Methods: We prospectively enrolled 1974 CKD patients (1180 male/794 female, mean age: 53.2 years) who had OPG and electron beam computed tomography (CT) or multi-detector CT for CAC scoring at baseline. A CAC score of > 400 Agatston unit (AU) s was used to define severe CAC. In term of definition for CAC progression: among those with no baseline CAC, incidence was defined as an annual increase in CAC score ≥ 5 AUs. Among those with baseline CAC, progression was defined as 15% annual increase.

Results: Mean serum concentrations of OPG amounted to 6.79 ± 3.53 pmol/L. Among 1974 patients, 1011 (51.2 %) had CAC score >0 and 209 (10.6 %) had scores > 400. Higher OPG levels were associated with the present CAC but not severe CAC at baseline. [LnOPG, presence: OR =2.033, P = 0.001; severe CAC: OR =1.700, P =0.070]. Among 827 patients with 4-year follow up CAC scores, 22 (4.9%) participants without CAC at baseline had incident CAC and 243 (63.8%) participants with CAC at baseline had CAC progression. Among subjects without CAC at baseline, higher OPG levels were associated with incident CAC (LnOPG, OR = 5.045. P = 0.042). However, OPG were not associated with CAC progression among participants with CAC at baseline or in total.

Conclusions: Our results indicated that higher serum OPG levels are associated with the presence and development of CAC non-dialyzed CKD patients. However, OPG does not seem to be involved in severity and progression of CAC.

Marijuana Use and CKD in an Urban Population

Flor Alvarado,[1] Dingfen Han,[1] Alan B. Zonderman,[3] Michele K. Evans,[4] Deidra C. Crews.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Intramural Research Program, NIA, NIH, Baltimore, MD; [4]National Institutes of Health/National Institute on Aging, Baltimore, MD.*

Background: Marijuana is the most commonly used illicit drug in the US. Little is known about the relation of marijuana with kidney outcomes. We examined the association of marijuana use and CKD among a cohort of African American and white adults in Baltimore, Maryland.

Methods: We examined baseline data from the Healthy Aging in Neighborhoods of Diversity across the Life Span study. Marijuana use was self-reported and defined as never, former or current. CKD outcomes were prevalent reduced kidney function (eGFR <60 ml/min/1.73m^2) or prevalent albuminuria (urine albumin-to-creatinine ratio (ACR) >=30 mg/g). The association of marijuana use with CKD outcome was examined using multivariable logistic regression.

Results: Among 2352 participants, there were 56% never, 30% former and 14% current marijuana users. Current marijuana users were younger, with fewer yrs of education, and were more likely to be male, African American and use cigarettes, opiates and/or cocaine than never or former marijuana users; but were less likely to have hypertension or diabetes. Overall prevalence of reduced kidney function was 5.3%, with 6.1% of never, 4.6% of former and 3.4% of current marijuana users having reduced kidney function. Overall prevalence of albuminuria was 11.5%, with 12.2% of never, 10.9% of former and 9.7% of current marijuana users having albuminuria. There was no independent association of marijuana use with reduced kidney function or albuminuria.

Conclusions: Marijuana use was prevalent among this urban population. We found no independent association of marijuana use with prevalent CKD. The effects of marijuana use on long term renal outcomes warrants further study.

Logistic regression models of reduced kidney function by marijuana use status

Model	Marijuana Use	Odds Ratio (95% CI)

Effect of -55C/T Polymorphism of Uncoupling Protein 3 Gene on Risk for New-Onset Diabetes in Chinese Peritoneal Dialysis Patients: A Prospective Cohort Study

Yun Chen,[1] Shuqi Dai,[1] Da Shang,[1] Chuan-Ming Hao,[2] Tongying Zhu.[1] *[1]Huashan hospital, Fudan university, Shanghai, China; [2]Huashan Hosp., Shanghai, China.*

Background: Patients who have no history of glucose intolerance could develop diabetes mellitus after the initiation of PD therapy due to a high glucose load. Different genetic background may result in risk modulation. However, it has been rarely explored among PD patients. Uncoupling protein 3 (UCP3) belongs to a family of mitochondrial transporters and is associated with energy homeostasis. The aim of our study was to investigate the effect of polymorphism of the UCP3 promoter (–55C/T) on the risk of new-onset diabetes mellitus (NODM) in PD patients.

Methods: Non-diabetic patients newly started on PD therapy between May 2005 and March 2018 were recruited (n=150). The -55C/T polymorphism of UCP3 was genotyped in all participants at baseline. Patients were divided into two groups based on the genotypic difference. The cohort was followed for up to 165 months (median: 60.1 months; interquartile range: 34.1 months). Cox regression models were used to analyze the impact of -55C/T polymorphism on risks of NODM. Association between glucose intolerance and genotypes were further ascertained in a second cohort of HOMA-IR low and high subjects.

Results: 62 patients (41.3%) had the genotype -55CC (wild group), whereas 88 patients (58.7%) were T carriers (mutant group). During the follow-up, 14 NODM occurred in the mutant group while only 4 occurred in the wild group. Patients in the mutant group experienced significantly higher morbidity (HR: 3.324; 95% CI: 1.088 to 10.151; p = 0.035). Even after adjustments for age, body mass index, total cholesterol, triglycerides, and HOMA-IR, genotypes with T allele remained an independent predictor of NOMD morbidity (HR: 5.804; 95% CI: 1.739 to 19.375; p = 0.004). In the mutant group, HOMA-IR values were higher. Frequencies of the T allele were 27.7% in the HOMA-IR low group compared with 42.1% (p=0.009) in the HOMA-IR high group. The variant of T allele was significantly associated with a higher HOMA-IR value (OR: 2,287; 95% CI:1.177-4.445; p=0.015).

Conclusions: The variant of T allele of UCP3 -55C/T polymorphism was associated with high insulin resistance and was an independent predictor of NODM in PD patients. Early identification of the genotype may provide scientific basis for clinic management of PD patients, improving the surveillance and prevention of diabetes.

GLP-1 Analogue Ameliorates Progression of Not Only Left Ventricular Hypertrophy But Also Atrial Volume in Patients with Type 2 Diabetes Mellitus on Peritoneal Dialysis

Takeyuki Hiramatsu. *Konan Kosei Hospital, Konan Aichi, Japan.*

Background: Diabetes mellitus (DM) is a progressive multifactorial disease associated with cardiovascular complications. Patients undergoing peritoneal dialysis also experience an increased incidence of cardiovascular disease. To prevent progression of systemic cardiovascular complications in DM patients, glycemic control is important. Moreover, left ventricular mass index (LVMI) or left atrial volume index (LAVI) were known to be the predictive factors for mortality in dialysis patients. In this study, we examined the efficacy and safety of the glucagon-like peptide analogue (GLP-1) to treat type 2 diabetes patients undergoing peritoneal dialysis.

Methods: Thirty-four type 2 diabetes patients who underwent peritoneal dialysis were enrolled. Participants were divided in two groups (Group A; n=24, liraglutide 0.9mg daily, Group B; n=10, duraglutide 0.75mg once a week). Prior to GLP-1 therapy, 16 patients used insulin, 8 used oral antidiabetic agents, and 3 used diet therapy. After liraglutide initiation, biochemical examination and echocardiography was examined at baseline and every 12 months for 36 months.

Results: In Group A, there were no differences in glycemic control before and after initiation of liraglutide. Nevertheless, medical adherence was improved after liraglutide use. After liraglutide use, brain natriuretic peptide (BNP) and human atrial natriuretic peptide (HANP) were significantly decreased. Moreover, echocardiographic finding showed LVMI and LAVI were significantly ameliorated instead of unchanged left ventricular ejection fraction or E/e'. Similar findings were shown after duraglutide use in Group B. (Table)

Conclusions: These findings suggest that GLP-1 analogue for type 2 diabetes patients undergoing peritoneal dialysis improved medical adherence and was effective for ameliorating left ventricular function. Moreover, it may ameliorate progression of diastolic function including E/e' and LVAI.

Higher Neutrophil to Lymphocyte Ratio (NLR) Associates with Poor Clinical Outcome Independent of Traditional Factors in Peritoneal Dialysis Patients

Chen Zhimin,[1,2] Abdul Rashid T. Qureshi,[3] Fei Han,[4] Xishao Xie,[5] Peter Stenvinkel,[6] Bengt Lindholm,[3] Xiaohui Zhang,[8] Jianghua Chen.[7] *[1]Kidney Disease Center, 1st Affiliated Hospital College of Medicine, Zhejiang University, Hang Zhou, China; [2]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [3]Karolinska Institutet, Huddinge, Sweden; [4]First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [5]Kidney Disease Center, The First Affiliated Hospital, Medical School of Zhejiang University, Hangzhou, China; [6]Karolinska University Hospital Huddinge, Stockholm, Sweden; [7]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [8]Zhejiang University, Hangzhou, China.*

Background: Neutrophil to lymphocyte ratio (NLR) is an inexpensive and widely available biomarker of inflammation that predicts clinical outcomes in dialysis patients. However, the association between NLR and mortality among patients treated with peritoneal dialysis (PD) is not fully explored.

Methods: In 767 incident PD patients (median age 50 years, 57 % males, 15% diabetes and 6% cardiovascular disease, CVD), baseline NLR andother metabolic biomarkers potentially linked to CVD were analysedin relation to mortality during follow up period of up to 60 months. All-cause and cardiovascular mortality risk associated with NLRwere analyzed with competing-risk regression models with transplantation as competing risk, adjusting for all investigated covariates.

Results: Patients with highest tertile of NLR were older, had higher creatinine and BMI and low serum albumin and parathyroid hormone (iPTH). In univariate analysis, NLR associated with white blood cell count (rho=-0.33, p=0.001), age (rho=0.10, p=0.01), calcium (rho=-0.10, p=0.01), iPTH (rho=0.09, p=0.01) and C-reactive protein (n=644; rho=0.10, p=0.01). Highest tertile of NLR associated with high all-cause mortality risk compared with low + middle tertiles, sub-hazard ratio (sHR) of 1.79 (95% CI, 1.18-2.73; p=0.006), and high CVD mortality risk, sHR 1.55 (95% CI, 0.85-2.85; p=0.01)

after adjusting for Framingham's score, presence of CVD, circulating levels of uric acid, creatinine, calcium, phosphate, Hb, iPTH, alkaline phosphatase, ALAT and ASAT, and calendar year of recruitment.

Conclusions: In patients undergoing PD, higher NLR was associated with increased all-cause mortality risk, independently of Framingham's risk score and additional confounders, suggesting that this biomarker of inflammation is a useful prognostic tool in PD patients.

SA-PO936

TH1 and TH2 Immune Response to External Stimuli in Patients on Peritoneal Dialysis

Arshi Rizwan,[1] Sandeep Mahajan.[2] *[1]Nephrology, All India Institute of Medical Sciences, New Delhi, India; [2]All India Institute of Medical Sciences, New Delhi, India.*

Background: Infections remain leading complication in patients undergoing peritoneal dialysis (PD). Peripheral blood mononuclear cells (PBMCs) provide first-line defense against invading pathogens. Cytokines are central host molecules involved in modulating the host environment during inflammatory conditions. Though few studies have demonstrated expression of cytokines from stimulated PBMCs in hemodialysis patients, no study has systematically looked at their function among patients on PD. We evaluated cytokines expression in PBMCs stimulated by various external stimuli in patients on peritoneal dialysis (PD group), patients having chronic kidney disease stage 5 not on dialysis (CKD group) and compared it with those of healthy controls.

Methods: PBMCs were isolated as per standard procedure and were seeded in tissue culture plates in a concentration of 1 × 106 cells/well. They were stimulated with phytohaemagglutinin (PHA, a potent T- and B-cell mitogen), peritoneal dialysate effluent (DE) and fresh peritoneal dialysis fluid (PDF; Baxter, India). To evaluate the cytokine productions by stimulated PBMCs, ELISA was performed.

Results: In CAPD patients the expression of TH1 (IL- 1β, TNFα, IFNg), TH2(IL-10, IL-4)cytokines from PBMCs stimulated by dialysis effluent was significantly lower, compared with CKD5 (*P*=.001, *P*=.001, *P*=.001, *P*=.001, and*P*=.001*P*=.004, respectively) and healthy controls (*P*=.001, *P*=.001, *P*=.001, *P*=.001, and *P*=.001, *P*=.001, respectively). Th1 (TNF-α, IFN-g, IL-1β,), Th2 (IL-4) and regulatory (IL-10) cytokines were significantly lower in PD patients when compared with healthy controls stimulated by dialysis effluent. PBMCs of PD patients stimulated by fresh fluid expressed reduced Th1 cytokines than those dialysis effluents. Cytokine immune response was significantly reduced when stimulated with PHA and dialysis effluent in PD patients as compared CKD5 patients and controls. Cytokines values were significantly more with PHA followed by DE and PDF respectively in each group.

Conclusions: Polarization of helper T-cells in response to mitogenic stimulation was blunted in CAPD patients compared with controls and CKD 5 resulting in a significant decrease in both Th1 cells and Th2 cells. These studies suggest that the clinical presentation of the dialysis was influenced by the type of cytokine (Th1 and Th2) production.

T Regulatory Cells in Uremia: Effect of the First Peritoneal or Hemodialysis Treatment

Carlotta Caprara,[1] Valentina Corradi,[2] Rahul Sharma,[3] Elisa Scalzotto,[1] Massimo de Cal,[2] Claudio Ronco.[4] *[1]IRRIV, Vicenza, Italy; [2]San Bortolo Hospital, Vicenza, Italy; [3]University of Virginia, Charlottesville, VA; [4]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy.*

Background: A major challenge for the immune system is to preserve tolerance to self while maintaining the ability to fight foreign pathogens and infectious agents. This function is largely performed by the $FOXP3^+$ T-regulatory (Treg) cells. In the literature, contrasting results have been reported about the influence of dialysis on Treg cells, in chronic kidney disease stage G5 (CKD G5) patients that show activated but impaired immune system. The aim of this study is to evaluate the changes in Treg cells numbers before and after the first dialysis treatment.

Methods: Peripheral blood samples for this pilot study were obtained from 21 CKD G5 patients not yet on dialysis (CKD G5): 8 started hemodialysis (HD, N = 8), 13 started peritoneal dialysis (PD, N = 13). Treg were studied by flow cytometry using CD3-PerCP; CD4-FITC; CD25-PECy7; CD127-PE and FOXP3-APC antibodies. Time point: T0 (before the first dialysis treatment); T1 (after 1 month). We performed Wilcoxon test for dependent samples to compare the mean percentage difference between T0 and T1 (Δ %): (100*(T1-T0)/T0).

Results: The total cohort (8HD and 13PD, n = 21) included 88.9% and 77% males in HD and PD groups respectively. Mean age was 68 in HD group and 67 in PD group. The proportion of lymphocytes and T lymphocytes did not change before and after the first dialysis treatment (as evaluated 1 month after the start of dialysis) in PD and HD patients. Treg cells (considered either as $CD25^+$ $FOXP3^+$, $Foxp3^+$ or $CD25^+$ $CD127^+$) analyzed as percentage of lymphocytes showed a statistically significant increase post-PD (median=35.92; p=0.0425 for $CD25^+$ $FOXP3^+$; median=30.85; p=0.0479 for $FOXP3^+$ and median=23.71; p=0.0215 for $CD25^+$ $CD127^-$); The same populations did not change after the first HD session (median=0.07; p=0.843 for $CD25^+$ $FOXP3^+$; median=2.32; p=0.945 for $FOXP3^+$ and median=6.69; p=0,742 for $CD25^+$ $CD127^-$).

Conclusions: Our study is the first to evaluated the effect of PD or HD treatment on the status of T-regulatory cells to understand their role in immune homeostasis. PD was more effective in increasing Tregs levels when analyzed at one month post dialysis and may contribute to improvement of inflammatory status. Thus, PD may contribute to better outcomes for patients with renal dysfunction by not only restricting inflammation, but also maintaining homeostasis of peritoneal and renal tissues.

SA-PO938

Implication of Inflammasome Activation in the Progression of Peritoneal Fibrosis in Mice

Hiroyuki Kadoya, Yuji Sogawa, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Medical School, Kurashiki, Japan.*

Background: During peritoneal dialysis, the peritoneum is exposed to bioincompatible dialysate, which causes tissue fibrosis, which then limit the long-term effectiveness of peritoneal dialysis. Peritoneal fibrosis is the end result of chronic inflammation reactions induced by a variety of stimuli including peritonitis, allergic responses. Thus, understanding the molecular events that drive fibroproliferation and matrix deposition has been a favored area of investigation. However, the detailed mechanisms underlying peritoneal fibrosis process have not been elucidated. Considering that activation of inflammasome triggers chronic inflammation, which ultimately causes fibrosis. We investigated whether inflammasome activation causes peritoneal fibrosis.

Methods: We used ASC-deficient mice (ASCKO) to investigate the role of inflammasome, which ASC are critical components of the inflammasome. C57Bl/6 mice (WT) were used for control. Peritoneal fibrosis was induced by chlorhexidine gluconate (CG) into the peritoneal cavity of mice every other day for 4 weeks. VX-765 (100 mg/kg/day), an inhibitor of caspase-1 activity, was administered by gavage for 2 weeks. The mice were divided into the following groups; (1) WT-vehicle, (2) WT-CG, (3) ASCKO-vehicle, (4) ASKO-CG, and (5) WT-CG/VX-765.

Results: After exposure to CG, WT-CG mice showed the progression of peritoneal fibrosis evaluated by Masson's trichrome stain, and also been observed to enhance mRNA expression of TGF-β in peritoneal tissue. Increased expressions of inflammasome components, NLRP-3 and ASC, were demonstrated in WT-CG. Increased Caspase-1 activity and concomitant overproduction of IL-1β and IL-18 were also demonstrated in the WT-CG. These changes were suppressed in the ASCKO-CG and VX-765 injected mice. Furthermore, ASC-positive cells were merged with the immunofluorescent staining for the macrophage marker F4/80. Therefore, inflammasomes were mainly activated in the infiltrating macrophages.

Conclusions: Our results suggest that inflammasome activation plays a pivotal role in the development of peritoneal fibrosis in infiltrated macrophages. Thus, inflammasome activation in macrophages could be a new therapeutic target for chronic inflammation-induced peritoneal fibrosis.

SA-PO939

Innate Immunity Dysfunction: A Prospective Study on Peritoneal Dialysis and Hemodialysis

Ana C. Figueiredo,[3] Rita Leal,[1,2] Helena O. Sa.[1,2] *[1]Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Nephrology Universitary Clinic, Medicine Faculty of University of Coimbra, Coimbra, Portugal; [3]Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal.*

Background: The immunological disorder associated with chronic kidney disease is complex since there is a coexistence of a proinflammatory state and immunological deficiency, both contributing to patients' morbidity and mortality. The immune dysfunction on end-stage renal disease covers both innate and adaptive immunity, although disturbances in the innate branch are far less described in the literature. The aim of the present work is to study the innate immune system changes in patients undergoing hemodialysis and peritoneal dialysis, and if significant residual renal function influences innate immunity.

Methods: A prospective, case-control study was performed using peripheral blood samples from 21 patients undergoing PD, 20 patients undergoing HD and 12 healthy patients. Whole blood cells were analyzed and quantification of leukocyte subpopulations and surface molecules was made by flow cytometry using different fluorescent antibody conjugates.

Results: There was a significant decrease in monocytes and dendritic total cell counts in dialysis patients compared to healthy controls. Natural killer cells in hemodialysis patients, compared to peritoneal dialysis and controls, had enhanced expression of the receptors NKp30, NKp44, CD94/NKG2C, and IFNg, indicating enhanced cytokine production, and increased expression of CD57. Hemodialysis patients also presented more pro-inflammatory markers in iNKT and gdT cells than peritoneal dialysis patients.

Conclusions: Our study suggests an innate immunity dysfunction in dialysis patients, more evident in hemodialysis patients that express a proinflammatory profile and chronic activation of the innate immunity system.

SA-PO940

Mean Corpuscular Volume Associates with Clinical Outcome in Incident Peritoneal Dialysis Patients

Chen Zhimin,[1,2] Abdul Rashid T. Qureshi,[3] Xiaohui Zhang,[8] Fei Han,[4] Xishao Xie,[5] Bengt Lindholm,[3] Peter Stenvinkel,[6] Jianghua Chen.[7] *[1]Kidney Disease Center, 1st Affiliated Hospital College of Medicine, Zhejiang University, Hang Zhou, China; [2]Division of Renal Medicine and Baxter Novum, Department of Clinical Sciences, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [3]Karolinska Institutet, Huddinge, Sweden; [4]First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [5]Kidney Disease Center, The First Affiliated Hospital, Medical School of Zhejiang University, Hangzhou, China; [6]Karolinska University Hospital Huddinge, Stockholm, Sweden; [7]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [8]Zhejiang University, Hangzhou, China*.

Background: Mean corpuscular volume (MCV), a measure of the average size of circulating erythrocytes, is used for differential diagnosis of anemia and for monitoring macrocytosis. While several studies revealed that MCV is associated with mortality in various clinical settings, it is unclear whether this association applies to PD patients. We investigated the relationship of MCV with all-cause and cardiovascular mortality in incident PD patients.

Methods: In 767 incident PD patients (median age 50 years, 57 % males, 15% diabetes, DM, and 6% cardiovascular disease, CVD), MCV andother metabolic biomarkers potentially linked to CVD were analysedat baseline. We investigated factors associated (Spearman correlations) with MCV at baseline and during follow up period of up to 60 monthswe analysed the association of MCV with mortality risk using competing-risk regression models with transplantation as competing risk and adjusting for covariates.

Results: In univariate analysis, MCV associated with white blood cell count (rho=-0.12, p=0.001), age (rho=0.15, p<0.001), BMI (rho=-0.15, p<0.001), gender (rho=-0.14, p=0.002), uric acid (rho=-0.15, p<0.001), HDL cholesterol (rho=0.10, p=0.005), parathyroid hormone (rho=0.12, p=0.001), ASAT (rho=0.12, p=0.001) and DM (rho=-0.09, p=0.01). Compared with middle+ high tertiles, the lowest tertile of MCV associated with decreased all-cause mortality risk, sub-hazard ratio (sHR) of 0.61 (95% CI, 0.42-0.89; p=0.01), and with decreased CVD mortality risk, sHR 0.50 (95% CI, 0.29-0.87; p=0.01) after adjusting for age, gender, DM, CVD and calendar year of recruitment.

Conclusions: In incident PD patients, after adjusting for age, sex, and presence of CVD and diabetes, low MCV was independently associated with decreased all-cause and CVD mortality risk. These results suggest that monitoring of MCV may provide useful prognostic information in patients treated with PD.

SA-PO941

Genetic or Pharmacologic Blockade of Enhancer of Zeste Homolog 2 Inhibits the Progression of Peritoneal Fibrosis

Na Liu,[1] Yingfeng Shi,[2] Andong Qiu,[4] Shougang Zhuang.[3] *[1]shanghai east hospital, Shanghai, China; [2]Nephrology department Shanghai Dongfang Hospital, Shanghai, China; [3]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [4]Tongji University, Shanghai, China*.

Background: Dysregulation of histone methyltransferase enhancer of zeste homolog 2 (EZH2) has been implicated in many cancers. However, the role of EZH2 in peritoneal fibrosis remains unknown.

Methods: We investigated EZH2 expression in peritoneal dialysis (PD) patients and assessed its role in peritoneal fibrosis induced by chlorhexidine gluconate (CG) or high glucose peritoneal dialysis fluid (PDF) in mice by using 3-deazaneplanocin A (3-DZNeP), and EZH2 conditional knockout mice in fibroblasts.

Results: An abundance of EZH2 was detected in the peritoneum of patients with PD associated peritonitis and the dialysis effluent of long-term PD patients. EZH2 was also highly expressed in the peritoneum of mice after injury by CG or PDF, and treatment with 3-DZNeP attenuated peritoneal fibrosis and inhibited activation of several pro-fibrotic mechanisms. Moreover, delayed administration of 3-DZNeP inhibited peritoneal fibrosis progression, reversed established peritoneal fibrosis and reduced matrix metalloproteinases-2 (MMP-2) and MMP-9 expression. Finally, EZH2-KO mice exhibited less peritoneal fibrosis compared with EZH2-WT mice. In cultured peritoneal mesothelial cells, EZH2 inhibition resulted in suppression of α-SMA and Collagen I and preservation of E-cadherin.

Conclusions: These results indicate that EZH2 is a key epigenetic regulator that promotes peritoneal fibrosis. Targeting EZH2 may have the potential to prevent and treat peritoneal fibrosis.

SA-PO942

Nuclear Factor of Activated T Cells 5 (NFAT5) Mediates Peritoneal Fibrosis via Modulation of Nod-Like Receptor-3 (NLRP3) Inflammasome

Duk-Hee Kang,[1] Eun sun Ryu,[1] Dal-ah Kim,[1] Hyun-Jung Kang,[1] You Jin Kim,[3] Sun-Hee Park,[2] Yong-Lim Kim.[2] *[1]Ewha University College of Medicine, Seoul, Republic of Korea; [2]Kyungpook National University Hospital, Daegu, Republic of Korea; [3]Kyungpook National University, Daegu, Republic of Korea*.

Background: NLRP3 inflammasome is a multiprotein oligomer that promotes the maturation of IL-1β and IL-18. NFAT5 is an essential transcription factor regulating cellular homeostasis to hypertonicity-induced osmotic stress, and recently reported as pro-inflammatory and pro-fibrotic mediator. We investigated whether NFAT5 played a role in peritoneal fibrosis and epithelial-to-mesenchymal transition (EMT) via a modulation of NLRP3 inflammasome

Methods: The expressions of NFAT5 and components of NLRP3 inflammasome (NLRP3, ASC, and procaspase-1) were evaluated in human peritoneal mesothelial cells (HPMCs) and animal model of peritoneal fibrosis. Effects of siNFAT5, siNLRP3, siASC or NLRP3 inflammasome inhibitor (MCC950) on EMT of HPMCs were evaluated. Peritoneal EMT and fibrosis were compared in adenoviral vector of TGFβ (ad-TGFβ)-injected NFAT5 +/+ and +/- mice

Results: TGFβ increased NFAT5 expression and its nuclear translocation in HPMCs. TGFβ-induced EMT was associated with an up-regulation of NLRP3, ASC, procaspase-1 and an increased production of IL-1β/IL-18. siNFAT5 ameliorated TGFβ-induced NLRP3 inflammasome pathway and EMT with an increase in E-cadherin promotor activity as well as a decrease in snail expression and nuclear translocation of β-catenin. siNLRP3, siASC, and MCC950 also alleviated TGFβ-induced EMT. In NFAT5$^{+/-}$ mice, ad-TGFβ induced peritoneal fibrosis were ameliorated with a reduction in peritoneal thickness compared to wild-type NFAT5 $^{+/+}$ mice

Conclusions: This data suggest NFAT5 plays a key role in peritoneal fibrosis via tonicity-independent mechanism by either an inhibition of E-cadherin transcription and activation of NLRP3 inflammasome. Modulation of NFAT5 and NLRP3 inflammasome in peritoneum could be a novel approach to protect peritoneal fibrosis in PD patients

SA-PO943

Crucial Role of NLRP3 Inflammasome in the Development of Peritoneal Dialysis-Related Peritoneal Fibrosis

Erika Hishida,[1,2] Takanori Komada,[1,2] Tetsu Akimoto,[1] Masafumi Takahashi,[2] Daisuke Nagata.[1] *[1]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Yakushiji, Shimotsuke-shi, Tochigi, Japan; [2]Division of Inflammation Research, Center for Molecular Medicine, Jichi Medical University, Yakushiji, Shimotsuke-shi, Tochigi, Japan*.

Background: Long-term peritoneal dialysis (PD) therapy leads to peritoneal inflammation and fibrosis. However, the mechanism underlying PD-related peritoneal inflammation and fibrosis remains unclear. Recent evidence indicates that sterile inflammation triggered by danger signals is mediated through a multiprotein complex called the NLRP3 inflammasome. In the present study, we investigated the role of NLRP3 inflammasome in the pathophysiology of peritoneal fibrosis using a mouse model of methylglyoxal (MGO)-induced PF.

Methods: C57BL/6J (wild-type [WT]) and ASC-deficient mice were mainly used throughout the study. PF was induced by intraperitoneal injection of peritoneal dialysis fluid (PDF) (100 mL/kg) containing 40 mM MGO solution for 3 weeks, 5 consecutive days per week. The control group received the same volume of PDF. In in vitro experiments, human umbilical vein endothelial cells (HUVEC) and primary mouse lung vascular endothelial cells (MLVEC), were stimulated with MGO.

Results: Inflammasome-related molecules were upregulated in the peritoneum of MGO-treated mice. MGO induced parietal and visceral peritoneal fibrosis in wild-type mice, which was significantly attenuated in mice deficient in NLRP3, ASC and interleukin-1β. ASC deficiency reduced the expression of inflammatory cytokines and fibrotic factors, and the infiltration of macrophages. However, myeloid cell-specific ASC deficiency (ASC$^{f/f}$; LysM$^{cre/+}$) failed to inhibit MGO-induced peritoneal fibrosis. MGO caused hemorrhagic ascites, fibrin deposition, and plasminogen activator inhibitor-1 upregulation, but all of these manifestations were inhibited by ASC deficiency. Furthermore, in vitro experiments showed that MGO induced cell death via the generation of reactive oxygen species in vascular endothelial cells, which was inhibited by ASC deficiency.

Conclusions: Our results showed that endothelial NLRP3 inflammasome contributes to PD-related peritoneal inflammation and fibrosis, and provide new insights into the mechanisms underlying the pathogenesis of this disorder.

A Novel Device Allows Simplicity and Independence to Peritoneal Dialysis (PD) Patients

Tatiana Tanasiychuk,[1] Daniel Kushnir,[1] Alon Antebi,[1] Jerom Marcuson,[1] Amnon Gil,[1] Oleg Sura,[1] Victor Frajewicki,[1] Sydney Benchetrit,[2] Yael Einbinder.[2] *[1]Carmel Medical Center, Haifa, Israel; [2]Meir Medical Center, Kfar Saba, Israel*.

Background: Although peritoneal dialysis is considered a simple method of renal replacement therapy accesible to almost every one, it is still underutilized worldwide. The barriers could be difficulties in fine motor skills, decreased vision, insecurity of performing a precise method alone, time consumption and more. liberDi's portable PD system (PPDS™) is a newly developed small automatic device intended for PD exchange. It uses a small electric battery operated pump for inflow/outflow mechanism to drain and fill the dialysate at a controllable rate. The device makes the exchange after automatic disinfection of the connectors. The PPDS™ also enables monitoring of effluent dialysate (stream flow, fluid clarity, temperature) and transmits the data to the PD center. This first-in-human open single arm, multicenter clinical trial was performed in 2 different PD units- Carmel Medical Center and Meir Medical Center in Israel. The goal of the study was to verify safety of the liberDi's PPDS™ as primary endpoint toward evaluating its usability and feasibility.

Methods: The trial includes 10 stable chronic adult CAPD patients, treated more than 3 months, used to do at least 3 exchanges daily. During the trial a single exchange was

performed in the PD clinic via the liberDi's PPDS™ under supervision of the PD team, followed by a one-month clinical follow-up.

Results: Average drainage time was 10.7±2.3 min, filling time 8±2.6 min. Three patients noted mild abdominal discomfort at the end of the draining and start of filling (not unusual for them), while one patient showed slow drainage and shifted to a regular manual exchange. None of the patients developed peritonitis during the follow- up period. One patient died due to acute ST elevation myocardial infarction 5 days after the trial procedure, which was considered as unrelated to the procedure itself.

Conclusions: This first-in-human study showed the safety of liberDi's PPDS device demostrating its feasibility in a single automatic PD exchange. Its use seems to be convenient, easy and safe.

The Significance of Mini-PET and Fibrosis-Related Factors in Effluents in Peritoneal Function

Keisuke Horikoshi,[1] Norihiko Sakai,[1] Hisayuki Ogura,[1] Koichi Sato,[1] Taro Miyagawa,[1] Hiroyuki Yamauchi,[1] Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[1] Yasunori Iwata,[1] Miho Shimizu,[1] Satoshi Oota,[2] Yoichi Ishida,[2] Takashi Wada.[1] *[1]Kanazawa University, Kanazawa, Japan; [2]Toyama City Hospital, Toyama, Japan.*

Background: Peritoneal dysfunction characterized by peritoneal fibrosis is the problem of long-term peritoneal dialysis. Recent studies have reported that sodium sieving (ΔNa) in mini-PET has the correlation with free water transport (FWT) and peritoneal fibrosis. We previously reported that lysophosphatidic acid (LPA) signaling-dependent connective tissue growth factor (CTGF) was significant to peritoneal fibrosis. Therefore, we examined the association of mini-PET markers with fibrosis-related factors in effluents.

Methods: We performed mini-PET (1hr-dwell) for 43 patients (60 samples) and assessed peritoneal function-related factors such as ΔNa and FWT. ΔNa was determined by the difference of sodium concentration in dialysate between 1hr and 0hr, and FWT by ultrafiltration volume except for the influence of sodium removal. In addition, we measured autotaxin (ATX), which is the enzyme of LPA production pathway, and CTGF concentrations as the fibrosis-related factors. We also performed standard-PET (4hrs-dwell) to assess D/P Cr and D/D0, and estimated the association of these values with mini-PET markers as well as the fibrosis-related factors.

Results: ΔNa had the correlation with FWT (r=0.86, p<0.01), D/P Cr (r=-0.28, p<0.05), D/D0 (r=0.40, p<0.01). In cases observed over the years (n=16), ΔNa at 1st year had the correlation with FWT (r=0.82, p<0.01) and D/P Cr (r=-0.65, p<0.01) at 2nd year. The changes of ΔNa had the correlation with the change of ultrafiltration (r=0.61, p<0.05). Moreover, ΔNa had the correlation with ATX (r=-0.80, p<0.01) and CTGF (r=-0.75, p<0.01).

Conclusions: ΔNa and fibrosis-related factors in effluents have the possibility to be the predictive factors of peritoneal function.

SA-PO946

Nintedanib Attenuates the Development and Progression of Peritoneal Fibrosis

Feng Liu,[2] Shougang Zhuang,[1] Chao Yu.[3] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Shanghai East Hospital, Shanghai, China; [3]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China.*

Background: Nintedanib, a FDA approved triple tyrosine kinase inhibitor, has antifibrotic effects in idiopathic pulmonary fibrosis and renal fibrosis. Here, we examined the effect of nintedanib on the development and progression of peritoneal fibrosis.

Methods: Daily intraperitoneal injections of chlorhexidine gluconate (CG) induced peritoneal fibrosis in mouse and TGF-β1 was used to induce fibrotic changes in cultured human peritoneal mesothelial cells. The effects of nintedanib were determined by histochemical and immunofluorescent staining, immunoblot and ELISA analysis.

Results: Administration of nintedanib immediately after injury prevented the onset of peritoneal fibrosis and delayed administration of nintedanib (3 days after the onset of peritoneal fibrosis) halted fibrosis progression. Nintedanib treatment abrogated the increased phosphorylation of PDGFR, FGFR, VEGFR, Src, decreased the expression of extracellular matrix(ECM) protein (Fibronectin and type I Collagen), inhibited the expression if marker proteins of mesenchymal phenotype (α-SMA,β-Vimentin) and transcription factors(Snail and Twist), increased expression E-Cadherin, blocked the phosphorylation of Smad3, STAT3, and NF-κB during peritoneal fibrosis; it also inhibited the accompanying overproduction of proinflammatory cytokines (MCP-1, TNF-α, IL-1β, and IL-6) and the infiltration of macrophages (CD68-positive) to the injured peritoneum, and reduced the peritoneal increase of CD31-positive blood vessels after injury. Moreover, delayed administration of nintedanib significantly induced MMP-2 expression and inhibited TIMP-2 expression. Finally, nintedanib abrogated TGF-β1–induced the epithelial-to-mesenchymal transition, ECM protein overproduction and phosphorylation of aforementioned cell signaling molecules in cultured human peritoneal mesothelial cells.

Conclusions: These results demonstrate that nintedanib may inhibit epithelial-to-mesenchymal transition, extracellular matrix overproduction inflammation and angiogenesis, and improved extracellular matrix degradation, possibly through its blockade of RTKs and Src simultaneously. It suggests that nintedanib may have therapeutic potential in attenuating onset and progression of peritoneal fibrosis.

Deletion of Matrix Metalloproteinase 10 Ameliorates Peritoneal Fibrosis

Takuya Ishimura,[1] Akira Ishii,[1] Keisuke Osaki,[1] Naohiro Toda,[3] Keita P. Mori,[1,2] Takaya Handa,[1] Motoko Yanagita,[1] Hideki Yokoi.[1] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]TMK project, Medical Innovation Center, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Kansai Electric Power Hospital, Osaka, Japan.*

Background: Peritoneal fibrosis is one of major characteristics of peritoneal membrane damage. Our group previously reported highly upregulated genes in the peritoneal membrane from chlorhexidine gluconate (CG)-treated peritoneal fibrosis mice compared with control in microarray analysis, one of which was matrix metalloproteinase-10 (MMP-10). MMP-10 was a proteinase protein degrading components of extracellular matrix (ECM) and was known to be associated with arteriosclerosis or tissue repair. Although deletion of MMP-2 and MMP-9, which were called gelatinases, ameliorated peritoneal fibrosis, the role of MMP-10 has not been elucidated in peritoneal fibrosis yet.

Methods: To investigate the role of MMP-10 in peritoneal fibrosis, we induced peritoneal fibrosis by intraperitoneal injection of chlorhexidine gluconate in wild-type (WT) and MMP-10 knockout (KO) mice. We administrated 0.01 mL/gBW of 0.1% CG in 15% ethanol and 85% phosphate-buffered saline (PBS) 3 times per week for 4 weeks. Control mice received intraperitoneal injection of PBS. Peritoneal sections were stained with Masson's trichrome and were analyzed by immunohistochemical study.

Results: We identified upregulation of MMP-10 by 8.6-times in the peritoneum from CG-treated WT mice by a microarray analysis. There were no histological changes in the peritoneum between PBS-treated WT mice and PBS-treated MMP-10 KO mice. CG-treated WT mice had a remarkable thickening of peritoneum, an increased number of αSMA-, F4/80-positive cells in the peritoneum, and upregulation of MMP-10 mainly within the mesothelial cells and fibroblasts in the submesothelial area of the peritoneum. In contrast, CG-treated MMP-10 KO mice showed reduction of peritoneal thickness and accumulation of αSMA-, F4/80-positive cells in the peritoneum. Furthermore, the peritoneal enhanced expression of Tgfb1, Col1a1, Ctgf, and Ccl2 (MCP1) in WT mice was remarkably reduced in MMP-10 KO mice.

Conclusions: These results indicate that MMP-10 is upregulated in mesothelial cells and fibroblasts in peritoneal injury and can aggravate peritoneal fibrosis. Therefore, inhibition of MMP-10 could become a therapeutic strategy in peritoneal fibrosis.

SA-PO948

Valsartan Ameliorates High Glucose-Induced Peritoneal Fibrosis by Blocking mTORC1 Signaling

Liu Jing. *Affiliated Drum Tower Hospital, Medical School of Nanjing University, Institute of Nephrology, Nanjing City, China.*

Background: Increasing evidences suggest that angiotensin II type 1 receptor (AT1R) blockers prevent peritoneal fibrosis (PF) under high glucose (HG) conditions. The study aimed to investigate the undefined mechanisms by which AT1R blocker valsartan on HG induced PF.

Methods: We used HG peritoneal dialysis solution (PDS) in a mouse peritoneal dialysis model to induce *in vivo* PF and HG in human peritoneal mesothelial cells (HPMCs) *in vitro* to stimulate extracellular matrix (ECM) accumulation.

Results: After the injection of 4.25% PDS for 4 weeks, mice showed typical features of PF, including markedly increased peritoneal thickness, excessive matrix deposition, increased peritoneal permeability, and higher expressions of ECM markers, such as α-smooth muscle actin (α-SMA) and collagen I. Valsartan significantly ameliorated these pathological changes at either week 6 or 8. These effects of valsartan were closely correlated with a decrease in the activation of mammalian target of rapamycin complex 1 (mTORC1) pathway, which was mediated through the down-regulation of protein expressions of phosphorylated-mTOR (p-mTOR), p-eukaryotic initiation factor 4E-binding protein 1 (p-4EBP1), and P-p70 S6 kinase (p-S6K1). Further analysis showed the protein expression of p-mTOR, p-4EBP1, p-S6K1 was positively correlated with the expression of either α-SMA or collagen I in the peritoneum. *In vitro*, HG increased the protein expressions of α-SMA and collagen I in a dose dependent manner, while valsartan significantly inhibited HG-induced ECM accumulation in HPMCs. The effect was also accompanied by a decrease in the activation of mTORC1 pathway. Furthermore, mTOR agonist-MHY1485 could reverse the downregulation of ECM components in HPMCs, even in the presence of valsartan.

Conclusions: We conclude that valsartan shows a protective effect on HG-induced PF by inhibiting the activity of mTORC1 pathway.

Pasp Deletion Mutation Reduced the Virulence and Pathogenic Ability of Pseudomonas aeruginosa

Tianjun Guan,[2] Anqun Chen,[1] Wan Ziming.[3] *[1]ZhongShan Hospital, Xiamen University, Xiamen, China; [2]nephrology, xiamen zhongshan hospital, Xiamen, China; [3]Nephrology, The first affiliated hospital of chongqing medical university, Chongqing, China.*

Background: Pseudomonas aeruginosa is a very important conditional pathogen commonly existing in the environment, and it is the main pathogen of catheter-related infection in peritoneal dialysis. The formation of intraductal biofilm is an important reason, and the expression of PasP protein is increased in Pseudomonas aeruginosa, which is easy to form biofilm. It is intended to further explore the effect of PasP protein on the virulence of Pseudomonas aeruginosa.

Methods: the pasP gene of Pseudomonas aeruginosa PAO1 was knocked out by homologous recombination method, and the PAO1::pasP strain was constructed. The following parameters of parental bacteria and homologous recombinant bacteria were observed: colony morphology, biofilm forming ability, minimum bactericidal concentration of common antibiotics to bacteria, tolerance of bacteria to temperature, determination of bacterial virulence (pyocyanin, protease, elastase). Difference analysis of protein spectrum were performed;

Results: the pasP gene of Pseudomonas aeruginosa PAO1 was successfully deleted, PAO1::pasP was successfully constructed by homologous recombination. The relative virulence of PAO1::pasP was weaker than that of parent bacteria, including the weakening of biofilm formation ability and the decreasing tolerance to temperature. the production of pyocyanin, protease, elastase were all decreased. The expressions of two-component reaction regulator, two-component sensor, ATP binding protein of ABC transporter, bacteriophage protein, purine binding protein, and the two-component reaction regulator, two-component sensor, ATP binding protein, bacteriophage protein and purine binding protein of PTX transporter decreased, Aer2 protein, type IV flagellin Flp and rhamnose glycosyltransferase subunit A were significantly lower than in PAO1::pasP strain than in parental bacteria.

Conclusions: Pseudomonas aeruginosa pasP gene is involved in the biofilm formation and QS sensing system, and pasP gene deficient strains show weaker bacterial virulence and pathogenic ability.

SA-PO950

Effluent DcR2 Is a Novel Biomarker for Peritoneal Fibrosis in Peritoneal Dialysis Patients

Jia Chen,[1] Yani He.[2] *[1]Daping hospital, Chongqing, Chongqing, China; [2]Daping Hospital, Chongqing, Chongqing, China.*

Background: Peritoneal fibrosis is the most severe complication of peritoneal dialysis (PD), but lack of noninvasive biomarkers for monitoring the rate of progression of peritoneal fibrosis. Decoy receptor 2(DcR2), a marker of senescence, has been used to evaluate the degree of differentiation of tumors. The aim of this study is to determine whether peritoneal effluent DcR2 could serve as a novel specific and sensitive biomarker for assessing peritoneal fibrosis.

Methods: 149 PD patients (PD duration>6 months) were enrolled in our unit from 2008 to 2018, free from acute infection and recent peritonitis. The fibrosis of peritoneal biopsy tissues were detected by Masson trichrome staining. Effluent and serum DcR2 levels were measured by ELISA and effluent appearance rate (AR) were calculated. The association of DcR2-AR with clinical parameters were analyzed. Receiver operating characteristics (ROC) curve analyzed area under the curve (AUC) of AR DcR2 for assessing peritoneal fibrosis. Double staining was undertaken for DcR2 with peritoneal mesothelial cells and fibroblast marker vimentin and fibrotic markers α-SMA and FN.

Results: There were 75 patients with peritoneal fibrosis and 74 without. Effluent and serum DcR2 levels had no statistical difference between two groups, but DcR2-AR levels were higher in patients with peritoneal fibrosis compared with normal peritoneum. Effluent DcR2-AR levels were associated with Duration of PD, total glucose exposure, past peritonitis (%) and 4h D/P. The area of under curve was 0.74 for peritoneal fibrosis, with a sensitivity of 73% and specificity of 76%, respectively. DcR2 was co-expressed with vimentin and colocalized with α-SMA and FN in peritoneal tissue.

Conclusions: Effluent DcR2 can could potentially serve as a novel biomarker for peritoneal fibrosis and may reflect senescence of fibroblasts in PD patients.

Hepcidin, Iron Status, and Mineral Metabolism in Peritoneal Dialysis Patients

Hyo Jin Kim,[1] Minjung Kang,[2] Tsogbadrakh B. Bodokhsuren,[2] Eunjeong Kang,[2] Kook-Hwan Oh.[3] *[1]Dongguk University College of Medicine, Gyeongju-si, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Few studies have examined the association between hepcidin, iron status, and bone mineral metabolism in peritoneal dialysis (PD) patients. The present study aimed to investigate the association of hepcidin with iron status and bone mineral metabolism in PD patients.

Methods: Patients who started PD at Seoul National University Hospital from January, 2010 to August, 2018 and who had not received renal replacement therapy before and whose baseline serum samples were available were enrolled. Serum hepcidin levels were measured by enzyme-linked immunosorbent assay (ELISA) using Hepcidin 25 (bioactive) HS ELISA kits (DRG Diagnostics, Marburg, Germany), according to the manufacturer's protocol. Multivariable linear regression analysis was used to identify the association of hepcidin with iron status and bone mineral metabolism.

Results: A total of 162 incident PD patients were analyzed. The patients were 45.4±13.6 years old and 78 (48.1%) were male. The median serum hepcidin level was 50.67 ng/mL (interquartile range, 25.34-83.61 ng/mL). Mean hemoglobin level was 10.4±1.3 g/dL. The prevalence of hemoglobin <10 and <11 g/dL were 40.1% and 67.9%, respectively. Hemoglobin (Pearson correlation, -0.19; P = 0.014) and ferritin (Pearson correlation, 0.59; P< 0.001) were associated with hepcidin in unadjusted analysis. In multivariable linear regression analysis with adjustment for multiple confounders, hepcidin was positively associated with ferritin (β=0.66; 95% confidence interval, 0.50-0.81; P< 0.001). There were not significant associations between hepcidin and markers of mineral metabolism: calcium (Pearson correlation, -0.01; P = 0.161), phosphorous (Pearson correlation, -0.05; P = 0.538), LogPTH (Pearson correlation, 0.05; P = 0.554), 25(OH)VitD (Pearson correlation, 0.04; P = 0.683). Hepcidin levels were not significantly different according to use of iron therapy, erythropoiesis stimulating agents or phosphate binders.

Conclusions: Hepcidin was positively associated with ferritin. There were not significant associations between hepcidin and markers of mineral metabolism in our PD patients.

SA-PO952

Prognostic Value of Serum and Dialysate APX-501 in Chronic Dialysis

Jin Joo Cha,[1] Jungmin Joa,[1] Jeonghwan Lee,[2] Jung Pyo Lee,[2] Chun Soo Lim,[2] Hyung Ah Jo,[3] Sang Youb Han,[3] Jong Hyun Jhee,[4] Seon Deok Hwang,[4] Dong-Young Lee,[5] Young Sun Kang,[1] Dae R. Cha.[1] *[1]Korea University, Ansan, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [3]Inje University, GoYang, Republic of Korea; [4]Inha University College of Medicine, Incheon, Republic of Korea; [5]Seoul Veterans Hospital, Seoul, Republic of Korea.*

Background: Patients on chronic dialysis are known to be in a chronic inflammation associated with increased oxidative injury, which results in increased morbidity and mortality. Recently APX-501 protein was identified to have regulatory role on oxidative stress. In the present study, we examined the clinical utility of APX-501 levels in serum and dialysate in chronic dialysis patients.

Methods: This study was a multicenter, prospective study that examined the level of serum and dialysate APX-501 in patients on chronic dialysis. Patients on dialysis (both peritoneal (PD) and hemodialysis(HD)) were enrolled between January 2016 to February 2018. Serum APX-501 level was measured using ELISA method. Time to overall mortality was recorded as the primary endpoint. For secondary endpoint, admission for major adverse cardiac events (MACE) and admission due to infection were recorded.

Results: Of 216 patients, patient on PD consisted of 136 patients. 37.5% of PD patients were enrolled initiating PD as the first dialysis modality (defined as new PD). During follow up period of 625±172.8 days, 15 patients died (6.9%), 27 experienced MACE (12.5%), 64 admitted to the hospital due to infection from any cause (29.6%). PD peritonitis event was reported in 35 patients (25.7% of PD group), of which 17(48.6%) patients were who initiated PD for the first time. Serum APX-501 did not predict overall mortality, MACE or acute infection event during the follow up period. In PD patients, dialysate APX-501 level was increased in patients who were initiating PD, and those with increased level of baseline dialysate APX-501 were at an increased risk of incidence for infection including PD peritonitis.

Conclusions: Dialysate APX-501 level may help to predict the risk of infection, especially the risk of PD peritonitis. Whether it can predict imminent PD peritonitis should be studied.

SA-PO953

Systems Biology Analysis of Lithium-Mediated Cytoprotection in PD

Rebecca Herzog,[1] Guadalupe T. Gonzalez- Mateo,[2] Maria Bartosova,[3] Claus peter Schmitt,[4] Christoph Aufricht,[1] Klaus Kratochwill.[1] *[1]Medical University of Vienna, Vienna, Austria; [2]Molecular Biology Research Centre Severo Ochoa, Spanish Research Council, Madrid, Spain; [3]Center for Pediatric and Adolescent Medicine, Heidelberg, Germany; [4]Centre for Pediatric and Adolescent Medicine, Heidelberg, Germany*.

Background: Peritoneal dialysis fluids (PDF) harm peritoneal cells, leading to transdifferentiation and cell death. Lithium chloride (LiCl), a clinically applicable kinase inhibitor, improved survival of immortalized mesothelial cells. Due to its availability and well-characterized pharmacological profile, LiCl could be a promising molecule to be used as local cytoprotective additive to PDF. The pleiotropic effects of LiCl on mesothelial cells, have not yet been investigated.

Methods: Here, we analyzed the protective potential of LiCl added to PDF in a systems biology approach which combined transcriptomics and proteomics analyses followed by validation in human samples and a chronic mouse model.

Results: PDF with LiCl caused significantly lower cell injury of primary human mesothelial cells in a dose dependent manner. PD-induced cell injury was associated with significantly differential expression of 478 genes and 92 proteins compared to control, LiCl in PDF altered 749 genes and 102 proteins. Pathway over-representation and molecular process enrichment tests showed a strong regulation of angiogenesis related pathways in response to PDF. Analysis of transcripts and proteins that were counter-regulated in PDF with LiCl compared to PDF alone, yielded candidates associated with the LiCl effect, with the small heat shock protein αB-crystallin as most strongly regulated candidate. αB-crystallin was significantly upregulated by PDF but close to control level with LiCl in the omics and targeted analyses. Modulated expression of αB-crystallin, which has been described as regulator of VEGF-mediated angiogenesis, confirmed its regulatory involvement in PD-induced pathomechanisms. Uremic as well as non-uremic mice showed significantly reduced peritoneal membrane thickening and transdifferentiation with LiCl. PDF-induced increased VEGF and αB-crystallin levels in peritoneal membranes were reduced with LiCl. The relevance was confirmed in significantly upregulated abundances of mesothelial αB-crystallin in biopsies from children treated with PD, compared to age-matched healthy controls or with CKD5.

Conclusions: The beneficial effects of LiCl in PDF may be explained by counter-regulation of the PD-induced angiogenesis via the novel target αB-crystallin. Reduction of cell damage and fibrosis suggests therapeutic potential of this intervention.

SA-PO954

Probiotics Decreased Concentrations of Indoxylsulphate in PD Patients

Xujiao Chen, Sixiu Chen, Linxi Huang, Zhiguo Mao. *Changzheng Hospital, Shanghai, China, Shanghai, China*.

Background: Clearance of protein-bound uremic toxins (PBUTs) by dialysis is a challenge in the treatment of uremic patients. P-cresylsulphate (PCS) and indoxylsulphate (IS) are protein-bound uremic toxins which produced in the intestine by certain intestinal bacteria, and the productions of them are affected by various intestinal environmental factors. Quantitative and qualitative alterations in gut microbiome are noted in patients with end-stage renal disease (ESRD). The indol- and p-cresol-forming bacterial families were found more abundant while the formation of short-chain fatty acidswas diminished. These changes in intestinal microbial metabolism may contribute to increased IS and PCS production. Treatment with probiotics may reduce serum/plasma PCS and IS levels, but there have been no randomised controlled trials to test the effects of probiotics on the serum PCS and IS levels in peritoneal dialysis(PD) patients.

Methods: We conducted a randomized controlled trial to evaluate the effects of probiotics on serum IS and PCS. Participants were randomized to probiotics or control group. Probiotics group received Bifid Triple Viable Capsules 0.42g orally 3 times daily for 12 weeks, IS and PCS concentrations were determined by HPLC/MS/MS and blood biochemical parameters were assessed during the study. Patients were followed up to observe the long terms clinical outcomes.

Results: A total of 60 patients were included in the clinical trial. Total IS level was significantly lower in probiotics group than in control group at week 4, 8, and 12. Free IS in probiotics group was also lower than in control group at week 8 and 12. However, there were no difference of total and free PCS between two groups during 12 weeks. After 10.20±4.48 months follow up, it showed that the incidence of peritonitis in the treatment group was significantly lower than that in the control group(log rank *P*=0.038). However, there were no significant difference in the incidence of PD failure, cardiovascular mortality and all-caused mortality.

Conclusions: Administration of probiotics decreased serum IS level effectively in PD patients. Benefits of PD patients' outcomes from IS reduction by probiotics awaits further large size and long duration clinical trials to verify.

Contribution of Proximal Tubular Solute Clearance in Residual Kidney Function

Ke Wang,[1] Michelle H. Nguyen,[2] John R. Kundzins,[1] Anne Goodling,[3] Yan Chen,[1] Leila R. Zelnick,[3] Andrew N. Hoofnagle,[1] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]Kidney Research Institute, Seattle, WA.*

Background: Residual kidney function (RKF) is associated with better health outcomes in end-stage kidney disease (ESKD). Current assessment of RKF relies on creatinine and urea clearance to estimate the glomerular filtration rate. Proximal tubular secretion is an essential intrinsic kidney function that is rarely measured in ESKD. We measured the kidney and peritoneal clearances of tubular secretory solutes in a primary cohort of incident peritoneal dialysis (PD) patients and determined association with uremic symptoms.

Methods: We enrolled 29 incident PD patients with RKF. We used liquid chromatography-mass spectrometry to quantify plasma, 24-hour urine, and dialysate concentrations of ten tubular secretory solutes. We calculated the kidney and peritoneal dialysis clearances of secretory solutes, creatinine, and urea standardized to 1.73m^2. We created a composite secretory clearance score as the average of each solute clearance. We assessed symptom severity using the Dialysis Symptom Index.

Results: The mean age of our cohort was 55 years, mean dialysis duration was 4 months, and mean $GFR_{urea+Cr}$ was 7.8 mL/min/1.73m^2. The kidney clearances of secretory solutes ranged from 1.3 ml/min/1.73m^2 for p-cresol sulfate to 94.6 ml/min/1.73m^2 for hippurate (**Table**). The residual kidney clearance of each secretory solute was substantially higher than peritoneal dialysis clearance. Worse dialysis symptom severity was correlated with a lower composite secretory clearance score (r= -0.46; p=0.01) and, to a lesser extent, lower $GFR_{urea+Cr}$ (r= -0.35; p=0.06).

Conclusions: Among incident PD patients, tubular secretory solutes are more avidly cleared by residual kidney function than peritoneal clearance. Secretory solute clearance correlates more strongly with the severity of uremic symptoms compared with $GFR_{urea+Cr}$.

Funding: NIDDK Support

Table: Residual kidney and peritoneal dialysis solute clearance

	Clearance (ml/min/1.73m^2)		
Solutes	Kidney	Peritoneal	Kidney/Peritoneal
Filtration			
Urea	6.5 [5.0, 14.4]	7.5 [6.2, 10.1]	0.9 [0.5, 1.8]

L-Carnitine Supplementation Preserves Residual Renal Function in Patients Undergoing Peritoneal Dialysis

Sakuya Ito, Yosuke Nakayama, Yusuke Kaida, Tomofumi Moriyama, Goh Kodama, Yuka Kurokawa, Yunosuke Yokota, Kei Fukami. Division of Nephrology, Department of Medicine, Kurume University School of Medicine *Kurume University School of Medicine, Kurume, Japan*.

Background: Residual renal function (RRF) is the most important factor to maintain well-being and quality of life in patients undergoing peritoneal dialysis (PD). Carnitine plays a central role in fatty acid b-oxidation and energy production by transporting long-chain fatty acids from the cytoplasm to the mitochondria. Furthermore, carnitine was reported to inhibit oxidative stress. We recently reported that serum carnitine levels were significantly decreased in patients undergoing PD. Therefore, we investigated the impact of L-carnitine supplementation on peritoneal function and RRF in these patients.

Methods: Total 24 PD patients with a mean age of 62.6 ± 9.5 years and a mean PD duration of 515.1 ± 382.5 days were randomly assigned to the L-carnitine (750 mg/day, n = 12) or control (n = 12) group and followed for 6 months. Serum free carnitine (FC) and acyl-carnitine (AC) levels were determined by enzyme cycling method. Additionally, the following parameters were measured before and after the treatment period: clinical chemistry, peritoneal function, RRF, urine volume, urinary L-FABP, serum LPO, and serum MDA.

Results: Both serum FC and AC levels, which did not differ at baseline between the two groups, significantly increased in the L-carnitine group after treatment (4.7 ± 9.2, 128.2 ± 29.9 and 12.8 ± 3.3, 50.9 ± 16.6 μmol/L, respectively). Both the Δrenal Kt/V and Δurinary volume, which decreased after 6 months in the control group, were preserved in the L-carnitine group (–0.26 ± 0.32 vs –0.02 ± 0.22, p = 0.043; –367.1 ± 473.3 vs 99.2 ± 316.2 mL, p = 0.010, respectively). The Δserum LPO levels were significantly lower in the

L-carnitine group (0.33 ± 0.81 vs –0.58 ± 0.67 nmol/mL, p = 0.007), whereas the Δurinary L-FABP and Δserum MDA levels tended to decrease by L-carnitine treatment (19.5 ± 53.7 vs –24.1 ± 65.0 ng/mL, p = 0.087, -0.02 ± 0.04 vs 0.08 ± 0.06 ng/mL, p = 0.177). Furthermore, there was an inverse correlation between Δurinary volume and ΔL-FABP (r^2 = 0.585, p = 0.004) in the L-carnitine group.

Conclusions: L-carnitine supplementation is a promising therapeutic strategy for maintaining RRF by alleviating oxidative stress in L-carnitine-deficient patients undergoing PD.

SA-PO957

Protective Effect of COMP-Angiopoietin 1 on Peritoneal Vascular Permeability and Peritoneal Transport Function in Uremic Peritoneal Dialysis Rats

Yuanyuan Shi. *Shanghai Ninth People's Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China.*

Background: The angiopoietin-1 (Ang-1)/Tie-2 signaling pathway plays a crucial role in the maintenance of vascular stabilization and permeability.

Methods: Thirty-six male Sprague-Dawley rats were randomly assigned to the sham operation group, uremia group or uremia+PD group (each n=12). Then, COMP-Ang-1 adenovirus or vehicle adenovirus was injected into twenty other uremic PD rats via the tail vein (each n=10). A peritoneal equilibration test (PET) was performed to evaluate peritoneal transport function before the rats were euthanized. Peritoneal vascular permeability was assessed by measuring FITC-dextran (4 kDa) and FITC-BSA (69 kDa) leakage. The pericyte coverage rate was quantified by anti-CD31 and anti-Desmin immunofluorescence staining. Expression of endothelial junction proteins and Ang-1/Tie-2 signaling were examined by western blotting. The levels of proinflammatory adhesion molecules and cytokines in the peritoneum were measured by real-time quantitative polymerase chain reaction (PCR).

Results: Compared to the sham controls, uremic rats were characterized by decreased pericyte coverage, downregulated endothelial junction protein expression and increased FITC-BSA and FITC-dextran leakage, accompanied by increased levels of proinflammatory adhesion molecules and cytokines, increased D/Pcr and decreased ultrafiltration. After infusion of PDF for 4 weeks, more marked changes were noted. Peritoneal Ang-1 protein expression and Tie-2 phosphorylation were significantly lower in uremic rats than in control rats and were further significantly reduced in uremia+PD rats. After COMP-Ang-1 administration, phosphorylation of the Tie-2 receptor was significantly increased. Treatment with COMP-Ang-1 also significantly enhanced pericyte coverage, upregulated endothelial junctions expression and inhibited the leakage of FITC-BSA and FITC-dextran from the peritoneal vasculature induced during PD therapy; these changes were accompanied by reduced peritoneal tissue levels of proinflammatory adhesion molecules and cytokines, decreased D/Pcr and increased ultrafiltration.

Conclusions: COMP-Ang-1 exerts a protective effect against damage-induced peritoneal vascular permeability and inflammation at least in part by enhancing pericyte coverage and endothelial junction protein expression, which subsequently significantly improves peritoneal transport function.

SA-PO958

Cross-Omics Analysis of Transcriptome, Proteome, and Metabolome Dynamics During Peritoneal Dialysis

Klaus Kratochwill, Rebecca Herzog, Christoph Aufricht. *Medical University of Vienna, Vienna, Austria.*

Background: Peritoneal dialysis effluent (PDE) represents a rich but underexplored source of molecular markers for the prediction of clinical outcome, therapy monitoring and investigation of deregulated molecular and cellular processes during PD. Novel PD-fluids (PDF) may enable patient-tailored interventions, such as peritoneal immunomodulation. Alanyl-glutamine (AlaGln) has recently been shown to have beneficial effects in experimental and clinical PD. Modern high performance methods allow monitoring of hundreds of analytes in parallel. In this study, we investigate the transcriptome, proteome and metabolome of PDE samples with or without AlaGln-addition to PDF.

Methods: Samples from a cross-over RCT, investigating AlaGln supplementation of PDF, were analyzed in a cross-omics analysis of effluent cells (RNAseq), soluble proteins (LC-MS) and metabolites in the PDE and plasma (targeted MS) to investigate the effect of AlaGln on the interplay of peritoneal cell populations and fluid transport. Peritoneal immune-competence was analyzed by functional ex-vivo stimulated cytokine release of effluent cells. From each PD dwell, PDE was analyzed at multiple time-points. Bioinformatic analysis results and pathway analysis results from the different datasets were conjoined to reveal novel insights into the "PD-effluentome".

Results: We were able to quantify ~10,000 cellular transcripts, and 2,700 proteins and 300 metabolites in the PDE. Changes in the proteome could in part be explained by co-regulated biological processes observed on the transcript level. The remaining effects on the proteome are likely due to changes in transport characteristics, supported by clinical findings in patients treated with AlaGln. These results correlated with restoration of suppressed peritoneal immune responses by AlaGln. Bioinformatic analysis of proteome-metabolome interference was employed to discriminate local and systemic regulation and transport.

Conclusions: This combined investigation of proteomic and metabolomic properties of PDE represents the first cross-omics analysis of poorly understood molecular processes during PD and the obtained results enable a further step to unravel the beneficial effects of AlaGln-supplementation. Our data also suggest feasibility of multi-omics approaches to investigate pathomechanisms and interventions relevant in PD.

SA-PO959

Markers of Oxidative Stress, Inflammation, and Endothelial Dysfunction in Diabetic and Non-Diabetic CKD Patients on Peritoneal Dialysis

Sai N. Sameera,[1] Venkata A. Yalamanchili,[2] Lakshmi A. Y,[3] Harini N. Devi,[4] Sunnesh Reddy,[1] Siva K. Vishnubotla,[1] Ram Rapur.[1] *[1]Nephrology, Sri Venkateswara Institute of Medical Sciences, Tirupati, India; [2]Dallas Nephrology Associates, DeSoto, TX; [3]Radiology, Sri Venkateswara Institute of Medical Sciences, Tirupati, India; [4]Biochemistry, Sri Venkateswara Institute of Medical Sciences, Tirupati, India.*

Background: Oxidative stress, inflammation and endothelial dysfunction represents the key triad for development and progression of atherosclerosis. In this study we assessed the markers of oxidative stress, inflammation and endothelial dysfunction in diabetic and non-diabetic chronic kidney disease (CKD) patients on peritoneal dialysis (PD).

Methods: This is a Cross-sectional study in 100 patients on PD among which 52 patients were non-diabetic and 48 diabetic. Blood samples were measured for oxidative stress markers- Malondialdehyde (MDA), Ferric Reducing Ability of Plasma (FRAP), Inflammatory markers - Interleukin-6, hsC-Reactive Protein (hs CRP), Fibrinogen and markers of endothelial dysfunction-Nitric Oxide (NO). Carotid Intimal Medial Thickness (CIMT) and number of plaques was measured by imaging studies. Comparisons between the two groups for continuous variables were assessed with the Student's unpaired *t*-test and for categorical variables with χ2-test.

Results: MDA is found to be elevated in both group of patients on PD though there was no significant difference (p- 0.279). FRAP was decreased in both diabetic and non-diabetic patients on PD (p- 0.850). The markers of inflammation-interleukin 6, hs CRP were found to be significantly higher in diabetics when compared to non-diabetics (p- 0.001). Serum fibrinogen was found to be elevated in diabetic compared to non-diabetics though not significant (p- 0.181). The markers of endothelial dysfunction- nitric oxide, carotid intimal medial thickness, lipid profile and atherogenic indices was found to be significantly higher in diabetics compared to non-diabetics (p- 0.001). The number of plaques found were significantly higher in diabetic compared to non-diabetics (p- 0.05).

Conclusions: Our study showed presence of increased markers of inflammation and endothelial dysfunction in diabetics compared to non diabetic CKD patients on PD. Markers for oxidative stress were found to be elevated in both subset of patients on PD. These findings will have clinical implications regarding the progression of atherosclerosis in diabetic compared to non-diabetic CKD patients on PD and need to be reconfirmed in a larger sample size.

SA-PO960

Alanyl-Glutamine Decreases Cellular Injury and Enhances Cytoprotective Responses in Endothelial Cells During PD-Fluid Exposure

Rebecca Herzog,[1] Maria Bartosova,[2] Claus peter Schmitt,[3] Christoph Aufricht,[1] Klaus Kratochwill.[1] *[1]Medical University of Vienna, Vienna, Austria; [2]Center for Pediatric and Adolescent Medicine, Heidelberg, Germany; [3]Centre for Pediatric and Adolescent Medicine, Heidelberg, Germany.*

Background: Vasculopathy, hypervascularization, and diabetes-like damage of vessels are important factors limiting peritoneal dialysis (PD). The composition of all currently available PD fluids (PDF) leads to morphological and functional changes in the peritoneal membrane in adults and infants. During PDF exposure, relevant cellular pathomechanisms might be similar to those in hyperglycaemic diabetic conditions. This study focuses on omics-based characterization of endothelial cell injury and stress responses with or without addition of alanyl-glutamine (AlaGln).

Methods: Protein profiles of primary human umbilical vein endothelial cells (HUVEC) exposed to medium-diluted conventional PDF with or without 8mM AlaGln were analysed by gel-based proteomics. Cell damage was assessed by quantification of lactate-dehydrogenase (LDH) release. Microdissected omental arterioles of children treated with conventional PDFs and healthy controls were analysed with quantitative multiplex mass spectrometry. In-vitro findings were related to PD-induced arteriolar changes based on abundance profiles of proteins identified in both proteomic analyses.

Results: Marked cellular injury of HUVEC after PDF exposure was associated with a molecular landscape of the enriched biological process clusters 'glucose catabolic process', 'cell redox homeostasis', 'RNA metabolic process', 'protein folding', 'regulation of cell death', and 'actin cytoskeleton reorganization' that characterize PDF cytotoxicity and counteracting cellular repair process respectively. Addition of AlaGln to PDF preserved endothelial cell integrity shown by significantly decreased LDH-release and by restored control levels of proteins in PDF perturbed processes, especially enhancing protein folding capacity and response to stress. Comparison to human arterioles confirmed overlapping protein regulation between endothelial cells in-vitro and in-vivo, proving harmful effects of PDFs on endothelial cells leading to drastic changes of the cellular process landscape. Cellular damage and proteome changes in HUVEC were counteracted by AlaGln in-vitro.

Conclusions: In summary, this study elucidates potential mechanisms by which AlaGln exerts cytoprotective effects in PD-induced endothelial cell damage, offering therapeutic targets to reduce side effects of PD.

SA-PO961

Ionic Conductivity Uses on Evaluation of Peritoneal Transporter Type

Hilda M. Cervantes,[1] Oscar Zambrano.[2] [1]*Instituto Mexicano del Seguro Social, Leon, Mexico;* [2]*IMSS, Morelia, Mexico*.

Background: Peritoneal equilibrium test (PET) was developed to evaluate peritoneal transport rate on peritoneal dialysis users, being the gold standard. Based on test results, peritoneal transport can be classified as: high, medium high, medium low and low. This classification has clear implications, since it allows making particular recommendations and patients individualized treatment. PET carries long realization time, given this, studies on ionic conductivity show good correlation with creatinine concentration ratio between dialysis product and plasma (D/PCreat), making it novelty on peritoneal function evaluation

Methods: An analytic transversal study was made on 200 patients diagnosed with chronic kidney disease (CKD) on ambulatory continuous peritoneal dialysis (ACPD) from nephrology department at Unidad Medica de Alta Especialidad (UMAE) 1 of Instituto Mexicano del Seguro Social (IMSS) at Leon, Guanajuato. A modified PET was made, following standardized steps and classifying peritoneal transport, then cut point value of ionic conductivity was determined by under-the-curve analysis (UTC).

Results: Sensible cut values were found, which may allow using ionic conductivity as a suitable test to classify peritoneal transport as low, medium high and high, not so for medium low

Conclusions: Ionic conductivity test shows moderate accuracy to classify peritoneal transport.

Table 1. Clinical and biochemical characteristics of each peritoneal transport type

	Low transport (n=67)	Medium low transport (n=39)	Medium high transport (n=39)	High transport(n=55)	Significance

SA-PO962

Uric Acid Clearance in Peritoneal Dialysis Patients

Xi Xiao,[1] Yuan Peng,[1] Xuan Huang,[1] Meiju Wu,[1] Xueqing Yu,[2] Xiao Yang.[1] [1]*The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China;* [2]*Department of Nephrology, Guangdong Provincial People's Hospital, Guangzhou, China*.

Background: There's a paucity of systematic study focus on the clearance of UA in peritoneal dialysis (PD). The aim of this study was to investigate the peritoneal UA transport and its influence factors in PD patients.

Methods: This was a cross-sectional study. The patients who performed peritoneal equilibration test (PET) and Kt/V from April 1, 2018 to April 31, 2019 were enrolled. The demographic data, clinical and laboratory parameters including the UA levels in the dialysate, blood and urine samples were collected.

Results: Totally 122 prevalent PD patients(male 55.7%) were enrolled in this study, with a mean age of 46.2±13.1 years and a mean peritoneal UA clearance (pUACL) of 40.1±6.9 L/week/1.73 m^2. The average mass transfer of UA between 0-4h dwell with 2L of 2.5% dextrose solution was 22.2±5.2 mg/h. Compared with the normal serum UA group, the hyperuricemia group showed significantly lower pUACL (38.0±5.7 vs.41.8±7.3L/week/1.73m^2, p=0.003). The bivariable correlation analysis revealed that the serum UA levels was positively correlated with the UA mass transfer (r=0.715, p<0.001) but negatively correlated with pUACL (r=-0.310, p=0.001). Furthermore, the higher (high or high-average) transporters showed greater pUACL than the lower (low or low-average) transporters (42.0±7.1vs.36.7±4.9L/week/1.73 m^2, p<0.001). The 4 hours dialysate to plasm (4h D/P) ratios of UA correlated fairly well with the ratios of creatinine (r=0.933, p<0.001). And the correlation between the pUACL and 4h D/P UA (r=0.446, p<0.001) or creatinine (r=0.428, p<0.001) were similar. Among the widely used solute removal evaluation indicators, the peritoneal creatinine clearance performed best to predict higher pUACL in the ROC analysis (area under curve AUC 0.951,95%CI0.908-0.993). On multivariable logistic regression, each 1kg/m^2 decrease of BMI [odd ratios (OR) 0.761, 95% CI0.634-0.913], each 1mL increase of the dialysis dose (OR1.001,95%CI1.000-1.002), each 0.1% increase of the average glucose concentration of dialysate (OR1.400,95%CI1.017-1.927), female sex (OR5.170,95%CI1.819-14.695) and higher transporters (OR5.749,95%CI 1.795-18.406) were independently associated with higher pUACL.

Conclusions: The clearance of UA in PD were similar to that of creatinine. Increasing dialysis dose or glucose concentration of the solution may help to control the hyperuricemia in lower transporters.

Funding: Government Support - Non-U.S.

SA-PO963

Impact of Renal Replacement Therapies over Quality of Life of ESRD Patients

Araly Garcia, Bernardo Moguel, Gabriela Leal. *Instituto Nacional de Cardiologia, Mexico City, Mexico*.

Background: Renal transplant is generally considered as the ideal renal replacement therapy (RRT). Nonetheless, at the moment, hemodialysis and peritoneal dialysis remain as the main alternative treatment options for patients with end stage renal disease (ESRD). The negative impact of ESRD on the quality of life (QoL) has already been well described, and improvement of QoL could actually be translated into lower mortality.

Methods: Transversal, cohort, observational study, evaluating ESRD patients subjected to renal transplant (RT), undergoing hemodiafiltration (HDF) or automated peritoneal dialysis (APD). QoL was assessed using the Kidney Disease Quality of Life Questionnaire (KDQOL-SF), as well as Becks inventories for anxiety and depression. Additional factors like dialysis quality, body composition, and muscle strength were also assessed.

Results: 82 patients met the inclusion criteria: 32 RT patients, 26 on APD and 24 on HDF. 43% of them were in the age range between 31- 50 years. Lower phase angles and muscular strengths were measured in the HDF and APD groups when compared to RT patients (p=0.005) (p=0.0003). As for QoL, RT patients obtained better scores when compared to the other groups, however, statistically significant differences were only observed in five of the categories, which ultimately emphasized the importance of disease burden (p=0.0006) and effects of disease (p=0.0001). The HDF group had a slight tendency towards better QoL results than the APD group, without reaching statistical significance. Hydration status measured with bioelectrical impedance analysis revealed greater levels of overhydration in the HDF group, as expected, since measurement was performed pre HDF treatment (p=0.14). Higher levels of anxiety and depression were observed in the HDF group.

Conclusions: QoL of RT patients is superior to that of patients remaining on dialysis, yet on most of the categories assessed in the KDQOL-SF, no statistical significance was observed, suggesting QoL is acceptable, or even satisfactory, in patients on HDF and APD. As for these two dialysis modalities, there was no significant difference of QoL in our study group.

SA-PO964

Using Endoscopic Ultrasound-Guided Fine-Needle Aspiration (EUS-FNA) on Pancreatic Lesions in Peritoneal Dialysis (PD) Patients

Susie Q. Lew,[1] Ali A. Khan,[3] Brandon Rieders,[2] Satyanisth T. Agrawal.[3] *[1]George Washington University Medical Center, Washington, DC; [2]George Washington University Hospital, Washington, DC; [3]George Washington University, Washington, DC.*

Introduction: Any invasive procedure involving the abdominal or pelvic regions in a PD patient raises concerns for infection, bleeding, and peritoneal fluid leakage. EUS-FNA is a well-established minimally invasive GI procedure to diagnose and stage cancers of the pancreas, upper GI tract, and mediastinum. We report the pre-procedure preparation, peri-procedure precautions, and outcomes of 2 PD patients who underwent EUS-FNA for suspicious pancreatic lesions. These cases are the first to be reported in the literature.

Case Description: Patients performed the following to avoid complications and ensure the best outcome: 1-Performed additional dialysis daily for 3 days pre-procedure to optimize volume, electrolyte, and acid-base status as well as remove uremic toxins to improve platelet function. 2-Stopped any medications that would interfere with coagulation. 3-Reported to EUS-FNA with minimal PD fluid and received IV prophylactic antibiotics (ampicillin 1 gm and gentamicin 1 mg/kg) within 1 hr pre-procedure to minimize peritonitis risk. 4-Delayed restarting PD for 48 hrs to reduce peritonitis, bleeding and PD fluid leakage risks. 5-Monitored for abdominal pain, low blood pressure, fever, and GI symptoms such as nausea, vomiting, or diarrhea. During the EUS-FNA procedure, an endoscope with high frequency ultrasound capability examined the entire pancreas and the cystic lesion in the pancreas was sampled using a 22-gauge FNA needle. Samples were sent for pathologic evaluation. Patient-1's findings were consistent with pancreatic pseudocyst. Patient-2's findings were consistent with mucinous cyst, either side-branch intraductal papillary mucinous neoplasm or mucinous cystic neoplasm. PD risks (peritonitis and PD fluid leakage) and EUS-FNA risks (perforation, infection, iatrogenic pancreatitis, bile peritonitis, fistulization, and malignancy seeding) were not appreciated. Patient-2 noted bloody PD fluid on a manual exchange without hemodynamic compromise. PD fluid cleared after another rapid exchange.

Discussion: Take away lessons: EUS-FNA can be performed safely in PD patients with minimal short term complications. Appropriate measure should be taken to ensure peritonitis, bleeding, and PD fluid leakage risks are minimized (see points 1-5 above) EUS-FNA can be used to evaluate pancreatic lesions and malignancies for diagnosis and staging.

SA-PO965

Elevated WBC Count in the Peritoneal Fluid After Transcatheter Arterial Chemoembolization and Microwave Ablation of Hepatocellular Carcinoma in a Peritoneal Dialysis Patient: A Case Report

Aisha Shaikh,[1,2] Rebaika Chopra,[4] Jeremy D. George,[3] Jonathan Gross.[5] *[1]Nephrology, James J. Peters Medical Center VA, New York, NY; [2]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Medicine, James J. Peters VA Medical Center, Bronx, NY; [5]New York University-Langone Medical Center, New York, NY.*

Introduction: Hepatitis C is a risk factor for hepatocellular carcinoma (HCC). The prevalence of Hepatitis C is high among end stage renal disease (ESRD) patients, and these patients are at high risk for developing HCC. In the past decade, transcatheter arterial chemoembolization (TACE) combined with microwave ablation (MA) have emerged as an effective therapy for HCC. These therapies can decrease the tumor burden while patients are on the liver transplant wait-list. Here we present an ESRD patient on peritoneal dialysis who developed a high white blood cell count in the peritoneal fluid following the TACE and MA procedure

Case Description: A 63-year old male with ESRD on Peritoneal Dialysis (PD), and cirrhosis due to Hepatitis C was diagnosed with HCC. At the time of the HCC diagnosis, the patient was listed for a combined liver-kidney transplant. The patient underwent TACE and MA, but immediately following the procedure he developed fever (101°F) which subsided within 24 hours. As part of the fever workup, the peritoneal fluid was sent for white blood cell (WBC), gram stain and culture. The peritoneal fluid WBC was found to be elevated: 1131 (57% PMN, 19% lymphocytes), remaining elevated for more than a month. Notably, it was not accompanied by any associated signs or symptoms such as abdominal pain or cloudy peritoneal fluid. The peritoneal fluid gram stain and culture remained negative, and the patient was able to continue PD without any problems

Discussion: TACE induces ischemic necrosis through arterial chemoembolization, and MA induces coagulative necrosis through thermal ablation. The most common complications of these therapies include fever and abdominal pain likely related to underlying tumor necrosis. It is important for Nephrologists to be aware of the complications related to these therapies, as was seen in our patient who developed an elevated WBC count in the peritoneal fluid. However, this persistent WBC elevation was not accompanied by abdominal pain, cloudy fluid, infection, and did not warrant PD catheter removal or cessation of PD. To the best of our knowledge, this is the first reported case of elevated WBC in peritoneal fluid in a PD patient following the TACE and MA procedure

SA-PO966

A Quality Improvement Program to Reduce Avoidable Hospital Stays for Dialysis Patients Presenting to the Emergency Department

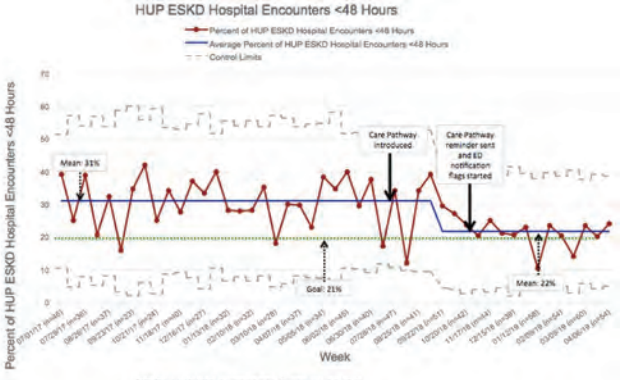
Tiffany Wong,[2] Julian M. Lejbman,[1] Christopher K. Snider,[3] Stefanie B. Porges,[2] Siddharth P. Shah.[2] *[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [2]Hospital of the University of Pennsylvania, Philadelphia, PA; [3]Penn Medicine, Philadelphia, PA.*

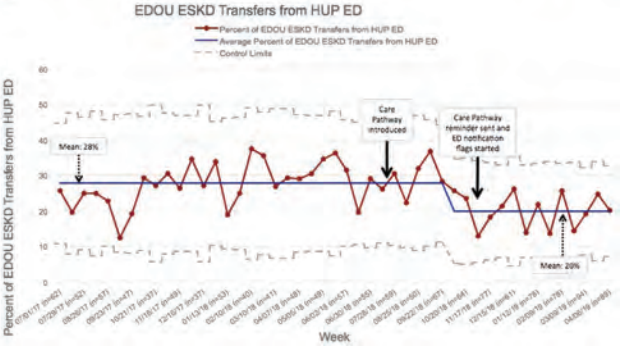
Background: When an End Stage Kidney Disease (ESKD) patient presents to the ED, if he/she requires dialysis, this may result in a costly hospital stay. In Fiscal Year 2017 at the Hospital of University of Pennsylvania, 70% of ESKD patients who presented to the ED were admitted to an inpatient service or transferred to the ED observation unit (EDOU) and 31% of these hospital stays were <48 hours. We believe hospital stays <48 hours can be potentially avoidable.

Methods: A multidisciplinary team was formed with members from the departments of nephrology and emergency medicine (EM). We used Voice of the Customer to survey key stakeholders (RNs, advanced practitioners, residents, attendings, social workers, clinical resource coordinators, and representatives from large dialysis organizations). We performed a root cause analysis using the Ishikawa fishbone model. As a countermeasure, we developed a care pathway to standardize management of patients' dialysis needs, with dialysis provided in the hospital before discharge or as an outpatient (introduced July 2018). A second plan-study-do-act cycle was performed in November 2018. New countermeasures included an alert identifying the patient as a dialysis patient with specific dialysis unit information and working with the hospitalist superutilizer program to identify additional dialysis patients appropriate for the program.

Results: After introduction of the care pathway, hospital stays <48 hours decreased from 31% to 22% and transfers from the ED to EDOU from 28% to 20%.

Conclusions: By utilizing QI tools and developing a care pathway as a countermeasure, we were able to decrease the percent of hospital stays <48 hours, which we believe represent potentially avoidable hospital stays.





SA-PO967

Reducing Hospitalizations with Artificial Intelligence and Clinical Decision Support: Lessons Learned

Andrew Long,[1] Adriana M. Lindsey,[2] Joanna Willetts,[1] Hao Han,[1] Sheetal Chaudhuri,[1] Cara S. Gallagher,[2] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Andrew Aronson,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Health Partners, Leander, TX.*

Background: Artificial intelligence has the potential to improve healthcare. Previously, we created a model to predict which patients with kidney failure treated in outpatient dialysis clinics were at risk for all cause hospital admission in the next week. This model has an area under the receiver operating characteristic curve (AUROC) of 0.78 with a sensitivity of 69% and specificity 72%. Here we discuss lessons learned from integrating this model in a telephonic intervention.

Methods: Starting in December 2018, our analytics team partnered with a team of nurses who perform chart reviews and telephonic outreach to manage a large population of patients distributed across the United States. The goal of the outreach is to reduce the

number of hospitalizations. The workflow consists of pulling patients from a worklist, reviewing a chart, documenting any needs identified, and then calling the patient if warranted. Through the last few months, we have utilized agile techniques to iteratively improve each step of this process using observations, surveys, and data analytics.

Results: We deployed the predictive model as a worklist ranked by risk score through an excel sheet format. Initial review demonstrated that 1) excel sheets are difficult to use to display individual patient data, and 2) significant time was spent digging through electronic charts. To help mitigate these issues, we built a dashboard that showed the prediction-based prioritization worklist as well as an integrated patient view. Testing of the dashboard with 3 nurses increased the number of chart reviews by over 50%. We believe this is likely due to aggregating information from multiple electronic health records, reducing the time spent searching for information. Further, nearly every nurse who uses this new system has reported an increase in job satisfaction. To date, the existing workflow results in 70% increase in chart reviews per day with 250% increase in calls per day. Investigation of hospitalization rate is still underway.

Conclusions: Building healthcare predictive models is only part of the story for artificial intelligence to improve healthcare. Additional work must be conducted to understand how to fully integrate predictive models into existing and newly designed clinical workflows.

SA-PO968

Impact of In-House Dialysis Schedule Change on Hospital Readmission Rate in Hemodialysis Patients

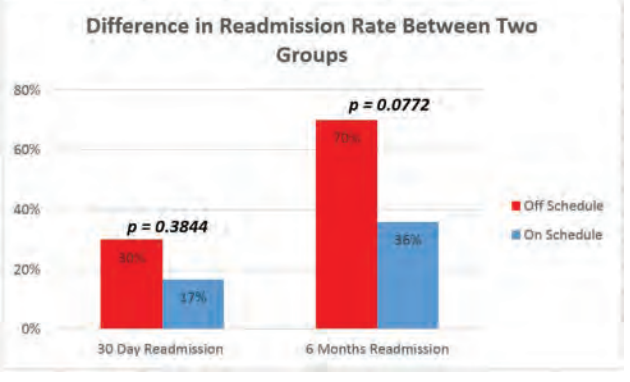
Abdul Qadeer,[1] Chelsea C. Estrada,[2] Muhammad R. Mustafa.[1] *[1]Stony Brook University Hospital, Coram, NY; [2]Stony Brook University Medical Center, Stony Brook, NY.*

Background: ESRD patients on Hemodialysis (HD) have high frequency of hospitalization and readmissions for multiple reasons. Once inpatient, they may not get HD treatments on their designated days (MWF or TThS) due to various reasons, including nursing availability and patient condition. We hypothesized that changing HD schedule could impact readmission rate due to care coordination factors

Methods: Data was collected from EMR at Stony Brook University Hospital for adult HD patients admitted from January 2019 to October 2019. First admission was taken as index admission, and dialysis days on index admission were noted as on or off-schedule. Patients who received ≥2 HD treatments on days other than their outpatient schedule were labelled as "off-schedule". The readmission rate within 30 days and 6 months and baseline demographics was compared using Fisher's exact test. Continuous variables were compared with t-test

Results: In total, 46 patients were reviewed, of them 10 were labeled as "off-schedule" and 36 as "on-schedule". Mean age of all patients was 60.8±18.6 years, 61.1% were male and 47% Caucasian, with no differences between groups. Both diabetes as cause of ESRD (70% vs. 44.4%), and history of CHF (80% vs. 50%) were more frequent among the off-schedule. Dialysis access between groups was not different. The 30-day readmission rate was not statistically significant (30% vs. 16.7%, p-value 0.3844) between two groups. However, six month readmission rate showed a trend towards significance in off-schedule vs on-schedule group (70% vs. 36%, p-value 0.0772, OR 4.128, 95% CI 0.9315-16.14). There were no deaths in either group at 6 month follow up

Conclusions: Off-schedule inpatient dialysis had no effect on 30 day readmission rate. A trend towards increased rate of readmission within 6 months was observed. Future studies involving more patients and longer follow up are necessary to see the impact of on schedule HD for hospitalized patients



SA-PO969

Patterns of Emergency Department Visits Among American Dialysis Patients

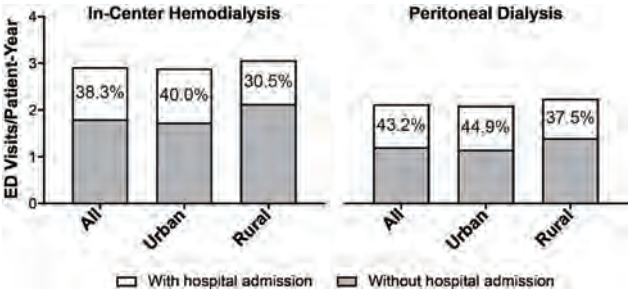
Kathryn S. Gray, Dena E. Cohen, Francesca Tentori, Steven M. Brunelli. *DaVita Clinical Research, Minneapolis, MN.*

Background: Dialysis patients are at risk for medical events requiring immediate intervention in the Emergency Department (ED). Despite this, patterns of ED visits among the contemporary dialysis population have not been described.

Methods: Data were derived from the 2016 Centers for Medicare and Medicaid Services 100% claims sample. Included patients were those who, in a given calendar month and for the preceding 3 months, were Medicare A & B eligible, diagnosed with ESRD, and treated with either in-center hemodialysis (ICHD) or peritoneal dialysis (PD). Core-based statistical areas were designated as urban; other regions were considered rural. Causes of ED visits and hospital admissions were ascribed based on the associated ICD-10 code and grouped using Clinical Classification Software categories. Outcomes were described as rates, counts, and percentages; no statistical comparisons were performed.

Results: Patients treated with ICHD (N=321,934) had 2.9 ED visits/patient-year; with 38.3% of visits resulting in hospital admission. PD patients (N=35,720) had 2.1 ED visits/patient-year, with 43.2% of visits resulting in admission. For both modalities, the majority of all hospital admissions initiated in the ED: 80.1% for ICHD and 74.8% for PD. ICHD patients residing in rural areas had a higher rate of ED visits compared to urban areas (3.1 vs 2.9/patient-year), although a smaller percentage of those ED visits resulted in hospital admission (30.5% vs 40.0%), corresponding to a lower overall hospitalization rate among rural patients (1.3 vs 1.4 admissions/patient-year). Similar trends were observed for PD. Across modalities, ED visits attributed to Diseases of the Circulatory System and Injury and Poisoning were common and likely to result in hospital admission; ED visits attributed to Infectious and Parasitic Diseases almost invariably resulted in admission.

Conclusions: ED visits are common among dialysis patients and precede the majority of hospitalizations. Understanding causes and patterns of ED visits may facilitate interventions to reduce the frequency of ED visits and subsequent admissions.



SA-PO970

Predictors of Need for Recurrent Emergency Medical Service Transport to an Emergency Department After Dialysis Initiation

Karthik K. Tennankore,[1] John E. Bartolacci,[2] Judah Goldstein,[2] David Clark,[1] Janel M. Swain,[3] Amanda J. Vinson.[1] *[1]Dalhousie University/NS Health Authority, Halifax, NS, Canada; [2]Dalhousie University, Halifax, NS, Canada; [3]Emergency Health Services Nova Scotia, Dartmouth, NS, Canada.*

Background: Dialysis patients are frequently transported to the emergency department (ED) by Emergency Medical Services (EMS) due to acute illness. However, little is known about the predictors of recurrent transport to the ED (EMS-ED), based on characteristics at the time of dialysis initiation.

Methods: We analyzed a cohort of adult (≥18 years) patients affiliated with a large quaternary care center who initiated chronic dialysis from 2009-2013 (last follow-up: 2015). Data on patient characteristics at the time of dialysis initiation was linked to regional EMS data. Candidate predictors of recurrent EMS-ED transport included comorbid conditions, dialysis characteristics and frailty severity (using the first version of the clinical frailty scale score; CFS). Time to recurrent EMS-ED was analyzed using the Anderson-Gill counting approach, accounting for competing risks of death and transplant.

Results: A total of 455 patients were included in the study, 246 (54%) had one or more EMS-ED events, 90 (20%) never required an EMS-ED at last follow-up, and 15% and 12% experienced transplant or death as their first event, respectively. The mean age of the cohort was 62 ± 15 years, 89% were Caucasian, and 34% were of female sex. Patients were highly comorbid (48% had diabetes, 30% had coronary artery disease and 17% had peripheral vascular disease) and 97/381 with available data on frailty severity had a CFS score of ≥5 corresponding to "mildly to severely frail". After adjustment, increasing CFS score (subdistribution hazard ratio (SHR) 2.41, 95% confidence interval (CI) 1.48-3.95 for CFS 3-4; and SHR 3.05, 95% CI 1.73-5.38 for CFS ≥5 relative to a CFS 1-2), rheumatologic disease (SHR 1.54, 95% CI 1.04-2.29), end-stage renal disease (ESRD) secondary to polycystic kidney disease (SHR 2.00, 95% CI 1.11-3.59 relative to glomerulonephritis as cause of ESRD) and > 3 months of nephrology follow-up prior to dialysis initiation (SHR 1.52, 95% CI 1.10-2.08) predicted recurrent EMS-ED.

Conclusions: Patients are at a high risk of EMS-ED after dialysis initiation. Frailty severity (at the time of dialysis initiation) is the strongest predictor of recurrent EMS-ED and this may be important to guide informed decision making and resource planning for dialysis patients.

SA-PO971

High-Frequency, Distinctive Staffing and Outcomes: Improving the Dialysis Experience

Juliane Lauar, Luiza Lins, Kelia Xavier, Vilber Bello, Adolfo Simon, Istenio Pascoal. Centro Brasiliense de Nefrologia & Dialise *Centro Brasiliense de Nefrologia & Dialise, Brasilia, Brazil.*

Background: Frequent dialysis has consistently improved patient outcomes. Professional staffing of dialysis affects patient care quality and safety. Requirements for physician presence during dialysis and for nursing staff levels are highly variable worldwide. We have set up a 24-stations in-center short daily hemodialysis (SDHD) program whose all day long care is provided by two on-site nephrologists, certified nurses, renal dietitians and psycologists with fulltime dedication. This report outlines the impact of 10 years of combining daily hemodialysis with selected clinical staffing on patient outcomes.

Methods: Nephrologist schedule, patient to staff ratios, adverse events rates (hypotension, medication errors, patient falls), vascular access profile (type, infection rates), patient compliance (missed treatment rate), hospitalization (days per patient-year [pp-y]), cumulative survival and kidney transplantation rates were assessed in 200 private-insured patients (122M/78F; mean age 58.0±18.5yrs, 18-96) receiving in-center SDHD (6-7 x/wk; lasting 115.4±11.2min, 90-180; ultrapure dialysate and single-use high-flux dialyzer).

Results: From June 2009 to May 2019 four out 5 nephrologists shared equitable schedule 7 days/wk, each one prescribing up to 24 patients in 2 parallel and 2 sequential 6-hour workday. In 2009 we stopped hiring technicians and moved to 100% nurses staffing, reaching 21 fulltime certified nurses (up to 3:1 ratio). Additionaly, 2 dietitians and 2 psycologists assist 80 current patients (40:1 ratios). In 2018 symptomatic hypotension occurred in 3% of 20,035 treatments, medication errors in 17 occasions (none critical) and no patients fell in the unit. Over the 10-year study period, arteriovenous fistula was used in 53% and tunneled catheter in 47% of prevalent patients, with bacteremia rate of 0.27 and 0.50 events per 1,000 days. Missed treatment rate was 1.49% or 4.6 days pp-y. Hospital length of stay was 2.9 days pp-y, 5-year survival was 64% and average kidney transplantation rate was 7.5%. Duplicating nephrologist presence and replacing technicians with certified nurses doubled labor costs, largely offset by higher productivity (five 2-hour shifts/day) and longer dialysis vintage.

Conclusions: This intensive dialysis modality delivered by a first-rate clinical staffing represents an unparalleled approach toward an optimal treatment.

SA-PO972

Improvements in Quality of Care of Incident Hemodialysis Patients: An International Multicenter Study

Maciej Drozdz,[1] Szymon Brzosko,[2,3] Joao M. Frazao,[4,5] Fatima F. Silva,[6] Werner Kleophas,[7,8] Partha Das,[1] Stefan H. Jacobson.[9] DaVita International *[1]DaVita International, London, United Kingdom; [2]DaVita Poland, Bialystok, Poland; [3]1st Department of Nephrology and Transplantation, Medical University of Bialystok, Bialystok, Poland; [4]DaVita Portugal, Amadora, Portugal; [5]Department of Nephrology, São João Hospital Center, Porto, Portugal; [6]Davita Portugal, Amadora, Portugal; [7]DaVita Deutschland, Dusseldorf, Germany; [8]Clinic for Nephrology, Heinrich-Heine University, Dusseldorf, Germany; [9]Karolinska Institutet, Stockholm, Sweden.*

Background: The transition from predialysis care to initiation of hemodialysis (HD) has received increased attention, as this period is one of exceptionally high vulnerability. This analysis focuses on improvements in quality of HD care during the first 6 months.

Methods: We included 3462 patients (mean age 65.9, 41% females) on HD (incident <90 days, n=603, prevalent >90 days, mean 55 months, n=2859) from 56 DaVita centers in Poland and Portugal. We compared all incident to all prevalent patients (t-test and Chi-2) and analyzed improvements in quality of dialysis care in a subgroup of patients (n=258) who were followed prospectively for 6 months (paired t-test and McNemar analysis). Linear and logistic regression was used to identify features associated improvements in care.

Results: Incident (<90 days) vs all prevalent (>90 days) patients: Compared with all prevalent patients, incident patients had lower Kt/V: 1.4 vs 1.7 ***; lower Hb: 9.9 vs 11.0 g/dL ***; lower TSAT: 26% vs 31% ***; lower ferritin: 305 vs 541 ng/ml ***; lower albumin: 37 vs 40 g/dL ***; lower UF vol/HD session: 1687 vs 2260 mL ***, similar Charlson comorbidity index (CCI): 6.9 vs 6.9 (p=NS); more use of central dialysis catheters (CDC) 68% vs 26% ***; less use of AV fistulae (AVF) 34% vs 70% ***. Incident patients <90 days on HD vs the same patients after 6 months of dialysis (n=258): Treatment time increased from 679 to 715 min/week ***; dialysis blood flow increased from 294-329 mL/min ***. Linear and logistic regression including age, gender, Kt/V, albumin, diabetes and CCI showed that improvements in Kt/V at 6 months and a shift from CDC to AVF was associated with female gender, HR 0.27 (CI 0.13-0.34; ***) and HR 0.48 (CI 0.24-0.98; **), respectively. **p<0.01, ***p<0.001, NS=not significant

Conclusions: This large European multicenter analysis of incident hemodialysis patients indicates that the use of medical protocols and medical targets assures significant improvements in quality of care and a shift from CDC to AVF, which may correspond to better outcomes.

Paired statistical analysis of quality of dialysis care over 6 months

SA-PO973

Pre-ESKD Nephrology Care and Employment at the Start of Dialysis

Ahmed A. Awan,[1] Bo Zhao,[1] Samaya J. Anumudu,[1] Vivian Ho,[2] Wolfgang C. Winkelmayer,[1] Kevin F. Erickson.[1] Baylor College of Medicine *[1]Baylor College of Medicine, Houston, TX; [2]Baker Institute for Public Policy, Houston, TX.*

Background: Employment is associated with improved sense of well-being in general population and higher quality of life in patients with kidney disease. Patients who receive nephrology care prior to onset of End-Stage Kidney Disease (ESKD) experience better health outcomes, perhaps due to smoother transitions to ESKD. We examine whether pre-ESKD nephrology care can also help patients to remain employed when starting dialysis.

Methods: We used a national ESKD registry to identify all patients in the United States between the ages of 18 and 54 who initiated dialysis from January 1st, 2006 to December 31st, 2014 and who were employed 6 months prior to ESKD. Using a multivariable (Modified Poisson) regression model, we examined the independent association between ≥ 6 months of pre-ESKD nephrology care and employment at the start of dialysis. Additionally, we measured geographic variation in pre-ESKD nephrology care by county-level population quintiles among patients who were excluded from the primary cohort due to age or pre-ESKD employment status. We then examined whether geographic variation in pre-ESKD care is associated with employment at dialysis initiation.

Results: Of the 75,700 patients included in study cohort, 36,940 (49%) reported receiving pre-ESKD care for ≥ 6 months. At the individual patient level, ≥6 months of pre-ESKD care was associated with a 21 % increase in the relative risk (RR) of remaining employed at dialysis initiation (95% CI: 20% to 23%). While geographic variation in pre-ESKD care was strongly correlated with a patient's likelihood of receiving pre-ESKD care, there was no association between geographic measures of pre-ESKD care and the likelihood of employment at initiation of dialysis

Conclusions: Despite there is a strong association between pre-ESKD care of ≥ 6 months and employment at the time of dialysis onset, geographic variation in pre-ESKD care is not associated with the likelihood of remaining employed. This suggests that while pre-ESKD care may be necessary for some patients to remain employed, it may not, by itself, be sufficient to foster employment.

SA-PO974

Andon System in Hemodialysis

Franklin C. Barcellos,[2,1] Maristela Bohlke,[2] Larissa R. Ribeiro.[2] *[1]University Federal of Pelotas, Pelotas, Brazil; [2]Universidade Católica de Pelotas, Pelotas, Brazil.*

Background: Maintenance hemodialysis is a treatment that imposes clinical challenges and expenses to the health care system. Patients with end stage renal disease (ESRD) require disproportionately high use of health care in the USA, with <1% of the population using about 7% of the Medicare resource. Similar data have been reported in the other countries. The health care system have unchanged cost trajectories over the past 20 years, often neglecting one of the essential elements of successful innovation: a disciplined approach to meeting consumers' needs. Evolving to new service models on hemodialysis (e.g. encouraging automation of process) may be important. Currently the dialysis service is organized in shifts counting on own teams (doctors, nurses, and cleaning staff). Waiting time between shifts is often long, resulting in an excessive number of working hours for the staff and poor quality of life for patients. Our aim was to minimize "waiting time" for patients on in-center HD, in southern Brazil through the Andon System, method pioneered in the Toyota Production System and part of the Lean approach.

Methods: This incenter HD takes care of about 130 ESRD patients, performing more than two thousand HD session/month. An external totem attached to an inward video monitor was installed to record the patient arrival and to allocate it in the queue. The patient is identified by the system through a barcode card printed by the hospital. The admission process is done using the Andon method. The order of arrival is arranged on the computer screen from the hemodialysis room, sparing the staff work of calling the patient.

Results: Before implantation, the Lead time was one hour and thirty minutes. After the automation, the minimum transition time between HD sessions has been reduced to 30 minutes. Currently the unit starts working at 6 a.m., with the closing time around 9 p.m. (before the intervention it was 11 p.m.). Around one thousand and six hundred hours/year was spared, with an estimated savings of almost $ 80,000.

Conclusions: Examining the patient needs rather than the available delivery-system resources, can lead to the exploration of more efficient and effective ways of provide the services. The wages of health-care professionals are a key contributor to the high cost of in-center HD. Turning the dialysis service into a continuous flow mapping can be a true innovation agenda in hemodialysis care.

SA-PO975

Impact of National Payment Contracts on VA Spending and Access to Outpatient Community Dialysis

Virginia Wang,[1,2] Shailender Swaminathan,[5] Emily A. Corneau,[3] Matthew L. Maciejewski,[1] Amal Trivedi,[5] Ann M. O'Hare,[4] Vincent Mor.[5] *[1]Durham VAHCS, Durham, NC; [2]Duke Univ, Durham, NC; [3]Providence V AMC, Providence, RI; [4]VA Puget Sound HCS, Seattle, WA; [5]Brown Univ, Providence, RI.*

Background: End-stage kidney disease (ESKD) is common among Veterans. VA's limited capacity to deliver dialysis care means that VA relies heavily on community providers, making chronic dialysis the largest VA expenditure for outpatient community care. In the past, VA paid for non-VA dialysis on a local, ad hoc basis, with some payments exceeding Medicare rates. In 2011 the VA began implementing payment policies to standardize the process of pricing non-VA dialysis care, including use of the Medicare fee schedule and national dialysis contracts. This study examined the effect of VA's standardized pricing policies on VA costs and patient outcomes.

Methods: We used an interrupted time series design and 2006-2016 VA, Medicare, and the US Renal Data System data to identify Veterans receiving VA-financed dialysis in the community from non-VA providers. Changes in price over time for non-VA dialysis were ascertained from >7M VA-paid community dialysis claims. We performed multivariable regression analyses, using differential trend and intercept shift models, to examine the effects of VA pricing policies on: VA treatment prices for non-VA dialysis, access to non-VA dialysis care (number of non-VA dialysis facilities, patient distance to non-VA dialysis care), and 1-year mortality, controlling for patient and facility fixed effects.

Results: The cohort comprised 24,130 Veterans who received ≥1 VA-finaned community-based chronic dialysis treatment in 2006-2016. Before implementation of national contracts, treatment prices for non-VA dialysis care varied widely across VA facilities from $61 to $1,575 per treatment. After implementation of national contracts, there was much less variation in the cost of treatment across individuals ($73.40 to $663.37) and the average price per dialysis session dropped by 40% (p<0.001). Over the same time period, the average number of dialysis facilities providing VA-paid dialysis care grew from 19 to 37 and there were no changes in patient distance to non-VA dialysis facilities (p=0.81) or 1-year mortality (12% vs. 11%, p=0.98).

Conclusions: VA's policy to standardize national dialysis contracts resulted in a substantial increase in the value of VA-financed community dialysis care by reducing spending with no adverse effect on Veterans' access to care nor on mortality.

SA-PO976

ESRD Quality Incentive Program Payment Reductions, Mortality, Utilization, and Cost

Eric W. Young,[1] Zhechen Ding,[1] Alissa Kapke,[1] Delia Houseal,[2] Jeffrey Pearson,[1] Marc Turenne.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Centers for Medicare and Medicaid Services, Woodlawn, MD.*

Background: The ESRD Quality Incentive Program (QIP) adjusts Medicare payments to dialysis facilities based on their performance on a set of quality measures. We assessed whether the magnitude of ESRD QIP payment reductions was associated with several important patient outcomes that are largely not an intrinsic part of the QIP measure set.

Methods: We compared mortality, utilization of healthcare services and Medicare payments per patient-year during 2015-2017 for facilities in each ESRD QIP payment reduction category corresponding to their QIP performance for the same year. The patient cohort consisted of Medicare fee-for-service beneficiaries receiving chronic dialysis for ESRD on the first day of each year. Patients were attributed to the first facility that provided treatment during the year. The data sources include Medicare claims and enrollment files. Descriptive findings were confirmed with regression models that adjusted for patient factors (age, sex, race, ethnicity, diabetes, duration of ESRD and dual eligibility).

Results: Most patients were treated in facilities that did not receive an ESRD QIP payment reduction (Table). There was a stepwise increase in rates of mortality, hospitalization, hospital days and Medicare payments per year in facilities with successively larger payment reductions. The increase in Medicare payments was largely for inpatient services. All findings were statistically significant in adjusted regression models.

Conclusions: Mortality, utilization and Medicare payments were substantially higher for patients treated in facilities whose contemporaneous performance on ESRD QIP measures resulted in a payment reduction. Moreover, these outcome measures increased stepwise with the magnitude of facility payment reductions. The findings are consistent with the hypothesis that the ESRD QIP measures and scoring system capture meaningful determinants of healthcare quality and value.

Funding: Other U.S. Government Support

Patient Outcomes vs. Facility QIP Payment Reduction

		ESRD QIP Payment Reduction				
		0%	0.5%	1.0%	1.5%	2.0%
Patient Years		763,902	163,635	42,808	9,437	2,949
Mortality (%/Yr)		15.6%	16.3%	17.3%	21.2%	24.5%
Utilization (per Pt-Yr)	Hospitalizations	1.63	1.93	2.04	2.34	2.44
	Hospital Days	10.85	13.10	14.36	17.96	20.91
Payments (per Pt-Yr)	Total	$75,285	$79,729	$82,090	$94,446	$99,810
	Inpatient	$24,761	$28,678	$30,701	$37,560	$40,881

SA-PO977

Dialysis Facilities with Recurring Payment Reductions Under the ESRD Quality Incentive Program (QIP)

Marc Turenne,[1] Zhechen Ding,[1] Alissa Kapke,[1] Delia Houseal,[2] Jeffrey Pearson,[1] Eric W. Young.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Centers for Medicare and Medicaid Services, Woodlawn, MD.*

Background: The ESRD QIP is designed to promote quality of care through financial incentives that reward improvement. It is not known whether a lack of improvement in certain aspects of quality may lead some facilities to consistently receive payment reductions under the ESRD QIP. We assessed the extent to which there are facilities continuing to receive payment reductions over time, whether this is more common among certain facility types, and whether this results from lower performance on certain ESRD QIP measures.

Methods: We studied 6,135 dialysis facilities eligible for the ESRD QIP in each payment year (PY) from 2017-19. Data sources include Medicare claims and CROWNWeb. We compared ESRD QIP measure scores among facilities with a payment reduction for 0, 1, 2, or 3 PYs. We used descriptive analyses and Poisson regression to examine factors associated with the number of PYs with a payment reduction.

Results: Among ESRD QIP eligible facilities during 2017-19, 60.5% had no payment reductions, 23.9% had a payment reduction in 1 PY, 10.6% had a payment reduction in 2 PYs, and 5.0% had a payment reduction in all 3 PYs. Payment reductions in all 3 PYs were more common among facilities that are independent (17.5%) or hospital-based (14.3%), treat ≥100 patients (6.1%), and in ESRD Networks 2 or 7 (13.8% and 11.2%). These findings were statistically significant based on Poisson regression. Facilities with recurring payment reductions had lower average scores for all clinical ESRD QIP measures (Table).

Conclusions: Dialysis facilities that receive recurring payment reductions under the ESRD QIP have lower performance across a range of quality measures. It is important to assess both opportunities and potential challenges for improvement among facilities with recurring payment reductions.

Funding: Other U.S. Government Support

Average facility measure score, ESRD QIP PYs 2017-19

SA-PO978

Expansion of the ESRD Payment Bundle and Dialysis Facility Closures in the United States

Sayna Norouzi,[1] Bo Zhao,[1] Ahmed A. Awan,[3] Wolfgang C. Winkelmayer,[1] Vivian Ho,[2] Kevin F. Erickson.[1,2] *[1]Baylor College of Medicine, Bellaire, TX; [2]Baker Institute for Public Policy, Houston, TX; [3]Baylor college of medicine, Houston, TX.*

Background: The inclusion of formerly separately billable injectable medications into the ESRD payment bundle in 2011 led to concerns that some facilities facing higher costs would close, disrupting care delivery and limiting access to care for some patients. We examined whether patients were more likely to be affected by dialysis facility closures after the 2011 payment reform, and whether factors that influence closures changed following te payment reform.

Methods: We identified all patients receiving in-center hemodialysis in the United States between 2005 and 2015 and tracked dialysis facility closures throughout this time period. We used an interrupted time-series regression model to examine immediate and longer-term changes in the odds of being at a facility that closed following enactment of the expanded ESRD payment bundle. We then included interaction terms in a series of logistic regression models to examine whether the associations among selected patient, dialysis facility, and geographic characteristics and facility closures changed after 2011.

Results: Dialysis facility closures were relatively uncommon throughout the study period, ranging from 92 facilities (2.0%) affecting 3,725 patients in 2005 to 32 facilities (0.2%) affecting 797 patients in 2014. In a model where we adjusted for changes over time in patient, geographic, and dialysis facility characteristics, the odds of being affected by a dialysis facility closure did not change significantly immediately after enactment of the expanded ESRD payment bundle. Over time, the odds of being affected by a dialysis facility closure decreased by 18% (OR 0.82; 95% CI 0.81 to 0.84) each year after 2011. Patients who were black and those in rural areas and hospital-based facilities experienced a relative *increase* in the likelihood of being affected by closures after 2011, while patients who were Hispanic, dual-eligible and at smaller dialysis facilities experienced a relative *decrease* in the likelihood of being affected by closures after 2011.

Conclusions: We did not find evidence that the 2011 expanded ESRD payment bundle was associated with an increased impact of facility closures on patients receiving outpatient dialysis. However, the likelihood of being affected by facility closures changed for some potentially high risk patient groups.

Associations Between Mortality and Payment Reductions Under the Centers for Medicare & Medicaid Services (CMS) ESRD Quality Incentive Program (ESRD QIP)

Shannon Griffin,[1] Jeffrey Marr,[1] Andrew Breck,[1] Dominick Esposito,[1] Adebola O. Adeleye.[2] *[1]Insight Policy Research, Arlington, VA; [2]CMS, Woodlawn, MD.*

Background: The implementation of CMS' ESRD QIP in 2010 introduced financial incentives for certified dialysis facilities to provide high/adequate levels of care. Under the QIP, underperforming dialysis facilities receive a Medicare payment reduction of up to two percent. This study assesses how QIP penalties are associated with 1-year mortality during performance years (PY) and the likelihood of death in the years after each quality assessment.

Methods: We used Medicare claims, enrollment, and CROWNWeb data to examine mortality among outpatient dialysis patients enrolled in Medicare fee-for-service between 2010 and 2017. We used a Cox Proportional-hazards model to measure survival by payment reduction percentage and a difference-in-differences (DD) model to evaluate whether the gap in mortality between penalized and non-penalized facilities changed over time. We adjusted both models using facility and patient characteristics.

Results: Compared to facilities that received no penalty based on 2017 performance, 2017 mortality at penalized facilities was 9% higher (1.091 hazard ratio; $p < 0.001$). Mortality rates were also higher for facilities that received higher reductions: for PY2017, mortality at a facility with a 2% reduction was about 21% higher than at a facility with no reduction and 7% higher at a facility that received a 0.5% reduction (1.209 and 1.069 hazard ratios, respectively; $p < 0.001$). Results were similar for PY2010–2016. The difference in probability of death among patients at penalized facilities compared to non-penalized facilities decreased slightly after the performance year by up to 1 percentage point. DD model estimates varied in size and statistical significance across years and amount of time elapsed after each performance year.

Conclusions: Receiving an ESRD QIP payment reduction is correlated with same-year mortality among Medicare fee-for-service dialysis patients, and higher reduction amounts are associated with higher mortality rates. The differences in mortality between penalized and non-penalized facilities persisted after each performance year, though these differences decreased modestly in subsequent years.

Comprehensive Kt/V Measurement in the Medicare ESRD Quality Incentive Program: Including More Facilities and Recent Improvements in Pediatric and Home Dialysis

Alissa Kapke,[1] Katherine Hanslits,[1] Marc Turenne,[1] Jeffrey Pearson,[1] Delia Houseal,[3] Amanda Szymanski,[1] Alan B. Leichtman,[1] Eric W. Young.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Arbor Research, Ann Arbor, MI; [3]Centers for Medicare and Medicaid Services, Woodlawn, MD.*

Background: In prior Payment Years (PY), facilities primarily treating pediatric patients were often excluded from QIP dialysis adequacy measures for not treating 11 or more eligible patients. In the PY19 QIP, to include more facilities treating pediatric patients, CMS introduced a Comprehensive Kt/V measure combining age groups and modalities.

Methods: Trends in Comprehensive Kt/V were retrospectively assessed using Medicare claims and CROWNWeb data from 2012-2018. Comparisons of Kt/V QIP scores among facilities eligible for the measure in PY19 to those eligible in the prior year used publicly available Performance Score Summary Reports. Pediatric facilities were defined as having more than 50% of period prevalent patients <18 years old; home dialysis facilities were defined as having more than 50% of period prevalent patients on home HD or PD.

Results: The national average Kt/V QIP score in PY19 was 8.0, an increase of 0.6 points over PY18. However, the average Kt/V score was lower for facilities newly eligible for the measure in PY19 compared to facilities eligible in both PY19 and PY18 (5.8 vs. 8.2). For pediatric facilities, the average score in PY19 was 4.0 (N=47), compared to 7.6 (N=8) in PY18. For home dialysis facilities, the average PY19 score was 5.6 (N=409), compared to 6.9 (N=287) in PY18. Performance rates for Comprehensive Kt/V were lowest among pediatric patients, but improved since initial data collection in July 2012 (Figure).

Conclusions: The change to the Comprehensive Kt/V measure in PY19 resulted in the inclusion of more pediatric and home dialysis facilities and lower Kt/V scores for these subgroups. Increases in Comprehensive Kt/V performance rates improved among pediatric PD and home dialysis patients in 2017 and 2018.

Clinical Quality Outcomes in Dialysis Facilities Performing Clinical Research

Kurt Mussina,[2] Vladimir Rigodon,[2] Lori Vienneau,[3] Joanna Willetts,[3] Sheetal Chaudhuri,[3] Marta Reviriego-Mendoza,[3] John W. Larkin,[3] Len A. Usvyat,[3] Jeffrey L. Hymes,[3] Robert J. Kossmann,[3] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Frenova Renal Research, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: Clinical research trials in kidney disease are underperformed compared to most chronic or acute disease states (Giovanni F, et al. JASN 2004). Barriers between stakeholders in clinical trials further impedes its advancement. Uncertainty regarding the impact of clinical trials on quality scores, star ratings, and related reimbursements might be contributing to such hurdles. We compared the profiles of clinical quality scores at a large dialysis organization (LDO) between clinics performing research trials vs those that did not.

Methods: We analyzed data from in-center hemodialysis (HD) patients treated at the LDO from 2016 to 2018. We performed a pooled analysis of the percent of patients achieving targets for the clinical quality measures for: albumin (≥4g/dL), mineral bone disorder (calcium ≤10.0mg/dL, phosphate 3.0-5.5mg/dL, and iPTH 150-600pg/dL), hemoglobin (10-11g/dL), adequacy (kt/V>1.2), diabetic foot checks, missed HD treatments, and catheter use.

Results: We included data from 252 and 2201 facilities with and without clinical research, respectively. We observed no remarkable differences in clinical quality scores for clinics that performed research trials, versus clinics without research (Figure 1).

Conclusions: Findings indicate there are no meaningful differences in clinical quality scores in dialysis facilities conducting research or not. These results are of importance to clinicians and providers considering involvement in clinical research, to advance care paradigms and the state of the art in nephrology.

How to Reduce the Costs of Hemodialysis Treatment in Low-Income Countries

Malik Touam. Association RAMM-Paris-France *Necker Hospital, Paris, France.*

Background: We aimed to design a low-cost (~5000 €) dialysis monitor (LCDM) to increase access to hemodialysis (HD) in low-income countries.

Methods: LCDM is a hermetic tank with a volume of 64 l. The dialysate circulates in a closed circuit and in a single pass without mixing between the fresh dialysate and the spent dialysate. The experimental simulation setup was: 4-hour HD session; 70 kg body weight; variable dialysate flow rates (QD); blood flow rate (QB) of 300 ml/min; FX 100® dialyser; dialysate as a solution of NaCl at 155 mmol/l; "blood" as a solution of NaCl + 30 mmol/ urea l , 996 µmol/l creatinine; ultrafiltrate flow (UF) controlled by a 1% resolution pump. Samples from the inputs and outputs of the dialyzer were taken simultaneously by two operators.

Results: Table 1 shows the quality of the removal of urea and creatinine with a QB of 300 ml/min and a QD of 250 ml/min for twelve sessions of 4 hours. Table 2 shows the result of several ultrafiltration tests and the significant absence of deviation between the prescribed volume and that obtained. LCDM device meets dialysis standards and UF control equivalent to the performance of conventional HD monitors, and also reduces water consumption by around 50%.

Conclusions: LCDM is an original low cost HD monitor which paves the way to an industrial prototype. This device, along with the reuse of dialyzers/extracorporeal lines, and lactate dialysates, would drastically reduce the cost of HD in low income countries

Table 1

	UREA	CREATININE

The Nephrology Association of Karnataka (NAK) Multicentric Dialysis Practice Pattern: A Cross-Sectional Pilot Study in Karnataka, India

Arvind Conjeevaram,[1] Dr.Anupama Y J,[2] Lloyd Vincent,[3] Nanda kumar B. Sastry.[4] For the NAK Study Group *[1]Nephrology, The Bangalore Hospital, Bangalore, India; [2]Nanjappa Hospital, Shimoga, Shimoga, India; [3]Narayana Health, Bangalore, India; [4]Ramaiah Medical College and Hospital, Bangalore, India.*

Background: The rising prevalence of chronic kidney disease (CKD) in India poses a major challenge due to absence of a national registry and validated data capture systems. Policy makers as well as treating physicians face dilemmas due to absence of evidence. Karnataka, a State in South India, with over 200 dialysis centers, lacks systems and processes to ensure comprehensive data capture. The present cross sectional study, is part of NAK's initial attempt to develop and validate norms and systems for a comprehensive statewide dialysis registry in India.

Methods: Nephrologists from various dialysis centers across Karnataka state were invited to participate. Data was captured from consenting centers, after ethics board clearance. Cloud based electronic repository (Amazon Web Space) with online platform (Renalyx NIS) was used. Only confirmed prevalent CKD-V pts on maintenance hemodialysis (HD) or peritoneal dialysis (PD) were included. Unlinked, anonymized demographics and clinical details were analyzed using SPSS, Version 16.0.

Results: 2050 patients (70% male) from 32 hospitals were recruited. Mean age was 53.49 (±14.09) years. Mean BMI was 23.68. 1909 (93.1%) were on HD. Nearly 70% had dialysis vintage >1 year. Etiology wise, 801 patients (39.1%) had Diabetic Kidney Disease, 506 (24.7%) Hypertensive Nephrosclerosis, 272 (13.3%) Chronic glomerulonephritis and 92 (4.5%) chronic interstitial nephritis. At initiation of HD, 1378 (67%) had temporary catheters & 466 (22.7%) had arteriovenous fistulae (AVF). However 1691 (82.5%) prevalent pts had an AVF as current vascular access. While 56.4% were on 3/week HD, 33.2% were on 2/week HD. 121 patients (5.9%) were hepatitis C positive & 31 (1.5%) were hepatitis B positive. 8.7% pts were not on any blood pressure medications, 27.6% of pts were on 1 med, 27.7% were on 2 meds, 23.1% were on 3 or more meds. Of 104 patients (4.7%) on CAPD, 57.6% had percutaneous PD catheter insertion and 40.4 % had it surgically inserted. 81.7% were on 4 exchanges/day with 94% CAPD being manual.

Conclusions: This study highlights wide differences in dialysis practices within the state of Karnataka in South India. The vast majority of the patients were on HD. Fistula first initiative needs greater focus. Granular data capture would provide more knowledge for improvement and policy.

SA-PO984

Characteristics and Effectiveness of Dedicated Care Programs for Patients Starting Dialysis: A Systematic Review

Mirna Attalla,[1] Zoe Friedman,[2] Samuel A. Silver.[1] *[1]Queen's University, Kingston, ON, Canada; [2]Queen's University, Toronto, ON, Canada.*

Background: The transition period during dialysis initiation is associated with increased morbidity and mortality. Transitional care units are increasingly being used to reduce the risk of complications during this vulnerable period. The objectives of our systematic review were to determine the characteristics of existing transitional care programs and their effect on clinical outcomes.

Methods: We used a search strategy to search Embase, Ovid Medline, Web of Science, Cochrane Central and CINAHL for English-language studies that evaluated dedicated programs for management for incident dialysis patients; our timeline included studies published from start of database to date. Any study design was eligible, but we required the presence of a control group and patient-relevant outcomes (e.g. mortality, central venous catheter use, and quality of life). We extracted data describing the intervention, participant demographics, comorbidities, type of renal replacement therapy, and follow-up period. We assessed study quality using the Newcastle-Ottawa Quality Assessment Scale (NOQAS).

Results: The search strategy yielded 8557 studies; 62 full texts were evaluated and 9 studies with 13,033 patients were included. 6 studies evaluated in-center hemodialysis and 3 evaluated peritoneal dialysis. All included studies were observational. 5 studies were rated as high quality, with scores of 8-9 on the NOQAS evaluated programs that provided patient education, structured patient monitoring and a structured vascular access program. Three high quality studies that were similarly structured to provide intensive education and patient monitoring at the start of dialysis suggested a trend towards reduction of mortality and use of central venous catheters. However, study heterogeneity precluded meta-analysis. No studies evaluated for an effect on home dialysis or transplant uptake, and few collected feedback from patients and staff on their sustainability.

Conclusions: Few high-quality studies have evaluated dedicated programs for patients new to dialysis, and most only measure for an effect on mortality and vascular access. Further research is needed to design and evaluate these models of cares before widespread implementation, with an emphasis on patient-relevant outcomes, such as home dialysis uptake, transplant, and quality of life.

SA-PO985

Is Initiation of Twice-Weekly Maintenance Hemodialysis an Acceptable Option?

Satish Mendonca, Devika Gupta. *Nephrology, Army Hospital (Research & Referral), New Delhi, India.*

Background: Twice weekly maintenance hemodialysis (HD) is not an acceptable form of renal replacement therapy primarily because there are not enough studies to prove its sustainability. However with the concept of incremental dialysis and residual renal function gaining ground this can definitely prove to be a good option for initiation of hemodialysis. The benefits of twice weekly hemodialysis at initiation are significant with respect to economic issues, patient quality of life, access longevity and preservation of residual renal function. We present a three year follow up of patients on twice weekly HD and outcomes.

Methods: This was a three year observational folllow up of 88 patients initiated on twice weekly HD. Children, pregnant ladies, and patients being worked up for renal transplant were excluded from the study. Adequacy and basic cost effective hematologial and biochemical parameters were studied monthly in each patient. In case of complications develoing in the form of recurrent fluid overload, uncontrolled hypertension, refractory anaemia, hyperphosphatemia and features of malnutrition, the patient was shifted to thrice weekly HD.

Results: 16406 sessions of HD were studied analysing adequacy, residual renal function, cardiovascular outcomes, mineral bone status and socioeconomic factors and vascular access. Majority of the patients had a urine output of 1176 ml at initaion with a RRF of 3.1ml/min. BP was controlled in 93.19% of patients and left ventricular hypertrophy was seen in 37.2%. SpKt/v was 1.75, eKt/V was 1.38 and Std Kt/V was 2.8. IDWG was 1.91 Kgs with a mean ultrafiltration of 2600ml. There were 27.2% deaths during this period the commonest cause being cardiovascular causes and emergency HD was required in 0.24% of sessions.

Conclusions: Twice weekly HD at initiation is a favourable option with increments, in case of requirement, as majority of patients had a good urine output and RRF at commencement. It also preserves the residual renal function, reduces cost and improves the quality of life. Lack of vascular access is a major cause of morbidity and mortality as seen and more focus is required at this end. Adequacy parameters are fallaciously high as they are dependent on ultrafiltration volumes and body weight. A prime factor favouring twice wekly HD is economic and social factors in the form of cost of travel and distance/ time to reach dialysis centre.

Funding: Government Support - Non-U.S.

SA-PO986

Planned Incremental Hemodialysis (PIHD) Is a Cost-Effective and Patient-Centered Renal Replacement Therapy (RRT)

Toshimasa Takahashi,[1,2] Toshiyuki Nakao,[2] Yoshie Kanazawa.[2] *[1]Bousei Shinjyuku Minamiguti Clinic, Tokyo, Japan; [2]Organization for Kidney and Metabolic Disease Treatment, Setagaya ward, Japan.*

Background: Hemodialysis (HD) in Japan is the highest quality of RRT in the world, but its cost is increasing continuously. The conventional thrice-weekly regimen is a common way to introduce HD but not Incremental hemodialysis (IHD) in Japan. When HD patients' conditions are sufficiently managed by once-/twice-weekly HD with good adherence to their diet, its cost reduction effect can be expected.

Methods: We selected 26 CKDG5 outpatients with good-adhered of diet, we initiated PIHD considered residual renal function individually and careful follow-ups from 2013 to 2018. The average age was 63.7 (36 to 90), and 69.2% was men. Their causes of ESRD include chronic glomerulonephritis (38.5%), diabetic kidney disease (26.9%), nephrosclerosis (23.1%), and others (11.5%; polycystic kidney disease, chronic interstitial nephritis, Hypoplastic kidney). We also examined the cost of IHD.

Results: Initiation of HD was performed as follows: 11 patients were treated with once-weekly HD, and their mean eGFR was 4.49 and mean urine volume was 1510 mL/ day. 15 patients were treated with twice-weekly HD, and their mean eGFR was 2.97 and mean urine volume was 1278 mL/day. At the end of 2018, six patients, who had been treated once-weekly for 8 months on average, were transited to twice-weekly HD. Five patients, who had been treated twice-weekly for 15.6 months on average, were transited to thrice-weekly HD. Three patients have continued once-weekly HD for 3 to 11 months. 13 patients have continued twice-weekly HD for 16.4 months on average. The overall 1-year survival rate of PIHD was 91.8%, and the 5-year survival rate was 88.3%. On January 2019, we have 27 (24.5%) once-/twice weekly and 87 thrice-weekly HD patients(total 110 maintenance HD) in our clinic. The monthly costs of dialysis in January 2019 were as follows: 146,000 yen for once-weekly, 254,500 yen for twice-weekly, and 396,200 yen for thrice-weekly HD. The calculated one-year cost of 110 patients was reduced by 10.02% as

compared with the cost for all patients receiving the conventional thrice-weekly HD (4.28 vs 4.76 million yen/year, respectively.) Limitation: The cost of January 2019 is based on the current Japanese medical insurance system. Selection bias cannot be avoided.

Conclusions: PIHD is a patient-centered RRT that provides cost-effective and sustainable treatment for ESRD patients.

SA-PO987

Hepatitis B Virus Vaccine Immune Response in Dialysis Patients and Mortality: A Meta-Analysis

Suwasin Udomkarnjananun,[1] Kullaya Takkavatakarn,[2] Kearkiat Praditpornsilpa,[1] Bertrand L. Jaber,[3] Somchai Eiam-Ong,[1] Paweena Susantitaphong.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Division of Nephrology, King Chulalongkorn Memorial hospital, Bangkok, Thailand; [3]St. Elizabeth's Medical Center, Boston, MA.*

Background: Despite the effectiveness of the hepatitis B virus (HBV) vaccine in the general population, dialysis patients frequently do not develop a protective immune response. We performed a systematic review and meta-analysis to identify patient- and dialysis-related factors that are associated with HBV vaccine immune response in dialysis patients, and the association between the immune response to the HBV vaccine and mortality.

Methods: Electronic databases were searched for studies of dialysis patients that compared the characteristics of HBV vaccine responders and non-responders. Mortality was analyzed according to the vaccine immune response[NC1]. Random-effects meta-analyses were performed to compute a weighted mean difference (WMD), a pooled odds ratio (OR), and a pooled risk ratio (RR) between groups.

Results: We identified 63 studies (57 cohort studies and 6 clinical trials) with a total of 6,867 dialysis patients receiving the HBV vaccine, resulting in 4,764 (69%) responders and 2,103 (31%) non-responders. By meta-analysis, relative to non-responders, HBV vaccine responders were younger (WMD -4.6 years, P<0.001) and less likely to have diabetes mellitus (pooled OR 0.65, P<0.001), and they were less likely to carry the human leukocyte antigen (HLA) DR3 (pooled OR 0.38, P=0.01). HBV vaccine responders also had a higher serum albumin (WMD 0.12 gm/dL, P<0.001), a higher normalized protein catabolic rate (WMD 0.12 gm/kg/day, P<0.001), a higher hemoglobin (WMD 0.14 gm/dL, P=0.048), a higher parathyroid hormone level (WMD 44 pg/mL, P=0.004), and a higher Kt/V (WMD 0.10, P<0.001). Compared to non-responders, HBV vaccine responders had a 36% lower risk for all-cause mortality (pooled RR 0.64, P<0.001), a 26% lower risk for cardiovascular-related mortality (pooled RR 0.74, P=0.01), and a 24% lower risk for infection-related mortality (pooled RR 0.76, P=0.29).

Conclusions: In dialysis patients, the lack of immune response to the HBV vaccine is associated with older age, diabetes mellitus, HLA-DR3 status, lower nutritional status, lower hemoglobin, lower PTH level, and lower dialysis adequacy. Tackling some of these modifiable factors (e.g., nutritional status and dialysis adequacy) might improve the HBV vaccine immune response.

SA-PO988

Immune Response to Influenza Vaccination in Dialysis Patients: Analysis of Four Consecutive Seasons

Jaromir Eiselt,[1] Daniel Rajdl.[2] *[1]Internal Dept. 1, Charles University, Plzen, Czechia; [2]Dept. of Biochemistry, Plzen, Czechia.*

Background: Hemodialysis (HD) is associated with the state of immune dysfunction. In our previous study we identified low antibody response to influenza vaccine as an independent predictor of mortality in HD population. In the present study we tried to determine the factors influencing the immune response to influenza vaccination.

Methods: We analyzed data of a total of 46 HD patients who were vaccinated against influenza in four consecutive seasons from 2015/16 to 2018/19 and completed the 4-year follow-up. Their pre- and post-vaccine hemagglutination-inhibition antibody titres (HIA), iron status, C-reactive protein (CRP), albumin, parathyroid hormone and 25-OH vitamin D were measured each year at the time of vaccination. Post-vaccination seroprotection rates in consecutive seasons were compared using Cochran's Q test with multiple comparisons. To identify variables associated with the immune response to vaccine, analyses were performed using Spearman's correlation among post-vaccine rise in HIA, demographic data and the above mentioned biomarkers.

Results: Seroprotection rates changed during the 4-year follow-up, but >70% of seroprotection against all vaccine strains was achieved in all 4 years except H1N1 strain in a 2018/19 season. Results are summarized in table 1. We did not prove significant correlations among intensity of immune response to influenza vaccine and iron status, CRP, albumin, iPTH and 25-OH vitamin D.

Conclusions: The immune response to influenza vaccine varies from year to year in the HD population, but the percentage of seroprotection, with rare exceptions, is very high. We did not find a significant association between the potential factors of immunodeficiency (markers of inflammation / malnutrition, bone metabolism or iron status) and the level of seroprotection in HD patients.

Funding: Government Support - Non-U.S.

Vaccine strain / season	2015/16	2016/17	2017/18	2018/19

SA-PO989

Pneumococcal Vaccination Status and Mortality Risk in a National Dialysis Cohort

Connie Rhee,[1] Amy S. You,[1] Hamid Moradi,[1] Elani Streja,[2] Arksarapuk Jittirat,[3] Christina Park,[2] Tracy Nakata,[1] Michael B. Nakata,[1] Csaba P. Kovesdy,[4] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[5] *[1]University of California, Irvine, CA; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [3]University Hospitals Cleveland Medical Center, Cleveland, OH; [4]University of Tennessee Health Science Center, Memphis, TN; [5]School of Medicine, University of California, Irvine, CA.*

Background: Infection-related deaths are the second most common cause of mortality in end-stage renal disease (ESRD) patients, with pulmonary sources as the second dominant contributor following bacteremia/sepsis. While clinical practice guidelines recommend that ESRD patients undergo pneumococcal vaccination, large population-based studies suggest that non-vaccination is common, particularly in the setting of patient decline or contraindication. We thus sought to examine the relationship between pneumococcal vaccination status and mortality risk in a national dialysis cohort.

Methods: Among 976 ESRD patients from the national Biospecimen Registry Grant Program (BioReG) receiving dialysis treatment over the period of 1/2008-12/2014, we examined the relationship between pneumococcal vaccination status and all-cause mortality risk using unadjusted and multivariable Cox models adjusted for socio-demographic characteristics (e.g., age, sex, race, and ethnicity).

Results: In the overall cohort, mean ± SD age was 59 ± 14 years; 47% were female; 39% were Black; and 18% were of Hispanic ethnicity. During the follow-up period, 89.5% vs. 10.5% of received vs. did not receive pneumococcal vaccination. In unadjusted analyses, non-vaccination status was associated with a two-fold higher death risk: HR (95% CI) 2.02 (1.41-2.91), p<0.001. Following adjustment for socio-demographic characteristics, associations between non-vaccination status and higher mortality risk persisted: adjusted HR (95% CI) 1.53 (1.05-2.22), p=0.03.

Conclusions: In a national dialysis cohort, non-receipt of pneumococcal vaccination was associated with higher mortality risk. Further studies are needed to identify management strategies and develop clinical tools that augment vaccination rates in the ESRD population.

HCV Eradication Campaign in a Dialysis Clinic in Argentina: Nephrologists' Role in Patient Safety

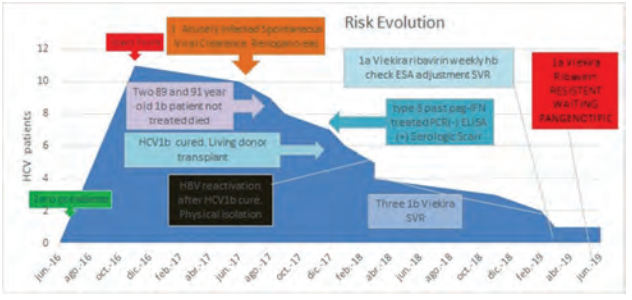
Pablo E. Bevione, Fernando J. Perretta, Esperanza Berhongaray. *Fresenius Medical Care, Pilar, Argentina.*

Introduction: Hepatitis C (HCV) increases mortality in dialysis patients and carries a worse prognosis for transplant. Still outbreaks continue to be reported. Direct antiviral agents (DAA) open the door to HCV free units with individual benefits and overall patient security.

Case Description: In 2016 eleven HCV patients were transferred to our zero prevalence clinic. As Infection risk rises with the number of positive patients and DAA were recently available, medical decision was to start the fight against HCV. Whole staff participation was of key impact. Remote hepathologist advice was enough except for complex cases. ELISA III was used for screening. PCR and posterior genotiping were done as no pangenotypic was available. Seven PCR + patientes were genotype 1b and two 1a. Spontaneous viral clearence occured in one of three 1b acutely infected patients. Three 1b patients were not treated due to their short life expectancy. One patient had Hepatitis B (HBV) and HCV 1b coinfection requiring hepathologic surveillance. Cirrhosis did not developed but HBV activation ocurred after HCV sustained virologic response (SVR). All Four HCV 1b patients were effectively treated with 90 day Viekira Pak Abbvie (Ombi/Pari/Rit/Dasa). Two HCV 1a patients were treated with Viekira Pak + Ribavirin needing ESA adjustment and weekly Hb check. Only one HCV 1a patient did not achieve response despite supervised compliance. Re-genotyping was done and pangenotypic scheduled. No patient had cirrhosis nor was IV drug user. Functional isolation was applied while viremic,

general when SVR and "N2 functional isolation" while no viremic but waiting SVR. No side effects but great relief was reported when SVR obtained.

Discussion: HCV eradication in the dialysis setting is an achievable goal even in 2019 Argentina. Preventing harming our patients, lowering their mortality and even curing some part of their chronicity is becoming possible. A clear north heading and a tight biosecurity are essential for a safe trip for our patients on care.



SA-PO991

Efficacy and Tolerability of Sofosbuvir and Daclatasvir for Treatment of Hepatitis C Genotype 3 in Patients Undergoing Maintenance Hemodialysis

Shafiq ur Rehman Cheema. *Nephrology, Allama Iqbal Medical College, Lahore, Pakistan.*

Background: There is paucity of data using direct anti-virals agents (DAA) in patients on maintenance hemodialysis infected with HCV-genotype 3. Sofosbuvir (SOF) based therapy leads to high rates of SVR with few side effects (18), however its use is restricted to patients with an eGFR of ≥ 30 ml/min per 1.73 m^2. The aim of this study is to evaluate DAA therapy in patients infected with HCV-genotype 3 on maintenance hemodialysis (MHD)

Methods: In this prospective open label, parallel, non-randomized interventiona trial, group1 received 400 mg daily sofosbuvir/ 60 mg daily daclatasvir; while group 2 received thrice a week 400 mg sofosbuvir/ daily 60 mg daclatasvir for 12 weeks. Patients with compensated cirrhosis received therapy for 24 weeks. Patients were classified as having compensated cirrhosis based on clinical data, Child-Pugh score and abdominal imaging. Fibro Scan and EGD were performed when indicated. Baseline data were obtained before, during and after therapy. HCV viral load was assessed at week 4, 8, at end of therapy and 12 weeks after treatment. The primary end point was acheivment of SVR. SVR was defined as undetectable viral load 12 weeks after completion of therapy.

Results: Eighteen patients were enrolled in each group. Mean age was 47.22±14.17 in group 1 and 53.89±14.11 in group 2. Mean duration of known infection was 4.61±1.84 years in group 1 and 3.55±1.92 years in group 2. Four (22.2%) patients in group 1, while six (33.3%) in group 2 had cirrhosis. Genotype 3 was most common with 12 (66.6%) in group 1, and 11 (61.1%) in group 2. Three patients (16.6%) had prior HCV treatment in group 1, while 02 (11.1%) in group 2. Three patients in group 1 left treatment (non-compliance) while one left in group 2 (adverse effects = skin rash). All patients in both groups achieved undetectable viral load at 12th week. Overall 29/32 (90.62%) patients achieved SVR (group 1= 15/15 or 100%; group 2= 14/17 or 82.35%). Three patients in group 2 who did not achieved SVR were all infected by genotype 1 and two of them had previously received treatment with interferon.

Conclusions: DAA therapy using sofosbuvir and declatsavir is highly effective and tolerable in patients with HCV genotype 3 undergoing maintenance hemodialysis, especially when given daily. Decreasing the dose or frequency of SOF may lead to decreased SVR or higher relapses.

SA-PO992

Viral Hepatitis Infections in Hemodialysis Facilities in a Non-Government Controlled Area in Syria

Mohamed A. Sekkarie,[1] Hani S. Alashawi,[4] Nabil Karah,[2] Aula Abbara.[3] *[1]Nephrology and Hypertension Associates, Bluefield, WV; [2]Umea University, Umea, Sweden; [3]Impeiral college London, London, United Kingdom; [4]WHO, Gaziantep, Turkey.*

Background: The prevalence of hepatitis C infections in the Syrian end stage renal disease (ESRD) population has been reported to be around 15% or less in both goverment controlled areas and host countries of Syrian refugees. The prevalence of this condition in non-government controlled areas, known to have limited resources for healthcare delivery and quality control, is unknown.

Methods: In January of 2019 we conducted a cross sectional survey of all dialysis facilities operating in a non-government controlled area in Northwestern Syria. Collected information included sources of funding of operations, available resources, patients demographics and testing of patients and staff for hepatitis C and HIV antibodies, hepatitis B surface antigen (Hep B SAg), and recent history of blood transfusion. The study was conducted by the WHO and non-government organizations (NGO's)

Results: All 20 dialysis facilities identified in the area participated in the study. Funds for operation were provided by 11 different charitable NGO's for 17 of these centers, the other three were funded by a local health directorate (n= 2) and the Turkish goverment (n=1). The area had two nephrologists and most facilities were covered by internists. Two facilites had no physician coverage. Some facilities had telenephrology care from US nephrologists. There was no regulatory body to supervise the operation of the facilities. Among 598 patients hepatitis C virus antibodies were present in 300 (50%) varying between 5 and 84% per facility. Hep B SAg was + in 32 patients (5%). One patient was HIV +. Among 148 staff members the prevalence of hepatitis C antibody was 3% and hepatitis B surface antigen 5%. The median time on dialysis for the hepatitis C positive patients was 3 years versus 2 years for the hepatitis C negative patients (P < .01). No funding is currently available to confirm the diagnosis by nucleic acid testing or for treatment.

Conclusions: Hepatitis C prevalence in this non-government area of Syria seems to be much higher compared to published data on patients in the government areas and countries hosting Syrian refugees. Limited resources and inadequate regulatory environment are contributing to this problem. Educating staff about infection control methods, and their reinforcement are of high priority. NGO's and renal societies should collaborate on this effort.

Polymorphism rs368234815 of Interferon-λ4 Gene and Development of Antibodies to Surface Antigen of Hepatitis B Virus in Hemodialysis Patients

Alicja E. Grzegorzewska, Monika K. Swiderska, Adrianna Mostowska, Pawel P. Jagodzinski. *Poznan University of Medical Sciences, Poznan, Poland.*

Background: The rs368234815 (TT/ΔG) polymorphism of interferon-λ4 gene (*IFNL4*) alone or in combination with other genes may be involved in hepatitis B virus (HBV) surface antigen (HBsAg) clearance in non-uremic subjects infected with HBV. We investigated whether *IFNL4* rs368234815 is associated with the development of HBsAg antibodies (anti-HBs) in response to HBV vaccination or infection, and HBsAg loss after HBV infection in uremic patients treated with hemodialysis (HD).

Methods: To evaluate the association between anti-HBs and rs368234815, non-responders to HBV vaccination (n=122) were compared with responders (n=121), and HBsAg positive patients not able to develop anti-HBs (n=35) were compared with HBsAg negative subjects who generated anti-HBs (n=65) after HBV infection. All anti-HBs negative subjects (n=189) were also compared with all anti-HBs positive patients (n=190). To evaluate the association between HBsAg loss after HBV infection and rs368234815, all HBsAg positive patients (n=39) were compared with all subjects who eliminated HBsAg (n=97). Patients were genotyped for *IFNL4* rs368234815 polymorphism by a polymerase chain reaction-restriction fragment length polymorphism method.

Results: Rs368234815 genotypes were distributed in accordance with Hardy-Weinberg equilibrium. The tested polymorphism was not associated with anti-HBs development either after HBV infection or HBV vaccination as well as with HBsAg loss (analyzes in models of inheritance and differences in variant allele frequencies yielded P>0.05). Adjustment for age at renal replacement therapy (RRT) onset, RRT duration, and positive antibodies to hepatitis C virus revealed that patients harboring the ΔG allele had 1.59-fold (0.98-2.56, P=0.057) higher risk for remaining anti-HBs negative after HBV vaccination or infection compared with the TT/TT subjects.

Conclusions: *IFNL4* rs368234815 is not associated with anti-HBs development in HD patients. Therefore, this polymorphism alone cannot be useful as a predictor either of responsiveness to HBV vaccination or HBsAg seroclearance in HBV infection. However, due to the relatively small number of the examined patients and borderline associations, further studies exploring this subject are reasonable.

SA-PO994

Exploring the History and Outcomes of Hepatitis B Core Antibody-Positive Hemodialysis Patients Focusing on Occult Hepatitis B

Chandrika Chitturi, Sandeep S. Soman. *Henry Ford Hospital, Dearborn, MI.*

Background: Occult HepatitisB (OHB) is defined as hepatitisB core antibody (HBcAb) positivity(pos) in the absence of surface antibody (HBsAb) or surface antigen (HBsAg). The reported incidence in hemodialysis (HD) patients (pts) is 0.3% - 58%. Our study is among the first in the US to examine the history of OHB. This work is of interest in HD pts to estimate HepatitisB transmission risk.

Methods: A retrospective study of 352 HBcAb pos HD pts at a medium sized dialysis organization was performed from 2010 to 2017. Primary outcomes were the development of HBsAb pos(considered protective) or development of HBsAg pos or new HepatitisB viremia(adverse events). Univariate and multivariate regression analysis was used to study pertinent risk factors for the outcomes comparing OHB and NonOHBpts.

Results: In our study 98 (27%) pts had OHB. Each group had similar baseline demographics, while OHB pts had a higher ALT, proportion of drug use and HepatitisC compared to nonOHB pts (Tab1). There were 15 adverse events (10 viremias) in the nonOHB group. Only 1 adverse event (viremia 19 copies/mL) was seen in the OHB group (Tab2). Conversely, OHB status was a statistically significant predictor of protective HBsAb development in follow up, occurring at a 7 fold increase compared to nonOHB pts. Univariate analysis showed that history of liver disease, HepatitisC and drug use predicted HBsAb development (Tab3). History of liver disease raises risk of adverse events in an unadjusted models (P<0.05) (Tab4).

Conclusions: OHB pts at our center tend to develop protective HBsAb titers over time rather than develop viremia/antigenemia in contrast to nonOHBpts. Our study finds that OHB confers minimal risk of potential transmission of HepatitisB among HDpts.

A Study on Prevalence of Hepatitis C Virus Infection and Its Genotype Distribution Among Chronic Renal Failure Patients on Maintenance Hemodialysis: A Single-Center Experience

Minaxi Patel,[1] Himanshu V. Patel,[2] Ansy H. Patel.[3] [1]*Institute of Kidney Diseases and Research Center - Institute of Transplantation Sciences, Ahmedabad, India;* [2]*Institute of Kidney Disease and Research Centre, Ahmedabad, India;* [3]*BJ Medical College, Ahmedabad, India.*

Background: Hepatitis c virus (HCV) infection is a very common infection in chronic renal failure (CRF) patients on maintenance hemodialysis (HD). Genotype detection is crucial for management of chronic hepatitis c patients, prediction of prognosis, epidemiological study and also for vaccine preparation. Based on the sequence divergence, till date HCV strains are divided into 7 main genotypes and multiple subtypes (67 confirmed, 20 provisional).

Methods: The aim of this study was to find out single centre prevalence and distribution of HCV genotypes in CRF patients on maintenance haemodialysis (MHD). Genotyping was performed by nested reverse transcriptase PCR. Isolation of HCV RNA, reverse transcription and nucleic acid amplification of 5' UR was carried out. Biotinylated oligonucleotide primers were used to generate amplified product and reversely hybridized to type-specific probes on nitro-cellulose strips. Conjugate and substrate were added post-hybridization to observe the generated bands which were then matched with control bands. The genotypes studied were 1a to1c, 2a to 2d, 3a to 3f, 4a to 4k, 5a and 6a.

Results: Out of 2550, 210 patients (12.14%) (Male: 166, Females: 44) were HCV positive. Genotype 1 was found in 179 (85.2%) and genotype 3 in 31(14.8%) patients. Amongst genotype 1, subtype 1a, 1b, 1ba and undetermined comprised 71.4%, 24.6%, 0.6% and 3.4% respectively. Amongst genotype 3, subtypes 3a, 3b and undetermined comprised 70.9%, 9.7% and 19.4% respectively. No other genotypes were found.

Conclusions: HCV infection was found in 12.14 % CRF patients on MHD with genotype 1 (85.2%) being predominant followed by genotype 3 (14.8%) in our study.

SA-PO996

Impaired T Cell Functionality in ESRD Is Not Reversed by Immune Checkpoint Blockade

Yen-Ling Chiu,[1,2] Fang-Yun Lay,[1] Szu-Yu Pan,[1] Kai-Hsiang Shu.[2] [1]*Far Eastern Memorial Hospital, Banciao, New Taipei City, Taiwan;* [2]*National Taiwan University, Taipei, Taiwan.*

Background: Polyfunctional T cells are critical for maintaining protection against pathogens. Patients with end-stage renal disease (ESRD) are at increased risks for infection but their pathogen-specific T cell function is not well understood.

Methods: 32 healthy individuals and 57 patients on maintenance hemodialysis were enrolled in this study. All the donors were seropositive for CMV. In addition to PMA/ionomycin, CMV peptide pools (IE1 and pp65) were used to stimulate PBMCs and four effector functions were measured by multicolor flow cytometry (IL-2, TNFα, IFNγ and CD107a) to identify polyfunctional T cells (cells capable of all four functions). The statistical comparisons were performed using the Kruskal-Wallis equality-of-populations rank test.

Results: The age of the two groups was similar (mean, 60 years old). ESRD patients showed increased levels of T cell differentiation, including the decrease in CD4+ and CD8+ T_N cells and the increase in the CD4+ and CD8+ T_{EM} and T_{EMRA} cells. T cells from ESRD patients exhibited significant impairment in their effector functions in response to PMA/ionomycin, and such impairment is independent from differentiation status. While the cellular frequency of virus-reactive CD4+ and CD8+ T cells were similar, polyfunctional T cell response were dramatically reduced in the ESRD. The CD8+ CMV-pp65-reactive polyfunctional cell frequencies showed the most dramatic reduction, 12.4% in healthy donors versus 0.8% in ESRD patients ($p<0.001$). We further identified that immune checkpoint molecules PD-1 and TIM-3 are upregulated on T cells from ESRD patients; nevertheless, immune checkpoint blockade therapy and regulatory T cell depletion did not reverse the dysfunction phenotype. Transcriptome analysis demonstrated pathway enrichment of advanced T cell differentiation in ESRD but did not demonstrate the enrichment of exhaustion related genes in T cells from ESRD patients.

Conclusions: Renal failure patients are characterized by a dramatic loss of polyfunctional T cells and impairment in T cell effector functions, which might explain the increased risk for infection and cancer. Although inhibitory receptors such as PD-1 are upregulated, such phenomenon is distinct from T cell exhaustion.

SA-PO997

Pre-ESRD Infection Event and Post-ESRD Mortality in Patients with Advanced CKD Transitioning to Dialysis

Cheng chia Lee, Chih-Hsiang Chang. *Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: Accumulating evidence indicates that infection is a frequent event in patients with non-dialysis advanced chroinc kidney disease (CKD) and that reduced estimated glomerular filtration rate(eGFR) is associated with a higher risk of subsequent short-term mortality. However, It remains unclear whether infection events before entering dialysis have a long-term negative impact on patients with advanced CKD who survive to permanent dialysis.

Methods: Using Taiwan National Health Insurance Research Database, we enrolled 62,872 patients with advanced CKD who transitioned to maintenance dialysis between January 1, 2004 and December 31, 2013. We identified 20,566 (32.7%) patients who had at least one infection episode during the pre-dialysis advanced CKD period. We used multivariable Cox models to determine the association of pre-dialysis infection exposure with all-cause mortality after starting dialysis. Furthermore, we analyzed the risk of post-ESRD mortality according to four quartiles based on the annual number of infection episodes during pre-dialysis advanced CKD.

Results: Compared with no infection during advanced CKD, the presence of infection exposure during that period was independently associated with a higher risk of first-year mortality (hazard ratio [HR] 1.42, 95% confidence interval [CI] 1.35–1.50) and the increased risk still exits during entire follow-up period (HR 1.22, 95% CI 1.19–1.25). The risks also increased incrementally with higher annual number of infections during advanced CKD (P for trend< 0.001).

Conclusions: Pre-ESRD infection events are associated with increased risk of ealy and late post-ESRD moratlity in patients with advanced CKD transitioning to dialysis.

Funding: Private Foundation Support, Government Support - Non-U.S.

All-cause mortality in patients with and without infection history during pre-dialysis advanced CKD

Implementation of Antibiotic Stewardship (AS) in a Large Dialysis Organization

Chance Mysayphonh,[1] Tory Scoggins,[1] Patricia McCarley,[1] Lorien S. Dalrymple,[1] Norma J. Ofsthun,[1] Eric D. Weinhandl,[1,2] Jeffrey L. Hymes.[1] [1]*Fresenius Medical Care North America, Waltham, MA;* [2]*University of Minnesota, Minneapolis, MN.*

Background: Fresenius Kidney Care (FKC) implemented an antibiotic stewardship (AS) program to ensure blood cultures were drawn prior to antibiotic administration and to optimize the selection of empiric antibiotic therapy, timing of de-escalation of broad-spectrum antibiotics, and the duration of antibiotic therapy.

Methods: The FKC AS program consisted of the following: 1) a care pathway for catheter-related blood stream infection (BSI); 2) implementation of a software platform that allowed for real-time monitoring of blood cultures, prescription of IV antibiotics, and blood culture (BC) and sensitivity results; 3) a pharmacist to monitor BC results and IV antibiotic treatment; and 4) educational programs. Starting in 2018, a targeted deployment of the AS program was undertaken sequentially in four regions. To examine the effect of AS on BSI rates, we identified hemodialysis (HD) patients in FKC facilities between January 1, 2016, and March 31, 2019 and ascertained vascular access (VA) type in use during each HD session and positive BC results. To estimate effects of the intervention,

we fit a series of Poisson regression models of BSI incidence, adjusted for region, VA type, secular trend, seasonality, and region-specific timing of the launch of the intervention.

Results: The cohort included 42,535 HD patients; 696,106 patient-months (80% with fistula/graft, 20% with catheter); and 3,747 BSIs (39% with fistula/graft, 61% with catheter). Among all 4 regions, the adjusted secular trend during the study era was 7% lower BSI incidence per year. After accounting for this trend and seasonality, the adjusted relative rate (ARR) of BSI incidence after the launch of AS was 0.58 (95% CI 0.48-0.70), relative to expected incidence in the absence of the intervention. The ARR was 0.78 with fistula/graft and 0.48 with catheter; ARR varied among the regions (Table).

Conclusions: Implementation of AS was associated with a reduction in BSI incidence relative to modeled trends. However, outcomes differed by access type and region.

Funding: Commercial Support - Fresenius Medical Care North America

	Fistula/Graft		Catheter

Bloodstream Infections in Relation to Environmental Cultures in 12 Dialysis Units in New York City

Nasser M. Alnazari,[3,1] Sean Yaphe,[2,1] Steven Weiss,[4] George N. Coritsidis.[1,4]
[1]Nephrology, Icahn school of medicine at Mount Sinai, New York, NY; [2]Henry Ford Hospital, Royal Oak, MI; [3]Elmhurst Hospital Center, Elmhurst, NY; [4]Atlantic Dialysis Management Services, New York, NY.

Background: Infections are an important complication of end-stage renal disease (ESRD) and represent a significant contribution to morbidity and mortality rates. Central venous catheters (CVC) contribute to bloodstream infections (BSI). We examine environmental cultures in 12 units of a small dialysis organization (SDO) in New York City in comparison to bloodstream infection surveillance data to discern whether a potential association exists.

Methods: Direct and non-direct care staff members and the dialysis unit environment (dialysis chair, dialysis machine, laptop, television remote, doorknobs, countertops, etc.) were cultured. Jewelry worn and method of hand hygiene were noted. Cultures that grew normal flora, or airborne contaminate were considered negative. This data was compared with the number of bloodstream infections in 2018 and standardized infection ratio (SIR) of CVC BSI.

Results: A total of 560 environmental cultures were collected: 349 from the dialysis environment and 211 from staff. Of the total cultures, 25% were positive, while 18.5% of staff cultures were positive. 56% of staff performed hand hygiene immediately prior to culture: 6.2% with alcohol-based sanitizer, 49.2% with soap and water, and 0.5% with both. 18.5% of staff also wore jewelry, namely non-direct care personnel. Table 1 displays the percentage of all positive cultures and positive direct-care staff cultures in each unit, as well as their associated number of BSIs and SIR.

Conclusions: The 12 units of this SDO have BSI rates that are lower than predicted. Additionally, environmental cultures are in large majority negative. This suggests that these dialysis units are following infection protocol and reducing the spread of BSIs. Infections that do arise may be stemming from other environmental sources, which include the home environment and other healthcare settings. Staff is not following the latest CDC guidelines regarding using hand sanitizer preferentially over hand washing, which is an opportunity for education and improvement

Table 1: Environmental culture growth compared to BSI and SIR in 12 units of an SDO in New York City

Analysis of Dual-State Antibiotic Prescription Practices in the ESRD Population

Ilay Rakhman,[1,2] Sean Yaphe,[3] Carly E. Munro,[5] Aaron S. Stern,[3,2] Teresa Lubowski,[4] Ti-Kuang Lee,[4] George N. Coritsidis.[3] *[1]Nephrology, Elmhurst Hospital, Queens, NY; [2]Mount Sinai Hospital, New York, NY; [3]Elmhurst Hospital Center, Elmhurst, NY; [4]IPRO, Albany, NY; [5]Maimonides Medical Center, Brooklyn, NY.*

Background: We previously analyzed outpatient oral antibiotic prescriptions (ABP) for end-stage renal disease patients on hemodialysis (ESRD) in New York State (NYS). Nearly 50% of ABPs had no associated infectious diagnosis. Here, we compare ABPs between NYS and South Carolina (SC).

Methods: 2018 NYS and SC Medicare part B and D data were collected and linked to ICD-10 diagnosis (DX) codes. Patients under 18 years of age, on peritoneal dialysis, or who had chronic kidney disease were excluded. ICD-10 codes were classified into 14 DXs. Chi-square analysis was used to compare data between NYS and SC.

Results: Table 1 presents the top 5 infection DXs. Incidence of ABPs was 619.9/1000 patients in NYS compared with 597.3/1000 patients in SC. In both states nearly 40% of ABP were categorized as nonspecific symptoms or had no DX. The top 10 ABPs were also similar between states (Table 2). Trimethoprim-sulfamethoxazole was prescribed often in both states despite not being recommended in ESRD.

Conclusions: Antibiotic selection and sources of infection were similar in both states, and indications are often not clear. This suggests that antibiotic guidelines in ESRD is a national problem. The number of skin infections may reflect access complications.

Table 1: Top 5 Infectious Diagnosis			
	NYS	SC	P
Respiratory	19.48%	19.96%	0.39

Microbiome in Tunneled Catheters of Patients Receiving Maintenance Hemodialysis

Anuradha Wadhwa,[1,2] Travis R. Jameson,[1] Michael Zilliox,[1] Kavitha Vellanki,[1] Vinod K. Bansal,[1] Benjamin Ling,[1] Julia Schneider,[1] Holly J. Kramer.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Hines VA Hospital, Chicago, IL.*

Background: Sepsis is one of the leading causes of morbidity and mortality in patients receiving maintenance hemodialysis via catheter. Bacteremia in dialysis patients generally results from contamination of the catheter lumen (biofilm). Dialysis catheter lumen is instilled with sterile heparin solution at the end of dialysis treatment and discarded prior to next treatment. The aim of our pilot study was to identify the presence and characteristics of microbiome in heparin fluid in tunneled catheters.

Methods: For 20 hemodialysis patients with catheters, 3 ml samples of heparin (mixed with blood) in catheter lumen was collected. Bacterial DNA was isolated and amplified using multiple displacement amplification; 16S rRNA sequence analysis was used to identify and characterize the microbiome. Sample diversity of the sequence positive composition was quantified using the inverse Simpson, and Chao indices.

Results: Among the 20 patients with a tunneled hemodialysis catheter, median age was 54 (range 20-80 years), 50% were male, and race was African American in 50% and white in 20% and rest were Hispanic or Asian. Median catheter days was 127 (range 42 to 347 days). Seven of the 20 catheter fluid samples had greater than 200 reads. One specimen was dominated (greater than 50%reads) by the genera Lactobacillus. This patient with dominance of Lactobacillus species in the catheter microbiome was a young female with catheter duration of 344 days. The other 6 showed no dominant species and showed high diversity with inverse Simpson Index 6.25 (95% CI 4.34, 11.11) and Chao index of 35.22 (95% CI 27.42, 43.02).

Conclusions: The microbiome of heparinized fluid in tunneled dialysis catheters does not appear to be sterile. Information on the catheter biome may be used to predict future blood stream infections and/or to develop protocols for infection prevention.

Change in the Incidence and Pattern of Staphylococcus aureus Bacteraemias in Haemodialysis Patients: 12-Year Single-Centre Experience

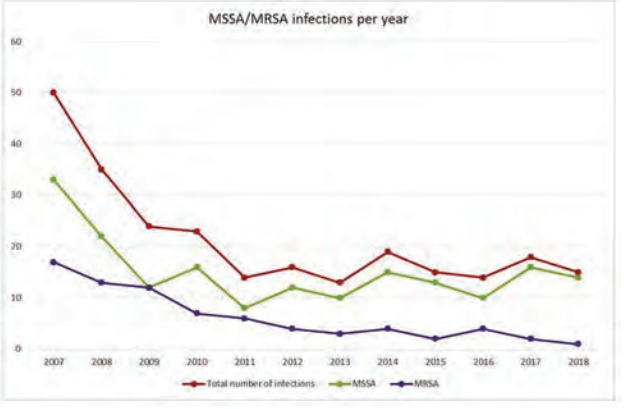
Moira Stanley,[4] Jonathan W. Hurst,[3] Jayakeerthi Rangaiah,[2] David Makanjuola.[1] *[1]Renal unit, Epsom & St. Helier University Hospitals NHS Trust, Surrey, United Kingdom; [2]Microbiology, Epsom & St. Helier University Hospitals NHS Trust, Surrey, United Kingdom; [3]Renal unit, Epsom and St Helier University Hospitals NHS Trust, Surrey, United Kingdom; [4]St. Helier Hospital, Wrythe Lane, Carshalton, Epsom & St. Helier University Hospitals NHS Trust, Surrey, United Kingdom.*

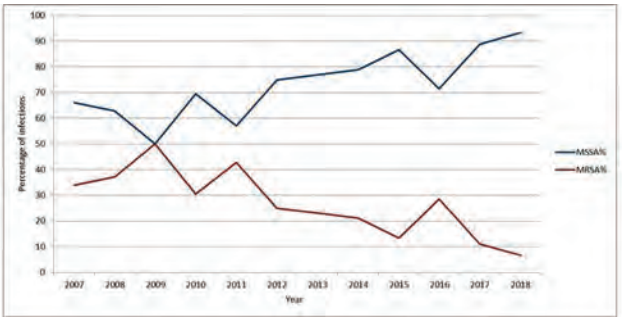
Background: Patients on haemodialysis (HD) are greater risk of infection if they dialyse through lines, than with via arteriovenous fistulae or grafts. The most commonly implicated organism is *Staphylococcus aureus* (SA), which can cause metastatic infections e.g endocarditis, osteomyelitis. There has been a focus on reducing the incidence of infections, especially methicillin resistant SA (MRSA). We looked at the incidence of methicillin sensitive SA (MSSA) and MRSA in HD patients with SA bacteraemia at our centre over the last 12 years.

Methods: Data were collected from the hospital's microbiology database of all the SA bacteraemias in HD patients between 2007 and 2018.

Results: There were 261 bacteraemias in 1361 patients, from a total of 32,000 dialysis episodes. 62.8% were male. Median age was 67 years (range 18-96). Blood cultures grew MSSA - 71%, MRSA - 29%. 78% occurred in patients dialysing via lines. The incidence of infections fell from 50 in 2007 to 15 in 2018. The proportion of MSSA infections increased however.

Conclusions: There was a significant reduction in SA bacteraemias, but an increase in the proportion of MSSA bacteraemias. It is important not to allow the reduction in numbers (in particular of MRSA) to lead to complacency in the efforts to reduce the numbers of MSSA and other infections in this particularly vulnerable group of patients.





SA-PO1003

A Clinical Nomogram for the Prediction of Early Mortality in Elderly Patients Initiating Dialysis for ESRD

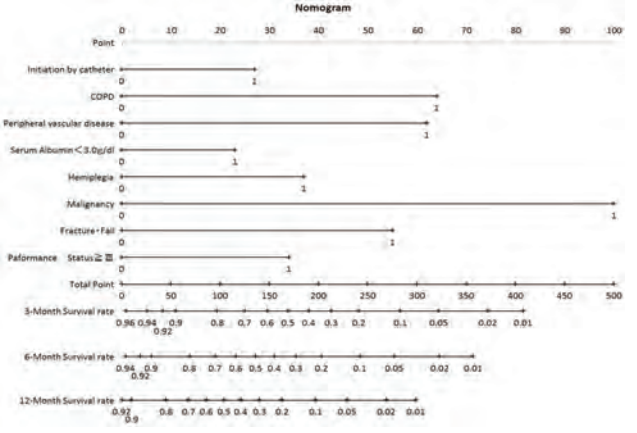
Masaki Yoshida, Kazue Ueki. *Sanshikai TOHO hospital, Midori, Japan.*

Background: The number of elderly patients (>80 years) with end-stage renal disease is rapidly increasing. The initiation of dialysis extends the duration of survival; however, the rate of early mortality—mortality within the first few months after the initiation of dialysis—is reportedly higher than the rate of late mortality.

Methods: We retrospectively studied a cohort of 300 patients, aged 80 years or older, in whom dialysis was initiated between January 1, 2010 and December 31, 2017. The rate of early mortality was assessed using the Kaplan-Meier method and the equivalence of survival curves was tested using log-rank tests. The univariate and multivariate analyses were performed using the Cox proportional-hazards model. To evaluate nomogram performance, we assessed both the discrimination and calibration of these models. Two hundred bootstrap resamples were used for internal validation of the accuracy estimates to reduce over-fit bias and to determine 95% confidence intervals

Results: The nomogram was built from eight predictors of initiation of dialysis by the temporary catheter (Hazard Ratio[HR] : 1.58, P=0.025), COPD (HR : 2.93, P=0.008), Peripheral vascular disease (HR : 2.82, P=0.019), Hemiplegia (HR : 1.87, P=0.011), Malignancy (HR : 5.37, P<0.001), Serum Albumin<3.0g/dl (HR : 1.48, P=0.061), Bone fracture by the fall within one year (HR : 2.52, P=0.010) and Performance status≧3(HR : 1.77, P=0.025). Nomogram to predict 3-, 6- and 12-month survival using eight easily available clinical characteristics. To use the nomogram, locate patient's variable on the corresponding axis; draw a line to the points axis, sum the points, and draw a line from the total points axis to the 3-, 6- and 12-month survival rate axis.

Conclusions: We developed and validated a nomogram that predict early mortality in elderly patients starting dialysis for end-stage renal disease. Nomogram might help nephrologists make a shared decision with patients and families regarding the initiation of dialysis.



SA-PO1004

Measurement of Dialysate Sodium: Beware of Assay Artifact

Pierre-Antoine Brown,[2] Swapnil Hiremath.[1] *[1]University of Ottawa, Ottawa, ON, Canada; [2]The Ottawa Hospital, Ottawa, ON, Canada.*

Background: Dialysate sodium is traditionally set at a constant in the range of 136 to 140 mmol/L. However, increasing dialysate sodium, either as a constant, or using sodium ramping, modelling, or using biofeedback systems, can decrease intradialytic hypotension, and symptoms. An individualised dialysate sodium prescription may decrease thirst, interdialytic weight gain and blood pressure. There are some reports that the measured dialysate sodium concentration may vary from the the ordered sodium. This quality assurance study was conducted to measure the bias between machine reported conductivity and the actual delivered dialysate sodium and determine the factors associated with the bias.

Methods: We conducted analyses on 3 different dialysis machines by running patient-free dialysis sessions with varying combinations of sodium and potassium baths. With the different permutations of the 3 machines, sodium and potassium baths. The conductivity meters of the machines were validated prior to each run using a calibrated external handheld conductivity meter. Dialysate samples were sent for measurement of sodium (indirect ion selective [ISE] method) using the Siemens Vista 1500 analyzer in an accredited clinical laboratory, using serum and urine modes. Samples were obtained from the arterial dialyser port. The primary outcome was quantification of the bias between ordered and measured dialysate sodium, defined as the mean difference between the two. The secondary outcome was to measure the variation of the bias based on certain prespecified covariates.

Results: Overall data are available as 230 measurements from 85 sessions. Overall, there was a significant difference between ordered sodium level and measured sodum (mean +5.6, standard deviation [SD] 1.8 mmol/L), with the delivered sodium being higher. There was no significant difference between the different machines, differing sodium ordered (135 or 140), K bath (2 or 3K), time (0, 1, 2, 4 hours). However, there was a marked difference between using serum mode (+ 6.0 SD 1.6) and urine mode (mean 1.5, SD 2.9).

Conclusions: Since serum plasma is composed of 7% solids, the serum measurement has a correction factor that should not be applied when measuring samples with lower amouont of proteins. In the case of the dialysate, using urine mode for measurement of electrolytes corrects the apparent bias in delivered sodium.

SA-PO1005

Impact of the Serum Sodium and Chloride Difference on All-Cause Mortality in Japanese Hemodialysis Patients: The Miyazaki Dialysis Cohort Study

Tatsunori Toida,[1,2] Yuji Sato,[3] Kazuo Kitamura,[4] Shouichi Fujimoto.[1,3]
[1]Department of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [2]Department of Internal Medicine, Miyazaki Prefectural Nobeoka Hospital, Nobeoka city, Japan; [3]Dialysis Division, University of Miyazaki Hospital, Miyazaki, Japan; [4]Department of Internal Medicine, Circulatory and Body Fluid Regulation, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan.

Background: Few studies have examined the relationship between the acid-base balance and mortality in hemodialysis patients. In actual clinical settings, the regular collection of blood gas data is rarely conducted. In theory, the serum sodium and chloride difference (SCD) is equal to the anion gap plus bicarbonate, and we herein investigated whether SCD as a simple acid-base balance index affected the risk of mortality in maintenance hemodialysis patients.

Methods: Study design: Cohort study. Setting, Participants: Data from the Miyazaki Dialysis Cohort study, including 1113 hemodialysis patients aged ≥18 years, dialysate sodium 140 mEq/L, with SCD pre- and post-dialysis. Predictors: Pre-dialysis SCD, <33, 33 to 35, 35 to 37, ≥37 (reference), and post-dialysis SCD <36, 36 to 37, 37 to 39, ≥39 (reference) according to quartiles. Outcomes: All-cause mortality during a 2-year follow-up. Measurements: The crude mortality rate in each group was assessed using a Kaplan–Meier analysis with the Log-rank test. Hazard ratios (HRs) were estimated using Cox's model for the relationships between SCD categories and mortality, and adjusted for potential confounders. Patients in the higher group were set as our reference category.

Results: Among the 1113 patients in this cohort study (median age [interquartile range], age 69 [59-77] years, dialysis vintage 72 [34-141] months, and females 42.7%), 154 patients died during the follow-up. The Kaplan-Meier analysis showed that the survival rate was significantly lower in patients in the lowest SCD (<36) group post-dialysis than in those in the other groups (Log-rank test, P<0.01), whereas no significant differences were observed pre-dialysis (Log-rank test, P=0.26). Cox's regression analysis showed that the lowest SCD (<36) group post-dialysis was independently associated with an increased risk of mortality (adjusted HR [95% CI] 2.01 [1.25-3.23]). No relationship was observed between pre-dialysis SCD levels and all-cause mortality.

Conclusions: Among Japanese maintenance hemodialysis patients, low SCD levels post-dialysis, but not pre-dialysis, increased the risk of mortality. The present results suggest that SCD post-dialysis is a predictor of mortality.

SA-PO1006

Anion Gap Predicts Early Mortality After Starting Dialysis in the Elderly

Yohei Arai,[2,1] Hiroyuki Tanaka,[3] Emi Sakamoto,[2] Shingo Shioji,[3] Isao Kondo,[2] Minami Suzuki,[2] Daisuke Katagiri,[2] Manami Tada,[2] Fumihiko Hinoshita.[2]
[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]National Center for Global Health and Medicine, Tokyo, Japan; [3]Yokosuka Kyosai Hospital, Yokosuka, Japan.

Background: The kidney has the principal role in the maintenance of acid-base balance. Metabolic acidosis develops due to reduced renal function and excretion of the daily acid load. It is well known that uremia causes an increase in the serum anion gap (AG). However, it is not known whether changes in AG is associated with mortality after starting dialysis. Therefore, we investigated the association between AG and early mortality after starting dialysis in elderly patients with end-stage renal disease (ESRD).

Methods: We conducted a retrospective cohort study to investigate the association between AG and early mortality after starting dialysis in the elderly. The cohort consisted of patients aged 75 years old or older who started dialysis for ESRD at the National Center for Global Health and Medicine from 2010 to 2017 and at Yokosuka Kyosai Hospital from 2007 to 2011. They were stratified into three groups (G1-3) based on delta AG (ΔAG). ΔAG was calculated using a following equation, ΔAG = serum sodium level - (serum chloride level + serum bicarbonate level) - 12. The primary outcome was death within a year of the start of dialysis. Data were analyzed using Cox proportional hazard models with adjustments for baseline characteristics.

Results: We enrolled 254 patients (males, 59%). Median ΔAG was 2.6 (G1, >3, n=111; G2, 0-3, n=103; G3, <0, n=40). During a mean follow-up of 320 days, the primary outcome was observed in 43 patients. G1 and G3 had significantly higher hazard ratios (HR) for the primary outcome than G2 (G1, HR 2.47, 95% confidence interval 1.13-5.37; G3, HR 3.86, 95% confidence interval 1.62-9.16). After adjusting for baseline characteristics, G1 had significantly higher adjusted hazard ratio (aHR) for the primary outcome than G2 (G1, aHR 3.63, 95% confidence interval 1.56-8.45; G3, aHR 2.33, 95% confidence interval 0.88-6.19).

Conclusions: It is noteworthy that there is an obvious J-curve phenomenon between AG and early mortality after starting dialysis in the elderly.

SA-PO1007

Comparing the Prognostic Value of eGFR and Residual Urine Volume in New Dialysis Patients

Chiehlun Yang,[1] Xinxin Ma,[1] Yan-ru Chen,[1] Chen Gangyi,[3] Yu Peng,[2] Hui Peng.[1]
[1]The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [2]Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China; [3]The First Affiliated Hospital of Guangzhou University of Traditional Chinese Medicine, Guangzhou, China.

Background: Residual renal function (RRF) is a pivotal predictor for long-time outcome of maintenance dialysis patients that can be assessed by simply measuring residual urine volume (RUV) or calculating estimated glomerular filtration rate (eGFR) at the start of dialysis. However, it remains unknown which one is better for prognostic evaluation as the substitution of RRF in new dialysis patients.

Methods: This is a multiple-center, retroperspective cohort study. Patients who started dialysis between January1, 2008 and December 31, 2017 at the third affiliated hospital of Sun-Yat Sen University were eligible for the study with follow-up through June 30, 2018. The data was collected at the start of dialysis. All eGFR was calculated by eGFR-EPI equation. Main endpoint was all-cause mortality. The predictive accuracy and discriminative ability of the nomogram were determined by a concordance index (C-index) and calibration curve and were compared with eGFR-EPI and RUV. The results were validated with data from dialysis patients at the other two institution enrolled from 2008 to 2017.

Results: 612 patients were included in the primary cohort, while 236 patients were enrolled in the validation cohort. Compared with eGFR, RUV showed a better prognostic value for dialysis patients both in the primary and validation cohort either by K-M method or cox regression analysis. Independent risk factors derived from multivariable analysis of the primary cohort to predict mortality were age, diabetes mellitus, mean blood pressure, albumin, uric acid which were all assembled into the nomogram with RUV (nomogram B) or with eGFR (nomogram A). The calibration curve for the probability of mortality showed that the nomogram B (RUV) predictions were in better agreement with actual observations. The C-index of nomogram B (RUV) for predicting mortality was 0.680 (P =0.004), which was statistically higher than the C-index values of nomogram A (0.570). The results were confirmed in the validation cohort.

Conclusions: Our results show that higher residual urine volume at the beginning of dialysis was associated with lower risk of mortality, that indicates the RUV has a better prognostic value than eGFR at the beginning of dialysis for maintenance dialysis patients.

SA-PO1008

Impaired Secretory Clearance in the Residual Kidney of Hemodialysis Patients

Christian G. Bolanos,[1,2] Sheldon Leong,[1] Natalie Plummer,[1,2] Timothy W. Meyer,[1,2] Tammy L. Sirich.[1,2]
[1]Nephrology, Stanford University, Palo Alto, CA; [2]Veterans Affairs Palo Atlo, Palo Alto, CA.

Background: Residual kidney function is associated with survival and better control of fluid and inorganic solutes in patients on hemodialysis (HD). This study assessed the extent to which the residual kidney maintains the ability to clear organic solutes by tubular secretion.

Methods: Plasma and timed urine were collected to measure kidney clearances for the secreted solutes hippurate (HIPP), indoxyl sulfate (IS), and p-cresol sulfate (PCS) in 10 patients on twice weekly HD with residual kidney function and in 10 control subjects. Clearances were expressed in terms of the free, unbound solute levels. Clearances were normalized to the GFR (fractional clearances) to assess the degree to which solutes were secreted. GFR was calculated as the mean of the creatinine and urea kidney clearances.

Results: As expected, the GFR was much lower in the HD patients than control subjects (4.0±2.0 vs. 97±18 ml/min/1.73m^2, p<0.001). Kidney clearances of HIPP, IS, and PCS were also much lower in the HD patients. The fractional clearances of these solutes remained greater than 1 in the HD patients, confirming that they were cleared by secretion. The degrees to which secretory clearances of these solutes were maintained relative to GFR in the residual kidney, however, varied greatly. Fractional HIPP clearance was preserved in the HD patients as compared to control subjects (15±10 vs. 19±5, p 0.35). Secretion of IS and PCS, however, declined to a greater degree than the GFR in the residual kidney of HD patients, so that their fractional clearances were markedly lower than the control subjects (IS: 9.2±6.1 vs. 31±18, p<0.001; PCS: 4.4±2.7 vs. 12±3, p<0.001).

Conclusions: Secretory clearances of organic solutes are variably impaired in the residual kidney of HD patients. Residual secretory function cannot therefore be assessed by measurement of a single solute. Further studies will be required to assess the residual kidney's contribution to removal of medications and uremic solutes which are cleared by secretion and guide adjustment of medication doses and dialysis prescriptions.

Funding: Veterans Affairs Support

Solute	Clearance (ml/min/1.73m2)		Fractional Clearance	
	HD	Control	HD	Control

SA-PO1009

Non-GFR Determinants of Endogenous Filtration Markers in Dialysis Patients

Wieneke Michels,[1] Seungyoung Hwang,[2] Raymond T. Krediet,[3] Friedo W. Dekker,[1] Tariq Shafi.[4] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]American Psychiatric Association, Washington, DC; [3]Academic Medical Center, Amsterdam, Netherlands; [4]University of Mississippi Medical Center, Jackson, MS.*

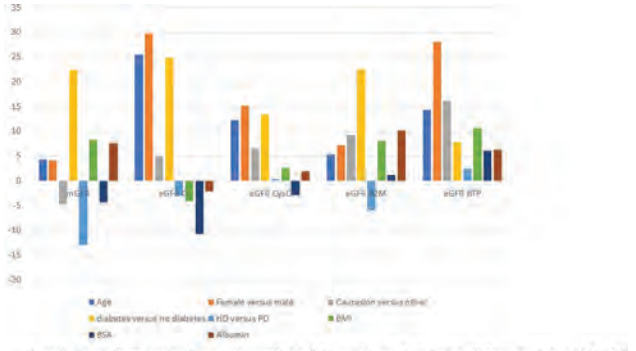
Background: When kidney function declines, measurement of residual kidney function (RKF) becomes challenging, while the importance of precise measurement rises. We sought to understand the non-GFR determinants of endogenous filtration markers (Beta-2-microglobulin (B2M), Beta-Trace Protein (BTP), and cystatin C) in dialysis patients.

Methods: We measured GFR (mGFR; average of urinary urea and creatinine clearance) and estimated GFR (eGFR) from endogenous markers in patients from the Netherlands Cooperative Study on Adequacy of Dialysis (NECOSAD) cohort. We used stacked generalized estimating equation (GEE) models to estimated associations of several factors with eGFR, including mGFR.

Results: 1107 patients were eligible for inclusion, of whom 224 without RKF. Mean age was 61 (± 15) years, and mean mGFR was 4,4 (± 32,1) ml/min/1.73m2. In those with RKF. BTM, BTP and Cystatin C were all associated with age. Only BTP was associated with race. All associations became smaller after accounting for mGFR. Compared to creatinine, the effect of age was significantly smaller for B2M and the effect of sex was significantly smaller for B2M and Cystatin C After adjustment for age, sex and race associations dialysis modality was significantly less strong associated with BTP than with mGFR. Additional adjustment for mGFR resulted in a smaller associations for diabetes with cystatine C when compared to creatinine. However, diabetes was stronger associated with BTP than creatinine.

Conclusions: In dialysis patients, BTP, B2M, and cystatin C were mainly influenced by mGFR, but additionally by age sex and race. Furthermore, diabetes and dialysis modality also influenced these results. Use of these makers for GFR estimation should account for these influences.

Funding: Government Support - Non-U.S.



Associations of age, sex and race are unadjusted. Associations of diabetes, dialysis modality, BMI, BSA and albumin (g/dL) are adjusted for age, sex and race

SA-PO1010

Eliminating Routine Post-Dialysis Serum Urea Nitrogen Measurements in Hemodialysis: Testing a Proposed Method Using Conductivity Dialyzer Clearance to Determine Protein Catabolic Rate

John Howard, Andrew I. Chin. *University of California Davis Medical Center, Sacramento, CA.*

Background: Traditionally, pre and post-HD BUN measurements are used to determine Kt/V and normalized protein catabolic rate (PCRn). Timing and care of post-HD BUN sampling is critical for results to be accurate. A method of estimating PCRn without the post-HD BUN, utilizing conductivity clearance and only a pre-HD BUN, has recently been proposed. We tested this method in a cohort of patients in which online conductivity clearance monitoring (OCM) and clearance by usual formal kinetic modeling were measured.

Methods: We used a retrospective cohort of 39 patients totaling 271 HD treatments during which OCM and routine monthly laboratory tests with formal kinetic modeling for Kt/V and PCRn were performed. Data (including residual renal function) were entered into the Solute-Solver® version 2.11 online 2-pool kinetic modeling program. For volume of distribution of urea (V), we tested 3 values for each treatment: 1) average of 6 months prior kinetic model V; 2) Watson formula estimated V; and 3) Chertow formula estimated V. Output data of interest included the estimated post-HD BUN, spKt/V and PCRn based on these estimated values.

Results: The spKt/V by OCM underestimated that of formal kinetic modeling with a mean difference of 0.40, primarily driven by difference in V. The overall correlation of spKt/V was modest. Using pre-HD BUN with OCM to estimate PCRn as proposed by Daugirdas, we found a good correlation between PCRn by kinetic modeling and OCM method (Fig 1).

Conclusions: In this retrospective evaluation, the method using OCM without a post-HD BUN, as proposed by Daugirdas, appears to adequately estimate PCRn. The post-HD blood draw, subject to inaccuracies due to improper sampling technique, is potentially problematic in traditional determinations of HD adequacy and calculation of PCRn. OCM based calculations of Kt/V and PCRn remove this potential source of error. This process has practical applications and should be further validated.

Relationship Between Phosphate Binder Type and Gut Microbiome-Derived Uremic Toxin Levels in Hemodialysis Patients

Lin-Chun Wang,[1] Mirell Tapia,[1] Xia Tao,[1] Joshua E. Chao,[1] Ohnmar Thwin,[1] Hanjie Zhang,[1] Stephan Thijssen,[1] Peter Kotanko,[1,2] Nadja Grobe.[1] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Phosphate binder choice may differentially affect gastrointestinal physiology (e.g. colonic transit time and gut microbiota composition). Interestingly, patients on sucroferric oxyhydroxide (SFO; Velphoro®) have lower rates of constipation than those taking sevelamer carbonate (SEV; Renvela®). We hypothesized that phosphate binder choice may affect serum levels of gut microbiome-derived uremic toxins (UTOX). We examined the relationship between the type of prescribed phosphate binder and gut microbiome-derived UTOX levels in hemodialysis (HD) patients treated with either SFO or SEV.

Methods: Weekly blood samples and bowel movement diaries were collected from 16 HD patients during six consecutive weeks per subject. Stool types were categorized according to the Bristol Stool Chart. Nine substances including eight UTOX (7 gut microbiome-derived; 1 mammalian-derived) and tryptophan (TRP) were quantified in serum using liquid chromatography–mass spectrometry. For each substance, we calculated the median concentration per subject, then the median across all subjects. We also report the differences in median serum concentrations between the treatment groups and their respective 95% confidence intervals.

Results: Subject characteristics are shown in Table 1. The SEV group reported a 3.3-fold higher frequency of stool types 1 and 2 (constipation), while stool types 5 to 7 (diarrhea and urgency), indicating reduced colonic transit time, were 1.5-fold more frequent in the SFO group. Most gut microbiome-derived UTOX, including three protein-bound UTOX, showed a trend towards lower serum levels in the SFO group, while one mammalian-derived UTOX and TRP were higher in the SFO group (Table 2).

Conclusions: Compared to SEV, SFO may lower the serum levels of gut microbiome-derived uremic toxins, putatively by decreasing colonic transit time.

Table 1. Hemodialysis patient characteristics. All patients on thrice-weekly dialysis regimen.

Characteristics	Total (n=16)	SEV (n=8)	SFO (n=8)
Female / Male	5 / 11	3 / 5	2 / 6
Age [years]	55.1 ± 13.7	58.3 ± 13.5	51.9 ± 14.0
BMI [kg/m²]	27.5 ± 5.9	27.1 ± 7.1	27.9 ± 4.9
Dialysis Vintage [years]	4.8 ± 3.8	5.1 ± 4.6	4.4 ± 3.2

Values are mean ± SD. BMI: Body Mass Index, SEV: sevelamer carbonate (Renvela®), SFO: sucroferric oxyhydroxide (Velphoro®)

Table 2. Serum UTOX and TRP levels.

	Gut Microbiome-derived							Mammalian-derived	Nutritional Marker
Substance	TMAO	IG	PAG	IS	CMPFA	PCS	HA*	KYNA	TRP
SFO	31.5	0.8	92.2	98.5	1.8	87.0	160.8	1.3	21.0
SEV	39.8	1.9	111.6	88.8	1.8	88.8	375.2	1.0	18.6
Δ Median (CI)	-8.3 (-23.1;8.9)	-1.1 (-2.4;1.4)	-19.4 (-86.1;43.2)	9.6 (-55.9;46.9)	0.0 (-1.0;0.7)	-1.8 (-51.7;49.2)	-14.4 (-84.8;96.5)	0.3 (-0.3;0.6)	2.6 (-2.3;9.0)

Values are median serum concentrations in µmol/L and analyzed by Wilcoxon rank sum test. CI: Confidence Interval, SEV: sevelamer carbonate (Renvela®), SFO: sucroferric oxyhydroxide (Velphoro®), TMAO: trimethylamine-N-oxide, IG: indoxylglucuronide, PAG: phenylacetylglutamine, IS: indoxylsulfate, CMPFA: 3-carboxy-4-methyl-5-propyl-2-furanpropionic acid, PCS: p-cresylsulfate, HA: hippuric acid, KYNA: kynurenic acid, TRP: tryptophan. *HA is derived from both the gut microbiome and mammalian sources.

SA-PO1012

Comparison of Actual Dietary Intakes in Hemodialysis Patients: A Prospective Observational Study

Kyoung Hye Kong,[1] Hyung Jung Oh,[2] Dong-Ryeol Ryu.[1] *[1]Ewha Womans University, Seoul, Republic of Korea; [2]Ewah Womans' University, Mokdong Hospital, Seoul, Republic of Korea.*

Background: Although appropriate dietary adjustments in hemodialysis (HD) patients are important, most HD patients have difficulty adhering to dietary therapy due to the stress of a restricted-food diet or loss of appetite, which eventually leads to malnutrition and other complications. The actual dietary intakes among HD patients stratified by nutritional status have not yet been studied.

Methods: In total, 111 HD patients from five dialysis centers were stratified into 2 groups based on subjective global assessment (SGA): the well-nourished group vs. the poorly-nourished group. The 7-day dietary intakes and food behaviors of the two groups were compared. Logistic regression analysis was performed to reveal the factors associated with the poorly-nourished status.

Results: The enrolled HD patients consumed an average of 23.44 kcal/kg/day and 0.92 g/kg/day of protein. However, they also consumed an average of 3285 mg/day of sodium, 1856.91 mg/day of potassium, and 760.61 mg/day of phosphorus. The poorly-nourished group ate out and ate fried food significantly more frequently than the well-nourished group. More frequent eating out, more frequent fried food consumption, and lower serum albumin level were significantly associated with the poorly-nourished status.

Conclusions: These findings demonstrate the differences in actual dietary intake patterns and food behaviors of well- and poorly-nourished HD patients. However, further research should be performed on HD patients to design customized nutritional education, consultations, and dietary management.

Table 1. 7-day dietary research between the two groups stratified by the nutritional status

	Total N=111(100%)	Nutritional status: Well-nourished group N=81(72.9%)	Nutritional status: Poorly-nourished group N=30(27.0%)	*P-value*

Dietary Advanced Glycation End Products Restriction Effects on Intestinal Bacterial Flora and Microinflammation State in Maintenance Hemodialysis Patients

Meng Wang, Hua Liu. *First Affiliated Hospital of Medical College of Xi'an Jiaotong University, Xi'an, China.*

Background: It had been found that dietary AGEs was related to markers of inflammation and oxidative stress in a population of end stage renal disease (ESRD) patients undergoing dialysis. This study was to explore the effects of dietary advanced glycation end products(AGEs) restriction on microinflammation state and intestinal bacterial flora in maintenance hemodialysis(MHD) patients.

Methods: Patients were randomized to normal group(n=10) continuing the same diet, and intervention group taking a dietary AGE restriction for one month(n=10). Blood and stool samples were collected before and after intervention. Highsensitive C-reactive protein and interleukin-6 were detected. The alteration of gut microbiomes were analyzed by bacterial 16S rDNA amplification and DNA pyrosequencing to determine the presence of bacteria.

Results: Plasma High-sensitive C-reactive protein and interleukin-6 levels were significantly reduced in dietary AGEs restriction group($p<0.05$). The number of Bifidobacterium and Lactobaeillus decreased whereas the number of E. coli and Enterococcus faecalis increased $p<0.05$) in intervention group.

Conclusions: This study showed significant microbiota differences between two groups in MHD patients, might provide evidence for reducing uremic toxin from the view of gut microbiota, and play a role in improving life quality of patient. More research is needed.

SA-PO1014

Comparison of Three Nutritional Screening Tools for Predicting Mortality in Maintenance Hemodialysis Patients

Junzhi Chen, Min Liang. *Nanfang Hospital, Guangzhou, China.*

Background: There has been a great consensus that the key first step in the evaluation of nutritional status is to identify "at risk" status by using the validated nutritional screening tools. However, an effective and simple nutrition screening tool has not been identified in maintenance hemodialysis (MHD) patients. To the best of our knowledge, the comparison of mortality predictability between the objective score of nutrition on dialysis (OSND) and the malnutrition-inflammation score (MIS) or the geriatric nutritional risk index (GNRI) has not been conducted in previous studies.

Methods: A cohort of 1,025 MHD patients were enrolled from 8 hospitals. The MIS, OSND, and GNRI were measured at baseline. All-cause mortality and cardiovascular (CV) mortality were the major study outcomes. Harrell's C statistics were derived to examine the discrimination between three tools and mortality.

Results: The median follow-up duration was 28.1 months. The MIS (per standard deviation (SD) increase, HR =1.35, 95% CI: 1.18–1.55), the OSND (per SD decrease, HR =1.24, 95% CI: 1.09–1.42), and the GNRI (per SD decrease, HR =1.26, 95% CI: 1.10–1.43) were all significantly associated with the risk of all-cause mortality. More importantly, the mortality predictability of the MIS appears similar to the GNRI ($P=0.182$) and greater than the OSND (MIS *vs.* OSND: $P=0.001$; GNRI *vs.* OSND: $P=0.045$). Similar results were found for CV mortality.

Conclusions: Each of the three nutritional screening tools was significantly associated with an increased risk of all-causes and CV mortality. The mortality predictability of the MIS was similar to the GNRI and greater than the OSND.

Results of Harrell's C Statistic

Variables	Harrell's C Statistic (95%CI)	P-value	
All-cause mortality			
MIS	0.62 (0.58, 0.66)	Ref.	0.001
OSND	0.56 (0.52, 0.60)	0.001	Ref.
GNRI	0.6 (0.56, 0.64)	0.182	0.045
CV mortality			
MIS	0.62 (0.58, 0.67)	Ref.	0.001
OSND	0.55 (0.50, 0.60)	0.001	Ref.

SA-PO1015

The Efficacy of Probiotic, Prebiotic, and Synbiotic Supplementation in Modulating Gut-Derived Circulatory Particles Associated with Mortality in Dialysis Patients: Systematic Review and Meta-Analysis

Daniel S. March,[1] Arwel W. Jones,[2] Nicolette C. Bishop,[3] James Burton.[1,3] *[1]University of Leicester, Leicester, United Kingdom; [2]University of Lincoln, Lincoln, United Kingdom; [3]Loughborough Univeristy, Loughborough, United Kingdom.*

Background: There is accumulating evidence that modification of the microbiota through prebiotic, probiotic or synbiotic supplementation in individuals with end-stage renal disease receiving dialysis may be efficacious in reducing circulating levels of toxic metabolites. This systematic review and meta-analyses provides an up to date synthesis on the effects of supplementation on circulating levels of toxic metabolites, markers of uremia and inflammation, blood lipids and other clinical outcomes.

Methods: Seventeen databases were searched, supplemented with internet and hand searching. Randomised controlled trials of adult end stage renal-disease individuals receiving either haemodialysis or peritoneal dialysis were eligible. Trials were restricted to those which had administered a prebiotic, probiotic or synbiotic as an oral supplement. Primary outcomes were measures of circulating endotoxin, indoxyl-sulphate and p-cresyl sulphate.

Results: Twenty-one trials were eligible (1152 randomised participants) of which 19 trials were considered to have a high risk of bias. The number of trials available for meta-analysis varied for each primary outcome. Synthesised data indicated that supplementation significantly reduced circulating levels of endotoxin (standardised mean difference -0.61, 95% confidence interval -1.03 to -0.20, P=0.004, I2=0%), indoxyl-sulphate (-0.34, -0.64 to -0.04, P=0.02, I2=0%) and p-cresyl sulphate (-0.34, -0.61 to -0.07, P=0.01, I2=0%). For secondary outcomes supplementation significantly reduced gastrointestinal symptoms (-0.54, -1.02 to -0.07, P=0.02, I2=0%). There were no significant effects on any secondary outcome measure.

Conclusions: Supplementation reduces toxic metabolites associated with cardiovascular disease and mortality in individuals receiving dialysis. However, the majority of trials included were low in quality.

SA-PO1016

Association of Race/Ethnicity and Pre-ESKD Disease Duration with Subsequent Dialysis Mortality in US Veterans with ESKD

Guofen Yan,[1,2] Robert Nee,[3] Keith C. Norris,[4] Tom Greene,[5] Mohammed N. Oliver,[6] Wei Yu,[1] Alfred K. Cheung.[5,2] *[1]University of Virginia, Charlottesville, VA; [2]Veterans Affairs Salt Lake City Healthcare System, Salt Lake City, UT; [3]Walter Reed National Military Medical Center, Vienna, VA; [4]UCLA, Marina Del Rey, CA; [5]University of Utah, Salt Lake City, UT; [6]Virginia Department of Health, Richmond, VA.*

Background: The mortality rate of patients undergoing dialysis is exceptionally high. The role of disease duration before end-stage kidney disease (ESKD) on subsequent dialysis mortality is not clear due to lack of data on the accurate time of CKD onset. Using a national incident CKD cohort we recently constructed, we examined the association between disease duration prior to ESKD and dialysis mortality by race/ethnicity.

Methods: We first identified all subjects with new onset CKD (stage 3-5) in the U.S. Veteran Affairs database since 4/1/2002. CKD onset was determined by two eGFRs (based on CKD-EPI equation) <60 mL/min/1.73 m^2 at >90 days apart. We then extracted the subset of patients who started dialysis with at least one year of follow-up until 5/1/2016. Disease duration was determined as time from the date of CKD onset to the date of first dialysis. Hazard ratios for death were examined for duration of <1 year, 1-3 years, and 3-5 years as compared to duration of ≥5 years for each race/ethnicity, adjusted for covariates including age at ESKD onset, gender, last eGFR prior to first dialysis, and major comorbid conditions such as diabetes, hypertension, and cardiovascular diseases.

Results: Of 28,129 incident dialysis patients included, 8,874 were Black, 1,892 Hispanic, and 17,363 White. The median duration from CKD onset to ESKD onset was 2.7 years for Blacks, 2.8 for Hispanics, and 3.3 for Whites. More than half of Blacks (55%) and Hispanics (53%) developed ESKD within 3 years of CKD onset, compared to 46% of Whites. After adjustments, shorter disease duration before ESKD was significantly associated with greater mortality on dialysis for Blacks, but not for Whites and Hispanics (Table). P value for testing the differential associations across three racial/ethnic groups was 0.003.

Conclusions: Our findings suggest the association of disease duration before ESKD and dialysis mortality differed by race/ethnicity, prompting the need to delineate the factors responsible for these differential associations.

Funding: NIDDK Support

Adjusted hazard ratios (HR) by race/ethnicity

	Black			Hispanic			White

Does Erythrocyte Stimulating Agent (ESA) Exposure Contribute to the Obesity Paradox?

Jeffrey I. Silberzweig,[1,2] Thomas Parker,[1] Kwan Kim,[1] Daniel M. Levine.[1] The Governing Body of The Rogosin Institute *[1]The Rogosin Institute, New York, NY; [2]Nephrology & Hypertension, Weill Cornell Medicine, New York, NY.*

Background: Epidemiologic and retrospective data document a survival advantage for obese (BMI > 30 kg/m^2) patients treated by maintenance hemodialysis (HD). Prospective data suggest that higher ESA doses are associated with adverse clinical outcomes.

Methods: Our quality program reviews the proportion of patients with hemoglobin (hgb) between 10-11.5 g/dL and ESA dosing and costs. We sought to understand variations by comparing ESA requirements based on BMI.

Results: The facility with the lowest average patient weight has the lowest average ESA cost (See table). ESA exposure decreased as BMI increased (p<0.0001). Hgb levels did not vary with BMI. (See figures.) There is a trend towards longer survival among obese patients.

Conclusions: ESA exposure varies with BMI in our patient population; hgb does not. ESA costs and doses vary with BMI. We hypothesize that lower ESA exposure contributes to improved survival among obese patients with CKD treated by HD.

Funding: Clinical Revenue Support

Impact of Weight on ESA Cost per Treatment Q1 2019

Facility	ESA Cost/Treatment ($)	Average Patient Weight (kg)	ESA Cost/Treatment/kg ($/kg)

Efficacy and Safety of CKD-11101 (Darbepoetin-Alfa Proposed Biosimilar) Compared with Darbepoetin Alfa in Patient on Hemodialysis

Yaerim Kim,[1] Yong-Lim Kim,[2] Soo Wan Kim,[3] Duk-Hee Kang,[4] Kang Wook Lee,[5] Won Suk An,[6] Jung Pyo Lee,[7] Kwon Wook Joo,[1] Dong-jin Oh,[8] Jun-Young Do,[9] Jin hyuk Paek,[10] Woo Yeong Park,[11] Kyubok Jin,[10] Su-Kil Park.[12] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Kyungpook National University Hospital, Daegu, Republic of Korea; [3]Chonnam National University Medical School, Gwangju, Republic of Korea; [4]Ewha University College of Medicine, Seoul, Republic of Korea; [5]Chungnam National University Hospital, Daejeon, Republic of Korea; [6]Dong-A University, Busan, Republic of Korea; [7]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [8]Myongji Hospital, Koyang, Republic of Korea; [9]Yeungnam University Hospital, Daegu, Republic of Korea; [10]Keimyung University School of Medicine, Daegu, Republic of Korea; [11]Dongsan Medical Center, Daegu, Republic of Korea; [12]Asan Medical Center, Seoul, Republic of Korea.*

Background: Anemia is critical problem which is caused by deficiency of endogenous erythropoietin (EPO) synthesis in patient on dialysis. Darbepoetin-alfa is a useful EPO with long elimination half-life. Herein, we aim to evaluate the efficacy and safety of intravenous CKD-11101 (biosimilar darbepoetin-alfa) compared with darbepoetin-alfa in patients undergoing hemodialysis.

Methods: The study group composed with 24 different institutes was divided by randomized, double-blinded, and prospectively. Follow-up duration was 24 weeks which was consisted with 20 weeks of maintenance and 4 weeks of evaluation period. All patients underwent the stabilization period to achieve target baseline hemoglobin (Hb) as 10-12 g/dL before randomization. After randomization, patients received EPO by weekly or biweekly with adjusted dose following the permitted rule of darbepoetin alfa. First, we compared the efficacy of CKD-11101 to darbepoetin-alfa. Secondly, we investigated the safety of CKD-11101.

Results: A total of 403 patients were randomized to two different groups during June 2015 and June 2017. Among randomized populations, 78 (19.35%) were dropped-out with major infraction or side effect, 325 (80.65%) patients completed the investigation. The average administered dose of EPO was not different in both groups; 74.90 ± 56.85 mcg and 61.96 ± 43.51 mcg in CKD-11101 and darbepoetin-alfa, respectively. During the study period, the percentage of patients with targeted Hb was 19.44% (28/144), and 20.95% (31/148) with CKD-11101 and darbepoetin-alfa, respectively (p = 0.750). There was no difference in rate of patients need to be changed the dose; 95.83% (138/144) and 93.24% (138/148) with CKD-11101 and darbepoetin-alfa (p = 0.331). There was only one patient who needed to be transfused in each group.

Conclusions: The difference in change of the level of Hb, dose of EPO, and achievement rate to target Hb during study period was comparable between two groups. CKD-11101 has an equivalent therapeutic efficacy compared with the darbepoetin-alfa in patient undergoing hemodialysis.

SA-PO1019

Vitamin E Polysulfone Dialyzer Improves Erythropoietin Hyporesponsiveness in CKD Patients on Dialysis with Low-Grade Inflammation

Jean-Paul Cristol,[1,2] Marion Morena.[1,2] on behalf of the EVIA study and VIVRE cohort *[1]Department of Biochemistry and Hormonology, University Hospital Center of Montpellier, Montpellier, France; [2]PhyMedExp, University of Montpellier, INSERM, CNRS, Montpellier, France*.

Background: This work aimed at evaluating vitamin E-coated polysulfone (PS) membrane (VItabranE®, VIE) effect on erythropoietin hyporesponsiveness through two prospective multicenter studies, one controlled randomized study (*Study-1*) and one observational study *(Study-2)* in chronic kidney disease patients on dialysis with low grade inflammation after a 12-month period.

Methods: *Study-1*. 60 dialysis patients with CRP level in the range [5-20] mg/L were randomly assigned in a 1:1 ratio to either PS control 'C' group (n=30) or 'VIE' group (n=30). *Study-2*. 148 eligible dialysis patients out of a total of 244 included, with mean baseline CRP level at 11±12 mg/L and with EPO overconsumption were dialysed with VIE. Administered EPO dose was recorded and blood samples withdrawn at inclusion and after 3, 6, 9 and 12 months of treatment in both studies.

Results: After a 12-month treatment, VIE use was associated to a reduction in EPO doses in both studies. In *Study-1*, we observed a ΔEPO dose at -2710.5±3983.7 IU (p=0.011) corresponding to a 24% reduction when comparing M12 and M0 in VIE group vs -1074.5±5151.4 IU (p=NS) in C group. No improvement in inflammatory markers (CRP, IL-6, TNF-alpha and fibrinogen) or impairement of nutritional parameters (albumin and transthyretin) were observed over the period. In *Study-2*, a 28% EPO reduction (p=0.001) was reported when comparing M12 and M0, associated to a 31% iron dose reduction (p=0.002) and stable hemoglobin and serum iron levels. Here again, no improvement in CRP level was obtained.

Conclusions: Both multicenter prospective studies confirm that vitamin E-coated PS membrane can improve EPO efficacy in dialysis patients with low grade inflammation. Such positive effect appears independent of inflammation and nutritional parameters but associated with an improvement of iron metabolism.

The Effect of Supplementation with Zinc Acetate Hydrate for Hypozincemia on Renal Anemia

Eiichi Sato,[1] Manaka Degawa,[2] Takao Ono,[2] Hongmei Lu,[2] Mayuko Amaha,[3] Mayumi Nomura,[2] Daisuke Matsumura,[2] Tsukasa Nakamura,[2] Yuko Ono,[4] Yoshihiko Ueda.[5] *[1]Division of Nephrology, Department of Internal Medicine, Shinmatsudo Central General Hospital, Matsudo City, Chiba Prefecture, Japan; [2]Shinmatsudo Central General Hospital, Matsudo city, Japan; [3]Toho University School of Medicine, Nakano-ku, Japan; [4]Dokkyo Medical University, Koshigaya Hospital, Koshigaya, Saitama prefecture, Japan; [5]Saitama Medical Center, Koshigaya, Japan*.

Background: Whether zinc supplementation with zinc acetate hydrate for hypozincemia improved renal anemia in hemodialysis patients was examined.

Methods: Study participants included 21 hemodialysis patients who presented with a serum zinc level of less than 60 mg/dL and who were administered zinc acetate hydrate at 50 mg (the dose was reduced to 25 mg, as appropriate) for 6 months. Patients having a hemorrhagic lesion, acute phase diseases (pneumonia or cardiac failure) or hematologic disease, and those whose treatment was switched from peritoneal dialysis to hemodialysis were excluded. The change in the erythropoietin resistance index (ERI) before and after the administration of zinc acetate hydrate, was examined; ERI was defined as the dose of erythropoiesis-stimulating agent (ESA; IU/week/body weight [kg]/hemoglobin content [g/dL]). The difference between the two groups was analyzed using a Wilcoxon signed rank sum test and a difference with $p < 0.05$ was considered statistically significant.

Results: The study patients consisted of 19 males and 2 females aged between 41 and 95 years (mean ± standard deviation [SD]; 67.1 ± 13.6). Changes in values of measured parameters, before and after the administration of zinc acetate hydrate, were as follows: blood hemoglobin content did not change significantly from 10.0 – 13.6 g/dL (11.5 ± 1.0 g/dL) to 10.2 – 12.4 g/dL (11.4 ± 0.7 g/dL); the serum zinc concentration significantly increased from 33 – 59 mg/dL (52.4 ± 7.6 mg/dL) to 57 – 124 mg/dL (84.1 ± 16.3 mg/dL; $p < 0.01$); the dose of ESA significantly decreased from 0 – 12,000 IU/week (5,630 ± 3,351 IU/week) to 0 – 9,000 IU/week (4,428 ± 2779; $p = 0.04$); and the ERI was significantly reduced from 0 – 18.2 (8.1 ± 5.1) to 0 –16.0 (6.3 ± 4.3; $p = 0.04$).

Conclusions: Zinc supplementation in patients with hypozincemia increased the serum zinc concentration and significantly reduced the ESA dose and ERI, suggesting that a correction of hypozincemia contributes to an improvement in patients' renal anemia.

SA-PO1021

Wearable Device for Continuous, Noninvasive Monitoring of Blood Hemoglobin Levels in Hemodialysis Patients

David J. Kuraguntla, Samit K. Gupta, Forrest Miller. *GraftWorx, South San Francisco, CA*.

Background: Maintenance of euvolemia is a major challenge for hemodialysis patients, who account for a combined 6.5M annual hospital days. Clinical outcomes could be improved, and healthcare costs lowered, by preventing fluid overload. This study presents a novel wearable device that enables remote monitoring of multiple key fluid status metrics in dialysis patients. This device, SmartPatch, incorporates multi-wavelength photoplethysmography (PPG) and acoustic, thermal and mechanical sensors to measure blood hemoglobin concentration (Hb), hematocrit (Hct), oxygen saturation and volumetric flow rate. The SmartPatch system also comprises an end-to-end data path that facilitates secure data transmission and analysis and generates actionable alerts. The aim of this study was to evaluate the system's ability to accurately and precisely measure Hb and Hct, critical markers for anemia that dictate dialysis treatment.

Methods: 29 hemodialysis patients with arteriovenous fistulas currently undergoing hemodialysis were recruited across three clinical sites. Each of these patients had a SmartPatch device placed on the skin over their fistula. A total of 257 sets of multi-channel PPG data were recorded and analyzed using the GraftWorx data hub and software backend. A subset of 76 reads was used to train an Hb quantitation algorithm, with reference values obtained from a HemoCue Hb 201+ device. This algorithm was then tested on the remaining 181 reads to determine the accuracy and precision of the SmartPatch when measuring Hb and Hct.

Results: The SmartPatch system measured Hb and Hct with respective root-mean-square error (RMSE) of 0.863 g/dL and 2.585 Hct compared to reference values obtained from the HemoCue device, whose accuracy has been reported to be between 0.3 and 1.6 g/dL (0.9 to 4.8 Hct). The standard deviations for each read on the same patient–with the same device–were computed and averaged, weighted by group size, as a measure of precision. These precision metrics were computed to be 0.283 g/dL and 0.85 Hct for Hgb and Hct, respectively.

Conclusions: The results of this study illustrate the ability of the wearable SmartPatch system to non-invasively measure blood Hb and Hct in hemodialysis patients with AV fistulas, to a degree of accuracy comparable to available methods. This study also demonstrated the efficacy of the end-to-end GraftWorx data path.

SA-PO1022

Clinical Significance of Red Cell Distribution Width (RDW) in ESRD Initiated with Hemodialysis (HD)

Takeshi Ito,[1] Takatoshi Morinaga,[1] Daijo Inaguma,[2] Atsushi Fukatsu,[3] Hirofumi Tamai.[1] *[1]Anjo Kosei Hospital, Anjo-cho, Japan; [2]Fujita Health University, Toyoake, Japan; [3]Fukatsu Medical Clinic, Anjo, Japan*.

Background: RDW is routinely measured in complete blood count indicating the variation of erythrocyte volume. RDW is affected by nutritional and inflammatory status. Recently worse survival of high RDW patients has been reported in coronary disease, chronic kidney disease, HD and peritoneal dialysis. To evaluate the clinical significance of RDW in ESRD, we studied 1) correlation of clinical data with RDW, 2) influence of HD and 3) prognostic value in survival.

Methods: Subjects were 873 patients in 17 centers participating in Aichi Cohort Study of Prognosis in Patients Newly Initiated into Dialysis (AICOPP) from 2011 to 2013. Subjects were divided into two categories (RDW Low< 15.5, High ≥ 15.5%). RDW and clinical parameters obtained at the initiation of hemodialysis (RDW-1) including laboratory data and comorbidities were analyzed statistically. RDW after stable hemodialysis was established (RDW-2) was compared with RDW-1 and categorized in four groups High-High (H-H) 43.4%, High-Low (H-L) 6.5%, Low-High (L-H) 9.0%, Low-Low (L-L) 41.0%. Factors affecting these changes were studied. Correlation in each category with mortality was analyzed using Kaplan-Meier method. All-cause, CVD, infection and malignancy mortality were compared using multivariate Cox proportional hazard analysis.

Results: RDW-1 was correlated with high CRP (p=0.003) and low total cholesterol (p=0.027) but not with other parameters. 84% was remained in the same category after initiation of HD, and H-H group showed highest mortality, L-H next, and L-L was lower and interestingly H-L was lowest (Log rank test: P<0.001). Characteristics of this small group was that brain natriuretic peptide was higher than other group (p<0.033) while ejection fraction was similar suggesting the complication of uremic cardiopathy which was recovered by HD. During a median follow-up duration of 1,297 days, 228 subjects died. All-cause (HR 1.41: 95%CI 1.07-1.86), CVD (1.65: 1.07-2.61) and infection (2.72: 1.44-5.60) mortality were higher in High RDW. No correlation with malignancy was noted. (HR1.09: 95%CI 0.58-2.11).

Conclusions: In ESRD patients, RDW is influenced by inflammation and nutrition. In HD patients, low RDW at baseline and lowered RDW after HD suggests better prognosis. In HD patients with high RDW, infection and CVD are statistically higher as a cause of death.

SA-PO1023

Coagulation and Circulating Heparin Profile in Patients with ESRD Undergoing Maintenance Hemodialysis

Emily Bontekoe,[2] Arjun S. Grewal,[2] Jasdeep S. Bajwa,[3] Fakiha Siddiqui,[2] Vinod K. Bansal,[1] Omer M. Iqbal,[4] Debra Hoppensteadt,[1] Jawed Fareed.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Chicago, Riverside, IL; [3]University of Rochester, Mississauga, ON, Canada; [4]Loyola University Chicago, Maywood, IL.*

Background: Unfractionated heparin is widely used as an anticoagulant for maintenance hemodialysis in end-stage renal disease (ESRD) patients. Since these patients are administered with heparin repeatedly throughout treatment, it is hypothesized that detectable circulating levels of heparin may be present in their blood 48 hours post-dialysis session. The profiling of these parameters may provide the hemostatic status of patients in reference to circulating residual heparin in the pre-dialysis blood samples.

Methods: This study included 95 patients with ESRD undergoing maintenance hemodialysis, which was administered 3 times per week in 48-hour intervals. Plasma samples were analyzed utilizing clot-based methods including activated partial thromboplastin time (aPTT), prothrombin time (PT), and thrombin time (TT). Employing a chromogenic assay, the circulating levels of heparin in each patient were measured. All of these samples were also analyzed for thrombin generation capacity using calibrated automated thrombogram (CAT, Diagnostica Stago. Paris, France).

Results: In the clotting assays, prothrombin time was elevated (16.4±20.3 sec.) in comparison to the normal control (11.1±2.1 sec.;p<0.05). Activated partial thromboplastin time was also prolonged (43.09±43.1 sec.) when compared to normal human plasma (32.3±4.2sec.;p<0.05). The thrombin time values were markedly higher (44.6±83.1 sec.) in comparison to normal (11.2 ±2 sec.;p<0.001). Circulating heparin levels, measured by anti-Xa methods, were found to be 0.11± 0.21 U/ml and anti-IIa levels being 0.25±0.27 U/ml;(p<0.05). In the thrombin generation assay, the ESRD samples showed wide variation and a lowered thrombin generation value (107±55.2 nM) in comparison to normal control (185±16.5 nM;p<0.05).

Conclusions: These results suggest patients undergoing maintenance hemodialysis exhibit a mild hypo-coagulable state as determined by PT and aPTT methods. The circulating levels of heparin were lower in anti-Xa compared to anti-IIa, suggesting the presence of higher molecular weight components of circulating heparin. These studies suggest that ESRD patients on maintenance hemodialysis exhibit a hypocoagulable state in which circulating residual heparin may contribute to the overall hemostatic deficit.

SA-PO1024

Measurement and Characterization of Circulating Heparin in Heparin-Naive ESRD Patients on Maintenance Hemodialysis

Jasdeep S. Bajwa,[2] Vinod K. Bansal,[1] Arjun S. Grewal,[3] Debra Hoppensteadt,[1] Emily Bontekoe,[3] Fakiha Siddiqui,[3] Jawed Fareed.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]University of Rochester, Mississauga, ON, Canada; [3]Loyola University Chicago, Wauconda, IL.*

Background: In a cohort of 95 ESRD patients undergoing maintenance hemodialysis, 30 patients did not receive any exogenous heparin during their routine dialysis sessions. However, these patients showed an increase in their PTT, anti-Xa, and anti-IIa assays which were neutralized upon heparinase treatment indicating the presence of endogenous heparin. The objective of this study is to quantify and characterize the heparin in this cohort of the ESRD patients.

Methods: Thirty heparin-naïve patients were identified through a chart review. Pre-dialysis blood samples collected from these patients were centrifuged to obtain plasma which was frozen at -70°C. These samples were thawed in batches and each sample was divided into two equal volumes; one sample was supplemented with saline while the other was mixed with a heparin digesting enzyme (Heparinase-1). These samples were analyzed for aPTT using a clot-based assay, amidolytic anti-Xa, and anti-IIa assays using specific chromogenic substrates. The test results were compiled as group mean +/- 1SD.

Results: The results collected from these patients showed an average PTT in the pre-Heparinase sample of 36.5 +/- 24.8, which decreased to 30.9 +/- 5.5 in the post-Heparinase samples (P=0.224). Anti-Xa and Anti-IIa are markers used in the study to demonstrate Heparin activities – a decrease upon Heparinase treatment in these activities confirms the presence of circulating Heparin. The average Anti-Xa in pre and post-Heparinase were 0.08 +/- 0.15 and 0.02 +/- 0.07 (P<0.05), whereas the average Anti-IIa in pre and post-Heparinase were 0.24 +/- 0.30 and 0.13 +/- 0.12, (P<0.05). These results indicate there was heparin activity present in the pre-Heparinase samples, but that activity was reduced in the post-Heparinase samples.

Conclusions: These findings demonstrate that there is endogenous heparin present in these heparin naïve patients. It has been hypothesized that endogenous heparin in these patients may have originated from endothelial sites. The shedding of heparin from endothelium may reflect endothelial dysfunction which has been reported in ESRD patients and may be correlated the severity of the pathogenesis of ESRD.

SA-PO1025

Persistence of Circulating Residual Heparin in ESRD Patients Undergoing Maintenance Hemodialysis

Arjun S. Grewal,[2] Jasdeep S. Bajwa,[4] Emily Bontekoe,[2] Debra Hoppensteadt,[1] Omer M. Iqbal,[3] Jawed Fareed,[1] Vinod K. Bansal.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Chicago, Wauconda, IL; [3]Loyola University Chicago, Maywood, IL; [4]University of Rochester, Mississauga, ON, Canada.*

Background: ESRD patients who receive routine maintenance hemodialysis are administered with unfractionated heparin to prevent thrombotic complications. The hemostatic dysregulation along with detectable levels of circulating heparin may cause them to be in a hypocoagulable state. The purpose of this study is to determine the circulating levels of heparin in ESRD patients and its characterization using heparinase digestion methods.

Methods: Blood plasma samples collected at routine pre-dialysis sessions from 95 ESRD patients undergoing maintenance hemodialysis were analyzed for the presence of residual heparin utilizing standard laboratory methods such as aPTT, Anti-Xa and Anti-IIa activities On a centrifugal analyzer (ACL-Elite: Instrumentation Laboratory, Bedford, MA). The levels of heparin were calculated in terms of units per ml relative to the USP reference standard. Heparinase digestion was used to confirm the presence of heparin.

Results: Wide intra individual variations were noted in the different tests carried out on these samples. The pre-heparinase aPTT was 43.1 ± 49.8 seconds whereas the post-heparinase clotting time was 31.1 ± 10.2 seconds (P<0.0002). The mean anti-Xa activity pre-heparinase was 0.11 ± 0.21 U/ml whereas the post-heparinase anti-Xa activity was 0.04 ± 0.14 U/ml (P<0.0001). The mean anti-IIa activity for the pre-heparinase samples was 0.25 ± 0.27 U/ml whereas the post-heparinase samples had a mean of 0.14 ± .15 U/ml (P<0.0007).

Conclusions: The presence of residual heparin was demonstrated by both clot- based and amidolytic assays in the plasma samples collected from ESRD patients prior to their next-dialysis session. Since these samples were obtained 3 days following the last dialysis session the presence of significant levels of heparin was surprising. Upon heparinase treatment of these samples, the aPTT and the anti-Xa and IIa tests were restored to near normal levels. Our studies confirm the presence of residual heparin in pre-dialysis plasma samples obtained from ESRD patients. The Anti-IIa activity was greater pre-heparinase and it was not decreased to the same extent as Anti-Xa after heparinase digestion. These results suggest that heparin found in ESRD patients plasma is of high molecular weight origin with delayed clearance.

SA-PO1026

Heparin-Free Dialysis: A Phase 2 Pilot Study Using Asymmetric Cellulose Triacetate (ATA) Dialyzers

Björn K. Meijers,[1] Bert Bammens,[2] Katrien D. Vusser,[1] Amaryllis H. Van Craenenbroeck,[2] Kathleen Claes,[3] Pieter Evenepoel.[2] UZ Leuven *[1]UZ Leuven, Leuven, Belgium; [2]University Hospitals Leuven, Leuven, Belgium; [3]University Hospital Gasthuisberg, Leuven, Belgium.*

Background: Not all dialysis patients tolerate heparin anticoagulation. Heparin should be avoided in patients at high risk of bleeding. Strategies include saline infusion, citrate-containing dialysate, regional citrate anticoagulation and heparin-coated membranes. We recently studied the combination of a heparin-coated membrane and citrate-containing dialysate, with a success rate of 94%. Although this combination resulted in low rates of clotting, heparin-coated membranes are not ubiquitously available. The quest for easy to perform, safe and affordable heparin-free dialysis is on. Asymmetric cellulose triacetate (ATA) dialyzers have a low degree of platelet contact activation and might be an alternative to heparin-coated dialyzers.

Methods: We performed a phase II pilot study in maintenance dialysis patients. The 'Strategies for Asymmetrical Triacetate dialyzer heparin-Free Effective hemodialysis (SAFE study)' was a two-arm open-label cross-over study. In Arm 1, patients were dialyzed using a 1.9 m2 ATA membrane (Solacea™-19H, Nipro Corp., Japan) in combination with citrate (1 mM) containing dialysate. In Arm 2, patients were dialyzed with the same 1.9 m2 ATA membrane, in combination with high volume predilution hemodiafiltration. The primary endpoint was the success rate to complete 4 hours of hemodialysis without preterm clotting.

Results: We scheduled 240 dialysis sessions (120 per arm) in twenty patients. Ten patients were randomized to start in Arm 1, the others to Arm 2. All patients crossed to the other arm halfway the study. 232 (96.7%) study treatments were delivered. Overall, 23 clotting events occurred, 7 in Arm 1 and 16 in Arm 2. Success rate in Arm 1 (ATA + citrate containing dialysate) was 90.8 / 94.0 % (intention to treat/ as treated). Success rate in Arm 2 (ATA + predilution HDF) was 83.3 / 86.2 % (intention to treat/ as treated). Therapy survival was borderline significantly better in Arm 1(Mantel-Cox log rank $P = 0.05$).

Conclusions: Asymmetric cellulose triacetate (ATA) dialyzers have a low clotting propensity. In combination with citrate-containing dialysate, asymmetric cellulose triacetate (ATA) may be a suitable alternative to heparin-coated membranes for systemic heparin-free hemodialysis.

Hemodialysis with a Citrate Containing Ca- and Mg-Free Dialysis Fluid: Exit Heparin?

Gijs M. De Jong,[1] Mario R. Korte,[1] Henricus J. Vermeer,[2] Joost van Rosmalen,[3] Jan V. Meulen.[1] *[1]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands; [2]Clinical Chemistry and Haematology, Albert Schweitzer Hospital, Dordrecht, Netherlands; [3]Biostatistics, Erasmus MC, Rotterdam, Netherlands.*

Background: Hemodialysis (HD) with heparin increases mortality of bleeding. Regional anticoagulation with citrate (C) HD (infusion of C before dialyzer, Ca-, Mg-free dialysis fluid and Ca/Mg substitution after dialyzer) may decrease this risk, but is laborious. This study describes the effect of adding C to the Ca-, Mg-free dialysis fluid.

Methods: In 12 HD patients on anticoagulants (6 vit. K antagonist; 6 acetylsalicylic acid), 2 HD sessions with dalteparin (D) and 2 with C were performed. During D dialysis fluid contained Ca 1.5 and Mg 0.5 mmol/l. During C, a Ca-, Mg-free, 0.8 mmol/l C containing dialysis fluid was used. Ca 540/ Mg 240 mmol/l substitution was 35 ml/h. Before, during and after HD, urea, ionized Ca (iCa), Mg were tested and clotting tests (APTT, NATEM full blood CT (ROTEM Delta, Tem-innovations Munich) were done. Clotting phenomena in venous airtrap and dialyzer were graded by visual inspection (grade 0-2 respectively 0-3). Data were analyzed using linear mixed models to account for repeated measurements.

Results: No HD was stopped prematurely. During C, clotting tests remained unaltered (APTT 31 vs 32 vs 32 sec; NATEM CT: 1079 vs 1052 vs 1048 sec). At D, clotting tests became significantly abnormal (APTT: 32 vs 42 vs 35 sec; NATEM CT: 1132 vs 2892 vs 1913 sec; p<0.001). Small clots in the venous airtrap were seen in 3/46 sessions (2C and 1D). There were significant more clotting phenomena in the dialyzer after C vs D (mean (95% CI) score 1.8 (1.6-2.1) vs 1.0 (0.7-1.2), p<0.001). spKt/V was slightly but significantly lower after C than after D (mean (95% CI) score 1.53 (1.37-1.69) vs 1.61 (1.45-1.76), p=0.045). iCa was stable during C but increased during D (C: 1.18 vs 1.15 vs 1.19; D: 1.16 vs 1.24 vs 1.25 mmol/l). In C, iCa after the dialyzer showed adequate anticoagulation (iCa 0.18 mmol/l). Mg increased slightly in C and decreased in D with a significant difference (p<0.001) during and after HD (C: 1.04 vs 1.06 vs 1.09; D: 1.00 vs 0.86 vs 0.84 mmol/l).

Conclusions: HD with a 0.8 mmol/l citrate, calcium- and magnesium-free dialysis fluid was slightly but clinically irrelevant inferior to HD with dalteparin without changing clotting tests in patients. Thus, citrate HD probably may prevent the increased risk of bleeding in patients already on maintenance anticoagulants.

SA-PO1028

Effect of Taurolidine Citrate and Unfractionated Heparin Combination on Inflammatory Response and Dialysis Adequacy in Hemodialysis Patients

Magdy M. El-Sharkawy, Haitham Ezzat, Khaled M. Rezk, Ahmed Emara, Reem M. Elsharabasy, Amr M. Mansour. *Nephrology department, Ain Shams university, Cairo, Egypt.*

Background: In hemodialysis (HD) patients, Catheter-related infections and dysfunction are a major health problem. In Egypt, recent data show that 6.6% of HD patients use catheters, of which short term catheters represent 59.6% and 40.4% with long-term catheters. In this study, we **aim** to assess the effect of using Taurolidine citrate and unfractionated heparin combination, as a lock solution for temporary dialysis catheters, on inflammatory markers, incidence of catheter related infections (CRIs) and dialysis adequacy in HD patients.

Methods: A randomized controlled clinical trial included 60 stable HD patients from Ain-Shams University hospitals at the time of catheter insertion. Patients were randomized into 2 groups: **Group 1**: 30 Patients received *taurolidine citrate (4%) and 500 i.u of heparin* as a catheter lock after HD session. **Group 2**: 30 Patients received *unfractionated heparin (heparin sodium 5000i.u/ml)* as a catheter lock after HD session. Both groups were followed up for 1 month period and monitored for signs of CRbsI. Also, Urea reduction ratio (URR) were measured weekly. Highly sensitive CRP & Interleukin 6 (IL-6) were measured at baseline and 1 month after using the lock solutions. Blood cultures were withdrawn in patients who developed signs of CRIs.

Results: Group 1 (mean age 39.5 ± 14, 46.7% males), **Group 2** (mean age 39.3 ± 14, 60% males). As regard *inflammatory markers*, a significant difference was noted between the 2 groups one month after catheter insertion (***P***: 0.001 and 0.018 for hsCRP and IL6 respectively), with the higher levels of inflammatory markers showed in group 2. *Catheter performance* determined by URR and blood flow rate between the 2 groups by the 4th weeks was significantly different in favor of group**1**, suggesting better performance of the catheter (***P*** :0.007 and 0.001 respectively). *CRIs* were demonstrated in **9** patients group **2** (30%) in contrast to **1** patient only in group **1**(3.3%) (***P*** 0.006).

Conclusions: We may conclude that using Taurolidine citrate and unfractionated heparin combination as a lock solution for temporary dialysis catheters was associated with lower levels of inflammatory markers and lower incidence of CRIs when compared to the standard unfractionated heparin lock. Its use also was associated with better catheter performance.

SA-PO1029

Anticoagulation for People Receiving Long-Term Hemodialysis: A Cochrane Review and Meta-Analysis

Suetonia Palmer,[1] Patrizia Natale,[2,3] Marinella Ruospo,[2] Giovanni F. Strippoli.[2,3] *[1]University of Otago, Christchurch, New Zealand; [2]Diaverum, Lund, Sweden; [3]University of Bari, Bari, Italy.*

Background: Hemodialysis requires safe and effective anticoagulation to prevent clot formation during the procedure. Low molecular weight heparins (LMWH) may provide more predictable anticoagulant effects and be simpler to administer than unfractionated heparin (UFH) but may increase risks of bleeding. This Cochrane review evaluates the benefits and harms of anticoagulation strategies for long-term hemodialysis.

Methods: We searched the Cochrane Kidney and Transplant Register of Studies for randomized controlled trials evaluating anticoagulant agents administered for hemodialysis treatment in adults with end-stage kidney disease (ESKD). Two authors independently screened citations for eligibility, extracted data, and assessed risk of bias using the Cochrane tool. Evidence certainty was evaluated using GRADE.

Results: Eighty-seven studies (3548 participants) were eligible. Median trial duration was 0.75 months (range 1 week to 24 months). Median trial age was 58.2 years (range 10.93 to 74 years). Methodological risks of bias were high or incomplete for most studies. Forty-three studies (2066 participants) compared LMWH with UFH. The certainty of the evidence was very low or low for all outcomes. Two of 43 studies reported the outcome for extracorporeal dialysis circuit thrombosis, with one study reporting one or more events. LMWH had very uncertain effects on dialysis circuit thrombosis compared to UFH (very low certainty evidence). Four studies reported zero major bleeding events (very low certainty evidence). No study reported time to achieve dialysis vascular access hemostasis. LMWH had uncertain effects on all-cause mortality (relative risk [RR] 2.41, 95% CI 0.62, 9.33; low certainty evidence). A single study reported the effect of LMWH on dialysis adequacy, measured as KT/V, such that meta-analysis could not be performed. Treatment effects of other anticoagulants were very uncertain.

Conclusions: Evidence for different forms of anticoagulation for hemodialysis is of very low certainty due to methodological limitations in existing trials and paucity of trial data. This review suggests the need for a head-to-head trial of LMWH versus UFH that is sufficiently powered to assess critical clinical outcomes such as bleeding, dialysis adequacy, mortality or cardiovascular events, or complications related to dialysis vascular access.

SA-PO1030

Real-World Effectiveness of Sucroferric Oxyhydroxide in European Hemodialysis (HD) Patients: A 1-Year Retrospective Study

Charles Chazot,[2] Manuel A. Ferreira,[6] Rosa Ramos,[4] Attilio Di Benedetto,[3] Birgit Kagermeier,[7] Dr. Astrid Feuersenger,[5] Melanie Wolf,[5] Hans-Juergen Arens,[5] Sebastian Walpen,[1] Stefano Stuard.[4] *[1]Vifor Fresenius Medical Care Renal Pharma, Glattbrugg, Switzerland; [2]NephroCare Tassin-Charcot, Sainte Foy-Les-Lyon, France; [3]NephroCare, Naples, Italy; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Fresenius Medical Care Deutschland GmbH, Bad Homburg v.d.H., Germany; [6]NephroCare, Vila Franca de Xira, Portugal; [7]Fresenius Medical Care, Contract Clinical Services, Bad Homburg, Germany.*

Background: Retrospective analysis evaluated the effectiveness of the phosphate binder (PB), sucroferric oxyhydroxide (SO), for serum phosphorus (sP) control among European HD pts in routine practice.

Methods: De-identified data were extracted from a clinical database (EuCliD5) for adult HD pts (France, Italy, Spain, Portugal, Russia) newly prescribed SO between Jan 2015–Jan 2019 for up to 1 year. PB pill burden and sP were compared between baseline (BL; 3-month period prior to SO prescription) and 4 consecutive quarters of SO therapy (Q1–Q4) for the overall cohort and 3 subgroups: PB-naïve pts treated with SO monotherapy (mSO), and PB pre-treated pts either switched to SO monotherapy (PB→mSO), or who added SO to another PB (PB+SO).

Results: The overall cohort comprised 1096 pts (mean age: 60.6 years; 65.8% male) including 796, 188 and 53 pts in the PB+SO, mSO, and PB→mSO groups. Comparing BL and Q1–Q4 for the overall cohort, SO provided consistent reductions in mean sP, and increased the % pts achieving sP target (≤5.5 mg/dL) (**Fig.A**). Of the 3 subgroups analyzed, mean BL sP levels were highest among PB+SO pts (5.9 mg/dL) and lowest among PB→mSO pts (5.43 mg/dL) (**Fig.B**). % of pts achieving sP target increased in all 3 subgroups during Q1–Q4, but to the greatest extent in the mSO and PB+SO groups. For PB+SO pts, sP improvements were achieved with a similar number of PB pills prescribed at BL prior to SO (6.5 vs. 6.2 pills/day at Q4). SO pill burden was low across all 3 subgroups (2.1–2.8 pills/day).

Conclusions: This real-world analysis suggests SO can improve sP control among HD pts either administered as monotherapy or add-on therapy to another PB, without increasing pill burden.

Funding: Commercial Support - Vifor Fresenius Medical Care Renal Pharma

Figure: sP control and PB pill burden during baseline and SO follow-up (Q1–Q4)

	Baseline	Q1	Q2	Q3	Q4
Mean sP (mg/dL)	5.83	5.48	5.26	5.26	5.24
SO pill burden (pills/day)	0	2.3	2.5	2.6	2.6
Total PB pill burden (pills/day)	6.3	5.1	5.0	5.3	5.2

	Baseline			Q1			Q2			Q3			Q4		
Mean sP (mg/dL)	5.67	5.43	5.90	5.28	5.44	5.53	4.96	5.25	5.33	5.00	5.33	5.30	5.13	5.03	5.28
SO pill burden (pills/day)	0	0	0	2.2	2.7	2.4	2.1	2.6	2.6	2.1	2.8	2.7	2.3	2.8	2.7
Total PB pill burden (pills/day)	0	2.1	6.5	2.2	2.7	6.0	2.1	2.6	6.0	2.1	2.8	6.2	2.3	2.8	6.2

*Use of another PB therapy (sevelamer, lanthanum or calcium-based PB) in addition to SO in at least in one quarter (Q1–Q4).

Impact of Hyperphosphatemia Severity on Serum Phosphorus Reduction with Sucroferric Oxyhydroxide: A Subgroup Analysis of the VERIFIE Study

Piergiorgio Messa,[10] Marc G. Vervloet,[1] Markus Ketteler,[2] John N. Boletis,[9] Angel Luis M. De Francisco,[4] Philip A. Kalra,[5] Jorge B. Cannata-Andia,[11] Manuela Stauss-Grabo,[6] Anja Derlet,[6] Sebastian Walpen,[7] Linda Ficociello,[12] Jacques B. Rottembourg,[13] Christoph Wanner,[3] Denis Fouque.[8] *[1]Amsterdam University Medical Center, Overveen, Netherlands; [2]Robert-Bosch-Krankenhaus, Stuttgart, Germany; [3]University Hospital, Wuerzburg, Germany; [4]Hospital Univ. Marques de Valdecilla, Santander, Spain; [5]Salford Royal Hospital NHS Trust, Salford, United Kingdom; [6]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [7]Vifor Fresenius Medical Care Renal Pharma, Glattbrugg, Switzerland; [8]University Claude Bernard, Pierre Benite, France; [9]Laiko General Hospital, National & Kapodistrian University of Athens, Medical School, Athens, Greece; [10]Maggiore Hospital, Milan, Italy; [11]University of Oviedo, Oviedo, Spain; [12]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [13]Groupe Hospitalier Pitié-Salpêtrière, Nephrology, Paris, France.*

Background: Sucroferric oxyhydroxide (SFOH) is an iron-based phosphate binder indicated for the treatment of hyperphosphatemia in dialysis patients.

Methods: VERIFIE is a non-interventional, prospective, multicenter, European cohort study evaluating the real-world safety and effectiveness of SFOH in dialysis patients with hyperphosphatemia. This interim analysis, performed 24 months after study initiation, evaluated serum phosphorus (sP) changes during SFOH treatment in 4 subgroups of patients stratified according to their sP levels at baseline (>4.5 to ≤5.5 mg/dL; >5.5 to ≤7.0 mg/dL; >7.0 to ≤8.5 mg/dL; >8.0 mg/dL).

Results: In total, 874 patients who received ≥1 dose of SFOH and had effectiveness follow-up data available, were included in the subgroup analysis, which evaluated sP changes during the first 12 months of treatment. Approximately 40% of patients received concomitant phosphate binders (in addition to SFOH) during the study. Statistically significant ($p<0.001$) reductions in sP from baseline through Month 12 were observed among patients with baseline sP >5.5 to ≤7.0 mg/dL, >7.0 to ≤8.5 mg/dL or >8.5 mg/dL. Smaller reductions in sP were observed in the >4.5 to ≤5.5 mg/dL subgroup (**Figure**). Overall, reductions from baseline in mean sP were greater among patients with higher baseline sP levels.

Conclusions: This subgroup analysis demonstrated that treatment with SFOH can lower sP in real-world dialysis patients with hyperphosphatemia, regardless of their baseline sP levels, and these reductions were sustained over 12 months.

SA-PO1032

Association of White Blood Cell Count and Cause-Specific Mortality in Incident Hemodialysis Patients

Tiffany Zai,[3] Steven Nguyen,[3] Antonio Aguirre,[1] Christina Park,[1] Jui-Ting Hsiung,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Connie Rhee,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN; [3]University of California at Irvine, Orange, CA.*

Background: Previous studies have shown higher white blood cell (WBC) counts to be strongly and independently associated with all-cause mortality in incident maintenance hemodialysis (HD) patients. However, the association between WBC count and cause-specific mortality in incident HD patients is unknown.

Methods: In a retrospective observational cohort study of 109,767 HD patients from a large US dialysis organization (2007-2011), we examined cardiovascular (CV) and infectious mortality associations with baseline WBC. Using Cox models, we examined the associations with three hierarchical adjustments for case-mix variables, albumin, and additional laboratory markers of malnutrition and inflammation (MICS).

Results: Mean patient age of the cohort was 63 ± 15 years; 44% of patients were female, 32% were African American, and 58% were diabetic. Patients with higher WBC levels (≥8.0 $x10^3/mm^3$) had a higher CV and infectious mortality risk compared to the reference group (7-<8.0 $x10^3/mm^3$) in baseline models, and across all levels of adjustment. In the fully adjusted models, compared to the reference, patients with WBC ≥10.0 $x10^3/mm^3$ had a 22% higher risk of CV mortality (hazard ratio [HR]: 1.22, 95% CI: 1.14, 1.30) and a 58% higher risk of infectious mortality (HR: 1.58, 95%CI: 1.38, 1.82) [Figure].

Conclusions: Among incident HD patients, higher WBC count is associated with higher CV and infectious mortality risk, independent of other markers of malnutrition and inflammation, including albumin. These data suggest that higher WBC may be indicative of stronger risk of infectious mortality outcomes but further studies are needed to ascertain its use as a predictive marker in HD patients.

SA-PO1033

Hypersegmented Neutrophils in Hemodialysis Patients and Cobalamin (B12) Requirements

Styliani Vakiani,[1] Andreas Bozikas,[1] Konstantinos Dimitrakopoulos,[2] Kalliopi Pozoukidou,[1] Eleni Kitoukidi,[1] Antigoni Martika,[1] Asimoula Koteli,[2] Sofia Spaia.[1] *[1]Nephrology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [2]Microbiology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece.*

Background: Estimation of Nuclear Hypersegmentation of Neutrophils (HN) has been widely used as an indicator of Vitamin B12 (B12) or Folate (FO) deficiency. We chose to monitor the above as an indicator of functional deficiency of B12, since B12 supplementation, either for reducing the level of homocysteine (HC) or as factor decreasing erythropoietin (EPO) resistance in hemodialysis (HD) patients (pts), still remains a controversial issue.

Methods: Serum B12 levels were calculated from 57 HD pts prior to HD, after having received weekly intramuscular B12 injections (1000 μg Cyanocobalamine) for the past

6 months. All pts had smears of their peripheral blood examined to assess percentage of cells with HN, finding consistent with B12 deficiency. Hgb, MCV, FO, HC, PTH levels, Kt/V and EPO requirements were also recorded. Testing was repeated 6 months after discontinuation of B12 supplementation and 6 months after re-challenging with B12. FO supplements were administered throughout the study. Ferritin levels were kept > 200 ng/mL.

Results: Nuclear Hypersegmentation of Neutrophils was found in 55% of our patients to exceed the accepted level of 5% and reached 100% after stopping B12 supplementation along with a significant increase in EPO requirements, though B12 levels were well above the upper normal limit. EPO needs returned to previous levels after re-challenge with B12. HC and FO levels were unaffected. No difference in other parameters were observed.

Conclusions: In this study maintaining FO levels stable, we have demonstrated that despite high B12 blood levels, there is a functional deficiency which is reversed by B12 supplementation. HN seems to be a sensitive indicator of this process. The elevated percentage of HN in these pts (55%) has not been elucidated in the literature. When B12 was discontinued, 100% of the neutrophils nuclei were rendered hypersegmented but responded to B12, 6 months later, lowering overall EPO requirements. In spite of this beneficial effect, the optimal frequency and supplemental dose remain to be clarified.

Effect of Interleukin-6 on All-Cause Mortality in Renal Dialysis Patients: A Systematic Review

Matthew J. Holmes, Emma H. Elphick, Matthew Tabinor, Hatem Ali, Simon J. Davies, Mark Lambie. *University Hospital North Midlands, Stoke-on-Trent, United Kingdom.*

Background: In patients post myocardial infarction, there is strong evidence from a large randomized controlled trial of an anti-inflammatory that the association between chronic inflammation and mortality is causal. We aimed to assess how consistent with a causal interpretation is the evidence linking chronic inflammation and mortality in end stage kidney disease. We undertook a systematic review of the association between Interleukin-6 levels and mortality in patients undergoing dialysis.

Methods: MEDLINE, Embase, PsychInfo and Cochrane databases were searched for prospective cohort studies and randomised controlled trials published up until December 2018. Two independent reviewers selected papers reporting relationships between all-cause mortality and systemic inflammation as defined by IL-6, in adult dialysis patients. Demographics, all-cause mortality, and cardiovascular mortality data were extracted and reviewed in a descriptive fashion.

Results: Of the 1,324 papers initially identified, 28 were selected for the review with a total of 7,490 participants (range 50 to 959). Despite significant heterogeneity in analytical approach, higher levels of IL-6 were associated with worse all-cause mortality in 26 of the papers. In 18 of the 26 studies results were from multivariable survival analyses adjusting for age (65%), gender (58%), diabetes (46%), dialysis duration (35%), albumin (46%), smoking (27%), and CRP (27%). All 6 of the 25 studies assessing cardiovascular mortality, all of which reported multivariable analysis, found that IL-6 levels were predictive. The remaining two studies reported all-cause mortality in relation to variants in the -174G/C IL-6 polymorphism. Both studies found that the CC variant was associated with increased mortality compared to the GG variant (hazard ratio 1.71 [95%CI 0.98-1.78] and 3.58 [1.41-9.07, p<0.01]), although the relationship between the polymorphism and levels of IL-6 is less clear.

Conclusions: Systemic inflammation, assessed by plasma IL-6 concentration, is consistently associated with increased all-cause and cardiovascular mortality in adult dialysis patients. This is consistent with, but not proof of, a causal association.

SA-PO1035

An Exploratory Clinical Trial on the Efficacy and Safety of the GLP-1 Receptor Agonist Dulaglutide in Patients with Type 2 Diabetes Mellitus on Maintenance Hemodialysis

Daisuke Ugamura,[2,7] Michihiro Hosojima,[6,7] Hideyuki Kabasawa,[6,7] Naohito Tanabe,[1] Yuta Yoshizawa,[2,7] Ryohei Kaseda,[8] Emiko Kono,[9] Aya Takeyama,[5] Takayoshi Miura,[10] Hirokazu Fujikawa,[3] Hajime Yamazaki,[11] Hiroki Sasage,[5] Ikuo Aoike,[4] Yoshiaki Miura,[10] Yoshiki Suzuki,[12,7] Ichiei Narita,[8,7] Akihiko Saito.[2,7] *[1]Health and Nutrition, University of Niigata Prefecture, Niigata, Japan; [2]Applied Molecular Medicine, Niigata, Japan; [3]Maihira Clinic, Niigata, Japan; [4]Koyo Medical Clinic, Niigata, Japan; [5]Niigata Saiseikai Sanjo Hospital, Sanjo, Japan; [6]Clinical Nutrition Science, Niigata, Japan; [7]Niigata University, Niigata, Japan; [8]Clinical Nephrology, Niigata, Japan; [9]Nagaoka Chuo General Hospital, Nagaoka, Japan; [10]Miura Medical Clinic, Shibata, Japan; [11]Nagaoka Red Cross Hospital, Nagaoka, Japan; [12]Niigata University Health Administration Center, Niigata, Japan.*

Background: Dulaglutide is a once-weekly glucagon-like peptide-1 (GLP-1) receptor agonist approved for the treatment of type 2 diabetes mellitus (T2DM). However, the efficacy and safety of dulaglutide remain unclear in insulin-treated patients with T2DM on maintenance hemodialysis (HD).

Methods: Fourteen insulin-treated T2DM patients on maintenance HD were enrolled. Dulaglutide treatment was initiated and the insulin dose was adjusted as needed. Primary outcomes were changes in the mean and standard deviation (SD) of blood glucose (BG) levels evaluated by continuous glucose monitoring (CGM) for 6 days, and glycoalbumin (GA), HbA1c, and mean daily total insulin dose from baseline over 24 weeks. Secondary outcomes were changes in treatment satisfaction levels from baseline, measured using the Diabetes Treatment Satisfaction Questionnaire (DTSQ) and Diabetes Therapy-Related Quality of Life questionnaire (DTR-QOL) scores. Changes in body composition, including body mass index (BMI), fat mass (FM), skeletal muscle mass (SMM), and rate of interdialytic weight gain (IDWG), were also assessed.

Results: Two patients discontinued the study because of severe nausea or protocol deviation. In the full analysis set, the mean GA change was -3.1% (p = 0.008). Although the mean and SD values of BG and HbA1c levels did not change significantly, mean daily total insulin dose decreased significantly by -16.3 U/day (p = 0.001). Moreover, no significant changes were observed in area over the glucose curve <70 mg/dL per 24 h (AOC<70) in CGM. Six cases of gastrointestinal disorders were reported; however, both the DTSQ treatment satisfaction score (p = 0.029) and DTR-QOL total score (p = 0.014) improved significantly. BMI and FM changes were -0.6 kg/m^2 (p = 0.001) and -2.6 kg (p = 0.029), respectively. SMM and IDWG did not significantly change.

Conclusions: Dulaglutide may help improve glycemic control, body composition, and QOL without increasing hypoglycemia in insulin-treated patients with T2DM on maintenance HD.

SA-PO1036

Impact of Diabetic Nephropathy on Morbidity and Mortality in a Large Cohort of Hemodialysis Patients in Saudi Arabia

Ezzedine Abderrahim,[1] Ayman Sabri,[2] Mahmoud A. Ahmed,[2] Saad S. Alobaili,[2] Afef Dridi,[2] Ibrahim A. Jubran,[2] Wisam H. Al-Badr.[2] *[1]Davita Saudi Arabia, Riyadh, Saudi Arabia; [2]Davita Care-KSA, Riyadh, Saudi Arabia.*

Background: The aim of this study was to evaluate the impact of diabetes as a cause of ESRD on morbidity and mortality in a large cohort of Saudi hemodialysis patients.

Methods: All patients referred to Davita-Saudi Arabia clinics to continue ESRD treatment with hemodialysis from October 2014 to December 2018 were included in this analysis. The study population was divided in Group 1, corresponding to patients referred with the diagnosis of diabetes as a cause of ESRD and, Group 2, in whom ESRD was attributed to other causes with or without diabetes as a comorbidity. Mortality and hospitalization rates were calculated by dividing the number of events by the cumulative period of follow-up. Logistic regression was used to identify parameters that were independently associated with mortality and hospitalization.

Results: The cohort included 3508 patients (54% men). Patients with diabetic nephropathy represented 40.3% of included patients (G1), their mean age was of 58.1 ± 14.5 years vs. 48.7 ± 17.4 in Group 2 (p<0.0001). There was a slight male predominance in both groups with a sex ratio of 1.20 in G1 vs. 1.16 in G2 (NS). The proportion of patients who were hospitalized was of 31.7% in G1 vs. 22.3% in G2 (p<0.0001), corresponding to a rate of 38.8 per 100 patient-years (CI, 95%: [36.15-41.46]) in G1 vs. 21.8 per 100 patient-years (CI, 95%: [20.20-23.31]) in G2. Mean duration of hospital stay was of 4.8 days per patient in G1 (CI, 95%: [4.8-4.9]) vs 2.5 days in G2 (CI, 95%: [1.4-2.5]). The mortality rate was of 10.5 per 100 patient-years in G1 (CI, 95%: [9.10-11.86]) vs. 5.1 in G2 (CI, 95%: [4.33-5.83]). After adjustment for age, gender, type of vascular access and, time on HD, hospitalization, and mortality risks were of 1.61 (CI, 95%: [1.33-2.11]) and 1.47 (CI, 95%: [1.24-1.73]) in G1 compared to G2.

Conclusions: Saudi patients hemodialyzed for ESRD related to diabetic nephropathy, are with a higher risk for the number of hospitalization, hospital length stay and, mortality in comparison to those hemodialyzed for other causes.

SA-PO1037

The Impact of Antidiabetic Drugs on Morality in Diabetic Patients Undergoing Hemodialysis

Yi-Ting Chen,[1] Cheng chia Lee,[2] Chih-Hsiang Chang,[1] Yu-yun Chou.[1] *[1]Chang Gung Memorial Hospital, Taoyuan, Taiwan; [2]Chang Gung memorial hospital, Taipei, Taiwan.*

Background: Diabetes mellitus (DM) is associated with an increased risk of morbidity and mortality in patients undergoing hemodialysis (HD). Insulin and other oral antidiabetic drugs (OAD) are usually long-term given for glycemic control. However, there has been little research that have analyzed the long-term effect of antidiabetic drugs to mortality rate. The aim of this study is to evaluate the impact of use of antidiabetic drugs on the risk of mortality in such patients.

Methods: In this retrospective cohort study, we identified 212 diabetic HD patients who continued using at least one kind of antidiabetic drugs for more than 6 months in Chang Gung Memorial Hospital between November 1, 2009 and November 31, 2016. We excluded patients that had dialysis duration less than 6 months (N=60) and follow-up time less than 6 months (N=9). The final cohort comprised a total of 143 patients. Primary outcome was all-cause mortality. Hazard ratios (HR) were calculated by Cox proportional hazard regression models which were used to adjust for age, gender, laboratory data and different antidiabetic drugs use.

Results: In all 143 patients, mean age was 60.9 ± 12.2 years; 43.4% of patients was male and mean dialytic duration was 45.1 months. 71 patients (49.7%) used insulin for glycemic control, 54 (37.8%) used Sulfonylurea, and 25 (17.5%) used Dipeptidyl peptidase-4 inhibitors. After a median follow-up duration of 39.0 months, 60 patients died. Cox-multivariate analysis revealed only age (HR = 1.04, p =0.001), serum albumin (HR = 0.206, p <0.001), and insulin users (HR = 2.39, p= 0.011) to be independent

predictors of mortality. The finding persisted after adjusting for hemoglobin A1c level being treated as both a categorical variable or a continuous variable.

Conclusions: This study demonstrated that compared with non-insulin users, insulin users were associated with a higher risk of mortality in diabetic HD patients, independent of glycemic control.

Cox-multivariate analysis for all-cause mortality

	Hazard ratio(HR)	95% Confidence interval(CI)	p value
Age	1.040	1.015-1.065	0.001
Albumin	0.206	0.093-0.461	<0.001
Insulin	2.389	1.223-4.669	0.011

Multivariate adjustments were made for gender, dialysis duration, hemoglobin, triglycerides, use of Sulfonylurea, Dipeptidyl peptidase-4 inhibitors, and Hemoglobin A1c level.

SA-PO1038

Standardized Clinical Foot Examination in Prevalent Diabetic Hemodialysis Patients: Association with Mortality and Hospitalization

Szymon Brzosko,[2,3] Maciej Drozdz,[1] Joao M. Frazao,[4,5] Fatima F. Silva,[4] Werner Kleophas,[6,7] Partha Das,[1] Stefan H. Jacobson.[8,9] DaVita International *[1]DaVita International, London, United Kingdom; [2]DaVita Poland, Bialystok, Poland; [3]1st Department of Nephrology and Transplantation, Medical University of Bialystok, Bialystok, Poland; [4]Davita Portugal, Amadora, Portugal; [5]Department of Nephrology, São João Hospital Center, Porto, Portugal; [6]DaVita Deutschland, Dusseldorf, Germany; [7]Clinic for Nephrology, Heinrich-Heine University, Dusseldorf, Germany; [8]Karolinska Institutet, Stockholm, Sweden; [9]Danderyd Hospital, Stockholm, Sweden.*

Background: Atherosclerosis, neuropathy and SHPT contribute to increased risk of peripheral vascular disease (PVD) and adverse outcomes (eg, ulcers, limb amputation, hospitalizations and mortality) in diabetic patients on HD. Both the ACC/AHA and KDIGO guidelines recommend screening of individuals at risk. This study analyzed the frequency of foot complications following implementation of a standardized foot examination in 345 prevalent diabetic HD patients in 12 DaVita centers in Poland (n=177 pts) and Portugal (n=168 pts). Hospitalizations and cause-specific mortality were documented during 24 months follow up.

