nephropathy (78.71± 144.61mg/mMol)

Conclusions: Hypertensive nephropathy, diabetic nephropathy and CKD of unknown aetiology are the leading clinically defined nephropathies among the sub-Saharan African population

Design and Patient Characteristics of a Study to Assess the Renoprotective Effects of the SGLT2 Inhibitor Dapagliflozin in Non-Diabetic Proteinuric Kidney Disease (DIAMOND)

Claire Dekkers,[1] David Cherney,[8] Heather N. Reich,[2] Sean Barbour,[3] Abdul halim Abdul gafor,[4] Soo Kun Lim,[9] Muh Geot Wong,[7] Gozewijn D. Laverman,[5] Marc G. Vervloet,[6] Ron T. Gansevoort,[1] Hiddo J. L Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Toronto General Hospital, Toronto, ON, Canada; [3]University of British Columbia, Vancouver, BC, Canada; [4]University Kebangsaan Malaysia Medical Centre, Kuala Lumpur, Malaysia; [5]ZGT Almelo, Almelo, Netherlands; [6]Amsterdam University Medical Center, Overveen, Netherlands; [7]Renal & Metabolic Division, The George Institute for Global Health, Sydney, NSW, Australia; [8]Nephrology, University Health Network, Toronto, ON, Canada; [9]Univeristy Malaya Medical Centre, Kuala Lumpur, Malaysia*.

Background: Sodium glucose co-transporter 2 (SGLT2) inhibition decreases albuminuria and reduces the risk of kidney disease progression in patients with type 2 diabetes. These beneficial effects are likely mediated by activation of tubuloglomerular feedback by natriuresis, leading to decreased intraglomerular hypertension. Since non-diabetic kidney diseases are also characterized by glomerular hypertension, we tested the hypothesis that in patients with non-diabetic proteinuric kidney disease, SGLT2 inhibition with dapagliflozin reduces proteinuria and acutely and reversibly reduces glomerular filtration rate (GFR).

Methods: We designed a multicenter double-blind randomized placebo controlled 6-week cross-over study to assess the change from baseline in 24-hour proteinuria with dapagliflozin 10 mg/day in patients with proteinuric kidney disease without diabetes (ClinicalTrials.gov identifier: NCT03190694). The secondary endpoint was the change in iohexol-derived GFR. The main inclusion criteria were: urinary protein excretion >500 mg/24hr and ≤3500 mg/24hour, eGFR ≥25 mL/min/1.73m^2; stable dose of RAAS inhibitors.

Results: Patients with non-diabetic kidney disease were enrolled between November 2017 and April 2019. A total of 58 patients were screened of whom 53 patients were randomized in this ongoing study. The mean age at screening was 51 (SD 13) years and 32% were female. Mean screening eGFR was 59 (29) ml/min/1.73m^2 and median proteinuria 1074 (25th to 75th Percentile 810 -1400) mg/24hr. Overall, blood pressure was well controlled (SBP/DBP 128 (15) /78 (8) mmHg) and mean body weight was 83.0 (20) kg. Mean HbA_{1c} was 5.6 (0.4) % and mean hemoglobin level 138 (20) g/L. All patients were using a RAAS inhibitor.

Conclusions: This is the first placebo controlled clinical trial to examine the effects of an SGLT2 inhibitor in a non-diabetic population at risk for progressive kidney function loss. Final study results are expected in December 2019.

TH-PO444

Effect of Bardoxolone Methyl on Kidney Events in Patients with CKD Stage 4 and Type 2 Diabetes at High Risk of Adverse Kidney Outcomes

Christoph Wanner,[1] Gerald B. Appel,[2] Geoffrey A. Block,[3] Melanie Chin,[3] Daniel W. Coyne,[4] Angie Goldsberry,[3] Lesley Inker,[5] Colin J. Meyer,[3] Stuart M. Sprague,[6] Peter Stenvinkel,[7] Hiddo J. L Heerspink.[8] *[1]University Hospital, Wuerzburg, Germany; [2]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [3]Reata Pharmaceuticals, Inc., Irving, TX; [4]Division of Nephrology, Washington University School of Medicine, St. Louis, MO; [5]Tufts Medical Center, Boston, MA; [6]NorthShore University HealthSystem University of Chicago, Chicago, IL; [7]Karolinska University Hospital Huddinge, Stockholm, Sweden; [8]University Medical Center Groningen, Groningen, Netherlands.*

Background: Increases in kidney function, including increases in inulin clearance and estimated glomerular filtration rate (eGFR), have been observed with bardoxolone methyl (Bard) in 11 studies enrolling approximately 3,000 patients with chronic kidney disease (CKD). The largest of these studies was Bardoxolone Methyl Evaluation in Patients with Chronic Kidney Disease and Type 2 Diabetes (BEACON), a multinational, randomized, double-blind, placebo-controlled phase 3 trial, which enrolled patients with type 2 diabetes and stage 4 CKD. We performed a *post-hoc* analysis of BEACON to characterize changes

in kidney function induced by Bard in subgroups of patients at particularly high risk of adverse kidney outcomes, including those with baseline eGFR below 22 mL/min/1.73 m^2 or with a urine albumin to creatinine ratio (UACR) > 300 mg/g.

Methods: Patients in BEACON (n=2185; NCT01351675) were randomized 1:1 to receive once-daily bardoxolone methyl (20 mg) or placebo. For the subsets of patients with baseline eGFR < 22 mL/min/1.73 m^2 (n=503 for Bard, n=514 for placebo) or baseline UACR > 300 mg/g (n=540 for Bard, n=578 for placebo), we compared the effects of Bard and placebo on a *post-hoc* composite kidney endpoint consisting of a sustained ≥30% decline from baseline in eGFR, sustained eGFR <15 mL/min/1.73 m^2, and end-stage kidney disease events.

Results: Patients with baseline eGFR < 22 mL/min/1.73 m^2 randomized to Bard were significantly less likely to experience the composite kidney endpoint than patients randomized to placebo; 45/503 (9%) Bard patients experienced an event compared to 111/514 (22%) placebo patients (hazard ratio 0.39; 95% CI, 0.28-0.55; p<0.001). For patients with baseline UACR > 300 mg/g, 58/540 (11%) Bard patients experienced an event compared to 105/578 (18%) placebo patients (hazard ratio 0.58; 95% CI, 0.42-0.80; p<0.001).

Conclusions: In the subsets of patients enrolled in BEACON who were at greatest risk for progression to kidney failure, the increases in eGFR with Bard were associated with a significant reduction in the likelihood of an end-stage kidney disease composite endpoint.

Effect of Aspirin on Cardiovascular Events, Mortality, and Bleeding Outcomes in Older Individuals with CKD

Kevan Polkinghorne,[1] James B. Wetmore,[2] Robyn L. Woods,[3] Anne M. Murray,[4] John J. Mcneil,[3] Paul J. Roderick,[6] Hugh Gallagher,[7] Rory Wolfe.[5] *[1]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [2]Hennepin County Medical Center, Minneapolis, MN; [3]Monash University, Melbourne, VIC, Australia; [4]Hennepin County Medical Center/Hennepin Healthcare, Minneapolis, MN; [5]Monash University/Department of Epidemiology & Preventive Medicine, Melbourne, VIC, Australia; [6]University of Southampton, UK, Southampton, United Kingdom; [7]Epsom & St Helier NHS Trust, Carshalton, United Kingdom.*

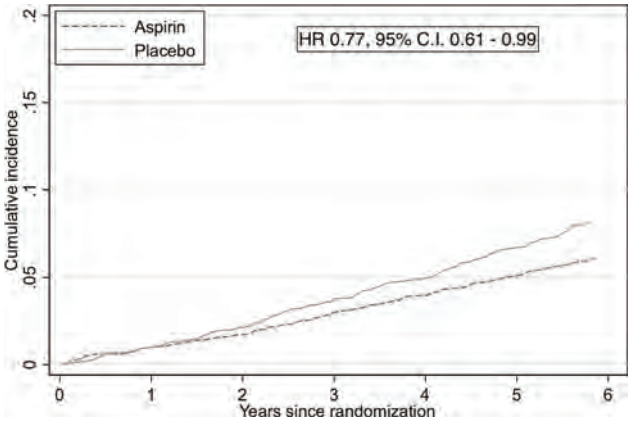
Background: The primary efficacy and safety of aspirin (ASA) in older people with chronic kidney disease (CKD) is unclear. ASPirin in Reducing Events in the Elderly (ASPREE), a large binational (Australia, US) RCT in elderly participants free of diagnosed CVD or disability, found no benefit of aspirin for primary prevention. The ASA To Target Arterial Events In CKD (ATTACK) trial is underway with a primary endpoint of major adverse cardiovascular events (MACE) in patients with CKD. To provide insights into whether ATTACK should consider exclusion of individuals aged >70 years, we examine the effects of daily 100mg ASA on outcomes in ASPREE participants with CKD.

Methods: ASPREE participants with eGFR <60, or ≥60mL/min with urine albumin creatinine ratio (UACR) ≥3mg/mmol, were included in these analyses. MACE was defined as a composite of fatal coronary heart disease, non-fatal myocardial infarction (MI), and fatal and non-fatal ischemic stroke. Other endpoints included all-cause mortality and major hemorrhage. In intention-to-treat time-to-event analyses, Cox proportional hazards models were used to compare the ASA group with the placebo group.

Results: Of 19,114 ASPREE participants, 4,758 had baseline CKD. Median eGFR was 56.2 mL/min/1.73m2 (IQR 50.2, 67.1), median UACR was 1.8 mg/mmol (0.6, 4.8). Sex, age, CVD risk factors, eGFR, and uACR were well-balanced between ASA and placebo groups. Participants with CKD randomized to ASA had a lower risk of MACE (HR 0.77, [95% C.I. 0.61, 0.99], figure), higher rate of major hemorrhage (HR 1.28, [0.98, 1.68]) and similar rate of mortality (HR 1.08, [0.89, 1.32]) compared to placebo.

Conclusions: The balance ofbenefit and harms of treatment with ASA in older people with CKD are unclear and merit ongoing investigation.

Funding: Other NIH Support - National Institute on Aging and the National Cancer Institute



Cummulative incidence MACE.

Oral Adsorbent AST-120 Improves Microcirculatory Impairment in Patients with CKD

Takayasu Ohtake, Yasuhiro Mochida, Kunihiro Ishioka, Hidekazu Moriya, Sumi Hidaka, Shuzo Kobayashi. *Kidney Disease and Transplant Center, Shonan Kamakura General Hospital, Kamakura, Japan.*

Background: Microcirculatory impairment plays an important role at an earlier stage for peripheral arterial disease (PAD) in patients with chronic kidney disease (CKD). To treat PAD as early as possible is mandatory to avoid lower limbs' amputation. Therefore, we evaluated whether uremic toxin-lowering therapy could improve microcirculatory impairment in patients with CKD.

Methods: Oral charcoal adsorbent AST-120 (Kremezin, Kureha Corporation, Tokyo, Japan) adsorbs indole, a precursor of indoxyl sulfate (IS), in the gastrointestinal tract so that IS does not accumulate in the body. We performed a prospective interventional clinical trial whether AST-120 could improve atherosclerotic surrogates in CKD patients (UMIN no. 000013577). As a primary endpoint, skin perfusion pressure (SPP) of lower limbs, and flow mediated dilation (FMD) were evaluated as surrogate of microcirculatory and macrocirculatory status, respectively. They were evaluated at baseline, 3, 6, and 12 months after AST-120 administration. Serum levels of total IS (free IS and protein-binding IS) and renal function (serum creatinine (sCr), 1/sCr) were also evaluated at baseline, 3, 6, and 12 months after AST-120 administration. Total IS was evaluated using HPLC method and expressed as μM.

Results: We enrolled 30 non-diabetic CKD patients (CKD stage; G3a (n=4), G3b (n=9), G4 (n=14), and G5 (n=3)), and AST-120 6 gram/ day was orally administered for 12 months. Serum creatinine (sCr) levels and 1/sCr at baseline were 2.03±0.85 mg/dL and 0.578±0.226 dL/mg (mean±SD), respectively. Monthly decline in renal function (slope of 1/sCr) after AST-120 administration did not change compared to that in pre-treatment period. However, serum total IS significantly decreased at 3 months after AST-120 administration (baseline: 11.7±8.6 μM to 3 months: 6.9±5.0 μM, p<0.01). Serum IS levels continued to be decreased for 12 months (p<0.01). Although FMD did not change during study period, SPP values in lower limbs constantly elevated, and was significantly improved at 12 months after AST-120 administration compared to baseline values (69.7 ± 14.6 vs. 78.8 ± 18.9 mmHg, p<0.05).

Conclusions: IS-lowering therapy significantly improved micro-circulatory impairment in non-diabetic pre-dialysis CKD patients.

TH-PO447

AST-120 Can Delay the Decline of Renal Function in Patients with CKD

Hitoshi Suzuki, Yusuke Fukao, Maiko Nakayama, Rina Kato, Yoshihito Nihei, Yusuke Suzuki. *Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: AST-120 (KREMEZIN®, Kureha Chemical, Tokyo, Japan) consists of oral spherical carbonaceous adsorbent, which was approved for use in delaying the initiation of dialysis and ameliorating the symptoms of uremia in patients with progressive chronic kidney disease (CKD). It adsorbs the precursor of indoxyl sulfate in the intestines and prevents indoxyl sulfate production. Indoxyl sulfate, initially identified as a major uremic toxin that causes uremic symptoms, contributes to CKD progression. Although international multicenter prospective trials of AST-120 did not slow progression of CKD in patients with moderate to severe CKD, present study evaluated the efficacy of AST-120 in preventing the progression of CKD and its indication in our Japanese cohort.

Methods: Antihypertensive therapy using renin-angiotensin-aldosterone inhibitor (RAS-i) and a low-protein diet is conventionally used to treat patients with CKD. We retrospectively recruited 225 patients with CKD treated with AST-120 from 2014 to 2016. Changes of serum levels of blood urea nitrogen (BUN) and eGFR were analyzed for 4 years, from 1 year before medication. Moreover, we elucidated the recommended timing of initiation of AST-120 administration.

Results: The mean eGFR and BUN at the baseline were 25.7 ml/min/1.73m^2 and 33.1 mg/dL, respectively. Decline of eGFR before AST-120 treatment was -5.4 ml/min/1.73m^2/year. After 1-year and 3-year medication with AST-120, the decline of eGFR was significantly improved to -1.1 and -2.3 ml/min/1.73m^2/year, respectively. AST-120 treatment was effective to decline the eGFR slope even in patients with diabetes mellitus as well as patients with high amount of proteinuria (over 1.0g/gCr). We next divided patients into 3 groups depending on baseline eGFR, *i.e.*, >50 eGFR ≥40, >40 eGFR ≥30 and eGFR<30 ml/min/1.73m^2 groups. The effect of AST-120 to prevent progression of CKD was the highest in >50 eGFR ≥40 group in which decline of eGFR was -7.8 to -2.0 ml/min/1.73m^2/year during intervention period.

Conclusions: Present study suggests that treatment with AST-120 may delay the decline of renal function in patients with CKD. Especially, AST-120 administration is recommended to initiate relatively maintained renal function (>50 eGFR ≥40). AST120 is useful for management of CKD patients.

Randomized Controlled Trial of Long-Term Safety and Efficacy of Veverimer for Treatment of Metabolic Acidosis

Donald E. Wesson,[1] Vandana S. Mathur,[4] Navdeep Tangri,[6] Yuri Stasiv,[2] Dawn Parsell,[2] Elizabeth Li,[5] Gerrit Klaerner,[2] David A. Bushinsky.[3] *[1]Baylor Scott and White Health and Wellness Center, Dallas, TX; [2]Tricida, Inc., South San Francisco, CA; [3]University of Rochester Medical Center, Rochester, NY; [4]Mathur Consulting, Woodside, CA; [5]PharmaStat, LLC, Newark, CA; [6]Nephrology, University of Manitoba, Ottowa, MB, Canada.*

Background: Metabolic acidosis in CKD is associated with accelerated GFR decline, augmented muscle catabolism and increased mortality. Veverimer, an oral, non-absorbed, counterion-free, polymeric drug candidate, selectively binds and removes HCl from the GI lumen.

Methods: We report a multicenter, randomized, blinded, placebo-controlled, 40-wk extension (n=196) of a 12-wk parent study (n=217) in patients with CKD (eGFR 20-40 mL/min/1.73m^2) and metabolic acidosis (serum bicarbonate 12-20 mEq/L) randomly assigned (4:3) to veverimer or placebo. The primary endpoint was safety; secondary endpoints were effect on bicarbonate level, patient-reported physical function (Kidney Disease and Quality of Life Physical Functioning Domain [KDQOL-PFD] and objectively measured physical function (repeated chair stand [RCS] test). A pre-specified time to event analysis for the composite outcome of death, RRT or eGFR decline ≥50% was also performed.

Results: Fewer patients on veverimer than placebo discontinued treatment prematurely (2.6% vs 9.8%) or experienced a serious adverse event (1.8% vs. 4.9%). No patients on veverimer died (vs. 2 on placebo) or discontinued due to an adverse event (vs. 1 on placebo) and the frequencies of common adverse events were comparable between groups. More patients on veverimer than placebo had an increase in bicarbonate (≥4 mEq/L or normalization) at Week 52 (62.7% vs. 37.8%, p=0.001) and higher bicarbonate levels were observed on veverimer at all time points (p<0.001). The KDQOL-PFD score improved on veverimer vs. placebo, with a mean placebo-subtracted (SE) change at end of treatment of 12.1 (3.3) points (p<0.0001). Veverimer specifically improved ability to climb 1 flight of stairs (p<0.0001) and all measures of walking (p<0.01) on the KDQOL-PFD. Time to perform the RCS test decreased by 4.3 (1.2) sec on veverimer vs. 1.4 (1.2) sec on placebo (p<0.0001). Veverimer was associated with longer time to the kidney composite endpoint (annualized incidence rate 4.2% [veverimer] vs. 12.0% [placebo], p=0.022).

Conclusions: Veverimer safely and effectively improved metabolic acidosis in patients with CKD. Our multicenter, randomized, controlled trial adds to the evidence that treating metabolic acidosis slows progression of CKD and improves physical function.

PHYOX: A Safety and Tolerability Study of DCR-PHXC in Primary Hyperoxaluria Types 1 and 2

Bernd Hoppe,[1] Pierre Cochat,[2] Sandrine Lemoine,[3] Graham W. Lipkin,[7] Amanda M. Gentile,[4] Bob D. Brown,[4] Ralf Rosskamp,[4] Sally Hulton,[5] Jaap Groothoff,[8] Michelle A. Baum.[6] *[1]University Hospital Bonn, Bonn, Germany; [2]Université ClaudeBernard Lyon1-, Bron, France; [3]Edouard Herriot Hospital, Lyon, France; [4]Dicerna Pharmaceuticals, Cambridge, MA; [5]Birmingham Childrens' Hospital, Birmingham, United Kingdom; [6]Boston Children Hospital, Wareham, MA; [7]Queen Elizabeth Hospital, Bimingham, UK, Birmingham, United Kingdom; [8]Amsterdam UMC (Academic Medical Center), Amsterdam, Netherlands.*

Background: Primary Hyperoxaluria (PH) is characterized by hepatic overproduction of oxalate due to three distinct genetic mutations. DCR-PHXC is an investigational RNAi therapeutic targeting the LDHA enzyme, which is involved in the final step of hepatic oxalate production.

Methods: Preliminary data from the ongoing PHYOX study (ClinicalTrials.gov: NCT03392896), a two-part, single-ascending dose study conducted in 25 Healthy Volunteers (HVs, Group A) and 18 PH patients (Group B, reported here). Eligible PH patients have PH1 or PH2, urinary oxalate (Uox) ≥0.7mmol/24Hr, and eGFR ≥30 mL/min/1.73m2. Group B is open label and has three PH1 Cohorts dosed at 1.5, 3, and 6 mg/kg DCR-PHXC and a 4th PH1/PH2 cohort (1.5 and 3 mg/kg DCR-PHXC). The primary objective is safety. Change in 24Hr Uox from baseline (the mean of two screening 24Hr urine collections) was assessed.

Results: Safety Results: Group A is complete with no clinical meaningful safety signals and no serious adverse events (SAEs). Two mild injection site reactions (ISRs) occurred. Group B: Fifteen adult and three adolescent participants have been dosed. Four SAEs have occurred in three participants. Two SAEs of reoccurring fever, both unrelated to study drug, occurred in one participant. An SAE of ureteral stone occurred in a different participant and was unrelated to study drug. A fourth SAE of appendicitis was reported in another patient, also unrelated to study drug. All four SAEs are resolved. Seven participants experienced mild or moderate ISRs and all resolved within 96 hours. **Efficacy Results:** Group B: Preliminary results following a single administration of DCR-PHXC are captured in table 1. At 6mg/kg one participant experienced undetectable levels of Uox at Days 57 and 85.

Conclusions: Observed reduction of 24Hr Uox following a single administration of DCR-PHXC in both PH1 and PH2 participants is a promising sign of DCR-PHXC's potential potency and duration of action.

Funding: Commercial Support - Dicerna Pharmaceuticals

Levothyroxine in Proteinuric CKD Patients Decreases Proteinuria and Improves Kidney Function: A Randomized, Double-Blind, Clinical Trial

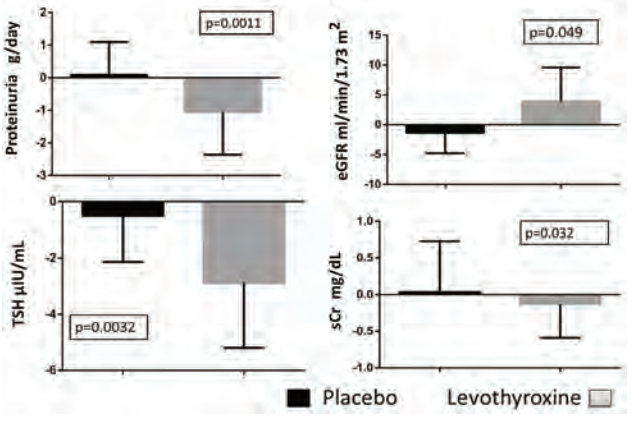
Guillermo Navarro Blackaller,[1,2] Guillermo Garcia-Garcia,[1,2] Jonathan Chavez,[1,2] Elsa edith Carreon bautista,[1,2] Pablo Maggiani,[1,2] Jorge I. Michel gonzález,[1,2] Francisco D. Romo rosales.[1,2] *[1]Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Universidad de Guadalajara, Guadalajara, Mexico.*

Background: Thyroid hormomes can affect kidney function. Elevated levels of TSH in CKD patients is associated to proteinuria, decrease in GFR, and progression to ESRD. We hypothesized that the use of levothyroxine (LTX) in proteinuric CKD patients with TSH levels between 2.5- 9.9 μIU/mL and normal FT4, decreases proteinuria and improves kidney function. Clinical trial registration number: NCT03898622

Methods: A double-blind, phase 2 randomized clinical trial, in proteinuric CKD patients, stage 3-5, not on dialysis, with TSH levels between 2.5-9.9 μIU/mL, and FreeT4 in a range of 0.7-1.8 ng/dL. All patients were already on ACE inhibitors or ARBs. Patients were randomized 1:1 to receive LTX (25-50mcg/day) or placebo for 12 weeks. The main outcomes were change in proteinuria, sCr, eGFR, TSH, and tolerability and safety of LTX.

Results: 163 patients were assessed for eligibility; 119 were excluded; 32 patients were randomized. Demographic and clinical characteristics between groups were similar. At 12 weeks, mean change in proteinuria (LTX vs placebo) was –1.1 (-4.1 to +0.9) g/day vs +0.20 (-0.4 to +2.1) g/day (p= 0.001); sCr –0.20 (-0.7 to +0.5) mg/dL vs +0.05 (-0.5 to +1.49) mg/dL (p=0.32); eGFR +4.04 ((+9.8 to -2.0) ml/min/1.73m^2 vs -1.96 ((-5.0 to +3.0) ml/min/1.73m^2 (p=0.049); and TSH -3.2 (-6.8 to +1.6) μIU/dL vs -0.4 (-3.09 a +1.87) μIU/dL (p=0.003), respectively (Fig 1). Adverse events were similar betwwen groups (7.14% vs 11.11%, p=1.0). No patient abandoned treatment because of adverse events.

Conclusions: LTX in proteinuric CKD patients decreased proteinuria and improved kidney function. Further studies are needed to determine the long-term impact of exogenous thyroid hormone treatment on proteinuria and CKD progression.



Mean change in proteinuria, sCr, eGFR, and TSH after 12-week treatment with LTX.

TH-PO451

Efficacy and Safety of Oral Ferric Maltol in Treating Iron-Deficiency Anemia in Patients with Non-Dialysis-Dependent CKD

Pablo E. Pergola,[1] Nelson P. Kopyt,[2] Mark R. Sampson.[3] *[1]Renal Associates, P.A., San Antonio, TX; [2]Lehigh Valley Hospital, Bethlehem, PA; [3]Shield Therapeutics, Knebworth, United Kingdom.*

Background: Iron-deficiency anemia (IDA) is a major cause of morbidity/mortality in CKD. Ferric maltol (FM) is an oral iron replacement therapy formulated to improve absorption and reduce adverse events (AEs). FM significantly increased hemoglobin (Hb) and iron indices from baseline to week 16 vs placebo (PL) in a phase 3 trial in patients with stage 3/4 CKD (Kopyt ASN 2018). We present 52-week data from that trial.

Methods: Patients aged ≥18 years with stage 3/4 CKD and IDA [Hb 8.0–11.0 g/dL + either ferritin <250 μg/L with transferrin saturation (TSAT) <25% or ferritin <500 μg/L with TSAT <15%] were randomized 2:1 to oral FM 30 mg or PL twice daily for 16 weeks, followed by open-label (OL) FM for a further 36 weeks. Changes from baseline to Week 52 in Hb, ferritin, and TSAT were assessed in the intent-to-treat population.

Results: Of 167 patients randomized (FM 111, PL 56), 125 started open-label FM, and 92 completed 52 weeks. Improvements in Hb and iron indices with FM during double-blind treatment were maintained with OL FM to Week 52, while changes in Hb and iron indices for those moving from PL to FM mirrored the changes seen with FM during double-blind treatment (Figure). Drug-related AEs (mostly gastrointestinal) were recorded in 24 patients in the OL phase. Eleven patients discontinued treatment because of AEs during the OL phase.

Conclusions: Long-term treatment with FM was associated with sustained and clinically meaningful increases in Hb and iron indices, further confirming efficacy of oral FM for treating IDA in patients with stage 3/4 CKD. There were no new safety signals with up to 52 weeks' treatment.

TH-PO452

The Effect of Proton Pump Inhibitor Use on the Development of Metabolic Acidosis and Decline in Kidney Function in Patients with CKD Stages G3a to G4

Sixto G. Giusti,[1] Yilu Lin,[3] Shuqian Liu,[1] Nazih L. Nakhoul,[2] Lizheng Shi,[1] Vecihi Batuman.[1] *[1]Tulane University, New Orleans, LA; [2]Tulane Medical School, New Orleans, LA; [3]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: Proton Pump Inhibitors (PPI) block H+, K+ - ATPase and are widely used for the treatment of GERD and PUD. H+-K+ ATPase is present in other organs, including the kidneys. Metabolic acidosis (MA) can hasten progression of kidney disease. We evaluated the relation between chronic PPI use in patients with CKD Stages G3a to G4, the development of MA, and the rate of decline in renal function. We hypothesized that CKD patients who have been on PPI for at least one year would have a higher prevalence of MA and faster progression of CKD compared to patients not on PPI therapy.

Methods: We extracted data of patients from the VA Informatics and Computing Infrastructure national database system. We included adult patients with CKD (eGFR <60 ml/min1.73m2) and a record of receiving care for at least 5 yrs at the VA starting on January 1, 1999, through May 31, 2018. We excluded patients on dialysis, patients that transitioned to renal transplant, or death. Our outcome measures included mean serum bicarbonate and progression of CKD, measured by the decline in GFR determined by the MDRD formula. We applied Propensity Score Matching to match the PPI group and the control group on age, sex, race, and Charlson Comorbidity Index. Kaplan-Meier curve & Cox regression were performed to analyze the associations of PPI use with MA, dialysis, all-cause mortality, and CKD progression (defined as a 10 unit decrease of eGFR from the baseline eGFR).

Results: The final sample included 1406 patients (age: 62.07±7.82, 62.02% of white) in PPI cohort with a median 4.7 yrs follow-up, and 573 patients (age: 63.25±7.00, 70.33% of white) in no-PPI cohort with a median 4.2 yrs follow-up. When compared to the no-PPI cohort, the PPI group had a significantly increased risk of CKD progression and dialysis (aHR, 1.43; 95% CI, 1.17 to 1.74; and aHR, 1.69; 95% CI, 1.03 to 2.77, respectively). Patients on PPI also had a higher risk of MA (aHR, 1.83; 95% CI, 0.88 to 3.82) and all-cause mortality (aHR, 1.25; 95% CI, 0.96 to 1.64), but these differences were not statistically significant.

Conclusions: The data suggest that chronic PPI accelerates progression of kidney disease in CKD patients. Chronic PPI use should be discouraged in this population.

A Metabolome-Wide Association Study of Kidney End Points in CKD Patients: Results from the GCKD Study

Inga Steinbrenner,[1] Peggy Sekula,[1] Ulla T. Schultheiss,[1] Matthias Schmid,[2] Kai-Uwe Eckardt,[3,4] Peter J. Oefner,[5] Anna Kottgen.[1] *[1]Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; [2]Department of Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Bonn, Germany; [3]Department of Nephrology and Medical Intensive Care, Charité – Universitätsmedizin Berlin, Berlin, Germany; [4]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander-Universität, Erlangen-Nürnberg, Erlangen, Germany; [5]Institute of Functional Genomics, University of Regensburg, Regensburg, Germany.*

Background: Chronic kidney disease (CKD) affects >10% of the adult population and is associated with increased risk of end-stage kidney disease (ESKD) and mortality. The underlying mechanisms are incompletely understood. A comprehensive screen of metabolites whose levels in urine are associated with kidney endpoints can identify novel biomarkers for CKD progression and may provide pathophysiological insights.

Methods: We performed Cox Proportional Hazards analyses relating incident kidney endpoints to levels of 1487 urinary metabolites quantified in 5088 participants of the German Chronic Kidney Disease (GCKD) study in a randomly selected discovery (N=3392) and replication (N=1696) sample adjusted for age, sex, eGFR and UACR at baseline. Main endpoints were time to ESKD (dialysis or transplantation) or renal death ("ESKD", N_{events}=241) and a composite endpoint that additionally included acute kidney injury AKIN stage 3 ("Composite", N_{events}=382). Urinary metabolites were measured using the Metabolon HD4 platform, $\log_2$-transformed and analyzed when quantified in at least 30 patients with an event. Cause-specific hazard (CSH) regression as well as subdistribution hazard (SH) analyses with death of other causes as a competing event were performed. Statistical significance was defined using a Bonferroni correction for the number of tested metabolites in both the discovery (p≤4e-05) and replication setting.

Results: Median follow-up time was 4.0 years. CSH analyses of the Composite and the ESKD event identified and replicated 20 and 8 significant metabolites, respectively. For the Composite event, there were both protective and harmful metabolites, with cause-specific hazard ratios ranging from 0.63 to 2.75 per doubling of metabolite levels. Many replicated metabolites have not yet been implicated in ESKD. They belong to different biochemical classes, with evidence for enrichment in one sub-pathway. Most associations remained after adjusting for additional clinical covariates. SH analyses showed almost identical results.

Conclusions: We identified 20 urinary metabolites significantly associated with adverse kidney events in a cohort of CKD patients, potentially providing new insights into the mechanisms of kidney disease progression.

Funding: Government Support - Non-U.S.

TH-PO454

A Randomized Controlled Trial of the Effects of Febuxostat Treatment on Markers of Endothelial Dysfunction and Renal Progression in Patients with CKD

Nanthawut Ninwisut, Naowanit Nata, Paramat Thimachai, Narittaya Varothai, Theerasak Tangwonglert, Pamila Tasanavipas, Amnart Chaiprasert, Ouppatham Supasyndh, Bancha Satirapoj. *Phramongkutklao hospital, Bangkok, Thailand.*

Background: Hyperuricemia relates to chronic kidney disease (CKD) progression, systemic inflammation and impaired endothelial function. Febuxostat, a novel nonpurine selective xanthine oxidase inhibitor, is potent and effective for decreasing serum uric acid levels. The study aimed to evaluate the effect of oral febuxostat on markers of endothelial dysfunction and renal function in CKD patients.

Methods: A total of 84 CKD stage III-IV patients with asymptomatic hyperuricemia were randomly assigned to either the febuxostat (40 mg/day, N=40) or the matching control (N=44) for 8 weeks. Serum uric acid, estimated glomerular filtration rate (eGFR), urine albumin, serum asymmetric dimethylarginine (ADMA), and high sensitivity C-reactive protein (hsCRP) were measured at baseline and at the end of study.

Results: Febuxostat administration significantly reduced the serum uric acid concentration in patients with CKD when compared with control [-3.40 (95% CI -4.19 to -2.62) vs. -0.35 (95% CI -0.76 to 0.06) mg/dL; P<0.001, respectively]. No significant difference in the changes in serum ADMA, hsCRP, eGFR and albuminuria, was identified between the two groups. Subgroup analysis in patients with decline serum uric acid after treatment, mean eGFR showed a significant increase in the febuxostat group (P=0.022), but no significant change in the palcebo group (P=0.802). The difference GFR change between groups was 1.97 ml/min/1.73 m^2 with 95%CI 0.15 to 4.64 at 8 weeks (P=0.03). Adverse events specific to febuxostat were not observed.

Conclusions: Febuxostat effectively reduced serum uric acid in the population of CKD without effect to endothelial dysfunction and systemic inflammation. It was able to preserve renal function in subgroup CKD patients with lower serum uric acid level after treatment.

TH-PO455

Long-Term Impact of Bariatric Surgery on Renal Outcomes at a Community-Based Publicly Funded Bariatric Program

Mark Mcisaac,[2] Maryam Jafari,[3] Bhanu Prasad.[1] *[1]Nephrology, RQHR, Regina, SK, Canada; [2]University of Saskatchewan, Oakville, ON, Canada; [3]RQHR-Research and Performance Support, Regina, SK, Canada.*

Background: Obesity is recognized as an independent risk factor for chronic kidney disease (CKD) through multiple direct and indirect biological pathways. Bariatric surgery is a proven, effective method for sustained weight loss. However, there is a relative paucity of data on the impact of bariatric surgery on renal outcomes.

Methods: 471 consecutive obese adult patients who underwent bariatric surgery between 2008-2015 were included in this observational retrospective cohort study. The patients were followed for two years post surgery at the Provincial Bariatric Surgery Clinic, Regina General Hospital, Saskatchewan. The primary objective was to evaluate the change in urine albumin/creatinine ratio (ACR) at the time of surgery and at 12 months post procedure. Secondary objectives were to determine the changes in ACR at (6 and 24 months), estimated glomerular filtration rate (eGFR) (6, 12 and 24 months), and HbA1c (12 and 24 months) post procedure. The change in body mass index (BMI), and metabolic outcomes (fasting glucose, total cholesterol, LDL, triglycerides, HbA1c) were also measured.

Results: Patients were predominantly female (81%) with a mean age (±SD) of 46 ± 10 years. The majority of patients (87%) had a BMI >40 kg/m2 and 81 % of the patients underwent Roux-en-Y gastric bypass. The mean BMI decreased from 47.7 ± 7.8 kg/m2 at baseline to 37.1 ± 7.9 kg/m2 at 6 months and 34.8 ± 8.8 kg/m2 at 12 months. In patients with microalbuminuria, ACR showed an improvement from a median [IQR] value of 5.1 [3.7-7.5] mg/mmol at baseline to 2.3 [1.2-3.6] mg/mmol at 6 months (p=0.007), to 1.4 [0.9-3.7] mg/mmol at 2-year follow-up (p < 0.001). Similarly, eGFR increased in patients with microalbuminuria from 109 ± 10 mL/min/1.73m2 at baseline to 120 ± 36 mL/min/1.73m2 at two-year follow-up (p=0.013). There were statistically significant reductions in triglycerides, fasting glucose, and HbA1c.

Conclusions: The results of our study suggest bariatric surgery significantly decreased weight and consequently improved renal outcomes. There was a significant improvement in albumin excretion rates and improvement in filtration rates. An improvement in metabolic outcomes was also seen (fasting glucose, cholesterol, and triglycerides) in patients with elevated BMI.

TH-PO456

Advanced CKD Is Associated with Higher and Not Lower Insulin Use

Daulton Grube,[2] Robert E. Boucher,[1] Na Zhou,[1] Guo Wei,[1] Debra L. Simmons,[3] Alfred K. Cheung,[1] Tom Greene,[1] Srinivasan Beddhu.[1] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]University of Washington, Rock Springs, WY; [3]University of Utah, Salt Lake City, UT.*

Background: As kidneys metabolize insulin, it is commonly held that insulin use is lower with more advanced CKD. On the other hand, more advanced CKD might result in progressive loss of beta cell function, increase in peripheral insulin resistance and contraindications to other antidiabetic medications, all of which might increase the need for insulin.

Methods: We related baseline level of kidney function with baseline and subsequent incidence of insulin use in 944,891 veterans in the VA system with a ICD-9 diagnosis of type 2 diabetes mellitus and at least one outpatient serum creatinine drawn between Jan 1, 2008 and Dec 31, 2010. Baseline and subsequent insulin use was identified by pharmacy data and tracked until Dec 31, 2013.

Results: There were 212,040 (22%) on insulin at baseline. Baseline characteristics by insulin use are summarized in Table. In a multivariable logistic regression model (adjusted for demographics, comorbidities, blood pressures, BMI, HbA1C and other anti-diabetic medications), compared to eGFR≥90, the odds ratios for baseline insulin use in those with eGFR of 30 to <45 and < 30 were 1.86 (95% CI 1.82 to 1.90) and 2.62 (2.19 to 2.34), respectively. Results were similar for incident insulin use in a Cox model adjusted for above (Fig).

Conclusions: Insulin use increased with more advanced CKD. Given the availability of newer anti-diabetic agents, the safety of insulin use in more advanced need to be evaluated in randomized controlled trials.

Proximal Tubular Secretory Clearance Is Associated with the Progression of CKD: The CRIC Study

Yan Chen,[1] Leila R. Zelnick,[2] Ke Wang,[1] Chi-yuan Hsu,[3] Alan S. Go,[4] Harold I. Feldman,[5] Rupal Mehta,[6] James P. Lash,[7] Sushrut S. Waikar,[8] L. Lee Hamm,[9] Tariq Shafi,[10] Stephen L. Seliger,[11] Michael Shlipak,[12] Mahboob Rahman,[13] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]University of California San Francisco, San Francisco, CA; [4]Kaiser Permanente Northern California, Oakland, CA; [5]University of Pennsylvania, Philadelphia, PA; [6]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [7]University of Illinois at Chicago, Chicago, IL; [8]Harvard Medical School, Boston, MA; [9]Tulane University School of Medicine, New Orleans, LA; [10]University of Mississippi Medical Center, Jackson, MS; [11]University of Maryland School of Medicine, Baltimore, MD; [12]San Francisco VA Medical Center, San Francisco, CA; [13]Case Western Reserve University, Cleveland, OH.*

Background: The secretion of organic solutes by the proximal tubules is an essential intrinsic kidney function. The clinical significance of tubular secretory clearance is uncertain.

Methods: We evaluated 3,416 participants from the Chronic Renal Insufficiency Cohort (CRIC) Study. We estimated the kidney clearances of 11 endogenous secretory solutes based on their measured concentrations in paired 24-hour urine and plasma samples at baseline using targeted mass spectrometry. CKD progression was defined by a 50% decline in the estimated glomerular filtration rate (eGFR), initiation of maintenance dialysis, or kidney transplantation. We used Cox proportional hazards regression to test associations of secretory solute clearances with CKD progression and all-cause mortality, adjusting for eGFR, albuminuria, and other potential confounders.

Results: There were 1,206 CKD progression events and 1,004 mortality events over a median follow-up of 6.0 and 9.6 years, respectively. After adjustment for eGFR, albuminuria, and other risk factors, lower kidney clearances of six secretory solutes (cinnamoylglycine, indoxyl sulfate, isovalerylglycine, kynurenic acid, pyridoxic acid, and xanthosine) were associated with greater risks of CKD progression (11%-21% greater risk per 50% lower secretory clearance; Table). Lower clearances of four solutes (hippurate, isovalerylglycine, tiglylglycine, and trimethyluric acid) were associated with all-cause mortality after adjustment.

Conclusions: Lower proximal tubular secretory solute clearance is associated with greater risks of CKD progression and all-cause mortality independent of eGFR and albuminuria. These findings suggest that estimates of tubular secretory clearances may provide complementary information to existing measures of glomerular filtration and integrity.

Funding: NIDDK Support

Table. Adjusted associations between secretory solute clearances and outcomes.

	CKD progression			All-cause mortality		
	HR[a]	95% CI	P-value[b]	HR	95% CI	P-value

Therapeutic Drug Monitoring Is Associated with Better Survival in Hospitalized Nondialysis CKD Patients Treated with Vancomycin

Yi-sheng Lin, Yuehlin Wu, Hsiao-Yun Hu, Feng shiang Cheng. *Taipei City Hospital, Taipei, Taiwan.*

Background: Vancomycin is widely used to treat patients infected by Gram-positive bacteria. Therapeutic drug monitoring (TDM) is routinely recommended for all patients treated with vancomycin to avoid underdoing and minimize the risk of toxicity. There are few studies, however, investigating the relationship between the TDM and clinical outcome in patient with chronic kidney disease treated with vancomycin.

Methods: We conducted a nationwide, observational population-based cohort. Claim data from Longitudinal Health Insurance Databases 2010 (LHID2010) which randomly chose one million beneficiaries from Taiwan's National Health Insurance Research Database are used. From LHID2010, all hospitalized non-dialysis chronic kidney patients (ND-CKD) who were more than 20 years old, less than 85 year old, and received vancomycin treatment were recruited. All subjected are grouped according to whether the application of TDM or not. Cox regression was performed to assess the relationship between vancomycin TDM and mortality within 90 days.

Results: There were 3434 patients enrolled for analysis. There were 762 patients (22.2%) received TDM. There was no significant difference between these two groups with the aspect of demographic and comorbidity(gender, age, hypertension, diabetes mellitus, heart failure, coronary artery disease, cerebrovascular accident, peripheral arterial disease, chronic obstructive pulmonary disease, liver disease, and malignancy), except that patients in medical centers received more TMD than those in non-medical centers(27.3% vs. 19.4%; p <0.001). Cox regression model indicated that TDM was associated with decreased risk for 90-day mortality (adjusted hazard ratio: 0.46; 95% confidence interval: 0.34-0.63; p <0.001). Moreover, age, male, heart failure, liver disease, and malignancy were also associated with increased mortality risk.

Conclusions: This is the first study to evaluate the importance of TDM in ND-CKD patients received vancomycin. In real practice, the application of TDM of vancomycin was even unexpectedly low in ND-CKD patients. Our results show ND-CKD patient with TDM of vancomycin is associated with reduced risk of mortality. The TDM of vancomycin in ND-CKD patients cannot be overemphasized.

TH-PO459

Frequency of eGFR and Albuminuria Measurement in Patients with Diabetes and/or Hypertension in 27 Health Care Organizations

Nikita Stempniewicz,[1] Elizabeth Ciemins,[1] Yingying Sang,[2] Kunihiro Matsushita,[2] Shoshana Ballew,[2] Morgan Grams,[3] Alex R. Chang,[4] Andrew S. Levey,[5] John K. Cuddeback,[1] Josef Coresh.[6,2] *[1]AMGA (American Medical Group Association), Alexandria, VA; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Geisinger Medical Center, Danville, PA; [5]Tufts Medical Center, Boston, MA; [6]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD.*

Background: Clinical guidelines for diabetes recommend screening for chronic kidney disease annually with spot urinary albumin-to-creatinine ratio (uACR) and estimated glomerular filtration rate (eGFR). For hypertension, measures are recommended at diagnosis to establish a baseline for medication use, and to screen for secondary causes of hypertension, with eGFR listed as a basic test, and uACR optional.

Methods: Using a large, geographically diverse clinical dataset from 27 health care organizations (HCOs), 580,950 patients with diabetes and 1,558,525 patients with hypertension were identified, among a population aged 18-85, with ≥ 1 face-to-face ambulatory encounter with a primary care provider in 2018, and no prior evidence of end stage renal disease. Measurement rates were described in 1-year (2018), 2-year (2017-2018), and 3-year (2016-2018) periods, overall and for HCOs at the 5th and 95th percentile. Measurements were limited to quantitative values recorded in a structured field in the HCOs' electronic health records.

Results: Overall, 89.1% of patients with diabetes and 85.1% with hypertension had eGFR measured in the 1-year period. Measurement rates for uACR were 45.2% for diabetes and 16.5% for hypertension in the 1-year period, and increased to 65.3% and 24.8% using the 3-year measurement period. Rates varied considerably across HCOs for uACR (e.g., 5th and 95th percentiles for the 3-year period were 25.3% and 79.6% among patients with diabetes). When limiting to patients with hypertension but no diabetes, uACR measurement rates were very low, even with eGFR < 60 (i.e., CKD G3+).

Conclusions: Most patients with diabetes or hypertension have eGFR measured, consistent with recommendations from clinical guidelines. uACR measurement rates were moderate and variable across HCOs among patients with diabetes, demonstrating an opportunity for improvement in clinical practice. Measurement rates for uACR were very low for hypertension without diabetes, even in the presence of reduced eGFR.

Lab	Measurement Period	Diabetes (DM)	Hypertension		
		All Patients (n = 580,950) Overall (5th - 95th percentile)	All Patients (n = 1,558,525) Overall (5th - 95th percentile)	No Diabetes (n = 1,096,955) Overall (5th - 95th percentile)	No DM, and eGFR < 60 (n = 161,242) Overall (5th - 95th percentile)
estimated GFR (eGFR)	1 year	89.1% (78.5 - 93.7%)	85.1% (74.4 - 89.5%)	82.7% (71.9 - 87.3%)	
	2 year	94.9% (84.4 - 97.9%)	93.1% (82.3 - 96.6%)	91.9% (80.7 - 95.7%)	
	3 year	96.0% (85.9 - 98.6%)	94.7% (84.2 - 97.8%)	93.9% (82.8 - 97.2%)	
Urine albumin to creatinine ratio (uACR)	1 year	45.2% (17.8 - 60.5%)	16.5% (5.9 - 23.7%)	3.7% (0.6 - 7.0%)	6.0% (0.8 - 10.9%)
	2 year	59.3% (23.1 - 75.0%)	22.1% (7.6 - 30.0%)	5.6% (1.3 - 9.5%)	8.7% (1.6 - 14.7%)
	3 year	65.3% (25.3 - 79.6%)	24.8% (8.4 - 32.6%)	6.9% (1.8 - 11.5%)	10.6% (2.6 - 18.2%)

Overall rates are patient weighted across all health care organizations (HCOs). Percentiles are calculated among the individual HCOs. Standard errors were <2.0% for each HCO and measure shown.

TH-PO460

Anti-Inflammatory Therapy in CKD Using Drug-Delivery Technology: Mechanisms and Effects of Renal NFkB Inhibition

Alejandro R. Chade,[1] Jason E. Engel,[2] Erika Williams,[2] Maxx Williams,[1] John A. Howell,[2] Gene L. Bidwell.[2] *[1]University of Mississippi, Jackson, MS; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: The NFkB pathway mediates chronic inflammation in chronic kidney disease (CKD). The NFkB p50/p65 heterodimer, once activated, translocates into the cell nucleus to stimulate inflammation via defining macrophage phenotype and production of inflammatory cytokines. We designed a construct of an inhibitor of the NFkB-p50 subunit (p50i) fused to a drug carrier (elastin-like polypeptide, ELP) equipped with a cell-penetrating peptide. We hypothesize that ELP-p50i therapy will inhibit production of inflammatory cytokines, ameliorate renal inflammation and injury in CKD

Methods: We first exposed LPS-stimulated macrophages to ELP-p50i to confirm its NFkB inhibitory activity. Next, CKD was induced in 10 pigs (bilateral renal artery stenosis+dyslipidemia). After 6 weeks of CKD, pigs were treated with single intra-renal ELP-p50i therapy (10 mg/kg) or placebo (n=5 each). Glomerular filtration (GFR) was quantified using multi-detector CT before and 8 weeks after treatment. Pigs were then euthanized and renal expression of NFkB, downstream mediators of NFkB signaling, circulating inflammatory cytokines, and renal morphology were quantified

Results: ELP-p50i inhibits nuclear translocation of NFkB in vitro. Fourteen weeks of CKD increased renal NFkB nuclear expression and renal mRNA expression of downstream mediators (TNF-α, MCP-1, and IL-6), accompanied by blunted GFR, increased plasma creatinine, and renal fibrosis. All these changes were improved after ELP-p50i therapy. Notably, intra-renal therapy also reduced circulating TNF-α and MCP-1 in CKD (Figure)

Conclusions: Our study provides mechanistic support, *in vitro* and *in vivo*, to the therapeutic potential of a targeted anti-inflammatory strategy using a novel drug-delivery technology. It also suggests that the kidney in CKD is both a source and target of inflammation that could be offset via specific molecular inhibition of NFkB signaling

Proximal Tubule Activation of B-Catenin Ameliorates Chronic Kidney Injury in Mice

Stellor Nlandu khodo,[1] Jane M. Tonello,[2] Melanie Phillips Mignemi,[2] Leslie S. Gewin.[3] *[1]Institute of Physiology, University of Zurich, Zurich, Switzerland; [2]Vanderbilt Medical Center, Nashville, TN; [3]Vanderbilt University, Nashville, TN.*

Background: Tubulointerstitial fibrosis (TIF) is the hallmark of chronic kidney disease (CKD), and growth factors play an important role in injury and TIF. The Wnt/b-catenin pathway has been shown to be protective in acute kidney injury (AKI), but is thought to promote CKD progression, likely mediated by b-catenin signaling in mesenchymal cells. However, the cell-autonomous effects of b-catenin signaling on chronically injured tubules remains unknown.

Methods: To address how proximal tubule (PT)-specific b-catenin alters the response to chronic injury, we generated conditional mice with constitutive activation of b-catenin in the PT (gGT-Cre;Ctnnb1$^{ex3fl/fl}$). We injured these mice and their floxed littermates using two models of AKI to CKD: aristolochic acid nephropathy (AAN) and ischemia reperfusion (IRI) plus delayed contralateral nephrectomy. We used murine PT cells for in vitro studies.

Results: Surprisingly, 6 weeks after AAN, injury score, KIM-1 transcript, cortical fibrosis and BUN levels were decreased in conditional mice compared to their controls, suggesting that b-catenin signaling in the PT is protective. Cortical tubular apoptosis was decreased in the conditional mice. Consistently, stabilizing b-catenin in vitro (Wnt3a or GSK-3 inhibitor) also reduced aristolochic acid (AA)-induced apoptosis. Oxidative stress reportedly switches b-catenin transcriptional binding partners from LEF/TCF to FoxO, but this has not been examined in PT cells. We found that oxidative stress, present in CKD, reduced LEF/TCF-dependent transcription in PT cells (Topflash and Axin2 mRNA)

and augmented FoxO3 activity. Co-IP studies showed that oxidative stress plus Wnt3a significantly increases nuclear FoxO3/b-catenin interactions. In the AAN model, injured conditional b-catenin mice have augmented nuclear FoxO3 expression in proximal tubules. Furthermore, FoxO3 was required for b-catenin's protective effect as mice with PT-specific b-catenin stabilization and FoxO3 deletion (using gGT-Cre) lost the protective effect in AAN. RNAseq on PT cells was performed and identified 19 novel b-catenin and FoxO3 targets.

Conclusions: In conclusion, b-catenin signaling within the proximal tubule mitigates AKI to CKD transition through its interaction with FoxO3. Ongoing efforts are examining this b-catenin effect in the IRI and validating novel targets in vivo.

Inhibition of Nα-Acetyltransferase Attenuates Renal Interstitial Fibrosis via Modulation of Epithelial-to-Mesenchymal Transition and Inflammation

Jongho Son,[1] Sungjin Chung,[2] Seok Joon Shin,[3] Cheol Whee Park,[2] Chul Woo Yang,[2] Eun Sil Koh.[2] *[1]The Catholic Universiry of Korea Yeouido St. Mary's Hospital, Seoul, Republic of Korea; [2]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [3]Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Incheon, Republic of Korea.*

Background: Nα-acetyltransferase 10 (Naa10), the catalytic subunit of N-acetyltransferase A, has been reported to be involved in the regulation of telomerase activity, DNA damage response, cytokinesis, microtubule reorganization and histone acetylation. This study was designed to investigate whether the pharmacological inhibition of Naa10 could affect the progression of renal tubulointerstitial fibrosis.

Methods: Remodelin 1mg/kg, a Naa10 inhibitor, was administered to the mice for 3 or 7 days following unilateral ureteral obstruction (UUO).

Results: Renal Naa10 expression after UUO was significantly enhanced but reduced by the Naa10 inhibitor remodelin. Masson trichrome and Sirius red staining demonstrated that Naa10 inhibition led to a decrease in renal interstitial fibrosis induced by UUO. In addition, the α-SMA- or TUNEL-positive cells were apparently decreased in obstructed kidneys with administration of remodelin. Furthermore, remodelin inhibited the increase in the mRNA levels of α-SMA, fibronectin, MMP-2, IL-1β, IL-6, TNF-α, TGF-β1 and ColIV without significant changes in mRNA levels of vimentin, E-cadherin and VE-cadherin and protein expressions of Nox1, Nox2, Nox4, SOD1, HO-1, NQO1 and catalase in obstructed kidneys. All these findings were apparent at day 7 after UUO. Collectively, these results indicate that longer treatment of remodelin mitigates UUO-induced renal interstitial fibrosis by affecting epithelial-to-mesenchymal transition (EMT) and inflammation.

Conclusions: Current study suggests that Naa10 inhibition could attenuate renal fibrosis through regulation of certain EMT- and inflammation-related factors.

Proximal Tubule-Derived Amphiregulin Amplifies and Integrates Profibrotic EGFR Signals in Kidney Fibrosis

Eirini Kefalogianni,[1] Manikanda raja Keerthi raja,[4] Julian Schumacher,[3] Sushrut S. Waikar,[2] Andreas Herrlich.[3] *[1]Washington University School of Medicine, St. Louis, MO; [2]Harvard Medical School, Boston, MA; [3]Washington University in St. Louis, St. Louis, MO; [4]University of South Carolina, Columbia, SC.*

Background: Sustained activation of epidermal-growth-factor-receptor (EGFR) in proximal-tubule-cells (PTCs) is a hallmark of progressive kidney fibrosis after acute-kidney-injury (AKI) and in chronic-kidney-disease (CKD), but the molecular mechanism(s) and particular EGFR ligands involved are unknown.

Methods: We studied EGFR activation in PTCs and in primary tubular cells isolated from injured kidneys *in vitro.* To determine the role of amphiregulin (AREG), a highly injury-upregulated low-affinity EGFR ligand *in vivo*, we used ischemia-reperfusion-injury (IRI) or unilateral-ureteral-obstruction (UUO) in AREG PTC-KO mice, or injection of soluble AREG (sAREG) into mice with PTC-KO of its releasing enzyme, a-disintegrin-and-metalloprotease-17 (ADAM17), and into ADAM17 hypomorphic mice. Serum AREG was measured by ELISA in a CKD patient cohort.

Results: We show that Yes-associated-protein-1 (YAP1)-dependent upregulation of AREG transcript and protein amplifies AREG signaling in a positive feedback loop and integrates signals of other moderately injury-upregulated low-affinity EGFR ligands (epiregulin, epigen, TGFα), which we show also require sAREG and YAP1 to induce sustained EGFR activation in PTCs *in vitro*. *In vivo*, sAREG injection sufficed to reverse protection from fibrosis after IRI in ADAM17 hypomorphic mice, and to reverse the corresponding protective PTC phenotype in injured ADAM17 PTC-knockout mice. AREG was necessary for the development of fibrosis, as AREG PTC-knockout mice were protected from fibrosis after IRI or UUO. In a nephrectomy cohort (n=78) of CKD patients, serum sAREG negatively correlated with kidney function.

Conclusions: Our results identify AREG as a key player in injury-induced kidney fibrosis and suggest therapeutic or diagnostic applications of sAREG in kidney disease.

TH-PO464

Graphene Quantum Dots Suppress Kidney Fibrosis After AKI by Affecting the Pericyte-Myofibroblast Transition

Lilin Li,[1] Seung Hee Yang,[2] Joo Hong Joun,[3] Jung Nam An,[4] Jeonghwan Lee,[4] Jung Pyo Lee.[1,4] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Department of Internal Medicine-Nephrology, Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Department of Medicine, Seoul National University, Seoul, Republic of Korea; [4]Department of Medicine, Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Renal pericytes are important in the pathogenesis of kidney disease. They are key to vascular survival can contribute to glomerular and interstitial fibrosis. Graphene quantum dots (GQDs) are novel nanomaterials with excellent biocompatibility. They have anti-oxidative, anti-inflammatory and immune regulatory effects. The purpose of this study is to demonstrate that GQDs can inhibit pericyte activation and reduce the conversion of pericytes into myofibroblasts, thereby suppress kidney fibrosis after acute kidney injury.

Methods: Unilateral ischemia-reperfusion injury (UIRI) was induced in 7- to 8-wk-old male wild-type C57BL6 mice. GQDs were injected in kidney fibrosis models through the tail vein and the animals were observed for 6 wk. Histopathological examination was performed on the kidneys using Masson's trichrome staining, and pericyte detection in tissue by Immunofluorescence technique. rhTGF-β1 was used in vitro experiments to induce pericyte-myofibroblast transition. Western blot analysis was used to detect the expression of fibrotic markers.

Results: At 6 wk after UIRI, GQDs treatment significantly attenuated interstitial fibrosis in UIRI models. GQDs administration significantly reduced the expression of α-smooth muscle actin, collagen I, and fibronectin, vimentin,TGF-beta1, Bax, and increased the expression of E-cadherin, smad7, and bcl2. In addition, the expression of PDGFR in the URI group was significantly increased compared with the control group, only a small part overlapped with NG2, and the overlap was significantly less than that of the normal group and away from the endothelial cells. Compared with the UIRI group, the expression of PDGFR was significantly decreased after GQDs treatment, and the overlap of PDGFR and NG2 was increased, and the signs of pericytes away from endothelial cells were improved. rhTGF-β1 was used in vitro experiments to induce pericyte injury, and the expression of NG2, a-SMA and collagen 1a1 was increased compared with the control group, and the dose-dependent decrease was observed after treatment with various concentrations of GQDs

Conclusions: We found that non-toxic doses of GQDs protect pericyte damage and inhibit the transformation of pericytes into myofibroblasts, there by plays an important role in anti-fibrotic processes after acute kidney injury.

TH-PO465

The Deletion of Akt1 Exacerbates the Renal Fibrosis via Transforming Growth Factor β1 Induction

Il Young Kim,[1] Byung Min Ye,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Miyeun Han,[2] Harin Rhee,[2] Eun Young Seong,[2] Sang Heon Song.[2] *[1]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [2]Pusan National University Hospital, Busan, Republic of Korea.*

Background: Renal fibrosis is the hallmark of all progressive kidney disease. However, the mechanisms of renal fibrosis are poorly understood. Previous studies have found the increased Akt activity in experimental renal fibrosis. In this study, we investigated the role of Akt1, one of the three Akt isoforms, in renal fibrosis using the murine model of unilateral ureteral obstruction (UUO).

Methods: In vivo, we subjected the wild type and *Akt1*$^{-/-}$ mice to UUO. In vitro, gene silencing of Akt1 was achieved using the short hairpin RNA delivered by the lentiviral vector in immortalized human proximal tubular cells (HK2 cells) and rat kidney fibroblasts (NRK-49F cells). Western blot and immunohistochemical stain were used to investigate the mode of action of Akt1 in vivo and in vitro.

Results: In immunohistochemical stain, the expression of Akt1 was significantly higher in obstructed kidneys of wild type mice compared with control sham kidneys and increased gradually as UUO progressed. The fibronectin, type I collagen, and heat shock protein 47 (HSP47) were markedly more expressed in obstructed kidneys of *Akt1*$^{-/-}$ mice than in those of the wild type mice. Transforming growth factor β1 (TGFβ1) was highly induced within 1 day of UUO in obstructed kidneys of *Akt1*$^{-/-}$ mice and the expression of TGFβ1 was significantly higher in the *Akt1*$^{-/-}$ mice than in the wild type mice as UUO progressed. Western blot showed that silencing of Akt1 increased the expression of TGFβ1, which was enhanced by angiotensin II stimulation in HK2 cells, but not in NRK-49F cells. Immunohistochemical stain demonstrated that the expression of cleaved caspase-3 in renal tubules was significantly higher in the *Akt1*$^{-/-}$ mice than in the wild type mice. Western blot showed that silencing of Akt1 increased the expression of cleaved caspase-3 in HK2 cells, but not in NRK-49F cells.

Conclusions: TGFβ1 was induced in vivo and in vitro by the genetic deletion of Akt1. Our findings suggest that deletion of Akt1 might contribute to renal fibrosis and tubular apoptosis via TGFβ1 induction.

TH-PO466

Knockout of Interleukin-36 Receptor Ameliorates AKI-to-CKD Transition via Prevention of Fibrosis and Inflammasome

Kadowaki Yuji,[1] Yoshio Terada,[2] Shimpei Fujimoto,[3] Yoshinori Taniguchi,[3] Masami Ogasawara,[4] Hirofumi Nishikawa,[3] Taro Horino,[5] Satoshi Inotani.[4] *[1]kochi medical school, Nankoku-city, Japan; [2]Kochi Medical School, Nankoku-city, Japan; [3]Kochi University, Nankoku, Japan; [4]Kochi university, Nankokushi, Japan; [5]Kochi Medical School, Kochi University, Kochi, Japan.*

Background: IL-36, a newly named member of the IL-1 cytokine family, includes 3 isoforms, IL-36α, IL-36β, and IL-36γ, all of which bind to a heterodimer containing IL-36 receptor (IL-36R). Little is known about the role of the IL-36 axis in fibrosis during AKI to CKD transition. We examined IL-36 function using mice AKI to CKD models and clinical samples.

Methods: We evaluated IL-36 function in two models of AKI to CKD transition by using IL-36R knockout (KO) and wild-type (WT) mice. First model, left renal ischemia was performed for 35min and right kidney was removed 21days later, and left kidney analyses at 28 days (IRI). Second model, we used aristolochic acid toxic nephropathy (AAN) in mice at 28 days. We evaluate the renal function and histological analysis of KO and WT mice in both models. Fibrotic changes and inflammasome were evaluated by RT-PCR, Western blot analysis. Immunohistologial analysis of collagen type IV, CTGF, and Masson trichrome staining were performed. In clinical study, we performed immunohistological examination of IL-36α in AKI to CKD patients renal biopsy sample.

Results: IL-36R was found to be expressed in the kidney mainly in proximal tubules in WT mice. IL-36R KO mice had significantly lower Cr and BUN at 28 days compared to WT mice in both models. Immunohistological examination showed mild tubular injury and fibrotic change in IL-36R KO mice compared to WT mice in both models. IL-36α/β/γ levels were increased after IRI and AAN, and IL-36α was expressed in lymphocytes and renal tubular cells. Immunohistologial analysis of collagen type IV and CTGF, and Masson trichrome staining revealed that massive fibrotic changes were observed in WT mice compared to KO mice. Protein expression of collagen type IV, CTGF, and inflammasome proteins(NLRP3, IL-1b, caspase 1) were also increased in WT mice compared to KO mice. IL-36α staining in renal-biopsy samples of AKI to CKD patients was enhanced.

Conclusions: Our results demonstrate that IL-36α is up-regulated in renal tissues in both mouse and human AKI to CKD transition, and that IL-36α stimulates collagen type IV, CTGF, and inflammasome in AKI to CKD transition models. Thus, IL-36α/IL-36R blockage could serve as a potential therapeutic target in AKI to CKD transition.

TH-PO467

The Novel NQO1 Donor Reduced Renal Fibrosis in Unilateral Ureteral Obstruction Mice

Dae Eun Choi,[2] Tae Woong Hwang,[2] Da bi Kim,[1,2] Eunji Kim,[1,2] Jin young Jeong,[1,2] Jwajin Kim,[2] Hae Ri Kim,[2] Jae wan Jeon,[2] Youngrok Ham,[2] Ki Ryang Na,[2] Kang Wook Lee,[2] Wonjung Choi,[2] Yoon-Kyung Chang.[3] *[1]Department of Medical Science, Chungnam National University, Daejeon, Republic of Korea; [2]Nephrology, Chungnam National University, Daejeon, Republic of Korea; [3]The Catholic University of Korea, Daejeon, Republic of Korea.*

Background: Reactive oxygen species (ROS) are thought to be a major factor in the development of acute renal injury and renal fibrosis in unilateral ureteral obstruction (UUO). NAD(P)H:quinone oxidoreductase 1 (NQO1) is a well-known antioxidant protein that regulates ROS generation. We generate the NQO1 donor, KL1333 and investigate whether KL1333 modulates the renal injury in UUO mice.

Methods: in vivo, 10 weeks old C57BL/6 male mice were divided 4 groups as following, sham, sham with KL1333, UUO, UUO with KL1333. KL1333 was treated oral route, 10mg/kg, daily. UUO were generated by tying left ureter, and after 7 days, the mice were sacrificed and kidney tissue were collected. in vitro, TGF beta treated HK2 cell were used. We analyzed renal injury using various stains, oxidative stress and tubular apoptosis using western blot and immunohistochemical stains.

Results: UUO mice kidney showed increased alpha SMA, collagen, masson trichrome stained area, and renal inflammation, compared to sham kidney. the KL1333 treatment decreased alpha SMA, collagen, masson trichrome stained area, and renal inflammation in UUO mice kidney. In addition, KL1333 increased the levels of HO-1, catalase, UCP2 in UUO mice kidney. Also, KL1333 increased NQO1, p-sirt1, and NAD+/NADH ratios in UUO mice. These finding indicate that KL1333 decreased UOO-induced oxidative stress and renal fibrosis.

Conclusions: NQO1 activation using KL1333 might be beneficial for ameliorating renal injury induced by UUO mice.

TH-PO468

Regulation of Renal Fibroblast Functions by Myocardin-Related Transcription Factor Focal Adhesion in Response to TGFβ$_1$

Norihiko Sakai,[1,2] Koichi Sato,[2] Hisayuki Ogura,[2] Taro Miyagawa,[2] Shinji Kitajima,[2] Tadashi Toyama,[2] Akinori Hara,[2] Yasunori Iwata,[2] Miho Shimizu,[2] Kengo Furuichi,[3] Takashi Wada.[2] *[1]Division of Blood Purification, Kanazawa University Hospital, Kanazawa, Japan; [2]Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan; [3]Department of Nephrology, Kanazawa Medical University, Kahoku-Gun, Japan.*

Background: Renal fibrosis is a common pathway resulting in end-stage renal disease regardless of their etiologies. As pathological findings, tissue fibrosis is characterized by the accumulation of fibroblasts and the excessive deposition of extracellular matrix (ECM). In general, cells can contact with ECM via multiprotein structures called focal adhesion composed of various cytoskeletal proteins and integrins. We have previously found the lipid mediator lysophosphatidic acid (LPA) and one of its receptors, LPA$_1$, contributes to the development of renal fibrosis through connective tissue growth factor (CTGF) expression, at least in part, via myocardin-related transcription factors (MRTFs; MRTF-A and MRTF-B). Recently, TGFβ$_1$ has also been reported to be involved in MRTFs pathway, however, the precise mechanisms how TGFβ$_1$-MRTFs signaling contributes to the regulation of renal fibroblast activities through focal adhesion remain to be investigated.

Methods: In this study, we focused on the effects of TGFβ$_1$ signaling on the activities of renal fibroblasts, especially through MRTFs signaling. Cultured renal fibroblasts were used to examine the activation of MRTFs signaling using promoter assays and the expressions of molecules in response to TGFβ$_1$. Renal fibroblasts were transfected with either siRNA targeting MRTFs or focal adhesion components to determine the impact of MRTFs-focal adhesion on renal fibroblast biologies.

Results: Promoter assay showed the activation of MRTFs signaling by TGFβ$_1$ in a dose- and a time-dependent manner in renal fibroblasts. The stimulation of renal fibroblasts with TGFβ$_1$ increased CTGF expression, while siRNA treatment targeting MRTFs suppressed it. In addition, TGFβ$_1$ enhanced fibronectin, various integrins (αv, β1 and β5) and cytoskeletal proteins such as zyxin and talin, all of which were MRTFs-dependent. The treatment of renal fibroblasts with integrin αv siRNA or integrin-linked kinase inhibitor attenuated CTGF expression in response to TGFβ$_1$. Finally, TGFβ$_1$ stimulated the proliferation of renal fibroblasts, however, CTGF siRNA treatment suppressed it.

Conclusions: Our results suggest that MRTF signaling mediates renal fibroblast biologies through focal adhesion formation in response to TGFβ$_1$.

Macrophage IRF4 Deletion Protects Against Renal Fibrosis as a Result of Decreased Macrophage Recruitment and Activation

Kensuke Sasaki, Yu Pan, Guannan Jin, Aolei Niu, Yinqiu Wang, Suwan Wang, Xiaofeng Fan, Raymond C. Harris, Ming-Zhi Zhang. *Vanderbilt University Medical School, Nashville, TN.*

Background: Macrophage infiltration and polarization plays a key role in recovery from acute kidney injury (AKI). Previous studies have indicated that persistent and aberrant presence of M2 macrophages leads to renal fibrosis after AKI. Interferon regulatory factor 4 (IRF4) plays an important role in macrophage M2 polarization. We examined the role of macrophage IRF4 in renal macrophage polarization and development of fibrosis after AKI.

Methods: Wild type (WT, IRF4$^{f/f}$) or LysM-Cre; IRF4$^{f/f}$ (macrophage IRF4$^{-/-}$) mice (male, 3 months, C57BL/6) were uninephrectomized, immediately followed by 32 min ischemia-reperfusion injury. Renal macrophages were isolated with a mixture of CD11b and CD11c microbeads. Bone marrow derived monocytes (BMDMs) were isolated and used for *in vitro* transwell migration and *in vivo* PHK26-labeled BMDM migration into injury WT kidneys. Peritonitis was induced by peritoneal injection of 3 ml of 4% thioglycolate.

Results: Compared to WT mice, LysM-Cre; IRF4$^{f/f}$ mice developed less renal fibrosis 4 weeks after severe AKI, as indicated by Sirius red staining and decreased profibrotic and fibrotic components including TGF-β1, TGF-β2, CTGF, α-SMA, fibronectin, and collagens I, III, IV. LysM-Cre; IRF4$^{f/f}$ mice had significantly fewer renal macrophages with less activation, as indicated by decreases in both Th1/M1 proinflammatory cytokines (TNF-α, MCP-1, IL-1α, IL-6, and IL-23α) and Th2/M2 pro-fibrotic cytokines (FIZZ1, CD206, CD209, B7-H4, IL-4Rα, and arginase 1). Flow cytometry and qPCR also determined low number and less activated renal macrophages (low levels of both Th1/M1 and Th2/M2 cytokines) in LysM-Cre; IRF4$^{f/f}$ compared to WT mice at 1 and 5 days after AKI. An *in vitro* migration assay showed that IRF4-/- BMDMs had decreased migratory ability. IRF4-/- BMDMs also had decreased ability to infiltrate into injured kidney as indicated by fewer renal PKH26 and F4/80 double positive cells. Finally, LysM-Cre; IRF4$^{f/f}$ mice had attenuated peritoneal macrophage infiltration in thioglycolate-induced peritonitis.

Conclusions: Macrophage IRF4 deletion protects against renal fibrosis after severe AKI, at least due in part to attenuated macrophage recruitment and activation in response to kidney injury, leading to decreased renal pro-fibrotic M2 macrophages.

LOXL4 Promotes Renal Fibrosis via Triggering Col1 Production

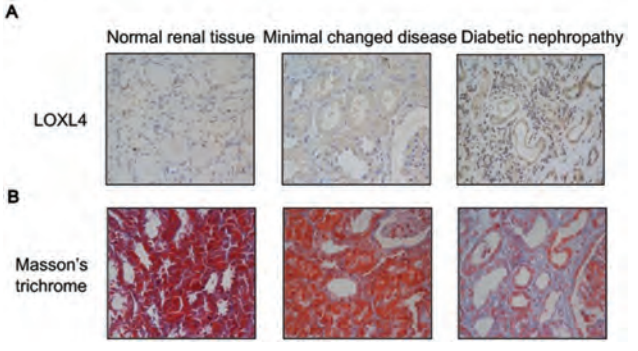
Saiya Zhu, Chen Yu. *Shanghai Tongji Hospital, Shanghai, China.*

Background: Renal fibrosis characterized by excessive deposition of extracellular matrix (ECM) represents a feature of end stage of kidney disease. ECM consists of collagen, fibronectin, elastin and so on. Over crosslinking of extracellular matrix acts as a key role in the process of fibrosis. Lysyl oxidase (LOXs) facilitates the crosslinking of collagen and elastin. Lysyl oxidase-like protein 4(LOXL4) is the latest member of the LOXs family. Till now, there is no report about the pathogenesis of LOXL4 during renal fibrosis. The aim of the current study is to uncover the role of LOXL4 in renal fibrosis.

Methods: Human renal specimens were obtained from renal biopsy and normal renal tissues adjacent to renal cancer after nephrectomized kidneys. Fibrosis in the kidney specimens was assessed by Masson's trichrome staining, and LOXL4 expression was examined by using IHC staining. We used unilateral ureteral ligation (UUO) kidney *in vivo* and used a cell line of rat fibroblast (NRK-49F) *in vitro* to demonstrate the underlying mechanism of LOXL4 with renal fibrosis by realtime-PCR and western blot analysis. We investigated the biological role of LOXL4 after over-expression or silencing its expression in NRK-49F.

Results: LOXL4 deposited in the fibrotic renal tissue in patients with diabetic nephropathy,which were significantly higher compared with that in renal tissues adjacent to renal cancer after nephrectomized kidneys and minimal changed disease. Compared with sham group, the expressions of LOXL4 and Col1 in the kidney of UUO group were extremely upregulated ($p<0.05$, n=5). TGF-β1 significantly increased the expression of LOXL4 and Col1 ($p<0.05$, n=5) in NRK-49F. After transfecting with LOXL4 overexpression plasmid, the Col1 expression was significantly increased. There was sharply reduction of Col1 in NRK-49F cells after transfected with LOXL4 siRNA.

Conclusions: LOXL4 was significantly increased in human and rat fibrosis, and TGF-β1/Smads promotes the expression of LOXL4. This indicates that LOXL4 is closely related to the renal fibrosis.



LOXL4 expression in human kidney tissues

TH-PO471

Macrophages Mediate Renal Fibrosis via C5AR1 Signaling

Ranjit K. Sahu,[1] Sandhya Xavier,[1] Daniel Chauss,[4] Behdad Afzali,[3] Didier Portilla.[2] *[1]University of Virginia, Charlottesville, AL; [2]University of Virginia Health System, Charlottesville, VA; [3]King's College London, London, United Kingdom; [4]NIH/NIDDK, Bethesda, MD.*

Background: Macrophages regulate innate immunity, inflammation, metabolism and tissue repair. We reported increased expression of intracellular complosome components, C1q, C3, C5 and anaphylatoxin receptors C3aR1 and C5aR1 in macrophages isolated from kidney tissue of mice receiving folic acid (FA) or unilateral ureteral obstruction (UUO). Recently, single cell transcriptomic study performed in UUO mice identified new proximal tubule sub clusters, but also increased expression of C5aR1 in UUO macrophages. We hypothesized that deletion of C5aR1 in macrophages reduces kidney fibrosis

Methods: C5aR1GFP$^{fl/fl}$ mice were generated by inserting LoxP sites flanking exon 2 as previously reported. C5aR1GFP$^{fl/fl}$ mice were crossed with mice expressing Cre-recombinase under control of the LysM promoter to generate LysM-Cre-C5aR1GFP$^{fl/fl}$ mice. LysM-Cre-C5aR1GFP$^{fl/fl}$ mice and C5aR1GFP$^{fl/fl}$ (control mice) received intraperitoneal injections of either vehicle (sodium bicarbonate) or FA in sodium bicarbonate. Two weeks later kidney tissue was harvested for analysis. Macrophages expressing C5aR1 and C5aR1 negative control macrophages were isolated from C5aR1GFP$^{fl/fl}$ mice by flow cytometry following UUO-injury and we performed RNA seq analysis of their trancriptome

Results: Flow studies and confocal microscopy using C5aR1GFP$^{fl/fl}$ reporter mice confirmed that macrophages are the dominant expressors of C5aR1 in both models of fibrosis. RNAseq analysis of GFP^{+} macrophages isolated from C5aR1GFP$^{fl/fl}$ mice subjected to UUO confirmed increased expression of *C5aR1* mRNA, as well as increased transcripts encoding markers of inflammation, including *Tlr4* and *Cxcl13*. GFP^{+} macrophages also exhibit increased expression of iron homeostatic genes, iron transporters and iron-recycling transcription factors. Immunohistochemistry, flow cytometry, qRT-PCR and western blots demonstrated reduced inflammation and fibrosis in whole kidney tissues from mice with selective deletion of C5aR1 in macrophages (LysMCreC5aR1GFP$^{fl/fl}$) compared to control mice treated with FA.

Conclusions: Increased expression of C5aR1 in macrophages represents an important pathophysiologic mechanism leading to increased tissue inflammation and organ fibrosis. We propose that increased iron-recycling and overload in C5aR1+ macrophages represents an important cellular mechanism leading to kidney fibrosis.

Ferroptosis Is Activated by TGF-β/Smad3-Driven Renal Fibrosis Both In Vivo and In Vitro

Guisen Li,[4] Xiang Zhong,[1] Xue Yang,[5] Huan Wang,[3] Yi Li,[2] Li Wang.[2] *[1]Department of Nephrology, Sichuan Academy of Medical Sciences and Sichuan Provincial People's Hospital, Chengdu, China; [2]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China; [3]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, Chengdu, China; [4]Sichuan Provincial People's Hospital, Chengdu, China; [5]Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital, Chengdu, China.*

Background: Ferroptosis is a novel non-programmed cell death driven by iron-based lipid peroxidation and its role in renal fibrosis is unknown. In this study, we hypothesized that ferroptosis is activated by TGF-β/Smad3-drivend renal fibrosis both *in vivo* and *in vitro.*

Methods: The morphology of ferroptosis and expression of ferroptosis indexes such as glutathione peroxidase 4(GPX4) and solute carrier family 7 member 11(SLC7A11) were detected both in TGF-β-stimulated rat tubular epithelial cells(rTEC) and unilateral ureteral obstruction(UUO) mouse model by electron microscopy(EM), IHC, western blot(WB) and quantitative real-time polymerase chain reaction(qRT-PCR). In addition, the ferroptosis was induced or inhibited by ferroptosis specifically agonist Erastin and inhibitor Ferrostatin in rTEC. Renal fibrosis markers of fibronectin(FN), collagen I(Col I) and α-smooth muscle actin(α-SMA) were detected by WB and qRT-PCR. Moreover, GXP4 was observed in SIS3 specifically inhibited Smad3 rTEC and Smad3 conditional knock out (KO) UUO mice by WB or IHC. The co-expression of P-Smad3 and GPX4 were detected by confocal and CO-IP in TGF-β-stimulated renal fibrosis in rTEC.

Results: The ferroptosis morphological changes including the shrucked volume of mitochondria, a reduced number of cristae and an increased density of bilayer membrane were observed in TGF-β-stimulated rTEC and renal tissue of UUO by EM. The expression of ferroptosis negatively indexes of GPX4 and SLC7A11 was significantly decreased in renal fibrosis both *in vivo* and *in vitro*. After ferroptosis induced by Erastin, the renal fibrosis markers of FN, Col I and α-SMA were significantly enhanced after TGF-β treatment for 24 hours, while renal fibrosis was decreased by Ferrostatin. In SIS3 specifically inhibited Smad3 rTEC and Smad3 KO UUO mice, GPX4 expression was significantly up-regulated. Confocal and CO-IP results suggested that the P-Smad3 and GPX4 was co-expressed in rTEC and physically combined with each other after TGF-β1 stimulated for 24h.

Conclusions: Ferroptosis is expressed in renal fibrosis both *in vivo* and *in vitro*. The intervention of ferroptosis by agonist and inhibitor has effect on the renal fibrosis in TECs. GPX4-mediated ferroptosis is dependent on TGF-β/Smad3 signaling in renal fibrosis. These data indicates that the potential role and mechanism of ferroptosis in TGF-β/Smad3-driven renal fibrosis.

Grape Seed Proanthocyanidin Extract Alleviates Renal Fibrosis by Inhibiting the Activation of the C3/HMGB1/TGF-β Pathway

Kun Wang, Haotian Wei, Yanyan Liu, Gang Xu. *Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Grape seed proanthocyanidin extract (GSPE) has been reported to exhibit a variety of protective effects, such as antioxidant, anti-tumor, anti-aging, hypoglycemic, anti-atherosclerosis and other pharmacological effects. Kidney disease is usually a pathogenic immune response to the kidney's autoantigen or local autoimmune response. As a member of the complement system, complement component 3 (C3) deposited in the kidney is now recognized as an important causative mediator of various human kidney diseases. In this study, we aimed to identify the effect of GSPE on C3 in the chronic kidney fibrosis and evaluate the possible mechanism.

Methods: Eight-week-old C57bl/6 mice were subjected to unilateral ureteral occlusion (UUO) with or without GSPE administration. Pathological damage, collagen deposition, interstitial inflammation and renal fibrosis were detected by histological staining, immunofluorescence and Western Blot. For the in vitro studies, mouse primary renal tubular epithelial cells (PTECs) and NRK-49F were used. In order to find possible inhibition targets for GSPE, we used complement C3 (C3a), HMGB1 and TGF-β1 to stimulate PTECs or NRK-49F, then the fibrosis-related proteins and inflammatory factor were analyzed by immunofluorescence, Western Blot or rt-PCR.

Results: In vivo, we observed that administration of GSPE relieves inflammation and chronic renal fibrosis in mouse models of UUO (unilateral ureteral obstruction). Our data indicated that GSPE inhibited C3 secreted by macrophages to relieve renal interstitial inflammation. In vitro, we found that C3 could stimulate HMGB1 translocation form nucleus to cytoplasm and promote the expression of pro-inflammatory cytokines including TGF-β1 in primary renal tubular epithelial cells (PTEC), which could be inhibited by GSPE. Meanwhile, GSPE could also decreased HMGB1-induced EMT of PTEC through suppresses the HMGB1/TLR4/p65/TGF-β1 pathway. In addition, the myofibroblast

activation was inhibited by GSPE via TGF-β1 /Smad2/3signaling pathways in normal rat kidney fibroblast (NRK-49F) cells.

Conclusions: Taken together, these observations provide that GSPE alleviates renal fibrosis by inhibiting the activation of C3/ HMGB1/ TGF-β pathway and could thus lead to find the potential therapy for the suppression of renal fibrosis.

A Water-Soluble Extract from Actinidia arguta (PG102) Can Inhibit Kidney Fibrosis

Jeonghwan Lee,[1] Lilin Li,[2] Jung Pyo Lee.[3] [1]*Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea;* [2]*Seoul National University College of Medicine, Boramae Medical Center, Seoul, Republic of Korea;* [3]*Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: PG102 is a water-soluble extract of hardy kiwifruit *Actinidia arguta*. We aimed to investigate whether treatment with PG102 can attenuate kidney fibrosis.

Methods: Male C57BL/6 mice (7-week-old, n = 14) were purchased. Treatment group (n = 7) was administered with PG102 per oral using Zonde needle at dosage of 100 mg/kg daily for 10 days. Control group (n = 7) was fed with distilled water. After this pre-treatment, unilateral ureteral obstruction operation performed, and mice were administered with PG102 or distilled water at the same dose for 10 days. After 10 days, mice were sacrificed. In addition, human kidney proximal tubular cells were cultured and challenged with TGF-β (2 ng/ml) with or without PG102 (2.5 and 5 μg/ml).

Results: Mice in both groups showed similar body weight and similar serum creatinine levels between groups. In the histopathologic specimen of Masson's trichrome stain, areas of kidney interstitial fibrosis attenuated in the treatment group (3.6 ± 0.9 % area vs. 8.7 ± 3.0 % area, P = 0.03). In the western-blot analysis, protein abundance of α-smooth muscle actin (50.6% of control), fibronectin (47.8% of control), p53 (20.8% of control) decreased, and protein abundance of e-cadherin increased (325.1% of control) in the treatment group. In immunohistochemical stain of phospho-p38, PG102 treated group showed decreased tissue expression of phosphorylated p38. In vitro experiment, human kidney proximal tubular cells treated with TGF-β and PG102 showed significantly decreased protein expression of α-smooth muscle actin (47.8% of control), and phospho-p38 (51.5% of control).

Conclusions: PG102 attenuates kidney fibrosis in the unilateral ureteral obstruction mice model and TGF-β-treated human kidney proximal tubular cells, p38 MAPK pathway is inhibited after treatment of PG102.

TH-PO475

Suppression of Transcription Factor OASIS Ameliorated Kidney Fibrosis

Masanori Obana,[1] Ayaha Yamamoto,[1] Takafumi Nakae,[1] Yoshiaki Miyake,[1] Takeo Harada,[1] Sayuri Mitsuoka,[1] Shunsuke Noda,[1] Makiko Maeda,[1] Kazunori Imaizumi,[2] Kotaro Matsumoto,[1] Yasushi Fujio.[1] [1]*Osaka University, OSAKA, Japan;* [2]*Hiroshima University, Hiroshima, Japan.*

Background: Old astrocyte specifically induced substance (OASIS), a transcription factor, was originally identified as an ER stress transducer. We found that there was a correlation between OASIS mRNA expression and the severity of tubular atrophy and interstitial fibrosis in patients with kidney diseases, analyzed by Nephroseq database. However, the pathophysiological roles of OASIS in kidney remain to be elucidated. The aim of this study is to determine the functional roles of OASIS in the development of kidney fibrosis.

Methods: OASIS expression was investigated by immunohistochemistry, immunoblotting and quantitative PCR. To assess the functions of OASIS in (myo) fibroblast, NRK49F cells, rat renal fibroblasts, were transduced with the lentivirus encoding OASIS shRNA, followed by TGF-β1 treatment. Twenty-four hours after TGF-β1 treatment, wound healing assay and proliferation assay were performed. To examine the effects of OASIS on kidney fibrosis, OASIS knockout (KO) mice were subjected to unilateral ureteral obstruction (UUO). At day 7 after UUO, Masson's trichrome stain and hydroxyproline assay were performed. To explore the downstream molecules of OASIS, DNA microarray was performed on OASIS KO myofibroblasts. Anti-bone marrow stromal antigen (Bst2) antibody was injected into mice at day 1 after UUO.

Results: The protein level of OASIS was increased in human fibrotic kidney. Consistently, mRNA and protein levels of OASIS were upregulated in UUO-induced murine fibrotic kidney. In addition, the number of OASIS-expressed myofibroblasts were elevated after UUO. OASIS expression was induced by TGF-β1 in NRK49F cells. OASIS knockdown suppressed TGF-β1-induced migration and proliferation of NRK49F cells. Moreover, kidney fibrosis was attenuated in OASIS KO mice (HP content (μg/mg): Wild type-UUO; 0.48±0.08, OASIS KO-UUO; 0.38±0.05, n=7, $p<0.05$). DNA microarray revealed that Bst2 was a candidate downstream molecule of OASIS. Finally, antibody blockade of Bst2 ameliorated kidney fibrosis after UUO (HP content (μg/mg): control IgGκ; 0.60±0.08, anti-Bst2 antibody; 0.49±0.09, n=6, $p<0.05$).

Conclusions: OASIS exacerbated kidney fibrosis in part by increased Bst2 expression. Suppression of OASIS could be a novel therapeutic strategy against chronic kidney disease.

TH-PO476

Investigation of the Role of Renal Tubular NFAT5 in Renal Fibrogenesis Caused by Unilateral Ureteral Obstruction

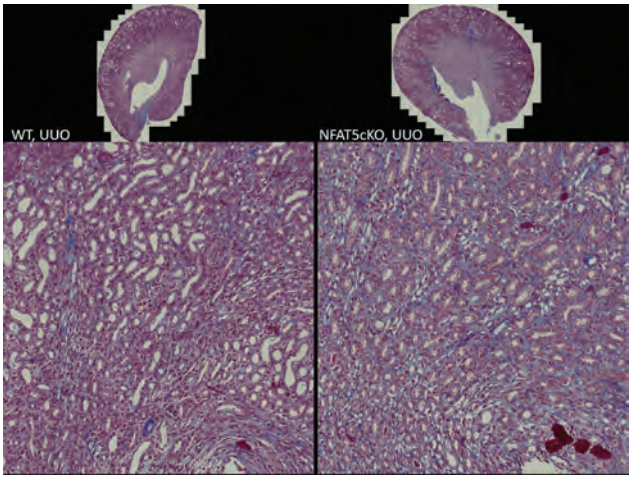
Makoto Ono, Naomi Matsuo, Yuichiro Izumi, Koji Eguchi, Akiko Hiramatsu, Yushi Nakayama, Hideki Inoue, Yutaka Kakizoe, Takashige Kuwabara, Masashi Mukoyama. *Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: NFAT5 (nuclear factor of activated T-cells 5) is a transcription factor that stimulates the expression of osmoprotective genes in response to extracellular hypertonicity, contributing to cell survival even in extreme hypertonic conditions. Not only hypertonicity but also hypoxia, oxidative stress, and toll-like receptor signaling, which promote fibrogenesis in the kidney, have been suggested to increase the NFAT5 activity. In the present study, we investigated the role of NFAT5 in renal fibrogenesis using renal tubular cell-specific NFAT5 conditional knockout (cKO) mice.

Methods: We generated renal tubular cell-specific NFAT5 cKO mice by crossing NFAT5 floxed mice with Pax8-rtTA/LC-1 mice, in which Cre recombinase was specifically expressed in renal tubular cells by the treatment with doxycycline. Wild-type (WT) mice and NFAT5 cKO mice were subjected to unilateral ureteral obstruction (UUO) or sham-operation. After 7 days, mice were sacrificed and kidneys were collected for analysis. The mRNA expression levels of NFAT5 and markers for fibrogenesis (TGF-β, α-SMA, CCL2, Col1, Col3, KIM-1, NGAL) in the kidney were examined by real-time PCR. Renal fibrosis was evaluated by Azan staining.

Results: In WT mice, the expression of NFAT5 mRNA was two times greater in the kidney from UUO mice than that from sham-operated mice. Fibrogenesis-related mRNAs were significantly increased in the kidney from UUO mice compared with that from sham-operated mice. In the UUO groups, the expressions of NGAL, TGF-β and collagen 3α1 tended to be higher in the kidney from NFAT5 cKO mice compared with that from WT mice. Azan staining showed a progression of fibrosis in the kidney from NFAT5 cKO mice.

Conclusions: NFAT5 in renal tubular cells may contribute to protective action against the development of renal fibrosis caused by UUO.



TH-PO477

CCN2 Module IV-Derived Decoy Peptides Attenuate Renal Fibrogenesis Through Inhibition of FAK Pathway in the Tubular Epithelium

Hiroaki Amano, Tsutomu Inoue, Hirokazu Okada. Department of Nephrology, Saitama Medical University *Saitama Medical University, Saitama, Japan.*

Background: CCN2 mediates the renal fibrotic action of TGF-b. We focused on CCN2 module-IV (M4) and its contribution to fibrogenesis. We previously demonstrated that M4 activated FAK (Focal Adhesion Kinase), PI3K, Akt, GSK-3b (Glycogen Synthase Kinase-3b) and b-Catenin using knock-in mice bearing M4-deleted, mutant CCN2 gene (mCCN2 mice). Furthermore, Erk1/2 and p38 were also phosphorylated by M4. Since FAK is directly activated by integrin, we considered that M4 interacts with integrin. Thus, we created decoy peptides (DCs) that mimic partial sequences of M4 and tested their anti-fibrotic effects.

Methods: Six types of DCs were designed as unmodified peptides that divide M4 into 10-14 aa and purified by HPLC. Each DCs was administered to wild-type mice with unilateral ureter obstruction (UUO) model, and histological examination and immunohistochemistry (IHC) were performed. Next, the human proximal tubular cell line, HK-2, was cultured for 24 hours in Ham's F-12/DMEM supplemented with 5% FCS, after which the medium was replaced with serum free medium, and added dissolved DCs directly to the medium. Activation of signal pathways was assayed with Western blots.

Results: Two of six DCs, DC2 and DC5, inhibited the progression of renal fibrosis in the UUO model. IHC revealed that accumulation of p-FAK in tubular epithelium cells (TECs) was suppressed in the DC2- and DC5-groups. Next, DC5 was selected for the in-vitro experiment because its aa sequence has been conserved in mouse and human. The levels of p-FAK were significantly lowered in the DC5-treated TECs compared to the control (p-FAK/FAK: 1.0+/-0.1 vs. 0.5+/-0.1, $p<0.01$). The levels of p-Akt, and p-GSK-3b

were also lowered (p-Akt/ Akt: 7.0+/-1.4 vs. 2.5+/-0.3, p<0.05), (p-GSK-3b/ GSK-3b: 3.2+/-0.3 vs. 1.6+/-0.6, p<0.05). Among MAPKs, only the levels of p-p38 were lowered by DC5.

Conclusions: DCs likely suppressed FAK-mediated renal fibrogenesis in mice. This finding is the same as that observed in the mCCN2 mice, suggesting that these DCs may have inhibited the interaction between M4 and integrin in TEC. The in-vitro experiments showed that down-stream signals activated by CCN2M4-Integrin-FAK pathway were PI3K-Akt-mediated phosphorylation of GSK-3b and p38 in TECs. The CCN2M4-Integrin-FAK pathway seems to be a promising, therapeutic target for attenuating renal fibrogenesis.

TH-PO478

Suppression of the Hippo Pathway in Tubular Cells Leads to Renal Fibrosis in Mice

Chunhua Xu,[1] Yang Wang,[1] Li Wang,[1] King lun kingston Mak,[2,1] Yu Huang,[1] Yin Xia.[1] *[1]The Chinese University of Hong Kong, Hong Kong, China; [2]Guangzhou Regenerative Medicine and Health-Guangdong Laboratory, Guangzhou, China.*

Background: The Hippo pathway controls organ size and tumorigenesis. The core components of the Hippo pathway consist of Mammalian Ste20-like kinases 1/2 (MST1/2) and their scaffold protein SAV1, large tumor suppressor 1/2 (LATS1/2) and their scaffold proteins MOB1A/1B, and two downstream effectors YAP/TAZ. Several components of the Hippo pathway, including SAV1, LATS1/2, and YAP/TAZ, have been found to be critically involved in embryonic kidney development or kidney disease. However, the role of MST1 and MST2 in kidney remains unknown.

Methods: We generated tubular cell specific Mst1/Mst2 double knockout mice by intercrossing floxed Mst1/Mst2 mice with Ksp-Cre transgenic mice. The Hippo pathway is restrained in renal tubular epithelium in Mst1/Mst2 mutant mice.

Results: We showed for the first time that MST1 and MST2 were highly expressed in all nephron segments and collecting ducts in mouse kidneys. Deletion of Mst1/Mst2 ($Mst1^{f/f}$;$Mst2^{f/f}$;Ksp-Cre) in mouse renal tubular epithelium resulted in increased kidney sizes starting from 4 weeks of age, coupled with increased YAP activity and cell proliferation in renal tubules. The Mst1/Mst2 mutant mice developed chronic kidney disease as indicated by progressive increases in tubular damage, inflammation, fibrosis and functional impairment. Deletion of Yap prevented kidney overgrowth and tubular damage in Mst1/Mst2 mutant mice and rescued the expression of many inflammatory factors measured at 4 weeks of age. More importantly, ablation of Yap prevented fibrosis development in Mst1/Mst2 mutant mice at 8 weeks of age.

Conclusions: We found that suppression of the Hippo pathway in renal tubular epithelium results in renal fibrosis via activation of YAP.

Funding: Government Support - Non-U.S.

The Association Losartan/Erlotinib Is More Effective in Attenuating Renal Fibrosis Formation by Blocking TACE-Dependent EGF Receptor Activation in 5/6-Nephrectomized Rats Under Vitamin D Deficiency

Rildo A. Volpini, Ana Carolina de Braganca, Daniele Canale, Michele S. Santos, Maria H. Shimizu, Antonio C. Seguro, Janaina G. Goncalves. *Faculty of Medicine - University of Sao Paulo, São Paulo, Brazil.*

Background: Hypovitaminosis D has been described as a risk factor for the progression of kidney disease. Among others, overactivity of renin-angiotensin system and renal fibrosis formation (RFF) are hallmarks of CKD. In an alternative RFF pathway, angiotensin II can mediate the activation of tumor necrosis factor-α converting enzyme (TACE), leading to release of TGF-α, which binds to and activates the epidermal growth factor (EGF) receptor (EGFr). Although many studies have focused on the mechanisms underlying RFF, novel anti-fibrotic therapies need to be evaluated in order to retard the progression of CKD. We evaluated the effects of losartan (L) and erlotinib [EGFr inhibitor (E)] in 5/6-nephrectomized rats under vitamin D deficiency.

Methods: Male Wistar rats were fed a vitamin D-free diet (D) for 90 days and submitted to 5/6 Nx (N) on day 30. We studied four groups: **DN**; **DNE** (6 mg/Kg/day IP for 53 days); **DNL** (50 mg/Kg/day in water for 53 days); **DNEL** (dual treatment). We performed immunohistochemistry for TACE, TGF-α, fibronectin, vimentin and α-SM-actin; ELISA in renal tissue for EGF and collagen 3 (col3); and immunoblot for p-EGFr.

Results: The dual treatment was more effective in blocking the TACE-dependent EGFr activation pathway demonstrated by lower expression of TACE, TGF-α, EGF and p-EGFr. In addition, we observed decreased expression of fibronectin, col3, vimentin and α-SM-actin in renal tissue.

Conclusions: Our results indicate that the dual treatment L+E may represent a novel anti-fibrotic strategy for attenuating CKD. Financial support: FAPESP 2018/12297-1, 2018/04930-6; CNPq 302599/2018-5.

Sphingosine Kinase 2 Deletion in Kidney Pericytes/Fibroblasts Protects Against Kidney Fibrosis via Suppression of Local Interstitial Inflammation

Shinji Tanaka,[1] Shuqiu Zheng,[1] Yugesh Kharel,[2] Jonathan E. Lipsey,[1] Diane L. Rosin,[2] Kevin Lynch,[2] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: Sphingosine 1-phosphate (S1P), which is produced by two different kinases, sphingosine kinase (SphK) 1 and 2, is a sphingolipid involved in myriad cell functions. We recently showed that *Sphk2*$^{-/-}$ mice were protected from renal fibrosis when compared to wild type or *Sphk1*$^{-/-}$ mice; bone marrow chimera experiments suggested that *Sphk2* deletion in non-hematopoietic cells contributed to the protection (PMID: 27799486). We hypothesized that *Sphk2* deletion in renal pericytes/fibroblasts confers the protection from progressive kidney fibrosis.

Methods: Folic acid (250 mg/kg) was given i.p. to male *Foxd1Cre*$^{+}$ *Sphk2*$^{fl/fl}$ (perivascular (pv) *Sphk2KO*) mice and *Foxd1Cre*$^{-}$ *Sphk2*$^{fl/fl}$ (WT) mice. For unilateral ischemia-reperfusion injury (IRI), left kidney was clamped for 30 min; right nephrectomy was performed at day 13. For bilateral IRI, both kidneys were clamped for 30 min. Mice were euthanized at day 14 to evaluate kidney fibrosis (folic acid and unilateral IRI) and at day 1 to evaluate the extent of acute kidney injury (folic acid and bilateral IRI). Primary renal pv cells were isolated from kidneys of pv*Sphk2KO* mice and WT mice.

Results: In both folic acid and unilateral IRI models, pv*Sphk2KO* mice demonstrated better kidney function (pCr, BUN), less kidney fibrosis (histology) with less macrophage infiltration, and suppressed expression of fibrosis-related genes (*Acta2, Col1a1, Col3a1*) in the kidneys compared with WT mice. In contrast, there was no difference between pv*Sphk2KO* mice and WT mice in kidney function, kidney *Kim-1/Ngal* expression, and histology at day 1. In *in vitro* studies, the expression level of *Sphk2* was much higher than that of *Sphk1* in WT pv cells. *Sphk2* KO pv cells expressed less inflammatory cytokines, such as *Ccl2, Il6, Cxcl1*, after LPS stimulation compared with WT pv cells. Furthermore, treatment with a selective Sphk2 inhibitor (SLM6031434) recapitulated the phenotype of *Sphk2* KO pv cells.

Conclusions: *Sphk2* deletion in renal pericytes/fibroblasts was protective against kidney fibrosis. *In vitro* studies suggested that suppressed production of S1P in *Sphk2* KO pericytes/fibroblasts contributes to suppressed expression of inflammatory cytokines when injury occurs, leading to less immune cell infiltration into the kidneys and ameliorated kidney fibrosis.

TH-PO481

Profiling Histone Modifications in the Normal Mouse Kidney and After Unilateral Ureteric Obstruction

Timothy D. Hewitson, Stephen G. Holt, Edward R. Smith. *The Royal Melbourne Hospital, Melbourne, VIC, Australia.*

Background: Post-translational modification of nucleosomal histones has emerged as a major determinant of chromatin structure and gene activity. In this study, we hypothesised that unilateral ureteric obstruction (UUO), a widely used model of tubulointerstitial injury, would be associated with a distinct pattern of histone (H) modifications (marks) in the kidney.

Methods: Mass spectrometry (MS) was used to profile 63 different histone marks, and their corresponding unmodified amino acid, in normal mouse kidneys and those after 10 days of UUO. A subsequent histochemical analysis further examined examples of specific marks that changed significantly after UUO, for which antisera are available. The distribution of marks was compared with markers of pathology and transcription.

Results: Histone marks were much more widely distributed and abundant in the normal kidney than usually appreciated. Although aggregate analysis of the MS results revealed net differences between control and UUO groups, residue-specific variations were subtle. Of 16/63 significant changes (P<0.05), only 8 were quantitatively different by more than 5%. Nevertheless, we identified several not usually examined in the kidney including marks in the globular domain of core histones (H3K79), linker histones (H1.4) and histone variants (H3.1K27, H3.3K27). In several cases there were complementary changes in different marks on the same amino acid. In situ staining showed compartment specific differences in the distribution of individual marks. Using H3K79Me2 as an example, mark enrichment was heterogeneous, but largely co-localised with tubular hypoxia and transcription, but not proliferation, apoptosis or interstitial pathology.

Conclusions: Our study highlights the importance of unbiased screening in examining histone marks. Simultaneous changes in multiple marks on the same amino acid are indicative of a coordinated histone mark signature. The heterogeneous enrichment of marks, even within the same tubule, highlights the importance of regulatory context.

Diabetic Glomeruli Stiffen as They Scar

Luisa Ulloa severino,[2,1] Xiaolin He,[2] Laura N. Poloni,[1] Darren A. Yuen.[2,1] *[1]University of Toronto, Toronto, ON, Canada; [2]St. Michael's Hospital Keenan Research Centre for Biomedical Science, Toronto, ON, Canada.*

Background: Glomerulosclerosis is an important manifestation of diabetic glomerular injury. Studies of mesangial cells (the main producers of scar in the glomerulus) have mostly focused on biochemical stimuli (eg. high glucose, TGF-β). However, increasing evidence suggests that biomechanical stimuli such as extracellular matrix stiffening can also activate mesenchymal cells. In particular, the mechanosensory transcription co-factors YAP and TAZ appear to link matrix stiffness to fibrogenesis. Our goal was to study changes in glomerular stiffness as diabetic injury progresses.

Methods: We studied male Akita$^{+/-}$ Ren$^{+/-}$ mice at early (8 wk old, n = 8) and late (26 wk old, n = 6) time points. These mice develop diabetes and renin-mediated hypertension, resulting in progressive glomerulosclerosis that mimics human diabetic kidney disease. Male non-diabetic, normotensive Akita$^{-/-}$ Ren$^{-/-}$ mice served as healthy controls. Parameters of glomerular stiffness (atomic force microscopy, AFM) and histology (picrosirius red, type 1 collagen, and YAP/TAZ immunostaining) were measured and correlated. Glomerular stiffness was measured in a minimum of 30 glomeruli per kidney.

Results: Mean glomerular stiffness and glomerulosclerosis values increased with age in both the diabetic, hypertensive Akita$^{+/-}$ Ren$^{+/-}$ mice and their non-diabetic, normotensive Akita$^{-/-}$ Ren$^{-/-}$ controls, although at each time point, diabetic, hypertensive Akita$^{+/-}$ Ren$^{+/-}$ glomeruli were significantly stiffer and more scarred than glomeruli in healthy Akita$^{-/-}$ Ren$^{-/-}$ controls (Table 1). At both early and late stages of diabetic kidney injury, stiffness increased with glomerulosclerotic burden. Reflecting this increased stiffness, glomerular cell YAP/TAZ activity was increased in Akita$^{+/-}$ Ren$^{+/-}$ mice at 26 weeks compared to wild type controls, as evidenced by increased YAP/TAZ nuclear localization.

Conclusions: As glomerulosclerosis progresses in diabetes, the stiffness of glomeruli, as well as the activation of the mechanosensitive, pro-fibrotic transcription co-factors YAP and TAZ, increases. Taken together, our data suggest a novel biomechanical stimulus for glomerulosclerosis progression in diabetes.

		Plasma glucose (mmol/L)	Body weight (g)	Systolic blood pressure (mmHg)	Urinary albumin (ug/day)	Right kidney/tibia length (mg/mm)	Right kidney/body weight (mg/g)	Glomerula stiffness (kPa)

TH-PO483

The Protective Effect of Prostacyclin in Renal Fibrosis

Jing Li, Chuan-Ming Hao. *Hushan Hospital, Fudan University, Shanghai, China.*

Background: Progressive decline of renal function is a hallmark of CKD, the mechanism of which is incompletely understood. Inadequate repairing process to injury has been reported to play an important role. Mounting evidence suggests that prostaglandins are important in serving as a "buffer"in response to physiological changes or pathophysiologic insults to tissues including the kidney. Importantly, under certain conditions such as aging and hypertension, prostacyclin (PGI_2), an active production of COX/PGI_2 Synthase (PGIS), is reduced. The present study provides data showing that PGI_2 plays an important role in response to renal injury to maintain adequate injury and repairing process. Low levels of PGI_2 are associated with enhanced renal fibrosis.

Methods: Mice with global PGIS gene deletion were obtained by crossing the floxed PGIS mice with the EIIA-Cre mice. The endothelial-specific PGIS-deficient mice were generated by mating the floxed PGIS mice with the TEK-CRE (Tie2-CRE) mice. Unilateral ureteral obstruction (UUO)was used as a renal fibrosis model. At days 10 after UUO, the mice were sacrificed, and the kidneys were collected.

Results: Immunohistochemistry showed that PGIS is primarily expressed in endothelial cells and vascular smooth muscle cells. The expression of PGIS was markedly induced following AKI and fibrotic kidney. Enhanced PGIS expression is associated with increased PGI_2 level. Losing one allele of PGIS (PGIS$^{+/-}$) significantly aggravated UUO -induced renal fibrosis, showing increased fibronectin, collagen I and α-SMA, and more extracellular matrix deposition in the section at 10 days after UUO comparing to their wild type littermates. Kidney thromboxane synthase expression is not significantly different between PGIS$^{+/-}$ mice and wild type littermates after UUO. Loss of one allele of PGIS did not change blood pressure. To examine the role of specific cells that express PGIS in renal fibrosis, we specifically deleted PGIS in endothelial cells. Endothelial-specific PGIS-deficient mice had normal blood pressure and renal function. Endothelial PGIS gene deletion also significantly aggravated UUO -induced renal fibrosis. Furthermore, the level of phosphorylated PKA substrates in the kidney of deficient mice was significantly reduced.

Conclusions: PGIS/PGI_2 plays an important role in protecting the kidney from fibrosis. Lack of PGIS enhances kidney damage. PGIS/PGI_2 is a potential target for CKD.

Plant Homeodomain (PHD) Finger Protein 14 (PHF14) Inhibits Renal Fibrosis via Repressing Connective Tissue Growth Factor Induced by Hypoxia-Inducible Factor 1 Alpha

Sixiu Chen, Linxi Huang, Zhiguo Mao. *Division of Nephrology, Kidney Institute of CPLA, Changzheng Hospital, Second Military Medical University, Shanghai, China.*

Background: Renal fibrosis is the final common pathological manifestation of chronic kidney diseases progressing to ESRD, while no effective way has been found to reverse it. Chronic hypoxia was thought to play an important role in renal fibrosis. PHF14, a novel histone binding protein, was discovered in our previous studies to be an innate inhibitor of renal fibrosis. However, the mechanism of PHF14 is not unraveled. We hypothesized PHF14 may be induced by hypoxia-inducible factor 1 α (HIF-1α), and repress the over-expression of connective tissue growth factor (CTGF) by regulating histone methylation.

Methods: We confirmed the biological function of PHF14 in PHF14 conditional knockout mice following aristolochic acid administration. Relationship between hypoxia and PHF14 has been explored in NRK52E cells. We detected the interactions of PHF14 with H3K4me3 and H3K27me3 using Chromatin Immunoprecipitation (ChIP) and Co-immunoprecipitation (Co-IP). We also generated PHF14-KO cell via CRISPR/Cas9 system.

Results: 1. Compared with controls, PHF14 conditional knockout mice presented aggravated renal fibrosis and worse renal function (Figure 1A-1C). 2. PHF14 was induced in hypoxia environment *in vitro*. And PHF14 was upregulated by HIF-1α stimulant DMOG and repressed by HIF-1α inhibitor KC7F2 (Figure 1D). ChIP detected HIF-1α binding on the promoter of PHF14 and CTGF. 3. PHF14 knockdown enhanced CTGF expression following DMOG stimulation *in vitro* and PHF14 could bind on the promoter of CTGF, which was proved by ChIP. 4. The enrichment of histone methylation in CTGF promoter induced by HIF-1 α was changed in PHF14-KO cells. Co-IP validated PHF14 could interact with H3K4me3 and H3K27me3.

Conclusions: Lack of PHF14 deteriorated aristolochic acid nephropathy in mice. PHF14, which was induced by HIF-1α, inhibited CTGF expression via regulating histone methylation in CTGF promoter.

High Throughput Sequencing of Human Kidney Tissue Implicates FRMD3 as Important in the Pathogenesis of Progressive CKD

Ross P. Doyle,[2,1] Caitriona M. McEvoy,[4] Eoin P. Brennan,[6] Peter J. Conlon,[3] Denise M. Sadlier,[6] Catherine Godson.[5] *[1]Mater Misericordiae University Hospital, Dublin, Ireland; [2]Diabetes Complications Research Centre, University College Dublin, Dublin, Ireland; [3]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [4]University Health Network, Toronto, Toronto, ON, Canada; [5]The Conway Institute of Biomolecular and Biomedical, Belfield, Dublin, Ireland; [6]University College Dublin, Dublin, Ireland.*

Background: The global health concern of Chronic Kidney Disease (CKD) is enhanced by the struggle to predict future disease events, particularly progression to End Stage Kidney Disease (ESKD). We examined the transcriptional profile of human kidney biopsies, aiming to provide insight into the mechanisms of progressive CKD. We evaluated the potential role of the candidate gene *FRMD3*in CKD progression.

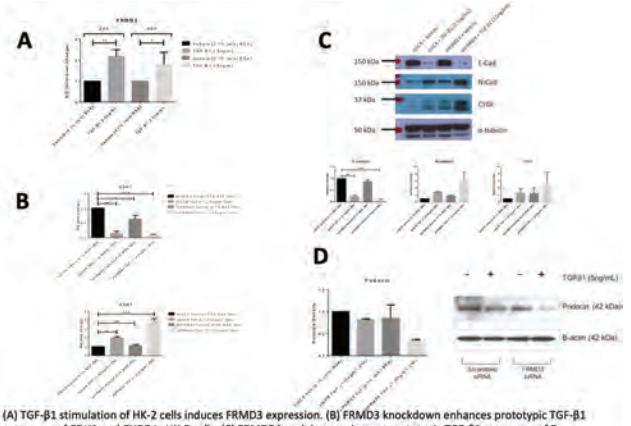
Methods: RNA extracted from kidney biopsy tissue was sequenced using high throughput techniques and gene expression correlated with clinical variables, eGFR and percentage tubulointerstitial fibrosis (%TIF) on kidney biopsy. We identified genes which were differentially expressed in patients experiencing progressive CKD (doubling of serum creatinine or reaching ESKD). Analyses were adjusted for age and sex of the patients, and

with a FDR cut-off of <0.05. Using established cellular models we examined the impact of knock-down of the gene *FRMD3*in human kidney epithelial cells and podocytes.

Results: We examined gene expression in discovery (n=24) and validation cohorts (n=23) and identified a subset of genes which correlated with the clinical variables, eGFR and %TIF, and were associated with CKD progression. Pathways of inflammation and immune system function are heavily represented in our dataset. *FRMD3* expressionwas consistently associated with worse kidney disease, with lower expression seen in patients with higher %TIF and lower eGFR, and in patients with progressive CKD. FRMD3 knockdown enhances the fibrotic responses to TGF-β1, including loss of E-cadherin, upregulation of N-cadherin and CTGF in human kidney epithelial cells, and exaggerated loss of podocin in immortalised human podocytes.

Conclusions: Inflammatory cell signaling pathways are driving forces in CKD progression. Loss of FRMD3 is associated with more severe kidney disease and CKD progression.

Funding: Private Foundation Support



(A) TGF-β1 stimulation of HK-2 cells induces FRMD3 expression. (B) FRMD3 knockdown enhances prototypic TGF-β1 responses of CDH1 and CHD2 in HK-2 cells. (C) FRMD3 knockdown enhances prototypic TGF-β1 responses of E-cadherin, N-cadherin and CTGF in HK-2 cells. (D) FRMD3 knockdown exacerbates the loss of Podocin following TGF-β1 treatment of human podocytes.

Collecting Duct-Specific Deletion of Renin Attenuates Obstruction-Induced Renal Fibrosis and Inflammation

Renfei Luo, Kevin Yang, Chuanming Xu, Fei Wang, Tianxin Yang. *Department of Internal Medicine, University of Utah, Salt Lake City, UT.*

Background: Increasing evidence demonstrates that renin is synthesized and secreted by the collecting duct (CD) as a component of the intrarenal renin-angiotensin system (RAS). The intarenal RAS is well known to contribute to the pathogenesis of chronic renal disease (CKD) in addition to hypertension. However, the precise mechanism of how intrarenal RAS is activated in the disease process is poorly characterized.

Methods: The goal of the present study was to examine the impact of CD-specific deletion of renin on renal fibrosis and inflammation in a mouse model of unilateral ureteral obstruction (UUO). CD-specific renin deletion was generated by crossing aquaporin-2-Cre mice with renin floxed mice (CD renin KO). UUO was performed by ligation of the left ureter near the renal pelvis in flox mice and CD renin KO mice.

Results: After 3 days of UUO, the renal medullary renin content, renin activity and renin mRNA in obstructed kidneys of flox mice were increased by 4.7-, 2.2- and 7.8-fold, respectively, which were all blocked by CD renin KO mice. In contrast, renal cortical renin was largely unaffected by UUO, irrespective of the genotype. Meanwhile, CD renin KO decreased the α-SMA (51.3±10.9%) and fibronectin (60.4±7.2%) protein expression and increased E-cadherin (2.1-fold) protein expression in obstructed kidneys. The content of hydroxyproline, a major component of the protein collagen, in obstructed kidneys of CD renin KO mice showed a significantly reduced generation compared with obstructed kidneys of flox mice. (KO+UUO: 7.7±0.9 versus flox+UUO: 12.3±1.6 ug/mg tissue; P<0.05). The Masson's trichrome staining (MST) data also showed that CD renin KO significantly attenuated UUO-induced collagen deposition and histological damage in the kidney. In parallel, CD renin KO reduced α-SMA (48.2±4.3%), fibronectin (38.6±7.4%), TGF-β (32.9±6.7%), IL-6 (20.6±6.1%) and TNF-α (47.2±5.2%) mRNA expression in obstructed kidneys.

Conclusions: Overall, these results suggest that overactivation of renal CD renin plays an essential role in driving local RAS to promote renal fibrosis induced by obstruction.

TH-PO487

Major Vault Protein Contributes to Tubulointerstitial Fibrosis in CKD

Cheuk Yin Wong, Caleb C. Chan, Chi pang Tai, Susan Yung, Daniel Tak Mao Chan. *The University of Hong Kong, Hong Kong, China.*

Background: Chronic kidney disease (CKD) is a major global issue leading to much morbidity and mortality. Tubulo-interstitial fibrosis is the final pathogenic pathway in the progression of CKD to end-stage renal failure. There is currently no effective treatment for kidney fibrosis. We previously reported that major vault protein (MVP), a key component in the vault complex, contributed to fibrogenesis in HK-2 cells in lupus nephritis. We extended our investigations to other causes of CKD.

Methods: MVP expression in renal biopsies from patients with CKD due to various causes was examined with cytochemical staining. Animal studies were carried out using unilateral ureteral obstruction (UUO) model in wild-type (WT) and MVP knockout (KO) mice, with the contralateral unobstructed kidney serving as control. Mice were sacrificed 14 days after UUO, and the kidneys were harvested and examined. The effect of MVP overexpression in HK-2 cells was investigated.

Results: Kidney biopsies from patients with IgA nephropathy, diabetic nephropathy, or idiopathic membranous glomerulonephritis with CKD showed markedly increased MVP expression, predominately in proximal tubular epithelial cells, compared with normal kidney specimens. MVP gene expression was negligible in normal mice. UUO significantly induced MVP mRNA expression, accompanied by tubular atrophy, increased tubulo-interstitial inflammatory cell infiltration, and matrix protein accumulation including fibronectin and collagen III. MVP KO in UUO mice was associated with reduced immune cell infiltration and decreased tubulo-interstitial collagen III and fibronectin expression compared with WT. Further data showed that MVP regulated collagen III at transcription level, whereas its effect on fibronectin expression was at the post-transcriptional level. MVP gene editing using CRISPR-Cas9 in HK-2 cells was accompanied by decreased MCP-1 secretion and fibronectin expression.

Conclusions: Our data show increased renal tubulo-interstitial MVP expression in CKD irrespective of original cause, which may contribute to inflammatory and fibrotic processes in CKD progression.

TH-PO488

Upregulation of miR-382 Contributes to AKI to CKD Transition via the PTEN/AKT Signaling Pathway

Yi Fang,[1,2] Xiaoyan Wang,[1,2] Qing Kuang,[1,2] Siyu Bao,[1,2] Ning Xue.[1,2] *[1]Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai, China; [2]Shanghai Medical Center of Kidney, Shanghai, China.*

Background: Acute kidney injury (AKI) is recently considered as a critical factor for the development of chronic kidney disease (CKD). But mechanisms driving AKI to CKD transition remain unclear. Previously we have discovered miR-382 as a novel target in TGF-β1-induced epithelial-mesenchymal transition and the development of tubulointerstitial fibrosis after AKI was accompanied with an overwhelmed activation of miR-382.

Methods: In our recent study of aristolochic acid nephropathy (AAN), we exam the effects of genetic absence or pharmacologic inhibition of miR-382 on the expression of NF-κB/PTEN/AKT signaling pathway and renal pathological changes.

Results: Renal fibrosis developed at 14 days after a single dose of aristolochic acid (AA, 10mg/kg,ip) and renal fibrotic lesions getting even more severe at 28 days after AA treatment. Renal abundance of miR-382 was detected increasing until 28 days post AA administration while inhibition of miR-382 partly reversed renal tubulointerstitial fibrosis. The protective effects of anti-miR-382 treatment against fibrosis was also verified in miR-382 KO mice. Protein expression of phosphatase and tensin homolog (PTEN), a target of miR-382, was down-regulated and subsequently its downstream phosphorylated protein kinase B (AKT) signaling pathway was activated during AA induced AKI to CKD transition. Furthermore, we found the up-regulation of miR-382 of renal epithelial cells was in part mediated by activation of NF-kB signaling secondary to AA exposure, with substantial elevation of pro-inflammatory cytokines such as interlukin-1β and tumor necrosis factor-α. In vivo study revealed that either miR-382 knockdown or miR-382 knockout was pivotal for inflammatory suppression. In vitro experiment confirmed that up-regulation of miR-382 in cultured HK-2 cells under AA exposure could be remarkably reversed by NF-kB siRNA.

Conclusions: These data supported a novel mechanism in which AA induced miR-382 up-regulation via NF-kB activation, therefore targeting PTEN/Akt signaling, contributing to the development of renal fibrosis secondary to acute AA related renal toxicity.

TH-PO489

Kinin in Hypertensive Kidney Disease: A Novel Therapeutic Target

Debargha Basuli, Rohan U. Parekh, Srinivas Sriramula. *East Carolina University, Greenville, NC.*

Background: Hypertensive kidney disease is the second leading cause of end-stage renal disease (ESRD) following diabetes. While inhibition of the renin-angiotensin system remains the current management of hypertensive kidney disease, we are still spending billions of dollars for hemodialysis and the incidence of ESRD is projected to increase in upcoming years. Thus, elucidating the pathogenesis of hypertensive kidney disease, particularly if there is any non-angiotensin pathway involved is important to formulate newer treatment strategies. Recently, a growing body of evidence suggests a role for kallikrein-kinin system in hypertension and kidney diseases. The effects of kinins are exerted through two G-protein coupled receptors- B1R and B2R. It has been recently shown that B1R regulates neurogenic hypertension in mice. However, the role of B1R in hypertension induced end-organ damage, particularly in the kidney has not been studied. This study examines the significance of B1R induced inflammation and fibrosis in the kidney.

Methods: Human kidney sections were used to study the expression pattern of B1R in kidneys by immunohistochemistry. Deoxycorticosterone acetate (DOCA)-salt hypertension model coupled with a whole body B1R knockout (B1RKO) mice were used to study the effect of kinin B1R blockade on hypertensive kidney disease. Hypertension induced renal damage was assessed by measuring the mRNA and protein expression of

fibrosis markers (collagen I/III, fibronectin, TGF-β). Renal inflammation was studied by assaying inflammation markers (TNFa, IL6, IL1b) and inflammatory cell infiltration.

Results: B1R is expressed in human kidneys predominantly in proximal tubular cells. Treatment with DOCA-salt significantly increased blood pressure ($p<0.001$) in wild-type mice, which was attenuated in B1RKO mice. B1R blockade decreased DOCA-salt-induced renal fibrosis. Moreover, DOCA-salt-induced increase in renal inflammation was significantly blunted in B1RKO mice.

Conclusions: Our data provide evidence that kinin B1R is expressed in human kidney and may have an important role in the pathogenesis of hypertensive kidney disease. In an animal model, B1R knockdown reduces hypertensive renal damage by decreasing inflammation and fibrosis. Kinin B1R offers a potential therapeutic target for the treatment of hypertension and hypertensive kidney disease.

TGFBI and Kidney Disease Progression

Wenjun Ju,[2] Kerstin Ebefors,[3] Debra L. Walter,[2] Sean Eddy,[2] Linda Cederblad,[1] Viji Nair,[2] Rajasree Menon,[2] Jeffrey B. Hodgin,[2] Susanna Eketjäll,[1] Anna Reznichenko,[1] Jenny C. Nystrom,[3,1] Markus Bitzer,[2] Matthias Kretzler,[2] Julie Williams.[1] *[1]AstraZeneca, Mölndal, Sweden; [2]University of Michigan, Ann Arbor, MI; [3]University of Gothenburg, Goteborg, Sweden.*

Background: TGFBI was identified as one of the genes whose hypomethylation is associated with chronic kidney disease (CKD) progression. Increased expression of TGFBI is reported in patients with diabetic kidney disease (DKD) and was considered to play a central role in a novel pathway that promotes DKD. However, the molecular mechanism of TGFBI in kidney disease progression remains to be determined.

Methods: Bioinformatic analysis was performed to investigate the association of TGFBI expression with kidney disease association in human and mouse models for kidney disease. Single cell RNAseq analysis, in situ hybridization and IHC were used to determine the cellular localization. Expression of key pathway genes was evaluated in TGFBI treated-human mesangial and podocyte cells by qRT-PCR and IHC.

Results: Higher expression of TGFBI is associated with increased kidney disease severity in transforming growth factor-β1 transgenic mice (Albumin/Tgfb1 Tg), developing focal segmental glomerular sclerosis and tubulointerstitial injury. In patients with various CKD etiologies, TGFBI expression is reversely correlated with glomerular filtration rate (GFR), including DKD and SLE. Single cell RNAseq analysis demonstrated that TGFBI is enriched in immune cells, followed by mesangial cells. In vitro mesangial cells can produce TGFBI and knock down reduces pathogenic proliferation. Treatment of podocytes with TGFBI leads to actin cytoskeletal rearrangement and fibrotic gene expression, suggesting that increased *Tgfbi* expression by mesangial cells may cause the podocyte injury. This is supported by the observation that Tg*fbi* mRNA is reversely associated with podocyte density ($r=-0.66$, $p<0.01$) in Tgfb1 Tg mice.

Conclusions: TGFBI is an important player in CKD/DKD progression by initiating podocyte injury which will lead to proteinuria.

TH-PO491

The Role of Renal Uric Acid Crystal Granulomas on CKD Progression in Mice and Humans

Stefanie Steiger, Markus Sellmayr, Moritz R. Hernandez Petzsche, Qiuyue Ma, Hans J. Anders. *Division of Nephrology, Hospital of the LMU Munich, Munich, Germany.*

Background: Tophaceous uric acid (UA) deposits are occasionally found on diagnostic kidney biopsies. Whether UA crystal granulomas are a cause or bystander of CKD is subject of debate. We hypothesized that renal UA granulomas associate with more severe interstitial fibrosis; therefore contribute to CKD progression. UA granulomas are mainly comprised of M1-macrophages. We thought to target a phenotype switch from M1- to M2-macrophages by activating adenosine receptor signaling in a mouse model of CKD with UA granulomas.

Methods: We screened 81,200 diagnostic kidney biopsies for the presence of UA granulomas to determine the prevalence and performed a case-control study to compare biopsies with and without granulomas for morphological abnormalities. Alb-creERT2/Glut9$^{lox/lox}$ (ki/ki) or Glut9$^{lox/lox}$ control mice were fed either a high-fat or chow diet with inosine. We assessed UA crystal deposits, GFR and the extent of kidney damage (MALDI-FTICR MS imaging, immunostaining, flow cytometry). Adenosine therapy was started after renal fibrosis had established.

Results: 84 out of 81,200 kidney biopsies showed UA granulomas, which revealed significantly more glomerulosclerosis and interstitial fibrosis compared to control biopsies. Ki/ki mice on chow diet with inosine developed only hyperuricemia (HU), whereas ki/ki mice on high-fat diet with inosine developed HU + CKD compared to control mice. Indeed, urate nephropathy caused a significant GFR decline compared to HU or control mice. MALDI-FTICR MS imaging confirmed UA crystal deposits that were associated with tubular atrophy, interstitial fibrosis and macrophage infiltration. Histological analysis showed that UA granulomas occur after renal fibrosis had established. Adenosine therapy significantly reduced the number of renal UA granulomas due to less M1- but more M2-macrophages, a process that attenuated CKD progression.

Conclusions: Renal UA granulomas are found in 0,1% of diagnostic kidney biopsies and associated with more renal fibrosis and tubular atrophy. Our *in vivo* data revealed that UA granulomas form after renal fibrosis had established. M1-macropages are essential for UA granuloma formation, and interfering with a switch from M1- to M2-macrophages prevents CKD progression. Together, UA granulomas develop secondary to renal fibrosis but contribute to accelerated kidney atrophy and dysfunction.

Dual Disruption of Endothelial Nitric Oxide Synthase and ApoE Gene Accelerates Kidney Fibrosis and Aging After Injury

Kenji Nishimura,[1] Seiji Kishi,[1,2] Arisa Ochi,[1] Hiroyuki Ono,[1] Masanori Tamaki,[1] Taichi Murakami,[1,3] Hideharu Abe,[1] Ken-ichi Aihara,[4] Kojiro Nagai.[1] *[1]Nephrology, Tokushima University Hospital, Tokushima, Japan; [2]General Medicine, Kawasaki Medical School, Kurashiki, Japan; [3]Ehime Prefectural Central Hospital, Matsuyama, Japan; [4]Community Medicine for Diabetes and Metabolic Disorders, Tokushima University, Tokushima, Japan.*

Background: Medical advances have made it possible to control diseases such as cancer, autoimmune diseases and infectious diseases, extending life for affected patients worldwide. On the other hand, CKD has become a lifestyle-related disease and lifestyle management is necessary to extend healthy life span. In this study, we clarify the effect of interaction between hypertension and atherosclerosis on renal fibrosis and aging.

Methods: Wild type (WT) mouse, apolipoprotein E$^{-/-}$ (ApoE KO) mouse, and endothelial nitric oxide synthase (eNOS)$^{-/-}$; ApoE$^{-/-}$ (WKO) mouse were obtained by crossing eNOS$^{+/-}$ mouse and ApoE$^{+/-}$ mouse. Unilateral ureteral obstruction (UUO) was performed on 8-10 weeks old male mice after blood pressure and lipid profile were measured. Mice were sacrificed 10 days after UUO. The degree of renal tubular injury, fibrosis and kidney aging were evaluated among the three groups.

Results: ApoE KO mice had higher total cholesterol and lower HDL cholesterol than WT mice. WKO mice manifested elevated blood pressure, higher total cholesterol and lower HDL cholesterol than WT mice. Compared with WT mice, ApoE KO and WKO mice showed sustained kideny injury molecule-1 expression and increased α-smooth muscle actin protein expression was found in WKO mice after UUO. mRNA expression of transforming growth factor-β, connective tissue growth factor and type 1 collagen was increased both in ApoE KO and WKO mice and the highest in WKO mice with statistical significance. The picro-sirius red positive stained kidney area was significantly higher in ApoE KO mice and WKO mice. The antioxidant, heme oxygenase-1 was significantly decreased in WKO mice. Furthermore, mRNA expression of p53, p21 and p16 were increased both in ApoE KO and WKO mice and the highest in WKO mice among three groups with significance. A significant increase in senescence associated β-gal positive tubule area was observed in WKO mice.

Conclusions: Mice at high risk for cardiovascular disease developed kidney fibrosis and aging even in the young mice after injury. Vulnerability to oxidative stress promotes fibrosis and aging. Managing lifestyle-related diseases from a young age is important for CKD prevention. This mouse model could be a good tool for elucidating the relationship between bad lifestyle and kidney fibrosis and aging.

Paraoxonase 1 Regulation of Renal Inflammation and Fibrosis in CKD

Fatimah K. Khalaf,[1] Chrysan J. Mohammed,[2] Prabhatchandra Dube,[1] Iman Tassavvor,[3] Andrew Kleinhenz,[3] Apurva Lad,[3] Amira F. Gohara,[3] Deepak K. Malhotra,[1] Steven T. Haller,[3] David J. Kennedy.[4] *[1]University of Toledo, Toledo, OH; [2]University of Toledo College of Medicine & Life Science, Toledo, OH; [3]University of Toledo College of Medicine and Life Sciences, Maumee, OH; [4]The University of Toledo Health Science Campus, Toledo, OH.*

Background: Paraoxonase1 (PON1) is a hydrolytic lactonase enzyme which is synthesized by the liver and circulates attached to high density lipoproteins. Clinical studies have demonstrated an association between diminished PON1 and progression of CKD however whether decreased PON1 is mechanistically linked to renal disease is unknown. We tested whether absence of *PON1* is mechanistically linked to progression of renal injury in a Dahl salt-sensitive model of hypertensive renal disease.

Methods: Experiments were performed on Dahl salt-sensitive rats (wild) and PON1 knock-out rats (*PON1* KO). Ten week old, male rats were maintained on high salt diet (8% NaCl) for up to 5 weeks to initiate renal disease.

Results: Early mortality was observed in 5 out of 12(41.6%) Pon1 KO rats (mean time until death=33 days), while no mortality was observed in wild type rats. At 4 weeks, Pon1 KO and wild type rats developed similar degrees of hypertension however Pon1 KO demonstrated significantly decreased renal function compared to the wild type rats as assessed by FITC-Sinistrin glomerular filtration rate as well as increases in cystatin C and urinary protein excretion. Upon histological examination, kidneys from Pon1 KO rats showed significant evidence of increased renal injury compared to the wild rats as noted by increased renal fibrosis, glomerular sclerosis, and tubular ischemia. Pon1 KO rats also showed significant increases in renal inflammation vs wild type, as measured by increased recruitment of CD68 positive immune cells in the renal interstitium. Further, expression of the key inflammatory genes (Timp-1, MCP-1, IL-6, COL1A1, and TGF-β) was significantly higher in renal tissue from Pon1 KO rats compared to the wild type rats. Also, Pon1 KO rats had significantly increased renal oxidative stress demonstrated by increased renal staining of the oxidative stress marker 8-OHdG as well higher urinary excretion of 8-OHdG vs. wild type. Finally, as activation of Src kinase has been shown to act as a common integrator of multiple pro-fibrotic signals we noted that, compared to wild type rats, renal tissue from Pon1 KO showed increased activation of Src kinase

Conclusions: Our data suggest a new role for PON-1 in regulating renal inflammation and fibrosis in the setting of hypertensive renal disease

TNFα Inhibition Decreases Fibrosis After Ischemia-Reperfusion Injury

Mai Abdelmageed,[3] Eirini Kefalogianni,[1] Andreas Herrlich.[2] *[1]Washington University School of Medicine, St. Louis, MO; [2]Washington University in St. Louis, St. Louis, MO; [3]School of Medicine, Washington University in Saint Louis, St. Louis, MO.*

Background: Renal fibrosis is a frequent complication of acute kidney injury (AKI) and sustained EGFR activation in tubule cells is a hallmark of this process. We have previously shown that injury-induced a disintegrin and metalloproteinase 17 (ADAM17) drives maladaptive repair and kidney fibrosis after injury, but the implicated ADAM17 substrates are unknown. At least two of the main physiological substrates of ADAM17 are upregulated by kidney injury, pro-TNFα and pro-EGFR ligands. ADAM17 releases the active forms of these molecules from the cell surface. We examined the individual contribution of TNFα and EGFR-dependent pathways using FDA-approved drugs in mice: (murine) Etanercept and erlotinib.

Methods: FVB-N mice were subjected to severe bilateral ischemia-reperfusion-injury (IRI) and assigned to 4 treatment groups: (1) vehicle, (2) murine Etanercept (soluble TNFα inhibitor scavenger), (3) Erlotinib (EGFR kinase inhibitor), (4) Erlotinib plus Etanercept. Treatments were started Day 0. Sham surgeries were performed as additional controls. Kidney injury and fibrosis were assessed by biochemical parameters and kidney tissue stains (Fibronectin, α-SMA and picrosirius red). GFR was measured by transdermal monitoring of FITC-sinistrin clearance. Phospho-EGFR levels were detected in kidney lysates by western blotting.

Results: All groups showed the same degree of initial kidney injury. Etanercept or Erlotinib individually significantly decreased renal fibrosis by approximately 40% compared to vehicle-treated mice, but there was no additive protective effect when the drug combination was used. In kidney lysates, Erlotinib (alone or in the combination) decreased EGFR phosphorylation, while Etanercept alone had no effect on p-EGFR.

Conclusions: Etanercept treatment significantly reduced fibrosis after AKI without affecting EGFR activation, and additional EGFR inhibition in combinatorial drug treatment did not further improve outcomes. This suggests that TNFα in the context of AKI-induced fibrosis acts downstream of EGFR. This opens a potentially new therapeutic window for etanercept, a well-tolerated FDA-approved drug, in human AKI.

The Competing Endogenous RNA Network in Renal Aging

Jie Li,[1] Hongli Jiang.[2] *[1]First Affiliated Hospital of Xi'an Jiaotong University, Shaanxi Xi'an, China; [2]First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: It is well known that aging is a continuous and gradual process that causes the physiological functions of all organ systems in the human body to gradually decline. The kidney, which is a metabolically active organ, is extremely susceptible to aging, but the mechanism of kidney aging is unclear. MicroRNAs (miRNAs) are a highly conserved small non-coding RNA of 18-25 nucleotides in length that inhibits protein expression at the post-transcriptional level or degrades target genes to regulate gene expression. Long-chain non-coding RNA (lncRNA) is a non-coding RNA consisting of 200 nucleotides. It is generally considered that they do not encode proteins, but are expressed in various forms at the RNA level. In ceRNA networks, lncRNAs bind to miRNAs via miRNA response elements (MREs), and miRNAs can also bind to the corresponding mRNA 3'UTR through specific binding sites, inhibiting the level of protein expressed.

Methods: Analyse the lncRNA expression profiles in different ages mouse using a microarray array. And predicted miRNAs and mRNAs that interact with lncRNAs. SA-β-gal staining and immunohistochemistry were operated for the detection of the p53, p16 expression in different ages. Then we use Masson and PAS staining to assess the degree of fibrosis in the kidney.

Results: Bioinformatics analysis results show that the expression of some lncRNAs decreased with age, and the corresponding miRNAs expression increased accordingly. With the increase of age, we detected that the expression of senescence-associated galactosidase gradually increased, the expression of p16 and p53 gradually increased, and the renal fibrosis gradually worsened.

Conclusions: With the increase of age, the expression of senescence-associated galactosidase gradually increased, the expression of p16 and p53 gradually increased, and the renal fibrosis gradually worsened. ceRNA network plays an important role in kidney aging.

TH-PO496

Impairment of CPT-1α and Fatty Acid Metabolism Aggravates Renal Fibrosis During Aging

Qi Yuan,[2] Yang Zhou,[1] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Jiangsu Nanjing, China.*

Background: Defects in renal fatty acid metabolism (FAM) pathway have been implicated in the development of renal fibrosis. Aged kidneys show significantly increased fibrosis with impaired kidney function. The mechanisms underlying the effects of FAM on renal aging and fibrosis have not been investigated. In this study, we investigated carnitine palmitoyltransferase-1α (CPT-1α) and FAM pathway as regulators of age-associated renal fibrosis.

Methods: Renal biopsy samples from 126 patients were examined by masson trichrome staining, oil red O staining and immunohistochemical staining for CPT-1α. To evaluate the effects of CPT-1α deficiency on age-associated renal fibrosis, age-matched tubular cell specific CPT-1$\alpha^{-/-}$ mice and their wild-type littermates were used.

Results: In patients, fibrosis and lipid accumulation in tubulointerstitial spaces were associated with the age of patients. After been followed up for 5 years, age and lipid accumulation were risk factors for the progression of renal fibrosis. As compared with wild-type litermates, renal dysfunction measure by blood urine nitrogen and serum creatinine, tubular damage evaluated by urinary KIM-1, NGAL and NAG, urinary albumin and protein excretion were all more severe in mice with tubular specific deficiency of CPT-1α at the age of 1-year-old. Meanwhile, more lipid accumulation, tubulointerstitial fibrosis, extracellular matrix deposition were observed in CPT-1$\alpha^{-/-}$ mice at the age of 1-year-old. The increased expression of aging proteins (p21, p53, PCNA), inflammatory factors (NF-κB, CD3, IL-1, IL-18) and apoptosis molecule (cleaved caspase3) and decreased expression of autophagy (Atg12, Beclin-1, LC3β, p62) in kidney of CPT-1$\alpha^{-/-}$ mice were accompanied by the dysregulated expression of FAM proteins, including PPARα, CD36, ACADL, ACOX1, FASN and ACLY. In primarily cultured tubular cells, down-regulation of CPT-1α resulted in increased ROS and decreased mitochondrial energy production.

Conclusions: Impairment of CPT-1α and fatty acid metabolism in tubular cells aggravates renal aging and fibrosis.

Protective Role of Kallistatin Against Renal Fibrosis in Unilateral Ureteral Obstruction

Wai Han Yiu,[1] Ye Li,[1] Sarah W.Y. Lok,[1] Wing han Liu,[1] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Kar Neng Lai,[1] Hui Y. Lan,[2] Sydney C. Tang.[1] *[1]The University of Hong Kong, Hong Kong, China; [2]The Chinese University of Hong Kong, Shatin, China.*

Background: Kallistatin is an endogenous serine protease inhibitor, which exerts anti-oxidative and anti-inflammatory function against kidney injury in animal models. However, it remains unknown whether kallistatin plays any protective effect in renal fibrosis, the final common pathway of all chronic kidney diseases.

Methods: Unilateral ureteral obstruction (UUO) was used to investigate the effect of kallistatin on renal extracellular matrix (ECM) protein expression and fibrotic signaling pathways. Renal kallistatin was either overexpressed by ultrasound-mediated microbubble kallistatin gene transfer or depleted by injection of anti-kallistatin antibody.

Results: Endogenous kallistatin expression was reduced in renal cortex of UUO kidneys. Kallistatin treatment significantly suppressed macrophage accumulation and the increase in ECM proteins including collagen type I and III as well as α-SMA. In contrast, injection with anti-kallistatin antibody aggravated renal fibrosis as evidenced by a further increase in ECM proteins. Moreover, depletion of endogenous kallistatin exacerbated UUO-induced Wnt4, β-catenin and Axin2 overexpression in the kidneys, while treatment with kallistatin reduced both Wnt4 and TGF-β over-expression in UUO kidneys.

Conclusions: Our results suggest a therapeutic role for kallistatin against renal fibrosis. Kallistatin exerts its anti-fibrotic effect in the kidney via modulating TGF-β and Wnt/β-catenin pathways, thereby offering a novel potential target of treatment for chronic kidney disease. **Fund support:** Research Grants Council of Hong Kong (GRF grant number 17151716, CRF grant number C7018-16G), Hong Kong Society of Nephrology and Hong Kong Kidney Foundation Research Grant (2017).

Semaphorin 3A Inhibitor Ameliorates Renal Fibrosis in Unilateral Ureter Obstruction Mice

Yizhen Sang, Kenji Tsuji, Kazuhiko Fukushima, Shinji Kitamura, Jun Wada. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Renal fibrosis is the common pathological pathway of progressive renal diseases. Semaphorin3A (SEMA3A) is a secreted protein involves in angiogenesis, cell motility and immune cell regulation. Previous reports suggest SEMA3A accelerates renal injury. However, it is unclear whether SEMA3A signaling is associated with renal fibrosis. Here we examined the role of SEMA3A on renal fibrosis using unilateral ureter obstruction (UUO) mouse model and examined the effects of SEMA3A-inhibitor (SEMA3A-I: provided from Dainihon Sumitomo Pharm).

Methods: 10-week old wild-type male C57BL/6N mice were assigned into three groups (n=5 / each): UUO group (UUO+daily saline injection), UUO+SEMA3A-I group (UUO+daily SEMA3A-I injection) and sham group. All the mice were sacrificed 2 weeks after UUO surgery. We analyzed the effect of SEMA3A-I *in Vivo* and *in Vitro*, using mouse proximal tubular cells (mProx24 cells). In addition, human samples of urine, serum and kidneys from biopsied patients (n=36) were collected to analyze the involvement of SEMA3A in renal diseases.

Results: The expressions of SEMA3A and the receptor, neuropilin-1 (NRP1) increased in renal fibrotic area in UUO group while SEMA3A-I significantly ameliorated UUO-induced renal fibrosis in Masson staining as well as tubular cell apoptosis in TUNEL staining. The expression of phospho-c-Jun, a downstream of c-Jun N-terminal kinase (JNK) signaling, known as the target of SEMA3A-NRP1 signaling, increased in UUO group compared to sham group. *In vitro* study, the treatment with SEMA3A in

mProx24 cells caused Epithelial-Mesenchymal Transition (EMT) with the increase of Vimentin/E-cadherin ratio as well as apoptosis, while SEMA3A-I treatment partially attenuated cisplatin-induced tubular cell apoptosis and TGFβ1-induced EMT. JNK inhibitor decreased SEMA3A-induced tubular apoptosis and EMT. These data suggest that SEMA3A causes renal injury via JNK signaling. The analysis of human data revealed the positive correlation between urinary SEMA3A and N-acetyl-β-D-glucosaminidase (r=0.531, p=0.007). In addition, the higher expression of SEMA3A in tubulointerstitial area were seen in human kidneys with severe renal fibrosis, confirming SEMA3A signaling is associated with tubular injury and fibrosis.

Conclusions: SEMA3A-I ameliorates UUO-induced renal fibrosis and tubular injury through the inhibition of JNK signaling.

Disturbed Phosphate Metabolism Facilitates Kidney Damage in Dahl Salt-Sensitive Hypertensive Rats

Qin Wang,[1,2] Kenichi Ishizawa,[3] Yoshikazu Nemoto,[4] Yutaka Miura,[7] Jinping Li,[8] Makoto Kuro-o,[5] Shigeru Shibata.[6] *[1]Teikyo University, Tokyo, Japan; [2]Nephrology, The Second Affiliated Hospital of Harbin Medical University, Harbin, China; [3]Shinsen-Ikebukuro Clinic, TOKYO, Japan; [4]Teikyo University hospital, Tokyo itabashi, Japan; [5]Jichi Medical University, Shimotsuke, Japan; [6]Teikyo University School of Medicine, Tokyo, Japan; [7]Jichi Medical University, Shimotsuke, Japan; [8]Teikyo university, Tokyo, Japan.*

Background: Several lines of evidence indicate that hypertensive end-organ damage is associated with altered phosphate metabolism. Here, we evaluated the effects of intestinal phosphate binding by sucroferric oxyhydroxide (SF) on renal damage in Dahl salt-sensitive rats, a model of hypertensive kidney disease.

Methods: Control rats received a normal diet containing normal (0.3%) phosphate. High salt (HS) group received a diet containing 8% NaCl and 0.3% phosphate for four weeks. A subgroup of HS rats received SF (HS+SF). We also evaluated the effects of phosphate loading in NRK-52E, a proximal tubule cell line.

Results: Compared with control, HS showed progressive increase in BP. Although urinary Na^+ and BP levels were similar between HS and HS+SF groups, albuminuria was significantly ameliorated in the latter. In PAS staining, SF attenuated glomerulosclerosis and tubulointerstitial injury in this model. Moreover, upregulation of inflammatory cytokines in renal tubules was significantly ameliorated by SF. Reduced inflammatory response in the tubulointerstitium of HS+SF rats were confirmed by quantitative evaluation of CD68 staining. In the heart, HS group showed myofiber hypertrophy and macrophage infiltration. However, only the latter was attenuated in HS+SF. We then evaluated phosphate metabolism in this model. Although plasma phosphate levels were not significantly different among three groups, fractional excretion of phosphate and plasma FGF23 levels were significantly elevated in HS group, which was attenuated by SF. In NRK-52E cells, phosphate loading significantly increased the expression of MCP-1. Removing calcium-phosphate crystals by centrifugation, but not the knockdown of sodium-dependent phosphate transporter Slc34a1, abolished the effect of phosphate.

Conclusions: Phosphate loading to renal tubules can aggravate renal inflammation likely through calcium-phosphate nanoparticle formation. These data support the pathological role of latent phosphate accumulation in hypertensive kidney damage.

Agonistic cMet Antibody Prevents Kidney Fibrosis in Acute Kidney Disease Mice Model

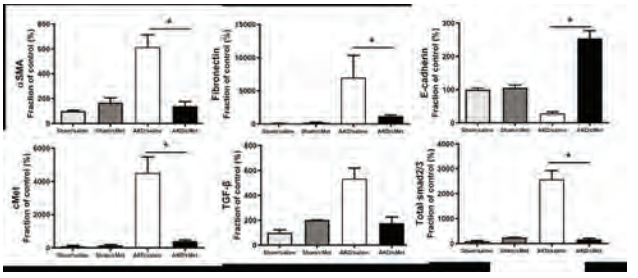
Jeonghwan Lee,[1] Lilin Li,[2] Jung Pyo Lee.[3] *[1]Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Boramae Medical Center, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: HGF/cMet signaling pathway plays important roles in kidney development and maintenance of normal adult kidney structure, and cMet activation is expected to prevent kidney fibrosis. We aimed to investigate whether treatment with agnostic cMet antibody can prevent kidney fibrosis in the acute kidney disease mice model.

Methods: Unilateral ischemic-reperfusion injury at left kidney was introduced in 7-week-old male C57BL/6 mice (n = 14) and raised for up to 28 days to induce acute kidney disease model. Agnostic cMet antibody (20 mg/kg) was injected via tail vein at a schedule of day -1, 0, 1, 3, and twice weekly thereafter in the treatment group (n = 7). Vehicle (saline) was injected via tail vein at the same schedule in the control group (n = 7).

Results: Kidney weight (left) per total body weight was significantly higher in the treatment group (0.63 ± 0.21% vs. 0.43 ± 0.22%, P = 0.022). In the histopathologic specimen of Masson's trichrome stain, areas of kidney interstitial fibrosis attenuated in the treatment group. In the western-blot analysis, protein abundance of α-smooth muscle actin (22.5% of control, P = 0.03), fibronectin (16.4% of control, P = 0.03), TGF-β (33.3% of control, P = 0.05), total (6.6% of control, P = 0.03) and phospho-smad2/3 (10.1% of control, P = 0.03) decreased significantly, and protein abundance of e-cadherin increased (912.4% of control, P = 0.03) significantly in the treatment group. In the real-time PCR analysis, mRNA expression of α-smooth muscle actin (11.5% of control, P = 0.006), collagen 1 (11.6% of control, P = 0.01), fibronectin (11.2% of control, P = 0.01), TGF-β (21.3% of control, P = 0.01) decreased significantly in the treatment group.

Conclusions: Agonistic cMet antibody attenuates kidney fibrosis in the mice unilateral ischemic reperfusion induced acute kidney disease model, and TGF-β and smad2/3 pathway involved in the kidney fibrosis are effectively suppressed in the treatment of agonistic cMet antibody.



Western Blot Results after Agonistic cMet Antibody Treatment

Lysine Deacetylase Inhibition Attenuates Tubulointerstitial Injury and Fibrosis in a Model of Proteinuric CKD

Vanessa R. Williams,[1] Ana Konvalinka,[2,3] Rohan John,[2] York P. Pei,[2,3] James W. Scholey.[3] *[1]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada.*

Background: There is a paucity of effective treatments for tubulointerstitial fibrosis associated with progressive CKD. Previously, we derived a CKD progression signature composed of differentially expressed genes based on aging and disease in *Col4a3*$^{-/-}$ mice, a model associated with proteinuria and progressive loss of kidney function. Through drug repurposing with the progression signature and the Connectivity Map we identified vorinostat, a lysine deacetylase (KDAC) inhibitor, as a potential therapy for CKD progression. Here, we examine effects of vorinostat treatment on tissue fibrosis in *Col4a3*$^{-/-}$ mice.

Methods: Male *Col4a3*$^{-/-}$ mice on a congenic 129/SvJ background were treated with vorinostat (50 mg/kg/day) or vehicle from 4 to 7 weeks of age by oral gavage. Mice were euthanized at 7 weeks of age. Plasma, urine, and kidney samples were collected. Kidney histological, function, inflammation, and fibrosis analyses were performed. Separate groups were followed for survival assessment. Finally, albumin-stimulated human proximal tubule epithelial (HK-2) cells were treated with vorinostat (5 μM) and used to assess mechanisms.

Results: Vorinostat treatment did not improve kidney function and had no effect on glomerulosclerosis scores, but significantly reduced tubular injury markers, KIM-1 and NGAL. This was associated with a significant increase in the lifespan of *Col4a3*$^{-/-}$ mice. *Col1a1, Fn1, Serpine1,* and *Tnf* mRNA levels were reduced in the kidneys of vorinostat-treated mice. Vorinostat administration lowered TGF-β1 and α-SMA protein levels in kidneys and urine, respectively. Treatment attenuated JNK phosphorylation in *Col4a3*$^{-/-}$ mouse kidneys. *In vitro*, vorinostat reduced albumin-induced activation of JNK, p38, and ERK in HK-2 cells. Vorinostat also attenuated the activation of activator protein 1 transcription factor *in vitro*.

Conclusions: Our findings suggest that KDAC inhibition and blockade of MAPKs may be effective treatment approaches to CKD associated with proteinuria and progressive tubulointerstitial injury.

TH-PO502

Lysine Methyltransferase SMYD2 Inhibition Ameliorates Renal Fibrosis Through Suppression of Renal Fibroblast to Myofibroblast Transition

Lirong Liu,[3] Feng Liu,[2] Chongxiang Xiong,[1] Evelyn Tolbert,[4] George P. Bayliss,[5] Shougang Zhuang.[1] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Shanghai East Hospital, Shanghai, China; [3]Guizhou Medical University, Guiyang, China; [4]Rhode Island Hospital, Providence, RI; [5]Alpert Medical School, Brown University, Providence, RI.*

Background: Although SMYD2, a SET and MYND domain protein with lysine methyltransferase activity, has been reported to mediate tumorgenesis and cystic growth, its roles in the pathogenesis of renal fibrosis has not been explored.

Methods: We investigated whether pharmacological inhibition of SMYD2 attenuates renal fibrosis in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO). We also used cell culture, immunoblot analysis, staining, and other techniques to study the mechanism by which SMYD2 mediates renal fibrosis and renal fibroblast activation and proliferation.

Results: SMYD2 was upregulated in interstitial fibroblasts and renal tubular epithelial cells of the kidney after urethral obstruction. Targeting inhibition of SMYD2 with AZ505, a highly selective inhibitor of SMYD2, protected mice from activation of renal interstitial fibroblasts and development of renal fibrosis. Mechanistic studies showed that AZ505 treatment reduced obstructive injury –induced arrest of epithelial cells at G2/M phase of cell cycle, phosphorylation of Smad3, ERK1/2, AKT, STAT3 and AKT as well as upregulation of transcriptional factors Snail and Twist. In vitro cultured renal interstitial fibroblasts, treatment with AZ505 or silencing of SMYD2 using specific siRNA also inhibited serum or TGF-b1-induced activation of and proliferation of renal interstitial fibroblasts.

Conclusions: These results implicate that SMYD2 is a key mediator of renal fibroblast activation and renal fibrosis. Given the availability of potent SMYD2 inhibitors, SMYD2 might be a potential therapeutic target for the treatment of chronic fibrotic kidney disease.

TH-PO503

Selective Inhibition of Histone Deacetylase 8 Suppresses Renal Fibroblast Activation and Mitigates Renal Fibrosis

Yunhe Zhang,[1] Evelyn Tolbert,[1] George P. Bayliss,[2] Shougang Zhuang.[1,2] *[1]Rhode Island Hospital, Providence, RI; [2]Alpert Medical School, Brown University, Providence, RI.*

Background: Histone deacetylase 8 (HDAC8), a unique class I zinc-dependent HDAC, is implicated in the pathogenesis of various rumors, however, its role in renal fibrogenesis remains poorly understood.

Methods: In this study, we examined the effect of HDAC8 inhibition on the activation of cultured renal interstitial fibroblasts and. the development of renal fibrosis in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO).

Results: Treatment of cultured renal interstitial fibroblasts with PCI34051, a selective HDAC8 inhibitor, or small interfering RNA-mediated silencing of HDAC8, inhibited their activation as indicated by decreased expression of alpha smooth muscle actin, fibronectin and type I collagen. In a mouse model of obstructive nephropathy, HDAC8 was up-regulated in renal epithelial cells of the injured kidney. Administration of PCI34051 immediately after UUO injury reduced the deposition of extracellular matrix proteins and inhibited activation of renal fibroblasts. Moreover, HDAC8 inhibition suppressed activation of several signaling pathways associated with the progression of renal fibrosis, including Smad-3, beta-catenin, signal transducer and activator of transcription 3 (STAT3), whereas increased expression of klotho and bone morphogenetic protein 7, two renoprotecive proteins, in the injured kidney.

Conclusions: Our results indicate that selectively targeting HDAC 7 can inhibit development of renal fibrosis and activation of renal fibroblasts by inactivation multiple profibrotic molecules and increasing expression of antifibrotic proteins. Thus, HDAC8 may be a druggable target.

Critical Role of lincRNA-p21 in Mediating Lipotoxicity-Induced Kidney Injury

Bin Li,[1] Joseph C K Leung,[1] Loretta Y.Y. Chan,[2] Wai Han Yiu,[1] Kar Neng Lai,[1] Sydney C. Tang.[1] *[1]The University of Hong Kong, Hong Kong, China; [2]Queen Mary Hospital, Hong Kong, China.*

Background: Ectopic lipid accumulation in kidney is a key factor in the etiology of lipotoxicity-induced kidney lesion. Emerging evidence unravels that long intergenic non-coding RNA p21 (lincRNA-p21) plays a pivotal role in diverse biological processes and diseases. However, little is known about the role of lincRNA-p21 in kidney diseases. We aim to identify the functional role of lincRNA-p21 in lipotoxicity-induced kidney injury.

Methods: Expression of lincRNA-p21 in kidney from mice (C57BL/6J) fed with normal diet (ND; 10 kcal%) or high-fat diet (HFD; 60 kcal%), as well as in palmitic acid (PA)-treated human proximal tubular epithelial cells line (HK-2 cells) was determined by qRT-PCR. Antisense locked nucleic acids (LNA) GapmeR technique was utilized to silence lincRNA-p21 expression in HK-2 cells, followed by evaluation of cellular inflammation, endoplasmic reticulum (ER) stress and apoptosis by qRT-PCR after PA exposure. Western blot and ELISA were performed to investigate the associated signaling cascades.

Results: Compared with ND-fed mice, a significantly increase in the expression of lincRNA-p21 was found in kidney biopsy from HFD-fed mice. Consistently, markedly upregulated expression of lincRNA-p21was observed in PA-treated HK-2 cells. By contrast, silencing lincRNA-p21significantly counteracted PA-induced gene expression associated with inflammation (IL6), ER stress (BiP, sXBP1 and CHOP) and apoptosis (BCL2). Additionally, PA suppressed PI3K/Akt/mTOR/Mdm2 signaling cascades and subsequently led to enhanced p53 activity, which consequently drove lincRNA-p21 expression in HK-2 cells.

Conclusions: PA acts through PI3K/Akt/mTOR/Mdm2 signaling pathway to up-regulate lincRNA-p21 expression in a p53-dependent manner, thereby contributing to lipotoxicity-induced pathological process in HK-2 cells. **Funding:** National Natural Science Foundation of China (81870496), Hong Kong Research Grants Council Collaborative Research Fund (C7018-16G) and Hong Kong Society of Nephrology Research Grant (2018)

Dicer Promotes Renal Recovery and Limits Interstitial Fibrosis Following Kidney Injury

Jamie Lin,[1] Sara Lovisa,[1] Michael Zeisberg,[2] Hikaru Sugimoto,[1] Fei Xiao,[1] George Calin,[1] Valerie Lebleu,[3] Raghu Kalluri.[1] *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]Univ Med Center of Goettingen, Goettingen, Germany; [3]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Renal tubulointerstitial fibrosis is the histopathological hallmark observed in chronic kidney disease; and activated fibroblasts, myofibroblasts, are the dominant extracellular matrix-producing cells that contribute to fibrosis development. Dysregulation or deletion of Dicer, a ribonuclease involved in microRNA (miRNA) generation, impacts kidney health and function. Since fibroblasts are key cells responsible for renal fibrosis, we investigated whether Dicer might effect myofibroblast and fibrosis formation by deletion of Dicer from myofibroblasts *in vivo*.

Methods: $Dicer^{fl/fl}$ mice were crossed with α-smooth muscle actin promoter (αSMA^{Cre}) mice, a marker of activated fibroblast, to generate WT (αSMA^{Cre-};$Dicer^{fl/fl}$) and Dicer conditional knock-out mice (αSMA^{Cre+};$Dicer^{fl/fl}$, hereafter $Dicer^{cKO}$). Mice were challenged to three different kidney injury models. MiRNAs from primary kidney fibroblasts were analyzed.

Results: Isolated human and mouse fibroblast from fibrotic kidneys demonstrated increased Dicer hypermethylation. $Dicer^{cKO}$ mice had no overt renal abnormalities. To determine whether deletion of Dicer in myofibroblast might impact the development of tubulointerstitial fibrosis, both WT and $Dicer^{cKO}$ mice underwent unilateral ureteral obstruction, nephrotoxic serum nephritis, and folic acid kidney injury. $Dicer^{cKO}$ mice displayed increased collagen deposition and tubulointerstitial fibrosis compared to WT animals in all three models. Furthermore, loss of Dicer resulted in an increase of proliferating, Ki67 positive, αSMA^{+} myofibroblasts. MiRNA array analysis of primary mouse fibroblasts from the UUO kidneys of $Dicer^{cKO}$ and WT mice revealed a differential expression of several miRNAs, including upregulation of miR-451, a Dicer-independent miRNA, in the $Dicer^{cKO}$ mice.

Conclusions: Renal tubulointerstitial fibrosis is the pathological sequelae observed in chronic injury. Dicer is critically involved in kidney homeostasis, and here we show that Dicer deletion in myofibroblasts resulted in differential miRNA expression and pathologic myofibroblast proliferation perpetuating fibrogenesis. Depletion of Dicer and associated miRNAs is pathogenic in various kidney injury models and accelerates kidney failure.

TH-PO506

The Transcription Factor STAT3 Plays Key Roles in the Development of Kidney Fibrosis by Increasing Proliferation and Differentiation of Pericytes into Myofibroblasts

Amrendra K. Ajay,[1] Li Zhao,[2] Shreyas Jadhav,[2] Yan Ding,[2] Li-Li Hsiao,[1] Joseph V. Bonventre.[2] Kidney Innovation Centre *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: STAT3 is a key transcription factor, which plays important roles in inflammatory diseases. STAT3 has been shown to transcribe genes important for the acute and chronic phase of various malignant. There is little information regarding the function of STAT3 in stromal cells.

Methods: Phosphorylation of STAT3 was evaluated in 5 patient biopsy samples using immunofluorescence. In mice, stromal cell-specific STAT3 deletion was performed by breeding STAT3 floxed mice with FoxD1 Cre mice. Kidney fibrosis was induced by administering 300 mg/kg folic acid (FA) or 5 mg/kg body weight aristolochic acid (AA). Cell migration was evaluated with wound scratch assays. RT-PCR, immunostaining and western blotting were performed to measure changes in STAT3-dependent genes and to quantitate pro-fibrotic cytokines.

Results: STAT3 phosphorylation was increased in tubular epithelial cells and interstitial cells of 5 human subjects with chronic kidney disease. Deletion of STAT3 from stromal cells protects mice from FA or AA-induced kidney fibrosis at 7- and 14-days post-treatment respectively. Fibrotic markers, including fibronectin, collagen1a1, and α-SMA were reduced in STAT3 KO mice. STAT3 KO mice show similar acute injury {shown by histopathology and mRNA levels of TNFa and KIM-1 (Kidney Injury Molecule-1, acute kidney injury marker)}. KIM-1 expression was decreased at 7 and 14 days in STAT3 KO mice. In human primary pericytes in vitro, STAT3 was phosphorylated after treatment with IL-6 or Colivelin (a small peptide activator of STAT3). Inhibition of IL-6-induced STAT3 phosphorylation significantly decreased the proliferation, production of profibrotic cytokines and differentiation of pericytes into myofibroblasts.

Conclusions: STAT3 plays key roles in the development of kidney fibrosis by increasing proliferation and differentiation of pericytes into myofibroblasts. Thus, STAT3 may be a potential therapeutic target for kidney fibrosis.

Sodium Thiosulfate Improves Renal Function and Oxygenation in L-NNA Induced Hypertensive Rats

Isabel T. Nguyen,[1] Astrid Klooster,[3] Martin Feelisch,[2] Marianne C. Verhaar,[1] Harry Van goor,[4] Jaap A. Joles.[1] *[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]University of Southampton, Southampton, United Kingdom; [3]Pathologie Friesland, Leeuwarden, Netherlands; [4]UMCG, Groningen, Netherlands.*

Background: Sodium thiosulfate (STS, $Na_2S_2O_3$), a H_2S donor, a vasodilator and anti-oxidant, is an attractive agent for alleviating the damaging effects of hypertension. In experimental setting, nitric oxide synthase (NOS) inhibition by L-NNA induces hypertension, renal dysfunction and damage. We hypothesized that 1) STS attenuates renal injury and improves renal function, hemodynamics and oxygen efficiency in hypertensive renal disease and that 2) STS on top of RAS inhibition will further improve aforementioned variables in comparison to RAS inhibition alone.

Methods: NOS was inhibited in male Sprague Dawley rats by administering L-NNA (40 mg/kg/day) in the food for 3 weeks. After one week of NOS inhibition, rats were split in 2 groups for the remaining 2 weeks, 1) L-NNA only and 2) L-NNA with STS (2 g/kg/day) in the drinking water. In a parallel study, rats were divided in 2 groups, 1) L-NNA with lisinopril (1mg/kg/day) mixed in the food and 2) L-NNA with both lisinopril and STS. After weekly systolic blood pressure measurements and 24h urine collection, hemodynamics and sodium reabsorption efficiency (TNa/QO_2, sodium reabsorbed per oxygen consumed) were assessed under isoflurane and kidneys were collected for glomerulosclerosis and mesangial matrix expansion scores.

Results: STS increased 24h excretions of sodium 3.5-fold and sulphate 30-fold, alleviated hypertension (165±5 vs. 228±5 mmHg, P<0.001), reduced plasma urea (11±1 vs. 21±4 mmol/L, P<0.05) and improved terminal GFR (503±25 vs. 260±45 µl/min/100 g BW, P<0.01), effective renal plasma flow (919±64 vs. 532±97 µl/min/100 g BW, P<0.01) and TNa/QO_2 (14.3±1.1 vs. 8.6±1.4 µmol/µmol, P<0.01). Combining STS with lisinopril further reduced renal vascular resistance (43±4 vs. 63±7 mmHg/ml/min/100 g BW, P<0.05) vs. L-NNA+lisinopril. Additionally, glomerulosclerosis was completely prevented (P<0.001) and mesangial matrix expansion (P<0.01) was markedly reduced in L-NNA+lisinopril+STS vs. L-NNA+lisinopril.

Conclusions: Our results suggest that supplementing H_2S has therapeutic potential in hypertensive renal disease and might be of additive value in already existing antihypertensive regimens despite the increase in sodium load.

Pemafibrate Exerts Renoprotective Effects by Activation of PPARα in Murine Kidneys

Daiki Aomura, Yuji Kamijo. *Shinshu University School of Medicine, Matsumoto, Japan.*

Background: Recently, free fatty acid (FFA) toxicity accompanying proteinuria was identified as a main cause of tubular damage, which was aggravated by an insufficiency of peroxisome proliferator-activated receptorα (PPARα). We have reported that strongly PPARα agonistic fibrate drugs exert renoprotective effects by PPARα activation in proximal tubular epithelial cells with FFA-overload nephropathy (FAON) tubular injury model mice. In the clinical setting, however, there have been no safe PPARα agonists for patients with chronic kidney disease (CKD) since fibrate drugs have severe dose-related adverse effects, including a decrease in kidney function. Pemafibrate (PMF) was approved in Japan in 2018 as the first selective PPARα modulator (SPPARMα). PMF has much more potent and specific PPARα-activating efficacy as compared with other fibrates and is excreted in the bile. Thus, the drug can achieve greater improvements in fatty acid metabolism with a highly reduced risk of diminished kidney function and other adverse effects. Although PMF can be safely prescribed for CKD patients, it is uncertain whether it activates PPARα in the kidneys or has renoprotective effects.

Methods: We examined the above possibilities using the kidneys of wild type mice and FAON model mice with and without 0.25 mg/kg/day PMF administration for 14 days.

Results: PPARα target gene expression in the kidneys was significantly decreased in FAON model mice and it was improved by PMF treatment. The PMF treated animals also exhibited decreased levels of tubular injury, urinary protein excretion, oxidative stress (OS), and pro-inflammatory apoptosis-stimulating responses, as well as stable fatty acid metabolism. Moreover, expression of the PPARα gene and its target mRNA-encoding proteins involved in OS, pro-inflammatory responses, apoptosis, and fatty acid metabolism were maintained with PMF treatment.

Conclusions: This study's results suggest that PMF activates renal PPARα, increases PPARα signaling, and imparts renoprotective effects.

TH-PO509

Calcineurin Inhibition but Not Dehydration in Rats Mimics Human Renal Histopathology of Patients with Chronic Interstitial Nephritis in Agricultural Communities (CINAC)

Gerd Schreurs,[2] Cynthia C. Nast,[1] Stuart Maudsley,[2] Patrick C. D'Haese,[2] Marc E. De Broe,[2] Benjamin A. Vervaet.[2] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]University of Antwerp, Antwerp, Belgium.*

Background: CINAC patients present a newly discovered constellation of proximal tubular lysosomal lesions which is also observed in patients experiencing calcineurin inhibitor (CNI) nephrotoxicity, suggesting that CINAC is a toxin-induced nephropathy involving calcineurin inhibition. An alternate hypothesis advocates chronic heat stress/dehydration as the major etiological factor for CINAC. Here, we evaluated in rats to what extent heat stress/dehydration versus CNI exposure reflects proximal tubular CINAC histopathology.

Methods: Wistar rats were divided in 3 groups. Group 1 (n=6) was given water ad libitum (control group). Group 2 (n=8) was water deprived for 10 hours per 24h, 5 days/week and were placed in an incubator (37°C) for 30 min/hr of water deprivation. Group 3 (n=8) underwent daily oral gavage with cyclosporine (50mg/kg body weight). Animals were weighed daily and urine was collected at day 3, 17 and 28. After 28 days, rats were sacrificed. Kidneys were collected for light (LM) and electron microscopic (EM) histopathological analysis as well as for cortical renal tissue proteomics.

Results: Cyclosporine rats developed focal cortical lesions mimicking those of CINAC patients: i.e. atrophic proximal tubuli with thickened basement membranes and associated tubulo-interstitial fibrosis, PASM staining demonstrating enlarged argyrophyllic granules in the affected proximal tubuli, LAMP1 immunofluorescent staining identifying a subset of these granules as lysosomes, and EM confirming the presence of enlarged lysosomes, some dysmorphic approaching CINAC lysosomes. In dehydrated rats, confirmed by urinary osmolality and fluctuating body weight associated with water deprivation, none of the cyclosporine features were observed. Proteomic analysis confirmed cellular toxicity by cyclosporine, whereas the dehydration group lacked any markers of such.

Conclusions: The histopathological analogy between CNI nephrotoxicity in rats and humans and CINAC suggests a toxicological etiology for CINAC. In rats, dehydration/heat stress alone does not lead to the constellation of proximal tubular lesions as observed in CINAC patients.

TH-PO510

Renoprotective Effect of Astragalus Root in a Rat Model of CKD

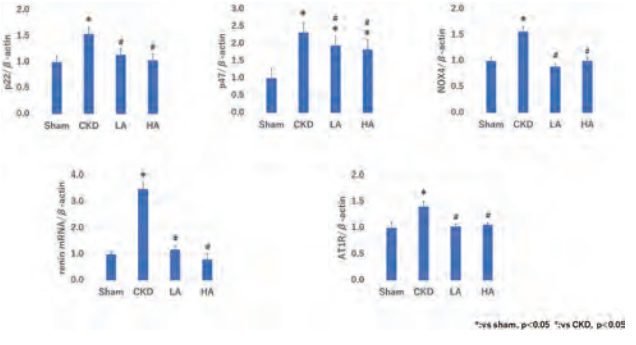
Nozomi Yamada, Hideki Fujii, Shunsuke Goto, Kentaro Watanabe, Keiji Kono, Shinichi Nishi. Division of Nephrology and Kidney Center *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Astragalus root is a commonly used herb in traditional Chinese medicine. Although it has been reported to have a renoprotective effect in clinical and animal studies, the pathophysiological mechanism remains unknown. In the present study, we examined the details of the renoprotective property of astragalus root using a rat model of chronic kidney disease (CKD).

Methods: CKD was induced by 5/6 nephrectomy using male Sprague Dawley (SD) rats. At 10 weeks, rats were classified into four groups and were orally administered vehicle (CKD), low-dose astragalus (LA, 400 mg/kg), and high-dose astragalus (HA, 800 mg/kg) once a day, except in the sham group (the sham, CKD, LA, and HA group). At 14 weeks, the rats were sacrificed for the evaluation of blood and urine samples and mRNA expression and histopathology in the kidney.

Results: At 14 weeks, the progression of kidney dyfunction was significantly slowed by administration of astragalus root (creatinine clearance: sham group; 3.8±0.3 mL/min, CKD group; 1.5±0.2 mL/min, LA group; 2.5±0.3 mL/min, HA group; 2.7±0.1 mL/min). Blood pressure and proteinuria also decreased in the astragalus root-treated groups. The urinary 8-OHdG excretion, which is an oxidative stress marker, decreased in the astragalus root-treated groups (sham group; 451.6±29.6 ng/day, CKD group; 1173.2±91.9 ng/day, LA group; 768.3±68.5 ng/day, HA group; 745.1±40.8 ng/day), and astragalus also decreased the oxidative stress score in the kidney, which was evaluated by immunostaining. In addition, mRNA expression of NADPH p22 and p47, renin and AT1R in the kidney decreased in the astragalus root-treated groups compared to the CKD group (Figure 1).

Conclusions: Our study suggested that astragalus root slowed the progression of CKD possibly through the suppression of oxidative stress.



TH-PO511

Treating CKD-Related Anemia with Erythropoietin and HIF- Prolyl Hydroxylase Inhibitors Improves FGF-23-Dependent and -Independent Outcomes

Megan L. Noonan,[1] Erica Clinkenbeard,[1] Pu Ni,[1] Samantha P. Tippen,[2] Rafiou Agoro,[1] William R. Thompson,[3] Matthew R. Allen,[1] Kenneth E. White.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]IU School of Medicine, Indianapolis, IN; [3]Indiana University, Indianapolis, IN.*

Background: In chronic kidney disease (CKD), high blood concentrations of the phosphaturic hormone FGF23 are associated with increased odds for patient mortality (>6-fold). Our lab has identified anemia as a potent driver of FGF23 expression. Patients with CKD ultimately develop anemia as the kidneys lose the ability to produce erythropoietin (EPO), in parallel with mineral metabolism alterations. We hypothesized that mitigating anemia through treatment with either recombinant EPO or HIF-PHi (hypoxia inducible factor-prolyl hydroxylase inhibitors), currently in clinical trials that elevate endogenous EPO, would reduce circulating bioactive, 'intact' FGF23 ('iFGF23'), thereby improving the pathogenic manifestations of CKD.

Methods: Using a novel murine inducible stem cell line (MPC2), we showed that the HIF-PHDi FG-4592 (Roxadustat) directly induced Fgf23 mRNA when differentiated into osteoblast-like cells (8-16 fold, $p<0.01$). Additionally, FG-4592 injection dose-dependently increased iFGF23 2-9 fold ($p<0.05$) in wild type (WT) mice with normal renal function. To determine the effects in CKD, mice were placed on a casein control or adenine diet to induce CKD, which resulted in markedly elevated iFGF23, hyperphosphatemia, hyperparathyroidism, and anemia. Separate cohorts were treated with either recombinant EPO or FG-4592.

Results: iFGF23 was significantly elevated (70-fold, $p<0.01$) in saline-treated CKD mice compared to controls. In CKD mice, EPO treatment improved total serum iron, and FG-4592 treatment led to marked induction of serum EPO ($p<0.01$). Importantly, circulating iFGF23 was significantly attenuated (>70%; $p<0.05$) in the CKD mice with EPO or FG-4592 administration, demonstrating that anemia is a primary driver of FGF23 in CKD. As expected with elevated iFGF23 in CKD mice, *Cyp24a1* mRNA increased ($p<0.01$), favoring low 1,25D. In contrast, both EPO and FG-4592 significantly enhanced *Cyp27b1* ($p<0.05$) and suppressed *Cyp24a1* ($p<0.01$) mRNAs in CKD mice, suggesting improved 1,25D synthesis. Indeed, EPO injection significantly increased serum 1,25D in control and CKD mice ($p<0.05$).

Conclusions: Collectively, these results support that treatment for anemia, via EPO or HIF-PHDi, leads to improved FGF23-dependent and -independent outcomes.

Fibroblast Growth Factor 23 Produces Arterial Stiffness Through Changes in Vascular Smooth Muscle Cell Phenotype

Juan R. Munoz-Castaneda,[1] Maria Encarnacion Rodriguez Ortiz,[1] Noemi Vergara segura,[1] Victoria Pendon-Ruiz de Mier,[3] Cristian Rodelo-Haad,[3] Juan M. Diaz Tocados,[1] Yolanda Almaden peña,[2] Mariano Rodriguez.[3] GC13. Calcium Metabolism. VAscular Calcification group *[1]Instituto Maimonides de Investigacion Biomedica de Cordoba (IMIBIC), Cordoba, Spain; [2]Unidad Investigacion.IMIBIC.Hospital Reina Sofia, Cordoba, Spain; [3]Hospital Universitario Reina Sofia, Cordoba, Spain.*

Background: In patients with chronic kidney disease (CKD), high levels of c-terminal fibroblast growth factor 23 (FGF23) are associated with cardiovascular disease and mortality. Vascular smooth muscle cells (VSMC) may present two differentiated functional phenotypes, contractile and synthetic. An excess of synthetic VSMC has been associated with vascular dysfunctions. It is unknown whether FGF23 may promote phenotypic transition causing vascular stiffness.

Methods: The expression of VSMC markers, miR-221 and miR-222 was determined in VSMC treated with high recombinant FGF23. *In vivo*, the VSMC markers were analyzed in aorta of rats receiving recombinant FGF23 for 14 days. Furthermore, the relationship between FGF23 and arterial stiffness was investigated in CKD patients stages 2-3.

Results: High levels of FGF23 promoted VSMC transition from a contractile to a synthetic phenotype. These effects were mediated through FGFR1 and Erk1/2 phosphorylation. Inhibition of both pathways enhanced contractile phenotype of VSMC. The pro-contractile microRNAs miR-221 and miR-222 were reduced by FGF23 and miR-221 transfection recovered the contractile phenotype of VSMC decreased by FGF23. In rats, exogenous infusion of FGF23 increased tunica media thickness and promoted synthetic phenotype reducing plasma levels of miR-221. In a group of CKD 2-3 patients it was observed an association between FGF23 and pulse pressure, reflecting vascular stiffness together with low plasma levels of miR-221 and miR-222.

Conclusions: FGF23 favors the transition of VSMC from contractile to synthetic phenotype causing vascular dysfunction and arterial stiffness. This may be a mechanism by which FGF23 contribute directly to the development of vascular disease in CKD patients.

FGF23-Mediated Activation of RAAS Contributes to Cardiac Hypertrophy and Fibrosis

Maren Leifheit-Nestler,[1] Ineke Boeckmann,[1] Jonas Lischka,[1] Beatrice Richter,[2] Jennifer Deppe,[1] Dieter Haffner.[1] *[1]Hannover Medical School, Hannover, Germany; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients with CKD develop LVH accompanied with LV fibrosis. One of the main causes are the increased FGF23 serum levels, which were shown to induce the calcineurin/NFAT pathway in cardiomyocytes. Additionally, CKD patients show a systemic activation of RAAS and FGF23 is discussed to stimulate RAAS activation, which could be an alternative mechanism for the progression of FGF23-mediated cardiac pathologies. However, underlying molecular mechanisms are unknown.

Methods: We evaluated LVH and fibrosis in association with cardiac FGF23 and the local activation of RAAS in heart tissue of 5/6 nephrectomized (5/6Nx) rats compared to sham-operated animals. In order to distinguish between FGF23-mediated LVH and fibrosis via calcineurin/NFAT or RAAS, we stimulated isolated neonatal rat ventricular myocytes (NRVM) and fibroblast (NRCF) with FGF23 in the presence and absence of cyclosporine A, losartan and spironolactone, and investigated hypertrophic and fibrotic pathways by qPCR, Western blot and functional analysis.

Results: Uremic rats showed increased relative heart weight accompanied with enhanced cardiomyocyte size and LV fibrosis compared with sham. The cardiac expression of *Fgf23* and RAAS genes were significantly increased in 5/6Nx rats and correlated with the degree of LV fibrosis. FGF23 stimulated the expression of RAAS genes in cardiac cells *in vitro* and induced NGAL indicating mineralocorticoid receptor activation. The FGF23-induced hypertrophic growth of NRVM was attenuated by pre-treatment with cyclosporine A, losartan and spironolactone. In addition, the FGF23-mediated induction of pro-hypertrophic NFAT target genes was blocked by inhibition of calcineurin, AT1R and mineralocorticoid receptor. In NRCF, FGF23 phosphorylated Smad2/3 and induced Tgf-b and Ctgf, which were only suppressed by pre-stimulation with losartan and spironolactone but not with cyclosporine A. Interestingly, FGF23 increased the proliferation of NRCF independent of calcineurin/NFAT and RAAS activation.

Conclusions: The FGF23-induced cardiac hypertrophy is mediated by both the activation of RAAS and calcineurin/NFAT. Moreover, FGF23 impact on cardiac fibrosis primarily via RAAS-mediated activation of Tgf-b/Smad pathway.

TH-PO514

FGF23 Does Not Induce Left Ventricular Hypertrophy in Female Mice with CKD

Claire Gerber, Vikas Chonira, Xueyan Wang, Maralee Capella, Guillaume Courbon, Valentin David, Aline Martin. *Nephrology and Hypertension, Northwestern University, Chicago, IL.*

Background: Increased levels of fibroblast growth factor 23 (FGF23) in chronic kidney disease (CKD) are associated with development of left ventricular hypertrophy (LVH) and mortality. Men progress more rapidly to end stage renal disease and have an increased risk of cardiovascular death compared to women. We assessed whether delayed onset of CKD and/or delayed elevations of FGF23 levels in females could explain better cardiovascular outcomes than in males.

Methods: We studied B6 wild-type (WT) and Col4a3^{null} male and female littermate mice with progressive CKD at 4, 8, 12, 16, and 20 weeks of age. At each time point, we analyzed parameters of kidney and heart morphology and function, and we measured serum FGF23 levels. In parallel, we assessed the lifespan in separate groups of mice.

Results: As previously described, Col4a3^{null} males display impaired kidney function, increased serum FGF23 levels, development of LVH and reduced lifespan. Both Col4a3^{null} males and females showed signs of proteinuria at 4 weeks (albumin to creatinine ratio

(ACR); p<0.05 vs. sex- and age- matched WT). Progressive decline in kidney function resulted in increased levels of blood urea nitrogen (BUN) after 8 weeks of age in Col4a3^{null} females, and only after 12 weeks in Col4a3^{null} males (p<0.05 vs. sex- and age- matched WT). By 20 weeks, elevations of BUN, ACR and hypertension were similar in Col4a3^{null} males and females. Serum FGF23 levels increased in both Col4a3^{null} males and females after 8 weeks (p<0.05 vs. sex- and age- matched WT). Interestingly, Col4a3^{null} females displayed higher FGF23 levels at all timepoints and steeper elevations of FGF23 levels during CKD progression than Col4a3^{null} males, resulting in 50% higher FGF23 levels at 20 weeks (p<0.05 vs. Col4a3^{null} males). Unlike Col4a3^{null} males, and despite earlier onset of kidney disease and higher elevations of FGF23 levels, Col4a3^{null} females did not develop LVH and lived 1.5 week longer than Col4a3^{null} males in average.

Conclusions: In this well-established model of progressive CKD, absence of LVH in female mice may represent a survival advantage compared to males. The earlier onset of CKD and higher FGF23 levels in females suggest a role for female-specific cardioprotective mechanisms that remain to be determined.

TH-PO515

INS-3001 Efficiently Inhibits Severe CKD-Induced Cardiovascular Calcifications by Directly Targeting Hydroxyapatite Growth and Deposition

Anja Verhulst,[1] Mattias E. Ivarsson,[2] Patrick D'Haese.[1] [1]*University of Antwerp, Antwerp, Belgium;* [2]*Inositec Inc., Zurich, Switzerland.*

Background: Prevention of cardiovascular calcification (CVC) in CKD patients currently is based on controlling CKD-specific risk factors such as hyperphosphatemia. A new therapeutic approach with potential higher efficacy consists in the use of molecules that directly interfere with the calcification process in the vessel wall, such as INS-3001. In this study we evaluated the efficacy of INS-3001, an inositol phosphate analog in a rat model of CKD-induced CVC.

Methods: CVC was induced in 48, 8 weeks old, male Wistar rats by the administration of an adenine (0.75%) and phosphate (0.92%) supplemented diet for 4 weeks, followed by a diet with 1.02% phosphate for 1 week until sacrifice. Rats were randomly assigned to 1 vehicle, and 3 INS-3001 groups (n=12 each) and treated with INS-3001 (5, 15 and 50 mg/kg) or vehicle (distilled water) by subcutaneous administration via osmotic minipumps during the last 4 weeks before sacrifice. CKD development was evaluated by measurement of serum creatinine and phosphate levels. CVC was evaluated on Von Kossa stained thoracic aorta tissue sections and by measurement of the total Ca content of the heart, abdominal aorta and a. carotis by atomic absorption spectrometry. Bone samples were analyzed by quantitative bone histomorphometry.

Results: Mortality rate was limited (≤1 animal/group). CKD developed to a similar extent in all groups. In the thoracic aorta, significantly lower Von Kossa positivity (area%) was measured in the INS-3001 group (50mg/kg) compared to the vehicle group (2.7±6.0 vs 14.5±15.1 %). Total Ca content of the abdominal aorta was also significantly lower in the INS-3001 (50mg/kg) group compared to the vehicle group (1.7±1.8 vs 14.5±13.9 mg/g tissue). Similar reductions in total Ca content were seen in the a. carotis and the heart. Quantitative bone histomorphometric analysis in vehicle treated rats showed a tremendously increased (not quantifiable) bone turnover. INS-3001 treated animals showed a significant increase in the bone area % (of total tissue area) compared to vehicles (42.3±14.6 vs 15.5±7.0 %). Neither osteoclast nor osteoblast morphology was affected.

Conclusions: In conclusion, INS-3001 is a promising molecule for the treatment of CKD induced CVC. Effects on bone have to be further investigated in a model with physiological bone turnover.

Intravenous FGF-23 Loading Exacerbates Heart Failure with Preserved Ejection Fraction

Tomohiro Saito, Masahide Mizobuchi, Yasuto Shikida, Tadashi Kato, Hiroaki Ogata, Fumihiko Koiwa, Tadao Akizawa. *Showa University School of Medicine, Yokohama, Japan.*

Background: The fact that FGF23 has an association with cardiovascular disease raises the question of whether it may not only be a biomarker of altered mineral metabolism and cardiovascular disease, but a therapeutic target. Herein, we studied the effect of continuous intravenous loading of FGF23 on mice of heart failure with preserved ejection fraction (HFpEF) model.

Methods: We used the deoxycorticosterone acetate (DOCA)-salt mouse model, which demonstrates mild hypertension and HFpEF. At the post-DOCA implantation day 7 mice were divided into two groups that received vehicle (DOCA+V) or FGF23 (DOCA+F) solution intravenously via a microinfusion pump for 10 days. Wild type mice were used as a control.

Results: Serum creatinine levels were comparable between the DOCA+F and the DOCA+V. Serum phosphorus levels were slightly increased in the DOCA+V compared with the control, whereas the levels remained normal in the DOCA+F. Serum FGF23 levels were slightly increased in the DOCA+V (249 pg/ml) compared with the control (51 pg/ml) and this increase was further amplified in the DOCA+F (1416 pg/ml). The heart weights were equal and significantly increased in the DOCA+V and the DOCA+F compared with the control. The DOCA+V (EF, 56%, E/A 1.0) showed HFpEF pattern, which was exacerbated in the DOCA+F (EF, 52%, E/A 0.7) assessed by echocardiography. Cardiac type I and type III collagen mRNA expressions were significantly increased in the DOCA+F compared with the control. Myocardial diameter was comparable between the DOCA+V (0.27 μm) and the DOCA+F (0.26 μm), whereas cardiac fibrosis was obvious in the DOCA+F (13,2 %) compared with the DOCA+V (7.0 %).

Conclusions: These results suggest that extremely high FGF23 levels have a crucial role in cardiac fibrosis which exacerbates HFpEF.

TH-PO517

The New RANKL Receptor LGR4 Regulates Vascular Smooth Muscle Cell Calcification in CKD

Natalia Carrillo-Lopez,[1] Laura Martinez-Arias,[1] Cristina Alonso-Montes,[1] Beatriz Martin-Carro,[1] Julia Martin-Virgala,[1] Carmen Palomo,[3] Adriana S. Dusso,[1] Manuel Naves,[1] Jorge B. Cannata-Andia,[1,2] Sara Panizo.[1] [1]*Bone and Mineral Research Unit. Hospital Universitario Central de Asturias. Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), REDinREN-ISCIII, Oviedo, Spain;* [2]*Department of Medicine, Faculty of Medicine, University of Oviedo, Oviedo, Spain;* [3]*Department of Internal Medicine. Hospital Universitario Central de Asturias, Oviedo, Spain.*

Background: PTH is a main regulator of RANKL and OPG in bone remodeling. These 3 molecules have a well-known role in vascular calcification (VC). Due to controversies in the direct role of PTH in VC and the discovery of leucine-rich repeat-containing G-protein-coupled receptor 4 (LGR4) as a new RANKL receptor, we analyzed LGR4 involvement in VC in chronic kidney disease (CKD).

Methods: *In vivo*: We analyzed LGR4, RANK, RANKL and OPG gene expression and aortic calcium content ijn CKD rats fed for 14 weeks a normal phosphorus (0.6% -NP-) or a high phosphorus(0.9% -HP-) diet with or without parathyroidectomy (PTX) and PTH 1-34 supplementation aiming to normalize PTH. Rats with normal renal function fed a NP diet were used as reference. *In vitro*: We analyzed LGR4, RANK, RANKL and OPG expression and calcium content in vascular smooth muscle cells (VSMC) from rat aortas exposed to 3 different culture media (control, calcifying or calcifying plus 10-7/10-9M PTH). To characterize the pathways involved in calcification, the same parameters were examined in VSMC upon silencing of LGR4 or PTH1R (main PTH receptor) or after incubation with specific protein kinase (PK) A or PKC inhibitors, or with forskolin, a specific PKA agonist.

Results: CKD significantly increased aortic LGR4 and RANKL mRNA expression and decreased OPG, increasing aortic calcium content. These changes were greater in the group with higher PTH (CKD-HP) and were prevented by PTX. There were no changes in RANK expression under any of the experimental conditions. In VSMC, 10-7M PTH, but not 10-9M PTH, increased LGR4 and RANKL, reduced OPG expression with increases in calcium content. LGR4 and PTH1R silencing significantly attenuated the increases in calcium content induced by 10-7M PTH. Furthermore, silencing of PTH1R and PKA inhibition, but not PKC inhibition, prevented the increases in RANKL and LGR4 and OPG reduction. Exposure to forskolin corroborated these results.

Conclusions: In CKD, high PTH increases the aortic expression of LGR4 receptor and its ligand RANKL and decreases OPG inducing VC. These PTH actions in VSMC involve binding to PTH1R and PKA activation. Thus, LGR4 was identified for the first time as a pro-calcifying factor of VSMC in CKD.

Increases in Osteocyte RANKL Correspond with Elevated Cortical Porosity in Adenine-Induced CKD

Corinne E. Metzger,[1] Elizabeth A. Swallow,[2] Matthew R. Allen.[1] [1]*Indiana University School of Medicine, Indianapolis, IN;* [2]*Indiana University, Indianapolis, IN.*

Background: Chronic kidney disease (CKD) increases bone fragility and fracture incidence. Bone loss in CKD preferentially occurs within the cortical bone through the development of porosity. For cortical pores to form, osteoclasts must be recruited into the cortex to locally induce bone resorption. Receptor activator of nuclear factor KB ligand (RANKL) is a key osteoclastogenesis regulator that is released by various cells within bone including osteocytes. We hypothesized that elevated cortical osteocyte RANKL coincides with the development of cortical pores in adenine-induced CKD.

Methods: Female C57BL/6J mice (8-wk-old) were fed a casein-based diet (0.9% P, 0.6% Ca) with 0.2% adenine (Ad) to induce CKD. Age-matched controls (Con) were fed the same casein-based diet without adenine. Mice were terminated after 2, 6, and 10 weeks.

Results: Serum blood urea nitrogen was elevated at all time points in Ad vs. Con confirming the induction of kidney disease. MicroCT of the distal 1/3 shaft of the femur demonstrated that Ad mice had porosity not different from Con at 2 weeks, mild cortical porosity at 6 weeks (1.9%; p<0.001 vs Con), and a greater average porosity at 10 weeks (4.1%, p=0.01 vs Con). At 2 weeks, the percentage of cortical osteocytes in the femoral shaft that stained positive for RANKL (%RANKL+) was 20% higher in Ad vs. Con while at 6 and 10 weeks %RANKL+ osteocytes were 115% higher and 277% higher, respectively, compared to Con. A time-by-treatment statistical analysis indicated significant impact of Ad treatment and a time-by-treatment interaction effect whereby Con groups had decreasing %RANKL+ osteocytes with age and Ad groups maintained high %RANKL+ osteocytes with age. This indicates adenine-induced CKD increased osteocyte RANKL in younger animals as well as prevented age-related declines in osteocyte RANKL as animals age in the presence of disease.

Conclusions: In conclusion, we determined that both osteocyte RANKL and cortical porosity are elevated over time in adenine-induced CKD. We hypothesize in CKD osteocytes release RANKL signaling osteoclasts into the cortical bone leading to the development of cortical porosity. Future research should address the factors altered in CKD, such as elevated parathyroid hormone, which are responsible for stimulating osteocytes to produce RANKL.

Effect of Acute Peritonitis on Serum Fibroblast Growth Factor 23 in a Rat Model of CKD: Possible Interaction Between FGF-23 and Inflammation

Nagwa M. Ramadan,[1] Hanan A. Mubarak,[1] Christina S. Yacoub,[1] Mohamed M. Elsebaie,[2] Noha Osman,[3] Mohamed M. Nasrallah.[3] *[1]Physiology, Faculty of Medicine, Cairo University, Giza, Egypt; [2]Faculty of medicine cairo University Egypt, Cairo, Egypt; [3]Internal Medicine, Kasr AlAiny School of Medicine, Cairo University, Giza, Egypt.*

Background: Cardiovascular diseases are the leading cause of death among patients with chronic kidney disease (CKD). Fibroblast Growth Factor 23 (FGF- 23) has been associated with mortality among those patients and was found to correlate with different parameters of inflammation among them. The interaction between FGF- 23, uremia and inflammation is still under investigation.

Methods: 40 rats assigned to 4 groups: Control sham-operated, Acute peritonitis, CKD and CKD + acute peritonitis. Acute peritonitis and CKD were experimentally induced. Serum creatinine, phosphorus, iFGF23,Vit.D, TNFa, HsCRP and bone furin mRNA were compared between groups.

Results: Compared to the control group; FGF- 23 was significantly higher in both the CKD & the acute peritonitis groups. FGF 23 reached the highest level in the CKD with induced acute peritonitis group. Furin mRNA was significantly lower in both the CKD and the acute peritonitis groups compared to the control group and it reached its lowest levels in the group with induced CKD and peritonitis. FGF- 23 was positively correlated to serum creatinine, phosphorus, TNFa&CRP while it was negatively correlated to serum Vit.D & Furin mRNA.

Conclusions: Inflammation is a potent upregulator of iFGF23 and could be a main promoter of FGF23 excess early in CKD. Acute peritonitis on top of CKD amplifies the inflammatory states which could contribute to worsening the clinical outcomes. Increased serum iFGF23 in inflammation could be due to decrease its cleavage by furin pro-protein convertase enzyme.

The Role of Mitochondrial Dysfunction in Matrix Vesicles (MV)-Induced Calcification of Recipient Vascular Smooth Muscle Cells (VSMC)

Neal X. Chen,[1] Kalisha O'Neill,[1] James M. Dominguez,[1] Sharon M. Moe.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Roduebush Veterans Affairs Medical Center, Indianapolis, IN.*

Background: Oxidative stress is increased in patients with CKD and associated with vascular calcification. We have previously demonstrated that cellular derived MV, but not media derived MV, increase calcification of recipient normal rat VSMC in association with activation of mitogen activated protein kinase (MAPK), increased intracellular calcium $[Ca]_i$ derived from the endoplasmic reticulum (ER), and increased NADPH oxidase (NOX) 1 expression. We hypothesized that cellular MV induced generation of reactive oxygen species (ROS) from mitochondrial dysfunction in the recipient VSMC.

Methods: Ten ug of MV were co-cultured with recipient VSMC in calcification media (high phosphorus) for up to 7 days and alteration of ROS production examined by CellRox using confocal microscopy. Mitochondrial superoxide generation was determined by MitoROS. Direct mitochondrial respiration was measured by Seahorse XF Analyses. Mitochondrial contents of respiratory complexes was determined using total OXPHOS by Western blot. Some cultures were incubated with the NOX1/4 inhibitor GKT137831.

Results: MV increased ROS production by 146% at 24 h and continued to increase by 106% at day 7 in recipient VSMC during calcification. Incubation with GKT137831 reduced ROS production and decreased $[Ca]_i$ in recipient VSMC. We then determined if mitochondria dysregulation was the source of the increased ROS production in recipient VSMC. Adding MV had no effect on mitochondrial superoxide production or mitochondrial contents in recipient VSMC. Seahorse experiments demonstrated that there was no effect of MV on basal oxygen consumption (OCR), ATP production, maximal respiratory capacity or reserve respiratory capacity in recipient VSMC. These results suggest that MV-induced cytosolic ROS production is not due to mitochondrial dysfunction in recipient VSMC.

Conclusions: Cellular MV induce ROS production in recipient VSMC during calcification. However, this increased ROS is not mediated via mitochondrial dysfunction and thus likely represents a response to increased $[Ca]_i$ release from the ER and/or other cell signaling pathways. Further understanding the mechanism by which MV induce calcification of normal VSMC to propagate calcification is needed to facilitate the development of targeted therapies.

The Effect of PKD Gene Mutation on Bone

Berenice Y. Gitomer,[1] Renata C. Pereira,[9] Isidro B. Salusky,[2] Wei Wang,[3] Katharina Hopp,[4] Anna J. Jovanovich,[5] Zhiying You,[6] Kristen L. Nowak,[7] Michel Chonchol.[8] *[1]Div. Renal Diseases and Hypertension, Aurora, CO; [2]Mattel Children's Hospital, Los Angeles, CA; [3]University of Colorado Anschutz Medical Campus, Aurora, CO; [4]University of Colorado Denver, AMC, Aurora, CO; [5]Denver VA / University of Colorado, Denver, CO; [6]UC Denver, Aurora, CO; [7]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [8]University of Colorado, Aurora, CO; [9]University of California, Los Angeles, CA.*

Background: Kidney cysts are an invariant feature of autosomal dominant polycystic kidney disease (ADPKD). However, patients with *PKD2* vs. *PKD1* mutations typically have milder disease. We showed previously that ADPKD patients with normal kidney function have a low turnover bone defect. The goal of the current study was to determine whether PKD gene mutations cause differential changes on osteoblast primary cilium structure or gene expression in osteoblasts.

Methods: Primary osteoblast cultures were established from human bone obtained by iliac crest bone biopsy. In order to visualize the primary cilium, cells were serum deprived to suppress cell division and treated with LiCl. The primary cilium was stained with anti-acetylated tubulin and the base with anti-pericentrin. Cilia length was measured on 200 -300 cells from each individual. RNAseq analysis was performed on RNA extracted from trabecular bone.

Results: Cilia on osteoblasts from ADPKD patients elongated more than those on healthy control osteoblasts in response to LiCl exposure and longer cilia were associated with PKD1 gene mutations (Figure 1). Elongation of osteoblast cilia from patients with other causes of adynamic bone disease did not differ from control cells, indicating that the gene mutation is responsible for the cilia abnormality in ADPKD. RNAseq analysis of bone from patients with PKD1 (N=12) or PKD2 (N=3) revealed decreased expression of several genes including COL1A2 and aggrecan proteoglycan (ACAN) in PKD1 compared to PKD2 bone.

Conclusions: PKD genotype affects both primary cilium structure and gene expression in bone from patients with ADPKD. Cilia structural abnormalities appear to be a result of the primary gene defect as they do not occur in patients with adynamic bone disease due to other causes.

TH-PO523

Effect of Reduction of Bone Advanced Glycation End Products (AGE) Accumulation on Bone Mechanical Properties in a Rat Model of CKD-Mineral Bone Disorder (CKD-MBD)

Neal X. Chen,[1] Shruthi Srinivasan,[1] Matthew R. Allen,[1] Tom Nickolas,[3] Joseph M. Wallace,[5] James M. Dominguez,[1] Kalisha O'Neill,[1] Keith G. Avin,[2] Sharon M. Moe.[1,4] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University-Indianapolis, Indianapolis, IN; [3]Columbia University Medical Center, New York, NY; [4]Roduebush Veterans Affairs Medical Center, Indianapolis, IN; [5]Indiana University Purdue University Indianapolis, Indianapolis, IN.*

Background: Reduced bone quality is a key determinant of skeletal fragility in CKD. We have previously demonstrated that treatment with an AGE breaker ALT-711 decreased serum FGF23, reduced aorta expression of receptor for AGE (RAGE) and calcification in a rat model of CKD-MBD. We hypothesized that reduction in AGE accumulation and/or RAGE activation in bone will improve CKD-induced bone fragility.

Methods: Using a slowly progressive rat model of CKD, the Cy/+ rat, we compared four groups of animals [1: Normal (NL); 2: CKD; 3:CKD+ALT-711(3mg/kg); and 4: CKD+ 3% calcium in drinking water (Ca, lowering PTH and reducing bone remodeling). Treatment was started at 25 weeks of age (~50% kidney function) and ended at 35 weeks (~15% function). Bone AGE content was determined in demineralized femur shaft using fluorescence plate reader, normalized by collagen (hydroxyproline) content. Bone marrow (BM) were collected and RAGE expression determined by real time PCR. Bone geometry/architecture were determined with microCT. Bone mechanical properties were assessed by 4-point bending.

Results: There was increased AGE accumulation in bone and RAGE expression in BM in CKD rats vs. NL. Treatment with ALT-711 or calcium normalized both bone AGE levels and BM RAGE expression in CKD. MicroCT assessment of proximal tibial bone demonstrated lower trabecular bone volume fraction (BV/TV) in CKD rats. Calcium but not ALT-711 treatment increased trabecular BV/TV in CKD rats. CKD rats also had higher cortical porosity compared to NL and ALT-711 or calcium treatment each significantly reduced the cortical porosity in CKD rats. Bone mechanical analysis demonstrated that while several properties were lower in CKD rats, calcium, but not ALT-711 treatment, normalized these mechanical properties in CKD rats.

Conclusions: There is increased AGE accumulation in bone and RAGE expression in BM from CKD rats. Treatment with the AGE breaker ALT-711 early in the course of CKD decreased bone AGE levels and RAGE expression in BM in association with reduction in cortical porosity but without improvement of bone mechanics. Calcium treatment (which lowers PTH) showed similar bone efficacy to ALT-711 but increased serum levels of calcium and FGF23.

TH-PO524

Bone Assessment by High-Resolution Peripheral Quantitative Computed Tomography in Premenopausal Stone-Forming (SF) Women

Priscila L. Esper,[1] Thalia L. Melo,[1] Milene S. Ormanji,[1] Valéria D. Caparbo,[2] Liliam Takayama,[2] Rosa M. Pereira,[2] Ita P. Heilberg.[1] *[1]Universidade Federal de São Paulo, Sao Paulo, Brazil; [2]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Nephrolithiasis has been associated to low bone mineral density (BMD). Bone assessment by Dual-energy X-ray absorptiometry (DXA) is widely used in clinical practice but has limitations as it only measures areal BMD (aBMD). New non-invasive technologies such as high-resolution peripheral quantitative computed tomography (HR-pQCT) provides additional information regarding bone quality and microarchitecture.

Methods: Forty-four (44) stone-forming (SF) premenopausal women (33.4±9.2 years old) and 202 age-matched healthy premenopausal women (33.7±9.0 years old) were included. aBMD was analyzed by DXA and volumetric BMD (vBMD), structure and biomechanical parameters of the distal radius and tibia were assessed by HR-pQCT.

Results: SF presented a trend for lower aBMD versus controls at L1-L4 (0.979±0.115 vs 1.013±0.111 p=0.06) and significant lower aBMD at femoral neck (0.787±0.11 vs 0.826±0.118 p=0.02), total hip (0.896±0.116 vs 0.932±0.12 p =0.04) and distal radius (0.668±0.049 vs 0.686±0.047 p=0.03). As shown in Table 1, trabecular number (Tb.N) was significantly lower and trabelcular separation (Tb.Sp) was significantly higher in SF compared to controls at both sites. Trabecular vBMD at distal radius was also significantly lower in SF versus controls.

Conclusions: Premenopausal SF women presented lower areal BMD than controls. HR-pQCT further disclosed that the trabecular compartment possibly accounts for this finding, due to lower trabecular volumetric BMD at distal radius, lower trabecular number and increased trabecular separation at both distal radius and tibia. The underlying mechanism for these important alterations of bone quality in this population deserves further investigation.

Funding: Government Support - Non-U.S.

Total Flavonoids of Astragalus Ameliorates Renal Injury-Related Mineral and Bone Metabolic Disorder in the CKD-MBD Model Rats by Regulating FGF23-Klotho Signaling Axis, Compared with Calcitriol

Yigang Wan,[1] Buhui Liu.[2] Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School *[1]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China; [2]Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjng, China.*

Background: Recently, chronic kidney disease-mineral and bone disorder (CKD-MBD) has become one of serious complications occurring in the CKD patients. Hence, the development of a new treatment for CKD-MBD is very important in clinics. FGF23-Klotho signaling axis is a pivotal regulator of MBD in the CKD-MBD patients. Targeting FGF23-Klotho signaling axis in response to renal injury-related MBD has been thereby identified as the multi-targets in the treatment of CKD-MBD. In China, total flavonoids in the flower of *Abelmoschus manihot* (TFA), a natural extract has been frequently used to improve renal dysfunction in the CKD patients. But the potential mechanisms *in vivo* of TFA on renal injury-related MBD remained unclear. Here, we verified whether TFA could ameliorate renal injury-related MBD in the CKD-MBD model rats by targeting FGF23-Klotho signaling axis in the kidney, compared to calcitriol (CAL).

Methods: Twenty-eight rats were divided into 4 groups, the Sham, the Vehicle, the TFA and the CAL groups. The appropriate doses of TFA, CAL and distilled water were administrated with oral for 3 weeks after the induction of CKD-MBD by adenine-administration and mononephrectomy, respectively. The changes in parameters of renal injury and bone abnormality in urine, blood, bone and kidneys were analyzed. The kidney and femur bone were isolated for histomorphometry, immunohistochemistry and Western blot at sacrifice.

Results: For the CKD-MBD model rats, renal injury and bone abnormality were significantly revealed, and there was a potential connection between renal injury and bone abnormality. Moreover, TFA alleviated renal dysfunction and tubulointerstitial pathological changes, improved calcium-phosphorus metabolic disorder and bone lesion, and regulated FGF23-Klotho signaling axis and ERK1/2-SGK1-NHERF-1-NaPi2α pathway in the kidney. Notably these beneficial actions *in vivo* of TFA were markedly different from CAL.

Conclusions: We clarified that TFA, different from CAL, can improve renal injury and bone abnormality, and that, more importantly, these ameliorative effects on renal injury-related MBD are closely associated with the regulation of FGF23-Klotho signaling axis and ERK1/2-SGK1-NHERF-1-NaPi2α pathway in the kidney. This study provided the first evidence that TFA directly contributes to the prevention of CKD-MBD.

Increases in Circulating Granulocyte Neutral Sphingomyelinase 2 Expression in Dialysis Patients Correlate Directly with the Propensity for Vascular Calcification

Natalia Carrillo-Lopez,[1] Catalina Ulloa,[3] Javier Rodriguez-Carrio,[4,5] Sara Panizo,[1] Laura Martinez-Arias,[1] Beatriz Martin-Carro,[1] Julia Martin-Virgala,[1] Carmen Rodriguez-Suarez,[3] Jorge B. Cannata-Andia,[1,2] Adriana S. Dusso.[1] *[1]Bone and Mineral Research Unit. Hospital Universitario Central de Asturias. Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), REDinREN-ISCIII, Oviedo, Spain; [2]Department of Medicine, Faculty of Medicine, University of Oviedo, Oviedo, Spain; [3]Division of Nephrology, Hospital Universitario Central de Asturias, Oviedo, Spain; [4]Area of Immunology, Department of Functional Biology, University of Oviedo, Oviedo, Spain; [5]Bone and Mineral Research Unit, Hospital Universitario Central de Asturias, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain.*

Background: Systemic inflammation is a risk factor for atherosclerosis and vascular calcification in the general population and in chronic kidney disease (CKD) patients. Because increases in neutral sphyngomyelinase 2 (nSMase2) are essential for the severity of age-induced inflammation in health and atherosclerosis in the ApoE null mouse and contribute to initiate medial calcification in uremia, this study evaluated whether leukocyte gene expression of nSMase2 and its inducer in the vasculature, TNFα, could estimate the propensity for vascular calcification.

Methods: Peripheral blood mononuclear cells (PBMC) and granulocytes, from 28 peritoneal dialysis (PD) patients and 16 normal adults, matched for age and gender, were obtained from fresh blood using Fycoll gradient. A lumbar X-ray measured Kauppila index (KI) to estimate subclinical (KI<5) or clinical (KI>5) risk for vascular calcification (VC).

Results: In adults older than 40 with normal renal function, PBMC TNFα mRNA levels correlated directly with age ($r=0.61$; $p<0.05$; $n=10$), a risk factor for vascular damage. Furthermore, PBMC TNFα increased by 52% in peritoneal dialysis patients ($p<0.03$) compared to controls and, similar to the vasculature, PBMC nSMase2 gene expression increased in parallel with the elevations in TNFα in both healthy adults ($r=0.57$; $p<0.02$; $n=16$) and PD patients ($r=0.56$; $p<0.01$; $n=28$). In circulating granulocytes, TNFα was also 2-fold higher in PD patients, but with levels 2.2-fold lower than those in PBMC, even in normal controls. Significantly, the increases in granulocyte nSMase2 correlated directly with KI>5 ($r=0.65$; $p<0.05$; $n=11$), a recognized biomarker of the clinical risk for vascular calcification, but not with TNFα.

Conclusions: While in PBMC, the higher TNFα mRNA levels correlating with increases in nSMase2 may estimate the degree of systemic inflammation, the increased granulocyte nSMase2 gene expression appear sufficient to reflect VC risk.

TH-PO527

Analysis of Cortical Bone Transcriptome Reveals Suppression of Bone Formation Pathways by Iron Therapy in Experimental CKD

Edwin Patino,[1] Stephen B. Doty,[2] Divya Bhatia,[1] Adrian Y. Tan,[1] Mary E. Choi,[1] Oleh M. Akchurin.[1] *[1]Weill Cornell Medical College, New York, NY; [2]Hospital for Special Surgery, New York, NY.*

Background: Iron has been implicated in bone physiology and bone disorders. Most anemic patients with CKD require iron therapy. Iron excess has been shown to cause loss of bone mass in patients without CKD. However, the effects of iron therapy on the pathways underlying development of CKD-MBD remain largely unknown.

Methods: CKD was induced in mice by a 0.2% adenine diet, starting at 3 weeks of age. Femurs, kidneys, and blood were harvested at 3- and 8-week time-points in 4 groups of mice: - CTR: controls without CKD - CKDnoFe: untreated CKD - CKDPOFe: CKD + 0.5% carbonyl iron diet - CKDIPFe: CKD + weekly intraperitoneal injections of iron dextran, 0.5g/kg Femurs were analyzed by micro-CT and histology. RNA was extracted from femur diaphyses harvested at 3 weeks. RNA sequencing was performed on Illumina HiSeq4000 with single-end 50 bps and analyzed using STAR (V2.5.2) and DESeq2 package.

Results: By 3 weeks of experimental period, CKDnoFe mice developed renal injury and fibrosis and were mildly anemic. CKDPOFe and CKDIPFe mice did not have anemia at 3 weeks. No changes in bone microarchitecture were yet detected at 3 weeks in any group. At 8 weeks, CKDnoFe mice displayed progression of anemia and loss of the cortical bone volume. Compared to the CKDnoFe group, CKDPOFe and CKDIPFe mice had milder anemia, but more severe bone loss at 8 weeks. The expression of genes implicated in both bone formation (*Wnt16*, *Wnt2b*, *Dmp1*, *Mmp13*, *Spp1*, *Ank*) and bone resorption (*Ctsk*, *Acp5*, *Calcr*, *Clcn7*, *Slc4a2*) was higher in CKDnoFe than in CTR, consistent with increased bone turnover. In CKDPOFe and CKDIPFe groups, the expression of genes implicated in bone formation was lower than in CKDnoFe. At the same time, the expression of osteoclast genes associated with bone resorption was similar between CKDnoFe, CKDPOFE, and CKDIPFe groups.

Conclusions: In this model of CKD, both oral and parenteral iron therapy affected bone transcriptome before changes in bone microarchitecture. These transcriptional effects of iron, consistent with the suppression of bone formation pathways, without a corresponding effect on bone resorption pathways, likely represent early events in the process of bone loss associated with iron therapy in CKD. Our findings warrant attention to the potential unrecognized effects of iron on bone health in patients with CKD.

$25(OH)D_3$ Alone Stimulates Expression of $1,25(OH)_2D_3$-Responsive Genes, Calbindin-D9K, and Megalin in mpkDCT Cells Where the Cyp27b1 Gene Was Deleted by CRISPR-Cas9

Takahiro Kikuyama,[1] Takao Susa,[2] Mimi Tamamori-Adachi,[2] Masayoshi Iizuka,[2] Shunya Uchida,[1] Tomoki Okazaki,[2] Shigeru Shibata.[1] *[1]Internal Medicine, Teikyo University School of Medicine, Itabashi, Tokyo, Japan; [2]Biochemistry, Teikyo University School of Medicine, Itabashi, Tokyo, Japan.*

Background: During vitamin D synthesis, $25(OH)D_3$ (25D3) is converted to the active form, $1,25(OH)_2D_3$ (1,25D3), by CYP27B1 in the proximal tubule of the kidney, then the latter exerts its function via vitamin D3 receptor (VDR). In the kidney, the 1,25D3-VDR axis is responsible for the increase in calcium reabsorption. Recently, it has been reported that 25D3 has bioactivity in certain tissues derived from *Cyp27b1* knockout mice. On the other hand, others reported that 25D3-fed *Cyp27b1* knockout mice produced normal level of 1,25D3 in the plasma. Such 1,25D3 might have been brought about by the other unknown enzyme(s) and it would be difficult to prove the direct cell-intrinsic activity of 25D3 (but not 1,25D3) using the *Cyp27b1* knockout mouse models.

Methods: We used CRISPR-Cas9 system to knock out *Cyp27b1* gene in the mouse kidney distal tubule cell line, mpkDCT cells. We then investigated the 25D3 function in these cells.

Results: *Cyp27b1* knockout mpkDCT cells did not produce any measurable 1,25D3 after 25D3 administration to the cells. We found that 10^{-7} M of 25D3 translocated VDR into the nucleus and promoted expression of the positive control *Cyp24a1* gene in the *Cyp27b1* knockout mpkDCT cells. Microarray analysis also revealed that the exhaustive target gene profiles of 25D3 showed results similar to those of 1,25D3. Subsequently, we confirmed that 25D3 induced the expression of calcium reabsorption-related genes, Calbindin D9K (*S100g*) and Megalin (*Lrp2*), in the way analogous to 1,25D3.

Conclusions: In this study, we showed that a high dose(s) of 25D3 exerted vitamin D3 activity directly in the kidney cells without the aid of CYP27B1 function. We surmise that the ability to induce VDR target genes may provide a novel benefit with 25D3 in certain tissues. In the case of decreased CYP27B1 activity in advanced CKD, high concentrations of 25D3 may have a promising effect to maintain the serum calcium level.

Increased Subset of Low-Density Granulocytes in Dialysis Patients Associated with the Degree of Abdominal Aorta Calcification

Javier Rodriguez-Carrio,[4,1] Natalia Carrillo-Lopez,[2] Catalina Ulloa,[5] Mariana Seijo,[1,6] Minerva Rodriguez,[5,7] Carmen Rodriguez-Suarez,[5] Jorge B. Cannata-Andia,[2,3] Ana Suarez,[4] Adriana S. Dusso.[2] *[1]Bone and Mineral Research Unit, Hospital Universitario Central de Asturias, Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain; [2]Bone and Mineral Research Unit. Hospital Universitario Central de Asturias. Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), REDinREN-ISCIII, Oviedo, Spain; [3]Department of Medicine, Faculty of Medicine, University of Oviedo, Oviedo, Spain; [4]Area of Immunology, Department of Functional Biology, University of Oviedo, Oviedo, Spain; [5]Division of Nephrology, Hospital Universitario Central de Asturias, Oviedo, Spain; [6]Laboratorio de Enfermedades Metabólicas Óseas, Hospital de Clínicas, Instituto de Inmunología, Genética y Metabolismo (INIGEM) CONICE-UBA, Buenos Aires, Argentina; [7]REDinREN-ISCIII, Oviedo, Spain.*

Background: Although systemic inflammation increases the risk for adverse vascular outcomes in chronic kidney disease (CKD), the exact players remain unclear. The emerging evidence of the relevance of low density granulocytes (LDGs) in inflammatory conditions led us to evaluate whether LDGs may be associated with inflammatory/pro-calcifying features in CKD.

Methods: LDGs subsets were identified by flow cytometry in peripheral blood mononuclear cells (PBMCs) from 33 CKD patients undergoing peritoneal dialysis and 15 healthy controls (HC). An additional cohort of 16 CKD patients undergoing hemodialysis and 6 HC was recruited for replication. Defensin3a (DEF3a, a marker of early granulopoiesis) gene expression on PBMCs was quantified by qPCR.

Results: Total LDGs (CD15+) and both CD14lowCD16+ and CD14-CD16- subsets were increased in CKD. The relative frequency of the CD14-CD16- subpopulation among the total CD15+ pool was increased in CKD. Both LDG subsets differed in origin and maturation status as demonstrated by their CD11b, CD31, CD62L, Interferon receptor 1 (IFNAR1) and CD68 expression and size/granularity (FSC/SSC) features. LDGs subsets were not associated with parameters of bone and mineral metabolism, time on dialysis, serum cytokines or treatments. The increased CD14-CD16-CD15+ correlated directly with Kauppila scores and DEF3a expression in PBMCs, whereas no association was found with CD14lowCD16+CD15+.

Conclusions: CKD is associated with elevated LDGs, showing a skewed distribution towards a CD14-CD16-CD15+ enrichment in blood which correlated with vascular calcification. DEF3a expression in PBMC could be a marker of LDG expansion. These findings support an unprecedented role for LDGs in CKD immunopathogenesis.

Macrophage Migrasomes Is a Crucial Determinant of Subcutaneous Microvascular Calcifications in Patients with Calciphylaxis

Xiaodong Zhu, Yuqiu Liu, Xiaotong Xie, Haifeng Ni, Ri-ning Tang, Beibei Wu, Bi-Cheng Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China*.

Background: Calciphylaxis is rare syndrome in hemodialysis patients who typically manifest as subcutaneous microvascular calcifications. Macrophage has been proposed to a prime mediator of calciphylaxis. However, the pathogenesis remains unclear. Here, we document that macrophage produce a previously unrecognized nanostructures called "migrasomes" (M-mig), which involve in microvascular calcifications in calciphylaxis.

Methods: Skin biopsy specimens from patients with calciphylaxis (n=34) were collected. The possible relation between M-mig and subcutaneous microvascular calcifications was studied. The stray artery from experimental mice were treated with M-mig under high Ca/P stimulation or hemodialysis patient· serum. The calcifying M-mig were assessed by TEM, Energy dispersive spectroscopy and Fluo-3 staining.

Results: Ultrastructural analysis revealed that macrophage produce a previously unrecognized nanostructures called M-mig (A. arrow) that originate from the filament like fibers (A. triangle). Pathology of skin biopsy surprisingly showed that macrophages infiltration (C. brown) was adjacent to the calcium deposition (D. green) in subcutaneous arteries which were rich in M-mig. Subsequently, TEM imaging revealed that mineral deposit in or on membrane of M-mig (B. asterisk). In murine model, when the stray artery incubated with M-mig under high level Ca/P or hemodialysis patient· serum, notablely, some mineral crystal enveloped M-mig and penetrated into inner lumen of the vascular wall, where microcalcifications deposition were observed by fine Fluo-3 staining. The microcalcifications were approved to correlation with calcific M-mig. In vitro, calcific M-mig showed a shift to larger size over time under high level Ca/P. Our study strongly suggests that M-mig could serve as the nucleating foci for mineralization and calcific M-mig initiates the microcalcification.

Conclusions: Our study documents that macrophages produce a formerly unrecognized nanostructure M-mig which involves in vascular microcalcifications. The discovery highlights the contribution of macrophages to vascular calcifications via M-mig and provides clues to the pathogenesis of calciphylaxis.

Evidence of Circadian Rhythm of Plasma Activin A, Its Disturbance by CKD, and Contribution of Activin A Secreted from Injured Kidney

Anders Nordholm,[1,2] Søren Egstrand,[1,2] Maria L. Mace,[1,2] Marya Morevati,[2] Klaus Olgaard,[2] Ewa Lewin.[1,2] *[1]Department of Nephrology, Herlev Hospital, Copenhagen, Denmark; [2]Department of Nephrology, Rigshospitalet, Copenhagen, Denmark*.

Background: Activin A is an interesting new factor in CKD-MBD. It is a member of the TGF-β family, essential in kidney development and repair. Increased systemic activin A might be a biomarker of CKD-MBD that can be targeted for CKD-MBD prevention and therapy. Disrupted circadian rhythm (CR) causes detrimental health effects and CRs are observed in mineral metabolism. Our hypothesis is that increase in circulating levels of activin A is associated with disruption of circadian rhythm of plasma activin A, and parameters of mineral homeostasis in CKD.

Methods: CRs of activin A (pg/ml), FGF23 (pg/ml), PTH (pg/ml) and P (mM) were measured every 6th hour in control (Ctr) and CKD rats (5/6 nephrectomy) on low (LP), standard (SP), and high phosphate (HP) diet (N=8-26). Isolated renal vein and artery sampling was performed in kidney injury rats (14 days unilateral ureter obstruction, UUO) and healthy Ctr.

Results: Activin A was 2.5-fold higher in renal vein compared to artery in UUO (V:246±22, A:100%, $p<0.05$) but unaltered in Ctr (V:100±6, A:100%, ns) indicating renal secretion in kidney injury. Plasma activin A exhibited CR in Ctr ($p<0.01$ by cosinor analysis) with 300% higher values at acrophase (437±59) compared to nadir (106±7) ($p<0.05$). CKD obliterated the CR of activin A. Plasma FGF23 showed CR in Ctr ($p<0.05$) with peak at 14:00 (877±42), while the CR was obliterated in CKD rats on LP and SP even though FGF23 was suppressed in CKD LP ($p<0.05$). In CKD HP FGF23 was increased ($p<0.01$) and the CR was disturbed with shift in acrophase to 09:00 (4173±316). Plasma PTH exhibited CR in Ctr ($p<0.0001$), while the rhythm was disturbed in CKD ($p<0.05$) despite prevention of sHPT in CKD LP ($p<0.05$). Plasma P showed CR in all groups ($p<0.05$). However, the CR was disturbed in all CKD groups with shift in acrophase from 16:00 in Ctr to 19:00 (LP), 17:00 (SP), and 00:00 (HP).

Conclusions: Existence of a circadian rhythm of circulating activin A is established for the first time. The rhythmicity of activin A is disturbed in CKD rats and is associated with disturbed circadian rhythms of P and P regulating hormones PTH and FGF23. In injured kidney activin A is induced and secreted to venous effluent which can contribute to the disturbed circadian rhythm of activin A in uremia.

TH-PO532

An Internal Molecular Circadian Clock Operates in the Parathyroid Gland and Is Disturbed in CKD

Søren Egstrand,[1,2] Anders Nordholm,[1,2] Maria L. Mace,[1,2] Marya Morevati,[2] Klaus Olgaard,[2] Ewa Lewin.[1,2] *[1]Dept. of Nephrology, Herlev Hospital, University of Copenhagen, Copenhagen, Denmark; [2]Dept. of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark*.

Background: Parathyroid hormone (PTH) secretion exhibits a well-known circadian rhythmicity (CR) which is disturbed in secondary hyperparathyroidism (sHPT). The mechanism behind the CR of PTH is, however, unknown and not correlated to the CRs of calcium (Ca) and phosphate (P). Furthermore, the parathyroid gland is not controlled by a superior "hypothalamic-pituitary axis". The possible existence of a molecular circadian clock in the parathyroid cell has not previously been examined.

Methods: Normal male Wistar rats were kept in 12h:12h light:dark cycle and fed *ad libitum*. Parathyroid glands were harvested with 4 hours interval for 24 hours, along with plasma samples for PTH (pg/ml), P (mM), total Calcium (mM), Urea (mM) and Creatinine (μM). (N=38; 6 per timepoint). Gene expression was examined by qPCR analysis. sHPT was induced by 5/6 nephrectomy and high phosphorus diet for 24 weeks. (N=10 and 16 age-matched controls).

Results: Parathyroid glands showed clear expression of core molecular clock genes: *Bmal1*, *Clock*, *Per1-3*, *Cry1-2* and *Rev-Erbα*. The circadian rhythmicity was examined by cosinor analysis fitted to a period of 24h and was significant for *Bmal1* ($p<0.0001$), *Per2* ($p<0.0001$), *Per3* ($p<0.0001$), *Cry1* ($p<0.0001$), *Cry2* ($p=0.002$) and *Rev-Erbα* ($p<0.0001$). Significant rhythmicity was also found for the cell cycle gene *Cyclin D1* ($p=0.003$). In parathyroid glands from uremic rats, downregulation of *Clock* (1.61±0.38 vs. 4.19±1.21, $p=0.041$) was found, as well as circadian clock output gene *CSNK1ε* (1.05±0.24 vs. 2.27±0.34, $p=0.047$). Also cell cycle gene *Cyclin D1* was downregulated in uremic rats (1.20±0.24 vs. 3.36±0.73, $p=0.041$).

Conclusions: The existence of a parathyroid molecular circadian clock is demonstrated for the first time. The expression of the parathyroid circadian clock genes is disturbed in uremic parathyroid glands, which potentially can contribute to the disturbed circadian rhythmicity of circulating PTH and to the development of parathyroid hyperplasia in uremia.

Possible Clinical Relevance of Growth Hormone-Stimulated α-Klotho Upregulation

Tetsuhiko Sato,[3] Megumi Koike,[1] Hiroko Segawa,[1] Ken-ichi Miyamoto,[1] Masafumi Fukagawa.[2] *[1]University of Tokushima Graduate School, Tokushima, Japan; [2]Tokai University School of Medicine, Isehara, Japan; [3]General Medicine, Nagoya Daini Red Cross Hospital, Nagoya, Japan*.

Background: An aging suppressor protein, α-Klotho, known as a key factor for calcium-phosphorus homeostasis, is believed to have diverse physiological properties, because its global genetic deletion animal model shows short-stature and multi-organ dysfunction, resulting in early death. Interestingly, recent studies suggest that pituitary function plays an intriguing role, because growth hormone (GH)-producing pituitary adenoma significantly upregulates systemic α-Klotho levels. In end stage kidney disease (ESKD), growth spurt of pediatric patients is disturbed and often GH-resistant, whereas adult bone mineral disorder remains an unsolved clinical entity.

Methods: To elucidate the magnitude of GH/α-Klotho axis on both pituitary and bone-mineral reaction, we performed experiments involving GH administration to wild-type mice and adenine-induced kidney failure mice. GH was intraperitoneally given to 4-week-old male mice (C57BL/6J). We examined α-klotho mRNA expression, quantified by RT-PCR, in the pituitary gland and cancellous bones of mice with or without kidney dysfunction. Additionally, we performed immunohistochemistry (IHC) analysis of α-Klotho expression, surgically obtained from patients with pituitary adenomas.

Results: Exogenous GH increased α-klotho mRNA levels in the pituitary, and more robustly in cancellous bones. Strikingly, kidney failure cancelled GH-induced α-klotho expression in the pituitary and trabecular bones. Unexpectedly, GH administration induced modest α-klotho mRNA expression and markedly increased urinary excretion of soluble α-Klotho in wild-type mice, suggesting that GH triggers systemic circulation of α-Klotho in the bloodstream. IHC results indicated that pituitary GH-producing adenomas expressed α-Klotho more strongly than other (ACTH-producing, TSH-producing, or non-functioning) adenomas.

Conclusions: Established chronic kidney disease causes bone mineral disease, possibly by disrupting GH/α-Klotho axis. GH supplementation alone fails to catch up bone growth in juvenile patients with ESKD partly because of disrupted GH-triggered α-Klotho upregulation. Its stimulation might be a treatment option for patients with refractory bone and mineral disorders in ESKD. Organ-specific activation of GH/α-Klotho pathway might be a therapeutic target for restoring each organ function, leading to ideal organ rejuvenation and longevity.

Pin1 Isomerase Activity Determines PTH Gene Expression in Uremic Secondary Hyperparathyroidism

Alia Hassan,[1] Rachel Levin,[3,1] Justin Silver,[1] Morris Nechama,[2] Tally Naveh-Many.[1] *[1]Nephrology, Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Pediatric Nephrology, Hadassah Hebrew University Medical Center, Jerusalem, Israel; [3]Nursing, Jerusalem College of Technology, Jerusalem, Israel.*

Background: Secondary hyperparathyroidism (SHP) is a common complication of CKD that correlates with morbidity and mortality. In experimental SHP there is increased PTH secretion, gene expression and parathyroid cell proliferation. The high PTH gene expression is due to increased PTH mRNA stability mediated by the balanced protein-PTH mRNA interaction of AUF1 (AU-rich binding protein 1) that stabilizes and KSRP (K-homology splicing regulatory protein) that destabilizes PTH mRNA. Pin1 binds to and isomerizes phosphorylated Ser/Thr-Pro motifs in target proteins, including mRNA binding proteins. Pin1-KSRP interaction leads to dephosphorylation of KSRP at Ser181 that then binds to PTH mRNA with higher affinity to induce PTH mRNA decay. In SHP, Pin1 isomerase activity is decreased and phosphorylated KSRP fails to bind PTH mRNA, resulting in increased PTH mRNA stability and levels. Pin1 activity is regulated by phosphorylation at Ser16 and Ser71 that disrupts its interaction with target proteins and catalytic isomerase activity.

Methods: We performed proteome and phospho-proteome analysis of parathyroids from normal and adenine high phosphorus induced CKD rats. Pin1 phosphorylation was demonstrated by immunofluorescence staining. The PKA activator forskolin or PKA inhibitor H89 were added to mouse thyroparathyroid glands in culture or HEK293 cells transfected with a PTH expression plasmid. Secreted PTH was measured by Elisa and mRNA levels by qRT-PCR.

Results: Phospho-proteome analysis confirmed KSRP hyper-phosphorylation in parathyroids of SHP rats, that would prevent PTH mRNA-KSRP binding and decay. It also identified new Pin1 targets and signaling pathways. Phosphorylation of both Pin1 Ser16 and Ser71 was increased in parathyroids of SHP rats, correlating with the decreased Pin1 activity. Accordingly, parathyroid extracts from SHP rats showed increased in vitro phosphorylation activity towards recombinant GST-Pin1. PKA activation, that leads to Pin1 Ser16 phosphorylation, increased PTH secretion in parathyroid organ cultures and PTH mRNA in transfected HEK293 cells. PKA inhibition had the opposite effect.

Conclusions: Pin1 activity is central to the pathogenesis of SHP by orchestrating PTH mRNA-protein interaction and thus mRNA decay. The resulting increased PTH mRNA stability leads to the high serum PTH levels in SHP.

Novel Calcimimetic and Calcilytic Activity of Dietary Plant Polyphenols

Edward A. Ross,[1] Alexander J. Bosak,[1] Timothy A. Gilbertson,[1] Bradley J. Willenberg,[1] Alicia R. Willenberg,[1] Naima Dahir,[1] Otto Phanstiel.[2] *[1]Department of Internal Medicine, College of Medicine, University of Central Florida, Orlando, FL; [2]Department of Medical Education, College of Medicine University of Central Florida, Orlando, FL.*

Background: Plant-derived polyphenols have diverse medicinal effects involving multiple signaling pathways. With grapes reportedly improving human bone mass and associated with hypercalcemia in certain dogs, we hypothesized a new mechanism involving the calcium sensing receptor (CaSR): some compounds being calcilytic, others calcimimetic. We study CaSR and species-specific effects of plant-derived polyphenols in human and canine cells.

Methods: CaSR modulation by polyphenols was studied in pCMV-human-CaSR plasmid transfected human HEK293T cells and canine MDCK Type II cells using dual luciferase reporter (DLR) and Fura-2AM ratiometric calcium dye assays, respectively, for grape seed and pomace extracts (GSE, GPE) and plant-derived polyphenols cyanidin-3-sophoroside (C3S), cyanidin-3-glucoside (C3G), delphinidin-3-O-glucoside, procyanidin B2, kaempferol 3-β-D-glucopyranoside and resveratrol. DLR assays in HEK293T cells used 1μg/mL GSEs, GPEs or polyphenols over 65h. Live intracellular MDCK calcium imaging via Fura-2AM was studied over six minutes with 5μM of each polyphenolic compound in 1.0 then 3.0 mM Ca^{2+} media to assess calcimimetic or calcilytic activity. Cinacalcet was a positive calcimimetic control and was tested to rescue grape calcilytic activity. YM-254890 was a control for blocking the CaSR pathway.

Results: In HEK293T cells 1μg/mL GSE and GPE were calcimimetic (raising intracellular Ca^{2+}), while the individual polyphenols C3G and C3S were calcilytic in both species. Cinacalcet inhibited the polyphenol-induced calcilytic effects. Surprisingly NPS-2143, a human calcilytic, was a calcimimetic in dogs.

Conclusions: This is the first evidence that polyphenols found in common foods affect calcium signaling by CaSR modulation and have species-specific calcimimetic or calcilytic properties. From preliminary data for grape extracts and individual polyphenolic compounds, we conclude that 1) these mechanisms explain how naturally-derived nutraceutical compounds may influence both human and canine medicine; 2) may provide the, heretofore, unexplained mechanism of lethal grape toxicity in dogs which 3) could lead to the development of antidotes that target the CaSR. In addition, elucidation of the active chemical moieties could guide therapeutic nutraceutical development for human bone mineral metabolism disorders.

TH-PO536

Cell Cycle Acceleration in Parathyroid Glands Is Caused by the Combination of CKD Environment and High-Phosphorus Diet in the Adenine Rat Model Because of Suppression of CDKN1B Expression

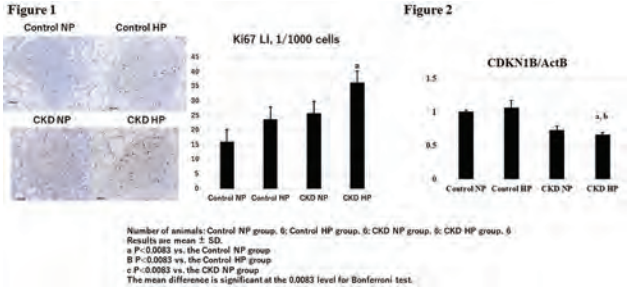
Taketo Uchiyama,[1] Ichiro Ohkido,[1] Akio Nakashima,[2] Yatsumu Saito,[3] Takashi Yokoo.[2] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [2]The Jikei University School of Medicine, Tokyo, Japan; [3]The Jikei University School of Medicine, Tokyo, Japan, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) disrupts mineral homeostasis and is characterized by secondary hyperparathyroidism (SHPT). SHPT is characterized by abnormally increased proliferation of parathyroid cells, although the underlying mechanism remains largely unknown. Previously, we reported that an increase in Ki67 immunohistochemical expression was observed in 5/6 nephrectomy rats fed the high phosphorus diet. The aim of this study was to investigate the role of the CKD environment with and without high-phosphorus diet in SHPT progression, particularly cell cycle acceleration in the parathyroid glands.

Methods: CKD was induced by a diet containing 0.75% adenine. For 2 weeks, few CKD rats and few control rats were fed diets containing 0.9% phosphorus (normal phosphate diet); other CKD rats and control rats were fed diets containing 1.3% phosphorus (high-phosphate diet). In a gene expression analysis related with cell cycle, such as *CDKs*, *CKIs* and *cyclins*, TaqMan probes were used to conduct quantitative polymerase chain reactions. Ki67 and cyclin-Dependent kinase inhibitor 1B (CDKN1B) protein expressions were analyzed immunohistochemically.

Results: Among the CKD rats, there was no significant difference in severity of CKD status between those fed the normal phosphorus diets (CKD NP rats) and those fed the high-phosphorus diets (CKD HP rats); however, the increase in Ki67 immunohistochemical expression in cells was observed in only CKD HP rats (Figure 1). Thus, SHPT and severe CKD-mineral and bone disorder status were induced only by high-phosphorus diets in CKD rats. CDKN1B expression, which plays an important role in the G1/S checkpoint, was significantly decreased only in CKD HP rats (Figure 2).

Conclusions: Only CKD HP rats showed a significant reduction in *CDKN1B* gene and protein expression. Our data indicated that CDKN1B plays a major role SHPT progression and cell cycle acceleration and is an important target in SHPT therapy.



TH-PO537

Dicer and MiRNA Deletion Leads to Ectopic Parathyroids

Alia Hassan,[1] Rachel Levin,[2,1] Justin Silver,[1] Tally Naveh-Many.[1] *[1]Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Nursing, Jerusalem College of Technology, Jerusalem, Guinea-Bissau.*

Background: Ectopic parathyroid glands are a diagnostic and operative challenge in patients with hyperparathyroidism and are attributed to abnormal embryonic parathyroid migration. miRNA have vital roles in biology and development. The final step of miRNA maturation is mediated by Dicer. We have generated parathyroid specific Dicer knockout (PT-*Dicer*$^{-/-}$) mice to specifically delete parathyroid Dicer and miRNAs. The PT-*Dicer*$^{-/-}$ mice had normal basal serum PTH levels but an impaired increase in PTH in response to acute and chronic hypocalcemia and uremia. Parathyroid glands develop from the parathyroid-thymus common primordia and migrate to their adult location adjacent to the thyroid. We now show that in addition to parathyroid stimulation, Dicer and miRNA are central to parathyroid embryonic development.

Methods: We generated by cre lox recombination mice with parathyroid-specific Dicer knockout (PT-*Dicer*$^{-/-}$) and parathyroid specific YFP (PT-*YFP*), where the parathyroids can be identified under a fluorescence microscope. Mouse thyro/parathyroid histological slides were stained for PTH.

Results: Surprisingly, the parathyroid glands were absent in most thyroid sections of the PT-*Dicer*$^{-/-}$ mice, despite normal basal PTH. We identified ~75 % of parathyroids in control mice (n=45) but only ~20 % in PT-*Dicer*$^{-/-}$ and heterozygote PT-*Dice*$^{+/-}$ mice (n=63 and 14), most of which were small, some showing atypical follicular structures. Heterozygote PT-*Dicer*$^{+/-}$ mice also had an impaired increase in serum PTH after a low calcium diet, like homozygote PT-*Dicer*$^{-/-}$ mice, indicating that *Dicer* haplo-insufficiency abrogates the position of the parathyroid glands and parathyroid stimulation by hypocalcemia. To identify ectopic parathyroids in the PT-*Dicer*$^{-/-}$ mice, we generated parathyroid specific YFP (PT-*YFP*) mice. Unlike control PT-*YFP* mice, 80% of the PT-*Dicer*$^{-/-}$; *YFP* mice had no detectable parathyroid glands. Instead, there were small clusters of ectopic parathyroid cells scattered on the trachea. 20% of the PT-*Dicer*$^{-/-}$ mice had a single parathyroid gland

in the anterior mediastinum or adjacent to the thyroid. These findings explain the absence of parathyroids in thyroid sections of *Dicer*$^{-/-}$ mice and indicate that Dicer and miRNA are required for parathyroid differentiation and morphogenesis.

Conclusions: Parathyroid Dicer and miRNA are essential for development, migration, localization and function of the parathyroids.

Dietary Protein and Branched Chain Amino Acids Protect the Kidney from Phosphate Burden

Karin Shimada, Isao Matsui, Ayumi Matsumoto, Nobuhiro Hashimoto, Seiichi Yasuda, Sachio Kajimoto, Yohei Doi, Satoshi Yamaguchi, Keiichi Kubota, Tatsufumi Oka, Yusuke Sakaguchi, Kazunori Inoue, Takayuki Hamano, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Phosphate homeostasis is critically important for the maintenance of health. High phosphate intake has been reported to be harmful for the kidney. Although levels of dietary phosphate intake closely correlate with dietary protein intake, effects of dietary protein on phosphate toxicity remain uncertain.

Methods: Phosphate-induced chronic kidney disease (CKD) model were prepared by feeding a diet containing 2% phosphate to male Wistar rats for 6 weeks. Rats were randomly divided into 3 groups based on concomitant feeding of 12.5%, 25%, or 37.5% casein. Similar models were prepared by feeding ovalbumin instead of casein. We also analyzed effects of dietary branched chain amino acids (BCAA) on phosphate-induced kidney injury.

Results: Dietary casein suppressed serum levels of creatinine and phosphate, but elevated serum urea nitrogen, in a dose dependent manner. Dietary casein did not affect levels of food intake nor fecal phosphate. Although dietary casein elevated urinary protein in normal Wistar rats without phosphate burden, dietary casein did not increase urinary protein in phosphate-fed CKD rats. Both real time PCR and histological analyses revealed that dietary casein protected the kidney from phosphate-induced toxicity. Dietary casein maintained the mitochondrial integrity in tubular cells, and thereby suppressed oxidative stress. Ovalbumin showed even better renoprotective effects with unchanged serum urea nitrogen and suppressed urinary protein. To investigate underlying mechanisms of renoprotection by dietary proteins, we measured plasma amino acid levels and found that both dietary casein and ovalbumin elevated plasma valine, leucine, and isoleucine. Dietary supplementation of BCAA abrogated the toxic effects of phosphate to the kidney in a manner similar to that observed in ovalbumin-fed rats. Although dietary casein and ovalbumin increased water intake and urinary volume, BCAA affected neither of them.

Conclusions: Dietary protein protects the kidney from phosphate burden. BCAA supplementation may be even better way to suppress phosphate toxicity to the kidney.

Do You Know What Your Experimental Animals Eat?

Annabel Biruete,[1] Shruthi Srinivasan,[1] Kalisha O'Neill,[1] Colby Vorland,[3] Kathleen M. Hill Gallant,[2,1] Weijing Cai,[4] Jaime Uribarri,[5] Nancy Johnston,[1] Matthew R. Allen,[1] Neal X. Chen,[1] Sharon M. Moe.[1] *[1]Indiana University School of Medicine, Muncie, IN; [2]Purdue University, West Lafayette, IN; [3]Indiana University, Bloomington, IN; [4]Mount Sinai Medical center, New York, NV; [5]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Autoclaved diet use has been increasing in research animal facilities due to its ability to reduce infection. The high heat generated through autoclaving could have various effects on a diet. Our goal was to determine how autoclaved-induced increases in dietary advanced glycation end products (AGE) affect properties in a model of chronic kidney disease-mineral and bone disorder (CKD-MBD).

Methods: Cy/+ (CKD) rats and normal (NL) littermates were assigned to 1 of 3 diets: autoclaved 0.7% phosphorus grain-based diet for 28 wks (**AGEs**), autoclaved diet for 17wks followed by non-autoclaved 0.7% bioavailable phosphorus casein-based until 28 wks (**AGEs + Casein**), or a non-autoclaved diet for 17wks followed by a non-autoclaved casein-based diet (**non-AGEs+Casein**) until 28 wks. We examined kidney function, plasma biochemistries, and intestinal gene expression (phosphate transporters, the receptor for AGE (RAGE), and NADPH-oxidases). We assessed the effects of disease (CKD vs NL), diet, and the interaction by two-way ANOVA.

Results: Autoclaved diet contained 3.5-fold more of the AGE carboxymethyllysine and 2.5-fold more methylglyoxal than the non-autoclaved diet. There was a disease-by-diet interaction on the plasma DNA oxidation marker 8-OHdG, driven by differences between the NL and CKD rats fed the AGEs and AGEs + Casein diets. AGEs diet led to increased progression of CKD that was further augmented by the casein diet ($P_{interaction}$=0.03). There was a disease-by-diet interaction on phosphorus, PTH, and FGF23 driven by the higher values in the CKD rats fed the AGEs + casein diet ($P_{interaction}$<0.05 for all). At the intestinal level, NaPi2b was 2-fold higher in the rats fed the non-AGEs + casein diet (P_{diet}<0.0001). Intestinal RAGE was 2- to 4-fold higher in the rats fed the AGEs and AGEs + casein diets (P_{diet}<0.0001). This was mimicked by a higher expression of DUOX2 (P_{diet} = 0.0019).

Conclusions: Autoclaved diet contains higher levels of AGE and leads to increased systemic oxidative stress and more rapid progression of CKD-MBD phenotype if combined with a bioavailable phosphorus diet. Eating an autoclaved diet also altered intestinal transporters regulating AGE, NADPH-oxidases, and phosphate. These studies highlight the critical importance of dietary aspects, including autoclaving, in the study of CKD-MBD.

TH-PO540

Intestinal Environmental Control and Renal Protection by Intestinal Alkaline Phosphatase (IAP)

Hiroko Segawa, Sumire Sasaki, Yuki Arima, Ai Hanazaki, Megumi Koike, Kazuya Tanifuji, Ken-ichi Miyamoto. *Tokushima University, Tokushima City, Japan.*

Background: Hyperphosphatemia is an independent risk factor for mortality, and prevention and correction of it is a major goal of the treatment of chronic kidney disease (CKD). Inorganic phosphate (Pi) balance is maintained by intestinal absorption, renal excretion, and bone accretion. Especially, the regulation of intestinal Pi absorption is an important target for the treatment of hyperphosphatemia. Intestinal alkaline phosphatase (IAP) is a brush border phosphomonoesterase that catalyzes the hydrolysis of nonspecific Pi ester bonds at an alkaline pH, and a plasma membrane-bound glycoprotein that dephosphorylates several substrates, including Pi additives. The relationship between IAP and Pi metabolism is not clear. We investigated whether intestinal alkaline phosphatase 3(Akp3), the enzyme that hydrolyzes dietary Pi compounds, is a target for the treatment of hyperphosphatemia in CKD.

Methods: We analyzed Pi homeostasis in Akp3 knockout mice (Akp3$^{-/-}$), and studied the progression of renal failure, and intestinal environment in an Akp3$^{-/-}$ renal failure model.

Results: In humans, rats, and mice, intestinal alkaline phosphatase (IAP, AKP3) is expressed throughout the gastrointestinal tract with the highest expression in the duodenum. Akp3$^{-/-}$ mice have high luminal ATP concentrations, which affects bacterial growth in the gut. Changes in the extracellular ATP concentration affected Pi transport. In the renal failure model, genetic deletion of Akp3 suppressed abnormal mineral homeostasis, progression of renal failure and inflammation of the intestinal and whole body in Akp3$^{+/+}$. As a result, Akp3$^{-/-}$ extended the life span compared to Akp3$^{+/+}$. In the Akp3$^{-/-}$ renal failure model, hyperphosphatemia was alleviated by suppression of intestinal Pi absorption via paracellular mechanisms as well as transcellular Pi transport.

Conclusions: Elucidation of the mechanism of suppression of renal disease progression confirmed by Akp3$^{-/-}$ could contribute to the development of a new CKD treatment.

TH-PO541

PiT-2 Is the Main Transporter Responsible for Intestinal Phosphate Absorption in Human

Yasuhiro Ichida,[2] Daniel Weis,[1] Shuichi Ohtomo,[2] Nadine Kaesler,[1] Christoph Kuppe,[1] Tessai Yamamoto,[2] Naoaki Murao,[2] Hiroko Segawa,[3] Yoshiki Kawabe,[2] Naoshi Horiba,[2] Ken-ichi Miyamoto,[3] Jürgen Floege.[1] *[1]RWTH University of Aachen, Aachen, Germany; [2]Chugai Pharmaceutical Co., Ltd., Gotemba, Japan; [3]University of Tokushima Graduate School, Tokushima, Japan.*

Background: In chronic kidney disease (CKD) patients, adequate management of hyperphosphatemia is critical. Phosphate is absorbed in the small intestine via passive and active transports. NaPi-IIb is thought to be the main transporter for the active route, but a selective NaPi-IIb inhibitor failed to ameliorate hyperphosphatemia in patients with CKD. Transporters besides NaPi-IIb are thought to contribute to active phosphate transport in humans.

Methods: We examined the protein expression levels of NaPi-IIb, PiT-1, and PiT-2 in the small intestine of humans and rats by mass spectrometry (LC-MS/MS). To evaluate the influence of kidney disease, these 3 transporters were also assessed in CKD/dialysis patients and CKD rat models. Phosphate metabolism including intestinal phosphate uptake was evaluated, and protein expression levels were compared in rats.

Results: In humans, intestinal NaPi-IIb protein expression was low and PiT-2 protein expression dominated. PiT-2 protein was mostly expressed in the duodenum and jejunum where most of the phosphate is absorbed. PiT-2 expression levels were similar in CKD or dialysis patients and normal subjects. Compared to humans, in normal rats NaPi-IIb was predominantly expressed in the upper small intestine. Expression levels significantly decreased with age, and this correlated with lower serum phosphate concentration and the velocity of phosphate uptake in intestinal brush border membrane vesicles (BBMV). In rat CKD models, NaPi-IIb protein expression decreased significantly and low-affinity sodium-dependent phosphate transport dominated in intestinal BBMV. The nature of this transport remains unknown, as PiT-1 or PiT-2 protein expression in these animals remained undetectable by LC-MS/MS.

Conclusions: Major species differences in the intestinal phosphate absorption system were identified between humans and rats. Unlike in rats, PiT-2 appears to be the dominant intestinal phosphate transporter in humans and its expression was unaltered in patients with CKD. Thus, we identify PiT-2 as a promising pharmacological target for the treatment of hyperphosphatemia in dialysis and/or CKD patients.

TH-PO542

Inhibition of Sodium Phosphate Transporter Npt2a Increases Urinary Phosphate Excretion and Improves Experimental Vascular Calcification in Rats

Juergen Klar,[2] Anja Giese,[1] Alexander Ehrmann,[2] Christoph Thiel,[2] Bernd Riedl,[2] Frank Eitner.[2] *[1]Bayer AG, Berlin, Germany; [2]Bayer AG, Wuppertal, Germany.*

Background: A dysregulated phosphate homeostasis is strongly associated with mortality, cardiovascular events and vascular calcification, particularly in patients suffering from CKD. Inhibition of the tubular phosphate transporter Npt2a provides a novel and unique mechanism to address phosphate homeostasis imbalance.

Methods: Npt2a activity was measured in a cell based assay, using a stable CHO cell line with inducible Npt2a expression. Male Wistar rats were used for all experiments. Healthy rats were treated orally with BAY 767, a potent Npt2a inhibitor developed at Bayer AG. Vascular calcification was induced by administration of a pan-FGFR inh. (25mg/kg) for 10 days.

Results: BAY 767 was identified as potent Npt2a inhibitor, with an IC_{50} of 2.9/6 nM on rat/ human Npt2a, respectively, selective over Npt2b, Npt2c and Pit-1. Single dose treatments of healthy rats resulted in a significant, dose-dependent increase in urinary phosphate excretion within 16h. Multiple dose treatments (3d) significantly reduced plasma phosphate levels from 2.0 mmol/ L to 1.6 mmol/ L at the highest tested dose. Congruent levels of FGF-23 as well as PTH were decreased to 46% and 43% as compared to untreated controls, respectively. In an experimental vascular calcification model, treatment with the Npt2a inhibitor significantly inhibited vascular calcification and normalized plasma phosphate levels in comparison to untreated rats that developed massive vascular calcification and hyperphosphatemia. In the same model 2.2% lanthanum carbonate was not beneficial with respect to vascular calcification.

Conclusions: Our results show for the first time that treatment with a Npt2a inhibitor improves vascular calcification by addressing urinary phosphate excretion and phosphate homeostasis in rats. Npt2a inhibition may provide a new therapeutic principle for patients suffering from disbalanced phosphate homeostasis and vascular calcifications, including CKD patients.

High Phosphate-Inducing Valvular Interstitial-Endothelium Cross-Talk Through mir-382/SOD2 Axis in CKD with Valve Injury

Li-ting Wang, Yu-xia Zhang, Si-Jie Chen, Yu Guo, Xiao-chen Wang, Li-Hua Ni, Kaiyun Song, Xiaoliang Zhang, Bi-Cheng Liu, Ri-ning Tang. *Institute of Nephrology, ZhongDa Hospital, school of medicine, Southeast University, Nanjing, China.*

Background: CKD valve injury is the main cause of CVD among CKD patients, but it underlying mechanisms are still unknown. Previous studies demonstrated valve interstitial cells (VICs) participate in valve injury to produce excessive quantities of the valvular ECM. Recent findings suggested valve interstitial-endothelium crosstalk are closely related to valve homeostasis and injury. Hence, we want to investigate the mechanism between VECs and VICs upon high phosphate (HP) stimulation.

Methods: We used c57/b mouse and HP-stimulated VIC as in vivo and in vitro model of CKD, respectively. Transwell migration were performed to determine VIC could aggravate valve endothelial cell(VEC) EndMT upon HP stimulation by qPCR, WB and immunofluorescence. ELISA were performed to detect the expression of TGFβ-1 in VIC cell supernatant. The expression of key factors involved in EndMT process, such as CD31, VE-cadherin, α-SMA, FSP1 were evaluated by western blotting and immunofluorescence. qRT-PCR was used to measure levels of miR-382 in VEC.

Results: TGFβ-1were significantly increased in VIC upon HP stimulation. Transwell migration were proved VIC could aggravate VEC endothelial-to-mesenchymal transition (EndMT) upon HP stimulation, with the up-regulation of mesenchymal markers (FSP1 and α-SMA) and stem cell markers (CD44 and CD10) and down-regulation of the endothelial marker (CD31, VE-cadherin), consistent with CKD aortic valve samples. Knockdown of EC miR-382, which was up-regulated by TGFβ1, could attenuate TGFβ1-induced loss of the endothelial marker VE-cadherin and CD31. miR-382 was confirmed by 3'-untranslated region reporter assay to target superoxide dismutase 2 (SOD2) that were downregulated at the protein level by TGFβ1. Knockdown of miR-382 attenuated TGFβ1-induced downregulation of SOD2. Overexpression of SOD2 ameliorated loss of the endothelial marker and CKD aortic leaflets thickening.

Conclusions: VIC could secret TGFβ-1 upon HP stimulation, which lead to EndMT through mir-382/SOD2 axis. This could cause CKD aortic leaflets thickening and aggravate valve injury.

A Crossover Study of Continuous Intake of the Different Phosphorus Bioavailability Meal in Healthy Japanese

Yoko Narasaki,[1,2] Michiyo Yamasaki,[1] Misaki Katsumoto,[1] Yutaka Taketani.[1] Tokushima University *[1]Tokushima University, Irvine, CA; [2]Research Fellowships of Japan Society for the Promotion of Science for Young Scientists (JSPS), Tokyo, Japan.*

Background: Dietary phosphorus (P) management based on its bioavailability is crucial to prevent and treat the risk of cardiovascular disease and mortality in both general population and chronic kidney disease (CKD) patients. Our previous study has demonstrated that P bioavailability in various independent foods as the relative value of sodium P supplement. However, it reminds unclear that P bioavailability in mixed meal. Thus, we conducted the short-term dietary intervention study that ingested mixed meal consisting of different P bioavailability foods.

Methods: We conducted an open-label crossover study of 4 different test meals consumed for 5 days by 5 men and 5 women healthy young subjects, aged 20-30 years old. We obtained multiple points of blood and 24 h urine samples at before and after each intervention. Each meal was designed to have the same amount of P (1,200 mg/d) and only a half of P (600 mg/d) sources varied as test foods: soybean and tofu, pork and ham, milk and process cheese, and sodium P supplement for low, medium, high, and control P bioavailability test food, respectively.

Results: After continuous ingestion of high P bioavailability meal, fasting serum intact fibro blast growth factor 23 (iFGF23) levels increased, accompanied with decrease in serum 1,25-dihydroxyvitamin D levels and urinary P excretion [Figure 1]. Additionally, serum P and iFGF23 levels were lower in low P bioavailability meal compared with other test meals throughout the day. These results indicate consuming higher P bioavailability food results higher increase of iFGF23 which reflect more severe P burden.

Conclusions: Habitual ingestion of low P bioavailability food decreases P burden despite equivalent amount of P and may contribute to reduce the risk of disease and mortality in CKD patients.

TH-PO545

Extracellular Matrix Stiffness Modulates Calcification of Vascular Smooth Muscle Cells via Phosphate Uptake

I-Chia Liu,[1] Brandon To,[1] Shiyu Li,[1] Rajesh Mohandas.[1,2] *[1]University of Florida, Gainesville, FL; [2]North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Background: In patients with chronic kidney disease (CKD), stiffening and calcification of blood vessels are common and predict mortality and adverse cardiovascular events. Our preliminary data suggests that stiffening occurs early in CKD and could be independent of calcification. Stiffness of the extracellular matrix (ECM) has also been shown to influence differentiation of pluripotent stem cells. Thus, we hypothesize that stiffness of the ECM will increase phosphate mediated osteoblastic transformation and calcification of vascular smooth muscle cells.

Methods: Human aortic smooth muscle cells (HASMCs) were plated on polyacrylamide gels of varying stiffness: 8kPa, 50kPa, or plastic (~10,000kPa). Cells were cultured in either control or calcification medium (3.0mM phosphate and 2.7mM calcium). After 7 days in culture, alkaline phosphatase activity (ALP), intracellular phosphate and calcium content in cells were measured and normalized to total protein content.

Results: There was a 4-fold increase in calcium in HASMCs plated on 8kPa (243 ± 124 μg/mg of protein) compared to those on 50kPa (954 ± 59 μg/mg of protein, $P<0.05$) and a 9-fold increase from 50kPa to plastic (8246 ± 1324 μg/mg of protein, $P<0.05$) (Fig 1). HASMCs on plastic had a near 2-fold increase in ALP activity when cultured in calcification medium (0.58 ± 0.12 vs 0.33 ± 0.05 mU/μg of protein, $P<0.05$), while cells on 8kPa (0.36 ± 0.02 vs 0.35 ± 0.04 mU/μg of protein, $P>0.05$) and 50kPa (0.33 ± 0.03 vs 0.39 ± 0.05 mU/μg of protein, $P>0.05$) showed no appreciable increase in ALP activity. Similar to ALP data, phosphate uptake was increased in cells plated on plastic (2.21-fold increase, $p<0.05$) but not for the 8kPa and 50kPa gels in calcification media (Fig 2).

Conclusions: Our study showed that ECM stiffness increases calcification of HASMC. Osteoblastic transformation was abolished on soft gels. The decrease in osteoblastic transformation appears secondary to downregulation of phosphate uptake. Targeting molecular pathways that mediate stiffness induced upregulation of phosphate uptake might decrease calcification and improve cardiovascular outcomes in CKD.

ASARM Peptide Reverses Hyperphosphatemia; Prevents Calciphylaxis-Like Lesions; and Corrects Renal, Bone, Brain, and Cardiovascular Calcification in a Rat Model of CKD

Peter S. Rowe, Jason R. Stubbs, Alan S. Yu, Ellen T. McCarthy. *University of Kansas Medical Center, Kansas City, KS.*

Background: Abnormalities in mineral metabolism, bone and vascular calcification occur in Chronic Kidney Disease (CKD-MBD). Cognitive function also declines as the disease progresses. Bone ASARM peptides are strong inhibitors of mineralization and induce hypophosphatemia by inhibiting phosphate uptake from the gut. We hypothesize treatment of CKD-MBD rats with ASARM peptides will reverse hyperphosphatemia, correct mineralization defects and improve mortality.

Methods: To test our hypothesis, we used a rat 5/6 Nephrectomy experimental model (NEPHREX) and sham operated rats (SHAM) as controls. Male rats (16 wk, 250 gm) were fed a high phosphate diet to worsen mineral metabolism defects (2% P, 2000 IU Vit D and 0.8% Ca; TEKLAD 170496). ASARM peptide was infused continuously for 4 weeks using subcutaneous implantation of Alzet osmotic pumps. Sera collections were taken at the beginning and end of the study.

Results: NEPHREX rats treated with ASARM-peptide showed major reductions in hyperphosphatemia, and improved renal, bone, brain and cardiovascular calcification compared to controls treated with vehicle (Figure 1). Also, the high phosphate diet NEPHREX rats developed sub-dermal medial blood vessel calcification and calciphylaxis like lesions. The subdermal blood vessel calcifications did not occur in 56-NEPHREX rats treated with ASARM-peptide.

Conclusions: In summary our study shows ASARM peptides infused into a rat model with CKD corrects hyperphosphatemia and improves bone and renal mineralization abnormalities. These findings also confirm our hypothesis and supports the utility of ASARM peptide treatment in patients with CKD-MBD.

Funding: NIDDK Support

Effect of PARP Inhibition on the Development of Vascular Calcification (VC) in CKD Rats

Ellen Neven,[1] Patrick D'Haese,[1] Catherine M. Shanahan,[2] Melinda Duer,[4] James A. Harrison,[3] Anja Verhulst.[1] *[1]University of Antwerp, Antwerp, Belgium; [2]King's College London, LONDON, United Kingdom; [3]Cycle Pharmaceuticals, Cambridge, United Kingdom; [4]University of Cambridge, Cambridge, United Kingdom.*

Background: A new therapeutic approach for VC consists in the use of molecules directly interfering with the calcification process. Potential candidates for this are Poly ADP Ribose Polymerase (PARP) inhibitors. Through the understanding of PARP/PAR processes that occur in new bone formation, it has recently been discovered that VC is also mediated by PARP/PAR processes that release PAR from dying cells in the vascular wall. We evaluated the effect of the PARP inhibitor minocycline (MC) on the development of VC in a rat model with adenine-induced CKD.

Methods: 56 male Wistar CKD rats were randomly assigned to 4 study groups (n=14 each) and treated daily during 6 wks with either tap water (CKD-Veh) or MC at doses of 5, 10 or 50 mg/kg respectively. MC treatment was initiated 1 wk after the start of adenine dosing (0.75% in diet during 4 wks). VC was evaluated by measuring arterial calcium (Ca) content as well as area % Von Kossa positivity. Bone status was evaluated by quantitative histomorphometric analysis of static and dynamic bone parameters.

Results: Mortality was limited as only 1 animal died before the study end. MC did not impact renal dysfunction nor did it affect PTH, phosphorus, Ca or FGF-23 levels. Arterial Ca content as well as area % Von Kossa positivity, indicated MC treatment to dose dependently decrease calcification in the aorta, carotid and femoral arteries which became significant in the 50 mg/kg group. Compared to CKD-Veh rats MC treatment went along with a tendency towards a lower bone area which however, was inversely associated with the MC dose and was abolished when the mineralized area over bone area was considered. Similar patterns were observed for the bone formation and mineral apposition rates respectively. No significant effect of MC treatment on the number of osteoblasts and osteoclasts was observed.

Conclusions: MC treatment reduced VC without affecting renal function and associated mineral disturbances, suggesting a direct and local action on the arterial wall. The beneficial effects on the vasculature reveal that PARP inhibition might be a promising, safe and effective treatment of VC. Further studies are warranted to get a more profound insight in the potential effects of MC on bone.

Inorganic Polyphosphate Amplifies the Macrophage-Inflammatory Response Induced by Lipopolysaccharide

Toru Ito, Suguru Yamamoto, Yoshikatsu Kaneko, Shin Goto, Fumitake Gejyo, Ichiei Narita. *Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Recent studies have revealed that inorganic polyphosphate (polyP), a linear polymer of orthophosphate, is involved in various physiological events like blood clotting, inflammation and energy metabolism. Infection, particularly sepsis, is a major cause of death in patients with chronic kidney disease (CKD) and is associated with high levels of phosphate in the serum. However, the role of phosphate in the induction of an inflammatory response during CKD is largely unknown. In this study, we examined the effect of polyP on lipopolysaccharide (LPS)-induced macrophage proinflammatory signaling *in vitro*.

Methods: A reaction of THP-1 derived macrophages with LPS (1.0 ng/mL) from *Escherichia coli* and polyP of various chain lengths (1, 2, 3, 15, 65, 100, 700 mer) and concentrations (1-200 µM, calculated as an orthophosphate monomer) was carried out. The levels of inflammatory cytokines released into the culture medium were measured using ELISA. The expressions of proinflammatory cytokine mRNAs of IL-1β, TNFα and IL-6 and signaling proteins like NF-κβ and MAPK were analyzed by real-time PCR and western blotting, respectively. The effect of polyP on LPS binding to the Toll-like receptor (TLR) 4 on cells and its structure was examined by quartz crystal microbalance (QCM), flow cytometry and fluorescence microscopy visualization, and isothermal titration calorimetry (ITC) and dynamic light scattering spectroscopy (DLS), respectively.

Results: PolyP amplified the inflammatory cytokine production induced by LPS (IL-1β, 50 µM polyP-65: 23.0 ± 2.9 pg/mL; 1 ng/mL LPS: 440.8 ± 45.7 pg/mL; 1 ng/mL LPS + 50 µM polyP-65: 1666.6 ± 162.4 pg/mL, $p<0.05$) in a dose- and chain length-dependent manner, whereas orthophosphate had no such effect. It also enhanced the expression levels of proinflammatory cytokine mRNAs, LPS-induced macrophage signaling (indicated by an increased expression of NF-κβ, MAPK) and LPS micelle formation. Results of QCM, flow cytometry and fluorescence microscopy showed that polyP bound directly to LPS, enhancing its interaction with TLR4.

Conclusions: This study suggests that polyP may be important in promoting an LPS-induced inflammatory response in macrophages and could be a form of phosphate associated with acute inflammation in patients with CKD.

TH-PO549

Resveratrol Ameliorates High-Phosphate-Induced VOT and AMC in CKD Through Regulating Wnt/β-Catenin Signaling

Xiaowen Huang,[2] Weichun He.[1] *[1]Nanjing Medical University, 2nd Affiliated Hospital, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Vascular smooth muscle cells (VSMCs) to osteoblast-like cells transdifferentiation (VOT) induced by high-phosphate is a crucial step in the development of arterial medial calcification (AMC) in patients with chronic kidney disease (CKD). Our previous study demonstrated that Wnt/β-catenin signaling played an important role in promoting VOT and calcification in VSMCs induced by high-phosphate. Studies in cancer field have confirmed that resveratrol, a natural polyphenol, could regulate Wnt/β-catenin signaling. However, the potential effect of resveratrol on VOT and AMC through Wnt/β-catenin signaling remains to be elucidated.

Methods: An animal model of chronic renal failure with AMC was established by feeding rats a diet containing 0.75% adenine and 0.9% phosphorus. VOT and AMC in arterial ring was induced by placing isolated thoracic aortic rings from mice in culture medium containing 10 mM β-glycerophosphoric acid (β-GP). VOT and calcification of cultured VSMCs was also induced by 10 mM β-GP. The effect of resveratrol on VOT and/or calcification was observed in the *in vivo*, *ex vivo* and *in vitro* models mentioned above. The regulation of resveratrol on Wnt/β-catenin signaling in VSMCs was also examined.

Results: Resveratrol ameliorated AMC in chronic renal failure rats fed with high-phosphate diet and calcium deposition in arterial rings and VSMCs cultured in a high-phosphate environment. Resveratrol suppressed the induction of Runx2, osteocalcin and osteopontin and restored the expression of SM22α in arterial rings and VSMCs treated with high-phosphate. *In vitro*, resveratrol inhibited the upregulation of two forms of active β-catenin, dephosphorylated on Ser37/Thr41 and phosphorylated on Ser675 sites, and β-catenin nuclear translocation, stimulated by high-phosphate. Furthermore, porcupine and wntless was induced in VSMCs treated with high-phosphate in a time-dependent manner, which could be inhibited by resveratrol. Resveratrol also inhibited the phosphorylation of LRP6 induced by high-phosphate. However, it seemed that resveratrol couldn't inhibit the expression of Runx2 induced by Wnt3a.

Conclusions: The results presented in our study suggest that through targeting Wnt/β-catenin signaling, which in turn impeding VOT induced by high-phosphate, resveratrol possesses an effect on retarding AMC in CKD.

Increased Basal Tone and Impaired Smooth Muscle Cell Contractility of the Carotid Artery in a CKD Rat Model

Geoffrey Van den bergh, Patrick D'Haese, Anja Verhulst. *University of Antwerp, Antwerp, Belgium.*

Background: Increased arterial stiffness (AS) is linked to aging and accelerated in patients with CKD. Traditionally, CKD has been closely associated with the development of arterial media calcifications (AMC), which together with changes in extracellular matrix composition are typical examples of passive stiffening. AS, on the other hand also has cellular, active components. Endothelial induced relaxation and vascular smooth muscle cell (VSMC) contractility, in response to pressure changes, are crucial to maintain a proper vessel tone. Using a CKD rat model this study aims to unravel the passive and active mechanisms underlying CKD related AS.

Methods: Eight Wistar rats were administered an adenine supplemented/phosphate rich diet for a period of 8 wks to induce CKD-related AMC, and compared to 8 age-matched control rats with normal renal function. Serum creatinine and phosphate were determined to follow up CKD development. AMC was investigated by measuring bulk Ca content in the aorta. AS was evaluated *in vivo*, using echo evaluation of the abdominal aorta pulse wave velocity (PWVa). An in house *ex vivo* organ bath setup to mimic cyclic stretch, was used to evaluate endothelial and VSMC functionality and to quantify the Peterson's elastic modulus (Ep, measure of AS).

Results: As could be concluded from serum creatinine and phosphate levels, severe CKD developed in the adenine fed rats. Significantly higher Ca content in the aorta ($p<0.01$) of adenine rats confirmed AMC development. After 8 wks, adenine fed animals showed increased AS, both *in vivo* and *ex vivo*: significantly higher PWVa ($p<0.01$) and Ep ($p<0.01$) compared to controls. Furthermore, adenine rats have increased, pressure dependent, basal tone and diminished VSMC contractility ($p<0.01$).

Conclusions: The adenine rat model is suited to investigate the progressive character of AS. We observed an interplay between active and passive components. The reduction in VSMC contractility is detrimental for the arterial system to buffer pulsatile flows at higher pressures, further promoting AS. A logical next step would be to include earlier time points to study endothelial contribution and VSMC shift towards a pro-calcifying phenotype. Discovery of early mechanisms underlying AS will contribute to the development of novel AS preventive treatments.

The Inhibitory Effect of Zinc Chloride on Phosphate-Induced Calcification via Suppression of HIF1a Expression in Human Vascular Smooth Muscle Cells

Masanori Tokumoto,[1] Shunsuke Yamada,[2] Toshiaki Nakano,[2] Takanari Kitazono,[3] Hiroaki Ooboshi.[4] *[1]Department of Internal Medicine, Fukuoka Dental College, Sawara-ku, Japan; [2]Kyushu University, Fukuoka, Japan; [3]Department of Medicine and Clinical Science, Fukuoka, Japan; [4]Fukuoka Dental College, Fukuoka, Japan.*

Background: Vascular calcification is a life-threatening pathophysiological abnormality in CKD. It was demonstrated that phosphate (P), a main inducer of vascular calcification, enhances oxidative stress and its resultant inflammation, leading to osteochondrogenic differentiation and calcification in cultured vascular smooth muscle cells (VSMCs). Because plasma Zn levels are low in CKD patients and Zn has anti-inflammatory effects, we examined effects of $ZnCl_2$ on P-induced inflammation, osteochondrogenic differentiation, and calcification in human VSMCs.

Methods: Human VSMCs were cultured in DMEM plus 10%FCS and 2.0mM P with 0, 0.5, 1, 5, 10, 50, or 100 mM $ZnCl_2$ for 3, 7 or 14 days. The precipitated calcium contents and expression of inflammatory mediators, osteochondrogenic differentiation markers and its inducers, including HIF1a and VEGF, were evaluated.

Results: At 14 days, $ZnCl_2$ inhibited calcification in a concentration-dependent manner, and high concentrations (>=10mM) of $ZnCl_2$ reduced calcification by almost 90% ($p<0.01$). Moderate to high concentrations (>=5mM) of $ZnCl_2$ suppressed expression of osteochondrogenic differentiation markers (SOX9, MSX2, and RUNX2) and inducers (BMP2, PiT1, and MMP2) ($p<0.01$). Moreover, moderate to high concentrations of $ZnCl_2$ suppressed IL-1b expression at earlier time points (3 and 7 days, $p<0.01$) and also inhibited expression of HIF1a and VEGF, a downstream gene of HIF1, through the period ($p<0.01$). Expression of both HIF1*a* and VEGF positively correlated with IL-1b expression, precipitated Ca content, and expression of BMP2, SOX9, MSX2, RUNX2, PiT1, and MMP2, respectively ($p<0.01$).

Conclusions: $ZnCl_2$ can directly inhibit P-induced inflammation and HIF1a expression, leading to suppression of osteochondrogenic differentiation and calcification in human VSMCs.

M2 Macrophages Promote Mouse Aortic Smooth Muscle Cells Calcification by the SGK1-TGFβ1 Axis

Beibei Wu, Xiaodong Zhu, Yuqiu Liu, Yuteng Jiang, Bi-Cheng Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Macrophages play an important role in vascular calcification (VC). Recent researches show that SGK1 is a highly attractive candidate for developing vascular smooth muscle cells (VSMCs) calcification. Importantly, TGFβ1 induces VC through regulating osteo-/chondrogenic transdifferentiation of VSMCs. However, whether macrophages promote VSMCs osteo-/chondrogenic transdifferentiation via SGK1 and the associated mechanisms is unknown.

Methods: Mouse aortic smooth muscle cells (MAoSMCs) with the supernatant from diverse stimutited-macrophages (M0-CM, M2-CM, M2-EMD-CM; EMD: SGK1 inhibitor) were treated with or without TGFβ1 receptor inhibitor. Calcium deposition was evaluated by alizarin red and von Kossa staining. Intracellular calcum contents were measured via calcium quantification kit. Expressions of specifc-osteogenic markers, SGK1 and TGFβ1 were examined by RT-qPCR, western blotting, immunofluorescence staining or Elisa kit.

Results: MAoSMCs produced significant calcium deposits in M2-CM. Furthermore, M2-CM promoted MAoSMCs transdifferentiation, which was characterized by expression of osteo-/chondrogenic markers (Runx2, ALPL, FGF23) or decrease of the MAoSMCs marker (SM22α). Exploring the mechanism of the above phenomenon, we found that the expression of SGK1 and TGFβ1 were significantly increased in M2 group compared with M0 group ($P<0.05$). Interestingly, when blocking SGK1 expression, the expression of TGFβ1 was down-regulated in M2. In addition, inhibiting expression of SGK1 or TGFβ1 can partially blocked MAoSMCs osteo-/chondrogenic transdifferentiation and calcification. Subsequent analyses by using calcium quantification kit, alizarin red and von kossa staining showed that recombinant mouse TGFβ1 increased calcium content in MAoSMCs and promoted MAoSMCs transdifferentiation, which the expression of osteo-/chondrogenic markers obviously increased($P<0.05$), while MAoSMCs marker markly decreased($P<0.05$).

Conclusions: M2 macrophages SGK1-TGFβ1 axis contribute to promote MAoSMCs osteo-/chondrogenic transdifferentiation.

TH-PO553

Combining Phosphate Binder Therapy with High Vitamin K2 Diet Inhibits Vascular Calcification in an Experimental CKD Animal Model

Aegida Neradova,[2,1] Grzegorz B. Wasilewski,[4] Selene Prisco,[4] Marjolein M. Caron,[5] Tim J. Welting,[5] Bert V. Rietbergen,[6] Rafael Kramann,[7] Jürgen Floege,[3] Marc G. Vervloet,[2] Leon J. Schurgers.[4] *[1]Dianet, Amsterdam, Netherlands; [2]Amsterdam University Medical Center, Overveen, Netherlands; [3]RWTH University of Aachen, Aachen, Germany; [4]Maastricht University, Maastricht, Netherlands; [5]Maastricht University Medical Center, Maastricht, Netherlands; [6]Biomedical Engineering, University of Technology, Eindhoven, Netherlands; [7]RWTH Aachen University, Lemiers, Netherlands.*

Background: Hyperphosphatemia may contribute to cardiovascular disease and mortality. Therefore, phosphate binders (PB) are widely used, but a proof of risk reduction is lacking. By binding vitamin K PB may offset beneficial effects of phosphate reduction on vascular calcification (VC). Here we tested whether high vitamin K2 supplementation in combination with PB can inhibit VC in an experimental animal model for CKD.

Methods: Description of the model (Figure 1). Blood chemistry was analyzed to verify the CKD model. Aortic arch, abdominal aorta and cartilage was analyzed for calcification using high resolution micro CT scan (in parafin embeded aortas and formalin fixed tibia's) and by inactive ucMGP using conformation specific antibodies.

Results: 3/4Nx resulted in increased circulating creatinine (mmol/L) and urea (mmol/L) ($p < 0.01$ for both). PB combined with low vitamin K2 diet resulted in significant vascular and cartilage calcification. On the contrary, PB combined with high vitamin K2 revealed significantly less ectopic calcification. Immunohistochemical staining of tissues for ucMGP revealed that ucMGP was present at sites of vascular calcification, mainly in the low vitamin K2 treated groups, indicating severe vascular vitamin K deficiency (Figure 2).

Conclusions: These experiments demonstrate that PB therapy in CKD cannot prevent VC, but that the combination with high vitamin K2 did. The inhibitory effect on vascular and cartilage calcification of combined phosphate binder with vitamin K2 therapy lies in the synergy of phosphate control and correction of vitamin K deficiency.

Evidence for Disordered Acid-Base Balance in Calcium Stone Formers

Kristin J. Bergsland, Elaine M. Worcester, Fredric L. Coe. *University of Chicago, Chicago, IL.*

Background: Normal women (W) have higher urine pH (UpH) than normal men (M). Thus W are predisposed to urine calcium phosphate (CaP) crystallization which occurs at higher UpH, and CaP stones are more common in W; M are more likely to form calcium oxalate (CaOx) stones due to lower UpH. In a General Clinical Research Center, we investigated whether W CaOx stone formers (SF) and M CaP SF, who are atypical for their sex, have abnormal acid-base balance or renal acidification and if so, what components of acid-base metabolism are responsible for the altered UpH.

Methods: We measured UpH and determinants of acid-base regulation in 25 normal subjects (13 M), 18 CaOx SF (12 M) and 17 CaP SF (9 M). We collected 15 urines and 20 blood samples over a 15 hour day; diet was fixed. Gastrointestinal anion excretion (GIAE) = [(Na + K + Ca+ Mg) - (Cl + P)] in urine.

Results: Ammonia (NH_4) excretion was higher in CaP SF of both sexes and W CaOx SF vs same sex normal (N) even after adjustment for sulfate and GIAE (Table). Urine citrate (U Cit) and fractional excretion of citrate (FE Cit) were lower than N in M CaP SF. Net acid excretion (NAE) was high in all M SF vs normal M. W CaOx SF had lower GIAE than W CaP SF or W N (1.50 ± 0.26 mEq/hr vs 2.48 ± 0.22 or 3.11 ± 0.18 resp., $p<0.05$).

Conclusions: CaP SF of both sexes and women CaOx SF have different but clear disorders of acid-base handling, the former seemingly localized to abnormal renal proximal tubule acidification and the latter to aspects of food anion absorption.

Regulation of Claudins by Metabolic Acidosis via Calcium-Sensing Receptor in Rat Kidney

Gheun-Ho Kim,[1] Chor ho Jo,[2] Sua Kim.[2] *[1]Hanyang University College of Medicine, Seoul, Republic of Korea; [2]Hanyang University, Seoul, Republic of Korea.*

Background: Metabolic acidosis (MA) may present with nephrocalcinosis and nephrolithiasis because of hypercalciuria. Most of the calcium reabsorption paracelluarly occurs through tight junctions in the proximal tubule (PT) and thick ascending limb (TAL) whereas the distal convoluted tubule and connecting tubule are the major regulatory sites of active calcium transport. However, the regulatory contribution of paracelluar calcium transport in the PT and TAL to hypercalciuria in MA remains to be elucidated.

Methods: Male Sprague-Dawley rats were randomly divided into four groups to see the effects of calcium-sensing receptor (CaSR) stimulation (using cinacalcet) and inhibition (using NPS-2143) in the presence of MA: controls (n=6), cinacalcet-treated (n=6), NH_4Cl-loaded (n=6), and NH_4Cl/NPS-2143-cotreated rats (n=6). After seven days' animal experiment, renal claudin expressions were examined by semiquantitative immunoblotting, qPCR analysis, and immunofluorescence microscopy.

Results: Urinary calcium excretion was insignificantly increased by cinacalcet treatment, and it is significantly elevated by NH_4Cl loading and reversed by NPS-2143 coadministration. Renal claudin-2 protein/mRNA were not altered by cinacalcet treatment, and they were suppressed by NH_4Cl loading and recovered by NPS-2143 coadministration. Claudin-16 protein/mRNA and claudin-19 protein/mRNA were not altered by cinacalcet treatment, and they were also downregulated by NH_4Cl loading and reversed by NPS-2143 coadministration. Consistently, claudin-14 protein/mRNA were upregulated by NH_4Cl loading and reversed reversed by NPS-2143 coadministration. Furthermore, CaSR protein/mRNA were upregulated by NH_4Cl loading and reversed by NPS-2143 coadministration. The effects of acid loading were confirmed by immunofluorescence microscopy.

Conclusions: In metabolic acidosis, not only claudin-2 in PT but also claudin-16/19 in TAL are downregulated to produce hypercalciuria. The CaSR in rat kidney appears to have a regulatory role in MA-induced hypercalciuria.

Familial Hypocalciuric Hypercalcemia (FHH) Induced by Gene Deletion of Transient Receptor Potential Canonical 1 (TRPC1) Channels Is Independent of Gender, Like Ca Sensing Receptor (CaSR) Mutations

Usman A. Khan,[1,2] Bonnie Eby,[1] Alexander Lau,[1] Ezza Tariq,[1] Muhammad B. Mahmood,[1] Kai Lau.[1,2] *[1]University of Oklahoma Health Science Center, Oklahoma City, OK; [2]Medical Service, Oklahoma City VA Hospital, Oklahoma City, OK.*

Background: Previously in TRPC1 null males, we reported the mouse phenotypes of FHH, causally related to reduced cell free [Ca] & hyperparathyroidism, like human FHH induced by haploid loss-of-function mutations in the CaSR gene. But haploid TRPC1 deletion induces only hypercalcemia, no hypocalciuria or hyperparathyroidism. Here we tested the hypothesis that phenotypes in TRPC1 null mutation are gender non-specific, like CaSR mutations.

Methods: In age-matched female mice, we performed classical metabolic balance studies & measured blood & urine Ca & Mg.by standard methods. We analyzed creatinine by HPLC & calciotropic hormones by mouse ELISA.

Results: Similar to null males, 7 mon old TRPC1 null females also exhibited hypocalciuria, whether expressed as mean 24 h urine Ca (1 ± 0.1 [SE] vs 1.6 ± 0.1 mg/d, p<0.03), as urine Ca:creat ratio (2 ± 0.2 vs 3 ± 0.1, p<0.02), or as Ca clearance (13 ± 2 vs 22 ± 1 µl/min, p< 0.01). Like null males, TRPC1 null females were also hypercalcemic, whether fasted (9.8 ± 0.3 vs 8.1 ± 0.4 mg%, p<0.005) or fed ad lib (9.6 ± 0.2 vs 8.5 ± 0.2 mg%, p<0.005). Mean fasting serum PTH in TRPC1 null females (609 vs.461 pg/ml) was numerically higher, but shy of statistical significance which we found in null males. But the hypercalcemia in null females failed to suppress PTH, suggesting similar dysregulation in PTH secretion by TRPC1 deficiency like the null males. Indeed, over the same range of serum Ca (9.6 - 10.8 m%), PTH was 35% higher in null females (652 ± 45 vs 484 ± 42 pg/ml, p<0.04). In contrast to the disturbed Ca homeostasis, there was no difference between null & wild type females in serum or urine Mg, again, similar to comparable data on Mg metabolism between null & wild type males. Mean fasting serum calcitriol (353 vs 332 pg/ml) & calcitonin (2.1 vs. 2.1 pg/ml) were similar between female genotypes, like comparable data between male genotypes.

Conclusions: We conclude that deletion of the gene encoding TRPC1 channels produces the phenotypes of hypocalciuric hypercalcemia in females as in males though hyperparathyroidism is milder. Our data support the current concept that alongside CaSR, by mediating store-operated Ca entry, TRPC1 plays a key role in intracellular Ca homeostasis & in regulating PTH secretion.

Deletion of the Proton Receptor OGR1 in the Osteoclast Impairs Metabolic Acidosis-Mediated Bone Resorption

Nancy S. Krieger,[2] Luojing Chen,[1] Jennifer Becker,[1] Michaela Chan,[2] David A. Bushinsky.[1] [1]*University of Rochester Medical Center, Rochester, NY;* [2]*University of Rochester, Rochester, NY.*

Background: Metabolic acidosis (Met) induces bone resorption. Using mice with a global deletion of OGR1 we demonstrated that loss of OGR1, a G protein-coupled H^+ sensing receptor, impairs H^+-induced bone resorption. OGR1 activity in both osteoblasts (OB) and osteoclasts (OC) was altered by Met. To determine if Met directly activates OGR1 in OC, rather than indirectly through the OB, we generated a conditional knockout with an osteoclast-specific deletion of OGR1 (OC-cKO). We tested the hypothesis that the lack of OC OGR1 would lead to increased bone mass in actively growing mice which generate large amounts of metabolic acid.

Methods: OC-cKO mice were generated from a LysM-cre mouse and OGR1flox/flox mouse. We examined bones from 3 month old female mice using micro-computed tomography (µCT) and immunohistochemistry. Mesenchymal stem cells (MSC) from femurs of OC-cKO and control (ctl) mice were differentiated to OC. Mature OC were detected by TRAP staining. Mature OCs grown on cover slips were incubated in neutral (pH 7.4) or Met (pH 7.1) medium for 45 min and then stained for NFATc1 to define active OCs.

Results: µCT demonstrated increased bone in OC-cKO (Bone Volume / Total Volume: 34.9±4.6 % (OC-cKO) vs 11.3±0.7 % (ctl); Trabecular (Tb) Thickness: 0.07±0.006 mm (OC-cKO) vs 0.05±0.001 mm (ctl); Tb. Number: 6.3±0.1/mm (OC-cKO) vs 4.3±0.1/mm (ctl); all p<0.05). TRAP staining of tibia sections indicated a decrease in OC number / bone surface from OC-cKO (4.6±0.7/mm (OC-cKO) vs 7.4±0.2/mm (ctl)) and OC surface area / bone surface (13.8±5.3% (OC-cKO) vs 26.6±2.2% (ctl)). We observed that OC derived from MSC of OC-cKO have less TRAP staining in OC / well (10.7±2.1 (OC-cKO) vs 38.9±9.7 (ctl)) and decreased OC surface area (mm^2/well: 0.05±0.01 (OC-cKO) vs 0.19±0.02 (ctl)). OC-cKO OC in response to Met had decreased nuclear translocation of NFATc1, a master transcriptional regulator of OC differentiation and proliferation, compared to ctl (17.0±2.6% (OC-cKO) vs 29.7±3.3% (ctl) p<0.05) but no difference at pH 7.4.

Conclusions: Our results indicate that OC OGR1 is directly regulated by Met and important in acid-induced bone resorption. Characterization of the direct role of OGR1 in acid-induced bone resorption may assist in understanding bone loss associated with the metabolic acidosis in patients with chronic kidney disease.

Subdued, an Anoctamin 4 Homolog, Changes Calcium Oxalate Crystal Formation in Drosophila Renal Structures Revealing Potential Roles in Mammals

Daniel R. Turin,[1] Mariah Arneson,[1] Heather L. Holmes,[1] Pablo Cabrero,[2] Julian A. Dow,[2] Muthuvel Jayachandran,[1] John C. Lieske,[1] Eva Furrow,[3] Michael F. Romero.[1] [1]*Mayo Clinic, Rochester, MN;* [2]*University of Glasgow, Glasgow, United Kingdom;* [3]*University of Minnesota, St. Paul, MN.*

Background: Anoctamins function as Ca^{2+} activated Cl^- channels (CaCC) or as phospholipid scramblases. Using a miniature schnauzers GWAS, we discovered a risk locus for recurrent calcium oxalate (CaOx) stones harboring an *anoctamin 4 (ANO4)* variant. Human stone formers have decreased *ANO4* protein in urinary vesicles. In *Drosophila* Malpighian tubules (MTs) the ANO4-homolog, *subdued*, functions as a CaCC and scramblase. *Subdued* also functions in bacterial defense, so we knocked it down to determine if bacterial infection changes crystal growth.

Methods: *Subdued* knockdown (KD) in MT principle cells was used a MT-promotor and a *subdued*-RNAi. CaOx crystallization experiments were conducted on ex-vivo MTs by 1h addition ofsodium oxalate (NaOx); while prolonged feeding (4d) assays used food with NaOx. With DIC optics, we imaged CaOx birefringence then counted crystals using ImageJ. Uropathic *E. coli* (UPEC) were fed to flies or added to NaOx solution before an overnight time-lapse.

Results: The canine *ANO4* variant has a 0.01 allele frequency at a conserved residue (humans, canines and *Drosophila*). Rapid crystallization experiments show that *subdued-KD* MTs have less CaOx crystals than controls. However, feeding assays showed that MT *subdued-KD* produces enlarged crystals. These assays also show clustering and biofilms that change crystal appearance with patterning similar to human kidney stones. UPEC facilitates CaOx crystal aggregates.

Conclusions: The *Drosophila* avatar illustrates that *subdued* (ANO4) aggregates CaOx. An apparent pathogenic variant is conserved in mammals and flies; *subdued*'s role in fly bacterial infection indicates a possible additional role of ANO4 in kidney stones. Examining antibacterial treatments or other aspects of CaOx crystal formation with UPEC may allow an antibiotic approach to more efficiently eliminate kidney stones. Future experiments will determine the localization of ANO4 in mammalian kidneys to better understand the cell specific pathology. Finally, these studies indicate that this simple kidney stone avatar- the fly – continues to provide new insights to the mechanistic role of specific genes and infection.

Spatial Mapping of Cell Populations in the Human Kidney Papilla Using 3D Tissue Cytometry

Mohammad S. Makki,[2] Seth Winfree,[2] James Williams,[2] Tarek M. El-Achkar.[1] [1]*Indiana University, Indianapolis, IN;* [2]*Indiana University School of Medicine, Indianapolis, IN.*

Background: Kidney stone disease or nephrolithiasis affects 10% of US population with estimated healthcare cost of more than $10 billion. To date, no clear mechanisms have been identified for the initiation and progression of kidney stone disease. A contributing factor to this knowledge gap is a poor understanding of the various cell types comprising the nephronal segments and the surrounding interstitium in the papilla. To fill this gap, we developed a novel methodology to classify cell types of the papilla based on spatial and morphological features, lectin binding properties which reflects carbohydrate content and staining with Aquaporin 1 (AQP1, detects thin descending limbs and descending vasa recta). The long-term goal is to link subpopulations of cells with other assays such as transcriptome and proteome profiling, and advance our understanding of the renal papillary micro-environment.

Methods: Papillary biopsies were obtained at the time of percutaneous nephrolithotomy or from reference nephrectomy tissues. Fifty-micron thick sections of papilla were stained with fluorescently labelled DBA (*Dolichos Biflorus*), PNA (Peanut Agglutinin), and/or AQP1. Large scale 3D imaging was performed with confocal microscopy, followed by 3D tissue cytometry analysis using our software tool Volumetric Tissue Exploration and Analysis (VTEA).

Results: With this strategy, VTEA analysis deconvolved all the cells in the papillae into specific subpopulations, which were directly visualized within the tissue. Various subtypes of $AQP1^+$ thin descending limb cells or $AQP1^-$ thin ascending limb cells were classified based on the presence of co-labeling with DBA and/or PNA. Collecting ducts and ducts of Bellini, which are easily identified by morphological features, stained predominantly with PNA. AQP1 weak staining cells that did not stain with any lectins were identified as vascular cells of the vasa recta.

Conclusions: Using a straightforward fluorescence based staining strategy, we can distinguish subpopulations of epithelial and vascular cells in the papilla. Implementing this strategy to link cell subtypes with "omics" signatures will define the biological significance of these subpopulation, and advance our understanding of the complex homeostasis within the papilla and its perturbance by stone disease

Antibiotics Affect the Intestinal Microbiome and Alter Kidney Stone Formation in Genetic Hypercalciuric Stone-Forming Rats

Joshua M. Stern,[3] Nancy S. Krieger,[1] John R. Asplin,[2] Ignacio Granja,[2] Sylvia O. Suadicani,[3] Luojing Chen,[1] Jennifer Becker,[1] Michaela Chan,[1] David A. Bushinsky.[1] [1]*University of Rochester Medical School, Rochester, NY;* [2]*Litholink Corporation, Chicago, IL;* [3]*Albert Einstein Medical School, Montefiore Medical Center, New York, NY.*

Background: There is growing evidence that antibiotic exposure is associated with incident stone disease. The intestinal microbiome (IMB) can rapidly shift in response to outside stimuli such as antibiotics. We utilized genetic hypercalciuric stone-forming (GHS) rats, whose pathophysiology parallels that of human hypercalciuria and who spontaneously form calcium phosphate (CaP) stones, to determine the effect of antibiotics on the intestinal microbiome, urine ion excretion and stone formation.

Methods: 116th generation GHS rats were fed a fixed amount of a normal Ca (1.2%) and P (0.65%) diet, housed in metabolic cages and divided into 3 groups (n=10): control (CTL) diet, or supplemented with ciprofloxacin (Cipro, 5 mg/d) or Bactrim (250 mg/d). Urine and fecal pellets were collected at 6, 12 and 18 wks for analyses. Fresh fecal pellets were stored at -80oC and then prepared for analysis by DNA extraction and amplification of the 16S rRNA V4 region using barcoded primers on an Illumina platform. QIIME was used for analysis. At 18 wks kidney stone formation was determined by Faxitron analysis and assessed by 3 blinded reviewers.

Results: After 18 wks, urine Ca decreased with Bactrim (CTL=13.7± 0.4, Bactrim=12.1±0.4 mg/d, p<0.05) as did urine oxalate (CTL=1.2±0.04, Bactrim=0.8±0.02 mg/d, p<0.05). CaP supersaturation increased with Bactrim (CTL=6.8±0.4,

Bactrim=8.4±0.5, p<0.05) while CaOx supersaturation fell (CTL=16.2± 0.6, Bactrim=12.0±0.4, p<0.05). Calcification was increased by Bactrim (CTL=1.0±0.2, Bactrim=2.98±0.3, p<0.05). Cipro was not different from CTL for any parameter. Analysis of the GHS IMB shifted substantially and principal component analysis showed the Bactrim group and controls clustered separately (p=0.001). Microbial diversity negatively correlated with urinary oxalate in all animals (R=-0.46, p=0.006), and positively correlated with urinary pH in the Bactrim treated group (R=0.76, p=0.01).

Conclusions: Bactrim altered the IMB of GHS rats and also caused a fall in urine Ca, increased CaP supersaturation and increased calcification while Cipro did not change urine ion excretion or calcification. Whether the alteration in the IMB is mechanistically related to the changes in urine ion excretion and calcification remains to be determined.

TH-PO561

Cystathionine-Gamma-Lyase Deficiency Protects Against Calcium Oxalate Nephropathy

Yimin Lu,[2] Suresh Krishna Ramakrishnan,[2] Muriel Auberson,[2] Fanny Durussel,[2] Olivier Bonny.[1,2] *[1]Service of Nephrology, Lausanne University Hospital, Lausanne, Switzerland; [2]Department of Pharmacology and Toxicology, University of Lausanne, Lausanne, Switzerland.*

Background: Cystathionine-gamma-lyase (CSE), along with cystathionine-beta-synthase (CBS) and 3-mercaptopyruvate sulfurtransferase (3-MPST) contribute to the production of the gazotransmitter hydrogen sulfide (H_2S) in various tissues. In the kidney, CSE is expressed in the cortex and in the outer stripe of the outer medulla, but its role remains elusive. Recent studies using pharmacological inhibition of CSE, or CSE deficient mice, have suggested a pro-inflammatory role of H_2S in various inflammatory mouse models. Moreover, administration of H_2S donor worsened the inflammation in these models. Here, we explored the role of CSE in a recently established mouse model of renal calcium oxalate crystallopathy.

Methods: CSE-deficient ($Cse^{-/-}$) mice were obtained from Dr. Ishii (Showa Pharmaceutical University, Tokyo, Japan). Eight-week old $Cse^{+/+}$ or $Cse^{-/-}$ male mice were allocated to either 1.5% calcium plus 1.5% hydroxyproline-enriched diet or to control diet for 3 weeks. Mice were kept in metabolic cages for 24h urine collection before termination of the experiments. Indirect methylene blue method was used to measure H_2S producing capacity of renal tissue. Crystal deposits were assessed by Pizzolato staining, and fibrosis and inflammation by trichrome staining. Fibrosis and inflammation parameters were further evaluated by qPCR.

Results: At baseline, *Cse*$^{-/-}$ mice have suppressed *Cse* mRNA expression, but unaffected levels of *Cbs* and *3-Mpst* in kidney tissue. Kidneys of *Cse*$^{-/-}$ mice had reduced H_2S producing capacity compared to *Cse*$^{+/+}$ littermates. Renal morphology and function were normal at baseline in both genotypes. After three weeks exposure to calcium-hydroxyproline-enriched diet, *Cse*$^{+/+}$ mice displayed significantly higher serum creatinine and blood urea nitrogen levels, while *Cse*$^{-/-}$ mice had normal renal function. *Cse*$^{-/-}$ mice had decreased crystal deposits, lower inflammation and fibrosis, as assessed by histomorphology and qPCR. Crystal-adherent proteins were less expressed in *Cse*$^{-/-}$ mice and in primary culture of proximal tubules exposed to calcium-oxalate crystals.

Conclusions: CSE deficiency protects from inflammation and fibrosis in a model of renal calcium oxalate crystallopathy, and preserves renal function. Collectively, our data show that H_2S-producing enzymes might be suitable pharmacological targets for calcium-oxalate nephropathy.

TH-PO562

Chlorthalidone Plus Potassium Citrate Decreases Calcium Oxalate Stone Formation Better Than Either Agent Alone While Also Improving Bone Quality in Genetic Hypercalciuric Stone-Forming Rats

Nancy S. Krieger,[2] Marc Grynpas,[3] Daiana Spataru,[3] John R. Asplin,[1] Ignacio Granja,[1] Luojing Chen,[2] David A. Bushinsky.[2] *[1]Litholink Corporation, Chicago, IL; [2]University of Rochester Medical Center, Rochester, NY; [3]Samuel Lunenfeld Research Institute of Mount Sinai Hospital, Toronto, ON, Canada.*

Background: To study human idiopathic hypercalciuria (IH) we developed an animal model, genetic hypercalciuric stone-forming (GHS) rats, whose pathophysiology parallels that found in human IH. All GHS rats spontaneously form calcium oxalate stones when the oxalate precursor, hydroxyproline is added to the diet. Here we tested the hypothesis that CTD and KCit combined would effectively reduce CaOx stone formation and improve bone quality in the GHS rats better than either agent alone.

Methods: 113th generation GHS rats were fed a fixed amount of a normal Ca (1.2%) and P (0.65%) diet with 5% hydroxyproline added, housed in metabolic cages and divided into four groups. Diets were supplemented with KCl (4 mmol/d) as a control, KCit (4 mmol/d), CTD (4-5mg/kg/d)+KCl, or KCit+CTD. Urine (u) was collected at 6, 12, and 18 wks for analyses and kidney stone formation and bone parameters were determined at 18 weeks.

Results: Compared to the KCl control, KCit reduced uCa (KCl=17.2±0.3 mg/d, KCit=14.4±0.3), CTD reduced it further (CTD=13.0±0.6) and KCit+CTD reduced it even further (KCit+CTD=9.3±0.4). The combination of KCit+CTD decreased uOx compared to all other groups. There were no significant differences in CaOx supersaturation in any group. Compared to KCl (stone formation with a range of 0-4: KCl=2.1±0.1), KCit did not alter stone formation (2.0±0.3), while there was less stone formation in the GHS rats fed with CTD alone (CTD=1.6±0.2). The combination of KCit+CTD (0.8±0.2) resulted in significantly fewer stones than CTD or KCit alone. Vertebral trabecular bone was increased by both CTD (38.5±3.2% vs CTL=26.8±5.1%) and KCit+CTD (34.7±3.4%), p<0.05 for both. Cortical bone area was increased by CTD (7.3±0.3 mm2 vs CTL=6.9±0.2 mm2) but not altered with KCit+CTD or with KCit alone. Mechanical properties of trabecular bone were improved by CTD alone, but not the combination.

Conclusions: Thus in GHS rats, when fed a diet that results solely in CaOx stone formation, the combination of KCit+CTD prevented stone formation better than either agent alone. The improvements in bone quality were principally due to CTD alone; adding KCit provides no additional benefit.

TH-PO563

Understanding the Pathogenesis of Human Kidney Stone Disease by Spatially Mapping Its Proteome

Victor Hugo Canela,[1] Elaine M. Worcester,[2] Tarek M. El-Achkar,[3] James Williams.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Chicago, Chicago, IL; [3]Indiana University, Indianapolis, IN.*

Background: Nephrolithiasis affects approximately one-in-eleven people in the United States. A detailed hypothesis of the mechanisms of stone disease etiology remains elusive, and thus difficult to treat and prevent. The present study aims to advance the understanding of the pathogenesis of stone disease by determining the pattern of protein organization within the matrix of human kidney stones.

Methods: The approach of this work relies on an innovative technique to perform histological sectioning of calcium oxalate (CaOx) stones following demineralization. Multi-photon imaging and label-free proteomics were used on laser micro-dissected (LMD) specific regions to assess proteome identity and signaling across spatial coordinates within the stone-matrix.

Results: The average area of LMD samples for proteomic analysis was $1.64x10^6 \mu m^2$, and these samples yielded an average of 629 distinct proteins. Dissection of broad regions of CaOx stone by LMD yielded similar proteins as found in larger specimens of pulverized CaOx samples. Proteins identified in LMD and pulverized samples included those involved in cell injury and repair as well as important mediators of the immune system (e.g. fatty acid synthase, osteopontin-D, complement C3). More recent results show brilliant autofluorescence of decalcified CaOx stones, which will allow LMD of distinctive regions of the stone without staining.

Conclusions: Utilization and optimization of these techniques will pave the way for a deeper understanding of kidney stone formation. Future investigation of the stone-matrix proteome will provide insight into underlying events that could become therapeutic targets to prevent stone growth.

Funding: Other NIH Support - P01 DK056788

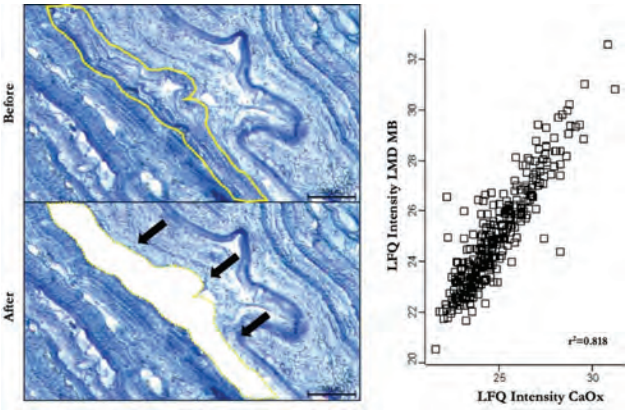

Figure 1 LMD of human kidney stones. Demineralized stone-matrix on LMD slides were stained with methylene blue (before). Dissection of broad regions of CaOx stone by LMD (after) yielded similar proteins as found in larger specimens of pulverized CaOx stone powder (right).

Exploring Mechanisms of Protein Influence on Calcium Oxalate Kidney Stone Formation

Jeffrey Wesson,[1,2] Garrett K. Berger,[3] Jessica A. Eisenhauer,[4] Brian R. Hoffmann.[3] *[1]VA Medical Center, Milwaukee, WI; [2]Medicine/Nephrology, Medical College of Wisconsin, Milwaukee, WI; [3]Medical College of Wisconsin, Milwaukee, WI; [4]Medical College of Wisconsin - Kidney Disease Center, Milwaukee, WI.*

Background: Calcium oxalate monohydrate (COM) crystals are the primary constituent of most kidney stones, but urine proteins in stone matrix are believed to be critical to binding crystals into stones. Recent data have shown that hundreds of proteins appear in stone matrix with no explanation for inclusion of these various proteins. We have proposed a stone formation model with protein stimulated COM aggregation based on polyanion-polycation aggregation, which is supported by finding that matrix is highly enriched in strongly anionic and strongly cationic proteins. Many proteins are likely drawn to such aggregates due to their limited solubility in water. Finding similar protein

enrichment in both polyarginine (pR) induced aggregates of urine proteins and COM stone matrix would support this hypothesis.

Methods: Purified proteins (PP) were obtained from random urine samples from six healthy adults by ultradiafiltration. Protein aggregation was induced by adding pR to PP solutions at each of two concentrations; 0.25 and 0.5 μg pR /μg of PP. The resulting protein aggregates were separated by centrifugation, yielding aggregate (pRB) and supernatant fractions. Samples of each fraction and the original PP mixture were lyophilized and sent to the Proteomics Core Laboratory at Mayo Clinic for analysis.

Results: SDS gel electrophoresis revealed selective inclusion of urine proteins in pRB, which was shown to mimic COM matrix protein distributions by mass spectrometry analysis. Notable differences include enrichment of albumin and uromodulin in the pRB at the 0.5 μg pR addition compared to relative exclusion from COM matrix, while at 0.25 μg pR, albumin stayed in solution likely due to its weaker anionic charge, suggesting that aggregation was "overdriven" at the 0.5 μg pR addition. Many intracellular or nuclear proteins, that were prominent in COM matrix, were not observed in pRB, likely reflecting their absence in PP.

Conclusions: Aggregates induced by pR addition to PP samples collected a protein mixture that mimicked the protein distribution observed in COM matrix, supporting our hypothesis. The apparently discordant behavior of uromodulin may simply reflect its anionic character in this overdriven model. Future experiments will need to include observations of selective protein binding to COM crystal surfaces for comparison with these data.

TH-PO565

TRPV5 Surface Expression Contributes to Glucose-Induced Hypercalciuria

Cameron J. Menezes, Kristin J. Bergsland, Elaine M. Worcester, Fredric L. Coe, Benjamin S. Ko. *University of Chicago, Chicago, IL.*

Background: Lemann et al. showed that feeding normal (N) patients a glucose bolus increases fractional excretion of calcium (FECa). In addition, our group has shown that general feeding caused a significantly increased FECa of idiopathic hypercalciuric stone formers vs N patients. These observations imply a post prandial effect in calcium handling, with clinical implications for stone formers. We sought to identify transporter protein targets that mediate the effect of glucose induced hypercalciuria.

Methods: 5 N women were placed on a low salt (65 mEq/d) diet for 3 days. Patients then fasted overnight, and reported to the Clinical Research Center for serial blood and urine collections for 5 hours, consuming 100 grams of glucose at 2 hours. Endogenous lithium clearance was measured to calculate distal delivery. Urine was filtered, spun and ultracentrifuged to isolate urinary exosomes from selected time points. Resulting samples were assayed by ELISA for transporter protein abundance of TRPV5. Student's T-Tests were used to compare the last fasting period to periods of maximal change for metabolic parameters. A generalized linear model (GLM) was used to model the fractional excretion of distally delivered Ca (FEDCa).

Results: FECa rose with glucose feeding (p=0.02). Distal delivery of calcium did not differ significantly between the final fasting and any of the fed periods. FEDCa rose in parallel with FECa and rises significantly from the fasting period (p=0.015). TRPV5 expression decreased significantly after glucose feeding (p=0.047). A GLM (Table) with FEDCa as dependent, revealed TRPV5 and its known effector parathyroid hormone as significant predictors of FEDCa, with the overall model accounting for half the variation in FEDCa (R^2=0.503).

Conclusions: We have recreated the hypercalciuric effect of glucose feeding, and have localized it to the distal nephron in a cohort of young women. The finding of reduced TRPV5 in urinary exosomes implies protein trafficking away from the apical membrane, and thus identifies TRPV5 as a key mediator of FEDCa in this setting.

Funding: NIDDK Support

Effect	Coefficient	95% CI	P-Value
Constant (FEDCa)	41.8	[28.8, 54.9]	<0.001
TRPV5	-2.7	[-4.2, -1.3]	0.001
Serum PTH	-0.41	[-0.77, -0.05]	0.028

Constant coefficient is in %. TRPV5 effect is in %/pmol/mg Cr. PTH effect is in %/pg/mL.

TH-PO566

Matting Calcium Crystals by Melamine Improves Stabilization and Prevents Dissolution

Eugenia Awuah boadi, Bidhan Bandyopadhyay. *Institute for Clinical Research, Washington, DC.*

Background: Kidney stone recurrence has been shown to be as high as 50% within 10 years of stone elimination with renal stone recurrence rate among individuals who have received some form of intervention being as high as 40%. Recent studies have implicated melamine, a nitrogen-rich crystalline compound used in making plastics in nephrotoxicity. Our previous findings show that melamine induces calcium crystal formation and growth in a concentration dependent manner, however melamine's impact on recurrences remain unclear. We therefore investigated whether melamine's role in crystal stabilization/ retention could be contributing to the increased rates of kidney stone recurrence.

Methods: To examine the role of melamine, oven dried preformed CaOx and CaP crystals incubated with melamine were analyzed under an SEM/EDS microscope; morphological and elemental composition of samples were collected and analyzed. Time dependent dissolution and stabilization studies were performed using Alizarin red pH 4.3 and 6.8 to identify CaOx, CaP respectively remaining in solution. Dissolution experiments were conducted in the presence of known crystal inhibitors.

Results: We show here that the presence of melamine increases crystal retention/ stability even with the added presence of an inhibitor. Again ammeline, a similar triazine compound does not induce crystal growth. Similarly, our SEM/EDS analysis showed that melamine in the presence of calcium crystals acts as a nucleation site allowing for crystal deposition and ultimately crystal growth.

Conclusions: Together, our results highlights the mechanism utilized by melamine in calcium crystal growth as well as the pathological stabilization and retention of these crystals in the presence of known inhibitors of crystallization such as citrates, commonly used to alleviate the calcium stone conditions.

Funding: NIDDK Support, Other NIH Support - National Institute of Biomedical Imaging and Bioengineering (EB021483)

Expression of an Anti-Fibrotic Molecule, Smad Anchor for Receptor Activation (SARA), Is Significantly Decreased in Kidneys of Patients with CKD

Xiaoyan Liang,[1] Anthony Chang,[2] H. William Schnaper,[1,3] Tomoko Hayashida.[1,3] *[1]Northwestern University, Chicago, IL; [2]UChicago Medicine, Chicago, IL; [3]Lurie Children's Hospital, Chicago, IL.*

Background: Fibrosis is a final common characteristics of chronic kidney disease regardless of the primary injury. Many means to prevent cellular fibrotic processes have been explored with little success to date. We recently reported at previous ASN meetings, that overexpressing SARA in pericytes, one of the progenitor cells for fibroblasts in fibrosing kidney, prevents them from transdifferentiating to fibroblasts, hence inhibits fibrosis in chemically-induced interstitial fibrosis model in mouse. These findings suggest a novel approach in preventing fibrosis at a step where a progenitor cell acquires scar forming phenotype. Here, we evaluated relevance of the findings in human patient samples.

Methods: Kidney sections were freshly cut from archived, formalin-fixed paraffin-embedded biopsy samples. Biopsy samples include 5 with focal and segmental glomerulosclerosis (FSGS), 5 with diabetic nephropathy and 5 non-fibrosing controls. Sections were stained with Alexa 647 conjugated anti-SARA antibody and DAPI and evaluated with Nikon A1 confocal microscope. Thereafter, tubulointerstitial area of the sections were dissected using Zeiss PALM laser-capture microdissection system, and total RNA was extracted following digestion with proteinase K. RNAs were pre-amplified for SARA and β-microglobulin with Bio Rad prime PCR system, and mRNA levels were quantified with real-time PCR.

Results: SARA was highly expressed in proximal tubular epithelial cells and cells in the interstitium in non-fibrosing controls. In contrast, it was barely detected in samples from patients with FSGS or diabetic nephropathy. Consistant with the findings with immunostaining, SARA mRNA levels were significantly lower in samples from patients with FSGS or diabetic nephropathy ($P < 0.05$, Fig 1).

Conclusions: These results, consistent with our animal models, suggest that loss of SARA is pathogenic in fibrosis. SARA could be a novel therapeutic target in human CKD

TH-PO568

Are Bone Biopsies Needed Only in Patients with PTH Results Outside the KDIGO Target Range?

Madhumathi Rao, Florence Lima, Marie-Claude M. Faugere, Hartmut H. Malluche. *University of Kentucky, Lexington, KY.*

Background: The 2017 KDIGO guideline update for chronic kidney disease - mineral bone disorder (CKD-MBD) in CKD-5D recommends that parathyroid hormone (PTH) levels be maintained 2 to 9 times upper normal for the assay (150-600pg/mL). There is no information on histologic bone abnormalities within vs. outside the KDIGO target PTH range.

Methods: We analyzed 142 bone biopsies done between 2004-2019 on CKD-5D patients performed for a variety of indications (fracture, hypercalcemia, osteoporosis, calciphylaxis and prior to parathyroidectomy (PTX)). The objective was to examine to what degree bone biopsies are helpful in management of patients with PTH levels outside or within the KDIGO target range.

Results: Mean age was 49±15 years, 46% were male and 63% white. Median (IQR) PTH was 776 (333-1348) pg/mL; there was a weak inverse relationship with age (r=-0.2, p<0.05), but no difference by race. Most of the biopsies (56%) were performed in patients with PTH levels >600 pg/mL (PTH>600 group); 33% of the biopsies were done in patients within the target KDIGO range (KDIGO target PTH group) and 11% in patients with PTH<150 pg/mL (PTH<150 group). The KDIGO target PTH group showed severe hyperparathyroid bone disease (HPTBD) with high to very high bone turnover (BTO) in 69%, mild to moderate HPTBD in 21% and low turnover bone disease (LTBD) in 10%. The PTH<150 group showed either LTBD or mild to moderate HPTBD. Patients within and below the KDIGO guideline were over twice as likely to show low bone volume on their biopsy (OR 2.2 95%CI 1.03-4.7). Anti-resorptive treatment was recommended in 7 patients in the KDIGO target PTH group, and anabolic therapy in 4 patients in the PTH<150 group. In the PTH>600 group, the concordance with severe HPTBD and high to very high BTO on biopsy was 92%, with moderate HPTBD in 8%; 44% subsequently underwent PTX.

Conclusions: Patients with PTH levels within the KDIGO target range show heterogeneity in their bone abnormalities with both HPTBD and LTBD, and bone loss. Contrary to current practice, these patients may be a unique risk group needing bone biopsy for targeted management of CKD-MBD. While bone biopsies are clearly also needed in patients with PTH levels below target, the procedure adds relatively little information in patients with levels above target.

TH-PO569

Magnesium Exposure Increases Fracture Risks in Patients with CKD

David Chih-Yu Yang,[1,2] Der-Cherng Tarng.[1] *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]Institute of Clinical Medicine, National Yang-Ming University School of Medicine, Taipei, Taiwan.*

Background: Bone fracture is a serious complication in CKD patients, which may lead to disability and reduced survival. In advanced CKD patients, blood magnesium (Mg) concentrations are usually above the normal range due to reduced kidney excretion of Mg. Excessive bone Mg may play a role in mineralization defects, leading to renal osteodystrophy. The present study aims to examine the relationship between Mg-containing antacid exposure and risk of incident hip fracture of CKD patients in a large, nationwide database.

Methods: Patients aged above 20 years old and diagnosed with CKD were identified from the National Health Insurance Research Database (NHIRD). From these eligible participants, study subjects in the case group were patients who were diagnosed with hip fracture, whereas the control group were selected randomly and matched to a case-patient by age, month and year of cohort entry, and Charlson comorbidity index score. The antacid usage, including Mg, aluminum, calcium, and other demographic characteristics, were analyzed.

Results: We enrolled 10,361 CKD patients with hip fracture, among which the mean age was 69.7 years old, and 54.7% was non-dialysis CKD. As compared to non-users, Mg-containing antacid users were significantly more likely to experience hip fracture (Adjusted odds ratio (OR) 1.15, 95% CI, 1.08 to 1.23; p < 0.001). Also, subgroup analysis showed that such risk exists in both non-dialysis CKD patients and long-term dialysis patients. In contrast, aluminum or calcium containing-antacid use did not reveal such association in our cohort. Next, we examined the influence of Mg-containing antacid dosage on hip fracture risk, the adjusted OR in the first quantile (Q1), Q2, Q3 and Q4, were 1.11 (95% CI, 1.02 to 1.20; p = 0.016), 1.23 (95% CI, 1.13 to 1.35; p < 0.001), 1.33 (95% CI, 1.21 to 1.46; p < 0.001), and 1.20 (95% CI, 1.09 to 1.33; p = 0.001), respectively, showing that such risk exists regardless of the antacid dosage.

Conclusions: Our findings indicated that there is a strong link between Mg-containing antacid exposure and incident hip fracture risk in both non-dialysis CKD and dialysis patients, suggesting that Mg-containing antacid should be cautiously prescribed in the CKD population.

Increase in Fat Mass Has Protective Effect on Bone Mineral Density Loss After Initiation of Dialysis Therapy

Ken Iseri,[3,2] Abdul Rashid T. Qureshi,[1] Xin Li,[3] Lu Dai,[3] Olof Heimburger,[3] Peter F. Barany,[3] Bengt Lindholm,[3] Peter Stenvinkel.[3] *[1]Renal Medicine and Baxter Novum, Clintec, Karolinska Institutet, Stockholm, Sweden; [2]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [3]Renal Medicine and Baxter Novum, Clintec, Karolinska Institutet, Stockholm, Sweden.*

Background: In contrast to general population, increased fat mass (FM) was reported to have a beneficial effect on mortality risk in dialysis patients. However, the effect of FM on bone status is unclear. We investigated the association between bone loss after initiation of dialysis and changes of fat mass during 1-year of dialysis therapy.

Methods: 246 patients initiating hemodialysis (HD; n=105) or peritoneal dialysis (PD; n=141) were investigated at initiation of dialysis and after 1 year on dialysis. Measurements included: whole body dual-energy X-ray absorptiometry (DXA) for assessment of bone mineral density (BMD) and body composition; nutritional status by subjective global assessment (SGA) and handgrip strength as percentage of controls (HGS%); and, various biochemical biomarkers including insulin growth factor-1 (IGF-1).

Results: During 1-year of dialysis therapy, T- and Z-scores decreased significantly compared to baseline (both p<0.05). Whereas there was no statistically significant change in body weight during 1-year dialysis therapy, total FM, trunk FM and peripheral FM increased significantly compared to start of dialysis, while lean body mass (LBM) decreased. In multivariate linear mixed model, changes of total FM, trunk FM, peripheral FM and LBM were positively associated (all p<0.05) with changes of BMD at all sites except head after adjusting for several confounders (sex, age, height, smoking, physical activity, SGA, HGS%, parathyroid hormone and dialysis modality. Furthermore, changes of serum IGF-1 levels were positively associated with changes of total FM, trunk FM and peripheral FM (p<0.05), but not LBM.

Conclusions: An increased fat mass, central as well as peripheral, appears to have a protective effect on bone loss 1 year after initiation of dialysis. We speculate that the observed effect - which might be one contributor to the beneficial effect of FM on mortality risk in dialysis patients - could be partially explained by enhancement of IGF-1.

Association Between Normalized Protein Catabolic Rate (nPCR) and the Risk for Bone Fracture in Patients Undergoing Hemodialysis: The Q-Cohort Study

Shotaro Ohnaka,[1,2] Hiroaki Tsujikawa,[2] Shunsuke Yamada,[2] Masatomo Taniguchi,[3] Masanori Tokumoto,[4] Kazuhiko Tsuruya,[5] Toshiaki Nakano,[2] Takanari Kitazono.[2] *[1]Tagawa Municipal Hospital, Tagawa, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan; [3]Fukuoka Renal Clinic, Fukuoka, Japan; [4]Department of Internal Medicine, Fukuoka Dental College, Sawara-ku, Japan; [5]Nara Medical University, Kashihara, Japan.*

Background: Normalized protein catabolic rate (nPCR) is used as a surrogate of daily protein intake and nutritional status in patients receiving maintenance hemodialysis (HD). It remains unknown whether nPCR affect the incidence of bone fracture in HD patients.

Methods: A total of 2,869 patients registered to the Q Cohort Study, a multicenter, prospective, observational study, were followed up for a median of 4 years. The primary outcome was bone fracture at any site. The main exposure was nPCR level at baseline. Patients were divided into four groups based on their baseline nPCR levels (Q1: <0.85, Q2: 0.85-0.95, Q3: 0.95-1.05 [reference], Q4: ≥1.05 g/kg/day). We examined the relationship between nPCR levels and the risk for bone fracture using a Cox proportional hazards risk model.

Results: During the follow-up period, 136 patients experienced bone fracture at any site. In the multivariable analyses, the risk for bone fracture was significantly higher in the lowest (Q1) and highest (Q4) nPCR groups compared with Q3 group (hazard ratio [95% confidence intervals]: Group 1, 1.93[1.05-3.66]; Q2, 1.27[0.68-2.44]; Q3 1.00 (reference); Q4, 2.21[1.27-4.02]. Even when analyses were limited to those whose dialysis vintage was longer than 2 years, the association remained unchanged.

Conclusions: Our results suggest that both lower and higher nPCR values increase the risk for bone fracture in HD patients. Further studies are necessary to confirm our observation and elucidate the underlying mechanisms on the association between nPCR level and bone fracture in HD patients.

TH-PO572

Five-Year Changes in Quadriceps Muscle Properties and Risk of Hip Fractures in Older Adults with Reduced and Normal Kidney Function: Nine Years of Follow-Up of the AGES-Reykjavik Study

Elisa A. Marques,[1] Joao L. Viana,[2] Diogo V. Leal,[2] Vilmundur Gudnason,[3] Gunnar Sigurdsson,[5] Thomas Lang,[7] Sigurdur Sigurdsson,[6] Thor Aspelund,[3] Kristin Siggeirsdottir,[3] Lenore J. Launer,[4] Gudny Eiriksdottir,[3] Tamara Harris.[4]
[1]Research Center in Sports Sciences, Health Sciences and Human Development (CIDESD), University Institute of Maia (ISMAI), Maia, Portugal; [2]University Institute of Maia, Maia, Portugal; [3]Icelandic Heart Association, Kopavogur, Iceland; [4]National Institute on Aging, Bethesda, MD; [5]Icelandic Heart Association Research Institute, Kópavogur, Iceland; [6]The Icelandic Heart Association, Kópavogur, Iceland; [7]University of California, San Francisco, San Francisco, CA.

Background: Chronic kidney disease (CKD) is associated with poor muscle and bone health, as well as an increased risk of fractures. However, the prediction of fractures from muscle-related parameters in older adults with impaired kidney function remains unknown. Therefore, this study aimed to determine the association of accelerated worsening of muscle properties over 5 years and incident hip fracture among older adults with reduced (estimated glomerular filtration rate < 60 ml/min/1.73 m^2)and normal kidney function.

Methods: A total of 2311 older adults (33.1% CKD stage 3-4), aged 66-91 years at baseline from the Age, Gene/Environment Susceptibility (AGES)-Reykjavik Study, who had completed data on baseline serum creatinine and potential covariates, and valid thigh quantitative computed tomography (QCT) scans and isometric testing at baseline and 5-years later were studied. Fracture predictors included: cross-sectional area (CSA, cm^2), attenuation (Hounsfield unit), and maximum rate of torque development (RTD, N*m/s). Analyses employed Cox-proportional hazard regression models adjusted for potential covariates.

Results: During the median follow-up of 5.7 years, 202 (8%) hip fractures occurred. Having reduced kidney function was associated with an increased risk of hip fracture (HR= 1.6, 95% CI 1.2 – 2.1) compared to having normal kidney function. Adjusted for confounders, an accelerated decline (highest tertile of decline) in quadriceps muscle CSA was associated with higher hip fracture risk (HR =1.62, 95% CI= 1.03–2.54) only in reduced kidney function older adults, while an accelerated decline in muscle attenuation and RTD were not significant predictors of hip fracture in both normal and reduced kidney function subjects.

Conclusions: Our findings support that monitoring quadriceps muscle quantity changes and implementing exercise regimens may be two essential and clinically feasible steps to prevent functional decline and fracture risk, particularly in older adults with reduced kidney function.

Trabecular Bone Score Predicts Osteoporotic Fracture in CKD Patients

Eunjin Bae,[1] Jeonggu Na,[1] Tae won Lee,[1] Ha nee Jang,[2] Junhyeong Cho,[1] Se-Ho Chang,[1] Dong Jun Park.[1] *[1]Gyeongsang National University Hospital, Changwon, Republic of Korea; [2]Gyeongsang National University Hospital, Jinju, Republic of Korea.*

Background: Chronic kidney disease and mineral bone disease (CKD-MBD) is a common complication of CKD and this is associated with higher risk of fracture, morbidity and mortality. Current guidelines recommend measurement of bone mineral density (BMD) in CKD patients. However, the focus is only on bone turnover and bone density, and there is no guideline for trabecular bone score (TBS) for trabecular bone microarchitecture in CKD patients. We aim to evaluate the role of TBS in predicting osteoporotic fracture in CKD patients.

Methods: We retrospectively enrolled 125 patients with CKD between 2016 and March 2019. Lumbar spine TBS was extracted from dual-energy X-ray absorptiometry, and we categorized the TBS into three groups as lowest (≥ 1.31), moderate (1.31-1.23), and highest risk group (≤ 1.23). The logistic regression analysis was used to assess osteoporotic fracture risk.

Results: Of 125 patients, mean age was 65.9 ± 14.2 years, 49.6% were on dialysis, 11.2% was highest risk group by TBS. Patients with highest risk group by TBS were significantly older, had lower height, weight, serum 25-OH vitamin D, serum sodium level, BMD *T*-score (lumbar spine, femur neck and total hip) than lower risk group. TBS significantly correlated with BMD *T*-score (lumbar spine, femur neck and total hip), height, weight and serum creatinine level (P <0.001). Osteoporotic fracture was identified in 20 (16.0%) patients. In univariate analyses, old age, women, lower weight, TBS tertile group, lower potassium level were significantly associated with osteoporotic fracture. In multivariate analyses, only highest risk group by TBS was significantly associated with increased osteoporotic fracture risk after adjustment for demographic, comorbid, medication use, and previous fracture.

Conclusions: Lumbar spine TBS significantly correlated with BMD *T*-score and predicts osteoporotic fractures in patients with CKD.

TH-PO574

Usefulness of Trabecular Bone Score and Central Quantitative CT for Assessment of Bone in CKD Patients

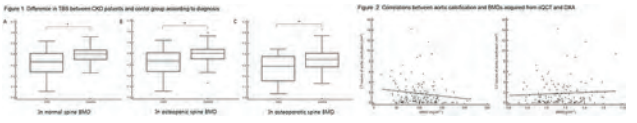
Keunyoung Kim, Injoo Kim, Kyoungjune Pak, Seong-jang Kim, Su Jung Choi, Yunkyung Jeon, Sang soo Kim, Eun Young Seong, Sang Heon Song. *Pusan National University Hospital, Pusan, Republic of Korea.*

Background: The aims of this study are to propose the usefulness of central quantitative computed tomography(cQCT) and trabecular bone score(TBS) in bone assessment and to show the characteristics of diagnostic discordances in patients with chronic kidney disease(CKD) compared with healthy control.

Methods: This retrospective study included 135 patients (M : F, 73 : 62) with CKD that bone mineral density (BMD) was checked with both cQCT and dual energy absorptiometry (DXA) at the lumbar spine (LS) and femur neck (FN) area. Healthy control included 380 participants who visited hospital of a health check-up (M : F, 170 : 210). The discordancy refers to the diagnostic difference between two sites of DXA or between two modalities of DXA and cQCT. TBS was calculated from DXA images. The volume of abdominal aortic calcification (AAC) was measured using HU threshold (above 130HU) of CT images for cQCT. We classified bone state into three categories such as normal BMD, osteopenia and osteoporosis.

Results: The diagnosis rate for osteoporosis using T-score of FN was not significant different between two groups. Using T-score from only LS, osteoporosis was less common in CKD group compared with control (6.7% vs. 11.8%, P = 0.024). In CKD patients, the results of cQCT showed more osteopenia or osteoporosis among subjects with normal BMD in LS of DXA: osteopenia (n = 49, 31.9 %), osteoporosis (n = 12, 8.9%). Also, CKD patients had significantly lower value of TBS than control group within the same diagnostic category based on DXA (Figure 1). Furthermore, evaluating the discordancy between FN and LS in DXA, the rate of higher BMD of LS was more common than that of FN in CKD patients (85.7% vs. 14.3%; P < 0.001) compared with control group (49.4% vs. 50.6%). The volume of AAC has significant positive correlation with BMD from cQCT (r = -0.188, P = 0.031) whereas that showed negative correlation with BMD from DXA (r = 0.046, P = 0.456, Figure 2).

Conclusions: TBS and cQCT should be proper diagnostic method for the accurate assessment of bone in CKD patients because DXA may overestimate LS BMD. Probably, the AAC would contribute to increase the unexpected increase of LS BMD unlike actual bone status.



TH-PO575

A Novel Magnetic Resonance Imaging Biomarker of Tibial Bone Quality in CKD

Fabio R. Salerno,[1,2] Alireza Akbari,[2] Lisa Hur,[1] Christopher W. McIntyre.[2,1]
[1]Medical Biophysics, Western University, London, ON, Canada; [2]The Lilibeth Caberto Kidney Clinical Research Unit, London Health Sciences Centre, London, ON, Canada.

Background: The assessment of uremic bone disease remains a challenge, with available blood-based markers correlating poorly with gold standard histological assessment of bone. Novel quantitative imaging biomarkers with potential for standardization are needed to avoid the need for bone biopsy studies. Our objective is to initially explore the clinical associations of a novel MRI-based biomarker of bone quality of the tibia in healthy controls, CKD stage 3-5 and HD patients.

Methods: 10 healthy controls, 38 CKD stage 3 to 5 patients and 15 HD patients underwent MR with $^1H^+$-weighted imaging of the right calf. Acquired images were analyzed as shown in Figure 1 and the tibial cortical-trabecular bone ratio (CTR) was calculated for each subject. CTR values were compared between groups with Student's t-test for independent samples. Correlation analyses plotting CTR values in different groups against standard blood biomarkers were also run and standard curves interpolated as appropriate.

Results: Refer to Figures 1 and 2.

Conclusions: Worsening renal function is associated with significant reduction in directly image CTR. This may represent a promising imaging biomarker of CKD-MBD and identifies erythropoiesis as being associated with bone quality in CKD patients.

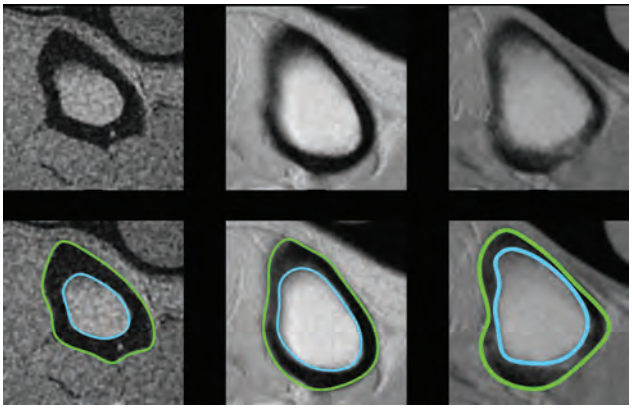


Figure 1: Sample raw and segmented images of the right tibia in a healthy control (A, B), CKD (C, D) and HD patient (E, F).

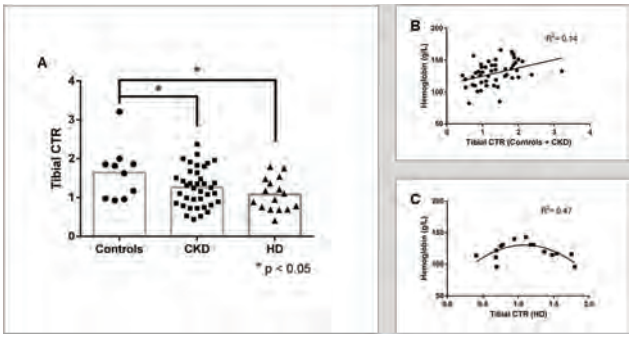

Figure 2: A decrease in CTR was observed in CKD and HD patients when compared to Controls (A). A weak linear relationship was observed between CTR and Hemoglobin levels in Controls+CKD patients (B) and a polynomial-quadratic relationship was observed in HD patients (C).

TH-PO576

Can a New ^{18}F-NaF PET/CT Scan Replace Bone Biopsy to Determine Bone Turnover in Patients with CKD-MBD?

Marie H. Vrist,[1] Frank H. Mose,[1] Claire A. Fynbo,[3] Jorn Theil,[3] Bente Langdahl,[2] Thomas G. Lauridsen,[1] Jesper N. Bech.[1] *[1]University Clinic of Nephrology and Hypertension, Holstebro, Denmark; [2]Aarhus University Hospital, Aarhus N, Denmark; [3]Department of Nuclear Medicine, Herning Hospital, Herning, Denmark.*

Background: CKD-MBD is an enormous problem in dialysis patients. Before optimal treatment can be accomplished, bone turnover has to be established. The golden standard, double tetracycline-labeled transiliac bone biopsy, has many disadvantages and is seldom performed. Bone biopsy is cumbersome, expensive, painful, and invasive. It would therefore be of outmost interest to develop an alternative method to establish bone turnover. The purpose of this ^{18}F-NaF PET/CT trail is to implement a new method for several region determination of bone turnover in patients with CKD-MBD.

Methods: A pilot study was conducted in which 17 dialysis patients underwent the new dynamic/static ^{18}F-NaF PET/CT scan. This scan method is initiated with a 60 min. thoracic dynamic scan followed by a 30 min. whole-body static scan. Venous blood samples are drawn at -5, 40, 50, 60 and 90 minutes after a 150 MBq ^{18}F-NaF intravenous injection. A 3-tissue compartment model is used to estimate regional bone ^{18}F-NaF clearance (K_i). K_i is an expression for bone turnover. One cardiac (left ventricle) volume-of-interest (VOI) and four thoracic vertebrae VOIs are placed. Time activity curves are generated. The software PMOD is used for this analysis. Moreover multi-point Patlak analysis is conducted. The PMOD analysis and the Patlak analysis are compared. Finally, the patients underwent double tetracycline-labeled transialic bone biopsy. As a control of the new method, the scan-bone turnover was then compared with the biopsy-bone turnover.

Results: To date, data have been obtained from 9 of 17 included patients. Preliminary results of PMOD analysis demonstrated a vertebral mean K_i-value of 0.041 ±0.01 ml/min/cm^3. The corresponding value by multi-point Patlak analysis was 0.035 ±0.01 ml/min/cm^3. Ki-values present the same range as previously published data for diverse patient groups. We are looking forward to compare results from this new method with results from the bone biopsies and hopefully we get the pleasure of presenting the full dataset at Kidney Week 2019.

Conclusions: The ^{18}F-NaF PET/CT seems feasible for measurement of bone turnover in CKD-MBD. The next step will be to appraise the clinical value to determinate changes in K_i (bone turnover) after medical intervention.

TH-PO577

Associations Between Body Composition on Cortical Bone Quality in CKD

Maria A. Aponte farias,[1] Pascale Khairallah,[1] Natalia E. Cortez,[2] Sanchita Agarwal,[3] Joshua Sung,[3] Tom Nickolas.[1] *[1]Columbia University Medical Center, New York, NY; [2]University of California, Davis, Davis, CA; [3]Columbia University, New York, NY.*

Background: Obesity is considered beneficial to bone health due to well-established positive effects of mechanical loading of weight on bone formation. However, studies have reported that excessive fat mass may not protect against osteoporosis: high fat mass was associated with low total bone mineral density. Renal osteodystrophy (ROD) is associated with impaired cortical bone quality due to hyperparathyroidism, but the effects of fat and muscle mass on cortical bone in ROD are unclear. We hypothesized that body composition independently affects cortical bone and that muscle and fat mass have opposing effects on the cortex.

Methods: In 77 patients with mean +/- SD age of 59+/-10 years and with CKD stages 3-5D, we scanned the distal radius and tibia by high-resolution peripheral quantitative CT to measure cortical density, thickness and porosity. We measured total fat, muscle mass and percent body fat by whole body dual-energy X-ray absorptiometry. Cortical measures were correlated with age, sex, BMI, percent body fat, fat free muscle index, PTH, calcium, phosphorus and 25(OH)D. Linear regression models adjusted for age, sex and PTH determined whether muscle and fat mass were independent predictors of cortical bone quality.

Results: At the radius, higher muscle mass was associated with thicker cortices and higher percent body fat was associated with thinner cortices that had fewer and smaller pores (Table). At the tibia, higher muscle mass was associated with thicker, while higher fat content was associated with thinner cortices. In MV regression, higher muscle mass was associated with thicker cortices at the radius and tibia while higher fat mass was associated less porous cortices at the radius. Older age was associated with more severe cortical porosity at the radius (p=0.03) and tibia (p<0.001).

Conclusions: In CKD 3-5D, muscle and fat mass independently predicted, and had opposing effects, on cortical bone quality. Further studies evaluating underlying mechanisms linking muscle and fat to cortical bone quality are needed.

Funding: NIDDK Support, Private Foundation Support

Poor Correlation of Static Markers of Bone Turnover at the Iliac Crest vs. Greater Trochanter in Autopsy Specimens

Jan M. Hughes-Austin,[1] Kathryn D. Dwight,[1] Charles Ginsberg,[1] Ann M. Tipps,[1] Isidro B. Salusky,[2] Joachim H. Ix.[1] *[1]University of California, San Diego, La Jolla, CA; [2]Mattel Children's Hospital, Los Angeles, CA.*

Background: Iliac crest bone biopsies and histomorphometry are the gold standard in the diagnosis of abnormalities within the Chronic Kideny Disease - Mineral and Bone Disorder (CKD-MBD), yet fractures more frequently occur around the greater trochanter of the hip. We compared bone turnover markers between these 2 anatomical sites in autopsies.

Methods: We collected bone tissue samples from the ipsilateral iliac crest and greater trochanter in 10 deceased individuals undergoing autopsy at University of California, San Diego between March-August 2018. Because post-mortem osteoblasts last <48 hours, we used osteoclast surface relative to bone surface (Oc.S/BS), eroded surface relative to bone surface (ES/BS), and osteoid volume relative to bone volume (OV/BV) as markers of bone turnover. We evaluated the correlation of these markers between the iliac crest and greater trochanter using Pearson correlations.

Results: Average age of these individuals was 57±16, 30% were women, and average time from death to autopsy was 3±2 days. We found that the Pearson correlation of Oc.S/BS at the iliac crest vs. greater trochanter was 0.44, p=0.37. Similarly, Pearson correlation of ES/BS and OV/BV were 0.30, p=0.44, and 0.003, p=0.99, respectively.

Conclusions: We found poor agreement of static measures of bone turnover between the iliac crest and greater trochanter. These data suggest that bone histomorphometric measures of the iliac crest may not provide reliable information about bone turnover at other anatomic sites.

Hyperparathyroidism Helps to Explain the Disagreement Between Bioimpedance and Dual-Energy Absorptiometry in the Analysis of Nutritional Status

Shirley F. Crispilho,[2] Eduardo J. de Sa C. Filho,[1] Kalyanna S. Bezerra de carvalho,[1] Rosa M. Pereira,[1] Vanda Jorgetti,[1] Rosilene M. Elias,[1,2] Rosa M. Moyses.[1] *[1]Universidade de Sao Paulo, Brazil, Brazil; [2]Universidade Nove de Julho, São Paulo, Brazil.*

Background: Body composition is critical in the evaluation of patients with CKD and can be obtained from multifrequency bioelectrical impedance analysis (BIA) or from the gold standard dual-energy absorptiometry (DXA). Previous studies have shown disagreements between these two methods, mainly regarding the bone mineral content (BMC). We hypothesized that secondary hyperparathyroidism, which is associated with bone loss, is the main responsible for this discrepancy.

Methods: We studied 20 pre-dialysis CKD patients (CKD) and 29 on hemodialysis (18 with severe hyperparathyroidism (HD-SHPT) and 11 already submitted to parathyroidectomy at least 1 year before our analysis (HD-PTX). The total-body composition was determined using DXA and BIA.

Results: HD-SHPT patients tended to be younger (CKD = 52.5 ± 14.3 ys.; HD-SHPT = 41.6 ± 14.9 ys.; HD-PTX 44.9 ± 13.4 ys.; p = 0.06), but had lower BMC measured through DXA (CKD = 2,266 ± 565 g; HD-SHPT = 1,808 ± 522 g; HD-PTX 2,301 ± 658 g; p = 0.04). This difference was not found in BMC measured by BIA (CKD = 3,011 ± 596 g; HD-SHPT = 2,896 ± 711 g; HD-PTX 2,650 ± 467 g; p = 0.30). The highest disagreement between DXA and BIA was found in HD-SHPT group (CKD = -711 g; HD-SHPT = - 915 g; HD-PTX -688 g; p = 0.004). There was a significant correlation between the difference of BMC obtained from DXA and BIA with parathormone (PTH; r = -0.394; p = 0.006) and alkaline phosphatase (AP; r = -0.489; p < 0.0001).

Conclusions: Our results confirm that BIA should be interpreted cautiously in patients with SHPT since higher PTH and AP lead to a greater disagreement between these methods. Moreover, the recovery of bone mass and the decrease of the disagreement after PTX support our hypothesis. BIA loss of accuracy occurs because BMC is not measured, but obtained from an algorithm derived from normal individuals, using the fat-free mass values. Therefore, BMC overestimation is associated with an underestimation of lean mass. This misinterpretation might compromise the management of the nutritional status, as well as of the bone disease, in SHPT patients.

TH-PO580

Female Sex Enhances the Association of Secondary Hyperparathyroidism with Increased Bone Turnover Marker in Aged Patients Receiving Hemodialysis

Naoto Hamano,[1] Hirotaka Komaba,[1,2] Takatoshi Kakuta,[3] Takehiko Wada,[1] Yuichiro Takahashi,[4] Toru Hyodo,[5] Miho Hida,[6] Masafumi Fukagawa.[1] *[1]Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]The Institute of Medical Sciences, Tokai University, Isehara, Japan; [3]Tokai University Hachioji Hospital, Hachioji, Japan; [4]Jinken Clinic, Ebina, Japan; [5]Eijin Clinic and Cambodian Association of Nephrology, Hiratsuka, Japan; [6]Kurata Hospital, Hiratsuka, Japan.*

Background: Female patients undergoing dialysis are at higher risk of fracture than male patients, suggesting the involvement of postmenopausal osteoporosis. However, little is known about the impact of menopause on altered bone metabolism associated with secondary hyperparathyroidism in this population.

Methods: We analyzed data from a cohort of 654 patients receiving maintenance hemodialysis. We examined the hypothesis that female sex is associated with elevated levels of bone-specific alkaline phosphatase (BAP) and enhances the association between intact parathyroid hormone (PTH) and BAP in aged hemodialysis patients.

Results: Females had significantly higher levels of BAP compared to males in patients aged ≥50 years, but not in patients aged <50 years (*P* for interaction by age <0.001). This difference observed in the aged population remained significant after adjustment of age, diabetes, dialysis vintage, body-mass index, and PTH. In the overall cohort or in either of the age subgroups, increased PTH was significantly associated with increased BAP independently of age, diabetes, dialysis vintage, and body-mass index. Among patients aged ≥50 years, the association between PTH and BAP was pronounced in females compared with males (*P* for interaction by sex <0.001), but such effect modification by sex was not observed among patients aged <50 years.

Conclusions: Our results show that female sex enhances the increased bone turnover associated with secondary hyperparathyroidism in aged hemodialysis patients, highlighting the involvement of postmenopausal osteoporosis in high-turnover renal osteodystrophy.

Treatment with Lanthanum Carbonate (LC) May Reduce Bone Mineral Density (BMD): Six-Year Observation in Hemodialysis (HD) Patients

Jyunichiro Hashiguchi,[2] Satoshi Funakoshi,[1] Kenji Sawase,[2] Tayo Kawazu,[2] Takuya Kubara,[2] Masatoshi Hayashida,[1] Sayaka Miyazaki,[2] Mashumi Ide,[2] Tomoya Nishino,[3] Takashi Harada.[2] *[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Kidney Center, Nagasaki, Japan; [3]Nagasaki University School of Medicine, Nagasaki, Japan.*

Background: LC is one of the most powerful phosphate binders (PB) for the treatment of hyperphosphatemia in HD patients. However, whether LC can increase BMD or not is still controversial. This study was performed to examine the effects of LC on alteration of BMD in HD patients.

Methods: Subjects were divided into 2 groups and compared. Group 1: Twenty-two HD patients who were treated with non-LC PB for 6 years (14 males and 8 females; mean age, 66.7±7.4 years old; mean HD duration, 11.4±7.6 years). Group 2: Fourteen HD patients who were treated non-LC PB for 3 years, then were converted to receive LC for 3 years (5 males and 9 females; mean age, 62.7±5.5 years old; mean HD duration, 9.7±6.6 years). BMD in these patients were estimated by digital image processing (DIP).

Results: As shown in Figure, the alteration ratio in BMD for group1 was -1.6% / year over 6 years, whereas the alteration ratio was -2.0% / year in the former 3 years, then declined to -7.9% / year in the latter 3 years in group 2. The decrease ratio of BMD for group 2 at 6 years was significantly lower than that of group 1 (p<0.05).

Conclusions: The decline of BMD was constant through 6 years in group 1; whereas the decline of BMD was accelerated after the treatment was converted from non-LC PB to LC in group 2. These observations suggest that administration of LC may reduce BMD in HD patients for some mechanisms.

Polymorphism in the Human Matrix Gla Protein Gene Is Associated with the Progression of Osteoporosis in Hemodialysis Patients

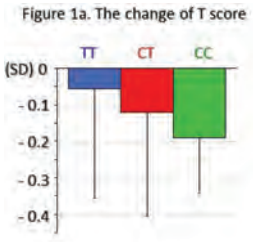
Yukiko Hasuike,[2,1] Tomoko Kimura,[2,1] Kosuke Mizusaki,[2,1] Aritoshi Kida,[2,1] Masayoshi Nanami,[2,1] Yasuyuki Nagasawa,[2,1] Takahiro Kuragano,[2,1] Masaharu Ishihara.[2,1] *[1]Hyogo College of Medicine, Nishinomiya City, Japan; [2]Internal Medicine, Division of Kidney and Dialysis, Nishinomiya, Japan.*

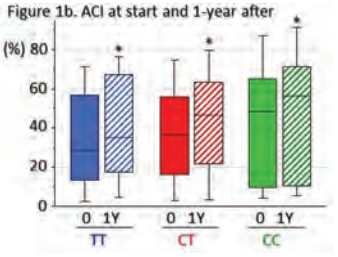
Background: Matrix Gla protein (MGP) is an important protein related osteoporosis and vascular calcification. Single nucleotide polymorphisms (SNPs) coding regions of the MGP gene affect the transcriptional activity. We investigated the relationship between the SNPs and progression of osteoporosis and vascular calcification in patients undergoing hemodialysis (HD).

Methods: This is a prospective and single center study. Using blood samples, SNPs on the MGP gene promoter T-138C (rs1800802, direct sequencing) was investigated. Bone mineral density (femoral, DEXA, T score) and vascular calcification index (ACI, abdominal CT) were examined at start and 1-year after. Several factors related bone: fibroblast growth hormone, bone-type alkaline phosphatase (BAP), and tartrate-resistant acid phosphatase (TRACP5b), uremia: Ca, P, parathyroid hormone-intact, and 25(OH) vitamin D, and inflammation: high-sensitivity CRP, tumor necrosis factor-α, interleukin-6 were measured. The change of T score and ACI were investigated.

Results: The distribution of the T-138C genotype was TT (47.5%), CT (40.0%) and CC (12.5%,). T score of all participants (n=80) at 1-year after was lower than that at start. T score for the CT and CC genotype were significantly decreased. The changes of T scores for the CC, CT, and TT genotype were shown (Figure 1a). The multiple regression analyses revealed that the change of BAP, TRACP-5b, and ACI were the independent predictors of T score change (standardized regression coefficients were -0.443, -0.276, and 0.400, respectively, R^2=0.659). ACI for each genotype were increased (Figure 1b), and there were no differences of ACI change among 3 genotypes.

Conclusions: The MGP-138C genotype may be associated with decrease in T scores in HD patients. The genotype of the MGP gene might be a genomic biomarker that is predictive of osteoporosis.





TH-PO583

Effects of Diuretics Furosemide and Hydrochlorothiazide on CKD-MDB: A Prospective Randomized Study

Raquel F. Vasco, Rosa M. Moyses, Rosilene M. Elias. *Nephrology, Hospital das Clinicas HCFMUSP, São Paulo, Brazil.*

Background: Diuretics are often prescribed to patients with CKD to control fluid overload and hypertension. Diuretics may affect CKD-MBD since thiazides are associated with reduced calciuria, reduction/maintenance of PTH levels and increased bone density while loop diuretics have the opposite effect. These effects are still debatable and not fully elucidated in patients with CKD. **Objective**: To evaluate the effects of furosemide (FURO) and hydrochlorothiazide (HYDRO) on CKD-BMD in patients with stage 3 CKD in a regular follow-up.

Methods: This was a RCT comparing HYDRO (25mg/day) and FURO (40mg/day) on urinary and biochemical variables including parathyroid hormone (PTH), alkaline phosphatase (AP), calcium (Ca), CTx and P1NP. After a washout period, patients were randomized to either the HYDRO or FURO group and followed for 1 year, by the same observer, blinded to randomization. Bone effects were also evaluated by Dual X-ray absorptiometry (DXA).

Results: 40 patients with a median of 62 years were included, 20 were randomized to each group, which presented similar characteristics after randomization (for age, gender, eGFR, weight, PTH, Ca, 25(OH)Vitamin-D, and AP). There was a reduction of urinary Ca in the HYDRO group and an increase in the FURO group ($p=0.02$), in addition to a tendency of a higher total serum Ca in the HYDRO group ($p=0.06$). There was no difference in PTH and 25(OH)Vitamin-D levels, albeit there was an annual percentage increase of 1,25 (OH)2ViTD in the FURO group (12.7 ± 32%) and a reduction in the HYDRO group (-13.6 ± 21%), $p=0.048$. CTX, P1NP, and AP increased in the FURO group and reduced in the HYDRO group (all $p<0.05$). No significant difference was found in the percentage change of bone density measured by DXA, only a tendency to greater loss in the proximal 1/3 of the distal radius, more pronounced in the FURO group ($p=0.06$).

Conclusions: Furosemide and hydrochlorothiazide had opposite effects on the CKD-MBD in a 1-year follow-up study. Furosemide seems to be associated with an increase and hydrochlorothiazide with reduced bone remodeling, a fact not evidenced by PTH change. Whether PTH would change in more advanced CKD or in a bigger sample size warrants further investigation.

TH-PO584

Associations of Bone-Related Markers and Cognitive Function in Hemodialysis Patients

Ping-Hsun Wu,[1,3] Yi-Ting Lin,[2,4] Jer-Chia Tsai,[5,6] Mei-Chuan Kuo.[1,6] *[1]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [3]Graduate Institute of Clinical Medicine, College of Medicines, Kaohsiung Medical University, Kaohsiung, Taiwan; [4]Graduate Institute of Clinical Medicine, College of Medicines, Kaohsiung Medical University, Kaohsiung, Taiwan; [5]Division of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [6]Faculty of Renal Care, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: Patients undergoing hemodialysis (HD) have a higher risk of cognitive impairment than the general population but limited data elucidated the biomarkers on this. We evaluate the association of bone turnover markers on cognitive function among 251 prevalent HD enrollees in a cross-sectional study.

Methods: 251 HD patients (median age=57.8; 55% men) without a prior stroke or dementia diagnosis were enrolled. Circulating levels of 8 bone markers (receptor activator of nuclear factor kappa-B ligand [RANKL], dickkopf-related protein 1 [DKK1], fibroblast growth factor 23 [FGF23], leptin, osteocalcin [OC], Osteopontin [OPN], osteoprotegerin [OPG], sclerostin [SOST]) were analyzed by a multiplex immunobead assay (Millipore, St Charles, MO, US). The association between bone-related markers and cognitive function test (Mini-Mental State Examination [MMSE], Montreal Cognitive Assessment [MoCA], and Cognitive Abilities Screening Instrument [CASI]) were investigated in a linear regression model.

Results: Among 8 bone-related markers, RANKL was the only bone markers found associated with cognitive function (MMSE, MoCA, and CASI test) in HD patients (Figure). In stepwise multiple linear regression analysis, the positive association remained statistically significant in MoCA (β=1.14, 95% CI 0.17 to 2.11) and CASI (β=3.06, 95% CI 0.24 to 5.88). Short-term memory (β=0.52, 95% CI 0.01 to 1.02), mental manipulation (β=0.51, 95% CI 0.05 to 0.96), and abstract thinking (β=0.57, 95% CI 0.06 to 1.09) were significant domain in CASI score.

Conclusions: Serum RANKL levels were found potential associated with higher cognitive function test in HD patients. Further large scale and prospective studies are needed to confirm our findings.

TH-PO585

Bone Phenotype in Patients with ESKD Treated with Proton Pump Inhibitors

Pieter Evenepoel,[1] Kathleen Claes,[6] Bert Bammens,[1] Björn K. Meijers,[5] Etienne Cavalier,[4] Geert J. Behets,[2] Patrick C. D'Haese,[3] Dirk R. Kuypers.[1] *[1]University Hospitals Leuven, Leuven, Belgium; [2]University of Antwerp, Antwerp (Wilrijk), Belgium; [3]University Antwerp, Edegem, Belgium; [4]University of Liege, CHU Sart-Tilman, Liege, Belgium; [5]UZ Leuven, Leuven, Belgium; [6]University Hospital Gasthuisberg, Leuven, Belgium.*

Background: Proton pump inhibitors (PPIs) are suspected of having a negative impact on the skeleton and possibly increasing the risk of osteoporosis in the general population and patients with chronic kidney disease. Underlying pivotal pathophysiological mechanisms include calcium malabsorption, gastrin-mediated parathyroid gland stimulation, vitamin B12 deficiency, and impaired function of osteoblasts and osteoclasts. The present cohort study aimed to map the impact of PPI use on the bone phenotype in end stage kidney disease (ESKD) patients.

Methods: Bone mineral density (BMD, by dual energy x-ray absorptiometry, DXA) both at the lumbar spine and hip (total hip and femoral neck) and bone turnover markers (BTMs; bone alkaline phosphatase, tartrate-resistant acid phosphatase 5b, procollagen type I N-terminal propeptide) were assessed in 308 patients with ESKD (53.7 ± 13.1 yrs, male 64%), with bone histomorphometry data available in 69 patients. On-hundred and three patients (33%) were treated with PPIs (cases). Laboratory parameters of mineral metabolism including calcium, phosphate, magnesium, parathyroid hormone (PTH), fibroblast growth factor 23 (FGF23) and sclerostin, parameters of inflammation (C-reactive protein, Interleukin-6), vitamin B12 levels, and nonphosphorylated-uncarboxylated isoform of MGP (dp-ucMGP), as a proxy of vitamin K status were assessed in all patients.

Results: ESKD patients on PPI therapy showed lower BMD at the hip, while BTMs and bone histomorphometry were not different from controls. PPI users, furthermore, were characterized by older age, more cardiovascular morbidity, lower serum magnesium, lower phosphate and FGF23, and higher serum dp-ucMGP levels and parameters of inflammation. PTH and vitamin B12 levels did not differ between PPI users and non-users. PPI use associated with BMD at the femoral neck, independent of classical (age, gender, BMI) and non-classical (vitamin K status, cardiovascular disease, inflammation) determinants.

Conclusions: PPI use in patients with ESKD independently associated with low BMD at the hip. Our data argue against an important role of PTH, vitamin B12 or dysfunctional osteoblast and osteoclast in the pathophysiology of PPI-related osteoporosis in ESKD. The link between PPI use and poor vitamin K status needs further investigation.

TH-PO586

Proton Pump Inhibitor Use and Risk of Major Fractures in Kidney Transplant Recipients

Beini Lyu,[1] Margaret R. Jorgenson,[4] Karen Hansen,[3] Arjang Djamali,[2] Brad C. Astor.[2] *[1]University of Wisconsin-Madison, MADISON, WI; [2]University of Wisconsin, Madison, WI; [3]University of Wisconsin School of Medicine and Public Health, Madison, WI; [4]UW Health, Madison, WI.*

Background: Fracture is a significant problem among kidney transplant recipients (KTRs). Proton pump inhibitors (PPIs) are among the most commonly prescribed drugs in KTRs and have been associated with a higher risk of fractures in the general population. This study aimed to determine how PPIs use is associated with the incidence of major fractures in KTRs.

Methods: Using the Wisconsin Allograft Recipient Database (WisARD), we identified 155 major fracture events that occurred at least 12 months after transplantation between 2000 and 2015. Each eligible case was matched using incidence density sampling with five controls on age, sex, race, transplantation year (±3 years), living versus deceased donor and prior transplantation. PPI and histamine 2-receptor antagonists (H2RA) use during the year prior to the index date were identified. The association between prior PPI/H2RA use and incidence of major fractures were assessed by conditional logistic regression.

Results: A total of 155 cases were matched to 685 controls. A higher proportion of cases had a history of diabetes and cardiovascular disease. During the year prior to the index date, cases had lower serum albumin, higher phosphorus, higher iPTH, and higher alkaline phosphatase. A higher proportion of cases ever used corticosteroid and bisphosphonate. 67.7% of cases and 51.5% of controls ever used a PPI, and 15.5% of cases and 11.3% of controls ever used an H2RA. PPI use was associated with higher incidence of major fractures in unadjusted analysis (OR=2.4, 95% CI: 1.6-3.5). The association remained similar when adjusting for demographic and transplant-related covariates (OR=2.3, 95% CI: 1.5-3.6); and further adjusting for use of corticosteroid, bisphosphonate, vitamin D and calcium supplement (OR=1.9, 95% CI: 1.2-3.1). H2RA use was not associated with higher incidence of major fractures in adjusted analysis (OR=1.0, 95% CI: 0.5-1.8). The associations between PPI use and major fractures remain similar in participants who never used a bisphosphonate in the prior year.

Conclusions: PPI use may be associated with a higher risk of major fractures among KTRs. Clinicians should carefully evaluate the risk factors for fracture, weight the risk versus benefit before prescribing PPI, and have interval assessment of continued PPI use in KTRs.

TH-PO587

Follow-Up of Bone Mineral Density Changes in De Novo Kidney Transplant Recipients Treated with Two Doses of the RANKL Inhibitor Denosumab

Claudia A. Kobel,[1] Nicole Graf,[2] Rudolf P. Wuthrich,[1] Marco Bonani.[1] *[1]University Hospital Zurich, Zurich, Switzerland; [2]graf biostatistics, Winterthur, Switzerland.*

Background: Studies in women with post-menopausal osteoporosis have shown that discontinuation of treatment with denosumab leads to an increased risk of vertebral fractures because of rebound bone turnover and rapid loss of bone mineral density (BMD).

Methods: In an extended analysis of a randomized clinical trial examining the effect of denosumab on BMD we analyzed the effect of denosumab withdrawal on BMD changes. A group of 25 *de novo* kidney transplant recipients (KTR) which were treated for 1 year with two six-monthly doses of denosumab (D) on top of standard treatment (daily calcium and vitamin D) were compared to a control group of 29 KTR which received standard treatment alone. BMD changes were analyzed by repeated DXA shortly after transplantation (baseline), after 6 and 12 months (active treatment phase) and once or twice after 2 to 6.5 years (follow-up phase).

Results: Figure 1 shows the change of total lumbar BMD (g/cm^2) over time by randomisation group. The BMD at the lumbar spine declined markedly (arrow) after discontinuation of treatment with denosumab (D) but increased again thereafter. Thus, the average monthly change in lumbar spine BMD from month 12 onward was only 0.1±2.8‰ in the denosumab group but 1.5±1.9‰ in the control group (p=0.021). The average monthly change in lumbar spine BMD from baseline to follow up was similar in the control and denosumab group (1.1±1.2‰ vs 1.5±2.4‰, p=0.788). Similar results were seen at the total hip.

Conclusions: In *de novo* KTR treated with two doses of denosumab, we detect a marked decrease in lumbar spine and hip BMD when denosumab is discontinued. To prevent the decline in BMD after denosumab discontinuation, bisphosphonate treatment might be considered to antagonize the enhanced bone turnover.

Funding: Clinical Revenue Support

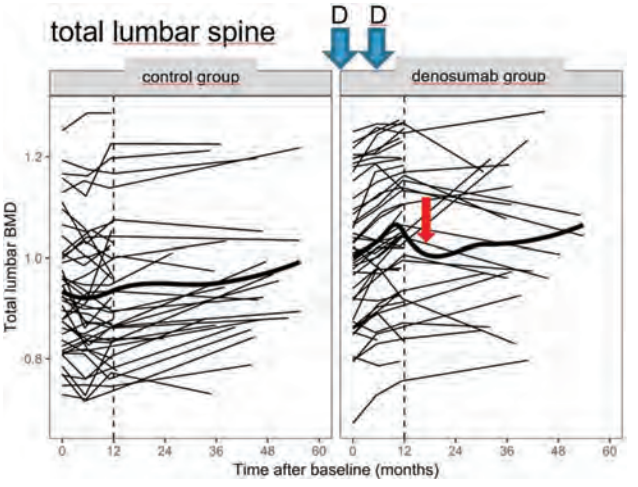

Figure 1: Total lumbar BMD over time

TH-PO588

The Effect of Increasing Dialysate Magnesium on Calciprotein Particles, Inflammation, and Bone Markers in Subjects with ESKD: Post Hoc Analyses from a Randomized Controlled Trial

Iain O. Bressendorff,[1,2] Ditte Hansen,[2] Andreas Pasch,[3] Stephen G. Holt,[4] Morten Schou,[5] Lisbet Brandi,[1] Edward R. Smith.[4] *[1]Department of Endocrinology and Nephrology, Nordsjælland's Hospital, Hillerød, Denmark; [2]Department of Nephrology, Herlev and Gentofte Hospital, Herlev, Denmark; [3]University Hospital Bern, Bern, Switzerland; [4]The Royal Melbourne Hospital, Melbourne, NSW, Australia; [5]Herlev and Gentofte Hospital, Herlev, Denmark.*

Background: The formation of fetuin-A-laden mineral-containing nanoaggregates, calciprotein particles (CPP), act as an important component of the humoral defenses against ectopic calcification. Magnesium (Mg) has been shown to delay the transition of amorphous calcium/phosphate-containing primary CPP to crystalline apatite-containing secondary CPP *ex vivo*, but the effects of increasing dialysate Mg on the endogenous CPP load is unknown.

Methods: *Post-hoc* analyses from a randomized double-blind parallel-group controlled clinical trial of 28 days treatment with high dialysate Mg of 2.0 mEq/L versus standard dialysate Mg of 1.0 mEq/L in 57 subjects undergoing maintenance hemodialysis for end-stage kidney disease. CPP particle load, markers of systemic inflammation and bone turnover were measured in serum at baseline and follow-up.

Results: After 28 days of treatment with high dialysate Mg, serum total CPP (–52%), primary CPP (–42%), and secondary CPP (–68%), were all lower in the high Mg group ($p < 0.001$), but were unchanged in the standard dialysate Mg group. Concentrations of tumor necrosis factor-alpha (–20%) and interleukin-6 (–22%) were also reduced with high dialysate Mg treatment ($p < 0.01$). With respect to effects on bone turnover markers, high dialysate Mg resulted in higher levels of bone-specific alkaline phosphatase (a marker of bone formation) (+17%) but lower levels of tartrate-resistant acid phosphatase 5b (a marker of bone resorption) (–33%) ($p < 0.01$). Inflammatory cytokines and bone turnover markers were unchanged in the standard dialysate Mg group over the same period. Correlation analyses between changes in the various parameters suggest that increasing serum Mg reduces CPP release from bone and thus lowers systemic inflammation related to CPP particle load.

Conclusions: Increasing dialysate Mg reduces CPP particle load and systemic inflammation, while also increasing markers of bone formation and decreasing markers of bone resorption.

TH-PO589

Plasma Osteopontin Levels Directly Correlate with Intact Parathyroid Hormone and Alkaline Phosphate Levels in ESRD

Aleksander D. Druck,[2] Dimpi Patel,[3] Debra Hoppensteadt,[1] Vinod K. Bansal,[1] Jawed Fareed.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University of Chicago Stritch School of Medicine, St. Charles, IL; [3]Loyola University Chicago Stritch School of Medicine, Forest park, IL.*

Background: Bone turnover disorders and reduction in bone mineral density are commonly observed in end stage renal disease (ESRD) patients. Osteopontin (OPN) is a glycol-phosphoprotein that stimulates osteoclast adhesion to bone. OPN may play a significant role in the pathways involved in bone turnover disorders. The objective of this study was: (1) to identify plasma levels of OPN in ESRD and normal populations, and (2) to elucidate if relationships exist between OPN and iPTH, and OPN and alkaline phosphatase.

Methods: Plasma levels of OPN were measured via commercially available enzyme linked immunosorbent assays (ELISAs) in ESRD patients (n=92). A chart review was conducted on these patients to identify levels of intact parathyroid hormone (iPTH)

andalkaline phosphatase at time of plasma draw. Additionally, levels of total calcium, albumin, calcium corrected for albumin, phosphorus, ferritin, white blood cell count (WBC), and platelet count (PLT CT) were identified at time of plasma draw via the chart review. OPN levels were also measured in normal control patient plasma (n = 49) purchased from George King Bio-Medical, Inc., Overland Park, KS.

Results: The ESRD cohort showed a statistically significant elevation of OPN plasma levels ($p < 0.0001$, Mann-Whitney t-test) compared to the normal group. Spearman correlation tests revealed a significant positive correlation of OPN with iPTH ($p < 0.0001$; $r = 0.5606$, 95% confidence interval = 0.3968 to 0.6898) and OPN with alkaline phosphatase ($p < 0.0001$; $r = 0.4381$, 95% confidence interval = 0.2494 to 0.5948) in the ESRD cohort. No statistically significant correlations were identified between OPN and total calcium, calcium corrected for albumin, albumin, phosphorus, ferritin, WBC, and PLT CT ($p > 0.05$).

Conclusions: OPN levels are significantly elevated in ESRD patients. Furthermore, OPN levels were also found to be positively correlated with the bone turnover biomarkers iPTH and alkaline phosphatase. These studies suggest that hyperparathyroidism secondary to ESRD increases circulating iPTH, stimulating osteoblast and osteoclast activation and differentiation that increases alkaline phosphatase and OPN production, ultimately resulting in increased bone turnover.

TH-PO590

Infilling of Individual Cortical Pores in the Setting of CKD

Elizabeth A. Swallow,[1] Corinne E. Metzger,[1] Max A. Hammond,[2] Tom Nickolas,[3] Sharon M. Moe,[1] Matthew R. Allen.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University - Purdue University Indianapolis, Cincinnati, OH; [3]Columbia University Medical Center, New York, NY.*

Background: Cortical porosity is the most prominent skeletal phenotype in the setting of chronic kidney disease (CKD), and likely contributes to the increased fracture risk in CKD. Reducing cortical porosity is likely to confer improved bone mechanical properties yet data on this topic are limited. Although strategies aimed at prevention of cortical porosity development would be ideal, a more likely clinical scenario would require that existing cortical porosity be reduced through pore infilling. The purpose of this work was to test the hypothesis that cortical porosity can be reversed indicating porosity infilling.

Methods: Skeletally mature male rats (n=6) with established CKD (BUN > 2x normal age-matched animals and PTH values of ~500-2500 pg/mL) were scanned with high resolution CT before and after 5 weeks of 3% calcium drinking water to suppress PTH.

Results: Baseline imaging showed cortical porosity of the distal tibia ranging from 0.5% to 10.1% across the six animals. After 5 weeks of treatment PTH values ranged from ~30-80 pg/mL, BUN was unchanged, and cortical porosity was < 1% in all animals. Using a newly developed MATLAB program that allows tracking of individual pores, the overwhelming majority of pores (93%) completely filled in over the 5 week period while 6% of pores became smaller and only 2% of pores newly developed. Preliminary analysis on kidney transplant patients (n=2), using high-resolution peripheral CT scans of the distal tibia, show that that over 60% of the pores either completely infill or get smaller one year following kidney transplant. This was offset by newly formed pores or pores that got larger over the year, resulting in overall porosity being unchanged.

Conclusions: These data confirm that in the setting of CKD, cortical pores can fill in and that analysis methods that tracking individual pores over time provides a unique view of the dynamic changes to cortical bone porosity.

Evaluation of Provincial Initiatives in Integrated Renal Palliative Care: A Baseline Assessment of Pre-Implementation Patient Perspectives

Alice Wang,[2] Sarah A. Thomas,[1] Sushila Saunders,[1] Adeera Levin,[3] Gaylene M. Hargrove,[4] Juliya Hemmett.[1] *[1]BC Renal, Vancouver, BC, Canada; [2]UBC, Richmond, BC, Canada; [3]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [4]Island Health, Victoria, BC, Canada*.

Background: Early goals of care (GOC) conversations show improved patient outcomes and reduced health care costs. However, content and timing of these conversations have been variable. BC Renal has recently implemented a province-wide multipronged approach to improve palliative care in nephrology, which requires systematic evaluation to demonstrate efficacy as part of ongoing quality improvement. Patient perspectives are presented here as part of a larger evaluation framework. Our objectives were to assess baseline advanced directives experiences and perspectives in patients with advanced renal disease (CKD, peritoneal dialysis, home hemodialysis and in-center HD) across 5 health authorities in British Columbia (BC).

Methods: Interventions include: 1)Serious illness conversation guide (SICG) workshops at regional meetings and implementation of a "train the trainer" SICG program, 2)Online best practice guidelines to GOC and renal disease symptom management, and 3)Online patient resources. Pre-implementation telephone interviews (~15 minutes each) were conducted with 30 randomly selected patients across BC. Interviews were analyzed quantitatively for patients' involvement in GOC and qualitatively for common themes. Following baseline assessment, a 1 year follow up across all jurisdictions in BC will be undertaken to evaluate improvements to the palliative care approach.

Results: 67% of patients interviewed have advanced directives and living wills; this is more common in patients on dialysis (75%) than in patients with CKD (50%). Only 30% of patients had detailed discussions with their health providers about life-sustaining therapy or palliation in case of a life-threatening condition; this varied across health authorities. While most patients did not find GOC discussions to be difficult, they would prefer if providers initiated discussion at multiple time points and had more time to provide information.

Conclusions: This baseline patient perspective assessment informs strategies for improvement in the quality, quantity, timing and frequency of GOC discussions. The provincial integrated palliative nephrology initiative targeting these identified gaps in care will be evaluated in 1 year as part of a holistic evaluation framework.

TH-PO592

Evaluation of Provincial Initiatives in Integrated Renal Palliative Care: A Baseline Assessment of Pre-Implementation Clinician Practices

Juliya Hemmett,[1] Alice Wang,[2] Sarah A. Thomas,[1] Sushila Saunders,[1] Adeera Levin,[3] Gaylene M. Hargrove.[4] *[1]BC Renal, Vancouver, BC, Canada; [2]UBC, Richmond, BC, Canada; [3]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [4]Island Health, Victoria, BC, Canada*.

Background: Early goals of care (GOC) conversations show improved patient outcomes, enhanced quality of life, and reduced health care costs. However, content and consistency of these end of life discussions have been variable. Based on a recent needs assessment from renal care providers, BC Renal has implemented a multipronged approach to improve palliative care in nephrology. This large-scale project requires systematic evaluation to demonstrate efficacy as part of ongoing quality improvement. Our objective was to assess baseline quantity and quality of GOC directives and discussions documentation in patients with advanced renal disease across 5 health authorities in British Columbia (BC).

Methods: This study has a one year duration, and includes all renal units in health authorities across BC. Interventions include: 1)Serious illness conversation guide (SICG) workshops at regional meetings and implementation of a "train the trainer" SICG program, 2)Online best practice guidelines to GOC and renal disease symptom management, and 3) Online patient resources. A pre-implementation chart audit was conducted on 30 randomly selected charts from CKD and dialysis clinics. The contents of the chart audit included: 1) Presence and location of GOC directive and GOC discussion, 2) Correlation between chart data and provincial renal database (PROMIS), and 3)Evaluation of GOC as per the SICG framework.

Results: The chart audit showed the majority of patients had GOC directives documented (80%), most within the last year (57.6%). GOC discussions were less commonly documented (47%); wide variability across health authorities (0-100%) existed. Documentation regarding GOC was sparse in PROMIS (23%). Prognosis and patients' level of understanding was frequently documented during GOC discussions (92.3% & 69%), patients' goals and involvement of family was less frequent (53% & 46%).

Conclusions: Our pre-implementation baseline assessment informs that room for improvement in the quantity of GOC discussions as well as consistency in documentation across health authorities and in PROMIS exists. Documenting family involvement and patient goals can be improved. This baseline data will guide further quality improvement initiatives.

TH-PO593

Artificial Intelligence Hospitalization Risk Model-Guided Selection for Enhanced Psychosocial Care

Sheetal Chaudhuri,[1] Jessica Demaline,[3] Stephanie Johnstone,[1] Amy R. Weissman-Hunt,[1] Hao Han,[1] Yue Jiao,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Dugan Maddux,[1] Franklin W. Maddux.[2] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Medical Care, Waltham, MA; [3]Fresenius Health Partners, Austin, TX*.

Background: A large dialysis organization (LDO) leverages an artificial intelligence (AI) risk model to help guide screening for a Social Work Intensive (SWI) program in value-based care (VBC) settings. SWI provides enhanced psychosocial care to improve quality of life, thereby reducing hemodialysis (HD) non-adherence/hospitalizations. In conventional models, patients are screened for SWI based on team identification of non-adherence or difficulty achieving outcome goals. We assessed if AI-directed SWI enrollment in VBC yielded comparable benefits to conventional clinician-based paradigms. The statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of the Centers for Medicare & Medicaid Services (CMS). The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Methods: We used data from patients enrolled in SWI in 2017. In VBC, a 12-month hospital admission risk model guided SWI screening. In conventional care, SWI screening was based on clinician evaluation of risk. Patients screened positive for barriers in depression, stress, and sleep were enrolled into SWI and provided tailored weekly interventions for 8 weeks. We calculated admission and HD non-adherence 3 months before and after SWI enrollment in VBC and conventional settings.

Results: Among 6425 patients (conventional n=4646, VBC n=1779) enrolled in SWI program, hospital admission rates were similar before SWI enrollment between care settings, but HD non-adherence rate was lower in VBC settings. Admission and HD non-adherence rates were consistently lower 3 months after SWI enrollment in both a VBC and conventional setting (Figure 1A & B).

Conclusions: AI-directed SWI screening and enrollment in VBC appears to have consistent improvements in outcomes compared to clinician-based identification of risks in conventional settings. Use of this AI technology may help streamline efforts and allowing more time to focus on patient care.

A Qualitative Exploration of Treatment Burden and Its Impact on Quality of Life Among CKD Patients in Qatar

Fadwa M. Al-Ali,[1] Asma M. Almansouri,[1] Abdullah I. Hamad,[1] Nadir Kheir,[3] Mohamed Izham,[2] Rania A. Ibrahim,[1] Ahmed Awaisu.[2] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Qatar University, Doha, Qatar; [3]University of Auckland, Aukland, New Zealand*.

Background: Chronic kidney disease (CKD) patients typically experience comorbidities and complications resulting in complex treatments. Treatment-related burden ultimately impair adherence and quality of life (QoL). Quantifying treatment-related burden and QoL using quantitative measures may not provide an in-depth understanding of this phenomenon. We performed a study to qualitatively explore and describe treatment-related burden and its impact on QoL among CKD patients in Qatar.

Methods: One-to-one semi-structured interviews with CKD patients were conducted. An interview guide was developed based on literature review, conceptual model and discussions among the research team members. The interview questions addressed several components including facing life limitations and stressors (physical, psychological, social, financial and nutritional). The interviews were audio-recorded, transcribed verbatim, and analyzed thematically.

Results: Randomly selected twenty-four CKD patients (10 pre-dialysis and 14 hemodialysis) of diverse characteristics were interviewed. Two themes related to the factors that reduce perceived treatment burden and improve patients' QoL emerged: (1) religion and faith in God; (2) quality of the care provided (including health care providers and facility quality and establishing family-like environment). On the other hand, five themes related to the factors that increase perceived treatment burden and worsen patients' QoL emerged from the interviews: (1) medication burden (polypharmacy, side effects, medication formulation, and non-adherence); (2) lifestyle changes imposed on CKD patients; (3) challenges with international travels; (4) financial burden and; (5) empathy.

Conclusions: Qualitative Thematic analysis has yield two factors that reduced perceived treatment burden and improved patients' QOL; religion and faith in God, and quality of the care provided. Medication burden, life style changes, challenges with international travelling, financial burden, and empathy were factors that worsen perceived treatment-related burden and HR-RQOL. Our study suggests that identified factors that increase treatment-related burden should be considered when designing healthcare interventions directed toward CKD population

TH-PO595

Profiles and Determinants of Dialysis Recovery Time in Incident Hemodialysis

Yue Jiao,[2] Vladimir Rigodon,[3] Murilo H. Guedes,[5] Roberto Pecoits-Filho,[5] Juliana E. Leme,[5] Jochen G. Raimann,[4] Peter Kotanko,[4,7] Thyago P. Moraes,[5] Ravi I. Thadhani,[6] Franklin W. Maddux,[1] Len A. Usvyat,[2] John W. Larkin.[2,5] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Frenova Renal Research, Waltham, MA; [4]Renal Research Institute, New York, NY; [5]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [6]Cedars-Sinai, Los Angeles, CA; [7]Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Hemodialysis (HD) is lifesaving, yet can associate with symptoms (e.g. nausea, cramping and fatigue). Dialysis recovery time (DRT) surveys capture the perceived time after HD to return to performing regular activities. We characterized the profiles and determinants of DRT in incident HD treated at a large dialysis organization (LDO) in the United States.

Methods: We used data at an LDO during 2014 through 2017 for patients who completed a DRT survey ≤180 from first date of HD. DRT survey was administered as part of KDQOL questionnaire. DRT survey asks: "How long does it take you to be able to return to your normal activities after your dialysis treatment?". Categorical answers were: <0.5, 0.5-1, 1-2, 2-4, >4 hours. Distinctions in demographic and clinical variables were assessed between DRT categories, with <0.5 hours as a reference.

Results: We analyzed data from 98616 HD patients who completed the DRT survey in the first 180 days of HD. Patients were 62.6±14.4 years old, 57.8% male, 69.1% white race, 64.7% used a catheter. Incident HD patients typically had a DRT <1 (19.1%) or >4 hours (22.9%). All demographic and clinical variables had some association with longer DRT categories compared to a DRT <0.5 hour, with exception of HD treatment time, interdialytic weight gain, and phosphate levels. Select variables are noted in Table 1.

Conclusions: More than 20% of incident HD patients report a DRT >4 hours. Longer DRTs are associate with most demographic and clinical variables. Remarkable factors associated with longer DRTs include: catheter use; lower albumin, sodium and iPTH levels; lower Kt/V, ultrafiltration volume by body weight, ultrafiltration rates, and treatment frequency. Patient centered strategies to optimize the HD therapy need to be tested and may have potential to improve how patients feel from HD and enhance their quality of life.

Funding: Commercial Support - Fresenius Medical Care North America

TH-PO596

Impact of Elobixibat on Chronic Constipation in Patients on Hemodialysis Assessed Using the Patient Assessment of Constipation-Quality of Life Questionnaire

Daigo Kamei,[1] Yuiko Kamei,[2] Masashi Nagano,[3] Michio Mineshima,[1] Kosaku Nitta,[1] Ken Tsuchiya.[1] *[1]Tokyo Women's Medical University, Tokyo, Japan; [2]Tokyo Metropolitan Health and Medical Treatment Corporation, Tokyo, Japan; [3]Nerima Sakuradai Clinic, Tokyo, Japan*.

Background: Hemodialysis patients are prone to constipation caused by fluid restriction, water removal, food restriction, complications, and drugs among other causes, and their quality of life (QOL) is adversely affected. Elobixibat is a highly selective inhibitor of an ileal bile acid transporter, leads to the augmentation of bile acid levels in the colon, and subsequently enhances colonic motility and secretion. Administration of elobixibat to hemodialysis patients with chronic constipation may improve QOL by a novel mechanism of action. However, the impact of elobixibat on chronic constipation in patients on hemodialysis has not been reported to date. This study aimed to evaluate the effect of elobixibat on the QOL of hemodialysis patients with chronic constipation.

Methods: This was a multicenter study. We used the Japanese version of the Patient Assessment of Constipation-Quality of Life (PAC-QOL) questionnaire. Altogether, 26 patients (18 males and 8 females) aged from 47–90 years, who satisfied the Rome 3 diagnostic criteria for functional constipation were enrolled. These patients were additionally administered elobixibat 10 mg/day and responded to the PAC-QOL questionnaire at baseline and after 4 weeks. Bayesian statistics were used to confirm our results.

Results: The number of spontaneous bowel movements per week increased significantly from 2.5 ± 1.2 to 4.0 ± 2.0 ($p < 0.001$). The Bristol Stool Form Scale score significantly improved from 1.8 ± 0.8 to 3.6 ± 0.7 ($p < 0.001$). The physical discomfort score decreased significantly from 1.92 ± 0.82 to 0.99 ± 0.74 ($p < 0.001$). The psychosocial discomfort score decreased significantly from 1.19 ± 0.95 to 0.64 ± 0.60 ($p < 0.001$). The worries/concerns and satisfaction scores also decreased significantly from 1.87 ± 0.75 to 1.28 ± 0.61 ($p < 0.001$) and 2.80 ± 0.62 to 1.94 ± 0.79 ($p < 0.001$), respectively. The total PAC-QOL score showed a significant decrease from 1.85 ± 0.69 to 1.18 ± 0.58 ($p < 0.001$). Bayesian statistics confirmed the significance of these results.

Conclusions: Administration of elobixibat to hemodialysis patients with chronic constipation reduced the scores of PAC-QOL and improved the patients' QOL. Elobixibat may therefore serve as a new option for the treatment of constipation in hemodialysis patients.

TH-PO597

Dietary Patterns Associated with Kidney Function Decline and Incident CKD in the General Population: The LifeLines Cohort Study

Qingqing Cai, Louise H. Dekker, Martin H. De Borst, Gerjan Navis. *University Medical Center Groningen, Groningen, Netherlands*.

Background: Nutrition strongly impacts the incidence and progression of chronic kidney disease (CKD). Recently, reduced rank regression (RRR) has emerged as a method that identifies dietary patterns in an exploratory way while using prior knowledge to select a set of response variables. The aim of this study was to identify a specific dietary pattern associated with renal function using RRR, and to evaluate its association with CKD incidence.

Methods: We included 78,350 participants from the LifeLines population-based cohort in the Northern Netherlands. All participants were free of CKD (defined as $eGFR_{CKD\text{-}EPI}$ <60 mL/min/1.73 m^2) at baseline and completed a second visit four years later. Dietary intake was ascertained with a 110-item food frequency questionnaire. The dietary pattern, stratified by sex, was constructed cross-sectionally by RRR, with eGFR as a response variable. Multivariable logistic regression was used to study the association between dietary patterns score and CKD incidence or an eGFR decline of ≥20%, adjusted for potential confounders.

Results: Among women, the eGFR-associated dietary pattern was characterized by high intake of eggs, low-fat and high-fat cheese, and legumes and low consumption of sweetened dairy drinks, desserts, cake and cookies, sweet sandwich toppings, white meat,

and commercially prepared dishes. The male dietary pattern was characterized by high consumption of high-fat and low-fat cheese, bread, full-fat milk, fruits, vegetables, beer, and low consumption of white and red meat. After a mean follow-up of 3.9 years, 7,612 participants experienced a >20% eGFR decline and 2,072 participants developed CKD. The eGFR-based diet was associated with a lower risk of eGFR decline (OR 4th vs 1st quartile, women: 0.84 [95% CI 0.76-0.92]; men: 0.74 [0.65-0.84] and of incident CKD (women: 0.60 [0.50-0.73]; men: 0.52 [0.41-0.66]).

Conclusions: The results provide support for potential diet interventions to prevent renal function decline and CKD. RRR may be a useful tool for identifying dietary patterns that affect renal function and CKD development.

TH-PO598

The Impact of Eating During Hemodialysis Treatment on Nutritional Measures in In-Center Hemodialysis Patients

Brandon Kistler,[1] Mickala Ritter,[1] Jagdish Khubchandani,[1] Connie Rhee,[2] Kamyar Kalantar-Zadeh.[3] *[1]Ball State University, Muncie, IN; [2]University of California Irvine, Huntington Beach, CA; [3]University of California Irvine, School of Medicine, Orange, CA.*

Background: Poor nutritional status is common among patients receiving hemodialysis (HD) treatment. Providing nutrition during HD treatment may improve nutritional status and outcomes, but remains controversial. This has led to the adoption of different in-center dialysis unit nutrition policies. Therefore, we sought to examine the relationship between policies on food intake during treatment and nutrition-related measures.

Methods: We analyzed data from Phase 5 of the Dialysis Outcomes and Practice Patterns Study (DOPPS) to look at the relationship between baseline nutrition-related measures (serum levels of albumin, phosphorus, potassium, and body mass index (BMI)) and clinic policy related to eating during HD (not allowed, patients may eat food provided by clinic, patients may bring food from home, or patients may eat food provided by clinic and/or brought from home). We limited our analysis to only countries with clinics utilizing all four policies on eating during HD. Nutritional measures were compared by ANCOVA with individual differences determined by least square difference post-hoc. Additionally, the odds of having an albumin >3.4 g/dl were determined by multivariable logistic regression.

Results: Among 5,358 HD patients (61% male, age 66±15 years, vintage 4±6 years) included in the analysis, serum albumin and potassium were highest and phosphorus the lowest in patients dialyzing at clinics that provided food during HD ($p<0.05$). Body mass index (BMI) was highest among patients dialyzing at clinics that allowed patients to bring their own food. Compared to patients who dialyzed at clinics where they were not allowed to eat, the odds of having an albumin above 3.4g/dl was higher in those dialyzing at clinics where food was provided by the clinic (Adjusted OR=2.0, 95% CI 1.6-2.6) and those with food provided by the clinic and also allowed to bring their own food (Adjusted OR=1.6, 95% CI 1.3 – 2.0).

Conclusions: Patients who dialyze at clinics that provide food during HD treatment exhibit higher serum albumin, higher potassium, and lower phosphorus levels than patients who dialyzed at other clinics. Whether in-center nutrition and eating policies contribute to differences in other clinical outcomes including quality of life, hospitalizations, and mortality warrants additional studies.

TH-PO599

Improved Diet, Sleep, and Strength Among CKD Patients Following 6-Week App Intervention with Personalized Mentoring

Nataliia Karpenko,[2,1] Benjamin T. Dorn.[2,1] *[1]RenalMate, Greenbrae, CA; [2]Livzo, Campbell, CA.*

Background: CKD is a long-term condition which affects approximately 14% of the general population in the United States. CKD influences circulatory dysfunction, anaemia, malnourishment, strength degeneration, muscle integrity, glucose imbalance, and decreased bone thickness. Additionally, up to one third of CKD patients have depression. For CKD patients, adherence to the CKD diet is critical for maintaining quality of life, yet few studies have focused on methods to improve and maintain patients' adherence

Methods: In our trial 6-week "Remote Chronic Disease Management" Programme, nine (9) patients at various stages of CKD consented to participate and were provided with a smartphone app called RenalMate. The app allows for daily monitoring of self-reported data (Food log, Sleep, Stress and Activity Level), as well as a remote connection to fitness, dietician, and health mentors. Importantly, the social community and mentoring team provided accountability for the self-reported data tracking and diet/exercise adherence. In addition to daily feedback from coaches and other patients, participants were given weekly progress reports during individualized teleconference sessions with their coach

Results: By the end of the 6-week program, 78% of participants lost weight, and of those 14% lost 17-20 pounds and 72% lost 3-6 pounds. 89% of participants improved their strength during the programme. 71% of participants reduced their stress level from high/very high to medium/ low. 89% either increased their nightly hours of sleep or maintained a healthy 7-8 hours. These improvements were also seen by the participants. 89% felt more restful with higher levels of energy by the end of the programme. 72% felt they improved their diet overall. And most importantly, 100% said they would recommend the programme to a friend

Conclusions: This combination of self-reporting, comprehensiveness of data tracking, as well as the use of a specialized social app and weekly teleconferences with coaches represents a novel and scalable approach to CKD management. Participants improved in both quantitative and qualitative measures of health. Future studies should expand on the role of education and the long-term impact of such programmes, involving wider multidisciplinary teams (MDT) for example, healthcare scientists to provide CKD patients education surrounding laboratory parameters

TH-PO600

Development of an International Standard Set of Nutritional Priorities for Patients with Non-Dialysis CKD

Vincenzo Bellizzi,[1] Juan J. Carrero,[2] Philippe Chauveau,[6] Patrizia Calella,[4] Lina Johansson,[5] Pablo Molina,[7] Siren Sezer,[8] Denis Fouque.[3] European Renal Nutrition (ERN) working group at the European Renal Association–European Dialysis and Transplant Association (ERA-EDTA). *[1]University Hospital "San Giovanni di Dio e Ruggi d'Aragona", Salerno, Italy; [2]Karolinska Institutet, Stockholm, Sweden; [3]University Claude Bernard, Pierre Benite, France; [4]Azienda Ospedaliera Universitaria OO.RR. San Giovanni di Dio Ruggi d'Aragona, Salerno, Italy; [5]Imperial College Healthcare NHS Trust, London, United Kingdom; [6]Aurad-Aquitaine, Gradignan, France; [7]Department of Nephrology. Hospital Universitario Dr Peset., Valencia, Spain; [8]Atilim University Faculty of Medicine, Ankara, Turkey.*

Background: Protein energy wasting is common in CKD and associated with poor outcome. Many studies have been conducted to improve nutrition in CKD, but outcomes may not be relevant to patients / clinicians and are variable. These problems can diminish the value of interventions as means to improve patient's lives. This project aims to identify areas of intervention and improvement in nutritional management of non-dialysis CKD based on shared priorities of stakeholders.