Methods: The protocol includes: history of the patient (ulcers, amputation), inspection of feet (skin, nails) and examination of the pedal pulses (a dorsalis pedis and a tibialis posterior) Foot complications were classified according to Wagner (grade 0-5) and PVD was classified by pulse measurement (normal vs weak or missing). We analyzed risks associated with hospitalization and mortality using Cox proportional hazard models.

Results: Mean age of patients (58% men) was 70.4 (SD 14) yrs. A normal pulse in L and R a dorsalis pedis and in L and R a tibialis post was found in 17% and 10% of patients, respectively. All other patients had weak or absent pulses. The Wagner score was 0 or 1 in 88% of patients, 2-3 in 6%, and 4-5 in 5%. All-cause mortality was 31% during the 2 year follow up. 71% of patients had at least one hospital stay. Cardio-cerebrovascular disease, PVD, and infection accounted for 76% of all mortality. In unadjusted analyses presence of weak or absent pulses in a dorsalis pedis was significantly associated with all-cause mortality RR 2.1 (CI 1.1-4.3; p<0.05). In adjusted models including age, sex, Hb, albumin, Kt/V, vascular access, phosphorus, PTH and Charlson score, only albumin was associated with mortality (RR 0.89, CI 0.84-0.94; p<0.001) and risk of hospitalization (RR 0.92, CI 0.89-0.96; p<0.001).

Conclusions: Implementation of a standardized foot examination protocol in diabetic patients on HD showed a high prevalence of clinically significant complications that warrant close attention. This clinical tool is suitable to identify patients at high risk of future complications and could be the basis of a program to improve overall health outcomes.

SA-PO1039

Epidemiology of Pericardial Effusions in Patients with ESRD on Hemodialysis

Leyla Gasimli-Gamache, Shilpa Vijayakumar, Haseena Sahib, Erin M. Taub, Sahar Ahmad, Sandeep K. Mallipattu. *Stony Brook University Hospital, Stony Brook, NY.*

Background: Cardiovascular disease, including pericardial disease, remains a prominent cause of morbidity and mortality in patients with end-stage renal disease (ESRD). The prevalence, clinical and prognostic significance of pericardial effusions (PE) in ESRD patients has not been well established. This study examines the epidemiology of PE in patients on chronic hemodialysis (HD).

Methods: This was an observational, retrospective study of chronic HD patients (> 2 months on HD) from Stony Brook University Hospital Kidney Center from January 1, 2010 to November 31, 2017 with analysis of transthoracic echocardiograms (TTE) along with corresponding clinical and demographic data. Effusions were classified by size: trivial (< 5 mm), small (5-10 mm), moderate (10-20 mm), or large (≥ 20 mm) echo-free space in end-diastole, as per European Society of Cardiology guidelines. Statistical analysis was conducted in SAS v9.4 using parametric and non-parametric tests as appropriate.

Results: A total of 185 TTEs from 82 patients on HD were analyzed. Twenty-nine (35.4%) patients had some degree of PE. Sixteen (19.5%) patients had trivial, thirteen (15.9%) had small, five (6%) had moderate and two (2.4%) had large (including one with tamponade physiology requiring pericardiocentesis) PE. Eighteen patients had multiple TTEs during the study period and were found to have varying degrees of PE (ranging from none to moderate). Patients with PE had a significantly lower median age compared to those who did not have PE (54 years old vs. 65 years old), with the moderate/large effusions primarily observed in relatively younger patients (median age of 46). Patients with lower serum albumin levels had significantly higher numbers of PEs, with the most severe PEs seen in the groups with the lowest albumin levels (3.2 g/dL). Patients with PE also had a lower mean hematocrit level compared to those without PE (29.6% vs. 32.7%). No significant association was found between the presence of PE and gender, ethnicity, cardiac ejection fraction, change in weight compared to dry weight, urea reduction ratio, or kt/v.

Conclusions: Approximately one-third of patients on chronic HD therapy had some degree of PE. In this study, relatively younger age, lower levels of serum albumin and lower hematocrit were independently associated with increased prevalence of PE.

SA-PO1040

The Association of Dialysis Adequacy, Body Mass Index, and Mortality Among Hemodialysis Patients

Kyung Hoon Yang,[3] Yuntac Lim,[2] Yuji Lee.[1] *[1]University of California at Irvine, Orange, CA; [2]samsungchangwon hospital, Busan, Republic of Korea; [3]Samsung Changwon Hospital, Changwon, Republic of Korea.*

Background: We examined the relationship between adequacy of hemodialysis (HD) and mortality in HD patients according to body mass index (BMI).

Methods: We retrospectively reviewed patient data from the Korean Society of Nephrology registry, a nationwide database of medical records of HD patients, from January 2001 to June 2017. We included patients who were ≥18 years old and receiving maintenance HD. Patients were categorized into three groups according to baseline BMI (<20 (low), 20 to <23 (normal), and ≥23 (high) kg/m^2). Baseline spKt/V was divided into six categories.

Results: Among 18,242 patients on HD, the median follow-up duration was 5.2 (IQR, 1.9–8.9) years. Cox regression analysis showed that, compared to the reference (spKt/V 1.2–1.4), lower and higher baseline spKt/V were associated with greater and lower risks for all-cause mortality, respectively. However, among patients with high BMI (n=5,588), the association between higher spKt/V and lower all-cause mortality was attenuated in all adjusted models ($P_{interaction}$<0.001). Compared to patients with normal BMI and spKt/V within the target range (1.2–1.4), those with low BMI had a higher risk for all-cause mortality at all spKt/V range. However, the gap in mortality risk became narrower for higher values of spKt/V. Compared to patients with normal BMI and spKt/V in the target range, those with high BMI and spKt/V <1.2 were not at increased risk for mortality despite low dialysis adequacy.

Conclusions: The association between spKt/V and mortality in HD patients may be modified by BMI.

SA-PO1041

Survival of Hemodialysis Patients in Saudi Arabia: A Large 4-Year Observational Analysis

Ezzedine Abderrahim, Ayman Sabri, Mahmoud A. Ahmed, Saad S. Alobaili, Ibrahim A. Jubran, Afef Dridi, Wisam H. Al-Badr. *Davita Care-KSA, Riyadh, Saudi Arabia.*

Background: The aim of this study was to analyze survival rates in a large cohort of patients receiving hemodialysis in 22 outpatient clinics all over Saudi Arabia (KSA) and also to identify factors influencing the risk of mortality.

Methods: We included all patients referred to DaVita-KSA clinics to continue renal replacement with hemodialysis from October 2014 to December 2018 (n=3508). Survival rates were calculated according to the actuarial method and the Cox proportional model was used to identify factors influencing mortality.

Results: Altogether 3508 patients on hemodialysis were included (54% men, 46% women) with a mean age of 52.5 ± 16.9 years. Diabetic nephropathy (40.3%) and hypertensive nephropathy (35.7%) accounted together for 75.8% of all causes of ESRD. Only 38.2% of patients had available autogenous /graft fistulae ready for use at the date of their transfer to Davita clinics vs. 65% at the last follow-up (p<0.0001). During the study period, 462 patients (13%) had been transferred to other dialysis facilities, 245 (7%) had been transplanted and 398 (11%) were deceased, representing an annual mortality rate 7.1% patients. Cardiovascular and cerebrovascular complications accounted for 49.0% of known causes of death and 14.3% were attributed to infections, while 40.4% of death causes remained unknown. Survival rates were of 98.0, 93.9, 87.7 and 73.3% at 3, 6, 24 and 48 months, respectively. The predictors of mortality identified by multivariate regression analysis were: Older age category (RR: 3.5, 95% CI: 2.4-4.9); p< 0.0001), dialysis duration before joining Davita-KSA clinics <3 months (RR: 1.4, 95% CI: 1.1-1.7) diabetes as a cause of ESRD (RR: 1.5, 95% CI: 1.2-1.8)), and catheter as vascular access (RR: 1.4, 95% CI: 1.1-1.8).

Conclusions: Survival at 2 and 4 years was high (88% and 73%) despite a high percentage of diabetics, that the annual mortality was of 7.1% and that cardio-cerebrovascular causes accounted for about the half of known causes of deaths. Use of a central dialysis catheter was identified as a modifiable predictor of mortality. Efforts should be increased toward an early creation of, and a timely shift to, an AV fistula.

SA-PO1042

Dialysis Outcomes at 12 Months Among Patients Starting Hemodialysis in India

Oommen John,[1,4] Abhinav Bassi,[1,4] Kamal D. Shah,[3] Sradha S. Kotwal,[2,4] Rohina Joshi,[5,4] Stephen Jan,[5,4] Martin P. Gallagher,[2,4] John Knight,[2,4] Vivekanand Jha.[1,4] Dialysis Outcomes Study Group *[1]George Institute for Global Health, New Delhi, India; [2]Renal and Metabolic Division, George Institute for Global Health, Sydney, NSW, Australia; [3]NephroPlus Dialysis Centres, Hyderabad, India; [4]Faculty of Medicine, University of New South Wales, Sydney, NSW, Australia; [5]The George Institute for Global Health, Sydney, NSW, Australia.*

Background: Hemodialysis (HD) is the dominant renal replacement therapy (RRT) in India. Despite a national free dialysis programme since 2016, outcomes in dialysis have received limited attention. 1000 incident HD patients were followed up to evaluate the determinants of outcomes. We describe the baseline socio-demographic and clinical characteristics associated with 12-month survival on HD.

Methods: 1000 participants were recruited from 2016 to 2018 at 16 dialysis facilities across 9 Indian states. Demographic, clinical, socioeconomic and quality of life parameters were collected through a secure online data collection platform. We examined the association of survival with age, gender, education, family income, OoP expenditure, insurance coverage, vascular access, hemoglobin and intradialytic weight gain. Chi-square and Fishers T tests were used to test for associations and a p value of <0.05 was deemed significant.

Results: The median age (IQR) was 58 (18) years, and 29% were female. 20% of the participants had education beyond school. 80% of the females worked within the home, while 44% of the males were retired or not working. Of those who had a job, 9% changed their occupation. Median monthly family income was US$ 500 (586). Median distance traveled for dialysis was 10 (15) kms. 75% funded dialysis out of pocket (OoP), 19% had government or an employer-based, while 6% had private insurance. The median monthly OoP expenditure was US$ 360±220 for uninsured participants and US$ 180±140 for insured participants. At 12 months, 53.4% remain on HD, 18.5% had died, 14.9% withdrew from dialysis, 7.5% received a transplant, 2.9% switched to PD, and 2.8% were lost to follow-up. Survivors had shorter travel distance, higher family income, hemoglobin and lower interdialytic weight gain. In the QoL analysis, the highest decline of function was observed in the domain of self-care(16%) followed by mobility(15%).

Conclusions: In this national HD cohort, 64% continued on RRT at 12 months. Availing dialysis closer to home, adequate financial risk protection was associated with continuing on dialysis. Hemoglobin levels more than 10 g/dL and low Inter dialytic weight gain were strongly associated with survival. Monitoring outcomes in dialysis provides an opportunity to identify modifiable factors to improve quality and inform policy.

SA-PO1043

Survival in Patients Who Return to Dialysis with Kidney Allograft Failure: The Argentinian Dialysis Registry Study

Gustavo Laham,[1] Maria C. Giordani,[2] Liliana Bisigniano,[3] Viviana Tagliafichi,[3] Guillermo J. Rosa diez.[2] *[1]Nephrology Section, Centro de Educación Medica e Investigaciones Clínicas(CEMIC), Buenos Aires, Argentina; [2]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [3]INCUCAI, CABA, Argentina.*

Background: The number of patients (Pts) who return to dialysis (Dx) after Kidney allograft failure (KAF) is increasing. The outcome of these Pts remain unclear. Some studies showed lower survival rates in KAF Pts than transplant naïve incidents dialysis (TNID) Pts. Our aim was to compare outcome of KAF versus Pts on waiting list (WL) and those with a kidney transplant contraindication (KTC)

Methods: We performed a retrospective observational study using data from the Argentinian Dialysis Registry between 2005 and 2016. We recorded demographics, laboratory markers and vascular access at entry. To compare mortality between the 3 groups Kaplan Meier, log rank test and Cox regression were used

Results: This study included 75722 Pts of which 2734 (3.6 %) were KAF Pts. The TNID (n=72988) Pts were significantly older, included higher percentages of males, diabetic and hypertensive when compared with Pts who started Dx after KAF. Regarding Dx modality, 5.8 % of Pts initiated PD in KAF group vs 3.9 % in TNID group (p<0.0001). There was a high percentage of Pts starting HD with transient catheters, being 66.1% and 65.5 % in KAF and TNID group respectively. Overall mortality was 54.6 % during follow up. Death probability between the 3 cohorts (KAF(n=2734) vs WL (n=14630) vs KTC(n=58358) revealed a significant difference (log-rank test: 10734.5; P< 0.0001) indicating worse survival for KTC incident Dx Pts cohort and best survival for WL. We also performed a survival curve adjusting for covariates that were statistically significant for mortality in Cox multivariate analysis. We found that KAF Pts had as poor outcome as KTC Pts. Multivariate Cox analysis showed that age >65 years: HR: 1.845 (1.79-1.89) P < 0.0001**,** transient catheter: HR: 1.303 (1.26-1.34) P < 0.0001, male sex: HR: 1.043 (1.01-1.07) P < 0.0002, diabetic: HR: 1.273 (1.22-1.31) P < 0.0001, hemodialysis modality: HR: 1.168 (1.07-1.27) P < 0.0004, hepatitis C: HR: 1.303 (1.26-1.34) P < 0.0001 and Albumin: HR: 1.247 (1.21-1.28) P < 0.0001 were strongly associated with mortality, while being on waiting list: HR: 0.285 (0.23-0.35) P < 0.0001 was found to be protective

Conclusions: Patients who return to Dx after KAF have higher mortality than WL patients and similar to KTC patients

SA-PO1044

A Comparison of Death Records Between the USRDS and a Large Health Care System

John J. Sim,[3] Sally F. Shaw,[1] Hui Zhou,[1] Jiaxiao Shi,[2] Steven J. Jacobsen.[1] *[1]Kaiser Permanente Southern California, Pasadena, CA; [2]Kaiser Permanente, Pasadena, CA; [3]Nephrology & HTN / Research and Evaluation, Kaiser Permanente Southern California, Pasadena, CA.*

Background: The accuracy of mortality data is important when determining the mortality rates for the end stage renal disease (ESRD) population and assessing interventions to improve survivability or quality of life. Little research has been done to examine the completeness and accuracy of the USRDS mortality reports. The purpose of this study is to compare mortality records from a large integrated health system with the USRDS registry.

Methods: A retrospective cohort study (1/1/2007-12/31/2016) of ESRD patients within Kaiser Permanente Southern California (KPSC), an integrated health system, was performed. Patients were linked to the USRDS death records and evaluated. KPSC mortality data are obtained from several sources, but primarily from California state death certificates. USRDS mortality data are similarly obtained from several sources, but primarily from CMS form 2746.

Results: A total of 4827 death records were found between 2007 and 2016. There were 4189 death records found in both KPSC and USRDS databases, 609 found only at KPSC and 29 found only at USRDS. An average of 12.7% of death records per year were captured at KPSC but missing from the USRDS database. Of the 4189 death records, 86.92% of KPSC death records had consistent dates of death (DOD) with the USRDS. A few death records had a DOD that differed by more than a week (1.03%) to more than a year (0.07%).

Conclusions: These data suggest that mortality information from the USRDS could be systematically under-ascertained. Researchers should use caution when using USRDS mortality data because of the potential for incompleteness of the data as currently collected. The use of additional sources of information may supplement and help overcome these challenges.

Sex-Specific Survival Advantage In Patients Undergoing Hemodialysis: Ten-Year Outcomes of the Q-Cohort Study

Hiroaki Tsujikawa,[1] Shunsuke Yamada,[1] Hiroto Hiyamuta,[1] Masatomo Taniguchi,[2] Shigeru Tanaka,[1] Kazuhiko Tsuruya,[3] Kumiko Torisu,[1] Toshiaki Nakano,[1] Takanari Kitazono.[4] *[1]Kyushu University, Fukuoka, Japan; [2]Fukuoka Renal Clinic, Fukuoka, Japan; [3]Nara Medical University, Kashihara, Japan; [4]Department of Medicine and Clinical Science, Fukuoka, Japan.*

Background: The survival advantage of females is observed in the general population. However, there is a controversy on the survival benefits of being females compared to males in patients undergoing hemodialysis. The aim of the study was to compare the risk for infection-related and all-cause mortality between males and females in patients undergoing hemodialysis.

Methods: A total of 3,504 Japanese hemodialysis patients aged ≥18 years were prospectively followed for 10 years. The primary outcomes were infection-related and all-cause deaths. Multivariable-adjusted hazard ratios (HRs) with 95% confidence intervals (95% CIs) of these outcomes were calculated using a Cox proportional hazards model.

Results: During the median follow-up period of 5.3 years, 448 died of infection and 1736 patients died of any cause. Compared with males, the multivariable-adjusted HRs (95%CIs) for infection-related and all-cause deaths in females were 0.47 (0.41–0.55) and 0.34 (0.25–0.44), respectively. This relationship was remained significant even when propensity score matching or inverse probability of treatment weighting (IPTW) adjustment methods were employed. Furthermore, even when the competing events of non-infection-related deaths were taken into account, the infection-related mortality rate in females was significantly lower than that in males.

Conclusions: The current study showed that the female advantage in survival is observed in patients undergoing hemodialysis. Further studied are necessary to confirm the survival benefit of females and its underlying mechanism in patients receiving hemodialysis.

SA-PO1046

Rural vs. Urban Residence and Survival on Chronic Maintenance Dialysis in US Veterans

Naveen Rathi,[1] Robert E. Boucher,[1] Guo Wei,[1] Tom Greene,[1] Sydney E. Hartsell,[1] Karen H. Gribbin,[2] Byron Bair,[2] G Paul Eleazer,[3] Srinivasan Beddhu.[1,2]
[1]University of Utah School of Medicine, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT; [3]Salt Lake City VAMC, Salt Lake City, UT.

Background: Most of the VA dialysis centers are urban. Veterans receiving maintenance hemodialysis (MHD) care in non-VA rural facilities may have ↑ mortality. Hence, rural and urban disparities might explain the better survival of veterans initiating MHD within the VA.

Methods: We examined a national cohort of veterans who initiated MHD from May 2012 to May 2016 by combining United States Renal Data System data obtained from VA Information Resource Center and VA Corporate Data Warehouse data obtained via VA Informatics and Computing Infrastructure. We defined rural and urban residence by zip codes. We used USRDS data to define VA and non-VA dialysis facilities, dialysis quality metrics and time to death.

Results: 46,470 veterans were included. VA veterans were younger, less likely to be white, had lower income and higher prevalence of traumatic brain injury and PTSD. However, irrespective of rural or urban residence, veterans who received dialysis care within the VA had better 5-year survival than veterans who received care outside the VA (Fig).

Conclusions: Veterans who received dialysis care within the VA had better survival compared to those who received care outside of the VA regardless of rural or urban residence.

Funding: Veterans Affairs Support

Baseline Characteristics

	Non-VA-care (N=43,900)		VA-care (N=2,570)

SA-PO1047

Impact of Altitude on Dialysis Patient Characteristics and Outcomes

Sheetal Chaudhuri, Hao Han, Marta Reviriego-Mendoza, Brian S. Ash, Janice D. Lindsay, John W. Larkin, Len A. Usvyat, Jeffrey L. Hymes, Robert J. Kossmann, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Barometric pressure, oxygen pressure as well as ultraviolet radiation are environmental factors that variate by altitude and have the potential to impact outcomes. Patients undergoing hemodialysis (HD) tend to suffer from several chronic conditions and could vary depending on the elevation they reside in. We aimed to define the characteristics and outcomes of the HD population at a large dialysis provider (LDO) by the altitude of residence.

Methods: We used data from HD patients treated at the LDO in 2018. Patients were stratified by the average elevation of the state of residence extracted from the US Geological Survey. Average state elevations were defined as: high (>4000 feet), mid (1000 to 4000 feet), and low (<1000 feet). We defined patient demographics, comorbidities, clinical characteristics and outcomes in the different elevations.

Results: Among a population of 244720 HD patients, 59% resided at low elevation, 35% at mid elevation, and 6% lived at high elevation. The percentage of females varied from 41-43% in the three elevations, and age ranged from 63-64 years old. Low elevations had the lowest percentage of white and Hispanic patients (whites: 44% vs 55% and 68% at low, mid and high elevations respectively; Hispanics: 5%). Low elevations had the smallest percentage of patients with diabetes (66%, 69% and 70% at low, mid and high elevations), while it had the highest number of patients with heart diseases (congestive heart failure: 21% vs 19% and 13% at low, mid and high elevations; ischemic heart disease: 21% vs 19% and 12% for low, mid and high elevations; hypertension 66% vs 67% and 70%, at low, mid and high elevation). Patients more commonly received an extra HD treatment in higher elevations (7% vs 8% and 9% at low, mid and high elevation). Low elevation also had the highest hospitalization rates (1.9 vs 1.8 and 1.7 at low, mid and high elevation).

Conclusions: HD patient characteristics and outcomes vary by elevation. In low elevations heart diseases were more prevalent, patients more often received an extra HD treatment, and patients had higher hospital admission rates. Diabetes was more prevalent in higher elevations in HD patients. Further adjusted analysis are needed to identify the influences of altitude on practice patterns and outcomes.

SA-PO1048

Racial Differences Among Recipients of Staff-Initiated CPR in Outpatient Dialysis Clinics

Samuel A. Hofacker,[3] Matthew Dupre,[2] Kimberly Vellano,[4] Bryan Mcnally,[4] Laura P. Svetkey,[1] Patrick H. Pun.[1] *[1]Department of Medicine, Division of Nephrology, Duke University School of Medicine, Durham, NC; [2]Department of Population Health Sciences, Duke University School of Medicine, Durham, NC; [3]Duke University School of Medicine, Durham, NC; [4]Emory University, Atlanta, GA.*

Background: Sudden cardiac arrest is the leading cause of death among hemodialysis patients. Despite practice guidelines recommending basic life support training for all hemodialysis clinic staff, rates of staff-initiated CPR are sub-optimal. Little is known about whether patient and clinic characteristics are associated with lower rates of dialysis staff-initiated CPR.

Methods: We examined data in the Cardiac Arrest Registry to Enhance Survival, a national surveillance registry with data submitted from 23 statewide registries and 70 additional communities, along with dialysis clinic data from the Centers for Medicare & Medicaid Services to identify cardiac arrests in outpatient hemodialysis clinics as well as characteristics of the rescue response between 2013 and 2017. Using multivariable logistic regression, we examined the likelihood of receiving dialysis staff-initiated CPR based on patient and dialysis clinic characteristics.

Results: Of the 1,581 patients who experienced cardiac arrest in hemodialysis clinics, 88.0% received staff-initiated CPR. 91.1% of White and 84.8% of Black patients received staff-initiated CPR (p=0.009). After accounting for patient age and sex, clinic characteristics, dialysis clinic neighborhood characteristics, and U.S. region (see Table), Black patients remained significantly less likely to receive staff-initiated CPR than White patients (aOR 0.45, 95% CI, 0.28 to 0.73). There was no relationship between patient race and dialysis staff automated external defibrillator application.

Conclusions: Black patients are significantly less likely than White patients to receive staff-initiated CPR during cardiac arrest in dialysis clinics across the US. Further understanding of resuscitation practices in dialysis clinics is necessary to address this finding.

Funding: NIDDK Support

Racial Disparities in Advance Care Planning in Patients Receiving Maintenance Dialysis

Fahad Saeed,[1] Susan K. Ladwig,[2] Ronald M. Epstein,[2] Kevin Fiscella.[3] *[1]University of Rochester Medical Center, Rochester, NY; [2]University of Rochester, Rochester, NY; [3]URMC, Rochester, NY.*

Background: There is a paucity of literature on racial differences in completion of advance care planning (ACP) documents among maintenance dialysis patients. We studied differences in the presence of advance care planning (ACP) documents in patients receiving maintenance dialysis.

Methods: A forty-one item questionnaire was administered to adult patients receiving maintenance dialysis in seven dialysis units located in the city of Cleveland, Ohio, and its suburbs. Of the 450 patients who were asked to participate in the study, 423 (94%) agreed. Of those who responded, 285 were African Americans, and 114 were Caucasians The questionnaire Items assessed patients' knowledge of their kidney disease, attitudes toward chronic kidney disease (CKD) treatment, and preference for end-of-life (EoL) care. A single question was used to assess completion of advance care planning documents "Have you completed any of the following?: (a) Living will (b) Personal directive/Medical Order for Life-Sustaining Treatment (MOLST) form (c) Healthcare proxy document (d) Enduring power of attorney (e) None of the above/Don't know." All responses about power of attorney were excluded from the current analyses. We used logistic regression to identify predictors of completion of any ACP document. Candidate predictors were patient demographics, attitudes toward CKD treatment, and EoL care preferences.

Results: African American race (OR 0.56, CI 0.35, 0.92, p=0.02) and lack of prognostic discussions (OR 0.48, CI 0.27, 0.87, p=0.02) were associated with a lower odds of having any advance care planning document. Age >65 years (OR 2.1, CI 1.35, 3.26, p=0.001) and religiosity (OR 3.76, CI 1.52, 9.27, p=0.003) were associated with higher odds of completion of ACP documents.

Conclusions: Racial disparities exist in completion of ACP documents. Factors associated with lower odds of advance care planning include African American race and the absence of prognostic discussions. Future interventions are needed to mitigate racial disparities in completion of ACP and encourage prognostic discussion with dialysis patients.

SA-PO1050

Mortality and Morbidity Among African American Patients with Sickle Cell Disease and ESRD Initiating Dialysis

Kabir O. Olaniran,[1] Sagar U. Nigwekar,[1] Nwamaka D. Eneanya,[2] Sophia Zhao,[1] Norma J. Ofsthun,[4] Lorien S. Dalrymple,[4] Franklin W. Maddux,[4] Ravi I. Thadhani.[3] *[1]Massachusetts General Hospital, Boston, MA; [2]University of Pennsylvania, Philadelphia, PA; [3]Cedars-Sinai, Los Angeles, CA; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: High rates of mortality have been described in sickle cell disease patients with end-stage renal disease (SCD-ESRD), however, risk factors for mortality and associated morbidity have not been elucidated. We examined vascular access failure (VAF), hospitalization and mortality among a cohort of adults with SCD-ESRD.

Methods: We identified adult, black patients with SCD who initiated peritoneal or in-center hemodialysis (PD or ICHD) dialysis in Fresenius Kidney Care clinics between 2000-2014 with up to 10 years of follow up. Patients with SCD were matched 1:3 to a reference population of black patients receiving PD or ICHD without SCD or sickle cell trait using age, sex, year of dialysis initiation and end-stage renal disease (ESRD) network. Multivariable Cox proportional hazards models were used to examine time to first VAF, first hospitalization, and 10-year mortality. Unadjusted mortality rate differences were estimated between vintage categories 2000-2004 and 2010-2014.

Results: We identified 504 SCD-ESRD patients and 1,425 matched reference patients. The mean age was 47±14 years, 49% were female, 95% were receiving ICHD and median follow up was 2 (IQR 1-4) years. SCD-ESRD was associated with a higher risk of VAF (adjusted HR 1.23; 95% CI 1.03-1.48), hospitalization (adjusted HR 1.60; 95% CI 1.42-1.80) and 10-year mortality (adjusted HR 1.58; 95% CI 1.31-1.96). Univariate analysis produced similar results. Hemoglobin < 8g/dl, higher weekly epoetin doses, higher ultrafiltration rates, dialysis catheter use, and low serum albumin were associated with higher mortality in SCD-ESRD. Changes in 10-year mortality rates in SCD-ESRD were non-significant between 2000-2004 and 2010-2014 (203 to 145/1,000 person-years, p=0.06) in contrast to a downward trend in mortality in the reference in the same period (109 to 57/1,000 person-years, p<0.01).

Conclusions: SCD-ESRD was associated with a higher risk of VAF, hospitalization and mortality. Although mortality rates decreased in the SCD-ESRD population during the timeframe of observation, rates did not decline to the same extent observed in the reference population. Prospective studies are needed to better characterize risk factors for mortality and address target parameters to improve outcomes in SCD-ESRD.

SA-PO1051

Global Kidney Health Atlas 2019: Current Status of ESKD Care in World Countries and Regions

Aminu K. Bello,[1] David W. Johnson.[2] * Co-Chairs, ISN Global Kidney Health Atlas on behalf of the Global Kidney Health Atlas Team *[1]University of Alberta, Edmonton, AB, Canada; [2]Princess Alexandra Hospital, Brisbane, QLD, Australia.*

Background: Although substantial literature describes the costs and consequences of end-stage kidney disease (ESKD), limited data are available on the capacity to deliver kidney replacement therapy (KRT) and conservative kidney management (CKM) across the world. We aimed to collect information on current global capacity (availability, accessibility, quality and affordability) to deliver KRT (dialysis and transplantation) and CKM.

Methods: A cross-sectional survey conducted from July to September 2018 by the International Society of Nephrology (ISN) across 182 countries using a purposive sample of key stakeholders identified by ISN's national and regional leaders.

Results: Responses were received from 160 of 182 countries (87.9%), including 317 of 460 individuals (68.9%, 2–4 respondents per country), representing 98.6% (7338.5 million of 7441.5 million) of the world's population. Results showed wide variation in capacity and structures for KRT and CKM, funding mechanisms, health workforce, service delivery and available technologies. Information on the prevalence of treated ESKD was available in 42% (n = 91) of countries worldwide, with estimates varying >800-fold from 4 to 3392 per million population (pmp). While there was at least some reported availability of hemodialysis, peritoneal dialysis, and kidney transplantation in 100%, 76%, and 74% of countries, respectively, dialysis and kidney transplantation were accessible to >50% of patients in only 70% and 29% of countries that offer the services, respectively. CKM was available in 124 (81%) countries. Worldwide, the median rate of nephrologists was 9.96 pmp, and this varied with income level.

Conclusions: The analysis demonstrates significant variability worldwide in both the burden of ESKD as well as the current capacity for KRT and CKM. This includes important gaps in services and workforce. These findings have implications for policy and advocacy efforts aimed at promoting universal, equitable access to the full spectrum of ESKD care.

SA-PO1052

Characteristics and Outcomes of Hemodialysis Patients by Population Density

Hao Han, Sheetal Chaudhuri, Brian S. Ash, Janice D. Lindsay, Marta Reviriego-Mendoza, John W. Larkin, Len A. Usvyat, Jeffrey L. Hymes, Robert J. Kossmann, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Population density associates with distinct profiles of health in the general population. Patients undergoing hemodialysis (HD) could be affected by the urbanicity level of their residence. We classified the characteristics and outcomes of HD patients at a large dialysis organization (LDO) by population density.

Methods: We analyzed 2018 data from HD patients. They were classified according to the county level population density defined by the Rural Institute, University of Montana: i) Metropolitan: ≥50,000 residents with integration to adjacent counties; ii) Micropolitan: ≥10,000-50,000 residents with integration to neighboring counties; iii) Rural: <10,000 residents. Median income data was obtained from the US Census database. We defined the profiles of demographics, clinical characteristics, and outcomes by level of population density.

Results: We analyzed data on 254322 HD patients. Of those, 84% resided in a metropolitan county, 10% lived in a micropolitan county, and 6% resided in a rural county. Average age was 64 years old in all population densities. More females lived in an urban county (44% vs 42% and 42% in metropolitan, micropolitan and rural counties, respectively). White race varied from 49%-52% and was the highest in micropolitan and lowest in metropolitan counties. Metropolitan areas had the highest proportion of Hispanics (13% vs 7% and 5% in metropolitan, micropolitan and rural counties). Median income was the highest in metropolitan areas ($54883 vs $43060 and $39630 in metropolitan, micropolitan and rural). In metropolitan to rural counties, the prevalence of comorbid conditions varied from 67-69% for diabetes, 19-22% for congestive heart failure, and 19-23% ischemic heart disease. In rural counties, patients less commonly received an extra HD treatment each week (7%, 7%, and 5% in metropolitan, micropolitan and rural). Hospital admission rates were higher in metropolitan areas (1.8 vs 1.7 and 1.7 admissions per patient year in metropolitan, micropolitan and rural).

Conclusions: Our findings suggest the characteristics and outcomes of HD patients vary by the population density of their residence. Further analyses are needed to understand the influence of practice patterns, access to health care, and distinctions in demographics on patient outcomes.

SA-PO1053

Association Among Primary Care Involvement, Death, and Hospitalizations for Patients Newly Started on Dialysis: A Population-Based Study from Ontario, Canada

Samuel A. Silver,[1] Eric McArthur,[3] Kristin Clemens,[4] Ron Wald,[2] Amit X. Garg.[5] *[1]Queen's University, Kingston, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]Institute for Clinical Evaluative Sciences, London, ON, Canada; [4]Western University, London, ON, Canada; [5]London Health Sciences Centre, London, ON, Canada.*

Background: The transition to dialysis is a vulnerable time, where patients may benefit from nephrology and primary care support. However, the role of primary care for patients on dialysis is poorly defined. We sought to determine whether primary care physician (PCP) involvement during the transition to dialysis improves outcomes.

Methods: Using linked administrative databases in Ontario, Canada, we conducted a population-based study of patients who initiated chronic dialysis between 2005-2014 and survived at least 90 days. We defined persistent PCP involvement as both 1) high usual provider of care index in the 2 years before dialysis, an established measure of PCP continuity and 2) ≥1 visit with the usual provider in the 90-days after dialysis initiation. We used propensity scores to match patients 1:1 based on indicators of baseline health. The primary outcome was all-cause mortality and secondary outcomes included all-cause and disease-specific hospitalizations.

Results: We identified 19,099 patients who survived for >90 days. There were 6612 patients (35%) with persistent PCP involvement who were matched 1:1 to 6391 patients without persistent PCP involvement. Persistent PCP involvement was not associated with a lower risk of mortality 2 years after cohort entry (14.5 deaths per 100 person-years vs 15.2 deaths per 100 person-years; hazard ratio [HR] 0.96, 95% CI 0.89-1.02). There was no difference in the rate of all-cause hospitalizations (HR 0.96, 95% CI 0.92-1.01), and persistent PCP involvement was not associated with a lower risk of any disease-specific hospitalization except for diabetes (HR 0.88, 95% CI 0.80-0.97).

Conclusions: Persistent PCP involvement during the transition to dialysis was not associated with a lower risk of mortality or all-cause hospitalization. These additional visits have opportunity costs for patients and economic costs for the healthcare system, suggesting primary care redesign may be needed to better support patients during this vulnerable period.

SA-PO1054

Trends in Outcomes for Patients Receiving Renal Replacement Therapy in Canada

Juliana Wu,[1] Michael Terner,[1] Michael Manno,[1] Scott Klarenbach.[2] *[1]Canadian Institute for Health Information, Toronto, ON, Canada; [2]University of Alberta, Edmonton, AB, Canada.*

Background: Alternate renal replacement therapy (RRT) modalities offer different survival and quality-of-life outcomes for patients. Recent technological and process advances in dialysis treatments and transplantation offer the opportunity for better survival outcomes for patients. Longitudinal data from the Canadian Organ Replacement Register (CORR) for patients receiving RRT in Canada allows for national-level tracking of patient outcomes over time. We analysed patient data from the CORR to investigate the near-, mid- and longer-term survival outcomes for patients receiving RRTs including hemodialysis (in-centre and home), peritoneal dialysis and kidney transplantation (living and deceased donors).

Methods: The dataset comprised 74,108 patients registered in the CORR between 2003 and 2017 for all provinces excluding Quebec. We calculated graft and patient survival rates at 3 months, 1-, 3-, 5- and 10-years after start of dialysis and after transplantation. We calculated Kaplan–Meier survival rates for 10 years after start of dialysis and after transplantation, and we adjusted rates based on a direct-adjusted Cox model controlling for patient age, sex and primary diagnosis of renal disease.

Results: Crude 5-year patient survival rates was highest in the living-donor transplant group (94.6%), followed by the deceased-donor transplant group (88.3%), PD treatment group (51.3%) and HD treatment group (40.9%). Between 2003 and 2012, crude 5-year survival rates for dialysis patients have increased by 6.6 and 7.0 percentage points for HD and PD patients, respectively. Graft survival rates improved over the 10 years by 0.9 and 4.6 percentage points for those who received a donation from a living or deceased donor, respectively.

Conclusions: Crude survival rates have generally increased over time across all RRT modalities, with similar rank order of survival between modalities as previously reported. Improvements in survival rates may reflect improvements in technology, technique, and patient education and characteristics, and process improvements within dialysis and transplant programs in Canada. CORR national data allow measurement and reporting of this important outcome as a performance measure.

SA-PO1055

Inverse Relationship Between Waist Circumference and Body Mass Index on Risk for All-Cause Mortality in Hemodialysis Patients: A Nationwide Population-Based Cohort Study

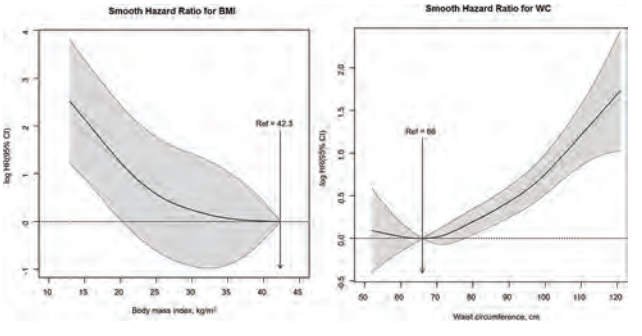
Chang Seong Kim,[1] Hong sang Choi,[2] Eun Hui Bae,[2] Seong Kwon Ma,[1] Soo Wan Kim.[1] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: Obesity underlies a high risk of all-cause and cardiovascular mortality in patients with end-stage renal disease. We investigated that the association between waist circumference and body mass index (BMI) and mortality in patients undergoing hemodialysis through a nationwide large population-based study.

Methods: Using nationally representative data from the Korean National Health Insurance System, 6,823,298 participants aged over 40 years with information for waist circumference and BMI were followed up during 4.5 years.

Results: The mortality rate is greater in hemodialysis patients with highest waist circumference category than those with lowest waist circumference category (5.67 per 100 person-years, ≥ 100 cm in men and ≥ 95 cm in women; 4.09 per 100 person-years, < 80 in men and < 75 in women). However, participants with higher BMI showed lower mortality rate than those with lower BMI (3.83 per 100 person-years in ≥ 30 kg/m^2 and 6.87 in < 18.5 kg/m^2). Multivariable Cox regression analysis found that participants with highest waist circumference category had higher risk of all-cause mortality than those with waist circumference 85 to 90 in men and 80 to 85 in women (reference group) [adjusted hazard ratio (HR), 1.280; 95% confidence interval (CI), 1.057–1.550], while those with lowest waist circumference category showed significantly lower risk of mortality compared to reference group (adjusted HR, 0.819; 95% CI, 1.410–1.929). Inversely, BMI categories ≥ 23 kg/m^2 were associated with significantly lower risk for mortality compared to the reference group (18.5 to 23 kg/m^2), with adjusted HR of 0.734 for BMI of 23 to 25 kg/m^2, 0.591 for BMI of 25 to 30 kg/m^2 and 0.530 for BMI ≥ 30 kg/m^2.

Conclusions: Central obesity measured by waist circumference is associated with all-cause mortality in hemodialysis patients, whereas body volume measured by BMI is an inverse relationship with this outcome.



SA-PO1056

Effect of Serum Uric Acid Level on Mortality Risk in Maintenance Hemodialysis Patients

Ming Li,[1] Canming Li,[2] Zengchun Ye,[2] Hui Peng,[2] Tan-qi Lou.[2] *[1]Nephrology, The Third Affiliated Hospital of Sun Yet-Sen University, Guangzhou, China; [2]The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: There is still much controversy about the relationship between serum uric acid level and all-cause or cardiovascular mortality in hemodialysis patients.

Methods: A retrospective cohort study was conducted to enroll 201 MHD patients in the Third Affiliated Hospital of Sun Yat-sen University. The baseline data of clinical and laboratory examinations were compared. The correlation between serum uric acid level and clinical variables was analyzed by Pearson correlation coefficient. Kaplan-Meier and Cox proportional hazard regression model was used to examine the association between serum uric acid and all-cause and cardiovascular mortality in HD patients.

Results: The average age of patients was 56.9 ± 16.7 years, and the average baseline serum uric acid level was 531.1 ± 137.9 umol/L. With 442 umol/L, 523 umol/L and 620 umol/L as the boundary points, the patients were divided into four groups according to the level of serum uric acid. The lowest quartile group was older and had more diabetes mellitus than the highest quartile group ($P< 0.05$). Compared to the highest quartile group, the serum albumin, serum phosphorus and serum creatinine were lower in the lowest quartile group, while the hypersensitive C-reactive protein were higher($P < 0.05$). Pearson correlation coefficient showed that uric acid level was positively correlated with albumin, serum phosphorus and serum creatinine. After a median follow-up of 49.8 months, 66 (32.8%) all-cause deaths and 37 (18.4%) cardiovascular deaths were recorded. Kaplan Meier method showed that with the decrease of serum uric acid, all-cause mortality (Log Rank = 23.63, P = 0.000)and cardiovascular mortality(Log Rank =23.10,P=0.000) increased. Cox proportional hazard model was used to correct age, sex, complications. It was found that for every 100 umol/L increase in baseline serum uric acid level, the risk of all-cause mortality decreased by 24.1% [HR 0.759 (0.595-0.968), P=0.026]. Compared to the highest group, all-cause mortality [HR 0.287 (0.118-0.696), P=0.006] and cardiovascular mortality [HR 0.147 (0.032-0.677), P=0.014] were higher in the lowest serum uric acid quartile group.

Conclusions: Low serum uric acid level increases the risk of all-cause mortality and cardiovascular mortality in MHD patients.

Lactate Rising: The "Unconventional" Use of Continuous Renal Replacement Therapy in Metformin-Associated Lactic Acidosis

Bashir El-Khoury, Ian J. Stewart. *US Air Force, Travis Air Force Base, CA.*

Introduction: Metformin is considered first-line therapy for many patients with type II diabetes mellitus (DM2). Metformin toxicity is a rare, yet potentially fatal complication of chronic metformin use with an incidence of ~4.2 cases per 100,000 patient years and a mortality rate between 30-50%. Extracorporeal treatment with intermittent hemodialysis (iHD) remains the modality of choice for severe metformin poisoining. However, patients with metformin-associated lactic acidosis (MALA) often present similarly to patients with septic or cardiogenic shock with severe hemodynamic instability making iHD treatment less desirable. I present a case of severe metformin toxicity treated successfully with continuous venovenous hemofiltration (CVVH).

Case Description: A 75 year old male with history of hypertension, DM2, and chronic kidney disease presented with altered mental status, nausea, vomiting, hypoglycemia and dyspnea. His home medications included metformin 1 gm twice daily and Lisinopril. The patient was intubated and found to have an initial arterial pH of 6.82, serum bicarbonate of 4 mmol/L, potassium of 6.3 mmol/L, SCr of 8.1 mg/dL, white blood cell count of 23.3 x10^9/L and lactate of 20.5 mmol/L. He required maximal doses of both norepinephrine and vasopressin for hemodynamic support. An EKG demonstrated peaked T-waves; therefore, a temporary femoral dialysis catheter was placed and CVVH was initiated. Initial concern was for ischemic bowel versus septic shock, however, MALA was also considered. Lactate levels decreased over the subsequent 24 hours to <2.0 mmol/L and arterial pH increased to >7.4, and the patient was discharged from the hospital six days later. One week after discharge, the metformin level returned at 37 mg/L confirming the diagnosis of metformin toxicity.

Discussion: Metformin toxicity is a rare, but treatable condition that poses unique challenges to clinicians given its similar presentation to more frequently observed clinical ailments. Although iHD has been the preferred modality for treatment of MALA, this case demonstrates that not only is CVVH an acceptable alternative, but may be the safest modality given the diagnostic uncertainty initially present. More studies evaluating the utility of CVVH in MALA may be beneficial to determine the optimal modality of extracorporeal therapy in patients with this rare but fatal condition.

SA-PO1058

Presence of Bisphenol S in Haemodialysis Patients: Environmental and Dialysis-Associated Exposure

Alberto Ruiz,[1] Sebastian Mas,[1] Pedro Abaigar,[2] Javier Santos,[2] Vanesa Camarero,[2] Emilio E. Gonzalez-parra.[1] *[1]Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; [2]Hospital Universitario de Burgos, Burgos, Spain.*

Background: In recent years, many studies demonstrated the effects xenobiotic of BPA, as results of these evidences; the industries are replacing BPA for different analogues such as Bisphenol S, it is a structural analogue, where in central quaternary carbon has been replaced by a sulfone. Due to of this similitude structural between BPA and BPS further studies promote to investigate the bioavailability and toxicities of BPS, and especially in the renal patient because of neither there is no literature about this group. In this study, our objective is to determine the plasmatic levels of BPS in comparison with BPA in the terminal renal patient and the influence of dialysis membrane.

Methods: The concentration of total BPS, BPA and hippuric acid (free, conjugated with sulphate or glucuronate, or bound to proteins) was determined by single reaction monitoring mass spectrometry (SRM-MS).

Results: BPA and BPS were measured in two groups: one of 10 healthy subjects (blood donors) and the other of 14 patients in hemodialysis (hemodiafiltration) which they were previously dialyzed for a week with cellulose triacetate (CTA) membranes. BPS in healthy controls were in almost all cases below LOD of 0.05 ng/mL, while in hemodialysis patients regardless of the membrane used was 0.32 ± 0.52 ng/mL. BPA in healthy controls range from 0.8 ± 0.7 ng/mL and 16.96 ± 58.57 ng/mL in renal patients. When membranes are compared, we found an increase of both after one dialysis session with polynephron (BPA: 45.63 ± 54.58 ng/mL at pre-dialysis vs 49.41±44.67 ng/mL at post-dialysis; BPS: 0.42±0.35 ng/mL at pre-dialysis vs 0.56 ± 0.36 at post-dialysis). On the other hand, with the polysulphone membrane exist there is a greater increase in the accumulation of BPA compared with BPS (BPA 51.4 ± 60.31 ng/ml at pre-dialysis vs 62.86 ± 77.39 ng/mL at post-dialysis; BPS: 0.59 ± 0.82 ng/mL at pre-dialysis vs 0.58 ± 0.47 at post-dialysis).

Conclusions: Similar to BPA, BPS accumulates in the renal patient as a result of the excretion problems of these patients along with the contribution of the dialysis membranes itself. However, the quantities measured are an order of magnitude lower than those measured for BPA both in a single dialysis session as well as in long-term dialysis (3 months or more).

SA-PO1059

Exposure to Wildfire Smoke Increases Mortality in US Hemodialysis Patients

Yuzhi Xi,[4,1] Abhijit V. Kshirsagar,[2] Timothy J. Wade,[3] David Richardson,[2] M. Alan Brookhart,[2] Ana G. Rappold.[3] *[1]Epidemiology, University of North Carolina, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC; [3]United States Environmental Protection Agency, Research Triangle Park, NC; [4]Oak Ridge Institute for Science and Education, United States Environmental Protection Agency, NHEERL, Chapel Hill, NC.*

Background: Wildfires are a significant source of fine particulate matter ($PM_{2.5}$) that is causally related to mortality. Our objective is to assess the effect of wildfire-$PM_{2.5}$ on daily mortality among patients receiving chronic in-center hemodialysis (HD) in the US.

Methods: From the United States Renal Data System (USRDS), we identified patients who 1) had Medicare as primary payer, 2) survived first 3 months of dialysis, and 3) visited dialysis clinics within the 627 counties impacted by at least one large wildfire between 2008-2012. Outcomes were daily all-cause mortality and all-cause mortality by place of death (clinical and nonclinical). Exposure was county-level daily wildfire-$PM_{2.5}$ concentrations. We tested the association of wildfire-PM2.5 exposure to daily mortality using time series analysis, while controlling for time-dependent factors (temperature, etc.) and by design for time-independent characteristics (demographics and comorbidities). The immediate (same day) effect and the cumulative effect of 1, 7, 14, and 30 days of the exposure to wildfire-$PM_{2.5}$ on mortality were expressed as adjusted rate ratios (RR) per 10 mg/m^3 increase in $PM_{2.5}$.

Results: Among 48,454 deaths, the RR of the same day effect on all-cause mortality was 1.04 (95%CI: 1.01-1.07) and the cumulative effects of 1, 7, 14, and 30 days following the exposure were 1.05 (1.02-1.08), 1.07 (1.03-1.11), 1.06 (1.01-1.10), and 1.07 (1.01-1.12), respectively. For all-cause death occurring in non-clinical settings, the RR of the same day effect was 1.07 (95%CI: 1.02, 1.12), and the respective RRs of cumulative effect were 1.07 (95%CI: 1.02, 1.12), 1.09 (95%CI: 1.02, 1.15), 1.07 (95%CI: 1.00, 1.15), and 1.09 (95%CI: 1.01, 1.18).

Conclusions: Wildfire-$PM_{2.5}$ exposure was associated with a ~5% increase in daily all-cause mortality rate among HD patients. These deaths occurred in non-clinical settings such as homes, where exposure to $PM_{2.5}$ may be exacerbated. The first of its kind study highlights the impact of environmental exposures on a fragile population, and the need for additional research. This abstract does not reflect EPA policy.

SA-PO1060

Long-Term Effect of Particulate Matter on Mortality Risk of Patients with ESRD

Jae Yoon Park,[1] Jiyun Jung,[4] Yong Chul Kim,[2] Yon Su Kim,[5] Jung Pyo Lee,[3] Ho Kim.[4] *[1]Dongguk University Ilsan Hospital, Gyeonggido, Republic of Korea; [2]SNUH, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Seoul National University, Seoul, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Aerodynamic particulate matter (PM) significantly worsens morbidity and mortality in various diseases, especially in cardiovascular and pulmonary diseases. However, little is known for relationship between PM and mortality of end-stage renal disease (ESRD).

Methods: 5041 patients who began dialysis from August 2008 to February 2015 were prospectively enrolled in the Clinical Research Center for End-Stage Renal Disease cohort study. We assigned daily mean concentration of PM < 10 μm in aerodynamic diameter (PM_{10}) to each participants for provincial-level divisions (si-do) by the location of station. Time-varying Cox proportional hazard models were used to investigate the relationship between PM_{10} and mortality of ESRD patients who have received dialysis. Stratified analysis was also conducted by potential confounders such as age, sex, smoking status, education, insurance, marital status, and social and familial support.

Results: During the follow-up period (mean 4.18 years), 1475 deaths occurred among 5041 participants. We found non-linear relationship between PM_{10} and mortality. Based on a threshold level at 44.15μg/m^3, although lower PM_{10} group had higher HRs for mortality with decrease in PM_{10} (HR 0.71, CI 0.69-0.74), higher PM_{10} group had higher HRs with increase in PM_{10} (HR 1.25, CI 1.22-1.28). Those who married and highly educated were at high risk in both groups, but opposite tendency was shown in each groups when stratified by population density, family and social support and the number of hospitals.

Conclusions: We found that the mortality of ESRD patients has contrary effects based on a threshold level of PM_{10}. It may be caused by toxicity of PM and characteristics of behavior at the region with relatively low concentration of PM_{10}.

SA-PO1061

The Effect of Dialysis on Aryl Hydrocarbon Receptor Binding Activities in Patients with CKD

So-young Lee. *Eulji University Hospital, Seoul, Republic of Korea.*

Background: Persistent organic pollutants (POPs) are well-known endocrine disrupting chemicals reported to be associated with various metabolic diseases. We hypothesized that POPs levels are increased in patients with chronic kidney disease or undergoing dialysis, thus further complicating the disease course. In this study, we measured serum POPs levels using a highly sensitive cell-based arylhydrocarbon receptor (AhR) dependent luciferase activity (CALA) assay in end stage renal disease (ESRD) patients undergoing dialysis or not, and compared differences between patients.

Methods: Patients undergoing peritoneal dialysis(22), hemodialysis(38) for at least 36 months, and and intracellular ATP levels were measured and compared according to treatment modality. We performed a correlation analysis between AhR binding activities and ATP levels and various clinical parameters.

Results: AhR binding activities differed significantly between groups, AhR binding activity was higher in non-dialysis CKD patients, compared to patients undergoing dialysis, and higher in patients undergoing hemodialysis compared to peritoneal dialysis. AhR binding activities decreased after hemodialysis treatment in HD patients. ATP level was the higher in healthy controls, compared to pre-dialysis CKD patients, and patients with peritoneal dialysis and hemodialysis. AhR binding activities and intracellular ATP levels showed significant correlations with multiple clinical parameters associated with cardiovascular risk factors.

Conclusions: POPs were associated with chronic kidney disease, and ESRD, while dialysis treatment reduced POPs levels. Further studies are mandated to specify the AhR binding activities and to evaluate the exact role in patients with chronic kidney disease

SA-PO1062

Cancer in Hemodialysis Patients

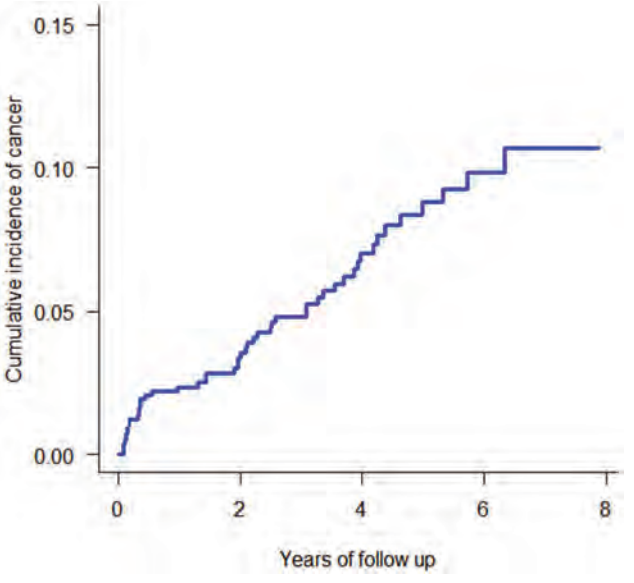
Jose E. Navarrete. *Emory University, Atlanta, GA.*

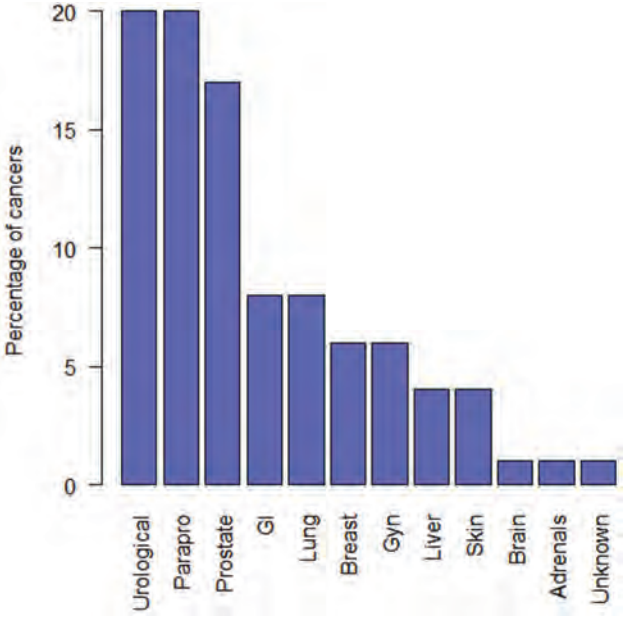
Background: Describe the incidence of cancer in hemodialysis patients. Describe the most common types of cancer in hemodialysis patients.

Methods: Incident hemodialysis patients enrolled in the Emory Dialysis program form 1/2011 to 12/2015 were followed until the diagnosis of cancer, death or censoring up to 12/31/2018. Time from inititation of dialysis to diagnosis of cancer and type of cancer was recorded.

Results: 902 patients were enrrolled in the hemodialysis program. 25 (2.8%) patients with prior cancer were excluded from the analysis as well as 51 patients followed less than a month. The remaining 826 patients are the base of this report. 51 patients (6.2%) developed a new cancer. Cancer patients were older (65 vs 57). The cumulative risk of cancer is presented in figure 1 (11%). The most common cancers were urological (20%), paraproteinemia (20%), prostate (17%), gastrointestinal (8%), lung (8%), breast (6%), gynecological (6%), liver (4%), skin (4%) and brain, adrenals and unknown primary with 1% (Figure 2)

Conclusions: The cumulative risk of cancer was 11% over 8 years. Cancer patients were older and had a lower hemoglobin. Urological, paraproteinemias and other solid organ cancers represent the majority of cancer diagnosed and this information could be used to delineate strategies for early detection of cancer in hemodialysis patients.





SA-PO1063

Concomitant Prescription of Gabapentinoids and Opioids Predicts Mortality and Morbidity Among US Dialysis Patients

Paul L. Kimmel,[1] Salina P. Waddy,[2] Adan Z. Becerra,[3] Julia B. Ward,[3] Kevin Chan,[1] Chyng-Wen Fwu,[3] Paul Eggers,[1] Kevin C. Abbott.[1] *[1]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [2]Atlanta Veterans Administration, Washington, DC; [3]Social & Scientific Systems, Inc., Durham, NC.*

Background: The opioid epidemic is a public health emergency and appropriate prescription of medications for pain symptom management remains a challenge. Increasingly, providers prescribe gabapentenoids (gabapentin and pregabalin) for pain despite limited evidence to support their off-label use and reports of abuse in combination with opioids. We sought to estimate the prevalence of concomitant gabapentenoid and opioid prescriptions and evaluate the effect of concomitant prescriptions on morbidity and mortality among end-stage renal disease (ESRD) patients in the US.

Methods: We used the United States Renal Data System to identify ESRD patients who were continuously treated with dialysis and had part A, B, and D coverage for all of 2010. Part D filled prescription claims were used to identify whether each patient had filled a prescription for opioids, gabapentin, and pregabalin in 2010. Patients were followed for all-cause death, discontinuation of dialysis, and hospitalizations.

Results: The study population included 153,758 ESRD patients who met inclusion criteria. Concomitant prescription of an opioid and gabapentin (15%) was more common than concomitant prescription of an opioid and pregabalin (4%). In adjusted analyses

using Cox models, concomitant prescription of an opioid and gabapentin was associated with increased risk of death (HR=1.16, 95% CI= 1.12, 1.19), dialysis discontinuation (HR=1.14, 95% CI= 1.03, 1.27), and hospitalization (HR=1.33, 95% CI= 1.41, 1.53). Similarly, concomitant prescription of an opioid and pregabalin was associated with increased mortality (HR=1.22, 95% CI= 1.16, 1.28) and hospitalization (HR=1.37, 95% CI= 1.33, 1.41), but not dialysis discontinuation (HR=1.13, 95% CI= 0.95, 1.35).

Conclusions: Concomitant prescription of opioids and gabapentenoids among US dialysis patients is common and is associated with worse outcomes. We were unable to identify the reasons why drugs were prescribed. The mechanisms underlying adverse effects are unclear, but prescription of gabapentenoids may be a marker for a sicker patient. Future research should investigate the potential harms of concomitant use of these drugs prospectively and identify safe alternatives for pain symptom management.

SA-PO1064

Geographic Variation of Increasing Mortality Risk in Black Dialysis Patients with Medicare Fee-for-Service Coverage

Eric D. Weinhandl,[1,2] Debabrata Ray,[1] Kristine Kubisiak,[1] Allan J. Collins.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Minnesota, Minneapolis, MN.*

Background: We recently reported that the weekly risk of death in black dialysis patients with Medicare fee-for-service coverage increased between 2014 and 2017, from 25.2 deaths per 10,000 patients per week to 27.1 deaths per 10,000 patients per week (*Am J Nephrol*, 2019). We aimed to assess whether this increase was homogeneous across US Census Divisions.

Methods: Using Medicare Limited Data Sets, we identified all black patients with Medicare Part B claims documenting outpatient dialysis from January 2014 to December 2017. For each calendar week (Monday to Sunday), we identified patients who had at least one outpatient dialysis session and who were alive at the end of the week; we calculated the proportion of patients who died during the subsequent calendar week. From the time series of weekly death rates in each US Census Division, we fit an autoregressive integrated moving average model to assess secular trend.

Results: The cohort included 208,768 unique patients; 23,685,808 patient-weeks; and 62,200 deaths. Mean age was 59.2 ± 14.0 years, 53% were female, and 54% of patients were concurrently enrolled in Medicare and Medicaid. Weekly mortality rates among all black patients were 25.1, 26.3, 26.5, and 27.1 deaths per 10,000 patients per week in 2014, 2015, 2016, and 2017, respectively. Death rates per 10,000 patients per week, by Census Division, are displayed in the table. Weekly mortality rates increased both monotonically and significantly ($P < 0.05$) in the South Atlantic and East South Central regions, an area that stretches from the Mississippi and Ohio Rivers to the Atlantic Ocean.

Conclusions: Increasing mortality among black dialysis patients with Medicare fee-for-service coverage appears to be a unique feature of the southeastern part of the United States. The extent to which this trend reflects dialytic factors versus broader health and socioeconomic trends is unclear, but merits detailed investigation.

	2014	2015	2016	2017	*P* for trend
New England	24.5	21.6	27.5	22.9	0.68
Middle Atlantic	26.5	27.4	27.1	26.5	0.98
East North Central	26.2	26.9	28.1	27.7	0.42
West North Central	24.4	24.7	22.9	26.2	0.57
South Atlantic	24.6	26.0	26.2	27.3	<0.01
East South Central	23.6	26.0	26.4	27.0	0.04
West South Central	26.3	26.2	26.3	27.5	0.35
Mountain	19.9	20.9	24.5	24.3	0.31
Pacific	24.8	28.6	26.8	28.2	0.23

SA-PO1065

Effect of Probiotic Supplementation on Regulatory T Cells and Inflammatory Monocytes in Patients Undergoing Hemodialysis

Eunho Choi,[1] Jihyun Yang,[1] Myeong soo Park,[2] Sewon Oh,[1] Myung-Gyu Kim,[1] Sang-Kyung Jo.[1] *[1]Korea University Anam Hospital, Seoul, Republic of Korea; [2]BIFIDO Co., Ltd., Hongchun gun, Republic of Korea.*

Background: Emerging evidence suggests that intestinal dysbiosis might contribute to systemic inflammation and cardiovascular diseases in dialysis patients. This study investigated the effects of probiotics supplementation on various inflammatory parameters in hemodialysis (HD) patients.

Methods: This study included 22 patients undergoing maintenance HD (IRB No. 2018AN0346). Patients received probiotics twice daily for 3 months (Zigunduk Bifidus Premium from BIFIDO Co, total 10 billion CFU of *Bifidobacterium bifidum* BGN4, *Bifidobacterium longum* BORI, *Lactobacillus acidophilus* AD031, and *Enterococcus facium* BH06). The percentages of CD14+CD16+ proinflammatory monocytes and CD4+CD25+ regulatory T cells (Treg) were determined by flow cytometry. Serum levels of calprotectin and zonulin (novel biomarkers of intestinal inflammation), and cytokine response to lipopolysaccharide (LPS) challenge, as well as various clinical parameters were compared before and after probiotics supplementation.

Results: The percentage of Treg showed a significant increase after 3 months of probiotic supplementation compared with baseline levels (8.6% vs. 3.5%, p<0.001), and the event count of CD14+CD16+ proinflammatory monocytes decreased significantly over baseline counts (194 vs. 310 cell numbers, p<0.05). LPS stimulation-induced interleukin (IL)-10 and IL-6 levels increased significantly (1159 vs. 517 pg/mL, and 37431 vs. 27663 pg/mL, respectively, p<0.05). Serum levels of calprotectin but not zonulin significantly decreased after probiotic supplementation.

Conclusions: These preliminary data suggest that probiotic supplementation may modulate systemic inflammation via expansion of Treg, suppression of proinflammatory monocytes, as well as reduction of gut inflammation in patients undergoing HD. Thus, targeting intestinal dysbiosis might be a new therapeutic strategy.

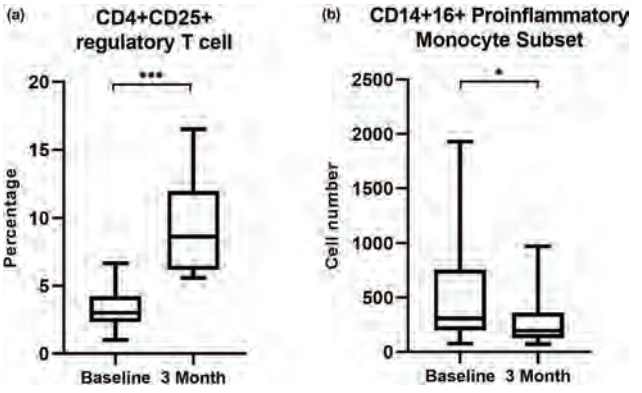


Figure 1 (a) CD4+CD25+ Treg percentage (b) Actual event count of CD14+CD16+ proinflammatory monocyte subset * p<0.05, *** p<0.001

SA-PO1066

Metabolic Changes in Peripheral Blood Mononuclear Cells Isolated from Dialysis Patients with Vascular Access Dysfunction

Mehmet M. Altintas, Salvatore DiBartolo, Beata Samelko, Monnie Wasse. *Rush University Medical Center, Chicago, IL.*

Background: As numerous complex pathologies can stem from cellular energy dysfunction, we aimed to elucidate whether mitochondrial dysfunction contributes to arteriovenous fistula (AVF) and arteriovenous graft (AVG) failure in a cohort of dialysis patients. We used peripheral blood mononuclear cells (PBMCs) as the model system of disease monitoring for bioenergetic analyses.

Methods: The bioenergetics study was conducted using PBMCs and serum from dialysis patients with AVF or AVG (re)stenosis. PBMCs and serum are isolated from whole blood through the use of a density gradient centrifugation, aliquoted and frozen at -80°C until analysis. On the day of analysis, PBMCs from healthy controls and patients were thawed, diluted and counted before being seeded into Seahorse XF24 assay plate to detect changes in mitochondrial respiration. The bioenergetics analysis was performed in the presence of Seahorse XF medium (free of bicarbonate, pH 7.4) using mitochondrial stress test kit and Seahorse flux analyzer. In order to test the metabolic changes caused by patient serum, we used commercially available control PBMCs and treated those with 10% serum from healthy controls and patients in 6-well plates. After 24 hours, cells were harvested and loaded to Seahorse XF24 assay plates for the bioenergetic analysis.

Results: We developed a technique to measure mitochondrial oxygen consumption in PBMCs isolated from dialysis patients with AVF or AVG (re)stenosis and control PBMCs fed with patient's serum for 24 h. In PBMCs of patients, we found a reduction in each of fundamental parameters of mitochondrial function such as basal respiration, ATP turnover, proton leak, maximal respiration and spare respiratory capacity. A similar trend was observed when the control PBMCs were cultured in the presence of 10% serum from patients for 24 h.

Conclusions: Our data demonstrates a correlation between mitochondrial oxygen consumption of PBMCs and end-stage renal disease (ESRD) in a case-control study of 30 patients. We propose a link between mitochondrial dysfunction and vascular access failure since PBMCs are exposed to metabolic and hemodynamic stimuli in the vasculature. Our findings and the methodology may help identify individuals at risk for hemodialysis vascular access dysfunction.

SA-PO1067

Evaluation of NATEM (ROTEM Delta) in Whole, Non-Citrated Blood in Hemodialysis Patients During Citrate and Dalteparin Anticoagulation

Gijs M. De Jong,[1] Henricus J. Vermeer,[2] Mario R. Korte,[1] Joost van Rosmalen,[3] Jan V. Meulen.[1] *[1]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands; [2]Clinical Chemistry and Haematology, Albert Schweitzer Hospital, Dordrecht, Netherlands; [3]Biostatistics, Erasmus MC, Rotterdam, Netherlands.*

Background: Standard clotting tests are performed in citrated blood. To investigate clotting in a study comparing citrate vs dalteparin anticoagulation during hemodialysis (HD), a NATEM in whole blood was developed using non-citrated blood. This study evaluates this NATEM.

Methods: 12 HD patients on anticoagulants (6 vit. K antagonist; 6 acetylsalicylic acid), underwent 2 standard HD sessions with dalteparin and 2 sessions using a Ca/Mg-free, 0.8 mmol/l citrate containing dialysis fluid with Ca/Mg substitution at the venous needle. Before, during and after HD, blood was taken for NATEM (ROTEM Delta, Tem-innovations Munich) in non-citrated (NC-) and citrated tubes (NC+). Clotting time (CT) is the time from starting the measurement until clot formation starts. Clot formation time (CFT) is the time from CT until a clot firmness of 20 mm is reached. Alpha is the angle of tangent between 0 mm and the curve when the clot firmness is 20 mm. A10 and A20

describe the clot firmness after 10 and 20 minutes. Maximum clot firmness (MCF) is the greatest vertical amplitude. NC+ within 10 minutes of NC- were considered to be simultaneous measurements. Data were analyzed using linear mixed models to account for repeated measurements and using linear regression to assess bias between methods. Median (M) and interquartile range (IQR) are reported.

Results: NC- CT (n=130; M 1116, IQR 942 – 1455 sec) and NC+ CT (n= 126; M 937, IQR 747 – 1281 sec) were correlated (Spearman rho 0.71; p<0.001). There was a constant and a proportional bias with NC- CT giving higher values than NC+ CT. After 45-60 minutes 2 duplicate NC+ were performed. The mean of these CT values (n= 43; M 546, IQR 448 – 776 sec) showed a significant constant bias towards the initial NC+ indicating a decrease of CT in time. Spearman rho correlations between NC- and NC+ were for CFT 0.44, alpha 0.53, A10 0.52, A20 0.58 and MCF 0.63 (p < 0.001).

Conclusions: (Anti)coagulation in citrate HD can be measured with NATEM in whole, citrated blood (NC+), NATEM (NC-) in whole, non-citrated blood can be done but is not necessary. However; results in NC+ change over time. This dictates that NC+ should be performed at a set time after sample collection.

Hospitalization Patterns in a Large Saudi Hemodialysis Population

Ezzedine Abderrahim, Ayman Sabri, Mahmoud A. Ahmed, Saad S. Alobaili, Afef Dridi, Ibrahim A. Jubran, Wisam H. Al-Badr. *Davita Care-KSA, Riyadh, Saudi Arabia*.

Background: Our aim was to analyze patterns and risks of hospitalizations in a large cohort of hemodialysis patients treated in 22 outpatient clinics all over Saudi Arabia (KSA).

Methods: The study included all patients admitted at Davita-KSA clinics to continue hemodialysis treatment during the period from October 2014 to December 2018. Overall and cause-specific hospitalization rates were calculated by dividing the number of hospitalizations by the cumulative period of follow-up. Logistic regression was performed to identify factors predisposing to hospitalization.

Results: 3508 patients were included (1897 males, 1611 females) with a mean age of 52.5 ± 16.9 years. During a cumulative follow-up period of 5584 years, 1576 hospitalizations were recorded in 26.1% of included patients, 38.7% of them had repeated admissions. Infectious causes, including those related to vascular access, accounted for 34.1% of all recorded hospital admissions vs. 18.8% for cardiovascular complications. The overall hospitalization rate was of 28.2 % patient-years with an annual duration of 3.4 days per patient. Infectious complications, not related to vascular access, accounted for the highest cause with an annual rate of 6.73 % vs. 5.32% for cardiovascular causes and 4.83% for hospitalizations attributed to vascular access creation and complications. The median length of hospital stays 11.5 days (range: 2-244 days) with an annual rate of 3.39 days per patient. This rate ranged from 0.05 for hospitalizations related to vascular access to 0.70 and 0. for infectious causes. Predictors of hospitalization were: Female gender (RR: 1.34, 95%; CI: 1.15-1.56), Age ≥ 65 years (RR: 1.32, 95% CI: 1.11-1.58); time on dialysis (RR: 1.44 per year, 95% CI: 1.34-1.55) diabetic nephropathy (RR: 1.61, 95% CI: 1.38-1.89), and Catheter as vascular access (RR: 1.38, 95% CI: 1.17-1.63)). Among all these factors, Diabetic nephropathy predisposed to a prolonged hospital stay.

Conclusions: Infectious complications were the leading cause of hospitalization among our hemodialysis patients and resulted in the longest hospital stay. Female gender, Age ≥ 65 years, Diabetic nephropathy, Catheter as vascular access and, time on dialysis were found as predisposing to hospitalization but only diabetic nephropathy is associated with prolonged hospitalization.

SA-PO1069

Profiles of Dialysis Recovery Time in Incident Home and In-Center Hemodialysis

John Danziger,[2] John W. Larkin,[3] Yue Jiao,[3] Marta Reviriego-Mendoza,[3] Sheetal Chaudhuri,[3] Andrew Long,[3] Joanna Willetts,[3] Dugan Maddux,[3] Jeffrey L. Hymes,[3] Len A. Usvyat,[3] Ravi I. Thadhani,[4] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Harvard Medical School, Brookline, MA; [3]Fresenius Medical Care North America, Waltham, MA; [4]Cedars-Sinai, Los Angeles, CA.*

Background: Home hemodialysis (HHD) includes frequent treatments typically 4-6 times per week and yields a higher adequacy and fluid removal. HHD associates to reductions in dialysis recovery time (DRT) compared to in-center HD (ICHD) in prevalent patients who switch to the modality. DRT is a measure of the perceived time after HD a patient feels they can return to performing normal daily activities. We characterized the profiles of DRT in incident patients treated with HHD and ICHD.

Methods: We used data from adult incident HD patients treated at a large dialysis provider who completed a DRT survey ≤180 days from the first date of dialysis (FDD) during 2014 to 2017. DRT survey is administered with the annual KDQOL questionnaire and asks: "How long does it take you to be able to return to your normal activities after your dialysis treatment?" Categorical answers include: <0.5, 0.5-1, 1-2, 2-4, >4 hours. We calculated the percentage of patients in DRT categories for the HHD and ICHD groups.

Results: We analyzed data from 1091 HHD and 98616 ICHD patients who completed the DRT survey ≤180 days from FDD. A lower proportion of HHD patients reported DRT >1 hour compared to ICHD (Figure 1). About half of HHD patients (53.9%) and a quarter (25.2%) of ICHD patients reported a DRT <0.5 hour.

Conclusions: Incident HD patients treated by HHD appear to experience a shorter DRT compared to ICHD. These findings show consistent signals with the Frequent Hemodialysis Network trial results in prevalent HD (Garg Kidney Int. 2017). Patients who chose HHD modality may be younger and have distinct clinical presentations and adjusted analysis are needed to substantiate these findings.

Provision of Outpatient Backup Dialysis in a Home Hemodialysis Unit

Claire Kennedy,[1,2] Bourne L. Auguste,[1,2] Michael Y. Girsberger,[1,2] Thatsaphan Srithongkul,[1,2] Rose Faratro,[4] Christopher T. Chan.[3,2] *[1]Nephrology, Toronto General Hospital, Toronto, ON, Canada; [2]Medicine, University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada; [4]University Health Network, Toronto, ON, Canada*.

Background: Patients doing home hemodialysis (HHD) require support from the parent unit when medical, dialysis-related and psychosocial issues arise at home. It is important that each HHD program makes provision for timely clinical assessment and back-up hemodialysis (HD), although this need has not been well quantified previously.

Methods: This was a retrospective, single-center cohort study of a HHD unit with an open-door policy in terms of clinical assessment and back-up HD during weekday office hours. Back-up HD in the incenter HD unit was organized for outpatient situations that arose outside of these hours. Emergency situations were directed to the emergency department (ED). The HHD unit electronic and paper medical records were reviewed for a twelve-month period. The uptake of outpatient back-up HD was established and reasons for this need were summarized.

Results: There were 104 to 107 prevalent patients in the HHD program during the twelve-month period. 79 outpatients attended for back-up HD (167 separate issues requiring 254 back-up HD sessions). Back-up dialysis was performed most commonly for medical reasons; followed by vascular access issues, technical issues, respite HD and post-operative/post-procedure HD (Figure). The majority of these issues necessitated one back-up HD session, facilitated in the HHD unit during weekday office hours. Respite HD for psychosocial reasons accounted for a small proportion of provided back-up HD.

Conclusions: One to two staffed dialysis stations were required each weekday for back-up HD in this HHD program of 100+ patients. Prompt access to clinical assessment and back-up HD in the parent HHD unit may relieve pressure on the incenter HD unit, ED and inpatient ward, and may facilitate ongoing HHD technique survival.

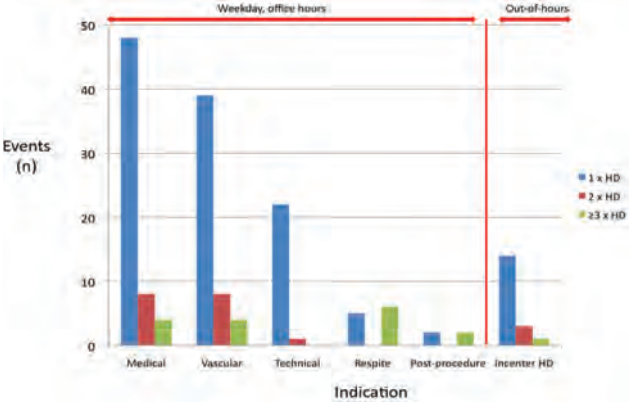

Figure: The number of separate events necessitating back-up outpatient HD that arose in a twelve-month period, and the number of back-up HHD sessions each issue required.

SA-PO1071

Barriers to Home Hemodialysis in Saskatchewan Canada: Results from a Provincial Survey

Lucas Diebel,[2] Christine Day,[3] Sachin Shah,[5] Maryam Jafari,[4] Bhanu Prasad.[1] *[1]Nephrology, Regina General Hospital, Saskatchewan Health Authority, Regina, SK, Canada; [2]College Of Medicine, University of Saskatchewn, Regina, SK, Canada; [3]Nephrology, Saskatchewan Health Authority, Regina, SK, Canada; [4]RQHR- Research and Performance Support, Regina, SK, Canada; [5]Nephrology, St Pauls Hospital, Saskatchewan Health Authority, Saskatoon, SK, Canada*.

Background: Home hemodialysis (HHD) offers similar, and perhaps even superior clinical outcomes to in-center hemodialysis (HD) at a fraction of the cost. HHD remains underutilized as remote HD patients in Saskatchewan often relocate or travel hundreds of kilometers weekly in order to receive dialysis related care. The purpose of this study was to determine the barriers to receiving HHD in our province.

Methods: We conducted a cross sectional survey of in center HD patients across the province of Saskatchewan. 740 in center HD patients (two academic sites, 7 satellite units) were approached by study coordinators. 421 patients (n=268 in the main units and n=153 in the satellite units) agreed to participate in the study. A five-point Likert scale survey was created to identify barriers to HHD with questions addressing HHD awareness and knowledge, accessibility, home constraints, impact on family members, and risks/ fears/beliefs surrounding HHD. Responses were anonymous and tabulated using a data collection tool.

Results: Only 76% of patients were aware of HHD. 46% of patients felt they had no understanding of the benefits or risks of HHD. Despite only 8% of patients being told they were unsuitable for HHD by their nephrologist, only 28% had ever considered it as a treatment option. Other prominent barriers to HHD were: satisfaction with in center HD (76%), medical supervision during HD (76%), opportunity to socialize with in center HD patients (73%), increase in utility payments (54%), and fear of having a major health event at home (51%). Other home constraints (space, inability to make modifications to the home) also figured prominently (35%).

Conclusions: In this study, we identified patient specific barriers to HHD in a prevalent cohort of HD patients. Several barriers were identified with a few consistent themes being identified, including deficiencies in knowledge and awareness, home constraints, and perceived benefits of in center care (satisfaction with current care, socializing with patients and staff, and fear of a catastrophic event at home). The most frequently reported knowledge barrier was a lack of understanding of the benefits and risks of HHD. While the study does not reflect views of all the patients, this information will be valuable in designing an educational program to improve adoption of HHD within our province.

SA-PO1072

Differences in Perceptions of Home-Based Dialysis Therapies Among the Renal Multidisciplinary Team

Krishna Poinen,[1] Mark Canney,[1] Lee Er,[2] Michael A. Copland.[1] *[1]University of British Columbia, Vancouver, BC, Canada; [2]BC Renal, Vancouver, BC, Canada*.

Background: Patients with end stage renal disease are encouraged to pursue home-based dialysis therapy (HDT) with the aims of improving quality of life, increasing patient autonomy and reducing the cost to the health care system. In the multidisciplinary setting, patients have exposure to nurses, clinicians and allied health staff, all of whom may influence a patient's modality choice. We aimed to evaluate the perceptions of HDT amongst multidisciplinary team members and identify avenues for further education

Methods: An electronic survey was distributed over a 6-week period to 695 non-transplant multidisciplinary team members across multiple renal centers in British Columbia, Canada. The survey contained questions about work environment, patient/ system factors in choosing HDT, perceived knowledge of HDT and the need for further education. Results were stratified by 5 categories of respondent: nephrologists, nurses in 3 clinical areas (facility hemodialysis, HDT, pre-dialysis), and allied health (pharmacists, social workers, dieticians)

Results: A total of 334 respondents were included (48% response rate). The majority of respondents in all categories stated that they would choose HDT if they were ever to require dialysis. The majority also recommended that a higher proportion of patients should receive HDT, especially patients who work or study. Facility nurses were believed to have the least impact on a patient's choice of modality, yet they also perceived themselves as key patient educators. Facility and HDT nurses favored in-center dialysis and HDT respectively for patients with lower socioeconomic status, lower education or a language barrier. All respondents acknowledged the benefits of HDT for cost-savings and improved patient survival. The majority of nurses and allied health staff felt the need for further education in HDT, favoring practical over knowledge-based educational opportunities

Conclusions: The majority of the renal multidisciplinary team members would welcome increased uptake of HDT due to benefits on the patient and healthcare system level. Nurses differed substantially in their perceptions of modifiable barriers to HDT depending on their primary area of work. Further HDT education has the potential to bridge these gaps and help patients make informed decisions about their dialysis modality

SA-PO1074

Clinical and Biological Comparison Between Nurse-Assisted Home Hemodialysis (NAHHD) and In-Center Hemodialysis (CHD) in Home-Bound and Multicomorbid Hemodialysis Patients: One-Year Results

Bassam O. Bernieh,[1] Satarupa Gogoi,[1] Ahmed A. Ahmed,[2] Bienmelyn L. Hernandez,[1] Teena J. Ramos.[1] *[1]HHD Home Healthcare, Abu Dhabi, United Arab Emirates; [2]Tawam Hospital, Al Ain, United Arab Emirates*.

Background: Home hemodialysis (HHD) is a renal replacement modality used to treat active, autonomous, and relatively, healthy dialysis patients. The steady increase in the number of dialysis patients, with multi-comorbidities and limited mobility is creating a significant burden on the active hospital beds, and on the outpatient dialysis units. The clinical and biological outcome, of treating those highly comorbid and disabled dialysis patients with nurse assisted home hemodialysis (NAHHD) at home compared to in-center HD, is unknown. We are reporting the results of one year on NAHHD, compared to one year in CHD.

Methods: The data of 19 patients, treated in center hemodialysis (CHD) for average period of 12 months (4-14), was compared retrospectively, to average period of 12 months (4-25), on (NAHHD) for the same set of patients. All patients were dialyzed by Fresenius 5008 machine in center and by NxStage System One Cycler at home. Reasons for shifting patients to NAHHD program were: bed-confinement/ limited mobility in 12 (63%), morbid obesity in 3 (16%), psychiatric disorder/ mental retardation in 3 (16%), and others 1(5%).

Results: The mean age of the patients was 69.33 ± 12.08 (42-90) years. Etiology of ESKD was DM in 15(79%), HTN in 3(16%) and others 1(5%). The average number of comorbidities was 9.6 ± 3.07 (6-16). Vascular Access type: AVF 9(48%), AVG 1(5%), PC 7(37%), and AVG/PC/AVF 2(10%). The comparison between the results while in CHD and during NAHHD are illustrated in the Table.

Conclusions: In home bound and multi comorbid hemodialysis patients; NAHHD by using NxStage System One cycler, is safe, efficient, with better clinical and biological outcome, compared to in center HD.

Average Comparison of clinical and biological parameters in 19 patients

Parameter	NAHHD	In-center HD	P-Value	Decision
Albumin g/L	39	33	0.04	S
Ca mmol/L	2.2	2.2	0.14	NS
PO4 mmol/L	1.4	1.7	0.04	S
PTH pg/mL	331	594	0.000	S
Hb g/L	111	106	0.03	S
ESA monthly dose mcg	80.3	111.3	0.003	S
Iron monthly dose mg	171	177	0.04	S
Std Kt/V	2.21	2.16	0.12	NS
UF Weight Gain (L)	1.8	2.2	0.01	S
Dialysate volume L/session	26	120	0.000	S
Dialysis Frequency (sessions/week)	4	3	0.04	S
Dialysis Time (minutes/session)	216	230	0.04	S

S: = Significant: NS = Not Significant

SA-PO1075

Profiles of Demographics, Nutrition, and Outcomes in Home and In-Center Hemodialysis

John Danziger,[2] Sheetal Chaudhuri,[3] Joanna Willetts,[3] Marta Reviriego-Mendoza,[3] John W. Larkin,[3] Len A. Usvyat,[3] Joseph E. Turk,[3] Jeffrey L. Hymes,[3] Robert J. Kossmann,[3] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Harvard Medical School, Brookline, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: Home hemodialysis (HHD) may have favorable attributes related to the provision of better adequacy and fluid removal with more frequent treatments. HHD has been associated with improved blood pressure control and lower all-cause/cardiovascular event rates. We characterized the demographics, nutritional status, and outcomes among patients undergoing HHD and in-center hemodialysis (ICHD) at a large dialysis organization (LDO).

Methods: We used data from HHD and ICHD patients treated at the LDO in November 2018 to January 2019. We profiled the average proportion of HHD and ICHD patients achieving target goals for i) albumin ≥4mg/dL, ii) mineral bone disorder (MBD)

with calcium ≤10.0mg/dL, phosphate ≥3.0-≤5.5mg/dL, and intact parathyroid hormone (iPTH) ≥150-≤600pg/mL, and iii) central venous catheter (CVC) <90 days. We also calculated the unadjusted hospital admission rates per patient per year (ppy) for the groups.

Results: We included data on 171,712 patients (HHD n=4141, ICHD n=167571). A larger proportion of HHD patients were younger (HHD=55.5, ICHD=63.5 years), male (HHD=63%, ICHD=57%), and white race (HHD=55%, ICHD=47%). A greater proportion of HHD patients achieved target albumin levels (HHD=51%, ICHD=37%), yet a slightly lower proportion of HHD patients achieved MBD goals (HHD=46%, ICHD=49%). The proportion of patients with catheter exposure >90 days was relatively consistent between groups (HHD=13%, ICHD=15%). Patients treated with HHD exhibited lower hospital admission rates (HHD=1.07, ICHD=1.55 admits ppy).

Conclusions: Patients treated with HHD more commonly achieved nutritional goals for albumin compared to those treated with ICHD. HHD patients may have unique eating habits with more protein and dietary phosphate intake that may be leading to lower MBD goal achievement compared to ICHD. HHD patients tended to have less hospital admissions compared to ICHD, yet an adjusted analysis is needed to validate this observation in a population group with distinct demographics.

SA-PO1076

Enhancement of Solute Clearance Using an Experimental Pulsatile Push Pull Dialysate Flow Mode for the Quanta SC+: A Novel Clinic-to-Home Hemodialysis System

Clive Buckberry,[2] Detlef H. Krieter,[1] Paul Komenda,[2] Horst-Dieter Lemke,[1] John Milad.[2] *[1]University Hospital Würzburg, Würzburg, Germany; [2]Quanta Dialysis Technologies, Alcester, United Kingdom.*

Background: The SC+ hemodialysis system is a small, easy to use dialysis system designed to improve patient access to self care and home hemodialysis. A prototype of the SC+ device with a pulsatile push pull dialysate flow was developed for evaluation purposes.

Methods: The pumping action of the prototype SC+ system was modified by altering software algorithms controlling the sequencing and timings of the valves and pumps associated with the flow balancing chambers that push and pull dialysis fluid to and from the dialyzer; no additional modifications to the hardware or consumables were required. Solute clearance performance was assessed in the prototype SC+ system across a range of molecular weights in two related series of laboratory bench studies. The first measured dialysis fluid moving across the dialyzer membrane using ultrasonic flowmeters to establish the validity of the approach; solute clearance was subsequently measured using fluorescently tagged dextran molecules as surrogates for uremic toxins. The second study used human blood doped with uremic toxins. In both, the performance of the SC+ prototype was assessed alongside reference devices operating in HD and pre-dilution hemodiafiltration (HDF) modes.

Results: Initial testing with fluorescein-tagged dextran molecules (0.3 kDa, 4 kDa, 10 kDa and 20 kDa) established the validity of the experimental pulsatile push-pull operation in the prototype SC+ system to enhance clearance and demonstrated a 10 to 15% improvement above the current HD mode used in clinic today. Additional testing using human blood indicated a comparable performance to pre-dilution HDF.

Conclusions: The observed enhancement of solute transport is attributed to the disruption of the boundary layers at the fluid-membrane interface which, when used with blood, minimizes protein fouling and maintains the surface area available for mass and fluid transport. In contrast with current HDF technologies, this improvement in performance has been achieved without the introduction of any additional complexity to the device hardware or fluidic circuit consumable sets maintaining ease of use of the SC+ system.

SA-PO1077

Convective Daily Home Dialysis Program Development: Preliminary Outcomes

Philippe Nicoud. *Centre de Néphrologie du Mont Blanc, Sallanches, France.*

Background: Since 2014, 370 ESRD French patients entered a new short daily home dialysis program based on a convective therapy. We present here the primary clinical and biological outcomes of the first 140 patients treated.

Methods: The epidemiological and clinical characteristics of these 140 patients treated with this technique were analyzed after retrospective data collection. Weekly dialysis performance was evaluated according to the standardized Kt/V (SDT) using the Gotch method. Data were collected during the in-center training periods of each patient prior to their final home installation.

Results: The anonymized data of 140 patients in the technique (age: 53 ± 7 y, weight: 74.2 ± 16.5 kg) were collected. Sex ratio: Male 74%; Female 26%. 123 patients (88%), were diabetes type II free and 80 patients (57%) have kept a residual kidney function. 98 patients (70%) had full time job. 228 home daily dialysis sessions were performed between 2014 and 2017, average time 124 ± 12 min per session, 5.8 ± 0.4 sessions per week. Average blood flow was 284 ± 19 mL/min, dialysate flow 181 ± 6 mL/min. Average Convection volume excluding weight loss was 3.040 ± 1.059 mL per session. The urea Kt/V SDT, was greater than 2.1 in 184/215 (86%) sessions (figure) and the average ultrafiltration rate was 8.5 ± 5, 1mL/h/kg.

Conclusions: This work illustrates the clinical and biological profile of the first patients treated with a short daily home dialysis convective technic. It gives the level of performance in terms of urea RR, convective volume achieved and ultrafiltration rate. These results have to be confirmed and refined by a broader multicentric retrospective study, RECAP, currently underway, which include all the ESRD patients entering this technique between January 2014 and June 2018.

SA-PO1078

Daily Home Hemodialysis (DHHD) in Large Patients: Observation and Data from the Knowledge to Improve Home Dialysis Network in Europe (KIHDNEy) Cohort

Hafedh Fessi. *Hopital Tenon, Paris, France.*

Introduction: Obesity is steadily increasing among HD patients (15–26% in W.Europe), responsible for high morbidity and mortality due to multiple metabolic abnormalities and cardiovascular risk factors: insulin resistance, infections, hypertension, sleep apnea… and for reduced mobility. Kt/V target is poorly evaluated as usual formulas overestimate V.

Case Description: A male patient aged 34, 200kg weight, BMI 54.2kg/m2, presents CKD5 due to segmental and focal hyalinosis, is dialyzed incenter 3x5h=15h/week for 3 years, complains of severe fatigue and joint pain reducing his mobility, and of restless leg syndrome disrupting his sleep, stops working but agrees to train on SystemOne. Prescription is 6x150mn=15h/week, same duration as incenter. Dialysate and blood flow rates are 200 and 450ml/min. Restless leg syndrome disappeared and he complains less of fatigue at 4 weeks. Mobility improved and he returns to work after 2 months. Joint pain decreased at 6 months. Biological parameters improve as early as week 4: decrease in pre-dialysis urea 23 vs 38mmol/l and b2m 15.3 vs 21.4mg/l. Albuminemia increases from 35.9 to 45.6 g/l. Phosphoremia is stable, phosphorus chelators unchanged. Fistula used daily for 2 years (buttonhole) doesn't present complication.

Discussion: The retrospective Cohort Study KIHDNEy involved 219 patients on DHHD in 5 European countries. 101 patients (46.8%) had a normal BMIn, avg 21.8kg/m2, 47 patients (21.8%) had a high BMIh, avg 36.3kg/m2 (30.1–53.7). 68.1% of BMIh patients were male, aged 51.7±11.4. 66.0% of BMIh dialyzed ≥6x/week, cumulative time was 16.6±3.1h/w vs 14.0±3.6 for BMIn. Ultrafiltration rate was low, 4.6±3.5 ml/kg/h vs. 7.4±5.0. Dialysate volume was greater: 38.3% used ≤25 L/session vs. 75.2%. Mean stdKt/V 2.5 at 6 and 12 months did not vary and was equivalent to BMIn, 2.6(p=0.91). Baseline phosphoremia did not change at 6 and 12 months (1.70, 1.73, 1.63mmol/l, p=0.44). PO4 chelators decreased by 17% (3.07, 2.92, 2.53 tablets, p=0.04). Antihypertensives decreased by 37% (1.44, 1.03, 0.91, p<0.01). Conclusion: Evaluation of V with bioimpedance is recommended to customize prescription for obese and very large patients. Thus DHHD is adequate, with high clearance and low ultrafiltration. It improves clinical outcomes and quality of life, which are as good as normal size patients, and addresses the mobility challenge.

SA-PO1079

A Study to Evaluate a New Hemodialysis Device in the Home

Troy J. Plumb,[2] Jeffrey Mulhern,[3] Sarah S. Prichard,[4] Brittany Lim,[1] Michael A. Aragon.[1] *[1]Outset Medical, San Jose, CA; [2]University of Nebraska Medical Center, Omaha, NE; [3]Fresenius Kidney Care Pioneer Valley Dialysis, Springfield, MA; [4]Independent Consultant, Montreal, QC, Canada.*

Background: The Tablo® Hemodialysis system is an automated, sensor-based system that simplifies operation and produces on demand dialysate without the need for separate water treatment. It is currently indicated for use in acute and chronic care settings. The purpose of this study was to describe the patient population enrolled in a home study and the rate of adherence to the dialysis frequency protocol requirement.

Methods: A prospective multicenter, open-label, non-randomized, cross-over study was completed to evaluate Tablo in the home by subjects with end stage renal disease (ESRD) who are on stable dialysis regimens. The FDA-approved study required an In-Center arm with 32 treatments, a transition period of 8-16 treatments, and an In-Home arm with 32 treatments. Dialysis frequency was 4 times per week. The primary efficacy endpoint was a weekly standardized Kt/V of ≥ 2.1, and the primary safety endpoint was the mean number of adverse events from a pre-specified list. The secondary endpoint was ultrafiltration (UF) rate within 10% of the prescribed UF goal.

Results: Thirty patients from 8 dialysis units in the US were enrolled, and 28 per-protocol patients completed 1742 treatments. Compliance to the protocol dialysis frequency in the per-protocol group was 97%. Preliminary analysis suggests the study met all safety and efficacy endpoints.

Conclusions: Patients in the study were representative of the overall dialysis population. Protocol compliance was high and preliminary data indicates study objectives were achieved.

Validation of Revisions to the NxStage Dosing Calculator

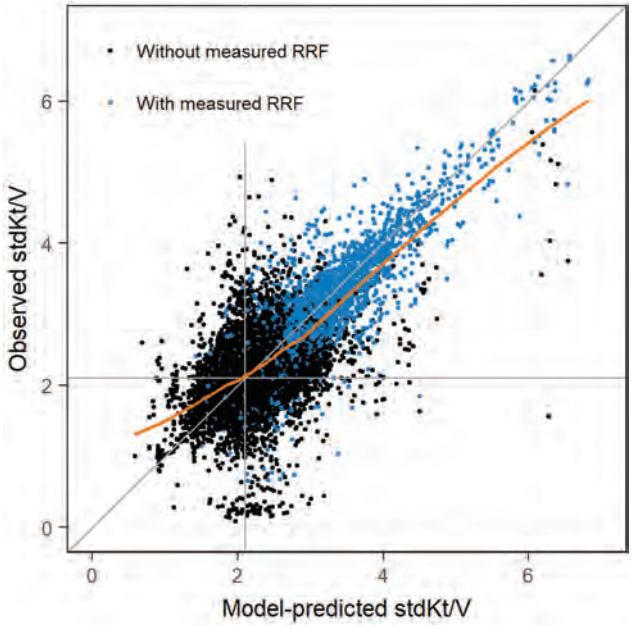
Kristine Kubisiak,[1] Eric D. Weinhandl,[1,2] Norma J. Ofsthun,[1] Lorien S. Dalrymple,[1] Michael A. Kraus,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Minnesota, Minneapolis, MN.*

Background: The NxStage Dosing Calculator (DC) is an online tool that can be used to identify hemodialysis prescriptions that achieve a specified standardized *Kt/V* on the NxStage System One (NSO) platform. The DC has recently been revised to align with formulae in *Kidney Disease Outcomes Quality Initiative* guidelines and to permit incorporation of residual renal function (RRF). We used home hemodialysis (HHD) patient data from a large dialysis organization to validate DC revisions.

Methods: We identified adult patients who initiated HHD with NxStage equipment in Fresenius Kidney Care (FKC) clinics between March 1, 2016, and December 1, 2018. Patients were followed from completion of HHD training to discontinuation of HHD with NxStage equipment at FKC. We collected patient-days with pre- and post-dialysis blood urea nitrogen (BUN) measurements and retained those with exact adherence to prescribed treatment frequency during the preceding 7 days. We derived model-predicted standardized (std) *Kt/V* from the HHD prescription, and observed std *Kt/V* from BUN measurements, before and after DC revisions.

Results: The cohort included 3427 patients and 23,408 patient-days with BUN measurements. Over 91% of patient-days were accompanied by 4 or 5 weekly treatments, and RRF was measured in 19%. Model-predicted and observed std *Kt/V*, given DC revisions, are displayed in the figure, with a smoothed trend in orange. DC revisions increased the proportion of variation in observed std *Kt/V* that was explained by model-predicted std *Kt/V* from 26% to 58%.

Conclusions: Revisions to the NxStage DC have improved concordance of predicted and observed std *Kt/V* in HHD patients, especially near guideline targets. RRF is influential on forecasted *Kt/V*, so continued reliance on RRF in HHD patients requires accurate, timely data about RRF.



SA-PO1081

The Ambiguous Identity of Home Hemodialysis in Medicare Claims

Eric D. Weinhandl,[1,2] Kristine Kubisiak,[1] Allan J. Collins.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of Minnesota, Minneapolis, MN.*

Background: Home hemodialysis (HHD) is performed in a home, which may be a private residence or a skilled nursing facility (SNF). Although the Centers for Medicare & Medicaid Services issued a condition code in 2005 for dialysis in a SNF, the code is rarely used. Epidemiologic and actuarial analysis of HHD in Medicare claims is thus compromised by an uncertain mix of two very different care settings. We analyzed Medicare expenditures among contemporary HHD patients, stratified by probable status of the HHD program as a SNF-oriented provider.

Methods: Using 2016 Medicare Limited Data Sets, including 100% of institutional claims and 5% of physician/supplier claims, we tallied Medicare Parts A and B expenditures, excluding those for outpatient dialysis, for HHD patients. We used public use files to remove wage indices from all expenditures. We stratified patients according to one facility-level factor: the percentage of patients in the facility on December 31, 2015, who had resided in a SNF during any part of 2015, as shown in the Dialysis Facility Report. For simplicity, we stratified HHD patients according to whether this facility-level factor was <40% versus ≥40%. Within each stratum, we calculated expenditures per patient-year (PY).

Results: Total Medicare Parts A and B expenditures, excluding those for dialysis, were $52,678 and $191,242 per PY among HHD patients in facilities with <40% and ≥40% prior-year prevalence of SNF residency. This factor was associated with large relative rates in inpatient facility, skilled nursing facility, and ambulance transport expenditures, as shown in the table. Analysis of individual facilities with HHD patients and the highest values of prior-year prevalence of SNF residency routinely revealed providers that deliver on-site hemodialysis in the SNF setting.

Conclusions: HHD in Medicare claims clearly reflects two phenotypes. CMS must address this inherent ambiguity to facilitate meaningful evaluation of outcomes on HHD.

	Prior-year prevalence of SNF residency	
	<40%	≥40%
Inpatient facility	$28,542	$108,080
Skilled nursing facility	$2,182	$51,356
Home health agency	$1,250	$612

Surfacer Inside-Out Access Procedure for Effective and Quick Placement of Venous Catheters in Patients with Thoracic Central Venous Obstruction

Gurkan Sengoelge,[1] Roman Reindl-Schwaighofer,[1] Maurizio Gallieni,[2] Tobias Steinke,[3] Adrian Ebner,[4] Silke K. Brunkwall,[6] Vladimir Matoussevitch.[5] *[1]Division of Nephrology and Dialysis, Medical University of Vienna, Vienna, Austria; [2]Ospedale San Carlo Borromeo - ASST Santi Paolo e Carlo - University of Milano, Milano, Italy; [3]Schön Klinik Düsseldorf, Düsseldorf, Germany; [4]Centro de Interveciones Endovasculares, Asuncion, Paraguay; [5]Vascular Access Unit, University of Cologne, Germany, Köln, Germany; [6]Vascular Center, University hospital Malmö, Sweden, Malmö, Sweden.*

Background: Thoracic central venous obstruction (TCVO) associated with repeated insertion or prolonged use of central venous catheters (CVCs) is common in hemodialysis populations. The ***S**urfacer System to Facilitate **A**ccess in **V**enous Occlusions* (SAVE) Registry was designed to evaluate the performance of the Surfacer, a novel inside-out procedure for patients with limited or diminishing upper body venous access or pathology impeding standard access methods. During this prospective, single-arm, multicenter, international registry, the Surfacer System was integrated during routine clinical care to facilitate right-sided placement of CVCs in patients with TCVO.

Methods: Five sites enrolled 30 patients in the SAVE Registry. Enrollment occurred between February 2017 and September 2018. Patient demographics, medical history and type of TCVO based on Dolmatch et al (*J Vasc Interv Radiol*. 2018;29:454-460) were collected at enrollment. Twenty-nine of the 30 patients with TCVO required CVCs for hemodialysis and 1 for chronic apheresis. Surfacer performance (success rate of CVC placement, procedural and fluoroscopy time), device-related adverse events, catheter malpositionings and postprocedural complications were documented during the procedure and upon hospital discharge.

Results: Baseline venography revealed 30% of patients had Type 4 occlusions, 26.7% had Type 3, 16.7% has Type 2, and 26.7% had Type 1. Successful CVC placement was achieved in 29 patients (96.7%). Mean completion time was 24 ±14.9 minutes, mean fluoroscopy time was 6.8 ± 4.5 minutes and mean contract volume use was 29.7 ± 22.2. The procedure was discontinued in 1 patient (3.3%) due to significant vascular anatomical tortuosity. There were no adverse events or complications.

Conclusions: The Surfacer Inside-Out access procedure enables effective, safe and quick placement of right-sided venous catheters in patients with thoracic central venous obstructions.

SA-PO1083

Effect of Early Cannulation with Plastic Cannula on Patency of Arteriovenous Fistula for Hemodialysis

Kehui Shi,[1] Masanori Wakabayashi,[2] Hongli Jiang.[3] *[1]Department of Dialysis, the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]Bousei Daiichi Clinic, Numazu, Japan; [3]Department of dialysis, First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: Plastic cannulas for hemodialysis have been used in Japan for many years; however, effect of early cannulation with plastic cannulas on arteriovenous fistula (AVF) patency is unknown. We studied if early cannulation with plastic cannulas would affect AVF patency.

Methods: ESRD patients who underwent primary AVF operations were divided into an early cannulation group with first cannulation time (FCT) within<10 days and a late cannulation group with FCT≥10 days. The Kaplan-Meier method and multivariable Cox regression models were used to investigate AVF patency.

Results: 122 patients were enrolled in the study (mean age, 72.5 yr;64.8%male;52%diabetes mellitus;89%RCAVFs), median FCT was 6 days. Kaplan-Meier analysis showed that there was no statistically significant between-group difference in primary or secondary patency rates. Early cannulation was not found significantly associated with primary patency or secondary patency after age, gender, the presence of diabetes mellitus, hypertention and being on hemodialysis were adjusted.

Conclusions: Early cannulation with plastic cannulas might not affect AVF patency, maybe we can cannulate AVFs earlier than 10 days after AVF creation to avoid the use of central venous catheters.

Table 1. Hazard ratios for primary patency of arteriovenous fistulas according to first cannulation time (n=122)

	FCT<10 days	FCT≥10 days	
	HR (95% CI)		*P*-value
Cases, n (%)	88 (72.1)	34 (27.9)	
Model 0[a]	1.11(0.70–1.77)	1.00 (reference)	0.651

SA-PO1084

Assessment of Arteriovenous Fistula Maturation Using Central-Venous Oxygen Saturation and Estimated Upper-Body Blood Flow

Laura Rosales,[1] Hanjie Zhang,[1] Brenda K. Chan,[1] Marilou Mateo,[1] Seth Johnson,[1,3] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine, New York, NY; [3]Easy Water for Everyone, Yonkers, NY.*

Background: Arterio-venous fistula (AVF) is the optimal vascular access in most hemodialysis (HD) patients. However, AVF maturation is difficult to assess. Central-venous oxygen saturation ($ScvO_2$) and upper-body blood flow (UBBF) increase during AVF maturation. We followed AVF maturation using $ScvO_2$ and estimated UBBF (eUBBF).

Methods: We studied 19 patients from an ongoing AVF quality improvement project. $ScvO_2$ and hematocrit were measured with Crit-Line (FMC, Waltham, MA) between minutes 5 and 20 into HD, and eUBBF was computed as recently described (Rosales, Blood Purif, 2019).

Results: Following AVF creation, $ScvO_2$ and eUBBF increased in 9 patients with unassisted AVF maturation and in 4 un-cannulated patients with good clinical AVF function (1 transplanted, 1 transferred, 2 awaiting cannulation) (**Table 1**). These indicators increased less in 5 patients requiring assisted AVF maturation and in one patient who succumbed to sudden cardiac death with a clinically matured AVF.

Conclusions: Our preliminary results indicate that $ScvO_2$ and eUBBF provide point-of-care bio-signals that report AVF maturation and hemodynamic adaptation to the AVF. Advantages of this method are low costs, operator-independence, and scalability.

ScvO2 and eUBBF before and after AVF creation.

	Before AVF creation		Week 1 after AVF creation		Change between week 1 and pre AVF creation [%]		Week 4 after AVF creation		Change between week 4 and pre AVF creation [%]	
	ScvO2 [%]	eUBBF [L/min]	ScvO2 [%]	eUBBF [L/min]	ScvO2	eUBBF	ScvO2 [%]	eUBBF [L/min]	ScvO2	eUBBF
Successful unassisted maturation and CV adaptation (N= 9)	62.8 [60.5;63.5]	1.5 [1.2; 1.5]	76.4 [72.3;77.8]	2.8 [1.9; 3.0]	19.5 [15.9; 27.4]	75.0 [54.8; 87.1]	76.0 [74.6;80.9]	2.0 [1.9;3.1]	22.6 [15.4; 25.9]	57.7 [32.0;138.5]
"Clinical" maturation and CV adaptation (N=4)	61.9 [56.3;66.8]	1.1 [0.9; 1.3]	72.9 [69.5;74.7]	1.9 [1.3; 2.0]	9.7 [3.6; 30.4]	47.9 [6.9; 108.4]	66.2 [65.6;77.9]	1.5 [1.3;2.4]	19.9 [-2.1; 36.0]	57.7 [10.0;160.5]
Assisted maturation and CV adaptation (N=5)	62.2 [62.2;64.9]	1.2 [1.0; 1.3]	72.3 [70.7;74.0]	1.5 [1.4; 1.9]	13.9 [13.6; 16.2]	39.5 [32.3; 45.1]	71.2 [66.9;73.5]	1.7 [1.3;1.7]	9.6 [1.7; 44.2]	26.1 [21.3;41.8]
Failed CV adaptation (N=1)	71.2	2.3	76.9	3.0	8.0	27.6	72.6	1.8	2.0	-23.8

SA-PO1085

The Importance of Monitoring Blood Flow in the Maintenance of Vascular Access in Patients Under Hemodialysis

Ioannis Griveas.[1,2] *[1]Nephrology, 417 Army Share Fund Hospital, Athens, Greece; [2]Dialysis Unit "Nefroiatriki", Athens, Greece.*

Background: The usefulness of blood flow monitoring (QA) in arteriovenous fistula (AVF) of patients with End Stage Renal Disease (ESRD) under hemodialysis (HD) patients is a current controversy in the international literature. Although all of the clinical guidelines for vascular access include monitoring protocols to prevent thrombosis (VA), randomized clinical trials (RCTs) have failed to consistently demonstrate the benefits of QA-based surveillance protocols. We present our experience of evaluating the usefulness of QA measurement using Doppler (DU) ultrasound in patients under HD.

Methods: 168 patients from two HD centers were under follow up for 3 years. The classic QA tracking method was applied to all once a year and moretimes on clinical indications. The episodes of thrombosis in vascular access that occurred acutely (group 1) and the interventions episodes made on the basis of DU findings (group 2) were recorded.

Results: During the 3-year follow-up period, 24 interventions were required to restore the functioning of vascular access. Of these, 8 were made after an acute event (group 1) and 16 after a finding derived from a DU control (group 2). Of the 8 acute cases of AVF or graft thrombosis, 5 ended up with a central venous catheter. Of the 16 cases requiring intervention after an ultrasound finding 12 events maintained the type of vascular access they had and 4 ended up with a central venous catheter. Group 1 required hospitalization of more than one day in 3 cases, which did not occur in any of Group 2 incidents.

Conclusions: Periodic QA measurement using DU significantly helps maintain vascular access of patients, limiting their days of hospitalization and significantly contributing to their better quality of life.

SA-PO1086

Global Home Dialysis Therapy Perceptions and Practices: An International Survey

Paul N. Bennett,[1] Denise Eilers,[3] Fang Yang,[1] Christy A. Price Rabetoy.[2] *[1]Satellite Healthcare, San Jose, CA; [2]ANNA, Piney Flats, TN; [3]United Township Area Career Center, Davenport, IA.*

Background: Home hemodialysis (HHD) and peritoneal dialysis (PD) prevalence varies throughout the world. Home dialysis policies and clinician knowledge affect home dialysis prevalence. The goal of this study was to identify international policies and perceptions exploring: reimbursement of patient costs; telehealth; staff home visits; solo dialysis and patient training.

Methods: A 13 item web-based questionnaire was distributed to home therapy program clinicians in the 30 highest home dialysis prevalent nations worldwide. Questions explored patient reimbursement, telehealth, patient training, solo dialysis, home and clinic visit frequency. IRB approved surveys were independently translated into 9 languages with translation validation by an external translation service.

Results: 395 respondents from 30 nations using 7 different languages responded. 64% were aligned with combined HHD and PD programs, 29% PD only and 7% HHD only. 29% of programs had less than 20 patients, 30% had 20 to 50 patients, 22% had 51 to 100 patients and 19% had greater than 100 patients. 31% of all programs reported patient costs reimbursement, with non-US programs much more likely to report reimbursement than US programs (US 11%, non-US programs 59%, $\chi 2=93.6$, $p<0.0001$). Telehealth use was low throughout the world (23% prevalence), contrasting with 83% of respondents agreeing telehealth would improve home dialysis care. 31% of all programs enabled flexible training out of work hours. 72% of US clinicians agreed that monthly clinic visits were needed in comparison to 44% of non-US clinicians ($\chi 2 = 83.7$, $p<0.0001$). 31% of respondents agreed that dialysis partners are always required for home dialysis.

Conclusions: Global variation in home therapy protocols, knowledge and attitudes exist. Telehealth, cost reimbursement, training flexibility and acceptance of solo dialysis is low. Addressing these hurdles to home dialysis may increase home dialysis growth.

SA-PO1087

Costs of Hemodialysis in Survivors During the Incident Year by Vascular Access Type

Joanna Willetts,[1] Sheetal Chaudhuri,[1] Maria Radonova,[1] Eric D. Weinhandl,[1,3] John W. Larkin,[1] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Franklin W. Maddux.[2] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Medical Care, Waltham, MA; [3]University of Minnesota, Minneapolis, MN.*

Background: Estimated cost of care of hemodialysis (HD) access types vary and infrequently account for survival. We identified benchmarks for Medicare expenditures in patients in an End Stage Renal Disease Seamless Care Organization (ESCO) who had an arteriovenous fistula/graft (AVF/AVG) implanted, or had only a central venous catheter (CVC), and survived various follow-up periods. The statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of the Centers for Medicare & Medicaid Services (CMS). The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Methods: We used data from adults at a large dialysis organization (LDO) who: 1) had Medicare as payor, 2) were treated at an ESCO by HD, 2) had an AVF/AVG implanted ≤90 days from first date of dialysis (FDD) or exclusively had a CVC, and 3) survived a 6, 9, or 12-month follow-up from FDD. We compared mean Medicare expenditures per member per month (PMPM) in AVF/AVG versus CVC patients who survived each follow-up period, as well as the entire incident year.

Results: Survivors with an AVF/AVG implanted ≤90 days of FDD had a lower Medicare expenditures PMPM from 90 days after FDD to the 6-month (AVF/AVG=$7,157±6,457 [n=1566]; CVC=$8,290±8,585 [n=723]; $p<0.001$), 9-month (AVF/AVG=$6,636±4,919 [n=1211]; CVC=$7,539±6,917 [n=483]; $p<0.01$), and 12-month (AVF/AVG=$6,424±4,333 [n=839]; CVC=$7,133±6,379 [n=309]; $p=0.03$) follow-up, as compared to CVC patients. Among survivors of the entire incident year, AVF/AVG patients consistently had a lower cost at the 9- and 12-month follow-up (both $p<0.05$) versus CVC patients, yet only favorable trends were seen at the 6-month follow-up ($p<0.19$).

Conclusions: Implantation of an AVF/AVG in the first 90 days of HD was associated with lower costs during the incident year of HD compared to CVC patients without a permanent access placed. Findings represent a sub-group who survived each defined period, or the overall incident year, yielding unadjusted comparisons with equivalent exposure times between access types. However, distinctions in survival between AVF/AVG versus CVC patients should be considered.

SA-PO1088

Percutaneous Transhepatic Venous Access for Hemodialysis: A 25-Year Experience

Rafael A. Souza, Fabio M. Torres, Fábio A. Reis, Guilherme P. Santa Catharina, Igor Smolentzov, Bruno C. Silva, Hugo Abensur. *Nephrology, University of Sao Paulo, São Paulo, Brazil.*

Background: Vascular access is vital for hemodialysis (HD) patients, and some of them exhibit occlusions in the most common sites of catheter insertion. In such dramatic situations, percutaneous transhepatic (PT) placement of HD catheters can provide alternate vascular access for HD. Our objectives were to retrospectively evaluate survival, safety and complications associated with PT catheters in a HD center at a tertiary hospital in Brazil.

Methods: All PT catheters were placed in patients who had exhausted other vascular access sites, by an experienced interventional vascular team. The following outcomes were evaluated: catheter removal due to low flux, infection or catheter rupture. Additionally, death or kidney transplantation with functioning catheter were also noted. Data is expressed as median (25;75) percentiles, and crosstabulated in chi-square tests.

Results: During a 25-year period, 24 PT catheters were placed in 7 patients (one woman and six men). Median age at catheter insertion was 51 (33; 54) years and dialysis vintage of 197 (40; 522) months. Median PT catheter survival was 277 (24; 537) days. Catheter removal for low flux, infection and rupture was observed in 46%, 21% and 13% of patients, respectively. Removal for low-flux rate was 1.3/1000 patients-day and for infection, 0.59/1000 patients-day. Two patients died with functioning catheter and one underwent kidney transplantation. Two patients are currently dialyzing with PT catheters and no complications were observed. Reasons for TP catheter removal when comparing first *vs* non-first insertions were different (chi-square 9.24, $p=0.01$), as catheter rupture was more frequently observed in first insertion and low-flux in non-first insertions (table 1).

Conclusions: Using TP catheters in patients with multiple access failure is a feasible procedure, as overall infection and thrombosis rates are similar to other sites of catheter insertions. Patients should be advised about catheter-related care, especially in first insertion, in order to avoid catheter rupture.

Table 1. Outcomes according to catheter insertion

Event	First Catheter		p
	Yes	No	
Rupture	0	3	0.021
Low-flux	10	1	0.041
Infection	3	2	1.0

SA-PO1089

Where Should the Non-Tunneled Catheter Tip Be Placed for Hemodialysis? Fourth vs. Second Intercostal Space

Héctor R. Ibarra-Sifuentes,[1] Raymundo Vera,[3] Elisa M. Guerrero Gonzalez,[2] Michelle Morcos sandino,[1] Concepcion Sanchez Martinez.[3] *[1]Universidad Autonoma de Nuevo Leon, Monterrey, Mexico; [2]Hospital Universitario UANL, San Nicolas de los Garza, Mexico; [3]Hospital Universitario, Monterrey, Mexico.*

Background: Non-tunneled catheters (NTC) for hemodialysis are an indispensable vascular access and very common in patients in need of hemodialysis, especially urgently. The insertion method used for the placement of NTC can reduce serious complications.

Methods: Randomized clinical trial with adult patients at the University Hospital, Autonomous University of Nuevo Leon, Monterrey, Mexico, who required emergency hemodialysis by NTC. The NTC were inserted percutaneously with the ultrasound-guided modified Seldinger technique. Patients were randomized to NTC tip placement on the fourth intercostal space (4IS) and to the second intercostal space (2IS). The main outcome are to number of dysfunction, repositioning and relocation episodes due to NTC placement.

Results: The study included 115 patients who were placed on NTC for hemodialysis, with an average age of 51 years, 55% were female, the mean height was 163 cm, no difference between the groups. The incidence of catheter dysfunction and catheter relocation were not different. Catheter repositioning was presented in 50 and 16% for the 4IS insertion and 2IS groups, respectively (p 0.001).

Conclusions: The placement of the hemodialysis NTC tip on the 2IS decreases the incidence of repositioning, without affecting the incidence of dysfunction or repositioning when compared to 4IS. The search for new methods of catheter placement to reduce the potential complications of invasive treatments on renal replacement therapy is still pending.

Table 1. Primary outcome in classic and intervention group.

	Classic Group (4IS)	Intervention Group (2IS)	p
Disfunction, n(%)	4 (8%)	2 (4%)	0.39
Repositioning, n (%)	25 (50%)	8 (16%)	0.001
Relocation, n (%)	0 (0%)	1 (2%)	0.13

4IS, fourth intercostal space; 2IS, second intercostal space.

SA-PO1090

Ultrasound-Guided Protocol Safely Eliminates Chest Radiography After Non-Tunneled Catheter Placement in Urgent Hemodialysis

Héctor R. Ibarra-Sifuentes,[1] Jose L. Avila Velazquez,[3] Raymundo Vera,[2] Giovanna Y. Arteaga Muller.[2] *[1]Universidad Autonoma de Nuevo Leon, Monterrey, Mexico; [2]Hospital Universitario, Monterrey, Mexico; [3]University Hospital, Monterrey, Mexico.*

Background: Despite its morbidity and mortality, the Non-tunneled catheter (NTC) continues to be an indispensable vascular access when imminent need for Hemodialysis. The confirmation of the proper NTC placement and complications detection are a real concern to optimize patient safety.

Methods: Prospective, comparative study. Included patients aged >17 years with life-threatening complications (uremic syndrome, potasssium >6.5 mmol/L, acidosis pH <7.2 with high anion gap and HCO3 <15 mmol/L and pulmonary edema) all resistant to management and urgent Hemodialysis need. After NTC placement with ultrasound (US) guided Seldinger technique in the right internal jugular vein; investigators performed a saline flush test and performed thorax evaluation for pleural sliding and pleural point with US and chest x-ray (CXR). Objetive is to compare successful venous placement and immediate detection of complications derived from NTC placement with US and CXR.

Results: 113 patients were involved, 60% in the emergency room. Their mean age was 50 years, 62% were male. The main causes of NTHC placement were uremic syndrome (41%) and fluid overload (28%). The mean blood urea nitrogen was 111 mg/dL. The correct NTC placement was documented in all patients when the US and CXR were used. The agreement between US-guided protocol and CXR protocol is good (Kappa= 1). Only 1 pneumothorax developed, correctly detected in the US-guided protocol, with a high NPV (100%). The median evaluation time for US and CXR were 3 and 37 minutes, respectively; median difference of 34 minutes (p <0.0001).

Conclusions: The US is an effective tool for the assesemnt of adequate NTC placement and immediate complications detection in patients with urgent need of hemodialysis when compared to CXR.

SA-PO1091

A Rare Complication of a Permanent Haemodialysis Line

Asmaa Y. Al- Chidadi, Arun prasath Perumal thiagarajan, Sourjya Kar, Bahareh Arsalanizadeh. *North West Anglia NHS Foundation Trust, Peterborough, United Kingdom.*

Introduction: Starting haemodialysis via an IJ permanent line is sometimes unavoidable in late presenters. Grievious complications can sometimes happen including this rare case report.

Case Description: A 67 years old female started HD via a permanent IJV line in Sep 2013 for 18 months untill a left sided AV fistula (AVF) was created, which then went to require multiple fistuloplasties. Eventually a right sided AVF was fashioned, while the left AVF was still in place. In May 2018, she presented with extensive trunkal varicose veins. 4 weeks later, she was admitted with large-volume hematemesis and hypovolemic shock requiring Critical care admission. Emergency endoscopy showed extensive esophageal varices. A CT scan showed an SVC stenosis and a thrombus extending and involving the left AVF. There was no evidence of liver cirrhosis. This was believed to be caused by previous IJ line. Intervention was deemed unsafe because of the risk of fatal bleeding. She was then anticoagulated and dialysis resumed via a femoral permanent line.

Discussion: Central venous thrombosis is not an uncommon complication among haemodialysis population starting dialysis via permanent IJ lines. However, it is very rarely reported to cause bleeding oesophageal varices. In the case we are presenting, the additional presence of two functioning fistulae had led to extensive venous drainage into her blocked SVC and encouraged the formation of extensive collaterals, the oesophageal varices are one of them. It was technically difficult to treat the SVC stenosis but the fact that her fistulae clotted relieved some of the back pressure on the varices and reduced future bleeding risk.

SA-PO1092

A Tragic Missed Opportunity: Leadless Cardiac Devices in Hemodialysis Patients

Sayee Sundar Alagusundaramoorthy, Ali I. Gardezi, Micah R. Chan. *University of Wisconsin, Madison, WI.*

Background: There is a frequent need for placement of cardiac implantable electronic devices (CIEDs) in hemodialysis patients. Placement of a CIED is associated with central vein stenosis, infections and access failure. Cardiac electrotherapy has advanced significantly with the availability of s-ICDs and Leadless pacemakers. The goal of this study is to assess the effectiveness of these devices in patients.

Methods: We conducted a retrospective study of adult ESRD patients who underwent leadless cardiac device placement between January 2014 - September 2018.

Results: Among patients who underwent leadless device placement, 14 patients were on renal replacement therapy (15.38%). Mortality among these patients after leadless device placement was 33.3%. There were no episodes of bacteremia requiring long term antibiotics or extended hospitalization post device placement. Patients with AVF required interventions due to stenosis of their peripheral veins, however the access remained patent until the end of the follow-up period.

Conclusions: A small minority of patients on dialysis underwent leadless device placement. Theses devices are associated with lesser incidence of catheter related bacteremia and sustained access patency in patients. Consideration should be given to the placement of such devices in patients on or close to needing renal replacement therapy.

Access characteristics in patients pre and post leadless device implantation

Venous Access for Hemodialysis	Tunneled Dialysis Catheter	Arterio-venous Fistula	Arterio-Venous Graft
At the time of Device placement	58.33% (7)	33.33% (4)	8.33% (1)
Bacteremia prior to device placement requiring prolonged antibiotics and lead removal	25% (42.85%)	8.33% (25%)	8.33% (100%)
Incidence of Central Venous stenosis	8.33% (14.28%)	8.33% (25%)	0
Need for intervention after device implantation	0	33.33% (100%)	0
Bacteremia post leadless device placement	0	16.67% (50%)	0
Access patency post device implantation	58.33% (7)	33.33 % (4)	8.33% (1)
Mortality	25% (42.85%)	8.33% (25%)	0

SA-PO1093

Reducing Early Catheter-Related Bloodstream Infection in Hemodialysis Patients

Timothy J. Koh, Benjamin Z. Khoo, Sanamatum Ningombam, See Cheng Yeo. *Tan Tock Seng Hospital, Singapore, Singapore*.

Background: Dialysis catheter-related blood stream infection (CRBSI) is a leading complication in hemodialysis (HD) patients, and is associated with increased risk of mortality, invasive procedures, extra hospitalization and/or increase in length of stay. Poor tunneled dialysis catheter (TDC) care by patient, inadequate skin preparation before TDC insertion and lack of prophylactic antibiotics during TDC insertion may contribute to early CRBSI. We examined the role of bundled interventions to reduce early CRBSI in HD patients with newly inserted TDC.

Methods: Between April to September 2017, we instituted a bundle of measures to reduce CRBSI in patients from two designated wards (intervention group); patients in other wards received usual care (control group). In the intervention group, daily chlorhexidine bath was administered for all patients prior to TDC insertion and nasal decolonization was performed for methicillin-resistant Staphylococcus Aureus carriers. In this group, prophylactic intravenous antibiotics was also administered at TDC insertion and topical antibiotics were applied to the exit site post-insertion. Patients were educated on TDC care and this was reinforced prior to discharge. Early CRBSI was defined as any new bacteremia occurring within 30 days of TDC insertion, and the rate of CRBSI was compared between the intervention and control groups.

Results: 308 TDC insertions or exchanges were performed during the study period (153 in intervention group and 155 in control group), of which there were 18 (5.8%) episodes of early CRBSI. Microbiological profile includes gram positive (8 episodes, 44.4%), gram negative (7 episodes, 38.9%), polymicrobial (2 episodes, 11.1%) and fungal (1 episode, 5.6%) organisms. In the intervention group, early CRBSI occurred in 5 (3.3%) TDC insertions while early CRBSI occurred in 13 (8.4%) TDC insertions in the control group, with a trend towards significance ($p = 0.056$). The interventions were well tolerated and cost effective, with the project resulted in significant healthcare cost savings.

Conclusions: The frequency of early CRBSI was successfully decreased, with a trend towards significance, using a comprehensive bundle of interventions. Further follow-up with regards to CRBSI frequency and analysis on the effectiveness of individual interventions would be helpful in assessing the utility of these measures.

SA-PO1094

Long-Term Outcomes of Catheter-Related Bloodstream Infections

Justin Lee Loy,[1] Gajapathiraju Chamarthi,[1] Shahab Bozorgmehri,[1] Kartikeya Cherabuddi,[1] Rajesh Mohandas.[1,2] *[1]University of Florida, Gainesville, FL; [2]Gainesville VA Medical Center, Gainesville, FL.*

Background: Catheter-related bloodstream infections (CRBSIs) are common in patients receiving hemodialysis through a central venous catheter. In addition to antibiotics, treatment may include replacement of the catheter, exchange over a guide wire, or the catheter maybe left unchanged (salvage therapy). While these modalities are equally efficacious in the short run, the effect on long term infectious complications like endocarditis and epidural abscesses is not known. The purpose of our study was to determine the long-term complications of CRBSI and determine if catheter salvage or exchange is associated with an increased risk of long-term complications.

Methods: We retrospectively studied 100 randomly selected adult patients on hemodialysis admitted to a 1000 bed academic university hospital between May 1st, 2010 and April 30th, 2017 with CRBSI. Baseline demographics and clinical characteristics were stratified by line disposition. Multivariable logistic regression models were used to analyze the association between line disposition and long-term complications, adjusted for age, intensive care unit admission, and isolated organism.

Results: The mean age was 59.6 ± 15.7 years with 36% males and 64% females. Methicillin-resistant *Staphylococcus aureus* (MRSA) was the most common organism isolated (26%). 45% of catheters were replaced, 43% were exchanged, and 12%were salvaged. After excluding those who died and had catheter discontinued, 28% of the 75 patients developed long term complications. The long-term complications rates were 40% for catheter salvage, 32% for replacement and 21% for exchange ($p=0.383$). In univariate analysis there was no difference between groups. However, when adjusted for age, organism and ICU stay, patients with catheter exchange were less likely to develop long term complications compared to those with salvage therapy (adjusted OR: 0.14; 95%CI: 0.02-0.83). There was no statistically significant difference between the other groups.

Conclusions: Our results showed that there is a high incidence of long-term complications in patients admitted with CRBSI. The incidence was highest in those with catheter salvage. These results suggest the need for caution with catheter salvage and an adequately powered randomized controlled trial to determine the long-term safety of catheter salvage in patients with CRBSI.

Epidemiology and Clinical Outcomes of Staphylococcus aureus Bacteraemias in Haemodialysis Patients; 12-Year Single-Centre Experience

Jonathan W. Hurst,[2] Moira Stanley,[3] Jayakeerthi Rangaiah,[2] David Makanjuola.[1]
[1]Renal unit, Epsom & St. Helier University Hospitals NHS Trust, Surrey, United Kingdom; [2]Renal unit, Epsom & St. Helier University Hospitals NHS Trust, Surrey, United Kingdom; [3]Renal Unit, Epsom & St. Helier University Hospitals NHS Trust, Surrey, United Kingdom.

Background: Patients on haemodialysis are at risk of access associated infections. The risk is greater in patients dialysed through lines, than those dialysing via arteriovenous fistulae (AVF) or grafts (AVG). Studies have shown that the most commonly implicated organism is *Staphylococcus aureus* (SA), which has a tendency to cause metastatic infections e.g endocarditis, osteomyelitis. We decided to look at the incidence and clinical outcomes in haemodialysis (HD) patients with SA bacteraemia in patients at our centre over the last 12 years.

Methods: Data were collected from the hospital's microbiology database of all the confirmed bacteraemias in HD patients between 2007 and 2018. We looked at the demography, type of dialysis access, and the outcomes following the bacteraemias.

Results: There were 261 bacteraemias in 1361 patients who had a cumulative total of 32,000 dialysis episodes over the 12 year period. Of the patients with bacteraemias, 164 (62.8%) were male. The median age was 67 years (range 18-96). The dialysis access at the time of the bacteraemia was as follows: AVF/AVG 57(22%), dual access - AVF or graft + line - 50 (20%), dialysis line 147 (56%), not documented 7 (3%). The blood cultures grew methicillin sensitive SA (MSSA) in 71% and methicillin resistant SA in 29% of cases. 204 (77%) cases occurred in patients dialysing through lines. Details about complications were available in 199 patients and are shown in Table 1.

Conclusions: Our data show that the bacteraemias and complications were most common in patients dialysing with lines, and emphasise the importance of trying to achieve dialysis through AVFs or grafts as soon as is possible.

Table 1 – Complications following SA bacteraemias

COMPLICATION	NUMBER (%)	LINES	AVF/GRAFTS
Discitis	5	4	1
Endocarditis	13	9	4
Septic arthritis	4	3	1
Death	26	21	5
Total	48	37 (77%)	11 (23%)

SA-PO1096

Reduction in Number of Hospital-Acquired Methicillin-Resistant Staphylococcus aureus Dialysis Catheter Related Bloodstream Infections: Role of Nasal Mupirocin and Chlorhexidine Body Wash

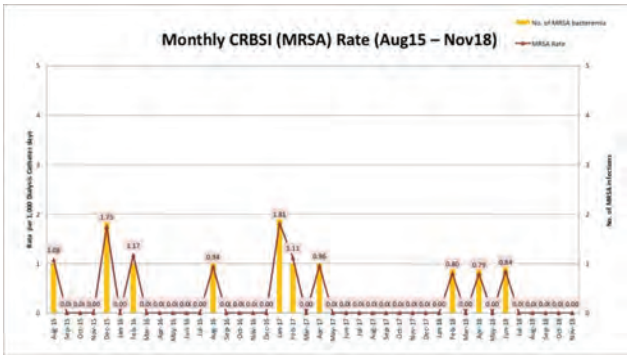
Sreekanth Koduri, Chang Yin Chionh. *Changi General Hospital, Singapore, Singapore.*

Background: Central Venous Catheter-Related Bloodstream Infections (CRBSI) are an important cause of hospital acquired infection associated with morbidity, mortality and cost. Patients undergoing haemodialysis using a catheter are at significant risk for developing CRBSI, especially with Methicillin-resistant Staphylococcus aureus (MRSA), resulting in serious complications. In our 1000-bed regional hospital, the average CRBSI(MRSA) rate was 0.56 per 1,000catheter days. A quality improvement project was initiated with an aim to reduce the rate by 50%.

Methods: Following the formation of a multidisciplinary team, the catheter insertion protocols and catheter care protocols were harmonised throughout the hospital. A decolonization protocol with Mupirocin 2% nasal cream along with Chlorhexidine bodywash for 5days, was initiated prior to dialysis catheter insertion. Monthly data on prescription and delivery of nasal and skin decolonisation protocol was collected. The CRBSI (MRSA) rates were collected monthly by averaging the number of infections per 1000 catheter days.

Results: Analysis of the data from July 17 – November 2018 showed a significant improvement in the CRBSI rates, after the robust implementation of nasal and skin decolonization protocol (>95%). The average CRBSI (MRSA) rate has improved to 0.14 per 1,000 catheter days from a baseline of 0.56 per 1,000 catheter days (Figure 1). Even though the improvement in CRBSI (MRSA) is believed to be due to introduction of the decolonization protocol, the outcome may have been influenced by other interventions.

Conclusions: The causes of CRBSI can be multifactorial and a multidisciplinary approach is required to reduce the infection rates. With nasal and skin decolonization prior to dialysis catheter insertions, the CRBSI rates, especially related to MRSA can be reduced significantly, as shown in our experience.



SA-PO1097

Use of Gentamicin-Citrate Lock Reduced Catheter-Related Bloodstream Infection Rates in Hemodialysis Patients: Results of a Natural Experiment

Wael F. Hussein,[1,2] Fang Yang,[1] Sumi J. Sun,[1] Graham E. Abra,[1,2] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Department of Medicine, Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA.*

Background: Use of central venous catheters (CVC) is a major risk factor for infections, a leading cause of morbidity and mortality in hemodialysis (HD) patients. Use of gentamicin 320 μg/mL in 4% sodium citrate lock (GCL) was previously shown to reduce the rate of CVC-related bloodstream infection (BSI). We report on the change of CVC-related BSI rates in four centers experiencing high BSI rates while using heparin catheter lock (period 1 [P1]) after switching to GCL (period 2 [P2]).

Methods: Retrospective observational study. Patient characteristics at time of switch to GCL were obtained from the provider's EHR. CVC patient-months and reported events of CVC-related BSI were obtained from the NHSN database. The rate ratio for pooled rates for P2:P1 was calculated and tested for significance.

Results: There were 684 and 896 CVC patient-months in P1 and P2 respectively. Mean patient age was 64 ± 14 years, and 48% were female. Monthly CVC-related BSI rates are shown in Figure 1. Pooled CVC-related BSI rates were 2.8 and 0.6 per 100 patient-months for P1 and P2 respectively, representing an 80% reduction in the rate of BSI (rate ratio 0.20, 95% Confidence interval 0.08 – 0.54, p = 0.0004).

Conclusions: These results are consistent with results from a previous trial, but in real-practice setting. Use of the gentamicin-citrate lock significantly reduces CVC-related BSI.

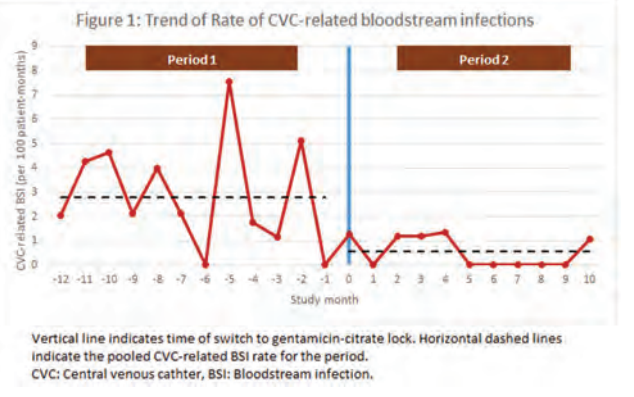


Figure 1

SA-PO1098

Prevalence and Conversion Rates of Central Venous Catheters in Hemodialysis: A Comparative Study of Public US and Mexican Dialysis Providers

Pablo Maggiani,[3] Shimul Sheth,[2] Jochen G. Raimann,[2] Jonathan Chavez,[3] Jorge J. Font,[3] Jose A. Torres,[3] Rodolfo A. Moreno,[3] Veronica Valdivia cerda,[3] Cynthia G. Cervantes,[3] Christian P. Flores,[3] Marisol Lopez,[3] Peter Kotanko,[2] Guillermo Garcia-Garcia.[1] *[1]Hospital Civil De Guadalajara, University of Guadalajara, Zapopan, Mexico; [2]Renal Research Institute, New York, NY; [3]Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico.*

Background: Central venous catheter (CVC) as vascular access in hemodialysis (HD) associates with adverse outcomes. Early CVC-to-fistula conversion has been associated with improved outcomes. While socioeconomic disparities between the U.S. and Mexico exist, not much is known about how CVC prevalence and conversion rates compare

Methods: We retrospectively studied incident HD patients at the Hospital Civil de Guadalajara Fray Antonio Alcalde (HC) and the U.S. Renal Research Institute clinics (RRI) between 2014-2018. We compared CVC rates at HD initiation and conversion rates between months 1 and 6 between HC and RRI. Data were presented as mean±SD and count(%), rates were compared using χ^2 tests. A logistic regression model was built to identify factors associated with continued CVC status

Results: Patient characteristics and CVC conversion rates are shown in Table 1. During the observation period 174 and 824 patients started HD in HC and RRI, respectively. At HD initiation CVC prevalence was 97% at HC and 69% at RRI, respectively. The CVC conversion rate between months 1 and 6 was 10.6% in HC and 28.1% in RRI, respectively (p=0.0004). Albumin was the only significant variable associated with continuous CVC status in the RRI group (OR 0.52, CI 95% 0.37-0.44). An association was observed, although not significant between diabetes and the persistence of the catheter in HC patients (OR 0.5, CI 95% 0.13-4.19)

Conclusions: CVC prevalence and conversion rates differ between RRI and HC. Higher CVC prevalence in HC patients at HD initiation is likely due to more frequent "crashing" into HD, less pre-dialysis care, and socioeconomic disparities, reflecting the realities of an urban public hospital providing HD to a largely uninsured population. The presence of diabetes in HC seems to contribute as a barrier to CVC conversion, perhaps due to the economic cost that it entails. The impact of CVC conversion rates on patient outcomes warrants future studies

SA-PO1099

Outcomes of Upper Limb Arteriovenous Fistula After Insertion of Ipsilateral vs. Contralateral Tunnelled Vascular Catheters: A Single-Centre Experience

Jason Diep, Angela Makris, Imelda De Guzman, Jeffrey Wong, Ananthakrishnapuram N. Aravindan, Govind S. Narayanan. *Liverpool Hospital, Greenfield Park, NSW, Australia*.

Background: Observational data suggest that the use of central venous dialysis catheters is associated with reduced subsequent Arteriovenous Fistula (AVF) maturation and survival, but it's unclear if catheters directly affect AVF function. Catheter related central vein stenosis could affect flow and maturation of a subsequent AVF on the same side. To explore this further we aim to compare the outcomes of AVF created ipsilateral or contralateral to previous Tunnelled Vascular Catheters (TVC).

Methods: We retrospectively examined our vascular access database and electronic medical records of all patients who started dialysis at all units linked to Sydney Southwest Local Health District. We identified 142 patients who started dialysis with a TVC and subsequently had their first AVF created between Jan 2013 and Dec 2017. For patients with multiple AVFs only the first was included. All fistulas were monitored as per local policy. Successful fistula use (cannulated with two needles for ≥ 2 consecutive weeks) was analysed at 6 and 12 months after initial creation. We used Chi-Square test and logistic regression to analyse outcomes.

Results: 40 AVFs (12 upper arm, 33 right arm) were created ipsilateral to previous TVC insertion side and 102 AVFs (31 upper arm, 5 right arm) were contralateral. Median age (68 years, range=28-84; 66 years, range=25-87; p=0.38), the proportion of males (77.5% and 68.6%, p=0.29), and prevalence of diabetes (60.0% and 63.7%, p=0.70) were similar between ipsilateral and contralateral groups respectively. At 6 months, 40.0% of ipsilateral AVFs were functioning compared to 59.6% of contralateral AVFs (OR=0.45, CI=0.21-0.99, p<0.05). After adjusting for other factors (age, sex, diabetes, and hypertension) using a backwards conditional regression, non-smokers (p=0.005) and contralateral AVF placement (p=0.021) were associated with a greater AVF function at 6 months. There was no difference in functioning AVFs at 12 months (57.6% ipsilateral versus 65.9% contralateral, OR=0.70, CI=0.31-1.61, p=0.41).

Conclusions: Successful use of AVF was lower at 6 months in patients with AVF created ipsilateral to prior TVC insertion. Careful planning of prior TVC and future AVF locations should be guide management of long term vascular access.

SA-PO1100

The Diagnostic Value of Multi-Detector CT Venography for Catheter-Related Central Venous Stenosis in Hemodialysis Patients

Letian Yang,[1] Yuliang Zhao,[2] Tianlei Cui,[1] Ping Fu.[1] *[1]West China Hospital of Sichuan University, Chengdu, China; [2]Division of Nephrology, West China Hospital, Sichuan University, Chengdu, China.*

Background: Central venous stenosis (CVS) is a common complication in hemodialysis patients, especially those who are dialyzed through a catheter. The objective of our study was to assess the diagnostic value of Multi-detector CT venography (MDCTV) for catheter related-CVS compared with conventional digital subtraction angiography (DSA) in hemodialysis patients.

Methods: Between October 1, 2012 and September 30, 2018, hemodialysis patients admitted to our center for suspected catheter related-CVS who received both MDCTV and DSA were retrospectively enrolled. We compared the sensitivity, specificity, Cohen's kappa coefficient (κ) of MDCTV compared to DSA.

Results: A total of 1533 vascular segments in 219 patients were analyzed. Among the 280 lesions identified by DSA, 156 were correctly identified by MDCTV. MDCTV had a high specificity (96.73%) but a low sensitivity (55.71%), with a moderate inter-test agreement (κ=0.5930). In stratified analyses of vascular segments, the specificities of MDCTV were 89.93% (superior vena cava), 98.95% (left innominate vein), 95.33% (right innominate vein), 99.53% (left subclavian vein), 97.61% (right subclavian vein), 97.13% (left internal jugular vein), and 95.86% (right internal jugular vein), while the sensitivities were 90.00%, 65.52%, 66.67%, 87.50%, 40.00%, 20.00% and 8.11%, respectively (Figure 1).

Conclusions: MDCTV was a reliable imaging technique with high specificity in being able to diagnose catheter related-CVS in hemodialysis. However, the low sensitivity in some vascular segments diminished its value as a screening test. MDCTV seemed to have better diagnostic value for centrally localized CVS in superior vena cava and innominate veins.

Funding: Government Support - Non-U.S.

SA-PO1101

Kidney Disease Education: Marker or Effector of Improved Vascular Access Outcomes

Ashutosh M. Shukla,[1,2] Rupam Ruchi,[1] Shahab Bozorgmehri,[1] Tezcan Ozrazgat-Baslanti,[1] Rajesh Mohandas,[1] Mark S. Segal.[1,2] *[1]University of Florida, Gainesville, FL; [2]North Florida South Georgia VHS, Gainesville, FL.*

Background: Despite 2 large systemwide initiatives, vascular access outcomes for US incident end-stage renal disease (ESRD) patients continue to be suboptimal. Pre-ESRD renal care is the strongest predictor of vascular access readiness. Studies have shown that Kidney Disease Education (KDE) improves the quality of pre-ESRD care

Methods: We examined the impact of KDE on the incident vascular access rates among US adult ESRD Medicare beneficiaries since the implementation of CMS-KDE policy (2010-2014). Co-primary outcomes were incident fistula (AVF) rates and composite of incident fistula and/or graft rates (AVF±AVG). Secondary outcomes were composite maturing AVF±AVG, and any form of non-catheter vascular access (AVF±AVG in use or maturing). Multivariate analyses were performed in 4 progressive models (model1: KDE, model2: model1+socio-demographic adjustments, model3: model2+comorbidity and functional status adjustments, and model4: model3+adjustments for pre-ESRD renal care)

Results: Of the 309743 patients with their first dialysis as hemodialysis between 2010-14, 2916 (<1%) had at least one KDE during pre-ESRD (KDE cohort) whereas 306827 had no KDE (non-KDE cohort). All primary and secondary vascular access outcomes were significantly superior among the KDE cohort and the effect was maintained across all progressive multivariate models (Table). Stratified analyses further confirmed that the positive associations of KDE to vascular access did not dissipate even after accounting for pre-ESRD renal care, which has the strongest association with the vascular access outcomes (Table 2)

Conclusions: Pre-ESRD KDE is associated with improved quality of CKD care as judged by the incident vascular access outcomes. The positive effects of KDE is maintained across all baseline socio-demographic, comorbidity, and functional status variables, and is additive to the pre-ESRD renal care. Wider use of pre-ESRD KDE across advanced CKD patients may improve incident vascular access outcomes among US ESRD patients

Incident Vascular Access Outcomes among the Study Cohorts

Outcomes N (%)	KDE Cohort (N = 2,916)	Non-KDE Cohort (N = 306, 827)	Impact of KDE on the Odds of Achieving the Incident Vascular Access Outcomes in progressive multivariate models

SA-PO1102

Patient Values Toward Vascular Access Across Differing Age Groups

Anamika Adwaney,[1] Neill D. Duncan,[1] Edwina A. Brown,[1,3] Damien Ashby.[2]
[1]Hammersmith Hospital, London, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]Renal and Transplant Centre, Imperial College London, London, United Kingdom.

Background: Current guidance strongly supports the arteriovenous fistula over a catheter in all patients regardless of age. However, an increasing proportion of the prevalent haemodialysis population is now made up of older and comorbid patients who may require a greater healthcare burden to achieve a fistula. It has been demonstrated in other areas of healthcare that this patient group have distinct healthcare values, defined as fixed general preferences regarding treatment goals, when compared to younger patients. The role of values in vascular access preference has not been studied.

Methods: Structured interviews were conducted in a group of prevalent haemodialysis patients, all unaware of the purpose of the study. Questionnaires described a set of non-renal healthcare scenarios, with patients asked to make a trade-off decision for each. Priority scores for four treatment goals were determined by weighted analysis of the decisions. The treatment goals were: longevity, comfort, aesthetics and convenience.

Results: From 106 patients enrolled across 4 dialysis satellites, 104 patients (aged 16-94, 56% male) completed interviews for analysis. Questionnaires revealed the most important values in order of descending priority score (mean+/-se): convenience 3.7+/-0.8, comfort 2.6+/-0.7, aesthetics -1.2+/-0.7, and longevity -5.0+/-0.8. Compared to those under 55, older patients (over 70) unconsciously assigned higher priority scores to convenience (7.9 vs -1.3, p<0.001) and comfort (6.5 vs -2.9, p<0.001), and lower priority scores to aesthetics (-5.2 vs 4.6, p<0.001) and longevity (-9.2 vs -0.4, p<0.001). Access choices similarly predicted priorities: compared to those with a fistula, patients dialysing via catheter assigned higher priority scores to convenience (4.8 vs -0.3, p=0.007) and comfort (4.6 vs -4.2, p<0.001), and lower priority scores to aesthetics (-2.7 vs 3.7, p<0.001) and longevity (-6.7 vs -0.8, p<0.001). In a matched group analysis, the effect of age and access on healthcare priorities were independent.

Conclusions: Unconsciously assigned priorities show that amongst older patients, convenience and comfort are more important than longevity and aesthetics, and access choices appear to depend on similar values. Healthcare values should be understood when making access decisions with patients, particularly in older age groups.

SA-PO1103

Timely Creation of Peripheral Vascular Access for Planned Initiation of Hemodialysis

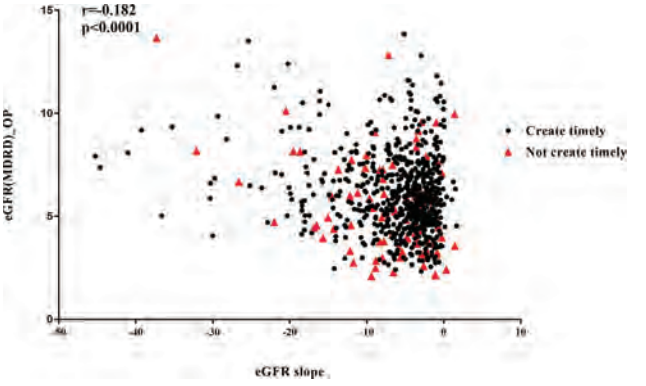
Yi-Wen Chiu,[1,2] Lee-Moay Lim,[2,1] Ming-Yen Lin,[1,2] Shang-Jyh Hwang.[2,1]
[1]Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan.

Background: Factor associated with timely creation of peripheral vascular access (VA) for planned initiation of hemodialysis is not clear.

Methods: From 2003 through 2016, every patient enrolled in integrated CKD program for more than 6 months and closed with the status of HD were included. The eGFR slope was counted between CKD program enrollment and VA creation or starting HD, which came first. We defined VA created timely as using VA when starting HD.

Results: Total 998 ESKD patients were included. (Age 65±12 y/o, Male 53%, DM 50%) The portion of VA created timely, created not timely and not created were 69%, 9% and 22%, respectively. By calendar year, created timely had the percentage increasing and around 74% in the last 6 years. Compared with not created, VA created timely had shallower eGFR slope (-4.2(-7.4, -2.3) *vs* -5.6(-10.8, -3.1), ml/min/1.73m^2/yr; p<0.0001), lower eGFR on first HD (4.3(3.4, 5.4) *vs* 4.6(3.4, 6.0), ml/min/1.73m^2; p=0.011) and longer stay at CKD program (729(417, 1439) *vs* 504(309, 1077), days; p<0.0001). There was a negative association of eGFR at VA creation with eGFR slope among VA created before HD (figure 1, r=-0.182, p<0.0001). Compared with created not timely, VA created timely had longer duration after VA creation till HD (108(53, 237) *vs* 14(7, 28); p<0.0001), shallower eGFR slope (-4.2(-7.4, -2.3) *vs* -4.8(-9.7, -2.2); p<0.0001), higher eGFR at VA creation (5.9(4.8, 7.2) *vs* 5.1(3.8, 7.1); p<0.005) and longer stay at CKD program (729(417, 1439) *vs* 521(312, 1048); p<0.0001). In multivariable analysis, only higher eGFR at VA creation (p=0.004) and shallower eGFR slope (p=0.05) were significant with timely creation of VA.

Conclusions: We disclosure that the stay in CKD program and eGFR slope are associated with timely creation of peripheral VA for HD initiation, and may be helpful with determining the time of peripheral VA creation.



SA-PO1104

The Impact of Comorbidity Index on the Association Between Vascular Access Type and Clinical Outcomes Among Elderly Patients Undergoing Hemodialysis

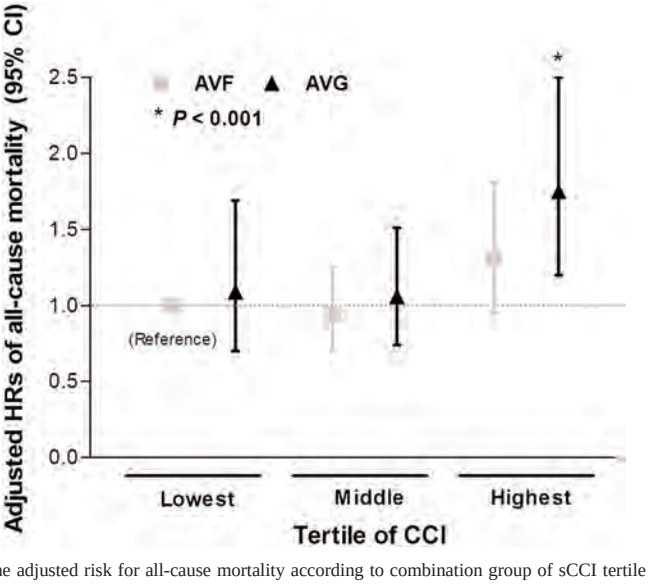
Jong Hyun Jhee,[1] Seoung woo Lee.[2] *[1]Inha University College of Medicine, Incheon, Republic of Korea; [2]Inha University Hospital, Incheon, Republic of Korea.*

Background: The optimal type of vascular access for the elderly undergoing hemodialysis is controversial. We aimed to evaluate the impact of comorbidity burden on the association between vascular access type and mortality risk among elderly patients maintaining hemodialysis.

Methods: A total of 23,100 patients with ≥65 years undergoing hemodialysis were recruited from the Korean end-stage renal disease registry data (2001-2018). Study subjects were stratified into tertile according to simplified Charlson comorbidity index (CCI) and compared the survival and hospitalization rate among the type of vascular access.

Results: Among all tertiles of sCCI, CVC use showed highest risk of mortality than AVF use. In the lowest to middle tertile, no difference was observed in survival rates between the use of AVF and AVG. However, in the highest tertile, AVG use showed higher risk of mortality than AVF use. When subjects were classified according to a combination of sCCI tertile and access type (AVF vs. AVG), patients with the highest CCI with AVG showed 1.75-folded increased risk of mortality than those with the lowest sCCI with AVF. Hospitalization rates due to access malfunction were highest in patients with CVC in all sCCI tertiles. In the highest tertile, patients with AVG showed increased rates of hospitalization compared to those with AVF due to access malfunction. However, hospitalization rates due to access infection were highest in patients with AVG in all tertiles.

Conclusions: The use of AVF may be of benefit and switching to AVF should be considered in elderly hemodialysis patients with a high burden of comorbidity.



The adjusted risk for all-cause mortality according to combination group of sCCI tertile and the type of vascular access (AVF vs. AVG)

SA-PO1105

The Impact of Vascular Access Type on the Survival and Quality of Life in Incident Hemodialysis Patients: Comparisons Among Arteriovenous Fistula, Graft, and Temporary Catheters

Do Hyoung Kim,[1] Chun Soo Lim.[2] *[1]Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Arteriovenous fistula (AVF) is the preferred vascular access for haemodialysis (HD); however, the association between vascular access and quality of life (QOL) is not well-known. We investigate the relationships between HD vascular access and all-cause mortality, health-related quality of life (HRQOL) and depression in a large prospective cohort.

Methods: A total of 1461 patients for whom HD was newly initiated were prospectively enrolled. The initial vascular access types were classified as AVF, arteriovenous graft (AVG) and central venous catheter (CVC). The primary outcome was all-cause mortality and the secondary outcomes were HRQOL, depression and all-cause hospitalisation. Kidney Disease Quality of Life Short Form 36 and Beck's depression inventory scores were measured to assess HRQOL and depression, respectively.

Results: Of 1461 patients, 314 patients started HD via AVF, 76 via AVG, and 1071 via CVC. In the survival analysis, patients with AVF or AVG showed significantly better survival than those with CVC (*P*=0.015). The numbers of annual hospitalisation were not different among the groups. The AVF and AVG groups had a significantly higher Kidney Disease Quality of Life Short Form 36 score and a significantly lower Beck's depression inventory score than the CVC group at 3 months and 12 months after the initiation of dialysis.

Conclusions: Patients with AVF or AVG have a better survival and HRQOL score and are less depressed than those with CVC. These suggest that the choice of vascular access in incident HD patients is important in terms of mortality and quality of life.

Hemodialysis Costs by Vascular Access Type and Outcomes in the Incident Year

Joanna Willetts,[2] Sheetal Chaudhuri,[2] Maria Radonova,[2] Eric D. Weinhandl,[2,3] John W. Larkin,[2] Len A. Usvyat,[2] Terry L. Ketchersid,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]University of Minnesota, Minneapolis, MN.*

Background: We profiled Medicare expenditures over time among incident hemodialysis (HD) patients in an End Stage Renal Disease Seamless Care Organization (ESCO), stratified by vascular access type. The statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of the Centers for Medicare & Medicaid Services (CMS). The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Methods: We identified adult HD patients in a large dialysis organization (LDO) who: 1) were treated in an ESCO clinic, 2) had Medicare as payer, 3) had arteriovenous fistula/graft (AVF/AVG) implanted ≤90 days from first date of dialysis (FDD) or exclusively had a central venous catheter (CVC) throughout follow-up. We compared average costs of care per member per month (PMPM) in AVF/AVG versus CVC patients from 90 days to 6, 9, or 12 months after FDD. We stratified those with outcomes and censored their data in subsequent periods.

Results: Patients with an AVF/AVG implanted had lower average Medicare expenditures from 90 days from FDD to the 6, 9, and 12-month follow-up compared to those treated exclusively with a CVC (Figure 1; all p<0.05). Costs did not differ in any follow-up period among AVF/AVG versus CVC patients who died, received a transplant, or transferred out of the facility. However, survival was 6, 4, and 1 percentage points higher in AVF/AVG versus CVC patients at the 6, 9, and 12-month follow-up periods, respectively.

Conclusions: Compared to incident HD patients with exclusive CVC, those with an AVF/AVG placed within 90 days of initiation had a lower cost of care over the first year of HD. Costs in those with outcomes during a follow-up period were not distinct between AVF/AVG versus CVC groups.

SA-PO1107

Vascular Access Type Was Not Associated with Mortality and the Risk for Cardiovascular Death in Elderly Chinese Hemodialysis Patients

Yang Yu, Ping Fu. *West China Hospital of Sichuan University, Chengdu, China.*

Background: The objective of this study was to examine the impact of VA type on cardiovascular and all-cause mortality as well as the predictors for outcome in elderly Chinese patients.

Methods: In the retrospective study, patients who initiated HD aged ≥ 70 years and received a primary VA creation were enrolled between January 2007 and October 2018. Clinical characteristics of VA, and outcomes were collected from the electronic medical record and the local Death Index. Kaplan-Meier analysis, and multivariate regression analysis were employed.

Results: A total of 358 elderly Chinese HD patients with median aged 74(72-78) years was analyzed. During the study period of 25.8 (12-43) months, 54 patients (15.1%) and 113 patients (15.1%) died of cardiovascular events and all-cause, respectively. The modality of VA type was not associated with mortality. Furthermore, CHF and DBP were the independent predictors for cardiovascular mortality (HR for CHF =3.462; HR for DBP per 1 mmHg elevated =1.033).

Conclusions: The modality of VA types showed insignificant effect on mortality in elderly Chinese population, while the presence of CHF and preoperative DBP might be used for the risk assessment of cardiovascular death.

Hemodialysis Access in the Elderly and Survival

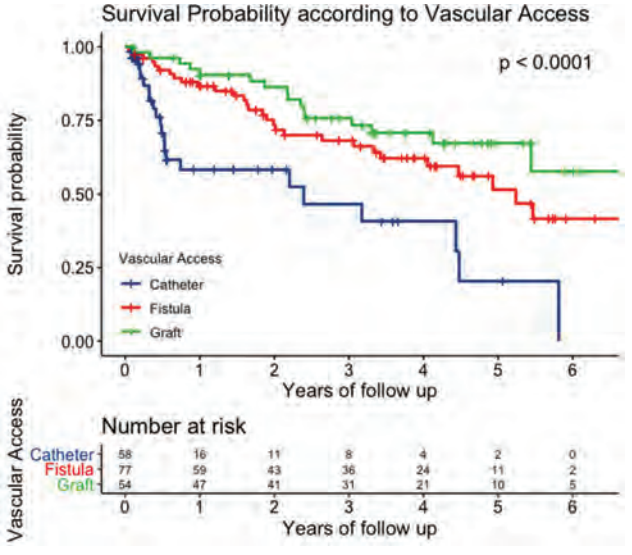
Jose E. Navarrete. *Emory University, Atlanta, GA.*

Background: To determine if achiveing the goal of having an AV fistula impacts survival in elderly dialysis patients.

Methods: Incident hemodialysis patients age 70 or older admitted to Emory Dialysis program form 1/2011 to 12/2015 were followed until death, transplant, or censoring up to 12/31/18. Demographic, laboratory and hemodialysis data were obtained. Patients were categorized as **C** if they only dialyzed with a catheter, **G** if they were able to dialyze with a graft and **F** if they used a fistula for dialysis.

Results: 189 patients were included. 30%, 29% and 41% of patiens used a **C**, **G** or **F** respectively. Demographics and comorbidities were similar among groups but diabetes was more common (65%) in **G** users than **C** or **F** (40 and 56%). Use of **C** was associated with lower survival compare to **G** or **F** (Figure 1). Patients using **C** were more likely to be hospitalized than those using **G** (RR 1.8, CI 1.1-3.1, p=0.005) or **F** (RR 2.6, CI 1.5-4.5, p<0.01). Hospitalization risk was higher in patients with **G** compared **F** (RR 1.4, CI 0.9-2.4, p=0.3) but the difference was not statistically significant. IV antibiotics use was more common in patients with C. 10.5%, 6.5% and 3.7% of patients used IV antibiotics in the catheter, graft and fistula groups respectively (p<0.05).

Conclusions: Elderly patients dialyzed with a catheter had lower survival than patients dialyzed with a graft or a fistula. There was no survival difference between patients using grafts or fistulas for dialysis. Patients using a dialysis catheter were significantly more likely to receive IV antibiotics and were hospitalized more often than patients using a fistula or a graft. There was no difference in hospitalization rate between **G** and **F.** These results underscore the importance of avoiding dialysis catheters as long term dialysis AV access and suggest that AV graft could be a reasonable dialysis access option in elderly patients.



SA-PO1109

Age and Arteriovenous Fistula Placement, Maturation, and Patency Loss in Elderly: A Competing Risk Analysis

Joyce Z. Qian,[1,2] Derek Ng,[1] Mara McAdams-DeMarco.[1,3] *[1]Department of Epidemiology, Johns Hopkins University, Baltimore, MD; [2]Medical Technology and Practice Patterns Institute, Bethesda, MD; [3]Department of Surgery, Johns Hopkins University, Baltimore, MD.*

Background: Choosing the optimal vascular access for older hemodialysis (HD) patients is of primary importance. Our study aims to determine the association of age with arteriovenous fistula (AVF) placement, maturation, primary patency loss, and abandonment in the U.S. older HD patients.

Methods: We identified three national retrospective cohorts of incident HD patients aged 67 years and older who initiated dialysis (43,851), had an AVF placed (14,892), or had the placed AVF matured (7,528) from United States Renal Data System (USRDS). AVF maturation, primary patency loss, and abandonment were ascertained monthly. Cut-off value for age categorization was identified by restricted cubic splines (RCS). Cause-specific and subdistribution proportional hazards models were used with kidney transplantation, peritoneal dialysis, and death treated as competing events. We compared inverse probability weighted (IPW) cumulative incidence functions (CIFs) by Gray's test.

Results: Of 43,851 patients who initiated HD, 39.4% had an AVF placed. Among 14,892 patients with a placed AVF, 68.9% achieved maturation. In 7,528 matured AVFs, 75.2% had primary patency loss and 25.2% abandoned. Patients ≥77 years old had significantly lower probability for AVF placement (adjusted cHR 0.96, 95% CI 0.92-0.99; adjusted sHR 0.92, 95% CI 0.89-0.95; Gray's test p<.0001) and maturation (adjusted cHR 0.95, 95% CI 0.91-0.99; adjusted sHR 0.93, 95% CI 0.90-0.97; p<.0001) as compared to those 67-<77. However, age is not associated with AVF primary patency loss (adjusted cHR 1.05, 95% CI 1.00-1.11; adjusted sHR 1.04, 95% CI 0.99-1.09; p=0.091) or abandonment (adjusted cHR 1.05, 95% CI 0.95-1.15; adjusted sHR 1.03, 95% CI 0.94-1.13; p=0.613).

Conclusions: In conclusion, the chance of AVF maturation is the most important consideration for vascular access planning. AVF might not be the best vascular access for older HD patients approaching eighty years old.

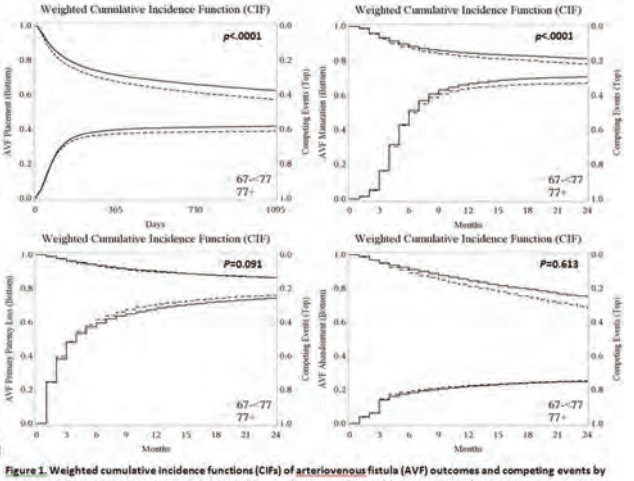


Figure 1. Weighted cumulative incidence functions (CIFs) of arteriovenous fistula (AVF) outcomes and competing events by age group in hemodialysis patients aged 67 and older. *P* values were obtained from Gray's test for equality of CIF. Bottoms lines: AVF outcomes; top lines: competing events including death, kidney transplant, and transfer to peritoneal dialysis.

Outcomes of ePTFE Grafts as Dialysis Access in Chinese Population: A Retrospective Analysis

Yuan Luo, Xueqin Bian, Chunfeng Gu, Xian Wu, Hong Ye, Junwei Yang. *Second Affiliated Hospital Nanjing Medical University, Nanjing, China.*

Background: With an increasing prevalence of end-stage renal disease and life expectancy of Chinese patients on renal replacement therapy, the quality and availability of superficial vessels can be limited and reduced with time. Arteriovenous access using ePTFE grafts have advantages compared with tunneled cuffed dialysis catheters. Guidelines suggest the usage of ePTFE grafts as access if native fistula is not possible. The aim of our study is to analysis the outcomes of AVGs that we have implanted in our patients.

Methods: We had retrospectively reviewed all the patients who had an AVG during October 2014 to June 2018 in our center. The demographic characteristics,duration of dialysis,laboratory tests, location and configuration of AVG, operation outcome,as well as the patency rate were collected and analyzed.

Results: A total of 262 patients were included in the investigation with the mean age of 60.1±13.8 years old. 56.5% of the study population was female gender. The most common comorbidities were hypertension (83.9%) and diabetes (47.7%). The range of follow-up period was from 10 to 54 months. The configurations of the grafts were 76.7% loop and 23.3% straight, and 62.6% of them were created on forearm. There was no operation-related mortality. Technical successful rate was 100%. However, 3 early failure were noted. The primary and secondary patency rates were 72.8% and 92.3%, 54.5% and 88.8%, 25.6% and 77.8%, 20.9% and 62.3%, 16.7% and 53.3%, at 6, 12, 24,

36, 48months, respectively. There was no difference between the primary and secondary patency of grafts on forearm and upper-arm (p-value: 0.337 and 0.812). The primary and secondary patency of straight grafts on upper-arm was better than loop grafts on upper-arm (p-value: 0.017 and 0.017). These patients required a mean 0.67 interventions per year and there is no difference between the location and configuration of AVGs.

Conclusions: Straight upper-arm AVGs has superiority of primary and secondary patency than loop. Arteriovenous access using ePTFE grafts seems to be an alternative in patients with poor superficial vessels.

Funding: Government Support - Non-U.S.

SA-PO1111

Evaluating Factors Predicting Outcomes of Secondary Patency of Arteriovenous Grafts for Hemodialysis

Ioannis E. Giannikouris,[1] Stavros Spiliopoulos,[2] Periklis P. Kyriazis,[3] Luisa Scarpati,[4] Giuseppe Bacchini.[5] *[1]Medifil SA Private Hemodialysis Center, Athens, Greece; [2]ATTIKO University Hospital, Athens, Greece; [3]Beth israel Deaconess Medical Center, Chicopee, MA; [4]Università degli studi della Campania Luigi Vanvitelli, Naples, Italy; [5]Nephrology, Hemodialysis and Peritoneal Dialysis Unit, Vascular Access Unit and Renal Transplanation, A. Manzoni Hospital, Lecco, Italy.*

Background: Our objective was to analyze outcomes in terms of secondary survival (CSS) and secondary patency rate (SPR) of AVG and to determine prognostic factors for these outcomes.

Methods: It was a retrospective, single-center analysis. Incident HD patients that received implantation of an AVG for angioaccess from January 2015 to December 2018 were included. Demographic factors, timing, type, and site of implanted AVG, as well as types of treatment of VA malfunction or failure, were recorded. Outcomes included CSS and SPR in 12, 24, 36 and 48 months. Kaplan-Meier survival analysis was conducted; univariate and multivariate analyses were used to evaluate prognostic factors.

Results: Data from 223 patients were analyzed. Those involved 119 proximal (arm) AVG, 101 loop (forearm) AVG, and 1 leg AVG, of which 147 were ePTFE grafts, 39 acute cannulation AVGs, and 37 biological vascular conduits. CSS was 49±4 months and SPR were 74%, 63%, 52%, 43% in 12, 24, 36 and 48 months, respectively. Multivariate analysis demonstrated that secondary patency was not associated with age, gender, duration in HD, graft position, stent deployment or use of cutting balloon angioplasty. Patency was negatively affected by graft type (acute cannulation HR, 3.09, 95% CI,1.66–5.75, p⟨0.005, biological HR, 0.70, 0.39–1.24, p=0.218), presence and number of successfully treated thrombotic events, with differences, noted depending on the type of treatment selected (Fogarty thrombectomy HR, 3.63, 1.89-6.98, p⟨0.005, Trerotola thrombolysis HR,3.14,1.53-6.43, p=0.002). A positive correlation was demonstrated between the increasing number of successful pre-emptive angioplasties and VA secondary patency (HR,0.90, 0.83-0.98, p=0.019). After 4.2±4.5 angioplasties per access, the association of CSS and stenosis proved to be weak (HR, 0.74, 0.32-1.70, p=0.474), a finding that requires further analysis.

Conclusions: Factors such as age, site or time on dialysis, traditionally thought to adversely affect access prognosis may not influence secondary outcomes of AVG. The use of new technology conduits, stenting or sophisticated endovascular catheters and declogging techniques may not contribute to prolonging access survival. Prompt stenosis recognition and pre-emptive correction could be a milestone in our continuous challenge for improving patency.

SA-PO1112

Comparing Outcomes of Forearm Loop and Arm Curved Configurations of Arteriovenous Grafts for Hemodialysis

Ioannis E. Giannikouris,[1] Stavros Spiliopoulos,[2] Periklis P. Kyriazis,[3] Luisa Scarpati,[4] Giuseppe Bacchini.[5] *[1]Medifil SA Private Hemodialysis Center, Athens, Greece; [2]ATTIKO University Hospital, Athens, Greece; [3]Beth israel Deaconess Medical Center, Chicopee, MA; [4]Università degli studi della Campania Luigi Vanvitelli, Naples, Italy; [5]Nephrology, Hemodialysis and Peritoneal Dialysis Unit, Vascular Access Unit and Renal Transplanation, A. Manzoni Hospital, Lecco, Italy.*

Background: We conducted a comparative analysis of outcomes of newly placed proximal upper arm straight grafts (pAVG) and distal forearm loop grafts (dAVG).

Methods: Retrospective, single-center analysis. Incident dialysis patients with newly placed AVGs involving the brachial or radial artery, pAVG or dAVG, were studied from 2015 to 2018. Primary survival (PS), primary assisted survival (APS) and secondary survival (ScS) (months) and patency rates for both conduit configurations were determined. Number of patency maintenance and access salvation interventions were recorded and compared.

Results: Data from 185 patients were analyzed, 108 patients received pAVG and 101 dAVG of loop configuration. PS was demonstrated to be 6.7±1.0 months for pAVG and 6.3±1.1months for dAVG (p=0.925), when APS was 21.7±4.0 for pAVG and 13.0±4.5 for dAVG (p=0.448). ScS was 48.3±5.4 for pAVG and 50.1±5.0 months for dAVG (p=0.829). An average of 3.03±3.76 angioplasty procedures was performed for patency maintenance in pAVG and 4.93±4.78 in dAVG, respectively (p=0.006). Moreover, 0.26±0.55 and 0.74±1.05 stents were deployed in pAVG and dAVG, respectively (p=0.001), with 20.3% of proximal grafts and 44.3% of distal conduits requiring stenting to maintain patency (p=0.002). In 28.6% of pAVGs and 41.9% of dAVGs no access salvation intervention was required, while in 71.4% of pAVGs and 58.1% dAVGs thrombectomy, transluminal thrombolysis or both were performed in order to restore patency, differences that were non-significant (p=0.355). Primary patency was 32% and 17% for pAVG and 28% and 18% for dAVG in 12 and 24 months, respectively. Assisted primary patency was 54%, 41%, 28% and 22% for pAVG and 46%, 35%, 25% and 19% for dAVG in 12, 24, 36 and 48 months, respectively. Secondary patency was 77%, 60%, 50% and 42% for pAVG and 70%, 64%, 52% and 42% for dAVG in 12, 24, 36 and 48 months, respectively.

Conclusions: Distal forearm grafts seem to perform similarly to proximal arm conduits since both configurations serve their respective purpose. Intensive follow-up, access surveillance, pre-emptive patency maintenance interventions are all essential for these outcomes, especially in the distal loop configuration. In order to preserve a maximal number of access sites, the forearm location should be advised to be considered first.

SA-PO1113

Prognosis of Vascular Access in Hemodialysis Patients with Autosomal Dominant Polycystic Kidney Disease

Chih-Ching Lin.[1,2] *[1]Taipei Veterans General Hospital, Taipei City, Taiwan; [2]School of Medicine, National Yang Ming University, Taipei, Taiwan.*

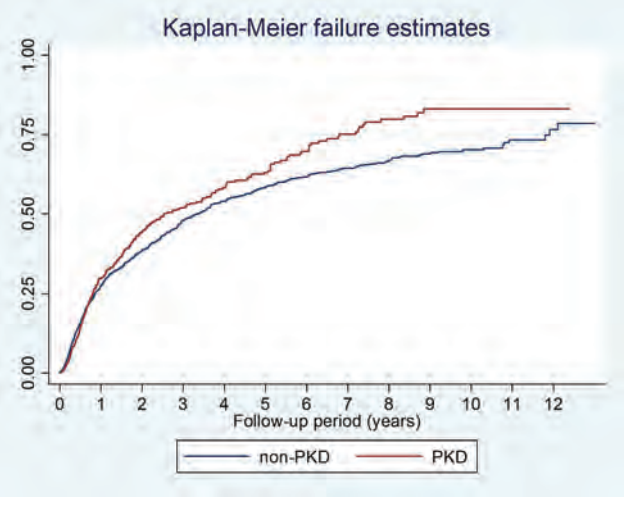
Background: Vascular diseases, including aneurysms of intracerebral arteries and abdominal aorta are commonly observed in patients with autosomal dominant polycystic kidney disease (ADPKD). We aimed to investigate the difference in the risk of malfunction of arteriovenous fistula or graft (AVF/AVG) between hemodialysis (HD) patients with and without ADPKD.

Methods: We enrolled 354 HD patients with ADPKD and 28264 HD patients without ADPKD in this study. Only 1062 propensity score-matched HD patients without ADPKD were included for analysis. The outcomes include the rate of AVF/AVG malfunction which is defined as the need for the first interventional procedure of either angioplasty, thrombectomy or creation of another AVF/AVG for all HD patients within 3 months, 1, 5 and 10 years respectively.

Results: The malfunction rate (per 100 person-years) of AVF/AVG for ADPKD and non-ADPKD was (1) 20.1 and 30.38 [HR=0.68, P=0.144] within 90 days, (2) 34.85 and 30.38 [HR=1.08, P=0.517] in first year, (3) 23.56 and 20.46 [HR=1.12, P=0.154] within 5 years, (4) 17.82 and 12.59 [HR=1.36, P=0.004] between 1st and 10th years, and (5) 22.6 and 17.52 [HR=1.21, P=0.015] at all period respectively.

Conclusions: In comparison with non-ADPKD patients, ADPKD patients had a trend of lower risk of AVF/AVG malfunction in the first 90 days but a significant higher risk after 1 year of AVF/AVG creation.

Funding: Government Support - Non-U.S.



Kaplan-Meier figure estimates show any new AVF cration or PTA representing AVF failure There is an overlapping of curves of the ADPKD and non-ADPKD group around 1-year follow-up period.

Resolution of High-Output Heart Failure, Recurrent Ascites, and AKI in a Renal Allograft After Ligation of the Arteriovenous Graft

Sandeep A. Padala,[1] George M. Hinnant,[1] Rajan Kapoor,[2] Imran Y. Gani.[3] *[1]Augusta University, Augusta, GA; [2]Augusta University / Medical College of Georgia, Augusta, GA; [3]SELF, Augusta, GA.*

Introduction: A good vascular acces is crucial for effective dialysis. Arteriovenous graft (AVG) is an arteriovenous fistula (AVF) with a prosthetic interposition between the artery and vein. The complications can include infection, lymphedema, aneurysmal dilations, stenosis, high output heart failure (HOHF), steal syndrome and thrombosis. Ligation of the AVG should be considered in patients presenting with unexplained HOHF. Herein, we present a case of HOHF, recurrent ascites, AKI and slow graft function following a kidney transplant that resolved only with ligation of the AV graft.

Case Description: A 48-year-old Caucasian female with past medical history significant for end Stage Renal Disease (ESRD) secondary to congenital anomalies of the kidneys. She was on hemodialysis (HD) via right thigh AVG. Following AVG placement,

she experienced recurrent ascites (on and off) requiring multiple paracentesis. Extensive Gastrointestinal (GI) and cardiovascular (CVS) workup did not reveal any etiology and she was taken off the transplant list due to the ascites. Due to poor clearance through her AVG, she underwent right upper extremity AVF to continue dialysis. Eventually her ascites resolved without any intervention, following which she had a deceased donor kidney transplant (DDKT). It was complicated by volume overload and recurrent ascites resistant to diuretics and required multiple paracentesis. The creatinine did not come below 3.7 and was diagnosed with slow graft function. The sister donor kidney achieved a normal creatinine in two weeks after transplant. Echo was suggestive of normal EF, elevated left atrial pressures, severely dilated left atrium and moderate pulmonary hypertension ~ 57 mmHg. Serum Albumin Ascites Gradient (SAAG) was 1.5 g/dL and ascitic protein > 2.5 g/dL. A decision was made to ligate the old right femoral AVG and soon the Cr improved to 1.5 with complete resolution of ascites.

Discussion: Our case emphasizes the importance of hemodialysis access ligation to treat HOHF, a known complication of hemodialysis access. Our case is unique in that the patient is a kidney transplant patient who was taken off the transplant list due to unexplained ascites and who again developed recurrent ascites, slow graft function and AKI post-transplant that completely resolved with ligation of AVF.

SA-PO1115

De Novo ANCA-Associated Glomerulonephritis in Post-Transplant Kidney

Enzo C. Vasquez jiménez,[1] Magdalena Madero,[1] Virgilia Soto,[2] Sergio Vazquez.[3] *[1]Instituto Nacional de Cardiologia, Ciudad de México, Mexico; [2]INC Ignacio Chavez, Mexico City, Mexico; [3]National Institute of Cardiology, Mexico City, Mexico*.

Introduction: De novo pauciimmune (ANCA-positive) GN in renal transplant is rare. Clinically, there is a rapid rise in serum creatinine level, accompanied by an active urine sediment, with or without symptoms of vasculitis involving others organs. The ANCA associated vasculitides can lead to segmental necrotizing or global necrotizing inflammation of the glomeruli, with the formation of crescents, an absence or paucity of glomerular immunoglobulins or complement, and ussualy rapidly progressive glomerulonephritis

Case Description: We report three cases of patients with living donor kidney transplant who had chronic kidney disease of undetermined cause, with a long time since the transplant. They developed graft dysfunction and proteinuria, so a renal biopsy was performed. Table 1

Discussion: Urinary abnormalities such as microhematuria and proteinuria are good indicators for the diagnosis of relapsing and de novo glomerulonephritis in kidney allograft in both cases. Combined with the urinary abnormalities, a confirmation of characteristic histological lesions to ANCA-V; necrotizing crescentic glomerulonephritis and/or small vessel vasculitis, by renal biopsy was required for the diagnosis of ANCA-V. The outcome of renal function is usually bad, with loss of renal function and fibrosis; In the case of the first patient, a second renal biopsy was performed with interstitial fibrosis III, and in the case of patient 2, she is currently under treatment.

Characteristics of patients

A Case of De Novo Fibrillary Glomerulonephritis in Post-Kidney Transplantation

Pooja Tanjavour,[1] Shreemayee De,[1] Daniel Angeli,[1] Adedamola M. Adeboye,[1] Heather R. Lefkowitz.[2] *[1]Newark Beth Israel Medical Center, Newark, NJ; [2]The Nephrology Group PA, West Orange, NJ*.

Introduction: Fibrillary glomerulonephritis (FGN) is a rare glomerular disease that results from deposition of Congo red-negative fibrils in glomerulus. Renal biopsy have shown that these fibrils, which consists of polymorphic IgG, are deposited mostly in mesangium and subendothelium areas. Recent studies show that DnaJ heat shock protein family member B9 (DNAJB9) has been associated with FGN. Patients usually present with nephrotic syndrome, hypertension, and hematuria. About 50% of the patients progress to end stage renal disease (ESRD). There are rarely reported cases of patients who present with de novo FGN post-kidney transplantation. Here we discuss a case of a patient with FGN post-kidney transplantation.

Case Description: This is a 61 year-old African American male with history of hypertension, ESRD on HD secondary to Diabetic Nephropathy, s/p Deceased Donor Renal transplant in March 2013, Hepatitis C, history of Banff 1A acute cell mediated rejection (August 2013), was evaluated for rise in creatinine to 3.1 from baseline of 2.0. in March 2019. He also had nephrotic-range proteinuria, hypertension without any other symptoms. He underwent transplant kidney biopsy, which showed Congo red-negative fibrillar deposits in glomeruli. Immunofluoroscence was consistent with FGN with lambda-chain restriction. He also had high Hepatitis C viral load of 273000 IU/ml. Immunofixation showed no monoclonal spike. FGN in this patient is presumed secondary to chronic Hepatitis C, thus was referred for Hepatitis C treatment and oncology referral for cancer screening.

Discussion: A retrospective study from University of North Carolina showed that among the FGN cases, Hepatitis C is most commonly reported in the African American population, and this is the group likely to transition to dialysis. Our patient was found to have high Hepatitis C viral load at the time of FGN diagnosis, thus supporting the hypothesis that Hepatitis C may be a causative factor of FGN. A case in 2013 reported a 56 year-old patient with a history of Hepatitis C who developed progressive renal graft failure due to FGN diagnosed 8 years after transplant. These studies indicate that Hepatitis C may be involved in developing fibrils in FGN, thus highlighting the importance of treating Hepatitis C virus for longer durability of renal allograft

SA-PO1117

BK Polyomavirus Nephropathy with Multiorgan Involvement: Whole-Genome Sequencing Data from a Killer Virus

Sanjeet Roy,[1] Carol J. Weida,[5] Jeffrey S. Huo,[2] Philip Roehrs,[3] Darci L. Grochowski,[4] Aasma Nalwa,[1] Harsharan K. Singh,[1] Piotr A. Mieczkowski,[1] Volker Nickeleit.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Levine Children's Hospital, Charlotte, NC; [3]Atrium Health, Levine Children's Hospital, Charlotte, NC; [4]Atrium Health, Charlotte, NC; [5]Pathology, Carolinas Pathology Group, Charlotte, NC*.

Introduction: Post kidney transplantation "organ limited" BK-polyomavirus (BKPyV) nephropathy (BKN) is a known complication. BKPyV infections with multi-organ involvement and severe morbidity are rare. 6/10 reported cases occurred in patients with lymphoproliferative disorders, with AIDS (3/10) and post renal transplantation (1/10). Whether severe immunosuppression, specific BKPyV strains, and/or viral gene mutations promote systemic viral spread is unknown. Here we report the first case of fatal BKN with multi-organ involvement from which detailed deep virus genome sequencing data are available.

Case Description: Patient: 24-year old woman with sickle cell anemia, status post CD34+ selected, T-cell depleted allogeneic peripheral blood stem cell transplantation (tx). Clinical data: Multiple post tx episodes of GVHD. Since post tx day 174 progressive BKPyViremia, very low CD3, CD4, CD8 counts, low immunoglobulin titers. Since day 459 progressive renal failure. Since day 631 respiratory distress; no hemorrhagic cystitis. Since day 651 pancreatitis. On day 696 patient death due to renal and respiratory failure. Autopsy findings: Productive PyV infection of both kidneys (PVN class 3), pancreas, and lungs with diffuse alveolar haemorrhage. Severe depletion of bone marrow and lymphoid organs. Whole Genome Sequencing data (from kidney, lung and pancreas): No diagnostic genomic mutations; systemic infection by episomal BKPyV strain Ib2. Viral mutations restricted to NCCR control domain with severe deletions, duplications and insertions in the "P,Q,R" NCCR sequences (largely sparing the "O" and "S" sequences). BKPyV-NCCR mutations more abundant and profound than those reported in BKN. No genetic evidence of mutant BKPyV 'metastatic' spread from one organ site to another.

Discussion: This is the first report identifying the common Ib2 strain of BKPyV in a case of multi-organ infection. Presumably profound immunosuppression allowed for evolution of mutated BKPyV strains. Severe rearrangement solely observed in the viral control region NCCR likely enhanced replication and pathogenicity with infection of uncommon organs such as pancreas and lung. Renal failure and multi-organ involvement due to mutated BKPyV should be considered in severely immuno-compromised patients.

SA-PO1118

Mystery Mass in an Asymptomatic Kidney Transplant Recipient

Guneet S. Kochar,[1] Beatrice P. Concepcion,[2] Gowri Satyanarayana.[2] *[1]Vanderbilt University Medcial Center, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN*.

Introduction: Malakoplakia is a rare inflammatory granulomatous mass comprised of partially digested bacteria due to the inability of macrophages to completely digest an infectious organism. It is most often seen in immunocompromised patients. Here we present a case of malakoplakia in a recent kidney transplant recipient with a complex urologic history who was otherwise asymptomatic.

Case Description: A 64-year-old male who received a living unrelated kidney transplant four months ago, complicated by slow graft function after transplant, and right femoral AV fistula ligation one month ago presents with two weeks of swelling in his right groin. He had bladder cancer with cystectomy and creation of an Indiana pouch with urinary diversion nineteen years ago, subsequent development of stomal stenosis and a ureteroenteric stricture causing obstructive nephropathy. The obstruction and chronic hypertension led to renal failure requiring hemodialysis. His creatinine improved after ligation of the right femoral AV fistula. Two "knots" in his right groin developed two weeks after fistula ligation and began draining purulent fluid. He admitted to intermittent cloudy urine draining from his urostomy but denied fevers, chills, allograft pain, weight loss, fatigue, malaise. A CT scan revealed a possible post-operative hematoma versus an indeterminate mass. Surgical exploration revealed scant seropurulent drainage, and organized inflammatory and necrotic tissue. Pathology was significant for PAS-diastase

and iron stains with numerous intracytoplasmic targetoid inclusions, consistent with pathognomonic Michaelis-Gutmann bodies. Cultures were positive for E. coli. The patient was treated with 4 weeks of ceftriaxone with subsequent resolution of his groin swelling.

Discussion: While malakoplakia is a rare diagnosis, this should be considered in the differential of any immunosuppressed patient with a mass. Tissue diagnosis, to confirm with specific request for PAS and von Kassa staining allows for identification of the pathognomonic Michaelis-Guttmann bodies. Cultures identify a causative organism and allow for targeted treatment. Most commonly, *E. coli* is the underlying pathogen, but *Klebsiella*, *Pseudomonas*, *Enterococcus*, and *Streptococcus* have been identified. Finally, careful evaluation of the immunosuppressive regimen should be undertaken if malakoplakia is identified.

SA-PO1119

An Interesting Case of Anti-HLA-C Antibody-Mediated Acute Humoral Rejection and Fabry-Like Zebra Bodies in a Renal Transplant Recipient

Mohammad W. Abuzeineh, Ahmad J. Ziadeh, Preethi Yerram. *Division Of Nephrology, University Of Missouri, Columbia, MO.*

Introduction: Detection of Donor Specific Anti-bodies (DSA) is essential in diagnosing Antibody-mediated renal allograft rejection (AMR). HLA-C antibodies testing is not part of routine DSA pre-transplant evaluation, but they have been reported to cause AMR. We present a case of AMR secondary to DSA against HLA-C, and incidental finding of ultrastructural zebra-bodies under Electron Microscopy (EM), raising suspicion for undiagnosed Fabry's disease, eventually determined to be of uncertain significance.

Case Description: A 39-year old African American male with ESRD due to hypertensive nephropathy underwent 2A/2B/2DR mismatched cadaveric transplant in 2014. Post-transplant Creatinine (Cr) was 1.4-1.6 mg/dl. Four years later, Cr was found to be elevated at 2.16 mg/dl. Allograft biopsy showed early chronic transplant glomerulopathy without evidence of acute cellular or humoral rejection. EM showed ultrastructural zebra-patterned lipid inclusions in podocytes (Fig 1), suspicious for donor-derived Fabry's disease, which turned out to be of unclear significance. Cr worsened and he developed nephrotic range proteinuria and hematuria. Repeat biopsy showed capillaritis and arteritis with focal fibrinoid necrosis (Fig 2), with weak and focal C4d deposits on IF. DSA were positive to Cw7 and Cw2. He was treated for acute AMR with pulse steroids, IV immunoglobulin, plasmapheresis and rituximab but his renal function worsened and he became dialysis-dependent.

Discussion: This case report emphasizes the role of HLA-C antibodies in causing AMR, and demonstrates the need for their recognition in the pre- and post-transplant period. In addition, the incidental presence of zebra-patterned lipid inclusions in podocytes in transplant renal biopsy doesn't necessarily indicate Fabry's disease.

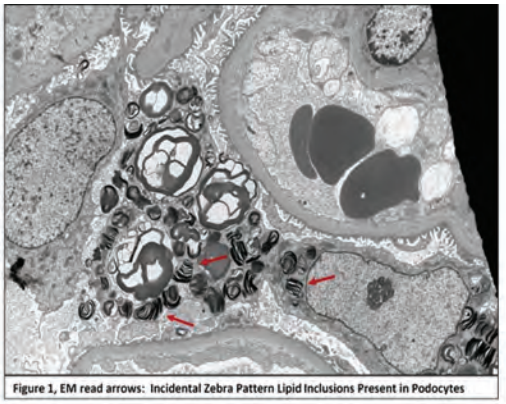

Figure 1, EM read arrows: Incidental Zebra Pattern Lipid Inclusions Present in Podocytes

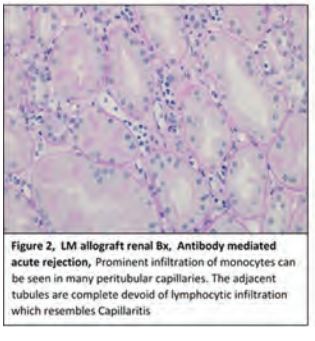

Figure 2, LM allograft renal Bx, Antibody mediated acute rejection, Prominent infiltration of monocytes can be seen in many peritubular capillaries. The adjacent tubules are complete devoid of lymphocytic infiltration which resembles Capillaritis

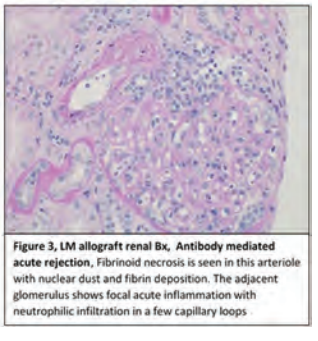

Figure 3, LM allograft renal Bx, Antibody mediated acute rejection, Fibrinoid necrosis is seen in this arteriole with nuclear dust and fibrin deposition. The adjacent glomerulus shows focal acute inflammation with neutrophilic infiltration in a few capillary loops

SA-PO1120

Metastatic Round Cell Sarcoma in a Renal Transplant Recipient

Reshma Shettigar,[1] Robert J. Walker,[2] Tracey L. Putt.[3] *[1]Nephrology, Dunedin Public Hospital, Dunedin, New Zealand; [2]University of Otago, Dunedin, New Zealand; [3]Dunedin Hospital, Dunedin, New Zealand, Dunedin, New Zealand.*

Introduction: We present a rare case of metastatic round cell sarcoma in a renal transplant recepient. Our literature search shows this is a first reported case round cell sarcoma in this group of patients.

Case Description: 57-year-old male, end stage renal failure due to polycystic kidneys, underwent deceased donor renal transplantation. Patient received standard induction immunosuppression with basiliximab and maintainence immunosuppression of mycophenolate, tacrolimus and prednisone. 6 months post transplant patient noticed a lump about 4 cm in diameter on the medial side of the lower end of his thigh. Ultrasound showed that this mass was arising from the Sartorius muscle. He further underwent a biopsy of this mass, which showed un-differentiated round cell sarcoma. Staging CT scan did not show any evidence of metastatic disease. It was decided patient would have radiation therapy followed by surgical removal of sarcoma. A week prior to surgery, he presented with severe back pain and epistaxis. Blood test revealed thrombocytopenia with platelet count of 9* 10^9/litre. CT scan showed several metastatic lesions in lumbar spine and femur and lungs. Patient was deemed to unwell to tolerate chemotherapy. We did discuss with patient regarding stopping or reducing immunosuppression at the time of diagnosis of metastatic disease, as this might slow the progression of disease, however patient refused this. Patient was managed with platelet transfusion and analgesia with a plan to offer radiation therapy for pain. Patient was referred to Hospice for management of symptoms and end of life care and passed away 2 weeks later.

Discussion: Sarcomas are heterogeneous group of aggressive malignant tumors of mesenchymal origin that make up less than 1% of adult malignancies. Unlike Kaposis sarcoma, which is associated with immunosuppression, round cell sarcoma has never been reported in renal transplant recipient. Role of immunosuppression contributing to the genesis and progression of this tumor is unknown. Despite treatment with aggressive chemotherapy and radiation therapy, prognosis with metastatic round cell sarcoma is extremely poor. In our patient, sarcoma on intially testing was limited disease and thought to be curable. However within 1 months time, it progressed from solitary lesion to multiorgan metastasis. We think Immunosuppression might have contributed to accelerated progression.

SA-PO1121

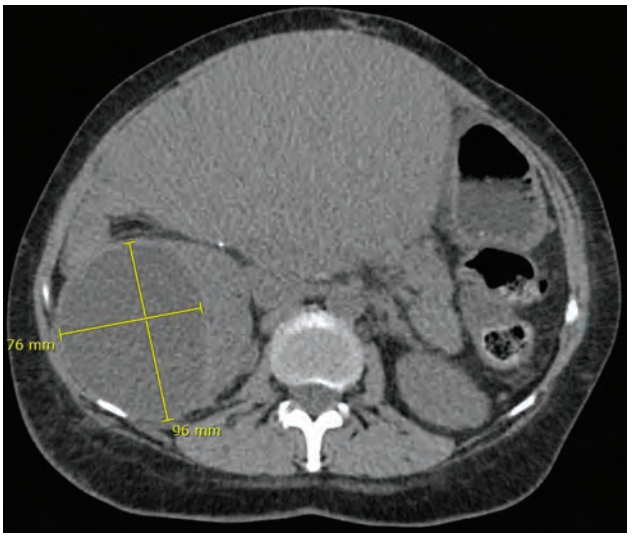
Renal Aspergillosis After Liver Transplant

Rahul Kumar, Ali Mehdi, Roulan Abu Hweij, Richard A. Fatica. Cleveland Clinic Foundation, Ohio *Cleveland Clinic Foundation, Cleveland, OH.*

Introduction: Renal aspergillosis is a rare life-threatening disorder in liver transplant recipients. Only 3 cases have been reported in the literature to date. This dreaded complication usually occurs within 90 days of transplant but late onset has been reported. We hereby present a case of renal aspergillosis occurring one year after liver transplantation.

Case Description: A 40-year-old white female presented with right-sided abdominal pain and vomiting for two weeks. Her history was significant for cryptogenic cirrhosis for which she had a living donor liver transplant one year prior. Two months before admission, she was found to have a spontaneous right renal subcapsular hematoma and acute kidney injury with previously normal eGFR, which was managed conservatively. Immunosuppression on admission included tacrolimus and MMF. Work up showed WBC 30000/uL and a creatinine of 3.5 mg/dl. CT scan showed expansion of the right renal subcapsular hematoma, measuring 10 x 9.6 x 7.6 cm and compressing the renal parenchyma. She was urgently taken for exploration and was found to have a large abscess with nonviable kidney. As such, evacuation and nephrectomy was performed. Pathology showed acute pyelonephritis with abscess, necrosis, and necrotizing granulomas containing fungal organisms consistent with Aspergillus species. She was treated with antifungal therapy for three months. The kidney function continued to deteriorate following many subsequent ischemic insults. The patient eventually required dialysis.

Discussion: Renal aspergillosis in liver transplant recipients carries significant morbidity and mortality. Risk factor includes severe immunosuppression, kidney failure, prior urological procedures, CMV or HHV-6 infection, and fulminant hepatic failure as a cause for transplant. Although renal aspergillosis is uncommon, a high degree of suspicion is required in transplant recipients as early detection and treatment can be life-saving.



SA-PO1122

Collagenofibrotic Glomerulopathy in a Renal Transplant Patient

Sarah Gilligan, Divya Raghavan, Monica P. Revelo Penafiel, Josephine Abraham. *University of Utah, Salt Lake City, UT.*

Introduction: Collagenofibrotic glomerulopathy is a rare disease that can occur in childhood in an autosomal recessive inheritance pattern or sporadically in adults. It is non-immune mediated and is characterized by deposits of type III collagen in the mesangial and subendothelial areas of the glomeruli. Per prior case series, the average age of onset is 40 years. The rate of progression is variable and it sometimes results in end-stage renal disease.

Case Description: The patient is a 66 year old male with ESRD due to biopsy proven ANCA-negative pauci-immune crescentic glomerulonephritis, coronary artery disease, atrial fibrillation, and hypertension who underwent living unrelated renal transplant via paired exchange in December of 2016. His anti-rejection regimen was tacrolimus, everolimus, and prednisone. His post-transplant creatinine nadir was 1.5 -2.0 mg/dl but had slowly risen to 3.0 – 3.8 mg/dl in the months prior to evaluation. He had a negative DSA, low positive BK blood titers (peak of 244,000 copies/mL down to 838 copies/mL), and proteinuria of 500 – 1000 mg/g. His renal transplant biopsy demonstrated chronic changes with 30% interstitial fibrosis and tubular atrophy and arteriolar hyalinosis secondary to calcineurin inhibitor toxicity with no evidence of transplant rejection. The glomeruli exhibited focal accumulation of PAS pale material in the capillary lumina and in the mesangium. Immunofluorescence was negative. On electron microscopy, there were subendothelial and mesangial deposits of curvilinear collagen fibrils compatible with collagenofibrotic glomerulopathy. Unfortunately, additional tissue was not available for immunohistochemical staining. The patient's native renal biopsy was reviewed with no evidence of similar deposits. The donor's records were also reviewed showing serum creatinine of 0.93 mg/dl with no significant proteinuria. The patient was transitioned from tacrolimus to belatacept with improvement in his serum creatinine to 2.34 mg/dl.

Discussion: Collangenofibrotic glomerulopathy is an extremely rare disease and in this case it is unclear whether it was donor derived or developed de novo after renal transplant. Renal biopsy of the donor would be the definitive diagnostic test but was not indicated with normal donor kidney function.

SA-PO1123

Allograft Mucormycosis Presenting as AKI

Aimen Liaqat,[1] Praveen Kandula,[1] Adedamola M. Adeboye,[2] Hameeda Khan.[1] *[1]Saint Barnabas Medical Center, Livingston, NJ; [2]Newark Beth Israel Medical Center, Newark, NJ.*

Introduction: Mucormycosis is a life-threatening complication of kidney transplantation associated with a 50% mortality rate. About 25 cases of renal involvement have been reported in the literature.

Case Description: A 62-year-old asymptomatic diabetic male was seen in the clinic 6 weeks after an uncomplicated 0 antigen mismatch living donor kidney transplant from his sister. He received basiliximab induction and standard immunosuppression. Labs showed an acute rise in creatinine (0.8 mg/dl to 1.5 mg/dl). Transplant ultrasound revealed hydronephrosis and creatinine worsened despite stent placement. Allograft biopsy was negative for rejection. His graft function worsened and dialysis was started on day 5. A nuclear scan showed decreased uptake in upper and middle poles. Intra-operative allograft exploration, biopsy and angiogram on day 7 revealed good perfusion but fungal hyphae were seen. A pulmonary nodule was seen on Chest X-ray ordered for worsening respiratory status on day 7. Whole body imaging revealed 3 scattered, cavitary pulmonary nodules suggesting disseminated fungal disease. Emergent transplant nephrectomy was performed and a repeat wedge biopsy revealed hyphae in the glomerular, tubular and vascular segments suggestive of allograft mucormycosis. Immunosuppression was stopped and Amphotericin was initiated.

Discussion: Risk factors in the post-transplant period include heightened immunosuppression (induction and anti-rejection therapy), diabetes, donor transmission, surgical contamination or presence of immunomodulating viruses (CMV and Hepatitis C). Being angioinvasive, mucor leads to thrombosis, ischemia or irreversible tissue necrosis. Histopathology is diagnostic and demonstrates ribbon-like, aseptate hyphae with wide angled branching. Blood and tissue cultures have a poor diagnostic yield. Management includes extensive surgical debridement, graft removal and antifungal agents. Amphotericin is the first line drug and posaconazole has been used as a step down or salvage therapy. Experimental therapies with iron chelation, hyperbaric chamber and cytokines (like G-CSF) have been tried with minimal benefits. Diagnostic challenges such as lack of serological tests, isolation difficulties and poor staining techniques delay recognition. A high index of clinical suspicion and prompt action with aggressive surgical resection and anti-fungal therapy is necessary for a favorable outcome.

SA-PO1124

Treatment of Valganciclovir-Resistant Cytomegalovirus with Letermovir

Nathan H. Raines,[1] Alexander Morales,[2] Pitchaphon Nissaisorakarn,[3] Amar Pandit,[1] Amtul Aala.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Memorial Hospital of Rhode Island/Alpert Medical School of Brown University, West Warwick, RI; [3]Jacobi Medical Center, Bronx, NY.*

Introduction: Cytomegalovirus (CMV) resistance to ganciclovir is an important concern post- kidney transplant. Resistance is often mediated by one of two mutations: UL97, which encodes a kinase responsible for phosphorylation and activation of ganciclovir; and UL54, which encodes the viral DNA polymerase targeted by ganciclovir (Vez et al, Clin K J 2014). Alternatives to ganciclovir include foscarnet and cidofivir, but their use can be limited by nephrotoxicity and marrow suppression. Letermovir is an anti-CMV agent approved by the FDA for prophylaxis against CMV infection post-transplant. It inhibits CMV replication by binding to the terminase complex not affected by the mutations seen in ganciclovir-resistant CMV, and has minimal myelosuppresive and nephrotoxic effects.

Case Description: This is a 73 year old woman with a history of ESRD due to anti-GBM disease who underwent deceased donor renal transplant in January 2019. She was considered high risk for CMV as a CMV IgG negative patient who received a kidney from a CMV IgG positive donor. In February 2019 she was found to have a detectable CMV viral load, rising throughout March and April despite increased doses of valgancyclovir. She was admitted in April 2019 for treatment with Foscarnet. CMV resistance genotyping showed a UL97 mutation predicting Ganciclovir resistance. CMV viral load peaked at 4.0 log 10 IU/ml and began to downtrend after 1 week of Foscarnet. She then developed AKI and pancytopenia with severe neutropenia which was likely Foscarnet-induced. In consultation with infectious disease we started oral letermovir 480mg twice for 7 days then converted to daily dosing until viral load becomes undetectable. Her viral load has downtrended to < 2.1 log 10 IU/ml on letermovir after 2 weeks of therapy. Neutropenia has recovered, and her AKI has improved.

Discussion: Letermovir is currently being studied for treatment of CMV resistant to ganciclovir (ID NCT03728426, phase 2 investigation). Here we present a case of an individual with proven UL97 mutation-driven ganciclovir-resistant CMV who developed severe side effects precluding further use of foscarnet and was started on Letermovir for treatment of CMV. CMV viral load improved to barely detectable levels on treatment with letermovir alone, without marrowsuppressive or nephrotoxic side effects.

SA-PO1125

Crystal Conundrum: Renal Allograft Failure from Recurrent 2,8 Dihydroxyadenine Nephropathy

Kim Phung L. Nguyen,[1] Angelina Edwards,[2] William F. Glass,[3] Akshta Pai,[4] Aleksandra De Golovine.[5] *[1]University of Texas Health Science Center at Houston, McGovern Medical School, Houston, TX; [2]University of Texas at Houston Health Science Center, Houston, TX; [3]University of Texas – Houston Medical School, Houston, TX; [4]University of Texas Houston/McGovern Medical School, Houston, TX; [5]UTHSC-H, Houston, TX.*

Introduction: Post transplant crystalline nephropathy, a rare occurrence, can significantly impact allograft outcomes. Here we present a case of adenine phosphoribosyltransferase (APRT) deficiency resulting in excess adenine and consequentially insoluble 2,8-dihydroxyadenine (2,8-DHA) crystals leading allograft failure.

Case Description: A 68-yo man with ESRD presumably due to hypertension presented for deceased donor renal transplant. Pre transplant evaluation was unremarkable. Imaging of native kidneys revealed multiple cysts without stones. He received a 2A1B1DR HLA mismatch kidney, crossmatch negative, PRA 89%, blood group identical kidney from a hypertensive, diabetic deceased donor with KDPI of 75%. Patient received thymoglobulin induction followed by maintenance immunosuppression with prednisone, tacrolimus and mycophenolate mofetil. The surgical procedure was uneventful. A zero-hour biopsy showed donor-derived disease consisting of mild arteriosclerosis, 9% global glomerulosclerosis, 10% interstitial fibrosis. Postoperative allograft function was delayed. Hemodialysis (HD) was started on postop day (POD) 3. Renal ultrasound was unremarkable. Immunologic assessment with DSA was negative. On POD 14, transplant biopsy was performed showing acute tubular epithelium injury with numerous birefringent crystals initially interpreted as calcium oxalate crystals, suspicious for hyperoxaluric condition. Daily HD and supplementation with pyridoxine and calcium acetate were initiated. Renal function did not improve. Closer inspection of the biopsy with special stains revealed features of the crystals suspicious for 2,8-DHA nephropathy consistent

with APRT deficiency. Patient was started on allopurinol, fluid infusion and low purine diet. HD was discontinued. Genetic testing revealed a homozygous pathogenic variant for the APRT sequence. Renal allograft function remained poor and progressed to primary nonfunction of the renal allograft.

Discussion: Although 2,8-DHA crystals, often misdiagnosed, resemble calcium oxalate crystals in being birefringent under cross-polarized light, crystals have a slightly yellow-brown coloration, and unlike oxalates, are argyrophilic with Jones silver stain. Timely diagnosis of 2,8-DHA nephropathy and aggressive management with xanthine dehydrogenase inhibitor and low purine diet may salvage the renal allograft.

SA-PO1126

West Nile Virus: A Peculiar Cause of Fever and Encephalopathy in a Transplant Patient

Kurtis J. Swanson, Fahad Aziz, Sandesh Parajuli. *UW Health, Madison, WI.*

Introduction: West Nile Virus (WNV) is an uncommon viral encephalitis. Here we describe an unusual presentation of WNV encephalitis in a kidney transplant recipient.

Case Description: 65 year old woman with ESKD due to fibrillary glomerulonephritis, recurrent UTIs, T2DM s/p living related donor kidney transplant with basiliximab induction, CMV -/+, EBV -/+, no PRA/DSA maintained on standard triple immunosuppression who presented with fever, dysuria. On presentation she was febrile, tachycardic, normotensive, and with normal mentation. She recently was treated for multi-drug resistant E. Coli UTI, but had persistent symptoms, positive UA and started on empiric pipercilin-tazobactam. Urine culture grew the same E. Coli. Blood cultures remained negative. She was narrowed to ceftriaxone. Despite appropriate coverage, she remained febrile, weak, and developed a dense hypoactive delirium. She developed dysarthria prompting Neurology consultation and head imaging, which were unremarkable. Over days, her mental status did not improve and exam changed with new spasticity/hyperreflexia. A lumbar puncture was performed, showing lymphocytosis and CSF WNV IgM positivity via ELISA testing with an index value of 9.73 (1.1 or greater suggestive of WNV). With this diagnosis, her immunosuppression was reduced to azathioprine/prednisone along with 1 dose of IVIG. Over days, her delirium resolved. She had a prolonged course of rehabilitation. Her graft function remained stable throughout her illness.

Discussion: West Nile Virus is a rare disease associated with marked neurological sequelae including weakness often lasting months. Diagnosis is often challenging, as manifestations can be non-specific and involve multiple organ systems. A high index of suspicion and thorough neurologic evaluation are key to diagnosis. CSF IgM is a useful test, specific for neuroinvasive WNV as IgM does not cross the blood brain barrier. Interpretation can be difficult as it usually takes 4-10 days to manifest. Interestingly, it can persist for 12 months i.e. may represent prior infection in some cases. Aside from insect repellent, no other preventative measures or directed therapies exist to quell this infection, which ultimately requires supportive care. West Nile Virus is a key differential diagnosis in the transplant patient with encephalopathy and its recognition is vital to guiding prognosis and management.

SA-PO1127

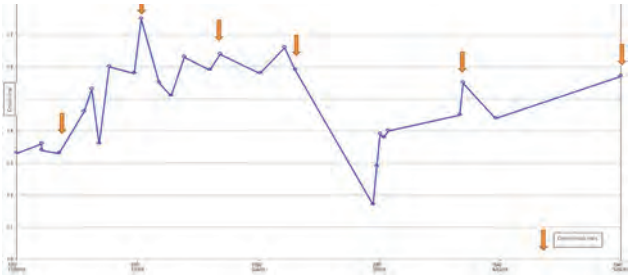
Contrary to Expectation: Preserved Renal Function After Using PD-1 Inhibitor Cemiplimab-rwlc in a Kidney Transplant Recipient

Muhannad Leghrouz, Svetomir N. Markovic, Aleksandra Kukla. *Mayo Clinic, Rochester, MN.*

Introduction: The use of the immune checkpoint inhibitors in transplant recipients with malignancy is associated with the risk of graft failure due to acute rejection. Here we present the first reported case of using Cemiplimab-rwlc (Libtayo), a recently approved programmed death receptor-1 (PD-1) blocking antibody for locally advanced and metastatic cutaneous squamous cell carcinoma (CSCC), in a kidney transplant recipient.

Case Description: 48 yo male with a history of ESRD secondary to ADPKD, received 5/6 ABDR HLA mismatch living donor kidney transplant in May of 2016. He had class II DSAs (DR4 with MFI 1975). He received Thymoglobulin induction and maintenance immunosuppression with Tacrolimus, MMF and Prednisone. Protocol allograft biopsy at 2 years post transplant showed Banff borderline acute cellular rejection. At 2 years post transplant, he was diagnosed with metastatic CSCC of head & neck, HPV positive. Tacrolimus and MMF were discontinued and patient was switched to Sirolimus. Treatment included Mohs procedure, chemotherapy (paclitaxel/carboplatin/cetuximab) for 4 cycles and radiation for 5 months. He had good response to the cervical lymph nodes metastasis but had minimal sustained response to skull metastasis. Subsequently, he was switched from intratumoral 5FU to intratumoral IL2 and started on immunotherapy with Cemiplimab (Libtayo). Prednisone was discontinued. He underwent excision of scalp lesion and right cortical mastoid metastatectomy while on the full dose of Sirolimus, which he tolerated well. His kidney function remained stable throughout over 5 months follow up period (Figure-1).

Discussion: Literature reports a substantial risk of rejection in kidney transplant recipients who are treated with immunotherapy. However, as our case shows, PD-1 inhibitor Cemiplimab (Libtayo) can be used with preserving allograft function on a Sirolimus-based immunosuppression regimen. More data is needed in to guide clinicians and to appropriately counsel patients regarding the risks and benefits of immunotherapy medications.



SA-PO1128

Sampling Site Matters: A Falsely Elevated Tacrolimus Level After Stopping IV Infusion in a Patient with Central Venous Catheters

Salam Kadhem,[1] Israa Al-Ani,[1] Kawther F. Alquadan.[2] *[1]University of Florida, Gainesville, FL; [2]Shands Hospital/University of Florida, Gainesville, FL.*

Introduction: Tacrolimus levels abnormalities constitute a major concern to transplant nephrologists. Based on these values; decisions are made to adjust Tacrolimus doses to achieve adequate immunosuppression. The recognition of pitfalls with these laboratory tests becomes crucial to better interpret the accuracy of these results, specifically when dealing with critically ill patients using intravenous Tacrolimus where a large subset of these patients have central venous catheters that are used for infusions and blood sampling. We are reporting a case of falsely elevated Tacrolimus levels after discontinuation of the medication.

Case Description: A 52-year-old male with history of gastroparesis and kidney transplantation in 2011, presented with sever nausea, vomiting and inability to tolerate oral intake including his oral tacrolimus for one day prior to admission. On presentation, his Tacrolimus level was 3.1 ng/mL. Intravenous continuous infusion of Tacrolimus was initiated via a PICC line. Two days later, his symptoms have resolved and subsequently transitioned back to oral Tacrolimus. Next day Tacrolimus trough (drawn from the PICC line after multiple flushes) came back at 38.9 ng/mL, repeated level confirmed to be more than 30 ng/mL. Immediately, his oral tacrolimus was held. Interestingly, he did not exhibit any signs or symptoms of tacrolimus toxicity and his renal function remained stable at baseline. Rechecked daily troughs for the next 3 days were 23, 17 and 19 ng/mL, despite holding tacrolimus. Simultaneous samples were drawn from both PICC line and peripheral vein showed great discrepancy with troughs of 39.0 ng/mL and less than 3.0 ng/mL respectively. Historically, a similar misinterpretation occurred which led to prolonged hospital stay with potential compromise to his immunosuppression.

Discussion: Falsely elevated Tacrolimus levels in samples drawn from central venous catheters have been reported to last several days despite rinsing the catheter. Studies have shown evidence of reversible adsorption of the drug from the inner walls of different catheters. Raising awareness to this misleading phenomenon helps avoiding dangerous dose reductions of the immunosuppressive drug and unnecessarily prolonged hospital stay. Sampling for Tacrolimus level should always be drawn from peripheral veins.

SA-PO1129

Angiotensin II Type I Receptor (AT1R) Antibody-Associated Collapsing FSGS in a Renal Allograft

Amar Pandit, Nikhil Agrawal, Grace Malvar, Francesca Cardarelli, Yael K. Heher, Amtul Aala. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Post renal transplant de novo collapsing FSGS could be associated with AT1R antibody.

Case Description: A 66-year-old man with type 2 diabetes mellitus underwent pre-emptive renal transplant for CKD of unproven etiology. He was HLA high risk with low level donor-specific DP1 antibodies and was induced with ATG and maintained on mycophenolate, tacrolimus and prednisone. Cytotoxic and flow cytometry cross matches were negative. Four weeks later he was noted to have proteinuria, which soon progressed to nephrotic range, while creatinine remained at baseline (1 mg/dl). Kidney biopsy was suggestive of acute humoral rejection with G1 glomerulitis, mild PTCitis and 60% C4d. HLA screen showed persistent low-level antibodies against DR52. Endothelial cell cross match was positive, indicating a non-HLA antibody mediated process. Treatment was initiated with pulse steroids, IVIG, plasmapheresis. AT1R antibody level was 14 units/ml (borderline) at 2 weeks and progressed to >40 units/ml at 4 weeks, following which he was started on Losartan and PLEX extended to 15 sessions. 3 months after the transplant, nephrotic range proteinuria persisted (10-12 g), however further escalation of immunosuppression was prevented by disseminated trichophyton infection and recurrent surgical site abscesses. Creatinine had increased to 2.4 mg/dl and a repeat biopsy showed diffuse collapsing glomerulopathy. C4d remained diffusely positive. Allograft function continued to decline and he returned to dialysis 8 months post-transplant.

Discussion: AT1R receptor is highly expressed on endothelial cells and podocytes and antibodies against it are known to cause acute humoral rejection. AT1R antibodies could potentially cause FSGS by enhancing the effects of AT II, which regulates matrix synthesis and cell proliferation. It also enhances the expression of transient receptor potential cation channel 6, which leads to FSGS in animal models. This report illustrates a case of AT1R antibody mediated humoral rejection with progression to an unusual clinical presentation (de novo collapsing FSGS), which was resistant to aggressive therapy.

A Unique Immunosuppression Strategy in a Patient with Atypical HUS Undergoing Kidney Transplant

Sohaib Zahid,[1] Kristin Krupa,[2] Kiumars Ranjbar tabar,[3] Kalathil K. Sureshkumar,[1] Sabiha M. Hussain.[1] Allegheny Health Network *[1]Nephrology, Allegheny Health Network, Pittsburgh, PA; [2]AHN, Pittsburgh, PA; [3]Allegheny General Hospital, Pittsburgh, PA.*

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is a rare disease with estimated incidence of 1-2 per 1,000,000 caused by uncontrolled activation of alternative complement pathway due to genetic mutations mainly in complement inhibitor factors. Herein, we present a patient with atypical HUS who underwent deceased donor kidney transplant (DDKT) and successfully treated with a unique immunosuppressive strategy.

Case Description: A 23 year old female with no significant past medical history had a complicated pregnancy at age 18 with pre-eclampsia requiring emergent cesarean section. Post-partum, she developed acute kidney injury, anemia, thrombocytopenia and elevated LDH with normal ADAMTS-13 levels. Kidney biopsy showed acute thrombotic microangiopathy (TMA). Genetic testing revealed heterozygous missense mutations in complement factor H and complement factor H-related gene 5. She was diagnosed with atypical HUS and initiated on eculizumab but without renal recovery and was maintained on hemodialysis. Five years later patient was called in for DDKT with KDPI of 14%. Her PRA was high at 76%. She received a dose of eculizumab pre-operatively followed induction with by Thymoglobulin and methyl prednisolone. We chose maintenance immunosuppression with belatacept instead of tacrolimus along with mycophenolate mofetil (MMF). Eculizumab was continued. Her creatinine improved to 0.9mg/dl. Two months post-transplant, she developed acute T- cell mediated rejection type 1b successfully treated with methyl prednisolone followed by maintenance steroid therapy and increased dose of MMF. Serum creatinine remains at 1 mg/dl at 1 year follow up.

Discussion: Immunosuppressant management in aHUS patients with high PRA undergoing kidney transplant is challenging. Calcineurin inhibitors and DDKT itself are potential triggers for endothelial damage leading to TMA. Belatacept is a selective T-cell co-stimulation blocker which has not been reported to induce TMA. Our case demonstrates the safety and efficacy of Thymoglobulin induction followed by belatacept/MMF maintenance along with eculizumab in highly sensitized patient with aHUS.

SA-PO1131

Success of Intensive Immunosuppression to Prevent Post-Transplant Recurrence of C3 Glomerulonephritis in Children

Eloise Colliou,[1] Anne F. Maisin,[2] Marie-Alice Macher,[2] Theresa Kwon,[2] Claire Dossier,[2] Isabelle Vrillon,[3] Veronique Fremeaux-Bacchi,[4] Georges Deschênes.[2] *[1]CHU Toulouse, Toulouse, France; [2]Pediatric Nephrology, APHP, Robert-Debre Hospital, Paris, France; [3]Pediatrics, University Hospital of Nancy, Nancy, France; [4]Immunology, APHP, HEGP, Paris, France.*

Introduction: C3 glomérulonephritis (C3GN) is characterized by the dysregulation of complement alternative pathway and is frequently associated with autoantibodies stabilizing the C3 or C5 convertase. There is currently no specific treatment and the renal prognosis is poor with a high risk of early recurrence post-transplant, leading to graft loss in more than 50% of cases, despite the use of Eculizumab.

Case Description: Two patients received a living donor transplant and one a deceased donor. Bi-nephrectomy was performed 5 +/-2 months before transplantation. Steroids (60mg/m^2/d) and MMF (1500mg/m^2/d) were started at least 1 month prior to transplant. Eculizumab was started 14 days before transplant in the 2 patients with a living donor and the 3rd patient was on long-term treatment. One session of immunoadsorption was performed 8h prior the renal graft for all. They received an induction by thymoglobulin or Basiliximab followed by Tacrolimus [T0 : 8-10 ng/ml], associated with MMF [AUC 50-60 µg.h.ml], steroids and Eculizumab. No early recurrence occurred. Protocolar renal biopsies at 3 months only showed C3 deposits in 1 patient without any inflammation. After a follow-up of 3, 6 and 15 months, none of the patients developed proteinuria or hematuria under Eculizumab. One patient developed a BK virus replication (4.8 log) at M4 that led us to decrease immunosuppression, this was complicated with acute cellular rejection (1B) at M5. eGFR at last follow-up was 55 ml/min/1,73m^2 in this patient and 80-86 ml/min/1,73m^2 in the two other patients.

Discussion: Intensive immunosuppression pre and post-transplant may prevent post-transplant recurrence of C3GN.

SA-PO1132

De Novo Cytomegalovirus-Triggered FSGS After Kidney Transplantation Associated with APOL1 Risk Allele

Mallika Gupta, Anuja Java. *Washington University in St. Louis, Saint Louis, MO.*

Introduction: Recurrent and de novo glomerulonephritis (GN) account for 18% to 22% of death-censored kidney allograft failures. We report a case of de novo cytomegalovirus (CMV)-associated FSGS after kidney transplantation from an African American (AA) donor.

Case Description: A 52-yr-old White female (WF) with ESRD secondary to HTN underwent a 4-antigen mismatched, CMV D+/R-, deceased donor renal transplant from a 43-yr-old AA male in July 2018. Induction immunosuppression included methylprednisolone and Thymoglobulin followed by tacrolimus, mycophenolic acid (MMF) and prednisone. Serum creatinine (Cr) was 1 mg/dl at discharge. In Feb 2019, the patient presented with abdominal pain, diarrhea, and fever. Creatinine was 1.3 mg/dl, which worsened to 7.9 mg/dl over 5 days. Spot urine protein creatinine ratio (UPC) was 15. Infectious workup revealed CMV viremia (29,7460 IU/ml). Patient had discontinued valganciclovir (VGCV) 3 months after transplant. Allograft biopsy revealed podocyte effacement. Despite treatment for the CMV viremia (VGCV 900 mg po qd and discontinuation of MMF), Cr worsened and hemodialysis (HD) was initiated. VGCV was switched to IV ganciclovir 3 x wk with HD leading to clearance of viremia. Creatinine improved and HD was discontinued in April 2019. UPC improved to 7. Biopsy tissue sent for APOL1 risk variant genotyping revealed compound heterozygosity for G1/G2.

Discussion: Approximately 13% of AA carry two APOL1 risk variants. Increased risk of graft loss following kidney transplantation is associated with these alleles. However a second hit is required. Mechanisms for CMV-induced podocytopathy via injury to permeability barrier have been postulated. Our case exemplifies CMV as a second hit causing podocytopathy in a recipient with heterozygosity for APOL1 in an AA donor. Studies to better understand the mechanisms and predisposing factors for APOL1-associated kidney diseases are critical since recipients from donors with the risk alleles may warrant tailored management. Of note, the mate kidney was transplanted in a 48-yr-old WF who recently completed the 9-month CMV prophylaxis. Questions arise: 1) Should the duration of viral prophylaxis be extended in the second patient, 2) Should increased frequency of viremia screening be considered and, 3) Should aggressive antiviral strategies be considered at first identification of viremia?

SA-PO1133

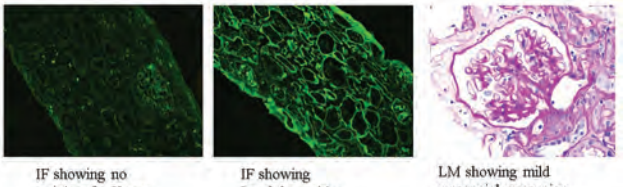
Donor Derived Cell-Free DNA Positivity: Does It Always Denote Allograft Rejection?

Meenakshi Sambharia, Kalathil K. Sureshkumar, Sohaib Zahid, Bhavna Chopra. *Allegheny General Hospital, Pittsburgh, PA.*

Introduction: Donor derived cell free DNA (dd-cfDNA) is a novel serum biomarker now available to predict acute rejection in renal allografts. Presence of dd-cfDNA > 1% suggests allograft injury; caused by acute rejection. We describe a rare form of post-transplant lymphoproliferative disorder (PTLD) presenting as positive dd-cfDNA.

Case Description: A 64 yo white male who underwent living related kidney transplant 3 years earlier with baseline serum creatinine(Cr) around 1.5 mg/dl presented with worsening allograft function. Serum Cr was 9mg/dl with 4.5 grams/day proteinuria. Elevated dd-cfDNA level at 2.5% prompted a renal allograft biopsy. Light microscopy showed mild mesangial matrix expansion, Immunofluorescence showed 3+ deposition of lambda light chain in a linear pattern along glomerular and tubular basement membrane suggestive of lambda light chain deposition disease(LCDD)-refer to figure 1. A subsequent bone marrow biopsy was consistent with lamda light chain restricted plasma cell dyscrasia. Patient was started on chemotherapy with cyclophosphamide, bortezomib, and dexamethasone along with plasmapheresis. Within a month, his renal allograft function improved with Cr of 1.6 mg/dl. After 6 months, he underwent autologous stem cell transplant(SCT)and currently remains in remission on Ixazomib. Repeat bone marrow biopsy and kidney biopsy have been normal. Cr remains at 1.3-1.5mg/dl one year post SCT. Repeat dd-cfdna levels remained <1%.

Discussion: This is the first reported case of lambda restriced LCDD, a rare form of PTLD in renal allograft presenting as positive dd-cfDNA. Elevated dd-cfDNA in our patient likely reflects allograft injury resulting from parenchymal infiltration with neoplastic cells along with light chain depostion. Our case highlights the need to include unusual causes of allograft injury in the differential diagnosis in patients presenting with renal allograft dysfunction and elevated dd-cfDNA. Allograft biopsy remains the gold standard in reaching a definite diagnosis.



IF showing no staining for Kappa | IF showing Lambda positive | LM showing mild mesangial expansion

SA-PO1134

Non-T Cell Depleting Induction Therapy Predisposes to Early Human Adenovirus Infection as Compared with T-Cell-Depleting Therapy: Case Report and Review of Literature

Sami M. Akram, Lilly M. Barba. Division of nephrology, HUCLA *Harbor-UCLA Medical Center, Torrance, CA.*

Introduction: Human Adenovirus (HAdV) infections are increasingly recognized in post kidney transplant patients. We report a unique case of early post op HAdV infection presenting with a space occupying lesion in the allograft, evolving to bladder masses. We reviewed the literature to assess the effect of non T-cell depleting agents on frequency of early and late HAdV infection.

Case Description: A 38-year-old male, with end stage kidney disease (ESKD) due to IgA nephropathy underwent deceased donor renal transplant (DDRT). He received induction with Basiliximab. Post op course was uneventful. On post op day 8 he was admitted with fever (39.2 deg. C) and diarrhea of 2 days duration. Upon review of systems he had mild cough with mucoid sputum. On exam, he was tachycardiac with no allograft tenderness. Rest of the physical exam was unremarkable. Cellcept was held. The BioFire Film Array was positive for adenovirus. There was no viremia. He was lymphopenic and

serum creatinine rose from 0.9 to 1.2 mg/dL. Colonoscopic biopsy showed microscopic colitis. Ultrasound showed a space occupying lesion in the upper pole of the allograft and a mass in the bladder. Fever resolved on hospital day 8 without additional interventions. Cystoscopy revealed multiple masses in the bladder and in the ureter. Bladder biopsy was consistent with cystitis cystica glandularis.

Discussion: Non T-cell depleting agents prevent further T cell mediated immune responses while allowing other cell surface protein receptors such as CD48, CD80, and CTLA4, to be available for adenoviral entry. This causes the host to be vulnerable to viral entry in the early post-transplant period. Adenovirus integrates into the DNA, producing harmful proteins causing cellular injury and tumorogenesis. Literature review supports that early HAdV infections occur predominantly in patients who received non T-cell depleting induction therapy (Table 1.) Therefore, a high index of suspicion for HAdV infection should be maintained in febrile patients who receive non T-cell depleting induction therapy.

Table 1: Induction Therapy and Pattern of HAdV infection.

	Basiliximab / Daclizumab	T-cell Depleting Agents
Early Infections (4wks +/- 2 wks.)	13	3
Late Infections	1	9

P value = 0.00039;

Result is significant at P <0.05.

SA-PO1135

Simultaneous Acute Rejection and Recurrent Focal Segmental Glomerulosclerosis: A Match Made in Renal Transplantation

Anita Shah,[1] Maulin Shah,[1,2] Venkat Ramanathan.[1,2] [1]*Baylor College of Medicine, Houston, TX;* [2]*Michael E. DeBakey Veterans Affairs Medical Center, Houston, TX.*

Introduction: Simultaneous recurrent focal segmental glomerulosclerosis (FSGS) and acute rejection is extremely rare in kidney transplant recipients. In resistant FSGS cases failing conventional immunosuppression, addition of repository corticotropin injection (Acthar Gel®) may lead to proteinuria resolution.

Case Description: A 34-year-old man underwent deceased donor kidney transplantation for ESRD related to possible FSGS. Other medical history included hypertension and obesity. He had immediate allograft function with basiliximab induction. Maintenance regimen included tacrolimus, mycophenolate and prednisone. Eleven weeks after transplantation, he had sudden onset of nephrotic-range proteinuria (urine protein-creatinine ratio of 11.3 g/g from baseline of 0.5 g/g), generalized edema and acute kidney injury (serum creatinine 2.4 mg/dL from baseline 1.6 mg/dL). Kidney transplant biopsy was performed expecting histologic evidence of recurrent FSGS. Surprisingly, biopsy showed Banff II-B acute cellular rejection and segmental podocyte injury. He was treated for rejection and recurrent FSGS with anti-thymocyte globulin, solumedrol, plasmapheresis (TPE) and IVIg. Following TPE and immunosuppression intensification, his proteinuria improved briskly to 0.37 g/g with parallel decline in creatinine to baseline. Despite ongoing TPE and IVIg, his proteinuria recurred (8-10 g/g) with worsening creatinine. Repeat kidney biopsy showed complete resolution of rejection, but with 25% residual foot process effacement. With failure of two doses of rituximab and 40 TPE sessions to improve his proteinuria, he started corticotropin injections twice weekly. After 3 months of corticotropin, TPE was stopped, and corticotropin tapered off over another 3 months. He is now in complete remission of proteinuria with stable kidney function.

Discussion: Pre-transplant FSGS patients should be closely monitored in the post-transplant period for FSGS recurrence. Simultaneous presence of two diagnoses underscores the importance of performing kidney biopsy in those with proteinuria and acute kidney injury post-transplantation. Recurrent FSGS treatment in allografts resistant to conventional treatments may remit with corticotropin. Concurrent acute vascular rejection and recurrent FSGS is rare. In the era of significant organ shortage, all options should be tried to save the allograft.

SA-PO1136

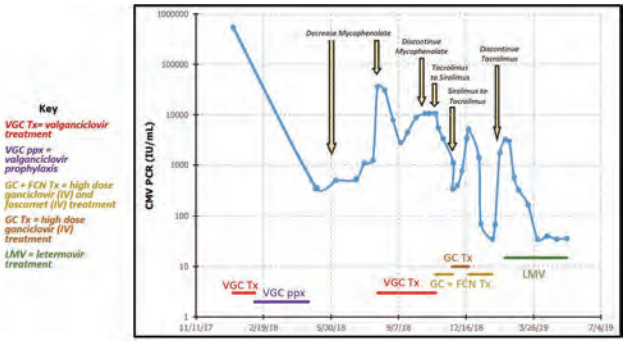
Letermovir Therapy for Resistant Cytomegalovirus in a Kidney Transplant Recipient: Case Report

Devender Singh,[1] Adley I. Lemke,[2] Allyson Hart.[1] [1]*Nephrology, Hennepin Health Care, Minneapolis, MN;* [2]*Hennepin Healthcare, Hopkins, MN.*

Introduction: Cytomegalovirus (CMV) infection is a leading cause of morbidity in kidney transplant recipients. Resistant CMV strains and medication toxicities complicate treatment. We describe a case of multidrug resistant CMV suppressed with letermovir after treatment with second line agents.

Case Description: 63 year old female with history of living donor kidney transplant (CMV donor + / recipient -) presented with severe diarrhea and leukopenia a month after stopping valganciclovir prophylaxis. CMV viral load was 544,002 copies/mL and she was given 3 weeks of treatment and 2 months of prophylaxis using valganciclovir. Low level viremia followed discontinuation of prophylaxis. After the viral load exceeded 30,000 copies/mL treatment was resumed without successful viral suppression. Genotyping revealed resistance to valganciclovir, foscarnet, and cidofovir. She was initiated on foscarnet and high dose ganciclovir. Upon therapy discontinuation, viral load increased again and oral letermovir 480 mg daily was started. Since introducing letermovir she maintained CMV suppression for 3 months. For treatment course please see figure 1.

Discussion: Resistance to agents for the treatment of CMV is increasing. Valganciclovir alternatives have significant toxicities and necessitate parenteral administration. Letermovir is a novel agent that inhibits the cleavage of CMV DNA concatemers by targeting the pUL56 subunit of the terminase enzyme complex. Letermovir is not myelosuppressive, it is available in an oral formulation, and does not require dose adjustments for renal function. Recently letermovir was approved for CMV prophylaxis in allogeneic hematopoietic stem cell transplant recipients, but use in solid organ transplant is being investigated. Letermovir for salvage therapy has been reported but widespread use has not been adopted due to the low barrier to resistance. Our unconventional approach using combination foscarnet and ganciclovir treatment then switching to letermovir presents a possible niche for agent's use to sustain suppression of a multidrug resistant CMV.



SA-PO1137

Fanconi Syndrome from Adenovirus Treatment in a Renal Transplant Patient: A Rare Complication from Novel Therapy with Brincidofovir

Daniel Varela,[1] Yasar Tasnif,[2,3] Mourad Alsabbagh.[4,1] [1]*University of Texas Rio Grande Valley, El Paso, TX;* [2]*DHR Health Transplant Institute, McAllen, TX;* [3]*College of Pharmacy, University of Texas at Austin, Austin, Taiwan;* [4]*Doctors Hospital at Renaissance, Edinburg, TX.*

Introduction: Brincidofovir is an oral pro-drug of cidofovir currently in Phase III clinical trials. In comparison to cidofovir, it displays lower nephrotoxic potential. We present a case of Fanconi syndrome within a week of therapy of brincidofovir for a patient with Adenovirus infection. This rare side effect has not been reported in the literature.

Case Description: We present a 62 year old woman with chronic kidney disease due to diabetes mellitus-2 and hypertension, who received a deceased donor kidney transplant. Induction therapy included alemtuzumab, solumedrol, and mycophenolate mofetil. Her baseline serum creatinine post-transplant was 0.7. Two months later her renal function began to worsen. A renal biopsy was performed which showed no evidence of acute cellular or antibody mediated rejection. However, BK virus as well as Adenovirus was found in both blood and urine. Immunosuppression medications were minimized; IVIG therapy for severe BK viremia and brincidofovir for Adenovirus viremia was initiated due to worsening viremia (656,000 copies/mL). She was readmitted to the hospital five days later due to acute graft dysfunction and a repeat biopsy revealed cellular IIA rejection. She completed the first course of brincidofovir but was readmitted for worsening renal function and brincidofovir was restarted due to reemergence of Adenovirus. Due to sepsis requiring ICU management, immunosuppression medications were stopped. On follow-up in the clinic, the patient was found to have glycosuria, phosphouria, hypomagnesemia and hypouricemia consistent with Fanconi syndrome. Aggressive electrolyte repletion was started and Brincidofovir stopped as this was determined to be most likely cause. Electrolyte imbalances gradually improved after stopping brincidofovir.

Discussion: Brincidofovir was utilized as therapy for Adenovirus infection due to its reported lower incidence of nephrotoxicity compared to standard therapy with Cidofovir. However, the side effect of Fanconi syndrome complicated the course of therapy. Fanconi syndrome is a known side effect of cidofovir, and due to brincidofovir's lower incidence of nephrotoxicity this side effect may not be anticipated. Patients receiving brincidofovir should be monitored for Fanconi syndrome by frequent follow-up, especially electrolytes in the serum and urine.

SA-PO1138

A Rare Case of Monoclonal Immunoglobulin Deposition Disease (MIDD) in a Transplant Recipient

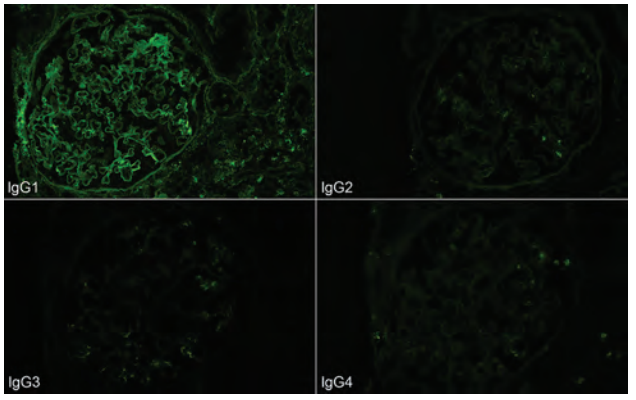
Joseph Tasch,[1] Clarissa A. Cassol,[2] Isabelle Ayoub,[1] Mark A. Kleman,[2] Priyamvada Singh.[1] [1]*The Ohio State University Wexner Medical Center, Columbus, OH;* [2]*The Ohio State University, Columbus, OH.*

Introduction: A 36-year-old male with ESKD presumed secondary to Type-1-diabetes received a kidney-pancreas transplant on 09/19/2017, complicated with pancreatic-vein thrombosis (day two post-op), requiring pancreas re-transplant 10/24/2018. He received induction with ATG (cumulative-dose 5 mg/kg) and maintenance with tacrolimus (trough average 8), and everolimus.

Case Description: He had multiple admissions for nausea, vomiting, and prerenal AKI. His creatinine rose from a nadir post-transplant of 1.24mg/dl to a range of 2 mg/dl. At 18 months post-transplant, he developed anasarca with creatinine rise to 2.9mg/dl. Work up revealed nephrotic syndrome with UPC 10gm/gm and serum albumin 2.7g/dl. Urine amylase (44U/L), serum amylase (16 U/L), c-peptide (2.8ng/mL), and HbA1c (5.7). A transplant-kidney biopsy showed combined antibody and T-cell-mediated rejection grade 1B (Banff 2017). EM showed finely granular powdery subendothelial and mesangial electron-dense deposits. IF showed 2+ linear IgG1 heavy-chains along the GBM. Findings

were suggestive of MIDD. He was treated with steroids, and creatinine improved to 0.86mg/dL, though no improvement in pancreatic-function, leading to the resumption of insulin.

Discussion: The pancreas-kidney Donor was a 25-year old-white- healthy male with KDPI<20. Given the donor's age, donor-derived MIDD would be unlikely. The recipient SPEP, UPEP, and free-light-chain ratio were unremarkable. There was no pathological evidence of MIDD in his gastrointestinal and spleen biopsies. Whether the deposits are donor or recipient derived is unclear. We plan to closely monitor with yearly free light chains, and bone-marrow biopsy. Recurrence of MIDD is almost universal in kidney-allografts even without detectable paraprotein. The etiology for graft-failure remains elusive, though MIDD as a contributor is a theoretical possibility. Our case shows the importance of early transplant biopsy with the performance of IF and EM for all patients with suspected glomerular pathology.



SA-PO1139

De Novo Transthyretin Amyloidosis After Domino Liver Transplant Causing Kidney Graft Failure: A Case Report

Fábio A. Reis, Guilherme P. Santa Catharina, Igor Smolentzov, Flavio De paula, Elias David-Neto, Jose O. Reusing. *University of Sao Paulo (USP), Sao Paulo, Brazil.*

Introduction: Domino Liver Transplant (DLT) refers to a sequential transplant (Tx) where a recipient receives a liver from a donor who has usually Familial Amyloid Polyneuropathy (FAP). DLT increases the chance of getting a liver but poses the risk of the recipient manifesting amyloidosis years later. The current case describes a patient who received a kidney Tx 13 years after a DLT and developed *de novo* systemic amyloidosis with neuropathy.

Case Description: Male 69 yo, diagnosed with Hepatitis C and Hepatocellular Carcinoma, underwent a DLT transplant with a liver from a FAP donor. After 13 years of Tx he developed ESRD due to Cyclosporine toxicity and recurrent pyelonephritis. One year later he underwent a deceased donor kidney Tx under Basiliximab, Mycophenolate and Tacrolimus immunosuppression. Three years later, he presented progressive lower limbs paresthesia and weakness (electroneuromyography confirmed polineuropathy); anasarca, dyspnea and bilateral pleural effusion (echocardiography showed new diastolic dysfunction and myocardial hypertrophy) and progressive symptomatic hypotension episodes. Because of non-proteinuric subacute kidney graft dysfunction and dyspnea he was hospitalized and initiated hemodialysis. Kidney graft biopsy demonstrated acute tubular necrosis (ATN), light glomerulitis, C4d and Congo Red negative, and no signs of Tacrolimus toxicity. On the other hand, sural nerve biopsy stained Congo Red positive and confirmed Amyloid Neuropathy. Graft failure was attributed to ischemic injury, due to arterial hypotension secondary to autonomic neuropathy. Other features as neurogenic bladder with post-void retention and new myocardial hypertrophy without arterial hypertension were also attributed to amyloidosis. Dialysis ultrafiltration was progressively hindered by untreatable hypotension and he died 2 months later.

Discussion: This case illustrates the occurrence of Transthyretin Amyloidosis with severe manifestations in a recipient of DLT. We point out the differential diagnosis of kidney graft failure, here described as ATN as an indirect consequence of Amyloidosis.

SA-PO1140

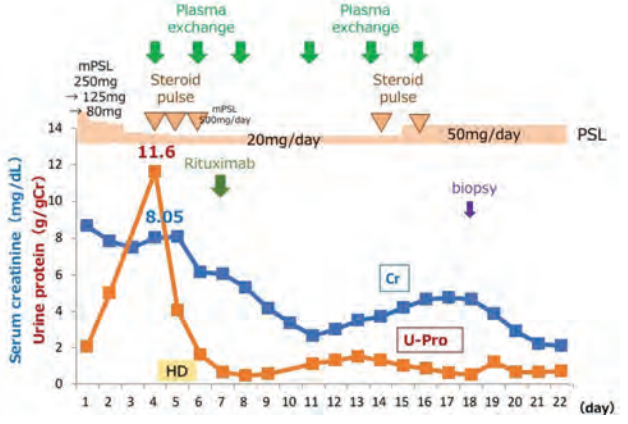
De Novo Minimal Change Disease Immediately After Renal Transplantation

Fumiaki Tanemoto, Masahiko Nagahama, Masaaki Nakayama. *St. Luke's International Hospital, Tokyo, Japan.*

Introduction: De novo minimal change disease (MCD) is quite a rare cause of post-transplant nephrotic syndrome (NS). Only a few cases have been reported, partially due to the stringent criteria for this diagnosis. We report a challenging case of de novo MCD while the patient was on induction therapy immediately after transplantation.

Case Description: A 49-year-old male with end-stage kidney disease due to nephrosclerosis received ABO-compatible living kidney transplantation from his 47-year-old wife with four mismatches in HLA typing. Induction therapy included steroids, mycophenolate mofetil tacrolimus and basiliximab. At post-transplantation day 4, serum creatinine increased to 8.05 mg/dL with massive proteinuria (11.6 g/d). Although the flow cytometric crossmatch test for HLA came back negative, the patient received steroid pulse, plasma exchange and rituximab for possible recurrent focal segmental glomerulosclerosis (FSGS). Kidney function and proteinuria were improved soon after those treatments. The allograft biopsy taken on day 18 showed no specific glomerular changes under light microscopy; however, foot process effacement of podocytes was noted under the electron microscopy. De novo MCD was diagnosed. The patient has been achieved complete remission for one year since the transplant.

Discussion: De novo MCD after kidney transplantation is quite rare, but seems to have favorable prognosis. Nephrotic-range proteinuria usually develops immediately or shortly after transplantation, even when the patient is on induction therapy. Due to indistinguishable clinical course as well as similar histology of FSGS and MCD, it is possible that patients labeled as FSGS who respond readily to steroids or plasmapheresis may have MCD rather than FSGS. Therefore, the diagnosis of de novo MCD should be always considered even when induction therapy is given, especially if minimal light microscopic findings are detected.



SA-PO1141

Not a Classic Chickenpox Infection: Retinal Necrosis in a Renal Transplant Patient

Keysha Lopez vega, Mariela Marquez Pantoja, Fatima B. Cintron-Rosa, Ileana E. Ocasio Melendez, Carlos G. Rivera-Bermudez. *Nephrology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico.*

Introduction: Viruses are common opportunistic infection among kidney transplant patients. Varicella-zoster virus (VZV) is often reactivated at 6 to 12 months after transplant as Herpes Zoster (HZ). Primary VZV infection is less common and is more severe. We present the case of a kidney transplant recipient with a severe complication of primary VZV infection.

Case Description: A 42-year-old-woman with hypothyroidism, post-transplant diabetes mellitus, end stage kidney disease due to renal agenesis status post kidney transplant (2006) on Tacrolimus 2mg in the morning and 1.5 mg in the evening, mycophenolic acid 360 mg thrice daily, levothyroxine and insulin regimen was admitted to our institution after ophthalmology evaluation. Four weeks prior to admission she was hospitalized at another institution due to primary VZV infection, reported relative with HZ and no prior VZV vaccination, she was treated with intravenous (IV) acyclovir and discharged home with oral (PO) acyclovir after no new skin lesions occurred. Two weeks after initial onset she developed a rash at the dorsum of the hands and left eye blurry vision. She was evaluated by ophthalmology and was admitted with left acute retinal necrosis due to HZV. Evaluation was significant for no fever, no visible vesicular skin lesions but impaired left pupillary reflex and left facial nerve palsy. Laboratory results showed leukocytosis, creatinine level on baseline, 1.8 mg/dL, and hyperglycemia. She was started on acyclovir 1 gram IV every 8 hours, IV hydration and mycophenolic acid was discontinued. She received intravitreal ganciclovir every 48 hours for two weeks. After the second dose of gancylovir she noticed improvement of blurry vision and resolution of symptoms after first week of treatment. She was discharged home with PO acyclovir 800 mg every 4 hours and decreased mycophenolic acid dose to 180 mg twice daily.

Discussion: Our patient developed a rare complication of primary VZV infection, acute retinal necrosis, 13 years after kidney transplant. Recent studies show incidence of VZV after kidney transplant is less than 1%. This case emphasizes the importance of VZV vaccination in the pre-transplant period and vaccination of close contacts. Early and prompt intervention is needed in those patients with visual complications since they are at risk of vision loss.

SA-PO1142

Utility of Donor-Derived Cell-Free DNA for Detecting Allograft Rejection with PD-L1 Checkpoint Inhibitor Use

Laila Lakhani,[1] Sami Alasfar,[1] Anshul Bhalla,[1] Amtul Aala,[2] Evan J. Lipson,[4] Daniel C. Brennan.[3] *[1]Johns Hopkins Hospital, Baltimore, MD; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Johns Hopkins, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD.*

Introduction: Donor derived cell free DNA (dd-cfDNA) is a useful biomarker that originates from allograft cells undergoing injury. Levels <1% have strongly correlated with absence of active rejection. We describe a case where serial dd-cfDNA monitoring allowed the use of immune checkpoint inhibitor therapy in a renal transplant recipient.

Case Description: A 72 year old man with ESRD from ADPKD underwent living unrelated kidney transplant in Dec 2010. His immunosuppression regimen included tacrolimus 2mg bid, mycophenolate 500mg bid and prednisone 5mg daily. In July 2017, he was diagnosed with metastatic squamous cell cancer. He underwent radiation therapy followed by chemotherapy with Cetuximab. However, in the setting of disease progression, PD-L1 inhibitor was considered. A baseline dd-cfDNA was 0.23%. PD-L1 inhibitor, Pembrolizumab, was initiated in Nov 2017 with serial dd-cfDNA monitoring (weekly x 8 weeks, followed by monthly). Despite serum creatinine fluctuations (Fig 1), the relative change in dd-cfDNA of <65% and overall <1% (Fig 2) reassured of a low likelihood of active rejection, allowing the continuation of therapy. Pembrolizumab was used for about 1 year; however, subsequent imaging was concerning for local disease progression and Pembrolizumab was discontinued in Nov 2018. Thereafter, his dd-cfDNA returned to baseline with excellent allograft function, suggesting that the initial elevation may have been from tumor death.

Discussion: Dd-cfDNA is a helpful noninvasive marker for diagnosing graft rejection with checkpoint inhibitor use. Future investigations into sequencing the dd-cfDNA will help determine whether it is of tumor vs allograft origin.

Francisella novicida: An Exceedingly Rare Cause of Pneumonia in a Kidney Transplant Recipient

Enrique Acosta,[1] Jose A. Castillo-Lugo,[2] Roberto L. Collazo-Maldonado,[2] Edward A. Dominguez.[3] *[1]Methodist Dallas Medical Center, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX; [3]Methodist Transplant Physicians, Dallas, TX.*

Introduction: *Francisella novicida* is a gram negative coccobacilli that very rarely causes human illness. Its close relative *F. tularensisis* is well known for causing tularemia. Unlike *F. tularensis*, there have been no documented cases of *F. novicida* transmission to humans by through arthropod bites. All documented cases are associated with patients who are immunocompromised. Common clinical symptoms include fever, myalgias, lymphadenopathy, and pneumonia. *F. novicida* infection in humans is exceedingly rare and therefore often difficult to diagnose accurately. Only 11 cases of infection in humans have been documented.

Case Description: A 63-year-old AA woman with history of hypothyroidism and End Stage Kidney Disease on hemodialysis secondary to hypertension was admitted to the hospital for an elective kidney transplant. She underwent an en blocpediatric kidney transplant and received thymoglobulin induction due to the presence of a high cPRA of 91%. On post-op day 3 she developed hypoxemia with increased oxygen requirements and high-grade fever on post-op day 5. Chest CT showed diffuse bilateral patchy pulmonary infiltrates. Initial suspicion was volume overload or capillary leak syndrome due to thymoglobulin. However, oxygen requirements did not improve with ultrafiltration. Bronchoscopy with broncho alveolar lavage (BAL) was performed on post-op day 7. Initial blood cultures revealed gram negative coccobacilli. She was started on empiric meropenem, micafungin, and vancomycin which did not improve clinical status and Infectious Disease service added empiric fluoroquinolones. *Francisella novicida* was isolated in 2 sets of blood cultures and in BAL specimens. Final identification was performed at Centers for Disease Control and Prevention in Fort Collins, Colorado. The patient completed 14 days of fluoroquinolones and symptoms subsided. Kidney function improved and she is no longer on dialysis.

Discussion: Per our literature review, this is the first time that this bacteria has been isolated in a specimen other than blood or lymph node. Notably, there was an outbreak of *F. novicida* in a correctional facility in the patient's hometown in 2011. This case illustrates the value of a thorough history, the importance of interdisciplinary management, and the crucial role of early recognition of sepsis in solid organ transplant patients.

SA-PO1144

A Unique Case of Persistent Hypoxia in a Post-Kidney Transplant Patient due to Occlusion from Hemodialysis Reliable Outflow Graft Causing Right to Left Shunt

Michael Connery, Samer Kareem, Savneek S. Chugh. *Westchester Medical Center, White Plains, NY.*

Introduction: The Hemodialysis Reliable Outflow (HeRO) vascular access graft is a method of vascular access able to bypass a central venous occlusion. Cannulas within the superior vena cava (SVC) can lead to occlusion and syndromes such as SVC syndrome, subclavian steal and esophageal varices. We report a unique case of a chronically occluded HeRO graft in a renal transplant patient causing SVC occlusion leading to right to left shunting and hypoxia.

Case Description: A 56 year-old woman presented with worsening shortness of breath and documented hypoxia. She also had left arm weakness without swelling. She had a history of ESRD with HeRO graft which connected her left brachial artery to the left internal jugular vein and emptied into the IVC. It had not been used for 10 years since her first kidney transplant. The graft had occluded. A TTE with bubble study revealed bubbles in the left heart when injected in the left arm after Valsalva concerning for right to left shunt. Her HeRO graft was obstructing the SVC, left brachiocephalic vein (BCV), and left subclavian vein and she was found to have a persistent vein of Marshall with Cardinal vein extending from the mid portion of the BCV to the left superior pulmonary vein. The proximal section of the HeRO graft was removed and endarterectomy with patch angioplasty were performed on the BCV and SVC and the cardinal vein was ligated. After surgery her hypoxia had resolved.

Discussion: This is a case of a complication of long-term unused vascular access in a renal transplant recipient. Vascular occlusion is a common complication of indwelling catheters but can produce atypical symptoms. We have not been able to find any similar case studies of central occlusion induced hypoxia. This was a result of a shunt from abnormal vasculature that worsened with progressive obstruction of the left brachiocephalic vein. Removal of the offending catheter and ligation of the shunt cured the patient of her presenting symptoms. Detailed coordination between cardiology, vascular surgery, cardiothoracic surgery, and renal teams was vital for diagnosis and management.

SA-PO1145

Angiotensin II Type 1 Receptor Antibody (AT1-R Ab) Mediated Rejection in HLA-Incompatible Kidney Transplant Recipient

Yousuf Kyeso,[1] Sami Alasfar,[1] Amtul Aala.[2] *[1]Nephrology, Johns Hopkins Hopsital, Baltimore, MD; [2]Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Donor-specific antibodies (DSAs) create an immunologic barrier to transplantation. The IgG degrading enzyme derived from Streptococcus pyogenes (IdeS), an endopeptidase, cleaves human IgG into F(ab')2 and Fc fragments inhibiting complement-dependent cytotoxicity and antibody-dependent cellular cytotoxicity. We report unique case of non-HLA antibody mediated rejection in IdeS recipient

Case Description: A 40 years old male with history of ESRD due to IgA nephropathy who received IdeS as part of a phase 2 IRB approved trial in preparation for positive flow crossmatch deceased donor kidney transplant. Immediately post IdeS his crossmatch became negative. Patient also received IV alemtuzumab and rituximab for induction as part of the study protocol. One-week post-transplant, HLA-DSA rose to the cytotoxicity positive level and he was empirically treated for antibody mediated rejection with 11 sessions of plasmapheresis and intravenous immunoglobulin (IVIg). His HLA-DSA became flow negative. Maintenance immunosuppression included prednisone 5 mg daily, tacrolimus, and mycophenolate mofetil 1-gram BID. Six months later, laboratory data revealed an increase in serum Cr from 1.0 to 1.4 mg/dL and HLA-DSA remained flow negative. Further histocompatibility testing showed increase in pre-transplant level of AT1-R Ab from 14 units/ml to > 40 units/ml (positive:>17 units/ml). Kidney pathology detected chronic active antibody mediated rejection. Patient was immediately started on IV solumedrol and losartan 50 mg daily, he also finished 5 sessions of plasmapheresis and IVIg. One week later, serum Cr trended down to 1.0 mg/dL and AT1-R Ab level dramatically improved to 10 units/ml.