Methods: This Delphi consensus project involved 4 phases: systematic review to identify topics reported in studies involving nutritional outcomes (domains, measures) in non-dialysis CKD; review round of topics by 10 expert nephrologists in nutritional care; second review round by 105 Stakeholders (dietitians, nurses, patients) to refine the international Delphi survey to be distributed worldwide (Dec.2018 – May.2019) to patients, caregivers, clinicians, researchers, to develop consensus on clinical and research priorities in nutrition in non-dialysis CKD. The survey included 60 topics grouped in 5 categories, 11 sub-categories. Participants were invited to rate topics priority (importance) by 9-point Likert scale. Consensus for topic prioritization was defined as the combination of median ≥7 and ≥70% participants scoring 7-9 and <15% scoring 1-3 on the Likert.

Results: 1.224 subjects completed the survey; 43% were physicians, 25% dietitians, 16% patients, 8% nutritionists and 8% nurses; 62% were female and 87% from Europe. 30 topics reached priority consensus by health-care providers; patients gave priority to only 15 topics. All stakeholders agreed with prioritizing topics supporting patients to choose and personalize of diet; patients gave low priority to common issues of research interest, low-protein, low-sodium, renal progression (<65%), energy, quality proteins, malnutrition (<55%), or no priority, very-low, vegetarian, DASH, Mediterranean diets (<25%).

Conclusions: This project emphasizes agreements and disagreements among stakeholders in what matter the most regarding nutritional care management of patients with non-dialysis CKD. These differences should be considered in research and clinical practice; establishing targets to prioritize will enhance the relevance and impact of research and patient care.

TH-PO601

Clinical Significance of Nutritional Predictors in Prevalent Hemodialysis Patients

Eunjin Bae,[1] Junhyeong Cho,[4] Jeonggu Na,[1] Tae won Lee,[2] Ha nee Jang,[3] Se-Ho Chang,[2] Dong Jun Park.[1] *[1]Gyeongsang National University Changwon Hospital, Changwon, Republic of Korea; [2]Gyeongsang National University Hospital, Changwon-si, Gyeongsangnam-do, Republic of Korea; [3]Gyeongsang National Univ. Hospital, Jinju, Republic of Korea; [4]Changewon Gyungsang National University, Chang-won, Republic of Korea.*

Background: Nutrition has been consistently important in end stage renal disease patients. However, it is difficult to obtain adequate nutritional status while avoiding fluid overload, hyperphosphatemia and hyperkalemia in hemodialysis patients. We studied the clinical significance of serum albumin and other nutritional markers in maintenance hemodialysis patients.

Methods: We retrospectively enrolled patients who received hemodialysis for more than 3 months from 2016 to March 2019, excluding patients who died within 30 days. We evaluated the factors associated with all-cause mortality and major adverse cardiovascular events (MACE). In addition, we investigated factors related with sarcopenia defined as skeletal muscle mass index (SMI) ≤10.75 kg/m^2 (men) or ≤6.75 kg/m^2 (women) by using a BIA machine (InBody S10; Biospace, Korea).

Results: Of 284 patients, 63.7% were men, mean age was 64.2 ± 12.4 years, mean body mass index (BMI) was 23.7 ± 6.9 kg/m^2, and the most common underlying disease were hypertension and diabetes. During a median follow up of 16.7 months, 13.7% (n=39) patients experienced a MACE, 12.3% (N=35) patients died. In multivariate Cox analyses, lower albumin, higher CRP level and history of CVD were significantly related with all-cause mortality even after adjustment for covariates. SMI had a significant positive correlation with BMI, serum phosphorus, BUN, creatinine and uric acid level. SMI was not predicted all-cause mortality in total group, but was significantly predicted all-cause mortality in diabetes subgroup. In the logistic regression analyses, older, lower BMI, diabetes and male sex were significantly associated with sarcopenia. In addition, higher serum calcium, phosphorus level, history of CVD, cerebrovascular accident (CVA) were significantly associated with MACE.

Conclusions: In prevalent hemodialysis patients, nutrition, inflammation and precious CVD are the major risk factors for all-cause mortality. SMI might be an important predictor for all-cause mortality in diabetic patients. In patients with history of CVD or CVA, management of serum calcium and phosphorus is particularly important in aspect of MACE.

TH-PO602

Association of Inflammation with Dynapenia and Sarcopenia in Hemodialysis Patients: A Pilot Observational Study

Rajesh B. Kumar,[1] Rachana H. Jasani,[1] Paras Dedhia,[1] Viswanath Billa,[2] Shrirang Bichu,[2] J. Kothari,[3] Alam Mohd shah,[1] Virendra Gupta.[1] Apex Kidney Care *[1]Apex Kidney Care, Mumbai, India; [2]Bombay Hospital, Mumbai, India; [3]Hinduja Hospital, Healthcare & Apex Kidney Foundation, Mumbai, India*.

Background: Chronic inflammation is directly related to an increased cardiovascular mortality in hemodialysis patients. Low muscle strength (dynapenia) and low muscle strength in addition to decreased skeletal muscle mass (sarcopenia) often coexist with obesity in chronic hemodialysis patients. The main aim was to study the association of inflammation with sarcopenic obesity (SO) and dynapenic obesity (DO) in chronic hemodialysis patients.

Methods: High sensitivity C-reactive protein (hs CRP) was estimated using Nephelometry. hsCRP >10 mg/L was considered positive for inflammation. Body Composition Analysis through bioelectrical impedence was utilized to assess body fat and lean tissue index (LTI). Muscle strength was determined using handgrip strength (HGS) analysis. Dynapenia was defined by HGS <26 kg for men and < 18 kg for women. Sarcopenia was defined as LTI <10.7 kg/m^2 in men and <6.7 kg/m^2 in women. Obesity was defined as percent body fat > 25% in men and > 35% in women. Prevalence of inflammation in patients with DO and SO was reported.

Results: Of 81 patients, 49 were males. Their average age was 56.9± 16.1 years and average dialysis vintage was 2.9±2.4 years. All patients were on thrice a week hemodialysis. The etiology of kidney disease was diabetic kidney disease in 49%, hypertension in 31%, chronic tubulo interstitial disease in 7%, chronic glomerulonephritis in 4% and others in 9% patients. Mean hsCRP of was 12.4±11.9 mg/L. The overall prevalence of DO was 20.9% and SO was 16%. The prevalence of inflammation in patients with DO was 52.9% and without DO was 47.0%. The prevalence of inflammation in patients with SO was 46.1% and without SO was 37.1%. The prevalence of inflammation in diabetic patients with DO was 66.5% and that in diabetic patients with SO was 59.8%.

Conclusions: The prevalence of inflammation was higher in patients with both DO as well as SO, especially in diabetic population. Further long term studies are needed to assess the relationship between DO, SO and inflammation and their outcomes in hemodialysis population.

TH-PO603

Simultaneous Use of Bioimpedance Vectors Analysis (BIVA) for Dry Weight Adjustment and Oral Nutritional Supplementation in Hemodialysis Patients

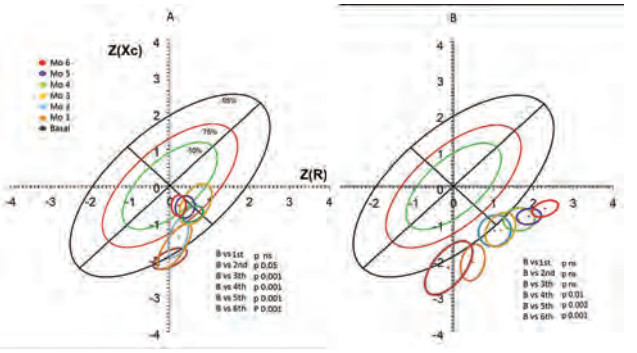
Iris Nieves-Anaya,[2] Enrrique Torres-Mendoza,[3] Mónica B. Vargas ojeda,[4] Ximena Atilano carsi.[1] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, Mexico; [2]Universidad Autónoma de Queretaro, Queretaro, Mexico; [3]Hospital General ISSSTE Queretaro, Queretaro, Mexico; [4]Universidad Autónoma de Querétaro, Querétaro, Mexico*.

Background: Protein energy wasting and overhydration are two complications present in renal patients that must be treated simultaneously. The objective of this study was to compare the effectiveness of the simultaneous use of BIVA and oral nutritional supplementation against the exclusive use of BIVA on the nutritional status and body composition of patients on hemodialysis

Methods: Patients were randomized in two groups for 6 months intervention. In both groups, dry weight was adjusted by BIVA as necessary to reach euhydration. Group A (n=17) an individualized diet plus one can of nutritional supplement was given daily to patients. Group B (n=15) only the specific diet was provided. Nutritional status was evaluated with the Malnutrition Inflammation Score (MIS) and handgrip strength was measured at the beginning and the end of the study

Results: Mean age was 55.76 ± 17.6 years for group A and 53.71 + 11.8 for group B, dialysis vintage 24.47 ± 5.08 months and 18.88 ± 11.04 respectively. No significant baseline differences between groups were found and any patient was well nourished. After intervention, nutritional status improved significantly in group A, from 47 to 83% for mild undernutrition and from 53 to 17% for moderate undernutrition ($p<0.05$), while in group B, nutritional status worsened from 53 to 27% for mild undernutrition and from 47 to 73% for moderate undernutrition ($p<0.05$). Handgrip strength was increased in 58% of patients in group A and 21% in group B ($p < 0.03$). Dry weight was achieved in 100% of patients in both groups. At the end of the study, group A vectors indicated less body fluid and better nutritional status, unlike to the vectors of group B which indicated less body fluid but a worse nutritional status. ($p<0.007$ A vs. B)

Conclusions: Conjunctive use of oral nutritional supplementation and bioelectrical impedance vectors analysis, to determine dry weight, improves nutritional status and body composition in patients undergoing hemodialysis



TH-PO604

A Simplified Protein-Energy Wasting Scoring System for Survival Prediction in Korean Incident Hemodialysis Patients

Myung sung Kim,[1] Young Eun Kwon,[1] Hye Min Choi,[1] Dong-jin Oh,[1] Shin-Wook Kang.[2] *[1]Myongji Hospital, Goyang-si, Republic of Korea; [2]College of Medicine, BK21, Yonsei Univ., Seoul, Republic of Korea*.

Background: Even though protein-energy wasting (PEW) is a crucial risk factor for survival in end-stage renal disease (ESRD) patients, a convenient and reliable assessment method to determine PEW in ESRD patients has not been established. However, a recent study proposed a simplified PEW scoring system based on the PEW diagnostic criteria, which was predictive for European ESRD patients' survival. This study aimed to validate the prognostic significance of the simplified PEW score in Korean incident hemodialysis patients.

Methods: Data were retrieved from a prospective cohort study from the Clinical Research Center for ESRD in Korea. The simplified PEW scoring system is graded from 0 (the worst) to 4 (the best), which consists of four components: serum albumin, body mass index, serum creatinine/body surface area, and normalized protein nitrogen appearance. Since the number of patients in the PEW score 0 group was too small (n=14), the PEW score 0 and 1 groups were combined into a same group. The survivals of the four groups (PEW score 0~1, 2, 3, and 4) were compared by Kaplan-Meier plot, and multiple Cox regression analysis was performed to identify the association between the PEW score and patients' survival.

Results: A total number of 430 patients were included in this study. The numbers of patients in the four score groups were 77 (score 0~1), 158 (score 2), 145 (score 3), and 50 patients (score 4). The mean age was 61.1 years and male was 59.8%. Kaplan-Meier plot revealed that the lowest PEW score group had the worst cumulative survival or there was a significant difference in patient survival across the groups (log-rank test, $P<0.001$); 2-year mortality rates of 15.6% in the score 0~1 group, 8.2% in the score 2 group, 1.4% in the score 3 group, and 2.0% in the score 4 group. In multiple Cox regression analysis, moreover, PEW score was a significantly independent factor for mortality even after adjusting for confounding variables (PEW score 0~1 as a reference; PEW score 2, hazard ratio [HR] 0.450, 95% confidence interval [CI] 0.262–0.772, $P=0.004$; PEW score 3, HR 0.165, 95% CI 0.070–0.385, $P<0.001$; and PEW score 4, HR 0.101, 95% CI 0.013–0.760, $P=0.026$).

Conclusions: A simplified PEW scoring system is a practical and reliable method for predicting mortality in Korean incident hemodialysis patients.

TH-PO605

Malnutrition and Protein Energy Wasting in Pediatric CKD

Carol Shen, Dana Liebstein, Hilda E. Fernandez. *Columbia University NYP Morgan Stanley Children's Hospital, New York, NY*.

Background: Malnutrition (malnut) predisposes CKD patients (pts) to poor growth through hormonal & metabolic derangements, decreased appetite & inflammation. Protein energy wasting (PEW) describes a state of decreased protein stores, associated w/ impaired growth and poor outcomes in peds. Few studies investigate the relationship between malnut, PEW & CKD progression in peds pts.

Methods: Retrospective chart review of pts 0 – 25 yrs with CKD stages 1-5 seen in peds renal clinic from 2013 - 2018. Diagnosis of malnut based on the Consensus Statement of the Academy of Nutrition and Dietetics/American Society for Parenteral and Enteral Nutrition. eGFR calculated by revised Schwartz equation. PEW scores (PEWS) assigned based on peds criteria (Abraham A, et al, 2014). Minimal PEW definition requires any positive test in ≥2 of PEWS categories. Linear regression was performed to determine effect of z-score for height (HZ), weight (WZ), BMI (BMIZ), weight-for-length (WLZ) or PEWS on eGFR. Mixed-effects models performed to determine effect of diagnosis of malnut and PEW on change in eGFR. $P < 0.05$ was significant.

Results: Of 135 pts, 68 (50.3%) were classified as malnut & 50 (37%) met minimal PEW criteria during a median 1.8yrs [0.9-3.5] follow-up. Majority diagnosed w/ malnut were male (65%), white (36%), w/ a median age of 14.2yrs [7.4-17.6], w/ CKD Stage 3 at time of 1st visit (50%) and a congenital anomaly of kidney and urinary tract diagnosis (46%). Majority were diagnosed with malnut based on Decline in Weight/Height Z-score (38%) using 2 data points as indicators. Linear regression showed no significant effect of

HZ, WZ, BMIZ, WLZ or PEWS on eGFR. Mixed-effects analysis of eGFR in pts w/ & without diagnosis of malnut demonstrate a significant worsening decline in eGFR for pts w/ malnut (-2.44 vs -1.41ml/min/1.73m^2/yr, p<0.001). Mixed-effects analysis of eGFR w/ diagnosis of malnut showed no significant difference in eGFR decline before or after diagnosis of malnut. Pts who met minimal PEW criteria had a significant worsening decline in eGFR compared to those who did not (-2.44 vs -1.72ml/min/1.73m^2/yr, p<0.001).

Conclusions: Malnutrition and PEW are common in peds with CKD. Our preliminary data demonstrate a trend in mild/moderate CKD for worse eGFR decline in pts with malnut and PEW. Future study will further characterize relationship between malnutrition, PEW and peds CKD outcomes.

TH-PO606

The Effect of Oral Pioglitazone on Muscle Protein Breakdown in Peritoneal Dialysis Patients: A Randomized Controlled Trial

Morakot Muthanugulwong, Bancha Satirapoj, Pamila Tasanavipas, Narittaya Varothai, Paramat Thimachai, Amnart Chaiprasert, Naowanit Nata, Ouppatham Supasyndh. *Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Insulin resistance which occurs common in patients on chronic continuous ambulatory peritoneal dialysis (CAPD) plays an important role in decreasing available glucose and protein for muscle anabolism. Thiazolidinediones is a PPAR receptor agonist with a high ability to increase insulin sensitivity and possibly their anabolic effects on improve sarcopenia.

Methods: A randomized, placebo-controlled trial, 31 CAPD patients (age 57.0±15.2years in pioglitazone group and 60.5±15.4years in placebo group) were randomly allocated into two groups: pioglitazone (15 mg/day) and placebo for 16 weeks. Sarcopenia biomarkers include serum myostatin level and body composition by Dual-energy X-ray absorptiometry (DXA) were determined before and after the intervention.

Results: At baseline, serum myostatin level was 6.40±3.14 ng/mL in pioglitazone group and 5.12±3.53 ng/mL in placebo group and relative skeletal muscle index was 7.14±1.18 kg/m^2 in pioglitazone group and 6.52±1.33 kg/m^2 in placebo group. Serum myostatin level significantly decreased in the pioglitazone group compared to the placebo group at 8 weeks (-1.32 (95%CI -1.98 to -0.66) vs. 0.56 (95%CI -0.48 to 1.61) ng/mL; P=0.003) and at 16 weeks (-2.32 (95% CI -3.11 to -1.53) vs. 0.10 (95% CI -0.71 to 0.92) ng/mL; P<0.001). However, relative skeletal muscle index, fat mass and body weight did not change significantly in the both groups. No significant changes were observed in blood pressure, fasting plasma glucose, hemoglobinA1C, and serum creatinine compared with baseline in either group. No serious side-effects including hypoglycemia and heart failure was detected.

Conclusions: The study indicates that 16-weeks of pioglitazone treatment reduced the serum sarcopenia biomarkers but showed no effect on the muscle mass in no diabetic CAPD patients.

TH-PO607

Muscle Quality Assessment by Texture Analysis on ^{1}H-Magnetic Resonance Images in CKD Patients

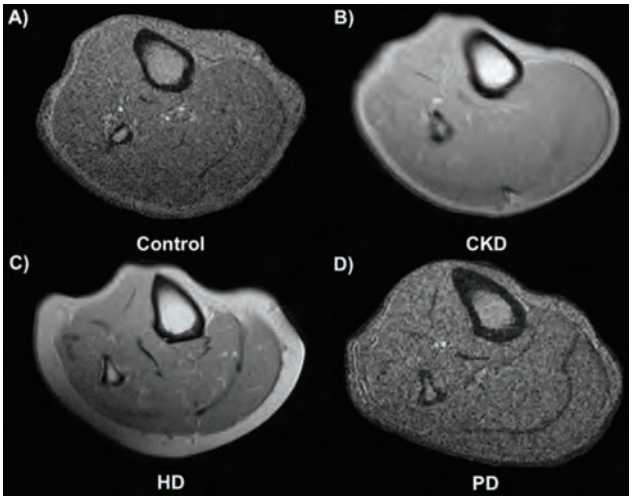
Lisa Hur,[1] Fabio R. Salerno,[1] Alireza Akbari,[2] Christopher W. McIntyre.[2] *[1]Western University, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada.*

Background: Chronic kidney disease (CKD) is associated with reduction in skeletal muscle quality from the interplay of inflammation and malnutrition, resulting in reduced exercise capacity. Muscle quality can be assessed by texture analysis of images acquired by ^{1}H-Magnetic Resonance Imaging (MRI). The study objective is to compare muscle quality using MR images between healthy controls, CKD, hemodialysis (HD) and peritoneal dialysis (PD) patients. We hypothesize that progressive CKD and dialysis therapy are associated with muscle quality changes that can be detected by texture analysis.

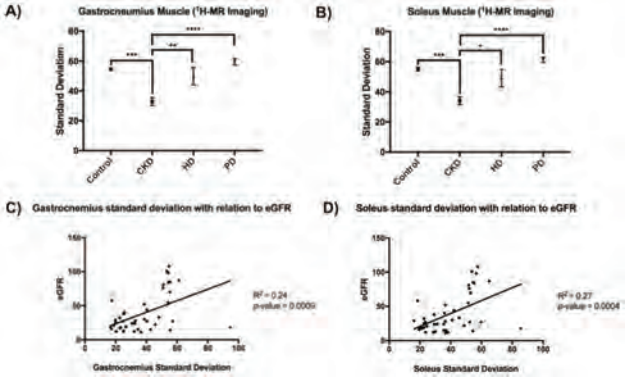
Methods: ^{1}H T1-weighted images of the calf were acquired on control, CKD, HD, and PD patients. Mid-slice was used to delineate the gastrocnemius and soleus muscle. Heterogeneity of the muscle was quantified by the standard deviation (SD) within the regions. One-way ANOVA was used to assess significance between groups. Pearson correlation analysis was completed between estimated glomerular filtration rate (eGFR) and SD of the muscles at CKD stages 1-5 (HD and PD cohort excluded).

Results: Refer to Figures 1 and 2.

Conclusions: Homogeneous characteristics seen in CKD cohort may be indicative of muscle wasting and fibrosis. MRI based quality assessment may provide potential non-invasive evaluation of the uremic state on skeletal muscle structure and function.



Proton T1-weighted MR image of the calf



Mean SD and standard error bars of (A) gastrocnemius (B) soleus muscle in control, CKD, HD, PD. Pearson correlation of SD and eGFR in (C) gastrocnemius (D) soleus muscle.

TH-PO608

Skeletal Muscle Index from CT Scans Can Predict Muscle Strength in CKD

Samuel L. Lampe,[1] Alissa A. Cranor,[2] Kimberly Swinney,[3] Erik Imel,[2] Keith G. Avin,[3] Sharon M. Moe,[2] Ranjani N. Moorthi.[2] *[1]Indiana University Internal Medicine, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University, Indianapolis, IN.*

Background: Sarcopenia is associated with poor clinical outcomes in chronic kidney disease, but is often under-recognized during clinical encounters. Muscle mass and intramuscular fat are measures of muscle quantity and quality but requires DXA and extremity MRIs or CTs. We hypothesize that muscle quantity and intramuscular adiposity, measured on abdominal CT scans done for clinical care, can be used to predict grip strength in patients with CKD stage 5-5D and in healthy patients.

Methods: We studied 19 patients with CKD stages 5-5D and 12 healthy individuals who had measures of grip strength. Records were reviewed for abdominal CT scans performed as part of their clinical care. The regions of interest were muscles at the level of the L3: psoas, erector spinae, quadratus lumborum, transversus abdominus, external and internal obliques and rectus abdominus. Skeletal muscle index (SKMI) and intra-muscular adipose tissue index (IMATI) were calculated as cross-sectional areas, corrected for height (cm^2/m^2) using Hounsfield unit ranges (skeletal muscle: -29 to 150 and adipose tissue: -190 to -30). We used linear regression to determine the independent relationship between SKMI and IMATI respectively with grip strength in univariate analyses and adjusted for covariates.

Results: Mean age was 48.5+/-12.5 y, BMI was 29.2+/-8.1kg/m^2, 55% white and 52% were male. Mean SKMI was 48.9+/-9.1 cm^2/m^2 and was not significantly different between those with CKD and without CKD. On univariate analysis, age, presence of CKD, sex and SKMI were significantly associated with grip strength (all p<0.05). Using multivariate linear regression SKMI, adjusted for sex and presence of CKD was associated to be a significant predictor of grip strength (p=0.014), with the model containing these 3 variables explaining 68% of the variability in grip strength. IMATI was not a signficant predictor of grip strength in univariate or multivariate models.

Conclusions: Incidental CT scans can be used to assess skeletal muscle cross-sectional area which is a useful predictor of hand grip strength. Poor handgrip strength or weakness

is a criteria for detecting sarcopenia in clinical practice and is associated with disability and frailty. Identifying those with probable sarcopenia during routine care provides an opportunity to attempt to intervene to regress or prevent worsening of sarcopenia.

TH-PO609

Hypercatabolism, Body Composition, and Physical Function in Advanced CKD

Na Zhou,[1] Robert E. Boucher,[1] Guo Wei,[1] Amalia Caamano,[1] Tom Greene,[1] Srinivasan Beddhu.[1,2] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]VA SLC Healthcare System, Salt Lake City, UT.*

Background: It has been hypothesized that impaired physical function in CKD is the result of a hypercatabolic state leading to protein and energy wasting. We tested whether basal metabolic rate (BMR) is higher and accounts for impaired physical function in more advanced CKD.

Methods: We examined baseline data in 99 participants of an ongoing physical activity intervention trial (NCT 02970123) expected to be completed in Sep, 2019. Results will be updated with follow-up data for ASN presentation. Standardized protocols were used to measure BMR with indirect calorimetry (MedGem, Microlife Medical, Inc. Golden, CO) and body composition including fat free mass (FFM) and body fat% (BF%) with bioelectrical impedance analysis(Quantum X,RJL Systems, Clinton Township, MI) and physical function with 6-minutes walk distance (6-min WD).

Results: Demographic and clinical data by CKD stages are summarized in Table. Median(IQR) for BMR was 16.3 (14.8,18.2)kcal/kg/day. Mean values for FFM, BF% and 6-min WD in the entire cohort were 61±15kg, 31±10%, and 385±66m respectively. In separate multivariable linear regression models (adjusted for age, gender, race, ethnicity and diabetes), more advanced CKD was not associated with BMR or BF%, had non-significant, negative association with FFM and significant, negative association with 6-min WD (Table). The association of advanced CKD with lower 6-min WD persisted with further adjustment for BMR, FFM and %BF (Table).

Conclusions: Impaired physical function in CKD was not explained by BMR in the current study. Further studies are needed to test whether lack of anabolism rather than hypercatabolism plays a significant role in wasting and frailty in CKD.

Grip Strength at Dialysis Initiation Predicts Hospitalization over Time

Ranjani N. Moorthi,[1] Alissa A. Cranor,[1] Judy Hindi,[1] Kathleen A. Lane,[1] Keith G. Avin,[1] William F. Fadel,[1] Ravi I. Thadhani,[2] Sharon M. Moe.[1] *[1]Indiana University, Indianapolis, IN; [2]Cedars-Sinai, Los Angeles, CA.*

Background: Patients new to dialysis are frequently hospitalized. Currently, prediction models for risk of hospitalization use clinical and demographic factors. Grip strength is an objective measure of muscle weakness that is easily measured in dialysis units and is associated with mortality in prior studies. We hypothesize that grip strength is an independent predictor of the total number of hospital days over 2 years of follow-up in incident dialysis patients, after adjusting for demographic and clinical variables.

Methods: This is a prospective cohort study of 195 incident dialysis patients with grip strength testing at enrollment with a median of 647 days of follow-up. Outcome data from all hospitalizations > 48 hours were collected by patient self-report, and verified in the electronic record. We examined the longitudinal relationship between baseline grip strength as a continous variable with total number of days spent in the hospital in the follow-up period using zero-inflated Poisson regression. Univariate relationships were initially studied, followed by grip strength adjusted for clinical/ demographic variables in multivariate models.

Results: The baseline study population was 53% men with mean age of 54.3±13.3 yrs who were enrolled a median of 92 days after dialysis initiation. Mean grip strength was 27.9±12.8 kg. 60.5% of subjects had at least 1 hospitalization in the follow-up period. The median (IQR) number of hospital days was 6(0-17). 74.6% of hospitalizations were ≤ 8 days in duration. Age, black race, dialysis vintage and modality, diabetic nephropathy as primary kidney disease, residual kidney function and comorbidities (diabetes, cardiovascular disease) and grip strength were univariately associated with increased number of hospital days (all p<0.05). In multivariate models, a 5kg higher grip strength at baseline was associated with a rate ratio of 0.96 (95% CI of 0.94-0.99) or a 4% decrease in total days in the hospitalization in the follow-up period (p=0.0009).

Conclusions: In our cohort of 195 incident dialysis patients, we show that grip strength independently predicts total days in the hospital when added to known predictors of hospitalization in patients on dialysis. Routine measurement of grip strength in those newly starting dialysis may help identify those most at risk of hospitalizations over time.

TH-PO611

Association Between Vitamin D Level and Muscle Strength in Patients Undergoing Hemodialysis

Seok hui Kang,[1] Youn su Lee,[3] Jun-Young Do,[1] Jun Chul Kim.[2] *[1]Yeungnam University Hospital, Daegu, Republic of Korea; [2]CHA Gumi Medical Center, CHA University, Gumi-si, Gyeongsangbuk-Do, Republic of Korea; [3]Yeungnam University Medical Center, Deagu, Republic of Korea.*

Background: Considering conflicting results or heterogeneity in study design, further investigations are needed to identify the definite association between vitamin D level and muscle health. Our study aimed to address these issues and to evaluate the association between vitamin D level and muscle mass indices, strength, or physical performance through comprehensive measurements in patients undergoing hemodialysis.

Methods: This study was performed in a tertiary medical center. We included patients undergoing hemodialysis with age ≥20 years. A total of 84 patients were enrolled. The patients were divided into tertiles based on the 25-hydroxy (25-OH) vitamin D level as follows: lowest tertile (Lowest T, n = 28), middle tertile (Middle T, n = 28), and highest tertile (Highest T, n = 28). We evaluated the association between the tertiles and clinical outcomes including nutritional status, muscle mass, muscle function, handgrip strength (HGS), physical performance, and health-related quality of life scales (HRQoL).

Results: There were no significant differences in the muscle mass indices and nutritional markers according to tertiles of 25-OH vitamin D level. However, 25-OH vitamin D level as a continuous variable or the tertile of 25-OH vitamin D level as a categorical variable was positively associated with HGS. Logistic and linear regression analyses showed a consistent superiority of the Highest T in HGS compared with the Lowest or Middle T. Although the statistical significance was weak, the scores of various physical performance tests and the HRQoL scales were the highest in the Highest T, among the 3 tertiles.

Conclusions: The present study demonstrated that serum vitamin D level is associated with HGS in patients undergoing hemodialysis regardless of muscle mass indices or nutritional status.

TH-PO612

Exploration of Dietary Protein Intake and Skeletal Muscle Mass and Function in Non-Dialysis CKD

Eleanor F. Gore, Thomas J. Wilkinson, Alice C. Smith. Leicester Kidney Lifestyle Team *University of Leicester, Leicester, United Kingdom.*

Background: CKD patients are characterized by skeletal muscle wasting and poor physical function. Poor nutritional intake (of protein and energy) contributes to muscle wasting and loss of physical function in ESRD. However, the role of dietary protein in non-dialysis CKD remains topical. In healthy older adults, higher protein intake protects against sarcopenia and improves physical function. Recent studies suggest restricted protein intake is associated with loss of muscle mass in CKD but these are limited and the non-dialysis CKD population remains insufficiently researched. This study evaluated the relationship between protein intake, muscle mass, and physical function.

Methods: Average daily protein intake (g/kg) for 30 non-dialysis CKD patients (50% male, age 62.8±10.8, eGFR 36.9±20.5) was assessed using a food frequency questionnaire. Participants were categorised as having low protein intake defined by WHO and KDIGO recommendations (<0.8g/kg/day). Total skeletal muscle mass % was measured by bioelectric impedance analysis and rectus femoris muscle size by ultrasound cross-sectional area (CSA). Physical function was assessed using gait speed, handgrip strength, and the short physical performance battery (SPPB). Differences between groups were explored using linear regression (adjusted for age, sex, and ethnicity).

Results: Higher protein intake (≥0.8g/kg/day) was associated with a 15% greater muscle mass, 24% larger rectus femoris CSA, and 11-20% greater lower limb physical function in non-dialysis CKD (see Table 1).

Conclusions: This work suggests a higher dietary protein intake protects against muscle wasting which, in turn, preserves physical function in this group. Further research is required to confirm these findings which suggest efforts to increase protein intake in this group may confer favourable effects on muscle and functional preservation.

Funding: Private Foundation Support

TH-PO613

Uremic Dysbiosis Causes Sarcopenic Phenotype Through Reduction in Muscle Mitochondria and Attenuation of Insulin-Stimulated Muscle Protein Synthesis

Kiyotaka Uchiyama, Shu Wakino, Takaya Tajima, Tomoaki Itoh, Yoichi Oshima, Junichiro Irie, Hiroshi Itoh. *Keio University, School of Medicine, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) leads to clinically relevant sarcopenia, defined as reduced exercise endurance and muscle atrophy, which are novel risk factors associated with morbidity and mortality in CKD patients. However, the pathophysiology of uremic sarcopenia remains incompletely defined. Recent reports have shown alterations in the gut microbiota to be associated with the etiology of CKD. Using germ-free (GF) mice, we aimed to determine whether and how uremic dysbiosis causes uremic sarcopenia.

Methods: CKD was induced in specific-pathogen-free mice via an adenine-containing diet; control mice were fed a normal diet. Fecal microbiota transplantation (FMT) into GF mice was performed by oral gavage using cecal samples obtained from either control mice (control-FMT mice) or CKD mice (CKD-FMT mice). Vehicle mice were gavaged with sterile phosphate-buffered saline. Sarcopenic phenotype was evaluated after 2 weeks.

Results: Compared with control mice, CKD mice had sarcopenic phenotypes, including significant decrease in running distance, handgrip strength, and skeletal muscle mass. Sarcopenic phenotypes were reproduced in CKD-FMT mice as compared with control-FMT mice and were associated with reduced muscle mitochondria and attenuation in insulin-stimulated phosphorylation of S6 kinase beta-1, indicating reduced muscle protein synthesis. In addition, serum concentrations of indoxyl sulfate, phenyl sulfate, and hippuric acid among uremic solutes as well as fecal concentrations of indole and phenol among bacterial fermentation products were increased in CKD-FMT mice as compared with the concentrations in control-FMT mice. Gut microbiome analysis using 16S rRNA genes sequences revealed decrease in *Lactobacillus* and *Lactonifactor* and increase in *Allobaculum*, *Clostridium cluster IV*, and *Alistipes* in CKD mice as compared with those in control mice. All of these alterations in gut microbiome remained in CKD-FMT mice as compared with those in control-FMT mice.

Conclusions: Uremic dysbiosis can directly contribute to sarcopenic phenotypes even in the absence of the host CKD condition. Increased concentrations of microbiota-derived fecal putrefaction products, serum uremic solutes, and resultant insulin resistance can mediate the effects of uremic dysbiosis.

TH-PO614

A Pilot Study on Association of Arterial Stiffness with Dynapenia and Sarcopenia in Hemodialysis Patients

Rajesh B. Kumar,[1] Paras Dedhia,[1] Rachana H. Jasani,[1] J. Kothari,[2] Shrirang Bichu,[3] Viswanath Billa,[3] Virendra Gupta,[1] Alam Mohd shah.[1] Apex Kidney Care *[1]Apex Kidney Care, Mumbai, India; [2]Hinduja Hospital, Healthcare & Apex Kidney Foundation, Mumbai, India; [3]Bombay Hospital, Mumbai, India.*

Background: Low muscle strength (dynapenia) and low muscle strength plus low skeletal muscle mass (sarcopenia) are often found to be coexisting with obesity in chronic hemodialysis patients. As arterial stiffness is directly related to cardiovascular mortality, it was of interest to study its association with dynapenic obesity (DO), sarcopenic obesity (SO) in this population.

Methods: Arterial stiffness was estimated from brachial cuff-based oscillometric device Mobil-O-Graph. Body Composition Analysis through bioelectrical impedence was utilized to assess body fat and lean tissue index (LTI). Muscle strength was determined using handgrip strength (HGS) analysis. Dynapenia was defined by HGS <26 kg for men and < 18 kg for women. Sarcopenia was defined as LTI <10.7 kg/m^2 in men and <6.7 kg/m^2 in women. Obesity was defined as percent body fat > 25% in men and > 35% in women.

Results: Of 206 patients, 124 were males. Their average age was 55.3± 15.4 years and average dialysis vintage was 2.8±2.7 years. All patients were on thrice a week hemodialysis. Of 206 patients, 44% were diabetic, 58% were hypertensive and 29% had ischemic heart disease. The prevalence of dynapenia was 87.8% and that of sarcopenia was 42.7%. Prevalence of DO and SO was 19.4% and 14.5% respectively. The prevalence of arterial stiffness in patients with DO was 72.5% and that in patients with SO was 70%.

Conclusions: Prevalence of arterial stiffness is high in patients with DO and SO. Further studies are needed to evaluate interventions for reducing dynapenic and sarcopenic obesity and their impact on reduction in arterial stiffness inorder to reduce cardiovascular mortality.

TH-PO615

Lower Kidney Function Is Associated with Impaired Leg Skeletal Muscle Mitochondrial Oxidative Capacity

John Howard,[1] Chenoa R. Vargas,[1] Baback Roshanravan,[1] Jorge Gamboa,[3] Jonathan Himmelfarb,[2] Ian H. de Boer,[2] Kevin Conley,[2] Bryan R. Kestenbaum.[2] *[1]University of California Davis Medical Center, Sacramento, CA; [2]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [3]Vanderbilt University, Nashville, TN.*

Background: Evidence suggests abnormal uremic environment may contribute to mobility limitation by impairing muscle mitochondrial function. We tested the association of kidney function with in vivo muscle mitochondrial oxidative capacity among patients with CKD.

Methods: The Muscle Mitochondrial ENergetics and Dysfunction (MEND) study was designed to evaluate determinants and consequences of skeletal muscle mitochondrial functioning in CKD. We recruited 57 participants (38 CKD and 19 controls) from a clinic-based population. We measured mitochondrial oxidative capacity of the tibialis anterior leg muscle (ATPmax) during exercise recovery using 31Phosphorus magnetic resonance spectroscopy. We determined associations of GFRcrcysc with ATPmax by using multivariable linear regression adjusting for age, sex, waist/hip ratio, and diabetes.

Results: Participants were 62 ±14years old with 32% female and 32% prevalence of diabetes (33% in controls). GFRcrcysc in the CKD group was 38 +19ml/min compared to 98 ±15 in controls. Mean ATPmax was 0.6 ±0.16mM/sec in CKD group and 0.8 ±0.18 in controls. After adjustment, CKD was associated with 0.18mM/sec lower (95% CI 0.27, 0.09; P<0.001) ATPmax. Diabetes was associated with 0.12mM/sec lower (95%CI 0.23, 0.02; P=0.02) ATPmax compared non-diabetes after adjustment. In continuous analysis, each 10ml/min/1.73m2 lower eGFRcrcysc was associated with a 0.03mM/sec lower ATPmax (95% CI 0.04, 0.01; P<0.001) (Figure). Among those with GFRcrcysc<60, correlates with ATPmax included bicarbonate level (r=0.39, p=0.02), C-reactive protein (r=-0.31, P=0.07), albuminuria (r=-0.33, P=0.05), and phosphorus (r=-0.21, p=0.2).

Conclusions: Lower kidney function and diabetes are associated with direct in vivo measurements of leg muscle mitochondrial oxidative capacity.

TH-PO616

Impaired Leg Muscle Mitochondrial Oxidative Capacity by Phosphorus-31 Magnetic Resonance Spectroscopy (^{31}P MRS) Is Associated with Lower Physical Functioning in CKD

Chenoa R. Vargas,[1] John Howard,[2] Baback Roshanravan,[3] Jorge Gamboa,[4] Kushang V. Patel,[6] Ian H. de Boer,[5] Kevin Conley,[6] Bryan R. Kestenbaum.[6] *[1]UC Davis Internal Medicine, Davis, CA; [2]University of California Davis Medical Center, Sacramento, CA; [3]University of California Davis, Davis, CA; [4]Vanderbilt University, Nashville, TN; [5]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [6]University of Washington, Seattle, WA.*

Background: Maintaining functional independence is the top health priority reported by patients living with CKD. Impaired mitochondrial function is hypothesized to be a key mechanism underlying mobility limitation in CKD.

Methods: The Muscle Mitochondrial ENergetics and Dysfunction (MEND) study was designed to evaluate determinants and consequences of skeletal muscle mitochondrial functioning in CKD. We measured mitochondrial oxidative capacity of the tibialis anterior leg muscle (ATPmax) during exercise recovery using ^{31}P MRS in 57 participants (38 CKD and 19 controls). We evaluated physical function by self-reported physical functioning-10 (PF-10 of the KDQOL) and performance on the Timed Up and Go (TUG) test. Statistical models adjusted for age, sex, waist/hip ratio, and maximal leg strength.

Results: Participants were 62 ±14years old and 32% had diabetes. GFRcrcysc in the CKD group was 38 ±19ml/min compared to 98 ±15 in controls. Among participants with CKD, lower muscle ATPmax correlated with slower TUG performance (r=-0.42; p=0.009) and lower PF-10 score (Figure). Results did not change after adjustment. Addition of ATPmax to the adjusted model weakened the association of CKD with physical functioning (PF-10) score by 50% (Figure) and TUG performance by 46% compared to controls.

Conclusions: Direct measurements of leg skeletal muscle mitochondrial capacity are associated with objective and subjective measures of physical functioning in patients with CKD. Mitochondrial impairment may contribute to mobility limitation in CKD.

Indoxyl Sulfate-Induced Apoptosis in C2C12 Cells

Seok hui Kang,[1] Youn su Lee,[2] Jun-Young Do.[1] *[1]Yeungnam University Hospital, Daegu, Republic of Korea; [2]Yeungnam University Medical Center, Deagu, Republic of Korea.*

Background: Indoxyl sulfate is a well-known uremic toxin and associated with skeletal muscle atropy in chronic kidney disease. However, there are few studies regarding precise molecular mechanism. The aim of the study was to identify indoxyl sulfate induced apoptosis as a molecular mechanism.

Methods: Mouse C_2C_{12} myoblast were purchased and cultured in Dulbecco's modified eagle medium. After cell adhesion, cultured medium was changed containing with uremic toxins and cultured. Reactive oxygen species (ROS) production and CCK assays were performed. Tunnel staining, phase contrast microscopy, and flowcytometry were also performed.

Results: ROS production was increased as dose of indoxyl sulfate increased. Apoptosis was increased as dose of indoxyl sulfate increased. In addition, tunnel stained cell count increased as dose of indoxyl sulfate. Cell confluence decreased as dose of indoxyl sulfate. Flowcytometry using Annexin V and PI showed that proportion of double positive cell increased as dose of indoxyl sulfate.

Conclusions: Our results demonstrate that indoxyl sulfate is associated with apoptosis of myoblast through ROS production.

TH-PO618

β2-Receptor Agonism Averts Indoxyl Sulfate-Induced Sarcopenic Phenotype of Mouse Skeletal C2C12 Myotube

Takaaki Higashihara, Hiroshi Nishi, Koji Takemura, Masaomi Nangaku. *The University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Sarcopenia is a condition characterized by loss of skeletal muscle mass and function. In patients with chronic kidney disease, sarcopenia is recently attracting attention because of its strong association with increased morbidity and mortality. However, the direct association with uremia and sarcopenia is not fully elucidated yet. The aim of this research was to investigate the mechanism and therapeutic intervention for sarcopenia induced by uremia.

Methods: The mouse myogenic cell line C2C12 (ATCC®CRL-1772) was treated with indoxyl sulfate (IS) and evaluated as to cell viability (MTS assay), cytotoxicity (LDH assay, Trypan blue), cell morphology (measure the length and diameter of C2C12 myotubes), the expression of muscle atrophy related genes (quantitative-PCR) and protein levels of myosin heavy chain (MyH) and fast/slow twitch muscle fibers (Western blot). Moreover, clenbuterol and salbutamol as β2-stimulants were assessed for effect on the IS induced myocyte phenotypic changes.

Results: IS blunted C2C12 myoblast cell proliferation and reduced myotube length and diameter. IS treatment up-regulated mRNA expression of muscle atrophy related genes (MuRF-1 and Atrogin-1), and reduced protein levels of MyH and fast twitch muscle fiber, but not slow twitch muscle fiber. On the other hand, clenbuterol and salbutamol partially attenuated IS-induced upregulation of MuRF-1 and Atrogin-1, and prevented the degradation of MyH and fast twitch muscle fibers.

Conclusions: β2-agonist has a therapeutic potential for preventing IS induced muscle atrophy, predominantly fast twitch muscle fiber atrophy.

TH-PO619

Mitochondrial Dysfunction/NLRP3 Inflammasome Axis Contributes to Angiotensin II-Induced Skeletal Muscle Wasting via PPAR-γ

Wei Ding. *Shanghai Ninth People's Hospital, Shanghai, China.*

Background: Although the angiotensin II (Ang II) level is elevated in patients with chronic kidney disease or heart failure, and directly causes skeletal muscle wasting in rodents, the molecular mechanisms of Ang II-induced skeletal muscle wasting and its potential as a therapeutic target are unknown.

Methods: We investigated the NLR Family Pyrin Domain Containing 3 (NLRP3) inflammasome-mediated muscle atrophy response to Ang II in C2C12 myotubes and *Nlrp3* knockout mice. We also assessed the mitochondrial dysfunction (MtD)/NLRP3 inflammasome axis in Ang II-induced C2C12 myotubes. Finally, we examined whether a peroxisome proliferator-activated receptor-γ (PPAR-γ) agonist could attenuate skeletal muscle wasting by targeting the MtD/NLRP3 inflammasome axis *in vitro* and *in vivo*.

Results: We demonstrated that Ang II increased NLRP3 inflammasome activation in cultured C2C12 myotubes dose dependently. *Nlrp3* knockdown or *Nlrp3*$^{-/-}$ mice were protected from the imbalance of protein synthesis and degradation. Exposure of C2C12 to Ang II increased mitochondrial ROS (mtROS) generation, accompanied by MtD. Strikingly, the mitochondrial targeted antioxidant not only decreased mtROS and MtD, it also significantly inhibited NLRP3 inflammasome activation and restored skeletal muscle atrophy. Finally, the PPAR-γ agonist protected against Ang II-induced muscle wasting by preventing MtD, oxidative stress, and NLRP3 inflammasome activation *in vitro* and *in vivo*.

Conclusions: This work suggested a potential role of MtD/NLRP3 inflammasome pathway in the pathogenesis of Ang II-induced skeletal muscle wasting, targeting the PPAR-γ/MtD/NLRP3 inflammasome axis may provide a therapeutic approach for muscle wasting.

Skeletal Muscle Mitochondrial Response to Wheel Running in a Rat Model of CKD

Keith G. Avin,[1] Meghan C. Hughes,[2] Shruthi Srinivasan,[3] Neal X. Chen,[3] Kalisha O'Neill,[4] Robert L. Bacallao,[3] Sharon M. Moe,[3] Christopher G. Perry.[2] *[1]Indiana University-Indianapolis, Indianapolis, IN; [2]York University, Toronto, ON, Canada; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Indiana University Medical Center, Indianapolis, IN.*

Background: We have previously found that treadmill running had detrimental effects upon mitochondrial pathways, while wheel running had multi-system beneficial effects in CKD rats. We hypothesized that wheel running would have beneficial effects on skeletal muscle mitochondria.

Methods: We used the $Cy/+_{IU}$ rat model of naturally occurring CKD (n = 12-14/group) to compare muscle bioenergetics in CKD rats versus NL littermates, and CKD versus CKD rats that performed 10 weeks of wheel running (from 25(~stage 2 CKD) to 35 weeks (~ESRD)). 1) Muscle protein lysates of the extensor digitorum longus (EDL, fast fiber type) and soleus (slow fiber type), were directly assessed for protein content of the mitochondrial respiratory subunit complexes by OXPHOS. 2) These muscles were permeabilized with direct assessment of mitochondrial respiration (Oxygraph-2k, Oroboros) in the presence of different substrates ((5Mm pyruvate, 2Mm malate; 25um-10mM ADP; 5mM glutamate; 20mM succinate).

Results: *EDL*: no difference in mitochondrial complex protein content or respiration in CKD vs NL. Wheel running reduced complexes I-IV subunit protein content (CKD-W vs CKD, $p<0.05$), but no difference respiration. *Soleus:* mitochondrial complex I was reduced in CKD vs NL, while complex III was reduced in the CKD-W vs CKD (both $p<0.01$). Respiration rates were increased in CKD (vs NL) for 300 and 500uM ADP ($p<0.01$), but not for state II (pyruvate, malate). In contrast, wheel running increased state II (i.e. pyruvate, malate) and 25uM ADP (compared to CKD; both $p<0.01$)) respiration.

Conclusions: Skeletal muscle from CKD rats did not demonstrate dramatic changes in mitochondrial content or respiration. Wheel running in CKD rats, compared to no wheel running, reduced isolated mitochondrial respiratory subunit content particularly in the EDL. Given there was no difference in respiration with lowered mitochondrial content there was a compensatory response. These data support that the systemic benefits of wheel running may not be due to direct changes in mitochondrial function in skeletal muscle, suggesting a more indirect effect.

TH-PO621

Correlates of Physical Inactivity Across Kidney Disease Stages: An Observational Multicentre Study

Thomas J. Wilkinson,[1] Amy L. Clarke,[3] Daniel Nixon,[1] Katherine L. Hull,[2] James Burton,[1] Alice C. Smith.[1] Leicester Kidney Lifestyle Team *[1]University of Leicester, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Coventry, United Kingdom; [3]University College London, London, United Kingdom.*

Background: The importance of physical activity (PA) in the health and management of CKD is well established. Understanding causes of PA behaviour is essential for the development of potential interventions and promotional initiatives. We aimed to determine the prevalence and individual correlates of PA behaviour across the spectrum of kidney disease.

Methods: 5258 patients across 17 geographically diverse sites were stratified into CKD stages 1-2, 3, 4-5, haemodialysis (HD), peritoneal dialysis (PD) and renal transplant recipients (RTRs). Physical activity was assessed using the GP Physical Activity Questionnaire. Potential correlates of PA included clinical, co-morbidity and demographic data, self-efficacy, stage of change (Transtheoretical Model) and cardiorespiratory fitness (VO_2 peak estimated using Duke Activity Status Index). Multi- and bi-nominal generalized models were used to explore differences and correlates of PA. Unless stated, data expressed as odds ratio (OR).

Results: Prevalence of physical inactivity was high and worsened with disease progression (Fig 1). Overall, being older (OR=1.03), female (OR=1.27), having additional co-morbidities (OR=1.17), lower Hb (OR=.93) and lower VO_2 peak (OR=.92) were associated with being inactive. Patients in a receptive stage of change (OR=.35) and with higher self-efficacy (OR=.70) were more likely to be active. Stage of disease modified the interactions of age, sex, and VO_2 peak with PA.

Conclusions: In the largest cohort of its kind, we established that physical inactivity is highly prevalent across all stages of renal disease, reaching a nadir in those requiring dialysis and 'recovering' in those with a transplant. Our study emphasises the urgent need

to evaluate and implement strategies that can effectively support individuals in changing their PA behaviour. In particular, approaches to promote self-efficacy may increase the likelihood that patients will engage and continue with PA.

TH-PO622

A Multicenter Exercise Intervention for Persons Transitioning to Dialysis Using the "Exercise Is Medicine" Framework

Susan Ziolkowski,[2] Ahad A. Bootwala,[3] Ram Jagannathan,[1] Shuchi Anand,[4] Felipe Lobelo.[5] *[1]Emory School of Medicine, Atlanta, GA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Emory University, Skokie, IL; [4]Stanford University, Stanford, CA; [5]Emory University School of Public Health, Atlanta, GA.*

Background: Physical activity is associated with improvement of cardiovascular health, physical function, transplant outcomes and survival in persons with CKD. Yet at the time of dialysis initiation, 44% of individuals cannot walk one block and 56% cannot climb 12 stairs.

Methods: We are conducting a pilot and feasibility randomized controlled trial (NCT03311763) using the American College of Sports Medicine 'Exercise is Medicine' framework in patients with eGFR < 45 ml/min/1.73m^2 not on dialysis, in racially and ethnically diverse regions (San Jose, CA and Atlanta, GA). Group 1 receives a wearable activity tracker and exercise counseling; Group 2 additionally receives 8 weeks of twice-weekly group exercise sessions from a fitness professional trained in CKD related concerns (high/ low blood pressure and glucose, dialysis access precautions). Physical activity questionnaires (i.e. SF-12, IPAQ) and measurements [6-minute walk test (6MWT), handgrip strength, anthropometrics] are obtained at baseline, 8 and 16 weeks. Fitness trackers record daily step totals.

Results: 51 patients were recruited (23 San Jose, 28 Atlanta). 82% of participants were non-white, 55% have diabetes and mean baseline eGFR was 30.9 ± 9.7. 6MWT means were 399 ± 118m (Group 1) and 433 ± 118m (Group 2), compared with 571 ± 90m previously reported in pooled analyses of healthy individuals. 7 individuals were hospitalized and 3 transitioned to dialysis during the study. Complete data will be available Fall 2019.

Conclusions: We successfully integrated recruitment, physical activity assessment and group exercise into diverse clinical settings servicing minority patients with advanced CKD. At baseline patients have poor capacity and experience a high burden of hospitalizations.

Exercise with Blood Flow Restriction Is Safe and Tolerable and Enhances Strength Adaptations Among Dialysis Patients

Matthew Clarkson,[1] Steve F. Fraser,[1] Catherine Brumby,[3] Paul N. Bennett,[2] Lawrence P. McMahon,[3] Stuart Warmington.[1] *[1]School of Exercise and Nutrition Sciences, Deakin University, Geelong, VIC, Australia; [2]Satellite Healthcare, San Jose, CA; [3]Department of Renal Medicine, Eastern Health, Melbourne, VIC, Australia.*

Background: Haemodialysis (HD) patients have reduced exercise capacity, impaired muscle structure and function, and reduced exercise capacity. Intradialytic exercise interventions can improve subsequent declines in physical function associated with higher mortality with good adherence. Blood flow restriction (BFR) exercise enhances muscle strength and size adaptations to low-intensity exercise, thought to be insufficient for such adaptions. This technique appeals in ESKD but is yet to be evaluated in this population. The aim of this research was to assess haemodynamic safety and tolerability of BFR aerobic exercise in HD patients and the efficacy of a 6 week intervention.

Methods: In study 1, HD patients underwent a 3-phase program of supervised aerobic low-intensity exercise. Phase 1: 2 short bouts of cycling during 2 HD sessions. Phase 2: 2 short bouts of cycling with BFR whilst off HD on 2 separate days. Phase 3: 2 short bouts of cycling with BFR during 2 HD sessions. Participants with severe cardiovascular disease or known haemodynamic instability on HD were excluded. Outcome measures were haemodynamic (heart rate (HR) and blood pressure (BP)) and perceptual responses (exertion (RPE) and discomfort (RPD)) during exercise sessions. Study 2, a 6 week intervention, included a BFR group, undergoing 2 bouts of cycling with BFR during HD sessions, a non-BFR cycling group did 20 min continuous cycling during HD sessions, a usual care control group did no exercise. Outcomes included 3-rep maximum leg strength, and the 30-second sit-to-stand (30STS).

Results: There were increases in HR, systolic BP and mean arterial BP ($P<0.05$) post exercise for both exercise groups, with a delayed mean arterial BP reduction of 11.0 ± 1.3 mmHg ($P<0.01$). Adjusted for age and baseline, leg strength increased by 16±5% with BFR, compared with 9±5% in the non-BFR group, and no change in controls; 30STS increased only with BFR ($P < 0.05$). Across 452 sessions there were 6 minor adverse events, all episodes of self-resolving pre-syncope (4 after BFR exercise, 2 after non-BFR exercise).

Conclusions: Comparing BFR aerobic exercise to standard aerobic exercise during HD, haemodynamic safety and tolerability is comparable while strength and related physical function is increased with BFR aerobic exercise after 6 weeks exercise training.

TH-PO624

Lysosome: At the Crossroads Between Na^+-K^+-ATPase and NLRP3 in Hyperuricemia-Induced Renal Tubular Injury

Jing Xiao, Zhibin Ye. *Nephrology, Huadong hospital affiliated to Fudan University, Shanghai, China.*

Background: We previously demonstrated the impairment of Na^+-K^+-ATPase (NKA) and NLPR3 signaling in hyperuricemia (HUA)-induced renal tubular injury and NKA was degraded in lysosomes. Here, we investigated the role of lysosome in NKA and NLRP3 signaling under HUA induce renal tubular injury.

Methods: Proximal tubular epithelial cells (PTECs) were incubated with different concentrations (50 μg/mL~200μg/mL) of UA for different times (6h~48 h), and the expression of NLRP3, lysosomal-associated membrane protein 2 (LAMP2), cathepsin B (CB) and interlukin-1β (IL-1β) were detected. CB inhibitor (Ca-074 methyl ester, Ca-074 Me) 10Mm or hydroxychloroquine (HCQ, 50 μM) was added to PTECs for 2h in advance, with the inhibition of NKA by its α subunit siRNA for 48h with or without the UA stimulation, NLRP3, LAMP2 and CB as well as mitochondrial function were detected. In vivo, SPF SD rats were divided (n=4 in each group) into control, HUA group [oxonic acid (OA) 750 mg/kg/d gavage for 8 weeks]; HCQ group (HCQ, with OA 750mg/kg/d for 8 weeks and HCQ 25 mg/kg/d gavage since the 5th week and for 4 weeks); and febuxostat group (Feb, with OA 750mg/kg/d for 8 weeks and Feb 3 mg/kg/d gavage since the 5th week for 4 weeks). Renal cortex NKA activity, its expression, CB, LAMP2, NLRP3, IL-1β and uncoupling protein 2 (UCP2) were examined.

Results: UA time and dose-dependently increased the expression of LAMP2 and CB. Ca-074 Me or HCQ alleviated the expression of NLRP3, LAMP2 and CB, mitochondrial dysfunction caused by UA and/or NKA siRNA. OA significantly increased serum UA levels in SD rats and developed reduced urinary UA excretion, renal cortex NKA activity and its expression, increased the expression of NLRP3, Il-1β, CB, LAMP2, and UCP2 expressions, compared with control. HCQ, but not Feb treatment, significantly increased urinary UA excretion. HCQ demonstrated similar effects with Feb in enhancing renal cortex NKA activity and expression, reducing the expression of NLRP3, Il-1β, CB, LAMP2, and UCP2 expressions, compared with HUA group.

Conclusions: UA induces lysosomal damage to release lysosomal contents and activate NLRP3 inflammasome. Lysosomal function protection could alleviate NKA-NLRP3 signaling pathway and effectively improve mitochondrial function *in vitro* and *in vivo*, suggesting that lysosome function plays an important role in HUA-induced renal tubular epithelial cell injury.

TH-PO625

The Influence of an Elevated Serum Uric Acid Levels for Cardiovascular Events in the General Population with Normal Renal Function

Yuki Matsuura,[1] Koichi Asahi.[2] *[1]Iwate medical university, Morioka, Japan; [2]Iwate Medical University, Morioka, Japan.*

Background: The significance of an elevated serum uric acid (SUA) level as a risk factor for the onset of cardiovascular events (CVEs) remains controversial. Since the SUA level is affected by the impaired renal function, we evaluated the association between the SUA level and the incidence of CVEs in the Japanese general population without chronic kidney disease (CKD).

Methods: The baseline survey items were the SUA level, age, sex, body mass index (BMI), blood pressure, blood sugar, hemoglobin A1c, serum creatinine, estimated glomerular filtration rate, urinary albumin/creatinine ratio, total cholesterol, and electrocardiogram findings (existence of atrial fibrillation). Baseline data were measured in participants of annual health checkups from a community-based population. After the exclusion of CKD, the subjects were stratified into sex-specific quartiles of SUA (n = 15,036, mean age 63.2 ± 10.0 years in men and 60.6 ± 9.6 years in women, men 33.5%, including 5,038 men and 9,998 women). The endpoint was determined as the composite of CVEs (stroke, myocardial infarction, and sudden cardiac death). A Cox regression analysis was performed to examine the sex-specific relationship between the baseline SUA level and the onset of CVEs.

Results: During a mean follow-up period of 8.8 years, we confirmed 611 CVEs (304 in men, 307 in women). After adjusting for traditional risk factors (age, BMI, hypertension, diabetes mellitus, hypercholesterolemia, atrial fibrillation), the hazard ratio for the onset of CVEs did not differ among the quartiles in men (q1 (2.1≤SUA(mg/dl)≤4.8) = reference, q2 (4.9≤SUA(mg/dl)≤5.6) = 0.80, q3 (5.7≤SUA(mg/dl)≤6.4) = 1.01, q4 (6.5≤SUA(mg/dl)≤12.0) = 0.99; p = 0.447). In contrast, in women, a significant trend was observed (q1 (2.0≤SUA(mg/dl)≤3.7) = reference, q2 (3.8≤SUA(mg/dl)≤4.3) = 1.28, q3 (4.4≤SUA(mg/dl)≤4.9) = 1.58, q4 (5.0≤SUA(mg/dl)≤10.3) = 1.58; p = 0.035).

Conclusions: In the Japanese general population with normal renal function, an elevated SUA level is considered an independent risk factor for the onset of CVEs in women but not in men.

TH-PO626

Nifedipine Modulates Renal Lipogenesis and Fibrosis via the AMPK/SREBP Transcriptional Pathway: An In Vivo CKD Model and Translational Study

Yen Chung Lin.[1,2] Taipei Medical University *[1]Division of Nephrology, Department of Internal Medicine, Taipei Medical University Hospital, Taipei, Taiwan; [2]Division of Nephrology, Department of Internal Medicine, School of Medicine, College of medicine, Taipei Medical University, Taipei, Taiwan.*

Background: Overproduced free fatty acid induces inflammation and renal fibrosis. Weight reduction therapy including calcium loading method may decrease the above renal damage. However, calcium channel blocker affects lipid accumulation in extra-adipose tissue is in debate. Therefore, we want to initiate study on CKD animal and patients to realize effect of nifedipine on lipogenesis and renal toxicity.

Methods: 39 SD rat were divided in four groups including control, Doxorubicin (DR) treated, DR+nifedipine treated and high fat diet (HFD). In addition, nineteen renal transplant patients were also enrolled for the examination of graft fibrosis and lipid content via transient elastography. Lipogensis related enzymes including Sterol regulatory element-binding proteins (SREBPs), acetyl-coa carboxylase (ACC), fatty acid synthase (FAS), 5' AMP-activated protein kinase (AMPK) were tested.

Results: Hypertension and proteinuria were observed in DR, DR+Nifedipine and HFD group. However, TNF-α was expressed in DR group compared with control, and higher in DR+nefidipine group. ($p<0.05$) Renal fibrosis on pathology obviously occurred in DR and DR+nifedipine groups but not expressed in HFD group compared with control. ($p<0.05$) Immunohistochemistry of CD36 also significant higher in nifedipine treated group but not high fat diet group. ($p<0.05$) Western blot showed higher SREBP-1/2, ACC, and lower FAS. ($p<0.05$) P-AMPK/AMPK was lower in study groups. Low density cholesterol level was strongly correlated with graft kidney fibrosis and lipid accumulation. ($p<0.05$)

Conclusions: Nifedipine may potentiate renal fibrosis and lipid accumulation through SREBP-1/2 activation and lower AMPK activity in this in vivo study, similar results was observed in our previous in vitro study. Interestingly, hypercholesterolemia may correlate with renal fibrosis on graft kidney in CKD patients.

The Histone Deacetylase (HDAC) Inhibitor Belinostat Attenuates H_2O_2-Induced Senescence-Like State by Regulation of HDAC7 in the Human Renal Proximal Tubular Epithelial Cells

Jung Sun Park,[1] Hoon In Choi,[2] Donghyun Kim,[2] Chang Seong Kim,[2] Eun Hui Bae,[2] Seong Kwon Ma,[1] Soo Wan Kim.[1] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: Oxidative stress causes cell injury, disease, and aging. Renal aging is associated with decreased glomerular filtration rate, glomerulosclerosis, tubular atrophy, and fibrosis. HDAC7 modulates the cell cycle and induces cell senescence. We investigated the effect of HDAC inhibitor, belinostat on the H_2O_2-induced renal tubular senescence, and its underlying molecular mechanisms.

Methods: The effects of belinostat in H_2O_2-induced cell senescence was determined using human renal proximal tubular epithelial (HK-2) cells. H_2O_2-induced premature cellular senescence was detected by senescence-associated (SA)-β-gal staining and galactosidase activity, and the fluorescent dye 2',7'-dichlorofluorescein diacetate was used to measure intracellular reactive oxygen species (ROS). Cell cycle progression was measured by flow cytometry and immunoblotting, and the knock down of histone deacetylases 7 was induced by HDAC7 siRNA.

Results: We observed the effect of belinostat on cell cycle regulation of HDAC7 in H_2O_2-induced senescence-like cells. H_2O_2 increased SA-b-gal staining and increased protein expression of HDAC7, p-caveolin-1, p-Rb, p-P53, p-P21 and P27. It also increased phosphorylation of p-AKT, p-ERK1 / 2, p-JNK, and induced ER stress. In contrast, pretreatment of belinostat reduced protein expression of HDAC7 and p-caveolin-1 and cell cycle-related protein expression and the phosphorylation of p-AKT, p-ERK1 / 2, and p-JNK and reduced ER stress expression. SiRNA treatment of HDAC7 inhibited the expression of p-caveolin-1 and decreased SA-b-gal staining.

Conclusions: Treatment of belinostat may exert anti-senescence effect by controlling p-AKT, p-ERK1/2, p-JNK, and ER stress signal pathways via inhibition of HDAC7 in H_2O_2-treated HK-2 cells.

Transcriptional Regulation of Kidney Autophagy by Farnesoid X Receptor

Donghyun Kim,[1] Hoon In Choi,[2] Jung Sun Park,[3] Eun Hui Bae,[1] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea; [3]chonnam national university, Gwang Ju, Republic of Korea.*

Background: Autophagy is an evolutionarily conserved catabolic process that removes damaged organelles and maintains cellular energy homeostasis. Acute regulation by nutrient-sensing of autophagy and long-term transcriptional regulation by nuclear hormone receptor farnesoid X receptor (FXR) is well known. Also, kidney autophagy regulates TGFβ expression and suppresses kidney fibrosis. However, the functional role of FXR on TGFβ-induced kidney autophagy is relatively unknown.

Methods: Expression levels of LC3 protein and autophagy related genes were measured on treatment with TGFβ and FXR agonists, GW4064 and WAY-362450, in human proximal tubule cells (HK2 cells). Also, we tested expression levels of autophagy related proteins and genes in overexpression or downregulation of FXR in cells. Expression levels of protein and autophagy related genes were measured in the sham and UUO model of WT and FXR knock-out mice.

Results: Treatment with TGFβ (5 ng/ml) in HK2 cells resulted in an increase in the level of LC3 protein and autophagy related genes, along with an increase in fibrosis markers. Activation of FXR by agonists in TGFβ-induced HK2 cells regulates expression levels of LC3 I/II and Becn1. Autophagy related genes were decreased in FXR agonists treated HK2 cells. Also, autophagic flux was further increased on co-treatment with GW4064 and TGFβ in HK2 cells. Autophagy related genes have no GW4064 effects on down-regulation of FXR by siRNA in HK2 cells. Autophagy related genes were regulated by fasting/feeding in WT mice. Protein levels of LC3 and fibrosis markers were increased in FXR-KO UUO mice model compared to those of WT UUO mice model.

Conclusions: These data reveal a functional role of FXR for kidney autophagy regulator in TGFβ-induced HK2 cells and suggest that FXR may play an important role in the suppression of renal fibrosis through transcriptional regulation of kidney autophagy.

TH-PO629

Rhein Attenuated Palmitic Acid-Induced Renal Tubular Cell Injury by Regulating AMPK-mTOR-Autophagy

Wei Li, Kun Gao, Ping Xia, Yao Zhou, Wei Sun. Division of Nephrology, Affiliated Hospital of Nanjing University of Chinese Medicine *Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China.*

Background: Rhubarb is one of the widely used Chinese medicine herbs in the treatment of some kidney diseases. Rhein is an important monomer composition of Rhubarb which has multiple biological effects. Our previous studies have found that Rhein suppressed autophagy to protect renal cells. However, the underlying mechanism is still unclear. Metabolism disorder, especially dyslipidemia, attracts more and more attentions in recent years. In current study, we evaluated the protective effects of Rhein and the underlying mechanisms in palmitic acid (PA)-induced cell injury.

Methods: To study the toxicity of lipid, we use different concentrations of PA to induce HK2, human proximal tubular cell, injury. CCK8 cell viability detection, Tunel staining, FITC/PI flow cytometry and western blot were employed to analyze the protective effects of Rhein in PA-triggered HK2 impairment. Western blot and Fluorescence microscope were used to evaluated autophagy. Oil O stanning and Bodipy Probe were used to detect lipid in the cell.

Results: PA induced HK2 cells detatchment from the bottom, morphological changes and loss of cell viability after 24h incubation. The Rhein obviously reduced the cell damage elicited by PA, improved morphological changes, attenuated the loss of cell viability. Western blot analysis indicated that Rhein inhibited PA-induced autophagy as evidenced by the change of LC3 I to LC3 II bands. In addition, the fluorescence optical microscopy observation showed that PA activated autophagy. Moreover, autophagy inhibitor, chloroquine, did not affect autophagy flow in western blot analysis. These reuslts

indicated that PA did not influence lysome function. PA increased autophagy upstream by upregulating AMPK-mTOR possiblelly in western blot analysis. And the Rhein might prohibit AMPK to regulate mTOR - ULK1 pathway.

Conclusions: Rhein attenuated the PA-induced renal tubular cell injury by regulating AMPK-mTOR-Autophagy pathway.

Sodium Glucose Co-Transporter 2 Inhibitor Ameliorates Autophagic Flux Impairment on Renal Proximal Tubular Cells in Obesity Mice

Kazuhiko Fukushima, Shinji Kitamura, Kenji Tsuji, Yizhen Sang, Jun Wada. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Scineces, Okayama, Japan.*

Background: Obesity is supposed to cause to renal injury, and sodium glucose co-transporter 2 inhibitors (SGLT2-I) are reported to have possibilities to protect renal disorders. However, the SGLT2-I direct protective mechanism has been unclear. In this study, we investigated SGLT2-I effects focused on autophagic flux impairment in proximal tubular cells in obesity mice.

Methods: 5-week-old C57BL/6J mice were divided to normal diet (ND) fed group or 40 kcal % fat diet (HFD) fed group. After 9 weeks, we separated the mice, administrated 10.0 mg/kg/day SGLT2-I (empagliflozin provided from Boehringer-Ingelheim) group or solvent, hydroxypropyl methylcellulose (HPMC) group to each feeding group mice for 1 week. After total 10 weeks, urine was harvested for 24 hrs with ND. The mice were sacrificed, and serum plasma and kidneys were harvested. We investigated pathological analysis and protein expression focused on autophagy.

Results: The weight of HFD mice gained significantly than that of ND mice. HFD-SGLT2-I mice showed significant decrease of urinary N-acetyl-β-D-glycosaminidase (NAG) compared with HFD-HPMC group ($p < 0.05$). In oil red O staining, lipid accumulations were observed on proximal tubular cells in HFD-HPMC treated mice, however lipid accumulations were observed significantly decrease in HFD-SGLT2-I fed mice. HFD-HPMC mice showed significantly increase of p62 positive proximal tubules compared to ND-HPMC group. Interestingly, HFD- SGLT2-I showed significant decrease compared to HFD-HPMC group ($p < 0.05$). In electron microscopy, multilamellar bodies (MLBs), which shows the autophagosome or autolysosome storing lipids, appeared in proximal tubular cells of HFD-HPMC mice, however MLBs decreased in HFD-SGLT2-I group. In addition, abnormal formation of mitochondria was observed in proximal tubular cells of HFD-mice, and several mitophagosomes were observed in those treated with SGLT2-I.

Conclusions: SGLT2-I might have renal protective effects against obesity via improving autophagic flux impairment in proximal tubular cells by promoting autophagosomal degradation of lipids and damaged mitochondrias.

TH-PO631

Examining Transcriptional Coordination Among Pathways Using Single Cell Transcriptomics

Divyansh Agarwal. *University of Pennsylvania, Philadelphia, PA.*

Background: Recent evidence suggests that the intracellular activity of certain immune pathways, such as the complement, engages in novel cross-talk with metabolic pathways. This pathway-pathway interaction is critical in directing a catered cellular response. Single cell RNA sequencing (scRNA-seq) provides an unprecedented opportunity to understand whether certain biological pathways act in synchrony.

Methods: Using single cell transcriptomics data from five different T cell subtypes (CD4+ naïve, memory, helper and regulatory T cells, and CD8+ cytotoxic T cells), we developed a model for assessing the canonical correlation between two pathways. We examined the significance of the correlation using a modified permutation null distribution that accounts for technical covariates. Complement dysregulation is a hallmark of several kidney diseases, so we used the complement as a *bait* immune pathway to detect which metabolic pathways it is correlated with, and how that correlation differs across T cell subtypes.

Results: Using canonical correlation analysis, we detect pairwise coordination among biological pathways, and explore how the complement pathway might interact with various metabolic pathways in different T cell subtypes. We found that complement-metabolism crosstalk varies substantially by T cell subtype. For instance, while the complement pathway demonstrated a significant canonical correlation with the arachidonic acid and NAD metabolism pathways in CD4+ memory T cells, we did not find evidence for the same in CD4+ naïve T cells. Further, in the latter naïve T cell type, glycolysis and the pentose phosphate pathways showed evidence for transcriptional coordination with complement.

Conclusions: Our method is a widely applicable approach that can be used to assess the differences in pathway cross-talk between cell-types, as well between a healthy and disease state.

Examining the complement-metabolic axis using single cell RNA sequencing

TH-PO632

A Uremic Toxin, 3-Carboxy-4-Methyl-5-Propyl-2-Furanpropionate, Induces Cell Ferroptosis in Human Proximal Tubular Epithelial Cells via Reduced Glutathione Peroxidase 4 and Glutathione

Jung Sun Park,[1] Hoon In Choi,[1] Donghyun Kim,[2] Chang Seong Kim,[1] Eun Hui Bae,[2] Seong Kwon Ma,[1] Soo Wan Kim.[1] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: 3-Carboxy-4-methyl-5-propyl-2-furanpropionate (CMPF) was a uremic toxin metabolite of furan fatty acid that causes oxidative stress and accelerates the progression of renal failure. Ferroptosis is a form of cell death induced by accumulation of iron-dependent lipid-reactive oxygen species and inhibition of glutathione peroxidase 4 (GPX4). We investigated whether uremic toxin, CMPF affects renal proximal tubular cell damage by ferroptosis, a non-apoptotic form.

Methods: The fluorescent dye 2¢, 7¢-dichlorofluorescein diacetate was used to measure intracellular reactive oxygen species (ROS) following CMPF administration in human renal proximal tubular epithelial (HK-2) cells. The effects of CMPF on cell viability was determined using EZ-CyTox assays, and level of glutathione were determined by luminescence using the GSH/GSSH assay. glutathione peroxidase 4 (GPX4) proteins was determined by semiquantitative immunoblotting.

Results: Treatment of CMPF in HK-2 cells promoted the production of ROS. In addition, treatment with CMPF not only reduced the level of GSH but also decreased the expression of GPX4 protein. The ferroptosis inhibitor, lipophilic antioxidant, Fer-1, inhibited CMPF-induced ferroptosis, and iron chelators, DFO, also attenuated CMPF-induced ferroptosis in HK-2 cells.

Conclusions: The results of this study show that CMPF in HK-2 cells promoted the production of reactive oxygen species (ROS) and reduced the levels of GSH and GPX4 expression, resulting in cell death due to ferroptosis.

Donor-Recipient Gut Microbiota Similarity and Allograft Function Early After Kidney Transplantation

Ji Eun Kim,[1] Hyunjeong Cho,[5] Ji In Park,[6] Seung Hee Yang,[2] Jung Pyo Lee,[3] Dong Ki Kim,[1,2] Hajeong Lee,[1,2] Yon Su Kim.[4] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]Chungbuk National University Hospital, Cheongju-si, Republic of Korea; [6]Kangwon National University Hospital, Chuncheon-si, Republic of Korea.*

Background: Gut microbiota affects the development and maintenance of innate and adaptive immune function. However, the effect of microbial composition similarity between recipient and donor on graft function after kidney transplantation (KT) remains unknown.

Methods: We prospectively enrolled living donor KT cases at two centers. Stool samples were obtained before KT. Microbiota composition was analyzed using extracted metagenomic DNA from the feces, using the Illumina MiSeq system. Gut microbiome difference between donor and recipient was calculated by weighted Unifrac distance. Clinical outcome was defined as 6 month post-transplant graft function.

Results: The microbial distance was estimated from 55 donor-recipient pairs. The recipients were 47.7 ± 13.0 years old; donors, 47.5 ± 11.2 years old. Among 26 related, 25 spousal and 4 unrelated donor transplants, couples showed lesser microbial composition difference than genetically related pairs. Spousal donors more frequently sharing meals with their recipients. The number of meals eating together in a day was significantly correlated with microbial distance. In terms of graft outcome, eGFR at 6 month after KT

was significantly correlated with microbial distance (P=0.014). In addition, patients with the farthest quartile of microbial distance suffered from more rejection events in 6-month after KT.

Conclusions: In this study, we found that intestinal microbiome similarity between donor and recipient might affect allograft function early after KT.

Gut Microbiome and Circulating Uremic Solutes in Patients with CKD

Ji Eun Kim,[1] Ji In Park,[5] Hyunjeong Cho,[6] Seung Hee Yang,[2] Jung Pyo Lee,[3] Dong Ki Kim,[1,2] Hajeong Lee,[1,2] Yon Su Kim.[4] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [6]Chungbuk National University Hospital, Cheongju-si, Republic of Korea*.

Background: The relationship between gut microbiome and renal function through the gut-kidney axis comes into the spotlight. However, the changes of microbiome according to the stages of chronic kidney disease (CKD) and the dynamics of uremic toxins produced by gut microbiome are not yet known.

Methods: We prospectively enrolled 149 CKD patients with various renal functions and healthy kidney donors as controls. We collected fecal samples of all participants and the microbial profiling was performed by 16S rRNA sequencing. Also, we measured the level of 4 uremic toxins including p-cresyl sulfate, indoxyl sulfate, p-cresol glucuronide, and trimethylamine N-oxide in serum of all participants by Liquid chromatography–mass spectrometry.

Results: Among the 149 participants, control, CKD stage 1 to 2, CKD stage 3 to 5 without dialysis, CKD stage 5 with dialysis were 46, 36, 32 and 35, respectively. The four uremic toxins were significantly increased with elevation of CKD stage. In microbial analysis with fecal samples, the abundances of genera *Prevotella, Lachnospira and Dialister* significantly decreased as the stage of CKD advanced. While, the abundances of genera *Alistipes* and *Oscillibacter* significantly increased as the stage of CKD advanced. Then, the uremic toxin-related microbiota was identified, and all four uremic toxins were associated with *Alistipes, Oscillobacter* and *Lachnospira*. These three genera showed significant correlations with both renal function and metabolite production.

Conclusions: We found that the composition of gut microbiota changed according to the stage of CKD. Especially, genera *Alistipes, Oscillobacter* and *Lachnospira* were correlated with levels of major uremic toxins. These results shows that gut microbiota might be a crucial factor for progression of CKD.

TH-PO635

Gut-Derived Uremic Retention Solutes in Patients with CKD and Healthy Adults

Gretchen Wiese,[1] Annabel Biruete,[2] Elizabeth Stremke,[1] Amber Jannasch,[1] Riya Thakkar,[1] Sharon M. Moe,[2] Stephen R. Lindemann,[1] Ranjani N. Moorthi,[2] Kathleen M. Hill Gallant.[1,2] *[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Muncie, IN*.

Background: Elevated serum levels of the uremic retention solutes (URS), indoxyl sulfate (IS), p-cresol sulfate (PCS), and trimethylamine N-oxide (TMAO), have been observed in patients with late stage CKD/dialysis and have been associated with poor health outcomes. Diet is known to impact the production of these URS, yet no study to date has compared patients with mild/moderate CKD vs healthy adults on a controlled diet.

Methods: This secondary analysis aimed to determined serum and urine URS (sURS and uURS) in patients with mild/moderate CKD vs controls participating in a controlled feeding study. Patients with CKD (N=7, eGFR=29-55 mL/min/1.73m^2) were studied vs controls (N=7) matched for sex, age, and race. Subjects ate a diet controlled for macronutrients (protein 0.8g/kg/d), fiber (25g/d), P (1500mg/d), Ca (1400mg/d), K (3500mg/d), and Na (2400mg/d) content for 1 week. Fasting serum and urine were collected at the end of the study and IS, PCS, and TMAO were measured by LC/MS-MS. Differences between CKD and control were determined by paired comparisons, and associations were made by Pearson's correlations.

Results: Fasting sURS were higher in CKD vs controls (p<0.02). Fasting uURS (ratio to urine Cr) tended to be higher in CKD vs control, but only uIS reached significance (p<0.05). eGFR was inversely related to each sURS and uURS (r=-0.54 to -0.71, p=0.01-0.07). When correlations of eGFR with each sURS and uURS were evaluated by group (CKD or control), the inverse correlations persisted in CKD for sURS (r=-0.69 to -0.77, p=0.04-0.09), uTMAO (r=-0.79, p=0.03) and uIS (r=-0.77, p=0.04), but no associations remained in controls (p>0.30). There were strong correlations among the three sURS (r=0.82-0.95, p<0.001), which were strongest within CKD but still evident in controls. There were also strong correlations between the sURS and corresponding uURS (r=0.62-0.91, p<0.02), and these persisted within CKD and control groups.

Conclusions: These results show that URS are elevated in serum and urine in CKD vs matched healthy adults on a controlled diet. In the CKD patients, lower eGFR corresponded to higher serum and urine URS. Further studies are needed comparing different diets in patients with CKD to reduce the adverse health outcomes associated with URS production and retention.

TH-PO636

Parathyroid Hormone Enhances Gluconeogenesis via the PKC/FoxO1 Pathway in Proximal Tubules

Hiroyuki Tsukada,[1] Motonobu Nakamura,[1] Shoko Horita,[1] Wataru Fujii,[1] Tomohito Mizuno,[1] Nobuhiko Satoh,[1] Yusuke Sato,[2] George Seki,[3] Haruki Kume,[2] Masaomi Nangaku,[1] Masashi Suzuki.[4] *[1]Division of Nephrology and Endocrinology, The University of Tokyo, Tokyo, Japan; [2]Department of Urology, The University of Tokyo, Tokyo, Japan; [3]Yaizu City Hospital, Yaizu, Japan; [4]Tokyo Gakugei University, Koganei, Japan*.

Background: Parathyroid hormone (PTH) has been reported to enhance gluconeogenesis in proximal tubules (PTs), which may be comparable to that in liver. PTH is known to activate both cAMP/PKA and PLC/calcium/PKC pathways. In this study, we tried to determine the detailed mechanism of stimulatory effect of PTH on PT gluconeogenesis.

Methods: Freshly isolated rat and human PTs were incubated overnight in DMEM with 0.2 mM dibutyryl-cAMP (cAMP) or 1 nM PTH, and subsequently incubated with 10 nM insulin for 4 hours. Total RNA was extracted from the PTs. The mRNA expression of gluconeogenic enzymes (phosphoenolpyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G6P)) was determined by quantitative PCR. To clarify the signaling pathway of PTH, PTs were also treated with protein kinase A (PKA) inhibitor H89, protein kinase C (PKC) inhibitor Gö6983, or siRNA against FoxO1. In addition, we performed western blotting in the kidney cortex tissue to analyze the Akt phosphorylation. To examine the effect of PTH on hepatic gluconeogenesis, similar experiments were performed using primary cultured rat hepatocytes.

Results: In rat and human PTs, cAMP and PTH increased the mRNA expression of PEPCK and G6P by 5 and 3 times, respectively. Insulin almost completely abolished the stimulatory effect of cAMP, but failed to attenuate that of PTH. H89 completely abolished the stimulatory effect of cAMP without affecting that of PTH. By contrast, Gö6983 completely abolished the stimulatory effect of PTH without affecting that of cAMP. siRNA against FoxO1 inhibited the stimulatory effects of both cAMP and PTH. Insulin-induced Akt phosphorylation was preserved after incubation with PTH in the kidney cortex. In rat hepatocytes, cAMP, but not PTH, increased the mRNA expression of PEPCK and G6P.

Conclusions: Our results, for the first time to our knowledge, revealed that PTH enhances gluconeogenesis in PTs via PKC/FoxO1 pathway. We also found that insulin was able to induce the Akt phosphorylation but failed to suppress gluconeogenesis in the presence of PTH. PTH-enhanced gluconeogenesis as well as insulin resistance in PTs may at least partially contribute to altered glucose homeostasis reported in patients with hyperparathyroidism and/or pseudohypoparathyroidism.

The Effects of Dietary Glucose on Urinary Exosomal MicroRNA Expression in an Insulin-Resistant Mouse Model

Maurice B. Fluitt, Carolyn M. Ecelbarger. *Georgetown University, Washington, DC*.

Background: Exosomal microRNAs provide a unique entry point to elucidate the molecular mechanisms of several metabolic processes and disease, including glucose metabolism and diabetic kidney disease. In addition, these miRNAs hold promise as attractive early non-invasive markers of disease. However, one limitation to the use of miRNAs as novel therapeutic interventions and early markers of disease is the influence of environmental and dietary factors on its expression. The goal of this study was to determine the effects of dietary glucose (ingestion) on the excretion of urinary exosomal miRNAs in an insulin-resistant mouse model.

Methods: 8 TALLYHO/Jng male mice were divided into three treatment groups with normal access to normal or 10% glucose drinking water for three-weeks. 24-hour urine was collected at baseline and week 3. Urinary exosomes were isolated using commercially available miRCURY Exosome kits and confirmed by western blotting.

Results: A diabetes pathway specific miRNA array revealed that 12 UE miRNAs were differentially expressed from baseline and week-3. UE miR-34a-5p, miR-320-3p, miR-26a-5p, miR-26b-5p, miR-23a-3p, miR-21a-5p, miR-194-5p, miR-1907, miR-185-59, and miR-126a-5p were increased 2-fold or greater, while miR-361-5p and let-7e-5p were decreased 2-fold or greater from baseline to week-3 in glucose-treated mice.

Conclusions: These findings suggest that these miRNAs play important roles in regulating processes associated with the development of diabetes and its complications, including diabetic kidney disease, and have potential as early markers and therapeutic targets for improving insulin sensitivity and renal senescence.

Ezrin Regulates Multiple Solutes Reabsorption via the Regulation of Membrane Protein Localization in the Proximal Tubules

Ryo Hatano,[1] Kotoku Kawaguchi,[2] Takashi Miki,[3] Shinji Asano.[2] *[1]Chiba University, Chiba, Japan; [2]Ritsumeikan University, Kusatsu, Japan; [3]Chiba University, Graduate School of Medicine, Chiba, Japan*.

Background: Ezrin is a member of ERM (ezrin-radixin-moesin) proteins and works as a cross-linker between membrane protein and actin cytoskeleton. In kidneys, intense expression of ezrin is observed in proximal tubules, and it is postulated that ezrin plays important roles in tubular solute reabsorption via the regulation of apical membrane localization of several transporters. We previously reported that ezrin knockdown (*Vil2$^{kd/kd}$*)

mice show hypophosphatemia due to mislocalization of Na^+ dependent phosphate transporters and its scaffold protein, Na^+/H^+ exchanger regulatory factor 1 (NHERF1). However, we haven't investigated the influence of loss of ezrin on the membrane localizations of other transporters.

Methods: We performed a comprehensive proteomic analysis of renal brush border membrane vesicles (BBMVs) of proximal tubules from Wild type (WT) and *Vil2*$^{kd/kd}$ mice in this study. We also measured the plasma concentration and urinary excretion of nutrition including amino acids, glucose, and low molecular weight protein.

Results: We identified totally 1,412 proteins including 18.8 % of membrane integral proteins from WT and *Vil2*$^{kd/kd}$ mice. Scaffold proteins including NHERF1 and PDZK1 were significantly decreased in *Vil2*$^{kd/kd}$ mice. Several transporters including Slc5a1, Slc5a11, Slc22a4 and Slc22a5 showed marginally significant reduction ($0.05 < p < 0.1$). We also found that BBMV localizations of several other solute transporters associated with the reabsorptions of amino acids, glucose, and organic anions were totally decreased in *Vil2*$^{kd/kd}$ mice, suggesting that *Vil2*$^{kd/kd}$ mice exhibit the phenotype of Fanconi syndrome, which is accompanied with massive urinary solute waste. On the other hand, expressions of several proteins associated with actin remodeling, and endocytosis were increased in *Vil2*$^{kd/kd}$ BBMVs. *Vil2*$^{kd/kd}$ mice showed defective endocytosis of FITC-labeled β_2-microglobulin similar to Fanconi syndrome model mice.

Conclusions: These results suggest that ezrin plays important roles in the regulation of several membrane transporter localizations in the proximal tubules.

Funding: Government Support - Non-U.S.

TH-PO639

Relationship Between Plasma Concentration of Adiponectin and Kidney Function in the Elderly Subjects: Results of the PolSenior Study

Marcin Adamczak,[1] Sylwia M. Dudzicz,[1] Jerzy Chudek,[4] Jan E. Zejda,[2] Tomasz Grodzicki,[3] Andrzej Wiecek.[1] *[1]Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland; [2]Department of Epidemiology, Medical University of Silesia, Katowice, Poland; [3]Department of Internal Medicine and Gerontology, Jagiellonian University Medical College, Krakow, Poland; [4]Department of Internal Diseases and Oncological Chemotherapy, Medical University of Silesia, Katowice, Poland.*

Background: Adiponectin is an adipose tissue hormone involved in the regulation of glucose metabolism and fatty acid breakdown. Based on meta-analyzes, it was documented that higher plasma adiponectin concentrations in CKD patients are associated with lower risk of cardiovascular complications. As adiponectin is mostly metabolized in the kidneys it is important to establish the relationship between glomerular filtration rate (GFR) and adiponectinemia. The aim of this study was to assess the plasma concentration of adiponectin in relation to GFR in the older population-based PolSenior study cohort.

Methods: The PolSenior study was a multicenter study which assessed the health and socio-economic status of older adults in Poland. In 3913 subjects aged 65 years or above (2041 male and 1872 female, BMI 28.1±5.1 kg/m^2, mean age 79±9 years) plasma adiponectin concentration (ELISA; B-Bridge International) were measured. GFR was estimated using a short MDRD formula. The results are presented as means with standard deviations.

Results: In studied subjects eGFR was 76 ml/min/1.73 m^2. eGFR below 60 ml/min/1.73 m^2 was observed in 842 (22%) subjects. Plasma concentration of adiponectin was 11.9±6.4 μg/ml. In subjects with eGFR < 60 ml/min/1.73 m^2 significantly higher plasma adiponectin concentrations were observed compared to subjects with eGFR ≥ 60 ml/min/1.73 m^2 (12.5±6.7 vs. 11.8±6.3, p=0.01). In the elderly subjects plasma adiponectin concentration depends strongly on BMI (R= -0.28; p<0.001) and marginally on the kidney function (R=-0.05; p=0.005). Multivariate regression analysis including plasma adiponectin concentration, BMI, eGFR, occurrence of diabetes and hypertension, showed that BMI and prevalence of diabetes (b=-0.24, p<0.001, b=-0.11, p<0.0001, respectively) but not eGFR explain variability of plasma adiponectin concentration.

Conclusions: In the older subjects from general population plasma adiponectin is weakly affected by kidney function.

TH-PO640

RNA Sequencing Analysis of Experimental Uremia and Compensated Pancreatic Exocrine

Ning Qu,[1] Hongli Jiang,[2] Lei Chen.[3] *[1]First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China; [3]Xi'an Jiaotong University, Xi'an, China.*

Background: Malnutrition is a common problem in patients with chronic kidney disease (CKD). About 30 years ago, several studies showed that more than half of patients with end-stage renal disease (ESRD) suffered from exocrine pancreatic insufficiency. Recent years, some studies also reported this phenomenon. But it's not clear that if there is compensatory mechanism to help relieve the symptom.

Methods: Sprague-Dawley rats were divided into two groups: sham (group NC) and uremia (group U). Uremia group rats were processed with 5/6 nephrectomy for chronic renal failure. All rats were fed for 24 weeks. High-throughput sequencing technology was used to detect all gene expression differences in jejunum tissue samples of all rats. Differentially expressed genes were screened out and through functional annotation and enrichment analysis, gene expression signaling pathways of sham group rats and uremia group rats were screened out.

Results: The results showed that 95 up-regulated genes and 18 down-regulated genes were screened in uremia group compared with sham group. Analysis of GO function and KEGG signaling pathway enrichment showed that the above differentially expressed genes were mainly enriched in protein digestion and absorption, pancreatic secretion, fat digestion and absorption and other functions and pathways. The pancreatic secretion signaling pathway was related to our aim. RNA expressions of many genes increased including prss1, prss2, prss3, cpa1, cpa2, cpb1, cela3b, cela2a, ctrl, ctrb1, pla2g1b, pnlip, pnliprp1 and cel and these genes all code digestive enzymes like trypsin, carboxypeptidase, pancreatic elastase, chymotrypsin and phospholipase. Except trypsin, the enzymes above are usually detected by pancreatic secretion while their RNA expressions increased in the jejunum.

Conclusions: Patients with ESRD suffered from exocrine pancreatic insufficiency but we found that some pancreatic secreted enzymes increased RNA expressions in the jejunum of experimental uremia rats. So we can deduce that the jejunum could more or less compensate for exocrine pancreatic insufficiency of ESRD patients. However, the exact mechanism still needs to be studied further.

TH-PO641

The Pitfalls of Nephrology Care: Are Older Patients and Their Caregivers Getting What They Need?

Nwamaka D. Eneanya,[1] Taylor L. Stallings,[1] Shananssa Percy,[2] Tamar Klaiman,[1] Jennifer S. Temel.[2] *[1]University of Pennsylvania, Philadelphia, PA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Older patients with advanced chronic kidney disease lack knowledge and information regarding disease treatment and advance care planning. It is unclear whether clinicians and older patients have the same goals with regards to communication of treatment decisions and goals of care. We sought to explore perceptions of clinician behavior and patient preferences via interviews with nephrologists, primary care physicians, patients and caregivers regarding treatment for end-stage renal disease and advance care planning.

Methods: Between March 2017 and May 2018, we conducted individual semi-structured interviews with nephrologists, primary care physicians, older patients (age ≧ 65), and their caregivers. Transcripts were transcribed using TranscribeMe and reviewed in an iterative process. Using Nvivo 11, we coded all transcripts utilizing two codebooks (clinicians and patients/caregivers) and identified key themes. Three independent coders conducted thematic content analyses and discrepancies in coding were resolved through consensus coding.

Results: We interviewed 16 clinicians (nephrology, n = 8; primary care, n= 8), 10 patients, and 5 caregivers. We identified three key findings: 1) nephrologists felt their primary responsibility was to discuss dialysis and other treatments for kidney disease including conservative kidney management, 2) primary care clinicians felt that they should take the lead in helping patients navigate their disease management and also lead advance care planning discussions, and 3) patients' and caregivers' perspectives about dialysis, quality of life and planning ahead for their care were not adequately addressed by clinicians.

Conclusions: Our findings highlight the differences in opinions and expectations between clinicians, patients, and their caregivers regarding treatment decisions and advance care planning in nephrology. Importantly, patients and caregivers do not feel that their needs are being met. Further research is needed to test feasible models of patient-centered education to ensure all stakeholders feel valued.

TH-PO642

Palliative Care Consultation for Hospitalized Patients with Advanced CKD and Its Impact on Goals of Care

Muhammad Asif, Peyman Mamdouhi, Jennie Z. Ma, Emaad M. Abdel-Rahman. *University of Virginia, Charlottesville, VA.*

Background: Chronic kidney disease (CKD) is a complex disease associated with high morbidity and mortality. Prognosis is even worse when these patients require hospitalization and identifying their goals of care is crucial. Palliative care (PC) is a comprehensive patient-centered approach that can help guide future care. Scarce data is available assessing frequency of PC consultation (PCC) for these patients and its impact on goals of their care. We aimed to assess frequency of PCC in hospitalized patients with advanced CKD/ESKD and its impact on advance directive (AD) and do not resuscitate (DNR) ordering.

Methods: We retrospectively studied all patients with CKD with eGFR<60 ml/min / ESKD hospitalized at UVA between 1/1/2015-6/30/2017. Number of PCC, AD and DNR orders were recorded as well as patients' demographic and comorbidity data.

Results: 8653 patients with eGFR<60 ml/min were hospitalized 13,321 times during the study period. PCC was obtained in 1274/8653 (14.7%) patients. Patient consulted for PC were significantly older, sicker, with less BMI and more advanced kidney disease (all with P<0.0001) compared with patients who did no get PCC. AD was obtained in 157/8653 (1.8%) patients. While AD was obtained in 12.1% with PCC, it was obtained in 0.04% with no PCC. DNR were signed in 2055/8653 (23.7%). While DNR was signed in 70.5% with PCC, it was signed in 15.7% with no PCC. Patients signing DNR orders were significantly older (73.0 ± 13.8 vs 67.7 ± 14.6), sicker (Charlson 4.6 ± 3.8 vs 3.3 ± 3.1) with less BMI and more advanced kidney disease (eGFR <30 ml/min 39.4% vs 27.1%). There was a trend to have more blacks signing DNR compared to whites (P =0.059)

Conclusions: PCC are underutilized in the care of hospitalized patients with advanced CKD/ESKD. PCC plays a significant role in guiding patients' goals of care.

PCC versus No PCC

	PCC (n=1274)	No PCC (n=7379)
Percentage	14.7%	85.3%
Age (years)	69.9+/-14.4	67.0+/-14.7
Charlson score	5.0 +/- 4.0	3.3 +/- 3.1
Sex (F)	46.5%	47.6%
Race (W)	80.5%	79.7%
BMI <25 >40	41.2% 7.0%	25.2% 9.7%
eGFR 30-60 ml/min <30 ml/min	58.8% 41.2%	71.9% 28.1%
AD	12.1%	0.04%
DNR	70.5%	15.7%

TH-PO643

The Oldest Dilemma: Dialysis or Conservative Treatment?

Juan C. Santacruz, Alberto Alonso-Babarro, Gloria Del Peso Gilsanz, Maria A. Bajo, Ossorio Marta, Sara Afonso ramos, Helena Garcia-Llana, Rafael Selgas. *Hospital Universitario La Paz, Madrid, Spain*.

Background: In comorbid elderly patients with stage 5 renal disease (ESRD) and functional impairment benefit of dialysis is not clear. The objective of this study is compare survival, characteristics and outcomes of patients who choose conservative palliative care management from those who decide dialysis after a shared decision meeting.

Methods: Prospective observational cohort study in patients with ESRD (CKD-EPI <12 ml / min, or CKD-EPI <15 ml / min in diabetics) who: 1. Prefer conservative palliative care management or 2. Meet the following criteria: > 75 years with comorbidity (Charlson Comorbidity Index (CI) > 5) or functional impairment (Barthel Index <95 or Palliative performance score (PPS) <60). The decision between dialysis (D) vs conservative management (CV) was taken after a reception meeting with patient, closest family and multidisciplinary team (nephrologists, nursery, palliative care physician, psychologist). Nephrology and Palliative Care team drove follow-up until death.

Results: One hundred two patients were included with no differences in ESRD etiology. Seventy eight (76.5%) chose CV, 24 (23.5%) D, 16 hemodialysis and 8 peritoneal dialysis. 55% were male although females chose mostly CV (p=0.015). Average age was 83.4±5.5 ys, statistically significant in CV vs D (84,5±5.9 vs 80.8±3.1ys; p=0,033), no differences in CI. Functional status was statistically lower measured by Barthel Index (77.3±20.3 vs. 94.48±10.8; p<0,0001) and PPS score (64.26±15.5 vs. 84.1±1.7; p:0.000) in CV vs D groups. Follow-up time was greater in D vs CV (median 25.2±17.1 vs 9.75±10 mo; p=0.000). Only 4 patients of CV group changed their decision to dialysis. Forty patients (39%) from CV required visits from home palliative care team (median 5, mean 7.83±9.9 visits). Sixty six died, 62 from CV and 4 from hemodialysis (p=0,0000). Survival was 43% at one year and 20% at 2 years in CV vs 96% at one year and 91% at 2 years in D group (p=0,0000). Places of death were, in frequency: Palliative care unit (n=25), hospitalization (n=20), home (n=17), medical residence (n=5) and ER (n=3).

Conclusions: ESRD patients who decide conservative treatment are oldest, with decreased functionality and mostly women. Despite a lower survival the decision remains firm which would indicate a probable stability in quality of life throughout their last days.

Early Outcomes from an Ambulatory Kidney Palliative Care Program

Jennifer S. Scherer,[1] Derek S. Moriyama,[1] Chikadibia Agoha,[2] Abraham Brody,[3] Frank Modersitzki,[4] Joshua Chodosh.[1] *[1]New York University Langone School of Medicine, New York, NY; [2]CUNY School of Medicine, Suffern, NY; [3]New York University, New York, NY; [4]New York University School of Medicine, New York, NY*.

Background: Patients with advanced kidney disease have an elevated symptom burden, increased mortality, and poor quality of life. While palliative care can address these issues, nephrology patients infrequently receive such care. To address this, we implemented an ambulatory kidney palliative care program. We describe our initial outcomes.

Methods: Utilizing chart abstractions, we characterized the clinic population and symptom burden for patients seen from May 6, 2016-July 6, 2018.

Results: Ninety-four patients were referred; 74 (78.7%) patients seen. Forty (54.1%) had follow-up appointments (range 2-13). Mean patient age was 72.7 ±16 years with 32 (43.2%) on dialysis. The mean symptom burden (n=65) was 12 (± 4.9) symptoms (out of 17) with mean severity of 2 (range 0-4), representing moderate severity. The most common physical symptoms were nausea (78%), dyspnea (72%), pain (68%) and itch (66%). Eighty-seven percent reported anxiety and 73% reported depression. There was no difference in symptom burden between patients on dialysis and those on conservative management (n=22). Patients on conservative management were significantly older and had more comorbidities. By visit two, there was a significant reduction in global symptom score (21.9 vs 19.0, p=0.01) in addition to a reduction in anxiety (2.1 vs 1.7, p=0.03), vomiting (0.8 vs 0.2, p=0.04), and restless legs syndrome (1.3 vs 0.8, p = 0.02).

Conclusions: Patients with serious kidney disease treated in a kidney palliative care clinic have a high symptom burden regardless of treatment choice. The decision to pursue conservative management is more prevalent in older patients with more comorbidities. Follow up visits to the clinic demonstrated a decrease in symptom burden, suggesting that a dedicated kidney-palliative care clinic may be successful in managing symptoms and addressing unmet need.

TH-PO645

Redefining End-of-Life Care in Dialysis: A Concurrent Hospice and Dialysis Program for Terminal Dialysis Patients

Jane O. Schell,[1] Keith Lagnese,[2] Robert Taylor.[3] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Family Hospice & Palliative Care, Pittsburgh, PA; [3]DCi incorporated, Nashville, TN*.

Background: End of life for patients with end stage kidney disease (ESRD) is defined by increased health care utilization with limited access to hospice services. Financial and regulatory barriers within the Hospice Medicare Benefit often require patients to stop dialysis to receive hospice services. Unsurprisingly 40% of dialysis patients on hospice receive these services for three or less days. We developed a concurrent hospice and dialysis program with the goal to increase hospice utilization and improve patient, family and provider experience.

Methods: The ESRD Concurrent Care Program is a quality improvement initiative developed through partnership between Dialysis Clinic, Inc.'s Independence ESCO and UPMC Family Hospice in Pittsburgh, PA. The program offers concurrent hospice and palliative dialysis (10 sessions with weekly assessment) to terminal dialysis patients with an expected prognosis of two months or less and whose goals are comfort-focused. Palliative dialysis includes adjustment in the timing, frequency and delivery of dialysis to address symptoms and end of life goals. Outcomes measured include hospice length of stay (LOS), number of dialysis treatments provided and place of death.

Results: Since the program was initiated in January, 2018, 10 patients were offered the concurrent program. One patient elected to stop dialysis at enrollment. Of the remaining nine patients who elected the concurrent program, six survived to receive planned dialysis session(s). Among these six patients, 50% were female and all but one was Caucasian. Five of six patients received hemodialysis, and one patient received peritoneal dialysis. Hospice length of stay was almost 2 weeks (13.8 days, range of 7 to 28 days). The average number of dialysis treatments was 3.3 (range of 1 to 8 treatments). All patients died in a home-like environment. End of life goals attained included attending planned celebrations, spending time with family, and acheiving a sense of control.

Conclusions: Our concurrent hospice and dialysis program led to longer hospice LOS compared to general care trends. By allowing up to ten additional treatments, patients and families were able to achieve their end of life goals. Future direction involves expansion of the program within DCI with the goal to inform policy change in hospice delivery for dialysis patients at end of life.

TH-PO646

Survival of Elderly Patients with ESKD Managed Without Dialysis

Angela Chou,[1] Kelly C. Li,[2] Anna Hoffman,[4] Mark Brown.[3] *[1]St George Hospital, Cabramatta, NSW, Australia; [2]St George Hospital, NSW, Australia, Kogarah NSW, NSW, Australia; [3]St. George Hospital, Sydney, NSW, Australia; [4]St George Hospital Sydney, Kogarah, NSW, Australia*.

Background: Shared decision making (SDM) is important when considering whether an elderly patient ESKD should be managed with dialysis. Research has shown that physicians find these conversations difficult because of the relative paucity of data on survival of patients managed without dialysis.

Methods: We conducted a prospective observational study of 580 patients with CKD stages 4-5, aged ≤ 65 years between March 2009-August 2018 in our renal unit where SDM is actively implemented and conservative management is supported by a specific Renal Supportive Care (RSC) program. 148 dialysis patients attended the Pre-dialysis education clinic (PEC), 82 had not (non-PEC), and 280 patients were managed conservatively (CM) with RSC, an embedded multidisciplinary renal palliative care clinic. Survival was evaluated from: (1) Clinical pathway decision date; (2) eGFR ≤ 15; and (3) eGFR ≤ 10. Cox models were used to estimate survival adjusted for potential confounders identified as significant after multivariate regression analysis.

Results: CM patients were significantly older than PEC and non-PEC dialysis patients (mean±SD: 84±6 vs. 74±6 vs. 76±6; p<0.01) and had greater comorbidity (<0.01). From decision date, median survival was 6.0 years (Interquartile range [IQR] 2.5-9.5) in PEC compared with 3.3 (IQR 0.7-5.0) in non-PEC dialysis and 1.1 yrs. (IQR 0.4-1.7) in CM; p <0.01. From time eGFR ≤ 15, median survival was 7.8 years (IQR 3.5-12.6) in PEC, 5.6 (IQR 0.8-6.5) in non-PEC and 1.3 (IQR 0.5-2.0) in CM; p <0.01. From eGFR ≤ 10, median survival was 6.4 years (IQR 2.4-10.4) in PEC, 2.4 (IQR 0.5-6.0) in non-PEC and 0.7 (IQR 0.2-1.4) in CM; p <0.001. Non-PEC patients had lower eGFR than PEC at time of first visit (9±4 vs. 16±5 ml/min/1.73m^2, p<0.01). In the CM group, at least 51 (18%) patients did not reach eGFR ≤ 15 and the cause of death was mainly non-renal (41 out of 51; 92%). Older age reduced survival from decision date (HR 1.03, 95% CI 1.01-1.049; p<0.01).

Conclusions: The median survival of elderly patients managed conservatively was 15.4 and 8.5 months from the time of eGFR ≤ 15 and ≤ 10 respectively. Elderly patients who did not attend dialysis education prior to initiation had worse survival. This data should assist physicians with SDM discussions.

TH-PO647

Why Do Older Patients Choose Conservative Management?

Fahad Saeed,[1] Hugh Adams,[2] Ronald M. Epstein.[3] [1]*University of Rochester Medical Center, Pittsford, NY;* [2]*Nephrology Division, Rochester, NY;* [3]*University of Rochester, Rochester, NY.*

Background: Although many older patients with end-stage renal disease and limited prognoses prefer conservative management (CM), it is not widely offered in the US. Moreover, there is a dearth of US-based literature reporting clinical experience with shared decision-making regarding CM of advanced chronic kidney disease (CKD).

Methods: We describe the experience of 13 patients who opted for CM at the University of Rochester Medical Center's CKD clinic. Their reasons for choosing CM were categorized into four broad categories based on a review of their electronic medical records. A retrospective chart review conducted by two reviewers determined the status of advance care planning, hospice referral, and place of death.

Results: During the year 2016-2017, 13 patients opted for CM. The mean and median age of these patients was 81.8 years (standard deviation 7.3) and 83 years (interquartile range 11), respectively. Their reasons for choosing CM included: poor prognoses; a wish to maintain their quality of life; their desire for a dignified life closure; and the intention to protect family members from having to see them suffer, based on their own memory of having witnessed a relative on dialysis previously. A total of seven patients died: all received hospice services, five died at home, one at a nursing home and one at a hospital. Advance care planning was completed in 100% of the cases. Symptoms were managed in collaboration with primary care physicians.

Conclusions: Patients' decisions to forego dialysis and engage in CM were influenced by their values and previous experience with dialysis, in addition to co-morbidities and limited prognoses. Promoting the choice of CM in the US will require training of clinicians in competencies, including communication and decision-making skills, as well as basic symptom management.

TH-PO648

Racial Differences in End-of-Life Care Among Older Veterans with Non-Dialysis-Dependent CKD

Nwamaka D. Eneanya, Gary E. Weissman, Katherine Courtright, Peter P. Reese, Laura M. Dember, Scott D. Halpern, Jordana B. Cohen. *University of Pennsylvania, Philadelphia, PA.*

Background: Previous studies of veterans receiving dialysis demonstrated more intensive end-of-life (EOL) care among racial minorities than non-minorities. Little is known about racial differences in EOL care for older veterans with non-dialysis dependent chronic kidney disease (CKD).

Methods: We conducted a retrospective cohort study of veterans with incident stage 4 CKD from 2003-2014, age ≥70 years, and death before 1/18/17. Outcomes were a composite of intensive care (initiation of dialysis, invasive mechanical ventilation, cardiopulmonary resuscitation, or artificial nutrition) in the final month of life, and palliative care or hospice use in the final 6 months of life.

Results: 21,165 decedents met inclusion criteria. Non-Hispanic Whites were more often married and less often had hypertension, diabetes, and dementia compared to Non-Hispanic Blacks or Hispanics. In adjusted analyses, Non-Hispanic Blacks (OR 1.69, 95% CI 1.46-1.95) and Hispanics (OR 2.23, 95% CI 1.87-2.67) had a higher likelihood of intensive care compared to Non-Hispanic Whites. There was a significant interaction between death year and race with regard to hospice or palliative care use (p<0.01): compared with Non-Hispanic Whites, minorities had a similar likelihood of palliative care or hospice use before 2010, but higher use in recent years (Figure).

Conclusions: Historically, Non-Hispanic Black and Hispanic older veterans with CKD experienced more EOL intensive care and similar hospice or palliative care use compared with Non-Hispanic Whites. Following recent Veterans Health Administration investments in palliative care, minorities were more likely than non-minorities to use palliative care or hospice. More research is needed to assess how health system factors contribute to racial differences in EOL care.

TH-PO649

Retrospective Cohort Study of Patients Seen in a Specialized Renal Supportive Care Clinic

Alexandra E. Bursic,[1] Jane O. Schell,[1] Amar Bansal.[2] [1]*University of Pittsburgh Medical Center, Pittsburgh, PA;* [2]*University of Pittsburgh Department of Medicine, Pittsburgh, PA.*

Background: Palliative care is underutilized in advanced kidney disease care despite similar mortality and symptom burden as other life-limiting illnesses. Patients are less likely to engage in advance care planning (ACP) and often begin dialysis without an informed conversation about conservative care. As a result, patients with advanced renal disease are more likely to receive invasive, burdensome treatments at the end of life compared to those with other serious illnesses. We describe outcomes of a Renal Supportive Care Clinic (RSCC) at UPMC, staffed by dually trained nephrology and palliative medicine physicians.

Methods: We reviewed the medical records of all patients seen in RSCC during 2015, with follow-up through February 2019. We recorded documentation of ACP and whether patients had chosen a conservative care (CC) pathway without dialysis. Additional data collected included demographics, comorbid conditions, date that eGFR fell below 20 mL/min/1.72m^2, and death date (when available).

Results: A total of 48 patients were seen in RSCC in 2015. Mean age at first visit was 74 (± 8.7) years. Over half (60%) were female, and 14 (29%) were Black. Eight (17%) were receiving dialysis at the time of RSCC visit. Mean creatinine at presentation was 2.4 (± 1.5) mg/dL (excluding dialysis patients). ACP was performed with 43 patients (90%), and a surrogate decision maker was documented for 41 (85%). Seventeen patients (35%) had a documented goals of care conversation indicating a CC pathway. Of these patients, only 2 (12%) started dialysis. Among the 15 patients who remained on CC, 9 survived until the end of the study period. Six of these patients had an eGFR that never fell below 20. Of the remaining three patients, an average of 1500 (± 283) days elapsed between eGFR <20 and the end of the study period. Of the patients who died, mean length of time between eGFR <20 and death was 376 days (± 340).

Conclusions: Advance care planning conversations occurred frequently in RSCC, and a significant minority of patients chose conservative care without dialysis. Of CC patients, a majority survived the 4-year follow-up period (including several with eGFR<20). Among patients who died, mean survival after eGFR fell below 20 was greater than 1 year. Further research is necessary to determine how palliative care can be efficiently integrated into care delivery for advanced kidney disease.

TH-PO650

A Brief End-of-Life Screening Module Improves Knowledge About End-of-Life Desires in CKD Patients

Anthony J. Bleyer, Nathan Kim, Catherine Robey, Revathy Sampath-Kumar, Allison E. Wang. *Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: There are currently no published screening tools regarding end of life (EOL) care. An EOLmodule was developed and used by a nephrologist over the last decade. The module included three questions: 1) Whom would the patient like to make health care decisions in the event the patient is unable? 2) Is this the patient's next of kin? 3) In case of a medical catastrophe that resulted in severe changes in health and mentation that would be highly unlikely to be reversible, the patient would/would not want to be kept alive by artificial means, including dialysis. The checklist in general requires approximately 5 minutes for completion.

Methods: A retrospective review was performed on 398 patients seen in the outpatient clinic by the nephrologist who used the EOLM over ten years and a control group of 299 patients seen by other nephrologists at the same clinic. The following data were collected

from the electronic medical record: demographic data, information regarding EOL, patient comorbidities, and outcomes. All statistical analyses were conducted using SAS software.

Results: The EOLM was completed in 167 of 398 patients (42%) by the nephrologist using the EOLM. EOL was discussed in 17/299 (5.7%) patients seen by other nephrologists ($p<0.0001$). The mean age of patients using the EOLM was 63 years, 63% male, 55% with ESRD, 62% white, 31% African American. 89% of patients wanted comfort care in the event of a health catastrophe, with 6% desiring full care, and 5% undecided. 16 of 182 individuals (8.8%) identified an individual who was not their next of kin as the person that they would like to make healthcare decisions for them. 10/12 (83%) EOLM patients vs 19/37 (51%) control patients died during hospital admission and had documentation in the chart that EOL wishes were met ($p=0.089$).

Conclusions: An EOLM identified that the vast majority of CKD patients desire comfort care in the event of a health catastrophe. Nine percent of patients desired a surrogate decision maker who was not their next of kin and needed further documentation. Over ten years, only 12/167 patients died during a hospitalization. Patients with an EOLM were more likely to have EOL goals met (83% vs. 51%), though this was not significant due to lack of power.

TH-PO651

A Pilot Study of a Supportive Care Video Decision Aid on Knowledge for Elderly Patients with Advanced CKD

Nwamaka D. Eneanya,[1] Shananssa Percy,[2] Taylor L. Stallings,[1] David J. Steele,[2] Michael J. Germain,[5] Michael Paasche-Orlow,[4] Angelo Volandes.[3] *[1]University of Pennsylvania, Philadelphia, PA; [2]Massachusetts General Hospital, Boston, MA; [3]MGH, Waban, MA; [4]Boston University, Boston, MA; [5]Baystate Medical Center, Springfield, MA.*

Background: The benefits of dialysis remain uncertain for elderly and frail patients with advanced chronic kidney disease (CKD). Although non-dialytic supportive kidney care (SKC) is an option for this patient population, there have been a lack of studies on patient-facing decision aids that specifically include this treatment approach. We performed a randomized controlled trial to test the efficacy of a video decision aid on knowledge of SKC among elderly patients with advanced CKD. We also assessed preferences for SKC and satisfaction and acceptability of the video.

Methods: Eligible patients were: age ≥ 65 years, English-speaking, had Stage 4 or 5 CKD, and were referred by their primary nephrologists at two academic centers in the US. Patients were randomized to receive education via a short verbal script or video. The video included images of patients undergoing hemodialysis, peritoneal dialysis or SKC. Patients received a knowledge questionnaire before and after receiving the verbal or video education.

Results: Among 100 enrolled participants, the mean age was 76 ± 6 years. Many were female (49%), White race (66%), and had completed high school education (85%). Knowledge of SKC increased in both arms after receiving education ($p < 0.01$); there was no difference in knowledge improvement between groups (Table 1). There was not a significant increase in those who preferred SKC after receiving either type of education ($p = 0.20$). The majority of patients who viewed the video felt comfortable watching it (96%), felt the content was helpful (96%) and would definitely recommend the video to others (72%).

Conclusions: Compared to an ideal verbal educational script, a video decision aid was not different in improving knowledge of SKC. Patients who received video education also reported high satisfaction and acceptability ratings. Future research will determine the effectiveness of a SKC video decision aid on patient preferences for treatment in real-world settings.

Table 1. Knowledge and preference for supportive care

	Total (N=100)	Verbal script (N=50)	Video (N = 50)	P-value
Pre-education correct knowledge of supportive care (%)	41	38	44	0.54
Pre-education preference for supportive care (%)	21	26	16	0.22
Post-education knowledge of supportive care (%)	61	58	64	0.54
Post-education preference for supportive care (%)	26	30	22	0.36

TH-PO652

Rapid eGFR Decline Is Not Associated with Cognitive Impairment

James Tollitt,[1,3] Aghogho Odudu,[3] Daniela Montaldi,[3] Philip A. Kalra.[2,3] *[1]Salford Royal NHS Trust, Salford, United Kingdom; [2]Salford Royal Hospital NHS Trust, Salford, United Kingdom; [3]University of Manchester, Manchester, United Kingdom.*

Background: Cognitive impairment (CI) is underdiagnosed in patients with CKD. Unidentified CI may explain non-adherence to renal diet, fluid, medication and dialysis regimens. Determining if speed of eGFR decline is a significant risk factor for CI may help identify patients suffering from CI in CKD.

Methods: Patients enrolled into a UK longitudinal epidemiological non dialysis CKD cohort study without previously diagnosed CI underwent cognitive assessments. These included; Montreal Cognitive Assessment (MoCA) and Trail Making A and B (TMTA and TMTB). eGFR decline was measured by linear regression and percentage fall in eGFR prior to cognitive assessment. Multivariate logistic regression was performed for comorbidity and lifestyle values to determine factors predictive of CI. CI was defined as < 26 on MoCA and relative CI (rCI) defined by >-1.34SD of any cognitive Z score.

Results: 250 participants completed the MoCA and 239 participants underwent the MoCA and TMT. 44% and 17% of participants were diagnosed with CI or rCI using MoCA score (adjusted for education) and the Z score respectively. Fast eGFR decline (>-3mL/min/yr), measured over median 58 antecedent months was not associated with CI (Odds Ratio (OR) 0.589 95%CI 0.313-1.109) or rCI (OR 0.864 95%CI 0.369-2.021) in unadjusted analysis. >50% and >20% egfr drop over study period was not associated with CI or rCI. Older age and previous stroke were associated with CI after comorbidity adjustments. Only age was associated with rCI after same adjustments (Image 1).

Conclusions: Cognitive impairment is common in patients with CKD. Speed of eGFR decline is not a significant risk factor for CI in patients with CKD.

Intradialytic Cerebral Perfusion and Cognitive Outcomes in Older Adults on Hemodialysis

Dawn F. Wolfgram,[1] Wesley Richerson.[2] *[1]Medical College of Wisconsin, Wauwatosa, WI; [2]Medical College of Wisconsin/Marquette University, Milwaukee, WI.*

Background: End-stage renal disease affects over 600,000 Americans; with the majority of patients treated with hemodialysis (HD). Over two thirds of HD patients have significant cognitive impairment. Although causes of cognitive impairment may be multifactorial, there is some evidence that HD-process may lead to cognitive decline through cerebral ischemic disease from HD related hemodynamic fluctuations. We hypothesize that, at baseline white matter integrity will be associated with change in intradialytic cerebral perfusion and cognitive performance.

Methods: Participants are over the age of 50 who have been on HD fewer than 2 years. Our predictor variable is change in intradialytic cerebral oximetry (ScO2). We include three cognitive outcome measures; patient-reported cognition survey, neuropsychological assessment, and white matter integrity on MRI.

Results: Currently 25 participants are enrolled, with 20 completing all baseline measurements (5 unable to do MRI). The mean (SD) age was 65.4 (6.6) years. Majority were males (72%) and Caucasian (64%). Most had diabetes (64%) and hypertension (80%). Overall cerebral oximetry declined during HD session with a mean drop of 7.0 (2.9) %. Participants reported overall no cognitive issues with mean PROMIS cognition score of 55.3 (9.8) against normative score of 50 for the general population. This contrasts with the neuropsychological scores showing deficits in test of executive function (39.8 (7.6)) and processing speed (40.0 (9.1)), again against normative score of 50. Correlational analysis demonstrates that greater intradialytic drop in ScO2 was associated with lower FA scores in some white matter tracts.

Conclusions: In our interim analysis we see that HD patients have cognitive deficits in key domains of executive function and processing speed and worse white matter integrity compared to healthy controls. Our results also show that cerebral oximetry does fluctuate during routine HD sessions. Our preliminary analysis demonstrate a trend of greater intradialytic cerebral oximtery decline being associated with lower white matter integrity in certain tracts, but the currently small sample size shows variability in results. Enrollment is ongoing and future analysis will include more participants.

Association of CKD Markers with Dementia Markers on Brain MRI: The ARIC Study

Johannes B. Scheppach,[1] Aozhou Wu,[4] Rebecca F. Gottesman,[1] Tom Mosley,[5] Morgan Grams,[1] Richey Sharrett,[6] Josef Coresh,[2] Silvia Koton.[3] *[1]Johns Hopkins University, Baltimore, MD; [2]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [3]Tel Aviv University and Johns Hopkins University, Tel Aviv, Israel; [4]The Johns Hopkins University, Baltimore, MD; [5]Univ. of Miss. Med Center, Jackson, MS; [6]Johns Hopkins, Baltimore, MD.*

Background: Urine albumin-creatinine-ratio (UACR) and estimated glomerular filtration rate (eGFR) define chronic kidney disease (CKD) and are associated with an increased risk of dementia and cognitive impairment. Such pathologies are accompanied with damage to the structural integrity of the brain, which can be seen using magnetic resonance imaging (MRI). We therefore examined the association of ACR and eGFR with MRI structural brain abnormalities in participants in the Atherosclerosis Risk in Communities (ARIC) study.

Methods: We studied 1,525 ARIC participants aged 67-90 years who attended visit 5 (2011-2013), and had a brain MRI scan performed, and eGFR based on cystatin C and UACR measured. We analyzed the association of UACR and eGFR with reduced brain volume, increased white matter hyperintensity (WMH) volume, micro-hemorrhages and brain infarcts using linear and logistic regression models, adjusted for age, sex, race, education, Apolipoprotein E4 level, smoking, body mass index, total cholesterol level, hypertension, diabetes, stroke and intracranial volume (only for volume measurements). Effect sizes for eGFR and ACR were normalized to their interquartile range (IQR).

Results: Higher levels of UACR and lower levels of eGFR were associated with reduced brain volume in regions typically affected by Alzheimer's Dementia (AD), such as the hippocampus, and in non-AD related regions. Higher UACR and lower eGFR were also associated with increased WMH volume, and higher number of micro-hemorrhages and infarcts. The magnitude of the observed associations with MRI brain pathologies was similar between UACR and eGFR.

Conclusions: Higher UACR and lower eGFR are strongly associated with brain structural MRI abnormalities. These abnormalities include white matter lesions, infarcts, microhemorrhages and signs of brain atrophy, which manifest globally in regions typical for AD as well as other brain regions.

Renal Function Does Not Have a Graded Inverse Association with Cognition in the Elderly

Aditi Gupta,[1] Kevin F. Kennedy,[3] Srinivasan Beddhu,[2] Jeffrey M. Burns.[4] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Utah School of Medicine, Sandy, UT; [3]Independent, Overland park, KS; [4]University of Kansas School of Medicine, Kansas City, KS.*

Background: Studies have shown a graded relation between estimated glomerular filtration (eGFR) and cognition. However, these studies are limited by inadequate matching at baseline, poor selection of neuropsychological tests (use of tests meant for screening to assess cognition) or low numbers of older participants. In this study we used data from the Alzheimer's Disease Neuroimaging Initiative (ADNI), a NIH funded, longitudinal multicenter study for the early detection and tracking of cognitive impairment and dementia, to explore the association between eGFR and cognition in older adults.

Methods: We compared previously validated composite scores for memory and executive function in ADNI participants with and without cognitive impairment to assess the association with eGFR. We used CKD-epi equation for calculating eGFR. We divided the groups with and without cognitive impairment by baseline eGFR into <45, 45-60, 61-90 and >90 ml/min and analyzed differences in cognition between these groups. We also performed a linear multivariable analysis taking memory and executive function as the dependent variable and eGFR as a continuous independent variable.

Results: There were 1181 ADNI participants, 805 with cognitive impairment and 376 without (with available creatinine values at baseline). The mean ages were 73.3±7.7 and 74.5±5.6 respectively (p=0.006). Those with cognitive impairment were more likely male (58.6% vs 51.3%, p=0.018), and married (79.3% vs 68.6%, p=0.001). Race and ethnicity did not differ between the two groups (p>0.2). Mean eGFR was higher in the group with cognitive impairment (66.1±14) compared to the group with no cognitive impairment (63.9±14.8) (p=0.014). 6% of the participants had a eGFR<45, 22% eGFR 45-60, 51% eGFR 60-90, and 21% eGFR>90. In our multivariable model, memory scores decreased by 0.177 (p<0.001) and executive scores by 0.32 (p<0.001) for every 10 years increase in age in the entire cohort. Lower education was associated with lower memory and executive scores (p<0.001). There was no association between eGFR and memory (p=0.598) or executive scores (p=0.223) in the entire cohort.

Conclusions: We did not find an inverse relationship eGFR and cognitive impairment in the elderly in the ADNI Study.

The Effects of Testosterone Replacement Therapy (TRT) in Patients Established Dementia

Aditi Gupta,[1] Mariana Garcia-Touza,[6] Peter S. Wiegmann,[2] Virginia J. Savin,[3] Mukut Sharma,[4] Archana Goel,[5] Thomas Wiegmann.[5] *[1]University of Kansas Medical Center, Kansas City, KS; [2]Midwest Biomedical Research Foundation, Kansas City, MO; [3]KC VA Medical Center, Kansas City, KS; [4]KCVA Medical Center, Kansas City, MO; [5]VA Medical Center, Kansas City, KS; [6]Kansas City VA, Kansas City, MO.*

Background: Testosterone deficiency is common in both chronic kidney disease (CKD) and dementia. We have previously shown that dementia is associated with a faster progression of CKD, increased vascular disease and mortality. Here we examined the effect of TRT in patients with dementia and testosterone deficiency on progression of CKD progression, vascular disease and mortality.

Methods: Data from a large cohort of veterans diagnosed with low total testosterone (n=57,985) were used to determine the effect of TRT on the progression of CKD, cardiovascular events and all cause mortality in patients with dementia. Increase in serum creatinine to >1.5 mg/dl was taken as a measure of progression of CKD. Data were extracted using the Veterans Administration Informatics and Computing Infrastructure (VINCI), and analyzed using SAS. Propensity matching was used to adjust for age, vascular disease and follow up time. Results were compared using means tests, frequency tables, and odds ratios. P values ≤0.01 were considered significant.

Results: Of the 1,792 patients with dementia, 1,317 received TRT. Of the 57,985 controls without dementia, 44,434 received TRT. Baseline creatinine was similar in the dementia and control groups (1.06 mg/dl). TRT slowed the progression of CKD in patients with dementia (OR 0.63, 95% CI 0.51-0.79) and in controls (OR 0.89, 95% CI 0.88-0.91), and decreased all-cause mortality in patients with dementia (OR 0.61, 95% CI 0.49-0.75) and in controls (OR 0.85, 95% CI 0.84-0.87). TRT also decreased incident cerebrovascular accident (CVA) in dementia (OR 0.57,95% CI 0.41-0.79) and controls (OR 0.88, 95% CI 0.81-0.95), but incident myocardial infarction (MI) was decreased in controls only (OR 0.76, 95% CI 0.67-0.85). TRT did not reduce new diagnosis of retinopathy or nephropathy. Prior cardiovascular disease was more common in patients with dementia (% difference dementia/control), coronary artery disease (117), congestive heart failure (92), CVA (496), hypertension (67), MI (140), peripheral artery disease (129). Average follow up was 6.1 years.

Conclusions: TRT decreases the progression of CKD, CVA and all-cause mortality in patients with dementia. This finding is important, as dementia is associated with increased CKD progression, vascular disease and mortality.

TH-PO657

The Association of Depression with Geriatric Conditions in Older Adults with CKD

Christine Liu,[1,2] Jamie Giffuni,[5] Kieran Reid,[2] Sushrut S. Waikar,[4] Stephen L. Seliger,[3] Daniel E. Weiner.[2] *[1]Boston University School of Medicine, Boston, MA; [2]Tufts University, Boston, MA; [3]University of Maryland School of Medicine, Baltimore, MD; [4]Harvard Medical School, Boston, MA; [5]Baltimore Veterans Affairs Medical Center, Baltimore, MD.*

Background: Depression is common in CKD and is associated with increased mortality. Geriatric conditions are constellations of signs and symptoms that are usually multifactorial in origin. Many geriatric conditions are associated with increased mortality. Examples of geriatric conditions include cognitive impairment or dizziness. Given depression and geriatric conditions both impact mortality, the presence of both may have additive or synergistic effects in CKD. Our goal was to examin e if depressive symptoms were cross-sectionally associated with the frequency of geriatric conditions in older adults with CKD.

Methods: Baseline data from the Aerobics, Weights, and Renal Disease Study, a randomized trial of exercise in community-dwelling adults 55+ years with stage 3b-4 CKD, were used. The independent variable was depressive symptoms, defined as Beck Depression Inventory score ≥ 10 points (range 0 to 63). The dependent variable was number of geriatric conditions (cognitive impairment, poor physical function, dizziness, fatigue, and chronic pain). Cognitive impairment was defined as Montreal Cognitive Assessment < 26; poor physical function as Short Physical Performance Battery ≤ 7; dizziness as reported on the Memorial Symptom Assessment Scale; fatigue if responded ≥ "good bit of time" to feeling worn out on Short Form-36 (SF-36); and chronic pain if answered ≥ "moderate" pain on SF-36. A generalized linear regression model adjusting for age, sex, race, study site, BMI, diabetes, hypertension, and eGFR was used.

Results: Of 99 persons (25% female, 61% African-American, mean age 68.0±8.2 years, mean BMI 31.1±6.6 kg/m^2, mean eGFR 33.1±9.2 ml/min/1.73m^2), mean BDI score was 7.2±6.1 points (range 0 to 31) points. Mean number of geriatric conditions was 1.7±1.0 (median 1, IQR 1). After adjustment, depressive symptoms were associated with more geriatric conditions (β coefficient = 0.5129 (95% CI 0.0468, 1.000, p value = 0.03).

Persons with depressive symptoms had 1.9 geriatric conditions (least square means), while those without depression symptoms had 1.4 geriatric conditions (least square means).

Conclusions: In older adults with CKD, depressive symptoms correlated with the frequency of geriatric conditions. Future studies should investigate how geriatric conditions may worsen poor health outcomes in CKD patients with depression.

TH-PO658

Benzodiazepines, Opioids, and Mortality Among Hemodialysis Patients

Mara McAdams-DeMarco,[1] Abimereki Muzaale,[3] Sunjae Bae,[1] Nadia M. Chu,[1] Krista L. Lentine,[2] Dorry L. Segev.[1] *[1]Johns Hopkins, Baltimore, MD; [2]Saint Louis University, St. Louis, MO; [3]Johns Hopkins University, Baltimore, MD.*

Background: Mortality from benzodiazepine/opioid interactions is a growing concern in light of the opioid epidemic. HD patients suffer from a high burden of conditions which are treated with benzodiazepines and are 3-times more likely to be prescribed opioids than the general population. Therefore, they are at risk of mortality resulting from benzodiazepine/opioid interactions.

Methods: A cohort of 110,127 adults initiating HD (1/2013-12/2014) was assembled by linking USRDS/Medicare claims. Using adjusted Cox regression, we estimated the mortality risk associated with benzodiazepine prescribing (time-varying) and tested whether this risk differed by opioid prescribing.

Results: Within 1 year of HD initiation, 17.3% were prescribed a short- and 5.5% were prescribed a long-acting benzodiazepine. Co-prescribing of opioids and short- (78.7%) and long-acting benzodiazepines (81.8%) were common. Opioid prescribing was associated with short- (aHR=2.07,95%CI:2.00-2.14) and long-acting benzodiazepine prescribing (aHR=2.30,95%CI:2.15-2.47). Patients prescribed a short-acting benzodiazepine were at 1.53-fold (95%CI:1.45-1.61) increased mortality risk; this risk was exacerbated to 1.78-fold (95%CI:1.63-1.94) increased mortality risk with opioid co-prescribing ($p_{interaction}$=0.01). In contrast, long-acting benzodiazepine prescribing was inversely associated with mortality (aHR=0.85,95%CI:0.75-0.96) and there was no differential risk by opioid prescribing ($p_{interaction}$=0.57).

Conclusions: Patients initiating HD are commonly co-prescribed short-acting benzodiazepines and opioids which was associated with a 1.8-fold increased mortality risk. High-risk co-prescribing of short-acting benzodiazepine/opioids should be recognized by physicians caring for this vulnerable population.

Funding: NIDDK Support

Figure 1. Cumulative incidence of time to first short-acting benzodiazepine prescription among patients initiating hemodialysis (n=110,127) between 2013-2014, by race. Approximately 17.7% of white vs. 9.6% of non-white patients have used a short-acting benzodiazepine within six months of initiating dialysis.

Time Trends in Opioid Prescribing and Uncontrolled Pain in the Last Month of Life Among Patients with ESRD, 2010-2018

Melissa Wachterman,[1,2] Ann M. O'Hare,[3] Nancy L. Keating,[2] Erin Beilstein-Wedel,[1] Carly Meyer,[1,2] Susan T. Crowley.[4] *[1]Center for Healthcare Organization and Implementation Research, VA, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]VA Puget Sound Health Care System, Seattle, WA; [4]Veterans Health Administration, West Haven, CT.*

Background: Most patients with ESRD experience frequent, uncontrolled pain near the end of life. Opioids have long been a core component of pain management near the end of life. In response to the opioid crisis, organizations including the Veterans Health Administration (VA) and the Centers for Disease Control have developed guidelines intended to reduce opioid overuse at the population level. Little is known about how these efforts may have impacted opioid prescribing and pain among patients with ESRD near the end of life.

Methods: Using data from the VA, we identified all 3,370 patients with ESRD who died in a VA facility between 2010-2018 whose next-of-kin completed the Bereaved Family Survey. Using survey and pharmacy data, we assessed the mean daily opioid dose (in morphine equivalents) and the proportion with proxy-reported frequent uncontrolled pain, both focused on the last month of life. We used generalized estimating equations to assess time trends in these two outcomes after adjustment for patient demographics and medical comorbidity.

Results: From 2010 to 2018 mean daily opioid dose in the last month of life (in morphine equivalents) decreased by 1.4 mg per year (p=.006) (see Figure for mean doses by year). From 2010 to 2018 the percentage of patients with frequent, uncontrolled pain in the last month of life increased by 1.9% per year (p<.001) (see Figure for percentages by year). These differences persisted after adjustment for patient characteristics.

Conclusions: Decreases in opioid prescribing among patients with ESRD over the last decade have been accompanied by increases in uncontrolled pain near the end of life, highlighting potential unintended consequences of opioid safety initiatives.

Funding: Other NIH Support - National Institute on Aging, Veterans Affairs Support, Other U.S. Government Support

Kidney Biopsy in Elderly Chinese Patients

Mengqi Xiong,[1] Sheng Nie,[2] Long Wang,[1] Jin Dong,[1] Xin Xu.[3] *[1]National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]Renal Division, Nanfang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease, Guangzhou, China.*

Background: High-quality epidemiologic data on the spectrum of biopsy-proven kidney diseases among elderly patients are limited in China. This study aimed to examine the clinical characteristics and spectrum of kidney diseases in elderly patients who underwent native kidney biopsy.

Methods: We previously conducted a nationwide kidney biopsy survey including 178,803 patients from January 2002 to April 2018. A total of 10,597 native kidney biopsy performed in patients aged ≥65 years from 1590 hospitals across China were included in this study. The composition of kidney diseases and clinicopathologic correlations in different sexes, age groups, different period and regions were assessed.

Results: The most common indication for kidney biopsy in elderly patients was nephrotic syndrome (62.1%). Membranous nephropathy (MN) was the most frequent histological type (48.8%), followed by minimal change disease (9.8%) and IgA nephropathy (8.0%). We observed a increasing trend in the proportion of MN over the study period which was contemporaneous with a fall in the proportion of focal segmental glomerulosclerosis. There was no significant difference in major glomerular diseases between patients aged 65-79 years and ≥80 years after adjusting for sex, region, indication of biopsy, the level of the hospital that performed the biopsy and the time of kidney biopsy. Our study showed that the proportion of non-diabetic kidney disease (NDKD) is up to 62.7% in elderly diabetic patients underwent kidney biopsy, and the most common type of NDKD was MN. Compared with the patients aged 18-64 years underwent kidney biopsy over the same period, the proportion of renal artery injury (65.4% vs. 92.5%, p<0.001) was significantly higher, while phospholipase A2 receptor-positive MN (80% vs. 63.4%, p<0.05) was significantly lower in the very elderly patients (age≥80 years).

Conclusions: The spectrum of kidney diseases among elderly Chinese patients varied across sexes, age groups and regions and changed substantially from 2002 to 2018.

The Difference Between eGFR by Cystatin C vs. Creatinine Provides Clinical Information About Frailty in SPRINT

O. Alison Potok,[1] Joachim H. Ix,[1] Michael Shlipak,[2] Ronit Katz,[3] Amret T. Hawfield,[4] Michael V. Rocco,[4] Walter T. Ambrosius,[4] Monique E. Cho,[5] Nicholas M. Pajewski,[4] Anjay Rastogi,[6] Dena E. Rifkin.[1] *[1]UCSD, San Diego, CA; [2]San Francisco VA Medical Center, San Francisco, CA; [3]University of Washington, Seattle, WA; [4]Wake Forest School of Medicine, Winston-Salem, NC, NC; [5]University of Utah, Salt Lake City, UT; [6]Division of Nephrology, Los Angeles, CA.*

Background: In prior studies, the discrepancy between the glomerular filtration rate (eGFR) estimated using either creatinine [$eGFR_{Cr}$] or cystatin C [$eGFR_{Cys}$] has been treated as measurement error related to kidney function. We propose instead that clinical information about frailty and muscle strength is contained in these differences. We examined the difference between eGFR by cystatin C and creatinine and its relationship to frailty, in cross-sectional and longitudinal analyses.

Methods: 9092 SPRINT participants had baseline measures of serum creatinine and cystatin C. $eGFR_{Cr}$ and $eGFR_{Cys}$ were calculated using CKD-EPI equations, and eGFRDiff was defined as $eGFR_{Cys}$ - $eGFR_{Cr}$. A 37-item frailty index (FI) included questionnaires, past medical history, cognitive tests and laboratory data (excluding albuminuria and eGFR). As defined in prior studies, frailty was FI > 0.21.

Results: Average (SD) was 68 (±9) years for age and was 73 (±23) for $eGFR_{Cys}$, 72 (±20) for $eGFR_{Cr}$, and 0.45 (±15) mL/min/1.73m^2 for eGFRDiff. Compared to participants with minimal difference in eGFR, those with a substantially positive difference eGFRDiff (≥20 mL/min/1.73m^2) were younger (64 vs. 68 years) and more likely to be male (77% vs. 64%). Those with a substantially negative eGFRDiff (≤ -20 mL/min/1.73m^2) were more likely to be frail (OR=1.34 95%CI [1.11; 1.61], p<0.01 in fully adjusted model, Table 1), and were at higher risk for death (HR=1.64 95%CI [1.14;2.36] p=0.008).

Conclusions: In SPRINT, an $eGFR_{Cys}$ estimate that was substantially less than an $eGFR_{Cr}$ estimate was associated with underlying frailty. The difference between $eGFR_{Cys}$ and $eGFR_{Cr}$ may provide important information on functional status and prognosis that should be incorporated into clinical reasoning when evaluating these measures.

TH-PO662

The Difference Between eGFR by Cystatin C vs. Creatinine Provides Clinical Information About Frailty in CHS

O. Alison Potok,[1] Ronit Katz,[2] Nisha Bansal,[3] David Siscovick,[2] Joachim H. Ix,[1] Michael Shlipak,[4] Dena E. Rifkin.[1] *[1]UCSD, San Diego, CA; [2]University of Washington, Seattle, WA; [3]Kidney Research Institute, Seattle, WA; [4]San Francisco VA Medical Center, San Francisco, CA.*

Background: Kidney function is typically assessed using serum creatinine. Cystatin C is an alternative marker of kidney function. The clinical significance of having a difference in estimated glomerular filtration rate (eGFR) by these 2 measures is unknown. We hypothesized that the magnitude of this difference is associated with frailty.

Methods: In 4101 community-dwelling older adults from the Cardiovascular Health Study (CHS) cohort, we investigated the cross-sectional association of the difference in eGFR by cystatin C vs. by creatinine (eGFRDiff) at baseline with prevalent frailty, using logistic regression, and the longitudinal association of eGFRDiff with incident frailty and mortality at 5 years, using Poisson regression. eGFR was calculated using CKD-EPI equations based on either measure ($eGFR_{Cr}$ and $eGFR_{Cys}$ respectively), and eGFRDiff was $eGFR_{Cys}$ - $eGFR_{Cr}$. Frailty was assessed based on the Fried frailty score.

Results: Mean (±SD) age was 72 (±5) years, $eGFR_{Cr}$ was 73 (±17) and mean eGFRDiff was -1.4 (range -68.0 to 70.6) mL/min/1.72m^2. 39% were males, 5% African-American, 72% non-diabetics. Per 10-point increment in eGFRDiff, the prevalence of moderate frailty was 19% lower, and that of severe frailty was 36% lower, in fully adjusted model (Table 1). Higher eGFRDiff (per 10 mL/min/1.73m^2) was associated with lower incidence rate ratio for moderate (IRR 0.93, 95%CI [0.87; 0.99]) and severe (IRR 0.59, 95%CI [0.47; 0.74]) frailty, as well as lower risk of mortality (IRR 0.65, 95%CI [0.57; 0.76], p<0.0001).

Conclusions: Those with a lower $eGFR_{Cys}$ than $eGFR_{Cr}$ were more likely to have prevalent frailty and were at higher risk for incident frailty and mortality. Considering eGFRDiff as a marker of patients' functional status may be a useful clinical tool to assess important geriatric outcomes.

TH-PO663

Which Factors Explain the Difference Between Measured and Estimated GFR?

Albert Sigurdsson,[1] Runolfur Palsson,[1,2] Vilmundur Gudnason,[3] Olafur S. Indridason.[1] *[1]Landspitali - The National University Hospital of Iceland, Reykjavík, Iceland; [2]University of Iceland, Reykjavik, Iceland; [3]Icelandic Heart Association, Kopavogur, Iceland.*

Background: Estimated GFR (eGFR) based on serum creatinine (SCr) is frequently reported by clinical laboratories, despite a certain degree of imprecision. The aim of this study was to examine factors that could explain the difference between eGFR and measured GFR (mGFR) in an elderly population.

Methods: We analyzed data from the AGES-Kidney Study, in which 805 individuals above the age of 70 (mean (SD) age 79 (3.9) years) had mGFR values available with simultaneous measurement of SCr and cystatin C. The CKD-EPI equation was used to calculate eGFR based on SCr (eGFRcr) or combination of SCr and serum cystatin C (eGFRcr-cys). The absolute difference between mGFR and eGFR (mGFR – eGFR) was determined and multivariable linear regression used to estimate the association of numerous variables with this difference, including age, sex, medication use, body composition, muscle strength and comorbidities.

Results: Mean (SD) mGFR in the study group was 62.4 (16.4) mL/min/1.73 m^2, whereas mean eGFRcr was 65.7 (17.1) mL/min/1.73 m^2 and mean eGFRcr-cys 64.7 (17.9) mL/min/1.73 m^2. The difference between mGFR and eGFR ranged from –36 to 46 mL/min/1.73 m^2 for eGFRcr and –35 to 26 mL/min/1.73 m^2 for eGFRcr-cys. In the multivariable linear regression model, significant predictors of the difference between mGFR and eGFRcr were age (p=0.047), thigh muscle mass (measured by computed tomography) (p<0.001), results of timed up and go test (p<0.001), mGFR (p<0.001) and urinary albumin/creatinine ratio (p=0.013). Significant predictors of the mGFR and eGFRcr-cys difference were age (p<0.002), sex (p<0.001), thigh muscle mass (p<0.001) and mGFR (p<0.05).

Conclusions: These preliminary results suggest that several variables, in particular those pertaining to muscle mass and strength, associate with the difference between mGFR and both eGFRcr and eGFRcr-cys. Incorporation of these variables into eGFR equations might yield more precise GFR estimates in the elderly than current equations. In addition, age and sex may not be adequately accounted for in these equations.

TH-PO664

Albuminuria and eGFR in Midlife and Older Age as Risk Factors of Dementia: The ARIC Study

Johannes B. Scheppach,[1] Josef Coresh,[2] Aozhou Wu,[4] Rebecca F. Gottesman,[1] Tom Mosley,[5] Morgan Grams,[1] Richey Sharrett,[6] Silvia Koton.[3] *[1]Johns Hopkins University, Baltimore, MD; [2]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [3]Tel Aviv University and Johns Hopkins University, Tel Aviv, Israel; [4]The Johns Hopkins University, Baltimore, MD; [5]Univ. of Miss. Med Center, Jackson, MS; [6]Johns Hopkins, Baltimore, MD.*

Background: Urine albumin-creatinine-ratio (UACR) and estimated glomerular filtration rate (eGFR) define chronic kidney disease (CKD) and are related to microvascular disease and endothelial damage. We extend previous studies by examining UACR and eGFR measured at midlife and older age as risk factors for dementia. Furthermore, we compare eGFR based on creatinine with eGFR based on cystatin C and beta 2 microglobulin.

Methods: We studied 9,967 participants aged 54-74 years in the Atherosclerosis Risk in Communities (ARIC) study who attended visit 4 (1996-1999) and had creatinine, cystatin C, beta 2 microglobulin and UACR measured with follow-up to December 31st, 2017. We evaluated the hazard of incident dementia associated with eGFR (based on creatinine, cystatin C and beta 2 microglobulin) and log UACR adjusted for age, sex, race, education and apolipoprotein E4 level (Model 1) and additionally for smoking, body mass index, diabetes and antihypertensive medication (Model 2). We compared eGFR and UACR associations to those observed among visit 5 participants (N=4,626, age 70-90, 2011-2013). Effect sizes for each measure of CKD were normalized to the interquartile range (IQR) at Visit 4.

Results: We observed 1,821 incident dementia cases over 16 years of follow-up (438 after visit 5). Risk of dementia was higher with higher levels of albuminuria and lower levels of eGFR but only when GFR estimation was based on cystatin C or beta 2

microglobulin (Table). There was no substantial difference in risk of dementia associated with eGFR or UACR between the two baseline visits.

Conclusions: Higher albuminuria is strongly related to dementia incidence. Lower eGFR shows similar associations but only when the estimation is based on cystatin C or beta 2 microglobulin. This could be explained by newer biomarkers being less influenced by muscle mass. The results are similar in midlife compared to older age.

TH-PO665

Predictors for 1-Year Mortality Among Elderly Patients with CKD Stage 4 and 5 Initiated on Hemodialysis at Divine Word Hospital, Tacloban City, Philippines, 2014-2016

Joyce Rosario A. Matoza-Serna. *Internal Medicine-Nephrology, Divine Word Hospital, Tacloban City, Philippines.*

Background: Chronic kidney disease (CKD) prevalence among the elderly patients is increasing. This study aimed to describe the clinical and demographic profile of the elderly patients with CKD Stages 4 and 5; to determine the 1 year outcomes after HD initiation as to survival, death and its causes of mortality and to identify the predictors for 1 year-mortality among elderly CKD patients.

Methods: A descriptive retrospective study involving all elderly patients diagnosed with CKD Stage 4 and 5 initiated on hemodialysis at Divine Word Hospital in the year 2014 to 2016. Patients' demographic and clinical data, and the outcomes on hemodialysis in the form of 1-year survival or death were identified. Data were analyzed with the use of frequency distribution and percentages for categorical variables, and mean and standard deviation for continuous variables. Univariate cox regression was employed to identify the predictors of mortality.

Results: Eighty three participants were included in the study. The mean age was 73 years old, females comprised 56%, Dabetic Kidney Disease accounted to 58%, cardiovascular and metabolic co-mobidities were present in 91% and 65% of cases, respectively; and majority had no presume pre-HD nephrology care at 56%. Seventy five percent survived after 1 year from HD initiation. Female gender and hemoglobin level of <10 g/dL were significant predictors of mortality.

Conclusions: The predictors for 1 year-mortality among elderly patients with CKD stage 4 and 5 initiated on hemodialysis were female gender and anemia (hemoglobin of <10g/dL). Specific measures to address these risk factors must be implemented to improve survival in these patients.

TH-PO666

Walking While Talking in Older Adults with CKD

Jim Q. Ho, Joe Verghese, Matthew K. Abramowitz. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Divided attention tasks predict falls in older adults. Adults with chronic kidney disease (CKD) have an increased risk of falling compared with people without CKD; however, it is unknown whether they have greater divided attention task interference.

Methods: Three hundred thirty nondisabled adults ≥65 years of age from the community participated in quantitative and clinical gait assessments, including a validated cognitive-motor dual task measure (Walking While Talking [WWT] Test). Multivariable linear regression that adjusted for demographics, body mass index, comorbidities, and medications was performed to examine the relationship between estimated glomerular filtration rate (eGFR) and WWT gait markers. CKD was defined as an eGFR <60 ml/min/1.73m^2.

Results: One hundred thirty-four subjects (41%) had CKD. During WWT, participants with CKD had 5.8 cm/s (95% CI 0.6-11.0) slower gait speed, 2.4 cm (95% CI 0.05-4.7) shorter step length, and 2.0% (95% CI 0.2-3.8) greater time in the double support phase of the gait cycle compared with those without CKD. These abnormalities were related to severity of CKD: among participants with CKD, every 10 ml/min/1.73m^2 lower eGFR was independently associated with 3.3 cm/s (95% CI 0.4-6.1) slower gait speed, 2.0 cm (95% CI 0.7-3.2) shorter step length, 4.0 cm (95% CI 1.5-6.4) shorter stride length, 1.2% (95% CI 0.7-1.8) less time in the swing phase, and 1.6% (95% CI 0.7-2.5) greater time in the double support phase. To better capture the multidimensional characteristics of gait, factor analysis was performed using the principal component method and produced 3 independent gait domains: Rhythm, Pace, and Variability. Every 10 ml/min/1.73m^2 lower eGFR was associated with 0.2 standard deviation (95% CI 0.1-0.3) poorer performance in the Rhythm domain. There was no significant association between eGFR and the Pace or Variability domains.

Conclusions: CKD is associated with quantitative gait abnormalities while performing WWT tasks. Future studies should examine whether poorer performance on WWT tasks contributes to fall risk and is an early indicator of cognitive dysfunction in CKD.

TH-PO667

Risk Factors for Early Mortality Among Elderly Filipino Patients with Indications for Initiation of Hemodialysis: A Comparative Study

Paul carlo T. Relampagos, Jennifer Ivy Togonon-Leaño. *San Pedro Hospital of Davao City, Davao City, Philippines.*

Background: The worldwide incidence of kidney failure is rising. Globally, 5-10 million people die annually from kidney disease. In 2015, the Philippines reported a mortality rate of 3.9 per 100,000 population for kidney diseases. Of the 32,077 Filipinos on dialysis in 2015, 18,603 were initiated within the same year. Most are 60 years old and older, diabetic, and have other co-morbid conditions. Because, dialysis is a high-cost treatment, the Philippines enforced the Universal Health Coverage Bill. However, Filipinos continue to bear the financial burden of hemodialysis. These issues along with the Filipino cultural context question the practicality of initiating hemodialysis among the elderly. This study aims to identify factors significantly associated with early mortality and obtaining the early mortality rates among elderly Filipino patients initiated on hemodialysis and those who were not. To our knowledge, this is the first study of its kind on Filipinos.

Methods: This is a prospective, observational, cohort study. Dialysis-naïve elderly patients admitted from January to April 2019 in a tertiary hospital in the Philippines and were advised to initiate hemodialysis were enrolled. Demographic data and the presence of the following risk factors were obtained: diabetes mellitus, congestive heart failure, peripheral arterial disease, dysrhythmia, active malignancy, severe behavioral disorder, unplanned dialysis, hypoalbuminemia, ischemic heart disease, ventilator dependency, coma, sepsis, hepatic failure, COPD, BMI <18.5 kg/m^2, and total dependency for transfers. Individual outcomes (death against survival) between the two groups (initiated on hemodialysis against those were not—refused or consented for but were not initiated on hemodialysis) will be followed until four months after their attending nephrologists advised hemodialysis.

Results: 52 patients were enrolled in the study—52% initiated hemodialysis while 48% did not. Preliminary data shows more deaths among those initiated on hemodialysis (37%) than those who were not (32%). Risk factors identified among those initiated on hemodialysis and died include unplanned dialysis (100%), total dependency for transfers (83%), diabetes mellitus (67%), and hypoalbuminemia (67%).

Conclusions: The study is currently on its follow-up phase and will end by August 2019.

TH-PO668

Poor Outcomes in Kidney Transplant (KT) Candidates and Recipients with History of Falls

Nadia M. Chu,[2] Zhan Shi,[2] Christine E. Haugen,[2] Silas Norman,[1] Dorry L. Segev,[2] Mara McAdams-DeMarco.[2] *[1]University of Michigan Health Systems, Ann Arbor, MI; [2]Johns Hopkins, Baltimore, MD.*

Background: In patients with ESKD, serious falls resulting in hospitalization/fractures lead to lower chance of listing or KT. While it is likely that candidates and recipients have high frequency of injurious and noninjurious falls, it is unclear if less serious, noninjurious falls also lead to lower access to KT and if these risks extend to poor outcomes post-KT.

Methods: Using a 2-center cohort of KT candidates (n=3,666) and recipients (n=769), we assessed time to listing (Cox), waitlist mortality (Cox), and KT rate (Poisson) for KT candidates by history of falls (self-report, past 6 months) and recurrent falls (≥2 falls); for recipients, we assessed risk of mortality (Cox), all-cause graft loss (ACGL) (Cox), and length of stay (LOS) (Poisson).

Results: In candidates, 16.3% had history of falls; 6.5% had recurrent falls. Candidates with recurrent falls had lower chance of listing (aHR=0.7, 95%CI:0.6-0.8); those with single fall had a lower KT rate (aIRR=0.7, 95%CI:0.5-0.9). Single and recurrent falls were associated with greater mortality risk at evaluation and 1-year after evaluation; this risk declined over time. In KT recipients, 12.5% had a history of falls; 5.1% had recurrent falls. Single falls were associated with greater mortality risk (aHR=9.2, 95%CI:3.4-25.1) and ACGL (aHR=7.3, 95%CI:2.9-18.6) at KT and at 1-year post-KT; these risks declined thereafter. KT recipients with recurrent falls were at increased risk of a longer LOS (aHR=1.1, 95%CI:1.0-1.3).

Conclusions: Candidates (6.5%) and recipients (5.1%) had recurrent falls which were associated with decreased chance of listing and increased risk of waitlist mortality, post-KT mortality/ACGL, and longer LOS. Centers should consider employing falls prevention strategies as part of a comprehensive prehabilitation intervention.

Geriatric Renal Transplantation in India: A Single-Centre Experience

Vinant Bhargava,[1] Krishna K. Agrawaal,[2] Priti Meena,[1] Anil Bhalla,[1] Ashwani Gupta,[1] Anurag Gupta,[1] Devinder S. Rana,[1] Manish Malik.[3] *[1]Sir Ganga Ram Hospital, New Delhi, India; [2]Nepal Medical College and Teaching Hospital, Parasi-5, Nepal; [3]Sir Ganga Ram Hospital and GRIPMER, New Delhi, India*.

Background: Kidney transplantation is a deterrent all over the world in the elderly due to higher cardiovascular mortality and infections. Death censored allograft survival appears to be similar in elderly and young.

Methods: Data of elderly (age ≥60 years) patients who underwent renal transplant was assessed. Changes in renal function, complications, graft rejection and mortality over 12 months post-transplant were determined.

Results: In 71 patients, mean age was 63.3±3.5 years and 88.7% were females. Diabetic kidney disease (40.8%) was most common aetiology for renal failure. Serum creatinine (SrC) in immediate post-transplant period was 1.2±0.8 mg/dl. In follow-up, no significant change in SrC was observed at 3 months (1.2±0.7 mg/dl, p=0.458), 6 months (1.4±0.9 mg/dl, p=0.234), 9 months (1.4±0.9 mg/dl, p=0.148) and 12 months (1.5±1.0 mg/dl, p=0.105) in comparison to baseline value. Proportion of patients with SrC ≥ 2 mg/dl increased from 5.6% at baseline to 12.7% at 12 months. Overall, 39.4% patients developed one or more infections of which urinary tract infections (22.5%) were most common. Cytomegalovirus (CMV) and lower respiratory tract infections were observed in three (4.2%) patients each. Acute graft rejection occurred in three (4.2%) patients. Six (8.5%) patients died during the 12 months follow-up period. Among non-survivors, two patients died during hospital stay and infections were major cause for mortality.

Conclusions: In the elderly patients who underwent renal transplant, graft function was well maintained over 12 months. Urinary infections are of common occurrence. Rates of acute rejection and mortality were comparable to the literature from India.

TH-PO670

Geriatric Nephrology Patients Deteriorating and Dying in Acute Care: How Do They Die?

Anna Bendall,[1] Georgia Harris,[2] Jennifer L. Weil,[3] Caroline L. Scott,[4] David Marco,[3] Kathryn Ducharlet.[3] *[1]St Vincents Melbourne, Melbourne, NSW, Australia; [2]The University of Melbourne, Melbourne, VIC, Australia; [3]St Vincent's Hospital Melbourne, Melbourne, VIC, Australia; [4]St Vincent's Hospital Melbourne, Heidelberg, NSW, Australia*.

Background: Older patients with advanced kidney disease have complex medical and psychosocial needs, and providing comprehensive end of life care (EOLC) within acute healthcare settings is a challenge increasingly encountered by nephrologists. Data relating to the practice of EOLC within the inpatient nephrology setting is required to better inform and improve service provision. This study aims to review current care practices for deteriorating and dying patients admitted to the nephrology unit at St Vincent's Hospital Melbourne (SVHM), Australia.

Methods: Retrospective cohort study of patients aged >60years who died while admitted to the Nephrology unit at SVHM between 1/1/2013 and 31/12/2018.

Results: During the study period, 56 patients died while admitted to the Nephrology unit (average age 73years), and 84% were receiving long term dialysis (55% haemodialysis, 29% peritoneal dialysis). The average length of admission was 13 days, and patients had more than 2 admission in their final year of life. On average four invasive interventions were performed in the final 48 hours of life, including dialysis, intubation, parenteral feeding, intravenous fluids or antibiotics. Patients were admitted to the intensive care unit (ICU) in 42% of cases, and one third (32%) died in the ICU. At the time of admission only two patients had a formal advance care directive in place. During the admission, on the majority of occasions (75%) a documented discussion regarding goals of care (GOC) was held between a physician and the patient or caregiver, on average 3 days prior to death. Consultation by palliative care services occurred on one third (33%) of occasions, and in the final 24 hours an average of two uncontrolled symptoms were documented for each patient, including pain (52%), dyspnoea (41%), drowsiness (32%), and nausea (23%).

Conclusions: The majority of geriatric nephrology patients who died in the acute setting were receiving long term dialysis, and had a high burden of uncontrolled symptoms. One third of these deaths occurred in the ICU, and very few had advance care directives. This study illustrates opportunities for the clinician to improve care for older renal patients through earlier recognition of the dying patient, enhanced communication during EOLC planning, and greater emphasis on symptom control.

TH-PO671

Hemodialysis Patients Who Receive Physical Therapy: An Opportunity to Modify the Frailty Trajectory?

Nancy G. Kutner,[1] Yijian Huang.[2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Biostatistics and Bioinformatics, Emory University, Atlanta, GA*.

Background: Frailty markers, physical activity and gait speed (and muscle strength to a lesser extent), show decline over time among hemodialysis (HD) patients (J Gerontol 2019), but whether these patterns vary in association with receipt of physical therapy (PT) has not been investigated. In Medicare claims, we identified dates and types of outpatient PT services received by HD patients during their participation in the USRDS ACTIVE-ADIPOSE Study (AAS). We examined frailty measures assessed before and after receipt of PT that included therapeutic exercises (CPT code 97110) "to develop strength and endurance, range of motion and flexibility."

Methods: The AAS included a multi-center cohort of 771 prevalent HD patients aged 20-92 and was conducted 2009-2013 at 14 outpatient dialysis clinics in the Atlanta GA and San Francisco areas. Institutional review boards (Emory University; UCSF) approved the study and all participants provided written informed consent. At baseline and two annual follow-up assessments, trained study coordinators administered the Minnesota Leisure Time Activity (LTA) instrument to estimate kcal/week physical activity, and the Short Physical Performance Battery (SPPB) that includes chair stand, balance, and walk (gait speed) tests. Consistent with prior research, individuals with LTA-assessed kcal/week <500 were considered sedentary and 500+ non-sedentary, and total SPPB score (0-12) was categorized into three ordinal groups (<6, 7-9, 10-12).

Results: Medicare claims for outpatient PT were identified for 32 AAS participants: ages 32-82, 57% women, 81% black. Patient-reported reasons for PT emphasized mobility issues. At their post-PT follow-up evaluation: (1) Half had LTA scores = 500+ (non-sedentary), and kcal/week activity had increased from <500 pre-PT to 500+ post-PT for half of the non-sedentary group; (2) Although measured gait speed for most participants post-PT was consistent with values that characterize "limited community ambulators" (0.4-0.8 m/sec), two-thirds of participants either maintained SPPB scores > 7 pre-post PT or achieved SPPB scores > 7 post-PT.

Conclusions: Continued study of the role of PT in HD patient care is merited in larger patient cohorts. PT goals are patient-specific and include maintenance as well as improvement of function, with implications for the trajectory of frailty.

Physical Activity and Fatigue as Measures of Day-to-Day Resilience in Older Hemodialysis Patients

Rasheeda K. Hall, Jeanette Rutledge, Richard Sloane, Ciara T. Green, Carl F. Pieper, Cathleen Colon-emeric, Katherine Hall. *Duke University, Durham, NC.*

Background: Hemodialysis (HD) is a physiological stressor requiring day-to-day resilience, or an innate ability to recover after a HD session. Our objective was to assess whether physical activity (PA) and self-reported fatigue are representative measures of day-to-day resilience.

Methods: We recruited ambulatory adults aged ≥55 years receiving HD who did not have advanced dementia, hospice care, or long-term care residence. Participants completed PA monitoring via wrist actigraphy for 14 days with concurrent fatigue assessment: "On a scale from 0-10, rate your fatigue, with 10 being fatigue as bad as you can imagine". Fatigue was assessed within 4 hours after HD and in the morning and afternoon on non-HD days. Prior to a HD session, we assessed physical function via the short physical performance battery (SPPB) (range, 0-12) and grip strength. We measured correlation between PA (steps) and concurrent fatigue in 4-hour intervals. PA variability, a measure of PA change when not at HD, was calculated from the standard deviation of the difference (absolute value) in steps of each 4-hour interval. We measured correlation between PA variability and physical function.

Results: Among 29 participants, mean±SD age was 70.6±4.8 years, 55.2% (n=16) male, 72.4% (n=21) black race, and mean years of dialysis was 3.9±3.6. Mean SPPB, gait speed (from SPPB), and grip strength were 6.3±3.2 (<10 indicates functional impairment), 0.72±0.3 m/s, and 57.8±16.7 kg, respectively. Mean PA monitoring time was 12.9±5.7 days. Mean daily steps was lower on HD days than non-HD days (967.1±557.0 vs. 1158.6±816.4) (p=0.004). Mean fatigue scores on HD days and non-HD days were similar (4.1±2.7 vs. 3.5±2.5) (p=0.06). The correlation between 4-hour post-dialysis PA and fatigue was -0.19 (n=102, p=0.06). The correlation between PA and fatigue at all other 4-hour intervals was -0.17 (n=210, p=0.01). Mean PA variability was 140.0±67.3 steps and its correlation with SPPB, gait speed, and grip strength was 0.47 (n=28, p=0.01), 0.52 (n=27, p=0.01), and 0.71 (n=27, p<0.0001), respectively.

Conclusions: In this sample of older HD patients, higher PA and greater PA variability were associated with lower fatigue and better physical function, respectively. PA monitoring and interval fatigue may be useful measures for interventions targeting resilience.

Peripheral Artery Disease Exacerbates the Prognosis of Frailty in Patients with Hemodialysis

Hidemi Takeuchi,[2,1] Haruhito A. Uchida,[2] Nozomu Otaka,[2] Ryoko Umebayashi,[2] Hidetoshi Kanai,[1] Jun Wada.[2] *[1]Kokura Memorial Hospital, Kitakyushu, Japan; [2]Nephrology, Rheumatology, Endocrinology and Metabolism, Okatyama University, Okayama, Japan.*

Background: The clinical condition of frailty is the most problematic expression of the patients with hemodialysis (HD). The development of frailty is tightly associated with peripheral artery disease (PAD). However, the prognosis of the HD patients with frailty complicated with PAD remains unexplored. The purpose of this study is to identify the influence of PAD on the prognosis of HD patients with frailty.

Methods: We conducted a prospective and multicenter clinical study at 6 institutions. To evaluate the frailty status, we used the modified Fried's frailty phenotype model. PAD was defined according to the definition of TASC II (Trans-Atlantic Inter-Society Consensus II). Our primary endpoint of this study was the patients' survival and hospitalization.

Results: Of the 542 patients, 388 HD patients including 82 patients with frailty (21.4%), 204 with pre-frailty (52.6%) and 101 without frailty (26.0%), were enrolled in this study. At baseline, the participants were 67.2 ± 11.9 years of age with more male gender (62.4 %) than female. With an average follow-up period of 24.2 months, a total of 68 patients died; 26.5% of patients with frailty, 17.6% with pre-frailty and 9.9% without frailty. Cox proportional hazards model analyses indicated that frailty was associated with risk of death (hazard ratio [HR] 2.42, 95% confidence interval [CI] 1.12–5.23, adjusted for age and gender) and independently associated with the combined outcome of death or hospitalization (HR 2.85, 95% CI 1.74–4.69, adjusted for age, gender and all comorbidities), despite that PAD had no independent association with death and lower risk of the combined outcome. Furthermore, frailty complicated with PAD was independently associated with higher risk of death (HR 4.72, 95% CI 1.37–16.26, adjusted for age, gender and all comorbidities) and the combined outcome (HR 5.89, 95% CI 2.94–11.77, adjusted for age, gender and all comorbidities), compared with frailty only or PAD only.

Conclusions: Frailty itself significantly worsens the prognosis of patients with hemodialysis, and the presence of PAD further exacerbates the prognosis of frail patients with HD.

Blood Pressure Lowering for the Prevention of Cognitive Impairment and Dementia: A Systematic Review and Meta-Analysis

Diarmaid Hughes, Conor S. Judge, Robert P. Murphy, Maria Costello, Michelle Canavan, Martin O'donnell. *Health Research Board Clinical Research Facility, Galway, Ireland.*

Background: The benefit of blood pressure lowering for the prevention of cognitive impairment and dementia is unclear.

Methods: We performed a meta-analysis of large randomized controlled trials of antihypertensive therapy versus control that reported cognitive decline, cognitive impairment or dementia as an outcome measure. We determined whether antihypertensive therapy reduced the risk of cognitive impairment and/or dementia and explored whether its effect varied by baseline blood pressure, blood pressure difference between treatment groups and/or length of follow-up.

Results: Fourteen randomized controlled trials were eligible for inclusion. Antihypertensive therapy was associated with a statistically significant reduced risk of cognitive impairment (n=9) (odds ratio [OR], 0.92; 95% confidence interval [CI], 0.87-0.98) and dementia (n=12) (OR, 0.93; 95% CI, 0.88 to 0.99). Subgroup analysis of trials with a cumulative blood pressure difference above the median (6.5 mmHg) reduced the risk of dementia further (OR, 0.87; 95% CI, 0.80-0.96) (Figure 1). Antihypertensive therapy was not associated with a statistically significant reduction in the Mini Mental State Examination (MMSE) cognitive impairment score (n=5) (Mean change in MMSE, 0.44, 95% CI, -0.22–1.10) or a combination of the MMSE and the Trail Making Test (TMT) (n=7) (Standardised mean change, 0.10, 95% CI, -0.02–0.22). Meta-regression of baseline blood pressure, blood pressure difference or years of follow-up did not explain significant heterogeneity between studies for cognitive impairment or dementia risk.

Conclusions: Antihypertensive therapy reduces the risk of cognitive impairment and dementia.

Blood Pressure Lowering and Cognition: A Systematic Review and Meta-Analysis

Aditi Gupta,[1] Sophy Perdomo,[1] Srinivasan Beddhu,[3] Sandra Billinger,[2] Jeffrey M. Burns,[4] Gary Gronseth.[1] *[1]University of Kansas Medical Center, Kansas City, KS; [2]KU Medical Center, Kansas City, KS; [3]University of Utah School of Medicine, Salt Lake City, UT; [4]University of Kansas School of Medicine, Kansas City, KS.*

Background: Hypertension is a known risk factor for developing cognitive impairment and dementia, both vascular dementia and Alzheimer's disease. Here we present the results of our systematic review of the effect of lowering of blood pressure on cognition.

Methods: We conducted a systematic review and meta-analysis of randomized placebo-controlled trials with a pre-specified objective outcome of cognition, and with pharmacological interventions to lower blood pressure for at least 12 months in adults > 60 years. We searched MEDLINE, CENTRAL and The Cochrane Library (inception to May 2019). Two independent reviewers assessed trial quality and extracted data. Since the analyzed outcomes were different in the selected studies, we standardized these outcomes by calculating Cohen's D (SMD).

Results: Our initial search identified 2022 records. 1846 abstract were reviewed after removing duplicate records and out of these, 28 full-text articles pulled which met above inclusion criteria. Ten trials including 31,357 participants were included in the final analysis. The duration of the studies ranged from 1 year to median of 5.11 years.

Fig 1 shows internal validity of the included studies. Fig 2 shows the forest plot with the effect on cognition (standardized mean difference with 95% confidence interval). The net standardized mean difference for change in cognition was -0.041 (CI -0.076, -0.005) indicating a positive effect on cognition with lowering of blood pressure. I squared was 0% indicating minimal heterogeneity.

Conclusions: Although the overall effect is small, current data indicates that pharmacological lowering of blood pressure in older adults without prior cerebrovascular events slows cognitive decline.

Baseline Diastolic Blood Pressure Does Not Influence the Effect of Systolic Blood Pressure Lowering on Cognition in Type 2 Diabetes Mellitus

Aditi Gupta,[1] Robert E. Boucher,[2] Tom Greene,[3] Adam Parks,[1] Guo Wei,[3] Srinivasan Beddhu.[2] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Utah School of Medicine, Salt Lake City, UT; [3]University of Utah, Salt Lake City, UT.*

Background: In patients with low baseline diastolic blood pressure (DBP), lowering of systolic blood pressure (SBP) would lead to further lowering of mean arterial blood pressure. This can theoretically decrease cerebral perfusion and cognition. We examined the influence of baseline DBP on the effect of SBP on cognition.

Methods: We analyzed data from the Memory in Diabetes (MIND) sub-study of the Action to Control Cardiovascular Risk in Diabetes (ACCORD). We grouped the subjects by tertiles of baseline DBP and compared the effects of intensive (target <120 mm Hg) and standard (target <140 mm Hg) SBP control on cognition. Cognition was measured by Digit Symbol Substitution test (DSST), Rey Auditory Verbal Learning Test (RAVLT), Stroop test and the Mini Mental State exam (MMSE).

Results: Table 1 summarizes the baseline demographics of the 1,610 ACCORD-MIND participants divided by tertiles of DBP. Participates with lower DBP were older, and had a longer duration of diabetes. Figure 1 shows the DSST scores in the standard and intensive BP groups by baseline DBP tertiles. There was no difference in the change in DSST scores in the three groups.

Conclusions: Intensive SBP reduction in type 2 diabetes mellitus does not adversely affect cognition, even in those with low baseline DBP.

Association of Ambulatory Blood Pressure Pattern with Cognitive Function: The SPRINT Ambulatory Blood Pressure Study

Dena E. Rifkin,[11] Nicholas M. Pajewski,[12] Adam Bress,[1] Ruth C. Campbell,[13] William C. Cushman,[3] Tanya R. Gure,[4] William E. Haley,[5] Marie Krousel-wood,[6] Vasilios Papademetriou,[7] Roberto Pisoni,[2] Daniel E. Weiner,[8] Clinton B. Wright,[9] Andrew E. Moran,[14] Paul E. Drawz,[10] Joachim H. Ix.[11]
[1]University of Utah, Salt Lake City, UT; [2]Medical University of South Carolina, Charleston, SC; [3]Memphis VA Medical Center, Memphis, TN; [4]The OSU Wexner Medical Center, Columbus, OH; [5]Mayo Clinic, Jacksonville, FL; [6]Ochsner Clinic Foundation, New Orleans, LA; [7]Georgetown University, Potomac, MD; [8]Tufts Medical Center, Boston, MA; [9]National Institute of Neurological Disorders and Stroke, Rockville, MD; [10]University of Minnesota, Minneapolis, MN; [11]UCSD, San Diego, CA; [12]Wake Forest, Wake Forest, NC; [13]MUSC, Charleston, SC; [14]Columbia University Medical Center, New York, NY.

Background: In prior work with healthy older adults, abnormal night-to-day SBP ratio and lower 24 hour diastolic BP on ABPM were associated with worse cognitive function, findings not identified using clinic blood pressures. We examined whether these ABPM parameters were associated with cognitive function in participants in SPRINT, a randomized controlled trial of two different blood pressure targets in hypertensive adults.

Methods: Within SPRINT, 897 participants had 24 hour blood pressure measures collected at the 27 month visit. These readings were within 3 months of a comprehensive cognitive assessment. We examined whether ABPM parameters were associated with scores on the Montreal Assessment of Cognitive Function, logical memory delayed recall, and digit symbol coding test scores, after evaluating for interaction with random treatment assignment. We calculated odds ratios based on a beta-binomial model, with higher odds indicating better cognitive performance.

Results: Mean age was 71.5 ± 9.5, 67% were Caucasian. The intensive BP group had lower SBP and used more BP medication than the standard BP group. On the 3 cognitive tests studied, there was no difference in score between those in the intensive and standard groups, so these were combined. There was no association between night-to-day ratio and cognitive function test scores. After multivariate adjustment there was a modest association between higher diastolic BP (both in clinic and 24-hour) and better cognitive test scores on digit-symbol coding (figure).

Conclusions: Night-to-day blood pressure ratio was not associated with cognition in SPRINT. There was a modest association with diastolic blood pressure both in clinic and over 24 hours. This suggests that in this setting, non-dipping did not strongly associate with scores on cognitive function tests.

Dietary Sodium Intake and Cognitive Impairment in the Chronic Renal Insufficiency Cohort (CRIC)

Kristen L. Nowak,[1] Zhiying You,[1] Anna J. Jovanovich,[2,1] Michel Chonchol.[1]
[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Denver VA Medical Center, Denver, CO.

Background: Cognitive dysfunction is a well-documented occurrence in individuals with chronic kidney disease (CKD), affecting multiple domains of cognitive function. Dietary sodium may influence cognitive function via effects on cerebrovascular function and cerebral blood flow. We hypothesized that high dietary sodium intake, as measured by 24-hr urine sodium excretion, is as associated with a decline in cognitive function over time in adults with CKD.

Methods: 1,724 participants in the observational cohort study, CRIC, with measurement of 24-hr urine sodium excretion, and modified mini mental state exam (3MS) score at baseline and year 4, who were free from baseline cognitive dysfunction were included. Multivariable logistic regression was used to examine the association between baseline 24-hr urine sodium excretion and odds of incident cognitive impairment, defined as a decline 3MS score ≥1.0 SD below the mean change in completion score (mean±SD for change in 3MS score was -0.26±5.08). High baseline sodium intake was defined as excretion >150 mmol/d.

Results: Participants were 59±11 years, baseline estimated glomerular filtration rate (eGFR) was 45±13 ml/min/1.73m², and baseline 24-hr sodium excretion was 164±76 mmol/d. During follow-up of 4.1±0.2 years, 185 CRIC participants (11%) had a clinically significant decline in 3MS score (i.e. incident cognitive impairment). After adjustment for demographics, clinic site, smoking, body-mass index, eGFR, cardiovascular risk factors, physical activity, systolic blood pressure, and 24-hr urine protein, potassium, and creatinine, high baseline dietary sodium intake was associated with increased odds of incident cognitive impairment (OR: 1.56, 95% CI: 1.08-2.27 vs low sodium intake).

Conclusions: In adults with CKD who participated in CRIC, higher sodium intake was independently associated with increased odds of incident cognitive impairment.

TH-PO679

MRI Markers of Cerebral Small Vessel Disease in CKD Patients with TIA and Minor Stroke

Dearbhla Kelly, Peter M. Rothwell. on behalf of the Oxford Vascular Study *Centre for the Prevention of Stroke and Dementia, University of Oxford, Oxford, United Kingdom.*

Background: It has been hypothesized that cerebral small vessel disease (SVD) and CKD may be part of a multi-system vasculopathy, but their association may simply be as a result of shared risk factors (eg, hypertension).

Methods: In a population-based study of transient ischemic attack and ischemic stroke (OXVASC), we evaluated the MRI markers of cerebral SVD, including lacunes, white matter hyperintensities, cerebral microbleeds, and enlarged perivascular space. We studied the age-specific associations of CKD and total SVD burden (total SVD score) adjusting for age, sex, vascular risk factors, and premorbid blood pressure (mean blood pressure during 20 years pre-event).

Results: 1718 patients had complete magnetic resonance imaging protocol and creatinine measured at baseline. CKD was associated with total SVD score (odds ratio [OR], 2.83; 95% confidence interval [CI], 2.28–3.53; P<0.001), but mainly at age <60 years (<60 years: OR, 8.43; 95% CI, 3.12-22.78; P<0.001; 60–79 years: OR, 1.38; 95% CI, 1.02–1.87; P=0.038; ≥80 years: OR, 1.09; 95% CI, 0.74–1.6; P=0.676). The overall association of renal impairment and total SVD score was also attenuated after adjustment for age, sex, history of hypertension, and diabetes mellitus (adjusted OR, 1.05; 95% CI, 0.83–1.34; P=0.67), but the independent association of renal impairment and total SVD score at age <60 years was maintained (adjusted OR, 6.07; 95% CI, 2.22–16.59; P=<0.001). Associations of renal impairment and SVD were consistent for each SVD marker at age <60 years but were strongest for cerebral microbleeds (OR, 9.04; 95% CI, 2.76–29.61; P<0.001) and moderate–severe periventricular white matter hyperintensities (OR, 6.67; 95% CI, 1.95–22.86; P=0.003).

Conclusions: The association of CKD and cerebral SVD was attenuated with adjustment for shared risk factors at older ages, but remained at younger ages, consistent with a shared susceptibility, likely at a genetic level, to premature disease.

TH-PO680

Association Between Geriatric Nutritional Risk Index (GRNI) and the Increased Risk for Stroke in Patients Receiving Hemodialysis: Ten-Year Outcome of the Q-Cohort Study

Shoji Tsuneyoshi,[1] Yuta Matsukuma,[2] Hiroto Hiyamuta,[2] Shunsuke Yamada,[2] Takanari Kitazono,[3] Kazuhiko Tsuruya,[4] Toshiaki Nakano.[2] *[1]Kyushu university, Fukuoka, Japan; [2]Kyushu University, Fukuoka City, Japan; [3]Department of Medicine and Clinical Science, Fukuoka, Japan; [4]Nara Medical University, Kashihara, Japan.*

Background: Geriatric nutritional risk index (GRNI), a useful tool for the evaluation of nutritional status, is associated with increased risk for cardiovascular events in hemodialysis patients. Few studies have examined the association between GNRI level and the incidence of stroke in patients receiving hemodialysis.

Methods: A total of 3047 patients registered to the Q-Cohort Study, a multicenter, prospective observational cohort of hemodialysis patients, were examined. The main outcomes were the development of brain hemorrhage and infarction. The main exposure was GNRI, calculated by serum albumin level and body mass index. Patients were divided into quartiles based on the baseline GNRI level; Q4 : >99.8, Q3 : 95.6-99.8, Q2 : 90.7-95.5, Q1 : <90.7. The risks for either brain infarction or hemorrhage were estimated by multivariable-adjusted Cox proportional hazard risk models.

Results: During the follow-up period of 10 years, 149 patients developed brain hemorrhage and 326 patients developed brain infarction. Cox proportional hazard risk models showed that the risks for brain hemorrhage and infarction in Q1 were significantly higher than that in Q4 group: hazard ratio [95% confidence interval], 1.69 [1.19-2.42] and 1.85 [1.08-3.16], respectively. Furthermore, restricted cubic spline curves showed that a lower GNRI was incrementally associated with an increased risk for both brain hemorrhage and infarction.

Conclusions: Our results suggest that lower GNRI is a risk factor for brain hemorrhage and infarction in maintenance hemodialysis patients.

TH-PO681

Does CKD Predict Stroke Risk Independent of Blood Pressure? A Systematic Review and Meta-Regression

Dearbhla Kelly, Peter M. Rothwell. *Centre for the Prevention of Stroke and Dementia, University of Oxford, Oxford, United Kingdom.*

Background: Chronic kidney disease (CKD) appears to be an independent risk factor for stroke, with various purported mechanisms proposed. Low glomerular filtration rate (eGFR) is a risk factor for stroke independent of cardiovascular risk factors in epidemiological studies, but there has been no systematic assessment of the impact of more complete adjustment for blood pressure (BP) on the association.

Methods: We did a systematic review to February 2018 (MEDLINE/EMBASE) for cohort studies or randomized controlled trials that reported stroke incidence in adults according to baseline eGFR. Study and participant characteristics and relative risks (RR) were extracted. Estimates were combined using a random effects model. Heterogeneity was assessed by x^2 statistics and I^2, and by subgroup strata and meta-regression.

Results: We identified 168 studies reporting data on 5,611,939 participants with 115,770 stroke outcomes. 85 studies (3,417,098 participants; 72,996 strokes) provided adequate data for meta-analysis of eGFR and stroke risk. Incident stroke risk was increased among participants with eGFR <60 ml/min/1.73m2 (RR=1.73, 95% CI 1.57-1.90; p<0.001), but there was substantial heterogeneity between studies (p<0.0001; I2 - 78.5%). Moreover, the association was reduced after adjustment for cardiovascular risk factors, with progressive attenuation on more thorough adjustment for hypertension: single baseline BP measure (RR=1.63, 1.34-1.99; p<0.001); history or treated hypertension (RR=1.35, 1.24-1.46, p<0.001); multiple BP measurements over months to years (RR=1.10, 1.02-1.18; p=0.01).

Conclusions: The apparently independent relationship between CKD and stroke may be confounded by their shared association with long-term prior blood pressure, rendering other proposed mechanisms and related treatments unnecessary.

TH-PO682

Proteinuria as an Independent Predictor of Stroke: Systematic Review and Meta-Analysis

Dearbhla Kelly, Peter M. Rothwell. *Centre for the Prevention of Stroke and Dementia, University of Oxford, Oxford, United Kingdom.*

Background: Proteinuria has emerged as an important vascular risk factor for adverse cardiovascular events including stroke. Hypertension has been proposed as the principal confounder of this relationship but its role has not been systematically examined. We aimed to determine if proteinuria remains an independent predictor of stroke after more complete adjustment for blood pressure (BP).

Methods: We performed a systematic review, searching MEDLINE and EMBASE (to February 2018) for cohort studies or randomized controlled trials that reported stroke incidence in adults according to baseline proteinuria +/- glomerular filtration rate (eGFR). Study and participant characteristics and relative risks (RR) were extracted. Estimates were combined using a random effects model. Heterogeneity was assessed by x^2 statistics and I^2, and by subgroup strata and meta-regression, with a particular focus on the impact of more complete adjustment for blood pressure (BP) on the association. The quality of cohort studies and posthoc analyses was assessed using the Newcastle–Ottawa Scale.

Results: We identified 38 studies comprising 1,735,390 participants with 26,405 stroke events. Overall, the presence of any level of proteinuria was associated with greater stroke risk (18 studies; Pooled crude RR 2.00, 95%CI 1.63-2.46; p<0.001) even after adjustment for established cardiovascular risk factors (33 studies; Pooled adjusted RR 1.72, 1.51-1.95; p<0.001), albeit with considerable heterogeneity between studies (p< 0.001; I2=77.3%). Moreover, the association did not substantially attenuate with more thorough adjustment for hypertension: single baseline BP measure (10 studies; Pooled adjusted RR=1.92, 1.39-2.66; p<0.001); history or treated hypertension (4 studies; Pooled adjusted RR=1.76, 1.13-2.75, p=0.013); multiple BP measurements over months to years (4 studies; RR=1.68, 1.33-2.14; p<0.001).

Conclusions: Even after extensive adjustment, proteinuria is strongly and independently associated with incident stroke risk, possibly indicating a shared renal and cerebral susceptibility to vascular injury that is not fully explained by traditional vascular risk factors.

TH-PO683

Relationship of Serum Trimethylamine N-Oxide and Betaine Levels with Risk of First Incident Stroke in Chinese Hypertensive Patients

Jing Nie, Liling Xie, Youbao Li, Fengxin Zhu, Xianhui Qin. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Trimethylamine N-oxide (TMAO), a gut derived metabolite, has been shown to be atherogenic. Whether TMAO or its dietary precursors is associated with a risk of stroke remains unknown. We aimed to determine the relationship of serum TMAO and its dietary precursors including choline, L-carnitine and betaine levels with first stroke in hypertensive patients, and examine any possible effect modifiers.

Methods: We conducted a nested case-control study, including 622 patients with first stroke (including 502 ischemic stroke, 118 hemorrhagic stroke and 2 uncertain type of stroke) and 622 matched controls from the China Stroke Primary Prevention Trial (CSPPT). The primary outcome was a first stroke.

Results: Overall, the risk of first stroke increased with each increment of TMAO level [per natural log (TMAO) increment: OR, 1.22; 95%CI: 1.02-1.46). Compared with participants in the lowest tertile (<1.79 μmol/L) of TMAO levels, a significantly higher risk of first stroke was found in those in higher TMAO tertiles (≥1.79 μmol/L) (OR, 1.34; 95% CI: 1.00-1.81) or in TMAO tertile 3 (≥3.19 μmol/L) (OR, 1.43; 95% CI: 1.02-2.01). However, a U-shaped association between serum betaine and the risk of first ischemic stroke was observed. The risk of first ischemic stroke decreased with the increment of betaine (per 10 μmol/L increase: OR, 0.87; 95%CI: 0.77-0.99) in patients with betaine <77.7 μmol/L, and increased with the betaine increment (per 10 μmol/L increase: OR, 1.17; 95%CI: 1.01-1.36) in participants with betaine ≥77.7 μmol/L. Serum betaine had no obvious effect on the risk of first hemorrhagic stroke (per 10 μmol/L increase: OR, 0.98; 95%CI: 0.82, 1.17). Moreover, no significant association between either choline (OR, 1.05; 95%CI: 0.68- 1.64) or L-carnitine (OR, 1.05; 95%CI: 0.60-1.85) with the risk of first stroke was found.

Conclusions: Among Chinese hypertensive patients, higher TMAO levels were associated with increased risk of first stroke while the association between betaine levels and the risk of first ischemic stroke was a U-shaped, with a turning point at about 77.7 μmol/L.

The Impact of Change of Blood Pressure Stage According to the 2017 ACC/AHA Guideline on Cardiovascular Events Among Untreated Low-Risk Populations: A Nationwide Population-Based Cohort Study

Kyoung Hye Kong,[1] Hyung Jung Oh,[2] Dong-Ryeol Ryu.[1] *[1]Ewha Womans University, Seoul, Republic of Korea; [2]Ewah Womans' University, Mokdong Hospital, Seoul, Republic of Korea.*

Background: The 2017 American College of Cardiology/American Heart Association (ACC/AHA) hypertension (HTN) guideline defined new HTN thresholds. However, the evidence was largely based on studies conducted with a single baseline blood pressure (BP) measurement. Therefore, we investigated the impact of the change of BP stage according to 2017 ACC/AHA guideline on cardiovascular events (CVEs), with baseline and mean BP measurements during the follow-up of untreated, low-risk populations.

Methods: This retrospective, longitudinal study was conducted with 322,562 subjects aged ≥ 40 years without diabetes mellitus, chronic kidney disease, or previous CVE, enrolled in the Korean National Health Service-National Health Screening Cohort between 2002 and 2003, who had not taken antihypertensive medication during follow-up period. Subjects were categorized according to the 2017 ACC/AHA HTN guideline based on their baseline and mean BP during follow-up. The primary outcome of the study was newly developed CVEs (cardiovascular disease and mortality).

Results: During the median follow-up of 10 years, 2.51 events per 1,000 person-years occurred. Compared to normal (BP<120/80 mmHg) individuals, significantly increased risk of CVE was observed in individuals with stage 1 HTN (systolic BP 130-139/diastolic BP 80-89 mmHg), with both baseline and mean BP examinations. However, the hazard ratios for the CVEs using mean BP were higher those in using baseline BP. When subjects were categorized into 16 groups according to BP stages (and baseline versus mean BP measurements), the risk of CVD incidence was significantly lower when BP stage calculated using the mean BP decreased compared to the reference (the BP stage remained same between the baseline BP and mean BP) in the population with stage 1 and 2 HTN.

Conclusions: Stage 1 and 2 HTN, defined by the 2017 ACC/AHA guideline, were significantly associated with an increase of CVEs in the analysis with baseline and mean BP measurements among untreated, low-risk individuals. However, the mean BP was superior to the baseline BP for predicting CVEs. Moreover, the study suggests that physicians need to lower BP stage to prevent the occurrence of CVD when their patients, even those at low risk for CVEs, are in the stage 1 or 2 HTN groups at baseline.

TH-PO685

The Prevalence of Nonadherence in Patients with Resistant Hypertension: A Systematic Review

Gabrielle E. Bourque,[2] Julius V. Ilin,[1] Marcel Ruzicka,[1] Swapnil Hiremath.[1] *[1]University of Ottawa, Ottawa, ON, Canada; [2]The Ottawa Hospital, Ottawa, ON, Canada.*

Background: Resistant hypertension (RH) is common and is a risk factor for higher cardiovascular outcomes. These patients also undergo more screening intensity for secondary hypertension. Not all patients with apparent resistant hypertension have true RH. Reports of the prevalence of non-adherence vary widely from 3 to 86%. However intentional and non-intentional non-adherence are not differentiated in this data. Non-intentional non-adherence refers to occasional forgetfulness and can be diagnosed with pill counts or pharmacy refill data. Intentional non-adherence requires more intensive measures (such as therapeutic drug monitoring or directly observed therapy) to diagnose. The objective of this systematic review is to establish the overall prevalence of non-adherence in the RH population and differentiate the contribution of non-intentional and intentional non-adherence subtypes.

Methods: The databases MEDLINE, EMBASE, and the Cochrane library were searched for observational studies and randomized controlled trials reporting the prevalence of non-adherence in RH. The primary outcome studied is the pooled prevalence of non-adherence in RH. The secondary outcome examined will be the pooled prevalence of non-adherence based on indirect and direct measures of non-adherence. Weighted summary prevalence for the outcomes was estimated using the random effects model.

Results: The literature search retrieved 1415 non-duplicate citations. After applying eligibility criteria, 197 full text citations were retrieved, and 27 studies were included in the review. Most studies were retrospective database studies or cross-sectional in nature and (63%) used indirect measures of assessment such as medication possession ratio or the Morisky scale with 80% adherence being the most common cutoff used for diagnosis of non-adherence. The pooled prevalence of non-adherence was 31%, with high statistical heterogeneity (I-squared 99). The pooled prevalence was higher with direct measures (45%) than indirect measures (19%).

Conclusions: The prevalence of non-adherence varies based on the severity of hypertension, but also based on the method of measurement of adherence. Indirect measures underestimate the extent of true non-adherence. Incorporation of direct measures such as drug assays or direct observed therapy should be considered for more widespread adoption.

TH-PO686

Apparent Treatment-Resistant Hypertension (ATRH) Stratified by Ambulatory Blood Pressure Monitoring (ABPM) in CKD: A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study

Jesse Felts,[12] George Thomas,[1] Carolyn S. Brecklin,[11] Jing Chen,[2] Paul E. Drawz,[3] Eva Lustigova,[4] Rupal Mehta,[5] Edgar R. Miller,[6] Stephen M. Sozio,[7] Matthew R. Weir,[8] Dawei Xie,[9] Xue Wang,[10] Mahboob Rahman.[13] for the CRIC study investigators *[1]Cleveland Clinic, Cleveland, OH; [2]Tulane School of Medicine, New Orleans, LA; [3]University of Minnesota, Minneapolis, MN; [4]Kaiser Permanente Medical Group, Pasadena, CA; [5]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [6]Johns Hopkins University, Baltimore, MD; [7]Johns Hopkins University School of Medicine, Baltimore, MD; [8]University of Maryland School of Medicine, Baltimore, MD; [9]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA; [10]University of Pennsylvania, Philadelphia, PA; [11]University of Illinois, Chicago, IL; [12]University Hospitals Cleveland Medical Center, University Heights, OH; [13]Case Western Reserve University, Cleveland, OH.*

Background: ATRH defined using office blood pressure (BP) measurements, is common in patients with chronic kidney disease. Whether measurement of 24 hour ABPM is of value in risk stratification in patients with ATRH is unclear.

Methods: We analyzed data from the CRIC study, a prospective study of participants with chronic kidney disease. Office BP was measured by trained staff; 24 hour ABPM was measured using Spacelabs monitors. ATRH was defined as mean office systolic BP ≥ 140 mm Hg or diastolic BP ≥ 90 mm Hg on ≥ 3 antihypertensive medications, average ABPM daytime systolic BP ≥ 135 mm Hg or diastolic BP ≥ 85 mm Hg on ≥ 3 antihypertensive medications, or the use of > 3 antihypertensive medications. Outcomes were composite cardiovascular disease (CVD)(myocardial infarction, stroke, peripheral arterial disease, heart failure), renal outcomes (end stage renal disease or 50% decline in GFR), and groups were compared using Cox regression analyses.

Results: Of 475 participants with ATRH based on office BP, 40 participants (8%) had controlled ABPM consistent with white coat hypertension. ATRH based on office and ABPM criteria (ABPM-ATRH) was seen in 162 (34%), and 273 (54%) of participants had ATRH based on the use of > three antihypertensive medications. The control group was participants with BP controlled by office and ABPM criteria (n=711). While unadjusted event rates of composite CVD (8.19 vs 2.77 per 100 patient years) renal outcomes (12.75 vs 2.97 per 100 patient years), and mortality (4.93 vs 2.18 per 100 patient years) were higher, in adjusted analyses, the risk of composite CVD (Hazard ratio (HR) 1.27, 95% confidence intervals (CI) 0.59, 2.7), renal outcomes (HR 1.68 95% CI 0.88, 3.21), and mortality (HR 1.27 95% CI 0.5, 3.25) was not statistically significantly higher in participants with ABPM-ATRH group compared to the participants with controlled BP.

Conclusions: In our study population with chronic kidney disease, most patients with ATRH defined based on office BP have ATRH confirmed by ABPM. While ABPM defined ATRH was not an independent risk factor for outcomes, the presence of ABPM-TRH identified participants at high risk for clinical outcomes

TH-PO687

Can Central Blood Pressure Be Accurately Estimated in Individuals with and Without Systolic Blood Pressure Amplification?

Remi Goupil, Florence Lamarche, Cédric Kowalski. *Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

Background: Systolic blood pressure (SBP) does not always amplify from central to peripheral arteries. Individuals without SBP amplification (SBPamp) have higher aortic blood pressure (BP) despite similar brachial cuff SBP. To circumvent this discrepancy, the aim of this study was to determine if aortic SBP can be accurately estimated non-invasively in patients with and without SBPamp.

Methods: Patients undergoing non-urgent percutaneous coronary angiogram were recruited. Individuals with atrial fibrillation, ≥10 mmHg between-arm SBP difference or severe aortic stenosis were excluded. After the procedure, aortic and brachial intra-arterial BP were measured via radial artery approach using a fluid-filled catheter. Simultaneously, brachial and central cuff BP were measured in triplicate using a Mobil-o-Graph (IEM, Germany). This device estimates central BP via brachial pulse wave analysis by type I (SBP and diastolic BP) and type II (mean and diastolic BP) calibrations. Aortic-to-brachial SBPamp was defined as ≥5 mmHg increase between intra-arterial aortic and brachial SBP.

Results: Of the 151 patients recruited, only 85 had SBPamp. SBPamp+ and SBPamp- patients had similar characteristics, apart from higher augmentation in SBPamp- (Table 1). Central BP estimated with Type I or Type II calibration could not accurately determine aortic SBPs in both phenotypes (Table 2). Using the mean of both estimates only provided a slightly better accuracy.

Conclusions: Central BP measurements cannot identify the different aortic BP of the SBPamp phenotypes. A new central BP calibration may be needed to circumvent this problem.

Baseline characteristics	SBPamp+ (n=85)	SBPamp- (n=66)	p-value
Male sex	74%	74%	1.0
Age	66 ± 11	65 ± 9	0.6
Height (cm)	171 ± 10	170 ± 10	0.6
BMI (kg/m^2)	29 ± 6	30 ± 10	0.3
Active smoking	28%	27%	0.9
Diabetes	19%	17%	0.7
Hypertension	59%	55%	0.6
Dyslipidemia	55%	55%	0.9
Prior cardiovascular disease	39%	52%	0.1
eGFR (mL/min/1.73m^2)	80 ± 18	81 ± 18	0.7
Brachial cuff SBP	126 ± 15	126 ±16	0.8
Brachial cuff diastolic blood pressure	78 ± 9	78 ± 12	0.9
Heart rate (bpm)	67 ± 11	65 ± 11	0.3
Augmentation index @ 75 bmp	18 ± 10	22 ± 11	0.03
Pulse wave velocity (m/s)	10 ± 2	9 ± 2	0.09

SBPamp+ and SBPamp- denotes individuals with and without SBP amplification, defined as ≥5 mmHg increase between intra-arterial aortic and brachial SBP. Values are expressed as mean ± standard deviation. All blood pressure measures are expressed in mmHg. P-values are calculated using Pearson's chi-square and Student t-tests. SBP, systolic blood pressure.

Table 1

BP measurements	SBPamp+ (n=85)	SBPamp- (n=66)	p-value
Aortic SBP (intra-arterial)	126 ± 18	133 ± 22	0.05
Brachial SBP (intra-arterial)	140 ± 18	131 ±23	0.01
Central cuff SBP			
Type I calibration	117 ± 15	116 ± 14	0.6
Type II calibration	136 ± 18	135 ± 18	0.7
Mean of Types I and II	126 ± 16	127 ± 15	0.6
Aortic SBP mean difference			
Intra-arterial vs Type I	9 ± 11	16 ± 13	<0.001
Intra-arterial vs Type II	10 ± 15	2 ± 12	0.04
Intra-arterial vs Mean of Type I and II	1 ± 12	7 ± 11	0.2
Brachial cuff mean difference (vs intra-arterial)	14 ± 11	6 ± 13	<0.001

See Table 1. As per ARTERY guidelines, accurate BP estimation are defined as an absolute mean difference ≤5 ± 8 mmHg compared with the reference method.

Table 2

Life's Simple 7 and Risk of Cardiovascular Disease in the Chronic Renal Insufficiency Cohort

Mindy Pike,[1] Talat Alp Ikizler,[2] Loren Lipworth,[2] Cassianne Robinson-Cohen.[2] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: The American Heart Association (AHA) has identified seven modifiable factors, "Life's Simple 7", that contribute to heart health. The association between these ideal health behaviors and cardiovascular (CV) disease has not been examined among individuals with chronic kidney disease (CKD).

Methods: We studied 2,979 participants from the Chronic Renal Insufficiency Cohort (CRIC) Study. The AHA definitions for non-ideal health were used for body mass index (BMI≥25kg/m^2), total cholesterol (≥200 mg/dL), blood pressure (≥120 systolic and ≥80 diastolic), fasting plasma glucose (≥100 mg/dL), and physical activity (<75 min/week of vigorous physical activity or <150min/week of moderate/vigorous). Due to design constraints, modified definitions were used for smoking (current) and consuming an unhealthy diet (below median fruit and vegetables, fish, and whole grain intake, and above median urine sodium and sweetened beverage intake). The outcome was time to first adjudicated CV event, defined as heart failure, myocardial infarction, ischemic stroke, or death. Population attributable risk percent (PAR%) was estimated from Cox regression models including each Simple 7 factor, age, sex, race, income, education, family history of coronary artery disease, and estimated glomerular filtration rate.

Results: During a median follow-up of 7 years, 1,345 participants had an incident CV event (5.8/100 person-years). High fasting glucose contributed the most to CV burden, with a PAR of 20.1% (95% CI: 15.0-24.8). Physical underactivity, smoking, and high blood pressure accounted for a modest proportion of the population risk, while poor diet, BMI, and high cholesterol had nonsignificant PARs. In race-stratified analyses, high glucose remained the strongest contributor, but among white participants, physical underactivity also contributed significantly to risk (PAR: 17.6%; 95% CI: 9.2-25.2), while high blood pressure contributed significantly among blacks (PAR: 5.1%; 95% CI: 0.04-9.9).

Conclusions: Among individuals with CKD, high fasting glucose contributed the most to CV burden. Understanding the contributions of each modifiable risk factor may help target efforts to reduce CV incidence in this population.

TH-PO689

Hypertension Is Associated with Adverse Cardiovascular Outcomes Only When Both Brachial and Central Blood Pressures Are Elevated

Florence Lamarche,[1] Mohsen Agharazii,[2] Francois Madore,[1] Remi Goupil.[1]
[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]CHUQ-HDQ, Quebec City, QC, Canada.

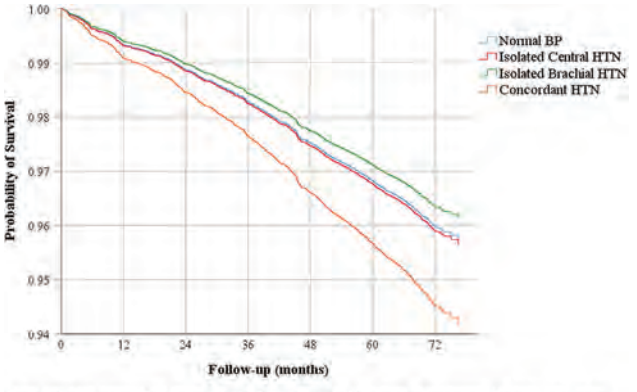
Background: The range of central blood pressure (BP) found in individuals with high-normal brachial BP overlaps the one found in hypertension (HTN) and normotension. As central BP is possibly a better predictor of cardiovascular (CV) disease, the aim of this study was to determine the risk associated with different central/brachial BP patterns.

Methods: 13,759 participants from a populational cohort with central BP and prospective data from governmental databases who were not treated for HTN were selected. Major adverse CV events (MACE) comprised myocardial infarction, stroke, heart failure and CV death. Thresholds for brachial and central HTN were identified as 135 and 125 mmHg respectively. Individuals were separated into 4 BP patterns: normal BP; isolated brachial HTN; isolated central HTN; concordant brachial and central HTN. CVE risk for each pattern was compared to normal BP with a Cox proportional hazard model.

Results: 688 MACE occurred over a median follow-up of 70.0 months. Characteristics of individuals in each BP phenotype are presented in Table 1. Only the concordant brachial and central HTN pattenr had higher risk of MACE [HR 1.37 95%CI (1.15-1.64), p=0.001] compared to normal BP (Figure 1). Sensitivity analyses with different definitions of central HTN and after stratification for sex yielded similar results.

Conclusions: In untreated individuals, both central and brachial BP need to be elevated to increase CV risk. These findings provide support for the utility of routine central BP measurements in clinical practice.

Demographic characteristics	Normal BP (n=10,611)	Isolated brachial HTN (n=394)	Isolated central HTN (n=496)	Concordant HTN (n=2,258)
n	10,611	394	496	2,258
Age	51 (46-57)	53 (47-60)	54 (49-62)	56 (51-63)
Male sex	43%	88%	38%	58%
Caucasian race	89%	88%	91%	89%
Cardiovascular disease	2%	2%	4%	2%
Diabetes	4%	8%	3%	6%
Active smoking	19%	22%	16%	21%
BMI (kg/m^2)	26 ± 5	28 ± 3	28 ± 5	28 ± 5
eGFR (ml/min/1.73m^2)	90 ± 14	87 ± 15	89 ± 14	88 ± 14
10-year Framingham risk score (%)	8 ± 7	17 ± 10	11 ± 7	18 ±12
LDL-c (mmol/L)	3.1 ± 0.8	3.1 ± 0.9	3.3 ± 0.9	3.3 ± 0.9
Heart rate (bpm)	70 ± 10	77 ± 11	65 ± 9	71 ± 11
Aspirin	6%	8%	11%	9%
Statin	10%	16%	16%	13%



Survival plot using Cox proportional hazard modelling with adjustment for age, sex, race, body mass index, active smoking, diabetes, CV disease, CKD, LDL-c, heart rate, aspirin and statin use.

Abnormal Left Ventricular Metrics and Subsequent Cardiovascular Events in Japanese and US Patients with CKD: Findings from the CRIC and CKD-JAC Studies

Takahiro Imaizumi,[1,2] Naohiko Fujii,[12] Takayuki Hamano,[3] Wei Yang,[4] Mayank Kansal,[14] Rupal Mehta,[5] Tariq Shafi,[6] Jonathan J. Taliercio,[13] Alan S. Go,[7] Panduranga S. Rao,[8] L. Lee Hamm,[9] Rajat Deo,[4] Shoichi Maruyama,[11] Masafumi Fukagawa,[10] Harold I. Feldman.[4] *[1]Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania, Philadelphia, PA; [2]Department of Advanced Medicine, Nagoya University Hospital, Nagoya, Japan; [3]Osaka University Graduate School of Medicine, Suita, Japan; [4]University of Pennsylvania, Philadelphia, PA; [5]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [6]University of Mississippi Medical Center, Jackson, MS; [7]Kaiser Permanente Northern California, Oakland, CA; [8]University of Michigan Health System, Ann Arbor, MI; [9]Tulane University School of Medicine, New Orleans, LA; [10]Tokai University School of Medicine, Isehara, Japan; [11]Nagoya University Graduate School of Medicine, Nagoya, Japan; [12]Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan; [13]Glickman Urological and Kidney Institute, Cleveland, OH; [14]University of Illinois at Chicago, Chicago, IL.*

Background: Left ventricular (LV) hypertrophy (LVH) is a risk factor for cardiovascular (CVD) events in patients with chronic kidney disease (CKD). The prevalence of LVH and the associated risk of subsequent CVD events in US and Japanese patients with CKD has not been clearly elucidated.

Methods: 3125 participants in the Chronic Renal Insufficiency Cohort (CRIC) Study and 1097 in the CKD Japan Cohort (CKD-JAC) Study underwent echocardiography. LV mass index (LVMI), LVH (defined as LVMI >50 g/m$^{2.7}$ in males and >47 g/m$^{2.7}$ in females), and LV geometry (concentric hypertrophy, eccentric hypertrophy, and concentric remodeling) were assessed. Cox proportional hazards survival analysis was implemented for the composite outcome of CVD, defined as any of the following events: hospitalization for congestive heart failure, myocardial infarction, stroke, interventions for peripheral artery disease, and any lethal cardiovascular events.

Results: The mean values of LVMI and the proportion of LVH in CRIC and CKD-JAC participants were 55.7 g/m$^{2.7}$ and 46.6 g/m$^{2.7}$, and 59.2% and 36.1%, respectively. CRIC participants had higher proportion of concentric LVH (51.6% and 23.1%, respectively). Incidence rates of the first CVD events in the CRIC and the CKD-JAC were 35.5 and 23.5 per 1000 person-years, respectively. LVH was significantly associated with the subsequent CVD events; HRs were 1.86 (95% confidence interval, 1.53–2.26) in the pooled cohort, 1.85 (1.50–2.29) in the CRIC, and 1.91 (1.15–3.16) in the CKD-JAC (P-interaction = 0.96). Adjusted HRs of LVMI (per 10 g/m2.7) were 1.23 (1.18–1.27) in the pooled cohort. Adjusted HRs stratified by race/ethnicity were 1.23 (1.14–1.31) in non-Hispanic Whites, 1.23 (1.16–1.29) in non-Hispanic Blacks, 1.19 (1.03–1.38) in Hispanics and 1.24 (1.07–1.43) in Japanese Asians (P-interaction = 0.94).

Conclusions: US patients with CKD had a higher prevalence of LVH and higher LVMI than Japanese patients with CKD. Despite the differences in LV metrics, the association between LVMI and subsequent CVD events was similar across ethnic groups. These findings also reinforce that LVMI may be a common therapeutic target across these diverse populations.

TH-PO691

Changes in QT Interval in Long-Term Hemodialysis Patients

Yoshihiro Matsumoto,[1] Yasuo Mori,[2] Shinji Kageyama,[5] Kazuo Arihara,[3] Sugiyama Toshikazu.[4] *[1]Shizuoka City Hospital, Shizuoka, Japan; [2]Shibukawa Clinic, Shizuoka, Japan; [3]Ohtemachi Clinic, Shizuoka, Japan; [4]Sugiyama Clinic, Shizuoka, Japan; [5]Kageyama Urological Clinic, Shziuoka city, Japan.*

Background: A prolonged QT interval on the electrocardiogram (ECG) is a risk factor for sudden cardiac death (SCD) in hemodialysis (HD) patients. This study investigated whether the heart rate-corrected QT (QTc) interval becomes prolonged in relation to the number of years undergoing dialysis treatment.

Methods: A total of 102 patients treated with HD for more than 7 years were studied. All patients had ECG data at 1, 4, and 7 years after HD initiation and 75 of the patients also had ECG data at 10 years after HD initiation. The control group comprised 68 age-matched individuals who had normal renal function and two available ECG reports at an interval of more than 4 years. Patients with ECGs showing heart rates <57 or >103 bpm, extrasystoles, or any rhythm other than sinus were excluded. QTc was measured according to the Bazett formula. The association between QTc interval and dialysis vintage was analyzed. Additionally, clinically relevant variables related to QTc duration at 1 year after HD initiation were assessed.

Results: The average QTc interval in the control group was 425 ms in the first year and 426 ms after an average of 6 years, indicating no significant difference. However, the QTc interval at 1 year after HD initiation in 75 HD patients was 436 ms, which was much higher than that in the control group (P<0.001). In addition, the QTc interval at 4, 7, and 10 years after HD initiation was 441, 439, and 449 ms, respectively, increasing with dialysis vintage (p=0.20, 0.42, and <0.001, for 1 year after HD initiation by Dunnett's multiple comparison). Multivariate regression analysis of baseline variables in 102 HD patients revealed that corrected calcium levels (p=0.041) and diabetes (p = 0.043) were independently associated with the longer QTc interval.

Conclusions: The QTc interval at 1 year after HD initiation was longer in HD patients than in the control subjects and was further prolonged over several years of HD treatment. Providing clinical management with a focus on QTc interval may be helpful for reducing the incidence of SCD in HD patients.

TH-PO692

Impact of Pulse Pressure and Mean Arterial Pressure on All-Cause and Cardiovascular Mortality in Subjects with Diabetes in a Nationwide Cohort from a General Japanese Population

Tatsunori Toida,[1,3] Yuji Sato,[2] Shouichi Fujimoto,[1,8] Tsuneo Konta,[4,8] Kazuhiko Tsuruya,[5,8] Yugo Shibagaki,[6,8] Kunitoshi Iseki,[7,8] Ichiei Narita,[9,8] Masato Kasahara,[13,8] Toshiki Moriyama,[11,8] Masahide Kondo,[12,8] Kunihiro Yamagata,[12] Koichi Asahi,[10,8] Tsuyoshi Watanabe.[14,8] *[1]Department of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [2]Dialysis Division, University of Miyazaki Hospital, Miyazaki, Japan; [3]Department of Internal Medicine, Miyazaki Prefectural Nobeoka Hospital, Nobeoka city, Japan; [4]Yamagata University Graduate School of Medical Science, Yamagata, Japan; [5]Nara Medical University, Kashihara, Japan; [6]St Marianna University Hospital, Kawasaki, Japan; [7]Nakamura Clinic, Urasoe, Japan; [8]Steering Committee for Research on "Design of the Comprehensive Health Care System for Chronic Kidney Disease Based on the Individual Risk Assessment by Specific Health Check", Fukushima, Japan; [9]Niigata University, Niigata, Japan; [10]Iwate Medical University, Morioka, Japan; [11]Osaka University Health Care Center, Toyonaka, Japan; [12]University of Tsukuba, Tsukuba, Japan; [13]Institute for Clinical and Translational Science Nara Medical University Hospital, Kashihara, Japan; [14]Fukushima Medical University School of Medicine, Fukushima City, Japan.*

Background: In the general population, blood pressure (BP) and physiological factors that influence arterial stiffness, such as pulse pressure (PP, difference between systolic BP [SBP] and diastolic BP [DBP]) and mean arterial pressure (MAP, 2/3 DBP + 1/3 SBP), are associated with mortality and cardiovascular (CV) outcomes; however, the impact of these markers in diabetic patients remains unclear.

Methods: Study design: Cohort study. Setting, Participants: Data from a nationwide database from the annual "Specific Health Check and Guidance in Japan", including 20,748 people with diabetes, eGFR≥30, aged 40 to 75 years, and 42.4% female. Predictor: SBP, DBP, PP, and MAP at baseline Outcomes: All-cause and CV mortality during a median follow-up of 5.3 years. Measurements: Hazard ratios (HRs) were estimated using Cox's model for the relationships between predictors and outcomes, and adjusted for potential confounders.

Results: During the follow-up, the incidence of death was 448 (4.1 per 1000 person-years), including 101 CV deaths (0.9 per 1000 person-years). HRs for all-cause mortality for each 1-SD elevation in SBP, DBP, PP, and MAP did not significantly increase. On the other hand, HRs for the CV mortality of MAP significantly increased, whereas those of other BP parameters did not, as shown in Table 1. Furthermore, when patients were divided into two groups based on the presence and absence of proteinuria, HRs for CV mortality for each 1-SD elevation in PP and MAP significantly increased in subjects without proteinuria. However, no parameters correlated with cardiovascular mortality in subjects with proteinuria.

Conclusions: In diabetes patients without proteinuria, markers of arterial stiffness, such as PP and MAP, may be suitable for predicting CV outcomes.

Multivariate analysis of blood pressure parameters and cardiovascular death.

Patient group (number)	SBP, 1-SD elevation HR (95% CI)	PP, 1-SD elevation HR (95% CI)	MAP, 1-SD elevation HR (95% CI)
DM* (n=20,748)	1.17 (0.91-1.49)	1.11 (0.88-1.41)	1.30 (1.02-1.64)
DM* with proteinuria (n=5,012)	1.01 (0.68-1.51)	0.86 (0.59-1.24)	1.15 (0.78-1.70)
DM* without proteinuria (n=15,736)	1.28 (0.94-1.75)	1.35 (1.00-1.81)	1.40 (1.04-1.91)

* Diabetes mellitus patients whose eGFR was more than 30 ml/min/1.73m2.

TH-PO693

Association of Metabolic Acidosis with Adverse Cardiovascular Outcomes in Patients with CKD

Nancy L. Reaven,[1] Susan E. Funk,[1] Vandana S. Mathur,[2] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Canada, CA; [2]Mathur Consulting, Woodside, CA; [3]University of Manitoba, Winnipeg, MB, Canada.*

Background: Metabolic acidosis is a known risk factor for chronic kidney disease (CKD) progression. Less is known about its association with cardiovascular disease in patients with advanced CKD. Here we assess the association of metabolic acidosis with adverse cardiovascular outcomes and its role as an independent predictor of cardiovascular outcomes in patients with pre-dialysis CKD.

Methods: De-identified electronic medical records (Optum® EMR), 2007–2017 were queried to identify patients with CKD Stages 3-5 with ≥2 consistent serum bicarbonate values 28–365 days apart, ≥3 eGFR values >10 and <60 mL/min/1.73m^2 and ≥2 years of post-index data or until death. Patients were followed for up to 10 years for evidence of new onset heart failure, stroke or acute myocardial infarction (MI), defined using ICD-9 and ICD-10 diagnosis codes. Metabolic acidosis and normal serum bicarbonate groups were defined by two serum bicarbonate values between 12 and <22 mEq/L and 22-29 mEq/L, respectively. Cox proportional hazards models were used to examine potential confounders: age, sex, race, eGFR, diabetes, hypertension, heart failure, coronary artery disease, peripheral vascular disease, and hemoglobin and serum albumin.

Results: 51,558 patients qualified for this longitudinal observational study. The incidence of adverse cardiovascular events at 2 years was significantly higher in patients with metabolic acidosis compared to patients with normal serum bicarbonate, [heart failure: 29.8 % vs. 22.8%, p<0.0001; stroke: 19.5% vs. 17.2%, p<0.0001; MI: 17.2% vs. 12.3%, p<0.0001, respectively]. During the up to 10-years of follow-up, serum bicarbonate was independently associated with adverse cardiovascular outcomes; hazard ratios per 1 mEq/L change: new onset heart failure, 0.976, CI: 0.971-0.981, stroke, 0.979, CI: 0.973-0.985; and MI, 0.964, CI: 0.958-0.970, respectively.

Conclusions: In this longitudinal analysis of > 51,000 non-dialysis CKD patients followed for up to ten years, serum bicarbonate levels below 22 mEq/L were associated with increased incidence of major adverse cardiovascular events independent of age, comorbid conditions and kidney function. Studies evaluating the mechanisms of these associations are needed.

Plasma Xanthine Oxidoreductase Activity Is Associated with CKD in a General Japanese Population: The Iwate Tohoku Medical Megabank Project

Yuka Kotozaki, Kozo Tanno, Koichi Asahi, Hideki Ohmomo, Ryo Otomo, Fumitaka Tanaka, Atsushi Shimizu, Kiyomi Sakata, Jiro Hitomi, Makoto Sasaki, Mamoru Satoh. *Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Yahaba, Japan.*

Background: Xanthine oxidoreductase (XOR, pmol/h/mL plasma) catalyzes the oxidation of hypoxanthine to xanthine and of xanthine to uric acid. An increase in XOR activity could cause intravascular damage through the oxidative stress. XOR activity could contribute to the pathogenesis of cardiovascular disease (CVD). Chronic kidney disease (CKD) and CVD are closely related. However, the association with XOR activity and CKD in a general Japanese population are not known. The purpose of this study is to investigate the association between XOR activity and CKD in a general Japanese population.

Methods: The Iwate Tohoku Medical Megabank Organization pooled individual participant data from a general population-based cohort study in Iwate prefecture (n = 1,675, male / female = 529 / 1,146, age = 66.2 ± 10.1 years). We classified as CKD stage (stage I ~ stage IV) using the estimate glomerular filtration rate of creatinine (eGFR, mL/min/1.73m2; eGFR < 60) and the urinary albumin to creatinine ratio (uacr, mg/gCr; uacr ≥ 30). Suita Score used to estimate the risk of the CVD. XOR activity was expressed as the log-transformed values (log10) for skewed variables.

Results: In males, XOR activity was significantly lower in stage IV of CKD compared to stage II (F = 4.66, p = 0.003; stage II vs. IV, 1.74 ± 0.38 vs. 1.27 ± 0.52, p = 0.009), and was related to CKD (OR = 1.87, 95% confidence interval (CI) = 1.16 – 3.01, p = 0.011). XOR activity was no significant difference among CKD stages in females (F = 1.73, p = 0.159), and was no related to CKD (OR = 1.19, p = 0.375). XOR activity was related to the high risk for CVD (Suita Score ≥ 41, males: OR = 4.24, 95% CI = 1.75 – 10.35, p = 0.001; females: OR = 2.88, 95% CI = 2.01 – 4.13, p < 0.001). The area under the curve (AUC) for XOR activity combined with Suita score was 0.61 (95% CI = 0.50 – 0.72, p = 0.051).

Conclusions: In conclusion, XOR activity is associated with CKD and the high risk for CVD in a general Japanese population. An increase in XOR activity may be related to decreased renal function and the CVD risk.

TH-PO695

Individuals Born Preterm Have an Increased Rate of Hypertension from Adolescence to Adulthood

Andrew M. South,[1,3] Elizabeth T. Jensen,[3] Patricia A. Nixon,[2,1] Lisa K. Washburn.[1] *[1]Pediatrics, Wake Forest School of Medicine, Winston Salem, NC; [2]Wake Forest University, Winston Salem, NC; [3]Epidemiology and Prevention, Wake Forest School of Medicine, Winston Salem, NC.*

Background: Preterm birth increases the lifetime risk of hypertension (HTN), but the prevalence of HTN in adolescents and adults and the change in blood pressure (BP) and incidence of HTN from adolescence into adulthood are undescribed. We hypothesized that subjects born preterm have an increased prevalence of high BP and HTN, a greater increase in BP/yr, and an increased incidence of high BP and HTN from adolescence to adulthood compared to term.

Methods: In a longitudinal cohort we measured BP at 3 visits in 220 adolescents born preterm with very low birth weight and 52 born term (mean age 14.4 yr). 148 preterm and 35 term subjects returned as adults (mean age 19.7 yr) and had BP measured at 2 visits. We defined high BP ≥120/80 and HTN ≥130/80 mmHg. We compared high BP and HTN prevalence in preterm vs. term in adolescents and adults with Fisher's exact test and calculated risk ratios with log-binomial regression. We calculated the change in BP/yr in preterm vs. term with linear mixed models. We calculated incident rate ratios comparing number of high BP or HTN measurements per person-yr from adolescence to adulthood in preterm vs. term with Poisson regression. All models were adjusted for race, HTN pregnancy, and birth weight z-score.

Results: Mean follow up was 5.5 yr (range 3.6-9.1). Preterm subjects had significantly higher systolic BP as adolescents and adults vs. term (mean difference 2.5 and 4.6 mmHg, respectively). In adolescents, the preterm vs. term high BP prevalence was 2% vs. 0%

(ns); no participants had HTN. In adults, the preterm vs. term prevalence of high BP was 13% vs. 3% (p=0.14) and HTN 9% vs 3% (ns). Preterm subjects had 4.4x increased risk of high BP as adults vs. term (0.6-31.6); this was attenuated after adjustment. The preterm-term difference in change in systolic BP was 0.3 mmHg/yr (95% CI -0.2 to 0.8); this was attenuated after adjustment. Preterm subjects had a 3.1x increased adjusted rate of high BP per person-yr (1.3-7.0) and a 2.7x increased adjusted rate of HTN per person-yr (0.9-7.5) from adolescence to adulthood vs. term.

Conclusions: Individuals born preterm had increased BP as adolescents and adults and increased rates of high BP and HTN from adolescence to adulthood compared to term-born peers. Early detection and treatment is important in this at-risk population.

TH-PO696

Obesity and Older Age Are Associated with Uncontrolled Hypertension in Children with Kidney Transplant in the Improving Renal Outcomes Collaborative (IROC)

Pamela D. Winterberg,[1,2] Rouba Garro,[1,2] Mike Kelleman,[1] Joseph T. Flynn,[3] Jens W. Goebel,[4] David K. Hooper.[5] *[1]Pediatrics, Emory University School of Medicine, Atlanta, GA; [2]Children's Healthcare of Atlanta, Atlanta, GA; [3]Seattle Children's Hospital, Seattle, WA; [4]Children's Hospital Colorado, Aurora, CO; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Hypertension (HTN) is common in children following kidney transplant (KT) and uncontrolled blood pressure (BP) is associated with long-term outcomes. This study determined risk factors for HTN diagnosis and BP control using registry data from the Improving Renal Outcomes Collaborative (IROC), after standardizing appropriate BP measurement

Methods: We examined the latest clinic visit for each patient >90 days post-KT in the IROC registry that had documented appropriate BP measurement and complete medication data. Appropriate BP measurement was defined as either normal oscillometric measurement (2004 NHBPEP 4th Report), or combined documentation of 5 minutes of rest, use of upper extremity, and appropriate cuff size on a manual measurement. Appropriate BP measurements were next classified using the staging definitions in the 4th Report, which were still in use by IROC for determining BP control in clinic. HTN diagnosis was defined by either active HTN medication or BP ≥ Stage 1. BP control was defined as normal BP stage (BP <90th percentile and <120/80 mmHg) for those with HTN. Overweight was defined as BMI ≥85 %tile or 35 kg/m^2. Clinicodemographic factors associated with HTN diagnosis and BP control were assessed with Chi-square tests, odds ratios (OR), and 95% confidence intervals.

Results: A total of 773 patients from 17 centers were included in the study. Of these, 469 (61%) met criteria for HTN diagnosis. HTN diagnosis was more frequent in patients that were overweight (73% vs 27%, p=0.003), ≥18 years old (72% vs 56%, p<.001), of African American descent (69% vs 59%, p=0.02), or on calcineurin inhibitors (p=0.002). Of those with HTN, 240 (51%) were well-controlled and 32% had BP ≥ Stage 1. Overweight patients (OR 1.71, CI 1.18-2.50) and those ≥18yo (OR 1.79, CI 1.21-2.64) were more likely to have uncontrolled BP. Overweight individuals also had more severe uncontrolled HTN (39% ≥ Stage 1) than normal weight individuals (27%, p=0.01).

Conclusions: Uncontrolled HTN is common in children with KT. Obesity was identified as a significant modifiable risk factor for both HTN diagnosis and BP control. Additional research is needed to identify factors contributing to higher rates of uncontrolled BP in pediatric kidney transplant recipients in early adulthood.

TH-PO697

Pediatric Hypertension Screening and Recognition in Primary Care Clinics in Canada

Linda Ding, Alexander Singer, Leanne Kosowan, Allison Dart. *University of Manitoba, Winnipeg, MB, Canada.*

Background: Pediatric hypertension is becoming increasingly prevalent. Comprehensive guidelines have been developed to guide the diagnosis, evaluation and treatment of hypertension in children. Adherence to these guidelines is unknown in Canada.

Methods: Electronic medical record (EMR) data from the Canadian Primary Care Sentinel Surveillance Network (CPCSSN) was used to determine rates of hypertension screening, follow-up and recognition across Canada for the 2011-2017 period. Data for children aged 3-17 with at least one clinical encounter were extracted. The 2004 guideline by the National Heart, Lung, and Blood Institute was used to define elevated blood pressure (bp=90-95th%ile), hypertension (bp>95th%ile), and screening frequency, as they were pertinent for the study period. Screening rates and follow-ups were evaluated by year. Bivariate analysis was used to compare clinical characteristics of the screened vs non-screened population.

Results: Of the available 378002 children, 22% had at least 1 blood pressure documented. Rates of hypertension screening increased from 18% (n=43387) of all visits in 2011 to 26% (n= 97835) in 2017. Follow-up visits occurred within 6 months for 25% (SD=0.02) of individuals with a normal blood pressure and 26% (SD=0.02) of individuals with elevated blood pressure. For those with hypertension, 57% (SD=0.07) had a follow-up visit within 6 months and 7% (SD=0.01) had a follow-up visit within 1 month. Blood pressure was measured in 76% (SD=0.03) of well child visits (n=42063). The screened cohort included more females (51.6% vs 50.3%, p<0.0001), had higher rates of pediatric diabetes (0.6% vs 0.3%, p<0.0001), and higher BMI (19.9 ± 5.2 vs. 17.9 ± 4.4kg/m2, p< 0.0001). Overall prevalence of hypertension was 2% (n= 715) based on having 2 documented blood pressures above the hypertension threshold, of those, 5.6% (n=40) had a diagnosis of hypertension or presence of an anti-hypertensive in the EMR.

Conclusions: Across Canada, rates of hypertension screening are low, with higher rates at well child visits. Patients that were screened had more cardiovascular risk factors including higher BMI and rates of diabetes. Recognition of hypertension is also poor suggesting pediatric hypertension should be a priority for knowledge translation interventions.

TH-PO698

Younger Age, Asian Ethnicity, and Better Self-Rated Health Are Associated with Unawareness of Hypertension in Community Population

Ming yan Jiang,[1,3] Min Zhuo,[2,3] Rui Song,[3] Jiahua Li,[3] Laura C. Polding,[4] Li-Li Hsiao.[3] Kidney Disease Screening and Awareness Program (KDSAP) research team *[1]Renal Division, Chi Mei Medical Center, Tainan, Taiwan; [2]Renal Division, Beth Israel Deaconess Medical Center, Boston, MA; [3]Renal Division, Brigham and Women's Hospital, Boston, MA; [4]Stanford School of Medicine, Palo Alto, CA.*

Background: Hypertension (HTN) is a major risk factor for chronic kidney disease and its related cardiovascular (CV) complications. It is projected to affect 1.56 billion individuals worldwide by 2025. However, the awareness of HTN remains low; nearly 16% of U.S. adults are unaware of their HTN status. This study aims to explore factors associated with unawareness of HTN in community level.

Methods: Kidney Disease Screening and Awareness Program (KDSAP) provides free screenings and education targeting underserved communities across U.S. and Canada, aiming to early detect and raise awareness of kidney disease. From October 2011 to May 2018, a total of 1,040 KDSAP participants with HTN were enrolled in this study. HTN was defined by self-report being diagnosed with or treated for the disease or high blood pressure during screening with systolic ≥ 140 or diastolic ≥ 90 mmHg. Awareness was defined by self-report.

Results: More than one third (n=374, 36%) of participants were unaware of having HTN; they were younger (57 vs. 66 years old, p<0.001) and higher in proportion of men (51.3% vs. 41.1%, p=0.002). The awareness is positively correlated with increasing age, < 40 (36.9%), 40~59 (56.1%) and ≥ 60 years old (73.0%) (p<0.001), with adjusted odds ratio (OR) 1.02 for every 1-year age increment (p<0.001). While no difference in awareness rates among ethnicities: Asian 64.1%, African American 64.2%, White 60.7% and Hispanic 66.3%; Asians were found to be associated with lower awareness compared with African Americans (OR 1.58, p<0.05) and Hispanic (OR 1.89, p<0.05) after adjusted for age, gender, ethnicity, education level, and self-reported diabetes, hyperlipidemia and CV disease. Interestingly, individuals who rated their health as "very good" or "excellent" were 70% less likely to be aware of having HTN compared to those who self-rated with "poor" or "fair" health (age- and gender-adjusted OR 0.30, p<0.001).

Conclusions: Our results showed a high unawareness of HTN among the KDSAP participants. Younger age and Asian ethnicity were associated with higher unawareness. In addition, self-rated health was inversely correlated with HTN awareness. Our results provide insights in developing effective venues to raise HTN awareness at the community level.

The Relationship of Change in Ankle Brachial Index with Mortality Among Individuals with CKD: The CRIC Study

Kirsten S. Dorans,[1] Hua He,[1] Jing Chen,[2] Mirela A. Dobre,[3] Alan S. Go,[4] L. Lee Hamm,[2] Bernard G. Jaar,[5] Rupal Mehta,[6] Mahboob Rahman,[3] Ana C. Ricardo,[7] Sylvia E. Rosas,[8] Anand Srivastava,[6] Jiang He.[1] On behalf of CRIC Study Principal Investigators *[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [2]Tulane University School of Medicine, New Orleans, LA; [3]Case Western Reserve University, Cleveland, OH; [4]Kaiser Permanente Northern California, Oakland, CA; [5]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [6]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [7]University of Illinois at Chicago, Chicago, IL; [8]Joslin Diabetes Center, Boston, MA.*

Background: Patients with chronic kidney disease (CKD) have an increased risk of peripheral arterial disease (PAD). Ankle-brachial index (ABI), a non-invasive measure of PAD, is a predictor of adverse events among individuals with CKD. In general populations, changes in ABI have been associated with mortality, but this association is not well understood among patients with CKD.

Methods: Prospective study of 2987 participants in the Chronic Renal Insufficiency Cohort (CRIC) Study without clinical PAD at baseline, and with at least one follow-up ABI measurement (taken at annual study visits). ABI was obtained by standard protocol. The association of change in ABI and mortality was studied using Cox proportional hazards regression.

Results: We found U-shaped associations of average annual change in ABI and cumulative average ABI with all-cause mortality (p for non-linearity ≤0.0001). Compared to participants with average annual change in ABI of 0 to <0.02, individuals with average annual change in ABI <-0.02, -0.02 to <0, or ≥0.02 had multivariable-adjusted hazard

ratios (95% CI) of 2.04 (1.57, 2.66), 1.25 (0.98, 1.58), and 1.68 (1.37, 2.05) for all-cause mortality, respectively. Compared to participants with cumulative average ABI between 1.0 and <1.4, multivariable-adjusted hazard ratios (95% CI) for those with cumulative average ABI of <0.9, 0.9 to <1.0, and ≥1.4 were 1.64 (1.33, 2.01), 1.22 (0.95, 1.55), and 1.29 (0.95, 1.75), respectively.

Conclusions: Findings from this study indicate that both larger decreases and increases in average annual changes in ABI (>0.02) were associated with higher risk of mortality. Monitoring changes in ABI over time may facilitate risk stratification for all-cause mortality among individuals with CKD.

TH-PO700

Natural History of Peripheral Artery Disease in Patients with CKD

Jing Chen,[2] L. Lee Hamm,[1] Kirsten S. Dorans,[2] Jerry Cornell,[3] Erin Mahone,[3] Matthew R. Weir,[4] Teresa K. Chen,[5] Anand Srivastava,[6] Stephanie M. Toth-Manikowski,[7] Harold I. Feldman,[8] Hua He,[2] Jiang He.[2] *[1]Tulane University School of Medicine, New Orleans, LA; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [3]Tulane University, Harvey, LA; [4]University of Maryland School of Medicine, Baltimore, MD; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]Northwestern University Feinberg School of Medicine, Chicago, IL; [7]University of Illinois Medical Center, Chicago, IL; [8]University of Pennsylvania, Philadelphia, PA.*

Background: The prevalence and risk of peripheral artery disease (PAD) are higher in patients with chronic kidney disease (CKD) compared to those without. The natural history of PAD in CKD has not been well studied.

Methods: We studied the natural history of PAD among 4571 participants without PAD procedures at baseline in the Chronic Renal Insufficiency Cohort (CRIC) Study. The mean follow-up duration is 7.6 years. Mixed effects models were used to assess the slope of change in ankle-brachial index (ABI). Cox proportional hazards models were used to examine the multivariable association of ABI slopes with PAD events, adjusting for time-updated confounding factors.

Results: The slopes of average annual ABI changes were characterized as rapidly (ABI change < - 0.03) or slowly (-0.3 to -0.001) decreasing, stable (<-0.001 to <0.001), rapidly (>0.05) or slowly (0.001 to 0.05) increasing. Compared to those with stable slope, multivariable-adjusted hazard ratios (95% CI) for incident PAD events were 2.80 (2.49, 3.17), 1.67 (1.55, 1.81), 1.42 (1.32, 1.54), and 1.92 (1.65, 2.23) for those with rapidly decreasing, slowing decreasing, slowly increasing, and rapidly increasing, respectively. The average time to develop the first PAD event was 7.38, 8.48, 8.46, 7.73, 7.50, or 6.59 years for those with baseline ABI of ≤0.9, >0.9-1.0, >1.0-1.2, >1.2-1.3, >1.3-1.4, or >1.4, respectively. Annual event rates per person year were 2.95%, 1.58%, 1.58%, 1.77%, 1.64%, or 2.64 % for CVD and 3.57%, 2.17%, 1.61%, 1.80%, 1.96%, or 2.03% for mortality by baseline ABI categories. Amputation and mortality rates were 17.86% and 8.74%, respectively, in year 1 and 22.02% and 13.69%, respectively, in year 5 after PAD-related revascularization.

Conclusions: This study indicates that either increase or decrease in ABI with time is associated with increased incident PAD events. Latent time of PAD is short for those with normal ABI. Complication rates are high among those with subclinical PAD. Prognosis is poor after revascularization. Our study suggests screening for PAD using ABI along with monitoring ABI changes may facilitate early detection of PAD progression and prevention. Further study is warranted to investigate the effect of intervention for significant change of ABI on improving clinical outcomes.

TH-PO701

Predictive Value of Cardio Ankle Vascular Index on the Risk of ESRD

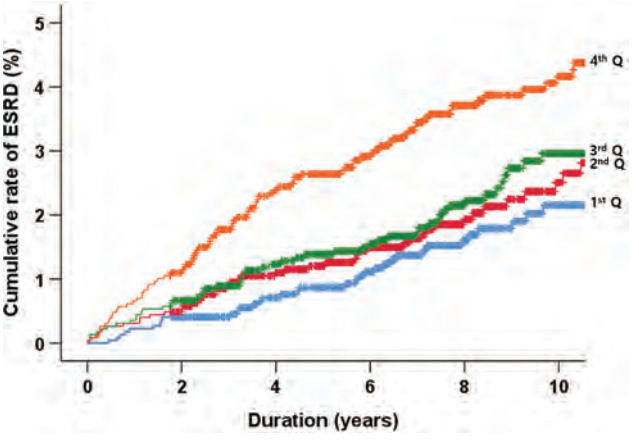
Jinseon Jeong,[1] Dong Ki Kim,[1] Seung Seok Han.[2] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Arterial stiffness is a great concern in relation to high mortality and cardiovascular event. However, the predictive value of pulse wave velocity, one of assessment tools for arterial stiffness, on the risk of end-stage renal disease (ESRD) remains unresolved.

Methods: A total of 9,005 patients who measured cardio-ankle vascular index (CAVI) were included in the study. Patients were divided according to the value (9.0) of CAVI or the quartiles of CAVI. The hazard ratios (HRs) of ESRD and all-cause mortality were calculated using the multivariable-adjusted Cox model. We also analyzed the competing risk regression to adjust the death.

Results: During the median follow-up period of 7 years (maximum 12 years), the events of ESRD and mortality occurred in 215 and 1,079 patients, respectively. The median value of CAVI was 8.5. The high CAVI group (> 9.0) had a higher risk of ESRD than the low CAVI group (HR, 1.65 [1.27–2.16]; $P < 0.001$). The risk of all-cause mortality was also higher in the high CAVI group than in the low CAVI group (HR 2.84 [2.51–3.21]; $P < 0.001$). Although the analysis was performed based on the quartiles, the 4th quartile group had a higher risk of ESRD (HR, 2.20 [1.48–3.27]; $P < 0.001$) than the 1st quartile group. The risk of all-cause mortality was also higher in the 4th quartile than in the 1st quartile (HR, 4.21 [3.46–5.12]; $P < 0.001$). The death-adjusted risk analysis also showed that the 4th quartile group had a high risk of ESRD than the 1st quartile (HR, 2.21 [1.49–3.28]; $P < 0.001$).

Conclusions: The measurement of CAVI by the pulse wave velocity may be needed to predict the risk of ESRD.



TH-PO702

CKD, Atherosclerotic Plaque Characteristics on Carotid Magnetic Resonance Imaging, and Cardiovascular Outcomes

Sydney E. Hartsell,[1] Robert E. Boucher,[1] Sankar D. Navaneethan,[2] Glenn M. Chertow,[3] Michel Chonchol,[4] William E. Haley,[5] Alfred K. Cheung,[1,9] Jackson T. Wright,[6] Tom Greene,[1] Raymond R. Townsend,[8] Niranjan Balu,[7] Dongxiang Xu,[7] Jie Sun,[7] Gador Canton,[7] Chun Yuan,[7] Srinivasan Beddhu.[1,9] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]Baylor College of Medicine, Sugar Land, TX; [3]Stanford University School of Medicine, Palo Alto, CA; [4]University of Colorado, Aurora, CO; [5]Mayo Clinic, Jacksonville, FL; [6]Case Western Research University, Cleveland, OH; [7]University of Washington, Seattle, WA; [8]University of Pennsylvania School of Medicine, Villanova, PA; [9]Salt Lake City VA Healthcare System, Salt Lake City, UT.*

Background: CKD is associated with high risk of cardiovascular (CV) events but it is unclear whether greater baseline prevalence and faster progression of atherosclerosis accounts for this phenomenon.

Methods: In a subgroup (N = 465) of Systolic Blood Pressure Intervention Trial (SPRINT) participants, we used carotid MRI to measure plaque presence and morphology at baseline and after 30-months. CKD was defined as baseline eGFR <60 ml/min/1.73m^2. Plaque was defined as max wall thickness> 1.5 mm or presence of lipid rich necrotic-core (NC+) or calcified (Ca+) plaques. As only NC+ plaque predicted primary SPRINT CV composite and not any plaque or Ca+ plaque, the current analysis used NC+ plaques. We related CKD status with NC+ plaque and the CV outcome.

Results: Overall, 196 (42%) patients had CKD and 137 (30%) had NC+ plaques. Baseline presence of NC+ plaque was unrelated to CKD status (OR 1.02, 95% CI 0.67 to 1.57). CKD was associated with a lower odds of NC+ plaque progression (OR 0.42, 95% CI 0.18 to 0.98) among participants with NC+ plaque at baseline and non-missing follow-up MRI (N = 96). There were 28 CV events over 1764 participant-years of follow-up. In a multivariable Cox model, both CKD (HR 3.47, 95% CI 1.42 to 8.47) and NC+ plaque (HR 2.58, 95% CI 1.07 to 6.18) were associated with an increased hazard of CV event. The interaction p-value for CKD status and NC+ plaque was non-significant (p = 0.55). However, patients with both had a significantly higher cumulative rate of CV events compared to patients with neither (Fig. 1).

Conclusions: We found no association between CKD status and the presence or progression of NC+ plaques, although both were independently associated with CV events. Thus, CKD may contribute to CV disease principally via mechanisms other than atherosclerosis. Moreover, a combination of carotid MRI and GFR estimation could be used to identify patients with hypertension at exceptionally high CV risk.

A Novel Magnetic Resonance Sequence That Accurately Detects Aortic Calcification

Jennifer S. Lees,[1,3] Alastair J. Rankin,[1,3] Luke Y. Zhu,[2] Giles Roditi,[2,3] Sokratis Stoumpos,[3] Patrick B. Mark.[1,3] *[1]University of Glasgow, Glasgow, United Kingdom; [2]University of Glasgow, Glasgow City, United Kingdom; [3]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Vascular calcification is a surrogate marker of cardiovascular disease in patients with renal disease. Computed tomography (CT) is the current gold standard for detecting vascular calcification. StarVIBE (Siemens Healthineers) is a free-breathing, non-contrast magnetic resonance imaging (MRI) sequence that can detect vascular calcification with advantages over CT: it is radiation-free and can be conducted alongside functional cardiac MRI. We compared MRI-StarVIBE with CT for detection of thoracic aortic calcification in patients with renal disease.

Methods: Paired thoracic CT and MRI scans (<24 hours apart) were obtained from patients with renal disease participating in two prospective cohort studies. Two investigators separately reviewed sagittal views on MRI-StarVIBE (JSL) and CT (AJR) of a 10 cm segment of thoracic aorta from the lower level of the descending aortic arch. Aortic calcification was quantified by manually tracing regions of interest on all image slices. We calculated percentage agreement for presence or absence of calcium on CT and MRI-StarVIBE. Linear regression analysis was used to compare calcium content on MRI-StarVIBE and CT. We randomly reassessed 10% of MRI and CT scans, blinded to the original scores, for inter-observer consistency of agreement using the intra-class correlation coefficient (ICC).

Results: Ninety patients (78 renal transplant; 12 haemodialysis) had paired MRI-StarVIBE and CT scans. Calcium was detected on 50.0% of CT scans and 55.8% of MRI-StarVIBE sequences; agreement was 92.2%. There was a strong, linear association between CT and MRI-StarVIBE calcium score (r2 = 0.89). Inter-observer consistency of agreement for calcium quantification was excellent for both CT (ICC 0.966, 95% CI 0.878-0.991, p<0.001) and MRI-StarVIBE (ICC 0.996, 95% CI 0.986-0.999, p<0.001).

Conclusions: MRI-StarVIBE is comparable to CT for evaluating aortic calcification without the need for exposure to potentially hazardous ionizing radiation in patients with established renal disease.

Funding: Private Foundation Support

Figure: Representative images of calcification (white areas along aortic wall) on CT (A, C) and MRI-StarVIBE (B, D). Images A and B are sagittal slices; images C and D are illustrative coronal slices.

Distribution of Myocardial Fibrosis by Native T1 Times Using Cardiac Magnetic Resonance Measurements in CKD

Anas Fares,[2] Eddie Hill,[3] Kevin Kalisz,[4] Armando Vergara-Martel,[2] Sanjay Rajagopalan,[3] Mirela A. Dobre.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]University Hospitals Cleveland Medical Center, Cleveland, OH; [3]University Hospitals, Cleveland Heights, OH; [4]Northwestern University, Chicago, IL.*

Background: Previous evidence suggests that native myocardial T1 relaxation times assessed by cardiac magnetic resonance imaging (MRI) are relevant biomarkers of the extension and severity of myocardial fibrosis in patients with chronic kidney disease (CKD). However, detailed classification and cutoffs of the T1 values in correlation with the severity of kidney disease have not been described

Methods: A cohort of 51 patients with eGFR>20 ml/min/1.73m^2 and without congestive heart failure underwent concomitant assessment of kidney function and noncontrast cardiac MRI using T1 mapping sequence technique in a 3T scanner. CKD was defined as eGFR<60 ml/min/1.73m2. T1 times were measured in all myocardial segments using the American Heart Association 16-segment method and utilizing an advanced post processing software. Student t tests and multivariate linear regression analyses were performed to test the association of CKD with segmental T1 times.

Results: 51 patients were enrolled in the study. Global T1 values in individuals with (eGFR<60) and without (GFR≥60) CKD were 1045.91 ±42.74ms and 1019.75±47.16ms (,p=0.02), respectively. T1 values for anteroseptal, anterior, and inferoseptal segments were 1083.33± 38.53ms and 1049.03±49.81ms(p=0.001), 1052.29±51.81ms and 1021.41±47.52ms (p= 0.01), 1061±40.61ms and 1016.4±60.06ms (p<0.001), in CKD and non CKD patients respectively. Basal T1 values were 1062.93±34.55ms and 1030.56±45.41ms (p<0.001) respectively. In models adjusted for demographics, co-morbidities, medications and eGFR, age was the only variable significantly associatiated with global T1 times.

Conclusions: Cardiac MRI T1 relaxation times can be surogate markers to risk stratify patients with CKD. The cardiac fibrosis in CKD is more prevalent in the basal, anterior and septal myocardial segments.

Association of Noninvasive Measures of Subclinical Atherosclerosis and Arterial Stiffness Cardiovascular Risk with Mortality and Cardiovascular Events in CKD: A Meta-Analysis

Panayiotis Kouis,[3] Andreas Kousios,[1] Athina Kanari,[2] Daphne Kleopa,[2] Stefania Papatheodorou,[2] Andrie G. Panayiotou.[2] *[1]Renal and Transplant Centre Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Cyprus University of Technology, Limassol, Cyprus; [3]University of Cyprus, Nicosia, Cyprus.*

Background: Non-invasive Cardiovascular disease (CVD) risk prediction, in subclinical stages, aiming to stratify patients and tailor interventions remains an unmet need in CKD. We summarize the association of carotid intima-media thickness (cIMT), coronary artery calcium score (CACS) and pusle-wave velocity with all-cause mortality, CVD mortality and CVD events in non-dialysis CKD and patients on dialysis.

Methods: Systematic review and metanalysis of prospective cohort studies.

Results: 24 out of 27984 studies were eligible for quantitative synthesis (5 for cIMT, 11 for CACs and 8 for PWV) involving 708, 3706 and 4393 patients respectively. In dialysis patients, cIMT was associated with all-cause mortality (relative risk (RR) per unit increase 1.08, 95% confidence interval (CI) 1.00-1.17, I^2:68%) and CVD mortality (RR: 1.29, 95% CI 1.14-1.47, I^2:0%). High Vs low CACS was associated with all-cause mortality (RR: 2.51, 95% CI: 1.66-3.79, I^2: 5.7%) and CVD events (RR: 3.77 95% CI: 2.16-6.58, I^2: 20.2%). High Vs low PWV was associated with all-cause (RR: 5.34, 95% CI 3.01-9.47, I^2: 0%) and CVD mortality (RR: 8.55, 95%CI: 4.37 to 16.73, I^2: 0%). The combined estimated for all-cause mortality per 1 m/s increment unit in PWV, was 1.25 (95%CI: 1.17-1.34, I^2: 0%) and for CVD mortality was 1.24 (95%CI: 1.16-1.34, I^2: 15.5%). In non-dialysis patients, CACs was associated with CVD events (RR: 4.02, 95%CI: 1.57-10.29, I^2: 63.4%). High Vs low PWV was associated with all-cause mortality (RR: 2.52, 95% CI 1.40-4.55, I^2: 62.6%).

Conclusions: cIMT, CACS and PWV are associated with all-cause, CVD mortality and events among patients with all stages of CKD. These markers could be considered for the evaluation of cardiovascular morbidity and mortality risks.

Table: Meta-analysis results for all three outcomes, shown separately for HD and non-HD patients.

	All-cause Mortality		CVD Mortality		CVD Events	
	HD patients	Non-HD patients	HD patients	Non-HD patients	HD patients	Non-HD patients
cIMT*	1.08 (1.00-1.17) (I^2: 68%)	n/a	1.29 (1.14-1.47) (I^2: 0%)	n/a	n/a	n/a
CAC†	2.51 (1.66 – 3.79) (I^2: 5.7%)	n/a	n/a	n/a	3.77 (2.16-6.58) (I^2: 20.2%)	4.02 (1.57-10.29) (I^2: 63.4%)
PWV†	5.34 (3.01 – 9.47) (I^2: 0%)	2.52 (1.40 to 4.55) (I^2: 62.6%)	8.55 (4.37-94.39) (I^2: 0%)	n/a	n/a	n/a
PWV*	1.25 (1.17 – 1.34) (I^2: 0%)	n/a	1.24 (1.16-1.34) (I^2: 15.5%)	n/a	n/a	n/a

Change and Clinical Significance of Serum IL-22 Concentration in Hypertensive Renal Damage Patients

Rong Tang, Ting Meng, Xiaozhao Li. *Xiangya Hospital, Central South University, Changsha, China.*

Background: CD4$^+$T cells and their secreted cytokines contribute to the development of hypertensive renal damage. Our previous study showed that Th22 cells and its effect factor interleukin-22 (IL-22) increased significantly in Ang II-induced hypertensive renal damage mice, might play a promoting effects. However, the effects of Th22 and IL-22 in hypertensive patients remain unclear. This study is to explore change of serum IL-22 concentration and its correlation with other clinical indexes in patients with essential hypertension and hypertensive renal damage.

Methods: 97 essential hypertension (EH) patients and 40 healthy control were enrolled in our study. The EH patients were divided into simple hypertension (SH) group (n=45) and hypertensive renal damage (HRD) group (n=52) according to 24h urinary protein (24h-UPRO) level. Basic clinical data were collected; serum IL-22, TNF-α and IL-6 levels were detected by ELISA; the proportion of Th22 cells in peripheral blood was evaluated by flow cytometry; IL-22 and IL-22 receptor (IL-22) expression in kidneys were determined by immunohistochemistry; serum high sensitivity C-reactive protein (hs-CRP) concentration was measured by immune turbidimetry. Correlation analysis was applied between serum IL-22 and other indexes.

Results: Serum IL-22 level and Th22 cells frequency in patients with hypertension were significantly higher than control participants. Compared with SH group, serum IL-22 level was elevated obviously in HRD group), and Th22 cells proportion was also higher in HRD group. Expression of IL-22 and IL-22R in kidneys were increased in hypertensive renal damage patients compared to control. Bivariate linear correlation analysis revealed that serum IL-22 level was positively correlated with systolic blood pressure (SBP), diastolic blood pressure (DBP), TNF-α,IL-6 and hsCRP; there was also a positive correlation between serum IL-22 concentration and Th22 cells proportion in hypertensive patients. Serum IL-22 level was positively correlated with 24h-UPRO level in HRD group.

Conclusions: Serum IL-22 and peripheral blood Th22 cells infiltration were significant increased in HRD group compared with SH group, serum IL-22 was closely

correlated with extent of hypertensive renal damage, indicating that serum IL-22 may involved in the pathogenesis of hypertensive renal damage.

Soluble Neprilysin, NT-ProBNP, and Growth Differentiation Factor 15 as Biomarkers for Heart Failure in Dialysis Patients (SONGBIRD)

Robert Claus,[1] Dominik Berliner,[2] Udo Bavendiek,[2] Nicolas Vodovar,[4] Sascha David,[1] Margret Patecki,[1,3] Jean-Marie Launay,[4] Hermann G. Haller,[1] Marcus Hiss,[1] Michael S. Balzer.[1] SONGBIRD investigators *[1]Dept. of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Dept. of Cardiology and Angiology, Hannover Medical School, Hannover, Germany; [3]Center for Renal, Hypertensive and Metabolic Disorders, Hannover, Germany; [4]Inserm UMR-S 942, Paris, France*.

Background: Dialysis patients are at increased risk of congestive heart failure (HF). However, diagnostic utility of NT-proBNP as a biomarker is decreased in patients on hemodialysis or peritoneal dialysis. Growth differentiation factor-15 (GDF15) and neprilysin (NEP) are biomarkers of distinct mechanisms that may contribute to HF pathophysiology in such cohorts.

Methods: We compared circulating concentrations of NT-proBNP, GDF15, and NEP along with NEP activity, individually or in combination, in patients on chronic dialysis without (n=80) and with HF (n=73; composite of HF with reduced [n=40] and preserved ejection fraction [n=33]), as diagnosed by clinical parameters and post-dialysis echocardiography. We used correlation, linear and logistic regression as well as receiver operating characteristic (ROC) analyses.

Results: Compared to controls, patients with HF had higher medians of NT-proBNP (16216 [interquartile range, IQR=27739] vs. 2883 [5866] pg/mL, p<0.001), GDF15 (7512 [7084] vs. 6005 [4892] pg/mL, p=0.014), but not NEP (315 [107] vs. 318 [124] pg/mL, p=0.818). Median NEP activity was significantly lower in HF vs. controls (0.189 [0.223] vs. 0.257 [0.166] nmol/mL/min, p<0.001). In ROC analyses, a base model combining clinical covariates (age, dyspnea score, systolic blood pressure, Charlson comorbidity index, history of HF or severe valve disease, extracellular to total body water ratio) and NT-proBNP distinguished HF from controls with an area under the curve (AUC) of 0.785 (95% confidence interval [CI] 0.714-0.856). NEP activity and GDF15 provided incremental utility over the base model. A multi-marker model combining clinical covariates, NT-proBNP, GDF15 and NEP activity demonstrated best discrimination of HF from controls (AUC=0.902, 95% CI 0.857-0.947, p<0.001 vs. base model).

Conclusions: We present novel comparative data on physiologically distinct circulating biomarkers for HF in patients on dialysis. NEP activity but not concentration and GDF15 provided incremental predictive information over clinical covariates and NT-proBNP and may aid in diagnosing HF in dialysis patients.

TH-PO708

Urinary N-Terminal Pro-Brain Natriuretic Peptide Is a Useful Biomarker for Cardiovascular Events in a General Japanese population: The Hisayama Study

Keisuke Yamasaki,[1,2] Jun Hata,[1,2] Yoichiro Hirakawa,[1,2] Satoko Sakata,[1,2] Toshiaki Nakano,[2] Takanari Kitazono,[2] Toshiharu Ninomiya.[1] *[1]Department of Epidemiology and Public Health, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan*.

Background: Serum N-terminal pro-brain natriuretic peptide (NT-proBNP) levels have been well accepted as an index for estimating cardiovascular risk in general practices. On the other hands, there is a possibility that urinary NT-proBNP is a non-invasive biomarker without requiring blood sampling, because NT-proBNP is excreted in urine. Therefore, the present study investigated the association between urinary NT-proBNP levels and the risk of cardiovascular disease (CVD) in a general Japanese population.

Methods: A total of 3,060 community-dwelling Japanese subjects aged ≥40 years without history of CVD were followed up for 8 years (2007-2015). Urinary NT-proBNP levels were divided into four categories using cutoff values of 23, 30, and 42 pg/mL, which were corresponding to guideline-based cutoff values of serum NT-proBNP, being 55, 125, and 300 pg/mL, based on the linear regression analysis of serum and urinary NT-proBNP concentrations (Pearson's correlation coefficient=0.75). The associations of urinary NT-proBNP levels with the risk of CVD and its subtypes were estimated by the Cox proportional hazards model.

Results: The median value of urinary NT-proBNP concentrations was 20 pg/mL (interquartile range 18-25 pg/mL). During the follow-up period, a total of 170 CVD events developed. The age- and sex-adjusted risk of CVD increased significantly with higher urinary NT-proBNP levels (p for trend <0.001). This association remained significant even after adjustment for conventional cardiovascular risk factors (hazard ratio [95% confidence interval]: 1.00 [reference] for ≤22 pg/mL, 1.13 [0.74–1.71] for 23–29 pg/mL, 1.59 [0.97–2.61] for 30–41 pg/mL, 1.78 [1.11–2.87] for ≥42 pg/mL; p for trend =0.01). A similar association was observed for total stroke (p for trend =0.01), but not for coronary heart disease (p for trend =0.36).

Conclusions: The present finding suggests that elevated urinary NT-proBNP level is a useful biomarker for the development of CVD, especially stroke, independent of conventional risk factors in a general Japanese population.

APOL1 Risk Variants, Subclinical Cardiovascular Disease, and Mortality in African Americans Initiating Hemodialysis

Teresa K. Chen,[1] Jessica Fitzpatrick,[2] Cheryl A. Winkler,[3] Elizabeth A. Binns-Roemer,[7] Celia P. Corona villalobos,[6] Bernard G. Jaar,[4] Stephen M. Sozio,[1] Rulan S. Parekh,[2] Michelle M. Estrella.[5] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]NCI, NIH, Frederick National Laboratory, Frederick, MD; [4]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [5]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [6]Johns Hopkins University, Baltimore, MD; [7]LEIDOS, Frederick, MD*.

Background: The role of *APOL1* risk variants in cardiovascular disease (CVD) remains unclear, especially among ESRD patients. We evaluated associations of *APOL1* with subclinical CVD and mortality in a cohort of African Americans (AA) initiating hemodialysis (HD) in the Predictors of Arrhythmic and Cardiovascular Risk in End-Stage Renal Disease (PACE) Study.

Methods: *APOL1* risk variants and ancestry markers were genotyped using custom Taqman assays and Infinium QC array kits. We defined *APOL1* risk status by a recessive genetic model (high=2 risk alleles; low=0-1 risk allele). We studied associations of *APOL1* high-risk status with baseline subclinical CVD (left ventricular [LV] hypertrophy, LV mass, ejection fraction, coronary artery calcification [CAC], pulse wave velocity) using logistic/linear regression and time to all-cause or CVD mortality using Cox hazards models, adjusting for age, sex and ancestry. In sensitivity analyses, we further adjusted for systolic blood pressure (SBP) and Charlson Comorbidity Index (CCI).

Results: Of 267 AA participants successfully genotyped, 27% were *APOL1* high-risk. At baseline, mean age was 53 years, 41% were female, 56% had diabetes, and mean SBP was 138 mmHg. In cross-sectional analyses, *APOL1* high- vs. low-risk status was independently associated with lower odds of LV hypertrophy and CAC, and lower LV mass. These associations remained robust upon further adjustment for CCI, but were attenuated when adjusted for SBP (Table). Over a mean follow-up of 2.5 years, *APOL1* risk status was not associated with all-cause or CVD mortality.

Conclusions: Among AA incident HD patients, *APOL1* high-risk status was associated with better subclinical measures of CVD, but these did not translate to improved survival. Future studies are needed to clarify the clinical implications of *APOL1* risk variants in AA with ESRD.

Funding: NIDDK Support, Commercial Support - Extramural Grant Program from Satellite Healthcare, a not-for-profit renal care provider

Table: Associations of *APOL1* risk status with subclinical CVD at baseline in PACE.[a]

	Model 1: adjusted for age, sex and ancestry	Model 2: Model 1 + CCI	Model 3: Model 1 + SBP

The Combined Prognostic Significance of Vascular Calcification and Alkaline Phosphatase in Patients with ESRD

Dongryul Kim, So yeon Hwang, YunJung Nam, Seok Joon Shin, Hye Eun Yoon. *Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Republic of Korea*.

Background: Vascular calcification (VC) is a well-known prognostic marker in patients with end-stage renal disease (ESRD), while there are conflicting results on the role of serum alkaline phosphatase (ALP) on cardiovascular event (CVE) and mortality. This study investigated whether there was a combined effect of VC and ALP on prognosis in patients with ESRD starting dialysis.

Methods: This was a retrospective cohort study including 587 incident ESRD patients from a single center. The aortic calcification index (ACI), an estimated of abdominal aortic calcification, was calculated by abdominal computed tomography as a measure of VC.

Patients were stratified into four groups according to the median ACI and serum ALP value. CVE and death were assessed as study outcomes. The association of VC and ALP on composite of end-point was analyzed. The modification effect between VC and ALP on composite of end-point was determined using an interaction product term.

Results: During a median follow-up duration of 3.1 (0.02 – 12.3) years, 140 patients (23.8%) developed CVE and 130 deaths (22.1%) occurred. In the stratified analysis, patients with higher ACI and lower ALP had a greater risk of composite of end-point compared to patients with combined lower ACI and ALP group (adjusted hazard ratio, 2.04; 95% confidence interval, 1.23 – 3.38; $P = 0.006$), and patients with combined higher ACI and ALP had the greatest risk (adjusted hazard ratio, 2.26; 95% confidence interval, 1.05 – 3.62; $P = 0.001$). The interaction between ACI and ALP on CVE and mortality was statistically significant ($P < 0.05$).

Conclusions: In conclusion, the combined effect of VC and higher ALP was associated with greater risk of CVE and deaths in ESRD patients starting dialysis. Serum ALP amplifies the risk of CVE and deaths associated with VC in ESRD patients.

TH-PO711

Adductome of HDL from Non-Diabetic Hemodialysis Patients

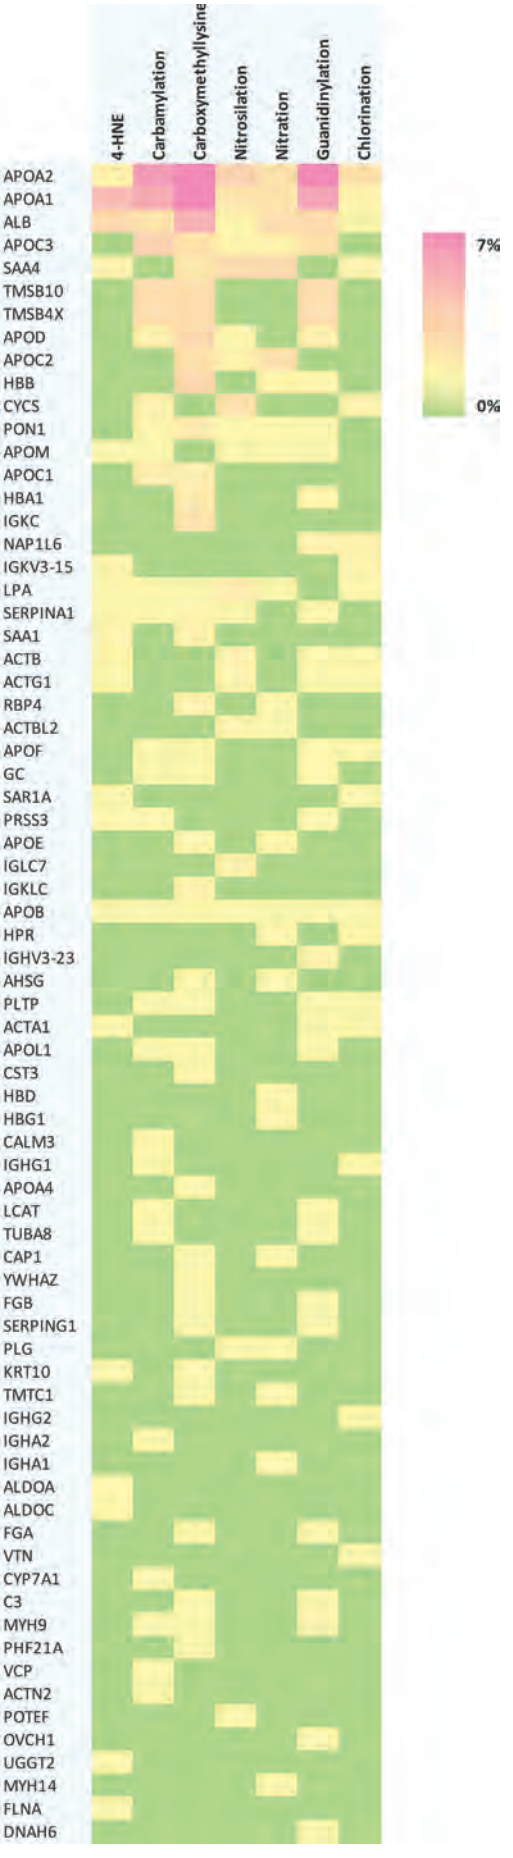
Nans Florens,[1,2] Catherine Calzada,[2] Frédéric Delolme,[3] Fitsum Guebre Egziabher,[1,2] Laurent Juillard,[1,2] Christophe O. Soulage.[2] *[1]Hospices Civils de Lyon, Lyon, France; [2]CarMeN, INSERM, U1060, INSA Lyon, Villeurbanne, France; [3]CNRS, Lyon, France*.

Background: HDL dysfunction could participe in the increased cardiovascular mortality in CKD. have been pointed out in this burden. Post-translational modifications (PTM) of HDL were highlighted as potential mediators of HDL dysfunction. We aimed to describe PTM of HDL proteins from non-diabetic hemodialysis (HD) patients.

Methods: HDL were sampled from the plasma of 9 non-diabetic HD and 9 potential kidney-donors patients with a sequential ultracentrifugation. Samples were analyzed using an nano-RSLC coupled on line with a Q-Orbitrap. Data were processed with Proteome Discoverer 2.2 software and quantified with a label free quantitation approach. Oxidation, acetylation, carbonylation (with 4-HNE), carbamylation, guanidinylation, chlorination, nitration and nitrosylation were set as variable modifications. Protein quantitation was based on pairwise ratios and ANOVA hypothesis test.

Results: 522 proteins were identified in HDL from HD patients and controls among which 73 (i.e. 14%) presented adduction sites. The main PTM were glycation (26%), guanidynilation (17%), carbamylation (15%), nitration (14%), carbonylation by the 4-HNE (11%), nitrosilation (9%) and chlorination (8%). Those proteins were involved in lipid metabolism, acute phase response, hemostasis, wound healing and muscular metabolism. Apolipoprotein A2 and 1 were the proteins the more prone to adduction (28 and 27% respectively) followed by serum albumin (15%), apolipoprotein C3 (9%) and serum amyloid A4 (8%, **Figure 1**). Most of the key-proteins of HDL metabolism were found to be adductable.

Conclusions: HDL from HD patients presented several post-translational modifications of their proteins. Those proteins are involved in most of the biological functions of HDL and their modifications could contribute the dysfunction of HDL in CKD.



TH-PO712

Outcome and Prognostic Factors in ESRD Patients with Acute Coronary Syndrome (ACS) Undergoing Percutaneous Coronary Interventions

Byounghwi Ko, Chan-Young Jung, Wonji Jo, Youngu su Joo, Jung Tak Park. *Yonsei University College of Medicine, Seodaemungu, Seoul, Republic of Korea.*

Background: Several risk factors have been recognized for acute coronary syndrome (ACS) undergoing percutaneous coronary interventions (PCI) in the general population. Risk factors for poor outcome in end stage renal disease (ESRD) patients differ from those who do not receive chronic dialysis. Although ESRD patients have been shown to be susceptible to cardiovascular diseases, the overall outcome and factors associated with prognosis is not well elucidated. Therefore, the characteristics and progress of ESRD patients who underwent PCI for ACS have been examined.

Methods: Retrospective analyses were conducted in ESRD patients who underwent PCI due to ACS from 1 January 2005 to 31 December 2018 at Yonsei University Health System, Seoul, South Korea. The patients were followed-up until 30th May, 2019. Demographic characteristics, laboratory parameter, echocardiographic findings, and dialysis related parameters at the time of PCI were collected.

Results: A total of 228 patients were included in the final analysis. The mean age was 66.9 ± 10.6 years, 146 (64.0 %) were male, and 82 (36.0 %) were being treated for diabetes. During a mean follow-up duration of 109.9 ± 94.8 months, 78 (34.2 %) cases of mortality were reported. When the patients were grouped into survivors and non-survivors, peripheral artery occlusive disease (PAOD) and left main coronary disease were more common among non-survivors. Echocardiographic ejection fraction (EF) and serum albumin levels were lower, while serum troponin T and CK-MB levels at the time of ACS were significantly higher among non-survivors. Multivariate logistic regression analysis revealed that concomitant PAOD (OR, 3.95; CI, 1.17-13.1), left main coronary disease (OR, 4.31; CI, 1.13-16.42), EF lower than 50% (OR, 8.30; CI, 1.84-37.41), lower serum albumin (OR, 4.29; CI, 1.44-12.79), and higher CK-MB (OR, 3.51; CI, 1.25-9.85) and troponin T levels (OR, 1.68; CI, 1.08-2.63) were significant factors related with in hospital mortality.

Conclusions: Outcome after PCI in ESRD patients with ACS was grave. Concomitant PAOD, echocardiographic findings, and cardiac enzyme levels could be practical factors predicting mortality in these patients.

TH-PO713

Dialysis Modality-Related Disparities in Sudden Cardiac Death: Hemodialysis vs. Peritoneal Dialysis

Hee-Yeon Jung,[1,2] Ji-Young Choi,[1,2] Jang-Hee Cho,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Yong-Lim Kim.[1,2] *[1]Kyungpook National University Hospital, Daegu, Republic of Korea; [2]School of Medicine, Kyungpook National University, Daegu, Republic of Korea.*

Background: Patients require risk stratification and preventive strategies for sudden cardiac death (SCD) according to dialysis modality, as the process of dialysis itself is a risk factor for SCD. This study aimed to compare the risk of SCD in patients receiving hemodialysis (HD) or peritoneal dialysis (PD).

Methods: Patients on HD or PD were included from the end-stage renal disease registry of the Korean Society of Nephrology between 1985 and 2017. The incidence and associated factors of SCD were analyzed according to dialysis modality.

Results: Among 132,083 patients, 34,632 (35.5%) patients died during 94.8 ± 73.6 months of follow-up. In patients on HD and PD ($P < 0.001$), 22.2 and 19.6% of total death were SCDs. HD was independently associated with SCD even after adjusting age and significant comorbidities (adjusted odds ratio [OR] 1.14, 95% confidence interval [CI] 1.07–1.22, $P < 0.001$). The presence of hypertension (adjusted OR 1.14, CI 1.08–1.22, $P<0.001$) and congestive heart failure (adjusted OR 1.26, CI 1.15–1.39, $P<0.001$) and age<65 (adjusted OR 1.06, CI 1.00–1.13, $P = 0.041$) were independent risk factors for SCD in patients on HD but not in those on PD. Diabetes was significantly associated with SCD regardless of dialysis modality.

Conclusions: Korean patients on HD compared to PD faced a higher risk of SCD attributable to cardiac comorbidities.

TH-PO714

Geographic Variations in Congestive Heart Failure and Ischemic Heart Disease in Dialysis Patients and Associations with Neighborhood Walkability

Marta Reviriego-Mendoza, Diane M. Rondeau, Hao Han, Brian S. Ash, Janice D. Lindsay, Sheetal Chaudhuri, John W. Larkin, Len A. Usvyat, Jeffrey L. Hymes, Robert J. Kossmann, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Higher neighborhood walkability associates with better cardiovascular health in the general population (Gaglioti et al., 2018) and positively associates to objective physical activity levels in hemodialysis (HD) patients (Han M et al. 2018). We assessed if neighborhood walkability is related with the prevalence of congestive heart failure (CHF) and ischemic heart disease (IHD) in HD patients throughout the United States (US).

Methods: We used data from HD patients treated at a large dialysis organization in 2018. We calculated the average percent of HD patients with CHF and IHD per state within the US. We obtained data on the Walk Score (www.walkscore.com) in the US. The Walk Score measures neighborhood walkability on a scale of 0 (poorest walkability) to 100 (greatest walkability) based on access to key destinations (e.g. grocery stores, restaurants, retail stores). We calculated the correlation coefficients between the average walkability score for each state versus CHF and IHD prevalence.

Results: Data from 254,322 HD patients was analyzed on a state level in the US. Overall, we found small positive relationships between higher Walk Score and a higher CHF (correlation coefficient (R)=0.12) and higher IHD (R=0.16) prevalence in the US. However, this was not a consistent finding in many geographies and individual states. There appears to be distinct dichotomy between Western States and Eastern States, as well as less significant differences between the Northeast and the Southeast regions of the US (Figure 1).

Conclusions: Findings suggest HD patients tend to have a higher prevalence of CHF and IHD in areas with higher walkability. Despite this, this observation is not universally observed at state level, and county level analysis is needed. Further analyses are needed to understand the relationships between walkability and heart diseases.

TH-PO715

Is It Worth Measuring Home Blood Pressure in Maintenance Hemodialysis Patients?

Sang Heon Song,[1,3] Hyeyun Jeong,[1] You Hyun Jeon,[1] Miyeun Han,[1,3] Harin Rhee,[1,3] Eun Young Seong,[1,3] Il Young Kim,[2,4] Dong Won Lee,[2,4] Soo Bong Lee.[2,4] *[1]Internal medicine, Pusan National University Hospital, Busan, Republic of Korea; [2]Internal medicine, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [3]Biomedical Reserch Institute, Pusan National University Hospital, Busan, Busan, Republic of Korea; [4]Research Institute for Convergence of Biomedical Science and Technology, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.*

Background: The proper control of blood pressure(BP) is an important issue in hemodialysis patients and accurate BP measurement is mandatory. Although various methods of measurement of BP have been proposed, there is no standard method. The aims of this study are that office BP and home BP were compared based on ambulatory blood pressure monitoring (ABPM) in hemodialysis patients and propose the usefulness of home BP.

Methods: A total of 40 patients undergoing maintenance hemodialysis were enrolled for analysis of BP measurement from July 2018 to March 2019. Home BP was defined as the average of BP measured in a relaxed posture 5 minutes after the morning awaking and before sleeping. Office BP was predialysis BP and ABPM was undertaken 24 hours on non-dialysis days using *Mobil-O-Graph® (NG, I.E.M. GmbH, Stolberg, Germany).*

Results: The average BPs according to methods were as follows: home BP, 135.80 ± 17.29/ 73.99 ± 7.92 mmHg; office BP, 145.85 ± 17.44/ 73.70 ± 10.61mmHg; awake ABPM, 130.1 ± 20.78/ 76.48 ± 9.05mmHg. When compared to office BP with ABPM, 35% of the patients had sustained normotension, 42.5% of the patients had sustained hypertension, 22.5% of the patients had white-coat hypertension and masked hypertension cannot be observed. Based on ABPM, type of all patients was non-dipper, of which reverse-dippers were 32.5%. We analyzed the difference in systolic BP(SBP) in the home, office, and ABPM awake BP. SBP was the highest in office BP followed by home BP and ABPM in sequence. BP differences were as follows; ABPM-home SBP (-5.70 ± 14.51mmHg, $P = 0.017$), home-office SBP (-10.05 ± 12.19mmHg, $P = 0.00$), ABPM-office SBP (-15.75 ± 14.51mmHg, $P = 0.00$). 45% of patients had a 10% or more difference and 62.5% had a 5% or more difference in SBP between home and office. Interestingly, patients who had frequent intradialytic hypotension(IDH) tended to have a large difference in home-office SBP.

Conclusions: This study showed that the difference between home BP and ABPM was found to be approximately one third of the difference between office BP and ABPM. Because of the discomfort of ABPM measurements in patients with hemodialysis, home BP is necessary for proper BP management to prevent IDH. Conclusively, we propose that home BP could be a therapeutic target instead of ABPM in hemodialysis patients.

TH-PO716

Appraisal of Kidney-Related Parameters in Predictive Models of Heart Failure

Gajapathiraju Chamarthi, Eddy J. De Jesus, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: The clinical course of patients with heart failure (HF) is known to be variable. Insights into factors that relate to subsequent adverse outcomes may help identify those patients in need of more intense monitoring and therapy. Several models have been developed for HF that simultaneously take into account multiple factors to

refine their predictive ability. The clinical relevance of kidney-related parameters has long been recognized in this setting. However, no study so far has explored how consistent they have appeared in various models. We sought to appraise kidney-related parameters (KRP) in contemporary models of HF.

Methods: Articles cited in PubMed database using keywords "heart failure", "prediction", and "model" were searched. Available data from clinical trials performed between January 1995 and December 2018 were included. The studies were selected if they prognosticated outcomes in HF population through a predictive model that consisted of at least 2 factors. Pertinent data on KRP (e.g. serum creatinine, blood urea nitrogen [BUN], and serum sodium level) were extracted and reviewed.

Results: A total of 15 studies with 82,706 participants were included, of which 5 were validated in a HF cohort different from the model derivation cohort. They consisted of a variety of HF populations (e.g. acute, chronic, carrying mechanical circulatory device) and the median number of included parameters was 7. There was substantial variation across models in the reporting of the KRP as well as the studied outcomes. While no study included estimated glomerular filtration rate, serum creatinine and BUN were included in only 6 and 4 studies respectively. Similarly, 4 and 7 models contained data on serum sodium level and blood pressure respectively. Serum uric acid and history of kidney disease were each included in only 1 study.

Conclusions: We found that available models for prediction of HF outcomes do not consistently include KRP while generally portending high prognostic ability. Development of these models is based on multivariate regression methods to define the proportional significance and coefficients of the prognostic variables. Therefore, this finding supports the notion that, contrary to conventional thinking, the impact of KRP on the outcomes of patients with HF may be confounded or modulated by other covariates (e.g. congestion) as the emerging data have implied.

TH-PO717

Sex Disparities and Risk of CKD: A Nationwide Cohort Study of 10.8 Million Adults in Korea

Shinchan Kang,[2] Chan-Young Jung,[2] Byounghwi Ko,[2] Wonji Jo,[2] Tae ik Chang,[1] Shin-Wook Kang.[2,3] *[1]Department of Internal Medicine, National Health Insurance Service Medical Center, Ilsan Hospital, Gyunggi-do, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; [3]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea.*

Background: There are substantial differences in public health issues between men and women. However, longitudinal studies of the relationship between sex disparities and incident chronic kidney disease (CKD) are scarce. In this study, we aimed to evaluate the association between sex disparities and incident CKD in healthy adults with normal baseline kidney function.

Methods: We analyzed a total of 10.8 million adults who underwent National Health Insurance Service health examinations between 2009–2015. The outcome of interest was incident CKD, defined as *de novo* development of eGFR <60 mL/min per 1.73m^2 (definition 1) or ≥25% decline in eGFR from the baseline values accompanied by eGFR <60 mL/min/1.73m^2 (definition 2).

Results: In this large national cohort comprised of 10.8 million healthy Korean adults who had eGFR ≥60 ml/min per 1.73 m^2, there were a total of 178,966 (1.66%) and 81,737 (0.76%) incident CKD events according to each CKD definitions, respectively, during a median follow-up of 4.8 years. Multivariable-adjusted Cox model showed that women were associated with significantly lower risk of incident CKD compared with men: adjusted hazard ratios (95% confidence intervals) for women (*versus* men) were 0.85 (0.84-0.86) and 0.86 (0.85-0.88) in models using CKD definition 1 and 2, respectively. These associations were robust irrespective of comorbid conditions, residential area, health behaviors, and use of antihypertensive drugs or statins. However, in elderly people aged ≥60 years, the risk of CKD was comparable between men and women.

Conclusions: In this large nationwide cohort, women had lower risk of CKD than men among healthy Korean adults.

TH-PO718

Gender Disparities in the Epidemiology and Outcome of Advanced CKD in Ageing Type 2 Diabetes Mellitus: A Multicenter Nationwide Analysis from a Primary Care Cohort of Thailand

Manoch Rattanasompattikul,[1,3] Sukit Raksasuk,[3] Moltira Promkan,[2] Sumana Masoodi,[2] Kanyaphak Ngerninta,[1,3] Nuttawut Rongkiettechakorn,[1,3] Aungkura Supokawej.[2] *[1]Golden Jubilee Medical Center, Mahidol University, Nakhon Pathom, Thailand; [2]Faculty of Medical Technology, Mahidol University, Nakhon Pathom, Thailand; [3]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Background: Chronic kidney disease (CKD) is a significant burden in elderly patients with type 2 diabetes mellitus (T2DM). The body of knowledge on the approach to elderly patients with CKD is still evolving. The status of senior women with advanced CKD has not been fully explored in our population.

Methods: This study evaluated patients ≥65 years old with T2DM from the largest National Health Security System (NHS) of Thailand from 2011 to 2014. We aimed to determine female gender with respect to the risk of advanced CKD (stages G4 and G5).

Results: Out of the 13,135 patients, 60% were female, 4.8% had CKD stage G4, and 1.4% had CKD stage G5. The mean age was 74±6 years old. The mean body mass index (BMI) was 23.4±4.2 kg/m^2. The prevalence of having advanced CKD by gender was 6.2% and 6.1% in females and males, respectively. The multivariate analysis identified the odds ratio (OR) of the female gender (adjusted OR; 95% confidence interval [CI]; *P*-value) as an independent risk factor for advanced CKD. **Model 1**without adjustment (1.02; 0.88–1.18; 0.76). **Model 2**with adjustments by religion, reimbursements, smoking, body mass index and comorbidity covariates included a history of cancer, depression, thalassemia, gout, dyslipidemia, and use of renin-angiotensin-aldosterone system (RAAS) blockage and statin drugs (1.29; 1.03–1.60; 0.024). **Model 3**was adjusted based on **Model 2**and yielded laboratory categories of cholesterol, and %glycosylated hemoglobin (HbA1c) (1.29; 1.03–1.59; 0.029).

Conclusions: Women have unique risks for developing kidney diseases. Epidemiological studies suggest that pre-dialysis CKD is more prevalent in women than in men. The present study found that elderly T2DM women had increased risks associated with advanced CKD. We hope this focus issue will increase awareness and challenge of the renal health of women.

TH-PO719

The Incidence of CKD and ESRD Is Higher in Hypertensive Men Than Women: A Systematic Review and Meta-Analysis

Misghina Weldegiorgis.[1,2] *[1]The George Institute for Global Health, University of Oxford, Oxford, United Kingdom; [2]The George Institute for Global Health, University of New South Wales Sydney, Sydney, NSW, Australia.*

Background: Hypertension, defined as systolic blood pressure (SBP) ≥140 mmHg, is an established risk factor for chronic kidney disease (CKD) and end-stage renal disease (ESRD). Whether sex differences in CKD and ESRD incidence exist among hypertensive individuals remains unclear. This systematic review and meta-analysis was conducted to evaluate the relative effect of hypertension on CKD and ESRD risk in women compared with men.

Methods: Cohort studies were systematically searched in Embase and PubMed until April 2017. Studies were selected if they reported a sex-specific relationship between SBP and CKD and/or ESRD. Random effects meta-analyses with inverse variance weighting were used to obtain sex-specific relative risks (RRs) and the RR ratio (RRR) (women to men) for incident CKD and ESRD.

Results: Data from six cohorts, including 2,382,712 individuals and 6,856 incident CKD events and 833 ESRD events, were identified. The RR for incident CKD or ESRD associated with hypertension versus ideal blood pressure (SBP <120 mmHg) was 1.58 (95% CI, 1.30-1.92) in women and 2.03 (95% CI, 1.65-2.49) in men. The RR for incident CKD or ESRD was 18% lower in women than in men (RRR 0.82 [95% CI, 0.71-0.94]) with no significant heterogeneity between studies (I^2=0%) (Figure 1).

Conclusions: Hypertension confers an 18% lower excess risk of incident CKD or ESRD in women compared with men. Sex differences in onset, duration, and severity of some risk factors, such as albuminuria, diabetes, cardiovascular disease, obesity, and socioeconomic status may explain part of the excess risk in men. Another explanation could be that women might be less likely to initiate dialysis or may be at increased risk of mortality than men. Future studies are warranted to more clearly elucidate the mechanisms responsible for the observed substantial sex differences.

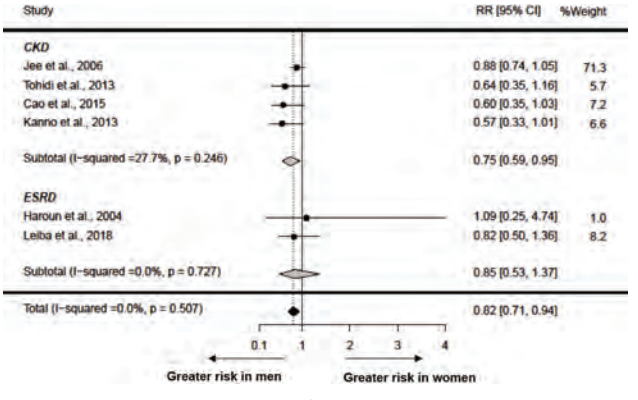

Figure 1. Women-to-men relative risk ratio for CKD and ESRD, comparing individuals in hypertension versus ideal BP

TH-PO720

Survival Advantage of Renal Transplantation over Dialysis Is Blunted in Women

Dan Sapoznikov, Michal Dranitzki Elhalel, Dvora Rubinger. *Hadassah Hebrew University Medical Center, Jerusalem, Israel*.

Background: The effect of gender on long term outcome in end stage renal disease is not well defined. Decreased LFα, a baroreflex index, and increased sdSV (stroke volume variability, a measure of myocardial responsiveness) were shown to predict poor prognosis in hemodialysis (HD) patients.

Methods: To assess factors associated with long term survival, clinical data and death events were monitored in 126 men (M) and 70 women (F) on HD and after renal transplantation (TX) during a follow up of 60 months. Continuous interbeat interval (IBI) and systolic blood pressure (SBP) and their variabilities were recorded using Finometer. LFα and sdSV were calculated from SBP and IBI spontaneous variations.

Results: Kaplan-Meier analysis showed a similar (76%) 5 yr survival in HD M and F. A significantly increased survival was noted in TX M compared with HD M (91%, p=0.031) while no such difference was noted in TX F (Figure1). Main death risk factors, LF α and sdSV are shown in Table 1. Age range, the prevalence of diabetes mellitus, hyperlipidemia and HD vintage were similar in M and F.TX was associated with improved blood pressure in all patients. Renal function was similar in TX M and F.

Conclusions: Our data show that despite higher comorbidity prevalence, TX significantly improved survival in M. The enhanced survival in TX M was associated with increased LFα and decreased sdSV, suggesting improved autonomic function. In F no significant changes in these measures were found and the survival benefit of TX was less prominent. The causes of the reduced effect of TX in F remain to be determined.

Real World, Hard Outcomes, and Sex Differences in AKI

Maria Isabel Acosta-Ochoa, Armando Coca, Alicia Mendiluce. *Hosptal Clinico Universitario, Valladolid, Spain.*

Background: Several studies focus on sexual dimorphism when suffering AKI, some of them report that women could be a protected against adverse events. We compared hard clinical outcomes between females and males in a real world cohort with AKI.

Methods: Retrospective cohorts study of hospitalized patients with diagnosis of AKI. We used KDIGO-2012 criteria for stratifying AKI severity, analyzed epidemiological and clinical variables and compared clinical outcomes: length of hospital stay, need for dialysis, dialysis dependence, and renal recovery.

Results: We included 1269 cases, 70% male, DM 42%, and CKD 61%. Table 1A shows clinical variables and Table1B results between groups. We found that mean Charlson's was higher in male individuals and women are hospitalized more frequently in medical wards. We found no statistically significant differences in hard clinical outcomes except for dialysis dependence at discharge (more in male individuals). We studied the effect of sex on death was using Cox regression analysis, univariate analysis revealed that sex was not a significant risk factor for death during AKI [HR (sex): 1.01, 95%CI: 0.78-1.30, p=0.95]; multivariate analysis including sex and AKI severity yielded similar results [HR (sex): 0.99, 95%CI: 0.77-1.29, p=0.98].

Conclusions: Experimental studies observe clear differences in clinical outcomes between genders when suffering AKI, some even concluding that female sexual hormones could be not only protective but also a possible treatment. In this real world study we observed a higher incidence of AKI in men than in women, consistent with previous larger epidemiological studies, and we only found that males are more frequently dialysis dependent at discharge. So we observed that women that suffer an AKI episode are not protected against it's deleterious effects.

A Sex-Specific Relationship Between Vascular Calcification and Incident Fracture in Patients with ESRD

Yeonhee Lee,[1,2] YunJung Nam,[3] So yeon Hwang,[3] Dongryul Kim,[3] Seok Joon Shin,[3] Hye Eun Yoon.[3] *[1]The Catholic University of Korea, Incheon, Incheon, Republic of Korea; [2]Internal medicine, Catholic medical center, Seoul, Republic of Korea; [3]Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Republic of Korea*.

Background: Vascular calcification (VC) is a major component of mineral bone disorders in patients with end-stage renal disease (ESRD). The presence of VC is associated with low bone volume in ESRD patients. Bone metabolism is affected by various factors including sex hormones. However little is known about the sex-specific relationship between VC and incident fractures in ESRD patients. This study investigated whether there was a sex-specific relationship between the degree of VC and incident fracture in ESRD patients starting dialysis.

Methods: This was a retrospective cohort study including 593 incident dialysis patients from a single center. The aortic calcification index (ACI), an estimated of abdominal aortic calcification, was calculated by abdominal computed tomography as a measure of VC. Patients with ACI in the upper tertile range were considered to have high ACI (>25.75). The occurrence of fracture was assessed as study outcome. The association between high ACI and incident fracture was analyzed according to sex.

Results: During a median follow-up duration of 34.7 (0.03 – 147.5) months, 74 patients (12.4%) developed fracture. In the male group (n = 328), the fracture-free survival rate was not different between patients with high ACI and those with low ACI (P = 0.075). In the female group (n = 265), the fracture-free survival rate was significantly lower in patients with high ACI compared to those with low ACI (P = 0.002). In the male group, the high ACI was not associated with incident fracture (unadjusted hazard ratio, 1.96; 95% confidence interval, 0.92 – 4.15; P = 0.080). In the female group, the high ACI was independently associated with incident fracture after adjustments for confounding variables (adjusted hazard ratio, 2.53; 95% confidence interval, 1.29 – 4.98; P = 0.007).

Conclusions: In conclusion, VC is associated with incident fracture in female ESRD patients starting dialysis, while there was no association between VC and fracture in male ESRD patients. There may be a sex-specific relationship between VC and fracture in ESRD patients

TH-PO723

Sex and Racial Disparities in Antidepressant Use and Hospitalization Rates Among Patients on Hemodialysis

Marta Reviriego-Mendoza,[1] Joanna Willetts,[1] Hao Han,[1] Sheetal Chaudhuri,[1] John W. Larkin,[1] Billy Kim,[1] Dugan Maddux,[1] Nwamaka D. Eneanya,[2] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Women are more affected by depression than men in the general population (Kimmel et al., 2007). We characterized if there were differences by sex and race in depressive affect (DA), antidepressant use, and hospitalization rates in hemodialysis (HD) patients.

Methods: We analyzed data of patients on HD treated during 2016 to 2017. We studied patients who completed DA screening via the patient health questionnaire-2 (PHQ2) and the Center for Epidemiologic Studies Depression Scale (CES-D-10). Those with PHQ2≥3 were further screened using the CES-D-10. Patients scoring ≥10 on the CES-D-10 or those with a prior diagnosis of depression or bipolar disorder were classified DA positive; screened patients with PHQ2<3 were classified DA negative. Analyses were stratified by DA status, antidepressant use, sex and race. We compared hospitalization rates between groups.

Results: In a population of 267,955 HD patients, A higher percent of women screened positive for DA when compared to men (6.5% vs 4.4%, respectively). Black women had less DA than white women (5.4% vs 7.5%). Antidepressants use by DA positive white women was 5.4% vs 3% for DA positive black women; DA negative white women had a higher use of antidepressants when compared to DA-negative black women (3% vs 2.3%, respectively). Similar findings were observed for men. Twenty-eight percent of patients were using an antidepressant; of those, 51.5% were women. White women had higher antidepressant use (36.7%), followed by white men (25.8%), black women (23.4%), and black men (15.9%). Hospitalization rates were higher for women than for men irrespective of depressive symptoms, antidepressant use or race ($p<0.0001$), and antidepressant use was associated with higher hospitalization rates when compared to non-users (women: 2.3 vs 1.6 per patient year (ppy, $p<0.0001$); men: 2.2 vs 1.4 ppy ($p<0.0001$)). Black women on antidepressants had higher hospitalization rates than white women (2.51 vs 2.27 ppy, $p<0.0001$).

Conclusions: We identified that women, particularly of black race taking antidepressants, have higher hospitalization rates when compared to those not taking any medication, irrespective of their current DA status. Future studies can elucidate reasons for these disparities in outcomes.

Gender Differences in Calcium Nephrolithiasis

Samuel Shin, Farai Gombedza, Eugenia Awuah boadi, Bidhan Bandyopadhyay. *Calcium Signaling Laboratory, Research Service, Veterans Affairs Medical Center, Washington, DC.*

Background: Nephrolithiasis continues to develop as a serious problem in the United States and around the world. As yet, the influence of gender on stone formation is unclear. We hypothesized that females are better adapted to higher urine pH than males. This difference could due to higher levels atrial natriuretic peptide (ANP) in pre-menopausal women compared to corresponding men. Interestingly, ANP levels are similar between older women and men. We have previously implicated transient receptor potential canonical 3 (TRPC3), Ca^{2+} channel, in the proximal tubule (PT), in the regulation of calcium stone formation, and have observed that $TRPC3^{-/-}$ mice show higher Ca^{2+} secretion and scattered urine crystals compared to wildtype (WT) mice. In the present study, we aimed to examine the gender-based role of pH by alkalization in $TRPC3^{-/-}$ mice predisposed with elevated [Ca^{2+}].

Methods: Male and female WT and $TRPC3^{-/-}$ mice were orally administered with either acetazolamide (ACZ), a diuretic for alkalization therapy, and/or calcium gluconate (CaG), a calcium supplement, for 4 weeks. Urine samples were collected weekly and assessed for pH, electrolytes, gene expression and crystals. Serum electrolytes and metabolites were also measured. Kidney tissue was collected for PT cell isolation, Ca^{2+} imaging and assessed for degree of calcification by birefringence and histopathology.

Results: Urine analysis showed more calcium crystals, higher [Ca^{2+}] and higher pH in female (WT and $TRPC3^{-/-}$) mice compared to males indicating. Similarly, calcification, fibrotic and inflammatory markers were elevated in female compared to male mice; and in $TRPC3^{-/-}$ compared to WT indicating stone-forming phenotype. PT cells isolated from treated female mice showed a substantial increase in Ca^{2+} entry when compared to corresponding males suggesting aberrant intracellular Ca^{2+} regulation.

Conclusions: Higher [Ca^{2+}] and higher pH are related to elevated calcium crystal formation. We have identified gender-based influences on stone-forming phenotypes following alkalization and/or elevated [Ca^{2+}], and our findings suggest that female mice are more susceptible to stone formation under these conditions. Our work contributes to understanding the complex combination of gender, age and lifestyle on the evolving epidemiology of nephrolithiasis. Crucially, we have unraveled a role for gender-specific therapies for kidney stone interventions.

Gender Differences in Presentation and Outcomes Among Patients with Atypical Hemolytic Uremic Syndrome (aHUS)

Christof Aigner,[1] Martina M. Gaggl,[1] Renate Kain,[2] Zoltan Prohaszka,[3] Raute Sunder-Plassmann,[4] Natalja Haninger-Vacariu,[1] Alice Schmidt,[1] Gere Sunder-Plassmann.[1] *[1]Department of Medicine III, Division of Nephrology and Dialysis, Medical University of Vienna, Vienna, Austria; [2]Department of Pathology, Medical University of Vienna, Vienna, Austria; [3]IIIrd Department of Internal Medicine, Research Laboratory, Semmelweis University, Budapest, Hungary; [4]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria.*

Background: Gender differences among patients with aHUS are not well established.

Methods: We describe and compare demographic, clinical and genetic data from female and male patients with a history of aHUS enrolled in the Vienna thrombotic microangiopathy (TMA) cohort.

Results: In this single center study, we identified 51 patients with a first manifestation of aHUS between 1981 and 2019. The median age at diagnosis was 28 years and 63% were female. Kidney biopsies were available from 32 patients (63%) and all but 1 showed features of TMA. At time of presentation 31 patients were dialysis dependent (no data for 3 patients). 23 received plasma and 7 eculizumab therapy. 7 recovered kidney function with therapy (3 eculizumab, 3 plasma exchange, 1 supportive). At last follow-up, 9 were deceased, 3 on dialysis, and 17 had a renal graft. Among the remaining 22 patients, 13 had an eGFR ≥ 60 ml/min per 1.73m^2. Gender specific results are indicated in Table 1.

Conclusions: The majority of aHUS patients enrolled in the Vienna TMA cohort were female. Women presented at younger age, more often harbored disease-causing genetic variants or a *CFH*- or *CD46*-risk haplotype, and had better kidney function at last follow-up as compared to males.

Women on Dialysis and Health-Related Quality-of-Life Measures

Fadwa M. Al-Ali, Tarek A. Fouda, Mostafa F. Elshirbeny, Rania A. Ibrahim, Mohamed Yahya Abdelhai Mohamed, Abdullah I. Hamad. *Hamad Medical Corporation, Doha, Qatar.*

Background: Dialysis patients have poor health-related quality of life (HRQOL). Gender differences in HRQOL are poorly studied in dialysis patients. We performed a cross sectional study to evaluate HRQOL measures in women on dialysis in the State of Qatar.

Methods: A cross-sectional study in dialysis patients. Demographic and clinical characteristics data were obtained from electronic medical records. We performed 3 questionnaires to assess HRQOL measures.1- The Center for Epidemiologic Studies Depression Scale (CESD-R) with depression diagnosed with score ≥18, 2- Brief Pain Inventory (BPI) to evaluate the severity of patients' pain (0-3 scale) and its impact on daily function. 3- The Pittsburgh Sleep Quality Index (PSQI) (poor sleep with PSQI >5).

Results: We studied 253 diaysis patients (female 137, 96 on peritoneal dialysis (PD), age 56+/-14, BMI 29+/-7). Most patients reported mild or no chronic pain (75.6%). More women had moderate to severe chronic pain than men (30% vs.16% p 0.01). 76.5% of diaysis patients reported poor sleep (81% of women vs. 70% of men p=0.069) and 39% had depression (52% women vs. 25% men $p<0.001$). We identified 3 factors associated with both depression and poor sleep. First, diabetic women on dialysis had more depression and poor sleep than non-diabetics (59% vs. 40% p0.03 and 92% vs. 79% p 0.02 respectively). Second, Women on hemodialysis (HD) had more depression and poor sleep than PD (54% vs. 46% $p>0.05$ and 88% vs. 65% p 0.001 respectively). Third, Older women ≥60 years had more depression (59% vs.42% p0.05) and poor sleep (92% vs. 76% p0.0008) vs. younger women. There was a strong correlation of PSQI score and CES-D score in women only ($R=0.67$ $p<0.0001$). There was no correlation between our studied HRQOL measures in women and calcium, phosphorus, PTH, Kt/V, LDL or vitamin D levels.

Conclusions: We found that women on dialysis had higher prevalence of depression, poor sleep and moderate to severe chronic pain than men. DM, HD and old age were

associated with a higher rate of depression and poor sleep. Understanding gender differences in dialysis patient can help guide treatment for high risk groups.

TH-PO727

The Effect and Safety of Postmenopausal Hormone Therapy and Selective Estrogen Receptor Modulators on Kidney Outcomes in Women: A Systematic Review

Sandi M. Dumanski, Sharanya Ramesh, Matthew T. James, Amy Metcalfe, Kara A. Nerenberg, Helen L. Robertson, Sofia B. Ahmed. *University of Calgary, Calgary, AB, Canada.*

Background: The number of postmenopausal women with or at risk of chronic kidney disease (CKD) is increasing exponentially. The benefits and risks of postmenopausal hormone therapy (PHT) and selective estrogen receptor modulators (SERMs) on kidney health outcomes in these women are poorly understood. This systematic review aimed to: 1) determine the effects of PHT and SERMs on kidney function and albuminuria in women, and, 2) characterize the risk of adverse outcomes of PHT and SERMs in the CKD population, who are already at an increased risk of venous thromboembolism and malignancy.

Methods: An electronic literature search was completed using a peer reviewed search strategy in MEDLINE, EMBASE, and the Cochrane Central Register of Controlled Trials. We searched published studies (1950- December 2018) examining the effect of PHT and SERMs on kidney function and albuminuria, and adverse outcomes in women with CKD. Two independent investigators screened identified citations examining the effect of PHT and SERMs on kidney outcomes in the general population of women, as well as adverse outcomes in the CKD population. Data was independently extracted from each eligible study, and the risk of bias was assessed. Results were synthesized in a descriptive manner.

Results: A total of 3,078 references were screened, and 18 studies met eligibility criteria. Compared with no treatment, use of PHT was associated with improved kidney function and unchanged or reduced proteinuria in more than 60% of studies that addressed this question. No studies were identified that reported on the safety of PHT in women with CKD. Studies addressing the effects of SERMs on kidney function were conflicting, with 2 studies reporting increased kidney function and reduced proteinuria, and another reporting decreased kidney function. Based on results from 2 small studies, SERMs did not have any increased risk of venous thromboembolism in women with CKD compared to placebo.

Conclusions: Existing studies suggest that PHT and SERMs are associated with improved kidney function, with no increase in albuminuria. Safety data in the CKD population is lacking. Available studies had significant limitations and heterogeneity, highlighting the need for rigorous prospective studies examining the effect of PHT and SERMs on kidney function, and their safety in CKD.

TH-PO728

Screening for Osteoporosis Represents a Missed Opportunity in Women with ESRD

Amir Kazory, Samuel Phen, Shahab Bozorgmehri, Tezcan Ozrazgat-Baslanti, Maryam Sattari. *University of Florida, Gainesville, FL.*

Background: Women with end-stage renal disease (ESRD) treated with hemodialysis (HD) have increased morbidity and mortality, and shorter life expectancy. In fact, the survival advantage that women have over men in the general population is markedly decreased in the HD population. The purpose of this study was to explore age-appropriate preventive care for women with ESRD on maintenance HD.

Methods: We performed a cross-sectional survey of adult patients with ESRD undergoing HD in two outpatient dialysis centers at the University of Florida. Interviews were conducted using a survey instrument that contained questions on demographic information, types of health care providers, and a number of preventive measures. We used United States Preventive Services Task Force (USPSTF) guidelines to determine eligibility and completion of screening for breast and cervical cancers as well as osteoporosis.

Results: Of the 132 patients who participated in this study, 66 (50%) were female. The average age of women was 60 (range = 22-84). The majority (95.5%, n=63) reported having a primary care provider (PCP). Out of the eligible patients, 81.4% (35/43) reported being up-to-date on breast cancer screening, 75% (33/44) on cervical cancer screening, and 16.7% (4/24) on osteoporosis screening. Having a PCP was associated with a trend towards higher adherence with preventive care measures.

Conclusions: Our study identifies "osteoporosis screening" as an opportunity to improve preventive care of women with ESRD treated with maintenance HD. The rates of osteoporosis screening were found to be even lower than the general population (i.e. 25%) in this cohort. Interestingly, women reported higher rates of screening for malignancies of breast and cervix compared to the general population. While there has been a shifting paradigm in diagnosis and management of osteoporosis in patients with ESRD, future studies are needed to identify patient and provider characteristics associated with higher likelihood of adherence to age-appropriate preventive care for female patients with ESRD.

TH-PO729

Cardiac Mortality in People with ESKD in Australia and New Zealand: A Cohort Study from 1980 to 2013

Emma L. O'Lone,[1] Nicole De la mata,[2] Angela C. Webster.[1] *[1]University of Sydney, Sydney, NSW, Australia; [2]The University of Sydney, Camperdown, NSW, Australia.*

Background: The presence of cardiac disease is an important predictor of mortality in people with ESKD. Therapies for reducing cardiac risk and treatment of cardiac events may be less effective in people with ESKD compared to the general population. We aim to review the standardised mortality ratios from cardiovascular disease (CVD) for people with ESKD in the Australian and New Zealand general population.

Methods: Cohort study of incident people with ESKD in Australia and New Zealand, 1980-2013. ANZDATA was linked with death registries to obtain cause of death. Summary data for cause specific death in the general population were obtained. We calculated mortality rates for CVD as defined by ICD10 codes and standardised mortality ratios (SMRs with 95% confidence intervals [CI]), compared with the general population, using indirect standardisation, by age, sex and calendar year.

Results: There were 60,823 participants contributing 381,874 years of observation time. In total there were 6847 cardiac deaths of which 5947 (86.9%) were ischaemic heart disease deaths. The rate of cardiac mortality compared to the general population was higher in women (women: SMR 8.3 95%CI 8.0-8.6, men: SMR 5.695%CI 5.5-5.8). Young women were particularly affected having over double the increased rate of cardiac mortality relative to the general population (ages 30-49: women: SMR 59.7 95%CI 51.8-69.0, men 17.7 95%CI 15.9-19.7). Relative cardiac mortality rates have improved over time for women but have been stable in men (Figure 1).

Conclusions: The mortality rates in the Australian and New Zealand ESKD population are higher than the general population. Young women with ESKD have an excessive relative risk of dying from cardiac disease, compared to young females in the general population. The relative risk of women dying from cardiac disease has reduced over time.

TH-PO730

Bisphosphonate Utilization Across the eGFR Spectrum

Silvia M. Titan,[1] Paola Laureati,[4] Yingying Sang,[6] Andrew S. Levey,[2] Alex R. Chang,[3] Morgan Grams,[5] Lesley Inker,[2] Juan J. Carrero.[4] *[1]Sao Paulo University Medical School, Sao Paulo, Brazil; [2]Tufts Medical Center, Boston, MA; [3]Geisinger Medical Center, Danville, PA; [4]Karolinska Institutet, Stockholm, Sweden; [5]Johns Hopkins University, Baltimore, MD; [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: KDIGO currently recommends bisphosphonate (BSP) use for osteoporosis patients with CKD G3a-G3b who have normal PTH and high risk of fractures. This study evaluated the frequency and factors associated with BSP use among osteoporosis patients from two healthcare organizations: Geisinger (2006-2017), Pennsylvania, United States; and Stockholm region (2006-2012), Sweden.

Methods: Incident osteoporosis was defined as the first ICD code for osteoporosis, and BSP use was defined as the prescription (Geisinger) or dispensation (Stockholm) of any BSP 6 months prior or up to 3 years following the diagnosis of osteoporosis. BSP use was compared across eGFR categories, accounting for the competing risk of death using multinomial logistic regression.

Results: There were 15887 women and 3200 men in Stockholm and 23645 women and 7026 men in Geisinger with incident osteoporosis. Overall, BSP use was 55% in Stockholm and 36% in Geisinger, with lower rates in the groups with eGFR <45 ml/min/1.73m^2. After adjustment for age and identified confounders, the odds of BSP prescription dropped progressively with lower eGFR, particularly in those with eGFR<60ml/min/1.73m^2 (Figure 1). In Geisinger, BSP use declined significantly over time.

Conclusions: Our results suggest that BSP use is not high in incident osteoporosis, with infrequent use in lower eGFR. Although we lacked data on PTH and fracture risk

score, this study raises concern about osteoporosis under-treatment in patients with eGFR 30-60ml/min/1.73m^2.

TH-PO731

Contraceptive Use and Elective Terminations in Women with Glomerular Disease

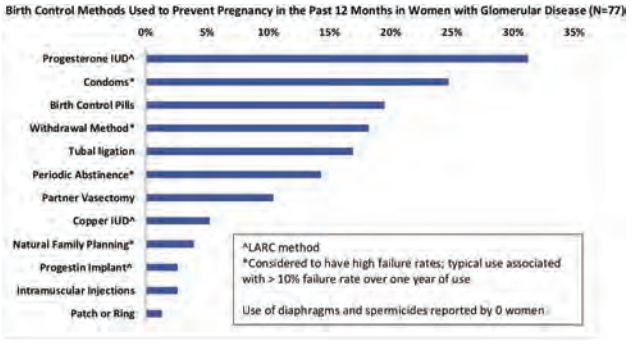
Monica L. Reynolds,[1] Caroline J. Poulton,[3] Lauren N. Blazek,[3] Austin K. Nichols,[4] Susan L. Hogan,[2] Ronald J. Falk,[3] Vimal K. Derebail.[1]
[1]University of North Carolina at Chapel Hill, Cary, NC; [2]University of North Carolina, Chapel Hill, Chapel Hill, NC; [3]UNC Kidney Center, Chapel Hill, NC; [4]Univeristy of North Carolina, Carthage, NC.

Background: As pregnancy with glomerular disease is considered high-risk, proactive planning is desired. Contraceptive preferences, including use of long-acting reversible contraception (LARC) that avoids estrogen associated hypertension (HTN) and venous thromboembolism (VTE), as well as elective termination rates in this population are largely unknown.

Methods: A women's health survey was distributed by email, mail and in-person to women ages 18-65 in the Glomerular Disease Collaborative Network, a prospective registry in the southeastern United States (US). This analysis was restricted to reproductive age women (< 50 years). Fisher's exact test assessed the association of elective terminations with race and disease type.

Results: Of 106 included (response rate 14.2%), the mean age was 36.7, BMI was 30.8 kg/m^^2, and 17.9% were African-American (AA). The most common diseases were IgA nephropathy (27.4%), Lupus nephritis (22.6%), FSGS (17.0%) and ANCA vasculitis (13.2%). Half (54.7%) had HTN, 23.6% were past or current smokers and 12.3% reported prior VTE. Over one-third (38%) were either unsure or did not believe that kidney disease increases risk for pregnancy complications. A total of 72.6% utilized a birth control method in the past 12 months to prevent pregnancy; one-third of which endorsed ≥ 2 methods in that period. The most common methods included progesterone intrauterine device, condoms, pills, and withdrawal (see figure). At least one elective termination was reported by 16.0% and was higher in AA vs non-AA women (31.6% vs 12.6%, p= 0.08) though not statistically significant.

Conclusions: LARC use within the past 12 months was remarkably high, yet 61.1% endorsed methods associated with high failure rates. This data precludes distinguishing between concurrent use of multiple methods vs single successive methods. Elective termination rates were not significantly different among subgroups and overall rates appeared lower than the general US population (24% by age 45) but this may be due to underreporting.



TH-PO732

Contraceptive Use Among Women with ESKD on Dialysis in the United States

Silvi Shah,[1] Annette Christianson,[2] Karthikeyan Meganathan,[1] Anthony C. Leonard,[1] Charuhas V. Thakar.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA, Cincinnati, OH.*

Background: Pregnancy in women with end-stage kidney disease (ESKD) is challenging. Nephrologists do not routinely counsel dialysis patients about contraception and little is known about contraceptive use in women with ESKD.

Methods: Using the United States Renal Data System from 1/1/2005 to 12/31/2014, we evaluated for each calendar year women aged 15-44 years who were on dialysis and had Medicare as the primary payer for the entire year. We studied trends in the use of contraceptive methods and used multivariable logistic regression with covariates and year, with subject as a repeated effect, to determine factors associated with contraceptive use.

Results: The study cohort included 36,450 women with 122,982 person-years. Mean maternal age was 34±6 year. Rate of any form of contraceptive use during the study period was 7.3 per 100 person-years (PHPY). Contraceptive use increased significantly from 2005 to 2014 (9.2 PHPY vs. 5.4 PHPY). From 2005 to 2014, the rate of intrauterine device insertions increased from 0.8 PHPY to 2.6 PHPY, tubal ligation rate increased from 0.4 PHPY to 0.2 PHPY, implant insertion rate increased from 0.1 to 0.4 PHPY, and hysterectomy rate increased from 1.6 PHPY to 3.7 PHPY. All races except Asians had a consistent increase in contraceptive use from 2005-2014. Compared to women aged 20–24 years, the contraception use was lower in women aged 25-29 years (OR, 0.81; CI, 0.74-0.89) and 30–34 years (OR, 0.65; CI, 0.41-0.77). As compared to white women, Asian women had lower contraceptive use (OR, 0.81; CI, 0.69-0.96) and Native American women had higher contraceptive use (OR, 1.34; CI, 1.09-1.64). As compared to women residing in southern areas, contraceptive use was lower in women residing in northeastern areas (OR, 0.85; CI, 0.77-0.93). Women with ESKD due to glomerulonephritis had higher contraceptive use than women with ESKD due to diabetes (OR, 1.20; CI, 1.10-1.31).

Conclusions: There has been a statistically significant increase in contraceptive use in women with ESKD on dialysis in the last decade. Younger age, Native American race, and ESKD due to glomerulonephritis were associated with higher likelihood of contraceptive use in ESKD patients.

TH-PO733

Racial Disparities and Factors Associated with Pregnancy in ESKD Patients on Dialysis in the United States

Silvi Shah,[1] Annette Christianson,[2] Anthony C. Leonard,[1] Karthikeyan Meganathan,[1] Charuhas V. Thakar.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA, Cincinnati, OH.*

Background: Pregnancy in women with end-stage kidney disease (ESKD) undergoing dialysis is not common due to impaired fertility. Literature concerning pregnancy in the dialysis population is scarce.

Methods: We evaluated a retrospective cohort of 47,667 women who were aged 15-44 years and were on dialysis between January 1, 2005 and December 31, 2013 from the United States Renal Data System, with primary Medicare claims data, and who carried Medicare as the primary payer throughout 40 weeks of follow-up. We calculated pregnancy rates, and using multivariable proportional intensity recurrent event survival analysis, we identified factors associated with pregnancy including race.

Results: Overall, 2354 pregnancies were identified in 47,667 women on dialysis. The pregnancy rate was 17.7 per thousand person-years (PTPY) (95% confidence interval (CI), 17.0-18.5), and was roughly stable over the nine calendar years. Native American, Hispanic, and black women had higher rates of pregnancy than did Asian or white women (23.2, 22.2, 19.2, 15.6 and 12.8 PTPY, respectively). Women on hemodialysis had a higher rate of pregnancy than did women on peritoneal dialysis (19.3 vs. 9.3 PTPY). In the adjusted survival analysis, a higher likelihood of pregnancy was seen in Hispanic women (HR, 1.65; CI, 1.42-1.91), Black women (HR, 1.47; CI, 1.29-1.66), and Native American women (HR, 1.94; CI, 1.43-2.64) than in white women; in women with ESKD due to malignancy (HR, 1.59; CI, 1.22-2.07), miscellaneous causes (HR, 1.50; CI, 1.25-1.80), glomerulonephritis (HR, 1.47; CI, 1.26-1.70), hypertension (HR, 1.41; CI, 1.22-1.64), and secondary glomerulonephritis/vasculitis (HR, 1.25; CI, 1.06-1.48) than with ESKD due to diabetes; and in women residing in the northeast (HR, 1.29; CI, 1.14-1.47) and midwest (HR, 1.20; CI, 1.06-1.35) than in the south. A lower likelihood of pregnancy was seen among women on peritoneal dialysis than on hemodialysis (HR, 0.45; CI, 0.39-0.53).

Conclusions: Factors associated with a higher likelihood of pregnancy includes race (Hispanic, black, and Native American), ESKD cause (glomerulonephritis, vasculitis, neoplasm, and hypertension), geographical region (northeast and midwest), and hemodialysis modality. This study improves our understanding of pregnancy in patients with ESKD.

TH-PO734

Urinary Extracellular Vesicles miR-143-3p: A Novel Candidate Biomarker for Preeclampsia

Sonja Suvakov,[1] Muthuvel Jayachandran,[1] Natasa Milic,[2,1] Vesna D. Garovic.[1]
[1]Mayo Clinic, Rochester, MN; [2]Medical Faculty University of Belgrade, Belgrade, Serbia.

Background: Preeclampsia (PE) is a complex pregnancy-associated disorder which is characterized by new-onset hypertension and proteinuria (>300mg) after 20 weeks of gestation. Recent study from our group showed that number of podocytes-derived urinary

extracellular vesicles (EVs) were increased in pregnant women with PE but their content of bioactive molecules are not known. Aim of this study was to assess differential expression of miRNAs in urinary EVs from pregnant women with and without PE.

Methods: Bio-banked cell-free urines from pregnant women with (n=5) and without (normotensive; n=5) PE were used for miRNA expression in urinary EVs. The expressions of miRNAs within urinary EVs were identified by XRNA Exosome RNA-Seq Library Kit. Validation of significantly changed candidate miRNAs between groups was performed by qPCR in the independent cohort of patients with (n=15) and without (n=15) PE. Sn-U6 and cel-miR-39 were used as reference and spike-in control respectively for data validation.

Results: A total of 184 miRNAs were identified in urinary EVs by RNA sequencing analysis whereas twenty eight miRNAs were significantly ($P<0.05$) changed in pregnant women with PE compared to women without PE. Selected candidates of 12miRNAs involved in renal pathophysiological processes were validated by qPCR. Among 12, only miR-143-3p remained significantly increased ($P<0.018$) in PE patients (both early (PE diagnosed <34 weeks) and late (>34 weeks) PE) compared to normotensive controls. The miR-95-3p was significantly decreased ($P<0.048$) only in patients with early PE. There was no correlation between changed miRNAs and urinary protein concentration. ROC analysis for miR-143-3p yielded an AUC of 0.776 and for miR-95-3p AUC=0.659.

Conclusions: Differential expression of miR-143-3p and miR-95-3p in urinary EVs from pregnant women with PE compared to normotensive pregnant women could be a new candidate biomarker for preeclampsia.

TH-PO735

Characterizing Fetal Outcomes in Women with Biopsy-Proven Primary Glomerular Disease

Laura E. Berall,[1] Isabel Arruda,[2] Morgan Yuan,[3] Dini Hui,[5] Nir Melamed,[4] Michelle A. Hladunewich.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [3]McMaster University, Hamilton, ON, Canada; [4]Sunnybrook Health Sciences Center, Toronto, ON, Canada; [5]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada*.

Background: It is well known that women with chronic kidney disease are at higher risk for worse maternal and fetal outcomes. However, the extent of these risks in women with biopsy proven primary glomerular disease has not been well described. This study aims to further characterize pregnancy outcomes in this population.

Methods: A database of women seen in a Pregnancy and Kidney Disease clinic at a tertiary care centre in Toronto, Canada was searched from January 2003 until July 2018 to identify women with biopsy-proven primary glomerular disease who had at least one pregnancy managed in this clinic. The primary study outcome was the live birth rate. Secondary study outcomes included birthweight, premature birth, spontaneous abortions and perinatal death (defined as stillbirth >20 weeks or neonatal death).

Results: 218 pregnancies in 148 women (IgA nephropathy *n*=79, FSGS *n*=69, membranous nephropathy *n*=23, hereditary nephritis *n*=21, membranoproliferative glomerulonephritis *n*=15, minimal change disease *n*=11), were identified. Of these, 84.6% resulted in a live birth. 35.6% were born under 37 weeks gestational age (GA), with 29.7% of these at less than 32 weeks GA. 57 babies were born under the tenth percentile for their GA, 26.3% of these babies were less than the third percentile. There were 23 spontaneous abortions (SA) at less than 10weeks GA and 5 SA at 10-20weeks GA. In this cohort, 3.9% of pregnancies resulted in perinatal death.

Conclusions: Women with biopsy-proven glomerular disease are at high risk of adverse fetal outcomes. Further work needs to be done to characterize fetal outcomes by sub-category of glomerular disease, as well as to examine maternal outcomes.

TH-PO736

FGFR4 Is Not Required for the Development of Cardiac and Renal Hypertrophy in Pregnancy

Beatrice Richter, Brian A. Czaya, Christopher Yanucil, Isaac D. Campos, Dominik Kentrup, Kylie Heitman, Christian Faul. *Division of Nephrology, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL*.

Background: Pregnant women develop cardiac and renal hypertrophy as an adaption to increased blood volume, which is reversible without causing organ injury. Fibroblast growth factor (FGF) 23 is a bone-derived hormone that increases phosphate excretion by targeting the kidney via FGF receptor (FGFR) 1 and klotho. In chronic kidney disease, high FGF23 levels are associated with cardiovascular injury and can directly induce cardiac hypertrophy. FGF23 binds to FGFR4 on cardiac myocytes in a klotho-independent manner, thereby activating pro-hypertrophic signaling. In injured kidneys, FGF23/FGFR4 signaling promotes fibrosis. Here, we investigated whether FGF23/FGFR4 signaling contributes to cardiac and renal hypertrophy during pregnancy.

Methods: Virgin female C57BL/6J wildtype (WT), FGFR4 knockout (KO), and FGFR4-385R/R knockin (KI) mice were mated with proven male breeders. After 24 hours, males were removed, and females were sacrificed after 18 days in late pregnancy (LP). Age-matched, non-pregnant (NP) females served as controls. Heart and kidney mass and serum levels of FGF23, phosphate and calcium were determined. Heart and kidney tissue were further analyzed by qPCR.

Results: WT and KO mice develop cardiac and renal hypertrophy in LP, indicated by increased heart weight/tibia length and kidney weight/tibia length ratios when compared to respective NP controls. This effect is not observed in pregnant KI mice. Serum FGF23 increases in LP in all three genotypes. In WT-LP mice, serum calcium levels increase, while serum phosphate is unchanged when compared to WT-NP controls. Furthermore, cardiac *Fgfr1* mRNA levels are reduced, and *Fgf23* and *Fgfr4* increased. In the kidney, *Fgf23, Fgfr1, Fgfr4* and *NaPi2c* mRNA levels are unchanged, while *NaPi2a* is decreased, and *klotho* and *Pit2* are elevated.

Conclusions: In LP, mice develop cardiac and renal hypertrophy and have elevated serum FGF23 levels. However, in this context FGFR4 does not seem to be required for the development of organ hypertrophy. Surprisingly, we found that activation of FGFR4 inhibits organ hypertrophy suggesting anti-hypertrophic actions of FGF23/FGFR4 signaling in pregnancy, which requires further mechanistic studies.

VEGF-Based Apheresis: A Targeted Therapy for Preeclampsia

Mahsa Matin,[2] Thomas Benzing,[1,2] Bernhard Schermer,[1] Henning Hagmann.[2] *[1]Faculty of Medicine and University Hospital Cologne, CECAD, Cologne, Germany; [2]Department II of Internal Medicine, Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany*.

Background: Preeclampsia is a pregnancy specific complication, occurring in 6 – 8 % of pregnancy cases and is the leading cause of 76,000 maternal and 500,000 prenatal deaths per year worldwide. Due to the current lack of effective treatment options and its high prevalence, developing an effective therapy for preeclampsia is of great importance. Based on the insight that elevated sFlt-1 plasma levels, by decoying VEGF and PlGF leads to preeclampsia, in the current study we set out to develop a highly specific sFlt-1 adsorption strategy to treat preterm preeclampsia.

Methods: According to *in silico* modeling a number of novel sFlt-1 ligand variants were generated and characterized by determination of equilibrium dissociation constant of the receptor binding affinity. The most affine candidates were chosen for immobilization on an optimized apheresis column. Binding efficiency, unspecifically bound proteins as well as release of VEGF and PlGF were analyzed in *ex vivo* experiments employing serum samples of patients with preeclampsia.

Results: We were able to successfully engineer an array of VEGF-variants with varying affinity to sFlt-1. One of them with a higher affinity to sFlt-1 than all its known isoforms. This VEGF molecule variant not only effectively captures sFlt-1, but additionally competes with and liberates both endogenous VEGF and PlGF. In experiments employing serum samples from 10 patients with preeclampsia this system yields 80% reduction of sFlt-1, while releasing around 85% PlGF and VEGF.

Conclusions: In this study we demonstrate a novel apheresis set up which enables adsorption of up to 80% of circulating sFlt1 with highest specificity, while further restoring angiogenic balance by liberating PlGF and VEGF. Our system is directly applicable for further testing in large animal models of preeclampsia, which is crucial to evaluate the effect of VEGF release on the pregnancy. In the future, our variants may allow for personalized and targeted therapy of preeclampsia at different stages of the disease.

TH-PO738

Infertility and Pregnancy Loss in Hispanic/Latino Women with CKD: Results from the Hispanic Community Health Study/ Study of Latinos (HCHS/SOL)

Monica L. Reynolds,[2] Laura R. Loehr,[2] Susan L. Hogan,[2] Yichun Hu,[2] Carmen Isasi,[3] Christina Cordero,[4] Ana C. Ricardo,[1] James P. Lash,[1] Vimal K. Derebail.[2] *[1]University of Illinois at Chicago, Chicago, IL; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Albert Einstein College of Medicine, Bronx, NY; [4]University of Miami, Miami, FL*.

Background: Hispanic/Latino individuals are less likely to be screened or receive optimal CKD treatment. This may be particularly detrimental for reproductive age women as CKD has been associated with infertility, menstrual irregularities, and pregnancy loss.

Methods: Using data from the HCHS/SOL baseline (2008-2011) and second study visits (2014-2017), we assessed CKD and self-reported infertility, cessation of menses, and nonviable pregnancy loss (<24 weeks gestation) in women age 18-45 years old. CKD was defined as one of the following at both study visits: albuminuria (urine albumin:creatinine [UACR] >30 mg/g) or an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2. To capture mild CKD and variation in visit measurements, we also included those with UACR >300 mg/g at any visit, eGFR <60 mL/min/1.73m^2 at one visit and <70 mL/min/1.73m^2 at the other, or if baseline UACR >30 mg/g while on RAAS-blockade. Survey-specific analyses were used to account for the two-stage probability sampling design. Multivariable survey logistic regression derived prevalence odds ratios (OR) with 95% confidence intervals for our outcomes of interest. Using a 10% change-in-estimate approach, covariates considered were age, body mass index (BMI), hypertension (HTN) and diabetes (DM).

Results: Of 2,589 included, 4.6% had CKD. Women with CKD were older (41 vs 38), had a higher BMI (34 kg/m^2 vs 30 kg/m^2), and more DM (32% vs 11%) and HTN (42% vs 12%). In adjusted analysis, those with CKD did not have a significantly increased odds of infertility, cessation of menses, or nonviable loss (see table). Among 635 women with pregnancies occurring specifically between baseline and second visit, the OR of nonviable loss with CKD was 1.7 (95% CI 0.5-5.8) but not statistically significant.

Conclusions: In this Hispanic/Latino cohort, CKD was uncommon and not associated with our outcomes of interest but our sample size limited statistical power. Considering the temporality of CKD diagnosis and pregnancy in a larger sample warrants further study.

Intrapartum Sildenafil Therapy Does Not Impair Renal Function in Young Adult Offspring of Preeclamptic Dahl S Rats

Hannah R. Turbeville, Michael R. Garrett, Jennifer M. Sasser. *University of Mississippi Medical Center, Jackson, MS.*

Background: Up to 10% of pregnancies are complicated by preeclampsia, and up to 15 million Americans are offspring of preeclamptic pregnancies. The Developmental Origins of Health and Disease hypothesis proposes that an adverse intrauterine environment programs the fetus to increased susceptibility to hypertension and renal function loss. We have shown that sildenafil citrate, a phosphodiesterase-5 (PDE-5) inhibitor, improves the maternal syndrome of preeclampsia in the Dahl S rat and reduces blood pressure of their offspring up to 21 weeks of age; however, long term kidney function in these offspring has not been examined. We hypothesized that PDE-5 inhibition during preeclamptic pregnancy improves long-term BP without significant reduction in renal function.

Methods: Female Dahl S rats on a 0.3% salt diet were mated and treated orally with sildenafil (50 mg/kg/day) or vehicle from gestational day 10 to delivery. Lactating dams and offspring were on normal chow for the duration of the study, and measurements were made at 12 weeks of age. Urine was collected (n=18-27/group) for measurement of urinary protein (Bradford assay) and creatinine (Jaffe reaction). Plasma was also collected at euthanasia (n=13-17/group) for measurement of blood urea nitrogen (BUN, enzymatic method) and creatinine, and creatinine clearance was calculated.

Results: Systolic BP (n=5-9/group, tail cuff) was greater in Dahl S rats of untreated mothers compared to offspring of sildenafil treated dams (VEH: 177±4 mmHg; SLD: 158±2 mmHg; p=0.0001). BP data were pooled due to lack of significant sex differences between treated groups. No significant differences in proteinuria were observed (VEH male: 102±8; SLD male: 101±8; VEH female: 55±5; SLD female: 75±6 mg/day). No significant differences in BUN were found between either sex or treatment group (VEH: 20.3±0.8; SLD: 18.16±0.7 mg/dL). While expected sex differences in creatinine clearance were maintained, there was no significant difference between the treatment groups (VEH male: 0.75±0.05; SLD male: 0.70±0.05; VEH female: 0.56±0.07; SLD female: 0.64±0.06 mL/min/g renal mass).

Conclusions: These data support the hypothesis that the use of a PDE-5 inhibitor during preeclamptic pregnancy improves the long-term BP without reduction of renal function in the offspring at 12 weeks of age.

TH-PO740

Obstetric Complications in Pregnant Dialysis Patients

Kathryn M. Martin,[1] Jennifer L. Waller,[1] N. Stanley Nahman,[1,2] Stephanie L. Baer,[2] Seema Faiyaz,[3] Lufei Young,[1] Wendy B. Bollag,[1] Mufaddal Kheda,[1] Maya Gibson,[1] Azeem Mohammed.[1] *[1]Medical College of Georgia at Augusta University, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA; [3]ARMC, Aiken, SC.*

Background: Obstetric complications, including spontaneous abortion (SAB) and pre-term labor (PTL), are more common in dialysis patients than the general population. Information, however, is limited by small numbers of patients studied. To examine these complications and the risk factors for their development in a national cohort, we queried the United States Renal Data System (USRDS).

Methods: Women ages 14 to 50 years starting dialysis between 2004-2011 were included. ICD-9 codes from hospital, physician, or detailed claims identified pregnant patients with SAB or PTL. CMS Form 2728 was used to identify demographics and etiology of ESRD. Generalized linear models were used to estimate the adjusted relative risk (aRR) of each outcome.

Results: There were 1393 pregnancies, with mean maternal age 34±9, 40% white race, and 91% on hemodialysis. ESRD etiologies were: 43% diabetes, 7% hypertension (HTN), 29% SLE, 18% glomerulonephritis (GN), and 3% polycystic kidney disease. The incidence of SAB and PTL was 7% and 10%, respectively. For SAB, there were no differences between ESRD causes. For PTL, the incidence was higher in those with renal failure from HTN, SLE, and GN. The aRR of SAB was higher in non-white, non-black race [2.30] and decreased with increasing maternal age [0.96]. For PTL the aRR increased with pre-eclampsia [1.66], eclampsia [2.00] and intrauterine growth retardation [3.56]. Risk of PTL decreased with increasing maternal age [0.91] and a diagnosis of septicemia [0.58].

Conclusions: SAB and PTL are common obstetric complications in pregnant ESRD patients and greatest in those with ESRD from HTN, SLE, and GN. It is unclear from this work why the risk of complications was decreased in older patients; however we would speculate that younger patients have higher prevalence of SLE, and thus more extensive systemic disease. Similarly, we would suggest that septic patients received more intensive medical therapy and pre-term care, decreasing the risk of complications. Understanding the high-risk groups for complications may improve pre-term care and outcomes.

TH-PO741

Successful Pregnancies In Kidney Transplant Recipients with Complement-Mediated Thrombotic Microangiopathy

Natalja Haninger-Vacariu,[1] Martina M. Gaggl,[1] Christof Aigner,[1] Zoltan Prohaszka,[2] Renate Kain,[1] Georg Bohmig,[1] Raute Sunder-Plassmann,[1] Gere Sunder-Plassmann,[1] Alice Schmidt.[1] *[1]Medical University of Vienna, Vienna, Austria; [2]Semmelweis Universtiy, Budapest, Hungary.*

Background: Pregnancies in patients with complement gene variant mediated thrombotic microangiopathy (cTMA) are challenging, and pregnancies in such patients after kidney transplantation (KTX) even more so.

Methods: We identified pregnancies of patients enrolled in the Vienna TMA cohort and report maternal demographics and pregnancy as well as delivery outcomes of eight pregnancies after KTX in three genetically high-risk cTMA patients (Case 1: CFH, CFI, CFHR1, CFHR3, and CD46 variants. Case 2 & 3: CFH and CD46 variants).

Results: The three women were 21±2 years of age at cTMA manifestation, 25±1 years of age at KTX, and 32±2 years of age at their latest deliveries. Preventive plasma therapy was used in three pregnancies, and one patient had ongoing eculizumab (ECU) therapy during two pregnancies. Six out of eight pregnancies (75%) resulted in the delivery of healthy children, all of them appropriate for gestational age (delivery at gestational week 38±1.5; one preterm, case 1/pregnancy 4; two caesarean sections; four vaginal deliveries). The mean birth weight was 3305±317g, the mean birth length was 50±1cm, and the mean head circumference was 34±1cm. In addition, one pregnancy is still ongoing at gestational week 28+5 (case 3/pregnancy 5). The other two included one early abortion (case 3/pregnancy 1 at gestational week 12 during ongoing ECU therapy) and one late fetal death (case 1/pregnancy 3 at gestational week 33+3), most likely not related to complement dysregulation. Kidney transplant function after delivery remained stable in all but one pregnancy (case 2/pregnancy 3). In this latter case, a severe cTMA flare occurred after delivery despite use of preventive plasma infusions. Kidney graft function could be rescued in this patient by terminal complement blockade.

Conclusions: Successful pregnancies can be accomplished in kidney transplant recipients with a history of cTMA. We used preemptive plasma therapy or ongoing ECU treatment in selected cases. Thus, becoming pregnant can be encouraged in kidney transplant recipients with native kidney cTMA. Extensive preconception counseling, however, is mandatory in such cases.

TH-PO742

Feto-Maternal Cross-Talk via Extracellular Vesicles and Sterile Inflammation During Preeclampsia Reprograms the Offspring for Increased Risk of Anti-GBM Disease

Shrey Kohli,[1,2] Anubhuti Gupta,[1,2] Shruthi Krishnan,[1,2] Berend H. Isermann.[3,2] *[1]Institute for Clinical chemistry and Pathobiochemistry, Otto-von-Guericke University Madgeburg, Magdeburg, Germany; [2]Institute for Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, Leipzig University, Leipzig, Germany; [3]Otto-von-Guericke University Magdeburg, Magdeburg, Germany.*

Background: Gestational vascular diseases such as preeclampsia (PE) are associated with maternal and fetal morbidity and mortality. PE is often associated with intra-uterine growth restriction (IUGR) predisposing for diseases later in life. We have shown that maternal extracellular vesicles (EVs) and platelets promote PE and placental sterile inflammation. We now aim to evaluate whether fetal re-programming due to EV induced pregnancy complications may predispose the offspring to an increased risk of renal diseases later in life.

Methods: EVs were injected in pregnant C57Bl/6 mice and pregnancy outcome (fetal death, IUGR, renal pathology) was studied. Proteinuria, renal histology, blood pressure and sFlt-1 was measured in the mother to establish PE-like symptoms. Embryonic and neonatal kidneys were evaluated for in-utero reprogramming. Offsprings from control and EV injected mothers were subjected to glomerulonephritis using anti-GBM serum and kidneys were studied for signs of renal disease.

Results: EV injections resulted in PE in the mother and IUGR in embryos and low birth weight. Whole embryos and neonatal kidneys from EV injected PE-mothers showed enhanced basal inflammasome activation (elevated NLRP3, cleaved IL-1β expression) indicating in-utero reprogramming. Anti-GBM serum injections into offsprings (age 8 weeks) from EV injected PE-mothers showed elevated albuminuria, impaired glomerular pathology (PAS staining), enhanced inflammasome activation, KIM-1 expression and reduced nephrin expression in kidneys compared to control offsprings (no PE) exposed to anti-GBM serum. Mechanistically, maternal EVs were taken up by trophoblast cells and reached the embryonic circulation. Maternal EVs contained bioactive cargos such as RNA and IL-1β. Importantly, exposure of EVs to RNase prior to injection or inhibition of IL-1R-signaling using anakinra abolished the inflammatory effects of maternal EVs on the embryo.

Conclusions: These results show that increased maternal EVs affect the embryo proper in addition to acute pregnancy complications. These effects on embryos persist during pregnancy and increase the risk for renal diseases in later life. Further studies are required to evaluate the mechanisms by which EVs can possibly cross the placenta predisposing the offspring to deleterious health effects.

TH-PO743

Maintaining Low Mean Blood Pressure Reduces Severe Adverse Events in Pregnant Women with IgA Nephropathy: A Single-Center Retrospective Study

Satoshi Kumakura,[1,2] Mai Yoshida,[1] Tasuku Nagasawa,[1] Koji Okamoto,[1] Sadayoshi Ito,[3,1] Mariko Miyazaki.[1,2] *[1]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University, Sendai, Japan; [2]Department of Blood Purification, Tohoku University Hospital, Sendai, Japan; [3]Katta Hospital, Shiroishi, Japan*.

Background: A number of young female patients with IgA nephropathy experience pregnancy because the disease population peaks at adolescent age. The clinical course of IgA nephropathy varies; therefore, not all cases receive treatment and follow-ups. However, the risk of pregnancy outcomes among the females with different disease severity and past treatment is not well-known.

Methods: Patients with IgA nephropathy who underwent perinatal care at our institution for 8 consecutive years were recruited for this study. We collected the clinical data by reviewing medical records of patients. Further, we analyzed the correlation between pregnancy outcomes and baseline characteristics, including age, BMI, eGFR, urinary protein (UP), mean blood pressure (MBP), anti-hypertensive drugs use, and past treatment for IgA nephropathy at the time of referral. We set the occurrence of severe adverse events (SAE) as primary outcome and preterm delivery (PreD), small for gestational age (SGA) infants, and low infant birth weight (LBW) as secondary outcomes. We performed logistic regression analysis for each outcome. According to CKD stages, eGFR and UP were categorized into 5 stages and 3 stages, respectively.

Results: We observed 33 pregnancies of 27 patients. Median age was 31 years, median eGFR was 95.5 ml/min/1.73 m^2, and median UP was 0.11 g/gCr. SAE occurred in 9 pregnancies. Age (OR = 1.26, p = 0.021), UP stage (OR = 2.92, p = 0.029), MBP (OR = 1.24, p = 0.01), and past methylprednisolone pulse therapy combined with tonsillectomy (OR = 0.14, p = 0.033) were the candidate predictor according to the univariate analysis. Consequently, MBP (OR = 1.33, p = 0.049) was the only predictor for SAE according to the multivariate analysis. Among PreD, SGA, and LBW, univariate analysis showed statistical significance in baseline characteristics as candidate predictors for SAE. However, multivariate analysis showed no statistical significance among those candidates.

Conclusions: Univariate analysis showed that less proteinuria, lower MBP, and treatment with combined therapy reduce risk of SAE, whereas multivariate analysis showed that MBP is the only predictor for SAE. Our study implies that patients with IgA nephropathy should receive treatments until their blood pressure normalizes before initiating pregnancy.

TH-PO744

Animal Models of Preeclampsia: A Renal Perspective

Oscar A. Garcia Valencia,[1] Tracey L. Weissgerber,[1] Marko Savic,[2] Jelena Milin-Lazovic,[2] Maria Lourdes Gonzalez Suarez,[3] Rangit R. Vallapureddy,[1] Diping Wang,[1] Hajrunisa Cubro,[1] Natasa Milic,[2] Marilyn Cipolla,[4] Vesna D. Garovic.[1] *[1]Mayo Clinic, Rochester, MN; [2]Department for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia; [3]University of Mississippi Medical Center, Jackson, MS; [4]Department of Obstetrics, Gynecology, and Reproductive Sciences, University of Vermont Larner College of Medicine, Burlington, VT*.

Background: Preeclampsia is a heterogeneous syndrome with different pathophysiological subtypes. Many animal models have been proposed, each based on different pathophysiology. The preeclampsia phenotype may differ depending on the model, the lab or personnel, or the animal supplier. Whereas some models reproduce the glomerular endotheliosis observed in preeclamptic women, others cause hypertensive renal injury. This systematic review examines the types of measurements performed to assess renal damage in papers that use animal models of preeclampsia.

Methods: PubMed and EMBASE were searched to identify articles using animal models of preeclampsia, published between January 2000 and September 2016. The search strategy included terms for hypertensive pregnancy disorders and term lists for identifying animal studies. Two independent reviewers followed standardized screening and abstraction protocols. Detailed information was abstracted from papers that included a common (>20 publications) model.

Results: 364 papers included a common model (NOS inhibition: n=112 (22%), reduced uterine perfusion pressure or subrenal aortic coarctation: 101 (19.8%), sFlt-1: 35 (6.9%), low dose endotoxin: 33 (6.5%), NaCl administration: 28 (5.5%), transgenic human angiotensinogen renin: 25 (4.9%), agonistic autoantibodies against the angiotensin II type 1 receptor: 23 (4.5%), or NaCl and corticosteroids: 20 (3.9%). 80.5% of studies reported maternal blood pressure. 44.2% measured proteinuria. Renal histopathology was rarely examined (12.4%). The proportion of papers that measured each characteristic was highly variable among models (blood pressure: 43% to 100% (range), proteinuria: 21% to 95%, renal histopathology: 5% to 40%). The proportion of papers reporting proteinuria and renal histopathology did not differ between papers with vs. without a preclinical agent. 40 (11%) studies acknowledged that the model may not apply to all preeclamptic women.

Conclusions: Renal histopathology is rarely reported, suggesting a need for better characterization of renal changes caused by preeclampsia models and preclinical agents. This is particularly important given that hypertensive renal injury observed in some models differs from the glomerular endotheliosis observed in preeclamptic women.

Mechanisms of Vascular Dysfunction in the Interleukin-10-Deficient Murine Model of Preeclampsia

Hajrunisa Cubro,[1] Karl A. Nath,[1] Sonja Suvakov,[1] Oscar A. Garcia Valencia,[1] Santosh Parashuram,[1] Wendy White,[1] Tracey L. Weissgerber,[1] Meryl C. Nath,[2] Natasa Milic,[3,1] Fernando Sontag,[1] Livius V. d'Uscio,[1] James L. Kirkland,[1] Tamara Tchkonia,[1] Zvonimir S. Katusic,[1] Joseph P. Grande,[4] Vesna D. Garovic.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Alabama at Birmingham, Rochester, MN; [3]Department of Biostatistics, Medical Faculty University of Belgrade, Belgrade, Serbia; [4]Mayo Foundation for Medical Research, Rochester, MN*.

Background: Preeclampsia (PE) is characterized by new-onset hypertension, proteinuria, endothelial dysfunction, and both macrovascular and microvascular injury in the second half of pregnancy. Based on observations that PE is associated with derangements in IL-10 signaling, we sought to test the hypothesis that endothelium-dependent vascular dysfunction is exacerbated in a murine model of PE based on the administration of human PE sera to interleukin (IL)-$10^{-/-}$ mice.

Methods: Pregnant wild type (WT) and IL-$10^{-/-}$ mice were injected with either normotensive (NT) or severe preeclamptic (sPE) patient sera on the 10th day of gestation. Blood pressure was measured at the beginning of pregnancy and before sacrifice on the 17th day of gestation. Vasomotor function of isolated aortas, albuminuria, and aortic gene expression were assessed.

Results: Pregnant IL-$10^{-/-}$ mice injected with sPE sera exhibited higher blood pressure (P = 0.002) and albuminuria (P = 0.0066) compared to controls. Contractions of the isolated aortas to phenylephrine were significantly augmented in the IL-$10^{-/-}$ mice injected with sPE sera compared to the pregnant controls (P < 0.001). This group also demonstrated impaired endothelium-dependent relaxation to acetylcholine compared to controls (P = 0.002). Treatment of isolated aortas with indomethacin normalized vascular reactivity of aortas derived from pregnant IL-$10^{-/-}$ mice injected with sPE sera (contraction: P = 0.009; relaxation to acetylcholine: P < 0.001).

Conclusions: In aggregate, this murine IL-$10^{-/-}$ PE model exhibits significant pregnancy-specific macrovascular dysfunction caused by enhanced contraction to phenylephrine and impaired endothelium-dependent relaxation. Observed alterations in vasomotor function are predominantly caused by enhanced activation of the cyclooxygenase pathway.

TH-PO746

Maternal and Fetal Outcomes in Women with CKD Diagnosed During Pregnancy

Denisse Arellano-Mendez,[1] Javier Soto-Vargas,[1] Efrain Chavarria-Avila,[2] Carlos D. Jimenez Mejia,[1] Isela Márquez magaña,[1] Renato Parra Michel.[1] *[1]Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Especialidad en nefrologia, Hospital General Regional No 46 del IMSS, Guadalajara, Mexico; [2]Universidad de Guadalajara, Guadalajara, Mexico*.

Background: Diagnosis of Chronic Kidney Disease (CKD) during pregnancy, has increased in recent years. It is associated with worst outcomes for the mother and the baby. Mexico has one of the highest incidence of CKD, but, little is known about the impact of CKD in our population. The purpose of this work is to present the outcomes in a cohort of Mexican women with CKD diagnosed during pregnancy.

Methods: A prospective observational study, 32 pregnant women with CKD were included with quarterly follow-up until three months after delivery and were compared with 117 age matched pregnant woman without CKD for hypertensive disorders of pregnancy, gestational age, low birth weight, preterm delivery and relevant clinical kidney events.

Results: No differences were found in baseline characteristics except for the serum creatinine. Hypertension was associated with CKD (P=0.001). Women with CKD had a greater number of caesarean sections (P=0.001), and their babies had lower birth weight, gestational age, and preterm delivery (P=0.006, 0.001 and 0.007 respectively). During pregnancy three patients required renal replacement therapy (RRT), which started at 8.6±4.1 gestational weeks. Two of them continued in RRT after the delivery. Only 19 (59.4%) of CKD patients went to the follow-up, eight (66.7%) of 13 patients with a hypertensive disorder of pregnancy were classified as chronic hypertension, and nine (90%) of 10 patient had persistent proteinuria. No deaths were reported during the follow-up.

Conclusions: CKD is associated with worse maternal and fetal outcomes. In our country, it is necessary to implement strategies to allow diagnosis of CKD during or ideally before pregnancy, a close follow-up by nephrologist and evaluate the impact of its intervention in maternal and fetal outcomes.

Table 1. Maternal and fetal outcomes

	CKD n= 32	Without CKD n= 117	*P*

Preeclamptic Women Have Decreased Circulating IL-10 Levels at the Time of Active Disease: Systematic Review and Meta-Analysis

Meryl C. Nath,[2] Hajrunisa Cubro,[2] Tracey L. Weissgerber,[2] Natasa Milic,[1] Vesna D. Garovic.[2] *[1]Medical Faculty University of Belgrade, Belgrade, Serbia; [2]Mayo Clinic, Rochester, MN.*

Background: Preeclampsia (PE) is a pregnancy specific disorder characterized by hypertension and proteinuria after 20 weeks of gestation. One hallmark of PE is an abnormal maternal immune response. As a key immunomodulatory cytokine, Interleukin-10 (IL-10) has been shown to be dysregulated in PE. However, studies have reported inconsistent findings about circulating IL-10 levels in PE and normotensive (NT) patients. The aim of the present systematic review and meta-analysis is to assess circulating IL-10 levels in PE and NT patients at two time points: before PE diagnosis and at the time of active disease.

Methods: PubMED, EMBASE, and Web of Science databases were searched to include all published studies examining circulating IL-10 levels in PE and NT patients. Differences in circulating IL-10 levels between PE and NT women were evaluated by standardized mean differences.

Results: Out of the 876 abstracts screened, 56 studies were included in the meta-analysis. At the time of active disease, women with PE (n = 1496) had significantly lower circulating IL-10 levels compared to NT women (n =1897) (SMD: -0.68, 95% CI: -1.08, -0.28; *P* = 0.0008). Circulating IL-10 levels were lower in both early/severe and late/mild forms of PE. Subgroup analysis revealed that the methodology used to measure circulating IL-10 levels (ELISA or multiplex bead array) and the sample type (plasma or sera) significantly influences the observed differences in circulating IL-10 levels between PE and NT women. Circulating IL-10 levels were not different before the time of active disease (SMD: –0.01, 95% confidence interval [CI]: –0.11, 0.08; *P* = 0.76).

Conclusions: These findings provide further evidence about the significance of decreased IL-10 levels in the pathophysiology of PE. Further studies are needed to elucidate the clinical implications of these findings and the treatment potential of IL-10 in PE.

Autoimmunity and Altered Renal Function Precede the Development of Hypertension in Female Mice with Lupus

Elena L. Dent, Michael J. Ryan. *University of Mississippi Medical Center, Jackson, MS.*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by circulating autoantibodies, hypertension, and renal injury. Kidney involvement is common in SLE and renal dysfunction is evident in patients with active renal disease, yet little is known about early changes in renal function that may contribute to the pathogenesis of hypertension. We hypothesize that the loss of immunological tolerance and subsequent production of autoantibodies in SLE leads to impaired renal hemodynamic function that precedes the development hypertension.

Methods: Female NZBWF1 mice, an established experimental model of SLE, and female NZW (control) mice were instrumented with carotid artery and jugular vein catheters to determine mean arterial pressure (MAP) and glomerular filtration rate (GFR) respectively at ages 15, 20, 24, 28, 31, and 34 weeks. MAP was measured in conscious, freely-moving mice. GFR was measured by the clearance of fluorescein isothiocyanate-inulin (FITC-inulin) after achieving steady state through continuous infusion for five hours.

Results: Circulating autoantibodies are signifcantly increased by 28 weeks of age in mice with SLE (P = 0.0135), whereas autoantibodies are unchanged in control mice (Figure 1). GFR increases at 28 weeks of age followed by a significant decline by 34 weeks of age (P = 0.0127, P = <0.0001) compared to 34 and 15 weeks of age respectively, in SLE mice. GFR is increased in control mice by 28 weeks of age (P = 0.002) and remains unchanged at other time points (Figure 2).

Conclusions: These data suggest that changes in renal hemodynamic function occur in female SLE mice prior to changes in MAP suggesting a mechanistic role for autoimmunity to directly impair renal hemodynamic function and promote the development of hypertension.

Funding: Veterans Affairs Support

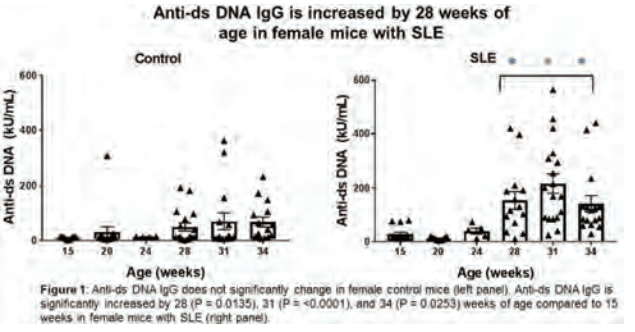

Figure 1: Anti-ds DNA IgG does not significantly change in female control mice (left panel). Anti-ds DNA IgG is significantly increased by 28 (P = 0.0135), 31 (P = <0.0001), and 34 (P = 0.0253) weeks of age compared to 15 weeks in female mice with SLE (right panel).

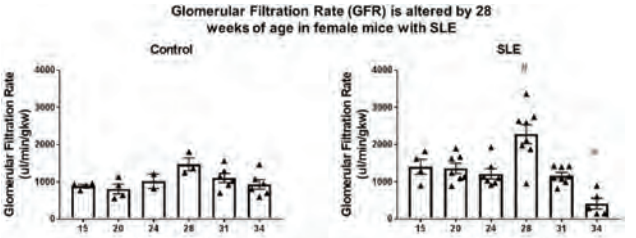

Figure 2: GFR does not change in female control mice (left panel). GFR is significantly increased by 28 weeks (# P = <0.0001) compared to 34 weeks of age and significantly decreased by 34 weeks (* P = 0.0127) compared to 15 weeks of age in female mice with SLE (right panel).

Sex Differences in Bioimpedance in Humans with Obstructive Sleep Apnea with Normal Kidney Function Before and After Continuous Positive Airway Pressure Therapy

David D. Nicholl,[1] Patrick Hanly,[2] Ann A. Zalucky,[4] Jennifer M. MacRae,[2] George Handley,[3] Darlene Y. Sola,[2] Sofia B. Ahmed.[2] *[1]Western University, London, ON, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]Healthy Heart Sleep Company, Calgary, AB, Canada; [4]University of Toronto, Toronto, ON, Canada.*

Background: Sex differences exist in obstructive sleep apnea (OSA) and chronic kidney disease (CKD), both of which are strongly associated and predispose patients to expanded total body water (TBW) and aberrant volume redistribution, resulting in significant morbidity. Continuous positive airway pressure (CPAP) therapy is an effective treatment for OSA which may alleviate this predisposition. While there are established sex differences in the pathophysiology of OSA and CKD, whether sex differences exist in TBW and other bioimpedance parameters in OSA subjects with normal kidney function and the impact of CPAP therapy remains unknown.

Methods: Twenty-nine (10 women, 19 men; age 49±2y) incident, otherwise healthy, and sodium replete OSA subjects (oxygen desaturation index [ODI] >15h^{-1}) with and nocturnal hypoxemia (SaO_2<90% for >12%/night) were studied pre- and post-CPAP therapy (>4h/night x 4 weeks) using bioimpedance technology. Total body water (TBW), extracellular and intracellular fluid volumes (ECF and ICF), ECF:TBW, ECF:ICF, fat free mass (FFM), body mass index (BMI) and other bioimpedance and anthropometric parameters were measured and evaluated for sex differences before and after CPAP therapy.

Results: Pre-CPAP, TBW (74.6±0.4 vs 74.3±0.2% of FFM, p=0.14; all values women vs men) and BMI (36±3 vs 35±1 kg/m^2, p=0.9) were similar between sexes, though FFM (56.3±1.7 vs 71.7±1.5% of weight, p<0.001) and absolute TBW (42.4±3.0 vs 57.1±1.6L, p<0.001) were lower in women. The proportion of ECF:TBW (0.50±0.006 vs 0.44±0.009, p<0.001) and ECF:ICF (1.00±0.002 vs 0.80±0.004, p<0.001) was increased in women despite overall reduced absolute ECF (21.3±1.7 vs 25.2±0.8L, p=0.006) and ICF (21.1±1.2 vs 31.9±1.0L, p<0.001) compared to men. Though CPAP corrected both OSA (ODI: 47.4±4.4 vs 3.3±0.4h^{-1}, p<0.001) and nocturnal hypoxemia (46.2±5.7 vs 8.3±2.7%, p<0.001), there were no within sex differences in bioimpedance or arthropometric parameters in response to CPAP therapy.

Conclusions: Women with OSA had expanded ECF compared to men. Differences in TBW distribution may contribute to sex differences in the pathophysiology of OSA in humans with normal kidney function. CPAP therapy for 1 month did not mitigate these differences.

TH-PO750

Characterizing Nonlinear GFR Decline in Children with Kidney Diseases

Derek Ng,[1] Bradley A. Warady,[3] Susan L. Furth,[4] George J. Schwartz.[2] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]University of Rochester, Rochester, NY; [3]Children's Mercy Kansas City, Kansas City, MO; [4]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: GFR decline in kidney disease is frequently treated as linear in clinical research. The Chronic Kidney Disease in Children (CKiD) cohort provided long-term follow-up to characterize and describe GFR decline using non-linear models and accounted for risk stage using the newly developed pediatric classification.

Methods: CKiD participants contributed up to 13 follow-up years and provided annual estimated GFR data. To account for diagnosis, separate models were fit by non-glomerular and glomerular diseases. Linear mixed effects models were fit with log GFR as the outcome and a quadratic effect of time, with random effects for intercept, time and time^2. Baseline proteinuria categories (<0.5, 0.5 to 2, >2mg/mgCr) modified each parameter. Empirical Bayes estimates quantified individual-specific entry GFR, and changes within 5 years and between 5 and 10 years and were stratified by baseline CKD risk stage (initial GFR entry and observed proteinuria). Stable GFR was defined as no decline.

Results: A total of 757 and 275 children with non-glomerular and glomerular CKD, contributed 3926 and 1213 observations with 45% and 30% contributing at least 5 years. Most participants entered at Stage A or B (lowest severity) risk: for the non-glomerular and glomerular groups, 48% and 39% were in Stage A; 32% and 31% were in Stage B, respectively. The quadratic term for time offered significantly better fit than a linear effect only, for both groups (both $p<0.001$), and proteinuria significantly modified GFR trajectory. Nearly all children (95%) with non-glomerular diseases and 74% of those with glomerular diseases experienced faster percent decline in the second 5 years compared to the first 5 years, regardless of initial CKD stage. About 1/3 had stable GFR in the first 5 years in both non-glomerular and glomerular groups (27% and 31%), and Stages A and B comprised the vast majority of these first 5 year stable groups (86% and 69%). However, only 5% and 14% had a stable GFR in the second 5 years, respectively.

Conclusions: In general, in children with kidney diseases, GFR decline was not constant, but accelerated over time, and there was substantially more variability in glomerular disease. Mixed effects models provided individual non-linear trajectories and the challenge of heterogeneous disease duration at study entry was overcome by stratification by baseline CKD risk stage.

Validation of Different Serum Creatinine-Based Estimating Equations in Pediatric Kidney Transplant Recipients in Comparison with Measured Glomerular Filtration Rate

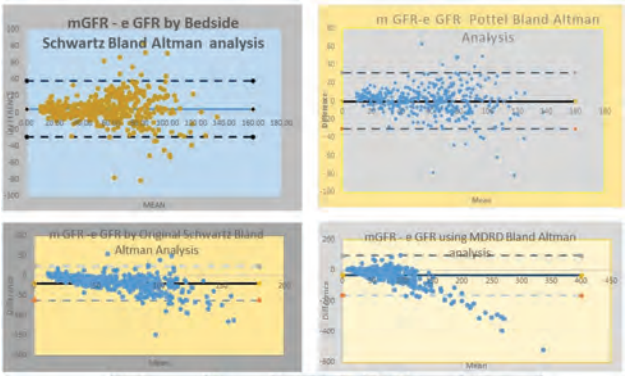
Vikas R. Dharnidharka,[1] Raja Dandamudi,[1] Neil Vyas,[2] Stanley P. Hmiel.[1] *[1]Washington University School of Medicine, St Louis, MO; [2]Case Western Reserve University, Forest Hills, NY.*

Background: The evaluation of allograft function is vital in the management of pediatric kidney transplant (pKTx) recipients. Serum creatinine (Scr) is the easiest everyday estimator of glomerular filtration rate (GFR) but both the absolute Scr value and the corresponding estimating equations (eGFR) are prone to considerable error. Measured GFR (mGFR) using plasma clearance of exogenous markers, while very accurate, is laborious as well as expensive, not suitable for everyday use. Prior studies have shown conflicting results regarding which eGFR equations are most accurate in comparison to mGFR. At our center, we have been performing measured GFR at 1 year post-pKTx; repeated every 2 years if mGFR > 40 ml/min/1.73m2, or yearly if mGFR ≤ 40. The aim of this study was to validate the different Scr-based eGFR equations in comparison to mGFR.

Methods: This retrospective study was conducted at St. Louis Children's Hospital from January 2000 to March 2019. We compared 415 mGFR values to 4 different Scr-based pediatric eGFR formulae (original Schwartz formula, modified Schwartz formula, Pottel formula and Modification of Diet in Renal Disease (MDRD) formula) from 125 pKTx recipients. Scr and children's height was measured on the same day as mGFR. We used Bland-Altman analysis to evaluate the bias between eGFR and mGFR. Higher precision was defined as lower width between the 95% limits of agreement (LOA). Accuracy was defined as percentage of eGFR that are within 30% of mGFR.

Results: The Pottel and modified Schwartz formulae had a high accuracy of 80% each and a low bias of < 5 ml/min/1.73 m2 (Figure). In contrast, the original Schwartz and MDRD formulae displayed a high bias and low precision and accuracy.

Conclusions: Of the Scr-based formulae, height independent Pottel and height dependent modified Schwartz formulae had low bias and high accuracy and either can be used to assess GFR in pKTx recipients. The original Schwartz and MDRD equations should not be used in this population.



Equation	Bias	Standard Deviation	95%LOA	Accuracy
Original Schwartz Formula	-19.62	21.9	-62.7 to 23.4	47%
Bedside Schwartz Formula	4.45	17.21	-29.98 to 38.18	80%
MDRD Formula	-35.42	65	-162 to 91.97	39%
Pottel Formula	-0.25	15.61	-30.84 to 30.35	80%

TH-PO752

Novel Nuclear Magnetic Resonance-Based Method for Prediction of Glomerular Filtration Rate Performs Well in Children

Jochen H. Ehrich,[1] Laurence Dubourg,[2] Sverker Hansson,[3] Jens Drube,[1] Lars Pape,[1] Katharina Schäffler,[4] Tobias Steinle,[4] Jana Fruth,[4] Sebastian Höckner,[4] Eric Schiffer.[4] *[1]Hannover Medical School, Hannover, Germany; [2]hospices civils de Lyon -Université Claude Bernard Lyon 1-INSERM U 820, LYON, France; [3]Sahlgrenska University Hospital, Göteborg, Sweden; [4]numares AG, Regensburg, Germany.*

Background: Estimation of glomerular filtration rate ($eGFR_{creat}$) in children requires different equations than in adults. This led to the development of different pediatric equations; however, these equations still show suboptimal performances in the upper and lower GFR range. Recently, a novel serum-based method for accurate prediction of GFR using a nuclear magnetic resonance (GFR_{NMR}) spectroscopy-based biomarker constellation (creatinine, myo-inositol, valine, and dimethyl sulfone) was developed. This method outperformed the conventional $eGFR_{creat}$ equations when validated in three separate cohorts of predominantly adult patients.

Methods: The value of the NMR-based biomarker constellation for GFR prediction specifically in children was investigated by testing its performance in a cohort of 39 children (20 girls, 19 boys) aged between 2 and 17 years. The NMR-based method was compared to $eGFR_{creat}$ obtained by the bedside Schwartz equation using measured GFR (mGFR) as reference standard. Pearson correlation coefficient (r) with 95 % confidence interval, root mean square error (RMSE), and the percentage of eGFR values within 30% of measured GFR (P30) were calculated to assess the accuracy of the methods.

Results: In a cohort comprising pediatric patients with various degrees of kidney impairment covering the whole GFR range, the NMR-based method showed a higher correlation with mGFR compared to $eGFR_{creat}$ (r=0.85 vs. r=0.80). Moreover, the RMSE was reduced from 35.5 for $eGFR_{creat}$ to 21.6 for GFR_{NMR}. The NMR biomarker constellation also showed a higher accuracy in mGFR prediction with a P30 of 79.5 % compared to 71.8 % for $eGFR_{creat}$.

Conclusions: Our results demonstrate that the NMR-based biomarker constellation accurately predicts GFR not only in adults but also in pediatric patients. In fact, the novel method outperformed the established bedside Schwartz equation. Thus, GFR_{NMR} allows reliable and continuous monitoring of kidney function at the transition from pediatric to adult renal care without the need to switch the estimation equation.

TH-PO753

Serum Cystatin C Levels at Birth in Very-Low-Birth-Weight Infants

Mariko Sawada. *Kurashiki Central Hospital, Kurashiki, Japan.*

Background: Serum Cystatin C (CysC) is commonly used as a marker of glomerular filtration rates in children and adults. Although the reference intervals (RIs) of serum CysC has been well investigated, few reports demonstrated serum CysC levels in premature infants. The aim of this study was to investigate the RIs of serum CysC levels at birth in premature infants.

Methods: Eighty very low birth weight (VLBW, birth weight less than 1,500 g) infants admitted to our NICU between January 2018 and May 2019 were included, except for neonates with congenital anomalies of the kidney and urinary tract. Clinical data and serum CysC at birth were retrospectively collected from their medical records. All serum CysC concentrations were analyzed using a latex immunoturbidimetric assay. The RIs was defined as the set of CysC values 95% of these population.

Results: Data of 69 VLBW infants were available for this study. The CysC levels of 66 cases were distributed within 95% of these population. The gestational age was 29.2±3.1 weeks, and the birth weight was 1,061±290 g. It was included 27 (40.9%) male infants. The RIs of serum CysC levels at birth was 1.58±0.21 mg/L. Serum CysC levels in male infants were significantly higher than that in female infants (1.59 vs. 1.53 mg/L,

p< 0.05). Serum CysC levels at birth did not related to gestational age, birth weight, and APGAR score. There was no difference between serum CysC levels in small-for-gestational age (SGA) and that in non-SGA infants.

Conclusions: The RIs of serum CysC levels at birth is higher than that in later life. Unlike serum creatinine, serum CysC concentrations are not affected by their mothers' kidney function, therefore serum CysC levels might be a useful marker to evaluate the kidney function of neonates at birth.

TH-PO754

Serum Creatinine, Cystatin C, and a Comparison of Estimated Glomerular Filtration Rates in Very Low Birth Weight Children at 6 Years Old

Masafumi Oka. *Pediatrics, Saga university, Saga, Japan.*

Background: According to the developmental organs of health and disease (DOHaD) theory, low birth weight is a risk factor for chronic kidney disease (CKD) in adulthood. However, there has been insufficient research into the renal function in school-aged children. In our research, we aimed to investigate the renal function of very low birth weight (VLBW), defined as less than 1,500g, children at six-year old and reveal risk factors of CKD.

Methods: We investigated 380 six-year old children who underwent a preschool physical examination, and had been among 504 VLBW infants discharged from the NICU in 1999-2011. The serum creatinine (Cr) and cystatin C (CysC) were measured, and for the >95 percentile group, a logistic regression analysis was used to study the relationships between the factors of gender, gestational age (GA), weight, height and head circumference at birth, and weight, height and BMI at the time of the physical examination. Additionally, the estimated glomerular filtration rate (eGFR) at the examination was calculated with the equation of Japanese child (JPN), Schwartz and chronic kidney disease epidemiology collaboration (CKD-EPI) and compared.

Results: Data for 337 subjects was recorded (age: 5.4±0.5 years, male:female ration = 167:170, GA: 28.3±2.7weeks, birth weight: 995±301g). Serum Cr was 0.34±0.07mg/dL and CysC was 0.77±0.13mg/L. In the >97.5 percentile group for Cr there were 7 subjects (2.1%), while for CysC, it was 13 subjects (6.4%). In the logistic regression analysis, the independent risk factors for high Cr values were GA (OR:2.25, 95%CI:1.06-4.80) and birth weight (OR:0.41, 95%CI:0.22-0.77). In the eGFR comparisons, the values were as follows: JPN (Cr:113.0±18.8 ml/min/1.73m^2, CysC:130.6±19.9 ml/min/1.73m^2), Schwartz(Cr:137.6±23.4 ml/min/1.73m^2, CysC:92.1±12.4 ml/min/1.73m^2), and CKD-EPI(Cr:191.1±19.5 ml/min/1.73m^2, CysC:125.6±15.1 ml/min/1.73m^2).

Conclusions: In this study of VLBW, there was a high frequency of high CysC values, and GA and birth height were identified as perinatal factors related to high Cr values. When CKD-EPI (Cr) was used in Japanese child, the values were higher than with other predictive equations.

TH-PO755

Is the Prognosis of a Single Functioning Kidney Benign? A Population-Based Study

Hadas Alfandary,[1,2] Orly Haskin,[1,2] Yael Borovitz,[1] Shelly S. Levi,[1,2] Amit Dagan,[1,2] Tomer Erlich,[3] Miriam Davidovits,[1,2] Oren Pleniceanu.[4] *[1]schneider children's medical center, Petah tikva, Israel; [2]Sackaler Faculty of Medicine, Tel Aviv University, Tel aviv, Israel; [3]sheba medical center, Tel Aviv, Israel; [4]Pediatric stem cell research institute, Sheba medical center, Petach Tqiwa, Israel.*

Background: Solitary functioning kidney (SFK) is an important condition in the spectrum of congenital anomalies of kidney and urinary tract (CAKUT). The long term outcome of congenital SFK is underactive research. We conducted a large scale population based study to investigate an early renal injury in adolescents with SFK.

Methods: We accessed data from the compulsory medical evaluation of 17 years old in Israel, prior to their enlistment for military service during 2006-2018. The incidence of SFK and the incidence of renal injury defined as proteinuria, hypertension or decreased eGFR were documented.

Results: of 978997 candidates, 354 had diagnosis of SFK. The peak incidence was 1:1500 in 2012. Male to female ratio 2.7:1. 28.1% of the cohort were overweight (BMI>25) Proteinuria was reported in 17% of the cohort. Systolic blood pressure above 120mmHg/ 130mmHg was documented in 53.8% and 28.1% respectively. Diastolic blood pressure above 80mmHg/ 85mmHg was documented in 12.8 and 9.1% respectively. eGFR below 90ml/min/1.73m2 was reported in 12.1%. Concomitant genital malformations were documented in 5.5%.

Conclusions: this large population based study documents a significant risk for renal injury among adolescent with SFK at the age of 17 years old.

TH-PO756

Pubertal Delay and Impact on Short Stature Among Girls with CKD

Hannah Kim,[1] Derek Ng,[5] Matthew Matheson,[5] Meredith A. Atkinson,[4] Bradley A. Warady,[3] Susan L. Furth,[2] Rebecca Ruebner.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Children's Mercy Kansas City, Kansas City, MO; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Children with chronic kidney disease (CKD) have delays in normal growth and pubertal development. We aimed to describe factors associated with delayed puberty including short stature among children with CKD.

Methods: A prospective cohort study was conducted using the Chronic Kidney Disease in Children (CKiD) study. Delayed puberty was defined as menarche at age 15 years or older. Short stature was defined as last available height 2 standard deviations below projected mid-parental height. Chi-squared and Wilcoxon rank-sum tests were used to assess factors associated with delayed menarche.

Results: Median age at menarche was 12 years (IQR, 12 to 14 years, Figure). 10% had delayed menarche. African American race, lower eGFR, and longer CKD duration at time of menarche were associated with delay in menarche ($p < 0.05$), and girls with delayed menarche had lower height and weight percentiles ($p<0.05$, Table). 61% of girls with delayed menarche had short stature compared to only 35% of girls without delayed menarche ($p=0.03$).

Conclusions: Median age at menarche is similar among girls with CKD and healthy girls. However, 10% of girls with CKD have delayed menarche, which may negatively impact final adult height.

Funding: NIDDK Support

Autotaxin Early Predicts Progressive Renal Fibrosis in CKD

Ching-Yuang Lin. *Pediatric Nephrology, Children's Hospital, China Medical University, Taiwan, Taichung, Taiwan.*

Background: Single-kidney FUBI (Failure of Ureteric Bud Invasion) mice in susceptible animals causes glomerular sclerosis and interstitial fibrosis in the remnant kidney. To identify potential biomarker, we applied cDNA microarray.

Methods: We examined serial changes with aging and investigated the single-kidney-FUBI mice for 15 months. Using microarray, gene expression and validation workflow, we identified potential biomarkers and validation using plasma samples from 146 patients with chronic kidney disease (CKD) of diverse etiologies.

Results: We identified autotaxin that were shared by FUBI mice and CKD patients. Autotaxin (ATX) protein expression expressed dramatically after age of 12 months in the single-kidney compared with double-kidney-FUBI mice. During the progression of human CKD, a gradual increase of plasma autotaxin level became significant in stage 3 CKD with the amplification of CKD severity. ATX was absent in normal human renal tissue but detected immunohistologically in the human specimen of renal dysplasia. ATX

also contributed a drastic increase in the expression of fibrotic components including: fibronection, α-smooth muscle actin, collagen I and TGF-β in aging. Also fibrotic proteins upregulated in cultured human podocytes treated by ATX in a dose dependent manner.

Conclusions: Our results indicated that ATX might serve as a novel tool for monitoring the progression of CKD. ATX might also be as a possible therapeutic target to slow progression of CKD.

TH-PO758

Predicting Pediatric CKD Progression with Urinary Metabolomics

Tom D. Blydt-Hansen,[1] Atul K. Sharma,[4] Robert H. Mak,[5] George J. Schwartz,[6] Bradley A. Warady,[2] David Wishart,[7] Susan L. Furth.[3] Chronic Kidney Disease in Children (CKiD) Study *[1]University of British Columbia, Vancouver, BC, Canada; [2]Children's Mercy Kansas City, Kansas City, MO; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]University of Manitoba, Winnipeg, MB, Canada; [5]UCSD, La Jolla, CA; [6]University of Rochester, Rochester, NY; [7]University of Alberta, Edmonton, AB, Canada.*

Background: Predicting progression in children with chronic kidney disease (CKD) may improve care and planning for renal replacement therapy. Adding urinary metabolome changes to existing clinical models may improve prognostication.

Methods: Urine samples from patients in the CKiD Study had targeted urinary profiling (138 metabolites/creatinine ratio). Time to event (TTE) was measured, with event defined as 50% decline in eGFR, eGFR <15 or start of renal replacement (composite). A TTE predictor was trained using partial least squares discriminant analysis (PLS-DA), reported as discriminant score (dscore). Log-logistic accelerated failure time (AFT) models were fitted to predict survival based on clinical features without/with dscore, and compared the mean bias for accuracy (t test) and precision (F test).

Results: 703 patients (61% male, aged 12.1±4.4 years, iGFR 51.7±23.9) were divided into 2/3 training, 1/3 test sets, and 222 had an event (cases). The dscore was trained on cases (2 PLS components) and validated in the test set. The dscore was significantly correlated with TTE (r=0.61, p<0.001). The model performed similarly using only the top 10 metabolites (r=0.60, p<0.001). No improvement was noted when training separate glomerular vs. non-glomerular strata. An AFT survival model fit to training data (N =469 with 148 cases) included GFR, proteinuria, and glomerular disease as predictors. The model including dscore & clinical features (AIC=756) had improved fit compared to clinical features alone (AIC=793, likelihood ratio test p<0.001). Using test cases (N=74), the mean bias (years) was 1.8±3.1 vs. 2.4±4.3, demonstrating superior accuracy (mean difference 0.6, p=0.04) and precision (F ratio=0.53, p=0.007). Empiric and predicted AFT survival curves were compared using test data (N=234, 74 cases) stratified by baseline GFR <60. The predicted survival curves ± dscore are shown for both strata (Figure).

Conclusions: The addition of a urinary metabolite classifier improves both predictive accuracy and precision of a CKD progression model, compared with clinical features alone.

Funding: NIDDK Support

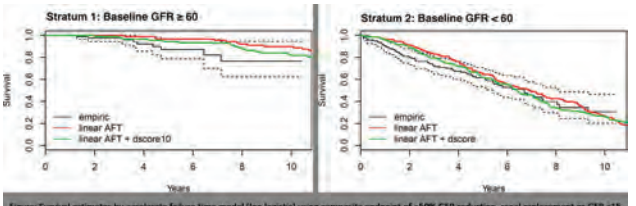

Figure: Survival estimates by accelerate failure time model (log-logistic) using composite endpoint of >50% GFR reduction, renal replacement or GFR <15 ml/min/1.73m², stratified by baseline iohexol GFR <60 ml/min/1.73m². In the test sample set (n=234), reported empiric survival is compared to the model with clinical features only (glomerular diagnosis, proteinuria, GFR) and to clinical features and the metabolite discriminant score (linear AFT + dscore).

Waikar,[5] Michael Shlipak,[6] Venkata Sabbisetti,[7] Mariana Cardenas-Gonzalez,[5] Bradley A. Warady,[8] Paul L. Kimmel,[9] Joseph V. Bonventre,[7] Chirag R. Parikh,[10] Mark Mitsnefes,[11] Michelle Denburg,[12] Susan L. Furth.[12] CKD Biomarkers Consortium *[1]Yale University, Woodbridge, CT; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Case Western Reserve University, Cleveland, OH; [4]University of Pennsylvania, Philadelphia, PA; [5]Harvard Medical School, Boston, MA; [6]San Francisco VA Medical Center, San Francisco, CA; [7]Brigham and Women's Hospital, Boston, MA; [8]Children's Mercy Kansas City, Kansas City, MO; [9]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [10]Johns Hopkins University, Baltimore, MD; [11]Cincinnati Children's Hospital, Cincinnati, OH; [12]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Left ventricular hypertrophy (LVH) is common in children with CKD and is associated with an increased risk of cardiovascular disease and mortality. Novel plasma biomarkers may help identify children at increased risk of developing LVH. We investigated whether the circulating plasma biomarkers of tubular injury (KIM-1) and inflammation (TNFR-1, TNFR-2, suPAR) are associated with LVH in children.

Methods: In the CKiD Cohort Study, children aged 6 months to 16 years old with an eGFR of 30-90 ml/min/1.73m² were enrolled at 54 centers in the US and Canada. We measured plasma KIM-1, TNFR-1, TNFR-2, and suPAR in stored plasma collected 5 months after study enrollment. Echocardiograms were performed one year after study enrollment. We assessed the cross-sectional association between the $\log_2$ biomarker levels and LVH (left ventricular mass index ≥95th percentile) using a Poisson regression model, adjusted for demographics (i.e., age, sex, race), body mass index, hypertension, glomerular diagnosis, proteinuria, as well as estimated glomerular filtration rate at study entry.

Results: Of the 544 children included, median age was 11 years [IQR: 8, 15], 335 (62%) were male, 162 (30%) had a glomerular cause of CKD, 92 (17%) had hypertension, median baseline eGFR was 54 [IQR: 40, 68] ml/min/1.73m², and median urine protein to creatinine ratio was 0.32 [IQR: 0.11, 0.94] mg/g. The overall LVH prevalence was 12% (N=65 events). All median biomarker levels were higher in children with LVH compared to those without LVH (p<0.05). In unadjusted models, two-fold greater plasma KIM-1, TNFR-1, TNFR-2, and suPAR concentrations were associated with LVH (KIM-1 relative risk [RR] per doubling: 1.39; TNFR-1 RR: 1.29; TNFR-2 RR: 1.54 and suPAR RR: 1.77) (**Table**). After adjusting for demographic and clinical characteristics, only higher plasma KIM-1 concentrations were associated with an increased risk of LVH (RR per doubling: 1.31, 95% CI: 1.04-1.64).

Conclusions: Elevated plasma KIM-1 is independently associated with LVH in children with CKD.

Funding: NIDDK Support

Table. Baseline Biomarker Concentrations and Risk of LVH

Biomarker, per doubling	Biomarker alone			Adjusted Model (age, sex, race)			Adjusted Model (plus BMI, hypertension, glomerular diagnosis)			Full Adjusted Model (plus eGFR, Pr/Cr)		
	RR	95% CI	P-value	RR	95% CI	P-value	RR	95% CI	P-value	RR	95% CI	P-value
Plasma KIM-1	1.39	[1.18, 1.64]	<0.001	1.40	[1.18, 1.67]	0.001	1.45	[1.19, 1.77]	0.001	1.31	[1.04, 1.64]	0.02
Plasma TNFR-1	1.29	[1.00, 1.65]	0.05	1.42	[1.10, 1.83]	0.007	1.41	[1.09, 1.83]	0.009	0.98	[0.66, 1.45]	0.92
Plasma TNFR-2	1.54	[1.05, 2.27]	0.026	1.65	[1.13, 2.42]	0.01	1.56	[1.08, 2.31]	0.02	1.02	[0.64, 1.64]	0.93
Plasma suPAR	1.77	[1.20, 2.61]	0.004	1.75	[1.18, 2.58]	0.005	1.59	[1.08, 2.34]	0.02	1.07	[0.67, 1.73]	0.77

Left ventricular hypertrophy (LVH) is defined as (LVM ≥95th percentile for healthy children and adolescents. Left ventricular mass index (LVMI) is an index of left ventricular mass to height (mass [g]/height [m]$^{2.7}$) to account for body size. Full model is adjusted for age, gender, race, glomerular diagnosis, body mass index, hypertension, protein to creatinine ratio (Pr/Cr), and baseline eGFR. KIM-1: kidney injury molecule-1. TNFR: tumor necrosis factor receptor. suPAR: soluble urokinase-type plasminogen activator receptor. *: Per doubling. RRs are for a continuous log2 change in biomarker levels.

Primary Hyperoxaluria Type 2: New Insight into Clinical Outcomes

Sander F. Garrelfs,[1] Hessel Peters-Sengers,[1] Jaap Groothoff,[1] Bodo B. Beck,[2] Michiel J. Oosterveld,[1] Pierre Cochat,[3] Graham W. Lipkin,[5] Eduardo C. Salido,[7] Bernd Hoppe,[4] Sally Hulton.[6] on behalf of the OxalEurope consortium *[1]Amsterdam UMC (Academic Medical Center), Amsterdam, Netherlands; [2]University of Cologne Medical Center, Cologne, Germany; [3]Université ClaudeBernard Lyon1-, Bron, France; [4]University Hospital Bonn, Bonn, Germany; [5]Queen Elizabeth Hospital, Bimingham, UK, Birmingham, United Kingdom; [6]Birmingham Childrens' Hospital, Birmingham, United Kingdom; [7]Hospital Universitario Canarias, La Laguna, Tenerife, Spain.*

Background: Primary hyperoxaluria type 2 (PH2) is a rare inherited disorder of glyoxylate metabolism causing nephrocalcinosis, renal stone formation and ultimately renal failure. PH2 had previously been considered to have a more favorable prognosis than PH1, but earlier reports are limited by low patient numbers and short follow up periods.

Methods: This study is based on gathered data from the European Hyperoxaluria Consortium (OxalEurope), encompassing the largest known PH2 cohort worldwide, providing a unique cohort enabling the description of longer-term outcomes in this rare disease.

Results: The dataset contained 101 patients from eleven countries. Median follow up was 12.4 years. Median ages at first symptom and diagnosis for index cases were 3.2 years and 8.0 years, respectively. Urolithiasis was the most common presenting feature (82.8%). Genetic analysis revealed 18 novel mutations in the *GRHPR* gene. Of 238 spot-urine analyses, 23 (9.7%) were within normal range as compared to less than 4% of 24-hour urine collections. Median intra-individual variation of 24-hour oxalate excretion was substantial (34.1%). At time of review 12 patients were lost to follow-up; 45 of 89 (50.6%) experienced chronic kidney disease (CKD) stage ≥2 and 22 patients (24.7%) had reached CKD5. Median renal survival was 43.3 years. 15 transplantations in 11 patients are described. Renal outcome did not correlate with genotype, biochemical parameters nor with the presence of nephrocalcinosis at presentation.

Conclusions: PH2 is not a benign disease and accurate diagnosis by 24-hour urine analysis and careful follow-up is required, in order to attempt to ameliorate its poor outcome. The role of liver transplantation remains unclear although it is evident that renal transplantation alone does not cure the disease.

Phase 1, Single-Dose Study to Assess the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of Etelcalcetide in Pediatric Subjects with Secondary Hyperparathyroidism Receiving Hemodialysis

Winnie Sohn,[1] Isidro B. Salusky,[2] Claus peter Schmitt,[3] Christina Taylan,[4] Johan Vande walle,[5] Jude A. Ngang,[1] Lucy Yan,[1] Bradley A. Warady.[6] *[1]Amgen Inc., Thousand Oaks, CA; [2]Division of Pediatric Nephrology, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Center for Pediatric and Adolescent Medicine, Heidelberg, Germany; [4]University Hospital of Cologne, Cologne, Germany; [5]UZGent, Gent, Belgium; [6]Children's Mercy Kansas City, Kansas City, MO.*

Background: The calcimimetic etelcalcetide is approved for treatment of sHPT in adult patients receiving hemodialysis. However, there are limited data on etelcalcetide safety and efficacy in pediatric patients.

Methods: This Phase 1 study (NCT02833857) evaluated the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of etelcalcetide after single-dose administration (0.035 mg/kg IV, corresponding to the approved lowest dose of 2.5 mg) in pediatric hemodialysis subjects in 2 cohorts (cohort 1: aged 12–<18 y; cohort 2: aged 2–<12 y). Treatment-emergent adverse events (AEs) were assessed. Etelcalcetide PK/PD was assessed post-dose on D1 at 10 min and 4 h, on multiple days until D10, and at the end of study (D30).

Results: Etelcalcetide administered to 11 subjects (mean [SD] age=10.3 [4.3] y; cohort 1, n=6; cohort 2, n=5) was well tolerated and reported AEs were consistent with the known etelcalcetide safety profile. One subject each in both cohorts reported treatment-related AEs (cohort 1: hypocalcemia; cohort 2: headache, paresthesia, and vomiting) and no serious AEs or deaths were observed. Mean serum corrected Ca (cCa) for all subjects was maintained >2.25 mmol/L. After dosing, PK exposures declined over time in both cohorts (Table). Median percent change in serum intact parathyroid hormone (iPTH) from baseline (cohort 1: 51.2 pmol/L; cohort 2: 84.0 pmol/L) reached the nadir on D1 at 4 h (cohort 1: –33.4%; cohort 2: –64.2%). In both cohorts, mean total Ca and cCa reached nadirs on D3 at 2.4 mmol/L, and mean ionized Ca on D1 at 4 h (1.1 mmol/L). Serum iPTH and cCa levels returned to baseline as etelcalcetide concentrations declined prior to the end of study in all subjects.

Conclusions: A single dose of 0.035 mg/kg was well tolerated, with no new safety concerns and PK/PD response was as expected. Given the high inter-subject variability, overlap in etelcalcetide concentrations, and small sample size, the differences in etelcalcetide exposures between the age groups were not likely to be clinically meaningful.

Growth in Children with Non-Glomerular Kidney Disease

Eujin Park,[1] IL-Soo Ha,[2] Hae Il Cheong,[2] Young seo Park,[8] Joo Hoon Lee,[8] Jae Il Shin,[3] Heeyeon Cho,[4] Kyoung Hee Han,[7] Seong heon Kim,[6] Min Hyun Cho,[5] Hee Gyung Kang.[2] *[1]Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [2]Seoul National University Children's Hospital, Seoul, Republic of Korea; [3]Yonsei University College of Medicine, Seoul, Republic of Korea; [4]Samsung Medical Center, Seoul, Republic of Korea; [5]Kyungpook National University Hospital, Daegu, Republic of Korea; [6]Pusan National University Children's Hospital, Yangsan, Republic of Korea; [7]Jeju National University School of Medicine, Jeju, Republic of Korea; [8]Asan Medical Center, Songpa-gu, SEOUL, Republic of Korea.*

Background: Growth retardation is one of common complications of chronic kidney disease (CKD) in children. Children with CKD from non-glomerular disease have been reported to have a higher risk of severe growth retardation than children with glomerular CKD. The objective of this study was to systematically compare growth parameters in children with non-glomerular CKD to those with glomerular CKD.

Methods: Baseline data from 437 children participating in the KoreaN cohort study for Outcomes in patients With Pediatric CKD (KNOW-Ped CKD) were analyzed. Growth was quantified by age-sex-specific height and weight standard deviation scores (SDS). We compared the height and weight SDS in children with non-glomerular CKD (*n*=325) to those with glomerular CKD (*n*=112).

Results: Median height and weight SDS in children with non-glomerular CKD was -0.82 [interquartile range (IQR) -7.67 to 2.75] and -0.81[IQR -10.54 to 3.05] while those of glomerular CKD were -0.41[IQR -5.58 to 2.91] and -0.35[IQR -6.72 to 3.44]. 24.9% of the non-glomerular CKD had height SDS below -1.88 (16% in glomerular CKD) and 32.3% had weight SDS below -1.65 (16% in glomerular CKD). 9.5% were using growth hormone (1.8% in glomerular CKD). Non-glomerular CKD patients were significantly shorter and lighter than glomerular CKD, and proportion of short stature and proportion of underweight were larger in non-glomerular CKD than glomerular CKD. When further grouped according to age, children younger than 2 years-old with non-glomerular CKD were the shortest and the most underweighted (median height SDS -2.04; IQR -6.86 to 1.95, median weight SDS -2.32; IQR -6.76 to 1.83). Significance of non-glomerular CKD was also found in analysis of risk factors for growth impairment; In multivariable analysis, the most significant risk factor of underweight was non-glomerular CKD, followed by anemia and proteinuria. In turn, underweight itself was the most important risk factor for height impairment in children with CKD.

Conclusions: In concordance with the previous report, children with non-glomerular CKD have a high prevalence of growth abnormalities in the KNOW-Ped CKD cohort. In this population, more intensive and early intervention through growth hormone treatment and nutritional supplementation is necessary, especially in young children with non-glomerular CKD.

TH-PO763

Catch-Up Growth but Not Growth Hormone Itself Is Associated with Renal Injury in Subjects Born Small for Gestational Age

Midori Awazu, Hironori Shibata, Mariko Hida, Tomohiro Ishii, Tomonobu Hasegawa, Kazuya Matsumura. *Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan.*

Background: Subjects born with low birth weight including those born small for gestational age (SGA) are at a risk for developing hypertension and chronic kidney disease due to reduced nephron number. Growth hormone (GH), given to SGA children without catch-up growth, can induce hyperfiltration leading to glomerulosclerosis. Catch-up growth may also be a risk factor of kidney disease. We investigated the effects of GH and catch-up growth in the development of renal injury in subjects born SGA.

Methods: Twenty-eight subjects (12 males and 16 females, age 4 to 27 years) born SGA were retrospectively investigated. Twenty-three were preterm-SGA, and 4 out of 5 term-SGA were syndromic. Fourteen subjects were treated with GH. Estimated GFR (eGFR) was determined by quintic equation for Japanese children (<19 years) or formulas for Japanese adults (≥19 years) by age and gender. Renal injury was defined as reduced eGFR <90 ml/min/1.73 m^2, elevated urine microalbumin/creatinine ratio (malb/Cr) ≥30 mg/g, or the presence of hypertension. Catch-up growth was defined as change in SD score in height or weight from birth to the time when the final height was achieved or to the time of study for those who have not reached final height.