Discussion: Although reduction of HLA-DSA with therapies such IdeS has allowed successful transplantation in highly sensitized patients, screening and surveillance for non-HLA antibodies such as AT1-R antibodies may be required in this high-risk population to prevent antibody mediated rejection

SA-PO1146

AT_1R and ETAR Antibodies, Proteinuria, and Renal Dysfunction in Pediatric Kidney Transplantation

Rim Elchaki,[1] Lucia Chen,[2] Patricia L. Weng,[1] Elaine F. Reed,[2] Eileen W. Tsai,[1,3] Robert B. Ettenger,[1] Meghan Pearl.[1] *[1]Mattel Children's Hospital at UCLA, Los Angeles, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]Duke University, Durham, NC.*

Background: Activating autoantibodies to Angiotensin II Type 1 Receptor (AT_1R) and Endothelin type A receptor (ETAR) are non-HLA antibodies which have been associated with poor kidney allograft outcomes. However, the association of these antibodies with proteinuria and renal dysfunction is unknown. We aimed to determine the association of AT_1R and ETAR antibodies (Ab) with proteinuria and renal allograft function in pediatric kidney recipients (KTRs).

Methods: 65 pediatric KTRs were monitored for 2 years after transplantation. ETAR-Ab and AT_1R-Ab (ELISA) were measured at 6 months (m), 12m, and 24m post-transplant and during episodes of rejection. Based on a receiver operating curve analysis, > 10 and >17 units/ml was considered positive for ETAR-Ab and AT_1R-Ab respectively. Renal function (updated Schwartz Equation) and proteinuria were also assessed at the above noted time points. Proteinuria was defined as ≥1+ (30-100 mg/dl) on urinalysis. Samples were excluded for factors that may result in false positives including high specific gravity ≥1.030, alkaline PH (≥8.5) and gross hematuria (n=3).

Results: AT_1R-Ab and ETAR-Ab were positive in 38 (58%) and 24 (37%) of patients during the first 24m post-transplant respectively. Proteinuria was present in 84 of 323 urinalysis samples (26%) with 44 patients (68%) positive during the first 24m post-transplant. We found that patients with both AT_1R -Ab and proteinuria had greater declines in renal function than patients with either predictor alone (p=0.004, Figure 1a). This relationship was also observed in patients with ETAR-Ab and proteinuria (p =0.018, Figure 1b).

Conclusions: Pediatric KTRs with AT_1R-Ab, ETAR-Ab, and proteinuria have greater declines in kidney function in the first 24m post-transplantation. This association highlights the potential detrimental effects of non-HLA antibodies on the renal allograft in the pediatric population.

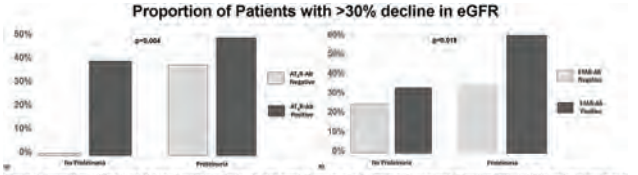

Figure 1: Proportion of Pediatric Kidney Transplant Patients with >30% Decrease in Estimated Glomerular Filtration Rate (eGFR) by Proteinuria and Non-HLA Antibody Status. In patients both with and without proteinuria, patients with AT1R-Ab (a) and ETAR-Ab (b) had greater declines in eGFR measured from their baseline from discharge to their lowest over the 24 month follow up period than patients without non-HLA antibodies.

SA-PO1147

Impact of Persistent and Transient Donor-Specific Antibodies Within First Year After Kidney Transplantation

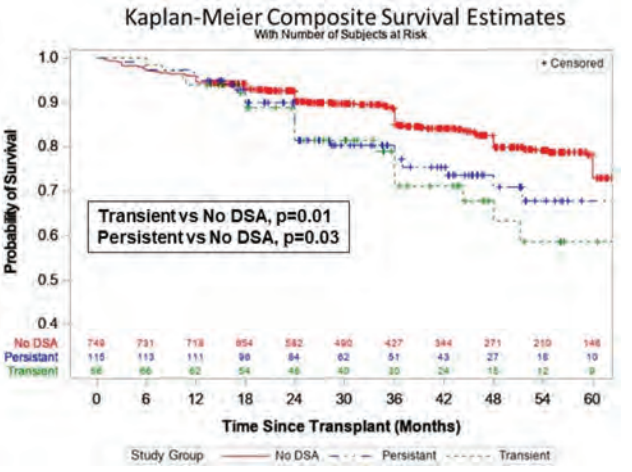
Akhil Sharma,[1,2] Dana R. Jorgensen,[2] Sundaram Hariharan.[2] *[1]Department of Medicine, Renal Electrolyte Division, University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: The importance of Donor Specific Antibody (DSA) surveillance within 1st year (yr) post kidney transplant remains unclear. We studied the impact of DSA pattern during the 1st yr post-txp on clinical outcomes.

Methods: 931 patients (pts) from 2013-17 were enrolled (HLA Compatible, Flow xmatch negative). Pts were grouped into Transient DSA (T-DSA, n=66; 1 positive test, Class I/II), Persistent DSA (P-DSA, n=115, >1 positive test, Class I/II), and No DSA (N-DSA, n=750) within 1st yr post-txp. DSA testing was done @ 1,3,6,9, & 12 mos. Biopsies (protocol 3&12 mos, & indication) were included. Surrogate marker for this study included incidences of TCMR and ABMR. Outcomes measured were pt survival, graft survival and composite of pt loss, graft loss and eGFR <20ml/min at last follow-up.

Results: During the 1st yr, DSA was detected in 19% of pts (7% T-DSA vs 12% P-DSA). There were no differences in baseline or txp characteristics, other than increased sensitization (cPRA>20%) in P-DSA pts (67% vs 47%, p=0.001). P-DSA pts developed DSA earlier for Class I (75±136 vs 121±132 days, p=0.03) and II (83±141 vs 192±185 days, p<0.001), when compared to T-DSA pts. After 1 yr, DSA detection was far less in N-DSA pts (Class I/II 4/8%) than in T-DSA (Class I/II 53/62%, p<0.001) or P-DSA (Class I/II 64/69%, p<0.001) pts. P-DSA pts experienced more clinical TCMR (14 vs 8%, p=0.04), ABMR (12 vs 0.8%, p<0.001), & less normal biopsies (4 vs 11%, p=0.02) than N-DSA pts, and more ABMR than T-DSA pts (12 vs 0%, p=0.003). There were no differences in sub-clinical TCMR/inflammation, tacrolimus levels, renal function, pt survival, or death censored graft survival among all groups. However, lower composite outcome was noted with T & P-DSA pts (Figure 1).

Conclusions: Persistent and Transient DSA within 1 yr had similar outcomes and lower composite outcome when compared to No DSA pts. Thus, detection of DSA within 1 yr, whether Persistent or Transient, is detrimental to renal allograft.



SA-PO1148

Impact of Treatment of Borderline Rejection on Subsequent T Cell-Mediated Rejection in Kidney Transplant Recipients

Kartik Kalra,[1] Ripudaman S. Munjal,[2] Srijan Tandukar,[1] Winn Cashion,[1] Itunu O. Owoyemi,[2] Puneet Sood,[2] Sundaram Hariharan,[1] Christine Wu,[2] Rajil B. Mehta.[1] *[1]Nephrology, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: The optimal management of borderline rejection (BR) seen in the early post-transplant period is unclear. Studies have shown that BR is associated with higher Subclinical or Clinical T-Cell Mediated Rejection (TCMR) within 1 year post-transplant. However, the role of steroids in attenuating this risk is unclear. We performed this study to evaluate the impact of treating BR with steroids on subsequent development of TCMR.

Methods: Adult kidney transplant recipients (N=183) with Subclinical or Clinical BR in the first 3 months post-transplant based on Banff 2005 criteria were divided into two groups: (i) No treatment group (N=143), and (ii) Steroid treatment group (N=40). We excluded prior TCMR, Antibody mediated rejection (AMR) and BK virus nephritis. All the patients with BR had their maintenance immunosuppression (MIS) optimized. All patients were induced with thymoglobulin (97%) or basiliximab (3%) and a rapid steroid taper over 5 days per protocol. Standard MIS was with tacrolimus and mycophenolate mofetil. Recipient, donor and transplant variables were similar between the groups. The subsequent development of subclinical and clinical TCMR over the course of the first year was followed.

Results: Refer to Results Table

Conclusions: Treatment of BR in early post-transplant period with steroids was not associated with lower rates of TCMR at 1-year post transplant. However, steroid dose varied in our study from 1 to 3 doses of methyprednisolone. Further studies with uniform dosing of steroids are required to establish definite treatment strategies for BR.

Results

	T Cell Mediated Rejection (Clinical or Sub Clinical)		Total	p-value
Treatment with Steroids	Yes	No		
Yes	10	29	39	0.52
No	30	114	144	
Total	40	143	183	

SA-PO1149

Phenotype of CD8 T Cells in Determining Risk of Acute Rejection in Kidney Transplant on Belatacept Regimen

Jun Shoji, Flavio Vincenti. *University of California San Francisco, San Francisco, CA.*

Background: Belatacept is a costimulatory blocker that is used as de novo maintenance immunosuppression in kidney transplantation. However, patients maintained on belatacept, mycophenolate, and corticosteroids have been noted to have more frequent and severe acute rejection than in calcineurin inhibitors. Experimental studies have shown synergy between costimulatory blockade and mTOR inhibitors. We investigated pretransplant recipient immune profiles to determine which subset of lymphocytes can predict acute rejection in patient on belatacept-based regimen.

Methods: We prospectively enrolled 65 kidney transplant recipients (31 deceased; 34 living donors) at our center to receive denovo belatacept from September 2012 to June 2018. PBMCs were collected prior to transplantation and at the time of biopsies. All patients received thymoglobulin for induction (3mg/kg divided into 2 doses) with belatacept 10mg/kg administered on POD 1, 4, 14, 28, 56, and 84. Monthly maintenance dose of 5mg/kg was given starting week 16. Patients were started initially on MPA but were converted to everolimus after 1 month, and all patients were maintained on prednisone.

Results: 16.9% developed acute rejection within the first year post transplant: 2 with ACR 1a, 1 with ACR 2a, 6 with ACR 2b, 1 with AMR, and 1 with simultaneous ACR 1a and AMR. All 11 rejections occurred in those who were on MPA and not on

mTORi. 12 patients were found to have borderline rejection on protocol biopsies (7 on mTORi, 5 on MPA). 42 patients did not have any inflammation on biopsies. 57 patients remained on belatacept, and 8 were converted to tacrolimus. Patients who had biopsy-proven rejection or borderline changes had significantly higher %$CD8^+$ $CD28^-$ T cells, and those who had rejection with low %CD8+CD28- were found to have high $CD2^{hi}$ $CD28^{hi}$ in CD8+CD45RO+ T cells. Belatacept patients receiving everolimus had more stable TIGIT expression on regulatory T cells.

Conclusions: This trial of combining belatacept with mTORi shows that it is possible to reduce the rate of acute rejection in belatacept-based regimens. The synergy between mTORi and belatacept may be related to mTORi's inhibitory effect on memory CD8+CD28-CD38+ cells that are refractory to costimulatory blockade. Pretransplant immunotyping to identify those with low percentage of CD8+CD28- & $CD2^{hi}$ $CD28^{hi}$ in CD8+CD45RO+ may reduce the risk of rejection on belatacept.

SA-PO1150

Use of Antithymocyte Globulins (ATG) to Treat Rejection in Kidney Transplantation Is Associated with Increased Risk of Viral Infections and with Increased Risk of Death in Older Patients

Caroline Dudreuilh,[1] Abigail Walker-Jacobs,[1] Linda J. Ross,[3] Dimitrios Anestis Moutzouris.[2] *[1]King's College London, London, United Kingdom; [2]Renal, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [3]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.*

Background: ATG is used to treat steroid-resistant T-cellular mediated rejection, vascular rejection and mixed rejection in kidney transplant recipients. Most of the studies which examined the efficacy and the safety of ATG did not include patients on modern immunosuppression regimes. In addition, they did not examine in detail the side effects of this potent treatment.

Methods: We studied the long-term efficacy and side effects of ATG in renal transplant recipients, who were treated with ATG between 2011-2018. We analysed the demographics, the types and rates of infection and cancer, the readmissions, the graft and patient survival.

Results: 87 (56 males) patients were treated with ATG in the study period. The mean age was 45 ± 13.5 years. The follow-up was 50.4 ± 36 months. The ATG was effective in treating rejection in 57 patients (66%). However, 49 patients (56%) developed bacterial and viral infections after ATG use with 20 (23%) patients developing severe infections (including 3 fungal infections and 1 mycobacterium infection). 40 patients (46%) were readmitted at least once for complications related to ATG. 5 (6%) patients developed cancer and 13 patients died during the study period. The patients who died were older when treated with ATG (p=0.34). In logistic regression, death was associated with age at treatment (p=0.042) but not with the ATG dose, the gender or history of previous transplant. There was no difference between the age (p=0.58) and the dose of ATG (p=0.09) among patients who were readmitted for ATG related complications and those who did not. The total dose of ATG was associated with increased risk of viral infections (p=0.027). This remained significant in logistic regression (p=0.033)

Conclusions: ATG is an effective treatment for rejection in kidney transplantation. However, it seems that it is associated with an increased risk of viral infections. In our cohort, older patients treated with ATG were at higher risk of death. This asssociation will be investigated further.

SA-PO1151

Preformed Donor-Specific Antibodies in Complement-Dependent Cytotoxic Cross Match Negative Living Unrelated Male-to-Female Spousal Kidney Transplantations Are Associated with an Increased Risk of Acute Antibody-Mediated Rejection

Koen Groeneweg, Frederique A. Van der toorn, Frans Claas, Marlies Reinders, Johan W. De Fijter, Darius Soonawala. *Leiden University Medical Center, Leiden, Netherlands.*

Background: Shortage of deceased donor kidneys has led to increased numbers of living unrelated kidney, in particular spousal, donors. Female recipients of a spousal kidney have an increased risk for pre-immunization and acute antibody-mediated rejection (ABMR). The aim of this study is to assess the incidence of ABMR and preformed donor specific antibodies (pDSA) in living unrelated donors (LURD) and to identify risk factors for acute ABMR.

Methods: We identified all 349 ABO compatible, CDC-crossmatch negative, LURD transplants performed at our transplant center between 1997 and 2015. All for-cause biopsies were classified according to the BANFF 2017 classification. All patients with ABMR were retrospectively tested for the presence of pDSA with multiplex and single antigen tests (Luminexâ). Risk factors for immunization were extracted from personal health records and questionnaires.

Results: The overall incidence of biopsy-proven acute rejection in the first 6 months was 20% (TCMR: 85%; ABMR: 15%); median time to onset of ABMR was 8 days (range 5-75 days). Outcome was poor in ABMR as compared with patients with TCMR or those w/o rejection (graft loss or eGFR <30ml/min at month-6: 36%, 12% and 2% respectively). Eight patients with ABMR were female (73%) and six of these (75%) were recipients of a spousal kidney. Of these spouses four had given birth to a child of their kidney donor and 2 received blood transfusions prior to transplantation. Retrospectively 80% of spousal recipients with ABMR had pDSA in the multiplex or single antigen test.

Conclusions: Female spousal kidney recipients have a relatively high risk of ABMR. Traditional methods for detecting pDSA are not sensitive enough to rule out pDSA. Multiplex and single antigen should be included in the standard work-up of potential female spousal kidney transplant recipients to prevent ABMR and guide the option of indirect (cross-over) donation.

SA-PO1152

Clinical Significance of Pretransplant Donor-Specific HLA Antibodies in Kidney Transplant Recipients of Hispanic Population

Idalia P. Avila, Luis E. Morales-Buenrostro, Abraham Cohen-Bucay, Silvia Ramirez. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.*

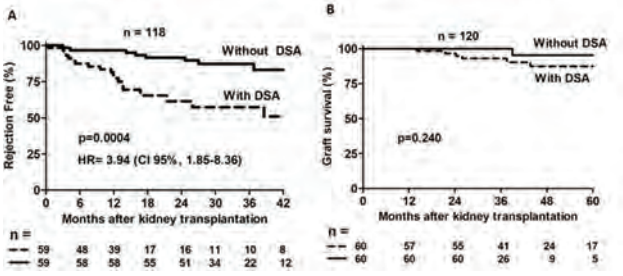
Background: Donor-specific HLA antibodies (DSA) before kidney transplantation (KT) is one of the major risk factors for humoral rejection and lower graft survival. In order to identify prognostic factors and develop follow up strategies in this high risk population, it is required for transplant center to share their outcome data.

Methods: Retrospective cohort and comparative study in KT recipients with pretransplant DSA measured by solid phase assays (Luminex), negative AHG-CDC-XM (living and deceased donor) and negative flow cross match (living donor). Our main objective was to determine graft survival and describe the incidence of acute rejection (AR) and renal function (eGFR by CKD-EPI).

Results: We identified 60 patients with pretransplant DSA and paired them based on donor type, induction therapy and maintenance immunosuppression to 60 KT recipients that did not have pretransplant DSA. The incidence of AR was higher in the pretransplant DSA group (35.5% vs. 15.2%, p=0.011) and the median time between KT and AR episodes was shorter in the pretransplant DSA group [12.8 (8.3-23.6) *vs* 32.1 (25.9-40.6) months, (p<0.0001)]. After 37.4 (range 29.2-52.3) months of follow up, eGFR was similar between groups [65.0 ± 22.0 vs 69.8 ± 21.4 ml/min/1.73m^2 (p=0.19)] and there was no difference in graft survival (87.7% vs 96.7% p=0.240) between groups with and without pretransplant DSA, respectively.

Conclusions: Although there is a higher incidence of rejection, KT recipients with pretransplant DSA had similar eGFR and graft survival. Therefore, this group of higher immunological risk could still be considered candidates for KT. One limitation of this study is the small sample size and short follow-up time. However, we propose that induction therapy with lymphocyte depleting agents and powerful maintenance immunosuppression, combined with follow-up strategies as protocol biopsies with early treatment of subclinical rejection could provide similar graft survival in KT recipients with and without pretransplant DSA.

Figure 1 Acute Rejection Free Survival (A) and Graft Survival (B) between KT recipients with pretransplant DSA and KT recipients without pretransplant DSA



SA-PO1153

Absence of Histologic Improvement Despite Reduction of Donor-Specific Antibodies with IVIG Treatment of Kidney Transplant Recipients

Stephanie Tsai,[1] Mohit Gupta,[1] Emmanuel Y. Edusei,[1] Vijay K. Sharma,[1] Jun B. Lee,[1] John R. Lee,[1] Thangamani Muthukumar,[1] Matthew Everly,[2] Darshana Dadhania.[1] *[1]Weill Cornell Medicine, Richmond, TX; [2]Terasaki Research Institute, Los Angeles, CA.*

Background: Donor-specific antibodies to donor HLA (DSA) are associated with higher incidence of antibody-mediated rejection and graft loss. Intravenous immunoglobulin (IVIG) exerts immunomodulatory effects in both humoral and cellular pathways. We examined the impact of IVIG therapy on circulating DSA, graft histology, and graft function.

Methods: 18 kidney transplant recipients with DSA maximum fluorescence intensity (MFI) ≥1000 treated with IVIG 1g/kg every 2 weeks x 6 months and a control cohort of 13 recipients with DSA managed as per physician preference were analyzed. In the IVIG-treated cohort, responders were defined by ≥50% reduction in DSA MFI-Sum at 18 months after start of IVIG. Baseline characteristics and graft function were compared between IVIG and control cohort.

Results: While there was no significant difference in baseline eGFR between groups, there was a significant decrease in eGFR in the control group at 18 months (Figure 1), and 23% of the control group had graft loss, compared to 0% in the treatment group. Ten recipients in the IVIG cohort met the definition of "responder." There were no significant differences in graft function between responders and non-responders at start of IVIG or at 18 months post-treatment (Table 1). There was no change in pre- and post-IVIG histologic Banff scores in both responders and non-responders (Figure 2a and 2b).

Conclusions: IVIG therapy is associated with DSA reduction and stabilization of renal allograft function in some patients. However, despite significant reduction in DSA,

there was no change in histologic parameters after IVIG therapy. Prospective randomized controlled trials with longer-term follow-up are needed to evaluate the beneficial impact of IVIG.

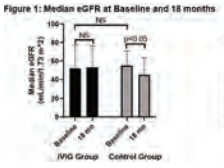


Table 1: Clinical Parameters of Responders and Non-Responders

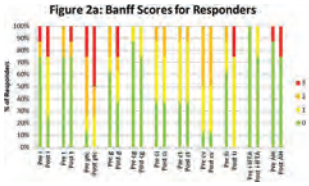
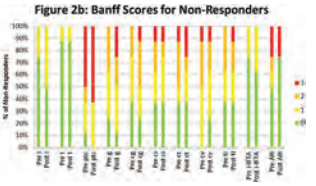
	Responders (n=10)	Non-Responders (n=8)	p-value
Creatinine at start of IVIG, median (IQR)	1.18 (0.87-1.53)	1.70 (1.04-2.09)	0.24
Creatinine at 18 months post-IVIG, median (IQR)	1.16 (0.88-1.63)	1.92 (1.05-2.22)	0.35
eGFR at start of IVIG, median (IQR)	57.5 (47.3-79.7)	48.0 (38.4-74.6)	0.41
eGFR at 18 months post-IVIG, median (IQR)	53.7 (43.7-82.1)	52.4 (33.8-72.9)	0.51
MALIS/Cr at start of IVIG, median (IQR)	97.4 (8.4-340.7)	75.5 (10.1-80.4)	0.50
MALIS/Cr at 18 months post-IVIG, median (IQR)	102.8 (3.7-324.7)	48.9 (37.2-68.4)	0.64





SA-PO1154

Quantitative Assessment of Active and Chronic Lesions in Renal Allograft Biopsies to Improve Reproducibility, Clinical Correlations, and Outcome Prediction

Marco Delsante,[1] Ilaria Gandolfini,[1] S.M. Bagnasco,[2] Umberto Maggiore,[1] Enrico Fiaccadori,[1] Avi Z. Rosenberg.[2] *[1]Medicina e Chirurgia, Università di Parma, Parma, Italy; [2]Johns Hopkins University, Baltimore, MD.*

Background: Banff classification system is based on recognition and scoring of descriptive lesions allowing for pathogenetic classification of rejection. Although expert pathologists readily recognize these lesions, the routine semi-quantitative Banff scoring can be poorly reproducible. Specific immunohistochemical (IHC) stains and new imaging techniques can allow for more precise quantification of tubulitis, interstitial fibrosis (IF) and microvascular inflammation (MVI) (Delsante,TI,2018).

Methods: Tubulitis: we included 12 transplant biopsies of CMR, borderline and no rejection from Parma Hospital (Italy). Analysis of whole slide images of CD3+PAS IHC stained sections allowed for continuous scoring of tubulitis, and results were correlated with urinary CXCL9 levels (a biomarker of cell-mediated rejection). IF: Measuring second harmonic generation (SHG) signal on FFPE unstained kidney section, we assessed collagen deposition in 57 kidney transplant biopsies (Johns Hopkins Hospital-JHH). MVI was quantified in 75 biopsies from JHH using a dual IHC stain (CD34-endothelium and CD45-leukocytes); quantitative scores of peritubular capillaritis and glomerulitis were correlated with donor specific antibodies (DSA) levels and graft outcome

Results: Tubulitis quantitative scores showed significant correlation with urinary CXCL9 levels in patients with histological diagnosis of CMR, borderline lesions or no significant tubular inflammation: mean CD3+ cell per tubule (r2 0.75), tubulitis ratio (r2 0.66) and CD3+ cells is most inflamed tubule (r2 0.70). Measurement of interstitial collagen deposition using SHG outperformed standard Banff score in predicting graft failure hazard(increase 3.87 times per 2SD unit increase of SHG density, 95%CI 1.06-14.16). The use of CD34-CD45 dual stain increased interobserver reproducibility of Banff ptc score and significantly correlated with serum DSA levels and risk of graft loss. In the same cohort, glomerulitis scores showed no correlation with DSA/allograft outcome.

Conclusions: For selected Banff lesions (ptc, t and ci/ct) quantitative measurements can increase clinical correlation compared to semi-quantitative scoring. Quantitative methods are being studied in larger cohorts to confirm clinical and prognostic significance.

SA-PO1155

Significance of Revised Diagnosis for Chronic Active T Cell-Mediated Rejection in 2017 Banff Criteria: Surveillance of 1-Year Screening Biopsy in Kidney Transplantation

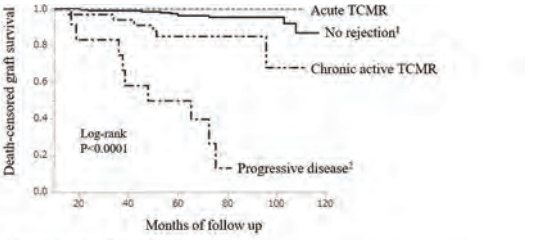
Kaneyasu Nakagawa,[1] Akihiro Tsuchimoto,[1] Kenji Ueki,[1] Yuta Matsukuma,[1] Yasuhiro Okabe,[1] Kosuke Masutani,[2] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Kyushu University, Fukuoka, Japan; [2]Fukuoka University, Fukuoka, Japan.*

Background: The diagnosis criteria of chronic active T-cell mediated rejection (TCMR) was revised in Banff 2017 consensus, but the association between the diagnosis of chronic active TCMR at 1-year screening biopsy (SB) and long-term graft prognosis of kidney transplantation has not been reported.

Methods: In this single-center retrospective study, we extracted kidney transplant recipients from 2009 to 2013 who underwent 1-year SB. All the 1-year SB were re-evaluated according to the Banff classification revised in 2017. The primary endpoint was defined as a doubling of creatinine based on values at 1-year after kidney transplantation or graft loss. Death with graft function was censored. The impact of the diagnosis of chronic active TCMR was examined using a Cox regression model.

Results: Among a total of 258 patients who underwent 1-year SB (male of 58% and median age [interquartile range] of 46 [35-56]), 32 patients were re-classified to chronic active TCMR. They were previously diagnosed as normal (n=3), acute TCMR (n=17), and borderline changes (n=12). During the median follow-up period of 6.4 years, 25 patients, including six patients with chronic active TCMR, reached the endpoint. In the multivariate analysis, chronic active TCMR was associated with a higher risk of graft failure compared with no rejection (hazard ratio 2.93; 95% confidence interval, 1.02-8.41: P=0.045).

Conclusions: The chronic active TCMR diagnosis revised in Banff 2017 consensus may be useful for prognostic prediction and may help detect unfortunate prognosis cases in kidney transplant patients who underwent 1-year SB.



[1]No rejection included normal and borderline changes.
[2]Progressive disease included antibody-mediated rejection, glomerulonephritis, and BK virus-associated nephropathy.

Treatment of C3 Glomerulopathy in Kidney Transplant Recipients: A Meta-Analysis

Maria Lourdes Gonzalez Suarez,[1] Charat Thongprayoon,[2] Michael A. Mao,[2] Wisit Cheungpasitporn.[1] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Mayo Clinic, Rochester, MN.*

Background: C3 glomerulopathy (C3G), a rare glomerular disease mediated by alternative complement pathway dysregulation, is associated with a high rate of recurrence and graft loss after kidney transplantation (KTx). We aimed to assess the efficacy of different treatments for C3G recurrence after KTx.

Methods: Databases (MEDLINE, EMBASE, and Cochrane Database) were searched from inception through 05/03/2019. Studies that reported outcomes of adult KTx recipients with C3G were included. Effect estimates from individual studies were extracted and combined using random-effects. Protocol for this meta-analysis was registered with PROSPERO (no. CRD42019125718).

Results: Twelve studies (7 cohort studies and 5 case series) consisting of 122 KTx patients with C3G (73 C3GN and 49 DDD) were included. The pooled estimated rates of allograft loss among KTx patients with C3G were 33% (95%CI: 12%-57%) after eculizumab, 42% (95%CI: 2%-89%) after therapeutic plasma exchange (TPE), and 81% (95%CI: 50%-100%) after rituximab. Subgroup analysis based on type of C3G was performed. Pooled estimated rates of allograft loss in C3GN KTx patients were 22% (95%CI: 5%-46%) after eculizumab, 56% (95%CI: 6%-100%) after TPE, and 70% (95%CI: 24%-100%) after rituximab. Data on allograft loss in DDD KTx patients after different treatment modalities were limited (1 cohort and 1 case series, 4/6 (67%) after eculizumab, TPE (1 case series, 0/2 (0%) at 6 months) and rituximab (1 cohort, 3/3 (100%) allograft loss). Among 66 patients (38 C3GN, 28 DDD) who receive no treatment (likely due to stable allograft function at presentation and/or clinical judgment of physicians), pooled estimated rates of allograft loss were 32% (95%CI: 7%-64%) and 53% (95%CI: 28%-77%) for C3GN and DDD, respectively. Among treated C3G patients, data on sMAC were limited to patients treated with eculizumab. 80% patients with elevated sMAC before eculizumab responded to treatment. In addition, all patients who responded to eculizumab had normal sMAC level after post-eculizumab.

Conclusions: Our study suggests that KTX patients with C3G treated with eculizumab had the lowest incidence of allograft loss (33%) when compared to those treated with TPE or rituximab. Among those who received no treatment for C3G due to stable allograft function, there is an incidence of allograft loss of 33% in C3GN and 53% in DDD.

SA-PO1157

Recurrence of Focal Segmental Glomerulosclerosis After Kidney Transplantation in an International, Multicenter Cohort from the TANGO Study

Audrey Uffing,[1,2] Paolo Cravedi,[4] Leonardo V. Riella.[3] TANGO-consortium *[1]Brigham and Women's hospital, Boston, MA; [2]Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands; [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Focal segmental glomerulosclerosis (FSGS) recurrence after kidney transplantation is a major risk factor for graft loss. However, the natural history, clinical predictors, and response to treatment remain unclear due to small sample sizes and poor generalizability of single center studies, and disease misclassification in registry-based studies.

Methods: As part of The Post-Transplant Glomerular Disease (TANGO) project, we performed a multicenter, international, retrospective observational study to determine the incidence, predictors and treatment response of recurrent FSGS.

Results: Amongst 11,742 kidney transplant recipients screened for FSGS between 2005-2015, 176 had idiopathic FSGS. FSGS recurred in 57 patients (32%, 95%CI: 25-39%) and 39% of them lost their graft over a median (IQR) of 5 (3.0-8.1) years (Figure 1). Multivariate Cox-regression revealed an increased risk for recurrence with older age at native kidney disease onset (HR 1.37 per decade, 95%CI: 1.09-1.56). Other predictors were white race (HR 2.14, 95%CI: 1.08-4.22), BMI at transplant

(HR 0.89 per Kg/m^2, 95%CI: 0.83-0.95), and native kidney nephrectomies (HR 2.76, 95%CI: 1.16-6.57). Loss of prior allografts due to FSGS increased the chances of a subsequent recurrence with 45% in a second graft and 100% in a third graft. Plasmapheresis and rituximab were the most frequent treatments (81%). Partial or complete remission occurred in 57% of patients and was associated with better graft survival.

Conclusions: Idiopathic FSGS recurs post-transplant in one-third of cases, increasing by 5-fold the risk of graft loss. Response to treatment significantly improves outcomes but is achieved in only half of cases. Multicenter collaborative efforts such as TANGO allow for the identification of novel risk factors for FSGS recurrence as well as for more precise estimates of recurrence incidence and outcomes.

Funding: Private Foundation Support

Precise Clinicopathologic Findings May Increase the Detection Rate of Gene Mutations in Pediatric Kidney Transplant Recipients with Focal Segmental Glomerulosclerosis

Naoto Kaneko,[1] Kenichiro Miura,[1] Taro Ando,[1] Takaya Iida,[1] Atsutoshi Shiratori,[1] Yoko Shirai,[1] Sho Ishiwa,[1] Tomoo Yabuuchi,[1] Taeko Hashimoto,[2] Kiyonobu Ishizuka,[1] Hidenori Sato,[3] Yutaka Harita,[4] Motoshi Hattori.[1] *[1]Tokyo Women's Medical University, Shinjuku-Ku, Japan; [2]Yamagata University, Yamagata-city, Japan; [3]Yamagata University Faculty of Medicine, Yamagata, Japan; [4]Dept. of Pediatrics, Tokyo University, Tokyo, Japan.*

Background: Whole exome sequencing (WES) has enabled precision medicine in kidney transplant recipients with focal segmental glomerulosclerosis (FSGS), because individuals with a monogenic cause have a very low expectancy of posttransplant recurrence. However, it remains unknown whether all recipients with FSGS should undergo genetic testing. Here, we investigated the likelihood of detecting pathogenic mutations in recipients with FSGS divided into subgroups based on clinicopathologic findings.

Methods: Nineteen pediatric transplant recipients with FSGS were recruited and classified based on their clinical and pathologic findings. Adaptive, drug-induced and virus-associated FSGS were classified as secondary FSGS. Patients with family history of FSGS or extrarenal manifestations were classified as familial/syndromic FSGS. Patients who showed nephrotic syndrome (NS) and diffuse foot process effacement (FPE) in their native kidneys or had a history of recurrence in a previous transplantation were classified as presumed primary FSGS. We performed WES and examined a subset of 114 genes associated with FSGS in all patients.

Results: The results of classification and genetic testing are shown in Figure. WES revealed that 0 (0%) of 8 patients with presumed primary FSGS and 10 (91%) of the other 11 patients carried gene mutations known to cause FSGS. Three of 8 (38%) patients with presumed primary FSGS had posttransplant recurrence, while no recurrence was observed in the other patients.

Conclusions: The detection rate of pathogenic mutations known to cause FSGS was very high in the kidney transplant recipients after excluding individuals with secondary and presumed primary forms based on our precise clinicopathologic findings such as family history, extrarenal manifestations, NS and diffuse FPE.

Attitudes to Clinical Pig Kidney Xenotransplantation Among Medical Providers and Patients

Luz A. Padilla,[2] Vineeta Kumar,[2] David K. Cooper,[2] Wayne Paris.[1] *[1]Abilene Christian University, Abilene, TX; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: In addition to governmental regulation and scientific expertise, the World Health Organization requires an extensive review of local opinions and attitudes prior to xenotransplantation (XTx) clinical trials. The current work will report the initial-phase of a multi-level public data collection process in preparation for clinical trials.

Methods: After university Institutional Review Board (IRB) approval, an anonymous online survey was emailed about attitudes towards XTx to medical center nephrologists, transplant surgeons, and nurses ("providers"). Pre and post-kidney transplant patients were randomly approached in the transplant clinic ("patients"). Both groups were requested to complete a 16-item likert scale survey with identical content. A total of 40 providers (51%; 40/78) and 163 patients (85%; 163/192) participated. Data were analyzed via SAS software.

Results: Eighty percent (32/40) of providers and 69% (113/163) of patients were agreeable to clinical XTx. Kidney providers rated the influence of religious beliefs (45%vs15%) and genetic engineering (43%vs25%) as being more important than patients ($p<0.05$). If risks and results were likely to be similar to kidney allotransplantation, providers were more supportive of XTx than patients (80%vs69%; $p<0.05$). If the results were likely to be less beneficial, patients were more likely to accept XTx as a bridge to allotransplantation (41%vs30%; NS). Both groups included <15% who identified concerns about (i) potential change in personality, (ii) how others would interact, (iii) a perception of being 'less human', or (iv) moral or ethical concerns. Logistic regression found that the odds of patients accepting XTx are 25 times greater if there are no religious concerns, and 82% more likely if it is a bridge to allotransplantation.

Conclusions: (i) There was strong support for XTx among both health providers and patients; (ii) providers over-estimated the influence of religious beliefs and genetic engineering on patient decisions, although religious beliefs still influenced patient attitudes; (iii) patient acceptance of XTx was not associated with likely medical outcome, per se; and (iv) there were few psychosocial concerns for either group. Overall, our findings would suggest that there is support for future clinical trials of XTx.

SA-PO1160

Outcome of ABO Incompatible Kidney Transplantation: With and Without Anti-CD20 Antibody Use

Amit Sharma, Harinder J. Gill. *Department of Renal Sciences (Nephrology, Dialysis, and Kidney Transplant), Fortis Hospital, Mohali, India.*

Background: ABO-incompatible (ABOi) kidney transplants help in crossing an important immunological barrier against kidney transplantation. The study was conducted to assess the feasibility of performing ABOi kidney transplants without the use of Anti CD20 antibody and comparison of their outcomes with ABOi kidney transplants using Anti CD20 antibody.

Methods: The study, conducted between April 2014 and March 2019, included 54 live donor ABOi transplant recipients. They were divided into two groups based on using rituximab ABOiR$^+$ (n=21) or without rituximab ABOiR$^-$ (n=33). All Patients were started on Tacrolimus, Mycophenolate mofetil and Prednisolone 10 days prior to tentative date of transplant. In addition, ABOiR$^+$ group received Injection Rituximab 200 mg. Plasmapheresis was done and low dose intravenous immunoglobulin (100 mg/kg) given until an acceptable isoagglutinin titer (1:4) was obtained on the date of transplantation. All patients received induction immunosuppression: Thymoglobulin (1 mg/kg/day for 3 days). **Main Outcome Measures:** Patient and allograft survival; 1-, 3-, 6-, 12-, and 18-month renal function; infectious complications; and incidence of rejection.

Results: 19.04% of the ABOiR$^+$ recipients and 30.3% of ABOiR$^-$ recipients were females. Median isoagglutinin titer at start was 1:32 (1:1 to 1:256) in ABOiR$^-$ group and 1:8 (1:1 to 1:256) in ABOiR$^+$ group. Mean number of plasmapheresis required were 3 in ABOiR$^-$ group and 2 in ABOiR$^+$ group. There was no significant difference between the post transplant serum creatinine in the two groups. In the ABOiR$^-$ group, there were 6 episodes of biopsy proven acute antibody mediated rejection (AMR) and 1 patient had acute cellular rejection (ACR). 1 episode each of AMR and ACR was observed in the ABOiR$^+$ group. Two patients succumbed to fungal sepsis in the ABOiR$^-$ group while three patients died of pneumonia in ABOiR$^+$ group.

Conclusions: This study suggests that with the use of Anti-CD20 treatment, successful ABOi transplantation is possible with lower incidence of AMR but is associated with increased incidence of sepsis.

Table 1: Patient characteristics of ABO incompatible transplant with rituximab use (ABOiR+) and without rituximab use (ABOiR-) groups

		ABOiR+ (n=21)	ABOiR- (n= 33)
Donor	Age (Mean ± SD) in years	49.23±8.48	47.12±12.15
	Females	76.19%	51.51%
Recipient	Age (Mean ± SD) in years	49.23±12.63	42.93±11.71
	Females	19.04%	30.30%
Serum Creatinine (Mean ± SD) in mg%	At discharge	1.18±0.29	1.39±0.59
	At 1 month	1.13±0.30	1.37±0.41
	At 3 months	1.16±0.36	1.27±0.33
	At 6 months	1.22±0.41	1.29±0.36
	At 9 months	1.26±0.51	1.29±0.34
	At 12 months	1.23±0.61	1.29±0.31
	At 18 months	1.31±0.88	1.30±0.36
Graft survival at 1 year		78.57% (n=14)	84.84% (n=33)
Patient survival at 1 year		78.57% (n=14)	84.84% (n=33)
Rejection episodes	AMR	4.76%	18.18%
	ACR	4.76%	3.03%
Infections	UTI in first 12 weeks	4.76%	3.03%
	Fungal septicemia	4.76%	6.06%
	Pneumonia	14.28%	0%

Outcomes of Different Induction Therapies in ABO-Incompatible Renal Transplant Recipients in the Tacrolimus Era

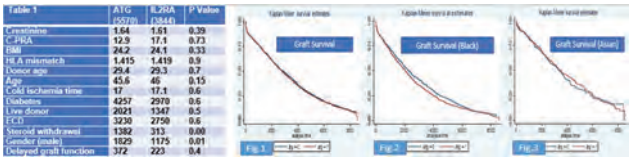
Karim M. Soliman,[1] Ahmed Daoud,[4] Hatem Ali,[2] Vinaya Rao,[5] Tibor Fulop,[1] Ingi Elsayed.[3] *[1]Medical University of South Carolina, Charleston, SC; [2]Heartlands hospital, Birmingham, United Kingdom; [3]university hospitals of north midlands, Stoke-on-trent, United Kingdom; [4]Cairo University, Cairo, Egypt; [5]MUSC Transplant Center, Charleston, SC.*

Background: ABO-incompatible renal transplantation is emerging as a safe and potentially acceptable routine procedure; however, outcomes of different induction therapies in ABO-incompatible renal transplant recipients (RTRs) remain insufficiently explored in the tacrolimus era.

Methods: Using data from organ procurement and transplantation network, all ABO-incompatible RTRs maintained on tacrolimus based immunotherapy between 2000 and 2017 were retrospectively reviewed. Data including age, sex, gender, ethnicity, functional status, diabetes, body mass index, cold ischemia time, number of previous transplants, panel reactive antibodies, donor type, donor age, HLA-mismatches, number of acute rejection episodes, induction therapies, maintenance immunotherapy, recipients and graft survival were collected (Table 1). Based on induction therapies administered, RTRs were divided into 2 groups; anti-thymocyte globulin (ATG) or interleukin-2 receptor antagonist (IL-2RA). Inverse probability weights were used to adjust confounders among different groups using propensity score analysis. Cox hazard regression analysis for adjusted data and treatment effects model were used to assess outcomes.

Results: Out of 14,414 RTRs, 8844 received IL2-RA while 5570 received ATG for induction. There were no significant differences between the IL2-RA and ATG groups in terms of early post-operative acute rejection episodes (95% CI ranges from -0.007 to 1.008, P=0.8), overall acute rejection episodes (CI ranges from -32.5 to 3.1, P=0.107) or graft survival (CI ranges from -169.6 to 199.3, P=0.87). Mean graft survivals were similar (7.8 vs 7.5 years, p=0.8), as well (Figure 1,2,3).

Conclusions: In the tacrolimus era, ATG as compared to IL2-RA induction therapy does not have a favourable graft or survival outcomes in ABO-incompatible RTRs.



SA-PO1162

Comparison of Clinical Outcomes Between High Anti-A/B Antibody Titer vs. Low Titer in ABO-Compatible Kidney Transplantation

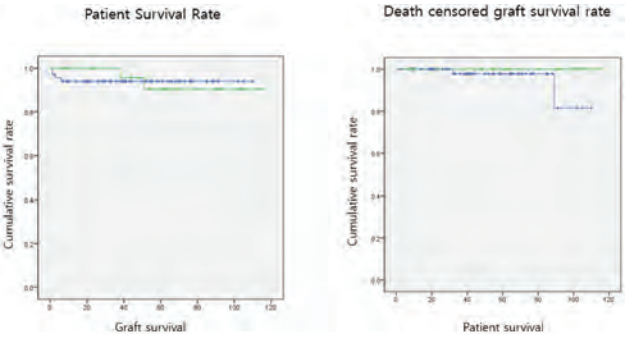
Jin ho Lee,[1] Yong ki Park,[3] Donghan Kim,[5] Joong Kyung Kim,[1] Joon Seok Oh,[2,1] Dongyeol Lee,[1] Hee yeoun Kim,[1] Yong hun Sin,[6] Woo Yeong Park.[4] *[1]Bong Seng Memorial Hospital, Busan, Republic of Korea; [2]Brigham and Women's Hospital, Chestnut Hill, MA; [3]Dongnae Bong Seng Hospital, Busan, Republic of Korea; [4]Dongsan Medical Center, Daegu, Republic of Korea; [5]Bongseng memorial hospital, Busan, Republic of Korea; [6]Bong Seng Hospital, Busan, Republic of Korea.*

Background: ABO incompatible(ABOi) kidney transplantation(KTP) reduces the waiting time of deceased donor KTP and extends the pool of living donor KTP. In recent data, ABOi KTP is known to have no significant difference in long term outcome compared to ABO compatible. However, high A/B antibody titer is still a challenge to overcome in ABOi KTP. In this study, high anti A/B antibody and low titer Ab were compared in ABOi KTP

Methods: We retrospectively evaluated 95 cases of ABOi KTP recipients from 2009 to 2018 in Bong Seng Memorial Hospital, BUSAN, South KOREA. High-titer isohaemagglutinin patients were defined by IgG anti A/B titres ≥1:256. There were 28 patients with high titer and 67 patients with low titer group. Primary outcome was patient survival and graft survival. The secondary outcome was bleeding tendency, biopsy proven rejection, plasmapheresis number, cost of treatment

Results: There was no statistical difference in the baseline characteristics between high and low titer group. Patient survival rate in the high titer group was not statistically significant compared to the low titer group. There was no significant difference in graft survival rate(Figure 1). There were no differences in complications such as bleeding tendency and number of blood transfusions. However, the anti-A / B antibody titer(49 ± 37 vs. 502 ± 384)(p=0.00) and the number of plasmapheresis(3.8 ± 1.7 vs. 7.2 ± 2.5)(p=0.00) were significantly lower in the low titer group. There was no difference in complications such as PTDM, angina, and myocardial infarction after transplantation. There were no significant differences in infection and rejection

Conclusions: High A/B antibody titer ABOi KTP showed no inferiority in clinical outcome compared to low titer. The authors suggested that the high Anti A/B antibody titer lower the medical alert thresholds from contraindication to high risk



SA-PO1163

Reuse of Immunoabsorption Columns in ABO-Incompatible(ABOi) Kidney Transplantation: A Single-Center Experience

Anil Bhalla,[1] Priti Meena,[1] Devinder S. Rana,[1] Ashwani Gupta,[1] Manish Malik,[2] Anurag Gupta,[3] Vinant Bhargava,[1] Vaibhav Tiwari,[1] Yogeshman Anand.[1] *[1]Sir Ganga Ram Hospital, New Delhi, India; [2]Sir Ganga Ram Hospital and GRIPMER, New Delhi, India; [3]Synegy Hospital, Uttarakhand, India.*

Background: ABO-incompatible (ABOi) Kidney Transplantation has results comparable to ABO compatible transplantation. This is because patients are desensitized at the pre-transplant stage using apheresis & Rituximab therapy with tacrolimus (TAC) based immunosuppression. In some patients, baseline titers are very high and repeated plasma exchange sessions also fail to bring titer to the desired level. Immunoadsorption (IA) technique is very effective in reducing titers in such cases. But, IA therapy is quite expensive, hence we have tried to reuse the filter to see the effectiveness.

Methods: 190 ABOi transplants have been performed at our center since 2012. Patients received Rituximab and triple immunosuppression. Baseline IgG & IgM were tested with gel method and it ranged from 1: 2 to 1: 1024. The antigen-specific IA technique was used in 64 patients. Two types of IA filters were used Glycorex – glycosorb & Adsopak. IA columns were reused after regeneration. No. of column reuse, adverse events, and Anti A / Anti B antibody titers were assessed. Glycosorb filter was processed by rising with 1000ml saline and sterilized with Ethylene trioxide(ETO). Adsopac column was reused by different regeneration technique using saline wash, acidic solution followed by buffer and alkaline solution and regeneration solution(sodium azide):The column was placed at 2° to 8°C. Antibody titers were estimated in the blood taken 10 minutes before the end of the procedure from the line immediately after the Column. Negative or low antibody titer indicated efficient antibody removal at the end of treatment &despite reuse of the columns. Columns were used maximally for 3 times.

Results: 64 ABOi patients underwent antigen-specific IA and could be transplanted. In 4 patients, the titers did not come to target levels and these had to subject to therapeutic plasma exchange to achieve the target levels. Incidence of hypotension, fever with rigors & failure to bring down the titer was significantly higher in adsopak filter as compared to Glycorex filter. Column reuse resulted in a cost saving of 5000 to 10,000 USD per patient.

Conclusions: Although IA technique is very effective, it is expensive and the cost of treatment increases considerably. Reuse sessions were tolerated well and titer could be reduced to target levels.

SA-PO1164

Kinetic Characteristics and Validation of a Patient-Based Model for Therapeutic Plasma Exchange in Transplant Patients

Pablo E. Galindo, Lluvia A. Marino-Vazquez, María F. Mejia, Ricardo Correa-Rotter, Luis E. Morales-Buenrostro. *Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, CDMX, Mexico.*

Background: Therapeutic plasma exchange (TPE) has become an important tool in kidney transplantation. The American Society of Apheresis gives TPE a category 1 indication for antibody mediated rejection (AMR). Understanding the kinetics of macromolecule removal is fundamental for rational prescription, optimization, and recognizing limitations of the TPE.

Methods: We evaluated 12 patients with biopsy confirmed AMR, who had indication for TPE. Each patient received 5 treatments every other day with 1.5 plasma exchanges, and all treatments where replaced with 5% albumin solution. Considering that Luminex is not a quantitative assay, we measured immunoglobulins (IgG, IgA, IgM) by immunoturbidimetry, and LDL cholesterol before and after each treatment. By knowing the initial value of macromolecules, their intravascular distribution, and the reduction ratio, we calculated the intravascular refill between treatments. Refill was independent of time, and constant for each patient through all treatments. We also identified three refill patterns. With this information we developed a predictive model for macromolecule kinetics during TPE, and conducted an internal validation of the model.

Results: We evaluated distribution prediction of the model and we obtained good correlation: IgG (r=0.94, 95%CI=0.91-0.96, R^2=0.88, P <0.001), IgA (r=0.89, 95%CI=0.84-0.92, R^2=0.8, P <0.0001), IgM (r =0.89, 95%CI=0.85-0.93, R^2=0.80 P <0.0001), LDL (r =0.94, 95% CI= (0.92-0.96), R^2=0.89 P <0.0001). The Bland Altman plots to evaluate agreement: IgG (Bias= 0.3, SD of Bias 23.45,95% Limits of agreement (-45–46)), IgA (Bias= -8.4, SD of Bias 13.95, 95% Limits of agreement (-35 to 19)), IgM (Bias= -0.13, SD of Bias 29.4, 95% Limits of agreement (-58 to 58)), and LDL (Bias= -17, SD of Bias 31.47,95% Limits of agreement (-78 to 44)).

Conclusions: The model predicted accurately the distribution of macromolecules after multiple treatments. The correlation and agreement was especially good for IgG, and IgA. Although the correlation was good for LDL, concordance was not, this can be explained by the intravascular distribution and the short half-life of this molecule. The model was programmed in an app format for IOS to make it practical. A validation cohort is being conducted.

SA-PO1165

Outcomes and Complications Following ABO-Incompatible Kidney Transplantation Performed After Desensitization by Antigen-Unspecific Immunoadsorption Devices

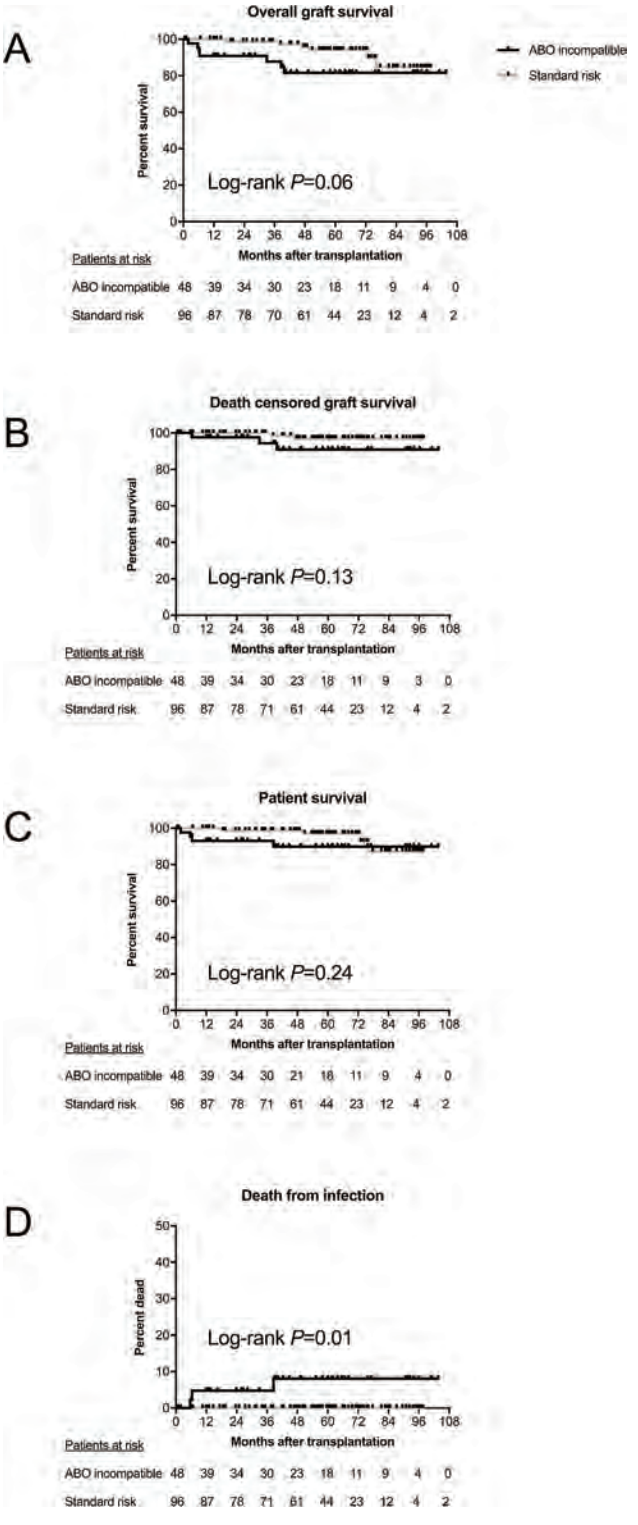
Claudius Speer, Florian Kälble, Christian Nusshag, Matthias Schaier, Claudia Sommerer, Martin G. Zeier, Christian Morath. *University Hospital Heidelberg, Heidelberg, Germany*.

Background: Due to the current organ shortage, ABO incompatible (ABOi) transplantations have been increasingly performed in recent years. The results seem comparable to those of compatible transplantations, but there have also been reports of increased side effects possibly due to the desensitization therapy.

Methods: To address an increase in severe infectious complications, we compared the outcomes of 48 ABOi transplant recipients to outcomes of 96 matched ABO compatible (ABOc) controls transplanted at Heidelberg University Hospital from 2005 to 2018. In addition, we conducted a subanalysis of high-titer (≥1:256) recipients compared to low-titer (<1:256) recipients.

Results: Over a follow-up period of 8 years, ABOi transplant recipients had comparable graft and patient survival as well as graft function compared to ABOc patients. T cell-mediated and antibody-mediated rejections were not different between groups. In ABOi transplant recipients, urosepsis (23% vs. 9%; p=0.019) and pneumonia with opportunistic pathogens (8% vs. 1%, p=0.025) appeared more frequently. As a consequence, a significantly higher number of deaths from infection have been observed after ABOi transplantations (6% vs. 0%, p=0.010). High-titer recipients (isoagglutinin titer of ≥1:256) showed a higher incidence of BK virus replication and postoperative bleeding complications.

Conclusions: ABOi kidney transplant recipients may be safely transplanted, even when they have a high anti-A/B antibody titer before surgery. However, particular attention has to be paid to severe infectious complications. Especially pneumonia causes an increased frequency of deaths from infections in ABOi kidney transplant recipients during early follow-up.



SA-PO1166

Recipient ABO Blood Group May Be Associated with Increased Mortality Risk Among Patients with Kidney Transplants

Monica S. Ng,[1,2] Shahid Ullah,[5,3] Gregory J. Wilson,[4,2] Stephen P. McDonald,[5,3] Matthew P. Sypek,[5,6] Andrew J. Mallett.[1,7] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; [3]Adelaide Medical School, University of Adelaide, Adelaide, SA, Australia; [4]Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [5]Australia and New Zealand Dialysis and Transplant Registry, South Australian Health and Medical Research Institute, Adelaide, SA, Australia; [6]Department of Nephrology, Royal Melbourne Hospital, Melbourne, VIC, Australia; [7]Faculty of Medicine and Institute for Molecular Bioscience, University of Queensland, Brisbane, QLD, Australia*.

Background: Blood groups A and B have been associated with increased risks of cardiovascular disease, infection and cancers. To date, the effect of recipient ABO blood group on patient survival has not been studied in ABO-matched solid organ transplantation.

Methods: All Australian and New Zealand transplant recipients who received ABO-compatible primary kidney transplant between 1995-2016 were analysed using data from the Australia and New Zealand Dialysis and Transplant (ANZDATA) registry. The exposure was recipients' ABO blood group, with the primary analysis being O / non-O and secondary analysis Individual blood groups. Outcome was patient survival. Recipient age, gender, ethnicity, body mass index, smoking status, comorbidities, primary kidney disease; donor type, age and gender; and transplant era were included in the multivariate model as confounders.

Results: On analysis of 15,523 kidney transplant recipients, blood group O was not associated with patient survival (hazard ratio (HR) 0.97, 95% confidence interval (CI) 0.91-1.05) compared to non-blood group O recipients. Blood group A was associated with reduced patient survival compared to non-blood group A recipients (HR 1.10, 95% CI 1.02-1.18).

Conclusions: This analysis suggests that blood group A recipients may have reduced patient survival compared to non-A recipients. Further research is required to confirm these findings and determine the source of this difference – be it biological or unmeasured confounders.

SA-PO1167

Mythbusters: Is Your ABO Titer Method Safe for Patients?

Shauna C. Jones,[1] Jill Adamski,[2] Theresa Kinard,[2] Karen Finegan,[1] Qun Lu.[2] *[1]Mayo Clinic Hospital, Phoenix, AZ; [2]Mayo Clinic, Phoenix, AZ*.

Background: As transplantation of group A2 kidneys to group B patients becomes increasingly common, so does the practice of sending titers to reference labs, some of whom may not be performing their titers in a way that promises optimum patient safety and outcomes. ABO titer cutoff for transplant eligibility differs widely between institutions, largely due to differences in titration methods. Our study sought to refute the notion that a DTT-treated titer read at immediate spin (IS) is an accurate assessment of IgG titer and to suggest widespread adoption of more appropriate, traditional titer testing methods.

Methods: A method comparison study was performed by testing Anti-A titers of 10 group B kidney transplant candidates at immediate spin (IS), traditional tube method (tube AHG), DTT-treated IS (IS DTT), and DTT-treated tube method (AHG DTT). Dilution controls were performed for each patient.

Results: All IS and 9 of 10 AHG titers were reduced by DTT treatment. The amount of reduction varied, as shown in Table 1, suggesting that the proportion of ABO titer which is IgM vs. IgG varies individually. The highest AHG tube titer (256) was reduced down to an IS DTT titer of only 4. In this instance a patient with a high titer Anti-A would have been eligible to receive an A2 transplant at many institutions which use IS DTT titers.

Conclusions: Traditional titer methods which measure IgM and IgG provide a more comprehensive and clinically valuable view than DTT-treated titers. The practice of performing IS DTT-treated titers and reporting as IgG titer is misleading, with possibly harmful implications for patients. Titer performance must be standardized to prioritize patient outcome. Clinicians who refer ABO titers to reference labs should thoroughly assess the method being used to perform these titers and demand a method which ensures patient safety.

Table 1

Patient	IS Tube	AHG Tube	IS DTT	AHG DTT	Δ IS (# of tubes)	Δ AHG (# of tubes)
1	32	32	4	16	-3	-1
2	64	256	4	64	-4	-4
3	32	32	8	32	-3	0
4	32	16	2	2	-4	-3
5	32	128	2	4	-4	-5
6	32	64	8	32	-2	-1
7	32	128	2	1	-4	-7
8	32	128	1	64	-5	-1
9	64	64	4	4	-4	-4
10	32	64	8	32	-2	-1

SA-PO1168

Graft Survival and Patient Outcomes in ABO-Incompatible Kidney Transplant with Baseline High and Low Isohemagglutinin Titers Compared with ABO-Compatible Transplant

Lovy Gaur,[1] Anil Bhalla,[2] Devinder S. Rana,[2] Ashwani Gupta,[1] Manish Malik,[3] Anurag Gupta,[2] Vinant Bhargava,[1] Aakash Shingada,[1] Anant Joshi.[2] *[1]Sir Ganga Ram Hospital, New Delhi, India; [2]Sir Ganga Ram Hospital, New Delhi, India; [3]Sir Ganga Ram Hospital and GRIPMER, New Delhi, India*.

Background: ABO incompatible kidney transplantation (ABOiKT) helps to increase donor pool. No study till date has compared outcomes in high & low baseline isohemagglutinin titers to that in ABO compatible transplants (ABOcKT). This study attempts to evaluate correlation of baseline anti-A & anti- B isoagglutinin titres on graft survival and patient outcome in ABOiKT as compared to ABOcKT.

Methods: This was a retro-prospective observational study evaluating 954 renal transplant recipients. Of these, 873 patients underwent ABOcKT. Of 81 patients who underwent an ABOiKT, 67 belonged to low titer group (baseline IgG ≤1:64) and 14 belonged to high titer group(baseline IgG≥1:128). Patients were followed up for 1 year. Graft survival, rejection episodes, patient survival & infections were assessed.

Results: Mean age of patients who underwent ABOcKT, ABOi-high titer group and ABOi-low titer group was 40.47±12.19,38.79±16.21& 40.37±12yrs respectively. Mean donor age was 45.08±10.26,49±11.42 & 45.91±10.15 yrs respectively. Majority of donors were females-68.8%,78.6% & 79.1% respectively. Chronic glomerulonephritis was most common cause of ESRD. HLA mismatches were lower in the ABOcKT group. Death censored graft survival was lower in high titer group (92.3%) compared to ABOcKT group (98.8%), p=0.231. Graft survival in low titer group (96.8%) was comparable to ABOc group(96.8%, p=0.328). Proportion of patients with biopsy proven rejections was lower in ABOcKT groups (6.5%) when compared to ABOi high (21.4%) & low titer groups (13.4%) respectively(p=0.063 and 0.033). Antibody mediated rejections were significantly fewer in ABOcKT group(1.8%) vs high titer(21.4%) & low titer group(11.9%) (p=0.003 and p<0.001). Patient survival was better in ABOcKT group(97.9%) compared to high (92.9%) and low titer (94.0%) groups. Most deaths were attributed to infections. Low titer group fared better than high titer group in having lesser infection episodes, though difference was insignificant(p=0.532).

Conclusions: High baseline isoagglutinin titers are associated with poor graft survival in ABOi grafts compared to ABOc grafts, even though the difference was not significant. High baseline antibody titers are associated with significantly greater number of rejections & infections

SA-PO1169

Association Between Post-Transplant Donor-Specific Antibodies and Recipient Outcomes in Simultaneous Liver-Kidney Transplant Recipients

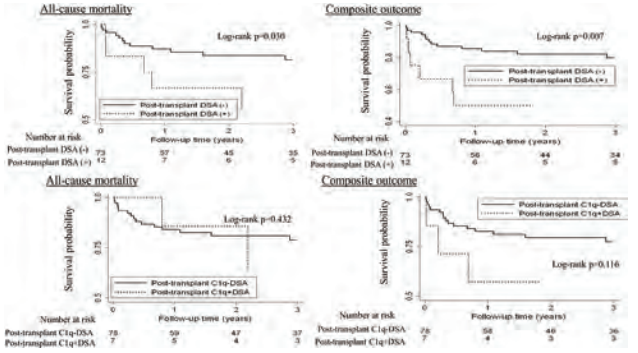
Masahiko Yazawa,[1,3] Orsolya Cseprekál,[6,1] Ryan A. Helmick,[1,2] Manish Talwar,[1,2] Vasanthi Balaraman,[1,2] Pradeep S. Podila,[9,10] Uchenna Agbim,[1,2] Sallyanne Fossey,[8] Sanjaya K. Satapathy,[7] Keiichi Sumida,[4] Csaba P. Kovesdy,[4,5] James D. Eason,[1,2] Miklos Z. Molnar.[1,2] METEOR (MEthodist Transplant EpidemiOlogy Research) Group *[1]Division of Transplant Surgery, Department of Surgery, University of Tennessee Health Science Center, Memphis, TN; [2]James D. Eason Transplant Institute, Methodist University Hospital, Memphis, TN; [3]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [4]Division of Nephrology, Department of Medicine, University of Tennessee Health Science Center, Memphis, TN; [5]Nephrology Section, Memphis Veterans Affairs Medical Center, Memphis, TN; [6]Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary; [7]Sandra Atlas Bass Center for Liver Diseases & Transplantation, Department of Medicine, Northshore University Hospital/Northwell Health, Manhasset, NY; [8]DCI, Inc, Nashville, TN; [9]Faith & Health Division, Methodist Le Bonheur Healthcare, Memphis, TN; [10]Division of Health Systems Management & Policy, School of Public Health, The University of Memphis, Memphis, TN*.

Background: There is a dearth of published data regarding the presence of post-transplant Donor Specific Antibodies (DSA), especially C1q binding DSA (C1q+DSA), and patient and kidney allograft outcomes in simultaneous liver-kidney transplant (SLKT) recipients.

Methods: We investigated 85 consecutive patients who underwent SLKT between 2009-2018 in our center. Associations between presence of post-transplant DSA [persistent and/or newly developed (de novo)] and C1q+DSA, and all-cause mortality and the composite outcome (mortality, allograft kidney loss, and antibody-mediated rejection) were examined using unadjusted and age and sex-adjusted Cox proportional hazards regression models.

Results: The mean age at transplantation was 56 years. Sixty and 26% of the patients were male and African-American, respectively. Twelve patients (14%) had post-transplant DSA and 7 (8%) patients had C1q+DSA. The presence of post-transplant DSA was significantly associated with increased risk of mortality (unadjusted model: Hazard Ratio (HR)=2.72, 95%Confidence Interval (CI): 1.06-6.98 and adjusted model: HR=3.20, 95%CI: 1.11-9.22) and the composite outcome (unadjusted model: HR=3.18, 95%CI: 1.31-7.68 and adjusted model: HR=3.93, 95%CI: 1.39-11.10) compared to the DSA negative group (Figure). There was no significant association between the presence of C1q+DSA and outcomes (adjusted model: HR=1.67, 95%CI: 0.43-6.45 for mortality, and HR=2.61, 95%CI: 0.70-9.75 for the composite outcome).

Conclusions: The presence of post-transplant DSA was significantly associated with increased risk of all-cause mortality and composite outcome including kidney allograft loss and ABMR. The presence of post-transplant DSA should not be ignored in routine patient care after SLKT even though pre-transplant sensitized status is usually neglected at the time of SLKT.



SA-PO1170

Renal Microvascular Autoregulation in an Ischemia-Reperfusion-Induced Model of Acute Kidney Injury

Bailey McEachen. *The University of Alabama at Birmingham, Birmingham, AL*

Background: Autoregulation alters renal vascular resistance (RVR) to keep glomerular filtration rate (GFR) stable during arterial pressure fluctuations. Ischemia-reperfusion-(IR)-induced acute kidney injury exhibits increased RVR and decreased GFR. Our previous study revealed that autoregulation was impaired in IR, but improved with acute treatment of ROS-scavenger and NADPH-oxidase-inhibitor. Therefore, we hypothesize that chronic antioxidant treatment (Tempol) preserves autoregulation by reducing oxidative stress and inflammation in IR rats.

Methods: Rats underwent 60 minute bilateral renal arterial occlusion, with or without Tempol (2mM, drinking water; 7 days), or sham surgery. Afferent arteriole (AA) autoregulatory behavior was assessed in blood-perfused juxtamedullary nephrons. Glomerular function was assessed by plasma creatinine, GFR using FITC-sinistrin, and proteinuria/albuminuria.

Results: SBP was normal across groups: 126-145mmHg (P>0.05) over 7 days. Plasma creatinine increased with IR (1.68±0.18 vs. 0.98±0.04mg/dL in shams, P<0.05), but remained normal in IR+Tempol rats (1.05±0.12mg/dL). Sham rats (n=3) exhibited pressure-dependent vasoconstriction. Control AA diameter averaged 12.2±0.9μm and decreased 32±3% from 65 to 170mmHg. In contrast, IR rats (n=2) lost autoregulatory capacity. AA diameter passively increased by 25% over 65-170mmHg, whereas IR+Tempol rats (n=2) maintained pressure-dependent vasoconstriction. GFR for shams remained constant (0.9-1.3mL/min/100g), while Tempol improved GFR to 0.5 compared to 0.0mL/min/100g in IR. Tempol treatment significantly reduced albuminuria (Day 3: Sham 0.5±0.1mg, IR 14.3±6.6mg, IR+Tempol 2.5±0.5mg) and proteinuria (Day 3: 12±1mg, 58±10mg, and 28±7mg respectively). mRNA expression of inflammatory markers MCP-1/TGF-β increased significantly in IR rats (6.7±1.5/4.0±0.5 vs. 1.1±0.2/1.0±0.1 in sham) and reduced in IR+Tempol rats (3.5±0.4/2.4±0.3).

Conclusions: Ultimately, antioxidant treatment preserved autoregulatory and kidney function in IR rats.

SA-PO1171

Endothelin-1 Promotes Renal Iron Deposition in Murine Models of Iron Overload

Rachel Meek. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Recent observations show that renal iron deposition correlates with plasma endothelin-1 (ET-1) in sickle cell disease (SCD). Iron accumulation in humanized SCD mice kidneys is ameliorated by a selective endothelin A receptor (ETA) antagonist, ambrisentan. Thus, we hypothesized that endothelial-derived ET-1 regulates iron trafficking in the kidney.

Methods: Vascular endothelial cell ET-1 knockout (VEET KO) male mice aged 12 weeks were injected with phenylhydrazine (40 mg/kg, IP) for two consecutive days to induce hemolysis and consequent iron overload. Heme oxygenase-1 knockout (HO-1 KO) mice, a model of iron overloading, aged 20 weeks were given ambrisentan (10 mg/kg/day, p.o.) for 4 weeks.

Results: VEET KO mice exhibited a higher survival rate relative to littermate control mice (66.7% vs 20% survival, n=9 and 5, respectively). Moreover, VEET KO mice with induced hemolysis have less renal iron deposition when compared with control mice (Prussian blue staining, 41.1 ± 5.1 vs 79.3 ± 0 Mpixel/μm, respectively). At baseline, iron trafficking mediators (TRF-1, DMT-1, FtH, FPN-1) assessed by RT-PCR were not upregulated in VEET KO mice when compared with control mice. HO-1 KO mice exhibited elevated plasma ET-1 (2.59 ± 0.78 vs 0.45 ± 0.09 pg/mL), cortical ET-1 mRNA expression (2-fold increase), and renal iron content (87.2 ± 27.5 vs 0.24 ± 0.2 Mpixel/μm) when compared with control mice; all were significantly reduced by ambrisentan. No significant changes in expression of iron uptake and storage mediators in KO mice. Ferroportin-1, an iron exporter, was significantly increased by ambrisentan.

Conclusions: These data suggest ET-1 contributes to renal iron overload.

SA-PO1172

The $SGLT_2$ Inhibitor Canagliflozin Reverts Hyperglycemia-Induced Metabolic Changes in Mouse Kidney Sections

Jose Chevere-Reyes. *The University of Texas at San Antonio, San Antonio, TX*

Background: Diabetes is associated with high rates of renal tubular glucose reabsorption, high kidney glycolytic activity and higher production of kidney injury markers. Canagliflozin is an SGLT2 inhibitor, used for type 2 diabetes and considered to have beneficial effects on the progression of diabetic kidney disease. This study tested the effects of Canagliflozin on renal metabolism in mouse kidney slices.

Methods: Kidneys were harvested from C57Bl/6 WT mice, sliced to 150 μM thick sections and incubated in media containing 7.2 mM glucose (NG) or 25 mM glucose (HG), without or with canagliflozin (1, 10 and 100 μM). Conditioned media was collected after 24h of incubation and metabolites were measured using YSI bioanalyzer and gas chromatography-mass spectroscopy. Additionally, kidney injury marker (KIM1) was measured by ELISA. Kidney tissues were frozen, sectioned to 10 μm sections using cryostat for mass spectrometry imaging (MSI) to identify spatial changes in glucose.

Results: In conditioned media, significant reduction in glucose ($p<0.0001$), and succinate and significant lactate ($p<0.001$) increase was noted in, HG compared to NG. MSI depicted increase in glucose in tissue sections treated with HG suggesting increased glucose uptake. Canagliflozin reduced the glucose uptake in both NG and HG treated tissue sections ($p<0.0001$ for HG and $p<0.01$ for NG groups). Likewise, 100 μM canagliflozin significantly reduced lactate in both glucose conditions. High glucose induced succinate and KIM1 were also reduced by canagliflozin.

Conclusions: Above results support the hypothesis that SGLT2 inhibitors, by blocking glucose uptake, can revert the metabolic changes induced by hyperglycemia and protect against tissue injury.

SA-PO1173

Missense Mutations in PKD1 Lead to Reduced Surface Localization of the Polycystins in ADPKD

Sanjna Girdhar. *Mayo Clinic, Rochester, MN.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD), characterized by the development of fluid filled cysts, is the fourth leading cause of renal failure in the US and is mainly caused by mutations in the genes PKD1 or PKD2 encoding the proteins Polycystin1 (PC1) and Polycystin2 (PC2) respectively. Localization of PC1 and PC2 to the cell surface is important for their function in cells, with a positive correlation between reduced surface protein levels to disease severity. The objective of this project was to quantify surface localization of a number of missense variant PC1 proteins, and combination of variants.

Methods: The single PC1 variants (p.Arg3277Cys, p.Met3346Leu, and p.Thr3270Met) were created by site directed mutagenesis and introduced into the full length PC1 tagged construct. In addition, variant combinations were similarly generated (p.Thr3270Met/p.Arg3277Cys, p.Met3346Leu/p.Thr3270Met, and p.Arg3277Cys/p.Met3346Leu/p.Thr3270Met), mimicking a variant combination detected in three ADPKD families. Epithelial cells from the kidney were transfected with constructs containing these single and combination variants. Immunofluorescence staining of the transfected cells was used to visualize the surface localized proteins.

Results: The intensity of the immunofluorescence signal, as determined by flow cytometry, indicated the amount of protein properly localizing to the cell membrane. The single variants were found to have reduced surface localization compared to wild type, with the surface localization further lowered as the number of significant variants increased.

Conclusions: Therefore an in cis combination of missense variants can significantly reduce PC1 surface localization, showing that a combination of hypomorphic alleles can result in a fully inactivating allele.

SA-PO1174

Electrogenic Transport Function of Low Temperature Rescued CLC-5: R345W Mutation and Towards Dent Disease Novel Therapies

Meihui Zhang. *Mayo Clinic, Rochester, MN.*

Background: Dent Disease type 1 (DD1) is an X-linked disorder characterized by low-molecularweight proteinuria, hypercalciuria, nephrocalcinosis, and kidney stones. DD1 has no effective therapy or treatment, although it is known to be caused by mutations in the *CLCN5* gene encoding ClC-5, a voltage-gated nCl-/H^+ exchanger found at the apical membrane of the proximal tubule and within endosomal membranes. Our previous studies revealed that functional defects of two novel *CLCN5* mutations (R345W, Q629X) were due to abnormal ClC-5 trafficking to the plasma membrane. Interestingly, R345W surface expression in cells could be rescued by lowering the incubation temperature from 37 to 30°C after transfection. However, the transport function of the rescued R345W has not been investigated.

Methods: Thus, we used whole cell patch-clamp electrophysiology to measure transport functions of transiently transfected renal proximal tubule cells (LLC-PK1) expressing wild type (WT) or R345W mutated ClC-5 incubated at 37 or 27°C.

Results: Cells expressing WT exhibited strongly outward rectifying current at positive holding voltages whereas R345W expressing cells incubated at 37°C demonstrated reduced current. Intriguingly, R345W expressing cells incubated at 27°C demonstrated significantly increased transport function compared to R345W expressing cells incubated at 37°C. We have also successfully established LLC-PK1 cell lines that stably express eGFP/HA double-tagged WT and mutant ClC-5. Using Western blot analysis, we documented that ClC-5 expression levels were sufficient to use these cells to screen candidate chaperones.

Conclusions: These results establish a rationale and the tools to explore the effect of pharmacological chaperones to facilitate proper protein folding and maturation of DD1 mutations, including R345W. Results could suggest new therapies for some populations of DD1 patients who currently have no specific therapy available.

SA-PO1175

Recessive Mutations in TLN1 Are a Potential Novel Cause of Nephrotic Syndrome in Humans

Roxanna Fouladi. *Harvard University, Cambridge, MA.*

Background: Nephrotic syndrome (NS) is characterized by a significant loss of protein in the urine causing hypoalbuminemia and edema. NS is categorized into steroid sensitive (SSNS) and steroid resistant nephrotic syndrome (SRNS). Steroid resistant nephrotic syndrome is the second most common cause of chronic kidney disease in the first three decades of life. Mutations in over 59 genes provide a monogenic cause in up to 29.5% of NS cases (*JASN* 26:1279, 2015). This implies that novel genetic and mechanistic causes of NS may explain some of the currently undiagnosed ~70% of cases. The mechanisms of steroid action in SSNS are still unknown and treatment options for SRNS are limited.

Methods: To identify additional monogenic causes of NS we performed whole exome sequencing in >2,000 individuals with NS. We identified a homozygous *TLN1* mutation in B3328-21 (c.5964_5966del, I1989del). We screened an additional cohort of 605 patients with NS with a Fluidigm Access ArrayTM for *TLN1* mutations and identified a compound heterozygous mutation in patient A3788-21 with SSNS (c.235A>G, M79V and c.3491G>C, S1164T).

Results: *TLN1* encodes a protein that binds to and activates integrins, coupling them to the actin cytoskeleton (*FEBS* Letters; 592:2108, 2018). Podocytespecific *Tln1* knock out mice have been described to develop an altered podocyte cytoskeleton structure, proteinuria, focal segmental glomerulosclerosis, and die at the age of 10 weeks likely due to renal failure (*JCI* 124:1098, 2014).

Conclusions: In conclusion, we have identified mutations of *TLN1* as a potential novel cause of nephrotic syndrome.

SA-PO1176

Plasma Fibroblast Growth Factor 23 (FGF23) and Protein Alpha-1-Microglobulin/Bikunin Precursor (AMBP) as Predictors of Cardiovascular Disease (CVD) Endpoints in The Boston Kidney Biopsy Cohort (BKBC)

Debbie Adam. *Harvard University, Cambridge, MA.*

Background: Chronic Kidney Disease (CKD) is a risk factor for the development of Cardiovascular Disease (CVD). Research into nontraditional risk factors could help to provide more information as to why this complex relationship exists. Specifically, fibroblast growth factor 23 (FGF23) and protein α1-microglobulin/bikunin precursor (AMBP) have both shown promise as renal failure biomarkers in CVD-related clinical trials. From this knowledge, we hypothesized that elevated levels of plasma FGF23 and AMBP in CKD patients would demonstrate an accelerated time to CVD endpoint.

Methods: The population of interest were patients enrolled for a native kidney biopsy date between 2006 and 2018 at Massachusetts General Hospital (MGH) and Brigham and Women's Hospital (BWH). Biological specimens were collected on all consented patients over the age of 18. Plasma FGF23 and protein AMBP were measured using multiplex immunoassay (inter-assay CV <10% for blind replicate samples). Univariate and multivariate regression models were generated to assess if plasma FGF23 and AMBP were predictors of CVD outcomes in CKD patients.

Results: Patients with the highest levels of plasma FGF23 had a 3.136 risk of reaching the composite CVD endpoint relative to patients with lower levels of plasma FGF23 (HR=3.136 (1.098-8.959), p<.05). Patients with mid-levels of plasma protein AMBP had a .312 risk of reaching the CVD endpoint(s) relative to patients with lower levels of plasma protein AMBP (HR=.312 (.122-.798), p<.05).

Conclusions: It can be inferred from our findings that plasma FGF23 can be used to predict cardiovascular outcomes in CKD patients, while the same cannot be said categorically for plasma protein AMBP.

SA-PO1177

IL-6 Mediated Activation of the Mineralocorticoid Receptor via Rac1

Oishi Paul. *Emory University, Atlanta, GA.*

Background: Hypertension (HTN) is characterized by excessive sodium (Na+) reabsorption and increased cytokine production, including interleukin 6 (IL-6). Aldosterone (Aldo) is the primary ligand for the mineralocorticoid receptor (MR) and studies suggest MR inhibition lowers blood pressure. However, Aldo levels are not always increased in HTN, suggesting alternate MR activation. Data from our laboratory have shown that IL-6 can activate the MR *in vitro*, and that Rac inhibition reduces mineralocorticoid response element (MRE) transcription. We hypothesize that IL-6 activates the MR via Rac1 in the late distal convoluted tubule (DCT), increasing activity of epithelial sodium channel (ENaC), a primary Na+ transporter in the late DCT (DCT2).

Methods: Using a voltohmmeter, we measured transepithelial resistance and voltage to calculate current in our cell culture model for DCT2 (mDCT15 cells). Cells were transfected with Rac1 expression vectors and treated (IL-6 [100ng/mL]).

Results: While IL-6 increased ENaC activity, Rac1 knockdown inhibited IL-6 induced ENaC (-1.16-fold change/baseline) activity. Since we observed that IL-6 induces nuclear MR translocation, we investigated whether Rac1 affects IL-6 mediated MR translocation. We cotransfected MR-eGFP tagged constructs and Rac1 expression vectors into mDCT15 cells. Cells were treated with IL-6 and visualized with confocal microscopy. Following IL-6 treatment, MR nuclear translocation was observed; however, with Rac1 knockdown, decreased MR translocation was observed.

Conclusions: We are the first to demonstrate cytokine-mediated ENaC activation in the DCT2. Additionally, these data suggest that Rac1 is crucial for IL-6 mediated ENaC activation and MR translocation, providing an alternate mechanism for increased ENaC Na+ transport during HTN.

SA-PO1178

Inhibition of Lymphangiogenesis Exacerbates Cisplatin Nephrotoxicity

Elisa Farrell. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: The lymphatic system is a complex network of channels responsible for lipid transport, fluid homeostasis, and immune response. The creation of new lymphatic vessels, or lymphangiogenesis, occurs primarily in development, though studies show that vascular endothelial growth factor C or D (VEGF-C or -D) stimulate *de novo* lymphangiogenesis in disease through interaction with their receptor, VEGFR-3. We have previously shown this process to occur following acute kidney injury (AKI). However, no previous studies have evaluated whether lymphangiogenesis is beneficial or harmful in AKI.

Methods: This study utilized MAZ51 [10 mg/kg bodyweight in DMSO intraperitoneally (i.p.)], a VEGFR-3 kinase inhibitor, to block lymphangiogenesis in a model of cisplatin nephrotoxicity (20 mg/kg bodyweight in saline i.p.). Mice were harvested 3 days post-cisplatin injection. Biomarkers of renal function, injury, inflammation, and lymphangiogenesis were measured.

Results: We report that inhibition of lymphangiogenesis exacerbates cisplatin nephrotoxicity. MAZ51 treated mice experienced significantly worsened kidney function, measured by elevated serum creatinine (1.1 ± 0.3 vs. 0.31 ± 0.05 mg/dL), decreased glomerular filtration rate (11.9 ± 3.9 vs. 80.6 ± 20.6 μl/min), and increased serum cystatin C. MAZ51 mice also experienced significantly increased expression of intrarenal KIM-1, compared with cisplatin alone treated mice. We also observed a significant rise in intrarenal inflammatory markers (*Csf1*, *Ccl2*, *Tnfα*) and heme oxygenase-1 (*Hmox1*), as well as increased cell death, compared with cisplatin alone controls.

Conclusions: Taken together, our study describes a novel role for lymphangiogenesis as an adaptive response following cisplatin AKI and may be a promising target for therapeutic intervention.

SA-PO1179

Role of Histone Deacetylase-1 in Interstitial Fibrosis

Kaitlyn Aldaz. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury can lead to chronic kidney disease through myofibroblast secretion of extracellular matrix (ECM) leading to interstitial fibrosis and a loss of kidney function. We reported that following ischemia-reperfusion-injury (IRI), the transcriptional regulator, histone deacetylase-1 (HDAC1) is increased in the kidney. Inhibition of HDAC1 reduced IRI-mediated interstitial fibrosis. We hypothesized that fibroblast HDAC1 was profibrotic and developed an inducible HDAC1 fibroblast knockout (KO) mouse.

Methods: Fibroblast HDAC1 was deleted in adulthood, and the male mice underwent sham or bilateral IRI (2-weeks of reperfusion) surgeries.

Results: Plasma creatinine was significantly elevated in control IRI mice (0.20 ± 0.02 mg/dl) compared to sham (0.12 ± 0.001) or KO mice (sham = 0.13 ± 0.009, IRI = 0.14 ± 0.02, $P_{Genotype}$ = 0.2, $P_{Surgery}$ = 0.02, $P_{interaction}$ = 0.03) suggesting that the KOs had better kidney function. Interstitial sirius red staining, α–smooth muscle actin (αsma), and fibronectin expression was increased in the control IRI mice compared to shams or KO mice. Next, Normal Rat Kidney 49 Fibroblast cells transfected with human HDAC1 or empty vectors. Injury was simulated by treatment of cells with TGF-β1, a master regulator of myofibroblast activation. Overexpression of HDAC1 did not significantly affect myofibroblast markers (αsma, fibronectin). TGF-β1 treatment led to myofibroblast activation, regardless of HDAC1 level. Interestingly, HDAC1 was found to suppress p53 expression, a master regulator of the cell cycle.

Conclusions: Together, our data suggest that fibroblast HDAC1 is profibrotic, but it may be through regulation of myofibroblast cell cycle, rather than direct effects on ECM secretion.

PUB001

Cystatin C Utilization for Kidney Assessment in Acute Care

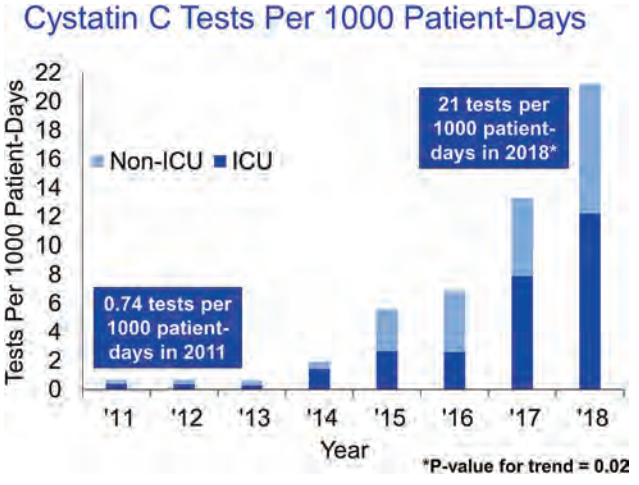
Hilary Teaford,[2] Diana J. Schreier,[1] Kristin C. Mara,[1] Andrew D. Rule,[1] John C. Lieske,[1] Kianoush Kashani,[1] Erin F. Barreto.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic Hospital, Rochester, MN.*

Background: Serum cystatin C (CysC) is a kidney biomarker used most extensively for staging chronic kidney disease. Recently the potential role for CysC in acute care has been recognized; however, settings where it is clearly useful remain to be defined. Our objective was to retrospectively evaluate trends and patterns of inpatient use of CysC in a tertiary hospital where the test was readily available.

Methods: This was a single-center, observational study of adults hospitalized at Mayo Clinic with ≥1 CysC result between 2011–2018. CysC testing was available in house, with a turnaround time of ≤3 hours, and per provider discretion with 1 exception. During 2 years of the 7-year study period, a vancomycin QI project using CysC was conducted in 3 ICUs. Analyses of CysC ordering trends over time used Poisson regression. Descriptive statistics characterized the context for use.

Results: Over 7-years, 8168 CysC levels were obtained, during 4890 inpatient admissions, for 4337 patients. We found a 28-fold increase in CysC use over time (2011: 0.74 tests per 1000 patient-days, 2018: 21 tests per 1000 patient-days; *P*=0.02; Figure). Nephrology was consulted in 40% of cases. The majority (72%) of patients underwent CysC testing during 1 of 3 scenarios: 1) AKI, 2) expected alterations in muscle mass, and 3) vancomycin dosing in the ICU QI project. Non-GFR determinants of CysC were identified with 47% of tests, most frequently corticosteroid use.

Conclusions: In this cohort of inpatients with ready access to CysC testing, CysC utilization significantly increased over the last 7-years. Themes for use included renal-dosing of drugs, AKI monitoring, and to assess GFR in patients with altered muscle mass. Non-GFR determinants frequently occurred, exposing opportunities for misinterpretation. Additional studies are warranted to define the optimal role for CysC in the inpatient setting.



PUB002

Urinary Urea Excretion as a Potential Early Biomarker of AKI

David G. Morais, Mirela Santinho, Talita R. Sanches, Victor F. Seabra, Leandro U. Taniguchi, Lucia Andrade, Camila E. Rodrigues. *São Paulo University, São Paulo, Brazil.*

Background: The diagnosis of AKI is based on reduced urine output or elevated serum creatinine (sCr), neither of which provide reliable, timely information. Current AKI biomarkers are costly and not widely used. Urinary urea excretion (UUE) is impaired early in chronic kidney disease (CKD), and increased UUE suggests renal recovery in hemodialysis weaning. In renal ischemia or sepsis, reabsorption of water and urea can increase, and fractional excretion of urea (FEU) is reduced during AKI. Little is known about the period before changes in diuresis or sCr. We hypothesized that low UUE would be a timely marker of AKI.

Methods: We evaluated critically ill adults with a clinical AKI score. In high-risk patients, urinary/serum urea and creatinine were measured daily for 7 days or until ICU discharge. The day before AKI diagnosis (D–1) was compared with the day of ICU admission of AKI-free patients (D1), in terms of UUE and urinary neutrophil gelatinase-associated lipocalin (NGAL). Baseline exclusion criteria were CKD, AKI, kidney transplantation, and a body mass index < 19 kg/m^2. AKI diagnoses were based on KDIGO criteria. Results are mean±SD.

Results: We included 41 patients (age, 53.9±16.5 years). The Simplified Acute Physiology Score 3 was 48.7±14.1, and sCr was 0.66±0.26 mg/dl. AKI was classified as septic/ischemic or nephrotoxic. As AKI progressed, the FEU decreased (40.8±9.1% on D–2, 26.1±7.4% on D–1 and 22.1±11.2% on D0; p < 0.05). UUE on D–1 correlated negatively with sCr on D0 (Figure 1). On D–1, FEU was lower in patients with septic/ischemic AKI than in those with nephrotoxic AKI (No-AKI: 30.2 ±11.2% vs Septic/ischemic AKI: 25.4±9.9% vs Nephrotoxic AKI: 42.6±14.2%, p< 0.05).

Conclusions: UUE could be a timely, inexpensive biomarker of AKI, especially septic/ischemic AKI. Supported by FAPESP.

Epidemiology and Outcome of Kidney Failure due to Snake Bites: Twenty-Three Years of Experience from South Batinah Region, Oman

Chandra Mauli Jha,[1] Hormaz D. Dastoor,[2] G. Gopi,[3] Sadiq A. Abdul Baqi,[4] Issa Al Salmi.[4] *[1]Pro vita Dialysis Services, NMC, Abu Dhabi, United Arab Emirates; [2]Rahba Hospital- Johns Hopkins International, Abu Dhabi, United Arab Emirates; [3]Nephrology, Rustaq Hospital, Rustaq, Oman; [4]The Royal Hospital, Muscat, Oman.*

Background: Snakebite is a significant global burden with high rate of mortalityand morbidity including Kidney Failure. Literature on renal failure among snake-bite patients of Middle East Gulf region is limited. A retrospective study of patients of renal failure in snake bites patients in South Batinah region of Oman during June 1995 to 31st March 2019 was undertaken.

Methods: As per policy all patients of snake bites in the region of South Batinah of Oman are referred to secondary care Rustaq Hospital. Paper and electronic Records of snake bite patients who developed acute renal failure requiring haemodialysis or managed conservatively during the period of study were studied retrospectively for demography, clincal characteristic & outcome.

Results: Incidence of snake bites in the region was 70 to 93 yearly with male preponderance. Renal failure occured in a minority (0-3 patients per year). While Male: Female ratio of snake bite was 3.46:1, female gender appeared to be at risk factor of developing renal failure (M/F: 0.4:1). Age of patients with renal failure varied from 21 to 78 years with majority between 37 to 55 years of age. 26 patients developed renal failure. There was significant drop in renal failure since 2010 while snake bite incidence remained unchanged. It might be possibly due to change in the policy of antivenom administration. Dialysis was required in 16 (61.5%) of patient of renal failure. Four patients progressed to ESRD. 13 patients lost follow up.9 patients are on follow up. Two among these 9 patients have CKD stage 3 and one has CKD stage 4 (eGFR 43, 55 & 23.6 ml/minute).

Conclusions: 1. South Batinah Region of Oman has high rate of snake Bites with male preponderance but the female gender appeared to be a risk factor of developing renal failure. **2.** There is decrease in incidence of renal failure among snake bite patients. possibly early administration of anti-venom may have a ptrotective effect against renal failure which is suggested by a definite recent trend of decrease in number of AKI due to snake bite after the policy of antivenom administration was modified in 2010 in favour of its administration at Primary health centre before referral to Regional Hospital. **3.** Acute renal failure due to snake bite may be a risk factor for progressive CKD. These patients must be followed up.

PUB004

Analysis of Cardiac Surgery Patients with AKI

Hongli Jiang,[2] Jinhong Xue.[1] *[1]Department of Blood Purfication, the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: To observe the incidence, clinical characteristics and risk factors of acute kidney injury (AKI) after cardiac surgery in our hospital, and provide evidence for better understanding and early intervention.

Methods: Retrospective analysis of patients with cardiac surgery from July 2017 to June 2018 in the First Affiliated Hospital of Xi'an Jiaotong University, screening patients with AKI and non-AKI recording their clinical data and analyzing risk factors.

Results: 1.575 patients were involved, AKI developed in 177 (31.78%) patients, whereas 4.17% of them received renal replacement therapy. Patients with AKI had significant higher mortality than patients without AKI (10.17%VS 0.5%, P<0.001). 2. The incidence of AKI stage 1, 2, and 3 was 19.13%(110/575), 5.22%(30/575), and 6.43%(37/575) respectively, and the mortality was 2.72%(3/110), 10%(3/30) and 32.43%(12/37). There was a statistically significant difference in mortality between three groups(P<0.001). 3. Multivariate logistic regression analysis showed that cardiopulmonary bypass (OR=1.436, 95%CI1.168-1.765), advanced age(OR=1.623,95%CI 1.311-2.009), previous cardiac surgery (OR=1.623,95%CI 1.311-2.009), high level of preoperative blood cystatinC (OR=1.623, 95%CI 1.311-2.009), perioperative infection (OR=1.436, 95%CI1.168-1.765) and intraoperative cardiopulmonary bypass time (OR=1.457, 95%CI1.077-1.971)were the independent risk factors of AKI after cardiac surgery. 4. The occurrence of AKI after cardiac surgery was mainly within 24 hours after surgery, accounting for 80.23% of AKI patients.

Conclusions: AKI can occur early after cardiac surgery. AKI has a significantly increased mortality compared with non-AKI patients. It should be alert to its risk factors and early intervention.

PUB005

Kidney and Patient Outcomes After AKI in a Dialysis Centre in Sokolov from January 2017 to July 2018

Erika Székelyová. *FMC, Velká Hledsebe, Czechia.*

Background: The incidence of acute kidney injury (AKI) is increasing. Epidemiological studies can not reliably clarify this phenomenon. Since January 2017 to July 2018 were treated 66 patients with hemodialysis due to AKI on dialysis centre in Sokolov. In our lecture we want to show the effect AKI on their renal function and mortality. We also want to present our usual procedures for the treatment of AKI.

Methods: We evaluated dates of group of acutely dialysed patient on our dialysis centre by retrospektive analysis. Our attention was focused on mortality and irreversible decline in kidney function of patients overall and in relation to age, gender and pre-existing chronic kidney disease (CKD).

Results: Patients with acute kidney injury had a maintenance phase that typically lasted between 7 and 21 days. The duration was dependent upon the length and severity of the initial ischemic episode; whether or not recurrent ischemia occured or exposure to nephrotoxins was ongoing. An irreversible decline in kidney function after recovery was more likely in patients over age 65 years, in male sex and those with pre-existing chronic kidney disease and with heart failure. AKI during hospitalization is associated with high in-hospital mortality. In our patient group this mortality was up to 48 %.

Conclusions: From our short-term follow-up of a relatively small group of patients have been produced conclusions similar to those from multicentre reputable studies. Patients who develop AKI should be evaluated because of the risk of new onset or worsening of pre-existing CKD.

PUB006

Observational Analysis of Patients with Liver Cirrhosis Receiving Continuous Renal Replacement Therapy: A Single-Center Experience in Korea

Sang Heon Song,[1,2] You Hyun Jeon,[1] Hyeyun Jeong,[1] Miyeun Han,[1,2] Harin Rhee,[1,2] Eun Young Seong.[1,2] *[1]Internal Medicine, Pusan National University Hospital, Busan, Republic of Korea; [2]Biomedical Research Institute, Pusan National University Hospital, Busan, Republic of Korea.*

Background: To date, there was few data about liver cirrhosis (LC) patients undergoing continuous renal replacement therapy (CRRT) despite of a high mortality rate. The aims of this study are to observe the prognosis of patients with LC undergoing CRRT and identify factors related to prognosis.

Methods: A total of 155 LC patients who initiated CRRT in intensive care unit (ICU) were enrolled and finally analyzed 142 patients retrospectively excluding 13 patients with liver transplantation from January 2013 to December 2018.

Results: The enrolled patients were admitted to the ICU for the following reasons: infection (25.4%), other LC-related complications (23.2%), gastrointestinal (GI) bleeding (16.2%), acute kidney injury (AKI) (9.2%), cardiovascular events (5.6%) and others (20.4%). The most common cause of starting CRRT was AKI with shock (76.1%) mostly associated with GI bleeding (31.7%) and sepsis (26.1%). In-hospital mortality was 67.6% and the most common cause of death was other LC-related complications (36.5%). Compared with survivor group, use of vasopressor(%) and SOFA, APACHE II, MELD and MELD-Na were significantly higher in non-survivor group (81.3 vs.58.7, P=0.004; 13.86±4.05 vs. 10.57±3.92, p=0.000; 27.52±7.53 vs. 23.90±5.91, P=0.007; 33.68±7.98 vs. 29.85±7.14, P=0.006; 33.18±5.53 vs. 30.65±6.13, P=0.015) whereas 6hr urine output before CRRT is lower in non-survivor group (91.78±123.64 vs. 214.78±263.91, P=0.004). In laboratory values, white blood cell count and prothrombin time INR were significantly higher (15.20±11.91 vs. 11.94±6.52, P=0.037; 2.69±1.98 vs. 1.93±0.92, P=0.002) in non-survivors, whereas total protein and pH were significantly lower in non-survivors than survivors (5.23±1.09 vs. 5.73±1.36, P=0.021; 7.25±0.15 vs. 7.31±0.14, P=0.036). In multivariable analysis, SOFA score (odds ratio[OR] 1.200, 95% confidence interval[CI] 1.073-1.343, P =0.001), log 6hr urine output before CRRT (OR 0.809, 95% CI 0.6555-0.998, P = 0.048) and albumin (OR 0.435, 95% CI 0.231-0.818, P = 0.001) were associated with mortality.

Conclusions: In-hospital mortality of cirrhotic patients received CRRT was much higher than that of all patients received CRRT, which was previously reported as 53.7%. SOFA score, 6hr urine output before CRRT and albumin were associated with mortality.

PUB007

New Oral Anticoagulants and the Risk of Post-Contrast AKI After Computed Tomography with Intravenous Contrast Medium

Semin Cho, Dong hwan Yun, Yong Chul Kim, Hajeong Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Seung Seok Han. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Post-contrast acute kidney injury (PC-AKI) is a great concern in relation to worse renal outcome. However, the relationship between the use of new oral anticoagulants (NOACs) and the risk of PC-AKI remains unresolved.

Methods: A total of 2,158 patients who received prophylactic hydration with normal saline and N-acetylcysteine before and after computed tomography with intravenous contrast medium were reviewed. Among them, NOAC and warfarin were used in 34 and 65 patients, respectively. The risk of PC-AKI was compared between patients with and without these agents. Additionally, a propensity score matching was performed in a 1:4 block for variables such as age, sex, weight, contrast volume, blood pressure, comorbidities, and baseline serum creatinine. PC-AKI was defined as an increase in serum creatinine by ≥ 0.3 mg/dl or ≥ 1.5 times above baseline within 96 hours. The risk of end-stage renal disease or all-cause mortality was also evaluated.

Results: The events of PC-AKI occurred in 141 patients (6.5%). The risk of PC-AKI in the NOAC group was not higher than in the warfarin or non-agent group: odds ratios were 1.5 (0.72–2.96) and 2.0 (0.68–5.61), respectively. The risks of end-stage renal disease and mortality after contrast media use did not differ between the groups. These trends remained consistent irrespective of multivariable adjustment. When a propensity score matching was applied, the NOAC group had a similar risk of PC-AKI to the non-use group with an odds ratio of 1.2 (0.32–4.11).

Conclusions: The use of NOAC does not increase the risk of PC-AKI in patients who undergo computed tomography with contrast medium.

PUB008

Renal Damage Associated with Intravitreal Administration of Anti-VEGF Drugs

María Fernández vidal, Candela Moliz, Beatriz Redondo navarro, Elizabeth Canllavi fiel, Teresa Bada Bosch, Hernando Trujillo Cuellar, Lucia Aubert, Justo Sandino Perez, Enrique Morales. *Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Vascular endothelial growth factor inhibitors (anti-VEGF) have been shown to be effective in the treatment of macular degeneration and diabetic macular edema. It is known that systemic administration of these drugs can produce adverse renal effects, such as decreased glomerular filtration rate (eFGR), proteinuria, hypertension or thrombotic microangiopathy. However, there is little information about it when the administration is intravitreal.

Methods: We analyzed the effect of anti-VEGF drugs with intravitreal administration on eFGR and proteinuria in diabetic patients, with and without chronic kidney disease (CKD), between 2017 and 2018.

Results: We included 40 diabetic patients (58% males) with a mean age of 74 ± 11.93 years, 92.7% being hypertensive and presenting 65.9% of the cases with CKD. 58.5% received bevazicumab, while the remaining 41.5% received ranibizumab. The evolution of eFGR and proteinuria are described in Table 1, where it stands out the increase in albuminuria and the decrease in eFGR in patients without previous CKD. Regarding the drug type, there were no differences but it is noteworthy that bevazicumab brushed the statistical significance (p 0.066) for the increase in albuminuria with respect to ranibizumab. On the other hand, within the CKD group, one patient presented two episodes of decompensation of heart failure after administration of an anti-VEGF drug, and two required the initiation of renal replacement therapy.

Conclusions: Based on the results of our cohort, we believe that it would be advisable to establish a closer monitoring in diabetic patients who are administered an intravitreal anti-VEGF drug, with determination of renal function as well as proteinuria to establish an early diagnosis of possible complications.

Table 1. Evolution of glomerular filtration rate (eFGR) and albuminuria, 6 months after administration of the anti-VEGF drug.

	No CKD (n = 14)	CKD (n =26)	Statistical significance (p)
Initial eFGR (*ml/min*) (X ± DS)	78.18 ± 11.05	34.17 ± 13.67	0.017
Initial albuminuria (*mg/g*) (X ± DS)	125.32 ± 228.88	739.34 ± 789.33	0.001
eFGR slope (%) (X ± DS)	8.31 ± 9.03	5.67 ± 23.82	0.025
Albuminuria (*mg/g*) (X ± DS)	1935.32 ± 6157.78	86.23 ± 215.90	0.07

PUB009

Comparison of Renal Function and Clinical Variables Between Patients With Sepsis And Cardiac Insufficiency

Daniel Z. Lo,[2] Marina L. Ramires,[3] Manoela F. Leite,[2] Leonardo B. Da silveira,[2] Miguel Angelo Goes,[1] Daniela M. Chiloff.[4] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Faculdade Israelita de Ciências da Saúde Albert Einstein, São Paulo, Brazil; [3]FICSAE, Sao Paulo, Brazil; [4]Escola Paulista de Medicina - UNIFESP, São Paulo, Brazil.*

Background: Heart failure (HF) is associated with large number of comorbidities that contribute to unfavorable outcomes, including acute renal failure (ARF). Sepsis is the leading cause of ARF in the critically ill patient.

Methods: We analyzed the medical records of 77 critically ill patients hospitalized at the Intensive Care Unit (ICU) of Hospital Israelita Albert Einstein. Patients hospitalized with decompensated HF and patients with a diagnosis of sepsis were compared. We compared demographic data, blood count parameters, renal function, liver enzymes, blood pressure and need for blood transfusion between HF and sepsis groups. KDIGO classification for acute renal injury. We performed t-test of student and chi-square to perform comparisons.

Results: Respiratory infection was the main cause of sepsis followed by gastrointestinal and bloodstream infections. KDIGO 2 was the most commonly found in all patients. Main finding was lower ejection fraction is associated with blood transfusion. Red Cell Distribution Width was higher in patients with decompensated HF when compared to septic patients (16.1 ± 2.1, 14.7 + -1.8, p = 0.02). Mean corpuscular

hemoglobin concentration values were higher in sepsis group (33.4±1.14, 32.3±1.19; p=0.04). Serum creatinine (3.9±0.8, 2.7±0.5, p=0.02), serum sodium concentration (140.5 ±5.8, 136.7±2.9; p=0.01), alkaline phosphatase (376.5±103.1, 120.5±18.5; p=0.03) and transaminases (AST [9328±4508, 159±98, p <0.001] and ALT [1967±888, 95.8±27.6; p=0.04] were higher in HF group, and diastolic pressure was lower in HF group (8.5±0,4; 9.6±0.3 mmHg; p=0.03). There were 9 patients in the sepsis group and 2 patients in HF group who required blood transfusion (p=0.01).

Conclusions: The results show that serum creatinine, Red Cell Distribution Width, serum sodium and liver enzymes were higher in severely ill patients with HF when compared to patients with sepsis.

PUB010

NephroCheck Meaning in Mild to Severe CKD: Single-Center Evaluation

Francesca K. Martino,[1] Ilaria Godi,[2] Sara Samoni,[1] Monica Zanella,[1] Alessandra Brendolan,[1] Claudio Ronco.[3] *[1]San Bortolo Hospital, Vicenza, Italy; [2]Universitá degli studi di Padova, Padova, Italy; [3]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy*.

Background: The Nephrocheck (NC) is an emerging marker in the diagnosis of kidney damage, especially in ill critical patients. Chronic kidney disease (CKD) could be a confounding factor in its clinical use. The aim of our study is to assess NC performance in the prediction of acute kidney disease (AKI) or the need of continuous renal replacement therapy (CRRT) in CKD patients.

Methods: We followed a group of 692 patients hospitalized in intensive care between 6/2017 and 9/2018. Demographic parameters, comorbidities, BMI, SOFA score, NC, Procalcitonin, lactate and serum Creatinine (S-Cr) levels were collected. Mild to severe CKD was defined by an eGFR of 15 and 60 ml / min, while AKI was defined by an increase of S-Cr≥ 0.3 mg / dl in 48 hours, or by an increase of 50% values of basal S-Cr or diuresis ≤ 0.5 ml / kg in 6 hours. All continuous parametric variables were presented as mean and standard deviation, while continuous nonparametric variable were reported as median values with interquartile range (IQR). All categorical variables were reported as percentage. T Student, Kruskal Wallis, and Pearson's chi-square tests were used to compare continuous and categorical variables, as appropriate. Finally, we evaluated the AKI predictors and the predictor of CRRT need by logistic regression. All tests were performed with the SPSS version 20 package.

Results: 14% of patients had an eGFR <60 ml / min. CKD Patients presented a higher prevalence of AKI (61% vs 23% p <0.001) and higher need of CRRT (14.4% vs 2.6% p <0.001), if compared to patients with eGFR ≥60 ml / min. Moreover, in CKD patients NC value showed a good ability to predict CRRT needs (OR1.08 p = 0.018) but it failed to predict the development of AKI (OR 1.03 p = 0.31).

Conclusions: By our preliminary results, the levels of NC in mild to severe CKD patients seems able to predict the need for CRRT.

Incidence of AKI in Intensive Care Units in Brazil: a Cohort Study

Antonio Jose Inda-Filho,[1,2] Heitor S. Ribeiro,[1] Edilene D. Vieira,[3] Mateus L. Ferreira,[3] Aparecido P. Ferreira.[1] NefroIntensimed Nephrology Clinic *[1]University Center ICESP, Brasília, Brazil; [2]Nephrology, Hospital Santa Lúcia, Brasília, Brazil; [3]Hospital Santa Lúcia, Brasília, Brazil*.

Background: Acute kidney injury (AKI) in Intensive Care Units (ICU) is common and it is a major problem to nephrologists and intensivists management. Little is known about associated factors and its incidence in low and middle-income countries, such as Brazil, where there is no reliable data available. Thus, the aim of this study was to investigate the incidence of AKI in ICU in Brazil.

Methods: A retrospective observational study in 3 ICUs from Brasília, Brazil. Data were collected in patients admitted in the ICUs from September 2017 to September 2018. Patients with end-stage renal disease on chronic dialysis were excluded. Demographic, clinical and laboratory data were recorded. Demographic data included age, gender, timing of hospital and ICU admission, comorbidity disease and primary diagnosis at ICU admission. Clinical data included Simplified Acute Physiology Score III, fluid balance status, the use of mechanical ventilator, vasopressor use and renal replacement therapy. Laboratory data included serum creatinine level. The primary outcome was AKI. The diagnosis of AKI was determined by KDIGO criteria. For the baseline serum creatinine, we used the most recent available serum creatinine before hospital admission. If the patients had no available data for baseline serum creatinine, then we estimated baseline serum creatinine using the lowest value between the serum creatinine at the time of hospital admission.

Results: This cohort study included 4453 patients from 3 ICUs, enrolled between September 2017 and September 2018. The average age of patients was 65.3 years and 50.0% were male. Based on the KDIGO criteria, 936 ICU patients (21.0%) were diagnosed with AKI during hospitalization. We had 275 patients (6.2%) who received RRT. Intermittent hemodialysis was the most common modality of RRT in our study (202 patients, 73.5%) followed by continuous RRT (34 patients, 12.4%).

Conclusions: This cohort study of the epidemiology of AKI in 3 ICUs in Brasília showed that AKI occurred in 936 patients (21.0%) during the time of ICU hospitalization.

Clinical data

	All Patients	Male	Female
Number of patients	4453 (100%)	2225 (50.0%)	2228 (50.0%)
AKI incidence	936 (21.0%)	472 (21.2%)	464 (20.8%)
Renal replacement therapy	275 (6.2%)	159 (7.1%)	116 (10.4%)
Mortality	474 (10.6%)	242 (10.9%)	232 (10.4%)

A Brief Evaluation of Clinical Characteristics, Behavior, and Possible Causes of Acute Presentation of CKD of Undetermined Etiology (AIN) in Sri Lanka

Shakila S. Premarathne,[7] Nishantha Nanayakkara,[1] Neelakanthi V. Ratnatunga,[2] Buddhisha S. Mahanama,[3] Rohana Chandrajith,[4] Duminda B. Basnayake,[3] Abdul W. Wazil,[5] Sulochana Wijetunge,[6] Chandika D. Gamage.[7] *[1]Teaching Hospital, Kandy, Kandy, Sri Lanka; [2]Faculty of Medicine university of Peradeniya Sri Lanka, Kandy, Sri Lanka; [3]Nephrology & Transplant Unit, Teaching Hospital, Kandy, Sri Lanka, Kandy, Sri Lanka; [4]University of Peradeniya, Peradeniya, Sri Lanka; [5]Teaching Hospital; Kandy; Sri Lanka, Kandy, Sri Lanka; [6]University of Peradeniya, Sri Lanka, Peradeniya, Sri Lanka; [7]Faculty of Medicine, University of Peradeniya, Sri Lanka, Peradeniya, Sri Lanka*.

Background: Acute symptomatic presentation of CKDu has been reported from India, Nikaraguwa and Sri Lanka. Socio demographic features of patients with acute symptoms are almost identical to those already described CKDu. The response of the kidney in these cases could be due to toxic exposure precipitated by behavior in an adverse environment. Such injury could be directly causative or indirectly contributing to the development and progression of CKDu.

Methods: 49 suspected AIN patients were recruited from May 2017 to May 2019. Histological assessment confirmed varying degree of inflammation in the background of chronic changes.

Results: All were reported from CKDu endemic areas of the country.98% were symptomatic and presented, in the Maha season (From September to March in following year). Average temperature during that period was 28^{0}C with a peak of 35^{0}C during April to May. Relative humidity was 60% and maximum of 90% reported in May. Majority of patients were males. 86% were either farmers or engaged in heavy manual work. The retrospective study findings through an interviewer administered questionnaire have revealed that 74% of patients had evidence of dehydration prior to the acute symptoms. Among them 32% and 68% of patients had symptoms of mild and moderate dehydration respectively. 78% of patients had recent unprotected exposure to agrochemicals. Drinking water source of most patients were protected dug well (51%). Betel chewing (73%), alcohol consumption (55%) and smoking (45%)were common among patients.

Conclusions: Acute symptoms in CKDu is found predominantly in male farmers who had evidence of dehydration and exposure to agrochemicals under hot humid conditions.

PUB013

Age as a Protective Factor from Mortality due to AKI

Ainhoa Castiella aranzasti,[1] Francisco javier Lavilla.[2] *[1]Universidad de Navarra, San Sebastián, Spain; [2]Clinica Universidad de Navarra, Pamplona, Spain*.

Background: We aimed to study if **clinical features** can be used **to evaluate prognosis** in AKI.

Methods: This is a **retrospective, observational study**. **Inclusion Criteria**: Adult Pts, SCR increase >20%. **Cohort**: 2746 hospitalized patients (Mean age: 63; SD: 14; Sex: 71%males). **Studied parameters**: Age (using subgroups of <65vs≥65; <65vs65-85vs≥85), SCR (basal-with previous measurement- and initial-at the diagnosis of AKI-), acute/chronic health status (*Individual Severity Index* -ISI and *Karnofsky*-KPS), treatment type (IHD,CRRT or both) and in-hospital mortality.

Results: We performed a **multivariate logistic regression analysis of mortality risk due to AKI** including age, sex, initial and basal SCR, standardised ISI and KPS prognostic indexes and type of AKI treatment received. **AKI in the elderly** (≥65yo) was more functional (49%vs34%) and required less RRT (25%vs29%). Mean ISI was higher and mean KPS was lower in ≥65; however, we stratified them and found the elderly were less likely to present with high ISI and low KPS (ISI>0.5 18%vs19%; KPS≥60 92%vs89%). We found **RRT, high ISI and low KPS to be predictors of mortality**. **Mortality was lower in elderly patients** (overall mortality rate: 473pts-17%; <65: 257pts - 9%; ≥65: 216pts–8%). **Age's association with mortality was inverse** (OR=0.98, 95%CI=0.96-0.99); **being ≥65 and the association with lower mortality had a greater magnitude** (Table 1); the association with being 65-85 remained similar, but the ≥85 group-mortality association was not statistically significant.

Conclusions: Age is inversely associated with mortality due to AKI in our sample, this association being statistically significant when evaluated on its own, and also when comparing rates between <65yo and ≥65yo. **Age is not an adverse prognostic factor of in-hospital mortality due to AKI**. The association between being ≥65yo and mortality suggests **age is a protective factor from mortality due to AKI**.

Table 1

Mortality		OR	P value	95% CI	Mortality	OR	P value	95% CI
Age	≥65 y.o.	0.57	0.000	0.42-0.77	65-85 y.o.	0.57	0.000	0.42-0.78

Dual Plasma Molecular Adsorption System Combined with Plasma Exchange and CVVH Improve Acute Liver Failure and Acute Renal Failure After Cardiopulmonary Bypass

Lingshuang Sun. *Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: Cardiovascular surgery patients use hypothermia cardiopulmonary bypass, may cause important organ ischemic injury, for example postoperative acute renal failure and acute liver failure, dual plasma molecular adsorption system (DPMAS) combined with plasma exchange, continuous CVVH can effectively improve liver function and renal function.

Methods: December 2018 - February 2019, Department of Cardiology, the First Affiliated Hospital of Xi'an Jiaotong University, underwent extracorporeal circulation, ascending aortic replacement, Bentall+ total arch replacement, elephant trunk or mitral valve replacement + tricuspid valvuloplasty, 3 patients, oliguria and AKI after 48 hours after operation was treated with CVVH and PE 1000 mL, followed by HA330-II tandem BS330 replacement plasma total volume 4500-5500 mL.

Results: One of the 3 patients underwent 3 times of PE+DPMAS, one case performed 2 times of PE+DPMAS, and one case performed PE+BS330. Total bilirubin: preoperative 16.26±6.91umol/L, first post 0h 72.23±13.95umol/L, first After 24h 91.1±11.18umol/L, after the second treatment 0h 55.35±8.41umol/L, after the third treatment 192h 86.3umol/L; creatinine: before operation 65±15.13umol/L, the first before 251.7±49.1umol / L, after the first treatment 0h 202±165.463umol/L, after the first treatment 24h 182.67±112.5umol/L, after the second treatment 0h 188±151.32umol /L, after the second time 98h 107.5±63.35umol/L

Conclusions: 24h after treatment compared with before treatment: total bilirubin decreased 24%, direct bilirubin decreased 33%, indirect bilirubin decreased 40%, AST decreased 89%, ALT decreased 66%, as DPMAS treatment mode can directly and effectively remove various kinds of patients Toxic substances, toxins, significantly shorten the course of disease.

PUB015

Anuric AKI with Rapid Recovery Secondary to Vancomycin and Aminoglycoside Nephrotoxicity

Michael Allon, Arun Rajasekaran. *University of Alabama at Birmingham, Birmingham, AL.*

Introduction: The increasing use of higher vancomycin doses has been associated with an increased incidence of vancomycin induced AKI, although the precise mechanisms remain unclear. We report a rare case of anuric AKI secondary to concomitant use of high doses of vancomycin and an aminoglycoside, which resolved completely after discontinuing these antibiotics and serial dialysis sessions using high flux membranes.

Case Description: A 22 year old woman with cystic fibrosis-associated bronchiectasis developed fever, dyspnea and a productive cough, consistent with a cystic fibrosis exacerbation. Her baseline kidney function was normal (serum creatinine 0.8 mg/dl). She was started on empiric antibiotics, including vancomycin 1 gm IV TID and tobramycin 180 mg IV daily. One week later she presented to the emergency department with a 5-day history of lower extremity edema, anorexia, profound nausea, and anuria (80 ml daily). She was afebrile, and her vital signs were stable. Pertinent labs included: serum creatinine of 12.6 mg/dl, random vancomycin level 200 mcg/ml, random tobramycin level 18 mcg/ml. Urinalysis revealed muddy-brown granular casts suggestive of ATN. Renal ultrasound was unremarkable. She was suspected as having anuric AKI due to vancomycin and gentamicin toxicity. The antibiotics were stopped, and she underwent 7 sessions of intermittent hemodialysis using high-flux membranes over the ensuing 2 weeks, with serum vancomycin and tobramycin reduced into the therapeutic range. Her urine output improved dramatically, and her renal function returned to normal.

Discussion: Vancomycin nephrotoxicity is on the rise, coinciding with the increase in recommended therapeutic vancomycin trough levels. The rapid rise in serum creatinine levels reflects both the AKI itself, as well as the competition of vancomycin and creatinine secretion by the same organic cation transporter in the proximal tubule. Synergistic use of vancomycin with an aminoglycoside may lead to worsening nephrotoxicity and can be mitigated by monitoring their plasma levels and subsequent withdrawal as necessary. Temporary hemodialysis using high flux membranes may hasten renal recovery by rapidly lowering the serum antibiotic levels.

PUB016

Relationship Between the Presence of Infectious Disease and Clinical Outcomes of Patients with Cardiorenal Syndrome Type 1

Jonathan Chavez,[1,2] Adriana Valle,[4,2] Guillermo Garcia-Garcia,[3,2] Jose A. Torres,[4,2] Jorge J. Font,[4,2] Christian P. Flores,[1,2] Joana G. Navarro gallardo,[4,2] Noe Martinez murillo.[4,2] *[1]Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico; [3]Hospital Civil De Guadalajara, University of Guadalajara, Zapopan, Mexico; [4]Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico.*

Background: Cardiorenal Syndrome type 1 (CRS-1) can be triggered by an infection. The pathophysiological basis is vascular congestion, which is why it has been treated with different strategies of diuretics, but in the presence of infection, where the inflammatory, neurohormonal and hemodynamic effects can compromise the efficacy of the diuretic therapy and potentially worsen clinical evolution. Here we compare the clinical evolution during the hospitalization of CRS-1 patients with and without infection.

Methods: This is a retrospective cohort study conducted in the Hospital Civil of Guadalajara "Fray Antonio Alcalde", from January 2015 to September 2018. Conducted in CRS-1 patients, we showed the clinical evolution and treatment strategies analyzed according to the presence or absence of infection. The study followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guideline.

Results: We identified 63 patients classified as having CRS-1, 28 (44.4%) were classified as having an infectious disease, the mean age in the group of infection was 62 years (±14.6) and 58 (±12.4) in no infection group. There were no statistically significant differences between the clinical outcomes of both groups, we found that in the infection group, the median length of hospital stay was 8 days and 7 days in the no infection group (p=0.065). Three patients (10.7%) of the group with infection received renal replacement therapy and 1 (2.9%) of the group without infection (p=0.315). In the group with infection 2 patients died (7.1%), while none in the uninfected group (p=0.194). sCr values trend to diminish in a similar manner trough the both groups. Serum **sodium** trend to increase thought the hospitalization but there was no significant difference between groups. During hospitalization we found that all patients received furosemide at least the first days of hospital stay, in addition the strategy of diuretics chosen for the treatment was similar between groups

Conclusions: Here we show that the clinical evolution of patients with CRS-1 is similar in the presence or absence of infection. We anticipate that this study may be a reason to expand knowledge in patients with CRS-1 and the presence of infection

Before Crystalluria: High-Dose Amoxicillin Infusion Leads to Intracellular Amoxicillin-Induced Osmotic Nephrosis

Cyril Mousseaux,[1] Vincent Frochot,[6] Cedric Rafat,[2] Emmanuel Letavernier,[4] Laurent Mesnard,[5] Yosu Luque.[3] *[1]Nephrology, Hopital Tenon, Assistance Publique des Hôpitaux de Paris, Paris, France; [2]Hôpital Tenon, AP-HP, PARIS 20, France; [3]Assistance Publique - Hopitaux de Paris, Paris, France; [4]Sorbonne Université, Paris, France; [5]INSERM UMR 1155, PARIS, France; [6]assistance publique hôpitaux de Paris, Paris, France.*

Background: Amoxicillin (AMX) is one of the most commonly prescribed antibiotics. Its renal toxicity is poorly described. The presence of urinary AMX crystals during acute kidney injury (AKI) has been proposed as a mechanism of intra-tubular precipitation. To date, deposition of AMX crystals within the kidney has not been reported.

Methods: We describe two cases of AMX-associated AKI and analysis of their renal biopsies using Fourier transform infrared spectroscopy (FTIR) and scanning electron microscopy (SEM). We then injected escalating doses of AMX (200-3000mg/kg/day intraperitoneally) for 2 days into rats and for up to 9 days in mice. Crystallization, renal function and histology of rodents were analyzed at sacrifice.

Results: Two patients of 58 and 68 years old were hospitalized for bacterial meningitis and developed ARF following high-dose AMX injection. They received 12g/day and 25g/day intravenously respectively. Optical microscopy analysis of their renal biopsies revealed in both cases severe tubulopathy with unexplained osmotic nephrosis(ON) lesions (Fig 1A). In one case, the FTIR analysis combined with the SEM showed an intracellular-tubular AMX deposit (Fig. 1B and C). Crystalluria was not observed in these two cases. Experimentally, injection of high dose AMX in rodents resulted in ARF with acute tubular necrosis and conspicuous ON lesions. No intraparenchymal AMX crystals or crystalluria were observed.

Conclusions: Our study suggests that in both humans and rodents, high dose AMX infusion leads to a yet unsuspected tubular toxicity. Renal lesions are featured by tubular ON surrounding intracellular-tubular deposits of AMX.

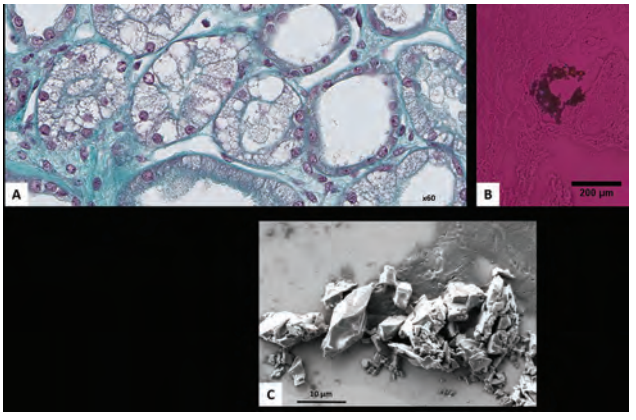

Figure 1. Histological features of AMX-associated nephropathy. A. Osmotic nephrosis and acute tubular necrosis. Masson's Trichrome. Magnification x60. B. Intra-tubular deposition of AMX. Magnification x10. C. Intra-tubular deposition of AMX under a scanning electron microscope. Magnification x6000.

Granulomatous Interstitial Nephritis (GIN) in a Patient with B-Cell Lymphoma

Syed Rizwan A. Bokhari,[1] Michael B. Stokes,[2] Muhammad khalid Tahir,[3] Raquel M. Rosen.[4] *[1]Nephrology, Bassett Health Care, Cooperstown, NY; [2]Columbia University Medical Center, New York, NY; [3]King Faisal specialist Hospital, Riyadh, Saudi Arabia; [4]Bassett Health Care, Cooperstown, NY.*

Introduction: GIN is a rare disease, seen in less than 1 % of renal biopsies. The commonest causes are infections, drug reactions, and sarcoidosis. We present a case of GIN in an elderly patient who presented with acute kidney injury (AKI) in the setting of recurrent B-cell lymphoma (BCL).

Case Description: A 67-year old Caucasian gentleman with history of large BCL in complete remission (2009), admitted with a relapse in November 2018, with weight loss, high grade fever of unknown cause and non-oliguric AKI requiring hemodialysis (HD). Physical examination showed no pertinent findings. Past Medical history included hypertension, with no prior history of kidney disease, liver disease or diabetes. Imaging showed bilateral enlarged kidneys (14 cm each). PET scan showed increased activity in both kidneys, liver and cervical lymph nodes, consistent with relapse of BCL. No mediastinal or abdominopelvic lymphadenopathy were noted. MRI of brain and bone marrow biopsy were unremarkable. Patient received multiple courses of antipyretics, antibiotics (Zosyn, Vancomycin) and 3 rounds of salvage chemotherapy with R-GCP followed by DHAC, with no significant improvement in renal function

Discussion: Labs revealed anemia (Hb 10.4) and elevated serum creatinine (Cr) 5.8 mg/dL (Baseline Cr 1.0-1.1). No other electrolyte or liver function tests abnormality were noted. Urine exam showed 2 + protein, > 5 RBC and 0.9 g proteinuria, with no RBC casts or abnormal WBCs. Autoimmune profile, complement levels and infectious profile, were all unremarkable. Serum ACE level was 26 U/L (ref 8-53). Percutaneous renal biopsy revealed diffuse GIN with CD3 positive (+) T cells and macrophages, no CD 20 + B cells, providing evidence against lymphomatous infiltration. Special stains for fungi and AFB were negative. The patient was subsequently started on prednisone 60 mg/day and received HD for 2 months. Kidney function subsequently improved, HD was stopped, and prednisone was tapered off after 8 weeks of use. Following month, patient underwent autologous stem cell transplant with most recent Cr 1.6 mg/dl and no proteinuria. GIN in this case was related to antibiotics used for fever of unknown origin. Although uncommon, GIN should be considered in the differential diagnosis of AKI in the setting of lymphoma with renal enlargement. Timely diagnosis and optimal management ensure a good outcome.

PUB019

Multiple Myeloma with the Onset of Ankylosis and Arthralgia and Subsequent Hypercalcinemia and Acute Renal Injury: A Case Report

Yunlin Feng,[2] Ping Zhang,[1] Hongling Yang.[1] *[1]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology of China, Chengdu, China; [2]Sichuan Provincial People's Hospital, Chengdu, China.*

Introduction: Ankylosis and arthralgia have rarely been reported as initial manifestations in multiple myeloma (MM).

Case Description: Here we reported a male patient with the onset of ankylosis and arthralgia, who had been seeing rheumatologists for one month without any conclusive diagnosis until admission due to hypercalcinemia and acute renal injury. MM was confirmed by bone marrow aspirate. Renal impairment due to cast nephropathy and nephrocalcinosis was confirmed by renal biopsy. He reported improvement of ankylosis and arthralgia in both knees after plasma exchange and hemodialysis and was then referred to Hematology Division, where he received three courses of dexamethasone and bortezomib chemotherapy. Renal function did not recover completely.

Discussion: Ankylosis and arthralgia are rare in MM and the mechanisms are not clear. Further immunological blotting might help to elucidate the pathogenesis.

PUB020

Clinical Profile and Outcome of Dialysis-Requiring AKI Among Elderly Patients in St. Luke's Medical Center-Quezon City from January 2014 to January 2019

Christine A. Salgado, Benjamin A. Balmores. *St.Luke's Medical Center Quezon City, Las Pinas City, Philippines.*

Background: The incidence rate of AKI is highest in the elderly. It is related to an increased rate of mortality, morbidity, and hospitalization, with the elderly population at high risk of developing dialysis-requiring AKI. It has been established that the temporal incidence of dialysis-requiring AKI and mortality has not yet been recently characterized, hence this study aims to determine the clinical profile and outcome of dialysis-requiring AKI among this population.

Methods: This is a descriptive, non-observational, retrospective, case series study. It includes elderly patients 65 years old and above, admitted at the center from January 2014 to January 2019 who were diagnosed to have dialysis-requiring AKI and underwent hemodialysis.

Results: Amon the 193 eligible patients, mean age was 77.08 ± 8.31, 55.44% males and 44.56% females. Most common co-morbidities identified were hypertension and diabetes. The most common encountered complication during hemodialysis was hypotension. The 30-day mortality rate is 61.66% and average length of hospital stay was 18 days. The average days from the day of hospitalization to initiation of hemodialysis was an 3 days. There is a significant change from baseline creatinine levels and eGFR to its measurements upon renal recovery.

Conclusions: Diagnosis of dialysis-requiring AKI in the elderly is associated with a poor outcome. It is related to an increased in-hospital stay. The most common complication observed during hemodialysis is still hypotension. Renal recovery can be expected when eGFR returns to baseline levels. There is a significant change from baseline creatinine levels and eGFR to its measurements upon renal recovery.

Table 1. Clinical profile of elderly patients with dialysis-requiring AKI (n=193)

	Frequency (%); Mean ± SD; Median (IQR)
Age	77.08 ± 8.31
Sex	
Male	107 (55.44)
Female	86 (44.56)
Co-morbidities	
Hypertension	147 (76.17)
Diabetes mellitus	102 (52.85)
Congestive Heart Failure	15 (7.77)
Chronic Obstructive Pulmonary Disease	21 (10.88)

Complications Associated with CRRT in a Community Hospital

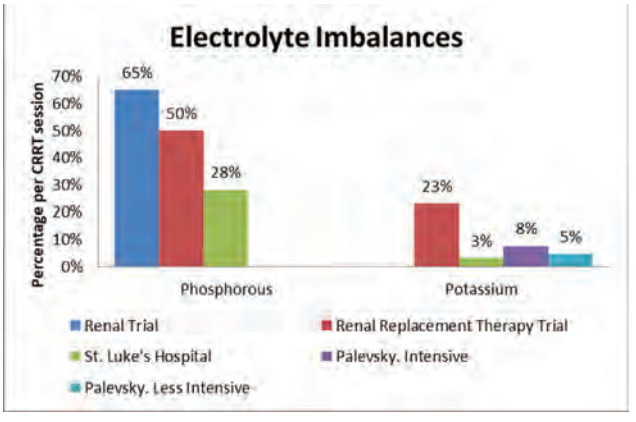
Maggie Meier,[1] Ricardo J. Camacho,[1] Ramza Haque,[1] Rajat Shailly,[1] Harinderjeet Kaur,[1] Nishith Alva,[1] Amir soheil Talebian,[1] Muhammad Farhan Asghar,[1] Thomas R. Pohlman.[2] *[1]St. Luke's Hospital, Chesterfield, MO; [2]St. Luke's Medical Specialists, St. Louis, MO.*

Background: Continuous renal replacement therapy (CRRT) is used for the treatment of critically ill patients with acute kidney injury, who are unable to tolerate intermittent hemodialysis due to hemodynamic instability. Complications of CRRT are the result of vascular access, bleeding, and electrolyte imbalances. In February 2016, CRRT became available in our community hospital in Chesterfield, Missouri. We investigated our initial complications associated with CRRT in our hospital and compared to complication rates reported in the literature.

Methods: We conducted a retrospective study of adult patients initiated on CRRT at St. Luke's Hospital in Chesterfield, MO between February 2016 and May 2018. The data was collected via Cerner Powerchart EMR.

Results: Among 52 qualified patients, there were a total of 162 dialysis sessions. Complications as number per dialysis session were as follows: 0/162 infections, 69/162 electrolyte imbalances, 3/162 arrhythmias, 7/162 bleeding, and 13/162 access problems. Out of the 69 electrolyte imbalances, 46 sessions had hypophosphatemia and 5 sessions had hypokalemia.

Conclusions: In a community hospital setting, within our first two years of implementing CRRT, we saw expected electrolyte imbalances in our patients (hypophosphatemia and hypokalemia); however, our incidence was less than in the literature. Infection, arrhythmias, and access related complications were also comparable to or lower than those in the literature. We attribute this to a common EMR orderset, limited CRRT utlization to our medical and surgical ICUs, and initiation of CRRT limited to nephrology.



PUB022

AKI due to Anticoagulant Related Nephropathy (ARN) and Thin Basement Membrane Disease (TBMD): Old Entities with a New Twist

Divya Monga, Swetha Rani Kanduri, Desiree Garcia Anton, Nihal M. Ali. *University of Mississippi Medical Center, Madison, MS.*

Introduction: ARN is a significant but under recognized complication of anticoagulation that is also associated with increased renal morbidity and all-cause mortality. It is defined as AKI without any other obvious etiology in the setting of INR>3, in patients on warfarin. TBMD is a relatively common cause of micro and less often macroscopic hematuria in adults.

Case Description: 66 year old male with hypertension, rheumatic heart disease with mechanical aortic and mitral valve replacement in 1995, on chronic warfarin therapy was admitted with AKI with serum creatinine 4.1mg/dL (baseline 1.3 mg/dL a month ago), anemia and brown colored urine for a week. His INR on admission was 2.8. All other pertinent history was negative. Physical exam and renal ultrasound were unremarkable. Urinalysis showed dysmorphic red blood cells. Work up including ANA, anti-GBM, HIV, Hepatitis panel, ANCA, Complements, SPEP, UPEP were negative. His warfarin was held and he was started on heparin infusion for renal biopsy. Renal biopsy showed acute tubular injury with recent and remote intratubular hemorrhages mostly in distal tubule. The intratubular granules stained positive for Gomori's stain, all consistent with ARN. Electron microscopy showed TBMD. With limited data on alternative anticoagulation options for mechanical heart valves, warfarin was restated at lower therapeutic goal, with subsequent improvement of renal function.

Discussion: ARN is known to most likely develop within 6-8 weeks of initiation of therapy, in the background of over anticoagulation. TBMD was most likely an additional risk factor that made our patient vulnerable to ARN. Although our patient was within therapeutic INR goal for his disease, it was higher than 3 few times in past. The dilemma is that although he had lived with these conditions, what triggered him to have an event now? We postulate that there may be a plausible third trigger that unmasked his underlying pathology. The other unsolved puzzle is management of patients who need warfarin and traditionally warrant higher INR goal. Our case is therefore unique with respect to timelines of presentation, and ARN diagnosis with no clear evidence of over anticoagulation for his clinical condition.

PUB023

Association of Continuous Renal Replacement Therapy Duration and the Outcome of Patients in Intensive Care Units

Junhyeong Cho,[1] Jeonggu Na,[2] Eunjin Bae,[2] Tae won Lee,[3] Ha nee Jang,[3] Hyun Seop Cho,[3] Se-Ho Chang,[2] Dong Jun Park.[2] *[1]Change-won Gyungsang National University, Chang-won, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Gyeongsang National University, Jinju, Republic of Korea; [3]Gyeongsang National University Hospital, Changwon-si, Gyeongsangnam-do, Republic of Korea.*

Background: Acute kidney injury (AKI) is a common clinical problem and one of causes of high mortality rate in Intensive Care Units(ICU). Many severe AKI patients have received renal replacement therapy. Among them with hemodynamic instability need to the continuous renal replacement therapy (CRRT). Some patients keep the CRRT longer duration, on the other hands, others keep it shorter. We studied if the difference in these periods affected the survival rate.

Methods: Retrospectively, we designed this study consist of adult patients who received CRRT were in ICU of our hospital from January 1, 2016 to December 31, 2016. They were divided two groups; less than 2 days (L group) and more than 2 days (M group). The clinical manifestation associated with each groups were analyzed. The value was expressed by median (range).

Results: All patients who received CRRT in the intensive care units(ICU) of our hospital from January 1, 2016 through December 31, 2016 were initially screened. (n=186). We excluded patients under 18 years, End stage renal disease, not agreed to access the data and 6-hour urine less than 300cc. We excluded 77 patients according to exclusion criteria. A total of 102 patients were included in the analyses. 41 patients in L group and 68 patients in M group. The median age of patients was 72(36-89) year-old in L group and 68.5(18-90) year-old in M group. Septic shock was the main cause of CRRT in both group. [26(63.40%) vs. 53(77.90%), P=0.123]. 28-day mortality rate was higher in L group than M group. [36(87.80%) vs. 44(64.70%), P=0.013]. Also lactic acid level was higher in L group than M group [9.4mmol/L(1.63-38.53) vs. 3.4mmol/L(0.7-18.72), p=0.001]. Other laboratory results and baseline disease were similar except for the presence of chronic liver disease(CLD). Interestingly, underline CLD was much higher in L group than M group. [17 (68.00%) vs. 8 (32.00%), p=0.001]

Conclusions: CRRT duration which AKI patients received in ICU was affected the mortality rate. Especially, on this study, patients with chronic liver disease have shorter dialysis durations and higher mortality rate when CRRT was performed due to AKI.

PUB024

Effects of 5-HT3A Antiemetic Drugs on Cisplatin-Induced Nephrotoxicity

Roman A. Shingarev, Sheron Latcha, Edgar A. Jaimes. *Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Cisplatin is an important component of chemotherapy for patients with lung, head and neck, and cervical cancer that induces cellular apoptosis by forming intrastrand DNA crosslinks that prevent DNA transcription. While desirable for malignant cells, cisplatin cytotoxicity in renal cortex leads to AKI. Tubular epithelial cell exposure to cisplatin is determined by its transport via organic cation transporter 2 (OCT2) and multidrug and toxin extrusion transporter 1 (MATE1). MATE1 is inhibited by 5-hydroxytryptamine-3 receptor antagonists (5-HT3 RA) commonly used as antiemetics in oncology. Our data indicates that ondansetron use in mice results in greater GFR loss relative to other 5-HT3 RA. We sought to examine the association of 5-HT3 RA use in patients receiving cisplatin with AKI.

Methods: In retrospective chart review, we identified 7,094 patients who received cisplatin, of which 3,997 (56.3%) were treated with a 5-HT3 RA that included either granisetron, ondansetron or palonosetron. Fisher's exact test tested for univariable associations between categorical variables. Multivariable associations with AKI were analyzed using logistic regression.

Results: Ondansetron accounted for 27% of overall 5-HT3 RA use. AKI was observed in 1,737 or 24.5% of patients receiving cisplatin. 5-HT3 RA use was independently associated with lower risk of AKI (OR 0.38; 95% CI, 0.23-0.65, p< 0.001). Other significant multivariable associations with AKI are found in Table.

Conclusions: Protective effect of 5-HT3 RA use in humans, contrary to our animal model, is likely accounted for by lesser inhibition of MATE1 by the most commonly used palonosetron. Increased risk of cisplatin-induced tubular toxicity in this scenario is likely further offset by the lower risk of pre-renal AKI from vomiting and anorexia, incited by cisplatin. Effects of the individual 5-HT3 RA on renal outcomes are the subject of active investigation.

	OR (95% CI)	p-value
Age	1.02 (1.01 - 1.02)	<.001
Male gender	1.46 (1.29 - 1.66)	<.001
Black race	3 (2.19 - 4.09)	<.001
White race	1.72 (1.34 - 2.2)	<.001

Bioimpedance in AKI: Corporal and Cardiothoracic Role in Evaluating Risk of Mortality and Renal Replacement Therapy Requirement

Francisco javier Lavilla, Paloma L. Martin Moreno, Omar J. González aróstegui. *Clinica Universidad de Navarra, Pamplona, Spain.*

Background: Evaluate application of Bioimpedance in AKI prognosis.

Methods: Observational. Creatinine increment >20%. Corporal bioimpedance (BIAC) study: Cohort of 205 patients (médium 67, male 73 %). Evaluate bioelectrical parameter:s phase angle (PA), Extracellular/intracellular water ratio (ECW/ICW), muscle mass (MM) and celular mass idex (CMI), and clinical parameters and prognostic index (individual severity index –ISI-), analytical renal, inflammatory and nutritional (days without optimal caloric intake 0, 1-3, 4-7 or > 7) and chronic health index (Karnofsky –K-, and ECOG). Cardiothoracic bioimpedance (BIAHEM) study: Cohort of 90 patients (médium 71 years, male 76.9%). Evaluate impedance (Z), cardiac output (CO), ventricular work index (VWI), systolic volumen (SV) and systemic vascular resistance index (SVRI) and Thoracic fluid volumen (TFV) Thoracic fluid volumen index (TFVI), and systolic volumen (SV) with clinical index prognosis (severity individual index –ISI), and metabolic, inflammatory and volemic parameters.

Results: BIAC study ISI was associated with PA (r=-0.244, p=0.003) ECW/ICW ratio (r=0.239, p=0.001). Peak CPR (c-reactive protein) with PA (r=-0.223, p =0.007) ECW/ICW (r=0.247, p <0.001), PA with lower Albumin (r=0.447, p<0.001). ECOG with PA (r=-0.369, p <0.001) and ECW/ICW (r=0.356, p<0.001). K with PA (r=-0.419, p<0.001) ECW/ICW (r=-0.356, p<0.001). MM with inspiratory volume (r=0.285, p=0.097). CMI was associated with inspiratory volume (r=0.338, p=0.098). Insufficient caloric intake with CMI (p=0.013) ECW/ICW (p<0.001) Exitus 8.9%. PA was independently associated with mortality risk (OR 0.391, p=0.039). ROC area 0.775, p=0.001,. PA lower than 3.8 indicates higher exitus risk. BIAHEM study: ISI was associated with SVRI (r=-0.249, p =0.020)-BNF (brain natriuretic factor) with CO (r=-0.292, p=0.013), VWI (r=-0.294, p=0.012), SVRI (r=0.337, p=0.004) SV (r=-0.333, p=0.004). Calcium with CO (r=-0.340, p=0.053) VWI (r=-0.351, p =0.042), Z with K (r=0.373, p=0.003) and ECOG (r=-0.260, p=0.043). TFV associated with respiratory failure (p=0.038) and SVRI with cardiovascular failure (p=0.037). Exitus 10.3%.

Conclusions: We can evaluate AKI prognosis with bioimpedance. Is associated with volemic and hemodynamic status evaluate with bioimpedance. We can use these to make a triage in AKI patient.

PUB026

Incidence of Contrast-Induced Nephropathy in Intermediate- to Very High-Risk Groups from a Single Center

Raja M. Rashid,[1] Zahid Nabi,[2] Zahid ul Zahideen.[3] *[1]CPSP, Islamabad, Pakistan; [2]KRL Hospital, Islamabad, Pakistan; [3]Department of Nephrology KRL islamabad, Sialkot, Pakistan.*

Background: Contrast induced nephropathy (CIN) is defined as an elevation of serum creatinine (Scr) of more than 25% or ≥0.5 mg/dl from baseline within 48-72 hours in the absence of alternate causes of acute kidney injury. Incidence of CIN in patients has been heterogeneously reported to be as low as 2% and as high as 50% depending upon the setting and population under scrutiny. It is an area of active clinical research and much controversy. There is no placebo controlled randomized controlled trials that establishes causation in CIN. Recently many studies have mushroomed that suggested that the risk of CIN is perhaps overestimated. Considering the international debate and the local scenario, we conducted this study to estimate the incidence of CIN in our center.

Methods: This prospective study was conducted between January and December 2018. It was approved by the ethical review committee and informed consent was taken from all patients. The patients in nephrology service with contrast media exposure and having Crcl between 20ml/min/m^2 and 60ml/min/m^2 were included in the study. As per CIN risk scoring system, only patients with intermediate to very high risk scores for CIN were included. Baseline creatinine was measured and post exposure RFTs were recorded at 24, 48 and 72 hours.

Results: Age of the patients ranged between 24 and 75 years (Mean 57 years) and 66% were of them were males. 80% of the patients underwent coronary angiography and 20% received contrast for computerized tomographic scans. Patients were equally distributed in the categories of intermediate, high and very high risk for CIN. 80% were hydrated per protocol prior to contrast exposure. Mean Scr of the cohort at baseline and after 72 hours were 2.12mg/dl and 2.10mg/dl respectively. Only 1 patient out of 30 patients, from the very high risk group, developed CIN.

Conclusions: The incidence of CIN in our small but high risk cohort was 3.3%. Among subgroup of the coronary artery disease patients that underwent angiography, majority benefited from life-saving interventions that were initially withheld for the overhyped fear of CIN. National level studies should document the local incidence so that informed decisions could be formulated tilting the risk benefit ratio of contrast exposure maximally in favor of the patients.

PUB027

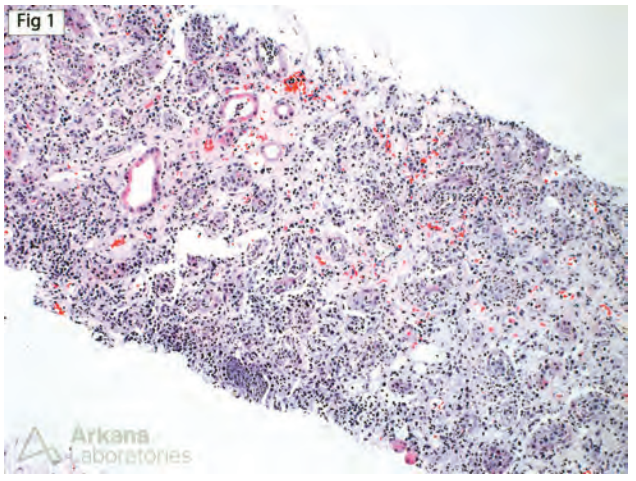
Can a Patient Develop Rapidly Progressive End-Stage Pyelonephritis?

Diana Mahbod. *Dallas Renal Group, Garland, TX.*

Introduction: Certain diagnoses can be inferred based on a kidney biopsy specimen alone. Pyelonephritis is one of these diagnoses, with a neutrophil-rich interstitial infiltrate, neutrophilic rimming of tubules with nutrophilic tubulitis, and neutrophilic casts. These findings are in contrast to acute interstitial nephritis which would demonstrate lymphocyte-rich inflammation. While AIN can progress rapidly and lead to dialysis-dependence, often improving with high dose steroids, acute pyelonephritis has not been described to lead to sudden onset renal failure with long-term dialysis dependence.

Case Description: A 57 year old male with history of chronic lymphaedema presented with a creatinine of 22 from baseline 0.8 several years prior. There was no evidence for UTI or obstruction. Urine studies revealed trace blood, moderate LE, 11 WBC and 2 RBC per HPF, with spot urine P/Cr of 4.5 grams/gram. Serologies and renal ultrasound were unrevealing except for large kidneys. Hemodialysis was initiated the day after admission for uremia and kidney biopsy revealed findings consistent with acute pyelonephritis. EM findings of patchy foot-process effacement suggested a possible unsampled focal segmental glomerulosclerosis. The patient remained dialysis-dependent despite a course of high-dose steroids, and rebiopsy was recommended but refused by the patient.

Discussion: Clinical context is crucial for interpretation of a pathology specimen but certain conditions such as acute pyelonephritis demonstrate pathognomonic findings. In this case, the biopsy findings were unexpected, especially the progression to presumed end-stage renal disease. When faced with diagnostic dilemmas, the clinician must consider whether alternative treatments exist to reverse the kidney damage, and alternative diagnoses must also be considered, with possible benefit to repeat kidney biopsy.



PUB028

Atg5 Overexpression in Proangiogenic Cells Significantly Improves Cell-Mediated AKI Protection

Daniel Patschan. *Innere Medizin 1 - Kardiologie, Angiologie, Nephrologie, Medizinische Hochschule Brandenburg, Brandenburg, Germany.*

Background: Acute Kidney Injury (AKI) significantly worsens the prognosis of hospitalized patients. Cell-based strategies have been established as reliable option for improving AKI outcomes in experimental AKI. Own studies performed in recent years utilized Proangiogenic Cells (PACs). Autophagy (AP) is commonly regarded as process of endogenous self-defense. The AP cascade, which may be stimulated by either substrate deprivation or certain exogenous / endogenous stressors, involves the activation of numerous proteins, the so-called Autophagy-related proteins (Atg proteins). Among these, Atg5 has been suggested to play a key role in augmenting AP. The current study evaluated whether selective Atg5 activation in syngeneic murine PACs may result in improved cell-mediated AKI protection.

Methods: Cultured murine PACs were selectively transfected for Atg5. Successful transfection was verified by detecting red fluorescing cells. AKI was induced in male C57/Bl6N mice (8-12 weeks) by bilateral renal ischemia (IRI - 40 minutes). Transfected cells were i.v. injected post-ischemia. Mice were analyzed 48 hours and 6 weeks later.

Results: IRI induced significant kidney excretory dysfunction as reflected by higher serum cystatin C levels (48 hours and 6 weeks). Cell administration (either native or after transfection) did not improve AKI outcomes at 48 hours. At 6 weeks, injection of native cells resulted in lower serum cystatin C, this effect was even more pronounced if transcfected cells were applied.

Conclusions: Together, our data show that selective Atg5 overexpression in murine PACs substantially augments cell-mediated AKI protection in the long-term. Thus, a new strategy for improving AKI protective effects of PACs has been identified.

PUB029

Validation of Transcutaneous Fluorescence for Monitoring Gut Permeability

Jonathan Street,[1] Asada Leelahavanichkul,[2] Peter S. Yuen,[1] Robert A. Star.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]Chulalongkorn University, Bangkok, Thailand.*

Background: At the gastrointestinal mucosa billions of microbes are in close contact with the host immune system. The maintenance of this barrier is vital for health and its compromise has been implicated in a variety of acute and chronic illnesses, including sepsis and chronic kidney disease. We have previously used transcutaneous fluorescence to measure the glomerular filtration rate using a fluorescent, inert i.v.-injected marker. We hypothesize that the transcutaneous fluorescence method can be adapted to measure intestinal permeability following oral gavage of a suitable marker.

Methods: Intestinal permeability was studied in the context of sepsis caused by the cecal ligation and puncture (CLP) surgical procedure. We compared 40 kDa FITC-Dextran and FITC-Ficoll as fluorescent markers. They were administered by oral gavage 3 hours prior to CLP to enable loading of the intestines. A transcutaneous fluorometer was attached to the skin (covering the spine) of each mouse, enabling the appearance of the fluorophore in the circulation to be detected. The stability of the fluorophores was evaluated in the blood and urine using ultrafiltration.

Results: Using the FITC-Dextran, post-mortem examination revealed significant fluorescence in the bladder despite the 40 kDa size of the parent molecule. After ultrafiltration of the urine, the fluorescence was able to pass through a 10 kDa filter indicating degradation, probably in the GI tract. In contrast, fluorescence from the injected FITC-Ficoll was not found in the urine. Following CLP, an increase in transcutaneous fluorescence was detected at ~3 hours that was absent in the sham.

Conclusions: This technique is a viable new approach for the measurement of intestinal permeability that avoids the need for blood collection. FITC-Dextran is degraded and can be filtered by the kidney. Using FITC-Ficoll should prevent underestimation of gut permeability due to glomerular filtration of fluorophore. Consistent with hemodynamic abnormalities and renal dysfunction, intestinal permeability can be detected ~3 hours after the induction of sepsis. We propose that gut permeability should be added to conventional multi-organ failure scores.

Biomarker-Based Differentiation of Hemodynamic and Intrinsic AKI Agrees with Clinical Adjudication by Nephrologists

Sherry Mansour,[1] Nadeen J. Khoury,[5] Ravi Kodali,[2] Sarthak Virmani,[1] Isaac E. Hall,[4] Peter P. Reese,[6] Francis P. Wilson,[1] Dennis G. Moledina,[1] Jason H. Greenberg,[2] Yu Yamamoto,[2] Yaqi Jia,[3] Heather Thiessen Philbrook,[3] Chirag R. Parikh.[3] DDS consortium *[1]Yale School of Medicine, New Haven, CT; [2]Yale University, Woodbridge, CT; [3]Johns Hopkins University, Newton, MA; [4]University of Utah, Salt Lake City, UT; [5]Henry Ford Health, Detroit, MI; [6]University of Pennsylvania, Ardmore, PA.*

Background: We aimed to determine if clinical adjudication by nephrologists agrees with the biomarker-based differentiation of AKI by urine biomarkers.

Methods: We abstracted and created graphical trends of longitudinal variables from 430 deceased donors charts. AKI was defined as a 0.3 mg/dL or 50% increase from the lowest recorded creatinine value. Three nephrologists independently reviewed AKI cases to adjudicate into hemodynamic, intrinsic or mixed subtypes; final diagnosis was determined by majority adjudication. If all three nephrologists disagreed, the phenotype was designated as mixed. We measured urine biomarkers at organ procurement and evaluated differences among AKI subtypes. Our secondary analysis assessed the association between subtypes and recipient delayed graft function (DGF) and 1-year eGFR.

Results: Of 430 donors, 68% had AKI; 36% were adjudicated as hemodynamic, 29% intrinsic, and 35% mixed. Stages 2 and 3 AKI, central venous pressure (CVP), and ventilator oxygen requirement were significantly higher in intrinsic AKI. There were no differences in vasopressor use or fluid balance. Biomarkers were significantly different in intrinsic AKI compared to other subtypes (**Figure)**. In secondary analysis, intrinsic AKI was independently associated with higher odds of DGF [aOR (95%CI); 2.52 (1.30, 4.88)] and lower 1-year eGFR [B coefficient (95% CI); -8 (-14, -2)] as compared to hemodynamic AKI after adjusting for donor and recipient characteristics. Results were similar when comparing intrinsic AKI to the mixed subtype.

Conclusions: Clinically adjudicated hemodynamic and intrinsic AKI were shown to be biologically different by urine biomarkers and were associated with different recipient outcomes.

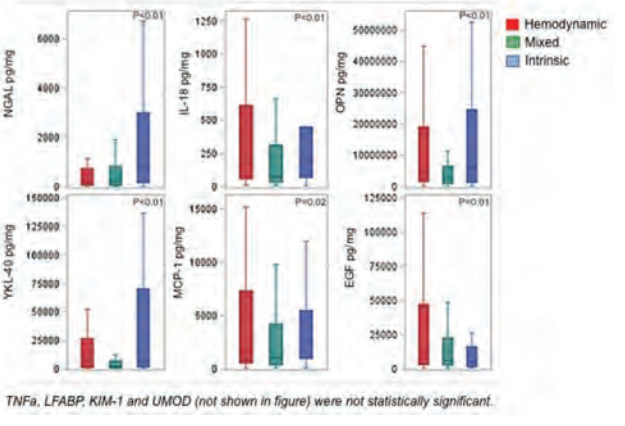
Distribution of Urine Biomarkers Among AKI Subtypes



TNFa, LFABP, KIM-1 and UMOD (not shown in figure) were not statistically significant.

PUB031

Kidneys Progressing from AKI to CKD Gradually Lose Their Inherent Potential to Recover

Lies Moonen,[4] Cristina Cuesta,[1] Francisco J. Lopez-hernandez,[2] Carlos Martinez-salgado,[3] Patrick C. D'Haese,[4] Benjamin A. Vervaet.[4] *[1]Institute for Biomedical Research of Salamanca (IBSAL), Salamanca, Spain; [2]IECSCYL - Instituto de Investigacion Biomedica de Salamanca, Salamanca, Spain; [3]Universidad de Salamanca, Salamanca, Spain; [4]University Antwerp, Edegem, Belgium.*

Background: It is increasingly clear that AKI can result in the development of CKD in humans. Murine renal unilateral ischemia-reperfusion injury (without contralateral nephrectomy; UIRI) models this AKI-CKD progression in the injured kidney (Le Clef et al, Plos One 2016). In mice, we and others demonstrated that contralateral nephrectomy (Nx), when performed shortly after UIRI (i.e. 3 days), is able to nearly completely attenuate the progression to CKD. Although non-translatable, Nx can be considered an experimental therapeutic intervention that incites inherent physiological repair/recovery

mechanisms in the kidney. Here, we investigate in rats to what extent contralateral Nx is able to attenuate or revert CKD progression when performed well beyond the acute injury phase, i.e. increased Nx delay time after UIRI.

Methods: AKI was induced in male Wister rats by left UIRI (60 min, 35°C body temp) after which contralateral Nx was performed 3, 10 or 20 days later. Renal function was assessed by serum/urine creatinine and transcutaneous GFR measurement 24h and 72h after Nx and weekly thereafter. In controls no Nx was performed until 24h before euthanization at week 11 to allow renal function assessment at that time. Rats were euthanized 11 weeks after Nx. Renal histology was evaluated by light microscopy.

Results: When no Nx was performed, renal function of the injured kidney decreased 44% compared to sham at week 11. Nx at day 3 induced full functional recovery from week 5 after Nx on, whereas Nx at day 10 and 20 led to a persistent 20% loss of renal function from week 1 after Nx on ($p<0.05$). Nx at day 3 was able to attenuate renal atrophy and tubulointerstitial expansion. Nx at day 10 and 20 were less efficient and led to 1.6 ($p>0.05$) and 2.6 ($p<0.05$) fold increase of tubulointerstitial area compared to sham. There was no difference in renal function outcome between Nx at day 10 and 20.

Conclusions: Early contralateral Nx after UIRI rescues renal function and morphology, whereas delayed Nx does not allow full recovery of the injured kidney. These results imply that a damaged kidney loses its intrinsic (compensatory) recovery potential over time and that an early intervention is more efficient in averting CKD outcome. The contribution of compensatory hypertrophy versus epithelial repair needs to be investigated.

PUB032

Role of Endothelial KLF4 in Determining the Severity of Cisplatin-Induced AKI in Mice

Wilfred Lieberthal,[2,1] Meiyi Tang,[2] Evgenii Boriushkin,[2] Sandeep K. Mallipattu.[2]
[1]Nephrology, Northport Veterans Administation Hospital, Stony Brook, NY; [2]Nephrology, Stony Brook Medicine, Stony Brook, NY.

Background: Cisplatin is a common cause of AKI in humans. The role played by the Kruppel-like Transcription-factor 4 (KLF4) in the pathogenesis of cisplatin-induced AKI is not known. This study had two objectives: i) to develop a novel model of cisplatin-induced AKI in mice and ii) to use this model to determine whether KLF4, expressed in endothelial cells (EC KLF4), contributes to determining the severity of this form of renal failure.

Methods: Cisplatin-induced AKI was induced by giving 3 daily doses of cisplatin (15mg/kg) (or its vehicle) to mice by intraperitoneal injection. Blood samples were obtained on Day 0 (immediately before the first dose of cisplatin/vehicle), and again on Days 4, 8 and 12.

Results: In wild type (WT) mice, the creatinines on Day 0 were comparable in the vehicle- and cisplatin-treated mice (0.098±0.005 and 0.112±0.004mg/dl respectively). On Day 4, the creatinines in vehicle- and cisplatin-treated mice were no different from those on Day 0. However, on Day 8, the creatinine in the cisplatin-treated group increased to 0.414±0.127mg/dl, and was higher than the creatinine in the vehicle-treated mice (0.122±0.007mg/dl) ($p<0.001$). On Day 12, the creatinine in the cisplatin-treated mice fell to 0.201±0.005mg/dl ($p<0.01$ vs day 8), and was comparable to the creatinine in the vehicle-treated mice (0.112±0.01mg/dl). We next compared the effects of cisplatin-induced injury in EC KLF4 KO mice and their Cre controls. The creatinines in the vehicle- and cisplatin-treated Cre and KO mice on Day 0 were comparable. On Day 4, all the KO mice (but none of the Cre mice) died after blood samples were obtained. The creatinine in cisplatin-treated KO mice on Day 4 was considerably higher (1.061±0.351mg/dl) than in the vehicle-treated KO mice (0.110±0.007mg/dl) ($p<0.001$). In the Cre mice, the creatinines in the vehicle- and cisplatin-treated mice on Day 4 were comparable to each other and to the creatinines on Day 0.

Conclusions: We have developed a model of cisplatin-induced AKI which is characterized by a developmental phase followed by a recovery phase. This pattern is similar to that observed in humans with AKI. We also show that EC KLF4 plays a major role in protecting endothelial cells from injury, and in reducing the severity of renal failure caused by cisplatin

PUB033

Interaction of Properdin and Macrophages in Renal Ischemia-Reperfusion Injury and Its Related Models

Wenting Li,[1] Yuanyuan Wu,[2] Yufang Zhang,[1] Hui Wang,[3] Weiwei Chen,[1] Bin Yang.[4,1] *[1]Nantong University, Nantong, China; [2]University of Nantong, Nantong, China; [3]Yancheng First People's Hospital, YanCheng, China; [4]University of Leicester, Leicester, United Kingdom.*

Background: Properdin, the only positive regulator of complement alternative pathway, may also act as a pattern-recognition molecule. Macrophages play critical roles in renal ischemia-reperfusion injury (IRI). However, the interaction of properdin and macrophages in renal IRI, and upon which the impact of erythropoiesis derived helix B surface peptide (HBSP) and cyclic HBSP (CHBP), are not well defined.

Methods: This study used a mouse model subjected to bilateral renal ischemia for 30 min, and followed by reperfusion for 6, 12, 24, 48, 72 h and 1 week, and with or without CHBP treatment at 48 h. In addition, RAW 264.7 macrophages were stimulated by H_2O_2 of 50, 100, 200 and 400 μmol/L for 24 h; or 200 μmol/L H_2O_2 for 6, 12, 24 and 36 h. Moreover, macrophages were pretreated with 30 nM of HBSP or 20 nmol/L of siRNA target properdin to validate the effect of properdin on IR related injury. Properdin, inflammation and apoptosis-related caspase-3 and HMGB-1, and apoptosis were detected.

Results: Properdin protein and infiltrated macrophages were increased in the IRI kidneys started at 24 h, peaked at 72 h, and fell at 1 week. With increased H_2O_2 concentration or incubation time in macrophages, properdin was increased first and then decreased, with highest levels at 200 μmol/L or 12 h, and positively correlated with HMGB-1 and cleaved caspase-3 in Macrophages. CHBP inhibited properdin in mouse kidneys at the early stage of IRI, while HBSP pretreatment also inhibited properdin increased by H_2O_2 in macrophages, with decreased HMGB-1, caspase-3 and apoptotic cells. However, Properdin siRNA reduced properdin mRNA, but increased HMGB-1 and cleaved caspase-3 protein compared to negative siRNA, with raised apoptotic cells.

Conclusions: The dynamic change of properdin was shown in IRI kidneys and H_2O_2 stimulated macrophages, associated with the mediators of inflammation and apoptosis. Inhibiting properdin by CHBP/HBSP in mice or macrophages is protective against early injury, whereas silencing properdin in macrophages with compromised clearance of apoptosis and inflammation may be detrimental. The differential roles between HBSP and properdin siRNA, and their underlying mechanisms are worthy to be further explored.

PUB034

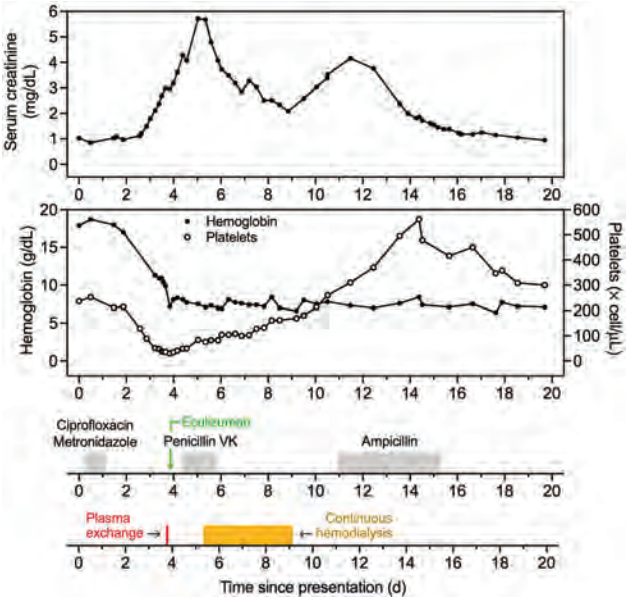
Escherichia coli-Associated Hemolytic Uremic Syndrome (HUS) Treated with Eculizumab

Graham T. Gipson. *Virginia Commonwealth University School of Medicine, Richmond, VA.*

Introduction: Eculizumab, a terminal complement inhibitor, is enjoying use in a number of complement-disregulatory disease. A major use of eculizumab is treatment of atypical hemolytic–uremic syndrome (aHUS). Since Shiga toxin–associated HUS (STAHUS) are driven by toxic complement dysregulation, it stands to reason that eculizumab might provide therapeutic benefit in STAHUS.

Case Description: A 41-year old white male presented with a 2-day history of abdominal pain and frankly blood diarrhea. The only antecedent event of note was consumption of sushi. Initial exam showed normal vital signs and bilateral lower abdominal tenderness without signs of peritonitis. He received empiric antibiotics (ciprofloxacin and metronidazole) along with supportive care. Over 24 h he developed hypoactive encephalopathy, severe azotemia with oliguria, and a sharp drop in hemoglobin and platelet count. After 96 h his stool culture disclosed *E. coli* O157:H7, thus prompting the diagnosis of *E. coli* O157:H7–associated hemorrhagic enterocolitis with probable neurologically significant HUS. He underwent one session of plasma exchange followed by a single 900-mg dose of eculizumab. Continuous hemodialysis was ultimately initiated for oliguric AKI. After almost 3 weeks in-hospital he enjoyed a near-total recovery and was discharged to a rehabilitation facility prior to return home. The chronology of key clinical events and laboratory parameters is shown in the figure.

Discussion: We demonstrate here the favorable clinical course of Shiga toxin–associated hemolytic–uremic syndrome (STAHUS) following a single dose of the terminal complement inhibitor eculizumab in an otherwise healthy adult patient. Successful cases like this add to the base of evidence that eculizumab is useful in treating multiple diseases driven by complement system dysregulation.



PUB035

Protection Afforded by Angiotensin II Receptor Activation Against AKI Is Associated with Upregulation of Tubular Autophagy

Hirohito Sugawara, Norihito Moniwa, Tetsuji Miura. *Sapporo Medical University, Sapporo, Japan.*

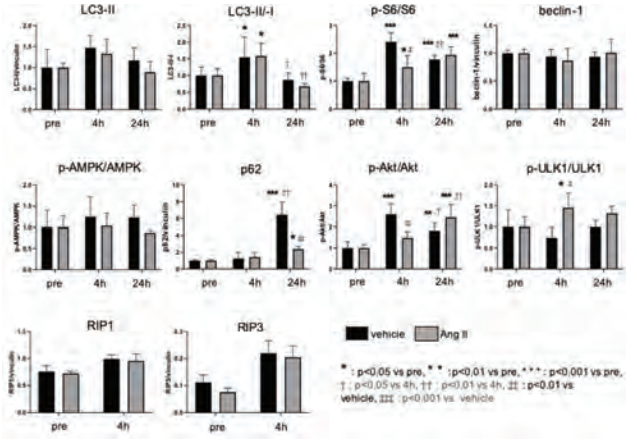
Background: Autophagy reportedly plays a protective role in acute kidney injury (AKI), and there is in vitro evidence to indicate autophagy upregulation by the renin-angiotensin system. Here we examined whether activation of the angiotensin II (Ang II)

receptor protects the kidney from ischemia-reperfusion (I/R) injury by upregulation of autophagy or modulation of necroptosis in vivo.

Methods: In Study 1, Sprague-Dawley rats were assigned into treatments with vehicle (Veh) or Ang II (200 ng/kg/min). Each drug was subcutaneously infused for 72 hrs. At the end of the infusion, kidneys were removed for assessment of autophagy. In Study 2, rats received treatments with Veh or Ang II and then underwent 30-min renal artery occlusion/reperfusion or sham surgery. Blood and kidneys were collected for assessment of renal damages and autophagy at 0.5, 4, or 24 hrs after the surgery.

Results: In Study 1, autophagosomes were increased in proximal tubular cells in the Ang II group than in the Veh group (0.88 vs. 0.29 a.u.; P=0.002). In Study 2, autophagosomes were increased at 4 hrs after I/R in the Veh group. BUN and ATN score were significantly lower in the Ang II group than in the Veh group at 24 hrs after I/R (99.2 vs. 123.3 mg/dl; P=0.004, 4.0 vs. 4.6; P=0.011, respectively). The number of autophagosomes was larger in the Ang II group than in the Veh group at baseline and 4 hrs after I/R (0.54 vs. 4.68; P<0.0001, 1.39 vs. 4.88 a.u.; P<0.0001, respectively). Akt phosphorylation was suppressed and ULK1-Ser555 phosphorylation was increased in the Ang II group at 4 hrs after I/R. RIP1 and RIP3 levels at baseline and after I/R were not affected by Ang II (Fig).

Conclusions: Short term infusion of Ang II increases autophagosomes in the renal tubular cells and alleviates I/R kidney injury. The renoprotective effect of Ang II may be associated with upregulation of autophagy but not with inhibition of necroptosis.



PUB036

Muscle-Renal Syndrome

Swetha Rani Kanduri, Karthik Kovvuru, Jorge L. Castaneda. *Medicine/Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Introduction: Pathophysiology of non-traumatic rhabdomyolysis caused by viral infection has been poorly understood. We present a case of Adenovirus infection causing severe rhabdomyolysis and AKI that required dialysis for 2 weeks before complete clinical renal recovery.

Case Description: 29-year-old African American female with hypertension presented with flu like symptoms and decreased urine output. She had body aches, sore throat, loss of appetite, fevers/chills, and bilateral lower extremity weakness for four days. Denied herbal supplements or over the counter medications. Admission labs; sodium 127mmol/L, bicarbonate 17mmol/L, BUN 31mg/dl, creatinine 4.9mg/dl, phosphorous 7.6mg/dl, AST 920 U/L, ALT 256 U/L, Creatine Kinase (CK) >100,000 U/L. Urine analysis with moderate leukocytes, protein, moderate blood and positive myoglobin. Proteinuria 500 mg/24hr. Sputum culture was positive for adenovirus and plasma PCR levels were 29,000 copies/ml. CMV, EBV, HIV, Hepatitis, Influenza, Corona virus, Para influenza, Streptococcus, Legionella, LDH, Haptoglobin, Schistocytes, ANA, anti Jo, La, SSA, SSB, myomarker panel, toxic alcohols, acetaminophen and salicylates levels have been negative. Adenovirus was thought to be responsible for rhabdomyolysis leading to acute kidney injury. CK persistently remained elevated and her oliguria persisted despite aggressive fluids. She required dialysis for 2 weeks before renal recovery. Adenovirus PCR levels were undetectable and CK levels trended down by the day of discharge.

Discussion: Adenovirus is a non-enveloped dsDNA virus. There are 7 Human Adenovirus species and up to 57 serotypes that could induce different clinical manifestations. The mechanism of rhabdomyolysis and renal involvement has been described in multiple review papers, involves fluid sequestration and subsequent activation of neuro humoral response, tubular damage induced by renal vasoconstriction, oxidative stress and obstruction. Relevant areas of further investigation is to have a better understanding in the pathophysiology of rhabdomyolysis at the muscular level induced by virus (direct damage vs induced by cytokines) and if early use of antivirals may arrest the sequence of events.

PUB037

Cyclo(His-Pro) Protects Against Cisplatin-Induced AKI Through Inhibiting the p53-Mediated Apoptotic Pathway

Jong joo Moon,[4] Yong Chul Kim,[4] Jinseon Jeong,[4] Ji Eun Kim,[4] Sunhwa Lee,[4] Jae Wook Lee,[3] Mi-yeon Yu,[4] Dong Ki Kim,[4] Yon Su Kim,[2,1] Seung Hee Yang.[1] *[1]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]National Cancer Center, Seoul, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Cyclo(His-Pro) (CHP) is an endogenous cyclic dipeptide that exerts cellular protective effects against anti-oxidative damages. However, the role and mechanisms for CHP in preventing cisplatin-induced nephrotoxicity remains largely unknown. In this study, we sought to investigate whether and how cyclo(His-Pro) prevents in cisplatin-induced acute kidney injury (AKI) mouse model.

Methods: In this study, a single intraperitoneal injection of cisplatin (10 mg/kg) was employed to induce AKI in ICR mice. To determine the role of CHP on cisplatin-induced AKI, the mice were pretreated with at different dosage CHP (1, 3 mg/kg) orally for 7 days before cisplatin injection. To explore the cell protective effect of CHP, in vitro study was also performed with primary cultured human tubular epithelial cells (hTECs). ROS assay was tested to measure antioxidant effect of CHP.

Results: The mice developed severe acute kidney dysfunction exhibited as elevated BUN and creatinine level at day 2 after cisplatin injection. Mice with pretreatment of CHP showed markedly attenuated cisplatin-induced acute kidney injury. Additionally, pretreatment of CHP improved the activity of superoxide dismutase (SOD) and glutathione peroxidase (GPx) which are the enzymes to defense against oxidative stress. Comparable findings were observed in the protein expression of p53, Bax, caspase-3, and c-Jun which is associated with apoptosis, especially intrinsic apoptotic pathway. In cultured hTECs, which is a human kidney epithelial cells, CHP showed a protective effect against oxidative stress that induced by H_2O_2. Additionally, live cell frequency was increased with CHP dose dependent manners. This study demonstrated that CHP may protect against cisplatin-induced tubular cell apoptosis and AKI through suppression of p53 and up-regulation of antioxidant defense.

Conclusions: Together, this study demonstrated that CHP may protect cisplatin-induced AKI through inhibiting apoptosis. Considering the effects of CHP, it can be applied to the AKI protection.

PUB038

Isoliquiritigenin Attenuates Lipopolysaccharide-Induced AKI Through Suppression of the HMGB1 Pathway Against Ferritinophagy

Yi Li,[1] Yun Tang,[1] Yanmei Wang,[1] Chan Wang,[2] Meidie Yu.[3] *[1]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology, Chengdu, China; [2]Department of Nephrology, Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital, Chengdu, China; [3]University of Electronic Science and Technology of China, Chengdu, China.*

Background: Septic acute kidney injury (AKI) mainly results in life-threatening renal dysfunction involving renal tubular injury to bring heavy burden to patients in intensive care unit (ICU). However, there is still a lack of therapy to prevent septic AKI effectively and inexpensive.

Methods: To observe the role and novel mechanism of isoliquiritigenin (ISL) which isolated from the roots of licorice in septic AKI, we used LPS to induce renal tubular injury upon septic AKI both in vitro and in vivo. 50mg/kg ISL was once given to the mice orally one hour before 1 mg/kg LPS i.p injection. 50 μM and 100 μM ISL respectively pre-treat the human renal tubular cells 5 hrs before 2 μg/ml LPS stimulation.

Results: ISL pretreatment apparently reversed LPS-induced renal dysfunction and ameliorated murine renal tubular injury. Furthermore, we observed that LPS induced autophagy and ferroptosis in renal tubular, whereas ISL pretreatment significantly suppress autophagy and ferroptosis of renal tubular both in vitro and in vivo. Mechanically, autophagy activated ferroptosis via NCOA4-mediated ferritinophagy. Moreover, HMGB1 is required for ferritinophagy in renal tubular. ISL treatment inhibited the expression of HMGB1.

Conclusions: These results suggest that ISL protects LPS-induced acute kidney injury through suppression of HMGB1 pathway in renal tubular against ferritinophagy.

Cysteinyl-tRNA Synthetase Alleviates Renal Ischemia Reperfusion Injury Through Its Anti-Pyroptosis Role in Tubular Epithelial Cells

Yi Li,[1] Meidie Yu,[3] Yun Tang,[1] Yanmei Wang,[1] Chan Wang,[2] Yunlin Feng.[4]
[1]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology, Chengdu, China; [2]Department of Nephrology, Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital, Chengdu, China; [3]University of Electronic Science and Technology of China, Chengdu, China; [4]Sichuan Provincial People's Hospital, Chengdu, China.

Background: Acute kidney injury (AKI) is a common yet poorly treated entity, characterized by high mortality and significant risk of developing chronic kidney diseases. The pathophysiological mechanism of AKI remains underinvestigated.

Methods: To further elucidate the mechanism of AKI, we performed a detailed molecular characterization of ischemia reperfusion injury(IRI) model both *in vitro* and *in vivo*.

Results: The data comprising label free proteomics analysis in renal tubular epithelial cells, histological studies of renal tissue from IRI rat model, and molecular characterization of targeted gene activity provided a comprehensive profile of injury and repair responses in kidney due to IRI. Label free proteomics analysis and renal histological studies highlighted cysteinyl-tRNA synthetase (CysRS) was associated with renal tubular atrophy following IRI. CysRS was shown to alleviate IRI both *in vitro* and *in vivo* through its suppression of NLRP3 inflammasome assembly, thus reducing the renal tubular epithelium damage mediated by caspase-1 dependent cellular pyroptosis.

Conclusions: Our current study identified CysRs could alleviate renal IRI damage through its anti-pyroptosis role in tubular epithelium. The findings might provide valuable evidence for investigating potential underlying pathophysiological mechanisms and novel therapeutic targets for AKI. Feng Yunlin, Li Yi should be addressed as corresponding authors and these two authors contributed equally to this study.

Label-Free Identification of the Potential Association Between RPS7 and SRP14 in HK_2 Cells upon Ischemia-Reperfusion Injury

Yi Li,[1] Yanmei Wang,[1] Yun Tang,[1] Chan Wang,[2] Meidie Yu,[3] Li Wang.[1] *[1]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology, Chengdu, China; [2]Department of Nephrology, Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital, Chengdu, China; [3]University of Electronic Science and Technology of China, Chengdu, China.*

Background: Renal ischemia/reperfusion injury (IRI) is one of the main reasons for acute kidney injury (AKI), which is associated with high mortality and end-stage renal disease (ESRD). However, we do not completely understand the mechanism of renal damage induced by IRI and renal failure with effective early diagnosis and treatment.

Methods: We performed LFQ Proteomic analysis and bioinformatics analysis of HK_2 renal tubular epithelial cells after ischemia for 45 min and reperfusion for 24 hrs. Then we identified the subsequent finding of LFQ and bioinformatics by RT-PCR and immunohistochemistryin renal IRI mouse model. To verify whether RSP7 and SRP14 interact, we validated by IP and cellular immunofluorescence.

Results: In current study, LFQ Proteomic analysis detected 28 proteins up-regulated by fold change>1.2 ($p<0.05$) and 45 proteins down-regulated by fold change<5/6 ($p<0.05$). The results of GO analysis showed these differentially expressed proteins could participate in biological processes, cellular components and molecular functions, mainly including multi-organism cellular process, interaction with host, intracellular organelle, protein binding, RNA binding and so on. KEGG systematically analysis revealed that the pathways involved in differential proteins include alanine, aspartate and glutamate metabolism, endocytosis, 2-Oxocarboxylic metabolism, TCA cycle and so on. In the network map, PPI analysis found an interaction between SRP14 and RPS7 in HK_2 renal tubular cells after IRI. Consistently with the results of PPI analysis, the RT-PCR and immunohistochemistry showed that the expression of SRP14 significantly increased and the expression of RPS7 significantly increased in murine renal tissue after IRI. The IP and cellular immunofluorescence confirmed that SRP14 and RPS7 are interacting.

Conclusions: Our data revealed increased expression of RPS7 and SRP14 *in vitro and in vivo*after renal IRI. And these results possible suggested the association of RPS7 and SRP14 in renal tubular epithelial cells after IRI. This finding might set base to further study of novel biomarkers and therapeutic targets for AKI caused by renal IRI. Li Wang and Yi Li should be addressed as corresponding authors and these two authors contributed equally to this study.

Cisplatin Induces Inflammation and Secretion of AKI Biomarkers in Kidney Organoids

Veronika Sander,[1] Jenny L. Digby,[1] Aneta J. Przepiorski,[2] Alan J. Davidson.[1]
[1]Department of Molecular Medicine and Pathology, University of Auckland, Auckland, New Zealand; [2]University of Pittsburgh, Pittsburgh, PA.

Background: The clinical use of the chemotherapeutic drug cisplatin is limited by its severe nephrotoxic side effects. The development of reno-protective therapies for cisplatin-induced acute kidney injury (AKI) is hampered by a lack of understanding of cisplatin-mediated nephrotoxicity. In recent years, kidney organoids derived from human pluripotent stem cells have been proposed as a platform to study AKI. Here, we describe a comprehensive approach to test the applicability of kidney organoids to model cisplatin-induced AKI.

Methods: Different doses of cisplatin were added to the culture medium of induced pluripotent stem cell-derived kidney organoids. Cisplatin-treated organoids along with controls were analysed for injury and inflammation markers by quantitative PCR, immunohistochemistry and antibody array.

Results: We found that organoids treated with cisplatin display increased levels of the kidney injury marker KIM1, DNA damage and cell death in a dose-dependent manner. Co-localization of the DNA double-strand break marker yH2AX with the different cell types in the organoids revealed that cisplatin predominantly affects proliferating cells suggesting a general cytotoxic effect reminiscent of the drug's impact on tumour cells. This result is contrary to cisplatin specifically damaging the proximal tubule *in vivo*. We measured low-level expression of proximal tubule-specific cisplatin transporters in organoids, providing one explanation for this observation. We further detected several AKI biomarkers and cytokines in the culture medium of cisplatin-treated organoids, consistent with the induction of an AKI-like inflammatory response. Notably, we observed peritubular accumulation of the injury biomarker Growth differentiation factor (GDF) 15 in cisplatin-treated organoids, and a worsening of cisplatin-induced injury when the organoids were co-treated with recombinant GDF15.

Conclusions: Our work validates the use of kidney organoids for modelling the inflammatory aspects of cisplatin-induced AKI and supports the potential of this human cell-based system for developing improved reno-protective therapies.

Role of Necroptosis in Contrast-Induced Nephropathy in a Rat Model of CKD and Its Modification by Tolvaptan

Satoru Shibata, Norihito Moniwa, Hirohito Sugawara, Toshiyuki Yano, Atsushi Kuno, Masato Furuhashi, Masaya Tanno, Takayuki Miki, Tetsuji Miura.
Sapporo Medical University, Sapporo, Japan.

Background: Risk of contrast-induced nephropathy (CIN) is high in patients with chronic kidney disease (CKD). However, there is no specific preventive measures for CIN in CKD. In this study, we examine role of necroptosis in the mechanism of CIN in CKD and its possible modification by tolvaptan and saline infusion.

Methods: Using male SD rats, CKD was induced by subnephrectomy (5/6 nephrectomy, SNx), and CIN was induced by administration of indomethacin (10mg/kg), L-NAME (10mg/kg) and contrast medium (1600 mg I/kg). First, rats were divided into sham (n=6), SNx (n=17), and SNx+CIN (n=17). Forty eight hours after induction of CIN, serum creatinine (sCr), blood urea nitrogen (BUN), urinary albumin creatinine ratio (ACR) were measured and protein expressions in the kidney were examined by western blot. Next, we assessed the effect of necrostatin-1 (Nec-1, 1.65 mg/kg), a necroptosis inhibitor, injected just before and 24 hours after induction of CIN on renal function. Finally, to examine the effect of Tol (10 mg/kg) combined with saline infusion on CIN in CKD, we compared SNx (n=7), SNx+CIN (n=11) and SNx+CIN+Tol (n=8).

Results: SNx+CIN increased in sCr, BUN and log ACR compared with other groups, and also increased in caspase 3, cleaved caspase 3, caspase 8, RIP1, RIP3 (Fig.1), suggesting that renal damage in CIN was associated with activation of apoptosis/necroptosis signals. sCr (0.69 vs 0.56 mg/dl, $P<0.01$), BUN (37.2 vs 28.6 mg/dl, $P<0.01$) and log ACR (5.9 vs 4.5, $P<0.01$) were lower in Nec-1-treated SNx+CIN than in vehicle-treated SNx+CIN. Tol partially improved BUN and ACR and suppressed elevation of RIP1 and RIP3 levels in SNx+CIN (Fig.2).

Conclusions: Necroptosis contributes to CIN in CKD and its detrimental effect may be suppressed by tolvaptan.

Uncovering a Functional Loop Between Renal Tubular Epithelial Cells and Double Negative T Cells

Mohanraj Sadasivam,[1] Sanjeev Noel,[1] Johanna T. Kurzhagen,[1] Abdel Hamad,[1] Hamid Rabb.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Renal epithelium is a major tissue in kidney. Renal epithelial cells play an important role in inducing defensive mechanism and fully participate in renal innate immune responses. On the other hand, CD4-CD8- double-negative (DN) T cells, a rare population in periphery are preferentially localized into renal epithelial tissues and spontaneously proliferate in the steady state and protect against AKI. However, the functional relationship between renal epithelial cells and kidney DN T cells are unknown. We hypothesize that renal epithelial and kidney DN T cells regulate each other homeostasis and function.

Methods: To test this hypothesis, we used B6 wild type and MHC knockout mice, T cell functional assays and *in-vitro* co-culture system. Renal tubular epithelial cells and lymphocytes from both kidney and lymph node were isolated, cultured and analyzed by flow cytometry.

Results: Our data demonstrate that renal tubular epithelial cells (RTE) induce significant expansion of DN T cells in cultures. Addition of DN T cells with RTE significantly increased the frequency (DN; 1.2 ± 0.6 vs RTE+DN; 13.8 ± 3.5, p≤0.0001) and absolute cell number (DN; 0.2 ± 0.1x10^4 vs RTE+DN; 2.9 ± 0.9 x10^4, p≤0.0001) of DN T cells in *in-vitro*. The increased DN T cell number is due to increased activation and proliferation of DN T cells. Further, the activation and proliferation is TCR-independent, as RTE from class-I and II MHC KO mice can also induce proliferation of DN T cells. *In-vitro* experiments show that IL-7, a product of epithelial cells, significantly increases DN T cell proliferation (DN; 30.1% ± 4.2 vs DN+IL-7; 76.2%± 3.3, p≤0.0001) with decreased apoptosis (DN; 60.5% ± 10.5 vs DN+IL-7; 36.3 ± 2.5, p≤0.0001). In addition, the IL-7 dependent expansion of DN T cells is limited to PD-1+ DN T cell subsets. Transwell experiments show that cell-mediated interaction is necessary for enhanced DN T-cell proliferation in co-culture. Reciprocally, DN T cells also increased the survival of kidney epithelial cells *in-vitro*. However, the underline mechanism are unknown and investigated further.

Conclusions: These findings demonstrate a previously unknown mechanism and functional relationship between RTE and DN T cells, and its role in maintaining each other homeostasis and function. Ongoing studies are evaluating these responses during AKI and repair.

The Effect of Nintedanib on Renal Interstitial Fibrosis

Donghyuk Kang,[2] Yun Jae Kwon,[2] Hyung Duk Kim,[2,1] Eun Nim Kim,[1] Yongjie Jin,[1] Ji Hee Lim,[1] Yaeni Kim,[2,1] Cheol Whee Park,[2,1] Bumsoon Choi.[3,1] *[1]The Catholic University of Korea, Seoul, Republic of Korea; [2]Seoul St. Mary's Hosp, Catholic Univ of Korea, Seoul, Seoul, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea.*

Background: Pericyte is known as the main source of myofibroblast in renal interstitial fibrosis. However, the mechanism of mediating pericyte-myofibroblast transitions is unclear. In this study, we examined the effect of nintedanib, a triple kinase inhibitor of platelet-derived growth factor receptor (PDGFR), fibroblast growth factor receptors (FGFR) and vascular endothelial growth factor receptor (VEGFR) on renal fibrosis to identify the main factor inducing pericyte changes.

Methods: Surgically created unilateral ureteral obstruction (UUO) mouse model was used to generate progressive renal fibrosis. 3 groups were assigned; control group (sham operation), UUO 10 days and UUO 14 days. Nintendanib was given by gavage after ureteral ligation. Pericyte was confirmed by PDGFR-beta and NG2 double stain.

Results: In UUO (D10) group, decrease of pericyte and vascular density, and increase of interstitial fibrosis were observed. These findings were more noticeable in the UUO (D14) group. Compared with the UUO (D10) group, interstitial fibrosis was attenuated in the nintedanib treated UUO (D10) group, and pericyte was increased. In the nintedanib treated UUO (D14) group, the fibrosis progressed more than nintedanib treated UUO (D10) group. But they showed ameliorated interstitial fibrosis and increased number of pericytes compared to the UUO (D14) group.

Conclusions: Nintedanib treatment resulted in attenuation of renal interstitial fibrosis in UUO mouse model. And nintedanib decreased pericyte-myofibroblast transition. This is thought to be due to VEGFR inhibition.

Paradigm Shift: Sepsis-Induced AKI Not due to Hypotension

Prince Amaechi,[1] Kingsley A. Lartey.[2] *[1]Spartanburg Regional Medical Center, Spartanburg, SC; [2]Spartanburg regional medical center, Greer, SC.*

Introduction: The patient is a 65 y/o man with a history of CKD 4 (eGFR 20- 25 ml/min), diabetes, stable chronic heart failure without recent exacerbation and hypertension. He was diagnosed with sepsis-associated acute renal failure (AKI) but in the absence of hypotension related etiology as to suggest acute tubular necrosis. We subsequently hypothize that sepsis-induced AKI may be the sequele of an adaptive to maladaptive inflammatory response rather than a purely hemodynamic phenomena.

Case Description: On presentation he was lethargic, hypothermic at 35.1 deg C, heart rate up to 107, eGFR 18 ml/min, peripheral leucocytosis 25 K/cmm, however his blood pressure (BP) was stable. The mean arterial blood pressure was significantly higher than 75 mmHg (94/65 mmHg) throughout hospital course and he did not require vasopressors or have shock. He was diagnosed with sepsis from ascending urinary tract infection due to Enterobacter Cloaca, as the source and was initially treated with Cefepime which was later changed to Levofloxacin in response to sensitivity report. Blood cultures, serology for HSV I/II PCR were negative. The patient however sustained AKI and given his comorbidities and previous CKD, he sustained inexorable decline in renal function and ended up needing to start dialysis due to uremic symptoms, with a new clinical designation as end-stage renal disease.

Discussion: We wish to point out that practicing clinicians are increasingly recognizing a concept we call "sepsis-induced AKI". It has been known that sepsis, major surgery, heart failure and hypovolemic shock are all associated with AKI & traditionally was taught to be due to ischemia on the basis of macro hemodynamic changes. However we document that AKI can occur in the absence of global hypoperfusion. In a paper published by Hermando Gomez et al. published in Shock. 2014 Jan; 41(1): 3-11 they attempted to put forward a theory for AKI in the absence of shock (or hypotension) involving DAMPs/PAMPs, abnormal signaling and oxidative stress response. Circulating factors from burn patients with sepsis-induced AKI can induce tubular and glomerular alterations in septic patients who do not have AKI (Crit Care. 2008; 12(2): R42.). We propose that it is time for a new paradigm for sepsis-induced AKI should lead to larger studies in translational medicine and randomized clinical trials.

PUB046

Mechanistic Insight for Increased Susceptibility to Cisplatin Nephrotoxicity with NHERF1 Loss

Adrienne M. Bushau,[1] Walter H. Watson,[1] Yuxuan Zheng,[1] Kenneth Gagnon,[1] Kathleen Kitterman,[1] Michelle T. Barati,[1] Leah J. Siskind,[1] Michael E. Brier,[1] Eleanor D. Lederer.[2] *[1]University of Louisville, Louisville, KY; [2]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

Background: Acute kidney injury (AKI) develops in 30% of patients who receive cisplatin (CIS), a widely used chemotherapeutic agent. We have previously shown NHERF1 loss results in increased susceptibility to CIS nephrotoxicity. We hypothesize that NHERF1 loss leads to an altered renal oxidative state resulting in increased susceptibility to CIS toxicity.

Methods: We treated 3-4 month old male wild-type (WT) C57BL/6 and NHERF1 knock out (KO) mice with vehicle or CIS (20 mg/kg dose IP) for 72 hours. Plasma, liver and kidney cortex were collected for measurement by HPLC of the reduced and oxidized forms of small molecular weight thiols (glutathione (GSH), glutathione disulfide (GSSG), cysteine (Cys) and cystine (CySS), the mixed disulfide between the two, cysteine-glutathione disulfide (CySSG); for measurement of lipid peroxidation by Thiobarbituric Acid Reactive Substances (TBARS); for γ-glutamyl transferase (GGTase) activity; and immunohistochemistry (IHC) for 4-hydroxynonenal (4-HNE) was performed in kidney tissue slices.

Results: In vehicle-treated mice, the only significant differences observed were a decrease in plasma CySS and an increase in liver GSSG in KO mice relative to WT. In response to CIS, plasma CySS and GSH decreased, while both Cys and CySS increased in the kidney in both genotypes. CIS had no effect on the kidney levels of any of the forms of GSH, but in the liver, all 3 forms (GSH, GSSG and CySSG) were decreased in CIS WT and KO mice, corresponding to a 6.5 mV oxidation of the GSH/GSSG redox couple in the liver of both genotypes. No significant differences were found in TBARS or GGTase activity with either treatment or genotype. IHC for 4-HNE showed no differences between genotypes for vehicle-treated kidneys, while CIS resulted in an increase in 4-HNE staining within the cortex and juxtamedullary (JM) region of both genotypes, more marked in the CIS KO kidneys, especially in the JM regions.

Conclusions: We conclude that loss of NHERF1 does not lead to changes in kidney GSH metabolism but does so in liver. CIS results in more pronounced expression of the 4-HNE adducts in the KO vs WT mouse kidneys. Therefore, the increased susceptibility of KO mice to CIS nephrotoxicity may be related to increased sensitivity to CIS itself.

PUB047

Suppression of Nrf2 Activity by HIF-1α Promotes Fibrosis After AKI

Corry D. Bondi, Brittney M. Rush, Mohammad M. Al-bataineh, Roderick J. Tan. *University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is a rapid reduction in renal function due to damage to tubular epithelia and can occur after ischemia/reperfusion injury (IRI). Ischemic injury results in both impaired oxygen and nutrient delivery to the kidney. Kidney tubular epithelial cells are particularly vulnerable to ischemic injury. To offer protection, cellular mechanisms have evolved to mitigate the damage of IRI while attempting to restore cellular homeostasis. Specifically, two notable cellular pathways are activated including nuclear factor erythroid 2 like 2 (Nrf2) and hypoxia inducible factor 1α (HIF-1α).

Methods: C57BL/6 mice were subjected to IRI. Ischemia times were titrated to induce mild to severe injury and kidneys were harvested at various acute and chronic time points post-reperfusion. To simulate mild and severe injury conditions *in vitro*, proximal tubular HK-2 cells were exposed to either nutrient replete or nutrient deficient conditions, respectively, in the presence of HIF activation with cobalt chloride ($CoCl_2$). Immunoblotting, co-immunoprecipitation, qPCR, and RNA interference were used.

Results: The protective Nrf2 activity is activated by mild ischemia but is suppressed by severe ischemia *in vivo*. Mimicking these results, HIF-1α activation in nutrient replete conditions *in vitro* enhances Nrf2 nuclear localization and activity, while HIF-1α activation in nutrient deficient conditions suppressed Nrf2 activity. Localization and activity of Nrf2 were restored upon siRNA-mediated knockdown of HIF-1α. These effects were not due to direct interaction between HIF-1α and Nrf2, since these proteins did not co-immunoprecipitate *in vitro*.

Conclusions: Our data confirm that severe AKI leads to a maladaptive reduction in Nrf2 activity and ultimately to renal fibrosis. This may be due to Nrf2 inhibition by HIF-1α under severe ischemia conditions. We propose that the capacity to recover from an ischemic insult can be attributed to regulation of the Nrf2 pathway by HIF-1α.

PUB048

Metabolic Alterations in a Mouse Model of Cisplatin-Induced AKI

Yong Jin (James) Lim,[2] Emily D. Hartjes,[3] Nicholas Tonial,[1] Aaron R. Haig,[4] Brad Urquhart.[3] *[1]University of Western Ontario, London, ON, Canada; [2]Physiology and Pharmacology, Western University, London, ON, Canada; [3]Western University, London, ON, Canada; [4]London Health Sciences Centre, London, ON, Canada.*

Background: Cisplatin-induced acute kidney injury (AKI) occurs in 1/3 of cisplatin-treated patients. Cisplatin-AKI is diagnosed by elevated serum creatinine (SCr), but nephrotoxicity develops before measurable changes to SCr. Novel diagnostic/predictive markers of AKI may explain why only certain cisplatin-treated patients get AKI. FVB/N mice are more susceptible to cisplatin-AKI than C57BL/6. These two strains were used to model the interindividual variability of cisplatin nephrotoxicity. We aim to: 1) Measure expression of renal transporters/enzymes involved in cisplatin disposition; 2) Investigate metabolic differences between FVB/N and C57BL/6 mice using metabolomics; 3) Determine the effects of pharmacological inhibition of Oct2 and Oat1/3 (cisplatin uptake transporters in proximal tubule) with inhibitors cimetidine and probenecid.

Methods: Mice were treated with 15 mg/kg cisplatin or saline by intraperitoneal injection and sacrificed 1,3, and 4 days post-treatment. A subset of mice were pre-treated with a combination of cimetidine+probenecid, 15 mg/kg and 200mg/kg respectively, 1 hour prior to cisplatin treatment. A repeat dose of cimetidine was given 6 hours after cisplatin injection. AKI severity was assessed by plasma creatinine quantification and histological analysis. Gene expression was assessed using RT-PCR. LC-MS was used for untargeted metabolomics.

Results: Renal mRNA expression of transporters Oct2 and Oat1, and metabolizing enzyme Ggt1 were higher (+20%,+38%,+45%;$p<0.05$) in untreated FVB/N mice compared to C57BL/6. Principal component analysis (PCA) of untreated plasma samples showed separation based on strain. PCA of day 4 plasma samples separated cisplatin and saline groups for both strains. LysoPC(16:0), taurine, indoxyl sulfate, phenyl sulfate and p-cresyl sulfate were metabolites altered in cisplatin-AKI. Pharmacological inhibition of Oct2 and Oat1/3 resulted in a non-significant reduction of SCr compared to cisplatin treatment alone.

Conclusions: FVB/N mice exhibited higher expression of various renal transporters/enzymes involved in cisplatin disposition compared to C57BL/6. PCA clustering of plasma samples from untreated mice indicates metabolic differences between strains; separation by treatment suggests that cisplatin alters the metabolic profiles of the mice. Future work will study the metabolic changes upon Oct2 and Oat1/3 inhibition.

In Vitro Models of AKI Reveal Cell Type-Specific Cytokine Responses

Giulio Podda,[1] Mark E. Dockrell.[2] *[1]St Helier Hospital, Carshalton, United Kingdom; [2]South West Thames Institute for Renal Research, Surrey, United Kingdom.*

Background: The nature and severity of the renal injury determine the progression from AKI to CKD. Renal tubule interstitial fibrosis is the final common pathway in end-stage renal disease and is characterized by abnormal deposition of extracellular matrix (ECM) produced by myofibroblasts. The role of TGFβ and MCP-1 in renal fibrosis is well known but there is also evidence for a role of different cytokines such as IL-18 and IL-15. However there is no significant data about these mediators in acute kidney injury. We reproduced three different in vitro model of AKI (septic, Ischaemia-reperfusion and toxicity drug related) with the aim to observe the response of these mediators to an acute insult that potentially could be considered as markers of AKI.

Methods: Primary human proximal tubular cells phenotypically expressing GGT were cultured in collagen, plasma and cellular fibronectin and harvested the supernatant of culture medium. We reproduced an in vitro model of AKI with NaN3 for ischaemia reperfusion, gentamicin as toxic drug and LPS (Lipopolysaccharides) as septic model. The treatment lasted for 18 hours followed by RNA extraction and PCR. Collagen and plasma-cellular fibronectin samples were tested for IL-18, IL-15, TGF β and MCP-1. We also analysed the NAG secreted by tubular cells in cell culture medium and we compare NAG with NGAL.

Results: Significantly higher NAG activity was detected in NaN3, LPS and gentamicin models of AKI compared to control (p= 0.0014, 0.0125 and 0.0028). NGAL results were below the level of detection. Results from the LPS model tended to be extreemly variable with no obvious patern despite relatively consistent NAG results. There was no significant change in TGFβ expression in any of the models. Gentamycin and NaN3 induced distinctly different cytokine resposnes. Gentamycin iinduced MCP1 and IL15 while reducing IL18 expression. NaN3 tended to increase MCP1 but to a lesser degree and did not alter the IL15/IL18 ratio. Unexpectedly culturing cell on cellular fibronectin without treatment altered MCP1 expression.

Conclusions: Our pilot data indicates that the cytokine responses of renal epithelial cells to AKI varies significantly depending on the nature and not the severity of the injury. The relative expression of key opposing mediators such as IL15 and IL18 may influence the nature of the renal recovery

Anemia and Kidney Function Decline Among the Middle-Aged and Elderly in China: Results from the China Health and Retirement Longitudinal Study (CHARLS)

Chao Yang,[1] Qinqin Meng,[4] Yafeng Wang,[4] Zaiming Su,[2] Guilan Kong,[2] Luxia Zhang,[1,2] Yaohui Zhao.[3] China Kidney Disease Network (CK-NET) Work Group *[1]Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China; [2]National Institute of Health Data Science at Peking University, Beijing, China; [3]National School of Development, Peking University, Beijing, China; [4]Institute of Social Science Survey, Peking University, Beijing, China.*

Background: Chronic kidney disease (CKD) is a public health burden worldwide. Anemia is common among patients with CKD and closely associated with kidney function progression. However, less is known regarding the longitudinal association between anemia and kidney function decline among the middle-aged and elderly population in China.

Methods: The China Health and Retirement Longitudinal Study (CHARLS) is a nationally representative longitudinal study starting from 2011. Participants without creatinine and demographic data in 2011 and 2015 were excluded. Anemia was defined according to WHO standards and rapid decline in kidney function was defined as a ≥16.9% (Quartile 3) decline in estimated Glomerular Filtration Rate (eGFR) calculated using the CKD-EPI equation during two visits. Multivariate logistic regression model was used to investigate their association.

Results: Altogether 7210 eligible participants were included in the final analysis, with a mean age of 58.6 ± 8.8 years. Rapid decline in kidney function occurred among 1802 (25.0%) participants. Those with rapid decline were more likely to be male, older, and to have lower eGFRs, anemia and hypertension. Anemia was significantly associated with rapid kidney function decline after adjusting for potential confounding factors (OR=1.64, 95% CI=1.32-2.04). The model using the continuous variable of hemoglobin (per 10 g/L) confirmed this positive association (OR=0.90, 95% CI=0.87-0.94) (Table 1).

Conclusions: Anemia is an important risk factor for the progression of CKD among the middle-aged and the elderly in China. Effective interventions targeting anemia could help reduce the risk of kidney failure.

Cumulative Intravenous Iron in Incident Hemodialysis Patients and Spikes of Serum Alanine Aminotransferase

Nolan M. Giehl,[1] Andrew I. Chin.[2] *[1]UC Davis Internal Medicine Residency, Sacramento, CA; [2]University of California Davis, Sacramento, CA.*

Background: Use of intravenous iron (IV Fe) is vital in the management of anemia in hemodialysis (HD) patients. In the general population, elevated alanine aminotransferase (ALT) is associated with increased serum iron parameters, possibly exhibiting evidence of liver injury. We aimed to determine the association of cumulative IV Fe and other known liver risks with spikes in monthly ALT lab levels in incident HD patients.

Methods: This retrospective quality study examined incident HD patients over 14 years. Baseline demographic and clinical characteristics included age, dialysis vintage, sex, race, ethnicity, weight, cumulative IV iron given, statin use, viral hepatitis status, diabetes mellitus, laboratory results (albumin, ferritin and TSat%) and recent hospitalization. Analysis included general estimation equations for assessment of spikes in monthly ALT (defined as >56 U/L, the upper end of normal of the lab) as the dependent outcome.

Results: The cohort included 585 incident HD patients: mean age at ESRD=57.2±16.1 years; 40.2% female; 27.1% non-Hispanic White and 30.9% Black; 48.5% DM; and 12.5% Hep C antibody positive. 155 (26.5%) patients experienced at least one spike of ALT. General estimation equations suggested that cumulative IV Fe by itself was *inversely* associated with spike in ALT. However, the interaction term of Ferritin*cumulative IV Fe was *positively* associated with spikes of ALT; we found other factors associated with spikes in ALT (see Table 1 for significant factors). Other factors analyzed but *not* associated with a spike in ALT included: vintage, serum albumin, gender, race, ethnicity, DM and recent hospitalization.

Conclusions: Cumulative IV Fe by itself was not positively associated with spikes in ALT, whereas serum Ferritin was strongly associated. Since IV Fe is often withheld from patients with high Ferritin levels, we included the interaction term of Ferritin with IV Fe in the analysis; we found this combined factor was positively associated with ALT spikes. In the full analysis, other factors positively associated with ALT spikes included: younger age, lower body weight, higher TSat%, on statin therapy, and positive Hepatitis C status.

Comparative Study Between Darbepoetin vs. Metoxi Polietilen Glycol-Epoetin Beta (CERA), in the Treatment of Anemia in Patients with Chronic Hemodialysis: Randomized Clinical Trial

Arturo Reyes Marin. *Nephrology, Hospital ISSEMYM, Estado de México, Mexico.*

Background: At present, we have differents erithropoyesis stimulating agents (ESA) for the treatment of anemia in chronic hemodialysis. In the last ten years, news ESA have been improved as Darbepoyetin (DA) and methoxy polyethylene glycol epoetin beta (CERA), theses ESA have better pharmacologyc efficacy and less frequency of administration. We did a randomized clinical trial between DA and CERA in the treatment of anemia in hemodialysis.

Methods: 160 adults patients in chronic hemodialysis with anemia (Hb 8 g/dl, Hto 24%)) were included, patients with malnutrition, cancer, multiorganic failure and older than 75 years were excluded. Patients were randomized in two groups, DA (n=80) received 40 mg every 5 days, subcutaneous route and CERA group (n=80)) received 75 mcg, every 10 days, subcutaneous route. The medications were taken in a double blind way. Hb and Hto were taken at the beginning of the study and monthly during 4 months. Ferrum profile was taken at the beginning and at the end of the study. ANOVA was used for the comparison of values the Hb and Hto in the differents measures. P values less 0.05 were considered significant.

Results: The basal values of Hb and hto in the DA group were: 9±1 g/dl and 27±2%, in the M group were: 8.9±1 g/dl and hto 28±1% (p > 0.05), at the end of study in the DA group Hb 12±1 g/dl and hto 36±2% in the M group Hb 11.9±1 g/dl and hto 35±1 % (p > 0.05). Ferritin and transferrin saturation were similar in both groups at the beginning and at the end of the study (p >0.05).

Conclusions: Darbopoyetin and Mircera had the same efficacy in the treatment of anemia in chronic hemodialysis, there were not differences. Both options are useful for the treatment in patients in hemodialysis.

Novel Probe to Detect Autophagy Flux in Proximal Tubular Cells

Marie Ito,[1] Tetsuhiro Tanaka,[1] Takeshi Wakashima,[2,1] Kenji Fukui,[2,1] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, the University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]JT CPRI, Osaka, Japan.*

Background: Autophagy is a pathway to degrade or recycle damaged organelle and macromolecules. In autophagy, autophagosome including part of cytosol and waste fuses with lysosome and the content is degraded by hydrolytic enzymes. As autophagosome forms, microtubule-associated protein light chain 3 (LC3-I) is conjugated with phosphatidylethanolamine to become LC3-II. Many of present methods to measure autophagy utilize LC3 as a marker, such as GFP-LC3 or western blotting (WB) to detect the conversion of LC3-I to -II. The existing methods have several limitations, such as the static evaluation of autophagy instead of flux evaluation or their reliability. In this study, we applied a novel probe, GFP-LC3-RFP-LC3ΔG to measure autophagy flux developed by Kaizuka, Morishita and his colleagues to proximal tubular cell line, HK2. Endogenous ATG4 cleaves the probe into equimolar GFP-LC3 and RFP-LC3ΔG. While GFP-LC3 is degraded as autophagy proceeds, RFP-LC3ΔG stays intact and serves as internal control. Thus 1-GFP/RFP reflects the amount of autophagy flux. We used HK2 cells transfected with the probe to evaluate autophagy flux in hypoxia or hypoxia inducible factor (HIF) stabilizer, enarodustat.

Methods: We transfected HK2 cells with pMRX-GFP-LC3-RFP-LC3ΔG, using lipofectamine 3000 (Thermo Fisher Scientific, USA). After selecting the cells with puromycin, single cell cloning was performed to pick up colonies without homologous recombination. Autophagy flux was evaluated using flow cytometry (BD biosciences, USA), and 1-GFP/RFP was calculated. We exposed the cells to amino acid depletion, a major autophagy inducer, for 4 hours and compared the results of the probe with existing LC3 WB. We also measured the autophagy flux in HK2 cells in 1% O2 for 0-48 hours and HIF stabilizer, 10 mM enarodustat for 0-48 hours.

Results: With amino acid depletion, autophagy flux was increased compared to normal medium, which was comparative to the result of WB. Under 1% hypoxia, autophagy was also increased over time, reaching almost 100% by 48 hours. Enarodustat increased autophagy more slowly.

Conclusions: We established HK2 cells stably transfected with autophagy probe for flux evaluation. After validating the cells using amino acid depletion, we evaluated the autophagy flux in hypoxia and HIF stabilizer and found that it was increased in both settings.

Inhibition of Angiotensin-Converting Enzyme 2 by Fibroblast Growth Factor 23 Through FGFR1

Cheng Xue,[1] Chenchen Zhou,[2] Bo Yang,[1] Bing Dai.[1] *[1]Shanghai Changzheng Hospital, Shanghai, China; [2]Yueyang Hospital, Shanghai, China.*

Background: Fibroblast growth factor 23 (FGF-23) is a protein which is responsible for phosphate and vitamin D metabolism in humans. Renin angiotensin-aldosterone system (RAAS) activation leads to phosphate retention and FGF-23 elevation in chronic kidney disease. This study was designed to investigate the unclear influence and mechanism of FGF-23 on angiotensin-converting enzyme 2 (ACE-2) of RAAS.

Methods: Rat renal tubular epithelial cells (NRK-52E) were treated with 0, 10, 25 and 100 ng/mL FGF-23 for 24h, respectively. Then renal epithelial cells were treated with 100 ng/mL of FGF-23 for 6, 12 and 24h, respectively. ACE-2 expression was detected by RT-PCR and western blotting. Angiotensin 2 (Ang-2) in cell supernatant was detected by enzyme linked immunosorbent assay (ELISA). Immunofluorescence was used to detect the localization and expression of ACE-2. FGF receptor 1 (FGFR1) was inhibited using FGFR1 inhibitor (PD173074).

Results: 100 ng/mL FGF-23 significantly inhibited mRNA and protein levels of ACE-2 in renal epithelial cells compared with 0, 10, and 25 ng/mL FGF-23 groups respectively. FGF-23 inhibited ACE-2 expression in a time-dependent manner, which was most significant at 24h. 100 ng/mL FGF-23 increased Ang-2 expression in the supernatant of renal epithelial cells compared with the control group by ELISA. Moreover, immunofluorescence found that the granular fluorescence of ACE-2 expressed mainly in the cell membrane and cytoplasm, and the fluorescence intensity of ACE-2 decreased after the treatment of 100 ng/mL FGF-23 compared with the control group. Treatment of FGFR1 inhibitor PD173074 (25nmol/mL) blocked the inhibiting effect of FGF-23 on ACE-2 in renal epithelial cells.

Conclusions: FGF-23 could inhibit the expression of ACE-2 through FGFR1 in renal tubular epithelial cells. The cross-talk between FGF-23 and RAAS is complex and needs future studies to investigate.

High-Dose Denosumab for the Management of Immobilization-Related Hypercalcemia in a Patient on Maintenance Hemodialysis: A Case Report

Weam Elnazer,[1] Mohammad Zaitoun,[2] Khalid Al-Alsheikh.[1] *[1]Nephrology Center, Armed Forces Hospitals Southern Region, Khamis Mushayt, Saudi Arabia; [2]Pharmacy Department, Armed Forces Hospitals Southern Region, Khamis Mushayt, Saudi Arabia.*

Introduction: Immobilization-related hypercalcemia arises due to a higher rate of osteoblastic bone formation compared to osteoclastic bone resorption. Renal impairment increases the risk of immobilization-related hypercalcemia. There is limited evidence about the safety and efficacy of denosumab in the management of immobilization-related hypercalcemia in hemodialysis (HD) patients.

Case Description: We report a case of successful treatment of immobilization-related hypercalcemia with denosumab 120 mg. A 55-year-old woman admitted to the ICU with suspected catheter-related bacteremia that led to septic shock. After 13 days of admission, the patient's corrected serum calcium rose to 3.39 mmol/l from a baseline of 2.52 mmol/l despite calcium carbonate and alfacalcidol discontinuation. Cinacalcet 60 mg once daily for 10 days, subcutaneous Calcitonin 250 mcg/dose for 6 days, a single dose of intravenous Zoledronic acid 4 mg, and a single dose of subcutaneous denosumab 60 mg were sequentially administered without response. Thus, subcutaneous denosumab 120 mg was administered and resulted in a gradual decline of the corrected calcium level from 4.18 mmol/l to 2.45 mmol/l over 3 weeks. Corrected calcium level was maintained below 2.8 mmol/l for 2 months later without notable adverse reactions. The patient's serum phosphorus level and PTH were within the normal ranges during the whole admission period.

Discussion: The management of immobilization related hypercalcemia in ESRD patients include withholding calcium and vitamin D, HD using a low-calcium dialysate (not available in our setting), Bisphosphonates, Cinacalcet, Calcitonin, and Denosumab. In our case, all management options were not effective except high dose denosumab. Cinacalcet has poor tolerability due to its common gastrointestinal side effects. Bisphosphonates lack of efficacy was possibly due to their limited antiresorptive action. Moreover, Bisphosphonates safety in ESRD patients is not well established and they are not recommended in this population for non-malignancy uses. Unlike Bisphosphonates, Denosumab lacks the need for renal dose adjustment. Besides, Denosumab has a rapid onset and extended duration of action. Our case showed that High-dose denosumab could be effective and safe for the management of immobilization-related hypercalcemia in HD patients.

Associations of Body Composition, Bone Mineral Density, Serum Phosphate, and Magnesium Levels in Hemodialysis Patients

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Kohji Usui,[2] Michiko Arita,[4] Takayuki Naito,[3] Shigehiro Doi,[5] Takao Masaki,[5] Kenichiro Shigemoto.[1] *[1]Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Ichiyokai Yokokawa Clinic, Hiroshima, Japan; [4]Ichiyokai East clinic, Hiroshima, Japan; [5]Nephrology, Hiroshima University Hospital, Hiroshima, Japan.*

Background: Sarcopenia, osteoporosis, hyperphosphatemia, and hypomagnesemia are reportedly associated with mortality in hemodialysis patients. This study aimed to assess the associations of body composition, bone mineral density (BMD), serum phosphate (P) and magnesium (Mg) levels in maintenance hemodialysis (MHD) patients.

Methods: Pre-dialysis laboratory data, post-dialysis body composition parameters by the Body Composition Monitor (Fresenius), and radius, lumbar spine, and femoral bone mineral density (BMD) using dual energy X-ray absorptiometry were assessed in MHD patients. Body composition, BMD, and clinical data were compared based on serum P and Mg levels. Multiple regression analyses for body cell mass index (BCMI): fat-free mass without extracellular water, and overhydration/extracellular water (OH/ECW) were performed, respectively.

Results: Among 264 patients (male: 65%, diabetes: 42%), mean age was 65±12 years and the median dialysis vintage was 79 (39–144) months. Serum P tertiles (T1–T3) were <4.5, 4.5–5.5, and <5.5 mg/dl. The low (T1) serum P group exhibited significantly (P<0.05) lower normalized protein nitrogen appearance (nPNA), intact parathyroid hormone (iPTH), lean tissue index, BCMI (6.5±1.8, 6.9±1.8, and 7.2±2.0 kg/m^2), intracellular water and significantly higher OH/ECW (9.2±10.0, 8.9±9.8, and 6.4±8.9, P<0.05) than other groups; BMD and coronary artery calcification score (CACS) did not differ. Serum Mg tertiles were <2.3, 2.4–2.5, and <2.5 mg/dl. Compared with other groups, the low (T1) serum Mg group showed lower nPNA and iPTH (P<0.05), but no significant differences in body composition parameters, BMD, or CACS. BCMI was significantly (P<0.05) associated with age (β:-0.30), presence of diabetes (β:-0.16), serum albumin (β:0.13), serum P (β:0.12), femoral BMD (β:0.23) [or radius BMD (β:0.41)], but not serum Mg or lumbar spine BMD. OH/ECW was significantly (P<0.05) associated with the presence of diabetes (β:0.21), serum P (β:-0.13), and femoral BMD (β:-0.19) but not age, serum albumin, Mg, or radius or lumbar spine BMD.

Conclusions: In MHD patients, associations among serum P levels (but not serum Mg levels), body composition parameters (BCMI, OH/ECW) and BMD were observed; serum P <4.5 mg/dl may indicate worse body composition and lower BMD.

Hip Fracture and CKD: Eighteen Years of a Temporary Perspective in a Spanish Hospital

Consolación Rosado rubio,[1] David Menendez g,[3] Dolores Barreda grande,[2] Gilda Carreño cornejo,[2] Rosario Manzanedo bueno,[2] Carmen Felipe fernández,[2] Jesus Martin.[3] *[1]Nephrology, Avila Hospital, ÁVILA, Spain; [2]Nephrology, Complejo Asistencial de Ávila, Ávila, Spain; [3]Complejo Asistencial de Avila, Avila, Spain.*

Background: Hip fracture (HF) is a frequent cause of morbidity and mortality in the elderly, who have a high incidence of chronic kidney disease (CKD). The recent concept of "uremic osteoporosis" shows that uremic toxins favor the loss of bone mass, increasing the rate of HF. However, CKD is not included in HF risk prediction tools, as FRAX. We study the characteristics of patients with CKD and HF, in order to determine if the impairment of renal function influences it prognosis to establish a risk profile of HF in CKD and to design intervention protocols. We compared patients with advanced CKD (GFR <20 ml / min) with the rest of patients with CKD (GFR <60 ml / min).

Methods: We have performed an observational, descriptive and transversal study of the characteristics of hospitalized patients with HF and ERC, from January 2000 to December 2018. The quantitative variables are expressed as median and interquartile range and qualitative ones are expressed as percentages. The comparisons were made with T of Student and Chi2, with a level of significance of p <0.05.

Results: In this period, 291 patients with CKD, were hospitalized for HF, 105 male (36.1%) and 186 female (63.9%). The rest of the variables are expressed in the following tables.

Conclusions: - CKD worsens the prognosis of HF: it makes surgical treatment difficult and increases the time of hospitalization and risk of death. - The increase in markers of bone mineral disease in advanced CKD favors the development of uremic osteoporosis, which is possibly responsible for this unfavorable profile of HF. - Patients with advanced CKD, heart failure and elevation of markers of the bone mineral disease, suffer a high risk of poor FC prognosis, needing special vigilance.

Thyroid Function Changes in Dialysis Patients with Severe Secondary-Hyperparathyroidism

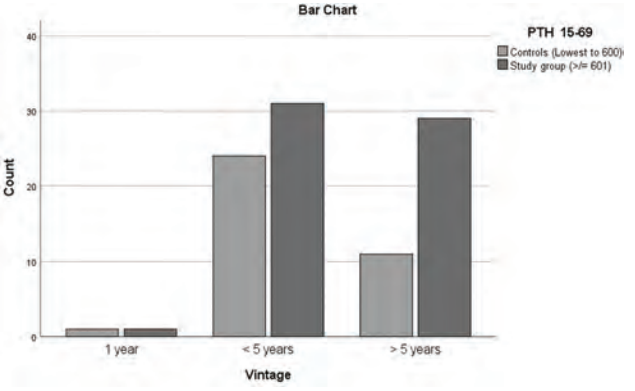
Zeenat Y. Bhat,[1] Sarah Nasser,[1] Mohamed E. Gismalla,[1] Muhammad O. Azam,[2] Nashat B. Imran,[1] Ronald Thomas,[1] Yahya M. Osman Malik.[3] *[1]Wayne State University, Detroit, MI; [2]Dallas Nephrology Associates, Dallas, TX; [3]Wayne State University Medical School, Detroit, MI.*

Background: Common complication of advanced Chronic Kidney Disease is secondary-hyperparathyroidism, which is associated with increased cardiovascular morbidity and mortality. While kidney-failure causes a wide array of thyroid abnormalities, little is known about whether uncontrolled hyperparathyroidism in dialysis patients is associated with thyroid-dysfunction and if this association has a relation to dialysis vintage and adverse cardiovascular outcomes

Methods: Parathyroid hormone(PTH) levels were dichotomized into groups of <600(controls: n=36) and ≥600(study group:n=62). Serum levels of PTH, thyroid function tests were obtained and statistically analyzed during two different times within a month-period. Using chart review, cardiovascular events, defined as coronary artery disease, heart-failure, and/or sudden cardiac death, that occurred over the past 5years were retrieved from the electronic medical records. In addition, dialysis vintage defined as short[<5years] and long defined as[≥ 5 years] was obtained. A Spearman's Rho correlation, Mann Whitney U test, and Fisher's Exact test were performed to determine the relationships between PTH, TSH, and FT4.

Results: There was no relationship between the thyroid and PTH levels as was TSH by PTH group was non-significant(p=0.98), as was the FT4 by PTH group(p=0.98). Controls arm had a higher % of shorter vintage(68.6%) compared to the study-group(51.7%), which was non-significant(p=0.134). Conversely, those in the study arm had a higher proportion of those in longer vintage arm(48.3%) than the control arm(31.4%)Fig1. A higher proportion of those with CVD(83.3%) were found in the control arm(83.3%) than those in the PTH study group(74.0%); p=0.41, which was non-significant.

Conclusions: No correlation was found between the severity of 2HPT and development of thyroid dysfunction and no statistically significant difference between two groups in CV outcomes. However, dialysis vintage was longer in study vs.control arm.



PUB059

Healthcare Cost of a Voracious "Hungry Bone Syndrome": How Far Can It Go?

Azharuddin Mohammed, Monther N. Alazwari, Najlaa Almalki. *Armed Forces Hospital Taif, TAIF, Saudi Arabia.*

Introduction: Protracted 'Hungry Bone Syndrome(HBS)' post parathyroidectomy(PTX) in haemodialysis(HD) may last upto 4 wk. We report a lengthiest case-81 days-and calculated for the first time healthcare cost and total therapy

Case Description: A 50yr F, HD for 7yr had Cinacalcet refractory symptomatic HPT (iPTH 4267 pg/ml) underwent total PTX with auto-transplantation(AT). HBS developed a wk later, demanding massive doses of calcium(Ca) -PO, IV bolus and infusion- and active vitamin D for 11.5 wk. Additional Ca required- pre, mid, end HD. Poor AT function at 3 wk(iPTH 12 pg/ml) compelled unlicensed rhPTH(Teriparatide) use to control HBS. Data on total therapy (salt/elemental) collected from medication and HD charts. Treatments listed in Tab1. Blood test(n) retrieved. Hospital stay verified. Procurement/finance provided unit prices. HBS lasted 81 days, needing large doses of remineralisation therapy (Tab.1). Mean daily ca.dose 21.3±9.5g/d (5.8 – 46.8 g) with highest in 3rd wk(Fig.1). Huge hospital cost($56686) was due to teriparatide followed by bed cost, Ca. and blood tests(n=154)

Discussion: HBS in sustained severe HPT require sizable remineralisation therapy with increasing risk factors, as this case– age, postmenopausal, female, SHPT+ vintage, high PTH 4267, high ALP 1550, large adenomas and low VitD. AT may not function as expected. HBS can be challenging for patients, clinicians, pharmacy(exhausted Ca. stock), nurses(dialysate modified to low bicarbonate 28 mmol-to keep ionized Ca. high) and managers. Substantial healthcare burden of HBS could be minimized by focussed prior assessment of severity risks, adequate preparation/timing and ensuring sufficient stocks of remineralisation therapies

	Daily (salt/elemental) g	Total (g)	Cost ($)

Correlation of Phosphate Levels with Homeostatic Model Assessment of Insulin Resistance in Non-Diabetic Non-Dialysis Stage 3-5 CKD Patients

Dian Samudra, Soebagijo A. Soelistijo, Chandra I. Mohani, Widodo Widodo. *Airlangga University Indonesia, Surabaya, Indonesia*.

Background: CKD is associated with insulin resistance which plays an important role in the pathogenesis of cardiovascular disease. In other hand, hyperphosphatemia that appeared in metabolic-bone disease, also associated with cardiovascular morbidity and mortality. The association between these two cardiovascular risk factors in CKD has not been determined yet.

Methods: This study was an observational analytic study with cross-sectional design, involving non-diabetic, predialysis CKD patients stage 3-5 from a tertiary referral hospital outpatient centre in Surabaya. Insulin resistance is described by using Homeostasis Model Assessment - Insulin Resistance (HOMA-IR). Analysis of relationship between phosphate levels and HOMA-IR is done by Spearman correlation test. P value is significant if <0.05. SPSS 23.0 software is used for data collection, recording and calculation.

Results: There were 40 patients. Mean of HOMA-IR levels in patients in stage 3A was 1.34 (±SD 0,16), stage 3B 1.84 (±SD 0,58), stage 4 3.01 (±SD 1,23), and stage 5 1.89 (±SD 1,14), and from overall results were 2.13 (±SD 1,15). Mean of phosphate level in CKD stage 3A was 3.45 (±SD 0,5), stage 3B 3.70 (±SD 0,77), stage 4 4.42 (±SD 1,57), and stage 5 4.99 (±SD 0,44), and from overall results were 4.51 (±SD 1,04). There was no correlation between HOMA-IR and phosphate level in CKD.

Conclusions: There was no correlation between phosphate levels and HOMA-IR in CKD stage 3-5 non-diabetic predialysis patients

PUB061

An Unexpected and Atypical Evolution Under Etelcalcide

Walid Arkouche,[1] Michel Gennaoui,[1] Dominique Eladari.[2] *[1]AURAR, Saint Gilles Les Bains, Réunion; [2]CHU Nord, Saint Denis, Réunion*.

Introduction: Cinacalcet increases the sensitivity of the calcium membrane receptor (CaSR) to extracellular ionized Ca leading to decreased secretion of PTH. Etelcalcide can activate the CaSR even under calcium free conditions indicating its additional function as direct CaSR agonist. Etelcalcide have a higher biological efficiency (decrease of PTH) than Cinacalcet.

Case Description: A 60 years-old men, with obesity, diabetes-2, hypertension, ischemic cardiopathy, and polyvascular disease, is treated for ESRD with chronic hemodialysis since October 2011. Hyperparathyroidism (sHPT) has been treated by subtotal parathyroidectomy in April 2016. Recurrence of sHPT occured in 2018. Parathyroid MIBI scan (11/2018) identified an ectopic adenoma in the antero-lateral side of the medio-lobar region of the left thyroid lobe. Treatment by Etelcalcide, along with the use of calcium enriched dialysis fluid (1.75 mmol/L) has been started in January 2018. Etelcalcide is administrated at the end of dialysis sessions, with a gradual increase in dosage. PTH remained very high for 13 months, followed by a collapse in February 2019 and a moderate rebound in April 2019 (Table). Alkaline Phosphatase, Bone Alkaline Phosphatase, Vit-D, Magnesium and Albumin are normal in april 2019.

Discussion: Similarly to Cinacalcet, Etelcalcide is expected to cause rapid and dose-dependent decrease of PTH. Here, the response is very delayed with almost no detectable effects of the calcimimetic during the first 13 months of treatment. Then suddenly, severe hypocalcemia developed associated with a collapse in PTH level indicating hypoparathyroidism. Surprisingly, while PTH secretion increased after withdrawal of Etelcalcide hypocalcemia persisted indicating peripheral (bone) resistance to PTH. This state resembles to acquired pseudo-hypoparathyrodism despite the absence of hypomagnesemia or major vitamin D deficiency. In conclusion, this case suggests that Etelcalcide can cause hypocalcemia not only by depressing PTH secretion but also might alter signaling pathways downstream to PTH receptor.

Evolution of results following Etelcalcetide treatment

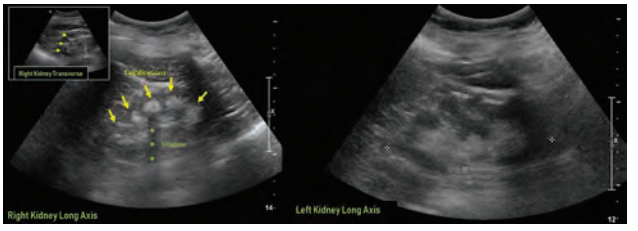
Unilateral Nephrocalcinosis and Isolated Hypocitraturia: A Curious Combination or Mere Coincidence?

Manoj Bhattarai, Samin Sharma, Abhilash Koratala. *Nephrology, UT Health San Antonio, San Antonio, TX*.

Introduction: Nephrocalcinosis is characterized by the deposition of calcium oxalate or phosphate in the kidney. A variety of inherited and acquired diseases have been associated with nephrocalcinosis and the most common metabolic cause is hypercalciuria with or without hypercalcemia followed by hyperphosphaturia. It is expected to be bilateral because of systemic origin, though unilateral cases have been reported. Herein, we present a unique case of unilateral nephrocalcinosis in a patient with hypocitraturia but no associated hypercalciuria or hyperphosphaturia.

Case Description: A 56-year-old Hispanic woman with a history of hypertension was seen for evaluation of chronic kidney disease. Serum creatinine was ~1.3 mg/dL, which was relatively stable compared to 4 months prior. A renal sonogram was obtained, which demonstrated findings suggestive of medullary nephrocalcinosis on the right [Figure]. Patient denied any history of nephrolithiasis in the past. Laboratory data did not demonstrate hypercalcemia, hypokalemia, metabolic acidosis or hyperparathyroidism. Vitamin D level was low-normal. Urine stone risk profile revealed normal 24-hour excretion of calcium (127 mg), phosphorus (310 mg) and oxalate (28 mg) but hypocitraturia was noted with a value of 71 mg/day [320-1240] as well as high sodium excretion of 329 mmol/day [<90 for hypertensives]. Medication history did not reveal any drugs implicated in hypocitraturia. She was treated with citrate supplementation and advised to restrict dietary sodium and increase consumption of fruits and vegetables.

Discussion: Hypocitraturia, a well-known known risk factor for nephrolithiasis and less commonly nephrocalcinosis is considered to be a systemic disorder. However, our case in addition to previously published small observational studies suggests that other local factors may play a role in the development of unilateral nephrocalcinosis. It is also not clear whether isolated hypocitraturia itself resulted in nephrocalcinosis or there was transient hypercalciuria in the past in our patient. It is of note that Once nephrocalcinosis is detected radiographically, it is unlikely to be reversed.



PUB063

Calcium Regulatory and Bone Turnover Biomarker Levels Do Not Indicate Presence of Osteoporosis and Osteopenia in ESRD

Aleksander D. Druck,[2] Dimpi Patel,[3] Debra Hoppensteadt,[1] Vinod K. Bansal,[1] Jawed Fareed.[1] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University of Chicago Stritch School of Medicine, St. Charles, IL; [3]Loyola University Chicago Stritch School of Medicine, Forest park, IL*.

Background: Concomitant BMD disorders like osteoporosis and osteopenia are often observed in ESRD patients. The criteria for diagnosis of a BMD disorder is through the evaluation of BMD by dual x-ray absorptiometry (DXA). This study aims to profile six biomarkers related to calcium regulation, bone turnover, and osteoblastic/osteoclastic activity in ESRD patients to determine if plasma levels of any markers were predictive of concomitant diagnosis of osteoporosis/osteopenia.

Methods: Plasma levels of osteopontin (OPN), bone morphogenic protein 7 (BMP-7), C-terminal collagen telopeptide I (CTX-I), IL-6, myeloperoxidase (MPO) and 25-hydroxyvitamin D2 and D3 (25(OH)D) were measured via commercially available enzyme linked immunosorbent assays in ESRD patients (n=92) and 50 normal healthy control samples. The ESRD cohort was further stratified into two groups: those with additional diagnosis of osteopenia or osteoporosis (n=23) and those without a BMD disorder diagnosis (n=69). The biomarker levels in these groups were compared to each other and to the normal population via Dunn's multiple comparisons test. Diagnosis of a BMD disorder was based upon T score reports of those who underwent a DXA bone scan. T scores between -1.5 and -2.5 indicated osteopenia, while a T score less than -2.5 indicated osteoporosis.

Results: In ESRD patients (n=92), OPN, IL-6, and MPO were significantly elevated compared to normal plasma samples (n=24-50; $p < 0.0001$, $p = 0.0146$, $p < 0.0001$). CTX-I was significantly decreased in ESRD patients compared to normal plasma samples (n=27; $p < 0.0001$). There was no statistically significant difference in 25(OH)D levels or BMP-7 levels between the ESRD cohort and normal plasma samples ($p > 0.05$). For all biomarkers evaluated, there was no statistically significant difference between ESRD patients with osteopenia/osteoporosis versus ESRD patients who did not have concomitant BMD disorder ($p > 0.05$).

Conclusions: Overall, there were significant differences in biomarkers related to bone turnover and osteoclastic/osteoblastic activity in ESRD patients compared to the normal population. These findings support the hypothesis that bone metabolism is significantly affected in patients with ESRD.

PUB064

Reducing Pill Burden of Phosphate Binders Has the Potential to Improve Patient Adherence

Nishit Modi,[1] Shalabh Gupta.[2] *[1]Unicycive Therapeutics, Inc, Los Altos, CA; [2]Unicycive, Los Altos, CA*.

Background: Pill burden and medication intolerance are important factors that influence phosphate binder adherence for managing hyperphosphatemia. The number and size of pills are key factors contributing to pill burden. We compared the pill burden of currently approved phosphate binders with lanthanum dioxycarbonate (RenaZorb), second-generation, lanthanum-based drug in development to evaluate its potential for improving patient adherence.

Methods: A literature analysis of phosphate-binding medications were examined to assess the impact of pill size and pill number on non-adherence in hemodialysis patients. We also compared their equivalent doses relative to the phosphorus binding capacity of 1 g calcium carbonate (PBED) in table 1.

Results: Amongst approved phosphate binders lanthanum carbonate and sucroferric oxyhydroxide have lower pill burden than other phosphate binders but higher discontinuation rates than some due to patient intolerance. Phase 1 data for lanthanum dioxycarbonate[1], suggest comparable urinary excretion of phosphate to published data for lanthanum carbonate.

Conclusions: Lanthanum dioxycarbonate has the potential to significantly improve patient compliance by offering a lower-in-class pill burden and smaller sized tablets to achieve similar therapeutic benefit as other phosphate binders. Reference: [1]Finn WF, DenupCiocca CJ, Joy MS et al. Double-Blind Dose-Ranging Study of Lanthanum Dioxycarbonate (Renazorb) in Healthy Volunteers Shows High Phosphorous Binding Capacity. Funding: Commercial Support - Unicycive Therapeutics Inc., Private Foundation Support

Dosages of selected phosphate binders required to reach a phosphorous binder equivalent dose (PBED). Table is modified from St. Peter[2]

Phosphate binder	Tablet strength (mg)	Tablet Size (mm)	Dose of binder needed to reach a PBED of 6 g/day [a]	Approximate number of tablets to reach PBED of 6 g day	Grams of calcium in 6 g PBED dose
Calcium carbonate	648	11	6	8	2.4
Calcium acetate	667	13	6	9	1.5
Lanthanum Carbonate	500 [b]	18	3	6	0
Sevelamer carbonate	800	19-21	8	10	0
Sucroferric oxyhydroxide	500	20	1.5	3.75	0
Ferric citrate	210	19	2	9	0
Lanthanum dioxycarbonate	500	11	2.1	4	0

[a] In US dialysis patients, PBED averages around 6 g/day. This means that patients require 6 g/day of calcium carbonate to control their serum phosphorous. [b] Tablets are sold by weight of lanthanum and not of lanthanum carbonate. 2 WL. St Peter, LD Wazny, E Weinhandl et al. Drugs, 2017, 77:1155-1186

High Fructose Diet-Induced Hypertension and Renal Damages Are Exacerbated in Dahl Salt-Sensitive Rats via Renal Renin-Angiotensin System

Lusi Xu. *Tohoku University Graduate School of Medicine, Sendai, Japan.*

Background: High-fructose diet (HFr) was reported to induce metabolic syndrome, salt-sensitive hypertension and multiple organ damages. However, it has been unknown whether the HFr-induced hypertension and renal damages exaggerate in subjects with salt sensitivity. Thus, we tested impacts of HFr on blood pressure, renal damages and expression of renal renin-angiotensin system(RAS) components in Dahl salt-sensitive (DS) and salt-resistant (DR) rats in a normal-salt intake condition.

Methods: Six-week old, male DS rats and DR rats were fed a control diet or a HFr (60% fructose) with a normal-salt content (1.25%) for 12 weeks. Systolic blood pressure (SBP) and urinary albumin excretion were measured every 2 weeks. After 12 weeks, plasma biochemical parameters and renal histology were examined. Furthermore, we tested effects of enalapril (10mg/kg/day) and candesartan (1mg/kg/day) in DS rats fed the HFr diet.

Results: Compared with the control diet, HFr significantly elevated SBP in DS rats (166±5 vs 115±2 mmHg) but not in DR rats (95±4 vs 90±2 mmHg). HFr induced albuminuria in both DS and DR rats (DS: 16.5±2.0 vs 3.9±0.4 mg/day; DR: 10.5±1.4 vs 5.0±0.7 mg/day). HFr significantly increased plasma triglyceride, uric acid and urea nitrogen in both DS and DR rats. However, HFr significantly increased creatinine clearance in DS rats but not changed in DR rats. HFr-induced glomerulosclerosis, podocyte injury and tubulointerstitial fibrosis exaggerated in DS rats compared with DR rats. HFr significantly increased the renal expression of renin, (pro)renin receptor ((P)RR), angiotensin converting enzyme (ACE), angiotensin II type 1 receptor (AT1-R) in DS rats. In contrast to DS rats, HFr significantly decreased the renin and AT1-R expressions without changing the (P)RR or ACE expression in DR rats. Both enalapril and candesartan attenuated the HFr-induced hypertension, albuminuria, and renal damages in DS rats.

Conclusions: Even in the normal-salt intake condition, HFr-induced hypertension and renal damages are exacerbated in DS rats compared with DR rats via renal RA system. HFr may have a higher risk to develop hypertension and renal damages in human with salt sensitivity, and RAS inhibitors are effective against the HFr-induced renal damages.

Cordyceps militaris Preserves Nephrin Expression on Podocyte Under TGF-β1 and Hyperglycemia Stimulation

Chia-Chun Wu,[1,2] Chien-wei Hsiung,[4] Ting-Feng Wu.[3] *[1]Chi Mei Medical Center, Tainan, Taiwan; [2]Pharmacy, Chia Nan University of Pharmacy and Science, Tainan, Taiwan; [3]Southern Taiwan University of Science and Technology, Tainan, Taiwan; [4]Phytomed Bio-Tech co., Ltd., Tainan, Taiwan.*

Background: Cordyceps militaris (CM) is a kind of fungus used as herbal medicine for multiple purposes. The study aim is to know the effect of CM on nephrin expression under the TGF-β1 and hyperglycemic stimulation.

Methods: Experiment 1: Cultured podocytes were divided into four groups treated with Group 1 Control, Group 2 TGF-β1 10ng/ml, Group 3 CM100ug/ml and Group 4 both CM and TGF-β1. Experiment 2: Podocytes were cultured in different mediums: Group 1 normal, Group 2 High glucose (HG; 30mM), Group 3 CM100ug/ml, in normal medium, Group 4 CM100ug/ml in HG medium. Protein was extracted on day 6 for nephrin analysis.

Results: The nephrin expression was significantly lower in the TGF-β1 group and higher in the CM group than it was in the control group. When podocytes were treated with CM and TGF-β1 simultaneously, the CM could restore the nephrin expression as compared to TGF-β1 group (Figure 1A). Hyperglycemia suppressed the nephrin expression and CM significantly attenuated this effect (Figure 1B)

Conclusions: CM might not only enhance the nephrin expression of podocytes but also attenuate the nephrin suppression from TGF-β1 and hyperglycemia.

Irisin-Regulated miR-29 Expression in db/db Mice

Wenbo Zhao, Dan Luo, Hongchun Lin, Hui Peng. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China.*

Background: In mice, it has been demonstrated that irisin plays a key role in metabolic regulation, energy expenditure. Both animal and in vitro studies have suggested that irisin exerts anti-inflammatory effects modulating the production of cytokines as IL-6, IL-1β and TNF-a. Inflammation and its consequent fibrosis are two main features of diabetic nephropathy. miR-29b is a novel therapeutic agent capable of inhibiting progressive renal inflammation and fibrosis. However, the function of irisin and miR-29b for regulation for diabetic nephropathy remain unexplored.

Methods: Male db/db mice and their normal littermates (db/m) at the age of week 12 were purchased from Laboratory Animal Services Centre, the Nanjing University of China. Groups of four mice were used, groups of db/m or db/db mice were treated with/without irisin or empty vector control from the age of week 12 and sacrificed at week 20, then to detecte the expression miR–29 of renal tissue.

Results: In groups of db/m or db/db mice were treated with/without irisin, miR–29a-3p, miR–29a-1-5p miR–29c-3p, and miR–29c-5p were no significant change(***P***>0.05). miR-29b was significant change(***P***<0.05), the group of db/db mice were treated with irisin had higher level of miR-29b, lower body weight and blood sugar Compared with db/db mice without irisin treatment.

Conclusions: The irisin may regulate miR-29b level, and improved metabolic regulation, energy expenditure, and inflammation state.

PUB068

MicroRNA Profile as a Therapeutic Target for Diabetic Nephropathy

Irtiza Hasan,[2,1] Tasnuva Rashid.[3,4] *[1]The University of Texas MD Anderson Cancer Center, Houston, TX; [2]Nephrology, University of Florida College of Medicine-Jacksonville, Jacksonville, FL; [3]University of Houston, College of Pharmacy, Pearland, TX; [4]Epidemiology & Human genetics, University of Texas School of Public Health, Houston, TX.*

Background: Diabetic nephropathy is a leading cause of chronic kidney disease in diabetic patients requiring renal replacement therapy. Chronic low-grade systemic inflammation coupled with impaired microvascular function, podocyte apoptosis, epithelial to mesangial transformation and fibrosis are the critical hallmarks for the pathogenesis of Diabetic Nephropathy. MicroRNAs (miRNAs) regulate the function of various downstream molecular pathways involved in Diabetic nephropathy pathophysiology.

Methods: This review focuses on the recent developments and identification of therapeutic potential of various miRNAs on the prevention and treatment of Diabetic Nephropathy. An in-depth systematic review of full-text original articles published in English in a period between 2008 and 2019 and indexed in PubMed, Ovid Medline or Embase was conducted.

Results: Stimulation of miRNAs that are commonly downregulated and inhibition of miRNAs that are upregulated or modulation of an intermediary target for miRNAs were found to be renoprotective and reduce albuminuria, decrease mesangial cell proliferation, decrease epithelial to mesenchymal transition, reduce podocyte foot process effacement and apoptosis & inhibit glomerular or tubulointerstitial fibrosis.

Conclusions: Therapeutic agents targeting the miRNAs have the potential in the prevention of diabetic nephropathy as well as early treatment and prevention of progression.

Renal Function Decline in Type 2 Diabetes: Post Hoc Analysis of LEADER

Johannes F. Mann,[1] Thomas Idorn,[2] Ofri Mosenzon,[6] Richard E. Pratley,[3] Soren Rasmussen,[4] Benjamin Wolthers,[4] Michael Nauck.[5] *[1]Friedrich Alexander University, Erlangen, Germany; [2]Novo Nordisk A/S, Soborg, Denmark; [3]AdventHealth Translational Research Institute for Metabolism and Diabetes, Orlando, FL; [4]Novo Nordisk A/S, Copenhagen, Denmark; [5]Diabetes Center Bochum-Hattingen, St Josef Hospital (Ruhr-Universität Bochum), Bochum, Germany; [6]Hadassah Hebrew University Hospital, Jerusalem, Israel.*

Background: Diabetic kidney disease (DKD) is a frequent complication in type 2 diabetes (T2D). Identifying patients at risk of fast DKD progression is key for early care. This LEADER post-hoc analysis describes patients with varying renal function decline.

Methods: LEADER (NCT01179048) was a randomized double-blind cardiovascular (CV) outcomes trial of liraglutide (≤1.8 mg/day) vs placebo, both added to standard care, in 9340 patients with T2D and high CV risk (median follow-up 3.8 years). Renal function decline (average decline in estimated glomerular filtration rate [eGFR] from month 6 to month 24 or later) was classified from patient-specific slopes estimated via linear regression. Disregarding treatment arms, patients were categorized according to annual eGFR decline (mL/min/1.73m²): ≤5 (77% of patients), >5 to ≤10 (17%), >10 to ≤15 (4%) or >15 (2%) and differences in baseline characteristics were investigated using 2-sided trend tests (Jonckheere-Terpstra for continuous, Cochran-Armitage for binary and Goodman and Kruskal's Gamma for ordinal parameters).

Results: Overall mean (standard deviation) eGFR decline was 2.2 (5.7) mL/min/1.73m2/year. Largest average eGFR decline was associated with longer T2D duration (P=0.02), higher baseline A1C (P<0.001), urinary albumin-to-creatinine ratio (UACR; P<0.0001), systolic (P<0.0001) and diastolic blood pressure (BP; P<0.01), total cholesterol (P=0.02), being a current smoker (P=0.04) and insulin use (P<0.01; Table). Patients with the largest eGFR decline tended to have higher eGFR at baseline (P<0.0001).

Conclusions: This post-hoc analysis confirmed the importance of glycemic levels, systolic BP levels and smoking status for the risk of fast annual eGFR decline (>5mL/min/1.73m2). Fast annual eGFR decline was associated with high baseline eGFR.

Funding: Commercial Support - Novo Nordisk

Clinicopathological Findings and Renal Outcome of Diabetic Nephropathy in Type 2 Diabetes: A Single-Center Study in Japan

Yuriko Kawai, Akira Ishii, Hideki Yokoi, Takeshi Matsubara, Kaoru Sakai, Shuichiro Endo, Motoko Yanagita. *Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Besides conventional clinical factors such as CKD stage, pathological findings have become important in diabetic nephropathy (DN) due to their usefulness to predict prognosis. In 2015, Japan Renal Pathology Society (JRPS) developed a new pathological classification of DN, describing the detailed glomerular changes compared to that Tervaert *et al*. had reported (J Am Soc Nephrol 21: 556-563, 2010). Recently, Hoshino *et al*. have created J-score, a novel DN pathological scoring system with the JRPS classification (Plos One 13: e0190923, 2018). They proved the J-score to be a significant predictor of renal outcome. Here, we investigated the association of pathological findings with renal prognosis in DN by utilizing the J-score.

Methods: We analyzed 13 followable Japanese patients who underwent renal biopsy and were diagnosed with DN in our department from Dec. 2006 to Aug. 2015. We evaluated their pathological findings based on the J-score and studied their associations to renal outcome (dialysis initiation, doubling serum creatinine level, or 50% eGFR decline) at three years after the biopsy.

Results: All patients had type 2 diabetes with the mean duration of 9.8 ± 8.8 years. Diabetic retinopathy was observed in 9 patients. At the time of renal biopsy, the mean values of age, serum creatinine level, eGFR, urinary protein level, HbA1c level, and systolic blood pressure were 55.0 ± 7.2 years, 1.4 ± 0.6 mg/dl, 47.7 ± 23.2 ml/min/1.73 m², 5.2 ± 4.0 g/gCre, 6.9 ± 1.8%, and 148 ± 22.7 mmHg, respectively. Renal biopsy findings included diffuse lesions in 11 patients, exudative lesions in 11 patients, nodular lesions in 9 patients, and mesangiolysis in 7 patients. According to the previous report, we divided patients into four groups (grades 1 to 4), those with the J-score 0-5 (grade 1), 6-10 (grade 2), 11-15 (grade 3), and 16-19 (grade 4), respectively. The detailed numbers of the patients in each group were as follows: one in grade 1, five in grade 3, and seven in grade 4. Renal events were found to be zero (0%) in grade 1, two (40%) in grade 3, and five (71%) in grade 4.

Conclusions: In our single-center study, we observed the trend of worsening renal prognosis as the grade of the J-score increased. This finding suggests the potential of the scoring system for prognostic prediction of DN.

Individual Effects of Liraglutide on Cardiorenal Risk Markers: Results from the LEADER Trial

Frederik Persson,[1] Emilie Hein Zobel,[2] Tine Hansen,[3] Soren Rasmussen,[4] Bernt Johan Von Scholten,[4] Benjamin Wolthers,[5] Peter Rossing.[1,6] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [4]Novo Nordisk A/S, Søborg, Denmark; [5]Novo Nordisk A/S, Søborg, Denmark; [6]University of Copenhagen, Copenhagen, Denmark.*

Background: Liraglutide has pleiotropic effects improving cardiorenal risk markers and beneficial effects on cardiac and renal outcomes. This LEADER post-hoc analysis investigated cross-dependency in the individual treatment response to liraglutide in 6 cardiorenal risk markers.

Methods: LEADER (NCT01179048) randomized patients (n=9340) to liraglutide or placebo (1:1) in addition to standard of care. We interrogated 6 markers at baseline and after 1 year of therapy: glycated hemoglobin (A1C), body weight, systolic blood pressure (SBP), urinary albumin-to-creatinine ratio (UACR), estimated glomerular filtration rate (eGFR) and low-density lipoprotein (LDL) cholesterol. In the liraglutide group, 'good responders' in a specific marker were defined as those with a change from baseline

(A1C, weight, SBP: observed difference; UACR, eGFR, LDL: observed ratio) within the best quartile (Q4); the remaining were classified as 'low responders'.

Results: Treatment difference (liraglutide-placebo) after 1 year: weight -2.4 (95% CI: -2.6;-2.2) kg; A1C -0.70 (-0.75;-0.65) %; SBP -1.9 (-2.6;-1.3) mmHg; treatment ratio (liraglutide/placebo): UACR 0.77 (0.73;0.81), eGFR 0.99 (0.99;1.0) and LDL 0.98 (0.97;0.99). In general, we observed statistically significant but not clinically relevant associations in risk marker response. Thus, for good vs low responders in A1C, the difference in weight change was -2.8 (5.5) vs -2.6 (5.0) kg (P=0.44); SBP -0.99 (18.0) vs -2.3 (17.5) mmHg (P=0.04), UACR 0.77 [2.0] vs 0.88 [1.7] (P=0.001), eGFR 0.94 [0.19] vs 0.97 [0.17] (P<0.001) and LDL 0.99 [0.34] vs 1.00 [0.33] (P=0.14) (Table).

Conclusions: Good response in 1 cardiorenal risk marker was not in general associated with a clinically relevant response in other markers. The substantial heterogeneity in individual risk marker response is important when effect of liraglutide is evaluated in the clinic.

PUB072

Prevalence of Triglyceride Deposit Cardiomyovasculopathy in CKD Patients

Yasuyuki Nagasawa,[1] Yukiko Hasuike,[1] Takahiro Kuragano,[2] Masaharu Ishihara,[1] Ken-ichi Hirano.[3] *[1]Hyogo College of Medicine, Nishinomiya, Japan; [2]Internal Medicine Division of Kidney and Dialysis, Nishinomiya, Japan; [3]Osaka University, Osaka, Japan.*

Background: Triglyceride deposit cardiomyovasculopathy (TGCV) had been recently described (Hirano K, et al. N Engl J Med 2008; 359(22): 2396) from heart transplantation patient. Primary TGCV is caused by genetic Adipose triglyceride lipase (ATGL)mutation. The lack of ATGL caused disorder of triglyceride metabolism resulting in the accumulation of triglyceride in many kinds of cells. Idiopathic TGCV is caused by decrease of activity of ATGL in spite of gene mutation from unknown reason. Idiopathic TGCV had been observed in diabetes patients (Ikeda Y, et al. Pathol Int 2014;64:325.). Washout ratio in BMIPP (123I-beta-methyl-P-iodophenyl-pentadecanoic acid) scintigraphy, which can evaluate the triglyceride metabolism in heart, manifested marked decrease. Jordan body, which is some kind of lipid vesicles, can be observed in white blood cells. Heart failure occurs because the metabolism in heart usually required triglyceride. As the prevalence of idiopathic TGCV remained unknown, we evaluate the prevalence of TGCV in CKD patients with heart failure from unknown origin.

Methods: Diabetes patients with chronic kidney disease and heart failure from unknown origin were evaluated by BMIPP scintigraphy, Wash out rate in BMIPP scintigraphy less than 5% was treated as positive for TGCV. All patients gave the written informed consent.

Results: Ten candidate patients were evaluated by BMIPP scintigraphy. Average of age was 51.4 years old. Average of creatinine was 6.1+-2.9mg/dl. Four patients (40%) had positive BMIPP study (Washout rate less than 5%), who were diagnosed as idiopathic TGCV. TGCV patients were significantly younger than non-TGCV patients (40.5+-1.1 years old vs 58.7+- 12 years old, P=0.0188). TGCV patients had worse heart failure (Ejection Fraction) than non-TGCV patients (33+-12% vs 47+-13%). There was no change of septum thickness (10.7+-2.2mm vs 9.6+-0.9mm). Coronary lesions had been overserved more frequently in TGCV patients than non-TGCV patients (100% vs 66%). Diabetic retinopathy had been overserved more frequently in TGCV patients than non-TGCV patients (75% vs 33%). It remained unclear the reason why TGCV was highly associated with diabetes CKD patients.

Conclusions: Prevalence of idiopathic TGCV patients was 40% in diabetes patients with chronic kidney disease and heart failure from unknown origins.

PUB073

Risk Factors of Cardiovascular Disease in Diabetic Hemodialysis Patients with Smoking Is Extremely High: Smoking Cessation Is Important to Their Prognosis

Hajime Hirano, Haruhito Azuma. *Osaka Medical college, Takatsuki City, Japan.*

Background: Prevention of the development of CVD, which is the major cause of death, is key to improving prognosis. We had investigated factors associated with CVD mortality risk in maintenance dialysis patients. In this study, an additional analysis was performed on data in hemodialysis patients with diabetic nephropathy compared with those having other underlying diseases. And furthermore, we investigated factors that influence CVD mortality risk in hemodialysis patients with diabetic nephropathy.