Results: There was no difference in current age, gestational age, birth weight, eGFR, malb/Cr, renal injury, height catch-up, or weight catch-up between subjects treated with GH and those not treated with GH (Table). Of all subjects, there was no cut-off SD score of height catch-up that separates those with and without renal injury. On the other hand, 12 out of 16 subjects (75%) with weight catch-up ≥1.6 SD had renal injury, whereas only 2 out of 11 (18%) with weight catch-up <1.6 SD had renal injury (P<0.05). On ROC analysis, a cut-off value of 1.595 SD in weight catch-up best predicted renal injury with 86% sensitivity and 62% specificity.

Conclusions: There was no difference in the prevalence of renal injury between SGA subjects treated with GH and those not treated with GH probably because the latter had spontaneous catch-up growth. Weight catch-up ≥1.6 SD appears to be a risk factor for renal injury.

Funding: Government Support - Non-U.S.

Patiromer Treatment of Hyperkalemia in Adolescent Children with CKD: Initial Results from EMERALD

Bradley A. Warady,[1] Coleman Gross,[2] Martha Mayo,[2] Jia Ma,[2] Joy Yllana,[2] Lana Shapiro,[2] Franz S. Schaefer.[3] *[1]Children's Mercy Kansas City, Kansas City, MO; [2]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [3]University of Heidelberg, Heidelberg, Germany.*

Background: Patiromer (PAT) is a sodium-free potassium (K^+) binder approved for treatment of hyperkalemia (HK) in adults (8.4 g once daily starting dose); it is not currently approved for use in children.

Methods: EMERALD (NCT03087058), an open-label, multiple-dose study, evaluates the pharmacodynamics (PD) and safety of PAT in children (2-<18 yr) with HK and CKD. It consists of a 14-d dose finding PD phase and a 5.5-mo long-term treatment (LT) phase. Patients (pts) must have eGFR <60 mL/min/1.73m^2, HK (serum K [sK] 5.1-<6.5 mEq/L) and not be on hemodialysis (HD). RAASi doses must be stable for ≥28 days before screening. Up to 54 pts will be enrolled into 3 sequential cohorts based on age. Cohort specific PAT starting doses with titration to obtain a target local K level of 3.8-5.0 mEq/L are being evaluated. Up to 3 starting doses per cohort may be assessed. The primary endpoint is the change in central lab sK from baseline to Day 14. Secondary endpoints include the proportion of pts with target sK (3.8-5.0 mEq/L, central lab) at Day 14 and through Week 26.

Results: Cohort 1 (age 12 to <18 yr, now completed) pts (N=14, mean age 14.5 yr) had a mean (SD) baseline sK of 5.54 (0.32) mEq/L and eGFR of 28.7 (13.7) mL/min/1.73m^2. The most common etiology of CKD was CAKUT (64%) and 57% of pts were on RAASi. All pts completed the PD phase of the study; 2 pts withdrew consent in the LT phase and 1 began HD after which sK data were censored. The starting dose for all patients was 4.2 g/d; 8.4 g/d was the most common final prescribed dose at study end (33.3%). sK decreased by -0.50 (0.54) mEq/L at Day 14 (N=14) and by -1.08 (0.74) mEq/L at Week 26 (N=11); 50% and 82% of pts achieved the target sK by Day 14 and Week 26, respectively. Adverse events (AE) were observed in 71% of pts and were mostly mild or moderate in severity (one severe, none serious). The most common class of AEs was gastrointestinal disorders (43%; diarrhea [21%], flatulence [14%], nausea [14%]). There was one AE of hypokalemia. Three pts experienced AEs considered related to study drug (none severe); no AEs led to study drug discontinuation.

Conclusions: Preliminary results from EMERALD suggest a 4.2 g/d PAT starting dose with titration resulted in clinically meaningful sK reduction in adolescents with CKD and HK and was generally well tolerated.

Rates of Prevalent Fracture Differ by Race and Ethnicity in Children with CKD

Marciana Laster,[1] Michelle Denburg,[2] Yusuke Okuda,[3] Juhi Kumar,[4] Susan L. Furth,[2] Kamyar Kalantar-Zadeh,[5] Bradley A. Warady,[6] Isidro B. Salusky.[1] *[1]Mattel Children's Hospital, Los Angeles, CA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]University of California, Irvine, Irvine, CA; [4]Weill Cornell Medical College, New York, NY; [5]University of California Irvine, School of Medicine, Orange, CA; [6]Children's Mercy Kansas City, Kansas City, MO.*

Background: Studies of healthy children demonstrate higher rates of fracture in Caucasian as compared to minority children. Although studies in adults with CKD have demonstrated greater risk of fracture in Caucasian adults as well, there is limited data on fracture rate differentials by racial-ethnic group in the pediatric CKD population.

Methods: In a sample of 742 children between the ages of 1.5 years and 18 years, with CKD stages 1-4 from the CKD in children (CKiD) cohort, we determined the relationship between racial-ethnic group and the reported history of fracture upon entry to the study. Using logistic regression, we sequentially controlled models for the potential confounders in Table 1 which were chosen based upon prior literature and bivariate p-values <0.1. Multiple imputation was used for missing values in the final model.

Results: The cohort characteristics and laboratory values are displayed in Table 1. Vitamin D levels were lowest in African-American children. 142 subjects reported ever having experienced a broken bone. In the fully adjusted and multiply imputed model, African-American and Hispanic children had 74% (OR [CI] 0.26 [0.14, 0.49] p=0.001) and 66% (OR [CI] 0.34 [0.17, 0.65], P<0.0001) lower odds of any fracture than Caucasian children at study entry, respectively (Figure 1).

Conclusions: Despite lower vitamin D levels, African-American children with CKD reported lower fracture frequency than Caucasian children. These findings in children with CKD are similar to those in healthy children. Additional studies to understand the pathophysiologic mechanisms behind these differentials are warranted.

A 24-Month Interim Analysis of a Phase 2 Trial Evaluating the Long-Term Efficacy and Safety of Oxabact OC5 in Dialysis Patients with Primary Hyperoxaluria Type 1 (PH1)

Bernd Hoppe,[2] Bastian Dehmel,[1] Ana Banos,[3] Ulrike Herberg.[4] *[1]OxThera IP AB, Lucerne, Switzerland; [2]University Hospital Bonn, Bonn, Germany; [3]OxThera AB, Trångsund, Sweden; [4]University of Bonn, Bonn, Germany.*

Background: In PH1, endogenous overproduction of oxalate in the liver results in significantly elevated plasma oxalate (Pox), high urinary oxalate excretion, recurrent urolithiasis and/or progressive nephrocalcinosis. This can lead to end-stage renal disease (ESRD) with patients requiring dialysis and combined liver and kidney transplantation. Dialysis is insufficient to remove oxalate and cannot match the endogenous production, resulting in high Pox and thus systemic oxalate deposition. Oxabact (OC5), is a formulation of *Oxalobacter formigenes*,an oxalate-metabolizing bacterium, that induces active secretion of oxalate from plasma to the intestinal lumen. This Phase II, open-label single-arm study investigated efficacy in reducing Pox and safety of OC5 in PH1 patients on a stable dialysis regimen.

Methods: Patients received OC5 (≥10^9 CFU lyophilized *O. formigenes*per dose, twice a day) until transplantation or until they reached a maximum of 36 months treatment duration. Pox was evaluated monthly. Cardiac function (echocardiography) was evaluated every 6 months. Safety was assessed continuously. This 24-months interim analysis represents the longest treatment intervention observed in patients with PH1 on dialysis to date.

Results: Eight subjects with a mean (SD) age of 33 (13) years were enrolled into the long-term treatment study. Three patients discontinued before reaching 24 months of treatment; two due to non-compliance to treatment and one due to a liver transplantation. The drop-outs did not have an impact on results. Total Pox was 158.3 (43.9) µmol/L at baseline (n=8), 119.8 (11.3) µmol/L at Week 52 (n=6), and was further reduced to 94.6 (31.9) µmol/L at Week 104 (n=5). Mean Left ventricular ejection fraction improved from 51.6 % at baseline (n=8) to 59.8% at Week 52 (n=6) and 59.4% at Week 104 (n=5). Seven subjects reported any Adverse Event (AE), most frequent AEs were infections and infestations and gastrointestinal disorders. Four subjects experienced 5 serious AEs, unrelated to treatment

Conclusions: Two years treatment with OC5 reduced mean Pox by approximately 40% in PH1 patients with ESRD without intensifying their dialysis regimen. This was also associated with an improved and stabilized cardiac function. OC5 was safe and well-tolerated.

DNA Methylation Program in Human Kidney Development

Hongbo Liu,[1,2] Ziyuan Ma,[1,2] Jihwan Park,[1,2] Szu-yuan Li,[1,3] Laura Goetzl,[4,5] Sara E. Pinney,[6,7] Rebecca Simmons,[8,7] Katalin Susztak.[1,2] *[1]Renal-Electrolyte and Hypertension Division, Department of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Institute for Diabetes, Obesity, and Metabolism, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [3]Division of Nephrology, Department of Medicine, Taipei Veterans General Hospital, Teipei, Taiwan; [4]Department of Obstetrics and Gynecology, Lewis Katz School of Medicine, Temple University, Philadelphia, PA; [5]Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern School of Medicine, University of Texas, Health Sciences Center at Houston, Houston, TX; [6]Division of Endocrinology and Diabetes, The Children's Hospital of Philadelphia, Philadelphia, PA; [7]Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [8]Division of Neonatology, The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Epidemiologic studies indicate that in utero nutritional alterations increase the risk of hypertension, and kidney disease in adults. Changes in the epigenome have been proposed to mediate the metabolic programming effect, as epigenome editing enzymes are regulated by substrates of the intermediate metabolism and changes in the epigenome can be maintained after cell division. DNA methylation is one of the most studied epigenetic factor that plays a key role in gene expression regulation and cell type specification. The methylation dynamics of human kidney development (pre and post-natal) remains unknown, therefore we analyzed genome-wide methylation changes of human kidney development and maturation.

Methods: Here we performed base resolution methylome analysis by whole genome bisulfite sequencing of human fetal kidneys, from 11.4 to 19.0 weeks of gestation and postnatal kidney tubules from 27 to 61 years of age (n=12). The SMART genome segmentation method was used to identify differentially methylated regions (DMRs). RNA-sequencing was performed to detect gene expression changes.

Results: Whole genome methylation analysis identified dynamic methylation changes during kidney development and maturation including, 5,280 regions gaining methylation (hyper-DMRs) and 4,316 regions losing methylation (hypo-DMRs) in adult kidney tubules. Methylation changes were enriched on gene regulatory regions. Hyper-DMR regions lost histone enhancer marks (H3K4me1 and H3K27ac) while hypo-DMRs gained enhancer marks. Function enrichment analysis indicated that developmental genes are gaining methylation while proximal tubule specific genes undergo demethylation. Consistently hyper-DMRs were enriched for kidney developmental transcription factors binding sites such as HOXC9 and SIX2, while hypo-DMRs were enriched for the proximal tubule-specific transcription factors (HNF family). Methylation showed correlation with gene expression such as the increase in expression of proximal tubule specific genes in adult and loss of expression of fetal genes in adult. Methylation and gene expression dynamics were conserved in mice.

Conclusions: Cytosine methylation, specifically enhancer regions, show dynamic changes in fetal development and postnatal maturation, the most prominent of them is the decrease in enhancer methylation and increase of expression of proximal tubule genes.

TH-PO768

Paradigm Shift: The Impact of Early Rapid Genomic Sequencing in the Diagnosis of Kidney Disease

Kushani C. Jayasinghe,[1] Zornitza Stark,[2] Catherine Quinlan.[3] Australian Genomics and the Melbourne Genomics Renal Genetics Flagship part of the KidGen collaborative *[1]Monash Health, Clayton, NSW, Australia; [2]Australian Genomics Health Alliance, Parkville, NSW, Australia; [3]The Royal Children's Hospital, Melbourne, VIC, Australia*.

Background: Rapid genomic sequencing with results available in clinically meaningful timeframes is becoming feasible. Its role in the diagnosis and management of patients with kidney disease is unclear.

Methods: Patients were recruited prospectively for rapid whole exome sequencing (WES) with analysis of a pre-determined phenotype specific list of genes of interest and results available in less than 2 weeks. This followed review by a nephrologist, clinical geneticist and genetic counsellor who considered inclusion if a result was likely to significantly impact clinical management, particularly avoiding kidney biopsies in younger children. Full author list online at KidGen.org.au

Results: Ten patients (7 pediatric, 5 female) were recruited ranging in age from 1 month to 55 years. Indications for rapid testing were to avoid a renal biopsy (8) and to facilitate transplant planning (2). Five patients received a definitive diagnosis (ADPKD, Dent disease, primary hyperoxaluria, Alport syndrome and ciliopathy), 1 received a diagnosis which was likely unrelated to their kidney disease (MIRAGE syndrome). One patient's negative result facilitated sibling donor workup. The most significant result in this cohort was an unexpected diagnosis of primary hyperoxaluria in a 6-month old presenting in renal failure. WES results were available within 5 days informing conversion from peritoneal dialysis to hemodialysis and planning for a sequential liver-kidney transplant. This avoided the significant morbidity of oxalate deposition in extra-renal tissues leading to fractures, visual impairment and heart failure and recurrence of the disease if an isolated renal transplant had been performed.

Conclusions: Rapid genomic sequencing has high diagnostic utility in selected patients with renal disease and can inform clinical management within meaningful timeframes. It has the potential to transform the diagnostic pathway for young children, particularly where invasive renal biopsies can be avoided.

TH-PO769

Longitudinal Associations Between Vitamin D and Blood Pressure in the CKD in the Children (CKiD) Cohort

Juhi Kumar,[1] Jennifer Roem,[2] Susan L. Furth,[3] Bradley A. Warady,[4] Meredith A. Atkinson,[5] Joseph T. Flynn.[6] *[1]Weill Cornell Medical College, New York, NY; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Children's Mercy Kansas City, Kansas City, MO; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]Seattle Children's Hospital, Seattle, WA.*

Background: Preclinical studies suggest that 25 hydroxy vitamin D (25OHD) modulates the renin-angiotensin-aldosterone system, vascular smooth muscle cells and the endothelium. Analysis of data from the "Effect of Strict Blood Pressure Control and ACE Inhibition on Progression of CKD in Pediatric Patients" study showed that subjects with 25OHD levels <20 ng/ml had a higher diastolic BP than those with levels ≥20 ng/ml (p=0.004). Children with 25OHD levels < 20 ng/ml in the CKiD cohort had SBP 0.29 standard deviations higher (95%CI: 0.07, 0.51, p=0.009) at baseline.

Methods: Longitudinal associations between hypertension (SBP or DBP ≥95th percentile) and baseline 25OHD (deficiency < 20 ng/ml) and 1,25$(OH)_2$D (per 10 pg/ml) levels), adjusted for baseline covariates, were examined using mixed-effects logistic regression that included a random subject effect to account for repeated measurements of the outcome within each subject. Covariates included were age, gender, race, years from visit 2, CKD etiology, BMI, GFR, proteinuria and medications used (antihypertensive, steroids, active and inactive vitamin D supplements). Study population included 536 subjects contributing 2741 visits (subset of n=365 with available ABPM measurements at visit 2 contributing 803 visits).

Results: Participants with 25OHD deficiency had greater odds of having systolic (OR 1.80, 95%CI: 1.22, 2.65; p=0.003) as well as casual hypertension (OR: 1.48, 95% CI: 1.04, 2.11, p=0.03). Male gender decreased the odds of hypertension. Higher BMI, nephrotic range proteinuria and active vitamin D use were associated with higher odds of systolic hypertension (Table 1). 1,25$(OH)_2$D was significantly associated with hypertension (OR= 0.81, 95%CI: 0.70, 0.95) in univariate analysis only. Neither vitamin D measures were associated with ABPM hypertension.

Conclusions: 25OHD deficiency is associated with higher odds of persistent casual hypertension. It may be beneficial to maintain 25OHD levels >20 ng/ml to optimize BP control in children with CKD.

Funding: NIDDK Support

Mental Health Diagnoses and Substance Use in Children with CKD in the CKD in Children (CKiD) Study

Jessica L. Stahl,[1,2] Ann Vander stoep,[1] Aaron G. Wightman.[2] *[1]University of Washington, Seattle, WA; [2]Seattle Children's Hospital, Seattle, WA.*

Background: Mental health disorders are more common in children with chronic illness than in healthy counterparts. While a high prevalence of depression has been noted in children with chronic kidney disease (CKD), other mental health diagnoses and substance use have not been well described.

Methods: We evaluated the prevalence of mental health diagnoses utilizing parent-reported child mental health diagnoses and self-reported substance use among participants age 1-16 years at enrollment in the CKiD study. Descriptive statistics were used to characterize the distribution of mental health diagnoses and age of onset. Chi-squared, t-test, and log binomial regression were used to compare demographic factors including sex, race, and maternal education, and CKD characteristics including glomerular versus nonglomerular disease, disease progression, and height between those with and without a reported mental health diagnosis.

Results: Among CKiD participants (n=891) prevalence of any mental health diagnosis or substance use was 55% with mean onset reported at 13 years. The most common conditions were learning disorders (22%), alcohol use (22%), attention deficit and hyperactivity disorders (19%), depression (15%), anxiety (13%), and cannabis use (10%), with 30% reporting multiple diagnoses. Those with mental health diagnoses were more likely to have a mother with some college education (PR 1.2, 95%CI 1.1-1.4) than those without a diagnosis. Reported mental health diagnoses were less common among those who identified as Latino. (PR 0.5 95%CI 0.2-0.8). There were no other significant differences in the assessed demographic or CKD characteristics between those with and without mental health diagnoses.

Conclusions: A broad spectrum of mental health diagnoses are common in children with CKD. Despite limitations inherent in using self-reported retrospective survey data, this study provides impetus for more in-depth assessment of mental health in children with CKD, advocacy for greater mental health resources, and the development of targeted therapies for children with CKD and their families.

A Young Adult Nephrology Transition Clinic: A Successful Model

Laura Nishi,[1] Craig B. Langman,[2,3] Cybele Ghossein.[2] *[1]Nephrology/HTN, Northwestern Medicine, Chicago, IL; [2]Northwestern University- Feinberg School of Medicine, Chicago, IL; [3]Nephrology, The Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Survival of pediatric patients with chronic disease has increased leading to a greater number of patients transitioning from pediatric to adult care. A formal pediatric to adult transition process is important in improving medical adherence in these young adults. Despite this, few adult nephrology centers have transition protocols in place. To address this, we implemented a combined nephrology transition of care program at Lurie Children's Hospital (LCH) and Northwestern Medicine (NM). Here we present our 5 year data.

Methods: The pediatric team identified transfer patients and communicated with the adult team, a nephrologist, PA and social worker, about patient history and potential obstacles to successful transition. The initial appointment occurred at LCH with subsequent visits at NM. During all visits, patients had one on one time with each of the providers. Monthly reviews were conducted to determine if proper follow up had occurred and if not, procedures of enhanced follow up including phone calls and email were implemented.

Results: A total of 84 patients were seen with the results outlined in Table 1. Successful transition was defined as at least one follow up visit in the adult clinic. 40% of patients required enhanced follow up. 21% of patients either unsuccessfully transitioned or had delayed drop out, defined as lost to follow up after a successful transition.

Conclusions: Based on our five year experience, transition of care from pediatric to adult nephrology providers can be successfully facilitated with a protocol driven model that includes engagement of adult and pediatric teams. This patient group, however, is still at high risk of being lost to follow up.

Table 1: Patient outcomes.

Outcome	Transition Program Particpants (n=84)
Successful Transition One visit Two visits Three + visits	65 (78%) 13 (15%) 15 (18%) 37 (44%)
Unsuccessful Transition	6 (7%)
Delayed Drop Out	12 (14%)
Pending Follow Up	7 (8%)
Un enrolled	6 (7%)

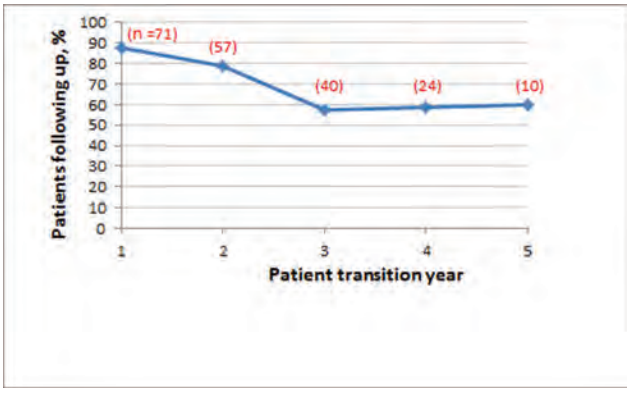

Figure 1: Follow up as a function of transition year.

Current Practice and Resources for Medication Adherence Assessment Among Pediatric Kidney Transplant Programs

Naureen Huda,[2] David K. Hooper,[3] Cozumel S. Pruette.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Adolescent/young adult kidney transplant recipients have 3 times the risk of allograft failure compared to other age groups. This is multifactorial, but barriers to medication adherence are a major contributor, present in up to 40%. To inform future adherence interventions, we assessed current practice patterns and resources available to address barriers to medication adherence among US pediatric kidney transplant programs.

Methods: Kidney transplant team members, including physicians (MD/DO), nurse practitioners (NP), physician assistants (PA), social workers (SW), and pharmacists, from 22 kidney transplant programs in the Improving Renal Outcomes Collaborative were surveyed about institutional characteristics, resources and current practice assessing medication adherence. 64 unique surveys were included, with representation from 22/26 (85%) of IROC-affiliated institutions.

Results: All teams indicated they have at least one MD/DO, nutritionist, and SW, which form the core team. Additional roles of NP, PA, transplant nurse, pharmacist, psychologist, and child life specialist were available in only some institutions. Each of 10 common barriers to medication adherence was reported to be assessed by at least one provider type during routine clinic visits. The majority reported assessing barriers to adherence at every clinic visit. However, subjective assessment methods were most commonly used, including forming a clinical impression based on history/exam and indirect and direct questions (Figure).

Conclusions: Provider assessment of medication adherence for pediatric kidney transplant patients varies among practices. While centers report that it is frequently assessed, subjective measures, which may overestimate adherence, are used most commonly. There is opportunity to standardize adherence barriers assessment with standard surveys/tools and to use objective measures, such as pharmacy refill records, to more accurately assess adherence. Future studies are needed to improve assessment of adherence.

A Single-Center Experience of Bortezomib in Pediatric Kidney Transplants With Long-Term Graft Outcome

Shefali Vyas,[1] Nihaal Nath,[2] Isabel Roberti.[1] *[1]Saint Barnabas Medical Center, West Orange, NJ; [2]West Orange High School, West Orange, NJ.*

Background: Acute antibody mediated rejection (aAMR) remains a challenge with poor renal allograft longterm outcome and unclear therapeutic efficacy of current therapies. We report the use of Bortezomib for treatment of persistent aAMR after failure of conventional therapy and long term graft and patient outcomes,.

Methods: Review of 118 kidney transplants (txp) from 2004-2019, noted - 4 had primary graft failure, 3 patients were deceased (2 with functioning grafts) and 3 were lost to follow up. 32 rejections- 12 with TCR and 20 with aAMR (biopsy proven by Banff criteria); All 20 aAMR received MP pulse, IVIG (1-2 g/Kg),10 PP treatments (1.5 to 2 plasma vol exchange/ rx) and Thymoglobulin (if ACR). On follow up 9/20 received Bortezomib 1.3mg/m2/dose IV x4 for persistent graft dysfunction with postivie DSA. Mean DSA titers (pre and post rx), eGFR, graft outcome, adverse effects infections were tracked in Bortezomib group. Graft outcome was also followed in patients with no rejection and + rejection aAMR/TCR.

Results: 9 received 10 doses of Bortezomib; Ethnicity: AA/Wh/ His/ Asian=33%(3)/33%(3)/22% (2)/ 11%(1), male 8 (89%), Age at txp :median 16.8 (3-20yrs), 7 (78%)received DDT, all received Induction (4 thymo for pre txp PRA >25%). Time to rejection: median 2.5 yrs (8 days- 8 yrs), 2 neg C4D and DSA; 1 de novo anti GBM GN and 1 had AT1R abs+. Infections: 1 oral Herpes+ oral candidiasis+ pneumonia, 1 herpes + atypical mycobacteria+ candida, 3 gastroenteritis and 1 C. difficle colitis, 1 prolonged EBV viremia and 1 cellulitis.(1.4 infections/pt) Follow up time: after txp 1-12 yr (median =3.8), postbortezomib = 0.5-9 yrs (median 1.5). Post bortezomib: eGFR improved from 58 to 79 ml/min/1.73M^2 (21%) and reduction in DSA = 36%. Other therapies: 1 Rituximab; 1 Cytoxan (anti GBM GN); 4 Thymoglobulin for TCR. Graft survival with Bortezomib: 100% at 1 and 3 yrs. 2 progressed to ESRD at 9 and 12 yrs (22% graft loss). Graft survival with no rejection (86): 92 % Graft loss overall: 24% (28/115): 4 primary non function, 2 expired with functioning grafts; Patient survival: 97.4%

Conclusions: Bortezomib was well tolerated well with few adverse effects; 36% reduction in DSA, 21% improvement in eGFR and graft loss 22%. Graft loss in children with no rejection was 8% compared to 47% with rejection (aAMR and TCR). Overall, graft loss was 24% and patient survival 97.4% as of last follow up.

TH-PO774

Fibroblast Growth Factor 23 and Anemia in Pediatric Renal Transplant Recipients

Blair N. Limm-Chan,[1] Katherine Wesseling-Perry,[1] Meghan Pearl,[1] Patricia L. Weng,[1] Eileen W. Tsai,[1,2] Mark R. Hanudel.[1] *[1]Pediatric Nephrology, University of California Los Angeles, Los Angeles, CA; [2]Pediatric Nephrology, Duke University, Durham, NC.*

Background: Pre-clinical studies have shown that anemia-related factors, specifically iron deficiency and increased erythropoietin (EPO), can induce FGF23 production. Studies of adult renal transplant recipients (RTR) have demonstrated independent associations between both lower iron levels and higher EPO concentrations and increased FGF23. In the present study, we evaluated cross-sectional and longitudinal associations between hematologic and FGF23 parameters in pediatric RTR.

Methods: Demographic, clinical, and standard biochemical data were collected from a cross-section of 59 pediatric RTR during routine clinic visits. Iron, EPO, C-terminal (total) FGF23 (cFGF23), and intact FGF23 (iFGF23) concentrations were measured in additional blood samples. Follow-up biochemical data and blood samples were collected from a subset of 29 patients six months later.

Results: Demographic, clinical, and baseline serum parameters are shown in **Table 1**. Neither cFGF23 nor iFGF23 was significantly associated with iron or EPO (**Table 2**). cFGF23 correlated inversely with hemoglobin (r=-0.38, p=0.003), while iFGF23 correlated positively with hemoglobin (r=0.28, p=0.03). The cFGF23-hemoglobin association remained significant after adjusting for eGFR, iron, and EPO. Change in cFGF23 over time tended to inversely correlate with change in hemoglobin (r=-0.34, p=0.07).

Conclusions: In pediatric RTR, differential associations between hemoglobin and cFGF23 vs. iFGF23 are observed, suggesting complex relationships among anemia, FGF23 production, and FGF23 metabolism that warrant further study.

Risk Factors for Early Readmission Post-Pediatric Kidney Transplantation: A Multicenter Study

Shanthi S. Balani,[1] Stephanie T. Nguyen,[5] Patricia L. Weng,[4] Daniel Ranch,[2] Jessica L. Brennan,[3] Paul R. Brakeman.[1] *[1]UCSF, San Francisco, CA; [2]UT Health San Antonio, San Antonio, TX; [3]UCSF Medical Center, San Francisco, CA; [4]UCLA, Los Angeles, CA; [5]University of California, Davis, Sacramento, CA.*

Background: Early hospital readmissions are associated with morbidity, mortality, significant health care costs and poor outcomes. To date, no published studies have evaluated risk factors for early readmission following pediatric kidney transplantation.

Methods: Retrospective chart review was performed for all pediatric kidney transplant recipients from 2012 – 2017 at the UCSF, UCD, UCLA and UT at San Antonio. Early hospital readmissions were defined as any unplanned admission within 30 days of being discharged from the hospital following a kidney transplant; admissions for elective procedures were excluded. Baseline characteristics evaluated included age, insurance type, race, prior dialysis, donor type, ischemia times, placement of transplant, induction agent, length of hospital stay, weekend discharge, hypertensive medications at discharge, tacrolimus levels, hemoglobin, albumin, and creatinine at discharge. Data regarding readmissions was collected, and analyzed using Student t-test for continuous variables and the chi square test for categorical variables.

Results: There were 308 pediatric kidney transplant recipients. The rate of early readmission was 31%. The leading causes for readmission were: elevated creatinine (30%), vomiting/diarrhea with dehydration (13%) and tacrolimus toxicity (8%). Discharge on weekend ($p<0.05$) and acute change in tacrolimus trough on day of discharge from 24-hours prior to discharge ($p=0.05$) significantly predicted readmissions. Other predictors that did not meet our criteria for significance for readmission included: elevated tacrolimus level on day of discharge($p=0.08$), more than 2 anti-hypertensives at discharge ($p=0.07$) and presence of ureteral stent at discharge ($p=0.07$). No difference was seen in readmission rates based on age, donor type, ischemia times, induction agent or length of initial hospitalization.

Conclusions: The rate of early readmissions for our pediatric population was similar to that reported in adult patients. Weekend discharge and change in tacrolimus significantly predicted readmission. Hospital course and discharge level factors were more predictive than patient related factors providing modifiable clinical factors for targeted interventions to reduce rate of readmissions in pediatric patients.

TH-PO776

Tandem Plasmapheresis on Continuous Renal Replacement Therapy in Pediatrics

Naile Tufan pekkucuksen,[1,2] Katharine Sigler,[4] Ayse Akcan Arikan,[2,3] Poyyapakkam Srivaths.[2] *[1]Pediatrics, Division of Pediatric Nephrology, University of FLorida, Gainesville, FL; [2]Pediatrics, Division of Pediatric Nephrology, Baylor College of Medicine, Houston, TX; [3]Pediatrics, Division of Critical care, Baylor College of Medicine, Houston, TX; [4]Texas Children's Hospital, Houston, TX.*

Background: Plasmapheresis (TPE) has been used successfully to reduce concentration of pathogenic antibodies, immune complexes, cryoglobulins and lipoproteins Continuous renal replacement therapy (CRRT) is the treatment modality for acute kidney injury, fluid overload and electrolyte and metabolic imbalance for unstable patients. Reported experience about simultaneous use of TPE and CRRT (referred to as tandem TPE) in pediatric (ped) patients (pts) is scarce.

Methods: We describe tandem TPE experience from our institution. Retrospectively reviewed ped pts receiving tandem TPE from 2013 to 2016. Centrifugal based TPE was performed, all CRRT patients received hemodiafiltration at minimum starting dose of 2000 ml/1.73m2/hour with regional citrate anticoagulation. For tandem TPE apheresis lines were "Y"ed in the circuit in parallel without using additional anticoagulation.

Results: 63 pts received tandem TPE, for a total 378 of TPE procedures on 1676 days of CRRT. Age ranged from newborn to 19 years old, weights ranged from 2.31 to 112.3 kg (17 pts were <10 kg and < 1 year old). Most common indications were coagulopathy and hepatic encephalopathy caused by acute liver failure (20 pts), thrombocytopenia associated multi-organ failure (TAMOF) (19 pts) and thrombotic microangiopathy (5pts). Median number of TPE session per pt was 5 (IQR:3;7). Median number of CRRT days was 12 (6; 37). All treatments were completed successfully. 57 (90%) patients had hypocalcemia and 59 (94%) patients had hypercalcemia at least one time during the treatments. 27 (43%) patients had citrate accumulation (defined by plasma total calcium/ionized calcium >2.5 mmol) during the treatments. All episodes were asymptomatic. Case mortality rate was 40%. Time to CRRT and TPE initiation was longer in non-survivors (NoS) vs survivors (3 d (1,9) vs 1 (1,2) & 4 d (2,13) vs. 2 (1,3) TPE) ($p=0.02$). PRISM score at ICU admission of NoS is significantly higher ($p=0.031$).

Conclusions: Tandem TPE treatment during CRRT can be effectively used in pediatric pts over a broad age and weight range. Complications including hypocalcemia are common though pts remained asymptomatic. Complex treatments need to be planned carefully with interdisciplinary team to address indications, technicalities and complications.

Renal Replacement Therapy of Hyperammonaemia in Pediatric Patients

Yeshwanter Radhakrishnan,[1] Rupesh Raina.[2] *[1]Akron General Medical Centre, Akron, OH; [2]Nephrology, Cleveland Clinic Akron General, Akron, OH.*

Background: Hyperammonemia is the accumulation of ammonia in the blood that may result in an acute life-threatening event in pediatric populations. Management of hyperammonemia proves to be difficult in pediatric populations given the non-specific clinical symptoms, the age-specific etiologies, and the lack of consensus in the treatment plan. In our review, we sought to systematically search the published literature to comprise guidelines for non-renal replacement therapy (RRT) and renal replacement therapy in pediatric patients.

Methods: A database search using PubMed/Medline, Embase and Cochrane was performed to include publications about hyperammonemia and renal replacement therapy in the pediatric population. An expert panel of pediatric nephrologists made up the workgroup and they were responsible to review and propose recommendations for renal replacement therapy guidelines for hyperammonemia children.

Results: The initial search returned a total of 477 citations of which only 25 studies met our inclusion criteria. A total of 132 patients were included in the study. Hemodialysis indications included hyperammonemia refractory to medical management and hyperammonemia coma. The most common of hyperammonemia was inborn errors of metabolism (IEM). Among the type of RRT used, CRRT had a 60% success rate and peritoneal dialysis (PD) had a 65% success rate

Conclusions: We recommend initiating renal replacement therapy when blood ammonia levels >150µmol/L with coma or cerebral edema and when blood ammonia level > 400µmol/L refractory to non-RRT measures. Intermittent hemodialysis is more effective than PD or CRRT as it clears ammonia faster but associated with rebound hyperammonemia and can cause hypotension and rapid osmotic shifts. PD is a quick alternative to immediate hyperammonemia management if CRRT is not available. Treating with high dose-CRRT allows for rapid clearance of ammonia done on a single dialysis run. A hybrid method of CRRT with ECMO support can increase the patient's blood volumes, allows for use of a larger cannula, avoids hemodynamic instability.

TH-PO778

A Case Series of Iodine-Induced Hypothyroidism in Children on Peritoneal Dialysis

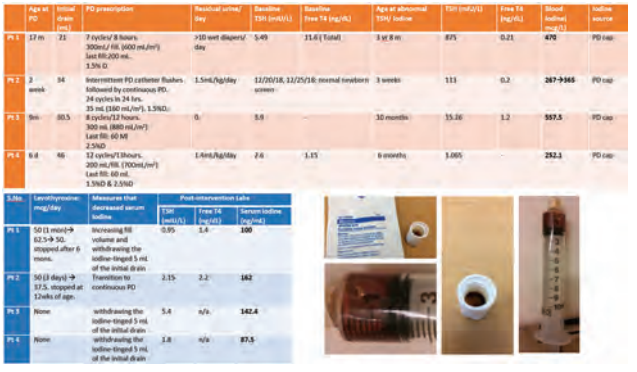
Sai Sudha Mannemuddhu,[1] Heather Morgans,[3] Naile Tufan pekkucuksen,[4] Bradley A. Warady,[2] Lawrence R. Shoemaker.[4] *[1]University of Florida. College of Medicine., Gainesville, FL; [2]Children's Mercy Kansas City, Kansas City, MO; [3]Children's Mercy Hospital, Kansas City, MO; [4]University of Florida, Gainesville, FL.*

Background: Young patients with end-stage renal disease who receive chronic peritoneal dialysis (CPD) are at increased risk for thyroid dysfunction. An extremely rare cause of thyroid dysfunction in these patients is iodine exposure. We report four patients who received CPD and developed Iodine overload and secondary hypothyroidism.

Methods: case series

Results: The 4 children, 3 weeks to 3.5 years of age, were cared for in two academic institutions in 2017-2019. Three patients were on automated cycler PD and one received manual flushes over a week and was on continuous PD. PD fill volumes ranged from 160 to 880 mL/m^2 BSA. They had normal baseline thyroid stimulating hormone (TSH) levels or normal newborn screens. They were on PD for periods of 1 week to 27 months, with median age of 6 months at presentation. 3 out of 4 patients had high TSH values ranging from 15-875 mIU/L, 2 of the 4 had a low free T4 from 0.2- 0.21 ng/dL, and all 4 had high serum iodine levels: 222-557.5 mcg/L (normal: <100 mcg/L). In every case, a transfer set with betadine gauge was utilized as part of their PD procedure. One patient developed overt hypothyroidism and heart failure and one experienced growth failure, while the other two were asymptomatic. Two patients required temporary treatment with levothyroxine (2.5 months – 6 months). Iodine levels decreased in all patients after switching them to continuous manual PD or by withdrawing the first 5 mL of iodine tinged fluid from the transfer set before connecting them to the PD cycler. Despite extensive investigation, no alternative sources of iodine exposure were detected.

Conclusions: Excessive iodine exposure and the potential for thyroid dysfunction, especially during infancy, is a poorly recognized complication of CPD. Increased awareness among nephrologists is needed so that prevention strategies and regular monitoring for this complication can be instituted.



Patient summary table. syringe and PD cap with iodine tinged fluid.

Physician Practices Regarding Physical Activity Restriction in Pediatric Hemodialysis Patients: A Qualitative Study

Raja Dandamudi,[1] Katherine Twombley,[2] Joseph T. Flynn,[3] Aadil K. Kakajiwala,[4] Deepa H. Chand.[5] *[1]Washington University in St. Louis School of Medicine, Glencoe, MO; [2]Medical University of South Carolina, Charleston, SC; [3]Seattle Children's Hospital, Seattle, WA; [4]Washington University in St Louis, St. Louis, MO; [5]Abbvie, Chicago, IL.*

Background: Children with chronic kidney disease (CKD) due to multiple hospitalizations and interventions have less physical activity. This sedentary lifestyle in CKD is associated with a higher cardiovascular mortality risk. In those patients receiving hemodialysis (HD) time spent on dialysis and restrictions on physical activity due to access also contribute. No consensus exists regarding physical activity restrictions based on vascular access type. The aim of the study is to assess pediatric nephrologists' practices regarding physical activity restrictions in children receiving HD.

Methods: The study was conducted through the Midwest Pediatric Nephrology Consortium using an anonymous, self-administered survey of pediatric nephrologists to evaluate the activity restrictions placed on HD patients with arteriovenous fistulae (AVF) and central venous catheters (CVC). The survey consisted of 19 items, 6 questions detailed physician characteristics with the subsequent 13 addressing physical activity restrictions.

Results: 35 responses (35% response rate) were received Average years in practice after fellowship: 11.5 years (range: 1-35). Dialysis units had 1– 12 stations (mean 6) Physical activity restrictions by physicians are summarized in tables. None of the participants reported accesses damage or loss that was attributed to physical activity and sport participation. Physicians practice is based on their personal experience, standard practice at their hemodialysis center and the clinical practices they were taught.

Conclusions: There is no consensus amongst pediatric nephrologists about physical activity that can be allowed in children receiving HD. Due to the lack of objective data, individual physician beliefs have been utilized to restrict activities in the absence of any deleterious effects to accesses. This survey clearly demonstrates the need for more prospective and detailed studies and guidelines regarding the physical activity and dialysis access care in order to optimize quality of care in these children.

Table I

Age groups(in Years) with number of patients in each group				
<2	2-5	6-10	10-18	>18
17	17	30	78	21

Table II

Type of Physical Activity	% physicians restricting	Comments
Push-up exercise	27	
Chin-up Exercise	34	
Weight Lifting	25	Those allowing weight use light weights of 5-10 lbs.
Organized sports	24	Among the organized sports wrestling and martial arts were universally restricted. Football, field hockey, ice hockey was also restricted by most of the physicians. 2 physicians restricted using Rifle/Shotgun.

Table III

Water exposure restrictions in patients with CVC	% physicians restricting activity
Showering	34
Bathing	66
Swimming in chlorinated pools	95
Swimming in Oceans	97.5
Swimming in fresh water	0

Colostomy in Children on Chronic Peritoneal Dialysis

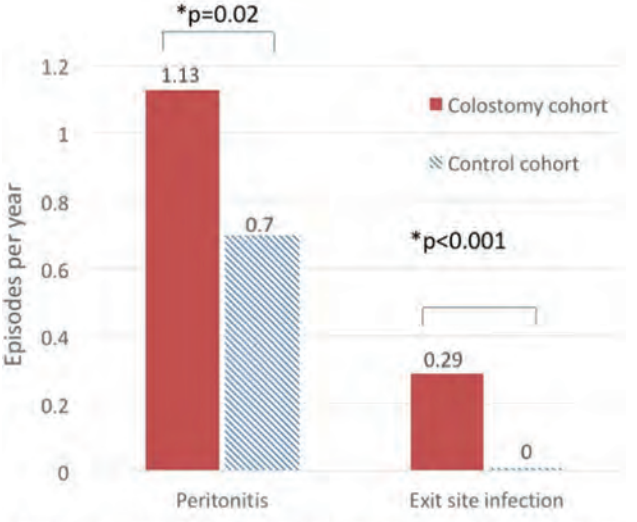
Yu hin E. Chan,[1] Dagmara Borzych-duzalka,[4] Franz S. Schaefer,[3] Bradley A. Warady.[2] International Pediatric Peritoneal Dialysis Network *[1]Paediatric Nephrology, Hong Kong Children's Hospital, Hong Kong, Hong Kong; [2]Children's Mercy Kansas City, Kansas City, MO; [3]University of Heidelberg, Heidelberg, Germany; [4]Medical University of Gdansk, Gdansk, Poland.*

Background: The aim of this study was to evaluate the outcome of children on chronic peritoneal dialysis (PD) with a concurrent colostomy.

Methods: Patients were identified through the International Pediatric Peritoneal Dialysis Network (IPPN) registry. Age-matched controls were randomly selected from the registry. Data were collected through the IPPN database and a survey disseminated to all participating sites.

Results: 15 centers reported 20 children who received chronic PD with a co-existing colostomy. The commonest cause of end-stage kidney disease was congenital anomalies of kidney and urinary tract (n=16, 80%). The main reason for placement of a colostomy was anorectal malformation (n=13, 65%). The median age at colostomy creation and PD catheter (PDC) insertion were 0.1 [IQR, 0-2.2] and 2.8 [IQR 0-2.2] months, respectively. The colostomies and PDCs were present together for a median 18 [IQR, 4.9-35.8] months. The median age at PDC placement in 46 controls was 4.2 [IQR, 3.6-10.8] months. 14 patients (70%) developed 39 episodes of peritonitis. The annualized peritonitis rate was significantly higher in the colostomy group (1.13 vs 0.70 episodes per patient year; p=0.02). Predominant causative microorganisms were staphylococcus aureus (15%) and pseudomonas aeruginosa (13%). There were 10 exit site infections (ESI) episodes reported exclusively in colostomy patients. Seven children (35%) died during their course of PD, in two cases due to peritonitis.

Conclusions: Although chronic PD is feasible in children with a colostomy, it is associated with an increased risk of peritonitis, ESI, and mortality. Continued efforts to reduce the infection risk for this complex patient population are essential.



Catheter-associated infection rates in the colostomy and control cohorts

TH-PO781

Mortality in Children with ESRD: A Guatemalan Retrospective Cohort Study

Josue A. Morales,[2] Angie L. Aguilar,[1] Randall M. Lou-Meda,[1] Larissa M. Almorza.[2] *[1]Fundanier, Guatemala, Guatemala; [2]Universidad de San Carlos, Guatemala, Guatemala.*

Background: Mortality rates and long-term survival data in ESRD children are sparse although different modalities of RRT have been used during decades We evaluate the mortality overtime in a tertiary hospital in Guatemala

Methods: After ethics approval, we performed a single center retrospective cohort study of all patients with ESRD younger than 18 years, between Jan2015 and Dec2017 Mortality rate was expressed as number of deaths/1000patients Mortality incidence rate, expressed as number of deaths/100patient-years was determined by, sex, RRT and age Long-term survival rates were calculated by Kaplan Meier test and significant confirm by Log Rank and Breslow tests

Results: A total of 370 charts were reviewed. Of those, 115 were from PD, 221 from HD and 34 from transplant. During the study period 25 patients died. Of those, 52%(13/25) were female, the mean age was 12.7yr(SD 3.4), 72%(18/25) were from HD and the rest from PD(7/25). No deaths from transplanted patients were reported during the study. The mortality rate in 2015, 2016 and 2017 were 50, 50 and 32/1000patients. The mortality incidence rate was 8.20/100patient-years. No difference in mortality incidence rate was found by sex (fem 8/100patient-years, masc 8.4/100patient-years). The highest incidence of mortality rate was found in the HD and in the 5-9 age group (17.35/100patient-years, 20/100patient-years). When analyzing long-term survival rates using Kaplan Meier, the overall mortality rate at 3 years was 20%; no significant difference was identified by sex (p, 0.509) nevertheless; a significant difference was found between HD(38%) and PD(16%), p, 0.001. Regarding age, no significant difference in mortality rate between the 5-9, 10-14 and 15-18 age groups was identified at 2 years (25%,15%,10%), (p, 0.174)

Conclusions: In our study, the overall mortality incidence rate was higher than reported in literature Mortality rate, incidence mortality rate and long-term survival were similar between the sexes. Among age, the 5-9 years group demonstrated the highest mortality rates Regarding RRT, the incidence mortality rates in PD is comparable with literature; however, our HD mortality rates are 4 times higher than what has patient-years Increasing the proportion of children treated with renal transplantation and PD rather than HD can improve survival further and costs in our centre

TH-PO782

The Effect of Socioeconomic Status and Distance to Specialist Hospital on Access to Paediatric Nephrology Care in England

Lucy A. Plumb,[1,5] Anna Casula,[5] Manish Sinha,[2] Carol D. Inward,[3] Yoav Ben-shlomo,[4,1] Fergus J. Caskey.[4,1] *[1]University of Bristol, Bristol, United Kingdom; [2]Paediatric Nephrology, Evelina London Children's Hospital, Guys & St Thomas' Foundation Hospitals NHS Trust, London, United Kingdom; [3]Bristol Royal Hospital for Children, Bristol, United Kingdom; [4]Population Health Sciences, Bristol, United Kingdom; [5]UK Renal Registry, Bristol, United Kingdom.*

Background: For children with end-stage kidney disease (ESKD), transplantation is the preferred treatment of choice, offering improved survival and quality of life. Pre-emptive transplantation (PET) is advocated as best practice. Access however is limited by late presentation of kidney disease, defined as starting renal replacement therapy (RRT) within 90 days of first presentation to a nephrologist. In this study we aim to explore whether socio-economic status (SES) or geographical remoteness from centre are associated with 1) timing of presentation to nephrology services and 2) access to PET.

Methods: A cohort study using UK Renal Registry and NHS Blood & Transplant data from 01/01/1996-31/12/2016 was performed. Children in England aged up to 16 years receiving chronic RRT were included. Exposures of interest were distance from home to paediatric nephrology unit (per 10km) and SES, as measured by the UK Index of Multiple Deprivation (IMD) quintiles. Study outcomes were 1) late presentation and 2) PET (transplant recorded as first RRT modality). Late presenters were excluded from the PET analysis. Multivariable logistic regression analyses were performed, covariates were determined *a priori* and included age, gender, ethnicity, renal disease and time-period.

Results: During the study-period, 1856 children received RRT (776 females, 41.8%), with a median age of 3.8 years at presentation. Of these, 426 were late presenters (24.4%); 37.4% of non-late presenters (n=1271 without missing data) underwent PET. No association was seen between distance or SES with late presentation, on crude or adjusted analyses. As SES increased, odds of PET increased by 12% per quintile (OR 1.12, 95% CI 1.02, 1.23, p=0.02). Similar findings were seen among White patients only to exclude any effect of ethnic minorities. Increasing distance from centre was strongly associated with PET in crude analyses, however this effect was markedly attenuated (p=0.16) in the fully adjusted model.

Conclusions: SES or distance from centre are not associated with late presentation of childhood kidney disease. Access to PET increases with SES. Clinicians should be aware of this finding and ensure timely support is provided to disadvantaged families in the pre-dialysis phase to ensure optimum access to early transplantation.

TH-PO783

Differential Metabolomic Profile Within Primary Hyperoxaluria Patients

Cristina Martin Higueras,[3,1] Eduardo C. Salido,[2] Bernd Hoppe,[1] Christian Kurts.[3] *[1]University Hospital Bonn, Bonn, Germany; [2]Hospital Universitario Canarias, La Laguna, Tenerife, Spain; [3]Institute of Experimental Immunology, Bonn, Germany.*

Background: The three types of primary hyperoxaluria (PH) are liver specific enzyme defects inducing endogenous oxalate overproduction, thus hyperoxaluria, urolithiasis and/or nephrocalcinosis, as well as intrarenal deposition of calcium oxalate crystals, leading to chronic kidney disease and renal failure (PH1&2). Severe infantile cases (PH1) directly present systemic crystal deposition (oxalosis), but otherwise the clinical progression of PH subtypes profoundly differs, for unknown reasons. PH patients bear pathogenic mutations in either *AGXT* (PH1), *GRHPR* (PH2) or *HOGA1* (PH3) genes, causing a misbalanced hepatic glyoxylate metabolism that overproduces oxalate. Here, we aimed to unveil other misbalanced metabolites in PH1, PH2 and PH3 both in mouse models and patients to understand the heterogenous pathogenesis of PH, to reveal new biomarkers for differential diagnosis and to find modulators of their immune response.

Methods: All patients signed an informed consent. Serum from 19 PH1, 5 PH2, 7 PH3 and 9 control patients as well as plasma from 4 PH1, 4 PH3, 4 PH1/PH3 and 4 wildtype mice were obtained. Samples were analyzed by the global metabolomics technology of Metabolon®, and stool samples (18 PH1, 6 PH3 patients; 4 PH1 and 4 wt mice) by the Institute of Microecology (Germany). Data followed log transformation and Welch's two-sample t-test for statistical analysis.

Results: PH3 mice metabolome showed stronger differences to wt than PH1, mostly in aminoacid, carbohydrate and xenobiotic related metabolism. Both PH1 and PH3 mice shared a strong misbalanced lipid metabolism. Xenobiotic metabolism correlated with differential microbiota in PH1 compared to wt mice. Ongoing human metabolome and microbiota analysis is aimed at translating our findings into the human situation.

Conclusions: Our preliminary findings suggest: i) increased levels of diverse metabolites may reflect impaired kidney function accumulating these compounds in the blood; ii) general reduction on lipid levels may reflect a weakened oxidative metabolism for energy production and impaired intracellular cascades, some of them related to inflammatory signaling; iii) microbiota may influence PH pathogenesis. Further exploration of candidate metabolites *in vitro* and *in vivo* may help elucidating their role in mechanisms of disease and their use as biomarkers for diagnosis and treatment.

Impact of Dialysis Adequacy on Morbidity in Children on Chronic Hemodialysis: A North American Pediatric Renal Trials and Collaborative Studies Report

Raja Dandamudi,[1] Karen Martz,[4] Stanley P. Hmiel,[5] Vikas R. Dharnidharka,[3] Aadil K. Kakajiwala.[2] *[1]Washington University in St. Louis School of Medicine, Glencoe, MO; [2]Washington University in St Louis, St. Louis, MO; [3]Washington University School of Medicine, St Louis, MO; [4]NAPRTCS, Rockville, MD; [5]St. Louis Children's Hospital, St. Louis, MO.*

Background: Reliance on small solute clearance as a measure of dialysis adequacy fails to fully quantify the intended clinical effects of dialysis therapy. We aimed to study the relationship between dialysis adequacy, as measured by single-pool Kt/V (spKt/V) and urea reduction ratio (URR), and patient morbidity as measured by growth, nutrition and anemia control.

Methods: We included 391 patients (median age of 14.3 years [range: 1.0 - 18.9]) in the North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) database receiving chronic hemodialysis three times a week. Using goal sp Kt/V of 1.2-1.5 and URR of 65-75% we compared weight, height, albumin, hemoglobin (Hb) and erythropoiesis stimulating agent (ESA) dose at 12 months from initiation of HD (initiated between Jan '03 to Dec '18). Kruskal-Wallis test was used to compare these measures in patients at, above, and below goal values of dialysis adequacy.

Results: Results of the univariate analysis are summarized (Table 1A & B). For patients with URR and spKT/V above goal, the median weight z-scores was 0.6 and 0.7 points lower when compared to those with values within goal levels. Similarly, for patients with URR and spKT/V above goal, the height z-scores was 1.0 and 0.8 lower than the within goal levels. Patients with URR < 65% had 0.7 g/dL higher median Hb compared to within goal levels of URR. We noted no significant relationship between dialysis adequacy and serum albumin, ESA doses

Conclusions: Preliminary results show significantly lower weight and height in patients with dialysis adequacy above goal values. This may reflect low volumes of distribution (V). Further analysis of the database at multiple time points from initiation of HD with help describe associations between dialysis adequacy and patient morbidity.

Univariate analysis between URR (1A) and Kt/V (1B) and measures of patient morbidity at 12 months after initiation of dialysis

TH-PO785

Metabolomic Profiling for Discovery of Biomarkers of Neurocognitive Impairment in Children with CKD

Michelle Denburg,[1] Yunwen Xu,[2] Alison G. Abraham,[8] Josef Coresh,[3] Jingsha Chen,[3] Casey Rebholz,[8] Eugene P. Rhee,[4] Harold I. Feldman,[7] Paul L. Kimmel,[6] Stephen R. Hooper,[9] Bradley A. Warady,[5] Susan L. Furth.[1] CKD Biomarkers Consortium *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Johns Hopkins School of Public Health, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [4]Massachusetts General Hospital, Newton, MA; [5]Children's Mercy Kansas City, Kansas City, MO; [6]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [7]University of Pennsylvania, Philadelphia, PA; [8]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [9]University of North Carolina School of Medicine, Chapel Hill, NC.*

Background: Mechanisms underlying neurocognitive impairment in CKD remain unknown. We sought to perform the first large-scale discovery of novel blood metabolite biomarkers of neurocognitive impairment in children with CKD.

Methods: Untargeted GC/MS2 and LC/MS2-based metabolomics quantification (Metabolon) was performed on baseline plasma samples from 498 Chronic Kidney Disease in Children (CKiD) participants. We applied linear regression models to examine the cross-sectional association between standardized, log transformed metabolites (n=825) and intellectual functioning (IQ score), adjusted for demographics, CKD-related clinical characteristics, and socioeconomic status (SES). Statistical significance was determined using a threshold to keep the false discovery rate (FDR) <0.05.

Results: Cohort characteristics were: 312 (63%) male; median age 12 years (IQR 8,15); median eGFR 52 mL/min/1.73m^2 (IQR 38, 64); 377 (76%) non-glomerular diagnosis. Median IQ score was 99 (IQR 87, 108). In unadjusted analyses, 13 metabolites were associated with IQ score. (Figure) Two metabolites, 2-hydroxyarachidate (a fatty acid) and xanthurenate (a product of tryptophan metabolism), were positively associated with IQ independent of age, sex, race, BMI z-score, hypertension, low birthweight/prematurity, glomerular vs. non-glomerular diagnosis, duration of CKD, proteinuria and estimated glomerular filtration rate (eGFR). With additional adjustment for SES, no metabolite associations with IQ were statistically significant.

Conclusions: Untargeted metabolomic profiling identified two metabolites associated with IQ in children with CKD that were independent of most demographic and CKD-related clinical factors, although the inclusion of SES eliminated the statistical significance of these relationships. Further studies are needed to extend these analyses to other neurocognitive domains and delineate mechanisms.

TH-PO786

Outcomes of Maintenance Dialysis in Children Younger Than 24 Months: A NAPRTCS Report

Shina Menon,[1] Jodi M. Smith,[1] Karen Martz,[2] Raj P. Munshi.[1] *[1]Seattle Children's Hospital, Seattle, WA; [2]NAPRTCS, Rockville, MD.*

Background: Peritoneal dialysis (PD) is the preferred mode of renal replacement therapy (RRT) in infants and young children with end-stage renal disease (ESRD). Hemodialysis (HD) is less used due to technical challenges and risk of complications in smaller patients. There are limited data on the impact of different dialysis modalities on clinical outcomes in this group

Methods: Data were extracted from the North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) registry. Demographic, clinical, and laboratory data on patients < 24 months age between January 1992 and December 2018 were analyzed. We compared patient survival and access to kidney transplantation using log rank test between children treated with PD or HD

Results: 1014 infants initiated dialysis therapy on PD; 114 on HD. Mean(SD) age at PD onset was 6.9 (6.8) months and at HD onset was 12.0 (7.2) months. Infants treated with PD more often had congenital anomalies of the kidney and urinary tract/obstructive uropathy (55% vs 40%, p<0.05). At 1, 6 and 12 months post dialysis onset, PD patients had significantly lower serum albumin (Figure 1). Hemoglobin was lower in HD patients at 1 and 6 months, but similar at 12 months between the groups. Time to transplant was lower for HD patients, but patient survival on dialysis was similar (Figure 2)

Conclusions: Although HD is not first line modality for RRT in younger children, 10% of children < 2years age start maintenance dialysis on HD therapy. Patients starting HD are more likely to be older and non-white. Patient survival on dialysis is similar irrespective of dialysis modality

Table 1: Characteristics of young children on peritoneal and hemodialysis

	Peritoneal Dialysis	Hemodialysis
N	1011	114
Age (months)	6.9 (6.8)	12.0 (7.2)*
Female	335 (33.1%)	41 (36.0%)
Non-White	388 (38.4%)	58 (50.9%)*
Primary disease		
Congenital anomalies of kidneys and urinary tract/Obstructive uropathy	568 (56.2%)	45 (39.5%)*
Other	443 (43.8%)	69 (60.5%)
Hematocrit (%)		
At 1 month	32.1 (5.9)	28.8 (6.4)*
6 month	32.9 (5.6)	30.1 (7.0)*
12 month	32.7 (5.6)	32.1 (5.6)
Albumin g/dL		
At 1 month	3.2 (0.8)	3.7 (0.7)*
6 month	3.4 (0.6)	4.0 (0.6)*

Cerebral Oxygenation Changes in Pediatric Chronic Hemodialysis

Alexandra Idrovo,[1] Poyyapakkam Srivaths,[2] Jessica Geer,[2] Sarah J. Swartz,[3] Ayse Akcan Arikan.[4] *[1]Texas Children's Hospital-Feign Tower, Houston, TX; [2]Texas Children's Hospital, Houston, TX; [3]Baylor College of Medicine, Texas Children's Hospital, Houston, TX; [4]Baylor College of Medicine, Houston, TX.*

Background: Intradialytic circulatory stress has been well described in adults as tissue ischemia to diverse organs (heart, gut and brain) during hemodialysis (HD). We aimed to determine if pediatric patients had intradialytic changes in cerebral oximetry (CEOx) by using near infrared spectroscopy (NIRS), a continuous, non-invasive method that uses infrared light to penetrate the skull and provides real time regional oxygen saturation (rSO2) from the frontal cortex. NIRS correlates well with more invasive measures of cerebral perfusion, doppler ultrasound and MRIs.

Methods: Prospective study in 14 patients <21 years old with more than 90 days on HD, on room air, without congenital heart disease. We used continuous NIRS and pulse oximetry (SpO2) monitoring, and obtained co-oximetry measured central venous oxygen saturation (SvO2) at the start, middle, and end of HD treatment. CEOx data was extracted at the exact times SvO2 was measured. Data collected over 2 HD treatments for each patient.

Results: Continuous monitor of spO2 showed no hypoxia during recorded HD treatments. Svo2 decreased from HD start 73(SD=7.7) to end of treatment 64.8(SD=9.1), mean difference 8.17(CI 2.3 to 14) p=0.01; CEOx also decreased from 74(SD=6.3) to 70(SD=5.7) mean difference 3.8(CI 1.5 to 6.2) p=0.002. For every 1 unit drop of SvO2 the CEOx decreased by 0.5 at the end of HD (β-1.0 (CI -2.6 to -0.4)).

Conclusions: Intradialytic CEOx and SvO2 falls significantly during HD in the absence of declining SpO2. These data suggest HD leads to cerebral dysoxia, though it is unclear whether the mechanism is related to decrease oxygen delivery, increased extraction or a combination of both at the tissue level. Future studies are needed to explore these physiological changes as well as the impact the cognitive functioning of children receiving chronic HD.

TH-PO788

Guidelines on Prescribing Prolonged Intermittent Renal Replacement Therapy (PIRRT) in a Child in an ICU Setting

Yeshwanter Radhakrishnan,[1] Rupesh Raina,[2] Manpreet K. Grewal.[3] *[1]Cleveland Clinic Akron General, Akron, OH; [2]Nephrology, Cleveland Clinic Akron General, Akron, OH; [3]Akron Nephrology Associates, Akron, OH.*

Background: Renal replacement therapies (RRT) are a cornerstone in the management of critically ill children who are often hemodynamically compromised. By virtue of their small size and large volume required in the extracorporeal circuit it often becomes difficult to perform conventional hemodialysis to provide RRT support in these children. Continuous renal replacement therapy (CRRT) is the accepted alternative but is associated with the high cost and limited availability. Thus, in resource-poor settings, peritoneal dialysis becomes the mainstay of management but has the disadvantages of increased risk of infections, inability to control the ultrafiltration and interfering with the ventilatory parameters. Prolonged intermittent renal replacement therapy (PIRRT) which is RRT given intermittently over a prolonged session is a modality that provides the advantages of a CRRT in a cost-effective way. PIRRT has been widely accepted in adults but data on PIRRT in children is sparse.

Methods: We searched the PubMed/Medline, Embase and Cochrane Database for all the publications on PIRRT and two experts from the Pediatric Continuous Renal Replacement Therapy (PCRRT) Workgroup assessed titles, abstracts, and full-text articles for extraction of data. The data from the literature search was shared with the PCRRT workgroup and expert panel recommendations were developed.

Results: We recommend that sustained low-efficiency dialysis (SLED) be initiated for all critically ill children requiring RRT along with inotropic support if necessary. SLED should also be initiated for acute kidney injury (AKI) with multi-organ dysfunction and poor Pediatric Risk of Mortality (PRISM) scores. The rates of blood flow and dialysate flow are decided based on hemodynamic stability and are usually similar to CRRT. Duration of therapy may be anywhere between 6-18 hours and may be performed 3 times a week or more. Any machine that is used for IHD may be used for delivering PIRRT provided it has the provision of lowering the blood flow and dialysate flow rates and can prolong the duration of therapy to 6-8 hours.

Conclusions: We recommend that sustained low-efficiency dialysis (SLED) be initiated for all critically ill children requiring RRT along with inotropic support if necessary.

TH-PO789

Identifying Factors Associated with Mortality in Pediatric Hemodialysis Patients Using a Machine Learning Approach

Verena Gotta,[1] Olivera Marsenic Couloures,[2] Georgi Tancev,[1] Julia Vogt,[3] Marc Pfister.[1] *[1]University of Basel Children's Hospital, Basel, Switzerland; [2]Yale University School of Medicine, New Haven, CT; [3]ETH Zurich, Zurich, Switzerland.*

Background: Mortality in pediatric end-stage renal disease patients is ≥30 times higher than in healthy children, and higher on chronic dialysis than after kidney transplantation. We aimed to explore factors associated with mortality on chronic hemodialysis (HD) in patients having started HD at pediatric age.

Methods: Data used originate from a cohort of patients <30 years on chronic HD since childhood, having received thrice-weekly HD between 2004 and 2016 in outpatient DaVita dialysis centres. Patients with 5-year follow-up since initiation of HD, or death within 5 years, were included. 106 variables ("features") relating to demographics, HD treatment and laboratory measurements were considered as predictors for 5-year mortality using a machine learning approach (random forest). Among correlated features (ρ>0.7) only the variable with higher clinical significance was retained. Accuracy was evaluated by 30 bootstraps.

Results: 363 patients were included in the analysis (n=84 <12 years and n=279 of 12-19 years at initiation of HD). Albumin and lactate-dehydrogenase were retained as the two most important features of 5-year mortality, other features retained in the final model included: lymphocyte count, red blood cell distribution width, red blood cell count, hemoglobin, z-score weight for age, post-HD systolic blood pressure, albumin/globulin ratio, ultra-filtration rate, creatinine and total spKt/V. Mortality was predicted with an accuracy of 81% (standard deviation: ±5%).

Conclusions: Mortality in paediatric patients on chronic HD is associated with multifactorial unspecific markers of nutrition, inflammation, anemia, cardio-vascular risk and dialysis dose. This highlights importance of multimodal intervention strategies besides adequate HD treatment. The association with lactate-dehydrogenase was not expected, but may indicate relevance of blood-membrane interactions, organ-malperfusion or metabolic changes during chronic HD treatment.

TH-PO790

CG200745, a Novel Histone Deacetylase Inhibitor, Attenuates Kidney Fibrosis in a Murine Model of Alport Syndrome

Sangheon Suh,[1] Hong sang Choi,[1] Chang Seong Kim,[1,2] Seong Kwon Ma,[1,2] James W. Scholey,[3] Soo Wan Kim,[1,2] Eun Hui Bae.[1,2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea; [3]University of Toronto, Toronto, ON, Canada.*

Background: Histone modification has been a target of therapy for progressive renal fibrosis. Here we report the protective effect of CG200745, a novel histone deacetylase inhibitor, on tubulointerstitial fibrosis in a murine model of Alport syndrome.

Methods: Col4a3$^{-/-}$ mice were used as a murine model of experimental AS. To examine the effects of CG200745 on the kidney of Col4a3$^{-/-}$ mice, CG200745 was orally administered in drinking water. To investigate the cellular mechanisms, HK-2 cells, a human proximal tubular epithelial cell line, were treated with CG200745 and/or angiotensin II (Ang II).

Results: Expression of fibrosis markers, such as αSMA, fibronectin and collagen I, significantly increased in Col4a3$^{-/-}$ mice at the age of 7 weeks, which was counter-regulated by CG200745 treatment, indicating attenuation of kidney fibrosis. CG200745 prevented the activation of transforming growth factor β (TGFβ) and its downstream Smad signaling in the kidney of Col4a3$^{-/-}$ mice. As critical upstream regulators of TGFβ signaling, Ang II, angiotensin converting enzyme (ACE), and TNFα-converting enzyme were upregulated and ACE2 and Mas receptor were downregulated, respectively, in the kidney of Col4a3$^{-/-}$ mice, suggesting activation of intra-renal renin-angiotensin system, with concurrent activation of inflammation and apoptosis, which were effectively suppressed by CG200745. Mechanistically, we found the positive feedback loop between RAS and TGFβ in HK-2 cells. CG200745 alleviated upregulation of TGFβ and activation of its downstream in Ang II-stimulated HK-2 cells by histone modification, preserving the protein expression of ACE2 and Mas receptor.

Conclusions: CG200745 targets TGFβ to preserve ACE2-Ang-(1-7)-Mas receptor axis and attenuates tubulointerstitial fibrosis in the kidney of Col4a3$^{-/-}$ mice.

SMPDL3b Regulates Proteinuria in Experimental Alport Syndrome

Alla Mitrofanova,[1] Antonio M. Fontanella,[3] Judith T. Molina David,[3] Javier T. Varona Santos,[3] Lorenza Macrina,[2,1] George W. Burke,[4] Sandra M. Merscher,[3] Alessia Fornoni.[3] Katz Family Division of Nephrology and Hypertension *[1]Nephrology, University of Miami, Miami, FL; [2]IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]University of Miami, Miami, FL; [4]University of Miami Miller School of Medicine, Miami, FL.*

Background: Sphingosine-1-phosphate lyase insufficiency causes accumulation of sphingosine-1-phosphate (S1P) and is associated with focal segmental glomerulosclerosis (FSGS), that is often characterized by the recurrence of proteinuria after kidney transplantation. We previously reported that podocyte injury in recurrent FSGS is associated with downregulation of sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b), an enzyme localized in lipid raft domains that regulates lipid composition and plasma membrane fluidity. Alport syndrome (AS) is an inherited glomerular disease with FSGS-like lesions. In this study we tested the hypothesis that dysregulation of renal SMPDL3b expression affects the generation of bioactive sphingolipids thus contributing the renal disease in AS.

Methods: Mice with experimental AS (Col4a3-/- mice) were used in this study. To investigate the contribution of SMPDL3b to the renal phenotype in AS mice, AS mice were crossed to mice with podocyte-specific *Smpdl3b* deficiency to generate Smpdl3b deficient AS mice (DKO). Animals were sacrificed at 20 weeks of age for in-depth phenotypical analysis of kidneys. All animal studies were performed in accordance with the NIH IACUC Guide. For statistical analysis One-Way ANOVA followed by Bonferroni's posttest was used.

Results: Mice with experimental AS develop proteinuria at 4 weeks of age and die of renal failure at 25 weeks of age. We demonstrated that SMPDL3b expression is 7-fold increased in kidneys of AS mice compared to wildtype littermates. We found decreased albumin-creatinine ratio (6,091±4,098μg/mg) in DKO mice compared to AS mice (27,395±17,387μg/mg). Improved proteinuria was not associated with improved body weight, serum creatinine levels, glomerular filtration rate (130.5±51.5μl/min/100gBW in controls and 153.7±34.4μl/min/100gBW in double knockout) or renal histology. DKO mice also demonstrated significantly lower levels of S1P (0.07±0.01pmol/mg) in kidney cortexes compared to AS mice (0.17±0.04pmol/mg).

Conclusions: Our data indicate that SMPDL3b expression may affect availability of S1P and regulate proteinuria levels in experimental AS. Thus, targeting SMPDL3b expression levels in the kidney may represent a novel approach to improve renal outcome in patients with AS.

The E3-Ubiquitin Ligase HUWE1 Is a Central Regulator in Podocyte Homeostasis

Marie Brand,[3,2] Martin Höhne,[4,2] Bernhard Schermer,[4,2] Thomas Benzing,[3,2] Linus A. Volker.[1,2] *[1]University Hospital of Cologne, Cologne, Germany; [2]CECAD, University of Cologne, Cologne, Germany; [3]University of Cologne, Cologne, Germany; [4]University Hospital Cologne, Cologne, Germany.*

Background: As terminally differentiated cells, podocytes depend on precise regulation of protein turnover and response to cellular stress in order to preserve homeostasis. Disruption of these processes can lead to podocyte damage and loss and subsequently to glomerular scarring and kidney disease. Ubiquitination is a posttranslational modification that targets proteins not only to proteasomal degradation, but also to different cellular pathways such as DNA repair, cell cycle regulation, and apoptosis. The HECT type E3-ubiquitin ligase Huwe1 has been shown to be a regulator of various intracellular signaling cascades in different cell types. To characterize the effects of Huwe-mediated ubiquitination in podocyte homeostasis *in vivo* and *in vitro*, we generated a podocyte-specific *Huwe1*-knockout mouse and HUWE1-deficient human podocyte cell lines.

Methods: To phenotype podocyte-specific *Huwe1*-knockout mice, we analyzed the urinary albumin/creatinine ratio and performed immunohistochemistry and electron microscopy. To elucidate the molecular effects of HUWE1 knockout on podocyte signaling, we generated a CRISPR/Cas9-mediated HUWE1-deficient human podocyte cell line and analyzed protein expression by mass spectrometry and RNA sequencing. To investigate HUWE1 specific alterations of ubiquitination, mass spectrometry after enrichment of ubiquitination sites was performed.

Results: Podocyte-specific loss of Huwe1 in mice caused kidney disease beginning at 5 weeks of age. Affected mice developed massive proteinuria and died prematurely of uremic complications. At the ultrastructural level, we saw extensive foot process effacement, podocyte vacuolization, and cell loss. Proteome and transcriptome analysis of HUWE1-knockout cells revealed significant differential regulation in a number of relevant pathways such as cell division, mitochondrial metabolism and autophagy. Analysis of the ubiquitome is ongoing.

Conclusions: The E3-ubiquitin ligase Huwe1 is pivotal for podocyte function and overall survival in mice. We identified HUWE1 as a central regulator of a multitude of cellular pathways to preserve human podocyte signaling and homeostasis. To address the complexity of affected cellular systems within the podocyte, a systems biology approach is required in order to develop new diagnostic and therapeutic strategies.

TH-PO793

Targeting of Endoplasmic Reticulum Stress Signaling Pathways for the Amelioration of $ANLN_{R431C}$-Induced Podocyte Apoptosis

Gentzon Hall,[1] Brandon M. Lane,[2] Guanghong Wu,[2] Megan Chryst-Stangl,[3] Robert F. Spurney,[1] Rasheed A. Gbadegesin.[1] *[1]Duke University Medical Center, Durham, NC; [2]Duke University, Durham, NC; [3]Duke Molecular Physiology Institute, Durham, NC.*

Background: We previously reported that mutations in anillin (ANLN) cause familial FSGS and that the $ANLN_{R431C}$ mutation induces aberrant activation of the PI3K/AKT/mTOR pathway and ER-stress-induced apoptosis in podocytes. To identify potential therapeutic targets for $ANLN_{R431C}$-induced podocyte apoptosis, we sought to further delineate the ER-stress signaling pathways downstream of the PI-3K/AKT/mTOR signaling pathway.

Methods: We quantified apoptosis in our established tGFP-, $ANLN_{WT}$- and $ANLN_{R431C}$-overexpressing podocyte lines using the BioTek® Lionheart FX automated live cell imaging system. Biochemical pathway analyses were performed in immunoblot assays.

Results: ER-stress signaling was activated in $ANLN_{R431C}$-overexpressing podocytes at 24 hours and knockdown (KD) of *CCAAT-enhancer-binding protein homologous protein* (*CHOP*), significantly reduced $ANLN_{R431C}$-induced podocyte apoptosis ($p<0.0001$). $ANLN_{R431C}$-overexpressing podocytes showed significantly increased apoptosis relative to $ANLN_{WT}$ and tGFP-overexpressing podocytes at 56 hours ($p<0.0001$). Pharmacologic inhibiton of mTOR and p70S6K significantly reduced $ANLN_{R431C}$-induced podocyte apoptosis at 72 hours ($p<0.0001$). Similarly, inhibition of calcineurin phosphatase and GSK3β, two upstream regulators of *CHOP* expression, significantly reduced apoptosis in $ANLN_{R431C}$-overexpressing podocytes relative to $ANLN_{WT}$ and tGFP-overexpressing podocytes ($p<0.0001$). *GSK3*β (KD) also significantly inhibited podocyte apoptosis at 72 hours ($p<0.0001$). These results confirmed our prior findings. Pharmacologic inhibition of the PERK and c-Jun N-terminal Kinase (JNK) significantly reduced $ANLN_{R431C}$-mediated apoptosis in podocytes ($p<0.0001$) highlighting the pathologic contributions of two additional signaling pathways to $ANLN_{R431C}$-induced podocyte apoptosis.

Conclusions: These findings broaden our understanding of the pathologic role of ER-stress signaling in $ANLN_{R431C}$-induced podocyte apoptosis and expand the repertoire of potential therapeutic targets for familial FSGS caused by ANLN mutations. *In vivo* modeling of the effects of the $ANLN_{R431C}$ mutation are needed to confirm the pathologic contribution of ER-stress signaling to podocyte apoptosis and to evaluate the efficacy of therapies targeting ER-stress pathways for the amelioration of $ANLN_{R431C}$-induced podocyte loss.

TH-PO794

TBC1D8B Mutations Implicate RAB11-Dependent Vesicular Trafficking in the Pathogenesis of Nephrotic Syndrome

Lina L. Kampf,[2] Ronen Schneider,[1] Lea Gerstner,[2] Mengmeng Chen,[2] Carsten Bergmann,[3] Friedhelm Hildebrandt,[1] Tobias F. Hermle.[2] Hermle lab *[1]Division of Nephrology, Boston Children's Hospital/Harvard Medical School, Boston, MA; [2]Medical Center - University of Freiburg, Freiburg, Germany; [3]Medical Center- University of Freiburg, Freiburg, Germany.*

Background: Steroid-resistant nephrotic syndrome (NS) frequently underlies CKD. Mutations in about 50 genes were identified as monogenic causes of NS and these genes rendered significant insight into podocyte biology. We previously reported mutations in *TBC1D8B* in two families with NS. TBC1D8B harbors a TBC domain, that commonly confers a functional role as a GTPase-activating protein (GAP) for specific Rab-GTPases. GAPs promote the inactive state of their Rab protein. However, the function of TBC1D8B and its pathogenetic role remained unclear.

Methods: To identify additional mutations of *TBC1D8B*, we performed whole-exome sequencing (WES). We analyzed the functional role of TBC1D8B and its mutations *in vitro* and conducted studies in podocyte-like *Drosophila* nephrocytes.

Results: We identified one hemizygous missense mutation (c.1316T>G, p.Phe439Cys) and two hemizygous nonsense mutations (c.1030C>T, p.Arg344* and c.1383G>A, p.Trp461*) in patients with NS. To explore the function of TBC1D8B and its target Rab proteins, we performed co-immunoprecipitation assays (coIP). We observed strongest interaction between RAB11 and TBC1D8B and specificity for the active form. Overexpressed murine *Tbc1d8b* bearing patient-derived mutations exhibited lower affinity for endogenous RAB11 than wild type protein. Silencing *TBC1D8B* in HEK293T cells increased basal autophagy and exocyst activity, two cellular functions that are independently regulated by RAB11. This suggests disinhibition of endogenous RAB11 and thus a regulatory role of TBC1D8B. CoIP assays further indicated interaction between TBC1D8B and the slit diaphragm protein nephrin. Both proteins co-localized in cultured podocytes. Knockdown of *Tbc1d8b* in *Drosophila* impaired function of the podocyte-like nephrocytes, and caused mistrafficking of the *Drosophila* ortholog of nephrin. Expression of *Rab11*-RNAi in nephrocytes entailed defective delivery of slit diaphragm protein to the membrane while *RAB11* overexpression revealed a phenotypic overlap to *Tbc1d8b* loss-of-function.

Conclusions: Novel mutations in *TBC1D8B* are monogenic causes of NS and our data indicate that TBC1D8B serves as a GAP protein for RAB11. TBC1D8B interacts with nephrin, being required for its trafficking. This connects RAB11-dependent vesicular trafficking to the pathogenesis of human NS.

Disruption of Crb2 in Podocytes After Birth Leads to Proteinuria

Akiko Tanoue,[1,4] Kan Katayama,[1] Keiko Oda,[1] Mika Fujimoto,[2,6] Yosuke Hirabayashi,[1] Shoko Mizoguchi,[1] Ayumi Haruki,[5] Takayasu Ito,[2] Tomohiro Murata,[1] Hideki Yokoi,[3] Masaaki Ito.[2] *[1]Mie university graduate school of medicine, Tsu, Japan; [2]Mie University Graduate School of Medicine, Mie, Japan; [3]Kyoto University Graduate School of Medicine, Kyoto City, Japan; [4]Murase hospital, Suzuka, Japan; [5]Mie University, Tsu, Japan; [6]Takeuchi hospital, Tsu, Japan.*

Background: Crumbs 2, Crb2 is one of the components of the Crumbs cell polarity complex and known to be expressed in the podocytes. There have been reports that CRB2 mutations were associated with steroid-resistant nephrotic syndrome in human. However, its precise mechanism is still unclear.

Methods: Crb2 floxed mice that had loxP sites flanking exon 7 and 8 were bred with NPHS2-Cre ERT2 mice to generate NPHS2-Cre ERT2 positive Crb2 floxed mice. Podocyte-specific Crb2 knockout mice after birth were made by injecting tamoxifen or negative control intraperitoneally for three days at two months of age. Urine, blood, and kidneys were analyzed in the two mouse groups at four months of age.

Results: NPHS2-Cre ERT2 positive Crb2 floxed mice that were injected tamoxifen showed massive proteinuria at four months of age compared to those that were injected negative control. Blood urea nitrogen or serum creatinine at four months of age was comparable between the two groups. Glomerular indices or fibrotic indices at four months of age were similar between the two groups.

Conclusions: Disruption of Crb2 in the podocytes after birth is related to inducing proteinuria.

TH-PO796

CRISPR/Cas9 Zebrafish Models Do Not Recapitulate 4 Human Monogenic Causes of Nephrotic Syndrome

Konstantin Deutsch, Ronen Schneider, Thomas M. Kitzler, Tilman Jobst-Schwan, Caroline M. Kolvenbach, Franziska Kause, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is characterized by proteinuria due to disruption of the glomerular filtration barrier and is a frequent cause of chronic kidney disease. Currently, more than 60 monogenic causes of human SRNS are known. Historically, zebrafish have been a commonly used animal model for human monogenic SRNS, using morpholino oligonucleotides. Recently, generation of zebrafish shifted to CRISPR-mediated knockout (KO), which often showed lack of recapitulation of the human disease phenotype in zebrafish (*Dev Cell* 32:97, 2015). We recapitulated the human SRNS phenotype due to Magi2 mutation (*Nat Commun* 9:1980, 2018) in a CRISPR model of magi2a (*Kidney Int* 95:1079, 2019). Recently, we discovered recessive mutations as novel causes of human SRNS in the following genes: *advillin* (*AVIL*) (*J Clin Invest* 127:4257, 2017), *PR/SET domain 15* (*PRDM15*), *deleted in liver cancer 1* (*DLC1*) and *Intersectin1* (*ITSN1*) (*Nat Commun* 9:1980, 2018).

Methods: To recapitulate monogenic causes of human SRNS and to study developmental phenotypes by CRISPR/Cas9 KO of the zebrafish orthologues *avil*, *dlc1*, *itsn1* and *prdm15*, we performed microinjections of multiple guide RNAs for each of the genes and generated stable KO zebrafish lines for these genes. Survival curves as well as phenotye assessments were generated for acute knockdown (KD) and stable KO zebrafish by monitoring larvae for 21 days.

Results: To assess larval-onset phenotype, we generated acute KD animals, which did not show a significant difference in survival or phenotype compared to animals injected with a non-binding control guide RNA and wildtype animals. We subsequently generated stable KO lines with 4 different KO-alleles for *AVIL*, 3 for *DLC1*, 4 for *ITSN1* and 6 for *PRDM15* respectively. None of these alleles showed a significant phenotypical difference in homozygous fish compared to heterozygous and wildtype controls.

Conclusions: Failure to recapitulate disease phenotypes in CRISPR models is currently predominantly attributed to upregulation of paralogues, triggered by mRNA degradation (*Nature* 568:197, 2019). In line with these results, CRISPR/Cas9 zebrafish models of the human SRNS genes *AVIL*, *DLC1*, *PRDM15* and *ITSN1* do not recapitulate the human phenotype of nephrotic syndrome and do not impede zebrafish larval survival.

TH-PO797

Biallelic ANKS6 and NPHP1 Mutations Alter Ciliary LKB1 Assembly in Late-Onset Ciliopathies

Hannah Schwarz, Markus Schueler, Nasrin Torabi sarijalo, Tilman Jobst-Schwan, Mario Schiffer, Karl X. Knaup, Michael S. Wiesener. *University Hospital Erlangen, Erlangen, Germany*.

Background: Nephronophthisis is a frequent cause of renal failure in children, presenting with progressive renal fibrosis and commonly include extrarenal organ involvement. The use of technological advances in DNA sequencing has led to a better understanding of molecular causes in rare kidney diseases. However, for most of these the cellular pathways involved still need to be identified. ANKS6 is a known member of the Inversin compartment and interacts with ANKS3. The Liver kinase B1 (LKB1) was recently shown to form a regulatory module in primary cilia with proteins linked to NPHP.

Methods: Genetic testing was performed in affected individuals with CKD of unknown origin. DNA was extracted from whole blood, enriched, and sequenced on a HiSeq2500. Patient-derived fibroblasts were harvested and cultured from skin biopsies of affected individuals, healthy parent and controls. From these patient derived cells functional studies on protein and RNA level using immunoblotting, immunofluorescence and qRT-PCR were performed.

Results: We identified biallelic mutations in the genes *NPHP1* and *ANKS6* in affected individuals with CKD of unknown origin. These segregated with the affected status and were absent from healthy controls. Functional studies in patient derived fibroblasts demonstrate that the identified mutations alter the ciliary assembly of LKB1 as well as of downstream signaling pathways, compared to healthy controls and heterozygous parental cells. Moreover, the detected mutations in *ANKS6* disrupt the Inversin-complex as the mutations lead to a loss of ANKS6, NPHP3, Inversin and NEK8 in primary cilia.

Conclusions: We identified the underlying molecular cause in affected individuals with CKD of unknown origin and observed an alteration of the ciliary assembly of LKB1 as well as of downstream signaling in patient derived cells. These findings support the presence of a ciliary LKB1-NPHP functional interaction. Moreover the results indicate that an alteration of ciliary LKB1 signaling could be a relevant mechanism for human ciliopathy and may play a wider role in renal disease. Functional studies on patient derived cells with rare inherited kidney diseases may lead to a better understanding of disease mechanisms. This could help to develop novel therapeutic strategies for treatment of such rare disorders.

TH-PO798

Accumulation of Globotriaosylceramide (GL3) in Podocytes (PC) in Fabry Nephropathy (FN) Is Associated with Progressive PC Loss

Behzad Najafian,[1] Camilla Tøndel,[3] Einar Svarstad,[3] João P. Oliveira,[2] Michael Mauer.[4] *[1]University of Washington, Seattle, WA; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Haukeland University Hospital, Bergen, Norway; [4]University of Minnesota, Minneapolis, MN.*

Background: Males with classic Fabry disease (FD) have a high incidence of end stage renal disease (ESRD). Processes leading to ESRD are poorly understood. α-galactosidase A gene defects lead to GL3 accumulation in the glomerulus, but this is progressive with age only in PC. PC are relatively resistant to enzyme replacement therapy and replicate poorly when lost. We aimed to examine if PC GL3 accumulation in FD is associated with PC loss.

Methods: Unbiased morphometric electron microscopic renal biopsy studies were performed in 58 males ages 27±13 years with classic FD genotype and/or phenotype.

Results: With increasing age there was an increasing fraction of PC cytoplasm occupied by GL3 inclusions [Vv(Inc/PC)], but this plateaued at age ~30. However mean PC volume (VPC) and total volume of GL3 inclusions/PC [V(Inc/PC)] continued to increase. V(Inc/PC) correlated with PC injury and loss evidenced by increased foot process width (FPW) and decreased PC number density per volume of glomerulus [Nv(PC/glom)]. The relationship between Nv(PC/glom) *vs.* V(Inc/PC) was best depicted by a power regression [$V(Inc/PC)=0.189\times Nv(PC/glom)^{-0.954}$] or 2 linear regression lines with an initial steep and a later milder slope. Piecewise linear regression analysis explained 81% of the variance of Nv(PC/glom) by V(Inc/PC), providing a breakpoint of V(Inc/PC) = 2009 μm^3. Patients with V(Inc/PC) > breakpoint showed an inverse correlation between age and Nv(PC/glom) (r=-0.70, p=0.008) and direct correlations between age and V(Inc/PC) (r=0.57, p=0.04) and VPC (r=0.67, p=0.01). Also, urinary protein excretion rate (UPER), a strong predictor of adverse renal outcomes in FD, correlated inversely with Nv(PC/glom) (r=-0.64, p=0.03) and directly with VPC (r=0.79, p=0.002), and FPW correlated inversely with Nv(PC/glom) (r=-0.74, p=0.04) in patients with V(Inc/PC) > breakpoint. However, in subjects with V(Inc/PC) ≤ the breakpoint there was no statistically significant relationship between age or UPER and PC parameters.

Conclusions: Given the known association between PC loss and irreversible focal and global glomerulosclerosis, this study supports an important role for PC loss, which beyond a certain point, is associated with the clinical progression of FN and argues for therapeutic intervention before critical PC loss has occurred.

Epigenetic Downregulation of Klotho via H3K27me3 Associated with Suppression of SGK-1 Survival Signaling in Aged Mouse Kidney

Xiaobin Han,[1] Zhongjie Sun.[2] *[1]Department of Physiology, University of Tennessee Health Science Center, Memphis, TN; [2]University of Tennessee Health Sciences Center, Memphis, TN.*

Background: Klotho deficiency is an important mechanistic driver of cell aging. However, the underlying mechanisms by which how Klotho is downregulated by epigenetics in aging cell have not been clearly elucidated.

Methods: In this study, we examined the role of H3K27me3 in the regulation of Klotho gene expression and pathways that influence the cell aging in the kidney of 30-months-old wild type (aged WT) C57BL/6 mice, and Klotho mutant mice compared to 6-months-old WT (young) mice, respectively.

Results: We demonstrated that the level of H3K27me3 was increased in the kidney of aged WT and Klotho mutant mice compared to young WT mice. Elevation of H3K27me3 was largely due to the downregulation of the histone 3 lysine 27 specific demethylase UTX and/or JMJD3 in the aging kidneys. Inhibition of Polycomb Repressive Complex C 2 (PRC2) using EED226 and GSK343 decreased the expression of H3K27me3 leading to increase in the expression of Klotho in primary cultured renal tubule cells determined by Western blot and Klotho promoter assay. Inhibition of PRC2 reduced level of H3K27me3 associated with Klotho promoter, suggesting that epigenetic downregulation of Klotho gene expression was due, at least in part, to histone 3 modification in the Klotho promoter region. ChIP qPCR revealed that H3K27me3 was enriched in the Klotho promoter region in the kidney of aged WT and Klotho mutant mice compared to young WT mice. Furthermore, our results showed that aging impaired SGK-1/FOXO3a signaling leading to upregulation of p53 and p16 in the kidney of aged WT and Klotho mutant mice.

Conclusions: We have first shown that epigenetic modification of histone mark H3K27me3 directly downregulates Klotho in the kidney of aged wild type mice. Aging exerts renal effects through hyperphosphorylation of mTOR which is independent of Klotho status. The normal aging and Klotho-deficient mediated aging share a common pathway through impaired SGK1 survival signaling leading to upregulation of FOXO3a, p53 and p16 in the kidney of aged WT and Klotho mutant mice. Thus, hormonal action of Klotho may be an alternative approach to activating SGK1 survival signaling for treating aging-mediated kidney disorders.

Efficacy and Safety of the Long-Acting C5-Inhibitor Ravulizumab in Adult Patients with Atypical Hemolytic Uremic Syndrome (aHUS)

Eric Rondeau,[1] Marie Scully,[3] Gema Ariceta,[2] Thomas D. Barbour,[4] Spero R. Cataland,[5] Nils Heyne,[11] Yoshitaka Miyakawa,[6] Stephan Ortiz,[7] Eugene Scott Swenson,[7] Marc Vallee,[7] Sung-Soo Yoon,[9] David Kavanagh,[10] Hermann G. Haller.[8] *[1]APHP; University Paris 6, PARIS, France; [2]Hospital Universitari Vall d' Hebron, Barcelona, Spain; [3]University College London Hospitals, London, United Kingdom; [4]Royal Melbourne Hospital, Parkville, VIC, Australia; [5]Ohio State University, Columbus, OH; [6]Saitama Medical University, Saitama, Japan; [7]Alexion Pharmaceuticals, Inc., Boston, MA; [8]Hannover Medical School, Hannover, Germany; [9]Seoul National University, Seoul, Republic of Korea; [10]National Renal Complement Therapeutics Centre, Newcastle upon Tyne, United Kingdom; [11]Tübingen University Hospital, Tubingen, Germany.*

Background: Ravulizumab was engineered to achieve extended complement C5 inhibition, given every 8 weeks, while retaining the proven efficacy and safety of eculizumab. Here we evaluate the efficacy and safety of ravulizumab in adults with aHUS.

Methods: This was a phase 3, single arm study (NCT02949128). Complement inhibitor-naïve patients (pts) aged ≥18 years who fulfilled diagnostic criteria for aHUS (exclusion of ADAMTS13 <5% activity and Shiga toxin-producing *Escherichia Coli*) and active thrombotic microangiopathy (TMA) received ravulizumab at 8-week intervals during the maintenance phase. The primary endpoint was complete TMA response during the initial 183-day evaluation period. Secondary endpoints included time to complete TMA response, components of complete TMA response over time, CKD stage, dialysis-free status over time and time to dialysis-free status.

Results: Fifty-six eligible pts were analyzed. Median age at baseline was 40 (range, 20–77) years and 36 (66%) were female. Complete TMA response was achieved in 30 pts (54%). 17/29 (59%) pts stopped dialysis (at a median time of 30 days). Primary endpoint and TMA parameter response over time is shown in the figure. Improvement in CKD stage from baseline was observed in 32/47 (68%) pts at Day 183. The most frequent serious adverse events were hypertension and pneumonia, each reported in 3 (5%) pts; 4 deaths not attributed to treatment occurred. No meningococcal infections were reported.

Conclusions: 8-weekly ravulizumab dosing produced immediate, sustained and complete complement inhibition resulting in rapid hematologic and renal response with no unexpected safety concerns.

Funding: Commercial Support - Alexion Pharmaceuticals, Inc.

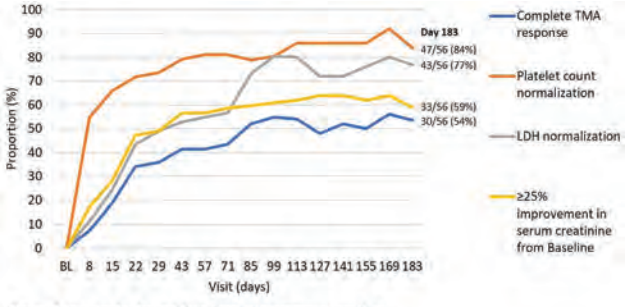

Figure. Primary endpoint and TMA parameter response over time

Complete TMA response is defined as normalization of platelet count, normalization of LDH, and ≥25% improvement in serum creatinine from baseline at 2 separate assessments obtained ≥28 days apart.

Platelet count normalization is defined as ≥150 x 10^9/L.

LDH normalization is defined as ≤246 U/L.

Identifying Thrombotic Microangiopathy Mimics

Nicolò Ghiringhelli Borsa,[1] Amanda O. Taylor,[1] Michael Jones,[1] Nicole Meyer,[1] Yuzhou Zhang,[1] Carla M. Nester,[1,2] Richard J. Smith.[1] *[1]Molecular Otolaryngology and Renal Research Laboratories, The University of Iowa, Iowa City, IA; [2]University of Iowa Stead Family Children's Hospital, Department of Pediatrics, Iowa City, IA.*

Background: Thrombocytopenia is one of the key diagnostic criteria for the clinical diagnosis of thrombotic microangiopathy (TMA). When thrombocytopenia presents with other hemolytic processes, distinguishing the correct diagnosis can be difficult. In an era of terminal complement blockade, the correct diagnosis is critical to determining the optimal treatment approach. Here we describe a cohort of patients clinically diagnosed with TMA but then incidentally identified to have a pathogenic variant in the glucose-6-phosphate dehydrogenase (*G6PD*) gene.

Methods: Targeted genomic enrichment with massive parallel sequencing (TGE+MPS) of genes implicated in TMA was used to screen 329 patients. Multiplex ligation-dependent probe amplification (MLPA) for copy-number variations (CNVs) in the *CFH-CFHR5* region was also performed.

Results: Of 329 patients screened, 7 patients were positive for well-described, pathogenic *G6PD* variants including 3 with the Union variant, 3 with the Sassari variant and 1 with the Chatham variant. All variants identified have been described as class II variants (1-10% G6PD residual activity). Of the 7 patients, 5 carry at least one complement gene variant, including 3 variants of unknown significance (1 *CFH* and 2 *CFI*), 1 pathogenic variant (*DGKE*), and 1 likely pathogenic variant (*CFHR5*). MLPA detected a heterozygous deletion of *CFHR1-CFHR4* in one patient while the remaining were unremarkable. Our findings indicate that approximately 2% of TMA diagnoses may be accounted for by G6PD deficiency.

Conclusions: G6PD deficiency should be included on the differential for someone diagnosed with a hemolytic anemia associated with thrombocytopenia. It remains unclear if G6PD deficiency plays a primary or a modifier role in the TMA-like presentation. Similarly, if G6PD deficiency is the primary etiologic agent, what role does enzyme deficiency play in the individual features of the underlying pathology of the TMA-like presentation (including thrombocytopenia and renal insufficiency) is unknown. Despite this gap in our understanding, considering G6PD deficiency on the differential has clear diagnostic and treatment implications. We conclude that *G6PD* gene testing is recommended in the workup of a clinical TMA, and G6PD enzyme testing is warranted when the acute process has resolved.

Risk for TMA Recurrence and Renal Outcomes After Eculizumab Discontinuation in aHUS: Results from the Global aHUS Registry

Gema Ariceta,[1] Fadi Fakhouri,[2] Lisa Sartz,[3] Benjamin Miller,[4] Vasilis Nikolaou,[5] David J. Cohen,[8] Andrew M. Siedlecki,[6] Gianluigi Ardissino.[7] *[1]Hospital Universitari Vall d' Hebron, Barcelona, Spain; [2]Centre Hospitalier Universitaire de Nantes, Nantes, France; [3]Skåne University hospital, Lund, Sweden; [4]Alexion Pharmaceuticals, Inc., Boston, MA; [5]Parexel, Uxbridge, United Kingdom; [6]Brigham and Women's Hospital, Boston, MA; [7]Center for HUS Prevention, Control and Management, Milano, Italy; [8]Columbia University, New York, NY.*

Background: Eculizumab (Ecu) modifies the course of disease in patients (pts) with atypical hemolytic uraemic syndrome (aHUS), but there are limited data to describe thrombotic microangiopathy (TMA) recurrence rates and long-term outcomes after Ecu discontinuation (d/c).

Methods: Pts in the Global aHUS Registry (NCT01522183) who received ≥1 month (mo) of Ecu with evidence of hematologic or renal response prior to d/c and with ≥6 mo of follow-up (f/u) were included. Those on chronic dialysis (≥3 mo) at the time of Ecu d/c were excluded. Classification as pediatric (<18 years) or adult was made at time of Ecu d/c.

Results: 151 pts (62% female) were included in the analysis: 34% were pediatric and 66% were adults (median [range] age at enrolment, 6.0 [0.6–17.1] and 35.7 [18.4–81.2], respectively), 11% had a family history of aHUS and 41% had a pathogenic variant or anti-CFH antibody. Median (range) duration of Ecu prior to d/c was 1.0 (0.1–5.1) and f/u was 2.3 (0.1–7.1) years. 24% experienced TMA recurrence after Ecu d/c. More pts required antihypertensives at f/u vs at d/c (71% vs 54%). Pts with a family history of aHUS, pathogenic variants, lower eGFR and extrarenal manifestations appeared to be at a higher risk of TMA recurrence (Table).

Conclusions: Discontinuation of Ecu is not without risk and may lead to TMA recurrence in some patients with aHUS. A careful assessment of risk factors prior to the decision to d/c Ecu is warranted.

Patient characteristics by TMA recurrence status			
Variable	All N=148*	TMA recurrence n=35	No TMA recurrence n=113
Median (range) duration of Ecu before discontinuation, years	1.0 (0.1– 5.1)	1.0 (0.1– 5.1)	1.0 (0.1– 4.5)
Median (range) eGFR prior to Ecu discontinuation, mL/min/ 1.73 m^2	57.1 (4.9–183.1)	50.5 (13.0–183.1)	65.8 (4.9–176)
Median (range) time to TMA recurrence after Ecu discontinuation, months	N/A	All: 5.3 (0.1–49.9) Pediatric: 5.1 (1.4–49.9) Adult: 10.2 (0.1–49.6)	N/A
Extra-renal manifestation at baseline, n (%)	CV 31 (21) Pulm 19 (13) CNS 36 (24) GI 55 (37)	CV 10 (29) Pulm 9 (26) CNS 10 (29) GI 14 (40)	CV 21 (19) Pulm 10 (9) CNS 26 (23) GI 41 (36)

TH-PO803

Familial Pregnancy-Associated aHUS and Acute Heart Failure Successfully Treated with Eculizumab

Anuja Java,[1] Zhen Ren,[1] Pooja Motwani,[2] John P. Atkinson.[1] *[1]Washington University in St. Louis, Saint Louis, MO; [2]CARTI, Little Rock, AR.*

Introduction: Atypical HUS is a rare thrombotic microangiopathy (TMA) characterized by anemia, thrombocytopenia (TP) and AKI. Mutations in genes encoding complement proteins have been identified in ~60% of patients. We report 3 sisters who developed aHUS after pregnancy. ADAMTS13 was normal in all.

Case Description: Sister 1: 25-yr-old Hispanic female (HF) presented 10 days postpartum (pp) in 2015 with anemia, TP, and AKI. Kidney biopsy showed a TMA which was treated with plasma exchange (PE) and steroids. Later she developed heart failure (HF) from mitral valve perforation requiring intubation, valve replacement & hemodialysis (HD). Eculizumab was initiated. Creatinine improved in 2 wk and HD was discontinued. Sister 2: 24-yr-old HF developed anemia, TP, and AKI 7 days pp in 2014, treated with PE. Creatinine deteriorated and HD was initiated. One year later, after the diagnosis in sister #1, aHUS was considered and eculizumab initiated. Creatinine improved and HD was discontinued after 2 years. Sister 3: 18-yr-old HF presented 7 days pp in 2006 with anemia, TP, and AKI. Kidney biopsy revealed a TMA which was nonresponsive to PE and HD was initiated. Course was complicated by HF due to severe mitral and tricuspid regurgitation. She was not treated with eculizumab since aHUS was not considered until after it was diagnosed in her two sisters (8 years later). Genetic testing for all 3: 1) Splice-site variant (c.287-2A>G) in membrane cofactor protein (MCP) known to be aHUS-associated; 2) A novel variant (G918E) in Factor H (FH) of uncertain significance; 3) A heterozygous variant (K441R) in Factor I, likely benign; 4) A heterozygous variant (N1050Y) in FH, likely benign. Our functional analysis for these variants reveals that the G918E is not secreted and leads to low FH levels. The N1050Y is normally secreted and has normal C3b and heparin binding properties. The K441R has normal secretion and activity. The splice-variant in MCP is expected to cause decreased expression of MCP leading to low levels.

Discussion: The sisters carry pathogenic mutations in both MCP and FH. It is unusual for patients with aHUS to carry multiple rare variants. Pregnancy was the trigger in this family (patients' paternal grandmother lost 10 of 12 pregnancies). Acute heart failure due to valvular disease is novel. Possible mechanism is thrombus formation followed by endocarditis.

TH-PO804

Complement Activation Causes Major Metabolic and Energetic Changes on Endothelial Cells

Magdalena Riedl Khursigara,[1] Valentina Bruno,[2] Christoph Licht,[1] Carolina Ortiz.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Santobono-Pausilipon Children's Hospital, Naples, Italy.*

Background: Complement dysregulation and formation of the membrane attack complex (MAC, C5b-9) on vascular endothelial cells (ECs) cause EC injury and can lead to thrombotic microangiopathy (TMA). Effects of chronic complement exposure on cellular level are not well established. Here, we especially focused on metabolic and energetic changes as previous data indicated that C5b-9 formation on the surfaces of ECs did not result in cellular necrosis or apoptosis.

Methods: Human blood outgrowth endothelial cells (BOECs) derived from healthy donors were sensitized with an anti-CD59 antibody. Complement activation was initiated by adding normal human serum. Microscopy, luminescence, flow cytometry and western blot were used to measure intracellular calcium, ATP, mitochondrial membrane potential as well as autophagy pathways, respectively.

Results: BOECs exposed to complement showed cell surface C5b-9 deposition followed by an abrupt rise in intracellular Ca^{2+} that was sustained over 6 hours. Under complement stress, cell motility was impaired, which resulted in defective wound healing. We suggested a defect in endothelial cell energy homeostasis as likely cause for the observed functional defects. Indeed, complement activation caused a sustained drop in intracellular ATP levels and mitochondrial membrane potential. These effects were reversible following discontinuation of complement stress (i.e., removal of serum or blockage of complement activation via C5-depleted or heat inactivated serum), indicating that ECs were still viable. Thus we hypothesized that ECs are able to switch on a survival machinery. In keeping with this we found upregulation of autophagy, as indicated by the degradation of the markers LC3 and p62.

Conclusions: In summary, chronic complement activation leads to an EC energy deficit. BOECs activate a survival machinery to sustain complement attack, including the re-sealing of the plasma membrane and the activation of autophagy. All cellular effects were reversible, implying a window of opportunity for treatment initiation and recovery of endothelial cell function.

TH-PO805

Epithelial Membrane Protein 2 (EMP2) Is Predominantly Expressed in Vascular Smooth Muscle Cells of the Kidney

Michael D. Donnan,[1,2] Rizaldy P. Scott,[1,2] Tuncer Onay,[1] Antoine Tarjus,[1] Ummiye venus Onay,[1] Susan E. Quaggin.[1,2] *[1]Feinberg Cardiovascular & Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Nephrology & Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Mutations in human gene Epithelial Membrane Protein 2 (EMP2) have been linked to childhood-onset nephrotic syndrome. However, we have previously reported that loss of Emp2 in mice does not cause nephrotic syndrome and that Emp2 lacks notable expression in podocytes or the glomerulus. Instead, we find that Emp2 has a distinctive vascular pattern of expression in multiple tissues including the kidney. As Emp2 is currently being investigated as a novel target for treatment of pathologic neovascularization and vasculo-proliferative diseases such as diabetes, we studied in detail the vascular expression of Emp2 across different organs as well as the kidneys.

Methods: We created a conditional floxed *Emp2* allele carrying a lacZ cassette that allows whole-mount β-galactosidase (β-gal) histochemical analysis of Emp2 expression. Tissues were evaluated as whole mount and additionally embedded in OCT and cryosectioned for immunohistochemical analysis. We created endothelial-specific knockout mice by breeding floxed Emp2 animals with a Cdh5-Cre/ERT2 driver strain. Emp2 mRNA was profiled in various tissues using qRT-PCR analysis.

Results: Expression of Emp2 by β-gal histochemistry was seen in the arterial vasculature of multiple tissues including the kidney. Within the kidney, β-gal activity is localized to renal arterial vessels where it is expressed in $Tagln^+$ ($SM22a^+$) vascular smooth muscle cells and is absent in $Podxl^+$ arterial endothelial cells, $Emcn^+$ renal veins and glomerular endothelial cells. *Emp2* expression within the kidney is unchanged upon endothelial specific knockout of the *Emp2* gene consistent with the lack of β-gal activity in the endothelial cells of $Emp2^{lacZ}$ reporter mice.

Conclusions: Our analysis reveals that Emp2 expression is largely confined to vascular smooth muscle cells of the arterial vasculature in the kidneys as well as multiple other organs. These findings provide important insights into the specific site of action of therapeutics designed to target Emp2.

Analysis of Mutant Human MUC1 Transgenic Mice with Mapped Transgene Suggests Systemic Manifestation of ADTKD-MUC1

Jun-Ya Kaimori,[1] Satoko Yamamoto,[2] Takuji Yoshimura,[3] Yoshitaka Isaka.[1] *[1]Osaka University Graduate School of Medicine, Suita Osaka, Japan; [2]Osaka University, Suita, Japan; [3]nara medical university, Kashihara, Japan.*

Background: Autosomal dominant tubulointerstitial kidney disease caused by mucin-1 gene mutations (ADTKD-*MUC1*) is an important cause of end-stage renal disease, the reported manifestations of which have been limited to within the kidneys. However, no reports about ADTKD-*MUC1* transgenic model animals have been published. Almost all *MUC1* mutations were previously identified in variable-number tandem repeats (VNTRs), within which sequencing is difficult. However, we previously discovered a novel *MUC1* mutation before these VNTRs.

Methods: We thus developed mu*MUC1* tg mice using this mutated cDNA driven by mouse *Muc1* promoter and examined their phenotypes. We identified the transgene integration site by targeted locus amplification.

Results: We identified the transgene integration site by targeted locus amplification, revealing that transgene integration did not disrupt any endogenous genes. Surprisingly, mice with high mutant MUC1 protein expression showed growth retardation with massive inflammation in skin, gut, lungs, and kidneys, due to ER stress. Because of malnutrition due to gastrointestinal tracts with inflammation, almost all growth-retarded mutant animals died after weaning. Interestingly, most animals with high mutant protein were male. Our patient re-examination in response to these tg mouse data revealed that patients had interstitial pneumonia, gastrointestinal inflammation, and dermatitis with sebaceous gland inflammation with mutant protein accumulation and ER stress.

Conclusions: These findings show that ADTKD-*MUC1* can exhibit systemic inflammatory manifestations.

A Uromodulin Mutation Resulting in Innate Immune System Activation

Matthew D. Plotkin,[1] Annjanette Stone.[2] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Uromodulin (Tamm-Horsfall) is secreted by the thick ascending limb into urine but also crosses basolateral membranes into the interstitium and blood. Uromodulin may function as part of kidney's innate immune system with pro and anti-inflammatory effects. Mutations in the UMOD gene are a cause of autosomal dominant tubulointerstitial kidney disease (ADTKD) due to tubular injury and endoplasmic reticulum (ER) stress. We identified a family with a novel UMOD mutation (C106F). Biopsies from affected members showed glomerular and interstitial inflammation atypical for ADTKD.

Methods: To determine if this mutation causes the observed phenotype through changes in membrane targeting and activation of the innate immune system, we examined a kidney epithelial cell line with stable transfection of mutant protein and developed a transgenic (tg) mouse with an orthologous cysteine to phenylalanine mutation (C105F) in the UMOD gene using CRISPR-Cas9 gene editing.

Results: LLC-PK1 cells expressing wt and mutant protein had increased basolateral secretion of protein compared with cells expressing wt or mutant protein alone. EM examination of mutant medium showed protein aggregates in contrast to filaments in wt medium. Immunoprecipitation of plasma uromodulin from tg/tg mice demonstrated dimer formation not seen in tg/+ or wt mice. Tg/+ and tg/tg mice displayed increased inflammasome activity at baseline with increased NLRP3 receptor, phospho NF-kB p65 and cleaved caspase 11 levels but no expression of ER stress markers. NLRP3 expression was located in macrophages and podocytes. Tg/+ mice developed glomerular and interstitial matrix deposition, myofibroblast proliferation and increased creatinine with aging. Following ischemia-reperfusion injury, tg/+ mice had no increase in inflammasome activation over baseline in contrast to wt littermates and displayed improved tubular repair and renal function at 7 days.

Conclusions: In summary, the C106F mutation results in glomerular and interstitial inflammatory kidney disease. A mouse model demonstrates that mutant protein enters the interstitium and blood and activates the innate immune system resulting in fibrosis with aging but improved repair following acute injury.

TH-PO808

Kidney Disease-Associated Variants of Apolipoprotein L1 Show Gain-of-Function in Cation Channel Activity

John C. Edwards, Jonathan M. Bruno. *St. Louis University, St. Louis, MO.*

Background: Variants in Apolipoprotein L1 (ApoL1) are responsible for increased risk of some progressive kidney diseases among people of African ancestry. ApoL1 is known to function as an amphitropic protein that can insert into phospholipid membranes and confer pH-regulated Cl- or K-selective permeability. Cl permeability is optimal when protein and vesicles are both mixed and assayed at pH 5.0. K permeability is optimal when protein and vesicles are mixed at pH 6.0 and assayed at pH 7.5. Whether these activities differ among the variants or contribute to disease pathogenesis is unknown.

Methods: Recombinant WT (G0) or each variant (G1, G2) were purified from E. Coli. We used a vesicle-based assay of voltage-driven ion flux. In brief, KCl-loaded vesicles were mixed with protein, extravesicular KCl removed, and voltage-driven efflux intiated by addition of either a K- or Cl-selective ionophore to assess Cl or K permeability, respectively. To assess membrane association, protein was mixed with vesicles under conditions that support K permeability, stripped with alkali, the membranes isolated by flotation through a sucrose cushion, and associated protein determined by quantitative western blotting.

Results: In each of 5 sets of purified protein, the K selective permease of G1 and G2 isoforms was significantly increased compared to G0. Combining all sets, initial efflux rates were 0.361 ± 0.028 for G0, 0.738 ± 0.081 for G1, and 0.688 ± 0.069 for G2 (%/sec, mean ± SEM; P<0.0025 for comparison of G0 with either G1 or G2). In contrast, we find no difference in the Cl selective permease activity among the isoforms. Compared to the WT, the two disease-associated variants show increased stable membrane association under conditions that support the K permease activity (amount bound: 56.2 ± 3.4 for G0, 76.6 ± 5.1 for G1, and 100.2 ± 11.8 for G2 (ng, mean ± SEM, n=8 for each; P<0.006 for G0 vs either G1 or G2; G1 vs G2 NS)).

Conclusions: Kidney disease-associated variants of ApoL1 show gain of function in the K permease activity, and show increased capacity to stably associate with membrane vesicles, suggesting that the increased activity may be due to more efficient membrane association and/or insertion. These data support a model in which enhanced potassium permeability may contribute to the progressive kidney diseases associated with high-risk ApoL1 alleles.

Bifunctional VDR-miR193a Axis Modulates APOL1 Expression in Human Podocytes

Vinod Kumar,[2] Himanshu Vashistha,[3] Kamesh R. Ayasolla,[4] Xiqian Lan,[4] Ashwani Malhotra,[5] Karl Skorecki,[6] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Medicine, Feinstein Institute of Research, Manhasset, NY; [3]Ochsner Health System, New Orleans, LA; [4]Feinstein Institute for Medical Research, Manhasset, NY; [5]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [6]Rambam Health Care Campus, Haifa, Israel.*

Background: APOL1 plays an important role in the maintenance of podocyte molecular phenotype. We have recently demonstrated that a vitamin D receptor (VDR) agonist (VDA) enhances the expression of APOL1 in human podocytes through down-regulation of miR193a. miR193a plays a vital role in the development of focal segmental glomerulosclerosis (FSGS) both in experimental animal models and humans. miR193a induces oxidative stress and negatively regulate the expression of Wilms Tumor Type (WT) 1 expression in podocytes. We hypothesize that VDR and mir193a inversely regulate each other.

Methods: Differentiated immortalized human podocytes (DPDs) and human embryonic kidney cells (HEKs) were treated with different concentrations of a VDR agonist (VDA, EB1089, 0, 5, 10, 50, 100 nM) for 48 hours (n=6); HEKs were transduced with either control or VDR plasmid (n=4); DPDs were transfected with either control of miR193a plasmids (n=4); DPDs were treated with either an empty vector or a specific miR193a inhibitor for 48 hours (n=4). RNAs and proteins were extracted. Protein blots were probed for VDR, APOL1, WT1, and GAPDH. RNAs were assayed for miR193a. cDNAs were amplified for VDR, APOL1, and WT1. To validate the putative binding of mi193a-5p to VDR 3'UTR, Luciferase assay was carried out. To examine the binding of VDR at miR193a promoter, ChiP assay was carried out. To evaluate the role of WT1, HEKs were transfected with control, VDR, or WT1 plasmids and protein blots were probed for VDR, WT1, APOL1, and GAPDH; RNAs were assayed for miR193a.

Results: Both VDA-treated DPDs and HEKs displayed upregulation of APOL1, VDR, and WT1 in a dose-dependent manner. VDR-transfected HEKs as well as DPD-treated with a miR193a inhibitor also showed an increase in APOL1 and WT1 but attenuated miR193a expressions. DPDs overexpressing miR193a showed diminished APOL1, WT1, and VDR expressions (both protein and mRNA). Interestingly, WT1 transfected HEKs showed downregulation of VDR, and VDR-transfected HEKs displayed increased expression of WT1. Luciferase assay showed putative binding sited of miR193a on VDR gene. ChiP assay also showed binding of VDR on miR193a gene. These binding sites suggest that both VDR and miR193a regulate each other.

Conclusions: Bifunctional VDR-miR193a axis regulates APOL1 regulate APOL1 directly as well as through modulation of WT1.

APOL1: A "Novel" Genetic Variant Associated with Podocytopathy in Chile

Marina Leiva Gonzalez,[4] Anita Plaza,[1] Eduardo Tobar,[3] Cristian E. Yáñez,[3] Diego Romero,[2] Ricardo A. Verdugo,[3] Gonzalo P. Mendez,[2] Sergio A. Mezzano,[1] Leopoldo G. Ardiles,[1] Paola Krall.[1] *[1]Universidad Austral de Chile, Valdivia, Chile; [2]Pontificia Universidad Catolica de Chile., Santiago, Chile; [3]Universidad de Chile, Santiago, Chile; [4]Hospital Intercultural de Nueva Imperial, Temuco, Chile.*

Background: The APOL1 G1 risk allele (rs73885319) is associated with kidney disease in African Americans. According to ExAC data, the G1 allele has an uneven distribution, reaching a high frequency (23%) in Africans, but is very rare (0.6%) in the Latino population. In 2016-2017, three patients in Southern Chile affected by kidney disease were identified as homo- or heterozygous G1 carriers. Here, we describe a study as a first effort to determine the prevalence and association of the G1 allele with podocytopathy in Chileans.

Methods: 50 FFPE-DNA samples of adult patients with a biopsy-proven podocytopathy and 1666 DNA samples of ChileGenomico DNA repository recruited along the whole country were analyzed to determine prevalence of the APOL1 G1 risk allele. Genetic analysis was performed by PCR combined with (NGS+Sanger) sequencing technology. Genetic association between the G1 allele and podocytopathy was analyzed by a 2x2 contingency table to estimate OR.

Results: Among the 50 cases with a biopsy-proven podocytopathy, 4 subjects carried one risk allele (G1/G0), while 8 out of the 1666 ChileGenomico subjects carried this genotype, resulting a positive genetic association between the allele and the podocytopathy (G1 allele frequency 4% vs. 0.24%; p<0.001). One of the 4 G1/G0 cases was HIV-positive; the second hit remains unknown in the other 3 cases. Odds ratio for the effect of the APOL1 G1 risk allele resulted 19.8 (95% CI 5.7-67.7).

Conclusions: Chilean population has a 1-5% African genetic ancestry that decreases from North to South. To our knowledge, this is the first study in Chile that explores the prevalence of the APOL1 G1 risk allele and its association with a podocytopathy. We confirmed a very low frequency of the APOL1 G1 risk allele dispersed in the Chilean population, but a significant prevalence among patients with podocytopathy. The clinical value of APOL1 risk alleles is still uncertain in our population and second hits in some patients remain unknown. More evidence is needed before considering the APOL1 genotype as an input to define clinical management and ethical issues have to been considered, particularly for the Afrodescendant migrants that have arrived in Chile the last years. APOL1, Bone Lead, and Kidney Disease: A Pilot Study Using Recall by Genotype

Aparna Saha,[2] Lili Chan,[2] Steven G. Coca,[2] Carol Horowitz,[2] Richard Cooper,[1] Girish N. Nadkarni.[2] *[1]Loyola University Chicago, Maywood, IL; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The *APOL1* high-risk genotype is frequent (14%) in African Americans (AAs) and is associated with increased risk of chronic kidney disease (CKD). However, only a fraction of individuals with the genotype have CKD indicating the presence of modifiers of disease risk ('second hits'). Nephrotoxic metals, including lead (Pb) are associated with kidney disease risk. We sought to assess whether *APOL1* genetic risk and bone lead concentration interact for CKD.

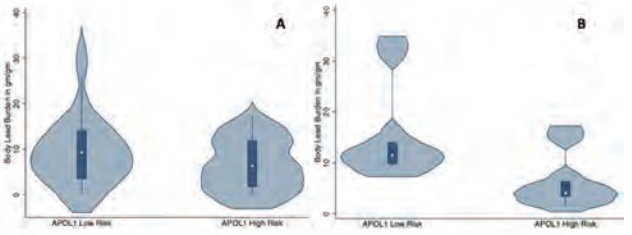
Methods: We recalled AA participants with *APOL1* high risk and low risk genotype from the Bio*Me* Biobank and matched them on age, sex, most estimated glomerular filtration rate (eGFR) and socio-demographics. We then measured tibia Pb indicating body lead burden (BLB) using X ray fluoroscopy. We then estimated the difference in BLB by APOL1 risk for a given eGFR using non-parametric tests.

Results: We recalled 30 AA participants (15 with *APOL1* high risk and 15 with *APOL1* low risk). The median age was 56, 66% were female and median eGFR was 59 ml/min. The median Pb was 9.2 gm/gm of bone (IQR 2.7-12) and was correlated with lower eGFR (R^2=-0.19). There was a trend towards lower Pb in individuals with *APOL1* high risk vs. low risk (median 6.9 vs. 10.6 gm/gm; p=0.10). This was more evident in individuals (n=10) with eGFR≤45 ml/min (median 3 vs. 11.5 gm/gm; p=0.07). (**Figure 1**)

Conclusions: Conditional on low eGFR, Individuals with *APOL1* high risk have lower BLB compared to those with *APOL1* low risk. Although larger studies are needed, this may suggest that CKD risk is potentiated by BLB at lower exposure levels in persons with *APOL1* high risk. Finally, this also serves as a proof-of-concept study using 'recall by genotype' for deep phenotyping of environmental exposures.

Funding: NIDDK Support

Figure 1. Distribution of Body Lead Burden in APOL1 high and low risk individuals



This figure shows the distribution and density of body lead burden in 30 APOL1 low (n=15) and high risk (n=15)individuals matched by age, sex, socio-demographics and recent kidney function. Figure 1 A shows distribution in all individuals and Figure 1B shows 10 individuals with a recent eGFR of <45 ml/min

APOL1 Genetic Variants Are Associated with Increased Risk of Coronary Artery Disease and Sudden Cardiac Death: An Autopsy Study in Sudden Death Registry

Liang Guo,[1] Marco Delsante,[2,3] Anne Cornelissen,[1] Xiaoqing Zhao,[1] Frank D. Kolodgie,[1] Myung Shin,[5] Maarten Hoek,[5] Jeffrey B. Kopp,[3] Avi Z. Rosenberg,[4,3] Harry R. Davis,[1] Renu Virmani,[1] Aloke Finn.[1,6] *[1]CVPath Institute, Gaithersburg, MD; [2]University of Parma, Parma, Italy; [3]National Institute of Diabetes and Digestive and Kidney Disease, National Institute of Health, Bethesda, MD; [4]Johns Hopkins University, Baltimore, MD; [5]Merck & Co., Inc, Kenilworth, NJ; [6]University of Maryland School of Medicine, Baltimore, MD.*

Background: Two genetic risk variants (G1 and G2) in APOL1, which encodes apolipoprotein L1, have been associated with kidney disease in African Americans, but whether these variants are associated with coronary artery disease or sudden cardiac death is conflicting.

Methods: Here we determined the APOL1 genotype (G0, G1, or G2) for 687 African Americans from the Sudden Death Registry of CVPath Institute. The cause of death was determined through cardiac autopsy and histopathology analyses, and categorized as sudden coronary death with or without coronary thrombosis (n=269), cardiac (non-coronary) death (n=174), and other causes (n=244). Genotyping revealed risk variants of APOL1 in 396 patients with 306 patients carrying 1 risk allele (182 G0/G1, 124 G0/G2), and 90 patients harboring 2 risk alleles (28 G1/G1, 46 G1/G2, 16 G2/G2). The APOL1 reference allele (G0/G0) was observed in 291 patients.

Results: Carriers of APOL1 risk alleles had a significantly increased risk of coronary thrombosis (relative risk 1.2006, ; 95% confidence interval, 1.0003 to 1.4409), particularly of coronary plaque rupture (relative risk, 1.2425; 95% confidence interval, 1.0136 to 1.5230). Individuals with only one risk allele (G0/G1 or G0/G2) still had significantly increased risk of coronary plaque rupture (relative risk, 1.2980; 95% confidence interval, 1.0083 to 1.6708). Further analyses suggested risk allele and hypertension are two independent factors contributing to plaque rupture. Moreover, carriers of G2 risk allele had a higher risk of cardiac causes of death (relative risk, 1.5040; 95% confidence interval, 1.0430 to 2.1705). Histopathologic analysis of the kidneys in selected age and gender matched 50 G0/G0 carriers and 50 carriers of two risk alleles showed borderline significant increases of glomerular density (p=0.08) and microcystic tubular dilation (p=0.07). A significantly higher global glomerulosclerosis was seen in carriers of two risk alleles (p=0.049), and the glomerulosclerosis is correlated with the coronary artery plaque burden (p=0.035).

Conclusions: The APOL1 high risk status is associated with higher risk of plaque rupture in coronary artery disease and sudden cardiac death.

Cystinosis Nonsense Mutation Read-Through Mediated by ELX-02 Restores Protein Function Using In Vitro and In Vivo Models

Matthew Goddeeris, Gregory Williams. *Eloxx Pharmaceuticals, Inc, Waltham, MA.*

Background: Cystinosis is a rare disorder caused by mutations of the cysinosin (*CTNS*) gene. Approximately 15% of cystinosis patients worldwide carry one or more nonsense mutations which halt translation of the CTNS protein through introduction of a premature stop codon. ELX-02 is an investigational synthetic eukaryotic ribosomal selective glycoside that induces read-through of nonsense mutations through interaction with the ribosome resulting in full-length functional proteins. ELX-02 is being developed as a therapy for genetic diseases caused by nonsense mutations such as nephropathic cystinosis and polycystic kidney disease.

Methods: This study evaluated the effects of ELX-02 on fibroblasts from patients with cystinosis homozygous for *W138X* mutation, as well as ELX-02 effects on mouse models of cystinosis with a *Y226X* mutation.

Results: In cystinosis patients' fibroblasts homozygous for the nonsense *W138X* mutation incubation of ELX-02 at escalating dose for 72 hours resulted in reduced half-cystine levels (at ≥100 μg/mL) up to normal levels, and significantly increased *CTNS* mRNA levels (at ≥200 μg/mL) by 2.5- to 3.5-fold. Treatment of compound heterozygous cystinosis patient human fibroblasts, $CTNS^{W138X/57kbDel}$ and $CTNS^{W138X/Frameshift}$ mutations, with ELX-02 resulted in increased *CTNS* mRNA levels and a trend in reduction of half-cystine levels. In a mouse model of cystinosis bearing a *Y226X* mutation, the PK of ELX-02 in plasma and kidneys and the renal half-cystine levels were evaluated following single and repeated bi-weekly subcutaneous administration of ELX-02 at 9 mg/kg for up to 21 days. Cystine levels decreased by 30% compared to control animals.

Conclusions: The pharmacodynamic effect of ELX-02 treatment on cystine levels suggests that ELX-02 induced functional read-through of cystinosin and demonstrated that the expressed protein reduced the accumulated lysosomal cystine by one third in the time frame of the experiment at the given dose. These results support the continued development of ELX-02 for the potential treatment of nephropathic cystinosis and other nonsense mutation mediated diseases of the kidney.

Studying the Link Between Nephropathic Cystinosis and Tubular Acidosis

Amer A. Jamalpoor,[1] Albertien M. van Eerde,[5] Marc Lilien,[2] Esther A. Zaal,[4] Celia Berkers,[4] Rosalinde Masereeuw,[3] Manoe J. Janssen.[4] Roos Masereeuw-group *[1]Utrecht Institute of Pharmaceutical Sciences, Utrecht, Netherlands; [2]Wilhelmina Children's Hosp Univ Med Ctr, Utrecht, Netherlands; [3]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands; [4]Utrecht University, Utrecht, Netherlands; [5]Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Recently, a 23-month old girl presented with rickets, metabolic acidosis, signs of renal Fanconi syndrome and increased granulocyte cystine levels. The suspected diagnosis was cystinosis, a disease caused by mutations in the *CTNS* gene (cystine transporter), leading to the lysosomal accumulation of cystine, causing organ damage, particularly the kidneys. However, genetic testing revealed no mutation in *CTNS*, but compound heterozygous pathogenic mutations in the *ATP6V1B1* gene. *ATP6V1B1* encodes the B1 subunit of the lysosomal V1 ATPase, which is deficient in distal renal tubular acidosis type 1B, but with an unknown link to cystinosis. The present study aimed to determine the link between renal tubular acidosis and nephropathic cystinosis.

Methods: CRISPR/Cas9 technology was used to knock-out the *ATP6V1B1* gene in conditionally immortalized proximal tubular epithelial cells (ciPTEC) and cell characteristics were compared to isogenic *CTNS*-/- cells. An untargeted metabolomics approach based on UHPLC-MS/MS was applied for the intracellular quantification of metabolites differentially expressed in knock-out and control cells. Fluorescence-based imaging assays were applied to monitor the lysosomal-autophagy dynamics (TFEB, LC3, and DQ-BSA) in ciPTEC.

Results: The *ATP6V1B1*-/- isogenic ciPTEC showed a significant increase in cystine accumulation compared to healthy control cells (0.26 vs. 0.13 nmol/mg protein; p<0.05). But this was significantly lower as compared to cystine accumulation in *CTNS*-/- cells (6.32 vs. 0.26 nmol/mg protein; p<0.05). Like the *CTNS*-/- cells, *ATP6V1B1*-/- cells demonstrated an abnormally increased autophagy as shown by the increased TFEB nuclear translocation (2-fold; p<0.05), increased accumulation of LC3 (2.3-fold; p<0.05), and increased lysosomal degradation of DQ-BSA (2-fold; p<0.05). Moreover, using metabolomics, we identified several metabolites and pathways that were altered (p<0.05) in both renal acidosis and cystinotic cells.

Conclusions: We successfully developed a new genetically engineered renal tubular acidosis cell model with isogenic controls. These cells provide a novel versatile tool to study the pathology of renal tubular acidosis. Metabolomics allowed us to bridge the gap between cystinosis and renal acidosis, with the future aim of finding druggable targets.

Impact of Enzymatic Degradation of Plasma Cysteine in a Mouse Model of Cystinuria Under Dehydration Challenge

Giulia Agnello, Jason F. Wiggins, Silvia Ferrati, Anthony G. Quinn, Scott W. Rowlinson. *Aeglea BioTherapeutics, Inc., Austin, TX.*

Background: Cystinuria is a genetic disease resulting from mutations in the *SLC3A1* and/or *SLC7A9* dibasic amino acid transporter genes. Disruption of transporter function leads to increased urine cystine concentrations that exceed the limit of solubility with cystine precipitation and stone formation. In addition to severe episodic symptoms including abdominal pain, affected patients require multiple procedural interventions with an increased risk of hypertension and chronic kidney disease. Although high fluid intake remains a cornerstone of therapy, these regimes are problematic and can lead to nocturia and increased day time frequency. Maintaining an adequate urine output is particularly challenging when oral hydration is compromised or during periods of increased fluid loss including occupational commitments such as troop deployments (PMID:16001591). We previously reported that enzymatic degradation of cystine reduces the propensity for kidney and bladder stone formation in a mouse model of cystinuria. Herein, we investigated the therapeutic potential of cystine enzymatic degradation as a therapeutic approach to prevent cystine stone formation in dehydration prone environments.

Methods: We used a murine model of cystinuria (*SLC3A1*-/-) that develops stones between 4 & 7 weeks of age (PMID:28165480) and rationed water to 65% to model

dehydration conditions. During water rationing, mice were administered either vehicle or a cystine degrading enzyme, and urine cystine concentration was monitored at specific timepoints prior to and after treatment.

Results: Pharmacodynamic analysis of urinary cystine demonstrated that enzymatic degradation of plasma cystine results in reduction of total cystine levels in urine despite temporary dehydration.

Conclusions: This study demonstrates that enzymatic degradation of cystine is effective at reducing the levels of cystine in urine in a mouse model of cystinuria in temporary dehydration conditions. Given that the incidence of urolithiasis is higher in conditions causing dehydration (e.g. warmer climates) (PMID:12709088), enzymatic degradation of cystine warrants further investigation as a new potential approach for disease management of cystinuric patients.

Whole-Exome Sequencing Reveals ATP6V1C2 as a Novel Candidate Gene for Recessive Distal Renal Tubular Acidosis

Tilman Jobst-Schwan,[1,2] Verena Klambt,[1] Amar J. Majmundar,[1] Shirlee Shril,[1] Florian Buerger,[1] Isabel Ottlewski,[1] Rezan Topaloglu,[3] Danko Milosevic,[4] Michelle A. Baum,[1] Patricia M. Kane,[5] Seth L. Alper,[6] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]University Hospital Erlangen, Erlangen, Germany; [3]Hacettepe University, Ankara, Turkey; [4]Zagreb School of Medicine, Clinical Hospital Centre Zagreb, Zagreb, Croatia; [5]SUNY Upstate Medical University, Syracuse, NY; [6]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Distal renal tubular acidosis (dRTA) is a rare renal tubular disorder characterized by hyperchloremic metabolic acidosis and impaired urinary acidification. Mutations in 3 genes (*ATP6V0A4, ATP6V1B1* and *SLC4A1)* constitute a monogenic causation in 58-70% of familial childhood-onset dRTA cases. *ATP6V0A4* and *ATP6V1B1* both encode for subunits of the vacuolar V-ATPase. Just recently, mutations in *FOXI1* have been identified as an additional cause. Therefore, we hypothesized that additional monogenic causes of dRTA remain to be discovered.

Methods: We performed panel sequencing and whole exome sequencing (WES) in a cohort of 17 families with 19 affected individuals with pediatric onset dRTA. Yeast growth assays and immunoblot analysis of vacuolar V-ATPase subunits were performed for *ATP6V1C2*. Transmembranous transport experiments were performed for *SLC4A2* after expression in *Xenopus* oocytes.

Results: We identified a causative mutation in 1 of the 3 "classical" known dRTA genes in 10/17 families (58%). Genomic DNA of the 7 unsolved families was then subjected to WES analysis. We identified mutations in 3 genes: *ATP6V1C2*, which encodes another kidney- specific subunit of the V-type proton ATPase (1 family); *WDR72* (2 families) which is an established disease gene for amelogenesis imperfecta, but was also previously implicated in V-ATPase trafficking in cells; and *SLC4A2* (1 family), a paralog of known dRTA gene *SLC4A1*. We then assessed 2 of these mutations for deleteriousness through functional studies. Yeast growth assays and immunoblot analysis of vacuolar V-ATPase subunits for *ATP6V1C2* revealed loss-of-function for the patient mutation with impairment of V-ATPase stability, strongly supporting *ATP6V1C2* as a novel dRTA gene. In contrast, *Xenopus* oocyte experiments did not reveal a functional impact of the *SLC4A2* mutation in the transmembranous transport experiments.

Conclusions: We provided a molecular diagnosis in a known dRTA gene in 10/17 families with dRTA (58%), identified a mutation in *ATP6V1C2* as a novel human dRTA candidate gene, and provided further evidence for phenotypic expansion in *WDR72* mutations from amelogenesis imperfecta to dRTA.

Proteomic Analysis of Urinary Exosomes in Patients with Gitelman Syndrome

Chih-Chien Sung,[1] Sung-Sen Yang,[2] Shih-Hua P. Lin.[1] *[1]Tri-Service General Hospital, Taipei, Taiwan; [2]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Gitelman syndrome (GS) are hereditary salt-losing tubulopathies resulting from defects of sodium-chloride cotransporter (NCC). Urinary exosome analysis of NCC by western blotting has been evaluated. However, the urine exosomal protein alterations in patients with GS remains unclear. Our purpose to examine urine exosomal protein alterations in patients with GS.

Methods: Urinary exosomes were further isolated by ultracentrifugation method. We applied isotopic demethylation labeling coupled with liquid chromatography-tandem mass spectrometry (LC–MS/MS) with CID to discover urinary exosomal target proteins in patients with GS (n=10) compared to health controls (n=10).

Results: We identified a total of 253 nonredundant proteins that were based on at least two distinct tryptic peptides. Of these, 241 proteins were quantified. Specifically, 90 proteins showed an altered pattern ($Log2|GS/Control| \geq 1$) in patients with GS including 50 upregulated proteins and 40 down-regulated protein. Renin-angiotensin system was the shared KEGG pathway/biological process in the upregulated differentially genes that compatible with the clinical presentation in GS patients with salt-losing tubulopathy and volume depletion. NCC has been identified in urinary exosome from health control but not from patients with GS that was consistent with the finding of NCC mutation in GS. Of interest, there is no significant change in specific exosome markers in CD9, CD81, phosphoglycerate kinase 1 (PGK1), L-lactate dehydrogenase A chain (LDHA), and Alpha-enolase (ENOA) that could be used as an internal control.

Conclusions: The identified proteins constitute potential targets for understanding the signal pathway or pathogenesis in in patients with GS. Further target protein needs to be validated in the future.

Funding: Government Support - Non-U.S.

TH-PO818

Investigating the Pathophysiology and a Potential Therapeutic Approach for Cystinosis

Amer A. Jamalpoor,[1] Esther A. Zaal,[2] Celia Berkers,[3] Elena N. Levtchenko,[4] Rosalinde Masereeuw,[5] Manoe J. Janssen.[3] *[1]Utrecht Institute of Pharmaceutical Sciences, Utrecht, Netherlands; [2]Biomolecular Mass Spectrometry and Proteomics, Department of Biomolecular Sciences, The Netherlands, University of Utrecht, Utrecht, Netherlands; [3]Utrecht University, Utrecht, Netherlands; [4]University Hospitals Leuven, Herent, Belgium; [5]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.*

Background: Nephropathic cystinosis is a severe genetic disorder caused by mutations in *CTNS* gene (cystine transporter), leading to the lysosomal accumulation of cystine and progressive organ damage. To date, no appropriate *in vitro* isogenic cystinotic cell models exist, a pre-requisite to study the link between the *CTNS* gene and the disease, and to investigate potential therapeutic strategies. Hence, our aim was to generate a cystinosis phenotype in human kidney cells using CRISPR/Cas9 and study cystinosis pathology.

Methods: We selectively knocked-out the *CTNS* gene in conditionally immortalized proximal tubular epithelial cells (ciPTEC). An untargeted metabolomics approach based on UHPLC-MS/MS was applied for the intra- and extracellular quantification of cystine and other metabolites differentially expressed in knock-out and control cells. Various assays were applied to monitor the lysosomal-autophagy dynamics (TFEB, LC3-II and DQ-BSA) in ciPTEC.

Results: The *CTNS-/-* isogenic cell line of ciPTEC showed a significant increase in cystine accumulation compared to healthy control cells (6.32 *vs.* 0.05 nmol/mg protein; $p<0.001$). Upon treatment with cystine depleting drug cysteamine, *CTNS-/-* cells showed a significant reduction in cystine levels (0.74 nmol/mg protein; $p<0.01$). Using metabolomics, we identified that not only cystine but also >25 metabolites and 9 metabolic pathways were affected ($p<0.05$) in cystinotic cells. *CTNS-/-* cells demonstrated an abnormally increased autophagy, confirmed by the increased TFEB nuclear translocation (2-fold; $p<0.05$), increased accumulation of LC3-II (2.3-fold; $p<0.05$) and increased lysosomal degradation of DQ-BSA (2-fold; $p<0.05$). Of note, cysteamine had no effect on the restoration of autophagy, which might explain its limited effect on treating renal Fanconi syndrome. However, a promising registered drug molecule was found to be effective either alone or in combination with cysteamine in resolving cystinotic manifestations.

Conclusions: We developed a genetically engineered cystinotic cell model with isogenic controls. These cells provide a novel versatile tool to study the pathology of cystinosis and develop screens for drugs with the potential to reverse the symptoms. Metabolomics allowed an unbiased analysis of potential new targets for treatment of cystinosis.

Clinical and Genetic Characteristics in Dent Disease 2 and Lowe Syndrome

Nana Sakakibara,[1] Kandai Nozu,[1] China Nagano,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Yuko Shima,[2] Koichi Nakanishi,[3] Kazumoto Iijima.[1] Department of pediatrics *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Wakayama Medical University, Wakayama City, Japan; [3]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan.*

Background: Dent disease is associated with low molecular weight proteinuria and hypercalciuria and caused by mutations in either two genes of *CLCN5* (Dent disease 1) or *OCRL* (Dent disease 2). On the other hand, Lowe syndrome is characterized by congenital cataract, developmental delay and Fanconi syndrome. Lowe syndrome is also caused by *OCRL* gene mutations, but the clinical severity differs between these two diseases. The reason for this difference remains unclear, but previous reports have shown that patients with any type of mutations before exon 7 were diagnosed with Dent disease, and those with truncating mutations after exon 8 were diagnosed with Lowe syndrome. The purpose of this study is to investigate the difference in clinical and genetic characters between Dent disease 2 and Lowe syndrome in the Japanese population.

Methods: We conducted gene test for clinically suspected cases of Dent disease or Lowe syndrome. In total, 22 male cases in 20 families were detected the mutations in *OCRL* gene. We retrospectively studied these patients to investigate the genotype-phenotype correlation in *OCRL* disorders.

Results: Eleven patients were clinically diagnosed with Lowe syndrome and 11 patients in 9 families with Dent disease 2. Seven novel mutations were identified. Four cases had mutations before exon 7, all of which were Dent disease 2. All patients who had truncating mutations or large deletions after exon 8 were diagnosed with Lowe syndrome, whereas missense mutations after exon 8 were associated with both Lowe syndrome and Dent disease 2. In other words, all cases of Dent disease 2 with mutations after exon 8 had missense mutations. Four of the patients diagnosed with Lowe syndrome were able to walk independently. Of these four cases, two had missense mutations and the other two had splice-site mutations.

Conclusions: As in previous reports, all patients with any type of mutations before *OCRL* exon 7 were Dent disease 2, and truncating mutation after exon 8 were Lowe syndrome. However, missense and splice-site mutations after exon 8 showed a spectrum ranging from Dent disease 2 to relatively mild Lowe syndrome.

TH-PO820

Inflammasome Activation in Primary Hyperoxaluria

Bernd Hoppe,[1] Julia Mehring,[2] Eicke Latz.[3] *[1]University Hospital Bonn, Bonn, Germany; [2]University of Bonn, Germany, Bonn, Germany; [3]Institute of Innate Immunity, Bonn, Germany*.

Background: In the primary hyperoxalurias (type I - III), increased production of oxalate in the liver consecutively leads to hyperoxaluria, urolithiasis and/or nephrocalcinosis. Hyperoxaluria causes deposition and internalization of calcium oxalate (CaOx) crystals in the epithelial cells of the proximal tubule. As a result, it activates the inflammasome pathway, which is a protein complex in the cytosol of macrophages. In a mouse model of CaOx induced inflammasome activation, the progression of renal damage was delayed by administration of a specific NLRP3 inflammasome pathway inhibitor. The aim of our present study was to investigate inflammasome activation in PH patients.

Methods: Serum samples from 50 PH patients (39 PH I, 6 PH II, 5 PHII) were collected. Thirtyfive patients had preserved renal function, 14 PH I an d1 PH II patient were on maintenance hemodialysis (HD). In addition, samples from 8 healthy controls and from 9 non PH HD patients were collected. So far, results from 9/6 PH patients with good renal function/HD and from 4 controls are available. Samples were examined for inflammation and organ damage markers by use of a proximity extension assay (PEA) (n=184). In PEA antibody pairs bind to the desired target structure and, if in close proximity to another, form a new PCR target sequence, which can be quantified using real-time PCR.

Results: The preliminary findings have shown no differences in inflammatory/organ damage markes among the three types of PH patients with preserved kidney function. However, there were signficiant reactions in dialysis dependent PH I patients. So far it is not yet clear whether these differences are caused by the advanced kidney disease or the dialysis therapy per se.

Conclusions: Our current results might allow the following conclusions: 1) the activation of the inflammasome described in the mouse model is only detectable late, e.g. in ESRD, 2) there is no inflammatory reaction to oxalate at all, 3) the response is below the detection limit, or 4) all three forms have a comparable inflammation and therefore no difference can be seen. The latter might suggest protective factors in type III or predisposing factors in types I and II.

TH-PO821

Understanding the Increased Burden of Advanced Primary Hyperoxaluria Type 1 (PH1): A Survey of Physician Experiences

David S. Danese,[1] Robert S. Murray,[1] Amy Monpara,[1] Rony Ben-David,[2] Tyler W. Crockett,[2] Melissa R. Holloway,[2] Kimberly Barr,[2] Shannon M. Doyle,[2] Ken Howie.[2] *[1]Alnylam Pharmaceuticals, Cambridge, MA; [2]Magnolia Innovation, Hoboken, NJ*.

Background: PH1 is a genetic disorder characterized by persistent hepatic overproduction of oxalate. Oxalate crystalizes with calcium to ultimately cause renal insufficiency and multi-organ damage. As PH1 progresses, patients may require intensive dialysis, and dual liver/kidney transplant is the only option to resolve the underlying metabolic defect and replace damaged kidneys. Here we describe the disease burden of PH1 in patients who have progressed to advanced kidney disease using insights from physician interviews conducted to better understand PH1.

Methods: Select participation criteria included: physicians in practice 2+ years; active role in diagnosing, treating, or managing 1+ PH1 patient(s) within last 5 years; spend ≥50% of time in direct patient care; able to review PH1 patient records. Patient history served as basis for further probing in 60-minute interviews involving open-ended questions from a semi-structured interview guide.

Results: 37 physicians reported on 54 PH1 patients. By time of diagnosis, 54% (N=29) of patients had progressed to advanced disease. Among patients with preserved renal function at diagnosis (N=25), 20% progressed to dialysis, with many others showing evidence of renal decline since diagnosis. Of all patients, 48% (N=26) required hemodialysis; of these, 47% required dialysis ≥4x/week, and 35% (N=9) required 6x/week. Patients were on dialysis for a mean of 2 (range: 0.25–6.5) years. 34% (N=19) of patients ultimately underwent transplant, typically dual liver/kidney transplant.

Conclusions: As PH1 progresses, the disease burden increases substantially, necessitating intensive dialysis and transplant. Often, patients progressed to advanced kidney disease before diagnosis, limiting opportunity to modify disease course. While intensive dialysis is intended to be a bridge to transplant, as it cannot keep pace with the oxalate overproduction and systemic deposition of oxalate that occurs at this stage, many patients spent an extended time on dialysis, which is associated with poorer outcomes. Patients require earlier diagnosis and effective therapies to prevent disease progression and the associated burden.

Whole-Exome Sequencing Identifies Nephrolithiasis (NL) Candidate Genes in Large Consanguineous Pakistani Families

Isabel Ottlewski,[1] Ihsan Ullah,[2,3] Amar J. Majmundar,[1] Ali Amar,[2] Shagufta Khaliq,[2] Muhammad Y. Zahoor,[3] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Division of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]University of Health Sciences, Lahore, Pakistan; [3]Molecular Biology & Biotechnology Section, Institute of Biochemistry and Biotechnology, University of Veterinary and Animal sciences, Lahore, Pakistan*.

Background: Nephrolithiasis (NL) affects 1 in 11 individuals worldwide and causes high patient morbidity, frequent hospitalizations and surgical interventions. We previously detected a monogenic cause in established NL disease genes in 15% of 268 American and European NL families (Halbritter *JASN* 26:543, 2015) and 7% of 235 Pakistani NL families (Amar *Hum Genet* 138:211, 2018). We, then, performed whole exome sequencing (WES) in 17 unsolved Pakistani NL families with multiple affected members and prominent consanguinity to discover novel candidate NL genes.

Methods: We performed WES variant analysis by applying multiple recessive and dominant genetic models based on pedigree structure. Candidate disease genes were evaluated further by kidney single-cell mRNA expression (Park *Science* 360:758, 2018), because known NL genes predominantly exhibit nephron tubular segment expression. Dominant candidate genes were additionally assessed for population variant intolerance, as known dominant NL genes associated with severe phenotypes show high genomic constraint.

Results: We detected deleterious mutations in 24 candidate genes in 12/17 total families. In 10 families with significant homozygosity (>100 Mb in at least 1 affected family member), we detected deleterious recessive mutations in 10 genes. Of these, we identified 2 novel recessive candidate genes (*INPP5B, GGTLC1*) based on nephron tubular expression. In 8 families with >3 affected members, we evaluated for dominantly inherited variants and detected deleterious mutations in 14 genes. Of these, we identified 1 dominant candidate gene (*HIPK3*) based on nephron tubular expression and high population variant intolerance.

Conclusions: By WES of 17 Pakistani NL families, we identified 2 novel recessive and 1 novel dominant candidate NL disease genes.

TH-PO823

Hypophosphatemia Linked to Chromosome X (XLH): Impact on the Quality of Life

Jose J. Broseta Monzo,[1] Luis Carlos Lopez Romero,[2] Elena Guillen,[1] Aina Gómez,[2] Julio H. Jaras.[2] *[1]Servei de Nefrologia i Trasplantament Renal, Hospital Clínic de Barcelona, Barcelona, Spain; [2]Servicio de Nefrología, Hospital Universitari i Politecnic La Fe, Valencia, Spain*.

Background: XLH is a rare disease, with dominant inheritance and where the genetic basis is the mutation of the PHEX gene, located in the short arm of chromosome 22. This gene codes for an endendendopeptidase, homologous named, which causes the overproduction of FGF- 23, a counterregulatory hormone of phosphate reabsorption by the sodium/phosphate cotransporters in the renal tubule, as well as increasing catabolism and decreasing the synthesis of the active form of vitamin D. The disease has a wide phenotypic variability and different studies have shown a significant impact on the quality of life (QoL) of these patients with reduced mobility and functional disability. A human anti-FGF-23 monoclonal antibody, burosumab, approved in the USA and Europe for the treatment of XLH, corrects the underlying pathophysiology of the disease. It has shown impressive efficacy in children and its study in symptomatic adults with this disease is under study. The objective of this study is to know the impact on the quality of life of a series of patients affected by XLH.

Methods: Longitudinal study with retrospective data collection of a series of patients affected by XLH who were in follow-up in the Department of Nephrology of the Hospital Universitari i Politècnic La Fe (Valencia). Data on the impact of the disease has been collected through a QoL test (EQ-5D-5L), and clinical and radiological variables were collected from the time of diagnosis until 2019.

Results: Data were collected from 18 patients, 38% males of 21.64 ± 11.61 years, of which all had osteomalacia or rickets of some degree, 94.4% short stature, 44% some type of affectation joint 16.6%, enthesopathies, 5.5% stenosis of the medullary canal and none craniosynostosis. Regarding the QoL, 75% referred problems for walking, 50% reported problems to perform their daily activities, 25% even for their own self-care, 50% referred anxiety or depression and 75%, pain. Their average score with respect to their state of health was 63.75 ± 22.86 out of 100.

Conclusions: XLH is a disease with different musculoskeletal manifestations that condition an important impact on the quality of life of patients in both physical and psychological aspects. That is why the appearance of burosumab as a new therapeutic strategy that blocks the physiopathological mechanism of the disease will change this paradigm.

TH-PO824

The Value of Genotypic and Imaging Information to Predict Outcomes in a Large Longitudinal ADPKD Mayo Cohort

Sravanthi Lavu, Lisa E. Vaughan, Marie E. Edwards, Sarah R. Senum, Fouad T. Chebib, Vicente E. Torres, Peter C. Harris. *Mayo Clinic, Rochester, MN.*

Background: Variability in severity of ADPKD is influenced by genic and allelic factors at the causative locus, plus other genetic and environmental factors. In a mutation characterized ADPKD cohort, we analyzed the predictive ability of the germline mutation and Mayo Imaging Class (MIC) to predict renal functional and structural outcomes.

Methods: Mayo Clinic patients >15 years having a *PKD1* or *PKD2* pathogenic variant were included (n=1072). Longitudinal eGFR (n=870) and htTKV (n=600) data were collected until ESRD. PKD1 patients were divided into truncating (Mutation Strength Group 1; MSG1), and strongly and weakly predicted non-truncating mutations (MSG2 & 3). The associations between MSG group or MIC and time to 50% loss of eGFR or ESRD or 50% increase in TKV were evaluated using Cox regression with age as the timescale.

Results: Median time from baseline to 50% eGFR loss/ESRD was 8.1, 8.8, 15.5 and 15.6 years for *PKD1* MSG1, 2, 3, and PKD2, and 6.7, 8.2, 10.7 and 17.2 years for MIC classes 1E, 1D, 1C & 1B, respectively (MIC class 1A survival was >50% throughout follow-up). This equates to *PKD1* MSG2, 3, and PKD2 being associated with a lower risk of 50% eGFR loss/ESRD compared to MSG1 [HR (95% CI): 0.69 (0.51-0.93), 0.35 (0.25-0.49), and 0.28 (0.20-0.40), respectively; P<0.001]; MIC classes 1A-1D were also associated with a lower risk of ESRD compared to class 1E [HR (95% CI): 0.039 (0.018-0.087), 0.10 (0.065-0.16), 0.19 (0.13-0.28), and 0.44 (0.30-0.63), respectively; P<0.001]. A multivariable model including both MSG and MIC had strong discriminatory ability (C-statistic of 0.802). Median time to 50% increase in htTKV was 8.3, 11.1, 12.9, 13.3 & not reached, respectively, for MIC 1E, 1D, 1C, 1B & 1A; hence the other imaging classes had a lower risk of reaching this endpoint than MIC group 1E (P<0.001). However, genotypic class was not found to be associated with a 50% increase in htTKV (p=0.56).

Conclusions: Genotype (MSG) and MIC are strong predictors of functional renal outcome in ADPKD; however, genotype was not associated with htTKV increase of 50%. Utilizing both genotype and imaging class is helpful for identifying patients with severe disease, thereby aiding selection of patients for clinical trials and treatment.

ADPKD Calculator: A New Tool to Help in the Detection of Patients with Rapid Progression

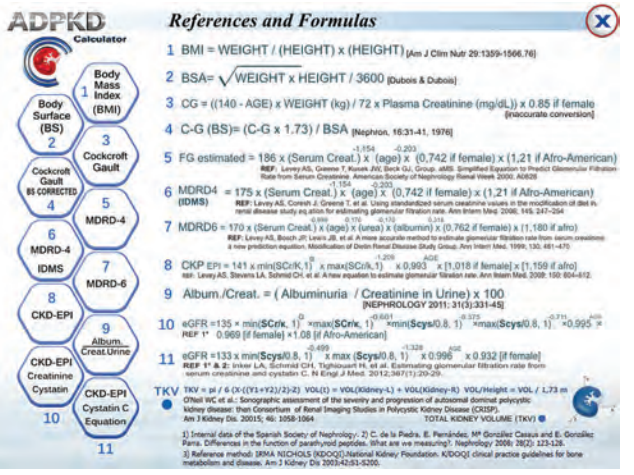
Ricardo Mouzo Mirco,[1] Juan A. González-Fernández,[3] Fernando Simal,[1] Manuel Heras Benito,[2] Emilio Sanchez.[2] *[1]Nephrology Unit, Hospital Universitario El Bierzo, Ponferrada, Spain; [2]Nephrology Unit, Sociedad Castellano Astur Leonesa de Nefrología, Salamanca, Spain; [3]Hospital Universitario El Bierzo, Ponferrada, Spain.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), a frequent hereditary renal disorder, is the etiology of 10% of t dialysis or renal transplant patients and approximately 70% will progress to end-stage renal disease in the fifth decade of life. In 2016 the ERA-EDTA published the Recommendations for the use of Tolvaptan, that included an Algorithm for the recognition of patients with rapid progression, to assess indications for initiation of treatment in ADPKD patients. Starting from this point, we have developed a new App for free use (Scientifically Endorsed by the SCALN), to facilitate detection of rapid progressions. The aim of this App is calculate variables of Renal Function, Total Renal Volume and by means of an Algorithms and Prediction Models, identify ADPKD patients with Rapid Progression.

Methods: Once the conditions of use have been accepted, the patient's data can be entered in various ways. The methods are described in the App itself in "References and Formulas" button as you can see in attached image.

Results: Body Mass Index. Body Surface. Renal Function (Cockroft Gault BMS corrected; MDRD-4; MDRD-4 IDMS; MDRD-6; CKD-EPI; Urine Albumin/Creatinine Ratio; CKD-EPI Cystatin; CKD-EPI Cystatin C Equation). CKD Stage KDIGO 2012 (wiht graphic representation). KIDNEY TOTAL VOLUME with link to Mayo Clinic Website (The user must be previously accepting Mayo Clinic Terms of Use). Identification of Rapid Progressing patients through the use of: 1) the Digitalized Algorithm of the ERA-EDTA Workings Groups cited; and 2) PRO-PKD Prediction Model.

Conclusions: ADPKD Calculator, allows the nephrologist to quickly and easily identify patients as Rapid Progressives, in order to proceed to implement those measures that may slow the progression to ESRD. Finally, the free access to this App from www.scaln.es, its availability in multiplatform and English/Spanish languages, facilitates the use of it.



TH-PO826

Expanded Imaging Classification of Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Kyongtae T. Bae,[1] Tiange Shi,[1] Cheng Tao,[1] Alan S. Yu,[2] Vicente E. Torres,[3] Arlene B. Chapman,[4] Ronald D. Perrone,[5] Godela M. Brosnahan,[6] Theodore I. Steinman,[7] William E. Braun,[8] Kaleab Abebe,[1] Peter C. Harris,[3] Doug Landsittel.[1] HALT PKD Consortium *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Kansas Medical Center, Kansas City, KS; [3]Mayo Clinic, Rochester, MN; [4]University of Chicago, Chicago, IL; [5]Tufts Medical Center, Boston, MA; [6]University of Colorado Denver, Aurora, CO; [7]Beth Israel Deaconess Medical Center, Boston, MA; [8]Cleveland Clinic, Cleveland, OH.*

Background: Mayo imaging classification of ADPKD is a widely accepted tool that uses height-adjusted total kidney volume (htTKV) and age to identify patients at highest risk for disease progression. The current Mayo classification, however, is applicable only to patients who have typical disease with diffuse cystic involvement (Class 1) by excluding 5-10% of patients (Class 2) with atypical kidney morphology whose htTKV do not appear to predict eGFR decline. Thus, for Class 2 patients, predicting the risk for progression remains uncertain.

Methods: Twenty-one patients of Class 2 with predominant exophytic cyst distribution were identified from the HALT-A study (558 ADPKD adults), and their htTKV were remeasured by excluding exophytic cysts to estimate revised htTKV (rev-htTKV). For the analysis, the odds ratio of reaching CKD stage 3 (CKD3) per 100 ml/m increment in htTKV were compared in both unadjusted and adjusted (covariates: baseline age, eGFR, BMI, sex and race) logistic models for (1) only Class 1 participants, (2) all participants with original htTKV and (3) all participants with rev-htTKV.

Results: All 6 logistic models showed significant association (p<0.001) between baseline htTKV and reaching CKD3. Estimated odds ratios of reaching CKD3 for all participants increased from use of htTKV to rev-htTKV for both unadjusted (from 1.26 to 1.31) and adjusted (from 1.18 to 1.26) models. Because rev-htTKV was always less than htTKV, the probability of reaching CKD3 decreased for all Class 2 participants. Furthermore, with rev-htTKV, the probability of outcome for Class 2 participants who did not reach CKD3 decreased more than those who reached CKD3.

Conclusions: For Class 2 with predominant exophytic cyst distribution, the association between baseline htTKV and CKD3 outcome became stronger with the use of htTKV remeasured after excluding exophytic cysts, compared to the use of original htTKV.

Funding: NIDDK Support

Comparison of odd ratios of reaching CKD3 with and without including class 2 in two different models

Outcome: CKD3, eGFR<60		Unadjusted model			Adjusted model		
Models	N	OR	95% CI	P	OR	95% CI	P
Excluding Class 2	433	1.29	1.21-1.38	<0.001	1.23	1.14-1.33	<0.001
Including Class 2, original htTKV	451	1.26	1.18-1.34	<0.001	1.18	1.10-1.27	<0.001
Including Class 2, rev-htTKV	451	1.31	1.22-1.40	<0.001	1.26	1.16-1.36	<0.001

TH-PO827

A Computable Phenotype for ADPKD

Mohamad A. Kalot,[1] Abdallah El alayli,[3] Mohammed N. Alkhatib,[5] Kerri A. McGreal,[4] Alan S. Yu,[4] Reem Mustafa.[2] *[1]University of kansas medical center, Kansas city, MO; [2]University of Kansas, Kansas City, KS; [3]Lebanese American University, Beirut, Lebanon; [4]University of Kansas Medical Center, Kansas City, KS; [5]Kansas University Medical Center, Kansas, KS.*

Background: Autosomal Dominant Polycystic kidney disease (ADPKD) is the most common inherited disease causing of end-stage kidney disease (ESKD). A computable phenotype is an algorithm used to identify a certain set of patients within an electronic

medical record system. Developing a computable phenotype that can identify patients with ADPKD will assist researchers in designing studies and clinical trial recruitment within this population.

Methods: We reviewed a random sample of 1000 medical charts from the University of Kansas Medical Center database. The sample was divided into four groups (A, B, C, and D) of 250 patients each. Group A included patients followed in nephrology clinics who had ICD (International Classification of Diseases) 9 or 10 codes for ADPKD, Group B included those with no ICD codes of ADPKD, but with ICD codes of renal cysts. Group C and D had patients who did not attend the nephrology clinic, with and without ICD 9/10 codes for ADPKD respectively. We used the ICD 9 codes 753.12-13, and the ICD 10 codes Q61.2-3 for ADPKD. We used the ICD 9 code 593.2 and the ICD 10 code N28.1 for renal cysts. For all medical records, we extracted family history of PKD, hypertension, glomerular filtration rate, proteinuria, kidney size, number of kidney cysts. Then, we compared the data to internationally accepted diagnostic criteria for ADPKD to determine the diagnosis of ADPKD (reference standard). We calculated test accuracy results for the proposed computable phenotype for ADPKD.

Results: The computable phenotype to identify patients with ADPKD who attended the nephrology clinic has a sensitivity of 98.7% (95% CI 96.4-99.7), a specificity of 84.1% (95% CI 79.5-88.1), a positive predictive value (PPV) of 83.4 % (95% CI 79.43 - 86.72%), and a negative predictive value (NPV) of 98.8% (95% CI 96.4-99.6). For those who did not attend the nephrology clinic the computable phenotype has a sensitivity of 97.1% (95% CI 93.3-99.0), a specificity of 82.0% (95% CI 77.4-86.1), a PPV of 74.0% (95% CI 69.2-78.3), and a NPV of 98.2[RM1] % (95% CI 95.7-99.2).

Conclusions: A computable phenotype using the ICD9 and 10 codes can correctly identify most patients with ADPKD, and can be used by researchers to categorize ADPKD patients' cohorts with limited inaccuracy.

TH-PO828

A Convolutional Neural Network for Large-Scale Segmentation of Kidneys in Autosomal Polycystic Kidney Disease

Luca Antiga,[1] Dr. imtiaz H. Mohiuddin,[2] Mary Dixon,[3] Annie Lutz.[4] *[1]Orobix Srl, Bergamo, Italy; [2]Otsuka Pharmaceutical, Rockville, MD; [3]Innovenn, Madison, WI; [4]Innovenn, Inc., Madison, WI.*

Background: Total kidney volume (TKV), along with age and Glomerular Filtration Rate (eGFR), is an early prognostic marker of progression in autosomal dominant polycystic kidney disease (ADPKD). Current manual or semi-automated methods for estimation of TKV from imaging data are laborious, time-consuming approximations subject to human perception and experience; this has hampered a widespread adoption of TKV as a biomarker in ADPKD. We report the development and performance of a fully automated method for kidney segmentation and TKV estimation from magnetic imaging (MR) data in patients with ADPKD on a large patient cohort using a deep learning approach. In addition, we describe how such an estimate can be employed for predicting disease progression and monitoring progression, with the aim of supporting clinical management.

Methods: We employ a fully-convolutional neural network based on the volumetric U-net architecture, trained on an extensive dataset of 1620 T2-weighted magnetic resonance imaging scans extracted from the multicenter TEMPO3:4 trial (NCT00428948); expert outlines were available as ground truth. The method is validated on 490 scans, not included in the training dataset, extracted from 179 individual subjects. Based on the data from the same trial, we develop a similarity model for the prediction of the expected TKV growth over time.

Results: We obtained a 90th percentile estimation error of TKV and its change over time of 13% and 11% of the baseline volume, respectively. We predict 3-year TKV based on baseline characteristics with R2 of 0.954 on the TEMPO3:4 placebo data.

Conclusions: The present work represents the first, large-scale example of fully automated TKV estimation in ADPKD that has been trained and validated on a large-scale, multi-centric dataset. When coupled with clinical data from the same trial, we demonstrate the ability of a machine learning algorithm to predict likely TKV progression with high accuracy. This prognostic information combined with other clinical findings may support clinical care.

TH-PO829

Expert-Level Segmentation Using Deep Learning for the Volumetry of Polycystic Kidney and Liver

Hyunsuk Kim,[2,9] Jong-woo Yoon,[2] Hyo Jin Kim,[3] Miyeun Han,[4] Eunjin Bae,[5] Hyun-seok Min,[1] Gwangho Choi,[9] Joonghyup Lee,[6] Jongsuk Choi,[7] Hyungjoo Cho,[1] Junga Koh,[8] Houn Jung,[10] Tae young Shin.[9] *[1]Tomocube, Seoul, Republic of Korea; [2]Hallym University, Kidney Research Institute, Chuncheon, Republic of Korea; [3]Dongguk University College of Medicine, Gyeongju-si, Republic of Korea; [4]Pusan National University Hospital, Busan, Republic of Korea; [5]Gyeongsang National University Changwon Hospital, Changwon-si, Republic of Korea; [6]Spectra, Seoul, Republic of Korea; [7]Dongguk University, Seoul, Republic of Korea; [8]Gangneung Dongin Hospital, Gangneung-si, Republic of Korea; [9]Hallym Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea; [10]Hallym University Medical Center, Chuncheon-si, Republic of Korea.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease, with serious impacts on patients. In polycystic kidney and liver diseases (PKLD), including ADPKD, volumetry is used to assess disease progression and drug efficiency. However, since no rapid and accurate method has been developed, volumetry has not been established in clinical practice, hindering the development of therapies for this disease. This study presents an AI-based PKLD volumetry method that showed powerful performance.

Methods: As a first experiment, the performance of AI was evaluated compared to ground-truth (GT). We trained a V-net based convolutional neural network on 175 ADPKD computed tomography (CT) segmentations (GT) produced by 3 experts using images from 214 patients. The Dice similarity coefficient (DSC), inter-observer correlation coefficient (ICC), and Bland-Altman plots of 39 GT and AI segmentations in the validation set were compared. Next, the performance of AI on the segmentation of 50 random CT images was compared to that of 11 PKLD specialists based on the resulting DSC and ICC.

Results: The DSC and ICC of the AI were 0.961 and 0.999729, respectively. The error rate was within 3% for approximately 95% of CT scans (error <1%, 46.2%, 1% ≤ error <3%, 48.9%). Compared to the specialists, AI showed moderate performance. Furthermore, an outlier in our results confirmed that even PKLD specialists can make mistakes in volumetry.

Conclusions: PKLD volumetry using AI was fast and accurate. AI showed comparable performance to that of human specialists, suggesting its practical use in clinical settings.

TH-PO830

Total Kidney Volume (TKV) Measurements in Autosomal Dominant Polycystic Kidney Disease (ADPKD) by 3D Ultrasound (3D-US) vs. Ultrasound Ellipsoid (US-EL)

Pedram Akbari,[3] Fatemeh Nasri,[3] Crystal F. Quist,[3] Elsa Guiard,[3] Ioan-Andrei Iliuta,[1] Syed E. Ahmed,[3] Luca Calvaruso,[2,4] Mostafa Atri,[1] Korosh Khalili,[1] York P. Pei.[1] *[1]University Health Network and University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]Toronto General Hospital UHN, Toronto, ON, Canada; [4]Università Cattolica del Sacro Cuore, Roma, Roma, Italy.*

Background: Total kidney volume (TKV) is a validated prognostic biomarker for risk assessment in ADPKD. TKV by magentic resonance imaging and manual segmentation (MRI-MS) is the "gold standard", but is relatively expensive, time-consuming, and not readily accessible. 3D-US is a new technology which may provide greater precision and accuracy for measuring TKV than US-EL. Here, we report a comparative study of these two US techniques for TKV measurements against MRI-MS.

Methods: We conducted a prospective study of 123 patients recruited at a PKD specialty center who underwent a standardized 3D-US and MRI. Kidney volumes (i.e. single kidney and TKV) by 3D-US and US-EL measured by 5 different experienced ultrasound technicians were compared to those by MRI-MS derived from an experienced radiologist blinded to patient clinical results. Bland-Altman plots were used to assess the agreement of TKV measurements by US vs. MRI.

Results: Table 1 shows the study patient characteristics. We found the accuracy of TKV measurements by US was operator-dependent and varied between different technicians. Compared to MRI-MS, Bland-Altman plots of TKVs by 3D-US and US-EL revealed a similar bias (-9.0% vs. -10.2%), range of diagreement (-42.25 to 24.31% vs. -41.25 to 20.85%), and difference of greater than 20% (27.2% & 24.3%), respectively. Converting height and age-adjusted TKV's to the Mayo Class Imaging Class (MCIC) we found a misclassifcation rate of 22.8% and 23.5% by 3D-US and US-EL, respectively.

Conclusions: TKV measurements by 3D-US and US-EL are less accurate than MRI-MS. Both US tecniques displayed similar bias, accuracy, and are operator-dependent; however, TKV by US-EL is simpler to use and more readily available. These factors need to be considered when US-dervied TKV is used for risk assessment in ADPKD as misclassification of MCIC (esp. 1B to 1C) can have important clinical consequence.

TH-PO831

Simplification of Total Kidney Volume Measurement Procedures for ADPKD

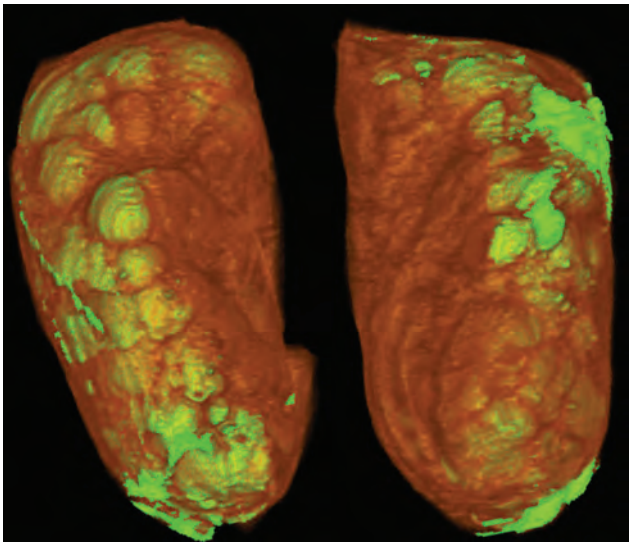
Ziba Mansoori,[1] Vivek Swarnakar,[1] Meyeon Park.[2] *[1]Quantitative Imaging Processing Center, UCSF, San Francisco, CA; [2]Medicine, Nephrology, UCSF, San Francisco, CA.*

Background: Total kidney volume (TKV) is an important measure of risk of disease progression in autosomal dominant polycystic kidney disease (ADPKD). Methods to measure TKV are labor-intensive and time-consuming, and not all centers have ability to measure TKV. We developed a technique to provide timely and reliable quantification of TKV using any sequence of abdominal magnetic resonance imaging (MRI).

Methods: Abdominal MRI scans of 74 consecutive patients from the UCSF Polycystic Kidney Disease Center of Excellence were selected. The technique was developed using functionality readily available in an FDA-approved commercial medical imaging analysis software (Ziosoft). Scans for the subjects were acquired from different scanner types (GE, Phillips) and field strengths (1.5 T, 3 T). On each scan the volumes of left and right kidneys were assessed. Measurements were done on coronal T2-weighted DICOM images (single shot fast spin echo/half-Fourier, slice thickness between 3 and 9 mm). The outer kidney contour was defined manually by tracing on each slice. The contour from each 2D slice was merged to create a true 3D volume of the kidney. The process is calibrated using parameters available in DICOM images. For some cases the cystic volume was measured for each kidney as well via a binary intensity value thresholding. The non-cystic volume was determined by digital subtraction of cystic volume from total kidney volume.

Results: Average time to implement these measures on standard non-contrast MRI sequence was 30 minutes. Comparing the TKV to measurements obtained by alternative methodology (reported by prior institutions on the same scans) revealed a concordance of > 90%.

Conclusions: Our technique is readily applicable to routine MRI images obtained for clinical purposes in ADPKD patients. Use of this technique may improve risk stratification availability for ADPKD patients.



3D volume rendering; cysts green.

TH-PO832

Performance of Ultrasound-Derived Average Kidney Length (aKL) for Risk Prediction in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Pedram Akbari,[3] Fatemeh Nasri,[3] Crystal F. Quist,[3] Elsa Guiard,[3] Ioan-Andrei Iliuta,[1] Syed E. Ahmed,[3] Luca Calvaruso,[2,4] Mostafa Atri,[1] Korosh Khalili,[1] York P. Pei.[1] *[1]University Health Network and University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]Toronto General Hospital UHN, Toronto, ON, Canada; [4]Università Cattolica del Sacro Cuore, Roma, Roma, Italy.*

Background: Total kidney volume (TKV) is a validated prognostic biomarker for risk assessment in ADPKD. However, accurate TKV measurements require magnetic resonance imaging (MRI), which is relatively expensive, time-consuming, and not readily accessible. To circumvent these issues, an ultrasound-derived aKL >16.5 cm (Kidney Int 88: 146-151, 2015) has been proposed as a diagnostic thresohld to identify patients with ADPKD at high-risk for progression. However, this approach has not been tested in a real world patient cohort.

Methods: We conducted a prospective study of 123 patients recruited from a PKD specialty center who underwent a standardized 3D-US and MRI. KLs from 3D-US were measured by 5 different experienced technicians; KLs and TKVs from MRI were derived by an experienced radiologist blinded to patient clinical results. Bland-Altman plots were used to assess the agreement of KLs by US vs. MRI. TKV adjusted for age and height was used to derive the Mayo Clinic Imaging Class (MCIC) and used as a "gold standard" for classifiying patients into low-risk (1A-1B) vs. high-risk (1C-1E) grouping.

Results: Table 1 shows the study patient characteristics. Good agreement was observed between US- and MRI-derived aKL with 98% of cases within 20% difference. Using aKL >16.5 cm as a diagnostic threshold yielded a sensitivity of 0.53, specificity of 0.92, false positive rate (FPR) of 0.14, false negative rate (FNR) of 0.31, and accuaracy of 0.74 for predicting high-risk MCIC (1C-1E).

Conclusions: US-derived aKL >16.5 cm provides a simple approach for risk stratification in ADPKD, but is associated with a FPR of 0.14 (i.e. 14% of low-risk patients misclassified as high-risk) and FNR of 0.31 (i.e. 31% of high-risk patients misclassified as low-risk). When a therapeutic decision (i.e. use of Tolvaptan) is based on accurate risk stratefication these errors have clinical consequence.

TH-PO833

How Well Do Risk Assessment Guidelines Perform for Autosomal Dominant Polycystic Kidney Disease (ADPKD)?

Syed E. Ahmed,[2] Pedram Akbari,[2] Elsa Guiard,[2] Crystal F. Quist,[2] Beili Shi,[2] Ioan-Andrei Iliuta,[1] Fatemeh Nasri,[2] Korosh Khalili,[1] York P. Pei.[1] *[1]University Health Network and University of Toronto, Toronto, ON, Canada; [2]Toronto General Hospital UHN, Toronto, ON, Canada.*

Background: The approval of Tolvaptan for treatment of ADPKD heralds a new era when mechanism-based therapy is now possible. However, Tolvaptan is an expensive drug that is associated with potentially serious side-effects. Thus, it is currently reserved for patients who are at high-risk for progression. Two sets of risk assessment guidelines for ADPKD are now available based on the consensus of two panels of nephrologists from Canada and Europe. However, how well do these guidelines perform in risk assessment has not been formally assessed.

Methods: We conducted a prospective study in 474 patients with typical imaging pattern of ADPKD by MRI who also had detailed clinical and laboratory data including total kidney volume (TKV). We used age- and height-adjusted TKV to derive Mayo Clinic Imaging Class as a "gold-standard" for risk assessment (i.e. low-risk: 1A-1B; high-risk: 1C-1E). We then applied the revised Canadian guidelines (Can J Kidney Health Dis. 2018; 5:2054358118801589) and European guidelines (NDT 2016; 31: 337-348) to our patient cohort to assess their performance.

Results: Applying the updated Canadian risk assessment algorithm resulted in exclusion of 52% (245/474) of patients in whom 65% were deemed to be low-risk (i.e. MCIC 1A-1B) and 35%, high-risk (MCIC 1C-1E). The resultant cohort (221/503) was enriched with 88% high-risk patients but also included 12% of low-risk patients. The European guidelines provide a 5-step hierarchal algorithm. Applying the first step based on age and CKD stages resulted in exclusion of 74% (351/474) of patients in whom 69% were deemed to be high-risk and 31%, low-risk. The resultant cohort (123/474) was enriched with 72% high-risk patients but also included 28% of low-risk patients. Applying the second step based on rate of eGFR decline resulted in a total exclusion of 93% (440/474) of patients in whom 59% were deemed to be high-risk and 41%, low-risk. The resultant cohort (34/474) was enriched with 82% high-risk patients but also included 18% of low-risk patients.

Conclusions: Risk assessment in ADKPD is an evolving process to be refined by new clinical data and test technologies. Guidelines that enrich "high-risk", while minimizing "low-risk", patients, have most clinical utility.

TH-PO834

Long-Term Safety and Tolerability of Tolvaptan (TLV) in Later-Stage ADPKD

Vicente E. Torres,[2] Arlene B. Chapman,[1] Olivier Devuyst,[3] Ron T. Gansevoort,[4] Ronald D. Perrone,[5] Jennifer Lee,[6] Molly E. Hoke,[7] Alvin Estilo,[7] Olga Sergeyeva.[7] for the REPRISE Trial Investigators *[1]University of Chicago, Chicago, IL; [2]Mayo Clinic, Rochester, MN; [3]University of Zurich, Zurich, Switzerland; [4]University Medical Center Groningen, Groningen, Netherlands; [5]Tufts Medical Center, Boston, MA; [6]Otsuka Pharmaceutical Development & Commercialization, Rockville, MD; [7]Otsuka Pharmaceutical Development & Commercialization, Princeton, NJ.*

Background: A hepatic safety signal for TLV emerged in the TEMPO clinical ADPKD program with the 1st 18 months (m) of treatment the time of greatest susceptibility. This phase 3b, open-label extension study (NCT02251275) evaluated long-term TLV safety in ADPKD pts; liver enzyme monitoring frequency was q1m for the first 18 m of treatment and q3m thereafter.

Methods: Pts entered from REPRISE, TEMPO 4:4, or prior trials (9 pts). TLV exposure before entry was ≤5 yrs for TEMPO 4:4 pts and ~1 yr for REPRISE TLV pts. Hepatic safety was monitored q1m in pts with <18m TLV treatment, then q3m thereafter. Starting TLV dose depended on prior trial; maintenance regimens in this study were daily split doses 45/15mg, 60/30mg, and 90/30mg, with down-titration allowed for tolerability.

Results: Of 1803 pts enrolled, 1800 received ≥1 TLV dose. Range of duration TLV exposure in this study was 1-1435 days (d); median exposure 651d (mean 697; SD 334, IQR: 538-924). Percentages of treatment-emergent AEs (TEAEs) were similar across the 3 subgroups but REPRISE PBO pts reported more TEAEs (3678) vs TLV (2965) and TEMPO 4:4 (3297). Most common TEAEs overall: thirst (23%), renal pain (20%), polyuria (20%), hypertension (17%), nasopharyngitis (15%), nocturia (15%). Aquaretic AEs (AAEs) were most frequent in REPRISE PBO (thirst 32%, polyuria 32%, nocturia 22%). No Hy's Law cases. TEAE ALT increased 2.8%; AST increased 0.6%. Median 245d to ALT increased, 251d to AST increased.

Conclusions: AAEs and discontinuations due to AEs were less frequent in pts with longer TLV exposure. No new Hy's Law cases with monthly monitoring during the first 18m of treatment, nor in previously TLV treated pts, nor in the 570 pts who started TLV in the present study. (Funding: Otsuka.)

TH-PO835

Quality of Life and Tolerability of Tolvaptan in Swiss ADPKD Patients

Manuel A. Anderegg,[1] Nasser Dhayat,[1] Grit Sommer,[2] Mariam Semmo,[1] Bruno Vogt,[1] Daniel G. Fuster.[1] *[1]Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, Bern, Switzerland; [2]Pediatric Endocrinology, Diabetology and Metabolism, Inselspital, Bern University Hospital, Bern, Switzerland.*

Background: Previous HRQoL assessments in ADPKD patients yielded conflicting results. In addition, the impact of Tolvaptan treatment on HRQoL outcomes in ADPKD patients is currently unknown.

Methods: The Bern ADPKD registry is an observational cohort study initiated in 2015. Inclusion criteria are age ≥ 18y, clinical diagnosis of ADPKD, informed consent. The main exclusion criterion is need for renal replacement therapy. We assessed HRQoL of ADPKD patients with the standardized Short Form-36 (SF-36) as part of the KDQOL-SF™ 1.3 questionnaire in yearly intervals. The SF-36 consists of 8 multi-item subscales (physical functioning, role-physical, bodily pain, general health, energy/vitality, social functioning, role-emotional, mental health), and two summary scores: Physical Component Summary (PCS) and Mental Component Summary (MCS). We transformed raw scores into T-scores (mean=50, SD=10, range 0-100) using contemporaneous Swiss general population norms. Higher scores indicate better HRQoL.

Results: Between October 2015 and May 2019, 121 ADPKD patients were recruited and Tolvaptan treatment has been initiated in 38 patients. In six patients (16%) treatment had to be discontinued within the first three months of treatment due to aquaretic side effects (n=4, 11%) or due to elevated liver enzymes (n=2; 5%), and in eight patients (21%) a dose reduction was necessary. We included 93 patients (28 with and 65 without Tolvaptan treatment) for which baseline and 1-year follow-up data were available. Thirty-nine patients were male (42%), median age was 45.7 y, median eGFR 70.4 ml/min and median total kidney volume 1197 ml. HRQoL at baseline was similar to the general population with a PCS of 48.6 (95% CI 46.2 – 51.0) and a MCS of 49.6 (95% CI 47.5 – 51.7). Patients with future Tolvaptan treatment had higher PCS scores than patients without future Tolvaptan treatment (52.8 versus 46.8; p<0.05). Individual subscales were not different. At 1 year follow-up HRQoL subscales, MCS and PCS scores were similar to baseline scores in both patients who received Tolvaptan and those who did not.

Conclusions: HRQoL in Swiss ADPDK patients is comparable to HRQoL in the general Swiss population. Furthermore, our data reveal that, beyond an initial adaptation to increased aquaresis, long-term treatment with Tolvaptan does not negatively affect HRQoL of ADPKD patients.

TH-PO836

Using Tolvaptan for ADPKD: Feasibility and Patient-Reported Outcome in the Real-Life Setting

Mussa Keaei,[1] Polina Todorova,[1] Simon Oehm,[2] Katharina Burkert,[2] Bastian W. Abend,[1] Thomas Benzing,[3] Volker R. Burst,[4] Franziska Grundmann,[3] Roman-Ulrich Mueller.[5] *[1]University Hospital Cologne, Cologne, Germany; [2]University Hospital of Cologne, Cologne, Germany; [3]University of Cologne, Köln, Germany; [4]Department 2 of Internal Medicine, Renal Division; University of Cologne, Cologne, Germany; [5]Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany.*

Background: Considering the polyuria induced by V2R-antagonists, there is concern regarding tolerability of tolvaptan in the real-life setting. How do patients cope with the increased urine volume? Is adherence sufficient to reach the desired effect and how is the quality of life (QoL) affected?

Methods: In the AD(H)PKD study, we collect data of ADPKD patients presenting with the question whether they should take tolvaptan on a yearly basis. As one aspect, we use self-developed questionnaires to raise patient-reported outcomes, aiming e.g. at complications and adherence. In addition, QoL and pain are recorded using the SF-12 Health Survey and a translated version of the HALT-PKD pain questionnaire.

Results: Since the start of the study in late 2015 we enrolled more than 560 patients. Urine volume increases to 5-7.5 liters in the majority of patients on tolvaptan. The largest increase occurs when starting the first dose step, whereas any further uptitration only leads to a minor change. Adherence to longterm-therapy is about 80%; most patients that discontinue tolvaptan report polyuria-associated events. The majority of patients do not consider the therapy a major problem. However, around two-thirds report that a minor adaptation of everyday life is necessary. The increased urine volume presents a burden *rarely* for ~65% and *often or always* for ~23%. Nonetheless, over 90% would recommend the therapy to other patients. Patients rarely skip a dose (1-2X p.m.) and do so equally spread for leasure-time, professional and medical reasons. QoL does neither differ between patients with or without tolvaptan in the whole cohort nor longitudinally in individual patients before and after starting.

Conclusions: Our data indicates that taking tolvaptan – despite the increase in urine volume – is well feasible for most patients without major adaptations to everyday life. Around 20% consider the polyuria a significant burden and about the same percentage discontinues the therapy in the long term. QoL is not affected by polyuria and nearly all participants would tell other patients to try the therapy if recommended by their nephrologist. Taken together, our data will help to increase confidence of nephrologists in using tolvaptan for ADPKD and to guide patient counselling when starting the treatment.

TH-PO837

Relationship of Tolvaptan Dose with the Rate of Decline in Kidney Function in ADPKD Patients

Taro Akihisa, Hiroshi Kataoka, Shiho Makabe, Ken Tsuchiya, Kosaku Nitta, Toshio Mochizuki. *Tokyo Women's Medical University, Tokyo, Japan.*

Background: Vasopressin receptor 2 antagonist, tolvaptan (TLV), has been shown to suppress the decline in kidney function and increase in total kidney volume in patients with autosomal dominant polycystic kidney disease (ADPKD). TEMPO 3:4 trial and REPRISE trial demonstrated that TLV suppressed the decline in kidney function. However, the dose of TLV and its relationships to kidney function decline have not been clarified. Therefore, we analyzed the TLV doses in ADPKD patients at our hospital, who were introduced to TLV, and the rate of eGFR decline after starting TLV.

Methods: The subjects were 57 patients who were administered TLV for at least 6 months at Tokyo Women's Medical University Hospital from September 2014 to December 2017. For patients who stopped the drug due to liver dysfunction, the observation period was until they discontinued the drug. TLV dose was calculated by dividing the accumulated dose that was actually prescribed by the number of administration days during the follow-up period. The primary outcome was Δ%eGFR during the follow-up period. The median value was calculated and logistic regression analysis was performed on the decreased kidney function group whose Δ%eGFR were less than the median value.

Results: There were 34 men and 23 women. The follow-up period was 2.1 years, age at start of administration was 41, TKV was 2,023.54 mL, and eGFR was 42.3 mL/min/1.73 m^2 (all median values). For CKD stage, there were 3 patients of G1, 11 patients of G2, 29 patients of G3, and 14 patients of G4. For the Mayo classification, there were 3 patients of class 1B, 21 patients of 1C, 20 patients of 1D, and 13 patients of 1E. The accumulated dose was 63.5 mg/day, and ΔeGFR was -4.3 mL/min/1.73 m^2 /year, Δ%eGFR was -11.0%.(all median values). The multivariate logistic analyses included age, sex, eGFR, hemoglobin, urinary osmolality the day after administration, accumulated dose of TLV, hypertension, hyperuricemia, determined that age (P <0.05), and accumulated dose of TLV (P <0.05) were independently associated with a decreased kidney function.

Conclusions: Increasing the TLV dose appears to suppress the decline in kidney function in ADPKD patients.

TH-PO838

Could Glomerular Filtration Rate be an Exclusion Criteria to Initiate Tolvaptan Therapy in Those Patients with ADPKD with Risk of Rapid Progression and Predict Renal Outcomes?

Jose C. Rodriguez-Perez,[1,2] Juan M. Fernandez,[1] Francisco Javier Rodriguez-Esparragon,[3] Carmen-Rosa Hernández-Socorro,[6] Elena Oliva Damaso,[1] Nestor Oliva-Damaso,[4] Lucas Robador,[6] Esteban Porrini.[5] *[1]Nephrology, University Hospital of Gran Canaria Dr. Negrin, Las Palmas Gran Canaria, Spain; [2]Ciencias Medicas y Quirurgicas, University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain; [3]Unidad de Investigación, Hptal Dr. Negrín, Gran Canaria, Spain; [4]Hospital Costa del Sol, Marbella, Spain; [5]Research Unit, University of La Laguna, Tenerife, Spain; [6]Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most frequent inherited renal disease and located among the four main causes of end stage renal disease (ESRD) in adult population.

Methods: To analyze the role of tolvaptan (TOLV) along time according with the initial estimated glomerular filtration rate (CKD-EPI) in those patients with CKD 1-4 with risk of rapid progression to ESRD (clinical, analytical and imaging scoring). **PATIENTS AND METHODS**: This is an observational and transversal study of our first cohort of 15 pts which initiates in TOLV at a 45/15 mg/d dose and escalating every two weeks until 120 mg/d (13 pts) or maximal tolerated dose (90 mg/d (2 pts)). Controls were made initially every two weeks and every 3 months at 18 months of TOLV.

Results: At the time of inclusion all patients 45.4 +/- 6.5 years old and 83.0 +/- 14.2 kg. 65% were men and the plasma creatinine were 0.98 to 2.58 mg/dl with a CKD-EPI of 53.3 +/- 23 ml/min (25.6 to 102.3). Total kidney volume adjusted for age and height ranged from 997 to 2634 cc. After being log-transformed GFR was normally distributed and parametric comparison was made. All treated patients showed a reduction in their GFR in correlation with the used doses (p=0.002). Since in the previous comparison de-escalation patients were included, patients were distributed in quartiles of GFR excluding filtering values corresponding to de-escalated doses as follows: (< 30 ml/min: 2 pts; 30-44 ml/min: 5 pts; 45-60 ml/min: 4 pts and >60 ml/min: 4 pts). In this analysis we do not show any correlation between GFR and TOLV treatment, even after one year of therapy. These data are in agreement with the REPRISE study (Torres V et al, NEJM 2017) results. In any of the quartile established we cannot find any significant relation between TOLV treatment, dose of TOLV and reduction of GFR.

Conclusions: The use of TOLV seems to be safe and effective even in those patients older than 50 years and with CKD stage 3b-4. Those patients with a GFR less than 30 ml/min must be on a one-to-one basis evaluated.

TH-PO839

Differential Effects of Tolvaptan on Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease Patients with PKD1 and PKD2 Mutations

Tomofumi Moriyama, Yosuke Nakayama, Yusuke Kaida, Sakuya Ito, Goh Kodama, Yuka Kurokawa, Kei Fukami. *Kurume University School of Medicine, Kurume, Japan*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common renal disease with a genetic origin. The renal prognosis of patients with polycystin 1 (*PKD1*) mutations was reported to be worse than those with *PKD2* mutations. At our hospital, 17 patients with ADPKD with known gene mutation profiles have been treated with the vasopressin antagonist tolvaptan since 2015. However, the relationship between specific gene mutations and the protective effect of tolvaptan on kidney volume and renal function remains unclear. Therefore, we assessed outcomes of patients with different gene mutations after one-year tolvaptan treatment.

Methods: All patients provided consent for genetic analyses. Genetic analysis by Sanger sequencing with a 3730 DNA analyzer was performed in 17 ADPKD patients, including 8 males and 9 females (mean age; 51 ± 11 years), who were treated with tolvaptan for one year. Total kidney volume (TKV) was evaluated with computer tomography using Ziostation 2, an auto-analysis system for TKV measurement.

Results: Mean values for TKV, eGFR, Δ%TKV/year, and ΔeGFR were 1569 ± 575 ml, 56.0 ± 22.5 ml/min/1.73 m^2, 14.1 ± 6.1%, and –5.9 ± 7.5 ml/min/1.73 m^2, respectively. *PKD1* and *PKD2* mutations were found in 4 and 3 patients, respectively, whereas no mutations in either gene were found in the remaining ten patients. The baseline total TKV, renal function, and changes in TKV did not differ among the patients with *PKD1* and *PKD2* mutations and those with unknown status (TKV, 1199 ± 212, 1449 ± 277, and 1770 ± 667 ml; eGFR, 58.6 ± 22.7, 60.7 ± 11.7, and 53.6 ± 24.4 ml/min/1.73 m^2; Δ%TKV/year, 10.8 ± 2.7%, 12.3 ± 4.3%, and 15.9 ± 6.7%, respectively). Tolvaptan treatment significantly improved the Δ%TKV/year in patients with *PKD1* mutations (–8.3 ± 10.2%, p = 0.03) and those with unknown status (–6.8 ± 8.6%, p < 0.001), but not in those with *PKD2* mutations (–1.7 ± 8.8%, p = 0.20). ΔeGFR did not change in any of the groups studied.

Conclusions: One-year tolvaptan treatment reduced Δ%TKV/year in patients with ADPKD with *PKD1* mutations and those with unknown mutation status but not in those with *PKD2* mutations.

TH-PO840

Clinical Pattern of Tolvaptan (TLV)-Associated Liver Injury in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Patients: Analysis of Pivotal Clinical Trials

David H. Alpers,[2] James H. Lewis,[3] Christine M. Hunt,[5,7] James W. Freston,[9] Vicente E. Torres,[6] Wenchyi Wang,[4] Hui Li,[4] Molly E. Hoke,[1] Olga Sergeyeva,[8] Alvin Estilo.[1] *[1]Otsuka Pharmaceutical Development & Commercialization, Princeton, NJ; [2]Washington University School of Medicine, St Louis, MO; [3]Georgetown University School of Medicine, Washington, DC; [4]Otsuka Pharmaceutical Development & Commercialization, Rockville, MD; [5]Duke University Medical Center, Durham, NC; [6]Mayo Clinic, Rochester, MN; [7]Durham Veterans Affairs Health Care System, Durham, NC; [8]Otsuka Pharmaceuticals, Princeton, NJ; [9]University of Connecticut Health Center, Farmington, SC.*

Background: In the TEMPO clinical program, an imbalance in the proportion of pts with elevated aminotransferases >3X upper limit of normal (ULN) was seen vs placebo (PBO). As 3 pts (2 from TEMPO 3:4 [NCT00428948], and 1 from the open-label extension, TEMPO 4:4 (NCT01214421]) met Hy's Law criteria, increased monitoring frequency was recommended. In the REPRISE clinical program, monitoring was q1m during the first 18m of TLV exposure and q3m thereafter.

Methods: An independent, blinded Hepatic Adjudication Committee examined data from REPRISE (NCT02160145) and its open-label extension (NCT02251275) in pts with aminotransferases >3X ULN using the 5-point U.S. DILI Network classification.

Results: In REPRISE 1370 pts were randomized to TLV (AM/PM split doses of 60/30mg or 90/30mg) or PBO. 1362 pts had postbaseline assessments of serum aminotransferases. 72 pts with ALT elevations >3X ULN were reviewed, and 14 were judged to have liver injury at least probably related to the study drug, but without liver failure or persistent liver injury. Elevations began ~2-3 m after study drug initiation and were seen to develop over the course of 12 m. No association with dose or systemic exposure was found, and no pts on TLV (n=681) or PBO (n=685) met the definition of Hy's Law. In the open-label extension, 1803 pts were enrolled (REPRISE: 60%; TEMPO 4:4: 40%); 1800 received ≥1 TLV dose and were analyzed. 1488 pts (83%) completed the study. The duration of TLV exposure ranged from short (≤1 m) to extended (>42 m), with a median exposure of 651 days. 1267/1800 (70.4%) pts had >18m TLV exposure. 53 cases were adjudicated, and 2 judged as probably related to TLV, but no Hy's Law cases were identified. The safety profile of TLV in these studies did not differ from that in TEMPO 3:4 except for the absence of Hy's Law cases, despite more advanced ADPKD pts being included in REPRISE.