Methods: This retrospective study was conducted with 201 outpatients with hemodialysis at our Blood Purification Therapy Center and our other related hemodialysis facilities (57 diabetic nephropathy and 144 others). Logistic regression analysis was conducted with outcome- measured as CVD death. Hemoglobin levels and blood pressure values before and after dialysis were summed up at 3, 6, and 12 months. A curve was obtained by changes in blood pressure per month and the area under the blood pressure curve (AUC) was calculated.

Results: Diabetic nephropathy was the highest mortality risk among underlying disease groups. A comparison with other underlying diseases revealed that significant differences were found for the variables older age ($p<0.001$) and a shorter history of hemodialysis ($p<0.001$) in patients with diabetic nephropathy. There was no significant difference in anemia control between two groups. Poor blood pressure control and higher dose of erythropoietin were found in patients with diabetic nephropathy. The multivariate analysis of risk factors for mortality in patients with diabetic nephropathy showed that smoking (odds ratio(OR): 4.71 [95%CI: 1.97~11.26, p<0.001], history of ischemic heart disease (OR: 2.56 [95%CI: 0.95~6.85, p=0.061], age (OR: 1.07 [95%CI: 1.03~1.13, p=0.002], and a history of dialysis therapy (OR: 0.78 [95%CI: 0.69~0.87, p<0.001] were risk factors.

Conclusions: Introduction to hemodialysis for patients with diabetic nephropathy, given higher CVD mortality risk, it is important to actively prevent the development of CVD shortly after hemodialysis. Furthermore, higher smoking rates with higher CVD mortality risk associated with smoking among patients with diabetic nephropathy suggested that smoking cessation is important for patients with diabetic nephropathy to improve their prognosis.

PUB074

Pentoxifylline in Diabetic Kidney Disease: The VA Pentoxifylline in Diabetic Kidney Disease PTXRx Study

David J. Leehey,[1,2] Kimberly Carlson,[3] Domenic Reda,[3] Linda Polzin,[3] Christina E. Clise,[4] Tamara Paine,[3] Douglas E. Lammie,[3] Rajiv Agarwal,[5] James S. Kaufman,[6] Robert Anderson,[7] Grant D. Huang,[8] Nicholas Emanuele.[1] *[1]Hines VA Hospital, Hines, IL; [2]Loyola University Medical Center, Maywood, IL; [3]Cooperative Studies Program Coordinating Center, Hines, IL; [4]VA CSP CRPCC, Albuquerque, NM; [5]Roudebush VA Medical Center, Indianapolis, IN; [6]VA New York Harbor Healthcare System, New York, NY; [7]Omaha VA Hospital, Omaha, NE; [8]Cooperative Studies Program Central Office, Washington, DC.*

Background: Diabetic kidney disease (DKD) is the most frequent cause of chronic kidney disease (CKD) and end-stage renal disease (ESRD) in the U.S. The recent CREDENCE trial demonstrated that the sodium-glucose cotransporter 2 (SGLT2) inhibitor canagliflozin reduced ESRD and cardiovascular events in DKD patients with an estimated glomerular filtration rate (eGFR) of 30 to <90 mL/min/1.73m^2 and a urinary albumin to creatinine ratio (UACR) of >300 to 5000 mg/g. This trial excluded patients with eGFR < 30 or lesser degrees of proteinuria. Recent experimental and clinical data suggest that the phosphodiesterase inhibitor pentoxifylline (PTX) may also decrease progression of DKD to ESRD. Putative mechanisms of action of PTX include an increase in intracellular cyclic AMP, inhibition of inflammatory cytokines, and reduced oxidative stress.

Methods: VA PTXRx is a randomized, controlled multicenter Veterans Affairs (VA) Cooperative Study to test the hypothesis that PTX, when added to usual care, leads to a reduction in the incidence of ESRD and death in type 2 diabetic patients with DKD when compared to usual care plus placebo. Secondary endpoints will be: (1) quality of life (2) time until doubling of serum creatinine, (3) hospitalization for congestive heart failure, (4) a three-point MACE (cardiovascular death, non-fatal myocardial infarction, non-fatal stroke), (5) peripheral vascular disease, (6) percentage of participants with ≥ 50% reduction in UACR from baseline, (7) Rate of change in eGFR per year during the study period. The key statistical assumption is that the primary endpoint will occur in 26.6% of the placebo group at six years with a risk reduction of 19% for PTX compared with the placebo group. The study aims to randomize 2510 participants to either PTX or placebo. Inclusion criteria are based on risk of ESRD from the KDIGO "heat map"; participants must be in one of the following categories: eGFR 15 to <30; eGFR 30 to <45 and UACR > 30 mg/g; eGFR 45 to <60 and UACR > 300 mg/g.

Results: N/A

Conclusions: If PTX is found to reduce the incidence of ESRD and/or death, this will provide another effective treatment for DKD which could extend to patient groups not currently candidates for SGLT2 inhibitors.

Effect on Major Renal Outcome of Continuous Metformin Use in Patients with Type 2 Diabetes and Advanced Kidney Disease: A Retrospective, Propensity Score-Matched, Common Data Model-Based Cohort Study

Yongjin Yi, Kipyo Kim, Jong Cheol Jeong, Ho Jun Chin, Ki Young Na, Dong-Wan Chae, Sejoong Kim. *Seoul National University Bundang Hospital, Seongnam-si, GyeonGgi-Do, Republic of Korea.*

Background: Metformin is an effective, inexpensive and widely used drug for type 2 diabetes (T2DM) patients. However, use of metformin is contraindicated in patients with advanced CKD owing to risk of lactic acidosis. Although several studies have revealed metformin-associated lactic acidosis has rare incidence rate, study for metformin effectiveness in those patients is hard to conduct because of established contraindication. This study aimed to generate real-world evidence for effect of metformin on renal outcome in a T2DM patients with CKD.

Methods: We performed a retrospective, propensity score matched, observational cohort study by using The Observational Medical Outcomes Partnership common data model version 5. We used medical data of 1.82 million patients in a tertiary hospital in Korea from 2003 to 2017. Study participants were identified by drugs, diagnosis codes and laboratory test values in combination with event time. More than six months ongoing of metformin treatment after each index time of EPI-CKD eGFR< 60 ml/min/1.73m^2 were considered as treatment group. Never use of metformin after three months since index time were considered as comparative group. Composite renal outcome was defined as receiving renal replacement therapy, having EPI-CKD creatinine-based eGFR< 15 ml/min/1.73m^2 or in-hospital death. After 1:1 propensity score-based matching (PSM), Cox proportional hazards model was used to analyze hazard ratio for the renal outcome.

Results: An 894 of metformin using patients and a 236 of non-metformin using patients were identified. After 1:1 PSM, we matched each of 154 patients in both groups. Mean follow-up time were 7.2 and 5.4 years, respectively. Baseline age, sex distribution, EPI-CKD eGFR, HbA1c level and spot urine albumin-to-creatinine ratio were not significantly different between groups. Continuous metformin use was associated lower outcome risk (HR=0.29, 95% CI [0.10-0.81], p=0.008).

Conclusions: Continuous use of metformin was associated with lower incident rate of composite renal outcome in T2DM patients with reduced renal function equivalent to advanced CKD. This longitudinal real-world study may support benefit of metformin in T2DM patients having reduced renal function for major renal outcome.

PUB076

Implementation of Routine Foot Checks Among Dialysis Patients at an Outpatient Dialysis Clinic

Mary O. Muoneke,[1] Jason Cobb,[2] James L. Bailey,[2] Janice P. Lea.[1] *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA.*

Background: Diabetes is the leading cause of lower limb amputations and renal failure in the United States. The risk of amputation is increased in people with long standing diabetes, poor glucose control, retinal or renal complications. The burden of diabetic foot disease on dialysis patients is huge as evidenced by high morbidity and mortality associated with it. Sadly, foot care is not an integral part of care provided in our clinics. Early recognition and management of risk factors for foot ulcers can delay the onset of adverse outcomes. Timely referral to a foot care specialist is critical in the care of these patients. We aimed to introduce foot examination as part of routine dialysis clinic care in order to identify patients at risk and refer for proper evaluation.

Methods: Patients with End Stage Renal Disease (ESRD) who had diabetes were identified by chart review. A total of 81 patients were identified. A foot check list was developed and distributed at the clinic. Foot exams were done by the nurses while patients were receiving scheduled hemodialysis. It was focused on physical examination, including checking for intact skin, corns and calluses, toe nail and checking for poor circulation. Foot education was provided at the end of the exam

Results: 81(52%) out of a total of 156 patients who were receiving dialysis care at the pilot site had diabetes. 79 (98%) of patients who had diabetes participated in the foot checks. About half of the patients had abnormal findings. The most notable finding was in-growing toe nails which was found in about 81% of the patients. Corns or Calluses were present in 32% of the patients. Non intact skin and abnormal color was found in 24% and 28% of the patients respectively. These patients with abnormal findings were referred to podiatry for further evaluation and care

Conclusions: Patents with abnormal foot exam were appropriately identified and referred to podiatry for further evaluation and treatment. We believe that regular foot exams for patients with ESRD who have diabetes is critical to their care. Our target is to implement routine foot care across all Emory dialysis clinics

PUB077

Analysis of 416 Non-Dialysis Inpatients with Diabetic Kidney Disease: A Retrospective Cohort Study

Yanmei Zhang,[2] Li X. Peng,[1] Meifang Liu,[2] Xusheng Liu,[2] Lei Zhang.[2] *[1]Guangzhou University of Traditional Chinese Medicine, Guangzhou, China; [2]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China*.

Background: Diabetic kidney disease (DKD) has become one of the major causes of end-stage renal disease worldwide. In China, there is an obviously increasing trend of hospitalization rate with DKD. We aim to explore the survival of hospitalized patients with DKD through a single-center retrospective analysis.

Methods: Patients in hospital during 2011/01/01 to 2016/12/31 diagnosed with DKD but without commencing renal replacement therapy (RRT) at the time of diagnosis were included, excluding patients whose interval between the time of diagnosis and the time of receiving RRT less than 3 months or only with baseline follow-up data. Taking death or receiving RRT as a composite endpoint, survival time was compared after dividing patients into different groups according to whether angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) was used or not and whether hemeturia occurred or not. Cox regression was used to analize the influence of ACEIs, ARBs and hemeturia on the prognosis of DKD.

Results: 416 patients were enrolled, of which 155 received RRT, 31 died, 176 survived and 54 were lost to follow-up. The median survival time for the whole with composite endpoint was 27.53 months. The median survival time of patients in 3 or 4 stage chronic kidney disease (CKD) was 33.03 months while it's 11.47 months in 5 stage CKD (P < 0.001). The median survival time of patients using ACEIs of ARBs was longer than that without using (43.03 months vs 17.60 months, P < 0.001). The use of ACEIs or ARBs had a lower risk of death or entering RRT when adjustment for case mix (gender, age, BMI, duration of diabetes, history of hypertension and use of diuretics) (HR, 0.390; 95% CI, 0.279-0.545; P < 0.001). The median survival time of patients without hemeturia was 39.30 months while those with hemeturia was 20.30 months (P = 0.002), and it's risk of composite endpoint was higher compared with patients without hemeturia after adjusting for gender, age, BMI, duration of diabetes, history of hypertension and use of diuretics (HR, 1.483; 95% CI, 1.040-2.115; P = 0.029).

Conclusions: The use of ACEIs or ARBs is considerably beneficial to the prognosis of DKD. Hemeturia is not conducive to the survival of patients with DKD, which needs further researches.

PUB078

Patterns of Hospitalisation in Individuals with and Without Diabetes: Results from a Large Australian Linked Cohort Study (EXTEND45)

Tamara K. Young,[1] Louisa Sukkar,[1] Carinna Hockham,[1] Amy Kang,[1] Min Jun,[1] Kris Rogers,[1] Carol A. Pollock,[2] David R. Sullivan,[3] Martin P. Gallagher,[1] Meg J. Jardine.[1] On Behalf of the Extend45 Steering Committee *[1]The George Institute for Global Health, Gladesville, NSW, Australia; [2]The University of Sydney, St. Leonards, NSW, Australia; [3]Royal Prince Alfred hospital, Camperdown, NSW, Australia*.

Background: Diabetes is a risk factor for cardiovascular and renal complications. We sought to compare hospitalisation rates in individuals with and without diabetes, and additionally examine the hospitalisations for cardiovascular disease (CVD) and end-stage renal disease (ESRD) in these groups.

Methods: The EXTEND45 Study (2005-2014) is a linked dataset that combines baseline questionnaire responses (2006-2009) with data from community pathology providers, medical services and prescription medication data (the Medicare Benefits Schedule [MBS] and Pharmaceutical Benefits Scheme [PBS]; provided by the Department of Human Services) and for participants of the population-based 45 and Up Study (n = 267,153). MBS and PBS data was linked by the Sax Institute and all other data sources by the Centre for Health Record Linkage. Individuals with diabetes were identified using pre-specified criteria. All hospitalisations between January 2006 and June 2014 were identified and the proportion and mean LOS of hospitalisations calculated.

Results: Amongst 151,760 individuals with linked pathology data, 24,400 met the criteria for diabetes. Of these, 17,293 (70.9%) received glucose-lowering pharmacotherapy at any time during the study period. The annual mean number of overnight hospitalisations per individual was 0.33 for those without diabetes, 0.62 for those with diabetes but not receiving pharmacotherapy and 0.66 for those with diabetes and receiving pharmacotherapy. The diabetes cohorts had a higher proportion of hospitalisations due to CVD (7.6-8.9%) and ESRD (0.8%) than individuals without diabetes (6.0% and 0.3%, respectively). Mean LOS for CVD-related hospitalisations for those receiving pharmacotherapy, for those with diabetes and not receiving pharmacotherapy, and for those without diabetes was 6.13 (SD 8.12), 6.02 (SD 6.80) and 5.41 (SD 6.58) days, respectively. The corresponding mean LOS for ESRD-related hospitalisations was 15.4 (SD 18.0), 13.0 (SD 19.4) and 14.5 days (SD 17.6) days respectively. Limitations include sampling biases in the opt-in design of the 45 and Up Study.

Conclusions: Differences in the patterns of hospitalisation between individuals with and without diabetes were observed. Factors driving this warrant further investigation.

PUB079

Noninvasive Method of Differentiating Diabetic Nephropathy and Nondiabetic Renal Disease Using Serum Bone Morphogenetic Protein 7 and TGF-Beta1 Levels

Jyothi P. Darshini. *Nephrology, AIG Hospitals, Hyderabad, India*.

Background: The current evidence for clinical benefits from the administration of BMP-7 in diabetic nephropathy remains limited, and mainly derived from animal models. In this context, this study is taken up with an aim to assess the circulating levels of serum TGF β1 and BMP 7 in patients of type 2 Diabetes mellitus and to assess the correlation between IFTA and serum BMP 7, TGF β1 levels.

Methods: This is a prospective observational study done from December 2014 to December 2016 in Department of Nephrology, Gandhi hospital, Hyderabad in 100 patients of type 2 Diabetes mellitus patients presenting with symptoms and signs of renal disease. **Selection Criteria: Inclusion Criteria:** Patients with Type 2 Diabetes mellitus presenting with clinical features of renal disease in the form of urinary abnormalities with or without rise in serum creatinine. **Exclusion Criteria** Diabetes mellitus with acute kidney injury DM with pregnancy Type 1 diabetes mellitus Type 2 diabetes mellitus without renal insufficiency and proteinuria

Results: Mean BMP 7 levels in histopathological class DN II was 28 ng/ml, DN III was 18±7.13 ng/ml, DN IV was 15.15±9 ng/ml. Over all Serum BMP 7 levels are lower in DN and the levels progressively decreased with increasing histopathological class of DN (P = 0.47). Over all serum TGF β1 levels are higher in patients with DN and the values progressively increased with increasing histopathological class of DN (P = 0.07). Mean BMP 7 levels in patients with IFTA < 25% in NDRD was 474.89 ± 58 ng/ml, in biopsy proven DN was 12 ± 5.8ng/ml, and the difference is statistically significant (P< 0.0001). Mean BMP 7 levels in patients with IFTA 25% to 50 % in NDRD was 460 ng/ml, in biopsy proven DN was 21.7 ± 12.8ng/ml and the difference is statistically significant (P = 0.02).

Conclusions: (1)Low serum BMP 7 and high TGF beta 1 levels may be used as screening markers to differentiate diabetic nephropathy and non diabetic renal disease, instead of subjecting the patients to an invasive procedure like renal biopsy. (2) Low serum BMP 7 and high TGF beta 1 levels have a strong correlation with increasing severity of histopathological class of diabetic nephropathy.

PUB080

How Important Is Glucose Nephrotoxicity in Type 2 Diabetes Mellitus-Associated Cardiovascular Risk?

Alberto Tejedor jorge,[1,3] Alberto Lazaro Fernandez.[1,2] *[1]Renal Physiopathology Lab, Nephrology, Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Hospital General Universitario Gregorio Marañón, Madrid, Spain; [2]Department of Physiology, School of Medicine, Universidad Complutense de Madrid, Madrid, Spain; [3]Department of Medicine, School of Medicine, Universidad Complutense de Madrid, Madrid, Spain.*

Background: Diabetes mellitus is frequently associated with different macro and microvascular lesions, widely accepted as responsible for the high cardiovascular morbidity and mortality associated with this pathology. It is also accepted that diabetic nephropathy is part of this spectrum of vascular involvement. Recently several multicenter clinical trials have digged into this association between diabetes and cardiovascular damage. The first one, EMPAREG, showed that the inhibition of SGLT2 in the proximal tubule reduced cardiovascular mortality, mortality from any cause, hospitalization due to chronic heart failure (CHF) and the progression of the renal lesion, but had little or no effect on non-lethal acute myocardial infarction (AMI) or non-lethal stroke. The studies on iSGLT2 that followed, CANVAS and DECLARE, have shown apparently discordant effects, with significant effects in some cardiovascular outcomes, but not in others. Although various explanations have been proposed, none justifies the heterogeneity between the studies. So, discussion about the existence or not of a class effect persists.

Methods: In this study, we perform a meta-regression of the three studies comparing the prevalence of any single or composite variable in the control group against the reduction in the risk obtained with every iSGLT2. And we compared the results with those of the HOPE study.

Results: Meta-regression shows that SGLT2 blockade reduces in a risk-dependent manner cardiovascular mortality, hospitalization due to CHF and the progression of nephropathy, but not the risk of stroke or AMI. The results are exactly as expected according to the HOPE study if the primary mechanism of cardiovascular protection in diabetes mellitus type 2 treated with iSGLT2 is the reduction in kidney damage.

Conclusions: We discuss the evidences of this interaction between iSGLT2 and renal tubular damage of different etiologies, the mediating role of the inflammasome activated by the renal tubular lesion on vascular and cardiac damage and propose an explanation for the absence of effects at the central nervous system level.

Lipoprotein(a) and Decline in Renal Function, Incidence of Cardiovascular Disease, and Mortality in Individuals with Type 2 Diabetes and Microalbuminuria

Niels S. Heinrich,[1] Bernt Johan Von Scholten,[2] Frederik Persson,[3] Tine Hansen,[3] Hans-Henrik Parving,[4] Peter Rossing.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Novo Nordisk A/S, Soborg, Denmark; [3]Steno Diabetes Center, Gentofte, Denmark; [4]Rigshospitalet, Copenhagen, Denmark.*

Background: Lipoprotein(a) (Lp(a)) has emerged as an independent risk marker for cardiovascular disease (CVD) in both general populations and populations with existing CVD. We investigated associations between Lp(a) concentrations and decline in renal function, incidence of CVD and all-cause mortality in individuals with type 2 diabetes, microalbuminuria and no history or symptoms of coronary artery disease.

Methods: Prospective cohort of 198 individuals with type 2 diabetes and microalbuminuria (moderately increased urinary albumin excretion rate (UAER) 30-300 mg/24 hours). All-cause mortality and CVD (fatal and non-fatal) events were tracked from national registries. Yearly p-creatinine was measured after baseline in 176 of the participants. The renal endpoint was defined as eGFR-decline of >30% from baseline. Cox regression analyses were applied both unadjusted and adjusted for traditional risk factors (sex, age, systolic blood pressure, LDL-cholesterol, smoking, HbA_{1c}, creatinine and UAER).

Results: Baseline mean (SD) age was 58.7 (8.6) years, eGFR 89.1 (17.4) ml/min/1.73m2, 77% were male, and median [IQR] UAER was 103 [38-242] mg/24-h. Median Lp(a) was 8.04 [3.42-32.3] mg/dL. Median follow-up was 6.1 years; 38 CVD events, 26 deaths and 43 renal events were recorded. For each doubling of baseline Lp(a), the following hazard ratios (95% confidence intervals) were found before and after adjustment respectively: 0.98 (0.84-1.15) and 1.01 (0.87-1.18) for a decline in eGFR>30%, 0.96 (0.81-1.13) and 0.99 (0.82-1.18) for cardiovascular events, 1.04 (0.85-1.27) and 1.06 (0.87-1.30) for all-cause mortality.

Conclusions: In this cohort of individuals with type 2 diabetes and microalbuminuria, the baseline concentration of Lp(a) was not a risk factor for decline in renal function, CVD events or all-cause mortality.

PUB082

Diabetic Fibrillosis: The Resurgence of an Entity of Unknown Significance

Anvesh G. *NIMS, Hyderabad, India.*

Background: Diabetic Fibrillosis(DF) is a rare glomerular abnormality detected in association with diabetic kidney disease(DKD). It is seen as random nonbranching fibrillary deposits in mesangium under electrone microscopy. First described by Zohar et alin 1970, only few case reports are available on this entity and we report the largest case series till date.

Methods: We reviewed all the cases of DKD who underwent renal biopsy for various indicationsin last two years (April 2017 to march 2019). Cases which were reported as DF in electron microscopywere collected. Clinical course, investigation reports and biopsy findings were analysed.

Results: DF was reported in 10(4.03 %) out of 248 cases of DKD. The mean age was 57.6±.6years (44-67). All were diabetic with mean duration 13±3.1years. The mean creatinine was 7.2±3.1mg/dl and nephrotic range proteinuria seen in 40%. Autoimmune and myeloma workup was negative. Light microscopy showed diabetic nephropathy class IVin all 10 cases. TheImmunofluorescence andcongo red stain was negative in all. GBM was thickened (range432 to 885 nm)in all cases along with random non branching fibrillary in mesangium. No spherular microparticles ortubuloreticular inclusions were seen.

Conclusions: DF is not an uncommon entity with a prevalence of 4.03 % in our case series. The clinical significance of this entity is yet to be determined. Larger prospective studies are needed to evaluate the correlation with long term renal outcomes.

PUB083

The Effects of Testosterone Replacement Therapy (TRT) in Patients with Established Dementia

Aditi Gupta,[1] Mariana Garcia-Touza,[2] Virginia J. Savin,[4] Peter S. Wiegmann,[3] Mukut Sharma,[4] Ram Sharma,[4] Thomas Wiegmann,[5] Vikas Singh.[4] *[1]University of Kansas Medical Center, Kansas City, KS; [2]Kansas City VA, Kansas City, MO; [3]Midwest Biomedical Research Foundation, Kansas City, MO; [4]Kansas City VA Medical Center, Kansas City, MO; [5]VA Medical Center, Kansas City, KS.*

Background: We have previously shown that TRT provides significant survival benefits and that patients with dementia have a faster progression of chronic kidney disease (CKD). Testosterone deficiency is common in both CKD and dementia. Here we examined if TRT slows CKD progression, cardiovascular disease and mortality in patients with dementia.

Methods: Data from a large cohort of veterans with low total testosterone were used to determine the effect of TRT on progression of CKD, cardiovascular diseases and all-cause mortality in patients with dementia (ICD9). Increase in serum creatinine > 1.5 mg/dl was taken as a measure of progression of CKD. Data were extracted using the Veterans Administration Informatics and Computing Infrastructure (VINCI), and analyzed using SAS. Propensity matching for age, followup time and prior vascular disease was used to adjust groups. Results were compared by means tests, frequency tables, odds ratio and p values (p=<0.01).

Results: Of 57,985 patients with testosterone deficiency, 1,317 with dementia diagnosis (Dx) had treatment (Dx_TRT) and 475 had none (Dx_No_TRT), compared to controls (Ctrl_TRT, N=44,434, Ctrl_No_TRT, N=13,551). Followup was shorter with DX (Ctrl vs Dx: 5.5 vs 4.4 yrs). Baseline age and creatinine were similar (59.3 vs 60.2 yrs; creatinine 1.03 vs 1.03 mg/dl). TRT provided significant reduction in all-cause mortality in both groups, (Odds Dx 0.61, 95% CI 0.49-0.75) vs (Odds Ctrl 0.85, 95% CI 0.84-0.87). TRT reduced the progression of CKD (Odds Dx 0.63, 95% CI 0.51-0.79 vs Odds Ctrl 0.89, 95% CI 0.88-0.91). TRT reduced CVA (Odds Dx 0.57,95% CI 0.41-0.79 vs Odds Ctrl 0.88, 95% CI 0.81-0.95). The effect on new MI was significant in Control only (Odds 7.6, 95% CI 0.67-0.85). TRT reduction of new diagnosis of retinopathy and nephropathy was not significant. Prior cardiovascular disease was more common with dementia (% difference Dx/Ctrl), e.g. CAD (117), CHF (92), CVA (496), HTN (67), MI (140), PAD (129).

Conclusions: TRT is associated with significant reductions in progression of early CKD[AG1], all-cause mortality and new cardiovascular diagnoses in patients with dementia even while dementia is associated with increased prior cardiovascular disease. [AG1]How are we defining early CKD?

Worsening of Dental Caries Is Associated with Arteriosclerosis Among Patients on Hemodialysis

Taro Misaki,[1,3] Yoshitaka Shimizu,[1] Kazuhiko Nakano.[2] *[1]Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan; [2]Osaka University Graduate School of Dentistry, Suita, Osaka, Japan; [3]School of Nursing, Seirei Christopher University, Hamamatsu, Japan.*

Background: Patients on hemodialysis (HD) must undergo HD therapy three times weekly and might be unable to visit a dentist. Dentists may hesitate to provide routine oral care to patients with HD, as they are medicated with anticoagulants and are thus particularly susceptible to bacterial infections; they might also experience unusual drug reactions. Patients on HD possibly have worse oral status than healthy people; this might predispose such patients to systemic complications.

Methods: The dental caries and periodontitis statuses of 80 patients on HD and 76 healthy individuals (controls) were compared using the decayed, missing or filled teeth

(DMFT) index and the *community periodontal* index (CPI), respectively. In addition, the clinical data of included patients and controls were analyzed after they provided written informed consent to participate in the study.

Results: All values for C4 level of dental caries, missing teeth index, and DMFT index score > 24 were significantly higher in patients on HD than in controls ($p < 0.05$). Pulse pressure and the prevalence of a history of heart disease, such as angina pectoris and acute myocardial infarction, were higher in patients with higher (> 24) DMFT index scores, compared with patients with low (< 24) DMFT index scores ($p < 0.05$). In contrast, CPI scores did not significantly differ between these two groups.

Conclusions: Prior reports have indicated that arteriosclerosis progresses concomitantly with increases in pulse pressure difference; progression of arteriosclerosis is associated with cardiovascular disease. Worsening of dental caries status may be associated with progression of arteriosclerosis among patients on HD.

Expansion of Monocytic Myeloid-Derived Suppressor Cells in Patients Under Hemodialysis May Lead to Cardiovascular Disease and Death

Yi-Dan Qiao,[1] Jie Chen,[1] Yan-Fang Xing,[3] Nan Jiang,[2] Xing Li.[1] *[1]the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]the Second Affiliated Hospital of Southern Universtiy of Science and Technology, Shenzhen, China; [3]the Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China*.

Background: The specific mechanism of cardiovascular vasculopathy in the context of end stage renal disease was not clear. In the present study, we investigated the clinical impact of myeloid-derived suppressor cell on hemodialysis patients and the mechanism.

Methods: Myeloid-derived suppressor cell was tested among hemodialysis patients under hemodialysis and their association with overall survival and cardiovascular disease was determined by survival analysis.

Results: Hemodialysis patients presented with a significantly higher level of monocytic myeloid-derived suppressor cells compared with healthy controls. Monocytic myeloid-derived suppressor cell was an independent prognostic factor for overall survival, heart failure and stroke illustrated by multivariate Cox regression, which indicated that monocytic myeloid-derived suppressor cell hazard overall survival of hemodialysis patients by inducing cardiovascular diseases. Monocytic myeloid-derived suppressor cell positively correlated to circulation monocyte counts and share the same surface marker with monocytes. T cell proliferations were significantly abrogated by the addition of hemodialysis related M-MDSCs in a dose-dependent manner which confirmed that monocytic myeloid-derived suppressor cell, instead of monocyte, contributed to cardiovascular disease. Besides, monocytic myeloid-derived suppressor cell presented higher level of CXCR4 and VLA-4 compared with monocytes, which indicated their enhanced capability to be recruited to atherosclerotic lesions. The expression of arginase I and activity of arginase also significantly raised in hemodialysis related monocytic myeloid-derived suppressor cells which indicated that they accelerated atherosclerosis by exhausting local L-arginine.

Conclusions: Above all, monocytic myeloid-derived suppressor cells was elevated in hemodialysis patients and an independent prognostic factor for overall survival and cardiovascular diseases. They might contribute atherosclerosis by enhanced recruitment to vascular lesions and exhausting local L-arginine.

PUB086

Uremic Toxins Nexus with Nutritional Profiles

Joan M. Gasco, Juan Robles bauza, Sheila Cabello Pelegrin, Joana M. Ferrer, Juan Rey Valeriano, Bernardino Barcelo. *Hospital Universitari Son Espases, Palma de Mallorca, Spain*.

Background: High protein intake is associated with increased levels of albumin-bound uremic solutes in hemodialysis (HD) patients (p). We analyze the patterns of the prototypic uremic toxins Indoxyl Sulfate (IS) and β2microglobulin (β2M) relationship with protein metabolism and inflammation.

Methods: Study of 60 chronic HD p. 60.8±1.8 (mean±SE) years. 32 M/28 F. 34 standard HD / 26 postdilutional hemodiafiltration (HDF). 54 p residual diuresis <500 ml/24 h. Dialyzer: 54 polynephron, 4 cellulosic. HD time 244±2.5 min. QB 357.5±6.6 ml/min. Q_D 500-800 ml/min. Pre/postHD serum IS total by HPLC. Pre/post (post in HDF p) serum β2M by nephelometry. UKM by Solute Solver. Midweek sessions. T-test or ANOVA for IS and β2M as dependent v, and as categorical factors: 1) Albumin (Alb) ≥ (25 p) or < (35 p) to 38 g/L; 2) C Reactive Protein (CRP) ≥ (22 p) or < (38 p) to 10 mg/L; 3) double pool normalized Protein Catabolic Ratio (dp nPCR) ≥ 1 (31 p) or < 1 (29 p) g/kg/day; 4) dp nPCR categorized by levels (<0.6 / 5 p 8.3%, 0.6-0.79 / 11 p 18.3%, 0.8-0.99 / 14 p 23.3%, 1-1.19 / 17 p 28.3%, >1.2 / 13 p 21.6%); 5) "nutritional profiles": catabolic (alb < 38 g/L and dp nCRP ≥ 1 g/kg/day) 12 p 20%, low intake (Alb < 38 and dp nPCR <1) 21 p 35%, high intake (Alb ≥ 38 and dp nPCR ≥ 1) 19 p 31.6%, anabolic (Alb ≥ 38 and dp nPCR < 1) 8 p 13.3%.

Results: PreHD uremic toxins (mean±SE): IS total 18,9±1.6 mg/L, β2M 35.6±1.9 mg/L. IS higher in the high vs the low dp nPCR group: 22.8 (18-27.6) vs 14.4 (10.6-18.8) mg/L (means and CI 95%) (p=0.0006). β2M higher in the low vs high Alb group: 40.9 (35.6-46.1) vs 29.4 (24.7-34.2) mg/L (p=0.002). IS higher in the high vs low dp nPCR group: 22.8 (18-27.6) vs 14.14 (10.6-18.8) (p=0.01). IS relationship with dp nPCR: <0.6 g/kg/day=12.9 mg/L, 0.6-0.79=16.9, 0.8-0.99=17.7, 1-1.19=23.4, >1.2=21.7. High intake (23.5 mg/L) and catabolic p (21.1 mg/L) had the mean highest levels of IS and anabolic (17.2 mg/L) and low intake (16.2 mg/L) the lowest. Catabolic (41.8 mg/L) and low intake p (38.5 mg/L) had the mean highest levels of β2M, and high intake (32.4 mg/L) and anabolic p (26. mg/L) the lowest.

Conclusions: IS concentrations had direct correlation to nPCR determined by protein intake. β2M had inverse correlation to albumin level and direct correlation with CRP. Catabolic p showed both IS and β2M highest levels.

Ultrafiltration Volume During Hemodialysis and Its Correlation with Central Pressure Parameters

Jafar Al-Said, Corazon Suyao. *Bahrain Specialist Hospital, Manama, Bahrain*.

Background: Determination of the ultrafiltration volume during hemodialysis (HD) is crucial for ESRD patients. It is challenging during HD to maintain a balance between excess fluid removal and hypoperfusion. Noninvasive central pressure measurement was utilized to identify the independent variables related to the ultrafiltration volume (UFV).

Methods: A cross-sectional study was performed to monitor the central blood pressure, using Mobil-O-Graph device, with peripheral brachial cuff for 10 hemodialysis sessions among 10 patients. The Central BP, Cardiac output (COP), Peripheral vascular resistance (PVR), Pulse Wave velocity (PWV), and Augmentation index (AUI) were continuously monitored during the whole hemodialysis sessions. Age, gender, BMI and cardiovascular risk were recorded from the medical files. The total and hourly ultrafiltration volume were calculated from the patients Pre, Post dialysis weight and the dialysis machines. Significant univariate correlations were selected to generate a multivariate linear regression equation to test all the independent variables.

Results: The mean age for the patients was 55 years (SD 8.6), BMI 27.7 kg/m^2 (SD 4.7). Five of the patients were males. Mean number of CV risks were 2 in each patient, not counting ESRD. We recorded 136 measurements of central pressure, COP, PWV, PVR and AUI over 10 Hemodialysis sessions. Mean COP was 5L (SD 0.9), mean AUI 28% (SD12), mean PWV 9m/s (SD 2), mean PVR 1858 dyn.s/cm^5 (SD 379), mean central pulse pressure 45mmHg (SD 16), mean central MAP 110mmHg (SD 12). The total and the hourly ultrafiltration volumes were recorded from the patients pre, post dialysis weight and the machines. The mean total UFV was 1891ml (SD 972) and the mean hourly UFV was 658ml (SD286). The total and the hourly UF volume were significantly correlated with age, gender, BMI, CV risk, COP, PWV, TVR, PVR, and central pulse pressure. However, the AUI and Central MAP were not significantly correlated. The UFV was determined by the age, gender, BMI, CV risk, COP, PWV, PVR, and central pulse pressure in a multivariate regression with an R^2 of 0.8.

Conclusions: Demographic factors, CV risk and Central pressure measurement, including pulse wave velocity, Central pulse pressure, cardiac output and peripheral vascular resistance were independent variables that determined the ultrafiltration volume during dialysis with an accuracy of 80%.

PUB088

Early Initiation of Hemodialysis in Advanced CKD with Severe Heart Failure Improves Survival and Quality of Life (QOL)

Chamberlain I. Obialo,[1] Elizabeth O. Ofili.[2] *[1]Renal Division, Morehouse School of Medicine, Atlanta, GA; [2]Cardiology Division, Morehouse School of Medicine, Atlanta, GA.*

Introduction: The survival benefits of early initiation of hemodialysis [HD] in patients with chronic kidney disease [CKD] has recently been called into question. Also the presence of heart failure [HF] at HD initiation is a strong predictor of high mortality. We present a case series of 3 non-diabetic patients with CKD stage 4 [CKD 4] and severe non-ischemic cardiomyopathy [NICM] in whom HD was initiated early as a result of recurrent hospitalizations for volume overload and diuretic resistance.

Case Description: The patients were elderly with history of hypertensive CKD, severe heart failure secondary to NICM and low ejection fraction. All were on standard HF therapy which included: angiotensin converting enzyme inhibitors or angiotensin receptor blockers, beta blockers, combination therapy with fixed dose Hydralazine with Isosorbide dinitrate and two diuretic agents [a loop and a distal tubule acting agent]. Each patient also had an Implantable Cardioverter-Defibrillator [ICD]. They were adherent with their medications but had recurrent hospitalization 2-3 times each month for worsening HF. As a result of these hospitalizations, it was decided that chronic HD should be initiated even though their mean estimated glomerular filtration rate at HD initiation was over 15 ml/min. They have been followed for a mean duration of 40 months since initiation of maintenance HD. The table provides a comparison of their clinical characteristics before and after HD initiation over 3 yrs. of follow up.

Discussion: The median survival of elderly HD patients with HF is less than 30 months but all the patients in this report were alive 40 months post HD initiation. Contrary to recent reports, early initiation of HD in select patients with advanced CKD and severe HF may improve QOL and survival. This should ultimately translate into reduced healthcare costs.

Results from the First Use of High Flux Dialysis in Algeria

Ala eddine Lasfer. *Nephrology-Dialysis, Etablissement Hospitalier Public M'sila, M'sila, Algeria.*

Background: Traditional low-flux dialysis is the only treatment currently available in Algeria, while high-flux dialysis can improve renal disease patient's health related quality of life, Water treatment remain one of the major obstacles to prevent this method from developing in our country. The aim of the study was to compare for the first time the effect of permeability of LF versus HF dialysis membranes on metabolic abnormalities control, Inflammation and body composition by bioimpedance spectroscopy.

Methods: Six prevalent patients on regular hemodialysis were enrolled in a prospective study, from M'sila hospital in Algeria, Chronic LF polysulfone membranes were used, all patients were switched to HF Polyethersulfone during one year. Predialysis samples were taken from the arteriovenous fistula while Postdialysis samples were taken from the arterial blood tubing after the dialyzer blood flow rate had been reduced to 80ml/min. Standard biochemical parameters, Albuminemia, C-reactive protein, Vitamin B12 and intact parathyroid hormone concentration were analyzed with standard laboratory techniques, β2microglobuline (β2M) by Chemiluminescence. The dialysis time and schedule, blood and dialysate flows, and the anticoagulation protocol were kept constant during the study period. Bacteriology water and Endotoxin assessment were performed each three months.

Results: We observed a significant decrease of pre-dialysis levels of β2M 44,27±5,47mg/l, 25,49±2,15mg/l respectively (p = 0.0002) and significant increase in Vitamin B12 between pre-HF and post HF dialysis (P= 0,011). However, we noticed no significant differences of the other parameters (Albumin, CRP, PTH), Hemoglobin mean levels remained stable with reduced erythropoietin doses. An increase in Lean tissue index and decrease in Fat occurred 6 months after the beginning of the trial (P= 0,564 and 0,113). On the other hand, we should state that the removal of small toxins was similar with HF and LF.

Conclusions: HF dialysis membranes seems to be more efficient in terms of metabolic abnormalities control for chronic hemodialysis patients than low-flux membranes. Reduction of β2M and improvement of nutritional parameters are encouraging us to use HF in our setting. Our greatest pleasure was when HF proved its tolerance without evidence of major adverse side effects. HF dialysis is feasible in our context with limited resources, so we look forward to spread it in all of Algeria hospitals.

PUB090

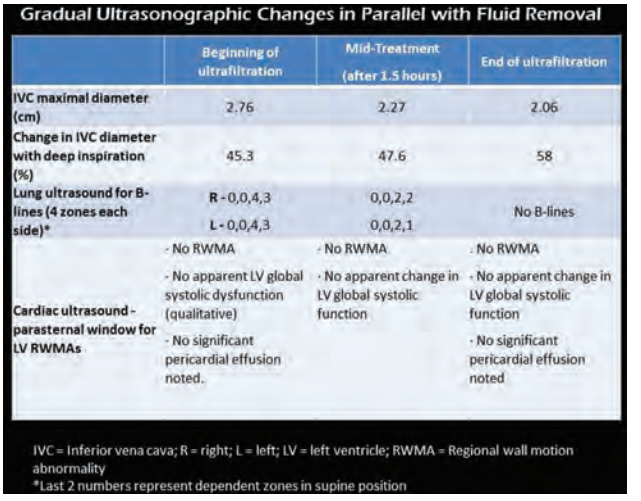
Enhancing Volume Management in Hemodialysis Through Integration of Point-of-Care Ultrasonography

Abhilash Koratala,[1,2] Gajapathiraju Chamarthi,[2] Amir Kazory.[2] [1]*University of Texas Health, San Antonio, TX;* [2]*University of Florida, Gainesville, FL.*

Introduction: Volume overload is associated with increased morbidity and mortality in patients with end-stage renal disease (ESRD). In routine practice, physical examination is commonly used to estimate volume status and guide ultrafiltration (UF) in hemodialysis (HD) patients. Herein, we describe a case in which point of care ultrasonography (POCUS) uncovered volume overload in an apparently euvolemic patient and changed the management strategy.

Case Description: A 68–year-old woman with a history of ESRD on maintenance HD presented with severe dyspnea. On physical examination, blood pressure was 260/110 mmHg, lungs were clear to auscultation, and there was no pedal edema. The last HD treatment was 2 days prior and the patient was at her estimated dry weight at the end of therapy. Nitroglycerin infusion resulted in improvement in BP and complete resolution of dyspnea over the next few hours. Since there was an unexplained significant discrepancy between her presentation and physical exam, POCUS was performed to more objectively assess volume status. Despite her apparent clinical euvolemia, focused sonography of the inferior vena cava, lung, and the heart revealed presence of significant fluid excess implying the need for aggressive UF. We were able to perform POCUS-guided UF to achieve an impressive 6.8% reduction in weight within 3 hours with no adverse event. Sonographic findings [**Figure**] and BP showed progressive improvement throughout the UF session.

Discussion: This case highlights the capability of POCUS to enhance patient care in ESRD, not only through uncovering of concealed hypervolemia, but also by guiding the UF process. In addition, limited cardiac POCUS can provide insights into patient's cardiac tolerance as transient changes in ventricular function and regional wall motion abnormalities are known to occur during HD. Future longitudinal studies need to explore whether these salutatory effects translate into improved outcomes.



PUB091

Effects of Ultrafiltration Rate (UFR) on Hemodialysis Patient Survival

Jose E. Navarrete. *Emory University, Atlanta, GA.*

Background: Increasing levels of UFR have been associated with higher mortality. We attempt to examine the effect of increasing levels of UFR on mortality of incident hemodialysis patients.

Methods: Incident hemodialysis patients admitted to Emory University Dialysis program form 1/1/11 to 12/31/15 were followed until death, transplant, or censoring up to 12/31/18. Demographic, laboratory and hemodialysis data including UFR and changes in blood pressure were obtained. Hospitalizations and common complications were extracted from the medical record. Patients were divided in 4 groups according to quartiles of UFR distribution (<4.9, 4.9-6.8, 6.8-8.8 and >8.8 ml/kg/h) and will be referred as Groups A, B, C and D.

Results: 903 incident patients were included. The average age of the cohort was 57.2 years, with a weight of 82kg and UFR of 7mL/kg/h. The differences between groups are presented in table 1. The survival probability was similar for all groups and is represented in Figure 1, The cumulative incidence of admissions was similar among groups.

Conclusions: We found no association between different quartiles of UFR on hemodialysis patient survival. Higher UFR was associated with younger age, lower weight and lower incidence of hypotension during dialysis. Incidence rate of admissions was similar among UFR groups.

Blood Pressure Elevation Just Before Cerebral Hemorrhage in Patients Undergoing Hemodialysis

Mineaki Kitamura,[1] Yohei Tateishi,[1] Takashi Harada,[2] Satoshi Funakoshi,[2] Takayuki Matsuo,[1] Akira Tsujino,[1] Tomoya Nishino.[1] *[1]Nagasaki University Hospital, Nagasaki, Japan; [2]Nagasaki Renal Center, Nagasaki, Japan.*

Background: Pre-symptomatic blood pressure elevation is known to be associated with intracerebral hemorrhage; however, only a few studies have reported this association. Cerebral hemorrhage is an important complication in patients undergoing hemodialysis, and it is possible to evaluate the pre-symptomatic situation from patients' dialysis charts. We investigated the association between blood pressure elevation and the onset of cerebral hemorrhage.

Methods: This study included patients undergoing hemodialysis who were treated for cerebral hemorrhage at our hospital between 2008 and 2016 (case group) and patients treated at Nagasaki Renal Center between 2011 and 2012 (control group). Data regarding participants' backgrounds were obtained from medical records and 3 consecutive dialysis charts just before the onset of cerebral hemorrhage (case group) and participants' birthdays (control group).

Results: The case group included 99 patients (mean age 65 years, median dialysis vintage 87 months, 67% men), and the control group included 339 patients (mean age 67 years, median dialysis vintage 56 months, 57% men). Compared with the control group, the case group showed a significant increase in systolic blood pressure (approximately 6 mmHg) during the last among 3 dialysis sessions (P=0.02). After adjusting for age, sex, dialysis vintage, history of diabetes and cerebrovascular disease, serum hemoglobin, calcium, and phosphate levels, antiplatelet drug use, and fluid removal rate, logistic regression analysis showed that blood pressure elevation over baseline levels was significantly associated with cerebral hemorrhage (odds ratio 1.02 per/mmHg, P<0.001). Multiple regression analysis showed that in the case group, blood pressure elevation was significantly associated with a history of diabetes (P=0.03) and lower serum calcium levels (P=0.01) but not with weight gain between dialysis sessions.

Conclusions: Blood pressure elevation over baseline levels, which may reflect failure of vascular system autoregulation, was associated with cerebral hemorrhage. The tendency of blood pressure elevation may depend on a patient's background.

PUB093

Percutaneous Left Atrial Appendage Closure: A Safe Alternative to Anticoagulation for Patients with Non-Valvular Atrial Fibrillation and ESRD on Hemodialysis

Marc Xipell Font,[1] Eduardo Flores,[1] Raquel Ojeda lopez,[2] Marta Arias,[1] Xavier Freixa,[1] Aleix Cases,[1] Francisco Maduell.[1] Nephrology Department; Cardiology Department; Hospital Clinic of Barcelona *[1]Hospital Clinic Barcelona, Barcelona, Spain; [2]University hospital, Córdoba, Spain.*

Background: The prevalence of non-valvular atrial fibrillation (NVAF) in patients with end-stage renal disease (ESRD) on hemodialysis is 13 to 27%. There is little evidence on the effectiveness and safety of vitamin K antagonists (VKAs) in them since their potential benefit have shown conflicting results. Moreover, direct oral anticoagulants are not recommended by current cardiology guidelines in patients on hemodialysis. Percutaneous left atrial appendage occlusion (LAAO) has demonstrated to be an alternative therapeutic option to anticoagulation for stroke prevention in NVAF. However, the evidence of its use in patients on hemodialysis is scarce. The aim of this study is to present our single-center experience of LAAO in ESRD patients on hemodialysis.

Methods: Retrospective chart review of clinical records, demographics, LAAO procedure and devices, complications, post-procedure therapy and oucomes of patients with ESRD on hemodialysis and NVAF who underwent a percutaneous LAAO in our center between January 2017 and January 2019.

Results: Eight patients (six males) with ESRD on hemodialysis underwent a percutaneous LAAO in our center. The mean age was 67.5 years (range 56–81; SD±7.2). All patients had permanent NVAF. The mean dialysis duration was 8.49 years (range 0.83-14.8; SD±6.2). The mean CHA2DS2-VASc and HAS-BLED scores were high [4.75 (SD±1.16) and 4.62 (SD±0.91), respectively]. All patients had history of a major hemorrhagic event (BARC Score ≥3). Contraindications for anticoagulation were gastrointestinal hemorrhage (n=3), repeated bleeding from the dialysis vascular access (n=3), intracranial hemorrhage (n=1) and massive epistaxis (n=1). All devices (5 Amplatzer-Amulet, 2 Watchmann and 1 LAmbre) were implanted successfully. Post-procedural antithrombotic regimen was based on antiplatelet therapy during 3.1±1.24 months. No deaths, cardioembolic events, device thrombosis or peri-device leaks, major adverse efects according to VARC criteria, or major bleeding were reported during a mean follow-up of 14.24 months (SD±9.44).

Conclusions: Percutaneous LAAO could be a safe and an effective alternative to anticoagulation in patients with NVAF and CKD in hemodialysis. Further studies will be necessary to confirm this hypothesis.

PUB094

Prefilter Hemodiafiltration with Heparin-Dose Minimization: A Safe and Effective Technique

Monica Sanchez cardenas,[1,2] Sergio Vazquez,[2] Enzo C. Vasquez jiménez.[2] *[1]UNAM, Ciudad de Mexico, Mexico; [2]National Institute of Cardiology, Mexico City, Mexico.*

Background: Unfractionated heparin (UFH) administered during hemodialysis (HD) has cumulative adverse effects; hence the importance of using the lowest possible dose and avoid overdosing.

Methods: We analyzed 30 patients with chronic hemodiafiltración (HDF) treatment divided in 3 groups: pos filter HDF with heparin standard impregnation dose (27±6.5 IU / kg), HDF pos filter with impregnation low dose (15±4.2 IU / kg); in both groups, heparin impregnation and maintenance were given, and a third group HDF pre-dilution only with heparin impregnation dose (27±12.8 IU / kg). We measured partial thromboplastin time (aPTT) and serum heparin levels at 30 and 190 min.

Results: HDF pre-dilution group received a significantly lower total dose than the other 2 groups; 1750 vs 2650/3444 UI/Kg (p <0.001), maintaining 30 min aPTT target (55,6±43.4) as aPTT 190 min (44,4±30.3), as well as effectiveness of the treatment (substitution volume of 51.4±11.8 L, Ktv 1.38±0.3). The other two groups reached aPTT 30 min target, but decreased towards the end of HDF sessions (aPTT 190 min). HDF pre-dilution did not increase clot formation (p <0.678). There were no major coagulation or bleeding events.

Conclusions: Pre dilution HDF with only impregnation heparin is a safe and effective method; after the amplification and reproduction of our results, it could represent an alternative treatment that minimizes UFH doses in order to reduce the associated adverse events.

Table 2. Paraclinical values according to the study group.

	Pos Filter Standard Dose N=10	Pos Filter Low dose N=10	Pre Filter Low Dose N=10	*p=
Total Dose Administered (IU)	3444±836	2650±502	1750±790	<0.001
aTTP 30 min (s)	50±19.7	38±5.8	55.6±43.4	0.372

The NLRP3 Inflammasome Plays an Important Role in IL-1β Secretion in Hemodialysis Patients

Denise Mafra,[1] Livia D. Alvarenga,[2] Ludmila F. Cardozo,[3] Roberta Salarolli,[2] Bruna Paiva,[1] Jessyca S. Brito,[2] Drielly V. Reis,[2] Julie ann Kemp.[1] Nutrição em Nefrologia *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Universidade Federal Fluminense, Juiz de Fora, Brazil; [3]Federal Fluminense University, Niterói, Brazil.*

Background: Inflammasomes have been elucidated as an important inflammatory agent in several diseases, including chronic kidney disease (CKD). These molecules are multimeric protein complexes that act as activators of the inflammatory process and can also be induced by other inflammatory mediators considered agonist, for example, the Nuclear Factor-κB (NF-kB). The most studied inflammasome is NLR pyrin domain-containing protein 3 (NLRP3) that cleaves pro-Interleukin 1β (IL-1β) to IL-1β mature, which is involved with activation of acute phase response proteins in the liver such as C-reactive protein, leading to systemic inflammation. Therefore, the aim of the present study was to evaluate the possible involvement between gene expression of NLRP3 and IL-1 β in hemodialysis (HD) patients.

Methods: Eleven HD patients [63.6% female, 50.9 ± 17.9 years, 49.0 (23 – 193) months on HD] were included in this study. Blood samples were drawn after 12h fasting, and the peripheral blood mononuclear cells (PBMC) were isolated. Quantitative Real-Time PCR analysis was performed using *7500 Real-Time PCR* System (*Applied Biosystems)* to evaluate the mRNA expression encoding NLRP3, IL-1β and NK-kB. High sensitive C-reactive protein (hs-CRP) plasma levels were analyzed using Bioclin® kit by automatic biochemical analyzer.

Results: NLRP3 mRNA expression was 0.83 ± 0.35, IL-1β was 2.1 ± 1.6 and NF-kB was 0.91 ± 0.32. The plasma levels of CRP were 4.3 (2.5 – 10.7) mg/dL. There was a positive correlation between the expression of the inflammatory factor NLPR3 and IL-1β (r = 0.73, p-value = 0.02) and between NLPR3 and hs-CRP (r = 0.75, p-value = 0.03).

Conclusions: The NLPR3 gene expression may lead to increased IL-1β gene expression and increased plasma hs-CRP levels. Then, the inflammasome-IL-1β axis should be more explored in CKD patients and therefore, as the NLRP3 inflammasome has been shown to be an important inflammatory marker, it may be a new target for alternative therapies in CKD patients on HD.

Evaluation of the Efficacy of a Very High Permeability Dialyzer and Comparison with Other High-Flux Dialyzer in Online Hemodiafiltration

Ana M. Garcia Prieto,[1] Almudena Vega,[1] Soraya Abad,[1] Nicolas Macias,[2] Ines Aragoncillo,[1] Diego Barbieri,[1] Andres F. Delgado Rodriguez,[2] Esther Torres aguilera,[2] Esther Hurtado ruiz,[1] Jose Luno.[2] *[1]Hospital Gregorio Marañón, Madrid, Spain; [2]Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

Background: Online hemodiafiltration (OL-HDF) techniques that combine diffusive and convective transport have been introduced in the last years, resulting in better outcomes in terms of cardiovascular mortality in hemodialysis patients. "Super high flux" dialyzers are now commercially available with the purpose of removing a large amount of larger middle solutes by achieving higher convective volumes. One of these high performance dialyzers, called Xevonta HI 23®Braun, with very high water permeability (*in vitro* ultrafiltration coefficient (Kuf) of 124 ml/h/mmHg), has been recently introduced, but there is still a lack of evidence on its use. The main objective of the present study is to evaluate the efficacy of this very high permeability (VHP) dialyzer and to compare it to other high flux (HF) dialyzer in OL-HDF.

Methods: In this crossover study, 14 prevalent OL-HDF patients were studied in two consecutive mid-week dialysis treatments, first with the VHP dialyzer and second with the HF dialyzer. Convective volumes, reduction ratios (RR) of different-sized molecules and other dialysis parameters were collected for the different dialyzers.

Results: Mean total convective volume per session was significantly higher with the VHP dialyzer than with the HF dialyzer (33.5±5.4 vs 30.9±4.6 litres/session; p 0.013). There were no differences in the reduction ratios of small or middle size molecules nor in *in vivo* Kuf, transmembrane pressures or albumin losses between the two dialyzers (Table 1).

Conclusions: VHP dialyzer achieves significantly higher convective volumes compared to the HF dialyzer and it is not inferior in the removal of small and middle molecules.

Comparison of dialysis parameters between dialyzers

DIALYSIS PARAMETERS	VHP dialyzer	HF dialyzer	p
Mean total convective volume (L/session)	33.5±5.4	30.9±4.6	0.01
Minimum TMP (ml/h/mmHg)	155.9±53.7	157.8±34.6	0.68
Maximum TMP (ml/h/mmHg)	244.85±41.1	230.7±38.1	0.09
Medium TMP (ml/h/mmHg)	213.6±47.2	205.5±32	0.28
Mean Kt/V per session	1.8±0.4	1.9±0.6	0.31
Mean ionic dialisance per session (ml/min)	287±25	284±40	0.27
In vivo Kuf (ml/h/mmHg)	40.9±10.8	38.2±6.1	0.3

VHP: Very High Permeability, HF: High Flux, TMP: transmembrane pressure, Kuf: ultrafiltration coefficient

PUB097

Observational Study of Individualised Dialysate Sodium Prescription to Manage Intradialytic Hypertension

Richard F. Singer,[1,2] Joyce Thanabal,[3,1] Krishna Pavan T. Echampati.[1] *[1]Renal, Canberra Hospital and Health Services, Garran, ACT, Australia; [2]School of Medicine, Australian National University, Acton, ACT, Australia; [3]Canberra Health Services, Canberra, NSW, Australia.*

Background: Intradialytic hypertension (IDH) associates with higher mortality risk but optimal treatment is uncertain. Increasing antihypertensives or reducing post dialysis target weight may lower intradialytic BP but increases the risk of hypotension. Standard dialysate [Na] at our unit had been 140 mmol/L, despite patient plasma [Na] often being lower or, rarely, higher than this. We thought that positive Na flux during dialysis likely contributed to BP rises during dialysis and introduced a clinical protocol to guide changes in dialysate [Na]. The protocol aimed to reduce net Na diffusion during dialysis.

Methods: IDH was defined as ≥10mmHg BP rise in >50% of 7 consecutive sessions. Patients identified with IDH had target weight and medications adjusted and were then re-assessed for IDH 3 months later. Those that still had IDH were offered an iterative adjustment of dialysate [Na] to target an equal blood inlet and outlet [Na]. The range of allowable dialysate [Na] was 135 to 145mmol/L. Thirst was assessed on a visual analogue scale from 0 to 100mm (100mm represents severe thirst), measured before, and 5 months after, dialysate [Na] modification. Target weight and medications continued to be adjusted as clinically required by attending physicians throughout the observation period.

Results: IDH was identified in 14 patients. After 3 months' medication/weight adjustment IDH was still present in 10. Of these, 8 consented to dialysate [Na] adjustment and 7 completed 5 months' follow-up (1 transferred out of area). Median age of consenting patients was 71 and mean dialysis vintage was 3.5 years. Median dialysate [Na] post adjustment was 136mmol/L (range 135 to 141). In those completing 5 months' follow-up; mean thirst scores improved from 33.3 to 23.6mm (p=0.07), mean pre-dialysis plasma [Na] fell from 138.1, to 135.3 mmol/L (p=0.05) and IDH was present in only 3 of the 7 patients at 5 months. No adverse events attributable to changes in dialysate sodium were recorded, but in 1 patient, dialysate [Na] was increased from 135 to 140 mmol/L during an admission for diarrhoea.

Conclusions: Due to the small and uncontrolled nature of this observational study, it is uncertain if individualising dialysate sodium by attempting to equalise the blood inlet and outlet sodium concentrations improves IDH. However, such changes appear to be safe.

PUB098

Effectiveness of Sacubitril-Valsartan in the Treatment of Heart Failure in ESKD Patients on Maintenance Hemodialysis

Sooraj Yesudas santhakumari.[1,2] *[1]Centre for KIdney and Genitourinary Diseases, Polakulath Narayanan Renai Medicity, Kochi, India; [2]Cochin Kidney Centre, Kochi, India.*

Background: Sacubitril-Valsartan (SV) has been used well in the treatment of heart failure with excellent results. However data regarding its effectiveness in End Stage Kidney Disease (ESKD) patients with heart failure is lacking

Methods: Twenty patients who were undergoing regular maintenence hemodialysis and who had at least two hospitalisations due to heart failure over the preceeding 6 months were included in the study. Patients were started on SV at a dose of 50 mg per day which was increased to a maximum tolerated dose of upto 200 mg per day. All had reduced ejection fraction. They were then followed up for a period of 6 months.

Results: There were 11 males and 9 females. The average age was 62.15 ± 9.02 years. There were 15 diabetics and 19 hypertensives. The average duration on hemodialysis was 14.9 months. The average number of hospitalisations before starting SV was 2.2 and average ejection fraction (EF) was 36.05 ± 10.55 percent. All were started with a SV dose of 50 mg per day and the maximum dose achieved was 115 ± 46.16 mg per day. Hyperkalemia was noted in 15 patents which was managed with diet and a reduction in dose. 2 patients expired - one at 2 months and the other at 5 months both unrelated to heart failure. There was a marked reduction in hospitalisations after starting SV. The mean hospitalisation number was 0.16 (p=0.012) post starting SV and the ejection fraction improved to 48.8±10.76 percent (p=not significant).

Conclusions: Sacubitril -Valsartan has been found to be very much useful in the management of heart failure in the general poupulation. Our study in ESKD patients undergoing hemodialysis has shown it is very much useful in this group also and its use has resulted in much less hospitalisations (statistically significant) and improved ejection fraction (not statistically significant). However there is the problem of hyperkalemia which needs to be closely monitored. Our experience has shown SV is beneficial in ESKD patients on hemodialysis with recurrent heart failure. But we need studies with a large number of patients to validate these findings.

PUB099

Information Technology Platform for Expanded Comprehensive ESRD Care

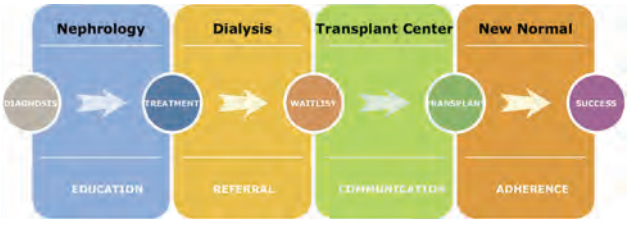
Eric Pahl. *OmniLife, Coralville, IA.*

Introduction: We are proposing an information technology (IT) platform that permits data informing pertinent quality metrics to be gathered, collated and tracked for all end-users. The most recent iteration of Centers for Medicare and Medicaid Services (CMS) Conditions for Coverage includes a transplant-based metric applicable to dialysis facilities, the Percentage of Prevalent Patients Waitlisted (PPPW). The IT platform will allow facilities to track their PPPW rates in real time. In addition to the PPPW, the IT

platform will offer a novel tool dialysis facilities can use to design and implement quality improvement projects around all steps of transplantation. Transplant centers can also make use of the IT platform to inform quality improvement projects around waitlist criteria and waitlist management. Nephrology practices can make use of the IT platform to actualize population-health level tracking the transplant education, referral, evaluation and listing of prevalent patients with advanced chronic kidney disease (CKD) and/or end-stage renal disease (ESRD).

Case Description: Technical Requirements: 1. Active on the federally certified Health IT product list 2. Linked to a patient record with unique patient identifier (UPI) 3. Facilitates instant and bi-directional communication capabilities among the patients, payers, providers, and other Health IT systems: a. Videos/Pictures/Files/Medical Imaging b. Recorded audio and video calls c. Text messaging d. Customizable Notifications e. Delivered/Read receipts f. Acknowledgment emojis g. Patient record data fields

Discussion: This proposal includes organ transplant with metrics and IT infrastructure/ platform to support the communication and coordination of the patients and providers in the network. The OmniLife platform provides the infrastructure supporting all technical requirements above, including an upcoming interface with BlueButton 2.0. OmniLife leverages existing IT systems to accelerate implementation throughout the provider network. Aim 1: implement the IT platform among an ESRD care provider network. Aim 2: reduce the cost of care for the patient population through better coordination of patients among providers.



PUB100

Vascular Access Transition and Hemodialysis Adequacy in Hemodialysis Patients

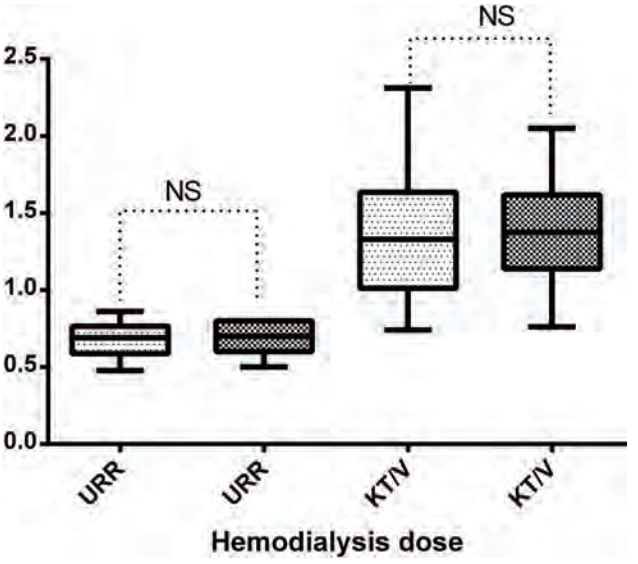
Javier Soto-Vargas,[2,3] Xochitl Guerrero,[1,3] Judith J. Velasco.[2,3] *[1]hospital civil fray antonio alcalde, Guadalajara, Mexico; [2]Nefrología, Universidad de Guadalajara, Especialidad de Nefrología, Hospital General Regional 46, Guadalajara, Mexico; [3]Nefrología, Unidad de hemodíalisis DIALTEC, Guadalajara, Mexico.*

Background: Fistulas are regarded as the best choice for vascular access in hemodialysis (HD) patients because they are associated with improve survival, and less infectious complications specially in incident patients. However, in Mexico, more than 90% of patients who start on HD with a non-tunneled central venous catheter (CVC), and the transition to a permanent vascular access is delayed for months or years. The Instituto Mexicano del Seguro Social (IMSS) is the largest health institution in Mexico who provide HD service. Due to the high incidence of end stage renal disease, this institute subrograte HD treatments from private ambulatory units, and the patients selected for this service are receiving HD sessions usually for two to three years. Our objective was to test if the change from non-tunneled CVC to fistulas or tunneled CVC were associated with better adequacy in chronic HD patients.

Methods: During March 2018 to April 2019 as part of a continuous improvement program, we changed all non-tunneled catheters to fistulas or tunneled catheters. We measured urea reduction ratio (URR), standard KT/V as well as hemoglobin and erythropoietin dose, serum calcium and phosphates before and after the vascular access change.

Results: A total of 50 (32.1%) patients changed their vascular access. The median time elapsed before the vascular replacement was 18 months (QR 6.7-32.6). 22 (44%) were male and 28 (56%) female. The median age was 49.4 years (QR 29.3-62.7). There were no differences between URR, KT/V, hemoglobin levels, erythropoietin dose or phosphate before and after the vascular change, however, there was a lower serum calcium after the change.

Conclusions: Change of vascular access to a fistula is not associated with better adequacy in terms of urea, anemia or calcium and phosphates.



Dose of dialysis before and after vascular change

PUB101

Use of XGBoost Machine Learning Model to Forecast the Changes in Dry Weights of Hemodialysis Patients

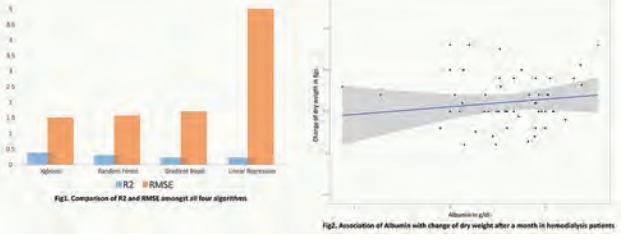
Shoab Saadat,[1] Naveen Naqvi,[2] Sidra Saadat.[3] *[1]Renal Medicine, Mid Essex Hospitals NHS Trust, Chelmsford, United Kingdom; [2]Medicine, Services Hospital Lahore, Islamabad, Pakistan; [3]Rawalpindi Medical College, Islamabad, Pakistan.*

Background: Making a clinical estimation of dry weights in the hemodialysis (HD) patients is a routine among renal physicians. The objective of this study was to develop a machine learning app to estimate dry weight of HD patients alongside the conventional clinical methods.

Methods: This was a prospective cohort study carried out from Jul to Dec 2018, at a tertiary care hospital in Pakistan. All the consenting patients (by non-probability convenience sampling) who had received HD for at least 3 months were included. A total of 78 patients were enrolled. An MBBS qualified physician administered a proforma to the patients at the start of a one-month observational period recording predictors like age, sex, income, HD related variables etc. Dry weight as an outcome was estimated clinically by the in-charge renal consultant at the start and end of this observational period. We used R statistical software version 3.5.2 for the analysis.

Results: The study population included 53% (42/78) males and a median age of 58 years. We divided the data into training and testing sets and built four models from the training set; Linear regression (R2=0.24, RMSE=9.71), Gradient Boost (R2=0.24, RMSE=1.72), Random forest (R2=0.31, RMSE=1.58) and Xgboost (R2=0.39, RMSE=1.52). The best performing model Xgboost which was able to explain about 39% variance in the dependent variable. A mobile app was later developed which takes in the predictors from last month and can estimate dry weight change expected in a given patient. There are plans to increase the sample size thus improving the accuracy of the model and to perform a cost-benefit analysis in terms of work-hours saved per week down the line.

Conclusions: We were able to develop a predictive model using Xgboost machine learning algorithm which could estimate a change in dry weight in a given HD patient one month from the start of the enrollment. This model was then implemented in the form of a mobile app which can be used by clinicians around the world to get a better estimate of dry weight changes in their HD patients. Future plans are to increase the sample size to further improve the accuracy.



PUB102

Malnourished CKD Patients: Screening Malnutrition Using a Short Nutritional Assessment Questionnaire and Body Mass Index

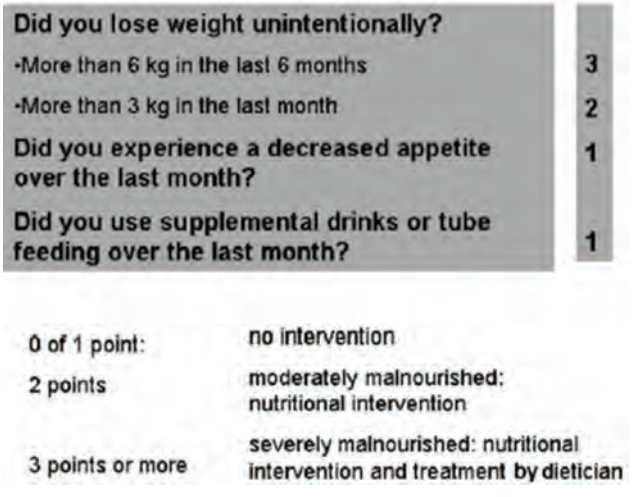
Kristianne rachel P. Medina, Porshia B. Comes. *University of Santo Tomas Hospital, Laoag City, Philippines*.

Background: Malnutrition is prevalent among hemodialysis patients. Its diagnosis and treatment is important because of its adverse consequences. However, an ideal and comprehensive nutrition assessment is time-consuming and expensive. A valid, quick and easy screening tool is therefore essential to its recognition and subsequent management. Short Nutritional Assessment Questionnaire is a 3 item screening tool developed by statistical analysis of 26 questions to determine 3 questions most predictive of nutrition status- unintentional weight loss, decreased appetite and use of supplemental drinks or tube feeding. It is >75% sensitive and 83% specific. Patients with SNAQ score ≥2 points are considered malnourished.

Methods: This cross-sectional correlational study determined malnutrition prevalence among hemodialysis patients at University of Santo Tomas Hospital using SNAQ and body mass index and their association. Nutritional status of 94 patients was evaluated by completion of SNAQ and BMI measurements.

Results: Subjects consisted of 50 women and 44 men, with mean age of 58 years. Based on SNAQ scores, 10% was moderately malnourished and 14% was severely malnourished. Based on Asia-Pacific BMI Classification, 11.7% was underweight and 47% was overweight-obese. Using Spearman R, there is a statistically significant moderate negative correlation between SNAQ scores and BMI (inverse relationship). This supports that SNAQ can be used to predict malnutrition but since the correlation is only moderate at best, it cannot be used to exclude the diagnosis.

Conclusions: Undernutrition among hemodialysis patients is not as prevalent as expected however, increasing prevalence of overweight/obesity is an emerging concern. SNAQ can be used to aide in recognition of malnutirition and as such, its use among hemodialysis patients should be encouraged.



Short Nutritional Assessment Questionnaire

PUB103

Centre-Level Factors Independently Affect Survival in Hemodialysis Patients: Findings from a Multicentre Cohort in India

Kamal D. Shah,[1] Arpita Ghosh,[2] Sumathi Kolli,[1] Vivekanand Jha.[2,1] NephroPlus Dialysis Centres *[1]NephroPlus Dialysis Centres, Hyderabad, India; [2]George Institute for Global Health, New Delhi, India.*

Background: Mortality of patients on dialysis in India is higher than that reported from western countries. Clinical and socioeconomic factors play an important role in determining survival of these patients, as do differences between dialysis centres. We examined differences in survival across dialysis centres in a large Indian dialysis network, accounting for patients' characteristics.

Methods: We analyse data from 12,640 patients who received dialysis at 129 centres managed by NephroPlus, India's largest dialysis provider between January 2014 and December 2017. The outcome is the time since the patient comes to the dialysis centre until death or end of follow-up. We use a mixed effects Cox proportional hazard model to examine the differences in mortality between dialysis centres, after accounting for the patient characteristics.

Results: Of the 12,640 patients, 3060 (24%) died during the follow-up period (median of 342 days). 4090 (32%) patients were lost to follow up. The 129 dialysis centres were distributed across cities in urban (33%), semi-urban (26%) and rural (41%) areas of India. 64% were setup under PPP programs (Public Private Partnership). About 54% were visited by a nephrologist at least once a week. The overall unadjusted mortality rate was 21.3 per 100 patient years. The individual-level variables that were associated with the outcome were age, having temporary dialysis catheter, history of heart attack or heart failure and lower income and less education. There was substantial variation in mortality between dialysis centres after accounting for the individual-level variables – with centre effects ranging between less than half to over 2.26 times the average risk, and an estimated variance of 0.18. Dialysis centres with high patient volume performed better than low-volume centres. Also, dialysis centres in the rural areas fared worse than the ones in urban areas.

Conclusions: There exist differences in survival between dialysis centres that are not explained by patients' individual characteristics. Of the various centre-level characteristics that we explored, patient volume was found to be associated with patient survival. Future research should explore other possible explanations for observed variation in patient survival across dialysis centres – differences in care practices and other patient characteristics.

PUB104

It Is Not Just Care: Haemodialysis Patients Free from HCV Infection in Qatar - A Multidisciplinary Approach

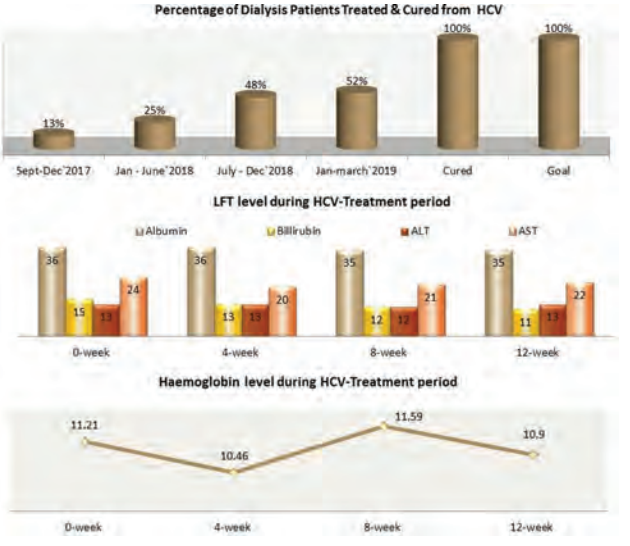
Fadwa M. Al-Ali,[1] Mohamed A. Elesnawi,[1] Farrukh A. Farooqi,[2] Sahar Aly,[2] Aisha Abdulla,[2] Tarek A. Fouda,[2] Iman ibrahim m. a. Khater,[2] Fadumo Y. Yasin.[2] *[1]Dialysis, Hamad Medical Corporation, Doha, Qatar; [2]Hamad Medical Corporation, Doha, Qatar*.

Background: Hepatitis C is an infectious disease caused by the hepatitis C virus (HCV). Chronic hepatitis C develops in most people infected with HCV and can cause serious complications, such as end-stage liver disease. Although no vaccine is available to protect against hepatitis C, interventions can prevent HCV transmission. HCV infection can be treated with antiviral drugs and, in most cases, successfully cured, reducing the risk of morbidity/mortality and theoretically risk for transmission. Qatar National Plan for HCV control by 2020 was launched in December 2014, elaborated by a group of stakeholders from the Qatar ministry of Public Health and Hamad Medical Corporation. Then Approved and adopted by the Qatar Government (MOPH). In 2017, WHO accepted to support the development and implementation of national multispectral policies and strategies for hepatitis C prevention and control in Qatar, based on local epidemiological context of HCV. The prevalence of HCV in Haemodialysis patients in Qatar is 8.4%.

Methods: Non-Interventional, single-Center cohort study, including retrospective collection of real world data on 64 Hemodialysis patients infected with HCV, 33 of them completed the 12 weeks treatment and 12 weeks follow up period. Using of Ombitasvir, Paritaprevir, and Ritonavir (Viekirax) has been accepted as a treatment option in this group of patients.

Results: from 64 HCV positive Patients we initiate the treatment for 33 patients for 12 weeks and 100% of them cured, during the treatment biochemical values was within normal limits.

Conclusions: The outcome of first phase treatment of Hepatitis C in patients on HD is highly effective, it was 100 %. Successful HCV antiviral treatment will decrease the risk for infection transmission within dialysis units, and reduce the occurrence of complications occurring after kidney transplantation.



PUB105

Evaluation of a Mobile Digital Health Intervention (patientMpower) to Capture Patient-Reported Data and Symptoms and Optimise Fluid Management in Hemodialysis

Colin Edwards,[1] Conall M. O'Seaghdha,[2] Donal J. Sexton.[3] *[1]PatientMpower, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland; [3]Trinity Health Kidney Center, Trinity College Dublin, Dublin, Ireland*.

Background: Digital health tools to capture relevant patient-reported health data are available for many chronic conditions but few are available for hemodialysis patients. patientMpower is a mobile digital health intervention which connects wirelessly to measurement devices [e.g. blood pressure (BP) meter, digital weighing scales] enabling patients to have real-time access to relevant health data and encourage greater participation in managing their condition.

Methods: We designed a prospective, pilot-scale, open-label, randomised, 2 x 28-day crossover, sham-controlled protocol to evaluate patientMpower in optimising fluid management (NCT03403491). After a 2-week run-in, ambulatory hemodialysis patients were randomly allocated to patientMpower app+weighing scales+BP meter [patientMpower intervention (pMp)] or to a sham version of the app [sham intervention] for 28 days and then crossed over to the alternative intervention for 28 days with no washout. (See Figure.) The planned sample was 50 patients. There was no change to patients' usual care. Patients were asked to record weight, BP, symptoms, fluid intake & medicines adherence daily during the pMp period. pMp calculated and displayed weight gain relative to individualised target (dry) weight to each patient. pMp delivered tailored feedback messages (dependent on actual weight gain) to optimise fluid intake between dialysis sessions. Sham intervention did not enable patients to record any data and did not provide feedback.

Results: Primary endpoint was patient engagement (usage metrics & patient questionnaire). Secondary endpoints were comparison of pMp vs. sham on clinic-observed interdialytic weight gain (IDWG), ultrafiltration volumes and BP. Patient-recorded and clinic-observed IDWG and BP were also compared.

Conclusions: This design allows evaluation of engagement with a mobile digital approach to feedback relevant information to hemodialysis patients. It can provide data on the impact of active self-monitoring on hemodialysis parameters.

Association of Religious Affiliation with Hospitalization Rates in the Dialysis Population

Marta Reviriego-Mendoza, Yue Jiao, Tammy M. Bolles, Dugan Maddux, Felicia N. Speed, John W. Larkin, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: People reporting spirituality tend to have better physical and mental health, especially for low income, chronically ill patients. (Koeing, 2015. Adv. Mind Body Med). We investigated if belonging to a spiritual congregation is associated with improvements in hospitalization in hemodialysis (HD) patients from a large dialysis organization (LDO) in the United States.

Methods: We used data from adult HD patients who had a comprehensive social work assessment completed in 2017. We analysed responses to the questions: "Is spirituality an important part of a patient's life" and "If yes, are they a member of a spiritual community?" Information on congregation number and adherents per county was obtained from the 2010 US Religion Census. A Poisson regression analysis was utilized for comparisons of hospital admissions and day rates. We adjusted for age, sex, race, albumin and vintage. The association between belonging to a religious congregation and hospital days and hospitalization rates was investigated.

Results: We analyzed data on 186026 patients. A total of 75% patients reported being part of a spiritual community. Over the 1-year follow-up after social work assessment was completed, the hospital admission rates for patients not belonging to a congregation was higher than for patients who belong to a spiritual congregation (1.65 ppy vs 1.59 ppy). The hospital days for patients not belonging to a congregation was higher as compared with patients who participate in a spiritual congregation (11.37 vs 11.02 ppy). An adjusted regression model showed significantly higher rate of hospital admissions [relative rate (RR) = 1.04; p-value = 0.0035] and hospital days (RR =1.02; p-value = 0.1198) in patients not belonging to a congregation, as compared with patients belonging to a spiritual congregation.

Conclusions: Our analysis shows that belonging to a religious congregation is associated with lower hospitalization rates. Being part of a congregation may increase the patient's exposure to a community environment, resulting in better selfcare. Further investigation is warranted to elucidate whether spirituality/community environment affects dialysis patients' outcomes.

Mental Health and Perspectives on Death in Patients with CKD and Their Family Caregivers: A Prospective Study

Beatriz D. Pereira, Filomena M. Kirchmaier, Neimar D. Fernandes, Natalia M. Fernandes. *Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil*.

Background: The treatment of chronic kidney disease (CKD) generates overload in the health of patients and caregivers. Objective: To assess the physical and mental health and perspectives about the death of patients and their family caregivers.

Methods: Prospective cohort study in a four-year follow-up. Evaluation by questionnaires (Socio-economic, Short Form-36, ILSS (Inventory of Lipp Stress Symptoms), HADS (Hospital Anxiety and Depression Scale), SSPS (Social Suppot Perception Scale), Fatigue Pictogram and Brief Perspective on Death Scales). Analysis performed in SPSS 17.0.

Results: At the initial time 21 patients and 21 caregivers participated, in the second evaluation 14 patients and 21 caregivers. Patients had a mean age of 57.28 years (± 16.29). The caregivers had a mean age of 55.35 years (± 15.61). Over time, levels of anxiety and depression tend to decline in patients ($p = 0.028$) and caregivers ($p = 0.017$). In patients the stress level tended to decline ($p = 0.082$) including the psychological symptoms of stress ($p = 0.001$). It should be emphasized that initially there is a difference in the evaluation of psychological symptoms of stress among patients and caregivers ($p = 0.071$), at which time the lowest Functional Capacity in the patient ($p = 0.010$) is also observed. Patients tend to be more physically limited ($p = 0.013$) with an increase in the large physical domain ($p = 0.005$) and increase social aspects over time ($p = 0.080$). As for caregivers, they tended to increase vitality ($p = 0.093$), as well as to increase levels of emotional social support ($p = 0.087$) together with a decrease in physical stress symptoms ($p = 0.051$). Regarding beliefs about death, most interviewees presented the death perspective as unknown (27.90 ± 5.49), followed by the prospect of post-death reward (27.48 ± 7.87) and death as natural phenomenon (22.38 ± 4.05). It is observed that the belief about death as a natural phenomenon is less frequent among patients (21.00) when compared to caregivers. There was no impact of the psychological variables of patients and caregivers at the beginning of follow-up on mortality.

Conclusions: Caregiver overload is remarkable. Because it is a disease with high mortality, it is fundamental to approach beliefs about death in patients and family caregivers.

PUB108

Adductome of Serum Albumin from Hemodialysis Patients: An Exploratory Study

Nans Florens,[1,3] Frédéric Delolme,[2] Laurent Juillard.[3,1] *[1]Hospices Civils de Lyon, Lyon, France; [2]CNRS, Lyon, France; [3]University of Lyon, Lyon, France*.

Background: Chronic kidney disease (CKD) is associated with an increased cardiovascular (CV) morbidity/mortality and post-translational modifications (PTM) of proteins could participate to this burden. PTM of serum albumin (SA) and especially carbamoylation have been linked with an increase CV mortality among HD patients. We aimed to describe the adductome of SA from hemodialysis patients.

Methods: Plasma of 3 hemodialysis and 1 healthy control patients were analyzed using an nano-RSLC (high performance liquid chromatography) coupled on line with a Q-Orbitrap mass spectrometer. Oxidation, acetylation, carbonylation (with 4-HNE), carbamoylation, guanidinylation, chlorination, nitration and nitrosylation were set as potiential mass excesses on histidine (H), lysine (K) and tyrosine (Y) of SA.

Results: Among 102 post-translational modifications found on HD SA or control SA, 49 were only found onto peptides of SA from HD patients. The main specific PTM were glycation (27%), carbamylation (24%), carbonylation by 4-HNE (14%), nitrosylation (14%), nitration (10%) and guanidylation (10%) while chlorination was not found. These PTM were located in all the domains of SA and especially hit lysines (K), histidines (H) and tyrosine (Y) from domain I of SA. Y150 and K199, two main amino-acids from Sudlow site I (warfarine biding site) were found to be modified in HD SA only.

Conclusions: Serum albumin from HD patients presented several unique post-translational modifications of their proteins compared to control. As key-amino-acids were found adductable, PTM of SA could contribute the dysfunction of SA in HD patients. Further analysis should be conducted to investigate the role of such PTM in the key functions of SA.

PUB109

Comparison of Cognitive Impairment by Montreal Cognitive Assessment (MoCA) with Sarcopenia in Hemodialysis Patients

Heeryong Lee,[1] Jeongmyung Ahn,[1] Dong Ryeol Lee,[1] Mi young Jeon,[1] Hongmin Park.[2] *[1]Maryknoll medical center, Busan, Republic of Korea; [2]Hallym university medical center, Seoul, Republic of Korea*.

Background: Sarcopenia has been implicated in the increased risk for cognitive impairment. Hemodialysis patients are at increased risk for sarcopenia. In this cross-sectional study, we investigated the relationship of sarcopenia with cognitive impairment in hemodialysis patients.

Methods: Total 118 hemodialysis patients, 64 men and 54 women, aged 40 years or older were included in the study. The Montreal cognitive assessment (MoCA) was used to assess cognitive performance. The MoCA consists of seven separate items (visuospatial/executive, naming, attention, language, abstraction, delayed recall, orientation).

Demographics, body composition, and history of cardiovascular diseases were assessed as covariates. The cut-off of the MoCA score of the diagnosis of cognitive impairment was 22 points. The European Working Group on Sarcopenia in Older People (EWGOP) diagnostic criteria were applied to diagnose sarcopenia. The muscle mass was measured using Bioimpedance analysis and muscle strength was measured using handgrip strength.

Results: Of the patients included, 55 (women 36.4 %) were diagnosed with sarcopenia (46.6 %). The incidence of sarcopenia was higher in older patients (67.0 vs 70.0, p=0.046), but there was no difference in other variables. There was significant difference in the cognitive impairment ratio according to the presence or absence of sarcopenia (31 (56.3%) vs 28 (44.4%), p=0.046). Odd ratio (OR) and 95% confidence interval (95% CI) of cognitive impairment was calculated sarcopenia status. Compared to non-sarcopenic, sarcopenic hemodialysis patients had the ORs of 1.09 (95% CI of 1.05-1.15, p=0.030) for cognitive impairment.

Conclusions: Sarcopenia was significantly associated with cognitive impairment in hemodialysis patients. Cognitive impairment reduces the quality of life of hemodialysis patients. Therefore, it is important to prevent sarcopenia, which can cause cognitive impairment in hemodialysis patients.

PUB110

Prevalence and Risk Factors of Anemia in 1161 Patients on Maintenance Hemodialysis

Mengjun Liang, Ning Su, Xing Zhang, Zongpei Jiang. *The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*.

Background: Management of anemia is a remarkable issue in hemodialysis. Studies on prevalence and risk factors of anemia, especially the dialysis related factors in patients undergoing hemodialysis are limited.

Methods: A multi-center cohort study enrolled 1161 patients on maintenance hemodialysis from ten medical centers in South Guangdong, China from July 2016 to September 2016 for research on prevalence and risk factors of anemia.

Results: There were 1161 patients enrolled in the cross-sectional study, among whom, 250 patients presented with anemia (Hb<90g/L), with the rate of 21.5%; 524 patients presented with hemoglobin concentration of 100-120g/L, with the rate of 45.1%. Comparing to the normal hemoglobin group (NHb group, 110≤Hb<130g/L), patients in anemia group presented with shorter duration of dialysis (26(10,53)months vs. 35(16,68) months in NHb group, p=0.003), less use of arteriovenous fistulas as dialysis access, less use of low molecular heparin for anticoagulation, fewer times of hemodiafiltration and hemoperfusion therapy, with the rates of 78%, 82%, 39.2% and 9.2% (vs. 89.2%, 91.6%, 57.3%, 16.6% in NHb group, p<0.001, 0.003, <0.001, 0.020), respectively. And they showed lower serum creatinine (933.2±291.3μmol/L vs. 1065.1±308.5μmol/L in NHb group, p<0.001), albumin (35.39±4.89g/L vs. 38.62±3.96g/L in NHb group, p<0.001), triglyceride (1.30±0.86mmol/L vs. 1.79±1.72mmol/L in NHb group, p<0.001), calcium level (2.10±0.26mmol/L vs. 2.19±0.29mmol/L in NHb group, p<0.001). Adjusting Logistic regression analysis indicated that frequency of dialysis ≤twice weekly (OR=1.721, 95%CI 1.201-2.466, p=0.003), use of unfractionated heparin for anticoagulation (OR=1.822, 95% CI 1.104-3.006, p=0.019) and hypoalbuminemia (OR=2.112, 95% CI 1.463-3.049, p<0.001) were independent risk factors of anemia in hemodialysis patients.

Conclusions: 21.5% patients on hemodialysis in South Guangdong presented with anemia (Hb<90g/L); 45.1% patients presented with hemoglobin concentration of 100-120g/L. The risk factors of anemia contained dialysis ≤twice weekly, use of unfractionated heparin for anticoagulation and hypoalbuminemia.

PUB111

Behavior of High-Sensitivity Cardiac Troponin I Levels in Asymptomatic Hemodialysis Patients

Germán Ortiz,[1] Ricardo Correa-Rotter,[2] Olynka Vega,[3] Mauricio Arvizu-Hernandez.[1] Institution: Department of Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico *[1]Instituto Nacional de Ciencias Medicas y Nutricion, Mexico, Mexico; [2]Institutor Nacional de la Nutricion, Mexico City, Mexico; [3]National Institute of Medical Sciences, Mexico, Mexico*.

Background: Troponins are biomarkers of choice for the diagnosis of myocardial injury. The interpretation of high-sensitivity troponin I levels in the context of hemodialysis (HD) patients is not clear, and there is no reported evidence of its behavior during HD treatment. The objective of the study was to explore kinetics of the hsTnI levels in HD patients.

Methods: Prospective cohort of 33 prevalent asymptomatic HD patients. Venous blood samples were taken to measure the Troponin I levels, during 5 different time periods, to evaluate the kinetics of this biomarker during HD: before the start HD (T0), at 2 hours after starting HD (T1), 60 min before the end (T2), 1 hour after disconnection (T3), and the last sample at the start of the next HD session (T4). The Troponin I levels are expressed in median with minimum and maximum. Non-parametric statistics were used.

Results: The mean age of the population was 41.5 years, 60.6% were female, 36.3% had diabetes, 72.2% systemic arterial hypertension, dialysis vintage was 25.6 months, mean Kt/ V was 1.65, and the average residual urinary volume was 580 ml. The median TnI levels were: T0: 7.4 ng/L (1.3-62.4), T1: 7.1 ng/L (1.2-64.1), T2: 7.2 ng/L (1.6-69.3), T3: 5.9 ng/L (1.6-59.5), and T4: 6.7 ng/L (1.3-63.2). Women had significantly lower TnI levels than men (p=0.03) in all sample times. Eighteen patients had history of cardiovascular disease (CVD), in them all the determinations were higher than in patients who had no history of CVD (p:0.009). Five patients (15.2%) had TnI levels grater than the normal range (16 ng/L), 80% with history of CVD.

Conclusions: The measurements of hsTnI levels during the HD remained stable with slight decrease in the different time tests, which suggest that the troponin I is not dialyzable due to its molecular weight. Troponin I levels were higher than the general population (16 ng/ml) in 15% of the cases. Patients with a history of CVD had higher levels of hsTnI in all measurements. The analysis of Echocardiographic changes and their relation to changes in troponins is still pending in order to have a better correlation of the biomarker with the dynamics of the heart.

F (0), M (1)	Age	T0	T1	T2	T3	T4	History of Cardiovascular Disease

PUB112

More Frequent In-Center Dialysis Associated with Decreased Hospitalization Length of Stay

Maggie Meier, Lalit Kalvala, Pablo D. Dayer. *St. Luke's hospital, Chesterfield, MO*.

Background: According to the United States Renal Data System (USRDS) as of 2017, ESRD patients on average are admitted to the hospital nearly twice a year and about 35% ESRD discharged have a readmission within 30 days. Approximately 33% total Medicare expenditures for dialysis patients are from hospitalizations, representing a significant financial burden. In 2014, Nxstage Dialysis Center in St. Louis, MO started doing more frequent in-center hemodialysis. We investigated the effect more frequent in-center hemodialysis on our patient's hospital days per year.

Methods: We conducted a retrospective study of adult patients undergoing more frequent hemodialysis at Nxstage Dialysis Center in St. Louis, MO between July 2014-May 2019. The data was collected via Clarity EMR.

Results: Between July 2014 and May 2019, a total of 14 patients were treated with more frequent hemodialysis. Of the 14 patients, 11 patients were hospitalized. In 2016, the hospital readmission rate was 16%. [Figure 1]

Conclusions: We found our patient population with more frequent in-center hemodialysis had clearly lower hospital days per patient year and readmission rates when compared with the national average as reported by USRDS. In 2016, our average hospital day per patient year was 6.41 days compared to 11.3 days. The 30-day readmission rate for hemodialysis patients in 2016 was 37% versus our more frequent in-center rate of 16%. One limitation of our study was our small sample size. However, more frequent in-center hemodialysis was associated with a decreased length of stay and readmission rates.

PUB113

Hepatitis B Virus (HBV) Conversion in a Patient with HBV Antibodies, CKD, and HIV

Rachael DiRienzo-Lawless,[1] Minna Park,[2] Diane Morris,[1] Gail N. Frumkin,[3] Migdalia Barekzei,[5] Barbara A. Casazza,[4] Jeffrey I. Silberzweig.[1] *[1]The Rogosin Institute, New York, NY; [2]Rogosin institute, Woodside, NY; [3]Frumkin Nephrology Associates, Forest Hills, NY; [4]Rogosin Institute Queens Dialysis Center, Woodside, NY; [5]Rogosin Institute Queens, Woodside, NY*.

Introduction: Hepatitis B serologies may be difficult to interpret in patients with CKD and HIV. Assumptions about serologies in the general population may not apply to patients with CKD especially those with concurrent HIV infection.

Case Description: A 59-year-old man became infected with HIV in 1983 then developed HIVAN and CKD. He began a course of maintenance hemodialysis in 2005. He was variably compliant with antiretroviral therapy; his HIV viral load was 48 IU/mL in February 2019. His serologies at that time demonstrated no hepatitis B surface antigens (HBsAg) or core antibodies (HBcAb); he had antibodies to hepatitis B surface antigen (HBsAb). His most recent hepatitis B (HBV) vaccination booster was in 2008. His last admitted IV drug use was in 2017 and he denied sexual activity since 2009.

He was hospitalized on October 3, 2018 because of hematemesis. He received transfusion of one unit of platelets which were leukocyte-reduced and irradiated; he was intubated and underwent bronchoscopy but required no red blood cell transfusions. Over the next two months, he was hospitalized twice for endocarditis and once for a dental procedure but he received no transfusions. Routine testing on April 2, 2019 revealed the presence of HBsAg, HBsAb and HBeAb but no HBcAb. Ten days later, the HBsAg result was negative; HBsAb and HBeAg were positive; HBcAb and HBeAb were negative; his HBV viral load was 1149 IU/ml Three weeks later, his antigen and antibody results were unchanged; HBV viral load decreased to 211 IU/mL.

Discussion: This case points out the difficulty in identifying new HBV infection in patients with HIV infection and CKD. In this case, the source of exposure is unclear. The only documented opportunity for exposure occurred during a hospital admission six months prior to detectable HBsAg serologies. The only documented transfusion was platelets which are not common carriers of viral infections. It also points out the difficulty in identifying the true virilogic status of such patients. Our patient has had HBsAb for almost 15 years so should not be susceptible to new infection yet serologies indicate a change in his antigen status and the presence of viral DNA in his blood. The role of his HIV infection is unclear as is its influence on his hepatitis serologies.

PUB114

Prevalence of Metabolic and Cardiometabolic Syndrome in Patients on Hemodialysis Program

Juan C. Trimino,[1] L. M. Perez-Navarro,[2] Gloria G. Garcia Villalobos,[1] Elba O. Medina,[2] Eduardo Guerrero,[1] Maria F. Garcia-Guevara,[1] Rafael Valdez-Ortiz.[1] *[1]Hospital General de Mexico, Mexico, Mexico; [2]Hospital General de México Dr. Eduardo Liceaga, México, Mexico.*

Background: The prevalence of metabolic syndrome (MS) and cardiometabolic syndrome (CMS) in hemodialysis (HD) patients is not well studied. The aim of this study was establish the prevalence of those syndromes in patients on hemodialysis program.

Methods: Cross-sectional study done in the HD unit. The MS was defined by ATP3 and harmonization criteria. To determine CMS, we included hyperuricemia and high LDL-c. We used descriptive statistic, absolute and relatives frequencies.

Results: Sixty seven patients were evaluated with mean age 40.16±16.12 years. Thirty-six were women (54%). Mean of dry weight was 56.11±9.66 kg; BMI 22.16±3.2 kg/m^2; mean of systolic blood pressure 134.24±21.93 mmHg and diastolic of 76.04±15.24 mmHg. Cholesterol 139.39±31.9 mg/dL; triglycerides 139.69±74.14 mg/dL; LDL-c 70.02±28.11 mg/dL; HDL-c 41.48±9.18; glucose 112.85±41.34 mg/dL; albumin 3.95±0.6 g/dL; and uric acid (UA) of 6.98±2.15 mg/dL. Nine patients (13%) had underweight; 73% (49) normal weight and 13% (9) overweight and obesity (Figure 1A). With ATP3 criteria, we identified MS in 36% (24) of patients and with harmonization criteria 40.4% (27) (Figure 1B); CMS, was identified in 54% (36) patients (Figure 1C)

Conclusions: The prevalence of MS and CMS in HD patients was common; however, the diagnostic criteria for those syndromes should be validated in patients with ESRD. HD by itself, increases the risk of death 20-fold high than general population, the presence of MS concurrent with ESRD could be increasing substantially the risk for cardiovascular diseases.

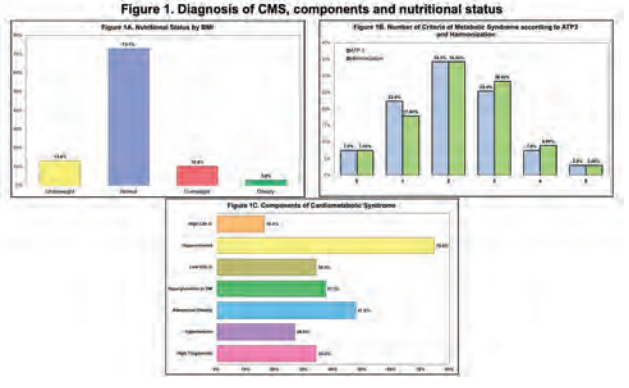

Figure 1. Diagnosis of CMS, components, and nutritional status

PUB115

Database Construction for Hemodialysis Patients in Sichuan Province

Daqing Hong,[1] Guisen Li,[2] Qiang He,[1] Li Wang.[1] *[1]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology of China, Chengdu, China; [2]Sichuan Provincial People's Hospital, Chengdu, China.*

Background: The incidence of hemodialysis(HD) is escalating dramatically in recent years, which brings about great challenge and also opportunities for Sichuan Quality Control Center of Renal Disease. In order to acquire general information, patient distribution, medical staff, medical equipments and the principle clinical indexes of HD patients, basing on previous experience in software designing, we initiated a provincial renal database, providing free HD software for the whole province.

Methods: The provincial database was a web-based database, which was set up with free connections to the HD software. In order to help dialysis center in Sichuan. We provided a free software (Jiangsu Huibang Information Technology Co., Ltd.), which could pack the data and upload to the provincial database. We also provide a connection protocol for other HD software that was already installed in HD facilities. The provincial database did not open manually input function in order to reduce the tasks for HD staff. The database was set up in May 2018. The free HD software was open for application from May 2018. Survey and visit interview was carried out to help setting up the database.

Results: There were 171 HD centers (around 1/2 of HD centers in Sichuan Province) completing the installation of free HD software by April 2019, among which, 77 HD centers begun to upload data to provincial database. There were 11583 HD patients in the database, accounting for about 1/3 of the HD patients in the whole province. The mean age was 55 years for the reported patients with a female proportion of 41.46%. The proportion of HD patients within treatment target for hemoglobin, serum calcium level, serum phosphorus level and serum albumin was 37%, 52% and 58% and 84% in year 2018.

Conclusions: A new strategy for setting up a provincial database from providing software in dialysis centers is an efficient way, which is not only good for dialysis quality control, but also is important for registry based studies.

Assessment of Quality of Life in Patients Undergoing Hemodialysis: A Single-Center Study

Amgad E. El Agroudy. *Medicine, Arabian Gulf University, Manama, Bahrain.*

Background: The purpose of this study was to investigate the relation between selected demographic and clinical characteristics and Quality of Life (QOL) scores in patients with end-stage renal disease (ESRD) who receive dialysis.

Methods: The study was conducted at one hemodialysis unit in Bahrain from May 2018 to July 2018. We used standard QOL Index score instrument Arabic form. This study included 100 patients (66 men and 34 women), aged 22-80 years treated with maintenance hemodialysis for 4-190 months. Inclusion criteria included dialysis for at least 3 months and age more than 18 years with no severe morbidities or psychological diseases.

Results: Following QOL scores were recorded: The health and functioning domain (64.8±15.3), the social and economic domain (65.6±14.1), the psychological/spiritual domain (74.9±14.3), and the family subscale domain (75.9±14.5). The male patients had none-statistically significantly reduced QOL and younger patients had better QOL scores. The QOL scores revealed a decreasing trend with decreasing level of education and they were higher among keep house patients. Also, the family subclass scores were significantly higher among the married patients. Correlations between the demographic characteristics and QOL scores showed that there was a significant negative correlation between family domain and educational level and marital status while there was a significant positive correlation between residence and psychological domain.

Conclusions: Age, gender, marital status, residence, ethnicity, education level, employment status, income, and duration on hemodialysis non-significantly affected one or more domains of QOL Index scores in such patients. Adequate management of these factors could influence patient outcomes.

PUB117

A New Approach to Assess Patient-Reported Outcomes of Patients with ESKD in an International Randomized Clinical Trial

Kathrin I. Fischer,[1] Peter J. Blankestijn,[2] Krister Cromm,[7] Bernard J. Canaud,[3] Claudia M. Barth,[9] Jorgen B. Hegbrant,[4] Giovanni F. Strippoli,[5] Andrew Davenport,[6] Matthias Rose.[8] CONVINCE Consortium *[1]Charité Universitaetsmedizin Berlin, Berlin, Germany; [2]University Medical Center, Utrecht, Netherlands; [3]FMC Deutschland GmbH, Bad Homburg, Germany; [4]Diaverum Renal Services Group, Lund, Sweden; [5]University of Bari, Bari, Italy; [6]Royal Free Hospital, London, United Kingdom; [7]Fresenius Medical Care, Bad Homburg, Germany; [8]Charité - Universitätsmedizin Berlin, Berlin, Germany; [9]BBraun Avitum AG, Melsungen, Germany*.

Background: The CONVINCE trial is an outcome-based RCT comparing high-dose hemodiafiltration (HDF) versus conventional high-flux hemodialysis (HD) in nine European countries. Primary objective is the comparison of all-cause mortality, one of the secondary objectives is the comparison of the experienced health status of patients. The aim of the CONVINCE Consortium was to develop a toolbox to assess the patient health status with a particular focus on constructs related to pathophysiological changes following implementation of the two dialysis modalities, which is applied in the CONVINCE trial.

Methods: We applied a state-of-the-art approach to develop the conceptual framework for the toolbox. Health aspects and constructs relevant for ESKD patients were identified in due consideration of international initiatives such as the SONG Initiative and ICHOM, a thorough literature review and interviews/focus groups with patients and experts. Psychometrically advanced instruments in combination with new measurement approaches were incorporated in the toolbox and applied in the CONVINCE trial.

Results: Out of 11 identified health domains and 41 ESKD-specific symptoms and health problems, we included 9 health domains and 20 symptoms/health problems in the toolbox according to the conceptual model of the CONVINCE trial. The compilation of the PRO assessments balanced comprehensiveness, respondent burden, and goal of measurement. Items to assess the proximal outcome *recovery time* and *treatment-related fatigue* were developed using state-of the art methods. Generic outcomes, e.g. physical function, depression and fatigue are measured by use of the psychometrically advanced tools of the PROMIS® initiative. Data collection started in Nov 2018 aiming to include 1,800 patients, which should be followed up for 24 moths including approx. 16 measurement points. First results of the baseline assessment will be presented.

Conclusions: The application of the toolbox using psychometrically advanced tools, instead of an off-the shelf PRO measure, facilitates the assessment according to a specific research objective. Thus, the impact of ESKD and treatment on patients can be accurately evaluated.

Scheduled vs. Emergency Dialysis in Undocumented Migrants with ESRD as Exemplified in France: Medical, Social, and Economic Issues

Alice Doreille,[4] Yosu Luque,[3] Laurent Mesnard,[2] Cedric Rafat.[1] *[1]Hôpital Tenon, AP-HP, PARIS 20, France; [2]INSERM UMR 1155, PARIS, France; [3]Assistance Publique - Hopitaux de Paris, Paris, France; [4]APHP, Paris, France*.

Background: Compared to scheduled chronic dialysis, emergency dialysis is associated with higher mortality, worsened quality of life, and additional medical expenses. Scheduled dialysis is struggling to emerge as the primary care approach for undocumented migrants with end-stage renal disease.

Methods: We analyzed the data of the undocumented migrants treated with dialysis in our intensive care unit (ICU) in Paris between April and May 2019

Results: A total of 18 undocumented migrants were managed in our nephrology ICU at Tenon Hospital in Paris, France. The majority (61 %) was not dialysed in their country of origin. Out of the 7 patients already dialysed, 71% had previously received dialysis treatment from another center in Europe. 40% of them left their country due to the laxk of kidney transplantation resources in their country of origin. 13 patients (72%) were scheduled for regular chronic dialysis treatment directly after their first admission in the ICU. Admission to chronic dialysis was delayed for three patients, with different waiting times before receiving scheduled dialysis: 11 days (resulting in 2 admissions for dialysis), 26 days (5 admissions for dialysis) and 77 days (11 admissions for dialysis). Two patients were never scheduled for chronic dialysis: one was in transit in France, the other was lost to follow up after being admitted in the ICU 6 times over 28 days. The total cost for these acute-care treatments was 242 770 USD, with a mean of 13 487 USD per patient, which is the equivalent of 45 dialysis per patient.

Conclusions: In France, despite that virtually all healthcare expenditure are funded by a national agencies system, there is a lack of standardization pertaining to the management of dialysis of undocumented migrants across the country. Each centre edicts its own policy based on physician's belief and local resources. In our center, despite an overall willingness for an expeditious scheduling of those patients in chronic dialysis, there remains a discrepancy in patients' care, mainly due to logistical issues. We believe that the benefits of scheduled chronic dialysis for undocumented migrants are threefold (for the patient, the physician and the society) thus legitimising it as the universal standard of care for this vulnerable population in our developed health resources countries.

PUB119

Neutrophil-to-Lymphocyte Ratio May Replace C-Reactive Protein in Predicting Prognosis of Patients on Maintenance Hemodialysis: A Longitudinal Study

Yoni Balboul,[2] Ada Azar,[3] Shai Efrati,[1] Ilia Beberashvili.[1] *[1]Nephrology Division, Zerifin, Israel; [2]Sackler School of Medicine/ NY American Program, Tel Aviv, Israel; [3]Nutrition Department, Zerifin, Israel*.

Background: The Neutrophil - to - Lymphocyte ratio (NLR) is a readily available marker closely associated with survival in maintenance hemodialysis (MHD) patients. Our purpose was to examine the cross-sectional and longitudinal relationships between NLR and C-reactive protein (CRP) levels and consequent associations with adverse clinical outcomes in this population.

Methods: A retrospective, longitudinal cohort study was conducted using a clinical database which included 554 patients (mean age of 67.6±14.2; 34% women) in a single center receiving MHD from November 2007 to July 2018. NLR, CRP and nutritional parameters were recorded at 0, 6, 12, 18, 24, 30, and 36 months followed by 58 additional months of clinical observations.

Results: In a linear mixed effects model adjusted for baseline demographics and clinical parameters including white blood cell count, NLR was associated with CRP levels at any given time-point of longitudinal observation (linear estimate : 1.53 (95% CI: 0.11 to 2.95, P=0.04) regardless of baseline NLR (NLR x Time interactions were insignificant). Longitudinal changes in NLR were inversely associated with serum albumin, creatinine, triglycerides and hemoglobin changes over time. For each 1.0 unit increase in NLR over time, the fully-adjusted all–cause mortality hazard ratio using Cox models with the time-varying risk effect was 1.04 (95% CI: 1.01 to 1.07, P=0.006). However, when CRP was included in this model, the relationship was no longer significant.

Conclusions: Longitudinal changes in NLR appear to be reliable in detecting changes in CRP over time and in predicting of all-cause mortality risk in MHD patients.

PUB120

Incident Dialysis Patients in a Country with High Prevalence of CKD

Rita Veríssimo, Rita Calça, Luís Leite de sousa, Eunice L. Cacheira, Ana C. Mateus, Patricia Q. Branco, Maria augusta C. Gaspar, Domingos S. Machado. *Centro Hospitalar Lisboa Ocidental, Hospital de Santa Cruz, Lisboa, Portugal*.

Background: In our country with a population around 10,000,000 inhabitants, by the end of 2018, 13,000 patients(pts) were treated with dialysis, 2607 of which incident pts. The majority started hemodialysis(HD), only 8,7% peritoneal dialysis(PD). Our aim was to compare characteristics and outcomes of both modalities in a single-center hospital serving a population of around 450,000 inhabitants.

Methods: A retrospective cohort study with 652 incident pts on renal replacement therapy between January 2013 and December 2017 in a single-center with follow-up until December 2018. Charlson Comorbidity Index(CCI) was calculated and pts divided into modality. Kaplan-Meier survival curves were estimated for subgroups defined by age (<65 *vs* >65) and a Cox proportional hazards regression used to estimate relative mortality risk, adjusting for CCI.

Results: 556(85,2%) started HD and 96(14,8%) PD. On HD 61.2%(n=340) were male *vs* 69.8%(n= 67) on PD; median(IQR) age 73(64-81) *vs* 57.5(41-70), 27% *vs*69.8% were <65 and 30.6% *vs*5.2% <80. Comorbidities concerned, 84.9%(n=472) *vs* 92.7%(n=89) had hypertension, 48.9%(n=272)*vs*37.5%(n=36) diabetes. The median(IQR) CCI was 8(6-10) *vs* 5(3-8),(p<0,001). Younger pts had 1-year survival rate of 89.1% on HD *vs*95.2% on PD; 3-year 77.9% *vs*86.6% and 5-year 76.2% *vs*74.9%. In older pts 1-year 70.5% *vs*86.2%; 3-year 47.1% *vs*74.3% and 5-year 34.6% *vs*74.3%. A Kaplan-Meier analysis showed a better survival for PD(*p*=0.004) in older pts while no difference was found in younger pts (*p*= 0.096). In a multivariable analysis, we found that pts being educated about dialysis was predictor of choosing PD(p<0.001). A multivariate analysis showed that CCI(OR 4,16, CI 95% 1,96-8,82; p<0,001) and HD(OR 2,87, CI 95% 1,35-6,10; p= 0,006) were independent predictors of mortality in older pts, while in younger pts the modality had no influence but CCI was an independent predictor of mortality(OR 5,19, CI 95% 2,51-10,72; p<0,001).

Conclusions: A higher percentage of PD incident pts compared to the national average was found, and in pts eligible for both modalities, previous education about RRT modalities was a predictor of choosing DP. Our cohort shows better survival for PD compared to HD in older pts and that higher CCI is associated with worst outcomes regardless of age.

PUB121

Assessment of Primary Cognitive Deterioration in Patients with Chronic Renal Disease in Hemodialysis

Henry J. Gonzalez Torres,[1] Luis A. Castillo,[2] Eddie Castro-Ahumada,[1] Stefani Chartouni-Narváez,[1] Lina M. Rodriguez-Rada,[1] Kelly Fernandez-Merlano,[1] Sandra Y. Hernandez-Agudelo,[1] Maria D. Velez-Verbel,[4] Gustavo Aroca Martinez.[3] *[1]Universidad Simon Bolivar, Barranquilla, Colombia; [2]Fresenius Medical Care, Santa Marta, Colombia; [3]Universidad Simon Bolivar / Clinica de la Costa, Barranquilla, Colombia; [4]Universidad Libre Secc. Barranquilla, Puerto Colombia, Colombia*.

Background: Patients with Chronic Kidney Disease (CKD) often present a variety of disorders in the Central and Peripheral Nervous System that have been widely described in the medical literature. However, its approach is only carried out when the signs

and symptoms that are evident, this causes that the intervention is only palliative. The Objective was to establish the degree of primary cognitive deterioration (PCD) in patients with chronic kidney disease on dialysis therapy.

Methods: A multicenter (3 IPS), cross-sectional study was conducted. The patients were given the Montreal Cognitive Assessment (MoCA) questionnaire with prior informed consent, and the latest paraclinical data (Hemoglobin, Sodium, BUN, Serum Creatinine), KtV, Date of the first dialysis were recorded. base disease and comorbidities. To establish a possible structure of dependence between the FAD and the Factors enunciated, the correlation coefficient was calculated, for which a generalized multivariate linear model (GML-M) was used. This was constructed using the own values of each Factor, through the technique of adding Factors.

Results: A total of 62 patients on dialysis were evaluated. 58.5% were men. The overall average age was 53 ± 16 years (women: 47 ± 16 years | men: 58 ± 15 years). The time on dialysis was 7.5 ± 5 years (women: 7 ± 5 years | men: 8 ± 5 years). Associated comorbidities were Hypertension (68%), Diabetes Mellitus (32%), Urinary Tract Infections (3%). Only two patients (3.5%) obtained not to classify them with primary cognitive impairment. A correlation of mixed effect between Age and Time on dialysis, however the value of R^2 is moderately weak (31.2%) although the significance value indicates that these are very significant (p-value <0.05), these results indicate the need to include the dose values in the model of dialysis as well as laboratory parameters, as well as co-morbidities and other relevant clinical data.

Conclusions: According to the Coef. Determination and Correlation is determined by the ratio of serum creatinine, phosphorus and total cholesterol, being a multivalued model dependent on the inverse interaction with the patient's age.

PUB122

Allergic Reactions Associated with Bicarbonate Bath During Hemodialysis

Syed Rizwan A. Bokhari,[1] Raquel M. Rosen,[1] Badamkhand Baatarkhuu,[1] William W. LeCates.[2] *[1]Bassett Health Care, Cooperstown, NY; [2]Bassett Healthcare Nephrology, Cooperstown, NY.*

Introduction: Allergic reactions during hemodialysis (HD) treatment have been well explained in the past. Most common causative factors implicated are secondary to dialyzers with synthetic or cellulose membranes. Other agents like latex, intravenous iron supplements, heparin and formaldehyde have also been reported. We report a case of end stage renal disease (ESRD) patient on HD with severe allergic reaction secondary to bicarbonate bath.

Case Description: We report a case of 49-year old gentleman with ESRD on HD secondary to diabetes and Hypertension, on HD for the last 5 years. Patient has been complaining of allergic reactions including rash and hives within half an hour to one hour after initiation of hemodialysis. His HD session was terminated earlier on few occasions in the setting of hypotension, contributed by anaphylactic reaction, in addition to hemodynamic changes. He was thoroughly investigated for any possible cause of allergic reaction and extreme caution was used in terms of changing the dialyzer types, latex exposure and any commonly implicated solution or medication, with no success. He was prescribed anti allergic medications and emollients with limited response. Allergic reactions usually subsided soon after HD session. After close observation and exclusion of any possible causative factor, he was found to be allergic to standard powdered bicarbonate cartridge by Gambro. He was switched to liquid bicarbonate solution and his allergic reaction completely resolved on following HD sessions.

Discussion: Allergic reactions due to variety of substances have been reported during HD sessions. As per literature review, the allergic reactions secondary to bicarbonate bath have not been reported in the past. Nephrologists and dialysis center staff should be vigilant to identify this rare cause of anaphylactic reaction.

PUB123

Impact of Cinacalcet on Secondary Hyperparathyroidism (SHPTH)

Jeffrey I. Silberzweig,[1,2] Thomas Parker,[1] Daniel M. Levine,[1] Yao Liu.[1] The Governing Body of The Rogosin Institute *[1]The Rogosin Institute, New York, NY; [2]Nephrology & Hypertension, Weill Cornell Medicine, New York, NY.*

Background: SHPTH is caused by reduced phosphate (P) excretion and hydroxylation of vitamin D (vitD) leading to decreased calcium (Ca) levels and stimulation of parathyroid hormone (PTH) secretion. Clinical findings include decreased bone mineralization and increased rates fractures, cardiovascular disease and mortality. SHPTH is treated with P binders, vitD analgogues (analogues) and calcimimetics (CM) like cinacalcet which suppresses PTH secretion via the calcium-sensing receptor. CM were added to the prospecitve payment system in January 2018; analogue use increased while CM use decreased.

Methods: Our QAPI program monitors levels of Ca, P and PTH with a goal of maintaining >98.5% of patients with Ca 8.5-10.2 mg/dL, 57% with P 3.5-5.5 mg/dL and >90% with PTH 100-750 pg/mL. Here, we evaluate the cost and effectiveness of CM using an intention-to-treat approach.

Results: Results from the 4th quarter of 2017 (baseline) were compared to the 3rd quarter of 2018 and the 1st quarter of 2019 for 996 patients present at all three time points. Ca showed no significant change; there were statistically significant increases in P and PTH. (See figures.)

Conclusions: CMs have not improved management of SHPTH in our real world analysis. Based on our average cinacalcet cost of $17.32 per treatment and the apparent lack of benefit, our analysis argues against use of cinacalcet for treatment of SHPTH.

Atypical Dialyzer Membrane Reaction: A Mask Behind the Curtain

Ebima C. Okundaye. *Nephrology, University of South Dakota Medical school, Rapid City, SD.*

Introduction: Prior to the advent of the polysulfone dialyzer membrane, dialyzer reaction was common with cellulose dialyzers and easily identified. In this report, we present a case of atypical dialyzer reaction manifesting as only difficulty in achieving ultrafiltration without eliciting the other classical dialyzer reaction symptoms. Our case is unique in the atypical pattern and feature of presentation of this dialyzer.

Case Description: A 56 yr old male with history of HTN, DM, and slowly progressive chronic kidney disease with nephrotic range proteinuria initiated on hemodialysis (HD) for acute renal failure with oliguria in setting of left foot cellulitis. Clinical examination reveals fluid overload with bilateral lung crepitations and 3 + bilateral pedal edema. His dialysis orders were Polysulphone high flux dialyzer F180 dialyzer. He had gradual increasing duration of HD from 2.5 hrs to 4 hrs on the third session with increasing blood. His Pre-Hemodialysis blood pressure (BP) was 140-160s systolic range. His BP meds were typically held pre-HD with last dose over 12 hrs pre HD. Patient repeatedly had

drops in his systolic BP to the 80s with symptoms of fatigue and dizziness requiring IVF boluses during dialysis. His post dialysis weight continue to be higher than his predialysis. Daily HD and increasing adjustment of blood flow as well low temp bath did not yield any changes. Dialyzer change on his 3rd session to F250 also did not make any difference. He did not describe any rash or fever with negative cultures and absence eosinophilia. Echocardiogram was normal. A suspected dialyzer reaction was elicited and dialyzer switched from the F series to the cellulose triacetate high flux. Patient on his 4th HD treatment and first with Ex 170 was able to tolerated HD well with no drop in BP and target UF of 2.3 L obtained successfully. Subsequent dialyses were uneventful despite advancement to the Ex 210 dialyzer use. **Outcome**-Patient's symptoms resolved after changing from the polysulphone series to a different one, a cellulose-based dialyzer membrane

Discussion: In this patient, the atypical pattern of presentation neither fit the classic type A nor Type B reaction. Episodic dialyzer reaction is rare at initiation in the absence of cardiac disease or pericardial tamponade. This case is atypical due to absence of these other causes of hypotension and resolution of the clinical symptoms with change of dialyzer membrane.

PUB125

Factors Associated with Achievement of a High Convective Volume Target on Post-Dilution Online Hemodiafiltration (HDF)

Ana Beatriz L. Barra,[1] Ana P. Silva,[1] Marcos Sandro F. Vasconcelos,[1] Frederico Ruzany,[1] Adrian M. Guinsburg,[1] Roberto Pecoits-Filho,[2] Jorge P. Strogoff-de-Matos.[3] *[1]Fresenius Medical Care, Rio de Janeiro, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Universidade Federal Fluminense, Niteroi, Brazil.*

Background: A higher convective volume (23 liters, 3x/week) has been associated with a lower risk of death in post-dilution online HDF. We aimed to identify factors associated with achieving a high weekly volume of convection

Methods: Retrospective analysis of all HDF patients at 13 dialysis units in Brazil in 2018. A convective volume of 69 L/week was considered the lowest adequate HDF dose.

Results: A total of 286 patients (67% men, 39% diabetics, 62±16 years-old, 33% with tunneled catheter, 43% on more frequent HDF [14% 4x/week, 29% on daily HDF] and 63% incident on HDF) underwent to 28,078 HDF sessions in the period. Weekly HDF time was 717±73 min (56.7% ≥720 min) and blood flow 347±45 mL/min. Weekly convective volume was 79.5 (IQR 69.0-87.6) L/week, with 75.7% reaching the target of 69 L/week. In the logistic regression model, having the target of 69 L/week as the dependent variable, female gender (P<0.0001), age (P=0.035), hemoglobin >12 g/dL (P<0.0001) and use of catheter (P<0.0001) were associated with the risk of not achieving the minimum dose, whereas blood flow ≥350 mL/min (P<0.0001), weekly HDF time ≥12 hours/week (P<0.0001) were independent factors positively associated with a high convective volume.

Conclusions: A high convective volume can be achieved by most of the unselected patients on HDF. The weekly HDF time is a modifiable variable that can be used to achieve the appropriate weekly convective volume.

PUB126

A Prospective Study on the Association Between Ultrafiltration Rate and Mortality in Hemodialysis Patients: The Effect Modification by Muscle Mass

Yuntac Lim,[2] Kyung Hoon Yang,[3] Yuji Lee.[1] *[1]Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon, Republic of Korea; [2]samsungchangwon hospital, Busan, Republic of Korea; [3]Samsung Changwon Hospital, Changwon, Republic of Korea.*

Background: The association between ultrafiltration rate (UFR) and mortality may be affected by muscle mass or volume status in maintenance hemodialysis (MHD) patients. However, there are no prospective data about those association in patients receiving MHD.

Methods: This was a prospective observational study on the patients (≥ 18 years old) who have been on MHD for at least three months and gave informed consent. A portable whole body bioimpedance spectroscopy device (BCM) was used for bioimpedance analysis measurement at baseline. Primary outcome was all-cause mortality.

Results: Among 169 patients, mean (SD) age was 62 ± 12 years and male were 59%. Mean (SD) UFR was 12.8 (11.1) mL/h/kg. Median (interquartile range, IQR) overhydration volume by BCM was 2.4 (1.4, 3.9) L. Median (IQR) lean tissue index (LTI) (calculated as lean tissue mass/height^2) was 12.4 (10.4, 14.6) kg/m^2. The median follow-up duration was 1.4 years. In an adjusted Cox regression analysis, greater mortality was associated with higher UFR. This association remained consistent even after adjusting for overhydration status. However, the association between UFR and mortality was modified by LTI ($P_{interaction}$=0.03); the association was only significant in patients with LTI of less than 12 kg/m^2.

Conclusions: Higher UFR was associated with increased all-cause mortality regardless of volume status in MHD patients. However, muscle mass may modify the association with higher UFR and increased mortality.

PUB127

Hospitalisation and Mortality in Hemodialysis Patients in India: A Single-Center Prospective Study

Prem P. Varma,[1] Geet Bajpai,[1] Elly Varma.[2] *[1]Nephrology, Venkateshwar Hospital, Delhi, India; [2]Banner University Medical Center, University of Arizona, Tucson, Tucson, AZ.*

Background: In India over 2 lakh new cases develop end stage kidney failure every year but only 10-20% are able to continue long term dialysis. USRDS 2014 hemodialysis (HD) data shows that average number of hospitalization was 1.7/patient/yr & duration of stay was 10.9 days. There is paucity of data on hospitalization & mortality in HD population from India. We prospectively studied the hospitalization & mortality in HD patients at our center.

Methods: All patients who came to our center for HD from Nov 2016 to May 2019 were the subjects of this study. Patients who had HD for less than a month or were on immunosuppressives or having underlying malignancy were excluded. Details of all the hospitalizations/ mortality were recorded & their relation with age, sex, underlying DM & CAD was studied. Analysis was done using SPSS 23.

Results: 395 patients came to our multi-specialty center for HD during the study period. Of these, 70 patients had HD for less than a month and were excluded; remaining 325 formed the study group. There were 201 males. Mean age of the study group was 56.86±13.98 y (range 18-84) & mean duration of follow up was 11.66±5.96 mo (range 1-31). Of these 325 patients, 40 received renal transplant, 46 died & 80 left for other centers after a mean follow up of 6.35±5.96 mo, 11.46±5.90 mo & 9.98±5.14 mo respectively. 198 (60.9%) of these 325 patients had 348 hospitalizations (mean 1.07±1.32 hospitalization/ patient). Total days of hospitalization were 1736 days (mean 8.77±10.03). The underlying reason for hospitalization was Infections (33%), Cardiopulmonary (31%), Vascular access related (19%), CNS complications (7%), & other causes were 10%. Hospitalization was significantly higher in those with advanced (age>60 years) (p=0.044). Presence of diabetes, gender & CAD status didn't show any significant association. 46 patients died after a mean follow up of 11.46±5.90 months. Mean age of this group was 61.45±13.29 years. Causes of death were sepsis (50%), CV events including SCD (39.1%), CVA in 6.5 % & miscellaneous causes in 4.34%. Mortality was significantly higher in those with advanced age(p=0.026) DM(p=0.026) & CAD (p=0.043).

Conclusions: Our follow up study of 11.46 months shows, hospitalization rate of 1.07/patient with duration of hospitalization 8.77 days. Infections were the leading cause of hospitalization & death. Advanced age, DM & CAD were associated with bad outcome.

PUB128

Risk Factors for Mortality in the Short- and Long-Term in Patients with Chronic Renal Disease After Renal Replacement Therapy

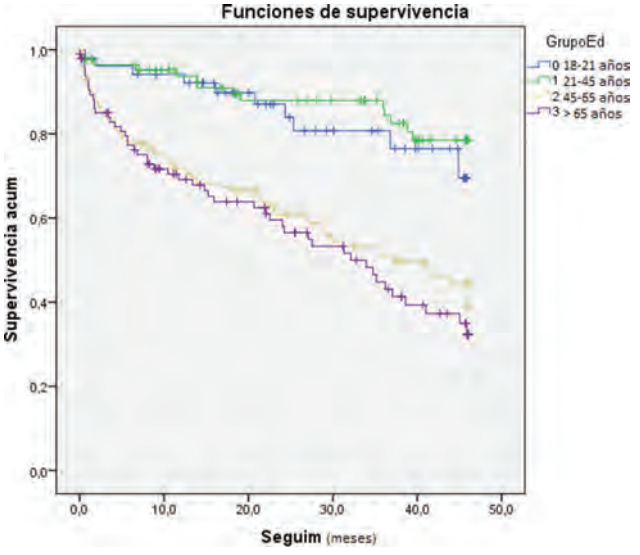
Juan O. Lluncor. *Universidad Peruana Cayetano Heredia, Lima, Peru.*

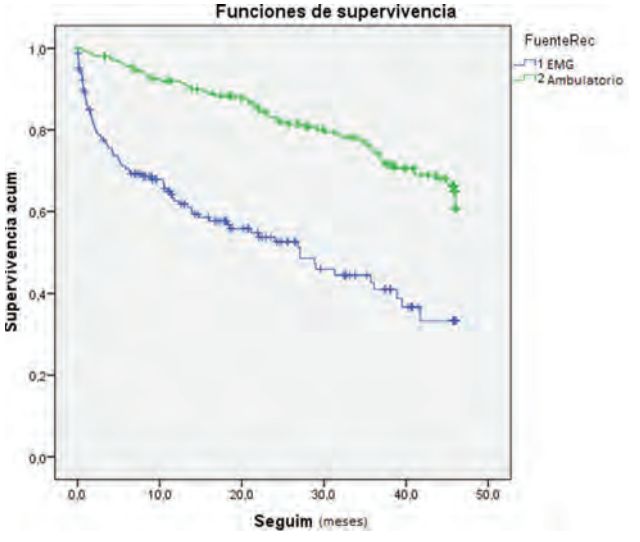
Background: Chronic Kidney Disease in Stage V (CKD5) and its need for Renal Replacement Therapy (RRT) has increased markedly in recent decades by the rise of chronic diseases and the opening of services to marginalized populations, generating relevant costs in health systems, the effect should be evaluated objectively to improve their efficiency. Objective: Evaluate the survival of patients with CKD5 in RRT from a population favored with a new financing system (SIS) in a General Hospital of MINSA, Lima-Peru, identifying the variables associated with poor prognosis.

Methods: Were studied patients benefit from the SIS with ERC5 incidents to the Emergency of the Hospital Cayetano Heredia (HCH) who entered TRR between September 2014 to December 2017 in whom survival was evaluated and analyzed factors associated with mortality. The evaluation was finalized in July 2018.

Results: 374 patients with CKD5 for RRT were studied, 169 were admitted for emergency and 205 on an outpatient basis. The variables found in this population were: age greater than 45 years (p = 0.000), female sex (p = 0.002) and admission to the program for emergency (p = 0.000).

Conclusions: Age (> 45 years), female sex and admission to the program for emergency were the conditions associated with higher mortality in patients benefiting from SIS to receive RRT.





PUB129

Prevalence of Obesity and Overweight in a Peripheral Dialysis Center and Its Association with Comorbidity Evaluated Through the Charlson Index

Eliana E. Olazo gutierrez, Javier Nieto. *Hospital General Universitario de Ciudad Real, Ciudad Real, Spain*.

Background: The obesity is accompanied by many comorbidities, it could be deduced that obese patients on hemodialysis (HD) follow the same pattern and therefore would be more prone to present cardiovascular complications. However, this hypothesis has not been proven yet. In fact, several studies have observed an inverse relationship between the Body Mass Index (BMI) and mortality, phenomenon called "paradoxical obesity. Objectives: To evaluate prevalence of obesity / overweight in a HD center and the body composition of HD patients by bioimpedance spectroscopy (BCM, Fresenius Medical Care), obtaining the fat tissue index (FTI) and the lean tissue index (LTI). Study the presence of different pathologies using the Charlson Comorbidity Index (CCI) and evaluate the relationship between the different diseases that make it up with obesity / overweight.

Methods: Cross-sectional descriptive study in January 2017 that included 73 patients. The BMI according to the WHO (World Health Organization) was analyzed and grouped the patients according to the FTI in tertiles: FTI ≤ 13.00; FTI = 13.01-19.00; FTI≥19.01. All the pathologies that make up the CCI, renal diagnosis, laboratory values and clinical parameters of HD were recorded.

Results: The prevalence of obesity was 28.77% and overweight was 32.88%. When studying the BMI with the different pathologies that make up the CCI, it turned out that the overweight patients presented a significantly higher percentage of diabetes with organic damage (P = 0.047). On the other hand, when relating the FTI with pathologies of the CCI, it was found that the percentage of patients with Congestive Heart Failure (CHF) was significantly higher as the tertile of the FTI was higher (P = 0.020). When finding these percentage differences by pathology, an ROC curve analysis was performed. This analysis revealed the FTI as a predictor of Congestive Heart Failure (AUC = 0.689, P = 0.028, CI 95% = 0.527-0.852), not being a predictor of this comorbidity the BMI (AUC = 0.645, P = 0.093, CI 95% = 0.455-0.806).

Conclusions: Over 60% of patients in the analyzed cohort were overweight or obese. Only diabetes with organic damage was associated with overweight, while Congestive Heart Failure with a higher FTI. Our results suggest that FTI determined by BCM can help predict better comorbidities than BMI, especially CHF

PUB130

Verification of Nutrition Maintaining Effects by Using Anti-Thrombotic PMMA Membrane (VENUS STUDY)

Ikuto Masakane. VENUS study group *Honcho-Yabuki Clinic, Yamagata, Japan*.

Background: Nutritional status and QOL are the most important indicators for the prognosis of dialysis patients, and the dialysis prescription which enables to maintain the nutritional status and improve QOL should be needed. Polymethylmethacrylate (PMMA) is a synthetic dialysis membrane with protein adsorptive property and was reported that it had beneficial effects on nutritional status and QOL of dialysis patients. In VENOUS study the beneficial effects of newly introduced anti-thrombotic PMMA (NF membrane) on the nutritional status and QOL of older dialysis patients were evaluated.

Methods: This study is a randomized control trial which compared PMMA with polysulfone (PS) on the patients older than 70 years old. The 54 registered patients were randomly assigned to the NF group (28 patients) or PS group (26 patients) and followed for 12 months. The nutritional status was considered by Malnutrition Inflammation Score (MIS) as a primary outcome, normalized protein catabolic rate (nPCR), and creatinine generation rate (%CGR) as a secondary outcome every 3 months. Patients symptoms as a QOL indicator were also monitored as a secondary outcome every 3 months on arthralgia, skin itchiness, irritable sense, fatigue, headache, dialysis related hypotension, leg cramps, and post-dialytic bed-free time.

Results: 11 patients in the NF group and 10 patients in the PS group were dropped out from the study. Finally, 15 patients in NF and 14patients terminated the study, however, 2 patients with the data deficit in each group were excluded. The MIS was increased at 6-, 9-month but there was no difference between 0-month and 12-month in NF group. The MIS was also increased at 9-month but was no difference between 0-month and 12-month in PS group. There are no remarkable changes were observed in nPCR, %CGR in both groups. Patients' symptoms were not different between NF group and PS group through the study period. However, the symptom total score was gradually reduced in NF group, but that in the PS group did not change.

Conclusions: In the current study we did not admit the advantages of new PMMA compared with PS on the MIS as a primary outcome. However, we could clarify the beneficial effects on the parameters of QOL only in NF group and it suggested that new PMMA membrane could ameliorate QOL of dialysis patients.

PUB131

User Satisfaction and Cost Savings of a Novel Hemodialysis System in an ICU Setting

Mohammed F. Rahman,[1] Morgan Jonathan,[2] Harold M. Szerlip.[2] [1]*Nephrology, Baylor University Medical Center, Dallas, TX;* [2]*Baylor University Medical Center, Dallas, TX*.

Background: AKI requiring RRT is increasing in frequency in the ICU. Because of hemodynamic instability the treatment of choice is either CRRT or PIRRT. The former is relatively expensive due to the cost of fluids and the latter technically difficult for non-dialysis nurses because it uses a dialysis machine. Outset Medical's Tablo is an all-in- one system with a user-friendly touch screen interface that requires minimal training and produces AAMI quality dialysate using tap water and conventional dialysate concentrate. The purpose of this pilot project was to assess whether the Tablo system was both easy to use and provided cost savings.

Methods: 17 ICU patients with AKI requiring renal replacement were treated for 6-12 hours using the Tablo system. Tablo was set up and run by the ICU nurse. Dialysis prescription, duration and ultrafiltration rate were left to the discretion of the attending nephrologist. Cost savings were compared with CRRT, nursing satisfaction was assessed by a Likert scale questionnaire.

Results: Compared to NxStage the majority of nurses found it easier to use (average score 4.8/5); most nurses felt comfortable providing treatment with this system after completion of training (average score 4.3/5) and they were also satisfied with Tablo as a treatment option (average score 4.8/5). Several participants also reported that the system was easy to transport and required less space. Comparing a 12-hour Tablo treatment to a 24-hour CRRT treatment using NxStage fluid at an effluent rate of 25 ml/kg/h would generate a cost savings of $303/day.

Conclusions: In our study, we found the Tablo system to be a viable alternative to CRRT. The nursing staff were easy to train and found this system straightforward to operate. In addition, because of its compact size Tablo took up less space, which is advantageous in the limited ICU environment. Importantly, Tablo when compared to CRRT led to significant cost savings at this facility.

Funding: Commercial Support - Outset medical supplied the Tablo machines.

PUB132

Extracorporeal Therapy in Cefepime-Related Neurotoxicity

Umair S. Ahmed. *Western Maryland Health System, Cumberland, MD.*

Introduction: Cefepime is a fourth generation cephalosporin with broad spectrum antimicrobial activity and is primarily excreted by the kidneys. It may rarely be associated with neurological side effects.

Case Description: Patient is a 61 years old male, with a history of end stage renal disease and on peritoneal dialysis, who was admitted with a 5 day history of lightheadedness. Work up showed orthostatic hypotension. Patient developed a low grade fever, non-productive cough and shortness of breath during his stay. A CT scan of the chest was suggestive of bilateral pneumonia. Patient was started on intravenous Cefepime 2 grams every 8 hours. Approximately 36 hours later, patient was noted to be confused. On reevaluation, patient was noted to be hemodynamically stable and not hypoxic. Detailed neurological exam showed that patient was alert but not oriented to his surroundings. No focal deficits were noted. A repeat infectious workup was unremarkable. The degree of azotemia was stable. CT brain, electrocardiogram and arterial blood gas were unremarkable. Due to clinical concern for Cefepime neurotoxicity, IV Cefepime was discontinued. Cefepime levels were not checked as they are not available at our hospital. Given the low clearance of Cefepime with peritoneal dialysis, patient had a temporary hemodialysis catheter placed and was started on hemodialysis. He underwent 2 sessions of hemodialysis in 2 days, 4.5 hours each using a Fresinius Optiflux F200 dialyzer with a blood and dialysate flow rates of 450 ml/minute and 750 ml/minute respectively. There was a complete resolution of confusion after 2 sessions of hemodialysis.

Discussion: The primary route of elimination of Cefepime is renal, with more than 80% of the drug excreted unchanged in patients with normal renal function. Cefepime-related neurotoxicity occurs mostly with incorrect dosing especially in the setting of renal dysfunction as the half life of the drug is increased from 2 hours to nearly 22 hours. However, it may also be seen in patients with appropriate dosing. Extracorporeal drug removal with dialysis may be needed to facilitate drug removal and improvement in neurological status. Peritoneal dialysis is less efficient at clearance of cefepime compared to hemodialysis, with clearance only 9% of that reported with hemodialysis.

PUB133

Can Metolazone Help Control Interdialytic Weight Gain and Serum Phosphorus Levels in Hemodialysis Patients with Residual Renal Output?

Martin Sedlacek. *Dartmouth-Hitchock Medical Center, Lebanon, NH.*

Background: Phosphorus is an important uremic toxin that is difficult to control in hemodialysis patients. Metolazone is a thiazide like diuretic that has been reported to increase urinary phosphate excretion through a carbonic anhydrase independent proximal tubular effect. Metolazone is frequently used in conjunction with furosemide to increase urine output in patients with advanced renal insufficiency from cardio renal syndrome, often as a last attempt to avoid repeated hospitalizations and dialysis, and is well tolerated in this population.

Methods: Here we summarize anecdotal clinical observations to see if the use of metolazone in conjunction with furosemide in hemodialysis patients with residual urine output might be beneficial to reduce high interdialytic weight gains and hyperphosphatemia.

Results: A medication and chart review reveals three ESRD patients with high interdialytic weight gains of >3-4 kg and a residual urine output of more than 500ml of urine a day who had metolazone 5mg daily added to furosemide treatment. All three patients had hyperphosphatemia in the 6.4-11mg/dl range. There was no effect on either interdialytic weight gain or serum phosphorus level and metolazone was stopped. A fourth patient had continued treatment with both metolazone and furosemide for several months since her renal transplant failed, and regardless, her dialysis treatments were complicated by constantly high serum phosphorus levels and high interdialytic weight gain.

Conclusions: In conclusion, these anecdotal observations suggests that the combination of a 5mg daily dose of metolazone with furosemide is no more effective to decrease interdialytic weight gain or decrease hyperphosphatemia in hemodialysis patients than furosemide alone.

PUB134

Kibow Multisite Hope Study Dialysis Randomized Clinical Trial Protocol: A Unique Double-Blind Placebo-Controlled Cross-Over Design Using Renadyl™ with Standard-Care Therapy (n=100, 5 Sites in the United States)

Natarajan Ranganathan,[1] Usha N. Vyas,[1] Pari Ranganathan,[1] Anthony Irvin,[1] Alan D. Weinberg.[2] *[1]Kibow Biotech, Inc., Newtown Square, PA; [2]Mount Sinai, Hackensack, NJ.*

Background: Hemo or peritoneal dialysis patients are fatigued after dialysis sessions, susceptible to infections, have poor quality of life due to the high blood levels of uremic toxins and, many are depressed. Outcomes like fatigue, pain, anxiety though major concerns and critically important to patients and clinicians may not be reported in clinical trials (Kid Int 2019; 95:1280-1283). The 2014 Standardized Outcomes in Nephrology (SONG) initiative established core outcome sets for nephrology trials (https://songinitiative.org/). An alternative regime to address some of these issues would benefit all dialysis patients. Renadyl™; a Pro/Prebiotic dietary supplement, is proven to reduce several uremic toxins in three pilot clinical trials with no reports of adverse outcomes. We propose to carry out large scale RCT to validate it as a Live Bio-Therapeutic (LBT) drug with needed IND and US FDA approval.

Methods: Six month RCT controlled cross over design in an outpatient setting. Renadyl™ will be orally given at 90 B CFU/day.

Results: Measured endpoints will be:1: Dialysis duration, Quality of Life (QOL). 2:Uremic metabolite panel, CBC, liver function test 3: Biomarkers including Indoles, p-Cresol, TMAO, KIM-1, NGAL, IL-6 and CRP.

Conclusions: This is the first-ever RCT proposed using Renadyl™ as a Live Bio-Therapeutic (LBT) drug for Dialysis patients. Being noninvasive the intervention avoids any possible infection. As a rare unconventional crossover design patients will be their own control for prudent data analysis. Secondly every patient gets the interventional product thus accelerating better patient recruitment. Significance of p-value alone does not help in the decision of the application of results to clinical care and its policy (Kid Int. 2019; 95:28-30). $P < 0.05$ and $P > 0.05$ can affect interpretation and lead to bias. Other parameters are also important. (Kor J Pain 2017; 30(4): 241-242). The addition of pro/prebiotics with standard care of therapy may possess excellent potential towards Dialysis applications worldwide. Seriously interested clinical PI's please contact: rangan@kibowbiotech.com

Experience with Directly Acting Antiviral Agents for Hepatitis C in Maintenance Hemodialysis Patients in a Single Center from Pakistan

Raja M. Rashid,[1] Zahid Nabi,[2] Zahid ul Zahideen.[3] *[1]CPSP, Islamabad, Pakistan; [2]KRL Hospital, Islamabad, Pakistan; [3]Department of Nephrology KRL islamabad, Sialkot, Pakistan.*

Background: The prevalence of Hepatitis C in Pakistan is around 6 % in general population. Prevalence of hepatitis C in manintenance HD paients is between 22 to 55%. Seroconversion rates are reportedly one of the highest in the world.

Methods: Patients on maintenance HD at our center were included in the study. All the patients recieved sofosbuvir with one of the other available oral antiviral agents. Pertinent data at baseline, 3 months, 6 months and 12 months.

Results: Total of 31 patients were included in the study with Mean age of 50.3 years with Standard Deviation of 16.8. Twenty patients were male (64.5%) and Eleven were Female (35.5%). Duration of Hemodialysis prior to starting treatment was 2 months to 150 months. Four different regimens were used depending upon the availability of Drugs all of them containing Sofosbuvir in dose of 400mg OD. Pre-treatment PCR was Positive in all patients. SVR at end of therapy that is 3 months was achieved in all patients that completed study period. One patient had relapsed after 15months of achieving SVR (previously treated with Sofosbuvir and ribazole). Successfully treated with sofosbuvir plus valpatasvir for 4 months and achieved SVR successfully. Only 4 patients experienced Anemia, all recieving ribazole.

Conclusions: DAA based therapy delivered expected and desired results of therapy without any major therapy related adverse events in our center.

PUB136

How ESRD Creates, Enhances, and Promotes Poverty for Patients in the United States

John D. Sullivan. *Boston University, Boston, MA.*

Background: It is well documented that the treatment is both expensive and takes a physical and financial toll on the patient and their respective families. Depending on the treatment modality, many patients fall out of the workforce under the age of 65 and depend on disability to survive creating an additional expense for the government and the general economy through a lower utilization of the workforce. The question, which has been somewhat explored, is if the diagnosis of renal failure leads to inevitable poverty? Despite coverage ratios and access to care, it still seems to negate that undergoing such a treatment regime removes the economic impact to the patient as well as society in general in addition, in many cases, of a quality of life previously experienced. If indeed dialysis results in patients facing an economic burden that translates into poverty, are there treatments that unlike in-center hemodialysis, can maintain a patient's employment and financial viability?

Methods: Accumulated Journal Articles

Results: CKD and ESRD places a tremendous financial burden on a patient and their subsequent family.

Conclusions: For the United States to step forward, like many of our health care equals and partners in Europe, the community, partnerships, and governmental organizations needs to address the issue from both a patient care and the humanitarian perspective as well as an economic analysis methodology and the general view on quality of life. Dialysis will always be an expensive treatment, but the costs can be reduced with a higher quality of life for patients. But the treatment doesn't have to cost as much as it does if providers

are willing to promote other modalities outside of the standard in-center thrice a week treatment that Fresenius and DaVita promote given their large investment in free-standing clinics. It must also be noted that these two providers create more wealth for their investors via this treatment option.

PUB137

A Home Away from Home: Patients' Experiences of Community Hemodialysis: A Qualitative Interview Study

Rachael C. Walker,[1] David Tipene-Leach,[1] Aria Graham,[2] Suetonia Palmer.[3]
[1]Eastern Institute of Technology, Napier, New Zealand; [2]Whakauae Research Centre, Whanganui, New Zealand; [3]University of Otago, Christchurch, New Zealand.

Background: Community hemodialysis is a sub-modality of home hemodialysis that enables patients to perform hemodialysis independent of nursing or medical supervision in a shared community house. This study describes the perspectives and experiences of patients using community hemodialysis in New Zealand to explore ways in which this dialysis modality may support the wider delivery of independent hemodialysis care.

Methods: Qualitative, semi-structured, in-depth interview study of thirty patients who had experienced community hemodialysis. Participants were asked about why they chose community hemodialysis and their experiences and perspectives of this hemodialysis modality. Data was analysed using thematic analysis.

Results: Twenty-five patients were interviewed (14 men and 11 women, 31 to 65 years of age). Most were of Māori or Pacific ethnicity and in part-time or full-time employment. Over two-thirds dialyzed for 20 hours a week or more. We identified four themes that described patients' experiences and perspectives of choosing and using community hemodialysis: reducing burden on family (when home isn't an option; minimizing family exposure to dialysis; maintaining privacy and self-identity; reducing the costs of home hemodialysis; gaining a reprieve from home); offering flexibility and freedom (having a normal life; maintaining employment; facilitating travel); control of my health (building independence and self-efficacy; a place of wellness; avoiding institutionalization; creating a culture of extended hour dialysis); and community support (building social inclusion; supporting peers).

Conclusions: Community house hemodialysis is a dialysis modality that overcomes many of the socioeconomic barriers to home hemodialysis, is socially and culturally acceptable to Māori and Pacific people, supports extended hour hemodialysis and thereby promotes more equitable access to best practice services. It is therefore a significant addition to independent hemodialysis options available for patients.

PUB138

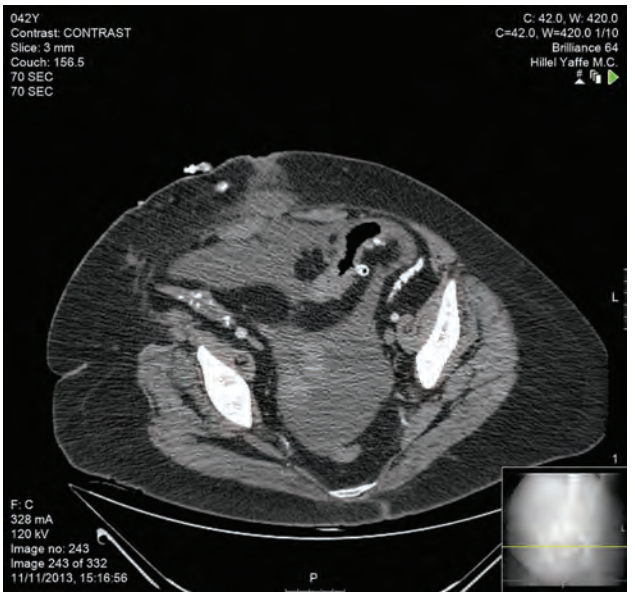
Omphalitis in Adult Peritoneal Dialysis Patients

Regina Gershkovich. *Nephology Department, Hillel Yaffe Hospital Hadera Israel, Netanya, Israel.*

Introduction: There are very few literary reports related to omphalitis in peritoneal dialysis (PD) patients which described peritonitis after severe omphalitis. We describe 2 cases of omphalitis that occured in adult PD patients with CAPD-related peritonitis preceding the event of omphalitis.

Case Description: The first patient, 44-year old woman, was presented with abdominal pain, swelling and local pain in umbilical area. Peritoneal effluent was clear with elevation of WBC and PMN cells count, culture was negative. US of umbilical region revealed thickening, infiltration of subcutaneous fat and suspected fluid collection near the inner side of the abdominal wall. Abdominal CT demonstrated fluid collection in subcutaneous region and smaller collection extended to peritoneal cavity. The patient was treated like culture-negative peritonitis with recovery of clinical signs of omphalitis. 1.5 months before the patient experienced an episode of culture -positive peritonitis, was treated and recovered. Peritoneal culture was negative after the treatment. The second patient, 67 year women, was presented with abdominal pain, redness and local warmth in the umbilical region. Dialysate was clear with a little increase in WBC and PMN count, culture was negative. US of abdominal wall demonstrated thickening and infiltration of abdominal fat in umbilical and periumbilical area. Two small peritoneal lesions of unknown origin were seen. The patient was treated like culture-negative peritonitis and omphalitis recovered. One month before the patient was treated for culture - negative peritonitis and recovered.

Discussion: Our cases caused us to suggest that the omphalitis may be a complication of peritonitis in PD patients. Perhaps this patients had a predisposition like remnants of the umbilical cord and high abdominal pressure converts this rare problem from occult to obvious.



Abdominal CT of the first patient

PUB139

First Onset of Exit-Site Infection, but Not Peritonitis, Is Influenced by Body Mass Index in Newly Patients Started on Peritoneal Dialysis

Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Department of Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: Peritoneal dialysis (PD)-related infections such as exit-site infection (ESI) and peritonitis, are leading causes of technique failure in patients undergoing PD. However, the incidence rate of ESI and the clinical factors associated with ESI have not been well investigated.

Methods: The present study aimed to assess ESI and peritonitis in patients newly started on PD. The clinical records of 55 patients for whom PD was initiated between January 1, 2012 and December 31, 2018 at a single center were retrospectively reviewed. The baseline clinical factors influencing the time to the first onset of ESI and peritonitis events, and the relation between ESI and peritonitis were investigated.

Results: The following patient characteristics were as follows: age (median, interquartile range), 68.0 (55.0–78.0) years; body mass index (BMI), 22.6 (20.1–26.0) kg/m^2; diabetes, 30.9%; step-wise initiation of PD, 47.3%; bag exchange by caregivers, 32.7%; serum albumin level, 3.2 (2.7–3.6) g/dL; serum creatinine level, 8.3 (5.9–9.6) mg/dL; and dialysate-to-plasma creatinine concentration ratio (D/PCr), 0.64 (0.54–0.75). The total number of ESI evets was 162, and the incidence ratio was 1.22 per patient year. The total number of peritonitis events was 33, and the incidence ratio was 0.22 per patient year. The onset of ESI during the initial 60 days correlated with BMI (γ = 0.49; p = 0.001), with D/PCr (γ = –0.52, p = 0.000), and with incidence ratio of ESI (γ = 0.35, p = 0.017), but not with peritonitis incidence. Cox proportional hazards model revealed that the first onset of ESI was significantly affected by BMI [hazard ratio (HR), 1.19; 95% confidence interval (95% CI), 1.04–1.36; p = 0.009] but not by diabetes (HR, 0.69; 95% CI, 0.25–1.86) or D/PCr (HR, 0.79; 95% CI, 0.03–19.0), and that the first onset of peritonitis was not significantly affected by any of the factors including BMI, diabetes, and step-wise initiation of PD. The number of ESI events was correlated with the number of peritonitis events (p = 0.04), but the incidence ratio of ESI did not correlate with the incidence ratio of peritonitis (p = 0.11).

Conclusions: High BMI was associated with the first onset of ESI but not with peritonitis. The onsets of ESI and peritonitis over time were not closely related.

PUB140

Eligibility and Patient Barriers to Peritoneal Dialysis in Patients with Advanced CKD

Ahmed P. Sokwala. *Aga Khan University Hospital, Nairobi, Kenya*.

Background: The burden of chronic kidney disease is on the rise in Kenya and is a significant cause of morbidity and mortality. While definitive treatment is renal transplantation, many patients require renal replacement therapy in the form of hemodialysis or peritoneal dialysis. The predominant modality utilized in Kenya is hemodialysis despite peritoneal dialysis having similar survival outcomes with the potential benefit of cost-effectiveness. There is need therefore to explore why peritoneal dialysis remains underutilized and whether patient factors may be contributory to barriers that limit the uptake of peritoneal dialysis. The main objective of this study is to determine eligibility for peritoneal dialysis of patients considered potential candidates for the modality. In addition, barriers to the same were determined. Further, the impact of presence of support on PD eligibility was determined

Methods: This was a descriptive cross-sectional study where patients who were were potentially PD candidates were consecutively recruited. A mutidisciplinary team assessed these patients for PD eligibilty and this was done using a standardized tool. Contraindications and barriers to the modality were recorded as was the presence or absence of support for provision of self-care PD. Other demographic and clinical data were also recorded using a standardized questionnare. The impact of support on PD eligibility was also determined.

Results: In this study on eligibility of patients with advanced CKD for self-care PD we found 68.9% of the patients eligible for self-care PD. Surgery-related abdominal scarring was the most common contraindication. Barriers to self-care PD were identifed in 45.9% and physical barriers were more common than cognitive barriers. Presence of support was associated with a significant increase in PD eligibility (p<0.001%)

Conclusions: A significant proportion of the population studied was eligible for peritoneal dialysis as a treatment modality. The presence of support may be an important factor to explore in patients with barriers to self-care PD as it may be associated with an increase in PD eligibility.

PUB141

The Effects of Fatigue and Depression on Clinical Outcome Among Different Dialysis Modalities

Yukio Maruyama,[1] Masaaki Nakayama,[2] Atsushi Ueda,[3] Mariko Miyazaki,[4] Takashi Yokoo.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Kidney Center, St Luke's International Hospital, Tokyo, Japan; [3]Department of Nephrology, Hitachi General Hospital, Ibaraki, Japan; [4]Research Division of Chronic Kidney Disease and Dialysis Treatment, Tohoku University Hospital, Sendai, Japan*.

Background: It is well-known that both fatigue and depression are common manifestation among dialysis patients. Additionally, they were reported to be associated not only with quality of life but also patient mortality. There are several relative factors including mental factors, anemia, inflammation and dialysis-relater factors. However, the difference among different dialysis modalities is still unknown.

Methods: In the cross-sectional study, we recruited 194 dialysis patients (mean age, 61±11 years; 134 males). Fatigue was assessed using Profile of Mood States (POMS), Visual Analogue Scale (VAS) and our original scales for fatigue, whereas depression was assessed using the Beck Depression Inventory-second edition (BDI-II).

Results: Our original scales for fatigue was strongly correlated with VAS, BDI-II and POMS. There were no significant differences of the markers for fatigue and depression among patients receiving peritoneal dialysis (n=94), hemodialysis (HD, n=26) and online hemodiafiltration (OHDF, n=74). Among HD and OHDF patients, fatigue was pronounced on the day on dialysis as compared to the day not receiving dialysis.

Conclusions: Further investigations will be needed to clarify the effects of fatigue and depression on the clinical outcome among the different dialysis modalities.

Subcutaneous Cuff Migration in Peritoneal Dialysis Patients: A Single-Center Observational Study

Yan-ru Chen, Wenbo Zhao, Zengchun Ye, Peizhi Wu, Canming Li, Hui Peng. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*.

Background: Cuff extrusion is an important reason of catheter-related infections in patients with maintenance peritoneal dialysis (PD). During the long-term follow-up, we found that subcutaneous cuff tends to slowly migrate to the exit-site of catheter in many PD patients. However, few study show the correlation between subcutaneous cuff migration and duration of PD, and seldom do they analyze the possible effect factors of cuff migration.

Methods: 124 patients who have been undergoing PD for more than 6 months were included in this one-year observational study at our Nephrology division from October 2017 to September 2018. The exposed length of PD catheter was measured with a soft ruler every three months. The exit-site of catheter, BMI, biochemical parameters, and dialysis adequacy indexes were monitored at the same time.

Results: The mean age of these PD patients were 53.1±12.0 yrs and the mean duration of PD was 50.0±24.9 ms. At the beginning of the follow-up, the exposed length of PD catheter was 9.5~16.5 cm (average13.9 ±1.4 cm) and 11.0~17.0 cm (average 14.2 ±1.3 cm) for one year later ($P < 0.001$). The average length of catheter exposure increased 0.28cm. BMI of these patients was 23.0 ±3.2 at baseline, and 23.2 ±3.2 for one year later ($P=0.11$). The length of catheter migration was negatively correlated with hemoglobin level (r = - 0.212, $P < 0.018$) and positively correlated with urea nitrogen level (r = 0.295, $P < 0.001$). There were no correlations between the length of catheter migration and serum albumin, immunoglobulin, pre-albumin, calcium, phosphorus, serum creatinine dialysis adequacy and exit-site infection. During the observational period, 1 patient developed shallow cuff extrusion. There was no exit-site infection during the observational period.

Conclusions: Based on our observation, subcutaneous cuff slowly migrates to the exit-site of catheter as the duration of PD increases in patients. It might be affected by hemoglobin level and urea nitrogen level in these patients. Preventing such cuff migration and extrusion need to be considered by peritoneal dialysis nurses.

PUB143

Outcome Measures for Life Participation in Peritoneal Dialysis: A Systematic Review

Karine E. Manera,[5,1] Wenjing Qiao,[5] Angela Ju,[5,1] Amanda Baumgart,[5,1] Yeoung Jee Cho,[2,3] Jenny I. Shen,[4] Jonathan C. Craig,[6] David W. Johnson,[2,3] Allison Tong.[5,1] *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [2]Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [3]Australian Kidney Trials Network, University of Queensland, Brisbane, QLD, Australia; [4]LaBiomed at Harbor-UCLA, Torrance, CA; [5]University of Sydney, Sydney NSW, NSW, Australia; [6]Flinders University, Adelaide, SA, Australia*.

Background: Patients receiving peritoneal dialysis (PD) require daily treatment and are at risk of potentially life-threatening complications, which can limit their ability to participate in activities of daily living. Despite being a prioritized outcome among patients and clinicians, it is infrequently and variably assessed in existing research. We aimed to identify the characteristics, content and psychometric properties of the measures used to assess life participation in PD research.

Methods: We searched MEDLINE, Embase, PsychINFO, and CINAHL from inception to March 2019 for all studies that reported life participation in patients on PD. The characteristics, dimensions of life participation and psychometric properties of these measures were extracted.

Results: In total, 78 studies were included (3 [4%] randomized trials and 75 [96%] observational studies). Across these studies, we identified 16 different measures that were used to report life participation. None of the measures specifically assessed life participation, but evaluated broader constructs (e.g. quality of life) that included questions on life participation. The 36-Item Short Form Survey (SF-36) and Kidney Disease Quality of Life Short Form (KDQOL-SF) were the most frequently used measurement tools, employed in 36 (46%) and 26 (33%) studies, respectively. Validation data to support the use of these measures in patients on PD were available for nine.

Conclusions: Life participation is inconsistently assessed across studies in PD, and some of the measures used have not been validated in the PD population. Establishing a standardized, validated measure of life participation will facilitate consistent and accurate assessment of this outcome, thereby enabling research to inform strategies which can help patients on PD better engage in their life activities.

PUB144

Single-Dose Prophylactic Antibiotic Did Not Significantly Reduce Peritonitis After Peritoneal Dialysis Catheter Insertion

Yaohui Chen, Chunyan Lang, Lin Yang, Yun Li. *Jiangxi Provincial People's Hospital, Nanchang, China*.

Background: It is recommended to use prophylactic antibiotics before the catheter insertion by ISPD guideline. Previously in our hospital, the physician who did the surgery would decide whether to use antibiotics according to patient's condition. To investigate the use of antibiotics around the Tenckhoff catheter insertion for continuous ambulatory peritoneal dialysis(CAPD) and its effect on the incidence of early peritonitis, we performed the retrospective study.

Methods: From Jan. 2012 to Mar. 2019, there were 642 patients underwent PD catheter insertion. Each patient's electronic medical record was reviewed to determine the use of antibiotics and the occurrence of peritonitis. Patients received catheter due to acute severe pancreatitis, retreated from PD or died within 14 days after the insertion were ruled out. The remaining patients fell to three groups: Systemic group(SG), due to lung, urinary tract, etc. infection, patients received antibiotics orally or intravenously(IV) for more than one dose (mostly more than three days) during the time from 3 days before to 14 days after the insertion; Prophylaxis group(PG), patients received a single dose Cephalosporin or Quinolone mostly IV before or in PD fluid after the insertion; Non-prophylaxis group(NPG), patients did not receive any antibiotics during the time frame set in SG. Peritonitis in 14 days after the insertion was recorded. Peritonitis rates were compared by Chi-square test.

Results: Out of total 642 patients, 28 were ruled out. The remaining 614 patients(318 men and 296 women) were as follow: 185 in SG, 164 in PG, and 265 in NPG. Peritonitis occurred in 5 patients(2.7%) in SG, 11(6.71%) in PG, and 32(12.08%) in NPG. The results of Chi-square test are as follow: SG *vs* PG, p=0.1215; SG *vs* NPG, p=0.0003; and surprisingly, PG *vs* NPG, p=0.0971. In terms of gender, peritonitis rates in men and women were 11% and 4.39% (p=0.0024). The differences among all groups in women were not significant (SG *vs* PG, p>0.9999; SG *vs* NPG, p=0.3541; PG *vs* NPG, p=0.3209), and in men were partial significant (SG *vs* PG, p=0.0282; SG *vs* NPG, p=0.0004; PG *vs* NPG, p=0.2468).

Conclusions: Our data suggest that single dose prophylactic antibiotic did not significantly reduce peritonitis following PD catheter insertion and male was more susceptible to early peritonitis after insertion.

PUB145

Activation of Renin Angiotensin System Disrupts the LDLr Pathway: A Novel Mechanism for Extracellular Matrix Accumulation in Human Peritoneal Mesothelial Cells

Liu Jing. *Affiliated Drum Tower Hospital, Medical School of Nanjing University, Institute of Nephrology, Nanjing City, China*.

Background: Peritoneal fibrosis (PF) is characterized by progressive extracellular matrix (ECM) accumulation in human peritoneal mesothelial cells (HPMCs) under high glucose (HG) conditions. The aim of this study was to explore the potential mechanisms of HG-induced production of ECM in HPMCs.

Methods: HPMCs were stimulated by HG. The activity of renin angiotensin system (RAS) was inhibited by valsartan or angiotensin II (AngII) type 1 receptor (AT1R) siRNA. Morphological changes in the cells were observed under an inverted microscope. Oil red O, filipin staining and high-performance liquid chromatography were used to examine lipid accumulation. The expression of low-density lipoprotein receptor (LDLr) regulation, the RAS component and ECM-associated markers were assessed by real-time PCR and western blot analysis.

Results: The results showed that after treatment with HG, HPMCs showed notable elongation consistent with the morphology of myofibroblasts, and the expression of ECM proteins such as α-smooth muscle actin (α-SMA), fibroblast specific protein-1 (FSP-1) and collagen I was increased. In addition, there was a parallel increase in lipid accumulation, the effect of intracellular lipid deposits was closely correlated with dysregulation of LDLr, which was mediated through the upregulation of LDLr, sterol regulatory element-binding protein (SREBP) cleavage-activating protein (SCAP), SREBP-2 and through enhanced coexpression of the SCAP with the Golgin. Further analysis showed that HG enhanced the gene and protein expressions of RAS component, such as renin, angiotensinogen, angiotensin-converting enzyme, AngII and AT1R. Interestingly, blocking RAS activity reversed the dysregulation of LDLr, even in the stimulaltion of HG. These effects were also accompanied by a decrease in the expression of ECM components.

Conclusions: Our findings demonstrated that increased RAS activity exacerbated ECM formation in HPMCs by disrupting LDLr regulation, which contributed to lipid disorder-mediated PF.

Serum Ferritin as a Predictor of All-Cause and Cardiovascular Mortality Depends on Systemic Inflammation in Peritoneal Dialysis Patients

Sha Fu,[2] Ying Tang,[1] Bo Liu,[2] Junzhe Chen,[2] Anping Xu.[1] *[1]Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Nephrology, SunYat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*.

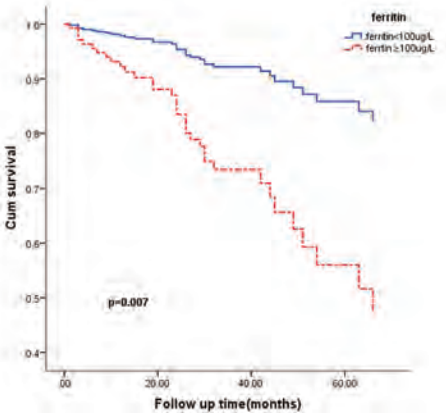
Background: It is proposed that inflammation may modify the association between serum ferritin and the adverse outcomes in hemodialysis patients. However, the optimal level of serum ferritin remains ambiguous at what level advantage outweighs the disadvantage in peritoneal dialysis patients when the inflammation taken into consideration. This study aimed to explore the optimal concentration of serum ferritin for the improving the outcome of peritoneal dialysis patients.

Methods: We classified 221 patients into two groups according to serum ferritin concentration (100ug/L) and followed up regularly from the date of catheterization to Dec 31th, 2016 at SunYat-Sen Memorial Hospital, China. Clinical and biochemical data were collected as baseline, and clinical outcomes such as all-cause, cardiovascular, infection -related mortality were assessed.

Results: The Kaplan–Meier survival revealed a significant worse survival accumulation in PD patients with higher serum ferritin under elevated hsCRP level (p=0.022). A multivariate cox regression analysis revealed that enhanced level of ferritin was independently associated with higher risk of all-cause and cardiovascular mortality in PD patients (HR=0.263, p=0.007 and HR=0.094, p=0.029) after adjustment for relevant confounding factors under the condition of hsCRP above 3mg/L. However, correlations were not statistically significant for serum ferritin and poor outcome within the normal range of hsCRP level.

Conclusions: Higher levels of serum ferritin were associated with increased risk of all-cause and cardiovascular mortality in patients undergoing PD only in the presence of elevated hsCRP level. The correlation of serum ferritin with poor outcome should take systemic inflammation into consideration.

Figure 2 Survival probability with respect to serum ferritin under elevated hsCRP levels by multivariate cox proportional hazards regression analysis with confounding factors adjusted.



PUB147

Hyperkalemia in Chronic Peritoneal Dialysis

Michael E. Ullian,[1,2] Andrew B. Elliott,[1] Karim M. Soliman.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Nephrology, Ralph H Johnson VA Hospital, Charleston, SC.*

Background: Since peritoneal dialysate contains no potassium, hypokalemia is expected in patients on chronic peritoneal dialysis (PD).

Methods: We explored retrospectively the incidence and potential mechanisms of hyperkalemia, not previously described, in 779 blood samples obtained monthly from 33 patients over 1 – 59 months of PD. Patients were dialyzed daily via cycler, usually 9 – 15 hours per day, with a "dry" period. Normal range of serum potassium concentrations was defined as the hospital standard: 3.5 - 5.1 meq/l.

Results: Although mean monthly serum potassium concentrations were in the normal range and stable over 59 months, we observed hypokalemia (< 3.5 meq/l) in 40 (5%) and hyperkalemia (> 5.1 meq/l) in 110 (14%) blood samples. The incidence of hyperkalemia did not change appreciably over Years 1 (15%), 2 (11%), 3 (19%), and 4 - 5 (22% [fewer samples]) of PD. Hyperkalemia was mostly modest: 5.2 – 5.4 (55%), 5.5 – 5.7 (21%), 5.8 – 6.0 (10%), > 6.0 (14%) (meq/l for each). Of the 33 patients, 39% displayed hyperkalemia only, 23% displayed hypokalemia only, and the remainder (38%) displayed both or neither. Comparing the hyperkalemia-only patients with the hypokalemia-only patients, we found no difference in use of potassium chloride therapy or medications that interrupt the renin-angiotensin system, small-molecule transport status, or renal urea clearance. We compared biochemical parameters from the hypokalemic and hyperkalemic blood samples and observed lower serum bicarbonate concentrations, higher serum creatinine concentrations, and higher blood urea nitrogen concentrations in the hyperkalemic samples ($p < 0.001$ for each), without difference in serum glucose concentrations.

Conclusions: In summary, our chronic PD patients exhibited hyperkalemia almost 3 times as frequently as hypokalemia. We wonder if high-potassium diet (patients are instructed to eat potassium-containing foods to prevent hypokalemia), non-compliance with therapy (evidence: more azotemia), increased muscle mass (evidence: higher serum creatinine concentration), cellular shifts of potassium (evidence: more metabolic acidosis), and/or the long period without PD each day contribute to the unexpected frequency of hyperkalemia in our population.

PUB148

Peritoneal Equilibration Test (PET) with Temporary Drainage at 60 Minutes: Utility to Identify Potential Risk of Severe Damage on Peritoneal Membrane

Mabel Alvarez quiroga, Martin E. Guinsburg, Rosanna V. Garofalo, Carolina V. Martinez, Adrian M. Guinsburg. *Fresenius Medical Care, Buenos Aires, Argentina*.

Background: Long term preservation of peritoneal membrane is key to maximize modality survival. Presence of ultrafiltration failure over time are commonly associated to fibrosis, inflammation and severe damage on peritoneal membrane. Several authors has postulated that measuring changes in sodium concentration (DipNa), and free water transport (FWT) could help to detect patients at risk of developing encapsulated peritoneal sclerosis (EPS). We aim to evaluate transport changes over time in our population.

Methods: We performed modified PET to peritoneal dialysis (PD) patients in Fresenius Medical Care Argentina between 06-2015 and 12-2018 and calculated FWT, small pore ultrafiltration, dipNa and d/p Cr h4 according to Bernardo et al.[1] Test results were correlated to time in PD to identify progressive damage. Patients with combination of DipNa < 5 mEq/l, FWT < 75 ml, total UF < 400 ml and d/p Cr h4 > 0.81 were classified at high risk for EPS. Pearson was used to evaluate correlation while Student t-test for mean comparisons.

Results: We included 549 incident and prevalent PD patients. Age 49.4±16.2 years, 48.2% male, diabetes 15.1%, time in PD 30.1±28.6 months. According to d/p Cr h4, transport type was 2.5% low, 13.9% low-average, 48.7% high-average and 32.3% high. Time in PD correlates negatively with DipNa (-0.214, p<0.001), FWT (-0.225, p<0.001) and total UF (-0.186, p<0.001) and positively with d/p Cr h4 (0.129, p 0.002). High risk for EPS was identified in 26 patients (4.7%) with significant greater time on PD (48.9± 32.5 vs 29.2±28.1 months) but no difference in age, gender, diabetes or peritonitis prevalence. Remarkable is that d/p Cr h1 showed a high correlation with d/p Cr h4 (0.793, p<0.0001).

Conclusions: Time in PD has a significant impact in transport changes of the peritoneal membrane. Performing modified PET test allowed to early identify membrane injury thus increasing detection of patients at potencial risk for EPS. High correlation between d/p Cr h1 and d/p Cr h4 may allow to shorten the test to just one hour long, mostly useful for patients with low tolerance to intraabdominal pressure increases. PUB149

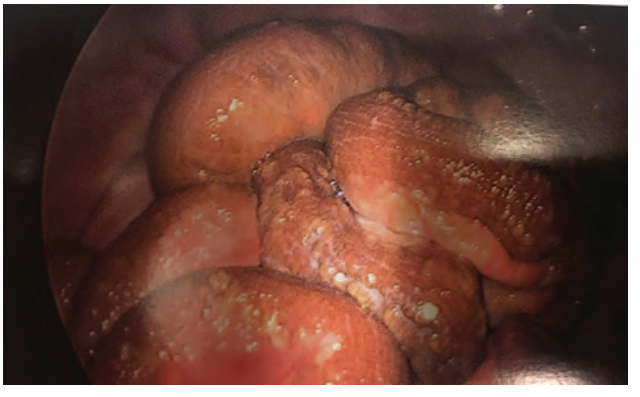
Encapsulating Peritoneal Sclerosis (EPS): Initial Presentation as Incidental Finding of Peritoneal Calcifications During Laparoscopic PD Catheter Placement

Zhi Xu, Moiz Dawood. *University of New Mexico Hospital, Albuquerque, NM.*

Introduction: EPS is a rare but devastating complication of longterm peritoneal dialysis (PD) characterized by inflammatory and fibrotic peritoneal capsule that entraps the bowel loops.

Case Description: A 64 year-old woman with end-stage kidney disease who had been on PD for 13 years was referred to a surgeon for a new PD catheter placement after temporary transfer to hemodialysis (HD) due to refractory peritonitis. During the laparoscopic procedure, the surgeon noticed many plaques of "sclerosing reactions" on her mesentery. No adhesions were observed. In light of the patient's long period of 13 years on PD, we were concerned about EPS and promptly transitioned her to HD. Up to this point, patient had done well on PD. She had effective ultrafiltration. She was a low transporter. Six months after her transition to HD, she was admitted to the hospital with anorexia and weight loss. She was found to have small bowel obstruction. She underwent lysis of adhesions and was noted to have dense fibrosis of the visceral peritoneum. She declined steadily and withdrew from care.

Discussion: As our case demonstrates, early diagnosis of EPS requires a high degree of vigilance. There are no specific tests to diagnose EPS. The early phase of EPS maybe indicated by appearance of ultrafiltration failure with change to high transporter status. Unfortunately EPS is usually diagnosed in the later progressive stage when intestinal obstruction becomes evident. As EPS becomes apparent, evidence supporting its diagnosis includes radiologic findings of loculated ascites and calcifications along the peritoneum and small bowel loops. Time on PD (> 5 years) is the only consistent predictor for the occurrence of EPS. The diagnosis of EPS mandates the immediate transition from PD to HD. There is no consensus regarding optimal treatment, which may include surgical lysis of intestinal adhesions, nutritional support, and immunosuppressive therapy with prednisolone and or tamoxifen.



PUB150

Comparison of Utilization of Peritoneal Dialysis (PD) Between a High-Volume PD Center (HVC) and a Low-Volume Center (LVC) in New York City (NYC)

Ernie Yap,[1] Shuchita Sharma,[2] Osama El Shamy,[2] Alan D. Weinberg,[2] Jaime Uribarri,[2] Subodh J. Saggi.[1] *[1]SUNY Downstate Medical Center, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: NYC has one of the lowest PD utilization rates within the United States but within NYC itself there is segmental distribution of facilities that have high PD utility rates. Metropolitan neighborhoods are generally considered to have adequate infrastructure support to sustain home-based programs. We compared a HVC to a LVC to identify potential factors that lead to sustenance of home-based programs such as PD.

Methods: We reviewed selected factors that would sustain a PD program from the 2017-2018 data of a HVC (n = 80) and compared them to a LVC (n = 12) located in Manhattan and Brooklyn, respectively. Proportions and rates were either analyzed via chi square statistics or Poisson rate models.

Results: See Table

Conclusions: Amongst the factors analyzed above, the only factor that demonstrated statistical significance was the rate of new-start PD patients in the HVC. Rates of patient loss to hemodialysis or kidney transplant as well as provider-to-patient ratios did not show statistically significant difference between centers. Contrary to previous publications that demonstrated that the disparity in the economies of scale influenced the safety and rate of complications; such findings were not seen in this study. Health care providers or institutions that would like to grow their home-based programs need to look at strategies that enhance patient recruitment.

Comparison between a high-volume PD center (HVC) and low-volume center (LVC) in 2017-2018 within New York City.

	HVC	LVC	P
Proportion of new patients per year/N	38/80 (0.48)	2/12 (0.17)	0.04
Proportion of patients lost per year/N	37/80 (0.46)	4/12 (0.33)	0.40
Hemodialysis to PD transitions	9/80 (0.11)	2/12 (0.17)	0.63
PD to hemodialysis transitions	27/80 (0.34)	5/12 (0.42)	0.75
Kidney transplant per year/N	10/80 (0.13)	0/12 (0)	0.35
Nurse to patient ratio	5/80	1/12	0.75
Nephrologist to patient ratio	2/80	1/12	0.33
Peritonitis rate (per patient months)	1/36	1/19.4	0.66
Exit site infection rate (per patient months)	1/76	1/47.4	0.74

Insight into the Mechanism of Electrolyte Management in Sorbent-Based Peritoneal Dialysis

Peter F. Haywood,[2] Vinod Gadi,[2] Sanjay Singh,[2] Mandar Gori,[2] Suresha B. Venkataraya,[2] Htay Htay,[1] Marjorie W. Foo,[1] Yue Wang.[2] *[1]Singapore General Hospital, Singapore, Singapore; [2]AWAK Technologies Pte Ltd, Singapore, Singapore.*

Background: Electrolytes play a key role in maintaining fluid balance, osmolarity, acid-base balance in healthy humans and hence the management of electrolytes is important to control the morbidity of CKD and ESKD patients. The positively charged electrolytes like sodium (Na^+), potassium (K^+), calcium (Ca^{2+}) and Magnesium ($Mg2^+$) together with negatively charged electrolytes like chloride (Cl^-), bicarbonate (HCO_3^-) and phosphate ($PO4^{3-}$) perform unique physiological functions and concentration above or below the normal range can affect homeostasis or specific organ function detrimentally.

Methods: The regulation of electrolyte balance in sorbent-based PD is managed by ion exchange mechanism, infusion and/or diet. Zirconium phosphate and zirconium oxide are used as cation and anion exchangers respectively. Certain electrolytes like sodium, bicarbonate and chloride are maintained by ion exchange processes while other ions like magnesium, calcium, potassium, phosphate are completely removed by the sorbent and managed by corresponding salt infusion and/or diet.

Results: The results of electrolyte management by AWAK sorbent cartridge, including follow up data, in one representative patient (P) who underwent nine AWAK therapies over a period of three days is shown below.

Conclusions: The specially formulated sorbent in AWAK PD device helps to regulate and maintain electrolyte concentration close to physiological levels and thus promising safe therapy.

PUB152

Regulation of Mesothelial Epithelial-to-Mesenchymal Transition by Vitamin D and Statins

Seth B. Furgeson,[1,2] Colin D. Bauer,[1] Isaac Teitelbaum.[1] *[1]University of Colorado, Aurora, CO; [2]Denver Health Hospital, Denver, CO.*

Background: Epithelial to mesenchymal transition (EMT) has been implicated in the pathogenesis of peritoneal sclerosis. The factors that regulate EMT in the peritoneum are incompletely understood. Data obtained in cell culture and in animal models of peritoneal dialysis indicate that active Vitamin D analogues and statins may attenuate the changes of EMT. We explored whether these compounds, at doses used in ordinary clinical practice, have effects on EMT in man. patients receiving PD.

Methods: Human peritoneal mesothelial cells (HPMCs) were obtained from peritoneal effluent. Patients included in the study had been on stable doses of the agent(s) of interest and devoid of peritonitis for at least 3 months. Patients were analyzed in four groups: Those using neither an active vitamin D compound nor a statin (N) (n=6) Patients using an active D compound but not a statin (D) (n=5) Patients using a statin but not an active D compound (S) (n=6) Patients using both an active D compound and a statin (B) (n=6) RNA was isolated from cell lysates and cDNA was generated using reverse transcriptase. Using quantitative real time polymerase chain reaction (qRT-PCR), transcript levels of E-cadherin (a marker of epithelial phenotype), smooth muscle alpha actin (EMT marker), Snail (EMT promoter), and IL-6 (pro-inflammatory cytokine) were measured. Results were normalized to transcript levels of GAPDH. Statistics were performed using ANOVA.

Results: The table shows relative levels of EMT transcripts normalized to GAPDH in all groups. Data is presented as mean (standard error). There were no statistically significant differences in transcript levels of E-cadherin, Snail, smooth muscle alpha actin, or IL-6 between the four treatment groups.

Conclusions: This data does not support the hypothesis that vitamin D or statins reduce EMT in patients on PD. However, the study does have several limitations, including possible heterogeneity in effluent cell mix and small sample size. Larger studies are needed to determine whether activated vitamin D or statins prevent EMT in patients receiving PD.

Table

	N	D	S	B
E-cadherin	0.72 (0.34)	0.56 (0.24)	0.53 (0.32)	1.1 (0.33)
Snail	0.56 (0.2)	0.73 (0.1)	0.73 (0.1)	0.52 (0.15)
SMA	2.6 (1.8)	1.17 (0.48)	0.92 (0.35)	1.5 (0.55)
IL-6	1.7 (0.79)	0.88 (0.38)	0.76 (.18)	0.74 (0.22)

PUB153

A Case of Catastrophic Calcific Uremic Arteriolopathy Involving Multiple Organ Systems in the Setting of ESRD

Anastasios Papanagnou, Waqar Ahmed. *Nephrology, Mount Sinai St. Luke's/West, New York, NY.*

Introduction: Calcific uremic arteriolopathy (CUA), or calciphylaxis, is a grave disease, associated with high morbidity/mortality, that presents with skin ischemia/necrosis and occurs, most commonly, in ESRD patients. Diagnosis is primarily a clinical one. Manifestations include painful, plaque-like subcutaneous nodules that progress to ischemic/necrotic ulcers with eschars. Although skin involvement is well known in diagnosing this disease, extra-cutaneous involvement has not been discussed extensively. We present a case of catastrophic CUA, involving multiple organ systems.

Case Description: 65 y/o woman with a PMH of ESRD, on CCPD, HTN, COPD, OSA, DM-2 and PAD p/w painful B/L LE ulcers, starting 2 weeks prior to admission with skin discoloration, progressing to painful ulcers with dark eschars. As there was high suspicion for CUA, patient was started on sodium thiosulfate and sensipar/sevelamer. Hospital course was complicated by aspiration pneumonia (s/p course of antibiotics), acute ischemic stroke (MRA) secondary to cardio-embolism (cardiac CT showing severe mitral annular calcification with areas of caseation necrosis). Anticoagulation was deferred due to her co-morbidities/risk of bleeding. Patient had persistent leukocytosis/bilateral submandibular swelling (concerning for parotitis), re-started on antibiotics; blood cultures and mumps titers were negative. She developed hematemesis, associated with abdominal pain and worsening hypoxia, conservatively managed with oxygen and PPI therapy. Subsequently, patient developed AMS with unresponsiveness. She was sedated, intubated and transferred to the ICU. CT Head showed a new large R temporal hematoma, midline shift and R uncal herniation, deemed not a surgical candidate. Family opted for comfort care. Shortly thereafter, patient was found to be in PEA arrest followed by asystole. She was later pronounced dead.

Discussion: This case highlights the multiple organ systems involved in this devastating disease process, which have been rarely emphasized in the literature. Treatment options are limited, and often do not attenuate its dismal prognosis. Six-month survival rate of patients with CUA is 50%. The advent of more awareness of the widespread involvement of CUA can help to diagnose this ominous condition early, and may help to mitigate its complications.

PUB154

A Case of Persistent Left Superior Vena Cava in a Hemodialysis Patient Detected During Left Upper Arm Arteriovenous Graft Thrombectomy

Aisha Shaikh,[1,2] Jeremy D. George.[3] *[1]Nephrology, James J. Peters Medical Center VA, Bronx, NY; [2]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Persistent Left Superior Vena Cava (PLSVC) is the most common thoracic venous anomaly with a reported incidence of 0.3% - 0.5% in the general population though the incidence can be up to 6% in patients with congenital heart disease. The majority of the patients with PLSVC are asymptomatic, with the anomaly usually discovered incidentally during central venous catheter (CVC) or cardiac pace-maker placement. This is a case of PLSVC in a hemodialysis patient discovered during a left upper arm arteriovenous graft (AVG) thrombectomy procedure

Case Description: 63-year old male with end stage renal disease presented to the dialysis unit with a clotted left upper arm AVG. The AVG (brachial artery to axillary vein) was created 6 months prior and was being used for hemodialysis treatment for 4 months. The patient did not have a prior history of CVC placement. During the AVG thrombectomy, the patient was found have a PLSVC with no accompanying Right SVC. The thrombectomy was successful, and the patient did not have any adverse events during or after the procedure. However, at the end of the thrombectomy procedure it was unknown if the patient had an accompanying cardiac anomaly or a left to right shunt. A contrast echocardiogram was performed which did not reveal a left to right shunt or any other cardiac anomaly

Discussion: PLSVC is generally an asymptomatic condition. In most patients, the left sided SVC drains into the right atrium through the coronary sinus. However, in up to 8% patients, the left sided SVC drains into the left atrium creating a left to right shunt. In addition, cardiac anomalies such as ventricular and atrial septal defects can be present. It is well known that during the AVG thrombectomy there is dislodgement of the clot downstream into the venous circulation, resulting in pulmonary emboli. These pulmonary emboli are generally small, and usually asymptomatic. However, in the presence of a left to right shunt, the patient is at potential risk for paradoxical embolism which could result in an embolic stroke. It is therefore important to determine the presence of left to right shunt in the setting of PLSVC to assess the risk of systemic embolism during a dialysis AV access thrombectomy

PUB155

Risk Factors Associated with Early Vascular Catheter Dysfunction

Andres Aranda,[1] Pablo Maggiani,[4] Violeta E. González montes,[1] Erendira A. Arellano,[1] Guillermo Navarro Blackaller,[2] Jonathan Chavez,[3] Joana G. Navarro gallardo.[4] *[1]Hospital Civil Fray Antonio Alcalde, Zapopan, Mexico; [2]Universidad de Guadalajara, RFC UGU250907MH5, Mexico; [3]Hospital Civil de Guadalajara, Guadalajara, Mexico; [4]Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico.*

Background: In our center, the majority of vascular catheters (Cath) are placed urgently, either for AKI or CKD, so it is imperative to obtain adequate functionality of the Cath to stabilize the patient. Risk factors associated with EARLY vascular catheter dysfunction (EVCD) have not been clearly studied

Methods: 66 patients had jugular Cath placement from Feb-May 2019. Primary objective:Risk factors associated with EVDC, defined as blood flow <250 ml/min at the first HD session. The Cath were placed guided by US. We analyzed age, gender, height, previous Cath, lab tests, Glasgow, BP, anatomic position, extrasystoles (EXS), #punctures, JV collapsability, Cath TUG-TIP-TOP, Cath size and type, heparin, complications, neck circ., breastbone-chin DIST, skin-JV DIST, JV and carotid diam. and DIST between JV-Carotid. A correlation matrix and uni- and multivariable logistic regression model were performed. P <0.05 significant

Results: 66 vascular Cath placements were analyzed. The EVDC was presented in 4 patients (6.06%). The incorrect position of the Cath TIP was associated with EVDC (OR 1.35, 95% CI 1.13-1.62, P = 0.0018). The presence of EXS during the procedure was associated with a lower risk of EVDC (OR 0.81, 95% CI 0.69-0.95, P = 0.0185). No other variable was significant. Factors associated with complications during the procedure were performing>= 2 punctures (OR 1.21, 95% CI 1.02-1.42, P = 0.027) and carotid diameter>= 0.85 cm (OR 1.55, 95% CI 1.10-2.20, P = 0.017)

Conclusions: Avoiding EVDC is importance in patients with an emergency HD. Only the incorrect position of the Cath TIP was associated with EVDC (OR 1.35, 95% CI 1.13-1.62, P = 0.0018) while the presence of EXS during the procedure was associated with lower risk of EVDC (OR 0.81, 0.69-0.95, P = 0.0185). Larger sample is need it

Is Basilic Vein Transposition an Alternative Option for Unsuitable Veins? An Indian Scenario

Vinant Bhargava,[1] Priti Meena,[1] Anurag Gupta,[1] Neha Jain,[2] Anil Bhalla,[1] Ashwani Gupta,[1] Krishna K. Agrawaal,[3] Devinder S. Rana,[1] Manish Malik.[4] *[1]Sir Ganga Ram Hospital, New Delhi, India; [2]UCONN Health, Hartford, CT; [3]Nepal Medical College and Teaching Hospital, Parasi-5, Nepal; [4]Sir Ganga Ram Hospital and GRIPMER, New Delhi, India.*

Background: According to the National Kidney Foundation's KDOQI, "radial-cephalic (RC) and brachial-cephalic (BC)" fistulae are the first choices for vascular access but in the absence of adequate veins or after failed RC/BC access, basilic vein transposition (BVT) provides an alternative autologous option for hemodialysis.

Methods: This is a prospective, observational study conducted in the Department of nephrology at Sir Ganga Ram Hospital, New Delhi. Forty five patients with end stage renal failure who underwent BVT during 1st January 2017 to December 2018 were included in the study. Patients were followed up for 1 year. All the complications including secondary interventions and patency rates were noted.

Results: Total number of patients included in the study was 45. The mean fistula maturation time was 40 ± 10 days. The mean age of patient was 49.98 years and 57% of the patients were male. The mean basilic vein diameter was 3 mm. Fistula thrombosis was the most common complication seen in 15.5% cases followed by limb edema in 10% and surgical site infection in 2 % of cases. 25 % patient required repeat interventions (fistula thrombectomy, balloon angioplasty etc.). The primary patency rate and secondary patency rate at 1 year of follow up were 80.5% and 89%, respectively.

Conclusions: BVT is the most viable and feasible surgical option for patients having unsuitable veins or failed radio-cephalic/ brachio-cephalic arteriovenous fistula for maintenance haemodialysis.

PUB157

Paclitaxel-Coated Balloon Angioplasty for Stenosis of Access in Patients Under Hemodialysis

Ioannis Griveas.[2,1] *[1]Nephrology, 417 Army Share Fund Hospital, Athens, Greece; [2]Helenic Open University, Athens, Greece.*

Background: The recording of the experience of the use of paclitaxel-coated balloons in patients with End Stage Renal Disease under hemodialysis (HD) exhibiting narrowing in arteriovenous fistulas (AVF).

Methods: 11 patients with ultrasonographically confirmed AVF dysfunction were subjected after angiographic screening to prosthesis with a simple angioplasty balloon, and then a balloon drug gradually released the drug paclitaxel. After the damage was restored, arteriovenous communication was used immediately. The degree of vascular stenosis, blood flow to it and kt / V before and after recovery were assessed by ultrasound. At the same time, the clinical course of the patient and the vestibule of the vessel were monitored for 6 months.

Results: In the 11 patients in the study after the damage was recovered, AVF was immediately treated without any problems. After angioplasty the degree of stenosis of the responsible vessel was statistically significantly reduced from 69.28% to 32.14% (p <0.05). Flow volume increased statistically significantly from 621.43 mils / min to 928.57 mils / min (p <0.05). The kt / v of patients improved from 1.25 to 1.6. During the 6-month follow-up, the clinical course of the patients was stable, no problems related to vascular access occurred. Restenosis occurred only to a patient.

Conclusions: Drug-releasing balloons can be a useful therapeutic option for patients with AVF stenosis due to accelerated endothelial hyperplasia. The use of paclitaxel-coated balloons helps reduce the risk of restenosis of arteriovenous anastomoses and is a safe and immediate solution to AVF management.

PUB158

Rethinking Access for Dialysis in Older People: Proposed Study Design

Anamika Adwaney,[1] Neill D. Duncan,[1] Edwina A. Brown,[3] Damien Ashby.[2] *[1]Hammersmith Hospital, London, United Kingdom; [2]Imperial College, London, United Kingdom; [3]Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, UK, London, United Kingdom.*

Background: The arteriovenous fistula is widely regarded as the best long-term haemodialysis access, due to fewer complications and longer patency, whereas tunnelled catheters have traditionally provided temporary access when emergency dialysis is required, or when a fistula has not been successful. However, the dialysis access landscape has changed with older and more comorbid patients making up a greater proportion. These patients have both poorer fistula outcomes and shorter life expectancy, and whilst fistula formation is still desirable it may be less tolerable. Catheters are increasingly advocated as a long-term access option for some older and more comorbid patients. We propose a pilot randomised controlled trial comparing a fistula to a tunnelled dialysis catheter, which has never been carried out before, in older haemodialysis patients to determine the optimal study design.

Methods: By performing a pilot randomised controlled trial we aim to; 1. Establish the willingness of patients to participate and the protocol drop-out rates in the two treatment arms. 2. Determine the best validated questionnaires to measure differences in quality of life between the two treatment arms. 3. Assess staff acceptability This study is an open label randomised controlled trial with a 12-month follow up period intended to answer key design issues. We will include patients aged over 70, with declining kidney function

and expecting to start haemodialysis within 6 to 12 months. Patients will be randomised in a 1:1 ratio to the fistula or catheter treatment group; the fistula group will be referred for fistula formation after randomisation and the catheter group will have a line inserted when dialysis is required. We aim to recruit 52 patients, 26 in each treatment arm, over an 8-month period.

Results: Patients will be followed for a minimum of 12 months. Data collection will be performed using electronic patient records and clinical correspondence.

Conclusions: The primary outcomes will be the willingness of patients to be randomised to either a fistula or a catheter and the study drop-out rate as defined in the fistula group as failure to achieve a fistula attempt within 3 months of randomisation. The secondary outcomes to be observed in this study include mortality, unplanned admissions, quality of life measurements and dialysis initiation.

PUB159

Ultrasound Evaluation and Interventional Therapy for Dialysis of Peripheral Vascular Access Stenosis

Xian Wu, Hong Ye, Yuan Luo, Chunfeng Gu, Xueqin Bian. *Second Affiliated Hospital Nanjing Medical University, Nanjing, China*.

Background: To investigate the patency rate and restenosis after percutaneous transluminal angioplasty(PTA) for the treatment of arteriovenous fistula(AVF) and arteriovenous graft(AVG)stenosis.

Methods: The patients who were successfully treated by PTA for the first time in the blood purification center of our hospital from January 2016 to June 2017, including 71 cases of AVF in the forearm, 52 cases of AVF in the upper arm and 59 cases of AVG were recorded. The data of different stenosis parts were analyzed before and after treatment and followed up for 12 months. The initial patency rate and assisted-PTA patency rate were observed at 3 months, 6 months, 9 months, and 12 months after ultrasound interventional therapy, and the initial patency time for patients who need to reintervention among all types of pathways were recorded.

Results: The initial patency rates at 3 months, 6 months, 9 months and 12 months after ultrasound interventional therapy were forearm AVF(98.59%,90.14%,71.93%,54.93%), upper arm AVF(90.38%,65.38%,42.31%,32.69%), AVG(91.53%,32.20%,6.78%,1.69%), and the PTA-assisted patency rates were forearm AVF(98.59%,97.18%,95.77%,94.37%), upper arm AVF(92.31%,86.54%,84.62%,80.77%), AVG(100%,98.31%,96.61%,93.22%), while the initial patency time was forearm AVF(8.99±3.54) months, upper arm AVF(6.33±3.01) months, AVG(4.80±1.40) months.

Conclusions: Ultrasound can comprehensively evaluate the function of peripheral vascular access, guide PTA treatment, and evaluate treatment outcomes. Ultrasound intervention therapy is the best initial patency rate for forearm AVF stenosis, the prognosis of upper arm AVF stenosis PTA is relatively poor due to the easy cephalic stenosis, although AVG has a short interval of restenosis, it can achieve a better long-term patency rate through regular intervention with ultrasound intervention.

Arteriovenous Access Use Is Associated with Greater Interdialytic Weight Gains and Ultrafiltration Rates in Veteran Hemodialysis Patients

Niraj Desai,[1,2] Jason A. Ayapana,[2] Steve Majerus.[2] *[1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Louis Stokes Cleveland VA Medical Center, Cleveland, OH.*

Background: High interdialytic weight gain (IDWG) and ultrafiltration rate (UFR) associates with adverse cardiovascular outcomes, fluid overload related hospitalization and mortality in HD patients. We examined whether IDWG and UFR was influenced by type of hemodialysis vascular access.

Methods: We conducted a retrospective observational study of patients at a single, outpatient Veteran's Affairs (VA) HD unit. Arteriovenous fistula (AVF) or graft (AVG) users were combined into a single AV group and compared to tunneled catheter users. Analyzed outcomes were UFR, IDWG, single pool KT/V and normalized protein catabolic rate (nPCR). Data were averaged across months of observation per patient. Patients who used both AV and catheter accesses were self-paired for comparison between access types. Mean differences and 95% confidence intervals (CI) between AV and catheter groups were calculated using 2-sample or paired t-test.

Results: 163 Veterans (age 67.9 years, HD vintage 40 months, 96% male, 87% Black) dialyzed at an outpatient VA HD unit between 8/2013–3/2018. Access use was AVF (n=118), AVG (n=25), and catheter (n=67). 32 patients converted between AVF (n=29) or AVG (n=3) and a catheter. Compared to patients using a catheter, patients using AV access had greater IDWG (275 mL [28-522] p=0.029) and UFR (0.97 mL/kg/hr [0.19-1.76] p=0.016). KT/V was slightly higher in the AV group (0.12 [0.06-0.19] p<0.001); there was no difference in nPCR (0.045 g/kg/min [-0.01-0.10] p=0.10). Similar patterns in IDWG, UFR and nPCR existed in self-paired patients (n=32) between months using AV access (mean 21 months) or a catheter (mean 13 months). Paired comparisons showed significant increases in IDWG (406 mL [135-677] p=0.005) and UFR (1.2 mL/kg/hr [0.2-2.2] p=0.02), with no significant increase in KT/V (0.07 [-0.00-0.13] p=0.055) and minimal increase in nPCR (0.06 [0.00-0.11] p=0.03) in months using AV access.

Conclusions: AV access use associated with increased IDWG (and hence increased UFR), independent of clinically significant gains in nPCR. This effect existed in the broad patient population and for patients who were self-paired to compare outcomes while using AV or catheter access.

PUB161

A Multimodal Patient Education Approach to Catheter Care in a Hemodialysis Unit: Do It Daily

Miten Dhruve. *Nephrology, Michael Garron Hospital, Toronto, ON, Canada*.

Background: Central venous catheters are the leading cause of mortality and morbidity in the dialysis population. Existing educational material is difficult to access ad impractical to use for re-education. By collaborating with patient partners, we have developed novel and innovative multi-modal patient educational materials, to improve patient knowledge, skills and confidence in catheter care.

Methods: Patients were administered a pre-education survey to collect their baseline knowledge, attitudes and skill levels. Educational materials were developed in liaison with patient partners. The materials were based on practice guidelines, and best practice recommendations. Educational materials included: two short videos, posters, easy to understand pamphlets, and fridge magnets using the catchphrase **"Do it Daily".** Post education surveys were conducted to assess their knowledge and skill levels.

Results: Thirty-three patients completed baseline surveys, education program and post education surveys. There was no significant difference in Knowledge or Skill level pre- and post-education survey; however, there was a trend towards increase in patient confidence regarding catheter self-care. Eighty nine percent of patients found the educational material and training easy to understand.

Conclusions: Multi-modal catheter-care educational material did not demonstrate an improvement in knowledge or skill level but was found to be easy to understand. This educational material, which utilizes directed and simplified information, is focused, innovative, and easy to implement.

PUB162

Performance of Machine Learning Model Deployed Within Multidisciplinary Care to Increase Optimal Dialysis Starts in Patients with Advanced Renal Function Loss

Edward M. Lee,[1] Xiaoyan Wang,[1] Ollie Fielding,[1] Jung Hoon Son,[1] Chris Kipers,[1] Tia Y. Yu,[1] Andrew Bohmart,[2] Frank Liu,[2] Jeffrey I. Silberzweig.[2] The PEAK team *[1]pulseData, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: In The Rogosin Institute's PEAK program, a multidisciplinary care team assists patients in making informed, optimal transitions to renal replacement therapy (RRT). The PEAK program educates patients about dialysis options and encourages home modalities and pre-emptive transplantation. In collaboration with a healthcare machine learning company pulseData, a machine learning (ML) model was deployed to systematically identify patients at high-risk of renal failure in the next 6 months and recommend enrollment into the PEAK program. The industry-standard Kidney Failure Risk Equation (KFRE) predicts kidney failure in the next two years, while the ML model predicts progression to eGFR < 10 mL/min/1.73m2 in the next six months. We compare the ML model against the KFRE by contrasting their performance in the Rogosin population.

Methods: Using longitudinal data from the EHR we created an ML algorithm using lab and diagnosis based features and then retrospectively calculated both the KFRE score and ML score as of November 1st 2018. We excluded patients without a recent eGFR value, patients with eGFR < 10, and patients on dialysis.

Results: There were 824 patients scored by the ML model and 644 scored by the KFRE. The patients whose KFRE score could not be calculated were given a KFRE score of 0. Of the 44 patient outcomes, the ML model correctly identified 39 in the top quartile of risk, while the KFRE only identified 28 at the same threshold, a dramatic improvement in sensitivity 89% vs. 64%.

Conclusions: The deployed ML model achieves 40% better precision and sensitivity than the benchmark KFRE. This improvement illustrates that incorporating ML models into clinical practice has greatly enhanced identification of the highest risk patients. Allowing the clinical team to focus on providing patients more access to education, the most important aspect of informed decision making for RRT.

PUB163

A New Idea for Longer Life of Arteriovenous Grafts Using Multidirectional Venous Outflow in Hemodialysis Patients

Manabu Asano,[1] Kenichi Oguchi,[1] Chihiro Kimikawa,[1] Minako Ando,[1] Machiko Okamoto,[2] Hitoshi Iwabuchi.[1] *[1]Bousei Hospital, Saitama, Japan; [2]Ikegami General Hospital, Tokyo, Japan*.

Background: Although a new device has been developed one after another, the status of arteriovenous graft (AVG) survival are far from satisfaction at this moment. As one solution to escape from sudden graft deaths, we have implanted a graft intentionally on axillary vein having multiple branches. The aim of the present study was to prove that our method contributed to the long-term AVG survival.

Methods: Hemodialysis patients who had implanted AVG in upper limbs in our hospital from Feb 2015 to Mar 2019 were recruited. Tapered (4-6 or 4-7 mm in diameter) polytetrafluoroethylene grafts were used in all cases. Branches of the axillary vein were carefully prepared and reserved for second outflow channels as many as possible. The anastomosis size were fixed to almost 15 mm. Primary AVG patency was defined as the time to first intervention, and secondary patency as the time to creation of a subsequent vascular access (VA). The Kaplan-Meier method was used to calculate for each.

Results: Forty-nine ipsilateral axillary AVG operations were done in 42 patients. Mean age was 71 years, with 17 males and 25 females. The median hemodialysis duration was 104 months and the mean follow-up period after operations was 398 days. The average time until the first cannulation was 13 days. There were two early (<30 days) access thrombosis. Any other early accidents were not detected. Forty of the 49 grafts developed late (>30 days) complications: postanastomotic stenosis on the outflow vein in 24 grafts, graft occlusion in 12 grafts, central vein stenosis in 2 grafts, infection in 2 patients. There were radiological intervention in 36 cases and surgical intervention in 4 cases for graft salvage. The primary/secondary patency rate at 6, 12, 24 months were 39.8/82.9%, 14.2/82.5% and 9.5/75.6% respectively. Angiography revealed that reserved venous branches had been working as a substitute for main drainer in some cases with occlusion or severe stenosis on juxta-anastomosis.

Conclusions: In order to avoid complete graft loss, our surgical procedure might be useful to extend the life of the axillary AVG. However, longer-term VA survival required the assistance of radiological and surgical interventional therapies in most cases.

PUB164

Decline in Renal Function-Slow with Fistu "Low"

Pran M. Kar. Department of Nephrology *VA Medical Center Orlando, Orlando, FL.*

Background: We would like to report a small study of 5 male patients with CKD who had undergone preemptive AV fistula placement in preparation for hemodialysis. Patients were subsequently followed for an extended period of time. Our study found a previously little known advantage of AV fistula placement in slowing the rate of decline in renal function(1). Our finding suggests the possibility of a decline in the progression of eGFR in patients with AV fistula.

Methods: In our patients, we used the reciprocal creatinine plot with time after the patients had an AV fistula placed to determine whether the decline in renal function has slowed down and if there is any correlation with age. We studied 5 males who had AV graft establishment in anticipation for need for RRT at the time of placement of the vascular access.

Results: Based on our observation all our patients had a slower decline in their renal function.

Conclusions: Even though our sample size was very small and only male patients, we can establish a signal that the preemptive placement of access for hemodialysis can slow down the decline in renal function. Underlying mechanism is not clear, but improved circulatory hemodynamics is plausible (2). Further studies with a larger more diverse patient population is needed to determine if early fistula creation can indeed delay the onset of renal replacement therapy in patients with advanced CKD. Integrating Engineering Principles in a Medical School Nephrology Curriculum

Jean L. Holley,[2,1] Hyunjoon Kong,[1,4] Eliot Bethke,[4] Kenneth R. Wilund,[3,4] Jennifer Amos.[4] *[1]University of Illinois Urbana-Champaign, Urbana, IL; [2]Internal Medicine, Carle Illinois College of Medicine, Urbana, IL; [3]University of Illinois, Urbana, IL; [4]Carle Illinois College of Medicine, Urbana, IL.*

Background: Nephrologists are concerned about the failure to attract young investigators and clinicians. An innovative curriculum may enhance nephrology's appeal. The Carle Illinois College of Medicine (CICOM) enrolled its first class of 31 students in 2018. CICOM integrates a traditional medical school curriculum with engineering, technology, innovation, ethics and humanities with the goal of developing physician innovators.

Methods: The entering class is 45% women, 71% engineering degree graduates with 39% having advanced degrees and a mean age of 26 yr. The 4 yr curriculum has 3 phases; phase 1 is 18 mo of problem-based learning (PBL) presenting the basic science medical areas by organ systems. The renal course was developed by a nephrologist, a basic scientist, and an engineer. The course is 5.5 weeks organized around 6 PBL cases (a living kidney donor and his brother with ESRD, cardiorenal AKI, rhabdomyolysis ATN, diabetic nephropathy, SIADH, and recurrent kidney stones). The engineering curriculum occurs simultaneously with the PBL cases: GFR and glomerular hemodynamics with the living donor case, mass transport and quantification with the AKI cases, flux and hemodialysis membranes with the ATN case, and crystallization kinetics with the kidney stone case. Engineering labs present boundary value problems from a clinical perspective to illustrate physiologic principles, e.g., estimating GFR with blood and osmotic pressures using Starling's law, determining maximum reabsorptions using the Michaelis-Menten equation, filtration using Darcy's law and dialysis membrane properties, and citrate modulation of kidney stone growth via kinetics and thermodynamics. Matlab and Simulink are used to study the physiology and chemistry of kidney filtration and realistic clearance responses to a variety of drugs and other solutes based on Huang's model (Pharmacometrics Syst. Pharmacol 2018;7:593-602).

Results: Weekly quizzes include basic and clinical science material as well as topics covered in the engineering labs. The mean score on the 5 weekly quizzes was 76±5% with a mean of 85%±26% on the engineering questions.

Conclusions: Engineering principles can be utilized to expand the approach and understanding of basic science learning topics in nephrology and may serve as a spark of curiosity for medical students to consider careers in nephrology.

PUB166

Active Learning and Clinical Integration to Promote Knowledge and Interest in Nephrology

Jean L. Holley,[1,2] Kenneth R. Wilund,[3] Hyunjoon Kong,[1] Eliot Bethke,[4] Jennifer Amos.[4] *[1]University of Illinois Urbana-Champaign, Urbana, IL; [2]Internal Medicine, Carle Illinois College of Medicine, Urbana, IL; [3]University of Illinois, Urbana, IL; [4]Carle Illinois College of Medicine, Urbana, IL.*

Background: Innovative strategies are suggested to promote interest in nephrology. Educators stress active learning as a way to create interest and knowledge retention. The 2018 opening of a new medical school (Carle Illinois College of Medicine, CICOM) integrating engineering, technology, innovation, ethics and humanities with early clinical exposure prompted us to design a 5.5 week nephrology course incorporating multiple forms of active learning into an organ system based curriculum.

Methods: Three course directors (a nephrologist, a basic scientist, and an engineer) developed the course. CICOM uses a problem-based curriculum (PBL) spanning 18 mo in which all traditional yr 1 and 2 medical school courses (with the addition of engineering and ethics/humanities) is covered. Five weekly quizzes and a comprehensive exam (n = 61 items) comprised of retired questions from Step 1 NBME exams were the evaluation tools. Six PBL cases, 1TBL (team-based learning on renal embryology), 3 engineering labs, 1 anatomy lab, and a patient interview (adolescent on CCPD) sessions were required. Optional sessions included: 3 physiology, 1 histopathology, 1 pathology, 11 clinical pathophysiology lectures, 7 short clinical case discussion sessions, and 1 journal club (tissue sodium). Clinical lecture topics were: U/A and kidney function*, urology, acid-base and K**, AKI*, disorders of Na*, measuring volume status, CKD*, GN*, stones, renal imaging, urinary tract infection, and renal nutrition (* indicates a session based on multiple short clinical cases on this topic also occurred).

Results: Student feedback was especially positive for the patient interview, short case discussions, the engineering lab on dialysis membranes, and the pathophysiology lectures which were attended by an average of 9-15/31 students. Class mean score on the comprehensive exam given after 7 mo of medical school was 74% with a mean of 77% by the NBME nationwide average (taken after 24 months of medical school). Class scaled score was 70 ±8 (SD).

Conclusions: Based on NBME scores, our students' knowledge after a 5.5 month course was comparable to the nationwide score obtained after 2 yrs of medical school. Students were positive about opportunities for active learning. It is hoped that early clinical exposure to nephrology via active learning sessions and engineering labs will enhance interest in the field.

PUB167

Virtual Reality and Education: A Framework to Guide Development and Integration

Georges Nakhoul,[1] Jonathan J. Taliercio,[2] Ali Mehdi,[3] Remy Daou,[4] John R. Sedor,[3] Joseph V. Nally,[3] John F. O'Toole,[3] S. beth Bierer,[3] Wendy M. Green.[5] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Glickman Urological and Kidney Institute, Cleveland, OH; [3]Cleveland Clinic, Mayfield Hts, OH; [4]Saint Joseph University, Beirut, Lebanon; [5]Cleveland State University, Cleveland, OH.*

Background: Recent advances in technology have lead to the creation of innovative teaching tools such as immersive simulations. With funding from the American Society of Nephrology, we are building a Virtual Reality (VR) platform aimed at delivering renal physiology content to medical students, internal medicine residents, and nephrology fellow. The content will be adapted to the level of the learner. In order to guide our project, we elected to develop a framework that can serve as an example to other similar endeavors.

Methods: We performed a literature review in order to determine the different factors needed to successfully develop and integrate an educational curriculum onto a VR platform. We then organized them into a guiding framework that we summarize below.

Results: Our model is learner-centric and encourages the learner to contribute both to the development of the curriculum and to the testing of the VR platform. The curriculum stems from an identified need and is developed with the assistance of both the facilitator and the learner. The platform development requires technical support that can be offered by institutional departments such as bio-engineering and bio-illustration. The relation between the learner and the facilitator is collaborative. In our particular case, we elected

to use problem-based learning cases and grounded our instructional methods in andragogy and constructivism. This part can be adapted to the particular need of the program. The end-goal is to impact learner knowledge with the intention to lead to a change in learner behavior and ultimately patient outcomes (See figure 1).

Conclusions: We offer a framework to guide the development and integration of an educational curriculum into a Virtual Reality (VR) platform.

PUB168

Can Twitter Help Shape the Future of Point-of-Care Ultrasonography in Nephrology?

Abhilash Koratala,[1,2] Deepti Bhattacharya,[3] Amir Kazory.[2] *[1]University of Texas Health, San Antonio, TX; [2]University of Florida, Gainesville, FL; [3]Reed Elsevier, San antonio, TX.*

Background: While there has been a renewed interest in the nephrologist-performed point of care ultrasonography (POCUS), standard guidelines for its practice (e.g. identification of the enablers and barriers) are lacking. Social media play an ever-increasing role in contemporary medical education; they can be powerful tools for shaping the future of emerging skills such as POCUS. Twitter provides a unique platform to gather opinions of health care professionals (HCP) from various specialties and geographic locations. We sought to explore whether Twitter polls can be used as a needs assessment tool to enhance data on the practice of POCUS.

Methods: We composed a series of 12 Twitter polls over a 36-day period (consisting of up to 4 options) accessible for 3 days each. The pre-planned questions were tweeted on a regular basis from a single handle with over 1000 followers. All questions contained the hashtag #POCUS to increase their dissemination and obtain responses from the intended HCP. The distribution of the responses was stored and analyzed after completion of the study.

Results: The median number of responses per poll was 83. Sixty-three percent of respondents opined that attending live workshops is the best way to start learning POCUS, and 49% preferred a 1-week hands-on supervised program to acquire confidence in scanning. Interestingly, half of the participants identified fear of missing pathology as the prime hurdle for nephrologists performing 'comprehensive' renal sonography. On a note of caution, 39% reported that they have personally seen a case of inadequate POCUS harming the patient. The abridged version of the questions and responses is presented in Figure 1.

Conclusions: This pilot study suggests that Twitter polls could efficiently provide valuable information regarding needs assessment and program development in emerging fields such as POCUS. Capture of an audience with a wide range of expertise at low or no cost is the advantage, while it does portend inherent limitations of survey-based research.

@NephroP POCUS

No.	Question	n	Option 1 (%)	Option 2 (%)	Option 3 (%)	Option 4 (%)
1	Best way to start learning POCUS	209	Workshops (63)	Colleague (16)	Other specialist (4)	Online resources (17)
2	Best way to acquire skills initially	57	Scan patients on own (30)	Observership (11)	1 week Hands-on (49)	Shadow EM doctor (10)
3	Willing to teach POCUS to other faculty	69	Yes (91)	No (7)	Other (2)	-
4	Minimum scan needed for competency	154	25 (39)	15 (8)	40 (40)	Other (13)
5	Preferred self-study resource	84	YouTube (39)	Twitter (36)	Blog posts (10)	Text books (15)
6	Ideal time for a POCUS-teaching video	87	<10 min (68)	Up to 20 (23)	Up to 30 (3)	Up to 1 hour (6)
7	How long it takes for volume assessment using POCUS	105	<5 min (50)	6-10 (34)	>10 (10)	Other (6)
8	How do you estimate LV ejection fraction on echo	82	Eye ball only (57)	Eye ball + Mitral M-mode (28)	Eye ball + fractional shortening (10)	Simpson method (5)
9	Do u routinely scan posterior lung zone	56	Yes (64)	No (32)	Other (4)	-
10	Major hurdle for doing 'comprehensive' renal ultrasound	58	Radiology push back (19)	Hospital privileges (7)	Missing pathology (50)	Time consuming (24)
11	Most worried consequence of nephrologist-performed POCUS	61	Poor image quality (10)	Wrong interpretation (59)	Not obtaining formal study when indicated (13)	Missing incidental findings (18)
12	Aware of any instances where inadequate/inappropriate POCUS harmed a patient	98	Yes (39%)	No (61%)	-	-

PUB169

A Healthcare Matrix Conference Enhances Nephrology Teaching of Interpersonal Communication, Professionalism, and Systems-Based Practice

Gregory L. Braden,[1] Amanda Duda,[1] Daniel L. Landry,[1] Reham Shaaban,[2] Anthony E. Poindexter.[1] *[1]University of Massachusetts Medical School-Baystate, Springfield, MA; [2]Baystate Medical Center, Springfield, MA.*

Background: A Healthcare Matrix was created to link the Institute of Medicine (IOM) aims assessment of patient care quality to the ACGME 6 core competencies (CC) of Patient Care (PC), Medical Knowledge (MK), Interpersonal and Communication Skills (ICS), Professionalism (PRO), Systems-Based Practice (SBP) and Practice Based Learning & Improvement (PBLI) (Jt Comm J Qual Patient Saf, 31:98, 2005).

Methods: Each patient case is evaluated in the presence of all patient care stakeholders, attendings, fellows and nurses. Using a spreadsheet, each CC is evaluated using IOM criteria as to whether the patient case is safe, timely, effective, efficient, equitable, & patient-centered.

Results: A summary of the number of quality issues per case with the number of interdisciplinary teams involved is presented in the table below. The number of teams averaged 3 per case. We found that a disagreement between teams on how best to manage the patients' primary nephrology disorder often lead to a breakdown in ICS, PRO and SBP in all patients' cases. The average teaching points per patient case was 2 for ICS & SBP and 1 for PRO. At the end, a consensus from all participating members created definitive PBLI guidelines for each patient's case.

Conclusions: The use of a Healthcare Matrix format for Nephrology M&M conferences creates significant learning opportunities for interdisciplinary discussions and for simultaneously teaching ICS, PRO and SBP not found in any other format for nephrology training.

Summary of Core Competency Teaching Points Per Case

Disorder	PC	MK	ICS	PRO	SBP	PBLI	# of teams
Pregnancy HUS	1	2	2	2	3	2	4
Renal infarct	1	2	2	2	2	1	3
ESRD options	1	1	2	1	1	2	3
CRRT timing	2	1	3	1	2	2	3
Myeloma kidney	1	2	2	1	2	2	3
Pontine myelinolysis	2	2	2	1	3	2	2
ECMO/LVAD/AKI	2	2	2	1	2	2	4
Lupus nephritis therapy	1	2	1	0	1	1	3
Dialysis withdrawal	1	0	2	1	1	1	3

Continuing Education Improves Health Care Provider Knowledge and Competence in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Dana Ravyn,[1] Beth Goodwin,[1] Rob Lowney,[1] Arlene B. Chapman.[2] *[1]CMEology, W Hartford, CT; [2]University of Chicago, Chicago, IL.*

Background: Little is known about the familiarity, knowledge, and competence of nephrologists or other health care providers regarding management of patients with ADPKD. It is unclear what impact continuing education (CE) has on this topic.

Methods: Learners were invited to participate in a multimedia online certified CE activity launched in March 2018. Participants completed pre-activity and post-activity assessments. We measured commitment to change and confidence before and after the activity. Results were analyzed using the chi-square test and Cohen's *d*.

Results: There were 3,799 participants, of whom 954 completed posttests. Twenty percent were physicians, 61% were nurses or physician assistants, and the remainder were other types of providers; the most common specialties were family medicine/internal medicine, nephrology, surgery, and critical care/emergency medicine. On completion, participants had increased confidence in achieving the aims of the learning objectives. Confidence in ADPKD-related practices increased after the activity, including overcoming barriers, translating evidence into care, and improving outcomes (Cohen's d=0.319-0.374). Ten multiple-choice questions/vignettes evaluated learning in pathogenesis, genetics, imaging, diagnosis, and management. Educationally and statistically significant improvements (P<0.001) were seen for all questions. For all participants, the mean increase in score from pretest (n=1086) to posttest assessment (n=954) was 59.0% (SD=3.2; range 43-79); results for nephrology participants were not substantially different from others. Importantly, baseline scores were low in all participants and the nephrology group, suggesting suboptimal knowledge of ADPKD. Among nephrology and all participants, the mean baseline scores were 33.4% (SD=3.9) and 30.0% (SD=3.5), respectively, and the mean posttest scores for nephrology and all participants were 85.8% (SD=2.5) and 89.0% (SD=1.7), respectively.

Conclusions: A CE activity effectively improved confidence, knowledge, and competence among providers who diagnose and manage patients with ADPKD. Baseline scores were low for all participants, suggesting the need for further education and increased awareness of ADPKD, especially given the evolving role of risk assessment for disease progression and the availability of disease-modifying therapy.

PUB171

Analysis of the Official ASN Hashtag #KidneyWk: How It Has Changed Outreach and Medical Education

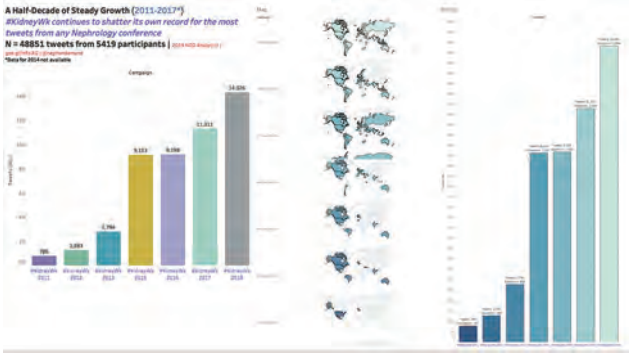
Hector M. Madariaga,[1] Edgar V. Lerma,[2] Tejas Desai.[3] [1]*Good Samaritan Medical Center, Brockton, MA;* [2]*Associates in Nephrology, SC, Berwyn, IL;* [3]*NOD Analytics, Charlotte, NC.*

Background: The official hashtag of the ASN is #KidneyWk. Since its inception in 2011, #KidneyWk has been an efficient channel for conference communications and an easy tool to use among attendees using social media (#SoMe) as an education tool. It has been a great connection for people who are unable to attend the live meeting.

Methods: Searching the @nephondemand database for tweets composed during #KidneyWk from 2011-2018, including total number of people tweeting, gender, location and total number of tweets.

Results: Since 2011, the number of social media (#SoMe) nephrology educators using the official #KidneyWk, has grown exponentially. Cumulatively, a total 5,419 #SoMe educators have tweeted 48,851 tweets. Each year #KidneyWk breaks its own previous record. #SoMe educators from Latin America and South Asia have increasingly contributed to the online learning in the last few years. In 2017, ASN made a policy change allowing attendees to take pictures during presentations, increasing engagement among attendees. Additionally, this change increased the number of multimedia tweets, thereby increasing the information density of each tweet. Female #SoMe educators were early adopters of #KidneyWk, but have not reached gender parity since that time.

Conclusions: #KidneyWk has been extensively used by ASN members attending Kidney Week. Since its creation the #SoMe community has increased in activity and has provided valuable educational material for learners globally. The #KidneyWk community of learners and educators is a great way to connect nephrologists around the world.



Global participation during Kidney Week. As seen in the figure, it has continued to grow since 2011

PUB172

Goal-Directed Protocol with Educational Approach Prolongs Continuous Renal Replacement Therapy (CRRT) Filter Life

Catherine C. Wells, Divya Monga, Neville R. Dossabhoy. University of Mississippi Medical Center Division of Nephrology *University of Mississippi Medical Center, Jackson, MS.*

Background: One of the biggest challenges faced in CRRT is sustaining the continuous extracorporeal circuit for the duration of therapy, in order to deliver the prescribed dose. There are many ways to prevent premature loss of the CRRT circuit (i.e. clotting and clogging). Our center has defined a CRRT protocol to deliver optimal CRRT while preventing premature loss of the circuit.

Methods: We collect and analyze Quality Assessment and Performance Improvement (QAPI) data on all CRRT treatments performed with the Baxter PrismaFlex ™ CRRT machine using Baxter TrueVue Analytics ™ QAPI outcome measures include average filter life, reasons for early loss of filter and delivered CRRT dose. Average filter life (the running hours per filter for every filter used averaged per month) is reviewed as a trend. Beginning October 2017, we observed a negative trend in above indices and hence we changed our education strategy for teaching and adherence to our protocol. We historically provided general education for all medical providers and nurses (dialysis, ICU) on CRRT concepts and the institutional protocol, annually. Starting October 2017, the education frequency was increased (every 1 to 2 months). In addition, QAPI outcomes data were included in the education, and education was added to the EMR ordersets in a format easily seen by ordering providers. Our last educational intervention was use of the new education-enhanced ordersets in August 2018.

Results: In 2017, we had noticed negative trends in our monthly average filter life. In 2018, after our final intervention, and strict adherence to our protocol, our average filter life trends improved. The average filter life for the quarter before the first intervention (April-June 2017) was **38.3 hours/filter**. The average filter life for the quarter after the last intervention (October - December 2018) rose to **53.7 hours/filter**. Throughout the intervention, average delivered dose of CRRT was 24-26 mL/kg/hour.

Conclusions: Implementing an educational strategy in response to QAPI outcomes, using a goal directed approach, improved CRRT filter life. Close monitoring of data trends, adaptable action plans and frequent education are the key elements to a successful QAPI program.

PUB173

Development of Tools Addressing Early CKD Management by Primary Care Providers

Gerren Hobby,[1] Andrea K. Easom,[1] Manisha Singh.[1,2] [1]*University of Arkansas For Medical Sciences, Little Rock, AR;* [2]*Nephrology, CAVHS, Little Rock, AR.*

Background: Of 400,000 Arkansans with Chronic Kidney Disease(CKD), only 10% are aware of it. Nephrologists can do a variety of things to improve chronic kidney disease (CKD) care, however, we see patients at late stages. Primary care providers (PCPs) offer the first line of defense against CKD and are pivotal in early diagnosis and management, including timely referrals. When addressed early, a fairly short list of measures could greatly improve outcomes for the patients. Our hypothesis is that PCPs could provide even higher quality care if given the tools to manage CKD easily. We aimed to develop a checklist of high-yield measures for CKD management which can be used by PCPs and their patients during an office visit. Making PCP's aware of the multiple ICD codes that can be used in the complex CKD care, along with the literature behind these recommendations would further enhance care.

Methods: A 10-point checklist of CKD management recommendations was designed by a core group of Nephrologists at UAMS. The list underwent content validation and revisions by a multidisciplinary group. This was pilot tested in a small group of PCPs. The checklist system includes : 1. Ten 'CKD talking points' for patients 2. A Ten point guideline-driven checklist for PCPs 3. Companion supporting explanations of each recommendation for PCPs. 4. ICD 10 codes with average reimbursement data for components of a primary care visit 5. Feedback forms

Results: The CKD Management Checklist system is an interactive platform designed for use during clinic visits with PCP's. The system addresses talking points with patients as well as guideline-based management recommendations for the providers. Initial feedback had been overwhelmingly positive, with additional comments about further needs of the primary providers.

Conclusions: A system of early CKD care and management tools using checklists has been developed to help provide guideline-based care in primary care settings. These are planned to be further tested and disseminated widely encouraging early care and closer collaborations between nephrologists and PCPs. Future plans include adding these to electronic medical health records and to provide continuing medical education credits to providers. CKD management checklist system has been developed to efficiently transfer evidence-based guidelines from nephrologists to PCPs and from PCPs to their patients.

PUB174

Teaching Point-of-Care Ultrasonography: Description of a Novel Curriculum for Faculty and Fellows

Daniel W. Ross,[1] Rushang Parikh,[1] Shamir Hasan,[2] Mala Sachdeva.[1] [1]*Zucker School of Medicine at Hofstra/Northwell, NY, Manhasset, NY;* [2]*Northwell Health, Port Washington, NY.*

Background: Ultrasound machines are becoming more portable and affordable. The increased availability of ultrasound machines has led many physicians to use point of care ultrasonography (POCUS) as an extension of physical examination. In Nephrology, POCUS has been used to image the kidneys and bladder and assess volume status. Here we describe a curriculum we used to orient faculty and fellows to an ultraportable ultrasound device.

Methods: We designed a three-hour curriculum for faculty and fellows. The course began with a review of ultrasound physics including discussion on frequency, reflection, attenuation. Next, knobology was discussed giving focus to the importance of depth and gain. Following these didactics, we performed a live demonstration using a hand-carried ultraportable ultrasound device. We demonstrated what we call the Renal Focused Ultrasound Exam (ReFUsE) which includes imaging of the kidneys, bladder, and lung. During the ReFUsE demonstration we reviewed optimal strategies for image acquisition and reviewed basics of image interpretation including how to identify hydronephrosis and how to interpret artifacts arising from the pleural line. Learners then had approximately one hour of hands on practice doing a ReFUsE on a standardized patient guided by an expert in POCUS. We maintained a 4 to 1 learner to expert ratio. The course concluded with an exercise where learners interpreted normal and abnormal images.

Results: Narrative feedback by learners was that the course was a good introduction but most felt that additional supervised practice would be required in order to attain proficiency in both image acquisition and interpretation.

Conclusions: POCUS is becoming more prevalent in nephrology practice. The optimal strategy for training faculty and fellows in POCUS is not clear and has yet to be defined. Here we described our introductory approach. Initial training should be followed up by continued direct observation by experts before proficiency can be achieved

PUB175

Trends in Twitter Coverage of Nephrology Conferences Through Novel Indices of Impact

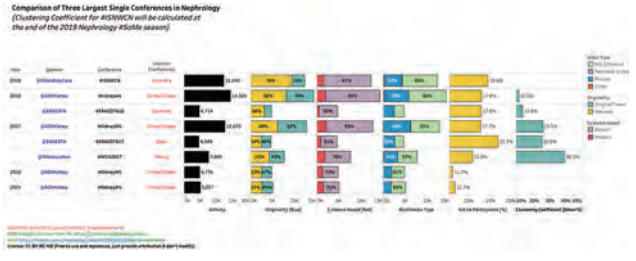
Carlos Cortes,[4] Gopal Basu,[1] Urmila Anandh,[2] Arvind Conjeevaram,[3] Fernanda Arce-Amare,[8] Sarah Gleeson,[5] Edgar V. Lerma,[9] Hector M. Madariaga,[6] Michal Malina,[7] Didem Turgut,[10] Sibel Bek,[11] Sanjeev Nair,[13] Gireesh M. Siddaiah,[12] Zoran Paunic,[14] Ana C. Pastor,[16] Tejas Desai.[15] @ISNEducation Social Media Team *[1]Alfred Hospital, Monash University, Melbourne, VIC, Australia; [2]Yashoda Hospitals, Hyderabad, India; [3]Bangalore Hospital, Bangalore, India; [4]Puerto Rico Kidney Care, San Juan, PR; [5]Middlemore hospital, London, United Kingdom; [6]Good Samaritan Medical Center, Brockton, MA; [7]Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [8]International Society of Nephrology, Mexico City, Mexico; [9]Associates in Nephrology, SC, Berwyn, IL; [10]Amasya State Hospital, Amasya, Turkey; [11]Kocaeli University School of Medicine, Kocaeli, Turkey; [12]M.S. Ramaiah Medical college, Bangalore, Bangalore, India; [13]Saveetha Medical College and Hospital, Chennai, India; [14]Special Hospital for Haemodialysis Fresenius Medical Care, Belgrade, Serbia; [15]NOD Analytics, Charlotte, NC; [16]Hospital Nacional Guillermo Almenara Irigoyen, Trujillo, Peru.*

Background: Social Media (#SoMe) helps in real-time, worldwide interactive distribution of knowledge from medical conferences. While conventional analytics provide a simple view of the Twitter activity of a conference, novel analytics provide insight and a framework for the assessment of innovative #SoMe strategies.

Methods: Twitter metadata of Kidney Week (2015-2018), ISN WCN (2017-2019) and ERA EDTA (2017-2019) was analysed by NOD Analytics (& Symplur) for % of original tweets, evidence support (tweets with link to evidence), multimedia (tweets with images, videos, audio files), percentage of active participants (>1 tweet/day), clustering coefficient (measure of connection amongst tweeters), and global reach.

Results: Nephrology conference Twitter activity has seen significant growth in the last 5 years. Kidney week recorded the highest number of tweets in 2018. ISN WCN had the greatest growth in Twitter activity from 2015 to 2019 (266 to 12240). The proportion of original tweets improved, with ISN WCN leading at 76% in 2019. An increase in multimedia content was common, with ISN WCN leading in the proportion of novel content such as poster interviews (n=259 (2017), 662 (2019)) and live visual abstracts in 2019. The percentage of evidence supported tweets remained <30% for all. Active participation increased from 11% in 2015 to ~20% with ERA EDTA 2017 and ISNWCN 2019 at the forefront. The clustering coefficient was highest for ISN WCN at 39.1%, indicating excellent tweeter-interaction. ISNWCN reached out to >90 countries across all the continents.

Conclusions: In-depth analysis of Twitter metadata of nephrology conferences with novel metrics indicates a considerable growth in both quantity and quality of conference coverage. The ISN WCN, with a dedicated #SoMe team, organised approach, novel strategies, society's support and peer interaction, leads in several metrics and delivers significant global academic impact.



Twitter performance metrics of nephrology conferences

PUB176

Welsh Kidney Club: Trainee-Led Development of a National Online Renal Community

Alexa Wonnacott,[1] Charlotte V. Brown,[2] Rhodri Pyart.[3] *[1]Cardiff University, Cardiff, United Kingdom; [2]Department of Nephrology & Transplant, University Hospital of Wales, Cardiff, Cardiff, United Kingdom; [3]Cardiff and Vale Health Board, Swansea, United Kingdom.*

Background: Renal Training in Wales is conducted across a single deanery with a strong national identity, but wide geographic spread can restrict opportunities to collaborate and network, leading to practice variation across centres and a diminished sense of community amongst trainees, which may negatively impact our ability to recruit new doctors.

Methods: We sought to create a trainee-led e-resource to promote inclusivity and equity of access to all training materials via: **A bespoke website - www.welshkidney.org** -"WKC Quick Guides" : Bullet-point guidance for daily encountered challenges (e.g. Management of IgAN) composed by individual trainees as Quality Improvement projects -Videos of renal simulation scenarios and interventional procedures performed by trainees -Renal diary of upcoming abstract deadlines/events -Research profiles demonstrating the breadth of available opportunities and promoting collaborative research ventures **Facebook** -Multidisciplinary "closed group" community where ideas and messages are shared **Twitter** -An international platform to showcase the work of the Welsh nephrology community and interact with the wider renal world Formal evaluation of the above web resources was conducted via electronic survey 6 months following initial launch.

Results: Google analytics showed >600 unique visitors to the website. The facebook group has 98 members, with excellent multi-disciplinary team (MDT) and multi-centric representation. @Welshkidneyclub twitter page has 215 followers, inclusive of renal institutions, charities and patient groups. 82% of the 60 survey respondents from across the renal MDT rated the website "very useful". Moreover, following a year with no nephrology applicants in Wales, 50% of our current junior doctors have expressed an interest in applying to nephrology training in Wales, 100% of whom have accessed the website to explore the opportunities presented.

Conclusions: The landscape of speciality training is rapidly evolving, with social networks increasingly accessed by trainees as channels for collaboration and learning. Using the tools presented here, we have empowered our MDT to establish the foundations of a national renal community, providing support to geographically isolated trainees. Outward presentation of a unified, inclusive training programme is essential to attract new trainees in the current global nephrology recruitment crisis.

PUB177

Enhancing Twitter's Educational Value for Point-of-Care Ultrasonography in Nephrology: A Reach Analysis

Abhilash Koratala,[3] Deepti Bhattacharya,[1] Amir Kazory.[2] *[1]Reed Elsevier, San antonio, TX; [2]University of Florida, Gainesville, FL; [3]UT Health, San Antonio, TX.*

Background: Point-of-care ultrasonography (POCUS) is an emerging field within nephrology; a novel educational tool may conceivably help its more widespread acquisition. While Twitter is an appealing platform to share POCUS-related material succinctly, the factors leading to higher engagement of the healthcare professionals with the tweets have yet to be identified. Using a twitter handle dedicated to POCUS (i.e. @NephroP), we sought to explore the impact of visual content [tweets with infographics vs. plain images], subtopic [renal POCUS vs. fluid volume assessment] and adding a well-known hashtag (#) in medical education (i.e. #FOAMed) to #POCUS on the reach of the tweets.

Methods: The potential reach of a tweet is estimated by the 'impressions' (I^o) and 'engagements' (E^o) defined as the number of times users saw the tweet and interacted with it respectively. One other helpful metric is the number of times a tweet has been reposted by another user, i.e., 'retweets' (R^o). We analyzed the 'top 15' tweets from the @NephroP handle over a 90-day period (February 20, 2019 to May 20, 2019) using built-in Twitter analytics.

Results: Interestingly, 100% of the top 15 tweets contained an image. The mean number of Io, E^o and R^o earned was 7823, 680.5 and 35.7 respectively. There was no difference in reach indicated by I^o (8362 vs. 6741, p= 0.35), E^o (785.2 vs. 471.2, p=0.17) or R^o (38.4 vs. 30.4, p= 0.35) between tweets containing infographics and those without. Tweets about urinary tract POCUS and those about volume assessment did not differ in Io (7788 vs. 8180, p=0.88), E^o (594.8 vs. 752.4, p=0.55) or R^o (36.2 vs. 37.1, p=0.91). Similarly, there was no difference between tweets with or without the hashtag #FOAMed in I^o (6969 vs 8798, p=0.26), E^o (557.4 vs 821.3, p=0.23) or R^o (32 vs 40, p=0.32).

Conclusions: Similar to reported data from general users, all top POCUS-related tweets contained an image. However, contrary to what would be expected for an image-based communication, presence of infographics or addition of an education-related hashtag does not seem to change the engagement of POCUS audience or dissemination of the content. The Twitter's built-in analytics represent a readily accessible means to enhance its educational value through identification of the factors that boost engagement of the audience in less well established fields such as POCUS.

PUB178

Point-of-Service Ultrasound in a Nephrology Clinic

Andrea L. Houze,[2] Inhae Baek,[2] Richard Amerling.[1] *[1]St. George's University School of Medicine, Great River, NY; [2]St. George's University, Grenada, West Indies, Springfield, ON, Canada.*

Background: Ultrasound is a versatile diagnostic tool but access and cost limit its use in Grenada. Technological advances have led to smaller, affordable probes that work with smart phones. We report our initial experience with point-of-service ultrasound as an aid to diagnosis and disease management in the setting of our busy public Nephrology Clinic at the Grenada General Hospital.

Methods: 17 random clinical encounters were evaluated in which patients underwent a medical history, physical examination, and urine dipstick testing, leading to a preliminary diagnosis. Point-of-service ultrasound using a Butterfly IQ probe attached to an iPhone 8 Plus was then performed to either confirm or alter the diagnosis.

Results: Ultrasound confirmed 12/17 diagnoses and led to 4/15 new diagnoses. One study was inconclusive (Table 1).

Conclusions: Point-of-service ultrasound is an effective diagnostic modality in the Nephrology Clinic. There is a steep learning curve associated with its use by ultrasound-naïve clinicians. With increased experience, the potential to improve diagnostic accuracy, and thus outcomes, is limitless.

Table 1. Results with Point-of-Service Ultrasound

Patient	Clinical Diagnosis	Ultrasound Findings
A	Nephrolithiasis with hydronephrosis	No stone seen
B	Metabolic syndrome	Hepatic steatosis
C	Metabolic syndrome	Hepatic steatosis
D	Metabolic syndrome	Hepatic steatosis
E	Enlarged thyroid	Diffusely enlarged thyroid; no cyst or mass
F	Metabolic syndrome	Hepatic steatosis
G	Acute on chronic kidney failure	Renal cyst; no hydronephrosis
H	CKD with suprapubic catheter	No hydronephrosis
I	Metabolic syndrome	No significant findings: normal liver
J	Renal cyst	Large benign renal cyst
K	Hypertensive cardiac and renal disease	Left ventricular hypertrophy, reduced ejection fraction
L	Metabolic syndrome	Hepatic steatosis
M	ESRD; right pleural effusion?	Large right pleural effusion
N	CKD 3; Rt. sided CHF	Right pleural effusion, enlarged RV
O	Ventral hernia	Inconclusive
P	PD catheter exit site/tunnel infection	Tunnel abscess
Q	Uremic pericarditis; calciphylaxis	Moderate pericardial effusion; cardiac calcification

PUB179

Nephrology Education and the Use of Social Media Among Irish Nephrologists

Laura M. Slattery,[1] Sinead Stoneman,[1] Ted J. Fitzgerald,[2] Matthew A. Sparks,[3] Silvi Shah,[4] Swapnil Hiremath,[5] Sean F. Leavey,[1] Catherine M. Brown.[1] *[1]University Hospital Waterford, Dublin 4, Ireland; [2]Royal College of Physicians of Ireland, Waterford, Ireland; [3]Duke University and Durham VA Medical Centers, Durham, NC; [4]University of Cincinnati, Cincinnati, OH; [5]University of Ottawa, Ottawa, ON, Canada.*

Background: Recent advances in technology allow instantaneous access to online resources such as journal articles, social media (Facebook, Twitter), blogs, visual abstracts and videos. These can now be accessed by anyone with a desire to share information, learn, or to highlight recent advances in the field. The aim of this study was to evaluate the use of educational tools in the Irish nephrology community and the extent of the use and attitude towards social media as a learning modality.

Methods: We conducted an online survey of Irish nephrologists and nephrology fellows which was disseminated via e-mail with 25 questions. These included the delivery of teaching at institutional level, ranking of educational resources, use of Twitter to seek nephrology resources and the appeals and pitfalls of social media in education.

Results: The response rate was 60%. There were 52 respondents (28 female) 18 consultants, 29 SpRs/fellows on a training scheme and 5 in stand-alone posts. 36 were<40 years old. 92% used "UptoDate" and 90.4% accessed journal articles online. 45.2% ranked "UptoDate" as their top resource, 29% ranked online journals, 24% ranked Twitter as their top resource. 51% use handheld devices to access these resources and 98% accessed these from home. 77% have a Twitter account, and 60% use it as an educational resource.33% of these respondents use Twitter daily. 91% were familiar with NephJC (33% have participated in/reviewed NephJC) and 86% with NephMadness. 85% were attracted to social media as an educational resource based on educational benefit, 78% on the basis of up to date information and 73% for the breadth of international opinion. In terms of pitfalls, 54% felt it is too easy to get lost in the volume of information, 48% cited concerns about confidentiality and 40% felt information was unreliable.

Conclusions: The utilisation of online resources and FAOMed among Irish nephrologists who responded to this survey is common. There is a high level of engagement with the use of social media, particularly Twitter, across all age groups. Future steps to improve engagement can be done with Irish fellows through Twitter, engagement with the NSMC internship and the introduction of a "Staying Connected in Nephrology" installation at our national conference with a plan to re-survey respondents in the next year

PUB180

Can Empathy Be Taught? Assessing Training Received in Chronic Renal Failure Diagnosis Delivery

Alice Doreille,[1] Eve Vilaine,[1] Xavier Belenfant,[2] Ziad Massy,[1] Yosu Luque,[1] Eric Rondeau,[1] Dan Benhamou,[1] Hélène François.[3] *[1]Assistance Publique - Hopitaux de Paris, Paris, France; [2]CHI André Grégoire, Montreuil, France; [3]CH Tenon, Paris, France.*

Background: The announcement of chronic kidney disease has a major impact on patients. Yet, the delivery of this diagnosis is not formally taught or even discussed within our medical curriculum. To fill this training gap, we set up a training course of chronic renal failure diagnosis delivery for residents in 2016. In this study, we evaluate the impact of this training over the years.

Methods: We evaluated participants' satisfaction in the training as well as the impact of the training on their clinical practice. A satisfaction questionnaire was submitted to all participants immediately after the training and in spring 2019. Self-questionnaires were used to assess participants' empathy, based on the Jefferson scale of empathy (from 20 to 140) before the training and immediately after. During spring 2019, we submitted an online questionnaire to assess empathy levels in residents and senior nephrologists in the Paris area.

Results: 46 residents were trained over 6 sessions through role play. 52 residents of the Paris area filled out the empathy questionnaire online. Half of them had received the training 5 to 34 months before. The other half didn't attend the training. 66 senior nephrologists with different types of practises took part in the study. 97% of the respondents rated the formation as either essential or very useful for their clinical practice. 76% of respondents considered the training to have a long-lasting effect on their clinical practice. Empathy scores using the Jefferson scale were similar in untrained and pre-training residents. Post training, participants' empathy score significantly improved and was sustained several months afterwards. Average empathy score for senior nephrologists was in between the untrained/pre-training residents and the post-training residents, with no significant difference.

Conclusions: Patient-centred care requires willingness to listen, empathy and kindness. These skills are thought to be innate and instinctive, but they can be learned and should be taught within the medical curriculum. Role-play and simulation are easy and effective ways of teaching this. It helps participants take a step back from their day-to-day practice. Being invited to play the patient role may also help participants understand the patient's position, pain and concerns.

Funding: Government Support - Non-U.S.

PUB181

A Different Technique: Real-Time Ultrasound Guidance Percutaneous Renal Biopsy Using the Perpendicular Needle Trajectory in a Training and Reference Center

Marcos G. Nava,[1] Jovanni C. Santana,[2] Bernardo Moguel.[2] *[1]Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico; [2]Instituto Nacional de Cardiologia, Ciudad de Mexico, Mexico.*

Background: Recently, a variant of the classical technique has been proposed a perforated ultrasound probe is used to guide the needle along a perpendicular trajectory to the terminal section of the lower kidney pole offering to the needle a 3-4 cm thick cortical tissue front which allows to obtain a cortical tissue sample with a single needle pass and less frequent complications.

Methods: We perform from November 2018 to May 2019 in 76 consecutive patients a real time ultrasound guidance percutaneous renal biopsy using the perpendicular needle trajectory variant technique. Perform by nephrology fellow supervised by an interventional nephrologist. We revised number of glomeruli the histological sample and the presence of complications associated to the procedure.

Results: Table 1

Conclusions: Renal biopsy continues to be gold standard for the diagnosis of kidney diseases, in our center using the new technique its possible to get a biopsy of smaller kidney size with a sufficient histological sample and complication were minors than reported in the literature.

Results

Patients, n.	76
Age.(years)	41.6±16.2
Male/Female, n	29/47
Hemoglobin (g/dL)	11.8±2.3

PUB182

Gender Disparities in Faculty at ASN Kidney Week 2012-2019

Deepa A. Malieckal, Hitesh H. Shah, Susana Hong, Kenar D. Jhaveri. *Nephrology, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.*

Background: Women remain underrepresented in academic medicine. To determine the proportions of female early program chairs, moderators and speakers at ASN Kidney Week (ASN-KW) from 2012 to 2019, we conducted this study.

Methods: The list of faculty names for 2012-2019 was accessed from the ASN-KW website and the genders of the early program chairs, moderators, and speakers was determined. Any undeterminable gender by name was checked twice with an internet search of their image or gender identifying information.

Results: In the years 2012-2016, there was a significant male predominance of early program chairs, moderators and speakers at ASN-KW. From 2017 onwards there was an uptrend in female moderators and speakers. From 2012-2016, the proportion of female speakers ranged from 20-27% of all speakers. The proportion of female speakers increased from 32% in 2017 to 40% in 2019. From 2012-2016 the female moderators ranged from 12 to 28% but increased to 49% in 2019. For early program chairs, female representation ranged from 18 to 38% from 2012-2019.

Conclusions: There is an increasing trend in the proportion of female moderators and speakers at ASN- KW since 2017. The uptrend in the recent 3 years could be related to the increase in female leadership within the ASN council. It is hopeful that this increasing

trend in proportion of female moderators and speakers at ASN KW continues. Other opportunities to enhance gender equality should also be considered by the nephrology communities and societies.

Gender disparities during ASN-KW 2012-2019

Just in Time Teaching Tips (JITT Tips): A Tool to Efficiently Teach Learners and Team Members in the Clinical Setting

Valerie S. Barta,[3] Maria V. DeVita,[1] Alice Fornari.[2] *[1]Lenox Hill Hospital-Northwell Health System, New York, NY; [2]Northwell Health, Manhasset, NY; [3]Hofstra Northwell School of Medicine Lenox Hill Hospital, New York, NY.*

Background: ACGME standards state that trainees must demonstrate communication skills that result in the effective exchange of information. It is imperative that training programs provide the proper tools to improve the learning environment for students who receive much of their instruction from resident/fellow supervisors who are themselves inexpert in teaching skills and conveying knowledge. Programs need to incorporate newer methods of teaching and communication to prepare trainees. Northwell Health GME leadership (NHGME) developed a new tool that provides a mechanism to electronically send content-specific clinical teaching tips just prior to educational opportunities. In a pilot study, NHGME collaborated with 7 required medical student clinical rotation leaders to develop relevant JITT infographics with evidence-based content and teaching cues. A series of 6 weekly JITT Tips were identified (generic and discipline specific) to be delivered to residents who engage with learners in the clinical environment via email or text. The targeted clinician educator received 1 JITT weekly in the early AM on a Monday for 6-8 weeks, at the start of the academic year and again at the 6-month mark.

Methods: Using this framework, the Division of Nephrology at Lenox Hill Hospital sought to create several renal focused JITT infographics. Renal faculty and fellows were assigned to the project. Fellows identified deficiencies in their knowledge, expertise and teaching skills, to guide initial discipline-specific topics to address with teachers and learners.

Results: Four topics were chosen that foremost reflect information that renal fellows should be able to teach to housestaff and medical students: acute kidney injury, acute glomerulonephritis, urinalysis and hyponatremia. Infographics templates were created providing both topic-specific content as well as key teaching phrases to engage and encourage the trainee.

Conclusions: JITT provides an innovative way to reinforce positive teaching behaviors and enhance the learning environment. This electronic communication is an adaptive learning system and is invaluable in connecting with early career physicians (residents and faculty) and medical students. An added bonus is engaging nephrology fellows in medical education in professional development as a medical educator in academic programs.

PUB184

Live Visual Abstracts: A Novel Method of Disseminating Scientific Information Live from a Conference

Aakash Shingada,[1] Arvind Conjeevaram.[2] *[1]Kidney Associates, Mumbai, India; [2]Bangalore Hospital, Bangalore, India.*

Background: Medical conferences pack a large amount of information, which is consumed by the attendees, often predominantly from a local or national geographical area. While live-tweeting of information presented at a conference can help to disseminate the key messages, it often leads to significant clutter. Combining the idea of visual abstracts and live-tweeting led to the concept of 'Live Visual Abstracting'. Live visual abstracts help disseminate scientific data from the conference in a concise, pictorial format.

Methods: The visual abstracts were created live, during the session and were tweeted out with the hashtag #LiveVisualAbstract. Over a period of 1 and half days, 7 Live visual abstracts were created and tweeted out. The variables studied were (i) number of times the tweet was seen (impressions), (ii) Number of interactions received for each tweet (Engagements) which included (a) the number of times the tweet was shared (retweets), (b) No of replies/comments per tweet (c) number of interactions leading to profile visits. The results were compared with the most popular media tweets covering the session from the same handle to assess the impact of #LiveVisualAbstract

Results: The tweets with #livevisualabstract received significantly greater number of impressions with a median of 1820 (1059 - 7040) impressions compared to the most popular tweets from the same session - 891(241 - 1869), P - 0.013. The number of engagements [124 (86- 339) vs 24 (9-56); P - 0.002], retweets [7 (5 - 14) vs 4 (0 - 5), p - 0.005], likes [21 (17 - 38) vs 7 (3 - 12), p - 0.002] and profile visits [3 (1 - 16) vs 1 (0 - 4), p - 0.002], were all significantly greater with #livevisualabstract. The number of comments/ replies did not differ between the two groups.

Conclusions: Our analysis shows that visual abstracts are promising tools of disseminating information not just for journal articles but also for conferences. This will help in minimizing clutter, spread information and potentially generate discussion which is the key to success of free online access to medical education (FOAMed).

Healthcare Transition in a Medical School Curriculum: Navigating the Transition Process of Chronically Ill Youth to Adult Healthcare

Sherene Mason,[1,2] Franklin T. Sylvester,[5,6] Alexis Thompson,[3,4] Anton M. Alerte.[2] *[1]Connecticut Children's Medical Center, New Haven, CT; [2]University of Connecticut School of Medicine, Farmington, CT; [3]Hasbro Children's Hospital, Providence, RI; [4]Warren Alpert Medical School of Brown University, Providence, RI; [5]Mount Sinai Hospital, New York, NY; [6]Icahn School of Medicine, New York, NY.*

Background: Increasingly pediatric patients with chronic conditions are surviving into adulthood. Successful transition from pediatric to adult healthcare reduces gaps and avoids poor health outcomes. Providers must attain the knowledge necessary to foster a successful process during their training. Within the undergraduate medical curriculum it is not apparent that any school has incorporated a non-discipline specific required healthcare transition course early into their curriculum particularly for early learners. We describe the implementation and evaluation of a healthcare transition course in our medical school curriculum.

Methods: A pre-course survey was distributed to 102 first-year medical students and 32 course facilitators within the Delivery of Clinical Care course (DoCC). The survey assessed knowledge, attitudes and practice surrounding healthcare transition. Results were used to design a healthcare transition course within the Adolescent portion of DoCC utilizing videos, reading and in-class case discussions with collaborative group problem solving. A similar post-course survey was emailed to students. Pre- and post-survey responses were compared using a two-sample t-Test assuming unequal variances.

Results: Pre-course survey response rates were 86.5% and 78.8% for medical students and course facilitators, respectively. Most students (95.5%) report no prior experience with healthcare transition as compared with 53.8% of facilitators. Only 5.6% of students and 11.5% of facilitators were able to correctly answer a question regarding the age to begin the patient transition process as recommended by the American College of Physicians. This increased to 59.2 % following the course. Students reported a more moderate level of comfort explaining (avg 3.43 on 1-5 scale, $p<0.001$) and participating in (avg 3.49 on 1-5 scale, $p<0.001$) healthcare transition after the course. Participants expressed preference for case-based learning (70% students, 96.1% facilitators) and group discussion (65.6% students, 69.2% facilitators) format.

Conclusions: The first-year medical student course on healthcare transition was well received by participating students. Early implementation of a healthcare transition course in undergraduate medical education can provide a pathway to mastering of the topic in clinical practice.

What Fellows Want: A First Survey of Nephrology Fellowship Training in Korea

Kyung Don Yoo,[1] Sejoong Kim,[2] Ki Young Na.[2] On behalf of Committee of the Training and Education, Korean Society of Nephrology at 2018 *[1]Ulsan University Hospital, Ulsan, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: The Korean Association of Internal Medicine (KAIM) introduced a shortening of the training period from the existing 4-year training system to a 3-year training program in 2017. In line with this, the demand for a full-time fellowship is expected to be different from that in the past in each sub-specialty. We, Korean Society of Nephrology (KSN), conducted a study surveying the full-time fellowship program for the first time.

Methods: From 2017 to 2018, physicians who were nephrology fellows were contacted. Through the cooperation of the KAIM, we secured an overall table of organization (T.O.) data in Korea. An anonymous questionnaire survey was conducted at each hospital without any compulsion.

Results: According to the data of the KAIM, specializing nephrologists showed modest growth from 47 to 58 people from 2007 to 2017. This was the third place, show 511 people in size subsequent to 1,849 people in majoring Gastroenterology & Hepatology, 563 people in Cardiology on 10 years from 2007. A total of 104 subjects were contacted and 93 questionnaires were obtained. There were 63 fellows in the first year (57.7%) and 24 in the second year (25.8%). Fifty-three (56.9%) were women, and 76% were married. The fellows who were respondents were engaging in 4.02 month on nighttime duty per year, and the mean number of night calls was 8.8 ± 11.7 per month. The hemodialysis unit training rounds worked an average of 7.8 ± 4.3 months per year. In the academic training program, seventy-five percent of nephrology fellows attended a conference together with a pathologist, and 71% of the fellows attended medical grand rounds. However, intervention nephrology training was scarce in spite of the need in this area with a rate as low as 13%. After the fellow training, they preferred to work in the hemodialysis unit rather than an academic position (61/93). The most critical issue regarding work-life balance for fellows in their training period was associated with the night-time duty, and salary.

Conclusions: This study was the first nation-wide questionnaire survey, and 89% of the overall nephrology fellows replied. We expect that it can be used as baseline data for the improvement of quality in full-time nephrology fellow training.

PUB187

Developing a Renal Fellow Curriculum in Telenephrology: Providing Nephrology Care to Underserved Rural Hospitals

Janice P. Lea,[1] Jason Cobb,[2] Jose E. Navarrete,[1] James L. Bailey,[2] Tahsin Masud,[1] Jerome S. Tannenbaum,[3] Jeff M. Sands.[4] Emory University *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Sanderling Healthcare, LLC, Nashville, TN; [4]Emory University Renal Division, Atlanta, GA.*

Background: Telemedicine has recently permeated into the nephrology space allowing patients in rural underserved areas to receive nephrology care in their local hospitals without transfer to larger healthcare systems. Due to the national shortage of nephrologists and to declining interest in the pursuit of renal fellowships, there is a need to train future nephrologists in telemedicine to build capacity of the renal workforce.

Methods: Our academic nephrologists at Emory University have been providing telemedicine services to both ESRD and non-ESRD patients (pts) in 3 rural hospitals in South Georgia (128 unique pts with 525 pt encounters) for the last 2 years and now will incorporate telenephrology training into our renal fellowship in the fall of 2019. Renal fellows will be trained during the second year clerkship for a period of at least 3 months. Fellows will be expected to perform at least 15 patient encounters along with a telenephrology attending. We currently average 25 encounters per month and thus have adequate volumes to reach this goal. Fellow competency will be evaluated after each rotation and feedback from fellows will be solicited in order to improve their training experience.

Results: Telenephrology curriculum will include fellow training on: 1) use of audio-video technology and electronic stethoscope to perform real-time history and physical exams remotely, 2) how to write hemodialysis (HD) orders and monitor dialysis sessions using non-traditional portable technology that supports electronic real-time data monitoring, 3) how to properly communicate and build rapport with referring physicians, and 4) develop and master process for remote urine microscopic examination using digital microscope adapters to electronically transmit images via secure web-based platforms.

Conclusions: The incorporation of a telenephrology curriculum into our renal fellowship program is innovative and will be a model for other training programs. Development of a method for remote urine microscopic examination will enhance the quality of telenephrology consults. The expansion of telenephrology services to more rural areas will help to build future nephrology workforce capacity and may increase medical resident interest in nephrology.

PUB188

Study on the Application of a Five-Star Teaching Model in Prevention and Control Health Education of Hemodialysis Patients with High Blood Phosphorus

Jin-mei Yin. *The Fifth Affiliated Hospital, Sun Yat-sen University, Zhuhai, China.*

Background: Hyperphosphatemia is an independent risk factor for the mortality rate of patients with chronic kidney disease. The rate of blood phosphorus compliance in developed areas in China is only 37.6%, which is far lower than that of developed countries. Controlling hyperphosphatemia has become an important issue. The core idea of the Five-Star Teaching Method is that under the principle of "focusing on solving problems", teaching should have the principle of continuously repeating the activation of original knowledge, demonstrating new knowledge, trying to apply exercises, and integrating and mastering four stages of circulation. This teaching method is considered to be High-quality, efficient teaching that meets the learning process and the psychological development requirements of learners. In recent years, the five-star teaching model has been applied to medical teaching and doctor-patient communication, and has achieved good evaluation.

Methods: With the aim of focusing on solving problems, the application repeats the activation of the original knowledge, demonstrates the new knowledge, attempts to apply the practice, and integrates the five-stage teaching mode of the four stages of the cycle to carry out up to 6 366 cases of maintenance hemodialysis patients in our district. Month's prevention and control education on hyperphosphatemia, observing the changes in the knowledge of disease-related knowledge, social support, medication compliance and satisfaction before and after intervention, and statistically at 3 months and 6 months after intervention. Pre-blood phosphorus levels change.

Results: After the intervention of the five-star teaching model, the degree of knowledge, social support, medication compliance and satisfaction of patients with disease-related knowledge increased significantly before intervention. At the same time, the pre-existing blood phosphorus level decreased gradually from 1.92±0.51mmol/l before intervention to 1.68±0.37mmol/l, and the phosphorus compliance rate increased from 43.5% to 54.9%. The difference was statistically significant.

Conclusions: Applying the five-star teaching mode to the phosphorus-controlled knowledge of hemodialysis patients can effectively reduce the blood phosphorus level and increase the phosphorus compliance rate.

PUB189

Hemodialysis in Patients with Severe Metabolic Acidosis: Insights from a Physiology-Based Mathematical Model

Alhaji Cherif,[1] Vaibhav Maheshwari,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Maintenance of acid-base homeostasis is one of the fundamental kidney functions. In patients with severe acute metabolic acidosis (MA), daily acid load production and intake overwhelm compensatory secondary responses. Severe MA can manifest itself in a multitude of pathologies and result in increased morbidity and mortality. In this study, we have developed a physiology-based model of acid-base regulation in order to investigate the use of hemodialysis (HD) to correct severe MA.

Methods: Our dynamic model of the HCO_3^-/CO_2 buffering system comprised Henderson-Hasselbalch mass-action kinetics, endogenous production of both CO_2 and H^+, loss due to non-bicarbonate buffering, ventilation, and renal regulation. Inducing several degrees of MA, we employed a dialyzer model to investigate the effectiveness of HD for correcting MA. Qualitative predictions of clinically observed post-HD acid-base status are demonstrated.

Results: We parameterized the model to induce severe MA steady-state conditions (pre-HD pH from 7.1-7.3) and showed the effect of different dialysate HCO_3^- concentrations (28-38 mM) on the acid-base status correction. We observed that pre-HD HCO_3^- increased (up to 2.03-fold change from the pre-HD values) to values below Gibbs-Donnan-corrected dialysate HCO_3^-, and pre-HD pCO_2 and pH increased only by up to 1.036 and 1.041-fold, respectively, at the end of HD. In addition, with less severe pre-HD MA, the change in pH over the course of HD increased to between 0.4% and 1.95%.

Conclusions: Our model qualitatively predicted serum HCO_3^-, pCO_2 and pH. Further clinical validations are needed to assess its predictive utility in clinical practice. Once validated, the model may be used to gain insights into the acid-base status and to individualize therapeutic interventions in patients with severe MA.

PUB190

Hyperkalemia in Ill Renal Patients from Lactated Ringer

Macaulay A. Onuigbo. *Medicine, The Robert Larner, M.D. College of Medicine, University of Vermont, Burlington, VT.*

Introduction: Balanced crystalloid solutions are touted to be superior to 0.9% saline. Our recent experiences call for caution with LR in older patients with advanced renal failure.

Case Description: **Patient #1**: An 83-yo man developed AKI following coronary angioplasty and stenting requiring hemodialysis (HD). While on 3x/week HD, he developed hyperkalamia following 750cc bolus of LR. (Figure 1). **Patient #2**: A 70-year old male with a solitary functional left kidney developed AKI from an obstructing stone. This was relieved by a JJ stent. Despite 2 liters of brisk of diuresis in one hour, he developed worsening hyperkalemia following 500cc of LR given in the OR (Figure 2).

Discussion: In the 2018 NEJM report on noncritically ill patients, the median baseline serum creatinine (MBSC) was 0.84 - 0.85 mg/dl in the balanced crystalloids and saline groups. Moreover, in the second NEJM report on critically ill patients, the MBSC was 0.89 mg/dl in both groups. Therefore, patients with more advanced renal failure may not tolerate these solutions as well. Furthermore, the median age of the noncritically ill cohort was 53-54 years, whereas the median age of the critically ill cohort was 58 years. Clearly, without prejudice to the touted advantages of balanced crystalloids, we would continue to argue for a more patient-centered approach to individualized patient care. One size does not fit all.

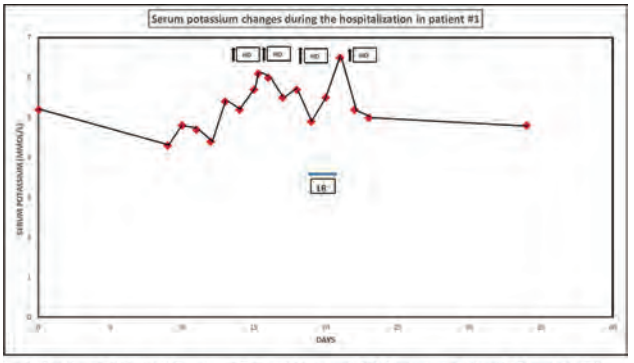

Figure 1: Hyperkalemia spike in patient #1 following Lactated Ringers (LR) Solution resuscitation for hypotension despite alternate daily hemodialysis (HD)

Hyperkalemia after LR despite alternate daily HD

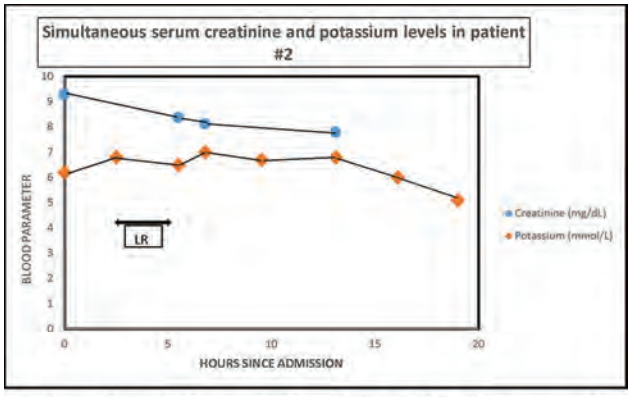

Figure 2: Hyperkalemia spike following Lactated Ringers (LR) in the OR despite falling creatinine and 2L of post-ureteric stent diuresis

Hyperkalemia despite diuresis after LR

PUB191

Positive Blood Alcohol (Al) Level in a Teetotaler

Hassan B. Attique, Ruchir D. Trivedi. *Uconn Health, Farmington, CT.*

Background: True hypotonic Hyponatremia (↓Na) despite a normal measured(M) serum(Se) osmolality(Osm) is common in patients with Al use. However, our case is unique that our patient(pt) whose asymptomatic(Asy) ↓Na warranted hospital admission various times and initially thought secondary to Al consumption vouched not having consumed Al entirely.

Methods: 49 year old male with cryptogenic end stage liver disease and CKD 4 secondary to HTN enlisted for dual liver kidney transplant, presented to vascular surgery suite for AVF creation. Initial workup revealed Asy ↓Na for which he was admitted. Physical exam was remarkable for 2+ lower extremity(LE) edema without ascites. His Se Na was 117meq/L with M Se Osm of 294mOsm/L. His BUN was 29mg/dL with calculated(C) Se Osm of 249mOsm/L and osmolar gap(Og) 44. When pt was asked about Al use, he mentioned that he is very aware of the potential consequences of consuming Al in his case. His toxin screen revealed blood Al level of 49mg/dL. Considering hypervolemic ↓Na with low urine Na < 20, this was suggestive of reduced effective circulatory volume. Pt was fluid restricted and his diuretics were resumed after which his Se Na improved to 127meq/L and was discharged. He was admitted after 3 months again for Asy ↓Na of 114meq/L with an Og of 47. His BUN was 25mg/dL. This time his blood Al level was 70mg/dL and his FeUr was 29%. His bilateral LE edema was less than before. He was again treated on the same lines. However this time, his nephrologist was informed about his blood Al level so that he can speak with the pt about updating transplant center. Further investigation into this matter finally revealed that pt was chewing tobacco containing Al.

Results: Hypervolemic ↓Na in the setting of liver cirrhosis is common but may raise concern for transplant candidacy when there is an Og. Our case is unique in describing the relation of chewing smokeless tobacco with high ethanol content;the same substance which breath analyzers have been programmed to detect. Usually, the amount of Al in smokeless tobacco may not be sufficient to keep one intoxicated but it can radically increase the rate of Al content in the breath usually termed as mouth Al which cannot be differentiated from the breath of Al intoxication. However, the quantity of chewing tobacco in our pt was so large that the blood Al level was positive.

Conclusions: Clinicians need to be aware of Al content in smokeless tobacco as a potential cause of high Se Og.

PUB192

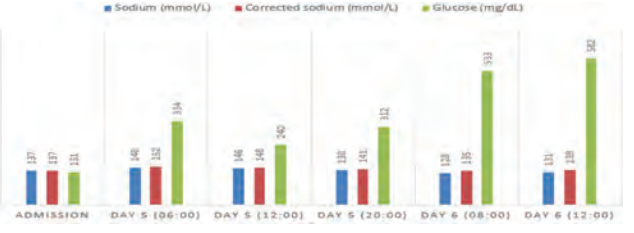
Be Mindful of Effective Osmoles When Instituting Therapy for Re-Establishment of Eunatremia

Manuel Dominguez. *Hospitalist Division, UT Southwestern Medical Center, Dallas, TX.*

Introduction: Hyponatremia is commonly encountered in clinical practice. Here we present a case of chronic hypernatremia complicated by acute hyponatremia.

Case Description: A 67-year old woman with DM was admitted to the hospital for assessment and management of nausea, vomiting and decreased oral intake. Laboratory data on admission were remarkable for serum Na of 137 mmol/L and glucose of 131 mg/dL. Despite pharmacological attempts to control nausea, the patient's oral intake remained poor. Follow up laboratory data were remarkable for hyperglycemia (serum glucose of 334 mg/dL) and hypernatremia with a serum Na of 148 mmol/L (corrected Na of 152 mmol/L; serum osmolality of 337 mOsm/kg). Repeat laboratory data six hours later were still remarkable for hyperglycemia (serum glucose of 240 mg/dL) and hypertonic hypernatremia with a serum Na of 146 mmol/L (corrected Na of 148 mmol/L). Next set of laboratory data, now fourteen hours after the first, showed a serum glucose of 312 mg/dL and Na of 138 mmol/L (corrected Na of 141 mmol/L). The patient was started on D-amino D-arginine vasopressin (DDAVP) followed by D5W IV. Twelve hours later, serum glucose was 533 mg/dL and Na was 128 mmol/L (corrected Na of ~135-138 mmol/L). D5W was discontinued and the patient was started on 3% NaCl IV. Four hours later and after ~50 mL of 3% NaCl, serum Na was 131 mmol/L (corrected Na of 139 mmol/L). Hypertonic saline was discontinued. Symptomatic management of nausea was optimized and the patient's oral intake improved. Follow up measurements of serum Na showed an increase toward reference values and a delta Na value <6 mmol/L in any 24-hour period (see image).

Discussion: This case highlights the interplay between effective serum osmoles and the importance of frequent monitoring of serum Na when instituting therapy for re-establishment of eunatremia. Correction of this patient's hypernatremia resulted in acute hyponatremia. Identification of glucose as an effective osmole allowed correction of serum Na. Failure to discontinue hypotonic fluids and discontinue DDAVP would have resulted in chronic hyponatremia and further decrease of serum Na, which had already corrected by 17 mmol/L in 24 hours.



PUB193

Management of Patients with Acquired Distal Renal Tubular Acidosis Among US Nephrologists and Rheumatologists

Kamyar Kalantar-Zadeh,[2] Robbie Mccarthy.[1] [1]*Rare Insights LLC, Ardmore, PA;* [2]*University of California Irvine, School of Medicine, Orange, CA.*

Background: AdRTA, which is linked with Sjogren's disease, systemic lupus erythematosus (SLE), primary biliary cirrhosis (PBC) and autoimmune hepatitis, is often encountered by rheumatologists and nephrologists. To better understand the interdisciplinary management of AdRTA patients a quantitative market research study was undertaken in Q1 2019

Methods: Between March 25th–April 15th, 2019, an online survey was conducted with 30 nephrologists and 20 rheumatologists in the USA on the subject of dRTA, with a focus on AdRTA. All screened respondents had direct clinical experience of AdRTA patients. The database was cleaned, and the collected data were analyzed by SPSS

Results: Rheumatologists reported larger SLE and Sjogren's caseloads than nephrologists, seeing an average of 177 cases of SLE patients in the past 12 months vs. 60 cases for nephrologists. Nephrologists saw similar numbers of patients with Sjogren's, PBC and AI Hepatitis in the past 12 months (27, 25, 24 respectively), vs. higher numbers

for rheumatologists (237, 50, 86 respectively). The number of AdRTA patients seen monthly was a relatively small percentage (approximately 1 in 100) of the overall number of patients seen by both specialists (see Figure). All nephrologists either agreed (20%) or strongly agreed (80%) with the statement *"In patients with autoimmune conditions in which AdRTA is co-morbid, such as Sjogren's and SLE, I take the lead in managing AdRTA*" compared to 20% of rheumatologists who disagreed, 20% who agreed and 60% who strongly agreed. One-third of nephrologists and 70% of rheumatologists agreed that AdRTA is underdiagnosed due to lack of knowledge and awareness in primary care [Figure]

Conclusions: Although patients with AdRTA are a small % of their patient caseloads, both nephrologists and rheumatologists have a role in managing AdRTA in patients with comorbid AI disease, with nephrologists more likely to consider themselves the lead physician than rheumatologists. The majority of physicians surveyed believe the AdRTA is underdiagnosed due to a lack of knowledge and awareness in primary care

PUB194

The Temperature, Volume, and Calcium Concentration of the Water in the Lung Influences the Serum Calcium Concentration of a Drowned Person

Takahide Kimura,[1] Seiki Yamada,[1] Takeshi Yokoyama,[1] Hiroyuki Shirai,[1] Masayuki Tanemoto,[1] Naoki Washida.[2] *[1]Nephrology, International University of Health and Welfare Atami Hospital, Atami, Japan; [2]International University of Health and Welfare Medical School, Atami, Japan.*

Background: Electrolyte concentrations of the solution getting into the lung will change the serum electrolyte concentrations of a drowned person. Serum calcium concentration (Ca) of drowned persons was analyzed according to places of drowning.

Methods: From September 2014 to March 2019, 22 persons were referred to our hospital because of drowning in hot spring. The Ca in them was compared with those of drowned persons in either the sea (n = 8) or house bathtubs (n = 5). Blood ionized calcium concentration (iCa) was also compared between the groups. In the persons drowned in hot spring, the volume of the water in the lung (Vol) was estimated by using images of computed tomography, and correlations of Ca and iCa with Vol were further examined.

Results: The sea-side hot spring water contained calcium of 36 mg/dL (9 mmol/L). In the drowned persons of the hot spring, the sea, and bathtubs, Ca was 13.04 ± 3.70, 10.29 ± 1.94 and 9.04 ± 1.24 mg/dL, respectively (p= 0.037, p< 0.001), and iCa was 1.55 ± 0.48, 1.46 ± 0.25, and 1.21 ± 0.12 mmol/dL, respectively (p = 0.823, p = 0.047). In the hot-spring-drowned persons, Vol was 1253 ± 673 mL and its ratio to the whole lung volume (Vol-ratio) was 0.43 ± 0.19. The Vol-ratio correrated with iCa (r= 0.386, p= 0.47).

Conclusions: The Ca in the hot-spring-drowned persons was significantly higher than those in the sea-drowned and bathtub-drowned persons. It correlated with the relative volume of the hot-spring water in the lung. Since the calcium concentration of the hot spring water is slightly lower than that of the seawater, the temperature in addition to the volume and calcium concentration of the water in the lung could have influenced the amount of calcium absorbed from the lung into the serum.

PUB195

Referral Patterns for Patients with Acquired Distal Renal Tubular Acidosis (AdRTA)

Robbie Mccarthy,[1] Ludovic Robin,[2] Kamyar Kalantar-Zadeh.[3] *[1]Rare Insights LLC, Ardmore, PA; [2]Advicenne S.A., Paris, France; [3]University of California Irvine, School of Medicine, Orange, CA.*

Background: AdRTA, which is linked with Sjogren's disease, systemic lupus erythematosus, primary biliary cirrhosis and autoimmune hepatitis, is often encountered by rheumatologists and nephrologists. To better understand key referral routes and issues for AdRTA patients a quantitative market research study was undertaken

Methods: Between March 25th–April 15th, 2019, an online survey was conducted with 30 nephrologists and 20 rheumatologists in the USA on the subject of dRTA, with a focus on AdRTA. All screened respondents had direct clinical experience of AdRTA patients

Results: Most AdRTA patient referrals to nephrologists (Nphs) and rheumatologists (Rhms) are from primary care (Nphs 60% and Rhms 61% - of total AdRTA referrals). Internal medicine accounted for 23% of AdRTA patient referrals to Nphs and 17% to Rhms. In the most recent 12 months, referral patterns were consistent with the most common routes of referral, but with more of an even split between primary care and internal medicine for both Nephs (38 vs 31%) and Rhms (38% vs 21%). Both specialists indicate around 6% referral rate from urologists, with very small numbers from other specialists considered potential referrers of AdRTA patients (inc. pediatric nephrology, dermatology, audiology and opthalmology). Both Nphs and Rhms either Agree (33% vs. 30%) or Strongly agree (67% vs 70%) that AdRTA is underdiagnosed due to a lack of knowledge and awareness of the condition in primary care. Only 20% of the total number of referrals to nephrologists came from rheumatologists

Conclusions: Most AdRTA patient referrals to rheumatologists and nephrologists are from primary care, with only small numbers of patients referred from other specialist physician types considered potential referers due to known AdRTA co-morbidities. There is concern among nephrologists and and rheumatologists that poor knowledge and education around AdRTA in primary care is lacking resulting in the potential for *"Patient issues [to be] worsened because of late referral to nephrology"*. The low percentage of referrals from Rhms to Nephs was suprising, potentially indicating that Rhms manage patient's AdRTA without the involvement of nephrology

PUB196

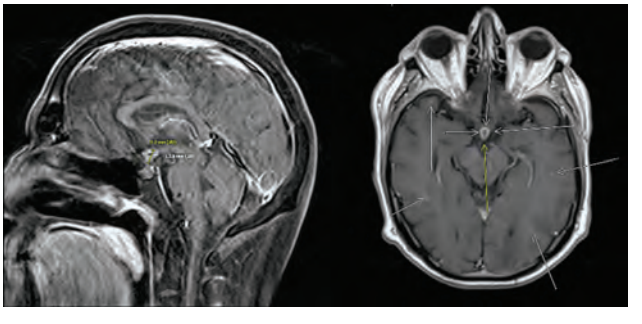
Stalking the Hypernatremia: A Case of Central Diabetes Insipidus due to Metastatic Small Cell Lung Cancer

Rupam Ruchi, Eddy J. De Jesus. *University of Florida, Gainesville, FL.*

Introduction: Symptoms from metastatic tumors in general are relatively rare, but when it involves the infundibular stalk, central diabetes insipidus (CDI) has remained the most common manifestation.

Case Description: A 70-year-old man with a 3-month history of small cell lung carcinoma, managed with Carboplatin, Etoposide, and Pegfilgrastim in an outside facility when diagnosed, transferred to our institution for Non-ST segment Elevation Myocardial Infarction. Initial labs showed hypernatremia of 146 mmol/L, urine specific gravity of 1.010, urine osmolality of 138 mOsm/Kg. As there were concerns for sepsis, he received 3 liters of normal saline that lead to the development of significant hypernatremia (156 mmol/L). His urine output was noted to be 12 L in the first 24 hours. On further questioning, he acknowledged feeling excessive thirst for the last 2 weeks. This was accompanied by polyuria and mild abdominal pain. Concern for possible carboplatin-induced partial nephrogenic diabetes insipidus (DI) vs central DI. With administration of 100 mcg desmopressin, urine output improved to 3 L and urine osmolality increased to 400. Upon holding desmopressin the next day, urine output again increased to 10 L accompanied by decrease in urine osmolality. This suggested Central DI. Magnetic Resonance Imaging (MRI) of the brain was done which showed diffuse innumerable sub-centimeter punctate metastases throughout the brain including 1 cm metastatic lesion to the hypothalamus/infundibulum/floor of the third ventricle with loss of normal spontaneous T1 hyperintensity of posterior pituitary gland

Discussion: In patients with DI and an intact thirst mechanism, hypernatremia develops due to increased excretion of free water and the lack of Antidiuretic Hormone (ADH). Metastasis to the pituitary stalk has been related to breast cancer as the primary source followed by lung cancer, prostate, and renal cell carcinoma respectively. At least 80% of vasopressin-synthesizing neurons must be destroyed before any clinical manifestations are evident. MRI remains the image diagnostic of choice for evaluation of the pituitary



PUB197

Hippurate Clearance Provides a Measure of Renal Plasma Flow

Kumar Rohit,[1] Avinash G. Adiga,[3] Aleksey Etinger,[1] Jerome Lowenstein.[2] *[1]New York University, Jersey City, NJ; [2]New York University Medical Center, New York, NY; [3]Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Prior to the introduction of eGFR in 1999, glomerular filtration rate and renal plasma flow were assessed by measuring the plasma clearances of inulin and para-amino hippurate. As this required constant infusion, timed urine collection and a

specialized laboratory, these measures were not widely available. Data available from the period identified a number of clinical disorders in which the ratio of GFR to renal plasma flow (Filtration Fraction) varied considerably. Filtration fraction was known to vary considerably in different clinical states. With the introduction of eGFR, renal plasma flow is no longer measured and renal function is judged solely by eGFR. With the recognition that endogenous hippurate was transported by OATs in the proximal tubule, we undertook studies to determine whether the clearance of hippurate would present a means of estimating renal plasma flow.

Methods: Studies were carried out in 5 subjects with hypertrophic cardiomyopathy under going right heart catheterization and 10 subjects undergoing electrophysiologic studies. Blood samples were obtained from the right renal vein and the IVC below the renal veins. A voided urine was collected 1-3 hours before blood sampling. Eight patients were receiving beta-blockers, two were receiving ACE inhibitors. Hippurate was measured utilizing MS-HPLC. Creatinine was measured by colorimetric technique.

Results: Among the 15 subjects, **extractionof hippurate**(IVC-RV/IVC) was .935 and .909 in two, from .739 to .58 in six. In the remaining seven subjects the findings suggested the RV catheter was not in the renal vein or the blood collected was an admixture of renal vein and IVC blood. The **clearance ratio**(**U/Phippurate**to **U/P creatinine**) was evaluated in 12 subjects; it ranged from 7.05 to 1.64 and exceeded 4 in five of the subjects studied.

Conclusions: The renal clearance of hippurate exceeded creatinine clearance in all subjects studied. Hippurate/creatinine clearance ratios greater than 4 suggests that hippurate clearance provides a measure of RPF. Ratios below 4.0 may reflect reduced renal plasma flow in some of the patients, who were studied during evaluation of either hypertrophic cardiomyopathy or cardiac arrhythmias. Reduced cardiac output or other medications may have reduced renal blood flow.

PUB198

Prevalence and Investigation into Community- and Hospital-Acquired Hypercalcemia

Rushang Parikh,[1] Kenar D. Jhaveri,[1] Vinodh Mechery,[3] Jamie S. Hirsch.[1,2] *[1]Division of Nephrology, Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Department of Information Services, Northwell Health, New Hyde Park, NY; [3]Northwell Health, New York, NY.*

Background: Hypercalcemia can be a presenting sign at hospital admission or may occur over the course of an admission. While workup and treatment protocols have been well-established, the prevalence of hypercalcemia and adherence to investigatory evaluation is largely unknown. We present data on the prevalence of hypercalcemia and seek to reclassify it in terms of community-acquired versus hospital-acquired hypercalcemia to further understand the nature and course of hypercalcemia.

Methods: We queried the enterprise EHR at 14 hospitals in a large integrated health system, for all admissions in 2018, with at least one serum calcium result greater than 10.5 mg/dL. We then defined two distinct patient cohorts: "community-acquired hypercalcemia" (CAH), where the first result is >10.5, and "hospital-acquired hypercalcemia" (HAH), where the initial result is normal and any subsequent result is >10.5. We performed data analysis on each cohort and assessed data on work-up of hypercalcemia.

Results: There were 202,109 admissions of which 2.2% of patients were admitted with hypercalcemia, and 0.6% of patients who developed at least 1 elevated calcium value during the hospitalization. Patients with CAH, had a mean age of 68 years (median 70 years). The mean length of stay was 170.2 hours with a median of 105 hours. Patients with HAH, had a mean age of 68.5 years (median 70 years). The mean length of stay for these patents was 381 hours with a median of 241.6 hours. The mean time to development of HAH was 7.5 days with a median of 4 days. We found that 82.3% of patients with CAH and 78.5% of patients with HAH had no work-up (including 25-Vitamin D, 1,25-Vitamin D, PTHrP, and PTH). Fewer than 2% of patients in either group had all 4 laboratory investigations performed.

Conclusions: With our distinction of community-acquired versus hospital-acquired hypercalcemia we find that there is a stark difference in the length of stay of these patients (170.2 hours vs. 380.9 hours). Furthermore, in both cohorts, most patients have incomplete or investigation performed for the cause of hypercalcemia, a major quality gap. Additional work is required to better understand the etiologies of these distinct hypercalcemic groups (e.g. hypercalcemia of malignancy, hyperparathyroidism, drug-induced hypercalcemia, or hypercalcemia of immobilization) as well as their outcomes.

PUB199

Pseudohyponatremia Caused by Severe Hypercholesterolemia

Khaled Boobes, Stephen W. Roderer, Isabelle Ayoub. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Pseudohyponatremia is a well-known phenomenon. Most commonly it is secondary to hyperproteinemia or hypertriglyceridemia. We present a case of pseudohyponatremia that was secondary to severe hypercholesterolemia.

Case Description: A 60-year-old woman who suffered from itraconazole-induce hepatitis was noted to have a serum sodium (Na) of 119 mmol/L (normal 133-143 mmol/L). She was initially admitted to a community hospital where she was treated with intravenous fluids and then fluid restriction with no change in her Na concentration. Ultimately, she was referred to our tertiary center where further workup revealed an elevated serum osmolality gap of 56 mOsm/kg (normal <10) with a mildly elevated serum osmolality of 307 mOsm/kg (normal 278-305 mOsm/kg). Serum glucose level was 131mg/dL (normal 70-99mg/dL). Total serum protein was low at 5.7 g/dL (normal 6.4-8.3 g/dL) with a mildly low serum albumin of 3.1 g/dL (normal 3.5-5 g/dL) ruling out the possibility of pseudohyponatremia secondary to hyperproteinemia. A lipid panel revealed elevated triglycerides at 350 mg/dL (normal <150 mg/dL), however, more surprisingly a cholesterol level of 2,730 mg/dL (normal <200mg/dL). Serum Na measured using a blood gas analyzer was 139mmol/L and thus the diagnosis of pseudohyponatremia was confirmed. Over the ensuing months, as her liver function improved, her cholesterol levels normalized and so did her Na levels on the chemistry panels.

Discussion: Pseudohyponatremia is a well-known phenomenon that is commonly associated with hypertriglyceridemia or hyperproteinemia. It has been reported in cases of hypercholesterolemia in the setting of obstructive jaundice. Our case is unique since the trigger was drug-induced hepatitis rather than an obstructive process. Clinicians should always have a high index of suspicion for pseudohyponatremia. Measuring the serum osmolality to rule-out an elevated osmolality gap must be one of the first steps in managing patients presenting with hyponatremia. Although uncommon, hypercholesterolemia can be an etiology for pseudohyponatremia, especially in liver disorders.

PUB200

Respiratory Failure as an Initial Presentation of Starvation Ketoacidosis

Sabine Karam,[1] Joudy Bahous,[2] Paul Rassam.[2] *[1]Medicine, Saint George Hospital University Medical Center, Beirut, Lebanon; [2]Saint George Hospital University Medical Center, Beirut, Lebanon.*

Introduction: The incidence of ketonemia has been estimated to be approximately 5%, in a hospital setting post-operatively, however it usually doesn't affect the peri-operative management.

Case Description: A 64-year-old female with a history of type 2 diabetes mellitus, hypertension, dyslipidemia and sigmoid cancer (adenocarcinoma T1N4) status post-proctocolectomy followed by chemotherapy presented with decreased appetite, severe abdominal pain and obstipation of 5 days duration. A CT scan of the abdomen showed partial small bowel obstruction. The patient failed conservative measures and underwent adhesiolysis 4 days later under general anesthesia. The intraoperative and the immediate post-operative period were uneventful. Two days post-operatively, the patient started complaining of shortness of breath and was found to be tachypneic. She was transferred to the intensive care unit for further monitoring. An arterial blood gas showed severe anion gap metabolic acidosis with appropriate respiratory compensation (see table). Further investigations revealed ketones in the blood and urine with a normal blood glucose. The patient received parenteral nutrition and her respiratory status improved promptly.

Discussion: In clinical practice, fasting is seldom suspected to the cause of severe metabolic acidosis. However depletion of the glycogen stores by prolonged fasting, in addition to a state of relative insulin deficiency secondary to the diabetic state of the patient might have accounted for this dramatic presentation. In conclusion, starvation ketoacidosis is a potentially serious cause of severe morbidity post-operatively and should be screened for in patients at risk such as diabetic patients with a poor nutritional status.

Hospitalization in Patients with ESRD Secondary to Polycystic Kidney Disease: A Cohort Study

David Clark, Karthik K. Tennankore, Amanda J. Vinson. *Dalhousie University/ NS Health Authority, Halifax, NS, Canada.*

Background: Patients with End-Stage Renal Disease (ESRD) secondary to Polycystic Kidney Disease (PKD) have been shown to have improved health outcomes compared to those with other ESRD diagnoses. Less is known about their comparative risk of hospitalization and time admitted in hospital following initiation of chronic dialysis. We compared the rate of hospitalization and days in hospital for patients with PKD versus other causes of ESRD.

Methods: We conducted a cohort study of all ESRD patients who initiated dialysis at a large quaternary centre between 1 Jan 2009 and 1 Jun 2015 (last follow-up 1 Jul 2016). Exposure was ESRD cause categorized as diabetes, ischemic/HTN, PKD, glomerulonephritis, unknown and other. Primary outcome was all-cause hospitalization rate (number hospitalizations/follow-up time) excluding transplant admissions. Follow-up commenced at the date of dialysis initiation or discharge date from hospital for those who started dialysis as inpatients. For the primary outcome, follow-up time was exclusive of time spent in hospital and concluded at the earliest of either death, admission for transplant or date of last follow-up. Secondary outcomes included the number of hospital days/total follow-up time. Comparisons between PKD and other ESRD causes were analyzed using negative binomial regression adjusting for demographics, dialysis access, comorbidities and laboratory values at dialysis initiation.

Results: The cohort consisted of 636 patients. 45 (7%) patients had ESRD due to PKD; the most common cause of ESRD was diabetes (35%). Patients with PKD were younger (56 ± 11 versus 62 ± 15 years), had a higher likelihood of PD access (44% versus 21%), more likely female (53% versus 36%), and had lower burden of comorbidity. A total of 24 PKD patients (53%) experienced 1 or more hospitalizations, but the rate was low (incidence rate 0.45/patient year), unadjusted incidence rate ratio of 0.55 (95% CI 0.41-0.72, P<0.001) compared with other causes. PKD patients spent 3.8 days in hospital/ patient year (IRR 0.36, 95% CI 0.33-0.39). In a multivariable adjusted model, the IRR for hospitalization remained low (0.54, 95% CI 0.39-0.74).

Conclusions: The risk of both hospitalization and time admitted were less for patients with ESRD secondary to PKD. These findings can help inform patient care decisions for those approaching chronic dialysis.

Identification of Housekeeping Genes for MicroRNA Expression Analysis in Pkd1-Deficient Mouse Models

Juan J. Moyano muñoz,[1] Ana C. Anauate,[1] Renata Meca,[1] Milene S. Ormanji,[1] Frederico M. Ferreira,[2] Andressa G. Amaral,[2] Mirian A. Boim,[1] Luiz F. Onuchic,[2] Ita P. Heilberg.[1] *[1]Nephrology Division, Department of Medicine, Federal University of São Paulo, São Paulo, Brazil; [2]Divisions of Molecular Medicine and Nephrology, University of São Paulo School of Medicine, São Paulo, Brazil.*

Background: There are no reports of systematic validation of genes commonly used for normalization of gene expression by RT-qPCR in kidney tissues of mouse models orthologous to autosomal dominant polycystic kidney disease (ADPKD). The aim of this study was to identify the most suitable housekeeping genes for RT-qPCR analyses of kidney tissues in *Pkd1*-deficient mouse models from eight currently used candidates.

Methods: Eight different control genes for microRNA (miR) studies were investigated in kidney tissues of *Pkd1*-deficient mouse models and their corresponding controls by RT-qPCR. All lines were generated and maintained on a C57BL/6 background. The expression of the candidate housekeeping genes (*miR-20a*, *miR-25*, *miR-26a*, *miR-191*, *miR-423*, *miR-547-3p*, *miR-674-5p* and *U6*) and 2 target genes (*miR-21* and *let-7a*) was analyzed in the kidneys of 10-12-week-old cystic mice ($Pkd1^{flox/flox}$:$Nestin^{cre}$, CY,n=10), non-cystic controls ($Pkd1^{flox/flox}$, NC,n=10), *Pkd1*-haploinsufficient mice ($Pkd1^{+/-}$, HT,n=6), wild-type controls ($Pkd1^{+/+}$, WT,n=6) and 15-day-old severely cystic mice ($Pkd1^{V/V}$,SC,n=7) and wild-type controls (CO,n=5). The stability of the candidate genes was investigated using six software applications: NormFinder, GeNorm, BestKeeper, DataAssist, comparative ΔCt and RefFinder.

Results: As shown in the table below, our comprehensive analysis identified *miR-26a* as the most stable housekeeping gene, although the best one varied among the models. Our analyses revealed upregulation of *miR-21* upregulation in SC and HT kidneys and trends of *let-7a* downregulation in CY and HT kidneys when expression was normalized to the best housekeeping gene *miR-26a*.

Conclusions: We have established the best housekeeping, *miR-26a*, for RT-qPCR analyses in kidney tissues of *Pkd1*-deficient mouse models.

Pain in Autosomal Dominant Polycystic Kidney Disease: Results from the DRINK Randomised Phase 2 Trial

Ragada El- Damanawi,[1,2] Michael C. Lee,[6] Tess M. Harris,[3] Laura B. Mader,[4] Richard N. Sandford,[5] Ian Wilkinson,[1,2] Fiona E. Karet,[5] Thomas F. Hiemstra.[1,2] *[1]Cambridge Clinical Trials Unit, Cambridge, United Kingdom; [2]Division of Experimental Medicine and Immunotherapeutics, University of Cambridge, Cambridge, United Kingdom; [3]Polycystic Kidney Disease Charity, London, United Kingdom; [4]Patient Led Research Hub, Cambridge, United Kingdom; [5]Division of Renal Medicine and Departments of Medical Genetics, University of Cambridge, Cambridge, United Kingdom; [6]Division of Anaesthesia, University of Cambridge, Cambridge, United Kingdom.*

Background: Pain affects 60% of the adult Autosomal Dominant Polycystic Kidney disease (ADPKD) population. Despite being an early and debilitating symptom, mechanisms of ADPKD-related pain (ACP) are poorly understood. We designed and administered an ADPKD-specific pain questionnaire to participants in the 'DRINK' Phase 2 study of water intake in ADPKD (NCT02933268), where 42 pre dialysis adult ADPKD patients were randomised to either high water (n=21) or ad libitum water (n=21) intake over 8 weeks follow up.

Methods: 'DRINK' participants completed the bespoke pain questionnaire on paper or via smartphone application. The questionnaire explored key domains including pain severity, quality, interference, frequency and location. Analgesic burden was also evaluated. Primary objectives were to describe the nature of ACP and develop a validated ADPKD-specific pain assessment tool.

Results: 39 participants completed 72 questionnaires during the study. 59% were Female, 90% White British with a mean±SD age 47±13 years. 69% had enlarged kidneys (bipolar length≥16.5cm), and median eGFR was 76 (47-111) ml/min/1.73m^2. 17% of respondents indicated pain frequency 0-1 times/week, 79% had pain 2-3 times/week and 4% had continuous pain. Pain severity was assessed using an 11-point numerical score further classified: 0-No pain, 1-3 Mild, 4-6 Moderate, >7 Severe. For overall pain, 36% had no pain, 38% had mild pain, 17% moderate pain, and 3% severe pain. In a multivariable regression model, pain severity was associated with increasing age, female gender, CKD stage 3 or worse and hypertension but not with kidney size.

Conclusions: In our cohort pain was common and severe. Despite the association between some markers of disease progression and pain severity, the poor correlation with kidney size suggests that there are mechanisms unrelated to renal anatomy that contribute to chronic pain in patients with ADPKD.

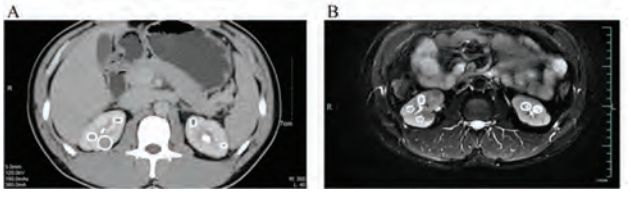
The Pathogenic AGTc.856+1G>T Mutation of a Patient with Multiple Renal Cysts and Hypertension

Wenqing Chen,[1] Bingjue Li,[2] Jianghua Chen,[3] Hong Jiang.[1] Key Laboratory of Kidney Disease Prevention and Control Technology, Zhejiang Province *[1]The First Affiliated Hospital of Zhejiang University, Hangzhou, China; [2]Zhejiang University, Hangzhou, China; [3]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Introduction: Angiotensinogen (AGT) is an essential member of the renin-angiotensin system (RAS), this system regulates blood pressure and affectsphysiological function of the kidney. Here we report a 29-year-old male Chinese with essential hypertension and cystic kidney disease. Direct sequence analysis of the patient and his parents revealed a mutation in the splice donor site of intron 2 of the *AGT* gene, c.856+1G>T. This mutation was a heterozygous form and inherited from mother.

Case Description: Direct sequence analysis of the patient and his parents revealed a mutation in the splice donor site of intron 2 of the *AGT* gene, c.856+1G>T. This mutation was a heterozygous form and inherited from mother, and the mother was diagnosed with essential hypertension over 20 years. We tested the serum angiotensinogen concentration and found the patient and the mother hadlowerserum angiotensinogen levels than the father. Function prediction of c.856+1G>T mutation using online software showed this intron mutation may affect protein feature by destroying normal splice site. These findings suggest that this intron mutation of the *AGT* gene is related to the patient's essential hypertension and cystic kidney disease.

Discussion: Studies found that mutations of the human *AGT* gene areinvolved in diseases such as recessive renal tubular dysgenesis (RTD) and essential hypertension (EHT). We presented a case of a new intron mutation of *AGT* Gene in a 29-year-old male Chinese with multiple renal cysts and hypertension, it is a heterozygous mutation inherited from his mother. The patient's renal function impairment progressed slowly. His renal cystic lesion and hypertension seem to be due to the presence of heterozygous c.856+1G>T mutation in the*AGT* gene. Animal experiments and large sample studies are needed to confirm the relationship of c.856+1G>T mutation in the *AGT* gene of angiotensinogen expression and renal cyst formation and hypertension.



Typical renal cystic structures of the enhanced CT image of the patient's kidneys.

AD(H)PKD: A Prospective Cohort Study on the Use of Tolvaptan in ADPKD

Franziska Grundmann, Simon Oehm, Polina Todorova, Victor Suárez, Volker R. Burst, Thomas Benzing, Roman-Ulrich Mueller. *Department II of Internal Medicine and Center for Molecular Medicine Cologne, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany*.

Background: The approval of tolvaptan as the first targeted therapy of autosomal-dominant polycystic kidney disease significantly changed treatment of this disease and the counselling of patients. But which patients are actually treated and how is the therapy managed and tolerated in the real-life setting?

Methods: To answer these questions, we initiated the AD(H)PKD registry which enrolls ADPKD patients who present with the question whether tolvaptan would be a treatment option. The cohort contains data of patients on Tolvaptan and without targeted treatment. We collect information on a yearly basis including lab values, kidney volume, quality of life, adherence, genotype, extrarenal manifestations, comorbidity, side effects and complications.

Results: Since the start of the study at the end of 2015 until now more than 560 patients could be enrolled. Here, we present data on the first 500 patients. Of those, 54.4 % (n=272) are female. Mean age at enrolment was 43.9±11.9 years (female (f): 44.1±12.1, male(m):43.7±11.6). While women were diagnosed with a mean age of 25.7±13.0 years, males learned about their disease at the age of 28.4±12.8 years. As expected, the majority of patients (87.6%; n=438) reported a positive family history with regard to ADPKD. In 83.4% of the cohort (n=417) arterial hypertension was diagnosed, 42.2% (n=211) experienced elevated blood pressure before the age of 35. Mean GFR at baseline visit (CKD-EPI) was 68±44 ml/min. Kidney function in females was more preserved than in males (f:72±53 ml/min, m: 64 ±28 ml/min). In 393 participants, renal volume could be calculated via radiologic imaging. In line with the more advanced loss of kidney function, height adjusted total kidney volume was larger in male patients (htTKV, f:875±543ml m:1350±1168ml). 24.9% (n=98) of the cohort were classified as Mayo A or B, 75.1% (n=295) as Mayo class C to E.

Conclusions: The AD(H)PKD study continues successful enrolment and provides valuable data on patient characteristics, selection strategies for targeted treatment and tolerability of tolvaptan in a real-life setting. We expect analyses concerning outcome parameters on tolvaptan treatment with a sufficient amount of 3 year follow up data in 2020. These results will be very useful for guiding treatment strategies and patient counselling in the future.

PUB206

Elderly-Onset Rapidly Progressive Renal Dysfunction with Renal Enlargement and Medullary Cystic Kidney Disease (MCKD) Might Be a New Disease Entity of Ciliopathy Unlike Traditional Hereditary MCKD

Shinya Kawamoto,[1] Hideo Misawa,[1] Yoshihiko Ueda,[2] Tetsuro Takeda.[1] *[1]Dokkyo Medical University Saitama Medical Center, Koshigaya, Japan; [2]Saitama Medical Center, Koshigaya, Japan*.

Introduction: Recently there have been several reports of rapidly progressive renal dysfunction in elderly patients with renal enlargement and MCKD in Japan. Here we reported three cases who have undergone dialysis with rapid progression and performed analysis of gene panel for target sequence of inherited kidney disease. But neither mutation of known MUC1 or UMOD was detected.

Case Description: 1.84-year-old Japanese woman without family history of kidney diseases was noted to have renal dysfunction of unknown etiology 1 year prior to admission. She had developed progressive renal dysfunction (Cr 3.7mg/dL). Her abdominal CT revealed bilateral renal enlargement and histological findings revealed marked tubular dilatation with extensive fibrosis in the interstitium, consistent with MCKD. She was initiated dialysis 3 month after. 2.74-year-old woman was noted to have mild renal impairment (Cr 1.1mg/dL) 1 year prior to admission. She developed progressive renal dysfunction (Cr 3.6mg/dL). Her serial abdominal CT revealed no evidence of renal enlargement before admission and bilateral renal enlargement at admission. Her histological findings revealed consistent with MCKD. She was initiated dialysis 5 month after. 3. 80-year-old woman was noted to have renal dysfunction (Cr 1.9mg/dL) 1 year prior to admission. She had developed progressive renal dysfunction (Cr 3.3mg/dL). Her CT revealed bilateral renal enlargement and histological findings revealed consistent with MCKD. She developed progressive renal dysfunction just before dislysis initiation 1 year after.

Discussion: We reviewed the literature on 16 subjects (thirteen similar cases reported in Japan since 2007 and our three cases). The age at renal biopsy was 70 years. Before renal biopsy, a rate of Cr elevation was 0.6 mg / dL / month, and renal biopsy was performed at 4.1 mg / dL of Cr. Urine protein were positive in all cases, urine occult blood was positive in 9 cases. Renal enlargement was observed in 13 cases. Renal biopsy findings showed minor glomerular changes and marked dilated renal tubules and interstitial fibrosis. After renal biopsy, 13 cases reached ESRD in 3.9 months. Target gene sequence of inherited kidney disease were performed in 6 cases, and neither mutation of MUC1 or UMOD was detected.

PUB207

Comparative Effectiveness of Disease-Modifying Agents in Patients with ADPKD: A Systematic Review and Network Meta-Analysis

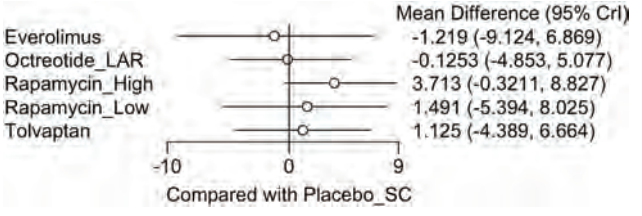
Nigar Sekercioglu,[1] Rui Fu,[2] Luciane C. Lopes,[3] Rosilene M. Elias,[4] Bryan M. Curtis.[5] ADPKD study *[1]Health Research Methods, Evidence and Impact, McMaster University, Hamilton, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Uniso, Sorocaba, Brazil; [4]Universidade de Sao Paulo, Sao Paulo, Brazil; [5]Memorial University, St. John's, NL, Canada*.

Background: ADPKD is the most common hereditary kidney disease with about 1:500 frequency, 100% penetrance and multisystem involvement. The purpose of this study is to explore the effectiveness and safety of disease-modifying agents for ADPKD.

Methods: We conducted searches on the MEDLINE, EMBASE and CINAHL databases from the inception to May 2019 for RCTs with ≥ six-month follow-up. Teams of two reviewers, independently and in duplicate, screened titles and abstracts, completed full-text reviews, and abstracted data. Eligible trials enrolled patients with ADPKD, randomized to receive rapamycin, everolimus, octreotide, tolvaptan, standard care, or placebo, and reported effects on patient-important outcomes (e.g., all-cause mortality), total kidney volume (TKV), glomerular filtration rate (GFR), or medication-related adverse events. We excluded preclinical experiments, crossover trials, and conference proceedings. We performed network meta-analysis (NMA) and pooled treatment effects as mean differences (MD) and calculated 95% credible intervals (Crls) using random-effects models. We applied the GRADE (Grading of Recommendations, Assessment, Development and Evaluation) approach to rate the quality of evidence.

Results: Our search yielded 635 citations, of which 11 met the inclusion criteria and involved a total of 3703 adults with ADPKD, including 2106 (56%) patients receiving treatments and 1597 (44%) receiving placebo and/or standard care. The random-effects models suggested rapamycin leads to a reduced change of TKV at 12 months (NMA MD, -436 [95% Crl, -639 to -212]. Twenty-five comparisons failed to reach statistical significance in the network estimates for the GFR outcome. Patients treated with rapamycin at high target dose had a higher likelihood of slowing of GFR decline as compared to those treated with other treatment categories.

Conclusions: Our results suggest that rapamycin reduced changes in TKV at 12 months and in high doses attenuated the GFR decline.



Network meta-analysis results for GFR. Forest plot of effectiveness outcome for mean GFR reduction at the end of the study period.

A Novel Genetic Model of Cystic Kidney Disease in the Mouse

Joshua S. Waitzman,[1,2] Ummiye venus Onay,[1] Susan E. Quaggin.[1] *[1]Medicine—Nephrology, Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA*.

Background: Polycystic kidney disease is the most common genetic cause of chronic kidney disease and end stage renal disease. While mutations in PKD1 and PKD2 cause most cases of autosomal dominant PKD, other genetic factors are thought to act as modifiers.

Methods: Using an ENU mutagenesis screen, we have identified a cystic kidney mutant that is transmitted in an autosomal dominant manner. We have characterized the mutation using both whole genome sequencing and RNA sequencing.

Results: Mice heterozygous for the trait develop glomerular and tubular cysts all along the nephron, but otherwise appear healthy. Mice that are homozygous for the trait develop hypoplastic, cystic kidneys, and are perinatally lethal with pulmonary hemorrhage. We have performed whole genome sequencing and identified potentially causative gene mutations on mouse chromosome 6. We have also performed RNA sequencing on kidneys from affected mice and matched controls and have identified significant changes in gene expression.

Conclusions: We present a novel mouse model of cystic kidney disease, which we have genetically and phenotypically characterized. We propose that the differentially regulated genetic elements that we have identified may represent genetic modifiers of cystic kidney disease.

PUB209

Just a Sugar Pill: Trehalose in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Daniel Atwood. *University of Colorado Anschutz, Aurora, CO*.

Background: ADPKD has been described as a case of suppressed autophagy. Trehalose (TRE) is a non-reducing disaccharide and FDA-approved food sweetener. Trehalose has demonstrated utility *in vivo* and *in vitro* as an autophagy inducer. The goal

of the present study was to test the interventional effects of TRE on cyst growth, kidney function, and autophagy-associated proteins in a hypomorphic *Pkd1*$^{RC/RC}$ mouse model of ADPKD.

Methods: Wildtype (WT) and *Pkd1*$^{RC/RC}$ (PKD) mice were treated with either tap water (VEH) or 2% TRE from 50-120 days of age. Water intake was recorded as it is known to affect cyst burden. Autophagy-associated proteins were measured in kidney homogenates by immunoblot: pBeclin1 (Ser15) (marker of initial steps of autophagosome formation), ATG12/5 complex (lipidates and inserts LC3B into autophagosome membrane), LC3-II (marker of autophagosomes) and Ras-related protein 9a (Rab9a) (marker of late steps of autophagosome maturation). Statistical analysis was performed on relative densitometry units (RDU) obtained from immunoblots (Table).

Results: See Table. TRE, that is slightly sweet, did not affect water intake, nor did it change serum arginine vasopressin (AVP) or serum copeptin levels, which are sensitive to water intake. LC3-II was increased by TRE in WT but not PKD kidneys. Rab9a was decreased in PKD kidneys and not affected by TRE. pBeclin1 was increased in PKD kidneys and restored by TRE. ATG12/5 complex was decreased in PKD kidneys and not affected by TRE. TRE did not reduce cyst number or two kidney weight (2KW) to body weight (BW) ratios or improve kidney function in PKD vs. WT.

Conclusions: The most striking finding was suppressed ATG12/5 complex and decreased Rab9a suggesting defects in LC3B lipidation and insertion into autophagosome and autophagosome maturation, respectively, in *Pkd1*$^{RC/RC}$ mice. These defects were not rescued by TRE. TRE did not reduce cyst burden or improve kidney function.

Funding: Veterans Affairs Support, Other U.S. Government Support

Autosomal Dominant Polycystic Kidney Disease (ADPKD): Optimization of the Evaluation of Total Kidney Volume

Roberta Fenoglio,[1] Savino Sciascia,[2] Dario Roccatello.[1] *[1]Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), Giovanni Bosco Hospital and University of Turin, Italy, Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Turin, Italy; [2]Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), Giovanni Bosco Hospital and University of Turin, Italy, Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Turin, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD**)** is the most common inherited renal disorder. It is characterized by progressive development of renal cysts and increase in total kidney volume (TKV). TKV is a critical requisite to initiate tolvaptan therapy. Patients (pts) must have a TKV >750 ml. To be eligible to treatment. To date, the gold standard for the radiological technique to measure TKV remains undefined. Aim: Comparison between currently available radiological techniques to measure TKV evaluated for tolvaptan therapy focusing on precision in TKV measuring, reproducibility and costs of the radiological technique. Patients selection**:** Patient with a diagnosis of ADPKD, with Genetic positivity or Familiar history of ADPKD and ultrasound evaluation.

Methods: Thirty-nine patients were screened for potential therapy with tolvaptan (range of age 18-49 yrs). Twenty-nine patients were excluded because of either e-GFR values of >90 ml\min (18 pts) or e-GFR values <40 ml/min (4 pts), refusal of treatment (3 pts), linguistic problems (2 pts), liver disease (1 pt) or currently breast feeding. Ten patients (6 female mean age: 38 years, mean creatinine value 1.1mg/dl, mean e-GFR 63 ml/min) were enrolled and were examined by Magnetic Resonance Imaging (MRI), Ultrasound and Computer Tomography (CT). TKV values were measured using the ellipsoid formula applied in each technique a. It was combined to manual evaluation in the case of MRI and CT. The values were compared by linear regression analysis and Altman-Plot graphs.

Results: As compared to CT and MRI, ultrasound, especially at the higher TKV values, gave over-estimated TKV values, MRI and CT showed comparable accuracy and reproducibility, especially when data were manually processed (R2= 0,99).

Conclusions: Ultrasound proved to be not as reliable as MRI or CT when measuring TKV. Patients age, comorbidities, availability of instrumentations and costs may influence the choice between MRI and CT, which appear to be comparably effective in TKV evaluation.

PUB211

Vaptans, New-Generation Diuretics, Exert Their Aquaretic Effect Through Inhibition of Aquaporin 2 Trafficking in Renal Collecting Duct Cells

Annarita Di Mise,[1] Maria Venneri,[1] Marianna Ranieri,[1] Mariangela Centrone,[1] Lorenzo Pellegrini,[2] Grazia Tamma,[1] Giovanna Valenti.[1] *[1]University of Bari, Bari, Italy; [2]Palladio Biosciences, Newtown, PA.*

Background: Selective vasopressin V2 receptor (V2R) antagonists (vaptans) are a new generation of diuretics. Compared with classical diuretics, vaptans promote the excretion of retained body water in disorders where plasma vasopressin concentrations are inappropriately high for any given plasma osmolality. Under these conditions an aquaretic drug would be preferable over a conventional diuretic. The clinical efficacy of vaptans is in principle due to impaired vasopressin-regulated water reabsorption *via* the water channel aquaporin-2 (AQP2).

Methods: Here, the effect of lixivaptan - a novel selective V2R antagonist - on the vasopressin-cAMP/PKA signaling cascade was investigated in mouse renal collecting duct cells expressing AQP2 (MCD4) and the human V2R. Compared to tolvaptan - a selective V2R antagonist indicated for the treatment of clinically significant hypervolemic and euvolemic hyponatremia -, lixivaptan has been predicted to be less likely to cause liver injury.

Results: In MCD4 cells, immunofluorescence localization of AQP2 and analysis by confocal microscopy showed that clinically-relevant concentrations of lixivaptan (100nM for 1h) prevented dDAVP-induced AQP2 phosphorylation at ser-256 and AQP2 translocation to the plasma membrane. Consistent with this finding, real-time fluorescence kinetic measurements demonstrated that lixivaptan prevented dDAVP-induced increase in osmotic water permeability.

Conclusions: These data represent the first detailed demonstration of the central role of AQP2 blockade in the aquaretic effect of lixivaptan and suggest that lixivaptan has the potential to become a safe and effective therapy for the treatment of disorders characterized by high plasma vasopressin concentrations and water retention.

Medullary Sponge Kidney with Recurrent Nephrolithiasis: A Genetic Disease?

Bindu A. Pillai,[1] Anjali Acharya.[2] *[1]Jacobi Medical Center, Floral Park, NY; [2]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Introduction: Medullary Sponge Kidney (MSK) is a malformation with tubular dilation of the collecting ducts and cystic dilation of the medullary pyramids of the kidney. It can manifest as nephrocalcinosis, nephrolithiasis, renal tubular acidification and concentration defects or rarely as frequent urinary tract infections. It can be seen in up to 20% of recurrent stone formers.

Case Description: A 62 year old woman with a history of nephrolithiasis for over 30 years, presented to the emergency department with dysuria and flank pain and was found to have recurrent kidney stones. The patient had undergone three extra corporeal shock wave lithotripsy (ESWL) procedures and numerous other urological procedures with stent placement for calcium oxalate and calcium phosphate stones. An ultrasound study done of the kidney showed images with uniform distribution of multiple stones, with distention of the medullary and papillary portions of the collecting ducts, suggestive of medullary sponge kidney. 24 hour urine studies were suggestive of hypercalciuria and hypocitraturia. Renal function remains normal, with no proteinuria or hematuria. Patient was encouraged a high fluid intake and normal calcium and low sodium diet. Thiazide was started with decrease in 24 hour calcium excretion.

Discussion: MSK is now thought to be a developmental disorder related to issues arising during renal morphogenesis. Problems with concomitant urteric bud and metanephric blastemal due to abnormal signaling of glial cell line derived neurotrophic factor (GDNF) and its receptor RET is speculated to play a role. Usually sporadic and asymptomatic, it can manifests in familial clusters. recurrent calcium nephrolithiasis and nephrocalcinosis are prominent features with hypercalciuria seen in almost 100% of MSK patients. Distal acidification defect seems to be a major player in pathogenesis. The clinical course varies from silent to indolent, to rarely progression of nephrocalcinosis. ESRD is seen in less than 10% of MSK patients. Diagnosis is radiographic with traditionally urography being the gold standard. Now Ultrasound, uro CT and MR urography are being used for diagnosis. Though there is no treatment for MSK, prophylactic therapy for stone prevention is crucial. Screening of family members should be considered as part of history taking.

PUB213

Association Between VDR Gene FokI Polymorphism and Renal Function in Patients with IgA Nephropathy

Manqiu Mo, Ling Pan, Yunhua Liao. *The First Affiliated Hospital, Guangxi Medical University, Nanning, China.*

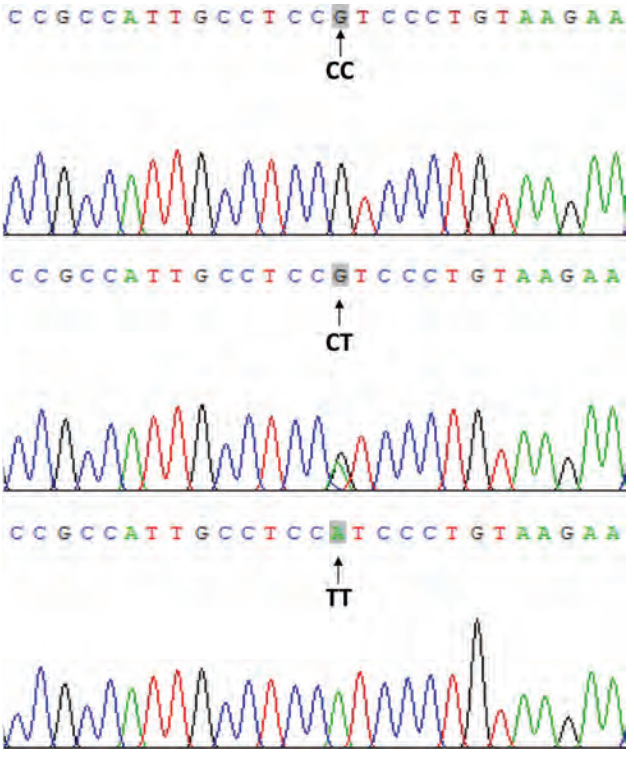
Background: To investigate the association between *VDR* gene *FokI* rs2228570 polymorphism IgA nephropathy (IgAN) and IgAN renal function and related clinical and pathological parameters, and to seek the genetic susceptibility genes for patients with renal dysfunction in IgAN.

Methods: Clinical and pathological data of 282 IgAN patients treated at the First Affiliated Hospital of Guangxi Medical University were collected, and *FokI* genotypes

were determined by PCR and direct sequencing. Patients were divided into the renal dysfunction group and normal renal function (control) group by estimated glomerular filtration rate (eGFR) and serum creatinine level.

Results: Among 282 patients with IgAN, 55.32% of patients had renal dysfunction (156/282). Frequencies of TT genotype and T allele in the renal dysfunction group were higher than those of the control group. Blood urea nitrogen, serum phosphorus (P), proportions of mesangial cell proliferation, interstitial fibrosis/tubular atrophy and crescents in T allele carriers were higher than those in non-T allele carriers, while eGFR and 25-Hydroxyvitamin D3 were lower in T allele carriers than non-T allele carriers. Multiple linear regression analysis showed that eGFR was affected by *FokI* genotypes in IgAN patients. Logistics regression analysis showed that middle and elderly age, elevated P, intact parathyroid hormone and TT genotype were independent risk factors for renal dysfunction in IgAN patients; the odds ratio of carrying the TT genotype was as high as 84.77 ($P<0.05$ for all).

Conclusions: Patients of IgAN carrying *VDR FokI* TT genotype have an increased risk of renal dysfunction. *VDR FokI* is closely related to renal function, calcium-phosphate metabolism and related pathological damage in IgAN patients.



Chromatograms of direct sequencing for *VDR FokI* rs2228570 polymorphism

PUB214

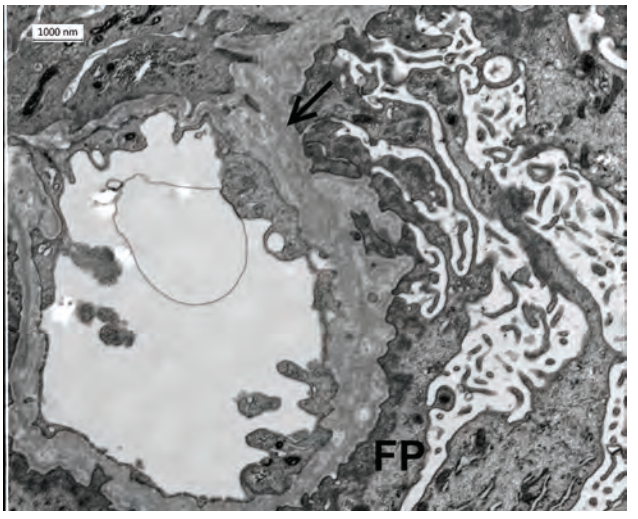
Tissue Is the Issue: When a Second Biopsy Reveals the True Diagnosis

Anne Marie Bogaert. *Nephrology, AZ Sint-Elisabeth, Zottegem, Belgium*.

Introduction: We describe the case of a woman 41-years old, followed at our outpatient clinic with stable microscopic haematuria and mild proteinuria since 10 years. Underlying diagnosis of minimal glomerular changes was made after initial kidney biopsy.

Case Description: After several years of stable clinical and biochemical follow-up, progressive proteinuria was present since the end of 2017, upon nephrotic range of 3,5g/24h. Therefore a new kidney biopsy was planned, revealing focal segmental glomerulosclerosis (FSGS). Further differentiation by electron microscopy (EM) suggested an underlying genetic disorder. Next generation DNA sequencing was performed and showed that the patient was heterozygous for a pathogenic mutation in the *COL4A3* gene. This disorder shows considerable heterogeneity and is in our patient associated with late onset of FSGS that developed on top of the basement membrane nephropathy. Establishing a genetic cause of disease in this patient avoids exposure to immunosuppressive regimens, used to treat primary FSGS, as such treatment is ineffective in genetic FSGS and may pose considerably toxicity.

Discussion: By this case we want to stress the importance of re-biopsy when there is non-explained substantial increase in proteinuria on long term follow-up. Furthermore EM can be helpful for further differentiation and treatment decision. Genetic testing in all patients with adult onset FSGS that cannot be regularly categorized by clinic-pathologic assessment should be considered. Establishing a genetic cause of disease in this patient avoids exposure to immunosuppressive regimens, used to treat primary FSGS, as such treatment is ineffective in genetic FSGS and may pose considerably toxicity.



Ultrastructural alterations: Splitting of the lamina densa is observed (arrow), resulting in irregular thickening and contouring of the glomerular basement membrane. The foot processes (FP) are effaced (x 7000).

PUB215

Renal Functional Reserve Capacity Through Acute Protein Load in Patients with Gitelman Syndrome

Bingbin Zhao,[1] Peng Xia,[1] Lei Zhang,[1] Ke Zheng,[1] Haiting Wu,[2] Xuemei Li,[1] Limeng Chen.[1] [1]*Peking Union Medical College Hospital, Beijing, China;* [2]*Peking Union Medical College Hospital, Beijing, China*.

Background: Gitelman syndrome (GS) is a recessively inherited salt-losing tubulopathy caused by the disorder of sodium-chloride co-transporter (NCC). This pilot study aims to evaluate the renal functional reserve (RFR) in GS patients by acute protein load, and to figure out the effect of connecting tubule glomerular feedback (CTGF) secondary to NCC dysfunction.

Methods: We recruited 19 healthy controls and 4 GS patients, diagnosed by clinical examination and genotyping. Serum and urine were collected before and after oral protein load (1.2g/kg of body weight) at different timepoints (-1h, 0h, 1h, 2h, 3h and 4h). RFR was evaluated by eGFR changes, based on creatinine and serum cystatin C clearance. The urinary metabolite of prostaglandin E2 (PGEM), the signaling molecule of CTGF metabolite, was tested by ELISA through the process.

Results: The average age of healthy control group was 27.1±2.9 yr and 47.7% were male. Their baseline creatinine clearance was 140.9±31.5 ml/min/1.73m^2 and a significant difference between stress and basal creatinine clearance ($p<0.001$) was observed, with a mean RFR of 32.8±20.8 ml/min/1.73m^2. In GS patients with an average age of 27.0±7.0 yr and 50% male, both the baseline creatinine clearance and RFR showed no significant difference between the patients and controls ($p=0.091$), neither in cystatin C clearance. A good agreement between the creatinine clearance and cystatin C-based GFR was found by Bland-Altman plots. Higher level of urinary PGEM in GS patients than that of controls was observed. After protein load, the urinary PGEM levels were increased in both groups.

Conclusions: GS patients had normal RFR stimulated by acute protein load. It might be associated with the activating of CTGF, afferent arteriolar vasodilation and increased blood flow and GFR.

PUB216

Enzyme Replacement Therapy and Fabry Nephropathy

Ana Paula Gueiros, Jose E. Gueiros, Andréa D. Santos, Natália S. Antunes, Ana cecília M. Siqueira. *CETREIM, Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil*.

Introduction: In Fabry nephropathy (FN), alpha-galactosidase deficiency leads to accumulation of glycosphingolipidis in all kidney cell types, proteinuria and progressive loss of kidney function. The aim of this study was to assess the clinical course of FN in two women with pathogenic mutations undergoing treatment with agalsidase beta (Fabrazyme®; Sanofi Genzyme, Cambridge, MA, USA) during a 6-year period.

Case Description: Case 1– AMSL, aged 61. Symptoms first appeared when the patient was aged 51, when she complained of myalgia, arthralgia, asthenia, dyspnea on exertion, tinnitus, abdominal pain and constipation. One year later, she was diagnosed with proteinuria and heart disease. She performed a kidney biopsy, which under light microscopy suggested deposit disease. No electron microscopy was performed. Genetic analysis demonstrated a mutation in exon 5 - p.K237X. At the time, she presented with creatinine (Cr) of 0.9 mg/dL and proteinuria of 1.2 g/day and an echocardiogram with a left ventricular mass (LV) of 392 g and LV mass index 238 g/m^2. In January 2012, she initiated enzyme replacement therapy (ERT) with agalsidase beta, 1.0 mg/Kg body weight once every 2 weeks, and conversion enzyme inhibitor. Currently, Cr is 1.0 mg/dL and proteinuria 0.3 g/day. During the follow-up period, there were no major cardiovascular

and/or central nervous system events. **Case 2**– DCBT, aged 60. The patient was diagnosed with cornea verticillata aged 13. Twelve years ago, she presented clinical signs of hypohidrosis, arthralgia, bradycardia and proteinuria. Genotyping revealed a C142R mutation. In 2012, after presenting a transient ischemic attack, she was commenced on ERT with agalsidase beta (1.0 mg/kg once every 2 weeks). At the time, she presented Cr 0.9 mg/dL and proteinuria 0.3 g/day. During the follow-up period, she presented three episodes of atrial fibrillation, which motivated treatment with propafenone and rivaroxaban. Currently, Cr is 0.8 mg/dL and proteinuria 0.17 g/day.

Discussion: This 6-year study has documented the effectiveness of agalsidase beta in patients with FN, despite delayed initiation of ERT.

PUB217

Mechanism of Mutation of AarF Domain-Containing-Kinase 4 (ADCK4) Glomerulopathy

Asmaa S. Abu-Maziad. Tomasiak Lab *Department of Pediatrics, University of Arizona, Tucson, AZ.*

Background: AarF domain-containing-kinase 4 (ADCK4) is a mitochondrial resident protein kinase belonging to the UbiB protein kinase-like family. Comprised of a single N-terminal transmembrane helix and C-terminal kinase domain, ADCK4 is thought to facilitate the ATP dependent biosynthesis of coenzyme Q10 (CoQ10). Mutations in *ADCK4*, an inherited mitochondrial nephropathy, result in defects in CoQ10 production as well as in activities involved in mitochondrial respiration, manifesting as early-onset proteinuria, focal segmental glomerulosclerosis/nephrotic syndrome, followed by end-stage renal disease (ESRD). The regulation of ADCK4 in CoQ10 biosynthesis is not well understood, necessitating biochemical and structural investigations into its functions. Furthermore, characterization of ADCK4 protein will help to discover a targeted therapy for this type of glomerulopathy/nephrotic syndrome. This work started with genetic anaysis of an 18-year-old female who presented with proteinuria at age of 5 years and developed ESRD at 20 years of age. Her family was noted with proteinuria and structural anomalies of kidney.

Methods: Genetic analysis using whole exone sequencing for a family with proteinuria and structural anomalies of kidney and urinary tract revealed a novel compound heterozygous mutation in the *ADCK4*. We generated a computational model to understand the mechanism of action of 2 novel identified mutations: I346S in the C-lobe of the ADCK4 kinase domain, and a termination at W520 that leads to the truncation of the C-terminal a5 helix.

Results: The alterations of ADCK4 c.1560G>A and c.1037T>G are novel mutations. Our computational model suggests potential mechanisms for alterations in protein function through either destabilization of important allosteric interactions necessary for kinase activation and/or conformational changes that facilitate enzyme activity.

Conclusions: ADCK4 is promising therapeutic targets for patients with *ADCK4* glomerulopathy that need a rigorous biochemical characterization. ADCK4 protein is not well characterized at biochemical level. Computational model to understand the mechanism of mutation suggests potential mechanisms for alterations in protein function destabilization of important allosteric interactions and/or conformational changes that facilitate enzyme activity. Ongoing work to reveal the biochemical and functional analysis of ADCK4 protein.

PUB218

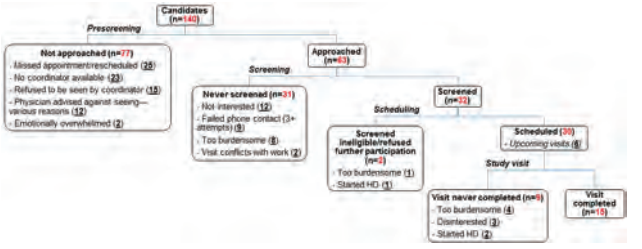
Challenges of Identifying Older Adults Initiating Hemodialysis

Eric Jia Yi Xu,[1] Tariq Shafi,[2,1] Mara McAdams-DeMarco,[1] Keiko I. Greenberg,[1] Carol A. Martire,[1] Brian Buta,[1] Karen J. Bandeen-Roche,[1] Jeremy Walston,[1] Ravi Varadhan,[1] Deidra C. Crews.[1] Resiliency in Dialysis Initiation (REDI) *[1]Johns Hopkins University, Baltimore, MD; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: Hemodialysis (HD) is a physical and psychological burden for older adults on maintenance HD. After HD initiation, while many do poorly, some older adults do quite well, recovering function with improved quality of life. Little is known about predictors of such resilience in CKD progression and transition to ESRD among older adults. We launched the Resiliency in Dialysis Initiation (ReDI) pilot study to identify short- and long-term physical resiliency indicators in older adults prior to, during and following HD initiation. Here we describe challenges in identifying participants for ReDI to inform future studies of similar design.

Methods: We aimed to recruit adults (age ≥55) with CKD who were expected to initiate HD within 8 wks. Eligible patients were prescreened in Nephrology clinic. Interested patients were formally screened by phone and those eligible were scheduled for a baseline visit. Recruited patients underwent testing including: ECG, echocardiogram, ACTH stimulation test, bioimpedance, spirometry, cognitive/physical function, psychosocial measures and accelerometry.

Results: We identified no patients expected to initiate HD within 8 wks. We then extended our inclusion criteria to eGFR ≤20mL/min/1.73m^2 and plans for future HD. Here (N=140), major barriers to prescreening (N=77) were missed clinic visits (32%) and patient refusal (19%). Barriers to screening (N=31) were disinterest (39%), failed phone contact (29%) and perceptions of study burden (26%). Barriers to baseline visit (N=9) were perceptions of burden (44%), disinterest (33%) and HD initiation prior to visit (22%). Over 5 mo, 15 (11%) eligible patients enrolled; 2 (13%) later initiated HD during hospitalization. (Figure)



Conclusions: Efforts to recruit older adults with CKD approaching dialysis in research studies should mitigate concerns of participant burden. Uncertainty surrounding which older adults with advanced CKD will initiate HD, and when, is a major factor limiting research in this area. Tools for short-term identification of older adults likely to initiate HD are needed.

PUB219

Hyponatremia in Elderly Patients with CKD Stages 3-5

Bogdan M. Sorohan, Bogdan Obrisca, Andreea G. Andronesi, Raluca Leparau, Vlad T. Berbecar, Roxana A. Jurubita, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania.*

Background: Elderly patients with chronic kidney disease (CKD) are at high risk to develop hyponatremia, which is associated with an increased risk of all-cause mortality. Our aim was to identify the frequency of hyponatremia and the associations with clinico-biological parameters in elderly patients with CKD stages 3-5.

Methods: We performed a retrospective observational study on 125 patients out of the 1739 hospitalized between 2015 and 2017 in our center. Inclusion criteria were: age ≥65 years, CKD stages 3-5 (not on dialysis). Volume status was measured by spectroscopic bioimpedance.

Results: The frequency of dysnatremia was 54.4%, including 50.4% hyponatremia and 4% hypernatremia. Regarding hyponatremia severity, 39 patients had mild, 15 moderate and 9 severe expression. Mean age was 73.6±6.5 years, 60% of patients had CKD stages 4-5 and the most frequent causes of CKD were hypertensive (31.2%) and diabetic nephropathy (30.4%). Mean BMI was 25.9±6.6 kg/m^2, 89.6% of patients were hypertensive, 41.6% diabetic, 37.6% had cardiac heart failure, 28.8% atrial fibrillation (AF), 40.8% ischemic heart disease (IHD), 14.4% peripheral artery disease, 16% history of stroke. Mean serum Na was 134±6.4 mmol/l, median overhydration status was 1L (-0.21- + 2.65) and 67.2% were diuretic users. Moderate and severe neurological symptoms were found in 12 and 6 patients, respectively. Patients with hyponatremia had more often AF (31.7% vs 25.8%), history of stroke (19% vs 12.9%), decreased levels of urea (85 vs 116 mg/dl) and no difference of eGFR. Moreover, there was a significantly decreased proportion of diuretic use (58.7% vs 75.8%, p=0.04), especially for loop diuretics (45.2% vs 54.8%, p=0.01), but a significant proportion of patients was treated with loop+aldosterone antagonist diuretic (15.9% vs 4.8%, p=0.03) in the hyponatremia subgroup. By multivariate logistic regression analysis, diuretic treatment reduced the risk of hyponatremia by 39% (OR=0.61; 95% CI 0.38-0.98; p=0.04) and the combination of loop and aldosterone antagonist therapy increased the risk 5.4 times (OR=5.43; 95% CI 1.35-2.89; p=0.01).

Conclusions: We showed that hyponatremia was frequent in elderly patients with CKD stages 3-5 and associated with cardiovascular comorbidities. Also, the diuretic treatment was an independent factor for hyponatremia.

PUB220

Epithelial Trophic Cytomegalovirus Causes Abortive Infection in Cultured Podocytes

Matthew C. Breeggemann,[1] Jurgen Heymann,[1] Qingxue Li,[2] Teruhiko Yoshida,[1] Jeffrey Cohen,[2] Jeffrey B. Kopp.[1] *[1]Kidney Diseases Branch, NIDDK, NIH, Bethesda, MD; [2]Laboratory of Infectious Diseases, NIAID, NIH, Bethesda, MD.*

Background: Cytomegalovirus (CMV) is a herpesvirus with broad tropism, allowing for infection of virtually all tissues. Clinical manifestations include retinitis, hepatitis, and kidney dysfunction, particularly in renal allografts. In native kidneys, CMV is associated with collapsing focal segmental glomerulosclerosis (FSGS). We investigated CMV infection of podocytes due to their central role in glomerular function.

Methods: Human urine-derived podocytes were cultured in collagen type I-coated flasks. Immunocytochemistry confirmed the presence of podocyte cell markers including podocalyxin, following cell differentiation. Cells were exposed to two CMV laboratory strains, TB40 or Towne, both which were engineered to express green fluorescent protein (GFP). GFP expression was analyzed by flow cytometry. RT-PCR of the early CMV gene product UL123 was performed. In order to test for a productive infection, conditioned cell media was added to a retinal pigmented epithelial cell line (ARPE) that is highly susceptible to CMV infection.

Results: Cultured podocytes demonstrated the capacity of infection when exposed to an epithelial trophic strain of CMV (TB40) as seen by GFP expression in up to 3% of cells and by RT-PCR for CMV gene expression, but not when exposed to a fibroblast trophic strain (Towne). ARPE cells exposed to cell media from infected cultured podocytes did not become infected with CMV.

Conclusions: Cultured human podocytes are susceptible to infection by an epithelial trophic CMV strain *in vitro* and this process appears to be abortive, as the infection is not transmitted to other cells. Future studies will assess cytopathic effects following CMV infection including changes in podocyte function. Studies of CMV infection of podocytes may provide mechanistic information about CMV-mediated glomerular injury, including collapsing FSGS.

Lyso-GL3-Mediated Podocyte Injury in Fabry Disease

Soyoung Kim,[2] Jeong suk Kang,[2] Samel Park.[1] *[1]Soonchunhyang University Cheonan Hospotal, Cheonan-si, Democratic People's Republic of Korea; [2]Department of Internal Medicine, Soonchunhyang University Cheonan Hospital, Cheonan-si, Chungcheongnam-do, Republic of Korea.*

Background: Podocyte injury is an early feature of Fabry nephropathy. Fabry disease is a rare X-linked lysosomal glycosphingolipid storage disorder resulting in the deficiency of the α-galactosidase A enzyme, eventually leading to end-stage renal disease. Globotriaosylceramide (lyso-GL3) is a bioactive molecule that accumulates in Fabry disease. However, the association between molecular mechanisms of lyso-GL3 and kidney damage is not well known. Thus, we investigated a mechanism how lyso-GL3 induced podocyte injury.

Methods: Cultured podocytes were stimulated with lyso-GL3 to induce Fabry disease mimic condition. Intracellular reactive oxygen species (ROS) generation was analyzed using 2'-7' dicheloro fluorescenin diacetate (CM-H2DCF-DA). Lyso-GL3-induced podocyte injury was evaluated by western blot, immunofluorescence, and albumin permeability analysis.

Results: Synaptopodin protein was significantly decreased and ROS was increased after lyso-GL3 treatment. Lyso-GL3 induced actin cytoskeleton rearrangement in podocyte. Fibronectin was increased in dose-dependent manners by treatment with lyso-GL3. Furthermore, lyso-GL3 treated podocytes showed the increased albumin permeability.

Conclusions: These results suggest that lyso-GL3-induced ROS and cytoskeletal reorganization may induce podocyte dysfunction in Fabry disease.

PUB222

Anti-Neutrophil Cytoplasmic Antibody (ANCA)-Positive Glomerulonephritis in Childhood: Description of a Single-Center Cohort

Rainer Büscher, Nora Bruns, Peter Hoyer, Anja K. Büscher. *Department of Pediatrics II, University Hospital, Essen, Germany.*

Background: Renal vasculitis is a severe manifestation of a anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitis and often presents as rapid-progessive glomerulonephritis (GN). In particular, elderly patients over 50 years are affected and data on pediatric patients are rare with shorter observation times.

Methods: We retrospectively analyzed all 14 pediatric patients in our center from 1999 to 2018 (12 female; mean age 13.2 years, mean observation time 7.2 years) with histologically confirmed ANCA-associated GN.

Results: 43% (6/14) of our patients developed end stage renal disease (ESRD), 4 patients at the time of diagnosis, 2 patients after 3 years and renal recovery could not be achieved despite laboratory remission. 4/6 ESRD patients were successfully transplanted after 2.3 years. Initially, 9/14 (64%) patients presented with extrarenal manifestations, primarily respiratory (7/14) and/or CNS (2/14) manifestations. Laboratory remission could be achieved in all patients with steroids and in addition, 5 patients received cyclophosphamide, 8 plasmapheresis and 9 patients rituximab. All 6 patients with ESRD at time of diagnosis were treated with steroids, plasmapheresis and rituximab. 7/14 patients presented with antibodies against myeloperoxidase (p-ANCA) and 7/14 against proteinase 3 (c-ANCA). All c-ANCA positive patients developed pulmonary symptoms but showed a better renal outcome (ESRD: 2/6 c-ANCA positive patients vs. 4/6 p-ANCA positive patients). On the contrary, 4/7 p-ANCA positive patients did not develop extrarenal manifestations. Renal recovery or occurence of extrarenal manifestations did not correlate with the antibody level, however, patients with ESRD showed a higher amount of affected glomeruli in renal biopsies. 2/14 patients (14%) developed a relapse of the disease 6 months and 16 years following transplantation which could be treated successfully with steroids and rituximab.

Conclusions: Several children with ANCA-positive vasculitis developed early ESRD without renal recovery after succesful antibody eliminiation. Extrarenal manifestations were frequently observed. The initial antibody level had no prognostic value for renal recovery or extrarenal mainfestations. However, patients with ESRD showed a higher amount of affected glomeruli in renal biopsies. Relapses were infrequently observed.

Thrombotic Microangiopathy vs. Class IV Lupus Nephritis in Systemic Lupus Erythematosus

Momin Alkhatib,[1] Steven Menez,[3] John Sperati,[2] Derek M. Fine,[2] Mohamed G. Atta.[4] *[1]Cairo University Faculty of Medicine, Cairo, Egypt; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins Medicine, Baltimore, MD; [4]Johns Hopkins Hospital, Baltimore, MD.*

Background: The kidney is often involved in systemic lupus erythematosus (SLE). Lupus in the kidney manifests predominantly as lupus nephritis or as vascular involvement with the severest form being thrombotic microangiopathy (TMA). The objective of this study was to capture the clinical and prognostic characteristics of TMA compared to class IV lupus nephritis in SLE patients.

Methods: We conducted a retrospective analysis of kidney pathological reports and laboratory data in 89 SLE patients. Renal prognosis was determined as the need for dialysis. All data were collected at the time when the biopsy was taken. Quantitative data were reported as mean and standard deviation, while categorical data were reported as frequency and percentage.

Results: Among 89 SLE patients screened, 27 met the inclusion criteria. Eight had TMA without evidence of ISN/RPS lupus nephritis and 19 had class IV lupus nephritis. No significant difference between the two groups according to age, gender or race. Patients in TMA group had significantly higher lactate dehydrogenase levels (718±499vs. 264±107.7 U/L, P = .009), serum C3 (100.6±39.3 vs. 65.8±27 mg/dL, P = .049), white blood cell count (14743.8±7933.3 vs. 5807.9±2053.2 x10E3/uL, P = .0004), fasting glucose level (121.5±39.8 vs. 92.1±19.4 mg/dL, P = .02), and total bilirubin (0.8±0.5 vs. 0.3±0.1 mg/dL, P = .007). Patients in TMA group had significant lower platelet count (158.4±88.6 vs. 240.3±100.3 x10E3/uL, P = .03), haptoglobin (68.8±116.1 vs. 166.8±95.4 mg/dL, P = .03), subepithelial deposits (P = .001), intramembranous deposits (P = .001), mesangial deposits (P = .009), lambda deposits (P = .015) and albumin deposits (P = .002). All TMA patients had negative Anti-DNA antibody titers. After a median follow up time of 53 weeks, renal prognosis in TMA patients was worse (P = .002). Among the TMA patients, 3 were dialysis dependent (37.5%), compared with none in class IV lupus nephritis patients. Mortality occurred in 2 TMA patients during the period of follow up.

Conclusions: Renal prognosis in TMA-associated SLE is worse than in class IV lupus nephritis. Laboratory findings can be suggestive, but renal biopsy remains superior for discrimination between the two groups.

PUB224

Renal Biopsy Performed to Diagnose Sarcoidosis but Diagnosed IgA Nephropathy: A Case Report

Yoshitaka Shimizu,[1] Taro Misaki.[2] *[1]Seirei hamamatu general hospital, Hamamatu, Japan; [2]Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan.*

Introduction: Renal disorder attributed to sarcoidosis generally causes tubulointerstitial damage. We herein report a case in which renal biopsy was performed for sarcoidosis diagnosis but was diagnosed as IgA nephropathy.

Case Description: We encountered a 69-year-old female with persistent proteinuria and hematuria. Her history included facial palsy and neurosarcoidosis diagnosed by bronchoscopy (CD4/CD8 ratio: 7.22) and CT findings (hilar lymph node swelling) 5 years prior to visiting our hospital. She was treated with prednisolone (PSL) 50 mg and her symptoms improved. PSL was gradually tapered and discontinued. She had no proteinuria and no hematuria 2 years previously (Cr 0.68 mg/dL). She was diagnosed with renal disorder (Cr 0.92 mg/dL, proteinuria 1+, hematuria 3+) 1 year previously, and she subsequently visited our hospital. CT showed lung hilar region lymph node swelling and multiple mottled shadows in the liver. Laboratory findings included the following results: ACE 36.5 U/ml, 1,25$(OH)_2$-vitamin D 67.4 pg/mL, soluble IL-2 receptor 2230 U/ml, proteinuria 0.46 g/day, and urine β-2 MG 9450 μg/L. We suspected recurrence of sarcoidosis and renal biopsy was performed for diagnosis. Mild to moderate increase of mesangial cells and matrix was observed in most glomeruli. Although tubulointerstitial injury was partially observed, epithelioid cell granuloma, which is characteristic of sarcoidosis, was not observed. IgA and C3 deposition in mesangial areas was observed in immunofluorescent analysis. Based on these findings, we diagnosed the patient with IgA nephropathy, not sarcoidosis, for the kidney lesion. Hepatic biopsy was then performed for definitive diagnosis, which showed epithelioid cell granulomas. The patient was finally diagnosed with sarcoidosis. She was subsequently treated with PSL 30 mg and her renal function and urinary findings improved.

Discussion: We experienced an interesting case that suggested IgA nephropathy diagnosed by renal biopsy and sarcoidosis diagnosed by liver biopsy. It is very rare for sarcoidosis to accompany IgA nephropathy. We speculate that IgA nephropathy occurred secondary to immune abnormality caused by sarcoidosis.

PUB225

Purtscher-Like Retinopathy: A Cue for Underlying Thrombotic Microangiopathy

Michael Allon, Arun Rajasekaran. *University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Purtscher-like retinopathy (PLR) is a retinal disorder characterized by acute visual loss and retinal findings including cotton-wool spots and intraretinal hemorrhages. PLR is a rare ophthalmological manifestation of systemic thrombotic

microangiopathy (TMA). We describe a patient who presented to the hospital with PLR and was subsequently diagnosed as having atypical hemolytic uremic syndrome (aHUS) with multiple organ involvement.

Case Description: A 36-year-old woman presented with a sudden onset of blurred vision, marked dyspnea, and decreased urine output. Vital signs were stable on admission. Fundoscopy revealed multiple bilateral peripapillary yellow-white patches like cotton wool spots, intraretinal hemorrhages, and macular edema suggestive of PLR. She was found to have worsening anemia (Hb 6.8 gm/dl), thrombocytopenia (platelet count 40,000/mm^3), and oliguric acute kidney injury (serum creatinine 8.3 mg/dl; unknown baseline renal function). Other pertinent labs included elevated LDH levels (1074 U/L), undetectable haptoglobin levels, normal coagulation profile, elevated D-Dimer (4303 ng/ml), and decreased fibrinogen levels (136 mg/dl). C3 levels were low (85 mg/dl), with normal C4 and CH50 levels. Autoimmune and infectious serologies were unremarkable. Serum vitamin B12 level was normal (628 pg/ml). A peripheral smear demonstrated numerous schistocytes. Stool shiga-toxin testing was negative. ADAMTS13 levels were normal (68%). Genetic testing panel for aHUS was unremarkable. A renal biopsy demonstrated TMA without segmental sclerosis, fibrinoid necrosis, karyorrhexis or crescents. No immune complex deposits were seen. She was treated with pulse dose steroids with slight improvement in her vision; and received 2 doses of Eculizumab. Renal function and hematological parameters failed to improve, and she was started on intermittent hemodialysis. Hospitalization was complicated by seizures secondary to posterior reversible encephalopathy syndrome because of systemic TMA. She later died owing to anoxic brain injury.

Discussion: aHUS is a subtype of TMA characterized by microangiopathic hemolytic anemia, thrombocytopenia, and renal failure. It occurs owing to dysregulation of the alternative complement pathway leading to vascular endothelial damage. The presence of PLR should alert physicians to evaluate for an underlying TMA. Unfortunately, no effective treatment for PLR exists.

PUB226

Apol1 Non-Risk and Renal Risk Variants mRNAs Directly Interact with Vitamin D Receptor (VDR) Protein in Podocytes

Alok Jha,[2] Vinod Kumar,[2] Kamesh R. Ayasolla,[2] Ashwani Malhotra,[3] Karl Skorecki,[4] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [4]Rambam Health Care Campus, Haifa, Israel.*

Background: The 3D structural bioinformatics approaches can provide useful insights into specific RNA recognition. The prediction of RNA structure helps understand the mapping of genotype (nucleotide sequence) and phenotype (secondary structure) in terms of computational modeling of evolutionary principles. RNAs adopt complex structures in the cellular environment, and RNA binding proteins bind to these complex secondary structures of the folded RNA and the exposed nucleic acid bases provide excellent recognition features for proteins and allow a much more vibrant ensemble for interactions.

Methods: The mRNA sequence of ApoL1 and its variants RNAs were retrieved by reverse transcribe and transcribing process, and the multiple sequence alignment (MSA) of mRNA sequences were performed by using R-COFFEE tool. The secondary and tertiary structures of ApoL1G0 and its variants ApoL1G1 and Apol1G2 were compared using mfold, RNAfold, RClick, and SETTER tools. After finding a VDR binding site in the ApoL1G0, G1 and G2 RNA tertiary structure, we docked VDR and PKR into the ApoL1G0, G1 and G2 RNA tertiary structures using NPDock tool that combines GRAMM program to perform a rigid body global search, ranking and scoring of best decoys using statistical potentials, clustering of best decoys and finally, a Monte Carlo Simulated Annealing procedure (with protein and nucleic acid molecules treated as rigid bodies) to optimize the protein-nucleic acid interactions in the representative clusters.

Results: The ApoL1G1 has two site-specific changes A1024G (Ser342Gly), and U1152G (Ile384Met) and the ApoL1G2 has deletions (A1162-U1167) of two codons AAC (N388) and UAU (Tyr389). These mutations correspond to the amino acid changes in ApoL1 variants ApoL1G1 and ApoL1G2 proteins. The ApoL1G0 RNA and VDR interaction are most robust in comparison to ApoL1G1 and G2 variants thermodynamically. However, in ApoL1G1 RNA-VDR complex, the number of essential hydrogen bonds are increased because of the mutated base G1152; as guanine substitution for an adenine increases essential hydrogen bonding interactions. However, ApoL1G2RNA and PKR complex formation is the most favored thermodynamically.

Conclusions: ApoL1 mRNA has a preference for protein binding and there may be a competition between VDR and Dicer or other miRISC complex protein.

PUB227

IgA Nephropathy: Role of Interleukin-17, a Novel Pilot Sequential Treatment

Miguel Uriol Rivera, Gonzalo Gómez marqués, Aina Obrador, Sonia Jimenez, Sheila Cabello Pelegrin. BIgART: Balear IgA Research Treatment *Hospital Universitario Son Espases, Palma de Mallorca, Spain.*

Background: IgA Nephropathy (IgAN) is the most common glomerulonephritis; unfortunately, it is refractory(r-IgAN) to immunosuppressive and angiotensin aldosterone inhibitors in some cases. The new pathogenic data in particular interleukin-17(IL-17) opens a new field to explore more effective treatments. We design an MNL Therapy (multicytokine normalization levels therapy) to control sequentially the possible cells (Th1, Th17, Treg lymphocytes), cytokines (IL-17 inhibition) and liposomal actions involved in IgAN. **Objective:** To evaluate the efficacy of the sequential administration of the paricalcitol and secukinumab on the proteinuria and creatinine in patients with r-IgAN.

Methods: This is a trial pilot treatment report. Changes in proteinuria (24hours-collected), plasma creatinine and urine N-Acetyl-B-D-galactosaminidase (u-NAG) during 6 months of follow-up (induction phase: month 0 to1 and maintenance phase: month 2 to 6). Evolutions of the hematuria, peripheral blood Th17, Treg (% of CD4) cells were also evaluated.

Results: Four patients were included. As whole proteinuria decreased 28, 45 and 30% from baseline at month 1, 3 and 6 respectively, including one patient who increased proteinuria. Hematuria disappeared at month 3 in all patients. Creatinine did not change over time. Treg did not change, while Th17 decreased in all patients, showing a change in the Th17/Treg profile. The u-NAG increased in 3 patients during the induction phase y decreased in all during the maintenance phase.

Conclusions: The sequential MNL therapy seems to be effective in IgAN patients; this effect was associated with a change in the inflammatory and pro-inflammatory profile. The changes in u-NAG were associated with benefits in proteinuria, which suggest that the treatment influences lysosomes activity.

PUB228

The Efficacy and Safety of Bortezomib-Based Treatment in Patients with Monoclonal Gammopathy of Renal Significance: A Single-Center Case Series Study

Yunlin Feng,[1] Jiamei Luo,[2] Chenglong Li,[2] Ping Zhang.[2] *[1]Sichuan Provincial People's Hospital, Chengdu, China; [2]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology, Chengdu, China.*

Background: Monoclonal gammopathy of renal significance (MGRS) is still an understudied disease. Bortezomib-based treatment has been shown to be effective in this population. However, the majority of relevant reports in China were single case reports. We presented our own experience on managing a series of MGRS patients by bortezomib-based treatment.

Methods: This retrospective study enrolled patients who had been diagnosed as MGRS and received bortezomib-based treatment in our division from January 2016 to January 2019. The diagnosis of MGRS was re-confirmed according to the updated International Kidney and Monoclonal Gammopathy Research Group consensus definition. Charts were retrospectively reviewed for demographic and clinical information. Serum creatinine and urinary protein were measured after each treatment to evaluate the renal outcome. Treatment-associated adverse events were also recorded. The outcomes were descriptively summarized individually.

Results: Nine patients (male/female=7/2) were included, with a median age of 68 (range, 49–73) years. All had been confirmed to have an abnormal plasma cell-originated pathologic clone by bone marrow flow cytometry. Median treatment duration was 5 (range, 1–7) weeks. The overall response rate of 33.3% (3/9), including one case of complete response and two cases of partial response. There were three episodes of severe infection, leading to an incidence of 7.3% (3/41).

Conclusions: Bortezomib-based treatment achieved a renal response of 33.3% in the treated nine MGRS patients. Incidence of adverse events was 7.3%, all being infection. A tailored and clone-targeted approach would be the core of future management.

A Prescribed Chinese Traditional Medicine, Shen Ping Decoction, Inhibits Multiple Protein Kinases Activated by PDGF in Human Mesangial Cells

Xianwen Zhang,[1,2] Zhi qiang Huang,[2] Joshua C. Anderson,[2] Lin Wang,[1] Stacy D. Hall,[2] Bruce A. Julian,[2] Yiping Chen,[1] Christopher D. Willey,[2] Jan Novak.[2] *[1]Longhua Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: A prescribed Chinese traditional medicine, Shen Ping decoction (SP), has been used in China to treat IgA nephropathy (IgAN) successfully for decades, reducing proteinuria and hematuria. Our previous work showed that SP inhibits mesangial-cell (MC) proliferation, phosphorylation of PDGFR-β, Axl and ERK1/2, induced by PDGF or pathogenic IgA1-containing immune complexes. Furthermore, SP inhibited phosphorylation of EGFR induced by angiotensin II. In this study, we used kinomic profiling to assess the effects of SP on tyrosine kinases in MC.

Methods: Primary human MCs were stimulated with 10 ng/ml PDGF for 15 min in the presence or absence of SP. Cell lysates were harvested and subjected to array-based profiling of protein-kinase activities against ~144 phosphorylatable peptide targets. These targets were mapped to upstream kinases that were then overlaid on network models.

Results: Global protein-tyrosine kinome profiling revealed that PDGF activated multiple kinases. Top 10 activated kinases were fms, RYK, Lyn, Flt3, TRKB, PDGFR, Txk, CCk4/PTK7, Ret, and Flt4. SP inhibited activation of multiple kinases that were induced by PDGF. Top 10 of those inhibited kinases were PDGFR-β, Ron, PDGFR, Flt4, Hck, ITK, RYK, CTK, Lmr1, and JAK1. Network-model analysis suggested that these kinases are mainly involved in signaling of PDGF/PDGFR pathway through STAT and NF-κB, cytoskeleton remodeling, TGF-β-mediated cellular proliferation, TGF-β-mediated transactivation of membrane receptor signaling, and MAPK-mediated cellular proliferation.

Conclusions: The inhibitory effects of the Chinese traditional medicine SP on multiple tyrosine-kinase activities activated by PDGF may provide a mechanistic explanation for SP activities in IgAN. Future studies are needed to identify active compounds in SP and then test them as targeted therapy of IgAN.

PUB230

Production of Human Podocyte PLA2R Protein with Application of Anti-PLA2R ELISA in Patients with Membranous Nephropathy

Tsai-yi Wu,[1] Kun-Hua Tu,[2] Cheng-Lung Ku.[1] *[1]Chang Gung University, Taoyuan, Taiwan; [2]Chang gung memorial hospital, Taoyuan, Taiwan.*

Background: Anti-phospholipase A2 receptor (PLA2R) autoantibodies could be found in 60~85% patients with idiopathic membranous nephropathy. It's believed that these autoantibodies attacking on the auto-antigens, membrane-form PLA2R upon the podocyte, form immune complex and then cause podocyte damage. To investigate the entities of these autoantibodies, we conduct a study to manufacture the recombinant human PLA2R protein with extracellular domain (soluble-form PLA2R).

Methods: The cDNA of extracellular PLA2R was cloned into specified vector, then transfected into Freestyle 293 system. After expression, protein is undergone purification with affinity chromatography. Recombinant protein was examined by Western blot, SDS-Page to confirm the protein properties. Finally, these recombinant proteins would be used as coating protein to detect plasma anti-PLA2R autoantibodies which are confirmed by commercial ELISA-kit (Euroimmune).

Results: According to the Western blot and SDS-Page, the recombinant proteins have accurate molecule weight. Recombinant human PLA2R protein can be used to detect plasma anti-PLA2R autoantibodies. Comparing to commercial ELISA-kit, the titers trends of autoantibodies are highly correlated (r=0.89).

Conclusions: We successfully manufactures recombinant human PLA2R protein. Entities of the protein was carefully examined. This recombinant protein could be applied as in-house anti-PLA2R ELSIA assay. Furthermore, the recombinant protein could help us to investigate the feature of anti-PLA2R autoantibodies from patient's sample in further studies.

PUB231

The Role of Secretary IgA in the Pathogenesis of IgA Nephropathy

Rina Kato,[1] Hitoshi Suzuki,[1] Yusuke Suzuki,[1] Masahiro Muto.[2] *[1]Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Faculty of Medcine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is the most frequent primary glomerulonephritis, characterized by glomerular deposition of IgA-containing immune complexes (IC). Dysregulation of mucosal immune system is recognized as a major cause of development of IgAN. Secretary IgA (SIgA), which is the dominant in external mucosal secretions, is characterized as the 'first line defense' of mucosal areas. Previous reports have shown that the serum level of SIgA is elevated in Dutch IgAN patients, and higher serum SIgA is associated with creatinine clearance and proteinuria. In addition, mesangial deposits of SIgA were detected in about 15% of IgAN patients, and observed a colocalization with IgA, MBL, and C4d. Currently, a strong evidence has demonstrated that galactose-deficient IgA1 (Gd-IgA1) and Gd-IgA1-containing IC are essential effector molecules in IgAN. In present study, we analyzed the association of SIgA and Gd-IgA1 in the pathogenesis of IgAN.

Methods: We measured serum SIgA in patients with IgAN (n=37), disease controls (n=5) and healthy controls (n=5) by ELISA. The associations between serum level of SIgA and serum Gd-IgA1, urine Gd-IgA1 and IgG-IgA IC in Japanese patients with IgAN were investigated. We also analyzed correlation between serum level of SIgA and clinical parameters (total serum IgA, eGFR, degree of hematuria and proteinuria) as well as the pathological findings (acute and chronic lesions).

Results: Serum levels of SIgA were not significantly different between patients with IgAN (2.443±0.81), disease controls (2.125±0.48) and healthy controls (2.318±0.74). There were no significant associations between serum level of SIgA and Gd-IgA1 or IgG-IgA1 immune complexes. Moreover, serum SIgA did not correlate with any clinical parameters and pathological phenotypes.

Conclusions: Serum level of SIgA was not elevated in Japanese patients with IgAN. Moreover, serum level of SIgA did not correlate with Gd-IgA1 and disease severity of IgAN. Thus, it is suggested that SIgA is not involved in the pathogenesis of IgAN.

PUB232

The Pharmacogenomic Association of FCGR2B-232I/T with Response to Treatment in Lupus Nephritis

Xiuwen Zhai, Qing Hou, Ling Wang, Zhi Li, Chun-Xia Zheng, Zhao-hong Chen, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: To determine FcγRIIB-I232T polymorphisms is relation to susceptibility, activityand treatment response to lupus nephritis (LN) of Chinese.

Methods: FcγRIIB-I232T genotype was determined by sequencing in LNpatients and 196healthy individuals from China. The disease activity index was calculated using theACR SLE Disease Activity Index (SLEDAI) and pathologicclassificationswere according toInternational Societyof Nephrology/Renal Pathology Society 2003 classification. Theassociationof FcγRIIB-I232Tpolymorphismwiththesusceptibility and activityin LNwere analyzed by Chi-square test. The correlations of FcγRIIB-I232Tpoly morphismwiththecompleteremission at 6 months were analyzed by logistic regression.

Results: The CC genotype wasassociated withincreased occurrence of LN(P=0. 022, odds ratio [OR] 2. 388 [95% confidence interval (95%CI) 1.111-5.132]. LN patients homozygous FcgRIIB-I232TCC variant showedhigherSLEDAI-2K (p = 0. 035), indicated by higher incidence of thrombocytopenia (p=0. 03), anemia (p=0. 02) and Class IV+V(p<0. 005), higher AI index (p=0. 042), lower level of C3 (p=0. 011). As toremission status between CC genotype and TT/CT genotype, the non-responder with CC genotype were much more than TT/CT genotype (p=0. 025, OR=3. 295, 95%CI 1.198-9.061). The patients who used the IV CYC therapy with CC genotype was more difficult to remiss (p= 0. 012, OR=19, 95%CI1.198-9.061).

Conclusions: The FcgRIIB-I232T polymorphism associated with susceptibility to lupus nephritis. Additionally, LN patients homozygous for FcgRIIB-I232T show more severe clinical manifestations. The finding that the homozygous FcgRIIB-I232T CC genotype was associated with non-complete response in the LN patients, especially the IV CYC therapy, implies that FcgRIIB-I232Tmay be broadly involved in disease pathogenesis and response to therapy.

PUB233

Clinical and Pathological Features and Renal Outcomes of Lupus Nephritis in Elderly Patients

Jin Liu, Hongdi Cao, Yi Fang, Weichun He, Junwei Yang. *Second Affiliated Hospital Nanjing Medical University, Nanjing, China.*

Background: Lupus nephritis (LN) is one of the most common and severe complications of systemic lupus erythematosus (SLE). Renal involvement is the second cause of death in patients with SLE. There are many risk factors associated with poor renal outcome, however, it has not been defined exclusivity. The retrospective analysis is to describe the clinical and pathological characteristics and renal outcomes of LN in elderly patients.

Methods: The clinical features of patients with LN from Jan 1,2012 to Dec 31,2017 in Center of Kidney Disease of 2nd Affiliated Hospital, Nanjing Medical University were collected and analyzed. SLE patients without renal biopsy were excluded. All LN patients were pathologically classified according to the 2003 International Society of Nephrology/ Renal Pathological Society (ISN/RPS) classification system.

Results: Among the 34 patients with biopsy-proven lupus nephritis, there were 32 (94%) females and 2 (6%) males, with an average onset age of (44.6±12.9) years old. Renal damage was the first symptom in 16(47%) patients and acute kidney injury (AKI) accured in 8(24%) patients. The incidence of blood system involvement, malar rash, pleurisy, arthritis and fever was 91%, 47%, 41%, 29% and 26% respectively. The highest positive rate of serum autoantibody was ANA(100%), and the following was Anti-Sm(59%) and Anti-dsDNA(53%). The incidence of low serum C3 was 91%. All patients were pathological classified based on ISN/RPS 2003 classification, only 4(12%) patients with class II and 1(3%) patient with class III, 29 (85%) patients with class IV, V, III+V or IV+V. 13(38%) patients with class IV, 3(9%) patients with class V, 5(15%) patients with class III+V and 8(23%) patients with class IV+V. These 34 patients with an average follow-up time of 1.2- 6 years (median duration was 4 years), 22 (64.7 %) patients were in completely remission, 9 (26.5%) patients were in partly remission, 3 (8.8%) patients relapsed.

Conclusions: The patients diagnosed with LN in our center have an older onset age. Proliferative lupus nephritis was the most common renal damage type in our center, and the renal outcome was favorable. In addition to the proven clinical risk factors and treatment regimens, compliance of patients and socioeconomic factors are also important factors affecting prognosis.

PUB234

NSAID-Related Minimal Change Disease and Interstitial Nephritis with Tertiary Lymphoid Organ Formation

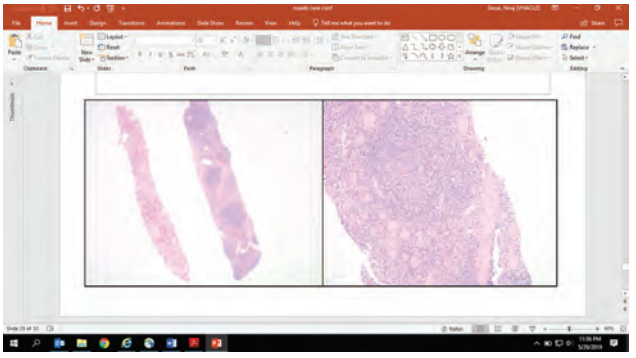
Niraj Desai,[1,2] Krishna P. Balabhadrapatruni.[1,2] *[1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Louis Stokes Cleveland VA Medical Center, Cleveland, OH.*

Introduction: Interstitial nephritis (AIN) and minimal change disease (MCD) are known complications of NSAID exposure. Intense inflammatory infiltrates occasionally lead to formation of tertiary lymphoid organs (TLOs) which are unencapsulated nodular aggregates consisting of a core of B-cells, surrounded by T-cells and neo-lymphatics. TLO's have been described in chronically rejected kidney allografts, IgA nephropathy and lupus nephritis. We report a case of TLO formation in NSAID induced AIN with MCD.

Case Description: A 69-year-old African American male was admitted with fatigue, anasarca and oliguria. Medical history was notable for remote right nephrectomy, prostate cancer, hypertension, and gout. The patient reported daily ibuprofen use (1200-1800mg/d) for 3 months prior to admission for shoulder pain. Admission blood work showed serum creatinine 11.4 mg/dL and serum albumin 1.8 g/dL. Urinalysis showed new 3+ proteinuria, 12 RBCs and 9 WBCs. A 24-hr urine collection measured 11.5 g protein. Serologic work up was negative. Renal ultrasound was normal. Kidney biopsy was performed. The histopathology sample revealed one core with normal glomeruli and mild focal interstitial infiltrate another core with near-total obliteration of renal architecture with a patchy dense lymphoid infiltrate with germinal centers separated by plasma cell rich infiltrate admixed with eosinophils. IF was negative. EM showed diffuse podocyte foot process effacement.

The patient was advised to avoid NSAIDS and was treated with oral prednisone 40mg/d for 6 weeks followed by a short taper. Serum creatinine improved to 1.3 mg/dL ('baseline') and proteinuria reduced to less than 30 mg/g following cessation of steroids.

Discussion: The above findings illustrate novel histopathology in NSAID induced nephrotoxicity and highlight the importance of chronic antigen stimulation in its pathogenesis. The functional significance of TLO's remains undefined, and it is unclear whether the presence of TLO's serve a pathologic or protective role.



PUB235

ANCA-Negative Necrotizing Crescentic Glomerulonephritis with C3 Deposits

Nathaniel C. Reisinger. *Cooper, Camden, NJ.*

Introduction: Ten percent of pauci-immune and crescentic glomerulonephritis is ANCA-negative. Isolated C3 staining on immunofluorescence can be suggestive of C3 glomerulopathy or can be non-specific. Here we report a case of ANCA-negative crescentic and necrotizing glomerulonephritis with C3 staining which presented a diagnostic dilemma.

Case Description: A 27 year old white woman was referred for elevated creatinine detected incidentally on routine laboratory evaluation. She complained only of lower extremity edema. She had a history of birth weight of 3 pounds and prior tendon-release surgery as a child for cerebral palsy. History was otherwise unrevealing. Vital signs were normal except blood pressure 150/95 mmHg and body mass index 31 kg/m^2. Exam disclosed mild edema and was otherwise unremarkable. Laboratories revealed creatinine of 1.6 mg/dL rising from 1.4 mg/dL at initial evaluation 1 month prior. Mild anemia and leukocytosis were noted with normal platelets. Urinalysis showed 3+ protein 2+ blood. Dysmorphic RBCs and RBC casts were noted on urine sediment. Urine protein to creatinine ratio was 1. ANA, ANCAs, and anti-GBM serologies were negative. Complements were within normal limits. Blood cultures were negative. Ultrasound demonstrated normal bilateral kidneys. Kidney biopsy demostrated diffuse necrotizing and crescentic glomerulonephritis. 11 of 23 glomeruli were globally sclerotic and 8 of 12 remaining had densely cellular crescents. Immunofluoresence disclosed only 2+ granular mesangial C3. Pronase digestion did not unmask deposits. Moderate to severe interstitial inflammation was noted with moderate interstitial fibrosis with tubular atrophy. Electron microscopy failed to demonstrate deposits. The patient was started on pulse steroids and rituximab. She had a good response with creatinine stabilizing at 1.4 mg/dL and urine protein to creatinine ratio falling to 0.08 at 6 months. C3 functional panel was essentially normal with only mild hemolytic activity. Repeat biopsy at 6 months showed chronic changes with resolution of the dominant C3 staining. Repeat ANCA serologic testing was negative.

Discussion: The differential diagnosis included ANCA-negative renal vasculitis, C3 glomerulopathy, and infection-related glomerulonephritis. We excluded infection clinically and initiated empiric treatment promptly. Repeat biopsy and C3 functional panel were helpful in prioritizing the differenential diagnosis.

PUB236

Nonclinical Safety and PK/PD of BION-1301, a Fully Blocking Antibody Targeting A PRoliferation Inducing Ligand (APRIL) for the Treatment of IgA Nephropathy

Joost Kreijtz,[1] Peter Van zandvoort,[1] Johannes Van de crommert,[1] Thomas Mueller,[3] Rik De greef,[2] Andrea van Elsas.[1] *[1]Aduro Biotech Europe, Oss, Netherlands; [2]Certara, Oss, Netherlands; [3]Aduro Biotech Inc, Berkeley, CA.*

Background: IgA Nephropathy (IgAN) is a common form of glomerulonephritis and its pathogenesis is thought to consist of sequential pathogenic hits, including the critical production of galactose-deficient IgA1 (Gd-IgA1) and auto-antibody formation ultimately leading to immune complex deposition, inflammation and functional deterioration of the kidneys. Serum levels of APRIL (A PRoliferation Inducing Ligand, TNFSF13) and levels of Gd-IgA1 are correlated with severity of disease (Zhao et al, 2012). As a ligand for the receptors BCMA and TACI, APRIL is thought to regulate B cells and plasma cells. In nonclinical studies treatment with an anti-mouse APRIL antibody was reported to reduce serum IgA and halt proteinuria progression in the IgAN "grouped ddY" mouse model (Kim et al. 2015; Myette et al 2019). Here we describe the nonclinical safety assessment of BION-1301, a humanized anti-APRIL antibody, to support its clinical development for the treatment of IgA Nephropathy.

Methods: A 14wk repeat-dose safety and pharmacokinetic/pharmacodynamic (PK/PD) study in non-human primates (NHP) (Cynomolgus monkey) was performed by biweekly intravenous (i.v.) administration of BION-1301 at three different dose levels. To support a potential change in route of administration, a 4wk repeat-dose NHP bridging study was conducted with weekly subcutaneous (s.c.) administration of BION-1301 at three different dose levels.

Results: In both the 14wk i.v. study and the 4wk s.c. study, BION-1301 was evaluated for safety, PK and PD. For PK and PD, BION-1301 levels, uncomplexed APRIL levels and immunoglobulin levels (IgA, IgG, IgM) were quantified in serum. Immunophenotyping was performed on peripheral blood to assess the impact of BION-1301 on the B cell compartment.

Conclusions: Results of these extended nonclinical pharmacology and toxicology experiments add to the BION1301 safety, PK, PD assessments reported earlier (Dulos et al, ASN 2018) and inform the ongoing clinical program to develop BION1301 for the treatment of IgAN.

PUB237

The Deposition of Immunoglobulin A on the Glomerular Loop Correlates with Severity Both Clinically and Pathologically in a Patient with IgA Vasculitis with Nephritis

Kazunori Karasawa,[1] Takahito Moriyama,[2] Kosaku Nitta.[2] *[1]Nephrology, Tokyo Women's Medical University, Tokyo, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan.*

Background: Immunoglobulin A vasculitis with nephritis (IgAVN) is considered to be systemic form of IgA nephropathy (IgAN). Both IgAN and IgAVN are defined by the presence of IgA dominant glomerular deposits. However, the pathological significance of the difference in glomerular location of IgA and other immunogrobulin deposits is remain unclear. In this study, we focused on the deposition of IgA on the glomerular loop and investigated.

Methods: We conducted a retrospective study of 37 adult patients of biopsy-proven IgAVN. We divided 37 IgAVN patient into two group: IgA deposition on the glomerular loop group (n = 11) and non-IgA deposition on the glomerular loop group (n = 26). We compared in terms of clinicopathological feature and renal prognosis in each group.

Results: 37 adults IgAVN patients (male:22, female:15) were analyzed. IgA deposit on the glomerular loop group of 11 patients. The onset age of IgAVN was predominantly higher in IgA deposition on the glomerular loop group. (48.2±17.9 vs 35.6±14.9) The average proteinuria was 3.39±2.57 g/day in the IgA deposition on glomerular loop group and 1.43 ±1.56 g/day in non-IgA deposition on glomerular loop group. (P=0.0036) In histrogical findings, there were many cases of crescent formation predominantly in the IgA deposition on glomerular loop group. (P = 0.039) There was no significant difference in eGFR value at the time of renal biopsy. (eGFR: 69.8±25.6 vs 82.7±25.2 P = 0.082) Renal function was predominantly worse in the IgA deposition on glomerular loop group in half a year after treatment. (eGFR: 49.5±16.9 vs 83.9±23.2 P = 0.0004) Hwever, there was no significant difference between the two groups in the initial dose of steroid and in combination with steroid pulse.

Conclusions: We have clearly shown that deposition of IgA on the glomerular loop correlates with severity both clinically and pathologically. These results suggested that these deposition may play a key role in the pathogenesis of IgAVN, and also suggested that the selection of therapy for IgAVN might be affected.

PUB238

Nephrotic Syndrome in the Elderly: Not Always What It Seems

Yedidiach Ortiz-Gonzalez, Krystahl Z. Andujar, Jose D. Ortiz. *Doctors Center Hospital, San Juan, PR.*

Introduction: Polypharmacy is defined simply as the use of multiple medications by a patient. Older adults are especially impacted by polypharmacy. The use of greater numbers of drug therapies has been independently associated with an increased risk for an adverse drug event (ADE).

Case Description: An 83-year-old man from Puerto Rico with hypertension, gout, benign prostate hypertrophy and chronic kidney disease, presented to the ED after progressive shortness of breath and bilateral leg edema for two weeks. As outpatient, he had more than 7 prescribed medications. He was found with generalized edema, hypoalbuminemia with associated shortness of breath, bibasilar crackles on auscultation, and scrotal swelling. On chest x-ray bilateral pleural effusions were noted. 24-hour urine collection revealed 6,439 mg of proteinuria. Volume status responded to IV diuretic therapy. PSA, SPEP, UPEP, immunofixation, serum free light chains, C3/C4, hepatitis profile and ANCA titers all were negative. There was no imminent need for dialysis. Kidney biopsy revealed diffuse interstitial infiltrate with numerous invading eosinophils, tubulitis without immune deposits or crescents identified. Acute interstitial nephritis (AIN) with concurrent glomerulopathy was diagnosed. Due to a gout flare, our patient had been prescribed Nabumetone 500 mg PO twice daily for one month prior to hospitalization by his primary care provider. As more than seven days had passed after initial presentation and the offending agent was discontinued, IV steroids were not started. Creatinine decreased to 2.5 from 4.0 mg/dL, and proteinuria improved. NSAIDs were added to his allergy medication list. He was discharged home without dialysis with follow-up as outpatient.

Discussion: On initial presentation, membranous nephropathy secondary to malignancy was suspected to be the cause of our patient's symptoms given his age and presence of nephrotic syndrome. However, AIN with concurrent minimal change disease was diagnosed on biopsy. AIN is not frequently associated with the nephrotic syndrome. Nonsteroidal anti-inflammatory drugs (NSAIDs) may cause AIN with concurrent

nephrotic syndrome due to minimal change disease or membranous nephropathy. Given the increased use of medications in the elderly and risk for an ADE, it is of upmost important to be vigilant of the possible side effects of NSAIDs in this population.

PUB239

Eosinophilic Granulomatosis with Polyangiitis Renal Disease

Allyson C. Egan,[1] Teresa Bada Bosch,[2] David R. Jayne.[3] *[1]Renal Medicine, University of Cambridge, Cambridge, United Kingdom; [2]Hospital Universitario 12 de Octubre, Madrid, Spain; [3]University of Cambridge, Cambridge, United Kingdom.*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a systemic necrotizing vasculitis affecting small to medium sized vessels, characteristically associated with asthma and eosinophilia[1,4]. EGPA renal disease is prevalent in approximately 25%.[2] Presentation includes focal and segmental necrotizing crescentric glomerulonephritis (NCGN),[1,3] eosinophilic interstitial infiltrates[4] or obstructive uropathy caused by vasculitic involvement of the ureters. The aim of our study is to analyse the prevalence, clinical manifestations and outcomes of EGPA patients with renal involvement.

Methods: We retrospectively analysed 142 patients with EGPA according to the criteria of the American College of Rheumatology or Chapel Hill Consensus 2012 definition. We selected patients with renal involvement defined by the presence of (A) Renal insufficiency serum creatinine (SCr) > 97 umol/L, or (B) haematuria and/or proteinuria (>1+ in urinalysis) or (C) obstructive uropathy.

Results: Of eleven (7.74%) patients with renal involvement, three presented with rapidly progressive kidney injury with SCr >290umol/L, 6 with SCr greater than >117umol/L and two had normal SCr [44-97umol/l]. Renal biopsy performed in 6 patients, demonstrated 3 NCGN, 2 had both NCGN and tubulointerstitial nephritis (TIN) with eosinophil infiltrates, and 1 had TIN with eosinophil infiltrates alone. All the patients with NCGN were ANCA positive, while the patient with TIN alone was ANCA negative. 2 patients had obstructive uropathy due to ureteric stenoses.

Conclusions: At the end of follow up 2 patients were renal transplant recipients, 5 had chronic kidney disease (CKD) and 4 maintained normal kidney function. Although renal involvement in EGPA is less frequent than in others AAV, it must be taken into account due to its potential to lead to end-stage renal failure. ANCA positive patients may present with NCGN leading to CKD. Furthermore, ANCA negative patients, may have manifestations such as TIN with eosinophil infiltrates or obstructive uropathy.

Patient No.	Sex	Age	sSCr (umol/L)	ACR (mg/umol)	Prot	Haem	ANCA	Renal biopsy/ Imaging	Treatment	SCr and outcome	Follow-up (years)

Table 1: Renal Involvement in EGPA EGPA eosinophilic granulomatosis with polyangiitis, SCr serum creatinine, ACR albumin creatinine ratio, Prot protein dipstick, Haem haematuria in dipstick, TIN tubulointerstitial nephritis, NCGN necrotizing crescenteric glomerulonephritis, Pd prednisolone, Cy cyclophosphamide, RTX rituximab, AZA azathioprine, MMF mycophenolate mofetil, MTX methotrexate, PLEX plasma exchange.

PUB240

Clinical and Pathological Manifestations of ANCA-Associated Vasculitis Superimposed on Rheumatoid Arthritis

Jianfang Cai, Haiting Wu. *nephrology, Chinese Academy of Medical Sciences, Peking Union Medical College Hospital, Beijing, China, Peking, China.*

Background: Patients with rheumatoid arthritis can have renal disorders, most of which are mild. However, ANCA-associated vasculitis may be superimposed on rheumatoid arthritis, with severe organ damage, especially renal failure. We try to investigate characteristics of ANCA associated vasculitis combined with rheumatoid arthritis

Methods: Patients with concurrent rheumatoid arthritis (RA) and ANCA associated vasculitis (AAV) were identified by searching medical database of the Peking Union Medical College Hospital and literature from January 2000 to December 2018. We excluded patients exposed to TNF-α inhibitors. Data on age, sex, involved organs, laboratory tests,renal pathology at the diagnosis of AAV, and therapeutic regimens of both RA and AAV were retrospectively retrieved and analyzed. To further explore whether there was any difference in clinical features and renal pathology between AAV patients with and without concurrent RA, we conducted a 1:4 matched case-control study. 36 controls were matched to 9 cases having renal pathology according to age and sex.

Results: 15 patients in our hospital and 27 patients from literature with concurrent RA and AAV were identified. They were 54 ± 17 years old at the diagnosis of AAV, and 29 (69.0%) of them were women. AAV was diagnosed 6(2,12)years later than RA. Kidney was the most frequently involved(80.9%). Those with renal involvement had an average baseline serum creatinine of 290 (148, 471) umol/L. Patients with RA were more likely to have AAV proved by renal biopsy than those without RA(15.0% vs 1.5%, p<0.001) AAV patients with concurrent RA were more likely to be asymptomatic(33.3% vs 2.8%, P=0.021)and presented lower eGFR [23.9±15.5 vs 34.3±24.3 ml/min/(1.73 m^2), p=0.049] at diagnosis as compared with those with AAV alone. However, the two groups did not differ in in the percentage of global sclerotic and cellular crescentic glomeruli (global sclerotic glomeruli 37.0±23.5% vs 26.9±24.0%,p=0.26,cellular crescentic glomeruli 23.1±18.7% vs 34.0±18.4%,p=0.11).

Conclusions: AAV was more frequent in patients with RA than those without RA. AAV superimposed on RA were more likely to be asymptomatic and with worse renal function.

PUB241

Use of Rituximab in Fibrillary Glomerulonephritis

Umair S. Ahmed. *Western Maryland Health System, Cumberland, MD.*

Introduction: Fibrillary glomerulonephritis (GN) is a rare glomerular disease characterized by glomerular deposition of randomly arranged non-amyloid fibrils. The prognosis of fibrillary GN is poor, with up to 50% of patients progressing to end-stage renal disease within 2 years of diagnosis. The optimal treatment is unknown. Two cases with fibrillary glomerulonephritis are presented who were treated with Rituximab with different outcomes.

Case Description: Patient 1 is a 72 years old male with 9 g proteinuria and biopsy proven fibrillary GN. He received 4 doses of weekly IV Rituximab 375 mg/m2 with subsequent reduction in proteinuria to 1.2 g. Two years later, proteinuria increased to 5 g. Due to a concern for recurrence, patient was given 2 doses of IV Rituximab 1 g each, separated by 2 weeks. Renal function since then, has remained stable on 6 month follow up with a serum creatinine around 1.8 mg/dl, while proteinuria decreased to 1.4 g. Patient 2 is a 68 years old female with 3.6 g proteinuria and biopsy proven fibrillary GN. Serum creatinine on diagnosis was 2.0 mg/dl. She received 2 doses of IV Rituximab 1 g each, separated by 2 weeks. Six months later proteinuria worsened to 4.6 g and she progressed to end stage renal disease. No evidence of monoclonal gammopathy was noted in either patient. Both patients received intravenous corticosteroids as premedication with Rituximab along with Losartan 100 mg daily.

Discussion: Due to the rare nature of this disease, no controlled trials have been conducted. Steroids and different cytotoxic drugs have been used in fibrillary GN without any proven benefit. Rituximab, a monoclonal anti-CD20 antibody directed against B cells has been used as a treatment due to the characteristic presence of polyclonal immunoglobulin deposits in the mesangium and glomerular basement membrane. There are reports that B-cell reconstitution with subsequent reappearance of detectable CD19+ cells may be responsible for relapse in fibrillary GN. Data on Rituximab therapy for fibrillary GN is limited and outcomes have been inconsistent. However, it provides an option to consider as untreated fibrillary GN will most likely result in progression of disease. More data is needed to prove its efficacy in this disease, and to assess the need to consider Rituximab administration as soon as CD19+ cells become detectable, despite the absence of clinically evident relapse.

PUB242

A Rare Case of AKI due to Thrombotic Microangiopathy (TMA) in Multicentric Castleman Disease (MCD)

Krishnakumar D. Hongalgi,[1] Parth Visrodia,[2] Andrea Lightle,[2] Shannon Murawski.[3] *[1]Nephrology, Albany medical center, Albany, NY; [2]Albany Medical Center, Albany, NY; [3]Albany Medical College, Albany, NY.*

Introduction: Castleman disease (CD) are rare lymphoproliferative disorders either unicentric (UCD) or diffuse multicentric (MCD). MCD features include diffuse lymphadenopathy (LAD), hepatosplenomegaly, anemia and systemic inflammatory symptoms. Approximately 1/2 are HIV + and 2/3rd HHV-8 +. Histological variants include hyaline vascular (HV), plasma- cell (PC) and plasmablastic (PB). Systemic lupus erythematosus (SLE), Hashimoto's thyroiditis, IGG4 related disease, viral infections and chronic cellulitis mimic MCD. AKI due to glomerulonephritis, amyloidosis, and interstitial nephritis have been reported. We report a patient with MCD who presented with proteinuria, microscopic hematuria and elevated serum creatinine caused by thrombotic microangiopathy (TMA).

Case Description: A previously healthy 26-year-old female from Ghana presented with 2 weeks history of progressive abdominal distention, fatigue, cough and intermittent epistaxis. Exam noted multifocal lymphadenopathy and hepatomegaly with tense ascites. Elevated acute phase reactants (CRP 201), anemia (Hgb 9.9 and few schistocytes), thrombocytopenia (platelets 68k), AKI (peak serum creatinine 2.1), lymphocytic ascites, hypoalbuminemia (albumin 2.7) and hypergammaglobulinemia suggested multisystem inflammation. Urine protein to creatinine ratio 1.1, few RBCs and WBCs in urine microscopy. Positive ANA, SS-A, coombs, D dimers. HIV and HHV-8 negative. DsDNA and complements normal range. ADAMTS 13 at 64. Vascular endothelial growth factor (VEGF) and interleukin 6 (IL-6) were elevated. Cervical LN biopsy showed interfollicular plasmacytosis. Renal biopsy showed no immune complex deposits but TMA. Patient responded to Siltuximab (anti-interleukin 6) and is in remission.

Discussion: SLE mimicking MCD was ruled out. Increased serum IL-6 has been noted in number of diseases characterized by renal TMA. IL-6 induces B-cell proliferation and expression of VEGF (Increased circulatory VEGF but down regulation of glomerular VEGF). IL-6 reportedly modulates release and cleavage of von Willebrand factor multimers. Inclusion of IL-6 and VEGF immunohistochemical stains would increase diagnostic accuracy. Blockade of IL-6 and IL-6R signaling could be curative provided the right diagnosis is made.

PUB243

Infection and Glomerular Disease: The Patient and Caregiver Perspective

Dorey A. Glenn,[1] Candace D. Henderson,[2] Kelly Helm,[4] Amy K. Mottl,[3] Keisha L. Gibson.[2] *[1]Nephrology and Hypertension, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina Kidney Center, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]NephCure Kidney International, King of Prussia, PA.*

Background: Individuals with glomerular disease (GD) comprise ~7% of the ~30 million Americans with chronic kidney disease. Both GD and immunosuppressive (IS) treatment place these patients at increased risk for infection. Patient and caregiver perspectives on the impact of infection on quality of life and vaccination behavior have not been previously described. Herein we present results from an electronic survey of the membership of NephCure Kidney International (NKI), a GD focused patient and family support network.

Methods: A 22 question web-based survey comprised of 20 close-ended and 2 open-ended questions was sent to members of NKI in the Fall of 2019. The survey was promoted with two social media posts and within an NKI newsletter. Quantitative and qualitative analyses were performed.

Results: We received 262 responses from 3171 e-mail invitations (response rate 8.3%). Fifty four percent (n=139) of responses were from parents of children with GD < 18 years of age and 46% of responses (n=123) were received from adult GD patients. The majority of respondents (95%) reported prior IS exposure, including steroids (95%), calcineurin inhibitors (76%), MMF (41%), rituximab (26%), and cyclophosphamide (19%). The majority of parental respondents (65%) and nearly half of adult respondents (45%) reported being very concerned about acquiring an infection. Since diagnosis, 56% of parents and 47% of adults with GD reported ≥ 2 emergency room visits or hospitalizations for treatment of infection. The majority of respondents (58%) reported more frequent infections since GD diagnosis, and 44% reported more infections while taking IS medications. Respondents reported that infections resulted in frequent interruption in social activities (29%), exercise (25%), and attending school (33%) or work (20%). Flu vaccination during the 2018-2019 season was reported by 76% of parental respondents and 64% of adult GD patients. Reasons for not receiving the flu vaccination included fear of reaction/relapse, perceived contraindication due to IS medications, and perceived provider recommendation.

Conclusions: Individuals with GD and their caregivers are concerned about infections, report frequent infection-related healthcare visits and interruption in activities. Infection remains a preventable and under-studied complication of GD deserving of additional study.

PUB244

Sequential Therapy for Remission Induction in Severe ANCA-Associated Glomerulonephritis

Amr Habbach,[1] Eric J. Gapud,[3] Brendan Antiochos,[2] Philip Seo,[4] Duvuru Geetha.[1] *[1]Johns Hopkins Hospital, Baltimore, MD; [2]Johns Hopkins, Baltimore, MD; [3]Johns Hopkins School of Medicine, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD.*

Background: The introduction of combination therapy with glucocorticoids (GC) and cyclophosphamide (CYC) or rituximab (RTX) has resulted in remission rates exceeding 90% in patients with ANCA associated vasculitis (AAV). However, early treatment related mortality remains a major concern and has driven the search for safer induction regimens exploring minimization or avoidance of GC and CYC. Most trials have excluded patients with severe renal disease. We report the outcomes of AAV patients with severe renal disease treated with sequential therapy (ST) starting with GC and oral CYC followed by transition to RTX.

Methods: Patients with new or relapsing severe AAV who presented with severe renal disease and/or RPGN were identified. RPGN was defined as at least a 20% decrease in e-GFR over a 2 week period along with hematuria and proteinuria. Induction treatment included pulse GC for 3 days followed by oral prednisone tapered to 5 mg by month 6, oral CYC adjusted for GFR until improvement in BVAS and serum creatinine at which point, CYC was stopped and induction dose of RTX was given. Use of Plasma Exchange PLEX was allowed. The primary outcome was complete remission defined as BVAS of zero by 6 months (6M). Descriptive data are presented as median with range and mean with SD.

Results: Nine patients met the inclusion criteria. Median age at diagnosis was 63 years. Majority were females, MPO ANCA positive and had a new diagnosis. The mean nadir (SD) e-GFR was 12 (5) with 3 requiring dialysis. Median BVAS at the time of diagnosis was 15. All patients received (ST) and 3 received PLEX. Median exposure to oral CYC was 35 days. The mean (SD) e-GFR and median BVAS were 26(12) and 3 respectively at the time of switching to RTX. The median prednisone dose at 6 months was 5 mg. The median follow up was 44 months. All patients achieved remission. One patient reached ESRD. The mean (SD) e-GFR in the remaining 8 patients at last FU was 37(27) and the mean (SD) e-GFR rise at 1 year was 26(25). Adverse events included 2 patients with pneumonia and 3 with bone marrow suppression. There were no deaths.

Conclusions: Sequential therapy with GC and CYC followed by RTX is effective for in AAV patients with severe renal disease. Therapy related adverse events comparable to other studies and further modification in ST with decrease in GC dosage should be explored.

PUB245

Multicenter Review of Types of Glomerular Diseases in the Emirate of Abu Dhabi: Six Years of Experience

Hefsa Al Shamsi,[1] Mohamed H. Hassan,[1] Bassem S. Mohamed Hendawy,[2] Reem El tahrawi,[2] Emad S. Khater.[3] *[1]Nephrology, SKMC, Abu Dhabi, United Arab Emirates; [2]Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates; [3]Shaikh Khalifa Medical Center, Abu Dhabi, United Arab Emirates.*

Background: Glomerulonephritis (GN) is a rising paramount renal disease that varies in etiology from inherited or acquired factors. Its severity can range from asymptomatic depictions to end stage kidney disease (ESKD). The aim of this study was to look at the patterns of biopsy-proven glomerulonephritis based on data from a multicenters in Abu Dhabi.

Methods: This study is a retrospective a cross sectional study. Included kidney biopsy were from all patients above the age of 18 years, over a six-year period from 2010 till 2015, who had diagnosis of glomerular disease other than diabetes mellitus. The number of reviewed biopsies was 416.

Results: The most common type of glomerulonephritis among the study sample were the IGA GN (22.8) followed by the FSGS (20.4%) followed by the SLE (19.7%). The least common types were Pauci Immune (1.7) There was female preponderance in lupus nephritis and pauci immune GN. The nationality comparison did not reveal a predominate GN among Emirati nationals. The age relationship to GN types showed that the majority (82.9%) of SLE patients, MCD (74.55 %) and non- categorized (71.4%) patients are young between the age of 18 to 39 years. On the other hand, 57.1%, 25% and 16.7% of patients with Pauci immune, other GN types and MPGN respectively are 60 years and older.

Conclusions: This study shows the histopathological variety of glomerular disease in Abu Dhabi. It could be a driving point to help understand GN better in the region.

PUB246

Incidence and Risk Factors of Serious Infections in ANCA-Associated Vasculitis with Renal Involvement

Aglaia Chalkia,[1] Konstantinos Thomas,[2] Athanasia Kapota,[1] Aikaterini A. Damianaki,[1] Pinelopi Kouki,[1] Dimitrios Vassilopoulos,[2] Dimitrios I. Petras.[1] *[1]Hippokratio Hospital of Athens, Athens, Greece; [2]National and Kapodistrian University of Athens School of Medicine, Athens, Greece.*

Background: Infection is one of the most commonly encountered problems in patients with ANCA-associated vasculitis (AAV) and contributes significantly in morbidity and mortality. We investigated the incidence, time, type and risk factors for serious infections and compared the incidence of non-prophylaxis with prophylaxis with trimethoprim–sulfamethoxazole in patients with AAV.

Methods: Retrospective, descriptive study of 21 patients with AAV and renal involvement diagnosed over the last five years in a tertiary center. Data on age, sex, disease and treatment characteristics and the type of serious infections were collected. Serious infections were defined as infectious episodes requiring hospitalization.

Results: Of the 21 patients the average age of diagnosis was 71.6 years (SD 10.9) and 43% were women. A total of 17 serious infections were identified in 11 patients during a median follow-up of 2.6 years (incidence: 19.6 per 100 patient-years). Pneumonia (47%) and urinary tract infections (18%) were the most frequent types of infection. More than half of the infections (65%) were recorded during induction treatment (Rituximab (RTX), Cyclophosphamide (CYC) or combination treatment CYC+RTX) and the remaining of them (35%) during the maintenance treatment (RTX or Mycophenolate Mofetil (MMF)). The majority of patients (76%, 16/21) received prophylaxis with trimethoprim–sulfamethoxazole. Among those who developed a serious infection (11/21) the induction treatment with combination CYC+RTX (36% vs 0%, p=0.03), hemodialysis/plasma exchange (63% vs 40%, p=0.3) and lung involvement (82% vs 70%, p=0.5) were more common. Additionally, this group of patients received less induction treatment with RTX (9% vs 50%, p=0.04) and prophylaxis with trimethoprim–sulfamethoxazole (45% vs 100%, p=0.01). Finally, one patient died due to gram-negative sepsis.

Conclusions: One in two patients with AAV and renal involvement experienced at least one serious infection during follow-up, with more frequent infections of the respiratory and urinary tract. The incidence of serious infection is particularly high during the first six months, and combination induction treatment (CYC+RTX) and the failure of prophylaxis with trimethoprim sulfamethoxazole are identified as risk factors.

PUB247

Proteinuria Could Not Be a Surrogate Prognostic Marker in IgA Nephropathy

Byoung-Soo Cho,[1] Hyaejin Yun,[1] Sung min Jung,[1] Won-Hee Cho,[2] Hyunsoon Lee.[3] *[1]Dr.Cho's Kidney Center, Seoul, Republic of Korea; [2]Kyung Hee University Hospital, at Gang-Dong, Seoul, Republic of Korea; [3]Hankook Renal pathology lab, Seoul, Republic of Korea*.

Background: To date the most widely well studied risk factor for progression to ESRD in patients with IgA nephropathy is proteinuria. Recent report suggests proteinuria reduction as a surrogate end point in trial of IgA nephropathy(2019,CJASN). Sensitivity of most biomarkers such as blood and urine gd-IgA1 level, IgG/IgA autoantibody, sCD89, sCD71, NGAL, KIM-1, Cystatin-C etc were compared with the amount of proteinuria. Most nephrologists do not performing kidney biopsy in patients without proteinuria or proteinuria less than than 500mg/day even though IgA nephropathy is suspected. However we recently experienced severe IgA nephropathy (HSD Lee, grade IV) in patients with normal urinalysis, and more than half the patients showed stationary or aggravated renal pathology at the follow up renal biopsy although urinalysis findings were normalized after methylprednisolone pulse therapy.

Methods: In our center we performed 892 renal biopsies during last 6 years, we experienced 253 IgA nephropathy, of which 152 cases were done follow up renal biopsies to see the pathologic changes who showed normalized urinalysis findings after methylprednisolone pulse therapy.

Results: Of the 253 patients 241 patients showed initial abnormal urinalysis like hematuria and or proteinuria. Eleven patients showed completely normal urinalysis, of which 5 cases were diagnosed as essential hypertension and 6 cases were normal urinalysis associated with lowered GFR. Of the 152 follow up renal biopsies we evaluated 99 cases who showed normalized urinalysis findings after therapy, of which 65 cases(65.7%) showed stationary or aggravated renal pathology.

Conclusions: In conclusion further long term studies are needed, proteinuria could not be a surrogate marker for prognosis of the IgA nephropathy, Regardless of proteinuria if associated with hypertension and or lowered GFR, renal biopsy should be done. Follow up renal biopsy might be needed to confirm the healing of IgA nephropathy regardless of urinary findings to see the disappearance of IgA deposition, decreasing mesangial and endocapillary hypercellularity, disappearance of crescent formation, decreasing sclerosis, etc.

PUB248

Long-Term Treatment with ACE-I/ARBs in Childhood Mild IgA Nephropathy

Yuko Shima,[2] Koichi Nakanishi,[1] Taketsugu Hama,[2] Yu Tanaka,[2] Hironobu Mukaiyama,[2] Masashi Sato,[2] Takuzo Wada,[2] Kandai Nozu,[3] Kazumoto Iijima,[3] Norishige Yoshikawa.[2] *[1]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan; [2]Wakayama Medical University, Wakayama, Japan; [3]Dept. of Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Japan*.

Background: ACE-I/ARBs have been widely used for treatment of IgA nephropathy (IgAN), however, there is no study showing outcome of long-term ACE-I/ARBs treatments in IgAN children with persistent mild proteinuria.

Methods: Out of 59 biopsy-proven mild (focal mesangial proliferation) IgAN children with ACE-I/ARBs from November 2000 to August 2018, retrospective data from 55 patients were available, and we compared clinical and pathological findings between patients with completed ACE-I/ARBs treatments and the others.

Results: There were 28 patients (50.9%) with completed ACE-I/ARBs treatment. Other 27 patients had been on treatments till the latest observation. Median observation periods to the latest observation was 8.7 [4.7-10.9] and 6.2 [1.8-12.3] years (completed vs non-completed) respectively. There was no significant difference in onset mode, clinical finings at renal biopsy (sex, age, duration from onset to renal biopsy, uP/Cr, eGFR), and pathological findings (MEST-C score). All patients in completed treatment group showed the disappearance of proteinuria (uP/Cr〈0.15 g/gCr) and hematuria (RBC〈5HPF). Median periods from the start of treatment to disappearance of proteinuria and hematuria were 3.6M and 12M in completed treatment group. At the latest observation, there was significant differences in mean blood pressure (91 vs 85 mmHg, p=0.03), eGFR (125.8 vs 119.9 ml/min/1.73m^2, p=0.04), uP/Cr (0.07 vs 0.24 g/gCr, p=0.04). Median duration of ACE-I/ARBs was 26.2M vs 74.6M and 4 patients in non-completed group showed CKD-G2A3 which were high risk of progression despite of subsequent additional immunosuppressive treatments.

Conclusions: We should pay careful attention to long-term treatment with ACE-I/ARBs for the childhood mild IgAN patients even if they show persistent mild proteinuria. Optimal timing of switch from ACE-I/ARBs to immunosuppressive treatments should be further investigated.

PUB249

Efficacy and Safety of the Combined Induction Therapy with Rituximab and Low Steroid Doses in Glomerulonephritis

Miguel Uriol Rivera, Gonzalo Gómez marqués, Aina Obrador. *Hospital Universitario Son Espases, Palma de Mallorca, Spain*.

Background: Proteinuria and acute renal dysfunctions are the main objectives for glomerulonephritis control. The autoimmune component of the primary glomerulonephritis (PG) is steadily assuming. The efficacy of the Rituximab and the low steroids doses (combined therapy: CT) in these diseases is not well known. Moreover, if there are differences in the effect of the CT among PG and secondary glomerulonephritis (SG) has not been evaluated. Objectives: Primary outcome: To evaluate the risk of death and or chronic renal replacement requirements (CRRT). Secondary outcome: the changes in the proteinuria [median(p25-p75), 24-hours collected) and estimated glomerular filtration rate (eGFR) (mean) during 24 months of follow-up. Potential differences between PG and SG were also assessed. Lethal infection was recorded as safety issue.

Methods: A retrospective study in a third level hospital was conducted. Rituximab (1g every two weeks for two doses) and methylprednisolone 120-250 mg/d X3d and subsequently, prednisone 30 mg/d was tapered and discontinued at month 3. Study period: From May 2008 to November 2018. eGRF was calculated using the CKD-EPI formula.

Results: Forty-four consecutive patients were included. PG: 14(32%) and SG: 30(68%). Median follow-up 44 months. 10(23%) patients died or needed CRRT. No differences in the primary outcome were observed between PG and SG (3 versus 7 patients, respectively P = 1). As a whole, eGFR increased from basal to month 12 (8.6 ml/min/1.73m2, P<0.01) and decreased from month 12 to 24 (4.8 mil/min/1.73m2, P<0.01); no differences between PG and SG were observed. Proteinuria decreased from basal to month 24 at the PG [from 4.0 (2.7-6.1g/d) to 0.21(0-1.7g/d), P<0.01] and at SG [from 1.4(0.3-4.1) to 0.45(0-0.6), P<0.01]. Six patients died, two of them (4.5%) due to a fatal infection and corresponded to SG.

Conclusions: The CT showed was efficacy without differences between the two glomerulonephritis types, which may represent a new therapeutic option in those patients. Fatal infections were seen in the secondary glomerulonephritis group.

PUB250

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposition Disease: Our Experience

Umesh Lingaraj. *Nephrology, Institute of nephrourology, Bangalore, India*.

Background: PGNMID is a rare disease affecting the native kidneys and transplanted kidneys. Here we present four cases of PGNMID that illustrate the challenges of diagnostic approach and highlight the allograft outcome after treatment with BORTEZOMIB

Methods: Patients with allograft biopsy showing PGNMID were included. In post transplant patients, their native kidney biopsy was reevaluated to determine the recurrence vs de novo nature of the disease. Patients were subjected to bone marrow aspiration, biopsy, SPEP, UPEP and immunofixation electrophoresis to identify the clone

Results: 1.20-year-old male presented with anasarca. he had nephrotic range proteinuria with micro haematuria. Renal biopsy showed PGNMID with Kappa chain restriction with MPGN pattern with focal crescents. He is being treated with subcutaneous Bortezomib. He has completed 12 doses of Bortezomib and is in partial remission. 2 : 26-year-old female, hypertensive presented with anasarca. On evaluation she had nephrotic syndrome with normal renal functions. Renal biopsy showed PGNMID with kappa light chain restriction with focal crescents with Mesangioproliferative pattern. Treated with 10 doses of Bortezomib after which she was lost to follow up 3. DDRAT with native kidney disease being immune complex mediated MPGN presented with edema after 7 months of transplant. Allograft biopsy showed PGNMID with Kappa chain restriction with MPGN pattern with focal crescents. However the clone could not be identified on bone marrow, SPEP, immunofixation electrophoresis. She is being treated with subcutaneous Bortezomib and is in complete remission after 25 doses. 4:LRRAT with native kidney disease being immune complex mediated GN with HBsAg positive status presented with hematuria 2 months post transplant. Allograft biopsy showed PGNMID with kappa chain restriction with MPGN pattern with focal crescents with ACMR. Treated with Bortezomib and steroids. However he had an aggressive disease course and had graft loss in 2 months and is currently Dialysis dependent

Conclusions: MPGN is a pattern of injury with varying causes. The most aggressive being plasma cell dyscrasias. This study shows the varying presentation and response of the same disease in 4 patients. a high degree of suspicion is required especially during transplant workup of patients with MPGN pattern on biopsy and all possible attempts should be made to rule out plasma cell dyscrasias.

PUB251

ANCA-Associated Crescentic Glomerulonephritis Can Be Concurrent with Another Immune Complex-Medicated Glomerulopathy: One Health Center Experience

Victoria Golas,[1] Michael S. Misuraca,[2] Hassan D. Kanaan,[3] Wei Li,[4] Ping L. Zhang.[4] *[1]Beaumont Farmington Hills, Livonia, MI; [2]Hypertension Nephrology Associates, PC, South Lyon, MI; [3]Beaumont Health, Royal Oak, MI; [4]William Beaumont Hospital, Royal Oak, MI.*

Background: Autoimmune disorders are known to trigger multiple systemic diseases. There are relatively few reports for a potential overlapping syndrome including ANCA associated crescentic glomerulonephritis (CGN) and another type of immune complex disease (ICD) in the kidneys. Here we present our experience for concurrent diseases between ANCA associated CGN and other ICD from a 4000-bed large health system (8 hospitals) over the past 10 years.

Methods: We evaluated our data base for 3757 renal biopsies over the past 10 years (2008 to 2018) and identified 13 cases with dual diagnoses of CGN and another ICD. Their clinical data were collected and pathologic findings are evaluated in detail.

Results: The concurrent cases represented 0.35% of our overall biopsies (13/3757). Patients' age ranged from 48 to 76 years old. There were 8 female patients and 5 male patients. All 13 patients had positive ANCA and CGN. Crescent percentage in the biopsies ranged from 10% to 78%. The other ICD included many types including membranoproliferative glomerulonephritis type 1 (MPGN, n = 5), post-infectious glomerulonephritis (n = 2), membranous glomerulopathy (n =1), mesangial glomerulonephritis (n = 1), type 3 lupus nephritis (n = 1), type 2 lupus nephritis (n = 1), IgA nephropathy (n = 1), and MPGN type 3 (MPGN, n = 1). Most of the ICD appeared to be mild, except one type 3 lupus nephritis debatable for primary or secondary crescent formation.

Conclusions: The crescent formation appeared to be dominant in most cases, leading us to believe that the crescent formation was mainly related to positive ANCA rather than minor ICD in most cases. Our findings support previous reports that there is a rare entity of overlapping syndrome composed of ANCA associated CGN and another ICD. Follow-up and analysis will be done to compare to the cases with only ANCA associated CGN for their clinical outcomes.

PUB252

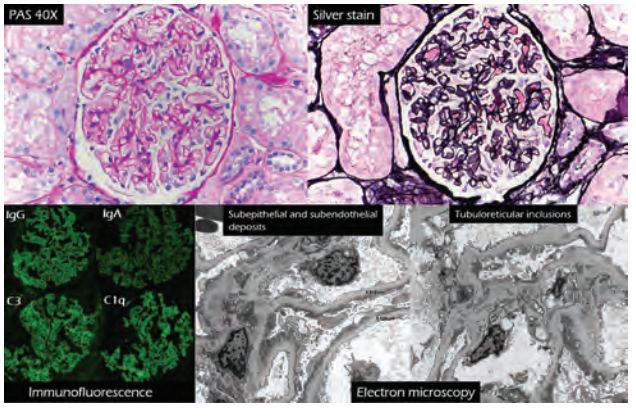
Membranous Lupus Nephritis Wearing the Mask of Minimal Change Disease: A Case for Caution

Manoj Bhattarai,[1] Yanli Ding,[2] Ahmad Altarawneh,[2] Abhilash Koratala.[1] *[1]Nephrology, UT Health San Antonio, San Antonio, TX; [2]UTHSCSA, San Antonio, TX.*

Introduction: Rarely, patients with systemic lupus erythematosus may present with lupus nephritis (LN) alone and have no extra-renal manifestations. We herein present one such case with other atypical features on serology and renal biopsy.

Case Description: A 24-year-old otherwise healthy Hispanic man presented with worsening shortness of breath and swelling in the feet. Laboratory data was consistent with nephrotic syndrome with a serum albumin of 0.8 g/ dL [3.2-5], LDL-cholesterol 452 mg/dL [20-129] and 24-hour urine protein of 8.7 g. Serum creatinine was normal. There was no history of rash or joint pains. Serologic work up for syphilis and viral hepatitis was negative. Antinuclear antibody test was positive (1:80) but anti-double stranded antibody and anti-smith antibody were negative. Serum complements were normal. A renal biopsy was obtained and the light microscopy (LM) was unremarkable suggestive of minimal change disease. He was started on steroid therapy and later immunofluorescence (IF) was reported as 'full house' pattern and electron microscopy (EM) showed subepithelial, mesangial and subendothelial deposits in addition to tubuloreticular inclusions consistent with membranous LN [Figure]. The patient was started on Mycophenolate mofetil therapy.

Discussion: Our case represents atypical presentation of SLE in a young male with isolated renal involvement and without anti-double stranded DNA or anti-smith antibodies. It also highlights the importance of obtaining renal biopsy and more importantly, the utility of IF and EM. The management of minimal change disease, as suggested by LM alone in our patient differs significantly from membranous LN. While standard in developed countries, nephrologists in several resource-poor countries have to pick patients who need these advanced microscopic studies. If EM cannot be performed routinely in all cases, a small portion of renal tissue should be saved in an appropriate fixative, to perform at a later date if needed.



PUB253

Clinical Implication of Fractional Excretion of Proteins: Albumin, A1-Globulin, A2-Globulin, B-Globulin, G-Globulin in Patients with Nephrotic Syndrome

Jung-woo Noh,[1] Ajin Cho,[2] Juhee Kim.[3] *[1]Chun & Cho's Medical Clinic & Dialysis Center, Seoul, Republic of Korea; [2]Hallym university Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [3]Department of Internal Medicine-Nephrology, Gangnam Sacred Heart Hospital, Korea, Republic of, Seoul, Republic of Korea.*

Background: Diagnostic approach on underling disease of nephrotic syndrome is a very important process in management of nephrotic syndrome. Besides traditional kidney biopsy and serologic tests, a few novel diagnostic approaches have been tried in this study.

Methods: 42 adult nephrotic patients, biopsy-confirmed with membranous glomerulonephritis (MGN) (n=30) and minimal change disease (MCD) (n=12) at Hallym University Medical Center from 2012 to 2016, were included. With those patients, fractional excretion (FE) of proteins (albumin, a1-globulin, a2-globulin, b-globulin, g-globulin) was retrospectively calculated from data of urine electrophoresis (UEP) and serum electrophoresis (SEP), which had been examined mainly to identify if there was monoclonal gammopathy or polyclonal gammopathy in the patients. Creatinine concentrations of serum and urine to calculate FE of each protein were from data of the same urine and serum samples for UEP and SEP examinations. Patients with serum creatinine > 1.2mg/dL and serum albumin > 3.0g/dL were excluded. To assess diagnostic performance of FE of the proteins, we used receiver-operating characteristic (ROC) analysis.

Results: There was not significant difference in age and serum creatinine levels between the two groups. Mean albumin levels were lower in MCD group than in MGN group (1.38 vs. 2.03, $p < 0.001$). FE of albumin (p=0.021) and g-globulin (p=0.023) was significantly higher in MCD group than in MGN group. However, differences in FE of a1-globulin (p=0.062), a2-globulin (p=0.466) and b-globulin (p=0.129) between the two groups were not significant. Areas under the ROC curve for FE of albumin and g-globulin were 0.770 (95% CI 0.602-0.938 p=0.007) and 0.741 (95% CI 0.578-0.904, p = 0.016), respectively. A FE of albumin > 0.202 could distinguish MCD from MGN with 75% sensitivity and 79.3% specificity. FE of g-globulin > 0.029 also could do with 75% sensitivity and 51.7 % specificity.

Conclusions: Authors, for the first time, tried FE of albumin, a1-globulin, a2-globulin, g-globulin as a tool to predict diagnosis of underlying causes of nephrotic syndrome. This method can be used as a helpful assistant method to make differential diagnosis on MGN and MCD in nephrotic patients with normal renal function.

PUB254

Relapse of Nephrotic Syndrome After Adrenocorticotropic Hormone Induced Remission: Implications of ACTH Antibodies

Snehal Shrivastava,[1] Bohan Chen,[3] Lance D. Dworkin,[2] Deepak K. Malhotra,[2] Rujun Gong.[3] *[1]Nephrology, University Of Toledo Medical Center, Toledo, OH; [2]The University of Toledo, Toledo, OH; [3]University of Toledo Medical Center, Toledo, OH.*

Background: Treatment of relapsing nephrotic syndrome is challenging despite newer immunosuppressive medications. Prolonged glucocorticoid use is the mainstay in management of proteinuric glomerulopathies but has extensive side effects. Alternatives like adrenocorticotrophic hormone (ACTH) have been successfully used to treat refractory glomerulopathies with superior outcomes compared to steroids. However, clinical responsiveness to ACTH therapy may vary, partly due to the development of de novo or acquired resistance.

Methods: A 25-year-old woman with steroid-dependent FSGS developed severe steroid side effects impacting her quality of life. ACTH monotherapy with biweekly subcutaneous injections of repository corticotropin of porcine origin was started. Immediate remission of proteinuria & reversal of steroid side effects was noted followed by a relapse of proteinuria & swelling in 10 weeks. In suspicion of ACTH-antagonizing factors, the patient's serum was collected & processed for Immunoblot-based antibody assay.

Results: Standard porcine ACTH was subjected to immunoblot analysis by incubating the blots with a rabbit anti-ACTH antibody as a positive control or with the patient's serum. The blots were developed using an anti-rabbit or anti-human IgG secondary antibody. Blots were probed by normal standard human serum & no bands demonstrated (control). Immunoblots developed by using patient's serum revealed abundant IgG antibodies reactive to a peptide band also probed by the anti-ACTH positive control antibody, suggesting the presence of high titers of anti-ACTH antibodies. ACTH antibodies were not associated with any clinical signs of hypoadrenocorticism, or other side effects except a delayed-onset resistance to ACTH therapy, entailing that these antibodies are likely specific for porcine ACTH & have negligible cross-reactivity with the patient's native ACTH.

Conclusions: ACTH is valuable in treatment of refractory proteinuric glomerulopathies. However, as is common with treatment with any biologic medication, natural ACTH, regardless of purity & origin, is antigenic in humans. It may cause formation of neutralizing antibodies in some sensitive patients, ensued by acquired resistance to ACTH. Our findings stress the need to develop ACTH analogs with less immunogenicity for improving its responsiveness in patients with glomerular diseases.

PUB255

Analysis of Clinical and Pathological Features of Renal Injury in Primary and Secondary Malignance Hypertension

Cong Zhang. *China-JapanFriendshipHospital, Beijing, China*.

Background: To understand different clinical and pathological features of renal injury among primary and secondary malignance hypertension (MHT) patients.

Methods: 143 cases of MHT patients with complete clinical and pathological records in the past 19 years were selected and analysis was performed respectively. Clinical variables including serum creatinine, urinary analysis. Renal pathological evaluation including the stenosis of small renal artery which was expressed as the ratio of inner and outer diameter of the small artery, ischemic glomerulus of kidney (including shrinkage and sclerosis), global sclerosis of glomerulus, the ratio of crescent to whole glomerulus, interstitial infiltration of inflammation cells, the area of renal interstitial fibrosis and renal tubular atrophy.

Results: Here were 50 cases of primary MHT, 42 male, 8 female, average age was 36±9; there were 93 cases of renal parenchyma related MHT male 74 and female19, average age was 34±8 (no significant difference of sex and age between two groups). 1. clinical features: etiological distribution among renal parenchyma related MHT showed 73 (77.4%) cases were IgA nephropathy. Compared with primary MHT, the amount of proteinuria in the renal parenchyma related MHT group was significant higher. (1.41±1.90 VS 3.32±2.48g/d, P<0.01), 2. pathological features: the typical pathological character in renal parenchyma related MHT was hypertrophy of endomysium which was described as "onionskin" like proliferation. Compared with primary MHT group, this feature was significantly lower in renal parenchyma related MHT group (100% VS 38.0%,P<0.01). renal small artery stenosis in renal parenchyma related MHT group was lower (the ratio of inner and outer diameter of small artery was 0.25±0.07 VS 0.44±0.08, P<0.05),ischemia changes was fewer (81±13% and 42±23%,P<0.01),higher prevalence of glomerular global sclerosis (0.6±2.1% and 16.4±17.5%,P<0.001), higher prevalence of crescent formation((2.3±1.2% and 9.5±13.4%,P<0.001).

Conclusions: Renal parenchyma diseases are common etiology of MHT, especially among IgA nephropathy (about three-forth among this group of patients). Compared with primary MHT, the renal parenchyma related MHT always appears as more proteinuria, pathological feature is characterized by more crescent formation, less "onionskin" like proliferation, less stenosis in renal tubular, less ischemia glumeruli.

PUB256

Case of ANCA-Associated Crescentic Glomerulonephritis in a Stone Cutter with Early Pulmonary Silicosis

Anita Kamarzarian,[1] Jimmy T. Pham,[2] Harpreet Sidhu,[3] Golriz Jafari.[4] *[1]UCLA -Olive View Medical Center, La Canada, CA; [2]UCLA Medical Center Olive View, Sylmar, CA; [3]Olive View UCLA, Redondo Beach, CA; [4]UCLA-Olive View Medical Center, Los Angeles, CA*.

Introduction: Report a case presenting with AKI that is found to be due to ANCA associated Crescentic Glomerulonephritis in a patient with class II Lupus nephritis. The ANCA vasculitis is associated in this case with pulmonary silicosis in a patient who works as a stone cutter.

Case Description: 48 yo male from from Honduras who has been in the US for 20 years presented to our hospital with cc of cough for 2 months productive of sputum. He had no significant PMHX. He worked as a stone cutter. In the ED he had CXR without acute pulmonary disease but labs show BUN of 44, Creatinine of 3.87, urinalysis showed positive protein and 47 RBC, 5 WBC. Urine albumin to creatinine ratio was 4.6 grams. PPD placed resulted as positive, subsequently patient placed in respiratory isolation to rule out TB with sputum collection. CT of chest non contrast showed patchy perilymphatic pulmonary micronodules and subtle peribronchiolar wall thickening and ground glass opacities. Per pulmonary service findings consistent with Silicosis. Cytology from bronchial lavage showed numerous alveolar macrophages with hemosiderin pigments. Serology was positive for ANA Speckled titer 1:2560 and Autoantibodies to myeloperoxidase (MPO) 152.8 AI. Complements were normal and dsDNA was negaitive. Patient's Renal Biopsy showed " Active crescentic GN with 75% involvement consistent with ANCA-associated Vasculitis, however underlying glomeruli display a "full house" pattern of IF staining and EM displays numerous mesangial with segmental sub epi and sub endo deposits with tubuloreticular inclusion c/w class II with segmental membranous features. Patient was initiated on RIPE therapy while undergoing the TB workup per ID consult and was given Okay to start immunosuppression with IV Cytoxan. At 4 months s/p 3 doses of IV Cytoxan, patient's BUN 27, creatinine 1.89 and UPC of 3 grams. Eventually patient was off RIPE therapy once cultures were finalized as Mycobacterium Fortuitum.

Discussion: Pulmonary Silicosis has been seen in stone workers. There are cases showing association of Silicosis with ANCA Vasculitis. Silicosis patients are at increased risk of pulmonary TB. Given positive PPD patient was initiated on RIPE therapy especially since Renal biopsy showed Crescentic GN that needed Cytoxan therapy until final cultures resulted in about 2 months and showed only Mycobacterium Fortuitum.

PUB257

Causes of Primary Nephrotic Syndrome in Adults Stratified by Race: An Update

Corinne L. Mbakop,[1] Vanesa Bijol,[2] Samuel J. Wahl,[3] Maria V. DeVita,[1] Jordan L. Rosenstock.[1] *[1]Lenox Hill Hospital- Northwell Health System, New York, NY; [2]Northwell Health Hofstra University, Lake Success, NY; [3]Lenox Hill Hospital, New York, Turks and Caicos Islands*.

Background: It has been recognized that the incidence of glomerular diseases varies based on race. Membranous glomerulopathy (MGN) has been classically the most common cause of primary nephrotic syndrome (NS) in adults but data from the 1990s showed that focal glomerulosclerosis (FSGS) was increasingly common, especially in black and Hispanic populations. In fact, FSGS appeared to surpass MGN to become the most common cause of NS in these racial groups, and some suggested this may be the case for whites as well. We undertook this study to look at the racial breakdown of NS in the 2000s from our biopsy population. We also carefully excluded patients with evidence of secondary disease and without full NS, which has not always been done in prior reports.

Methods: We reviewed all renal biopsies from the Northwell database, available from 2017-2018 (n=532) and from Lenox Hill Hospital specifically from 2010- 2016 (n=143). We extracted all cases of nephrotic syndrome and then excluded cases with secondary disease. Charts were reviewed for clinical data including race.

Results: Overall, there were 97 cases of primary NS including 39.2 % MGN, 29 % minimal change disease (MCD), 16.5 % FSGS, 11.3% IgA nephropathy (IgAN), and 4 % membranoproliferative (MPGN). In the primary NS population, overall there were 43 whites, 21 blacks, 16 Asians, 10 Hispanics, and 9 multiracial patients. Among whites, MGN was the most common cause of NS 40.5%, followed by MCD 31%, IgAN 14%, FSGS 9.5% and MPGN 5%. For blacks, FSGS was the most common cause with 37 %, followed by MGN 32%, MCD 21 %, MPGN 5% and IgAN 5%. Among Asians, both MGN and MCD were seen in 41 %, FSGS 12% and MPGN 6%. In Hispanic patients, MGN was found in 40%, IgAN 30%, FSGS 20 % and MCD 10%. Among the 38 cases of primary MGN, 22 were positive for PLA2R antibody on biopsy, which represents 58%. Of the 16 cases of FSGS, 31.3 % were classic FSGS, 37.4 % had tip lesion, and 31.3 % were collapsing.

Conclusions: This study updates the racial distribution of primary nephrotic syndrome. We found that MGN continues to be the most common cause of primary NS overall in our population. Unlike previous reports, FSGS is a relatively uncommon cause of NS in whites (less than MCD and IgAN). In blacks, FSGS remains the most common form of NS, supporting previous reports from the 1990s suggesting a marked increase in this population.

PUB258

Glomerular Diseases Epidemiology in the Wayú of the Colombian Caribbean Region

Andres Cadena,[1,2] Henry J. Gonzalez Torres,[1] Lina M. Rodriguez-Rada,[1] Kelly Fernandez-Merlano,[1] Stefani Chartouni-Narváez,[1] Maria D. Velez-Verbel,[3] Carolani A. Escalante méndez,[1] Gustavo Aroca Martinez.[4] *[1]Universidad Simon Bolivar, Barranquilla, Colombia; [2]Clínica de la Costa, Barranquilla, Colombia; [3]Universidad Libre Secc. Barranquilla, Puerto Colombia, Colombia; [4]Universidad Simon Bolivar / Clinica de la Costa, Barranquilla, Colombia*.

Background: he Wayú is one of the 102 indigenous towns that are found in Colombia, corresponds to 45% of La Guajira population. Despite this, is one of the 18 that are in danger of disappearing. This is due to the violence, displacement and extreme poverty experience by Wayú people, as well as a notable lack of access to health services. The objective was to characterize the glomerular diseases, primary and secondary in the Wayú community in the Colombian Caribbean region that are in the Nephropathy Colombian Register - NefroRed.

Methods: A descriptive and retrospective study was carried out in the Caribbean Colombian region. All the patients belonged to the Wayú Ethnic group, adults with Glomerular diseases. Those who had a renal biopsy with a diagnosis of GD between January 2008 and June 2018. All the patients were evaluated under clinical indications in a reference hospital. The histopathological findings by optical microscopy and immunofluorescence were correlated with the patients clinical history.

Results: A total of 48 renal biopsies were analyzed. The main clinical indication for the biopsy was nephritic syndrome (36%). The secondary (SGD) were more frequent than the primary (PGD), 55% versus 45%. For PGD, the lupus nephritis was the most frequent etiology (83%) and the main nephrological syndrome was nephritic syndrome (36%). Membranous nephropathy (33%) and segmental focal glomerulosclerosis (19%) were the SGD most frequents and the nephritic syndrome (22%) was the main biopsy indication.

Conclusions: The GD epidemiology revealed a predominance of SGD due to the relative high frequency of lupus nephritis in this population. Since the NEFRORED® establishment, the data collected in this document are relevant to obtain a better understanding of GD in Latin America, which improves the early reference of patients to clinical care and the usefulness of a database for future studies.

PUB259

Online Thai Glomerular Disease Registry: Paraprotein-Related Kidney Diseases

Ratana Chawanasuntorapoj. TGCN *Thailand Glomerular Disease Collaborative Network, Bangkok, Thailand.*

Background: Paraproteinemic-Related Kidney Disease (PRK) are the group of kidney diseases derived from the deposition of paraproteins or monoclonal immunoglobulins in the kidney, which are associated with the immunoproliferative disorder and non-proliferative monoclonal gammopathy. Amyloidosis and monoclonal Ig deposit diseases (MIDD) including light chain deposit disease (LCDD), and heavy chain deposit disease (HCDD) are the frequent glomerular involvement and lead to end stage renal disease approximately 20-60% within 1 year. Our study aimed to demonstrate the PKD in Thai Glomerular Disease Registry.

Methods: We conducted a prospective cohort study in the adults' native kidney biopsy proven glomerular diseases between July 2014 and April 2019. The clinical and laboratory parameters at the time of biopsy, pathologic findings, treatment regimens and clinical outcomes of amyloidosis and MIDD were recorded via on-line registry.

Results: We found the prevalence of amyloidosis and MIDD was 0.85% (18 amyloidosis, 3 LCDD, and 1 HCDD from 2,585 patients). The male to female ratio was 1.2:1. The average age, creatinine, albumin, globulin, and UPCR were 64 (39-86) years, 1.6 (0.6-7.2) mg/dL, 2.4±0.8 g/dL, and 3.1±0.6 mg/dL, and 5.55 (1.6-11.97) g/day. The average K/L ratio in amyloidosis and LCDD were 0.33(0.03-19.54) and 15.79(0.78-30.8), whereas in HCDD was 46.78. The patients presented with 77.3% of nephrotic syndrome, 9.1% of nephrotic nephritis, 4.5% of nephritis, 4.5% of asymptomatic proteinuria and 45.5% of initial Cr≥1.2 mg/dL. Median time to biopsy was 15.1 weeks (3-56.5 weeks). We found 7 multiple myeloma and 2 MGUS in our group. Only 2 cases had amyloid heart disease. Steroid with the chemotherapy were prescribed in 16 patients and 1 case followed by autologous stem cell transplantation. During of the median time follow up 11.5 months, we found remission in 4 cases (3-velcade based regimen, 1-ASCT), ESRD in 1 case(no chemotherapy), and dead in 5 cases after chemotherapy. The cause of dead was infection in 4 cases, and found dead probably from amyloid heart in 1 case.

Conclusions: Our study described the rare disease including amyloidosis and MIDD, but high mortality was found in this group. Most of the patients presented with initial high creatinine and time to biopsy was quite delay. The high mortality rate from infections reminded us to reconsider the effective and safety regimen.

PUB260

TAFRO Syndrome with Initial Presentation of Renal Thrombotic Microangiopathy: Cases Series of One Medical Center in Taiwan

Pei-Yi Fan, Tai-Di Chen, Cheng chia Lee, Chih-Hsiang Chang, Kun-Hua Tu. *Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: Castleman disease is one kind of benign lymphoproliferative disorder, with specific histopathologic feature of lymph nodes. According to the involved area, it could be divided in to uni-centric and multi-centric form. Multi-centric Castleman disease frequently have systemic manifestation, including to several subtypes such as TAFRO syndrome and idiopathic plasmacytic lymphadenopathy (IPL). All kinds of Castleman's disease would have renal manifestation. According to the literatures, renal thrombotic microangiopathy are frequently found in these patients. To date, there are few articles reporting renal manifestation of Castleman disease in Taiwan. We conduct a study to investigate the renal manifestation of Castleman disease.

Methods: This investigation was performed in a tertiary hospital. From 2000-2018 period, there are totally 125 patients receiving lymph node biopsy confirmed as Castleman's disease. After review of medical records, there are 3 patients with definite diagnosis of TAFRO syndrome. All of these 3 patients have renal manifestations of hypertension, sub-nephrotic proteinuria and microscopic hematuria. 2 of these patients received renal biopsy.

Results: Case 1 is one 25-year-old male with initial presentation of fever, anasarca, thrombocytopenia, hepatosplenomegaly, multiple lymphadenopathy and acute glomerulonephritis. The histopathologic feature of lymph node biopsy is hyaline vascular type. Renal biopsy revealed feature of thrombotic microangiopathy. Case 2 is one 63-year-old male with initial presentation of anasarca, thrombocytopenia, hepatomegaly, multiple lymphadenopathy and acute glomerulonephritis. The histopathologic feature of lymph node biopsy is plasma cell type. Renal biopsy also revealed feature of thrombotic microangiopathy.

Conclusions: Renal involvement is frequently found in multicentric Castleman disease. We reported 2 cases of TAFRO syndrome with initial presentation of renal thrombotic microangiopathy. Further research is still needed to investigate the pathogenic mechanism.

PUB261

FOrMe: The German Focal Segmental Glomerulosclerosis and Minimal Change Disease Registry

Linus A. Volker,[1,2] Franziska Grundmann,[1] Thomas Benzing,[1,2] Paul T. Brinkkoetter.[1] *[1]University Hospital of Cologne, Cologne, Germany; [2]CECAD, University of Cologne, Cologne, Germany.*

Background: Minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) are leading causes of nephrotic syndrome and associated with a relevant risk for the development of chronic renal insufficiency and end-stage renal failure. Incidences and prevalences vary significantly among Western countries. Within the German population, both MCD with an incidence of 3.2 per million population and FSGS with an incidence of 11.2, both entities are classified as rare diseases. There is a lack of systematic, large-scale, randomized intervention studies.

Methods: Within the framework of the DFG-funded Clinical Research Unit CRU 329 "Molecular Mechanisms of Podocytic Diseases - Nephrology on the Way to Precision Medicine", the FOrMe registry (The German Focal Segmental Glomerulosclerosis and Minimal Change Disease Registry) has been established as a nation-wide registry for pediatric and adult patients. It aims to collect 150 pediatric and 350 adult MCD and FSGS cases within the next 10 years. Within the registry, laboratory and clinical anamnestic parameters are linked with histopathological findings. Clinical data is collected systematically at inclusion and throughout the course of disease. Biological patient samples such as urine, serum, RNA, DNA, and tissue biopsy material are conserved and cataloged within the BioMaSOTA biobank already established at the University of Cologne, Germany.

Results: Registry structures have been established successfully. Patient acquisition and inclusion in the registry is ongoing since April 2019 at the University Hospital of Cologne. Additional centers are going to be initiated in the near future.

Conclusions: The FOrMe registry is recruiting since April 2019. As the central and largest German MCD / FSGS registry it will enable a translational approach to reconfirm the results of basic molecular research using precisely characterized human biomaterials and to develop new diagnostic and therapeutic approaches in the long-term.

How Lupus Glomerulonephritis Affects Renal Reserve?

Gustavo Aroca Martinez,[1] Alvaro A. Martinez Bayona,[2] Henry J. Gonzalez Torres,[3] Carlos G. Musso.[4] *[1]Universidad Simon Bolivar / Clinica de la Costa, Barranquilla, Colombia; [2]Fundación de Lupus del Caribe, Barranquilla, Colombia; [3]Universidad Simon Bolivar, Barranquilla, Colombia; [4]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.*

Background: Lupus nephritis (LN) is a severe complication of systemic lupus erythematosus (SLE), which has different manifestations such as urinalysis alterations, nephrotic syndrome, nephritic syndrome, rapidly progressive renal failure and evolution to end-stage chronic renal disease. Renal reserve (RR) is the kidney's ability to increase its basal glomerular filtration rate (GFR) by at least 20% after a protein overload. As far as we know there is no previous report regarding how acute lupus glomerulonephritis and its treatment affect RR. Thus, we decided to evaluate the RR in three young women suffering from a recently diagnosed lupus glomerulonephritis, and then we reevaluated their RR after they were treated with immunosuppressant drugs.

Methods: RR test consisted of obtaining two consecutive fast minuted-creatinine clearances (basal GFR) after an adequate patient's oral hydration (15 cc/Kg of tap water). Then, a high protein meal based on dairy products (1.2 g/Kg of protein) was delivered, and seventy minutes later, three successive minuted-creatinine clearances were measured. Finally, the difference between the higher post-prandial creatinine clearance (pick value) and the average between the two pre-prandial creatinine clearances (basal value) was obtained.

Results: RR was abolished (RR:0%) in the LN patients without treatment, while it was positive (RR≥ 20%), borderline (RR ≥ 5%) or negative (RR:< 5%), depending on their prescribed treatment: patient 1 and patient 2 were treated with double immunosuppressant treatment during 12 and 6 months, respectively; while patients 3 was treated only with methylprednisolone during 6 months.

Conclusions: It seems that acute lupus glomerulonephritis abolished the patient's renal reserve, which can be recovered by prescribing double immunosuppressant therapy.

PUB263

Urinary Sodium Is Associated with the Degree of Proteinuria in Patients with CKD

Bo Zhang. *The first affiliated hosptial of Nanjing Medical University, Nanjing, China.*

Background: Increased urinary sodium excretion, representing dietary sodium intake, is associated with hypertension. Low sodium intake has been associated with increased mortality in observational studies. Sodium and fluid retention is a hallmark and a challenge of the nephrotic syndrome (NS). This study aimed to evaluate the association between 24-hour urinary sodium and protein excretion in patients with chronic kidney disease.

Methods: We enrolled 1,142 patients with chronic kidney disease in Jiangsu Proince Hospital from May 1,2017 to May 1,2019. 24-hour urinary sodium and potassium was measured. In this group, Spearman correlation and partial correlation analysis were used to study the correlation between 24-hour urinary sodium and 24-hour proteinuria. We performed multivariate linear regression models, taking several covariates into account, including baseline eGFR and proteinuria.

Results: In our study, 24hour urine protein ranged from 17mg to 42003mg. 24hour urine sodium ranged from 3.5 to 569mmol. 24-hour urinary sodium was positively correlated with 24-hour proteinuria(r=0.102, P=0.001). Additionally, 24-hour urinary sodium was positively correlated with 24-hour urinary creatinine(r=0.354, P<0.0001). After adjusting the age, sex, BMI, eGFR, 24-hour urinary sodium was also positively correlated with 24-hour proteinuria.(Fig1a,b)

Conclusions: We found that in patients with CKD,24-hour urinary sodium positively associated with protein excretion, these data support high urinary sodium associate with marginal renal function, but whether the change of 24-hour urinary sodium as time goes by correlate with the progression of CKD is required to study.

Mepolizumab Therapy in Eosinophilic Granulomatosis with Polyangiitis as a Steroid-Sparing Therapeutic Approach

Allyson C. Egan,[1] Rona M. Smith,[2] David R. Jayne.[3] *[1]Renal medicine, University of Cambridge, Cambridge, United Kingdom; [2]Cambridge University Hospitals, UK, Cambridge, United Kingdom; [3]University of Cambridge, Cambridge, United Kingdom.*

Background: Eosinophilic granulomatosis with polyangiitis [EGPA] is characterised by the presence of tissue eosinophilia, necrotising vasculitis and granulomatous inflammation[1,2] which can lead to renal failure. In the recent trial, Mepolizumab (MEPO) In Relapsing or Refractory EGPA [MIRRA], treatment with the monoclonal antibody directed against IL-5 (300mg), accrued longer times in remission, reduced steroid exposure and relapse rates.[1,2] Identifying disease phenotypes such as organ involvement or the phasic stages of the disease, along with assessment of efficacy of 100mg would further guide the role of anti-IL5 therapy.

Methods: This retrospective, descriptive study analysed 8 patients with EGPA according to the American College of Rheumatology criteria or Chapel Hill Consensus 2012 definition. The aim of our study was to analyse the response and outcome for EGPA patients who received 100mg s/c of MEPO monthly for 52 weeks. Time points of commencement of MEPO and week 48-52 assessments were compared.

Results: MEPO was well tolerated and considered of clinical benefit, with seven/eight patients [87.5%] continuing therapy beyond 12 months, whilst on 100mg dosage. Four patients had prior therapy with rituximab and five had adjuvant conventional therapy. Seven had lower steroid therapy.

Conclusions: The study supports the efficacy of the steroids sparing capacity of anti-IL-5 therapy for treatment of EGPA. Adjuvant therapy with conventional immunosuppressants was well tolerated and renal function was preserved. REFERENCES 1. Wechsler ME et al. Cohort Study of Percutaneous Native Kidney Biopsies from Rural Center Predominantly Caucasian Groups

Ravi K. Thimmisetty,[1] Kiran Chintam,[2] Frank W. Braxton.[3] *[1]Nephrology, Cape Girardeau, MO; [2]Southeast hospital, Cape Girardeau, MO; [3]Nephrology Associates, Jackson, MO.*

Background: Renal Biopsies are very consequential in clinical practice and avail in understanding of pathophysiology's, treatment and prognosis of glomerular diseases.

Methods: Epidemiological retrospective analysis of native percutaneous kidney biopsies from a rural center. Reviewed medical records of percutaneous biopsies from 2013 to May 2019

Results: There were total of 118 percutaneous native kidney biopsies analyzed with the following results: Average age at the time of biopsy was 58.0 years (16-94). Gender wise, 59.6% were males and 39.8% were females. Unexplained acute renal failure is the most common indication for biopsy. 80.5% were Caucasians, 15.25% were African Americans. Most common histological diagnosis was Nodular glomerular sclerosis (32.20%). Next common biopsy diagnosis is ATN/AIN, combination found to be 18.64%. Third common histological diagnosis found to be FSGS (12.71%). Fourth histological diagnosis is IgA nephropathy 8.4%.

Conclusions: At our rural center, most common pathology in Caucasians found to have nodular glomerular sclerosis. 13.15% of patients have histological diabetic changes with no clinical or serological diagnosis of diabetes, suggestive of other factors inolving in pathophysiology. 31.6% of diabetics have alternate histological diagnosis. Next common pathology shown Acute/Chronic Interstitial Nephritis along with Acute tubular Necrosis, may explain the medications/infections a leading cause of Chronic Kidney Disease.

The Use of Direct Oral Anticoagulants in Membranous Nephropathy

Maximilian Wills, Sanjana Gupta, Alice M. Gage, Neil Ashman, Suzanne H. Forbes. Nephrology department, The Royal London Hospital *Royal London Hospital, London, United Kingdom*.

Background: Barts Health has a dedicated membranous nephropathy (MN) service with 15-20 incident cases per year. Nephrotic syndrome secondary to MN in particular is associated with arterial and venous thrombosis. There is little evidence to guide optimum pharmacological prophylaxis. In those considered high risk, options include warfarin, heparin or aspirin. The advent of direct oral anti-coagulants (DOACs) offers an alternative, though evidence of efficacy is isolated to case studies. All patients with an albumin <25g/L are offered anticoagulation. We describe our use of DOACs in a large single centre MN cohort.

Methods: Retrospective data from MN patients, collected between 2015-2019 was analysed. This included: demographics; frequency, type and timing of thromboembolic and bleeding events; biochemical data at initiation and cessation of agent.

Results: Total number of patients: 26 DOAC treatment courses: 30 Exposure to drug (patient days): 9899 Malignancy was excluded in all cases, with the exception of 1 case of MN secondary to cancer. There were 3 thromboembolic events in 3 patients; all events occurred on rivaroxaban and in PLA2Rab positive MN. Thrombotic events were all arterial, with no venous events, 2 cerebral artery infarcts and 1 lower limb arterial thrombosis. These patient's mean initial presentation PLA2Rab titres were 164 Kunits/L (75-248) and all were nephrotic at the time of the thromboembolic event. Events were 29, 128 and 340 days post DOAC initiation. 2 of these patients had a venous thrombosis prior to DOAC initiation. Event rate: 0.11 per patient year Safety data also demonstrated 3 bleeds in this patient cohort - all were minor as per ISTH criteria. 2 epistaxes and 1 associated with rectal prolapse, all without a haemoglobin drop.

Conclusions: Our experience is that DOACs are safe and effective in patients with MN and offer a viable anti-coagulant alternative.

HIV-Associated Nephropathy in Mexico: Report of Six Cases from the Instituto Nacional de Cardiologia "Ignacio Chávez"

Armando Armenta álvarez,[1] Marcos G. Nava,[2] Magdalena Madero,[1] Bernardo Moguel.[1] *[1]Instituto Nacional de Cardiología, Mexico City, Mexico; [2]Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.*

Background: Kidney disease is a common complication in HIV infection, which can shorten the life expentancy from patients. HIV associated nephropathy spectrum includes diseases directly related to the immune interaction related to HIV infection, diseases associated to opportunistic infections, and those associated to treatment.

Methods: This is an observational, descriptive, retrospective, longitudinal study. We reviewd clinical files from all HIV positive patients, that attended to the outpatient nephrology clinic. Those with kidney biopsy were included.

Results: During the last 3 years 12 patients with HIV infection where send to our clinic under suspicion of kidney disease, 6 of them required kidney biopsy. From those 6 patientes 83% presented partial remission. **See Table 1**

Conclusions: Since 1984 diverse Kidney Diseases associated to HIV have been reported. The leading cause globally is collapsing glomerulopathy, which was observed in 33% of our population, also ITN has a high prevalence in this population, in our population was present in 50% of patients, 2/3 of them were HAART related. To our knowledge this is the first report of HIV associated disease since 1998, back then Soriano et al, reported a high incidence (48%) of collapsing glomerulopathy, and 35% of mesangial involvement, since then incidence of collapsing glomerulopathy is almost the same.

HIV Associated Kidney Disease

Patient	CD4	Viral Load	Biopsy Finding	Treatment
1	600	Non detectable	Acute ITN NSAIDs + AA Amyloid	PDN 1 mg/kg
2	332	43	Membranoproliferative GMN Immunocomplex Mediated + Active TMA	3 plasmapheresis sessions + PDN 1 mg/kg + RAAS Blockade
3	749	Non detectable	Membranoproliferative GMN Immunocomplex Mediated	PDN 1 mg/kg + RAAS Blockade
4	500	Non detectable	Collapsing Glomerulopathy + Acute ITN HAART	Dialysis

Renal Chronicity Score a Predictor of CKD Progression in Glomerulopathies

Jineth L. Diaz villar,[2] L. M. Perez-Navarro,[1] Flor E. Rojas,[2] Angela M. Cordoba hurtado,[3] Ivan Rosero,[2] Virgilia Soto,[4] Rafael Valdez-Ortiz.[2] *[1]Hospital General de México Dr. Eduardo Liceaga, Mexico City, Mexico; [2]Hospital General de Mexico, Mexico City, Mexico; [3]Universidad Nacional Autonoma ee Mexico, Ciudad de Mexico, Mexico; [4]INC Ignacio Chavez, Mexico City, Mexico.*

Background: Chronic changes on renal biopsies are a strong predictor of chronic kidney disease (CKD) progression. The Renal Chronicity Score (RCS) grades the chronic changes based on severity and it has been proposed as a systemic approach to predict CKD progression.

Methods: Retrospective study of consecutive subjects with renal biopsy and Glomerulopathy in which clinical data and histopathologic analysis were taken. The data was assessed for descriptive and inferential statistics using t-test, X^2-test and Cox-regression-analysis to predict progression to CKD (GFR <60mg/dL). p ≤0.05 was considered significant.

Results: Five hundred subjects with renal biopsy and Glomerulopathy with a mean age of 39.1±15 years (43% female) were included. There were 157 subjects (31%) with Primary Glomerulopathy (PG) and 186 subjects (54%) with Secondary Glomerulopathy (SG). In the PG group 39% of the patients had focal and Segmental Glomerulosclerosis (FSGS), 27% had Membranous Nephropathy (MN), 17% had IgA Nephropathy, 15% had Membranoproliferative Nephropathy and 2% had Minimal changes disease. In the SG group 45% of the patients had lupus nephritis, 25% had diabetic nephropathy, 13% had FSGS, 10% had vasculitis, 6% had paraproteinemia and 1% had secondary MN. There were significant differences among both groups in Creatinine, Hemoglobin and CKD-EPI(p<0.001). Differences in The HR for developing CKD in PG and SG are shown in figure 1-1a.

Conclusions: RCS is associated to CKD progression at 6 months in primary and secondary Glomerulopathies. RCS is a good prognostic tool in primary and secondary glomerulopathies.

PUB269

Effects of Fangji Huangqi Decoction on the Expression of Heparanase of Adriamycin Nephropathy

Wenjing Wang,[1] Hongqin Sheng,[1] Lei Zhang,[1] Xusheng Liu.[2] *[1]Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China; [2]The Second Affiliated Hospital, Guangzhou University of Chinese Medicine, Guanghzou, China.*

Background: Albuminuria is a hallmark of glomerular disease and an independent risk factor for the progression of kidney disease. Fangji Huangqi Decoction (FHD) has a good research foundation of the treatment of kidney diseases. Many studies show that this decoction has a good clinical effect in the treatment of kidney diseases, especially in reducing edema and urinary protein. At present, a large number of experiments have proved that FHD can repair damaged glomerulus and protect renal function of the treatment of chronic kidney disease. Therefore, based on the current research status, this study investigated the protective effect on FHD on adriamycin nephropathy rats, and explored the therapeutic effect and possible mechanism of FHD on reducing proteinuria by observing Heparanase, an important molecule involved in maintaining the structure and function of glomerular filtration barrier.

Methods: 48 Wistar rats, 8 of them were randomly taken as normal control group, the others received intravenous injections of ADR via tail vein (the first dose was 5.5mg/kg, the second injection dose was 3mg / kg after 14 days), established adriamycin-induced nephropathy rat model, the model rats were randomly divided into model group, treating group by high-dosage and low-dosage medicine, and then administered intragastrically by medicine in corresponding dosage. In next 5 weeks, rats in each group were detected 24hours urinary Protein. Renal tissues routine was fixed, HE staining was used to observed the histopathology change of kidney. The expression of nephrin, podocin and CD2-associated protein in rats renal tissues was observed with immunohistochemistry. HPA expression was detected using reverse transcription PCR.

Results: 24h urinary protein quantitative and podocyte marker protein of the rats in the model group increased compared with the normal group, Heparanases expression in renal tissue decreased than those of normal groups,the above indexes in treating group were improved in different degrees.

Conclusions: 1. FHD can reduce the quantity of 24 hours urine protein of Adriamycin Induced Nephropathy rats, alleviate the histopathology change of kidney, protect the charge barrier against damage. 2. One of the effective mechanism of FHD is repairing glomerular filtration barrier damage by decreasing Heparanases expression.

PUB270

Loss of Podocytes by Detachment as Viable Cells: Cause and Consequences

Wilhelm Kriz.[1,2] *[1]University Heidelberg, Mannheim, Germany; [2]Neuroanatomy, Medical Faculty Mannheim, Mannheim, Germany.*

Background: Loss of podocytes underlies the development of CKD. Podocytes are not lost by apoptosis, rarely by necrosis. The major way of losing podocytes consists of detachment from the GBM as viable cells. What accounts for this phenomenon?

Methods: Theoretical analysis on the basis of structural observations

Results: Podocytes are exposed to the flow dynamic forces of filtration that tend to disconnect podocytes from the GBM. For detachment, these forces must surpass the anchoring forces. This seems to happen never with healthy podocytes. Precondition is an impairment of the connections of the foot processes (FPs) to the GBM, of the interconnection of FPs by the slit diaphragm or of the podocyte cytoskeleton itself. The flow dynamic forces include the tensile and the shear stress of filtration. As recently shown (Pediatr Nephrol 32: 405, 2017) podocytes lying downstream of the GBM are largely protected from tensile stress by the limited distensibility of the GBM. In contrast, the shear stress of filtrate flow acts on all parts of a podocyte and always in its actual height. Filtrate flow through the filtration barrier pushes the endothelium towards the GBM, in contrast, it pushes the FPs away from the GBM tending to detach them. The shear stress of filtrate flow has been uncovered as an important parameter of filtration by Endlich and Endlich (Semin Nephrol 32:327, 2012). They showed that the huge flow and the narrowness of the filtration slits lead to a magnitude of shear stress to the sides of FPs that is several folds higher than that of blood flow to the capillary wall. Thus, any impairment of the anchoring forces will create a precarious situation, in which podocytes may start to detach at some site creating a gap in the podocyte cover of the GBM. This must be considered as a mortal event, comparable to the triggering event in a dam break that cannot be repaired, but will inevitably proceed to the detachment of the involved podocytes. This is a long-lasting process (weeks, months?). No structural findings are obvious that could be interpreted to show the repair of a gap in the podocyte cover of the GBM. Considering that two podocytes may approach each other in an attempt to close a gap, the increasing shear stress will prevent a complete closure.

Conclusions: Consequently, defects in the podocyte cover of the GBM cannot be repaired, lost podocytes not be replaced.

PUB271

Effect of Sociodemographic Characteristics of Hemodialysis and Pre-Dialysis Patients on Treatment Burden

Abdullah I. Hamad,[1] Asma M. Almansouri,[1] Fadwa M. Al-Ali,[1] Rania A. Ibrahim,[1] Mincy M. Mathew,[1] Nadir Kheir,[3] Mohamed Izham,[2] Ahmed Awaisu.[2] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Qatar University, Doha, Qatar; [3]Pharmacy School, Aukland, New Zealand.*

Background: Treatment burden is the load imposed by healthcare on patients. The impact of sociodemographic factors on treatment burden has not been adequately studied in patients with chronic kidney disease (CKD). We are conducting the first study to investigate treatment burden among CKD patients in Qatar.

Methods: We conducted a cross-sectional study at FBJKC [the largest in Qatar with 465 hemodialysis (HD) patients and 230 pre-dialysis patients with GFR <20 ml/min]. Treatment-related burden was evaluated using the Treatment Burden Questionnaire (TBQ), which contains five domains (medications, lifestyle, social, financial, and administrative burdens). Data were analyzed using SPSS version 24.

Results: A total of 223 HD and 57 pre-dialysis patients were included. Age was 59+/-19 years and 54.6% were males. HD patients were more likely to be single, widowed or divorced compared to pre-dialysis (36.3% vs. 17.5% p 0.03). Pre-dialysis group reported higher college degrees and employment compared to HD (45.6% vs. 24.2% (p 0.006) and 56.1% vs. 25.1% (p<0.001) respectively). Native Qatari were more represented in HD compared to pre-dialysis (62.8% vs. 22.8%; p<0.001). Treatment burden (measured by TBQ score) was significantly higher in HD versus pre-dialysis patients (45 versus 25 p 0.001). The influence of sociodemographic factors on TBQ score among CKD patients is summarized in (Figure 1). Poorly educated, unemployed and retired patients had the highest TBQ score (p<0.05).

Conclusions: Treatment burden measured by TBQ is elevated among CKD patients in Qatar. Poor education, unemployment and retirement were associated with higher burden of treatment. Studying sociodemographic treatment burden among CKD patients will improve designing effective intervention strategies.

Impact on Urinary Oxalate Levels from the Use of Ezetimibe

Christopher L. Trautman,[1] Ivan E. Porter.[2] *[1]Mayo Clinic Florida, Jacksonville Beach, FL; [2]Mayo Clinic, Jacksonville, FL.*

Background: Calcium oxalate stones are the most common cause of nephrolithiasis in the United States. Patients are routinely advised to limit dietary intake of oxalate as a measure to prevent stone formation. Treatments of hyperlipidemia have been linked to increased oxalate absorption impacting urine concentrations. Smaller studies of less than 15 patients investigating ezetimibe (Zetia®), a selective cholesterol absorption inhibitor, have suggested increased urine oxalate levels with use of the drug. We attempt to better define this relationship of ezetimibe on urinary oxalate using a larger patient sample analyzing multiple urine collections on and off treatment.

Methods: We retrospectively reviewed all consecutive patients from 01/2018 through 04/2019 evaluated for nephrolithiasis with use of ezetimibe documented in their medical record at Mayo Clinic Florida. Demographic, clinical, and laboratory data were collected. Inclusion criteria consisted of age greater than or equal to 18 years, lipids treatment with ezetimibe all or in combination with a statin, and at least one urine supersaturation profile. Patients not seen in nephrology clinic despite use of ezetimibe and a urine supersaturation profile were excluded from analysis. Primary outcomes included increase in urinary oxalate with use of ezetimibe and reduction in urinary oxalate with discontinuation of medication. Methodology of statistical analysis to be determined.

Results: A total of 57 patients (average age 70, 68% male) were reviewed and under analysis with multiple urine supersaturations per patient. 24 hour urine oxalate levels appear to increase with use of ezetimibe.

Conclusions: Ezetimibe demonstrates a correlation with increased urine oxalate which may potentiate calcium oxalate stone formation.

PUB273

The Need for Further Investigation and Subspecialization in Sports Nephrology

Brian Wang,[1,3] Rajiv K. Dhamija.[2,1] *[1]University of California, Irvine, Orange, CA; [2]Rancho Los Amigos National Rehabilitation Center, Huntington Beach, CA; [3]Arrowhead Regional Medical Center, Colton, CA.*

Background: According to the ASN website, current subspecialties in Nephrology include Transplant, Interventional, dual certification in Critical Care Nephrology, and advanced training in Glomerular Disease and Dialysis. The growing field of athletic performance and recreation enthusiasts seeking competitive edges and training advantages warrant the need for specialty expertise pertaining to Nephrology. Investigation to the fundamentals of nutrition, metabolism, and efficient energy output have been limited from a renal perspective.

Methods: A systemic literature review was conducted on Pubmed through May 2019 pertaining to athletic performance and Sports Medicine. Publications included basic science, prospective clinical study, retrospective clinical study, meta-analysis, case series, review articles, and editorials. Various subjects such as combat sports, endurance training, strength and conditioning, and rapid weight loss were explored.

Results: We reviewed a total of 46 publications with 18 studies focusing on combat sports and 7 studies on high intensity interval training. No Nephrology specialty authors were involved in the reviewed studies. These publications showed limited investigational studies from a renal perspective evaluating athletic performances in the categories of electrolytes and minerals, fluid balance, hypertension, hematuria, trauma, rhabdomyolysis, transplant, and immunosuppression. Methods of hydration such as the increase use of energy drinks and effectiveness of alkaline water have been investigated in 8 journals. Nutritional supplementation from 8 journals, rapid weight loss studies from 3 journals, and thermoregulations from 3 journals in combat sports play an important role in both training and competitions. These investigational studies have limited insights and expertise into the effects relating to the renal system.

Conclusions: Traumatic brain injury and CTE led to the progression of Sports Neurology, similarly there are Nephrology associated morbidities and mortalities in sports injuries such as water intake, dehydration, and rhabdomyolysis. There is a lack of renal guidelines in regards to highly trained athletes who are undergoing intense training, sometimes in environmentally challenging situations. We believe further investigation from a Sports Nephrology perspective can advance the field of athletic performance and provide a safe training environment in the future.

PUB274

The Interaction of Poor Sleep Quality with Cardiovascular Risk Factors in the CKD Population

Mochammad Thaha,[1,2] Maulana A. Empitu,[3] Ika N. Kadariswantiningsih.[4] *[1]Department of Internal Medicine, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia; [2]Department of Internal Medicine, Universitas Airlangga Hospital, Surabaya, Indonesia; [3]Department of Pharmacology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia; [4]Department of Clinical Microbiology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia.*

Background: Sleep deprivation is strongly associated with cardiovascular disease (CVD) in general population. However, the significance of poor sleep quality in chronic kidney disease (CKD) is still unknown. This study explored some factors that may interact with sleep quality in CKD population.

Methods: This study assessed the sleep quality of 39 with non-dialysis CKD stage III-IV (ND-CKD) patients and 25 hemodialyzed CKD stage V (HD-CKD) patients using the Pittsburgh Sleep Quality Index (PSQI) questionnaire. Poor sleeper was defined as individual with PSQI > 5. The markers of inflammation such as hs-CRP and blood-count-based marker were measured right after the PSQI data were taken.

Results: HD-CKD group has higher prevalence of poor sleeper and cumulative PSQI score (30% vs. 60%, p=0.029; PSQI 4.5±4.4 vs 8±6, p=0.038). In ND-CKD group, there are association between short sleep duration with elevated diastolic blood pressure (r=0.421, p<0.05) and habitual sleep efficiency with platelet-to-lymphocyte ratio (r= 0.532, p<0.0001). In HD-CKD group, a requirement to use sleep medication was associated with elevated hs-CRP level (r=0.434, p=0.030) and decreased monocyte-to-lymphocyte ratio (r=- 0.410, p=0.042).

Conclusions: Some features of poor sleep quality in CKD patients including low sleep efficiency, daytime dysfunction and requirement to use sleep medication were associated with increased diastolic blood pressure, hs-CRP and blood-count-based inflammatory predictors. Thus, poor sleep quality possibly acts as a mediating factor that exacerbates the CVD risk in CKD.

Açai Juice (Euterpe oleracea mart.) Supplementation Reduces Lipid Peroxidation in Hemodialysis Patients: A Pilot Study

Denise Mafra,[1] Isabelle C. Martins,[2] Hervé Rogez,[2] Maria d. Pinheiro,[2] Keuri E. Rodrigues,[2] Abner A. Lima,[2] Jessyca S. Brito,[1] Bruna Paiva,[1] Luís C. Pinto,[3] Andréa D. Reis,[4] Barbarella D. Macchi,[2] José L. Nascimento.[2] *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Federal University Pará, Belém, Brazil; [3]Pará State University, Belém, Brazil; [4]São Paulo State University, São Paulo, Brazil.*

Background: Chronic kidney disease (CKD) patients on hemodialysis (HD) present oxidative stress, which has a strong association with cardiovascular complications. Several nutritional therapeutic strategies have been used to reduce the oxidative stress in these patients, and the Amazonian fruit *Euterpe oleracea*, known as açai, has shown a protective effect against oxidative stress, since it is rich in antioxidants as phenolic compounds. There is no study that evaluated the effect of açai on oxidative stress in CKD patients, then, the aim of this study was to evaluate the effects of açai supplementation on oxidative stress markers in HD patients.

Methods: This pilot study evaluated 18 HD patients assigned to either clarified and lyophilized açai juice supplementation with 20mL three times a week (1013 mg of gallic acid equivalent /100 mL), (8 patients, 55.5 ± 4.9 years, BMI 24.8± 2.5 Kg/m^2, 50.3 ± 11.3 months on dialysis) or control (no supplementation, 10 patients, 56.1 ± 3.4 years, BMI, 25.2 ± 0.7 Kg/m^2, 53.8 ± 10.1 months on dialysis) for eight weeks. Plasma levels of the oxidative stress markers malondialdehyde (MDA), nitrite, total glutathione (TG), catalase (CAT) and glutathione peroxidase (GPx) were evaluated before and after supplementation.

Results: Table 1 shows that MDA plasma levels were significantly reduced and, there was a tendency to increase the TG after açai supplementation.

Conclusions: Açai intake may be an alternative nutritional strategy to reduce oxidative stress markers in HD patients. However, more studies are needed to support this result.

Funding: Government Support - Non-U.S.

Oxidative stress profile before and after 8 weeks of supplementation with clarified açai (Euterpe oleracea) juice in HD patients.

Parameters		Açai Group (n=8)			Control Group (n=10)	
	Baseline	After 8 weeks	p-values	Baseline	After 8 weeks	p-values
MDA (pg/mL)	80.2 ± 9.5	66.1 ± 14.5	0.04	65.7 ± 18.4	76.7 ± 8.5	0.09
Nitrite (µmol/L)	37.2 ± 9.0	28 ± 4.3	0.27	32.9± 5.2	38.8 ± 4.4	0.43
TG (nmol/mL)	320.7 ± 59.2	492.7 ± 84.8	0.08	346.5 ±40.6	399.4 ±31.4	0.29
CAT (nmol/min/mL)	13 (10.7-15.1)	13.7 (12.6-16.5)	0.32	14.9 (11.4-16.2)	8.4 (7.7-12.9)	0.11
GPx (nmol/min/mL)	26.7 ± 1.7	30.5 ± 3.9	0.42	24.1 ± 1.4	27.2 ± 1.3	0.27

MDA = malondialdehyde; TG, total glutathione; CAT = catalase; GPx = glutathione peroxidase.

Serum Albumin Not Only a Marker of Nutrition: Multidisciplinary Interventions to Improve Albumin in a Peritoneal Dialysis Population in Qatar

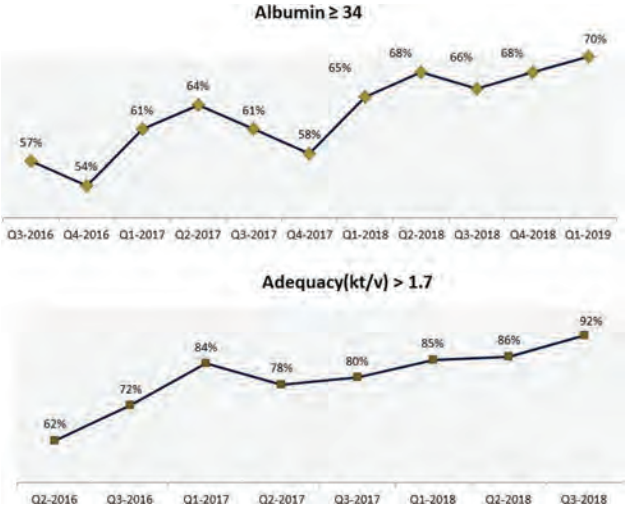
Mohamed A. Elesnawi, Fadwa M. Al-Ali, Vimala K. Lonappan, Aisha Abdulla, Sahar Aly, Linu chacko Chacko, Farrukh A. Farooqi, Tarek A. Fouda, Hanaa Ahmed. *Dialysis, Hamad Medical Corporation, Doha, Qatar.*

Background: Serum Albumin (SA) is a good predictor of adverse clinical outcomes in PD patients. At Qatar Fahad bin Jassam Kidney Center-HGH is the main provider for PD we had 180 PD patients and over the period of q 3 & q 4 2016 serum albumin (>34) fall down from the q1 & q2 2016, 65% & 64% to 57% & 54% respectively. With this hypoalbuminemia incident we decided to run a prospective improvement trial to improve the Serum Albumin level.

Methods: Multidisciplinary team was formulated that led by Nephrologist, and consist of PD Nurses, Dietician, Educator, Social worker and quality team to identify and to manage the hypoalbuminemia. We conducted a random survey to determine the food habits of patients, that taken almost routinely at home. We undertook root cause analysis for each case of hypoalbuminemia (SA<34) in the 6 months preceding the trial to identify any predisposing risk factors like inflammation, volume overload, effects of ARB medication, PD modality versus to the peritoneal membrane, loss of protein through urine etc. Inadequate dialysis may result in the retention of uremic toxins which can among other things, suppress appetite and result in malnutrition and morbidity. With the inadequate dialysis, patients lead to malnutrition, easy tiredness, prone to infections and admissions and to mortality.

Results: Serum albumin level >34 gm/L improved from 54% to 70% by end of March-2019. As the SA improves there is a good impact on the adequacy, mortality, inflammation, control of DM, technique failure and total quality of life. Dialysis adequacy improves from 62% to 92%

Conclusions: As we improve the Serum Albumin, patient's general health status and quality of life improved While correcting the PD prescriptions, adequacy had an impact, results in increase the appetite of patients



PUB277

Dietary Patterns (DP) in CKD Are Influenced by CKD Treatment Modality

Fernanda Santin,[1] Daniela Canella,[1] Camila A. Borges,[3] Bengt Lindholm,[4] Carla M. Avesani.[1,2] *[1]Rio de Janeiro State University, Rio de Janeiro, Brazil; [2]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [3]University of Sao Paulo, São Paulo, Brazil; [4]Karolinska Institutet, Stockholm, Sweden.*

Background: Dietary patterns (DP) are as important as food components such as protein and energy. We investigated DP in Brazilians with CKD and explored associations with treatment modality.

Methods: Weekly consumption of 12 food intake groups was analyzed cross-sectionally in 839 individuals (mean age 54 years, 45% males) from the 2013 Brazil National Health Survey with self-declared diagnosis of CKD undergoing non-dialysis (n=480), dialysis (n=48), and renal transplant (n=17) treatment or no CKD treatment (n=294). DP were derived by exploratory factor analysis of food intake groups. Food groups with factor loadings |0.35| were considered representative and used to define DP. Factor scores of DP were estimated for each person; a higher score indicating higher adherence to DP. Multiple linear regression models - adjusted by gender, age, education, skin color/race, rural/urban residence and geographical region - were used to evaluate associations between DP and CKD treatment.

Results: Two DP were identified: *Unhealthy DP* (positive loadings for red meat, sweet sugar beverages, alcoholic beverages and sweets and a negative loading for chicken, excessive salt and fish) and *Healthy DP* (positive loadings for raw and cooked vegetables, fruits, fresh juice fruit and milk). With untreated CKD as reference, *Unhealthy DP* was inversely associated with non-dialysis and dialysis treatment [β: –0.20 (95%CI: –0.33; –0.06) and β: –0.80 (–1.16; –0.45), respectively]; these groups had lower adherence to Unhealthy DP than the untreated CKD group. *Healthy DP* associated positively with renal transplant treatment [beta: 0.32 (95%CI: 0.03; 0.62)] suggesting that renal transplant group had better adherence to this DP than untreated CKD group.

Conclusions: Two dietary patterns were identified and were found to be associated with CKD treatment modality among Brazilians with CKD. These findings may inform future recommendations about dietary patterns in CKD patients.

PUB278

Ratio of Bioimpedance at Right Leg as a Potential Screening Tool of Cardiomegaly or Hypoalbuminemia in General Population

Haksoo Kim,[1] Ji young Lee,[2] Jai won Chang.[1] *[1]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]General health promotion center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea*.

Background: Under physiologic condition, the ratio of extracellular water(ECW) to total body water(TBW) remains tightly regulated in healthy persons. The impedance at low frequencies reflect ECW; at high frequencies, TBW. Hence, the ratio of bioimpedance at the right leg (rl-RBI=impedance at 50KHz/impedance at 500KHz, measured by Inbody 720®, Biospace Co., Seoul, South Korea) will be maintained within normal range.

Methods: To define the normal range of rl-RBI, we measured the level of rl-RBI in healthy subjects (n=20,216) without medical, surgical history and abnormal laboratory / imaging data. We classified our subjects by age, sex and body mass index (BMI, <18, 18~<20, 20~<22, 22~<24, 24~<26, 26~<28, 28~, Kg/m^2) and investigated the distribution of rl-RBI. Also, we estimated the differences of rl-RBI between healthy subjects and asymptomatic subjects with cardiomegaly (CT ratio>50%, M:F=69:152), hypoalbuminemia (serum albumin<3.5 g/dL, M:F=121:266), or both (n=14).

Results: We excluded the subjects with cardiomegaly and hypoalbuminemia simultaneously. The levels of rl-RBI in healthy female group were significantly lower than those of healthy male group at the same decades of age (p<0.001) or at classes of BMI (p<0.001). Compared with the just previous decade of age in healthy male group, rl-RBI significantly decreased with the increment of age (P<0.001). Compared with the just previous class of BMI, rl-RBI significantly increased with the increment of BMI in healthy male (~18 vs. 18~<20, p=0.022, others, p<0.001) and healthy female groups (all classes, p<0.001). In the male subjects under 50 years and female under 60, there was no difference in rl-RBI between cardiomegaly (-) and cardiomegaly (+). In the male and female under 40, rl-RBI was insignificant despite of hypoalbuminemia (+). However, when we compared rl-RBI between cardiomegaly (-) and cardiomegaly (+) according to the classes of BMI, significant differences revealed in male subgroups with BMI over 22 (p=<0.002) and in female subgroups with BMI over 18 (p=<0.007). In male and female subgroups with BMI over 18, rl-RBI of subjects with hypoalbuminemia was significantly lower at all classes of BMI (p=<0.001).

Conclusions: The novel index of hydration status, rl-RBI, could be useful to detect the subject with asymptomatic cardiomegaly or hypoalbuminemia after classification of BMI than age.

PUB279

Misreporting of Dietary Intake Among Participants in the Palm Tocotrienols in Chronic Hemodialysis (PATCH, USA) Study

Dina A. Tallman,[1] Deepinder Kaur,[1] Tilakavati Karupaiah,[2] Pramod Khosla.[1] *[1]Wayne State University, Detroit, MI; [2]Taylor's University, Petaling Jaya, Malaysia*.

Background: Misreporting of energy intake in dietary data collection includes both over and under-reporting and can result in biased inferences relating diet and health outcomes. Misreporting in the hemodialysis (HD) population is not well defined in the literature. This preliminary analysis assessed the associations of biologically implausible nutrient intakes on dialysis specific outcomes.

Methods: Dietary information was collected via 24-hr recalls taken quarterly over 15 months from 133 HD patients participating in a one year double-blind intervention (300 mg/d tocotrienols or placebo), which included KDQOL and anthropometric measures. Patients (95% African American; 63% male; age 59 ± 13 years; albumin 3.8 ± 0.3 g/dl; Kt/V 1.5 ± 0.2; vintage 65 ± 63 months) were enrolled from six clinics in Detroit, Michigan. Data was analyzed using Food Processor ESHA Research to calculate reported energy intake (rEI). The Harris-Benedict equation was used to predict energy expenditure and then multiplied by the physical activity level (PAL) 1.35 to estimate total energy expenditure (TEE). Each 24 hour recall was identified as either plausible or implausible using an rEI:TEE cutoff of < 0.76 or > 1.24. Patients were classified as implausible reporters if all the recalls collected were outside the cutoff range. Data collected at baseline was used in the analysis.

Results: Of 633 recalls analyzed, 53% indicated underreporting, 4% overreporting, and 41% acceptable reporting. Implausible reporters (23% of the cohort) had significantly higher body mass (107 ± 27 vs 85 ± 21 kg, p <0.001), BMI (35 ± 9 vs 29 ± 7 kg/m2, p <0.001), parathyroid hormone (913 ± 771 vs 615 ± 565 pg/ml, p <0.024) levels and lower HDL cholesterol values (41 ± 14 vs 51 ± 19, p <0.012). No differences were observed between implausible reporters and both KDQOL and anthropometric measurements.

Conclusions: Analyzing misreported diet data in HD patients may be useful in developing nutrition interventions targeted at improving dialysis specific outcomes. Implausible diet reports require further consideration before drawing conclusions between diet and health outcomes. (Supported by the Malaysian Palm Oil Board, Government of Malaysia)

PUB280

Echocardiographic Findings in Patients with CKD on Replacement Therapy with Hemodiafiltration

Félix A. Matías. *National Institute of Cardiology Ignacio Chavez, Ciudad de México, Mexico*.

Background: Chronic kidney disease is a risk factor for the development of cardiovascular complications, being these by itself the most frequent cause of death in this group of patients. In our institute, cardiovascular evaluation has been essential to offer comprehensive care to our patients.

Methods: Retrospective study of a transversal cohort. Patients of the hemodiafiltration unit of our institute were evaluated by 2D echocardiography during the period from 2016 to 2019. Emphasis was placed on the search for ventricular ejection fraction, ventricular mass as well as pulmonary arterial hypertension data such as systolic pressure of the pulmonary artery (PASP), maximum tricuspid regurgitation velocity (TRV).

Results: We analyzed 36 patients, 27 women and 9 men in the aforementioned period, who underwent 2D echocardiography. The average age of 37.08 years (range of 21 to 85). The average ventricular ejection fraction (LVEF) of 55.1% (range from 27 to 68.1%), the average ventricular mass index was 120.42 gr / m2. TAPSE (displacement of the tricuspid annulus) average of 21.47 mm. Right ventricular systolic function (FAC) was 45.17% on average. Regarding the pulmonary arterial hypertension data, the average PASP was 42.68 mmHg; 43 mmHg the average in men and 42.57 mmHg the average in women. The average TRV of 2.66 m / S; average in men of 2.72 and women of 2.64.

Conclusions: Defining pulmonary hypertension (PH) as a PASP ≥ 50 mmHg or TRV ≥ 2.5 m/s, 5 and 3 patients were detected respectively. Considering diagnosis of HP suspicion, a PASP between 35-49 mmHg or a TRV of 2.8-3.4 m / s, 21 and 11 patients were detected respectively. It was also shown that ventricular systolic dysfunction is a frequent problem in our study population, which leads a challenge during hemodiafiltration sessions.

Long-Term Renal Outcomes in Spontaneous Renal Artery Dissection: A Single-Center Experience

Harini Bejjanki, Gajapathiraju Chamarthi, Rajesh Mohandas. *University of Florida, Gainesville, FL*.

Background: Spontaneous renal artery dissection (SRAD), defined as dissection of the renal artery in the absence of trauma or arterial intervention, is extremely rare. Long-term clinical outcomes are not well described and hence there is no consensus on the ideal treatment and follow up of patients with SRAD. We report long term clinical outcomes in SRAD at an university hospital.

Methods: We used the integrated data repository to identify all patients with a diagnosis of 'renal artery dissection' between 1/2012-4/2019. A total of 54 patients met the criteria. Two authors independently performed chart review. Only five patients met criteria for SRAD

Results: Median age at the time of diagnosis was 64 years (Range 45-82 years). Of the five patients, 60 % (n=3) were males and 40% (n=2) were Caucasian. Majority of the patients (80%, n=4) were either current or former smokers and had a history of hypertension. None had diabetes. One patient was supsected to have fibromuscular dysplasia while no presdisposing disease or precipitating factors were identified in others. Mean admission creatinine was 0.89mg /dL (0.54- 1.2 mg/dL). Two patients developed mild acute kidney injury attributed to contrast, that resolved by discharge. Interestingly, more than half (60%, n=3) had evidence of renal infarction. Patients were initially treated

with anticoagulation (n=3), antiplatelet therapy (n=4) or a combination of the two (n=2). Only one patient required endovascular stent placement. The median follow up duration was 42 months. Follow up data showed no recurrent dissection in any of the patients. None of the patients developed chronic kidney disease (eGFR <60 ml/min), doubling of creatinine or end stage renal disease during the follow up period.

Conclusions: Our study showed that SRAD is rarely associated with AKI. Recurrences are rare and majority of our patients have preserved renal function on follow up. In patients with no underlying disease predisposing to renal artery dissection, the benign clinical course supports conservative management.

PUB282

Patient- and Societal-Level Factors Associated with Acute Decompensated Heart Failure (ADHF) Admission

Shweta Bansal,[1] Kristina M. Munoz,[3] Chakradhar Velagapudi.[2] *[1]University of Texas Health at San Antonio, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]Central Michigan University College of Medicine, Mount Pleasant, MI.*

Background: In the United States, a million patients are admitted annually with ADHF and approximately 25% of these are readmissions with 30 days. Much needs to be learnt about the root causes which lead to hospital readmission for better allocation of resources. We aim to identify factors associated with ADHF and hospital admission at the patient and societal level.

Methods: We reviewed charts of consecutive 109 congestive heart failure patients who admitted at the University Hospital, San Antonio with ADHF and were potential participants of a study evaluating usefulness of high-dose aldosterone antagonist for loop-diuretic resistant ADHF. Patient charts were examined for demographics, clinical parameters, and possible reasons leading to volume overload and hospital admission. Those reasons were categorized into following six groups: A) unable to afford medications; B) noncompliance with medications and/or dosage; C) no regular healthcare/insurance; D) noncompliance with food and/or diet restrictions; E) admission despite compliance with medications and dietary restriction; and F) couldn't determine.

Results: The mean age of study cohort was 56±13 yrs, 68% were male, 63% were Hispanics, 51% had diabetes, ejection fraction (EF) was 31±18% and pulmonary arterial systolic pressure (PASP) was 45±12mmHg. Lack of healthcare/insurance (Gr C) and medication availability (Gr A) in combine was the most common causes (34%) for ADHF admission. Admission despite compliance with medications and dietary restriction (Gr E) was the next common reason (30%), suggestive of either disease progression or inadequate dose of diuretics. No information was available regarding frequency of encounters within health care to allow adjustment in the dose of diuretics. On multiple comparison analysis, group C population with no regular health care/insurance was younger than rest of the groups. However, other demographics and co-morbidities did not differ between these groups. Moreover, the heart failure severity assessed by EF and PASP was also similar among all the groups.

Conclusions: Lack of accessibility to the health care and medications was the most common reason for ADHF admission in our study population. This group comprised of younger population. The results of our analysis provide guidance for the local health care policies to reduce ADHF admission and hospital cost.

PUB283

The Association of Dialysis Modality and Cardiovascular and Infectious Diseases: Peritoneal Dialysis vs. Hemodialysis

Masataka Banshodani, Hideki Kawanishi, Misaki Moriishi, Sadanori Shintaku, Shinichiro Tsuchiya. *Tsuchiya General Hospital, Hiroshima, Japan.*

Background: In end-stage kidney disease (ESKD) patients undergoing peritoneal dialysis (PD) or hemodialysis (HD), cardiovascular diseases (CVDs) and infectious diseases (IDs) are the most common causes of hospitalization and death. However, the association of dialysis modality and CVDs or IDs remains controversial.

Methods: This is a retrospective observational cohort study. Emergency hospitalization and mortality for CVDs and IDs excluding PD-related infections from 2010 to 2014 were evaluated between propensity score-matched PD and HD patients. Using Cox proportional hazards regression with adjustment for patient factors in December, 2009, risk factors of emergency hospitalization and mortality for CVDs and IDs were evaluated between the PD and HD patients.

Results: In matched 130 PD (75 men; mean age, 65.4 years; mean dialysis vintage, 3.3 years) and 130 HD (70 men; 66.6 years [*P*=0.4]; 3.1 years [*P*=0.5]) patients among 135 PD and 706 HD patients, emergency hospitalization rate (hospitalizations/person-years) for CVDs was significantly higher in PD group compared with HD group (0.138 versus 0.066, *P*=0.002). In log-rank test, CVD mortality was significantly higher in PD group compared with HD group (*P*<0.001). In Cox proportional hazards regression model, only PD was a significant predictor of both emergency hospitalization (HR, 2.70; CI, 1.53–4.77; *P*=0.001) and mortality (HR, 4.41; CI, 1.66–11.72; *P*=0.003) for CVDs, as well as age. Whereas, there were no associations between PD and emergency hospitalization and mortality for IDs in Cox proportional hazards regression model.

Conclusions: In this study, PD was one of the risk factors for CVDs in ESKD patients. PD patients should be maintained by strict control of body fluid balance.

PUB284

Development of an Inpatient Registry for Kidney and Hypertension-Related Disorders at Yokohama: The YCU-Kidney and Hypertension Registry

Tomohiko Kanaoka,[1] Rina Hiratsuka,[1] Koichiro Sumida,[1] Takehisa Iwano,[1] Sho Kinguchi,[1] Ryu Kobayashi,[2] Hiromichi Wakui,[1] Yoshiyuki Toya,[1] Kouichi Tamura.[2] *[1]Yokohama City University, Yokohama, Japan; [2]Yokohama City University Graduate School of Medicine, Kanazawa-Ku, Japan.*

Background: Patient registry has been increasingly important as a strategy to promote clinical research and to improve the patient care. Since Yokohama City University Hospital is one of the leading hospitals in Kanagawa Prefecture, a representative and well-known urban area in Japan, it should important to develop such a registry in the hospital. Thus, we started to construct an inpatient registry of kidney and hypertension-related disorders at Yokohama City University Hospital (YCU-Kidney and Hypertension Registry) from the beginning of 2018.

Methods: The categories of YCU-Kidney and Hypertension Registry include a series of inpatient information including the patients ID, age, sex, type of hospitalization (scheduled or emergency), purpose of hospitalization, renal biopsy (+/-), cause of kidney and hypertension-related disorders, and content of treatment including dialysis therapy (+/-). During the first year (from January to December 2018) of the YCU-Kidney and Hypertension Registry, total of 445 inpatients were registered, and all of data for information of the categories were securely stored in the electronic health record system (SS-MIX2) of Yokohama City University Hospital.

Results: We presently are able to securely access to the saved data and to analyze the updated tends regarding the detailed information of inpatients who were admitted to the YCU hospital due to kidney and hypertension-related disorders. We will present that more than half of the inpatients were derived from emergency admission at Yokohama City University Hospital which is located in an urban area in Japan, and will also present the detailed information about these inpatients in the YCU-Kidney and Hypertension Registry.

Conclusions: We intend to continue and expand the information recorded in the YCU-Kidney and Hypertension Registry, to improve the outcome measures including patient report type of outcome such as QOL and also to perform file case studies sorted out by diseases.

PUB285

Serum Hepcidin and Cardiovascular Events in ESRD

Kristin Danielson Pistis, Olof Heimburger, Peter Stenvinkel, Abdul Rashid T. Qureshi, Bengt Lindholm, Peter F. Barany. *Karolinska Institutet, Stockholm, Sweden.*

Background: Hepcidin, the central regulator of iron metabolism, has recently been suggested to play a role in the development of cardiovascular disease in patients with end-stage renal disease. We investigated whether hepcidin increases the risk for cardiovascular mortality in 234 patients with end-stage renal disease (ESRD).

Methods: 234 study subjects with ESRD stage CKD5D-ND were included in the cohort. Median age was 55 (30-68) years, 62 % were male, 35 % had CVD as baseline, 29 % had diabetes and median estimated glomerular filtration rate was 6.1(3.8-10.3). The following parameters were assessed: hepcidin (the sum of all isoforms), high sensitive CRP (hs CRP), presence of cardiovascular disease (CVD), and Framingham's CVD risk score. Patients were stratified into four groups based on their median level of hepcidin and median level of CRP (group 0: low hs CRP + low hepcidin; group 1: low hs CRP + high hepcidin; group 2: high hs CRP + low hepcidin; group 3: high hs CRP + high hepcidin).

Results: During a median follow-up of 42.5 (7.8-60) months, 57 patients died. In competing risk analysis, in crude analysis group 2 (sHR 2.07 95% CI 1.02-4.21) associated with all-cause mortality. When we adjusted for other confounders it lost its statistical significance.

Conclusions: The patients with high hs CRP + low hepcidin were associated with increased all-cause mortality in CKD patients in crude analysis.

Hyperaldosteronism and Fibromuscular Dysplasia: Two Potential Causes of Secondary Hypertension and Hypokalemia in One Patient

Wahid N. Syed,[3] Tiana Jespersen,[2] Brian Y. Young.[1] *[1]UC Davis Medical Center, Sacramento, CA; [2]University of California Davis, Sacramento, CA; [3]CHMG, Fresno, CA.*

Introduction: Hypertension (HTN) is common, affecting nearly 30% of U.S. adults, with 5-10% of these cases due to secondary HTN. Potential causes of secondary HTN include renal artery stenosis, from either atherosclerotic disease or fibromuscular dysplasia (FMD), and hyperaldosteronism. Here, we present a hypertensive, hypokalemic patient with both an aldosteronoma and FMD.

Case Description: A 59-year-old woman presented with an over 10 year history of HTN necessitating metoprolol, losartan and spironolactone, and hypokalemia requiring

potassium supplements. Her cardiologist initially pursued imaging with concurrent CT abdomen showing a 2.1 cm right adrenal nodule and renal duplex ultrasound showing 60% stenosis and beading of the right main renal artery consistent with FMD. Carotid artery duplex showed bilateral 50-70% stenosis from FMD. Nephrology consultation was asked to help diagnose and manage. Spironolactone was discontinued for 4 weeks and serum aldosterone (30 ng/dl) and plasma renin activity (< 0.1 ng/ml/hr) were drawn, with the elevated ratio highly suspicious of primary hyperaldosteronism rather than FMD as the cause of HTN. Salt challenge was deferred due to profound, persistent hypokalemia despite amiloride and potassium repletion. Adrenal vein sampling showed lateralization to the right adrenal adenoma. The patient underwent right adrenalectomy and her blood pressure and potassium normalized shortly after. She was off all medications within 2 weeks and remains stable 9 months post operation. She has not required any intervention for FMD and is undergoing conservative monitoring with her vascular surgeon.

Discussion: History and physical with attention to specific clinical clues remains the mainstay approach to diagnosing secondary HTN. HTN and hypokalemia can point to either a primary (e.g. adrenal adenoma or hyperplasia) or secondary (e.g. renovascular) hyper-aldosterone state. Initial workup should begin with biochemical diagnostics to direct imaging studies rather than vice versa. Given its physiologic relevance, beginning with interpretation of the aldosterone to renin ratio better directs and expedites a therapeutic plan, including in patients with a concomitant adrenal nodule and renovascular disease.

PUB287

Eosinophilic Granulomatosis with Polyangiitis Cardiac Disease

Allyson C. Egan,[1] Teresa Bada Bosch,[2] David R. Jayne.[3] *[1]Renal Medicine, University of Cambridge, Cambridge, United Kingdom; [2]Hospital Universitario 12 de Octubre, Madrid, Spain; [3]University of Cambridge, Cambridge, United Kingdom.*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA), is characterized by disseminated necrotising small vessel vasculitis with extravascular granulomas, amongst patients with the prodrome of asthma and tissue eosinophilia.[1,2] The French Vasculitis Study Group five-factor prognostic score (FFS) associates cardiac disease with a poorer prognostic group.[1,2]Histological findings in 7/9 cardiac transplant recipients, had evidence of EGPA in explanted native hearts despite ongoing immunosuppression.[2]

Methods: This retrospective, descriptive study analysed 18 patients with EGPA according to the ACR criteria or Chapel Hill Consensus 2012 definition. Identification of cardiac disease was based upon abnormalities in clinical condition, cardiac enzymes, ECG, ECHO and in some cases cardiac MRI. The aim of our study was to analyse the outcomes of patients with cardiac disease.

Results: All 18 EGPA patients were asthmatic and 15 were ANCA negative. At the time of mean follow-up 61.7 ±33.8 months, percentage survival in the cohort was 100%. Two patients had evidence of thrombo-embolic disease. Pulmonary and ENT involvement were common with cardiac disease, unlike renal disease. Table 1.

Conclusions: In accordance with literature, cardiac disease was found predominantly in ANCA negative patients. Therapy with conventional immunosuppression and biologic therapies had a favourable outcome. Early diagnosis of cardiac involvement is essential in guiding management decisions and prognosis. 1. Modification of the Effects of Intensive Systolic Blood Pressure Control on Risk of AKI by Baseline Body Mass Index

Adhish Agarwal,[1] Guo Wei,[1] Robert E. Boucher,[2] Tom Greene,[1] Srinivasan Beddhu.[2] *[1]University of Utah, Salt Lake City, UT; [2]University of Utah School of Medicine, Salt Lake City, UT.*

Background: The results of the Systolic Blood Pressure Intervention Trial (SPRINT) suggest increased risk of acute kidney injury (AKI) with intensive (INT) systolic blood pressure (SBP) control. It is unknown whether this effect persists across the body weight spectrum. We evaluated whether baseline body mass index (BMI) modified the effects of SPRINT intervention on risk of AKI.

Methods: SPRINT randomized 9361 high-risk non-diabetic participants with a SBP of 130 mm Hg or higher to either INT SBP target of < 120 mm Hg or standard SBP target of < 140 mm Hg. We used SPRINT BioLINCC data for our analysis. After excluding participants with a baseline BMI of <18.5 or > 50 Kg/m^2 (N= 9191), we evaluated the effects of INT SBP control on risk of AKI during the mean 4.1 years follow-up period in four strata (defined by baseline BMI of < 25, 25 to <30, 30 to < 35, and ≥ 35 Kg/m^2) and across baseline BMI as a linear variable using Cox proportional models. SPRINT defined 'AKI' as episodes of acute kidney injury or acute renal failure during the study period noted on admission or during a hospitalization reported in the hospital discharge summary as a primary or main secondary diagnosis.

Results: The mean age was 67.9 ± 9.4 years, 35.3 % were female, and mean baseline BMI was 29.8 ± 5.4 Kg/m^2. There were 1682, 3599, 2413, and 1497 participants in the four baseline BMI strata. Increased risk of AKI with INT SBP control persisted across the BMI spectrum as shown in the Figure. The effect of INT SBP control on AKI did not differ significantly between different baseline BMI levels (*P*-linear/categorical interaction 0.37/0.93).

Conclusions: INT SBP control increases risk of AKI across the BMI spectrum in high-risk patients without diabetes.

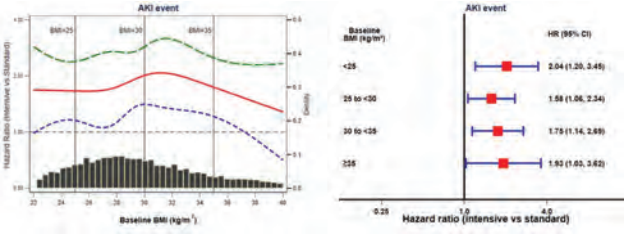

Figure: Spline Curve and Forest Plot (with Hazard Ratios) for risk of AKI with INT SBP control across baseline BMI spectrum in SPRINT

PUB289

Impact of Ambulatory Blood Pressure Monitoring (ABPM) on Blood Pressure Control and Medication Load in the Outpatient Clinic

Tarig Elraiyah, Neil K. Agarwal, Siddique Akbar, Sandeep Aggarwal, Ziauddin Ahmed. *Drexel University College of Medicine, Philadelphia, PA.*

Background: Utility of 24-hour ambulatory blood pressure monitoring (ABPM) is used for assessment of complex hypertension is established. Whether or not ABPM leads to changes of blood pressure, control, and medication load is unknown.

Methods: We retrospectively reviewed 35 charts of patients who received ABPM from a single outpatient nephrology office. Of the 35, 9 charts were excluded due to lack of follow up data. We collected demographic information: Age, Gender, Ethnicity, Diabetic status, CKD stage, Indication for ABPM. ABPM data Including: Average daytime pressures, Average nighttime pressures, total average pressures, nocturnal dipping, hypertensive load. Blood pressure readings for the 3 office visits prior to and after ABPM were recorded. Anti-hypertensive regiments prior to and after ABPM were recorded. We calculated pill burden by taking patients dose and dividing it by the maximum dose of the respective medication.

Results: Of the 26 patients (20 Female, 6 Male), 18 were African American, 5 were diabetic, 12 had CKD stage 3 or greater, and mean age was 55.7±17.5 years. The mean pre-ABPM systolic blood pressure (pre-SBP) was 139.2±14.6 mmHg, mean post-ABPM systolic blood pressure (post-SBP) was 134.8±21.1 mmHg. The mean systolic difference was 4.3±5.0mmHg (p=0.3931). The mean pre-ABPM diastolic blood pressure (pre-DBP) was 83.7±11.5 mmHg, mean post-ABPM diastolic blood pressure (post-DBP) was 80.3±12.9 mmHg. The mean diastolic difference was 3.4±3.4mmHg (p=0.3209). When comparing pill burden, the mean pill burden pre-ABPM was 1.04±0.87 pills, mean post-ABPM pill burden was 1.03±0.89 pills, the mean difference 0.01±0.24 pills (p=0.9623).

Conclusions: When comparing ABPM data, we found that there was no significant difference in blood pressure or pill burden after ABPM. Further studies are needed to evaluate the impact of ABPM on blood pressure and patient outcomes.

PUB290

Can Cocaine Use Be Diagnosed in ESRD Patients Using Hemodialysis Effluent?

Sourab Dhungel,[1] Sheetal Koul,[1] Wayne A. Satz,[2] Avrum Gillespie.[1] *[1]Temple University Hospital, Mickleton, NJ; [2]Temple University, Phila, PA.*

Background: Cocaine is a common cause of drug-related emergency department visits. Cocaine use can be difficult to diagnose in End Stage Renal Disease (ESRD) patients as denial is common and patients can't produce a urine specimen. Benzoylecgonine, cocaine's major metabolite, is a small water-soluble molecule and is detectable in the hemodialysis (HD) effluent using a reagent assay for urine. We utilize hemodialysis effluent as an alternate specimen to urine and blood in ESRD patients and report our results of testing hemodialysis effluent in patients with suspected cocaine use

Methods: A retrospective chart review was conducted between 9/1/16 and 2/28/19 in an urban Philadelphia hospital. We identified hospital admissions that contained both an ICD diagnosis code of ESRD and an order for Urine Drug Screen. For each admission we collected age, race/ethnicity, sex, admission diagnoses, and whether the specimen was urine or HD effluent. Data were analyzed using independent t-test, Fisher's exact test, and chi-square analyses.

Results: We identified 1103 ESRD patients with 3306 admissions for whom cocaine use was suspected. Only 264 (24%) had a drug screen submitted for analysis. Of these 264 patients, the average age was 55 years old (± 12), 39% were female, 73% black, 17% Hispanic, 5% white, and 5% other. Eighty-two patients (31%) had effluent sent. Twenty-four of these patients had at least one admission with a positive cocaine test. For 14 patients (58%) their HD effluent was always positive, 4 (17%) were positive between 75%-50% of the time, and 6 (25%) were never positive. Hyperkalemia and volume overload/pulmonary edema were common admitting diagnoses in both groups; however, chest pain was more common in the cocaine positive HD effluent group and altered mental status in the cocaine negative HD effluent group. There were no racial/ethnic differences in HD effluent cocaine positivity. More females were in the cocaine positive effluent group than males (61% vs 39%, p = 0.01).

Conclusions: Our data demonstrates the difficulty in collecting urine drug specimens in ESRD patients. Utilizing hemodialysis effluent for testing ESRD patients suspected of cocaine use appears to be a promising tool. Future studies are necessary to validate this simple test which could be used to find the prevalence of cocaine use related morbidity among ESRD patients and examine differences in cocaine use.

PUB291

Presentation of 17 Cases of Monoclonal Gammopathy with Renal Involvement: To Unify a Diagnosis in Retrospect

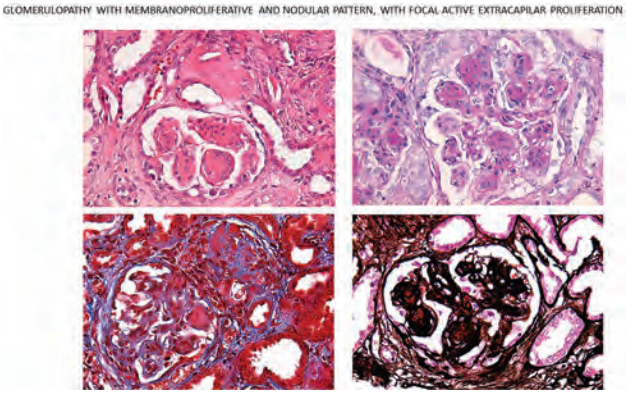
Félix A. Matías. *National Institute of Cardiology Ignacio Chavez, Ciudad de México, Mexico.*

Background: Monoclonal gammopathies consist of a heterogeneous group of disorders characterized by clonal proliferation of immunoglobulins produced by clones of plasma cells or B lymphocytes. Renal diseases associated with monoclonal gammopathy are different in their pathogenesis, kidney biopsy findings and presentation clinic.

Methods: In a period of 10 years, from **June 2008 to February 2018**, 17 cases with a histopathological diagnosis of renal involvement due to monoclonal gammopathy were identified in a single institution.

Results: The average age of presentation was 57.2 years. The histopathological findings of renal biopsy were 7 cases of cast nephropathy (myeloma kidney) of which 6 were positive lambda and 1 positive kappa, 1 case of glomerulopathy with nodular and nodular pattern with focal active extracapillary proliferation. In cases of amyloidosis, 6 cases presented with a glomerular, interstitial and vascular pattern, 1 case with involvement restricted to the vascular compartment and 2 with glomerular and vascular involvement. 5 patients required hemodialysis at the onset of the disease; 37.5% of cases of multiple myeloma. Of the patients diagnosed with amyloidosis 2 of them presented as nephrotic syndrome, 3 patients with predominance of heart failure, 1 patient with the combination Nephrotic syndrome plus heart failure, 1 patient presented with peripheral neuropathy and 2 patients with dysautonomia. During follow-up, 14 patients died or lost track of the institute; 1 patient is in remission of amyloidosis, 1 patient is in a bone marrow transplant protocol and one patient is on maintenance hemodialysis twice a week.

Conclusions: In the cardiology institute, renal and cardiac involvement are more frequently recognized as a form of initial presentation of monoclonal gammopathies, however, they are often underdiagnosed. The kidney is the affected organ where the disease is diagnosed. It is necessary the early recognition of these pathologies in our population to improve the prognosis of our patients.



PUB292

Obstructive Uropathy with Uremia due to Advanced Cervical-Uterine Cancer

Héctor R. Ibarra-Sifuentes,[1] Raymundo Vera,[2] Jose L. Avila Velazquez,[3] Michelle Morcos sandino,[1] Giovanna Y. Arteaga Muller,[2] Mara C. Olivo.[2] *[1]Universidad Autonoma de Nuevo Leon, Monterrey, Mexico; [2]Hospital Universitario, Monterrey, Mexico; [3]University Hospital, Monterrey, Mexico.*

Background: Cervical-uterine cancer (CUC) is a worldwide public health problem. Advanced CUC affects nearby regional structures causing obstruction. Rarely, obstructive uropathy can cause acute kidney injury (AKI), which leads to uremic syndrome with urgent treatment such as ureteral stent placement, nephrostomies and hemodialysis, as saving life modalities are required.

Methods: A retrospectively analysis of the AKI patients characteristics due to obstructive uropathy caused by advanced CUC presenting to the emergency department of Hospital Universitario, located in Monterrey, Mexico, during May 2014 to January 2019.

Results: 28 patients were analyzed with 45 ±11 as mean age (Table1). The main comorbidities were Diabetes Mellitus 5 (18%), and Hypertension 5 (18%). The mean evolution period was 22 ±20 years. 60% had metastatic CUC. The most common presenting symptom was general malaise and weight loss in 57 and 46%, respectively. The mean Blood Urea Nitrogen and Creatinine was 87±60 mg/dL and 6.9 ±6.5 mg/dL, respectively. 46% of the patients underwent JJ stent placement, and 39% required nephrostomies. The mean hospitalization period was 6.64± 7.64days. 10 patients (36%) died, with a mean survival of 6 ±6 months, no difference in mortality between treatments arms (long-rank test: 0.950).

Conclusions: Advanced CUC and obstructive uropathy presenting with AKI is a common public health problem on developing countries. They have a long period of evolution, the main symptoms are general malaise and weight loss and unfortunately had a short mean survival of 6 months. Integral clinical assessment is a crucial priority.

Severe Hypercalcemia: New Etiologies and Nephrological Management in a Reference Hospital

Jose L. Lerma,[1] Miguel Sánchez-Jáuregui Castillo,[2] Elena Ruíz,[1] Jesús Martín-Centellas,[1] Manuel Heras Benito.[1] Nephrology Service *[1]Nephrology, Hospital University, Salamanca, Spain; [2]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain.*

Background: Hypercalcemia is a metabolic disorder that can cause malignant ventricular arrhythmias, intestinal motility problems, decreased level of consciousness, neuromuscular irritation and, in very advanced situations, death. Although in its mild forms it is very frequent and causes mild symptoms, its severe forms are expression of serious pathologies, and can be the initial analytical data or the consequence of aggressive therapies or vitamin poisonings or prescription errors. It is interesting to evaluate the etiologies, and the Nephrologist therapies of a Reference University Hospital since it may be useful for future approaches Aims: 1. Establishing etiology of severe hypercacemia 2. Evaluating specific Nephrological/dialytic treatment and follow up.

Methods: Salamanca University Hospital Nephrology Service was consulted about severe hypercalcemia which was collected prospectively during a 36-month interval. A total of 31 patients (12 men, 19 women) presented Ca> 11.5, with a maximum of 19.5. Therapy and results were followed up. Statistical Analysis:SPSS 15.0

Results: Tumoral: 19/31(61.3%) were related to neoplasms with direct bone involvement (multiple myeloma:MM) or metastasis (Ca Mama, Lymphomas, Ca prostate). In some very frequent cancers, such as breast cancer, it was the first manifestation that led to hospital admission, diagnosis and subsequent treatment. Most frequent causes were *Hematological Neoplasms,* especially MM(first rank with a total of 5 cases) followed by Non-Hodgkin Lymphomas in 3 cases, and implied a poor prognosis as expression of highly advanced metatastatic bone disease. Mortality: 22%. Hemodialysis was done in 4 patients (12.9%). Biphosphonates :100% **Non tumoral** 12/31:(38.7%) *Calcifediol* Intoxication (n:5; 16,1%), *iatrogenic* (n:4) and *miscelaneous* (n:3). Hemodialysis :0. Biphosphonates :100% Mortality:0% Acute Renal Failure: 15%

Conclusions: 1)Severe Hypercalcemia is a serious increasing metabolic disorder that needs Dialytic Management in some cases. 2)Main etiology is neoplasms (61.3%), of hematological origin (38.7%), and solid tumor (bone metastasis). 3)Vitamin D intoxication (calcifediol) was an important understimated reversible cause (16.1%), especially in patients with previous CKD or liver disfunction. 4) Severe Hypercalcemia Management requires a multidisciplinar approach (Nephro-oncology)

PUB294

Lung Cancer and Renal Failure

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), Giovanni Bosco Hospital and University of Turin, Italy, Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Turin, Italy*.

Background: Since there are few epidemiological studies in the literature regarding cancer patients (pts) with renal failure (RF), studying the possible renal co-morbidities is especially important in order to improve the management of these pts. **Aim of work:** to evaluate the relationship between RF and pt survival in subjects with lung cancer.

Methods: We analyzed the data of pts receiving a diagnosis of lung cancer between 1/1/2015 and 30/06/2018 who underwent therapy and were followed-up for at least 3 months. The prevalence of RF at diagnosis or the new onset during therapy was examined by comparing different formulas for calculating the glomerular filtration rate (GFR) and matching any possible correlation between them.

Results: We analyzed 277 pts. GFR<90 ml/min was detected in about 60% of cancer pts at diagnosis, while in the middle-advanced stage, the prevalence of RF was much lower (10%). We obtained significant differences in the GFR depending on the various formulations that were used. The Cockroft-Gault formula tends to overestimate the number of pts with GFR ≤60ml/min in a statistically significant manner as compared to CKD-EPI and MDRD (p=0.001). The new onset was significantly more frequent in pts undergoing first line treatment with cisplatin as compared to carboplatin (p<0.001). The data also showed a worsening of RF even in some pts who were treated with new therapeutic protocols based on the use of so-called target therapies. The available literature data concerning these drugs is based on case reports or small case-series. The average survival of our pts series was 18.2 months. Pts whose renal function worsened during or after treatment showed significantly reduced survival (p=0.02). No difference was observed between pts with RF at diagnosis and pts with normal renal function. These results can be explained by the systematic proscription of nephrotoxic drugs in patients at risk, and further reinforce the indication for personalized therapies.

Conclusions: RF is frequent in pts with lung cancer and shows consistent prevalence during follow-up. The conventional measures of GFR do not provide univocal data, thus emphasizing the need to use highly performing formulations. Accurate screening for risk factors and devising customized protocols can drastically reduce the impact of these factors on the survival of patients.

PUB295

Renal Parameters at Diagnosis of Multiple Myeloma in a Predominant Minority Population

Vatsala Katiyar, Alfred T. Solomon, Rayli Pichardo, Ishaan Vohra, Albert M. Osei. *John H. Stroger Jr. Hospital of Cook County, Flossmoor, IL*.

Background: Although multiple myeloma may occur in all races, the incidence tends to be higher in Blacks of African descent. This abstract describes the broad range of renal abnormalities at the time of diagnosis in a mostly African American population.

Methods: Electronic medical records of all patients who had confirmed diagnosis of multiple myeloma from 2010 to 2018 in a large inner-city public teaching hospital were reviewed. Inclusion criterion was initial diagnosis at the institution and prior to initiation of chemotherapy. The international staging system (ISS) was determined and the range of values for the institution was used to define abnormalities.

Results: 186 subjects met the criteria for the analysis. Percentage of African Americans, Hispanics and Caucasians was 57, 16, and 18 respectively. Males: Females-56% vs 44% with non-African Americans having more males. Serum creatinine was ≥ 1.5mg/dl in 28% and there was no gender or racial differences. Renal impairment was independent of diabetes mellitus or hypertension but 76% occurred in those with ISS III (P<001). Hypercalcemia (25% vs 7%) and quantified proteinuria of >500mg/24 hours (55% vs 14%) were statistically significant in those with and without renal impairment at presentation. Hyponatremia of < 135mEd/L was present in 35% of all subjects but in 43% in those with ISS III. Low Anion gap <5 was present in 27% of subjects but contrary to previous reports there was no differences among the various immunoglobulin subtypes.

Conclusions: In a predominantly African American population, abnormal renal parameters abound at presentation of multiple myeloma but they seem to be determined more by the disease nature rather than demographics or preexisting co-morbidities

PUB296

Contrast Medium Increases DNA Radiation Damage and Delays DNA Damage Repair in Kidney

Shu Fujino, Shigehiro Doi, Toshiki Doi, Ayumu Nakashima, Takao Masaki. *Hiroshima University Hospital, Hiroshima-Shi, Japan*.

Background: Contrast-induced nephropathy (CIN) is a well-recognized cause of acute kidney injury in the clinical setting; however, no effective treatment for CIN has yet been established. Furthermore, contrast medium (CM) has also recently been shown to contribute to radiation-induced DNA damage in lymphocytes. In this study, we investigated the effect of CM on DNA damage and DNA repair in irradiated kidneys and kidney-derived cells.

Methods: For the *in vivo* study, male mice (8 weeks old) underwent unilateral nephrectomy. One week later, the renal artery was clamped for 30 min and iohexol (Ihx) was injected via the right retrobulbar sinus (CIN mice). The mice were then irradiated with 10 Gy of radiation (CIN-IR mice/IR mice) and kidneys were harvested 24 h after radiation. DNA damage markers (γH2AX, pATM, 53BP1, RAD51), the oxidative stress marker 8-hydroxy-2′-deoxyguanosine, and the macrophage marker F4/80 were examined by immunohistochemistry and western blotting. For the *in vitro* study, expression levels of DNA damage markers (γH2AX, pATM, 53BP1, RAD51) were examined in human renal tubular epithelium (HK-2) cells treated with iohexol (Ihx-HK2),1 Gy of radiation (IR-HK2), or both (Ihx-IR-HK2), using immunofluorescence.

Results: γH2AX, pATM, 53BP1, and RAD51 expression levels were significantly increased in CIN-IR mice compared with control, IR, and CIN mice. Expression of 8-hydroxy-2′-deoxyguanosine and F4/80 were also increased in CIN-IR mice. The numbers of RAD51 foci in HK-2 cells were similar in all groups, whereas γH2AX foci were significantly increased in Ihx-IR-HK2 compared with Ihx-HK2 and IR-HK2 at 1 h after radiation. γH2AX and 53BP1 foci were also increased in Ihx-IR-HK2 24 h after radiation.

Conclusions: CM increases DNA radiation damage and delays DNA damage repair, as well as increasing levels of oxidative stress and inflammation.

PUB297

Targeting Nuclear Receptor Interacting Protein 2 Blocks Podocyte Injury and Proteinuria

Qing Hou, Xiuwen Zhai, Zhao-hong Chen, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China*.

Background: Podocytopathy results in proteinuria and frequently progresses to chronic kidney disease; here we reported that targeted knockout of Nuclear Receptor Interacting Protein 2 (NRIP2) completely blocked podocyte injury and proteinuria.

Methods: NRIP2 was identified as the most centralized hub gene, arising from glomerular transcriptional profiles of renal biopsies from patients with podocytopathy.

Results: NRIP2 was upregulated and expressed, but not restricted, in glomerular podocytes. Genetic knockout of Nrip2 completely blocked podocyte injury and loss, and proteinuria in Adriamycin and Puromycin Amino Nucleoside nephropathy mice. Podocyte-specific induction of NRIP2 resulted in podocyte injury and glomerulosclerosis in zebrafish. Mechanistically, NRIP2 was required for β-catenin signaling activation via retaining nuclear β-catenin.

Conclusions: This work clearly identifies NRIP2 as a potential therapeutic target and a critical retention factor of nuclear β-catenin in podocytopathy.

PUB298

Biphasic MIF and SDF1 Expression Promotes CD44-Mediated Glomerular Parietal Epithelial Cell Migration in Focal Segmental Glomerulosclerosis

Naoko Ito, Kazuo Sakamoto, Michio Nagata. *University of Tsukuba, Tsukuba, Japan*.

Background: Focal segmental glomerulosclerosis (FSGS) is commenced with local synechiae by glomerular parietal epithelial cell (PEC) activation, including its migration and adhesion to glomerular tuft with podocyte detachment. However, the molecular signaling that mediates podocyte injury and PEC activation remains unknown. In FSGS, *de novo* CD44 expression in PEC has been known as a marker of PEC activation, and it may be involved in progression of segmental sclerosis. In the present study, we focused on the roles of CD44 and two chemokines, migration inhibitory factor (MIF) and stromal cell-derived factor 1 (SDF1), during podocyte injury-driven PEC activation.

Methods: NEP25/LMB2 mice, the toxin-induced podocyte injury model, were used (n=5). The glomerular expression of MIF, SDF1, CXCR4 and CD44 was assessed by immunostaining sequentially on day 0, 4, 8 and 12. Using immortalized mouse PEC (mPEC), *in vitro* study was conducted by real-time PCR, western blotting, and migration assay under MIF and SDF1 stimulation.

Results: In the early stage of podocyte injury (on day 4), podocytes expressed MIF and SDF1. As podocytes were detached (on day 8 and 12), PECs expressed CD44 with MIF, SDF1 and CXCR4. *In vitro*, MIF and SDF1 individually induced CD44 and CXCR4 on mPECs and promoted their migration which was inhibited by CD44 knockdown.

Conclusions: Biphasic expression of MIF and SDF1 in podocytes and PECs, and roles of these chemokines in PEC activation *in vitro* suggested that CD44-mediated PEC migration might be initiated by MIF and SDF1 and sustained through their paracrine and autocrine effect.

PUB299

Post-Translational Regulation of Endothelial-Derived CCN Proteins in Response to Uremic Serum from Haemodialysis Patients

Mark E. Dockrell. *South West Thames Institute for Renal Research, Surrey, United Kingdom.*

Background: Non-traditional risk factors play an important role in cardiovascular disease (CVD) observed in renal patients. Vascular smooth muscle cells (VSMC) dedifferentiation is a key step in neointimal hyperplasia. Endothelial cell derived CCN2/CTGF and CCN3/Nov could play opposing roles in regulating VSMC dedifferentiation and migration modulating neointimal hyperplasia. We aim to investigate the expression and alteration in the CCN protein axis in human endothelial cells in response to uremic serum donated by haemodialysis patients.

Methods: Blood samples were obtained from consented haemodialysis patients (n=10) and healthy control subjects (n=6). Serum was prepared and stored at -80°C. Human Umbilical Vascular Endothelial Cells (HUVEC) from a mixed donor pool were cultured in supplemented growth medium on collagen IV. Cells were incubated in serum-free(sf) media, sf media containing 10% v/v patient serum (PS) and sf media with 10% v/v control subject serum (CS). After 24 h, media was removed, cells lysed and RNA extracted. RNA was subject to reverse transcriptase followed by real time QPCR. Relative gene expression was calculated by ΔΔCt analysis. Following 72 h incubation of HUVEC in the conditions above, media was removed, centrifuged and stored. Cells were lysed and lysates prepared for PAGE Western Blotting.