Conclusions: In the REPRISE clinical program all cases of probable liver injury were reversible, consistent with earlier experience in TEMPO. No pts met Hy's Law criteria for more serious liver injury, possibly due to more frequent monitoring and earlier interruption of therapy. (Funding: Otsuka)

TH-PO841

Two Years of Follow-Up Experience with Tolvaptan Treatment in Autosomal Dominant Polycystic Kidney Disease

Judith Fatima Martins Munoz,[1] Eduardo Gutierrez-martinez,[2] Alberto Ortiz.[3] Group of Polycystic Kidney Disease from Madrid *[1]Nephrology, Hospital de Getafe, Madrid, Spain; [2]Hospital 12 de Octubre, Madrid, Spain; [3]Fundacion Jimenez Diaz, Madrid, Spain*.

Background: Autosomal dominant polycistic kidney disease (ADPKD) is the most common inherited kidney disease, it accounts for 10% of end renal disease cases. The aproval of tolvaptan in 2014 as the first targeted therapy of ADPKD was a significant progress. Since this year there are only a few data reported of the real experience with patients ADPKD. The objective of our study was to describe the effectiveness and safety profile of patients during the two first years of treatment.

Methods: Retrospective observacional study. We ncluded ADPKD patients with chronic kidney disease stage 1-3 and treated with Tolvaptan We collect data baseline data from 15 centres from Madrid (Spain). These data inludes lab values and kidney volumen.

Results: We included 143 patients. The mean follow up period was 8,7± 5,1 months. 51 % women, aged 42,7± 10,55 years with eGFR of 63,86±22,75 mL/min/1.73m2 and urine osmolality 445,89 ± 172,25 mOsm/kg. Baseline CKD: stage 1 (19,6%), 2 (34,3%), 3a (27,3%), 3b (16,8%) and 4 (2,1%). The total kidney volumen (TKV) was 1696,47± 1399 and class of Mayo Clinic classification :1B (0,7%), 1C (23,8%), 1D (31,5%), 1E (24,5%). The medium dose achieved was 100,69 ± 6,54 mg in 4,9 ± 3,8 weeks. The rate of adverse events was 74,1%. 68,56%)were those related to increase aquaresis (thrist, polyuria, nocturia and polidipsia). A total of 14 cases (9,8 %) experienced an elevation of liver-enzyme levels, but no cases of sever liver injury was reported. 31 patients (21,6 %) discontinued treatment after a period of 10,9± 5,4 months. The main reasons to dicontinuate were: aquretic effects (86% %), elevations of liver-enzyme levels 7% and 3,5% other efects. 9 patients (29%) reinitaed the treatment after a medium period of 7,02 ± 4,11 months. Adherence to the teraphy was 84,6 %. Renal function (Efgr) at 1, 6, 12, 18, 21 and 24 months was respectively:59, 83± 21,71 ml/min, 56,58 ± 20,22 ml/min, 58,38±19,5 m/min, 60,21 ±21,85 and 62,87 ± 21,83.

Conclusions: In our experience Tolvaptan could be considered as a safety drug in patients with ADPKD. The adherence of the treatment was good, with similar data

obtained in TEMPO 3:4 trial. Due to adverse events its neccesary monitor the enzyme liver levels, but no cases of fatal liver damage was reported. The renal function remains stable after two year of treatment.

TH-PO842

Tolvaptan Slows the Decline of Renal Function in Autosomal Dominant Polycystic Kidney Disease Independent of the Response to Total Kidney Volume: Analysis of the TEMPO 3:4 Japanese Cohort

Shigeo Horie,[1] Satoru Muto,[1] Haruna Kawano,[4] Tadashi Okada,[2] Yoshiyuki Shibasaki,[2] Tatsuki Ibuki.[3] *[1]Juntendo University, Tokyo, Japan; [2]Otsuka Pharmaceutical Co., Ltd., Osaka, Japan; [3]Otsuka Pharmaceutical, Tokushima, Japan; [4]Juntendo university, Tokyo, Japan.*

Background: In TEMPO 3:4 (NCT00428948), TLV slowed the increase in TKV and renal function decline over a 3-year period in patients with ADPKD. We conducted a post-hoc analysis of TEMPO 3:4 in the Japanese cohort to determine if there was an association between change in TKV and renal function in patients treated with tolvaptan.

Methods: The TLV-treated group of the Japanese cohort of TEMPO 3:4 was subdivided into responders (R; net TKV decrease) and non-responders (NR; net TKV increase) at Year 3. An analysis of potential correlations between TLV treatment and the effects on TKV and eGFR were performed.

Results: 147 patients (placebo (PBO): 55; TLV : 92 [R: 37; NR: 55]) were analyzed. At Year 3, the mean changes in TKV for PBO, TLV R, and TLV NR were 16.99%, -8.33% and 13.95%; mean changes in eGFR were -12.61, -8.47 and -8.58 mL/min/1.73 m^2. Female gender was a significant predictive factor for TLV inhibition of TKV growth. Compared with PBO, eGFR decline was significantly reduced in both R and NR groups (P<0.05), however, no difference was seen between R and NR. No difference in urine osmolality at Year 1, 2, and 3 was observed between R and NR.

Conclusions: TLV slowed the decline in renal function over a 3-year period in the Japanese cohort of patients irrespective to the effect of TLV on TKV. TLV treatment should not be terminated by the short-time growth of TKV.

TH-PO843

Glucocorticoid Metabolism in ADPKD Patients and the Effect of Treatment with a Vasopressin V2 Receptor Antagonist

Judith E. Heida, Isidor Minovic, Wendy E. Boertien, Stephan J. Bakker, Ron T. Gansevoort, André Van beek. *University of Groningen, University Medical Center Groningen, Groningen, Netherlands.*

Background: Vasopressin concentration is increased in Autosomal Dominant Polycystic Kidney Disease (ADPKD), and increases even further when a vasopressin V2 receptor antagonist (V2RA) is used as renoprotective treatment. We investigated the stimulatory function of these elevated vasopressin levels on the hypothalamic-pituitary-adrenal axis.

Methods: 24-hour urinary excretion of total cortisol, cortisone, THE, THF and aTHF were measured in 27 ADPKD patients using a validated high-performance LC-MS/MS assay. Results were compared to those in healthy controls (HC, n=81) and in IgA nephropathy patients (IgAN, n=27) that were matched for sex, age and kidney function. Next, in the ADPKD patients the effect of the V2RA tolvaptan (3 weeks of 90/30 mg split dose) was investigated on both urine and plasma glucocorticoid levels.

Results: In comparison to HC, ADPKD patients demonstrated lower 24 hour urinary excretion of total cortisol (p=0.001), cortisone (p<0.001) and cortisone break-down product THE (p<0.02), whereas in comparison to IgAN patients no differences were found (Table). Treatment with the V2RA increased urinary cortisone (p<0.001) and decreased aTHF excretion (p<0.001), without changing the urinary excretion of other glucocorticoid compounds or plasma levels.

Conclusions: ADPKD patients demonstrated a decreased urinary excretion of glucocorticoids compared to HC, both of biologically active and inactive compounds. This is not disease specific, but likely caused by their impaired kidney function. The V2RA increased excretion of glucocorticoids in the form of the inactive glucocorticoid cortisone, but without increasing active cortisol, neither in urine nor in plasma. Overall, renal function appears to have a stronger effect on glucocorticoid metabolism than vasopressin.

	Healthy controls	ADPKD baseline	ADPKD + VR2A	IgA Nephropathy

Effect of Lixivaptan on Pharmacokinetic (PK) and Pharmacodynamic (PD) End Points in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) in the ELiSA Study (PA-102)

Neil H. Shusterman,[1] Linda C. Hogan,[2] Lorenzo Pellegrini.[2] *[1]Palladio Biosciences, Inc., Haverford, PA; [2]Palladio Biosciences, Newtown, PA.*

Background: Blockade of the vasopressin V2 receptor has beneficial effects in non-clinical and clinical studies of patients with ADPKD. Lixivaptan is a novel, potent antagonist of the V2 receptor in Phase 3 development for treatment of ADPKD. We report the PK and PD results of the ELiSA study, the first clinical study with lixivaptan in ADPKD patients.

Methods: 32 subjects, Chronic Kidney Disease (CKD) Stages 1, 2, and 3, were enrolled at 14 sites in the US. Subjects received lixivaptan for 7 days at 1 of 2 BID dose levels to assess PK and PD endpoints after 1 and 7 days of treatment. AM and PM doses were separated by 10 hours. Full 24 hour PK profiles were obtained on Days 1 and 7 of dosing. PD endpoints were urine osmolality (Uosm), total kidney volume measured by MRI, eGFR, serum sodium, and plasma copeptin. Adverse events were assessed. Aquaretic tolerability was assessed through a specially designed questionnaire.

Results: At the high dose, lixivaptan caused profound declines in Uosm below the iso-osmolar level (300 mOsm/kg), indicating effective V2 receptor inhibition over extended time periods. Mean Uosm declined 80% to a minimum value of 84 mOsm/kg 2 hours after the first dose of lixivaptan. Importantly, 100% of subjects in CKD Stages 2 and 3 maintained Uosm below 300 mOsm/kg over 24 hours. The high dose of lixivaptan showed a strong, reversible effect on other PD variables, including serum sodium (mean increase of 1.9% from baseline) and serum copeptin (2.5 fold increase from baseline). The effect of lixivaptan on all PD endpoints tested compares favorably with historical data for tolvaptan. Conversely, the low dose of lixivaptan tested in this study acutely reduced Uosm but did not provide continued suppression below iso-osmolar levels over an extended period of time.

Conclusions: These Phase 2 data confirm that the high dose of lixivaptan tested is a fully pharmacologically effective dose of lixivaptan for ADPKD, whereas the low dose is emerging as the starting dose of lixivaptan. These results inform the appropriate titration dose range in the upcoming pivotal Phase 3 study with lixivaptan in ADPKD patients.

Safety and Efficacy Results from the SILK (Safety in Larger Kidneys) Cohort of KD019-101: A Phase 1b/2a Trial of the Tyrosine Kinase Inhibitor Tesevatinib for Patients with ADPKD

David A. Eiznhamer,[5] Pablo E. Pergola,[4] Michel Chonchol,[2] Ashraf El-Meanawy,[6] Theodore I. Steinman,[3] Karin Herrera,[5] Nicole Martins,[5] Swati Bhattacharya,[5] Olivier Schueller,[5] John L. Ryan,[5] Anjay Rastogi.[1] *[1]UCLA, Los Angeles, CA; [2]University of Colorado, Aurora, CO; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]Renal Associates, P.A., San Antonio, TX; [5]Kadmon Corporation, LLC, Cambridge, MA; [6]Medical College of Wisconsin, Milwaukee, WI.*

Background: The KD019-101 trial has evaluated safety and efficacy of tesevatinib in ADPKD patients. Tesevatinib is a tyrosine kinase inhibitor targeting the EGF receptor pathway previously implicated in the pathogenesis of ADPKD. Tesevatinib has been demonstrated to inhibit the growth of kidneys and preserve kidney function in PKD animal models.

Methods: The SILK cohort enrolled patients with eGFR ≥ 35 but ≤ 80 mL/min/1.73m^2 and htTKV ≥ 1000mL. Subjects were treated with 50 mg tesevatinib QD for up to 24 months. Subjects had MRIs to determine TKV at baseline and 6, 12, 18, and 24 months. Future eGFR prediction was performed using the Mayo Foundation and Medical Education and Research online tool.

Results: Thirteen patients (6M/7F) were enrolled. Ten of 13 subjects received at least 12 months of tesevatinib and are included in efficacy analysis. All subjects are included in safety analysis. Over 24 months the increase in htTKV was 8.7% per year. The mean slope of the best-fit line through eGFR measurements was -0.03 ml/min/1.73m^2. Modelled data using matching subject baseline criteria produced a line with a mean slope of -0.33. Similarly, while modelled data for a matched population predicts a 13.8% loss in eGFR, the mean decrease in eGFR over the treatment period was 6.6%. Commonly reported AEs were HTN, UTI, CPK increase, muscle spasm, and sinusitis. Grade 3 AEs were reported in 3 patients (CHF, HTN, and Herpes zoster) and were considered unlikely or unrelated to study drug. The CHF and Herpes zoster were considered SAEs. Four subjects discontinued treatment before 24 months, 2 due to AEs (increased amylase, fatigue), 1 to withdrawal of consent, and 1 lost to follow-up.

Conclusions: Tesevatinib 50 mg QD is well tolerated by ADPKD patients. Tesevatinib treatment results in preservation of kidney function as measured by eGFR when compared to predictive modelling data. An ongoing randomized placebo controlled trial is actively recruiting.

TH-PO846

High Salt Intake but Not High Protein Intake Leads to Increased Disease Progression in ADPKD

Bart J. Kramers,[1] Iris W. Koorevaar,[2] Ron T. Gansevoort,[2] Johan W. De Fijter,[3] Dorien J. Peters,[3] Priya Vart,[4] Jack F. Wetzels,[5] Robert Zietse,[6] Esther Meijer.[1] *[1]Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Radboud University, Nijmegen, Netherlands; [5]Radboud University Medical Center, Nijmegen, Netherlands; [6]Erasmus Medical Center, Rotterdam, Netherlands.*

Background: In chronic kidney disease salt restriction is advocated as renoprotective treatment, especially in proteinuric diseases. Whether protein restriction is beneficial remains controversial. It has been suggested that in autosomal dominant polycystic kidney disease (ADPKD), a mostly non-proteinuric disease, moderate salt restriction may also be beneficial. We investigated the association of sodium and protein intake with rate of disease progression in ADPKD, and what mediating factors could be.

Methods: We performed a post-hoc analysis of the DIPAK-1 trial, in which 305 ADPKD patients were randomized to 2.5 years treatment with lanreotide or standard care. Blood was collected every 3 months for eGFR assessment and 3 MRI-scans were performed to analyze total kidney volume (TKV). Blood pressure and plasma copeptin (a surrogate for vasopressin) were measured at baseline. Salt and protein intake were estimated from 24h urines, which were collected 6 times and calculated per kg ideal body weight. The effect of salt and protein intake on eGFR decline and TKV growth was analyzed with mixed models. We performed mediation analyses to elucidate potential mechanisms.

Results: Of the participants 53% was female, with an age of 48±7 yr, eGFR 51±11 mL/min/1.73m^2, TKV 2.4±1.6 L, salt intake 9.5±3.9 g/day and protein intake of 87±25 g/day. Salt intake was associated with annual eGFR decline during follow-up (-0.18 mL/min/1.73m^2 per gram of salt, p=0.02), whereas protein intake was not (p=0.3). Results were similar per kg ideal body weight (p=0.02 and p=0.3, respectively). The association between salt intake and annual change in TKV did not reach statistical significance (0.30% per gram of salt, p=0.07). There was also no association between total protein intake and TKV growth (p=0.1). The effect of salt intake on eGFR slope was not mediated by systolic blood pressure (3.5% mediation, p=0.3), but was significantly mediated by plasma copeptin (53% mediation, p<0.001).

Conclusions: Higher salt intake, but not higher protein intake may be detrimental in ADPKD. A five grams lower salt intake was associated with a 0.9 ml/min/1.73m2 lower rate of annual eGFR decline. The substantial mediation by plasma copeptin suggests that this effect is primarily a consequence of a sodium-induced rise in vasopressin.

Self-Monitoring of Urine Specific Gravity Using Study Smartphone Applications Promotes Adherence to High Water Therapy and Facilitates Remote Data Capture in the DRINK Randomised Trial

Ragada El- Damanawi,[1,2] Tess M. Harris,[4] Laura B. Mader,[3] Richard N. Sandford,[5] Ian Wilkinson,[1,2] Fiona E. Karet,[5] Thomas F. Hiemstra.[1,2] *[1]Cambridge Clinical Trials Unit, Cambridge, United Kingdom; [2]Division of Experimental Medicine and Immunotherapeutics, University of Cambridge, Cambridge, United Kingdom; [3]Patient Led Research Hub, Cambridge, United Kingdom; [4]Polycystic Kidney Disease Charity, London, United Kingdom; [5]Division of Renal Medicine and Departments of Medical Genetics, University of Cambridge, Cambridge, United Kingdom.*

Background: High water (HW) intake inhibits vasopressin, a key promoter of disease progression in Autosomal Dominant Polycystic Kidney Disease (ADPKD). Maintaining HW intake requires patient motivation and commitment to self-management. We evaluated the role of a smartphone application to facilitate adherence in 'DRINK', a randomised feasibility trial of HW versus ad libitum water intake in ADPKD (NCT02933268).

Methods: We developed a cross-platform smartphone application for home monitoring and remote submission of twice weekly urine specific gravity (uSG) results by participants enrolled in 'DRINK'. Participants targeted uSG ≤1.010 (HW) or >1.010 (AW). Fluid intake instructions were embedded in the app. Submitted data were transferred in real time to a central administration portal.

Results: 81% (34/42) of trial participants (HW n=16, AW n=18) used the app. Over the 8 week follow-up period, HW patients used the app to submit uSG data 92% (165/179) of the time compared to 91% (199/219) in the AW group, p=0.38. Baseline characteristics were similar between treatment arms amongst app users (female 53% vs 56% p=0.75, White British 81% vs 83% p=0.82, mean age 47±11 vs 43±11 years p=0.38, in the HW and AW groups respectively). Plasma osmolality was 290±9 (HW) vs 289±7 (AW) mOsm/kg (p=0.68) with a corresponding median uSG 1.010 IQR 1.010-1.015 (HW) and 1.010 IQR 1.010-1.015 (AW), p=0.52. Target uSG was achieved 79% of the time in the AW group and 80% in the HW group, p=0.75 (Figure).

Conclusions: Smartphone technology resulted in high levels of adherence to the study intervention, reliable remote data collection and attainment of target USG with separation between treatment arms. Incorporation of this methodology into future trials is feasible and enhances research efficiency.

Sotradecol Foam Sclerotherapy for Treatment of Symptomatic Cysts in ADPKD and Autosomal Dominant Polycystic Liver Disease

William P. Martin,[1] Newton Neidert,[2] Emily Bendel,[2] Marie E. Edwards,[2] Fouad T. Chebib,[2] Paul Novotny,[2] Walter K. Kremers,[2] Vicente E. Torres,[2] Marie C. Hogan.[2] *[1]St. Vincent's University Hospital, Dublin 4, Ireland; [2]Mayo Clinic, Rochester, MN.*

Background: Patients frequently describe mass symptoms & reduced quality of life (QoL) that correlate with visible large liver/kidney cysts in ADPKD/ ADPLD. Since 1/18/2017 we have used cyst drainage followed by sotradecol foam sclerotherapy (SFS) to treat symptomatic, large (≥5 cm in diameter) cysts. Small volumes (20cc max) of sotradecol sclerosant admixed with air are injected under fluoroscopy to ablate the epithelial cyst lining. We studied its safety & impact on QoL & organ volumes.

Methods: In this single-center, single-arm, prospective observational study, ADPKD and ADPLD patients with compressive symptoms due to dominant (liver or kidney) cysts are referred for SFS with 3% sotradecol performed under local anesthesia. QoL using linear analog scale assessment tool (LASA), SF-12, the polycystic liver disease QoL tool (PLD-Q), equivalent opioid dose (mg/24hr), & organ volumes (planimetry using CT/MR) are recorded at baseline & 6 months post-SFS. Changes over time were tested using Wilcoxon tests and confirmed using repeated measures mixed models. Improvements >0.5 SD were considered clinically meaningful.

Results: 45 patients (mean age 55yr, 84% female) are enrolled: 12 (27%) with ADPKD, 31 (69%) with ADPLD, & 2 (4%) with cystic disease NOS. 31 (69%) & 14 (31%) underwent first SFS for symptomatic liver & kidney cysts, respectively. 56 SFS procedures (mean 1.24 per patient) have been performed to treat 68 cysts (mean 1.51 per patient). Total PLD-Q, overall QoL, physical well-being, bodily pain, & vitality improved at month 6 (**Table**). Non-significant reductions in organ volumes seen at 6 months is likely due to small numbers. Longer term follow-up to 12 months is ongoing.

Conclusions: SFS directed at symptomatic large cysts was well tolerated, improved QoL at 6 months, & decreased early satiety, SOB, pain & fullness. Smaller volume instillations of SFS have replaced alcohol sclerotherapy in our practice and are a safe option for directed therapy of symptomatic large cysts in ADPKD and ADPLD.

KITGAG: A New Method for Urine and Liquid Biopsy Diagnostics: From Proteoglycan Urinary Fingerprint to Extracellular Like Vesicles (EVLs) Isolation

Marta Vizoso,[2] Victor Alvarez,[2] Olaya Lamas-Gonzalez,[2] Susana Bravo,[1] Cristobal Colon,[1] Miguel A. Garcia-Gonzalez.[2,3] *[1]Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain; [2]Health Research Institute of Santiago de Compostela (IDIS)., Santiago de Compostela, Spain; [3]Fundacion Galega Medicina Xenómica, Santiago de Compostela, Spain.*

Background: Glycosaminoglycans (GAG) are large polysaccharides formed by repeated sequences of disaccharides. These molecules are secreted and interact through glycosidic bonds with other molecules, such as proteins and lipids, forming the cellular matrix. GAGs are also part of the structures that cells use for endocrine or paracrine communication, like extracellular vesicles or exosomes; or interact with different secreted proteins. Glycosylation status of secreted glycoproteins/lipids can be altered in different

pathologies, as cancer or kidney diseases. Current techniques are not able to predict the evolution of kidney diseases. So there is a need of a new methodology that can be used as an indicator of early phases of the disease or prognosis of their evolution. A new method (KITGAG) has been developed for the separation of free GAGs and the fraction bound to them: based on "Dimethylmethylene blue" (DMB) dye property of specifically binding and precipitating sulfated GAGs in any type of biological sample (urine, serum, tissues...). After the obtaining of this fraction, proteins or lipids profiles can be analyzed by quantitatively or qualitatively methods (proteomics, lipidomics, image techniques...).

Methods: Urine samples have been collected from patients with polycystic kidney disease type I and type II in different stages of disease. Using KITGAG, GAG fraction has been isolated and characterized by different techniques; like Western Blot, mass spectrometry, and electron microscopy.

Results: We have identified markers in the urine from renal patients that appear to be altered in comparison to the healthy population. Likewise, several complexes formed by extracellular vesicles (ELVs), glycoproteins (uromodulin, albumin, IgA or IgG) and GAGs have also been discovered in urine samples, their function may be modulating the dialogue between different nephron segments and it can be altered in renal patients.

Conclusions: Analysis of GAGs fraction in urine samples lead to identification of new prognostic/diagnostic biomarkers of kidney diseases and other different pathologies; or for discovering and monitoring the effect of a therapy. Beside, we have discovered its potential as an isolation method for EVLs for its use in the study of new cellular communication pathways.

TH-PO850

AD(H)PKD-Copeptin as Biomarker in Patients with Autosomal-Dominant Polycystic Kidney Disease (ADPKD)

Simon Oehm, Sita Arjune, Volker R. Burst, Thomas Benzing, Franziska Grundmann, Roman-Ulrich Mueller. *Department 2 of Internal Medicine, Renal Division; University of Cologne, Cologne, Germany*.

Background: Prediction of disease progression in ADPKD is a challenging task. While there are established biomarkers such as total kidney volume (TKV), the identification of new and easily obtainable biomarkers is required to facilitate both prognostic assessment and patient selection regarding targeted therapy. Moreover, new biomarkers would ideally allow the prediction of long-term treatment responses. Post-hoc analyses of the TEMPO 3:4 study showed that copeptin could be one of those biomarkers. We investigated copeptin as a possible new biomarker in participants of the AD(H)PKD study.

Methods: Copeptin was tested in serum samples from patients of the AD(H)PKD study. These were collected and analyzed at first presentation as well as at follow-up visits. In total, we collected copeptin values from 369 patients, 54 of these during treatment with Tolvaptan. Copeptin values were analysed for both, their distribution in different patient groups (e.g. age, Mayo Class) as well as their response to Tolvaptan treatment.

Results: Copeptin values from 315 patients without tolvaptan treatment were significantly lower than copeptin values from patients receiving tolvaptan (8.65 pmol/l vs. 19.74 pmol/l; $p < 0.0001$). A consistent trend towards higher copeptin values with increasing stages of chronic kidney disease (CKD) was observed in both groups. This trend also applied for increasing TKV. Patients receiving tolvaptan showed higher copeptin values than patients without Tolvaptan treatment in all stages of CKD as well as all Mayo classes. In 8 patients longitudinal copeptin measurements prior to tolvaptan administration and on a dose of 90/30mg were available and revealed a significant increase after start of tolvaptan treatment (copeptin before tolvaptan: 5,6 pmol/l, copeptin while receiving tolvaptan 21,25 pmol/l; p=0.0007).

Conclusions: Our findings in the real-life setting are in line with the results from the post-hoc analysis of the TEMPO 3:4 study. Copeptin may serve as a new biomarker in ADPKD regarding both disease progression and response to tolvaptan treatment. Future analyses regarding disease outcome in correlation to copeptin will help to support the use of copeptin as an easily obtainable biomarker in daily clinical routine.

TH-PO851

Association Between Baseline Renal Blood Flow and CKD Progression in Autosomal Dominant Polycystic Kidney Disease

Vicente E. Torres,[6] Tiange Shi,[1] Doug Landsittel,[1] Kyongtae T. Bae,[1] Cheng Tao,[1] Alan S. Yu,[2] Arlene B. Chapman,[3] Michal Mrug,[4] Frederic F. Rahbari-Oskoui,[5] Peter C. Harris.[6] Consortium for Radiological Imaging Studies of Polycystic Kidney Disease *[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Kansas Medical Center, Kansas City, KS; [3]University of Chicago, Chicago, IL; [4]University of Alabama at Birmingham, Birmingham, AL; [5]Emory University School of Medicine, Atlanta, GA; [6]Mayo Clinic, Rochester, MN*.

Background: Previous Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP) studies have shown height-adjusted total kidney volume (htTKV) and renal blood flow (RBF) were independent predictors of renal disease progression. Here we describe an extended study to identify and evaluate the prognostic value of baseline RBF in ADPKD.

Methods: Linear mixed models were utilized to model the effect of baseline RBF on changes in GFR over time adjusting for baseline variables (age, htTKV, gender, mean arterial pressure, hypertension status, genotype, serum HDL cholesterol, serum LDL cholesterol, filtration fraction and protein intake) and (1) either urine albumin, sodium or phosphorus excretions and (2) either BSA or BMI. Logistic regression models were applied to predict CKD using baseline RBF adjusting for baseline age and htTKV. Likelihood ratio tests were conducted to assess the significance of the variables. Area under ROC curve (AUROC) were calculated to assess the models' prognosis ability for reaching CKD outcomes (stage 3A, 3B or 4).

Results: Higher baseline RBF is significantly ($p<0.001$) associated with higher GFR in ADPKD patients over time when adjusting for the baseline variables: (1) either urine albumin, sodium or phosphorus excretions and (2) either BSA or BMI. Baseline RBF is a strong independent predictor of CKD outcomes in both an unadjusted logistic model ($p<0.001$; AUROCs, from 0.75 to 0.78), or after adjustment for baseline age ($p<0.01$; AUROCs, 0.82 to 0.85), with similar results across CKD stages 3A, 3B or 4. The combination of baseline RBF and htTKV showed strong prognosis value for CKD outcomes after adjustment for baseline age (AUROCs, from 0.90 to 0.91).

Conclusions: Baseline RBF is a strong independent prognostic marker for renal disease progression in ADPKD. Renal blood flow could be used as a prognostic and potentially monitoring biomarker in this disease.

TH-PO852

Peak Renal Blood Flow Rate Correlates with Renal Function in Adults with ADPKD

Michal Schäfer,[1] Petter Bjornstad,[2] Nina Bispham,[3] Zhiying You,[4] Kristen L. Nowak,[5] Katharina Hopp,[6] Godela M. Brosnahan,[7] Michel Chonchol,[3] Berenice Y. Gitomer.[1] *[1]Div. Renal Diseases and Hypertension, Aurora, CO; [2]University of Colorado School of Medicine, Aurora, CO; [3]University of Colorado, Aurora, CO; [4]UC Denver, Aurora, CO; [5]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [6]University of Colorado Denver, AMC, Aurora, CO; [7]University of Colorado Denver, Aurora, CO*.

Background: Changes in renal blood flow (RBF) occur early in the course of autosomal dominant polycystic kidney disease (ADPKD) and precede the decline in glomerular filtration rate (GFR). The specific hemodynamic factors responsible for the decline in RBF and GFR in ADPKD are poorly defined. The objective of this study was to determine the relationships between flow hemodynamic parameters and GFR in adults with ADPKD.

Methods: All participants provided informed consent and studies were performed in accordance with the Helsinki guidelines. Renal flow indices were obtained by phase-contrast MRI situated in the mid-section of renal arteries. Images were acquired as previously described by the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP). GFR was measured by 125I-iothalamate clearance.

Results: Forty-five participants (18 male and 27 female) with a confirmed diagnosis of ADPKD were included in the study. The participant characteristics are shown in Table 1. Both Max Q (ml/s) (peak renal RBF)($r = 0.52$, $p= 0.05$) and Min Q (ml/s) (minimum RBF)($r = 0.52$, $p = 0.04$) were significantly positively correlated with measured absolute GFR ml/min. This relationship was independent of age, sex, systolic blood pressure and body mass index. However, neither total blood flow volume (ml) or maximum flow velocity (cm/s) correlated with measured GFR.

Conclusions: In this cohort of people with ADPKD with preserved kidney function both peak and minimum RBF rates significantly correlated with measured GFR. These data suggest that early hemodynamic alterations may be useful biomarkers of kidney function in early disease.

Funding: Other U.S. Government Support

Demographic characteristics of the study population

Parameter	Mean (N = 45)	Standard deviation
Sex M/F	18/27	
Age (years)	41	9
Body Mass Index	27.0	6.3
Iothalamate GFR (ml/min)	101	28
Estimated GFR (ml/min/1.73m^2)	92	17
Systolic Blood Pressure (mmHg)	124	11

Effect of Clinical, Radiological, and Genetic Factors on Progression to ESKD in Autosomal Dominant Polycystic Kidney Disease

Shehbaz Shukoor, Marie E. Edwards, Sravanthi Lavu, Timothy L. Kline, Sanskriti Shrivastava, Ghaith Zaatari, Maria V. Irazabal, Sarah R. Senum, Peter C. Harris, Marie C. Hogan, Ziad Zoghby, Vicente E. Torres, Fouad T. Chebib. *Mayo Clinic, Rochester, MN*.

Background: Cystic expansion damaging the renal parenchyma is thought to lead to end-stage kidney disease (ESKD) in autosomal dominant polycystic kidney disease (ADPKD). Here we examined (1) whether factors independent of cystic growth contribute to disease progression and (2) their role in *PKD1* compared to *PKD2* associated disease.

Methods: We designed a cross-sectional study of ADPKD patients with ESKD seen at the Mayo Clinic between 1992 and 2018 with available abdominal imaging at or near ESKD (n=294). Clinical, laboratory, genetic, and radiological data at the time of ESKD were obtained from electronic medical records. Kidney volumes were measured and adjusted to height (HtTKV).

Results: Compared to females (n=154, 52%), males had similar mean age of ESKD (54.6 vs 54.9 years), larger HtTKV (2440 vs 1594 ml/m, $p<0.01$) and higher incidence of macrovascular disease (27% vs 17%, $p=0.03$). In the univariate analysis, age ($p<0.01$) and HDL cholesterol ($p=0.02$) were negatively associated whereas male sex ($p<0.01$) and ischemic heart disease ($p=0.03$) were positively associated with HtTKV at ESKD. In the multivariate analysis, only age, sex and ischemic heart disease were significantly

associated with HtTKV at ESKD. ADPKD genotype was known in 182 patients (110 *PKD1* T, 55 *PKD1* NT, 17 *PKD2*). Age at ESKD was 49.8±9.4 years in patients with *PKD1* T, 57.4±10.4 in those with *PKD1* NT, and 65.2±10.3 in those with *PKD2* mutations (p<0.01). HtTKV was 2129±1141, 1835±1331 and 2019±1162 ml/m in patients with *PKD1T*, *PKD1NT* and *PKD2*, respectively (p<0.02). A negative correlation between age and HtTKV at ESKD was observed in the *PKD1* T group (r= -0.32, p<0.01) but not in the smaller and older *PKD1* NT and *PKD2* groups.

Conclusions: ADPKD patients who reach ESKD at an older age have smaller kidney volumes. This suggests that cyst burden is the main cause of GFR decline in patients reaching ESKD at younger age, whereas additional factors associated with aging (e.g. vascular remodeling) may contribute significantly to ESKD in older patients.

TH-PO854

Serum Bicarbonate but Not Urine Ammonium Predicts Renal Outcomes in Polycystic Kidney Disease

Charles J. Blijdorp,[1] David Severs,[1] Ron T. Gansevoort,[2] Robert Zietse,[1] Ewout J. Hoorn.[1] DIPAK consortium *[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands*.

Background: Recently, urine ammonium ($uNH4^+$) was shown to better predict renal outcomes in CKD than serum bicarbonate (sBic). Urinary acidification is impaired in patients with autosomal dominant polycystic kidney disease (ADPKD). Our aim was to analyze whether sBic or uNH4+ predicts renal outcomes in ADPKD.

Methods: We studied the predictive value of baseline sBic and $uNH4^+$ for worsening kidney function (30% decrease in eGFR or ESRD) in 305 ADPKD patients from the DIPAK-1 trial (lanreotide vs. placebo). Secondary outcomes were eGFR slope and change in height-adjusted total kidney volume (hTKV). Patients were followed for 2.5 years with monitoring of eGFR and 24-hour urine every 3 months. uNH4+ was measured using a phenol-hypochlorite reaction in 24-hour urine. Logistic regression was used for analysis. The fully adjusted model included age, sex, eGFR, albuminuria, serum potassium, hTKV, PKD mutation, treatment group, hospital, BMI, cardiovascular disease, hypertension, net endogenous acid production (NEAP) and sBic or $uNH4^+$.

Results: A lower sBic at baseline was associated with worse renal outcomes (adjusted hazard ratio lowest vs. highest sBic tertile 2.68, 95% CI 1.11 to 6.46, Figure). A lower sBic at baseline was also associated with steeper eGFR slope (p=0.01), and greater increase in hTKV (p=0.05). As expected, $uNH4^+$ correlated with dietary protein intake and NEAP (r 0.45 and 0.26, P<0.0001). However, $uNH4^+$ was not associated with the primary and secondary outcomes in both the unadjusted and adjusted models (Figure).

Conclusions: sBic but not $uNH4^+$ predicts renal outcomes in ADPKD. These findings support the notion that mechanisms of disease progression in ADPKD differ from other causes of CKD.

Biomarker Identification Using Serum Proteomics in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Sita Arjune,[1] Martin R. Späth,[1] Thomas Rauen,[3] Stefan Mueller,[2] Bernhard Schermer,[1] Thomas Benzing,[1] Volker R. Burst,[1] Franziska Grundmann,[1] Roman-Ulrich Mueller.[1,2] *[1]Department 2 of Internal Medicine, Renal Division; University of Cologne, Cologne, Germany; [2]Center for Molecular Medicine Cologne, Cologne, Germany; [3]University Hospital Aachen, Aachen, Germany*.

Background: The variable course of autosomal dominant polycystic kidney disease (ADPKD) makes it important to identify biomarkers that predict disease progression to allow optimal counseling and selection of patients for targeted therapies. Currently, MRI-based volumetric analysis is used as a standard diagnostic tool. In order to identify easily measurable biomarkers of ADPKD progression, we used mass spectrometric quantification of the serum proteome.

Methods: Hence, serum proteome analysis was performed by MALDI-TOF MS using label-free quantification. We compared ADPKD patients (n = 292) with healthy control subjects (n = 58) and IgA nephritis patients (n = 30) as an independent CKD control. Randomization of the samples was achieved using random sampling. For data evaluation normalized $\log_2$ transformed intensities were used and proteins were examined for their distribution in different patient groups (e.g. age, CKD stage, Mayo class). Clinical data of all patients were available from the AD(H)PKD registry.

Results: Mass spectrometric analysis of the serum proteome in ADPKD patients revealed differential expression of 19 proteins compared to healthy control subjects (q<0.05), 8 of these proteins also differed from IgA nephritis patients suggesting specificity for ADPKD. The identified proteins could be assigned to the regulatory pathways of IGF activity and hemostasis.

Conclusions: These results provide valuable insights into the alterations of the serum proteome in ADPKD and indicate that selected serum proteome markers may contribute to the improvement of ADPKD management and disease severity assessment in the future. The newly identified markers will now be investigated for their predictive potential and their role in the pathogenesis of ADPKD.

TH-PO856

Urinary Adenosine and Adenosine/Xanthine Ratio Associate with the Rate of eGFR Decline in a Cohort of Patients with Autosomal Dominant Polycystic Kidney Disease

Shosha E. Dekker, Elena Sanchez-Lopez, Darius Soonawala, Dorien J. Peters, Oleg Mayboroda, Johan W. De Fijter. *Leiden University Medical Center, Leiden, Netherlands*.

Background: The variable course of autosomal dominant polycystic kidney disease (ADPKD), and the advent of renoprotective treatment make it important to discover novel biomarkers for predicting renal disease progression. Based on in vivo data, we hypothesised that urinary ATP excretion is increased in ADPKD, which might contribute to disease progression. We applied urinary metabolomics to explore differences in purine metabolism compounds, as an indirect readout of ATP, and the association with estimated glomerular filtration rate (eGFR; CKD-EPI equation), and progressive loss of eGFR.

Methods: Targeted metabolic profiling using Liquid Chromatography-Mass Spectrometry was performed on single, spot urine samples of 187 ADPKD patients (mean age 48±10 years, 53% female, mean eGFR 53±20 ml/min/1.73m^2), and 139 other chronic, renal disease patients (mean age 56±17 years, 48% female, mean eGFR 54±33 ml/min/1.73m^2). Multiple regression analysis was used to describe the association between a pre-selected set of the metabolites and actual eGFR, and annual change in eGFR.

Results: Abundancies of adenosine, inosine, hypoxanthine, xanthine, and uric acid were determined and normalized. For all metabolites, no differences were found between ADPKD and non-ADPKD patients. Adenosine was most strongly associated with eGFR in the total cohort (F=92.35, P<2.2e-16, r^2=0.222) as well as in patients with ADPKD. In ADPKD, we additionally evaluated the association with rate of eGFR progression over time. For 131 patients (mean age 49±7 years, 50% female, mean eGFR 49±11 ml/min/1.73m^2, mean eGFR decline -3.4±-2.7 ml/min/1.73m^2 per year), sequential eGFR data were available. Linear regression analysis showed that the combination of adenosine and the adenosine/xanthine ratio had the strongest association with annual change in eGFR (F=6.70, P=0.002, r^2=0.095). Moreover, this model had additional value beyond that of baseline eGFR, age and/or total kidney volume.

Conclusions: In this pilot study, urinary adenosine and adenosine/xanthine ratio were associated with the rate of eGFR decline in patients with ADPKD. Validation of these findings is needed in a larger cohort with a varied distribution in rate of renal function decline.

TH-PO857

Systemic Endothelial Function Is Associated with Renal Disease Severity in Early Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Ali Y. Tug,[1] Walaa Elsekaily,[1] Kathleen Leistikow,[1] Fouad T. Chebib,[1] Peter C. Harris,[1] Martin G. Rodriguez- Porcel,[1] Alan S. Yu,[2] Lilach O. Lerman,[1] Amir Lerman,[1] Vicente E. Torres,[1] Maria V. Irazabal.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Kansas Medical Center, Kansas City, KS*.

Background: *In vitro* studies have shown impaired endothelium-dependent relaxation of small resistance vessels in patients with ADPKD. Peripheral-arterial tonometry (PAT) provides, with high reproducibility and no operator dependency, non-invasive measures of nitric oxide-mediated endothelial response. However, no study has evaluated endothelial function by PAT in patients with ADPKD. This pilot study tested the hypothesis that systemic endothelial dysfunction, as determined by PAT, would be detectable prior to development of hypertension and would correlate with renal disease severity determined by height adjusted total kidney volume (htTKV) in patients with ADPKD.

Methods: Twelve young (18-40 years), early stage (eGFR>90 mL/min/1.73 m^2), normotensive (without blood pressure medication) patients with ADPKD and age/sex matched controls (2:1), underwent medical questionnaire, blood and urine collection, abdominal MRI for TKV and renal blood flow (RBF), and PAT for reactive hyperemia index (RHI, normal value ≥2) determination.

Results: Main clinical and laboratory characteristics are shown in table 1. ADPKD patients presented with abnormal RHI levels, which correlated inversely with htTKV (R^2=0.394, p=0.039), and directly with RBF (R^2=0.485, p=0.017). There was no correlation between RHI, htTKV, or RBF and eGFR or other parameters listed in table 1.

Conclusions: Systemic endothelial dysfunction as determined by PAT may be an early marker of vascular changes in patients with ADPKD, and is associated with renal disease severity. These observations may suggest systemic endothelial function as a diagnostic and therapeutic target in patients with ADPKD.

TH-PO858

Risk of Hospital Encounters for Kidney Stones in Autosomal Dominant Polycystic Kidney Disease: A Cohort Study

Vinusha Kalatharan,[4] Blayne Welk,[4,2] Danielle M. Nash,[1,2] Stephanie Dixon,[2] Justin Slater,[2] York P. Pei,[3] Sisira Sarma,[4] Amit X. Garg.[1,2] *[1]London Health Sciences Centre, London, ON, Canada; [2]Institute for Clinical Evaluative Sciences, London, ON, Canada; [3]University Health Network and University of Toronto, Toronto, ON, Canada; [4]Epidemiology & Biostatistics, Western University, London, ON, Canada.*

Background: Patients with autosomal dominant polycystic kidney disease (ADPKD) are may be more likely to develop kidney stones than the general population. However, empirical evidence to this effect is lacking in the current literature. We studied the incidence of (i) a *de novo* hospital encounter with kidney stones, and (ii) stone interventions among patients with ADPKD compared to patients without ADPKD who were similar in their baseline health indicators.

Methods: Using large healthcare databases from Ontario, Canada, patients with and without ADPKD were identified using hospital encounters between April 1st, 2002 and March 31st, 2016. We used inverse probability of treatment weighting (IPTW) based on propensity score to ensure characteristics of baseline health indicators between the two groups were similar. We followed patients from cohort entry until the first recorded hospital encounter with a *de novo* stone, death, emigration from Ontario, or March 31st, 2017. We used a weighted Cox proportional hazards model to compare stone rates between the two groups. Death was treated as a censoring event in the primary analysis, and as a competing event in secondary analyses. We also performed analyses for time to first recorded stone intervention and abdominal imaging across all settings. Patients were followed for a mean (maximum) of 7.5 (15.6) years.

Results: ADPKD compared to no ADPKD was not associated with a higher risk of a hospital encounter with stones (92 patients of 2094 with ADPKD [4.3%] vs 80 patients of 2096 without ADPKD [3.8%]; 7.4 vs 6.2 events per 1000 person-years; hazard ratio 1.2 [95% CI, 0.9 to 1.6]. Similarly, ADPKD compared to no ADPKD was not associated with a higher risk of stone intervention (52 of 2094 [2.5%] vs 62 of 2096 [3.0%]; 4.1 vs 4.7 events per 1000 person-years; hazard ratio 0.9 [95% CI 0.6 to 1.2]). The results were similar when treating death as a competing event. ADPKD compared to no ADPKD was associated with a significantly higher rate of abdominal imaging (hazard ratio 1.2 [95% CI 1.1 to 1.3]).

Conclusions: ADPKD was not a significant risk factor for a hospital encounter with kidney stones. The perception that patients with ADPKD are more likely to develop stones may be due to increased surveillance.

TH-PO859

Outcome of Kidney Transplantation in Patients with Polycystic Kidney Disease: A Single-Center Study

Cheng-Hsu Chen,[1,2] Tung-Min Yu,[1,2] Ya-Wen Chuang.[1] *[1]Taichung Veterans General Hospital, Taichung, Taiwan; [2]School of Medicine, China Medical University, Taichung, Taiwan.*

Background: Renal transplant (RTx) is the best choice of life-quality of renal replacement therapy for patients with end-stage renal disease (ESRD). Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disorder and common cause of ESRD. Different from other causes of ESRD, ADPKD patients need more delicate pre-RTx evaluation for intracranial aneurisms, cardiac manifestation, and complications of liver and renal cysts. The outcome of RTx with ADPKD is still unknown in Taiwan.

Methods: We retrieved our 1327 RTx recipients with 1382 times (two recipients with 3 times, 48 recipients with 2 times) of RTx in the past 35 years. There were 41 recipients with ADPKD. This study evaluated the demographics, outcomes, and complications of RTx in patients with ADPKD compared with other nephropathies.

Results: The mean recipient age at first RTx was 42.9 ± 12.6 years, however, the ADPKD group (52.5 ± 10.1 yrs) was elder than other group (42.7 ± 12.7 yrs, P = 0.001). The gender of RTx recipients was female 586 (44.2%) and male 741 (55.8%), though, ADPKD group had higher male gender (28, 68.3%) than other group (713, 55.4%) without statistically significance (P = 0.245). Interestingly, the new onset diabetes after transplant (NODAT) was higher in ADPKD group (21, 51.2%) than other group (326, 25.3%; P = 0.005), and more malignancy (18; 43.9% vs. 360; 28.0%; P = 0.041). The patient survival was inferior in ADPKD group (38.9% vs. 70.3%; P = 0.018).

Conclusions: Further studies with multiple centers and greater numbers of patients are needed to compare more precisely the complications and results of transplant between patients with ADPKD and other recipients in Taiwan.

TH-PO860

Post-Kidney Transplant Intracranial Aneurysm and Hemorrhagic Stroke in Polycystic Kidney Disease

Ali D. Jandal, Beini Lyu, Brad C. Astor, Didier A. Mandelbrot, Arjang Djamali, Gauri Bhutani. *University of Wisconsin, Madison, WI.*

Background: Polycystic Kidney Disease (PKD) is associated with 6-9 times higher prevalence of intracranial aneurysm (ICA) and consequently, of hemorrhagic stroke than the general population. An appropriate screening strategy for ICAs in PKD post-kidney transplantation is not known.

Methods: The Wisconsin Allograft Recipient Database was queried to identify adult patients who received a primary kidney transplant at University of Wisconsin between 1/1/2000-12/31/2015. Cause of ESRD among kidney transplant recipients (KTRs) was categorized as PKD or non-PKD. History of ICA and hemorrhagic stroke at the time of transplant and incidence post-transplant were compared between PKD vs non-PKD using logistic regression and survival analysis.

Results: PKD recipients (N=520) were, in comparison to non-PKD (N=3494), older (52.8 vs 49.4 years), more often female (45% vs 38.8%) and white (93.5% vs 80.2%; p<0.01 for all). Pre-transplant dialysis was less common in PKD KTRs (56% vs 77%; p< 0.01). No significant difference was observed in pre-transplant hypertension (97.5% in PKD vs 96.2% in non-PKD KTRs; p=0.15). A history of ICA and prior hemorrhagic stroke was significantly higher in PKD recipients compared to non-PKD KTRs (2.7% and 1.92% vs 0.3% and 0.63%;p<0.01) even after adjusting for demographics and pre-transplant hypertension. Over a median post-transplant follow up 5.6 years (2.4-9.1) in PKD and 5 years (2.1-8.1) in non-PKD recipients, the incidence of ICA was higher in PKD (1.6 vs 0.3 per 1000 person years in non-PKD; p=0.02). The incidence of hemorrhagic stroke was similar between PKD and non-PKD recipients (0.3 vs 0.8 per 1000 person years; p=0.36). No strokes occurred at time of transplant.

Conclusions: Our findings show that incidence of hemorrhagic stroke in PKD KTRs was low. Regular interval screening for new ICA may not be necessary in PKD patients following kidney transplantation. The factors contributing to change in frequency of hemorrhagic stroke in PKD and non-PKD group in the post-transplant setting need further investigation.

Table 1

	PKD (N=520)	Non-PKD (N=3494)	Odds/Hazard Ratio	P-value
Pre-transplant ICA [N (%)]	14.7 (2.7)	12 (0.3)	8.6 (3.8,19.4)	p<0.01
Pre-transplant Hemorrhagic Stroke [N (%)]	10 (1.92)	22 (0.63)	2.9 (1.4, 6.3)	p>0.01
Post-transplant ICA [N (%)]	5 (0.99)	6 (0.17)	4.6 (1.3,15.9)	p=0.02
Post-transplant hemorrhagic Stroke [N (%)]	1 (0.2)	16 (0.46)	0.39 (0.05,2.94)	p=0.36

TH-PO861

Engaging Patients and Defining Outcomes: A Minority Engagement Effort

Reem Mustafa, Nedaa Husainat, Mohamad A. Kalot. *University of Kansas, Kansas City, KS.*

Background: Polycystic kidney disease (PKD) is an irreversible inherited disease that causes permanent worsening of kidney function. Despite being rare, PKD is the most common genetic cause of chronic kidney disease. The Establishing Meaningful Patient-centered Outcomes With Relevance for patients with Polycystic Kidney Disease (EMPOWER PKD) initiative aims to engage PKD stakeholders and patients to learn about health priorities, insurance issues, and patient engagement.

Methods: We utilized semi-structured focus groups. We developed and pre-piloted a guide that allowed for both conversational flow and consistency in questions among groups. We audio-recorded each group and transcribed the conversations verbatim. We performed an inductive thematic analysis. Two investigators completed all data coding independently and in duplicate. We compare the results of an ethnically diverse focus group to the other 7 that mainly included Caucasian participants.

Results: 14 individuals participated in this part of the study. Of these, (64.2%) reported having PKD, and (14.2%) being caregivers. The mean age of participants was 48.8 (range 29-75) years. The group included 85.75% African American and 7.1% reported more than one race. It was challenging to recruit this group and it required establishing relation with community nephrologists and faith-based organizations leads. Multiple participants stated that they would not have participated in the group was not exclusively ethnically diverse as they fear that their opinion may be outnumbered by a Caucasian majority. Some discussed believing that PKD was a "white" disease. Many discussed hiding their diagnosis which affected their activation and engagement and came with unanticipated psychological impacts. Several other themes emerged including fear of others finding out, isolation,

lack of support, helplessness, the need to lie about their condition, and victimization. Participants unanimously described lack of trust-worthy easy to understand educational resources for minorities as a main barrier to engagement.

Conclusions: With a treatment now approved for use in the US, it is important to be aware of patients' values and barriers to engagement which have pivotal effects on care. Additionally, it is essential to utilize resources to help activate patients of all racial and ethnic groups to be prepared for future treatments.

TH-PO862

Frequency of Polycystic Kidney Disease in Patients with Intracranial Aneurysm

Hirotsugu Iwatani,[1] Shintaro Koizumi,[1] Ayako Yajima,[1] Takatomo Shigeki,[1] Yoshiki Kimura,[1] Toshiyuki Fujinaka,[2] Masafumi Yamato.[1] *[1]Nephrology, National Hospital Organization Osaka National Hospital, Osaka, Japan; [2]Neurosurgery, National Hospital Organization Osaka National Hospital, Osaka, Japan.*

Background: Polycystic kidney disease (PKD) is characterized by the multiple cystic formation in the bilateral kidneys. It is also famous for the highly accompanying extra-renal manifestations such as intracranial aneurysm, valvular heart disease, liver cysts, pancreatic cysts, or intestinal diverticulum. The underlying and unifying mechanism of PKD is the abnormality of cilia. The frequency of intracranial aneurysm in patients with PKD is reported to be approximately 4 to 12%. However, the rate of PKD in patients with intracranial aneurysm is not known. Here, we aimed to investigate the frequency of PKD in patients with intracranial aneurysm.

Methods: Seventy-two patients with intracranial aneurysm who visited department of neurosurgery in our hospital, also visited department of nephrology between Nov 2017 and May 2019 for PKD screening. The screening modality was basically kidney ultrasound. If abdominal CT or MRI was already performed, we utilized them to diagnose whether or not the patients have PKD. In cases where PKD is highly suspected by questionnaire to the patients, we performed abdominal MRI or CT. We also investigated the family history of kidney disease, dialysis, intracranial hemorrhage, intracranial aneurysm, sudden death, or liver cysts. Thus we retrospectively investigated the PKD rate in cases with intracranial aneurysm. The ethics committee in our hospital approved this retrospective study.

Results: The patients' characteristics were as follows; age median 69 IQR (53-76) y.o., sex F/M 60/12, eGFR 69 (61-81) mL/min/1.73m^2. Out of the 72 cases, 43 patients had single intracranial aneurysm and 29 patients had plural intracranial aneurysm. Out of 72 patients, typical PKD was detected in one patient, and atypical PKD in another patient. Family history taking showed that 9 patients had relatives with kidney diseases, 4 had those with dialysis, 7 had those with intracranial aneurysm, 14 had those with intracranial hemorrhage, 14 had those with sudden deaths, and 2 had those with liver cysts.

Conclusions: PKD screening indicated that approximately 1-3% of patents with intracranial aneurysm had PKD.

TH-PO863

Clinical Characteristics of Patients with Early-Onset ESKD in Autosomal Dominant Polycystic Kidney Disease: A Case Series

Ranine Ghamrawi, Ghaith Zaatari, Shehbaz Shukoor, Sravanthi Lavu, Sarah R. Senum, Marie C. Hogan, Ziad Zoghby, Peter C. Harris, Vicente E. Torres, Fouad T. Chebib. *Mayo clinic, Rochester, MN.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) has high phenotypic variability. Mutations in *PKD2* versus *PKD1* lead to milder disease, with average ages at End-Stage Kidney Disease (ESKD) of 79.7 and 58.1yrs, respectively. Some patients reach ESKD in early adulthood, but factors leading to such poor prognosis are unclear.

Methods: This is a cross-sectional study of patients with ADPKD presenting between 1992 and 2018 to Mayo Clinic who reached ESKD by age ≤ 35 and had detailed clinical information pre-ESKD. Among 4307 patients with ADPKD, 1079 reached ESKD with 18 by age 35. Clinical, genetic and radiological data prior to ESKD onset were collected. Kidney volumes were measured and adjusted by height (HtTKV).

Results: Ten patients (55%) were male and 16 (89%) were Caucasian. The average age at ESKD was 30.3 (± 4.3) yrs. Average body mass index was 27.3(±5.6) Kg/m^2. Among the 13 patients with genetic screening, 8 (61%) had *PKD1* truncating and 5 (38%) had *PKD1* non-truncating mutations, and one had a possible in *trans PKD1* modifying allele. Seventeen patients were hypertensive (94%) with average age of onset of 23 (±6.5) yrs. Among 16 patients with abdominal imaging, 13 (81%) were classified as Mayo Class 1E and 3 (19%) as 1D. Mean HtTKV was 2148 (±1169) ml/m. Mean PROPKD score was 7.4 (± 1.5). The majority of patients had cyst hemorrhage (89%) and more than half had ≥ 2 episodes (55%). The average age of the cyst hemorrhage occurrence was 22 ± 8.5 yrs. Four (22%) patients had cyst infections, and 13 (72%) had at least a history of one episode of acute kidney injury. Seven patients (38%) had bilateral nephrectomies at time of ESKD due to recurrent cyst hemorrhage, three of whom were done concomitantly with their kidney transplantation.

Conclusions: We describe a series of patients with ADPKD who reached ESKD before age 35. All patients had *PKD1* mutations and large kidney volumes (Mayo Class 1E and 1D). The majority of the patients had one or more episode of cyst hemorrhage. Prospective studies would be helpful in ascertaining the role of cyst hemorrhage in accelerating the decline of kidney function in patients with ADPKD.

Multiple Urinary Tract Infections Are Associated with Genotype and Phenotype in Adult Polycystic Kidney Disease

Eray Eroglu. *Nephrology, Erciyes University School of Medicine, Kayseri, Turkey.*

Background: The association between UTI among genotypic and phonotypic properties of ADPKD patients is still obscure. Thus, we investigated the relationship between UTI and polycstin gene mutation with total kidney volume.

Methods: Ambulatory blood pressure monitoring was performed in all participants. Magnetic resonance imaging (MRI) was performed with a 1.5-T system, and total kidney volumes were calculated using mid-slice technique. To determine PKD1 and PKD2 genotype, we performed molecular and genetic tests involving the following steps: DNA isolation, next-generation sequencing (NGS) and data analysis.

Results: ADPKD patients with UTI had lower eGFR values than those without UTI [64.9(32.2-100.8) vs 89.5(59.0-110.0), (p:0.041)]. In addition, patients with UTI had significantly increased height adjusted total kidney volume than patients without UTI [950(290-1350) vs 345(243-780.0), (p:0.005)] (Figure-1). Multiple logistic regression analysis showed that the PKD1 truncating mutation and hTKV independently predicted UTI. The sensitivity and specificity of hTKV were 65% and 77% (cut-off >727cm^3) with an area of under the ROC curve of 0.70 (95% CI: 0.56-0.85, p:005) (Figure-2).

Conclusions: ADPKD patients with larger kidneys and PKD1 mutation are susceptible to increased risk of multiple UTI. Additionally, renal function decreased in ADPKD patients with multiple UTI history.

RAPID-ADPKD, the Retrospective Epidemiologic Study of Asian-Pacific Patients with Rapid Disease Progression of Autosomal Dominant Polycystic Kidney Disease: Design and Methods

Hyunjin Ryu,[1] Hayne C. Park,[7] Yun Kyu Oh,[2] Changlin Mei,[3] Angela Yee Moon Wang,[4] Jenq-wen Huang,[5] Gopi Rangan,[6] Curie Ahn.[1] RAPID-ADPKD study group *[1]Seoul National University Hospital, JongNo-Gu, seoul, Republic of Korea; [2]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea; [3]Shanghai Changzheng Hospital, Shanghai, China; [4]University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [5]NTUH, Taipei, Taiwan; [6]Westmead Institute for Medical Research, The University of Sydney, Sydney, NSW, Australia; [7]Kangnam Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: For effective treatment and early intervention in Autosomal dominant polycystic kidney disease (ADPKD) patients, identifying subgroups with rapid renal progression are important in ADPKD. This study was designed to identify the clinical characteristics of rapidly progressing ADPKD patients in Asia-Pacific area.

Methods: The RAPID-ADPKD is a multinational retrospective observational cohort study of ADPKD patients in the Asia-pacific area.

Results: Six hospitals from six regions (Australia, China, Hong Kong, South Korea, Taipei and Turkey) are participating in this study. Adult ADPKD patients, diagnosed by the unified criteria and with eGFR ≥45 mL/min/1.73m^2 at baseline will be included. Patients with other comorbidities that can affect renal function will be excluded. Demographic information, clinical characteristics, premorbid comorbidities, medications, eGFR, radiologic findings that can calculate height adjusted total kidney volume (htTKV), PKD-related complications and the PRO-PKD score will be collected. Rapid progression will defined as when any of following criteria are met: (i)an annual eGFR decline ≥5 mL/min/1.73m^2 in 1-year and/or ≥2.5mL/min/1.73m^2 per year over a period of 5-years; (ii)an increase in htTKV ≥ 5% per year from ≥3 radiologic images; (iii)Mayo classification 1C, 1D, or 1E or kidney length from ultrasonography of >16.5 cm (iv)*PKD1* truncated mutation with early symptoms (PRO-PKD score >6). All other patients without any of the criteria are classified as slow progression. The clinical characteristics of rapid progression group will be compared to slow progression group. In addition, the incidence rate, age of diagnosis, treatment complications between rapid and slow progression will be analyzed. The planned sample size of the cohort is 1,000 patients, and as Feb 28th 2018, data from 400 patients have been collected.

Conclusions: RAPID-ADPKD is the first large-scale multinational retrospective observational study of ADPKD in Asia-Pacific region and will identify the clinical characteristics, risk factors for disease progression and patterns of complications in Asian populations with ADPKD.

Neurological Complications After Very Early Bilateral Nephrectomies in Patients with Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Kathrin Burgmaier,[1] Anja K. Büscher,[2] Lars Pape,[3] Rukshana Shroff,[4] Maria Szczepanska,[5] Elke Wuehl,[6] Franz S. Schaefer,[6] Max Liebau.[7] *[1]University Hospital Cologne, Cologne, Germany; [2]University of Duisburg-Essen, Pediatrics 2, Essen, Germany; [3]Hannover Medical School, Hannover, Germany; [4]Department of Nephrology, London, United Kingdom; [5]SMDZ in Zabrze, SUM in Katowice, Zabrze, Poland; [6]University of Heidelberg, Heidelberg, Germany; [7]University Hospital Of Cologne; Children's Hospital, Koeln, Germany.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a pediatric disorder with pronounced phenotypic variability. Severely affected patients may undergo bilateral nephrectomies in the first months of life. The neurological outcome of these patients has not been studied in defined cohorts.

Methods: Within the international registry study ARegPKD 18 patients with very early (≤3 months of age at second nephrectomy, VEBNE) and 9 with early (3-15 months, EBNE) bilateral nephrectomies as well as 13 patients with very early dialysis onset (≤3 months, VED) not receiving bilateral nephrectomies were identified. Eleven patients with total kidney volumes (TKV) comparable to the TKV of VEBNE patients but without bilateral nephrectomies served as an additional control group. Descriptive statistics, multivariate and Kaplan-Meier analyses evaluated the neurological outcome and potential risk factors of the cohorts.

Results: Mean (SD) follow-up time ranged from 1.6(2.6) years for VED patients to 7.8(5.9) years for EBNE patients. VEBNE patients suffered more frequently from seizures (67%) and severe neurological complications (61%) in comparison to EBNE patients (seizures 11%, severe neurological complications 11%), VED patients (seizures 31%, severe neurological complications 15%) and patients of the TKV control group (seizures 27%, severe neurological complications 0%). In total, 5/51 (10%) patients suffered from severe hypotensive episodes. Multivariate Cox regression analysis revealed the report of a severe hypotensive episode as well as very early bilateral nephrectomies to be independent risk factors for severe neurological complications. Mortality, including mortality after palliative care, was highest among patients with very early onset of dialysis without bilateral nephrectomies.

Conclusions: Bilateral nephrectomies within the first three months of life may be associated with severe neurological sequelae. The indication for very early bilateral nephrectomies must be carefully considered.

Genetic and Functional Investigation of Nephron Number on Diabetic Kidney Disease

Meredith B. Cobb, Kurtis C. Showmaker, Wenjie Wu, Esinam M. Attipoe, Ashley C. Johnson, Michael R. Garrett. *University of Mississippi Medical Center, Jackson, MS.*

Background: Low nephron number has been linked with susceptibility to hypertension and CKD, but a clear connection between nephron number and hyperglycemic renal injury is lacking. Our current work seeks to investigate the association between nephron deficiency and the development of diabetic CKD using a unique model of nephron deficiency, the HSRA rat. HSRA are born with a single kidney 50-75% of the time while the remaining pups are born with two. The model provides a unique advantage for direct comparison of congenital one-kidney, nephron-deficient animals (HSRA-S, ~20,400 nephrons), nephrectomized two-kidney animals (HSRA-UNX, ~25,100 nephrons) and two-kidney littermates (HSRA-C, ~50,000 nephrons). Previous work demonstrated that HSRA-S develops increased renal dysfunction with age compared to HSRA-UNX and HSRA-C, which is greatly exacerbated in the presence of DOCA hypertension. This suggests that even slight nephron differences (-S vs –UNX) are important driver of elevated blood pressure, kidney injury and accelerate decline in kidney function.

Methods: To investigate the impact of hyperglycemia on renal injury in the HSRA rat, streptozotocin (STZ) was administered at 9 weeks of age in all three groups; animals were followed for 15 weeks.

Results: Despite overt hyperglycemia (350-450 mg/dl), the diabetic groups did not develop increased proteinuria compared to their non-diabetic counterparts, contrary to the impact of second insult of hypertension.

Conclusions: Current studies are investigating the impact of hyperglycemia after overt injury ("late insult") in HSRA-S (week >24) is observed. Additionally, studies to revisit the "early insult" of hyperglycemia with the addition of modest hypertension (130 mmHg) via DOCA have begun. To better understand the underlying genetic cause of renal agenesis, altered nephrogenesis in the solitary kidney, and perhaps the differential response of injury to hypertension and hyperglycemia, genetic linkage analysis has been initiated in the HSRA model to map the quantitative trait loci/modifier genes. This work, along with completed whole genome sequencing and annotation of HSRA genome will hopefully identify new genes/pathways relevant to nephrogenesis and provide insight into differences in the interaction between nephron number and secondary insults of hypertension and hyperglycemia.

Genetic Susceptibility of Diabetic Kidney Disease in Mice Is Linked to a Promoter Variant of XOR

Ilse S. Daehn,[1] Qin Wang,[1] Haiying Qi,[4] Liping Yu,[3] Shaolin Shi,[2] Gabriella Casalena,[6] Erwin P. Bottinger.[5] *[1]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]National Clinical Research Center of Kidney Disease, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [3]Mount Sinai School of Medicine, New York, NY; [4]Mount Sinai school of medicine, Chatham, NJ; [5]Hasso Plattner Insitute, Potsdam, Germany; [6]Icahn school of medicine at mount sinai, New York, NY.*

Background: Diabetic kidney disease (DKD) is the leading single cause of ESRD in the United States. Approximately 10-30% of diabetic patients develop DKD with comparable blood glucose levels, indicating a significant genetic contribution for disease susceptibility. Differential susceptibilities are also observed in well-defined inbred mice strains. The glomerulus is the primary site of injury with hypertrophy and podocyte depletion being the hallmarks for progressive DKD. We have demonstrated that ROS and mitochondrial oxidative damage accumulation in glomerular endothelial cells (GECs), leads to podocyte loss via endothelial-to-podocyte crosstalk in experimental DKD. However, the underlying mechanisms that contribute to differential susceptibility to DKD are poorly understood.

Methods: Inbred DBA/2J (D2) mice are susceptible, while C57BL/6J (B6) mice resistant to diabetes-induced podocyte depletion. We used the 39 strains of BXD (B6XD2) recombinant inbred and parental strains to map genetic loci associated with podocyte numbers after long-term diabetes (6mth). We identified a *cis*-acting regulatory (promoter) of the *Xdh* gene encoding xanthine dehydrogenase XDH/XO (xanthine oxidoreductase (*XOR*)). XORs catalyze the oxidation of purine substrates, xanthine and hypoxanthine, producing uric acid, and are a major enzymatic source of ROS.

Results: XOR expression in the kidney and XOR circulating activity were significantly increased in diabetic D2 but not B6 mice. XOR inhibition in diabetic D2 mice significantly reduced albuminuria, oxidative damage in glomeruli and prevented podocyte loss. The two nucleotide variant was shown to influence XOR activity *in vitro*. To determine whether the variant in *XOR* promoter underlie the differential responses to diabetes, we used CRISPR/Cas9 to knock-in the *XOR* variant of D2 into B6 mice. Indeed, the mutant B6-*Xor* mice had significantly higher XOR activity. These mice developed endothelial injury, with increased ROS and mitochondrial oxidative stress in GECs, podocyte foot process effacement and depletion, basement membrane thickening, albuminuria, glomerular sclerotic lesions and tubular injury, furthermore DKD in B6-*Xor* mice was prevented with XOR specific inhibition.

Conclusions: These data suggest that the identified promoter variant regulates XOR activity, and may be causal for DKD susceptibility.

Genes Involved in Diabetic Nephropathy in a Greek Population of Diabetic Type 2 Patients

Athanasios K. Roumeliotis,[1,2] Stefanos K. Roumeliotis,[5] Vassilios Liakopoulos,[4,2] Konstantia Kantartzi,[3,5] Ilias Thodis,[3,5] Stylianos A. Panagoutsos.[3,5] *[1]Achilleion Nephrology Center, Thessaloniki, Greece; [2]1st Internal Medicine Department, "AHEPA" University Hospital, Thessaloniki, Greece; [3]Democritus University of Thrace, Alexandroupolis, Greece; [4]Aristotle University of Thessaloniki, Thessaloniki, Greece; [5]University Hospital Of Alexandroupolis, Alexandroupolis, Greece.*

Background: The incidence and prevalence of diabetic nephropathy (DN), the major cause of end stage renal disease in diabetic type 2 patients (DM2), are continuously rising. Important role in the pathogenesis of DN play metabolic factors, the oxidative stress (OS) pathway and the patient's genetic substrate. Nevertheless, genome-wide association studies regarding the genetic causes of DN are few and inconclusive. The aim of our study was to find a possible genetic association between the single-nucleotide polymorphisms on the athway of OS studied and DN development.

Methods: Data from a genome-wide association study were utilized to perform a study between 102 DM2-DN (cases) and 230 DM2-non-DN (controls) diabetic type 2 patients of greek origin.

Results: The polymorphisms that exhibited a significant correlation with DN development were 44 and the corresponding genes were 20. Some polymorphisms are probably potentially protective and others could be implicated in DN development. The genes with an odds ratio below 1, possibly exhibiting a protective role, were: SPP1 (p=0.001), CCS (p=0.019), ALOX12 (p=0.04), OXR1 (p=0.042), PRNP (p=0.049). The genes with an OR>1, possibly contributing to DN development, were: TPO (p=0.002), TTN (p=0.002), AOX1 (p=0.005), NOS3 (p=0.005), PDLIM1 (p=0.005), EPHX2 (p=0.013), GPX4 (p=0.019), TXNRD2 (p=0.019), MTL5 (p=0.033), EPX (p=0.035), GPX3 (p=0.036), IPCEF1 (p=0.041), GSTA7P (p=0.041), GPX6&5 (p=0.044), VKORC1 (p=0.047).

Conclusions: In our study 44 polymorphisms with their 20 genes on the oxidative stress pathway were found to be potentially associated with DN in greek DM2 patients.

Enhancer of Zeste Homolog-2 (EZH2), a Histone H3 Methyltransferase, Launches Deptor Downregulation for Mesangial Cell (MC) Hypertrophy and Matrix Expansion in Diabetic Nephropathy (DN)

Falguni Das, Nandini Ghosh-choudhury, Balakuntalam S. Kasinath, Goutam Ghosh-Choudhury. *University of Texas Health Science Center, San Antonio, TX.*

Background: mTOR has emerged as a centerpiece in pathogenesis of DN. Deptor is an inhibitory component of both mTOR complexes (C1 and C2). We investigated epigenetic control of deptor expression and its relevance to mesangial cell hypertrophy and matrix protein expansion during the progression of DN.

Methods: Human MCs and OVE26 mice were used. Activation-specific antibodies, real time qRT-PCR, immunoblotting, plasmid-derived expression vector and shRNA transfection were employed.

Results: In MCs, 25 mM glucose (HG) decreased expression of deptor mRNA and protein in a time-dependent manner, resulting in increased activation of mTORC1 and C2 as judged by phosphorylation of S6 kinase (T-389) and Akt (S-473), respectively. To determine the mechanism of deptor downregulation, we considered the epigenetic mechanism involving the polycomb repressor complex-2 in which EZH2 promotes the trimethylation (Me3) of histone H3 at K27. HG increased the expression of EZH2 concomitant with increased H3K27 Me3. Deazaneplanocin (DZNep), an inhibitor of EZH2, blocked H3 Me3 and deptor downregulation induced by HG. Also, DZNep inhibited HG-stimulated mTORC1 and C2 activities. Similarly, shRNA against EZH2 inhibited H3K27 Me3, reversed HG-induced deptor inhibition and suppressed mTORC1 and mTORC2 activities. In contrast, expression of EZH2 increased H3 K27 Me3, decreased deptor expression and enhanced mTORC1 and C2 activities, similar to HG treatment. Furthermore, DZNep and shEZH2 significantly inhibited HG-induced MC hypertrophy and expression of fibronectin and plasminogen activator inhibitor-1 (PAI-1). On the other hand, EZH2 increased fibronectin and PAI-1 expression similar to HG. To address the *in vivo* relevance of our observations, we used OVE26 diabetic mouse. In the renal cortex of these mice, expression of EZH2 was significantly increased concomitant with increased H3K27 Me3, mTORC1 and C2 activities, and fibronectin and PAI-1 expression.

Conclusions: Our results for the first time uncover a precisely tuned balance between deptor suppression by EZH2 and activation of mTORC1 and C2 for HG-induced MC hypertrophy and matrix accumulation. The data lend support for testing EZH2 inhibitors in preclinical model for attenuation of complications of DN.

Urinary Kidney-Specific DNA Methylation Signature Correlates with Renal Function Decline in Diabetes

Takeshi Marumo,[1] Junichi Hoshino,[2] Wakako Kawarazaki,[1] Mitsuhiro Nishimoto,[1] Nobuhiro Ayuzawa,[1] Daigoro Hirohama,[1] Masayuki Yamanouchi,[2] Yoshifumi Ubara,[2] Atsuhisa Sato,[4,3] Tatsuo Shimosawa,[4] Toshiro Fujita.[1] *[1]The University of Tokyo, Tokyo, Japan; [2]Toranomon Hospital, Tokyo, Japan; [3]Division of Nephrology and Hypertension, IUHW Mita Hospital., Tokyo, Japan; [4]International University of Health and Welfare School of Medicine, Tokyo, Japan.*

Background: Renal tubular injury contributes to the silent decline in kidney function in patients with diabetes. Cell type-specific DNA methylation patterns have been used to calculate proportions of particular cell types. In this study, we developed a method to detect renal tubular injury in diabetic patients based on tubule-specific DNA methylation patterns in urine sediment.

Methods: To identify gene loci exhibiting proximal tubule-specific DNA methylation in the human urinary system, we used two approaches: genome-wide DNA methylation analysis using the Infinium MethylationEPIC BeadChip Kit and extrapolation from mouse CpG data obtained in our previous study. We next determined the methylation levels of proximal tubule-specific loci in urine sediment of diabetic patients and analyzed correlation with clinical variables.

Results: Genomic loci in gene A and G6PC were selectively unmethylated in proximal tubular cells compared to other parts of micro-dissected tissues obtained from normal kidney and bladder epithelium. The methylation levels of gene A and G6PC in urine sediment, deemed to reflect the proportion of exfoliated proximal tubular cells, correlated well with each other. Multivariate analysis with classic tubular injury markers and known risk factors of renal insufficiency in diabetic patients revealed that lower eGFR and lower methylation levels of gene A were independently associated with larger annual decline in estimated glomerular filtration rate (eGFR). Moreover, addition of urinary gene A methylation to a model containing eGFR and urinary albumin/Cr improved discrimination of diabetic patients with faster eGFR decline, which were defined as those losing eGFR at a rate of more than the 25th percentile of annual eGFR decline, with c-statistics from 0.698 to 0.756 and a significant improvement in reclassification with category-free net reclassification improvement.

Conclusions: This study demonstrates that diabetic patients with continual loss in kidney function may be stratified by a specific DNA methylation signature and provides the approach for using kidney cells in the urine for the non-invasive diagnosis of kidney diseases through epigenetic urinalysis.

Analysis of DNA Repair Factor KAT5 and DNA Methylation Modulators in Urinary Shedding Cells of Patients with Diabetic Kidney Disease

Akihito Hishikawa, Kaori Hayashi, Hiroshi Itoh. *Keio University School of Medicine, Tokyo, Japan.*

Background: Diabetic kidney disease (DKD) is the leading cause of ESRD worldwide. Therefore, early diagnosis is needed. We have recently discovered that DNA repair factor KAT5 is decreased in DKD podocytes, which may lead to impaired DNA repair with aberrant DNA methylation (Cell Rep 2019). Here we investigated the expression profiles of KAT5 and DNA methylation modulators in urinary shedding cells of patients with DKD as a potential diagnostic marker.

Methods: 60 outpatients who visited the nephrology department at Keio University Hospital were enrolled (Gender [Male 39, Female 21], Age 63±2, patients with diabetes 17 [eGFR 59.4±5.4], patients without diabetes 43 [eGFR 63.9±3.4]). 50ml of urine samples were collected and centrifuged, and mRNA was extracted to analyze the expression of phenotypical markers (nephrin; podocytes, AQP1; proximal tubular cells, AQP2; collecting duct cells) and epigenetic modulators in urine-derived cells by quantitative RT-PCR method as previously described. The association of the marker expression levels with

clinical data including presence of diabetes (DM) or hypertension (HT) was investigated using multivariate regression analysis.

Results: Urine KAT5/nephrin was decreased in diabetic patients (p=0.04) consistent with our previous basic study. On the other hand, KAT5/nephrin was increased in HT patients without DM (p=0.08), whereas it decreased in HT patients with DM (p=0.02). In addition, DNA methyltransferase DNMT1, 3A, 3B and DNA demethylation enzyme TET1, 3 expression adjusted with AQP1 or AQP2 respectively, increased in patients with HT. These expression tendencies correlated with the severity of HT especially in AQP1 adjustment. Moreover, DNMT1/AQP1 and DNMT3A/AQP1 had positive correlation with 1-year eGFR reduction rate. Multivariate regression analysis adjusted for proteinuria, age, eGFR and presence of DM also showed that DNMT1/AQP1 was associated with 1-year eGFR decline as the same extent with the presence of DM.

Conclusions: Urine KAT5/nephrin may be a potential diagnostic marker of DKD. Urine DNMT1, 3A/AQP1 is increased in HT patients and associated with 1-year eGFR reduction rate suggesting its possible role as a predictor of renal prognosis.

TH-PO873

Epigenetic Regulation of Gremlin-1, a Key Player in Diabetic Nephropathy Development

Vanessa Marchant,[2,1] Sergio A. Mezzano,[1] Marta Ruiz-Ortega,[3] Bredford Kerr.[2,4] *[1]Nephrology Division, Faculty of Medicine, Universidad Austral de Chile, Valdivia, Chile; [2]Centro de Estudios Científicos, CECs, Valdivia, Chile; [3]Cellular Biology in Renal Diseases Laboratory, IIS-Fundación Jiménez Díaz, Universidad Autonoma, Madrid, Spain; [4]Centro de Biología Celular y Biomedicina-CEBICEM, Universidad San Sebastian, Providencia, Chile.*

Background: Gremlin-1 (Grem1) is a protein highly expressed in the kidney of both diabetic nephropathy (DN) patients and experimental models. However, the molecular mechanism underlying the induction of Grem1 in DN is not fully understood. Emerging evidence supports a role for epigenetic regulation in the pathogenesis of diabetic nephropathy, but the epigenetic regulation of Grem1 has not been explored. This work aimed to study the role of epigenetic mechanisms in the control of renal expression of Grem1 and its association with diabetic nephropathy.

Methods: We first evaluated the renal expression of Grem1 in 4, 8, 12, and 16-week-old mice from a diabetic nephropathy model (BTBR ob/ob) and in 8-week-old mice from an epigenetic disruption model (Mecp2-null) by RT-qPCR. Additionally, we determined renal expression levels of Mecp2 in 16-week-old BTBR ob/ob mice by Western Blot. Next, the DNA sequence of Grem1 was analyzed with bioinformatics tools to identify potential methylable CpG islands (CGI). Chromatin immunoprecipitation using anti-Mecp2 antibody followed by PCR was performed to assess the binding of Mecp2 to the Grem1 CGI previously identified. Methylated DNA enrichment by MBD-capture was performed to evaluate the methylation level of the Grem1 CGI.

Results: We observed that Grem1 renal expression is increasing in BTBR ob/ob mice starting from 8 weeks of age and according to the progression of the phenotype associated with DN. Renal expression of Mecp2 in 16-week-old BTBR ob/ob mice was also increased. Additionally, Grem1 renal expression was increased in Mecp2-null mice compared to wild-type. Next, we identified a ~2 kb CGI in Grem1 sequence, that includes its transcription start site. We found that in the kidney of wild-type mice, there is a ~4% of basal methylation in two zones of Grem1 CGI and Mecp2 binds to several regions of the Grem1 CGI.

Conclusions: Our results strongly suggest that Mecp2 epigenetically represses Grem1 expression by binding to a methylated CpG island in Grem1 promoter and coding gene. These results allow us to propose that an epigenetic mechanism underlies the induction of Grem1 gene expression in diabetic nephropathy development. Comparison of Kidney Transcriptomic Profiles Between Patients with Early and Advanced Diabetic Nephropathy Reveals Potential New Mechanisms for Disease Progression

Ying Fan,[1] Zhengzi Yi,[2] Niansong Wang,[1] John C. He.[2] *[1]Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China; [2]Icahn School of Medicine at Mount Sinai, Elmhurst, NY.*

Background: Genome-wide gene expression profiling can be useful in providing a global picture of the disease pathogenesis and to identify potential new biomarkers and drug targets for DN.

Methods: We performed RNA sequencing of the whole kidney biopsy samples from 28 patients with early DN (n=6), advanced DN (n=22) and normal kidney tissues (n=9) from nephrectomy samples. Correlation of differentially expressed genes (DEGs) with renal function (eGFR) and histological parameters in the DN patients was analyzed. We took advantage of the recently published scRNA-seq data to perform a computational deconvolution analysis of the gene expression data from whole kidney to estimate the number of cells in the normal and diseased kidneys. Finally, we validated some of these findings by immunostaining of the kidney tissues from these patients.

Results: We found that a group of genes were upregulated at early DN but down-regulated in late DN, many of which were shown to be renoprotective, including those in the retinoic acid and glucagon-like peptide-1 receptor (GLP1R) pathways. Another group of genes that were downregulated at early DN, but highly upregulated in advanced DN, consisted mostly of genes known to be involved in progression of DN, such as those related to immune response and fibrosis. We found that the DEGs in the pathways of iron transport and cell differentiation were positively associated with eGFR, while those in the immune response and fibrosis pathways were negatively associated. We also found that individual renal pathology features were associated with the DEGs belonging to the unique GO terms and pathways. We performed deconvolution analysis of the RNA sequencing data to deduce the number of different cell types in DN by using recently published single-cell transcriptome datasets, which showed a significant increase in monocytes/macrophage, fibroblasts, and myofibroblasts in the kidneys from patients with advanced DN. Finally, we validated the expression of RBP4 and GLP1R and the markers of immune cells in the kidney tissues of these patients by immunostaining.

Conclusions: Our study provides potential molecular mechanisms for DN progression as well as the associations of DEGs with the functional and structural changes observed in patients with both early and advanced DN.

TH-PO875

Bioinformatic Analysis of Kidney Transcriptome Sequencing from Patients with Diabetic Nephropathy Based on Different Sequencing Platforms

Hongchun Lin, Dan Luo, Yongjie Li, Jun Song, Hui Peng. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: Diabetic Nephropathy (DN) is one of serious complications of diabetes mellitus. The changes in kidney gene expression profile in patients with DN remain unclear. The field has seen studies of kidney transcriptome sequencing data from patients with DN using different sequencing platforms with varied results. Our aim is to combine those sequencing data and find the differentially expressed genes(DEGs) profile in the kidneys of DN patients by means of bioinformatic analysis.

Methods: The microarray data of human diabetic glomeruli and tubules were screened in GEO database. The selection criteria were as follows: 1. The samples include both DN kidney tissue and normal ones; 2. The samples must be detected after the glomeruli or tubules were separated. 3. DN tissue is not subject to other experimental biological factors. In total, 82 cases of glomeruli and 77 cases of kidney tubule tissues, coming from GPL11670,GPL14663,GPL30122 platforms, were included to identify the DEGs. The contrast model is constructed on the DN and CTL data from the three platforms respectively, using limma function package in R software. We performed Bayesian Test according to contrast Model (Log FC > 1 and P < 0.05 were defined as DEGs). The results of gene intersection between different sequencing platforms were analyzed with STRING and DAVID on-line tools. Cytoscape was used to screen proteins with stable differential expression trend.

Results: There were 134 common DEGs with multiple sequencing platforms in the glomerular of DN patients which were enriched in the exosome process and Rap1 signaling pathway. Among them, 7 genes (WT1,FGF9,IGF1,ALB,TJP1,EGF,BMP7) exhibited the most stable protein interaction. 20 genes show a consistent trend of differential expression in kidney tubule. Exosome process is the most enriched biological process in functional analysis. Moreover, 3 genes (LUM,THBS2,VCAN) exhibited the most stable interaction. We confirmed the expression of these genes in the human protein library(HPA) and verified the different expressions in the kidneys of DN patients by RT-qPCR.

Conclusions: DEGs of microarray data in glomeruli and tubules of DN patients are not the same. DEGs from different sequencing platforms are inconsistent. The function of common DEGs in different platforms may be more closely related to the pathogenesis of DN.

Whole-Kidney 3D Imaging and Transcriptome Assessment in the UNx db/db Mouse Model of Diabetic Nephropathy

Frederikke E. Sembach, Brandon B. Boland, Lisbeth N. Fink, Urmas Roostalu, Jacob L. Skytte, Thomas Secher, Keld Fosgerau, Niels Vrang, Jacob Jelsing, Jacob Hecksher-Sørensen, Tanja X. Pedersen. *Gubra, Hørsholm, Denmark.*

Background: Diabetic nephropathy (DN) is associated with increased cardiovascular risk and shortened survival. The DN therapeutic landscape has remained almost completely unchanged for decades, largely due to the lack of translatable preclinical models. In this study, we assessed renal changes in uninephrectomized (UNx) *db/db* mice using light sheet microscopy (LSM) and RNA sequencing to better define the structural and functional changes associated with early progression of DN.

Methods: UNx was performed in 7-8 week old male and female *db/db* mice. Sham-operated *db/+* mice served as controls. Kidneys were preserved for histology, stereology, and RNA sequencing. In a separate study, UNx was performed in 18 week old male *db/db* mice. Mice were injected with lectin-594 immediately prior to termination to visualize glomerular morphology and to assess glomerular permeability via LSM. All mice were terminated at 24 weeks.

Results: Male and female UNx *db/db* mice showed similar progression of type 2 diabetes and urine albumin to creatinine ratio (UACR). Glomerular volume was increased in both genders relative to non-diabetic controls. Tubulointerstitial collagen III was increased in female UNx *db/db* vs. control mice, whereas glomerulosclerosis, as assessed by collagen IV/podocin colocalization, was significantly increased in male UNx *db/db* mice. Kidney RNAseq revealed increased expression of the glomerular marker *Nphs1* and the tubule markers *Lcn2*, *Spp1*, *Havcr1*, confirming glomerular hypertrophy and kidney injury. Glomerular number was determined by LSM and subsequent stereological assessment on the same kidneys, allowing direct comparison of the two methodologies. UNx and control mice demonstrated similar glomerular numbers (~16,000), whereas UNx

mice had increased glomerular volume (81,000 mm^3 vs 145,000 mm^3). Moreover, LSM revealed a marked increase in cortical lectin-594 staining, indicating glomerular leakage and emerging glomerular dysfunction in UNx *db/db* mice.

Conclusions: The use of whole-kidney 3D imaging in tandem with RNAseq offers a novel means of assessing individual glomerular structure and function during DN progression and represents a powerful technique to profile the preclinical efficacy of forthcoming DN therapeutics.

Early Changes in Kidney Transcriptomics and Proteomics in Streptozotocin-Induced Diabetes Model

Karina A. Barreiro,[1] Annukka Jouppila,[2] German G. Leparc,[3] Denis Delic,[4] Riitta Lassila,[5] Tobias B. Huber,[6] Harry B. Holthofer.[7] *[1]Institute for Molecular Medicine Finland FIMM, University of Helsinki, Helsinki, Finland; [2]Helsinki University Hospital Clinical Research Institute, Helsinki, Finland; [3]Boehringer-Ingelheim, Biberach, Germany; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [5]Hematology, Helsinki University Hospital, Helsinki, Finland; [6]University Medical Center Hamburg, Hamburg, Germany; [7]University of Helsinki, Finnish Institute of Molecular Medicine, Helsinki, Finland*.

Background: Diabetic kidney disease (DKD) is a progressive and feared microvascular damage in diabetes patients. It is the leading cause of end-stage kidney disease (ESKD) globally. There is strong evidence that cellular insulin resistance is a major driver of DKD progression. However, early pathways involved in the development of DKD are still poorly understood. Here we explored transcriptomics and proteomics of kidney tissue in streptozotocin (STZ) induced diabetic rat kidneys in order to confirm known and establish new early molecular changes associated with DKD.

Methods: To induce diabetes, one dose of STZ (50mg/kg) was administered in the intraperitoneal cavity to animals fasted overnight. Urine and kidneys were collected at days 1, 7 and 15 post injection. Sections cut of kidney cortex were used to isolate RNA and proteins. RNA was isolated using RNeasy Fibrous Tissue and subjected to small and long RNA sequencing. For protein analysis, tissue was homogenized in 7M urea, 2M thiourea, 4% CHAPS using Percellys® 24 homogenizer and subjected to LC-HDMS.

Results: 1 day after injection of STZ, an increase of in serum glucose levels and urine volumes was detected in STZ treated groups as expected. Distinct differences between diabetic and control groups in regard to miRNA, mRNA and proteins, respectively, were observed as early as day seven and also at day 15 post injection. At day 15, the gene enrichment analysis (GO: Biological process) of proteins reflected many known pathways involved in diabetes type II. These included pathways modulated at the onset of diabetes and those associated e.g. with glycolysis/gluconeogenesis and others. An exclusive transcriptional expression pattern was seen at each timepoint which should be very valuable to establish new molecular targets now available for verification in human DKD.

Conclusions: Our approach describes early molecular changes of DKD at transcriptomics and proteomics level. These results are valuable to define previously unidentified pathways involved and novel molecular targets in DKD.

Urinary Proteomics Identifies Signature of Early Type 1 Diabetes Linked to Keratan Sulfate Degradation and Lysosomal Enzymes

Julie Anh Dung Van,[1] Sergi Clotet Freixas,[2] Yesmino Elia,[3] Farid H. Mahmud,[3] James W. Scholey,[1] Ana Konvalinka.[2,1] *[1]University of Toronto, Toronto, ON, Canada; [2]University Health Network Toronto, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, AB, Canada*.

Background: Maladaptive changes have been described in the diabetic kidney long before the onset of microalbuminuria, in the form of renal hyperfiltration and hypertrophy. Our aim is to examine the urinary proteome of youths with early, uncomplicated type 1 diabetes and to examine the biological processes and pathways underlying early changes in the diabetic kidney.

Methods: We performed urinary proteomics on samples from 15 otherwise healthy youths with type 1 diabetes and 15 non-diabetic peers. All youths were < 19 years of age, free of comorbidity including microalbuminuria, and not using anti-hypertensive drugs. Urine volumes normalized to creatinine were subjected to 10-kDa ultrafiltration to isolate proteins. Proteins (200 micrograms) were digested with trypsin, fractionated using strong cation exchange chromatography, and analyzed on Q-Exactive mass spectrometer. MaxQuant software was used for peptide/protein identification and label-free quantification. The PathDIP database was searched to identify the top pathways associated with differentially excreted proteins. Proteins were validated in a second cohort of 30 youths with and without diabetes using enzyme-linked immunosorbent assays.

Results: Of the 2313 proteins quantified, 576 were detected across all thirty urine samples. Of these, 34 were differentially excreted between groups (Benjamini-Hochberg FDR, $Q < 0.05$). More than half of these differentially excreted proteins were lysosomal enzymes, and the dominant terms associated with these lysosomal enzymes include “hydrolase activity”, “glycosaminoglycan degradation”, and “keratan sulfate proteoglycan”. Increased urinary excretion rates of lumican and hexosaminidase A were validated in a second cohort, representing a core protein and an enzyme that degrades glycosidic bonds in keratan sulfate.

Conclusions: Lysosomal enzymes associated with keratan sulfate degradation were overrepresented in urines from youths with diabetes, suggesting that extracellular matrix remodeling may be an early response of the kidney to hyperglycemia.

TH-PO879

The Feasibility and Utility of Urinary Single-Cell Sequencing

Tong Zhou,[1] Kishor B. Devalaraja-Narashimha,[2] Rojesh Shrestha,[1] Jonathan J. Hogan,[4] Matthew Palmer,[1] Raymond R. Townsend,[3] Paolo Guarnieri,[5] Yi Wei,[2] Lea Sarov-Blat,[6] Carine Boustany,[5] Lori Morton,[2] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Regeneron Pharmaceuticals, Tarrytown, NY; [3]University of Pennsylvania School of Medicine, Villanova, PA; [4]Hospital of the University of Pennsylvania, Haddonfield, NJ; [5]Boehringer Ingelheim, Ridgefield, CT; [6]GSK, Collegeville, PA*.

Background: At present, histological assessment of renal biopsies remains the only approach to firmly diagnose renal diseases. However, it requires an invasive procedure which is associated with a small but existent risk for the patient. As kidney cells are continuously shed into the urine, we sought to investigate whether urinary single cell sequencing(SCS) can be used to predict changes occurring in renal biopsy samples. Here we report on the feasibility and utility of urinary SCS in the TRIDENT (Transformative research in diabetic nephropathy) cohort.

Methods: Patients with diabetes undergoing clinically indicated kidney biopsy were enrolled into the TRIDENT study, and were consented to participate in this ancillary study. Urine samples, spot and 24-hour collections, were obtained twice at one-month interval from 5 subjects for a total of 20 specimen. Urine scRNA-Seq was performed using 10xGenomics Chromium system. Results were correlated with kidney tissue pathology and compartment specific RNA sequencing.

Results: High-quality data was generated for 4 patients. Total number of cells detected in urine varied between 185-7260 across individuals but was not different between spot and 24-hour specimen and samples collected over a month. Cell identity was matched using mouse single cell gene expression markers. 20 different kidney cell types were identified in addition to the identity of several cell types are still being matched. Neutrophils and an unknown cell type (possibly bladder cells) were the predominant cell type in the urine. Endothelial and collecting duct intercalated cells were only detected in the spot urine sample, but all other cells were present in both collection. Urinary podocyte number correlated with proteinuria and eGFR. Urinary fibroblasts correlated with the degree of fibrosis measured histologically in renal biopsies obtained from the same patients. Urinary cell proportions correlated with renal bulk mRNA cell proportions.

Conclusions: Urine scRNA-Seq is feasible. This method can provide an insight into renal molecular, cellular, and histological changes. Urinary cell number and proportions seem stable and correlated with kidney specific changes. Overall, urinary scRNA-Seq may provide a non-invasive approach to diagnosing renal diseases.

TH-PO880

MicroRNA-155 Upregulation Induces Podocyte Insulin Resistance: A New Therapeutic Target in Diabetic Nephropathy?

Alexa Wonnacott,[1] Abigail C. Lay,[2] Fern Barrington,[2] Timothy Bowen,[1] Richard Coward,[2] Donald Fraser.[1] *[1]Cardiff University, Cardiff, United Kingdom; [2]University of Bristol, Bristol, United Kingdom*.

Background: Loss of podocyte-specific insulin-sensitivity results in histological features of diabetic nephropathy (DN) in mice, implicating this pathway in disease development. MicroRNAs (miRNAs) regulate expression of most mammalian protein coding genes at the post-transcriptional level, and are critical regulators of insulin responses in “traditionally” insulin-sensitive tissues, liver, fat and muscle. The role of miRNAs in podocyte insulin-signalling is unknown. We hypothesise that miRNA-driven loss of podocyte insulin responses triggers DN development.

Methods: Podocytes were rendered insulin-resistant by culture in diabetogenic media containing high dose insulin, glucose and inflammatory cytokines. Microarray analysis was performed to compare miRNA expression profiles of wild type and insulin-resistant podocytes, and differential expression of selected miRNAs was validated by RT-qPCR. *In vitro* manipulation of differentially expressed miRNAs was achieved using miRvana mimics and inhibitors, and insulin responses assessed by Western Blot and tritiated glucose uptake assay.

Results: Differential expression of 103 miRNAs was detected. Five miRNAs were selected for further study based on expression fold change, a statistical significance threshold of $p<0.0002$ and bioinformatic evidence of targets in insulin-signalling pathways. MiR-155,-146a,-222 and -204 were validated by RT-qPCR. MiR-155 overexpression in podocytes repressed expression of target mRNA PI3KR1, reducing subsequent Akt phosphorylation. Furthermore, Insulin-stimulated glucose uptake was reduced in miR-155 over-expressing podocytes.

Conclusions: MicroRNA-155 is upregulated in podocyte insulin-resistance *in vitro*. Insulin-resistance may be effected via PI3KR1 repression, leading to reduced insulin-signalling via the PI3K/Akt pathway and impaired downstream glucose uptake. Thus miR-155 may be therapeutically manipulated as a novel podocyte insulin-sensitiser to halt the progression of DN.

TH-PO881

The Role of LncRNA Meg3 in the Mitochondrial Dysfunction Induced by High Glucose in Podocytes

Qiongxia Deng, Wang Cheng. *The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai, Guangdong, China*.

Background: Podocytes have plenty of mitochondrial density to keep up with their high energy need. Mitochondrial dysfunction plays a key role in diabetic nephropathy(DN), which has been assumed related with Maternally expressed gene 3 (Meg3),a long

noncoding RNA expressing in normal human tissues. While the exact mechanism of Meg3 on this pathophysiological process is poorly understood.

Methods: FISH+IF was used to detect the expression of Meg3 in podocytes of patients with DN. Podocytes were exposed or not to 30mM high glucose in vitro to study the effect of high glucose on Meg3 expression. In addition, the expression of Meg3 was regulated by CRISPR-Cas9 system and lentiviral vector to explore its function in mitochondrial dysfunction.

Results: Meg3 expression in podocytes of diabetic kidney tissue was higher than that in normal kidney tissue. In cultured human podocytes, the expression of Meg3 increased with the prolongation of high glucose exposure time. The results of PCR detection were consistent with those of Arraystar, suggesting that high glucose can up-regulate the expression of Meg3. Knocked out Meg3 can improve podocyte injury and mitochondrial dysfunction induced by high glucose. By contrast, the podocytes over-expression of Meg3 aggravated injury, expressing less Nephrin and Synaptopodin. Abnormal expression of proteins associated with mitochondrial fusion and fission caused dynamic imbalance of mitochondria, more fragmentation, lower mitochondrial membrane potential levels.

Conclusions: Our study demonstrates for the first time that Meg3 can be upregulated by high glucose, inducing a dynamic imbalance of mitochondria, leading to damage to podocytes. This finding will provide a potential treatment strategy to alleviate the development of DN.

TH-PO882

Extracellular Vesicle Cargo Derived from Kidney Cell Lines Is Affected in Insulin-Resistant and Highly Insulin-Sensitive Conditions

Karina A. Barreiro,[3] Abigail C. Lay,[1] Richard Coward,[1] German G. Leparc,[4] Denis Delic,[5] Tobias B. Huber,[2] Harry B. Holthofer.[6] *[1]University of Bristol, Bristol, United Kingdom; [2]University Medical Center Hamburg, Hamburg, Germany; [3]Institute for Molecular Medicine Finland FIMM, University of Helsinki, Helsinki, Finland; [4]Boehringer-Ingelheim, Biberach, Germany; [5]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [6]University of Helsinki, Finnish Institute of Molecular Medicine, Helsinki, Finland.*

Background: Kidney disease (DKD) is common, costly and the most feared complication of long standing diabetes. It is now clear that cellular insulin resistance is a major driver of this disease. Here we explored the extracellular vesicle (EV) secretion pattern by key DKD target cellsin the glomerulus (podocytes, endothelial and mesangial cells) and proximal tubular cells by harvesting the entire secreted EV repertoire in insulin sensitive and insulin resistant cells using Hydrostatic Filtration Dialysis (HFD).

Methods: EVs were isolated from 50ml of cell culture mediafrom conditionally immortalized human cells. Cells were rendered hyperinsulin-sensitive by stable insulin receptor expression, and insulin resistant by culturing in a diabetic environment as recently published. Quality of the EV yield was verified with negative staining Electron Microscopy (EM) and Western blotting (WB). Vesicle concentration and size was determined by Nanoparticle Tracking Analysis (NTA). EV RNAs were profiled with Bioanalyzer Pico kit and subjected to miRNAseq, and mRNAseq. EV proteins were analyzed using tandem mass tag labeling.

Results: The isolated EVs appeared typical at EM and were positive for the EV-marker TSG101 in WB. RNA quantity and quality proved appropriate for miRNA analysis. 96 EV miRNAs and 109 mRNAs could characteristically discriminate between the cell types. Some EV miRNAs, mRNA and proteins showed treatment effects. KEGG and Gene Ontology gene enrichment analysis showed pathways associated with DKD.

Conclusions: EV analysis provides a novel approach to reveal valuable new details of the kidney secretome in the setting of insulin-resistant diabetic conditions. It is noteworthy that the characteristic changes can be found from culture medium of DKD target cell. Changes in the EV miRNAs, mRNA and proteomics may thus give valuable insight into mechanisms and targets to insulin resistance in DKD.

TH-PO883

Exosome-Mediated Tubulointerstitial Communication Promotes Renal Fibrosis in Diabetic Kidney Disease

Jin Wen,[1,2] Man J. Livingston,[3] Wei Zhang,[3] Chunyuan Guo,[3] Yanggang Yuan,[3] Ping Fu,[2] Zheng Dong.[3] *[1]Yongchuan Hospital of Chongqing Medical University, Chongqing, China; [2]West China Hospital of Sichuan University, Chengdu, China; [3]Augusta University Medical College of Georgia, Augusta, GA.*

Background: Renal tubular injury initiates fibroblast activation and drives overproduction of extracellular matrix, leading to renal fibrosis which is a final common pathway in progressive kidney diseases including diabetic kidney disease(DKD). However, it is unclear how injured tubular epithelial cells relay signals to neighboring fibroblasts and trigger the differentiation of fibroblasts to myofibroblasts. Recently, exosomes have been recognized as crucial mediators of intercellular communication. We hypothesized that exosomes might be involved in the communication between injured tubular cells and fibroblasts during the progress of DKD.

Methods: Exosomes were isolated from kidney tissues and mouse proximal tubular cells by differential centrifugation. In *in vivo*, renal cortex of Akita mice and STZ-induced C57/b6 mice were examined. In *in vitro*, BUMPT cells were cultured with normal glucose(NG) or high glucose(HG) for 8 days to collect exosomes in the conditioned medium(CM). Exosomes were characterized by TEM, NTA and western blot. The content of exosomes was analyzed by proteomics. To study the effect of tubular cell exosomes on fibroblasts, the tubular CM-derived exosomes were added to NRK-49 fibroblasts for 48 hrs, followed by the evaluation of cell proliferation and fibrosis.

Results: Exosome secretion decreased in renal cortex of DKD mice as compared to non-diabetic mice. Consistently, HG-incubated BUMPT cells had lower exosomes than NG cells. Notably, the exosomes from HG-incubated BUMPT cells stimulated higher levels of proliferation, morphologic change, and production of fibronectin, a-SMA, and collagen I in fibroblasts. 15 proteins showed differential expression in the exosomes from HG BUMPT-cells versus those from NG cells. Cytoscape analysis suggested two correlation networks of the differentially expressed genes. The higher expression of Eno1 and close relationship with clinical manifestation in DKD were further proved using Nephroseq v5 online platform.

Conclusions: DKD is associated with a decreased ability of exosome production and/or secretion in renal tubular cells. The exosomes from HG-incubated tubular cells are more effective in stimulating the proliferation and activation of fibroblasts. Thus, exosomes may provide a mechanism of tubulointerstitial communication in renal fibrosis and disease progression in DKD.

TH-PO884

Mass Spectrometry Imaging Reveals Alerted Metabolic Profiles of Small Molecules in Kidney Tissue Sections of Diabetic Mice

Annapurna Pamreddy,[3] Guanshi Zhang,[3] Jiwan J. Kim,[3] Manjula Darshi,[3] Dusan Velickovic,[1] Viktor Drel,[3] Ljiljana Pasa-Tolic,[1] Theodore Alexandrov,[2] Christopher R. Anderton,[1] Kumar Sharma.[3] Center for Renal Precision Medicine *[1]Pacific Northwest National Laboratory, Richland, WA; [2]European Molecular Biology Laboratory, Heidelberg, Germany; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: It was reported that 1,5-naphthlenediamine (1,5-DAN) hydrochloride assisted laser desorption ionization (LDI) mass spectrometry imaging (MSI) of kidneys, liver, and brain tissues allowed to visualize the spatial distribution and alteration of a broad range of small molecule metabolites including metal ions, amino acids, carboxylic acids, nucleotide derivatives, peptides, and lipids simultaneously. MSI has potential applications in small molecule *in situ* analysis (Huihui Liu et al., 2014).

Methods: In the current study, we employed a high resolution MALDI-MSI approach using 1,5-DAN hydrochloride as matrix to characterize small molecules in Akita (n = 3) and non-Akita (n = 3) mice kidney tissue sections at 20 μm spatial resolution. The data output was coupled to METASPACE for the annotation. SCiLS Lab and MetaboAnalyst were used for data processing and statistical analysis.

Results: In total, 107 metabolites were annotated by METASPACE in mice kidney tissue sections. MALDI MSI of kidney sections of F_1 Akita mice clearly exhibited profound alterations of intermediates in the tricarboxylic acid cycle (TCA) cycle, glutamate-glutamine cycle, malate-aspartate shuttle, and phospholipid metabolism, simultaneously. Various metabolites underwent relatively remarkable changes in diabetic kidney tissues compared with the non-diabetic ones. Particularly, diabetic kidneys had higher relative abundance of glucose, xanthine and hypoxanthine, while lower relative levels of citric acid, glutamine, linoleic acid and arachidonic acid were observed.

Conclusions: In summary, MALDI-MSI is potentially effective and widespread application in small molecule *in situ* analysis of mice kidney tissues. MALDI-MSI technology coupled with METASPACE shed new light on our understanding of pathobiology of diabetic kidney disease.

TH-PO885

The Effect of Kidney Cell Sex and Sex Hormone Stimulation on Kidney Metabolism: Implications for Diabetic Kidney Disease

Sergi Clotet Freixas, Julie Anh Dung Van, Aman Mehrotra, Adam J. Gehring, Minna Woo, Amy A. Caudy, Ana Konvalinka. *University Health Network, Toronto, Toronto, ON, Canada.*

Background: Male sex predisposes to diabetic kidney disease (DKD). We uncovered androgen-induced proteome perturbations in renal metabolism that may drive faster DKD progression in men. Our goal is to study cell sex- and sex hormone-specific metabolic alterations in human primary proximal tubule epithelial cells (PTEC).

Methods: PTEC from 3 male and 3 female donors were stimulated with control, dihydrotestosterone (DHT), or estradiol (EST) for 16h/24h. Chronic hyperglycemia was simulated by exposing sex hormone-treated PTEC to high glucose (25mM) for 96h. We assessed glycolysis (extracellular acidification rate, ECAR) and oxygen consumption rate (OCR) in a Seahorse analyzer. We measured extracellular glucose, intracellular ATP, oxidative stress (O_2^-), and apoptosis (phosphatidilserine). IL-6 and MCP1 were quantified by a Multiplex Assay.

Results: Male PTEC showed significantly higher ECAR and OCR, ATP-linked respiration, maximal glycolitic and respiratory capacity, superoxide levels and apoptosis compared to female PTEC ($p<0.05$). In male PTEC, ECAR was increased by DHT stimulation, whereas OCR was increased by DHT and EST. In male PTEC, media glucose levels were reduced by DHT. DHT-induced increase in glycolysis, OCR, oxidative stress and glucose consumption was prevented by androgen receptor (AR) inhibitors. ATP, O_2^-, apoptosis and secretion of IL-6 and MCP1 were increased by DHT, especially in male PTEC. Under hyperglycemia, DHT increased O_2^- and ATP. Promoter analysis revealed that 46/60 of our DHT-upregulated proteins may be regulated by MYC and/or SRY transcription factors (involved in glucose/glutamine metabolism and in male sex determination). Male sex and DHT were associated with increased AR and SRY gene levels ($p<0.05$). MYC was upregulated by DHT in male PTEC and by EST in female PTEC ($p<0.05$).

Conclusions: The metabolic function of PTEC and their response to sex hormones are influenced by cell sex. Male PTEC show higher glycolysis, oxygen consumption, and respiratory capacity than female PTEC. These differences are related to increased oxidative stress and apoptosis, and to enhanced AR and SRY expression. In male PTEC, DHT-induced protein changes are linked to a more glycolytic and oxidative phenotype, higher glucose consumption, oxidative stress, apoptosis, and IL-6/MCP1 secretion.

Alteration of Tryptophan-Kynurenine Metabolites in the Serum and Kidney in Diabetic Nephropathy

Shoko Matsushita,[1] Kazuo Takahashi,[1] Ryosuke Umeda,[1] Naotake Tsuboi,[1] Kazuki Nakajima,[1] Aya Yoshimura,[1] Kanako Kumamoto,[1] Masanori Kugita,[1] Hidetsugu Fujigaki,[1] Akihiro Mouri,[1] Yasuko Yamamoto,[1] Toshitaka Nabeshima,[1] Mitsutoshi Setou,[2] Shizuko Nagao,[1] Kuniaki Saito,[1] Yukio Yuzawa.[1] *[1]Fujita Health University, Toyoake, Japan; [2]Hamamatsu University School of Medicine, Hamamatsu, Japan.*

Background: It has recently been suggested that several metabolic pathways associated with diabetes interact to influence systemic metabolism, humoral response, and chronic inflammation, contributing to complications of diabetes. Tryptophan-kynurenine (TRP-KYN) metabolites play a vital role in several physiological and pathological conditions including diabetes. However, the contribution of TRP-KYN metabolites to the pathogenesis of diabetic nephropathy has not been established. Metabolomic data analysis was used to detect pathways of systemic interaction associated with the pathogenesis of diabetic nephropathy. We identified that TRP-KYN metabolism was one such pathway that contributed to the progression of diabetic nephropathy.

Methods: To identify TRP-KYN metabolites associated with diabetic nephropathy, we analyzed serum, urine, and tissue levels of TRP-KYN metabolites in an animal model of diabetic nephropathy using uni-nephrectomized spontaneously diabetic Torii fatty rats on 0.3% salt supplementation. Distributions of TRP-KYN metabolites in the kidney were analyzed using matrix-assisted laser desorption/ionization imaging mass spectrometry. Finally, we identified serum TRP-KYN metabolites in patients with diabetic nephropathy proved by renal biopsy.

Results: Profiling of TRP-KYN metabolites in an animal model of diabetic nephropathy revealed activation of the KYN pathway and accumulation of metabolites in kidney tissues. Changes in levels of TRP-KYN metabolites were also observed in patients with diabetic nephropathy. Additionally, the concentration of some metabolites was related to the severity of proteinuria, percentage of glomerular sclerosis, and grade of interstitial cellular infiltration.

Conclusions: Changes in the profile of TRP-KYN metabolites were observed both in animal models and humans with diabetic nephropathy. The concentrations of TRP-KYN metabolites may be associated with the progression of diabetic nephropathy.

Impact of Angiotensin Receptor Blockade on Metabolic Profiles in a Mouse Model of Diabetic Nephropathy

Kengo Azushima,[1,2] Jean-Paul Kovalik,[1] Jianhong Ching,[1] Susan B. Gurley,[3] Thomas M. Coffman.[1,4] *[1]Cardiovascular and Metabolic Disorders Program, Duke-NUS Medical School, Singapore, Singapore; [2]Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [3]Oregon Health and Science University, Portland, OR; [4]Duke University Medical Center, Durham, NC.*

Background: Changes in energy metabolism have been associated with susceptibility to diabetic nephropathy (DN). Blockade of the renin-angiotensin system (RAS) is renoprotective in DN, but effects of RAS inhibition on metabolic profiles in DN have not been clearly defined. To investigate this issue, we carried out metabolomics profiling in a mouse model of DN and tested the effects of RAS blockade on kidney metabolism.

Methods: We generated a mouse model of DN with underlying activation of the RAS by a renin transgene (ReninTg) driven by the albumin promoter on the *Akita* background of type I diabetes. We have shown that on a 129 strain background, *Akita-ReninTg* mice exhibit cardinal characteristics of human DN including high-grade albuminuria and glomerulosclerosis. 12-week old 129 *Akita-ReninTg* mice were treated with vehicle or the angiotensin receptor blocker (ARB) losartan for 12 weeks. Following treatment, kidneys were collected and metabolic profiles were determined by liquid chromatography-mass spectrometry.

Results: Before treatment, the 129 *Akita-ReninTg* mice had significant albuminuria (833±112 μg/day). Over the next 12 weeks, there was a progressive increase of albuminuria in the vehicle group that was prevented by ARB (1480±562 vs 193±42 μg/day; p=0.045). When compared to age-matched 129/SvEv parental controls, metabolomics profiles of kidneys from vehicle-treated 129 *Akita-ReninTg* mice showed significant reductions in levels of most amino acids, except for the branched-chain amino acids, while C3 and C5 acyl-carnitine levels were increased. ARB had no effect on these profiles. By contrast, most even-chain acyl-carnitine levels were substantially reduced in 129 *Akita-ReninTg* mice compared to parental controls and C2 acyl-carnitine level was increased toward normal with ARB.

Conclusions: There is a range of metabolic alterations in this DN model, suggesting multiple disruptions of metabolic pathways in the kidney. Reduced levels of even-chain acyl-carnitines in mice with DN suggest altered renal fuel metabolism and may reflect impaired fatty acid oxidation. The impact of RAS blockade on renal metabolic profiles was discrete, confined to a partial restoration of kidney C2 acyl-carnitine level, reflecting normalisation of renal fuel metabolism. These metabolic actions may contribute to the renoprotective effects of ARB.

Enarodustat, Hypoxia-Inducible Factor Stabilizer, Counteracts the Diabetic Renal Energy Metabolism Alterations Occurring in the Early Stages of Diabetic Kidney Disease

Sho Hasegawa,[1] Tetsuhiro Tanaka,[1] Tomoyuki Saito,[2] Kenji Fukui,[1,2] Takeshi Wakashima,[1,2] Masaomi Nangaku.[1] *[1]The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]JT Central Pharmaceutical Research Institute, Takatsuki, Japan.*

Background: Hypoxia-inducible factor stabilizers (HIF stabilizers) increase endogenous erythropoietin production and serve as novel therapeutic agents against anemia in chronic kidney disease. Although HIF induces the expression of various genes related to energy metabolism, the effects of HIF stabilizers on energy metabolism in renal tissue, especially in pathological conditions, remain obscure. Here, we analyzed the effects of enarodustat (JTZ-951; HIF stabilizer) on renal energy metabolism in streptozotocin (STZ)-induced diabetic rat model.

Methods: We divided the rats into three groups; group A (Sham), B (DKD) and C (DKD+enarodustat). First, vehicle (n = 5; group A) or 65 mg/kg of STZ (n = 19) were intravenously administered into rats 7 days before grouping. We selected the rats for group B and C (n = 7, for each group) by matching blood glucose and body weight of STZ-induced diabetic rats. Group A and B were given normal feed, while group C was given the feed mixed with 0.01% (w/w) of enarodustat. Kidney samples were collected 14 days after grouping. We conducted the transcriptome and metabolome analysis of these rats' renal cortical tissue.

Results: Transcriptome analysis of renal cortex revealed that fatty acid and amino acid metabolism were upregulated by diabetes and downregulated by enarodustat, while glucose metabolism was upregulated by enarodustat, showing that enarodustat reversed the renal metabolic alterations induced by diabetes. Metabolome data indicated accumulation of glucose and tricarboxylic acid (TCA) cycle metabolites and a reduction of amino acid concentration in diabetic renal cortex, while these metabolic alterations were mitigated by enarodustat. Moreover, enarodustat alleviated the accumulation of glutathione disulfide (GSSG) observed in diabetic kidney, indicating that enarodustat relieves the oxidative stress in diabetic kidney.

Conclusions: Enarodustat, HIF stabilizer, counteracts the diabetic renal energy metabolism alterations occurring in the early stages of diabetic kidney disease. Our study suggests that HIF stabilization may serve as a potential intervention targeting dysregulated energy metabolism of diabetic kidneys.

Selection of Suitable Housekeeping Genes for Mesangial Cell Studies with High Glucose and Angiotensin II Receptor Blocker

Nicole D. Hosni, Ana C. Anauate, Mirian A. Boim. *Nephrology Division, Universidade Federal de São Paulo, São Paulo, Brazil.*

Background: Real-time PCR (qPCR) is currently the gold standard method to gene expression studies. Identification of the best reference gene is a key point to perform high quality qPCR, being able to provide strong support for results, as well as acting as a source of bias when inappropriately chosen. Mesangial cells (MC), as an essential cell line in diabetic kidney disease (DKD) physiopathology, demand accurate analysis of the most excellent housekeeping (HK) gene to enhance validity of gene expression studies, especially regarding high glucose (HG) and DKD treatments, being angiotensin II receptor blockers (ex. Losartan) the most commonly used. Our objective was to evaluate the suitability and define the most stable reference gene for MC studies of an *in vitro* DKD model of disease and its treatment.

Methods: Five software packages (RefFinder, NormFinder, GeNorm, Bestkeeper, and DataAssist) and the comparative ΔCt method were adopted to analyze six different candidate genes: *HPRT, ACTB, PGAM-1, GAPDH, PP1A,* and *B2M*. RNA was extracted and cDNA was synthesized from immortalized mouse MC cultured in 4 groups: control (n=5; 5mM glucose), mannitol (n=5; 30mM, as osmotic control), HG (n=5; 30mM glucose), and HG+losartan (n=5; 30mM glucose and 10-4 mM of losartan). qPCR was performed according to MIQE guidelines in QuantStudio 7Flex (Applied Biosystems).

Results: *HPRT* presented higher stability values in RefFinder, ΔCt method, and NormFinder softwares (Table 1), while frequently used HK such as *GAPDH* and *ACTB* (Biederman et al. 2004) showed lower scores compared to *HPRT*.

Conclusions: This analysis provides support to the use of *HPRT* as a HK gene in mouse mesangial cell studies of gene expression via qPCR technique.

A Comprehensive Bioinformatics Analysis Reveals the Pivotal Role of Tubulopathy in Diabetic Nephropathy

Leting Zhou, Xiaobin Liu, Zhijian Zhang, Xiran Zhang, Jing Xue, Bin Liu, Liang Wang, Zhuxing Sun. *Wuxi People's Hospital affiliated to Nanjing Medical University, Wuxi, China*.

Background: Diabetic nephropathy(DN) is one of the main causes of ESKD worldwide. However, there is still a lack of a comprehensive understanding of the unique molecular mechanism of DN.

Methods: Over 250 Affymetrix microarray datasets of human glomerular and tubulointerstitial tissues were collected (Table 1). Next, a linear model was constructed, and the empirical Bayes method was used to select the unique differentially expressed genes (DEGs) of DN. The DEGs were further analyzed using the enrichment analysis. Finally, the protein-protein interaction networks(PINs) with established physical interaction were constructed, and based on the networks, hub genes were selected.

Results: A total of 980 unique DEGs were identified. Enrichment analysis revealed that a wide arrange of pathways are dysregulated in the pathogenesis of DN. Notably, the upregulated DEGs of tubulointerstitial compartment are mainly enriched in pathways related to glycosylation and immune responses, while the downregulated DEGs are strongly related to metabolism disorders(Figure 1). Moreover, a complex interaction network were found among the DEGs of tubulointerstitial compartment. Lastly, a list of genes, including EGFR, SUZ12 and TERF1, were identified as hub genes.

Conclusions: This bioinformatic analysis suggests that tubulopathy might play a pivotal role in the pathogenesis of DN.

Small RNA Sequencing Identifies Circulating sncRNAs That Are Differentially Expressed in Type 1 Diabetic Patients at Risk of Progressive Renal Decline

Marcus G. Pezzolesi,[1] Eiichiro Satake,[2] Mitsuo Kato,[3] Jose M. Lazaro guevara,[1] Markus Bitzer,[4] Rama Natarajan,[5] Andrzej S. Krolewski.[2] *[1]University of Utah, Salt Lake City, UT; [2]Joslin Diabetes Center, Boston, MA; [3]City of Hope, Duarte, CA; [4]University of Michigan, Ann Arbor, MI; [5]Beckman Research Institute of City of Hope, Duarte, CA.*

Background: Progressive renal decline is the fundamental disease process that underlies the development of end-stage renal disease (ESRD) in Type 1 diabetes (T1D). Work by our group and others has demonstrated that microRNA (miRNA) expression profiles are altered in T1D patients with diabetic nephropathy. In the present study, we used small RNA sequencing (sRNA-Seq) to identify circulating small non-coding RNAs (sncRNAs), non-coding regulatory RNAs typically 18-200 nucleotides in length, that are associated with progressive renal decline in T1D patients with normal renal function (eGFR>60 ml/min per 1.73m^2) from the Joslin Kidney Study (JKS).

Methods: sRNA-Seq was used to determine circulating sncRNA expression profiles in baseline plasma specimens obtained from two sub-groups of patients who were followed for 5-10 years from entry to the JKS: 76 rapid progressors, who experienced significant loss of renal function over the course of their follow-up (eGFR slope=-12.61 ml/min/1.73m^2/year), and 70 non-progressors, who experienced minimal decline in eGFR during their follow-up (eGFR slope=-1.43 ml/min/1.73m^2/year).

Results: Differential expression analysis identified more than 50 sncRNAs, including miRNAs, small nucleolar RNAs (snoRNAs), and small nuclear RNAs (snRNAs), that were significantly differentially expressed among rapid progressors and non-progressors, including miR-3168 (P = 8.7x10^{-7}), SNORD36C (P = 1.1x10^{-6}), and SNORD30 (P = 3.7x10^{-6}). Interestingly, we also found miR-3168 to be differentially expressed in an independent cohort of non-progressors and rapid progressors with impaired renal function from the JKS (P-value = 0.0006).

Conclusions: These data suggest that sncRNAs, including miR-3168, SNORD36C, and SNORD30, may be able to distinguish diabetic individuals who are at the greatest risk of losing renal function from those who are protected against these complications. The differentially expressed sncRNAs identified in this study represent novel therapeutic targets that may prove useful in inhibiting renal function decline in T1D.

A Novel Deep Learning Model Outperforms Cox Regression Model to Predict Renal and Cardiovascular Risk in Patients with Diabetic Kidney Disease

Sunil Belur nagaraj,[1] Michelle Pena,[1] Habib Hamidi,[2] Wenjun Ju,[2] Hiddo J. L Heerspink.[1] BEAt-DKD consortium *[1]Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; [2]University of Michigan, Ann Arbor, MI.*

Background: Predicting long-term risk in patients with type 2 diabetes and chronic kidney disease is important in clinical practice. We hypothesize that by using short-term dynamic changes in clinical characteristics, deep learning algorithm can accurately predict long-term renal and cardiovascular risk.

Methods: In total 3228 patients with type 2 diabetes and chronic kidney disease from two randomized controlled trials were used in this study: RENAAL (= 1513), IDNT (= 1715). We used a 2D convolutional neural network (CNN) to predict renal (doubling of serum creatinine and/or end-stage renal disease) and cardiovascular (CV; myocardial infarction, stroke and cardiovascular death) outcomes. We compared the prediction performance with a traditional Cox proportional hazard regression (Cox) model. Eighteen clinical characteristics from baseline until 6 months follow-up were used as predictors to train the model on RENAAL data. The model was then externally validated on the IDNT trial. The area under the receiver operator curve (AUC) was used to assess the performance of the CNN and Cox model in the IDNT trial.

Results: A total of 462 (27%) and 518 (30%) of patients in IDNT experienced a renal or CV outcome respectively during a median follow-up of 2.6 years. The AUC of the CNN model, including UACR, HbA1c, SBP, albumin and uric acid as important predictors, was significantly higher compared to the Cox regression model (figure) and obtained the state-of-the-art performance to predict the long-term renal and CV outcomes.

Conclusions: Using 6-month short-term dynamic changes in clinical characteristics, a deep learning algorithm identifies patterns to accurately predict long-term renal and CV risk. The proposed method offers the potential to create accurate and automated risk predictions models to identify high-risk patients who could benefit from intensified therapy.

The p21-Mediated and Senescence-Associated Hyperglycemic Memory in Diabetic Nephropathy Is Therapeutically Amendable

Shrey Kohli,[1,2] Moh'd Mohanad A. Al-Dabet,[1,2] Ahmed Elwakiel,[1,2] Ihsan K. Gadi,[5] Alba Sulaj,[3] Chris Dockendorff,[4] Peter R. Mertens,[5] Berend H. Isermann.[1,2] *[1]Institute of Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke University Magdeburg, Magdeburg, Germany; [2]Institute for Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, Leipzig University, Leipzig, Germany; [3]University Hospital Heidelberg, Heidelberg, Germany; [4]Marquette University, Milwaukee, WI; [5]Department of Nephrology, Hypertension, Diabetes and Endocrinology, Otto-von-Guericke-University, Magdeburg, Germany.*

Background: Diabetic nephropathy (DN) is a major cause of end-stage renal disease. A major challenge in DN is the failure of renal recovery upon improved blood glucose levels. The mechanisms underlying this phenomenon, known as the metabolic memory, remain unknown. We aimed to identify mechanisms contributing to the metabolic memory in DN.

Methods: Two mouse models with established DN (16 weeks after STZ-induced persistent hyperglycemia or 16 weeks old db/db mice) were used. Blood glucose was normalized for 6 weeks using an SGLT2-inhibitor. An unbiased approach (mRNA-seq) was used to evaluate pathways involved in metabolic memory. Candidate genes were studied in human diabetic patients and mice after lowering blood glucose. In vitro and in vivo studies were conducted to determine mechanistic and translational relevance.

Results: Despite a marked reduction of blood glucose levels, albuminuria and glucose induced changes in renal gene expression persisted, enabling to study mechanisms contributing to metabolic memory. PI3-kinase-Akt signaling, cellular proliferation and senescence, and complement-coagulation cascades were linked with metabolic memory. Sustained tubular expression of p21 – a senescence-associated cyclin-dependent kinase inhibitor –was confirmed in humans (histology, urinary p21) and mice (histology, RNA, protein) despite blood glucose lowering. Sustained p21 expression was linked with promoter demethylation and reduced DNMT activity and DNMT1 expression. In silico and in vitro analyses identified miR-148a as a potential regulator of DNMT1. The nephroprotective zymogen protein C was among the genes persistently repressed in DN. Increased tubular senescence, interstitial fibrosis, and albuminuria was confirmed in diabetic mice with a superimposed genetic deficiency of protein C activation. Substituting the protease activated protein C (aPC), mimicking biased aPC-signaling (parmodulin-2), or reducing miR-148a in addition to normalizing blood glucose reversed sustained tubular p21 expression, senescence, and renal damage in DN.

Conclusions: Epigenetically sustained p21-expression and associated senescence contribute to the metabolic memory in DN. This pathogenic mechanism can be targeted by inhibiting miR-148a or by mimicking cytoprotective aPC-signaling.

Inhibition of Yap/Taz Ameliorates Renal Fibrosis in Type 2 Diabetic Mice

Yu Wang, Li Wang, Wenbin Shang, Chunhua Xu, Yin Xia, Yu Huang. *The Chinese University of Hong Kong, Hong Kong, China.*

Background: Yap/Taz are central mediators of the Hippo pathway, which have been found to be involved in the pathogenesis of chronic kidney disease including diabetic nephropathy. The expression of Yap increases in both the kidney of diabetic mice and the renal proximal tubule epithelial cells in response to high glucose. However, the underlying mechanism of Yap/Taz in renal fibrosis remains largely unknown.

Methods: The HK2 cell line (human proximal renal tubular epithelial cells) were challenged by advanced glycation end-products (AGEs) for 48 hours. Cells were harvested for RT-PCR. Diabetic mice (*db/db*) and their control counterparts (*db/+*) were gavaged with atorvastatin (10 mg/kg/day for 2 months). Urine was collected by metabolic cages. At sacrifice, kidneys were harvested for Periodic Acid-Schiff staining, Masson's trichrome staining, and immunostaining. Expression of target proteins and genes were analyzed by Western blot and RT-PCR.

Results: In the present study, we found that the elevated expression of Yap/Taz target genes (CTGF and CYR61), COL1A1 and FN in HK2 cells after exposure to AGEs for 48 hours. Besides, the expression of Yap increased in the kidney of *db/db* mice. By contrast, oral treatment of *db/db* mice with atorvastatin (10 mg/kg/daily), a lipid-lowering drug with newly identified YAP inhibitory property, ameliorated albuminuria, glomerular hypertrophy, and renal fibrosis in diabetes. Atorvastatin suppressed the activity of YAP and TAZ as well as the expression of collagen 1, fibronectin, α-SMA and vimentin in the kidney of *db/db* mice.

Conclusions: In summary, atorvastatin is effective in ameliorating renal fibrosis probably in part through suppressing the activity of Yap in type 2 diabetic mice.

TH-PO895

The GPR120 Agonist TUG-891 Ameliorates Fibrosis in Diabetic Nephropathy

Tiantian Wei,[1] Liang Ma,[2] Ping Fu.[1] *[1]West China Hospital, Sichuan University, Chengdu, Sichuan, China; [2]Kidney Research Institute, Division of Nephrology, West China Hospital of Sichuan Univeristy, Chengdu, China.*

Background: GPR120/FFAR4 is a member of the G protein-coupled receptors that is activated by Omega-3 fatty acids. Recent studies demonstrate that GPR120 inhibits inflammation, regulates lipid and glucose metabolism, which mediates potent insulin sensitizing and anti-diabetic effects. TUG-891 is an a potent and selective agonist for GPR120. In this study, we examined the protective effects of GPR120 agonist TUG-891 in diabetic nephropathy (DN) and investigated the possible mechanisms.

Methods: The expression of GPR120 was detected in human renal biopsy tissue obtained from 18 patients with early or advanced DN and in normal renal tissues from patients with renal-cell carcinoma. Effects of TUG-891 on development of DN was investigated in male C57BLKS/J db/db mice and podocytes. TUG891 was administered by oral gavage at 35 mg/kg body weight once every 24 h in db/db mice for 4 weeks. Murine podocytes (MPC5) were cultured in high glucose (30mmol/L) and with TUG-891 (10umol/L). Collagen type 4, fibronectin, αSMA and TGF-β/smad2/3 were examined in vivo and in vitro. Furthermore, GPR120/β-arrestin2/TAK1 binding protein-1 pathway was measured.

Results: Decrease levels of GPR120 were detected in renal tissues from patients with DN. The intensity of GPR120 staining was negatively correlated with the progression of the disease. In db/db mice, administration of GPR120 agonist, TUG-891, attenuated urinary albumin excretion and delay the extent of glomerulosclerosis and tubulointerstitial fibrosis. Renal fibronectin, collagen type 4 and TGF-β/smad2/3 expressions were reduced by TUG-891. Nevertheless, GPR120 and β-arrestin2 expression were increased after TUG-891 treatment. The coexpression of GPR120 and nephrin were detected in kidney. In high-glucose-treated murine podocytes (MPC5), TUG-891 decreased the subsequent expression of collagen type 4, fibronectin, αSMA and TGF-β/smad2/3. It upregulated expression of GPR120 and β-arrestin2, suppressed the downstream TAK1/IKK/JNK/NF-κB signaling pathway of TAK1 binding protein-1, thus restored podocytes dysfunction.

Conclusions: Our results show that TUG-891 ameliorates kidney fibrosis and podocyte injury by activating the intracellular GPR120/β-arrestin2/TAK1 binding protein-1 pathway, which suggests its efficacy for treating type 2 diabetes associated DN.

TH-PO896

Angptl4 Is a Critical Mesenchymal Inducer That Contributes to Renal Fibrosis

Swayam P. Srivastava, Julie Goodwin. *Yale University School of Medicine, New Haven, CT.*

Background: Kidney fibrosis is characterized by excess deposition of extracellular matrix leading to renal function deterioration and kidney injury. Several angiopoietin-like proteins (ANGPTLs) regulate lipid metabolism in the kidneys. However, the role of angiopoietin-like 4 (ANGPTL4) protein has not been explored yet. We hypothesized that loss of ANGPTL4 would be protective against renal fibrosis.

Methods: Two mouse models were used to recapitulate renal fibrosis. In one model, a single dose of streptozotocin (STZ) was used to induce diabetes and diabetic nephropathy in global Angptl4 knockout mice (ANGPTL4 KO) and wild-type littermates; mice were monitored for 4 months post-STZ. In the second model, the surgical procedure of unilateral ureteral obstruction (UUO) was used to induce renal fibrosis in 10-week old global ANGPTL4 KO mice and wild-type littermates. Interstitial fibrosis was analyzed by histological analysis of Trichrome, Sirius red and Periodic-Acid–Schiff staining in the kidneys. Immunofluorescent staining of kidney tissue for mesenchymal markers was also performed. Blood glucose, kidney weight, and severity of proteinuria as measured by albumin-to-creatinine ratios were measured in animals subjected to both models. One way Anova with Tukey's post-test was performed for the analysis of statistical significance.

Results: At the time of sacrifice, diabetic global ANGPTL4 KO mice did not shown any significant difference in blood glucose compared to controls. However, kidney weight (-14.5%), collagen deposition (-55.4%), and albumin-to-creatinine ratios (-59.2%) were significantly lower in global ANGPTL4 KO mice when compared to wild-type controls (n=6/gentoype; $p<0.05$). Similarly, in the UUO model, we observed that the UUO-operated kidneys of global ANGPTL4 KO mice showed less collagen deposition (-48.9%) and interstitial fibrosis (-45.2%) when compared to those of the controls (n=7/genotype, $p<0.05$). Immunofluorescence analysis of kidney tissue from both genotypes revealed suppression of fibronectin and collagen-1 deposition in global ANGPTL4 KO mice compared to controls, in both models, suggesting suppression of mesenchymal activation.

Conclusions: We conclude that ANGPTL4-associated mesenchymal activation is critical for disruption of kidney homeostasis and contributes to renal fibrosis.

TH-PO897

Proteasomal Activation and the p38 and ERK Pathways Promote Loss of NF-E2 Expression and Induction of Pro-Fibrotic Signaling in TGF-b Treated Tubule Cells

Madhavi J. Rane. *University of Louisville, Louisville, KY.*

Background: TGF-β is a critical mediator of diabetes-induced renal fibrosis. Preliminary studies found TGF-β (10 ng/ml; 24 h) treatment of human renal proximal tubule (HK-11) cells decreased Nuclear Factor-Erythroid derived 2 (NF-E2) protein

expression and increased pro-fibrotic signaling in the kidney. Current studies identified signaling mechanisms by which TGF-β/diabetes regulates NF-E2 expression and renal fibrosis which may lead to generation of new therapies.

Methods: HK-11 cells were treated with 10 ng/ml of TGF-b for 24 h or pre-treated with p38 and MEK/ERK MAPK inhibitors namely, (0.3 μM) SB203580 and (25 μM) PD98059, or proteasome inhibitor MG132 (0.125 μM, 0.25 μM, 0.5 μM and 1 μM), for an hour prior to treatment with TGF-b. Cell lysates were immunoblotted with appropriate antibodies. HK-11 cells were transfected with pUSe vector/pUse-NF-E2 or with control siRNA or NF-E2 siRNA for 24 h followed by treatment with vehicle/TGF-b for additional 24 h. Cell lysates were immunoblotted with appropriate antibodies. Kidney homogenates from STZ-type 1 diabetic mice, OVE26 type 1 diabetic mice treated with vehicle/MG132, and db/db type 2 diabetic mice, were immunoblotted with appropriate antibodies.

Results: NF-E2 expression was decreased in kidney homogenates from STZ, OVE26, and db/db mice. Moreover, TGF-β (10 ng/ml; 24 h) treatment of human renal proximal tubule (HK-11) cells decreased NF-E2 expression and increased p38 and ERK activation and expression of pro-fibrotic proteins including, CTGF, FN and PAI-1. Over-expression of NF-E2 inhibited CTGF, FN, and PAI-1 expression in TGF-b treated HK-11 cells. Silencing NF-E2 expression induced CTGF expression. TGF-β treatment did not have any effect on NF-E2 transcription or on miRNA-361-5p in HK-11 cells. However, blockade of proteasome, in HK-11 cells and OVE26 mice preserved NF-E2 expression and inhibited pro-fibrotic signaling. Moreover, dual blockade of p38 and MEK/ERK prevented NF-E2 degradation and pro-fibrotic signaling.

Conclusions: Blocakade of p38 and MEK/ERK pathways and proteasomal activation during diabetes and TGF-b treatment of HK-11 cells prevents NF-E2 degradation and attenuates pro-fibrotic signaling in kidney cells.

Activated Alpha 2-Macroglobulin (α2M*) Mediates High Glucose-Induced Cell Surface GRP78 Activation and Profibrotic Responses in Mesangial Cells

Jackie Trink,[1,3] Renzhong Li,[1] Daniel Biltoft,[4] Yaseelan Palarasah,[4] Richard Van krieken,[1] Bo Gao,[3] Joan C. Krepinsky.[2] *[1]McMaster University, Hamilton, ON, Canada; [2]McMaster University, St. Joseph's Hospital, Hamilton, ON, Canada; [3]Nephrology, St. Joseph's Hospital, Hamilton, ON, Canada; [4]University of Southern Denmark, Esbjerg, Denmark.*

Background: Diabetic nephropathy is the leading cause of kidney failure in developed countries, characterized by glomerular accumulation of extracellular matrix proteins. High glucose (HG) induction of glomerular mesangial cell (MC) profibrotic responses plays a central role in its pathogenesis. We recently showed that the endoplasmic reticulum resident protein GRP78 translocates to the cell surface in response to HG to mediate Akt activation and profibrotic responses in MC. We also identified mesangial cell surface GRP78 (csGRP78) *in vivo* in diabetic mice. How csGRP78 is activated by HG, however, is unknown. The general protease inhibitor α2M, upon binding and activation by a protease, is known to interact with csGRP78 in cancer cells to elicit prosurvival signaling. Importantly, α2M was shown to be increased in diabetic patients' serum and saliva. We thus investigated its role in HG profibrotic responses in MC.

Methods: Primary rat and mouse MC were treated with HG (30mM) or the osmotic control mannitol and responses assessed using standard molecular biology techniques. Kidneys from type 1 diabetic Akita mice were stained for α2M and the activated α2M*.

Results: HG, but not mannitol, increased α2M mRNA and protein expression as well as media secretion by 24h. Significantly more α2M* was also seen in media after HG treatment. By immunohistochemistry, both native α2M and activated α2M* were increased in glomeruli and tubules of type 1 diabetic Akita kidneys, with expression increasing to 40 weeks of age. By immunofluorescence, glomerular α2M* was localized to the mesangium, identified by α8 integrin positivity. Knockdown of α2M prevented HG-induced Akt activation and upregulation of the matrix proteins collagen IV and fibronectin. Neutralization of α2M* using an antibody specific for the activated form prevented HG-induced matrix protein upregulation.

Conclusions: Production and activation of α2M is increased by HG in MC and in diabetic kidneys, and mediates HG-induced matrix upregulation. Future studies will determine whether inhibiting α2M* interaction with csGRP78 is an effective therapeutic target for the treatment of diabetic nephropathy.

Ketogenic Diet as a Protective Tool Against Progression to Diabetic Nephropathy in db/db Mice

Woo Yeong Park,[1,2] Yaerim Kim,[1,2] Jin hyuk Paek,[1,2] Sung Bae Park,[1,2] Seungyeup Han,[1,2] Kyubok Jin.[1,2] *[1]Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: The prevalence of diabetic nephropathy (DN) is increasing rapidly worldwide. A recent research reported that a ketogenic diet (KD) may reverse pathological processes, but the mechanism is uncertain. The purpose of this study was to investigate the efficacy and mechanism of KD against progression of DN in db/db mice.

Methods: *In vivo* experiment, 5-week-old C57 BLKS/J lar-Lepr^{db}/Lepr^{db} mice (n=27) were divided into the three groups as follows: normal chow diet group (n=7), high fat diet group (n=9), and KD group (n=11). We measured the random glucose until ≥ 250 mg/dL until 7 weeks, and fasting glucose and body weight weekly after that. At 12 weeks, we analyzed urine albumin to creatinine ratio after collecting urine during 24 hours. At 16 weeks, we measured energy expenditure of mice using metabolic cage. We sacrificed mice at 18 weeks, and checked histological change, reactive oxygen species (ROS), and autophagy analysis. *In vitro* experiment, we evaluated ROS production in HK-2 cells, which are renal proximal tubule cells, with low and high glucose media with 3-beta hydroxybutyrate at 24 hours. We also analyzed autophagic flux activation in HK-2 cells for the evaluation of mechanism.

Results: Body weights were significantly lower in the KD group compared with other groups, but there was no significant difference in the fasting blood glucose level among three groups. Urinary albumin/creatinine ratio was significantly lower in the KD group compared with other groups. Serum BUN and creatinine were significantly lower in the KD group compared with other groups. Histology and quantitative analysis showed KD delayed the progression in view of less thickened glomerular basement membrane and smaller mesangial area. KD showed an antioxidant effect in DCF-DA+DAPI staining and ROS level, and increased autophagy via the change of p62, Nrf2, and LC3 expressions *in vivo* study. *In vitro* mechanistic study showed 3-beta hydroxybutyrate inhibited oxidative stress by decreased ROS level, and stimulated autophagy by increasing LC3 and Nrf2 in HK-2 cells. Finally, we validated the effect of KD by *in vivo* and *in vitro* studies.

Conclusions: This study showed that ketogenic diet might delay the progression of diabetic nephropathy by augmentation of autophagy and inhibition of oxidative stress and inflammation through *in vivo* and *in vitro* studies.

TH-PO900

QiDiTangShen Granules Activated Renal Autophagy by Regulating Nutrient-Sensing Signal Pathways in db/db Mice

Xiangming Wang,[1] Li Zhao,[1,2] Amrendra K. Ajay.[2] *[1]Renal Division, Dongzhimen Hospital affiliated to Beijing University of Chinese Medicine, Peking, China; [2]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Proteinuria is an independent risk factor for diabetic nephropathy (DN). QiDiTangShen granules(QDTS) have been proven to reduce the proteinuria in patients with DN effectively. The present study was aimed at investigating the renoprotective mechanism of QDTS granules.

Methods: Firstly, main components of QDTS were identified by ultra-high liquid chromatography-tandem mass spectrometry and pharmacological databases, among which active components were screened by oral bioavailability and drug-likeness. The role on autophagy-related nutrient-sensing signal molecules was retrieved and analyzed through the Pubmed database. Secondly, C57BL/6J mice as normal control, db/db mice were randomly divided into three groups (model control, Valsartan and QDTS), and given intragastric administration for 12 weeks. Effectiveness and safety indicators, such as fasting and random blood glucose, urinary albumin excretion (UAE) and injury markers of liver and kidney were tested by glucose oxidase and radioimmunoassay, enzyme-linked immunosorbent assay and biochemical methods, respectively. Renal histological changes were evaluated by H&E, methenamine silver and Masson's trichrome staining. The quality and quantity of mitochondria and autophagic vesicles was observed by transmission electron microscope. Expressions of proteins related to nutrient-sensing signals and autophagy were assessed by western blot and immunofluorescence.

Results: 13 active components were screened from 78 components identified. Over half the components had already been reported to improve nutrient–sensing signals (AMPK, SIRT1 and mTOR). Compared with the model group, QDTS reduced UAE independent of blood glucose control, ameliorated renal mesangial hyperplasia and deposition of collagen fiber, improved the quality of mitochondria and the quantity of autophagic vesicles of renal tubular cells in db/db mice. The expression of Atg14, Beclin1and LC3-II were up-regulated, autophagic substrate transporter p62 was down-regulated in QDTS group. The expression of SIRT1, the proportion of both p-AMPK (thr172) / AMPK (total) and p-mTOR (ser2448) / mTOR (total) were also regulated by QDTS.

Conclusions: QDTS granules may regulate the nutrient-sensing signaling pathways to improve the renal autophagic activity and exert renoprotective effect.

Comparison Study of Calorie-Matched High-Fat and High-Sugar Diets on Renal Injury with Lysosomal Dysfunction in Pre-Diabetic Mice

Aya Yoshimura,[1] Tamio Yamaguchi,[2] Masanori Kugita,[1] Kanako Kumamoto,[1] Kazuya Shiogama,[3] Shizuko Nagao.[1] Education and Research Center of Animal Models for Human Diseases *[1]Education and Research Center of Animal Models for Human Diseases, Fujita Health University, Toyoake, Aichi, Japan; [2]Department of Clinical Nutrition, Faculty of Health Science, Suzuka University of Medical Science, Suzuka, Mie, Japan; [3]Division of Morphology and Cell Function, Faculty of Medical Technology, School of Health Sciences, Fujita Health University, Toyoake, Japan.*

Background: High fat and high sugar intakes are risk factors for diabetic nephropathy. However, no comparison study with calorie matched high fat and high sugar diets has been performed. In the present study, a high fat low carbohydrate (HFLC) diet and a normal fat high sugar (NFHS) diet, calorie/weight matched to the AIN93M standard rodent diet, were given to low dose streptozotocin (STZ) injected mice. Equal amounts of feed were given to determine whether HFLC or NFHS induce renal injury in the pre-diabetic stage.

Methods: CD1 male mice were randomly allocated to three pair-feeding groups from 7 to 20 weeks of age. The energy of all diets was 380 kilocalorie/100g. CONT: AIN93M diet with 10% (wt/wt) sucrose, 46.6% cornstarch, 15.5% alpha-cornstarch, 4% soybean oil; HFLC: diet with 31.1% alpha-cornstarch, 22% lard; NFHS: diet with 40.9% sucrose,

15.6% cornstarch, 15.5% alpha-cornstarch, 4% soybean oil. All other dietary ingredients were the same between diets. STZ (100mg/kg body wt) was injected at 17 and 18 weeks of age. Fasting blood glucose (FBG) was measured before and after STZ injection. After termination, kidneys were obtained for histology.

Results: Terminal body weight, total intake of food and energy, and serum creatinine level were not different between all groups. FBG was higher in HFLC but not in NFHS compared with CONT mice both before (at 17 weeks of age) and after STZ injection (at 20weeks of age). In kidney, the number of LAMP1 (lysosome-associated membrane protein 1)-positive vacuoles was significantly higher in HFLC compared with CONT and NFHS mice.

Conclusions: The present results suggest that the high fat diet, but not the high sugar diet, induces renal injury with impaired lysosome-mediated autophagic degradation, when total energy intake is identical in pre-diabetic mice.

Targeting the Gut-Kidney Axis Through Dietary Modification in Diabetic Nephropathy

Yan J. Li,[1,2] Xiaochen Chen,[1] Yik W. Loh,[1] Jian Tan,[3] Laurence Macia,[3] Steven J. Chadban,[1,2] Huiling Wu.[1,2] *[1]Kidney Node, Charles Perkins Centre, University of Sydney, Sydney, NSW, Australia; [2]Renal Medicine, Royal Prince Alfred Hospital, Sydney, NSW, Australia; [3]Nutritional Immuno-metabolism Laboratory, University of Sydney, Sydney, NSW, Australia.*

Background: Dietary fibre has been associated with decreased inflammation and mortality in CKD, with short-chain fatty acids (SCFA) derived from gut microbial fermentation of fibre proposed to mediate this effect. Here we explored the impact of dietary fibre content on the development of experimental diabetic nephropathy (DN).

Methods: Diabetes was induced using streptozotocin (STZ) in wild-type (WT) B6 and GPR43-/- mice. Diabetic mice were randomized to 4 diets; resistant starch (RS), high fibre (HF), zero fibre (ZF), control diet (NF), or supplemented with oral SCFAs (acetate 150mM, proprionate 100mM, butyrate 50mM). Gut microbiota composition was assessed by 16S rRNA sequencing of faecal DNA.

Results: All STZ treated mice developed diabetes and remained similarly hyperglycaemic. HF and RS fed mice were protected from DN, with reduced albuminuria ($p<0.01$), glomerular hypertrophy ($p<0.0001$), interstitial fibrosis ($p<0.0001$) and podocyte injury ($p<0.05$) at 12 weeks compared to those on NF and ZF. Diet markedly altered gut microbial composition by weighted UniFrac, with cluster separation of diabetic mice according to diet (ANOSIM p=0.0001, R=0.93). HF and RS feeding increased relative abundance of phylum *Bacteroidetes* at the expense of *Firmicutes* and expanded the SCFA producing *Prevotella* ($p<0.001$) and *Bifidobacterium* ($p<0.001$) genera compared to controls. This change in microbial ecology correlated with a significant increase in faecal SCFAs and serum acetate. Supplementation with SCFAs in diabetic mice achieved similar degrees of protection from albuminuria and histological injury. Acetate reduced expression of pro-inflammatory cytokine (IL6, IFNγ), chemokine (CCL2, CXCL10) and fibrosis (fibronectin, TGFβ1) genes in diabetic kidneys compared to controls ($p<0.05$). Diabetic mice deficient in GPR43, a receptor for SCFAs, were unresponsive to acetate supplements with no reduction in albuminuria compared to WT diabetic mice at 12 weeks.

Conclusions: Dietary fibre protects against DN through modulation of the gut microbiota, enrichment of SCFA producing bacteria and increased SCFA production. Similar protection achieved by SCFA supplement and absence of protection in GPR43-/- mice identify SCFAs as likely mediators of this effect. Dietary interventions targeting the gut microbiota warrant further investigation as a novel reno-protective therapy in DN.

TH-PO903

Effects of Esculin Treatment on $P2X_7$ Receptor and Klotho in Experimental Diabetic Nephropathy

Robson S. Serralha,[2] Adelson Rodrigues,[3] Inri Rodrigues,[4] Angela Bertolini,[4] Deyse Lima,[3] Moises Nascimento,[4] Margaret G. Mouro,[3] Manoel Silva,[4] Giovana Punaro,[3] Elisa M. Higa.[1] Laboratory of Nitric Oxide and Oxidative Stress *[1]Medicine Department/Unifesp, Sao Paulo, Brazil; [2]Universidade Federal de São Paulo, Sao Paulo, Brazil; [3]UNIFESP, Sao Paulo, Brazil; [4]Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: $P2X_7$ is a purinergic receptor which is activated under high concentrations of extracellular ATP, a common situation seen in *diabetes mellitus*, induced by the hyperglycemia. This receptor promotes calcium influx, which in large quantities activates biochemical processes culminating in programmed cell death. Constant activation of $P2X_7$ induces inflammatory responses and oxidative stress. A previous study in our Laboratory showed a correlation between $P2X_7$ and Klotho, since the latter can control phosphate metabolism. Coumarin derivates, as esculin, reduces oxidative damage seen in intestinal inflammation, arthritis and cognitive impairment related to diabetes. However, their pharmacodynamics are not yet fully understood. Thus, we aimed to evaluate the effects of esculin treatment on $P2X_7$ receptor expression and Klotho in the kidneys of diabetic rats.

Methods: Male Wistar rats, 7 weeks old, received a single dose of streptozotocin (60 mg/kg; i.v.) for diabetes induction; control received only the drug vehicle. Diabetes was considered at blood glucose levels greater than 200 mg/dL. The animals received daily doses of esculin (50 mg/kg, p.o.), during 8 weeks, forming CTL+ESC and DM+ESC groups. 24-hours urine and a small aliquot of blood were collected for biochemical analysis and the rats were euthanized at the end of the protocol. The kidneys were collected for Western blotting. Statistical analysis was performed in GraphPad Prism 6 and the results are described as mean ± SEM; significance for $p<0.05$.

Results: The diabetic rats presented 50% increase in $P2X_7$ protein content when compared to CTL. DM group treated with ESC had a 46% decrease in $P2X_7$. Klotho levels increased after ESC. We previously showed that Klotho, depleting phosphate, reduced $P2X_7$ and protected the rats against diabetic nephropathy. Furthermore, DM treated with ESC also presented lower proteinuria (38.72±4.82 vs 45.42±3.0) and urinary TBARS (indicative of lipoperoxidation) (232.3±28.83 vs 282.0±7.2) when compared with untreated ones.

Conclusions: Our data suggest that decreased $P2X_7$ perhaps via increasing Klotho, could be one of possible pathways for esculin to promote beneficial effects on the kidneys of diabetic animals.

TH-PO904

The Effect of A1AR on Diabetic Megalin Loss-Associated Albuminuria by Inhibiting Caspase-1/IL18 Signaling

Dongli Tian, Xiaoxiao Shi, Linfeng Zou, Yubing Wen, Limeng Chen. *Peking Union Medical College Hospital, Beijing, China.*

Background: The mechanism of exacerbation of albuminuria observed in A1 adenosine receptor knock-out ($A1AR^{-/-}$)mice with diabetic nephropathy (DN) is unclear. Here, we investigated the relationship of megalin loss and albuminuria, to identify the effect of A1AR in the pyroptosis signaling caspase-1/IL-18 of DN.

Methods: Successfully collected diabetic nephropathy patients' samples and built streptozotocin-induced diabetes mice model. Megalin, cubilin, and A1AR expression were detected in kidney tissue samples from DN patients and mice through immunohistochemical and immunofluorescent staining. A1AR, caspase-1, Interleukin -18 (IL-18) expression were analyzed using western blotting in wild-type and $A1AR^{-/-}$ mice. Human renal proximal tubular epithelial cells (PTC) were cultured with high glucose to observe the effect of A1AR agonist and antagonist on caspase-1/IL-18 and megalin injury.

Results: The loss of megalin, co-localized with A1AR at PTC, was associated with the level of albuminuria in diabetic patients and mice. The injury of megalin-cubilin was accompanied by the A1AR upregulation and the caspase-1/IL-18 signaling activation in mice with DN. More severe pathological injury, albuminuria, and megalin-cubilin loss were observed in $A1AR^{-/-}$ DN mice with more pronounced caspase-1 and IL-18 secretion. High glucose could stimulate the secretion of caspase-1 and IL-18, which was completely abolished by A1AR agonist and further aggravated by A1AR antagonist.

Conclusions: A1AR played an important role in protecting megalin loss associated albuminuria by inhibiting the pyroptosis signaling caspase-1/IL-18 in DN.

TH-PO905

Urinary L-FABP Reflects the Degree of Sarcopenia in a Diabetic Kidney Disease Model

Jun Tanabe,[1] Daisuke Ichikawa,[1] Kenjiro Kimura,[2] Yugo Shibagaki,[1] Atsuko Ikemori.[1,3] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [2]Tokyo Takanawa Hospital, Tokyo, Japan; [3]Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: Diabetic kidney disease (DKD) is a high-risk factor for onset of sarcopenia which leads to increase in all-cause mortality in patients with type 2 diabetes. Although the sarcopenia in DKD should be focused just before a super-aging society, there had not been a useful biomarker for monitoring the sarcopenia. The aim of this study is to reveal the correlation between urinary L-type fatty acids binding protein (L-FABP) known as a tubular marker and sarcopenia using novel model of DKD with sarcopenia.

Methods: Male spontaneously diabetic torii (SDT) fatty rats (n =5) were used as an animal model of type 2 diabetes with sarcopenia. Age- and sex-matched Sprague–Dawley rats (SD) (n = 7) were used as controls. Urine samples were obtained from the rats at 8, 12, 16, 20, and 24 weeks of age and muscle strength was evaluated by forelimb grip test at 12, 16, 20, and 24 weeks of age. Their kidney, and soleus and extensor digitorum longus (EDL) muscles were obtained at 24 weeks of age.

Results: Urinary L-FABP increased and muscle strength decreased along with age in the SDT rats. Renal tissue damage and accumulation of renal oxidative protein were observed at 24 weeks of age of the SDT fatty rats. Muscle weight, and cross-sectional areas of both type I and type IIb muscle fibers were significantly decreased in the SDT fatty rats compared to the SD rats. The muscle atrophy in the SDT fatty rats was induced due to decreased phosphorylation of S6K1 and increased expression of E3 ubiquitin ligases, atrogin-1 and murf-1. The levels of urinary L-FABP and the degree of renal tissue damage were significantly correlated with muscle weigh, diameter of muscle fibers and muscle strength.

Conclusions: Urinary L-FABP increased along with the progression of sarcopenia and reflected the degree of sarcopenia in DKD. In clinical practice, urinary L-FABP may be useful for monitoring the sarcopenia as well as DKD in the type 2 diabetic patients.

TH-PO906

Insulin Resistance Impacts the Host Defense Transcriptome in Kidney Intercalated Cells

Laura Schwartz,[1] Tad Eichler,[1] Kristin Bender,[1] Jing Zhao,[3] Pearlly Yan,[2] Ralf Bundschuh,[3] John D. Spencer.[1] *[1]The Research Institute at Nationwide Children's, Columbus, OH; [2]The Ohio State University Comprehensive Cancer Cen, Columbus, OH; [3]The Ohio State University, Columbus, OH.*

Background: Urinary tract infection (UTI) is a common problem in women. Select populations have increased UTI risk, including those with insulin resistance and diabetes. The kidney's intercalated cells (IC) play a key role in preventing UTI by regulating urine pH, releasing cytokines, secreting antimicrobial peptides (AMPS), and creating a barrier with apposing principal cells to prevent bacterial invasion. Our data show that insulin receptor (IR) deletion in murine ICs inhibits IC-insulin signaling and increases UTI risk *in vivo* while having no impact on glucose homeostasis or urine acidification. Here, we profile the transcriptome of ICs isolated from IR knockout (IRKO) mice and controls (IRflox) to identify insulin-mediated host defense mechanisms.

Methods: To delete the IR gene *Insr* in murine ICs, V-ATPase-Cre transgenic mice were bred with IR floxed mice. A tdT reporter was added to aid fluorescence-assisted cell sorting (FACS) of ICs and visualize IC-specific Cre-recombination. Limited cell RNAseq was performed on FACS-isolated ICs and read count data were analyzed for differentially expressed genes (DEG) using the R package edgeR. DEGs with fold-change >1.5 and a false discovery rate adjusted p-value < 0.05 were defined as differentially expressed. Pathway and gene ontology term enrichment analyses of DEGs were performed using the Enrichr tool and DAVID.

Results: FACS-enriched IC cells expressed IC-specific genes, like *Aqp6* and *Atp6v0d2*. Differential expression analysis revealed downregulation of 138 genes and upregulation of 232 genes in IRKO IC vs IRflox IC. A decrease in *Insr* as well as other downstream IR-regulated genes was confirmed in IRKO ICs. Functional annotation analysis identified enriched KEGG pathways including adherens junction, insulin resistance, and adipocytokine signaling. Gene ontology terms involved in innate immunity and intracellular trafficking were enriched. AMPs, including members of the defensin and ribonuclease A families, were downregulated.

Conclusions: These data suggest that IR-signaling impacts the IC host defense transcriptome and identifies IR-sensitive transcripts that may aid in pathogen defense by maintaining paracellular boundaries, regulating intracellular trafficking, and expressing AMPs. These studies may uncover new immune targets to prevent/treat diabetes-associated infections.

Alk/bmp9 Signalization as a New Target of Therapy in Diabetic Nephropathy

Cindy Lora Gil. *Nephrology, Maisonneuve Rosemont Hospital, Montreal, QC, Canada.*

Background: Diabetic kidney disease one of the most frequent microvascular long-term complications in diabetic patients and is a major cause for the need of dialysis. Currently therapies in diabetic nephropathy are focusing on glycemia control and adequate arterial pressure levels in order to maintain an adequant glomerular filtration rate. However, a few of them are targeting the endothelial damage or podocyte-endothelial crosstalk, which play a critical role in diabetic kidney disease progression. We have previously shown that Alk1, along with its ligand BMP9, plays an important function to maintain vascular integrity in diabetic animals. Loss of Alk1 signaling in diabetic animals led to dissociation of vascular junctions and increased vascular leakage. Given its role in the maintenance of endothelial quiescence and integrity, we evaluated the effects of Alk1 suppression on kidney integrity and renal function in diabetic mice.

Methods: We used mice with conditional deletion of Alk1 in the endothelium (Alk1ΔEC) to evaluate the role of Alk1 in glomerular filtration in STZ-induced diabetic mice. Mice were euthanized four months after the onset of diabetes and urine and serological analyzes were performed, along with immunohistochemical studies. Healthy patients biopsies were compared with patients already diagnosed with diabetic nephropaty

Results: We demonstrated that Alk1 haploinsufficiency worsens microalbuminuria and induces podocyte loss. Alk1 haploinsufficiency also increases extracellular matrix expression at the gromerular basement membrane. Furthermore, a significant increase in glomerular apoptosis was observed in Alk1ΔEC mice. Analysis of homozygous Alk1ΔEC mice also revealed a significant loss of glomerular endothelial cells. Alk1 expression in the glomeruali was observed in patients diagnosed with diabetic nephropay compared to the healthy patients.

Conclusions: 1. Partial loss of Alk1 in type I diabetic mice leads an increase in microalbuminuria compared to WT mice. 2. Heterozygous diabetic mice have an increase in apoptosis associated with podocyte loss. 3. Partial Loss of Alk1 in Diabetic mice Induces an increase in extracellular matrix synthesis. 4. The alk1 / bmp9 signaling could be a potential target of theraphy because it plays a critical role in the maintenance of glomerular endothelial cells and has an important functions to maintain glomerular integrity through a crosstalk podocyte-endothelial mechanism.

TH-PO908

Deletion or Inhibition of ARF6 Improves Albuminuria in Type 2 Diabetic Mice

Jamie Lin,[1] Jianyin Long,[1] Benny B. Chang,[2] Daniel L. Galvan,[1] Nathanael Green,[2] Farhad R. Danesh.[1] *[1]The University of Texas MD Anderson Cancer Center, Houston, TX; [2]Baylor College of Medicine, Houston, TX.*

Background: Podocytes are key glomerular cells that determine the progression of diabetic kidney disease (DKD), the leading cause of renal failure in the U.S. Small GTPase proteins regulate quintessential roles that govern cellular health – too much or too little GTPase activity can render podocytes susceptible to kidney injury. ADP-ribosylation factor 6 (ARF6), is a small GTPase protein that we previously showed is present in human and mouse podocytes and involved in podocyte response to *in vivo* glomerular injury models. Since ARF6 is involved in diverse cellular events (e.g. actin remodeling or endocytic trafficking) we hypothesized that hyperglycemia might result in alterations in ARF6 activity and contribute to the progression of DKD.

Methods: To investigate the *in vivo* role of ARF6 in diabetes, we generated an inducible podocyte-specific ARF6 knockout diabetic animal model. We also explored whether pharmacological intervention of ARF6 using an ARF6 inhibitor, Nav2729 (R&D Systems), might recapitulate the observations from our aforementioned transgenic animal model.

Results: High glucose cultured podocytes expressed significantly higher Arf6 mRNA and protein levels compared to normal glucose cultured podocytes. Isolated podocytes from diabetic ($Lepr^{db/db}$) mice had increased ARF6 expression compared to control ($Lepr^{db/+}$) mice. Furthermore, podocyte-specific ARF6KO mice had decreased urine albumin to creatinine ratio (UACR). To determine whether ARF6 might serve as a molecular target for pharmacological inhibition in DKD, diabetic mice were treated with an ARF6 inhibitor (NAV2729) or vehicle (DMSO) at 8 weeks of age. NAV2729-treated diabetic mice demonstrated significant improvement in the UACR compared to diabetic mice treated with vehicle suggesting a renal-protective effect of ARF6 inhibition.

Conclusions: These results suggest that ARF6 is an important protein involved in podocyte health and DKD. Inhibition of ARF6 might serve as a molecular target to prevent podocyte injury, albuminuria, and progressive renal functional decline.

Funding: NIDDK Support, Private Foundation Support

TH-PO909

Activation of Notch Signaling in Podocytes by Growth Hormone

Rajkishor Nishad, Anil K. Pasupulati. *University of Hyderabad, Hyderabad, India.*

Background: Growth hormone (GH) plays a significant role in normal renal function and overactive GH signaling has been implicated in nephropathy particularly in diabetes and acromegaly. Previous results have shown that podocytes, which play an essential role in kidney filtration, express the GH receptor (GHR), suggesting the direct action of GH on these cells. Activation of Notch signaling, which is crucial in early podocyte development, contributes to the glomerular disease upon maturation. In this study, we investigated whether GH activates Notch1 signaling in podocytes in γ-secretase dependent manner.

Methods: Swiss Webster male mice were infused with GH i.p (1.5mg/kg/day) for 4 weeks. Another group of mice was administered GH and DAPT (10 mg/kg/day) while control mice received PBS. Renal functional and histological studies were performed at the end of the experimental period. Simultaneously, human podocytes (HPC) were treated with GH (500ng/ml) in the absence or presence of DAPT (5μg/ml) and assessed the expression of Notch signaling and its downstream targets.

Results: Employing HPC *in vitro* and GH-injected mice model *in vivo*, we demonstrate that GH activates Notch1 signaling in a γ-secretase-dependent manner in podocytes. Pharmacological inhibition of Notch1 by a γ-secretase inhibitor (DAPT) abrogated GH-induced epithelial to mesenchymal transition (EMT) and associated podocyte injury. Importantly, our results show that DAPT treatment blocked the GH-induced cytokine release and attenuated glomerulosclerosis. Further, DAPT prevented glomerular basement membrane thickening as well as proteinuria induced by GH. Kidney biopsy sections from diabetic nephropathy patients reveal activation of Notch signaling in podocytes.

Conclusions: GH induces Notch1 signaling in podocytes, which may contribute to proteinuria through podocyte EMT as well as renal fibrosis. Blocking Notch activation with γ-secretase inhibitors ameliorates glomerular injury and proteinuria in conditions of GH-associated nephropathy.

Empagliflozin as an Add-On to Linagliptin Ameliorates Renal Interstitial Fibrosis in Spontaneously Diabetic Torii Fatty Rats

Goh Kodama,[2] Yosuke Nakayama,[1] Sakuya Ito,[2] Yunosuke Yokota,[2] Yusuke Kaida,[2] Kei Fukami.[2] Division of Nephrology, Department of Medicine, Kurume University School of Medicine *[1]Division of Nephrology, Department of Medicine, Kurume University, Kurume, Japan; [2]Kurume University School of Medicine, Kurume, Japan.*

Background: Recent clinical trials have shown that SGLT2 inhibitor significantly attenuates the rapid decline in eGFR and enhances blood pressure control. Further, DPP4-inhibitor has become the first-line therapy of blood glucose control in patients with diabetic kidney disease (DKD). However, whether dual therapy could prevent the development and progression of DKD are yet to be elucidated. Therefore, we investigated the effects of

empagliflozin as an add-on to linagliptin or vice versa on diabetes-induced renal injury in SDT fatty rats, a type 2 diabetic model of DKD.

Methods: Eight-week-old SDT fatty rats were divided into 5 groups, 1) SDT fatty rats untreated (SDT), 2) SDT fatty rats given 30 mg/kg of empagliflozin for 12 weeks (EMPA), 3) SDT fatty rats given 3 mg/kg of linagliptin for 12 weeks (LINA), 4) SDT fatty rats given empagliflozin for 6 weeks in addition with linagliptin for 6 weeks (EMPA–EMPA+LINA), and 5) SDT fatty rats given linagliptin for 6 weeks in addition with empagliflozin for 6 weeks (LINA–LINA+EMPA). All experimental groups were given water supplemented with 0.5% salt. All animals (20 weeks of age) were euthanized and parameters such as urine and blood chemistry, blood pressure (BP), renal pathology, and GFR were measured.

Results: At 14 weeks of age, SDT exhibited hypertension, which was not ameliorated in EMPA and LINA groups. However, at 20 weeks of age, BP decreased in all treated groups. Treatment with empagliflozin showed glycosuria and increased urinary sodium excretion. SDT showed albuminuria and glomerulosclerosis, which were not ameliorated in all the treated groups. Compared with SD, GFR was significantly higher in SDT, suggesting hyperfiltration, and it further increased in LINA. SDT manifested dramatically increased urinary L-type fatty acid binding protein levels, which were attenuated in LINA–LINA+EMPA (p=0.069 vs SDT). Besides, renal interstitial fibrosis was ameliorated in EMPA, EMPA–EMPA+LINA, and further reduced in LINA–LINA+EMPA, as evidenced by the Masson trichrome staining. Diabetes-associated interstitial TGF-b expression was inhibited only in LINA–LINA+EMPA (p<0.05 vs SDT).

Conclusions: Empagliflozin as an add-on to linagliptin might be a better therapy for diabetes-induced renal fibrosis than linagliptin as an add-on to empagliflozin and each drug.

Stakeholder Perspectives on Implementing Precision Medicine in Diabetic Kidney Disease

Michelle Pena,[1] Julia Czaja,[1] Joao M. Nabais,[2] Francesc xavier Cos claramunt,[3] John J. Nolan,[4] Thorsten Vetter,[5] Matthias Kretzler,[6] Maria F. Gomez,[7] Friedrich Schulze,[8] Dick de Zeeuw,[1] Hiddo J. L Heerspink,[1] Peter G. Mol.[1] BEAt-DKD Consortium *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Associação Protetora dos Diabéticos de Portugal, Lisboa, Portugal; [3]Primary Care Diabetes Europe, Barcelona, Spain; [4]European Diabetes Forum, Dublin, Ireland; [5]European Medicines Agency, Amsterdam, Netherlands; [6]U.Michigan, Ann Arbor, MI; [7]Lund University, Malmö, Sweden; [8]Boehringer Ingelheim International GmbH, Ingelheim, Germany*.

Background: One of the important aims of the Innovative Medicine Initiative BEAt-DKD consortium is to promote implementation of Precision Medicine (PM) in treating diabetic kidney disease (DKD). Engaging stakeholders is crucial in this process. We held a consensus workshop and conducted a survey of diabetes stakeholders to identify benefits and obstacles of PM, and to strategize solutions.

Methods: Sevently-one participants from 26 countries met in Amsterdam, the Netherlands over 2 days to develop a strategy to move PM forward in DKD. Represented stakeholder groups included patients with diabetes and advocates (n=11), academia (n=18), drug regulators (n=7), health technology assessors (HTAs)(n=6), industry (n=11), and health care providers (HCPs)(n=18). A survey was developed and pilot tested prior to implementation. Respondents were asked about their opinions on needs, benefits, and obstacles for introducing PM in DKD. A consensus discussion was held to strategize solutions.

Results: Stakeholders were mostly positive for PM in DKD (Figure). HTAs least agreed, while HCPs most agreed. Obstacles and concerns for PM included data safety, time contraints, and increased burden for assessments. Keys to successful implementation of PM would be increased engagement with patients, specific training for HCPs in PM, and early collaboration between stakeholders. All stakeholders responded that quality of life outcomes would be important to assess the impact of PM.

Conclusions: Diabetes stakeholders view PM in DKD positively. Implementing PM is complex as different stakeholders have different priorities. The consensus of all stakeholders was that early engagement and aligning stakeholders goals are critical to implement PM in DKD.

Urinary Complement-Enriched Inflammatory Proteome of an Overt Progressive Diabetic Kidney Disease

Salina Moon,[1] Heather L. Donsky,[1,4] John J. Tsay,[1,4] Edward P. Feener,[3] Simon T. Dillon,[2,4] Monika A. Niewczas.[1,4] *[1]Joslin Diabetes Center, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]KalVista Pharmaceuticals, Inc., Cambridge, MA; [4]Harvard Medical School, Boston, MA.*

Background: We aimed to advance our knowledge of the role of the local kidney inflammation in the progressive diabetic kidney disease (DKD) reflected by the urinary profiles of the inflammatory proteome.

Methods: We conducted a nested case-control study comprising a discovery panel of Joslin subjects with T1D and a validation panel of Joslin subjects with T2D (total n=112). All study subjects had an overt DKD at baseline (CKD stage 3-4 and albuminuria (median GFR: 46 mL/min/1.73m^2; median ACR: 653). Subjects experiencing renal function loss of eGFR > 40% within 5 years were defined as progressive DKD cases. 194 inflammatory proteins were measured in baseline urine samples using aptamer proteomics (SOMAscan).

Results: In the multivariate screen we identified a urinary proteomic profile consistently associated with progressive DKD in T1D and T2D. Complement proteins (CPL) accounted for almost half of our profile (twelve out of 26 (46%); enrichment: p<0.001). Chemokines (CHK) comprised the second-most abundant group of our profile (enrichment: p=ns; Fig. A - needle plot). In the adjusted mediation model (ACR - intermediate phenotype), all 26 proteins were associated with the renal slope. The protein effects were mainly independent from albuminuria (median proportion mediated (PM): 25%). One unit change in these proteins resulted in renal function loss between 1.5-7.3 mL/min/1.73m^2/yr. These proten effects markedly correlated between the T1D and T2D panels (p <10^{-5}; Fig. B - β estimates).

Conclusions: We have identified a significant urinary profile of the inflammatory proteome strongly associated with progressive DKD in subjects with an overt disease in both types of diabetes. Our data suggest that the complement system and chemokines seem to be important players of the disease process. Larger studies including subjects with early DKD are needed to evaluate the dynamic of these processes across DKD stages.

Proteomic Study of Circulating Proteins to Identify Novel Surrogate Markers for Progressive Renal Decline

Jan Skupien,[1] Katsuhito Ihara,[2] Zaipul I Md Dom,[2] Kristina V. O'Neil,[2] Andrzej S. Krolewski.[2] *[1]Jagiellonian University Medical College, Krakow, Poland; [2]Joslin Diabetes Center, Harvard Medical School, Boston, MA.*

Background: Clinical trials of renoprotection in diabetic nephropathy have been limited to high-risk patients with impaired renal function due to low incidence of clinical and traditional surrogate end-points. End-points based on serum creatinine may be affected by its high variation, especially in patients with normal renal function. No efficient trial design exists to test early interventions in moderate-risk patients with eGFR > 60 ml/min.

Methods: We followed 196 patients (44% female) with type 1 diabetes from Joslin Proteinuria Cohort (median albumin/creatinine ratio 852 mg/g) with normal baseline renal function (median eGFR 100 ml/min). During median 10 years of follow-up there were 110 cases of end-stage renal disease (ESRD) and 15 deaths. We quantified 455 proteins in baseline plasma samples using OLINK (Uppsala, Sweden) Proximity Extension Assay. In 110 patients we measured these proteins in a second sample collected after median 4 years of follow-up. Annualized proteins' increments (DELTAs) were tested as surrogate of ESRD using Cox regression models.

Results: In regression models adjusted for the change in eGFR the DELTAs of 13 proteins were significantly (Bonferroni-corrected) associated with time to ESRD. Also, their baseline concentrations were associated with time to ESRD independently from baseline eGFR (see Table). Prediction of time to ESRD was much more accurate with DELTAs of these proteins than with the change in eGFR (for example C-statistic for LAYN was 0.85 versus 0.78 for eGFR).

Conclusions: Serial measurements of circulating protein markers during a short follow-up are more accurate in ESRD prediction than measurements of creatinine-based eGFR. Surrogate outcomes derived from these candidate proteins may help designing efficient clinical trials. Replication of the findings in independent cohorts is under way.

Multi-Omics Data Integration Identifies Molecular Pathways Associated with Renal Response to Atrasentan

Wenjun Ju,[1] Paul Perco,[2] Viji Nair,[1] Sunil Belur nagaraj,[3] Frédéric Burdet,[4] Aimo Kannt,[5] Maria F. Gomez,[6] Charles E. Alpers,[7] Matthias Kretzler,[8] Hiddo J. L Heerspink.[3] Biomarker Enterprise to Attack DKD (BEAt-DKD) consortium *[1]University of Michigan, Ann Arbor, MI; [2]Medical University Innsbruck, Innsbruck, Austria; [3]University Medical Center Groningen, Groningen, Netherlands; [4]Swiss Institute of Bioinformatics, Lausanne, Switzerland; [5]Sanofi, Frankfurt, Germany; [6]Lund University, Malmö, Sweden; [7]University of Washington Medical Center, Seattle, WA; [8]U.Michigan, Ann Arbor, MI.*

Background: The endothelin-1 receptor antagonist atrasentan lowers urinary albumin:creatinine ratio (UACR) and reduces renal risk in patients with type 2 diabetes and chronic kidney disease (CKD). This effect markedly varies among patients. Aim of this study was to identify molecular pathways and biomarkers predicting the renoprotective effect of atrasentan.

Methods: In vivo and in vitro transcriptomics profiling was performed in kidney tissue from atrasentan treated BTBR ob/ob mice and human mesangial cell cultures respectively. A transcriptomic dataset from human diabetic kidney biopsies was used for cross-validation. Critically, microRNA, proteomics, and metabolomics profiles were generated in plasma and urine samples of a phase 2 trial (RADAR) in patients with type 2 diabetes and CKD treated for 12 weeks with atrasentan. Logistic regression analysis was performed to identify features associated with atrasentan response (UACR reduction ≥30%, n=42) versus non-response (UACR reduction <10%, n=8). Omics features were subjected to pathway analysis to identify patterns of UACR response to atrasentan across model systems and human disease.

Results: Clinical characteristics between responders and non-responders were similar. More than 1000 genes that were dysregulated in DKD mouse tissue were significantly reversed after atrasentan treatment and 513 genes in mesangial cells significantly changed after atrasentan treatment. Four miRNAs, 68 metabolites, and 210 proteins measured before atrasentan exposure in human samples predicted UACR response to atrasentan ($p<0.1$). Multi-omics integration revealed Sirtuin and ephrin signaling, NRF2-mediated oxidative stress response among the top ranked pathways associated with atrasentan response. A biomarker panel of 5 urinary proteins (including SOD1, CXCL10, PDGF) reflecting the identified pathways predicted UACR response to atrasentan with an area under the ROC curve of 0.82

Conclusions: We implemented a multi-omics data integration approach to derive molecular pathways associated with UACR response to atrasentan. The marker panel predicting atrasentan response in humans reflects a non-invasive surrogate of molecular pathways activated in human DKD and CKD, linking individual atrasentan response to known and novel CKD progression pathways.

TH-PO915

Magnetic Resonance Imaging Biomarkers Independently Predict GFR and Urine Albumin Creatinine Ratio

Lars Johansson,[1] Paul Hockings,[1] Kianoush Makvandi,[2] Gert Jensen,[2] Tim Unnerstall,[2] Henrik Leonhardt,[2] Lisa Jarl,[1] Camilla Englund,[1] Fredrik Erlandsson,[3] Anna K. Sundgren,[3] Johannes Hulthe,[1] Seema Baid-Agrawal.[2] *[1]Antaros Medical AB, Molndal, Sweden; [2]Sahlgrenska University Hospital, Göteborg, Sweden; [3]AstraZeneca, Gaithersburg, MD.*

Background: Estimated GFR (eGFR) and urine albumin/creatinine ratio (UACR) are the standard methods for assessing glomerular damage and renal function changes in clinical practice, Within-person variations are large in people with diabetes due to the complex nature of diabetic kidney disease (DKD). New non-invasive markers are needed to increase understanding of disease pathogenesis. We recently showed that magnetic resonance imaging (MRI) markers correlated strongly to both measured GFR (mGFR) and UACR. Here we seek to determine which MRI markers are independent predictors of mGFR and UACR.

Methods: ***Subjects*:** The study included 2 CKD2, 16 CKD3, and 20 CKD4 subjects with DKD, 18-79 years old, and 20 age- and gender-matched healthy controls. GFR was measured using iohexol clearance. UACR was assessed in the first morning sample. ***MRI techniques*:** - Renal hemodynamics with mean arterial flow (ml/s) - Renal microstructure, such as fibrosis and cellular infiltration, by measurement of Apparent Diffusion Coefficient (ADC) (mm^2s^{-1} x 10^{-3}) and R_1 (s^{-1}) - Renal oxygenation by measurement of BOLD R_2* (s^{-1}) - Renal macrostructure by kidney volume assessment (ml) ***Statistics*:** We performed multiple regression analyses in the control group and the CKD group separately: 1) with UACR, mean arterial flow, R_1 cortex, R_2* cortex, ADC cortex, and kidney volume as independent variables, and mGFR as the dependant variable; and 2) with mGFR, mean arterial flow, R_1 cortex, R_2* cortex, ADC cortex, and kidney volume as independent variables, and UACR as the dependent variable.

Results: The only independent predictors of mGFR in the CKD group were mean arterial flow ($p < 0.0001$) and kidney volume ($p = 0.03$), with none in the control group. The only independent predictors of UACR were cortical R_1 in the CKD group ($p = 0.005$) and kidney volume in the control group ($p = 0.01$).

Conclusions: It is well known that GFR is strongly linked to renal blood flow and therefore not surprising to see mean arterial flow emerge as an independent predictor of mGFR. The strong link between cortical R_1 and UACR indicates that cortical R_1, a measure of cellular infiltration in the cortex where the filtration barrier exists, may be a novel biomarker of kidney damage and warrants further investigation.

Assessment of MRI Filtration Fraction in Healthy Subjects and Patients with Diabetic Kidney Disease

Lars Johansson,[1] Paul Hockings,[1] Kianoush Makvandi,[3] Gert Jensen,[3] Tim Unnerstall,[3] Henrik Leonhardt,[3] Lisa Jarl,[1] Camilla Englund,[1] Fredrik Erlandsson,[2] Anna K. Sundgren,[2] Johannes Hulthe,[1] Seema Baid-Agrawal.[3] *[1]Antaros Medical, Molndal, Sweden; [2]AstraZeneca, Gaithersburg, MD; [3]Sahlgrenska University Hospital, Göteborg, Sweden.*

Background: Filtration fraction (FF) is the ratio of the glomerular filtration rate (GFR) to renal plasma flow (RPF) and therefore an important marker of glomerular health. FF is not normally measured, as estimation of RPF requires constant infusion of para-aminohippurate over 8 h (1). Therefore, quicker, simpler assays of FF are needed. We assessed a novel magnetic resonance imaging (MRI) technique to measure FF in patients with diabetic kidney disease (DKD). MRI was previously used to measure FF in kidney donors (2,3).

Methods: The study included 2 CKD2, 16 CKD3, and 20 CKD4 patients with DKD, 18-79 years old, eGFR between 15-60 ml/min/1.73 m^2 and 20 age-, gender-matched healthy controls. GFR was measured using iohexol clearance (mGFR). Renal blood flow (RBF) (ml/min) was measured by phase contrast MRI. The phase contrast MRI scan is a 5 minutes add-on to an MRI examination. MRI FF = (mGFR x BSA)/(RBF x 1.73) RBF was corrected for Body Surface Area (BSA) to use the same units as GFR. EVF (hematocrit) was not available and therefore RPF was not calculated.

Results: MRI FF % (Mean (SD)) was 8.28 (1.00)% for Healthy Controls; 6.57 (2.62) % for CKD2; 6.30 (0.93)% for CKD3; and 5.15 (1.36)% for CKD4. We tested for significant differences between groups (p 0.05) using Bonferroni/Dunn multiple testing correction. p-values less than 0.008 were significant. Differences in FF in controls vs both CKD3 and CKD4 ($p < 0.0001$), and CKD3 vs CKD4 (p 0.005) were significant.

Conclusions: Standard deviations in the CKD 2 group were relatively large as there were only 2 subjects in this group. All MRI FF comparisons between control subjects, CKD3 subjects and CKD4 subjects were statistically significant. This MRI FF measurement can be further improved by correcting RBF for extracellular volume in order to calculate RPF. **References** 1) Costanzo L (2007) Physiology. TH-PO917

Prediction of Rapid Kidney Function Decline in Type 2 Diabetes Using Machine Learning Combining Blood Biomarkers and Electronic Health Record Data

Girish N. Nadkarni,[1] Fergus Fleming,[2] James Mccullough,[2] Kinsuk Chauhan,[1] Divya A. Verghese,[1] John C. He,[1] John Quackenbush,[5] Joseph V. Bonventre,[3] Barbara T. Murphy,[1] Chirag R. Parikh,[4] Michael J. Donovan,[1] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]RenalytixAI, New York, NY; [3]Brigham and Women's Hospital, Boston, MA; [4]Johns Hopkins University, Baltimore, MD; [5]Harvard T.H. Chan School of Public Health, Boston, MA.*

Background: Individuals with type 2 diabetes (T2DM) are at increased risk of rapid kidney function decline (RKFD). The application of machine learning to integrate biomarkers with EHR data may lead to improved prediction of RKFD.

Methods: We selected individuals with T2DM with a baseline eGFR ≥45 and <90 ml/min/1.73 m^2 from the Mount Sinai Bio*Me* Biobank (n=871). We measured plasma levels of tumor necrosis factor (TNFR)1 & 2, and kidney injury molecule(KIM)-1 and employed

random forest (RF) models to combine the biomarkers with longitudinal clinical features extracted from the electronic health record (EHR) to predict RKFD (eGFR decline of ≥5 ml/min/1.73 m^2/year).

Results: In 871 participants, baseline eGFR was 74 ml/min/1.73 m^2, and median UACR was 13 mg/g. Overall, 164 (19%) of individuals experienced RKFD over a median follow-up of 4.7 years from the baseline specimen collection. In the training and test sets respectively, the combined RF model (clinical features plus biomarkers) had an AUC of 0.82 (95% CI, 0.81-0.83) and 0.80 (95% CI, 0.78-0.82), which outperformed a standard clinical model via logistic regression (AUC 0.64, 95% CI 0.63-0.65), a biomarker model alone (AUC 0.76, 95% CI 0.72-0.79), and RF model using clinical features alone (AUC 0.74, 95% CI 0.73-0.76). The RKFD score stratified 18%, 49%, and 33% of patients in the entire cohort to high, intermediate, and low-probability strata, respectively, with a PPV of 53% in the high-probability group and an NPV of 97% in the low-probability group (**Figure**).

Conclusions: In patients with type 2 DM, a RF model combining plasma biomarkers and longitudinal EHR data significantly improved prediction of RFKD over standard clinical or biomarker-only models. Further validation of such approaches is needed.

Distribution of RKFD Scores and Probability of Rapid Kidney Function Decline by Continuous and Categorical Strata

TH-PO918

Determinants of Urinary C-Megalin Among a Large Diabetes Cohort: Albuminuria, Reduced Kidney Function, and Demographic Factors

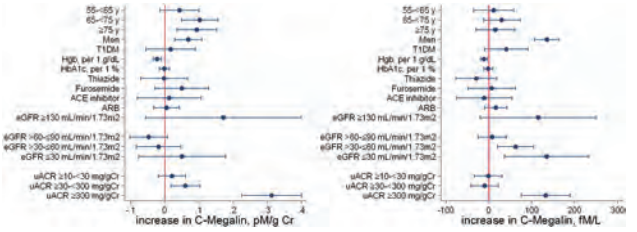
Noriaki Kurita,[1] Yasuaki Hayashino.[2] *[1]Department of Clinical Epidemiology, Fukushima Medical University, Fukushima, Japan; [2]Tenri Hospital, Nara, Japan.*

Background: Urinary c-megalin is a multi-ligand receptor shed from proximal tubule cells. It is expected as a biomarker for early kidney injury associated with diabetic kidney disease (DKD) among diabetes. The aim of this study was to examine the determinants of urinary c-megalin values.

Methods: This single-center cross-sectional study included 1491 Japanese patients with diabetes (including 104 type 1 and 1387 type 2 diabetes). The outcome was urinary c-megalin measured by enzyme-linked immunosorbent assay and expressed as both urinary creatinine (Cr)-corrected value (unit: pM/gCr) and non-corrected value (unit: fM/L). The candidate predictors were: age, type 1 diabetes, hemoglobin, hemoglobin A1c, antihypertensives, estimated glomerular filtration rate (eGFR: ≥130, >90-<130 [ref.], >60-≤90, >30-≤60, ≤30 mL/min/1.73m^2), and urine albumin Cr ratio (uACR: <10 [ref.], ≥10-<30, ≥30-<300 [i.e., microalbuminuria], ≥300 mg/gCr [i.e., macroalbuminuria]). The two-part model was fit to estimate the marginal effects of the predictors as urinary c-megalin values of both units have zero-inflated heavily skewed distributions.

Results: Cr-corrected c-megalin showed higher values associated with both microalbuminuria and macroalbuminuria (difference: 0.06 and 0.31 pM/gCr), whereas aging (≥65-<75 yr and ≥75 yr compared to <55 yr) was also associated with higher c-megalin values (Figure1). Uncorrected c-megalin showed higher values associated with macroalbuminuria (difference: 132 fM/L), eGFR >30-≤60, and ≤30 mL/min/1.73m^2 (difference: 62 and 134 fM/L). For both units, higher c-megalin values were associated with male sex and lower hemoglobin values.

Conclusions: Uncorrected c-megalin was independently associated with reduced kidney function and macroalbuminuria, both of which were included in a current concept of DKD. However, for both units, careful interpretation would be required as anemia and sex affect both units and especially, aging affects Cr-corrected values.



Marginal effects of predictors on urinary c-megalin values expressed as Cr-corrected (left panel) and uncorrected values (right panel). Error bars indicate 95% confidence intervals.

TH-PO919

Urinary Glycolic Acid Predicts Kidney Function Decline in Type 1 Diabetic Subjects

Manjula Darshi,[2] Jiwan J. Kim,[2] Tarunveer S. Ahluwalia,[1] Peter Rossing,[1] Per-Henrik Groop,[3] Kumar Sharma.[2] Center for Renal Precision Medicine *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]University of Helsinki and Helsinki University Hospital, Helsinki, Finland.*

Background: Diabetes is the common cause of chronic kidney disease (CKD) and end-stage renal failure. Albuminuria and eGFR are widely approved biomarkers to identify disease progression. However, due to considerable heterogeneity not all subjects progress at the same rate. Here we evaluated a set of urine metabolites toward prediction of rapid progression of CKD in patients with type 1 diabetes.

Methods: We used a nested case-control study in four diverse cohorts (CACTI, EDC, FinnDiane, and Steno) with long-standing type 1 diabetes and normal kidney function. Subjects were classified into slow decliners/controls with eGFR decline ≤1ml/min/1.73m^2/yr or rapid progressors/cases with eGFR decline of ≥3ml/min/1.73m^2/yr. In training phase 34 urine metabolites were measured from 595 subjects. The most prognostic biomarkers were validated on additional 200 subjects from the same 4 cohorts. Logistic regression model was used to predict rapid eGFR decline. Area under the curve (AUC) were used to assess model performance.

Results: Baseline mean eGFR and median ACR in training phase controls (n=340) and cases (n=212) were 91.97 (sd 18.68) and 9.44 (IQR 30), and 98.37 (sd 25.44) and 33.49 (IQR 283.01), respectively. Analysis with clinical variables revealed age, baseline ACR, and baseline eGFR to be significant predictors of rapid decline. Three metabolites 3-methylcrotonylglycine, glycolic acid and citric acid had a univariate association to rapid progression (FDR ≤ 0.05). When these 3 metabolites were added to the model with the clinical variables, 3-methylcrotonylglycine and glycolic acid remained significant ($p < 0.005$) but the predictive performance of the model did not improve. In a stratified analysis of eGFR≥60 ml/min/1.73m^2 and micro- or macroalbuminuria (MA+) group, 3 methylcrotonylglycine and glycolic acid significantly improved the AUC from 0.69 (0.45-0.84) to 0.76 (0.61-0.89). The metabolites were further validated in 95 controls and 95 cases with eGFR≥60 ml/min/1.73m^2 and micro- or macroalbuminuria (MA+). Glycolic acid was univariately associated with rapid decline (P<0.01) and remained significant when added to clinical model (P:0.04).

Conclusions: In subjects with albuminuria and normal eGFR (≥60 3ml/min/1.73m^2) urine glycolic acid may be useful as a prognostic biomarker along with clinical variables for loss of renal function.

Metabolomics Analysis of Urinary Biomarkers That Correlate with Kidney Injury in Diabetic African American Men

Heather A. Newman,[1] Elimelda M. Ongeri,[1] Scott H. Harrison,[1] Olugbemiga E. Jegede,[2] Robert H. Newman.[1] *[1]Biology, North Carolina A&T State University, Greensboro, NC; [2]Community Health and Wellness Center, Cone Health, Greensboro, NC.*

Background: African Americans (AA) are disproportionately burdened by diabetes and diabetic kidney disease (DKD). However, little is known about the cellular and molecular mechanisms underlying the onset and progression of DKD in this population. This is due, in part, to the fact that AAs are often underrepresented in biomedical research. We recently reported undiagnosed kidney injury in a significant proportion of diabetic AA men served by a community clinic in Greensboro, NC. The goal of the current study was to determine the association between specific metabolites and kidney injury in this population.

Methods: We used Biocrates Absolute IDQ p400 kits together with high-resolution liquid chromatography-mass spectrometry to analyze fasting urine samples from three groups of AA men; 1) diabetics with DKD (n=10), 2) diabetics but no diagnosed DKD (DM; n=55), and 3) age-matched non-diabetic controls (ND; n=15). Patients in the DM group were further stratified based on their urinary albumin-to-creatinine ratios (UACR) into normo- (UACR<30 mg/g; n=28), micro- (30 mg/g<UACR < 300 mg/g; n=20); and macroalbuminuria (UACR>300 mg/g; n=7). The concentrations of metabolites were normalized to the urinary creatinine levels, and compared through linear mixed models.

Results: The differentiating metabolites included glycerides, cholesterol esters, sphingolipids, glycerophospholipids, biogenic amines and amino acids. The levels of several metabolites correlated with UACR. These include the Pro and the Arg derivative, citrulline, and three biogenic amines (kynurenine, 4-hydroxyproline, and a-aminoadipic acid). 87 urine metabolites exhibited levels above the limit of detection of the assay.

Conclusions: The current data suggest that key metabolic pathways are altered in diabetes and DKD for this population. For instance, proline is a precursor during the biosynthesis of both 4-hydroxyproline and citrulline. Likewise, citrulline is also involved in nitric oxide production, consistent with our previous observation that inflammation markers correlated with severity of DKD in this population. Together, the metabolic biomarkers offer insights into the cellular and metabolic pathways that are dysregulated during the development of DKD in this population.

LC-MS/MS-Based Proteomics Analysis Reveals Correlations Between Kidney Injury and Mediators of Vascular Pathology, Inflammation, and Oxidative Stress in Diabetic African American Men

Elimelda M. Ongeri,[1] Aldeisha D. Smith,[1] Faihaa Ahmed,[1] Heather A. Newman,[1] Olugbemiga E. Jegede,[2] Robert H. Newman,[1] Scott H. Harrison.[1] *[1]Biology, North Carolina A&T State University, Greensboro, NC; [2]Community Health and Wellness Center, Cone Health, Greensboro, NC.*

Background: The prevalence of diabetic nephropathy (DN) is disproportionately high among minority ethnic groups in the US. African American (AA) men are especially underrepresented in research to identify biomarkers of DN which are then used for the development of diagnostic tools and therapeutics targets. The goal of the current study was to identify biomarkers present in the serum of diabetic AA men which correlate with kidney injury and thus gain insights on the cellular and molecular mechanisms underlying the progression of DN in this population.

Methods: Fasting blood and urine samples were obtained from AA men aged 18-65 years; (i) non-diabetic controls (n=22), (ii) diabetics (n=65), and (iii) diabetics with diagnosed kidney disease (n=13). Assays for urinary albumin, creatinine, kidney injury molecule 1 (KIM-1) and neutrophil gelatinase associated lipocalin (NGAL) were used for evaluation of kidney function. The serum samples were depleted of abundant proteins then subjected to global LC-MS/MS-based analysis. The data were searched using Proteome Discoverer 2.2 utilizing Sequest HT search algorithm. Linear regression modeling was conducted for screening changes in association with urinary albumin and creatinine ratio (UACR), and odds and fold changes calculated across groups.

Results: 29 of the identified proteins correlated with UACR. Among these are proteins involved in vascular pathology (vasorin, fibulin-1, neuropilin), inflammation (protein disulfide-isomerase, tenascin-X, vascular cell adhesion protein 1), oxidative stress (sulfhydryl oxidase 1), and ECM/ fibrosis (tenascin-X, fibulin-1).

Conclusions: The data suggest that the progression of kidney injury in AA men is associated with vascular pathology, inflammation, and oxidative stress. Vasorin has distinct glomerular localization and is down-regulated during vessel repair. Reversal of vasorin down-regulation inhibits TGF-β signaling diminishing injury-induced vascular lesions. AGEs, which are linked to DN, suppress the expression of neuropilin-1 in podocytes. Tenascin X, localizes in the mesangium of kidney glomeruli, activates latent TGF-β, and induces TFG-β/Smad signaling. Increased levels of fibulin-1 also associate with impaired kidney function.