Results: There was no significant difference in TGFβ1 or CCN2/CTGF RNA expression. Although serum significantly reduced CCN3 RNAthere was no difference between PS or CS treated cells. There was no measurable difference in LDH between cultures with any of the protocols. Although there was some variation in the protein expression from cells exposed to sera from different patients, there was still an overall significant increase of between 35 and 70% in the intact 36/38Kda CTGF from cells treated with PS compared to both CS and sf ($p<0.05$). PS treatment induced significantly less CCN3 protein than CS treatment (40-65 % reduction, $p<0.05$). The endothelial cell phenotypic marker VE cadherin was significantly reduced by PS treatment ($p<0.05$).

Conclusions: From our data, we conclude that serum from haemodialysis patients induces endothelial cells to alter the CCN2/CCN3 axis substantially in favour of VSMC differentiation and migration potentially driving vascular calcification in these patients.

The Spectrum of Clinical and Histopathological Diagnosis in Patients with Rapidly Progressive Renal Failure: An Indian Experience from a Tertiary Center

Neha Jain,[1,2] Anurag Gupta,[3] Devinder S. Rana,[3] Anil Bhalla,[3] Ashwani Gupta,[3] Manish Malik,[4] Vinant Bhargava,[3] Niraj Patel,[4] Sabina Yusuf.[3] *[1]UCONN Health, Hartford, CT; [2]Nephrology, Sir Ganga Ram Hospital and GRIPMER, New Delhi, India; [3]Sir Ganga Ram Hospital, New Delhi, India; [4]Sir Ganga Ram Hospital and GRIPMER, New Delhi, India.*

Background: Rapidly progressive renal failure (RPRF) is defined as progressive renal impairment over a period of a few weeks. The underlying etiology may be a primary renal disease or a systemic disorder. The data on RPRF from the Indian subcontinent is sparse. We aim to study the clinical profile and the histopathological findings on renal biopsy of patients presenting with RPRF at our center.

Methods: Consecutive patients presenting with renal failure of recent onset and rapidly progressing over the duration of weeks to less than 3 months with normal sized kidneys on ultrasound were included after informed consent. Kidney biopsy was performed under real-time USG guidance using the Bard® Max-Core® Disposable Core Biopsy instrument with all aseptic precautions. Two cores were obtained and samples sent for light and immunofluorescence microscopy in all cases. Clinical details including symptoms, signs, past history and investigations were recorded along with kidney biopsy findings.

Results: 100 patients who fulfilled the criteria were included. 65%(65) were males. The mean age of the study population was 44 years with 41%patients above 50 years of age. Most common presenting complaints were oliguria (84%) followed by edema (79%cases). Gross hematuria, fever, and joint pains were present in 20%, 22%, and 12% cases respectively. On kidney biopsy, rapidly progressive crescentic glomerulonephritis (RPGN) was the most common cause of RPRF accounting for (32)32% cases, with pauci-immune being the most frequent of all (14)14%. Acute interstitial nephritis was seen in (19)19% of patients, (5) 5% were found to have myeloma/amyloidosis and thrombotic microangiopathy was found in (3) 3% of patients. Other causes of RPRF included chronic sclerosing glomerulonephritis, focal segmental glomerulosclerosis, diabetic nephropathy, IgA nephropathy without crescents. Pauci-immune crescentic glomerulonephritis was seen as the most common cause of RPRF in the diabetic population.

Conclusions: The most common histopathological diagnosis in patients presenting with RPRF was rapidly progressive crescentic glomerulonephritis. The most common cause of rapidly progressive glomerulonephritis was pauci-immune crescentic glomerulonephritis, even amongst the diabetic sub-population.

PUB301

A Case Report of Podocytic Infolding Glomerulopathy with Bladder Tumor

Xianrui Dou, Jianyi Pan, Jiayi Chen, Jinzhong Chen. *Shunde Hospital of Southern Medical University, Foshan, China.*

Introduction: Podocyte infolding glomerulopathy (PIG) is a recently described condition with pathologic entity characterized by diffuse podocyte infolding into the glomerular basement membrane (GBM) associated with ultra-structurally demonstrable microspherular aggregates. The clinical features, significance, and pathogenesis of this condition are still not well delineated because only a few cases have been documented to date, almost all from Japan. Here we reported a case of PIG associated with bladder tumor in a Chinese woman.

Case Description: A 76-year-old Chinese woman was admitted to our hospital with gross hematuria,edema, massive proteinuria, hypoalbuminemia, hyperlipidemia, and kidney dysfunction. Laboratory test of urine exfoliative cytology suggested poorly differentiated cancer cells, indicating a diagnosis of bladder tumor. Renal biopsy was performed to determine the cause of proteinuria and kidney dysfunction. Histological examination of the biopsy specimen showed mild segmental mesangial hyperplasia in the glomeruli. Immunofluorescence staining did not show glomerular deposition of immunoglobulins, light chains, or complement components. Electron microscopy showed slightly and irregularly thickened glomerular basement membrane (GBM) with irregular membranous structures in the GBM, suggesting podocytic infolding glomerulopathy. There were no electron-dense deposits in the GBM, while various findings indicated podocyte injury.

Discussion: PIG is a rare morphological alteration of the glomerulus. It is appeared to have a plasma membrane structure in the glomerular basement membrane (GBM). By now, most case reports on PIG were from Japan. In this case, the patient displayed large amount of proteinuria, which was characterized by nephrotic syndrome, with repeated gross hematuria. However, gross hematuria disappeared after resection of bladder tumor, but proteinuria was not significantly relieved within 3 months of follow-up. The patient also showed hypertension and renal insufficiency, which agrees with previous reports. This patient was the first report of PIG with bladder epithelial cancer in the world. The pathogenesis of the disease remains unclear, and the therapeutic strategy on this disease needs to be further studied in the future.

PUB302

Analysis of a Histopathological Pattern of Renal Biopsy Specimens in Sri Lanka: A Single-Centre Study

Duminda B. Basnayake,[1] Abdul W. Wazil,[2] Nishantha Nanayakkara,[2] Mohamed Shafras,[2] Pradeep Priyadarshana,[2] Buddhisha S. Mahanama.[1] *[1]Nephrology and Renal Transplant, Teaching Hospital Kandy, Kandy, Sri Lanka; [2]Teaching Hospital, Kandy, Kandy, Sri Lanka.*

Background: Histopathological analysis of renal parenchyma is the gold standard diagnostic tool in renal medicine. We report our experience on renal biopsy and the histopathological patterns of renal diseases presented to Teaching Hospital Kandy.

Methods: This retrospective study included adult patients who had native renal biopsy during a period of 9 years & 4 months, from January 2010 to April 2019. A total of 2680 biopsies were performed. Indications for renal biopsy were as follows: nephrotic and nephritic syndromes, rapidly progressive glomerulonephritis, asymptomatic hematuria and renal failure of unknown etiology. Kidney biopsies were performed percutaneously, using an automated gun under ultrasound guidance. Light microscopy and immunofluorescent studies were used.

Results: A total of 2680 biopsies were examined; sample included 1332 males and 1348 females (age 12 - 88 years). Primary glomerulonephritis (GN) was reported in 1096 (40.9%) cases, secondary GN in 988 (36.9%), tubulo-interstitial disease in 382 (14.2%) and chronic kidney disease of unknown etiology (CKDu) in 214 (8%) cases. Among primary GN, Focal segmental glomerulosclerosis was the commonest seen in 11.41% biopsies, followed by minimal change disease in 10.11%, immunoglobulin A nephropathy in 9.14%, membranous GN in 5.7%, membranoproliferative GN in 3.76% and immunoglobulin M disease in 0.55% biopsies. Among secondary GN, lupus nephritis (LN) was the commonest seen in 15.45%, followed by diabetic nephropathy in 7.27%, post infectious GN in 7.1%, renal vasculitis in 4.25%, hypertensive nephropathy in 1.52%, amyloidosis in 0.85%, myeloma nephropathy in 0.22% and thrombotic microangiopathy in 0.18%. Among biopsies demonstrating tubulo-interstitial disease, chronic interstitial nephritis was the commonest seen in 8.05%, followed by acute interstitial nephritis in 4.4%, acute tubular injury in 1.64% and acute tubular necrosis in 0.14% cases. CKDu was commoner among males than females with a count of 174 (6.49%) & 40 (1.49%) respectively. Mean age of CKDu patients was 44.3 years.

Conclusions: Nephrotic syndrome was the leading indication for renal biopsy. LN and FSGS were the predominant histological patterns. Among females LN stands as the commonest pathology. CKDu shows a significant prevalence among middled aged men.

PUB303

Overestimation of Proteinuria in Urine Sample with Low Urine Creatinine Level

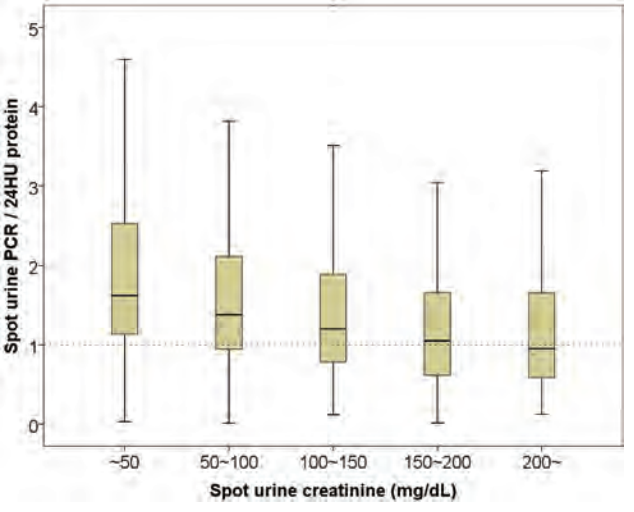
Han Ro,[1] Yun Jung Oh,[2] Chungsik Lee,[2] Ae jin Kim,[1] Ji Yong Jung,[1] Jae Hyun Chang,[1] Hyun Hee Lee,[1] Wookyung Chung.[1] *[1]Gachon University Gil Medical Center, Incheon, Republic of Korea; [2]Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: Proteinuria is an important indicator of prognosis in kidney disease. Spot urine protein/creatinine ratio is widely used because it is considered to be able to replace 24 hour urine protein. Previous studies tested the accuracy of spot urine protein/creatinine ratio using the specific gravity of urinalysis. However, in present study, we investigated whether urine creatinine affects proteinuria quantification without other tests.

Methods: We reviewed patients who underwent 24 hour urine protein (24HU protein) and spot urine protein/creatinine ratio (uPCR) simultaneously at Gachon University Gil Medical Center between June 2002 and June 2018. The subjects were 1,286 patients and 31 patients with membranous nephropathy were excluded. One thousand five hundred fifty four samples were reviewed.

Results: The mean of 24HU protein was 1.4 ± 2.4 g/day (range 0.006~22.7 g/day), and the mean of spot urine protein and creatinine were 165.4 ± 315.4 mg/dL (range 0.1~5500 mg/dL) and 105.3 ± 73.1 mg/dL (range 0.3~682.9 mg/dL), respectively. The ratio of uPCR to 24HU protein (uPCR/24HUprotein) was 6.8 ± 67.8. When the patients were divided into three groups (concentrated group 0~50 mg/dL, reference group 50~200 mg/dL, diluted group 200~ mg/dL) according to spot urine creatinine, uPCR/24HUprotein were 18.6 ± 146.7 (p = 0.003 vs. reference group), 4.0 ± 26.7, and 4.1 ± 12.6 (p=0.088 vs. reference group), respectively.

Conclusions: uPCR tended to overestimate proteinuria based on urine creatinine level (figure 1). When urine creatinine is less than 50 mg/dL, we need to pay attention to the interpretation of uPCR.



Spot urine protein/creatinine ratio to 24 hour urine protein according to urine creatinine levels

PUB304

The Profile of Biopsy-Proven Renal Tubulointerstitial Lesions in China

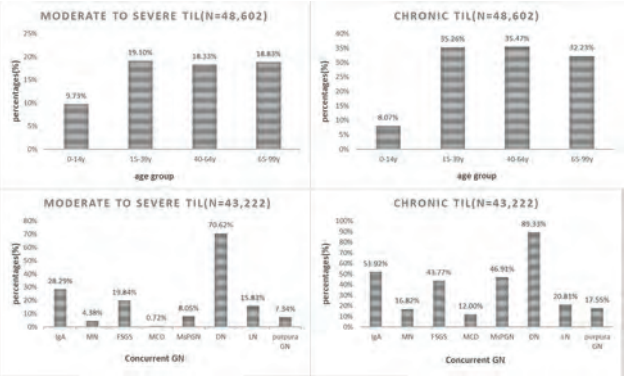
Jin Dong,[2] Sheng Nie,[1] Xin Xu,[2] Guobao Wang.[2] *[1]Nanfang Hospital, Southern Medical University, Guang Zhou, Guang Zhou, China; [2]National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Guang Zhou, Guang Zhou, China.*

Background: Renal tubules and interstitium are vulnerable to injury and associated with deterioration of kidney function in a variety of CKDs. However, high quality studies on the profiles of biopsy-proven tubulointerstitial lesions (TIL) is extremely limited.

Methods: We conducted a retrospective renal biopsy series study including 62,529 native biopsies at 1211 hospitals across China from 2015 to 2017. The TILs, including the shedding of tube epithelial, renal tubular atrophy, renal interstitial fibrosis, edema and inflammatory infiltration, were extracted from the pathological report by a nephrologist. We analyzed the profiles of TILs stratified by gender, age groups, biopsy indications, and concurrent glomerular diseases. We also examined the effect of renal arteriole injury on TIL.

Results: Of the 48,615 patients with TIL, 47,525 (97.76%) were complicated by glomerular disease. Renal interstitial inflammatory infiltration was the most common type of TIL (97.51%), followed by renal tubular atrophy (68.25%) and renal interstitial fibrosis (38.56%). Severe and chronic TIL was more common in adults than in children. The prevalence of moderate to severe TIL was 70.62%, 28.29%, and 19.84% in patients with diabetic nephropathy (DN), IgAN and FSGS, respectively. Similarly, patients with DN, IgAN, MsPGN were more likely to have chronic TIL. After adjusting for age,sex, hospital level, region, biopsy indication and type of concurrent glomerular diseases, patients with renal arteriole injury had a five-fold higher risk of TIL (OR 5.96, 95% confidence interval, 5.34 to 6.65).

Conclusions: In this large, multicenter renal biopsy series, the type and severity of TILs varied with age and concurrent glomerular diseases. Renal arteriole injury was associated with a significantly increased risk of TIL.



PUB305

Clinicopathological Features of IgG4-Related Kidney Disease: Case Series Study

Ping Zhang,[1] Qing Yin,[1] Yurong Zou,[1] Wei Wang,[1] Guisen Li,[2] Junru Wang.[1] *[1]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology of China, Chengdu, China; [2]Sichuan Provincial People's Hospital, Chengdu, China.*

Background: To investigate the clinicopathological features of IgG4-related kidney disease (IgG4-RKD) in Chinese patients.

Methods: We retrospectively analyzed the clinicopathological features of patients with IgG4-RKD and reviewed the relevant literature.

Results: There were 7 patients with IgG4-RKD, the male-to-female ratio was 4:3, and the mean age was 57±12 years. The most common clinical manifestation of these patients was acute or chronic renal insufficiency, while only one presented as nephrotic syndrome. Six patients had evidence of extrarenal involvement. Laboratory examination indicated that the serum IgG and IgG4 levels were elevated in all patients and IgE levels were elevated in four patients. Two patients were clinically diagnoses as ANCA associated vasculitis(AAV). All of the renal biopsies showed diffuse or focal dense lymphoplasmacytic cell infiltrates with scattered eosinophils within the renal interstitium, accompanied by interstitial fibrosis with a"storiform" pattern and tubular atrophy and dropout in fibrotic regions. On immunostaining, IgG4/IgG+ plasma cells ratio was >40% in all of the patients and the number of IgG4+ plasma cells was ≥10/HPF in five patients. Apart from tubulointerstitial nephritis(TIN), three patients had glomerular lesions, one of them had membranous nephropathy, the other two revealed necrotizing vasculitis with formation of crescents in the glomerular capsule, that was consistent with AAV. All the patients were treated with prednisolone, and combination of cyclophosphamide was administered in the two patients with AAV. The median follow-up time was 2 years, 5 of 7 patients revealed complete remission or partial remission, and all patients were alive at the most recent follow-up. One patient with AAV was on dialysis.

Conclusions: The combined application of morphology, immunohistochemistry, and clinical data may facilitate the diagnosis of IgG4-RKD. In the progressive stage of IgG4-RKD, the ratio of IgG4+ to IgG+ cell should be considered a useful metric for diagnosis. In rare cases, we should consider possible coexistence or overlap of AAV and IgG4-RKD.

PUB306

Lipoprotein Glomerulopathy in the Indian Subcontinent: Report of Four Cases

Pooja Maheshwari, Alok Sharma. Department of Renal Pathology and Transmission Electron Microscopy *Dr Lal Path Labs Limited, Delhi, India.*

Introduction: Lipoprotein Glomerulopathy (LPG) is an extremely rare hereditary glomerulopathy presenting with proteinuria, variable degree of renal insufficiency and disturbances in lipid metabolism. LPG exhibit special predilection to kidney and histological hallmark of the disease is presence of laminated, lipid-containing thrombi within dilated glomerular capillaries. Disease progression results in overt nephrotic syndrome and end stage renal disease.

Case Description: We report four cases referred to our centre with complete clinical profile which showed histological, immunofluorescence and ultrastructural features of LPG on renal biopsy. Patients age range was between 21 to 65 years with equal gender distribution, however both males were below 30 years and both females were more than 50 years. Three patients presented with edema and hypertension and all had dyslipidemia. Nephrotic range proteinuria was seen in 3 cases while one had subnephrotic range proteinuria. Two cases had normal renal functions while 2 had mild renal insufficiency. All the cases showed enlarged glomeruli with pale lipid containing thrombi in dilated capillary lumina. Segmental tuft sclerosis (FSGS) was seen in all cases and three showed capillary wall double contour formation. Immunoflourscence was negative in all the cases and ultrastructural examination showed lamellated thrombi composed of variably sized lipid droplets, prominent subendothelial rarefaction, mesangial interposition and reduplication

of glomerular basement membrane. Follow up between 1 month and one year is available, proteinuria has improved to variable extent with lipid lowering agents and renal function parameters are stable.

Discussion: Since the first report of LPG in 1989, approximately 150 cases and 15 different Apolipoprotein E gene mutations in a heterozygous form have been described to play a causative role. Exact pathogenetic mechanism remains to be defined, however abnormal intraglomerular lipid trafficking may be the underlying factor. Though most cases of Lipoprotein Glomerulopathy are of Asian ancestry, mostly Japanese, it has never been described in Indian subcontinent. Kidney biopsy is very important in diagnosis of LPG, as identification of lipid thrombi within glomerular capillaries with high index of suspicion in dyslipidemic patients may play a crucial role and chances of missing the disease can be minimized.

PUB307

Prevalence and Risk Factors in Preterm Infants with Nephrocalcinosis

Heeyeon Cho, Jeong yeon Kim. *Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Nephrocalcinosis is a relatively common clinical condition in preterm infants, and the prevalence of nephrocalcinosis in premature infants ranges from 7% to 41 % in the different studies. Nephrocalcinosis in preterm neonates are known to be affected by multifactorial etiologies such as low gestational age, low birth weight, bronchopulmonary dysplasia, fluid restriction and other various causes. The aim of this study was to evaluate the prevalence and the risk factors of nephrocalcinosis in Korean infants born preterm.

Methods: We retrospectively analyzed the medical records of 27 preterm infants who were admitted to a neonatal intensive care unit from January 2015 to December 2016 and diagnosed as having nephrocalcinosis during hospitalization and 1-year follow-up. The diagnosis of nephrocalcinosis was made by the medical history and renal ultrasonography.

Results: The prevalence of nephrocalcinosis in Korean infants born preterm is 4.1%. The median age at the time of diagnosis was 72 days (17 - 548 days), and the male-to-female ratio was 1.1:1. The median gestational age was 28.8 weeks and body weight at birth was 1149.4±693.5 grams. The risk factors of nephrocalcinosis included patent ductus arteriosus (n=13, 48.1 %), bronchopulmonary dysplasia (n=11, 40.7%), the use of vitamin D (n=23, 85.2%), and diuretics (n=5, 18.5%). The serum levels of calcium and phosphorous at the time of diagnosis were 10.3±1.0 and 5.7±1.1 mg/dL, respectively. The hospitalization period was 119.3±63.4 day, and 1 patient died during follow-up. Although nephrocalcinosis persisted in 8 patients during the first year of life, only 3 patients visited the outpatient clinic of pediatric nephrology.

Conclusions: The prevalence of nephrocalcinosis in Korean infants born preterm was relatively low. Nephrocalcinosis in preterm infants might be associated with impaired renal function in the future, and the cooperation between the neonatologists and nephrologists is necessary. Future research for interventions to prevent nephrocalcinosis in preterm infants is crucial.

PUB308

Hypernatremia and Neurological Outcomes in Children

Madeleine Didsbury,[1,2] Joshua Y. Kausman,[1,3] Catherine Quinlan.[1,3] *[1]Department of Nephrology, The Royal Children's Hospital, Melbourne, VIC, Australia; [2]Sydney School of Public Health, The University of Sydney, Sydney, NSW, Australia; [3]Murdoch Children's Research Institute, Melbourne, VIC, Australia.*

Background: Hypernatremia in hospitalized children is associated with increased mortality and neurological insult, particularly in children with rapid fluctuations in serum sodium level. Current clinical guidelines recommend a reduction of 0.5mmol/L per hour or less, to reduce known complications of cerebral edema, seizures and increased mortality. Recent evidence amongst adults with hypernatremia found no difference in mortality between those who received more rapid or less rapid correction, however there are no large scale trials in the paediatric population. The aim of this study is to examine the association between the rate of correction of hypernatremia, neurological outcomes and all-cause mortality in children.

Methods: A retrospective review was conducted over a three year period from May 2016 until May 2019 in a large tertiary academic pediatric hospital. Eligible participants were identified through interrogation of the electronic medical record (Epic). All patients aged 6 months – 18 years seen at the Royal Children's Hospital with a serum sodium result demonstrating moderate to severe hypernatremia (defined as at least one serum level of 150mmol/L or greater) were included in the analysis. Demographic and clinical data were collected. The relationship between rate of serum sodium correction and neurological injury and mortality was assessed using multivariate logistic regression. Outcomes including mortality, cerebral oedema, seizures, encephalopathy, myelinolysis and decreased level of consciousness were determined using direct chart review.

Results: Over the three year study period, 337 children had a serum sodium level of 150mmol/L or greater and were included in the study. 51.2% of included patients were female, and the median age was 4.2 years. The majority of children had a sodium level in the range of 150-160mmol/L (n=198, 59%). 118 children (35%) had a sodium level between 160-169mmol/L, and 21 children (6%) had a sodium level of 170mmol/L or greater. The most common primary admission units of the cohort were cardiac services (21.3%), neurosurgery (18.1%), and general medicine (16.2%).

Conclusions: Hypernatremia remains a common and concerning occurrence in our hospital inpatients. Our analyses will help to further delineate the relationship between rate of sodium correction in children with hypernatremia and neurological and mortality outcomes.

PUB309

Malignancy After Pediatric Kidney Transplantation: A Single-Center Experience

Jiwon Jung, Joo Hoon Lee, Young seo Park. *Department of pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea.*

Background: Malignancy has become a major burden in transplantation patients with more potent immunosuppressants and longer graft survival. Although there is cumulating cases with malignancy after pediatric kidney transplantation(KT), reports regarding incidence, manifestations, and prognosis are rare. We aimed to investigate the incidence, manifestations, and outcomes of malignancy after pediatric KT in our center.

Methods: We retrospectively reviewed medical records of 143 patients aged under 18 years old who had KT between January 1990 and January 2019 at Asan Medical Center.

Results: Patients had KT at an mean age of 13.2 ± 4.4 years (range, 1.4 – 18.0 years), with mean follow up period of 11.7 ± 7.8 years. In total, 11 patients (7.7 %) had malignancy after KT. Malignancy was diagnosed after a mean period of 7.0 ± 5.9 years (range, 0.5 – 20.6 years) after transplantation. Mean age at diagnosis of malignancy was 20.7 ± 6.1 years. Eight patients out of 11(72.7 %) were diagnosed as post-transplant lymphoproliferative disease(PTLD), and other three patients had papillary thyroid cancer, mucoepidermoid cancer of hard palate, and T-cell acute lymphoblastic leukemia(ALL), respectively. PTLD was diagnosed within 4.3 ± 3.3 years (range, 0.5 – 9.8 years) after KT. Three patients with PTLD (37.5 %) expired. Among 3 patients with malignancy other than PTLD, one patient with mucoepidermoid cancer showed progression despite surgical resection and chemotherapy. Other two patients were cured without recurrence. Four patients (57.1 %) among the survivors who were all diagnosed with PTLD are currently on follow up with preserved renal function which did not deteriorate during the treatment of malignancy. Details of the cases are described on the attatched table.

Conclusions: PTLD was the most common malignancy after KT in children, occurring at 5.6 % of patients within average of 4.3 ± 3.3 years after KT in our center. Careful follow up is needed especially regarding the possibilities of PTLD after KT in children.

Estimated Nephron Number in Japanese Children with Wilms Tumor

Saeko Hatanaka,[1] Go Kanzaki,[1] Daishi Hirano,[2] Rina Oba,[1] Takaya Sasaki,[1] Nobuo Tsuboi,[1] Takashi Yokoo.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Minato-ku, Japan; [2]Department of Pediatrics, The Jikei University School of Medicine, Minato-ku, Japan.*

Background: It has been postulated that an inherited nephron loss would lead to the development of chronic kidney disease (CKD) in later life. Consistent with this hypothesis, recent studies have reported that low birth weight is associated with an increased risk of CKD. However, the effects of birth weight and nephron number in children on development of noncommunicable CKD in adult age have not been elucidated. We, therefore, estimated nephron number in living children with Wilms tumor.

Methods: We evaluated the children with Wilms tumor at Jikei University School of Medicine Hospital who underwent an enhanced CT scan and nephrectomy. Nephron number was calculated by multiplying cortical volume of a healthy side by the glomerular density in a nephrectomy sample, as like Figure 1.

Results: Two children operated on at the age of 16 months (CASE1) and 11 months (CASE2) old for Wilms tumor were identified. The estimated number of nephrons was 843,590 per kidney in CASE1, and 1,021,397 per kidney in CASE2 (Table 1).

Conclusions: These results suggested the possibility of being able to estimate nephron number in living children with Wilms tumor. Further studies involving much larger numbers of subjects are required to determine the role of nephron number in children.

Table 1. Patients Characteristics.

	Gestational age	Birth weight (g)	Serum Cr (mg/dL)	\nephron number (/kidney)
CASE1	40 weeks 3/7	2,318	0.17	843,590
CASE2	40 weeks 0/7	2,934	0.30	1,021,397

Positive Emotions of Caregivers of Children with CKD: A Qualitative Systematic Review

Zhi Hao Ong,[1] Cheng han Ng,[1] Muhammad Isyazmi Bin Mohamad Isa,[4] Megan Kiew,[3] Pei Loo Tok,[2] Yvonne P. Ng.[2] *[1]National University of Singapore, Singapore, Singapore; [2]National University Hospital Singapore, Singapore, Singapore; [3]Ngee Ann Polytechnic, Singapore, Singapore; [4]University of Queensland, Brisbane, QLD, Australia.*

Background: Negative emotions such as distress, fear, and anxiety are commonly experienced by caregivers of children with Chronic Kidney Disease (CKD). However, the caregiving process may also bring about positive emotions. This study aims to explore and summarise positive emotions of the caregivers.

Methods: A systematic review was performed using the PRISMA guidelines to identify qualitative research studying experiences of caregivers of children (ages 1 to 18) with CKD. Databases (PubMed, PsycINFO, Embase, Scopus, Cochrane) and grey literature (Google Scholar) were searched for relevant articles. The initial search yielded 17,493 title and abstracts. With an agreed upon selection criteria by the authors, 14 papers were accepted for analysis and were independently coded by 2 authors for Thematic Analysis. Critical Appraisal Skills Programme (CASP) checklist was used for grading quality of papers.

Results: Fourteen studies comprised 386 caregivers of children with CKD. Although most caregivers had experienced various negative emotions, some reported improved relationships with the patient, their families, and other caregivers. Some factors that contributed to this phenomenon include the long periods of time spent together, heavy dependence for emotional support, patient's appreciation of care provided and teamwork in providing care for the patient. These strengthened bonds can help them better cope with problems faced during caregiving.

Conclusions: To our knowledge, this is the first review focusing on identifying positive emotions of family members caring for children with CKD. Strengthening of familial relationships and with other caregivers can occur in the caregiving process despite the multitude of negative emotions experienced. Healthcare professionals can use the results of this study as a foundation to develop support systems to further strengthen these relationships. Further studies could focus on how these positive emotions aid and influence in the care-taking process.

PUB312

Coping Strategies Employed by Families of Paediatric Patients with Chronic Kidney Disease - A Qualitative Systematic Review

Zhi Hao Ong,[1] Muhammad Isyazmi Bin Mohamad Isa,[2] Cheng han Ng,[1] Megan Kiew,[4] Yvonne P. Ng,[3] Pei Loo Tok.[3] *[1]National University of Singapore, Singapore, Singapore; [2]University of Queensland, Brisbane, QLD, Australia; [3]National University Hospital Singapore, Singapore, Singapore; [4]Ngee Ann Polytechnic, Singapore, Singapore.*

Background: Caregiving for paediatric patients with Chronic Kidney Disease (CKD) has been associated with many psychological burdens. These caregivers would then employ various methods to allow themselves to manage such emotions. This study aims to explore the various strategies that caregivers for paediatric patients with CKD have to cope with their psychological burdens.

Methods: Searches were run on 6 electronic databases including PubMed, PsycINFO, Embase, Scopus, Cochrane and Google Scholar using MeSH terms and keywords for title abstracts. The initial search yielded 17,493 title and abstracts, and 5 papers were identified for independent line-by-line coding by 2 authors and thematic analysis. Quality of included articles was assessed via the Critical Appraisal Skills Programme (CASP) checklist.

Results: Five studies comprised 103 caregivers of children with CKD. Caregivers turn to various coping strategies when dealing with the psychological burden of caring for the patient. During the information hunger phase of initial diagnosis, there is a tendency for caregivers to search for information on internet and they are concerned of information quality. Coping strategies include reliance on religion, friends and family, emotional adjustments and social support groups. Social support strategies include peer support in the form of meetings and online support groups and support from medical staff. Emotional adjustment strategies include acceptance, emotional release and self-comfort.

Conclusions: To our knowledge, this is the first qualitative systematic review that focuses on coping strategies employed by family members of CKD paediatric patients. Coping strategies of different nature are employed by caregivers to manage their negative emotions. The Information presented would serve as a basis for healthcare professionals to better understand these caregivers and develop person-centred support structures for them to cope with their negative emotions.

PUB313

Decreasing Rates of Peritonitis Among Children Undergoing Peritoneal Dialysis in Puerto Rico

Keila M. Mestey,[3,1] Jeannette M. Morales,[1] Marta P. Suarez-Rivera,[2,1] Nilka deJesus-Gonzalez.[4,2] *[1]University of Puerto Rico School of Medicine, San Juan, PR; [2]Pediatric Nephrology, University of Puerto Rico Pediatric Hospital, San Juan, PR; [3]Universidad Central del Caribe School of Medicine, Bayamon, PR; [4]University of Puerto Rico, San Juan, PR.*

Background: Peritonitis is a life-threatening complication ofperitoneal dialysis(PD). From 2006-2016, higher than expected peritonitis rates (0.82 episodes/year vs. 0.5 episodes/year) were reported among children receiving PD in Puerto Rico (PR). Perioperative PD catheter care interventions were developed to address this disparity.

Methods: Retrospective chart review of patients undergoing chronic PD in PR from 2006-2018. Patients with incomplete data were excluded. Peritonitis defined as peritoneal WBC>100cells/mm3 and polymorphonuclear cells>50% and peritoneal fluid culture. Demographic(age, sex), clinical and outcome (peritonitis rate, change of modality and death) variables recorded. High peritonitis rate defined as >0.5 episodes/yr. Associations were assessed using Fisher exact test.

Results: 53 patients underwent PD, 32 were included. Age at initiation 9yrs(6days-20yrs), 50% males. Time on dialysis 865 patient-months. 57 peritonitis episodes documented, for a rate of 0.82 episodes/year in first cohort and 0.34 episodes/year for recent cohort. Younger age at insertion was significantly associated to modality change (p0.047 and 0.044). Two patients died not associated with peritonitis.

Conclusions: Peritonitis rates were higher than national rates in the earlier cohort (0.82 episodes/yr vs. 0.32 episodes/yr). Younger age was associated to modality change. Younger children in dialysis have higher risks of morbidity. Decreasing infection rate may be associated with implementation of catheter care protocol, shorter dialysis vintage and restarting of local transplant program. Close monitoring of infection rates and trends result in better outcomes for patients on dialysis.

PUB314

ESRD in a Pediatric Population in a Southern Algerian Province

Messaoud Hadj mahammed. *Ghardaia Central Hospital, Ghardaia, Algeria.*

Background: End stage renal disease (ESRD) in pediatric population is a major challenge for medical and paramedical staff In Algeria, the number of children reaching ESRD increases annually. Epidemiological studies of the pediatric ESRD in Algeria are few. The statistical data are collected but there is no operable national register. The objectives of this study are to: Estimate the prevalence and the annual incidence of ESRD in the pediatric population of Ghardaïa and to Determine the epidemiological characteristics of dialyzed children

Methods: In this retrospective study, we included all patients under the age of 19 years at the time of the ESRD, living in Ghardaïa, treated at least 03 months by hemodialysis (HD) or peritoneal dialysis (DP) during the period between 01/01/2005 to 12/31/2018. Information was collected from the medical files, interrogation of patients and their parents.

Results: Thirty (34) children were included. The average age was 12 years (1-19), sex ratio (M / F) was 0.88 (16/18). The average annual incidence of pESRD in our series was: 12 pmarp / yr. and The prevalence is : 135 pmarp (Per million age related population). The frequency was high for patients between 10 and 14 years of age (44%) Congenital abnormalities of kidneys and urinary tract (CAKUT) were the first cause of ESRD in our study (26 %) hereditary nephropathies (23 %) primary Glomerular nephropathy (20 %), cortico-resistant nephrotic syndrome was the chief of wire. In 30 % of the cases, the etiology was not found; this is mainly due to delayed diagnosis Hemodialysis is the first treatment method for incident (61%) and prevalent (67 %) patients. It was in most cases urgent (70%), anemia was predominantly present at the time of dialysis (89%). A very high mortality rate (23 %) was founded mainly due to dialysis insufficiency, A very low school enrollment (45 %) and significant retardation of growth (73 %). 15 % was regularly followed in pediatrics during years of dialysis The transplant rate (9 %) is very low, only 3 patients has been transplanted

Conclusions: Our study is of of the few works on the pediatric ESRD in southern of Algeria; we were able to raise the following remarks: - A high incidence and prevalence of pediatric ESRD compared to Europe or the USA - Delayed diagnosis of chronic kidney disease detrimental to patient survival - Very limited access to specialized therapies (urological surgery, genetic tests)

PUB315

Myasthenic Crisis (MC) Precipitated by Omalizumab (Om) Therapy (Rx): A Rare Adverse Reaction

Hassan B. Attique, Ruchir D. Trivedi. *Uconn Health, Farmington, CT.*

Background: Om is humanized glycosylated monoclonal(M) antibody(Ab) of IgG subtype that specifically binds to circulating immunoglobulin E (IgE) and hence has a role in treatment of severe allergic asthma. Om or its constitutive ingredients can trigger immune cross-reactivity and generate secondary autoimmune(AI) reaction by promoting formation of acetylcholine receptor (AChR) or muscle specific tyrosine kinase (MuSK) antibodies(Abs) and potentially precipitate MC. Majority of described adverse reaction to Om is limited to ocular myasthenia gravis (MG). We describe a case of full blown MC from Om with complete resolution of symptoms after therapeutic plasmapharesis (TPE) and stopping Om Rx.

Methods: 61 year old female who had initial diagnosis of MG for almost 20 years, was on maintenance Hemodialysis secondary to hypertensive nephrosclerosis for almost a decade. Around 7 years ago, she was started on Om Rx for non-atopic asthma and she was receiving it on twice monthly basis since then. Two years ago, she started having exacerbation of MG requiring intravenous immunoglobulin (IVIG) Rx. She counted 5 separate relapses at 3 months interval during this time requiring multiple courses of IVIG Rx. Initially symptoms were limited to ocular MG. However, last three relapses were involving difficulty in breathing and swallowing. She improved with three sessions of 1 x volume TPE and stopping Om Rx.

Results: Om has a biological half life of 5 days and typically given twice a month. Information derived from WHO Global individual case safety record database, VigiBase® suggests that there can be latency period of 0.5 to 2.5 years between starting of Om Rx and first appearance of MC symptoms. Precise etiopathogenesis of MG in setting of Om is not well described. Proposed mechanisms may include immune cross-reactivity, impurities in drug triggering secondary AI response and leakage of immunogenic protein A. Precipitation of MC has also been described with other M Abs like Nivolumab and Ipilimumab.

Conclusions: In conclusion, our case report suggests that high level of vigilance is required while using newer M Abs as reversible side effects such as MC can occur with use of Om years after its first exposure through complex and yet unidentified AI mechanisms. Om due to its high molecular weight, less protein binding and volume of distribution, can be effectively removed by TPE and this may provide a therapeutic option.

PUB316

Factors Predicting Ertapenem-Induced Neurotoxicity in Hemodialysis Patients

Wasim El Nekidy,[1] Hazem Elrefaei,[2] Masa Adwan,[2] Nizar M. Attallah,[2] Farah Kablaoui,[2] Islam Ghazi,[3] Janise Phillips.[2] *[1]Cleveland Clinic - Abu Dhabi, Windsor, ON, Canada; [2]Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; [3]Philadelphia College of Pharmacy/University of the Sciences, Wayne, PA.*

Background: Ertapenem is an antibiotic used to treat resistant organisms and is frequently utilized in hemodialysis (HD) patients. The FDA approved dosing in this population is 500 mg intravenously daily based on a single pharmacokinetic (PK) study with a single ertapenem dose. Several reports and experts suggested an association of this dose and neurotoxicity in HD patients. The neurotoxicity rate of 1.9% is recorded in the normal population; hence, the purpose of this study is to identify the risk factors associated with neurotoxicity in the hemodialysis population.

Methods: A retrospective study was conducted in patients who received ertapenem and dialysis at Cleveland Clinic Abu Dhabi between May 1st, 2015 and March 31st, 2019. Patient demographics, comorbidities, concomitant drugs (known to induce neurotoxicity), and seizure history were collected after receiving the Research Ethics Committee approval.

Results: A total of 110 eligible patients were identified. Ten patients (9%) developed neurotoxicity. Of those cases, 8 patients (7.2%) developed seizures while 2 patients (1.8%) developed laryngospasm. The ten patients that developed neurotoxicity were all males with average age of 73.8 ± 9.4 years. Eight patients had established chronic kidney disease and 2 patients had acute kidney injury. Six patients received the recommended dose of 500 mg IV daily while 4 patients received 1 g daily for a few days before dose adjustment. The first episode of neurotoxicity occurred after 10.3±5.2 days of the start of therapy. The most common factors identified in patients who developed neurotoxicity were kidney disease (10), anemia (8) with hemoglobin of 82.3±12.9, history of stroke (5), and dementia (5).

Conclusions: Ertapenem dose, length of therapy, anemia, male gender, and history of stroke were the main risk factors associated with the development of neurotoxicity in hemodialysis population. The recommended dose of ertapenem in hemodialysis patients might impose higher risk of developing neurotoxicity as compared to normal population. Further PK studies are needed to investigate drug accumulation with multiple doses.

PUB317

Cost-Effective Therapeutics for Patients with ESRD: A Guide for the Practicing Nephrologist

Blake P. Van court,[1] Mihran V. Naljayan,[2] Farshid Yazdi.[1] *[1]Louisiana State University Health Sciences Center New Orleans, New Orleans, LA; [2]LSUHSC School of Medicine, New Orleans, LA.*

Background: Patients with end-stage renal disease (ESRD) are often put on complex regimens of medications to manage comorbidities and improve quality of life. Lower income individuals tend to be affected by increases in drug prices, as the average ESRD patient pays nearly $114 out of pocket per month for medications. It is hypothesized that cost-effective medications are available at national pharmacy chains and can be used to promote better health outcomes.

Methods: This study was conducted by utilizing national pharmacy websites' data on prices of common drugs prescribed to ESRD patients. A comprehensive list was compiled and categorized by drug class.

Results: A total of 48 drugs were found across the four nationwide pharmacies Wal-Mart, Target, Walgreens, and Kroger Specialty Pharmacy. Of the 48 drugs recorded, 34 (71%) were found to be a part of a generic discount plan, with drugs ranging from prices of $3.00/ 30 day supply to $16.66/ 30 day supply. Antihypertensives produced the highest quantity of drugs (28), of which 27 were on generic plans (only Labetalol was not), with an average cost of $6.09. Of the drugs used to treat diabetes, five sulfonylureas drugs were found on discount lists, while no insulin drugs were found. No immunosuppressants or phosphate binders were found on generic drug lists.

Conclusions: The data collected indicates that many of the most commonly prescribed drugs for treating comorbidities in patients with ESRD are available in generic form at a low cost to patients. It is hoped that the data provided will help to increase patient adherence and can be easily used as a tool for practicing nephrologists in the form of a pocket card or mobile app.

PUB318

Acute Interstitial Nephritis in the Broad-Spectrum Antibiotic Era

Juan C. Duque,[2] Karla G. Carias martinez,[1] Vasuki N. Venkat,[3] Marco A. LadinoAvellaneda.[3] *[1]Jackson Health System, Miami, FL; [2]University of Miami, Miami, FL; [3]Miami VA Medical Center/University of Miami/ Jackson Memorial Hospital, Plantation, FL.*

Background: Acute interstitial nephritis (AIN) is an important cause of acute kidney injury, especially in hospitalized patients. In recent years broad spectrum antibiotics has been associated to AKI and specially AIN, however the relationship between bacteremia, antibiotics and severity of biopsy damage has not been reported. We present a case series of patients with acute kidney injury with biopsy proven AIN in the setting of vancomycin and piperacillin/tazobactam use for patients with infections.

Methods: This retrospective study assessed the association between broad spectrum antibiotics, bacteremia and the incidence of acute interstitial nephritis. The study included 22 patients (biopsy-proven) who had an episode of AKI with diagnosis of AIN while on broad spectrum antibiotics at the Bruce Carter VA Medical Center Miami from January 2015 through July 2017. The effects of antibiotics on renal function were determined analyzing patient comorbidities with infection event and comparing the kidney function before and after the AKI episode in association with the histopathological analysis and treatment outcomes.

Results: All the patients included were men. The mean age of the included patients was 58.7 (±11). Total of hypertensive patients was 18 (81,8%), diabetes 17 (77.2%) and CKD 11 (50%) with initial creatinine 1.5 (±0.9). Positive blood cultures were seen in 5 patients (22.7%) and 17 (77.2%) negative blood cultures but positive soft tissue infections. A total of 13 (59%) were only on Vancomycin, 11 (50%) on piperacillin/tazobactam and 10 (45.4%) on both. Total of 4 (18.1%) biopsies were read as mild severity, 13 (59%) moderate and 5 (22.7%) severe. Creatinine before the AKI was 1.5 (±0.9), at the time of biopsy was 3.4 (±2.1) and 2.3 (±1.7) 6 months post biopsy/treatment. Total of 6 (27.2%) patients required RRT, and 5 (83.3%) had history of CKD and only 1 (20%) did not recover after treatment. Total of 19 (86.3%) patients achieved complete recovery and 3 (13.6%) did not recovery requiring continuation of RRT.

Conclusions: Vancomycin nephrotoxicity it's associated to elevated levels in the blood. Our review shows that interstitial nephritis is also a cause of vancomycin nephrotoxicity and is not associated to a high concentration. Other risk factors for vancomycin nephrotoxicity are age, presence of CKD and the concomitant use of piperacillin/tazobactam.

PUB319

The Gender Disparity in Living Kidney Donation Has Worsened over 20 Years: Factors and Observations

Mariana S. Markell, Angelika C. Gruessner. *SUNY Downstate Medical Center, Brooklyn, NY.*

Background: It has previously been reported that women donate more kidneys than men. It was thought that socioeconomic factors might play a role, with men historically acting as "breadwinners', but this role has changed over the past 20 years. We examined gender patterns and associated factors in living donation from 1998-2018.

Methods: All 112,700 living donor (LD) kidney transplants reported to UNOS/OPTN between 1998 and 2018 were analyzed. Only adult donors were included in the analyses. The time period was divided into 3-year intervals to adjust for yearly fluctuations. Logistic regression models were used to assess the odds for women to donate a LD kidney adjusted for possible risk factors.

Results: Overall, 60.5% of all living donors were women. Beginning in 2007, the odds ratio (OR) of female donation was progressively higher compared to 1998-00 ranging from 1.049 (2007-09, CI 1.001-1.059) to 1.144 in 2016-18 (CI 1.091-1.200). Except for over 70 years of age, the OR for women vs men donating was significantly higher for all age groups, with highest being the 40-50 yr group (1.621, CI 1.557-1.687). No racial differences could be detected. When donor relationships were examined in a subgroup analysis, 72% of spousal donors were women (10,062 vs 3,745), 68% of life partner donors (375 vs 169), 62% of parent to child (7,309 vs 4,573), but only 56% of child

to parent (10,444 vs 8,356). Gender disparity differed across regions, ranging from 1.194 (CI 1.123-1.269) for region 11 to 1.16 (1.081-1.259) for region 6 compared to Region 9. All differences were significant at p<0.0001.

Conclusions: 1. Women continue to donate kidneys at a much higher rate than men, and the rate is progressively increasing. 2. There were differences in the disparity seen across regions which may reflect case-mix or practice patterns, although race did not seem to have an overall impact. 3. Spousal donors are still predominantly woman to man, as are donations by life partners. 4. Parent to child donation was also predominantly women, but child to parent and sibling donation did not show as great a disparity. 5. Although biological factors may play a role in these findings, factors that may discourage men from donating should be explored, as well as potential biases on the part of providers, in order to improve living donation rates overall.

PUB320

Acute Pancreatitis Risk After Kidney Transplantation: Propensity Score Matching Analysis of a National Cohort

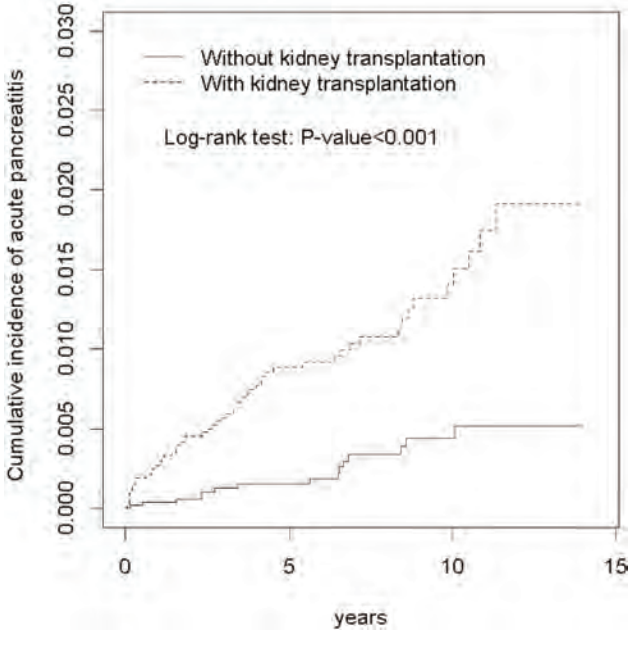
Ya-Wen Chuang, Tung-Min Yu, Ming-Ju Wu. *Taichung Veterans General Hospital, Taichung, Taiwan.*

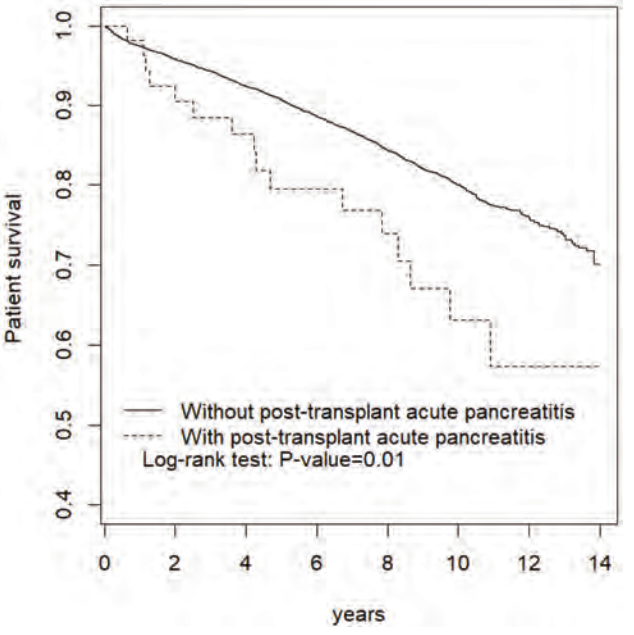
Background: Data for elucidating post-kidney transplantation (KT) acute pancreatitis (AP) risk are limited and no large-scale cohort study has investigated the impact of AP after KT.

Methods: Data from Taiwan National Health Insurance (NHI) Research Database (NHIRD) were calculated through the method of propensity score matching to compare the pancreatitis risk in patients with and without KT.

Results: The overall pancreatitis incidence rates were 1.71 and 0.61 per 1,000 person-years in the KT and non-KT groups, respectively and corresponding adjusted HR (aHR [95% CI]) for pancreatitis was 2.42 (1.43–4.10) in the KT group. In the multivariable model, AP risk was higher in transplant patients with alcohol-related illnesses (aHR: 3.85, 95% CI: 1.36–10.9), gall stone disease (aHR: 3.43, 95% CI: 1.45–8.14), or past history of pancreatitis (aHR: 9.94, 95% CI: 4.98–19.8). Of note, recurrent AP risk was significantly higher in the KT group (aHR: 9.77, 95% CI: 3.33–28.7). Patients with post-KT AP demonstrated shorter patient and allograft survival than did those without (both $P < 0.001$, respectively).

Conclusions: In conclusion, KT recipients are very likely to be associated with AP. Moreover, their inferior outcomes are strongly associated with post-KT AP.





PUB321

Ambulatory Blood Pressures in Pediatric and Young Adult Renal Transplant Recipients

Debora Matossian. *Lurie Children's Hospital, Chicago, IL.*

Background: Ambulatory blood pressure monitoring (ABPM) is the gold standard method to assess abnormalities in the circadian rhythm and blood pressure in renal transplant recipients (RTR). There is limited data in the ABPM patterns on pediatric RTR.

Methods: Retrospective chart review of RTR who had had at least 1 ABPM completed. Categorical variables were reports as counts & percentages and continuous variables as means with standard deviations. Linear mixed model given multiple observation per patient and odds ratios (OR) were calculated.

Results: Cohort (N=20) characteristics included, mean estimated glomerular filtration (eGFR) 57.96 ml/min/1.73m2, 60% male, 80% Caucasian, 85% normal body mass index, 55% had congenital anomalies of the kidneys and urinary tract (CAKUT) as cause for end stage kidney disease, 80% on dialysis prior to transplant, 60% received a living donor kidney. 50% had an abnormal ABPM. Of the 50% with normal ABPM half had finding of nocturnal hypertension (HTN) (normal awake blood pressure). Of the entire cohort, 43% had masked hypertension, 68% lacked a nocturnal dip, and 64% had left ventricular hypertrophy (LVH) (i.e. Ieft ventricular mass index >95th percentile). 67% of patients with LVH were on anti-hypertensive medications. Average tacrolimus trough was 6 ng/ml. Presence of LVH and abnormal ABPM had a 3.3 OR to having a reduced eGFR (<60 ml/min/1.73m2)

Conclusions: Findings demonstrate that ambulatory hypertension is common in both children and young adults after kidney transplantation. Masked HTN, nocturnal HTN and lack of nocturnal dip would not have been found by other means. The elevated prevalence of LVH supports the case for close blood pressure monitoring and target end-organ dysfunction surveillance as part of standard of care for these patients.

PUB322

Vitamin C, Vitamin B12, and Folic Acid Blood Levels and Their Association with Proton Pump Inhibitors Use in Renal Transplant Recipients

Josiane C. Martins, Miguel Moyses-Neto, Natalia T. Bellafronte, Paula G. Chiarello, Elen A. Romao. *Division of Nephrology, Ribeirao Preto Medical School, Sao Paulo University, Ribeirao Preto, Brazil.*

Background: Use of proton pump inhibitors (PPIs) is frequent in renal transplant recipients. PPIs may interfere with the absorption of micronutrients. The objective of this study was to evaluate the blood levels of vitamin B12, vitamin C, folic acid of renal transplant recipients who used a PPI.

Methods: Of the patients at the transplantation outpatient clinic, 239 were eligible for the study, of whom 122 did not agree to participate and 39 were excluded; the remaining 78 patients were divided into two groups: PPI(omeprazole) intake (56) and control (22). It was evaluated: body composition (BMI), food intake (24-hour dietary recall), and vitamins blood tests. The findings were reported as percentage or mean and standard deviation. Associations with p <0.05 were considered significant for all analyzes.

Results: The groups did not significantly differ in demographic and clinical characteristics; there was a predominance of males (64%) and systemic arterial hypertension as underlying disease. The mean age was 49.52 years (± 12.7). Mean transplantation time of the group taking PPI was 68 (± 67.9) months and the GFR was 60 (± 20) mL/min/1.73 m^2, while in the control group the mean transplantation time was

116.9 (± 105.6) months and the GFR was 59.95 (± 13.1) mL/min/1.73m^2. Blood vitamin C was adequate in the majority of patients taking PPI and insufficient in all patients in the control group. Blood levels of vitamin B12 (98.2 and 90.9%) and folic acid (92.5 and 95.5%) were adequate in most patients of both groups (p> 0.05). The food intake recall was used to quantify the intake of macro and micronutrients, and no significant difference between the groups was found, except for vitamin C intake, which was higher in the group taking PPI (86.23 ± 116.0 mg) compared to the control group (42.57 ± 29 mg) (p = 0.01). Regarding BMI, 51.8% of the patients taking PPI were eutrophic and the remainder obese; in the control group, 36.3% were eutrophic, 54.5% obese, and 9% underweight. The results of body composition were similar between groups.

Conclusions: The findings of this study suggest that the intake of PPIs by renal transplant patients does not impair the nutritional status based on vitamin B12, vitamin C, and folic acid serum levels or based on body composition.

PUB323

Multidisciplinary Reconciliation of Renal Transplant Recipients' Medications: A Single-Center Experience

Mohammad Zaitoun,[1] Weam Elnazer,[2] Hany El Hennawy,[3] Ahmed Mahedy,[4,2] Khalid Al-Alsheikh.[2] *[1]Pharmacy Department, Armed Forces Hospitals Southern Region, Khamis Mushait, Saudi Arabia; [2]Nephrology Center, Armed Forces Hospitals Southern Region, Khamis Mushait, Saudi Arabia; [3]Transplantation Surgery Unit, Armed Forces Hospitals Southern Region, Khamis Mushait, Saudi Arabia; [4]Internal Medicine Department, Banha Faculty of Medicine, Banha, Egypt*.

Background: Transitions of healthcare increase the risk of medication errors. Besides, renal transplant recipients are at increased risk of errors due to frequent medication modifications and administration of multiple high alert medications. This study aimed at describing a single center experience in renal transplant recipients' medications reconciliation and its impact in preventing medication errors.

Methods: A prospective observational study was conducted from Jan. to May 2019. Multidisciplinary medication reconciliation process was implemented in the renal transplant unit of the armed forces hospitals southern region, Saudi Arabia. A clinical Pharmacist reviewed the best possible medication history (BPMH) list, developed by admitting physician and nurses, versus admission medications within 24 hours of admission. Upon discharge, clinical Pharmacist reviewed discharge medications against pre-admission BPMH and medications administered within 24 hours. For Post-discharge, clinical pharmacist conducted medication reconciliation of first outpatient clinic prescriptions against discharge ones. Physicians were contacted to resolve any detected discrepancies

Results: Twenty-four patients were transplanted during the study period (54.16% males, mean age = 39.3 years SD=16.8 years), 71 unintended medications discrepancies were detected (2.96 per patient). The majority of these discrepancies found during discharge reconciliation (64.8%) followed by admission (25.35%) and post-discharge (9.85%). The medications involved in these discrepancies included medications of osteodystrophy (23.9%), anemia (15.5%), immunosuppression (12.7%), electrolytes (12.7%), anticoagulation (11.3%), hypertension (8.5%) PPIs (5.6%) and diabetes (4.2%), the remaining 5.6% were miscellaneous medications, 95.8% of unintended discrepancies were prescription-related while the remaining were due to dispensing errors. Physicians resolved all unintentional discrepancies based on clinical pharmacist's recommendations. Omissions constituted 57.8% of errors prevented, while the remaining were commission errors (23.9%), changed dose (16.9%) and wrong duration (1.4%).

Conclusions: Multidisciplinary medication reconciliation seems to be effective in reducing medication errors and promoting renal transplant patients' safety

PUB324

Nocardia Infection in Kidney Transplant Recipients: A Single-Center Experience

Caroline L. Matchett,[1] Arjang Djamali,[2] Didier A. Mandelbrot,[2] Sandesh Parajuli.[2] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]U of Wisconsin Hospital, Madison, WI.*

Background: Nocardiosis is an uncommon, but life-threatening opportunistic infection that disproportionately affects the immunocompromised host. Although transplant-related Nocardiosis is well-recognized, data in kidney transplant patients remains limited.

Methods: A retrospective chart review of all patients at our institution with a history of kidney transplant and at least one positive culture for *Nocardia* between 1999-2019 was performed.

Results: During the 20-year study period, 10 patients had *Nocardia* infection. Eight were deceased donor kidney transplant recipients, and the mean age at time of transplant was 56.0 ± 14.5 years. Induction agents included alemtuzumab (n = 5), basiliximab (n = 4), and anti-thymocyte globulin (n = 1). Nocardiosis occurred at a mean of 11.5 ± 31.6 months (range, 6-102) months after transplant. Breakthrough *Nocardia* infection occurred in 5 patients receiving double strength (160/800 mg) trimethoprim-sulfamethoxazole (TMP-SMX) prophylaxis for *P. carinii* pneumonia. Immunosuppressive regimens at time of nocardiosis diagnosis consisted of prednisone (n = 10), tacrolimus (n = 9), and mycophenolate (n = 8). The most common site involved was the lung. TMP-SMX was the most frequently used antimicrobial for treating nocardiosis (9 of 10); it was administered as single-drug therapy (4 of 10) or as combination therapy with other antimicrobials (5 of 10). Overall mortality was 60% (6 of 10); fifty percent (3 of 10) of deaths were attributable to *Nocardia* infection.

Conclusions: To the best of our knowledge, this is the largest case series of *Nocardia* infection in kidney transplant recipients. TMP-SMX prophylaxis did not appear to provide protection from *Nocardia* infection, but appeared to be associated with less severe disease. Overall outcomes remain poor. Practitioners should maintain a high degree of suspicion for this pathogen in the months to years after transplant.

Table 1. Basic characteristics.

	Age at time of transplant (years)	Sex	Race	Main Underlying Condition	Dialysis vintage (months)	Type of transplant	HLA mismatch	Induction immunosuppression
Patient 1	73	Male	White	Chronic Glomerulonephritis, Unspecified	23	Deceased donor	4	Basiliximab

Thymoglobulin Adversely Affects the Outcome of ABO-Incompatible Transplants

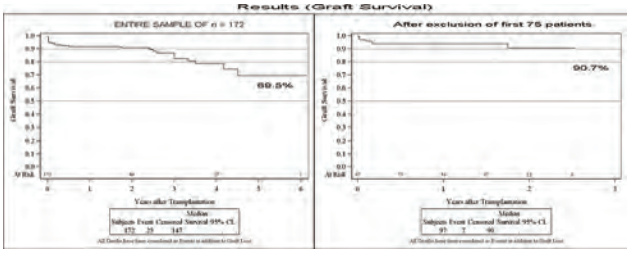
Vivek Pathak. *Nephrology, Kovai Medical Center and Hospital, Coimbatore, India*.

Background: Abo-incompatible transplants are becoming more common with higher long term success rate but yet many centers are reporting unexpected graft loss due to antibody mediated rejection. We analysed our data and found something unexpected that induction with Thymoglobulin caused higher graft loss.

Methods: 172 patients who underwent renal transplantation between May 2012 till July 2018 were analysed. Thymoglobulin was used for induction in 31 and Basiliximab was used in 141 patients. They received maintenance immunosuppression with steroid, MMF and tacrolimus. Observation period was of 10 to 84 months.

Results: Acute rejection was seen in 18 patients(10.4%) and cellular rejection was uncommon. Graft loss was seen in 13 and 12 patients died. Graft nephrectomy due to antibody mediated rejection was done in 6/31 Thymo group and 2/141 of Basiliximab group in first week. 2 patients who were doing well with Basiliximab induction with normal kidney function at 1 week where given Thymo to make them steroid free. Their Anti-A and Anti-B titres started rising immediately from 1:8 to 1:256 in 3 days and both lost the graft. We checked Anti-A and Anti-B titres in ABO compatible transplants before and after Thymo induction but did not observe any rise in 25 patients. Thymo was not used for induction after first 75 patients so there was a clear dfference in graft survival which improved after stopping Thymo Patient survival was 96.9% at 1 year and 81.2% at 5 years. Graft survival improved after dividing the group in first 75 subsequent patients which can be seen in the graph. Graft survival was 82% at 3 years, 69.5% at 5 years in overall 172 patients and 90.7% at 3 years after excluding first 75 patients. Acute antibody mediated rejection could be treated sucessfully in remaining 10 patients.

Conclusions: This study clearly shows the adverse influence of Thymoglobulin induction on graft survival in ABO-incompatible transplants. Graft loss can be reduced by avoiding this treatment.



PUB326

Successful Treatment of Recurrent Focal Segmental Glomerular Sclerosis After Renal Transplant with LDL Apheresis Is Associated with Low Levels of Soluble Urokinase Plasminogen Receptor Activator (suPAR)

Vasil Peev,[1] Stuart M. Sprague,[2] Joshua Zaritsky,[3] Jochen Reiser.[4] *[1]Division of Nephrology, Rush University Medical Center, Chicago, IL; [2]NorthShore University HealthSystem University of Chicago, Chicago, IL; [3]Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE; [4]Rush University Medical Center, Chicago, IL.*

Introduction: Recurrent FSGS remains to be a devastating condition without specific therapy. SUPAR has been reported as a cause of FSGS and its removal is affected by plasmapheresis (PLEX). We report a successful treatment of recurrent FSGS with LDL apheresis.

Case Description: We report a case of a 21 year old male with a biopsy proven idiopathic FSGS diagnosed at age of 12 with a relapsing course and progression to end stage renal disease despite aggressive multi drug therapy. He received a living related renal transplant from his mother with immediate FSGS recurrence in the allograft. His pre transplant sUPAR levels were measured at 12.39 ng/ml. Post transplant PLEX was initiated promptly followed by two doses of rituximab with very poor clinical response. Ninety days after the transplant surgery he was offered treatment with LDL apheresis device (Liposorber LA-15, by Kaneka Pharma America LLC). His chemistries demonstrated serum creatinine (SCr) of 4.0 mg/dl, eGFR of 20ml/min, serum albumin 1.8 mg/dl, proteinuria of 13 g/g based on spot urine protein to creatinine ratio (U P/C) and sUPAR level of 5.3 ng/ml. He received six twice weekly LDL apheresis treatments followed by seven weekly sessions. He also received oral prednisone therapy (60 mg daily for 3 weeks), followed by gradual taper over 6 weeks to maintenance daily dose of 5 mg in addition to IV solumedrol (500mg) following each of the weekly apheresis treatments. His sUPAR levels declined gradually throughout the treatments and reached nadir of 1.9 ng/ml following his 13th session. The remainder of the chemistries demonstrated SCr of 1.7 mg/dl, eGFR of 50 ml/min, U P/C of 800mg/g, serum albumin of 3.7 mg/dl. The LDL apheresis treatments lowered sUPAR levels more significantly (aprox. 47%) and were associated with much lesser rebound than what has been reported in patients with recurrent FSGS receiving PLEX.

Discussion: LDL apheresis lowers sUPAR levels to a greater degree and with less rebound than PLEX. This treatment modality can be successfully applied in patients with post transplant FSGS recurrence.

Simultaneous Liver Kidney Transplantation Using Single Subcostal vs. Dual Incisions: Does Incision Really Matter?

Brianna Ruch,[1] Amit Sharma,[1] Gaurav Gupta,[2] Chandra S. Bhati,[2] Adrian Cotterell,[1] Marlon F. Levy.[1] *[1]Virginia Commonwealth University, Richmond, VA; [2]Virginia Commonwealth University Health System, Richmond, VA.*

Background: Simultaneous liver-kidney transplantation (SLKT) is commonly performed using a subcostal incision for the liver allograft and a right iliac fossa incision for retroperitoneal kidney transplantation (Dual Incision, DI). Some surgeons use a single subcostal incision (SI) for SLK (with intraperitoneal kidney) to reduce the cold ischemia (CIT) and operative times. We report our outcomes using single and dual incisions for SLKT.

Methods: Retrospective analysis of all SLKT done at our center (2015 to 2019) was performed. Outcomes after SI and DI were compared using standard t-test for unequal variances. A p-value <0.05 was considered significant.

Results: 16 SLKT were performed (5 SI and 11 DI). Recipient demographics and early outcomes are shown in table 1.

Conclusions: Simultaneous liver kidney transplantation using a single subcostal incision did not show statistically significant benefit in length of hospital stay, opioid requirements on discharge or allograft function when compared to using dual incisions. Use of single incision for SLKT reduced the CIT for kidney allograft but was associated with a higher incidence of early bile leaks requiring operative intervention. Our initial outcomes need to be confirmed in larger studies.

Adiponectin Influences Skeletal Muscle Mass in Renal Transplant Recipients

Hiroki Adachi, Keiji Fujimoto, Nobuhiko Miyatake, Keiichiro Okada, Kazuaki Okino, Kengo Furuichi, Hitoshi Yokoyama. *Kanazawa Medical University, Uchinada, Japan.*

Background: The sarcopenia in chronic kidney disease is an important issue, however. The long-term association between skeletal muscle mass and serum adiponectin (ADPN) after renal transplantation (RTX) has not been investigated.

Methods: A retrospective survey of 51 patients who received renal transplantation at our hospital after 1998 (living donor: 40, cadaveric kidney: 11, 31 males and 20 females) was performed. The associations with the psoas muscle index (PMI), intramuscular adipose tissue (IMAC), and serum high molecular weight (HMW) - ADPN were investigated over time. In addition, the association of post-transplant diabetes mellitus (PTDM) with PMI and IMAC was investigated.

Results: The age at the time of transplantation was inversely correlated with PMI before RTX and positively correlated with IMAC before RTX (rS=-0.427, p=0.002; rS=0.501, p=0.001, respectively). Compared with that before RTX, PMI gradually increased after RTX (p<0.01). On the other hand, IMAC decreased at 1 year after RTX and then re-increased at 5 year after RTX (p<0.05). Moreover, the increase of the mean change of PMI after RTX was significantly influenced by the increasing mean change of HMW-ADPN levels on the multivariate analysis (beta=-0.140, p=0.003). Otherwise, the increases in the mean change of PMI and IMAC were detected as provocative factors of PTDM (beta=1.574, p=0.030 and beta=172.5, p=0.034, respectively).

Conclusions: In renal transplant recipients, sarcopenia judged by the mass and quality of psoas muscles after RTX may be associated with the alteration of serum HMW-ADPN levels and PTDM.

PUB329

Incident Gout After Renal Transplantation in Gout-Naive Patients: Large Database Analysis

Brian LaMoreaux, Megan Francis-Sedlak, Robert J. Holt. *Horizon Therapeutics plc, Lake Forest, IL.*

Background: Patients undergoing kidney transplantation are at increased risk for developing hyperuricemia and gout compared to the general population (generally attributed to the frequent use of calcineurin inhibitors, cyclosporine and tacrolimus). However, the proportion of renal transplant patients that develop gout and the timing in which this occurs post-transplant is less established. This study sought to describe and quantify the incidence of gout in gout-naïve patients undergoing renal transplantation.

Methods: This retrospective analysis of Humana Research Database 2007-2017 claims data (private insurance and Medicare) was performed by identifying kidney transplant patients who were in plan for at least 6 months before and 5 years after transplant. Only patients without an ICD-9/10 gout diagnostic code within 6-months prior to transplant were included. Included patients were then examined for cumulative incidence of gout post-transplant.

Results: The database contained 16,454 patients that underwent kidney transplant. Of these, 920 patients underwent renal transplant, were in plan for at least 6 months before and 5 years after transplant, and did not have a gout diagnostic code before transplant. Of these, 212 patients (23%) had a post-transplant gout code while in plan, and 175 (19%) developed gout within 5 years post-transplant. The proportion of patients with gout progressively increased over time post-transplant and did not plateau. (**Figure 1**)

Conclusions: Gout is a known frequent comorbidity in solid organ transplant patients, but the timing and proportion of transplant patients who develop gout is not well described. Using a large database analysis, this analysis showed that the proportion of

gout-naïve patients undergoing kidney transplantation who develop gout is high and that this proportion only increases as patients are followed over a longer period of time.

Funding: Commercial Support - Horizon Therapeutics plc

PUB330

Impact of Recipient Age Older Than 70 Years on Outcomes Following Listing for Kidney Transplant: A Single-Center Analysis

Ripudaman S. Munjal, Srijan Tandukar, Kartik Kalra, Dana R. Jorgensen, Sundaram Hariharan, Christine Wu. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Background: Increasing number of older kidney transplant (KT) candidates poses a significant challenge for waitlist (WL) management. We hypothesize that advancing age impacts patient survival on the WL, after de-listing and post-KT. Our aim was to examine the magnitude of this age effect.

Methods: Out of 1965 patients listed for KT, the age distribution were: Group I: 19-60y (WL 1152, KT 631), Group II: 61-70y (WL 622, KT 238), Group III: >70y (WL 191, KT 71) (Table 1). Among KT patients, baseline donor, recipient and transplant variables were recorded (Table 2). The outcomes analyzed among KT patients were death, graft loss and impending graft loss (eGFR<20 mL/min per 1.73 m^2) (Table 2 & Fig 1).

Results: Only 71 WL patients >70y (37%) got a KT compared to 631 (55%) in Group I. Both among patients who were on WL and de-listed, the mortality rate was highest among patients >70y (12% and 20%) followed by Groups II and I (Table 1). The causes of de-listing were for physiological, medical or social reasons. There was a lower rate of living donor KT (24%) and higher KDPI (53±23%) in patients >70y (Table 2). Higher rates of death with a functioning KT was noted in patients >70y. Kaplan-Meier Actuarial Patient Survival was lower in the Group III than Group I (p<0.0001) (Fig 1). However, death censored graft survival rates were similar across all groups (p=NS).

Conclusions: Rates of KT in patients >70y is significantly lower than in younger WL patients. The mortality rate was highest among patients >70y in WL, de-listed and KT patients. Hence, active WL surveillance is mandatory for older patients. Strategies to identify sub-groups of older patients who will benefit from KT needs to be explored.

Table 1. Proportion of waitlisted patients who were transplanted or died while on WL or after delisting

Age at listing (yrs)	Number of patients N (%)	Transplanted N (%)	Died on WL N (%)	Died After Delisting N (%)	Still Listed N (%)
19-60	1152 (59%)	631 (55%)	82 (7%)	57 (5%)	382 (33%)
61-70	622 (32%)	238 (38%)	59 (9%)	64 (10%)	261(42%)
>70	191 (10%)	71 (37%)	23 (12%)	39 (20%)	58 (30%)

PUB331

Low Rates of Preemptive Kidney Transplantation: A Root Cause Analysis to Identify Opportunities for Improvement

Mona M. Alshahrani. *Mcmaster University, Hamilton, ON, Canada.*

Background: Preemptive living donor kidney transplantation, has several advantages over transplantation after dialysis initiation including improved patient survival and reduced healthcare costs. The St. Joseph's Healthcare Hamilton transplant program performs approximately 30 living donor kidney transplants each year, however only 20% of are preemptive. When trying to improve complex healthcare problems such as this, an in-depth root cause analysis can be conducted to fully understand program-related barriers.

Methods: We conducted a retrospective observational study of random sample of 50 living donor kidney transplants in our program that were performed between January 1, 2017 and September 30, 2018. Root Cause Analysis (RCA) provided methodology for this study.

Results: Of the 50 recipients, only 11 (22%) achieved a preemptive transplant. The majority of those who achieved a preemptive transplant were referred with a GFR ≥ 15 (64%). Sixteen recipients (32%) were already on dialysis at the time of referral. Of the remaining 23(46%) who were referred preemptively, Major root causes were identified, 18 (78%) had a GFR less than 15 at the time of referral, 12 (37.5%) had medical issues resulting in delayed clearance for transplant, 9 (28%) participated in the Kidney Paired-Exchange program and 8 (25%) required evaluation of multiple living donors before an eligible donor was found. On further analysis of the durations for assessment milestones, it was found that the median time from recipient referral to clearance was just over 13 months. It was also found that the median time from donor contact to clearance was nearly 8 months. Both of these were longer than ideal.

Conclusions: Our analysis demonstrates that the timing of recipient referral is a significant cause of failing to achieve preemptive kidney transplantation. Additional studies with further investigation of referral practices and modality education as well as causes for delays during the assessment process are needed.

PUB332

Early-Onset Anemia After Kidney Transplantation Is an Independent Risk Factor for Graft Loss

Laura C Fuentes-Mendez,[1] L. M. Perez-Navarro,[1] Virgilia Soto,[2] Rafael Valdez-Ortiz.[1] *[1]Hospital General de Mexico, Distrito Federal, Mexico; [2]INC Ignacio Chavez, Mexico City, Mexico.*

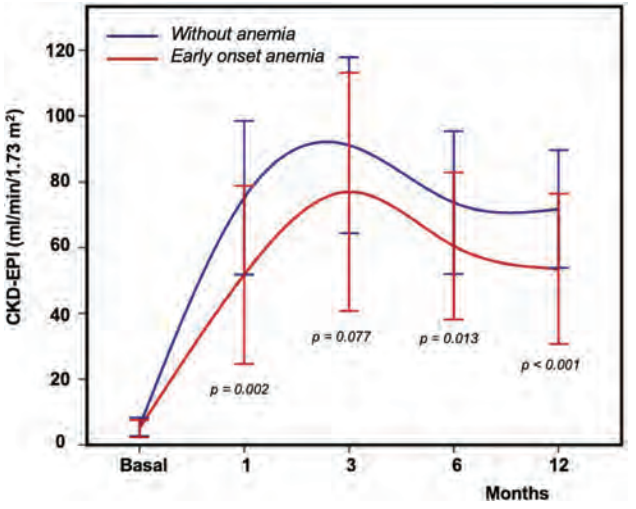
Background: Post-transplant anemia (PTA) is multifactorial and highly prevalent. PTA is associated with graft loss and in most studies with increased mortality. The purpose of this study was to assess whether the presence of anemia at first month post transplant is an independent risk factor of graft survival.

Methods: Patients who underwent kidney transplantation followed-up at a single center who survived at least 1 year after transplantation were included. Data were collected

from the kidney transplant registry from 2012 to 2016. Demographic and clinical data were collected at baseline, 1, 3, 6 and 12 months post transplant. Patients were divided into two groups (anemic and nonanemic) based on the presence of anemia (hemoglobin 10.5 g/dl at first month post transplant). Primary outcome was a composite of patient and graft survival.

Results: Our cohort included 64 patients with follow-up of 28.6 ± 11.4 months, 16 (25%) had early PTA. Baseline characteristics such as age, gender, type of donor, etiology of endstage kidney disease, induction therapy, type of primary immunosuppression, histological characteristics of the zero and follow-up biopsy were similar in both groups. During the study period, a decrease in renal function was observed in the group of early anemia (Figure 1). Creatinine clearance at last follow-up was significantly lower in anemic (58.1± 21.7 ml/min) and nonanemic group (72.3 ± 18.3 ml/min) (p= 0.013). A Kaplan–Meier survival analysis at 5-year post-transplant showed significantly poorer graft survival in the anemic group, p= 0.03. On multivariable analysis, the anemia group was significantly associated with graft loss (HR 12.6, 95% CI 1.5-15.7, p=0.19).

Conclusions: In this study, early onset anemia was independently associated with graft loss, without differences in mortality. PTA must be corrected immediately to avoid poor prognosis outcomes.



PUB333

Cytomegalovirus Pathology in Renal Transplanted Patients: Determining Factors And Relation With Graft And Patient Outcomes

Carlo M. Alfieri,[1,2] Paolo Molinari,[1] Maria Teresa Gandolfo,[1] Mariarosaria Campise,[1] Donata C. Cresseri,[1] Piergiorgio Messa.[1,2] *[1]Nephrology, Dialysis and Renal Transplantation, Fondazione IRCCS Ca' Granda Ospedale Policlinico Milan, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy.*

Background: CMV pathology (CMVp) is frequently observed during renal transplantation (RTx). Its impact on graft and patients (RTxp) outcomes is still debated. Our observational retrospective study evaluates:1) the prevalence and the factors related to CMVp, CMV infection (CMVi) and CMV disease (CMVd) during the 1st year of RTx; 2) the link between CMVp and graft and RTXp survival.

Methods: In 505 RTxp (age:50[41;58]yrs–87 males, follow up (FU) 8[5-11]yrs), RTx between 2004-2016, clinical and biochemical data were recorded at 1(T1) and 12(T12) months of RTx. Donor(D) and Recipient(R) CMV serology was tested at RTx. CMV IgG-D+/IgG-R- RTxp (12%, D+R-) and high risk RTXp received CMV prophylaxis for 3 monyhs. CMVp was defined by either CMVi (CMV replication without CMVd signs) or CMVd (CMV replication with symptoms and/or need of antiviral therapy/reduction of immunosuppression). The outcomes investigated were:1) graft: reduction (T1-T12) of eGFR (MDRD) >20%; reduction (T1-end of FU) of eGFR>50% (eGFRr>50%); graft loss (GL); eGFRr>50% + GL; 2) RTxp survival at the end of FU.

Results: 90% of RTxp had a deceased D kidney, 73% were haemodialysed (HD+) before RTx. Dialysis vintage (DV) was 50[33-75]mths. ATG were used in 12%. Steroids dose was 880[840-105]mg and 2272[2598-3223]mg at T1 and T12. During the 1st year of RTx, 45% of RTxp had CMVp (CMVp+). CMVp+ were older than CMVp-. Females, HD+ and D+R- were more prevalent in CMVp+. At T1, CMVp+ had lower albumin(alb), haemoglobin and higher PTH, uric acid and CRP than CMVp- and, both at T1 and T12, received higher steroid dose. Alb-T1 was the most significant modifiable factor related to CMVp+ (p=0.009 OR 0.50), also after the addiction of D+R- to the model (alb-T1:p=0.008 OR 0.48; D+R-:p=0.01 OR 2.16). CMVd(25%) had lower DV and higher prevalence of D+R- than CMVi(19%). GL and death were observed in 11% and 8% of RTxp. In survival analyses, no relation between CMVp, CMVi and CMVd and outcomes were found.

Conclusions: CMVp is highly prevalent during the 1st year of RTx. Alb-T1 has high impact in CMVp insurgence and might reflect the influence of the pre-RTx status in CMVp. CMVp doesn't influence early and long term outcomes, experienced however in few RTxp. Future studies, prospective and with more RTxp, might better elucidate this issue.

PUB334

Antibody-Mediated Rejection Detection: A Noninvasive Perspective

Nidal Alhosainat, Ann Kathleen N. Gamilla-Crudo, Syed A. Hussain, Muhammad A. Mujtaba. *Univ. of Texas Medical Branch, Galveston, TX.*

Background: Antibody mediated rejection (AMR) is a dreaded complication after a kidney transplant. Usual markers such as a rise in serum creatinine and/or the development of proteinuria may be too late to detect graft dysfunction. Although a kidney biopsy is still the gold standard for diagnosis, it is invasive and molecular changes may have already occurred prior to changes in histology. Monitoring the increase or development of de novo donor specific antibodies (DSA) and detection of donor-derived cell-free DNA (ddcfDNA) are some of the tools in current use to detect early rejection prior to a rise in serum creatinine. We aim to examine the relationships of these biomarkers before and after treatment as the conglomerate of these tests may be better than one test alone.

Methods: We studied five patients who received a kidney transplant from years 2007-2019 at our institution. Serum creatinine, urine protein/creatinine (UPC), and DSA were followed routinely. DSA surveillance was done at 1, 3, 6, 12 months then yearly post-transplant. A kidney biopsy for cause was obtained in all of them. Four patients had ddcfDNA testing. The patients were treated based on biopsy results. Serum creatinine, UPC and DSA were prospectively followed at 1, 3 and 6 months after treatment.

Results: In two of five patients, creatinine was at baseline during the time of biopsy. UPC during rejection was significant only in two patients while all patients had a significant increase in DSA. Only two of four patients had ddcfDNA results compatible with rejection. (Results Table Image)

Conclusions: Based on our findings with a series of patients, no single test was superior to a kidney biopsy when used alone. The detection of a significant increase in DSA after transplant even without a rise in serum creatinine or proteinuria should alert one to proceed with a kidney biopsy. Testing for ddcfDNA may or may not be helpful and more studies are needed to elucidate its role.

Patient	Baseline Cr (mg/dl)	Cr at Rejection (mg/dL)	Baseline UPC	UPC at rejection	Baseline DSA (MFI)	DSA at rejection (MFI)	ddcfDNA at rejection (%)
1	1	1.4	0.15	0.07	No DSA	C1 (16805) C2 (13206)	1.2

Azathioprine-Associated Acute Fibrinous Organizing Pneumonia in a Post-Renal Transplant Patient: Rare Case

Sunil Dharmani. *NHMMI Hospital Dept of Nephrology Lalpur, Raipur, India.*

Introduction: Acute fibrinous organizing pneumonia may occur as an idiopathic variety or in association with autoimmune diseases, occupational, environmental exposures or drug reactions as well as various infections. Azathioprine may lead to acute fibrinous organizing pneumonia.

Case Description: A 62Yr old man with a history of diabetes mellitus, hypertension, sickle cell trait and chronic kidney failure (DKD-biopsy proven) is a post renal transplant recipient (04/02/18). He was on triple immunosuppresent(tacrolimus, azathioprine and wysolone). Initially he was taking mycofenolatemofitil for 2 months, later due to multiple episodes of loose motion MMF was replaced with Azathioprine. 40 days later he presented with c/o –Non-productive cough, sore throat, fatigue, fever, Shortness of breath, generalised weakness. Various pulmonary, cardiac and infectious etiologies were ruled out. Lab test shows normal CBC, PCT<0.25, S.ANA was negative, negative blood and urine culture, respiratory panal was negative, BK virus and cytomegalovirus was negative, Urine legionella antigen and mycoplasma pneumonia came to be negative, Gene expert was also negative. Pleural fluid was transudative, shows low cell count and Pleural ADA was 20. A chest x-ray showed a consolidation in right middle lobe that was further verified by CT chest. Empirical antibacterial and antifungal were started, no response of antibiotics seen in 2 weeks so Open lung biopsy was performed. azathioprine was replaced with MMF and High dose of steroid (1mg/kg) was started. Patient improved gradually after stopping azathioprine. Serial X-rays showed resolution of opacity. Histopathology of lung biopsy was compatible with a AFOP. The patient was diagnosed as an AFOP probably secondary to Azathioprine.

Discussion: Acute fibrinous organizing pneumoniais a rare but important differential diagnosis to consider in patients having flu like symptoms with radiological changes of ground glass opacity non-responding to antibiotics. The patient presented here was suspected to have an respiratory infection. However, reassessment of the case led to the diagnosis of a AFOP. AFOP should be an important diagnostic consideration in patients presenting with flu-like symptom, not responding to antibiotics, in patients taking azathioprine.

PUB336

A Successful Kidney Transplant in a Patient with Inferior Vena Cava Thrombosis and Esophageal Varices

Hussein M. Bagha,[1] Nishma Gajjar,[2] Aisha A. Bajaber,[3] Ahmed Twahir.[4] *[1]Nephrology, M.P Shah Hospital, Nairobi, Kenya; [2]M. P. Shah Hospital, Nairobi, Kenya; [3]University of Nairobi, Nairobi, Kenya; [4]Parkland Kidney Centre, Nairobi, Kenya.*

Introduction: Kidney transplant is the preferred treatment for patients with chronic kidney disease on dialysis. Prolonged use of dialysis catheters are associated with complications like infections, thrombosis and development of superior vena cava syndrome. Superior vena cava obstruction is known to be a rare cause of esophageal varices and can lead to upper gastrointestinal bleeding. Finding a venous thrombosis prior to transplant may provide additional challenges by further increasing the risk of graft failure.

Case Description: A 27 year old male patient known to have end stage renal disease and systemic arterial hypertension presented for kidney transplantation. He had been on hemodialysis for six years. His access was a left femoral tunneled catheter which was changed to a temporary catheter due to a catheter related blood stream infection. He had had several subclavian and internal jugular vein catheters fixed before which had led him to develop superior vena cava syndrome with multiple areas of thrombosis within the superior vena cava. He had been started on warfarin for the same. During the work up for the kidney transplant, he developed hematemesis and an endoscopy done showed esophageal varices which were managed conservatively. A CT aortogram showed a ten centimeter non-occlusve thrombus in the inferior segment of the inferior vena cava and an occlusive chronic thrombus of the left common iliac vein. The patient was started on enoxaparin for three months. He underwent a successful kidney transplant. The graft kidney was placed in the right iliac fossa and the renal vessels were anastomosed to the external iliac vessels.

Discussion: Superior vena cava syndrome is a common complication of prolonged use of dialysis catheters inserted in the subclavian and internal jugular veins. Rarely, it can cause esophageal varices which can lead to upper gastrointestinal bleeding. Our patient presented a challenge in that he had esophageal varices which increased his risk of bleeding and he required anticoagulation for the inferior vena cava thrombosis for a successful transplant. The other dilemma was where to place the graft kidney and which vessels to use for anastomosis as he had a ten centimeter clot in the inferior vena cava. We opted to wait for three months and anticoagulated him with enoxaparin and then transplanted him.

PUB337

An Analysis of Epidemiology, Etiology, and Outcomes of Acute Pancreatitis in Renal Transplant Recipients

Dharmendra Bhadauria. *Sanja Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Acute pancreatitis after renal transplantation is seldom seen, yet a dreadful complication. The causes include traditional causes and immunosuppressive medications, viral infections. Classical symptoms are not always present at onset, which may cause delay in diagnosis. The available literature on pancreatitis in renal transplants is either as case reports or case series. Large studies with longer follow up period and outcome in renal transplant patients with pancreatitis are lacking. We conducted this retrospective study to analyze the incidence, clinical features, causes of pancreatitis in our institute in post azathiophrine era.

Methods: We conducted a single center retrospective study of renal transplant recipients who suffered at least one episode of acute pancreatitis during a period from Jan 2002 to September 2018. We followed IAP/APA (International Association of Pancreatology/American Pancreatic Association) evidence based guidelines for confirming diagnosis of acute pancreatitis and included only patients who fulfilled these criteria. Once the diagnosis is confirmed we retrospectively analyzed the aetiology, clinical features, management and outcomes of renal transplant recipients with pancreatitis.

Results: Twenty-six patients (males 81%; mean age 38.5 years) out of 1350 allograft recipients developed 39 episodes of acute pancreatitis. The incidence of acute pancreatitis was estimated to be 0.12% per patient year (1.9% patients). The interval between transplantation and pancreatitis ranged from < 1month to 14 years. Four patients had pancreatitis in immediate post transplant period (<1 month). Etiology included were drugs chiefly (61.4) gallstones (19.3%), structural lesions (11.5%) and viral infections (7.8%). Clinical presentations, laboratory parameters were similar to pancreatitis in non transplant patients. Graft dysfunction was noted in twenty patients (77%) and all showed either partial or complete recovery. Patient survival was good with 88% of the patients surviving the episode while three (11.5%) patients expired during the episode. Mean duration of follow up was 34.14(0-108) months. The 1-year, 5-year and 10-year survival rates after an episode of acute pancreatitis was 65.78%, 55.67% and 27.83%.

Conclusions: Pancreatitis after renal transplantation is a rare complication with better outcome than what has been reported in the past.

PUB338

Prevalence and Predictors of Sensory Polyneuropathic Signs and Symptoms in Renal Transplant Recipients

Svea Nolte,[1] Jesse M. Hofman,[1] Antonio W. Gomes Neto,[1] Jan willem Elting,[1] Michele F. Eisenga,[1] Marco van Londen,[1] Stephan J. Bakker,[1] Ilja M. Nolte,[1] Bianca De greef,[2] Catharina Faber,[2] Jan-Stephan Sanders,[1] Daniel J. Touw,[1] Ivonne Lesman,[1] Stefan P. Berger,[1] Gea Drost.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Maastricht University Medical Center+, Maastricht, Netherlands.*

Background: Sensory polyneuropathy is a common finding in renal transplant recipients (RTR). Patients with end stage renal disease are at a high risk to develop uremic or diabetic polyneuropathy. Kidney transplantation frequently fails to improve polyneuropathic signs and symptoms post- transplantation. However, little is known about the exact prevalence of post-transplantation sensory polyneuropathy. Therefore, our aim is to determine prevalence and possible predictors for sensory polyneuropathy in RTR.

Methods: RTR and healthy subjects, examined prior to renal donation, were included in the TransplantLines biobank and cohort study at the University Medical Center Groningen. The primary outcome was the result of the adapted modified Toronto Clinical Neuropathy Score (amTCNS), a scoring tool designed to quantify neurological complaints and to rate symptoms of sensory polyneuropathy. Information on relevant clinical parameters i.e. age, height, presence of diabetes mellitus, serum urea levels, eGFR, levels of parathyroid hormone, potassium, folic acid, vitamin B-12, and use of calcineurin inhibitors was collected from all subjects. A chi-square test was used to compare prevalence of sensory polyneuropathy between RTR and healthy subjects. Multivariable linear regression analysis was performed to assess the relationship between explanatory variables and sensory polyneuropathy.

Results: A total of 209 RTR (65.1% males) with a mean age of 54.9±13.4 (range 17-80) years, and 122 healthy subjects (46.7% males) with a mean age of 55.9±11.2 (range 27-75) years were included. Signs and symptoms of sensory polyneuropathy were present in 48 (23.0%) RTR and in 6 (4.9%) healthy subjects (P<0.001). Serum urea (st. b=0.28, P=0.003) and age (st. b=0.25, P=0.001) were independent predictors of sensory polyneuropathy in RTR.

Conclusions: Polyneuropathic signs and symptoms are more common in RTR than in healthy subjects. Serum urea and age are independent predictors of sensory polyneuropathy in RTR, making uremic polyneuropathy the most likely underlying etiology in this particular patient setting.

PUB339

Outcomes of Late Acute Rejection Treatment with r Anti-Thymocyte Globulin (r-ATG) 1 Year Post Kidney Transplant

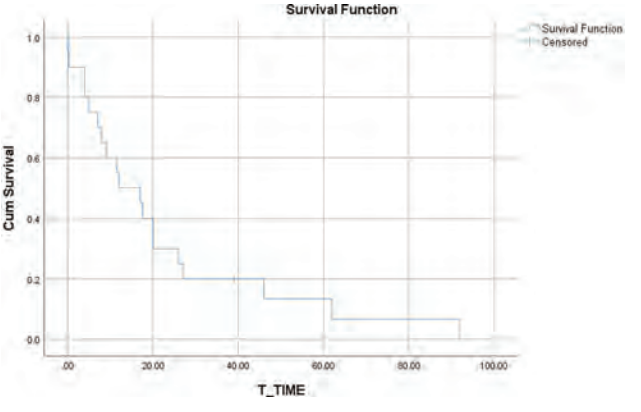
Asad Riaz, Asif A. Sharfuddin, Tim E. Taber, Oluwafisayo O. Adebiyi, Muhammad S. Yaqub. *Indiana University School of Medicine, Indianapolis, IN.*

Background: The aim of this study is to investigate the relationship of Late Acute cellular Rejection (LAR) episodes, treated with r-ATG one year post transplantation, with reversibility of graft dysfunction and long-term graft survival

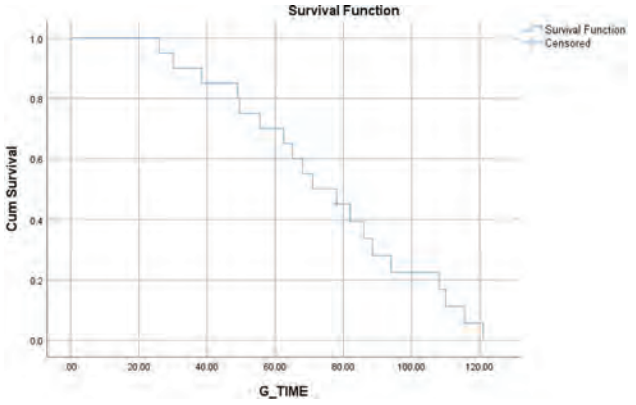
Methods: Data of 20 recipients reviewed who received r-ATG between 2009 and 2016 for biopsy proven LAR. Age at transplant 33.9 ± 15 years, 11 M, 9 F and 11 Caucasians with biopsy proven LAR one year post transplant. Non-adherence was the most common reason for acute rejection (65%). Mean r-ATG cumulative dose was 6.25 mg/kg. All recipients received IV steroids/ oral Prednisone taper. Maintainance immunosuppression included Calcineurin Inhibitors, Antimetabolites and Prednisone.18 recipients had Banff 1B or higher grade acute celular rejection (ACR). 4 recipients had combined ACR and Antibody Mediated Rejection.

Results: Pre biopsy Cr 1.75 +/- 0.7. Cr at the time of biopsy 5.45 +/- 2.87. Time lapse (days) between baseline Cr and Biopsy was 157.4 +/- 193.2. Post r-ATG Cr at 6 mon was 3.3 +/-1.8. Post r-ATG, 9 (45%) recipients had graft failure before 12 months, 7 had graft failure between months 13 to 36 and 4 had functional graft beyond 36 months. Only 1 recipient has a functional graft to date (92 months post r-ATG treatment). Mean Graft survival from date of transplant was 73.8 months +/-27.6 and graft survival post r-ATG was 22.6 months +/- 23.3.

Conclusions: Late Acute Cellular Rejection severely reduces long term graft survival Acute rejection treatment with r-ATG should be used in very selective patients as it may benefit only very few patients.



Post r-Thymo Graft Survival



Post Transplant Graft Survival

Comparison of Outcomes with and Without Induction Therapy in Low-Risk Renal Transplant Recipients

Sabina Yusuf,[1] Anurag Gupta,[2] Devinder S. Rana,[1] Vinant Bhargava,[1] Ashwani Gupta,[1] Anil Bhalla,[1] Manish Malik,[1] Neha Jain.[3] Sir GangaRam Hospital *[1]Department of Nephrology, Sir Ganga Ram Hospital, New Delhi, India; [2]SYNEGY Hospital, Uttarakhand, India; [3]UCONN Health, Hartford, CT.*

Background: With low rates of acute rejection with current maintenance immunosuppression consisting of steroids, MPA and tacrolimus, question arises whether induction offers any additional benefit in low risk renal transplant recipients. This study evaluated outcomes with and without induction in low risk renal transplant recipients.

Methods: A prospective observational study in which 100 low risk renal transplant recipients were included and divided into 2 groups – one that received induction and another that did not. They were followed for 1.5 years. Three end points were compared - efficacy of induction, patient and graft survival and adverse effects.

Results: Incidence of rejection in early post transplant period did not differ (4% NO IND vs 6% IND; p=0.171). Rejection as cause of late graft dysfunction was seen in 16% in IND vs 20% NO IND; (p=0.603). No difference in serum creatinine at end of 1.5 years was seen. Graft survival was also similar. Relapsing and recurrent UTIs (46% IND vs 16% NO IND; p=0.09), hospitalization requiring infections (76%IND vs 64% NO IND; p=0.119 NS) were more common in IND. CMV infection affected only IND (6% vs none; p=0.07). Patient survival at 1.5 years was comparable (94% IND vs 96% NO IND; p=0.646).

Conclusions: The study showed comparable results between IND and NO IND with however an increased incidence of infections and hospitalizations in IND group. Use of induction may be avoided in low risk renal transplant recipients.

PUB341

Variations of Serum Creatinine in Patients with Hospitalizations in the First and Second Year of Renal Transplantation

Daniel Murillo brambila,[1] Monica C. Jimenez Cornejo,[2] Maria Concepcion Oseguera-Vizcaino,[3] Jose A. Lugo,[1] Nidia R. Alvarez,[1] Alejandro Bautista Arana,[1] Dulce L. Ibarra moran,[4] Marco A. Covarrubias.[3] *[1]Antiguo Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara "Fray Antonio Alcalde", Guadalajara, Mexico; [3]Hospital Civil de Guadalajara, Guadalajara, Mexico; [4]Hospital civil antiguo, Guadalajara, Mexico.*

Background: The kidney transplant patients the main causes of hospitalization are infections and kidney graft rejection. The aim of this study is to analyze the variations in serum creatinine levels in kidney transplant patients who had hospitalizations in the first and second year of transplantation.

Methods: Retrospective observational study, 28 patients with kidney transplant were selected in the 2016-2018 period, divided into two groups; First year and second year of transplantation, the data was taken from the database of the Civil Fray Antonio Alcalde hospital in Guadalajara, demographic characteristics are shown in numbers, percentages, mean, standard deviation and non-parametric Wilcoxon.

Results: The baseline characteristics of the 28 patients, 15(53.6%) are male, a mean of 28.5 years of age, 19(67.9%) was living donor, 9(32.1%) from a brain death donor, the average number of hospitalizations was assessed in the first and second year 1.94 and 1.8 respectively, main diagnoses of hospitalization were urinary tract infections and graft rejection, baseline creatinine in the first year group with an average of 1.3mg/dl and the second year group an average of 2.6mg/dl, the Wilcoxon test comparing baseline creatinine and creatinine variations at the end of the follow-up of both first year P=0.51 and second year group P=0.31

Conclusions: No significant differences were found in both groups in the variations of creatinine levels with respect to baseline levels, which concludes that hospitalizations in the first two years of kidney transplantation have a minimal impact on creatinine levels and that probably related to renal functional reserve of the graft

PUB342

Current State of Renal Transplant Patients in a Southern Area of Algeria

Messaoud Hadj mahammed. *Ghardaia Central Hospital, Ghardaia, Algeria.*

Background: Renal transplantation (RT) is the best treatment for end stage renal disease (ESRD). The aim of this study, is to examine the clinical situation of transplant patients in Ghardaia

Methods: In this observational and descriptive study, we included all kidney transplant patients for more than a year, and living in Ghardaia we examined the patients and consulted their medical files

Results: Twenty-six patients are included, the average age is 35 (22 - 53), sex ratio is 0.6, the average duration in dialysis was 5 years, two preemptive grafts, all the patients were in hemodialysis befor graft. The kidney donor was, in 36% a siblings, 32% a parent, 22% a spouse, 2 cases of unrelated donor, the average donor age was 42 the average duration of the transplant is 7.5 years The estimated GFR by CKD EPI is 53 ml / min / 1.73 m2 (23 - 102) 68% of patients are hypertensive, dyslipidemia present in 23% and overweight in 45% of cases, no case of diabetes Infectious complications are frequent: urinary 40%, pneumocystis 23 % and brucellosis 17 %, one case of cryptococcal disease. surgical complications are rare, 03 cases of ureteral stenosis immunosuppressive therapy is: ciclosporin 40%, tacrolimus 45%, two patients on sirolimus and five patients without corticosteroids A case of PTLD (Kaposi's tumor) in a young patient of 32 years old and a case of breast neoplasia in a 42 years old woman only 03 graft biopsy was performed

Conclusions: Despite the young age of the patients, short duration of transplantation and an adequate immunosuppressive treatment, the function of the grafte is weak The infectious risk to unusual germs is important, it is probably due to rural living and climatic conditions high heat and drought Non-collaboration between the transplanting centers and local nephrologists, absence of systematic graft biopsies, and the scarcity of experienced laboratories, are not neligible factors.

PUB343

Incident Parkinson Disease in Kidney Transplantation Recipients: A Nationwide Population-Based Cohort Study in Korea

Seon Ha Baek,[1] Ji Eun Kim,[2] Yong Chul Kim,[2] Dong Ki Kim,[2] Hajeong Lee.[3] *[1]Hallym University Dongtan Sacred Heart Hospital, Hwaseong-si, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Patients with end stage renal disease (ESRD) have a substantially increased Parkinson disease (PD) risk, but few studies have examined the risk of PD in kidney transplant (KT) recipients. In this study, we aimed to estimate the risk of incident PD in KT recipients compared with general population (GP) or ESRD patients.

Methods: From the Korean National Health Insurance Service database, we identified incident KT recipients aged ≥ 40 years without any history of PD between 2007 and 2015. We also established two control cohorts without a history of PD: 1) GP cohort of insured

subjects without a history of kidney disease, 2) ESRD cohort of incident ESRD subjects, with frequency matched for age, sex, and inclusion year. PD was diagnosed on the code of the International Classification of Disease, 10th Revision (G20-22).

Results: We followed 8,198 KT recipients, ESRD patients, and GP for 44,808, 36,559, and 46,578 patient-years, respectively. Their mean age was 51.2 years and 59.7% were men. Over observation periods, 18, 43, and 13 incident PD occurred in KT, ESRD and GP group, respectively. KT recipients showed a significantly lower risk of incident PD compared to ESRD patients (adjusted hazard ratio [HR] 0.32, 95% confidence interval [CI], 0.18 to 0.56, P<0.001) and a similar risk of incident PD compared to GP group (adjusted HR 0.99, 95% CI 0.40 to 2.60, P<0.001) even after adjustment including age, sex, diabetes mellitus, hypertension, dyslipidemia, and Charlson's comorbidity index, income. The strongest predictor for incident PD was older recipient age in KT recipients.

Conclusions: We found that risk of incident PD after KT was significantly lower than ESRD patients and similar to GP. Older age at the time of KT was an independent risk factor for PD occurrence in KT recipients.

PUB344

Clinical and Pathological Factors Influencing Residual Renal Function After Living Donor Nephrectomy

Okubo Akihiro,[1] Hideki Yokoi,[1] Kaoru Sakai,[1] Takeshi Matsubara,[1] Motoko Yanagita.[2] *[1]Department of Nephrology, Kyoto University Hospital, Kyoto, Japan; [2]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Living kidney transplantation is an established renal replacement therapy for end-stage renal disease patients. To assess living kidney donor's renal function, computed tomography (CT) and renal scintigraph was used to evaluate single renal function. Low total kidney volume (TKV) is reported to be associated with a decline in GFR after living kidney transplantation. However, pathophysiological findings such as glomerulosclerosis at the time of one-hour protocol biopsy are not fully evaluated as factors influencing post-transplant renal function. In this study, we evaluated the correlation of potential influencing factors including TKV and glomerulosclerosis with pre- and post-transplant renal function in living kidney donors.

Methods: This is a retrospective study including all 37 living related kidney donors seen at Kyoto University Hospital from January 2013 to April 2019. Estimated glomerular filtration rate (eGFR) was calculated using equation for Japanese population from serum creatinine levels at pre- and post-transplant. TKV was calculated from the 3D volume-rendered images of enhanced CT, and adjusted to standard body surface area (BSA) by individual BSA. The ratio of number of non-glomerulosclerosis per that of whole glomeruli (non-GS) was evaluated by protocol renal biopsy at one hour after renal reperfusion. This study protocol was approved by the Ethics Committee on human research of the Graduate School of Medicine, Kyoto University.

Results: We evaluated 37 living kidney donors (35.1% male, mean age 58.2 ± 12.0 years). Mean pre-transplant eGFR was 75.7 ± 12.1 ml/min/1.73m^2, mean post-transplant eGFR; 44.9 ± 7.75 ml/min/1.73m^2, adjusted TKV (aTKV); 349.3 ± 58.4 ml, and non-GS; 0.892 ± 0.086. Pre-transplant eGFR was associated with aTKV and aTKV×nonGS (r=0.525, 0.569 respectively, p<0.01). Post-transplant eGFR was associated with age(≧65 years old, p<0.01), aTKV, non-GS, and aTKV×non-GS (r=0.527, 0.344, 0.626 respectively, p<0.05). The rate of eGFR decline was associated with age (≧65 years old, p=0.044), but not with aTKV and non-GS, aTKV×non-GS.

Conclusions: Pre-transplant eGFR was more associated with aTKV×non-GS than aTKV. These results suggest that non-GS and age are correlated with post-transplant renal function, and non-GS also tends to influence pre-transplant renal function in living kidney donor.

PUB345

Outcomes of Renal Transplantation in Adult Patients with Primary Focal Segmental Glomerulosclerosis: A Single-Centre Experience

Manasi Jyothish,[1] Desley Neil,[3] Miriam Berry.[2] *[1]University of Birmingham, Birmingham, United Kingdom; [2]Department of Renal Medicine, University Hospitals Birmingham, Birmingham, United Kingdom; [3]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is the most common primary glomerular cause of end stage kidney disease (ESKD). Renal transplantation in patients with FSGS is complicated by recurrent disease, which is reported in 30-50% of cases and may lead to graft loss. It is important to identify patients at high risk of recurrent disease to improve transplant outcomes and to inform the consent process.

Methods: We performed a retrospective database search (n=3533) of all patients with primary FSGS transplanted at our centre over a 50 year period, and evaluated their transplant outcomes. Recurrent disease was diagnosed on renal transplant biopsy in patients with proteinuria. Data are expressed as median +/- interquartile range.

Results: We identified 111 transplants in 106 patients with ESKD due to primary FSGS. Detailed follow up data were available for 80 patients; 59% male 41% female with median age at transplantation 43 (+/- 18) years. 66% patients were Caucasian. 69% transplants were from live donors. Median follow up period was 7.5 years. Recurrent FSGS occurred in 16% (n=13) patients; 55% male and 61% Caucasian. Length of time from transplant to recurrence was between 3 months and 10 years. Graft loss due to recurrent FSGS occurred in 77% (n=10) patients with recurrent disease.

Conclusions: Our large single centre study shows that recurrent FSGS following renal transplantation is much lower than in published studies, but that recurrent disease leads to graft loss in most patients. This data will inform shared decision making in patients with primary FSGS.

PUB346

Different Dosages of Rituximab in ABO-Incompatible Kidney Transplant: A Comparative Study of B Cell Count, Antibody Titre, and Graft Function

Deepak S. Ray, Sharmila Thukral, Nikhil N. Shinde. *Rabindranath Tagore International Institute of cardiac sciences, Kolkata, India.*

Background: Forty percent of live -related donors from family are lost because of ABO blood group incompatibility in India. To increase the donor pool, ABO-Incompatible Transplants, which have shown equally good results as that of ABO-Compatible transplants is gaining popularity. One cocern of ABO-I transplantation is over immunosuppression and related complication. Rituximab, which depletes B cells is an important constituent in the desensitisation protocols of ABO-I transplantations. Dose of Rituximab varies from center to center from 100mg/body to 500mg/body. There are only few studies comparing the efficacy and adverse effects of various doses of Rituximab. We studied the efficacy of Rituximab in a low dose (100mg/body) versus higher dose (200mg/body) by comparing B cell count (CD-20) and comparing the patient and graft outcomes.

Methods: The study was conducted in Narayana Health Hospitals (RTIICS), Kolkata from December 2016 to November 2017. Total 64 patients of ABO-I kidney transplant patients with initial ABO blood group Antibody titer of 512 or, less were included and devided in to two groups :A and B. Two weeks prior to transplantation Gr A patients received 100 mg of Rituximab and Group B 200 mg. They received simillar desesitisation treatments. Their Serum creatinine, Antibody titer, B cell count besides the complications (if any) were monitored for one year.

Results: No diference was found between two groups in base line characterstics, follow up antibody titer, B cell count, rejection, graft survival, patient survival. Though infection rate was more in patients receiving 200mg Rituximab, it was not stastically significant.

Conclusions: In patients of ABO-incompatible renal transplant with intial ABO antibody titer of 512 or, less Inj Rituximab in a dose of 100 mg gives simillar graft and patient outcome as Inj Rituximab of 200 mg in shorter term. The Rejection rate, Antibody titer, B cell count is comparible in both higer dose and lower dose of Rituximab. The rate of infection is lower in low dose Retuximab. Patients with ABO ab titer of 512 or, less may be given inj Rituximab in a lower dose (100mg/body)

PUB347

Kidney Transplants from Uncontrolled Donation After Circulatory Death Do Not Show Greater Risk for Infection

Beatriz Redondo navarro,[1] Maria Molina,[1] Jimena Cabrera,[2] Candela Moliz,[1] Esther Gonzalez monte,[1] Ana M. Hernandez vicente,[1] Enrique Morales,[1] Eduardo Gutierrez-martinez,[1] Manuel Praga.[1] *[1]Hospital Universitario 12 de Octubre, Madrid, Spain; [2]Programa de Prevencion y tratamiento de las glomerulopatias, Montevideo, Uruguay.*

Background: Kidney transplantation is the best renal replacement therapy but there are acknowledged associated risks including infection. We aimed to assess if known risk factors for infection (as delayed graft function (DGF), immunosuppresion) where significant in cases of uncontrolled donation after circulatory death (uDCD).

Methods: To evaluate possible greater risk of infection of uDCD recipients in comparison with donation after brain death (DBD) recipients. - Unicentric retrospective study of case and controls, comparing 237 uDCD recipients with 237 DBD recipients. All uDCD recipients received Thymoglobulin as induction therapy and delayed introduction of calcineurin inhibitor (CIN), with CMV prophylaxis with valgancyclovir for 3-6 months. Some DBD recipients received induction therapy with basiliximab. - We systematically collected data of infectious events which required hospitalization, fungal infections and viral infections detected in outpatient clinic.

Results: See Table

Conclusions: UDCD recipients did not show increased risk for infection provided that they receive adequate prophylaxis therapy, despite greater DGF and induction therapy with thymoglobulin. Incidence of CMV infection is lower in uDCD recipients, which is attributable to CMV prophylaxis.

Association Between Clinical-Demographic Factors Pre-Transplant and Mortality in Receptors of Deceased Donor Kidney

Beatriz O. Moura,[1] Daniela M. Chiloff,[1] Caio C. Delfino,[1] Mariana V. Tordin,[2] Giovanna M. Zavadzki,[1] Carolina A. Franco,[1] Letícia C. Albeny,[3] Felipe Kenzo Yadoya Santos,[3] Miguel Angelo Goes.[1] *[1]Escola Paulista de Medicina UNIFESP, São Paulo, Brazil; [2]FAM, São paulo, Brazil; [3]Universidade Federal de São Paulo, São Paulo, Brazil.*

Background: Demographic and clinical factors can be associated with deleterious consequences in renal transplant and decreased survival of the patient. **Objective:** to evaluate the association between demographic and clinical factors pre-renal transplant with mortality in recipients of deceased donors.

Methods: We performed the follow-up of 255 renal transplant patients from deceased donors at the Hospital do Rim-UNIFESP for 10 years (2008-2018). We evaluated demographic data such as age, sex, immunosuppressive drugs, serum creatinine from donors pre-transplant. We analyzed sodium and Hgb concentration pre-renal transplantation, cold ischemia time, KDPI, delayed graft function (DGF), acute rejection episode and mortality as outcome. We compared Mortality and Non-Mortality groups. We performed binary logistic regression using mortality as response variable after comparisons.

Results: Forty-eight patients progressed with mortality. 38 patients had infection, 6 patients had cardiovascular disease as the main cause and 2 died of unknown cause. Mortality time of 3.2 ± 0.3 years after transplant. Mortality group were older (52 ± 10, 47 ± 12, p = 0.02). The concentration of Hgb was lower in the mortality group (10.3 ± 1.1, 11.2 ± 0.9 g/dl; p = 0.01). There was no difference in sex, serum sodium, donor creatinine, KDPI, immunosuppressive drugs, cold ischemia time and DGF between groups. There were 14 patients from Mortality group had at least one episode of acute rejection in the follow-up period (29.2%; p = 0.03). The concentration of Hgb pre- renal transplant (OR = 0.779, 95% CI 0.659-0.921, p = 0.03) and the patient's age (OR = 1.049, 95% CI 1.016-1.083, p = 0.04) were independent predictors of mortality.

Conclusions: Lower Hgb concentration pre-transplant and the patient's age were independent predictors for mortality in deceased donor renal transplant recipients.

PUB349

Association Between Clinical-Demographic Factors Pre-Transplant and Chronic Renal Allograft Nephropathy in Receptors of Deceased Donor Kidney

Daniela M. Chiloff,[1] Beatriz O. Moura,[2] Letícia C. Albeny,[2] Felipe Kenzo Yadoya Santos,[2] Caio C. Delfino,[1] Mariana V. Tordin,[4] Giovanna M. Zavadzki,[2] Carolina A. Franco,[2] J. Medina-Pestana,[5] Miguel Angelo Goes.[3] *[1]Escola Paulista de Medicina - UNIFESP, São Paulo, Brazil; [2]Universidade Federal de São Paulo, São Paulo, Brazil; [3]Federal University of Sao Paulo, Sao Paulo, Brazil; [4]FAM, São paulo, Brazil; [5]Hospital do Rim e Hipertensão, Sao Paolo, Brazil.*

Background: Renal allograft failure is one of the most common causes of end-stage renal disease. Demographic and clinical factors can be associated with deleterious consequences in renal transplant. **Objective:** to evaluate the association between demographic and clinical factors pre-renal transplant with chronic renal allograft nephropathy (CRAN) in recipients of deceased donors.

Methods: We performed the follow-up of 255 renal transplant patients from deceased donors at the Hospital do Rim-UNIFESP for 10 years (2008-2018). Interstitial fibrosis and tubular atrophy (IF/TA) in renal allograft biopsy was considered as CRAN. We evaluated demographic data such as age, sex, immunosuppressive drugs, serum creatinine from recipients and donor. Hemoglobin (Hgb) concentration and CKD-EPI were evaluated after 6 months of transplant, cold ischemia time, duration of delayed graft function (DGF), acute rejection episode and CRAN as outcome. We compared CRAN and Non-CRAN groups. We performed binary logistic regression using CRAN as response variable after comparisons.

Results: CRAN occurred 5.5+0.25 years in fifty-two patients. Donor creatinine was higher in CRAN group (1.85±0.82, 1.44± 0.37, p=0.008). CKD-EPI was lower in CRAN group (47.3 ± 4.9, 61.1 ± 1.6 g/dl; p = 0.01). Hgb concentration was lower in CRAN group (11.8 ± 2.6, 13.4 ± 2.4 g/dl; p = 0.004). There was a higher frequency of patients with DGF (p=0.02) and acute rejection episode (p=0.01) that developed CRAN. There was no difference in immunosuppressive drugs and cold ischemia time between groups. Donor creatinine (OR = 3.354, 95% CI 1.198-9.389, p = 0.02), acute rejection episode (OR = 0.340, 95% CI 0.132-0.878, p = 0.03) and concentration of Hgb in 6 months after renal transplant (OR = 0.818, 95% CI 0.677-0.989, p = 0.04) were independent predictors of CRAN.

Conclusions: Donor creatinine, acute rejection and lower Hgb concentration 6 months after transplant and the patient's age were associated with CRAN in deceased donor renal transplant recipients.

PUB350

A More Realistic Assessment of Waiting Time for Transplant Patients

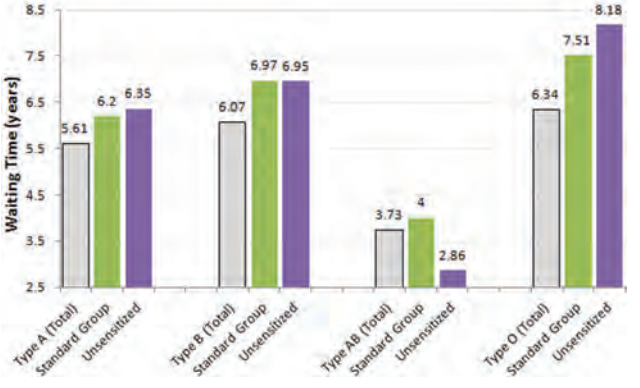
Laurel Ormiston,[2] Shannon Radomski,[3] Gayle M. Vranic,[1] Jack Moore,[4] Beje S. Thomas,[1] Alexander Gilbert.[1] *[1]MedStar Georgetown Transplant Institute, Washington, DC; [2]Georgetown University School of Medicine, Washington, DC; [3]Georgetown University Medical School, Washington, DC; [4]Washington Hospital Center, Kensington, MD.*

Background: Waiting times for transplant candidates are routinely presented to patients by transplant centers. However, with the increased complexity of the new Kidney Allocation System (KAS), these reported times may no longer be accurate for patients who do not qualify for higher allocation priorities. We aimed to quantify these differences.

Methods: We conducted a retrospective analysis of all deceased donor transplants at our center beginning December 4, 2014. We used data from UNOS to determine waiting time and the priority pool in which each kidney was allocated. Within each blood group we compared waiting times for recipients who received a kidney from a priority pool (including cPRA98%+; prior living donation; registration prior to age 18; and 0-20% EPTS) to recipients who received an organ allocated within a standard pool (local, regional, and national; blood type identical or permissible). Additionally, within the standard pool we compared waiting times for unsensitized (cPRA=0%) vs low-sensitization (cPRA 1-97%) recipients.

Results: Among the recipients were 121 blood group A, 74 group B, 16 group AB, and 160 group O. Standard patients experienced waits ranging from 7.1% to 18.4% longer than the mean waiting times for the entire ABO group. This equated to waiting times that ranged from 0.3 years to 1.2 years longer than the usually quoted times for their blood groups. When we looked at unsensitized patients the mean waiting times were even longer among group A, B and O patients- increased by 13.2%, 14.5%, and 29% respectively. For blood group O in particular, the mean waiting times were 2 years longer than the average time for the entire group.

Conclusions: Recipients who do not qualify for priority allocation can expect significantly increased wait times compared to the average time for the entire group which is what is most often quoted to patients. Factors such as sensitization, EPTS, and other priority characteristics must be considered in setting expectations for waiting time of individual patients.



PUB351

AKI in Liver Transplant Recipients: Is It Too Bad?

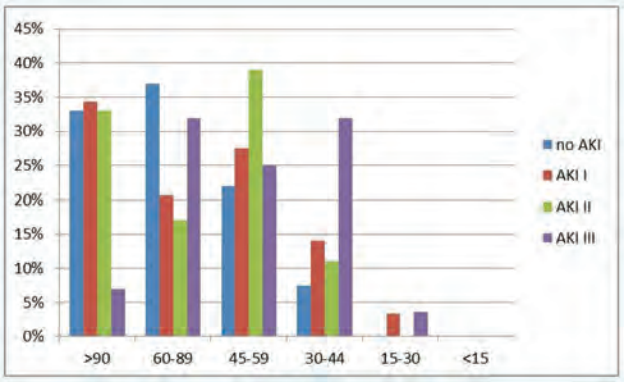
Rula A. Abdulrahman,[1] Venkatesh Kumar Ariyamuthu,[1] Bekir Tanriover.[2] *[1]UTSouthwestern, Dallas, TX; [2]UT Southwestern, Richardson, TX.*

Background: AKI after Orthotopic liver transplant (OLT) is a common complication with an incidence varying widely between 17-90%. It impacts patient survival, morbidity and duration of stay. We conducted a retrospective study in our institution is to identify predisposing risk factors and assess 1 year patient and renal outcomes after AKI in OLT recipients.

Methods: Data were collected from electronic medical record system for OLT recipients, between January 2015 to October 2017. Total 110 patients were included; age range was between 22 and 73 years. They were classified according to sex, race, presence of other co morbidities like hypertension, diabetes and the presence of micro proteinuria. GFR and creatinine were collected at the of transplant, 3 months, and one year after and compared to the base line. Patients were classified into AKI I, AKI II, AKI II and no AKI according to KDIGO criteria. Primary outcomes were chronic kidney disease (CKD), end stage renal disease (ESRD) and death within 1 year in patients who had AKI.

Results: Out of 110 patients; 8 died, 6 of them had AKI III (about 5% of total and 17.6% of the AKI III population). 34 patients had AKI III (31%), 22 (20%) of them required renal replacement therapy (RRT) (continuous renal replacement therapy and hemodialysis) during the perioperative time. None of them has required RRT at 3 months or at one year. 57% of the patients who had AKI III at the perioperative period, ended up with CKD III at 1 year, only 3.4% had CKD IV and none with CKD V at one year. Fig 1 shows relation between GFR at 1 year and AKI severity. Higher INR associated with more severe AKI, as well as alcoholic and HCV liver cirrhosis.

Conclusions: AKI during perioperative time in liver transplant recipients is very common, and might require RRT, although one year outcome remains good.



Relation between GFR at 1 year and AKI severity

PUB352

Potential Simultaneous Acute Tubular Necrosis and Immunological Rejections Following Renal Transplantation

Ina Kurbegovic-Skaljic,[1] Rabail Aslam,[1] David J. Cimbaluk,[1] Maria Oppermann,[2] Michele H. Prod,[1] Siva Kanangat.[1] *[1]Rush University Medical Center, Chicago, IL; [2]RUSH System for Health, Chicago, IL.*

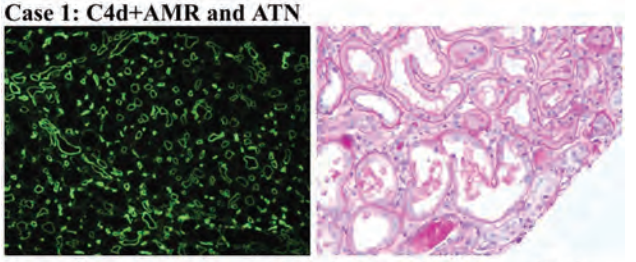
Background: To highlight the simultaneous occurrence of acute tubular necrosis (ATN), cellular and antibody mediated rejection (AMR) after renal transplantation (Tx). They constitute the bulk of renal allograft pathology and administration of appropriate therapeutics is essential based on specific causes for graft dysfunction

Methods: We evaluated 112 renal allograft biopsies with histological evidence of ATN for immunological rejections (IR) and conditions related to chronic rejections. The patients with a diagnosis of ATN and potential IR, or symptoms of chronic rejections were further analyzed based on detectable HLA and Non-HLA antibodies (Ab).

Results: Immunohistopathological findings revealed 35 cases with chronic rejection, 5 with C4d- AMR, 3 with C4d+AMR, and 3 with TCR. The C4d+ and C4d- AMR correlated with HLA donor specific antibodies (DSA). All patients had HLA DSA and >1 non-HLA Ab based on a panel of 33 non-HLA targets.

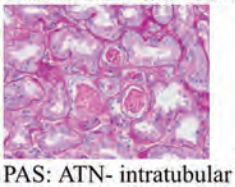
Conclusions: ATN and acute or chronic IR could co-exist. Cases with ATN and Type 1 AAMR based on staining for kidney injury molecule-1 have been reported previously. Also, Exfoliative Renal Tubular Epithelial Cells [ERTEC] bound to IgG have been found in ATN cases preceding clinical rejection. IgG bound ERTEC could indicate an early IR. ATN could lead to such immunological changes by exposing altered self-antigens or neoantigens leading to IR. Elaboration of these findings could help in development of novel therapeutics. ATN could lead to such immunological changes by exposing altered self-antigens or exposure of cryptic neoantigens leading to IR of the allograft. Elaboration of these findings could help in development of novel therapeutics.

Case 1: C4d+AMR and ATN



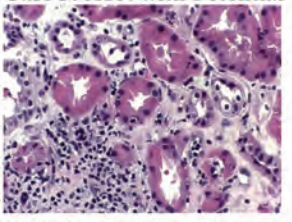
C4d-diffuse and strong positivity in the peritubular capillaries, consistent with acute AMR.
PAS: ATN- intratubular luminal debris, thinning of tubular epithelium (TE), loss of brush border (BB), mitotic figures in tubular epithelial cells (EC).

Case 2: ATN with no evidence of AMR or ACR

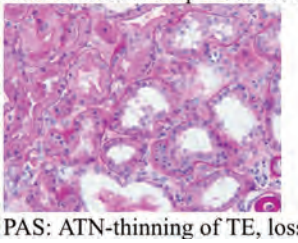


PAS: ATN- intratubular luminal debris, thinning of TE, loss of BB.

Case 3: ATN with Potential TCR



H&E: Features suspicious for ACR.



PAS: ATN-thinning of TE, loss of BB.

PUB353

Clinical Outcomes of High Kidney Donor Profile Index (KDPI) in Kidney Transplants

Khalid M. Elharrif, Farah Abifaraj, Omar S. Al-Taweel, Nidal Alhosainat, Syed A. Hussain, Ann Kathleen N. Gamilla-Crudo, Muhammad A. Mujtaba. *UTMB, Galveston, TX.*

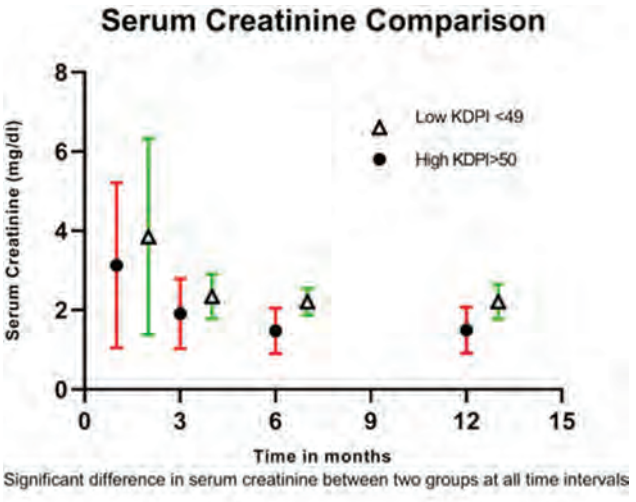
Background: KDPI score is designed to assess the expected kidney function in a kidney transplant recipient. Lower KDPI scores are associated with longer estimated allograft function. There is a high incidence of discard of high KDPI kidneys. However it is well proven that older patients on dialysis have high waitlist mortality and they may still benefit from a timely transplant utilizing this resource.

Methods: A retrospective review of prospectively collected data was conducted on 81 patients with deceased kidney donor transplants. Patients were divided into High KDPI (≥50, n=34) and Low KDPI (≤49, n=47) groups. Patient demographics, EPTS scores, serum creatinine at different time intervals, delayed graft function- DGF, and biopsy proven rejection were analyzed. A paired t-test was used for continuous variables and Fisher's exact test for categorical variable. P value of <0.05 was considered to be significant.

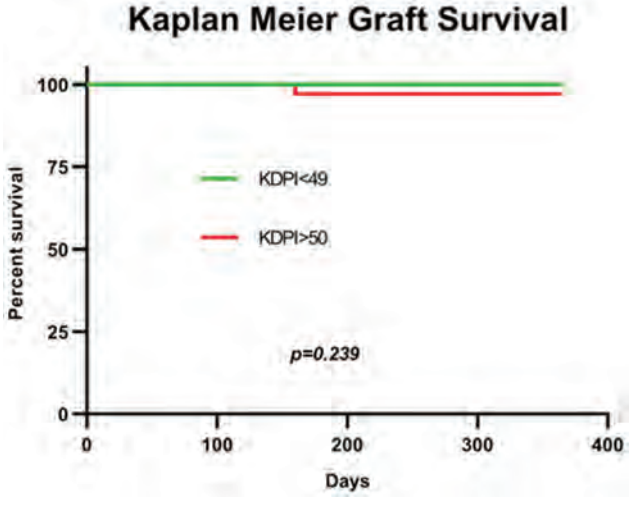
Results: Majority of recipients were Hispanic with mean age 54± 11. Median KDPI for low and high group was 22 and 64 respectively. One year Kaplan Meier Allograft survival and rejection rates were comparable between groups; however there was significant difference in DGF and serum creatinine favoring low KDPI group. Table and graph illustrate the result.

Conclusions: High KDPI kidneys have comparable short term survival and rejection rates to low KDPI kidneys with slight compromise of organ quality. Selective patient with high waitlist mortality may still benefit from a timely high KDPI kidney transplant.

	Low KDPI n=47 (≤49)	High KDPI n=34 (≥50)	P Value
EPTS score	34	44	0.091
DGF	1	8	0.0035
Rejection	12	9	1.0
Serum Creatinine at 1 year	1.21+0.44	1.49+0.58	0.026



Significant difference in serum creatinine between two groups at all time intervals



PUB354

A 10-Year Review of Laboratorial Tests Abnormalities in Renal Transplant Patients with Detectable Cytomegalovirus Viral Load

Maria N. Pestana,[1] José Alves,[2] Ana F. Gomes da silva,[4] Pedro M. Vieira,[3] Luis Resende,[5] Miguel Goncalves,[5] Gil Silva.[6] *[1]Hospital Central Funchal, Funchal, Portugal; [2]Clinical Pathology Department, Serviço de Serviço de Saúde da Região Autónoma da Madeira, Funchal, Portugal; [3]Centro Hospitalar do Funchal – Hospital Dr. Nélio Mendonça, Funchal, Portugal; [4]Nephrology Department, Hospital Dr. Nélio Mendonça, Funchal, Portugal; [5]Hospital Central do Funchal, Funchal, Portugal; [6]Hospitalal Central do Funchal, Funchal, Portugal.*

Background: Cytomegalovirus (CMV) is one of the most frequently detected viruses in renal transplant recipients. Clinical manifestations of CMV infection are frequently nonspecific contributing to the difficulty of a quick diagnosis. CMV viral load is an independent risk indicator for CMV disease.

Methods: We conducted a retrospective study which enrolled the total population of renal transplant recipients. Unique CMV DNA molecular test requests were selected between 2009 and December 31st2018, using the Laboratory System Modulab® Werfen v3.0. Positive CMV viral load was agreed at >250 copies/mL. Parallel hematological, biochemical and molecular microbiology ldata were retrieved in positive requests.

Results: Total transplant recipient population was composed by 71 unique patients (49 males (66.1%) and 21 females (33.9%). Patient mean age was 48,3 years (±11,8). 245 Unique CMV DNA molecular test requests were found, with 170 requests (62 unique patients) presenting with CMV DNA viral load >250 cp/mL ((min 263; max 590000; mean 262). The most frequently found hematological abnormality was lymphopenia <1500 u/L (60,1% requests) followed by leucopenia <4500u/L in 28,2% unique requests. Thrombocytopenia <150000u/L was found in 17,1% of the requests. The most frequently found biochemical abnormality was high serum creatinine >1,5mg/dL (46,7%). The most strong positive correlation of all the hematological and biochemical tests and CMV viral load was found between glutamate-oxaloacetate transaminase (GOT) andCMV viral load and (R=0,47). Correlation analysis between glutamate-pyruvate transaminase and CMV viral load showed a very weak correlation (R=0,0026). We also observed that a small patient subgroup (n=6) had simultaneous positive plasma CMV DNA and urinary BKV DNA with a common CMV viral load >500cp/mL.

Conclusions: Subtle laboratory abnormality patterns work as important tools to the suspicion of CMV infection. This work shows that CMV infection must be remembered as a possible diagnosis in patients presenting with lymphopenia, leucopenia, and rise of liver enzymes, particularly GOT, which in this study raised significantly and proportionally to the CMV DNA viral load.

PUB355

Effect of De Novo Donor-Specific Antibodies (DSA) on Graft Function in Renal Allograft Recipients

Anil Bhalla,[1] Ravi K. Singh,[1] Ashwani Gupta,[1] Devinder S. Rana,[1] Manish Malik,[2] Anurag Gupta,[1,3] Vinant Bhargava.[1] *[1]Sir Ganga Ram Hospital, New Delhi, India; [2]Sir Ganga Ram Hospital and GRIPMER, New Delhi, India; [3]SYNEGY Hospital, Uttarakhand, India.*

Background: The availability of potent immunosuppressive agents has decreased acute cellular rejection rates, however, chronic deterioration of graft function continues to be a clinical challenge. Chronic Antibody-mediated rejection (cAMR) is an important cause of allograft failure in renal allograft recipients. cAMR is caused by the development of antibodies that do not preexist but develop after transplantation. These antibodies are directed against (foreign) graft HLA class I and II antigens and are known as de novo donor specific antibodies (DSA). DSA lead to allograft injury through complement-dependent or complement independent mechanisms resulting in glomerulitis, peritubular capillaritis, and transplant glomerulopathy. Routine immune monitoring of HLA antibodies can be used to guide immunotherapy and permit early intervention.

Methods: Prospective Observational Study. Patients undergoing renal transplant at Sir Ganga Ram Hospital in 2017 were screened for pre transplant DSA. A total of 72 DSA negative pre transplant patients were followed for 18 months. Clinical characteristics of patients were noted. DSA was tested at 6, 12 and18 months post transplant.

Results: Total of 72 patients were included. de novo DSA negative patients (N=63) with mean age 40.73 years (SD=13) and de novo DSA positive patients (N=9) with mean age 34.66 years (SD=6.61). At 18 months, serum creatinine mean (SD) of de novo DSA negative patients was 1.41mg/dl (0.42) while for de novo DSA positive was 1.27mg/dl (0.38), p-value 0.552. eGFR, mean (SD) at 18 months in de novo DSA negative group was 58.2 (19.03) 6ml/min/1.73sq m and in de novo DSA positive 56.47 (22.83) ml/min/1.73sq m, p-value 0.798. Tac levels(SD) at 18 months, in de novo DSA negative patients was 6.87 (2.29) ng/ml while in de novo DSA positive group, it was 6.05 (1.59) ng/ml. Urine protein creatinine ratio (SD) at 18 months in de novo DSA negative group was 0.30 (0.82) while in de novo DSA positive group, it was 0.31 (0.30).

Conclusions: De novo DSA developed in 12.5% of Patients after 18 months post transplant. There is no significant graft dysfunction at the time of appearance and a trend is noted of younger age and lower TAC levels in these de novo DSA patients.

PUB356

Time Trends in Kidney Transplantation in South Korea: A Nationwide Cohort Study from 2007 to 2015

Sehoon Park, Ji Eun Kim, Yong Chul Kim, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Detailed nationwide information regarding recent status and time-trends of kidney transplantation in South Korea is limited.

Methods: We performed a nationwide, population-based cohort study using the national claims database of Korea in which nationwide health insurance is provided. We included kidney transplant recipients under age 70 from 2007 to 2015 and their demographic and clinical characteristics were collected. The prognostic variable was death-censored graft failure, and graft failure was determined when patient returned to maintenance dialysis.

Results: Number of kidney transplantation showed increasing trend, and the number increased from 820 in 2007 to 1755 in 2015. The incidence proportion of kidney transplantation among end-stage renal disease patients under age 70, which was below 3% in 2007, reached approximately 4% in 2015. The median age of the kidney transplant recipients consistently increased from the past, and proportion of patients with underlying diabetes mellitus was prominently increased, reaching 42.1 % in 2015. The dialysis duration before transplantation was significantly increased, and in 2015, about 35.2 % kidney transplantation was performed after more than 5 years of dialysis, which was 9.6% in 2007. Regarding maintenance medication usage, proportion of patients who were prescribed with tacrolimus greatly increased, while cyclosporine was less frequently used. One-year maintenance immunosuppressive medication possession ratio was consistently increased from the past. Transplantation-related costs was greatly increased during the

study period, particularly regarding government coverage, whilst patient burden for insured costs were decreased from the past. Overall prognosis of kidney transplantation was improved in the recent periods, reaching approximately 80% 10-year graft survival in the recent periods.

Conclusions: Kidney transplantation is becoming a more prevalent modality of renal replacement therapy. While old-age transplantation is becoming more common, prognosis has been generally improved, but related insured costs were increasing prominently.

PUB357

Variability in Blood Tacrolimus Levels with Generic Immunosuppression in Kidney Transplant Patients in Western Mexico

Alejandro Garcia Rivera,[1] Omar H. Sanchez Vazquez,[1] Ana L. Garcia-Vera,[1] Renato Parra Michel,[2] Caridad Leal,[3] Jorge fernando Topete reyes,[4] Leonardo Pazarin-Villaseñor,[3] Isela Márquez magaña,[1] Mario A. García Cárdenas.[5] *[1]Instituto Mexicano del Seguro Social, Zapopan, Mexico; [2]Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Hospital General Regional No.46, Instituto Mexicano del Seguro Social., Zapopan, Mexico; [3]IMSS, Guadalajara, Mexico; [4]Universidad de Guadalajara, Aguascalientes, Mexico; [5]Universidad de Guadalajara, centro univesitario de ciencias de la salud, Instituto mexicano del seguro social, Hospital General Regional 46, Guadalajara, Mexico*.

Background: Tacrolimus is recommended as first-line therapy in most kidney transplant protocols. It has a narrow therapeutic index and routine blood levels monitoring is required to assure its effectivity and to limit its toxicity. In our center, kidney transplant patients receive generic immunosuppression and are subject to frequent changes in generic brands of tacrolimus. There are few studies regarding the variability of blood tacrolimus levels according to tacrolimus generic formulations

Methods: Retrospective observational study. Electronic medical records of kidney transplant patients greater than one year and in immunosuppressor treatment with tacrolimus were reviewed, and blood tacrolimus levels, tacrolimus generic brand, daily tacrolimus dose and weight dose was registered. Tacrolimus levels were also compared to CYP3A5 polymorphisms

Results: A total of 84 patients whose electronic medical records were complete (tacrolimus dose, blood tacrolimus levels, and tacrolimus brand) were included. 57 (67.8%) of those patients had Limustin, 20 (23.8%) were receiving Pisa, and 7 (8.3%) had Akrocell. Daily tacrolimus dose and tacrolimus weight dose was similar between groups. Mean blood tacrolimus levels were 6.28 ng/mL for Limustin, 7.08 ng/mL for Akrocell and 8.51 ng/mL for Pisa, with a significant statistical difference and a p value of 0.006. We found no significant difference between cytochrome CYP3A5 polymorphisms distribution, thus the differences in the blood tacrolimus levels cannot be attributed to differences in liver metabolism of the drug.

Conclusions: There is variability between different generic brands of tacrolimus regarding blood tacrolimus levels. They are lower in Limustin brand, despite a similar daily and body weight dose compared to other groups, which is not explained by differences in liver metabolism of the drug. The long term effect that this could cause is not known. Blood tacrolimus levels should be monitored frequently, especially if brand changes are often made.

Variable	Tacrolimus brand			p
	Akrocell	Limustin	Pisa	
Patients	7	57	20	n= 84
Blood tacrolimus levels (ng/mL)*	7.08	6.28	8.51	0.006
Daily tacrolimus dose (mg/día)*	4.14	4.54	4.15	0.582
Weight dose (mg/kg/day)*	0.065	0.066	0.063	0.938

*Values are shown as means. Analysis between groups was made with ANOVA and T3 Dunnett test was used as a post-hoc test.
A result was considered as statistically significant if p<0.05.

PUB358

Practical Utility of Various Scores for the Evaluation of Deceased Donor Kidneys

Florian G. Scurt,[1] Peter R. Mertens,[1] Hermann G. Haller,[3] Christos D. Chatzikyrkou,[1] Jan U. Becker.[2] *[1]Otto von Guericke University Magdeburg - Medical Faculty, Magdeburg, Germany; [2]University Hospital Cologne, Köln, Germany; [3]Clinic for Nephrology, Hannover Medical School, Hannover, Germany*.

Background: Marginal organs have been associated with inferior graft and patient outcomes and several scores have been proposed for the evaluation of deceased donor kidneys in order to facilitate the best possible allocation combination and to improve graft and patient survival. We retrospectively validated their performance in predicting outcomes in donor kidney evaluation biopsies.

Methods: We retrospectively evaluated the records of 223 consecutive adult cadaver renal transplant recipients with donor evaluation biopsies. Taking into account donor and recipient clinical data and graft histopathology, we performed a retrospective explorative univariate analysis of graft function at 3 and 12 months and 1- and 3-years graft and patient survival for the following scores: Navarro (2011), Ortiz (2004), Balaz (2013), Lopes (2004), Snoeijs (2008), Remuzzi (1999), Nyberg (2003), Rao (2009), Foucher (2009), Schold (2005), Port (2002), Anglicheau (2008), 3-year-Leuven (2013), Irish (2010), KDRI/KDPI and EPTS.

Results: In our cohort of 223 patients, for 3- and 12-month graft function most of the scores performed well; performance for 1- and 3-year graft survival was best for combined clinico-pathological scores like 3-year-Leuven (p=0.032 and p=0.008, respectively). For one-year patient survival, combined clinico-pathological scores like 3-year-Leuven (p<0.001) and Anglicheau (p=0.016) performed as well as the purely clinical scores like KDRI (p=0.001), Rao (p<0.001) or Nyberg (p=0.001).

Conclusions: Composite scores which also consider graft histology like 3-year-Leuven, Rao and Nyberg seem to be better suited to predict graft survival than purely clinical scores. For the prediction of patient survival, graft histology does not matter as much. These scores should be tested for their performance in a prospective multicentric study design.

PUB359

Severe Allograft Rejection Requiring Allograft Nephrectomy in a Renal Transplant Patient After One Dose of Pembrolizumab

Natalie Smith,[1] Sandeep A. Padala,[1] Muhammad I. Saeed,[4] Imran Y. Gani,[3] Rajan Kapoor.[2] AU transplant *[1]Augusta University, Augusta, GA; [2]Augusta University / Medical College of Georgia, Augusta, GA; [3]SELF, Augusta, GA; [4]Augusta University Medical Center, Augusta, GA.*

Introduction: There is a high risk of kidney transplant rejection with Anti-PD-1 Monoclonal Antibody, Pembrolizumab (Keytruda) use. We presented a case of patient needing renal allograft nephrectomy for severe allograft rejection after one dose of Pembrolizumab

Case Description: 46-year African American Female with past medical history significant for ESRD secondary to HTN underwent DDKT. Ten years after transplant she got diagnosed with moderately differentiated endometrial adenocarcinoma. PET-CT showed tumor invasion to the uterus, cervix, vagina, metastatic regional lymphadenopathy and distant lung metastasis. Diagnosis of Stage IV-B grade 2 endometrioid endometrial cancer and she underwent 6 cycles of Carboplatin/Paclitaxel along with debulking surgery. Follow-up CT after completion showed increasing size of iliac chain lymph nodes concerning for worsening disease. Decision to start Pembrolizumab was made and first dose of Pembrolizumab was given with a baseline creatinine of 1.3-1.5mg/dl. Two weeks after the dose she was admitted with severe, acute onset right lower quadrant pain with low-grade fevers with a creatinine of 3.2 mg/dl. Her creatinine rose to 8.2 mg/dl within 48 hours of admission. Due to high degree of suspicion for renal allograft rejection she was started on high dose of IV steroids. Patient progressively became anuric and became dialysis dependent. She required two more admissions for recurrent severe pain over her transplant allograft site, hematuria and low grade fever. Her renal transplant ultrasound showed an increase of the size of allograft to 14 cm [as compared to 11 cm 3 weeks back], with more echogenicity and now with new hydro-ureteronephrosis. Given her recurrent severe allograft pain, persistent low grade fevers and increase in the size of a renal transplant allograft, she required a transplant nephrectomy for refractory allograft rejection. The gross allograft nephrectomy specimen showed an enlarged, mottled, necrotic and hemorrhagic kidney.

Discussion: A risk-benefit analysis must be completed prior to initiation of therapy and if the benefit of using Pembrolizumab outweigh the risks, only then this immunotherapy must be considered. To the best of our knowledge, this is the first case of severe recurrent rejection of renal transplant allograft requiring an allograft nephrectomy.

PUB360

Incidence and Clinical Consequences of Immunosuppressant Cessation in Kidney Transplant Recipients: A Single-Center Experience

Kyung Don Yoo, Kyung sun Park, Jongha Park, Jong Soo Lee. *Ulsan University Hospital, Ulsan, Seoul, Republic of Korea*.

Background: Immunosuppression agents are essential for maintaining allograft survival in kidney transplantation (KT). But some patients become non-adherent to immunosuppressant due to misunderstanding of patient, socioeconomic or psychological factors, and little has been known about clinical implication of these cases.

Methods: This is a retrospective analysis of KT cases of single center from 1998 to 2016. Patients who had completely stopped taking the immunosuppressants for more than six months and who were regularly followed up at our center were defined as medication non-adherence (MNA) group and included for final analysis.

Results: During the mean follow-up period of 63.9 months, 8 patients of total 354 KT recipients (2.3%) were included in MNA group. The mean age of the MNA group was 30.2 ± 7.1 years, and that of the control group was 45.3 ± 12.3 years (p <0.001). The number of HLA mismatch was 2.0 ± 1.0 for the MNA group and 3.4 ± 1.5 for the control group (p = 0.013). During the follow-up period, 13 cases of graft failure (GF) occurred from the control group, whereas from the MNA group, 7 out of 8 patients experienced GF. The mean duration from transplantation to GF of the MNA group was 84.7 months. The patients' death did not occurred from the MNA group. In multivariate Cox regression analysis, MNA was a definite independent risk factor after adjustment for confounders (HR 24.6, 95% CI 4.9-123.1).

Conclusions: Arbitrary withdrawal of immunosuppressant was clarified for the most important risk factor for allograft loss in KT recipients. Further research is warranted for the perspective of patient-oriented mechanism of medication non-adherence.

PUB361

Impact of Delayed Graft Function over Allograft Survival and Long-Term Kidney Outcomes After Transplantation in a Peruvian Hospital 2012-2017

Juan E. Rodriguez, Denese C. Mego. *Hospital Nacional Alberto Sabogal Sologuren, Essalud, Lima, Peru.*

Background: Delayed graft function (DGF) is an early complication in kidney transplant recipient, defined as the hemodialysis requirement during the first week after transplantation. Some studies have found that DGF is associated to less allograft survival and worse long term kidney function. The primary outcome is to analyze the impact of DGF over allograft survival and kidney outcomes after one year after transplantation.

Methods: Retrospective study identified 71 adult patients, deceased-donor, kidney-only transplant recipients between 2012 and 2017. We used comparative studies using Chi Square test and T-student test. All of the statistical analysis were realized by the SPSS program. We compared cold ischemia time (CIT) and DGF with allograft survival using a multivariable linear probability Cox model.

Results: The average age of patients was 43.34 years (19-68 years), most of them from male gender. The principal cause of renal chronic disease was unknown (57.7%), followed by glomerular disease (9.9%) and Diabetes (7%). The average age of donors was 41.8 years, most of them male gender and the main cause of brain death was stroke. The serum donor creatinine (srCr) before transplant was around 1.18mg/dl (0.39-2.7mg/dl). The average of CIT was about 17.7 hours (9-26 hours). In the early transplant, four patients didn't have kidney function, 15 patients had DGF and 52 patients had immediately kidney function(IKF). As main causes of DGF were acute rejection and acute tubular necrosis (ATN). T-student test shown an average of srCr at one year after transplant around 1.2mg/dl in recipients who had IKF and 1.59mg/dl in recipients with DGF (P=0.54). Chi square test shown that recipients who had DGF had an OddsRatio in 3.9 (IC 1.07 – 14.45) to achieve a srCr over 1.5mg/dl in a year after transplant in contrast with recipients who had achieved an IKF after transplant (P= 0.032). We applied a probability model by Cox and determined a graft kidney survival of 98% in a year, 96% in three years and 94% in five years. There was not an important relation between DGF and CIT with graft survival.

Conclusions: Delayed graft function is an important negative risk factor for an optimal graft function. We could not find a significative relation between DGF, CIT and graft survival.

PUB362

Women Compared with Men on Maintenance Hemodialysis Exhibit Unique Biomarker Patterns

Aleksander D. Druck,[1] Dimpi Patel,[1] Arjun S. Grewal,[1] Vinod K. Bansal,[1,2] Debra Hoppensteadt,[1,2] Jawed Fareed.[1,2] *[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL; [2]Loyola University Medical Center (LUMC), Maywood, IL.*

Background: Patients with end-stage renal failure on maintenance hemodialysis (MH) have higher mortality risk compared to the general population. Understanding of these unique mortality risk factors have not been fully explored by gender. The objective of this study was to examine unique biomarkers by gender and ethnicity in a cohort of MH patients compared to normal controls.

Methods: 92 MH patients in a single hospital-based dialysis unit in December 2017 consented with IRB approved protocol. Whole blood samples were drawn pre-dialysis into 3.2% sodium citrate; citrated plasma samples processed using ELISA for selected biomarkers: BMP-7 (bone morphogenetic protein 7), MPO (myeloperoxidase); IL-6 and IL-8 (proinflammatory cytokines), CTX-1 (C-terminal collagen telopeptide) and OPN (osteopontin glycol-phosphoprotein). Data compared as mean ± SD by gender and gender/ethnicity; p-value trends reported due to small sample size/low statistical power.

Results: Mean age 60.5 ± 13.3 Yr (range 20-88); BMI 29.1 ± 5.4. Significant differences were seen between controls and MH patients for all biomarkers. No differences seen by gender for all other biomarkers except BMP-7 and MPO. Gender difference by ethnicity only seen in African Americans.

Conclusions: Women had higher MPO and lower BMP-7 levels compared to men. This difference remained when African American women were compared to African American men but less pronounced in low sample size of Caucasians. Patterns of biomarkers, particularly BMP-7 and MPO, were unique between genders. Patterns were also seen within ethnicity but small sample size reduced statistical power to examine further. BMP-7 may be associated with adynamic bone disease and has also been known to reduce vascular calcification in uremic animal models. MPO may infer inflammatory status. The significance in MH population, particularly significance or relevance of pattern, is unknown and requires further investigation.

Funding: Other NIH Support - This project was supported by the T35 AI125220 student training grant from the National Institute of Allergy and Infectious Diseases (NIAID) of the National Institutes of Health (NIH).

	N	BMP-7 (pg/mL)	N	MPO (pg/mL)

Maternal and Fetal Outcomes of CKD Pregnancy on Mexican Patients

Victoria G. Maldonado Gomez, Diana Ramirez-Flores, Milagros M. Flores Fonseca, Adriana Banda Lopez, Salvador Mendoza Cabrera, Benjamin Gomez-Navarro. *IMSS, HECMNO, Zapopan, Jalisco, Mexico.*

Background: Women with CKD have higher rates of miscarriage and more challenges to achieve better fetal and maternal outcomes, compared with general population. The effect of pregnancy on renal disease accelerates the irreversible decline of GFR and progress to ESRD, increasing maternal mortality and the incidence of cesarean deliveries. We conducted a retrospective review with the purposed to assess clinical maternal and fetal characteristics and outcomes of CKD during pregnancy.

Methods: We analyze a single center retrospective review of pregnant women with CKD of 17 Mexican patients. Baseline maternal information, demographics, clinical and biochemical data were reviewed. Gestational age of pregnancy loss or delivery was recorded. Outcomes maternal, birth weight, prematurity, Apgar, neonatal UCI admission and fetal death. Statistical analysis was done with SPSS version 26.0. The categorical variables were analyzed using chi-square test or Fisher's exact probability test, as appropriate. The continuous variables were analyzed using the Student's t test. A value of $p < 0.05$ was regarded as statistically significant.

Results: Mean age was 28.00±5.48 years. The mean duration of CKD as 57.07±57.12 months. 5 patients were diagnosed with CKD during pregnancy. 12 patients were nulliparous and 5 patients were multiparous. We observed significant correlation between pregnancy onset and conception in thrombocytopenia (r=0.651) and serum creatinine (r=0.448). Mean gestational age at delivery was 35.36±2.99 weeks. Average weight was 1.78 ± 0.66 g. Fetal live birth rate was 76%. We compare stillbirth pregnancies with live birth pregnancies on Table 1.

Conclusions: This was the first study that evaluated CKD during pregnancy and its results. Our findings correlate with other studies, but further studies are need that evaluate counseling before, during and after conception in pregnant women with CKD which could achieve better results for the binomial.

Table 1. Comparison of still birth pregnancies and live bith pregnancies

	Still birth pregnancies	Live birth pregnancies	P
Age (years)	34.00 ± 9.64	27.23 ± 3.09	0.002
Weight before pregnancy (kg)	71.33 ± 21.94	60.23 ± 9.01	0.024
Timing before CKD (months)	17.00 ± 26.85	74.40 ± 58.06	0.060

PUB364

Preconception Care in Patients with Chronic Autoimmune Diseases of the Kidneys Treated with Immunosuppressants

Magdalena B. Kaziuk. *Chair and Department of Nephrology and Transplantology, Jagiellonian University Medical College, Krakow, Poland.*

Background: Chronic autoimmune diseases of the kidneys treated with immunosuppressants pose a great threat to the life of the mother and foetus. The best solution is to get pregnant at the time of remission or the use of immunosuppressants at a maintenance dose. Evaluate the dependence between pre-conception care and its lack on the clinical condition of the patient suffering from chronic kidney diseases, who got pregnant.

Methods: The study covered 40 women aged 20-40 who got pregnant while suffering from a chronic autoimmune disease of the kidneys (25 patients with chronic glomerulonephritis, 10 patients with diagnosed lupus nephritis (LN) and the remaining ones with rheumatoid arthritis and antiphospholipid syndrome).

Results: Pregnancy was unplanned in 17 women with glomerulonephritis and 6 with lupus nephritis. The remaining patients used full pre-conception care. Statistically significant dependence was observed between the unplanned pregnancy with incorrect clinical values (creatinine>1mg%, protein in urine>0.5 g/day, arterial hypertension, large doses of immunosuppression) on the presence of renal failure in women in the period from 3 months to 2 years after delivery ($p<0.001$). Women without pre-pregnancy preparation, without previous consultation or nephrological preparation delivered prematurely by Caesarean section ($p<0.005$).

Conclusions: Pregnancy in patients with chronic diseases of the kidneys without proper pre-conception care and constant nephrological and gynaecological monitoring constitutes a great threat to the life of the mother and child.

PUB365

Nontraumatic Unilateral Renal Artery Dissection with Renal Infarcts

Ravi K. Thimmisetty,[1] Zeenat Y. Bhat,[2] Yahya M. Osman Malik.[3] *[1]Nephrology, Cape Girardeau, MO; [2]Wayne State University, Detroit, MI; [3]Wayne State University Medical School, Detroit, MI.*

Introduction: We are presenting a case of unilateral right renal artery dissection with renal infarcts managed conservatively

Case Description: 32 year old Caucasian female without any prior medical history presents to the ER with a chief complaint of right lower quadrant abdominal pain, sudden in onset, sharp in nature and radiating to right flank. Denied any urinary symptoms including increased urinary frequency, dysuria or hematuria. She is an active smoker and takes daily birth control pill (estrogen and progesterone). Vitals showed temperature of 97.4 °f, blood pressure 114/75, respiratory rate of 20 per min, saturating 99% on room air.

Abdominal exam showed soft, non–tender, no costovertebral angle tenderness. Rest of the exam is with in normal. Labarotary results showed sodium 137, potassium 4.1, chloride 100, bicarbonate 24, creatinine 1.15 mg/dl, calcium 9.4 mg/dl. Rest of the labs were within normal limits. Urinalysis showed specific gravity >1.06, Ph 7.0, negative blood, negative nitrite, 50 to 100 squamous epithelial cells. CT scan of abdomen with IV contrast showed focal area of nonenhancement in the right kidney highly suggestive of an infarct. Right renal arteriogram showed dissection within the distal right renal artery just proximal to the bifurcation of uncertain etiology and multifocal infarct of the right kidney likely embolic in etiology. Echocardiogram showed mild positive bubble study. Hypercoagulable work up came to be negative. Patient was managed conservatively and discharged on apixaban

Discussion: Literature on Unilateral renal artery dissection is quite scanty. Isolated Renal artery dissection poses a diagnostic and therapeutic challenge to physicians. Not sure if this is an early sign of rare presentation of fibromuscular dysplasia or occult embolic infarction. Need more cases for better understanding pathophysiology and efficient treatment

PUB366

Potassium Binders for Chronic Hyperkalemia in People with CKD: A Cochrane Review and Meta-Analysis

Patrizia Natale,[1,2] Suetonia Palmer,[3] Marinella Ruospo,[1] Valeria M. Saglimbene,[1,4] Giovanni F. Strippoli.[1,2] *[1]Diaverum, Lund, Sweden; [2]University of Bari, Bari, Italy; [3]University of Otago, Christchurch, New Zealand; [4]University of Sydney, Sydney, NSW, Australia*.

Background: Hyperkalemia is a common electrolyte abnormality in patients with chronic kidney diseases (CKD). Sodium polystyrene sulfonate (SPS) and calcium polystyrene sulfonate (CPS) are widely used but may cause severe gastrointestinal symptoms. Patiromer and sodium zirconium cyclosilicate (ZS-9) are newer potassium binders which may cause fewer gastrointestinal side-effects. This Cochrane systematic review evaluated the benefits and harms of potassium binders for treating chronic hyperkalemia among people with CKD.

Methods: We searched the Cochrane Kidney and Transplant Register of Studies for randomized controlled trials (RCTs) evaluating potassium binders for chronic hyperkalemia administered in adults and children with CKD. We categorized treatments as newer agents (patiromer or ZS-9) and older agents (SPS and CPS) in separate analyses for some outcomes. Two authors independently screened citations for eligibility, extracted data, and assessed risk of bias using the Cochrane tool. Evidence certainty was evaluated using GRADE.

Results: Twelve studies (1340 participants) were eligible. Medial trial duration was 3.5 weeks (range 12 hours to 52 weeks). There were no trials that evaluated treatment in children. Mean study age ranged from 53 to 73 years. Risks of bias were generally high or uncertain. Seven studies (774 participants) compared a potassium binder to placebo. Patiromer or ZS-9 had uncertain effects on all-cause mortality (relative risk [RR] 0.32, 95% CI 0.01, 7.57). The treatment effect of older potassium binders on all-cause mortality was very unclear, and no study reported outcome data for cardiovascular mortality. Potassium binders had uncertain risks of nausea (RR 2.10, 95% CI 0.65, 6.78), vomiting (RR 1.72, 95% CI 0.35, 8.51), diarrhea (RR 1.03, 95% CI 0.24, 4.51), and constipation (RR 1.68, 95% CI 0.65, 4.37).

Conclusions: Evidence for different potassium binders to treat chronic hyperkalemia in people with CKD is of low certainty due to serious imprecision and trial methodological limitations. This review suggests the need for a large, adequately powered trial of potassium binders versus placebo that assesses clinical outcomes such as cardiovascular mortality, cardiac arrhythmias, health-related quality of life, and major gastrointestinal symptoms.

PUB367

Risk Factors for Hospitalization and Critical Illness in CKD

Jefferson L. Triozzi, Jingbo Niu, Carl P. Walther, Wolfgang C. Winkelmayer, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX*.

Background: Chronic kidney disease (CKD) is a known risk factor for hospitalization. Specific predictors of hospitalization with critical illness among patients with non-dialysis-dependent CKD are unclear.

Methods: A retrospective cohort study was conducted among patients ≥ 18 years of age with CKD in a CKD registry from a safety net health system. Patients with CKD stage 5 (eGFR < 15 mL/min) were excluded. We obtained baseline characteristics including details of insurance and medical comorbidities. Details of hospitalization events were obtained during a three year period after the diagnosis of CKD. Poisson regression was used to determine associations between baseline characteristics and 1) the number of hospitalization days and 2) the number of hospitalizations requiring intermediate or intensive level of care. Analysis was stratified by CKD stage and adjusted for baseline characteristics.

Results: Among 8,302 patients with CKD (1/1/2011 and 7/30/2015), 1,298 patients (15.6%) were hospitalized during a 3-year follow-up period. Factors associated with increased incident rate ratio of hospitalization days among all stages of CKD include: congestive heart failure [3A: 2.6 (2.2, 3.1), 3B: 1.8 (1.5, 2.3), 4: 1.3 (1.0, 1.8)], cardiovascular disease [3A: 1.2 (1.1, 1.5), 3B: 1.4 (1.1, 1. 7), 4: 1.7 (1.3, 2.3)], mild anemia [3A: 1.6 (1.4, 2.0), 3B: 1.8 (1.4, 2.2), 4: 1.6 (1.1, 2.3)], and moderate/severe anemia [3A: 4.2 (3.1, 5.7), 3B: 4.3 (3.3, 5.6), 4: 2.3 (1.5, 3.3)]. Factors associated with increased incident rate ratio of hospitalization with critical illness include: congestive heart failure [3A: 3.8 (3.1, 4.5), 3B: 1.5 (1.2, 1.9), 4: 1.5 (1.0, 2.0)] and moderate/severe anemia [3A: 3.6 (2.9, 4.6), 3B: 4.1 (2.9, 5.7), 4: 2.0 (1.2, 3.4)].

Conclusions: Among patients with non-dialysis dependent CKD, congestive heart failure and anemia are associated with a higher risk of hospitalization with critical illness and with longer hospitalization stay. Targeted, effective interventions to reduce the hospitalization burden in CKD patients with heart failure or anemia is needed.

PUB368

Prevalence of Frailty in Nephrology Patients and Impact of Socioeconomic Factors

Melanie Betz,[1] Arlene B. Chapman,[1] Saurabh Chawla,[1] Sai prasad Gadapa,[2] Samantha Gunning,[2] Nevin Murthy,[1] Javeria F. Syed,[1] Victoria T. Vo.[1] *[1]University of Chicago Medicine, Chicago, IL; [2]University of Chicago, Chicago, IL*.

Background: Frailty is common among patients with CKD. Frailty compromises the ability to recover from illness and stressors, putting patients at risk for poor health outcomes. Little research has been done to describe the prevalence of frailty in a non-dialysis CKD population or investigate the impact of socioeconomic factors.

Methods: Frailty was assessed using the Frailty Phenotype (FP) for patients aged 65 years or more in a nephrology clinic at an urban medical center. The FP was administered by Nephrology fellows or a Registered Dietitian. Socioeconomic factors were obtained from zip code census data.

Results: Analysis included 56 patients with a mean age of 75±8 years, BMI of 28.7±7.2kg/m^2 and GFR of 35±17ml/min; 54% were female, 79% were black and 75% lived in high poverty areas. Only 20% were found to be non-frail, whereas 55% were pre-frail and 25% were frail/very-frail. Females, patients with a lower GFR, lower median household income or living in a high poverty area were more likely to be frail. Reduced physical activity was the most common frailty factor; weight loss was the least common.

Conclusions: Frailty is prevalent among adults over 65 years in a nephrology clinic. Frailty is more common in patients with low income. Frail patients present unique challenges with diet recommendations and medications to help prevent malnutrition, hypotension, hypoglycemia and falls. More research is needed to determine interventions to reduce frailty and improve outcomes.

Demographics & Clinical Characteristics by Frailty Level

	All Patients	Robust	Pre-Frail	Frail/Very Frail	p-value

Targeted Program Designed to Address Missed Follow-Ups on Abnormal Tests: A Proposal for Population Health Partnership

Junqiao Chen,[1,2] Michael R. Udwin,[2] Yisheng Chiang,[2] Michael H. Kanter.[3] *[1]ISCTE-IUL, Lisboa, Portugal; [2]Evolent Health, Arlington, VA; [3]Kaiser Permanente, Pasadena, CA.*

Background: Chronic kidney disease is not always identified and managed in an optimal and timely manner. A single abnormal creatinine measurement embodies the challenges of reliably following up abnormal laboratory test results. The Kaiser Permanente creatinine safety program has demonstrated its feasibility in an integrated health system to close the loop on a large cohort of patients. However, when we tested Kaiser's program design within a population health partnership (an external organization contracted for value-added services), modification was required to better engage physicians and utilize limited resources.

Methods: Literature research and meetings with experts experienced in population health.

Results: The modified program re-purposes the business value proposition, from improving patient safety and avoiding malpractice claims, to increasing risk adjustment (RAF) revenue and reducing care gaps. Because a population health organization typically has no access to electronic health record, the Kaiser's method (a nurse ordering a test for a physician to sign) would not work. We propose using population health managers to engage physicians during visits to the practices. When appropriate, we propose the integration of this information into RAF, patient outreach and care management workflows. To identify a manageable cohort of patients and reduce alert fatigue for physicians, we propose the focus be on patients at high risk for renal disease per predictive model and those who have experienced an event of potential care coordination deficiency. The Screening for Occult Renal Disease (SCORED) model is selected due to its validity and its computerizability by claims. Care coordination deficiency may occur when (1) tests are performed during emergency room visits or unplanned hospital stays; (2) tests are performed on or after the discharge date of planned hospital stays; (3) a primary care physician orders significantly more labs and imaging compared to peers (above 95th percentile). We are exploring partnership opportunity to refine and test this program.

Conclusions: A program design to embrace business and clinical complexity in population health partnership is proposed to address missed follow-up on abnormal creatinine. More details on the testing of this design will be shared with conference audience, and feedback is welcome.

PUB370

Prevalence of Unhealthy Behaviors Among Different Stages in Thai CKD Patients in ESCORT-2

Teerawat Thanachayanont,[1] Kriang Tungsanga.[2] *[1]Bhumirajanagarindra Kidney Institute, Bangkok, Thailand; [2]King Chulalong Memorial lHospital, Bangkok, Thailand.*

Background: We are conducting quasi-experimental study to evaluate the effect of integrated care model for Chronic Kidney Disease management in rural community of Thailand (ESCORT-2 study). Lifestyle modification is an important aspect of CKD management. Prevalence of health-related behaviors are important information for planning strategy to achieve healthy lifestyle.

Methods: We analyzed the baseline data of ESCORT-2. Prevalence of lifestyle behaviors reported herein (including cigarette smoking, analgesic use, non-steroidal anti-inflammatory drug [NSAID] use, use of herbal medicine, intensity of exercise and adherence to prescribed medication) were obtained was collected with patient history interview during their hospital visit.

Results: 914 CKD stages 3 and 4 were enrolled in the study. The baseline prevalence of some unhealthy behaviors in our cohort is considerably high [Cigarette smoking 26.4%, Analgesic 34.9%, and herbal use 23.4%]. Prevalence of cigarette smoking, analgesic use and herbal use were not different among different stages of CKD. Use of NSAID, lack of exercise and poor medication adherence were less in more advanced stage of CKD.

Conclusions: The baseline data of this study revealed high prevalence of cigarette smoking, analgesic and herbal use even in advanced stage of CKD. However prevalence of NSAID use, lack of exercise and poor medication adherence were low and less in advanced stage of CKD. On going study are being conducted to observe the effect of these unhealthy behaviors on CKD progression and the impact of integrated care on improving lifestyle modification.

Dynapenia, Muscle Mass, and Fracture Risk in CKD (Stages 1-5 ND)

Secundino Cigarran,[1] Brandon Monzón,[2] Ana maria Sanjurjo amado,[5] Nicolas Menendez,[3] Manuel P. De vicente,[3] Lourdes Gonzalez tabares,[4] Juan Latorre,[1] Jesus Calvino.[5] *[1]Nephrology, Hospital Da Costa, Vigo, Spain; [2]family Physcian, Hospital Da Costa, Burela, Spain; [3]Nephrology Research Unit, Hospital Da Costa, Burela, Spain; [4]Hospìtal Lucus Augusti, Lugo, Spain; [5]Sergas, Burela, Spain.*

Background: Sarcopenia is highly prevalent in patients with Chronic Kidney Disease (CKD). Definition of Sarcopenia in the Elderly (EWGSOP 2018) includes low muscle mass associated to low muscle strength and/or low physical performance. In CKD, the relationship between protein synthesis and protein catabolism is altered producing an increase in the speed of skeletal muscle loss. The objective is to evaluate the influence of muscle mass and function with the risk of fracture, in patients with CKD 1-5 ND.

Methods: Cross-sectional study.880 patients were included. FRAX (Fracture Risk Assessment Tool) test was performed, considering the high risk of vertebral fracture at 10 years≥10% and hip at 10 years≥3%.Muscle mass was evaluated by vectorial BIA (BiaVector, Akern, Fl Ita). Strength was performed by handgrip(Akern, Fl, Ita) in Kg. Renal function was assessed by CKD-EPI and MDRD.

Results: Age 70.17±10.49 years, 60.7% women. Frequencies of CKD stage(S) were:S1 6.1%, S2 18%;S3 56.1%;S4 15.6% and S5 4.2%.Pts with dynapenia were significantly older. The glomerular filtration rate and the risk of osteoporotic fracture were significantly higher in the dynapenic subjects ($p \leq 0.05$). However, the risk of hip fracture was only significant in the dynapenic women (Table). Interstitial fluid measured did not show statistical significance.

Conclusions: Dynapenia is a related risk of vertebral fractures in both sexes. Hip fracture risk is higher in women. In both cases muscle mass is normal. The promotion of physical exercise in order to: increase the traction on the bone, stimuli the muscle and increase the bone structure is relevant in these patients. Dynamometry evaluation should be included as a routine tool in clinical practice

Needs Assessment of a Collaborative Telenephrology Care Model for Rural Veterans

Melissa L. Swee,[1,2] M. Lee Sanders,[1,2] Kantima Phisitkul,[2] Angie R. Thumann,[2] Nikki L. Neuzil,[2] Bradley S. Dixon.[1,2] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City Veteran's Health Administration, Iowa City, IA.*

Background: Chronic kidney disease (CKD) is a growing medical problem affecting over 40 million Americans, with Veterans having a 34% higher prevalence of CKD than the general population. Early identification of CKD by primary care providers can lead to earlier specialist referral which may help delay the progression of disease and improve outcomes. However, there is a limited supply of kidney specialists to address this disease burden, particularly in rural settings. Telenephrology consultation provides an appealing collaborative option for rural providers to increase consultative access.

Methods: A cross-sectional retrospective review was performed on 53085 patient records within the Iowa City Veterans Affairs (VA) Health Care System from March 2017 to March 2019. Variables abstracted included creatinine, eGFR, urine microscopy and urine dipstick results, urine albumin-to-creatinine ratio, and urine protein-to-creatinine ratio, as well as documentation of an outpatient nephrology visit. We analyzed the data using descriptive statistics.

Results: The charts of 53085 Veterans were reviewed, of which 11790 (22.2%) were diagnosed with CKD stages 3-5 based on eGFR. Among these, 10498, 943, and 349 were diagnosed with CKD stages 3, 4, and 5 respectively. Of the 12541 Veterans who had urine dipstick and microscopy data, 4363 had hematuria. Of the 23407 Veterans who had urine protein assessment, 3212 and 309 (13.7% and 1.3%) had micro- and macroalbuminuria, respectively. Among the 2627 Veterans who had urine protein to creatinine ratios, 471 had a value between 0.2 to 1, 183 had a value between 1 to 3.5, and 358 had a value higher than 3.5. Overall, only 1950 of these patients were seen directly by nephrologists in the VA system, with an additional 87 being evaluated by a community nephrologist. Therefore, only approximately 17% of patients with the above findings had been seen by a kidney specialist.

Conclusions: There is a significant burden of kidney disease with an increasing demand for kidney specialists that surpasses the current supply of practitioners. Our data suggest that only up to 1 in 6 Veterans with CKD in this predominantly rural healthcare system have been evaluated by a kidney specialist. Telenephrology e-consults are one mechanism to extend care to ensure that these needs are being met.

Serum Uric Acid Is Associated with CKD Progression: Insights from the CKD-REIN Cohort

Mathilde Prezelin-Reydit,[3,1] Christian Combe,[1] Jerome Harambat,[1,7] Ziad Massy,[2] Celine Lange,[5,4] Marie Metzger,[4] Oriane Lambert,[4] Benedicte Stengel,[4] Karen Leffondre.[6,3] *[1]CHU de Bordeaux, Bordeaux Cedex, France; [2]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [3]Equipe Biostatistique, INSERM U1219 Bordeaux Population Health, Bordeaux, France; [4]CESP, Inserm U1018, Kidney and Heart Team, Villejuif, France; [5]Biomedicine Agency, La Plaine Saint-Denis, France; [6]University of Bordeaux, Bordeaux, France; [7]Equipe LEHA, INSERM U1219 Bordeaux Population Health, Bordeaux, France.*

Background: The association between hyperuricemia and CKD progression is not well established in Europe and, to our knowledge, has not yet been investigated using longitudinal measurements.

Methods: We used data from the on-going French multicenter CKD-Rein cohort study, which included patients with CKD stages 3 to 5 between 2013 and 2016. All uric acid measures were taken into account, from inclusion to the occurrence of renal replacement therapy (RRT), death, or end of follow-up, whichever came first. We used a shared random-effect model for the joint analysis of individual trajectories of uric acid and hazard of RRT and death. Hazard ratio were adjusted for age, sex, primary kidney disease, metabolic syndrome, cardiovascular disease, proteinuria (< 30, 30-300, > 300 mg/day), and the CKD-EPI estimated glomerular filtration rate (eGFR) at baseline.

Results: A total of 2781 patients (65.5% men, median age 69 years) were included. At baseline, the median eGFR was 31.8 mL/min/1.73m2 and the median uric acid value was 425 μmol/L. During a median follow-up of 3.2 years, 434 patients received RRT and 264 died before RRT. After adjustment, an increase of 100 μmol/l of the current level of uric

acid was associated with a significantly increased hazard of death or RRT, at any time of follow-up (HR 1.11, 95%CI 1.03-1.20).

Conclusions: The current level of uric acid is associated with an increased hazard of death or RRT in European patients with CKD stage 3 to 5.

PUB374

Prevalence Estimate of Secondary Distal Renal Tubular Acidosis Among Patients with Sjogren Syndrome and Systemic Lupus Erythematosus in a US, Employer-Sponsored Health Insurance Population

Linda Law,[1] Josephine Li-McLeod,[3] Gary L. Bryant.[2] *[1]Advicenne, Cincinnati, OH; [2]University of Minnesota, Minneapolis, MN; [3]Stratevi, Boston, MA.*

Background: Secondary distal renal tubular acidosis (2º dRTA) involves impairment in the distal tubule, leading to insufficient renal acid secretion, which can result in metabolic acidosis, hypokalemia, nephrolithiasis, nephrocalcinosis and bone demineralization. While primary dRTA is caused by genetic factors, 2º dRTA may result from autoimmune disorders, such as Sjögren's syndrome (SS) or systemic lupus erythematosus (SLE), which also attack the distal tubule. While 2º dRTA is rare, US prevalence may be under-reported. This analysis utilizes administrative claims data to estimate the prevalence of 2º dRTA among patients with SS or SLE in a US employer-sponsored insurance (ESI) population.

Methods: Utilizing the Truven MarketScan® Commercial and Medicare Supplemental Databases from Jan 1, 2016–Dec 31, 2016, 2º dRTA patients were identified as follows: at least 1 inpatient or ≥2 outpatient claims ≥30 days apart for SS (ICD-10-CM: M35.0x) or SLE (ICD-10-CM: M32.xx) or acidosis (ICD-10-CM: E87.2). Patients were also required to have a claim for an alkalinizing agent or have a diagnosis of other disorders resulting from impaired renal tubular function (ICD-10-CM: N25.89). MarketScan Commercial Insurance Weights were then applied to project the sample to the total US ESI population.

Results: A total of 100,680 patients with ICD-10-CM diagnosis code of SS, SLE, or acidosis were identified. Of these, 1,125 were prescribed an alkalinizing agent or had a diagnosis code of impaired renal tubular function. Applying the insurance weights to this sample, this projected to an estimated 6,716 secondary dRTA patients, which extrapolates to an estimated 2º dRTA patient prevalence rate of 3.88 per 100,000 in the 2016 US ESI population.

Conclusions: The ability to unequivocally identify 2º dRTA patients based on a diagnostic code is limited. This approach used claims data to provisionally identify and estimate the prevalence of 2º dRTA patients in the US ESI population. According to the Kaiser Foundation, ESI represents 49% of the total US population. Further research is needed to validate this approach to effectively identify and characterize the treatment experiences of dRTA patients.

ACEI/ARB Use in Patients with CKD and at Risk for CKD in Two Large Health Systems

Susanne B. Nicholas,[1] Ning Li,[1] Kenn B. Daratha,[2] Obidiugwu Duru,[1] Cami R. Jones,[2] Jenny I. Shen,[3] Radica Z. Alicic,[2,4] Sterling McPherson,[2,4] Katherine R. Tuttle,[2,4] Keith C. Norris.[1] *[1]David Geffen School of Medicine, Los Angeles, CA; [2]Providence St. Joseph Health, Spokane, WA; [3]LaBiomed at Harbor-UCLA, Torrance, CA; [4]Washington State University College of Medicine, Spokane, WA.*

Background: Rates of ACEI/ARB use in patients with CKD and At-risk for CKD are unknown. We completed a retrospective analysis of ACEI/ARB use in CKD and At-risk for CKD patients from the UCLA-PSJH CKD Registry, populated from electronic health records.

Methods: The cohort: >2.6 million adults (2006-2017) based on labs and/or administrative codes for CKD, hypertension, diabetes mellitus, or pre-DM. We conducted analyses on patients with CKD (N=84,150) and At-risk for CKD (N=807,211) with ≥3 eGFRs ≥15ml/min/1.73m^2, followed for an average (SD) of 5.4±2.4years. Logistic regression assessed the relationship between baseline eGFR and ACEI/ARB use, controlling for age, gender and race/ethnicity. We compared proportions of patients on ACEI/ARB for each year from study entry between decliners and non-decliners (≥2mL;<2mL/min/1.73m^2/year) identified by least squares fit to individual eGFR trajectories. Linear mixed effects (LME) models evaluated the association between time-varying ACEI/ARB use with eGFR trajectories in decliners vs. non-decliners; controlling for age, gender and race/ethnicity for CKD patients.

Results: More registry patients were 45-64years (41%), female (56%), White Non-Latino (83%) and non-decliners (74%), p<0.001. At qualifying entry to the registry, only 13% of CKD and 5% At-risk CKD decliners were on ACEI/ARB. In comparison, 11% CKD and 4% At-risk CKD non-decliners were on ACEI/ARB. Logistic regression showed that higher baseline eGFR was associated with higher rates of ACEI/ARB use for CKD (OR=1.01, 95% CI 1.01, 1.01) and At-risk CKD patients (OR=1.00, 95% CI 1.00, 1.00). LME models for ACEI/ARB use over the period of follow up showed that ACEI/ARB was associated with an increase in eGFR trajectories (1.17, 95% CI: 0.71, 1.63) in CKD patients.

Conclusions: The study showed a gap in ACEI/ARB use in CKD patients. Rates of ACEI/ARB use in CKD patients is higher compared to At-risk CKD patients, and ACEI/ARB use in CKD patients is associated with improved renal function over time.

PUB376

Significant Predictors of Progression of Renal Dysfunction and Adverse Events for Non-Dialysis CKD Patients

Takahiro Kuragano. *Internal Medicine Division of Kidney and Dialysis, Nishinomiya, Japan.*

Background: It is well established that several factors such as anemia, hypertension, hyperuricemia, metabolic acidosis, and chronic kidney disease (CKD)-mineral and bone disorder (MBD) are associated with progression of CKD or adverse events of these patients. However, the significant factors which associated with progression of CKD or adverse events under the condition of appropriate control which according to guidelines have not been cleared.

Methods: The study was an observational study for a period of 3 years. In 88 patients with various stages of CKD (not on renal replacement therapy (RRT)) who were treated by nephrologists, we evaluated the association between clinical parameters and renal adverse events, in addition to the hospitalization resulting in cardiovascular disease or infection by time-dependent Cox hazard model.

Results: Unexpectedly, under the condition of appropriate control by nephrologists, hypertension, hyperuricemia, metabolic acidosis, iron metabolism, and inflammation were not selected as significant predictors of progression of renal dysfunction or adverse events. In multiple regression analysis, baseline blood level of lower Hb (β=0.497, P<0.001) and vitamin D 125 (β=0.258, P=0.006), and higher int-PTH (β=-0.334, P=0.001), urinary phosphorus (β=0.328, P=0.001), urinary β2MG (β=-0.225, P=0.031) and urinary protein (β=0.280, P=0.02) levels were selected as significant predictors of decline of estimated glomerular filtration rate (eGFR) or 1/ creatinine(Cr) at the end of the study. In the Cox hazard model, low calcium (HR: 0.37, P=0.026), high phosphate (HR:5.90, P<0.001), low 125 vitamin D (HR: 0.94, P=0.013), high int-PTH (HR:1.02, P<0.001) level, use of a phosphate binder (HR: 4.95, P=0.012), and use of vitamin D analogs (HR:3.75, P=0.014) are selected as risks for adverse event including initiation of RRT.

Conclusions: In this study, we found that among several factors, anemia and CKD-MBD related factors were selected as significant predictors for the progression of renal dysfunction. Furthermore, although phosphate binder or vitamin D analogs were administered appropriately, CKD-MBD factors were associated with RRT initiation or adverse events of these patients. From these results, we presumed that the early intervention or strict control for CKD-MBD factors might attenuate the risk for adverse events of CKD patients.

PUB377

Associations of Heart Failure and Diabetes with Mortality in CKD Patients: A Single-Center, Algorithm-Based Insight

Bernd Hohenstein, Eric Seibert, Olaf Hergesell, Thomas Weinreich, Helmut Reichel. *Nephrological Center Villingen-Schwenningen, Villingen-Schwenningen, Germany.*

Background: Chronic kidney disease (CKD) shows a well-known stage-dependent increase in mortality. Heart failure (HF) and diabetes mellitus (DM) are two important factors potentially driving adverse outcomes (Kidney Int. 2018 June; 93(6): 1281–1292). Recent drug developments offer new therapeutic perspectives for HF and DM. However, there is a tremendous lack of reliable data from the German CKD population raising uncertainty about the relevance of such factors and subsequent interventions. We sought to improve the current situation with an initial monocentric approach.

Methods: A single-center analysis was performed using an Algorithm-based approach using the MD Explorer Pro software. We analyzed all patients (pts) out of a 5-year-period between April 1st, 2014 and March 31st, 2019. Diabetic pts were identified by ICD-10 codes E10, E11 and E14, CKD pts by ICD-10 N18.3-18.5 and HF pts by ICD-10 50.1, 50.9, I11, I13 and the terms "Kardiomyopathie" and "Herzinsuff". Age ranges were chosen from 0-100 years and below 65 years. The diagnosis of HF or DM had to appear for the first time during the defined period. Mortality (MO) was calculated as % pts of the corresponding group that died through the time period and was analyzed for CKD with HF, CKD without HF and CKD with DM in CKD stages 3, 4 and 5.

Results: We analyzed 14.454 datasets. 5154 pts had a HbA1c of >6% at least once, 3683 pts received the corresponding ICD diagnosis de novo. CKD3-5 was present in 7.530 pts, HF in 1838 pts out of which 49 received Sacubitril/Valsartan. The combination of HF and DM was present in 840 pts. MO in 48 pts with DM and without (wo) CKD was 0%. MO was highest in CKD5 with HF (30.3%) and lowest in CKD3 wo HF (3.6%). Overall the MO was higher in HF groups compared to groups wo HF or with DM. Pts aged 65 or younger had a much lower MO in CDK3 or 4 which increased with CKD5 (table).

Conclusions: This monocentric analysis of a large dataset demonstrated higher MO in CKD3-5 pts with newly diagnosed HF than in pts wo HF or with newly diagnosed DM. While this effect was less pronounced in CKD3/4, deaths in association with HF increased by 1/3 in CKD5 patients. A multicentric analysis approach should be used to generate more precise data on these associations in the German CKD cohort.

PUB378

Suggested Target Value for Serum Uric Acid in Advanced CKD Patients to Reduce the CKD Progression

Yumiko Nakamura, Mai Aoyagi, Kaori Takayanagi, Maki Okamoto, Yu Shimozato, Yuta Kogure, Minoru Hatano, Takatsugu Iwashita, Tomonari Ogawa, Hajime Hasegawa. *Saitama Med Center, Saitama Med Univ, Kawagoe, Japan.*

Background: Recently, the role of uric acid (UA) as a factor that promotes progression of renal damage has been noticed. We retrospectively analyzed the factors affecting the rate of renal damage progression of non-diabetic CKD patients. We report

the results of the study, which suggested that serum uric acid level may have an impact on the progression of renal damage.

Methods: Patients who were newly received dialysis therapy in our facility between Jan 2015 and Dec 2018, and those whose results of a blood test six months prior to starting the dialysis were available were selected as study subjects. Patients with diabetic nephropathy or urological diseases as a primary disease were excluded, and 144 patients were finally included into the study. The subjects were divided into two groups: a rapid progression group (R group, 35 cases), whose baseline eGFR was 15 mL/min or greater, and slow progression group (S group, 109 cases), whose eGFR was lower than 15 mL/min. We examined the difference between the groups in the baseline values (BL value) and those when dialysis was started (D value) of the following parameters: UA, proteinuria, Na, K, Mg, Ca, P, bicarbonate concentration as well as blood pressure (BP).

Results: Only UA-D value showed a significant difference between the R and S groups, and no difference was observed in UA-BL value or all other parameters such as BP, proteinuria and electrolytes (8.62±2.56 in R, 7.14±1.60 mg/dL, p<0.01). Next, we examined the correlation between the rate of eGFR decline and UA-D value using single regression analysis. No significant correlation was found in the S group, however, weak correlation was shown in the R group (R=0.503, R2=0.25, and p=0.0034). The ROC analysis of UA-D value corresponding to the median value of eGFR-decline showed 8.5 mg/dL as a UA-D cut-off value.

Conclusions: These results suggest that the control level of UA may affect the rate of progression of renal damage. At present, there are no established criteria for the controlling of serum UA concentration in advanced CKD patients. Present study may suggest that the UA value lower than 8.5 mg/dL contributes to reduce the renal damage progression.

PUB379

Annual Change of Estimated Glomerular Filtration Rate as an Alternative Surrogate Marker for ESRD

Suryeong Go,[1] Ho Jun Chin.[1,2] *[1]Seoul National University Bundang Hospital, Seongnam, Gyeong-gi, Republic of Korea; [2]College of Medicine, Seoul National University, Seoul, Republic of Korea.*

Background: Doubling of serum creatinine or 57% declining of eGFR as standard surrogate marker for ESRD requires long-term follow up which made profound obstacles for research in nephrology. It has been suggested that eGFR decline of 30% to 40% over 2 to 3 years may be acceptable for alternative end-point for renal outcome, yet it is unclear whether estimation methods of eGFR affect diagnostic accuracy and annual rate of eGFR change (eGFR slope) can also be used as a surrogate marker for ESRD.

Methods: Laboratory data including serum creatinine acquired in baseline and 12 months follow-up periods was analyzed from 348 CKD (stages G1-G4, 20-61years) patients' cohort from three tertiary referral hospitals in South Korea, prospectively. The data of incidents to become ESRD was extracted from the ESRD registry of Korea additionally for more than 3 years after cohort observation. The eGFR was calculated by both modified MDRD equation (eGFRm) and CKD-EPI 2009 creatinine equation (eGFRc) using IDMS-traceable creatinine value. We compared the effectiveness of each parameter to estimate the risk of ESRD using diagnostic accuracy indices.

Results: There were 11.8% (41/348) of ESRD patients during 38-month of follow up period. The accuracy to estimate ESRD was more effective with eGFR percent change than eGFR slope using both eGFRs. AUCs to predict ESRD were 0.804 (0.721-0.887) for eGFRm change, 0.802 (0.718-0.886) for eGFRc change while 0.705 (0.624-0.785) for eGFRm slope, and 0.692 (0.610-0.774) for eGFRc slope (P<0.003). The findings of diagnostic accuracy of eGFRm criteria showed similar patterns as those of eGFRc criteria. The criterion of eGFRc decrease of ≥ 30% and ≥ 40% shows similarly high accuracy compared to eGFRc decrease of ≥ 57%, the standard surrogate marker. The sensitivity and specificity to estimate incident ESRD were 58.5% and 92.2% with the criteria of eGFRc 30% decline, 41.5% and 94.8% with the criteria of eGFRc 40% decline, and 9.8% and 97.7% with the criteria of eGFRc 57% decline, respectively.

Conclusions: There were no differences of AUC to estimate ESRD between eGFR calculated by CKD-EPI equation and modified MDRD equation. The percent change of eGFR provided more diagnostic accuracy for renal outcome than the parameter of eGFR slope. The annual percent change of eGFR ≥ 30% can be suggested to alternative surrogate marker for ESRD.

PUB380

Association of Overweight with Glomerular Density and Glomerular Swelling in CKD Patients

Ryo Zamami,[1] Kentaro Kohagura,[2] Masanobu Yamazato,[3] Akio Ishida,[1] Yusuke Ohya.[1] *[1]University of the Ryukyus, Nishihara-cho, Japan; [2]University of the Ryukyus Hospital, Nishihara-cho, Japan; [3]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: Although glomerular hypertension suggested to be associated with progression of obesity-related glomerulopathy, its contribution is not known in chronic kidney disease (CKD) patients with overweight. In this study, we examined the association between glomerular density, which reflects the total glomerular number, glomerular swelling, which reflects glomerular hypertension, and obesity in overweight CKD patients.

Methods: We recruited 76 CKD patients who underwent renal biopsy from January 1, 2016 to June 30, 2017. Overweight was defined as body mass index (BMI) 25 kg / m^2 or more. We examined glomerular density and glomerular diameter according to the presence or absence of overweight.

Results: The median age, blood pressure, BMI and creatinine clearance (CCr) of the subjects were 51, 123/70 mmHg, 25 kg / m^2 and 70 ml / min, respectively. The CCR of overweight group was comparable to that of non-overweight group (70ml/min vs. 62ml/min). Overweight group showed lower glomerular density (2.2 / μm^2 vs. 2.8 / μm^2, p = 0.027) and larger maximum glomerular diameter (251 μm vs. 208 μm, p <0.001). Multivariate analysis revealed that BMI was significantly associated with maximum glomerular diameter, independently of age, sex, systolic blood pressure, diabetes mellitus, CCr, and use of renin-angiotensin-aldosterone inhibitors.

Conclusions: In CKD patients, mild obesity suggested to be associated with glomerular hypertension accompanied with decreased absolute glomerular number. Therefore, glomerular number may be potentially reduced in overweight group even if their CCr was comparable to those of non-overweight group.

PUB381

Prevalence of CKD in Tuscany: A Demographic Picture by the Regional Health Agency Database

Fiammetta Ravaglia,[1] Francesco Profili,[3] Giuseppe L. Spatoliatore,[2] Paolo Francesconi,[4] Alberto Rosati.[5] *[1]Ospedale Santo Stefano, Prato, USL Toscana Centro, Sesto Fiorentino (FI), Italy; [2]San Giovanni di Dio Hospital, Firenze, Italy; [3]Regional Health Agency of Tuscany, Florence, Italy, Florence, Italy; [4]Health Regional Agency of Tuscany, Florence, Italy; [5]AUSL Toscana Centro, Florence, Italy.*

Background: In Italy, CKD3-5 prevalence ranges from3.5%to5.7% in men and from2.4%to6.2% in women, lower than US(overall prevalence14.2%, CKD 3-4 6,2% by NHANES surveys), while European data are less homogeneous with an extremely variable CKD prevalence(1.7-5.9%); elderly are usually under-represented. Objective: After a pilot study based on administrative data in a Tuscan city in 2011-2013, we show the results of the same approach conducted on the whole Tuscan population in 2018 (3,736,968residents, 6.2%of Italian population) to estimate CKD3-5 prevalence, with sub-analysis in diabetic, hypertensive and heart disease patients, and to compare it with European and US populations.

Methods: Administrative data were collected from the health database of Tuscany Region. Outpatients, residents in Tuscany, >20yr with a SCr in 2018 by IDMS to estimate GFR by CKD-EPI equation were included and stratified in CKD3a, 3b, 4-5(RRT patients excluded). Expected cases for each CKD stage, sex and age class were obtained by applying specific rates by sex, age and comorbidity to total population. Expected cases were standardized by age and sex using EU27 and US populations.

Results: Of the 3,736,968 Tuscany residents, 2,730,349(73.1%) were >20yr and performed at least one SCr in 2018. 180,167(6.6%) individuals had eGFR <60 ml/min distributed as follows: stage3a=4.1%,3b=1.6%,4-5 0.8%. CKD3-5 prevalence increased with age, in 45-74yr group was 4.8%, while among >80yr was 43.9%: stage3=37.4%,4-5=6.5%. Age and sex distribution of CKD3-5 showed higher prevalence in females and elderly(p<0.0001). CKD3-5 prevalence among diabetics was 23.4%, among hypertensive 20.3% and among patients with heart disease 43.3%.

Conclusions: Our data confirm an overall CKD 3-5 prevalence among adults in Tuscany similar to US(6,6% vs 6,9%). Nevertheless, if we standardise our data on US population we obtain a much lower prevalence(3,3% vs 6,9%). This contradiction may be due both to the higher prevalence of young people <35yr in US and in Europe compared with Italy, leading to a "dilution effect" of our raw prevalence after standardisation on other populations and to a higher prevalence of elderly >75yr in our population, burdened with CKD 3-5. Administrative data allow an objective evaluation of CKD prevalence overcoming the methodological bias of other studies.

PUB382

The Ratio of Fat to Calories Associated with Decline of Glomerular Filtration Rate: A Cross-Sectional Study of 8322 Participants from the China Health and Nutrition Survey (CHNS)

Zifeng Liu, Wenbo Zhao, Xun Liu. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Although there are some reports on the association of dietary patterns and chronic kidney disease (CKD), no data exists regarding the relation between ratio of fat to calories and renal function progress. The purpose of this study is to examine the association between ratio of fat to calories and renal function.

Methods: We use data from The China Health and Nutrition Survey (CHNS), a population based observational cohort study in 9 different provinces over China. the data were collected from the 2009 wave of the CHNS, in which 11,978 participants took part in the survey. During this survey fasting blood samples were collected and detection was conducted. Adult population aged no less than 18-year-old were excluded in our analyses (n = 10,120). We excluded serious diseases(n=224), body disability that affects going out(n=3), lack of blood sample collection(n=1273) and lack of diet information(n=298). Finally, 8322 participants (3878 men and 4444 women,) were included in analyses. Renal function was measured by estimated glomerular filtration rate (eGFR) (CKD-EPI Equation)

Results: Ratio of fat to calories, age, residence, netincome, vegetable intake, hyperuricemia, diabetes, tea drinking, triglycerides, total cholesterol, HDL-C, LDL-C, ApoA, ApoB, and serum uric acid were risk factors of the decline in renal function. After adjusting for confounders (age, gender, education, residence, income, vegetable intake, fruit intake, total protein intake, sleeping duration, eat away from home, LPA, screen time, tea drinking, alcohol drinking, soda drinking, water intak, snacks intake, HGB, albumin, triglycerides, total cholesterol, HDL-C, LDL-C, ApoA, ApoB, UA, UREA, hyperuricemia, diabetes and hypertension), patients in high ratio of fat to calories dietary pattern were found to be at independen risk of the decline in renal function. (odds ratio: 1.27, 95% CL: 1.14, 1.41).

Conclusions: We observed that a high ratio of fat to calories dietary pattern was directly associated with the decline in renal function.

PUB383

The Risk of Socioeconomic Inequality in the Control of Diabetes Mellitus (DM), Hypertension (HA), and CKD in the Context of the Unified Health System (UHS)

Luciana D. Tirapani,[2] Rosalia M. Huaira,[1] Fernando A. Colugnati,[3] Natalia M. Fernandes.[1] *[1]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil; [2]Fundação Instituto Mineiro de Estudos e Pesquisas em Nefrologia, Juiz de Fora, Brazil; [3]NIEPEN/FM/UFJF, Juiz de Fora, Brazil.*

Background: There is evidence that correlates socioeconomic factors with a higher prevalence and risk factors for HA, DM and CKD. OBJECTIVES: To evaluate the impact of social risk factors in patients with HA, DM and CKD.

Methods: Retrospective cohort from August / 2010 to December / 2014. Inclusion criteria: Patients over 18 years of age and who have undergone at least 2 visits at the Hiperdia Center in Juiz de Fora, which are referred for primary health care. Variables analyzed: socio-demographic data were collected at admission and the other variables (clinical and laboratorial) were collected in care. Clinical control goals related to hypertension, DM and CKD were evaluated, considering the markers at the beginning of follow-up and at the end of the study.

Results: A total of 6,369 patients were evaluated, of which 2,036 of the hypertension clinic, 2,336 from the DM and 1,997 from the clinic of CKD. We can observe the effectiveness of the treatment through the increase of the patients who managed to reach the goal of blood pressure control, from 42.7% at the beginning of the follow-up to 62.6% at the end. The same occurs with glycemic control, initially 32.1% were in the target, at the end of the study this percentage rose to 41.9%. Patients had low family incomes in all groups, with 53% with a family income of up to two minimum wages among hypertensive patients, with 54.8% among diabetics and 51.2% of chronic renal patients. We found income impact only in the diabetic group with family income up to minimum wage, OR1,155 (CI 1,042 - 1,281 p=0.006).

Conclusions: The color, income and education had a low impact on the progression of hypertension, DM and CKD. Only income impacted on the progression of DM, possibly due to the fact that access to medications by the population with the lowest income was restricted to the classes available in the UHS.

PUB384

Association of Serum Phosphorus with Long-Term Hemoglobin Variability in Chinese Patients with CKD

Liping Yang,[1] Jinwei Wang,[2] Luxia Zhang,[3] Ming Hui Zhao.[4] *[1]Renal division, Guang'anmen hospital of China Academy of Traditional Chinese Medical Sciences, Beijing, China; [2]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [3]Peking University Institute of Nephrology, Beijing, China; [4]Peking University First Hospital, Beijing, China.*

Background: Cross-sectional studies have revealed that there are independent correlations between serum phosphorus and anemia in patients with wide spectrums of chronic kidney disease. In this study we were intended to evaluate the association of baseline phosphorus level with long-term hemoglobin variability in patients followed up in the cohort of C-SRTIDE.

Methods: There were 850 participants who were followed up for at least 2 years, and with hemoglobin measured at baseline, year 1 and year 2, were selected for the analysis. Socio-demographic status, medical history, anthropometric measurements and biochemical parameters were compared among serum phosphorus quartiles. Anemia was defined according to WHO criterion. Hemoglobin variability was defined by within-patient SD, residual SD, within patient range, slope, coefficient of variance. Hemoglobin fluctuation was defined as never anemia (NA), constantly anemia (CA), normal HGB exhibited anemia thereafter (NEA), and anemia which returned to normal thereafter (ARN). General linear regression or multinomial logistic regression were applied to evaluate the association of serum phosphorus with the measurements of hemoglobin variability in appropriate.

Results: Serum phosphorus level was stratified by quartiles (<1.05mmol/L, 1.06~1.18 mmol/L, 1.19~1.32 mmol/L, >1.32 mmol/L). There were significant differences of HGB variability parameters among quartiles of phosphorus. Serum phosphorus level was significantly correlated with residual SD of HGB in both univariable (coefficient=0.661, *P*=0.0013) and fully adjusted multivariable linear regression model (coefficient=0.497, *P*=0.03). Compared with NA, the ORs for serum phosphorus in CA, NEA and ARN were 16.62(7.46, 36.99), 12.70 (4.91, 32.89) and 8.96(3.47, 23.15) respectively in univariate logistic regression, and 3.059 (1.003, 9.33), 3.247 (0.999, 10.53), 3.649 (1.22, 10.90) respectively in multinomial logistic regression analysis.

Conclusions: Serum phosphorus was independently associated with long-term hemoglobin variability. Further exploration of the impact of serum phosphorus on long-term hemoglobin control during follow-up would be warranted.

PUB385

Perpetual Risk of Oxalate Nephropathy After Gastric Bypass Surgery

Krishna P. Balabhadrapatruni, Niraj Desai. *Cleveland VAMC, Case Western Reserve University, Cleveland, OH.*

Introduction: Oxalate nephropathy, a known complication of bariatric surgery, is characterized by deposition of calcium oxalate crystals in renal parenchyma and is often recognized only in advanced stages, thus, increasing risk of ESRD. We report a case of a patient with more than 15 years of near-normal renal function following bariatric surgery who suddenly developed oxalate nephropathy.

Case Description: A 70-yr old male was referred to renal clinic for AKI. History notable for hypertension, morbid obesity s/p Roux-en-Y gastric bypass 18 years ago, CAD, hypothyroidism, h/o panniculectomy 3 years ago complicated by infection requiring multiple and prolonged antibiotic courses. Serum creatinine (Cr) had increased to 2.8 mg/dL from usual 1.2-1.5 mg/dL for several years, thought to be in the setting of relative hypotension. No urine sediment or proteinuria noted, no obstruction. AKI improved after adjusting medications (ACEI, thiazide) but Cr stabilized at 2mg/dL. Few months later Cr again increased to 4.8 mg/dL. A kidney biopsy was performed, after extensive evaluation did not reveal any etiology, and showed severe tubular accumulation of calcium oxalate crystals, severe tubular atrophy and interstitial fibrosis. Immunofluorescence and electron microscopy were non-contributory. 24-hr urine showed elevated oxalate excretion. Patient was then started on low fat, low oxalate diet and calcium supplements following which Cr improved to ~3mg/dL and has remained stable since then.

Discussion: Enteric hyperoxaluria, a complication of bariatric surgery, increases risk of nephrolithiasis and oxalate nephropathy. The underlying pathophysiology is complex and yet to be fully defined but the pivotal role of inflammasome recruitment and activation (especially NALP3) has recently been described in animal models. Inflammasomes can be activated by acute kidney injury thus potentiating crystal deposition and propagation of inflammation leading to fibrosis if unchecked, as is evidenced in the above case.

PUB386

Association of Pre-ESRD Laxative Use with Post-ESRD Outcomes

Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Ankur A. Dashputre,[1] Suryatapa Kar,[1] Fridtjof Thomas,[1] Yoshitsugu Obi,[2] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Constipation is associated with various adverse clinical outcomes like all-cause and cardiovascular (CV) mortality. Constipation is highly prevalent in advanced CKD and typically managed by laxatives; however, little is known about the association of laxative use in advanced CKD with outcomes after dialysis initiation.

Methods: We examined the association of laxative use over the last two years preceding transition to dialysis with all-cause and cause-specific mortality following dialysis initiation in 61,119 US veterans transitioning to ESRD from 10/2007-3/2014. Laxative use was defined as having ≥2 prescriptions of laxatives of ≥30-day supply each that were 60–365 days apart during the two-year pre-ESRD period. Associations were examined using Cox (for all-cause) and competing risk (for cause-specific mortality) regressions with adjustment for demographics, comorbidities, medications, nephrology care, cumulative length of hospital stay, vascular access type, and clinical variables.

Results: The mean (SD) age of the cohort was 70 (11) years; 92% were male; 24% were African American; and 59% were diabetic. The use (vs. non-use) of laxatives prior to ESRD transition was associated with lower risk of all-cause and CV mortality, but not with infectious mortality, after transition to ESRD, with adjusted hazard/subhazard ratios [95% CI] of 0.85 [0.82-0.89], 0.83 [0.77-0.89], and 0.90 [0.77-1.06], respectively (Figure).

Conclusions: Pre-ESRD laxative use is associated with lower post-ESRD all-cause and CV mortality risk. Further studies are needed to elucidate the underlying mechanisms and determine if effective fecal management with laxatives confers a survival benefit in advanced CKD patients transitioning to dialysis.

PUB387

A Cost Analysis of Monitoring Pre-Dialytic Patients in a Multidisciplinary Outpatient Clinic: Minimizing Costs

Celso S. Moraes Jr,[2] Alyne Schreider,[2] Natalia M. Fernandes,[1] Fernando A. Colugnati.[1] [1]*Medicine, Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil;* [2]*Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil.*

Background: The advancement of chronic kidney disease (CKD) in Brazil does not seem to be a reason for alert for fiscal austerity policies on health in the Brazilian context. Objective: To evaluate the costs of the Unified Health System (UHS) with the service provider throughout the evolution of CKD in pre-dialytic care, comparing with the costs of UHS to dialysis service providers.

Methods: Retrospective cohort of patients followed in a clinical center specialized in pre-dialysis care. The center focused on preventive care for Diabetes Mellitus (DM), Systemic Arterial Hypertension (SAH) and CKD. Data from 537 patients were evaluated in the period from 2011 to 2014. Sociodemographic data, stage of CKD, comorbidities and referral to dialytic therapy (DT) were analysed. On the CKD evolution data, we calculated the transition probabilities between stages of the disease, following the parameters defined by Kidney Disease Improving Global Outcomes (Figure 1). The costs of pre-dialysis outpatient care were based on micro-costing (bottom-up) and performed according to the risk stratification: (i) CKD; (ii) CKD + SAH; (iii) CKD + DM; (iv) CKD + SAH + DM.

Results: In general, a pre-dialysis program can generate an average reduction of R $ 33,023.12 (± R $ 1,676.80) for each year avoided in DT, already paying its operations, thus being cost-minimizers.

Conclusions: These results indicate that in the medium term (4 years) the real possibility of obtaining results visible to a budget that in the last 10 years has disbursed R $ 24 billion for DT.

PUB388

Applying Novel Kidney Failure Risk Equations Applications to New Patient Referrals: A 6-Month Retrospective Review

Laura M. Slattery. *St Vincent's University Hospital, Dublin, Ireland.*

Background: Chronic kidney disease represents a significant health and economic burden. An estimated 20% of Irish people over the age of 45 have CKD, and approximately 4,000 patients have ESKD. Timely speciality referral is imperative to slow CKD progression and enable expedient planning for dialysis or transplant workup where appropriate. Tangri *et al* developed a 4-variable kidney failure risk equation that was validated in Canada. These risk equations showed high discrimination when validated in 31 multinational cohorts.

Methods: The study involved a retrospective chart review of new patient referrals to the Renal Service over six months (June-December 2016). The four variable KFRE was used to predict the 2 and 5 year probability of ESKD incorporating age, gender, uPCR/ACR, creatinine and eGFR.

Results: Of the 178 new referrals (92 males, 87 females) 137 patients had complete data for KFRE. 13.9% had eGFRs >90mL/min/1.73sq.m, 21.22% had eGFR 60-89mL/min/1.73sq.m, 45.25% had eGFR 30-60mL/min/1.73sq.m, 12.8% had eGFR 15-30mL/min/1.73sq.m and 2.79% had eGFR < 15mL/min/1.73sq.m.

Conclusions: The KFRE has significant implications for design, delivery and resourcing of clinical services. From the results of this review, 59 patients stratified as low risk by the KFRE (43%) would not have required referral to Nephrology Clinic; a low-risk letter detailing the explanation for same could be forwarded to referring GPs. In cases where the risk is borderline, the 6 variable KFRE could be applied. Applying the KFRE to CKD referrals may afford greater discrimination regarding discharge of patients. A limitation of this tool is applying it to all new referrals as decreased eGFR is not the only indication for referral. In this study 22 patients were referred for investigation of recurrent stones, microscopic haematuria and optimisation of hypertension. Application of a risk based triage scheme would lead to both an improvement in wait times and expedite access to patients at highest risk of progression to ESKD.

Results

	Number of patients	Discharged at first review	Discharged within one year	% under ongoing follow-up
Low risk	59	13	21	42
Intermediate risk	13	3	1	69
High risk	65	6	5	83

PUB389

Physical Activity Improves Kidney Function in CKD Patients; Improved Kidney Function Shortens Hospital Stays

Alexis King,[1] Lewis E. Jacobson,[2] Jonathan M. Saxe,[2] Jamie Williams,[2] Paul Harper,[2] Courtney D. Jensen.[3] [1]*Kinesiology and Community Health, University of Illinois Urbana-Champaign, Urbana, IL;* [2]*St. Vincent Hospital, Indianapolis, IN;* [3]*University of the Pacific, Stockton, CA.*

Background: Patients with chronic kidney disease (CKD) suffer diverse health complications. Participation in regular physical activity predicts improved outcomes in many clinical populations. Limited data support the effectiveness of physical activity as an adjunct intervention for CKD patients. However, isolated effects on estimated glomerular filtration rate (GFR), serum albumin, and length of hospital stay (LOS) remain undefined.

Methods: We analyzed 43 consecutively-admitted patients at a Midwestern hospital in 2018; all patients had a comprehensive metabolic panel, reported physical activity behavior, and had a diagnosis of CKD or end-stage renal disease (ESRD). Descriptive statistics characterized the study sample (means, standard deviations, categorical percentages). Independent-samples t-tests assessed differences between active and sedentary patients. We tested the effect of daily physical activity on GFR and serum albumin using linear regressions, holding constant liver function, use of dialysis, dyslipidemia, and kidney transplant status. We estimated the effect of GFR and serum albumin on hospital LOS using a negative binomial regression.

Results: Patients were 62.8±17.8 years old, 55.3% were male, 44.2% were physically active, 67.4% had a diagnosis of CKD, and 32.6% had ESRD. Mean GFR was 24.9±12.7 mL/min, serum albumin was 3.1±0.7 g/dL, and LOS was 5.8±6.1 days. Active patients had 30.7% higher GFR (p=0.048); they had higher serum albumin and shorter LOS but those differences did not reach significance. With confounders held constant, physical activity predicted an increase in GFR of 8.1 mL/min (p=0.015; 95% CI: 1.64-14.47) and an increase in albumin of 0.5 g/dL (p=0.033; 95% CI: 0.04-0.85). Each 1 g increase in albumin predicted a 39.9% shorter LOS (p<0.001; 95% CI of IRR: 0.46-0.79) and each 1 mL increase in GFR predicted a 1.6% shorter LOS (p=0.023; 95% CI of IRR: 0.97-1.00).

Conclusions: In our sample of patients with CKD or ESRD, regular engagement in physical activity associated with improved kidney function, as measured by GFR and serum albumin. In turn, improvement in these biomarkers predicted shorter hospital stays. Although patients with kidney disease represent a diverse population with varying physical capacities, encouraging activity where possible may lead to improved clinical outcomes.

PUB390

Changes in FGF-23, Neutrophil/Platelet Activation Markers, and Angiogenin in Advanced CKD and Effect on Arterial Stiffness

Myung sung Kim, Hye Min Choi, Young Eun Kwon, Sol Kim, Dong-jin Oh. *Myongji Hospital, Koyang, Republic of Korea.*

Background: The aim of this study was to measure changes in fibroblast growth factor-23(FGF-23), activation markers of neutrophil(elastase, lactoferrin) and of platelet(mean platelet volume per platelet count ratio, MPR), and angiogenin according to the chronic kidney disease(CKD) stages, and evaluate the association between these markers with arterial stiffness using brachial-ankle pulse wave velocity(ba-PWV).

Methods: According to the estimated glomerular filtration rate(eGFR) calculated by the CKD-epidemiology collaboration equation, patients were allocated to five groups: control(eGFR ≥90 ml/minute/1.73m^2, n=22), stage 2(eGFR 60–89, n=17), stage 3(eGFR 30-59, n=22), stage 4(eGFR 15-29, n=17), and stage 5(eGFR ≤14 and hemodialysis, n=30). The serum FGF-23, elastase, lactoferrin, MPR, and angiogenin concentrations were measured to verify the association between the parameters with clinical(age, sex, presence of diabetes mellitus, blood pressure), biochemical(calcium, phosphorus, uric acid, intact parathyroid hormone(iPTH), low-density lipoprotein cholesterol, high sensitivity C-reactive protein) variables, and ba-PWV levels in the CKD patients.

Results: The mean ba-PWV(cm/s) values were 1497.2±206.4 in the control, 1649.0±247.9* in stage 2, 1655.8±260.3* in stage 3, 1823.0±402.4*** in stage 4, and 1905.2±374.1** in stage 5. As CKD stages progress, the mean $\log_{10}$(FGF-23) concentrations were 0.77±0.27, 0.97±0.48, 1.10±0.35**, 1.35±0.48***, and 2.12±0.82****; the mean angiogenin(pg/ml) levels were 230.6±70.5, 283.0±53.5*, 347.3±76.9**, 445.9±90.6***, and 370.9±142.4*** (*p<0.05 vs control; **p<0.05 vs control, stage 2; ***p<0.05 vs control, stage 2, 3; ****p<0.05 vs control, stage 2, 3, 4). The mean elastase to neutrophil ratio and lactoferrin to neutrophil ratio in CKD stage 3-5 were significantly lower than the control and CKD stage 2. Multivariate linear regression analyses showed that age, pulse pressure, mean arterial pressure, iPTH, and FGF-23 were independently associated with ba-PWV values.

Conclusions: Circulating FGF-23 and angiogenin concentration gradually increased as CKD advanced whereas neutrophil activation markers in CKD stage 3-5 were significantly lower than the control and stage 2 CKD. FGF-23 were weakly associated with ba-PWV in patients with CKD and no previous cardiovascular disease.

PUB391

CINAC Lesions in Kidneys of European Dairy Cows

Bert De Jonge,[1] Richard Ducatelle,[1] Laurien Sonck,[1] Cynthia C. Nast,[4] Benjamin A. Vervaet,[3] Marc E. De Broe.[2] *[1]Ghent University, Merelbeke, Belgium; [2]University of Antwerp, Lokeren, Belgium; [3]University Antwerp, Antwerp, Belgium; [4]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: CINAC is a form of chronic kidney disease of unknown etiology observed in Sri Lanka, Central America and several other tropical countries. Electron microscopically this disease is characterized by enlarged dysmorphic lysosomes in the proximal convoluted tubular cells of the kidney. This can be seen histologically on Jones silver stain as intracytoplasmic large irregular argyrophilic granules. Etiology is unclear but toxic exposure to agrochemicals is one of the possible causes. Cattle are at increased risk for uptake of agrochemicals through feeding and drinking water.

Methods: We investigate if these lesions seen in CINAC patients on Jones stain are also present in European cattle and if so there is any correlation with signs of chronic interstitial nephritis (CIN). At the slaughterhouse a kidney sample of 48 dairy cows older then 5 years and 11 beef cattle type bulls younger then 2 years were collected and histologically evaluated on H&E and Jones silver stain.

Results: In 44 of 59 kidney samples, a varying degree of intracytoplasmic accumulations of brown granular pigment was present in tubules in the outer medulla on H&E, visible on Jones stain as argyrophilic granules. In 41 kidney samples a varying degree of interstitial lymfo-plasmocytic inflammation and fibrosis with multifocal tubular atrophy was present. Transmission electron microscopy (TEM) was performed on 12 kidneys with 4 of them having lesions on Jones stain. In 2 out of 12, both of them having lesions on Jones stain, CINAC-like lysosomes were present. Interestingly in any of the 11 beef cattle type bulls argyrophilic granules or signs of CIN were present.

Conclusions: The lesions as described above could point at a CINAC-like disease at an early stage. Though CKD is not a common disease in cattle, it is possible these animals never reach further stages of the disease because of early death (often at 1/3th of life expectancy). Origin and significance of the argyrophilic granules is unclear. No histological lesions were present in the younger beef type bulls. This could indicate lesions did not develop because of a shorter toxic exposure time. Further toxicological, electron microscopic and epidemiologic investigation is needed to further clarify the significance of these findings.

PUB392

Patients with Kidney Stone of Uric Acid or Calcium Oxalate Are at Higher Risk of Lower Bone Mineral Density

Jiong Tian. *Zhejiang University, Hangzhou, China*.

Background: Kidney stone disease prevalence and recurrence rates are increasing in recent decades. Kidney stones have not only been associated with an increased risk of CKD and ESRD but also to lower bone mineral density (BMD). Diagnosis of osteopenia and osteoporosis by routine CT abdominal scans has been evaluated to be clinically practical and reliable in Chinese population. Hounsfield unit (HU) <175 was a good cut-off value for diagnosis of lower BMD.

Methods: Kidney stone formers and non-stone CKD patients hospitalized in our kidney disease center from Jan 2015 to May 2019 were included for study. Demographic and clinical data were documented. Chemical composition of stones were detected by Fourier transform infrared spectrometer. BMD score was expressed as the mean value of HU of L1-L5 vertebra. Mean values were compared by independent T test or one-way ANOVA. Correlation was performed using the Pearson correlation coefficient. Categorical data were analyzed using Chi square test. Multi-factor lineal and logistic regression were applied to find the independent risk factor.

Results: 107 cases of kidney stone formers and 43 cases of non-stone CKD patients were eligible for analysis and 'stone group'vs'CKD group'were named for comparison. The percentage of lower BMD in stone group were higher than that in CKD group (64.5% vs 44.2%, $p<0.05$). Stone group were divided into three subgroups according the chemical composition of the kidney stone as uric acid group (n=26), apatite group (n=38) and calcium oxalate group (n=43). BMD scores in uric acid group and calcium oxalate group were lower than that in CKD group (156±37.6, 153±44.7 vs 153±44.7; $p<0.01$, $p<0.05$). While in apatite group the BMD score was comparable to that in CKD group (173±61.0 vs 184±56.3, $p>0.05$). Male percentage was lower in apatite group compared with that in uric acid group and calcium oxalate group (26% vs 88% 83%, $p<0.001$) while the BMD score in apatite group was the highest among the three stone subgroups. Although there were no difference in age among the four groups (the three stone subgroups and CKD group), the age was the unique and independent risk factor related to lower BMD in the multi-factor regression analysis.

Conclusions: Kidney stone formers are at higher risk of lower BMD, especially those with stone of uric acid or calcium oxalate composition. Aging is an independent risk factor for osteopenia.

PUB393

Factors Associated with Kidney Disease in Colombian Indigenous Communities

Gustavo Aroca Martinez,[1,3] Henry J. Gonzalez Torres,[2] Grupo de investigación Asocolnef.[3] *[1]Universidad Simon Bolivar / Clinica de la Costa, Barranquilla, Colombia; [2]Universidad Simon Bolivar, Barranquilla, Colombia; [3]Asociación Colombiana de Nefrologia, Bogota, Colombia*.

Background: In the world there are 45 million indigenous people, Colombia there are 102 ethnic groups, being the 2nd with the largest number of ethnic groups. According to the Colombian High Cost Account, 11,685 were affiliated with an indigenous service company and the rest to other entities, 99.4% are affiliated in the subsidized regime and 0.57% contributory. The objective was to describe the sociodemographic, clinical, exposure factors and health regimen in some indigenous communities in Colombia, to characterize their risk of kidney disease.

Methods: Cross-sectional observational study, was collect date sociodemographic, clinical, exposure factors and health regimen after signing informed of respondents consent and physical examination with measurement was performed anthropometric data, proteinuria blood pressure, glucose measurement, hematuria and strip. At this stage no mass screening creatinine was performed.

Results: A total of 1774 persons over 17 ethnic groups, were surveyed. The most frequent age range was between adults (27-59y) with a representation of 59.6%. The sample was mainly composed of women (61.8%), which mainly dealt home. Economic activity was most important agriculture (32.6%). 78% said be covered by the state health system. 16.6% had a presumption diagnosed prediabetes, diabetes mellitus 5.8% of 4.3% and antecedent. It was found that 14.5% of women were diagnosed presumption of hypertension with sisto commitment-diastolic, systolic blood pressure, 13.1% and 6.5% diastolic hypertension. 18% of men had presumed diagnosis of hypertension with sisto commitment-Diastolic, 20.8% systolic hypertension and diastolic hypertension 5.3%. 12.5% of individuals had a history of hypertension confirmed. 12.3% had a history of urinary tract infection and 5.9% nephrolithiasis. 28.3% were overweight and 11.4% obese. 1.4% had hematuria and proteinuria 13.8%. Regarding risk behaviors 14.4% and 39.1% smoked they reported having a regular consumption of alcohol. As discovery, one case of nephritis Class IV and nephrolithiasis (n:2) were diagnosed. 1% reported a regular consumption of alcohol.

Conclusions: This population is vulnerable, being necessary to assess distal determinants of their own habitat and implement longitudinal studies studying the behavior of kidney disease to promote transdisciplinary design and implementation of programs to control.

PUB394

Heat Stress as the Main Cause of CKD in Agricultural Communities: Seven Arguments Against the Hypothesis

Chulani A. Herath,[5] Channa Jayasumana,[2] P. mangala C. De silva,[3] Benjamin A. Vervaet,[1] Marc E. De Broe.[4] *[1]University Antwerp, Antwerp, Belgium; [2]Faculty of Medicine, Anuradhapura, Sri Lanka; [3]Harvard Medical School, Malden, MA; [4]University of Antwerp, Lokeren, Belgium; [5]Sri Jayawardenepura General Hospital, Colombo 5, Sri Lanka*.

Background: There are two main hypothesis on the uncertain etiology of the global epidemic of chronic interstitial nephritis of agricultural communities (CINAC): the toxic hypothesis implicating an environmental/occupational toxin and the heat stress/dehydration hypothesis (HSDH) suggesting recurrent heat stress induced acute kidney injury to cause chronic kidney disease. Our aim is to demonstrate that heat stress is unlikely to be the main cause of CINAC.

Methods: The following data sets are used to refute the HSDH as the driver of CINAC: 1. Geographical, 2. Climatological, 3. Epidemiological, 4. Ecological 5. Physiopathological, 6. Biochemical and 7. Agrarian.

Results: 1. Geographical: Absence of CINAC in many hot agricultural regions of the world is a stronger anti-correlation than the correlation assumed by presence of CINAC in a few such regions. The mosaic pattern of case distribution in Sri Lanka contradicts the HSDH. 2. Climatological: It is doubtful that the small temperature increases in the latter twentieth century even with extreme temperature fluctuations caused devastating renal effects. 3. Epidemiological: CINAC is seen in people not exposed to hot working conditions, while it is not seen in many occupations with higher temperature exposure. Detection of pathologically proven CINAC in vineyards of France and absence in sugar cane plantations in Cuba argues against HSDH. 4. Ecological: Individuals drinking spring water are not affected in contrast to those drinking from shallow wells in nearby communities in Sri Lanka 5. Physiopathological: It is doubtful that the degree of community-acquired pre-renal AKI seen in field studies of agricultural workers is adequate to cause CINAC. 6. Biochemical: Biochemical changes postulated to perpetuate CKD have not been proven. 7. Agrarian: In Sri Lanka, mechanization of paddy farming has reduced farmers' heat exposure since the late 20th century but CINAC epidemic has continued. Workers in high altitude sugar cane plantations in El Salvador are also exposed to heat stress but the prevalence is low.

Conclusions: It is plausible that heat stress is an important contributor to perpetuation of CINAC, but is unlikely to be the main driving force. An environmental/occupational toxic exposure is more credible as a main drive of this epidemic.

PUB395

New Findings Support Toxicological Origin of Chronic Interstitial Nephritis in Agricultural Communities

Channa Jayasumana,[2] P. mangala C. De silva,[3] Chulani A. Herath,[4] Benjamin A. Vervaet,[1] Marc E. De Broe.[5] *[1]University Antwerp, Antwerp, Belgium; [2]Faculty of Medicine, Anuradhapura, Sri Lanka; [3]Harvard Medical School, Malden, MA; [4]Sri Jayawardenepura General Hospital, Colombo 5, Sri Lanka; [5]University of Antwerp, Lokeren, Belgium.*

Background: Two main hypotheses; the toxic hypothesis and the heat stress/dehydration hypothesis put forward to explain the etiology of chronic interstitial nephritis in agricultural communities (CINAC). Recent findings suggest calcineurin inhibition could be a possible pathway leading to proximal tubular damage in CINAC. Analysis of drinking water for organic substances revealed it is contaminated with several pesticide residues. Interestingly some of them show calcinurin inhibition properties.

Methods: 50 water samples (1 L each) collected from drinking water sources of CINAC endemic area: Anuradhapura district in Sri Lanka. Water extracted on a C-18 SPE cartridge, blown down to 1ml and analyzed by GCMS. ELISA method was used to detect glyphosate.

Results: Glyphosate (3-20 ppb), Propachlor (40-900 ppb), Diazinon- orgnophosphate (200-650ppb), Propanil (86-1850 ppb) were detected in drinking water sources. Detection frequency was as follows: Propachlor (42/50), Diazinon 37/50), Propanil (32/50) and glyphosate 28/50).

Conclusions: Our previous findings revealed drinking water in CINAC endemic regions contain high amount of calcium, magnesium, fluoride and silica. However, inorganic substances couldn't directly correlated to the etiology of disease. Further, in an epidemiological study, we found that usage of glyphosate, paraquat, byspiribac, mancozeb, MCPA and organophospate are associated with CINAC. The present study confirms the presence of pesticide residues in drinking water sources. Pesticides with calcineurine inhibitory properties in drinking water could be the nephrotoxic agents behind the CINAC.

PUB396

Associations Between Nephrologists' Cognitive Load and Practice Setting Characteristics

Adam S. Wilk,[1] Rachel E. Patzer,[2,1] Kelsey M. Drewry,[1] Cam Escoffery,[1] Janice P. Lea.[2] *[1]Rollins School of Public Health, Emory University, Atlanta, GA; [2]Emory University, Decatur, GA.*

Background: Among specialists, nephrologists are particularly at risk of burnout, and satisfaction with the profession is declining. Burnout, time pressures, stress, and poor work-life balance are associated with cognitive load, which can negatively affect clinical decision making, and may be greater in some practice settings. We will examine how cognitive load varies across care settings for nephrologists.

Methods: We are administering a new and innovative survey—the Transplant and Home Dialysis Recommendations Survey of Nephrologists, or THRoNe—in a nationally representative sample of n=120 nephrologists (non-pediatric). The THRoNe, which we have pre-tested and validated rigorously using a modified Delphi approach with 12 nephrologists and subject experts, collects data on nephrologists' cognitive load and other practice and physician characteristics. Nephrologists are asked to characterize their cognitive load through 12 survey items related to workload, time pressures, stress, distractions, and workplace satisfaction. We will construct an index to support classifying nephrologists' cognitive load as high, moderate, or low. Key practice characteristics include principal setting type (dialysis facility, CKD clinic, hospital, or other), perceived competence of non-physician clinical staff (e.g., nurses, dialysis technicians), average patient case complexity (e.g., % with CKD stage IV/V/ESRD, % with low health literacy), patient insurance mix (% Medicaid, % uninsured), and patient race/ethnicity mix (% black/African American, % Hispanic). We will describe the distributions of nephrologists' cognitive load overall and for each related survey item, and we will use linear regression models to test for associations between cognitive load and key practice characteristics, adjusting for physician factors (e.g., years in practice, sex, race/ethnicity).

Results: Data collection is ongoing. We anticipate obtaining a response rate of ≥70%, in line with response rates achieved in other difficult-to-reach clinician samples using our evidence-based recruitment protocol.

Conclusions: We will determine how U.S. nephrologists' cognitive load varies across practice settings. Follow-on work will need to examine implications for variation in CKD patients' quality of care across settings and opportunities to reduce cognitive load to improve CKD care quality.

Kidney Check: Identifying Kidney Disease and Diabetes in British Columbia First Nations Communities

Catherine Turner, Craig Settee. Can-SOLVE CKD Network *Can-SOLVE CKD Network, Vancouver, BC, Canada.*

Background: Kidney disease has a strong impact on the health and wellness of Indigenous communities in Canada. Therefore, a national strategy to improve kidney health must include meaningful, culturally appropriate engagement with Indigenous peoples. The Can-SOLVE CKD Network is a pan-Canadian patient-oriented kidney research initiative that is working to improve the health of all Canadians and bring Indigenous ways of knowing into health research.

Methods: The Can-SOLVE CKD Network is working with British Columbia Renal and the First Nations Health Authority to develop and implement a new program that will bring kidney, diabetes, and blood pressure checks to First Nations communities. Kidney Check is a screening, triage, and treatment program using point-of-care testing and trained health care teams. Each participating community has the opportunity to design and work with the Can-SOLVE CKD team to develop a locally acceptable program, which helps to identify healthy kidneys as well as those with mild, moderate or severe kidney problems. The results will be shared with participants in real time. Each person tested will also participate in building their own kidney health plan, including follow-up goals for maintaining kidney health.

Results: Ten BC communities have been chosen through a transparent process to be part of phase 1 of the program, which is launching in Spring 2019. The ultimate aim is to roll out Kidney Check to all Indigenous communities in BC. Kidney Check programs are also under development in Alberta and Manitoba.

Conclusions: The Kidney Check program aims to help keep kidneys healthy and is working in partnership with First Nations communities to do so.

PUB398

High Uric Acid Level with Gouty Arthritis: A Risk Factor for CVD in CKD Patients? A Clinical-Based Study

Uma D. Alappan,[1] Raj Alappan.[2] *[1]Emory University, Undergraduate, Atlanta, GA; [2]Renal Associates, LLC, Columbus, GA.*

Background: Hyperuricemia (HU) & Cardiovascular Disease (CVD) is a common occurrence in CKD patients who may develop Gouty Arthritis (GA). Though unestablished, HU is considered a CVD risk factor and may also cause CKD progression & retinal disease. This study correlates uric acid (UA) to CKD patients with CVD.

Methods: 513 CKD patients from Renal Associates LLC (2016-2018) were retrospectively-analyzed using initial visit data for CKD Stages; H/O MI, HTN, Diabetes, Arthritis, CVD: CAD/Chest Pains/CHF, OSA; Diuretic-Use; US Data; UA, Cr, eGFR, CrCl, PO4, PTH, D3, HBA_1C, & Gout Treatment. UA was correlated to Age, Sex, Race, BMI, Smoking/Alcohol-Use, CKD Stages, & other variables. HU was defined as UA≥6.5 mg/dL. 2-Sample T-Test for Means & Chi-Square: Independence were used for analysis.

Results: Data for 513 patients was 256(49.9%) Males, 238 Cauc(46.4%), Af Am 266 (51.9%), CVD 165(32.3%), Diabetes 287(56.2%), HTN 482(94.3%), 284(55.6%) Diabetic/HTN. HU and GA were 257(50.1%) & 256(49.9%). 262(51.6%) used diuretics. Mean age was 66.55 yrs, BMI 33, BP 141/73. Means (mg/dL) were UA 7.92, Cr 1.92, Serum Ca+ 9.49, PO4 3.66. eGFR/CrCl were 55.98,59.68 mL/min. Means for albumin, PTH, & D3 were 4.1 g/dL, 83.63 pg/mL, & 28.39 U. Cauc with CVD had higher UA than Af Am with CVD: 8.4 v 7.8 mg/dL p<0.03. HTN-GA patients had higher UA than Non-HTN-GA patients: 8.12 v 6.73 mg/dL p<0.04. GA patients had stronger correlation to CVD/CAD (p<0.02, p <0.005) than HU patients.

Conclusions: Higher CKD stages (3-5) correlated to higher UA and higher CVD occurrence. GA patients with higher UA had higher CVD/CAD occurrences compared to HU patients. Higher UA correlated to higher diuretic-user percentage. We propose: because higher UA levels were observed in Diuretic-Users, and Gout, CVD, CAD, Arthritis, & MI patients, we should perhaps consider treating higher UA-levels preemptively.

CKD Stages vs. Uric Acid & Cortical Thickness

Does the Incidence of Dementia Increase After General Anesthesia in Patients with CKD? A Nationwide Population-Based Cohort Study

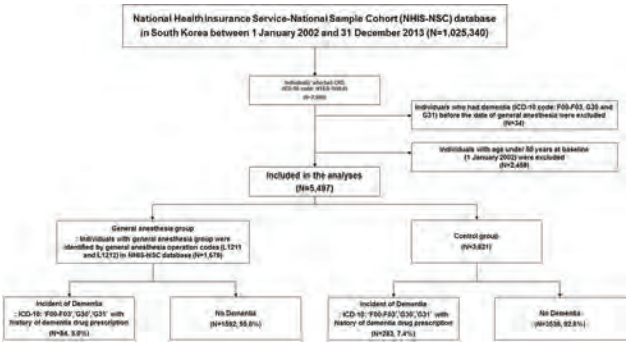
Kyung Don Yoo,[1] Kyung sun Park,[1] Jongha Park,[1] Jong Soo Lee,[1] Clara T. Kim.[2] *[1]Ulsan University Hospital, Ulsan, Seoul, Republic of Korea; [2]Hallym University, Gangwon-do, Republic of Korea.*

Background: Patients with chronic kidney disease (CKD) were regarded as increasing the risk of cognitive dysfunction according to kidney function. However, little is known about the relation of intraoperative aspect for CKD patients with general anesthesia.

Methods: A population-based prospective cohort study was conducted using the Korean National Health Insurance Service-National Sample Cohort database over 50 yrs, including CKD from 2003 and 2013. The primary outcome was the incidence of dementia using Korean Classification of Diseases codes, and receipt of medication such as donepezil, rivastigmine, galantamine, and memantine. Time-varying Cox regression analysis was applied for risk analysis of dementia.

Results: The 84 of the 1,676 participants of general anesthesia groups had developed newly dementia after surgery (5.0%). Of the 3,821 control groups that had CKD but did not have general anesthesia, 283 participants had presented incident dementia (Figure 1). In time-varying Cox regression analyses revealed that general anesthesia group did not increase the development of dementia in CKD patients, compare to control group (HR 1.053, 95% CI 0.819-1.353) after adjustment of age, sex, health security certification, history of depression, diabetes, hypertension, cerebrovascular disease, ischemic heart disease, quintile group for health care visit frequency and Charlson comorbidities score. Male sex, old age, history of depression and cerebrovascular disease were an independent risk factor of incident dementia in CKD patients, irrespective of anesthetic methods.

Conclusions: In CKD patients, general anesthesia operation did not increase the risk of incident dementia. Subgroup analysis was warranted, especially in patients with advanced CKD, including dialysis.



PUB400

Prognostic Investigation of CKD Patients in Japan by a Large Multi-center Retrospective Observational Study

Yuji Kamijo,[1] Yosuke Yamada,[1] Daiki Aomura,[1] Masatsugu Aida,[2] Shitotomo Yamauchi.[2] Nagano Kidney Evaluation Association: NKEA *[1]Department of Nephrology, Shinshu University School of Medicine, Matsumoto, Japan; [2]Ethic Co., Ltd., Chiyoda, Japan.*

Background: Since the background and medical interventions for CKD have changed in recent years, its prognosis and the contribution of known risk factors may have shifted as well. To clarify this possibility, we conducted a prognostic investigation of CKD patients in Japan by means of a large multicenter retrospective observational study. We also examined for surrogate markers to predict the hard endpoints of death and ESKD requiring renal replacement therapy.

Methods: Patients seen among 15 general hospitals in Japan between January and March 2014 were surveyed using medical records. The selection criteria were age >20 years, eGFR <60 mL/min/1.73 m^2, and medical treatment for CKD. Baseline patient characteristics, eGFR changes, and hard outcomes during observation were investigated.

Results: A total of 11233 CKD patients (60% male, mean age: 72 years, CKD G3a: 50%, G3b: 28%, G4: 15%, G5: 7%, mean eGFR: 41.5 mL/min/1.73 m^2, urine protein positive: 45%, diabetes: 46%, use of RAS inhibitors: 55%) were analyzed. During the mean observation period of 2.34 years, hard endpoints occurred in 1499 subjects (13.3%). Diminished eGFR was seen in patients with higher CKD stage at baseline, and the occurrence of hard endpoints increased with the degree of eGFR decrease during 2 years. Statistical analysis of the relationship between eGFR changes and hard endpoints indicated that various indices, including hazard ratio, population attributable risk, number needed to treat, and number needed to harm, were significant in patients displaying over 30% eGFR reduction during 2 years. Kaplan-Meier testing and multivariate Cox regression analysis demonstrated that CKD stage and proteinuria at baseline were significant risk factors for composite outcomes (30% eGFR reduction during 2 years and ESKD/death), whereas diabetes, sex, age, and use of RAS inhibitors, exerts little effect.

Conclusions: ESKD and death occurred at a high rate in real-world Japanese CKD patients. A 30% eGFR reduction during 2 years might represent a surrogate marker predicting hard endpoints. CKD stage and proteinuria remained the major risk factors of an unfavorable prognosis, whereas diabetes had only weak detectable association. Kidney disease prevention strategies should be targeted not only for diabetes but for all CKD patients.

PUB401

Investigation of TMAP as a Novel Biomarker of Kidney Function

Nicole A. Sidor,[2] Thomas Velenosi,[1] Brad Urquhart.[1] *[1]Western University, Belle River, ON, Canada; [2]Physiology and Pharmacology, Western University, London, ON, Canada.*

Background: Although kidney function is critical for determining drug dosing and diagnosing chronic kidney disease (CKD), there is a lack of sensitive biomarkers for detecting early changes in kidney function. While the current gold standard is creatinine, serum levels of creatinine do not change until approximately 50% of kidney function has been lost. We previously used metabolomics to discover new biomarkers and identified *N,N,N*-trimethyl-L-alanyl-L-proline betaine (TMAP) as a novel biomarker of kidney function.

Methods: A liquid chromatography coupled to mass spectrometry (LCMS) method was developed for the quantitation of TMAP in CKD patient and control plasma samples, and evaluate changes in plasma concentration as CKD progresses. Plasma samples were spiked with varying concentrations of TMAP to generate a standard curve. Liquid chromatography coupled to quadrupole – time of flight (QToF) mass spectrometry was used to determine the concentration of TMAP in plasma of healthy controls and patients with CKD.

Results: Preliminary analysis of chromatogram response (areas under the peaks) of healthy control, CKD, HD and PD patient plasma samples (n= 3 for each) does not show significance by one way ANOVA (p= 0.2225); However, with a 6-fold, 7-fold and 3.5-fold increase in relative areas for CKD, HD and PD respectively when comparing TMAP levels in controls to controls, analysis of further samples shows promise.

Conclusions: TMAP has previously been shown to be a more sensitive indicator of decreased renal function than serum creatinine, the current standard for renal function evaluation. Quantitation of absolute levels of TMAP in plasma shows that as CKD progresses, TMAP plasma concentration increases.

Mortality Rates and Geographic Distribution of CKD in Peru

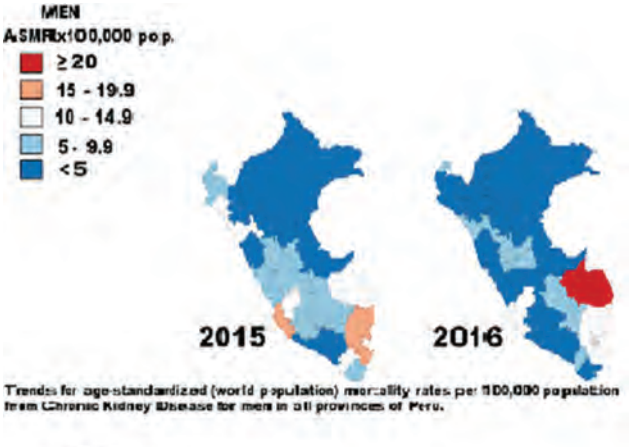
George Vasquez-Rios,[1] Junior S. Torres-Roman,[2] Carlo La vecchia,[3] Javier A. Neyra.[4] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]Universidad Nacional San Luis Gonzaga, Ica, Peru; [3]Università degli Studi di Milano, Milan, Italy; [4]University of Kentucky Medical Center, Lexington, KY.*

Background: The prevalence of chronic kidney disease (CKD) is alarmingly high in Latin America. Importantly, mortality rates in these patients have not been comprehensively explored. We aimed to examine the case of Peru.

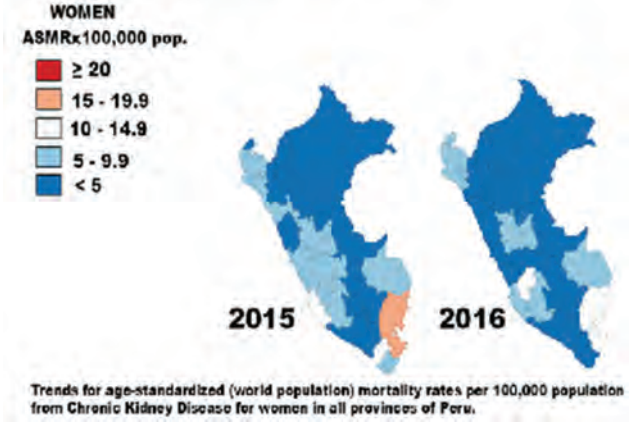
Methods: Secondary analysis from the Deceased Registry of the Peruvian Ministry of Health (PMH) database. Data pertaining to 24 provinces across the coast, highlands, and rainforest were obtained from 2015-2016. Code 585.9 was used to identify CKD deaths based on ICD 9. The PMH registry classifies deaths based on the birthplace of the patient. Calculations were made assuming an underreporting rate of 40% (PMH). We computed age-standardized mortality rates (ASMR) per 100,000 person-year. Cluster map was used to visualize data across regions.

Results: Overall, a total of 3607 deaths were identified in CKD individuals; being male predominantly affected(M:F ratio:1.18). ASMR (per 100,000 individuals) decreased among men from 7.48 to 5.02 (2015-2016). Similarly, ASMR decreased in women from 6.27 to 4.22 within the same period. In a sub-analysis by regions, ASMR among men/women decreased in the coast and in the highlands. However, ASMR (per 100,000 individuals) increased in the rainforest, from 2.87 to 2.97 in men, and from 2.41 to 2.42 in women. Such mortality rate increment corresponded to two rainforest provinces: Madre de Dios and Loreto.

Conclusions: Mortality rates in individuals with CKD in Peru are higher in male than females. While mortality rates among both gender groups decreased within the study period, there are marked regional differences. In the rainforest (mainly Madre de Dios and Loreto), mortality rates exhibited increment in both gender groups. These findings warrant special attention to identify specific epidemiological risk factors and guide intervention and policy.



Trends for age-standardized (world population) mortality rates per 100,000 population from Chronic Kidney Disease for men in all provinces of Peru.



Trends for age-standardized (world population) mortality rates per 100,000 population from Chronic Kidney Disease for women in all provinces of Peru.

Patient and Care Partner CKD Self-Efficacy

Jamie A. Green,[1] Christina Yule,[2] Heather Bonaparte,[3] Felicia Hill-Briggs.[4] *[1]Geisinger Medical Center, Danville, PA; [2]Geisinger Health System, Danville, PA; [3]Geisinger, Danville, PA; [4]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Self-efficacy is an essential skill for chronic disease self-management; however, many nephrology patients rely on the assistance of a loved-one to help manage their care. We sought to better understand the self-efficacy skills of patients and their care partners.

Methods: We surveyed patients and care partners enrolled in a pilot study of a problem-solving intervention to support kidney disease self-management. We administered 6 questions from the chronic kidney disease self-efficacy (CKD-SE) instrument problem solving subscale. Responses were scored on a 10-point Likert scale from 1=not at all confident to 10=totally confident. Paired t-tests were used to compare differences between patients and care partners.

Results: 11 patient-care partner dyads were surveyed. Dyad pairs were spouses (n=8), parent/child (n=2), and friend (n=1). Mean age was 68 for patients and 62 for care partners. The majority of patients were male (63%) and care partners were female (72%). Result of the CKD-SE instrument are shown in Table 1.

Conclusions: Care partners report significantly higher CKD self-efficacy than patients. Involvement of care partners may help to improve the CKD management of patients.

CKD and Cardiovascular Risk Factors Among a "Healthy" Guatemalan Population Screened During World Kidney Day 2019

Ever O. Cipriano,[2] Pablo Garcia,[1] Vicente Sanchez Polo.[2] Nefrologia, Instituto Guatemalteco de Seguridad Social *[1]Stanford University, Palo Alto, CA; [2]Instituto Guatemalteco de Seguridad Social, Guatemala, Guatemala.*

Background: Chronic kidney disease (CKD) is a critical global health problem. Data on CKD are limited in low-income and middle-income countries (LMICs). Cardiovascular disease it's a rising epidemic in LMICs. Screening is an important strategy to address the burden of CKD in LMICs. Here we present the outcomes of a small, CKD screening programme during the World Kidney Day 2019 on patients with no known disease in rural and urban Guatemala. The objectives were 1) to assess the burden of renal disease and 2) to assess the burden of CV disease in a population with no known disease in rural and urban Guatemala.

Methods: We evaluated 300 patients 20 years or older without known renal or CV disease. These patients were located in Guatemala City (urban area), Quetzaltenango (Rural) and Escuintla (Rural). We excluded subjects who had already CKD or CV disease diagnosis. We used the abbreviated Modification of Diet in Renal Disease (MDRD) equation to estimate the GFR. We defined CKD as a eGFR < 60 mL/min/1.72 m2 or albuminuria > 30 mg/d.

Results: The mean age was 42 years, the average BMI was 28 kg/m2, 41% of these patients were overweight and 22% were obese. We found that 4.5% of the patients met GFR criteria suggestive of CKD. The incidence of CKD was higher in the Southern Coast (9%) when compared with the urban areas in Guatemala (2.5%). Regarding renal function, the eGFR was higher (115.42 ml/min) in the urban population than in the rural urban populations (100 ml/min) (p <0.05). There was no difference in the Protein/Creatinine (P / Cr) ratio within the group analyzed.

Conclusions: In the screening carried out on World Kidney Day 2019 we established that the presence of risk factors to develop CV disease is low. We noticed an higher incidence of CKD in the coastal area, which is consistent with previous reports describing the CKD epidemic in the Mesoamerican region. The main limitation was the definition of CKD, according to the Kidney Disease Improving Global Outcomes (KDIGO), CKD can be defined as either damage to kidneys or a glomerular filtration rate (GFR) of < 60 mL/ min per 1.73 m2 for a period of ≥ 3 months and we only measured once.

PUB405

Mortality and Renal Risk Factors in a Cohort of Toba Aborigines, Chaco, Argentina

Maria Eugenia V. Bianchi,[1] Ornella Pacce,[3] Eduardo N. Rodríguez,[4] Ana M. Cusumano.[2] *[1]School of Medicine. Northeast National University, Resistencia, Chaco, Argentina; [2]CEMIC, CABA, Argentina; [3]Facultad de Medicina Universidad Nacional del Nordeste, Corrientes, Argentina; [4]School of Medicine. Northeast National University, Corrientes, Argentina.*

Background: The Province of Chaco, at the northeast of Argentina, concentrates a high proportion of toba aboriginal people (4% of the population). Originally gatherers and hunters, during last century they have been forced to migrate from rural areas to the outskirts of the cities, in particular to Resistencia (Province capital city). A cohort of 385 suburban toba people has been followed since 2003, in order to identify cardiovascular and renal risk factors. The objective is to describe mortality rate, survival curves and hazard ratios for death causes during the period 2013-2018.

Methods: Medical records were revised. 25 individuals were lost of follow up. Weight, height, waist circumference (WC), urine and serum creatinine, fasting glucose, uPr/uCr ratio were measured. GFR by MDRD-4 formula and renal risk (RR by KDIGO classification: no risk, moderate, high and very high risk) were calculated. Hypertension was defined as >140 mmHg systolic or >90 mmHg diastolic blood pressure; diabetes as fasting glucose >126 mg/dl. BMI was classified according to WHO, being obesity >than 30; central obesity (CO) was defined as WC >102 in men and >90 cm in women. Proteinuria was estimated as uPr/uCr ratio mg/g: ≤150, stage 1, 150 ≤ 300 stage II and ≥ 300 stage III. Renal risk (RR) defined as KDIGO. Kaplan Meir curves and Cox proportional hazards regression models were applied.

Results: 358 medical records were revised. 45 (12,5%) individuals had died, 6,2% females, mean age 53,87 yrs old, 24 % hipertensive, 34% with CO, 2% DBT, 34,6% proteinuric, 5,3% with GFR < than 60 ml/min. About RR, 63 % had no RR, 2,5% classified as Moderate, 12% as high and 2 % as very high RR. Causes of mortality were: CVD 20 (5,6%), Ca 12 (3,4%), TBC 9 (2,5%) and Miscelaneas 4 (1,1%). Mortality rate was 12,6. Actuarial survival for the whole cohort was 14,90 years (14,68- 15,14); for Ca was 13,94, for CVD 12,34, for TBC 9,73 and for Misc 9,73 yrs (Log Rank: 0,00). Hazard ratio was significative with RR variables alone, adjusted by age and multivariate. Mortality rate in Chaco Province general population is 7,1/00, with similar causes of death.

Conclusions: This cohort of Toba people living in the outskirts of Resistencia city, has a high mortality rate, being causes of death similar to the observed in general population in the Province. RR was a predictive factor for mortality.

PUB406

Low Flow Colonic Ischemia (LFCI) Associated with Renoprotective Use of Renin-Angiotensin inhibitor Therapy (RASIT)

Joseph C. Mihindu,[1,2] Joseph C. Yarze,[3] Michael Chase.[4] *[1]Adirondack Nephrology Associates PC, Queensbury, NY; [2]Medicine/Nephrology, Glens Falls Hospital, Glens Falls, NY; [3]Massachusetts General Hospital, Boston, MA; [4]Medicine, Glens Falls Hospital, Glens falls, NY.*

Introduction: Renin-Angiotensin inhibitors are commonly utilized Renoprotective agents in multiple nephrological conditions. Some recipients may even be normotensive. Multiple Hemodynamic Adverse effects may be encountered. We present 6 episodes of LFCI in 3 patients in association with RASIT found retrospectively in a single practice over 15 years. LFCI may represent a form of uncommon Ischemic adverse event of RASIT.

Case Description: 1. 41 year old WM with morbid obesity, recurrent macro microhematuria, mild proteinuria, hyperfiltration, hypertension, with Renal biopsy: Thin Basement Membrane Disease. On RASIT he developed two episodes of severe abdominal pain, lower Gi bleeding(LGIBL) with colonoscopic Ischemic Colitis(CI). RASIT was reduced with no subsequent recurrence. 2. 37 yo WM with recurrent macro microhematuria, proteinuria hypertension with Renal biopsy: IgA Nephropathy. On RASIT he developed acute abdominal pain LGIBL and Colonoscopic IC. RASIT was reduced with no subsequent recurrence. 3. 69 yo WF with Stage 3 chronic kidney disease, hypertension and mild proteinuria. On RASIT she developed acute abdominal pain, LGIBL with Colonoscopic IC; had 2 subsequent episodes of CI. RASIT was reduced with no subsequent recurrence.

Discussion: RASIT commonly utilized renoprotective therapy in multiple nephrological conditions including: IgA nephropathy, Proteinuric states, Diabetic Nephropathy and Chronic Kidney Disease. Hemodynamic adverse effects including hypotension, syncope and orthostatic symptoms may be encountered. Ischemic Involvement of colonic watershed area most likely due to hypotensive episodes, may be another ischemic manifestation. Exact mechanism is unclear, likely related to reduced blood flow in colonic watershed area. Direct effects of RAST on: GI tract, microvasculature, thrombotic, Immunologic and Imflammatroy pathways may be speculative. Olmesartan associated Chronic Enteropathy, RASIT associated Bowel angioedema, worsening Inflammatory Bowel disease have been described. Acute LFIC seen in our patients seems phenotypically different. Patients on RASIT presenting with LGIBL and abdominal pain, LFCI should be considered in the differential diagnosis. Dose reduction may prevent recurrent episodes. Although these are anecdotal cases possibility of Ischemic Colitis as a possible adverse effect of RASIT may warrant further study.

PUB407

Exploring Cardiorenal Interactions During Therapy of Chronic Heart Failure with Preserved Ejection Fraction

Harini Bejjanki, Gajapathiraju Chamarthi, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: The complexity of cardiorenal interactions in heart failure (HF) has been increasingly recognized. Rise in serum creatinine (RSC), once considered a universally ominous sign, is now known to portend mixed prognostic values depending on the clinical setting. While heart failure with preserved ejection fraction (HFpEF) is common and includes half of the cases with HF, no established beneficial therapy exists for it. As such, aggressive management of comorbidities remains the key in the care of these patients. We sought to evaluate currently available data on the renal impact of therapies for HFpEF.

Methods: Articles cited in PubMed database using keyword "heart failure with preserved ejection fraction" were searched. Available data from contemporary randomized controlled trials (RCTs) of chronic HFpEF therapy performed between January 2008 and December 2018 were included in the analysis. These studies evaluated the role of renin-angiotensin-aldosterone system suppression in the setting of HFpEF and included data on renal function.

Results: A total of 408 citations were reviewed and 7 RCTs with 9039 participants were included. The mean age was 71.3 years and 56.9% were men. Mean baseline serum creatinine and eGFR were 1.1 mg/dl and 67 ml/min respectively. There was substantial variation across studies in the reporting of the renal parameters post-intervention as well as recording of the RSC. Whether the primary cardiovascular endpoint was achieved or not (e.g. 6-min walk test, cardiovascular death, or unplanned hospitalization), RSC consistently developed more frequently in the intervention (6-36.2%) than the control group (4-20.6%) in those studies that reported it (mean 16.1±11.8% vs. 8.9±6.81% respectively).

Conclusions: To our knowledge, this is the first report focusing on the cardiorenal interactions and HFpEF therapy. Available evidence from contemporary studies suggests that RSC observed during HFpEF therapy may not per se portend untoward impact on the outcomes. While these results challenge our conventional thinking, they are in line with emerging data in other settings such as acute HF. Future studies need to explore whether this observation reflects development of RSC in the absence of true kidney injury, or it is related to other factors such as competing effect of therapies on the kidney and the heart.

PUB408

National Survey of Patients' Attitudes Toward Gout

Josie Peterson,[1] Michelle Winokur,[2] Amanda Conschafter.[2] *[1]Alliance for Gout Awareness, Washington, DC; [2]Alliance for Patient Access, Washington, DC.*

Background: Gout, a form of arthritis, afflicts more than 8 million Americans with painful attacks that come on suddenly. Many people don't realize the relationship between gout and chronic kidney disease. And gout, left untreated, can lead to other serious health problems, include kidney stones.

Methods: A national online survey was conducted Dec 2018-Jan 2019 for the purpose of gaining perceptions of gout from patients 21+. Questions were designed to gauge patients' understanding of gout, its causes and treatments, and how stigma and shame about gout affect their life and efficacy to seek appropriate treatment.

Results: Of the 169 patient respondents, 57% were female, 42% were male. Nearly all respondents (97%) acknowledged gout as a serious disease. Three-quarters (75%) know natural remedies aren't sufficient to treat gout, yet 73% say it's hard to get proper treatment. Despite patients' knowledge, 93% believe most people don't know gout is simply a form of arthritis. More than half of respondents (52%) indicated that they are often too embarrassed to talk about the disease and 41% said they believe people look down on those with gout. Roughly half (46%) attribute their gout to eating too much unhealthy food and drinking alcohol in excess.

Conclusions: Even though patients themselves have good awareness that gout is a serious disease, their knowledge doesn't protect them from feelings of shame, stigma and self-blame related to eating unhealthily as their cause of gout. Patients' feelings may be due, at least in part, to public perceptions of the disease. Survey results show that for gout patients to get a proper diagnosis, appropriate treatment and the community of support they need, education efforts for both gout patients and the public must continue to expand. This is vital for management of patients' gout and can have an effect on related conditions such as chronic kidney disease.

PUB409

Efficacy of Empagliflozin on Albuminuria Reduction in Patients with Non-Diabetic Kidney Disease

Yosawaj Pugtao, Suree Yoowannakul, Worawon Chailimpamontree, Anutra Chittinandana. *Division of Nephrology, Department of medicine, Bhumibol Adulyadej Hospital, Bankok, Thailand.*

Background: Empagliflozin, a sodium-glucose cotransporter 2 inhibitor, has been demonstrated to reduce proteinuria and slow renal progression in diabetic kidney disease. This study was conducted to determine the effect of empagliflozin in lowering albuminuria in patients with non-diabetic kidney disease.

Methods: We studied 28 patients who had persistent urine albumin to creatinine ratio (UACR) more than or equal to 30 mg/g and estimated glomerular filtration rate (eGFR) more than 30 mL/min/1.73 m^2. The patients were randomized 1:1 into empagliflozin group receiving oral empagliflozin 10 mg/day plus standard treatment and control group receiving only standard treatment. All patients were evaluated at baseline, 4, 8, and 12 weeks. The primary outcome was the change of UACR at 4, 8,12 weeks follow-up and the secondary outcomes were difference of blood pressure, eGFR, body weight and adverse side effects.