Prediction and Validation of Exenatide Risk Marker Effects on Progression of Renal Disease: Insights from EXSCEL

Lindsay Clegg,[2] Nienke Idzerda,[1] George L. Bakris,[3] Robert C. Penland,[4] David W. Boulton,[2] Hiddo J. L Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]AstraZeneca, Gaithersburg, MD; [3]The University of Chicago Medicine, Chicago, IL; [4]Astrazeneca Pharmaceuticals, Watertown, MA.*

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RA) may slow progression of renal disease in patients with type 2 diabetes (T2D). We previously developed the PRE score that translates multiple short-term drug effects into a predicted effect on long-term outcomes. We assessed the short-term effects of the GLP-1 RA exenatide on multiple cardio-renal risk markers, and aimed to determine whether the PRE score could predict the renal effects of exenatide observed in the EXSCEL cardiovascular outcomes trial.

Methods: Changes from baseline to six months in multiple risk markers were evaluated for glycated hemoglobin (HbA_{1c}), systolic blood pressure (SBP), urine albumin:creatinine ratio (UACR), body mass index (BMI), hemoglobin and total cholesterol. The renal outcome was defined as a composite of a sustained 30% decline in estimated glomerular filtration rate (eGFR) or end-stage renal disease. The effect of exenatide on the composite of 40% eGFR decline or ESRD was also assessed. Relationships between multiple risk markers and long-term renal outcomes were determined in patients with T2D from the ALTITUDE study using multivariable Cox regression analysis. These relationships were applied to short-term changes in risk markers observed in EXSCEL to predict the likely drug induced impact on renal outcomes.

Results: Compared with placebo, mean HbA_{1c}, BMI, SBP, and total cholesterol were lower at six months with exenatide, as was the incidence of micro- or macroalbuminuria. The PRE score predicted a relative risk reduction for the 30% eGFR decline / ESRD endpoint of 11.3% (HR 0.89; 95%CI 0.83 to 0.94), compared with 12.7% (HR 0.87; 95%CI 0.77 to 0.99) observed risk reduction. For the 40% eGFR / ESRD endpoint, the predicted and observed risk reductions were 11.0% (HR 0.89; 95%CI 0.82 to 0.97) and 13.7% (HR 0.86, 95%CI 0.72 to 1.04), respectively.

Conclusions: The PRE score, integrating multiple short-term risk marker changes, predicted the observed renal risk reduction with exenatide treatment as observed in the EXSCEL trial. The results of the present study support further clinical trials to prospectively assess the renal efficacy of exenatide.

Myostatin Promotes Tubular Inflammation in Diabetic Nephropathy

Daniela Verzola,[1] Annalisa Carta,[2] Samantha Milanesi,[2] Michela Saio,[4] Francesca Viazzi,[3] Daniela Picciotto,[3] Francesca Costigliolo,[3] Chiara Barisione,[5] Giacomo Garibotto.[3] *[1]University of Genoa Di.M.I. Nephrology, Genoa, Italy; [2]University of Genoa IRCCS San Martino, Abbasanta, Italy; [3]University of Genoa IRCCS AOU San Martino, Genova, Italy; [4]University of Genoa, Hospital IRCCS-IST San Martino, Genova, Italy; [5]University of Genova, Genova, Italy.*

Background: Inflammation contributes to the tubulointerstitial lesions of diabetic nephropathy. Myostatin (MSTN), a member of the Transforming growth factor-β family, has been identified as a mediator of inflammation and insulin resistance in type 2 diabetes. MSTN has also been identified in the tubulointerstitium of porcine kidney, but its role in the human kidney is not known. The aims of the current study were (1) to investigate MSTN expression in the normal kidney and in kidney biopsies with documented diabetic nephropathy (DN); (2) to the functional role of MSTN in tubular inflammation and fibrosis, using an established PTEC culture system.

Methods: MSTN mRNA was analyzed in microdissected tubuli and glomeruli from normal kidneys (N=19), DN (n=23, proteinuria 3.8±1.0 g/d, eGFR= 33±7 ml/min) and IgA biopsies (n= 12, proteinuria 2.7 g/d, eGFR= 39±5 ml/min) and protein was studied by immunohistochemistry. In vitro, HK-2 (human PTEC line) was exposed to MSTN (500 ng/ml) for 48 hours. We evaluated mRNAs by rt PCR, proteins by western blot, cell proliferation by CFSE incorporation, oxidative stress by CellROX staining.

Results: Laser capture microdissection showed an overexpression of MSTN mRNA (~8- to 10-fold increase) in the tubulointerstitium compartment in DN. Immunoreactive MSTN was overexpressed in the tubulointerstitium from DN patients (~4-8 fold increase) but not in nondiabetic control subjects and co-localized with interstitial infiltrating CD45+ cells. The intensity of tubulointerstitial MSTN expression correlated directly with tubular atrophy (R= 0.64; p<0.001). When proximal tubule HK-2 cells were treated with MSTN, they showed a decrease in proliferation, together with NF-kB activation and upregulation of downward inflammatory chemokines, SMAD 2/3 and fibronectin mRNA and protein. In addition, MSTN induced intracellular ROS release and upregulated NADPH oxidase, an effect which was mediated by ERK activation.

Conclusions: In conclusion, our data show that MSTN is upregulated in the tubulointerstitium of DN and associates with tubulointerstitial fibrosis. Its proinflammatory and profibrotic effects in human tubular cells suggests that MSTN plays a role in the progression of DN.

Gut Microbiome-Derived Phenyl Sulfate Contributes to Albuminuria in Diabetic Kidney Disease (Part 2)

Takaaki Abe,[1] Koichi Kikuchi,[1] Daisuke Saigusa,[2] Koki Mise,[3] Tomohiro Nakamura,[2] Jeffrey B. Kopp,[4] Takafumi Toyohara,[1] Eikan Mishima,[1] Takehiro Suzuki,[1] Atsushi Hozawa,[2] Takashi Wada,[5] Jun Wada,[3] Yoshihisa Tomioka.[6] *[1]Tohoku University Graduate School of Medicine, Aoba-ku, Sendai, Japan; [2]Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; [3]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [4]NIDDK, NIH, Bethesda, MD; [5]Kanazawa University, Ishikawa, Japan; [6]Tohoku University Graduate School of Pharmaceutical Sciences, Sendai, Japan.*

Background: Diabetic kidney disease (DKD) represents a major cause of ESRD. However, since it is difficult to identify patients who are at risk of progression, specific biomarker is needed.

Methods: 362 patients in a multi-center clinical study in diabetic nephropathy (U-CARE) with full data were selected. The plasma PS level was measured by LC–MS/MS. The correlation between the PS level and various factors was calculated using Spearman Rank-Order Correlation. Multiple regression analysis and logistic regression analysis were used to identify the factors independently associated with PS or the development of 2-year ACR deterioration, respectively.

Results: Participants had a mean age of 63.3 years and 56.9% were male. The blood glucose was 154.2 ± 56.4 mg/dl and the HbA1c was 7.2 ± 1.1 %. The eGFR was 73.8 (17.1 – 115.4) ml/min/1.73 m^2 and the albumin to creatinine ratio (ACR) was 11.0 (1.0 – 6407.4) mg/gCr. The serum PS level was 3.3 μM (0 – 68.1 μM) and suPAR was 460.8 (142.0. – 2740.2) pg/ml. The basal plasma PS level significantly correlated with ACR, eGFR, age, duration, HbA1c and uric acid, but not with suPAR. Multiple regression analysis revealed that ACR was the only factor that significantly correlated with PS. By stratified logistic regression analysis, in the microalbuminuria group, PS was the only factor related to the amount of change in the 2-year ACR in all models, with an odds ratio of 2.02 (CI: 1.04-3.92). ROC curve analysis further showed that a combination of suPAR

with known factors increased the c-statistics value and the value were further increased with the PS combination.

Conclusions: PS is related to ACR and could predict the 2-year ACR deterioration in DKD patients, especially with microalbuminuria (Nature Commun. 10: 1835, 2019).

The Acute Effect of Selonsertib on eGFR Is a Result of Creatinine Transport Inhibition, Not Alteration of Renal Function

Elijah J. Weber, Cara H. Nelson, Brian J. Kirby, Winnie Weng, Fang Chen, Uptal D. Patel, Anita Mathias. *Gilead Sciences, Inc., Foster City, CA.*

Background: Selonsertib (SEL) is a first-in-class small molecule inhibitor of apoptosis signal-regulating kinase 1 (ASK1) in clinical development for the treatment of diabetic kidney disease (DKD). As small, dose-dependent, and reversible increases in serum creatinine were observed across clinical studies, an analysis of in vitro and clinical data was conducted to identify and confirm the mechanism by which SEL decreases estimated GFR (eGFR) without changing measured GFR (mGFR).

Methods: In vitro studies assessed the potential for SEL and its inactive metabolite, GS-607509, to inhibit renal transporters (OCT2, MATE1, and MATE2K) and determined their IC_{50} values. Clinical studies in healthy subjects included a multiple ascending dose (MAD) study (SEL 1 to 100 mg or placebo, QD) to assess the effects of SEL on eGFR. Additionally, a mechanistic study (SEL 18 mg or placebo, QD) evaluated the effect of SEL on renal function using iohexol to measure GFR before, during, and after treatment for 2 weeks. Meta-analyses of clinical studies were conducted to quantify the magnitude and consistency of the acute effect across patient populations.

Results: Based on the 2017 FDA drug interaction guidance, SEL and GS-607509 demonstrate low potential for inhibition of OCT2 ($C_{max,u}/IC_{50} > 0.1$). SEL, but not GS-607509, is a potential inhibitor of MATE1 and MATE2K ($C_{max,u}/IC_{50}$ of > 0.02). In the MAD study, a dose-dependent reduction in eGFR was observed and was reversible upon washout of SEL (A). Results from the mechanistic study showed no change in mGFR for subjects taking SEL or placebo (B). Regardless of baseline eGFR, meta-analyses showed at the 18 mg dose, a consistent acute percent decrease (median 7.3%) in eGFR across patient populations.

Conclusions: The totality of data from in vitro and clinical studies indicate that the acute effect of SEL on eGFR is dose-dependent, reversible, and a result of inhibition of renal creatinine transporters without altering mGFR. Clinical trials evaluating the efficacy of SEL on slowing the loss of kidney function will need to account for these acute effects.

Genome-Wide Expression Quantitative Trait Loci Analysis for Circulating miR-1287-5p and miR-339-5p and ESRD in Type 1 Diabetes

Eiichiro Satake,[1] Marcus G. Pezzolesi,[2] Zaipul I Md Dom,[3] Kristina V. O'Neil,[1] Hiroki Kobayashi,[3] Katsuhito Ihara,[1] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]University of Utah, Salt Lake City, UT; [3]Joslin Diabetes Center, Harvard Medical School, Boston, MA.*

Background: microRNAs are short endogenous non-coding RNA molecules that are involved in gene regulation and play important roles in the pathogenesis of various kidney diseases. Previously, we identified risk and protective miRNAs (miR-1287-5p and miR-339-5p) strongly associated with progression to end stage renal disease (ESRD) in diabetes. To identify expression quantitative trait loci (eQTL) that influence plasma levels of these miRNAs and onset of ESRD in Type 1 diabetes (T1D), we performed a genome-wide miR-eQTL analysis.

Methods: Plasma levels of the two miRNAs were measured using HTG Molecular Diagnostics' EdgeSeq platform and genotyping of 325,735 single nucleotide polymorphisms (SNPs) was performed using Illumina's HumanCoreExome BeadArray in 240 T1D patients. Association analyses between plasma levels of miR-1287-5p and miR-339-5p were used to identify eQTL using linear regression implemented in PLINK. To assess the relationship between the candidate eQTLs and the development of ESRD, we applied logistic regression using an additive model in 437 T1D patients.

Results: Trans miR-eQTL analysis revealed that 13 SNPs that affect plasma levels of miR-1287-5p or miR-339-5p (P<5e-5). Among them, in logistic models, we identified 2 SNPs associated with onset of ESRD: rs4624519 in the LINC02033 (OR: 0.64 (95%CI=0.48-0.85); p=0.0024) and rs10963040 in the CNTLN gene (OR: 1.43 (95%CI= 1.04- 1.96); p=0.028).

Conclusions: We identified SNPs that have regulatory effects on circulating miRNAs and play roles in progression to ESRD in T1D.

The Circulating Exosomal MicroRNAs Related to Albuminuria in Patients with Diabetic Nephropathy

Hyoshik Kim,[1] Yon hee Kim,[1] Hyunjin Noh,[1] Moo Yong Park,[2] Soon hyo Kwon.[1] *[1]Soonchunhyang University Seoul Hospital, Soonchunhyang University Medical College, Seoul, Republic of Korea, Seoul, Republic of Korea; [2]Internal medicine, Soonchunhyang University Hosptial, Bucehon, Republic of Korea.*

Background: Diabetic nephropathy (DN) is associated with high risk of cardiovascular disease and mortality. Exosomal microRNAs (miRNAs) regulate gene expression in a variety of tissues and play important roles in the pathology of various diseases. We hypothesized that the exosomal miRNA profile would differ between DN patients and patients without nephropathy.

Methods: We prospectively enrolled 74 participants, including healthy volunteers (HVs), diabetic patients without nephropathy, and those with DN. The serum exosomal miRNA profiles of participants were examined using RNA sequencing.

Results: The expression levels of 107 miRNAs differed between HVs and patients without DN, whereas the expression levels of 95 miRNAs differed between HVs and patients with DN. Among these miRNAs, we found 7 miRNAs (miR-1246, miR-642a-3p, let-7c-5p, miR-1255b-5p, let-7i-3p, miR-5010-5p, miR-150-3p) that were uniquely up-regulated in DN patients compared to HVs, and miR-4449 that was highly expressed in DN patients compared to patients without DN. A pathway analysis revealed that these eight miRNAs are likely involved in MAPK signaling, integrin function in angiogenesis, and regulation of the AP-1 transcription factor. Moreover, they were all significantly correlated with the degree of albuminuria (figure 1).

Conclusions: Patients with DN have a different serum exosomal miRNA profile compared to HVs and these miRNAs may be promising candidates for the diagnosis and treatment of DN and cardiovascular disease.

Correlation between miRNAs and albuminuria

Mature miRNAs	albuminuria (r/p-value)
miR-1246	0.373/0.001
miR-642a-3p	0.362/0.002
let-7c-5p	0.428<0.001
miR-1255b-5p	0.240<0.039
let-7i-3p	0.300/0.009
miR-5010-5p	0.254/0.029
miR-150-3p	0.347/0.002
miR-4449	0.497/<0.001

TH-PO928

Hypoxia in Individuals with Type 1 Diabetes and Macroalbuminuria Is Associated with Autonomic Dysfunction

Jens christian Laursen,[1] Kim K. Clemmensen,[1] Christian S. Hansen,[3] Lars J. Díaz,[1] Per-Henrik Groop,[2] Marie Frimodt-Moller,[1] Luciano Bernardi,[2] Peter Rossing.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [3]Steno Diabetes Center, Gentofte, Denmark.*

Background: Blood oxygen saturation (SpO2) in the supine position is lower in individuals with type 1 diabetes (T1D) compared to healthy controls (CON). This has been suggested to be linked with cardiovascular autonomic dysfunction (CAD). Presence of CAD in individuals with T1D and diabetic nephropathy is associated with cardiovascular mortality. Our aims were to investigate SpO2 levels in individuals with T1D and different albuminuria-stages compared to CON and to explore associations between SpO2 and baroreflex sensitivity (BRS), a sensitive measure of CAD.

Methods: One-hundred-and-five individuals with T1D and normoalbuminuria (NORMO) and 24 individuals with T1D and macroalbuminuria (MACRO) were compared to 55 CON. SpO2 was measured with pulse oximetry first for one minute in the supine position and then for five minutes in the standing position. A linear mixed-effects model was fitted with SpO2 as outcome and albuminuria-status as exposure, adjusted for sex, age and smoking, with a random person effect. Association between SpO2 and BRS was tested with linear regression analysis and adjusted for albuminuria-status, sex, age and smoking.

Results: In CON, NORMO and MACRO respectively, mean (SD) age was 42.7 (12.6), 43.9 (11.1) and 58.6 (11.0) years; HbA1c was 33.2 (2.4), 63.9 (12.0) and 63.1 (11.7) mmol/mol; BRS was 15.2 (9.5), 13.8 (10.6) and 4.9 (3.2) ms/mmHg; plasma/serum creatinine was 78.3 (12.6), 67.6 (11.5) and 117.1 (53.1) µmol/L; and baseline SpO2 was 97.5 (1.4), 97.0 (1.4) and 96.2 (1.9) %. From supine to standing position, SpO2 increased in CON and NORMO, but not in MACRO. Overall, in mixed effects model mean difference in SpO2 between NORMO and CON was -0.7% (p=0.03) and mean difference in SpO2 between MACRO and CON was -1.4% (p<0.001). In all participants together, SpO2 was positively correlated with BRS (p=0.03).

Conclusions: Individuals with T1D and normoalbuminuria had lower SpO2 than healthy controls and the macroalbuminuria-group had even lower SpO2. SpO2 was positively correlated with BRS. Microvascular damage in lungs of individuals with macroalbuminuria may lead to hypoxia contributing to autonomic dysfunction. It remains to be investigated if low SpO2 contributes to excess cardiovascular mortality in individuals with T1D and diabetic nephropathy.

TH-PO929

Biomarker Identification for Diabetic Kidney Disease at the Early Stage

Haiyan Fu,[1] Shijia Liu,[2] Haili Zhu,[1] Lu Zhang,[3] Dong Zhou.[4] *[1]Renal Division, State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Division of Clinical Pharmacology, the affiliated hospital of Nanjing University of Chinese Medicine, Nanjing, China; [3]Renal Division, the affiliated hospital of Nanjing University of Chinese Medicine, Nanjing, China; [4]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage renal disease. As the most common microvascular complication of diabetes, DKD is a knotty clinical problem in terms of its diagnosis and management. Currently, renal biopsy remains the most reliable approach to distinguishing a true DKD, non-DKD, or mixed form. Our present study focuses on early biomarker identification to monitor the onset of DKD in type2 diabetes (T2D) patients. We expect the identified biomarker could eventually be translated into the solid backup resources to avoid invasive biopsy in patients.

Methods: Based on our previous findings, combine with the data refinery in public repository centers, we identified 3 proteins which play critical roles in the development of DKD, including Serum Amyloid A-1 (SSA1), matrix metalloproteinase-7 (MMP-7), and Tenascin C (TNC). We designed a standard cohort study by dividing the trial into 3 phases: training, testing, and validation phase. In the training phase, we enrolled 202 candidates including DKD or T2D or healthy adults from a single medical center. In the testing phase, we enrolled 680 patients at different stages of DKD or healthy adults from the same medical center. Serum SAA1, MMP-7, and TNC, urinary MMP-7 and TNC were measured. Two machine learning models, linear discriminant analysis (LDA) and support-vector machines (SVM), were applied in this study. The external validation is now pending.

Results: Compared with the healthy adults, serum and urinary SAA1, MMP-7, and TNC were significantly increased at each stage of DKD in patients. However, if directly compared with the T2D patients without kidney disease, none of the above markers could individually serve as an early warning marker to alert the onset of kidney disease in the T2D patients. The diagnostic outcomes analyzed by SVM were shown via the receiver operating characteristic (ROC) for the direct comparison between the T2D and the DKD patients at early stage. In SVM model, combined serum SAA1, MMP-7, and TNC provided area under curve at 0.95 between the T2D and the DKD early stage patients. In addition, a combination of serum SAA1 and MMP-7 is able to more precisely distinguish the boundary between the early and advance stages of DKD.

Conclusions: Analysis using SVM model by combining SAA1, MMP-7, and TNC in serum is promising to predict the onset of kidney complication in T2D patients.

TH-PO930

Association of Low Serum Adiponectin Levels with Aortic Stiffness in Patients with Diabetic Kidney Disease

Liang-Te Chiu,[1] Lin Lin,[1] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Adiponectin plays an important role in cardiovascular disease through its anti-inflammatory and anti-atherogenic properties. The purpose of the present study was to examine the clinical variables and the relationship between serum adiponectin levels and aortic arterial stiffness in diabetic kidney disease (DKD).

Methods: Fasting blood samples were obtained from 80 patients with DKD. DKD is identified clinically by persistently high urinary albumin-to-creatinine ratio (UACR) ≥ 30 mg/g and/or sustained reduction in estimated glomerular filtration rate (eGFR) below 60 ml/min per 1.73 m^2. Carotid-femoral pulse wave velocity (cfPWV) was measured by using pressure applanation tonometry. cfPWV values of > 10 m/s represented the high aortic arterial stiffness group, while values ≤ 10 m/s defined the control group, according to the ESH-ESC 2013. Serum adiponectin level was measured using an enzyme immunoassay.

Results: In total, 41 patients with DKD (51.3%) were defined as high aortic stiffness group. Compared to the control group, high aortic stiffness group had high prevalence of male gender (P = 0.043), older age (P = 0.011), higher systolic blood pressure (P = 0.002) and UACR (P = 0.007), whereas serum adiponectin level (P = 0.001) were lower. After adjusting for confounders, serum adiponectin level (odds ratio (OR): 0.930, 95% confidence interval (CI): 0.884–0.978, P = 0.005), age (OR: 1.089, 95% CI: 1.028–1.154, P = 0.004), and systolic blood pressure (OR: 1.040, 95% CI: 1.013–1.068, P = 0.004) were independent predictors of aortic stiffness. Multivariable analysis showed that the serum adiponectin level (β = -0.309, adjusted R^2 change = 0.087, P = 0.002) was negatively associated with cfPWV values in DKD patients. The area under the receiver-operating characteristic (ROC) curve predicting aortic stiffness by serum adiponectin level in DKD patients was 0.728 (95% CI: 0.617-0.822, P = 0.0001).

Conclusions: Among DKD patients, serum adiponectin level was inversely associated with cfPWV values and was independent predictor of aortic stiffness.

Feldman,[1] Jeffrey R. Schelling.[14] *[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [2]Tulane University, New Orleans, LA; [3]Brigham and Women's Hospital, Boston, MA; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Yale University, Woodbridge, CT; [6]UAB School of Medicine, Birmingham, AL; [7]UCSD, San Diego, CA; [8]University of Illinois at Chicago, Chicago, IL; [9]Johns Hopkins University, Baltimore, MD; [10]Tufts Medical Center, Boston, MA; [11]San Francisco VA Medical Center, San Francisco, CA; [12]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [13]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [14]Case Western Reserve University, Cleveland, OH; [15]The Children's Hospital of Philadelphia, Philadelphia, PA; [16]Boston University School of Medicine, Framingham, MA; [17]Tulane School of Medicine, New Orleans, LA.*

Background: DKD is the leading cause of end-stage kidney disease (ESKD) in the US. There is an unmet need for biomarkers to identify patients at high risk for DKD progression.

Methods: CRIC participants with diabetes, estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m^2, and plasma collected at baseline (N=1315) were eligible for this case-cohort study. Eligible participants were randomly selected for the subcohort (N=597); cases were all participants who developed DKD progression, defined as ESKD or 40% eGFR decline (N=538, 240 in the subcohort). Plasma biomarkers (KIM-1, TNFR-1, TNFR-2, MCP-1, suPAR, & YLK-40) were measured using a novel multiplex platform. Spearman correlations estimated relationships between markers, eGFR, and proteinuria. Weighted Cox regression models adjusted for age, sex, race, education, blood pressure, hsCRP, body mass index, smoking, eGFR, and proteinuria estimated the relation of markers with DKD progression. Mixed effects models estimated the relationship of markers with change in yearly eGFR.

Results: The median follow-up was 8.7 (6.4-9.3) years. The mean change in eGFR was -0.6 and -4.1 ml/min/1.73m^2 among non-cases and cases, respectively. TNFR-1 and TNFR-2 were the most correlated markers (ρ=0.85). All markers inversely correlated with eGFR. Higher marker levels associated with greater risk of DKD progression **(Table)**. Four markers associated with eGFR decline.

Conclusions: Higher plasma levels of KIM-1, TNFR-1, TNFR-2, MCP-1, suPAR, and YKL-40 were independently associated with increased risk of DKD progression. These biomarkers may yield prognostic and mechanistic value for future DKD research.

Funding: NIDDK Support

Adjusted associations of Plasma Biomarkers with DKD progression.

	ESRD or 40% decline in eGFR (HR, 95% CI)	Change in yearly eGFR ml/min/1.73m2 (β, 95% CI)
KIM-1	1.5 (1.2, 1.9)	-0.5 (-0.8, -0.2)
TNFR-1	2.1 (1.6, 2.8)	-0.4 (-0.7, -0.1)
TNFR-2	2.1 (1.5, 2.7)	-0.5 (-0.8, -0.2)
MCP-1	1.4 (1.2, 1.7)	-0.01 (-0.2, 0.2)
suPAR	1.7 (1.3, 2.2)	-0.3 (-0.6, 0.0)
YKL-40	1.4 (1.2, 1.6)	-0.4 (-0.6, -0.2)

Urine Myo-Inositol, the Novel Prognostic Biomarker for Diabetic Kidney Disease: A Targeted Metabolomics Study Using Nuclear Magnetic Resonance

Soie Kwon,[1] Jung Nam An,[2] Jeonghwan Lee,[3] Yong Chul Kim,[4] Dong Ki Kim,[5] Yon Su Kim,[6] Jung Pyo Lee.[2] *[1]Seoul national university, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [3]Department of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Republic of Korea; [4]SNUH, Seoul, Republic of Korea; [5]Seoul National University Hospital, Seoul, Republic of Korea; [6]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Estimated GFR (eGFR) and urine proteinuria are currently the strongest predictive biomarker of CKD regardless of the cause. For more precise prediction according to the cause of CKD and to identify treatment options, metabolomics has been increasingly applied to identifying new biomarkers of diseased specific CKD. We investigated the association between urine metabolites and ESRD progression in diabetic kidney disease (DKD) cohort.

Methods: Based on previous our animal study, targeted metabolomics (n=26) was performed using nuclear magnetic resonance. Prospectively stored urine samples consecutive patients with DKD stage 1 to 5 (n=208) and their healthy controls (n=26) were analyzed. Cross-sectional association between measured metabolites and eGFR were compared. Multivariate cox models were conducted for the risk of ESRD and mortality.

Results: ESRD occurred in 103 (44.0%) patients and the number of death was 65 (27.8%). The median fold change of metabolites compared with control groups, 7 metabolites (glucose, mannose, myoinositol, lactate, succinate, fumarate and choline) revealed a trend according to CKD stages. Linear regression identified myo-inositol is best-associated metabolite with eGFR. The relationship between competitive metabolites and outcomes was investigated by multivariate Cox models after adjusting for the baseline covariates (Table1). Of which, 4 metabolites (myoinositol, glycerol, fumarate, oxoisocaproate) had predictive value for ESRD and only myo-inositol retained predictive significance in mortality (aHR 1.004, 95% CI 1.002–1.006, p-value <0.001).

Conclusions: Our results suggest the myoinositol, previously defined as vitamin B8, can be a predictive biomarker to predict the risk of ESRD progression in DKD. Myoinositol, as a secondary messenger of insulin and confirmed safe compound, further mechanism study is needed.

Table 1. Risk of end-stage renal disease according to the urinary metabolites

Metabolites/Cr	Unadjusted			Model 1			Model 2		
	HR	CI	P	HR	CI	P	HR	CI	P
Myo-inositol	1.005	1.000-1.010	<0.001	1.003	1.001 - 1.005	0.001	1.003	1.001 - 1.005	0.011
Glycerol	1.004	1.000-1.010	0.009	1.004	1.001 - 1.008	0.007	1.005	1.001 - 1.009	0.022
Fumarate	1.076	0.840-1.380	0.022	1.093	1.007 - 1.187	0.033	1.105	1.014 - 1.204	0.023
Oxoisocaproate	1.374	0.750-2.520	0.034	2.147	1.557 - 2.959	<0.001	1.670	1.146 - 2.434	0.008

only 4 significant metabolites were described; Model 1: adjusted for age, sex, HTN, eGFR; Model 2: adjusted for model 1 plus laboratory findings

Angiotensin II Receptor Blocker (ARB) Alters the MicroRNA Profile of Extracellular Vesicles in Diabetic Nephropathy

Hyoshik Kim,[1] Yon hee Kim,[1] Hyunjin Noh,[1] Moo Yong Park,[2] Soon hyo Kwon.[1] *[1]Soonchunhyang University Seoul Hospital, Soonchunhyang University Medical College, Seoul, Republic of Korea, Seoul, Republic of Korea; [2]Internal medicine, Soonchunhyang University Hospital, Bucheon, Republic of Korea.*

Background: The renin-angiotensin system (RAS) is a major target of diabetes nephraphy therapy. Angiotensin II receptor blockers (ARBs) decrease proteinuria and mortality associated with diabetes nephropathy. Extracellular vesicles (EVs) contain miRNAs that play a role in cell-to-cell communication and are biomarkers of disease. Whether ARBs modulate miRNAs in EVs is not known.

Methods: We prospectively enrolled 6 ARB naïve patients (male=4, female=2) with diabetic nephropathy and hypertension along with age-sex matched healthy volunteers (HVs). After collecting baseline samples, an ARB (losartan 50 mg) was added to the patients' drug regimens. Serum EV microRNAs were profiled using RNA sequencing at baseline and 3 months after initiation of ARB therapy.

Results: RNA sequencing identified 130 miRNAs in the EVs from HVs and patients. ARB therapy decreased the expression of 5 miRNAs (miR-328-3p, miR-199a-5p, hsa-miR-16-5p, miR-1277-3p and miR-4284) in the EVs from patients. Expression of 3 miRNAs (miR-660-5p, miR-20b-5p and miR-143-3p) was increased after ARB therapy. Biological analysis identified the predicted involved pathways of the decreased miRNAs after ARB treatment (table 1).

Conclusions: Our study demonstrates that ARBs affect the expression of miRNAs in EVs from hypertensive patients. The change in expression of miRNAs in EVs due to ARB therapy is a novel aspect of the RAS. Further study is needed to identify the role of these miRNAs in diabetes.

The predicitve pathway of angiotensin receptor blocker responsive miRNAs

Polyols and Branched Chained Amino Acids Are Associated with Present and Future Renal Impairment in Type 1 Diabetes

Nete Tofte,[1] Tommi Suvitaival,[1] Kajetan Trost,[1] Ismo Mattila,[1] Simone Theilade,[2] Signe Abitz Winther,[1] Tarunveer S. Ahluwalia,[1] Marie Frimodt-Moller,[1] Cristina Legido quigley,[1] Peter Rossing.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Steno Diabetes Center, Hellerup, Denmark.*

Background: Improved understanding of the pathophysiology causing diabetic nephropathy is imperative. The aim of this study was to uncover associations between serum metabolites and renal outcomes in persons with type 1 diabetes.

Methods: In total, 637 persons with type 1 diabetes were included. Non-targeted serum metabolomics analyses were performed using two-dimensional gas chromatography coupled to time-of-flight mass-spectrometry. Longitudinal data at follow-up on development of renal events were obtained from national Danish health registries over a median of 5.5 years. A composite renal endpoint (n=123) consisted of estimated glomerular filtration rate (eGFR) decline from baseline (≥30%), development of end-stage renal disease (eGFR < 15 ml/min/1.73m^2, dialysis or renal transplantation) and all-cause mortality. Metabolites with significant associations (p<0.05) in cross-sectional analyses were analysed with Cox proportional hazards models for either specific or composite endpoint. Adjustments included traditional cardiovascular risk factors and correction for multiple testing.

Results: A data-driven partial correlation analysis revealed a dense fabric of co-regulated metabolites and clinical variables dominated by eGFR. After statistical analyses, ribonic acid and myo-inositol were inversely associated with eGFR and positively associated with macroalbuminuria (urinary albumin excretion rate (UAER) ≥ 300 mg/24h) (p<0.02). Longitudinally, ribonic acid was associated with the combined renal endpoint (HR 1.8, CI [1.3-2.3], p=0.001). Further, ribonic acid (HR 2.2, CI [1.6-3.0], p<0.001) and myo-inositol (HR 2.7, CI [1.6-4.3], p=0.001) were both associated with higher risk of eGFR decline ≥30%. The hydroxy butyrate 3,4-dihydroxybutanoic acid was cross-sectionally associated with micro- (UAER 30-299 mg/24h) and macroalbuminuria, UAER and inversely associated with eGFR (p<0.04), while branched chain amino acids were associated with eGFR and lower risk of the combined renal endpoint (p<0.02).

Conclusions: Alterations in serum metabolites, particularly polyols and amino acids, were associated with renal endpoints in type 1 diabetes highlighting molecular pathways associated with development of kidney disease.

Circulating Long Noncoding RNAs Are Associated with Diabetic Nephropathy and Normalize After Simultaneous Pancreas-Kidney Transplantation

Koen Groeneweg, Yu wah Au, Johan W. De Fijter, Anton J. Van Zonneveld, Marlies Reinders, Roel Bijkerk. *Leiden University Medical Center, Leiden, Netherlands.*

Background: Diabetes mellitus can lead to end-stage renal disease and cardiovascular injury. Simultaneous pancreas kidney transplantation (SPKT) replaces kidney function and restores endogenous insulin secretion. Circulating long noncoding RNAs (lncRNAs) are promising biomarkers in (cardiovascular) disease and can provide insight into pathogenesis. However little is known about these markers in vascular injury in the context of diabetic nephropathy (DN) and after SPKT.

Methods: We performed a pilot study of 40.173 lncRNAs in plasma of healthy controls and patients with diabetic nephropathy. Based on these results, as well as a dedicated literature search, we assessed 14 candidate lncRNAs of which 9 were detectable in plasma samples in DN (n=14), SPKT (n=35) and healthy controls (n=15). All DN patients were studied longitudinally before and 1, 6 and 12 months after SPKT. LncRNAs that were detected in less than 95% of the samples were excluded from the study. Angiopoietin-2 and soluble thrombomodulin (sTM) were measured using ELISA as a markers for vascular injury.

Results: MALAT1 was significantly higher (p=0.002) in patients with DN (median 13.8, IQR 2.9-16.3) compared with healthy controls (median 0.16, IQR 0.1-1.3). The first month after SPKT MALAT1 normalized from 13.8 to 0.3 (p=0.012). EPHA6, LIPCAR

and G003293 showed a similar pattern with significant decline after SPKT (resp. p=0.01, p=0.01 and p=0.04). Interestingly we observed a strong correlation between MALAT1, EPHA6 and LIPCAR with blood pressure and vascular injury marker sTM.

Conclusions: Circulating lncRNAs associate with DN and vascular injury and normalize after SPKT. As such, lncRNAs are potentially interesting biomarkers for disease progression in diabetic nephropathy and may provide insight into the underlying pathophysiology.

TH-PO936

Systemic Inflammation Precedes New-Onset Microalbuminuria in Diabetes Mellitus Type II: A Post Hoc Analysis of the ROADMAP Study

Christos D. Chatzikyrkou,[1] Jan Menne,[2] Sabine Brandt,[3] Anja Bernhardt,[4] Peter R. Mertens,[4] Hermann G. Haller,[2] Florian G. Scurt.[5] *[1]Universitaetsklinikum Magdeburg, Magdeburg, Germany; [2]Medical School Hannover, Hannover, Germany; [3]University Hospital Magdeburg, Magdeburg, Germany; [4]Universitätsklinikum Magdeburg, Magdeburg, Germany; [5]Otto von Guericke University Magdeburg - Medical Faculty, Magdeburg, Germany*.

Background: The aim of the case-control study was to investigate if serum biomarkers indicative of vascular inflammation and endothelial dysfunction can predict the development of microalbuminuria in patients with diabetes mellitus type II.

Methods: Amongst participants enrolled in the **ROADMAP** (Randomized Olmesartan And Diabetes MicroAlbuminuria Prevention) and observational follow-up (**OFU**) studies, a panel of 15 serum biomarkers was quantified from samples obtained at initiation of the study and tested for associations with the development of new-onset microalbuminuria (defined as a urinary albumin to creatinine ratio (UACR) of more than 35 mg/g in women or more than 25 mg/g in men) during follow-up. A case-control study was conducted with inclusion of 172 patients with microalbuminuria and 188 matched controls. Non-parametric inferential, nonlinear regression, mediation and bootstrapping statistical methods were used for the analysis

Results: The median follow-up time was 37 months. At baseline, mean concentrations of CXCL-16, TGF-β1 and angiopoietin-2 were higher in patients with subsequent microalbuminuria. In the multivariate analysis, after adjustment for age, sex, BMI, HbA1c, duration of diabetes, LDL, smoking status, blood pressure, baseline UACR, eGFR, time of follow-up and cardiovascular disease, CXCL-16 (OR 2.60, 95% CI 1.71-3.96), angiopoietin-2 (OR 1.50, 95% CI 1.14-1.98) and TGF-β1 (OR 1.03, 95% CI 1.01-1.04) remained significant predictors of new-onset microalbuminuria (p<0.001). Inclusion of these biomarkers in conventional clinical risk models for prediction of microalbuminuria increased the AUC from 0.638 to 0.760 (p <0.001).

Conclusions: In type II diabetes patients elevated plasma levels of CXCL-16, angiopoietin-2 and TGF-β1 are independently predictive of microalbuminuria. Thus, these serum markers improve renal risk models beyond established clinical risk factors.

TH-PO937

Soluble Urokinase Receptor Level as Biomarker in Biopsy-Confirmed Diabetic Nephropathy

Gabriela Lupusoru,[1] Andreea G. Andronesi,[1] Ioana Ailincai,[1] Georgia Micu,[1] Bogdan M. Sorohan,[1] Bogdan Obrisca,[1] Mircea Lupusoru,[2] Georgiana Fratila,[1] Oana Ion,[1] Danut Andronesi,[1] Gener Ismail.[1] *[1]Fundeni Clinical Institute, Bucharest, Romania; [2]UMF Carol Davila Bucharest, Bucharest, Romania*.

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease worldwide associated with significant cardiovascular morbidity and mortality. The serum levels of soluble form of podocyte membrane urokinase activator receptor (suPAR) were found to be significantly elevated in patients with DN, making it a potential biomarker for assessing the severity of disease in these patients. The aim of this study was to explore the association between suPAR levels and renal pathological findings in patients with biopsy-confirmed DN.

Methods: We performed a cross-sectional study on 33 patients with biopsy-confirmed DN admitted in our department. The following clinical variables and laboratory parameters were assessed at the time of kidney biopsy: age, gender, time since DM diagnosis, BMI, arterial blood pressure (BP) values, treatment, serum creatinine, estimated glomerular filtration rate (eGFR, calculated by CKD-EPI equation), 24-hour proteinuria and suPAR levels. Histological scoring was made according to that of Tervaert et al (JASN, 2010, 21 (4) 556).

Results: 33 patients were included (8 F, 25 M), with mean age 56.6±11.5 y, BMI 28,1±4,3 kg/m2, DM1 (n=4) and DM2 (n=29), months since DM diagnosis (140.7±87.9 mo), hypertensive (n=30), SBP(151.5±24.3mmHg), DBP (83.7±11,1 mmHg), eGFR (34.4± 24.8 ml/min), serum creatinine (2.74± 1.78mg/dl), 24-hour proteinuria (2.64±2.9g/l), ACEI or ARB use (20/33). Serum suPAR levels were 7.41±3ng/ml. SuPAR levels were positively correlated with age of diabetes (r=0.363, p=0.038), serum creatinine (r=0.493, p=0.004), degree of glomerulosclerosis (r=0.405, p=0.024), degree of tubular atrophy/interstitial fibrosis (r=0.740, p<0.001), degree of arteriosclerosis (r =0.694, p<0.001), and negatively correlated with eGFR (r = -0.675, p<0.001).

Conclusions: Our study confirmed the presence of high serum levels of suPAR in patients with DN and we suggested that these are associated with age of DM, renal function, degree of glomerulosclerosis, tubular atrophy/interstitial fibrosis and arteriosclerosis. Serum suPAR might be a useful biomarker for assessing severity of renal impairment in DN, but requires future validation on larger series of patients

TH-PO938

Association of Angiogenesis Markers with Kidney Outcomes in Patients with Type 2 Diabetes

Kinsuk Chauhan, Divya A. Verghese, Neha Debnath, Lili Chan, Girish N. Nadkarni, Steven G. Coca. *Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Deregulated angiogenesis may play a key role in kidney disease in type 2 diabetes (T2D). We assessed the associations of 7 angiogenesis biomarkers with kidney outcomes in a contemporary clinical cohort.

Methods: We used banked plasma specimens from a cohort of patients with T2D from the EMR and USRDS-linked Mount Sinai Bio*Me* Biobank (n=870). We measured the angiogenesis biomarkers (FLT-1, PIGF, TIE-2, VEGF, VEGF-C, VEGF-D, and bFGF) in plasma specimens banked from the time of enrollment in Bio*Me* using the Mesoscale multiplex platform. Using multivariable Cox Regression, we evaluated the association of biomarkers with a composite kidney outcome of sustained 40% decline in eGFR or ESRD. We also examined the association between biomarker ratios (FLT-1/PIGF and combination of VEGF, VEGF-C, VEGF-D) with kidney outcomes.

Results: Median follow-up time for the population was 4.5 (IQR, 3.3-6.1) years, baseline eGFR was 68 (IQR, 55-80) ml/min/1.73 m^2, and UACR was 13 (IQR, 4-66) mg/g. After adjusting for demographics, comorbidities, medications, and baseline eGFR, PIGF (adjusted HR 2.1 per doubling; 95% CI 1.5-3.1) and FLT-1 (adjusted HR 1.6 per doubling; 95% CI 1.1-2.2) were independently associated with the kidney outcomes (Figure). However, when adjusted for TNFR1, TNFR2, and KIM-1, the independent associations between biomarkers and the kidney outcomes were attenuated to null. There were no associations between the biomarker ratios and kidney outcomes.

Conclusions: Higher baseline plasma PIGF and FLT-1 are associated with kidney outcomes during follow-up in patients with T2D. Since models including TNFR1, TNFR2, and KIM-1 nullified the association of FLT-1 and PIGF with kidney outcomes, this indicates the possibilities of shared pathways between these biomarkers. More studies are needed to find a definite association between these biomarkers and kidney outcomes in T2D population.

Characteristics of 24-Hour Ambulatory Blood Pressure in Non-Dialysis Patients with Diabetic Kidney Disease

Xiaoqiu Chen, Shicong Song, Qiongxia Deng, Ruowei Wen, Cheng Wang. *The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai, Guangdong, China*.

Background: Data about characteristics of 24-hour ambulatory blood pressure in non-dialysis patients with diabetic kidney disease was limited.

Methods: We monitored 24-hour ambulatory blood pressure in non-dialysis patients with diabetic kidney disease from the nephrology division, the fifth affiliated hospital of Sun Yat-Sen University from August 2000 to October 2018, and compared with primary chronic glomerulonephritis patients matching in age(±5 years old), sex and CKD stages. The target organ damages were measured by carotid intima-media thickness, left ventricular hypertrophy, diastolic dysfunction, eGFR<60ml/min and massive proteinuria. Blood pressure loads, circadian rhythm and target organ damages in two groups were evaluated and compared. Multivariate logistic analyses were used to evaluated the relationship between blood pressure loads and target organ damage parameters.

Results: 202 patients with diabetic kidney disease were enrolled in this study. The mean age of the patients was 57±9 years and 66.3%(134/203)were men. Compared with control patients, patients with diabetic kidney disease had a higher level of systolic blood pressure in clinic, daytime, nighttime or 24-hour ambulatory measurement. They also had a higher proportion in reversed dippers(34.2% vs. 24.8%,*P*=0.038) and target organ damage evaluations, like the carotid intima-media thickness(69.3% vs. 26.2%,*P*<0.001), left ventricular hypertrophy(63.4% vs. 50.0%,*P*=0.009), diastolic dysfunction(74.3% vs. 46.0%,*P*<0.001) and massive proteinuria(51.0% vs. 25.7%,*P*<0.001). Multivariate logistic analyses, which included both clinic and ambulatory blood pressure, showed that only 24-hour systolic blood pressure independently predicted significantly the target organ damage.

Conclusions: Patients with diabetic kidney disease had a higher systolic blood pressure loads, a higher percentage of reversed dippers and a more severe target organ damage. 24-hour systolic blood pressure was independently associated with target organ damage.

TH-PO940

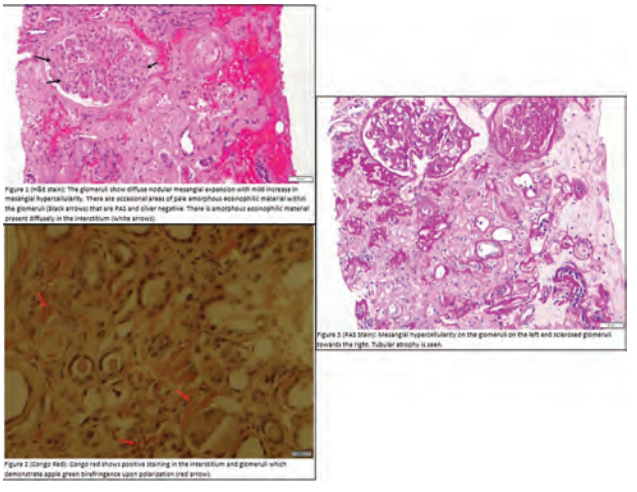
The Triple Whammy: An Unexpected Case of Leukocyte Chemotactic Factor 2 Amyloidosis (ALECT2) with Diabetic and Hypertensive Nephropathy

Tanvi Nandani Tarun,[1] Preethi Yerram,[2] Mariam P. Alexander.[3] *[1]University of Missouri - Columbia, Columbia, MO; [2]University of Missouri, Columbia, MO; [3]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Introduction: Amyloidosis is a disorder resulting from abnormal deposition of misfolded beta-sheet fibrils. ALECT2 is a recently identified entity with high incidence in certain ethnic populations.

Case Description: A 56 year old Hispanic female with history of Diabetes Mellitus (not on therapy for a few years), presented with lower extremity edema and elevated blood pressure. Patient was noted to have nephrotic range proteinuria of >4 gm/day, and elevated Creatinine of 3.6 mg/dl. Serological work up for glomerulonephritis was negative. We proceeded with kidney biopsy given lack of proper explanation for her presentation. Biopsy showed evidence of amyloid deposition, but in the context of negative immunofluorescence study, and patient's ethnicity, LECT2 type amyloid deposition was suspected, which was further identified by Liquid Chromatography (LC) with tandem Mass Spectrometry (MS). Renal biopsy also showed changes consistent with diabetic and hypertensive nephropathy.

Discussion: ALECT2 mostly involves the liver and kidneys. Renal involvement usually presents with slow, progressive renal failure, bland urine sediment, and variable proteinuria. Prognosis of ALECT2 is better than other forms of Amyloidosis, with 1/3rd of patients progressing to ESRD. Renal transplant is an option, but the disease can recur in the transplanted kidney. Our case report demonstrates the need to maintain a high degree of suspicion for ALECT2 in patients of certain ethnicities such as Hispanics, presenting with renal impairment, bland urine, and variable proteinuria. In addition, it is very important to accurately identify the amyloid deposits by LC/MS on the renal biopsy to prevent misdiagnosing ALECT2 as AL amyloidosis, and avoid potentially harmful investigations/therapy.



TH-PO941

A Case of Fibrillary Glomerulonephritis with a High Level of Myeloperoxidase-ANCA

Tomohiko Asakawa, Makoto Araki. *Suwa Central Hospital, Chino, Japan.*

Introduction: Gross hematuria with renal dysfunction suggests the possibility of rapidly progressive glomerulonephritis (RPGN) and requires urgent attention. Anti-neutrophil cytoplasmic antibody (ANCA)- associated vasculitis (AAV) represents RPGN and is characterized by elevated serum ANCA levels and pauci-immune crescentic glomerulonephritis. But it is well known that the presence of a high titer of ANCA does not imply the presence of disease.

Case Description: A 71 year-old woman was admitted with the chief complaint of gross hematuria. Her laboratory values indicated a Cr 1.52 mg/dl and advanced proteinuria of 7.5 g/g·Cr. There was no fever, and her white blood cells were within the normal range. Further examination revealed a high myeloperoxidase (MPO) -ANCA level (96.6 U/ml, normal < 3.5), no monoclonal proteins, and normal complement levels. Thus, a renal biopsy was performed; it showed mesangial proliferation in all 13 glomeruli and crescents formation in 5 glomeruli. Immunofluorescent staining was positive for IgG, C3, and C1q. The deposition of fibrils was recognized in the glomerulus by electron microscopy. In addition, immunohistochemical staining for DNA-J heat shock protein family member B9 (DNAJB9) was strongly positive in the glomerulus. These results indicated the presence of fibrillary glomerulonephritis (FGN). Hence, we performed induction therapy with prednisolone and intravenous cyclophosphamide, and subsequently the patient's renal function improved.

Discussion: From the histological findings, it was considered that the patient's renal dysfunction was caused by either FGN alone or from concomitant AAV and FGN. FGN is a rare disease found in 1% of renal biopsies. Although renal damage of FGN is caused by immune complexes, only approximately 17% of the cases are positive for M-protein, and 2% have hypocomplementemia. As the diagnosis required electron microscopy examination, some cases may have been overlooked. DNAJB9, a recently discovered histological marker of FGN, is expected to improve diagnosic accuracy and therefore increase the number of reported cases.

TH-PO942

A Rare Case of Dual Glomerulopathy: Fibrillary Glomerulonephritis (FGN) and Membranous Nephropathy (MN) in a Patient with Chronic Inflammatory Demyelinating Polyneuropathy

Sheikh Raza Shahzad,[1] Elvira Gosmanova,[2] Llewellyn A. Foulke,[1] Krishnakumar D. Hongalgi.[1] *[1]Albany Medical Center, Albany, NY; [2]Stratton VA Medical Center and Albany Medical College, Albany, NY.*

Introduction: FGN is a rare glomerular disease characterized by random fibrillary deposits. Usually idiopathic, it can be associated with malignancy, monoclonal gammopathy, or autoimmune disease. Its association with MN with CIDP is rare.

Case Description: A 68-year-old Burmese female presented with lower extremity edema and paraparesis of a 3-month duration. Her history was significant for latent tuberculosis, HTN and uncontrolled DM2 (last A1c of 14.5%). On exam, hypertension, renal anasarca and paraparesis were noted. Labs were significant for hypoalbuminemia (1.8) and nephrotic range proteinuria (6.8g/24hr). Serum Cr was at baseline (0.6). ANA (320), C3, C4, and Kappa/Lambda ratio (1.86) were mildly elevated. HIV, hepatitis panel, RPR, anti-dsDNA Abs, SPEP, UPEP, antiphospholipid Abs, cryoglobulins were negative. CT scan showed left renal vein thrombus. Electromyography showed mixed axonal polyneuropathy and she was diagnosed with CIDP. Renal biopsy revealed diffuse mild mesangial expansion, Congo red negative. No Kimmelstiel-Wilson nodules were seen. Immunofluorescence (IF) demonstrated diffuse granular capillary and mesangial staining for IgG (3+), C3 (2+), IgA (1+), C1q (trace), kappa (4+) and lambda (4+). IF staining for M-type PLA2R showed 3+ diffuse, granular staining predominantly in subepithelial distribution. EM showed segmental mild BM thickening and subepithelial granular deposits with diffuse effacement of foot processes (>90%). In addition, there were regions of mesangial and para-mesangial intramembranous non-branching fibrillary deposits, 12-28nm in diameter. The renal disease was treated with furosemide, lisinopril, prednisone, and tacrolimus with improvement in proteinuria and lower extremity edema. CIDP was treated with IVIG. The patient is currently in clinical remission with stable CKD4.

Discussion: While FGN may have granular subepithelial deposits that mimic MN, positivity for anti-PLA2R is unique, suggesting dual glomerulopathy with coincidental Primary MN. FGN associated with MN in the setting of CIDP is very rare. More studies are needed to help understand these complex associations.

TH-PO943

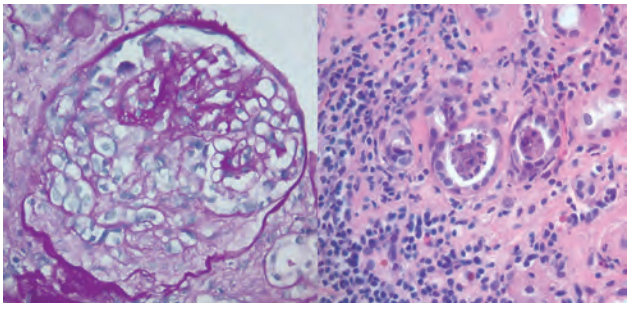
IgA Nephropathy Associated with Intravesical Bacillus Calmette-Guerin: A Case Report

Kyrstin Alexander,[1] Vijay Vanguri,[2] Kenneth M. Ralto.[2] *[1]UMASS Memorial Renal Medicine, Worcester, MA; [2]University of Massachusetts Medical School, Worcester, MA.*

Introduction: BCG immunotherapy has remained crucial in the treatment of non-muscle invasive bladder cancer. Serious systemic complications can occur including granulomatous inflammation in various organs (BCGosis), reactive arthritis, and disseminated BCG. We present a unique case of BCGosis associated with new onset IgA nephropathy (IgAN).

Case Description: A 79 year-old man with type 2 diabetes, chronic kidney disease stage 3A received intravesical BCG therapy two months prior to presentation and developed caseating granulomas of the liver thought secondary to *Mycobacterium bovis* abdominal infection. He subsequently presented with altered mental status, dyspnea, abdominal pain, and acute kidney injury two weeks after starting antitubercular therapy. RIPE therapy was discontinued, however his creatinine continued to rise. He developed uremic symptoms with a creatinine peaking at 4.0 mg/dL, nephrotic-range proteinuria and an active urine sediment with many dysmorphic RBCs and mixed cellular cell casts. Prednisone 50 mg daily was started, and a kidney biopsy was arranged. Serologic evaluation was unremarkable and complement levels were normal. Renal biopsy showed focally crescentic IgAN with acute tubular injury and focal necrosis (Figure). He was continued on a prolonged steroid taper and lisinopril was started. After several months his creatinine had improved to 2.70 mg/dL.

Discussion: This is the first reported case of IgAN associated with intravesical BCG therapy. Treatment is challenging given the need to balance immune suppression with antitubercular treatment. BCGosis is a rare but serious complication of BCG therapy and has been associated with other renal pathology including granulomatous interstitial nephritis, Henoch Schönlein purpura and membranous nephropathy.



TH-PO944

A Rare Case Report of Systemic Lupus Erythematosus (SLE) with Acute Nephritis, Antineutrophil Cytoplasmic Antibody (ANCA)-Associated Vasculitis, and Thrombotic Thrombocytopenic Purpura (TTP)

Solomiia Savedchuk,[1] Sohail Farshad,[3] Dillon Karmo,[1] Alexandra Halalau,[2] Abhishek Swami.[4] *[1]Beaumont Health, Royal Oak, MI; [2]Beaumont Hospital, Troy, MI; [3]Beaumont Health System, Royal Oak, MI; [4]Southeast Michigan Kidney Center, Troy, MI.*

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a potentially fatal disorder that requires urgent identification and treatment. The association of TTP with systemic lupus erythematosus (SLE) and vasculitis has been reported, however, never simultaneously.

Case Description: A 33-year-old woman with history of SLE presented with acute abdominal pain, fever, arthralgias, and skin rash. She had acute severe hypertension, diffuse abdominal tenderness, and petechial rash. Diagnostic work-up revealed active urine sediment with proteinuria and hematuria, elevated creatinine, anemia, and thrombocytopenia. She was diagnosed with acute lupus nephritis and early microangiopathic hemolytic anemia in the setting of hypertensive urgency and started on intravenous methylprednisolone 500 mg once a day. Within 48 hours she developed shock with multiorgan dysfunction and succumbed to her illness. Laboratory tests later showed ADAMTS13 activity less than 10% consistent with TTP and p-antineutrophil cytoplasmic antibody (ANCA) positivity. Autopsy revealed small vessel vasculitis of the visceral organs. Kidney biopsy demonstrated diffuse proliferative glomerulonephritis.

Discussion: This case illustrates the occurrence of SLE nephritis, p-ANCA vasculitis, and severe TTP with rapidly fatal course, and the importance of having a low threshold for initiating plasma exchange therapy. Based on our literature search, this is the first case to report on these three afflictions occurring at the same time. The nonspecific signs and symptoms of TTP may hamper a physician's ability to suspect it on clinical grounds alone, especially in patients with underlying autoimmune conditions. Therefore, when patients with SLE present with thrombocytopenia and features of MAHA, the possibility of TTP should be considered with prompt initiation of empiric plasmapheresis while awaiting test results for confirmation.

TH-PO945

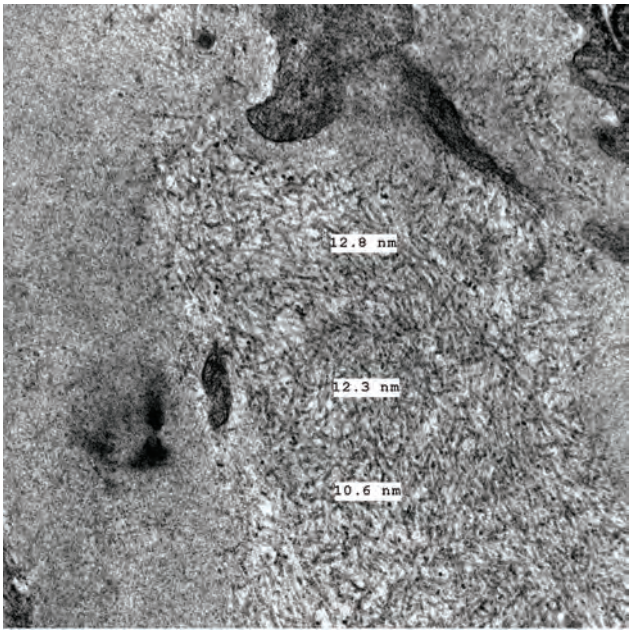
Leukocyte Chemotactic Factor 2 Amyloidosis (ALECT 2) in a Young Female

Obiajulu Kanu,[1] Sheikh B. Khalid,[2] David Howell,[4] Koyal Jain.[3] *[1]UNC Hospitals, Nephrology, Chapel Hill, NC; [2]UNC at Chapel HIll, Chapel Hill, NC; [3]University of North Carolina Kidney Center, Chapel Hill, NC; [4]Duke University and Durham VA Hospitals, Durham, NC.*

Introduction: ALECT2, initially described in 2008 is now the third most common cause of renal amyloidosis. Patients typically present in the seventh decade of life. We describe a unique case of ALECT2 presenting in a young female after a previous biopsy diagnosis of IgA Nephropathy.

Case Description: A 46-year-old Hispanic female with CKD 3 due to IgA nephropathy was evaluated for rising creatinine from 1.7 to 2.7 mg/dL and proteinuria (Urine protein/creatinine 3.5 g/g). She was on losartan, triamterene-hydrochlorothiazide. Repeat kidney biopsy showed moderate to severe interstitial fibrosis and tubular atrophy with 70% globally sclerotic glomeruli on light microscopy. Immunohistochemistry was positive for Ig A and equivalent lambda and kappa stains. Electron microscopy revealed abundant fibrillary deposits and a Congo red stain for amyloid was strongly positive. Liquid chromatography mass spectrometry analysis was consistent with ALECT2 amyloidosis. She was referred to an Oncologist and placed on doxycycline based on evidence of amyloid resorption from studies of other amyloid subtypes. Her creatinine improved (1.7-2mg/dl) although with persistently elevated proteinuria at 3.7g/day.

Discussion: Most cases of ALECT2 described are in older population and it is unclear if age at diagnosis affects prognosis. There is yet no specific treatment for ALECT2. For patients who progress to ESRD, renal transplantation has been shown to be a good therapeutic option. So far, very few studies have described patients with IgA nephropathy and ALECT2. We describe an uncommon case in a young patient, and it highlights the need for thorough re-evaluation of patients with acutely worsening renal function or proteinuria, in the setting of known renal disease. A repeat biopsy is often required in such cases as a different pathology is a possibility.



TH-PO946

IgA Nephropathy in Patients with Psoriatic Arthritis: A Case Series and Systematic Review of the Literature

David Steinmetz,[1] Maylene K. Qiu,[1] Matthew Palmer,[1] Jonathan Dunham,[1] Jonathan J. Hogan.[2] *[1]University of Pennsylvania, Woodbridge, CT; [2]Hospital of the University of Pennsylvania, Haddonfield, NJ.*

Introduction: There are cases in the literature of patients with IgAN and PsA, leading to the hypothesis that they may be biologically associated. Here, we present 2 cases and a systematic review of the literature of IgAN coexisting with PsA.

Case Description: Case 1: A 26 year-old man with a history of psoriasis in childhood was diagnosed with PsA at age 20 after developing back pain and bilateral dactylitis. NSAIDs and leflunomide were ineffective, but arthralgias improved on oral methotrexate and adalimumab. SCr was 1.1-1.3 mg/dL (eGFR 52 mL/min) and UA showed 2+ blood, trace protein, 10-20 RBCs/hpf and no WBCs. UPCR ranged from 100-300 mg/g. Microhematuria persisted and Cr increased to 1.6. A kidney biopsy showed IgAN (Oxford M1, E1, S0, T0, C1). He continued on methotrexate and adalimumab; 3 years later, SCr is 1.1, he has normal proteinuria and no hematuria. Case 2: A 56 year-old woman had severe psoriasis since childhood and a 10-year history of PsA (axial and non-axial joints) controlled with infliximab until she stopped treatment due to atypical mycobacterial pneumonia. She then presented with AKI requiring hemodialysis. Kidney biopsy showed IgAN (M1, E1, S1, T0) and AIN, attributed to rifampin or ethambutol. She was treated with prednisone and recovered kidney function after 20 days. One year later, she presented with shortness of breath, edema, eGFR 9 mL/min, UPCR 3.64, and microhematuria. Repeat kidney biopsy showed IgAN (M1, E1, S1, T1). She was treated with steroids and cyclophosphamide, with improvement to eGFR 22 mL/min. Four months later, she expired with unknown cause of death.

Discussion: Literature Review Our systematic review of the literature identified 16 additional cases of coexisting IgAN and PsA dating back to 1982. Including our two, the cases comprise 14 male and 4 female patients from the USA, Europe, and Japan. Median age of diagnosis of PsA and IgAN were 42 and 47, respectively, with only 1 pediatric case. PsA predated IgAN in 10 patients (median time from PsA to IgAN diagnosis in these patients 5 years). Serum IgA levels were elevated in 7/8 patients for whom this was described. There is heterogeneity in these patients' presentations, treatments, and outcomes. Conclusion Further study is warranted to determine whether there is a pathophysiological link between IgAN and PsA.

TH-PO947

The Cryo Menace

Sri Mahathi P. Kalipatnapu,[2] Chandra Kanth Chaturvedula,[1] Maria M. Picken,[1] Julia Schneider.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Macneal Hospital, Berwyn, IL.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) and cryoglobulinemia is a well-recognized complication of HCV infection. We present an interesting case of persistent cryoglobulinemia and MPGN despite sustained remission of hepatitis C treated with Harvoni (direct-acting antiviral).

Case Description: 56 year old man with a history of Hepatitis C cirrhosis, previously treated with Harvoni, was referred for proteinuria and hematuria. Besides mildly elevated transaminases and indirect Bilirubin, his metabolic profile was unremarkable. Protein creatinine ratio was 2gm/gm. Hepatitis C PCR was undetectable. Serology showed low complement levels and normal values of HbA1c, ANA, Anti ds-DNA, ANCA,

Anti-PLA2R abs, and hepatitis B and C antibody. Serum and urine, protein electrophoresis with immunofixation, failed to reveal any monoclonal proteins. Interestingly, cryoglobulins were detected in the serum and a renal biopsy demonstrated membranoproliferative glomerulonephritis with abundant, non-organized, predominantly subendothelial deposits (Fig A)

Discussion: MPGN is a pattern of glomerular injury that is characterized by mesangial hypercellularity, endocapillary proliferation, and double-contour formation along the glomerular capillary walls associated with cryoglobulinemia and Hepatitis C infection. Treatment with direct-acting antivirals (DAA) has curative sustained viral response (SVR), which has been shown to demonstrate cryoglobulinemic quiescence. Our case is unique given the persistence of circulating cryoglobulins and continued glomerular injury, despite SVR. Case of vasculitis and DAH in a patient with Hepatitis C treated with Harvoni was previously reported. This probably suggests that these antibodies propagate disease activity independent of HCV RNA load. Treatment with immunosuppression may be warranted, if there is nephrotic range proteinuria, a reduced estimated glomerular filtration, and/or severe histologic changes such as crescents on renal biopsy.

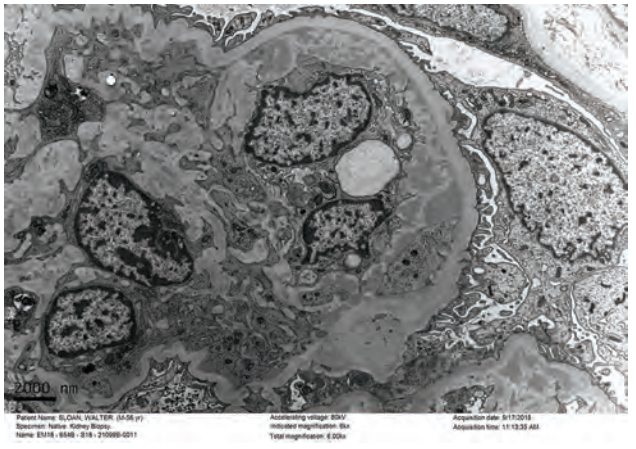


Fig A

TH-PO948

Acute Lupus Hemophagocytic Syndrome as Initial Presentation of Membranous Lupus Nephritis: Case Report with Successful Treatment

Sajid Q. Ansari,[1] Prasanth Lingamaneni,[2] Albert M. Osei,[2] Juan D. Sarmiento,[3] Erica R. Vormittag-Nocito.[4] *[1]University of Illinois at Chicago, Chicago, IL; [2]John H. Stroger Jr. Hospital of Cook County, Flossmoor, IL; [3]John H. Stroger Jr. Hospital, Chicago, IL; [4]University of Illinois, Chicago, IL.*

Introduction: Acute Lupus Hemophagocytic Syndrome(ALHS) is a rare entity. It is highly unusual to diagnose lupus nephritis in an adult presenting as ALHS. Both ALHS and SLE responded well to therapy with MMF with steroids, which has rarely been described in literature

Case Description: 40-year-old Hispanic lady with fibromyalgia, hypothyroidism and hypertension, presented with fever, weakness, myalgia and photosensitivity. Physical examination was significant for alopecia and 3/5 muscle strength in lower extremities. No evidence of synovitis or organomegaly. Investigation: creatinine 0.4, albumin 2.4, AST 168, ALT 52, LDH 387, ALP 108, triglycerides 674, ferritin 3211, hemoglobin 7.1, WBC 0.9, platelets 127, ANA+ (>1:160), +dsDNA, +smithAb, low C3 and C4. UA was positive for RBC and protein. Urine protein/creatinine ratio was 1.2g/day. Bone marrow biopsy was done, showing erythrophagocytosis. Soluble IL-2 receptor (CD25) level and CD8 immune competence panel were normal. She fulfilled SLICC criteria for SLE. Renal biopsy showed membranous lupus nephritis class V She was started on prednisone 60 mg daily and MMF 500 mg twice a day and later increased to 1000 mg twice a day and gradually, prednisone was tapered down to 5 mg daily. Significant improvement in symptoms noted and labs including ferritin, triglycerides and blood counts bacame normal and protenuria resolved.

Discussion: HLH (Hemophagocytic lymphohistiocytosis) is a life-threatening disorder associated with high mortality Secondary HLH results from underlying infectious, malignant and autoimmune conditions. When HLH is attributed to SLE, it is called Acute Lupus Hemophagocytic Syndrome(ALHS). Incidence of HLH in SLE is estimated to be around 0.9% to 4.6% with a mortality rate varying from 5% to 35%. Clinical manifestations include high-grade fever, hepatosplenomegaly, lymphadenopathy and coagulopathy. Abnormal laboratory findings include cytopenias, hyperferritinemia and hypertriglyceridemia. There are no randomized trials to guide therapy. Treatment in ALHS is aimed at managing the underlying condition. If unresponsive Etoposide is used. This case highlights the importance of early recognition of ALHS, to prevent high morbidity and mortality. MMF and prednisolone induction and maintenance therapy is a viable option in patients with ALHS

TH-PO949

Minimally Proliferative Glomerulonephritis with Mesangial Deposition of Monoclonal IgM Lambda in a Patient with Marginal Zone Lymphoma and Acute Hepatitis C

Sudip Ghimire,[1] Jason R. Pettus,[2] Martha L. Graber.[1] *[1]Dartmouth Hitchcock Medical Center, Hanover, NH; [2]Dartmouth-Hitchcock Medical Center, Lebanon, NH.*

Introduction: We present an unusual renal manifestation of splenic marginal cell lymphoma and hepatitis C virus infection.

Case Description: A 57 year-old man presented with recurrent angio-edema. Abdominal CT showed splenomegaly and enlarged lymph nodes. Bone marrow biopsy showed splenic marginal cell lymphoma (MCL) with monoclonal lambda restriction. Three weeks later he developed acute hepatitis C, viral load > 30 x 106 / IU/ml. One month later he developed nephrotic syndrome and RBC casts. Urine protein increased from 14 mg/dl to 7.8 g/day, serum albumin 3.2 g/dl. Serum cryoglobulins were negative and creatinine was 1.0 ml/dl. ANA, ANCA, C3, C4 were normal. Renal biopsy showed mild focal mesangial hypercellularity and no endocapillary proliferation, necrotizing lesions, crescents, or microthrombi. Congo red negative. There was granular mesangial deposition of IgM lambda. IgG, C3, IgA, Kappa, and C1q were negative. EM showed diffuse foot process effacement and no fibrillary or microtubular forms.

Discussion: MCL is rare, 5-10% of NHL. There is an association of MCL with HCV seropositivity, mechanism unknown. Case reports describe 3 patients with MCL and MPGN with monoclonal IgM deposits, either IgM kappa or IgM lambda predominant. Our patient had acute HCV with negative cryoglobulins; previous cases had both chronic HCV infection and cryoglobulinemia or cryoglobulinuria. Electron microscopy in our patient did not show cryoglobulinemic immune deposits. The hepatitis C virus may be causally involved in MPGN with monoclonal IgM associated with MCL by a mechanism independent of the production of cryoglobulins. IgM Lambda in Mesangium

TH-PO950

Congophillic Fibrillary Glomerulonephritis: A Diagnostic Challenge

Viduranga Wijeratne,[1] Meena Shingde,[2] Jasveen K. Renthawa,[2] Subramanian K. Kumar.[3] *[1]Gosford Hospital, Gosford, NSW, Australia; [2]ICPMR Westmead Hospital, NSW Pathology, Westmead, NSW, Australia; [3]Gosford Nephrology, Terrigal, NSW, Australia.*

Introduction: Fibrillary glomerulonephritis is characterised by the presence of randomly orientated nonbranching fibrils larger than those found in amyloid and lack the histochemical staining of amyloid. The absence of Congo Red reactivity has traditionally been a defining feature to differentiate it from amyloid glomerulopathy. We examined two cases showing the existence of Congophillic fibrillary glomerulopathy.

Case Description: Case 1: A 67 year old man presented with peripheral oedema and subnephrotic proteinuria on a background of poorly controlled hypertension. Initial renal biopsy suggested a focal segmental glomerulosclerosis with 13.9 nm fibrils on electron microscopy in the previous year. Despite treatment with rituximab, cyclosporin and cyclophosphamide, there was ongoing proteinuria with repeat renal biopsy showing Congo Red positive staining with 15.9 nm fibrils present. A monoclonal gammopathy of uncertain significance with IgM lambda was found. Case 2: A 51 year old man presented with newly diagnosed diabetes and was found to have subnephrotic proteinuria and microscopic haematuria. He underwent a renal biopsy finding Congo Red positive deposits with ultrastructural findings of 20 nm fibrils. Subsequent screening for malignancy and lymphoproliferative disease were negative. Despite immunosuppression with rituximab, cyclophosphamide and prednisone, the patient continues to have ongoing proteinuria.

Discussion: These two cases highlight the importance of recognising cases of Congophillic fibrillary glomerulonephritis which represents both a diagnostic and management challenge. Differentiating the renally-limited from the systemic immunoglobulin related amyloidosis is crucial to prevent misdiagnosis and inappropriate treatments such as the chemotherapy used to treat amyloid or immunotactoid glomerulopathy. Careful analysis of the ultrastructural characteristics combined with mass spectrometry and the use of novel biomarkers such as DnaJ homolog subfamily B member 9 (DNAJB9) could help discern such cases of Congophillic fibrillary glomerulonephritis.

TH-PO951

Double Trouble: Pulmonary-Renal Syndrome due to IgG4-RD and Myeloperoxidase-ANCA Vasculitis

Tanuja Yalamarti,[1] Pooneh Alborzi,[3] David A. Chetrit,[2] Michelle L. Rumbaugh.[2]
[1]Pennsylvania hospital of UPENN, Philadelphia, AL; [2]Pennsylvania Hospital, Philadelphia, PA; [3]Pennsylvania Nephrology Associates, P.C., Philadelphia, PA.

Introduction: IgG4-related disease (IgG4-RD) is a fibro-inflammatory condition that could be similar or overlap with ANCA-associated vasculitis (AAV).

Case Description: 38- year old female with a history of inflammatory arthritis and high ANA titer, but no definite diagnosis of lupus, on hydroxychloroquine presented with chest pain, dyspnea and hemoptysis for one month. She also reported recurrent sinusitis, arthralgia, and Raynaud's symptoms. Urinalysis revealed hemoproteinuria and cellular casts. Urine protein/creatinine was 2.8 grams. Serum creatinine rose from 0.7 to 1.08 mg/dl. CT Chest showed right upper lobe consolidation with cavitation. Anti MPO antibody was positive for >100 U/ml (0.0-9.0 U/mL). Serum complements were normal and anti-double strand DNA was negative. Initially, the patient was diagnosed with microscopic polyangiitis (MPA). However, lung biopsy noted a fibro-inflammatory lesion with elevated IgG4 positive plasma cells (20-30 per HPF) typical of IgG4-RD. Serum IgG4 level was elevated. Kidney biopsy showed membranous glomerulonephritis with cellular crescents and numerous subepithelial and intramembranous deposits that were negative for PLA2R immunofluorescence. Acute tubulointerstitial fibrosis was noted. Lack of C1q deposition and absence of tubuloreticular inclusions argued against lupus membranous disease. Patient was ultimately treated with pulse dose steroid and Rituximab, which induced remission of both IgG4-RD and MPA manifestations.

Discussion: In the literature, two entities have been described: IgG4-RD with ANCA positivity and AAV associated with increased IgG4-positive plasma cells. Our patient presetned with crescentic membranous GN and a very high anti MPO antibody. The histological features of lung biopsy however showed characteristics of IgG4-RD. Although membranous GN is reported both with AAV and IgG4- RD, it is not a typical renal biopsy finding of either of those diseases. Corticosteroids are the first line therapy in IgG4-RD without any adjuant immunosuppressive therapy. However, because of ANCA positivity and the presence of crescentic GN, our patient was treated with rituximab as well in addition to the steroids. We need to consider the possibility of IgG4-RD in patients with AAV and vice versa for appropriate treatment plan and prognosis assessment.

TH-PO952

IgG-4 Positive Linear Deposition Anti-Glomerular Basement Membrane Nephritis with Negative Glomerular Basement Membrane Antibody (GBM Ab)

Felipe S. Naranjo,[1] Sadichhya Lohani,[1] Lukasz Kiljanek,[4] Xin Gu,[3] Michael J. Choi.[2] *[1]Nephrology, Johns Hopkins Hospital, Baltimore, MD; [2]Nephrology, MedStar Georgetown University Hospital, Washington D.C, DC; [3]Pathology, Louisiana State University, Shreveport, LA; [4]Nephrology, MedStar Shah Medical Group, Hollywood, MD.*

Introduction: Anti-glomerular basement membrane (anti-GBM) nephritis is an antibody mediated small vessel vasculitis usually caused by IgG antibodies with predominance of IgG1 and IgG3 directed against basement membrane antigens.

Case Description: 22 years old morbidly obese male with history of asthma, recurrent ear infections requiring Eustachian tubes, smoking and exposure to polyvinyl chloride, presented with 3 months of fatigue and was found to have proteinuria on urinalysis. He denied fever, chills, chest pain, cough or hemoptysis, abdominal pain, melena, arthralgias, edema, dysuria, hematuria or tea-colored urine. On physical exam, he was afebrile with stable vital signs and absence of sinus tenderness, lymphadenopathy, synovitis, rash and edema. Chest, cardiovascular and abdominal exam were unremarkable. 24-hour urine protein was 3.8g and albumin was 2.4g. Urinary sediment showed red cell casts. Labs showed a serum creatinine: 1-1.2mg/dl, serum albumin 3.7g/dl, HbA1c 5.2% and negative anti-DNA, ANA, cANCA, pANCA, PR3, MPO, anti-GBM, RF, Jo-1, cryoglobulins, HIV, HBV, HCV, SPEP and UPEP. Serum complement levels and free light chains ratio were normal. Renal ultrasound showed normal size kidneys. Chest CT showed scattered pulmonary nodules < 5 mm. Renal biopsy showed proliferative glomerulonephritis with 2/17 glomeruli with crescents and positive linear reaction for IgG4 along the GBM in immunofluorescence and foot process effacement in electron microscopy. He was started on prednisone 80mg and cyclophosphamide 2.5mg/kg/d; plasmapheresis was not done due to negative anti-GBM titers. Few months later he was started on lisinopril 40mg. After 19 months of treatment, 24-hour urine protein decreased to 0.14g.

Discussion: Usually anti-GMB nephritis presents as rapidly progressive GN rather than with nephrotic range proteinuria. Patients with deposition of IgG on the GBM on immunofluorescence and negative for circulating antibodies by conventional assays, may be positive when tested by highly sensitive biosensor assays. In anti-GBM disease, IgG1 and IgG3 subclasses are the usual antibodies but rarely IgG4 as these antibodies may not be detected on routine assays. Patients with diabetic nephropathy may present with linear IgG but should not have crescents or cellular casts as noted in our patient.

TH-PO953

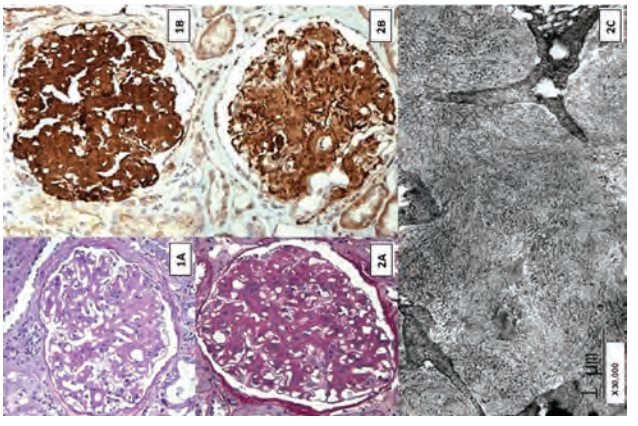
A Case of Familial Fibrillary Glomerulonephritis in Living Related Kidney Transplantation (LRKT)

Anushya Jeyabalan,[1] Doloretta Piras,[2] Heather K. Morris,[1] Ibrahim Batal,[1] Gerald B. Appel.[1] *[1]Columbia University College of Physicians and Surgeons, New York, NY; [2]Azienda Ospedaliera "G. Brotzu", Cagliari, Italy.*

Introduction: Fibrillary glomerulonephritis(FGN) is a rare form of kidney disease found in ~1.0% of adult native kidney biopsies with only 4 reported cases of familial FGN. The discovery of protein DNAJ heat shock protein family (Hsp40) member B9 (DNAJB9) has aided diagnosis of FGN.

Case Description: A 49-year-old African-American man was found to have proteinuria on routine exam with UPCR 6 g/g and serum creatinine(Cr) 1.0 mg/dL. Renal biopsy later revealed FGN. Light microscopy(LM) showed diffuse mesangial matrix expansion with thickened glomerular capillary walls(GCW) (Fig 1A) with negative Congo red stain. Immunofluorescence(IF) showed 3+ staining for IgG, C3 and lambda(L), 2+ staining for kappa(K). Electron microscopy(EM) showed linear, randomly arranged fibrils with average diameter of 16 nm. DNAJB9 stain done later was strongly positive (Fig 1B). Further workup did not reveal monoclonal gammopathy and he had no known family history of kidney disease. He was treated with steroids as immunosuppressive therapy(IST). He presented to Columbia 5 years later with CKD Stage 5, thus further IST was held. At age 55, he underwent LRKT from his son. Prior to organ donation, his son had SCr of 0.88mg/dL, UA with negative blood and trace protein, UPCR 95mg/g. Post revascularization kidney biopsy showed FGN. LM showed mild mesangial proliferation with scattered double contours (Fig 2A) and negative Congo red stain. IF showed mesangial and segmental GCW staining for IgG(2+), C3(1-2+), C1(1+), K(2+) and L(2+). DNAJB9 stain was positive (Fig 2B). EM showed randomly oriented fibrils with mean diameter of 18 nm (Fig 2C). These findings are consistent with donor-derived FGN, indicating a familial form of FGN.

Discussion: We describe a form of familial FGN confirmed by DNAJB9 staining on biopsy. Presence of well-formed fibrils and glomerular changes in the donor kidney despite minimal clinical findings suggest in-depth evaluation of related donors may be important in FGN.



TH-PO954

A Case of Poststreptococcal Glomerulonephritis with Concurrent ANCA-Associated Vasculitis and Aortitis: Challenges in Diagnosis and Treatment

Monisha Panda,[1] Madeeha Abdul Ghaffar,[2] Umesh K. Manchandani.[2] *[1]American University of the Caribbean School of Medicine, Chadds Ford, PA; [2]Northwell Health/Staten Island University Hospital, Staten Island, NY.*

Introduction: Aortitis is an uncommon condition with either infectious or rheumatologic etiology. Common rheumatologic causes of aortitis include the large vessel vasculitides, Takayasu's arteritis and giant cell arteritis; however, other rheumatologic causes exist, such as ANCA-associated vasculitides (AAV). A few previous cases of aortitis associated with perinuclear antineutrophil cytoplasmic antibody (p-ANCA) and anti-myeloperoxidase (MPO) antibody have been reported, however, in medical literature, AAV is infrequently discussed in association with large vessel involvement. It is rare to find cases of post-streptococcal glomerulonephritis (PSGN) in which there is concurrent AAV affecting large vessels.

Case Description: We report a case of a 36-year old Hispanic woman with an initial presentation of right leg cellulitis with positive antistreptolysin-O titers. Her past medical history was significant for previous right leg skin lesion and right groin lymph node abscesses. She developed hematuria during her admission and severe epistaxis. Due to worsening kidney function and persistent hyperkalemia, hemodialysis was initiated. Kidney biopsy results supported PSGN. P-ANCA, MPO, and proteinase-3 (PR3) antibody assays were positive. Magnetic resonance angiography results supported aortitis. Due to treatment for active infection, immunotherapy was postponed. Repeat P-ANCA, PR3, and MPO were persistently positive. Subsequently, she developed a cough and hemoptysis, after bronchoscopy she was determined to have diffuse alveolar hemorrhage. Methylprednisolone and plasmapheresis were initiated, followed by induction of rituximab.

Discussion: This case highlights a diagnostic dilemma in vasculitis classification: determining whether the aortitis was due to ANCA-associated vasculitis, large vessel arteritis, or an infectious process. Renal biopsy and clinical picture supported an infectious etiology of glomerulonephritis, thus the positive p-ANCA and MPO antibody assay were initially thought to be induced by infection, however, our patient had persistently positive ANCA results and developed DAH. This case also highlights the challenge in starting immunosuppressive treatments during infection, and, finally, the response to Rituximab and plasmapheresis therapies.

TH-PO955

Collapsing Glomerulopathy in an APOL1 Compound Heterozygous Patient with CMV Infection: The Double Hit Theory

Faris Al faris, Krishnakumar D. Hongalgi. *Albany Medical Center, Albany, NY.*

Introduction: Collapsing glomerulopathy (CG) is a rare and aggressive variant of focal segmental glomerulosclerosis (FSGS). Commonly associated with human immune deficiency virus (HIV). We present a case of CG in an HIV-negative African American (AA) patient with Cytomegalovirus (CMV) infection. The patient is compound heterozygous for APOL1 risk variants. We propose that CMV can act as a "second hit" in the pathogenesis of CG in the genetically predisposed individuals.

Case Description: A 31-year-old AA female with sickle cell disease was admitted with 2 weeks of fever, malaise, nausea, vomiting, cough and chest wall tenderness. On admission her serum creatinine was 2.39 mg/dl and peaked at 7.19mg/dl. Urine investigations revealed nephrotic range proteinuria. CMV DNA PCR was positive in plasma and urine. Renal biopsy showed features of collapsing glomerulopathy, characterized by collapse of the capillary loops, prominence of the overlying epithelial cells and extensive effacement of foot processes. Genetic testing showed compound heterozygous mutations in the APOL1 gene. The patient was treated with high dose steroids and anti-viral therapy with ganciclovir. With resolution of CMV infection, she made full renal recovery.

Discussion: CG as well as other nephropathies have well established racial disparity, predominantly affecting AA patients. The discovery of apolipoprotein L1 gene (APOL1) helped improve our understanding of genetic predisposition to renal disease. Increased risk can be attributed to the presence of two specific variants in the APOL1 gene (G1 and G2). These variants are present in about 30% of APOL1 alleles in the AA population. Individuals with one or two risk alleles are at greater risk for developing FSGS, hypertension-attributed ESRD, sickle cell-associated kidney disease, HIV-associated nephropathy, and shortened graft survival of kidney transplants. CG was initially described in HIV patients but also associated with viral infections (e.g. parvovirus B19 and CMV), lymphoproliferative disorders, autoimmune diseases and sickle cell disease. CMV infection could be a second hit in the genetically susceptible patient. Identification of CMV infection in patients with CG is important as they usually improve with treatment of the viral infection.

TH-PO956

Favorable Effect of Bortezomib in Patients with Noninfectious Mixed Cryoglobulinemia Complicated with B Cell Lymphoma: Experience of Two Cases

Yusho Ueda. *Division of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan.*

Introduction: Non-infectious mixed cryoglobulinemia (MC) is rare disorder associated with autoimmune or hematological diseases, eventually causing systemic vasculitis with organ damage. Due to the low frequency of this disease, the therapeutic strategy for non-infectious MC has not been established. Here we report that two cases with non-infectious MC complicated with B cell lymphoma who had good response to a combination of corticosteroid and bortezomib (BTZ), a proteasome inhibitor used for the treatment of multiple myeloma and B cell Lymphoma.

Case Description: Case1. A 61-year-old man with a medical history of mucosa-associated lymphoid tissue (MALT) lymphoma presented with nephrotic syndrome, purpura, and congestive heart failure. Laboratory tests revealed monoclonal IgM-κ and presence of cryoglobulins (CG). A renal biopsy showed glomerulonephritis with the deposits of IgM-κ. A diagnosis of non-infectious cryoglobulinemic glomerulonephritis was made and treatment was initiated with corticosteroid, rituximab and plasma exchange with no improvement of clinical manifestations. After the informed concent, the patient received BTZ in combination with corticosteroid, leading to amelioration of his clinical manifestations. Case2. A 69-year-old man presented with dyspnea due to severe nephrosis. Serum monoclonal IgM-κ and CG were detected. A bone marrow biopsy revealed low-grade B-cell lymphoma. He was diagnosed with cryoglobulinemic glomerulonephritis due to non-infectious MC complicated with B cell lymphoma. He was treated with a combination therapy of BTZ with corticosteroid, and achieved clinical remission of nephrotic syndrome.

Discussion: We presented two case of non-infectious MC complicated with lymphoma in whom BTZ was added in the treatment protocol to ameliorate renal manifestations. The improvement of renal function was associated with the disappearance of serum CG and decrease of serum levels of monoclonal IgM-κ. These findings suggest that BTZ suppresses the IgM-κ producing plasma cells and the deposition of CG in glomeruli, leading to the improvement of nephrosis. BTZ had anti-inflammatory effects as well, presumably involved in the protection of renal injury. This is a first report to show that treatment protocol including BTZ lead favourable outcome in patients with non-infectious MC with B cell lymphoma.

TH-PO957

Recurrent C3 Glomerulonephritis

Hameeda Khan, Aimen Liaqat. *Saint Barnabas Medical Center, West Orange, NJ.*

Introduction: C3 Glomerulopathy encompasses dense deposit disease and C3 glomerulonephritis. On electron microscopy it is defined as C3 deposits more than 2 orders of other immunoglubulins. Pathogenesis involves activation of alternative complement pathway due to genetic or acquired mutations. Post infectious glomerulonephritis with persistent hematuria or proteinuria is termed as atypical. We present a case of C3 glomerulonephritis presenting as post infectious glomerulonephritis then crescenteric C3 treated with immunosuppression.

Case Description: A 54 year old female with history of glomerulonephritis (2008, 2017) presented with hemtaturia. Labs significant for creatinine 3mg/dl (baseline1.7), protein excretion 2g/day, C3 9mg/dl and C4 20mg/dl. Urine analysis with 4000 red blood cells. Workup for acquired factors showed normal factor H, serum C5b-9, negative C3 nephritic factor and CH50 less than 10mg/dl. Urine and blood cultures, antibodies to Proteinase-3, myeloperoxidase and genetic testing was negative. Intravenous steriods were given twice daily for 4 days, transitioned to prednisone. Due to increased creatinine hemodialysis was initiated. Biopsy showed crescenteric C3 dominant proliferative glomerulonephritis. Immunofluorescence 3+C3, 2+kappa and 1+lambda. Electron microscopy showed scattered subepithelial hump-like intermembranous and mesangial deposits. After 6 doses of cyclophosphamide 750mg, in 3 months renal function stabilized with creatinine 1.34mg/dl, urine protein excretion 0.8g and C3 153mg/dl. In 2008, kidney biopsy showed post-infectious glomerulonephritis, low C3 and CH50 responsive to steroids. In 2016 she presented with pyelonephritis, creatinine 2.8mg/dl, protein excretion 2 g/day, urinalysis 3+ red blood cells, low C3 and normal C4. Biopsy showed membranoproliferative glomerulonephritis with crescents. Immunofloresence positive for IgG 2+, C3 2+, kappa 1+ and lambda 2+. Creatinine and C3 levels normalized post steriod therapy.

Discussion: Atypical Post infectious glomerulonephritis and C3 glomerulopathy are two sides of the same coin involving alternative complement pathway activation as shown by our patient's biopsy findings. Due to repetitive steriod and immunosuppression responsiveness we conclude that recurrent cases of atypical post infectious glomerulonephritis be investigated for alternate pathway mutations. Novel anticomplement medications such as eculizumab may also be used.

TH-PO958

Anti-GBM Disease: A Case Report of an Atypical Presentation

Feras Al Shami,[1] Josef Bautista,[2,1] Mark Birkenbach,[3,1] Tarek Nizami.[3] *[1]Brown University /Rhode Island Hospital Nephrology Fellowship Program, West Warwick, RI; [2]Hypertension & Nephrology Inc., Providence, RI; [3]Rhode Island Hospital, Providence, RI.*

Introduction: Anti GMB disease is a rarely encountered, but well known entity. It can present with nephritic syndrome, alveolar hemorrhage, or both. It is typically associated with positive circulating anti GBM antibodies. We are repotting a case of seronegative anti GBM antibody disease presenting with RPGN picture.

Case Description: A 59 year old female with a history of hemochromatosis presented with complaints of night sweats and fevers. She was sent to the hospital by her PCP with abnormal labs and hypertension. Her physical exam was unremarkable. Her labs were remarkable for creatinine of 3.05 mg/dl, BUN of 32 mg/dl, eGFR of 23 ml/min/1.73 m and CRP of 113. Dipstick urinalysis was positive for blood and protein. Urine sediment exam showed dysmorphic RBCs. Measured urine microalbuminuria was 299 mg/g of creatinine. Extensive serological workup, including testing for anti GBM antibodies, was negative. Light microscopy exam of a kidney biopsy showed focal granulomatous and crescentic glomerulonephritis as well as focal interstitial granulomatous inflammation with giant cells. The immunofluorescence studies revealed findings consistent with IgG type anti-glomerular basement membrane disease. After pulse methylprednisolone was started, the creatinime started to trend down. The patient was eventually treated with prednisone tapper and rituximab with continuous improvement in her GFR.

Discussion: Anti GBM disease is frequently associated circulating IgG antibodies that commonly target cryptic, conformational epitopes within the NC1 domain of the alpha 3 chain of Type IV Collagen. These antibodies are usually detected in sera using different conventional serological methods. Seronegativity in anti GBM disease is extremely rare. We identified less than 10 cases describing this atypical presentation in the literature. In one case, anti GBM detection was variable with each relapse. Sero negative anti GMB disease has also been described to recur in renal allografts. Anti GBM antibodies are known to be heterogeneous with respect to collagen type IV domain reactivity in the sera of patients with anti-GBM antibody disease. This could explain the seronegativity of anti GBM disease when conventional serological methods are used. Cases with sero negative anti-GBM disease present challenges not only for diagnosis but also management, since anti GBM titers cannot be used to monitor these patients.

TH-PO959

Hydralazine-Induced Crescentic Pauci-Immune Glomerulonephritis Associated with Multi-Antigenicity

Antonia Tharian, James Drakakis. *NYU Winthrop, Manhasset, NY.*

Introduction: Hydralazine use is common for treatment of hypertension, and heart failure with the ability to induce lupus as a rare complication. Though mechanisms are not understood, it may also be a causal factor in antinuclear cytoplasmic antibody (ANCA) vasculitis (AAV). This emerging syndrome is characterized by crescentic pauci-immune

glomerulonephritis and classically positive antibodies, including anti myeloperoxidase (MPO) and anti-histone. We report a case notable for the wide array of auto antibodies, the combination of which has not been previously reported.

Case Description: A 71 year old male presented to the hospital with a two month history of fatigue. His past medical history included hypertension for which he was taking Hydralazine, and an ischemic cardiomyopathy. His lab results showed an elevation in serum creatinine of 3.2 mg/dL from a baseline of 1.2 – 1.3 mg/dL. Urinalysis revealed proteinuria and hematuria with accompanying red blood cells. Serologies returned positive not only anti-histone antibodies, but also for both MPO and anti-proteinase 3 (PR3) antibodies. In addition, was a high titer ANA, double stranded DNA, low C3, presence of lupus anticoagulant, and anti-cardiolipin IgG. Kidney biopsy revealed focal segmental necrotizing and crescentic glomerulonephritis, pauci-immune type, acute and subacute. CT chest was negative for pulmonary hemorrhage. Taken together, these findings seemed consistent with a drug induced AAV. Deemed to be the culprit, Hydralazine was discontinued and treatment rendered with pulse dose steroids, transitioning to tapering Prednisone and two doses of Rituximab. This led to a marked clinical and serologic improvement, which was not only rapid, but also proved durable.

Discussion: Drug induced AAV has been linked to certain agents, including Hydralazine. The presentation may be severe, and often associated antibody positivity such as MPO and anti-histone may hold the key to the diagnosis. Our case illustrates a vaster splay of antibodies, the combination of which has not been previously described. The mechanism by which these are induced and the implication to disease response and progression need be investigated further. Thorough medication history to identify those at risk, rapid discontinuation of the drug and prompt treatment may all lead to improved clinical outcomes.

TH-PO960

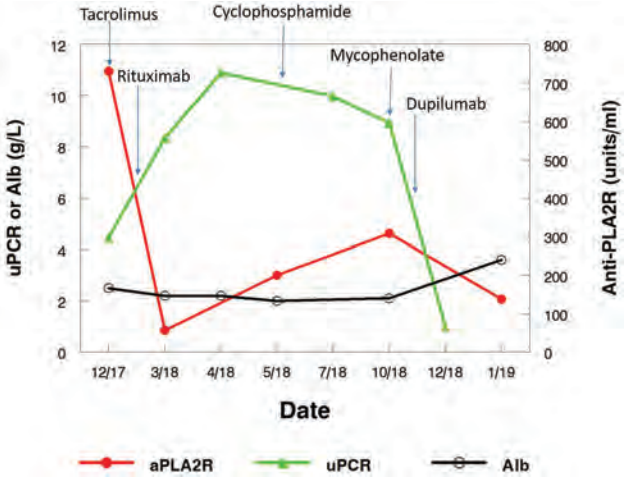
Dupilumab and Primary Membranous Nephropathy

Jessica M. Greco,[1] Swati Arora,[2] Jennifer Sopkovich,[3] Brad H. Rovin.[4] *[1]Ohio State Wexner Medical Center, Columbus, OH; [2]Nephrology, Allegheny Health Network, Pittsburgh, PA; [3]The Ohio State Wexner Medical Center, Gahanna, OH; [4]Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Primary membranous nephropathy (MN) is an immune complex-mediated disease. In most cases patients develop autoantibodies to the phospholipase A2 receptor (PLA2R), often of IgG4 subclass. Effective immunosuppressive treatment of MN results in a decline in anti-PLA2R that precedes clinical resolution of the disease. We recently saw a patient who had PLA2R-positive MN that did not have a durable response to multiple therapies. She had severe atopic dermatitis that was treated with dupilumab, an interleukin-4 (IL-4) receptor antagonist. After dupilumab was started the nephrotic syndrome resolved.

Case Description: A 21 year-old female with a history of asthma and severe atopic dermatitis since childhood presented with nephrotic syndrome. A kidney biopsy showed PLA2R-positive MN. The Figure shows treatments, immunologic responses, and clinical responses over time. Despite significant immunosuppression her eczema persisted and worsened so dupilumab was started. Within 2 months of initiating dupilumab the anti-PLA2R levels decreased, albumin normalized, and the nephrotic syndrome resolved.

Discussion: MN, an autoimmune disease that involves activation of T-follicular helper cells and B cells. Several pro-inflammatory cytokines are increased in the urine and serum of patients with MN, including IL-4. IL-4 promotes B cell isotype switching to IgG4, differentiation of naïve T-helper cells to Th2 cells, and inhibits the differentiation of Th1 cells. Th2 cells then release IL-4 leading to a positive feedback loop. MN is characterized histologically by IgG4-dominant subepithelial immune complexes. Dupilumab is a human monoclonal antibody that blocks the IL-4 alpha receptor, inhibiting the effects of IL-4 and IL-13. IL-4 blockade in MN may help attenuate anti-PLA2R IgG4 antibody production, and combined with traditional immunosuppression treat refractory MN. Further prospective studies are warranted to define the role of IL-4 antagonism in the management of MN.



TH-PO961

Is Liposorber an Option for Lipoprotein Glomerulopathy in Pediatric African American Males?

Juhi A. Gor,[2] Guillermo Hidalgo.[1] *[1]Eastern Carolina University, Greenville, NC; [2]Brody School of Medicine at East Carolina University, Greenville, NC.*

Introduction: Lipoprotein glomerulopathy is a rare inherited renal disease that is characterized by the accumulation of lipoproteins leading to the formation of lipoprotein thrombi with markedly dilated glomerular capillaries. The disorder is associated with an ApoE mutation leading to massive proteinuria and dyslipidemia with high chance of progression to chronic kidney disease. The first publication of a case was reported in 1989 by Saito, and has since been commonly reported in adult individuals of Japanese and Chinese descent.

Case Description: Interestingly, our report looks into the presentation of lipoprotein glomerulopathy in a 7 year old African American male who has been followed since birth for hypertension, hypercholesterolemia, nephrotic range proteinuria, and multiple past episodes of prerenal AKI. A renal biopsy was performed and diagnosis of lipoprotein glomerulopathy was confirmed by histological diagnosis from Vanderbilt. Genetic testing revealed a heterogeneous *mutation of ApoE2*. The patient also presents with hemihyperplasia of the right lower extremity, increasing our suspicion for a possible accompanying *WT1 gene mutation*. Treatment has been focused on controlling hypertension and symptoms of chronic kidney disease. Patient has been taking a beta blocker, angiotensin converting enzyme inhibitor, and calcium channel blockers for hypertension. These medications have been effective in reducing the blood pressure from 140-150/100 to 120-130/80. To treat for hypercholesterolemia that imposes continued damage on the kidneys of patients with this disorder, he has been taking fibrates and statins, but his cholesterol levels continue to be elevated, while triglyceride levels are well controlled. Further treatment evaluation is being focused on the possibility of beginning patient on Liposorber once per month to remove the high levels of LDL. Kidney transplant consideration is low due to recurrence being reported in all past transplanted kidneys.

Discussion: This case illustrates the possible expansion of a rare renal disease outside of commonly targeted population. Recognition of lipoprotein glomerulopathy and its clinical features will become critical in future evaluation of nephrotic syndromes in the pediatric population.

TH-PO962

Minimal Change Disease in an 82-Year-Old Man with Type 2 Diabetes Without Histologic Evidence of Diabetic Glomerulosclerosis on Renal Biopsy

Carl K. Zainaldin,[1] Omar Mushfiq.[2] *[1]Augusta University/Medical College of Georgia, Dunwoody, GA; [2]Kidney Clinic of Athens, Athens, GA.*

Introduction: Minimal change disease (MCD) in older adults with type 2 diabetes mellitus (T2DM) is a rare occurrence. Finding MCD in this population *without* diabetic glomerulosclerosis (DGS) is even more uncommon. We found only 16 reported cases of MCD in the setting of adult type 2 diabetes. Only 4 of those were confirmed to have MCD in the absence of DGS. We report a case of MCD in an 82 year old man with type 2 diabetes whose kidney biopsy showed no histologic evidence of diabetic glomerulosclerosis.

Case Description: An 82 year old man with a 10-year history of T2DM on insulin for 1 year presented with a one week history of lower extremity edema and shortness of breath. On presentation his serum creatinine was 1.4 mg/dl and his serum albumin 2.4 gm/dl. Protein in 24-hour urine was 14 grams. Serology and serum protein electrophoresis were negative. Kidney biopsy was performed. Light microscopy showed normal glomeruli with no evidence of glomerulosclerosis. Electron microscopy revealed diffuse effacement of foot processes diagnostic of minimal change disease. Patient was started on prednisone and achieved complete remission in 5 weeks. At his six-month follow up he was doing well. His creatinine was down to 1.0 and urine protein/creatinine was 0.07 g/g.

Discussion: This case illustrates the value of kidney biopsy in the diagnosis of severe nephrotic syndrome in adults with T2DM. Nephrotic syndrome occurring in a patient with diabetes is often presumed to be due to diabetic glomerulosclerosis and renal biopsy is usually not performed. However, in this patient there were a number of pivot points that suggested further exploration was necessary, including the degree of proteinuria and abruptness of the onset. This case is of clinical significance because MCD in an older diabetic can be easily missed, but if diagnosed, is almost always curable as it was in this patient. Our patient adds to the literature of MCD presenting in older adults with T2DM and provides a new upper age of reported occurrence. It is uncertain as to whether this is a truly rare occurrence or the result of under-reporting because kidney biopsy is infrequently performed in older adults with similar presentation. It is possible that the true incidence of MCD in older adults with T2DM may be less rare than the literature suggests.

TH-PO963

Unusual Presentation of Cryoglobulin-Positive Fibrillary Glomerulonephritis

Edward G. Medeiros,[1] Nathan Calabro-Kailukaitis,[2,1] Matthew R. Lynch.[3] *[1]Nephrology, Brown Medicine, Providence, RI; [2]Brown University, Providence, RI; [3]Brown Medicine, East Providence, RI.*

Introduction: Fibrillary glomerulonephritis encompasses approximately 1% of adult native kidney biopsies. Although considered a predominantly idiopathic disease, up to 1/3 reveal a secondary cause such as monoclonal gammopathy, autoimmune disease or malignancy. In the two largest case series published to date, only 2 of 126 had positive serum cryoglobulins; it is unclear if these patients had concurrent HCV infection. A

disease already associated with poor outcomes, little is known about those with Fibrillary GN and positive serum cryoglobulins.

Case Description: A 66 year-old female with history of longstanding diabetes mellitus, hypertension and stage III chronic kidney disease with serum creatinine 1.6mg/dL six months prior was admitted with abnormal labs including serum creatinine of 7mg/dL on routine testing. She denied localizing symptoms to explain worsening renal function. She was afebrile and initial blood pressure was 170/90mmHg. On physical exam, lungs were clear and there was no rash or edema. Repeat labs revealed serum creatinine 7.49mg/dL, BUN 57mg/dL, serum albumin 3.3g/dL and 7 grams of protein on 24hr collection. Urine sediment showed hematuria with dysmorphic RBCs and numerous WBCs. Further tests for HBV, HCV, HIV, ANA, ANCA, and anti-GBM were negative. Hypocomplementemia with undetectable C4 and normal C3 was present, along with elevated rheumatoid factor at 152 IU/mL; serum cryoglobulins were positive. SPEP was weakly positive for IgG lambda. Renal biopsy exhibited global glomerular sclerosis, and diffuse deposition of haphazardly arranged 15nm filaments within glomerular capillary walls and mesangial matrix on electron microscopy. Staining for DNAJB9 was positive. Despite treatment with Rituximab for 4 weeks, her disease progressed and required renal replacement therapy. Serum cryoglobulins remained positive after treatment.

Discussion: Fibrillary GN is a rare disease associated with poor renal outcomes and progression to ESRD. Only two previous cases of Fibrillary GN had positive serum cryoglobulins. There is little evidence to guide therapy in this disease, and even less is known about those with positive serum cryoglobulins. Efforts to identify secondary causes in such patients should include viral illness, malignancy and autoimmune disease. Further investigations to evaluate more effective therapeutic options are needed.

TH-PO964

Remission of Refractory THSD7A-Associated Membranous Nephropathy Using Rituximab: A Case Report

Hu Ningning,[1] Fujun Lin.[2] [1]*Renal Division, Department of Internal Medicine, Xin Hua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China;* [2]*Xin Hua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai, China.*

Introduction: Rituximab (RTX) is reported to induce clinical remission in 60-80% of primary membranous nephropathy (MN) patients. Due to the rarity, only four thrombospondin type-1 domain-containing 7A (THSD7A) associated cases were included in clinical trials of RTX treating MN, without detailed description of clinical information or treatment outcome. Here, we reported the successful RTX treatment of a THSD7A-associated MN patient non-responsive to tacrolimus and glucocorticoids.

Case Description: A 72-year-old male was admitted to Xinhua Hospital because of persistent nephrotic-range proteinuria and non-responsive to tacrolimus and glucocorticoids. Laboratory results included 24hr proteinuria 6.2g, serum albumin 2.15g/dL and serum creatinine 1.39mg/dL. Renal biopsy results suggested MN with negative glomerular staining of phospholipase A2 receptor and IgG4 but positive THSD7A by immunohistochemistry. Serum THSD7A-antibody titer was 1:100 by indirect immunofluorescence. The patient had radical rectectomy 7 years ago without metastasis. Rectal cancer tissue was reviewed and weakly positive THSD7A staining was found, which can be seen in 43% of rectal tumors. Intensive screening ruled out cancer recurrence or metastasis and RTX was given at weekly dose of 375mg/m2 for four weeks. At month 6, the patient achieved partial proteinuria remission and THSD7A-antibody titer decreased to 1:10.

Discussion: In this refractory case, the treatment of RTX achieved partial remission of proteinuria and circulating THSD7A antibody depletion at month 6, supporting its good efficacy on THSD7A-associated MN. We also emphasize that screening for malignancy is warranted in THSD7A-associated MN before immunosuppressive therapy.

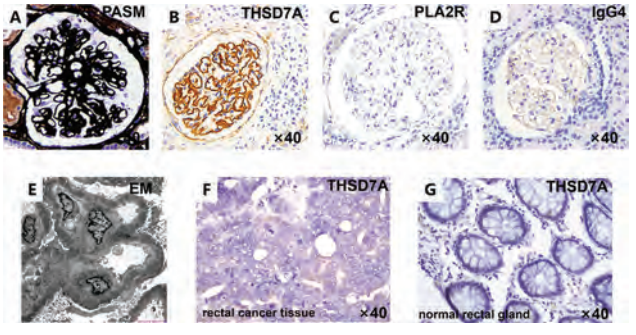


Fig.2 Histological findings.

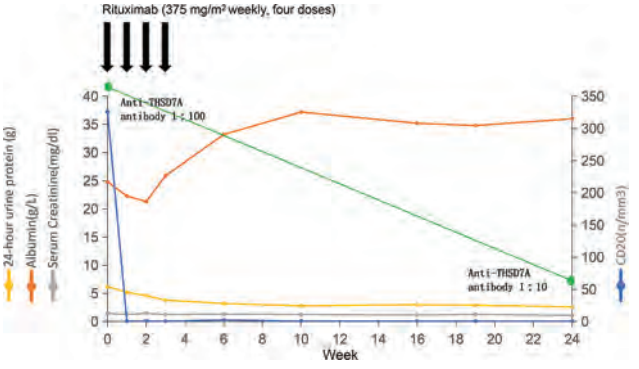

Fig.2 A summary of the clinical course.

TH-PO965

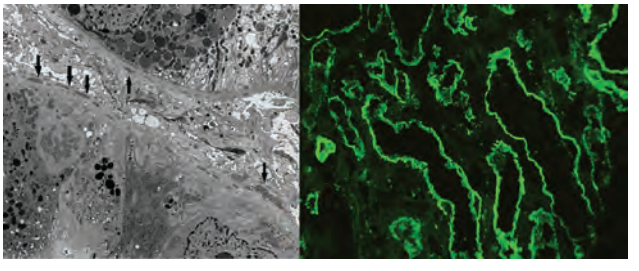
Tubular Basement Membrane Deposits in Lupus Nephritis

Anum Malik, Roulan Abu Hweij, Leal C. Herlitz, Georges Nakhoul. *Cleveland Clinic Foundation, Cleveland, OH.*

Introduction: Glomerular lesions are the main renal finding in lupus nephritis (LN). Extraglomerular deposits can be observed in more than half of LN biopsies but are typically observed in conjunction with glomerular findings. We present a unique case of LN with tubulointerstitial inflammation secondary to prominent TBM immune deposits without glomerular activity.

Case Description: 27 year old African American male with systemic lupus erythematosus (SLE) for 5 years, with biopsy proven LN class V, was admitted from nephrology clinic for work up of acute kidney injury. He was initially treated with hydroxychloroquine (HCQ) and prednisone at the time of his SLE diagnosis. On diagnosis of LN, 4 years later, mycophenolate mofetil (MMF) was added, which he was intolerant to and discontinued. He had 2 episodes of SLE flares for which rituximab was given. Azathioprine was added to his regimen of prednisone and HCQ after the second SLE flare. Prior to current presentation, the patient had started to taper his prednisone and was on 10mg daily. In this setting, his serum creatinine (SCr) rose to 4.32mg/dl from a baseline of 1.4-1.6mg/dl; C3 was low at 77; C4 was normal; dsDNA antibody was negative. He had an active urinary sediment. He was started on 125mg of methylprednisolone intravenously for 3 days. Renal biopsy was pursued to re-stage his LN and further determine the immunosuppression needed. Pathology showed active tubulointerstitial inflammation secondary to prominent TBM immune deposits without glomerular activity. He also had changes consistent with class V LN. He was discharged on oral prednisone 60mg daily, with a weekly 10mg taper, MMF 250mg daily, which he agreed to retry and HCQ 400 daily.

Discussion: Only 11 cases have shown predominant TBM LN in the literature. Studies have shown a correlation with TBM immune deposits and a twofold higher risk of end-stage renal disease or doubling of SCr after controlling for other factors. Thus, this finding is of prognostic significance. Treatment of predominant tubulointerstitial LN is not established. Most reported patients did not require cytotoxic immunosuppressive treatment and responded well to steroids alone.



TH-PO966

Renal Manifestations Associated with Bartonella Infection

Christina Mariyam joy, Tingting Li, Anitha Vijayan. *Washington University in St. Louis, St. Louis, MO.*

Introduction: Culture negative endocarditis constitutes about 8% of all cases. Bartonella henselae is a common causative organism. Here we discuss 3 cases of GN associated with B.henselae infections masquerading as vasculitis, IgA and focal necrotizing C3 GN.

Case Description: Case 1: A 56 y/o man with LVAD presented with SOB and AKI with rapid rise in SCr from 1 to 3.45mg/dL over 3 weeks. Lab showed positive ANA, ANCA (+PR3) and normal complements (Table). Renal pathology was highly suggestive of infection-associated GN. Additional w/u revealed B.henselae Ab IgG > 1:1024 and TEE revealed possible vegetation in RV pacemaker lead. He was treated with Doxycycline and rifampin, plus oral prednisone. F/U SCr in 1 year was 1.1mg/dL. **Case 2:** A 42 y/o man with bioprosthetic AV valve presented with a vasculitis rash and AKI

(SCr increased from 1.8 to 4 mg/dL). Labs showed hypocomplementemia and +ANA. Renal pathology revealed focal endocapillary proliferation with crescents. Infectious w/u revealed B.henselae and quintana IgG >1:1024, IgM >1:20. TEE revealed AV vegetation and was taken emergently for AV replacement. AV valve PCR was positive for Bartonella. Despite aggressive care post AVR, pt died on post-op day 9. **Case 3: A** 64 y/o man with prosthetic MV mitral valve, was admitted for evaluation of rapidly rising SCr (1.1 mg/dL to 6 mg/dL) over 2 wks. ANA/ANCA were neg. Renal pathology showed focal necrotizing crescentic GN with which stained for IgM, C3 and C1q. TEE showed MV vegetation and infectious w/u revealed B henselae and B quintana IgG >1:1024. He was started on HD, steroids, abx and underwent MV replacement. Pt was dialysis independent 3 mo after discharge.

Discussion: These cases demonstrate the need for high index for clinical suspicion for infectious etiology for GN in the presence of prosthetic valves or mechanical devices. Our 3 cases had very low clinical suspicion for infection at the time of initial evaluation. Serological tests and renal pathology prompted infection work up. Although all the patients had the same disease and had similar treatment, renal outcomes were very different. Awareness of Bartonella infection and early detection could have favorable patient outcomes.

Case	Age/Sex	Creatinine (baseline/ @Biopsy)	ANA	ANCA	C3/C4	Organism	Location of vegetation	Renal biopsy: Light	Renal biopsy: IF	Renal biopsy: EM	Outcome
1	56/M	1/3.5	1:160	Positive/ PR3	110/19.6	B.henselae IgG >1:1024	RV lead of LVAD	Focal proliferative glomerulonephritis, Cellular crescents	C3, C1q	Rare mesangial electron dense deposits, mild podocyte effacement	F/U Cr at 1 yr - 1.1
2	42/M	1.8/4	1:160	Positive (-MPO/-PR3)	21/4.2	B.henselae/B.quintana IgG >1:1024, IgM >1:20	Prosthetic AV	Focal segmental endocapillary proliferation, Crescents	IgA, C3, C1q	Severe podocyte effacement	Death
3	64/M	1/6	Negative	Negative	70/21.8	B.henselae/B.quintana IgG:1:1024	Prosthetic MV	Focal necrosis and crescents	IgM, C3 and C1q	Scattered mesangial electron dense deposits	Off dialysis after 3 months F/U Cr - 2.8

TH-PO967

Lupus-Like Membranous Nephropathy in the Setting of Well-Controlled HIV Infection

Kalyan Prudhvi, Molly Fisher. *Montefiore Medical Center/ AECOM, Bronx, NY.*

Introduction: Immune complex glomerulonephritis associated with HIV infection encompasses a heterogeneous spectrum of glomerular diseases associated with immune deposits including membranous nephropathy. Membranous nephropathy with atypical features such as full house immune staining resembling lupus has been rarely described in HIV infection. We report a case of lupus like membranous nephropathy in the setting of well-controlled HIV infection successfully treated with rituximab.

Case Description: 56-year-old Hispanic female with schizophrenia, type 2 diabetes mellitus, hypertension, HIV infection, and serum creatinine 0.7mg/dL presented with 5.3 grams of proteinuria. Her HIV infection was well-controlled with viral suppression on antiretroviral therapy and diabetes was controlled with no microvascular complications. Serologic workup included a positive ANA with a negative double stranded DNA antibody, normal C3 and C4 levels, negative SPEP, negative syphilis antibody, positive hepatitis C antibody and positive hepatitis B core antibody with viral suppression. Renal biopsy demonstrated immune complex glomerulonephritis with a membranous pattern. Full house staining was IgG predominant and numerous subepithelial, paramesangial deposits and tubuloreticular inclusions were seen. PLA2R stain was positive but serum anti-PLA2R antibody was negative. Although she had a positive ANA, she had no other clinical signs or symptoms of lupus. In the absence of another etiology, we concluded she had lupus like membranous nephropathy possibly associated with HIV infection. Despite conservative treatment for 6 months, proteinuria worsened to 7.1 grams. She was subsequently treated with rituximab. Within 2 months, her proteinuria improved to 3.1 grams consistent with partial remission.

Discussion: Lupus like glomerulonephritis with a membranous pattern has been rarely described in HIV infection. Our patient had a positive ANA but no other serological or clinical features of lupus. Although full house immune staining was seen, IgG predominated with mostly subepithelial deposits and her PLA2R stain was positive, suggesting this may be primary membranous nephropathy with atypical features. There are a variety of glomerular diseases observed in HIV positive individuals and this case highlights the importance of the renal biopsy for appropriate diagnosis and treatment

TH-PO968

Laser Microdissection and Tandem Mass Spectrometry, a Valuable Method to Identify Components of Glomerular Deposition Diseases: A Case Report

Kotoko Shinya, Akihiro Minakawa, Yuri Ishizaki, Kumiko Aso, Ryuzoh Nishizono, Masao Kikuchi, Hiroko Inagaki, Yuji Sato, Shouichi Fujimoto. *University of Miyazaki, Miyazaki, Japan.*

Introduction: The diagnosis of glomerular deposition diseases (GDDs), including proliferative glomerulonephritis with monoclonal IgG deposition (PGNMID), requires evidence of pathogenic deposits in the glomerulus. Laser microdissection (LMD) and Tandem mass (MS/MS) spectrometry, which can identify the deposit's structure, might be valuable for this purpose in theory. Here, we report a case of PGNMID suggesting the applicability of MS/MS spectrometry in the diagnosis of GDDs.

Case Description: A 38-year-old woman was admitted to our department with a 7-month history of moderate proteinuria and without a history of hematological disease. A 24 hour urinary test showed proteinuria excretion of 1.2 g/day with no microscopic hematuria. A blood test showed 0.63 mg/dL of creatinine, 5.98 g/dL of total protein and 3.54 g/dL of albumin. Cryoglobulinemia was not detected. A renal biopsy showed membranous nephropathy by light microscopy together with granular deposits in subendothelial, subepithelial, and intra-glomerular basement membranes by electron microscopy. An immunofluorescence (IF) study showed restricted IgG1-Kappa deposition, which was validated by MS/MS spectrometry using several glomerulus dissected by LMD from a paraffin-embedded specimen, which showed an IgG1-heavy chain and Kappa-chain variable lesion. Therefore, we were able to diagnose the patient with PGNMID, and initiate treatment with an angiotensin converting enzyme inhibitor. The patient's renal function has been stable up until the time of writing this report.

Discussion: In the current case, we found that the pathogenic deposit shown by immunostaining was consistent with the result of MS/MS spectrometry. Based on the observations of this case, we validated MS/MS spectrometry's ability to detect deposits. The evidence of pathogenic deposits is critical in the diagnosis of GDDs. Although IF is commonly used, this process can only test for a limited number of deposit antigens. In theory, LMD and MS/MS spectrometry could detect a broader spectrum of deposit and might enable a better understanding of GDDs. <Acknowledgment> LMD and MS/MS analysis was performed by Drs. Yoshinaga, Yazaki, Sekijima (Shinshu University)

TH-PO969

Mercury in Natural Health Products as a Cause of Membranous Nephropathy

Stephen B. Tanner, Vivek Sharma, John W. Idoux. *Nephrology, Baylor Scott and White, Temple, TX.*

Introduction: Membranous nephropathy (MN) is characterized by subepithelial deposits along the glomerular basement membrane and it is the most common cause of nephrotic syndrome in white adults (1, 2). 80% of cases are primary with antibodies to specific podocyte antigens, Phospholipase A2 Receptor (PLA2R) or thrombospondin type-1 domain-containing 7A (THSD7A). The remainder are secondary to a variety of causes including malignancy and drugs (2). Mercury is a cause of MN with exposures from skin-lightening creams and traditional medicines (1,3). An emerging concern is use of natural health products (NHPs) including vitamins, supplements, and herbal remedies. The composition of these products is not tightly regulated and some have been shown to contain mercury (4). We present a case of MN due to mercury intoxication related to use of NHPs.

Case Description: 39-year-old white male with past medical history of depression presented with worsening bilateral lower extremity edema and abdominal distention over the past month. He was taking multiple herbal supplements daily for 6 months. He denied changes in urine output, use of non-steroidal anti-inflammatory drugs, illicit drugs, or alcohol. He reported eating fish 1 meal per month. On evaluation, He demonstrated anasarca. No other abnormalities noted on physical examination. Lab work demonstrated normal renal function, nephrotic range proteinura, hypoalbuminemia, and hyperlipidemia. Urine protein-to-creatinine ratio was elevated at 14.3 (ref 0.00 - 0.19). ANA, hepatitis B and C, C3, and C4 were normal. Heavy metal serum screen returned mercury of 22.1 ug/L (0.0 to 10.0 ug/L) and 24- hour urine mercury was >80 ug/L (0.0 - 5.0 ug/L). Renal biopsy was consistent with membranous nephropathy. PLA2R and THSD7A were negative. The offending agents were discontinued. He started on Cyclosporine A, Atorvastatin, and Apixaban. Cyclosporine A was weaned off quickly following final diagnosis. He continued on Atorvastatin and Apixaban for 12 weeks. By 12 weeks, all lab parameters returned to normal.

Discussion: Mercury-induced membranous nephropathy is a known, but rare entity that has been associated with skin-lightening creams, Chinese herbal medicines, and now NHPs. Our case highlights the necessity of through medication review to identify causes of nephrotic syndrome that may respond to simple measures such as discontinuation of offending drugs.

A Horse in the Land of Zebras: A Case of Minimal Change Disease After Celecoxib Exposure

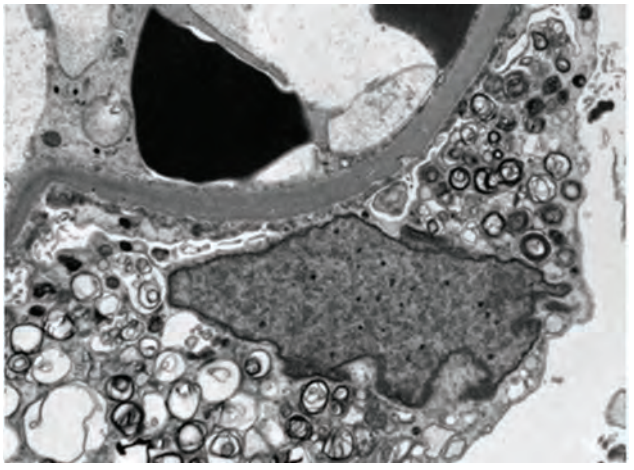
Daniil Shimonov,[1] Steven Salvatore,[2] Roman A. Shingarev.[3] *[1]NYP-Weill Cornell Medical Center, Forest Hills, NY; [2]Weill Cornell Medical College, New York, NY; [3]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Non-selective NSAIDs are the most common cause of secondary minimal change disease (MCD). This association has not been established for selective COX-2 inhibitors, such as celecoxib. We present a case of celecoxib-associated MCD with unique diagnostic and therapeutic features.

Case Description: 71 y/o F presented with abrupt nephrotic syndrome after a 2-week course of celecoxib. She has depression treated with sertraline and HTN controlled with diuretics. On presentation, her serum Cr was 0.8 mg/dl and her proteinuria (PU) measured 8 g. It did not improve with celecoxib discontinuation and lisinopril addition. Kidney biopsy revealed MCD without tubular or parenchymal pathology, however, foot process effacement was accompanied by lamellated "zebra" bodies in some podocytes (Figure) and minimal mesangial IgA deposits. Testing for genetic abnormalities and enzymatic activity of α-galactosidase ruled out Fabry disease. Her PU resolved after a 2-month prednisone course, but she relapsed soon after steroids discontinuation. Retreatment with a longer prednisone taper led to a prompt resolution of PU followed by another relapse accompanied by AKI. The second kidney biopsy showed MCD, new moderate interstitial fibrosis (IF) and tubular atrophy (TA), but no phospholipidosis. Her kidney function

returned to baseline after 2 months, during which she was supported by dialysis, but PU persisted despite steroids. Subsequent addition of mycophenolic acid led to partial PU remission.

Discussion: Unlike prior sparse case reports documenting celecoxib-associated MCD, our patient did not initially have any IF or TA, nor did her PU remit spontaneously after celecoxib discontinuation. Although MCD responded well to prednisone, it eventually became steroid-resistant. While IgA deposits were deemed incidental and benign, sertraline-induced phospholipidosis could weaken the podocyte ability to maintain its structural integrity possibly exacerbating PU.



Zebra bodies

TH-PO971

Fulminant Nephrotic Syndrome with Minimal Glomerular Findings Associated with a Pancreatic Neuroendocrine Tumor

Laila Lakhani, Yousuf Kyeso, John Sperati. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Introduction: Neuroendocrine tumors (NETs) are a rare, heterogenous group of tumors that can present as benign or malignant lesions. Rare reports have associated NETs with membranous nephropathy. We report a patient with nephrotic syndrome and minimal glomerular findings who experienced clinical remission upon tumor resection.

Case Description: A 53 year old female with history of hypothyroidism presented with anasarca, 24-hour urine protein 4.2 g, hypoalbuminemia 2.1 g/dL, and acute kidney injury (serum creatinine 0.8 mg/dL increasing to 1.8 mg/dL). Kidney biopsy demonstrated normal glomeruli by light microscopy, mild tubular atrophy, and mild interstitial fibrosis. Immunofluorescence was unremarkable and electron microscopy revealed minimal foot process effacement with no electron dense deposits. Congo red staining was negative for amyloid. The acute kidney injury resolved. Eight months later, a pulmonary artery embolism was diagnosed, and she was noted to have 26 g on 24-hour urine protein collection. Serological evaluation for HIV, hepatitis C, hepatitis B, C3/C4, ANA, ANCA, SPEP, UPEP, serum free light chains, and PLA2R antibody were all normal/negative. UPCR decreased to 8 g/g on an ACEi. Six months later, UPCR again increased to 18 g/g, and repeat kidney biopsy demonstrated diffuse and moderate tubular injury, mild interstitial inflammation with clusters of eosinophils, and 25-30 % foot process effacement with no evidence of immune complex deposition. Abdominal MRI revealed an enhancing lesion in the tail of the pancreas that on resection was a well-differentiated, nonfunctional pT1N0 neuroendocrine tumor positive for chromogranin and synaptophysin with KI67 index <1%. One month after resection, urine dipstick protein was negative with albumin 3.5 g/dL, and 6 months later UPCR was 0.08 g/g, albumin 4.0 g/dL, and creatinine 0.9 g/dL.

Discussion: This case expands the association of NETs and nephrotic syndrome to include histologic lesions with minimal glomerular findings. The spontaneous remission with tumor resection supports the role of a circulating tumor-associated factor in the pathogenesis.

TH-PO972

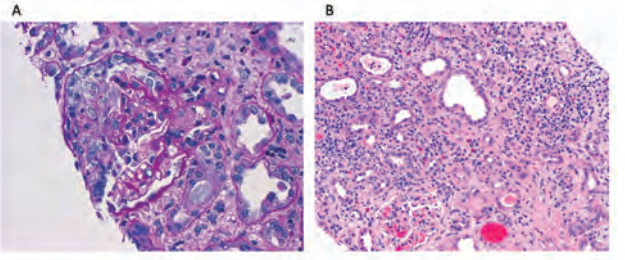
TNF-Alpha Inhibitors and ANCA-Associated Vasculitis: The Culprit or an Innocent Bystander

Nasim Wiegley, Tiana Jespersen, Kuang-Yu Jen, Maryam Afkarian, Shubha Ananthakrishnan. *University of California, Davis, Sacramento, CA.*

Introduction: Anti-tumor necrosis factor-alpha agents (TNF-α) have become integral in the management of autoimmune diseases such as rheumatoid arthritis (RA). Although these agents are generally well tolerated from a renal perspective, they have been associated with paradoxical development of both systemic and organ-limited vasculitis, including glomerulonephritis. Also, few case reports describe acute interstitial nephritis (AIN) caused by anti-TNF-α agents. We describe a case of simultaneous ANCA-associated vasculitis (AAV) and AIN in a patient with RA maintained on etanercept.

Case Description: A 69-year-old East Indian woman with well-controlled RA on etanercept developed gross hematuria and acute renal injury with serum creatinine peak at 8.4 mg/dl, without any other symptoms such as arthritis, stiffness or rash. Urine microscopy showed numerous isomorphic and few dysmorphic red blood cells, no cellular casts. Serologic studies were notable for positive myeloperoxidase-antineutrophil cytoplasmic antibodies (MPO-ANCA). Renal biopsy demonstrated ANCA-associated vasculitis (AAV) with rare cellular crescents and acute tubulointerstitial nephritis. Etanercept was discontinued due to concern for drug-induced vasculitis. The patient was treated with high-dose steroids and rituximab with subsequent improvement in renal function.

Discussion: Anti-TNF-α agents have been associated with different renal pathologies including AIN, as well as glomerular processes such as pauci-immune crescentic GN. Determining causality is a challenge because RA is independently linked to AAV as an overlap syndrome. In our patient, lack of clinically evident RA flare and concomitant presence of AIN on biopsy more strongly supported etanercept as the underlying etiology. A high index of suspicion for drug-related vasculitis is required in patients with primary rheumatic disorders treated with biologic agents. Discontinuation of anti-TNF-α therapy and prompt initiation of immunosuppression for treatment of vasculitis are the cornerstone of management.



A: Cellular crescent, B: Acute interstitial nephritis

TH-PO973

Not So Stellar: IgA Nephropathy Secondary to Immunotherapy Treatment for Psoriasis

Keyla J. Davila- Marcano,[1] Ranil S. Gajanayaka,[2] Madappulli A. Wickrama,[3] Roberto L. Collazo-Maldonado,[2] Lisa M. Sebastian.[2] Methodist Dallas Medical Center *[1]Methodist Hospital Dallas, Dallas, TX; [2]Dallas Nephrology Associates, Southlake, TX; [3]Baylor Scott and White Hospital, Richardson, TX.*

Introduction: The increasing use of immunotherapy to treat inflammatory diseases and malignancy has resulted in an increase in glomerular injury reports. IgA deposition in the kidney has been associated with systemic conditions which include ulcerative colitis, seronegative spondyloarthropathies, dermatitis herpetiformis, CLD, and malignancies. These patients may show IgA deposits in the kidney mesangium, but IgA nephropathy is rarely diagnosed as patients do not always develop proteinuria or renal insufficiency. The discovery of IgA deposits in these patients is usually an incidental finding in autopsy. The incidence of glomerular disease in psoriasis is rare. We present this case of a patient with psoriatic arthritis that developed nephrotic syndrome with a kidney biopsy with IgA nephropathy after starting treatment with Ustekinumab.

Case Description: A 40 y/o Caucassian man with past medical history of psoriatic arthritis. He was treated with adalimumab, but became ineffective and it was changed to Ustekinumab. He had been receiving for 2 years at a dose of 45 mg every 2 weeks. After starting Ustekinumab, he developed nephrotic syndrome with proteinuria 6g/24h and worsening kidney function with a creatinine 1.6mg/dL (baseline creatinine 1.0 mg/dL). Physical examination remarkable for hypertension with BP 145/102 mmHg and bilateral leg edema+2. Serologic work up including ANA, ANCA, dsDNA, C3, C4, Hepatitis panel and cryoglobulinemia resulted negative. Kidney biopsy showed IgA nephropathy with mesangial hypercellularity. Ustekinumab was discontinued, and he was started on prednisone 60 mg PO daily and losartan 50 mg po daily. Kidney function has remained stable after 2 months of follow up with significant improvement in the proteinuria.

Discussion: Psoriasis has not typically been associated to glomerular disease. Immunotherapy agents have been mostly described to cause renal injury in the form of TMA, FSGS, ATN, AIN. Few cases have been reported of glomerular disease, particularly IgAN, in patients receiving Ustekinumab. In this case, the patient presented nephrotic syndrome only after receiving treatment with Ustekinumab. Nephrologists should be suspicious of the relationship of this agent and IgAN. It is important to diagnose early to ensure adequate treatment to minimize long term kidney complications.

TH-PO974

A Case of Anti-Glomerular Basement Membrane Disease Recognized a Month After the Diagnosis of Membranous Nephropathy

Atsuro Kawaji, Yosuke Nakagawa, Naoto Hamano, Masahiro Koizumi, Takehiko Wada, Masafumi Fukagawa. *Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan.*

Introduction: Most of the patients with anti-glomerular basement membrane (GBM) disease present with rapidly progressive glomerulonephritis. However, in rare cases, this disorder develops following membranous nephropathy (MN). Here, we report a case of anti-GBM disease which developed shortly after the diagnosis of MN.

Case Description: A 76-year-old Japanese woman with hypertension and dyslipidemia was found to have nephrotic-range proteinuria and microscopic hematuria without increase in serum creatinine level. Although a renin-angiotensin system inhibitor was

initiated, massive proteinuria persisted and hypoalbuminemia had deteriorated over the following ten months, resulting in nephrotic syndrome. Kidney biopsy demonstrated thickening of GBM with a diffuse granular pattern of IgG and C3 staining along GBM on immunofluorescence microscopy. Electron microscopy revealed subepithelial and intramembranous electron-dense deposits, which led to the diagnosis of MN (stage II-III). At this diagnosis of MN, anti-GBM antibody was not detected in her serum. One month later, she was admitted with persistent fever and oliguria. She got anuric soon after the admission and hemodialysis (HD) therapy was initiated. Laboratory test revealed a high titer of anti-GBM antibody (276 IU/mL), and plasmapheresis therapy combined with corticosteroids was also initiated. The second biopsy showed severe necrotizing glomerulonephritis throughout all glomeruli with cellular crescents. Immunofluorescence microscopy demonstrated deposition of IgG along GBM in both linear and granular patterns. Her renal function did not recover in spite of decrease in titer of anti-GBM antibody, and she has been eventually on maintenance HD.

Discussion: The conformational change of GBM by MN may unmask hidden epitope in the non-collagenous domain 1 of typeIVcollagen, which could induce autoimmune response. Further studies are needed to determine whether MN could cause such autoimmunity.

TH-PO975

IgA Dominant Infection-Related Glomerulonephritis in the Setting of Acute Ehrlichiosis

Zafira Chowdhury,[2] Yevgeniy Borshchenko,[1] Michael B. Stokes,[3] Minesh Khatri,[1] Naveed N. Masani.[1] *[1]Nephrology, NYU Winthrop, Mineola, NY; [2]NYU Winthrop Hospital, Mineola, NY; [3]Columbia University Medical Center, New York, NY.*

Introduction: IgA-Dominant staining on immunofluorescence (IF) with diffuse endocapillary proliferative glomerulonephritis (GN) on light microscopy (LM) has a differential diagnosis that includes primary IgA nephropathy, Henoch-Schönlein purpura (HSP), and IgA-dominant infection related GN. We report a case of acute ehrlichiosis infection with concomitant GN. To date, there have been no reported cases of ehrlichiosis associated GN.

Case Description: A 70-year-old male with a petechial rash, 13 pound weight gain, bilateral lower extremity edema, and serum creatinine 1.6 mg/dl (12 months prior to presentation was 1.0 mg/dl). Urinalysis revealed 3+ protein, 2+ blood; protein:creatinine ratio of 5.3 g/g (urinalysis 12 months previously was negative for blood and protein). Serum albumin was 3.8 g/dL. Glomerular serologies, including complement levels and antineutrophil cytoplasmic antibodies, were either normal or negative. An IgM titer for *Ehrlichiosis chaffeensis* was strongly positive at 3.7 (normal < 1.0). Renal biopsy findings revealed diffuse endocapillary proliferation, widespread mesangial and global endocapillary hypercellularity, endothelial swelling, and mild activity. Of note, there was significant intracapillary leukocyte accumulation including neutrophils. There was minimal patchy tubular atrophy and interstitial fibrosis, comprising 10% of the cortex. IF was significant for 2+ IgA and 1+ C3. Electron microscopy revealed electron dense deposits in the mesangium and subendothelial locations, along with 40% foot process effacement. No subepithelial humps were identified. Given the patient's clinical timing of acute ehrlichiosis infection and GN, these findings support the diagnosis of an IgA-dominant infection related GN. The presence of neutrophils on LM and 1+ C3 staining on IF, albeit less than the IgA staining of 2+, also support the diagnosis.

Discussion: The LM pattern of proliferative GN with IgA dominance requires clinical correlation. Specific laboratory and biopsy findings including degree of IgA and C3 staining and presence of neutrophils can help distinguish this entity from HSP and IgA nephropathy, as well as timing of renal dysfunction with relationship to onset of infection.

TH-PO976

Case Report of Membranous Glomerulonephritis Secondary to Papillary Thyroid Carcinoma

Khalid M. Elharrif, Farah Abifaraj, Marjan Afrouzian, Hania Kassem. *University of Texas Medical Branch, Galveston, TX.*

Introduction: Secondary Membranous glomerulonephritis(GN) is most commonly seen in the setting of autoimmune disease, infection, neoplasia, and with certain therapeutic agents. Malignancies associated with secondary membranous GN are solid tumors such as carcinomas of the prostate, lung, breast, bladder, or gastrointestinal tract, and less frequently hematologic malignancies, such as chronic lymphocytic leukemia. We report a rare case of secondary membranous GN secondary to papillary thyroid carcinoma(PTC). We are not aware of any previous reports of a similar association.

Case Description: A 35-year-old female without significant past medical history, presented with nephrotic range proteinuria (10.6 g of proteinuria in 24 hours) and other features of nephrotic syndrome. Kidney biopsy diagnosis was consistent with secondary MGN with mesangial deposits and variegated deposits in terms of size and distribution. Anti PLA2R antibody serology and immunohistochemical staining were negative. Further work up for secondary MGN, including ANA and viral hepatitis, was negative. Patient underwent age-appropriate cancer screening and was eventually found to have a thyroid nodule with biopsy-proven diagnosis of PTC. The patient underwent thyroidectomy. One month post surgery, her proteinuria significantly improved (down to 4.5 g of proteinuria in 24 hours) with subsequent improvment of her volume status.

Discussion: Secondary Membranous nephropathy is associated with malignant conditions such as solid tumors and less commonly hematological malignancy. We present a unique case of MGN, secondary to PTC, with dramatic improvement of proteinuria post thyroidectomy. This case emphasizes the importance of clinical workup after a diagnosis of secondary MGN, which in our patient, led to the discovery of an unexpected PTC and its successful treatment.

TH-PO977

Doxycycline-Associated Minimal Change Disease

Rushang Parikh,[1] Nupur N. Uppal,[2] Vanesa Bijol.[3] *[1]Zucker School of Medicine at Hofstra/Northwell, NY, Manhasset, NY; [2]Hofstra Northwell School of Medicine, Great Neck, NY; [3]Northwell Health Hofstra University, Lake Success, NY.*

Introduction: Minimal Change Disease (MCD) is a disease that usually affects adolescents, however 10-25% of nephrotic syndrome in adults is also caused by MCD. Major causes that precipitate MCD in adults include infection, neoplasm, allergy, and drugs. We describe a rare case of MCD associated with doxycycline use.

Case Description: A 24-year-old Caucasian female with history of IBD presented to emergency department (ED) with worsening swelling of lower extremities. 4 weeks prior she was diagnosed with Influenza A, treated with Oseltamivir, and the week before presentation had mild fever when was diagnosed with acute sinusitis and initiated on doxycycline therapy. After taking doxycycline for 4 days, she started having "dizzy spells" followed by appearance of severe swelling over lower extremities with palpebral and perioral edema. Her systolic BP was 150s which was unusual for her. UA performed at Urgent Care center revealed RBCs in the urine and protein of 300 mg. She was transferred to ED, where was noted to have persistently elevated BP, with repeat UA also showing RBCs and protein. Spot urine protein/Creatinine was elevated at 10.3, with a serum creatinine of 0.62 mg/dL and albumin of 2.1 g/dL. Patient underwent kidney biopsy which showed "extensive effacement of visceral epithelial cell foot processes, suggestive of minimal change disease, and thin glomerular basement membranes, suggesting an inherited abnormality of basement membrane collagens." She was started on high-dose prednisone, to which she responded well. Her lower extremity swelling and proteinuria completely resolved within 2 weeks of corticosteroid therapy, and prednisone was subsequently tapered.

Discussion: Doxycycline is a widely available antibiotic that is readily used in the treatment of multiple pathogens. It is not typically associated with MCD however it has been shown to cause MCD in mice due to causing overexpression of VEGF-A in the kidneys which results in albuminuria and minimal change disease. To our knowledge, there has been only one reported case of doxycycline related MCD in humans. Physicians including internists, infectious disease specialists and nephrologists need to be aware of this potential adverse effect of doxycycline.

TH-PO978

Collapsing Focal Segmental Glomerulosclerosis and Diffuse Infiltrative Lymphocytosis Syndrome with Renal Involvement in Acute HIV Infection

Erum Z. Malik, Duncan B. Johnstone. *Temple University School of Medicine, Philadelphia, PA.*

Introduction: Human Immunodeficiency Virus (HIV) infects and damages podocytes leading to HIVAN, a collapsing form of focal and segmental glomerulosclerosis. HIV also causes dysregulation of the immune system, which rarely can cause CD8+ T-cells to infiltrate and attack various organs, leading to Diffuse Infiltrative Lymphocytosis Syndrome (DILS). We present the first case of simultaneous HIVAN and DILS with renal involvement, occurring only 6-8 weeks after infection during the initial phase of acute HIV seroconversion.

Case Description: A 20 year old Hispanic male was diagnosed with acute HIV based on known exposure, negative serology, and positive p24 antigen. Three weeks later, he was admitted with fever, chills, myalgias, severe dry mouth, neuropathic pain of both legs, and declining urine output. Compared to labwork three weeks prior, new labs showed seroconversion of HIV, a 10-fold increase in CD8+ T-cells, new hyponatremia (123 mEq/L), and renal failure (creatinine 5.24 mg/dL, prior 0.98). Urinalysis showed 300+ protein (while oliguric). Sonogram showed bilaterally enlarged and echogenic kidneys suggestive of interstitial nephritis. He denied using any medications including herbals. Biopsy showed collapsing FSGS with severe interstitial inflammation, and staining demonstrated these were CD8+ T-cells. He started steroids, losartan and anti-retrovirals. His symptoms of xerostomia and neuropathy improved daily, along with an increase in urine output.

Discussion: This report is the first to describe both HIVAN and DILS simultaneously, and of additional significance, both conditions arose early at the time of HIV seroconversion. HIVAN typically occurs in advanced HIV as an AIDS defining illness but was reported twice in early HIV. DILS is a multi-organ disorder of increased, dysregulated CD8+ T-cells that infiltrate one or more organs, most often the salivary glands and lungs. When kidneys are affected, DILS shows similarities to allergic interstitial nephritis (enlarged and echogenic kidneys, tubular proteinuria, interstitial infiltrate on biopsy), but with DILS the cells are CD8+ T-cells. Renal and extra-renal symptoms of DILS can respond to HAART and prolonged steroids.

TH-PO979

Clinical Course of a Patient Treated for Dense Deposit Disease (Monoclonal Protein Associated)

Yevgeniy Borshchenko,[1] Win Win Moe,[1] Kamal Nayyar,[1] Antonia Tharian,[2] James Drakakis.[1] *[1]Nephrology, NYU Winthrop, Mineola, NY; [2]NYU Winthrop, Manhasset, NY.*

Introduction: Dense deposit disease (DDD), a subcategory of C3 glomerulopathy is a rare entity characterized by uncontrolled activation of the alternative pathway (AP) of the complement cascade. When diagnosed in the older population, there is often an

accompanying monoclonal gammopathy of undetermined significance (MGUS). As the monoclonal protein may perturb AP regulation, treating with chemotherapy need be considered. We report a case of DDD (MGUS associated) first treated with bortezomib, later switched bortezomib plus cyclophosphamide and dexamethasone (CyBorD). As there was no histologic or serologic improvement, daratumumab was introduced with stability of kidney function.

Case Description: A 62 year old male was evaluated for a serum creatinine (Cr) of 1.3 mg/dL with urine protein of 3 g/g. There were low C3 and C4 levels. Urinalysis showed 3+ blood with 86 red blood cells. Serum immunofixation detected an IgG kappa monoclonal protein. Plasma cell count on bone marrow biopsy was 8%. Renal biopsy showed diffuse mesangial and segmental endocapillary proliferative glomerulonephritis with membranoproliferative features. Immunofluorescence had intense deposition of C3. Global, marked electron dense deposits were seen. As findings were consistent with DDD, bortezomib was initiated. After 3 months, this was held for observation. Cr then was 2.5 mg/dL with urine protein/creatinine of 4.5 g/g. Six months later, bortezomib was resumed but not effective. CyBorD followed, but Cr rose to 3.5 mg/dL. Second kidney biopsy revealed severe tubular atrophy and interstitial fibrosis. At this point, weekly daratumumab with bortezomib was started. After several months, renal function has not declined further and proteinuria reached nadir of 2.9 g/g.

Discussion: Monoclonal gammopathy has emerged as a potential driver of the complement dysregulation, known to characterize DDD. Although there have been several strategies reported, there is no standard approach to guide therapy. While chemotherapy is not used to treat MGUS, it is appropriate in cases whereby the monoclonal protein manifests as a form of C3 glomerulopathy (DDD). This case demonstrates various options which may be utilized to curtail renal morbidity. While bortezomib alone and CyBorD were not effective, our patient has achieved ongoing clinical and laboratory stability with daratumumab.

TH-PO980

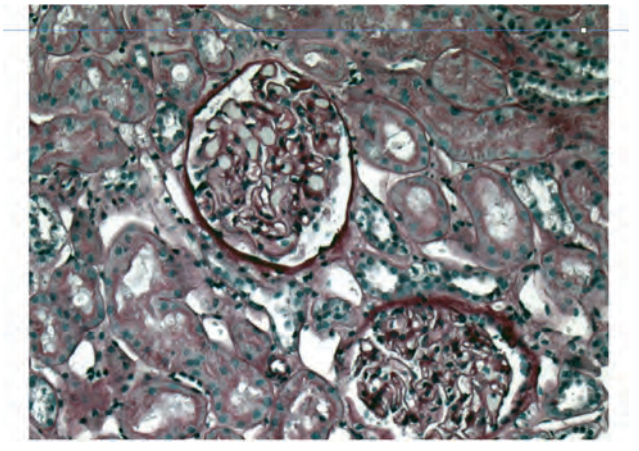
Chronic Inflammatory Demyelinating Polyneuropathy and Concurrent Membranous Nephropathy Associated with Anti-Contactin-1 Autoantibodies

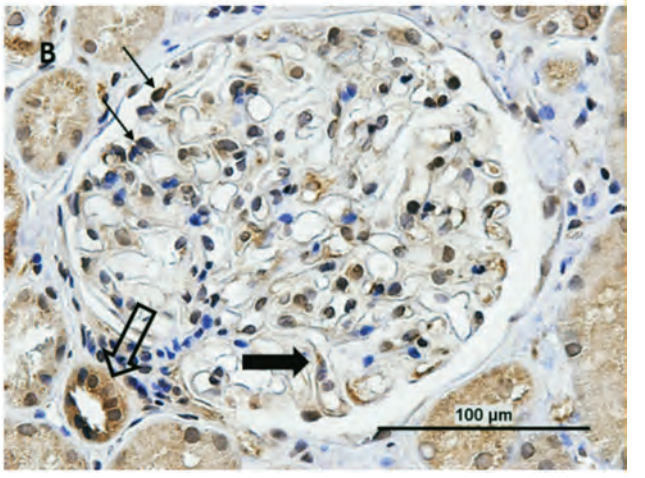
Ola Tarabzuni. *Department of Nephrology, Mcmaster, Hamilton, ON, Canada.*

Introduction: MN is a common cause of nephrotic syndrome in nondiabetic adults. CIDP is an acquired disorder of peripheral nerves. Antibodies directed against the paranodal axonal cellular adhesion molecule contactin-1 and its binding partner neurofascin have been identified in some severe cases of CIDP. Case reports of patients with co-existing MN and CIDP have been published, but an underlying disease mechanism has not been described in these patients

Case Description: A 45-year old male was diagnosed with CIDP in March 2015. He was treated with prednisone, IVIG and azathioprine with good response. In September 2016, he presented with nephrotic syndrome with 22 g/day of protein. He underwent a renal biopsy which showed stage 2 MN. Renal function was normal and anti-phospholipase 2 antibody was negative. Malignancy, infectious, and routine autoimmune investigations were negative. Additional serology was positive for IgG4 anti-contactin-1 antibody. Neurofascin antibody was negative. We examined renal tissue for the presence of contactin-1 antigen. The patient's biopsy was strongly positive for this antigen, while 2 control were negative. Cyclosporine was added to the patient's regimen with good resolution of proteinuria.

Discussion: Anti-contactin-1 antibodies have been identified as a cause of CIDP. This is the first report of these antibodies being identified in a case of secondary membranous nephropathy. Anti-contactin 1 antibody may be a novel diagnostic test in this condition.





TH-PO981

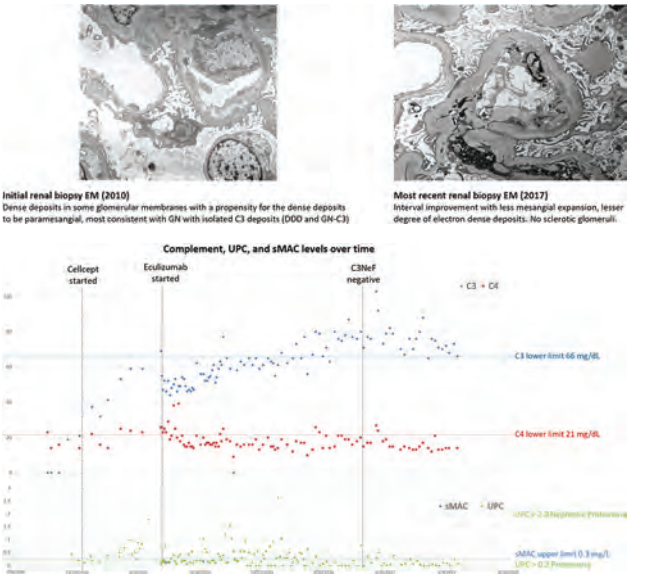
A Case of Pediatric Dense Deposit Disease (DDD) in Remission for 7 Years on Eculizumab

Kimmy T. Vuong, Katayoon Shayan, Elizabeth G. Ingulli. *UCSD Rady Childrens Hospital, San Diego, CA.*

Introduction: DDD affects only 2-3 people per million. Slowing the disease course is critical because 50% of affected children progress to ESRD within 10 years, ultimately requiring dialysis or renal transplant. Recurrence post-transplant leads to at least 50% of graft loss. Current guidelines suggest Eculizumab as a potential treatment for refractory cases defined by persistent proteinuria, hematuria, alternative complement pathway activation or elevated C3 nephritic factor (C3NEF).

Case Description: A 5 year old previously healthy male presented with at least 2 months of asymptomatic microscopic hematuria without associated illness or relevant family history. He had normal BP, a normal exam, mild proteinuria (UPr/UCr 0.43), hematuria (URBCs >25), hypocomplementemia (C3 <20 mg/dL, C4 23 mg/dL), normal renal function and albumin. Renal biopsy had membranoproliferative glomerulonephritis with isolated intramembranous deposits. Complement genetic analysis was negative. Functional studies showed alternative pathway complement activation and the presence of C3NEF.

Discussion: He received steroids and Cellcept 700 mg/m2/d but continued to have complement activation (based on functional studies), microhematuria and worsening proteinuria (UPC peak 1.8). He was weaned off steroids and Cellcept (after 7 months) then received Eculizumab without significant adverse effects or complications. A follow-up renal biopsy improved and his proteinuria, hematuria. Functional studies suggest ongoing complement activation and lapses in therapy increase proteinuria. Thus, eculizumab has been continued for 7 years. To date, he may have one of the longest DDD remissions on Eculizumab monotherapy. Further studies including a randomized controlled trial of Eculizumab monotherapy could define parameters for starting and discontinuing treatment.



TH-PO982

Urinary angiotensinogen predicts renal disease activity in lupus nephritis

Wei Cao. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: A non-invasive indicator of renal histological lesions and disease activity in lupus nephritis (LN) is needed for timely and targeted treatment before overt renal injury. Here, we tested the utility of urinary angiotensinogen (UAGT) to predict renal disease activity in LN.

Methods: A prospective, three-stage study was performed in patients with LN. In stage I, UAGT was measured in 140 newly-diagnosed LN patients. In stage II, UAGT was monitored in 61 subjects from stage I for up to 12 months. In stage III, UAGT was monitored in 12 LN patients before, during and after the onset of renal flares.

Results: In stage I, UAGT significantly increased in LN patients, correlating well with kidney AGT expression and histological activity. Patients with LN Class IV exhibited the highest UAGT compared with other histopathological classes of LN. For identifying LN class IV, a particularly aggressive type of LN, UAGT outperformed the conventional clinical measures and improved their performances. In stage II, UAGT decreased after immunotherapy and remained low in patients with LN remission during follow-up. In stage III, an elevation in UAGT predicted recurrence of LN, and a decline in UAGT after a renal flare heralded the remission of disease before conventional clinical measures.

Conclusions: UAGT in LN is a promising indicator for dynamical surveillance of renal disease activity and prediction of renal flares.

Funding: Government Support - Non-U.S.

TH-PO983

Association Between Kidney Tissue Estrogen Gene Signature and Nephrotic Syndrome Remission

Tiffany R. Bellomo,[1] John R. Hartman,[2] Michelle A. Hladunewich,[4] Michelle M. O'Shaughnessy,[3] Andrea L. Oliverio,[1] Matthias Kretzler,[1] Maria Larkina,[1] Laura H. Mariani.[1] *[1]Nephrology, University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Stanford University, Palo Alto, CA; [4]University of Toronto, Toronto, ON, Canada.*

Background: Kidney disease severity and rate of progression are reported to be higher in males than females, which may in part be mediated by glomerular sex hormone receptor expression. We developed a kidney tissue estrogen gene signature to examine associations between estrogen signaling and remission from nephrotic syndrome.

Methods: Patients with active FSGS, MCD, MN, or other nephrotic syndrome at enrollment in NEPTUNE, a multi-center observational cohort study were studied. Our outcome of interest was complete remission, defined as a uPCR ≤0.3 g/g. Our exposure of interest was a novel estrogen z-score. First, genes affected by estrogen signaling were defined as any gene related to ESR1 and 2 in both the HumanBase (Flatiron Institute) and MSigDB (Broad Institute) databases. Genes were limited to only those with estrogen response elements in the promoter region and 21 genes of interest were identified. Genome wide RNA expression data from the glomerular compartment of kidney tissue were used to calculate a z-score (X-mean/SD) for each gene. Each patient's overall z-score was generated from the average of the individual gene z-scores.

Results: Among the 177 patients, 67% were male, mean age was 34 years, mean eGFR was 86 ml/min/1.73m2, and mean uPCR was 2.8 g/g. A cox proportional hazards model controlling for age, sex, eGFR, and uPCR demonstrated a significant association between overall Z score and time to complete remission (HR 4.59; 95% Cl 1.4-15.1; p=0.012). Figure 1 shows unadjusted association of z-score median split with time to remission.

Conclusions: Higher estrogen score was associated with a higher hazard for complete remission. This estrogen gene signature could be used in both research and clinical practice to more carefully risk stratify patients. These findings also identify the estrogen receptor as a potential therapeutic target in glomerular disease.

Proximal tubular cell isolation during human acute kidney injury

Sophie M. De Seigneux,[4,2] David Legouis,[1,2] Pierre Galichon.[3] *[1]Intensive Care Unit, Geneva University Hospital, Geneva, Switzerland; [2]Department of Medicine and Cell physiology, University of Geneva, Geneva, Switzerland; [3]Sorbonne Universite, Paris, France; [4]Service of Nephrology, Geneva University Hospital, Geneva, Switzerland.*

Background: There is an urgent need to discover and validate the pathophysiological pathways involved in human acute kidney injury (AKI). Proximal tubular cells (PTCs) are the cells primarily injured during AKI and their maladaptive repair contribute to AKI to chronic kidney disease (CKD) transition. It is very important to develop non-invasive tools that will help to improve our understanding of the signaling pathways contributing to the maladaptive repair.

Methods: We collected urine from patients hospitalized in the ICU of University Hospital of Geneva, presenting or not AKI. We here propose a novel method to isolate specifically PTCs from human urine using a combination of Magnetic-Activated Cell **Sorting (MACS)** sorting and Fluorescent-Activated Cell **Sorting** (FACS). We have characterized the sorted cells, and show how these cells can be used to determine pathophysiological pathways in human AKI.

Results: Isolated PTCs are viable, can be cultured for at least three passages (a) and retain the expression of several proximal tubule specific markers at the level protein (b) and of mRNA (c). We report that our technique is more sensitive than routine microscopic approach used to identify the presence of tubular cells in the urine during clinical AKI (d). There is a clear correlation between isolated PTC cell numbers and the severity of AKI as defined by KDIGO staging guidelines (e). RNA sequencing and pathway analysis confirmed alterations in PTCs cell cycle in AKI patients, which correlated to the severity of AKI (f).

Conclusions: We show that isolation of PT cells from urine is possible during human AKI episode. These cells can be used to study the pathways involved in AKI and we could confirm alterations of the cell cycle in PTCs collected from AKI patients. Thus, we believe that PTCs isolated from human urine will allow the identification and characterization of novel pathways in AKI and the AKI to CKD transition.

Background: Racial/ethnic disparities exist among glomerular disease patients with respect to access to care and patient outcomes. However, few data exist on how race/ethnicity influences protocol adherence and data completeness in clinical research studies. Identification of such disparities will improve trial design and enhance generalizability of research findings.

Methods: CureGN is a 70-center prospective cohort study of patients with MCD, FSGS, MN, IgA nephropathy, or IgA vasculitis. We compared metrics on retention, visit completion, data [clinical, patient-reported outcomes (PRO), laboratory, pathology] and biosample collection [urine, blood, including RNA and DNA] across racial/ethnic groups using repeated measures logistic regression with generalized estimating equations and Cox proportional-hazards models.

Results: Overall protocol adherence was high (80-97%) for all races and ethnicities. Among 2243 adults and children enrolled at time of data analysis, significant differences in visit completion and sample collection were observed, with lower scores for Blacks and Hispanics on many metrics (Table).

Conclusions: Significant racial/ethnic differences in protocol adherence exist among enrollees with glomerular disease in CureGN. Rates were significantly lower in blacks and Hispanics. The diversity of research staff and site investigators may influence these disparities. Creation of a diverse Patient Advisory Council might reduce disparities.

[i] repeated measures logistic regression with generalized estimating equations

TH-PO986

Rapid Genome Sequencing to Guide Clinical Decision Making in FSGS

Maddalena Marasa,[1] Dina Ahram,[1] Atteeq U. Rehman,[3] Adele Mitrotti,[1] Namrata G. Jain,[1] Patricia L. Weng,[2] Stacy E. Piva,[1] Byum hee Kil,[1] Hilda E. Fernandez,[1] Natalie S. Uy,[1] Debanjana Chatterjee,[1] Jai Radhakrishnan,[1] Gerald B. Appel,[1] Dominick Santoriello,[1] Andrew S. Bomback,[1] Fangming Lin,[1] Vivette D. D'Agati,[1] Vaidehi Jobanputra,[3,1] Simone Sanna-Cherchi.[1] *[1]Columbia University Medical Center, New York, NY; [2]UCLA, Los Angeles, CA; [3]New York Genome Center, New York, NY.*

Background: About 30% of children with focal segmental glomerulosclerosis (FSGS) have a genetic cause. While genetic forms are usually resistant to immunosuppressants, steroids are still the first-line treatment regardless of individual genetic make-up. We hypothesized that rapid whole genome sequencing (WGS) at diagnosis will help guide clinical management by a) improving diagnosis, b) sparing immunosuppressive treatment in cases with Mendelian mutations, c) identifying cases responsive to targeted therapy, d) improving counseling for both renal and extrarenal disease, and e) improving transplant evaluation and outcome.

Methods: We conducted CLIA-certified rapid WGS to guide decision-making in 10 children and young adults affected by biopsy-proven FSGS where a genetic diagnosis could affect therapeutic decision. Return of results (ROR) included therapeutic, familial and pre-transplant counseling.

Results: Turn-around time from consent to ROR averaged 20 days (15-42). WGS identified a diagnostic genotype in 5/10 patients and prompted biopsy revision in 2 cases leading to management change in virtually all cases, including holding/stopping immunosuppression in 6/10 cases, new treatment in 5/10 cases and improved transplant evaluation in 2 cases (Fig. 1). Genetic diagnosis also prompted early screening for subclinical neurological disease in a patient.

Conclusions: Rapid WGS in FSGS can improve medical management and possibly outcome by sparing ineffective and toxic treatment, identifying forms amenable to etiologic treatment, and inform familial counseling and pre-transplant evaluation thus optimizing organ allocation.

The Soluble VEGF Receptor sFlt-1 Contributes to Endothelial Dysfunction in IgA Nephropathy

Yaling Zhai, Yanna Dou, Jing Xiao, Zhanzheng Zhao. *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

Background: Endothelial injury is a common manifestation in IgA nephropathy (IgAN). After the previous identification of the upregulated soluble fms-like tyrosine kinase-1 (sFlt-1) correlates with endothelial injury in IgAN, in the present study, we further explored the role of sFlt-1 in endothelial injury in IgAN.

Methods: We enrolled 72 patients with IgAN and detected the sFlt-1 levels. The polymeric IgA1 (pIgA1) complexes were isolated from the pooled plasma samples of another 10 patients with IgAN. Apoptosis proteins were detected in cultured human umbilical vein endothelial cells (HUVECs) with recombinant sFlt-1 or the caspase-9 inhibitor, Z-LEHD-FMK stimulation.

Results: We identified there were positive correlations between sFlt-1 and IgA-IgG complex as well as vWF levels in patients with IgAN. The sFlt-1 levels in HUVECs were

significantly upregulated by pIgA1 complex derived from IgAN patients in a concentration-dependent manner. The proliferation ability of HUVECs was damaged when stimulated by sFlt-1 protein in a time- and dose- dependent manner. And the apoptosis rate was up-regulated significantly as the stimulation concentration of sFlt-1 increased. We found sFlt-1 challenge could significantly increase the expression of vWF and ET-1. In addition, sFlt-1 could increase the levels of caspase-9, caspase-3, Bax and mitochondrial membrane potential; facilitate the release of cytochrome C from mitochondria to cytoplasma. In contrast, Z-LEHD-FMK attenuated high sFlt-1-induced HUVECs apoptosis.

Conclusions: Our study demonstrated that sFlt-1 expression was up-regulated by challenged by pIgA1 complex derived from patients with IgAN, which then facilitated human umbilical vein endothelial cells apoptosis through the mitochondrial-dependent pathway.

The Levels of Plasma suPAR May Not Discriminate the Patients with Poor Therapeutic Reactivity Among Adult Japanese Focal Segmental Glomerulosclerosis and Minimal Change Disease

Takaya Ozeki, Takuji Ishimoto, Sawako Kato, Yoshinari Yasuda, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan*.

Background: Soluble urokinase-type plasminogen activator receptor (suPAR) was originally reported as a specific biomarker for focal segmental glomerulosclerosis (FSGS). Recently, several studies negatively showed the importance of suPAR on the diagnosis of FSGS. However, there are few reports investigating the utility of suPAR as a marker for predicting therapeutic reactivity among adult minimal change disease (MCD) and FSGS.

Methods: Multicenter retrospective cohort study. Among the biopsy-proven MCD/FSGS patients during 2005-2015 at Nagoya university and 14 affiliated hospitals, the patients who collected their plasma at biopsy according their consent were included. Age>20, relapsed cases, non-nephrotic cases or cases who had already received any immunosuppressive treatment at biopsy were excluded. Plasma suPAR level were measured by ELISA (R&D Systems). The patients were divided into 2 groups whether they could attain complete remission within 4 weeks or not (responders or non-responders). We compared suPAR level between MCD/FSGS or responders/non-responders and evaluated the correlation suPAR level and other clinical variables.

Results: Ninety-nine cases (MCD/FSGS: 65/34, responders/non-responders: 67/32) were included to the analyses. The patients with FSGS or non-responders demonstrated more impaired kidney function at baseline. The median value of plasma suPAR was MCD/FSGS: 2253.8 vs. 3290.9 pg/mL(p<0.001) and responder/non-responder: 2334.1 vs. 3080.7 pg/mL(P=0.020). There was moderate negative correlation between plasma suPAR levels and eGFR (Speaman's rho: -0.42). When analyzing the patients with eGFR>=60, the median value of plasma suPAR was MCD/FSGS: 2253.8 vs. 3290.9 pg/mL(p<0.001) and responder/non-responder: 2334.1 vs. 3080.7 pg/mL (P=0.55).

Conclusions: Plasma suPAR level was observed significantly higher among FSGS and non-responders. However, we cannot ignore the affection from the patients' kidney function. Among patients with preserved renal function, plasma suPAR levels were still higher in those diagnosed with FSGS, whereas the levels were not different between non-responders and responders. We plan to present additional results including urine specimen of same patients.

Association Between Histologic Variants of Focal Segmental Glomerulosclerosis and Outcomes: Results from the Japan Renal Biopsy Registry

Takehiko Kawaguchi,[1] Toshiyuki Imasawa,[1] Hiroshi Kitamura,[1] Moritoshi Kadomura,[1] Shoichi Maruyama,[2] Takaya Ozeki,[2] Ritsuko Katafuchi,[3] Kazamasa Oka,[4] Yoshitaka Isaka,[5] Hitoshi Yokoyama,[6] Hitoshi Sugiyama,[7] Hiroshi Sato.[8] *[1]National Hospital Organization Chibahigashi National Hospital, Chiba, Japan; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]National Hospital Organization Fukuokahigashi Medical Center, Koga, Fukuoka, Japan; [4]Hyogo Prefectural Nishinomiya Hospital, Hyogo Nishinoniya, Japan; [5]Osaka University Graduate School of Medicine, Suita, Japan; [6]Kanazawa Medical University, Ishikawa, Japan; [7]Okayama University Graduate School, Okayama, Japan; [8]Clinical Pharmacology and Therapeutics, Graduate School of pharmaceutical Sciences, Tohoku University, Sendai, Japan*.

Background: Focal Segmental Glomerulosclerosis (FSGS) is a leading cause of end stage kidney disease (ESKD). The previous studies suggested that FSGS histologic variants of the Columbia classification were associated with clinical outcomes, but the impact of FSGS variants on outcomes has not comprehensively been investigated in Japan.

Methods: Data on patients with primary FSGS of Japan Renal Biopsy Registry from 2010 to 2013 were analyzed. The outcome measures were 30% decline in estimated glomerular filtration rate (GFR30), progression to ESKD, and the first clinical remission (CR: proteinuria<0.3g/day) during 60 months after the biopsy. Multivariable Cox models were used to compare the outcomes among variants, adjusted for age, sex, baseline eGFR, nephrotic proteinuria (NP), and immunosuppressive treatment (IS).

Results: 311 patients were enrolled [median age: 52 (IQR 33, 66) years, male: 63%; baseline eGFR: 58 (IQR 40, 80) ml/min/1.73m^2, NP: 54%, IS: 54%]. The distribution of variants was 47% (n=147) FSGS not otherwise specified (NOS), 19% (n=59) tip (TIP), 16% (n=50) perihilar (PERI), 13% (n=40) cellular (CEL), and 5% (n=15) collapsing (COL). During the follow-up, 87 patients (28%) developed GFR30, 25 (8%) ESKD, and 118 (38%) reached CR. No significant differences in GFR30 and ESKD were found among variants, but TIP was significantly associated with CR compared with PERI [adjusted HR (95% CI), 2.2 (1.0, 4.8) (Figure).

Conclusions: Based on the Japanese national registry in the modern era, FSGS variants did not have a significant impact on GFR30 or ESKD during 60 months, while the variant types were associated with CR. Larger sample size, especially for COL, and longer follow-up may be needed to detect a statistically significant difference in the outcomes among FSGS variants.

TH-PO990

Clinical Outcome and Molecular Profile of Perihilar FSGS Are Similar to Other FSGS Subtypes

Neal Doshi,[1] Maria Larkina,[1] Cynthia C. Nast,[2] Jean Hou,[2] Louis-Philippe Laurin,[4] Sean Eddy,[1] Matthias Kretzler,[1] Patrick H. Nachman,[3] Laura H. Mariani.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]University of Minnesota, Minneapolis, MN; [4]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada*.

Background: Perihilar (PH) FSGS is hypothesized to be a result of podocyte loss from secondary causes including obesity, hypertension and low nephron mass. It is assumed to have a more favorable outcome than the immune mediated subtypes of FSGS, including FSGS NOS, but prior studies have included a referral population more likely to have a severe phenotype.

Methods: NEPTUNE is a multi-site observational cohort study of children and adults with nephrotic syndrome, enrolled at the time of clinically indicated renal biopsy. Cox models for time to either remission [defined as urine protein to creatinine ratio (UPCR <0.3mg/mg)] or ESRD/40% eGFR decline were adjusted for age, GFR, uPCR, race, and sex. Genomewide mRNA expression data from kidney biopsy tissue was generated using Affymetrx 2.1 ST platform. Differentially expressed genes (FDR <1%) for perihilar FSGS compared to all other subtypes was determined using Significance Analysis of Microarrays (SAM).

Results: Among 111 patients with FSGS, 28 were PH, 19 Collapsing, 13 Tip, and 51 NOS. Gene expression was available from the glomerulus compartment for 39 patients and from tubulointerstitial compartment for 56. Comparing PH to NOS subtype, there were no differences in obesity (71% vs 78%), edema (32% vs. 36%), or hypertension (25% vs. 38%). 52% of patiehts with a PH lesion had >50% foot process effacement. Adjusted survival models showed no difference in time to complete remission or loss of eGFR between PH and NOS subtypes (p-value 0.88 and 0.22, respectively) [Fig 1]. Only 3 glomerular (of 25,583) and 6 tubular genes (of 23,397) were differentially expressed between PH vs other subtypes.

Conclusions: Patients with PH lesions as defined by the Columbia classification criteria had similar clinical presentations, rate of remission and loss of GFR as compared to the NOS subtype. The tissue molecular profile was also similar for PH patients as compared to other subtypes, raising the possibility that the mechanism of underlying tissue damage may be shared across the subtypes despite heterogeneous initial insults and varied pathologic categories.

TH-PO991

FSGS Outcome Comparison: Idiopathic Collapsing Glomerulopathy vs. Not Otherwise Specified Variant

Mateus J. Luvizotto, Gerard F. Sales, Cristiane B. Dias, Giulia gabriela B. Figueiredo, Aline L. Resende, Denise M. Malheiros, Precil D. Neves, Luis Yu, Viktoria Woronik, Lectícia Jorge. *University of Sao Paulo, Sao Paulo, Brazil*.

Background: Focal segmental glomerulosclerosis (FSGS) is a morphologic pattern of glomerular injury that frequently progresses to end-stage renal disease. Histologic variants express variable rates of progression. Collapsing Glomerulopathy (CG) has usually been associated with poor renal outcomes, while the not otherwise specified (NOS) variant has better outcomes. The goal of this study was to compare the two histologic forms and identify clinical features of progression.

Methods: A retrospective analysis was performed on all CG and NOS cases diagnosed by kidney biopsy between 1996 and 2016 at the University of Sao Paulo. Clinical and laboratory data were collected at baseline and at the end of follow up. We excluded cases chronic viral infection, drugs, any suspected immune-mediated disease and diabetes. We analyzed histological, clinical and follow-up data and compared among variants. Outcome was defined as ESRD or doubling of baseline creatinine.

Results: Clinical features of the groups CG and NOS are summarized in Table 1. There was no significant difference in age, gender, albumine, hemoglobin, hematuria, proteinuria, among the two groups. The immunofluorescence of the renal biopsies showed a greater predominance of IgM and C3 in the CG compared to the NOS variant. The NOS form was significantly associated with a better renal outcome.

Conclusions: The collapsing and NOS variants had similar baseline CKD-EPI, however the collapsing form had a worse renal outcome. Moreover, Further studies are necessary to explore the different immunofluorescence patterns among the forms.

Table 1 -Clinical features of the groups NOS and CG

n	NOS(n=32)	CG(n=57)	p value
Age(Y)	33.2±18.4	32.0±16.3	0.79
Male (n, %)	14(43)	32(56)	0.26
Creatinine (mg/dL)	1.34±1.0	1.84±0.7	0.02
CKD-EPI baseline	74.85±37.7	62.85±39.1	0.16
Proteinuria (g/day)	10.04±4.5	8.08±6.3	0.22
Hematuria	8(25)	28(49)	0.55
Albumin (g/dL)	1.89±0.8	2.15±0.9	0.30
Hemoglobin (g/dL)	13.0±2,1	12.6±2.2	0.51
Creatinine at the end	2.41	7.33	
IgM positive (%)	6 (33)	26(60)	0.05
C3 positive (%)	7 (38)	29(70)	0.02
Creatinine duplication or ESRD (%)	8(25)	32(65)	0.00

Data showed as mean(+/-SD).

TH-PO992

Study on Association of Initial Prednisolone Dose with Remission, Relapse, and Infectious Complication in Adult-Onset Minimal Change Disease

Kaori Tanabe,[1] Ken-ichi Samejima,[1] Hideo Tsushima,[1] Katsuhiko Morimoto,[2] Masaru Matsui,[3] Miho Tagawa,[1] Masahiro Eriguchi,[1] Yasuhiro Akai,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Nara-ken, Japan; [2]Nara Prefecture Western Medical Center, Ikoma-gun, Nara, Japan; [3]Nara Prefecture General Medical Center, Nara, Japan.*

Background: Majority of patients with minimal change disease (MCD) are steroid sensitive with good renal prognosis. However, about half of the cases relapses during prednisolone (PSL) tapering after remission of nephrotic syndrome. The initial dose of PSL varies by reports from 0.5 to 1 mg/kg/day. But little is known about the optimal PSL dose for initial treatment of MCD.

Methods: This is a retrospective multicenter cohort study on treatment-naïve adult patients with MCD diagnosed by renal biopsy from 1981 to 2015. The exposure of interest was initial dose of PSL <0.683 mg/kg/day (median) (Group L) compared to ≥0.683 mg/kg/day (Group H). Cumulative remission and relapse after remission were compared using Cox regression adjusted with for baseline characteristics. Median time to remission, 4-week remission rate, and incidence of infection that requires hospitalization during the 6 months following steroid therapy were also compared using Mann-Whitney U test and Chi-square test.

Results: Among 70 patients who met the criterion, 38 (54.3%) were male and the average age was 46.8 ± 20.1 years. During a median follow-up of 3.2 years, 67 (95.7%) achieved complete remission and 35 (52.2%) relapsed after remission. The median initial dose of PSL was 0.63 and 0.73 mg/kg/day in Group L and H, respectively. There was no significant difference in remission rate between Group L and H at 4 weeks (74.3 vs 71.4%; p=0.79). The median time to remission in Group L was comparable to that in Group H (15 vs 14 days; p=0.66). Multivariable Cox hazard model revealed that initial dose of PSL was not a significant predictor for remission (HR 1.23, 95%CI 0.67 to 2.26, p=0.51), but Group L had a trend toward higher relapse rate (HR 2.18, 95%CI 0.94 to 5.25, p=0.07). There was no significant difference in 6-month incidence of infectious complication between the groups (Group L, 5.7% and Group H, 2.9%, p=0.56).

Conclusions: The initial dose of PSL was not associated with time to remission and remission rate, but lower initial dose of PSL had a trend toward higher relapse rate. The results in this study suggest that the dose of PSL would be tapered carefully after remission, when initiating treatment with lower dose of PSL.

A Pilot Study of a Gluten-Free Dairy-Free Dietary Intervention in Children with Steroid-Resistant Nephrotic Syndrome

Maria jose Perez saez,[1,2] Audrey Uffing,[4] Juliette Leon,[9] Naoka Murakami,[4] Andreia Watanabe,[12] Thiago J. Borges,[4] Venkata Sabbisetti,[4] Pam Cureton,[11] Victoria Kenyon,[10] Leigh Keating,[2] Karen Yee,[4] Carla A. Satiro,[7] Gloria Serena,[10] Friedhelm Hildebrandt,[5] Cristian Riella,[8] Towia Libermann,[2] Minxian Wang,[13] Julio Pascual,[6] Joseph V. Bonventre,[4] Alessio Fasano,[10] Leonardo V. Riella.[3] *[1]Hospital del Mar, Barcelona, Spain; [2]Renal, Brigham and Women's Hospital, Boston, MA; [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [4]Brigham and Women's Hospital, Brookline, MA; [5]Boston Children's Hospital, Boston, MA; [6]Hospital del Mar, Parc de Salut Mar, Barcelona, Spain; [7]Instituto da Criança HCFMUSP, Sao Paolo, Brazil; [8]Beth Israel Deaconess Medical Center, Boston, MA; [9]Hôpital Necker-Enfants Malades, PARIS, France; [10]Massachusetts General Hospital, Boston, MA; [11]MassGeneral Hospital for Children, Ellicott City, MD; [12]School of Medicine - University of Sao Paulo, Sao Paulo, Brazil; [13]Broad Institute, Cambridge, MA.*

Background: Steroid-resistant nephrotic syndrome (SRNS) in children often fails immunosuppression and progresses to kidney failure. Case reports have suggested potential beneficial effects of dietary changes on SRNS, especially gluten-dairy restrictions. Zonulin is a circulating protein upregulated in gluten sensitivity, which regulates intestinal barrier. We hypothesize that zonulin might also alter permeability of podocyte tight junctions and contribute to SRNS activity.

Methods: Prospective non-randomized pilot study to investigate the effect of a gluten and dairy-free (GF/DF) diet in children with SRNS. The study was organized as a four-week summer camp with prospective collection of blood, urine and stool.

Results: 16 patients (mean age 7 years, range 2-21) met the eligibility criteria. Ten patients had FSGS, while six minimal change disease. Whole exome sequencing did not reveal any SRNS-associated variants. Complete remission following implementation of GF/DF diet occurred in two patients (13%, Fig A –marked in blue and red). Furthermore, GF/DF diet showed anti-inflammatory effects on the immune system in all participants, reducing circulating Th17 cells by 78% (Fig B) and decreasing levels of pro-inflammatory cytokines (Fig C). Microbiota analysis revealed a higher fraction of *Faecalibacterium prausnitzii* upon dietary intervention. Circulating zonulin levels over 106 ng/mL differentiated responders from non-responders (Fig D).

Conclusions: GF/DF may be an effective coadjuvant treatment in a subset of children with SRNS, in particular those with high zonulin levels. Diet intervention can also have anti-inflammatory benefits. A summer camp is a feasible way to implement dietary interventions in children and assess its short-term effect.

Rituximab as a Rescue Treatment of Primary Podocytopathies in a Brazilian University Center

Gabriel T. Sales, Danilo E. Fernandes, Daniel R. Rocha, Gianna Mastroianni-kirsztajn. *Nephrology, Federal University of Sao Paulo, Sao Paulo, Brazil.*

Background: Focal and segmental glomerulosclerosis (FSGS) and minimal change disease (MCD) are two primary glomerulopathies which usually present with nephrotic syndrome and classified together as podocitopathies. The first one is common in adults and the second one in children. The currently available treatments for both diseases have important side effects. High rates of steroid and cyclosporine resistance and dependence are indicative

that new therapeutic options are mandatory. The main objective of our study is to describe the profile of patients with podocytopathy who used rituximab in a brazilina university center.

Methods: This is a retrospective cohort including 18-year-old or older patients with kidney biopsy showing MCD or FSGS who have used at least 1 dose of rituximab between 2012 and 2018, with a minimum of 6 months of follow up after infusion. Epidemiological, clinical and histological variables were analyzed. Were considered responders patients with at least a 35% reduction in proterinuria and an increment of 0.5 g/dL of serum albumin.

Results: Twenty-eight patients fulfilled the inclusion criteria, 57% female, median creatinine and age at the time of the infusion was 1.1 mg/dL and 33 years-old, respectively. The main indications were lack of response to traditional immunosuppressors and frequent relapse during or after corticosteroid withdrawal, with previous use of cyclosporine in 76% and prednisone in 96%. Median 24-h urinary protein at infusion were 8.40 g (5.30 - 12.64, IQR) in non-responders and 7.65 g (1.34 - 17.63, IQR). After 3 months they resulted 7.06 g (5.62 - 9.97, IQR) and 0.25 g (10 - 5.51, IQR), respectively. The complete remission rate in 3 was 24% and in 6 months was 10%. Partial remission was present after 3 months in 33% of the cases. Evaluating non steroid resistant patients, 58% of them had partial remission at 3 months while no steroid resistant individual had any type of remission. In relation to side effects, 18% had an infection episode up to 6 months after infusion and 2 patients presented rash, with no severe drug reaction.

Conclusions: Rituximab is a possible option to use in FSGS and MCD especially in individuals considered steroid-sensitive and dependent and with an acceptable safety profile.

TH-PO995

Rituximab Treatment of Minimal Change Disease (MCD) and Focal Segmental Glomerulosclerosis (FSGS) in Adults

Anushya Jeyabalan,[1] Renu Regunathan-Shenk,[2] Andrew S. Bomback,[1] Wooin Ahn,[1] Jai Radhakrishnan,[1] Pietro A. Canetta,[1] Gerald B. Appel.[1] *[1]Columbia University Vagelos College of Physicians and Surgeons, New York, NY; [2]George Washington School of Medicine and Health Sciences, Washington, DC.*

Background: Previous smaller retrospective and prospective studies have suggested that rituximab may be an effective therapy for adult patients with MCD and FSGS who have steroid dependent nephrotic syndrome.

Methods: We reviewed the charts of 82 adults seen at Columbia University Medical Center between 2014 to 2019 who received rituximab for treatment of MCD or FSGS. We analyzed clinical, biopsy, and laboratory data pre-infusion and at follow up (F/U). We categorized patients as frequently relapsing/steroid dependent (FRSD), infrequently relapsing (IR), steroid resistant (SR), and multi-drug resistant (MDR, failed 2 or more prior immunosuppressive medications(IS)) based on their clinical course.

Results: Of 80 patients biopsied, 41 patients had MCD, 34 had FSGS, 5 had podocytopathy associated with another diagnosis, 2 patients had nephrotic syndrome without previous biopsy. Median age was 40 years and 60% were male. 48 patients were Caucasian, 11 African-American, 17 Hispanic and 6 Asian. Disease categories included 41 FRSD, 7 IR, 9 SR and 25 MDR. The median duration of F/U was 30 months (range 1-156 months). 51/82 (62%) patients achieved complete remission (CR, UPCR <0.5 g/g) and 11/82(13%) achieved partial remission (PR, UPCR 0.5-3.5 g/g) at F/U. All CR/PR occurred by 7 months after infusion of rituximab. 20/82 (24%) did not achieve CR/PR. Of the 61 patients in CR/PR, 48 (79%) patients were off all other IS at F/U. 36/41(88%) FRSD patients achieved CR/PR, and while 11/25(44%) MDR patients achieved PR, none achieved CR. 13/82(16%) patients progressed to ESRD, 8/13(62%) of these patients were MDR. 25/82(30%) patients relapsed, median time to relapse was 22 months from last rituximab infusion. 18 patients were retreated with rituximab, and 13/18(72%) achieved CR.

Conclusions: This large study confirms the benefit of rituximab in achieving remission of proteinuria and reduction of immunosuppression in adults with MCD or FSGS. Patients with MDR disease were less likely to respond to rituximab.

TH-PO996

Study of Long-Term Recurrence and Adverse Effects of Rituximab Treatment in Adults with Steroid-Dependent Minimal-Change Nephrotic Syndrome

Erika Yamaguchi,[1] Yuko Iwabuchi,[2] Kazunori Karasawa,[3] Takahito Moriyama,[2] Kosaku Nitta.[2] *[1]Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [2]Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]Department medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: The effect of rituximab treatment on the minimal-change nephrotic syndrome came to be known widely. However, there are few reports about the long term clinical course after rituximab treatment. Therefore, we studied a 60-month recurrence and the adverse effects from start of the rituximab treatment.

Methods: We performed a retrospective study of the clinical course of 52 MCNS patients who had rituximab treatment at interval of 6 months. We compared the clinical findings between the 60-month period before and 60-month period after the first rituximab infusion.

Results: Significant reduction in the average number of relapses was observed during the 60-month period after the first rituximab infusion as compared with the findings during the 60-month period before the first rituximab infusion (8.9 vs 0.7, p<0.001). Oral administration of immunosuppressant containing prednisolone at 60-month was significantly decrease from the start of rituximab. There were no severe adverse effects during the 60 month period after the first rituximab. However, mild infusion reactions occurred 60 times (14.4%). Also, two patients had leukopenia (3.8%), another one had myocarditis (1.9%), another one had buttocks abscess (1.9%), and another two patients had hypogammagolbulinemia (3.8%).

Conclusions: Our results revealed that rituximab therapy was associated with reduction in the number of relapses and in the total dose of immunosuppressant needed. And the results also revealed that rituximab was safe for MCNS patients. However a few patients had some adverse events, so it is important to observe all patients after rituximab treatment regularly.

TH-PO997

The Incidence and Timing of Infectious Complications Relating to Immunosuppressive Treatment Among Adult Japanese Minimal Change Disease and Focal Segmental Glomerulosclerosis: A Retrospective Study

Takaya Ozeki, Sawako Kato, Yoshinari Yasuda, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Among adult minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS), some patients require high-intensity or long-term immunosuppressive therapy because of poor treatment response or relapses. However, there are few reports investigating the incidence of infectious complications and its timing during immunosuppressive therapies.

Methods: Multicenter retrospective cohort study. MCD/FSGS diagnosed by kidney biopsy from 2005 to 2015 at Nagoya university and 15 affiliated hospitals were included. Age<20, non-nephrotic cases, secondary cases, patients who did not receive any immunosuppressive treatment or patients who dropped-out within 4 weeks were excluded from the analyses. The incidence and its timing of infections that were treated under hospitalization were evaluated using Kaplan-Meier method.

Results: Among 298 cases (MCD/FSGS: 243/55 cases), 270 (89.9%, MCD/FSGS: 95.1/67.3%) attained complete remission (CR). The median values of duration for CR were 14 days in MCD and 38 days in FSGS (p=0.05). Thirty-nine (13.1%) patients suffered from infections at least once during entire observation and pneumonia was the most common (11 cases). Twenty-two out of 39 (56.4%) cases had infections within 6 months from the initiation of immunosuppressive treatment. In Kaplan-Meier analysis, the risk for infections were higher in FSGS patients (p=0.034 vs. MCD) or elderly patients (age≥65, p<0.001 vs. age<64). When patients were categorized into 4 subgroups according to the duration for CR (patients who attained CR within 4 weeks, 4-8 weeks, 8-16 weeks and over 16 weeks), poor-responders (CR over 16 weeks) demonstrated the highest risk and early-responders (CR within 4 weeks) showed the lowest risk for infections (p>0.001 in log-rank test). Multivariate Cox proportional hazard model showed that elderly patients (adjusted HR: 3.35, 95% CI: 1.61-6.97, p<0.001), baseline eGFR (adjusted HR: 0.83 for every 10 mL/min/1.73m2, 95% CI: 0.63-0.99, p=0.038) and poor-responders (adjusted HR: 4.80, 95% CI: 1.86-12.35, p=0.001) were associated to infections.

Conclusions: Among patients with adult MCD/FSGS, infections relating to immunosuppressive therapies should be taken in mind especially in poor-responders as well as elderly.

TH-PO998

Incremental Reduction of Proteinuria and Kidney Survival in FSGS

Jonathan P. Troost,[1] Howard Trachtman,[2] Frederick J. Kaskel,[3] Aaron L. Friedman,[7] Marva M. Moxey-Mims,[4] Jennifer J. Gassman,[6] Liron Walsh,[8] Debbie S. Gipson.[5] *[1]University of Michigan, Ann Arbor, MI; [2]NYU Langone Health, New York, NY; [3]Children's Hospital at Montefiore, Bronx, NY; [4]Children's National Health System, Washington, DC; [5]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [6]Cleveland Clinic, Cleveland, OH; [7]University of Minnesota, Minneapolis, MN; [8]Goldfinch Bio, Boston, MA.*

Background: Proteinuria remission has been shown to predict disease progression in focal segmental glomerulosclerosis (FSGS). This study examines if incremental reductions in proteinuria are associated with improved kidney survival even if a complete or partial remission is not reached.

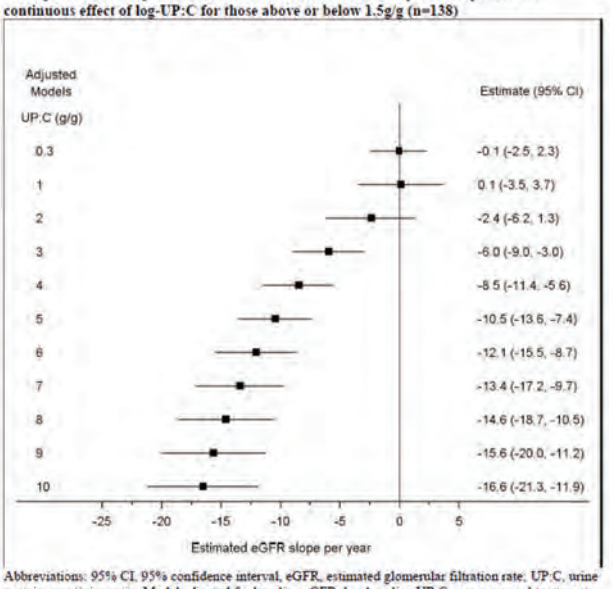
Methods: Data are from the NIH/NIDDK FSGS clinical trial of 138 steroid resistant patients randomized to cyclosporine or mycophenolate mofetil (no difference in trial endpoint of proteinuria remission). Linear-mixed effects models tested if week 26 proteinuria was associated with subsequent slope of estimated glomerular filtration rate (eGFR). Stratified Cox-proportional hazards models tested if time-varying proteinuria was associated with time to kidney failure. Model interaction terms and sensitivity analyses tested for an incremental impact of proteinuria on outcome for those with urine protein: creatinine ratio >1.5g/g. Analyses were adjusted for age, race, baseline proteinuria and eGFR, and treatment arm.

Results: A 1-log increase in proteinuria was associated with a -5.1 ml/year difference in change in eGFR per year (95% CI=-8.3 to -2.0 p<0.001). There was an analogous relationship between time-varying proteinuria and time to kidney failure: HR per log-proteinuria=3.94 (95% CI=1.79 to 8.68 p<0.001). Findings remained the same when limited to those with proteinuria >1.5g/g at week 26.

Conclusions: These findings agree with previous reports of an important proteinuria threshold at approximately 1.5g/g associated with a large clinical benefit, but also support that a reduction in proteinuria—even if not to below 1.5g/g—is still associated with improved survival. Clinical trials should consider reductions in proteinuria as a marker of future preservation of kidney function.

Funding: NIDDK Support, Commercial Support - Goldfinch Bio, Pfizer inc.

Figure. Results of linear mixed effects model of the impact of week 26 proteinuria on subsequent eGFR slope. Third-order interaction used to fit separate slopes for the continuous effect of log-UP:C for those above or below 1.5g/g (n=138)



Abbreviations: 95% CI, 95% confidence interval, eGFR, estimated glomerular filtration rate; UP:C, urine protein: creatinine ratio. Model adjusted for baseline eGFR, log-baseline UP:C, age, race, and treatment arm.

Impact of Sparsentan on Quality of Life (QoL) in Focal Segmental Glomerulosclerosis (FSGS) Patients in DUET: An Interim Analysis

Howard Trachtman,[1] Jonathan J. Hogan,[2] Beatrice Ferguson,[3] Radko Komers.[3]
[1]NYU School of Medicine, New York, NY; [2]University of Pennsylvania, Philadelphia, PA; [3]Retrophin, Inc., San Diego, CA.

Background: FSGS has been shown to impair patients' (pts) QoL. DUET, a phase 2, randomized, active-control study, examined QoL in pts with FSGS.

Methods: In the 8-week randomized double-blind treatment period (DB), pts received sparsentan (SPAR) or irbesartan (IRB), after which all randomized pts who continued in an open-label extension received SPAR (SPAR:SPAR or IRB:SPAR, respectively). The SF-36 questionnaire was administered to adults at baseline (BL), Week 8, Week 48 and Week 144. Norm-based scoring was used for the physical (PCS) and mental (MCS) component scores (mean±SD).

Results: Seventy-three patients were randomized to SPAR and 36 to IRB with a mean baseline UP/C of 3.61 and 3.12 g/g, respectively, and median eGFR of 73.4 and 65.1 mL/min/1.73 m^2, respectively. There were no clinically meaningful differences between the SPAR and IRB groups in the cross-sectional PCS or MCS at BL and Week 8. The mean change from BL to Week 8 between the SPAR and IRB groups for PCS (p=0.5103) and MCS (p=0.8725) did not differ. Importantly, there were no meaningful changes over time during the open-label extension in PCS or MCS from BL to Week 48, or Week 144 both in SPAR:SPAR and IRB:SPAR (Table).

Conclusions: Using the SF-36, the physical and mental QoL component scores in DUET were similar in SPAR- and IRB-treated patients during the DB. QoL parameters remained stable over time (2 years) in participants electing to remain on long-term open-label treatment with SPAR regardless of original randomization to SPAR or IRB and were not adversely affected by dual blockade of the AT_1 and ET_A receptors.

Funding: Commercial Support - Retrophin, Inc., San Diego, CA

TH-PO1000

FSGS Minimal Change Disease Patient-Reported Outcome (PRO) Measure Development

Noelle E. Carlozzi,[2] Howard Trachtman,[3] Liron Walsh,[5] Susan F. Massengill,[4] Hailey Desmond,[2] Chris Lynam,[5] Debbie S. Gipson.[1] *[1]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]NYU Langone Health, New York, NY; [4]Levine Children's Hospital, Charlotte, NC; [5]Goldfinch Bio, Boston, MA.*

Background: Assessment of how patients feel and function are needed for clinical care and research for focal segmental glomerulosclerosis (FSGS) and treatment-resistant minimal change disease (MCD). The objective of this study was to develop a PRO appropriate for use in children and adults with FSGS and MCD.

Methods: Participants (PTS) were recruited from nephrology practices, Kidney Research Network registry and NephCure Kidney International social media. Eligibilty criteria: proteinuria (UPC ≥ 1) within the prior 12 months, eGFR > 30 ml/min and no other severe health condition. Interviews for concept elicitation were conducted in-person for children < 14 yrs and in-person or by phone for ≥ 14 yrs. Interviews were transcribed and reviewed by 2 investigators who developed a hierarchical taxonomy or "codebook" through an ongoing, iterative, deductive and inductive analytical process. Concepts were pooled with those elicited from 30 adults with FSGS participating in the initial FSGS PRO development initiative.

Results: 43 interviews with FSGS children (n=11) and adults (n=11), and MCD children (n=8) and adults (n=13) were completed. MCD interviews are ongoing. Latent content analysis suggests FSGS and MCD impact physical, social and mental HRQOL regardless of age or diagnosis. Physical complaints of swelling, fatigue and pain were endorsed by the majority of PTS. PTS described their experiences with medication and associated side effects, as well as lifestyle changes made to manage disease (i.e., diet and medical visits). Interviews often detailed a profound impact on physical abilities and life participation. PTS described the negative impact these symptoms had on their mood and sense of self with a majority of PTS endorsing feelings of anxiety. Depression was common in MCD and about half of expressed feelings of frustration. Finally, PTS with MCD also talked about the toll that frequent and unpredictable relapse had on leisure and work/school activities.

Conclusions: FSGS and MCD can have a profound impact on HRQOL in children and adults. While there is an existing PRO for adults with FSGS, our results suggest that there are commonalities to the FSGS-MCD patient experience that will enable the generation of a disease specific FSGS- MCD PRO for use in children and adults. Measure validation initiatives will be required prior to broad spectrum use.

Funding: Commercial Support - Goldfinch Bio

TH-PO1001

Alport Syndrome: Phenotype-Genotype Correlation in Lithuanian Families

Agne Cerkauskaite,[1] Rimante Cerkauskiene,[2] Marius Miglinas.[3] *[1]Vilnius University, Institute of Clinical medicine, Vilnius, Lithuania; [2]Children's hospital, Vilnius University Hospital Santaros clinics, Vilnius, Lithuania, Vilnius, Lithuania; [3]Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.*

Background: Alport syndrome (AS) is a rare inherited collagen IV nephropathy, caused by mutation in COL4 genes leading to progressive kidney injury with extrarenal manifestations including ocular and hearing abnormalities. Exact incidence of AS is not well known due to clinical and genetic heterogeneity of the disease. The diagnosis of AS is confirmed by a pathogenic mutation in the COL4A5 gene, associated with X-linked AS or pathogenic mutations in COL4A3 or COL4A4 genes inherited in autosomal pattern.

Methods: Data analysis of the clinical, histological and genetic records of the patients with suspected AS was made. Inclusion criteria were associated with a high grade suspicion for AS such as positive family history, hematuria as an early sign of the disease, progressive chronic kidney disease (CKD), sensorineural hearing loss and several ocular abnormalities.

Results: 87 patients with suspected Alport syndrome (23 children and 64 adults), 51 females and 36 males were included. 33 patients were suggested to have Alport syndrome due to specific renal biopsy findings. Other patients had positive family history. Diagnosis of AS was genetically confirmed in 74 % patients, with COL4A3, COL4A4 and COL4A5 genes 82 %, 8%, 10% respectively. In total 20 different familial mutations were found. All patients had hematuria. Progressing chronic kidney disease was seen in 39 % of the patients with an average age at diagnosis 15,4 years (14 – 40 y), whereas 36 % patients with CKD had end-stage renal disease and underwent on dialysis. CKD was significantly more frequent and more numerous in *COL4A5* comparing with *COL4A3* and *COL4A4* genes mutations. Disease progression correlated with the age ($p<0.05$). Hearing abnormalities were presented in 22,4 % of all AS cases. Ocular abnormalities and vision alterations were seen in 18,4 % patients and were strongly associated with COL4A5 gene mutations.

Conclusions: COL4A5 mutations cause more severe phenotypic manifestation in male patients, specially related with a more severe renal phenotype while mutations in COL4A3 or COL4A4 are related with autosomal AS with milder clinical alterations. Further epidemiological studies are needed for better understanding of AS manifestations.

TH-PO1002

Description of Alport Disease in Female Children and Adolescents

Selasie Goka,[1,2] Lawrence A. Copelovitch,[1,2] Daniella Levy Evez.[1,2] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]Nephrology Division, Philadelphia, PA.*

Background: Alport disease (AD) is a multi-system disease historically thought to be presymptomatic in young females given inheritance is most commonly X-linked. Prior descriptive studies and outcome data have focused mainly on males and adult women. The aim of this study was to describe the clinical presentation and course of the females with AD in a large pediatric medical center.

Methods: A single center retrospective review of pediatric females with AD seen at Children's Hospital of Philadelphia between 1987 - 2018. All females with ICD 9/10 codes for Alport, familial hematuria and hereditary nephritis were identified. GFR was calculated using the bedside CKiD equation. Hypertension was defined as systolic or diastolic blood pressure ≥95th percentile for age, gender and height. Proteinuria was defined as ≥ 30 mg/dL of protein.

Results: 217 subjects were identified, 164 of them excluded for an incorrect diagnosis. 16 charts were missing. 37 female patients were confirmed to have AD and included in the analysis. Mean age of presentation was 5.4 ± 3 yrs with mean follow-up of 6.3 ± 4 yrs. 14 patients had genetic testing, with 80% demonstrating heterozygous mutations in the COL4A5 gene. Biopsies were performed in 11 patients. The remaining patients were diagnosed based on clinical manifestation and family history. At the end of follow up at least one episode of gross hematuria was observed in 15 patients, proteinuria in 21 patients, and GFR <90 ml/min/1.73 m2 in 3 patients. Seven patients had an abnormal audiogram. See Table 1 for pertinent clinical findings. One patient required dialysis and received a deceased donor transplant.

Conclusions: Most females diagnosed with AD in childhood have persistent microscopic hematuria and normal renal function. Gross hematuria, proteinuria, and subclinical hearing involvement were common findings suggesting that AD should not be overlooked in girls with nephritis.

Funding: Other NIH Support - T32 DK007006-43

Clinical Characteristics of Females with AD

	Presentation (n=37)	End of Follow Up (n=37)
Family History	29 (78.4%)	29 (78.4%)
Hematuria (microscopic)	33 (89.2%)	35 (94.6 %)
Hematuria (gross)	13 (35.1%)	15(40.5%)
Proteinuria	12 (32.4%)	21(56.8%)
Mean GFR (ml/min/1.73m2)	116 ± 23	119 ± 36
Patients with GFR <90 ml/min/1.73 m2	3/27* (11.1%)	3/26* (11.5%)
Hypertension (SBP or DBP ≥ 95th %)	2(5.4%)	3(8.1%)

TH-PO1003

Genetic Polymorphism in C3 Is Associated with CKD Progression in IgA Nephropathy

Sara T. Ibrahim,[1,2] Rajkumar Chinnadurai,[2] Ibrahim Ali,[2] Iman E. Elgohary,[1] Ahmed G. Adam,[1] Philip A. Kalra.[2] *[1]internal medicine and nephrology, faculty of medicine Alexandria university, Egypt, Alexandria, Egypt; [2]Salford Royal Hospital NHS Trust, Salford, United Kingdom.*

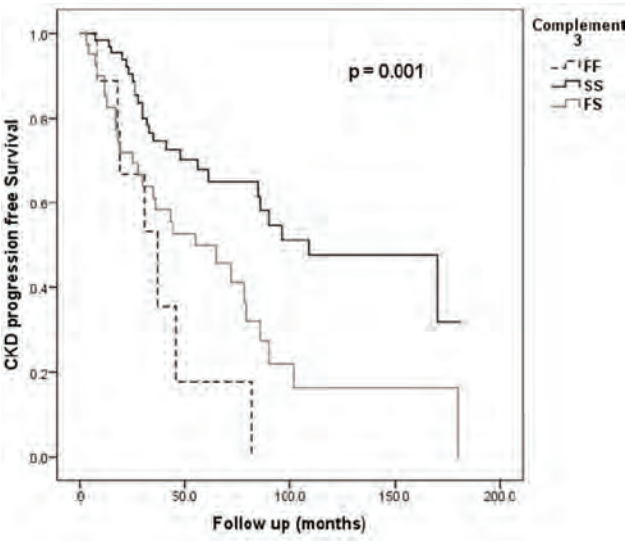
Background: A single nucleotide polymorphism (SNP) in complement factors can harmfully affect their activity. The commonest SNP in C3 is R102G, causing two allotypic variants: C3 fast (C3F) and C3 slow (C3S). C3F has been shown to be prevalent in CKD, especialy IgA nephropathy but no study has explored its role in CKD progression.

Methods: Delta (Δ) eGFR (±ml/min/1.73m^2/yr) for 2038 patients in the Salford Kidney Study (SKS) was calculated by linear regression, with ≤-3ml/min/1.73m^2/yr defined as rapid progressors (RP) and those between -0.5 and +1ml/min/1.73m^2/yr labelled stable progressors (SP). All patients had ≥2-years follow-up and eGFR-time graphs were analysed to ensure no AKI episodes contributed to CKD progression. We also studied all biopsy-proven GN patients in SKS regardeless of their ΔeGFR. R102G was analyzed by real-time PCR. The association between C3F and progression (ESRD or ≥40% decline in eGFR) was analysed using Cox regression.

Results: There were 255 SP and 259 RP with median delta eGFR (0.07 vs. -4.7 ml/min/1.73m^2/yr). There was no significant difference in C3 allele frequency between the two groups as a whole: C3F 27% in RP vs. 24.3% in SP p = 0.32. In the subgroups analysis there were 37 patients with IgA nephropathy (21 RP and 16 SP), in this group there was a significantly higher frequency of C3F in RP (38.6% vs. 9.4% in SP; p<0.001). In the GN group there were 269 patients, containing 114 IgA nephropathy patients. Cox regression showed strong and independent association between C3F and progression only in the IgA nephropathy with HR =1.9 (95% CI 1.1 – 3.1; p 0.018) for C3FS, increasing further for C3FF to HR =2.8 (95% CI 1.2 – 6.2; p 0.014).

Conclusions: C3 SNP; R102G; is associated with CKD progression in patients with IgA nephropathy but not in other causes of CKD.

Funding: Government Support - Non-U.S.



TH-PO1004

The Study of the FUT2 Gene Carrying a Nonsense Mutation in IgA Nephropathy

Jieshuang Jia. *Shanghai General Hospital, Shanghai, China.*

Background: The pathogenesis of IgA nephropathy is related to the dysbacteriosis, but FUT2 gene carrying nonsense mutation plays a role in the intestinal flora disorder.

Methods: To verify that FUT2 gene with nonsense mutation is associated with IgA nephropathy. We collected 104 cases of physical examination and 56 cases of IgA nephropathy diagnosed by renal biopsy from June 2017 to December 2018. We extracted genomic DNA to detect FUT2 gene, test serum biochemical markers, intestinal barrier function indicators (diamine oxidase DAO and D-lactic acid DL), and collected the blood pressure(BP), 24 hour urinary protein and renal pathology.

Results: 1. We found that 5 patients (8.9%) of IgA nephropathy carry a nonsense mutation on FUT2 gene and there is no nonsense mutation in 104 healthy people. 2. The levels of the BP 146±11.43mmHg, serum creatinine(Cr)138.34±23.54μmol/L, serum uric acid(UA)424.39±116.45μmol/L, 24 hour urinary protein2.69±1.8g, DAO18.75±4.96U/L and DL 40.14±10.25mg/L are significantly higher in patients carrying a nonsense mutation than those without mutation group which is respectively 111±12.43mmHg, 72.56±25.72μmol/L, 375.96±102.01μmol/L, 1.50±0.73g, 4.25±5.59U/L and 15.78±5.67 mg/L(P<0.01). 3. The number of eGFR 75.71±11.18ml/min/1.73m^2 in the mutation group is obviously decreased than that in the non-mutation group 98.72±12.91 (P<0.01). 4. The melanocyte proliferation, glomerular sclerosis, and interstitial fibrosis were significantly observed in the mutation group, the score was 3.6±0.54. In the non-mutation group, the score was 1.6±0.65 (P<0.05).

Conclusions: 8.9% of patients with IgA nephropathy have nonsense mutations on FUT2 gene. Compared with the non-mutation group, the BP, serum Cr, UA, 24 hour urinary protein, DAO and DL are significantly higher in the mutation group, but eGFR is obviously decreased. Renal pathology suggests that the score of mesangial cell proliferation, glomerular sclerosis and interstitial fibrosis are increased in the mutation group. Studies of IgA nephropathy have shown that higher serum Cr, 24 hour urinary protein, BP and lower eGFR are positively correlated with disease progression and that the higher score of the renal pathology suggest a poor prognosis. Finally we infer that nonsense mutations on FUT2 gene can affect the intestinal barrier function and accelerate the progression of IgA nephropathy, and its mechanism still needs further study.

TH-PO1005

Significant Intestinal Flora Disturbance Is Discovered in IgA Nephropathy Patients

Zhengxia Zhong,[1,2] Jiaxing Tan,[2] Wei Qin,[2] Li Tan,[3] Yibing Yang.[1] *[1]Affiliated Hospital of Zunyi Medical University, Guizhou, China, Zunyi, guizhou province, China; [2]West China Hospital of Sichuan University, Chengdu, Sichuan, China; [3]West China Hospital, Chengdu, China.*

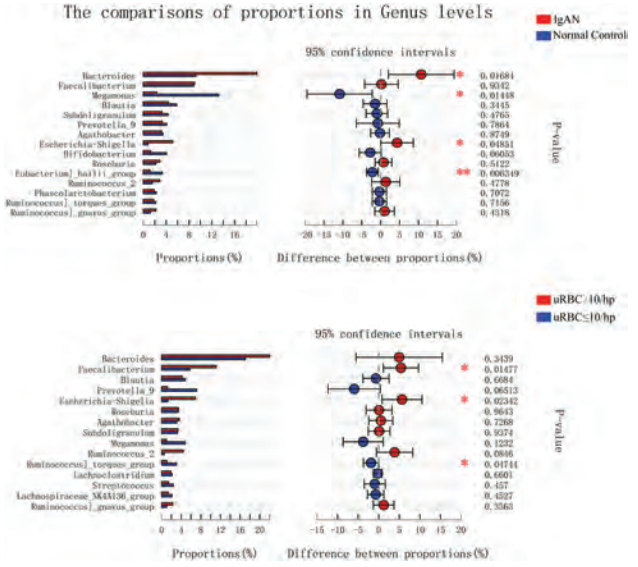
Background: IgA nephropathy (IgAN) is an autoimmune glomerular disease, manifested by hematuria with or without proteinuria. The pathogenesis has not been clarified yet. This study investigated the relationship between IgAN and gut microbiota composition to understand gut-kidney axis.

Methods: 44 patients with biopsy-proven IgAN and 15 healthy controls were enrolled. The patients were divided into two groups based on levels of urine red blood cells (uRBC). Compositions of intestinal flora were assessed by 16sRNA microbial profiling approach.

Results: The proportions of Escherichia-Shigella (5.16%±8.25% vs 0.83%±1.12%, P=0.04) and Bacteroides (19.9%±16.34% vs 9.20%±6.21%, P=0.02) increased significantly in IgAN patients, compared with normal control. Conversely, Bifidobacterium (1.29%±3.51% vs 4.07%±7.62%, P=0.06), Eubacterium hallii (1.16%±2.07% vs 3.36%±3.78%, P=0.01) and Megamonas (2.36%±7.67% vs 13.2%±25.7%, P=0.01) was markedly decreased.

Subgroup analysis indicated patients with higher level of uRBC tended to have higher rates of Escherichia-Shigella (6.93%±9.48% vs 1.27%±1.67%, P=0.02) and Faecalibacterium (11.16%±7.73% vs 5.77%±4.42%, P=0.02), compared with lower uRBC group. Moreover, the levels of Bifidobacterium were not detected in 72.9% IgAN patients. Interestingly, the patients lack of Bifidobacterium were more likely to have lower level of eGFR (87.49±34.50 vs 104.64±13.67, P=0.03) and higher level of uric acid (398.93±135.26 vs 300.56±93.19, P=0.05), suggesting that Bifidobacterium might have potential renoprotective effects and its loss might contribute to the progression of IgAN.

Conclusions: IgAN are featured by increase in pathogenic bacteria and reduction of beneficial bacterium. Potential intestinal flora disturbance might be related to the occurrence of IgAN, which could become a new therapeutic target.



TH-PO1006

BAFF-Dependent IgA Production Does Not Play a Pivotal Role in the Pathogenesis of Murine IgA Nephropathy

Jin sug Kim,[1] Hitoshi Suzuki,[2] Toshiki Kano,[2] Yusuke Fukao,[2] Maiko Nakayama,[2] Yusuke Suzuki.[2] *[1]Kyung Hee University School of Medicine, Seoul, Republic of Korea; [2]Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. Although our understanding of this disease have improved by remarkable progress, its pathogenesis has not yet clearly understood. Recent studies suggested B cell activating factor belonging to the TNF family (BAFF), which participates in the activation of B cells and class switch of IgA, as a potential disease marker of IgAN. However, the role of BAFF in the development and progression of IgAN remains unclear. In this study, we investigated the pathological role of BAFF in IgAN using a grouped ddY mice which is the spontaneous murine model of IgAN.

Methods: Mice with IgAN designated grouped ddY were treated with PBS or anti-BAFF monoclonal antibody (anti-BAFF Ab) by intraperitoneal injection every three days for four weeks. We measured the levels of urinary albumin, serum immunoglobulins (IgA, IgG, and IgM), and serum IgA-IgG immune complex at the beginning and end of the treatment. The levels of serum aberrantly glycosylated IgA were also measured using biotinylated Ricinus communis agglutinin-I (RCA-I) and Sambucus nigra bark lectin (SNA). We further assessed glomerular depositions of IgA and C3 by immunofluorescence staining, and analyzed changes of B cell population in spleen and bone marrow using flow cytometric analysis.

Results: Anti-BAFF Ab treatment significantly decreased serum levels of IgA, IgG, and IgM as compared with PBS treatment in the murine IgAN model ($p < 0.001$, $p = 0.003$, and $p = 0.002$, respectively). However, it did not affect urinary albumin excretion, serum levels of IgA-IgG immune complex, and serum levels of aberrantly glycosylated IgA. Glomerular depositions of IgA and C3 as well as B cell population in spleen and bone marrow were also not affected by anti-BAFF Ab treatment.

Conclusions: Anti-BAFF Ab treatment was effective to inhibit the production of immunoglobulins, but not nephritogenic IgA in murine IgAN model. Our results suggest that BAFF-dependent IgA production may not play a pivotal role in the pathogenesis of IgAN.

TH-PO1007

High Serum IgA/C3 Ratio Better Predicts a Diagnosis of IgA Nephropathy Among Primary Glomerular Nephropathy with Proteinuria ≤1 g/d: An Observational Cross-Sectional Study

Jun Zhang. *Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Serum immunoglobulin A (IgA)/C3 ratio is considered to be an effective predictor of IgA nephropathy (IgAN). This study aims to explore the diagnostic value of serum IgA/C3 ratio in IgAN among primary glomerular nephropathy in China.

Methods: We recruited 1095 biopsy-diagnosed primary glomerular nephropathy patients including 757 IgAN patients and 338 Non-IgAN patients. Social demography, serum immunological indexes and other clinical examinations were measured. IgAN cases were propensity scored matched (PSM) to Non-IgAN cases on the logit of the propensity score using nearest neighbor matching in a 1:1 fashion with a caliper of 0.02 with no replacements, according to age, gender, BMI, proteinuria and eGFR.

Results: We found that, both in the full cohort and PSM cohort, serum IgA/C3 ratio in IgAN group was significantly higher than those in Non-IgAN group. The same results were also obtained at different levels of proteinuria and renal function stratification. In the PSM cohort, there was no difference in IgA/C3 ratio in patients with IgAN between different proteinuria groups and different CKD groups. The area under the ROC curve (AUROC) for IgA/C3 ratio in distinguishing IgAN among primary glomerular disease was 0.767 in the full cohort and 0.734 in the PSM cohort. The highest AUROC of IgA/C3 ratio was in the proteinuria≤1 g/d group (0.801 in the full cohort, and 0.803 in the PSM cohort); however, there was no difference between all the CKD groups. Meanwhile, the diagnose accordance rate of diagnostic of IgAN among all those patients with IgA/C3 ratio > 3.5304 was as high as 92.02% in the full cohort. Multivariate logistic regression analysis showed, IgAN was independently correlated with age, albumin, CKD 2 stage and CKD 3-5 stage (versus CKD 1 stage) and IgA/C3 ratio.

Conclusions: The present study provided clear evidence that IgA/C3 ratio is an effective predictor of IgA diagnosis, especially in patients with proteinuria ≤ 1g/d. In order to study the effectiveness of this biomarker and to determine a standardized cut-off value, large-scale studies are necessary.

TH-PO1008

Single Nephron Parameters in Patients with IgA Nephropathy

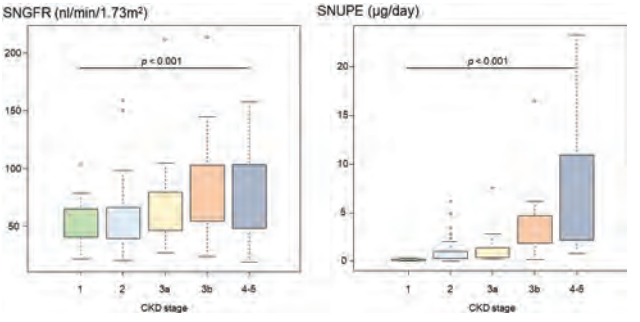
Hirokazu Marumoto, Nobuo Tsuboi, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Go Kanzaki, Kentaro Koike, Tetsuya Kawamura, Takashi Yokoo. *Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Background: The progression of IgA nephropathy (IgAN) may be characterized by progressive loss of functional nephrons and subsequent alterations in single nephron function in remnant nephrons. In this study, we estimated total nephron number and examined the related single nephron parameters in patients with IgAN at different renal function stages of the disease.

Methods: The total nephron number was calculated using a simplified method based on the combined use of unenhanced computed tomography and stereology-based estimation of non-sclerotic glomerular density on renal biopsy (Sasaki T et al. 2018, ASN). Single-nephron glomerular filtration rate (SNGFR) and single-nephron urinary protein excretion (SNUPE) were calculated by dividing the estimated glomerular filtration rate (eGFR) and urinary protein excretion by total nephron number, respectively. The glomerular volume (GV) was estimated from the measured mean glomerular area.

Results: A total of 107 Japanese IgAN patients (age 43, male 54%, eGFR 61.5 ± 24.2 ml/min/1.73m^2, urinary protein excretion 1.4 ± 1.6 g/day) were included. The total nephron number ranged from 78,000 to 1,989,000 per kidney (602,000 ± 378,000 on average per kidney). SNGFR showed a positive correlation with the GV ($r = -0.37$, $p < 0.001$). Advanced renal impairment of CKD stage 3b or more was characterized by increased SNGFR and markedly elevated SNUPE levels (**Figure**).

Conclusions: These results suggest a close association between loss of functional nephrons and changes in single nephron parameters in remnant nephrons, in parallel with progression of IgAN.



TH-PO1009

Urinary Cytokines as Non-Invasive Biomarkers of IgA Nephropathy

Min hye Kang,[1] Jin sug Kim,[1] Hyeon Seok Hwang,[1] Yang gyun Kim,[2] Su Woong Jung,[2] Won-Hee Cho,[2] Kyung hwan Jeong.[1] *[1]Kyunghee University Hospital, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gang-Dong, Seoul, Republic of Korea.*

Background: Immunoglobulin A nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. Although renal biopsy is the gold standard of diagnosis, accessibility in clinical practice is poor. Therefore, need for development of non-invasive diagnostic tools such as biomarker has emerged. In this study, we investigated the clinical relevance of 16 urinary cytokines in patients with IgAN.

Methods: The levels of 16 urinary cytokines from 110 biopsy-proven IgAN patients, 15 non-IgAN glomerulonephritis, and 15 normal controls were measured using multiplex assays. Samples were collected from the first spot urine of the morning on the day of renal biopsy. To account for variations in urine concentration, urinary cytokine levels were normalized to urine creatinine. We analyzed the correlations of urinary cytokines with clinical and pathological parameters in IgAN patients. The predictive value of urinary cytokines for adverse renal outcome, which defined as chronic kidney disease (CKD) stage 3 or above at the last follow-up, was also investigated using receiver operating characteristic (ROC) curve analysis

Results: As compared with patients in non-IgAN glomerulonephritis group and normal controls group, patients in the IgAN group showed significant higher urinary cytokine levels of interferon-inducible protein 10 (CXCL10), endocan, growth differentiation factor 15 (GDF15), interferon gamma (IFN-r), interleukin 6 (IL-6), mannan-binding lectin (MBL), nephrin, and transferrin R (TfR) ($p < 0.05$). The urinary levels of endocan, GDF-15, IL-6, and TfR showed significant correlation with estimated glomerular filtration rate (eGFR) (r=-0.240, p=0.005; r=-0.240, p=0.006; r=-0.254, p=0.003; and r=-0.386, p=0.001, respectively). Urinary protein excretion was significantly correlated with CXCL10, IL-6, and TfR (r=0.205, p=0.002; r=0.210, p=0.017; r=0.165, p=0.040, respectively). ROC curve analyses showed that urinary protein to creatinine ratio, GDF-15, and IL-6 had a moderately predictive value for adverse renal outcome (area under the curve > 0.7).

Conclusions: Urinary cytokines have potential as disease specific biomarkers of IgAN. Further large and prospective studies of extended duration are needed.

TH-PO1010

Plasma CXCL16: A Biomarker Predicts Renal Inflammation and Progression of IgA Nephropathy

Ran Luo, Shuwang Ge, Gang Xu. *Tongji Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: Noninvasive biomarkers associated with IGAN prognosis are urgently needed for clinical practice. This study was to investigate whether CXCL16 was associated with pathology and renal outcome in IGAN.

Methods: 230 patients with IGAN diagnosed by renal biopsy between 2012 and 2014 at Huazhong University of Science and Technology Tongji hospital, were included in the study. Follow-up time was up to 42.5 months. The renal outcome was defined as composite endpoints, including ESRD and doubling of plasma creatinine. Plasma CXCL16 level was measured by ELISA. Inflammatory cells including CD4+, CD8+, CD20+ and CD68+ cells in renal biopsy tissues and renal CXCL16 expression were detected by immunohistochemistry.

Results: Plasma CXCL16 levels correlated with serum creatinine ($p< 0.0001$, r=0.362), estimated glomerular filtration rate ($p< 0.0001$, r=-0.411), albumin ($p=0.0019$, r=-0.2068). In renal biopsy specimens, the density of CD8+, CD4+, and CD20+ cells were significantly associated with plasma CXCL16 levels. Mesangial hypercellularity and tubular atrophy/interstitial fibrosis according to the Oxford classification were associated with the plasma levels of CXCL16. ROC curve showed that plasma CXCL16 levels had a predictive value for composite endpoints (cut-off CXCL16=2.968ng/ml, AUC=0.593, sensitivity=0.611, specificity=0.618). Higher plasma CXCL16 levels predicted worse renal outcome during follow-up (Log-rank, $p=0.006$) by Kaplan-Meier analysis. In multivariate Cox proportional hazard analysis, plasma CXCL16 levels at the time of renal biopsy were found to be an independent predictor of composite endpoints after adjustment for age, gender, mean arterial blood pressure and serum albumin ($p= 0.012$). Immunofluorescence results showed that the receptor CXCR6 was expressed in renal CD8+ T cells, not in CD4+ T cells. plasma CXCL16 levels were positively associated with renal CXCL16 expression in tissues (r = 0.316, $p=0.018$). In vitro, IFN-γ promoted CXCL16 expression in HK2 cells through NF-κB pathway. CXCL16 had a chemotactic effect on Jurkat T cells and directly acted on NRK-49F cells to promote fibrosis.

Conclusions: Plasma CXCL16 levels correlate with IGAN pathology and prognosis. CXCL16 may be a risk factor for progression of IGAN.

TH-PO1011

Impact of Histological Findings of Thrombotic Microangiopathy on the Prognosis of Patients with IgA Nephropathy

Rafael A. Souza,[1] Fabio M. Torres,[1] Fábio A. Reis,[1] Rafaela B. Pinheiro,[1] Igor Smolentzov,[1] Guilherme P. Santa Catharina,[1] Livia B. Cavalcante,[2] Precil D. Neves,[1] Cristiane B. Dias,[1] Denise M. Malheiros,[2] Luis Yu,[1] Viktoria Woronik,[1] Lectícia Jorge.[1] *[1]Nephrology, University of São Paulo (USP), São Paulo, Brazil; [2]Patology, University of São Paulo (USP), São Paulo, Brazil.*

Background: IgA Nephropathy (IgAN) is the most common primary glomerulopathy in the world. The Oxford classification considers glomerular and tubulo-interstitial changes as prognostic markers of the disease, however, vascular alterations such as Thrombotic Microangiopathy (TMA) were not included in this classification. The aim of this study is to evaluate the impact of TMA on the prognosis of IgAN patients.

Methods: This is a retrospective cohort study of histological findings of native kidney biopsies between 1999 and 2018 in an academic center. The primary outcome was the TMA impact on loss of renal function and progression to ESRD.

Results: The cohort included 118 patients, 54% women, 73% caucasian, mean age of 33 years (25; 43), followed-up of 65 months (27; 115), with similiar treatment regimens. At the moment of diagnosis, 68% patientes presented with hypertension, 90% hematuria, 12.5% Complement consumption, mean SCr 1.45mg/dL (0.99; 2.6), eGFR 48.8 mL/min/1.73m^2 (27.5; 78), Albumin: 3.4 g/dL (2.9, 3.8), 24h proteinuria 2.01g (1.1, 3.7). Distribution according to Oxford classification: 76% M1, 36% E1, 70% S1, 38% T1 or T2, 29% C1 or C2. Patients with TMA had more hypertension (100 vs 61%, p <0.0001), hematuria (100 vs 87.6%, p = 0.0001), higher SCr (3.8 vs 1.38 mg/dL, p = 0.0001), lower eGFR (18 vs 60 mL/min/1.73m^2, p = 0.0001), Complement consumption (28.5 vs 10.4%, p = 0.003), lower Hemoglobin (10.6 vs 12.7g / dL, p <0.001) and Platelets (207 vs 267 x10^3, p = 0.001) when compared to non-TMA patientes. Comparing the two groups, the only difference at the Oxford classification found was more patients with E1 at TMA group (68 vs 32%, p = 0.002). In the primary outcome analysis, patients with TMA presented faster loss of renal function (ΔeGFR / year: -6.8 vs -1.65 mL/min/1.73m^2, p=0.01), more frequent and faster evolution to ESRD (71.4 vs 21.6%, p <0.0001; 3 vs 16 months, p = 0.003 respectively).

Conclusions: Histological findings of TMA at IgAN implies on worse outcomes. Our findings suggest that vessel assessment may have an impact on prognosis of patients with IgAN and the presence of vascular lesions should be contemplated in the Oxford Classification.

TH-PO1012

Primary IgA and Membranous Nephropathies with Collapsing Glomerular Pattern: A Case Series

Rafael A. Souza,[1] Fabio M. Torres,[1] Fábio A. Reis,[1] Guilherme P. Santa Catharina,[1] Igor Smolentzov,[1] Livia B. Cavalcante,[2] Precil D. Neves,[1] Cristiane B. Dias,[1] Luis Yu,[1] Viktoria Woronik,[1] Lectícia Jorge.[1] *[1]Nephrology, University of São Paulo (USP), São Paulo, Brazil; [2]Patology, University of São Paulo (USP), São Paulo, Brazil.*

Background: The presence of collapsing pattern is often associated with severe clinical manifestations and renal impairment. These findings and its outcomes in primary Membranous (MN) and IgA (IgAN) Glomerulopathies is poorly studied. The aim of this study is to analyse the impact of collapse lesions on renal survival.

Methods: Clinical data was obtained through the analysis of medical records of patients with IgAN and MN confirmed by kidney biopsies between 2009 and 2018 at a tertiary academic center. Patients presenting collapsing glomerular pattern were investigated for APOL1 risk alleles by direct gene test (sequencing by SANGER). Increase in SCr and progression to ESRD were assessed as primary outcomes.

Results: IgAN and MN were diagnosed in 280 patients and collapsing lesions were identified in 13 samples (9 IgAN and 4 MN). The cohort included 12 patients (one patient was excluded for presenting IgAN associated with HIV infection), 9 men, mean age of 35.5 ± 11 years, 92% caucasian, 50% hypertensive, 42% required dialysis at the time of biopsy. Laboratory findings included: mean SCr 5.3 ± 4.2 mg/dL, eGFR 29.7 ± 32.6 mL/min/1.73 m^2, Serum Albumin 3.1 ± 1 mg/dL, 24h proteinuria 5.2 ± 3.2 g, 83% presence of hematuria, hemoglobin 10.3 ± 2.3 g/dL and platelets 214 ± 80 x 10^3/mm^3. The direct gene test for allele APOL1 was performed in 9 patients resulting only 1 variant of risk (APOL1 G2/G2) in a patient with IgAN. During 1 year of follow-up the mean SCr increased to 5.7 ± 4.1 mg/dL and 50% progressed to ESRD. These findings are greater than our previous IgAN cohort with 111 patients, in which a decline of eGFR of 2.3 mL/min/1,73m^2/year was found.

Conclusions: We observed the presence of collapse lesions in 4.3% of the biopsies with Primary IgAN and MN and it was associated with worse renal outcomes. Although the APOL1 variant is a known factor for Collapsing Glomerulopathy, only 1 patient was found with variant of risk. Unknown predisposing factors may be involved in the collapsing pathogenesis.

TH-PO1013

Influence of Tubular and Interstitial Lesion on Proteinuria Remission and Long-Term Renal Prognosis in IgA Nephropathy with Crescent Lesion Treated with Immunosuppressive Therapy

Takayuki Fujii, Satoshi Suzuki, Junya Koshizaka, Nobuaki Yamauchi, Mayu Morimoto, Noriko Terasaki, Tanaka Hiroaki. *Seirei Sakura Citizen Hospital, Sakura, Japan.*

Background: Currently, the Oxford classification added crescent (C) score to the conventional mesangial hypercellularity (M), endocapillary hypercellularity (E), segmental sclerosis (S), and interstitial fibrosis and tubular atrophy (T) score in IgA nephropathy (IgAN). Although C lesions may be improved with immunosuppressive therapy, renal prognosis with C lesions combined with T lesions remains unclear. We studied proteinuria remission and renal prognosis after steriod therapy in IgAN patients with C lesions in relation to the presence or absence of T lesions.

Methods: This single-center retrospective cohort study included 135 patients with C lesions among 694 patients diagnosed with IgAN and could be followed for ≥1 year or started renal replacement therapy (RRT) within 1 year. Proteinuria remission and renal prognosis (50% decrease in eGFR or initiation of RRT) after steroid therapy were evaluated in relation to the presence of C lesions with and without T lesions (C1T1 and C1T0, respectively). A similar analysis was conducted in a propensity-matched cohort.

Results: There were 101 patients with C1T0 and 34 with C1T1, and 52 patients in C1T0 and 18 in C1T1 were treated with steroid therapy. The mean observation period was 9.2±7.4 years. Age, mean blood pressure, and daily urinary protein excretion were higher and eGFR was lower in C1T1. Compared to supportive care, steroid therapy caused significant proteinuria remission and renal prognosis improvement in C1T0 (log-rank p<0.01). However, in C1T1, steroid therapy achieved significant proteinuria remission (p<0.01), but no renal prognosis improvement effect was seen (p=0.25). In the propensity-matched cohort, significant proteinuria remission (p<0.01) and renal prognosis improvement (p<0.01) were achieved by steroid therapy in C1T0. In C1T1, although proteinuria remission rate at 2 years was higher in those given steroid therapy than those not given (57% vs 29%, p=0.27), there was no significant difference in renal prognosis between the two groups (p=0.46).

Conclusions: In IgAN patients with C lesions, proteinuria remission is achieved by steroid therapy. However, when there are concomitant T lesions, the effect of steroid therapy in improving renal prognosis is limited.

TH-PO1014

Examination of the Factor Related to the Prognosis in IgA Nephropathy Patients with Mild Proteinuria at Diagnosis

Sayuri Shirai,[1] Takashi Yasuda,[10] Hanako Matsunobu,[9] Hiroo Kumagai,[8] Daisuke Ichikawa,[3] Yugo Shibagaki,[2] Yoshinari Yasuda,[7] Shoichi Maruyama,[6] Tetsuya Kawamura,[5] Yusuke Suzuki.[4] *[1]St. Marianna University School of Medicine, Kawasaki, Japan; [2]St Marianna University Hospital, Kawasaki, Japan; [3]St Marianna University of Medical School, Yokohama City, Japan; [4]Juntendo University School of Medicine, Tokyo, Japan; [5]Jikei University School of Medicine, Tokyo, Japan; [6]Nagoya University Graduate School of Medicine, Nagoya, Japan; [7]Nagoya University Graduate School of Medicine, Nagoya, Aichi-ken, Japan, Nagoya, Japan; [8]National Defense Medical College, Tokorozawa, Japan; [9]Self-Defense Forces Central Hospital, Tokyo, Japan; [10]Hospital, Tokyo, Japan.*

Background: The prognosis for patients with IgA nephropathy (IgAN) with urinary protein <0.5 g / day has been considered good, but there are few reports on factors that affect their renal prognosis.

Methods: A total of 1171 adult patients who was diagnosed with IgAN by the first renal biopsy between 2002 and 2004 were registered in the Nationwide Retrospective Cohort Study in IgAN from 42 institutes all over Japan. In 394 patients with a baseline urinary protein (U-Prot) <0.5 g/day having sufficient data and observation period, a long-term renal outcome was analyzed. The primary outcome was an increase of more than 50 % in serum creatinine levels from the baseline.

Results: Primary outcome was observed in 12 patients (3.0 %). Of 394 patients, 330 had eGFR ≧60 ml/min and U-Prot <0.5 g/day [Clinical Grade (CG) Ia] and 64 had eGFR <60 ml/min and U-Prot <0.5 g/day (CG Ib). There was a significant difference in the incidence of renal outcome between the two groups (log-rank test p<0.001 between CG Ia and CG Ib). Hazard ratio (HR) in CG Ib vs. CG Ia was 9.67 (95 % CI: 2.90–32.23). On univariate analysis using Cox proportional hazards analysis, high uric acid, male, and no remission up to 2 years after renal biopsy were the significant risk factors, whereas tonsillectomy or corticosteroid therapy did not improve the renal outcome. In multivariate analysis using those significant factors, only eGFR <60 ml/min was selected as a significant independent factor (HR in CG Ib vs. CG Ia was 37.1 (95 % CI: 3.11–444.0).

Conclusions: In the present study, we confirmed that eGFR <60 ml/min was an independent risk factor in IgA nephropathy patients with mild proteinuria (<0.5 g/day). It is necessary to verify these results in the ongoing prospective study with a large cohort in the future.

TH-PO1015

Sex-Related Disparities in IgA Nephropathy Progression

Akihiko Koshino,[1] Hisayuki Ogura,[1] Koichi Sato,[1] Taro Miyagawa,[1] Shinji Kitajima,[1] Akinori Hara,[1] Yasunori Iwata,[1] Norihiko Sakai,[1] Kengo Furuichi,[2] Takashi Wada.[1] *[1]Department of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Kanazawa Medical University, Kahoku-Gun, Japan.*

Background: Sex related disparities in prognosis of CKD has been reported. We investigated the influence of gender on prognosis in immunoglobulin A nephropathy(IgA) nephropathy.

Methods: This was a multi-center retrospective study. Patients were divided into two groups according to gender. The clinical features at renal biopsy and renal outcomes during the follow-up were collected and analyzed. Renal outcomes were defined as 30% estimated glomerular filtration rate (eGFR) decline from base line. The prognostic effects of gender were evaluated by Cox regression models

Results: Total of 238 eligible patients with IgA nephropathy were enrolled (male: 124, female: 114). Male patients had higher body mass index and HDL cholesterol levels than female patients. There was no statistical difference on other features including age, blood pressure, eGFR and proteinuria. Median follow-up period was 88 (43 - 133) months. In survival analysis, male showed higher hazard ratio (HR) of 30% eGFR decline than female (HR 1.8, 95% confidence interval(CI): 1.1-3.4, p=0.03). Multivariable Cox regression analyses matched BMI and HDL cholesterol revealed that gender was also detected as a prognostic factor (HR 1.4, 95% CI 1.1-2.2, p=0.02). In gender-based survival analysis, eGFR and proteinuria are common risk factors of 30% eGFR decline. In particular, hypertension in men and lower HDL cholesterol in women was gender specific risk factor of 30% eGFR decline.

Conclusions: Sex related disparities in progression of IgA nephropathy was suggested.

TH-PO1016

Diagnosis, Treatment, and Outcome of IgA Nephropathy with vs. Without Comorbid Diabetes Mellitus

Manish K. Saha,[1] Caroline J. Poulton,[1] Yichun Hu,[3] Ronald J. Falk,[1] Susan L. Hogan,[2] Amy K. Mottl.[2] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC; [3]UNC Kidney Center & Divisions of Nephrology & Hypertension, Chapel Hill, NC.*

Background: The U.S. pandemic of diabetes mellitus (DM) has greatly complicated the diagnosis and clinical care of patients with glomerular diseases, such as IgA nephropathy (IgAN), the most common glomerular disease in the world. Our aim was to study the influence of DM on the diagnosis, treatment and clinical outcome of patients with IgAN.

Methods: We conducted a retrospective chart review of patients from the Glomerular Disease Collaborative Network (GDCN) inception cohort of adults with a pathologic diagnosis of IgAN on native biopsies performed between 1/1/1999 - 6/30/2018. GFR was estimated based using the CKD-EPI$_{SCR}$ equation obtained at the time of kidney biopsy. Urine protein:creatinine ratio was measured from a random urine collection.

Results: There was only one patient with type 1 DM and only two patients had histologic diabetic glomerulosclerosis. Indications for kidney biopsy and baseline blood pressure was similar for the two groups. Detailed baseline characteristics, immunosuppressive treatments and clinical outcomes are displayed in Table 1.

Conclusions: Patients with IgAN with versus without diabetes do not differ in the severity of proteinuria or eGFR at the time of diagnosis. Despite a reduced usage of steroids among patients with IgAN and diabetes, follow-up proteinuria and rate of eGFR decline do not differ from those with IgAN without comorbid diabetes. Larger, long term studies are required to fully understand the relationship between DM and IgAN.

Funding: Clinical Revenue Support

Sociodemographic and clinical characteristics of Ig A nephropathy patients with versus without comorbid diabetes.

Characteristics	IgAN without DM N=53 Median (IQR)	IgAN with DM N=25 Medican (IQR)	p-value
Age, years	40 (31, 51)	55 (46, 59)	0.0007
Female, N (%)	20 (37.7)	8 (32.0)	0.8
NonHispanic white race, N (%)	40 (78.4)	20.0 (83.3)	0.8
Baseline eGFR, mL/min/1.73m2	47 (32, 79)	47 (24, 64)	0.4
Baseline urine protein:creatinine, g/g	2 (1.0, 4.0)	2 (1.4, 6.0)	0.1

Characteristics of IgA Nephropathy in the Elderly: Results from a Multicenter, Large-Scale, Long-Term Observational Cohort Study

Ryoya Tsunoda,[1] Joichi Usui,[1] Junichi Hoshino,[2] Takayuki Fujii,[3] Satoshi Suzuki,[3] Yoshifumi Ubara,[4] Kenmei Takaichi,[2] Kunihiro Yamagata.[1] *[1]Department of Nephrology, University of Tsukuba, Tsukuba-City, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [3]Department of Nephrology, Seirei Sakura Citizen Hospital, Sakura-City, Japan; [4]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan.*

Background: Aging of population is a worldwide matter. Especially in Japan, more than 10 years passed after super-aged society had come. Due to increasing number of kidney biopsy underwent for elderly people, the number of aged people who diagnosed IgA nephropathy is also growing. However, little is known about characteristics of IgA nephropathy in the elderly. The indication of corticosteroids or renin-angiotensin system inhibitors is unclear.

Methods: We defined "elderly patients" as patients aged 65 or over at the diagnosis, and "younger patients" as 15-64 years old. Using our multicenter, large-scale, long-term retrospective cohort of IgA nephropathy diagnosed by kidney biopsy during 1981-2013, we extracted elderly patients and investigated their cross-sectional clinical characteristics, pathological features, and renal survival compared to younger patients. Survival analysis was performed by Kaplan-Meier method.

Results: The age at kidney biopsy was dramatically increasing during 30 years of registration period. Among 1,924 patients, 151 (7.8%) patients were aged 65 or older. Their median follow-up period was 46 [18-95] month, and their estimated glomerular filtration rate (eGFR, mL/min/1.73m^2) was 42.7 [27.1-53.4]. The proportion of CKD stage G1-2 in elderly patients was only 16%, while 60% in younger patients. Amount of urine protein was 1.0 [0.42-2.2] g/gCr. Twenty-five percent of elderly patients had diabetes, while only 5% of younger patients had. The percentage of totally sclerosed glomeruli in elderly patients was higher than that of younger patients. In survival analysis, elderly patients with proteinuria ≥1g/gCr, those having diabetes, and those with global sclerosis in more than half of glomeruli, were significantly associated with poor renal prognosis. Similar to younger patients, corticosteroids were used for 37.7% of elderly patients. However, use of corticosteroids or renin-angiotensin system inhibitors for the elderly patients were not associated with better long-term renal outcome.

Conclusions: Population of IgA nephropathy rapidly aged in Japan. IgA nephropathy in the elderly was characterized by progressed CKD with decreased eGFR and global sclerosis of glomeruli. We need to establish a strategy for treatment for IgA nephropathy in the elderly.

Analysis of Japanese Histological IgA Classification Using Probabilistic Analysis Associated with the Bayesian Theorem

Takeshi Nakata,[1] Kohei Aoki,[1] Akihiro Fukuda,[1] Naoya Fukunaga,[1] Masato Tanigawa,[2] Hirotaka Shibata.[1] *[1]Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Oita University Faculty of Medicine, Yufu-shi, Japan; [2]Department of Biophysics, Oita University Faculty of Medicine, Yufu-shi, Japan.*

Background: Regarding the pathological diagnosis of IgA glomerulonephritis (IgAGN), the Oxford classification is widely used globally, although in Japan, the Japanese Society of Nephrology (JSN) published its original pathological classification. For appropriate classification, the Oxford classification requires more than 8 glomeruli, whereas the Japanese classification requires more than 10 glomeruli. However, no study has yet investigated the relationship between the total number of glomeruli and pathological classification by probabilistic analysis. The present study aimed to report how the total number of glomeruli affects the "lumped system" of the Japanese histological IgA classification using probabilistic analysis associated with the Bayesian theorem.

Methods: Ninety-nine patients from 2000 to 2009 diagnosed IgAGN by renal biopsy at Oita University Hospital were included. Certified pathologist diagnosed IgAGN using light microscopy and fluorescence microscopy. We used the third edition of IgAGN classification of JSN. We used Bayesian theorem for Probabilistic analysis. We used three models of the prior distribution. First is actual distribution; Second is a similarity of actual distribution by using the beta function, third is no information for the prior distribution by using the beta function. The ethical committee of Oita University approved this survey.

Results: The median total number of collected glomeruli was 12 [Quartile 7,19]. When the cut-off level was set to less than 60% of the posterior probability, 21 cases (33%) were excluded (7 cases had more than 10 glomeruli, 14 cases had less than 9 glomeruli). When cases with less than 9 glomeruli were excluded before the Bayesian probability test, only 8 cases (12%) showed less than 60% of the posterior probability. However, 19 cases with less than 9 glomeruli showed more than 60% of the posterior probability. Thus, these 19 cases were considered as exclusion cases for classification. The results were the same using the three models of the prior distribution.

Conclusions: It may be better when using the IgA pathological classification of JSN to adopt the probabilistic analysis associated with the Bayesian theorem instead of considering only the total number of obtained glomeruli.

Factors Associated with ESRD in an IgA Nephropathy Cohort

Saeed K. Shaffi,[1] Ambreen Gul,[2] Christos Argyropoulos,[1] Mark L. Unruh.[1] *[1]University of New Mexico, Albuquerque, NM; [2]Dialysis Clinic Inc, Albuquerque, NM.*

Background: In IgA nephropathy patients, >1 g/day of proteinuria, presence of mesangial hypercellularity, segmental glomerulosclerosis, interstitial fibrosis and tubular atrophy (IFTA) and crescents on kidney biopsy are associated with progression to ESRD. We describe the factors associated with ESRD in an IgA nephropathy cohort with a substantial number of Native Americans and Hispanics.

Methods: We created a cohort of biopsy-proven IgA nephropathy from the UNM kidney biopsy registry which includes biopsies performed between 2002-2016. The demographic and clinical data were abstracted from the electronic medical record. The incidence of ESRD was obtained by chart review until 2016. We used age and sex adjusted Cox proportional hazards models to study the association of the predictor variables (mesangial and endocapillary hypercellularity, segmental glomerulosclerosis, IFTA, crescents, and proteinuria) with the incidence of ESRD. Patients were censored upon death or the last follow-up date for the ESRD outcome. We reported hazard ratios for ESRD with 95% confidence intervals (CI).

Results: Of the 66 patients identified with IgA nephropathy, there were 40.9% females, 36.4% Caucasians, 22.7% Hispanics, and 21.2% Native Americans. Mean biopsy age was 35.2 years (SD 16.9). Median creatinine (Cr) and CKD-EPI Cr equation eGFR were 3.1 mg/dl (IQR 2.8), and 23.2 ml/min/1.73m^2 (IQR 27), respectively. Mean proteinuria was 1.9 g/g (SD 2.7). A total of 45% of patients developed ESRD with a mean follow-up of 4 years. Patients with IFTA involving ≥50% of the cortical area and those with >50% glomeruli exhibiting global glomerulosclerosis were 4.86 and 2.86 times more likely to develop ESRD than the comparison group, respectively. (Fig 1)

Conclusions: This study demonstrates that significant glomerulosclerosis and IFTA are associated with the development of ESRD in an IgA nephropathy cohort comprising of many Native Americans and Hispanics.

The Association of Hematuria with MEST-C Score and Renal Outcomes in IgA Nephropathy

Shane A. Bobart,[1] Mariam P. Alexander,[1] Khaled Shawwa,[1] Lisa E. Vaughan,[1] Ranine Ghamrawi,[1] Lynn D. Cornell,[1] Sanjeev Sethi,[1] Richard J. Glassock,[2] Fernando C. Fervenza,[1] Ladan Zand.[1] *[1]Mayo Clinic, Rochester, MN; [2]David Geffen School of Medicine at UCLA, Laguna Niguel, CA.*

Background: Hematuria is common in IgA Nephropathy. However, current prognostication is largely based on the degree of proteinuria and MEST-C scores found on renal biopsy. We asked: 1) Are MEST-C score components associated with the presence of hematuria at the time of biopsy? 2) Is hematuria an independent risk factor for change in GFR after adjusting for follow-up time, proteinuria, MEST-C score and treatment?

Methods: We identified 125 patients with IgA Nephropathy and MEST-C scoring who were not on immunosuppression at biopsy. We compared clinical and laboratory parameters by hematuria at baseline using equal variance t-test for continuous measures and Chi-square test for categorical measures. Generalized estimating equations were used to evaluate the association between the degree of hematuria and eGFR throughout follow-up, where degree of hematuria was considered as ordinal (<3, 3-10, 11-20, 21-30, 31-40, 41-50, 51-100, >100 RBC/hpf).

Results: Ninety seven of 125 patients had hematuria at baseline (>3 RBCs/hpf), and were more likely to have M1, E1 and C ≥1 lesions (P<0.05 for all) compared to patients without hematuria. Seventy two of the 125 patients had follow up data available (median [IQR] 3.7 years [2.1, 7.0]; of these, 60 (83%) had hematuria at baseline. Nine of the 72 patients progressed to ESKD, with 6 of these 9 having >1 gram proteinuria and hematuria at baseline. An increase in degree of hematuria was significantly associated with an eGFR decline of -0.81 mL/min/1.73 m^2, (95% CI -1.44 to -0.18, P=0.01). Results were similar after adjusting for follow-up time, proteinuria, MEST-C and treatment during follow-up (P<0.05 for all) and after restricting analysis to patients with hematuria and proteinuria >1

gram/d at baseline. T was the only score found to be significantly associated with a decline in eGFR (P<0.001 with and without adjustment).

Conclusions: Hematuria at follow up is an independent predictor of eGFR decline after adjusting for follow-up time, proteinuria, MEST-C score and treatment. This suggests that monitoring the degree of hematuria as well as proteinuria is important for guiding treatment; however, RCTs using a decline in hematuria as a primary surrogate outcome measure are needed.

Application of International Tool for Risk Prediction in IgA Nephropathy in Mexican Patients

Flor E. Rojas,[3] Jineth L. Diaz villar,[3] Myriam K. Perez,[3] Ivan Rosero,[3] Angela M. Cordoba hurtado,[1] Virgilia Soto,[2] Rafael Valdez-Ortiz,[3] L. M. Perez-Navarro.[3] *[1]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico; [2]INC Ignacio Chavez, Mexico City, Mexico; [3]Hospital General de México Dr. Eduardo Liceaga, Mexico City, Mexico.*

Background: IgA nephropathy is one of the main causes for chronic kidney disease with a progressive deterioration of kidney function with a 10-year risk for end stage kidney disease ranging from 5-60%. Risk stratification is important for immunosuppressive therapy selection so a risk score was developed called international score tool for risk prediction in IgA nephropathy. The aim is determine the strength of association between the international score tool for risk prediction in IgA nephropathy and the lowering of the glomerular filtration rate at 6 months in Mexican patients with IgA nephropathy.

Methods: The study is a retrospective cohort with descriptive statistics, the international score for risk prediction in IgA nephropathy at the Hospital General de Mexico; a Pearson's correlation test was performed with a significative p value <0.05 and IC95%.

Results: Twenty patients were included, mean age 35.2± 14.06 years, 65% (13) were male, glomerular filtration rate(GFR) at biopsy was 72.93± 40.67 ml/min/1.73 m2 CKD-EPI, GFR at 6 months post-biopsy 71.42 ± 36.05 ml/min/1.73m2 CKD-EPI. The correlation between the risk for lowering GFR by 50% at 6 months presented a strong correlation with a statistical significance (Figure 1).

Conclusions: The international score for risk prediction in IgA nephropathy can be used in Mexican patients.

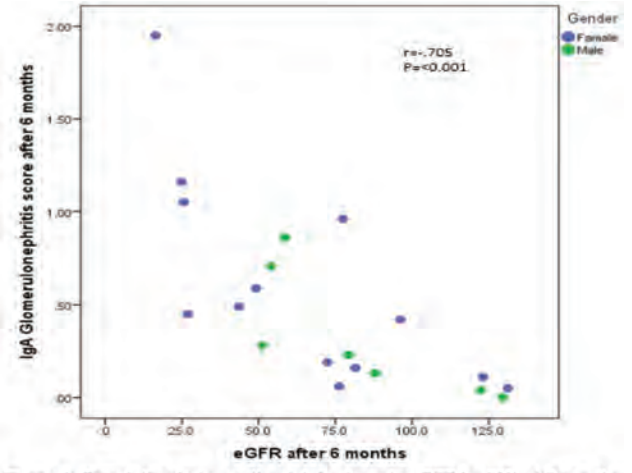

Figure 1: Correlation between the risk for lowering GFR by 50% at 6 months

Decision Tree Prediction Models for the Development of ESRD in Immunoglobulin A Nephropathy

Xin Han, Yi Tang, Wei Qin. *West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis worldwide and up to 40% will develop end-stage renal disease (ESRD) within 20 years.

Methods: The aim of this study was to develop a predictive model to predict the risk of progressing to ESRD by using decision tree algorithm. Data were evaluated from biopsy-proven IgAN patients in West China hospital, Sichuan University in China between 2009 to 2017. 2 final models were selected by Gini index and the area under receiver-operating characteristic (ROC) curve.

Results: Clinical model was developed by only clinical factors, as pathological model was conducted by both clinical and pathological factors. In clinical model (Figure 1), recursive partitioning indicated that the best single predictor of renal deterioration was proteinuria, followed by severe urine acid for patients with severe proteinuria (> 0.98 g/d). Systolic blood pressure (SBP) and estimated glomerular filtration rate (eGFR) were placed in the third tier of the decision tree model. T and S score were put at high levels in pathological model (Figure 2) and followed with eGFR at third level. Proteinuria and SBP were placed at forth level. Nephrotic syndrome was presented at last. The accuracy of clinical and pathological model were 0.85 and 0.86, respectively. The ROC of clinical model was 0.83, compared with pathological model with 0.85.

Conclusions: Decision model can practically predict the risk of incidence of ESRD in IgAN patients. Model with pathological factors can be more accurate.

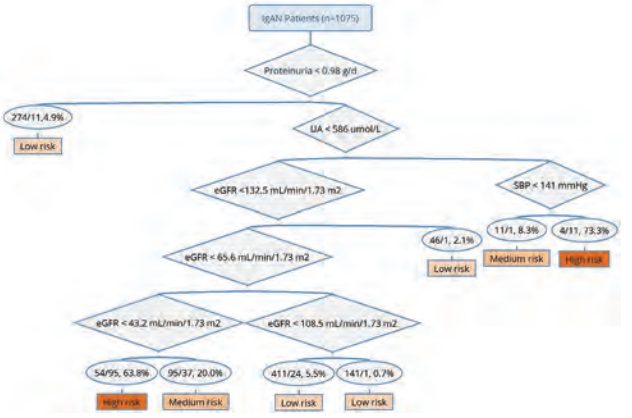

Figure 1. Clinical model of incidence of ESRD in IgAN (Line to left: yes; right: no)

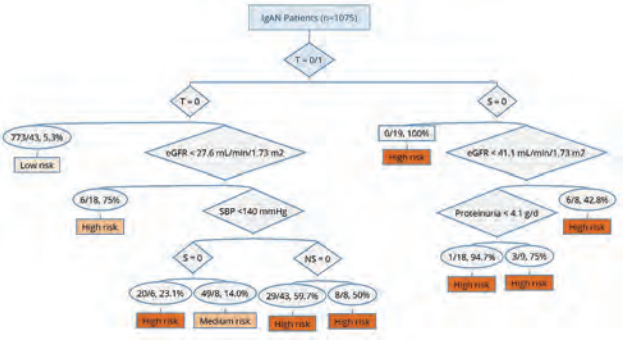

Figure 2. Pathological model of incidence of ESRD in IgAN (Line to left: yes; right: no)

TH-PO1023

Risk Prediction Model Including Therapeutic Options in IgA Nephropathy

Keiichi Matsuzaki,[1,2] Hitoshi Suzuki,[2] Takumi Imai,[3] Rei Aida,[3] Sean Barbour,[4] Daniel C. Cattran,[5] Ritsuko Katafuchi,[6] Yusuke Suzuki.[2] *[1]Kyoto University Health Service, Kyoto, Japan; [2]Juntendo University Faculty of Medicine, Tokyo, Japan; [3]Graduate School of Medicine, Kyoto University, Kyoto, Japan; [4]University of British Columbia, Vancouver, BC, Canada; [5]Toronto General Hospital, Toronto, ON, Canada; [6]National Hospital Organization Fukuokahigashi Medical Center, Koga, Fukuoka, Japan.*

Background: Recently derived prediction model for kidney outcome of IgA nephropathy (IgAN) based on clinical and pathological predictor variables from multi-ethic cohorts (Barbour SJ, JAMA Intern Med. 2019) is a potentially valuable tool in terms of its application to daily clinical practice as well as for clinical trial design. However, since timing of intervention including immunosuppressive therapy is highly variable and is dependent on patient characteristics, pathology, physician preference, country bias etc. The prediction equation currently does not include therapeutic factors after renal biopsy. Therefore, we derived and validated model used at 6 months after renal biopsy with therapeutic factors in Japanese dataset from original multi-ethic cohorts.

Methods: The outcome was defined as the composite outcome of 50% decline in eGFR or ESKD. We derived the renal prediction model including treatment within 6 months after the biopsy by Cox regression modeling with variable selection using the derivation dataset. The performances of the Cox models and the prognostic scores were evaluated based on Akaike information criteria (AIC) and the discrimination ability measured by Chambless and Diao's C-statistics. The derived score was externally validated using the validation dataset by C-statistics, calibration slope.

Results: Japanese patients from the multi-ethnic cohorts were divided to 564 derivation and 582 validation datasets. Over a median 3.31 and 4.63 years of follow-up, 10.1% and 17.2% reached the outcome, respectively. Among the variables at biopsy and treatments, eGFR, blood pressure, proteinuria at biopsy, T and C score, immunosuppression (IS) use, tonsillectomy and interactions between IS and C score, eGFR and tonsillectomy were selected for the prediction model. The derived prediction model achieved better performance compared to the model including only the variables at biopsy (AIC: 599.1 vs 562.6, C: 0.83 95%CI 0.75 – 0.89, ΔC: 0.05, 95%CI 0.00-0.12). The performance of the score remained fine in the validation dataset (C: 0.92, 95% CI 0.86-0.96, calibration slope: 0.97, 95%CI 0.82-1.11).

Conclusions: We derived and validated the risk prediction model at 6 months after renal biopsy including therapeutic options. This model may be useful guide for appropriate treatment in Japan.

TH-PO1024

Spontaneous Remission in Asian Patients with IgA Nephropathy Treated with Conservative Therapy

Daisuke Ichikawa,[1] Shiika Watanabe,[4] Tomo Suzuki,[2] Yugo Shibagaki.[3] *[1]St Marianna University of Medical School, Yokohama City, Japan; [2]Kameda Medical Center, Kamogawa, Japan; [3]St Marianna University Hospital, Kawasaki, Japan; [4]St. Marianna University Hospital, Kawasaki Citiy, Japan.*

Background: There are few studies describing IgA nephropathy (IgAN) patients with persistent microscopic hematuria with or without minimal proteinuria. However, spontaneous remissions of hematuria and proteinuria were uncommon.

Methods: 62 adult patients with IgAN who received conservative treatment at least 5years were investigated. We investigated remission rate of hematuria and proteinuria and assessed the period and the decline of renal function. Remission of proteinuria and hematuria were defined as consecutive three times of proteinuria <0.3 g/gCr and urine red blood cells <5 /HPF throughout an observation period of at least 6 months respectively.

Results: 38 (61.3%) patients had remission of hematuria, 24 (38.7%) patients had remission of proteinuria, and 19 (30.6%) patients had both remissions. The group with proteinuria <1.0 g/gCr group, the remission rate was 64.2%. The group with proteinuria <0.5 g/gCr group had a higher remission rate than the group with proteinuria ≧0.5 g/gCr group at the time of renal biopsy. The median time to remission of hematuria was 2.8 years (IQR 1.6-4.2), and that of proteinuria was 2.6 years (IQR 1.7-3.4). Patients who showed renal function decline (30% decline of eGFR from baseline) were significantly older, had significantly lower eGFR and higher proteinuria at the time of renal biopsy. Only two patients with normal renal function and normal range of proteinuria at diagnosis showed 30% eGFR decline. The two patients had persistently proteinuria >0.5 g/gCr after five years.

Conclusions: Relatively high rate of spontaneous remission were shown. In the proteinuria <0.5 g/gCr group, there is high rate of remission of hematuria and proteinuria and renal function was preserved. In the case of proteinuria <1.0 g/gCr, it may be possible to observe over three years with conservative therapy.

TH-PO1025

Analysis of Appropriate Treatment for IgA Nephropathy with Mild Proteinuria

Shota Ogura, Takahito Moriyama, Kazunori Karasawa, Kosaku Nitta. *Tokyo Women's Medical University, Tokyo, Japan.*

Background: The 2012 KDIGO clinical practice guidelines recommended the renin angiotensin system inhibitors (RASIs) for the IgA nephropathy (IgAN) patients with mild proteinuria (0.5 to 1 g/day) as treatment. However, in Japan, tonsillectomy and steroid pulse therapy (TSP) was frequently employed in a lot of institutions, even though corticosteroid therapy was recommended only for the patients with persistent proteinuria over 1 g/day, despite of 3-6 months of supportive care, and tonsillectomy was not recommended. Then, we analyzed the appropriate treatment for the IgAN patients with mild proteinuria.

Methods: In this retrospective cohort analysis, 127 patients diagnosed as IgAN by renal biopsy from 1980 to 2015 in our institution, and had mild proteinuria (0.5 – 1.0 g/day) and eGFR ≧60 ml/min/1.73m2 were analyzed. We divided them into three groups: patients treated with TSP (TSP, n=34), with oral prednisolone (oPSL, n=33), and with conservative therapy (CON, n=50). We analyzed the clinical and histological backgrounds at renal biopsy, remission rates of proteinuria (U-P) which met < 0.3 g/g creatinine(Cr), urinary red blood cell (U-RBC) < 5/high power field (HPF), and both of them (clinical remission: CR) for 5 years, and 10- years renal survival rate among three groups.

Results: The clinical and histological backgrounds were similar among three groups (median U-P was around 0.70 g/gCr (p=0.28), median eGFR was around 80.0 ml/min/1.73m2 (p=0.14) and median U-RBC were around 20/HPF in each group (p=0.48)). The remission rate of U-RBC was significantly higher in TSP (94.2%) than oPSL (60.4%, p=0.03) and CON (40.5%, p<0.0001), and also higher in oPSL than CON (p=0.02). The remission rate of U-P was significantly higher in TSP (83.1%) than in CON (30.6%, p<0.0001), and higher in oPSL (66.4%) than CON (p=0.0007), but similar between TSP and oPSL (p=0.36). The results of CR were similar with the results of U-P (TSP=oPSL>CON). There was no patient progressed to end-stage renal disease in each group. In multivariate Cox regression analysis, TSP and oPSL were independent factors for the remission of urinary findings, but TSP was not superior to oPSL.

Conclusions: In the treatment for IgAN with mild proteinuria, TSP was superior to oPSL in remission of U-RBC, and TSP and oPSL were superior to CON in the remission of urinary findings, but not for the 10-years renal prognosis.

TH-PO1026

Corticosteroids Improves Renal Survival in Chinese Patients with Early-Stage IgA Nephropathy

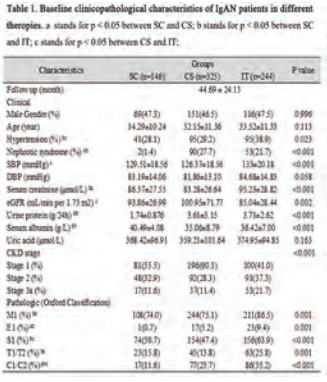
Gaiqin Pei,[1,2] Yi Tang,[3] Wei Qin.[3] *[1]Division of Nephrology, Department of Medicine, West China Hospital, Sichuan University, Chengdu, Sichuan, China., Chengdu, China; [2]West China School of Medicine, Sichuan University, Chengdu, Sichuan, China., Chengdu, China; [3]West China Hospital of Sichuan University, Chengdu, China.*

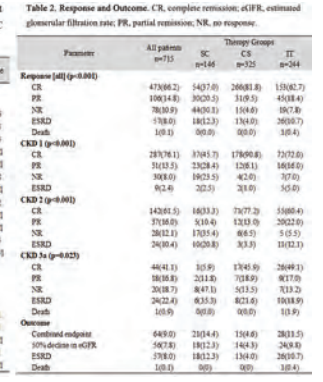
Background: The therapy for immunoglobulin A nephropathy(IgAN) patients remains controversial. This study aims to evaluate the effects of corticosteroids and immunosuppressive therapy in Chinese early stage IgAN patients with estimated glomerular filtration rate(eGFR) ≥45mL/min/1.73 m^2 and mean proteinuria≥1g/24h.

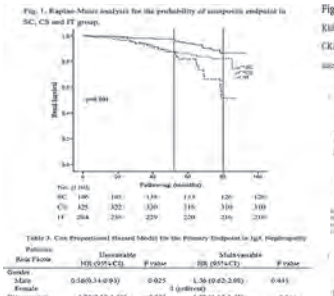
Methods: Patients with biopsy proven IgAN were retrospectively enrolled from 2007 to 2016. Patients were categorized into supportive care (SC), steroids alone(CS), and steroids plus immunosuppressant(IT) groups. Responses to therapy included complete remission(CR), partial remission(PR), no response(NR)and end stage renal disease(ESRD). The renal outcome was defined as a 50% decline in eGFR and/or ESRD.

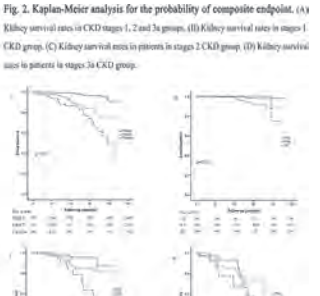
Results: 715 patients(Male 47% and Female 53%)were recruited and followed for a mean of 44.69±24.13 months. The rate of CR was 81.8%, 62.7%, 37% in CS, IT, SC group, respectively. Renal outcomes were remarkably better in CS group(4.6%)compared with SC(14.4%)and IT(11.5%)group(p<0.001). Moreover, 36-month and 80-month renal survival was significantly better in CS group (98.3% and 86.4 %)than in the IT(94.2% and 82.4%)and SC(94.0% and 51.6%)group. Early CKD stage disease presented with better kidney survival(p<0.001). Further analysis for CKD stage 1 patients suggested no difference among 3 groups. In CKD stage 2 patients, CS alone or with IT could improve renal survival rate when compared with SC alone(p<0.001and 0.007). But, no statistical significant difference could be found between CS and IT groups(p=0.219). For CKD stage 3a patients, renal survival rate in 3 groups were poor(p=0.398). Multivariate model showed that hypertension(HR 1.99, 95% CI 1.16-3.42;p=0.012); serum creatinine (HR 1.02, 95%CI 1.00-1.05;p=0.024); E1 lesion(HR 3.10, 95% CI 1.14-8.42;P=0.027) and T1/T2 lesion (HR 3.34, 95% CI 1.98-6.33;P<0.001)remained as independent predictors of renal survival.

Conclusions: The use of corticosteroids in addition to ACEI/ARB significantly improve the short-term renal outcome in early-stage IgAN patients.









TH-PO1027

Effect of Corticosteroid Therapy for Patients of IgA Nephropathy with Crescents

Mengjun Liang, Jiafan Zhou, Xing Zhang, Zongpei Jiang. *The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Patients with IgA nephropathy (IgAN) presented proteinuria≥1g/d and eGFR≥50ml/min/1.73m^2 after supportive treatment had been advised 6-month course of corticosteroids therapy. Update of Oxford classification of IgAN had recommended

crescents be added to the MEST score for they were predictive of outcome. Whether we should take some more positive therapy for crescents?

Methods: We conducted a single-center, retrospective cohort study enrolling 46 patients from 2017.01 to 2018.06, diagnosed with IgAN by renal biopsy. Eligible patients had proteinuria of 0.5~3.5g/d, eGFR≥30ml/min/1.73m^2 and crescent proportion<50%. Patients were divided into two groups, one for classical steroid treatment (intravenous methylprednisolone 0.25g/d for 3 days at the beginning of months 1, 3 and 5, plus oral prednisone 0.5 mg/kg/d for 6 months, called 1-3-5 Group) and the other assigned an optimized steroid therapy (intravenous methylprednisolone 0.25g/d for 3 days at the beginning of months 1, 2 and 3, plus oral prednisone as above, called 1-2-3 Group). The primary endpoint was remission of proteinuria, secondary endpoint was deterioration in renal function.

Results: There were 23 patients in each group and no significant differences in age, gentle, baseline proteinuria and eGFR between the two groups, except for the proportion of crescents (for Oxford C1 and C2: 52.5% and 13% in 1-3-5 Group vs. 95.7% and 4.3% in 1-2-3 Group respectively, p=0.001). After 6 months therapy, proteinuria in 1-3-5 Group was 0.5(0.2,0.8)g/d (vs. 1.2(0.8,2.6)g/d at baseline, p<0.001) and that in 1-2-3 Group was 0.3(0.2,0.6)g/d (vs. 1.5(0.7,2.6)g/d at baseline, p<0.001). 78.3% of patients in 1-3-5 Group had got remission of proteinuria,while 95.7% in 1-2-3 Group (p=0.187). The 6th month eGFR in 1-3-5 Group was 80.7(59.8,116.2)ml/min/1.73m^2 (vs. 77.5(54.8,104.6) ml/min/1.73m^2 at baseline, p=0.212), while that in 1-2-3 Group was 97.8(68.6,130.9)ml/ min/1.73m^2 (vs. 79.5(52.9,108.7)ml/min/1.73m^2 at baseline, p=0.002). The slope of eGFR in 1-3-5 Group was 0.7(-1.7,3.3)ml/min/1.73m2/month, while that in 1-2-3 Group was 3(1.2,5.4)ml/min/1.73m2/month, p=0.027. None of the patients had met side effects.

Conclusions: Our preliminary results had indicated that optimized steroid therapy had equal effect on reducing proteinuria but more significant advantage to protect against renal function deterioration in IgAN with crescents.

TH-PO1028

Clinical Response to Budesonide in Biopsy-Proven IgA Nephropathy

Umesh Lingaraj. *Nephrology, Institute of Nephrourology, Bangalore, India.*

Background: Primary IgA nephropathy is the most prevalent chronic glomerular disease worldwide. STOP-IgAN trial has questioned the benefit of systemic immunosuppression And significant (24%) mean UPCR reduction from baseline has been concluded from NEFIGAN study. So in this study we aimed at studying the effect of oral controlled release budesonide in biopsy proven IgA nephropathy patients.

Methods: This is a interim analysis of on going study conducted in department of Nephrology, Institute of Nephro-Urology, Bangalore, India from May 2017. A total of 40 patients with biopsy proven IgA nephropathy were included in study. All patients were optimised on RAS inhibitors, Omega 3 fatty acids and budesonide. A decision to start all drugs together was considered as isolated RAS inhibitors will not prevent immunological damage by ongoing IgA deposition. Based on histology (MEST SCORE) patients were started with 9mg and 12mg budesonide. Patients with crescents were treated with oral and IV cyclophosphamide and prednisone followed by budesonide. All patients were regularly followed up every 4 weeks to monitor vitals, Renal function test and Urine PCR. Our primary outcome was mean change from baseline in 24 hr urine protein at the end of 3rd and 6th Month. Clinical response was defined as complete (CR), partial (PR) or non-responders (NR) according to recent definitions.

Results: 22(55%) were males and 18 (45%) were females. Mean age was 48.27 yrs. Mean creatinine at presentation was 3.02 gm Mean proteinuria at presentation was 3.83 gm / 24 hours 11(40) had eGFR > 45ml/min/1.7m2 And 29(40) had eGFR < 45ml/min/1.7m2 All patients were optimised with RAS inhibitors and omega 3 fatty acids 3(7.5%) were treated with cyclophosphamide, prednisone and budesonide 3(7.5%) were treated with prednisone and budesonide. 34 (85%) were treated with budesonide. RESPONSE: CR-7(40)19% PR-18(40)49% NR-12(40) 32% Lost follow up - 3(40) CR and PR was higher in eGFR >45ml/min/1.7m2 (20% vs 18.5% and 50%vs 44%). NR was higher in eGFR < 45ml/min/1.7m2. (37% vs 39%) Percentage change in mean 24 HUP from baseline: 29.02%. Mean change in Serum Creatinine from baseline: 0.9 mg/dl

Conclusions: Budesonide, together with optimised RAS blockade, reduced proteinuria in patients with IgA nephropathy. Our patients probably had the advantage of blocking the intestinal access of IgA dysregulation right from presentation, hence reflecting a slightly better outcome than NEFIGAN trial.

TH-PO1029

Systemic GCS Exposure from Nefecon Administration, Estimated from Suppression of Endogenous Cortisol Production

Markus Jerling,[1] Sofia Rendón-Rapp,[2] Jens Kristensen.[2] [1]*Markus Jerling Consultancy AB, Stockholm, Sweden;* [2]*Calliditas Therapeutics AB, Stockholm, Sweden.*

Background: Nefecon is a unique two-step release oral formulation for the treatment of IgAN by a targeted delivery of budesonide to the Peyer's patches in the lower small intestine, aiming at local immunosuppression of B-cells responsible for the production of secretory galactose-deficient IgA antibodies. In a phase 2b study once daily oral treatment with Nefecon for 9 months reduced proteinuria and stabilised eGFR. Budesonide has a high first-pass metabolism of 90% resulting in limited systemic GCS exposure. The potency of steroids can be assessed by the HPA-axis derived suppression of endogenous cortisol production.

Methods: A study in 24 healthy subjects compared the change in serum cortisol levels over 24 hours after single doses of 8 mg NEFECON, 16 mg NEFECON, and 9 mg ENTOCORT in a randomised cross-over design. Urine cortisol excretion over 24 hours and plasma budesonide pharmacokinetic pqqarameters were also compared.

Results: A 9 mg dose of ENTOCORT corresponded to 11.7 mg of NEFECON for serum cortisol suppression. NEFECON 16 mg and ENTOCORT 9 mg caused similar decreases in urine cortisol excretion. Budesonide $AUC_{(0-24)}$ was comparable for NEFECON and ENTOCORT per mg dose but with approximately double C_{max} values for NEFECON.

Conclusions: The higher ratio Cmax / AUC for Nefecon compared to Entocort demonstrate a shorter duration of release with a longer period of low budesonide plasma concentrations during the 24 hour period. The net effect is a lower cortisol suppression per mg dose. A published study has shown that 29 mg of Entocort is equivalent to 20 mg of prednisolone for plasma cortisol suppression. The combined studies indicate that 16 mg of Nefecon is equivalent to 8 mg of prednisolone for plasma/serum cortisol suppression.

		Baseline	NEFECON 8 mg	NEFECON 16 mg	ENTOCORT 9 mg
Serum Cortisol $AUC_{(0-24)}$ (nmol*h/L)					
	Mean (sd)	5372 (1126)	3479 (1128)	2971 (1153)	3034 (706)
Change	Mean (sd)		-1901 (710)	-2401 (895)	-2215 (778)
Urine Cortisol Amount Excreted (0-24 h) (nmol/day)					
	Mean (sd)	110 (48.0)	65.2 (34.8)	56.1 (32.8)	55.1 (31.9)
Change	Mean (sd)		-44.3 (40.5)	-53.7 (34.6)	-54.8 (35.8)
Plasma budesonide PK parameters					
$AUC_{(0-24)}$ (pg*h/mL)	Mean (sd)	13.076 (7901)	29.493 (21498)	12.220 (8944)	
C_{max} (pg/mL)	Mean (sd)	3154 (2463)	6507 (5920)	1763 (1173)

Effects of Tonsillectomy Monotherapy of Advanced-Stage IgA Nephropathy: A Case Series Study

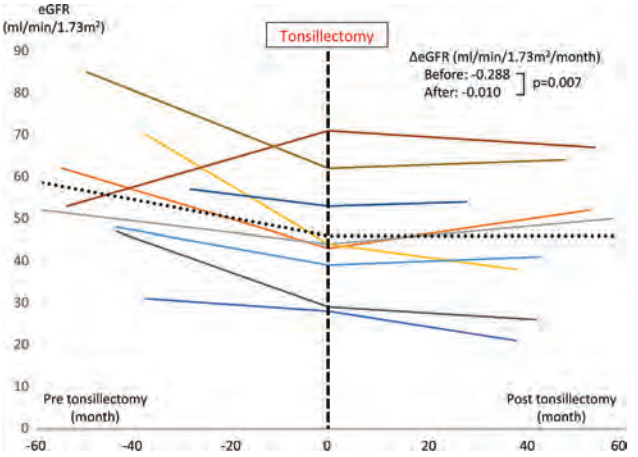
Hirokazu Marumoto, Nobuo Tsuboi, Kentaro Koike, Tetsuya Kawamura, Takashi Yokoo. *Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Previous studies on Japanese patients with IgA nephropathy (IgAN) suggest the superiority of combination tonsillectomy and corticosteroid pulse therapy compared to corticosteroid pulse therapy alone; however, the efficacy of tonsillectomy monotherapy remains poorly understood.

Methods: Inclusion criteria consisted of patients with biopsy-proven IgAN with an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m^2 after 2 or more years of conventional therapeutic interventions, or those with an average urinary protein excretion > 500 mg/day for at least 6 months. Clinical characteristics, including renal function decline, were compared during the same observation periods before and after tonsillectomy.

Results: The patient cohort consisted of 5 males and 4 females, with an average age of 43 years. All patients had been treated with RAS inhibitors. Mean serum levels of creatinine were 1.32 mg/dL, with patients waiting an average of 161 months from initial diagnosis to tonsillectomy. Microscopic hematuria (1.10 vs. 0.20 grade, p = 0.003) and total urinary protein excretion (646 vs. 389 mg/day, p = 0.03) decreased significantly after tonsillectomy, relative to those before tonsillectomy. The slope of eGFR significantly improved after tonsillectomy versus before tonsillectomy (**Figure**; a mean value is shown as dashed line).

Conclusions: Tonsillectomy is an effective treatment option for advanced IgAN patients with persistent hematuria and proteinuria, independent of conventional therapeutic interventions.



TH-PO1031

Treatment of Henoch-Schönlein Purpura Nephritis with Hydroxychloroquine: A Retrospective Cohort Study

Yixuan Pan, Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Hydroxychloroquine (HCQ) is a mild immunosuppressive agent. It has been used clinically as an effective drug in the treatment of rheumatic diseases such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). We aimed to study

the clinical efficacy of hydroxychloroquine in the treatment of Henoch-Schönlein purpura nephritis (HSPN), as well as the occurrence of adverse reactions.

Methods: This was a retrospective cohort study involving 76 HSPN patients. Twenty-two patients who had been treated with hydroxychloroquine were included in the exposure group, while 54 patients in the non-exposure group were treated with ACEI/ARB and/or other immunosuppressive agents instead of hydroxychloroquine. The patients were followed up for 6-34 months (median 14 months). Death, end-stage renal disease or transferring to renal replacement therapy (dialysis or renal transplant),eGFR decreasing by more than 30% over baseline within 2 years, serum creatinine doubling from baseline level were considered end events.

Results: There was no significant difference in the remission rate of proteinuria between the exposed group and the non-exposed group. The remission rate of proteinuria in patients treated with hydroxychloroquine alone was 88.89%. At the end of the follow-up period, no death or dialysis occurred. The eGFR of 3 patients in the non-exposed group decreased by more than 30% compared with the baseline (30%, 34% and 41% respectively), while only one person in the exposed group (54%). No significant adverse events were recorded during HCQ treatment.

Conclusions: Hydroxychloroquine can mildly and safely reduce proteinuria in patients with HSPN.

TH-PO1032

Long-Term Renal Outcomes In Patients with IgA Vasculitis: A Single-Centre Retrospective Cohort Study

Chee Kay Cheung,[1,2] Jonathan Barratt,[1,2] Reem Al-Jayyousi.[2] *[1]University of Leicester, Leicester, United Kingdom; [2]John Walls Renal Unit, University Hospitals of Leicester, Leicester, United Kingdom.*

Background: IgA vasculitis (IgAV; Henoch Schönlein purpura) is a small vessel vasculitis that most commonly affects children but also occurs in adults. The long term outcome from IgAV in adult patients with renal involvement is not well described, and treatment protocols are variable.

Methods: We conducted a retrospective study of renal outcomes in patients with IgAV with histologically confirmed renal involvement seen previously within our adult renal service. We searched our local renal and pathology databases for those diagnosed between 1990-2018. Demographic data including age, sex, ethnicity and date of presentation were recorded. Clinical data included serum creatinine and albumin, proteinuria (urine protein:creatinine ratio; UPCR) at presentation and follow up, as well as biopsy findings and treatment.

Results: We identified 59 patients seen within this time period, with median follow up of 64.5 months (interquartile range (IQR) 20.5-114.8). Mean age at diagnosis was 34.5 (±SD 18.4) years. 37 (63%) were male, 45 (88.2%) were Caucasian. 20 (33.9%) had documentation of a prior skin rash (the remainder presented concurrently), occurring a median of 6 months before, with 11 (18.6%) undergoing a skin biopsy. Median eGFR at diagnosis was 84 (42.3-90) ml/min/1.73m^2. Median UPCR at presentation was 120 (21.7-481.7) mg/mmol, with 19 (32.2%) having nephrotic-range proteinuria (UPCR > 350 mg/mmol), and 8 (13.6%) with nephrotic syndrome (as previous, plus serum albumin ≤ 30 g/L). 24 (40.7%) patients had evidence of crescents on renal biopsy. 16 (28.1%) were treated with prednisolone alone, and 15 (26.3%) combined with another agent, most commonly mycophenolate mofetil. At last follow up, 38 (64.4%) had an eGFR >60 ml/min, and 21 (35.6%) below. 8 reached ESRD, at a median of 25 months (2-68.8) months. All had nephrotic range proteinuria (UPCR >350 mg/mmol) at presentation. When compared to those with similar UPCR at presentation, the patients who reached ESRD were younger, had lower eGFR at presentation and had a higher failure rate in achieving remission from their proteinuria.

Conclusions: Overall, in this cohort, patients with IgAV who achieved proteinuria <1g/d had a good outcome. Those who presented with nephrotic range proteinuria with failure to achieve any remission from their proteinuria had a poor outcome in terms of renal survival.

TH-PO1033

Incidence of Biopsy-Proven Kidney Disease Among Kaiser Permanente Northern California Patients in 2018

Vivek Charu,[1] Maryam Aghighi,[1] Jessica B. Lapasia,[2] George Lai,[2] Jennifer W. Lin,[2] Tracy Y. Jonelis,[2] Megan L. Troxell,[1] Neeraja Kambham,[1] Sijie Zheng.[2] *[1]Pathology, Stanford University School of Medicine, Palo Alto, CA; [2]The Permanente Medical Group, Northern California, CA.*

Background: Accurate population-level estimates of the incidence of glomerular (G) and primary tubulointerstitial diseases (TI) are lacking. Obtaining such estimates is challenging as accurate diagnosis typically requires a kidney biopsy and lack relevant population-level denominators. Here we provide population-level estimates of biopsy-proven G & TI diseases in a cohort of ~4.3 million at Kaiser Permanente Northern California (KPNC) in 2018.

Methods: We reviewed all KPNC 2018 renal biopsy reports, and categorized patients into known G & TI disease groups. Incidence rates and associated standard deviations were calculated per 100,000 persons, stratified by age and sex.

Results: 673 native kidney biopsies were performed in 2018, corresponding to 15.8 biopsies/100,000 persons. The incidence of common biopsy-confirmed G & TI diseases are provided in the Table. IgA nephropathy is the most common diagnosis (incidence 2.3/100,000 persons), followed by focal and segmental glomerulosclerosis (1.6/100,000), lupus nephritis (1.4/100,000), pauci-immune GN (1.3/100,000), and membranous nephropathy (1.3/100,000). 19.5% patients undergoing kidney biopsy in this cohort had evidence of diabetic nephropathy (n=131), 21.4% of whom had an additional G or TI diagnosis (n=28).

Conclusions: Here we provide incidence estimates of biopsy-confirmed G & TI diseases in a large, racially and ethnically diverse population. Comparison with population-level estimates in other cohorts will help determine the true incidence of these diseases.

Biopsy-proven kidney disease, KPNC, 2018. *Incidence rates/100,000 persons

	Total (rate*; SE)	Males (rate*; SE)	Females (rate*; SE)
All biopsies	673 (15.8; 0.6)	339 (15.4; 0.8)	334 (16.3; 0.9)

One Year of the State Registry of CKD in Aguascalientes Mexico: Have We Found a New Hotspot of CKD?

Jose M. Arreola Guerra. *Centenario Hospital Miguel Hidalgo, Aguascalientes, Mexico.*

Background: According to the Institute for Health Metrics and Evaluation, in Mexico the global burden attributed to chronic kidney disease (CKD) is one of the highest worldwide. Unfortunately the country don't have any official registry. Since June 2018, the Health Council from Aguascalientes brought together the main health institutions that provide renal replacement therapy to start the state registry of CKD

Methods: Describe the results of the first year of data collection of the Aguascalientes CKD registry

Results: Until May 2019, 2,574 patients have been registered, of whom 93 have died and 321 are transplanted. The estimated prevalence is 1,526 pmp (n= 2,160). The most common causes are CKD are: of unknown origin (n= 981, 45.4%), Diabetes Mellitus (n=681, 31.5%), Systemic Arterial Hypertension (n= 326, 15%). The most prevalent modality of renal substitution was hemodialysis (n= 1,365, 63.1%). 59% are men (n= 1,274). The average age of the patients included was 46.5 years, with a bimodal distribution. The first group between 20 and 39 yo (n= 1,107, 51.2%) and the second between 50 and 69 yo (n= 843, 39%). Since January 2012, 389 kidney biopsies have been performed in the state. The main diagnosis was focal and segmental glomerulosclerosis(FSGS) (n= 128, 32.9%), followed by lupus neph (n= 55, 14.1%), IgA neph (n= 48, 12.3%), minimal changes dis (n= 45, 11.5) and membranous neph (n= 22, 5.6%)

Conclusions: In Aguascalientes Mexico, we have a high prevalence of CKD. The main cause is of unknown origin. The main affected group are young adults between 20 and 40 y and the most frequent glomeulopathy in this group was FSGS. At this moment a study of screening of CKD in adolescents in the state is being developed which is expected to contribute to the study of the causes of CKD in our population

Characteristics by age groups

Variable	Group 1 (20 to 39 yo) n= 1,107	Group 2 (50 – 69 a) n= 843	p value
Male sex, n(%)	726 (65.5)	486 (57.6)	<0.01
CKDuknown origin, n (%)	574 (51.8)	225 (26.6)	<0.01
Diabetes, n(%)	83 (7.5)	352 (41.7)	<0.01
HTN, n(%)	109 (9.8)	136 (16.1)	<0.01
Renal Biopsies	N= 136	N=44	p value
FSGS, n(%)	60 (44.1)	12 (27.2)	0.04
Lupus N, n(%)	19 (13.9)	8 (18)	0.45
IgA N, n(%)	17 (12.5)	8 (18)	0.40

FSGS: Focal segmental glomerulosclerosis, HTN: Systemic Hypertension, N: Nephritis

Biopsy Proven Diagnosis of CKD in Sub-Saharan Africa: An H3 Africa Cohort Study

Manmak Mamven,[1,2] Titilayo O. Ilori,[1] Ogochukwu C. Okoye,[3] Rulan S. Parekh,[4] Jeffrey B. Hodgin,[6] Rasheed A. Gbadegesin,[5] Shikhar Kumar,[1] Akinlolu O. Ojo,[1] Dwomoa Adu.[7] H3 Africa Kidney Disease Research Network *[1]The University of Arizona, Tucson, AZ; [2]Medicine, University of Abuja, Abuja, Nigeria; [3]Medicine, Delta State University Teaching Hospital, Oghara, Nigeria; [4]The Hospital For Sick Children, Toronto, ON, Canada; [5]Duke University Medical Center, Durham, NC; [6]The University of Michigan, Ann Arbor, MI; [7]University of Ghana, Accra, Ghana.*

Background: Chronic kidney disease is increasingly prevalent in **Sub-Saharan Africa** (SSA) and a major factor leading to increased morbidity and mortality. Treatment of CKD, specifically glomerulonephritis (GN) is paramount to reducing CKD progression, morbidity and mortality, however, little is known about the types and incidence of primary glomerulonephritis (GN) nor is pathological diagnosis feasible throughout SSA.

Methods: Among 500 native kidney biopsies performed so far at 10 centers across Africa, we assessed patterns and types of glomerular disease in participants with eGFR greater than 15mls/minute enrolled in the H3 Africa Kidney Disease network cohort study from 2017-2019. Biopsies were performed with real time ultrasound guidance and samples were shipped for processing and evaluation of light, immunofluorescence and electron microscopy by 2 US pathologists. We present preliminary results on demographic, clinical and biopsy data obtained.

Results: Demographics and baseline characteristics: The mean age was 30.68 ± 13.12 years, there were 231 males(50.4%), 357 (77.95%) patients were Nigerians, 99 (21.62%) and were Ghanaians. The mean eGFR was 66.27 ± 37.20. 10 (9.17%) had high blood pressure, 11 (2.43%) had diabetes, 6 (1.32%) were hepatitis B positive and 1 (0.22%) was positive to hepatitis C.

Conclusions: FSGS, membranous nephropathy and minimal change disease were the most frequent primary glomerulonephritis among adults in our region. Lupus Nephritis is a common secondary GN in Sub Saharan Africa.

Funding: NIDDK Support

Type	Biopsy diagnosis - (n=500)
Membranous GN	108
FSGS	152
Minimal Change Disease (MCD)	79
MPGN	3
IgA nephropathy	3
Amyloidosis	3
Cresenteric GN	3
Immune complex GN (unclear etiology)	4
FGGS & IFTA, unclear etiology	11
Lupus nephritis	134

The Spectrum of the Biopsy-Proven Glomerular Disease in Taiwan: A Single-Center Experience

Wei chiao Sun, Tai-Di Chen, Cheng chia Lee, Chih-Hsiang Chang, Kun-Hua Tu. *Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: Glomerular diseases are still leading causes of end-stage renal disease. The diagnosis of these disease relies on the interpretation of the renal biopsy. The sonography-guided biopsy is still the major tool to acquire an accurate pathologic diagnosis. The spectrums of the glomerular disease are varied in different regions. Grossly, IgA nephropathy is the leading cause of primary glomerular disease in Asia. To date, there are few articles which report the disease spectrum in Taiwan. This study conducts a retrospective investigation of 19-years cohorts in a single medical center. The trend of disease spectrum was evaluated and analyzed.

Methods: This investigation was performed in a tertiary hospital. From 2000-2018 period, totally 2,391 patients first received renal biopsy. After excluding 71 cases of tubulointerstitial disease, 270 cases of end-stage renal disease, advanced chronic kidney disease, inadequate sampling, and failed interpretation, there are still 2,050 cases with a clear diagnosis.

Results: Membranous glomerulopathy is the leading category in 2,050 cases (404, 19.7%), followed by IgA nephropathy (306 cases, 14.9%), minimal change nephropathy (283, 13.8%), focal segmental glomerulosclerosis (180, 8.8%). In the secondary disease, lupus nephritis account for 18.4% of the 2050 cases (378), followed by diabetic nephropathy (200, 9.6%), and paraproteinemic renal disease (60, 2.9%). Notably, the incidence of the membranous glomerulopathy is decreasing by year. In contrast, the ratios of IgA nephropathy is increasing gradually.

Conclusions: Membranous glomerulopathy is the major category in 19-years cohort of a single medical center, although the incidence is decreasing by year. Further investigation of change of disease spectrum is necessary.

TH-PO1037

Positive Family History for CKD in Patients with Primary Glomerular Diseases: Disease Onset and Comorbidities in the CureGN Cohort

Lucrezia Carlassara,[1] Maddalena Marasa,[2] Rasheed A. Gbadegesin,[3] Debbie S. Gipson,[4] Matt G. Sampson,[5] Bruce A. Julian,[6] Simone Sanna-Cherchi,[2] Krzysztof Kiryluk,[2] Andrew S. Bomback,[2] Ali G. Gharavi.[2] *[1]Universita' degli Studi di Brescia, Vicenza, Italy; [2]Columbia University, New York, NY; [3]Duke University Medical Center, Durham, NC; [4]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [5]University of Michigan, Ann Arbor, MI; [6]University of Alabama at Birmingham, Birmingham, AL.*

Background: A positive family history (pFHx) has been associated with worse outcomes for some glomerulonephritides (GNs), but this has not been rigorously examined in a prospective cohort. A pFHx for chronic kidney disease (CKD) can be indicative of Mendelian hereditary diseases, or may reflect a polygenic risk or unmeasured environmental risk factors.

Methods: We studied the association of a self-reported pFHx of CKD with renal function, age at the time of diagnosis and comorbidity burden, in the Cure Glomerulopathy Network (CureGN), a prospective multi-center observational study of GN patients (N=2281) with Focal Segmental Glomerulosclerosis (FSGS), Minimal Change Disease (MCD), Membranous Nephropathy (MN), IgA Nephropathy (IgAN), or IgA Vasculitis (IgAV). Comparisons between patients with and without pFHx were analyzed via Chi-square/Fisher and ANOVA/Wilcoxon test.

Results: A CKD pFHx was present in 352 (15%) patients: 28% of FSGS, 21% of MN, 15% of IgAN, 13% of MCD, and 9% of IgAV cases. CKD pFHx was associated with lower eGFR at GNs onset in entire cohort ($p=1.0x10^{-11}$), IgAV (p= 0.0002), FSGS (p= 0.0004), IgAN (p= 0.001), and MN (p=0.02) but not MCD patients. CKD pFHx was associated with older age at the GNs onset with adults IgAN (p= 0.006) patients. CKD pFHx was significantly associated with a higher prevalence of several comorbidities, even after adjusting for age, sex, ethnicity, race, body mass index, and smoking habit (Table 1).

Conclusions: Patients with a CKD pFHx have lower eGFR at presentation and have higher prevalence of certain comorbidities than patients without such family history. The association with allergies, asthma and COPD point to shared biology and environmental factors. Identifying this association may help to elucidate common genetic or environmental causes, shed light on disease pathogenesis, improve GNs management, and ultimately may help develop preventive measures.

Funding: NIDDK Support

Table 1: Comorbidities significantly associated with patients with a pFHx for CKD.

Racial/Ethnic Differences in Socioeconomic Status (SES) and Health-Related Quality of Life (HRQL) Among Children with Glomerular Disease in Cure Glomerulonephropathy (CureGN)

Jill Krissberg,[1] Margaret Helmuth,[2] Diego H. Aviles,[17] Yi Cai,[3] Rasheed A. Gbadegesin,[4] Keisha L. Gibson,[5] Larry A. Greenbaum,[6] Guillermo Hidalgo,[7] Sangeeta R. Hingorani,[8] Sandra Iragorri,[18] Myda Khalid,[9] Richard A. Lafayette,[10] Sherene Mason,[11] Rulan S. Parekh,[12] David T. Selewski,[15] Howard Trachtman,[13] Katherine R. Tuttle,[14] Katherine Twombley,[15] Tetyana L. Vasylyeva,[19] Scott E. Wenderfer,[16] Michelle M. O'Shaughnessy.[10] *[1]Stanford Health Care, Redwood City, CA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Helen DeVos Children's Hospital, Grand Rapids, MI; [4]Duke University Medical Center, Durham, NC; [5]University of North Carolina Kidney Center, Chapel Hill, NC; [6]Emory University, Atlanta, GA; [7]Eastern Carolina University, Greenville, NC; [8]Seattle Children's Hospital, Seattle, WA; [9]Indiana University, Indianapolis, IN; [10]Stanford University, Stanford, CA; [11]Connecticut Children's Medical Center, New Haven, CT; [12]The Hospital For Sick Children, Toronto, ON, Canada; [13]NYU Langone Health, New York, NY; [14]University of Washington School of Medicine, Spokane, WA; [15]Medical University of South Carolina, Charleston, SC; [16]Baylor College of Medicine, Houston, TX; [17]LSUHSC, New Orleans, LA; [18]University of Oregon, Portland, OR; [19]Texas Tech Health Sciences Center, Lubbock, TX.*

Background: Race/ethnicity, disease severity/duration, and lower SES have been associated with poorer HRQL in children with glomerular disease; however, the relative importance of these factors has not adequately been explored.

Methods: CureGN is a 70-center cohort study of patients with MCD, FSGS, MN, or IgAN/IgAV. We compared pediatric patient characteristics (demographics, disease duration/severity, medications, SES) at enrolment across racial/ethnic groups. Multivariable logistic and linear regression models, created using best subsets and backwards selection, were used to examine associations between race/ethnicity and HRQL, as measured by missed school days due to kidney disease and baseline PROMIS questionnaire items.

Results: Among 515 White, 146 Black and 74 Hispanic children, Blacks were most likely to have FSGS/MCD and had the lowest eGFR, highest urine protein, lowest serum albumin, and most severe edema. Compared to Whites, Blacks or Hispanics were less likely to have private insurance (59, 35, and 32%, p<0.001), and their parents/guardians were less likely to have completed college (18, 7, and 10% of mothers, and 30, 12, and 12% of fathers, p<0.001). Racial/ethnic differences in HRQL were small (below the Minimally Important Difference of 3) and generally not statistically significant (table). No differences in missed school days due to kidney disease were observed.

Conclusions: Among pediatric CureGN patients, SES varied by minority status such that Black or Hispanic (vs. White) children were less likely to have private insurance and their parents received less formal education. After adjusting for SES and other factors, minority status was not associated with HRQL as measured within this study.

Racial/Ethnic Differences in Socioeconomic Status (SES) and Health-Related Quality of Life (HRQL) Among Adults with Glomerular Disease in Cure Glomerulonephropathy (CureGN)

Jill Krissberg,[1] Margaret Helmuth,[2] Salem Almaani,[3] Bartosz Foroncewicz,[13] Guillermo Hidalgo,[4] Sangeeta R. Hingorani,[5] Michelle A. Hladunewich,[6] Koyal Jain,[7] Jeffrey B. Kopp,[8] Richard A. Lafayette,[9] Barbara Moszczuk,[13] Krzysztof Mucha,[13] Jordan G. Nestor,[10] Rulan S. Parekh,[11] Katherine R. Tuttle,[12] Tetyana L. Vasylyeva,[14] Michelle M. O'Shaughnessy.[9] *[1]Stanford Health Care, Redwood City, CA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]The Ohio State University Wexner Medical Center, Columbus, OH; [4]Eastern Carolina University, Greenville, NC; [5]Seattle Children's Hospital, Seattle, WA; [6]University of Toronto, Toronto, ON, Canada; [7]University of North Carolina Kidney Center, Chapel Hill, NC; [8]NIDDK, NIH, Bethesda, MD; [9]Stanford University, Stanford, CA; [10]Columbia University, New York, NY; [11]The Hospital For Sick Children, Toronto, ON, Canada; [12]University of Washington School of Medicine, Spokane, WA; [13]Medical University of Warsaw, Warsaw, Poland; [14]Texas Tech Health Sciences Center, Lubbock, TX.*

Background: Adults with glomerular disease have poor HRQL. However, the effect of race/ethnicity and SES on HRQL in this population remains largely unknown.

Methods: CureGN is a 70-center cohort study of patients with MCD, FSGS, MN, or IgAN/IgAV. We compared adult patient characteristics (demographics, disease duration/severity, medications, SES) across racial/ethnic groups. Multivariable logistic and linear regression models, created using best subsets and backwards selection, were used to examine associations between race/ethnicity and HRQL, as measured by missed school due to kidney disease and baseline PROMIS questionnaire items.

Results: Among 854 White, 220 Black, and 120 Hispanic adults, Blacks were most likely to have FSGS and had the highest urine protein, lowest serum albumin, and most severe edema. Hispanics were most likely to have IgAN/IgAV and had the lowest eGFR. Compared to Whites, Blacks or Hispanics were less likely to have completed college (48, 27, and 29%, p<0.001) or to have private insurance (76, 65, and 50%, p<0.001), and were more likely to be on medical/disability leave or unemployed (11, 23, and 24%, p<0.001). No racial/ethnic differences in missed work/school were observed. Blacks (but not Hispanics) had significantly worse global physical health, global mental health, and fatigue (table). However, after adjusting for SES and other factors, these differences in HRQL largely disappeared.

Conclusions: Among CureGN participants, Black or Hispanic (vs. White) participants were less likely to have completed college, to have private insurance, or to be employed. However, minority race/ethnicity was not independently associated with HRQL as measured in this study.

A Novel Approach in Differential Diagnosis of Primary Glomerulonephritis Using the Decision Tree Algorithm Model Based on Biomarkers Panel

Elena Saganova, Olga Galkina, Vasiliy Sipovskii, Alexey Smirnov. *Pavlov First Saint-Petersburg State Medical University, Saint-Petersburg, Russian Federation.*

Background: Recent studies showed that measurement of various biomarkers (BM) can be useful in differential diagnosis of some primary glomerulonephritis (GN) forms. Our aim was to develop an algorithm for differential diagnosis of primary GN based on BM panel using decision tree learning approach.

Methods: 74 patients [39 male, age Me (min 18; max 83) – 37,5 (25; 54) years] with biopsy proven primary GN and without AKI, infectious diseases, severe heart failure, respiratory insufficiency, cancer, abnormal thyroid status, treatment with prednisolone more than 10 mg/per day were included in the study. Based on the results of kidney biopsy (KB) in 7% of cases minimal change disease (MCD) was diagnosed, in 27% – FSGS, in 27% – membranous nephropathy (MN), in 39% – IgA-nephropathy. BM were measured in the morning on the day of KB: serum creatinine(sCr), albumin(sAlb), CysC(sCysC), 24-hour total protein(24hTP), urinary (24-hour collection) cystatin C(uCysC), transferrin(uTr), IgG(uIgG), α1-microglobulin(uα1-mg), β2-microglobulin(uβ2-mg), serum/urine magnesium. The Classification and Regression Trees (CART) learning algorithm with FACT-style direct stopping as pruning criteria was used to create a model for differential diagnosis. Complete machine learning, statistical analysis were performed with Statistica v.12.

Results: A decision tree algorithm was developed including ten predictor variables: age, sAlb, uTrans, t24hTP, sCysC, uIgG, uβ2-mg, sCr, uα1-mg, EFMg. This algorithm accurately classified patients with MCD in 100% cases (5 out of 5 cases), FSGS - 80% (16/20 cases), MN - 85% (17/20 cases), IgA-nephropathy - 96,6% (28/29 cases) (Figure 1).

Conclusions: A "decision tree" algorithm based on age and few urinary, serum BM can be a powerful diagnostic tool in differential diagnosis of primary GN. Application of this algorithm allows to evaluate patients with high risk progression of CKD, identify treatment targets before or instead of KB.

APOL1 Risk Alleles in Glomerular Diseases

Candace D. Henderson,[1] Jaeline Anguiano,[1] Dhruti P. Chen,[1] Koyal Jain,[1] Yichun Hu,[2] Susan L. Hogan,[3] Ronald J. Falk.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]UNC Kidney Center & Divisions of Nephrology & Hypertension, Chapel Hill, NC; [3]University of North Carolina, Chapel Hill, NC.*

Background: Impact of *APOL1* variants in glomerular diseases is not well described. In published studies, 0 or 1 risk variant in *APOL1* do not influence progression to end stage renal disease (ESRD), but two risk variants increase risk. We examined *APOL1* variant association with developing ESRD in patients with glomerular disease.

Methods: The Glomerular Disease Collaborative Network (GDCN) is a large registry in southeastern US of patients with glomerular diseases including ANCA vasculitis, membranous glomerulopathy (MN), focal segmental glomerulosclerosis (FSGS), minimal change disease (MCD), and lupus. African-American patients with DNA samples from the GDCN were evaluated. Fisher's exact, Wilcoxon rank, and Kaplan-Meier curves with log rank tests were used to evaluate differences between high risk (2 variants) and low risk (0/1 variant). Proportional hazards models adjusted for age were used to evaluate time to ESRD by high vs. low risk variant with hazards ratios and 95% confidence intervals reported (HR, 95% CI).

Results: Two APOL1 variants were observed in 27% of 252 patients across all diseases except MCD, and most frequently in FSGS (50/93=54%), Table. Those with high risk variant were 1.9 times more likely to progress to ESRD (95% CI 1.2-3.0). In FSGS, high and low risk variants progressed similarly to ESRD (HR 1.0, 95% CI 0.5-1.7), but in other glomerular diseases those with the high risk variant were 2.5 times more likely to progress to ESRD (95% CI 1.2-5.1), Figure.

Conclusions: High-risk variants were present in most glomerular diseases studied, and common in FSGS. However, impact on progression to ESRD was not evident in FSGS, but influential in other glomerular diseases.

Characteristic, n (%) unless otherwise noted	Low Risk n=183	High Risk n=69	p-value
Disease Type:			
Focal segmental glomerulosclerosis (FSGS)	43 (23%)	50 (72%)	
ANCA vasculitis	57 (31%)	8 (12%)	
Lupus nephritis	52 (28%)	6 (9%)	
Minimal change disease	9 (5%)	0 (0%)	
Membranous nephropathy	22 (12%)	5 (7%)	
Age at disease onset(yrs), Median(IQR)	31 (17, 53)	28 (17, 40)	0.12
Male	38%	38%	0.99
Progressed to ESRD	27%	45%	0.01

Functional Subclasses of Nephrotic Syndrome Identified Using Consensus Non-Negative Matrix Factorization Clustering of Kidney Tubulointerstitial Tissue Transcriptome

Habib Hamidi,[1] Sean Eddy,[1] Matthias Kretzler,[1] John R. Sedor,[2] John F. O'Toole,[2] Lawrence B. Holzman,[3] Laura H. Mariani.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Cleveland Clinic, Cleveland, OH; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Interstitial fibrosis and tubular atrophy are common patterns of injury in glomerular diseases, but it is unknown whether multiple mechanisms can result in this pattern of injury and if mechanisms change as disease progresses. Consensus non-negative matrix factorization (NMF) is a clustering approach used with tumor specimen transcriptomics to identify functionally relevant subtypes.

Methods: NMF clustering was applied to tubular mRNA expression from kidney biopsies from the NEPTUNE cohort, a prospective cohort of children and adults with nephrotic syndrome enrolled at the time of clinically indicated kidney biopsy. Individual gene expression levels from the tubular compartment were normalized to mean expression to maximize individual patient differences. Cox proportional hazards models were fit for complete proteinuria remission (CR, UPCR <0.3 mg/mg) and ESRD/40% eGFR decline. Significance analysis of microarray identified cluster specific differentially expressed genes that were used in pathway enrichment analysis to determine functional relevance.

Results: NMF separated 188 patients into 4 clusters which did not differ age (p 0.46), sex (p 0.77) or UPCR (p 0.46). The clusters did not segregate by disease etiology (Fig). Cluster 2 had lower mean eGFR (56 mL/min vs 83, 66 and 66; p <0.01) and greater UPCR (5.1 vs 2.8, 2.1,4.0; p <0.01), black race (39.5% vs 25%, 12%, 6%, p <0.01). In unadjusted models, cluster 2 had less CR (HR 0.65, p-value 0.14) and greatest loss of eGFR (HR 2.8, p-value <0.01). Pathway enrichment of cluster-specific genes demonstrated unique processes (Fig).

Conclusions: NMF identified functional subclasses in the tubular kidney tissue mRNA of patients with nephrotic syndrome which crossed traditional diagnostic classifications of FSGS, MCD and MN. Functional analysis revealed both shared and specific pathways associated with the clusters which could help to identify therapeutic targets.

Elevated Plasma Free Sialic Acid Levels in Individuals with Reduced Glomerular Filtration Rates

Federico Fuentes,[2] Marjan Huizing,[1] Jodi Blake,[2] William Gahl,[1] Nuria Carrillo,[1] Jeffrey B. Kopp.[2] *[1]National Institutes of Health/National Human Genome Research Institute, Bethesda, MD; [2]NIDDK, NIH, Bethesda, MD.*

Background: Sialic acid (SA) is a negatively charged, terminal monosaccharide present on glycoconjugates. They are important contributors to the polyanionic component of the glomerular filtration barrier, which regulates permeability selectivity. Free SA is filtered but not reabsorbed by the human kidney, in contrast to other sugars known to be reabsorbed by tubular cells. We determined plasma free SA levels of subjects with proteinuric diseases and diverse levels of estimated glomerular filtration rate (eGFR) to assess a correlation and emphasize this understudied feature of SA.

Methods: Free SA (Neu5Ac) was determined in plasma samples from 16 proteinuric subjects and 22 individuals with normal renal function with a validated LC-MSMS assay.

Results: There was a strong inverse relationship between eGFR and plasma SA levels (R^2 =0.70, p <0.0001). Plasma SA levels ranged between 114-206 ng/mL in subjects with normal eGFR (>90mL/min/1.73 m^2). While in subjects with decreased eGFR (<30 mL/min/1.73 m^2), plasma SA levels were at least three-fold higher (431-1260 ng/mL range).

Conclusions: It is important to emphasize the often-overlooked feature of renal handling of free SA. If increased plasma SA levels are encountered in subjects, compromised renal function/decreased eGFR should be considered. Of note is that pathologic hyposialylation of glomerular glycoconjugates, associated with podocyte effacement, has recently been implicated in human glomerulopathies. The relation between plasma free SA levels and glomerular hyposialylation remains to be investigated.

TH-PO1044

Urinary Podocalyxin Protein Excretion Is an Early Biomarker in Age-Associated Kidney Disease

Akihiro Fukuda,[1] Akiko Kudo,[1] Miho Suzuki,[1] Kohei Aoki,[1] Takeshi Nakata,[1] Hiroyuki Kurosawa,[3] Masanori Hara,[4] Naoya Fukunaga,[1] Hirotaka Shibata.[2] *[1]Oita University, Yufu, Japan; [2]Oita University Faculty of Medicine, Yufu city, Japan; [3]Denka Seiken Co., Ltd, Gosen, Japan; [4]Niigata Wellness (Iwamuro Health Promotion Center), Niigata, Japan.*

Background: Aging is the strongest known risk factor for end-stage kidney disease. Many factors including aging can cause podocyte injury. If the initiating injury causes a critical level of podocyte depletion, it can lead to glomerulosclerosis and progression. Age-associated reduction in podocyte density (increased glomerular volume per podocyte) is associated with podocyte hypertrophic stress and failure that leads to glomerulosclerosis in model systems and humans. Urinary podocyte excretion can be used to monitor glomerular disease activity and progression. This study investigated whether urinary podocyte protein excretion can be used for monitoring age-associated kidney diseases.

Methods: From June 2018 to March 2019, spot urine samples were collected from 261 healthy volunteers without diabetes, hypertension and albuminuria during medical checkups by age groups (20–29 years: n=48; 30–39 years: n=53; 40–49 years: n=59; 50–59 years: n=52; ≥60 years: n=49) We investigated the urinary supernatant (U-PCX) and sediment (Sed-PCX) podocalyxin protein levels by ELISA to reflect podocyte injury and podocyte detachment, respectively, and urinary albumin/creatinine ratio (U-ACR).

Results: There were no significantly differences in systolic blood pressure, fasting blood glucose, and body mass index among the groups. However, estimated glomerular filtration rate significantly decreased with age (20–29 years: 94±14.5 ml/min/1.73 m^2 vs ≥60 years: 74.5±14.1 ml/min/1.73 m^2, p<0.01)). U-PCX was significantly increased in the ≥60 years group (20–29 years: 94.4±57 vs. ≥60 years: 124.1±63.1 μg/g Cre, p<0.01). U-ACR was also significantly increased in the ≥60 years group (20–29 years: 5.2±4.2 vs. ≥60 years: 8.0±5.6 mg/gCre, p<0.01), but the levels were far lower than the microalbuminuria level. Meanwhile, Sed-PCX did not differ among the groups.

Conclusions: U-PCX, but not sed-PCX, was significantly increased the ≥60 years group without hypertension, diabetes, and microalbuminuria compared with other groups. These results suggest that age *per se* is a risk factor for podocyte injury and that U-PCX can be used for as an early (prior to overt albuminuria and podocyte detachment) biomarker in age-associated kidney disease.

Exosomal Micro RNA as a Diagnostic Tool in Kidney Biopsy Cohort

Teruhiko Yoshida,[1,2] Yoshifumi Hamasaki,[2] Yoshihisa Miyamoto,[3] Yohei Komaru,[3] Kent Doi,[2] Jeffrey B. Kopp,[1] Masaomi Nangaku.[4] *[1]NIDDK, National Institutes of Health, Bethesda, MD; [2]University of Tokyo, Tokyo, Japan; [3]the University of Tokyo Hospital, Tokyo, Japan; [4]the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Despite recent advances, clinical renal diagnosis requires pathological examination of a kidney biopsy. Micro RNAs (miRNAs) in exosomes are promising biomarkers for kidney disease diagnosis and management. We sought to identify diagnostic miRNAs in exosomes from blood and urine obtained from subjects with diabetic nephropathy.

Methods: We performed a prospective single-center cohort study, enrolling patients who underwent kidney biopsy at the University of Tokyo Hospital. Blood and urine samples and clinical parameters were obtained at the time of the kidney biopsy. Exosomes were isolated from blood and urine by ultracentrifugation and RNA was extracted. We selected candidate miRNAs by TaqMan array card and measured expression by quantitative PCR. The outcome variable was standardized pathological diagnosis. We confirmed the principal findings by experiments in streptozotocin (STZ)-induced diabetic mice.

Results: The study population consisted of 102 patients who underwent kidney biopsy, including 8 with diabetic nephropathy and 23 with diabetes who had other kidney diseases. For the diagnosis of diabetic nephropathy, a clinical model (diabetic history, retinopathy and hematuria) had moderate accuracy, with AUC [95% CI] 0.65 [0.44-0.81]. Urinary exosomal miR-486 added significant accuracy when combined with the clinical model, showing AUC 0.92 [0.76-0.98] (p=0.003). In STZ diabetic mice, miR-486 expression was reduced by 94% in urinary exosomes (p=0.003) and by 40% in laser capture micro-dissected glomeruli (p=0.02) compared with non-diabetic mice.

Conclusions: Levels of miRNAs in urinary exosomes correlated with the histological diagnosis of diabetic nephropathy and may be a promising non-invasive diagnostic tool.

Differences in Disease Activity by Sex and Pubertal/Menopausal Status in Primary Glomerulonephropathies

Andrea L. Oliverio,[1] Sarah Mansfield,[2] Salem Almaani,[5] Isabelle Ayoub,[5] Kira Clark,[3] Hilda E. Fernandez,[10] Pascale Khairallah,[11] Michelle M. O'Shaughnessy,[6] Monica L. Reynolds,[4] Katherine Twombley,[7] Shikha Wadhwani,[8] Tetyana L. Vasylyeva,[12] Jarcy Zee,[2] Michelle A. Hladunewich,[9] Laura H. Mariani.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Oregon Health and Science University, Portland, OR; [4]University of North Carolina at Chapel Hill, Cary, NC; [5]The Ohio State University Wexner Medical Center, Columbus, OH; [6]Stanford University, Palo Alto, CA; [7]Medical University of South Carolina, Charleston, SC; [8]Northwestern University Feinberg School of Medicine, Chicago, IL; [9]University of Toronto, Toronto, ON, Canada; [10]NYP-CUMC, New York, NY; [11]Columbia University Medical Center, New York, NY; [12]Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: CKD has been observed to progress more slowly in women than men. However, large studies examining associations between sex, reproductive stage, and disease activity and progression in primary glomerulonephropathies are lacking.

Methods: CureGN is a 70-site prospective cohort study of patients with MCD, FSGS, IgAN/IgAV, or MN. Patients with available eGFR, UPCR, and reproductive stage at enrollment were studied. Reproductive stage was categorized as pre-pubertal (Tanner stage I-III), post-pubertal (Tanner stage IV-V, or menarche for females), or post-menopausal (females only). Multivariable mixed linear models adjusted for baseline data at time of enrollment (Table) were fit to examine change in eGFR and UPCR over time.

Results: Median follow-up from enrollment was 2.1 (IQR 1.0-3.1) yrs. Among 1202 patients with available enrollment eGFR, adjusted (Model 3) eGFR slopes amongst females were +0.71, -0.84, and -1.43 ml/min/1.73m2 per year for pre-pubertal, post-pubertal, and post-menopausal women, respectively (Table). For pre-pubertal and post-pubertal males, eGFR slopes were -1.14 and -1.19 ml/min/1.73m2 per year, respectively. Adjusted UPCR slopes by sex and reproductive stage are also shown in the Table.

Conclusions: The protective effect of female sex on eGFR decline was most notable prior to puberty. Of all groups, post-menopausal women had the fastest eGFR decline. Unlike post-pubertal males and females, pre-pubertal participants experienced no significant decrease in UPCR over time, and menopausal status did not seem to impact the rate of UPCR decline seen in post-pubertal females.

Development of a Clinician-Reported Outcome Measure for Edema Assessment

Noelle E. Carlozzi,[1] Howard Trachtman,[2] Liron Walsh,[3] Chris Lynam,[3] Debbie S. Gipson.[4] *[1]University of Michigan, Ann Arbor, MI; [2]NYU Langone Health, New York, NY; [3]Goldfinch Bio, Boston, MA; [4]University of Michigan Mott Children's Hospital, Ann Arbor, MI.*

Background: Patients report edema is a high impact manifestation of proteinuric kidney disease. However, evaluation of edema is not standardized and can manifest as localized or generalized swelling. Accurate and valid assessment of edema is important for patient care and clinical trials of patients with proteinuric kidney disease. The objective of this study was to develop a clinician reported outcome measure (ClinRO) for edema assessment for use with patients with glomerular disease.

Methods: Semi-structured interviews were conducted with pediatric and internal medicine nephrology clinicians (physicians and advanced practice providers) to elicit physical exam findings of edema manifestations, documentation, and importance. Concepts were derived from these interviews, confirmed with clinicians and then used to create the Edema ClinRo.

Results: 14 clinicians participated in the study, including 7 pediatric and 7 internal medicine experts. Concepts identified included assessment of body regions (periorbital, extremities, trunk and if patient endorsed genitals) and severity rating. The ClinRO was generated (**Figure**) in an iterative fashion with input from clinician stakeholders. Online training and certification modules were developed for use and a user acceptance testing step was implemented

Conclusions: The Edema ClinRO was developed based upon pediatric and internal medicine clinician input using best practice methods to support implementation of standardized edema assessment in clinical and research contexts. User acceptance testing of the ClinRO has been completed and for the training module is underway. With web-based Edema ClinRo dissemination and data collection, the utility of this measure will be assessed as a future step.

Nephrotic Syndrome Edema – Clinician Rating Scale

INSTRUCTIONS: This scale is designed to assess edema that is specific to nephrotic syndrome. Ratings should be based on the clinician's impression using all available information, including the clinical exam and information provided by the patient when available. Circle the numerical value associated with your rating for each area of the body.

Periorbital	0	Absent	No obvious swelling
	1	Mild/Moderate	Area around eyes is visibly swollen (without impairment of vision or blinking)
	2	Severe	Swelling is very obvious and interferes with blinking or with opening of eyes
Arms	0	Absent	No obvious swelling
	1	Mild/Moderate	Mild swelling is visible
	2	Severe	Endorse if any of the following: pitting, arms seem grossly swollen or distorted
Hands	0	Absent	No obvious swelling
	1	Mild/Moderate	Mild swelling is visible
	2	Severe	Pitting on dorsal part of hand or swelling that impairs flexion in fingers
Sacral	0	Absent	No indent made by pressing
	1	Mild/Moderate	Slight indent OR moderate indent (pitting is present and ≤4mm deep)
	2	Severe	Large indent (pitting is severe and >4mm deep)
Abdomen	0	Absent	No obvious swelling
	1	Mild/Moderate	Fluid wave is present but not tense
	2	Severe	Tense ascites or pitting edema present
	99	Unable to assess	Circle a reason: Obesity Other:
Genitals *"Only examine if endorsed by patient"	0	Absent	No patient-endorsement
	1	Mild/Moderate	Swelling is visible, but no obvious difficulty with mobility
	2	Severe	Swelling visibly impedes mobility
Thigh *"Only examine if endorsed by patient"	0	Absent	No patient-endorsement
	1	Mild/Moderate	Slight OR moderate indent (pitting is present and ≤4 mm deep)
	2	Severe	Large indent (pitting is severe and >4 mm deep)
Lower leg	0	Absent	No indent made by pressing
	1	Mild/Moderate	Slight indent OR moderate indent (pitting is present and ≤4mm deep)
	2	Severe	Large indent (pitting is severe and >4mm deep)
Ankle or foot	0	Absent	No indent made by pressing
	1	Mild/Moderate	Slight indent OR moderate indent (pitting is present and ≤4mm deep)
	2	Severe	Large indent (pitting is severe and >4mm deep)

Can Estimated Glomerular Filtration Rate (eGFR) Slope Be a Good Outcome Measure for Glomerular Disease?

Brenda W. Gillespie,[1] Abigail R. Smith,[2] Jarcy Zee,[2] Debbie S. Gipson,[3] Sarah Mansfield,[2] Laura H. Mariani,[1] Margaret Helmuth,[2] Bruce M. Robinson.[2]
[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Michigan Mott Children's Hospital, Ann Arbor, MI.

Background: Unlike chronic kidney disease (CKD), where trajectories of eGFR over time are commonly linear, trajectories in glomerulonephropathy (GN) are often variable, with excursions into high eGFR (hyperfiltration), acute kidney injury (AKI) and sudden drops to kidney failure. This makes the use of eGFR slope, a statistically powerful progression outcome, challenging in this population. Our objective was to assess the prevalence of nonlinear features and propose adjustments to facilitate use of eGFR slope as an outcome measure.

Methods: Using data from CureGN, patients with at least one year of follow-up, at least 5 eGFR measurements, and a diagnosis of Minimal Change Disease (MCD) were included. Analysis was restricted to MCD due to high prevalence of high eGFR (>120 mL/min/1.73 m²). Linear regression models were fitted to each participant's data with and without winsorizing (capping) eGFR values at 120 mL/min/1.73m² with the rationale that values above 120 represented high filtration rates but not clinically improved eGFR. Trajectories were deemed linear if root mean squared error (RMSE) was ≤20; we examined individual nonlinear trajectories to assess deviation from linearity.

Results: 74 adult (mean±SD age = 43.2±19.1, range 18-82) and 116 pediatric (mean±SD age = 7.7±3.6, range 2-16) participants were included. At least one eGFR>120 was present in 22% of adults and 83% of children. Linear fits were improved after winsorizing: 76% (95% adult, 64% pediatric) had good fits prior to, and 96% (96% adult, 96% pediatric) had good fits after winsorizing. Based on visual assessment of trajectories, most cases with nonlinear fits had apparent AKI, and a few had sudden kidney failure. In AKI, allowing the fit to include outlying point(s) provided a reasonable overall slope estimate. In kidney failure, the linear fits did not follow each curve but often captured the overall trend very well (Figure).

Conclusions: Linear models of eGFR have previously been used in analyses of CKD data; the added features of winsorizing and data examination will enhance their use for GN patients with MCD.

TH-PO1049

Time-Updated Systolic Blood Pressure and Progression of CKD in Patients with Glomerulonephritis

Hyung Woo Kim,[1] Seonghun Kim,[2] Boyoung Nam,[2] Jimin Park,[2] Jung Tak Park,[1] Seung Hyeok Han,[1] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1]
[1]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea.

Background: Many guidelines on optimal target of blood pressure in chronic kidney disease are largely based on studies in diabetic and hypertensive patients. However, there is lack of evidence that this blood pressure goal can also be applied to patients with glomerular diseases. The aim of this study was to clarify the longitudinal association between blood pressure and CKD progression in patients with glomerulonephritis.

Methods: We studied 1,016 biopsy-proven patients who were diagnosed with primary glomerular diseases such as IgA nephropathy (n=756 [74.4%]), membranous glomerulonephritis (n=144 [14.2%]), and focal segmental glomerulosclerosis (n=116 [11.4%]) from 2005 to 2017. The main exposure of interest was baseline and time-updated systolic blood pressure (SBP). The primary outcome was a composite of a ≥50% decrease in eGFR from baseline or end-stage kidney disease. We used time-varying cox model and marginal structural model for time-updated SBP.

Results: During 1,607 person-years follow up, the primary outcome occurred in 658 (64.8%) patients. The mean age was 43.6±14.7 years and baseline eGFR was 90.4±28.0 ml/min/1.73 m². 665 (65.5%) patients had the history of previous hypertension. Using time-varying cox model, compared with SBP of 120 to 129 mmHg, the hazard ratios for the primary outcome were 1.01 (95% CI, 0.84 to 1.22), 1.11 (95% CI, 0.88 to 1.40), 1.36 (95% CI, 1.04 to 1.78), respectively. The marginal structural model also showed consistent results. The corresponding HRs for the noted SBP categories were 1.04 (95% CI, 0.87 to 1.24; *p*=0.68), 1.14 (95% CI, 0.92 to 1.41; *p*=0.24), 1.43 (95% CI, 1.08 to 1.89 *p*=0.01), respectively. This association was consistent regardless of subgroups by age (<60 vs. ≥60), gender, previous hypertension, baseline eGFR (≥45 vs. <45), and proteinuria (<1g vs. ≥1g).

Conclusions: Among patients with glomerular diseases, SBP >140 mmHg was significantly associated with higher risk of CKD progression.

TH-PO1050

Identifying Outcomes Important to Patients with Glomerular Disease and Their Caregivers: A Multinational Nominal Group Technique Study

Simon A. Carter,[1] Talia M. Gutman,[1] Charlotte Logeman,[1] Yeoung Jee Cho,[2] Jessica Ryan,[3] Jenny I. Shen,[4] Andrea K. Viecelli,[5] Angela Yee Moon Wang,[6] Martin E. Wilkie,[7] Jonathan C. Craig,[8] Allison Tong.[9] SONG-GD Investigators
[1]Centre for Kidney Research, Sydney, NSW, Australia; [2]Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [3]Monash Health, Clayton, VIC, Australia; [4]LaBiomed at Harbor-UCLA, Torrance, CA; [5]Princess Alexandra Hospital, Brisbane, QLD, Australia; [6]University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [7]Sheffield Teaching Hospitals, Sheffield, United Kingdom; [8]Flinders University, Adelaide, SA, Australia; [9]The University of Sydney, Seven Hills, NSW, Australia.

Background: Outcomes that are important to patients with glomerular disease remain uncertain and therefore shared-decision making can be challenging. We aimed to identify and prioritize outcomes important to patients and their caregivers, and the reasons for their choices.

Methods: We purposively sampled patients aged ≥18 years with glomerular disease and their caregivers from Australia, Hong Kong, United Kingdom and United States. Participants identified, ranked and discussed outcomes. Each outcome was ranked using a relative importance score between 0 and 1. Qualitative data were analyzed thematically.

Results: Across 16 focus groups, 132 participants (100 patients, 32 caregivers) identified 58 outcomes. Patients were aged 19 to 85 years (mean 51 years), 47 (47%) were female and 29 (29%) were on dialysis or had received a kidney transplant. Thirty eight (38%) had kidney-limited glomerular disease, 31 (31%) had glomerular disease with systemic features, and 31 (31%) had other or unknown subtypes. The ten highest ranked outcomes were: kidney function (importance score 0.42), mortality (0.29), need for dialysis or transplant (0.22), life participation (0.18), fatigue (0.17), anxiety (0.13), impact on family (0.12), infection and immunity (0.12), ability to work (0.11) and blood pressure (0.11; Figure 1). The top five outcomes were identical for patients and caregivers. The top three outcomes were the same across disease subtypes. Three themes explained the reasons for these rankings: constraining day-to-day experience, impaired agency and control over health, and threats to future health and family.

Conclusions: Patients with glomerular disease and their caregivers highly prioritize kidney health and survival, as well as life participation, fatigue, anxiety and the impact on family. Consistent reporting of these outcomes in trials may improve shared decision-making.

Mood, Anxiety, and Hyperactivity Disorders in Patients with Glomerular Disease

Hailey Desmond,[1] Anne Waldo,[1] Andi J. Callaway,[11] Patrick E. Gipson,[1] Gia J. Oh,[2] Michelle M. O'Shaughnessy,[3] Meg Modes,[4] Matthew Elliott,[5] Sharon G. Adler,[6] Anne Pesenson,[7] David T. Selewski,[9] Noelle E. Carlozzi,[1] Elaine S. Kamil,[10] Debbie S. Gipson,[1] Susan F. Massengill.[8] *[1]University of Michigan, Ann Arbor, MI; [2]Randall Children's at Legacy Emanuel, Portland, OR; [3]Stanford University, Palo Alto, CA; [4]Patient Advocate, Livonia, MI; [5]Metrolina Nephrology Associates, Charlotte, NC; [6]Harbor-UCLA Medical Center, Torrance, CA; [7]The Polyclinic, Seattle, WA; [8]Levine Children's Hospital, Charlotte, NC; [9]Medical University of South Carolina, Charleston, SC; [10]Cedars-Sinai Medical Center, Los Angeles, CA; [11]The Nephrotic Syndrome Foundation, Alamo, CA.*

Background: Patients with chronic health conditions are at heightened risk for psychiatric disorders; yet in glomerular disease (GD) little is known about the prevalence of mood, anxiety, and hyperactivity disorders or associations with patient and disease characteristics.

Methods: This study included patients with GD enrolled in the Kidney Research Network multisite patient registry. Encounter, diagnosis, medication, lab, and vital sign data are extracted monthly from participants' electronic health records. ICD9/10 diagnosis codes were used to identify psychiatric disorders, including anxiety and depressive disorders and attention deficit disorder (ADD). Longitudinal GEE models were used to analyze the odds of being diagnosed with a psychiatric disorder. Potential covariates in the models included age at kidney disease onset, sex, race, ethnicity, and time-varying treatment, eGFR and urine protein:creatinine ratio (UP:C). Continuous variables are presented as median (IQR).

Results: Data were available for 938 patients with a 51 (IQR: 25-92) month follow up and kidney disease onset age of 19 (IQR: 5-41) yrs. 202 (21.5%) were diagnosed with a psychiatric disorder at a rate of 4.3 per 100 pt-yrs, with 78 of those having two or more disorders. The most common disorders were anxiety (n=145, 3.1 per 100 pt-yrs), depression (n=101, 2.1 per 100 pt-yrs), and ADD (n=29, 0.6 per 100 pt-yrs). Adolescents vs adults (OR: 2.4, 95% CI: 1.5-4.0), white vs Asian race (OR: 2.7, 95% CI: 1.3-5.6), steroid treatment (OR: 2.5, 95% CI: 1.4-3.8) and higher UP:C (OR per log: 1.2, 95% CI: 1.0-1.3) were significantly associated with psychiatric disorder diagnosis.

Conclusions: Select psychiatric disorders were documented in approximately one quarter of patients with GD and were associated with adolescence (vs adulthood), steroid therapy, higher proteinuria, and white (vs Asian) race. This may be an underrepresentation as data is based on what was documented in participants' electronic health record. A difference in prevalence by race may suggest a difference in assessment and diagnosis rather than true difference in prevalence. These findings suggest mental health screening may be warranted in patients with GD.

Nephrotic Syndrome Acquired Hypercoagulopathy Is Strongly Associated with Proteinuria and Hyperlipidemia

Bryce A. Kerlin,[1] Amanda P. Waller,[1] Jonathan P. Troost,[2] Samir V. Parikh,[3] William E. Smoyer,[4] Matthias Kretzler.[5] *[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]University of Michigan, Ann Arbor, MI; [3]Ohio State University Medical Center, Columbus, OH; [4]Nationwide Children's Hospital, Columbus, OH; [5]U.Michigan, Ann Arbor, MI.*

Background: Nephrotic syndrome (NS) is complicated by hypercoagulopathy and predilection for venous thromboembolism (VTE). Routine anticoagulant prophylaxis is controversial. Thrombin generation assay (TGA), a measure of hypercoagulopathy, has known predictive value for VTE in non-NS patients. We have shown that TGA is directly proportional to NS severity in animal NS. We sought to determine if TGA is correlated with human NS severity.

Methods: NEPTUNE biorepository plasma aliquots (*N*=150) were obtained (excluding patients on anticoagulants or with prior VTE) along with phenotypic data. TGA was performed and endogenous thrombin potential (ETP) calculated as the area under the thrombin activity curve. Plasma albumin levels were also determined.

Results: TGA was undetectable in 3 (2%) of the NEPTUNE samples (excluded). Univariate linear regression on the remaining 147 samples revealed significant relationships with: Age (*B*=-16), Proteinuria (log-UP:C; *B*=265), Plasma Albumin (*B*=-657), Total Cholesterol (*B*=2,129), eGFR (*B*=10), and Steroid (*B*=853) or RAAS-blockade (*B*=-573) treatment. Histologic NS classification was not significantly associated with ETP. Multivariable modeling revealed an interaction between remission status and proteinuria, such that UP:C was independently predictive of ETP in patients with active disease (*B*=828; *P*<0.0001; Figure). Age (*B*=-15; *P*=0.005) and Total Cholesterol (*B*=1,448; *P*=0.0001) were also independently predictive. The final multivariable model was highly correlated with ETP (R^2=0.35). Similar NS-severity univariate relationships were demonstrated in our local cohort.

Conclusions: Proteinuria and hyperlipidemia were associated with ETP. These data suggest that analysis of these NS severity markers and ETP in relation to thrombotic events in patients with NS may inform their utility as a future guide to anticoagulant prophylaxis.

Anticoagulation and Anti-Platelet Prescribing in Glomerular Disease: An Observational Study

Joseph Doan,[1] Elaine S. Kamil,[9] Janine R. Vintch,[2] Debbie S. Gipson,[3] Tiane Dai,[1] Matthew Elliott,[4] Lili Tong,[5] Michelle M. O'Shaughnessy,[6] Janine A. La page,[7] Susan F. Massengill,[8] Liz Y. Chen,[11] Patrick E. Gipson,[10] Sharon G. Adler.[2] *[1]Nephrology, Harbor UCLA, Torrance, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [4]Metrolina Nephrology Associates, Charlotte, NC; [5]LABiomedical Research Institute at Harbor-UCLA, Torrance, CA; [6]Stanford University, Palo Alto, CA; [7]Los Angeles Biomedical Research Institute, Torrance, CA; [8]Levine Children's Hospital, Charlotte, NC; [9]Pediatric Nephrology, Cedar-Sinai Medical Center, Los Angeles, CA; [10]University of Michigan, Ann Arbor, MI; [11]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA.*

Background: Nephrotic syndrome confers thromboembolism (TE) risk. We report frequencies of TE and anticoagulation (AC) and antiplatelet (AP) prescribing in patients with/without nephrotic-range proteinuria enrolled in Nephcure Kidney Research Network (KRN) Registry.

Methods: Patients with glomerular disease (GD) from all KRN sites were included. Encounter, diagnosis, meds, lab, and vital sign data were extracted monthly from patients' EMRs. Patients were grouped into those with at least one UPCR ≥3.5 g/g (Nephrotic) vs those with UPCR always <3.5 g/g (Non-nephrotic). TE and AC/AP prescription (Rx) frequencies were determined. Follow-up was censored at ESRD.

Results: Nephrotic (n=568) and Non-nephrotic (n=404) groups were similar in age/sex. Mean eGFR (93 vs. 70 ml/min/1.73m2, p<.001) and UPCR (4.9 vs. 0.7 g/g, p<.001) were higher, and serum albumin lower (3.1 vs. 3.9 g/dL, p<.001) in Nephrotics vs. Non-nephrotics. Nephrotics and Non-nephrotics had: FSGS/C1Q (59% vs 41%); Minimal change/IgM/MesPGN (77% vs 23%); Membranous (79% vs 21%), IgA (28% vs 7%), or other GD (54% vs 46%). 90 Nephrotics and 52 Non-nephrotics had no biopsy (mostly children). Median follow-up for Nephrotics (57 mos) was longer than Non-nephrotics (49) (p<.001). There were 70 TE: 9.2% of Nephrotics (n=52) vs 4.5% of Non-nephrotics (n=18) (p<.005). AC/AP Rxs were more frequent in Nephrotics (203 of 568, 36%) than Non-nephrotics (67 of 404, 17%)(p<.0001). The 203 Nephrotics had AC/AP Rx as follows: heparin, enoxaparin, fondaparinux (64%); aspirin (58%); warfarin (11%); alteplase, urokinase (9%); Factor Xa inhibitors (Xai, 5%); and/or clopidogrel, ticagrelor (4%). Non-nephrotics (n=67) had heparin, enoxaparin, fondaparinux (46%, p<.0001 vs Nephrotics); aspirin (61%); warfarin (12%); alteplase, urokinase (9%); Xai (6%); and/or clopdiogrel, prasugrel, dipyriadamole (9%).

Conclusions: In KRN, TE and AC/AP prescriptions were twice as frequent in Nephrotics than Non-nephrotics. Heparin/congeners were prescribed 6 times more often than warfarin in Nephrotics; 3 times more often in Non-nephrotics. Aspirin was prescribed frequently and Xai infrequently in both groups. These variable practices suggest a need for further exploration of AC/AP indications/efficacy/ safety in GD patients.

TH-PO1054

Patterns and Trends of Infection Among Hospitalized Patients with Different Types of Chronic Glomerulonephritis: A Retrospective Study Spanning 18 Years from a Single Tertiary Hospital

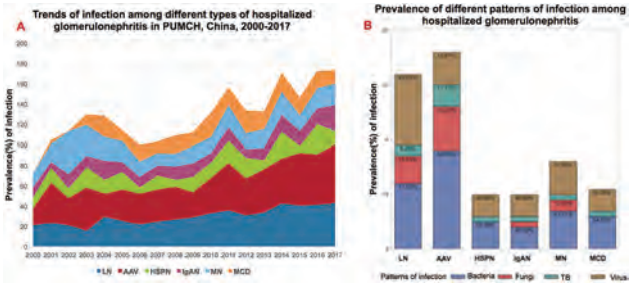
Xiaohong Fan, Hang Li, Xuemei Li, Xuewang Li, Jianfang Cai. *Division of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China*.

Background: It remains unclear whether the patterns and trends of infection are differentials among different types of glomerulonephritis.

Methods: We conducted a retrospective analysis using the database of hospitalization with chronic glomerulonephritis in Peking Union Medical College Hospital (PUMCH), China from 2000 through 2017. The tenth revision from the International Classification of Diseases (ICD-10) codes of discharge diagnosis was used to identify infectious diseases and 6 kinds of glomerulonephritis including lupus nephritis (LN), systemic vasculitis (AAV), Henoch-Schönlein purpura nephritis (HSPN), IgA nephritis (IgAN), idiopathic membrane nephropathy(MN), and minimal change disease(MCD). Cochran-Armitage trend test and Logistic regression were used for analysis.

Results: Between 2000 and 2017, there were 15,714 hospitalizations with aforementioned chronic glomerulonephritis. Their mean age was 51.7±19.8 years and 39.4% were males. The annual prevalence of overall infection increased steadily from 14.7% in 2000 to 33.0% in 2017 among all (p for trend <0.001). We found significant increasing trends of overall infection in LN, AAV, HSPN, IgAN, and MCD, but not in MN **[**Figure A]. Hospitalized patients with LN, AAV, and MN were more likely to have **the** infection as compared with those with IgAN (OR: 3.53, 95%CI 3.14-3.95, 3.92, 95%CI 3.30-4.64, and 1.36, 95%CI 1.17-1.57, respectively) after adjustment for age, gender, hypertension, and diabetes. The bacteria and virus infections were the top two infectious diseases, patients with LN, AAV, and MN also had **a** higher proportion of fungi infection **[**Figure B].

Conclusions: There had been an increasing trend of infection in hospitalized patients with chronic glomerulonephritis except for those with idiopathic membrane nephropathy. Prevalence of infection and infection patterns varied among hospitalized patients with different glomerulonephritis.



TH-PO1055

Trends of Infection Among Hospitalized Patients with Chronic Glomerulonephritis: A Retrospective Study Spanning 18 Years from a Single Tertiary Hospital

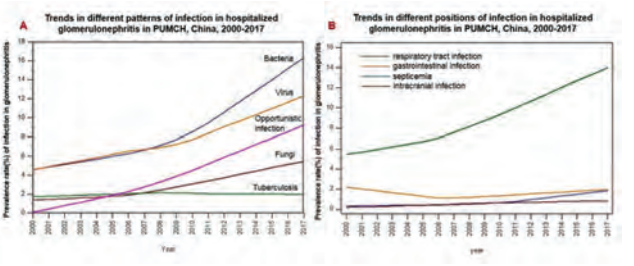
Xiaohong Fan, Hang Li, Xuemei Li, Xuewang Li, Jianfang Cai. *Division of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China*.

Background: Infection is one of the most important complications in patients with chronic glomerulonephritis. It confers an additional risk of death. However, its trends over the years in patients with chronic glomerulonephritis have seldom been demonstrated.

Methods: We conducted a retrospective analysis using the database of hospitalization to estimate current trends in different infectious diseases among hospitalized patients with chronic glomerulonephritis in Peking Union Medical College Hospital, China from 2000 through 2017. The tenth revision from the International Classification of Diseases (ICD-10) codes of discharge diagnosis was used to identify infectious diseases and different kinds of glomerulonephritis. The diagnosis of glomerulonephritis was further validated by data from our renal pathology reporting system. Cochran-Armitage trend test was used for analysis.

Results: Between 2000 and 2017, there were 18,307 hospitalizations with glomerulonephritis. Their mean age at admission was 51.7±19.8 years and 52.8% were males. The overall prevalence of infection among patients with chronic glomerulonephritis was 21.2%. The annual prevalence of overall infection increased from 14.9% in 2000 to 32.0% in 2017 (p for trend <0.001). The annual prevalence of bacteria, virus, and fungi infection, and opportunistic infection increased from 2000 to 2017, however, that of tuberculosis remained stable [figure A]. Over the years, the prevalence of respiratory tract infection, septicemia, and intracranial infection increased steadily(p for trend <0.001),in contrast, that of gastrointestinal infection stayed unchanged(p=0.49) [figure B].

Conclusions: There had been an increasing prevalence of infection was increasing in patients with chronic glomerulonephritis over the years fro 2000 to 2017, except that of tuberculosis and gastrointestinal infection.



TH-PO1056

Cancer Development and Mortality Differences in Patients with Glomerulonephritis After Renal Biopsy

Hyunjin Ryu,[1] Ji Young Ryu,[2] Kipyo Kim,[2] Sejoong Kim,[2] Ki Young Na,[2] Dong-Wan Chae,[2] Ho Jun Chin.[2] Korean GlomeruloNephritis Study Group *[1]Seoul National University Hospital, JongNo-Gu, seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, SungNam, Republic of Korea*.

Background: This retrospective cohort study was conducted to evaluate the cancer incidence in renal biopsy proven glomerulonephritis (GN) patients during the follow ups and to find out the mortality differences according to cancer occurrence.

Methods: This is a retrospective cohort study conducted in a single center. Among 1,600 patients who have underwent renal biopsy between 2003 and 2017, in Seoul National Bundang Hospital, after excluding 611 patients who are inappropriate for the analysis, a total 929 adult patients were analyzed. (Figure) Baseline clinical characteristics, renal biopsy result and types and dose of immunosuppressant usages during the follow-up were collected. Incidence of cancer was censored when the 1st cancer was diagnosed and the mortality was detected during the follow ups.

Results: During the mean 52.4 months (range 1.0-166.7 months) of follow-up, total 49 cases were newly diagnosed as cancer. When we compared the clinical characteristics between the patients who developed cancer and the others, cancer patient were older and had higher prevalence of coronary heart disease and diabetes, lower level of hemoglobin and higher immunosuppressant usage. When the multivariate Cox regression analysis were conducted to find out the risk factors for the cancer development, membranous nephropathy (MN) pathologic diagnosis showed hazard ratio of 2.6 (95% CI 1.32-5.30) after adjusting age, gender, clinical parameters and usage of immunosuppressant. In the subgroup analyais among MN patients, age was the only significant risk factor for the cancer development afte adjusting other confouders. During the follow up, total 86 patients died. In the MN patients, the patients who developed cancer had higher mortality with hazard ratio of 5.95 (95% CI 1.36-26.09, p=0.018) compared to MN patients without cancer, when the multivariate Cox's proportional hazard model were conducted.

Conclusions: Among the GN population without concurrent cancer, patients with MN should be aware of cancer developments during the follow up, since they have significant higher risk of cancer devolvement and which results in higher mortality rate.

TH-PO1057

CCR2 Inhibition Improves Glomerular Ultrastructure In Vivo in Models of Focal Segmental Glomerulosclerosis (FSGS)

Zhenhua Miao, Linda Ertl, Dale Newland, Xiaoping Zang, Bin N. Zhao, Yu Wang, Simon K. Yau, Shirley Liu, Ton H. Dang, Penglie Zhang, James J. Campbell, Israel Charo, Rajinder Singh, Thomas J. Schall. *ChemoCentryx, Inc., Mountain View, CA*.

Background: FSGS is a histologic diagnosis resulting from glomerular injury primarily affecting podocytes, and characterized by the presence of focal and segmental scarring in the glomeruli. Treatment failure is common with current standard of care, and FSGS is causal in at least 4% of patients with ESRD. Several lines of evidence support roles for CCR2 in the pathogenesis of CKD, including FSGS. We have recently shown that a CCR2 antagonist improved renal structure and reduced proteinuria in the murine models of FSGS. To further understand the mechanism by which CCR2 antagonism affords protection in FSGS, we have used EM to examine the effects of CCR2 antagonist on podocyte integrity.

Methods: The 5/6 nephrectomy model of murine FSGS was used to investigate the efficacy of CCR2 antagonist. Kidney injury was assessed by urinary albumin excretion rate (UAER), urine albumin creatinine ratio (UACR), histopathology and EM. Both transmission EM (TEM) and scanning EM (SEM) were performed on kidney samples.

Results: In 5/6 nephrectomized mice, UACR was rapidly and significantly reduced after treatment with CCR2 antagonist (42% and 77% reduction comparing to vehicle treated by week 1 and 2; p=0.04 and 0.025, respectively). The number of glomeruli with sclerosis was reduced by 54% based on analysis of 50-75 glomeruli per kidney. Podocyte integrity was also improved with CCR2 inhibition. Specifically, analysis by both SEM and TEM revealed that podocyte foot process (FP) effacement and slit diaphragm (SD) disruption were improved by CCR2 antagonism, as were the characteristically thickened and denuded GBM. After two weeks of treatment with CCR2 antagonist, FP number was significantly increased with respect to vehicle treated mice (2.10/um GBM vs 1.53/um GBM, p < 0.0001).

Conclusions: Treatment with CCR2 antagonist provides rapid renal protection in the murine model of FSGS, as measured by improved proteinuria and renal structure. Furthermore, CCR2 blockade protected podocyte integrity, as measured by both SEM and TEM. These results provide further evidence that specific inhibition of CCR2 has therapeutic potential in the treatment of FSGS. CCR2 antagonism thus represents a novel and mechanistically distinct approach for the treatment of FSGS.

TH-PO1058

Non-Canonical Expression of CCR2 on Renal Progenitor Cells and Activated Parietal Epithelial Cells: Key to Therapeutic Effect of CCR2 Inhibition in CKD?

Bin N. Zhao, Zhenhua Miao, James J. Campbell, Linda Ertl, Xiaoping Zang, Yu Wang, Chris Li, Rajinder Singh, Israel Charo, Thomas J. Schall. *ChemoCentryx, Mt View, CA.*

Background: Rapid benefits to proteinuria and renal structure are seen with inhibition of CCR2 in models of diabetic nephropathy (DN) and focal segmental glomerulosclerosis (FSGS), and in a human DN trial. However, the mechanism of CCR2 inhibition in renal protection is unclear. Known expression of CCR2 on monocytes does not adequately explain the rapid pharmacologic benefits observed. We used a variety of methods to characterize CCR2 expression on renal progenitor cells (RPCs, $CD133^+CD24^+$) in Bowman's capsule, and on activated parietal epithelial cells (PECs, $CD133^+CD24^+CD44^+$), which play a role in glomerulosclerosis.

Methods: One copy of CCR2 was replaced by red fluorescent protein (RFP) under the control of the mouse CCR2 promoter. CCR2-RFP mouse glomeruli were obtained by a non-enzymatic disruption of kidneys, sieving and low speed centrifugation and analyzed by flow cytometry for CCR2 expression. CCR2 in FSGS was modeled by Adriamycin (ADR) induced kidney injury.

Results: CCR2-RFP positive cells were detected in CD45 positive and CD45 negative renal cell populations. The majority of renal $CD45^-$ RFP^+ cells were CD133 positive but CD24 negative, and are yet largely uncharacterized. However $CD133^+CD24^+$ RPC's, while unchanged in absolute number before and after ADR challenge, showed a dramatic increase (20-40 fold) in the proportion that were CCR2-RFP+ after ADR injury. Furthermore, after ADR challenge, the expression of CD44 (a marker for activated PECs) was increased in the $CD133^+CD24^+$ population. Immunofluorescence confirmed an RFP signal in the glomeruli and Bowman's capsule.

Conclusions: This is the first report of the presence of CCR2 on non-hematopoietic renal parenchymal cells. The non-canonical CCR2+ cells are positive for CD133, CD24, and CD44 consistent with their being renal progenitor cells and activated PECs. These populations are markedly upregulated during kidney injury. These cells may be the targets of the CCR2 inhibitors that have been shown to be efficacious in murine models of CKD, as well as in human DN patients. CCR2 antagonism represents a novel approach for the treatment of CKD, including FSGS, and these studies are an important step in understanding the mechanism of their therapeutic benefit.

TH-PO1059

Altered Podocyte-Endothelial Cross-Talk and Increased Oxidative Stress in Patients with FSGS

Nina A. Van de Lest,[1] Malu Zandbergen,[1] Ron Wolterbeek,[2] Jan A. Bruijn,[1] Marion Scharpfenecker.[1] *[1]Leiden University Medical Center, Dept.Pathology, Leiden, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands.*

Background: The podocyte is thought to be the mainly affected cell type in focal segmental glomerulosclerosis (FSGS). However, recent studies have also indicated a role for glomerular endothelial cells and for changes in crosstalk between these cells and podocytes in the development of FSGS. In an animal model for FSGS, it has been shown that endothelin-1 (ET-1) production by podocytes induces oxidative stress in endothelial cells, which subsequently induces podocyte loss. In this study, we investigated ET-1 signalling and associated oxidative stress and podocyte loss in patients with FSGS.

Methods: We selected 42 biopsies of patients with FSGS and 8 healthy controls and stained them for the endothelin receptor A (ET_AR) and nephrin. The number of glomeruli with ET_AR-positive endothelium and of glomeruli with nephrin loss were scored. In addition, FSGS patients and 10 protocol transplantation biopsies without specific pathology were stained for 8-OXO-G to indicate oxidative stress. Glomerular 8-OXO-G positivity was measured using ImageJ.

Results: In patients with FSGS, the mean percentage of glomeruli with ET_AR-positive endothelial cells was higher compared to healthy controls (52% vs. 7%; $p<0.001$). Also nephrin loss was observed in glomeruli of patients with FSGS. The percentage of glomeruli with ET_AR-positive endothelium correlated with the percentage of glomeruli with nephrin loss (rho=0.49; $p<0.01$). Moreover, the odds of having nephrin loss was higher for glomeruli with ET_AR-positive endothelium compared to ET_AR-negative glomeruli (OR: 2.0; $p<0.0001$). The median percentage of glomerular 8-OXO-G positivity was not significantly different between the two groups (0.90 vs 0.61; $p=0.29$). However, in patients with FSGS 8-OXO-G accumulation (median positivity ≥ 1.5) appeared to be more frequent compared to controls (40% vs 10%; $p=0.07$). Moreover, glomeruli with ET_AR-positive endothelium showed more 8-OXO-G positive staining (1.8 vs 2.3; $p=0.038$).

Conclusions: Patients with FSGS have increased positivity of ET_AR in glomerular endothelial cells and endothelial ET_AR positivity correlates with the degree of podocyte damage. In addition, glomerular oxidative stress, as indicated by the presence of 8-OXO-G, is increased in a subset of patients with FSGS and 8-OXO-G levels are higher in glomeruli with ET_AR-positive endothelial cells.

TH-PO1060

Knockdown of Podocyte Nephronectin by Glomerular Endothelial Cell-Derived MicroRNA-192 Leads to Alterations in GBM

Janina Müller-Deile,[1] Nina Sopel,[2] Chitkale Hiremath,[4] Alexandra Ohs,[2] Denise K. Marciano,[3] Ilse S. Daehn,[6] Mario Schiffer.[5] *[1]University of Erlangen, Erlangen, Germany; [2]Universitätsklinikum Erlangen, Erlangen, Germany; [3]University of Texas Southwestern Medical Center, Dallas, TX; [4]UTSouthwestern, Dallas, TX; [5]University Hospital Erlangen, Erlangen, Germany; [6]Mount Sinai School of Medicine, New York, NY.*

Background: Nephronectin (NPNT) is an extracellular matrix protein downregulated by either TGF-β or miR-378a in podocytes. Knockdown of npnt leads to proteinuria, podocyte effacement and splitting of the glomerular basement membrane (GBM) in zebrafish larvae. Here we investigated the regulation von NPNT by TGF-β and miRs as well as GBM phenotype after knockdown of NPNT more in detail by using cell culture, zebrafish and mice models.

Methods: By using mouse SMAD2/3 knockout podocytes as well as selective inhibitors of the TGF-β pathway we analyzed the TGF-β-NPNT axis more in detail. We overexpressed this miR in zebrafish larvae and analyzed the glomerular phenotype. Finally podocyte specific knockdown of Npnt was investigated in Npnt -/-;Six2-cre mice.

Results: TGF-β regulation of NPNT is mediated by the canonical TGF-β pathway in a SMAD-dependent manner. We identified glomerular endothelial cell-derived miR-192 as a regulator of NPNT in podocytes. Transfection of cultured podocytes with a miR-192 mimic down regulated NPNT expression. Overexpression of miR-192 in zebrafish larvae induced edema, proteinuria and GBM thickening similar to the phenotype after morpholino induced npnt knockdown (Fig. 1A). We characterized the phenotype of npnt knockdown in more detail by using SBF-SEM that allowed a three dimensional on the zebrafish glomerular filtration barrier in zebrafish (Fig. 1B). The unique GBM pathology was further confirmed in a mouse model with specific knockout of Npnt in podocyte progenitor cells (Npnt -/-;Six2-cre mice) (Fig. 1C).

Conclusions: The results confirm the role of podocytic npnt for proper GBM function and suggests its regulation by podocyte- and glomerular endothelial cell-derived miRs.

β1 Integrin Activation and Signaling in Endothelium-Initiated Podocyte Injury

Gabriel M. Cara-Fuentes, Madhusudan M. Venkatareddy, Rakesh Verma, Puneet Garg. *University of Michigan, Ann Arbor, MI.*

Background: Integrins are heterodimeric transmembrane proteins that anchor cells to the extracellular matrix but also play a key role as bi-directional (outside-in and inside-out) signaling mediators. Our aim is to determine the activation state and role of podocyte β1 integrins in a transient model of podocyte injury.

Methods: 8-10 week-old mice were injected intraperitoneally with LPS (10 μg/g) or PBS (control) and urine collected prior to and after injection. In another set of experiments, mice were injected with a β1 integrin "blocking" antibody (HMβ, 2.5 μg/g) 20 hours prior to LPS. Albuminuria was measured by ELISA. Mouse kidney tissue was processed for immunohistochemistry. Glomerular isolation was performed for western blotting and RT-PCR.

Results: LPS injected mice had significantly higher albuminuria than controls. In podocytes, β1 integrin activation, FAK and nephrin phosphorylation occurred 18 to 32 hours after LPS injection. Pre-treatment with HMβ1 antibody significantly reduced albuminuria 24 h following LPS, suggesting that activation of podocyte β1 integrin plays

a role in albuminuria. Immunofluorescence confirmed binding of HMβ1 to glomerular endothelial cells and podocytes, suggesting a possible crosstalk between these cells. Since β1 integrin activation can occur due to outside-in and inside-out signaling, we investigated the chronology of events involving endothelial, glomerular basement membrane (GBM) and podocytes. By immunohistochemistry, western blotting and RT-PCR, we found that endothelial and GBM injury preceded β1 integrin activation, nephrin phosphorylation and foot process effacement, suggesting an outside-in β1 integrin activation.

Conclusions: LPS activates β1 integrin on podocytes and leads to FAK and nephrin phosphorylation in vivo. Targeting endothelia/podocyte β1 integrin reduces albuminuria. Changes in glomerular endothelial cells and GBM precede podocyte injury, suggesting that activation of podocyte β1 integrin may be triggered by an outside rather than inside signal in this model of podocyte injury.

TH-PO1062

Podocyte Protective Effects of TRPC5 Inhibitor AC1903 in Human iPSC-Derived Podocytes and Kidney Organoids

Yiming Zhou,[1,2] Maheswarareddy Emani,[2] Juan lorenzo B. Pablo,[2] Anna Greka.[1,2] *[1]Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [2]Broad Institute of MIT and Harvard, Cambridge, MA.*

Background: The TRPC5-Rac1 pathway has been shown to induce podocyte injury and loss in two pre-clinical rat models: a transgenic rat FSGS model and a spontaneous hypertensive rat model. The TRPC5 blocker AC1903 protects podocytes in both models. However, less is known about the effect of this compound in rat models that are more easily amenable to drug development programs, such as the puromycin aminonucleoside (PAN)-induced nephrosis model. Furthermore, the effect of AC1903 in human podocytes remains elusive. Here, we aim to investigate the effect of AC1903 in the puromycin aminonucleoside(PAN)-induced nephrosis in rat, as well as in PAN-treated human iPSC-derived podocytes and kidney organoids.

Methods: A single i.p. injection of PAN (50mg/kg) was given to wild-type Sprague-Dawley rats (Male, 4-5 weeks, Charles River). AC1903 was administered twice a day for 7 days after PAN injection. 24-hour urine albumin levels were measured on day 7. Human iPS cells were used to generate podocytes and kidney organoids (according to Subramanian A. et al. 2019 http://dx.doi.org/10.1101/516807). PAN treatment was used to induce human podocyte injury in these in vitro model systems, and the effects of AC1903 were assayed by Western Blotting, immunofluorescence staining and confocal microscopy.

Results: We found that a single i.p. injection of PAN-induced podocyte injury and foot process effacement (FPE) as well as a significant increase in urine albumin levels 7 days after injection. Treatment of proteinuric PAN rats with AC1903 significantly reduced foot process effacement and proteinuria. PAN treatment of human iPSC-derived podocytes and kidney organoids triggered the TRPC5-Rac1 injury pathway leading to ROS production and cytoskeletal dysregulation. These effects were reversed by AC1903, showing for the first time that TRPC5 inhibition benefits human podocytes and kidney organoids.

Conclusions: Taken together, our results confirmed the relevance of the TRPC5-Rac1 pathway in human kidney tissue thus highlighting the potential of this therapeutic strategy for patients.

TH-PO1063

GFB-887, a Small Molecule Inhibitor of TRPC5, Attenuates Proteinuria in Animal Models of FSGS, Minimal Change Disease, and Diabetic Nephropathy

John F. Reilly,[1] Marie F. Coeffet-LeGal,[1] Xin-Ru Pan-Zhou,[1] Kristin M. Joly,[2] Toni L. Richards,[2] Liron Walsh,[1] Jean-Christophe Harmange,[1] Craig F. Plato,[2] Peter H. Mundel.[1] *[1]Goldfinch Bio, Inc., Cambridge, MA; [2]Plato BioPharma, Inc., Westminster, CO.*

Background: Focal segmental glomerulosclerosis (FSGS) is a podocytopathy with proteinuria and a high likelihood of progression to end stage renal disease (ESRD). Minimal change disease (MCD) is a podocytopathy resulting in nephrotic syndrome and is frequently refractory to current therapies. Diabetic nephropathy (DN), the most common cause of ESRD worldwide, is also characterized by proteinuria and podocyte loss. The Ca^{2+}-permeable transient receptor potential canonical 5 (TRPC5) channel is a critical mediator of proteinuria. Activation of the TRPC5 pathway in podocytes culminates in activation of Rac1, which is the primary driver of proteinuria in many forms of proteinuric kidney disease. Inhibition of TRPC5 channel activity with tool compounds has been shown to protect against proteinuria and podocyte loss in AT1R transgenic and Dahl salt-sensitive rats.

Methods: We evaluated GFB-887, a potent, subtype-selective TRPC5 inhibitor, in two models of FSGS, the unilaterally nephrectomized (UNx) deoxycorticosterone acetate (DOCA)-salt rat model and the AT1R transgenic rat model with the phenotype accelerated by UNx and continuous administration of angiotensin II at a sub-pressor dose. GFB-887 efficacy was also assessed in the low-dose puromycin aminonucleoside nephrosis (PAN) rat model of MCD and the ZDSD rat model of DN.

Results: Inhibition of TRPC5 by GFB-887 attenuated albuminuria in hypertension-induced FSGS in DOCA-salt rat model without altering blood pressure, and also in the non-hypertensive AT1R rats. In both FSGS models, GFB-887 demonstrated efficacy in a therapeutic context by reducing established albuminuria. GFB-887 also reduced albuminuria in the PAN model of MCD and in the ZDSD model of DN.

Conclusions: GFB-887, a subtype-selective small molecule inhibitor of TRPC5, demonstrated efficacy in reducing proteinuria in animal models of FSGS, MCD and DN.

Aged TRPC6 KO Mice Have a Novel Renal Phenotype

Louise K. Farmer, Monica Gamez, Rebecca R. Foster, Moin Saleem, Gavin I. Welsh. *University of Bristol, Bristol, United Kingdom.*

Background: Focal segmental glomerulosclerosis is a form of nephrotic syndrome which leads to end stage renal failure. The disease can be genetic or idiopathic and mutations in transient receptor potential cation channel 6 (TRPC6) can cause nephrotic syndrome. Patients with TRPC6 mutations tend not to develop symptoms until later life. TRPC6 KO mice have previously reported no detrimental kidney phenotype, with blood pressure, glomerular morphology and albumin excretion like WT animals. However, these have been studied early in life and to date there has been no study on the effect of TRPC6 KO with ageing. We therefore aged TRPC6 KO mice and looked at their phenotype at 10-16 months.

Methods: An ex vivo glomerular albumin permeability assay developed by our group was used to determine glomerular permeability (Desideri *et al*, 2018). Mouse kidneys were harvested and imaged using an electron microscope to measure the dimensions of the glomerular filtration barrier. Mouse urine was collected by spot collection and the urinary albumin-to-creatinine ratio was quantified.

Results: Aged TRPC6 KO mice were not proteinuric and had normal albumin creatinine ratios. However, we also used a highly sensitive, ex vivo glomerular permeability assay, developed by our group, to look for differences in permeability between aged TRPC6 KO and control mice. Glomerular permeability was significantly ($P< 0.0001$) increased in older KO mice (6.615e-007±4.002e-008 cm/s) compared to age-matched wild type controls (2.643e-007±5.332e-009 cm/s), suggesting a pathological effect of TRPC6 KO. An increased width of both ordinary ($P=0.0054$) and anchoring ($P=0.022$) podocyte foot processes was observed in the aged TRPC6 KO mice (ordinary (0.35±0.01 vs 0.27±0.01 μm) and anchoring (0.51±0.05 vs 0.29±0.03 μm)) compared to control mice (ordinary 0.27±0.01 μm) and anchoring (0.29 ± 0.03 μm)). There were also significantly fewer foot processes in the TRPC6 KO mouse $P=0.046$). The GBM thickness was increased ($P=0.018$) from 0.29±0.02 μm in control to 0.36±0.005 in KO animals, demonstrating that old TRPC6–/– mice have morphological changes on the structure of the GFB.

Conclusions: We have demonstrated that in a mouse model, knockout of TRPC6 results in increased glomerular permeability and alterations to the structure of the glomerular filtration barrier in aged mice. This phenotype correlates with disease progression in human patients.

Pharmacologically Stimulating Nitric Oxide-Soluble Guanylate Cyclase Signalling to Prevent Podocyte Injury

Daan C. 't Hart, Johan Van der vlag, Tom Nijenhuis. *Nephrology, RIMLS, Radboud University Medical Centre, Nijmegen, Netherlands.*

Background: The effects of nitric oxide (NO) on podocytes are not known. We hypothesize that NO production by glomerular endothelial cells (GEnC) acts on podocytes as a protective paracrine factor in the glomerulus, thereby preventing podocyte injury. We propose a mechanism in which NO-mediated soluble guanylyl cyclase (sGC) activation results in enhanced cGMP synthesis and reduced expression/activity of the Ca^{2+}-permeable Transient Receptor Potential Channel 6 (TRPC6), thereby inhibiting deleterious podocyte signalling processes. Several market approved drugs for non-renal disorders act on sGC. We aim to investigate glomerular NO-sGC signalling and the potential of repurposing sGC activators to prevent podocyte injury.

Methods: *In vitro* experiments were performed using conditionally immortalized GEnC and podocytes. NO production was visualized using the NO sensitive dye DAF-FM diacetate. Podocyte injury was induced with 0.25μg/mL adriamycin for 24hrs, with or without co-exposure of NO-donor SNAP (200μM) or sGC activators Cinaciguat (2μM) and Riociguat (20μM).

Results: Two forms of nitric oxide synthases (NOS; i.e. iNOS and eNOS) were expressed by GEnC and podocytes, whereas both cell types produced NO. GEnC particularly produced NO under (physiological) flow conditions. Interestingly, neuronal NOS (nNOS) was solely expressed by podocytes when injury was induced. All sGC subunits were expressed by podocytes. Stimulation of sGC via either SNAP or Riociguat elevated cGMP production in podocytes. Importantly, SNAP, Cinaciguat and Riociguat all reduced adriamycin-induced TRPC6 overexpression in human podocytes. No additional reduction of adriamycin-induced TRPC6 overexpression was observed when SNAP was co-administered with either Riociguat or Cinaciguat.

Conclusions: Our data supports the hypothesis of a paracrine NOS-NO-sGC axis between GEnC and podocytes. Moreover, sGC stimulation via SNAP or through repurposing drugs that activate sGC exert a protective effect on podocytes. Glomerular NO production might therefore play an important role in preserving the integrity of the glomerular filtration barrier. When experimental animal models for glomerular disease will confirm our *in vitro* findings, we will design clinical studies to evaluate the therapeutic effect of sGC activators to treat glomerular diseases.

Evaluation of the Human FSGS-Inducing ANLN R431C Variant in CRISPR-Cas9 Mice

Brandon M. Lane,[1,2] Guanghong Wu,[1,2] Megan Chryst-Stangl,[1,2] Gentzon Hall,[2,3] Robert F. Spurney,[3] Laura Barisoni,[4] Sara E. Miller,[4] David Howell,[4] Rasheed A. Gbadegesin.[1,2] *[1]Pediatrics, Duke University School of Medicine, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]Medicine, Duke University School of Medicine, Durham, NC; [4]Pathology, Duke University School of Medicine, Durham, NC.*

Background: We previously reported that the *ANLN R431C* variant causes focal segmental glomerulosclerosis (FSGS) and induces endoplasmic reticulum (ER) stress induced apoptosis in cultured human podocyte cells. To further understand the molecular mechanisms underlying disease, we examined the phenotypic effects of this variant *in vivo* using a CRISPR-Cas9 generated mouse model.

Methods: We generated an orthologous *ANLN R431C* knock-in point mutation in mice (*R426C*) using CRISPR-Cas9 technology. $ANLN^{+/+}$, $ANLN^{R426C/+}$, $ANLN^{R426C/R246C}$ mice were challenged with a sub-therapeutic dose of nephrotoxic antibodies at 22 weeks and evaluated for 5 weeks post injection. Kidney sections were evaluated by two independent pathologists, blinded to genotype, through PAS staining and electron microscopy.

Results: When challenged with nephrotoxic antibodies in a kidney disease resistant genetic background, $ANLN^{R426C/R246C}$ mice displayed increased proteinuria compared to $ANLN^{R426C/+}$ (p=0.049) and $ANLN^{+/+}$ (p=0.0064) mice. Light microscopy evaluation of $ANLN^{R426C/R246C}$ kidney sections revealed increased protein casts (p<0.0001), as well as larger (p=0.018) and more sclerotic (p=0.0005) glomeruli when compared to wildtype littermates. Semi-quantitative analysis using electon microscopy revealed increased podocyte effacement and ER stress including evidence of dilated cisternae, damaged mitochondria, and abnormal autophagy in the $ANLN^{R426C/R246C}$ mice. Additionally, cultured primary $ANLN^{R426C/R246C}$ podocytes displayed increased apoptosis compared to $ANLN^{+/+}$ podocytes (p=0.049).

Conclusions: $ANLN^{R426C/R246C}$ mice display increased susceptibility to glomerular injury when compared to $ANLN^{+/+}$ littermates. Additionally, $ANLN^{R426C/R246C}$ mouse podocytes displayed similar ER stress and apoptotic phenotypes to cultured $ANLN_{R431C}$ human podocytes, lending further credibility to these results. Further evaluation of this mouse line in a genetic background that is more kidney susceptible to kidney disease should provide a necessary model to evaluate potential therapeutic compounds that have successfully rescued apoptotic phenotypes in cultured $ANLN_{R431C}$ human podocytes.

TH-PO1067

The Drosophila Nephrocyte Model of Podocyte Slit Diaphragms Reveals a Role for the Basal Polarity Complex in Slit Diaphragm Formation

John S. Poulton. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The podocyte slit diaphragm (SD) plays a key role in glomerular filtration. Mutations in the apical polarity protein Crb2 are present in some cases of steroid-resistant nephrotic syndrome. Animal models indicate an important role for apical polarity proteins in podocyte polarity and SD formation, suggesting cell polarity is a central aspect of podocyte development and function. Surprisingly however, mutations in basal polarity proteins do not cause significant defects in mouse podocytes, even though they express basal polarity proteins. Thus, it is difficult to interpret the relationships between the polarity complexes in podocyte development and SD formation.

Methods: To explore the potential role of the basal polarity proteins in SD formation, I performed a genetic analysis of the basal polarity proteins in SD formation and SD protein localization using the Drosophila nephrocyte, a popular model for podocyte SDs.

Results: I found that all of the canonical basal polarity proteins (Dlg, Scrib, Lgl, and Par-1) play important roles in the localization of nephrocyte SD proteins (Nephrin, Neph1, ZO-1). Loss of Dlg was also associated with dramatically reduced nephrocyte SD number and SD mislocalization; I am currently examining the role of the other basal proteins on SD formation. Loss of Dlg also appears to perturb Crb localization, suggesting the basal and apical polarity complexes function together in nephrocyte SD formation. Importantly, genetic interaction studies suggest the basal proteins work in concert to direct the formation of the nephrocyte SD. Genetic interaction studies also identified an important relationship between the basal polarity proteins and the SD-associated polarity protein Par-3, as well as the SD adaptor protein ZO-1.

Conclusions: Genetic analysis of the Drosophila nephrocyte has revealed a key role of the basal polarity proteins in SD formation. The genetic interaction studies are consistent with these proteins working as a conserved module, determining the localization of core SD components, likely through their interactions with proteins such as Par-3 and ZO-1. We are continuing to define the mechanism by which the basal polarity complex contributes to SD formation, their relationship with apical polarity proteins like Crb, and extending our analysis of the basal polarity proteins to a vertebrate podocyte model.

TH-PO1068

Functional Analysis of a Novel FSGS-Associated ACTN4 Mutation in Podocytes and Drosophila Melanogaster

Johanna Odenthal,[1] Sebastian Dittrich,[1] Bodo B. Beck,[4] Bernhard Schermer,[1] Thomas Benzing,[2] Markus M. Rinschen,[3] Paul T. Brinkkoetter,[1] Malte P. Bartram.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]University of Cologne, Köln, Germany; [3]The Scripps Research Institute, La Jolla, CA; [4]University of Cologne Medical Center, Cologne, Germany.*

Background: The actin cytoskeleton is a central element of podocyte morphology and homeostasis during health and disease. Alpha-actinin4 (ACTN4) has been shown to play an important role in podocyte architecture and function and mutations in the *ACTN4* gene are associated with focal segmental glomerulosclerosis (FSGS). Here, in a pediatric patient presenting with steroid resistant nephrotic syndrome (SRNS) and FSGS, gene panel sequencing of genes associated with rare kidney diseases identified an undescribed *de novo*, potentially disease-causing variant of *ACTN4* that was not found in available genome or exome databases. Aim of this study was to characterize this variant and elucidate its pathogenic potential for podocyte homeostasis.

Methods: We analyzed patient-derived primary urinary cells (PUCs) as well as cultured human podocytes that express the novel ACTN4 mutant. Results were obtained using quantitative proteomic analysis as well as cell biology studies *in vitro*. In order to perform *in vivo* studies, we exploited *Drosophila melanogaster* genetics and characterized Actinin loss in nephrocytes, podocyte-like cells of the fruit fly. Here, rescue experiments with human *ACTN4* wildtype, other previously described, pathogenic *ACTN4* mutations as well as the novel variant will give further insight into its pathogenicity.

Results: Mapping the PUC proteome, we quantified more than 3000 proteins as compared to healthy controls. PUCs of the index patient showed high abundance of DNA-damage response associated proteins, and depletion of the known ACTN4 interactor ZNF385. Cultured human podocytes overexpressing the ACTN4 mutant present with disturbed appearance and localization of the actin cytoskeleton and first experiments suggest the ACTN4 mutant to impact cell viability. Knockdown of *Drosophila* Actinin in nephrocytes leads to a severe functional phenotype, as cells no longer perform proper filtration. Morphologically, we could show that localization of the nephrocyte diaphragm is perturbed, suggesting false architecture of the nephrocyte.

Conclusions: Our results indicate that the identified novel *ACTN4* mutation leads to a strong phenotype *in vitro*, likely making it a disease-causing mutation. The *in vivo* data underline the importance of actinin in nephrocyte architecture and function.

TH-PO1069

Using Drosophila Nephrocytes to Identify Specific States of Podocyte Disease Correlated with a Dysregulation of Insulin-Dependent Signals

Lucas Kuehne,[1] Johanna Odenthal,[1] Bernhard Schermer,[1] Thomas Benzing,[2] Paul T. Brinkkoetter.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]University of Cologne, Köln, Germany.*

Background: Insulin signaling with its relation to metabolic cascades, including the regulation of anabolic and catabolic processes via mTOR and the FoxO transcription factor, is one of the most complex signaling networks, playing a key role in podocyte health and disease. This study aims to test whether Drosophila nephrocytes can be used to efficiently screen for dysregulated insulin signaling pathways in different forms of steroid resistant nephrotic syndrome (SRNS).

Methods: Several mutations that are known to cause SRNS have been characterized in Drosophila and can be modeled using the GAL4-UAS-system. These mutations lead to a dysfunction in different cellular compartments, e.g. the mitochondria. Here, we use the Drosophila nephrocytes to screen for dysregulated insulin signaling in specific states of podocyte disease. The phenotypic characterization is based on Tracer-Uptake-Assays, IF-staining and electron microscopy, while a dysregulated insulin signaling can be observed via qPCR, Western Blot and a FoxO-mCherry-reporter line.

Results: The correlation between mitochondrial dysfunction and hyperactive insulin signaling, based on a cell-specific Prohibitin-2-knockdown, could be confirmed in *Drosophila* nephrocytes. While the Prohibitin-knockdown lead to a functional phenotype with a reduced uptake of FITC-albumin, there were no obvious morphological changes. This phenotype could be rescued by an inhibition of the mTOR kinase via rapamycin.

Conclusions: Drosophila nephrocytes show a clear correlation between mitochondrial dysfunction, initiated by a Prohibitin-knockdown, and hyperactive insulin signaling. Consequently, the nephrocytes can be used as an efficient *in vivo* model to characterize insulin-dependent signaling pathways in podocytes.

Linking Polarity Signaling and Mechanotransduction in Drosophila Nephrocytes

Sybille Köhler,[1,2] Bernhard Schermer,[1] Thomas Benzing,[3] Barry Denholm,[4] Paul T. Brinkkoetter.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]BIomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom; [3]University of Cologne, Köln, Germany; [4]Edinburgh University, Edinburgh, United Kingdom.*

Background: Polarity signaling through the aPKC-Par polarity complex is essential for the development and maintenance of the podocyte architecture and the filtration function of the kidney. Despite its well-established role in aPKC-mediated signaling, neither loss of Par3A nor Par3B causes a glomerular disease phenotype. However, genetic depletion of both, Par3A and Par3B resulted in severe proteinuria and renal failure.

Methods: We utilized *Drosophila* nephrocytes to study the functional role of Par3 proteins in greater detail. Nephrocytes are the homolog cells of mammalian podocytes and express the Par3A/B homolog Bazooka at the nephrocyte diaphragm.

Results: Nephrocyte-specific depletion of Bazooka resulted in disturbed nephrocyte diaphragm morphology and severe filtration defects, indicating the conservation of this important pathway throughout species. To study the underlying mechanisms, we performed proteomic analysis of Bazooka-depleted nephrocytes and identified an upregulation of focal and cell adhesion proteins, actin-associated proteins and mechanosensors such as Cher (Filamin) and Rhea (Talin). The putative mechanosensor protein Filamin was identified to be upregulated upon injury in podocytes as well. As podocytes face constant mechanical stress due to blood pressure and filtration, we further investigated the functional role of the mechanosensor protein Cher in nephrocytes. Interestingly, loss of Cher did not cause morphological changes, but resulted in a significantly increased filtration function. Proteom data from Cher depleted nephrocytes revealed an upregulation of ECM associated proteins such as Viking (Col4A) and Mucin and a downregulation of proteins involved in cell adhesion processes and actin-binding.

Conclusions: Our study thereby provides the first data linking polarity signaling and mechanotransduction in nephrocytes.

TH-PO1071

Rab11-Dependent Recycling Maintains Nephrin at the Slit Diaphragm

Rakesh Verma, Gabriel M. Cara-Fuentes, Puneet Garg. *University of Michigan, Ann Arbor, MI.*

Background: A role of endocytosis for podocyte biology has previously been proposed. In humans, until recently no direct endosomal regulator had previously been implicated in nephrotic syndrome. Whole exome sequencing identified mutations in Rab5 and Rab11 regulatory proteins resulting in congenital nephrotic syndrome and FSGS. Rab5 and Rab11 are expressed ubiquitously, suggesting perturbation of trafficking of podocyte-specific proteins as one potential mechanism for podocyte-restricted phenotype. We reported deletion of nephrin in an adult mature glomerulus, a small fraction (10-15%) of nephrin remains at the membrane and is sufficient to maintain the slit diaphragm for 4-6 week. In vitro studies have suggested that membrane bound nephrin undergoes endocytic recycling. We hypothesized that in our model recycling is responsible for maintenance of nephrin at the membrane following nephrin deletion.

Methods: Standard biochemical and cell biology techniques were used to analyze kidneys from knockout mice. Cre-loxP system was used to generate podocyte specific deletion of nephrin, VPS34 and Rab11.

Results: Combined deletion of nephrin and VPS34 results in an earlier phenotype compared to deletion of nephrin or vps34 alone. Immunogold EM analysis reveals accumulation of Nephrin in vesicles suggesting involvement of Vps34-dependent endocytic pathway in nephrin's maintenance at the slit diaphragm. As VPS34-generated PI3P affects trafficking to early endosome as well as recycling endosomes we generated a mouse model where rab11a and rab11b are deleted in a podocyte-specific manner in an adult mice. Deletion of rab11b alone does not result in a phenotype, whereas combined deletion of rab11a and rab11b results in development of proteinuria at 4-6 week following deletion. Simultaneous deletion of nephrin/rab11a/rab11b results in an earlier phenotype where mice develop proteinuria at 1 week following deletion along with foot process spreading. Analysis of nephrin at the membrane indicates a faster decline following deletion of rab11a/b.

Conclusions: Simultaneous deletion of Rab11 and nephrin results in an earlier phenotype and shortens nephrin's half life at the membrane. Our model provides us with mechanistic insights into human mutations where perturbation of endosomal regulatory proteins result in proteinuric kidney disease.

Targeting Defective Trafficking of Slit Diaphragm Protein in INF2-Related Podocytopathy and FSGS

Hua Sun,[1,2] Martin R. Pollak.[2] *[1]Nephrology, Boston Children's Hospital, Boston, MA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.*

Background: Focal segmental glomerulosclerosis (FSGS) caused by mutations in INF2 is characterized by mistrafficked nephrin, which comprises the slit diaphragm (SD) of podocytes by its extracellular domain, suggesting INF2 plays an important role in maintaining the surface transport of INF2. This hypothesis is supported by a zebrafish model in which INF2 knockout led to glomerular dysplasia with mistrafficked nephrin, and INF2 R218Q knockin mice which showed defective recycling of nephrin and recovery of the SD following protamine perfusion. This study is to delineate this newly recognized role of INF2 in regulating the trafficking of nephrin, and how it is disrupted by FSGS-causing mutations.

Methods: By performing a yeast 2 hybridization screen, I found the interaction of INF2 with signaling molecules involved in vesicle trafficking pathways. Their interactions with wildtype or FSGS-causing mutants of INF2 were analyzed using yeast mating and co-IP. Podocytes with INF2 knockout or R218Q knockin were treated with antagonists for these pathways, and the trafficking of nephrin was studied by surface biotinylation and fluorescent based trafficking assays, live cell imaging with analysis using KymographClear, KymographDirect and TrackMate software.

Results: Yeast mating and Co-IP demonstrated the interaction of INF2 with mDia (a Rho effector), Dynein light chain 1 (Dynll1), Nipsnap3a (a SNARE protein), molecules involved in cytoskeleton regulation and lipid raft dependent vesicle trafficking. The interactions were disrupted by FSGS-causing mutations of INF2, suggesting the dysregulated pathways by INF2 mutants contributed to the pathogenesis of FSGS. Podocytes with INF2 knockout or R218Q knockin showed impaired nephrin recycling, which was rescued by targeting these pathways using Rho inhibitor (C3 transferase), Dynein inhibitor (Ciliobrevin) or lipid raft sequestrator (Nystatin).

Conclusions: INF2 plays a key role in maintaining the functional trafficking of nephrin by modulating 1) Rho/mDia signaling that halts vesicle movement; 2) Dynein mediated retrograde transport; 3) Lipid raft dependent vesicle trafficking. This role of INF2 can be disrupted by FSGS-causing mutations, leading to mistrafficked nephrin and disintegrity of SD. The dissection of the dysregulated pathways underlying the mistrafficked nephrin will provide new therapeutic targets for INF2 related podocytopathy and FSGS.

Inhibition of Kynurenine 3-Monooxigenase (KMO) Alters NAD Balance and Mitochondrial Function in Murine and Human Glomerular Cells and Contributes to Proteinuria in Zebrafish

Patricia Bolanos-Palmieri,[1] Heiko J. Schenk,[3,2] Patricia A. Schroder,[2] Mario Schiffer.[1] *[1]Nephrology, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; [2]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [3]Hannover Medical School, Hannover, Germany.*

Background: KMO is an enzyme of the kynurenine pathway (KP) and as such it is key for tryptophan (trp) catabolism. KMO uses kynurenine (kyn) as a substrate and participates in the production of important bioactive metabolites. Systemic KP dysregulation has been linked to a variety of pathologies, including CKD. Since the enzymes of the KP are expressed in the kidney, we aim to describe the effects of their dysregulation on glomerular cells.

Methods: KMO inhibition was performed in a transgenic zebrafish line that facilitates the detection of proteinuria. Embryos were treated with a KMO inhibitor or kyn starting at 48hpf. At 96hpf the phenotype was recorded and samples were collected for metabolite analysis by mass spectrometry. Since KMO is located in the mitochondria and participates in the production of NAD, mouse parietal epithelial cells (PEC), as well as human and murine podocytes (POD) were incubated with a KMO inhibitor; the levels of NAD^+, NADH and mitochondrial membrane polarization were determined. Alterations in the bioenergetics parameters were also assessed by measuring the oxygen consumption rate after KMO inhibition.

Results: Our results show that inhibition of KMO leads to the accumulation of upstream kynurenine metabolites in the treated larvae. Additionally, proteinuria and edema were observed after KMO inhibition, in line with our previous results from morpholino mediated knockdowns. Treating the larvae with exogenous kyn also leads to mild proteinuria. In vitro data show that KMO inhibition reduces the NAD^+/NADH ratio in POD, and leads to mitochondrial depolarization in POD and PEC. A reduction in spare respiration, coupling efficiency and an increase in proton leak accompanied the mitochondrial phenotype in POD. We also show that glomerular cells are capable of taking up kyn from the media, suggesting that kyn is not only relevant as a biomarker, but may directly contribute to disease etiology.

Conclusions: Taken together our results highlight the importance of trp catabolism via the KP within the context of renal cell biology, where a reduction in KMO activity alters the energy metabolism of POD and leads to kyn metabolite imbalances that ultimately may impact the glomerular filtration barrier.

Sulfatases, in Particular SULF1, Are Important for the Integrity of the Glomerular Filtration Barrier in Zebrafish

Heiko J. Schenk,[1,4] Anna K. Masseli,[1,4] Patricia A. Schroder,[4] Patricia Bolanos-Palmieri,[2,1] Jan Hegermann,[3] Jan H. Braesen,[3] Hermann G. Haller.[1,4] Haller Lab
[1]Hannover Medical School, Hannover, Germany; [2]University of Erlangen-Nurnberg, Erlangen, Germany; [3]Medizinische Hochschule Hannover, Hannover, Germany; [4]Mount Desert Island Biological Laboratory, Salisbury Cove, ME.

Background: 6-O-endosulfatases (sulfs) are important enzymatic components involved in the regulation of heparan sulfate by altering the sulfatation pattern. Specifically in the kidney, sulfs have been implicated in the glomerular podocyte-endothelial cell crosstalk and in the preservation of the glomerular filtration barrier (GFB) in different mouse models. Since it has been shown that in zebrafish larvae, Sulf1, Sulf2a, and Sulf2b are expressed in the pronephric kidney we set out to establish if a reduction in sulf expression leads to GFB dysfunction.

Methods: To evaluate the integrity of the GFB, we measured a GFP-tagged vitamin D binding protein derived from *Tg(l-fabp:eGFP-DBP)* zebrafish in the retinal vessel plexus of the zebrafish larvae at 96 hpf. Sulf-deficiency was induced using different morpholinos. The integrity of the GFB was evaluated by electron microscopy. Paraffin sections of sulf-deficient larvae were analyzed using immunofluorescence microscopy. Dextran microinjections and *in vivo* confocal imaging of the vasculature using *Tg(flk:mcherry)* larvae were carried out.

Results: Here, we show that a reduced sulf expression following MO-knockdown in zebrafish larvae promotes damage to the GFB leading to renal plasma protein loss from the circulation. Moreover, a combined knockdown of Sulf1, Sulf2a and Sulf2b is associated with severe morphologic changes including narrowing of the fenestration between glomerular endothelial cells as well as thickening of the glomerular basement membrane, and podocyte foot process effacement; suggesting that glomerular damage is an underlying cause of the circulatory protein loss observed after MO injection. Additionally, we show that a decrease in sulf expression reduces the bioavailability of VegfA in the glomerulus of the pronephros, which may contribute to the structural changes observed in the glomeruli of morphant fish. Furthermore, consistent with previous results, knockdown of the sulfs is associated with arteriovenous malformations in particular in the tail region of the larvae.

Conclusions: Overall, taken together our results suggest that 6-O-endosulfatases are important in the preservation of GFB integrity and a reduction in their expression levels induces phenotypic changes that are indicative of renal protein loss.

Implementation of an Artificial Neural Network for Automated Podometrics in Human Kidney Specimens

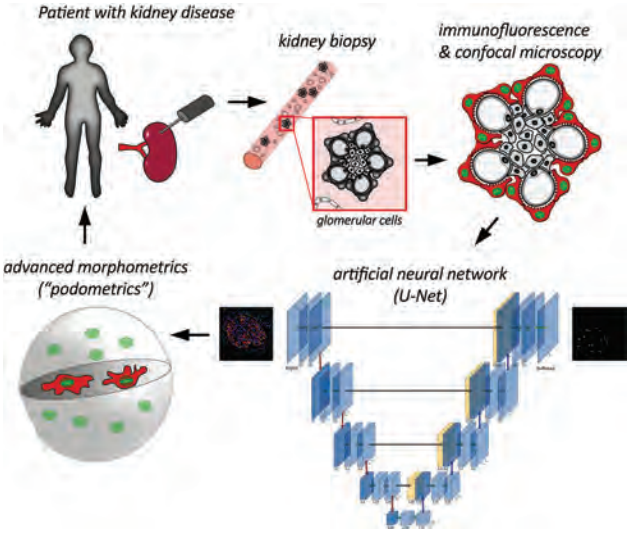
Martin Klaus,[1] Marina Zimmermann,[2] Lukas Gernhold,[1] Christoph Kuppe,[3] Milagros N. Wong,[1] Nicola Wanner,[1] Fermin Person,[4] Thorsten Wiech,[5] Rafael Kramann,[6] Stefan Bonn,[7] Tobias B. Huber,[1] Victor G. Puelles.[1] *[1]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Center for Molecular Neurobiology, University Clinic Hamburg-Eppendorf, Hamburg, Germany, Hamburg, Germany; [3]University Hospital of RWTH Aachen, Aachen, Germany; [4]University Hospital Basel, Basel, Switzerland; [5]Department of Pathology, University Hospital Hamburg Eppendorf, Hamburg, Germany; [6]RWTH Aachen University, Lemiers, Netherlands; [7]Institute for Medical Systems Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Advanced morphometrics to study podocytes (podometrics) may provide robust readouts for diagnosis, prognosis and management of patients with glomerular diseases. However, their clinical implementation is limited by their time-consuming nature. Thus, artificial neural networks emerge as interesting tools to bring podometrics closer to the bedside.

Methods: Ground truth data was determined in 318 images (144 training, and 174 testing), acquired using immunofluorescence and confocal microscopy. An artificial neural network (U-Net) was implemented, optimised via a systematic grid search and compared to an automatic ImageJ-based segmentation tool. Dice scores (pixel-based), F1 scores (object-based), and spearman correlations were calculated to validate each method against the ground truth. Model-based stereology podometrics were determined using segmented data.

Results: In nephrectomy samples, U-Net provided higher Dice and F1 scores than those obtained with ImageJ ($P<0.0001$), with stronger correlation indices for U-Net ($R=0.94-0.95$, $P<0.0001$) compared to ImageJ ($R=0.61-0.66$, $P<0.01$). In ANCA-associated glomerulonephritis, Dice and F1 scores were also higher in U-Net ($P<0.0001$) compared to ImageJ with stronger correlation indices in U-Net ($R=0.91-0.94$, $P<0.0001$) compared to ImageJ ($R=0.59-0.79$, $P<0.01$).

Conclusions: Our optimised artificial neural network (U-Net) provides readouts that are comparable to manual segmentation and superior to conventional segmentation tools, even in the context of glomerular disease. These findings bring us one step closer to the use of automatic podometrics as a clinical instrument.



We have implemented an artificial neural network to automatically extract the data required for the estimation of podometrics in clinical samples.

Single-Cell Transcriptome Profiling of the Mouse and Human Glomerulus

Bing He,[1] Ping Chen,[1] Sonia Zambrano Sevilla,[1] Dina Dabaghie,[1] Jing Guo,[1] Mark Lal,[2] Rickard Sandberg,[1] Jaakko Patrakka.[1] *[1]Karolinska Institutet, Stockholm, Sweden; [2]AstraZeneca, Gothenburg, Sweden.*

Background: Though the mouse is widely used to model human glomerular diseases, systematic transcriptome comparison of principal cell types forming the glomerular filtration barrier between two species is lacking. To address this question, we generated single cell RNA sequencing (scRNA-seq) libraries from mouse and human glomerular cells.

Methods: Mouse glomeruli were isolated from 8 wt adult C57BL/6J mice via magnetic bead perfusion. Human healthy glomeruli were purified from 8 donor kidney biopsies via a sieving procedure. Viable single cells of enriched glomeruli were unbiasedly sorted to 384-well plates and scRNA-seq was performed using the Smart-seq2 protocol. For data comparison between 2 species, we focused on podocytes, glomerular endothelial cells (GEC) and mesangial cells (MC).

Results: In total, 2416 mouse cells and 788 human cells passed quality control. Unsupervised clustering of these cells identified Nphs1$^+$ podocytes, Kdr$^+$ GECs, Pdgfrb$^+$ MCs and other cell types such as tubular cells and immune cells. Interestingly, Cldn1$^+$ mouse parietal epithelial cells were captured. Overall comparison showed more genes detected in podocytes than other two cell types. In podocytes, about 70 genes were identified as human-specific, of which half of them showed restricted expression in podocytes. Most human-specific genes have not been implicated in the podocyte function. However, important exceptions were detected, such as PLA2R1 encoding a major autoantigen of human membranous nephropathy, which was absent in mouse podocytes. On the other hand, only 5 genes were identified as mouse-specific. In GEC and MC, < 20 genes showed apparent human-specificity and only 3 genes mouse-specificity. Differential species-specific cell expression patterns for selected genes were validated by analyzing bulk RNA-seq data, qPCR and immunostaining.

Conclusions: Our results highlight differences between mouse and human glomerular molecular signatures that are essential to design and interpret translational studies.