Results: Thirteen patients were randomized into empagliflozin group and 15 patients into control group. Empagliflozin significantly reduced UACR from baseline at 8 weeks but not 4 and 12 weeks when compared to control. Median UACR change from baseline after treatment at 4, 8, 12 weeks were -31(-120,4), -74(-200,-11), -100(-230,85) mg/g in empagliflozin group compared with -22 (-108, 54), 9 (-52, 103), and 0 (-52, 207) mg/g in control group (p = 0.447, 0.011, 0.279 respectively). There was no difference between both groups in eGFR, diastolic BP, BW and adverse effects. Systolic blood pressure was significantly lower in empagliflozin group [median 118 (113, 127) mmHg] when compared to control group [median 132 (128, 139) mmHg] (p=0.021) at 8 weeks. There were found only one patient with genital mycotic infection in empagliflozin treatment group. No hypoglycemic event was found in both groups.

Conclusions: Empagliflozin temporarily reduces UACR from baseline and lower SBP at 8 weeks when compared to control. Further large placebo-control RCT with long-term follow up need to be done to verify the effect.

Median change of UACR

PUB410

Increase of 1,25-Dihydroxyvitamin D Levels in Sarcoidosis Patients with Renal Dysfunction

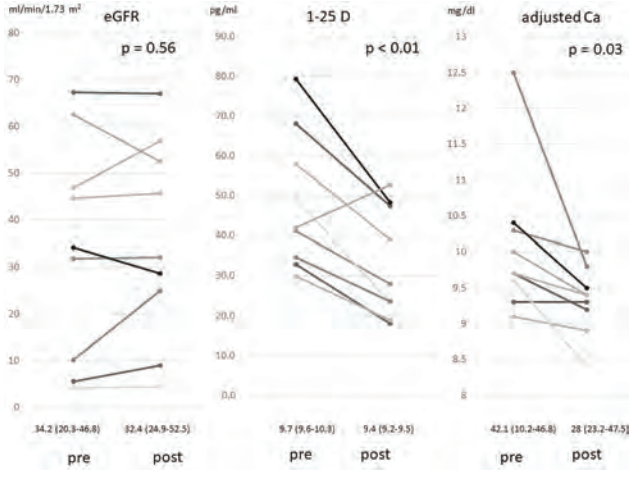
Naoya Toriu,[1,2] Keiichi Sumida,[3] Yoichi Oshima,[4] Hiroki Mizuno,[2] Masayuki Yamanouchi,[5] Junichi Hoshino,[2] Yoshifumi Ubara.[2] *[1]Kyoto university, Kyoto, Japan; [2]Toranomon Hospital, Kyoto, Japan; [3]University of Tennessee Health Science Center, Memphis, TN; [4]Shizuoka Municipa Shimizu Hospital, Shizuoka, Japan; [5]Okinaka Memorial Institute for Medical Research, Tokyo, Japan.*

Background: In sarcoidosis, renal involvement includes hypercalcemia-related nephrocalcinosis and granulomatous tubulointerstitial nephritis. Hypercalcemia is thought to be due to increased production of 1, 25 dihydroxyvitamin D (1-25D), but 1-25D levels have not been evaluated in sarcoidosis patients with renal dysfunction.

Methods: We enrolled 9 sarcoidosis patients who underwent renal biopsy, and compared the serum 1-25D concentration and eGFR with those in 428 non-sarcoidosis patients who had renal dysfunction (stage 2 or higher CKD with an estimated glomerular filtration rate <90).

Results: Serum calcium and 1-25D levels were significantly higher in the sarcoidosis patients than in the non-sarcoidosis patients ($p < 0.01$ and $p = 0.01$, respectively). There was a positive correlation between 1-25D and eGFR in the patients without sarcoidosis ($r = 0.693$; $p < 0.01$). As the renal function of sarcoidosis patients was improved by steroid therapy, the serum 1-25D and adjusted serum calcium levels decreased to near the median values in non-sarcoidosis patients. On renal biopsy, CD68 staining was positive for tissue macrophages in all 8 patients who had tubulointerstitial nephritis (with or without typical granulomas), while Von Kossa staining showed calcification of tubules near or inside granulomas in 6 of these 8 patients.

Conclusions: While tissue macrophages promote development of tubulointerstitial nephritis and 1-25D overproduction in renal sarcoidosis, hypercalcemia secondary to elevation of 1-25D may be related to renal calcification and granuloma formation.



PUB411

Association Between Insulin Resistance and Glomerular Filtration Rate in Patients with Non-Diabetic Pre-Dialysis CKD

Ardityo R. Ardhany, Rendy R. Bramantya, Soebagijo A. Soelistijo, Chandra I. Mohani, Widodo Widodo. *Airlangga University Indonesia, Surabaya, Indonesia.*

Background: Metabolic syndrome is one of the recognized cause of kidney disease. Insulin resistance, as one of the component in metabolic syndrome, is known to be one of the condition occurs in patients with chronic kidney disease (CKD), even in those who doesn't diagnosed with diabetes. The relationship between insulin resistance and the decline of glomerular filtration rate (GFR) in non diabetic patients is remain to be studied.

Methods: This is a cross sectional observational analytic study involved 35 subjects of CKD patients with non-diabetic predialysis who were diagnosed based on KDIGO criteria. The study population was CKD patients in the Outpatient Clinic of a tertiary referral hospital, Dr. Soetomo Hospital Surabaya. Insulin resistance is determined by calculation using the HOMA-IR formula, and GFR is estimated using Cockroft-Gault formula.

Results: There were 35 subjectd, 25 male and 10 female. The average age is 52.5 years, the lowest age is 31 years and the highest age is 60 years. Patients with stage 3 CKD were 11 people, stage 4 were 6 people and stage 5 were 18 people with mean for overall GFR 21,38 ± 16,69 ml/min/1,73 m^2. HOMA-IR levels were 1.61 ± 1.13, with a median of 1.15 (0.32-4.59). There was a significant negative relationship between GFR and insulin resistance ($p = 0.000$, $r = -0.828$).

Conclusions: Insulin resistance and GFR has significant negative relationship in non diabetic predialysis CKD patients.

PUB412

Association Between 1,25-Dihydroxycholecalciferol Level (Calcitriol) with Homeostatic Model Assessment of Insulin Resistance in Non-Diabetic Non-Dialysis Stage 3-5 CKD Patients

Ratih Nursiana, Soebagijo A. Soelistijo, Chandra I. Mohani, Widodo Widodo. *Internal Medicine, Airlangga University, Surabaya, Indonesia.*

Background: Mineral and bone metabolism disorder in the form of 1,25-dihydroxycholecalciferol (calcitriol) deficiency is one of the factors that increase the morbidity and mortality of patients with chronic kidney disease (CKD). CKD is also associated with insulin resistance which has an important role in the pathogenesis of cardiovascular disease. From several studies had been reported that there is increasing evidence that vitamin D metabolism affects insulin resistance, but the relationship between calcitriol deficiency and insulin resistance in CKD patients is still unknown.

Methods: This analytic observational study with a cross-sectional design involved 40 non-diabetic non-dialysis stages 3-5 CKD subjects who met the inclusion and exclusion criteria. The variables studied were calcitriol levels measured by the Enzyme-Linked Immunosorbent Assay (ELISA) and HOMA-IR methods calculated using the HOMA-IR formula where fasting insulin levels were measured by the two-site chemiluminescent immunometric assay method. Analysis of the relationship between independent variables and dependent variables using the Spearman correlation test according to data distribution with a correlation coefficient (r).

Results: There were 40 subjects, 28 males and 12 females. The average age is 52 ± 6.891 years. The mean for Body Mass Index (BMI) is 20.81 ± 1.148 kg /m^2. The majority of subjects (50%) are at CKD stage 5. The median calcitriol is 27.24 pg /mL. The mean HOMA-IR is 2.13 ± 1.150. There was a negative correlation between calcitriol levels with HOMA-IR ($r = -0.380$; $p = 0.015$).

Conclusions: There was a significant negative correlation between 1.25-Dihydroxycholecalciferol levels (calcitriol) with HOMA-IR in non-diabetic non-dialysis stage 3-5 CKD patients.

PUB413

Obesity as Risk Factor for CKD Progression and Incident Cardiovascular Events in Patients with Prevalent CKD

Diego Barbieri, Marian Goicoechea, Ana M. Garcia Prieto, Ursula Verdalles, Ana Perez de josé, Eduardo Verde, Esther Hurtado ruiz, Andres F. Delgado Rodriguez, Jose Luno. *Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

Background: Obesity is a known risk factor for incident chronic kidney disease (CKD) and for cardiovascular events (CVE). However the role of obesity in CKD progression has not been well stablished yet. Our study aimed to evaluate the role of obesity in CKD progression and incident CVE in a sample matched for recognized CKD progression factors such as age, renal function and albuminuria.

Methods: Prospective observational study from 2008 to 2018. 212 patients with prevalent CKD stages 3-4 were Propensity Score Matched for age, baseline renal function and albuminuria and divided according to obesity status (defined as BMI ≥30). After matching 166 patients were followed-up. Anthropometric characteristics, renal function and cardiovascular risk factors were measured at baseline. Renal event during follow-up was defined as creatinine dupliaciton, estimated glomerular filtration rate (eGFR) decline ≥50% or needing renal replacement therapy. CVE was defined as congestive heart failure, any coronary syndrome, cerebrovascular accident or peripheral sympthomatic arteriopathy.

Results: 83 obese and 83 non obese patients were analized; mean age was 68±13 yo and mean eGFR 48,4±22 ml/min. Mean follow up time was 88,4±36 months. CKD progression: 18 obese patients vs 21 non-obese patients presented a renal event during follow-up (Log-rank 0.21; p=0.64). Renal survival was not different between both gruops when adjusted to baseline albuminuria tertiles. Baseline renal function (HR 0,973, p=0,006) and albuminuria (HR 1,00, p=0,001) were the only CKD progression predictors in a model adjusted for age, sex, blood pressure, obesity (HR 0,95; p=0.89) and diabetes. Cardiovascular events: 17 patients in the non-obese group and 30 patients in the obese group had a CVE during follow-up (log Rank 4,44, p=0,03). Obesity had no predictive value for CVE in a model adjusted for sex (HR 0,50, p=0,049), baseline renal function (HR 0,98, p=0,045), previous CVE (HR 2,97, p=0,001), diabetes (ns) and age (HR 1.04, p<0.01).

Conclusions: In our simple obesity is not a risk factor for CKD progression. Obesity is statistically related with developing major CVE although it losses predictive value when adjusted to renal function, sex and previous CVE.

PUB414

CKD Outcome Using Cause, GFR, and Albuminuria Staging System in Qatar

Ahmed F. Hamdi,[1] Mohamad M. Alkadi,[2] Omar Fituri,[1] Essa Abuhelaiqa,[1] Awais Nauman,[2] Muhammad Asim,[2] Adel A. Abdelaziz,[1] Hassan A. Al-Malki.[1] *[1]Hamad General Hospital, Doha, Qatar; [2]Hamad Medical Corporation, Doha, Qatar.*

Background: Primary Objective:- 1-To apply CGA classification system to stratify our pool of CKD patients into well defined risk groups. 2-Estimation of relative risk of CGA stage in relation to kidney outcome and patient outome (cardiovascular and all cause mortality). Secondary Objective:- To correlate CGA stage with covariates including age, sex, race and cardiovascular disease (CVD) risk factors.

Methods: Retrospective evaluation was carried out for CKD patients under follow up in oupatient nephrology clinics from January 1st 2001 till December 31st 2016. All patients diagnosed as CKD with different stages were included. Patients were screened for :Demographic data;Cause of kiney disease, Date at diagnosis of CKD, eGFR at time of diagnosis of CKD and at last follow up, degree of Albuminuria/proteinuria, Comorbid conditions, Use of ACEI/ARBs, Renal outome as well as Patient outcome.

Results: 969 patients were included. Mean follow up period was10.14 years. 8.24% reached endpoint outome as follows :expired 1.44% and ESRD 6.8%. Hazard risk to reach end point was depenedent on cause of CKD, being highest with combined DM and HTN followed by HTN alone, DM alone and finally other causes (figure 1). Univariate analysis revealed that risk factors showing statistical significance to reach endpoint included older age, associated cardiovascular disease in addition to higher proteinuria, body mass index (BMI) and PTH levels at time of diagnosis of CKD. Multivariate analysis revealed that use of ARBs/ACEI was associated with significant less incidence of death and ESRD.

Conclusions: Cause of CKD should be considered together with eGFR and degree of albuminuria during evaluation for risk of progression of CKD patients. Special formulas including CGA together with other riak factors (age, BMI, CVD,.) might be invented to help predict prognosis of such patients.

Effect of Simulated In-Bed Training of Urination on Reducing Rate of Postoperative Dysuria in Patients After Renal Biopsy

Hong-li Shang, Hui-qun Li, Yan-ru Chen. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Postoperative dysuria is one of the most common complications after renal biopsy. This study aimed to investigate whether the simulated in-bed training of urination is able to relieve the symptoms of postoperative dysuria in patients undergoing renal biopsy.

Methods: Patients who underwent renal biopsies between Jan 2017 and Dec 2018 were recruited. We reported the proportion and characteristics of patients underwent the simulated training of postoperative in-bed urination before the procedure, and compared with that of patients did not receive the training. The training refers to the simulation of postoperative conditions before the renal puncture procedure, during which the patient lay on the bad and finished an urination episode facing a chamber pot. The training was carried out within 30 minutes before the renal biopsy.

Results: A total of 531 patients underwent renal biopsies and 509 (95.9%) of them underwent the training. After renal biopsies, 439 patients had voluntary urination on the bed, accounting for 86.2% of the total number of trainees, and 28 patients who had induced urination, while 42 patients needed urethra catheters. There were 300 (58.9%) patients completed self-urination on the bed within 3 hours after the renal procedure, and the number of patients who completed self-urination on the bed within 6 hours was 396, accounting for 77.8% of the total number of trainees. For the 22 patients who did not receive the training, 11 (50.0%) of them were able to voluntary urinated, while the other 11 patients needed assisted urination care.

Conclusions: Simulated training of in-bed urination is able to reduce occurrence of dysuria associated with renal biopsy.

PUB416

Conservatively Managed Patients with Advanced CKD: What Medications Can Be Deprescribed?

Sadia Jahan,[1] Michelle L. Rice,[1] Carla E. Scuderi,[1,2] Louise Purtell,[3,4] Cassandra Rawlings,[1] Ann Bonner,[3,4] Helen G. Healy.[1,4] *[1]Metro North Hospital and Health Service, South Brisbane, QLD, Australia; [2]School of Pharmacy, University of Queensland, Brisbane, QLD, Australia; [3]Queensland University of Technology, Brisbane, NSW, Australia; [4]NHMRC Chronic Kidney Disease Centre of Research Excellence, Brisbane, QLD, Australia.*

Background: Patients entering a Conservative Management Pathway (CMP) from advanced chronic kidney disease (CKD) have a legacy of high pill burden. An important component of CMP is judicious deprescribing, noting that tools described in the literature including the Beers or STOPP/START criteria do not take into consideration the patient's symptoms and trajectory which is the focus of Kidney Supportive Care (KSC). The referral criteria to the KSC program includes patients on the non-dialysis CMP, on kidney replacement therapy (KRT) with high symptom burden and those who are pre-decision making. We aim to examine the number and type of prescribed medications of patients on CMP and identify medications that potentially may be deprescribed due to limited benefit.

Methods: Retrospective analysis of patients on a non-dialysis CMP referred to KSC Feb 2016 – Feb 2019. Only patients that were conservatively managed and not on a KRT care pathway were included. Patient demographics and clinical profile were extracted from the medical record. Medication lists were compiled by a renal pharmacist and assessed at last/ most recent KSC attendance. Medications that were highlighted as suitable to be deprescribed were grouped; with key groups including statins, proton pump inhibitors (PPIs) and supplementary vitamins.

Results: 47 patients met the inclusion criteria for these analyses, median age 83 years (range 29-92) and 53% were female. 74% had CKD 5 with the remainder having CKD 4. Total number of prescribed individual medications ranged from 5-31 (median = 13). Statins were prescribed for 36% patients, PPI for 55% and vitamins for 49%. 38/47 (81%) patients had at least 1 identified medication that could be deprescribed and 8/47 (17%) were on all three (statin, PPI and supplementary vitamins).

Conclusions: Deprescribing medications has the virtue of reducing medication burden, financial cost and side effects, contributing to important quality of life. Many patients continue to receive medicines with limited therapeutic benefit whilst on CMP despite the scope for de-prescribing these medications. More research is required to develop a deprescribing tool in this unique population.

PUB417

Prevalence of CKD in the National Hospitalization Database in Ecuador as a Pointer to CKD of Undetermined Etiology Prevalence

Ramya Bhargava,[1] Sriram Narsipur,[3] Anna M. Stewart ibarra.[2] *[1]Nephrology, Upstate Medical University, Syracuse, NY; [2]SUNY Upstate Medical University, Syracuse, NY; [3]Upstate Medical University, Syracuse, NY.*

Background: Chronic Kidney Disease of uncertain etiology (CKDu) is a emerging healthcare crisis in South America, primarily affects young males with no pre-disposong factors such as diabetes or hypertension, and has been reported extensively from Nicaragua and Guatemala. CKDu results in increased mortality in working age males, often pushing entire families into poverty. Though it has been reported in Ecuador, the extent of the problem is not known. There is no renal registry and access to primary care is variable depending on the geographical area and the patient's socio-economic status.

Methods: As part of a mixed-methods scoping study, we analysed the national hospitalization database for the years 2010 to 2015 for ICD10 codes N18 (CKD) and N19 (Unspecified kidney failure) for prevalence amongst men and women, and across different ages. Since there is no separate ICD10 code for CKDu, N18 and N19 were used.

Results: Image Table

Conclusions: There is a clear increase in the prevalence of CKD in hospitalized males < 40 years of age from 2010 to 2015 in Ecuador. This study is limited by insufficient data on outpatient community CKD. While there is an increase across all ages, likely because of better reporting, there is a striking doubling of cases in working age men < 40 years of age. It is not possible to opine from the data if this is all CKDu, but this pattern of CKD is similar to the pattern of CKDu incidence in other countries. Our data supports the need for well-designed prevalence studies to define the scope of CKDu contributing to the observed rise in CKD in Ecuador, in a vulnerable population with potential global health implications.

Diagnostic Value of NT ProBNP in CKD Patients with Acute Decompensated Heart Failure

Syeda H. Zartash,[1] Sidra Saleem,[1] Zain Rasool,[1] Nimra N. Zaman,[1] Shahbaz Sarwar,[1] Shahmeer M. Nawaz,[1] Shahryar A. Sheikh,[1] Shamila Afshan,[2] Abeera Mansur.[1] *[1]Doctors Hospital and Medical Centre, Lahore, Pakistan; [2]Punjab Institute of Cardiology, Lahore, Lahore, Pakistan.*

Background: NT pro-BNP is a promising marker of integrated cardiorenal function in the setting of volume overload. However, diagnosis of volume overload in CKD patients is complicated by NT-proBNP levels that are higher than in the non CKD patients. The aim of this study is to establish a cut off value for NT Pro BNP in CKD patients for Acute decompensated Heart Failure(ADHF)

Methods: From 1st May, 2018 through 30th April, 2019, 450 patients who presented in the Emergency Department of Doctors Hospital, Lahore with acute dyspnea and potential fluid overload were assessed. Out of these, 85 patients who had simultaneous echocardiography and NT Pro BNP measurement were included in the study. Both CKD (<60ml/min GFR) and non CKD patients with reduced ejection fraction(LV EF<40%) and preserved ejection fraction(LV EF≥50%) were included. eGFR was measured using the CKD-EPI equation and all data was analysed using SPSS version 25.

Results: Mean value of NT Pro- BNP in patients with eGFR < 60 ml/min with Volume Overload and Pulmonary Capillary Wedge Pressure(PCWP) >15mmHg as determined by 2D echo (Group A) and in patients with eGFR > 60 ml/min with volume overload and PCWP >15(Group B) is 1895.74+10.57 and 550.66±7.42(pmol/L) respectively, as shown in Image 1. In Group A patients, NT pro BNP cut off value of 1900 resulted in sensitivity and specificity of 63% and 71.21% respectively with a Negative predictive value(NPV) of 87.04% and accuracy of 69.41%(p value 0.003), as shown in Image2.

Conclusions: The cutoff value of NT Pro BNP for diagnosis of ADHF in CKD progressively increases as the stage of CKD increases. To obtain optimal results, cut off concentrations have to be adjusted for renal function

CKD Stage	Mean NT pro BNP ±S.D(pmol/L)
3	1570.2 ± 12.75
4	1946 ± 8.92
5	2939 ± 13.11
None	550.66 ± 10.22

	Variables	Sensitivity(%)	Specificity(%)	PPV(%)	NPV(%)	Accuracy(%)	p-value
NT pro BNP>1900	Group A	63	71.21	38.71	87.04	69.41	0.003
	Group B	32.14	86.36	50	75	70.21	0.194

Effect of Educational Program on Lowering Blood Pressure and Urinary Protein in Japanese CKD Patients

Katsuya Tanigaki,[2] Akira Ishii,[5] Shinya Yamamoto,[5] Keiichi Kaneko,[5] Hirosuke Nakata,[1] Naoya Kondo,[4] Kaoru Sakai,[7] Shuichiro Endo,[6] Hideki Yokoi,[5] Takeshi Matsubara,[6] Motoko Yanagita.[3] *[1]Kyoto university hospital, Kyoto city, Japan; [2]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]Kyoto university, Sakyo-ku, Japan; [5]Kyoto University Graduate School of Medicine, Kyoto, Japan; [6]Kyoto University, Sakyo-ku, Japan; [7]Kyoto University Hospital, Kyoto, Japan.*

Background: Educating patients by interprofessional collaboration with doctors, nurses, pharmacists and nutritionists is effective in controlling chronic kidney disease (CKD) progression. We have been conducted an inpatient CKD educational program by multiple occupations and compared the effects of the program on various kidney diseases.

Methods: We retrospectively reviewed 31 Japanese patients who participated in our one-week CKD educational program from April 2014 to April 2019. All patients took low-salt diet (6 g/day) and were carried out 24-hour urine testing twice during the program. In addition, we examined clinical features of 18 patients (10 in diabetes mellitus (DM) group and 8 in non-DM group) whose antihypertensive drugs were not changed during the program.

Results: The mean age of patients was 72.8 ± 11.7 years, and 68% were male. Nephrosclerosis was the most common diagnosis (61% [19 of 31]), followed by diabetic kidney disease (35% [11 of 31]), IgA nephropathy (10% [3 of 31]) and so on. The average body weight decreased from 67.3 kg to 64.8 kg (3.7% reduction), the systolic blood pressure (BP) decreased from 140.3 mmHg to 131.6 mmHg (6.2% reduction), and the urinary protein decreased from 1.84 g/day to 1.37 g/day (25.5% reduction), and the 24-hour urinary sodium excretion decreased from 107.4 mEq/day to 77.8 mEq/day (27.6% reduction) during the one-week program. In a study of 18 patients whose antihypertensive drugs were not changed, the BP and the urinary protein level on the first day of program was higher in DM group (DM group: 138.2 mmHg vs non-DM group: 132.8 mmHg, DM group: 2.31 g/day vs non-DM group: 1.29 g/day, respectively). In DM group, the percentage of BP reduction was higher (DM group: 9.3% vs non-DM group: 1.8%), while the percentages of proteinuria and body weight reduction were lower during this one week program (DM group: 16.0% vs non-DM group: 29.5%, DM group: 3.4% vs non-DM group: 3.7%, respectively).

Conclusions: Our educational program was effective on lowering BP and urinary protein of CKD patients. Furthermore, the BP-lowering effect was obvious especially in DM patients probably due to the promotion of sodium sensitivity as previously reported.

PUB420

The Efficacy and Safety of Endothelin Receptor Antagonist on Renal Outcomes: An Updated Systematic Review of Randomized Trials

Muh Geot Wong,[2] Edmund Y. Chung,[1] Sunil Badve,[5] Meg J. Jardine,[2] Brendon L. Neuen,[2] Min Jun,[3] Hiddo J. L Heerspink,[4] Dick de Zeeuw,[4] Vlado Perkovic.[2] *[1]NSW Northern Sydney Health District, Lindfield, NSW, Australia; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [4]University Medical Center Groningen, Groningen, Netherlands; [5]St George Hospital, Kogarah, NSW, Australia.*

Background: Preclinical studies suggest that blockade of the endothelin receptor reduces proteinuria and may confer renal protection. With the recent publication of the SONAR trial, this systematic review and meta-analysis aims to summarize evidence from randomized controlled trials (RCT) regarding the benefits and risks of ERA on renal outcomes.

Methods: MEDLINE, Embase and Cochrane Central Register of Controlled Trials were searched for RCTs evaluating ERAs in adults that reported renal outcomes. The primary outcome was kidney failure (end-stage kidney disease, renal failure, or doubling of creatinine, or as reported by the authors). The secondary outcomes were change in kidney function (estimated glomerular filtration rate or creatinine clearance), albuminuria and systolic blood pressure from baseline to last measurement, all-cause mortality, cardiovascular mortality and adverse events. Treatment effects were summarized using random-effects meta-analysis.

Results: Seven RCTs (7612 participants, median sample size 379, median follow-up weeks 16 weeks) met eligibility criteria. There was substantial heterogeneity in baseline kidney function and study population. Compared to placebo, ERA significantly reduced the risk of kidney failure (3 trials, risk ratio [RR] 0.76, 95%CI 0.65, 0.89) and albuminuria (3 trials, SMD -0.94, 95%CI -1.49, -0.40). ERA had uncertain effect on all-cause mortality (5 trials, RR 0.99, 95%CI 0.84, 1.17), cardiovascular mortality (2 trials, RR 1.11, 95%CI 0.67, 1.83), kidney function (6 trials, standardized mean difference [SMD] -0.06, 95%CI -0.23, 0.11) and pulmonary edema (2 trials, RR 1.37, 95%CI 0.91, 2.07); but increased the risk of systemic edema (7 trials, RR 1.19, 95%CI 1.03, 1.39) and hospitalization for heart failure (5 trials, RR 1.32, 95%CI 0.87, 2.01).

Conclusions: Short-term trials suggest that ERA treatment may reduce the risk of kidney failure and albuminuria. Adequately powered RCTs with long-term follow-up are required to evaluate whether ERA treatment improves renal outcomes.

PUB421

Mycophenolate Sodium in Primary Membranous Nephropathy: A Retrospective Analysis

Sree B. Raju. *Shiloh House, Hyderabad, India.*

Background: We studied the efficacy and safety of mycophenolate sodium (MMS) in primary membraneous nephropathy (MN)

Methods: A Retrospective observational study of 58 cases of treatment naïve MN. Patients were given prednisolone (20mg/day tapered to 5mg/day by 3 months) along with MMS (2 tablets of 360mg twice-a-day) and changes in eGFR and proteinuria from baseline to the end of one year were noted.

Results: A total 44 cases were included in analysis. There is no significant worsening of s.creatinine (0.85± 0.17 mg/dl v/s 0.95± 0.30 mg/dl, p=0.23) or eGFR (105.97 ± 19.10 v/s 97.18 ±20.35 ml/min/1.73m^2.P= 0.33). There is an improvement in s. albumin levels (2.17± 0.62 v/s 2.78± 0.59 gm/dl, p=0.001) and urinary protein levels (6811.36 ±1654.50 v/s 3360.34 ±2270.54 gm/day, p=0.001). At 12 months, partial response (PR) was seen in 29.54%, complete response (CR) in 20.45% and no response in 50%. The mean time to attain PR was 9.47± 1.8 mon and for for CR, 10.33 ± 1.5 mon. PLAR 2 positive cases had significantly earlier PR. The common complications were hypertension (18%) and diarrhoea (11%).

Conclusions: A 12-month course of MMS decreased proteinuria and improved renal function in patients with MN with less side effects.

PUB422

Renal Sarcoidosis: Clinical Presentations and Outcomes

Alfred T. Solomon, Qiyu O. Wang, Cagil D. Arslan, Amit J. Joshi, Ambarish Athavale, Peter D. Hart. *John H. Stroger Hospital of Cook county, Chicago, IL.*

Background: Renal sarcoidosis is one of the silent clinical manifestations of sarcoidosis. It typically causes gradual impairment in kidney function due to chronic tubulointerstitial disease with or without granuloma formation. In addition, it also affects calcium and phosphate metabolism.

Methods: Ten patients with renal sarcoidosis diagnosed between 2002 and 2017 were included in this study. All patients had biopsy proven renal sarcoidosis or sarcoidosis diagnosed by biopsy of other organs in addition to decline in kidney function with or without hypercalcemia, nephrocalcinosis or nephrolithiasis.

Results: All patients had extra renal involvement at the time of diagnosis 90%Lung, 10%Liver, 20%Skin). One patient had neurosarcoidosis with panhypopituitarism; another had Heerfordt syndrome. In all patients with renal biopsy, pathology showed granulomatous interstitial nephritis. Of the three who did not have renal biopsy, two had granulomatous dermatitis on skin biopsy and one had granulomatous hepatitis. Three patients had nephrotic range proteinuria. All patients were treated with oral steroids (Prednisone 60mg for 4 weeks tapered to 15-20mg daily over 2 months). No patient had nephrolithiasis or nephrocalcinosis on imaging. Renal function improved significantly at 6 months in all patients except one patient who had an eGFR of 5ml/min/1.73m2 at presentation. Hypercalcemia resolved in all but one patient by 2 months of treatment. Serum calcium correlated with eGFR (Pearson coefficient –0.4).

Conclusions: Renal involvement with sarcoid is a rare cause of CKD/AKI but responds well to steroid treatment even in patients with severe impairment of kidney function at presentation.

Epidemiologic and clinical features of patients

No. of patients	10(3 females, 7males)
Race	100% were African Americans
Age	36±10
Serum calcium	11.04±1.00
Hypercalcemia	70% of patients
Serum phosphate	6.49±3.04
PTH(Median and IQR)	36.65 and 193.18
25(OH) Vitamin D	17.25±4.72
eGFR	25.8±19.9
eGFR at 1 month	37.7±20.3
eGFR at 6 months	41.1±18.7
Proteinuria	1.11±1.10
Biopsy	70% diagnosed by kidney biopsy, 30% extra renal

PUB423

Renoprotective Role of Metformin in a Mouse Model of Adenine-Induced CKD

Hao Yi,[1] Chunling Huang,[2] Qinghua Cao,[1] Ying Shi,[3] Xinming Chen,[2] Carol A. Pollock.[4] *[1]Kolling Institute, Sydney, NSW, Australia; [2]University of Sydney, Sydney, NSW, Australia; [3]kolling institute, the University of Sydney, St. Leonards, NSW, Australia; [4]The University of Sydney, St. Leonards, NSW, Australia.*

Background: Chronic kidney disease (CKD) is a worldwide public health problem and current best clinical practice only slows the progress of renal fibrosis in CKD. Inflammatory and fibrotic signaling pathways play important roles in the progression of CKD. Thus, it may be beneficial to limit renal fibrosis through inhibiting target inflammatory and fibrotic responses. Metformin is a widely used glucose-lowering medicine for type 2 diabetes mellitus. Recent studies have explored its potential for many other clinical conditions including renal fibrosis. However, the exact mechanisms of metformin in limiting renal injury is not fully understood.

Methods: To examine the role of metformin in the development of CKD, C57BL/6 mice were delivered adenine (4mg in 200ul water) through gavage to induce CKD for 21 days. Mice given water only served as control. Coincident with adenine treatment, mice were administered with metformin (0.4 mg/ml) in drinking water or water only (control) for 21 days, at which time animal experiments were terminated, blood, urine and kidney were collected. Urinary albumin to creatinine ratio (UACR)was assessed; inflammatory and fibrotic markers and their signaling molecules were analyzed by immunohistochemistry (IHC), qRT-PCR and Western blotting.

Results: Adenine induced increase in UACR was attenuated by metformin treatment ($p<0.01$). Adenine increased expression of inflammatory markers MCP-1, F4/80, fibrotic markers type IV collagen, fibronectin and TGF-β1, and phosphorylation of Smad3, ERK1/2, and P38 in kidneys compared to control groups, which were partially reversed by metformin treatment (n=6, $p<0.01$).

Conclusions: Metformin attenuates adenine-induced renal interstitial fibrogenesis through both Smad and non-Smad signaling pathways.

PUB424

Smarca4 Regulates Vascular Smooth Muscle Cell Calcification Through Inhibiting Autophagy

Li Wang,[4] Chan Wang,[2] Yun Tang,[1] Yanmei Wang,[1] Meidie Yu,[3] Yi Li.[1] *[1]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology, Chengdu, China; [2]Department of Nephrology, Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital, Chengdu, China; [3]University of Electronic Science and Technology of China, Chengdu, China; [4]Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.*

Background: Vascular calcification(VC) is one of the most common clinical manifestations for patients with end stage renal disease(ESRD). However, the pathological mechanism of VC is not fully understood and there is no reliable early biomarker to predict the risk of VC.

Methods: In order to elucidate the mechanism of VS, we performed a detailed molecular characterization of high phosphorus indcued-VS model both *in vitro* and *in vivo*. The label free proteomics screening results of high phosphorus induced aortic vascular smooth muscle cells(ASMCs), pathological assessment, cellular charcterization and molecular signaling detection upon target gene elucidated a comprehensive profile about VS.

Results: Label free proteomics analysis and pathological studies highlighted Smarca4, also known as BRG1, significantly related to osteoblastoid differentiation from ASMCs during the development of VS. Smarca4 showed to regulates high phosphorus induced-VS by its anti-autophagy role associated with suppression of autophagysome formation and autophagy pathway.

Conclusions: Smarca4 regulates high phosphorus induced-calcification of ASMCs at an early stage involving its anti-autophagy role. Yi Li and Li Wang should be addressed as corresponding authors and these two authors contributed equally to this study.

Lnc-Gm44981 Induces Renal Aging by Regulating the p53/p21/RB Pathway

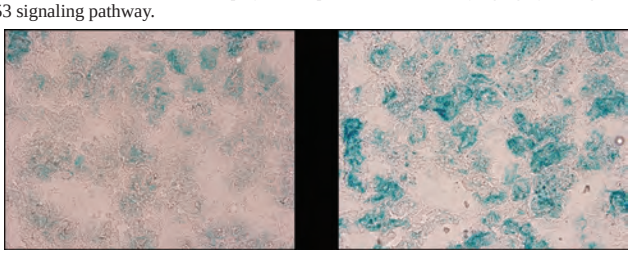
Jie Li,[1] Hongli Jiang.[2] *[1]First Affiliated Hospital of Xi'an Jiaotong University, Shaanxi xi'an, China; [2]First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

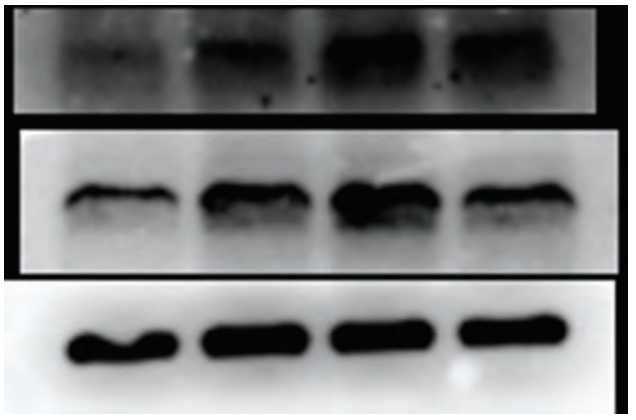
Background: Aging is a natural and gradual process of aging in the process of degenerative changes in tissues and organs of the body over time. The kidney, which is a metabolically active organ, is extremely susceptible to aging, but the mechanism of kidney aging is unclear. Long-chain non-coding RNA (lncRNA) is a non-coding RNA consisting of 200 nucleotides. It is generally considered that they do not encode proteins, but are expressed in various forms at the RNA level.

Methods: The expression of lnc-Gm44981 was detected using qRT-PCR. SA-β-gal staining and immunohistochemistry were operated for the detection of the p53, p16 and p21 expression in different ages. Transfection with lnc-Gm44981 siRNA to measure aging-associated protein expression levels in TCMK-1 cell.

Results: We found that the expression of lnc-Gm44981 decreased during aging. And we found that SA-β-gal expression gradually increased with age, and p53, p16 and p21 expression gradually increased. Then the transfection of lnc-Gm44981 siRNA has an effect on the expression of aging-related proteins.

Conclusions: lnc-Gm44981 plays an important role in kidney aging by acting on the p53 signaling pathway.





PUB426

Evidence of Urate Deposition in the Kidneys in Gout Patients

Brad A. Marder,[4] Puja Khanna,[3] Brian LaMoreaux,[2] Ada Kumar.[1] *[1]Horizon Pharma, PLC, Lake Forest, IL; [2]Horizon Therapeutics, Lake Forest, IL; [3]University of Michigan, Ann Arbor, MI; [4]Colorado Kidney Care, Denver, CO.*

Background: Gout is the most common inflammatory arthropathy in U.S. adults. Although tophi in the extremities are well known, urate deposition in the renal parenchyma is not as well recognized. Patients with gout commonly have concomitant renal disease, however, a causal role between these entities has not yet been established. Direct urate deposition in the renal parenchyma may be of significant interest since it could explain ongoing subclinical renal tissue damage and its potential role in the propagation of chronic kidney disease in gout patients.

Methods: PubMed (from 1940 to 2019) was searched to identify reports of autopsy, pathology and radiology imaging demonstrating urate deposition within the native renal parenchyma in patients with gout. Key words included: gout nephropathy, chronic urate nephropathy, renal tophi, gouty kidney, autopsy findings in gout, and renal imaging in gout. The reference lists from these publications were also used to identify additional articles. Literature referencing urate nephrolithiasis and renal transplants were excluded from the study.

Results: There were 25 articles documenting renal parenchymal urate deposition in gout patients confirmed by autopsy, biopsy and/or radiology imaging in native kidneys. Among the 19 articles examining urate deposition by autopsy or tissue sampling, 100% found renal urate deposition in the tubules and interstitium of the medulla. 68% found urate deposition in the renal cortex and/ or cortical scarring. 74% reported renal vascular pathology including arteriole fibrous thickening of the intima, hyaline degeneration and occlusions. In addition, 89% found inflammatory cells and fibrosis surrounding the parenchymal "microtophi". There were 6 imaging articles that all reported abnormal renal ultrasound findings in the medulla that were attributed to urate deposition.

Conclusions: Several case reports document renal parenchymal deposition of urate in patients with gout based on autopsy, pathology and imaging evidence. Renal urate vasculopathy was also commonly noted. Given the strong association of gout with renal disease, this demonstrates a need for further research to determine the clinical significance of urate deposition with respect to potential renal parenchymal injury and ongoing subclinical inflammation.

Modulation of Inflammatory and Fibrotic Processes by Histone Lysine Demethylase

Kyeong Pyo Lee,[1] Jiyeon Choi,[1] Young ok Kim,[1,2] Sunae Yoon,[1,2] Young soo Kim.[1,2] *[1]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea Uijeongbu St. Mary's Hospital, Uijeongbu-si, Gyeonggi-do, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Histone lysine methylation and demethylation has been suggested to have a modulating effect on inflammation and fibrosis.

Methods: In this study, we analyzed the effect of JIB-04, a pan inhibitor of Jumonji histone demethylase on inflammatory process in murine macrophage cell line, RAW264.3, and rat renal proximal epithelial cell line, NRK-49F.

Results: JIB-04 pretreatment prevented LPS-induced expression of inflammatory cytokines in RAW264.3 cells and TGF-b-induced expression of profibrotic cytokines and EMT markers in NRK-49F cells, respectively. In addition, JIB-04 pretreatment inhibited both NF-kB activation and increase of snail1.

Conclusions: Taken together, these results suggest that histone lysine demethylase may play a contributing role to the induction of fibrosis as well as inflammation in the kidney by modulating activation of key transcription factors. In the future, JIB-04 could be developed as a new anti-fibrotic agent.

PUB428

Effect of Kidney Fibrosis Using SAMiRNA, a Second-Generation RNAi Platform Technology

Seungseob Son,[1] Eun-Young Lee.[2] *[1]Bioneer, Daejeon, Republic of Korea; [2]Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea.*

Background: SiRNA silencing approach has long been used as a method to regulate the expression of specific target gene in vitro and in vivo. However, the effectiveness of delivery and the nonspecific immune stimulatory function of siRNA are the limiting factors for therapeutic application of siRNAs.

Methods: To overcome limitations in in vivo delivery of siRNA, we developed self-assembled micelle inhibitory RNA (SAMiRNA) composed of DNA/RNA hybrids made of individually bi-conjugated siRNA with hydrophilic polymer and lipid on their ends and characterized their stability, immune stimulatory function and in vivo silencing efficacy. We used unilateral ureteral obstruction(UUO) mouse model for *in vivo* system. Mouse in groups of six were subjected to Sham, UUO and received intravenous injection of SAMiRNA™-Amphiregulin

Results: SAMiRNA form very stable nanoparticles without significant degradation in the size distribution and polydispersity index over 1 year. Overnight incubation of SAMiRNA on murine PBMC did not cause any significant elaboration of innate immune cytokines such as TNF-α, IL-12 or IL-6, while unmodified siRNA or, liposome or liposome complex significantly stimulated the expression of these cytokines. Lastly, in vivo silencing efficacy of SAMiRNA was evaluated by targeting amphiregulin (AR) in UUO mouse models of Kidney fibrosis. Only two times of intravenous delivery of AR SAMiRNA significantly reduced the *interstitial* ***collagen accumulation*** *in the kidney.* In Safety and toxicity test of SAMiRNA™-Amphiregulin, we acquired data on preclinical toxicity, safety and effectiveness of SAMiRNA™ using rodent and no-rodents systems. And We have finally determined acute- and repeated-dose toxicity at GLP grade and general toxicity, Toxicokinetics, etc. at GLP grade. There appears to be no adverse effect on preclinical toxicity and safety.

Conclusions: SAMiRNA is a safe, stable and effective platform for silencing disease-associated genes, useful in therapeutic applications for Kidney fibrosis and various fibrotic diseases. Currently we are developing a First-in-class Kidney fibrosis RNAi drugs through Non-clinical toxicology studies. Through successful completion of this project, we will be able to IND application and Approval for Phase 1 Studies of our SAMiRNA™ platform technology to a number of therapeutic targets generated by Bioneer as well as other global companies.

PUB429

Low Circulating Transforming Growth Factor-β1 Level Is Associated with CKD

Talal Nakkar,[1] L. Lee Hamm,[2] Shuo Bai,[3] Jiang He,[4] Jing Chen,[1] Chung-shiuan Chen,[3] Moh'd Sharshir,[1] Mohammad Atari,[1] N. Kevin Krane,[3] Vecihi Batuman.[3] *[1]Tulane School of Medicine, New Orleans, LA; [2]Tulane University School of Medicine, New Orleans, LA; [3]Tulane University, New Orleans, LA; [4]Tulane School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: Transforming growth factor beta (TGF-β) plays a role in angiogenesis, differentiation, immunomodulation, and haematopoiesis. It remains controversial on association of circulating TGF-β1 level and chronic kidney disease (CKD).

Methods: We investigated the association of serum TGF-β1 level and CKD in 175 patients with CKD and 148 controls without. CKD was defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2 or presence of albuminuria. Multivariable analyses were used to examine the relationship of serum TGF-β1 level and CKD, adjusting for age, gender, race, physical activity, smoking, drinking, systolic blood pressure, glucose, low-density lipoprotein cholesterol, body mass index, history of cardiovascular disease, and use of angiotensin-converting enzyme inhibitors.

Results: The adjusted median (interquartile range) of TGF-β1 levels was 13879 (11285-16753) pg/mL vs 17379 (14642 -19761) pg/mL in CKD vs. non-CKD patients (P<0.0001). The multivariable adjusted odds ratio (95% confidence interval) for CKD comparing the lowest to the highest tertile of TGF-β level was 6.07 (2.71, 13.6). One standard deviation lower in log transformed TGF-β1 was associated with lower level eGFR and higher level of urine albumin.

Conclusions: These data indicates that decreased serum TGF-β1 level is independently associated with CKD and higher urine albumin level. Future study is warranted to investigate the effect of normalizing serum TGF-β1 level on improving CKD outcomes.

PUB430

The Effects of ELP-VEGF on Tumor Progression

Jamarius Waller, Jason E. Engel, Stephen Burke, Alejandro R. Chade, Gene L. Bidwell. *University of Mississippi Medical Center, Jackson, MS.*

Background: Vascular Endothelial Growth Factor(VEGF)plays a central role in promotion of angiogenesis and endothelial cell health. We showed that microvascular rarefaction, due to low VEGF levels, is a causative factor in renovascular disease(RVD) and chronic kidney disease(CKD). Recently, we developed a biopolymer-delivered VEGF by fusing VEGF-A_{121} to the elastin-like polypeptide(ELP) biopolymer, resulting in a chimeric protein(ELP-VEGF)that has extended pharmacokinetics and improved renal targeting. ELP-VEGF improved microvascular density, renal blood flow, and glomerular

filtration rate in swine models of RVD and CKD. However, there is concern that VEGF-based therapeutics may promote aberrant angiogenesis, especially in patients with undiagnosed tumors.

Methods: In order to determine if ELP-VEGF promotes tumor growth, we treated mice bearing triple negative breast tumors with ELP-VEGF at three doses, beginning at the therapeutic dose from our previous swine studies and escalating 10 and 100-fold(100ug/kg, 1mg/kg, 10mg/kg). Body weight and tumor size(monitored via caliper measurement and bioluminescence imaging)were assessed thrice weekly for five weeks. 35 days after treatment, mice were perfused with Microfil. Tumors were removed, weighed, and scanned via μCT to assess vascular density.

Results: There was no significant difference in tumor volume, luminescence, or mass amongst the groups. All groups had an average final tumor volume of approximately 1,500mm^3(±approximately 600mm^3)and an average tumor mass of approximately 1.1±0.5g(n=10). There was also no significance difference in body weight among all groups.

Conclusions: In conclusion, a single injection of ELP-VEGF, even at a dose 10-fold higher than the highest efficacious dose tested for renal disease, has no significant effect on tumor progression in a human xenograft breast cancer model.

Funding: Other NIH Support - R01HL121527, R41DK109737, R01HL095638

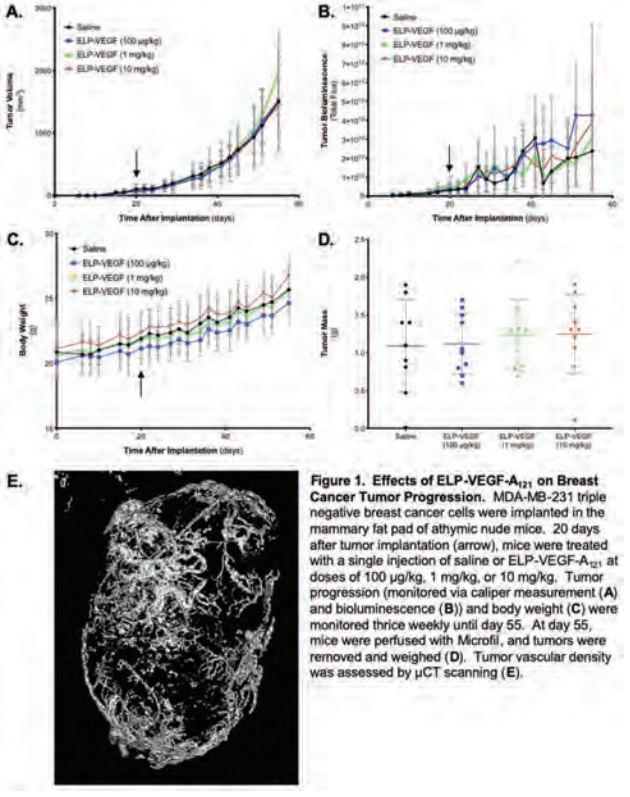

Figure 1. Effects of ELP-VEGF-A$_{121}$ on Breast Cancer Tumor Progression. MDA-MB-231 triple negative breast cancer cells were implanted in the mammary fat pad of athymic nude mice. 20 days after tumor implantation (arrow), mice were treated with a single injection of saline or ELP-VEGF-A$_{121}$ at doses of 100 μg/kg, 1 mg/kg, or 10 mg/kg. Tumor progression (monitored via caliper measurement (**A**) and bioluminescence (**B**)) and body weight (**C**) were monitored thrice weekly until day 55. At day 55, mice were perfused with Microfil, and tumors were removed and weighed (**D**). Tumor vascular density was assessed by μCT scanning (**E**).

PUB431

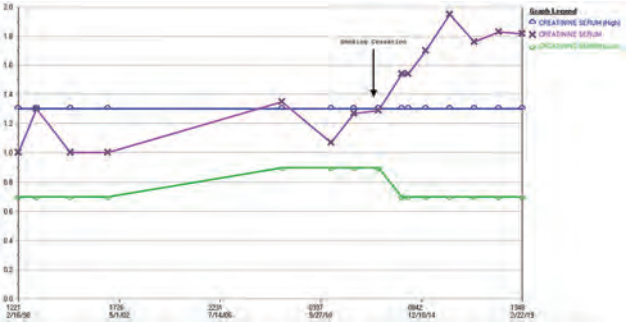
Cigarette Smoking Cessation Resulted in a Decline in Kidney Function: Paradox Explained

Khaled Boobes, Rasha Alawieh, Lee A. Hebert. *Ohio State University Medical Center, Columbus, OH.*

Introduction: Smoking tobacco is a well-known risk factor for cardiovascular disease and chronic kidney disease (CKD). Smoking cessation is always encouraged, but limited data is available regarding the short-term effects of smoking cessation on serum creatinine (Cr) and the actual and estimated glomerular filtration rate (eGFR)

Case Description: We present a case of a 59 years old patient who underwent a living donor kidney transplant in 1975. His serum Cr remained stable well within the normal range at about 1.0-1.3mg/dL up until 2013 when he quit smoking. His serum Cr started to gradually increase afterwards until it stabilized around 1.8mg/dL. Notably, his weight also gradually increased from about 105lbs to 130lbs. His serum Cr has since been stable at 1.8mg/dL. Renal ultrasound and broad relevant testing was negative/normal.

Discussion: Smoking cessation is well-linked to an increase in appetite and weight. Increased consumption of cooked meat is also known to increase serum Cr levels. Our patient did report an increase in appetite, meat consumption along with activity level after smoking cessation. We speculate that the low initial muscle mass in our patient coupled with the baseline decreased renal function made the increase in serum Cr more noticeable. Our literature search revealed multiple studies reporting the decrease in eGFR after smoking cessation, none of which however reported the relationship of Cr with weight changes and/or meat consumption. Conclusion: Smoking cessation could be linked to an increase in serum creatinine, that is related to increased creatinine production, not a decrease in GFR. This increase would be more evident especially in patients with low muscle mass and/or chronic kidney disease to begin with. Further studies need to be conducted to better characterize this phenomenon.



Serum Cr levels over time

PUB432

Graphene Quantum Dots Attenuate CKD Progression

Lilin Li,[1] Seung Hee Yang,[2] Joo Hong Joun,[3] Jung Nam An,[4] Jeonghwan Lee,[4] Jung Pyo Lee.[1,4] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Department of Medicine, Seoul National University, Seoul, Republic of Korea; [4]Department of Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Graphene derivatives - Graphene Quantum Dots (GQDs) have drawn much attention for its biomedical applications, such as bioimaging, drug delivery and tissue engineering. Also, the substances themselves have antioxidant, anti-inflammatory and immune regulatory effects. However, the role of GQDs in fibrotic diseases remains unclear. In this study, the effect of GQDs in kidney fibrogenesis was investigated.

Methods: Unilateral ureteral obstruction (UUO) was induced in 7- to 8-wk-old male wild-type C57BL6 mice. GQDs were injected in kidney fibrosis models through the tail vein. As in vitro model, rhTGF-β1 was used to induce epithelial to mesenchymal transition of kidney primary tubule epithelial cells. After treatment of GQDs, the pattern of change of fibrotic and mesenchymal markers and the activity of the TGF-β/Smads pathway and PI3K/Akt/mTOR pathway were evaluated. In addition, tubular apoptotic cell deaths were assessed.

Results: UUO induced renal fibrosis and morphological changes in the obstructed kidney, whereas administration of GQDs reduces fibrosis and improves kidney structural changes. At the mRNA and protein levels, GQDs significantly reduced the expression of fibrotic markers such as collagen 1a1, fibronectin and α-SMA and increased E-cadherin expression. GQDs significantly decreased TGF-β1 expression, as well as affected Smad-dependent signaling pathways and the PI3K/Akt/mTOR pathway. In addition, TUNEL staining and Bax/Bcl2 ratio were increased in the untreated group compared with GQDs-treated group.

Conclusions: This study revealed the role of GQDs in renal fibrosis, and its effectively attenuated fibrogenesis in 2 ways as follows: via the inhibition of Smad-dependent TGF-β signaling pathway and the anti-apoptotic pathway. Thus, GQDs may be a therapeutic option for the chronic kidney disease progression.

PUB433

DDAH1 Inhibitor PD 404182 Increases Serum Asymmetric Dimethylarginine but Does Not Promote Renal Fibrosis

Ming Wu, Chaoyang Ye, Meijie Yuan. *Shanghai Shuguang Hospital, Shanghai, China.*

Background: Plasma asymmetric dimethylarginine (ADMA) is a risk factor for chronic kidney disease, however we recently showed that renal ADMA is anti-fibrotic. ADMA is metabolized by dimethylarginine dimethylaminohydrolase isoform 1 (DDAH1). PD 404182 is a novel inhibitor of DDAH1 exhibiting anti-tumor and anti-HIV activities. We aimed to determine the effect of PD 404182 on renal fibrosis and explore its underlying working mechanisms.

Methods: After sham or unilateral ureteral obstruction (UUO) operation, 20-25g male c57 mice were treated with vehicle or PD 404182 for 13 days. Moreover, human kidney 2 (HK2) cells were treated with various concentrations of PD 404182 in the presence of 2.5 ng/ml TGF-β. Protein samples from *in vivo* and *in vitro* experiments were collected to assess renal fibrosis.

Results: Treatment with PD 404182 enhanced serum ADMA levels in UUO mice, however it did not change the deposition of extracellular matrix proteins, the expression of α smooth muscle actin (α SMA) and connective tissue growth factor (CTGF) in UUO induced fibrotic kidneys. We further showed that PD 404182 reduced the expression of DDAH1 in UUO kidneys which was correlated with increased production of ADMA. In TGF-β stimulated HK2 cells, PD 404182 dose-dependently increased ADMA production, and inhibited the expression of pro-fibrotic proteins. Exogenous addition of ADMA inhibited the expression of profibrotic proteins and attenuated the anti-fibrotic effect of PD 404182.

Conclusions: PD 404182 enhances serum ADMA levels but does promote renal fibrosis in obstructed kidneys, which is possibly due to a balance between serum and renal ADMA.

PUB434

Changes of Pericyte in Aging Kidney

Hyung Duk Kim,[2,1] Eun Nim Kim,[1] Yongjie Jin,[1] Ji Hee Lim,[1] Yaeni Kim,[2,1] Cheol Whee Park,[2,1] Bumsoon Choi.[3,1] *[1]The Catholic University of Korea, Seoul, Republic of Korea; [2]Seoul St. Mary's Hosp, Catholic Univ of Korea, Seoul, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea.*

Background: Our previous study have shown the changes of pericytes in aging mice kidney. However, its mechanism was unclear. And no such studies have been undertaken in human aging kidneys. In this study, we investigated the pericytes changes in human aging kidneys and mechanism of aging-related pericyte changes.

Methods: Renal biopsy from KT donors were analyzed. Donors under age 25 were assigned to young group and donors over age 60 to old group. 2, 24-months-old mice and 18-month-old mice treated with pentoxifylline for 6 months were analyzed with western blot.

Results: Changes of pericytes in human renal tissues were consistent with those in the aging mice model. In the old age group, pericytes were decreased and interstitial fibrosis was increased. Western blot analysis in mice kidney revealed that IL-1β, IL-6 and TNF-α were significantly increased in old age and significantly decreased in pentoxifylline group. Angiopoietin 2 was increased in old age group and decreased in pentoxifylline group.

Conclusions: In aging human kidney, pericytes have been shown to exhibit numerical reduction and loss of perivascular location as in the aging mice model. These changes in pericytes are thought to be induced by angiopoietin 2 excretion.

PUB435

Exosomal miRNA Exerkines Attenuate CKD by Extracellular Matrix Remodeling

Bjoern Tampe, Michael Zeisberg. *University Medical Center Goettingen, Goettingen, Germany.*

Background: Chronic kidney dissease (CKD) is still an unmet challenge because no effective therapies are available as of yet for clinical use. While various studies across multiple organs which demonstrated that endurance exercise (EE) protects from progressive organ failure by endocrine-like signalling via specific miRNA exerkines, little consideration has been paid as to whether any miRNA exerkines are released in a manner other than direct discharge into the circulation. It is becoming increasingly apparent that one of the main mechanisms by which scelettal muscle cells and distant organs communicate is by the release of cell-derived extracellular exosomes. Based on these pre-requisits, we here aimed to gain insights into the molecular mechanisms underlying successful reno-protection and to explore whether such pathways could be therapeutically targeted.

Methods: EE was performed in *C57BL/6*mice for 4 weeks before challenging with unilateral ureteral obstruction (UUO) for 7 days without EE. Exosomal miRNA signatures were analyzed by unbiased array-based approaches and confirmed by qRT-PCR in sclettal muscles, plasma exosomes and corresponding kidneys. By using miRNA mimics administered systemically, miRNA candidates for succesful protection during EE were confirmed for therapeutical implications.

Results: We identified a unique miRNA signature in muscle-derived exosomes and kidneys specifically during endurance exercise, associated with attenuation of progressive CKD. Systemic administration of miRNA mimics was equally effective to attenuate progressive CKD, supporting that endurance exercise-derived exosomal miRNAs are involved in reno-protection. On a mechanistic level, we provide evidence that exosomal miRNAs directly target and degrade *PAI-1*, associated with activation of the tPA/uPAR/plasmin pathway. Increased tPA/uPAR/plasmin stimulates ECM remodelling and degradation by activation of latent MMPs, in particular MMP-2 and MMP-9.

Conclusions: In summary, we here provide evidence that EE attenuates progressive CKD by enrichment of exosomal miRNA exerkines modulating ECM remodelling in chronically injured kidneys. Because miRNA mimics equally protect from progressive CKD, these findings further support therapeutical implications of exosomal exerkines as nature's exercise pill.

PUB436

Screening for Small Molecule Inhibitors of Kidney Injury Molecule-1 (KIM-1) Using a Cell-Based Functional Assay

Amrendra K. Ajay,[1] Venkata Sabbisetti,[2] Yutaro Mori,[2] Joseph V. Bonventre.[2] *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Kidney Injury Molecule-1 (KIM-1) is a transmembrane protein which is upregulated in injury to the proximal tubule. Plasma and urinary levels of KIM-1 are increased in patients with chronic kidney disease (CKD). KIM-1 serves as a prognostic marker for patients with CKD. Acutely KIM-1 takes up phosphatidylserine and oxidized lipids, advanced glycation end products (AGEs), and free fatty acids. Chronic expression of KIM-1 causes CKD in mice. This evidence suggests that KIM-1 expression contributes to the progression of CKD and inhibition of KIM-1 function may be beneficial for CKD patients.

Methods: Using cell-based functional assay for KIM-1 mediated uptake of ox-LDL, we screened for 14,414 unique small molecule compounds. After setting up a score for each compound, we selected and cherry-picked the 240 potential hits from the primary screening. We performed reconfirmation and dose dependency studies on two KIM-1 expressing cells (769-P cells and LLCPK-1 cells) expressing human KIM-1. A total of 32 compounds were selected based on reconfirmation and dose dependency studies as potential hits.

Results: We selected JB1 for secondary and tertiary assays as it was top scored. JB1 is not toxic to cells up to 11.11 μM. JB1 does not cleave KIM-1 indicating that JB1 inhibits the uptake of ox-LDL. JB1 doesn't quench DiI-Ox-LDL. JB1 significantly inhibits the uptake of BODIPY-labeled palmitic acid. Additionally, JB1 does not inhibit uptake by inhibiting Bcl-2 pathways.

Conclusions: We have developed a high throughput cell-based functional assay for screening compounds that can inhibit the uptake of ox-LDL by KIM-1. The small molecule inhibitors that we found can be of therapeutic importance for treating kidney disease.

Evaluation of Biomarkers of Interest in Nephrectomized Animals

Dominic Poulin, Rana Samadfam, Florence Poitout, Mari Elias, Ryan Schafbuch. *Charles River Laboratories, Senneville, QC, Canada*.

Background: Chronic kidney disease (CKD) is a worldwide health problem associated with morbidity and mortality, and its development and progression is related to various conditions such as hypertension, diabetes and dyslipidemia. Experimental models of CKD includes the 5/6 nephrectomy rat model, which shares multiple features observed in humans and therefore has been proven clinically relevant.

Methods: We investigated the effect of 5/6 nephrectomy on serum biochemistry and urinary kidney biomarkers, and bone markers as well as histopathological changes. For this purpose, blood and urine samples were collected from 6 control and 12 nephrectomized rats once monthly.

Results: Increases in serum urea nitrogen, creatinine, cholesterol and osteocalcin were consistently observed throughout the evaluation period. Increases in serum alpha2 macroglobulin, urine total protein, and urine biomarkers: osteopontin, neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule (KIM-1), cystatin C and β2-microglobulin, and decreases in serum albumin were observed over the course of the evaluation period. Lesions in the kidneys of nephrectomized rats were mild to moderate tubular hypertrophy and hyperplasia with dilatation and cast, resulting in an overall enlargement of the kidney; minimal to moderate tubular degeneration and regeneration; mild to marked glomerulopathy and minimal to mild chronic inflammation. Mineralized foci were also identified in the kidneys of nephrectomized rats by image analysis. Vascular changes were noted in small to medium size ventricular arteries and consisted of minimal mural degeneration and minimal to mild perivascular inflammatory cell infiltrates and fibrosis.

Conclusions: These changes observed in serum and urine samples, as well as histopathologically, are indicative of chronic kidney disease. Therefore the model is considered suitable for the investigation of new treatments for CKD.

PUB438

Cordyceps Militaris Extract Attenuates the Pathological Fibrotic Changes in Unilateral Ureteral Obstruction Mice Model

Chia-Chun Wu,[1,2] Chien-wei Hsiung,[3] Ting-Feng Wu.[4] *[1]Chi Mei Medical Center, Tainan, Taiwan; [2]Pharmacy, Chia Nan University of Pharmacy and Science, Tainan, Taiwan; [3]Phytomed Bio-Tech co., Ltd., Tainan, Taiwan; [4]Southern Taiwan University of Science and Technology, Tainan, Taiwan*.

Background: Cordyceps militaris (CM) is a kind of functional mushroom. This study aimed to evaluate the effect of CM in kidney fibrosis induced by unilateral ureteral obstruction (UUO) mice model.

Methods: Study mice were divided into five groups: Sham surgery, UUO, UUO+ solvent (saline), UUO + CM 150mg/kg (CM low dose) and UUO + CM 300mg/kg (CM high dose). Study agents were fed orally daily after UUO induction until animals were sacrificed on day 7. Kidney samples were collected for H&E stain and Masson's Trichrome stain. Severity of kidney damage was graded from one to five depending on severity: 1 = (< 1%); 2 = (1-25%); 3 = (26-50%); 4 = (51-75%); 5 = (76-100%). The value of $p < 0.05$ was considered statistically significant.

Results: All groups except sham surgery had obvious kidney damage range from 2-4. The interstitial fibrosis on H&E stain and Masson's Trichrome stain were both significantly less severe in CM low dose group compared to it was in UUO + solvent group. The CM high dose group had significantly higher scores in interstitial fibrosis both on H&E stain and Masson's Trichrome stain and ECM accumulation compared to CM low dose group. Besides, CM high dose group also had significantly higher scores on ECM accumulation and fibrosis on Masson's Trichrome compared to UUO + solvent group. (Figure 1)

Conclusions: According to our findings, an adequate dosage of CM might have an anti-fibrosis effect in kidney but a high dose CM might have a negative effect. Further studies on protein and mRNA expression to support this finding and investigate the molecular mechanisms are needed.

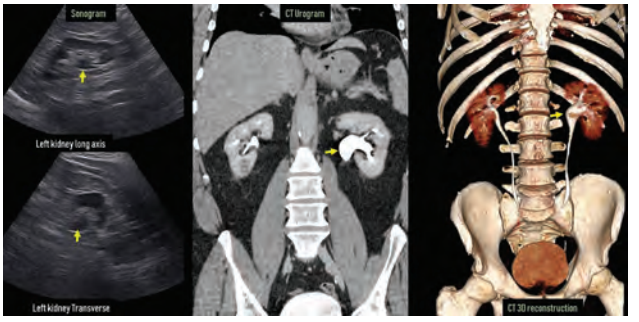
Extrarenal Pelvis Mimicking Parapelvic Cysts: Contrast Is the Key

Manzar Hussain,[2] Harini Bejjanki,[2] Israa Al-Ani,[2] Abhilash Koratala.[1,2] *[1]University of Texas Health science center, San antonio, TX; [2]University of Florida, Gainesville, FL*.

Introduction: Extrarenal pelvis refers to the presence of the renal pelvis outside the confines of the renal hilum. It is a normal anatomical variant that is found in ~10% of the population. An extrarenal pelvis appears as a hypoechoic mass just outside the renal sinus and can mimic a dilated pelvicalyceal system giving a false impression of hydronephrosis. In addition, it can also be confused with a parapelvic cyst. With renewed interest in point-of-care ultrasonography (POCUS), nephrologists must be aware of this finding and herein, we report a case where POCUS was not able to differentiate between these entities.

Case Description: A 62-year-old man with a history of nephrolithiasis and recurrent urinary tract Infections presented to the outpatient clinic for the management of chronic kidney disease stage 3. The renal sonogram showed the presence of a relatively well-defined anechoic lesion near the left renal pelvis, which could be a parapelvic cyst or mild hydronephrosis or an extrarenal pelvis. Because of the presence of microscopic hematuria, a computed tomography (CT) evaluation of the abdomen with contrast was obtained, which showed a left extrarenal pelvis [Figure] and multiple radiodense foci within the left pelvis, likely phleboliths. Subsequently, cystoscopy revealed a bladder tumor, for which he underwent resection with the resolution of hematuria.

Discussion: Renal sonogram might not be able to demonstrate the 'extrarenal' location of the extrarenal pelvis unless it is significantly dilated. Therefore, it can be easily confused with mild hydronephrosis or a parapelvic cyst. It is important to note that hydronephrosis appears as an anechoic 'branching' structure extending into the kidney instead of a 'well-defined' mass. In our case, CT Urogram has clearly demonstrated the extrarenal location of the pelvis without intrarenal extension. Parapelvic cyst was excluded because a cyst would not communicate with the collecting system and therefore, should not be filled with contrast.



PUB440

Hyperuricemia-Induced AKI Secondary to Leukemoid Reaction

Martha Catalina Morales Alvarez, David Doobin, Patricia Dharapak. *Icahn School of Medicine at Mount Sinai Beth Israel, New York, NY*.

Introduction: Uric acid has recently been recognized as an active nephrotoxic agent. Acute tumor lysis syndrome, recent cardiac surgery, rhabdomyolysis and cistplatin treatment are common clinical conditions associated with uric acid induced-acute kidney injury (AKI). Leukemoid reaction is an elevation of the white cell count >30 K/uL in absence of hematologic malignancies and secondary to solid tumors or infections. We describe the first reported case of uric acid-induced AKI secondary to leukemoid reaction.

Case Description: 56 year old male with history of sarcomatoid bladder carcinoma and prostate adenocarcinoma status post radical cystoprostatectomy (1 mo prior to admission) presented with weakness, fevers, and lower extremity edema. On admission, he was found

to have significant leukocytosis (180 K/uL) and a new intra-abdominal mass concerning for infected peritoneal carcinomatosis. Broad-spectrum antibiotics were initiated without significant improvement. A peripheral smear showed increased leukocyte count with bands but no blasts or schistocytes, favoring a leukemoid reaction from advanced neoplastic disease. His hospital course was complicated by oliguric AKI (creatinine of 2.0 mg/dl, up from 0.8 mg/dl) when WBC peaked at >200 K/uL within 1 week from admission. The uric acid level was found to be 21 mg/dl. Urinalysis revealed pyuria, hematuria, hyaline casts, and uric acid crystals. The patient was continued on intravenous fluids and received one dose of rasburicase. Within 24 hours, the creatinine improved to 1.66 mg/dl. Due to the patient's poor overall prognosis, the family elected to pursue comfort care.

Discussion: Uric acid has pro-inflammatory and vasoconstrictive properties and it has recently been described as a potential nephrotoxic agent. Crystal deposition and tubular toxic damage are the main mechanisms of injury, though recent studies have also implicated the role of severe afferent vasoconstriction. While our patient had several traditional risk factors for AKI, his kidney function deteriorated only after the WBC reached a level >200 K/uL and his uric acid peaked above 20 mg/dl. Leukemoid reactions are not associated with lysis syndrome. However, it might pose a potential complication in patients with an acute and rapid increase in WBC. Early consideration of this complication and timely rasburicase administration can salvage kidney function.

PUB441

A Solvent Drag: Traditional Meds Mixed with Ethylene Glycol in a Nigerian Patient on Dialysis

Muhammad S. Ajmal,[1] Adebowale I. Awosika-Olumo,[2] Olusola O. Ayinbode,[3] Rajeev Raghavan.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Walden University, Houston, TX; [3]GHMIGROUP INC, Houston, TX.*

Introduction: Unregulated traditional medications and their solvents are nephrotoxic. A Nigerian patient presented with a rapid progression of kidney disease following daily ingestion of an aphrodesiac dissolved in ethylene glycol. The diagnosis was confirmed with kidney biopsy and elevated serum oxalate levels. The epidemic of kidney disease in rural communities may in part be explained by this solvent.

Case Description: The patient is a 49-year-old Nigerian male with a 10-year history of diabetes mellitus and hypertension. One year prior to presentation, the serum creatinine was 1.6 mg/dl with 0.8 gram/day proteinuria. The patient began ingesting a traditional, herbal medication as an aphrodesiac. This is a customary practice in his village, outside Abuja, Nigeria. His serum creatinine increased to 8.9 mg/dl and the patient commenced thrice weekly hemodialysis. His local physician was concerned and the patient was sent to Houston, TX for a second opinion. Home medications included calcitriol, proton pump inhibitor (PPI), multivitamin, and a DPP-4 inhibitor. A full laboratory evaluation for immunologic or infectious causes of kidney failure was unremarkable. Kidneys were 12 cm bilaterally, with one non-obstructing calculi (7mm) in left kidney. A kidney biopsy revealed protracted tubular injury with isometric vacuolization and numerous calcium oxalate crystals. There was minimal glomerulosclerosis, and severe interstitial fibrosis / tubular atrophy. A serum oxalate level was subsequently checked, and elevated at 25 mcmol/L (Range 1.8-3.2). There was no evidence of primary hyperoxaluria. His local physician later ascertained that ethylene glycol was used a solvent for the traditional aphrodesiac. Kidney damage was irreversible and the patient returned to Nigeria.

Discussion: Worldwide, the increasing use of traditional, unregulated, herbal supplements has the potential to cause epidemics of kidney disease in rural communities. In Africa, attention has focused on nephrotoxic herbs (e.g. aloe vera and cymbopogon citrullus), but under-recognized is the role of the alcohol based solvent. Chronic use of ethylene glycol results in oxalate nephropathy. A thorough history and work-up should be pursued in all patients with a rapid decline in kidney function, even in the presence of known risk factors for CKD.

PUB442

Two Cases of Rhabdomyolysis with Near Normal Creatine Kinase

Tariq A. Khan,[1,2] Fnu Shehzad,[1,2] Satish Kumar.[1,2] University of Oklahoma Nephrology Fellowship Program *[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]VA Medical Center, Oklahoma City, OK.*

Introduction: Rhabdomyolysis (RM) is a well-known cause of acute kidney injury (AKI). Elevation of creatine kinase (CK) is considered essential for the diagnosis of severe AKI from RM. We present 2 cases of severe AKI from non-traumatic, non-exertional RM with mildly elevated CK.

Case Description: Case 1 A 55-year-old Caucasian male with history of DM and HTN was admitted with 1-week history of dyspnea and found to have AKI. There was no history of trauma or Illicit drug use. Exam showed BP of 150/80 and no edema. Serum creatinine was 1.4 mg/dl 2 months prior, 3.1 mg/dl on admission and rose to 12.6 mg/dl on day 6. UA showed 2+ blood, 3+ protein and 11 RBC's/ HPF. CK was 285 IU/L (1.2 x normal, day 2), LDH 552 IU/L (day 2) and plasma myoglobin 263 ng/dl (day 5). Urine myoglobin was undetectable when checked on day 6. Serum sodium was 128 mmol/L and plasma osmolality 291mOsm/Kg. Evaluation for rapidly progressive glomerulonephritis (RPGN) including ANA, ANCA, ASO, Anti GBM Ab, C3, C4, hepatitis panel and HIV was negative. A renal biopsy on day 4 showed severe acute tubular injury with many myoglobin casts. Renal function slowly returned to normal with conservative treatment. Case 2 A 48-year-old Native American male with history of DM, HTN, CAD and alcohol and cocaine abuse was admitted with 1-week history of dyspnea and found to have severe AKI. Exam showed BP of 141/100 and 1+ edema. Serum creatinine was 0.6 mg/dl 2 years prior and 23 mg/dl on admission. Serum sodium was 120 mmol/L and plasma osmolality 301 mOsm/kg. UA showed 2+ blood, 2+ protein and 2-5 RBCs/HPF. CK was 733 IU/L (2.9 x normal), LDH 421 IU/L and plasma myoglobin > 2000 ng/ml. Evaluation for RPGN, as in Case 1, was negative. A renal biopsy on day 5 showed severe acute tubular necrosis. He required dialysis for 6 days. Renal function continued to improve after stopping dialysis.

Discussion: Both patients had severe AKI with biopsy proven acute tubular necrosis. In both, CK was only mildly elevated and plasma myoglobin was more definitely elevated. Both had non-specific hematuria and proteinuria prompting evaluation for RPGN. Both patients had low plasma sodium with normal plasma osmolality consistent with pseudohyponatremia. The cause of pseudohyponatremia was not clear and would be an interesting subject for further study. Rhabdomyolysis should not be excluded as a cause of severe AKI based on near normal CK.

PUB443

Patient with AKI of Uncommon Etiology

Sushma Edara,[1] Madhu Kandarpa.[2] *[1]Kidney care specialists, Beavercreek, OH; [2]Kidney Care Specialists, LLC, Dayton, OH.*

Introduction: Acute kidney injury is a common complication of congestive heart failure. Here we present a case report of a patient with acute kidney injury complicating congestive heart failure but of unexpected etiology.

Case Description: 70-year-old man with history of hypertension, hyperlipidemia and Chronic Obstructive Pulmonary Disease(COPD) who hasn't seen a physician for several years presented with acute respiratory distress requring mechanical ventilation. He was treated for new onset heart failure and acute pulmonary edema. Echocardiogram reported left ventricular ejection fraction of 30% and global hypokinesis. He was extubated after 24 hours, but his creatinine increased rapidly from 1.9mg/dl at the time of initial presentation to 9.5mg/dl within 4 days post extubation. Anti-Neutrophil Cytoplasmic Antibodies and Anti-Nuclear Antibodies were negative; C3 and C4 were within normal limits. Renal biopsy was performed which surprisingly showed Cholesterol embolization along with interstitial fibrosis, tubular atrophy as well as mild acute tubular necrosis. CT angiogram showed Bilateral renal artery stenosis, occluded right main renal artery and severe near occlusive single left renal artery. Percutaneous transluminal angioplasty and stenting of the left renal artery was performed and placed on Clopidogel. Patient's blood pressure remained well controlled with no further acute pulmonary edema.

Discussion: Cholesterol embolization on biopsy prompted further workup. There was no preceding vascular intervention suggesting the cholesterol emboli was possibly a spontaneous event induced by hemodynamic stress which alters the endothelium. Mortality is likely to be high in these patients especially in elderly males, most commonly due to cardic and renal etiologies as per previous reports (1). 1. Am J Nephrol. 1993;13(6):489-93.

PUB444

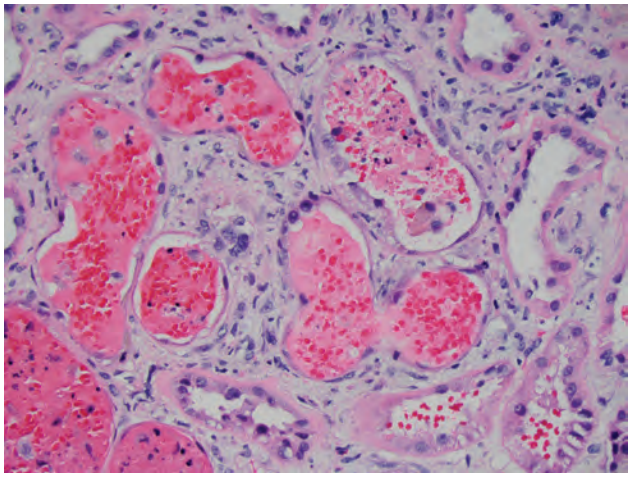
Anticoagulant-Related Nephropathy in IgA Nephropathy

Mal P. Homan,[1] Sharif Ali,[2] Sharon E. Maynard.[1] *[1]Lehigh Valley Health Network, Zionsville, PA; [2]Lehigh Valley Hospital, Orefield, PA.*

Introduction: Anticoagulant-related nephropathy (ARN) is a potential complication of warfarin use. This is the case of ARN in a patient with IgA nephropathy (IgAN).

Case Description: A 68-year-old man with cirrhosis, CKD stage 3, and atrial fibrillation on warfarin was admitted with edema, acute kidney injury (AKI), and gross hematuria. His creatinine was 2.9 mg/dL (baseline 1.4-1.6 mg/dL); INR was 2.5. Renal ultrasound was normal, urine-protein creatinine ratio (UPCR) was 1.9 g/g, serologic work-up was negative, and complement levels were normal. Renal function worsened. A kidney biopsy revealed mild mesangial hypercellularity with tubules containing red blood cell (RBC) casts, and mesangial IgA and C3 granular deposits. His anticoagulation was held, and renal function improved. On follow-up, his creatinine was 1.1 mg/dL and UPCR improved to 0.6 g/g.

Discussion: ARN causes RBC casts in the tubules leading to obstruction and AKI. Patients with IgAN may be at higher risk for ARN because of their propensity for hematuria. In the original description of ARN, underlying IgAN was present in 1/3rd of patients, and supertherapeutic INR was present in the majority of cases. Other risk factors include age, diabetes, hypertension, and cardiovascular disease. The risk of AKI in warfarin-treated patients with supertherapeutic INR is higher in those with CKD (33%) as compared to those without CKD (16.5%). Given the widespread use of warfarin and other anticoagulants, it is important to recognize the risk of ARN, and avoid excessive anticoagulation, particularly in patients with CKD and IgAN.



PUB445

AKI in a Patient with History of Recurrent Hemoptysis

Sushma Edara,[1] Madhu Kandarpa.[2] [1]*Kidney care specialists, Beavercreek, OH;* [2]*Kidney Care Specialists, LLC, Dayton, OH.*

Introduction: Presentation of patients with pulmonary-renal syndrome may vary. Here we present a patient with acute kidney injury after several episodes of hemoptysis.

Case Description: 65-year-old female patient with a history of recurrent episodes of shortness of breath and hemoptysis followes as idiopathic Pulmonary Fibrosis (PF) presented with creatinine of 5.5mg/dl. Her baseline creatinine was 1.2mg/dl 4 months ago, with no prior history of kidney disease. Patient had a family history of PF with no kidney abnormalities. Urinanalysis positive for moderate blood and proteinuria of 1.7mg/dl. Renal ultrasound was negative for hydronephrosis. Complement levels were within normal limits. Antinuclear antibodies, Anti GBS antibodies and rheumatoid factor were negative. Cytoplasmic and perinuclear anti-nuclear cytoplasmic antibodies (ANCA) positive at 1:640, proteinase3 (PR 3) elevated at 4.3U/ml, myeloperoxidase antibody (MPO) elevated at 47.7U/ml. Renal biopsy which showed Focal Necrotizing and crescentic Glomerulonephritis, MPO- ANCA associated with advanced chronic changes suspecting underlying Autoimmune etiology. Patient is being treated with oral prednisone and oral Cyclophosphamide after pulse methylprednisone. Patient continued to require hemodialysis hoping for renal recovery, but her pulmonary symptoms have resolved.

Discussion: In Retrospect recurrent episodes of hemoptysis despite prednisone alone probably indicative of vasculitis. Higher mortality rate of ANCA-associated vasculitis possibly can be lowered with serological testing in every patient with recurrent hemoptysis even without renal involvement at the time of initial presentation.(1) 1. DOI: 10.1055/s-0031-1279828

Anti-Brush Border Antibodies LRP2: A Rare Entity That Should Not Be Brushed Off

Keyla J. Davila- Marcano,[1] Ranil S. Gajanayaka.[2] Methodist Dallas Medical Center [1]*Methodist Hospital Dallas, DALLAS, TX;* [2]*Dallas Nephrology Associates, Southlake, TX.*

Introduction: Acute kidney injury (AKI) has been related to drugs, infectious and multiples autoimmune diseases against glomerular antigens. We present an under-reported case of AKI secondary to kidney anti-brush border antibodies LRP2(ABBA disease). Our case is remarkable due to the atypical presentation of nephrotic range proteinuria 7.3g in compare to sub nephrotic range proteinuria of previous cases reported. ABBA can present as an AKI, progress to ESRD or recur in a kidney transplant. This case alerts the clinicians about the diagnosis of tubular injury which is not part of the usual initial assessment. The existence of any IgG-containing TBM immune deposits without proliferative glomerular lesions should aware us about to the possibility of this disorder.

Case Description: A 72 y/o M with pmhx of HTN presents with acute kidney injury. Family, social and medication history were unremarkable. He presents with creatinine 1.5mg/dL, albumin 2.1 and 7.3 g of proteinuria. Glomerular work up resulted negative, urinalysis with proteinuria >300mg and blood positive. Physical examination remarkable for Bp 143/82, general weakness and bilateral leg edema. Kidney ultrasound was within normal limits. Kidney biopsy resulted with Anti Brush Border Ab disease/ LRP2 (Megalin Related Nephropathy). Patient was treated with IV steroids for 3 days and then started with prednisone 80 mg daily, MMF 750 mg BID, Bactrim SS 3 times a week.

Discussion: We present an underreported cause of AKI LRP2 associated with circulating autoantibodies to the tubular brush border protein LRP2/megalin and characterized by IgG- and LRP2-containing immune complexes in the TBM. This case should alert clinicians of other causes of AKI.

PUB447

Magnesium Toxicity: A Perfect Storm

Wut yi Hninn,[1] Ala Abudayyeh,[2] Maung htain K. Lin.[3] [1]*UTHealth, Houston, TX;* [2]*The University of Texas MD Anderson Cancer Center, Houston, TX;* [3]*Charles Wilson VA outpatient clinic, Houston, TX.*

Introduction: Hypermagnesemia is a rare condition in the *absence of renal failure* since the kidneys are effective in maintaining the normal plasma magnesium concentration. 50 to 70 % of the filtered magnesium is passively reabsorbed in the cortical aspect of the thick ascending limb of Henle. Loop reabsorption is appropriately diminished with magnesium loading, thereby allowing the excess magnesium to be excreted in the urine. Here we present a case of a patient with preeclampsia treated with IV magnesium that led to magnesium toxicity.

Case Description: 29 years old G1P0 admitted for preeclampsia and started on IV Mg Sulfate. After she received Nifedipine and IV labetalol post-partum, she developed shortness of breath, dizziness, abdominal pain and distension, decrease urine output. Hypomagnesemia caused flushing, delayed deep tendon reflexes (DTR), muscle weakness, lethargy, decrease respirations, bradycardia, and hypotension. Urinalysis showed pyuria, Leukocyte esterase, urine protein 10 mg/dl. Creatinine was 0.92 mg/dl and normal LFT. Due to worsening abdominal pain, milk of magnesium and miralax were given. She later became anuric with decreased DTR with Mg level at 11.3mg/dl, creatinine elevated to 4.3mg/dl and EKG showed sinus tachycardia[A1]. IV Calcium gluconate and Foley catheter placed at which point she had 1 Liter of urine. She was maintained on IVF and magnesium levels continued to decrease and normalization of her creatinine.

Discussion: Use of calcium channel blockers can potentiate neuromuscular blockade action of Mg SO4. Abdominal pain, urinary retention due to muscle relaxation, and milk of magnesia further potentiated her renal failure and cardiac toxicity. It is critical to recognize the hypermganesemia early since loss of DTRs common in Mg >7 mg /dl and cardiac conduction defects and arrest common in Mg >12mg/dl.

PUB448

Rare Case of Anti-GBM Antibody Disease with Thrombotic Microangiopathy Caused by Hypertensive Emergency

Irene Nunuk,[1] Joshua M. Mendoza,[1] Vijay Kannuthurai,[2] Frank J. O Brien.[3] *[1]Washington University School of Medicine in St. Louis, St. Louis, MO; [2]Barnes-Jewish Hospital/Washington University in St. Louis, St. Louis, MO; [3]Washington University in St. Louis, St. Louis, MO.*

Introduction: Anti-Glomerular Basement Membrane (GBM) Antibody Disease is one of the most aggressive form of glomerulonephritis resulting in renal insufficiency and more than 95% of patients have crescents at the time of biopsy. It can be renal limited or in combination with pulmonary hemorrhage (Goodpasture's syndrome). In rare case, glomerulonephritis can be seen concurrently with thrombotic microangiopathy (TMA), a disease involving endothelial injury that results in thrombosis in capillaries and arterioles and can lead to thrombocytopenia, anemia, purpura, and kidney failure. Here we present a rare case of anti-GBM with concurrent TMA.

Case Description: We present a case of a 57-year-old female with history of COPD who presents with hematuria, and blood pressures in the 200s/100. Labs notable for a creatinine of 13.02 from 4.2 a week ago (baseline 0.85 3 years ago). Other labs are notable for Hemoglobin 7.9, platelet 104, LDH 551 and haptoglobin <10 with schistocytes. Kidney biopsy showed necrotizing cellular crescents and focal segmental necrotizing lesions. Immunofluorescence showed linear capillary loop staining of the glomeruli, with antisera to IgG, C3, kappa, and lambda light chains suggestive of Anti-GBM antibody disease. Follow up laboratory testing confirmed the diagnosis as Anti-GBM antibody disease as the measurement of anti GBM IgG antibodies was 7.9.

Discussion: Anti-GBM disease is a rare disorder and a literature review revealed just 10 published accounts of concurrent anti-GBM and TMA in a total of 15 patients. Of those, 3 cases were attributed to TTP and abnormalities in ADAMTS13, 3 were attributed to complement-mediated TMA (aHUS), 1 was attributed to mechanical destruction due to hemodialysis, 1 was attributed to HUS, 1 was attributed to Heparin-induced thrombocytopenia, and 6 were not otherwise specified. No cases attribute the TMA to hypertensive emergency as we report here. In the setting of TMA, empiric plasmapheresis is generally initiated, however, many causes of secondary TMA including hypertensive emergency have not been shown to respond to treatment. This was consistent with our patient's presentation as the thrombocytopenia and MAHA failed to improve despite the plasma exchange. Our patient continued to have a decline in kidney function and eventually required hemodialysis.

PUB449

An Uncommon Case of Drug-Induced Acute Interstitial Nephritis

Mohammed Y. Al Mulhim, Negiin Pourafshar, Garland A. Campbell. *University of Virginia, Charlottesville, VA.*

Introduction: Drug-induced acute interstitial nephritis (DI-AIN) is a common cause of acute kidney injury (AKI) and often presents as an unexplained rise in serum creatinine level (SCr). Despite the frequency of acute interstitial nephritis (AIN), there remain cases under-diagnosed and under-treated.

Case Description: We report a 54 -year-old male, presented with fatigue for a week and had increased SCr from baseline 2.0 mg/dl to 21 mg/dl with a BUN of 125 mg/dl. He denied recent changes in his medications or recent use of over the counter or herbal agent. He remained anuric with worsening renal function, therefore requiring hemodialysis. Patient's kidney biopsy revealed moderate interstitial inflammatory infiltrate associated with interstitial edema consistent with AIN. Reported potential causes of the patient's AIN included amlodipine and allopurinol which he was taking for almost 4 years and both were held. Given rapidly progressive nature of this patient's presentation, steroid therapy was instituted. His urine output increased within 24 hours of initiation of steroid therapy. Hemodialysis was stopped one week later. At the time of discontinuation of dialysis, SCr was 2.5 mg/dl and following one month of steroid therapy, it was 1.8 mg/dl.

Discussion: Our case highlights the inherent difficulty in recognition of anuric DI-AIN, which would result in difficulty in decision making regarding proper management. After withdrawal of the offending drugs and initiation of steroid, a rapid improvement of kidney function was noticed. The diagnosis of DI-AIN is typically made with classic triad of rash, fever and eosinophilia within a few days of initiation of a culprit drug. However, these findings appear in a small number of patients, and the onset may be delayed by weeks or months after initiation of medication. Diagnosis relies on maintaining a high index of suspicion in those at risk and obtaining a kidney biopsy. The hallmark pathologic features are interstitial edema, interstitial inflammation with a predominance of lymphocytes and mononuclear cells, with variable numbers of eosinophils. The mainstay of treatment is discontinuation of the offending drug. Multiple studies have evaluated the benefit of steroid therapy to facilitate the recovery of renal function, with inconclusive results. This patient's timely recovery from dialysis could support the use of steroid in dialysis dependent AIN.

PUB450

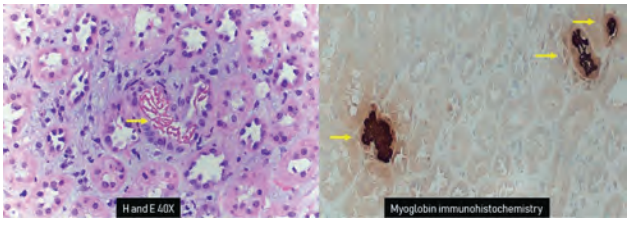
Amphetamine-Induced Myoglobinuric Kidney Injury: A Classic Yet Intriguing Tale

Samin Sharma, Manoj Bhattarai, Abhilash Koratala, Brittaini D. Bunce, Yanli Ding. *University of Texas Health Science Center San Antonio, San Antonio, TX.*

Introduction: Rhabdomyolysis, characterized by necrosis of muscle cells and release of their contents into the blood constitutes 7-15% of all cases of acute kidney injury (AKI) in the United States. We present a case of amphetamine-induced myoglobinuric kidney injury highlighting the importance of obtaining drug screen in the evaluation of AKI and present the classic renal pathology images of myoglobin cast nephropathy.

Case Description: A 41-year-old otherwise healthy man presented with abdominal discomfort, nausea and cola colored urine. His blood pressure at presentation was 174/93 mmHg. Laboratory data was significant for AKI with a serum creatinine of 12 mg/dL, rhabdomyolysis with a creatine kinase of >40,000 U/L [24-223]. Renal sonogram showed normal sized kidneys without hydronephrosis. The patient denied taking any illicit drugs, however, urine drug screen was positive for amphetamines. Urinalysis not only showed 3+ blood as expected with myoglobinuria but also >50 red blood cells/hpf and 4+ protein raising the suspicion for superimposed rapidly progressive glomerulonephritis (GN). Serum ANA and ANCA titers were negative. Renal biopsy demonstrated acute tubular injury (ATI) and myoglobin casts were confirmed by immunohistochemical staining [Figure]. The patient required a few sessions of hemodialysis but recovered gradually and creatinine trended down to 2.8 mg/dL at discharge.

Discussion: Amphetamine and its N-methylated derivative methamphetamine are known to cause AKI by several mechanisms, myoglobinuria-associated tubular injury (MTI) being the most common. Others include malignant hypertensive nephropathy, hyponatremia, necrotizing vasculitis and thrombotic microangiopathy. Renal biopsy should be undertaken when there is a suspicion for superimposed GN. Histology sections in MTI typically demonstrate ATI with variable flattening of tubular epithelial cells, loss of brush borders, and intratubular sloughed epithelial cells. Myoglobin casts are composed of round granules that may line up in chains or aggregate in clusters. Immunoperoxidase staining with antibody to myoglobin is usually strongly positive in the casts.



PUB451

Calcium Oxalate Nephropathy: A Rare Etiology of ESRD

Richa Handa, Muhammad A. Farooq, Jian Li, Sandeep S. Soman. *Henry Ford Hospital, Dearborn, MI.*

Introduction: Oxalate nephropathy is a rare cause of renal failure. It is characterized by tubular crystalline deposits of calcium oxalate leading to acute and chronic tubular injury, interstitial fibrosis and progressive renal insufficiency. There are two types of oxalate nephropathy, primary and secondary. Secondary hyperoxaluria is more common and is the result of increased dietary oxalate intake, decreased intestinal oxalate degradation, increased colonic permeability to oxalate. We present a case in which a patient with history of bariatric surgery (40 years ago) diagnosed with oxalate nephropathy and developed ESRD.

Case Description: A 74 y female with past medical history of gastric bypass surgery, (renal function was normal 1 year prior to hospital admission), NASH cirrhosis presented with abdominal pain, vomiting and melena. On presentation, the patient had creatinine of 12 mg/dl, bicarbonate of 7 mg/dl and hemoglobin of 5.8 gm/dl. Endoscopic evaluation showed two large varices. Due to minimal recovery of renal function, she was started on intermittent hemodialysis. Further workup showed positive ANA with titer of 1:640, positive dsDNA and low complement levels. Patient's urinalysis showed RBC>182/ HPF and proteinuria 100 mg/dl. Kidney biopsy showed acute tubular injury changes with tubular crystals consistent with calcium oxalate.

Discussion: According to National Center for Health statistics, the prevalence of obesity in the USA exceeds 30% and 228,000 bariatric surgeries were done in 2017. Electronic database for case reports and series with biopsy proven oxalate nephropathy in native or transplanted kidneys from 1950-01/2018 showed fat malabsorption (88%) and excessive dietary oxalate consumption (20%) as causes of oxalate nephropathy. According to a review, patients presented diagnosed with oxalate nephropathy between 4 months to 8 years after bariatric surgery. Diagnosis of oxalate nephropathy includes 24 hours urine collection for oxalate excretion and kidney biopsy. Treatment includes low-fat, low oxalate diet and high fluid intake. Secondary oxalate nephropathy is a rare cause of renal failure and can present after many years of bariatric surgery. Renal replacement therapy is required in >50% of patients, and most patients remain dialysis-dependent. Oxalate nephropathy should be suspected in a patient with remote history of bariatric surgery who presents with sub-acute renal failure.

PUB452

An Unexpected Cause of Renal Failure in a Patient with Diabetes

Mina Sourial,[2,1] Mary J. Dominguez,[2,1] Molly Fisher.[2,1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, Bronx, NY.*

Introduction: Granulomatous interstitial nephritis is the classic renal lesion seen but it uncommonly causes clinically significant renal disease and rarely presents in the absence of extrarenal lesions. We present a case of unexplained renal failure in a patient with recently diagnosed diabetes mellitus (DM) who underwent a renal biopsy which demonstrated granulomatous interstitial nephritis as the first manifestation of sarcoidosis.

Case Description: A 39-year-old African American male was admitted in August 2018 with new onset DM. At the time of his presentation, he was found to have serum

glucose of 727 mg/dl and an elevated serum creatinine 2.9 mg/dl (eGFR 29 ml/min) with no prior history of renal disease. Serum creatinine improved to 2.4 mg/dl after correction of hyperglycemia and volume expansion but then plateaued. No nephrotoxins were identified. Urinalysis revealed 6-10 wbc/hpf, urine protein/creatinine 380 mg/g with bland sediment. Serologic workup was negative. Renal ultrasound revealed enlarged kidneys measuring 12.4 cm and 13.6 cm. There was no improvement in renal function 1 month later so renal biopsy was pursued. Labs drawn pre-biopsy revealed new onset hypercalcemia with a serum calcium of 13.3 mg/dl and an increase in serum creatinine to 4.1 mg/dl. Hypercalcemia workup revealed 1,25-dihydroxyvitamin D level of 106 pg/mL. Chest x-ray was normal. Renal biopsy revealed complete loss of cortical architecture due to extensive interstitial inflammation and noncaseating granulomas. Stains for acid-fast and fungal organisms were negative. He was started on high dose prednisone 1 mg/kg/day for treatment of granulomatous interstitial nephritis in the setting of sarcoidosis. His hypercalcemia resolved and over the course of 3 months his serum creatinine improved to 1.7 mg/dl.

Discussion: Although granulomatous interstitial nephritis is a well described renal manifestation of sarcoidosis, it is often clinically silent and rarely occurs in the absence of extrarenal manifestations. Our patient's presentation of new onset DM was a red herring in the workup for his renal failure and highlights the importance of renal biopsy in all cases of unexplained renal failure. His hypercalcemia and extensive interstitial inflammation both likely contributed to his renal failure. Treatment with high dose prednisone resulted in resolution of hypercalcemia and significant improvement in his renal function.

PUB453

A Case of Acute Renal Infarction Associated with Hyperhomocysteinemia

Natalia Plotskaya, Neil K. Agarwal, Suzanne Boyle. *Nephrology, Drexel University College of Medicine, Philadelphia, PA.*

Introduction: Acute renal infarction (ARI) is a rare clinical diagnosis with an estimated incidence of less than 0.01%. The most common etiology is cardioembolic, but others include trauma, vasculitis, and hypercoagulable disorders. Many cases are deemed idiopathic. Here we present a case of ARI potentially attributable to hyperhomocysteinemia.

Case Description: A 61-year-old male with a history of radiculopathy presented with two days of right-sided abdominal pain. A week prior, he was evaluated for severe headache and vision impairment and was discharged after a normal head CT. On admission, physical exam revealed right flank tenderness. Labs showed a creatinine (cr) of 1.38 mg/dl (baseline, 1.05 mg/dl), leukocytosis (17 x 10E3/mm3), and transaminitis (ALT 57 IU/L, AST 71 IU/L), LDH was 915 IU/L, CRP 261 mg/L. CT abdomen/pelvis with IV contrast suggested right ARI from a thrombus in the right renal artery. Acute management included anticoagulation with unfractionated heparin. Thrombolysis was not performed, given the patient's development of fever, stabilization of creatinine, and lack of high-quality evidence for benefits vs. risks of the procedure. Given the patient's recent visual disturbance (potentially, amaurosis fugax), fundoscopic exam was performed, and was normal. No evidence of a cardioembolic source was identified. An extensive vasculitis panel was negative. Drug screen and blood/urine cultures, negative. Thrombophilia evaluation was negative, except an elevated serum homocysteine (Hcy) level of 46.6 mcmol/L. On day 5 renal doppler visualized flow within main renal arteries with normal resistive indices. Cr at discharge was 1.27 mg/dl.

Discussion: An extensive evaluation for the etiology of the ARI was negative with exception of a markedly elevated serum Hcy level. Hyperhomocysteinemia causes endothelial dysfunction and is a risk factor for cardiovascular disease. Hcy is an intermediary amino acid formed in methionine metabolic pathway. Elevated Hcy can be from genetic factors, reduced GFR, and drugs like fibrates and nicotinic acid. Although our patient had acute kidney injury, his level was higher than the reported mean for hemodialysis patients (20 mcmol/L), and it rose further post-discharge (99 mcmol/L). Because of this, empiric treatment with B12, folate, and B6 was started. This case emphasizes that Hcy levels should be included in the evaluation of idiopathic ARI.

PUB454

Cocaine-Induced ANCA Negative Vasculitis: A Diagnostic Dilemma

Kunal Bhuta, Kriti Devkota, Haris Mobeen, William DiFilippo. *SUNY Upstate Medical University, Syracuse, NY.*

Introduction: Cocaine is an addictive stimulant drug. In 2014, 913,000 Americans met the criteria for dependence or abuse of cocaine. Almost 69% of Cocaine is contaminated with Levamisole which has been found to be immunogenic with anti-neutrophil cytoplasmic antibody (ANCA) associated cutaneous vasculitis in 88-100% patients.

Case Description: 24-year old male with a history of substance abuse presented with bilateral lower limb weakness associated with burning pain and numbness in the right leg for 10 hours. He used cocaine one week prior to admission. Vitals were normal. See Table 1 for BMP. Labs also showed elevated SGOT of 1351 U/L, SGPT 460 U/L, elevated WBC. Urine analysis - pH 6.0, Hb 3+, RBC 14 and Protein 100. Renal ultrasound and Urine toxicology were negative. CPK levels (17,000 U/L) trended downwards. Urine microscopy showed muddy brown cast. Hepatitis serologies, Immunology including ANCA, C3, C4 were normal. Renal biopsy showed vasculitis, patchy interstitial edema along with focal collections of interstitial eosinophils. He was treated with hemodialysis and steroids.

Discussion: Cocaine can cause AKI by Rhabdomyolysis, Vasculitis, Platelet activation. Biopsy showed some focal vasculitis. Vasculitis in Cocaine abusers can be due to Levamisole, an anti-helminthic agent withdrawn due to multiple side effects. Levamisole is added to cocaine to enhance its euphoric effects. Levamisole induced ANCA positive vasculitis is well known. Our case is one of the few ANCA negative renal vasculitis responding to steroids. Levamisole is detectable in urine for only 5-6 hours making diagnosis challenging. The role of steroids in the treatment of this condition has not been established. This patient responded well to steroids likely due to presence of interstitial inflammation. Research is required to understand effective ways to treatment this condition. Until then, primary treatment continues to be cessation of drug use and renal replacement therapy if needed.

Basic Metabolic Profile

Sodium	135	136-145 mmol/L
Potassium	5.6	3.5-5.1 mmol/L
Bicarbonate	23	22-29 mmol/L
BUN	28	6-20 mg/dl
Creatinine	2.85	0.5-1.2 mg/dl
Glucose	115	70-140 mg/dl
Calcium	8.1	8.6-10.0 mg/dl

PUB455

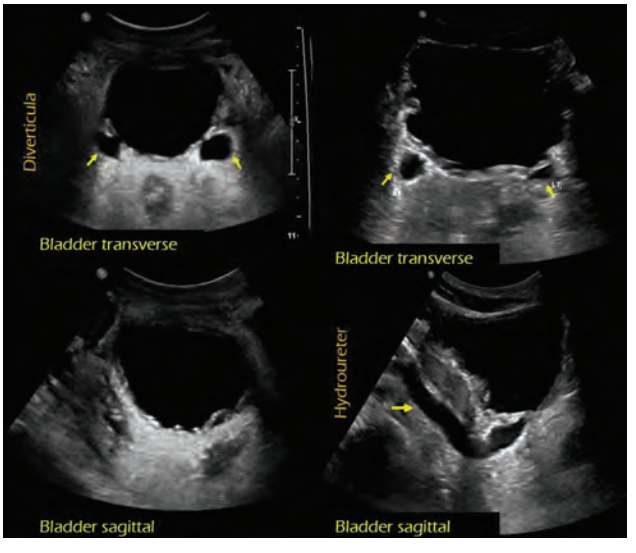
Two Variants of Mickey Mouse Sign on Urinary Bladder Point-of-Care Ultrasound: One with the Tail and One Without

Manzar Hussain,[1] Harini Bejjanki,[1] Abhilash Koratala.[2,1] [1]*University of Florida, Gainesville, FL;* [2]*University of Texas Health Science Center, San Antonio, TX.*

Introduction: For nephrologists, 'Mickey Mouse' by default reminds of dysmorphic red blood cells in the urine. With the increasing use of point-of-care ultrasonography (POCUS), we discuss the Mickey Mouse sign in the context of urinary bladder ultrasound. This case also illustrates the common POCUS aphorism, "one view is no view."

Case Description: A 72-year-old gentleman with a history of chronic kidney disease stage 5 secondary to autosomal dominant polycystic kidney disease, hypertension, and benign prostatic hyperplasia presented to the hospital with worsening signs of hypervolemia. He was also found to have worsening renal function compared to prior baseline, and nephrology was consulted for possible initiation of renal replacement therapy. On POCUS, the medical student reported that the patient had bilateral hydroureter. However, on a careful review of images and longitudinal scanning, the anechoic sac-like structures posterior to the bladder were found to be diverticula in the setting of chronic bladder outlet obstruction and not hydroureter [Figure: left panel is diverticula and right hydroureter]. Moreover, there was no hydronephrosis on either side.

Discussion: A bladder diverticulum is a sac or pouch that protrudes out of the bladder wall. Diverticulae may be congenital (primary) or acquired (secondary), and acquired diverticula from chronic bladder outlet obstruction are commonly encountered in the adult population. They appear as Mickey Mouse ears on bladder ultrasound, with the bladder representing the head. Hydroureter (s) can mimic diverticula in the transverse plane, but on the longitudinal scan plane, it usually appears as an anechoic tubular structure resembling the tail of the Mickey Mouse. Moreover, hydroureter is more likely to be associated with hydronephrosis than diverticula. Also, normal ureteric jets, that is a visualization of the normal physiological periodic efflux of urine on color Doppler will be seen with diverticula, while they are expected to be weak or absent in the case of a hydroureter.



PUB456

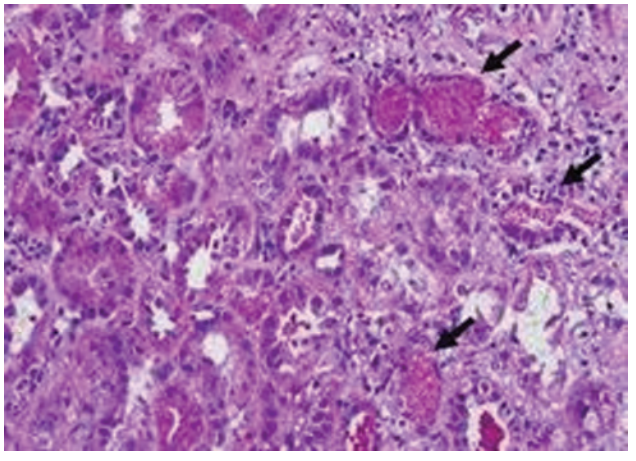
A Woman with Anticoagulant-Related Nephropathy (ARN): Recently Recognized AKI Syndrome

Hasan Zahid,[1] Ramla Abbas,[1] Ghulam M. Aftab,[1] Ramesh M. Kotihal.[2] [1]*Orange Park Medical Center, Orange Park, FL;* [2]*Nephrology Associates of NE Florida, Orange Park, FL.*

Introduction: Anticoagulant related nephropathy (ARN) is defined as an acute increase in international normalized ratio (INR) to >3.0, followed by evidence of acute kidney injury (AKI) within 1 week of the INR increase with no other obvious etiology. We present a case of a 65 year old female who developed AKI secondary to warfarin therapy.

Case Description: A 65 year old female with past history of protein S deficiency, hypertension and CKD stage 3 presented with blood in urine. She was found to have oliguric AKI with a supratherapeutic INR of 7.8 and Creatinine of 14.1 mg/dl while on warfarin therapy for multiple deep venous thrombi in the past. Home medications included warfarin and lisinopril. Review of systems was otherwise negative with no recent contrast administration. Exam was significant only for hematuria. Coagulation profile showed PTT of 46.9 seconds and PT of 82.5 seconds. All other labs were within normal limits. Several RBCs with RBC casts were seen on urinalysis. Urine protein creatinine ratio was 0.9. Ultrasound disclosed echogenic kidneys with no hydronephrosis. All medications including warfarin were held immediately on admission and despite volume resuscitation, BUN and Cr did not show any improvement. After 5 days of hospitalization her INR improved from 7.8 to 2.6 and Cr came down to 4.17 mg/dl. Renal biopsy revealed severe occlusion of renal tubules by red blood cells and casts with tubular cell damage consistent with acute tubular necrosis proving warfarin induced renal injury.

Discussion: There is growing evidence that ARN is a potentially serious complication of anticoagulation therapy. In addition to warfarin, there are several recent case reports that ARN can develop in patients on dabigatran or on apixaban. The recent retrospective analysis of RE-LY shed light on it as well. The higher prescription volume of anticoagulants, with lack of data on treatment for ARN, calls for large prospective trials.



PUB457

A Non-Respiratory Presentation of Sarcoidosis

Romela Petrosyan,[1] Mark D. Purcell.[2] *[1]University of South Carolina, Prisma Health Upstate, Greenville, SC; [2]Carolina Nephrology, PA, Simpsonville, SC.*

Introduction: Sarcoidosis is an inflammatory condition with presence of noncaseating granulomas. It can affect virtually every organ of the body and multiple triggers have been identified. A selection bias exists in the United States as most sarcoidosis clinics are run by pulmonologists and higher incidence is identified in African Americans who appear to develop more extensive and chronic pulmonary disease. Direct renal involvement occurs in less than 5% of sarcoidosis patients with granulomas seen in the kidney itself.

Case Description: A 28-year-old Nigerian male with past medical history of Malaria (treated in 2013) and Typhoid (treated in 2016) presented to the Emergency Department with acute renal failure with serum creatinine of 3.63mg/dL from baseline of 1mg/dL, 30lbs weight loss within two-month duration, myalgia, fatigue, and subjective low-grade fevers. He denied cough, shortness of breath, or any other respiratory symptoms. Renal ultrasound noted globular-shaped kidneys with increased echogenicity of the renal parenchyma. CT of the abdomen revealed prominent upper abdominal and retroperitoneal lymph nodes. Of note, the patient was found to be hypercalcemic with ionized Calcium of 6.2mg/dL, elevated 1,25-OH Vitamin D level of 78pg/mL and undetectable PTH, ANA negative, normal C3 and C4, and HIV non-reactive. The patient did not exhibit typical B-symptoms suggestive of underlying lymphoma and his flow cytometry was noted to be normal. During the work-up of his diagnosis, his renal function continued to decline and his serum creatinine peaked at 9.6mg/dL from 3.63mg/dL at presentation. Renal biopsy revealed chronic, active granulomatous tubulointerstitial nephritis. High resolution CT of the chest confirmed the mediastinal adenopathy and mild interstitial changes, consistent with sarcoidosis. However, through the course of his presentation, the patient did not develop respiratory symptoms.

Discussion: The risk of death or loss of organ function remains low in sarcoidosis and poor outcomes are typically limited to patients who present with advanced disease where irreversible fibrotic changes have occurred. Patients who require glucocorticoids in the first 6 months of presentation have a >50% chance of having chronic disease. This inspires vigilance on the physician to recognize the vast presentations, triggers, and genetic manifestations of patients diagnosed with this disease.

PUB458

Spontaneous Improvement Without Therapy in a Patient with Atypical Hemolytic Uremic Syndrome with p. I1157T in the C3 Gene Triggered by Influenza B Infection: A Case Report

Satoshi Yamazaki,[1] Hideki Matsumura,[1] Yuko Fujii,[1] Tomoko Tanaka,[1] Akihiko Shirasu,[1] Hyogo Nakakura,[1] Yuka Sugawara,[2] Yoko Yoshida,[2] Yoichiro Ikeda,[2] Akira Ashida.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Japan; [2]Nephrology and Endocrinology, The University of Tokyo, Tokyo, Japan.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a severe systemic disease characterized by thrombocytopenia, hemolytic anemia, and acute kidney injury. It has a poor prognosis, and the mortality rate was as high as 25% before the introduction of eculizumab therapy. In 50-80% of patients, an infectious event triggers the onset of aHUS. Among such triggers, influenza infection is relatively common, but most cases are of the H1N1 type or influenza A, and influenza B is only very rarely responsible.

Case Description: The patient was a 15-year-old boy who presented with a 2-day history of fever and macrohematuria, but no diarrhea. A nasal swab demonstrated positivity for influenza B virus antigen. On admission, he showed hemolysis with red blood cell fragmentation in a blood smear (LDH 1478 U/L, haptoglobin 6 mg/dL, Hb 13.8 g/dL), thrombocytopenia ($17x10^3/\mu L$) and acute kidney injury (serum creatinine 0.95 mg/dL) The serum creatinine level improved to 0.63 mg/dL in the recovery phase on day 11 after admission, and therefore the acute kidney injury was diagnosed as AKI stage 1 by KDIGO. These findings suggested incomplete TMA. ADAMTS13 activity was normal and a stool culture test failed to identify Shiga toxin-producing *Escherichia coli* or Shiga toxin 1 and 2. As manifestations such as hemolytic anemia and acute kidney injury were mild, the patient received peramivir hydrate for influenza B infection without plasma therapy or eculizumab therapy. He recovered and was discharged with no sequelae on hospital day 7. No relapse was observed for over 1 year. Subsequent genetic analysis identified mutation in *C3 (p.I1157T)*, confirming a diagnosis of aHUS.

Discussion: The symptoms in the present case were mild and improved spontaneously without specific therapy including plasma exchange or eculizumab. Japanese patients with *C3 p.I1157T* mutation, which was identified in this case are reported to show a favorable prognosis, and spontaneous recovery of an aHUS patient with MCP mutation triggered by influenza B has been documented. The data suggest that a mild defect of complement regulation including *C3 p.I1157T* resulted in the present patient's mild aHUS symptoms.

PUB459

Cardio-Renal Syndrome: Clinical Predictor of AKI

Natchaya Polpichai,[1,2] Ekamol Tantisattamo.[3,4] *[1]faculty of medicine, Prince of Songkla university, Hatyai, Thailand; [2]Department of Internal medicine, Baylor St. Luke's Medical Center, Houston, TX; [3]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [4]Multi-Organ Transplant Center, Division of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal oak, MI.*

Introduction: Acute tubular necrosis (ATN) is one of the most common causes of acute kidney injury (AKI) in hospitalized patients. Chronic pathophysiological changes in renal hemodynamic from an underlying cardiac disease named cardio-renal syndrome (CRS) is one of the risk factors of AKI. Nephrotoxic ATN can occur in patients who are at risk even in those with normal renal function. Close monitoring for renal function should prevent and early diagnose for AKI. We report a case of a middle-aged African American woman with chronic congestive heart failure(CHF) who received multiple nephrotoxic agents without judicious renal function monitoring and subsequently had a delay in diagnosis for non-oliguric AKI.

Case Description: A 43-year-old African American woman with a past medical history of advanced systolic heart failure secondary to mitrial valve (MV) regurgitation status post prostatic MV replacement and automatic intracardiac device (AICD) presented with fever. She developed acute decompensated heart failure and was found to have prosthetic acute MV endocarditis. Rifampicin, gentamicin, and cefazolin were initiated and the AICD was removed. She was diuresed with IV bumetamide. Her baseline serum creatinine (SCr) was 0.9-1.1 mg/dL, which had been stable until hospital day (HD) 15 when renal function was no longer checked. On HD 18, she had head and carotid CT angiography for pre-heart transplant work-up. Four days later, urine output (UOP) decreased to 460 ml/day and SCr increased to 5.44 mg/dL. She did not have hypotensive episode and sign of dehydration. A renal ultrasound showed bilateral cortical echogenicity without sign of obstruction. Unianalys revealed protein of 30 mg/dL and 1 RBC/HPF. FE_{Na} was 6.99%. Gentamicin was discontinued given its supratherapeutic level of 2.3 μg/mL. IV bumetanide was held. Followed-up daily renal function showed a gradually decreased SCr and an increased UOP.

Discussion: Our patient presented with AKI which is secondary to nephrotoxic ATN from gentamicin and IV contrast exposure. Although she had normal baseline SCr, her underlying CHF can contributed to renal hemodynamic impairment from type 2 CRS. The renal ultrasound supports underlying chronic kidney disease (CKD). Therefore, renal function should be closely monitored in such a high risk patient who has underlying CRS especially while receiving nephrotoxic agents in order to prevent and early diagnose for AKI.

PUB460

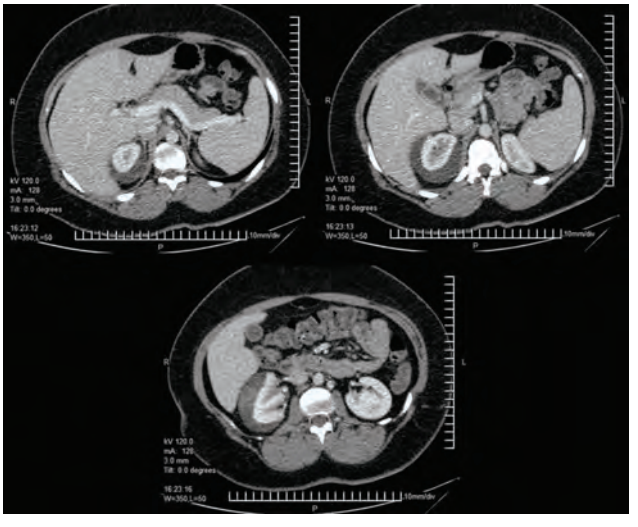
Wunderlich Syndrome as a Cause of Acute Low Back Pain and Hematuria: Case Report

Massabiel R. Arnaud,[3] Luis H. Sette,[1] Helena D. Rios,[2] Juliana G. Mota.[1] *[1]Universidade Federal de Pernambuco - UFPE, Caruaru, Brazil; [2]Hospital Getulio Vargas, Recife, Brazil; [3]Hospital das Clínicas - UFPE, João Pessoa, Brazil.*

Introduction: Wunderlich's syndrome is a rare event characterized by spontaneous perinephric / subcapsular hematoma. Characteristically presents the presence of pain in the flank or in all the abdomen, retroperitoneal mass and signs of hemorrhage. In most cases only nonspecific signs such as fever, nausea, vomiting and weight loss are seen.

Case Description: M.C.B, female, 23 years old presented with sudden pain throughout the abdomen with a predominance of posterior lumbar region, without irradiation, being at rest and without signs of local trauma. She also reported daily fever, nausea, and hyporexia. She sought emergency care where she had been given several medications but without remission of pain. No anemia and no leukicitosis were shown but C-reactive protein was high and urine summary leukocyturia and hematuria, therefore she was treated with antibiotics. A ultrasound was performed and found a hyperechogenic image with perirenal. CT scan of the abdomen found a subcapsular hemorrhage with perirenal hematoma in various degrees of evolution, evidencing compact hyperdense areas. An arteriography was performed with a right kidney supplied by a single artery, of normal size, without stenosis and seen deviation of the right kidney, which may correspond to extrinsic compression, with homogeneous parenchymal phase, with usual venous drainage. No arteriovenous shunt or contrast extravasation after selective catheterization of renal artery. Wunderlich's syndrome was confirme due to presence of spontaneous perirenal hematoma imaging and without other causal factors, she was released with conservative treatment and monthly follow-up with outpatient pain control, with the urology service.

Discussion: We describe a case that should be remembered as a differential diagnosis of non-traumatic low back pain associated with hematuria.



PUB461

Can Preventing the Flu Harm You? Unusual Case of Oseltamivir-Induced Acute Renal Failure Without Rhabdomyolysis

Maricarmen Milan-Esteva, Fatima B. Cintron-Rosa. *San Juan City Hospital, San juan, PR.*

Introduction: Oseltamivir is a neuraminidase inhibitor used for treatment of Influenza A/B and as chemoprophylaxis. Its use has been increasing after H1N1 pandemic in 2009. It works by attacking the flu virus to keep it from multiplying in your body and by reducing the symptoms of the flu. Side effects include nausea, vomit, headache, stomach upset and rarely renal failure. We report the unusual case of acute renal failure needing hemodialysis after being treated with Oseltamivir.

Case Description: We report the case of an 87-year-old female with past medical history of Diabetes Mellitus who presented to the Urgency Room complaining of 1 -day cough, fever, rhinorrhea and general malaise. Denied nauseas, vomit, abdominal pain, dysuria, chest pain, shortness of breath or edema. Laboratory results were remarkable for creatinine: 1.12 mg/dl, Urea: 24 mg/dl for a GFR: 33ml/min. No electrolyte anomalies. Urinalysis without bacteriuria, pyuria, microscopic hematuria or casts. Influenza rapid test was negative, but due to highly suspected diagnosis of Influenza, Oseltamivir 30mg twice daily was prescribed upon discharge for 5 days. Two-weeks later, patient returned to the Urgency Room with complaints of worsening hypoactivity, anorexia, gradual decrease in urinary output and disorientation for the last 4 days. Patient completed Oseltamivir without complications. This time, laboratory results showed a BUN: 116 mg/dl with Creatinine: 10.88 mg/dl, for a GFR: 3ml/min. Hyperkalemia 8.30 mEq/L not-hemolyzed and bicarbonate 8mEq/L. CPK: 199U/L. Renal sonogram without obstructions. Patient was diagnosed with Oseltamivir induced acute renal failure since other causes were ruled out.

Discussion: Oseltamivir (Tamiflu) is a neuraminidase inhibitors recommended for Influenza A and B, as well as for prophylaxis. Dose is adjusted renally to avoid kidney injury since is excreted renally. Most common side effects include nausea, vomit and abdominal disconmfort, but renal failure is rarely seen. In our case, patient ended with chronic renal replacement therapy after taking medication and no other causes were found. Caution should be taken when taking it as prophylaxis. No report has been found related as renal failure due to oseltamivir given as prophylaxis.

PUB462

Libido Enhancing Herbal Supplementation-Induced Acute Interstitial Nephritis

Tina Motazedi, Anita Shah, Samaya J. Anumudu. *Baylor College of Medicine, Houston, TX.*

Introduction: Acute interstitial nephritis (AIN) results from kidney injury characterized by inflammation in the kidney interstitium, often in the setting of exposure to offending medications[1,2]. We report a case of AIN in a healthy male after routine colonoscopy with exposure to multiple non-prescribed herbal medications.

Case Description: A 52-year-old previously healthy male on multiple herbal supplements including black maca, Tongkat Ali extract, Mucuna extract, and saw palmetto to increase libido presented to the hospital with acute kidney injury (AKI) approximately one month after a routine screening colonoscopy. The patient had no known kidney disease prior to his procedure. Post colonoscopy, he developed right sided flank pain followed by weight loss and anorexia. Labs were notable for creatinine of 4.06 mg/dL, Urinalysis with glucosuria, proteinuria and moderate leukocytes, with rare eosinophils in the urine. Renal ultrasound showed normal kidney sizes. Kidney biopsy was consistent with acute allergic interstitial nephritis, with mild interstitial fibrosis or tubular atrophy. Kidney function improved with cessation of all herbal supplements and treatment with prednisone.

Discussion: This case illustrates a rare cause of acute interstitial nephritis induced from herbal supplements and to the best of our knowledge has not been well reported in the literature. There is little known about the safety profile of these medications and the mechanism in which they induce such injury. Thorough history taking is imperative on part of clinicians to be able to identify these medications (that are often not reported initially), especially by nephrologists in settings where kidney injury cannot be explained by other processes. This allows for early diagnosis, kidney biopsy if possible, avoidance of future use of the medications, and prompt initiation of treatment in hopes to prevent long-term kidney damage.

PUB463

Mycophenolate Mofetil in an Atypical Granulomatous Pattern of Tubulointerstitial Nephritis and Uveitis Syndrome

Maxime Taghavi,[3] Agnieszka Pozdzik.[2,1] *[1]Centre Hospitalier Universitaire Brugmann, Brussels, Belgium; [2]Centre Hospitalier Universitaire, Hopital Burgmann, Braine l'Alleud, Belgium; [3]Brugmann Hospital, Brussels, Belgium.*

Introduction: Tubulointerstitial nephritis and uveitis (TINU) syndrome is a rare disease in which the underlying physiopathology is to date poorly understood though some hypothesize that infection, drugs and autoimmunity are involved. Diagnosis criteria exists and categorize TINU as definite when typical ophthalmologic features are present 2 months before or 12 months after tubulointerstitial nephritis (TIN), in the absence of other systemic disorder. Pathologically tubulointerstitial nephritis is always found as a constant. Granulomas are rare.

Case Description: We report a 31-years-old woman who came for fatigue, headache, fever, ophthalmic pain, weight loss and acute kidney injury (AKI) (plasma creatinine (PCr) 2 mg/dL). She had no medical condition except for a recent history of hypertension treated by nifedipin. Renal biopsy showed TIN and several, small non-necrotizing granulomas. Concomitantly, bilateral anterior uveitis with several, small granulomas was found. Laboratory tests showed high levels of C-reactive protein. Infectious serology and autoimmune screening were negative. Nifedipin was discontinued for more than 2 weeks regarding the possibility of drug-induced interstitial nephritis without, however, improvement of the renal function. Patient was therefore diagnosed with TINU syndrome after excluding other differential diagnosis such as tuberculosis, sarcoidosis and drug-induced TIN. As renal function declined (PCr 3.7 mg/dL), we started steroid puls for 3 days followed by daily oral progressive tapering. After 7 months, renal function normalized (PCr 0.88 mg/dL) and ophthalmic features were completely healed. Severe ophthalmologic relapse and creatinine increase motivated introduction of mycophenolate mofetil and resulted in rapid clinical improvement of pan-uveitis and renal function.

Discussion: There is no evidence-based guidelines regarding TINU treatment, however systemic steroids are widely used and renal outcome is usually good. Granulomatous pattern of TINU syndrome has been only rarely reported. It differential diagnosis can be very challenging because both TINU and sacroïdosis are diagnosis of exclusion. Here we suggest that Nifedipine can be a trigger for TINU syndrome. Also we report the potential benefit of MMF.

PUB464

Physiology or Pathology? An Interesting Case of Rise in Serum Creatinine in a Female-to-Male Transgender Patient

Pulkit Gandhi, Ankur Shah, Edward G. Medeiros. *Brown University, Providence, RI.*

Introduction: Transgender hormone therapy is a mainstay in the management of gender incongruence. Female to Male (FTM) transgender individuals are typically maintained on testosterone to induce a phenotype that matches their identity. Testosterone is known to have multiple renal adverse effects including tubular injury and FSGS. We present an interesting case of FTM transgender with a benign creatinine elevation while on testosterone and discuss the interpretation of serum creatinine (sCr) in transgendered individuals.

Case Description: A 36yo FTM transgender patient with past medical history of TIA secondary to PFO on clopidogrel was referred to our Nephrology clinic for consultation for an elevation in sCr. A review of records shows that his sCr has fluctuated between 1.1 and 1.3 mg/dl over the preceding 8 years. He denied any acute changes in health, recent or remote NSAID use, no LUTS. His only medications are clopidogrel, dextroamphetamine, and testosterone. Urinary microscopy was negative for cellular elements or casts. Urinary microalbumin/creatinine ratio was 3.8 mg/g. The most recent sCr was 1.3, estimating a GFR of 53 ml/min via the CKD-epi equation. A 24 hour urine collection was performed and the 24 hr urinary creatinine clearance was found to be 92 ml/min.

Discussion: Creatinine elevations in the setting of testosterone therapy can represent physiology or pathology. Acute kidney injury due to testosterone has a differential diagnosis including ATN, FSGS while a physiologic increase in skeletal muscle mass may result in increased creatinine generation. A careful examination of the urine and measurement of urinary protein excretion can help differentiate pathology and physiology. A 24 hour urine creatinine to estimate creatinine clearance was diagnostic in our patient of a state of altered physiology, not pathology. Interestingly, the creatinine clearance more closely approximated the CKD-Epi estimation of the male gender, not female gender in our patient. This experience was also seen in two case series of metabolic parameters during transgender hormone therapy, in which sCr was shown to rise 19-42% after initiation of therapy. In estimating eGFR in FTM patients on transgender hormone therapy, we recommend the male gender in calculations.

PUB465

NSAID Use Associated with Bilateral Renal Infarction: A Case Report

Jonathan B. Lis, Yejoo Jeon, William G. Chang. *Yale University School of Medicine, New Haven, CT.*

Introduction: Renal infarctions are caused by interruptions in renal arterial blood flow, and are relatively rare. We present the case of a 37 year old woman whose renal infarction was likely due to the vasoconstrictive effects of non-steroidal anti-inflammatory drugs (NSAIDs). Although high-dose NSAIDs are known to cause a decrease in renal perfusion, they are generally not implicated in renal infarction.

Case Description: A 37-year-old woman with a history of cholestasis during pregnancy presented to the emergency department with acute on chronic abdominal pain. She was given 60 mg of intravenous ketorolac, and discharged on ibuprofen 600 mg every 6 hours as needed. Her pain persisted and she returned 7 days later. Her vital signs were normal with mild hypertension. Physical examination was notable only for diffuse abdominal pain. Initial labs showed new acute kidney injury (AKI) and bland urinalysis. ESR and CRP were elevated; LDH was normal. Cardiac and hypercoagulability workups were normal. Computed Tomography (CT) scan revealed bilateral renal infarction, corroborated on renal ultrasound with doppler. The patient was treated with volume resuscitation. She was not anti-coagulated. She was discharged 3 days after admission with moderate improvement in creatinine. Follow-up 14 days after discharge showed normalization of creatinine.

Discussion: Despite imaging studies qualifying a diagnosis of renal infarction, LDH was normal, suggesting that the extent of renal tubular damage was not as profound as the imaging suggested. This is also supported by the improvement in renal function with only fluid resuscitation and no anticoagulation. Furthermore, workup for infectious, cardiogenic, autoimmune, renovascular, or hypercoagulable etiologies was negative. NSAID medication taken prior to presentation was thus the most likely causative factor. Mechanistically, hypovolemia prior to presentation may have caused a prostaglandin-dependent state, thus causing renal hypoperfusion when NSAIDs were introduced. To our knowledge, only one other similar case report exists in the literature, and this phenomenon may be more common than previously thought.

PUB466

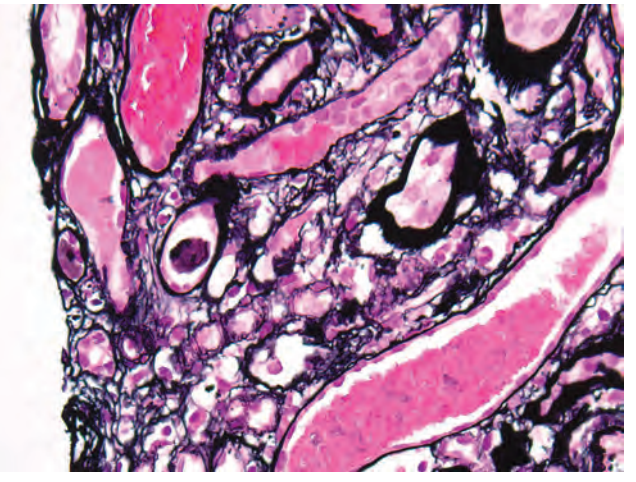
Toxic RBC Casts as the Culprit of Irreversible AKI in IgA Nephropathy

Bushra Syed,[2] Leal C. Herlitz,[1] Georges Nakhoul.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH.*

Introduction: Acute tubular necrosis(ATN) driven by RBC casts occurs in 20% cases of IgA nephropathy (IgAN). Similar mechanism of AKI is observed in Henoch-Schonlein nephropathy, thin basement membrane disease and anticoagulation related nephropathy. Eventhough, glomerular hematuria in the absence of proteinuria is considered a benign entity without long term renal impact, upto 25% of patients with macrohematuria related AKI have incomplete renal recovery. Poor prognostic factors include increased age, prolonged duration of hematuria, severity of ATN and degree of interstitial fibrosis.

Case Description: A 50 year old male with cryptogenic cirrhosis presented with AKI. He had flu like symptoms 2 weeks before presentation. Workup revealed elevated creatinine of 3.4mg/dl from a baseline of 1mg/dl. Urinalysis showed >25 RBC and protein:Cr ratio of 1.1g. On urine microscopy, dysmorphic RBCs and RBC casts were seen. Serological workup showed low C3 (77mg/dl), normal C4 and elevated ASO(476 IU/ml). Renal biopsy showed RBC casts and tubular vacuolization. IgA and C3 deposits were seen on immunofluorescence consistent with mesangioproliferative IgAN. Crescents were absent and there was minimal interstitial fibrosis. Scant subendothelial deposits were present on electron microscopy. Immunosuppression use was deferred in the absence of glomerular involvement and history of spontaneous bacterial peritonitis. Low dose lisinopril was initiated. After 3 months Cr had declined to 2.3.

Discussion: The ability of toxic RBC casts to independently cause AKI in the absence of glomerular involvement tends to be overlooked, but is now being increasingly recognized in cases of anticoagulant nephropathy. Intra tubular obstruction by RBCs, direct tubular toxicity by hemoglobin(Hb) byproducts and intra renal vasoconstriction play a role. Data on specific therapy is scarce and the role of renal heme oxygenase and Hb scavenging by CD163 receptors on tissue macrophages may provide a potential avenue for future therapeutic ventures.



PUB467

Subclinical Urea Cycle Defect Discovered in Pregnancy

Jaibir Bhullar,[1] Ravleen K. Saini,[1] Prashant S. Jadon,[1] Rayaan A. Rauf,[2] Anis A. Rauf,[3] William L. Whittier.[4] *[1]Avalon University School of Medicine, Youngstown, OH; [2]Amita Health Adventist Medical Center Hinsdale, Hinsdale, IL; [3]Nephrology Associates of Northern Illinois, Oakbrook, IL; [4]Rush University Medical Center, Chicago, IL.*

Introduction: We report a subclinical urea cycle defect (UCD) which manifested clinically in pregnancy. Mild variants of UCDs, often (-) by genetic analysis, can occur via a second hit leading to a high morbidity and mortality if not recognized.

Case Description: 33 YO G1P0 with no known PMHx presented at 35 weeks twin gestation w/ altered mental status & decreased fetal movement. BP 174/90, lethargy, 1+ edema. Labs: WBC 14, Hgb 5.4, Hct 15.3, platelets 33 (periph smear mod schistocytes), LDH 1359, haptoglobin<4 BUN 36, SCr 3.89, Alb 1.9, AST 348, ALT 182, Tbili 9.6 (conj 8.1), Lactate 8.0, NH3 61, INR 3.9. ADAMTS13 42%. UA 1+ prot +1 bld 3-5 rbcs. Up/c 410 mg/g. U/S confirmed fetal demise. She developed seizures & was emergently taken to C-section. She was listed for liver transplant & started on CVVH. She developed bowel ischemia requiring emergent colectomy. Within 1 week, her encephalopathy, kidney & liver failure resolved. CVVH was held, & her LFTs, NH3 and INR normalized w/out liver transplant. She began rehab w/ nutritional support via TPN & became obtunded with an NH3 of 375. Emergent HD was performed for NH3 clearance with improvement in her mental status. She was rechallenged with TPN & again developed encephalopathy with isolated hyperammonemia despite normal liver U/S, LFTs, INR and CBC. This eventually resolved by limiting protein in her TPN. Genetic analysis for Ornithine Transcarbamylase Gene (OTC) was (-).

Discussion: Our patient presented with acute fatty liver of pregnancy with hepatic encephalopathy & HELLP syndrome with eclamptic features. After delivery & supportive care, she improved. As isolated hyperammonemia with encephalopathy recurred after TPN, a subclinical UCD was suspected but testing was (-) for OTC. This test is only positive in 80% of cases andother enzymes in the urea cycle such as Carbamyl phosphate synthetase I, argininosuccinate lyase, or argininosuccinate synthetase could have been abnormal. Most UCDs present in the neonatal period from complete absence of these enzymes. When there is only partial deficiency, the symptoms often arise in adulthood after a second hit such as pregnancy. Genetic testing, especially with partial deficiency, can be (-), but the disease should be considered when there is isolated hyperammonemia & encephalopathy, especially after a protein load, in the absence of liver disease.

PUB468

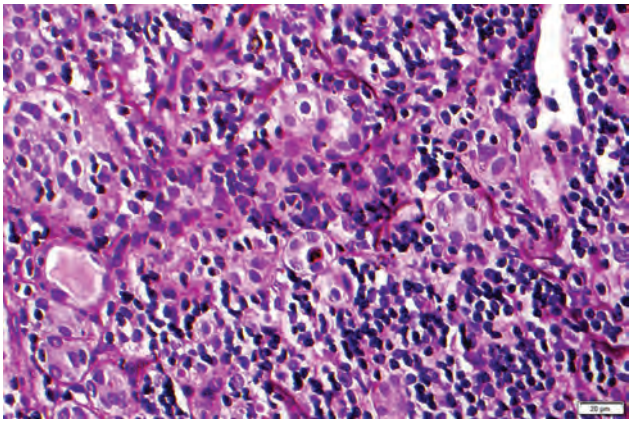
Dabigatran-Associated Acute Interstitial Nephritis

Kevin Fu,[1] Mariam P. Alexander,[2] Samih H. Nasr,[2] Scott D. Cohen.[1] *[1]George Washington University, Washington, DC; [2]Mayo Clinic, Rochester, MN.*

Introduction: There are few case reports of acute interstitial nephritis (AIN) in the setting of novel oral anticoagulants (NOACs). One described a patient on dabigatran who developed biopsy-proven AIN; another described a case of apixaban-related AIN. The mechanism of NOAC-associated AIN is unclear.

Case Description: A 79-year-old male with history of right RCC s/p nephrectomy in 2014, atrial fibrillation, and hypertension presented with 3 days of hematuria. He became anuric 24 hours prior to admission. His home medications were atorvastatin, dabigatran, and metoprolol; dabigatran was held on admission. Labs were significant for serum creatinine 11.7 mg/dL, BUN 107 mg/dL, potassium 7.2 mEq/L, INR 2.9, PTT 75 seconds; prior serum creatinine was 1.2 mg/dL. EKG showed peaked T-waves and hyperkalemia was treated medically. CT abdomen w/o contrast showed no hydronephrosis. Urinalysis showed specific gravity 1.020, pH 6.0, 4+ protein, moderate blood, >100 RBC/hpf, 5-10 WBC/hpf, and no cellular casts. Serologic studies were negative. Renal biopsy was recommended but due to coagulopathy and a solitary kidney, biopsy was postponed. The patient was initiated on hemodialysis (HD) for hyperkalemia and discharged. Two months later, he remained HD dependent, coagulopathy corrected, and he was readmitted for kidney biopsy. Biopsy showed acute and chronic interstitial nephritis. There was acute tubular injury with 4 out of 15 glomeruli globally sclerotic. The etiology of his tubular damage may have been secondary to anticoagulant-related nephropathy (ARN) although classic biopsy features of glomerular hemorrhage and renal tubules filled with RBC casts were not seen.

Discussion: This case expands the differential of AKI in the setting of anticoagulation to include not only ARN with associated acute renal tubular injury but also AIN. Despite stopping dabigatran and treatment with steroids for the past 12 weeks, there has been no renal recovery to date.



Biopsy showing acute and chronic interstitial nephritis.

PUB469

AKI After Advanced Heart Failure Therapy May Be Unrelated to Renal Perfusion

Eddy J. De Jesus, Geurys R. Rojas Marte, Amir Kazory. *University of Florida, Gainesville, FL.*

Introduction: The prevalence of advanced heart failure (AHF) is increasing due to the growing number of patients with heart failure (HF) and their improving survival. Percutaneous left ventricular assist device (PVAD) is a small axial flow pump that is placed across the aortic valve. It aspirates blood from left ventricle (LV) and expels it into the ascending aorta, hence unloading LV and improving hemodynamics. Renal function impairment is prevalent among patients with AHF but often improves after PVAD placement due to enhanced organ perfusion.

Case Description: A 48-year-old man with a history of HF with reduced ejection fraction (15-20%) and chronic kidney disease stage III-b was admitted for acute HF and cardiogenic shock, for which he received a PVAD (Impella 2.5) that stabilized his hemodynamics. However, within 24 hours, he developed acute kidney injury (AKI) and hyperkalemia of 7.2 meq/L mandating his transfer to our facility. Upon arrival, his serum potassium and creatinine levels were 6.7 meq/L and 4.5 mg/dL respectively with marginal urine volume. Renal replacement therapy (RRT) was started. Since AKI had developed unexpectedly after PVAD, a comprehensive workup was performed to explore its etiology. It revealed severe hemolysis with a drop in Hemoglobin by 1.3 g/dl within 7 hours, LDH 3233 IU/L, haptoglobin <30 mg/dl, and reticulocyte count up to 3.1% suggesting pigment-induced nephropathy as the cause of AKI. Due to traumatic placement of a Foley catheter and bleeding, urine studies were not reliable. The decision was made to retrieve the Impella device and replace it with an intra-aortic balloon pump to stop hemolysis. Six hours after the procedure, the patient's LDH level decreased to 1864 IU/L, followed by progressive increase in urine output; RRT could be discontinued 3 days later.

Discussion: While low renal perfusion is the primary reason for AKI in the setting of AHF, this case highlights a much less evident but reversible cause which could remain undetected unless specifically looked for. PVAD-induced hemolysis can be due to shear stress or improper positioning of the outlet in the subvalvular area. Development of pigment-induced AKI has been reported in only a handful of cases so far. High index of suspicion would be warranted in those unexpected cases of AKI developing after PVAD implantation especially if hemodynamic status is stabilized.

PUB470

Paroxysmal Nocturnal Hemoglobinuria: An Uncommon Cause of AKI

Parichi V. Buch,[1] Joshua D. King,[2] Bhuwan Kayastha,[1] Babak S. Jazayeri-Moghadass,[1] Simran Dhillon.[2] *[1]University of Maryland Medical Center, Baltimore, MD; [2]University of Maryland, Baltimore, MD.*

Introduction: Acute Tubular necrosis (ATN) is one of the common causes of acute kidney injury (AKI) seen in hospitalized patients. We are reporting a case of Acute tubular necrosis (ATN) due to Paroxysmal nocturnal hemoglobinuria. The release of free hemoglobin during hemolysis causing renal vasoconstriction, methemoglobin formation, renal hemosiderosis and proximal tubular toxicity causes acute kidney injury (AKI) in Paroxysmal Nocturnal Hemoglobinuria.

Case Description: A 20 year old man with a 5 month history of isolated hematuria presented with symptomatic anemia. On admission, he was found to have acute kidney injury (AKI) with a serum creatinine of 5.3 mg/dl and had evidence of intravascular hemolysis (hemoglobin 6.4 g/dl, low haptoglobin levels <20 mg/dl, high LDH levels 3533 U/L with absence of schistocystes on peripheral smear and negative direct Coomb's test). Urine analysis was positive for a large amount of blood with few red blood cells present on urine microscopy. A subsequent kidney biopsy revealed abundant pigment casts, severe tubular injury and abundant positive CD163 positive staining macrophages. The diagnosis of Paroxysmal Nocturnal Hemoglobinuria (PNH) was confirmed by flow cytometry PNH panel. After initiation of treatment with Eculizumab, the patient developed improvement in kidney function and reduction in intravascular hemolysis.

Discussion: Educate clinicians about uncommon causes of acute kidney injury. Understand the impact of Eculizumab on kidney function.

PUB471

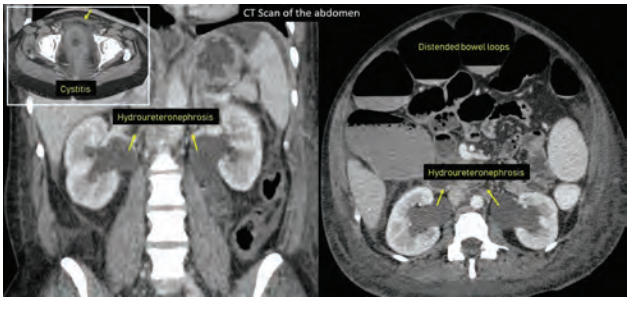
Ileus, Cystitis, and Obstructive Uropathy: An Unusual Presentation of Lupus

Joan J. Morales Lappot,[1] Abhilash Koratala,[1,2] Olanrewaju A. Olaoye.[1] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Nephrology, University of Texas, San Antonio, TX.*

Introduction: Systemic lupus erythematosus (SLE) has been reported to be associated with intestinal pseudo-obstruction and obstructive uropathy. Herein, we present the case of a patient with no known history of lupus who presented with these atypical manifestations.

Case Description: A 35-year-old woman with history of mixed connective tissue disease and hypertension presented with worsening lower extremity edema and abdominal distension for about a week. Blood pressure at presentation was 147/109 mmHg and she was afebrile. Laboratory data showed AKI with a serum creatinine of 2.56 mg/dL and thrombocytopenia with a platelet count of 42 thou/cu mm. Urinalysis was positive for 3+ proteinuria, without pyuria or hematuria. A CT scan of the abdomen demonstrated significant ileus, bilateral hydronephrosis, hydroureter and cystitis. There was no obvious structural cause for intestinal obstruction. Serum potassium was normal. The hydroureteronephrosis did not resolve completely despite ureteral stent placement and attempts at intestinal decompression. Because of persistent AKI, proteinuria and thrombocytopenia, further work up was obtained which was significant for positive ANA titer of 1:1280, decreased serum complements. Urine albumin-creatinine ratio was ~1g/g and anti-dsDNA antibodies were negative. As SLE can present with autoimmune cystitis, obstructive uropathy and intestinal pseudo-obstruction, we intended to treat her empirically with immunosuppressants without renal biopsy because of thrombocytopenia. However, she developed sepsis and became acutely ill prior to therapy. Interestingly, urine culture remained negative, suggestive of autoimmune cystitis together with urinalysis findings.

Discussion: High index of suspicion is required for atypical manifestations of SLE, especially in patients with a history of another autoimmune disorder. The underlying pathology of intestinal obstruction is incompletely understood but possibly related to immune complex deposition. Coexisting hydroureteronephrosis suggests there may be a central smooth muscle motility issue of neuropathic or myogenic nature.



PUB472

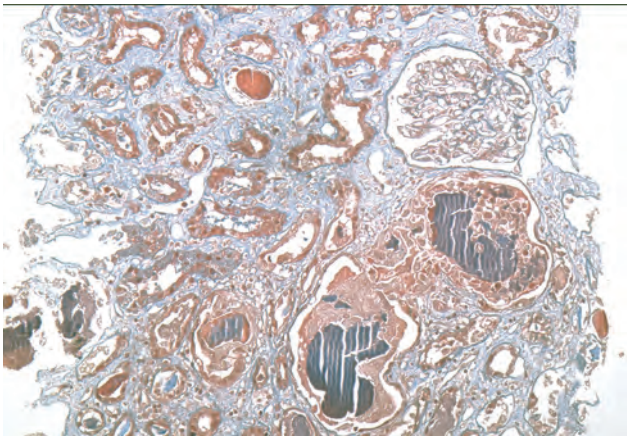
Leukocyturia: Not Always a Urinary Infection

Kelly Haughton. *Nephrology, Complejo Hospitalario Dr. Arnulfo Arias Madrid, Panama, Panama.*

Introduction: The increased presence of white blood cells in the urine, leukocyturia, can be interpreted as a urinary infection; however, the absence of a typical clinical picture accompanied by acute kidney injury and other findings in the urine may be the key to reach the actual diagnosis.

Case Description: A 32-year-old woman with no known pathologie went to the ER with constitutional symptoms, no fever. She was evaluated repeatedly before admission and prescribed with antibiotics for suspected urinary infection. Is hospitalized when the condition was accompanied by anasarca and increase in creatinine from 1.7 to 6.44 mg/dl. The diagnosis of acute kidney was made. Urinalysis 2+ albuminuria. Urinary sediment: leukocyturia and red blood cell cylinders. Renal ultrasound, normal size with increased echogenicity. A renal biopsy was performed, finding kappa light chain cylinders in the tubules as well as tubulointerstitial atrophy without glomerular involvement. The diagnosis of cast nephropathy was made and serum protein electrophoresis was performed, finding a monoclonal peak by free kappa chains. Bone marrow biopsy with 20% of mature plasma cells. The definitive diagnosis of Multiple IgG kappa myeloma with associated cylinder nephropathy (myeloma kidney) is made. Currently with clinical improvement; creatinine at 1.78 mg / dl after chemotherapy and awaiting for autologous bone marrow transplantation.

Discussion: The approach of leukocyturia without a typical clinical picture of urinary infection must include other renal diseases in the differential diagnosis. Renal disease is a common complication of monoclonal gammopathies secondary to the deposition of light chains in different compartments of the kidney in this case a "myeloma kidney". The evaluation of the urinary sediment rapidly ruled out the infectious diagnosis and determined the need for a renal biopsy. The approach of these patients involves a multidisciplinary team and timely diagnosis is key to give effective treatment of the underlying pathology.



PUB473

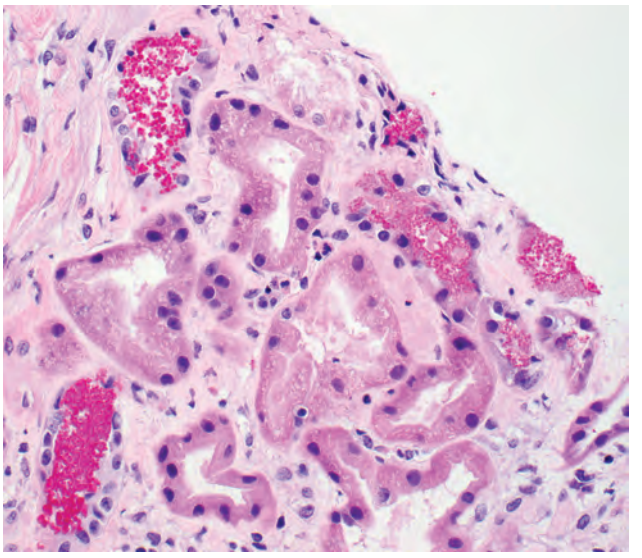
AKI Transurethral Resection of the Prostate Secondary to Pigment Nephropathy

Alice Chedid, Sadichhya Lohani, Jose M. Monroy-Trujillo. *Johns Hopkins University, Baltimore, MD.*

Introduction: AKI post TURP can be caused by intratubular precipitation of hemoglobin pigment secondary to hemolysis after the use of hypotonic solutions for irrigation during TURP.

Case Description: 78 year old male with history of atrial fibrillation and BPH presented to ER on same day after being discharged post TURP with generalized fatigue. Labs were relevant for serum Cr of 2.2 mg/dl (baseline 1.1 mg/dl prior to surgery). Physical exam unremarkable with clear lungs, benign abdomen and no lower extremity edema. Foley catheter in place with bloody urine. There was Initial concern for obstruction post TURP, however, CT scan revealed diffuse urinary bladder wall thickening and no evidence of hydronephrosis. Hospital course relevant for progressive renal failure with creatinine peak of 12.0 mg/dl at day 8. Relevant labs showed drop of hemoglobin from 15.4 gm/dl (pre-surgery) to 12 gm/dl (POD2) and LDH of 702 units/L. Haptoglobin 9 mg/dl (low). There was concern for hemolysis leading to pigment nephropathy. Patient underwent kidney biopsy on day 3: Acute tubular injury with intratubular hemoglobin casts. Mild interstitial inflammation (figure 1&2). Renal function improved with conservative management and creatinine began to improve by day 9. He did not require renal replacement therapy and latest creatinine is 1.6 mg/dl.

Discussion: Pigment nephropathy should be considered in any patient who presents with AKI post TURP procedure who develops renal failure and no evidence of obstruction is found on imaging studies. The use of hypotonic fluids for irrigation during the procedure and the presence of hemolysis on lab workup will help in diagnosis. The prostatic plexus can reabsorb significant amount of fluid during TURP. If hypotonic solutions are used, then there can be significant hemolysis leading to pigment nephropathy. Treatment is usually supportive and includes monitoring for dialysis needs.



Intratubular obstruction

PUB474

An Unusual Cause of Hypercalcemia

Luis A. Vazquez Zubillaga,[1] Saul N. Gonzalez Montalvo,[1] Naveen Punchayil narayanankutty,[1] Ragi Philips,[1] Catarina Regis,[1] Zain Mithani.[2] *[1]Jackson Memorial Hospital, Miami, FL; [2]University of Miami, Miami, FL.*

Introduction: Hypercalcemia above 14 mg/dL is often associated with malignancy, but patients with HIV need further investigation for opportunistic infections from granulomatous diseases such as *Mycobacterium Avium Intracellular* (MAI). Previous reports in the literature showed the association between MAI and hypercalcemia. We present a case of MAI infection causing hypercalcemia.

Case Description: 42 year-old male recently diagnosed with HIV/ AIDS (CD4 61) presents to the ED complaining of 4-month history of fevers, night sweats, diarrhea and twelve-pound weight loss. The patient was found to have subcentimeter hilar lymphadenopathy and bilateral pulmonary nodules, the largest measuring 1.2 cm. The patient underwent bronchoscopy with BAL analysis showed MAC. He was started on ethambutol and clarithromycin. The hospitalization course was complicated by non-oliguric acute kidney injury stage 3 with hypercalcemia of 16.3 mg/dL. Since there was no improvement with hydration and diuretics, hemodialysis was started with appropriate response. Hypercalcemia work up showed suppressed PTH and elevated 1,25-DIOH vitamin D levels, suspect secondary to increased production of calcitriol due to granulomatous disease.

Discussion: Hypercalcemia is a known complication of granulomatous disease, so clinicians should be aware of the variability in presentation of hypercalcemia with MAI. This case showed an atypical presentation of hypercalcemia in the setting of MAI infection. HIV patients who develop hypercalcemia should be investigated for this underlying infection.

PUB475

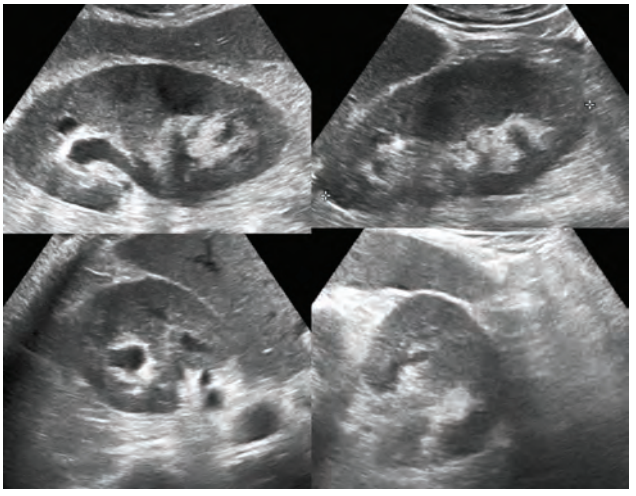
A Case of Obstructive Nephropathy After Endovascular Aneurysm Repair

Mayanka Kamboj. *University of florida, Gainesville, FL.*

Introduction: Acute kidney injury develops in 3-19 % of patients following abdominal endovascular aneurysm repair (EVAR). We present a case of osbtrcutive nephropathy related to post implantation inflammatory syndrome.

Case Description: 63 year old white male with history of hypertension, diabetes mellitus, infrarenal abdominal aortic aneurysm with endovascular repair 6 weeks ago presented with back pain and no urine output. He recently admitted to the hospital 1 week ago with back pain and leukocytosis presumed to be related to surgical site infection which was treated with antibiotics along with surgical wound incision and drainage. Imaging done during that hospitalization revealed minor type 2 endograft leak which was managed conservatively without any surgical intervention. Patient's baseline serum creatinine was 0.7 mg/dL which increased to 4.7 mg/dL and peaked to 6 mg/dL during the hospitalization. CT scan showed mild bilateral hydronephrosis, greater on the right associated with perifocal inflammatory process about the aortobiiliac system and Type II endoleaks involving the IMA and L2 level lumbar artery. Patient's creatinine initially improved to 1.7 mg/dL without any intervention. He underwent endoleak embolization procedure after which serum creatinine gradually worsened to 6 mg/dL along with increasing hydronephrosis on the imaging. Acute kidney injury was thought to be related to bilteral ureteral obstruction from periaortic fat stranding or contrast induced nephropathy. Patient underwent bilateral ureteral stent placement, after which the Serum creatinine improved to 0.7 mg/dL over the next 3 days.

Discussion: Post inflammatory syndrome is a systemic inflammatory response immediately following EVAR is seen in 14 to 60 % of the patients. Our patient had inflammatory process following EVAR, which worsened with embolization procedure and was aggressive enough to cause bilateral ureteral obstruction and acute renal failure



PUB476

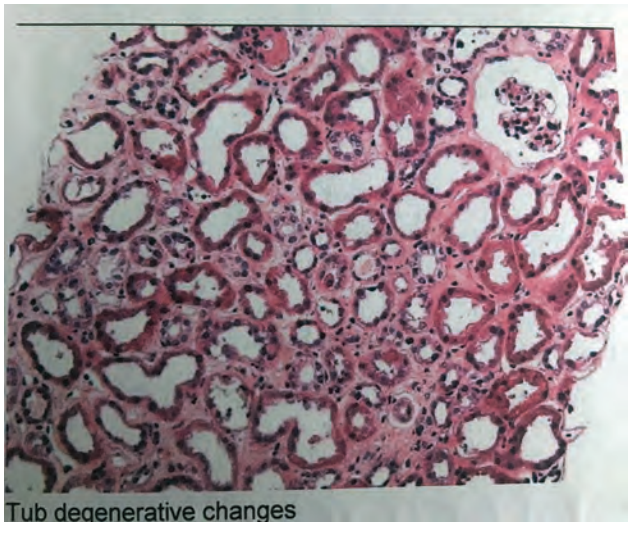
Oxalate Nephropathy After Antibiotic Use in a Gastric Bypass Patient

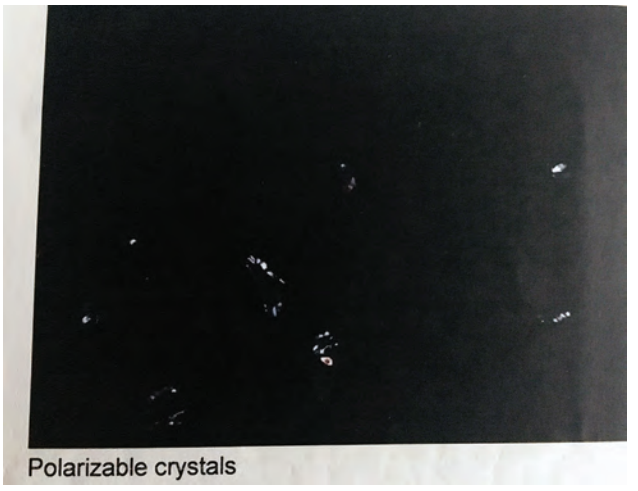
Aswathi E. Mathew,[1,2] Raymond Raut,[3] Panupong Lisawat.[4] *[1]CIFC, Danbury, CT; [2]Danbury Hospital, Danbury, CT; [3]Danbury Hospital Department of Nephrology and Hypertension, Danbury, CT; [4]Western Connecticut Health Network - Nephrology, Brookfield, CT.*

Introduction: This is a case of oxalate nephropathy secondary to antibiotic use for osteomyelitis in the setting of post gastric bypass surgery.

Case Description: A 73-year-old Caucasian female with history of gastric bypass surgery, history of recent right foot osteomyelitis treated with Vancomycin, Ampicillin and Sulbactam for proteus mirabilis presented with worsening renal function. She finished her antibiotic course for osteomyelitis prior to admission and was found to have Creatinine of 3.1 post antibiotic treatment. Kidney biopsy revealed ATN with many calcium oxalate crystals and tubular atrophy and interstitial fibrosis. Subsequently she required dialysis.

Discussion: Antibiotic use and gastric bypass anatomy could be related to oxalate nephropathy. Antibiotic use in this patient might have caused decreased gut microbial Oxalobacter Formigenes, resulting in increased colonic oxalate absorption and the development of calcium oxalate crystals in the kidney. Research in administration of oxalobacter probiotic may help identify a potential prevention of this condition.





PUB477

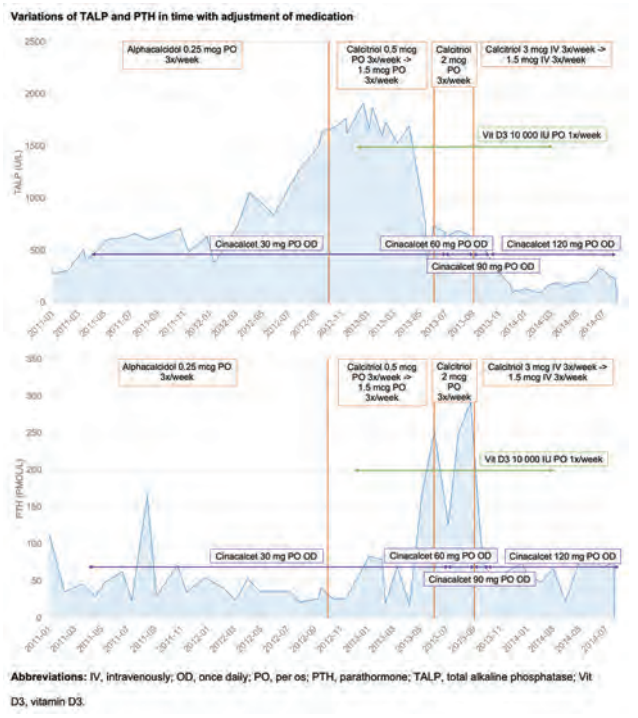
A Case of Secondary Hyperparathyroidism in a Patient on Hemodialysis with Parathormone Levels Within the Targets and High Total Alkaline Phosphatase

Jessica Kachmar,[1] Caroline Albert,[2] Marie-Eve Dupuis,[1] Michel Vallee.[3] *[1]Université de Montréal, Montreal, QC, Canada; [2]Biochemistry, Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada; [3]Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Introduction: Levels of parathormone (PTH) in dialysis patients are not always accurately correlated to the degree of bone remodeling. International guidelines suggest the use of other bone markers, such as serum total alkaline phosphatase (TALP). Although the measures of PTH and TALP are often considered as complementary, these two markers can evolve in opposite directions.

Case Description: Our patient was a 61-year-old Haitian woman on hemodialysis due to diabetic nephropathy. In 2011, she developed secondary hyperparathyroidism while on alphacalcidol. Cinacalcet 30 mg once a day was started since her phosphocalcic product was 4.81. She seemed to respond well to treatment, with her PTH reaching the targets set by guidelines. In 2012, she accused bone pain. Her laboratory results indicated high TALP (1772 U/L) with PTH within the targets (26.2 pmol/L) and low vitamin D (22.2 nmol/L). Her alphacalcidol was switched to calcitriol 0.5 mcg orally three times per week with vitamin D 10 000 IU orally once per week. In 2013, her bone pain was not relieved, with her TALP still high (1917 U/L) and her PTH within targets. An electrophoresis of TALP was done which showed that 97% was of bone origin. Multiple radiographs were also performed, which were suggestive of poorly controlled hyperparathyroidism. Her calcitriol and her cinacalcet were thus increased, and surprisingly, her PTH peaked significantly after this treatment adjustment as her TALP was lowering (cf. image), revealing her hyperparathyroidism.

Discussion: This case shows us that some patients on hemodialysis may suffer from secondary hyperparathyroidism despite having PTH levels within the targets set by KDIGO and emphasizes the importance of taking into consideration other bone markers such as TALP.



Abbreviations: IV, intravenously; OD, once daily; PO, per os; PTH, parathormone; TALP, total alkaline phosphatase; Vit D3, vitamin D3.

PUB478

A Case Illustrating Similarities and Differences Between Calcific Uremic Arteriolopathy (CUA) and Non-Uremic Calciphylaxis (NUC)

Frances F. Tian, Jennifer Kang, Anna C. Porter. University of Illinois at Chicago Nephrology *University of Illinois at Chicago, Chicago, IL.*

Introduction: CUA is a rare vasculopathy described in those with end-stage renal disease. NUC is an even less well-described clinical entity; one literature review identified 36 cases. The infrequency with which it is encountered renders NUC a formidable diagnostic challenge.

Case Description: A 57 year-old female with diabetes and peripheral vascular disease was admitted for suspected above-the-knee amputation stump infection and subsequently underwent right hip disarticulation. Post-operatively, she developed a left thigh eschar. A bedside skin biopsy was non-diagnostic. Due to clinical suspicion, the patient was taken to the operating room for a wedge biopsy that was diagnostic of NUC. The patient had no prior diagnosis of CKD and the GFR was only mildly low when adjusted for obesity and amputation. The patient was started on sodium thiosulfate (STS) and discharged. The patient was re-admitted a week later due to pain and lesion progression despite STS. Goals of care were revisited and she was ultimately discharged to hospice.

Discussion: NUC occurs in patients who have no or mild renal dysfunction. Risk factors include diabetes among others. This patient had no associated conditions except for uncontrolled diabetes since 2012. CUA and NUC both present with non-healing wounds, though CUA affects the trunk and NUC affects the extremities. One review of NUC cases demonstrated most patients had normal serum calcium (sCa) and serum phosphorus (sPhos). Pathophysiology is thought to be related to hyperphosphatemia, hypercalcemia, and hyperparathyroidism. This patient had no metabolic derangements besides mildly elevated sPhos, suggesting pathogenesis is more complex than current understanding. Diagnosis of CUA primarily clinical, but in atypical scenarios a biopsy is necessary. This patient had classic features on biopsy including intramural calcification as well as positive Von Kossa. Sensitivity of biopsy can be low, related to limited specimen depth or the non-specific histologic findings of early disease, as in this case. Treatment is limited though one review demonstrated STS was associated with improved healing and mortality, though in this case lesions progressed despite STS. Physicians must maintain a degree of suspicion for calciphylaxis if characteristic lesions develop, even in the absence of renal impairment.

PUB479

Too Much of a Good Thing: A Case of Hypercalcemia and Acute Renal Failure from Incorrect Dosing of Vitamin D Supplement

Ann Herron. *Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Hypercalcemia is known to cause acute renal failure through several mechanisms including renal vasoconstriction and volume depletion from nephrogenic diabetes insipidus. Here we describe a case of hypercalcemia and acute renal failure from incorrect ergocalciferol dosing that was treated effectively with IV fluids alone.

Case Description: A 55 year-old female with history of hypertension and type 2 diabetes presented to the emergency room with a week of progressive leg swelling, leg pain, and mild memory loss. Exam notable for mild hypertension and trace lower extremity edema. She was found to have a creatinine of 5.0 mg/dL (baseline <1 mg/dL), total calcium 12.5 mg/dL, and ionized calcium 6.76 mg/dL. On review of home medications, the patient noted being prescribed a daily vitamin D supplement by her primary care physician two months prior to admission. A family member brought her pill bottle from home, which confirmed a prescription for ergocalciferol 50,000 units daily. Subsequent hypercalcemia and AKI workup notable for vitamin D 25-OH level above assay at >96 ng/mL, vitamin D 1,25-OH 84.3 pg/mL, and PTH 4 pg/mL, as well as normal SPEP/UPEP, CK, TSH, uric acid, and UA. The patient received 3 days of aggressive IV fluid resuscitation with gradual improvement in renal function and calcium level. Labs one month after discharge showed creatinine 1.29 mg/dL and total calcium 9.9 mg/dL.

Discussion: Vitamin D intoxication has been well described in children, but is being increasingly recognized as a cause of hypercalcemia in adults as well. As more attention is drawn to the significance of vitamin D deficiency, and with the cultural shift toward naturalistic therapies, patients are more likely to seek out and be prescribed vitamin supplements. This case describes a unique cause of hypervitaminosis D due to medication error and highlights the need for detailed medication reconciliation that includes vitamin supplements and over the counter medications, particularly given the multiple formulations of many of these drugs. Ergocalciferol has a half life of around 2 weeks, and there is evidence to support the addition of bisphosphonates in the treatment of hypercalcemia from vitamin D overdose. However, bisphosphonates have the potential to cause hypocalcemia, and this case is an example of effective therapy with IV fluids alone.

PUB480

Calcific Uremic Arteriolopathy in a Patient with ESRD: A Case Report

Jacky vincent V. Omandam. *Makati Medical Center, Makati city, Philippines.*

Introduction: Calcific uremic arteriolopathy (CUA), also known as calciphylaxis, is a rare but life-threatening condition that is characterized by progressive cutaneous necrosis associated with small- and medium-sized vessel calcification, occurring in patients with end-stage renal disease (ESRD) on renal replacement therapy. It is a rare condition, described in 1% to 4% of patients on dialysis, mainly in those with a history of diabetes mellitus (DM), liver disease, and elevated calcium-phosphate product.

Case Description: We describe a case of a 42-years old, male, Filipino, known hypertensive, diabetic, a diagnosed case of chronic kidney disease secondary to diabetic nephropathy on hemodialysis three times a week for two years, who came in with severe progressive calciphylaxis in the form of a chronic painful non-healing necrotic wound on the glans penis. He was initially managed as a case of herpes zoster balanitis when he was seen in the emergency department for out-patient consult, but did not improved with oral acyclovir and oral antibiotics. Also noted in the second and third digit of his right hand, were non healing violaceous and necrotic plaques. Calciphylaxis of Chronic Kidney Disease was considered based on clinical, laboratory and radiologic data. Goals of care and prognosis were discussed with the patient. He opted to be managed medically. His hemodialysis sessions were continued and intensified to four times a week, and he was started on sodium thiosulfate 25g IV x 1 hour to start at the last hour of hemodialysis for three months. Other modalities utilized in the management of this case include hyperbaric oxygen therapy, and topical sodium thiosulfate. On follow-up, patient improved and is currently doing well on hemodialysis despite high mortality and morbidity seen in high patients with CUA

Discussion: The pathogenesis of CUA is not well understood, but is thought to be due to vascular calcification leading to soft tissue necrosis that is usually described in patients with end-stage kidney disease on dialysis. Our patient had several predisposing factors for calciphylaxis that had been present for a long time. Nevertheless, the immediate trigger for the acute worsening of calciphylaxis is unknown. Clinical diagnosis of CUA requires a high degree of suspicion.

PUB481

Calcific Uremic Arteriolopathy (CUA)

Sarah T. Suliman,[1] Jeremy Carlson,[3] Ronald L. Mars.[2] *[1]University Of Florida Jacksonville, Jacksonville, FL; [2]University of Florida Health Science Center, Jacksonville, FL; [3]University of Florida, Gainesville, FL.*

Introduction: CUA carries an extremely poor prognosis, mortality rate of at least 50%, and if coinciding with ulcerations, mortality may exceed 80%. Comorbid conditions increasing the risk of CUA include chronic kidney disease, time on dialysis, diabetes, obesity, secondary hyperparathyroidism and the use of calcium based phosphate binders, warfarin, iron and steroids. The disease usually presents as skin necrosis which can quickly become infected leading to multiorgan dysfunction, septic shock and death

Case Description: This is a 57 y/o man with ESRD receiving thrice weekly hemodialysis(HD)for five years, diabetes mellitius 2, atrial fibrillation receiving warfarin, chronic hyperphosphatemia with normal calciums and secondary hyperparathyroidism at goal for his stage CKD who presented with painful skin lesions compatible with CUA. Use of warfarin precluded obtaining a skin biopsy. Patient was treated with intensification of HD and sodium thiosulfate for nearly one year. Symptoms and skin lesions nearly healed after one year of continuous therapy. After four years of follow up, there has been no evidence of recurrence

Discussion: It is imperative for nephrologists to maintain a low threshold of suspicion for CUA and for when to begin treatment. When possible, the diagnosis should be confirmed with tissue biopsy. There is no clearly defined treatment, but it is generally accepted to treat with sodium thiosulfate for at least three months which can be extended depending on the patients' response. Any medications that can contribute to CUA should be stopped. Other therapies with variable rates of success include use of hyperbaric oxygen, parathyroidectomy, paradoxical use of steroids and bisphosphonates

PUB482

Severe Euglycemic Diabetic Ketoacidosis Secondary to Sodium-Glucose Cotransporter 2 (SGLT2) Inhibitor: A Diagnostic Challenge

John Howard, Nasim Wiegley, Niti Madan. *University of California Davis Medical Center, Sacramento, CA.*

Introduction: SGLT2 inhibitors are a relatively new class of antihyperglycemic agents that inhibit glucose reuptake in the kidney. These agents have been increasing in use likely due to favorable effects on glucose variability, weight loss and reduction of insulin doses as well as recent trials supporting their benefit in cardiac and renal disease patients. Of note, prior studies have shown very low risk of euglycemic diabetic ketoacidosis (euDKA) associated with use of SGLT2 inhibitors. Rarity of this presentation makes it a diagnostic challenge. We report a case of severe euDKA in a hospitalized surgical patient in order to raise awareness.

Case Description: A 46 year old woman with type 2 diabetes was admitted for necrotizing soft tissue infection of the buttocks. Home medications included metformin, empagliflozin 25mg daily, and insulin glargine. Initial evaluation showed blood glucose of 329 mg/dL, creatinine 0.90 mg/dL increased from baseline 0.43 mg/dL, bicarbonate 25 mg/dL, and lactate 1.5 mmol/L. She was taken for debridement on admission and again two days later, while remaining primarily NPO and receiving minimal insulin. Post-operatively she was noted to have encephalopathy and worsening respiratory status found to have pH 7.22 and pC02 <12 mmHg on arterial blood gas, bicarbonate <5 mg/dL, lactate 1.0 mmol/L, beta-hydroxybutyrate (BHB) 9.42 mmol/L (normal range 0.02-0.27 mmol/L), with blood glucose 115 mg/dL. Alcohol screen, salicylate, and acetaminophen levels were negative. She was diagnosed with euDKA and initiated on continuous intravenous insulin and lactated ringer's with dextrose. Her acidosis resolved over the following 12 hours and bicarbonate returned to normal levels in 24 hours with BHB of 1.39 mmol/L. She did not receive empagliflozin during admission.

Discussion: Euglycemic DKA is a serious medical condition. The rarity and atypical nature of this form of DKA makes it a diagnostic challenge. Risk factors associated with development of euDKA include infection, surgery, or decreased oral carbohydrate intake. SGLT2 inhibitors are gaining popularity, and a high index of suspicion is needed in caring for surgical patients on these agents. Monitoring anion gap and serum bicarbonate levels might be a better method of evaluating for DKA in such patients given euglycemic state.

PUB483

Recurrent Dialysis Disequilibrium in a Patient Receiving Inconsistent Hemodialysis

Hannah R. Abrams, Rajeev Raghavan. *Baylor College of Medicine, Houston, TX.*

Introduction: Dialysis disequilibrium syndrome (DDS) is characterized by transient neurologic symptoms during or immediately following a dialysis treatment. While nephrologists modify hemodialysis parameters in at-risk patients, the prevalence of DDS today is unknown, and peri-dialytic management of at-risk patients individually varies.

Case Description: A 68-year old patient presented to the emergency-room with her usual pre-dialysis symptoms of nausea and muscle cramps. She had received hemodialysis via right internal jugular tunneled dialysis catheter every 7-10 days since 2014, and was unable to obtain a dialysis home due to undocumented immigration status. Her pre-dialysis blood urea nitrogen level was 65 mg/dl. Upon completion of a 3-hour hemodialysis treatment with an ultrafiltration rate < 10 cc/kg/hr, the patient became obtunded and non-responsive to name. She had had 4 prior episodes of obtundation post-dialysis without identifiable cause. Other past medical history was significant for hypertension, diabetes, hypothyroidism, coronary artery disease, and remote cerebrovascular accident. Her post-dialytic mental status represented a significant deviation from her baseline cognitive impairment per her family. On admission, the patient was afebrile and hemodynamically stable, with no acute changes in EKG, chest X-ray, and CT head. The serum lactic acid, WBC count, glucose, sodium, B12, TSH, and folate were normal. Her post-dialysis BUN was 23 mg/dl, representing a 65% reduction. Without further treatment, the patient's mental status returned to baseline within 12 hours. In the absence of other explanation for her recurrent episodes of cognitive impairment after hemodialysis, the diagnosis of dialysis disequilibrium syndrome was applied.

Discussion: There are 47 published case reports of DDS. Amongst the 47 identified case reports, altered mental status/restlessness were most commonly reported (28/47). A 2012 survey of 252 practicing nephrologists found that over 50% had encountered at least one case of DDS within the preceding year, with 2% encountering more than 20 cases. DDS is likely under-reported and may be more common among patients receiving inconsistent hemodialysis. Therapy should always be tailored for high risk patients, and further investigations should explore if subclinical, recurrent DDS results in cognitive decline.

PUB484

Unique Case of Nephrogenic Systemic Fibrosis Without Exposure to Gadolinium in a Hemodialysis Patient

Mir tariq Ali,[1] Amjad Ali,[2] Yousef Boobes,[1] Fatima R. Alkindi,[1] Ahmad M. Chaaban.[1] *[1]Tawam Hospital, Al Ain, United Arab Emirates; [2]NHS, Chelmsford, United Kingdom.*

Introduction: Nephrogenic systemic fibrosis (NSF) is a rare condition, confirmed by pathological evaluation that has been strongly associated with previous exposure to gadolinium based contrast agents (GBCA). Many regulatory authorities including the FDA have issued warnings to the use of GBCAs in patients with chronic kidney disease. We are describing a case of a patient with end stage renal disease who recently started hemodialysis and developed NSF without previous exposure to GBCAs.

Case Description: A 62 year old female with long standing history of diabetes mellitus, hypertension and morbid obesity leading to end stage renal disease required initiation of hemodialysis since two months. She presented with history of skin induration, thickening and peeling that has started around the same time of starting dialysis and has progressively increased. The lesions described are in multiple areas of the body including the abdomen and both upper and lower limbs. A provisional diagnosis of calciphylaxis was proposed. However, a skin biopsy was performed that revealed, pronounce cellularity with spindle cell proliferation that express factor XIII and focally CD34 the changes involved full dermis and extend to the septa of subcutaneous fat. There are proliferation of fibroblast, epithelioid and stellate cells. Increase in dermal mucin highlighted by Hale colloidal iron with thickened collagen, consistent with a diagnosis of nephrogenic systemic fibrosis that was reviewed in three separate pathology centres. The patient did not have any previous exposure to gadolinium study GBCAs and in skin biopsy the gadolinium particles was not seen.

Discussion: After extensive review of the literature, we could find two cases of NSF reported in renal transplant patients without previous exposure to GBCAs. However, to our knowledge this is the first case reported in dialysis patient. Our case in addition to the other two cases reported in the literature emphasizes the need to re-address the underlying pathogenesis and potential causes of NSF.

PUB485

What Evil Lurks: Dialysis-Induced Reactions in a Critically Ill Patient

Dhruti P. Chen, Jennifer E. Flythe. *University of North Carolina Kidney Center, Chapel Hill, NC.*

Introduction: While adverse reactions on dialysis are rare with modern synthetic membranes, they do occur and can be life threatening. We describe a case of severe dialysis-induced reactions during both continuous renal replacement therapy (CRRT) and hemodialysis (HD).

Case Description: A 72 year old woman with a deceased donor kidney transplant 3.5 years prior and respiratory failure was transferred to our medical intensive care unit (ICU) for encephalopathy and acute kidney injury. She had presumed sepsis of unknown origin and worsening oliguria with volume overload and low blood pressure (BP). CRRT was started on ICU day 3 using an NxStage® machine with a gamma-sterilized polyethersulfone membrane. At CRRT start, her vitals were stable without vasopressors but within several minutes, her BP fell to 70/30 mmHg, and a norepinephrine drip was initiated. CRRT was paused, and her BP returned to baseline. When CRRT was restarted, she developed recurrent hypotension with eventual loss of pulse. CRRT was stopped, blood returned and patient resuscitated with chest compressions and epinephrine. Her BP stabilized, and she was quickly weaned off the epinephrine drip. The next day, HD with a gamma-sterilized, cellulose triacetate membrane was attempted with the same outcome. She was eventually successfully dialyzed using a polyethersulfone membrane with a pre-attached blood tubing set (all gamma-sterilized).

Discussion: The dialysis-induced events were consistent with type A dialyzer reactions, reactions characterized by early onset, IgE-mediated symptoms such as urticaria, bronchospasm and/or anaphylactic shock. The differential included shock and medication reaction, but her symptoms resolved upon stopping dialysis, and she was not on causative medications (e.g. heparin, iron). A negative serum ethylene oxide (ETO) IgE level 3 weeks

later made a dialyzer or tubing-based ETO reaction less likely, though false negative results have been reported up to 3.5 weeks after exposure. We can only hypothesize on the cause of her reaction, including potential dialysis equipment (membrane or tubing) contamination with ETO or other antigens.

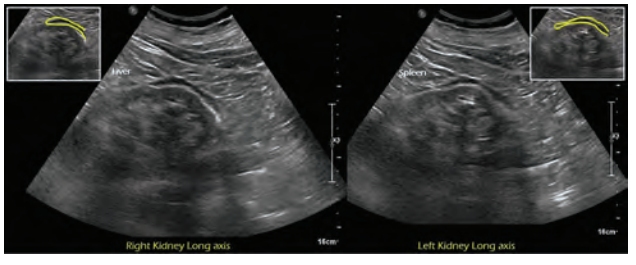
The "Double-Line" Sign to Identify Perirenal Fat Pad: A Must-Know Sonographic Sign

Salam Kadhem,[1] Harini Bejjanki,[1] Abhilash Koratala.[2,1] *[1]University of Florida, Gainesville, FL; [2]University of Texas Health Science Center, San Antonio, TX.*

Introduction: Perirenal fat is a fat pad located in the retroperitoneal space surrounding the kidney. As nephrologist performed point-of-care ultrasonography (POCUS) is on the rise, it's important to be aware of this structure for two reasons: 1. It can mimic free fluid in the Morrison's pouch and also subcapsular hematoma, which is particularly important when performing POCUS after a kidney biopsy 2. Recent epidemiological studies have shown that perirenal fat is a risk predictor for Cardiovascular disease, and it may turn out to be a promising target in the management of these patients. The 'double-line' sign we describe here can aid in the identification of this structure.

Case Description: A 52-year-old gentleman on maintenance hemodialysis was noted to have elevated hemoglobin (15 mg/dL) in the absence of erythropoietin stimulating agent therapy. A renal sonogram was performed to screen for renal mass/ renal cell carcinoma as the potential etiology for elevated hemoglobin, which demonstrated hypoechoic, sharply demarcated area in the perirenal area bilaterally mimicking intraperitoneal free fluid in addition to small kidneys with thin parenchyma. However, no intervention was undertaken because of the striking 'double-line' sign suggestive of perirenal fat pad bilaterally. Perirenal anechoic to hypoechoic structure surrounded by two hyperechoic bright lines [Figure-inset] constitutes this sign, where these echogenic lines are caused by fascial planes surrounding the kidney. Moreover, the fat pads typically contain low-level echoes within the hypoechoic region, unlike fluid and move with the kidney as it changes position during respiration. It may be difficult to distinguish this structure from post kidney biopsy subcapsular hematoma, but visualization of bilateral double-line sign favors fat pads.

Discussion: The double-line sign helps to distinguish free fluid in the hepatorenal or splenorenal space from the perirenal fat pad. Nephrologists performing POCUS should be able to recognize this sign to prevent unnecessary interventions and consultations.



PUB487

The Utility of Renal Replacement Therapy in Hepatic Encephalopathy

Ashish C. Ahuja. *UPMC Mercy, Pittsburgh, PA.*

Introduction: Severe liver failure may cause the brain to swell, leading to significantly altered sensorium. In the treatment of these patients, we utilize the ability of the gastrointestinal system to clear ammonia. However, we often come across patients who do not respond to this regimen. In this case, our patient was somnolent requiring intubation and had rising ammonia levels despite lactulose and rifaximin therapy. Although he had normal kidney function, we used CRRT and noted improvement in the patient's mental status.

Case Description: 58-year-old male who has a history of cirrhosis with portal HTN who presented with shortness of breath and cough for 2 weeks. He was initially admitted for COPD exacerbation. He developed further worsening respiratory failure requiring intubation and antibiotic therapy. CT chest revealed left upper lobe pneumonia and respiratory viral panel came back positive for H1N1 so he was started on Tamiflu. His physical examination off sedation included no purposeful movements and not following commands so he continued to be intubated. Ammonia level returned at 229. He received lactulose enema, lactulose 20mg QID, and rifaximin 500mg BID through orogastric tube. Given his minimal response and rising ammonia levels, CRRT was started. The next morning, his abdomen became increasingly distended and rigid. Abdominal X-ray revealed colonic ileus. Rectal tube was placed for colonic decompression. Lactulose was switched to Miralax QID and he received another CRRT session. The following day, he had increasing output from his rectal tube. Serial abdominal X-rays revealed decreasing colonic distention. He was extubated and started to communicate, eat by mouth and eventually transferred to the floor.

Discussion: We present an interesting case of a patient who presents with acute respiratory failure secondary to H1N1 influenza along with altered mental status secondary to hepatic encephalopathy. When conservative measures fail, clinicians sometimes consider more invasive techniques for HE, such as large portosystemic shunts or liver transplantation; however, not all patients are candidates for these procedures. This case sheds light on the utility of renal replacement therapy in the management of critically ill patients, even those without pre-existing kidney dysfunction or end-organ damage. Further studies are needed to quantify the extent to which renal replacement may benefit these patients.

PUB488

ESRD with Cardiac Ascites Managed with PleurX Drainage System

Keisuke Okamoto,[1] Amy M. Perry,[2] Fredrik Jenssen,[1] Michael E. Ullian,[1] Tibor Fulop.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Ralph H Johnson VA Medical Center, Summerville, SC.*

Introduction: The PleurX drainage system has been used to manage fluid from malignant and nonmalignant pleural effusions or malignant ascites at home, with more than 500,000 patients treated since 1997. We present a case of end-stage renal disease (ESRD) with refractory cardiac ascites managed with PleurX drainage system.

Case Description: A 65-year-old white Veteran presented with advanced heart failure (NYHA Class 4), multiple admission and diuretic-resistant edema formation with stage 5 CKD. While peritoneal dialysis (PD) would have been ideal, he was legally blind and did not have any family support for assisted PD. His medical scenario was initially stabilized with frequent hemodialysis (HD; x4/week) but he experienced recalcitrant ascites formation with severe and symptomatic intra-dialytic hypotension with net ultrafiltration. Moreover, the need for repeated paracentesis every 2 weeks posed a major emotional burden for our patient, including the discomfort and additional time-commitment of the procedure. After appropriate discussion and consenting with the patient, we requested a tunneled, single-lumen catheter placed into the abdominal cavity (PleurX drainage system; originally designed for repeated evacuation of pleural fluid accumulation), 4 months after HD initiation. Tolerability of HD improved and peripheral edemas well-controlled thereafter. Home health monitors his care and performs draining at least x3/week. Exit site care completed with local gentamycin cream and no interval peritonitis was observed so far (9 months).

Discussion: Cardio-renal ascites formation may represent a challenge to remove in those with coexisting severe heart failure and ESRD. Ascites fluid accumulation represents the hemodynamic "sinkhole" for patient with cardiac ascites and may be difficult to mobilize these during conventional HD. Plastic catheters in the blood stream are more likely to cause bacteremia than those placed in visceral surfaces (pleura, abdominal cavity). In those ESRD patients with cardiac and cirrhotic ascites, who cannot perform PD, establishing alternative and less-traumatic method of ascites drainage with PleurX drainage system may simplify the care and improve tolerability of HD.

PUB489

Diaphoresis, Bradycardia, and Urinary Incontinence as a Presentation of Dialysis Disequilibrium Syndrome

Waqar Ahmed, Steven D. Smith. *MSSM, New York, NY.*

Introduction: Dialysis disequilibrium syndrome (DDS) is an increasingly rare condition characterised by wide variety neurological symptoms of varying severity related to acute cerebral edema. We observed a unique presentation of bradycardia, diaphoresis and urinary incontinence along with unresponsiveness which has not been reported before.

Case Description: A 54 y/o African American female with ESRD secondary to DM and HTN on hemodialysis for 1 year presented to the ED with generalized body weakness after missing 3 hemodialysis (HD) sessions. Before the start of HD her physical/neurological examination and CT brain were normal. BUN=113mg/dl, Cr=19.5mg/dl, K=5.5mEq/L, Na=143mEq/L and tCO2=16mEq/L. HD was started with the following orders: 3.5hr; Qb 250ml/min; Qd 800ml/min; Dialyzer F160NR. After 1 hour of HD she was asymptomatic and Qb was increased to 375ml/min. Soon after completing the 3rd hour of HD she became acutely unresponsive to verbal/painful stimuli. HD was stopped immediately. BP=110/70, Pulse 90 then 2 episodes of bradycardia to the 40s were observed with spontaneous resolution after <30 seconds, normal reactive pupils, profuse diaphoresis, extremities warm and urinary incontinence. Seizure activity was not observed. EKG showed normal sinus rhythm with no ST/T wave changes. Acute hypoglycemia was suspected given the profound diaphoreis although the FSG was 120. IV dextrose (D50) was given empirically with no improvement. Blood urea nitrogen drawn 1 hour after stopping hemodialysis was 43mg/dl (URR - urea reduction ratio = 62%) and repeat CT brain was within normal limits. The patient improved clinically over the next 4-6 hours with no memory of the event. A neurology consultant attributed the event to DDS in the absence of any other likely cause.

Discussion: DDS was the most likely diagnosis in this patient with unresposiveness, bradycardia, diaphoresis and urinary incontinence during her 3rd hour of hemodialysis after having missed 3 dialysis sessions. There was no hypotension, hypoglycemia, CVA/ hemorrhage or CNS pathology, h/o seizures, or significant electrolytes abnormalities. This was a unique presentation of DDS, in which we observed increased parasympathetic activity characterized by bradycardia, diaphoresis and urinary incontinence along with unresponsiveness all of which resolved on stopping dialysis.

PUB490

Ammonia Clearance in Acute Liver Failure with Continuous Venovenous Hemodiafiltration

Warda Zaman, Tyler Woodell. *UCSD, San Diego, CA.*

Introduction: Hyperammonemia in acute liver failure and inborn errors of metabolism can cause life-threatening cerebral edema. While intermittent hemodialysis clears ammonia more rapidly, continuous renal replacement therapy (CRRT) is often used in acute liver failure due to hemodynamic instability and rebound of ammonia levels. Kidney Disease Improving Global Outcomes guidelines recommend an hourly effluent of 20-25 mL/kg/hr delivery with CRRT, but whether this applies to cases of hyperammonemia is unknown. We report the first case to our knowledge measuring the clearance of ammonia using continuous venovenous hemodiafiltration (CVVHDF) in a patient with acute kidney injury and hyperammonemia.

Case Description: A 27-year old previously healthy Hispanic man with alcohol overuse presented with one week of malaise, abdominal pain, and confusion after taking acetaminophen for flu-like symptoms. Physical exam was notable for obtundation, asterixis, scleral icterus; and laboratory studies were remarkable AST and ALT > 6000U/L; total bilirubin 9.1mg/dL; INR 6.3; ammonia 107uMol/L; and serum creatinine 4.7 mg/dL. Urine microscopy revealed multiple tubular epithelial casts and head CT showed diffuse sulcal narrowing. A diagnosis of grade 3 hepatic encephalopathy due to intracerebral edema from hyperammonemia from acute liver failure complicated by oliguric acute tubular necrosis was established, and the patient was listed for liver transplantation with a MELD of 40. CVVHDF was initiated on hospital day 1 with a total effluent of 33 mL/kg/hr was delivered (12 mL/kg/hr dialysis and 21 mL/kg/hr ultrafiltration). On hospital day 3, after 36 hours of uninterrupted CRRT, serum ammonia was 77 umol/L, effluent ammonia was 19 umol/L, and hourly effluent was 2700 mL. Using the Cordoba equation, we calculated an ammonia clearance of 11 mL/min. The patient's acute liver failure resolved without need for transplantation. He was transitioned to intermittent hemodialysis on hospital day 4, and achieved renal recovery becoming free from renal replacement therapy on hospital day 13. His most recent serum creatinine is 0.8 mg/dL.

Discussion: In this case of hyperammonemia, ammonia clearance was modest despite delivering an effluent volume that exceeded KDIGO practice guidelines. Given the increasing attention that CRRT is receiving for treatment of hyperammonemia, more work is needed to determine the optimal dose and method of CRRT in such instances.

PUB491

Utility of Procalcitonin (PCT) and Brain Natriuretic Peptide (BNP) in a Patient on Hemodialysis (HD)

Yun-Han Huang,[3] Leland R. Soiefer,[4] Matthew Abramson,[5] Jeffrey I. Silberzweig.[1,2] *[1]The Rogosin Institute, New York, NY; [2]Nephrology, Weill Cornell Medicine, New York, NY; [3]Weill Cornell Medical College, New York, NY; [4]Weill Cornell Medicine, New York, NY; [5]New York Presbyterian, New York, NY.*

Introduction: In the general population, PCT and BNP are used to assess likelihood of bacterial infection and volume overload based on absolute values above 100 pg/mL and 0.08 ng/mL respectively. Baseline values are elevated to a variable degree and both markers are cleared by high-flux dialysis membranes commonly used in the acute care setting resulting in ambiguity interpreting the meaning of PCT and BNP levels. We present a case showing their utility in resolving diagnostic uncertainty.

Case Description: An 84-year-old man was hospitalized with four weeks of worsening ascites, cough, and dyspnea. His initial BNP level was 1211 pg/mL and PCT was 0.40 ng/mL. Chest x-ray (CXR) showed pulmonary vascular congestion, bilateral pleural effusions and lower lung opacities. With large-volume paracentesis and ultrafiltration via hemodialysis, his symptoms improved. On day 6, dyspnea worsened and mental status declined. CXRs were unchanged from baseline. Ultrafiltration was increased with minimal improvement. A repeat PCT level on day 8 was 0.73 ng/mL, and he developed fever; chest CT revealed multifocal consolidation, and his respiratory and mental status improved with antibiotics.

Discussion: Interpretation of PCT and BNP can be challenging in patients with CKD treated by hemodialysis in the acute setting. The numerous potential causes of dyspnea in our patient created diagnostic uncertainty. Trends in the evels of PCT and BNP helped narrow our differential diagnosis improving our ability to successfully manage our patient.

PCT and BNP

Carbamazepine Intoxication and Role of Dialysis

Vivek Sharma,[1] Stephen B. Tanner,[1] Maaz Syed Ahmed.[2] Scott & White Memorial Hospital *[1]Nephrology, Texas A&M College of Medicine, Baylor Scott & White Memorial Hospital, Temple, TX; [2]Texas A&M; Baylor Scott & White, Temple, TX.*

Introduction: Carbamazepine (CMZ) at therapeutic levels is highly albumin bound. This limits effectiveness of extracorporeal elimination. It is not an established standard of care to utilize renal replacement and related techniques to support elimination in severe cases of CMZ overdose. Current literature is limited to case reports and case series which suggests to offer RRT in certain cases. High-flux hemodialysis is the preferred approach to extracorporeal elimination of CMZ (1). For clearance of CMZ, concentration of CMZ in the dialysate effluent should be measured. In addition some experts advocate that active metabolite carbamazepine-10,11 epoxide (CBZ–E), with its lower degree of protein binding, can be effectively cleared via extracorporeal modalities thereby limiting clinical toxicity. However, quantitative levels of this metabolite are not commonly measured. We present a case of severe CMZ toxicity in which extracorporeal treatment provided effective clearance of carbamazepine and CBZ-E.

Case Description: 24-year-old Caucasian female with 19 weeks of gestation was admitted with intentional carbamazepine overdose. She was severely encephalopathic with GCS of 6 on arrival. She was having seizures refractory to treatment and required intubation for airway protection. She was hemodynamically unstable needing vasopressor support. CMZ levels were found to be above the assay -limit (40.3 microgram/ml) on serial measurements at our lab. Normal reference range of 4.0-10 microgram/ml. After evaluation and literature review we started her on sustained low efficiency dialysis (SLED). After 10 hours of SLED, CMZ levels were lowered to a measurable range. Levels for CMZ and its active metabolite were sent from the dialysis effluent. She continued to show good clinical improvement with hemodynamic stability and improved neurological status. She was extubated. Clearances of CMZ and its metabolite CMZ-E were found be significant supporting the available limited data for use of extracorporeal therapy including SLED.

Discussion: Despite the scarce clinical evidence for high protein bound drugs like carbamazepine our experience supports use of extracorporeal removal in severe poisonings. Our case adds to the limited literature available for role of extracorporeal therapy for severe CMZ poisoning. It essentially means that non -protein- bound drug was eliminated which helped in eventually decreasing the toxic levels of CMZ.

PUB493

First Report of Short Bowel Syndrome Complicated with Uremia

Meng Wang, Hua Liu. *First Affiliated Hospital of Medical College of Xi'an Jiaotong University, Xi'an, China.*

Introduction: Patients with short bowel syndrome (SBS) often suffer from water-electrolyte disturbance, nutrient malabsorption, duing to shortened intestine. Some of the patients subsist largely on parenteral nutrition. Hemodialysis is main treatment of uremia, during which the excess water and electrolytes of the body are removed together with uremic toxins. SBS complicated with uremia is very rare. The treatments of the two diseases always conflicting. There is no relevant literature for reference.

Case Description: The patient was a 36-year-old woman with a 20-year history of Crohn disease who had undergone nine times intestinal resections and less than fifty centimeters residual intestinal, subsisted largely on parenteral nutrition now. Long-term use of analgesics and malnutrition, she got the chronic renal function failure half a year ago, when she had no choice but to start the hemodialysis treatment. With low body weigh(38kg),low blood pressure(85/43mmHg), hypo-albuminemia (30.4g/L), plenty of parenteral nutrition solutions, it was hard to evaluate the ultrafiltration volume. With very low serum phosphorus(0.04mmol/L), calcium(1.89mmol/L), PTH(3.8pg/ml), and active VD3(4.6ng/ml), she suffered with severe bone pain always. Meanwhile, long-term use of peripherally inserted central catheter (PICC), there was no conditons to estabolish conventional dialysis access. A specialized physician team established for the patient. The parenteral nutrition treatment prescription is adjusted according to the dietary guidance of chronic kidney disease, to provide right dosage of energy, protein, liquid, and electrolytes intake of HD status. Real-time monitoring of blood gas analysis during hemodialysis, timely replenishing glucose and electrolytes, maintaining the balance of acid-base, water and electrolyte. Supplemented erythropoietin, trace elements, and intravenous active vitamin D to improve uremia complications. At the same time, femoral vein cuffed tunnel was use for transition, we created the left forearm ulnar side arteriovenous fistula (AVF) as permanent vascular access. Now the nutritional status, uremia complications, and life quality of the patient improved significantly.

Discussion: Short bowel syndrome complicated with uremia is very rare. It is not only necessary to prevent the complications of continuous use of parenteral nutrition support, but also to intervene the complications related to maintenance hamodialysis.

PUB494

Using Intermittent and Continuous Venovenous Hemodialysis to Treat Hyperammonemia in Acute Liver Failure

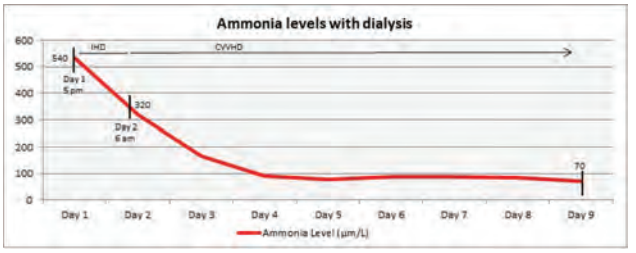
Jay A. Pandav, Samer Kareem, Shruti Kore, Savneek S. Chugh, Sanjeev Gupta. *Westchester Medical Center/New York Medical College, Pleasantville, NY.*

Introduction: Hyperammonemia with levels >200 μmol/L is usually associated with poor neurologic outcomes and death. The primary goal of renal replacement therapy (RRT) is to reduce blood ammonia concentration and achieve resolution of neurological symptoms. Although RRT has been used to treat hyperammonemia in neonates with inborn errors of metabolism, its use in adults is poorly studied. We present a case of severe hyperammonemia due to acute liver failure secondary to hepatitis A.

Case Description: A 70-year-old male with history of CAD and HTN was transferred from another hospital with jaundice and altered mental status secondary to acute liver failure. Labs were significant for creatinine of 3.26 mg/dL, INR 8.20, Bilirubin 11.8 mg/dL; AST/ALT of 7167/9544 U/L. Ammonia level was 540 μmol/L. Serology showed positive Hepatitis A IgM. CT head was negative for cerebral edema. He was started on intermittent hemodialysis (iHD) emergently followed by CVVHD. Ammonia levels dropped post iHD from 540 to 320 and <100 within 72 hours. His mental status initially worsened but improved after 2 days. Unfortunately, his hospital course was complicated by septic shock

and ischemic colitis. He went into cardiac arrest after subtotal colectomy and was made comfort care. He passed away on day 9 with ammonia level <100 μmol/L on CVVHD.

Discussion: Ammonia is similar to urea in terms of its clearance; hence both IHD and CRRT are effective in removing it. The longer ammonia remains elevated, the higher the chance of mental impairment. iHD is considered a preferred modality as it decreases ammonia concentrations rapidly. CRRT has been used successfully with iHD in children to prevent ammonia rebound. Our patient presented with very high ammonia levels, hence we started iHD to decrease the ammonia level rapidly followed by CCRT. He responded well within 48 hours with this method. His ammonia level remained less than 100 μmol/L subsequently. Currently, there is limited data regarding which modality to use in adult patients with hyperammonemia. More studies are needed to assess the efficacy of hemodialysis in these patients.



PUB495

Hypotension on Dialysis: It's Not Always Hypovolemia

Michael B. Shaw,[1] Jacob West,[2] Ruth E. Campbell,[2] Arjun Sekar.[3] *[1]Mercy One Des Moines, IA, Ankeny, IA; [2]Mercy Medical Center, Des Moines, IA; [3]Associates in Kidney Care, West Des Moines, IA.*

Introduction: Hypersensitivity reactions (HSR) to dialysis filters are rare and can be challenging to diagnose. Here, we describe a case of Type A HSR secondary to a polysulfone (PS) filter on continuous renal replacement therapy (CRRT).

Case Description: A 66-year-old male with NYHA IV heart failure and stage III chronic kidney disease presented for elective placement of a left ventricular assist device (LVAD). Initial creatinine was 1.6mg/dl. Post-operatively, he developed sustained ventricular tachycardia leading to anuric AKI & hyperkalemia. CRRT without ultrafiltration (UF) was initiated. He tolerated it for 30 minutes and then the circuit clotted. Within 2 minutes of restarting, mean arterial pressure (MAP) dropped to 30mmhg from 65mmhg with hypoxemia, needing intubation. It was stopped and the MAP improved spontaneously. A third attempt of CRRT with no UF again resulted in hypotension and cyanosis within 30 seconds despite pre-emptively increasing vasopressors and giving crystalloids. Relevant labs include a low C3, normal C4 & tryptase, and no eosinophilia. CRRT was immediately stopped and extracorporeal blood not returned. We switched to a cellulose based filter with concerns for HSR to the PS filter. Our CRRT machines were incompatible with other filters, so intermittent hemodialysis (HD) with blood & dialysate flows of 200ml/min & 400ml/min respectively with a cellulose filter was done successfully. Further HD sessions with cellulose filters had no issues.

Discussion: Our case describes a Type A HSR to PS dialysis filters with resolution after switching to a cellulose filter. HSR on dialysis was reported at 4.2/1000 sessions of dialysis per year for synthetic membranes and can be associated with dyspnea and hypotension. Type A reactions are immediate and type B delayed. It's often linked to a sterilizing agent ethylene oxide and AN-69 dialysis membranes in patients on ACE-Inhibitor which he wasn't on. Recent reports highlight other substrates, like PS membrane, as an important but under recognized cause of HSR. Hypersensitivity can be mediated by Immunoglobulin E or complement activation. Management includes; not returning blood from the extracorporeal circuit to avoid aggravating hypersensitivity, priming the dialyzer with saline to washout sterilant and switching to cellulose filters.

PUB496

Nephrology Team Leading Molecular Adsorbent Recirculation Therapy (MARS) Therapy: Case Reports

Karthik Kovvuru, Swetha Rani Kanduri, Jorge L. Castaneda. *University of Mississippi Medical Center, Jackson, MS.*

Introduction: Acute liver failure (ALF) from any cause has an extremely high mortality and sometimes liver transplantation is the only final treatment. Molecular Adsorbent Recirculation System (MARS) lead by Nephrology has been successfully used in two patients as a bridge to full recovery and liver transplantation respectively.

Case Description: 1) 34 Yr old Female presented with nausea, vomiting with labs significant for AST 15,785 U/L, ALT 10,888 U/L, Total Bilirubin 17.4 mg/dl, INR 2.32. Diagnosed with ALF due to Acute Hepatitis B, was started on N-Acetylcysteine, Lactulose, Rifaximin and Tenofovir. 24 hrs into admission her mentation worsened requiring intubation. CT showed cerebral edema. Decision was made to start MARS to remove toxins and help liver in regeneration by improving microenvironment. Received 56 hrs total of MARS therapy for four days. Bilirubin improved from 25.27 mg/dl to 9.5 mg/dl, mentation improved and was eventually discharged. **2)** 28 Yr old Male admitted for ALF secondary to alcohol intoxication. Labs were significant for AST > 7000 U/L, ALT > 7000 U/L, Bilirubin 8.41 mg/dl, Lactate >15 mmol/L. Due to lack of spontaneous recovery and worsening clinical condition he has been started on MARS therapy and listed for Liver transplant. Liver was transplanted after 54 hours of MARS therapy. Surgery related issues complicated his postoperative course. He is currently waiting long term rehab placement for continued recovery.

Discussion: MARS is a potential lifesaving therapy in selected patients. A multidisciplinary team is required to provide this extracorporeal therapy and nephrology should take the lead.

PUB497

Dialysis Disequilibrium Syndrome Despite Standard Preventive Measures

Julien Sanon,[1] Eric J. Bloom,[2] Saurabh Gupta,[2] Ji Young Shin,[2] Arul Vigg.[2] *[1]Einstein Healthcare Network, Cheltenham, PA; [2]Albert Einstein Medical Center, Berwyn, PA.*

Introduction: There have been very limited cases of dialysis disequilibrium syndrome (DDS) reported in recent literature. Compared to the 1970s and 1980s, our patients are admitted with a lower Blood Urea Nitrogen (BUN) concentration. Standard preventive recommendations for the first dialysis sessions have limited the incidence of DDS significantly. As a result, cerebral edema and brain herniation have become rare entities.

Case Description: Our patient is a 54-year-old female with hypertension, CKD stage 4 who presented with 2 weeks of fever, generalized weakness and shortness of her breath. Blood pressure (BP) was 194 /137. She was lethargic with asterixis. Lung exam revealed crackles. Her sodium was 131 mEq/L, potassium 4.5 mEq/L, bicarbonate 21 mEq/L, BUN 191 mg/dL, creatinine 16.6 mg/dL. Chest computed tomography (CT) had multifocal pneumonia with pulmonary edema. Dialysis was started for 2 hours with F16 dialyzer, blood flow of 250ml/min and dialysate flow of 500 ml/min. Within 5 minutes of dialysis, she became unresponsive and her systolic BP dropped to 98. The session was stopped immediately. Her mental status and her blood pressure improved in the afternoon but worsens in the evening. Dialysis was started overnight with the same prescription. She tolerated the procedure well until her blood pressure rose to the 200's and she became unresponsive 90 minutes later. Head CT showed cerebellar edema and tonsillar herniation. Calculated serum osmolality change pre and post dialysis was 27 mmol/L. Neurology diagnosed her with Posterior Reversible Encephalopathy Syndrome.

Discussion: DDS is a very rare complication of dialysis. Established protocols usually prevent this dreaded outcome. Our case is an important reminder that standard preventive recommendations may not be sufficient. Our patient had a complex presentation and did not benefit from the recommended measures. This syndrome has also been reported with continuous renal replacement therapy. Female with preexisting neurological conditions and BUN higher than 175 mg/dL are more prone to this condition. In this high-risk population, the use of one of the smallest dialyzers such as F3 with a lower than the recommended blood flow and dialysate flow rate might have a more desirable outcome.

PUB498

Addressing Social Determinants of Health in Haitian-American Patients with ESRD

Nicole M. Millan,[3] Fatimat O. Shotande,[2] Dollie D. Florence-Green.[1] *[1]Humanities, Health and Society, Florida International University Herbert Wertheim College Of Medicine, Miami, FL; [2]Florida International University Herbert Wertheim College of Medicine, Pembroke Pines, FL; [3]Florida International University, Doral, FL.*

Introduction: African Americans with ESRD have higher rates of morbidity and mortality. Social determinants of health (SDOH) such as attaining healthcare, legal assistance, appropriate nutrition, financial stability, employment and education create obstacles to achieve better outcomes. We compare interventions for patients with ESRD on hemodialysis in the setting of an interdisciplinary Neighborhood outreach program (NHELP). We aim to understand how addressing the SDOH affect morbidity and mortality.

Case Description: African Americans with ESRD have higher rates of morbidity and mortality. Social determinants of health (SDOH) are contributory as they create obstacles to attaining healthcare, legal assistance, appropriate nutrition, financial stability, employment, education. We compare interventions for patients with ESRD on hemodialysis in the setting of NHELP. We aim to understand how addressing the SDOH affect morbidity and mortality. The SDOH and associated obstacles were identified. **Results**: Patient A had 17 months of program participation with her most current student team. She received two home visits (one interdisciplinary, one social work only) and an average of 3.5 phone communications. She received academic support for her children, referral for dental care, and legal support filing for citizenship. Recurrent hospitalizations were a challenge for Patient A and NHELP team during her participation. Patient B had 21 months with a student team. She received 9 home visits and an average of 5.5 telephone communications. Patient B had private health insurance and full-time employment. Interventions included: mental health services, assistance with transplant process, education regarding improving diet and blood pressure control, help transitioning between dialysis centers, and dental referrals. Both patients received help applying for federal assistance to cover healthcare costs. Patient A received Social Security Disability and Medicare, while patient B only received Medicare. Both received social support and education to improve health literacy.

Discussion: Conclusion: Earlier access to interdisciplinary care decreased obstacles to health services vital for patients with ESRD. When SDOH were completely addressed, patient B received transplantation suggesting improved morbidity and mortality.

PUB499

A Case-Series Analysis of CKD and Disseminated Tuberculosis Treated in a Tertiary-Level Hospital

Elba O. Medina,[1] Laura Escobedo Jaime,[2] L. M. Perez-Navarro,[1] Rafael Valdez-Ortiz.[2] *[1]Hospital General de Mexico "Dr. Eduardo Liceaga", Mexico City, Mexico; [2]Hospital General de Mexico, Mexico City, Mexico.*

Introduction: End-stage renal disease is considered a factor predisposing to increased risk of tuberculosis (TB) with frequent extrapulmonary localization. The haemodialysis patients are at risk to develop TB disease 6.9 times more frequently due to imparied cellular immunity in chronic renal failure. The diagnosis of TB in Chronic Kidney Disease (CKD) is difficult because of frecuent extrapulmonary localization and non specific symptoms.

Case Description: *case1 :*32 years old man, Human Immunodeficiency Virus (HIV) negative (-) in HD, miliary TB, pleural and pericardial effusion, pericardiocentesis with adenosine desaminase (ADA) of 38 y GenXpert positive(+), computed tomography (CT) with tumor that destroys the sternoclavicular joint with Ziehl-Neelsen (Z/N) (+). *case 2 man:*26 years old, in HD, miliary TB, pleural effusion and pericardial effusion, isolated from bronchial wash, GenXpert, and Lowenstein Jensen medium (LJ) (+) pericardiocentesis with Z/N(+).*case 3:*42 years old woman, CKD stage IV, type 2 diabetes mellitus (DM2), arterial hypertension(AH), miliary TB, LJ (+) in sputum and detection of lymphangioleiomiomatosis by lung biopsy. *Case 4*:66 years old man, in HD, DM2, AH, CT with cavitated bilateral cervical lymph nodes, biopsy of lymph node with Z/N (+). Case 5:18 years old, HIV (+) with miliary TB, in HD; GenXpert in bronchial wash and LJ(+), pericardiocentesis with ADA 138, LJ(+). *case 6*:55 years old woman in HD, DM2, pericardial effusion, pericardiocentesis ADA 49.8, tuberculous pericarditis by biopsy.*case 7:*22 years old, in HD, meningeal cryptococcosis, bronchial wash Z/N and LJ(+).*case 8:*22 years old, in HD, disseminated TB, bronchial wash with Z/N and LJ(+), GenXpert of cervical lymph node(+).

Discussion: The link between CKD-TB increases morbimortality, extrapulmonary associations and disseminated are frequent and of difficult diagnosis, the TB screening and diagnosis performance is suboptimal in the CKD population, and there is limited evidence to guide protocols, the intentional search is required with molecular biology of several affected sites. So the diagnosis is made in advanced disease, which leads to a clinical torpid course because despite the treatment in our case series 5 of 8 patients died. So these patients are candidates if active tuberculosis it is discarded for chemoprophylaxis

PUB500

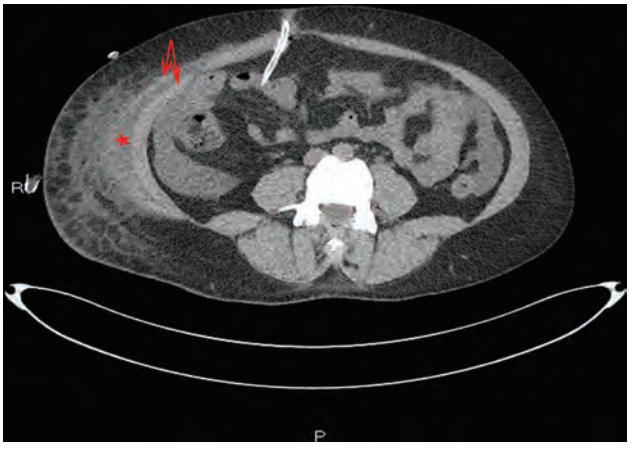
Oblique Leak

Dennis Hu,[1] Syed H. Bukhari,[2] Sana F. Khan.[1] *[1]University of Virginia, Charlottesville, VA; [2]University of Virginia Div. of Nephrology, Charlottesville, VA.*

Introduction: Most peritoneal dialysis associated leaks are associated with peri-catheter leaks, hernias and genital swelling. We present a case here of a patient whose peritoneal fluid was leaking into an area away from the catheter and in a location where no recent surgical intervention was performed.

Case Description: A 47-year-old female with end-stage kidney disease on continuous ambulatory peritoneal dialysis presented to the emergency department with a 48-hour history of poor ultrafiltration with absorption of approximately 300-1100 mL of each 2 liter dwell volume exchange. Additionally, the patient reported an area of hardened skin along her right lateral abdominal wall. Physical exam revealed normal peritoneal catheter exit site with no drainage or induration along the anterior abdominal wall. A 5 x 5 cm area of hard induration was palpable along her right lateral abdominal wall. CT scan was concerning for subcutaneous fluid along the right abdominal wall which tracked inferiorly causing separation of the oblique muscles (Figure 1). Given lack of intraperitoneal contrast material, location of the abdominal wall defect was not determined.

Discussion: Most peritoneal dialysis associated leaks are associated with peri-catheter leaks, hernias, and genital swelling. In our patient's case, physical exam and imaging around the catheter were unremarkable. Instead, the leak was located away from the current PD catheter and was on the opposite side of a previously placed peritoneal dialysis catheter. This case illustrates an atypical location for peritoneal leaks.



CT scan showing subcutaneous edema along the right lateral abdominal wall. Fluid tracking (asterisk) leading to separation of oblique muscles (arrows).can be seen here.

PUB501

Cefepime-Induced Neurotoxicity in a Peritoneal Dialysis Patient: An Increasingly Common Scenario

Tiana Jespersen, Shubha Ananthakrishnan. *University of California Davis, Sacramento, CA.*

Introduction: Cefepime is a generally well-tolerated antibiotic used for a variety of infections. Neurotoxic effects, including nonconvulsive status epilepticus (NCSE), have been described and are typically seen in patients with renal dysfunction or end-stage renal disease (ESRD) receiving high doses. While up to 70% of a given cefepime dose is removed with hemodialysis (HD), the clearance is reduced to only 25% with peritoneal dialysis (PD). We present a case of cefepime-induced neurotoxicity in a PD patient requiring treatment with temporary HD.

Case Description: An 82-year-old man with multiple system atrophy and ESRD on PD presented to our hospital with a decreased level of consciousness (LOC), found to have urinary retention. Empiric treatment for a complicated urinary tract infection was started with cefepime 1 g every 24 hours. On day 3, the patient developed aphasia and myoclonic jerks with further decline in alertness. An electroencephalogram (EEG) was performed demonstrating triphasic discharges suggestive of toxic encephalopathy. Despite 2 days of continuous peritoneal dialysis, his mental status remained poor. Cefepime was deemed the most likely culprit and on day 6, HD was pursued for increased drug clearance. HD was performed for 3 consecutive days with improvement in mental status after the first session and return to baseline after the third.

Discussion: The neurotoxic effects of beta-lactams have been attributed to γ-aminobutyric acid antagonism leading to diminished LOC, myoclonus, and NCSE. The connection between these symptoms and cefepime is often overlooked, especially in cases where dose adjustment was made for renal function or competing diagnoses exist. In our experience, patients on PD are more likely to be exposed to excessive cefepime doses because many providers are not aware of the poorer drug clearance this dialysis modality provides. Even when pharmacy oversight measures are in place, cefepime is not typically included in the list of monitored medications. Our institution has approved alternate broad-spectrum antibiotics (e.g., piperacillin-tazobactam) for use in the intensive care unit for patients with ESRD in hopes of reducing the incidence of cefepime-induced neurotoxicity. Meanwhile, HD remains the modality of choice for recognized cases.

PUB502

Hernia Repair and Peritoneal Dialysis: A Case Report of Successful Perioperative Management in Peritoneal Dialysis at a Veterans Hospital by an Interdisciplinary Team

Rajendra Mandalapu,[2,1] Marcia McBride,[3] Audra B. Hartwick,[2] Anne Mancino,[3] Manisha Singh.[2,1] *[1]University of Arkansas For Medical Sciences, Little Rock, AR; [2]Nephrology, CAVHS, Little Rock, AR; [3]CAVHS, Little Rock, AR.*

Introduction: Inguinal hernia is a common complication of peritoneal dialysis (PD). It is a usual practice in the United States to transition PD to hemodialysis (HD) for hernia repair due to concern for dialysate leak and hernia recurrence, despite recomended protocols to continue PD without this transition in appropriate patients. There are few reports of successful use. We report the first case of elective inguinal hernia repair in a continuous cycling PD (CCPD) patient using a personalized protocol at the Veterans Hospital.

Case Description: The patient is a 62-year-old African American man with a past history of hypertension, congestive heart failure, and end-stage renal disease (ESRD) on PD since 1 year. He was diagnosed with right inguinal hernia and planned for elective mesh repair. The patient expressed his wish of not wanting to switch to HD unless absolutely required. Multidisciplinary liaisons including the primary nephrologist, surgery team, renal dietician, PD nurse, and the patient's family worked out a modified, personalized version of the published protocols. The patient agreed that if there were any issues needing the transition during this period he would be switched to HD. The patient had right inguinal repair with large proline hernia system mesh early March and discharged the same day. Labs were done every 3 days to assess the need for dialysis. The PD nurse closely followed the patient with daily phone calls to assess functional status. We were able to implement the above protocol successfully without requiring to switch the patient to HD and without extending the hospital stay. His post-op course was complicated by hyperkalemia (potassium ranging from 5.2-6.0) due to poor diet compliance. The renal dietician revisited the prior advised diet modifications. Potassium returned to normal with medical management and diet control.

Discussion: Though there is literature on successful maintenance of PD during perioperative management, there are very few published reports. The use of recomended protocols is not robust. From our knowledge, this is the first case report at a Veterans hospital in the USA; our case demonstrates a successful modification of protocols for the US population with an interdisciplinary team approach, with no increase in the hospital stay.

PUB503

Severe Polymicrobial Peritonitis with a Successful Outcome

Seyedmahdi Pahlavani, Marie D. Philipneri. *Saint Louis University, University City, MO.*

Introduction: Polymicrobial peritonitis involving gram negative organisms is considered a serious complication of peritoneal dialysis and catheter removal might be warranted in refractory cases. We present a unique case with recent initiation of peritoneal dialysis who developed severe polymicrobial peritonitis.

Case Description: A 33-year-old female was recently diagnosed with end-stage renal disease and started on continuous cycling peritoneal dialysis (CCPD) one month ago. She presented with severe abdominal pain, vomiting, and constipation. Pertinent clinical findings included tachycardia and diffuse abdominal tenderness. Initial peritoneal fluid analysis showed leukocyte count 86,325 cells/μL with 92% segmented cells. On first day, intravenous vancomycin and cefepime were administered but peritoneal dialysis (PD) was not performed due to extreme pain. Repeat peritoneal fluid WBC count had increased to 148,000 with 76% segmented cells. An emergent surgical consult was sought. Abdominal CT scan did not reveal any obvious perforation or abscess. Peritoneal fluid culture returned positive with *Klebsiella Oxytoca and* and *Enterobacter Cloacae*, both sensitive to cefepime. CCPD using tidal setting, intraperitoneal (IP) cefepime (both daily loading and maintenance doses), and IP heparin 500 units/L in all PD bags were undertaken. Over the next five days, the patient demonstrated clinical improvement and peritoneal fluid leukocyte counts decreased to 5748 on day five and 387 on day seven. The patient was discharged home on CCPD and daily IP cefepime in long dwells. After completion of four weeks of intraperitoneal antibiotic the patient is free of symptoms and tolerating CCPD well.

Discussion: This case was unique because of the complexity of peritonitis in terms of severe abdominal discomfort, unusually high leukocyte count, and identification of two gram-negative bacteria. Following initial intravenous antibiotic administration, PD fluid WBC count markedly rose but IP antibiotics using both daily loading and maintenance doses in this patient who is new to dialysis with significant residual renal function was successful. Tidal CCPD facilitated management of patient's discomfort and continue PD. It was critical to thoroughly evaluate the patient for surgical indications and prudently manage constipation.

PUB504

Hemodialysis Catheter-Induced Air Embolism

Bhuwan Kayastha,[1] Farhan Ali,[1] Babak S. Jazayeri-Moghadass,[1] Parichi V. Buch,[1] Simran Dhillon.[2] *[1]University of Maryland Medical Center, Baltimore, MD; [2]University of Maryland, Bel air, MD.*

Introduction: Air embolism is one of the fatal complication associated with central line. In a dialysis patient it is less common but if it occurs it can be life threatening. Air can enter blood vessel through the dialysis catheter or through the blood pump due to a negative pressure in circuit. This complication is relevant to field of nephrology as it is a complication of use of central venous catheters with dialysis (1). We hereby report a case of paradoxical air embolism due to air entry from hemodialysis catheter.

Case Description: 72-year-old female with a history of end stage renal disease on home hemodialysis, was found unresponsive while on dialysis with a detached catheter. Work up showed, pneumocephalus, air embolism leading to acute stroke and cerebral edema. Echocardiogram showed intracardiac shunt. Finally, the patient died.

Discussion: This case illustrates the dreadful complication associated with dialysis catheter. Recognition of this complication is important to prevent air embolism by taking appropriate preventive measures while handling dialysis catheter and also to provide education to health care provider, patient about this complication. With improvements in dialysis techology the risk is reduced but sporadic cases are reported (2). There is paucity of data on management of air embolism, and preventive measures along with the recognition of the complications are essential. PUB505

Hyperglycemia-Induced Hyponatremia: A New World Record?

Jefferson L. Triozzi, Ramon Li, David Sheikh-Hamad. *Baylor College of Medicine, Houston, TX.*

Introduction: We present a case of hyperglycemia-induced hyponatremia, with a serum glucose value greater than the upper limit of laboratory detection. This poses a unique challenge. What is the approach to hyponatremia without a definitive measurement of serum glucose? The Guinness World Record for the highest serum glucose is 2,656 mg/dL--does our patient hold a new world record or is this a laboratory error?

Case Description: A 39-year-old male with no known medical history presents with hyponatremia of 102 mEq/L. His vital signs and physical examination are unremarkable. Blood glucose on point-of-care glucometer is >700 mg/dL and follow-up blood glucose on laboratory basic metabolic profile is >4000 mg/dL. There is no ketoacidosis. Nephrology was consulted for symptomatic hyponatremia in the setting of hyperglycemic hyperosmolar non-ketotic syndrome. Without accurate laboratory measurements, we estimate blood glucose by calculating the osmol gap. Measured serum osmolality is 350 mOsm/kg and calculated osmolality is 222 mOsm/kg, yielding an osmol gap of 128 mOsm/kg. Subtracting 10 mOsm/kg (for normal gap), and using a conversion factor of 18 for glucose, we estimate a blood glucose value of 2,124 mg/dL--an extreme value, but no Guinness World Record. The corrected sodium would be approximately 134 mEq/L (close to actual Na, once the glucose was normalized). The patient was treated with IV insulin and infusions of normal saline. He was discharged with a new diagnosis of type 2 diabetes mellitus.

Discussion: Glucose is osmotically active, shifting water from the intracellular compartment to the extracellular compartment and diluting sodium in the process. Following treatment with insulin, glucose is taken up by the cells and metabolized, water shifts back to the intracellular compartment, and dilutional hyponatremia is reversed. Rapid changes in serum osmolality can lead to life-threatening complications; thus, accurate laboratory values are critical. If the reported blood glucose of 700 and 4000 were used, the corrected sodium would be anywhere from 116 to 164 mEq/L, respectively, potentially misdirecting management. In this case, the correction of hyperglycemia alone was sufficient for safe "correction" of Na. Extreme values of blood glucose are associated with analytical errors. When faced with suspicious laboratory values, additional information should be used for verification.

PUB506

Management of Severe Metabolic Alkalosis in a Patient with Intractable Vomiting

Jordan Resnick,[1] Naga M. Komati,[3] Hameeda Khan,[4] Biruk Almaz.[2] *[1]RWJBarnabas Health, Livingston, NJ; [2]St Barnabas Medical Center, Livingston, NJ; [3]Modern Nephrology Transplant, LLC, West Orange, NJ; [4]Saint barnabas medical center, West orange, NJ.*

Introduction: Gastric secretion of hydrogen chloride is normally neutralized by bicarbonate secreted by the pancreas, liver, and intestines. Gastric outlet obstruction (GOO) may cause intractable vomiting with potentially life-threatening metabolic derangements including hypochloremic, hypokalemic, metabolic alkalosis. Prompt recognition and management is critical, however the decision if-when to dialyze a patient remains controversial.

Case Description: A 39-year-old male with HIV on HAART and Diffuse B-Cell lymphoma on R-EPOCH chemotherapy was admitted to the ED for intractable nausea and vomiting of one week's duration with accompanying significant weight loss. History revealed he had had a recent PET scan at an outside facility showing a gastric mass surrounding the pylorus and he was thus determined to have metastatic GOO. ABG revealed severe metabolic alkalosis 7.68/49/66 with a bicarbonate of 46 with an acute kidney injury. Intravenous normal saline with potassium replacement and pantoprazole was given and his alkalosis improved uneventfully.

Discussion: When opting for medical management in patients with true arterial volume depletion treatment typically begins with intravenous normal saline. Sodium, Chloride, and Potassium (replenishments) should correct hypokalemia and increase intravascular volume. Meanwhile, H2 blockers or proton pump inhibitors help curb nausea and decrease the quantity of HCL lost in the vomitus.[1] In select patients with poor kidney function and in whom increasing urinary bicarbonate output with acetazolamide is not feasible, acid infusions (ex: hydrochloric acid) can be cautiously considered. If the aforementioned measures fail and if there is no way to excrete acid in the urine, then dialysis is the best option. Beyond a certain point alkalemia (pH >7.65) becomes a medical emergency and carries a high risk of complications.[2] Despite the severity, a cutoff of when to choose to dialyze remains elusive. A survey of 25 Yale-affiliated nephrologists revealed that only 4 of 25 elected to use dialysis for patients with severe metabolic alkalosis.[3] When choosing a dialysate a low-bicarbonate dialysate is preferable as it rapidly improves alkalosis. In our patients' case, correcting the underlying cause is the best approach to permanently reverse his alkalosis.

PUB507

An Intentional Ingestion of 23.4 g of Potassium

Angelina M. Dixon,[1] Adrian J. Baudy.[2] *[1]Tulane University School of Medicine, New Orleans, LA; [2]Tulane University, New Orleans, LA.*

Introduction: Hyperkalemia from ingestion is relatively uncommon in patients with normal renal function. In most cases of ingestion, only one episode of renal replacement therapy is needed for clearance of excess potassium. While potassium supplementation is fairly safe, hyperkalemia can be associated with potentially life-threatening arrhythmias and cardiopulmonary arrest.

Case Description: A 63-year-old man with a prior history of HIV, Hepatitis C, CVA, and hypertension was brought to the hospital by EMS for altered mental status. His neighbor reported weakness for the past week and increasing confusion. The patient's vital signs were normal. He was confused but able to answer most questions appropriately. His lab results demonstrated a serum potassium level of 8.3 and a creatinine of 1.4 (baseline 1.0). An EKG demonstrated atrial fibrillation with a widened QRS interval, prolonged PR interval and peaked T waves. An abdominal x-ray demonstrated innumerable radiopaque pill fragments in the stomach. The pills were presumed to be the patient's home 10 mEq KCl tablets. The patient was given calcium gluconate, albuterol, insulin and glucose, sodium bicarb, and rectal sodium polystyrene sulfonate. An OG tube was placed and returned 600 mL of brown liquid as well as some small pill fragments. Repeat abdominal x-ray demonstrated persistent pill fragments in the stomach and a gastroenterology consult was placed for emergency endoscopy with pill removal. Upon endoscopy, the stomach appeared to have ischemic changes, but no pill fragments were visualized. Nephrology was consulted for emergent dialysis, and the patient was placed on intermittent hemodialysis for 2 hours followed by sustained low-efficiency daily dialysis for 6 hours. The patient's potassium normalized but increased to 6.5 less than 12 hours later, necessitating repeat intermittent hemodialysis and sustained low-efficiency daily dialysis.

Discussion: This case illustrates the need for repeat renal replacement therapy after a patient ingested 23.4 grams of oral potassium – 60 10 mEq KCl tablets in total. While there are case reports of overdose by IV KCl, oral potassium supplements have been considered safer due to delayed absorption and difficulty in taking large doses due to large pill size. In addition, severe hyperkalemia due to overdose by oral hyperkalemia is uncommon in patients with preserved renal function.

PUB508

Fanconi Syndrome and Hypomagnesemia: An Overlooked Association or Diagnostic Entity?

Christopher H. Girgis,[1] Pranay Kathuria.[2] *[1]Division of Nephrology, The University of Oklahoma - Tulsa, Tulsa, OK; [2]The University of Oklahoma College of Medicine, Tulsa, OK.*

Introduction: Fanconi's Syndrome is associated with hypophosphatemia, aminoaciduria, and renal glycosuria. However, there is significant variability in the phenotypical presentation of this disease process. Time to diagnosis and length of underlying etiologies such as multiple myeloma or medications can play a role in the presentation, specifically between acquired and congenital Fanconi's Syndrome. Though typically not considered a classical association with Fanconi's Syndrome, hypomagnesemia is occasionally noted in the literature in association with this disease and seems to be an underrecognized feature of this entity.

Case Description: A 65 year old female with history of recently diagnosed multiple myeloma (2 months prior), hypertension, and previously treated hypercalcemia now hypocalcemic presented with carpo-pedal spasms. One month prior she was treated with cyclophosphamide, bortezomib, dexamethasone, and denosumab. Corrected calcium was 6.2 mg/dL, bicarbonate 16 mEq/L, potassium 2.4 mEq/L, chloride 112 mEq/L, magnesium 1.3 mEq/L, phosphorus 1.3 mg/dL, anion gap 15, and creatinine 1.42 mg/dL with AKI with a baseline of 0.6 mg/dL. Urine bicarbonate was 8 in the setting of acidosis. Fractional excretion of magnesium was 28% in the setting of hypomagnesemia. Urine anion gap was 20, pH of the urine 8.0. No glucosuria. TTKG was 4.75 indicating potassium losses in the setting of hypokalemia. Aminoaciduria was present. With these findinds, the diagnosis of Fanconi's Syndrome, Renal Tubular Acidosis Type II in association with Multiple Myeloma was made. Oral replacements of electrolytes and Amiloride were started, with stabilization of electrolytes.

Discussion: Though hypomagnesemia is not classically noted as an association with Fanconi's Syndrome, such as glucosuria, aminoaciduria, and hypophosphatemia, it appears to be an under-recognized feature of this disease process. As stated in the limited literature with this association, there is cellular injury at the nephron primarily at the proximal tubular cells impairing passive reabsorption of magnesium in Fanconi's Syndrome. Underscoring this electrolyte disorder of this syndrome may better allow future clinicians to recognize hypomagnesemia in the setting of a non-anion gap metabolic acidosis and perhaps be considered as a diagnostic entity.

PUB509

Achieving Osmotic Stability in the Context of Critical Illness and AKI During Continuous Renal Replacement Therapy

Diana Fang,[1] Jorge O. Chabrier-Rosello,[2] Blaithin A. McMahon,[2] Tibor Fulop,[2,3] Anand Achanti.[2] *[1]College of Medicine, Medical University of South Carolina, Charleston, SC; [2]Department of Medicine - Division of Nephrology, Medical University of South Carolina, Charleston, SC; [3]Medicine Service, Ralph H. Johnson VA Medical Center, Charleston, SC.*

Introduction: The concept of osmotic stability during renal replacement therapy has received limited attention thus far. Customary pre-mixed continuous renal replacement therapy (CRRT) solution is manufactured with a sodium concentration of 140 mEq/L, potentially representing hypotonic solution when considering the protein-free serum sodium concentration of 154 mEq/L. We present an illustrative case of hypertonic saline (HTS) utilization after cardiac arrest and acute kidney injury to achieve osmotic stability during critical illness while performing CRRT.

Case Description: A 22-year-old male with no known past medical history presented after prolonged ventricular fibrillation with 75 minutes of resuscitative efforts before regaining spontaneous perfusing rhythm. On arrival, he was hypotensive and required multiple vasoactive agents. Central nervous system protecting hypothermia protocol and veno-arterious (VA) extracorporeal membrane oxygenator (ECMO) therapy were initiated at hospital admission due to refractory hypoxemia. Head CT scan did not show acute intracranial processes, but cardiovascular imaging procedures described global hypokinesis with thrombus formation in the left ventricle and aorta. Due to the combination of anuria, mixed metabolic respiratory acidosis and hemodynamic instability, we started CRRT in continuous veno-venous hemodiafiltration functionality with added HTS protocol, calculated to stabilize his serum sodium between 148-150 mEq/L. Serum osmolality was 304 mOsm/kg on initiation of CRRT and ranged between 321-317 mOsm/kg thereafter. Course was complicated by an acute right leg ischemia distal to VA ECMO cannula placement, which required salvage therapy with cryo-amputation. Vasoactive medication requirement and hemodynamics improved after the addition of IV hydrocortisone. Brain MRI 22 days post-arrest showed signals of limited hypoxic injury. He left the hospital in stable condition after 31 days with creatinine 1.9 mg/dL and limited neurological sequelae.

Discussion: Use of HTS during CRRT is a viable way to increase serum osmolality to address potential or manifest cerebral edema and reduce the degree of cerebral injury. Additional studies are warranted to explore the significance of osmolar shifts during CRRT in the critically ill with regards to neurologic outcomes.

PUB510

Hypokalemic Periodic Paralysis in Sjogren Syndrome

Mohammad faizan Riaz. *Nephrology, Allama Iqbal Medical College/Jinnah Hospital, Lahore, Pakistan.*

Introduction: Renal involvement in Primary Sjogren's syndrome is a rare event usually occurs in less then 10% of the patient and usually has a favorable prognosis. Renal involvement may include isolated electrolyte disorders, nephrolithiasis, nephrocalcinosis, Tubulointerstitial nephritis (TIN), and Glomerulonephritis. We report a case of periodic paralysis due to severe hypokalemia secondary to Distal Renal tubular acidosis (dRTA), with primary disease as Sjogren's syndrome.

Case Description: A 50 year old hypertensive male, presented with complains of generalized body weakness for the past 4 weeks, with complains of intermittent left flank pain. There was no history of any Urinary abnormalities, Gastrointestinal, Respiratory, or any history of autoimmune features. The only medicine, which the patient was taking, was amlodipine for his HTN. On examination the only significant findings were decreased power 3/5 bilaterally in lower extremities, with normal reflexes and normal sensory system. Basic metabolic panel revealed Normal **complete blood count (**CBC), with normal renal function tests and liver function tests. Serum electrolytes revealed potassium of 1.9 mEq/dl, Sodium 136 mEq/dl, Chloride 116 mEq/dl, Bicarb levels 10 mEq/l, Calcium 9.7 mg/dl, Magnesium 2.1 mg/dl, normal serum anion gap, urinalysis revealed pH of 8, with no proteinuria or active urinary sediment. Extractable Nuclear Antigen Antibodies (ENA) profile revealed Antinuclear antibodies titer of 1:320, **ANTI SS-B (La)** and **ANTI Ro-52** antibodies were strongly positive. Complement levels were normal. **24 Hrs Urinary potassium** levels were 32.34 mmol/24 Hrs and the urinary anion gap of 40 mEq/l. Ultrasonogram reveals 2 calculi in the lower pole, with mild hydronephrosis. Laboratory investigations were consistent with diagnosis of Primary Sjogren's syndrome with dRTA. We repleted the patient with intravenous potassium chloride and bicarbonate, with subsequent shift to oral potassium citrate, which remarkably improved the patients symptoms. The patient was referred to Rheumatologist for further management.

Discussion: Primary Sjogren's syndrome as with most rheumatologic diseases is more common in females, male presenting with renal involvement is scarcely reported to the best of our knowledge. Further diagnosing primary Sjogren's without any clinical symptoms (i.e xerostomia, or xeropthalmia) is a rare entity.

PUB511

Normal Saline Mitigates Refractory Alkalosis in Continuous Renal Replacement Therapy

Arun Rajasekaran, Ashita J. Tolwani. *University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Respiratory alkalosis is typically a sign of an underlying pulmonary or central nervous system disease. Emergent treatment is warranted when pH levels are above 7.5. Treatment is usually correction of the underlying cause. We describe a patient with refractory respiratory alkalosis on continuous renal replacement therapy (CRRT) which was offset by the use of normal saline (NS) in the pre and post-CRRT filter replacement fluids.

Case Description: A 68 year old lady on peritoneal dialysis (PD) presented with septic shock secondary to peritonitis. Hospitalization course was complicated by hypoxic respiratory failure necessitating mechanical ventilation, subsegmental pulmonary thromboembolism (PTE), and subacute ischemic white matter infarcts with no evidence of increased intracranial pressure or cerebral hemorrhage. She was on broad spectrum antimicrobials, stress dose steroids and vasopressors. PD catheter was removed; and she was started on Continuous Venovenous Hemodiafiltration modality of CRRT. The prefilter, dialysate, and postfilter replacement fluids were at 700 cc/hr, 700 cc/hr and 200 cc/hr respectively. Each of these solutions contained 35 mEq/L of bicarbonate given septic shock, severe lactic acidosis and fulminant hepatic failure. No fluid was actively removed through CRRT. Effluent dose was 26 ml/kg/hr. ABG was consistent with an acute uncompensated primary respiratory alkalosis (pH 7.7 and serum bicarbonate level of 23 mEq/L) which did not improve despite optimal sedation, pain control and varied ventilator setting adjustments. The etiology was thought to be due to central neurogenic hyperventilation secondary to cerebral infarction and peripheral pulmonic receptor stimulation caused by PTE. The pre and postfilter solutions were replaced by normal saline at 500 cc/hr each; with the dialysate and fluid removal rate remaining unchanged at 700 cc/hr and 0 cc/hr respectively. The total bicarbonate amount for this combination was 14 mEq/L. Effluent dose was 27 ml/kg/hr. Within 12 hours, serum bicarbonate levels decreased to 14 mEq/L and pH improved to 7.48. Despite this, she had worsening hypoxia and hypotension, and subsequently died.

Discussion: NS is acidic with a pH of 5.5-6, and its use in CRRT can help mitigate refractory alkalosis. Furthermore, dialysis against NS results in loss of bicarb down a concentration gradient since NS does not contain any alkali.

PUB512

Use of Gastric Anion Gap (GAG) in Acute Metabolic Alkalosis

Kalpana K. Vuppali, Eric J. Bloom, Saurabh Gupta, Ji Young Shin, Imara Dissanayake. *Nephrology, Einstein Medical Center Philadelphia, Philadelphia, PA.*

Introduction: Metabolic Alkalosis(MA) is a common electrolyte disorder seen in hospitalized patients. It is due to loss of acid or gain of alkali. MA is routinely seen in hospitalized patients with vomiting, use of diuretics, and Naso-Gastric(NG) suction.

Adverse effects of MA include hypokalemia, arrhythmias, and neuromuscular irritability which increases morbidity and mortality. We are presenting a case of MA in a patient with Ileus, who was successfully treated with Proton Pump Inhibitor(PPI) and Chloride Based-Intra Venous Fluids(CB-IVF).

Case Description: 67 y/o male with history of DM, HTN, CKD3 presented with AKI from obstructive uropathy from Hemangioma causing hydronephrosis and he underwent surgical resection with improvement of AKI. Post operatively patient developed Ileus and had significant drainage from NG suction. During this time, he had recurrence of AKI with severe MA with Venous Ph of 7.63. Serum electrolytes revealed Potassium(K) of 3.1meq/dl and CO2 50meq/dl with Creatinine of 7mg/dl. He was treated with CB-IVF and IV Protonix 40mg BID. Labs 24hrs after PPI showed improvement of CO2 to 44meq/dl and hypokalemia resolved with same Cr. We obtained the Gastric electrolytes to measure the Gastric Anion Gap(GAG) before and after PPI to monitor the response of MA as shown in Table.

Discussion: Patients with Ileus are at risk of losing large amount of UGI fluid and electrolytes by vomiting or NG suction and can generate severe MA. This case shows the importance of a simple measures such as PPI use with CB-IVF to improve Alkalemia. If patients cannot tolerate IVF (Eg: ESRD patients) then PPI alone may be used with good results. We showed the electrolyte pattern to illustrate physiological changes at cell level pre-and post-use of PPI. Gastric electrolyte secretion under normal stomach function has high Chloride(Cl) content which gives negative GAG. PPIs decreases Cl content in stomach by inhibiting parietal cell H+-K+-ATPase. Decreased Cl content in UGI fluid is a surrogate marker of decreased Proton secretion. Conclusion: PPI should be considered in the treatment of Metabolic Aklalosis caused by UGI loss.

Gastric Fluid Electrolytes Pre and 24hr Post PPI

	Pre	Post
Sodium meq/dl	39	39
Potassium meq/dl	8	9
Chloride meq/dl	111	43
Gastric Anion Gap (GAG)	-64	+5

PUB513

A Case of Severe Metabolic Alkalosis and Renal Insufficiency

Afshin Ahoubim, Alfred C. Cottrell. *Nephrology, LLUMC, Loma Linda, CA.*

Introduction: Vomiting, nasogastric aspiration and diuretics being the most common cause, metabolic alkalosis is defined elevation in serum bicarbonate, > 30 mmol/l, and arterial pH ≥7.45. The pathophysiology of metabolic alkalosis can be complicated, H^+ loss plus reduced filtered bicarb (i.e. renal hypoperfusion, CKD), bicarb reabsorption (i.e. hyperaldosteronisms, hypokalemia), H^+ secretion by α-intercalated cells (i.e. primary hyperaldosteronisms, chloride depletion), and/or Impaired bicarb secretion by pendrin (i.e. Cl depletion, CKD). Pco2 may increase as a compensatory mechanism. Patients can be asymptomatic or symptomatic due to underlying etiology and electrolyte disbalance; easy fatigability, dizziness, muscle weakness, tetany, cardiac arrhythmias, disorientation, seizures, and coma in patients with chronic liver disease.

Case Description: A 23-year-old African American male presented to ED with history of 3 months emesis which worsened 3 weeks with abdominal pain prior to presentation. He reports recent heavy alcohol consumption and smoking marijuana. His last recorded creatinine was 1.6, 2 months prior to presentation. On physical examination, the blood pressure was 116/59 mm Hg, pulse of 105, respiration of 20 and BMI 17.7. The patient was alert and oriented with respirations regular and unlabored. Labs were significant for blood glucose of 152, Na^+ 120, K^+ 2.5, Cl^- <60, Mg 1.4 mmol/L, bicarbonate 46, BUN 113, Cr 5.7, ABG 7.68/56/84/43. Urinalysis showed large leukocytes, small blood, RBC 5, and urine chemistry Na 18, K 61.1, Cl <10, Cr 115.1. He received 2 L normal saline and continued normal saline with potassium 40 mEq at 150 ml/hr and Pantoprazole 40 mg IV. Oral potassium initiated after he was able to tolerate oral intake.

Discussion: Severe metabolic alkalosis is a medical emergency due to electrolytes imbalance, specially, hypokalemia. History is the key to narrow down and diagnosis of underlying cause. In his case, the patient had multiple electrolyte disbalance, sever hyponatremia, hypokalemia along with renal insufficiency in setting of hyperemesis. We approached conservative management since our patient did not have chronic illnesses along with assessment at each step. His electrolytes improved by second day of hospitalization. BUN and Cr plateau and decline after 36 hours of hospitalization. Nevertheless, renal replacement therapy would have been the ultimate option if no renal recovery.

PUB514

The Double-Edged Sword of Desmopressin Acetate (DDVAP): Severe Hyponatremia Post-Renal Transplant Biopsy

Jinwoo Jung, Hanan A. Khairalla, Angelina Edwards, Akshta Pai, Aleksandra De Golovine. *University of Texas at Houston Health Science Center, Houston, TX.*

Introduction: DDAVP, a synthetic analogue of vasopressin, binds V2 receptors on kidney tubular and vascular endothelial cells, producing an antidiuretic effect and release of von Willebrand factor and factor VIII. Its use as a hemostatic agent prior to kidney biopsy reduces bleeding risk. However, it has been shown to increase risk of severe hyponatremia. We describe a case of DDAVP used prior to renal transplant biopsy leading to severe hyponatremia with neurologic manifestations.

Case Description: A 63 year old woman with end stage renal disease secondary to hypertension, underwent a blood group compatible, 1A2B0DR HLA mismatch deceased donor renal transplant, with thymoglobulin induction and maintenance with mycophenolate, tacrolimus, and prednisone. Post-op course was uneventful and nadir creatinine (Cr) was 0.8mg/dL. On post-op week 5, surveillance donor-derived cell-free DNA was elevated and de-novo donor specific antibodies were detected. Cr remained stable at 0.8mg/dL. Biopsy was performed given concern for rejection. Serum sodium (Na) was noted to be 140mmol/L and standard pre-biopsy intravenous 0.3mcg/kg DDAVP was given. Post-biopsy observation was uneventful and she was discharged home. That evening, she noted decreased urinary output and increased her free water intake. Transplant team was notified the next day, and she returned to the hospital, where Na was 123mmol/L. She had no neurologic manifestations. She was placed on fluid restriction. Six hours later, she developed nausea with vomiting and became acutely altered, with decreased responsiveness. She had worsened hyponatremia of 118mmol/L. She received 250mL of 3% normal saline resulting in correction of Na to 125mmol/L and complete resolution of encephalopathy.

Discussion: The use of DDAVP prior to renal transplant biopsies decreases bleeding risk in patients with and without renal impairment or coagulopathy. However, severe hyponatremia is increasingly being recognized as a potential complication and strategies to reduce risk are necessary. In our case, severe hyponatremia may have been avoided by clear patient understanding of potential decreased urinary output, avoiding excess free water intake, and transplant team notification. This case demonstrates the importance of careful selection, monitoring, and counseling of patients who receive pre-biopsy DDAVP.

PUB515

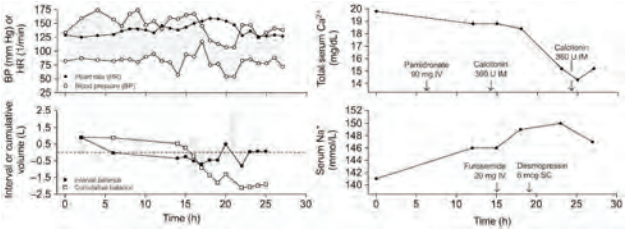
Antidiuretic Hormone: You Don't Know What You've Got 'Til It's Gone

Katie Bean, Graham T. Gipson, Jason M. Kidd. *Virginia Commonwealth University Health Systems, Richmond, VA.*

Introduction: Profound salt and water wasting may develop during severe hypercalcemia in patients with premorbid primary ADH deficiency (central diabetes insipidus).

Case Description: A 68-year-old man with panhypopituitarism presented with 3 days of lethargy, confusion, polyuria, polydipsia, and subacute hip pain. Admission vital signs showed tachycardia (HR 130/min) and hypertension (BP 159/87 mm Hg). Exam disclosed a thin older man who was restless and confused; lungs were clear and there was no edema. Key blood lab results were Na 141 mmol/L, K 2.9 mmol/L, and Cr 3.53 mg/dL without antecedent kidney disease. Blood total Ca was 19.8 mg/dL (RR: 8.9-10.7) and PTH was 16.6 pg/mL (RR: 8.7-77.1). A head CT showed multiple cranial osteolytic lesions. For hypercalcemia, he received two 1-L normal saline boluses over 7 h and then 90 mg IV pamidronate. After 12 h he had urinated >2.3 L. Tachycardia and hypertension worsened: HR 150/min and BP 167/90 mm Hg. Total blood Ca stayed high at 18.8 mg/dL. He was given 360 U IM calcitonin and 20 mg IV furosemide. Over the next 3 h his intake was 1.9 L of normal saline and urine output was 4.3 L, after which his HR rose to 160/min and BP fell to 107/54 mm Hg. It was discovered that his desmopressin (used at home for central diabetes insipidus) was not administered in >24 h. He was immediately given 6 mcg SC desmopressin. Urine output rapidly decreased and hemodynamics improved. Given premorbid diabetes insipidus, severity of hypercalcemia, and tenuous hemodynamics, we elected to initiate kidney replacement therapy.

Discussion: This case highlights the critical role of ADH in maintenance of normal body water volume. This patient was reliant on exogenous ADH to maintain normonatremia and appropriate volume status. His ADH was unavailable to him, and unopposed aquaresis ensued. Furthermore, he had partial nephrogenic diabetes insipidus and salt wasting, both from hypercalcemia; thus, he displayed profound diuresis. Generally, urine output drops with volume depletion due in part to ADH release. This case demonstrates what happens when ADH is absent and the consequences of unchecked urination.



PUB516

First Reported Case of H-NAGMA in a Patient Undergoing Continuous Bladder Irrigation

Andrew Valiquette,[1] Muhammad F. Anwar,[2] Joseph Thirumalareddy.[2] *[1]Creighton University School of Medicine, Omaha, NE; [2]Creighton University Medical Center, Omaha, NE.*

Introduction: Continuous bladder irrigation is a well-accepted treatment for clot evacuation in patients suffering from hemorrhagic cystitis. In this case we describe the development of a non-anion gap hyperchloremic metabolic acidosis in a patient receiving CBI for radiation-induced hemorrhagic cystitis. Secondary to fluid retention in the bladder following irrigation, the damaged urothelium permitted absorption of saline, producing a non-anion gap metabolic acidosis in addition to other symptoms of volume overload. Following treatment with IV sodium bicarbonate, this patient improved clinically, and the metabolic acidosis resolved.

Case Description: A 77 year-old female presented to the emergency department with a chief complaint of hematuria for 1 day. The patient had a past medical history of uterine cancer treated with radation, complicated by recurrent hemorrhagic cystitis. During the

course of stay, the patient required CBI for removal of clots within the bladder and to prevent urinary retention. Lack of drainage from the catheter was noted multiple times and between 8-10 L of fluid were drained providing symptom relief. On day 8, HCO3 was 11 mmol/L and Cl was 122 mmol/L. Acidosis began to improve by hospital day 9 after patient was started on 650 mg of sodium bicarbonate, with the patient's bicarbonate levels returning to 22 mmol/L after several days on bicarbonate.

Discussion: CBI with 0.9 percent normal saline (NS) is the standard of care for clot evacuation. Elliot *et al.*, studied exfoliation rates of urothelial cells in patients with chronic urinary tract infections and in patients with long-term indwelling catheters. They observed bladder irrigation was associated with an increased disruption of urothelial cells which in turn predisposes the bladder to recurrent infections. In 2014 Paolo *et al.*, reported acute severe pulmonary edema in an 85-yr-old male who underwent CBI. In this case, bladder irrigation led to systemic absorption of fluid from bladder urothelium that manifested as NAGMA. As the serum chloride level started to increase, it decreased serum HCO_3 causing H-NAGMA. Once we held bladder irrigation, the chloride levels decreased followed by improvement of HCO_3 and resolution of acidosis. The patient was not on IV fluids suggesting that systemic absorption occurred from bladder urothelium leading to pulmonary edema and acidosis.

PUB517

Metformin-Associated Lactic Acidosis: Treatment With Different Types of Renal Replacement Therapy

Raul Mellado,[2] Patricia C. Ruiz Palacios.[1] [1]*Soporte Renal Integral, Mexico, Mexico;* [2]*Hospital Ángeles del Pedregal, Mexico, Mexico.*

Introduction: A potential complication of metformin is the development of type B (non-hypoxic) lactic acidosis. We present the case report of two patients who were receiving treatment with metformin and developed severe metformin-associated lactic acidosis. Both whom recievied different types of renal replacement therapy for the management of lactic acidosis and renal failure.

Case Description: CASE 1. A 70-year old woman with type 2 diabetes treated with metformin, presented with neurological impairment, hemodynamically unstable and hyperlactatemic metabolic acidosis with serum lactate of 17 mmol/L, creatinine 5.04 mg/dL. We rule out different causes of severe lactic acidosis. Metformin serum levels were obtained with a total of 41mcg/mL. The patient received treatment with 23 hours of continuous hemodialysis. At the end the patient, recover her renal function to normal standards. CASE 2. A 63-year old man treated with metformin, presented with a history of abdominal pain accompanied by nausea and vomit. At his arrival to the ER we found him hemodynamically unstable and bradycardic, which, developed to asystolia soon after. He required advance cardiopulmonary life support and he was found with a hyperlactatemic metabolic acidosis with a serum lactate of 15mmol/L and creatinine 14.54 mg/dL; we ran serum metformin levels with a result of 14 mcg/ml. We started renal replacement therapy with conventional hemodialysis for 8 hours. It was interesting to watch a rebound and raise of metabolic acidosis 6 hours after we finish the first hemodialysis session. We then decided to reinitiate another 8-hour of hemodialysis; the patient did not require any other maneuver for acidosis with progressive improvement to his evolution. After he was discharged from the hospital he required once-weekly hemodialysis session only for one month.

Discussion: In our experience, both cases presented in the context of an acute kidney injury; another thing to highlight is that we found a rebound of lactic acidosis after the first hemodialysis session in a period of 6-hour. The different types of dialysis in both cases were effective, albeit intermittent dialysis allows a faster clearance of serum metformin levels with less time and cost, it should always be considered as first choice in all patients who have immediate access to it.

PUB518

Excessive Water Intake Causing Severe Metabolic Alkalosis

Julien Sanon,[1] Eric J. Bloom,[2] Daranee Chewaproug,[3] Imara Dissanayake.[2] [1]*Einstein Healthcare Network, Cheltenham, PA;* [2]*Albert Einstein Medical Center, Berwyn, PA;* [3]*Einstein Medical Center Philadelphia, Bryn Mawr, PA.*

Introduction: Severe metabolic alkalosis is one of the most dreaded acid-base disorders. It is defined as a pH of more than 7.60 with serum bicarbonate of more than 40 mmol/L. Clinical features include confusion, seizures, and cardiac arrhythmias. Mortality rate increases significantly with the severity of the alkalosis and can reach up to 80% with a pH of more than 7.60. We present a case of severe metabolic alkalosis with a pH up to 7.70 in a patient with a jejunostomy and a gastrostomy tube.

Case Description: The patient is an 82-year-old female with diabetes mellitus, cardiac arrhythmia and perforated gastric ulcer. She was admitted with syncope and found with severe metabolic alkalosis. Two months prior to her presentation, she had an open jejunostomy for tube feeds with a gastric tube for drainage. Formal instructions were to only take occasional sips of water. The day prior to admission, she had increased thirst and started to drink a large amount of water. She then noticed large drainage into her gastrostomy bag. Admission arterial gas showed a pH of 7.70, pCO2 of 70 mmHg. Blood work had sodium of 137 mEq/L, potassium of 2.5 mEq/L, chloride of 60 mEq/L, bicarbonate more than 50 mEq/Liter and glucose of 466 mg/dL. Urinalysis showed a pH of more than 9. EKG had atrial paced rhythm. CT of the abdomen had jejunostomy and gastric tube well positioned. The patient was treated aggressively with normal saline, potassium, Acetazolamide and Protonix. She improved significantly after 2 days with potassium of 3.1 mEq, chloride of 90 mEq/L, serum bicarbonate of 43.6 mEq/L.

Discussion: Our patient, had severe metabolic alklaosis secondary to massive gastrointestinal drainage in her gastric tube. In addition she was volume depleted contributing to her metabolic alkalosis. The excessive volume of water ingested prior to her presentation likely triggered the increased gastric secretion. We believe the gastric distension due to the ingsted water, resulted in excessive grastric secretions by stimulating the stretch receptor. The treatment includes aggressive hydration, potassium repletion, Proton Pump Inhibitor, Acetazolamide and hydrochloric acid infusion in refractory cases. Hemodialysis has also been used. Our case demonstrates that good outcome can be achieved with prompt, aggressive and appropriate treatment of severe metabolic alkalosis.

PUB519

Hyponatremia in a Patient Receiving Chemotherapy

Nikhila Thammineni,[1] Pradeep Kathi,[2] Mohamed E. Gismalla,[2] Yahya M. Osman Malik,[3] Zeenat Y. Bhat.[2] [1]*Detroit Medical Center/ Wayne State University, Detroit, MI;* [2]*Wayne State University, Detroit, MI;* [3]*Wayne State University Medical School, Detroit, MI.*

Introduction: Hyponatremia is common in cancer patients

Case Description: A 76 YO woman with a history of hypothyroidism, gout, HTN, CKD stage III, stage IVB recurrent metastatic endometrioid serous carcinoma treated with TAH-BSO and adjuvant chemoradiation was started on phase I chemotherapy protocol with Atezolizumab and Cabozantinib. During the 2nd cycle visit she was found to have a serum sodium of 122[baseline at 1st visit 138]. Review of systems has revealed loose stools few times/day 2 weeks associated with decreased food intake and increased fluid intake. Her medications include levothyroxine, allopurinol, hydrochlorothiazide, furosemide. Physical examination was unremarkable and appeared euvolemic. Her labs showed sodium (Na) 118, Sr osmolality 260, K 3.4, glucose 109, TSH 6.23, FT4 1.65, urine Na 45, urine osmolality 185. She was put on fluid restriction and careful NS infusion with temporary discontinuation of diuretics. She was discharged with a Na of 130 on day 3 with instructions to follow up in a couple of days. Etiology of hyponatremia in this patient is most likely multifactorial due to increased water intake with low solute intake and impaired diluting capacity of the kidneys with continued use of diuretics. In addition, coupled with Atezolizumab and cabozantinib therapy as superimposed factors cannot be ruled out as they have also been shown to cause hyponatremia. Although untreated or partially treated hypothyroidism is well known to impair urine diluting capacity, our patient was euthyroid which makes hypothyroidism less likely

Discussion: Hyponatremia is commonly diagnosed in cancer patients, but only in 1/3 of the cases is related to SIADH. Hyponatremia was seen in ≥ 2% of NSCLC patients treated with Atezolizumab in phase 1, 2 and 3 studies in the available literature. On the other hand, Cabozantinib used in the treatment of advanced renal cell carcinoma has also been shown to cause hyponatremia and it was reported in up to 20% of patients. With the growing armamentarium of oncologic treatments and their effects on electrolytes, a physician involved in managing the care of cancer patients needs to aware of these effects. SIADH is a known cause of hyponatremia but efforts be made to look for a reversible etiology before attributing it to SIADH which can help in a timely and appropriate management and reducing the cost of elaborate investigations

PUB520

Extreme Hypernatremia of Uncertain Cause Progressed in 1 Month

Masahiro Tomonari, Risa Terashima, Taketo Uchiyama, Kentaro Koike, Yukio Maruyama, Ichiro Ohkido, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Introduction: Hypernatremia, which is a common cause of impaired consciousness among elderly people, develops due to many factors. However, it is rare for the serum sodium concentration to increase to over 200 mEql/L. We herein report a case of extreme hypernatremia (sodium levels >190 mEq/L) of uncertain cause that progressed over a month.

Case Description: An 82-year-old woman was admitted to our hospital with impaired consciousness and a 3-day history of progressive weakness. One month prior to admission, she had shown pyelonephritis that was treated with antibiotics, and her serum sodium level had been 144 mEq/L on the day of discharge. From two weeks after discharge, she gradually lost her appetite and subsequently developed impaired consciousness and weakness of the whole body. On an initial examination, her conscious state was 4 on the Glasgow Coma Scale, but there were no obvious signs on head-computed tomography. Blood laboratory test results showed a sodium level of 205 mEq/L, blood urea nitrogen level of 133 mg/dL, creatinine level of 2.54 mg/dL, blood glucose level of 319 mg/dL, and serum osmolarity of 470 mOsm/kgH_2O. The patient was admitted to the intensive-care unit for treatment of severe hypernatremia and acute kidney injury secondary to dehydration. The intravenous administration of 5% glucose as hypotonic fluid was immediately started, with the maximum rate of correction of sodium concentration set at 8mmol/L/day. Nine days after admission, her serum sodium level had decreased to 147 mEq/L, and her consciousness had improved to the point where she could say a few words. Feeding training and physical rehabilitation succeeded, and she was discharged on the 64th day with no specific problems.

Discussion: In the present case, the patient lost 7 kg of her body weight over a month and was dehydrated. As there were no episodes of her having ingested too much sodium, her clinical symptoms and data suggested that she had instead lost too much free water. The loss of free water was attributed to an impaired thirst as a consequence of aging and osmotic diuresis secondary to hyperglycemia. Then, secretion of antidiuretic hormone (ADH) (3.1 pg/ml) may have been insufficient for her high serum osmolarity. Consequently, we have concluded that these multiple factors combined to lead to extreme hypernatremia.

PUB521

Prophylactic Dose of Posaconazole Causing Syndrome of Apparent Mineralocorticoid Excess

Nwabundo Anusim,[1] Naushaba Mohiuddin,[2] Ishmael Jaiyesimi.[1] *[1]Beaumont hospital, Royal Oak, MI; [2]St. Clair Speciality Physicians, Bloomfield hills, MI.*

Introduction: Acute myeloid leukemia (AML) is typically treated with induction chemotherapy and prophylactic antifungal, antiviral and antibiotics. Posaconazole (PCZ) is an extended-spectrum antifungal agent used during induction chemotherapy for AML. We report a case of acquired syndrome of apparent mineralocorticoid excess (AME) from prophylactic dose of PCZ. AME syndrome is characterized by hypertension, metabolic alkalosis and hypokalemia.

Case Description: A 62 -year-old female with newly diagnosed AML was treated with idarubicin, cytarabine, prophylactic PCZ, levaquin and acyclovir. She was normotensive, normokalemic with normal serum bicarbonate [$HCO3^-$] on admission. She developed hypokalemia and metabolic alkalosis on day five of treatment, initially attributed to diarrhea. Over 100 meq of potassium (K) supplementation per day was given with no improvement in hypokalemia, despite resolution of her diarrhea. Serum K nadir was 2.3 meq/l, serum $HCO3^-$ levels peaked to 33 meq/L. She was hypertensive despite febrile neutropenia, poor oral intake and start of losartan. Further investigation revealed Urine K/Cr (potassium to creatinine) ratio of 5.8meq/mmol (abnormally high for serum K of 2.3 meq/l), serum aldosterone of <3 ng/dl and renin of <2.1 pg/dl. PCZ was discontinued. Serum K, serum $HCO3^-$, Urine K/Cr ratio were followed at 1, 2 and 3 weeks. K supplementation was gradually decreased, and was completely discontinued at 3 weeks. Serum $HCO3^-$ and systolic blood pressure normalized to 24 meq/L and 110mmhg respectively.

Discussion: Resolution of AME, with discontinuation of PCZ is suggestive that the AME is attributable to PCZ. The mechanism of action is thought to be due to inhibition of the 11β-hydroxylase enzyme resulting in AME activity. There are a few case reports with similar presentation on therapeutic dose of PCZ. Prompt recognition of this adverse effect, even on prophylactic dose of PCZ, by oncologist and consulting nephrologist is necessary to avoid complications of severe refractory hypokalemia. Testing of urine K/Cr ratio, aldosterone and renin levels should be undertaken to screen for AME. Discontinuation of PCZ and starting an alternative antifungal becomes imperative, if AME screening is positive.

PUB522

Posaconazole-Induced Apparent Mineralocorticoid Excess

Amar Pandit, Alexander Morales, Nathan H. Raines, Pitchaphon Nissaisorakarn, Johannes S. Schlondorff. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Apparent mineralocorticoid excess should be considered when presented with hypokalemia, metabolic alkalosis and hypertension when on azole antifungals

Case Description: A 68-year-old lady with hypertension (on Losartan) and acute myeloid leukemia was admitted for management of relapsed AML. AML was treated with ARA-C, Daunorubicin, Etoposide and Lenalidomide. She had been on Tenofovir for hepatitis B reactivation. Current admission was complicated by prolonged diarrhea, MDR E. Coli bacteremia and neutropenia. She was treated with Ceftazidime, Vancomycin, Acyclovir and Posaconazole. Persistent hypokalemia/metabolic alkalosis were noted. Physical examination revealed a blood pressure of 159/69 mm Hg, heart rate 67/minute, mild pallor and trace lower extremity edema. Laboratories showed sodium 143 mEq/L, Chloride 93 mEq/L, potassium 2.8 mEq/L, bicarbonate 37mEq/L, BUN 8 mg/dL, Creatinine 0.7 mg/dL, Calcium 8.4 mg/dL, phosphate 3.2 mg/dL, pH 7.52, pCO2 46, pO2 223, urine chloride 101 mEq/L and potassium 50 mEq/L. Tenofovir can induce hypokalemia by causing proximal tubular damage, but this is associated with acidosis. Hypokalemia, metabolic alkalosis and worsening hypertension pointed towards a mineralocorticoid excess state. Serum cortisol levels were normal, CT of the chest/abdomen did not show pulmonary or adrenal masses. Renin and aldosterone levels were significantly suppressed at 0.05 ng/mL/h and 2ng/dL respectively, contrary to expectations with the use of Losartan. An apparent mineralocorticoid excess (AME) state was suspected and confirmed by a 24-hour urine cortisol/cortisone ratio of 0.89 (normal 0.3-0.5). She denied licorice intake. Review of literature indicated that azole anti-fungals like Posaconazole can cause AME. Spironolactone was initiated with resolution of all electrolyte abnormalities and hypertension.

Discussion: Cortisol is converted to cortisone in the distal tubule by 11 β-Hydroxysteroid dehydrogenase type 2 (11 β-HSD2). This enzyme prevents cortisol (usually > 1000-fold higher concentration than aldosterone) from activating the mineralocorticoid receptor, as cortisone does not activate this receptor. Posaconazole (and itraconazole) inhibits this enzyme causing a state of apparent mineralocorticoid excess and precipitating hypokalemia and alkalosis. Treatment includes either stopping posaconazole or starting Spironolactone.

PUB523

Severe Hypokalemia Caused by Untreated Distal Renal Tubular Acidosis: Dynamic Renal Potassium Handling in Action

Steve A. Balgobin,[1,3] Simon A. Carter,[1,2] Ingrid Tein,[1,3] Mathieu Lemaire.[1,3] *[1]Hospital for Sick Children, Toronto, ON, Canada; [2]Royal Children's Hospital Melbourne, Melbourne, VIC, Australia; [3]Pediatrics, University of Toronto, Toronto, ON, Canada.*

Introduction: In addition to severe acidosis, patients with untreated distal renal tubular acidosis (RTA) may develop symptomatic severe hypokalemia indicative of dramatic depletion of total body potassium stores. Although rare, it may be life-threatening because of cardiorespiratory compromise.

Case Description: We present the case of an 11-year-old girl with distal RTA caused by novel homozygous mutations in the gene encoding for the ATPase H^+ Transporting V1 Subunit B1 (ATP6V1B1; c.484_486del; p.Glu182del). Over several weeks, she stopped taking her medications (potassium citrate, potassium chloride and sodium bicarbonate). During this time, gradual progressive muscle weakness was documented. On admission, several serum laboratory investigations were abnormal: total CO_2 was 14 (normal range, 22-30), potassium (K^+) was 1.5 mmol/L (normal range, 3.7-5.0) and creatine kinase was 2223 U/L (normal range, 50-295). Physical examination revealed profound weakness, absent deep tendon reflexes, and paralytic ileus. Electrocardiogram changes characteristic of hypokalemia were also observed. A normal MRI of the brain and spine ruled out Guillain-Barre syndrome. Correction of acidosis and hypokalemia resulted in a complete reversal of all symptoms and laboratory investigations over three days. Supplementation of more than half of her calculated total body K^+ (~55 mEq/kg) had to be provided over two days to normalize serum K^+ concentration.

Discussion: A literature review from 1960 onwards revealed nine reports describing pediatric patients with RTA presenting with severe hypokalemia accompanied by varying degrees of muscle weakness. We provide a detailed overview of the clinical presentation, differential diagnosis and management for such patients. We also discuss the pathophysiology of urinary potassium wasting in the context of distal RTA, with a particular emphasis on the impact of stopping potassium and alkali supplementation on the development of severe hypokalemia. This case highlights that it can be very challenging to distinguish generalized muscle weakness caused by peripheral neuromuscular etiologies with that observed in patients with severe hypokalemia. It also emphasizes the fact that normalization of serum K^+ in a chronically undertreated patient with distal RTA requires replenishment of the severely depleted intracellular K^+ stores.

PUB524

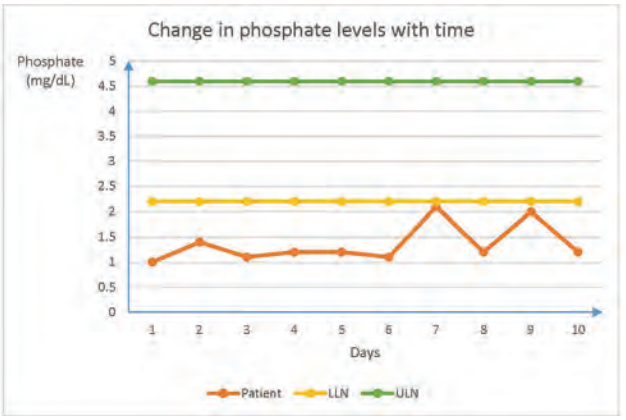
FGF-23-Mediated Severe Hypophosphatemia: A Rare Manifestation of Malignancy

Rasha Alawieh, Isabelle Ayoub, Eshetu L. Obole. *Department of Internal Medicine, Division of Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Hypophosphatemia is not an uncommon electrolyte disorder. It can be secondary to renal or non-renal etiologies. Identifying the underlying cause is essential for proper management.

Case Description: We present a case of a 61 year-old man with hypertension and diabetes who was admitted to our hospital for abdominal pain, and was eventually diagnosed with diffusely metastatic esophageal squamous cell cancer. His phosphate level was in the 1-2 mg/dL (2.2-4.6), reaching <1 mg/dL on multiple occasions. His hypophosphatemia was difficult to correct, despite IV and oral supplementation. Extensive workup showed elevated urinary fractional excretion of phosphate (55%) which reflects renal wasting. The serum calcium was high (11.8 mg/dL) and the PTH was low (12 pg/mL). Inactive Vitamin D (47 ng/mL) and active Vitamin D (25 pg/mL) were normal. The PTHrP was mildly elevated (2.9 pmol/L). There was no evidence of Fanconi's syndrome. Further evaluation revealed a significantly elevated FGF23 level of 2330 relative units (RU)/mL (Reference < 180) suggestive of an oncogenic osteomalacia-induced phosphate wasting. Unfortunately, the patient had advanced stage malignancy and passed away in less than a month after presentation.

Discussion: This case illustrates the importance of a thorough diagnostic workup of hypophosphatemia. Oncogenic osteomalacia is a rare paraneoplastic syndrome with musculoskeletal manifestations, usually seen in benign mesenchymal tumors. The mechanism of hypophosphatemia is secretion of FGF23 by tumor cells, which illustrates the important role of FGF23 in the bone-kidney axis. The management includes tumor localization and resection if possible, which is curative. The unusual aspects of this case are the presence of hypercalcemia, and the nature of the tumor being a metastatic squamous cell cancer.



PUB525

Diagnosis of Ethylene Glycol Toxicity from the Presence of a Lactate Gap

Babak S. Jazayeri-Moghadass, Joshua D. King, Bhuwan Kayastha, Parichi V. Buch, Simran Dhillon. *University of Maryland Medical Center, Baltimore, MD.*

Introduction: Ethylene glycol poisoning is life threatening and needs rapid recognition and treatment. The diagnosis of ethylene glycol intoxication is more challenging in situations like vague history or altered mental status. The presence of high anion gap metabolic acidosis with elevated lactate level without considering other facts such as osmolar gap, urine microscopy and toxicological studies could mislead practitioners and lead to severe complications.

Case Description: A 59 year-old woman presented to the emergency department with altered mental status, anion gap metabolic acidosis (21 mEq/L), and high lactate (17.0 mmol/L). Anion gap metabolic acidosis persisted despite initial treatment, however, the correction of lactate level was dramatically fast; lactate dropped from >17.0 mmol/L to 1.6 mmol/L in 4.5 hours, but anion gap remained the same at 21 mEq/L, at the same time, an elevation of serum creatinine from baseline 0.7 mg/dl to 2.25 mg/dl was noticed. Ethylene glycol toxicity was suspected from the clinical situation and an elevated osmolar gap (64 mmol/L); urine microscopy revealed extensive calcium oxalate crystals. Hemodialysis was performed urgently, resulting in resolution of acidosis; serum ethylene glycol levels returned as 23 mg/dL 2 days later.

Discussion: The initial diagnosis of ethylene glycol poisoning can be delayed and lead to life threatening complications. Glycolic acid, a metabolite of ethylene glycol, may be misread by certain laboratory analyzers as lactic acid. On patients with unclear history, elevated anion gap, and very high lactate acid, the possibility of ethylene glycol poisoning should always be considered. The presence of osmolar gap, urine crystals and rapid changes in serum lactate without a significant change in the anion gap may be helpful in making this diagnosis.

PUB526

An Interesting Case of Turmeric-Associated Hyperkalemia

Shamir Hasan, Deepa A. Malieckal. *Northwell Health, Port Washington, NY.*

Introduction: Advancements and understandings of modern medicine includes the acknowledgement of homeopathic and holistic approaches to health maintenance taken on by our patients. We also need to be aware of the possible side effects associated with their use. Turmeric is a spice that is commonly used for its rich flavor but has been increasingly popular for its possible health benefits.

Case Description: 67 yo M with history of HLD presenting for evaluation of long-standing hyperkalemia. Patient is active and uses a lot of supplements in order to preserve his health. The patient started the use of turmeric after 2005. He uses turmeric regularly and sprinkles it in all foods and in his teas daily. He exercises regularly and his only other medical problem is hyperlipidemia for which he was recently started on a statin. Vitals: BP 138/81, HR 67, SpO2 99%, Ht 5'10", Wt 149lbs, BMI 21.21 Physical Exam was unremarkable. Patient was asked to stop the use of turmeric (active compound: curcumin) after lab work on 12/27/2018 showed elevated serum potassium of 5.7. Repeat lab testing later (2/14/19), showed improvement of serum potassium to 5.2.

Lab Results

Date or range	Serum potassium or range	Serum creatinine or range
2/14/2019	5.2 (plasma K)	N/A
12/27/2018	5.7	0.86
8/27/2018	5.8	N/A
7/17/2018	5.6	0.90
3/13/2017	5	0.82
3/4/2016	5.6	0.79
Oct 2011-Nov 2015	5.4-5.7	0.81-0.91
Mar 2006-Jun 2010	4.6-5.4	0.86-0.9
Dec 2000-Aug 2005	4.2-6.5	0.8-1
3/25/1998	4.1	0.8
6/1/1992	4.9	1.1

Discussion: We report a case of turmeric associated hyperkalemia as a possible cause of hyperkalemia. We also discuss the likely mechanism of action: curcumin interferes with the binding of extracellular potassium to Na-K ATPase, causing an increase in serum potassium levels. This dysregulation can lead to low-level hyperkalemia, causing undue harm to specific patient populations. Awareness of this mechanism allows physicians to make accurate diagnoses. Additionally, knowledge of supplementations causing such changes in electrolyte balance will hopefully inspire further research into alternative medicines and their risks and benefits as they pertain to our patients and their health.

PUB527

Metastatic Adenocarcinoma Causing Spontaneous Tumor Lysis Syndrome

Aimen Liaqat,[1] Hameeda Khan,[1] Harsh Mehta,[1] Saad Amin.[2] [1]*Saint Barnabas Medical Center, West Orange, NJ;* [2]*RWJ Barnabas health, West Orange, NJ.*

Introduction: Tumor lysis syndrome (TLS) is an oncological emergency frequently associated with highly-proliferative hematological malignancies, usually after the initiation of chemotherapy. It is uncommon in solid tumors with some reports in uterine, lung, prostate, hepatocellular and pancreatic cancer. Spontaneous TLS (STLS) in a chemotherapy naïve patient is very rare. Exact incidence is difficult to ascertain because the data remains limited to case reports.

Case Description: A 53-year-old male was recently diagnosed with extensive metastatic disease involving multiple lymph nodes, hepatic, gastroesophageal junction, and an isolated rib mass. Lymph node biopsy was consistent with poorly differentiated adenocarcinoma and no apparent primary lesion was identified. Prior to initiation of chemotherapy, he was admitted for significant laboratory abnormalities including hyperkalemia (7.1mEq/L), acidosis (18mEq/L), hypercalcemia (9.8mg/dl), elevated creatinine (2.11mEq/L), hyperuricemia (13.9mg/dL), elevated LDH (4090 U/L) and liver enzymes. A diagnosis of STLS was made and treatment started with intravenous hydration and rasburicase. His labs showed improvement and he was eventually discharged on allopurinol.

Discussion: TLS is a constellation of metabolic abnormalities (hyperkalemia, hyperuricemia, hyperphosphatemia and hypocalcemia) described by the revised Cairo-Bishop Criteria. It results from rapid destruction of cancer cells during chemotherapy but rarely occurs spontaneously. Risk factors for STLS in our patient were high LDH levels and extensive metastatic involvement (particularly hepatic). Acute renal failure results from tubule precipitation of uric acid (urate nephropathy), calcium phosphate or hypoxanthine. In STLS, the released phosphorus is immediately utilized to regenerate new tumor cells and calcium binding of excess phosphorus is absent. Hyperphosphatemia and hypocalcemia were absent in our patient. Intravenous hydration and agents like allopurinol and rasburicase remain the mainstay of therapy, but renal replacement therapy may be required for severe cases. Factors like significant tumor burden, dehydration and renal failure, along with dramatic lab abnormalities can assist in early validation of the diagnosis even in the absence of a pathological confirmation or chemotherapy exposure. It is imperative to maintain a high level of suspicion because STLS can be fatal if left untreated.

PUB528

Severe Acidemia in Pregnancy with De Novo Acute Myeloid Leukemia

Keysha Lopez vega, Ileana E. Ocasio Melendez, Fatima B. Cintron-Rosa, Stephanie Colon Lopez, Carlos G. Rivera-Bermudez. *Nephrology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico.*

Introduction: Starvation ketoacidosis is an important cause of acidosis in pregnancy, specifically after the second trimester. A day of severe vomiting is enough to trigger this serious disorder and its presence should prompt physician to seek for exacerbating causes. We present a case of severe metabolic acidosis in a pregnant woman with underlying acute myeloid leukemia (AML).

Case Description: A 28-year-old woman at 35 weeks of gestation with a 5-day history of vomiting, pelvic and back pain, and dysuria was transferred to our institution with acidemia, pyelonephritis, suspected acute leukemia and preterm labor. Volume repletion with Lactated Ringer's solution and empiric antibiotherapy were given but acidosis worsened. Pregnancy was complicated at 28 weeks by nephrolithiasis with associated right-sided hydronephrosis requiring JJ placement. Physical exam revealed tachypnea, tachycardia and right costovertebral angle tenderness. Pertinent blood laboratory results were WBC 18 (109/l), blasts 74 (109/l), ANC 965 cells/l, Hgb 10.5 g/dl, platelets 124 (109/l), pH 7.21, pCO2 < 12.9 mmHg, HCO3 4.8 mmol/l, potassium 4.4 mmol/l, anion gap (AG) 28.5 mmol/l, delta ratio 0.8, creatinine 0.51 mg/dl, glucose 97 mg/dl, L-lactate 6.2 mg/dl and moderate ketones. Urinalysis showed pH 5, ketones 150, pyuria, hematuria, no glucose, and AG 67. Intravenous bicarbonate in dextrose was started and 24 hours after, patient had significant improvement of acidosis and was able to initiate oral intake, which lead to its resolution. Vaginal delivery was successfully achieved 4 days after our initial evaluation. Bone marrow was performed revealing AML.

Discussion: Pregnancy associated starvation ketoacidosis is mediated by relative insulin deficiency and enhanced lipolysis. Carbohydrate in dextrose solution more than bicarbonate administration lead to improvement of AG metabolic acidosis as the culprit of the disturbance was starvation. Our patient had life-threatening acidemia that can be

explained by poor oral intake concomitantly with immunosuppressed state and infectious process leading to preterm labor. RTA was considered but in the setting of high urine unmeasured anions due to ketoacidosis, urine AG was not reliable. Identification of acidemia etiology and rapid treatment was paramount to avoid further fetal and maternal complications including fetal demise.

PUB529

Management of Hyponatremia Overcorrection with 2.5% Dextrose in Water Solution in Diabetic Patient

Mariam Charkviani,[1] Natia Murvelashvili,[1] Mariam Aehtesham.[2] *[1]Internal Medicine, Amita Saint Francis Hospital, Evanston, IL; [2]Amita Sain Francis Hospital, Evanston, IL.*

Introduction: Overcorrection of hyponatremia is a medical emergency and associated with disastrous neuropathologic condition, osmotic demyelination syndrome. To minimize the risk of overcorrection, sodium correction rate should not exceed 6 to 8 mEq/L in any 24-hour period. We will present a case diabetic patient whose hyponatremia overcorrection was managed with 2.5% dextrose in water ($D_{2.5}W$) solution.

Case Description: 63-year-old male presents to our hospital for concern of possible bladder rupture. Patient had anuria and constipation for three days, associated with generalized abdominal pain and episodes of disorientation. At the emergency department, his initial labs at 8 pm showed severe hyponatremia with Na 116 mEq/L and acute kidney injury with creatinine 3.3. Foley was placed to relieve urinary tract obstruction and infusion of normal saline was started. CT abdomen was concerning for colonic impaction with possible bladder rupture and he was transferred to our hospital. Patient developed post-obstructive diuresis and by the time of arrival, repeated sodium was 130 mEq. Sodium overcorrection with 14 mEq occurred in less than 10-hour period. Normal saline was stopped, D5W with 250 ml/hr was started and desmopressin was administered. Next sodium level 3 hours later was even higher 133 mEq. As the patient had history of Diabetes Mellitus and was requiring excessive and rapid administration of fluids, use of $D_{2.5}W$ was decided. The goal was to decrease the sodium to <125 mEq in 24 hours period. Patient responded treatment and by 8 pm of the next day, sodium was 124 mEq. After that regular management of hyponatremia was started with appropriate correction rate and the patient was discharged home with sodium 134 mEq and no neurologic deficit.

Discussion: One of the strategies to avoid ODS after rapid overcorrection of hyponatremia is re-lowering of the sodium. Most commonly used re-lowering agents are D5W and Desmopressin. Our patient developed nephrogenic diabetes insipidus due to post-obstructive diuresis, didn't respond to desmopressin and was requiring high infusion rate of D5W. D5W is safe at low infusion rates but in rapid and excessive administration, especially in diabetic patients, serious adverse effects, hyperglycemia, hyperosmolar syndrome, and even intracerebral hemorrhage may occur. Usage of $D_{2.5}W$ of very rare and this case was exceptional.

PUB530

A Six-Pack of Paralysis in a Healthy 27-Year-Old

Ryan Mello,[1] James P. Gitter.[2] *[1]Abbott Northwester Hospital, Minneapolis, MN; [2]Kidney Specialists of Minnesota, Mendota Heights, MN.*

Introduction: Hypokalemic periodic paralysis is a rare disorder with autosomal dominant inheritance. A mutation in skeletal muscle Ca channels is the most common genetic abnormality. Attacks generally begin in 1st or 2nd decades of life and present as sudden-onset painless weakness/paralysis. Symptoms may be precipitated by heavy exercise, fasting, or high-carbohydrate meal. If hypokalemic periodic paralysis is suspected, workup should be focused on ruling out secondary causes of hypokalemia and weakness. Herein we present a case that demonstrates the importance of this workup in a somewhat atypical presentation of this rare condition.

Case Description: A previously health 27-year-old male presented due to severe weakness. Symptoms started two days prior to arrival with mild pain of the arms and legs and subjective weakness. No changes in physical activity. No changes in eating habits. The morning of admission, patient was unable to get out of bed. On admission, exam was notable for profound extremity weakness. Initial workup demonstrated K 1.7, Mg 2.1, phos 1.0, creatinine 0.95, CK 506, TSH 0.41, and QTc 622. Muscle weakness improved with potassium replacement. Subsequent urine studies did not demonstrate excess renal potassium loss and patient had no history of extra renal losses. Serum renin and aldosterone levels were within normal limits. CNS studies were unremarkable. Upon further questioning, patient reported drinking a six-pack of soda the day prior to admission (equivalent carbohydrate load to 8 pieces of a large pizza).

Discussion: Despite an atypical presentation of hypokalemic periodic paralysis (first episode in third decade of life, no family hx, and the presence of pain), the workup did not reveal an alternative diagnosis. There was no identifiable secondary cause of hypokalemia. No primary neurologic phenomenon identified, and despite muscle pain only mild elevation in CK and no myoglobinuria. QT was prolonged; however patient lacked any features associated with Anderson Syndrome. This case demonstrates the importance of having a high suspicion for hyperkalemic periodic paralysis in the setting of hypokalemia and weakness, even if some aspects of the presentation are not typical for the diagnosis. Also, the systematic approach for evaluating alternative diagnoses enabled prompt treatment and education regarding preventative measures.

PUB531

D-Lactic Acidosis: Uncommon and Oft Forgotten

Ambreen Azhar,[1] Martine Pollack-Zollman,[2] Steven D. Smith.[3] *[1]Mount Sinai St. Lukes, New York, NY; [2]Mount Sinai Hospital, NY, NY; [3]Icahn School of Medicine at Mount Sinai/St Luke's-Roosevelt Hospital Center, New York, NY.*

Introduction: Lactate (DL) is undetectable by standard analyzers and differs from L-lactate as it crosses the blood brain barrier which leads to neurotoxicity when D-Lactic Acidosis (DLA) ensues. DLA is a rare but known complication of short bowel syndrome (SBS) following a carbohydrate load. Due to a low index of suspicion DLA is often misdiagnosed and recurs.

Case Description: A 65 year-old woman was brought to the ED unconscious soaked in loose stools. She was unresponsive and withdrew on the right only concerning for stroke She had a metabolic acidosis (MA) (pH 7.17, pCO2 17 mmHG on VBG, HCO36 mEq/L, AG 17 mEQ/L, Cl 120 mEq/L, lactate 0.8 mmol/L). Urine toxicology, serum osmolar gap and CT head were not diagnostic. Lactated Ringers (LR) was started. Nephrology was consulted for worsening MA. A laparotomy scar was noted. Family who was not previously available for collateral, confirmed the patient had bowel surgery four years ago. Since then she had SBS with chronic diarrhea, developed new onset neurological symptoms requiring medications and had two suicide attempts. The family also noted she ate almost a whole cake in honor of her birthday a day before. We suspected DLA. Urine AG and osmolar gap was positive at 78 mEq/L and 420 mOsm/kg, respectively. LR was immediately stopped; IV sodium bicarbonate, IV thiamine and PO clindamycin were started. DL levels were not available. Within a few hours the neurological symptoms and MA resolved and she returned to her baseline.

Discussion: Our patient presented with classic DLA after a large carbohydrate load in the setting of altered gut microbiome in SBS. DL reduces intracellular pH and interferes with pyruvate metabolism by inhibiting pyruvate dehydrogenase complex (PDHC). The severity of symptoms may depend on the preexisting intracellular reserves of cofactors (i.e thiamine) for PDHC that are usually compromised in SBS which leads to a wide range of neurological symptoms. Commonly these patients have lower "AG" as anticipated by DL levels due to hyperchloremia and are wrongly treated with LR which contains DL and worsens symptoms, as seen in our patient, or are misdiagnosed as RTA and symptoms recur. Unfortunately, measuring DL is not practical and awareness is needed. Management consists of avoiding large carbohydrate meals, altering the gut flora with antibiotics and restoring cofactors.

PUB532

Double Trouble: A Case of Hyperkalemia from the Combination of Fluconazole and Heparin, and Its Treatment with Fludrocortisone

Ann Herron,[1] Rachel B. Fissell.[2] *[1]Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Medication-induced hyperkalemia is common and can be dangerous. Treatment options may be limited if a precipitating medication cannot be discontinued. We present a case of hyperkalemia from co-administration of fluconazole and heparin that improved with fludrocortisone.

Case Description: A 39 yo man with CML and recent MSSA endocarditis requiring mechanical MVR was admitted for rash and AKI with serum creatinine (SCr) 5.29 mg/dL. Workup notable for hematuria, proteinuria, and leukocytoclastic vasculitis on skin biopsy, suggesting post-infectious vs drug-induced vasculitis. Prednisone initiation led to gradual improvement in SCr. INR became supratherapeutic and warfarin was transitioned to IV heparin. One week later he developed Candida parapsilosis fungemia, and fluconazole was started. The following day he developed acute hyperkalemia up to 8.0 mmol/L without EKG changes. Whole blood potassium (WBPot) was checked with a point of care analyzer with a similar result. WBC, uric acid, LDH, haptoglobin, CK, and lactate levels were normal, serum bicarbonate 24 mmol/L, and SCr 1.3 mg/dL. He began fludrocortisone 0.1 mg daily for medication-induced hyperkalemia, as well as furosemide and oral bicarbonate. Heparin was discontinued the following day. WBPot improved with fludrocortisone but remained elevated at 5-6 mmol/L. Fluconazole was then discontinued, and WBPot stabilized at <5 mmol/L, at which time fludrocortisone was stopped.

Discussion: Heparin and azole antifungal agents, particularly ketoconazole, can lead to hyperkalemia by decreased aldosterone production. Fluconazole has been shown to have the same effect, though weaker, and only a few cases of fluconazole-induced hyperkalemia have been reported. This case provides further evidence of the potential for severe hyperkalemia from fluconazole, particularly when given with heparin, and highlights the importance of considering potassium-related drug interactions. There are a few reports of fludrocortisone use in heparin-induced hyperkalemia, and though fludrocortisone did not normalize this patient's potassium, it helped reduce it to a safer level while decisions were made regarding alternative therapies to heparin and fluconazole. This suggests that fludrocortisone can be used as a bridge to help prevent dialysis until safer medications are chosen.

PUB533

Hypercalcemia Secondary to Silicone-Induced Granuloma Treated with Ketoconazole

Bianca Madrid. *University of Miami, Miami, FL.*

Introduction: Hypercalcemia mediated via extra-renal 1, alfa-hydroxylase activity has been well described. We present a patient who developed hypercalcemia from silicone-induced granulomas.

Case Description: A 49 year-old female was referred to Nephrology in the out-patient clinic for evaluation of acute renal insufficiency and hypercalcemia. Her medical history included hypertension, endometriosis, recurrent nephrolithiasis, and cosmetic surgery. The initial workup for hypercalcemia and recurrent nephrolithiasis revealed hypocitraturia, hyperoxaluria and hypercalciuria. Vitamin D 1,25 (OH)2 was significantly elevated. Due to concerns for possible granulomatous disease, chest imaging was obtained. The CT chest revealed no acute pulmonary process, but there were prominent left para-aortic lymph nodes measuring up to 10 mm. The lymph nodes were not amenable to biopsy. Therefore, a FDG-PET was obtained to determined the metabolic activity of the lymph nodes. The PET/CT revealed diffuse hypermetabolic subcutaneous stranding predominantly involving bilateral gluteus and bilateral proximal thighs. The patient admitted to subcutaneous injections of silicone, and silicone-induced granuloma resulting in calcitriol-mediated hypercalcemia was diagnosed. The patient was referred to Plastic Surgery, but due insurance authorization constraints, surgical removal was not done. She was offered to start corticosteroids as treatment of the hypercalcemia, but the patient refused due to concern for the aesthetic adverse effects of steroids. Therefore, she was started on ketoconazole. Within 4 weeks of treatment, her serum calcium had decreased from 12.8 to 11.0mg/dL.

Discussion: The main treatment is surgical resection of the surgical implants or resection of the granulomatous tissue. Corticosteroids remain the primary therapeutic option for hypercalcemia produced by excessive production of 1,25-(OH)2 vitamin D3 by the macrophages present in the sarcoid granulomas. Ketoconazole is an imidazole antifungal that inhibits the 1, alfa-hydroxylase from the macrophage and has been used to treat hypercalcemia associated to primary hyperparathyroidism, tumors, sarcoidosis and tuberculosis. The patient presented is the first case of ketoconazole use for the treatment of hypercalcemia due to silicone-induced granuloma after injection for cosmetic purpose.

PUB534

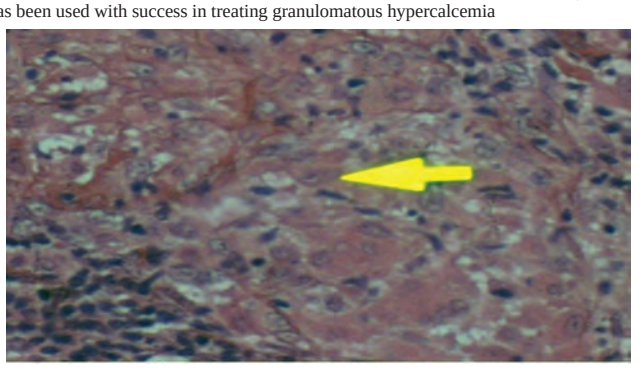
Tuberculous Lymphadenitis Presenting as Symptomatic Hypercalcemia and AKI: A Case Report

Raja M. Rashid,[1] Zahid ul Zahideen,[2] Zahid Nabi.[3] *[1]CPSP, Islamabad, Pakistan; [2]Department of Nephrology KRL islamabad, Sialkot, Pakistan; [3]KRL Hospital, Islamabad, Pakistan.*

Introduction: Incidence of Tuberculosis associated hypercalcemia has been variably reported to be as low as 2% and as high as 28% depending upon the studied population. However, severe or symptomatic tuberculous hypercalcemia are very rare entities. AKI is another very rare presentation of of granulomatous hypercalcemia. We are presenting a case of moderate hypercalcemia secondary to tuberculous lymphadenitis that presented with symptomatic hypercalcemia and AKI.

Case Description: 40 years old male presented to various doctors with increased urinary frequency and occasional constipation. His repeated urine examination was bland with negative cultures but renal function tests were mildly deranged consistently for past one month. When he presented to our center, he was afebrile but had enlarged inguinal and few cervical lymph nodes. Workup showed normal hemoglobin, urea of 143 mg/dl, creatinine of 4.1 mg/dl, serum calcium of 13 mg/dl and Phosphorous of 4 mg/dl. ESR was 60 and LDH was 160 IU/l. PTH was suppressed to 5pg/ml (15-65pg/ml). Right inguinal lymph node biopsy showed multiple granulomas comprising of epithelioid cells with Langerhans type giant cells, central caseating necrosis and no atypical cells. Patient was managed with aggressive hydration and Anti tuberculous therapy (ATT) along with steroids for 1 month. Patient showed marked improvement in RFT (Urea 24 mg/dl, creatinine 1.1) on discharge and calcium improved to 9.8 mg/ dl subsequently. After two months, his urea was 18mg/dl, creatinine 0.9 and calcium 9.2 with increased appetite, normal urinary frequency and bowel movements. On completion of ATT patient has normal RFTs and calcium levels.

Discussion: There is no established relationship between severity of hypercalcemia and various forms of tuberculosis. As in our case, short course of steroid alongside ATT has been used with success in treating granulomatous hypercalcemia



PUB535

Cisplatin-Induced Transient Renal Salt Wasting

Sourab Dhungel, Sheetal Koul, Lauren Ng. *Temple University Hospital, Mickleton, NJ.*

Introduction: Cisplatin is used in the management of many solid tumors and is known to stimulate hypothalamic AVP secretion resulting in SIADH. We present a less frequent cause of hyponatremia secondary to Cisplatin therapy that is important to distinguish from SIADH as choosing the wrong management approach can lead to worsening of hyponatremia.

Case Description: 47 y/o caucasian female with recently diagnosed small cell carcinoma of the cervix presented to the hospital with worsening confusion and lethargy after her third dose of Cisplatin/Etoposide as part of her first cycle of neoadjuvant chemotherapy. Serum sodium was 115 mmol/L compared to serum sodium of 142 mmol/L measured 3 days prior to start of chemotherapy. Measured serum Osm was 240 mOsm/kg H2O. Her blood pressure was low-normal with exam notable for dry skin. Urine Na was 75 mmol/L, urine creatinine was 22 mg/dL and FeNa was 1.4%. Urine Osm was 606 mOsm/kg and Urine specific gravity was 1.019. An initial diagnosis of SIADH vs Renal Salt Wasting was made and given the patient's mentation, she was treated with iv hypertonic saline with improvement in serum sodium. Over the next day, urine sodium values rapidly decreased to under 30 mmol/L with FeNa <<1 making SIADH unlikely. Serum sodium continued to improve with isotonic saline along with oral salt tablets while urine osmolality decreased to 335 mOsm/kg. The patient's mentation and serum sodium normalized within a week. Upon discharge, she completed 3 cycles of Cisplatin-Etoposide therapy without further recurrence of hyponatremia, aided by preventive saline administration with chemotherapy.

Discussion: Our patient's presentation fits with the hypothesis that she developed transient renal salt wasting that resolved spontaneously with appropriate urinary concentration returning 4 days after her last dose of chemotherapy. Cisplatin may cause hyponatremia by inducing SIADH &/or renal salt wasting. This may initially be difficult to distinguish but a careful assessment for volume depletion and distinction between the two conditions is warranted for correct management. It is notable that renal salt wasting in our patient was only transient and occurred in isolation without any other manifestations of tubular epithelial cell toxicity that are more common with Cisplatin use. It must also be pointed out that this effect did not recur with continued chemotherapy when combined with preventive saline infusions.

PUB536

Thiamine Deficiency as a Cause for Persistent Hyperlactatemia

Sheetal Koul, Sourab Dhungel, Avrum Gillespie. *Temple University Hospital, Philadelphia, PA.*

Introduction: Hyperlactatemia is often associated with tissue hypoxia also known as Type A lactic acidosis. However, it can result from less common mechanisms like thiamine deficiency as described in our patient. Effective treatment of persistent hyperlactatemia requires correct identification of the precipitating cause.

Case Description: A 47-year-old female with past medical history of schizophrenia presented to the ED with altered mental status. She was tachycardic without tachypnea and afebrile with stable blood pressure. She was confused, lethargic and appeared malnourished on physical exam. Laboratory data was significant for a bicarbonate of 6 mmol/L, anion gap of 24 mmol/L, lactate of 3.6 mmol/L and an osmolal gap of 23 mOSm/kg H2O. Blood, CSF, urine culture and CXR were negative. UA was notable for large ketones accounting for some of the anion gap. Blood ethylene glycol, methanol and ethanol levels were all undetectable. Despite volume resuscitation for presumed Type A lactic acidosis, hyperlactatemia persisted. She had no evidence of liver disease and was not on any offending medications. Urine drug screen was negative. Given persistent hyperlactatemia, thiamine level was then checked and was noted to be less than 6 nmol/L. She was treated with IV thiamine resulting in resolution of hyperlactatemia within less than 48 hours.

Discussion: In patients with persistent hyperlactatemia, absence of more common causes like tissue hypoxia and offending medications should warrant search for a less common etiology like thiamine deficiency. The mechanism of hyperlactatemia in thiamine deficiency is the impairment of pyruvate dehydrogenase activity. This etiology is more common in children or adults receiving TPN or with nutritional deficiencies.

PUB537

Parapelvic Cyst: A "Must Know" Differential Diagnosis for Hydronephrosis on Point-of-Care Ultrasound

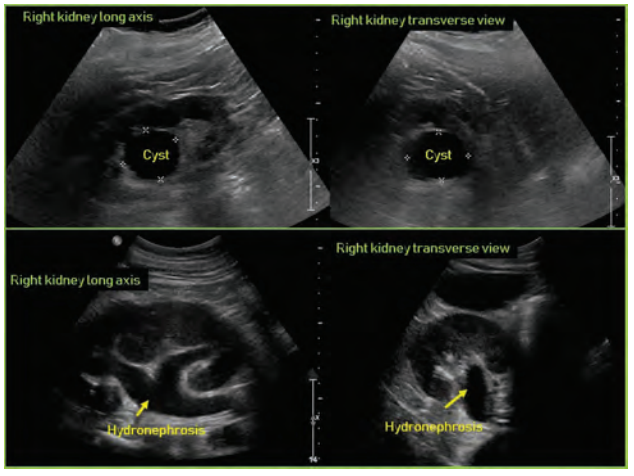
Amer A. Belal, Harini Bejjanki, Gajapathiraju Chamarthi, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Introduction: Point of care ultrasonography (POCUS) performed by the nephrologist is a valuable bedside tool that enhances patient care. Detection of obstructive uropathy is one of the most common indications for POCUS and hydronephrosis is relatively easy to recognize appearing as 'anechoic' or 'black' branching, interconnected areas in the renal collecting system. However, caution needs to be exercised in calling an anechoic structure in the renal pelvis as hydronephrosis, especially when attributing a patient's acute kidney injury (AKI) to this finding. Herein, we report a case of parapelvic cyst mimicking hydronephrosis.

Case Description: A 75-year-old woman with a history of hypertension and right total hip arthroplasty was admitted for infected hip prosthesis and started on intravenous

antibiotic therapy. She underwent revision hip surgery, suffered from myocardial infarction post-operatively and subsequently developed AKI stage III. Renal POCUS was suggestive of right moderate hydronephrosis. However, on careful review of the trainee-performed images [Figure, top panel], the anechoic area in the renal pelvis area was found to be a simple cyst mimicking hydronephrosis. The patient's renal failure was diagnosed to be secondary to acute tubular injury and she later required renal replacement therapy. A formal sonogram obtained a few days later confirmed the interpolar cyst.

Discussion: Parapelvic cysts can mimic hydronephrosis because of their anechoic nature and close proximity to the renal collecting system. Hydronephrosis appears as branching, 'interconnected' anechoic area [Figure, bottom panel] as mentioned above, while parapelvic cysts are seen as well-circumscribed 'noncommunicating' renal sinus cystic masses. Moreover, a parapelvic cyst is more spherical as opposed to irregular contour of hydronephrosis and is not connected to hydroureter distally.



PUB538

A Case Report of Gitelman Syndrome in an Adult Filipino Presenting with Hypokalemic Periodic Paralysis

Aldrin john S. Almario. *Bulacan Medical Center, Malolos, Philippines.*

Introduction: Gitelman Syndrome is a rare salt losing renal tubular disorder which can present with salt craving or thirst, constipation, muscle weakness or paralysis. This report presents a case of an adult Filipino with hypokalemic periodic paralysis. Laboratory examinations revealed hypokalemic metabolic alkalosis, hypomagnesemia, and hypocalciuria which are the main findings of Gitelman Syndrome.

Case Description: The case is a 30 year old Filipino, with no known co-morbidities, who presented with weakness of all extremities. Patient had been managed previously as a case of Hypokalemic Periodic Paralysis; however, with no identified etiology. The only remarkable physical examination finding was motor weakness - 1/5 and 0/5 on the upper and lower extremities, respectively. Pertinent laboratory examinations were - hypokalemia (2.14mmol/L), hypomagnesemia (0.55mmol/L), ABG of metabolic alkalosis, computed TTKG (transtubular potassium gradient) of 20.4, urine chloride of 99, and urine calcium/creatinine of 0.01. These findings, along with absence of thiazide use, were consistent with Gitelman Syndrome. Potassium and magnesium corrections were given. Response to management described as increased motor strength was noted after completion of treatment. Two weeks after discharge, patient claimed to have episodes of weakness. Repeat serum potassium was 2.47mmol/L. Potassium supplementation was then resumed which again improved the patient's weakness.

Discussion: Gitelman Syndrome is a rare and benign salt losing tubulopathy that can present with salt craving or thirst, constipation, muscle weakness or paralysis. As for this case, the patient presented with recurrent hypokalemia associated with weakness. Diagnosis is mainly based on symptoms and laboratory examination findings revealing the disorder's main features - hypokalemic metabolic alkalosis with hypomagnesemia and hypocalciuria. Genetic testing is still needed to identify mutations in the SLC12A3 gene which establishes the diagnosis. Due to the unavailability of the test, genetic testing was not done. Replacement of depleted electrolytes is the mainstay of treatment. Definitive treatment is not yet established. Recurrence of symptoms is expected as seen in the case wherein patient had episodes of weakness two weeks after hospital discharge.

PUB539

Steroid-Resistant Nephrotic Syndrome as a Novel Presentation of Mitochondrial Trifunctional Protein Deficiency

Hillarey Stone,[1] Rebecca C. Hjorten,[1] Anatalia Labilloy,[1] Lyan Alkhudairy,[1] Katherine A. Vandenheuvel,[1,2] Donna J. Claes,[1,2] Meredith P. Schuh.[1,2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH.*

Introduction: Steroid resistant nephrotic syndrome (SRNS) is a leading cause of pediatric kidney disease. Variants in several genes associated with mitochondrial cytopathies are known to cause SRNS. We describe the first reported case of SRNS as the initial presentation of mitochondrial trifunctional protein (MTP) deficiency.

Case Description: The patient was diagnosed with SRNS at 12 months of life. Biopsy showed diffuse mesangial sclerosis. Due to refractory edema, he underwent bilateral nephrectomy and dialysis initiation. At age 20 months, he received a deceased donor kidney transplant. Following transplant, he experienced severe hypotension, lactic acidemia, hypoglycemia, and liver dysfunction. Whole exome sequencing (WES) demonstrated compound heterozygosity with two novel variants in the *HADHB* gene, consistent with autosomal recessive MTP deficiency. Biochemical analysis of cultured fibroblasts confirmed the diagnosis. Despite a trial of CoQ10, carnitine, and other vitamins, he continued to deteriorate and died at age 21 months. Immunofluorescence (IF) was performed on patient kidney tissue to delineate the role of HADHB in nephrotic syndrome. IF of an age-matched control displayed HADHB throughout the renal tubules. In contrast, patient tissue revealed complete absence of HADHB throughout the kidney (Fig 1).

Discussion: MTP is involved in fatty acid oxidation and is essential for energy homeostasis, especially in times of fasting. MTP is encoded by two genes: *HADHA* and *HADHB*. Variants in these genes can cause MTP deficiency, presenting with early onset hypoketotic hypoglycemia and cardiomyopathy or later onset myopathy, rhabdomyolysis, and polyneuropathy. This is the first reported case of MTP deficiency presenting with SRNS. WES and IF of patient kidney tissue suggest that mutations in *HADHB* cause nephropathy and should be considered in patients with SRNS. Further research will define the specific role of HADHB in the development of nephrotic syndrome.

PUB540

Urgent Page: An Unusual Case of Abdominal Pain with Hypertension

Sneha Lakshman, Kanwal Anwar. *North Shore Medical Center, Salem, MA.*

Introduction: Renal Angiomyolipomas (AMLs) are the most common benign tumor of the kidney and are associated with tuberous sclerosis complex (TSC), pulmonary lymphangioleiomyomatosis (LAM) or most commonly, sporadic. AMLs are mostly asymptomatic but can present with flank pain, hematuria or rarely retroperitoneal hematoma due to rupture. Rupture of AMLs is rare but more frequent if the size is ≥ 4 cm.

Case Description: 47-year-old female with no past medical history presented with sharp left lower quadrant abdominal pain with nausea. She denied trauma, dysuria, hematuria, fever or chills. On presentation, her vitals were stable apart from an elevated blood pressure of 186/91. Exam was notable for left lower quadrant tenderness to palpation without costovertebral tenderness. Labs were significant for a hemoglobin 10.8 (baseline 12), creatinine of 1.17 (baseline 0.8). CT of abdomen and pelvis showed a 3 cm hemorrhagic angiomyolipoma near the lower pole of the left kidney with a large volume left renal subcapsular hematoma producing compressive deformity of its renal cortex. Patient was observed for the next 24 hours and she remained hemodynamically stable with stable hematocrit. She received adequate pain control and intravenous fluid and was discharged for follow-up as an outpatient in 6 weeks for surveillance. Her blood pressure at the time of discharge had improved to 140/70.

Discussion: Our case is a rare and unique presentation of renal AML as the patient not only presented with spontaneous retroperitoneal hematoma due to rupture of a renal AML but the size of AML was 3 cm. Moreover, the patient's hypertension was caused by renal parenchymal compression from the subcapsular and perinephric hematoma, a phenomenon known as Page kidney. In patients with life-threatening hemorrhage, selective renal artery embolization is recommended. All patients with AMLs should be screened for TSC, however, it is not necessary to screen for LAM. Surveillance for AML is dependant on size: for < 2 cm, ultrasound every 3-4 years, for 2-4 cm, annual renal ultrasounds, and > 4 cm tumors, surgical resection is recommended.

PUB541

Two Pearls in an Oyster: Thrombotic Microangiopathy due to Malignant Hypertension from Apparent Mineralocorticoid Excess in a Cushing Syndrome Patient with Primary Bilateral Macronodular Adrenal Hyperplasia

Catarina Regis, Jair Munoz Mendoza. Katz Family Division of Nephrology at University of Miami *University of Miami, Miami, FL.*

Introduction: Malignant hypertension (HTN) is characterized by severe HTN and target organ damage and can rarely cause thrombotic microangiopathy (TMA). Primary bilateral macronodular adrenal hyperplasia(PBMAH) causes Cushing's syndrome in less than 2% of the cases, leading to difficult to control HTN. We report this unique case of a patient with malignant HTN and TMA due to apparent mineralocorticoid excess from PBMAH.

Case Description: 47 year-old male, with malignant HTN for two years, uncontrolled on four antihypertensives (including diuretics) presented with fatigue, muscle weakness and unintentional weight gain (45 lbs). Physical exam remarkable for BP:160/100; weight 172lbs, moon face, central obesity with buffalo hump, supraclavicular and dorsocervical fat pads and purple abdominal striaes, proximal muscle weakness and thin/scaly skin. Primary Cushing's syndrome was suspected and confirmed with high free AM cortisol at 37mcg/dL, low ACTH at <5 p/mL. CT abdomen revealed bilateral adrenal adenomas. Further work up: microscopic hematuria and sub-nephrotic proteinuria (1.8g/24hs), Cr 1.2mg/dL. Kidney biopsy: intracapillary thrombi; marked podocyte hypertrophy, consistent with TMA. An extensive workup ruled out the most common causes of TMA like TTP, HUS and complement deficiency. On further tests, he was diagnosed with apparent mineralocorticoid excess through the high 24h urine free cortisol/ free cortisone ratio. A bilateral adrenalectomy was performed to treat the disease and at 12-month follow up visit, BP was controlled (110/70) only on Lisinopril 10mg/day and he had lost 48lbs. Proteinuria: 203 mg/24hs

Discussion: PBMAH causes Cushing's syndrome in less than 2% of cases. This patient also had TMA present, likely from two pathways: 1. Cushing's syndrome as a hypercoagulable state (high factor VIII levels, decreased fibrinolysis, and abnormal Von Willebrand factor) 2. Malignant HTN causing endothelial dysfunction and thrombi formation. Malignant HTN was secondary to the apparent mineralocorticoid excess from PBMAH. Both HTN and Cushing's syndrome resolved after bilateral adrenalectomy. PBMAH is a rare cause of Cushing's syndrome and, to the best of our knowledge, this is the first case of this condition causing apparent mineralocorticoid excess leading to HTN and TMA.

PUB542

Novel Heterozygous COL4A3 Mutation of the Type IV Collagen Alpha3 Gene in a Family with Thin Basement Membrane Nephropathy

Takashi Tani,[1] Takayasu Mori,[2] Kazumasa Hashimoto,[1] Akira Shimizu,[1] Shinichi Uchida,[2] Shuichi Tsuruoka.[1] *[1]Nippon Medical School, Tokyo, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan.*

Introduction: Thin basement membrane nephropathy (TBMN) and Alport syndrome (ATS) are familial nephropathy characterized by structural abnormalities in the glomerular basement membrane (GBM). Gene mutations in the type IV collagen α3 and α4 (*COL4A3/A4*) genes are reported to cause both ATS and TBMN with the autosomal recessive and autosomal dominant form, respectively. The renal function of TBMN is usually kept normal, whereas ATS typically results in end-stage renal disease (ESRD). Therefore, differentiation between TBMN and ATS is mandatory for correct prediction of prognosis and genetic counseling.

Case Description: A 39-year-old woman presented with recent diagnosis of hypertension, mild proteinuria (0.58 g/gCr/day), microscopic hematuria (50-99 HPF) and mild decrease in eGFR at 59.5 mL/min/1.73m^2. She experienced asymptomatic hematuria since childhood, and a family history of microscopic hematuria. She received a renal biopsy at the age of 29 years; light and electron microscopic findings revealed thinning of GBM and effacement of the podocyte foot processes. Blood pressure was 137/92 mmHg with the prescription of amlodipine (5mg per day). Physical examination was unremarkable with no lower extremity edema. The next-generation sequencing and Sanger Sequencing were performed on DNA samples of the patient and her family (father, elder sister, younger sister, nephew, daughter), and heterozygous *COL4A3*G415S mutation [*COL4A3*(NM_000091):c.G943A:p.G315S] was identified in each individual with persistent hematuria, except her nephew who never experienced hematuria. She was diagnosed of TBMN, and antihypertensive treatment by angiotensin receptor blocker decreased proteinuria to about 0.2g/gCr/day, increased eGFR, while microscopic hematuria persisted.

Discussion: Clinical diagnosis of this case was TBMN on the following basis; autosomal dominant hereditary form, no ESRD patients in the family, no irregular thickening and multilamination of the GBM in the kidney, and no type IV collagen α5 defect. Mild proteinuria and decrease in eGFR at admission were considered associated not with TBMN but with untreated hypertension. This is the first case of TBMN with the novel *COL4A3* hetero mutation of type IV collagen α3 which is responsible for the microscopic hematuria in this family.

PUB543

Severe Microangiopathic Anemia in an ESRD Patient Unmasks Complement-Mediated Atypical Hemolytic-Uremic Syndrome (aHUS) and Successful Management with Treatment of aHUS

Shweta Punj,[1] Anthony Chang,[2] Vikram Aggarwal.[1] *[1]Northwestern University - Feinberg School of Medicine, Chicago, IL; [2]UChicago Medicine, Chicago, IL.*

Introduction: Anemia amongst ESRD patients is mostly due to erythropoietin deficiency and disordered iron metabolism. We present an ESRD patient with severe complement-mediated hemolytic anemia due to aHUS. Identification of genetic abnormalities in complement regulatory proteins and use of complement inhibitors lead to successful resolution of near-fatal anemia. We posit that the underlying cause for ESRD might be related to aHUS presenting as ANCA-negative vasculitis.

Case Description: A 39-year old African-American female patient with ESRD was admitted for severe symptomatic anemia and need for red-blood cell transfusion despite erythropoietin-stimulating agents (ESA). She was evaluated a year prior for chronic kidney disease with a nephritic presentation. Serological evaluation was negative. Kidney biopsy reported as pauci-immune ANCA-negative glomerulonephritis with significant chronicity. Given renal-limited vasculitis and chronicity, she didn't receive immunosuppressives. Hemoglobin & renal function remained stable. Blood pressure was controlled with ACE-I. eGFR dropped in 4 months with a decline in hemoglobin and platelet count, needing dialysis and ESA initiation. Severe, transfusion-requiring anemia workup showed elevated LDH and reticulocyte count, undetectable haptoglobin, increased schistocytes and thrombocytopenia. She was started on Eculizumab for aHUS without plasmapheresis. Hemoglobin improved within 2 weeks and eventually normalized while on Eculizumab. Genetic testing for aHUS showed multiple, heterozygous, missense variants of complement factor H (CFH). Prior renal biopsy showed changes of arteriolopathy that cemented concerns for aHUS. She remains transfusion-independent and on Eculizumab.

Discussion: CFH mutations are the commonest amongst genetic causes for aHUS. In African-American patients, CFH variants might be just as impactful in causing CFH-related GN and ESRD. Our patient had hemolytic anemia due to complement-mediated aHUS with brisk response to Eculizumab. Testing reveals her genetic predisposition to aHUS with multiple CFH variants, common amongst ESRD patients of African-American ancestry. Besides being a rare cause for anemia in ESRD patients, we propose that complement-mediated aHUS might have been the original cause for ESRD in this patient.

PUB544

Fabry Disease: Management in Carriers for Enzyme Alpha-Galactosidase A (a-GAL A)

Yeshwanter Radhakrishnan,[1] Rupesh Raina.[2] *[1]Cleveland Clinic Akron General, Akron, OH; [2]Nephrology, Cleveland Clinic Akron General, Akron, OH.*

Introduction: Fabry disease is an X-linked recessive deficiency of the enzyme alpha-Galactosidase A (a-GAL A), resulting in the accumulation of globotriaosylceramide (Gb3) within lysosomes in a variety of cells. It is the second most common lysosomal storage disease with clinical manifestations ranging from asymptomatic to very severe cardiac manifestations and end-stage renal disease. We report a case of Fabry disease in a young female who was asymptomatic initially and slowly started showing renal manifestations of the disease.

Case Description: The patient is a 26-year-old female referred to our office by her primary care physician for evaluation of proteinuria and hematuria with CKD stage 1 with a significant history of renal disease in the family. She had complaints of tingling/pain in her hands and feet along with episodes of excessive sweating. On exam, she was found to have angiokeratomas in the periumbilical regions. Her baseline serum creatinine was 0.5 - 0.8. On genetic testing and she was noted to be a heterozygous carrier for the Fabry Disease. We suggested Enzyme Replacement Therapy (ERT) along with a focus on the control of blood pressure, metabolic derangements, lipids, blood sugars and avoidance of nephrotoxic drugs. We emphasized the importance of scheduled follow-up visits with subspecialties every 2-3 months to monitor the disease progression.

Discussion: Fabry disease can be diagnosed in males by detecting low a-GAL A activity in leukocytes or in the plasma. In women, a-GAL A activity level is unreliable for diagnosis and therefore it is necessary to perform mutation analysis of the a-GAL A gene. Carriers may be completely asymptomatic but with advancing age may develop left ventricular hypertrophy, valvular disease, cardiomegaly, myocardial ischemia, infarction,

arrhythmias, transient ischemic attacks, stroke, proteinuria, polyuria and end-stage renal disease. Adequate surveillance for the disease manifestations follow-up along with ERT is the main principle behind the treatment of Fabry disease. ERT with recombinant a-Galactosidase A may slow deterioration of cardiac and renal functions, while also helping in reducing pain and improving a overall quality of life. It is recommended that ERT be initiated as early as possible in female carriers with significant disease because of risk of cardiac, cerebrovascular and renal complications.

PUB545

Hypokalemic Periodic Paralysis

Ali T. AL Azzawi, Jorge L. Castaneda. *UMMC, Flowood, MS.*

Introduction: Hypokalemic periodic paralysis is a condition that causes muscle weakness beginning in childhood and adolescence. Mutations in the CACNA1S or SCN4A can cause HPP, those genes codify for proteins that control the flow of positive ions in muscle cells. We reported a case of HPP that carries a lot of frustration since patients usually have multiple ER and clinic visits before the right diagnosis.

Case Description: Patient is a 40 y.o white female who began having symptoms at the age of 12, initially with pain in legs that eventually progressed to her neck, shoulders, and hips. At age 20, her K^+ was detected around 3.5 mEq/L, and due to her symptoms, she was initially placed on steroids, which resulted in muscle weakness. At age 32, she developed a profound paralysis and her K^+ was found to be around 3.1 mEq/L. Since then, K^+ supplementation has been increased to 100 mEq daily, with additional K^+ administered PRN for acute paralytic episodes. She is also taking acetazolamide, amiloride, and eplerenone, a combination which has resulted in improvement.

Discussion: The initial hypokalemia starts with the separation of K losses (renal and extrarenal) and transcellular shifting. Unfortunately, There is no appropriate test to differentiate the potential mechanism. The total urine K^+, Urine K^+/Cr ratio and transtubular K^+ gradient (TTKG) are not completely accurate test due to renal physiologic mechanisms. Therefore after ruling out common etiologies, the approach should approximate unusual renal K^+ wasting conditions and transcellular shifting in parallel. (HPP) can be divided in to:(familial, associated with thyrotoxicosis and associated with cardiac dysrhythmias-Andersen Tawil syndrome). Genetic testing should be part of the armamentarium to get closer to the final diagnosis. A periodic paralysis genetic panel includes analysis of the following four most common associated genes: SCN4A, CACNA1S, KCNJ2 and RYR1. Unfortunately, genetic testing is not definitive since a proportion of patients lack abnormalities in the mentioned genes. Finally, the treatment will imply K^+ replacement with the adjuvant of K^+ sparing diuretics such as amiloride, triamterene and spironolactone. Close monitoring is required since other electrolyte abnormalities and acid base disorders may ensue. Our case report intent to raise the awareness of this rare condition and establish that multidisciplinary approach needed to delineate the diagnostic approximation of HPP.

PUB546

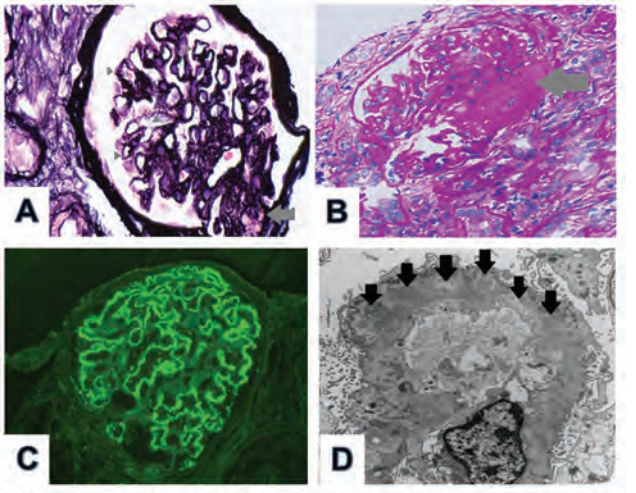
Overlapping Features of Membranous Glomerulonephritis and Focal Segmental Glomerulosclerosis in a Patient with Nephrotic Syndrome

Colton Jensen,[1] Danniele G. Holanda,[2] Melissa L. Swee.[1] [1]*University of Iowa, Waukee, IA;* [2]*University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Nephrotic syndrome may be classified into different histopathologic patterns, including membranous glomerulonephritis (MGN) and focal segmental glomerulosclerosis (FSGS). While MGN may be secondary to drug exposure, FSGS is more commonly seen due to obesity, uncontrolled hypertension, and HIV. Overlap between these two conditions is rare and, when coexisting, tends to clinically resemble primary MGN. We present a case with overlapping features of NSAID-induced MGN and FSGS.

Case Description: A 37-year old Caucasian male with chronic daily headaches on ibuprofen daily presented for elevated creatinine (2.4 mg/dL, compared to 0.8 mg/dL 3 years prior). Vital signs were notable for hypertension (219/107 mmHg), and physical examination was notable for 2+ pedal edema. Urinalysis showed 3+ protein and no blood. His UPC was 7.5. C3 and C4 levels, hepatitis B and C, HIV, ANA, dsDNA, RNP, Smith, SSA, SSB, and Histone serologies were within normal limits. Renal biopsy demonstrated MGN with negative PLA2R and THSD7A staining, global sclerosis in 3/23 glomeruli, segmental sclerosis in 3/23 glomeruli, and moderate tubular atrophy and interstitial fibrosis. He was advised to stop all NSAID use and was started on amlodipine, carvedilol, lisinopril, and spironolactone. At 2-week followup, his blood pressure was 110/72 mmHg, creatinine was 2.3 mg/dL, and UPC was 2.5.

Discussion: The coexistence of MGN and FSGS is a rare phenomenon, but may occur in patients who share risk factors like chronic NSAID use, uncontrolled hypertension, and obesity. Although the pathogenesis is unclear, MGN injury may contribute to FSGS since subepithelial deposits may hinder podocyte adhesion, and FSGS-mediated podocyte damage may lead to local antigen exposure and subepithelial immune complex formation.



Light microscopy (LM), 400x: A) JMS stain: glomerulus with capillary loop spikes and holes, characteristic of MGN (arrowheads), and segmental sclerosis with hyalinosis (FSGS, arrow). B) PAS stain: glomerulus with segmental sclerosis and hyalinosis. Immunofluorescence (IF), 400x: C) IgG stain: positive, global granular pattern of glomerular capillary loop staining. Electron microscopy (EM), 8,000x: A glomerular capillary loop with regularly distributed, subepithelial and intramembranous immune-complex mediated type electron dense deposits, in various stages of incorporation and absorption into the glomerular basement membranes.

PUB547

An Aggressive Form of Nephrotic Syndrome Secondary to IgA Nephropathy

Shashank Varakantam, Rohit Kumar, Kanwarpreet S. Tandon, Shalini Hemachandran, Hakan R. Toka, Dr. nemer Dabage. *Blake Medical Center, Bradenton, FL.*

Introduction: Patients with IgA Nephropathy (IgAN) often present with nephritic syndrome, but nephrotic syndrome (NS) is less common. Several features of IgAN have been associated with poor prognosis, including hypertension, glomerular range proteinuria and fibrosis on histopathology. Here we discuss a patient with IgAN presenting with NS and malignant hypertension.

Case Description: A 33 year-old Asian female with history of hypertension presented with one week of headache, nausea and vomiting. Physical examination remarkable for elevated blood pressure of 205/131 mmHg, periorbital swelling and lower extremity pitting edema. Laboratory findings showed elevated serum creatinine (2.9 mg/dl) and LDL (272 mg/dl). Urinalysis was negative for hematuria, showed 3+ proteinuria and microalbumin/creatinine ratio of 3881 mcg/mg consistent with nephrotic range proteinuria. When hypertension was controlled, work up for proteinuric kidney disease was initiated. Results were unremarkable, including autoantibodies and complements, except for a positive hepatitis B surface antigen. Renal biopsy revealed severe interstitial fibrosis and global glomerulosclerosis. Patient was diagnosed with IgA nephropathy due to the presence of mesangial IgA deposits on immunofluorescence (Oxford classification: M1 E0 S1 T2 C0). Her symptoms improved with blood pressure control. Immunosuppressive therapy was not considered due to chronicity of renal scarring.

Discussion: IgAN is the most common cause of glomerulonephritis, more frequent in Asians than Caucasians. IgAN typically has slow progression to end stage renal disease (ESRD) with ~30% of patients developing ESRD over ~20 years. Severity of disease is described using the Oxford classification. Our patient's Oxford score of 29 indicates five-year incidence of ESRD is likely greater than 50%. Significant morbidity and poor outcomes are reported in IgAN associated with NS, which is poorly understood. The occurrence of malignant hypertension and coexistent hepatitis B infection potentially increases risk of ESRD. Limited data is available on use of steroids for treatment of proteinuria in IgAN. Use of Renin-Angiotensin-System blockade for blood pressure control is recommended in proteinuric disease. Early identification, exclusion of other etiologies and management of high risk features can delay progression to ESRD.

PUB548

A Case of APOL1-Associated FSGS in a Sickle Cell Disease Patient

Nirav Parikh, Sunitha Kalyanam, Jason Cobb. *Emory University School of Medicine, Atlanta, GA.*

Introduction: Sickle cell disease (SCD) patients experience glomerular hyperfiltration and there are cases of SCD patients with nephrotic syndrome from FSGS and membranous nephropathy. High risk APOL1 risk variants (G1 and G2) have been associated with progression of chronic kidney disease (CKD), FSGS, and HIV associated renal disease in African-Americans. High risk APOL1 risk variants have been associated with progression of CKD and proteinuria in the SCD patient population. We present the first reported case of a SCD patient with APOL1 associated FSGS.

Case Description: This is a 24 year old African-American female with a past medical history of SCD hemoglobin SS, DVT, and avascular necrosis of hip. She was diagnosed with nephrotic syndrome with urine protein-creatinine ratio (UPC) of 25 g/g,

a serum albumin (sAlb) of 1.7 g/dL, and a serum creatinine (sCr) 1.2 mg/dL. Kidney biopsy showed APOL1 associated nephropathy (collapsing FSGS with 60-70% IFTA and microcystic tubular dilatation). She was initially treated with high dose steroids with UPC only improving to 16 g/g after 6 months. Prednisone was decreased and cyclosporine added with varying compliance. Edema improved and hospitalizations from volume overload decreased. 18 months later patient presented with sickle crisis and symptomatic anemia with hemoglobin nadir of 2.8 g/dL, sCr peaked at 3.2 mg/dL, sAlb 1.5 g/dL, and UPC of 23.5 g/g. Rituximab was given for autoimmune hemolytic anemia. Around 6 weeks later sCr improved 2.3 mg/dL, sAlb 2.2 g/dL, and UPC remains 20 g/g, however patient had no signs or admissions for volume overload.

Discussion: Historically glomerular hyperfiltration in SCD has been seen as a secondary cause of FSGS. This case is unique in being APOL1 positive and her severe presentation is more likely primary FSGS. We will continue follow-up closely and if continued improvement consider continuing low dose prednisone and additional rituximab.

PUB549

A Rare Case of Fibrillary Glomerulonephritis and Advanced Diabetic Glomerulosclerosis Class IIb in a Patient with Newly Diagnosed Nephrotic Syndrome

Odianosen I. Obadan, Smita Mahendrakar. *Rutgers New Jersey Medical School, Newark, NJ.*

Introduction: Fibrillary glomerulonephritis is a rare and underdiagnosed glomerular disorder. It was first described by Rosenmann and Eliakim in 1977. It is defined by the ultrastructural finding of haphazardly arranged, straight fibrils measuring 10 to 30 nm in thickness. According to literature, it coexists in about 20% of Type 2 diabetic patients but the connection between these is a topic of debate. We present a case of fibrillary glomerulonephritis coexisting with diabetic nephropathy in a type 2 diabetic with newly diagnosed Nephrotic syndrome.

Case Description: A 48 years old female with past medical history of CHF, polysubstance use, CKD and hypertension, who presented for follow up at renal clinic following discharge from the hospital. She had presented to the emergency room with uncontrolled blood pressure (245/112mmHg), acute kidney injury and nephrotic syndrome, physical examination generated 2+ pitting pedal edema. Creatinine level was 4.1 mg//dl, eGFR of 14, urinary protein excretion was 3.1g/day, total cholesterol of 229 mg/dL, LDL was 123mg/dL and albumin of 3.1g/dL, Kappa/Lambda ratio of 2.56, SPEP had positive polyclonal gammopathy. The patient's kidney biopsy showed fibrillary glomerulonephritis and diabetic nephropathy, moderately advanced, diffused diabetic glomerulosclerosis, interstitial fibrosis and tubular atrophy, severe arteriosclerosis and moderate arteriolosclerosis. She was offered treatment for high blood pressure with lisinopril, amlodipine, labetalol, clonidine and statins.

Discussion: Reports have shown that fibrillary Glomerulonephritis can coexist with diabetic nephropathy, but a true connection has not been proven. Accelerated glycosylation of proteins in diabetics and advanced glycosylation end products capable of cross-linking with other structural proteins as well as circulating proteins has been suggested as a possible pathophysiology. There is currently no effective therapy as most therapies are guided towards reducing proteinuria and cholesterolemia. Cytotoxic agents, plasmapheresis are used but are not ideal therapies and more studies need to be performed to determine the link between diabetic nephropathy and fibrillary Glomerulonphritis in order to determine the best or optimal therapy.

PUB550

A Rare Case of Idiopathic Nodular Glomerulosclerosis(ING) Secondary to Chronic Hypoxia from Persistent Asthma in an Elderly Male with Resistant Hypertension

Pramodh Chanumolu, Krishna S. Ravipati, Nirpeksh Jain, Siddhartha Kattamanchi. *Marshfield Medical Center, Marshfield, WI.*

Introduction: ING is a rare clinical entity which presents with reduced GFR and nephrotic range proteinuria. It is most common in elderly white males with hypertension, smoking, hypercholesteremia and vascular disease. It is indistinguishable from diabetic nephropathy on histopathology with diffuse nodular mesangial expansion associated with micro aneurysms, arteriolar hyalinosis and arteriolosclerosis with tubulo-interstitial fibrosis. We present a unique case of ING in elderly male with resistant hypertension and chronic hypoxia from persistent asthma.

Case Description: A 80Y old male patient with resistant HTN, CAD, CKD 3, persistent asthma admitted to hospital with complaint of dyspnea secondary to pulmonary edema from hypertensive emergency. He developed AKI on CKD and had >300mg of protein on routine u/a. On further investigations he had a urine microalbumin of 6269ug/mg and a protein/creatinine clearance ratio of 15.05. He underwent kidney biopsy which demonstrated areas of hyalinosis and nodules replacing normal glomeruli along with +2 interstitial fibrosis under light microscopy. No crescentic or necrotizing lesions identified. Immunofluorescence staining was negative and electron microscopy showed no electron dense deposits. These findings are consistent with diabetic nephropathy but our patient never had any history of diabetes which makes this unique. Other causes of nephrotic syndrome in elderly like para-proteins, PAL2R antibody, autoimmune panel (ANA, ANCA, ENA, Anti–GBM) were negative. No secondary causes except for h/o colon cancer in past and he is s/p resection with no recurrence. A tighter blood pressure control and use of ARBs improved his proteinuria and his protein on routine urine analysis was down to 100mg/dl. He is currently being followed in nephrology clinic on a monthly basis.

Discussion: It has been postulated that smoking promotes formation of advanced glycation end products (AGE), induction of oxidative stress, angiogenesis (increased PDGF, TGF B AND IGF-R) altering intrarenal hemodynamics. Our patient has chronic hypoxia from persistent asthma along with resistant hypertension which could be the likely culprits resulting in ING (he is not a smoker and never had diabetes). Further studies are needed to unravel the complex pathogenicity of ING resulting from chronic hypoxia.

PUB551

A Rare Case of Nephrotic Syndrome Precipitated by Pre-Eclampsia and Bevacizumab in a Patient with Underlying Diabetic Nephropathy

Parikshit Duriseti,[1] Jose Cabrales,[3] Mohammad Almeqdadi,[2] Aya Shnawa.[4] *[1]St. Elizabeth's Medical Center, Allston, MA; [2]St. Elizabeth's Medical Center, Brighton, MA; [3]St Elizabeth's Medical Center, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Introduction: Nephrotic syndrome is characterized by nephrotic range proteinuria (urinary protein excretion of over 3.5 grams a day), hypoalbuminemia, edema and hyperlipidemia.

Case Description: A 27-year-old female with hypertension, chronic kidney disease, uncontrolled type 1 diabetes mellitus complicated by proliferative diabetic retinopathy (treated with intravitreal bevacizumab) and nephropathy presented to the hospital in August 2018 complaining of dyspnea on exertion, 35-lbs weight gain and lower extremity pitting edema for 5 months, following delivery of her first pregnancy in March 2018. Her pregnancy was complicated by severe pre-eclampsia and acute kidney injury with the serum creatinine peaking at 1.4 mg/dl (from a prior known baseline of 0.5 mg/dl in 2017). She received intravitreal bevacizumab 2 months after her delivery. On presentation, she was afebrile, HR 94/min and BP 159/88 mm Hg. Labs included serum creatinine 1.4 mg/dl, albumin 2.7 g/dl and nephrotic range proteinuria with a spot urine protein-creatinine ratio of 13.6 g/g. Hepatitis serologies, HIV, ANA, complement profile, ANCA and serum anti-PLA2R antibody were normal. A kidney biopsy was performed which showed a background of advanced diabetic glomerulosclerosis with severe glomerular and podocyte injury concerning for collapsing glomerulopathy (CG). She was started on a diuretic regimen with improvement in her symptoms and was subsequently discharged home with close follow-up with her nephrologist.

Discussion: Pre-eclampsia has been associated with kidney injury causing thrombotic microangiopathy and collapsing glomerulopathy secondary to endothelial injury following inhibition of vascular endothelial growth factor (VEGF) by the soluble fms-like tyrosine kinase 1 (sflt 1) produced by placenta. Intravitreal bevacizumab, an inhibitor of vascular endothelial growth factor (VEGF), which is used in the management of proliferative diabetic retinopathy has similarly been associated with acute kidney injury and proteinuria/nephrotic syndrome with a wide spectrum of histological changes, including collapsing or proliferative glomerulonephritis, interstitial nephritis, and thrombotic microangiopathy. The precise mechanism of glomerular injury induced by VEGF-inhibitors is unknown and merits further studies.

PUB552

Diffuse Alveolar Hemorrhage: A Rare Manifestation of IgA Nephropathy

Jiun-Ruey Hu,[1] Cassie Kovach,[2] Anna M. Burgner.[2] *[1]Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; [2]Division of Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Pulmonary Renal Syndrome (PRS) describes combined renal and respiratory failure, often in the setting of glomerulonephritis (GN) with diffuse alveolar hemorrhage (DAH). IgA Nephropathy (IgAN) is the most common GN worldwide, but rarely causes DAH, and can be overlooked as a cause of PRS. We describe a case of PRS from IgAN successfully treated with plasmapheresis and glucocorticoids.

Case Description: A 71-year-old woman with hypertension and diabetes developed proteinuria and hematuria and her creatinine rose from 1.0 to 2.0 mg/dL over 9 months. Renal biopsy showed IgA nephropathy with 40-50% tubulointerstitial fibrosis and 15/33 glomeruli globally sclerosed. MEST-C score was M1, E1, S1, T1, C0. She was treated with maximum dose lisinopril. She had no findings to suggest an IgA vasculitis at the time of biopsy. Three months later she presented with dyspnea, cough, and fevers. Chest x-ray showed multifocal infiltrates concerning for pneumonia. Despite antibiotics and diuresis, she developed worsening hypoxic respiratory failure and acute kidney injury. Renal replacement therapy was started for volume removal with no improvement in respiratory failure. A bronchoscopy was diagnostic for DAH. Other vasculitic workup was negative, leaving IgAN as the etiology. With high dose steroids and 7 sessions of plasmapheresis, renal function improved, dialysis was stopped, proteinuria resolved, lung infiltrates cleared, and breathing returned to normal.

Discussion: Proposed mechanisms for DAH in IgAN include nonspecific mucosal hemorrhage, immune complex-mediated damage of the GBM (Type III hypersensitivity), or IgA-mediated capillaritis against GBM antigens (Type II hypersensitivity). Type II hypersensitivity is most likely given elevated IgA levels, deposition of IgA in lung tissue, and case reports of IgA deposits on the skin and circulating IgA1 immune complexes. The prognosis of PRS due to IgAN is variable. It is fatal in a quarter of patients and leads to end-stage kidney disease in half of patients. Recurrence of disease has also been reported. Given its rarity, there are no treatment guidelines. Patients are usually given glucocorticoids and sometimes methotrexate, cyclophosphamide, or azathioprine. Plasmapheresis has also been used in treatment.

PUB553

Typical Presentation of Immunoglobulin A Vasculitis in an Atypical Patient

Benjamin M. Forster,[1,2] Lisa K. Prince,[1] Maura A. Watson.[1,2] *[1]Walter Reed National Military Medical, Bethesda, MD; [2]United States Army, Silver Spring, MD.*

Introduction: Immunoglobulin A Vasculitis (IgAV) typically presents with renal dysfunction, palpable purpura, arthritis and abdominal pain. Ninety percent of cases occur in the pediatric population. Males present more frequently than females and IgAV is rare in blacks compared to whites and Asians. We present a case of nephrotic syndrome due to IgAV with prominent cutaneous manifestations in a middle aged black female.

Case Description: A 44-year-old black female with hypertension was seen for new onset nephrotic syndrome. Prior to presentation she was treated with trimethoprim-sulfamethoxazole for a presumed urinary tract infection (culture negative) followed by metronidazole for bacterial vaginosis. One week following completion of antibiotics, she developed anasarca, a pretibial palpable purpuric rash and abdominal pain which prompted three emergency department evaluations. She was initially treated with methylprednisolone for suspected erythema multiforme thought due to metronidazole. Her symptoms improved initially but worsened following steroid completion. Labs revealed proteinuria (12.5 grams), hypoalbuminemia (2.3 g/dL) and elevated creatinine from 1.2 mg/dL to 1.6 mg/dL. Skin biopsy revealed a leukocytoclastic vasculitis. Renal biopsy revealed focal and segmental proliferative glomerulonephritis with dominant IgA fluorescence along with diffuse podocyte foot process effacement and villous transformation. No glomerular obsolescence, interstitial fibrosis or tubular atrophy was noted. Treatment with prednisone 60mg daily was initiated and her abdominal pain resolved within one week. Her skin lesions began to clear by week two. Her proteinuria and albumin slowly improved with partial remission at four months with stable creatinine.

Discussion: This case highlights the typical presentation of IgAV in an atypical patient population. IgAV is well studied in the pediatric population, but rare in adults, females and black patients. Renal manifestations in adults are more severe with a worse prognosis compared to pediatric patients. No drugs have been implicated as a cause of IgAV previously, however, there are case reports in the adult population where metronidazole was received prior to diagnosis. Clinical manifestations including skin rash, abdominal pain, arthritis and renal involvement should raise the suspicion for IgAV even in adult patients previously described as low risk.

PUB554

A Case of ANCA Glomerulonephritis with Anti-GBM Double Positivity

Jonathan D. Pankow,[1] Hanan A. Khairalla,[3] Sara Faiz,[3] William F. Glass.[2] *[1]University of Texas Medical Center, Houston, TX; [2]University of Texas – Houston Medical School, Houston, TX; [3]University of Texas, Houston, TX.*

Introduction: Anti-glomerular basement membrane (GBM) disease and anti-neutrophil cytoplasmic antibody (ANCA) vasculitis are distinct causes of glomerulonephritis (GN), but patients with double positive serologies have overlapping characteristics with implications in management and prognosis.

Case Description: A 52-year-old male presented with several weeks of increasing shortness of breath, orthopnea, lower extremity edema, weight gain, and one week of hemoptysis one month after new onset gross hematuria. On arrival, he was hypertensive and hypoxic. Physical exam revealed 3+ lower extremity pitting edema, and bilateral pulmonary crackles. Labs revealed a creatinine (Cr) of 6.60 mg/dL (was 1.9 mg/dL one month prior), blood urea nitrogen of 72 mg/dL, and urinalysis with 3+ protein and 3+ blood. Urine microscopy revealed red blood cell (RBC) and muddy brown casts. Computed tomography of the chest revealed diffuse multi-focal airspace opacities. Serologic workup revealed elevated anti-myeloperoxidase (MPO)-ANCA of 99.2 U/mL and anti-GBM antibodies (Abs) of 40 U. The patient was initiated on hemodialysis by hospital day five and treated with pulse-dose steroids, IV cyclophosphamide, and initiated on plasma exchange for presumed anti-GBM disease. Renal biopsy revealed chronic smoldering ANCA-associated GN, but there was no linear staining to suggest anti-GBM disease. All glomeruli had segmental to focally global sclerosis. The patient ultimately remained dialysis dependent.

Discussion: About 30% of anti-GBM disease may have concurrent ANCA, and about 5-10% of ANCA-vasculitis may have concurrent anti-GBM Abs. ANCA and anti-GBM are distinct antibody populations, but their coexistence may be explained by initial ANCA-induced GBM injury, linear epitope exposure, and subsequent anti-GBM antibody formation. Double positive patients have anti-GBM phenotype early in disease course with aggressive disease at presentation and more alveolar hemorrhaging, and they have ANCA-vasculitis phenotype later in the disease course with higher risk of relapse but with better chance of recovery from hemodialysis. Double positive vasculitis is a hybrid disease phenotype that requires early aggressive treatment for anti-GBM disease but also demands careful long-term follow-up with strong consideration for maintenance immunosuppression for ANCA disease.

PUB555

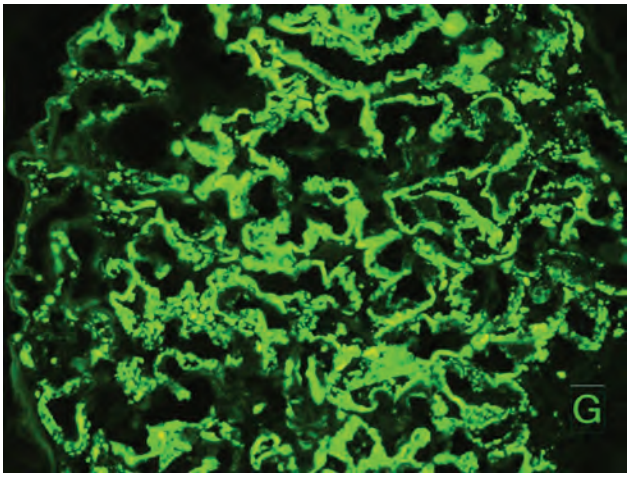
Hepatitis C-Associated Membranous Nephropathy: Key to Unlocking Podocytopathy?

Christopher H. Girgis, Krishna M. Baradhi. *Division of Nephrology, The University of Oklahoma - Tulsa, Tulsa, OK.*

Introduction: Membranous Nephropathy is typically associated with malignancy, infections, and idiopathic. Though the association with Hepatitis C and MN has been debated, there is growing amount of case reports in the medical literature to suggest this connection.

Case Description: A 54 year old white male with history of hypertension, pulmonary embolism, smoking and newly diagnosed HCV presented with anasarca and shortness of breath. Proteinuria was present without hematuria. Serum albumin was 1.8 with 22 grams of proteinuria on 24 hour collection. Direutics were started. Creatinine was 1.42 mg/dL on admission. 4 months prior, there were 9 grams of proteinuria and creatinine was 0.98 mg/dL. Lupus panel, cryoglobulin and HIV was negative. No diabetes mellitus. Renal biopsy was performed and diagnosed with Grade II Membranous Nephropathy with negative PLA2R staining. Given these findings, a diagnosis of MN associated with HCV was made. Statin, Vitamin D replacement, and an ACE inhibitor werer started. He was discharged with follow-up for treatment of Hepatitis C for hopeful resolving of the membranous nephropathy.

Discussion: Approximately 3% of the world population is infected with HCV. Membranoproliferative glomerulonephritis is most common pattern associated with HCV. Though still disputed as a direct cause, growing number of cases indicate strong association and further research must be emphasized on the mechanism of this virus at the glomerulus to which it causes this degree of proteinuria. Around 8.3 % of MN patients were HCV positive. The pathogenesis of MN may be related to the deposition of immune complexes containing HCV proteins in glomeruli. It is unknown how exactly Hepatitis C initiates at the glomerulus whether glomerulonephritis or podocytopathy. If future research can determine why certain processes only allow red blood cells as opposed to only albumin, these entities, through study of Hepatitis C, can provide the key to that question.



PUB556

Membranous Nephropathy and Malignancy: True, True and Unrelated

Rafael E. Rosario Amador, Steven D. Smith. *Icahn School of Medicine at Mount Sinai/St Luke's-Roosevelt Hospital Center, New York, NY.*

Introduction: Primary membranous nephropathy (MN) is associated with antibodies against the M-type phospholipase A2 receptor (PLA2R) on podocytes in 75-80% of cases with >99% specificity.

Case Description: A 71-year-old African American male presented with lower extremity edema and new-onset severe ascites. One year previously a colonic polyp was removed which was positive for invasive adenocarcinoma at which time he declined further surgical exploration and treatment. Large-volume paracenteses was negative for malignant cells with a Serum Ascites Albumin Gradient <1.1 (not suggestive of portal hypertension). Hospital course was complicated by lower extremity proximal deep vein thrombosis treated with anticoagulation (AC). Nephrotic range proteinuria (uPCR 10g/g) was found with serum creatinine 1.5 mg/dL, serum albumin 1.9 g/dL. His anti-PLA2R Ab measured by ELISA was very high x 2 (269 RU/mL, 711 RU/ml). The rest of the serologic proteinuria workup was negative and he was diagnosed with Primary MN. A renal biopsy was not performed given high bleeding risk. Treatment plan included RAAS blockade, continuation of AC and consideration of immunosuppressive therapy (IST) to mitigate severe and symptomatic nephrotic syndrome in consultation with oncology.

Discussion: Some experts have suggested that a renal biopsy is not required for diagnosis of primary MN in patients who present with anti-PLA2R Ab >20 RU/ml by ELISA with normal renal function and a negative work up for secondary causes. We suggest that this recommendation might be extended to patients such as this one despite an elevated creatinine and a condition well known to cause secondary MN (colon cancer). Prior to the advent of PLA2R Ab testing it has been thought that up to 20% of all cases of biopsy proven MN are secondary which may be an overestimation. Indeed, this case would have been classified as secondary MN in the past. Given the remarkable specificity of the PLA2R Ab at high levels it is more likely that this case represents primary MN in a patient who also happens to have a colon cancer. Interestingly, his entire presentation might have been explained by malignancy (ascites, DVT with hypercoagulable state) but nephrotic proteinuria which led to anti-PLA2R Ab testing allowed for the correct diagnosis of primary MN.

PUB557

Membranous Nephropathy Associated with Sjögren Syndrome, Primary Biliary Cirrhosis, and Autoimmune Hepatitis

Hisham N. Abu Farsak,[1] Barry M. Wall,[1,2] Geeta G. Gyamlani.[1,2] *[1]Nephrology, UTHSC, Memphis, TN; [2]Nephrology, VAMC, Memphis, TN.*

Introduction: Membranous nephropathy (MN) is an autoimmune glomerular disease with ~75% of cases are primary due to phospholipase A2 receptor antibody (PLA2RAb). MN may also be secondary to conditions such as autoimmune diseases, chronic infections, malignancy, and drug side effects.

Case Description: 63 year-old African-American female patient with a past history of Sjögren syndrome (SS), primary biliary cirrhosis (PBC), and autoimmune hepatitis, was referred to nephrology clinic for proteinuria. She was receiving azathioprine, hydroxychloroquine, and a tapering steroid regimen prior to seeing Nephrology. Serum creatinine was 0.6 mg/dL and urinalysis demonstrated protein (2+), negative for erythrocytes and leukocytes. She had non-nephrotic range proteinuria of 685 mg/g. Serologic studies were strongly positive for SS-A antibodies and also positive for anti-nuclear, anti-mitochondrial, and anti-smooth muscle antibodies, but negative for anti-dsDNA, anti-Smith antibodies, and PLA2RAb. Kidney biopsy revealed normal appearing glomeruli by LM. IF was for 3+ positive for coarsely granular deposits of IgG and IgA along capillary loops and mesangial regions and 2+ for C3 and 1+ for C1q. PLA2RAb staining was negative. EM showed numerous small subepithelial and rare mesangial electron dense deposits, features consistent with secondary MN.

Discussion: MN accounts for up to one-third of biopsied cases of nephrotic syndrome. Most cases of primary MN are due to PLA2RAb. Secondary causes of MN include autoimmune diseases, infection, drugs, and malignancy. Our patient developed secondary MN in association with multiple autoimmune related conditions, including SS, autoimmune hepatitis, and PBC. The combination of SS with kidney and liver involvement in one entity is extremely rare. Patients with SS can present with renal involvement of diverse etiology with chronic tubulointerstitial nephritis (TIN) with mild proteinuria and tubular dysfunction being the most common finding, followed by acute TIN. However, glomerular disease due to immune complex deposition, has been rarely described in SS and PBC. Renal involvement often goes unrecognized until significant renal dysfunction occurs. The renal lesions in SS can improve significantly with treatment, emphasizing the importance of early diagnosis with renal biopsy and aggressive treatment.

PUB558

Fibrillary Glomerulonephritis and Hashimoto Thyroiditis

Nirpeksh Jain,[1] Pramodh Chanumolu,[2] Tanmayee Benjamin,[1] Siddhartha Kattamanchi.[1] *[1]Marshfield Medical Center, Marshfield, WI; [2]Marshfield Clinic, Marshfield, WI.*

Introduction: FGN, a rare primary glomerular disease. Most previously reported cases were idiopathic. Underlying malignancy, dysproteinemia, or autoimmune diseases are not uncommon in patients with FGN. No fibrillary GN case report was found in association with Hashimoto thyroiditis.

Case Description: 41 y/o F of Micronesian descent. Recent URI, gestational DM and pre-eclampsia w/ SOB, found to have an acute onset grade III AKI & nephrotic syndrome requiring dialysis. Family hx- nephew w/ ESRD of unknown etiology; currently on dialysis. UA- 3+ protein, no RBC, no granular casts. ESR- 101, CRP- 2.1, mildly elevated LDH. Negative strep antibody, Cryoglobulins, HIV screening, ANCA panel, glomerular basement membrane antibody, Hepatitis panel and Double stranded DNA antibody. Monoclonal workup negative. ENA panel positive for SmRNP ab. Normal C3, mildly elevated C4 levels. Normal renal U/S. **Biopsy-** 75 glomeruli, 90% of the glomeruli globally sclerosed. Mesangial hypercellularity, expanded matrix and thickened capillary basement membranes. A single glomerulus with epithelial crescent. Hyaline deposits within capillary loops and mesangium. Interstitium with inflammatory infiltrate (3+), of lymphocytes, plasma cells and neutrophils. Medium and large-sized vessels with marked myointimal sclerosis (3+). **Immunofluorescence-** non-specific deposits of IgM, C3, and C1q (2+). **Electron microscopy-** Thickened capillary basement membranes, focal loss of foot processes, isolated intramembranous deposits and large sub-endothelial/ mesangial fibrillary deposits. **Fibrillary deposits with thickness of 20.0 nm.** CT chest- Multiple right thyroid nodules. No malignancy on Abd/pelvis CT and mammogram. **FNA thyroid- "Cellular Changes Consistent With Lymphocytic (Hashimoto's) Thyroiditis". Therapeutic Intervention-** Considering observation of an active crescent, initially was given 3 doses of 1g Methyl prednisone and was discharged on prednisone taper. Now dialysis dependent.

Discussion: Association with autoimmune disorders and exact pathogenesis of the disorder is unclear. Further case series of such cases might indicate an association between autoimmune disorders and Fibrillary GN.

PUB559

Clinicopathological Features of Hypocomplementemic Urticarial Vasculitis with Renal Involvement: A Case Series

Raluca Leparau,[1] Marina F. Paraschiv,[1] Bogdan Obrisca,[1,2] Bogdan M. Sorohan,[1,2] Sonia Balanica,[1] Roxana A. Jurubita,[1,2] Andreea G. Andronesi,[1,2] Gener Ismail.[1,2] *[1]Nephrology, Fundeni Clinical Institute, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.*

Introduction: Hypocomplementemic urticarial vasculitis (HUV) is a small vessel vasculitis with renal involvement in up to 50% of cases and heterogeneous clinical presentation. Given the rarity of this clinical entity, there is uncertainty about the clinical picture, treatment response and outcome, so additional data is warranted. Therefore, we report a case series of patients with HUV and nephrotic syndrome.

Case Description: The first patient was admitted in our department for oliguria, generalized edema and recurrent urticarial lesions. Laboratory testing showed acute kidney injury (serum creatinine 5,96 mg/dl), nephrotic syndrome (proteinuria 6 grams/24h) with active urinary sediment, while immunological work-up revealed antiC1q-antibodies and hypocomplementemia. She received immunosuppressive therapy with methylprednisolone and cyclophosphamide, without clinical response, remaining on chronic hemodialysis. The second patient presented with generalized edema and gross haematuria. Laboratory data confirmed renal impairment (serum creatinine 4.29 mg/dl), nephrotic syndrome (proteinuria 7 grams/24h) and important hematuria; immunologic results revealed antiC1q-antibodies and hypocomplementemia. Kidney biopsy was consistent with a membranoproliferative (MPGN) pattern of injury with diffuse crescent formation. After treatment with methylprednisolone, cyclophosphamide and plasma exchange, she achieved complete immunological and clinical remission. The third patient, with a past medical history of type 1 diabetes mellitus, was evaluated for generalised edema and recurrent urticarial lesions. Similar to previous cases, laboratory testing showed nephrotic syndrome (6.4 grams of proteins/24h), positive antiC1q antibodies, decreased complement levels, while renal function was preserved. Renal biopsy described a MPGN pattern with crescent formation, superimposed on a class III diabetic nephropathy. Despite cyclophosphamide and Rituximab treatment, she is still immunologicaly active and nephrotic.

Discussion: HUV is an unusual cause of nephrotic syndrome in adults. Our case series could add significant insight into the management and evolution of these patients.

PUB560

Early Appearance of HIV-Associated Nephropathy During Seroconversion

Joy M. Underwood,[2] Chris Pasvantis,[2] Hunter K. Huston.[3,1] *[1]UT Nashvile, Nashville, TN; [2]University of Tennessee, Nashville, TN; [3]Nephrology Associates, Nashville, TN.*

Introduction: HIV-Associated Nephropathy is a collapsing form of FSGS typically later in HIV infection of patients of African descent. We submit a case of early HIVAN presenting during seroconversion, with rapid decline in GFR requiring hemodialysis, that improved with initiation of HAART.

Case Description: A 27-year-old African American man presented with 2 months of chills, aches, and 25lb weight loss, and recent MSM. Initial labs included creatinine of 2.1, albumin 3.3, and 4+ protein on dipstick. Urine protein:Cr was 3.8, HIV serologies were positive, and CD4 count was 617. HAART was initiated, and renal biopsy obtained hospital day 3. Biopsy revealed focal and segmental glomerulosclerosis with early collapsing features, reticular aggregates, podocyte effacement, and diffuse tubular injury, consistent with HIVAN. Serum BUN and creatinine reached 135 and 12.4 respectively, prompting initiation of hemodialysis. At discharge, proteinuria had improved, though creatinine remained elevated at 6.8.

Discussion: HIVAN was first considered an AIDS-defining illness. Increasing number of cases occurring early in HIV have since been documented. Our patient's flu-like symptoms, CD4 count of 604, and high viral load were consistent with a recently seroconverted HIV infection. During seroconversion, the virus replicates in tubular and glomerular epithelial cells causing the biopsy characteristics seen in HIVAN: interstitial inflammation, microcystic tubular dilation, and sclerosing multiplication of glomerular cells. Rapid development of heavy proteinuria in early HIV, as seen in our patient, should prompt high-suspicion of HIVAN. Early renal biopsy should be performed as to not delay initiation of appropriate suggested therapies. Evidence for or against these therapies were garnered primarily from cohort studies and expert opinion. However, HAART therapy is recommended for all individuals found to be HIV positive as prompt initiation has been found to be associated with longer mean renal survival. ACE/ARBs are currently recommended for proteinuric patients. Steroids have been associated with improvements in proteinuria and decreased progression of baseline creatinine, and are recommended if there is rapid decline while on HAART. In this case, HAART was initiated and biopsy was obtained within seven days of last known normal renal function. A trial of steroids was begun, and renin-angiotensin inhibition was not added.

PUB561

Acute Tubulointerstitial Nephritis and Minimal Change Disease in a Patient with Allogenic Hematopoietic Stem Cell Transplant Complicated by Chronic Graft vs. Host Disease

Natalie Diaz-Cabrera,[1] Timothy M. Chow,[1] Sumit Gupta,[1] Elias Doumit,[1] Claude Bassil.[1,2] *[1]University of South Florida, Tampa, FL; [2]H. Lee Moffitt Cancer Center, Tampa, FL.*

Introduction: We present a case of adult-onset acute nephrotic syndrome (NS) due to minimal change disease (MCD) and acute tubulointerstitial nephritis (ATIN) following allogenic hematopoietic stem cell transplantation (allo-HSCT) and chronic graft versus host disease (GVHD).

Case Description: A 43-year-old male was referred to our nephrology clinic for evaluation of proteinuria and edema. He has a history of Hodgkin lymphoma treated with chemotherapy and mediastinal radiation followed by autologous HSCT complicated by relapsed disease requiring matched unrelated donor allo-HSCT. He developed acute GVHD following a rapid taper of tacrolimus which progressed to chronic GVHD. Patient had been off sirolimus for three months when routine labs showed serum albumin 2.5 g/dL compared to 4.1 g/dL two months prior. Urinalysis revealed protein levels greater than 500 mg/dL without hematuria or pyuria. Serum creatinine and blood urea nitrogen were 0.6 mg/dL and 12 mg/dL, respectively. Random urine protein to creatinine ratio was 7734 mg/g. His 24-hour urine protein was 7.1g and urine protein/creatinine ratio was 4.7. Additional laboratory results were negative for autoimmune, infectious, or

malignant etiologies. Light microscopy evaluation of a renal biopsy showed mild increase in glomerular mesangial cellularity and matrix deposition without endocapillary hypercellularity, segmental sclerosis, or cellular crescents. Focal interstitial inflammation was seen with an increased number of eosinophils. Immunofluorescence staining showed no specific pattern of antibody deposition. Electron microscopy showed uniform basement membrane thickening and 80% podocyte foot process effacement.

Discussion: NS is a rare complication following allo-HSCT associated with GVHD. Pathological etiologies include membranous nephropathy, thrombotic microangiopathy, and MCD, consistent with our findings. Our patient had a course of daily ibuprofen use for one month prior to presentation, which could account for his pathological findings of ATIN and MCD. Our case proposes the possibility of ATIN as an additional manifestation of renal GVHD. He was placed on oral prednisone with improvement of protein to creatinine ratio to 2.5 mg/g. Further studies will be required to identify the association between ATIN and renal GVHD.

PUB562

Membranoproliferative Glomerulonephritis Presenting with Overwhelming Cryoglobulin Deposition Masked by Acute Tubular Necrosis

Kostas Papamarkakis,[1] Gilbert W. Moeckel,[2] Peter S. Aronson,[3] Randy L. Luciano.[2] *[1]Yale University, New Haven, CT; [2]Yale University School of Medicine, New Haven, CT; [3]Yale School of Medicine, New Haven, CT.*

Introduction: This case highlights the importance of a thorough work up for acute renal failure, which includes determination of baseline renal function, temporality of renal insults with clinical history, urine sediment microscopy, and protein quantification. A low threshold for biopsy in the setting of active sediment, lymphadenopathy, and serologic markers can change management.

Case Description: The patient is a 46-year-old female with intellectual disability who presented with altered mental status and shock physiology, requiring resuscitation and pressor support. Her exam was pertinent for tachypnea, hypovolemia, bulky cervical lymphadenopathy, and a right knee effusion. She had anuric acute renal failure (BUN 67 and Creatinine 4.08, with normal renal function on outpatient labs 10-days prior). A urinalysis reported 4+ protein, 2+ blood. We obtained a spot urine total protein and creatinine, with a ratio of 38.17. Urine sediment by microscopy had florid coarse granular casts, tubular epithelial cells, and few non-dysmorphic RBCs. Retroperitoneal ultrasound was unrevealing. Renal replacement therapy was initiated for her presumed ATN. However, her lymphadenopathy, joint effusion, and severe proteinunria did not fit simple ATN. Serologies showed EBV IgM positivity with quantification log 2.96. She was otherwise Parvovirus, CMV, HIV, Hepatitis B&C negative. Quantiferon Gold, SPEP, IF and SFLC were also negative. Core biopsy of cervical node showed necrotizing and granulomatous lymphadenitis without malignancy. The patient underwent renal biopsy revealing lobular deposits in the mesangium, capillary loops, afferent arterioles, tubules, and Bowman's space. Small vessels contained fragmented RBCs and deposits with karyorrhexis. IF revealed 3+ C3, IgG and IgM. Supportive serologies included positive ANA, La, Ro, dsDNA, reduced C4 and normal C3.

Discussion: The patient's shock state could have distracted from the more ominous cause of renal failure. Anuric AKI due to ATN requiring RRT is not uncommon in critical care nephrology. Furthermore, lack of renal recovery leading to intermittent hemodialysis, likely would not necessitate secondary work up. It is important to have a suspicion for glomerular disease, especially in the setting of systemic findings that are associated with secondary causes of proteinuric renal failure.

PUB563

Scleroderma Renal Crisis with Subtle Clinical Signs in a Young Male

Ismaa Kiani. *Renal Medicine, University hospital Plymouth, Plymouth, United Kingdom.*

Introduction: A young man with unassuming scleroderma renal crisis with very subtle clinical signs. The reason this case is important from a renal prespective is atypical presentation of scleroderma renal crisis, it's a diagnosis not to be missed.

Case Description: A 43 year old man presented with history of headache and neck ache with nausea and vomiting for 6 weeks. Found to have high blood pressure with renal insufficiency. Systemic inquiry no history of oral ulcers, joint pain, rash, weight loss or features of Raynaud's phenomenon. Examination showed BP-180/100mmmHg with thicken skin over his hands. Differential diagnosis was hypertension leading to chronic renal failure, haemolytic uremic syndrome and scleroderma renal crisis. Initial investigations showed deranged renal function with features of thrombotic microangiopathy. Ultrasound kidneys-normal. ANA speckled patterns with 1:640 titres and rest of the autoimmune profile was normal. Renal biopsy : Consistent with features of thrombotic microangiopathy. Initially treated as HUS with 900mg of Eculizumab. His anti-RNA polymerase III came back as positive Our final diagnosis was scleroderma renal crisis based on renal biopsy, anti-RNA polymerase III positive, progressive renal failure with TMA and sclerodactyl of his hands.

Discussion: Our patient had atypical physical features of scleroderma and scleroderma renal crisis occurs in minority of such patients with anti-RNA polymerase III and ANA positive which is associated with an increased risk of developing scleroderma renal crisis. Our patient could fit in the criteria for systemic sclerosis sine scleroderma. Our patient was given eculizumab initially for suspected HUS but later stopped due the final diagnosis of scleroderma renal crisis. My question to the leading nephrologists at the conference would be if they have any experience in using eculizumab for scleroderma renal crisis as case reports are present which have advocated its use.

PUB564

A Case of Lupus Nephritis with Acute Tubulointerstitial Nephritis Presenting Multiple Low-Density Lesions on Contrast-Enhanced CT

Takahiro Yamano, Hiroyuki Kawahara, Shinya Hibino, Ryo Nishioka, Takeshi Zoshima, Satoshi Hara, Kiyoaki Ito, Ichiro Mizushima, Hiroshi Fujii, Mitsuhiro Kawano. *Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan.*

Introduction: Lupus nephritis (LN) usually involves glomeruli but sometimes involves the tubulointerstitium and contributes to renal dysfunction. However, there have been no case reports of the radiological abnormalities of tubulointerstitial lesions in LN. Here, we report a case of LN with acute tubulointerstitial nephritis(TIN) presenting with multiple low-density lesions on contrast-enhanced computed tomography (CT).

Case Description: A 27-year-old Japanese woman was admitted to our hospital due to a suspected flare-up of systemic lupus erythematosus(SLE). She had been diagnosed 2 years previously with SLEbased on malar rash and positivity for anti-nuclear, anti-ds-DNA, and anti-Sm antibodies, and treatment with prednisolone (PSL) 5 mg/day was initiated. She was transferred to our hospital 4 months ago because of fever, fatigue, left small malar rash, and renal dysfunction. Bilateral renal multiple low-density lesions were detected on contrast-enhanced CT. Her symptoms recovered spontaneously, so she was discharged under continued treatment with PSL at 20 mg/day. Three weeks ago, after tapering the PSL to 16 mg/day, joint pain, palmar and nail erythema, and fever appeared gradually, and she was re-hospitalized. A blood test showed a creatinine level of 0.91 mg/dL with no reduction in complement and no elevation of the anti-ds-DNA antibody level. Urinalysis showed a urinary protein level of 0.10 g/gCr, no microscopic hematuria, and no granular or erythrocyte casts. Contrast-enhanced CT revealed remaining bilateral renal multiple low-density lesions. Renal biopsy showed diffuse lymphoplasmacytic infiltration in the tubulointerstitium, indicating acute TIN. In the glomeruli, mesangial cell proliferation and endocapillary hypercellularity were observed with IgG- and C3-predominant deposition, leading to a diagnosis of LN ISN/RPS class III (A). The fever and joint pain were alleviated, and bilateral renal multiple low-density lesions disappeared when the PSL dose was increased to 30 mg/day.

Discussion: LN with acute TIN can present with bilateral renal multiple low-density lesions on contrast-enhanced CT. Tubulointerstitial lesions of LN should be considered as a differential diagnosis of renal multiple low-density lesions.

PUB565

C3-Dominant Post-Infectious Glomerulonephritis Occurring in a Patient with Methicillin-Susceptible Staphylococcus aureus Bacteremia

Stephen P. Regina,[1] Roberto L. Collazo-Maldonado.[2] Methodist Dallas Medical Center *[1]Methodist Health System, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: C3 glomerulopathies are a group of renal disorders characterized by complement dysregulation, and may represent a disease continuum. We present a case of C3-dominant post-infectious glomerulonephritis (PIGN) occuring in a patient with MSSA bacteremia who presented with AKI and nephrotic range proteinuria.

Case Description: This is a 48 year old man with history of poorly controlled type 2 DM and osteomyelitis of right great toe, s/p digital amputation, presenting with right foot swelling, pain, and erythema. Right foot exam notable for ulcerations but intact distal pulses. Admission sCr was 1.1. Admission blood cultures isolated MSSA in both sets, so patient was started on nafcillin. Echocardiogram did not show valvular vegetations. Podiatry was consulted and performed bone biopsies, which showed acute osteomyelitis. On hospital day 12, patient developed AKI with sCr 1.38 mg/dl, the following day trending up to 1.6 mg/dl. Urinalysis revealed 10-25 RBC, 5-10 WBC, and spot protein of 600 mg/dl, with 24 hour urine collection 10.4 g. Nephrology was consulted and autoimmune workup was negative with the exception of low serum C3 level. Renal biopsy revealed

C3-dominant immune complex glomerulonephritis superimposed on diabetic nephropathy. Electron microscopy revealed numerous mesangial electron-dense deposits and rare subepithelial deposits (humps). The epithelial foot processes show segmental effacement. Immunofluorescence showed 1+ segmental mesangial and pseudolinear glomerular staining for IgG, and 3+ global mesangial staining and segmental peripheral granular staining for C3, C1q was negative. The patient was treated with antibiotics with resolution of infection, normalization of kidney function and proteinuria, and normalization of complement levels.

Discussion: We present a case of C3-dominant PIGN. Renal biopsy should be performed in patients with presumed PIGN, who have abnormalities such as hypocomplementemia, progressive decline in renal function, or proteinuria. Electron microscopy findings can differentiate among subtypes of C3GN. In C3-dominant PIGN, the complement dysregulation is presumed to be transient or part of the recovery from infection. Treatment of infection should lead to improvement in renal function and normalization of serum C3 level. If the C3 level does not normalize, reclassification to C3 glomerulopathy is warranted.

PUB566

Full House on Immunofluorescence but No Lupus! Renal Limited Lupus-Like Nephritis

Faris Al faris, Emmanuelle Cordero Torres, Swati Mehta, Krishnakumar D. Hongalgi. *Albany Medical Center, Albany, NY.*

Introduction: Renal limited lupus-like nephritis is defined as kidney biopsy consistent with lupus nephritis (LN) without extra-renal organ involvement or positive serological markers for systemic lupus erythematous (SLE). This rare entity carries a poor prognosis. Data is limited on treatment options. We present a case of AKI with lupus-like nephritis "full house" pattern with negative serologies and absent extra-renal manifestations of SLE.

Case Description: A 55-year-old white male was originally hospitalized for sepsis with an unknown source. Blood cultures grew methicillin sensitive Staphylococcus aureus (MSSA). One week after admission, he developed acute renal failure. Pertinent labs include serum creatinine of 4.2, urine protein/creatinine ratio of 1144 mg/g, serum albumin of 2.1g/dl, negative ANA, anti-DNA antibodies, a weakly positive cANCA, pANCA, and low complement levels. HIV, hepatitis B and C virus serologies were negative. Renal biopsy showed a diffuse and global glomerulonephritis with a full house staining pattern on immunofluorescence microscopy, consistent with lupus nephritis class IV-G (A). His renal function continued to deteriorate requiring hemodialysis. The patient remained dialysis dependent and died within 6 weeks of initial presentation.

Discussion: In SLE, presence of renal involvement is significant for prognosis and treatment. There have been case reports of renal biopsy findings consistent with LN without extra-renal organ involvement or serologies sufficient to diagnose SLE at the time of biopsy. These cases were labeled in the literature as "renal limited lupus-like nephritis." They have been sub grouped into 3 categories: early presentation of SLE, seronegative lupus, and renal limited lupus like nephritis. Renal limited lupus like nephritis cases have no clinical manifestations, remained seronegative after years of follow-up, and had a worse prognosis compared to patients with SLE and seronegative LN. Infection associated GN has been reported to mimic renal limited lupus like nephritis on kidney biopsy. We need more research to help guide management in this rare and complicated disease condition.

PUB567

Microscopic Polyangiitis Presenting with Acute Abdominal Pain

Waqas Memon,[2,1] Muhammad S. Afzal.[3] [1]*Nephrology, Virginia Commonwealth, Richmond, VA;* [2]*Internal Medicine, Carle Foundation Hospital, Champaign-Urbana, IL;* [3]*Carle foundation hospital, Champaign, IL.*

Introduction: ANCA associated vasculitis is a small vessel vasculitis that includes granulomatosis vasculitis, Churg-Strauss syndrome, microscopic polyangiitis. We describe a patient of microscopic polyangiitis, who presented with abdominal pain, and acute kidney injury.

Case Description: A 69-year-old female with a past medical history of hypertension, and heart failure presented with right-sided abdominal pain and fatigue. On examination, she was afebrile, with a blood pressure of 166/72 mm/hg. Positive exam finding included mild right-sided abdominal tenderness on palpation. Laboratory testing revealed leukocytosis 19.10 10(3)/mcL, hemoglobin of 8.1 g/dL. Blood urea nitrogen (BUN) 85 mg/dL, and creatinine of 4.56 mg/dL. Urine analysis revealed 3+ blood and, 2+ protein. 24-hr urine protein was significant with 971 mg/24 hour. Computed tomography scan of the chest revealed chronic obstructive pulmonary disease (COPD) changes along with a right basilar infiltrates. Further laboratory workup revealed P-ANCA with a titer of 1:160. She was diagnosed with microscopic polyangiitis (MPA) based on the involvement of the lower respiratory tract, kidneys, gastrointestinal tract, along with a positive P-ANCA. During the hospital course, the patient required hemodialysis. After kidney biopsy, she was started on glucocorticoids. She required plasmapheresis followed by Rituximab. Eventually, the patient was transferred to a long term acute care hospital for further rehabilitation.

Discussion: MPA is an autoimmune systemic vasculitis that is associated with antineutrophilic cytoplasmic antibodies. These antibodies play a role in the pathogenesis, initially, neutrophils attach to endothelial surface of blood vessels and glomeruli with subsequent activation. Renal involvement is seen in more than 80% of cases and it can present as symptomatic urinary sediment and end-stage renal disease. The lungs are involved in up to 50% cases and present with diffuse pulmonary hemorrhage. Skin lesions are found in 30-60 % of patients and palpable purpura is the most common manifestation. Most common gastrointestinal symptoms are abdominal pain. Gastrointestinal bleeding can also occur in some cases but catastrophic hemorrhage is rare. When diagnosing a patient, ANCA is detected in 50-70% of cases and its absence does not rule out disease. Treatment primarily includes glucocorticoids but cyclophosphamide, azathioprine, and rituximab have been used.

PUB568

Systemic Lupus Erythematosus During Treatment of Autoimmune Hepatitis and Primary Biliary Cirrhosis

Miharu Kawanishi, Hirotaka Sonoda, Yuki Hoshino, Asuka Yamauchi. *Shimane University Faculty of Medicine, Izumo, Shimane, Japan.*

Introduction: The complication of systemic lupus erythematosus(SLE) with autoimmune hepatitis(AIH) and primary biliary cirrhosis(PBC) is very rare. We report a case developed SLE during treatment of AIH PBC.

Case Description: A 50-year-old woman had been receiving treatment for type 2 diabetes mellitus since 201X-10. There was no decline in her renal function, and her urinary protein(Up) tested negative. She was admitted with liver dysfunction in January 201X-7. Liver biopsy was performed, resulting in a diagnosis of AIH and PBC. Up gradually progressed from January 201X. She was admitted to our department in April 201X. Renal biopsy was performed. Twenty-six glomeruli were collected, and 18 of them had lesions. There were many chronic lesions, and more than 50% of the glomeruli were noted. In renal pathology studies, IgG, IgA, IgM, C3, C4, and C1q tested positive by the fluorescent antibody technique. During a serological examination, antinuclear antibody and ds-DNA antibody tested positive, and the patient was diagnosed as having lupus nephritis type IV(G)(C) based on the Systemic Lupus International Collaborating Clinics(2012) and International Society of Nephrology/Renal Pathology Society(2003). She began 60 mg of oral prednisolone(PSL) treatment. Proteinuria improved from 2.03 g/day at the start of treatment to 0.42 g/day on the 22nd hospital day. PSL dose was reduced to 50 mg/day. Then, Up tended to gradually increase, and pancytopenia was also observed during the same time. We considered the possibility that disease activity was high; therefore, mycophenolate mofetil 1 g/day was started and increased to 2 g/day. The Up level was slightly exacerbated with PSL dose reduction but leveled off at 0.7-0.9 g/day and then did not change with PSL dose reduction.

Discussion: The complication of SLE with AIH and PBC is very rare. A previous study demonstrated that autoimmune disease accounts for only 4.7% of cases of liver enzyme elevation in SLE patients. On the other hand, liver enzyme elevations are often accompanied by SLE; 50% of SLE patients have liver enzyme elevations. Therefore, it is very important to differentiate causes of liver enzyme elevations in SLE patients. The complications of SLE and AIH or SLE and PBC are relatively rare; however, AIH, PBC, or complications of AIH and PBC should be considered if liver disease is found in SLE patients.

PUB569

Pauci-Immune Crescentic Glomerulonephritis with Re-Initiation of Adalimumab for Crohn Disease

Robert C. Hartley, Sarah Gilligan, Nirupama Ramkumar, Christof Westenfelder, Laith Al-Rabadi, Martin C. Gregory, Adhish Agarwal, Monica P. Revelo Penafiel, Josephine Abraham. *University of Utah, Salt Lake City, UT.*

Introduction: Inflammatory bowel disease (IBD) is associated with a number of renal disease processes most commonly nephrolithiasis, IgA nephropathy and interstitial nephritis. Certain tumor necrosis factor alpha (TNFa) inhibitors, which are commonly used for treatment of IBD, have been rarely associated with pauci immune crescentic glomerulonephritis (PICG). We present a unique case of PICG in the setting of re-initiation of adalimumab (TNFa inhibitor) in a patient with Crohn's disease (CD)

Case Description: A 40-year-old woman presented with CD flare and abdominal pain, nausea, vomiting, poor oral intake, an intermittent pruritic rash and gross hematuria. She was treated with a steroid taper and re-initiation of adalimumab. On initial evaluation she was hypertensive with diffuse abdominal pain. Laboratory evaluation was notable for a serum creatinine for 3.6 mg/dL up from a baseline for 0.8 mg/dL, hematuria and proteinuria of 6.6 g/g. Serologic studies including ANA, MPO, PR3, hepatitis B and C and anti-GBM were negative. Complement C3 and C4 were normal. Imaging showed perinephric stranding and a small non-obstructing stone. Patient was treated with steroids, adalimumab, and IV fluids. Serum creatinine peaked at 5.8 mg/dL and then trended down and patient was discharged home with close renal follow up. She was readmitted with recurrent abdominal symptoms and a worsening serum creatinine and underwent a renal biopsy six weeks after initial evidence of acute kidney injury. Pathology showed PICG. She was treated with rituximab and an intensified steroid regimen. For her CD, she was transitioned from adalimumab to vedolizumab (an oral monoclonal antibody with gut selective anti-inflammatory activity) due to concern that adalimumab contributed to her PICG. At last follow up her serum creatinine was down trending but had not returned to normal.

Discussion: The TNFa inhibitors infliximab and etanercept have a rare association with PICG and in renal biopsy case series of patients with a history of IBD PICG has been reported. However, the association of adalimumab with ANCA negative PICG in this case is unique in the literature and may represent an under recognized etiology of glomerulonephritis in IBD.

PUB570

Immunotactoid Glomerulopathy in a Patient with Monoclonal B-Cell Lymphocytosis: A Rare Finding

Obiajulu Kanu,[1] Vimal K. Derebail,[2] Harsharan K. Singh,[2] Catherine C. Coombs,[2] Manish K. Saha.[3] *[1]UNC Hospitals, Nephrology, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]UNC Kidney Center, Chapel Hill, NC.*

Introduction: Monoclonal B-cell Lymphocytosis (MBL) and glomerular diseases are a rare association. We present an unusual case of an adult male who developed nephrotic syndrome and was found to have immunotactoid glomerulopathy secondary to MBL.

Case Description: A 54-year-old male with history of well-controlled hypertension on lisinopril was evaluated for significant bilateral leg swelling. Laboratory evaluation was remarkable for 24-hr proteinuria of 8g/day, eGFR of 85 ml/min/1.73m^2, and serum albumin 2.5g/dl. Autoimmune serologies, serum free light chains, serum immunoelectrophoresis, and imaging studies of the thorax and abdomen were unremarkable. Renal biopsy showed thickened capillary walls by light microscopy with IgG2 kappa monoclonal glomerular capillary wall deposits by immunofluorescence microscopy. Electron microscopy showed widespread foot process effacement and intramembranous deposits with a microtubular substructure, organized in parallel bundles, and measuring ~25nm in diameter. Flow cytometry of the peripheral blood showed very low-level clonal lymphocytes (1.4% of circulating white blood cells; 128 cells/microliter). Bone marrow aspiration revealed CD5-positive B-cell lymphoid proliferation with predominantly small lymphoid cells comprising 20% of marrow cellularity with a phenotype most compatible with MBL. The patient was started on bendamustine and rituximab (BR). After 6 cycles of BR regimen, repeat bone marrow biopsy showed 0.01% involvement and clinical symptoms improved with reduction in proteinuria to 1.6gm, normalization of serum albumin and preserved renal function.

Discussion: Immunotactoid glomerulopathy is characterized by glomerular capillary and/or mesangial organized deposits with a microtubular substructure. 40-50% of patients develop end stage renal disease within few years of diagnosis, underscoring the need for early diagnosis and treatment. Our case in a patient with MBL highlights the importance of evaluation for an underlying lymphoproliferative disorder with appropriate imaging studies, peripheral flow cytometry and bone marrow biopsy even in the absence of a peripheral paraproteinemia. An early target-directed therapy towards B-cell or plasma-cell clone may result in preservation of renal function.

PUB571

Membranous-Like Glomerulopathy with Masked IgG Kappa Deposits

Rhyan Maditz,[1,2] Jonathan J. Taliercio.[1,2] *[1]Cleveland Clinic, Cleveland, OH; [2]Glickman Urological and Kidney Institute, Cleveland, OH.*

Introduction: Glomerulonephritis is pathologically diagnosed by examining changes using light, immunofluorescence, and electron microscopy of the renal biopsy. Routine direct immunofluorescence on fresh tissue is consider the gold standard for the detection and characterization of immune deposits. An additional antigen retrieval step has recently been defined to unmask immunoglobulin visualization utilizing pronase digestion.

Case Description: 33-year-old female with a past medical history of three pregnancies presented to nephrology clinic for evaluation of proteinuria. During her second and third pregnancies she developed proteinuria. During her second pregnancy, a 24-hour urine collection revealed 0.53 grams of protein. During her third pregnancy, a 24-hour urine collection revealed 1.99 grams of protein. She never experienced hypertension or preeclampsia. Three months after her last delivery, her proteinuria persisted and was measured at 2 grams per day. Serologies returned positive for ANA and low C3. Renal biopsy performed and resulted with convincing membranous alterations and presence of extensive deposits by electron microscopy with immunofluorescence staining for C3 and C1q. The biopsy was sent for paraffin immunofluorescence. Staining returned positive for IgG segmental to global granular subepithelial deposits that stain 2+ Kappa. Proteinuria decreased to 500 mg per day without treatment. Renal function remained intact with a baseline creatinine of 0.8. Initiation of MMF +/- prednisone was discussed but to due improvement of proteinuria and intact renal function, the decision was made to continue conservative therapy by assessing proteinuria every three months.

Discussion: Routine immunofluorescence is considered the gold standard for detection of protein in kidney biopsies. Light-chain proximal tubulopathy crystalline inclusions in the proximal tubule occasionally do not react with immunofluorescence. Without unmarking of the immunoglobulin with pronase, many patients may be incorrectly labeled as C3 glomerulonephritis, a disease with C3-restricted deposits that can show predominance of subepithelial deposits by electron microscopy. Membranous-like glomerulopathy should be considered in all patient with unexplained proteinuria in the setting of autoimmune disease.

PUB572

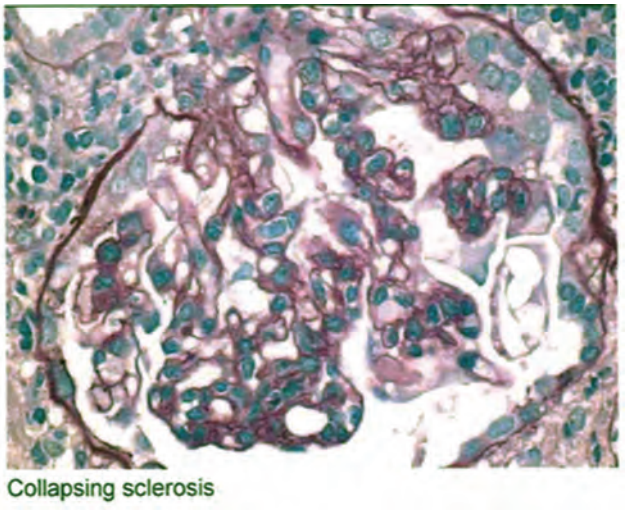
Lupus-Mediated Kidney Damage: Lupus Nephritis or Collapsing Glomerulopathy?

Hitesh Gurjar, Angel De la cruz tejada, Rabih Nasr. *BronxCare Health System, Bronx, NY.*

Introduction: Lupus nephritis is a well-known entity and treatment options for it are clearly defined. However, Lupus nephritis with collapsing glomerulopathy (CG) is less common and pose special challenges in terms of management

Case Description: 47-year-old Hispanic female presented with chills, epigastric discomfort and lower extremity edema for 10 days. 1-2+ bilateral lower extremity pitting edema found on examination. Labs revealed Normocytic anemia, hyperlipidemia, hypoproteinemia. Creatinine of 6.3 mg/dl Marked proteinuria. UPCR 17 g/g. Hypocomplementemia present. ANA titers 1:40. Anti-dsDNA, ANCA, anti SM and RNP negative. **Renal biopsy:** collapsing glomerulopathy superimposed on focal glomerulonephritis, immune complex type, suggestive of lupus podocytopathy **superimposed** on lupus nephritis class III. **Treatment:** patient treated with IV pulse Methylprednisolone 1g for 3 days and Cyclophosphamide 500 mg IV, and then Prednisone 80 mg daily. Creatinine levels improved from 6.3 mg/dL (first creatinine levels reported, on July/4/2018) to 2.8 mg/dL (on August/25/2018).

Discussion: Reports of SLE-related CG with Lupus Nephritis are lacking. The patient described in this case report has both findings. In the largest series of cases with biopsy-proven CG in the setting of SLE or SLE-like disease, Salvatore et al, showed that only 7 patients (out of 19) had morphologic changes of lupus nephritis along with CG findings. To the best of our knowledge, fewer than 25 cases have been reported about this specific finding. For the treatment of Lupus Nephritis class III/IV, the immunosuppressive treatment consists on induction and maintenance phases. As per the guidelines of the American College of Rheumatology, induction therapy should consist of steroids combined with mycophenolate or cyclophosphamide, for about 6 months. Rationale to use cytotoxic drug like cyclophosphamide in such cases is because these variants have progressive and relentless course.



PUB573

Progressive Multifocal Leukoencephalopathy: A Devastating Complication of Immunosuppression

Natacha Rigual soler,[1] Swati Mehta,[3] Loay H. Salman,[2] Mauricio Monrroy.[2] *[1]Nephrology, Albany Medical College, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Albany Medical College, Rensselaer, NY.*

Introduction: Progressive multifocal leukoencephalopathy (PML) is a rare demyelinating disease of the CNS caused by reactivation of the polyomavirus JC. Primary infection is asymptomatic, JC virus remains latent in the kidneys and lymphoid organs. Reactivation and lytic infection of olygodendrocytes may occur in immunosuppressed individuals. Hematological malignancies, transplant recipients and several drugs have been associated to it. We describe a case of PML during the use of Mycophenolate mofetil (MMF).

Case Description: 69 year-old man with creatinine (sCr) of 1.5mg/dL, HTN, and COPD, referred to us for AKI with sCr of 2.6 mg/dL. He was found to have proteinuria 4.5 g/g by spot ratio, dysmorphic RBCs, P-ANCA titer of 640, anti-MPO of 147 CU and anti-DsDNA of 59 IU/mL. Kidney biopsy showed Lupus Nephritis Class III. Induction of remission was achieved with Cyclophosphamide plus steroids with stabilization of renal function and resolution of hematuria after 3 months. Maintenance therapy started with MMF 1 gr. twice a day plus steroids. Clinical course was complicated by C. difficile diarrhea, and two episodes of GI bleed. Refractory anemia was treated with blood transfusions and erythropoietin (EPO) therapy. MMF was decreased to 500 mg BID to avoid myelosuppression. Twelve months into MMF therapy he developed new-onset motion sickness and diplopia, physical exam revealed orientation only to person, optic ataxia and ocular motor apraxia. Brain MRI showed several areas of white matter hyperintensity mainly in both parietal lobes and corpus callosum. PCR of CSF confirmed JC virus (> 2 million copies/mL). MMF was stopped and treatment with mefloquine and mirtazapine was initiated without any improvement. He was transitioned to hospice 31 days after diagnosis.

Discussion: This case reveals the devastating effects of JCV reactivation in patients undergoing immunosuppressive therapy for renal disease, even at doses considered low according to currently accepted guidelines. Cases of recovery of PML have been reported after immune reconstitution with withdrawal of the involved drug. Regretfully, already debilitated patients due to age and other comorbidities will likely not respond to this measure. Treatment with different drugs has been attempted but the success is mostly anecdotal. Pembrolizumab has been recently reported with promising results.

PUB574

IgA Nephropathy Causing Rapidly Progressive Glomerulonephritis

Neil Rangwani,[1] Mansur Assaad,[1] Rupesh Raina.[2] *[1]Summa Health Akron City Hospital, Akron, OH; [2]Cleveland Clinic, Akron General Medical Center, Brecksville, OH.*

Introduction: Although IgA nephropathy (IgAN) is the most common cause of glomerulonephritis worldwide, this condition is seldom reported as a cause of rapidly progressive glomerulonephritis (RPGN). Furthermore, it is not commonly reported as a cause of glomerulonephritis in African Americans. IgAN can rarely present as a more aggressive RPGN, and patients may display different degrees of renal dysfunction, hypertension, edema, and proteinuria. Prompt renal biopsy is often needed in these patients, as management often differs depending on the underlying pathology.

Case Description: A 26-year old African American male with no prior past medical history presented with acute-onset shortness of breath, cough, and musculoskeletal chest pain. Lab work was indicative of a new acute kidney injury with a creatinine of 4.02 mg/dL and notable proteinuria with a urine microalbumin-creatinine ratio of 7.5 mg/g. The patient was admitted, and the nephrology team was consulted. Further lab work showed a negative ANA level, negative ANCA titer, normal C3 and C4 levels, negative HIV screen, negative hepatitis panel, normal plasma aldosterone-renin activity ratio, and normal plasma metanephrine level. Although urinary free kappa light changes and free lambda light chains were notably elevated, the free kappa-lambda light chain ratio was within normal limits. Renal biopsy revealed IgA-mediated immune-complex glomerulonephritis with marked arteriosclerosis and glomerulosclerosis. He received high-dose intravenous (IV) methylprednisolone and IV bumetanide. The patient improved significantly and was discharged on a prolonged prednisone taper. The patient later started immunomodulatory therapy with mycophenolate mofetil for his biopsy-proven rapidly progressive IgA crescentic glomerulonephritis.

Discussion: Rapidly progressive crescentic IgA nephropathy is rare, and there are few reported cases showing evidence of progression to end-stage renal disease (ESRD) with variable response to immunosuppression. Current data suggests that renal survival in cases of rapidly progressive crescentic IgAN is 50% at one year and 20% at five years. There is only recently published data supporting the use of high-dose corticosteroids and immunomodulator therapy in patients with crescentic IgAN. Although a rare cause of RPGN, IgAN should be considered, and kidney biopsy should be pursued early so as to not delay appropriate renal-saving therapy.

PUB575

ANCA-Associated Glomerulonephritis with Linear GBM Staining in the Absence of Anti-GBM Antibody: A Variant of Double-Positive MPO and Anti-GBM Antibody

Janis Cho,[2] Yashpal S. Kanwar,[1] Vikram Aggarwal.[2] *[1]Northwestern University Medical School, Chicago, IL; [2]Northwestern University - Feinberg School of Medicine, Chicago, IL.*

Introduction: Anti-glomerular basement membrane antibody disease (Anti-GBM) is a rare disease with severe renal-pulmonary manifestation. About 10-38% of patients with anti-GBM nephritis also has positive ANCA at the time of diagnosis, most often P-ANCA. They are termed double positive and has different prognosis and outcomes. Recently, there has been described patients with renal biopsies with linear GBM immunoglobulin staining without detectable anti-GBM antibodies. Such diagnosis is termed atypical anti-GBM disease. We present a case with features of both atypical anti-GBM disease overlap with ANCA-associated vasculitis (AAV).

Case Description: A 70 year old Indonesian male with past medical history of vitiligo, chronic kidney disease, hypertension, and prostate cancer with recent radiation treatment was hospitalized for management of overt hematuria and acute kidney injury. He had nephritic presentation and no evidence of obstructive nephropathy. Kidney biopsy showed 40% crescentic glomeruli, necrotizing glomerular lesions, 20% sclerosis and tubular atrophy, few small subendothelial deposits on electron microscopy, and linear GBM reactivity with anti-IgG on immunofluorescence. Serology showed negative Anti-GBM antibody, positive P-ANCA antibody 1:160 and MPO antibody elevated to 21.4. He had no pulmonary manifestations. He received high dose steroid, 6 doses of plasmapheresis and rituximab. He was discharged with tapering steroids and received repeat rituximab in 2 weeks. At 3 month, creatinine improved to nadir 2.08 mg/dl and started azathioprine for maintenance therapy.

Discussion: Our patient had linear IgG staining consistent with Anti-GBM disease without anti-GBM antibody (Atypical anti-GBM disease) overlap with P-ANCA positivity. While overlap of typical anti-GBM disease and AAV has been described, co-existence of atypical anti-GBM nephritis and AAV as a variant is rarely reported. The overlap syndromes with double positive antibodies (anti-MPO and anti-GBM) has a distinct clinical phenotype needing better understanding of pathogenesis, recognition of specific epitope, classification, prognostication and different treatment strategies. Recently, anti-peroxidasin antibodies disrupting collagen structure of GBM and cross-reacting with MPO have been identified and can help elucidate such overlap syndromes.

PUB576

Successful Maintenance Treatment of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits with Low-Dose Steroids

Timothy M. Chow, Natalie Diaz-Cabrera, Octavio Chavez, John Paul Rosales, Claude Bassil. *University of South Florida, Tampa, FL.*

Introduction: We present the first known case of relapsed proliferative glomerulonephritis with monoclonal immunoglobulin deposits successfully treated with two courses of high dose prednisone followed by Rituximab and finally maintained in full remission on low dose corticosteroid therapy.

Case Description: A 58-year-old male with nephrotic-range proteinuria and hypertension was referred to nephrology for evaluation. Labs showed serum creatinine 1.2 mg/dL, albumin 2.7 gm/dL, and urine protein to creatinine ratio of 5.9 mg/g. Work-up was unremarkable including urine/serum protein electrophoresis with immunofixation, serum kappa/lambda ratio, and complement levels. Skeletal bone survey, bone marrow biopsy, and positron emission tomography-computed tomography were negative for evidence of malignancy. Kidney biopsy was pursued. Light microscopy revealed diffuse proliferative glomerulonephritis with prominent membranoproliferative features. Immunofluorescence showed subendothelial deposits positive for IgG-kappa and C3 and negative for IgG-lambda and IgM. IgG subtype stains were positive for IgG3. Findings were consistent with proliferative glomerulonephritis with monoclonal immunoglobulin deposits. Immunosuppressive therapy with high dose oral prednisone was begun. Proteinuria improved from 7.8 to 1.3 g/day but progressed upon tapering. Given the risk of disease progression he was treated with a four-week course of weekly rituximab infusions with 20 mg oral prednisone daily. Proteinuria improved from 8.9 g/day pre-infusion to 4.7 g/day two months after completion of infusions. Prednisone was then tapered to 2.5mg, but proteinuria persisted at 2.2 g/day. Prednisone was increased to 5mg. Over the next year the proteinuria gradually resolved to less than 0.2 g/day. Serum creatinine ranged from 1.1 to 1.3 mg/dL and microhematuria resolved. He has remained on this dose for two years with continued clinical remission.

Discussion: Treatment of PGNMID is undetermined but generally consists of immunosuppressive therapy with rituximab, high dose corticosteroids, bortezomib, or cyclophosphamide. We present the first reported case of successful clinical remission of relapsed PGNMID following induction with rituximab and maintenance therapy with low dose oral prednisone.

PUB577

Invasive Acanthamoeba Amoebiasis Mimicking Granulomatosis with Polyangiitis

Samuel J. Peeples,[1] Manish K. Saha,[2] Vimal K. Derebail,[3] Paul B. Googe.[3] University of North Carolina Kidney Center *[1]University of North Carolina Health Systems, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Invasive Acanthamoeba Amoebiasis is rare and often fatal; typically affecting immunocompromised patients involving the central nervous system, skin, and nasopharynx.

Case Description: Our patient is a 52 year old female with history of MALT lymphoma in remission and recently diagnosed granulomatosis with polyangitis (GPA) presenting with sepsis. Months before presentation she developed extensive necrotic skin lesions of the nasopharynx, arms, and legs. Skin biopsy suggested ANCA vasculitis with negative serologies and IFA. Her GPA treatment included steroids, methotrexate, and cyclophosphamide without improvement of lesions. Hypogammaglobinemia was diagnosed 1 month prior, concerning for common variable immunodeficiency (CVID) given history of recurrent sinusitis and low IgG/IgA. At presentation, she endorsed worsening skin lesions, was febrile, tachycardic, and had lactic acidemia. She was started on broad spectrum antibiotics for presumed superinfection of skin lesions with otherwise negative infectious work up. Repeat skin biopsy demonstrated cutaneous amoebiasis. On re-review of original skin biopsies it was felt that cutaneous symptoms may have been from tissue-invasive amoebiasis leading to severe inflammation mimicking vasculitis. Biopsy samples were sent to the CDC and demonstrated amoebic trophozoites for Acanthamoeba species. She was started on anti-Amoeba regimen including: Miltefosine, fluconazole, oral and topical sulfadiazine, IV pentamidine, flucytosine, and topical ketoconazole. Unfortunately she deteriorated over several weeks eventually experiencing multi-organ failure. Family decided to focus on the patient's comfort and she expired. It remains unclear why she developed disseminated Acanthamoeba amoebiasis but it is hypothesized she was susceptible due to CVID; possible exposures included well water and swimming in North Carolina lakes.

Discussion: Invasive Amoebiasis is rare and can be difficult to distinguish from GPA as both have a predilection to involve the nasopharynx and can be confused with vasculitis on histopathology. In immunocompromised patients with nasopharyngeal and skin lesions with biopsy suggestive of vasculitis, invasive amoebiasis should also be considered.

PUB578

Parvovirus B19: Does It Cause Kidney Disease? A Case Presentation and Review of the Literature

Katharine Hegerty,[1,2] Timothy C. Badrick,[3] Jagadeesh Kurtkoti.[4,2] *[1]Nephrology, Gold Coast University Hospital, Gold Coast, QLD, Australia; [2]Faculty of Medicine, Griffith University, Gold Coast, QLD, Australia; [3]Infectious Diseases, Gold Coast University Hospital, Gold Coast, QLD, Australia; [4]Gold Coast University Hospital, Southport, QLD, Australia*.

Introduction: Parvovirus B19 (HPVB19) is a DNA virus linked to multiple clinical syndromes and has been linked to glomerular disease. Here we present a rare case of acute HPVB19 infection and unexplained end stage kidney disease with literature review.

Case Description: A 20 year-old-male presented to an Australian teaching hospital with 3 weeks of nausea and vomiting, confusion, headache, diarrhoea, fevers, abdominal rash and pleuritic chest pain. He was hypertensive at 190/135mmHg with sinus tachycardia of 118bpm. He had a pericardial rub and saddle ST-elevation on ECG. Echo-cardiogram confirmed a moderate-sized pericardial effusion. His creatinine was 1930 umol/L with urea 61.4 mmol/L. Haemoglobin was 68g/L with platelets of 246 x10^9/L and an MCV of 84fL. Blood film and haemolysis screen were unremarkable. ADAMTS-13 was normal and a glomerulonephritis screen was negative. Urine PCR was 642 g/mol creatinine with 60 leucocytes x 10^6/L and 40 erythrocytes x 10^6/L. The patient was commenced on haemodialysis. Renal biopsy showed a mesangio-proliferative pattern. There was severe tubular atrophy and interstitial fibrosis, moderately severe arteriosclerosis and arteriolosclerosis and a chronic inflammatory infiltrate. Arterioles showed features of acute thrombotic microangiopathy. Immunofluorescence was non-specific. Electron microscopy revealed foot process effacement and tubuloreticular inclusions. Parvovirus particles were not seen. Persistent anaemia prompted HPVB19 serology with an initial negative test. However, 3 weeks later the IgM and IgG titres were elevated. HPVB19 DNA was detected in renal biopsy tissue on PCR. After 3 months, he showed no evidence of renal recovery.

Discussion: 10 cases have been reported with an acute illness associated with HPVB19 serum positivity for IgG and IgM, renal disease and renal tissue DNA PCR positivity. 2 patients had an FSGS lesion with the remaining 9 demonstrating endocapillary glomerulonephritis. A consistent correlation between PCR positivity for HPVB19 on renal tissue and renal disease has not been proven. This was a rare case of end stage kidney disease, fever, anaemia and pericarditis associated with acute HPVB19 infection. This work adds to the body of knowledge describing the potential for HPVB19 associated glomerulopathy in our patients.

PUB579

A Case of TAFRO Syndrome Associated with Membrano-Proliferative Glomerulopathy and Rescued from Dialysis Therapy by Use of Tocilizumab

Momoko Sekiguchi, Yuta Kogure, Minoru Hatano, Takatsugu Iwashita, Yu Shimozato, Akira Kurosawa, Maiko Yamasaki, Tomonari Ogawa, Koichi Kanozawa, Hajime Hasegawa. *Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan*.

Introduction: TAFRO syndrome is a rare disease of unknown etiology characterized by Thrombocytopenia, Anasarca, Fever with systemic inflammation, Reticular fibrosis in bone marrow and Organomegaly or lymph node swelling. TAFRO is occasionally accompanied by renal involvement leading to endstage renal failure, however, renal histopathology is rarely confirmed because of life-threatened rapid progression and thrombocytopenia. Here, we report a case of TAFRO syndrome showing membrano-proliferative glomerulopathy-like glomerular findings.

Case Description: An 80-year-old man was admitted to a local hospital because of high fever, anemia, bleeding tendency and systemic edema from 1 month prior to the admission to our hospital. He received RBC transfusion and diuretics administration, however, he rapidly developed renal failure requiring dialysis therapy on the 7th hospital day. After transferred to our hospital, he received 1 g of prednisolone (PSL) for 3 consecutive days with continuous hemodialysis, and TAFRO syndrome was suspected because of systemic inflammation and sever thrombocytopenia ($2x10^4$ per μL). The diagnosis was confirmed by lymph node biopsy showing hyaline-vascular finding similar to Castelman's disease and remarkable elevation of interleukin-6 and vascular endothelial growth factor. His clinical condition was apparently ameliorated by maintaining administration of PSL 30 mg a day, and his dialysis therapy was discontinued at the 67th hospital day. At that time, renal biopsy revealed membrano-proliferative glomerulopathy with slight tubulo-interstitial damage. Following PSL withdrawal, his renal function and proteinuria was worsened again. By this reason, Tocilizumab 400 mg was administered and repeated every 2 weeks. After start of Tocilizumab, his clinical condition was ameliorated again and stabilized. He was finally discharged on the 152nd hospital day.

Discussion: TAFRO syndrome usually become sever rapidly without renal biopsy, and clinical benefit of Tocilizumab is not generally established. Our case might be a valuable index to consider the mechanism of renal involvement and the clinical management.

PUB580

Pauci-Immune Crescentic Glomerulonephritis Associated with Multiple Myeloma: Case Report

Pedro Alejandro V. Galván,[2] Johnatan Ayala-Bejar,[1] Hernesto Hernandez,[2] Benjamin Gomez-Navarro,[2] Claudia A. Mendoza Cerpa,[2] Miguel Medina Perez,[2] Alejandro Pimentel.[2] *[1]Instituto Mexicano del Seguro Social, Guadalajara, Mexico; [2]IMSS Hospital de Especialidades Centro Médico Nacional de Occidente, Guadalajara, Mexico*.

Introduction: Crescentic glomerulonephritis (CGN) includes rapidly progressive glomerulonephritis (RPG) signified by sudden loss of renal function associated with crescent formation. Antineutrophil cytoplasmic antibodies (ANCA) associated vasculitis is the most frequent etiology and refers to a necrotizing glomerulonephritis without immune deposits by immunofluorescence (IF) but circulating ANCA antibodies. Multiple myeloma (MM) is a malignant proliferation of monoclonal plasma cells in the blood with frequent kidney damage. The coexistence of the ANCA-associated vasculitis (AAV) and MM is rare.

Case Description: We present a patient with renal biopsy by rapidly progressive glomerulonephritis. The diagnosis was AAV after histopathological examination but at the same time, the MM diagnosis was done. A 65 years old man presented with progressive edema since 5 days and weight loss with fatigue and low back pain since 3 months. No medical antecedents. The serum creatinine level at hospital admission was 1.8mg/dl. After 48 hours presented reduction in urine volume, increase of edema and dyspnea, and a rise of serum creatinine level to 3mg/dl. The diagnosis of RPG was done and started hemodialysis. The 24-h proteinuria was 2.7g, hematuria with 14% of acanthocytes, blood urea nitrogen was 41mg/dl, serum albumin was 1.9g/dl and serum globulin was 4.7g/dl; complement levels and antinuclear antibodies were normal. Serum IgG was 3210mg/dl and p-ANCA was positive. Renal ultrasound revealed increased size of kidneys. We perform renal biopsy and 11 glomerulus were obtained, 5 with crescentic lesions. Congo red staining was negative and IF analysis noted only intratubular cast with IgA positive staining. Besides, monoclonal protein was found by serum protein electrophoresis and bone marrow aspiration was performed and showed plasma cells count of 18%, diagnosing MM. The patient was diagnosed with AAV coexisting with MM, based on the ANCA titer, CGN and rapid loss of renal function.

Discussion: Hematological malignancies are the most common type of cancer coexistent with vasculitis, however MM is infrequent and simultaneous diagnosis is less common yet. Elderly patients should be screened for AAV and MM on the occurrence of unexplained renal failure.

PUB581

Diabetic Ketoacidosis and Atypical Hemolytic Uremic Syndrome: An Unlikely Pairing

Ibrahim Khambati,[1] Neda Shahoori,[1] Ramesh M. Kotihal.[2,1] *[1]Orange Park Medical Center - HCA Healthcare, Jacksonville, FL; [2]Nephrology Associates of NE Florida, Orange Park, FL*.

Introduction: Atypical hemolytic uremic syndrome (aHUS) is an extremely uncommon, life-threatening illness, characterized by the triad of microangiopathic hemolytic anemia (MAHA), thrombocytopenia, and acute kidney injury. Diabetic ketoacidosis (DKA) as a result of new-onset Type II diabetes mellitus has never been described as an initial presentation of aHUS.

Case Description: A 31-year old African American male with no past medical history presented with altered mental status. Four days prior to admission, the patient returned from a trip to Belize, where he exhibited new-onset polyuria, polydipsia, polyphagia and severe nausea. Initial assessment was consistent with DKA. Patient was also found to have acute kidney injury secondary to pre-renal azotemia. Four days into admission, clinical course deteriorated: patient developed MAHA (hemoglobin-6.9 g/dL & lactate dehydrogenase-3452 units/L), a drop in platelet count with schistocytes (260 to 18 K/cmm) and worsening kidney function; evolving from pre-renal azotemia to acute tubular necrosis with anuria. Despite initiation of hemodialysis, kidney function did not markedly improve (BUN-111 mg/dL & serum creatinine-12.20 mg/dL). This prompted renal biopsy which revealed thrombotic microangiopathy (TMA), cortical infarct and collapsing glomerulopathy. The differential diagnosis of TMA can include thrombotic thrombocytopenic purpura, Shiga-toxin-producing Escherichia coli hemolytic uremic syndrome and aHUS. As ADAMTS13 activity was normal (59%) and stool culture was negative for Shiga-toxin, a diagnosis of aHUS was made. Treatment was initiated with plasmapheresis in conjunction with IV eculizumab. Within five days of treatment, patient's condition improved and he was discharged home with outpatient hemodialysis.

Discussion: Prior to FDA approval of eculizumab, aHUS proved to be fatal in a large percentage of patients despite optimum known medical management (i.e. plasmapheresis). Even with eculizumab use, most aHUS patients develop end-stage renal disease and undergo chronic dialysis. Our patient due to early detection and initiation of the above, demonstrated normalization of kidney function and was able to come off hemodialysis 6-months post-discharge. This case highlights DKA as an atypical initial precipitant of aHUS and the importance of early eculizumab use for treatment in hospitalized patients over plasmapheresis alone.

PUB582

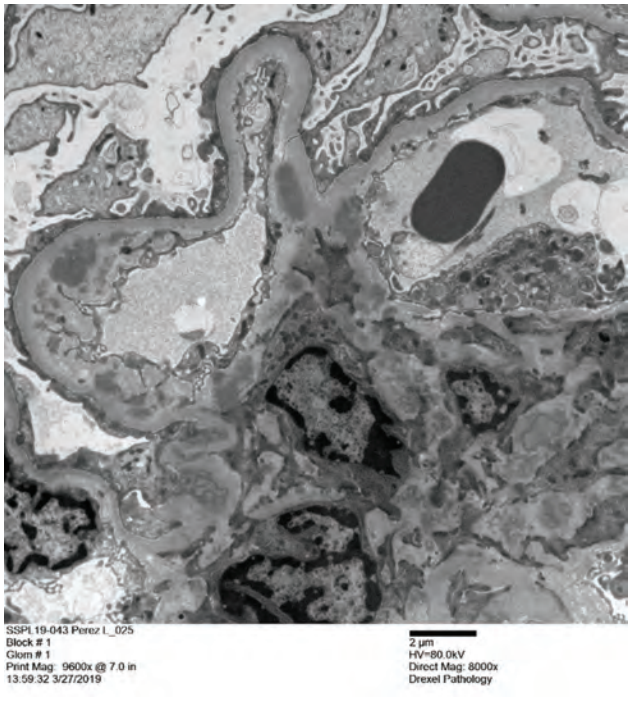
A Rare Case of Isolated IGA Nephropathy Without Granulomas Associated with Neurosarcoidosis

Siddique Akbar,[1] Sandeep Aggarwal,[2] Suganthi Soundararajan,[1] Jaime A. Baynes-Fields,[1] Tarig Elraiyah.[1] *[1]Drexel University, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA.*

Introduction: Systemic sarcoidosis associated with a variety of glumerular and interstitial lesions. We present an interesting case of neurosarciososis with concomitant IgA nephropathy without renal granulomas

Case Description: 40 years old Hispanic male with past history of, anemia, CKD stage 3 presented to hospital with, left sided facial droop and reduced visual acuity in the left eye. He reported, weight loss and night sweats few weeks prior. CT chest, abdomen and pelvis which showed diffuse nonspecific lymphadenopathy, head and neck imaging was unrevealing. Pertinent labs ACE level =97 unit/L (normal range 14- 82 units/ L) Quatiferon negative,. Patient was started on oral steroids. Lymph node Biopsy - reactive changes with non- necrotizing granuloma. He was diagnosed as neurosarcoidosis. Patient presented a month later with progressive lower limbs edema and AKI. Patient admitted he had not been compliant with his medications (oral steroids). Creatinine on admission = 2.5 mg/d l(baseline 1.7mg/dl), Urine protein to creatinine ratio was 3.5 g/ 24hours. Renal biopsy was performed. Renal biopsy showed LM- hypertensive nephropathy, focal Nephrosclerosis and mesangial hypercelkularity, IF was 3+ for IgA. EM showed mesangial and subendothelial electron dense deposits, diffuse foot process effacement (fig2). Patient was started on IV and oral diuretics, Oral Steroid treatment was restarted with improvement in creatinine to 2.0 mg /dl, edema and proteinuria.

Discussion: Sarcoidosis has been asoosicated with a myriad of glomerular and interstitial lesions. The epidemiological and biological factors affecting the phenotype of renal involvement in sarcoidosis need larger studies including renal biopsy, proteomic, metabolomics and genomic profiling of such patients.



PUB583

Hepatitis C Membranoproliferative Glomerulonephritis (MPGN) with Histologic Features Resembling Lupus Nephritis (LN)

Bo Yu, Hanning You, Duncan B. Johnstone, Iris J. Lee. *Temple University School of Medicine, Philadelphia, PA.*

Introduction: We discuss a case of hepatitis C (HCV) membranoproliferative glomerulonephritis (MPGN) with biopsy findings consistent with lupus nephritis (LN) in a patient without clinical and immunological criteria for systemic lupus erythematous (SLE). These findings posed both a diagnostic and treatment dilemma. Treatment by immunosuppression versus anti-viral medication hinged on a final diagnosis.

Case Description: A 50-year-old African American male with a history of, hypertension and HCV presented with anasarca, 6.9 grams proteinuria and a serum creatinine of 0.8mg/dl. ANA, anti-dsDNA, Smith, RNP, rheumatoid factor, cryoglobulin, and HIV were negative. C3, C4, CBC, and LFTs were normal. HCV viral load was 2.6 million copies. Kidney biopsy showed MPGN and immunofluorescence (IF) revealed C1q, C3 with full house staining for IgG, IgA, and IgM. Electron microscopy demonstrated mesangial, subendothelial, and subepithelial immune complex (IC) deposits along with 80% podocyte effacement. The biopsy appeared consistent with class III+V LN, but our patient lacked clinical and immunologic criteria for SLE. Despite biopsy features of LN, immunosuppression was not initiated. HCV was treated with Mayvert, resulting in a sustained viral response. Six months after viral clearance, proteinuria improved to 2 gms/gm on spot ratio, ANA remained negative and creatinine was stable at 1.2 mg/dL.

Discussion: In HCV MPGN, IC deposits are typically restricted to the subendothelial and mesangial compartments and are of the IgG class. Full-house IF staining is a pathognomonic feature of LN, but was observed in our patient who lacked criteria for SLE. Reports of full-house nephropathy with negative serologies for SLE exist. Conditions with the potential for polyclonal B cell expansion, such as HCV and HIV, can result in IC formation and staining patterns mimicking a "lupus-like" IF. This is seen with more frequency in HIV IC kidney disease or HIVICK, but rare for HCV. In our case, despite a biopsy suggesting class III+V LN, progression of disease was not observed and proteinuria improved without immunosuppression. Clinical context helped to avoid immunosuppression and target appropriate therapy against his HCV.

PUB584

Overlap Syndrome of IgA Nephropathy with Dense Deposit Disease

Shruti Kore,[1] Jay A. Pandav,[2] Savneek S. Chugh,[3] Sanjeev Gupta.[4] *[1]Westchester Medical Center/New York Medical College, Pleasantville, NY; [2]Westchester Medical Center, Valhalla, NY; [3]New York Medical College, Hartsdale, NY; [4]Westchester county medical center, Hartsdale, NY.*

Introduction: Dense deposit disease (DDD) also known as membranoproliferative glomerulonephritis (MPGN) type II, is a rare presentation of C3 glomerulonephrits (GN). Renal biopsy is required to diagnose DDD, with the pathognomonic feature being dense deposits along the GBM revealed by electron microscopy (EM) with strong positive Immunofluorescence staining for C3 in glomerular capillary loops. Overlap of C3GN or DDD with other GN is rarely reported. Here we present a very rare case of DDD overlapping with features of IgA nephropathy.

Case Description: A 33-year-old female with no past medical history, with normal previous two pregnancies presented with new onset proteinuria of close to 1gm during the end of her third trimester in her third pregnancy; complicated by post-partum pre-eclampsia for which she was started on anti-hypertension medications. She had persistent proteinuria and underwent kidney biopsy. EM showed mesangial ring forms and sausage-like intramembranous immune deposits which are classic features of DDD. Immunofluorescence showed 3+ staining for C3 in glomerular capillary loops and 3+ staining for IgA in mesangium. The distribution of IgA deposits were purely mesangial, which was confirmed by pronase immunofluorescence, supporting an additional diagnosis of IgA nephropathy. Serum creatinine at that time was normal and she had a UPCR of 3158 mg/g. She was subsequently managed with ACE inhibitor and started on prednisone 60 mg daily. Because of predominant DDD lesions and slowly declining renal function, she is currently being managed on the lines of C3GN.

Discussion: Nephrotic range proteinuria can present in advance stage of IgA nephropathy however it is also reported in overlap syndrome especially with minimal change disease or membranous nephropathy. To our knowledge, overlap of IgA with DDD has not been reported in the literature and our case is a rare co-existence. Although the patient has IgA deposits, it is the DDD which is primarily responsible for worsening kidney function. We think that these patients should have full work up for DDD as treatment may be challenging.

PUB585

Epstein-Barr Virus Associated Hemophagocytic Lymphohistiocytosis Syndrome and Collapsing Focal Segmental Glomerular Sclerosis

Walaa S. Dabbas, Lakshmi K. Pathak. *Nephrology, University of Illinois, College of medicine, Chicago, IL.*

Introduction: Collapsing glomerulopathy is a distinct and aggressive clinicopathologic variant of FSGS. Here is an case of collapsing FSGS in the setting of the diagnosis of Hemophagocytic Lymphohistiocytosis secondary to acute EBV infection.

Case Description: A 46 year old AA male with PMH of HIV, Hypertension, asthma, CKD was admitted with flu-like symptoms including headache, fever, cough, vomiting and diarrhea. Exam was significant for fever and hepatosplenomegaly. laboratory tests were significant for a pancytopenia, elevated liver enzymes and elvated creatinine. Renal US showed increased echogenicity. UA revealed Protein 500 mg/dl, RBC 3/hpf, WBC 3/hpf. 24hrs urine protein 3.8 gms. Serology including ANA, ANCA, and Anti GBM were negative. C3 and C4 normal. HepB and Hep C were negative. CT chest, abdomen and pelvis showed multiple bilateral centrilobular nodules within lung bases measuring & diffuse lymph nodes. Mediastinal mass biopsy reported Lymphohistiocytic infiltrates with focal granulomatoid features and rare atypical cells. Bone marrow biopsy reported hypo cellular bone marrow with focal trilineage hematopoiesis, mild erythroid hyperplasia and prominent histiocytic proliferation in loose clusters with erythrophagocytosis, consistent with lymphohistiocytic hemophagocytosis Patient was diagnosed as Hemophagocytic Lymphohistiocytosis secondary to EBV infection (viral load 75.077 copies/ml). The renal biopsy showed Focal segmental glomerulosclerosis (FSGS, collapsing type). Global glomerulosclerosis with diffuse interstitial fibrosis and tubular atrophy involving 50% of the cortex and acute tubular necrosis. Patient was initiated on hemodialysis due to uremic symptoms. Treatment for HLH was initiated with chemotherapy. He was discharged from hospital on thrice weekly dialysis

Discussion: Collapsing glomerulopathy may occur either idiopathic or in association with many infectious and inflammatory conditions. There are some case reports linking glomerulopathies associated with EBV. Demonstration of viral protein with in glomerular cells found in some cases suggesting that the glomerular injury could be a collateral effect of the viral driven inflammation. EBV infection causing hemophagocytic lymphohistiocytosis is a potentially fatal syndrome characterized dysregulation of immune activation.

PUB586

Polyautoimmunity Syndrome with Renal Involvement: Kaleidoscopic Presentation of a Systemic Syndrome

Eduardo Guerrero,[1] Diego F. Argudo sanchez,[1] Laura C Fuentes-Mendez,[1] Virgilia Soto,[2] Maribel Merino,[3] Juan C. Trimino.[1] *[1]Hospital General de Mexico, Mexico City, Mexico; [2]INC Ignacio Chavez, Mexico City, Mexico; [3]Instituto Nacional de Cardiologia, Distrito Federal, Mexico.*

Introduction: Polyautoimmunity is defined as the presence of more than one autoimmune disease; few publications emphasize kidney damage and its treatment. We present the case of a patient with polyautoimmunity syndrome and renal affection by three autoimmune diseases.

Case Description: 40-year-old female with history of systemic lupus erythematous diagnosed in February 2015, without renal involvement during follow-up. In May 2018 she complained of fatigue, generalized hyperpigmentation and thickening of the skin, Raynaud's phenomenon, followed by sclerodactyly and gastric reflux. In December 2018 she consulted rheumatology service, who diagnosed Sjögren Syndrome (dry mouth/eye symptoms, salivary gland biopsy, positive Schirmer test and anti-Ro elevation) and systemic scleroderma (thickening of skin on hands, telangiectasias, Raynaud's phenomenon, anti-topoisomerase II positive); after an arrangement to nephrology clinic because of serum creatinine of 2.24 and proteinuria in 24 hours of 1.2gr, a kidney biopsy was performed and revealed glomerulonephritis consistent with class II lupus, active tubulointerstitial nephritis with plasma cells and acute tubular injury, chronic glomerular hypoperfusion, grade II interstitial fibrosis, obliterative arteriolopathy, changes attributable to Sjögren's syndrome and scleroderma. Treatment was started on mycophenolate mofetil due to the risk of renal sclerodermic crisis. Currently, the patient reports clinical improvement and proteinuria decreased to 0.7gr/gr.

Discussion: Our case reports the renal affection of three autoimmune pathologies with different temporality and therapeutic approach. The difficulty lies in the treatment of renal disease with contraindication to the use of steroids for the treatment of tubulointerstitial nephritis due to risk of renal sclerodermal crisis. Likewise, the treatment of proteinuria with ACEI or ARB II is complex due to the probable masking of the aforementioned crisis.

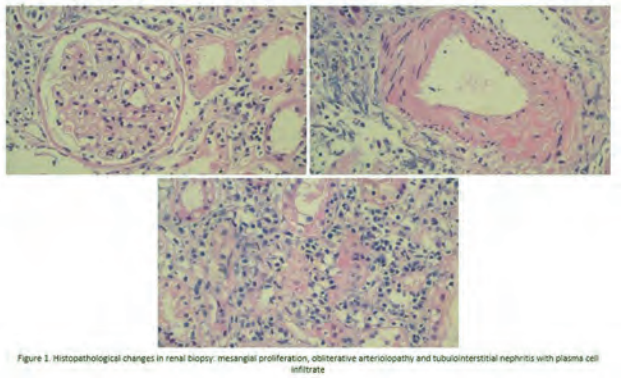


Figure 1. Histopathological changes in renal biopsy: mesangial proliferation, obliterative arteriolopathy and tubulointerstitial nephritis with plasma cell infiltrate

PUB587

Efficacy and Safety of Sofosbuvir Plus Simeprevir as Therapy for HCV-Associated Glomerulonephritis: Report of Two Cases

Raissa M. Arruda,[1] Andrea D. Batista,[1] Norma A. Filgueira,[1] Izolda M. De moura,[2] Luis H. Sette,[1] Edmundo P. Lopes.[1] *[1]Universidade Federal de Pernambuco, Recife, Brazil; [2]Universidade Federal de Pernambuco, Jaboatão dos Guararapes, Brazil.*

Introduction: HCV patients with glomerulopathies were treated, initially, peg-interferon (PEG-IFN) associated with ribavarin (RBV), but this therapy have been induced serious side effects and low sustained virologic response (SVR). The new direct-acting antivirals (DAAs) treatment are been considered revolutionary antiviral therapy, leading to infection cure in more than 90% of patients. Since 2016 new reports have emerged using DAAs in HCV-associated glomerulopathies but there are still few reports.

Case Description: Patient 1 - male, 41 year-old, with diagnosis of chronic HCV infection associated with glomerulopathy admited in 2016 with nephrotic syndrome with anti-HCV and HCV-RNA positive (viral load of 2,064,684 UI/mL and log 6). He was treated with SOF (400 mg/day) plus SIM (150 mg/day) for 12 weeks, evolving with normalization of aminotransferases normalizations and HCV-RNA negativity at the end of treatment and after 12 weeks (SVR), cryoglobulinemia negativity and significant proteinuria reduction. **Patient 2 –** male, 50 year-old, was diagnosed 24 years ago with HCV infection prior to blood donating. He lost outpatient follow-up and returned in 2005, when genotype 1b infection was identified. He had no response to PEG-IFN plus RBV and in 2014, he presented with thrombocytopenia, nephrotic syndrome, C3 and C4 consumption, cryoglobulinemia positive. In 2016, he was treated with SOF plus SIM for 12 weeks, evolving with transaminases normalization, HCV-RNA negativity at the end of treatment and after 12 weeks, cryoglobulinemia negativity and significant reduction of proteinuria. **Baseline and after treatment examens shown in Table.**

Discussion: This report describes two cases of HCV related Glomerulopathy with cryoglobulinemia treated with SOF plus SIM therapy showing no significant side effects and improvement hepatic and renal diseases.

Clinical and Laboratory Characteristics of Patientes Before and After Treatment with Sofosbuvir plus Simeprevir

	Patiente 1		Patiente2

PUB588

Collapsing Glomerulopathy Superimposed on Diabetic Nephropathy: A Case Series

Pooja Sadvidya. Manipal Institute of Nephrology and Urology *Nephrology, Manipal hospital, Bangalore, India.*

Introduction: Diabetic Nephropathy is the leading cause of End Stage Renal Disease (ESRD) in many countries. 35-45% of both Type-1 and Type-2 diabetic patients develop ESRD in 20-35 years. Some patients present with new onset nephrotic range proteinuria and detriorating renal functions. Renal biopsy showed non-diabetic glomerular leision in 10-12%. The development of collapsing glomerulopathy in the background of diabetic nephropathy is a very rare phenomenon. We present a case series of 6 cases of Collapsing Glomerulopathy superimposed on Diabetic nephropathy.

Case Description: The average age of our patients was 55years. All 6 patients had history of long standing Type -2 Diabetes Mellitus - average of 15 years. Baseline serum creatinine in 3 of them was in the range of 1.8 -3.5 mg/dl. The clinical presentation and indications for renal biopsy were: 2 patients had severe breathlesness due to volume overload requiring ICU care, 3 patients had worsening oedema and uncontrolled blood pressures, 1 patient had new onset hypertension and pedal oedema. All patients had nephrotic range proteinuria. 4 patients had severe renal failure at presentation and were initiated on dialysis. 2 patients had a serum creatinine of 2.4 mg/dl and 1.8mg/dl. Renal biopsy showed collapsing glomerulopathy superimposed on diabetic nephropathy. 1 had class IIb, 1 had class III, and 4 had class IV diabetic nephropathy. 3 biopsies had Interstitial fibrosis and Tubular atrophy (IFTA) more than 50%. All biopsies showed arterial hyalinosis. 4 patients who presented with severe renal failure were declared as ESRD and were continued on hemodialysis. 2 patients were in CKD stage 3 at presentation, progressed to ESRD by next 2 years and later underwent renal transplant.

Discussion: Collapsing Glomerulopathy contributes to an increased level or a new onset proteinuria in Diabetic nephropathy. This is usually intractable and rapidly progresses to End Stage Renal Diasease (ESRD). Collapsing Glomerulopathy in Diabetic nephropathyis presumbly due to ischemic podocyte injury and is of prognostic significance.

Patient no.	Age	Sex	Duration of Diabetes	Hypertension	Baseline s.creatinine	Baseline proteinuria	Indication for biopsy	S.creatinine at presentation	24 hour proteinuria	follow up duration	outcome
1	67 y	male	10 y	no	NA	1+	volume overload and ICU care	13 mg/dl	8 g	1 year	Dialysis dependent
2	39 y	male	10 y	yes	1.8 mg/dl	4+	worsening pedal oedema	5.7mg/dl	6 g	1 year	Dialysis dependent

From Membranous Nephropathy to Proliferative Glomerulonephritis with Monoclonal IgG1 Kappa Deposits: A Pediatric Case

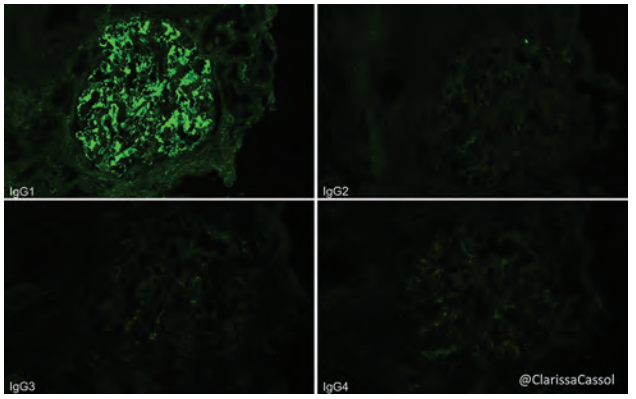
Rasha Alawieh,[1] Clarissa A. Cassol,[2] Priyamvada Singh,[1] Isabelle Ayoub.[1] *[1]Department of Internal Medicine, Division of Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH; [2]Department of Pathology, The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is a rare entity described mainly in adults with only 6 reported cases under 20 years of age. It is characterized by monoclonal immunoglobulin deposits in the kidney which can mimic immune complex glomerulonephritis. Histologic patterns described are membranoproligerative or endocapillary proliferative with membranous features. IF stains most commonly for IgG3 Kappa and EM reveals granular non-organized deposits. Dysproteinemia is detected in 30% of cases. This case illustrates the challenge of diagnosis of PGNMID in a young girl with primary membranous nephropathy (pMN).

Case Description: A 19- year old woman with pMN was transferred from the pediatric to the adult nephrology clinic with anasarca. At 13 years of age she was found to have nephrotic syndrome secondary to biopsy proven MN. The urine PCR was 4g/g. She received prednisone then a calcineurin inhibitor then rituximab without clinical response. A repeat biopsy three years later showed membranous like glomerulopathy with monoclonal IgG1 kappa deposits. Pronase digestion was not done. She was maintained on conservative therapy with RAAS blockade. Repeat work-up was significant for 24h urine PCR 10g/g, serum albumin 2g/dl, Scr up to 1.5mg/dl, + speckled ANA (1:320), negative serum PLA2R antibody. A third kidney biopsy showed PGNMID IgG1 kappa (**Figure 1**).

Serum free light chain K/L ratio was 1.09, SPEP and UPEP with immunofixation were negative for M-spike. Bone marrow biopsy with flow cytometry showed only a few polytypic plasma cells and the matrix-assisted laser desorption/ionization-time of flight mass spectrometry test for monoclonal protein was negative. She is being treated with bortezomib and dexamethasone.

Discussion: PGNMID can occur in children and young adults. It is unclear whether MN with IgG1 kappa is an early manifestation of a slowly progressive PGNMID IgG1 kappa. Repeat kidney biopsies may be of help in such scenarios.



PUB590

Secondary Syphilis-Associated Crescentic Glomerulonephritis

Marcelo S. Sampaio,[1,2] Jonathan E. Zuckerman,[3] Grigoriy Shekhtman,[1,2] Mandana Rastegar,[1,2] Richard M. Treger,[1,2] Glenn T. Nagami.[1,2] *[1]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]Nephrology Division, David Geffen School of Medicine, Los Angeles, CA; [3]Dept of Pathology & Lab Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Introduction: Syphilis-associated nephropathies are uncommon. Membranous nephropathy (MN) is the most well-recognized while crescentic glomerulonephritis (CGN) is rare. We report the second case in the literature of secondary syphilis-associated CGN.

Case Description: A 71-year-old male was admitted with shock and oliguric acute kidney injury with a serum creatinine of 3.89 mg/dL (baseline 1 mg/dL). He reported having a skin rash preceded by a transient painless penile lesion. Urine sediment showed dysmorphic RBCs, abundant WBCs, muddy brown and coarse granular casts. Urine protein/creatinine ratio was 3300 mg/g. Laboratory investigations revealed a positive (1:256) rapid plasmin reagin. Syphilis infection was confirmed by a reactive *Treponema pallidum* passive particle agglutination test. Immune and serologic tests were all negative including ANCA. A renal biopsy showed diffuse necrotizing CGN with greater than 75% cellular crescents and MN. The patient was treated with penicillin G, pulse methylprednisolone for 3 days, oral prednisone, and hemodialysis. He was discharged 20 days after admission, with improved urine output but remained dialysis dependent. At follow-up weeks later, the patient still required hemodialysis. He refused re-biopsy and no other immunosuppression was tried given his poor compliance with close follow-up visits.

Discussion: Syphilis-associated kidney disease is uncommon with a reported incidence of 0.3% and is usually associated with secondary syphilis. Secondary syphilis-associated CGN is very rare with only one previously reported case in the literature. As in infectious GN, treatment is aimed at the underlying infection. The use of corticosteroids is recommended by some experts when crescents are present. There is no clear evidence that additional immunosuppression is beneficial. In the first reported case of secondary syphilis-associated CGN described by Walker et al (Am. J. Med, 76: 1106-1112, 1984), plasmapheresis was empirically used for suspected vasculitis followed by corticosteroids and the acute kidney injury improved but without returning kidney function to normal. The present case adds to the evidence that secondary syphilis can be associated with crescentic glomerulonephritis. The clinical course of this patient points to the need for better treatments for this rare, yet important, condition.

PUB591

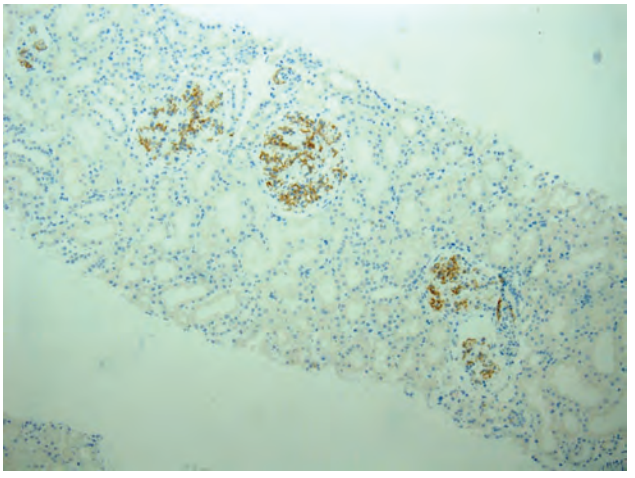
Fibrillary Glomerulonephritis Presenting as Hematuria

Hwarang S. Han,[1] Imran Tahir.[2] *[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Northeastern Health System, Tahlequah, OK.*

Introduction: Fibrillary glomerulonephritis (FGN) is a glomerular disease with pathognomonic findings seen on EM revealing randomly arranged nonamyloid fibrillary deposits that are 10 to 30nm. The disorder is found only in <1% of native kidney biopsies. Most patients present with nephrotic range proteinuria, hematuria and reduced renal function. We report a case of a patient with hematuria with normal renal function who was found to have FGN.

Case Description: A 51-year-old female came to clinic for evaluation of hematuria which was present for the past year. Urinalysis showed trace amount of protein and 3+ blood with RBC count of 5-15 per high power field. Protein to creatinine ratio was 0.6 mg/mg. Creatinine of 1.0 mg/dL and Hgb was 16.6 g/dL. CT showed no signs of nephrolithiasis. Urology performed cystoscopy with unremarkable findings. Renal biopsy revealed mesangial expansion, congo red negative, DNAJB9 immunohistochemistry positive in glomeruli, and electron microscopy showed mesangial areas and segmental regions of the capillary loops with deposition of randomly oriented non-branching fibrils that were mostly 20nm, warranting a diagnosis of FGN. Secondary workups were negative. Patient continues to have hematuria after 1 year of follow up but renal function remained stable with lisinopril 20mg daily.

Discussion: Fibrillary deposit glomerular diseases are divided into 3 main categories: amyloidosis, immunotactoid glomerulopathy, and FGN. Amyloid is congo red positive with fibrillary deposits that are about 10nm. Immunotactoid glomerulopathy is congo red negative and fibrils deposits are 30 to 50nm. FGN is congo red negative with fibril deposits of about 20nm. New markers such as DNAJB9 has shown to identify FGN without the need of EM. Serum level of DNAJB9 has also been shown to predict diagnosis of FGN. This case is unique since patient did not have the classic signs of FGN. Currently there are no optimal treatments for idiopathic FGN and high as 40-50% of patients develop ESRD.



DNAJB9 immunohistochemistry

PUB592

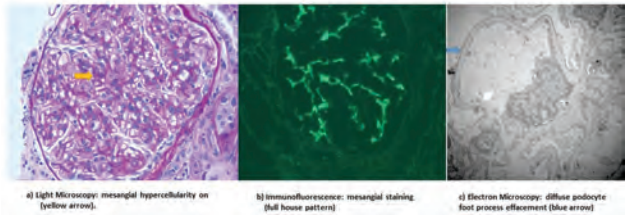
The Unsettling Shades of Lupus Nephritis: Emergence of a New (Sub) Class Rather Than Just a Rare Coexistence

Gajapathiraju Chamarthi, Amir Kazory, Xu Zeng, Mark S. Segal. *University of Florida, Gainesville, FL.*

Introduction: A widely accepted classification scheme for lupus nephritis (LN) has improved diagnostic consistency. However, there are still certain forms of LN that are poorly categorized. Herein, we present a rare case of lupus podocytopathy (LP) where we were fortunate to observe an evolution of the pathologic pattern over time.

Case Description: A 24-year-old African American woman with a history of lupus presented with acute kidney injury and proteinuria of 12 g/24 hours. A renal biopsy revealed class II LN with mesangial expansion and deposits. Due to the severity of proteinuria, the patient received mycophenolate mofetil and steroids, followed by cyclophosphamide, and then azathioprine. After two years, when she was in remission with a spot urine protein/creatinine ratio (UPCR) of 100 mg/g, the patient stopped taking her medications. After a year, she developed proteinuria (UPCR 5 g/g) and received oral steroids for a year. A year later, she relapsed again with UPCR of 6.8 g/g. A repeat kidney biopsy demonstrated mesangial expansion and hypercellularity without proliferative changes (i.e. suggestive of class II LN), electron microscopy revealed diffuse, almost complete, podocyte foot process effacement with microvillous changes confirming LP. Cyclophosphamide therapy resulted in gradual decrease in proteinuria to its current UPCR of 750 mg/g. Serum creatinine has remained within normal range over the years.

Discussion: While LP was initially thought to reflect a rare co-existence of LN with other glomerulopathies, the sparse data so far seem to denote it as an unclassified LN variant characterized by nephrotic-range proteinuria and diffuse foot process effacement in the absence of endocapillary proliferation. In order to avoid misclassification and management errors, clinicians should be aware of this variant; in the cases of a discrepancy between clinical presentation and histological findings a diagnosis of LP needs to be contemplated and the nephrologist should insist on electron microscopic examination of the glomeruli.



PUB593

Atypical Hemolytic Uremic Syndrome in a Patient with Primary FSGS

Sarah Gilligan, Robert C. Hartley, Martin C. Gregory, Nirupama Ramkumar, Monica P. Revelo Penafiel, Terrence S. Bjordahl, Josephine Abraham. *University of Utah, Salt Lake City, UT.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is an uncommon cause of acute kidney injury accompanied by hemolysis and thrombocytopenia. It can occur as a primary disorder or secondary to an underlying systemic disorder or drug.

Case Description: The patient is a 33 year old female diagnosed with biopsy proven minimal change disease in 2013. Subsequent biopsy in 2015 performed due to persistent nephrotic range proteinuria despite treatment showed focal segmental glomerulosclerosis (FSGS). She was treated with mycophenolate mofetil and steroids. In April 2018, her creatinine was 1.3 mg/dl with UPCR of 1.7 g/g. Mycophenolate and prednisone were stopped. She was given hormonal therapy for upcoming egg harvesting. In July she had UACR of 3.8 g/g and creatinine of 2.0 mg/dl and resumed her mycophenolate and prednisone. Her nephrotic syndrome worsened and she was admitted to the hospital in September. At that time, her creatinine was 3.4 mg/dl, UPCR 7.6 g/g, hemoglobin 10.6 g/dl and platelets 238 k/uL. Her creatinine, hemoglobin, and platelets rapidly worsened over the next five days (5.2 mg/dl, 6.8 g/dl, and 50 k/uL respectively). ADAMTS13 was 70%, shiga-like toxin was negative, C3 was mildly low, and C4 was normal. A lesion in her axilla was positive for varicella zoster virus (VZV). Eculizumab was started due to concern for aHUS. Renal biopsy demonstrated focal segmental and global glomerulosclerosis as well as changes of thrombotic microangiopathy (TMA) and tubular injury. Immunofluorescence was negative. Electron microscopy examination showed thickening of the glomerular basement membranes, expansion of subendothelial space, mesangiolysis, and nearly complete foot process effacement without electron dense deposits. Prior biopsies were reviewed with no evidence of TMA. Genetic testing was performed which was equivocal for aHUS genetic mutations. She was continued on eculizumab but progressed to ESRD.

Discussion: The trigger of aHUS in this patient remains unknown. Although there are case reports of genetic aHUS developing in patients with pre-existing FSGS, this is not a common association. There have also been case reports of VZV infection triggering aHUS. Finally, the patient was taking oral contraceptives and had recently undergone more intense hormonal therapy, either of which may have triggered aHUS.

PUB594

Pulmonary Renal Syndrome and Pauci-Immune Necrotizing Glomerulonephritis Associated with Hydralazine Use

Myungjin G. Kim,[1] John M. Childs,[3] Samir S. Patel,[2] Christina M. Yuan.[1] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Veterans Affairs Medical Center and George Washington University, Washington, DC; [3]US Navy, Bethesda, MD.*

Introduction: Hydralazine is commonly prescribed for hypertension (HTN) and heart failure. Side effects include headache, pre-syncope, tachycardia, and palpitations, and rarely, a lupus syndrome. We present a patient with pulmonary renal syndrome and rapidly progressing glomerulonephritis associated with hydralazine.

Case Description: A 66-year-old African American male with HTN, anemia, COPD, heart failure on hydralazine, peptic ulcer disease, and substance-abuse history was admitted with a Hgb of 4.3 g%. Gastrointestinal bleeding and hemolysis work-up were negative. 4 days after admission, he developed diffuse alveolar hemorrhage requiring intubation. Serum creatinine rose to 1.7mg% (1mg% baseline). Urinalysis showed granular casts, isomorphic hematuria, no cellular casts, and non-nephrotic proteinuria. He had a positive ANA, dsDNA and low complements (C3/C4). He was treated with 3 days of IV solumedrol pulse therapy followed by oral prednisone. Presumed diagnosis was pulmonary renal syndrome due to SLE. He was extubated after 3 days, with stable hemoglobin. Renal function worsened and renal biopsy was done. Light microscopy and DIF showed focal and segmental necrotizing glomerular lesions with cellular crescents (6/32), red-cell casts within tubules, positive fibrinogen (3+), C3 (2+), and low intensity (1-2+) IgG along basement membranes. Anti-GBM antibody was negative. Due to crescentic pauci-immune vasculitis, he began cyclophosphamide, transitioning to rituximab a few weeks later. Serum creatinine peaked at 2 mg%, and at last follow-up was 1.6mg%. Myeloperoxidase (MPO) ANCA (> 100 U/ml) and histone AB were positive, suggesting drug-induced SLE with ANCA positive pauci-immune glomerulonephritis, with hydralazine as the offending agent.

Discussion: Hydralazine is widely used, but may have rare, severe side effects, including lupus-like syndrome. In our patient, renal function stabilized after hydralazine discontinuation, and appropriate treatment for ANCA-associated glomerulonephritis. ANCA vasculitis has been rarely reported in hydralazine-associated lupus syndrome, and then in conjunction with MPO antibody, rather than Proteinase 3, as in our patient. *Disclosure: The views expressed are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense (DoD), or the U.S. Government.*

PUB595

Ruptured Intracranial Aneurysm as Presentation for Systemic Lupus Erythematosus (SLE) and Antineutrophil Cytoplasmic Antibody-Associated Vasculitis (AAV) Overlap Syndrome

Hamzeh Almasri,[1] Katarzyna A. Kadela,[1] Anuradha Wadhwa.[1,2] *[1]Loyola University Medical Center, Chicago, IL; [2]Hines VA Hospital, Chicago, IL.*

Introduction: We present a rare case of intracranial aneurysm rupture as presentation of SLE AAV (Systemic Lupus Erythematosus ANCA Associated Vasculitis) overlap syndrome. Only one other case of overlap syndrome presenting with hemorrhagic stroke has been reported. Two other cases have been reported to present with cerebral ischemia.

Case Description: 53-year female with HTN, h/o hemorrhagic pontine stroke (at age 50), inflammatory arthritis and CKD presented with headache and altered mental status. No family history of early stroke or HTN or kidney disease. HTN had been well controlled on metoprolol 25 mg daily and hydralazine 50 mg bid. CT scan showed diffuse subarachnoid hemorrhages with slightly greater involvement of R sylvian fissure and mild ventriculomegaly. EVD drain was placed and patient underwent urgent cerebral angiogram with coiling of ruptured R PCA aneurysm. No bleeding noted from L PCA aneurysm. Patients' clinical condition did not improve after coiling of aneurysm and EVD drain placement. She continued to have significant EVD drainage and was scheduled for VP shunt placement. Patients' baseline serum creatinine was ~ 1.5 mg/ dL with no known proteinuria or hematuria. On admission, patients' creatinine was 2.9. While frank hematuria after addition of antiplatelet agent resolved, she continued to have microscopic hematuria. Quantitation in urine showed 6.2 g/g proteinuria. Nephritic workup revealed + ANA (1:640), low complements, p-ANCA positive, MPO positive. Renal biopsy showed crescentic glomerulonephritis (Pauci-Immune). After initiation of steroids, patients mental status improved and EVD drainage decreased. Patient also received Cyclophosphamide. Her creatinine improved to previous baseline of 1.5 and proteinuria below 1g/g on follow up.

Discussion: Rapid neurologic and renal recovery was seen in response to immunosuppressive therapy. While renal involvement is common in SLE AAV, neurologic involvement is rare. To our knowledge, this is the second case described in the literature with overlap syndrome (+ANA and ANCA) presenting with intracranial hemorrhage. Prompt diagnosis and treatment is crucial in management of such complicated case.

PUB596

Double Trouble: Combined ANCA Vasculitis Relapse and Antibody-Mediated Rejection in a Kidney Transplant Recipient

Jennifer Scott,[1] Anthony M. Dorman,[3] Mark A. Little,[2] Declan G. de Freitas.[3] *[1]Trinity Health Kidney Centre, Dublin, Ireland; [2]Trinity College Dublin, Dublin, Ireland; [3]Beaumont Hospital, Dublin, Ireland.*

Introduction: A female kidney transplant recipient, presented with graft dysfunction associated with headache, polyarthralgia, sinusitis, epistaxis, fatigue and vomiting for 2 weeks. She had a history of PR3 positive anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV), diagnosed 6 years prior, resulting in end-stage renal disease, despite treatment with the CYCLOPS protocol and plasma exchange. She received a 'standard immunological risk' deceased donor kidney transplant 3 years later. Maintenance immunosuppression (IS) included Prograf 3mg BD, Mycophenolate Mofetil 750mg BD and prednisolone 5mg OD. The patient denied medication non-adherence.

Case Description: Examination was unremarkable. Initial investigations revealed severe non-oliguric acute kidney injury (creatinine 685 μmol/L from 110 μmol/L baseline). Urinalysis showed 4+ blood and 1+ protein. Anti-PR3 antibody level rose to 81 IU/ml from 5 IU/ml ten months prior. Urine CD163 was elevated at 1225 ng/mmol (<0.3). There was a significant development in the strength and breadth of both class I and II donor specific antibodies. Renal biopsy demonstrated focal necrotising crescentic glomerulonephritis, tubulointerstitial inflammation and strong global C4d positivity in peritubular capillaries, consistent with AAV relapse and antibody-mediated rejection (ABMR). The Molecular Microscope Diagnostic Report® independently identified severe TCMR and ABMR (figure 1). She was treated with pulsed methylprednisolone (500mg x 3 days), followed by tapering prednisolone, Rituximab 375mg/m^2 x 4 and continued maintenance IS. Management was influenced by prior IS exposure and the risk of- and subsequent development of infection. Unfortunately, she remained dialysis dependent and subsequently required graft nephrectomy for persistent rejection symptoms.

Discussion: While AAV relapse after kidney transplantation is rare, this case is a reminder that it can recur. The diagnostic biopsy in this case was supported by 2 novel techniques, a urine CD 163 and the Molecular Microscope Diagnostic Report®, identifying concomitant rejection and vasculitis. Despite treatment, the synchronous immunological mechanisms resulted in irreversible kidney damage. The wealth of objective evidence was key to personalising the risk-benefit of further IS in this case.

PUB597

Rare Presentation of Membranous Nephropathy in Pulmonary Alveolar Proteinosis and Minimal Change Disease

Arun Rajasekaran,[1] Ishita Misurya,[2] Rishabh K. Jain,[1] Huma Fatima,[1] Emmy K. Bell.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]All India Institute of Medical Sciences, Jodhpur, India.*

Introduction: Pulmonary alveolar proteinosis (PAP) is characterized by intra-alveolar accumulation of phospholipid and protein-surfactant material with minimal inflammation or fibrosis. Membranous nephropathy (MN) has rarely been associated with PAP and to

our knowledge has not been previously reported in minimal change disease (MCD). We describe a patient with MCD who subsequently developed MN in the setting of PAP.

Case Description: A 43-year-old female with low dose steroid-dependent MCD and idiopathic PAP associated with asthma and eosinophilia presented with acute dyspnea, fever, and malaise. She was found to have nephrotic range proteinuria, eosinophilia (18,000/mm^3) and eosinophiluria. Secondary causes of eosinophilia were excluded. Bone marrow biopsy revealed hypocellular marrow with eosinophilia without fibrosis, myeloproliferative or clonal hematopoietic processes. Serum IgE levels were elevated (3556 IU/L). Bronchoscopy confirmed PAP and bronchoalveolar lavage showed >85% eosinophils. She developed non-oliguric AKI with serum creatinine increasing from 0.8 mg/dl to 2.8 mg/dl. Urinalysis showed 3+ protein and 4+ eosinophils. 24-hour-urine collection demonstrated 10,428 mg of protein; serum albumin was 3.1 mg/dl. Autoimmune and infectious serologies were unremarkable, as were complement levels and serum immunofixation electrophoresis results. Renal biopsy showed subepithelial immune complex deposits with minimal basement membrane reaction, segmental thinning of GBM, and no eosinophilic infiltration. Serum PLA2R titers were negative and other secondary causes of MN were ruled out. Therapy with prednisone 120 mg/day resulted in rapid improvement in proteinuria and renal function (returned to baseline upon discharge). She was discharged on a steroid taper with no proteinuria noted after a month of treatment.

Discussion: MN is characterized by diffuse and global subepithelial immune complex deposits and associated GBM changes. Our patient's findings of early PLA2R-negative MN associated with PAP is consistent with secondary MN. This association has rarely been described and the occurrence of MN in a patient with known steroid-responsive MCD to our knowledge has not been reported. Further research is needed to elucidate the pathophysiology of MN in PAP.

PUB598

Glomerulonephritis in Patients with Ulcerative Colitis

Huanhuan Yin, Peng Xia, Xiaoxiao Shi, Xuemei Li, Hong Yang, Limeng Chen. *Peking Union Medical College Hospital, Beijing, China*.

Introduction: Inflammatory bowel diseases (IBD) is a systemic disorder with possible renal involvement, and we aimed to describe the spectrum of renal affection in our IBD patients. All the medical records of 949 IBD patients in Peking Union Medical College Hospital from June 2012 to October 2018 were reviewed, especially those associated with renal involvement. The detailed clinical and pathological features of glomerular disease were analyzed.

Case Description: The renal involvement was observed in 212 IBD patients(22.3% of all), including Crohn's disease (CD, 40.1%), ulcerative colitis (UC, 45.8%) and intermediate colitis (IC, 14.2%). The most common renal diagnosis was renal cyst (50.5%), followed by urolithiasis (29.2%), glomerular disease (8.0%), and tubulointerstitial disease (2.4%). Seven cases of UC associated glomerulonephritis, confirmed by renal biopsy, were mainly middle-aged males (34-72y; male: female= 5:2). UC was diagnosed by endoscopic biopsy and treated with 5-aminosalicylic acid and/or steroids and each patient had achieved clinical remission. The onset of renal disease occurred after a few years (0-25 years) of IBD diagnosis. The mean 24-hour urine protein(24hUP) was 3.63 (0-6.35)g, and the mean Scr was 1.92 (0.45-4.47)mg/dl. Histology showed membranous nephropathy (n=3), crescentic GN, IgAN, ECPGN, and lupus nephritis. All patients were complicated with autoimmune antibody positive. After treated by steroid (1mg/kg/d) and/or immunosuppressant, significant improvement in proteinuria and Scr were oberserved.

Discussion: Renal involvement of IBD is not rare, and the prognosis of UC associated glomerulonephritis is well.

Table 1 Clinical data of 7 cases of UC associated glomerulonephritis

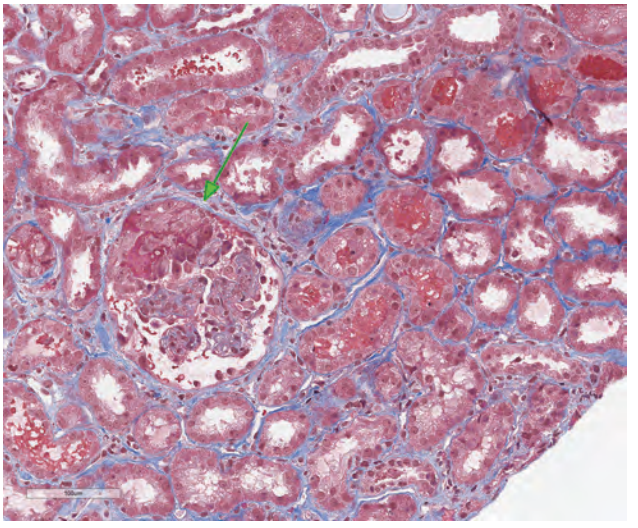
Rapidly Progressive Fatal IgA Nephropathy in a Patient with Longstanding Cirrhosis

Akshita Gupta,[2] John T. Ludwig,[1] Scott Buchowski,[1] Panduranga S. Rao,[1] Kent J. Johnson.[1] *[1]University of Michigan Health System, Ann Arbor, MI; [2]All India Institute of Medical Sciences (AIIMS), New Delhi, India.*

Introduction: IgA nephropathy associated with liver disease (hepatic IgAN) is a relatively common form of secondary IgAN, presenting with microscopic hematuria and normal kidney function in the majority of patients. Presentation as a rapidly progressive nephritis is rare. We report a case of IgA nephropathy secondary to liver cirrhosis that rapidly progressed to a fatal end stage renal failure.

Case Description: 57 yo male with history of cirrhosis (stable, listed for transplant), rheumatoid arthritis, and pan-hypopituitarism presented with edema, rash, dark urine, and AKI (KDIGO stage 3). No preceeding illness or fevers. UA with nephrotic range proteinuria and hematuria with acanthocytes. Work up with ANA, ANCA and complements were normal. Kidney biopsy revealed acute proliferative glomerulonephritis with some crescents. Predominant IgA and C3 deposits; electron microscopy showed large mesangial deposits. (MEST score M3E1S0T0). Initiated on pulse dose steroids with transient improvement before proteinuria, edema, and renal function rapidly worsened. Initiated hemodialysis one month after presentation. Despite aggressive medical management, the patient clinically declined. Family decided to transition to comfort measures and the patient died.

Discussion: We describe a case of rapidly progressive crescentic IgA nephropathy in a patient with cirrhosis. The presentation is atypical in its aggressive presentation and course. We hypothesize that in addition to the background deposition of IgA containing complexes due to the liver disease, "a second hit" (possibly an infection) precipitated and aggressive course of the disease. There is currently no specific treatment for hepatic IgAN in patients who develop rapidly progressive renal impairment, and management of such cases remains a challenge.



Trichrome stain. Acute crescentic glomerulonephritis, tubular red cell casts.

PUB600

A Rare Case of Collapsing Glomerulopathy

Peter E. Thorne, Beatrice P. Concepcion, Julia Lewis, Meghan E. Kapp. *Vanderbilt University Medical Center, Nashville, TN*.

Introduction: Collapsing glomerulopathy (CGP) can be related to infection, drugs, vascular disease, autoimmune disease, or be idiopathic. We report a case of CGP in a previously healthy patient presenting with acute hepatitis B infection and malignant hypertension.

Case Description: This 32 year-old African American man with no past medical history presented with two weeks of headache, weight loss, and increased urine output. He was found to have periorbital and lower extremity edema. Initial blood pressure was 190/120. Initial labs were notable for a serum creatinine of 2.8mg/dl, albumin of 2.8g/dl, platelet count of 134,000, total cholesterol of 265mg/dl, and estimated 24 hour urine protein of 15g/day with no hematuria. Renal ultrasound revealed normal sized kidneys and was negative for renal vein thrombosis. Echocardiogram demonstrated an ejection fraction of 25% and left ventricular hypertrophy. Serologic work-up was positive for Hepatitis B surface antigen, envelope antigen, and HBV-DNA (>170,000,000 IU/ml) and otherwise negative including HIV, HCV ab, Parvovirus B19, CMV, hemoglobin A1c and urine drug screen. Renal biopsy demonstrated CGP, thickened glomerular basement membranes and moderate hyalinosis of arterioles. Immunofluorescence had nonspecific staining and there were no immune complex deposits on electron microscopy. There was 10% visceral epithelial cell foot process effacement. There were no viral cytopathic changes. Tenofovir was initiated and aggressive blood pressure control was achieved during hospitalization. Subsequently, proteinuria decreased to 3g per day with a gradual improvement in serum creatinine to 2.1mg/dl at discharge.

Discussion: CGP is a distinct pattern of proliferative parenchymal injury with a number of infectious causes previously identified. There are few reported cases of its association with hepatitis B infection. In our case, an adult African American male presented with acute hepatitis B associated CGP and subsequent malignant hypertension leading to severe ischemic injury, nephrotic range proteinuria, renal dysfunction, and cardiac dysfunction. Our patient had signficant reduction in proteinuria and demonstrated stabilization of serum creatinine levels with initiation of antiviral treatment of hepatitis B infection and blood pressure control including the use of an angiotensin receptor inhibitor. This case suggests a causative role of hepatitis B in CGP.

PUB601

Collapsing Glomerulopathy: Report of 10 Cases

Monica Sanchez cardenas,[1] Virgilia Soto,[2] Karla B. Cano Escobar.[3] *[1]UNAM, Ciudad de Mexico, Mexico; [2]INC Ignacio Chavez, Mexico City, Mexico; [3]Instituto Nacional Cardiologia Ignacio Chavez, Tlalpan, Mexico.*

Introduction: Collapsing pathology represents one of the most aggressive forms of glomerulopathy described, representing 15% of the biopsies described as focal and segmental glomerulosclerosis. The knowledge of its characteristics in our population is crucial for its better understanding and management.

Case Description: **Materials and methods:** By reviewing the medical records, we proceeded to identify cases of collapsing glomerulopathy with complete clinical follow-up in our institute, registered from 2010 to date. **Results:** The age range at diagnosis was from 17 to 60 years, with 3 cases of the male gender and 7 registered women. The proteinuria recorded at diagnosis had an average of 10.01 gr (4.2-12 grams). The creatinine at diagnosis had an average of 3.8 mg/dl (0.47-11 mg/dl) with a mean basal albumin of 2.15 g/dl (1.0-3.4 gr/dl). Nine of the ten cases were hypertensive at diagnosis, with hematuria in eight of the cases. Similarly, 8 of the cases integrated complete diagnosis of nephrotic syndrome in the initial clinical presentation. Upon arrival at the institute, the average evolution time was 5.5 months (1-24 months) and the most common symptom of presentation was lower limb edema. One of the cases was linked to EBV, one to HIV and one was triggered after pregnancy. No specific etiology was identified in the rest of cases. Given the degree of progression of renal damage, it was necessary to start dialysis therapy during hospitalization in 5 of the 10 cases. In 4 of the cases, immunosuppressive therapy was given and in one more antiretroviral therapy at the beginning given the etiology of the glomerulopathy. In two of the cases, management was based on boluses of methylprednisolone, plasmapheresis and monthly boluses of cyclophosphamide. One of them reached a partial response in the first 3 months of follow-up. Two cases received methylprednisolone, plasmapheresis and rituximab, with a complete response in one of the cases. The rest of the cases did not reach any degree of clinical response.

Discussion: In our group of patients, despite the short time to diagnosis, the vast majority unfortunately were detected with advanced fibrosis without the possibility of treatment given the benefit risk ratio. In recent years, the trend is toward earlier diagnosis with the possibility of treatment and intentional etiology search. The prognosis regarding renal function continues to be discouraging.

PUB602

Use of IVC Filter in the Management of Post Percutaneous Renal Biopsy (PRB) Complicated by Perinephric Hematoma (PNH) and Acute RLE DVT in a Patient with C-ANCA-Positive Crescentic Glomerulonephritis

Aileen Wang,[1] Anton Cabellon,[1] Carrie L. Phillips,[1] Ayman Hallab,[1] Richard N. Hellman.[2] Indiana University Department of Medicine, Division of Nephrology, Division of Hematology, and IUHP *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University Division of Nephrology, Indianapolis, IN.*

Introduction: A 37 year old MWF with a prior history of morbid obesity, gastric bypass, hypertension, prior calcium oxalate nephrolithiasis presented to her local hospital with diarrhea, lower abdominal pain, arthralgia's, sinus congestion. She was found to have micro hematuria, 2 g proteinuria, metabolic acidosis, hyperkalemia and AKI with a serum creatinine of 4.5 mg/dL with prior normal renal function. A CT of the abdomen revealed normal kidneys but thickening of the terminal ileum, a positive ANA (1:320) and a Klebsiella urinary tract infection. She received IV fluids with bicarbonate, ceftriaxone and referred for PRB.

Case Description: The patient underwent right PRB under ultrasound guidance but post procedure she developed right flank pain and on CT and US was found to have an acute PNH. She was placed at bed rest. The morning post biopsy she developed acute RLE pain and swelling and an extensive RLE DVT. Hemoglobin fell from pre biopsy 9.5 g/dL to 6.8 g/dL. An IVC filter was placed. Anticoagulation was held initially. 10 day post renal biopsy a repeat US showed a resolving PNH. At this point heparin and then Coumadin was begun without incident and she did well clinically. Renal biopsy showed crescentic pauci-immune glomerulonephritis compatible with C-ANCA-associated vasculitis. Two glomeruli were obsolescent, 27/43 showed crescents and fibrinoid necrosis. She was treated with pulse steroids followed by prednisone taper. She received induction therapy with rituximab 375 mg/m2 of BSA weekly while in the hospital and to date has completed 4 doses of Rituximab. She has been doing well clinically and is asymptomatic. Serum creatinine has fallen to 1.67 mg/dl and U Protein to creatinine ratio to 1.48. Present hemoglobin is 11.8 g/dl. The IVC filter has been removed and she is on Coumadin anticoagulation.

Discussion: PNH occurs in 90% of patients immediately post renal biopsy but is clinically significant in only 2% of patients. Prior literature does not discuss the dilemma of post PRB complicated by PNH and acute DVT. Here we report a successful strategy of limited IVC filter use to prevent PTE and avoidance of anticoagulation in the face of acute post biopsy PNH.

PUB603

An Association Between HIV-Associated Nephropathy and HIV-Associated Immune Complex Kidney Disease: A Case Report

Rafael A. Souza,[1] Fabio M. Torres,[1] Fábio A. Reis,[1] Marcelo P. Menezes filho,[1] Daniela V. R. Cortes,[1] Jorge L. Espinosa Armijos,[1] Guilherme P. Santa Catharina,[1] Igor Smolentzov,[1] Livia B. Cavalcante,[2] Precil D. Neves,[1] Cristiane B. Dias,[1] Luis Yu,[1] Viktoria Woronik,[1] Lectícia Jorge.[1] *[1]Nephrology, University of São Paulo, São Paulo, Brazil; [2]Patology, University os São Paulo, São Paulo, Brazil.*

Introduction: The estimated prevalence of kidney disease in HIV-infected patients ranges from 2 to 17% and can be classified into HIV-associated Nephropathy (HIVAN) and HIV Immune Complex Kidney Disease (HIVICK), nonetheless the association of these two diseases is rarely described, since their physiopathology are not alike.

Case Description: Male, 51 years old, caucasian, BMI 23.8 kg/m^2, hypertensive, HIV virus carrier in antiretroviral therapy since 1994, with undetectable viral load and CD4 > 500 cells/mm^3 for over 20 years, presented with Nephrotic Syndrome in 2007, diagnosed with FSGS NOS variant after kidney biopsy. Several immunosuppressive regimens were performed, only partial remission was achieved and residual proteinuria (UPCR 2-3 g/g) persisted. Early 2019, the patient refered edema in the lower limbs, asthenia and new onset of proteinuria (UPCR 7,6 g/g), Serum Albumin was 2,1 g/dL, urinalysis revealed 23 rbc/field and worsening renal function was observed (SCr 1,73 to 3,64 mg/dL). Another kidney biopsy was performed. Light microscopy showed 11 glomeruli, 6 globally sclerotic. The remaining had focal collapsing lesions, basement membrane with occasional double contours and spikes. There was an extracapillary epithelial proliferation in one glomerulus, with indefinite features between a fibrocellular crescent or a pseudo-crescent. Immunofluorescence showed granular deposits of IgA (1+), IgG (2+), C3 (1+) and Lambda (2+) on mesangium and glomerular basement membrane, with global and diffuse distribution. Based on these findings, Immune complex-mediated Glomerulonephritis with associated Collapsing Glomerulopathy was diagnosed, consistent of HIVAN in association with HIVICK. No alleles at risk for APOL1 was found on genetic analysis (sequencing by SANGER).

Discussion: Although rare, HIV-positive patients, even with undetectable viral load, may develop immunological kidney disease (HIVICK) in combination with the non-immunological form (HIVAN). At our perspective, the kidney tissue could be seen as an viral reservoir, justifying a collapsing glomerulopathy even with long time of negative viral load.

PUB604

Partial Remission of Proteinuria with Bleomycin-Etoposide-Cisplatin (BEP) in Systemic Lupus Erythematous-Related Membranous Nephropathy and Ovarian Cancer

M. I. Villegas Kastner,[3] Katherine Garcia De De Jesus,[3] Janice B. Desir.[1,2] *[1]Nephrology/Internal Medicine, SBH Health System, New Rochelle, NY; [2]Kidney Medical Associates, PLLC, Bronx, NY; [3]Internal Medicine, SBH Health System, Bronx, NY.*

Introduction: Systemic Lupus Erythematous (SLE) and ovarian cancer (OC) are both associated with secondary causes of membranous nephropathy (MN). The incidence of OC with MN is rare and coexistence with SLE has not been documented in the literature. Use of conventional therapy for MN with OC may result in increased carcinogenesis. As such, mass resection and chemotherapy (CTx) are prioritized. First line treatment with Bleomycin-Etoposide-Cisplatin (BEP) has known nephrotoxic effects. Its impact on proteinuria is unclear. Here, we describe a case of MN secondary to SLE in the setting of OC with partial remission of proteinuria with BEP.

Case Description: A 31 year old female with SLE (diagnosed 2014) was seen in renal clinic May 2018 for new onset proteinuria. She was asymptomatic and screening labs showed creatinine (CR) 0.4 mg/dL and proteinuria 30 mg/dL. Her proteinuria rapidly progressed to 2.6 g/L and a renal biopsy showed MN secondary to SLE (ISN- RPS Class V). A CT abdomen performed 2 days post biopsy for evaluation of a renal hematoma noted an incidental ovarian mass. June 2018, the mass had increased in size and a diagnostic laparoscopy performed by gynecology (GYN) was concerning for an ovarian neoplasm. Her proteinuria peaked to 4.3 g/L and conservative management was advised with an ACE inhibitor pending mass resection and completion of CTx. August 2018, the mass was removed after reaching a size of 15.5 x 11 cm causing secondary bilateral hydronephrosis. Pathology showed a stage II immature teratoma and she was started on 3 cycles every 3 weeks of BEP. Complications included acute kidney injury and her ACE inhibitor was stopped September 2018. Repeat urine studies prior to CTx completion (November 2018) first showed protein 30 mg/dL and was subsequently negative. December 2018, one month off CTx, her proteinuria recurred to >500 mg/dL. She continues to follow in renal clinic for management of her MN.

Discussion: This case illustrates the first proposal of an anti proteinuric effect of BEP in SLE MN with OC. This is important to consider in the management of germ cell tumors with MN. It also has implications in other forms of secondary MN not responsive to standard therapy. Further research is required to understand the full treatment potential of these agents in MN.

PUB605

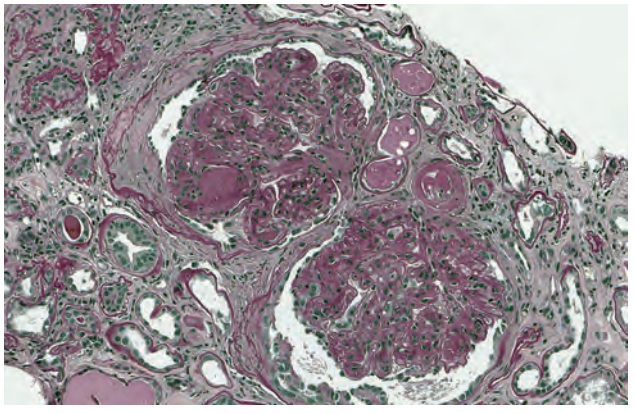
A Rare Case of Idiopathic Nodular Glomerulosclerosis in a Non-Diabetic and Non-Smoker with Untreated Hypertension

Yasolatha Chalicheemala. Nephrology Fellowship Program, DHMC *Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Nodular glomerular sclerosis is a classical finding in diabetic nephropathy. It can occur in the absence of diabetes, often in older men with long standing smoking, hypertension, Fibrillary GN, amyloidosis, Takayasu arteritis, light chain nephropathy, nodular variant of mebrano proliferative glomerulonephritis. We are reporting a case of idiopathic nodular glomerulosclerosis leading to nephrotic syndrome needing dialysis.

Case Description: 67 y/o non -smoker with no prior medical care with untreated hypertension for long time, presented with sudden onset of AKI following fall at home and prior progressive lower extremity edema and exertional SOB. Found to have complete heart block, oliguria, nephrotic syndrome with serologies negative for hepatitis, HIV, paraproteinemia, ANA, C-ANCA, P-ANCA, PLA2R Antibody with normal complements and HbA1C of 5.4. Renal biopsy showed diffuse global, nodular glomerulosclerosis, severe arterial hyaline sclerosis, interstitial fibrosis(80-90%), no evidence of immune complex deposition.

Discussion: Though not commonly seen, Idiopathic nodular glomerulosclerosis should be considered as one of the differentials for patients presenting with Nephrotic syndrome like in our case with no history of diabetes in a non smoker.



PUB606

Surprise on Renal Biopsy: Crescentic Glomerulonephritis

Latoya N. Gayle,[1] Marnie Aguasvivas,[1] Alejandro Matos wells,[2] Louis C. Jan.[3] *[1]Englewood Hospital and Medical Centre, Englewood, NJ; [2]Englewood, Englewood, NJ; [3]Bergen Kidney Center, Cresskill, NJ.*

Introduction: IgA Nephropathy(IgAN) is the most common glomerulonephritis, with variable presentation, prognosis and controversial treatment. Though less common in adults, there has to be a high index of suspicion in those with presentation of high-risk markers such as severe proteinuria and signs of systemic vasculitis. We present a 41-year-old female with leukocytoclastic vasculitis, proteinuria and normal renal function with focal crescentic glomerulonephritis

Case Description: 41-year-old Asian female, no prior illness, presented with a purpuric lower extremity rash, knee and ankle pain. Skin biopsy revealed leukocytoclastic vasculitis.4 months later, her random urine protein was 3099mg/gm creatinine, 2+ blood on urinalysis with normal creatinine(CR) 0.7(0.5-1mg/dL) and urine protein:CR 2g/g. Save for positive ANA and elevated CRP of 17.9(<10mg/L), her dsDNA, Hepatitis, ANCA, cryoglobulin, ASO and serum protein electrophoresis were negative. Total cholesterol and triglycerides elevated at 203(<200mg/dL) and 321(<150mg/dL) respectively. Normal-sized kidneys and echogenicity on renal ultrasound. Background of cutaneous vasculitis in the presence of proteinuria, prompted renal biopsy. It revealed Focal crescentic glomerulonephritis with scattered glomerular double contours, consistent with IgAN. Treatment was commenced with Prednisone, Ramipril and Atorvastatin, resulting in complete resolution of her proteinuria, rash, normalization of her triglyceride and cholesterol levels. She has been in remission with normal BUN and CR

Discussion: IgAV is 33 times more common in children, however it is important to exclude in any patient, who presents with purpura. Though treated conservatively in children, in adults, renal disease can be very severe, particularly in crescentic IgAN, which has poor prognosis and increased progression to renal failure. KDIGO guidelines recommend immunosuppressive agents such as cyclophosphamide for its therapy, however the long-term outcome is little known. Our patient with normal CR, had focal crescentic GN, in remission after use of corticosteroids(CS), chosen due to her young age and normal CR. Pozzi et al, noted that CS reduced proteinuria and decline in renal function, with use in all classes of IgAN. More guidelines on treatment and their outcomes in adults with IgAN is needed, though from our case, corticosteroid monotherapy can be an option, with close follow up of renal function

PUB607

Thrombectomy for Renal Vein Thrombosis in Membranous Nephropathy

Elisa Park,[1] Peyman Borghei,[2] John Sy,[2] Anna Jin,[2] Joline L. Chen.[1] *[1]University of California, Irvine, Irvine, CA; [2]Long Beach VA Medical Center, Long Beach, CA.*

Introduction: Bilateral renal vein thrombosis is a rare complication of nephrotic syndrome. We hereby report a case of extensive systemic thrombosis with successful percutaneous suction thrombectomy

Case Description: A 45-year-old male with no past medical history presented with lower extremity edema, dyspnea, right flank pain and pleuritic chest pain for two days. A diagnostic computarized tomography (CT) revealed a nonocclusive acute thrombus in the bilateral renal veins, extending into the suprarenal infrahepatic Inferior vena cava (Figure 1A), and right lower lobe pulmonary emboli. Initial serum creatinine was 0.87mg/dL. A 24-hour urine collection revealed protein >4.5 g/day. Labs were also remarkable for a serum albumin of <1 G/dL and a positive Phospholipase A1 Receptor at 212 RU/mL. A renal biopsy showed membranous nephropathy. Due to significant flank pain (7-8/10) and severe clot burden, patient underwent percutaneous image-guided catheter-directed suction thrombectomy of bilateral renal veins, IVC, and right lower lobe branch pulmonary artery using CAT-8 Penumbra suction thrombectomy device with 500cc of clot removed. The patient's pain improved significantly the next day (2-3/10). Patient underwent renal biopsy on post op day two. Patient was anticoagulated with heparin and transitioned to apixaban. He was treated with modified Ponticelli protocol. Renal function remained stable one month post procedure. Follow up CT scan showed resolution of the bilateral renal vein thrombus (Fig 1B).

Discussion: Acute bilateral renal vein thrombosis is a rare complication of nephrotic syndrome, and can be associated with renal function decline. Thrombectomy may be considered a safe therapy to prevent sequalae of long term clot burden.

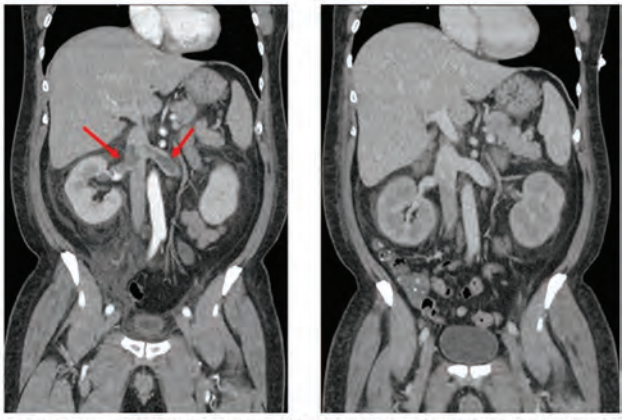


Figure 1A- Venous phase coronal CT scan image of the abdomen showing filling defects within the bilateral renal veins (red arrows) consistent with bilateral renal vein thombi. Figure 1B- Follow up Venous phase coronal CT scan image of the abdomen showing interval resolution of the previously noted bilateral renal vein thrombus.

PUB608

Coagulopathy and Nephrotic Syndrome in a Patient with AL Kappa Amyloidosis

Michael Bourla, Sophia L. Ambruso. *University of Colorado, Denver, CO.*

Introduction: We present a 64 year-old man with nephrotic-range proteinuria and coagulopathy from systemic kappa light chain (LC) amyloidosis and associated plasma cell dyscrasia.

Case Description: The patient presented with anasarca, hypotension and decreased oral intake. History was notable for chronic memory loss, cognitive decline and rapid deterioration preceding admission. On exam, he had BP of 76/59, HR 107, anasarca, lethargy, and confusion. Initial serum labs included creatinine of 3.0 (baseline 1.8), albumin of 1.1, and INR of 3.4 with normal liver function. Urinalysis had moderate blood and large protein, while direct microscopy revealed many non-dysmorphic RBCs and granular casts. Urine protein to creatinine ratio was 13g/g. Renal ultrasound showed normal sized kidneys. HIV, HCV, HBV, ANA, ANCA, C4, RF all normal. C3 mildly low at 75. SPEP revealed kappa monoclonal LC. Serum free kappa LC were 408, serum free lambda LC were 21.4, and kappa/lambda ratio was 19. Fat pad biopsy was unremarkable, however, the bone marrow biopsy showed 13% plasma cells on the aspirate and apple-green birefringence of three vessels with congo red staining showing vascular mural amyloid deposition. Official diagnosis: systemic kappa LC amyloidosis associated with plasma cell dyscrasia. Renal biopsy was not performed due to patient's coagulopathy. Hematology consulted due to the unusual finding of coagulopathy in a nephrotic patient. Coagulation factors V and X were found to be deficient (27% and 16%, respectively). Patient decided against chemotherapy and was discharged on hospice.

Discussion: A kappa-predominant AL amyloidosis is a less common cause of nephrotic proteinuria compared to the lambda LC variant, which occurs three times more often. It is suggested that AL Kappa Amyloidosis as a cause of nephrotic syndrome is more common with multiple myeloma, as seen in our patient. Interestingly, while nephrotic patients are generally thought to be hypercoagulable, our patient had an elevated and uncorrectable INR. Those with AL amyloidosis often have a bleeding diathesis which can be due to a coagulopathy, the presumed mechanism of which is factor X adsorption by

amyloid fibrils causing factor X deficiency, as observed in our patient. In patients with nephrotic syndrome and bleeding diathesis and/or coagulopathy, a unifying diagnosis can be AL amyloidosis.

PUB609

Nephrotic Syndrome in a Patient with Diabetes: Things Are Not Always as They Seem

Harshal P. Shah,[1] Ping Li,[2] Samir S. Patel.[3] [1]*Georgetown University Hospital, Arlington, VA;* [2]*Washington Veterans Affair Medical center, Washington, DC;* [3]*Veterans Affairs Medical Center and George Washinton University, Washington, DC.*

Introduction: Diabetic patients with renal involvement with proteinuria were previously thought to have diabetic nephropathy in up to 70% of cases. A kidney biopsy is not always pursued in these patients due to this presumed diagnosis, especially in the presence of uncontrolled blood sugars, long duration of diabetes, and other markers of microvascular disease such as retinopathy and neuropathy. The mainstay of treatment for these patients is strict glycemic control, the use of diuretics for volume management and inhibition of the renin-angiotensin-aldosterone system (RAAS). Despite treatment, mortality remains high with a progression to end stage renal disease. More recent literature has suggested that diabetics with atypical features have a non-diabetic renal disease or mixed renal disease in up to 50% of cases.

Case Description: A 37-year-old man with an 8-year history of DM2 without retinopathy A1c of 18% presented with anasarca and nephrotic syndrome. Laboratory studies revealed serum creatinine 1.2 mg/dL, albumin 1.0 g/dL, hyperlipidemia and UPCR 8 g/g. Kidney biopsy showed early diabetic nephropathy and he was started on standard treatment. He continued to have diuretic resistance with multiple episodes of AKI. He required three inpatient admissions for intravenous diuresis over the next 7 months. Due to atypical presentation and persistence of symptoms, repeat kidney biopsy was performed. Biopsy showed a FSGS lesion in a single glomerulus. Due to his uncontrolled diabetes, second line therapy with a calcineurin inhibitor (CNI) was started. Within the next 6 months, he achieved complete remission with reduction in proteinuria to <300 mg/g, normalization of albumin and resolution of edema.

Discussion: Diffuse foot process effacement on electron microscopy is a defining feature of diseases with proteinuria, and without an accompanying glomerular lesion on light microscopy, distinguishing FSGS from other proteinuric kidney diseases can be difficult. Current literature suggests glucocorticoids as first line-therapy in patients with primary FSGS with nephrotic syndrome. CNI's are reserved for steroid resistant or steroid dependent disease, and their use in early FSGS has not been extensively studied with RCT's. This case not only illustrates the importance of a kidney biopsy in diabetic patients, but also the quick resolution of FSGS with second line therapy.

PUB610

Toxic Effects of Tonic Water, a Case of Quinine-Induced Thrombotic Microangiopathy

Kishore Patcha, Josephine Abraham, Nirupama Ramkumar, Martin C. Gregory. *University of Utah, Salt Lake City, UT.*

Introduction: Quinine is one of the most common medications which can cause drug induced immune mediated Thrombotic microangiopathy. Here we present a case of thrombotic microangiopathy who exposed quinine in the form of tonic water.

Case Description: A 25-year-old female presented with flu-like symptoms including nausea, vomiting, diarrhea, malaise, and generalized abdominal pain. Diagnostic work-up showed elevated lipase (724U/L) mildly elevated liver enzymes and normal appearing liver and kidneys on CT abdomen/pelvis. Patient underwent cholecystectomy for presumed gall stone pancreatitis. Shortly after discharge, she noticed worsening swelling in her legs, abdomen, and weight gain of 30 lbs. Urinalysis showed 3+ proteinuria, hematuria, urine protein/creatinine ratio of 2.7g/g. Platelet count was 138 k/ul, Hgb;7.7g/dl, creatinine 1.58 mg/dL. Peripheral smear demonstrated schistocytes. Renal biopsy showed thrombotic microangiopathy consistent with TTP vs atypical HUS. While serologies were pending, she was treated with plsma exchange, Eculizumab 900mg, Rituximab 375mg/m2 and prednisone. ADAMTS 13 was 51%. Complements C3 and C4 were normal, Anti-Complement factor H, ANA, scleroderma antibodies and stool studies were all negative. On further review of history, she reported drinking tonic water intermittently as a restaurant server. Intermittent ingestion of quinine can cause TMA, quinine-dependent antiplatelet antibodies were tested and found to be negative.

Discussion: Quinine is a widely used remedy for leg cramp. Quinine was the first drug reported to cause TTP-HUS and it remains the most common cause of drug-induced TTP-HUS Quinine can bind to surface molecules, altering their structure and exposing new parts of the cell membrane molecule to plasma. These revealed sequences are then recognized by the immune system as foreign antigens. Drug-dependent antibodies can be detected by flow cytometry. Quinine dependent antibodies might be negative and in our patient the antibodies were likely removed by plasma exchange. If recurrent disease is to be prevented, clinicians must be aware of quinine as a possible cause of TMA.

PUB611

Quinine-Induced Immune-Mediated Recurrent Disseminated Intravascular Coagulation and Thrombotic Microangiopathy

Kishore Patcha, Martin C. Gregory, Nirupama Ramkumar. *University of Utah, Salt Lake City, UT.*

Introduction: Quinine is one of the most common medications which can cause drug induced immune mediated Thrombotic microangiopathy. Here we present a unique case of recurrent DIC and thrombotic microangiopathy in a patient who has been taking quinine supplements for leg cramps.

Case Description: A 81-year-old female with history of recurrent DIC was hospitalized with night sweats, fevers, chills, vomiting, acute kidney injury and recurrence of DIC. She underwent an extensive diagnostic work up to evaluate for occult malignancy and infection with negative results. Peripheral smear showed schistocytes and she had a WBC of 4.7 k/uL/, Hgb 10.6 mg/dL and platelets 10 k/uL. Serum creatinine was 6.55mg/dl, total bilirubin 8.2mg/dl, AST 831 u/l, ALT 366 u/l, albumin 3.1mg, LDH 5663u/l, D-dimer >20,000ug/ml, haptoglobin <10mg/dl, fibrinogen 430mg/dl. PTT 52 and INR 1.2. She was noted to have normal ADAMTS13 activity and stool studies were negative for Shiga toxin. Immunofixation electrophoresis and complements C3 and C4 were normal. Quinine-dependent antiplatelet antibodies were positive for both IgG and IgM. After eliminating quinine, she continues to improve clinically and creatinine trended down to 3.8 at time of discharge.

Discussion: Quinine is a widely used remedy for leg cramps. Several over the counter therapies, nutrition products, and beverages such as tonic water and bitter lemon contain quinine. Allergic reactions to quinine can be severe and can affect multiple organs. Quinine was the first drug to be associated with acute thrombocytopenia, and it remains the second most commonly reported cause of drug-induced thrombocytopenia. Quinine was the first drug reported to cause TTP-HUS, it remains the most common cause of drug-induced TTP-HUS. Development of quinine-dependent antibodies to antigens is thought to be the main mechanism. Quinine can bind to surface molecules, altering their structure and exposing new parts of the cell membrane molecule to plasma; these revealed sequences are then recognized by the immune system as foreign antigens. Drug-dependent antibodies can be detected by flow cytometry. Exposure to quinine can cause multiorgan failure, TMA, severe hemolytic anemia and it is critical to recognize quinine-induced disorders for prevention of recurrent disease.

PUB612

Rapidly Progressive Glomerulonephritis During Pregnancy or Just AKI?

Sergio Vazquez,[1] Bernardo Moguel,[2] Karla B. Cano Escobar,[3] Enzo C. Vasquez jiménez,[2] Virgilia Soto.[4] [1]*National Institute of Cardiology, Mexico City, Mexico;* [2]*Instituto Nacional de Cardiologia, Mexico City, Mexico;* [3]*Instituto Nacional Cardiologia Ignacio Chavez, Tlalpan, Mexico;* [4]*INC Ignacio Chavez, Mexico City, Mexico.*

Introduction: The hemodynamic, inflammatory, and immunologic shifts in pregnancy may unmask underlying kidney disease. Rapid loss of kidney function is critical for maternal and fetal outcomes, once we have an active sediment, we can suspect for diagnosis of Glomerulopathy. We found just 4 case reports in literature about rapidly progressive Glomerulonephritis during pregnancy (RPGN).

Case Description: We compare 3 cases of "de novo" glomerulopathies during pregnancy. A case that match with RPGN by definition (Patient 1), with the presentation of other 2 cases of glomerulopathies with clinical characteristics of RPGN (Patients 2,3), but with different histologic features. These are young women, two with diagnosis of SLE, the biopsy was performed without complications, indications were kidney injury, important proteinuria and active sediment. All cases required interruption of pregnancy. They received induction that included plasmapheresis and 2 patients required hemodialysis. 2 infants had infectious complications and one low birth weight. After 6 months of follow-up, the patients were without renal replacement therapy.

Discussion: The presence of renal activity does not constitute an absolute contraindication to maintain pregnancy, but the increased disease activity is related to worst maternal-fetal outcomes. A lot of information is missing about RPGN during pregnancy. May be biopsy is not imperative, but we considered in centers like ours in which we can have rapid biopsy results, as a guide that may have an impact in prognosis.

Rapid Loss of Kidney Function During Pregnancy

Case	1	2	3
Diagnosis	LN Class IV+V	LN Class IV+V	Collapsing Glomerulopathy
Maternal Age	27	30	27
Time of Diagnosis	30.6 weeks	28 weeks	12.5 weeks
Serum Creatine	5.7 mg/dl	1.2 mg/dl	3.0 mg/dl
Proteinuria	3 g/g	14.4 g/g	5.2 g/g
Active Sediment	Yes	Yes	Yes
Crescents	>50%	< 25%	No
Acute Tubular Necrosis	No	Yes	Yes
Renal Replacement Therapy	HD	No	HD
ANCA	Negative	Negative	NA
Treatment	MPD+CFM+RTX+PLEX	MPD+CF+PLEX	MPD+PLEX
Maternal/Fetal Outcomes	Neonatal CNS infection	Neonatal Pneumonia	Respiratory distress
Newborn Weight	2500 grams	920 grams	2590 grams
6 Months Follow up	eGFR 21 ml/min, UACR 0.6g/g	eGFR 65 ml/min, UACR 0.9g/g	eGFR 30 ml/min UACR 1.2 g/g

Primary Amyloidosis with Rapidly Progressive Pattern: Case Report

Lionel C. Vargas,[1] Virgilia Soto,[3] L. M. Perez-Navarro,[2] Rafael Valdez-Ortiz,[1] Juan C. Trimino,[1] Maribel Merino.[3] *[1]Hospital General de Mexico, Mexico City, Mexico; [2]Hospital General de México Dr. Eduardo Liceaga, Mexico City, Mexico; [3]Instituto Nacional de Cardiologia, Mexico City, Mexico.*

Introduction: Primary systemic amyloidosis (AL) is a plasma cells disorder characterized by fibrills deposition (8-15 nm) of monoclonal Ig light chains. The incidence is 0.9 cases per 100,000 persons.

Case Description: 68 years old female, resident of Mexico. History of DM2 and hypertension, both newly diagnosed. She began in July 2017 with asthenia, adynamia, headache, abdominal pain and nausea; she presented in the hospital with blood pressure of 180/100 mmHg, kidney function test: creatinine 5.9 mg/dL, urea 202 mg/dL (in November 2016, creatinine was 1.3 mg/dL). The patient was evaluated because rapidly progressive kidney failure pattern. She began with hemodialysis. On the work up, we found proteinuria of 0.26 gr/gr, erythrocyturia was not found. Renal ultrasound: normal kidneys; renal biopsy was performed: Glomerular-Interstitial and vascular Amyloidosis, Positive Lambda (immune amyloid). IgG: (3+) in the amyloid material, IgA, IgM and C3C: (1+) positive in the amyloid material, C1q, C4C and fibrinogen: negative, Kappa: negative, Lambda: (2+) positive in the amyloid material, red congo positive. (Figure 1) Clinical Diagnosis: Primary systemic amyloidosis.

Discussion: The mean age of presentation is 65 years. Less than 20% of patients show progressive renal failure (creatinine> 2 mg / dL). This patient had an unusual presentation of amyloidosis with a rapidly progressive loss of renal function. Cases of multiple myeloma (MM) with amyloidosis have been described. Both conditions are plasma cell proliferation and between them, there are minimum differences. A patient with clinical manifestations of AL, with no MM symptoms, would have AL diagnosis; however; if the patient has MM symptoms (anemia, bone pain, osteolytic lesions) the diagnosis would be MM with associated AL.

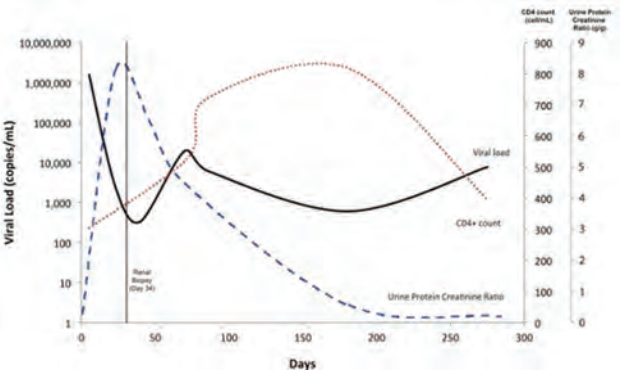
Transient Nephrotic Range Proteinuria After Acute HIV Infection

Andrew Vissing, Sara E. Jandeska. *Rush Children's Hospital, Chicago, IL.*

Introduction: Nephrotic syndrome is common among patients living with HIV. Although the majority of cases are diagnosed with HIV-associated nephropathy, a collapsing FSGS variant, immune-mediated etiologies and minimal change disease have also been described. There is an absence of literature describing acute HIV infection and its immediate renal sequelae. We describe a case of transient nephrotic range proteinuria without features of minimal change disease.

Case Description: A 17-year-old African-American male presented with pharyngitis, abdominal pain, fever, and lymphadenopathy. HIV antibody was undetectable but viral load measured 1.3 million copies/ml (CD4 count 304 cells/ml) suggestive of acute HIV infection. He was discharged with darunavir, emtricitabine-tenofovir, and ritonavir. Two weeks later, he presented with abdominal pain. Exam was notable for absence of edema. Chemistries showed acute kidney injury (BUN 25mg/dl, Cr 1.9mg/dl); a random protein/creatinine ratio was 9.2g/g. Serum albumin was 2.1 g/dl and cholesterol was 158 mg/dl. Work up of proteinuria was unremarkable. HIV viral load and CD4 count showed improvement on HAART. A renal biopsy showed normal glomeruli with acute tubular necrosis and absence of immune deposits. Electron microscopy showed global podocyte effacement. He was prescribed steroids. Over the next four months, he was repeatedly admitted for abdominal pain but never exhibited edema or hypercholesterolemia. He refused to take steroids and was noncompliant with HAART. Proteinuria gradually resolved, and remission was achieved five months after biopsy.

Discussion: We describe the acute onset of nephrotic range proteinuria due to diffuse podocyte injury without the examination or laboratory features of minimal change disease. Proteinuria developed with reconstitution of T cell immunity and decrease in HIV viral load and resolved without pharmacologic therapy. We propose that asymptomatic podocytopathy early in the course of infection could be a novel form of HIV-mediated renal disease.



PUB615

Case Report: Spontaneous Remission of Dialysis-Dependent Focal Segmental Glomerulosclerosis

Jian Cheng,[1] Alan Parnham,[2] Megan N. Turner.[3] Gold Coast Australia *[1]Westmead Hospital, Westmead, NSW, Australia; [2]Gold Coast University Hospital, Gold Coast, QLD, Australia; [3]Sullivan and Nicolaides Pathology, Bowen Hills, Queensland, NSW, Australia.*

Introduction: It is uncommon for focal segmental glomerulosclerosis (FSGS) to enter spontaneous remission. As far as the authors are aware there are no reports of a patient recovering renal function from this disease after long term dialysis.

Case Description: A 61 year old Caucasian female presented with nephrotic syndrome and acute kidney injury. There was no relevant medical history (including intravenous drug use) or medications. She was hypertensive and 33 pounds above her baseline. Urinalysis demonstrated 100 red blood cells/hpf, a protein to creatinine ratio of 7.5 g/g, albumin 1.8 g/dL. Creatinine increased from 0.68 to 1.45mg/dL. Vasculitic, infective and myeloma screen was normal. Renal biopsy demonstrated tip variant FSGS affecting 3 of 13 biopsied glomeruli, acute tubular injury, and mild interstitial fibrosis and tubular atrophy (IFTA) (figure 1). She was brought into remission by prednisolone 50mg and cyclosporin 100mg twice daily. 8 months later she re-presented with oligoanuric renal failure. Repeat renal biopsy confirmed FSGS, acute tubular injury and mild IFTA. Immunosuppressant therapy failed therefore was tapered and she was established onto maintenance dialysis. Remarkably 11 months on she spontaneously remitted: peritoneal equilibration test revealed a residual creatinine clearance of 20mL/minute. After ceasing dialysis her creatinine nadired at 1.15mg/dL and protein to creatinine ratio of 0.8g/g. She remained in remission until 7 years later where (now 70 years old) she became nephrotic with a creatinine of 5.94mg/dL. Biopsy reconfirmed FSGS (NOS category) of one tip, one perihilar and one cellular variant, with acute tubular injury and mild IFTA. After treatment with plasma exchange her creatinine has improved to 2.29mg/dL.

Discussion: This case of spontaneous remission in prolonged dialysis dependent FSGS prompts physicians to monitor the progress of all their patients with FSGS – Even those on dialysis!

PUB616

Cytomegalovirus Infection: A Possible Cause of Tip-Variant FSGS?

Cassie Kovach, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Collapsing focal segmental glomerulosclerosis (FSGS) is typically associated with HIV, but is also seen with other infections such as cytomegalovirus (CMV), parvovirus, and tuberculosis; autoimmune diseases; malignancies; and drug exposure.

Tip-variant FSGS has not been associated with infections. In our case a patient's initial biopsy read was collapsing FSGS and after not improving with steroids for 3 months, he improved quickly after initiation of anti-virals. However, overread of the biopsy by trained renal pathologist found tip-variant FSGS.

Case Description: A 69-year-old previously healthy man presented with sudden onset edema. Over 3 weeks his creatinine (Cr) increased from 0.8 to 3.8 mg/dL and he developed 19.8 g of proteinuria. Renal biopsy was read as collapsing variant FSGS with acute tubular injury, severe arterionephrosclerosis, and 20% interstitial fibrosis. Immunofluorescence was negative, and electron microscopy showed 100% foot process effacement. He was started on high dose prednisone and his Cr remained stable with no significant improvement in proteinuria. He presented 3 months later for a second opinion. HIV, parvovirus, quantiferon gold, SPEP, UPEP and complements were negative. CMV IgG and IgM were positive. CMV DNA PCR was 12,900 IU/mL. Valgancyclovir was added to the steroids, and within a week his creatinine started improving and then normalized. His proteinuria greatly improved. Valgancyclovir was stopped once CMV DNA PCR was negative, and steroids are being tapered. Overread of the biopsy by a trained renal pathologist fount tip variant FSGS. CMV immunostain was negative.

Discussion: Patients with the tip lesion are more likely to present abruptly with nephrotic syndrome and to respond to steroid therapy. It has been suggested the tip lesion may be an early form of FSGS not otherwise specified or a variant of minimal change disease based on biopsy studies. Our patient was on high dose steroids for 3 months with stabilization in creatinine but no improvement until anti-virals were initiated. An infectious cause was sought out due to the initial collapsing FSGS read. However, review of the slides revealed a tip variant FSGS, which has not been associated with infections. It is unclear whether the CMV was present at the time of biopsy, or was the result of several months of high dose steroids. However, the timing in improvement suggests it was contributing to the pathology.

PUB617

When Renal Artery Stenosis Should Get Intervention: A Case Report

Kostas Papamarkakis, Jeffrey M. Turner. *Yale University, New Haven, CT.*

Introduction: The two largest randomized control trials comparing medical therapy alone vs. medical therapy plus angioplasty and stenting for atherosclerotic renal artery stenosis (RAS), the ASTRAL & CORAL studies, did not show a difference in cardiovascular or renal outcomes between the two therapies. Despite the negative results, a subset of patients do benefit from angioplasty and stenting of renal artery stenosis. Here we present a case of rapid renal recovery and improved blood pressure control following revascularization therapy. We discuss the clinical considerations for selecting patients with RAS to undergo performing these procedures.

Case Description: The patient is a 76-year-old female with past medical history of hypertension and chronic kidney disease (solitary right kidney). She was referred to our hypertension specialty clinic for resistant hypertension and subacute decline in GFR over 9 months. Her blood pressure was persistently elevated (160-210mmHg/70-96mmHg) despite 4 drug therapy. She was volume overloaded on exam, and had a single abdominal bruit over her right epigastric area. Her labs were notable for a rise in serum creatinine from 0.9mg/dL to 4.2mg/dL over the previous 9 months. A serum aldosterone level was 1ng/dL and a plasma renin activity was 3.29ng/ml/hr. Our work up included a renal artery doppler revealing a solitary right kidney measuring 10.6cm. Resistive indices were 0.67 and peak systolic velocities were 367 cm/sec. The peak systolic velocity of the aorta was 110 cm/sec, with a renal:aortic peak systolic velocity ratio of ~3.3. The patient underwent angioplasty and stenting of her right renal artery, with rapid serum creatinine improvement to 1.09mg/dL. In addition, her blood pressure was well controlled on only 2 blood pressure lowering agents.

Discussion: This case demonstrates a dramatic improvement in renal function and blood pressure control following angioplasty and stenting for atherosclerotic RAS. While the current literature does not support the routine use of revascularization therapy for atherosclerotic RAS over medical therapy, a subset of cases should be considered for angioplasty and stenting. Patients likely to benefit include those with an elevated serum creatinine and a low resistive index on renal duplex, bilateral stenosis or unilateral stenosis with a solitary kidney, and uncontrolled hypertension despite 3 or more blood pressure lowering drugs.

PUB618

Atypical Myeloma Presenting as Chronic Hypokalemic Renal Tubular Acidosis

Anam Umar,[2] Ifedolapo O. Odebunmi,[4] Chamberlain I. Obialo.[1,3] *[1]Renal Division, Morehouse School of Medicine, Atlanta, GA; [2]Dept of Medicine, Morehouse School of Medicine, Atlanta, GA; [3]Dept. of Medicine, Morehouse School of Medicine, Atlanta, GA; [4]Dept of Medicine, Morehouse School of Medicine, Atlanta, GA.*

Introduction: Clinical presentation of multiple myeloma (MM) include renal dysfunction, hypercalcemia, anemia, proteinuria or bone disorder. Renal tubular acidosis (RTA) is an uncommon complication of established MM. Rarely, a variant MM with light chain proximal tubulopathy can manifest primarily with an electrolyte/acid-base disorder. We present a case in which the diagnosis of MM was preceded by years of hypokalemic RTA

Case Description: A 52-year-old female with no significant medical history was referred to the nephrology clinic for evaluation of her elevated serum creatinine and a 3–yr history of hypokalemia. Her review of system was normal and her only medications were multivitamins and potassium supplements. Physical exam and vital signs were within normal limits. Laboratory data were significant for serum creatinine of 2.4mg/dl, urea nitrogen of 20mg/dl, GFR of 27 mL/min/1.73 m^2, and potassium of 3.2mEq/L. Detailed review of her previous laboratory data revealed that she has had persistent hypokalemia for about 3 years and urinalysis with a pH of 5.0, 2+ proteinuria, and glycosuria. These were suggestive of a proximal type RTA. Current laboratory evaluation revealed a quantitative proteinuria of 6.5g/day. Infectious and immunologic workup including HIV, hepatitis panel, ANA, and complements were within normal limits. However, serum immuno-electrophoresis revealed a homogeneous spike in the gamma-globulin zone and a high free light chain which showed a kappa/lambda ratio of 178 [normal 0.26 - 1.65]. Renal biopsy showed: global and segmental sclerosis; distended proximal tubular cells with vacuoles and loss of brush border; tubular atrophy with interstitial fibrosis which were consistent with a light chain induced tubular injury. Bone marrow biopsy confirmed the diagnosis of MM. She was treated with combination chemotherapy and subsequently received an autologous bone marrow transplant. Hypokalemia resolved after the transplant

Discussion: Rare cases of Fanconi type RTA preceding the diagnosis of MM has been reported. It's often associated with toxic proximal tubulopathy as opposed to the classic cast nephropathy on renal biopsy. Accumulation of kappa light chains in the lysosomes of the proximal tubular cell is the postulated mechanism of the proximal tubular damage. This case emphasizes the need for an early referral to a nephrologist for evaluation of electrolyte/ acid-base imbalance.

PUB619

Tumor Lysis Syndrome in a Patient with Chronic Lymphocytic Leukemia

Nwabundo Anusim, Daniel E. Ezekwudo, Ishmael Jaiyesimi. *Beaumont Hospital, Royal Oak, MI.*

Introduction: Tumor lysis syndrome (TLS) occurs as a result of tumor cell death and release of intracellular contents into circulation resulting in multi-organ dysfunction and death. It rarely occurs spontaneously in patients with chronic lymphocytic leukemia (CLL). We present a 75-year-old female with a history of CLL in remission that presents with confusion and diagnosed with spontaneous TLS.

Case Description: A 75 year old Caucasian female with a history of stage 1 right sided breast cancer and left sided DCIS s/p mastectomy and tamoxifen for 5 years, CLL Rai stage IV treated due to symptomatic splenomegaly with bendamustine and rituximab (BR) with excellent hematologic response. Nine years post treatment with BR, hematologic analysis revealed lymphocytosis, progressive anemia, thrombocytopenia and splenomegaly. Subsequently, she presented at an outside facility with acute encephalopathy following a viral prodrome. Laboratory results showed white blood cell count (WBC) of 300 bil/L. She was transferred to our facility for emergent leucopharesis. On presentation, she was confused and oliguric. She had a WBC of 270 bil/L with predominant lymphocytosis 248 bil/L, creatinine 4.65 mg/dl, potassium 6.0mmol/L, phosphorus 4.9mg/dl, calcium 7.8mg/dl, bicarbonate of 7mmol/L and uric acid 16.1mg/dl. Peripheral blood smear revealed smudge cells but no blasts. She was aggressively hydrated, given rasburicase and emergent dialysis. Following dialysis, her mental status and renal function significantly improved. Bone marrow biopsy analysis showed hypercellular marrow with extensive involvement of CLL, CLL genotype showed an unmutated immunoglobulin variable region heavy chain status (IgVH) and cerebrospinal fluid analysis showed a flow cytometry positive for monotypic B-cell population with a CLL phenotype. She follows with her oncologist and will be started on Ibrutnib.

Discussion: TLS is an oncologic emergency and requires immediate treatment with aggressive hydration to prevent renal failure, seizures and cardiac arrhythmias resulting from the toxic intracellular material released during cell lysis[1]. High burden, chemo-sensitive tumors with high proliferation rate are high risk for TLS[2]. Spontaneous TLS is rarely seen in patients with CLL due to its low proliferation and very limited data on TLS in CLL has been reported[3]. Further investigation into the clinic-pathologic mechanism for TLS in patients with CLL is pertinent.

PUB620

Diagnostic Role of Cystatin C in the Assessment of Kidney Function on PARP Inhibitors

Hao Wang, Abdallah Sassine Geara, Jonathan J. Hogan. *Hospital of the University of Pennsylvania, Haddonfield, NJ.*

Introduction: Novel targeted therapies have expanded the arsenal of treatment options for various malignancies and led to significant improvement in prognosis. However, as new drugs rapidly enter the clinical arena, potential nephrotoxic effects are often poorly defined or understood but later increasingly recognized. Poly (ADP-ribose) polymerases (PARP) inhibitors are a class of medications that promote tumor cell death and have emerged as a treatment option for patients with solid-organ malignancies; namely, ovarian, breast, and pancreatic cancers. These medications interact with transporters along the renal tubules involved in the secretion of creatinine. An increase in serum creatinine has been reported in patients treated with these agents; in fact, in phase II open-label trials of rucaparib, an elevation in creatinine occurred in 92% of patients. However, it remains unclear whether these represent impact on creatinine secretion alone versus acute or enduring decrement to glomerular filtration rate.

Case Description: A 54-year-old man with stage 2 chronic kidney disease from prior cisplatin-toxicity and pancreaticobiliary adenocarcinoma was initiated on rucaparib, a PARP inhibitor. His past medical history was notable for type 2 diabetes on insulin. He did not use nonsteroidal anti-inflammatory drugs, angiotensin-converting enzyme inhibitors, or angiotensin receptor blockers. His baseline serum creatinine stabilized at 1.4 mg/dl (eGFR 57 ml/min/1.73m^2 by the CKD-EPI equation). Following PARP inhibitor therapy, his serum creatinine rose to 2.0 mg/dl (eGFR of 35 ml/min/1.73m^2). Renal ultrasound showed normal kidney size without evidence of hydronephrosis or stones. Concurrent serum cystatin C was 1.4 mg/dl, corresponding to an eGFR of 51 ml/min/1.73m^2 by the CKD-EPI cystatin C equation.

Discussion: Accurate assessment of kidney function for patients on PARP inhibitors impacts multiple aspects of care. Elevations in serum creatinine can be prevent patients from receiving IV contrast for needed surveillance imaging, can prompt nephrology referral and additional diagnostic testing, and potentially lead to hospital admissions for acute kidney injury. While cystatin C has been slow to gain traction for clinical use, it may have an important role in understanding renal effects of novel drug therapies, especially in the evolving world of onco-nephrology.

PUB621

Who Stole My Electrolytes? A Case of Fanconi Syndrome with Ifosfamide Use

Laila Babar,[1] Sohaib Zahid,[2] Deep Shah,[2] Obaid Ashraf,[2] Larisa Greenberg,[2] Christie Hilton.[2] *[1]Internal Medicine, Alleghany Health Network, Pittsburgh, PA; [2]Alleghany General Hospital, Pittsburgh, PA.*

Introduction: Ifosfamide is an anti-neoplastic alkylating agent used in to treat various malignancies. It has been linked to severe nephrotoxicity and can lead to Fanconi syndrome. This is a type II proximal renal tubular dysfunction characterized by hypophosphatemia, hypobicarbia, hypokalemia, glucosuria and amino aciduria. Nephrotoxicity with Ifosfamide is common but a complete Fanconi syndrome is rare, especially in adults.

Case Description: 64 year old gentleman with a history of myxoid spindle cell neoplasm was admitted for severe electrolyte abnormalities. He had received 5 cycles of Adriamycin, Ifosfamide and Mesna (AIM) along with 4400 cGy radiation and his cumulative Ifosfamide dose was 30g/m2. His last treatment was one week prior to presentation. He tolerated his cycles well with no grade 3-4 toxicities. On presentation, his creatinine was elevated at 1.84 from a baseline of 0.90, he had severe hypokalemia of 2.8, which did not correct with multiple runs of IV potassium. His bicarbonate level was 11, phosphate 1.2, magnesium 1.5 and his urinalysis was positive for glucose, ketones and protein. His fractional excretion of phosphate was elevated to 70%. Nephrology was consulted and he was diagnosed with Fanconi syndrome secondary to Ifosfamide toxicity. He was kept inpatient and received twice daily electrolyte supplementation and supportive treatment with IV hydration. After 10 days of supportive treatment he did not require further electrolyte supplementation.

Discussion: There is a 1.5-4% chance of developing Fanconi syndrome with Ifosfamide in children however, there have only been isolated case reports in adults. It is usually related to a high cumulative dose of 45-60 g/m2. The exact mechanism of renal injury is unclear but its related to the byproduct Chloracetaldehyde induced wasting of the ATPase in the Na/K cotransporter on the proximal tubule cells causing electrolyte wasting. The mainstay of treatment is symptomatic management with IV hydration and electrolyte supplementation. Early diagnosis and vigilant electrolyte monitoring is essential for a good outcome. Fanconi syndrome can occur days to weeks after treatment and should always be a differential in patients on AIM with electrolyte wasting. It is generally reversible and needs supportive care to ensure the electrolyte imbalance does not cause life threatening arrhythmias.

PUB622

A Unique Case of Clarkson Disease in a Multiple Myeloma Patient

Adedamola M. Adeboye,[1] Aimen Liaqat,[2] Seema Karanjgaokar,[3,1] Daniel Angeli.[1] *[1]Saint Barnabas Medical Center, Livingston, NJ; [2]Saint Barnabas Medical Center, West Orange, NJ; [3]Nephrological Associates, Livingston, NJ.*

Introduction: The first fatal case of a rare systemic capillary leak syndrome (SCLS) was reported by Clarkson and since then, approximately 100 cases have been reported. It is a rare syndrome that mimics septic shock and is frequently associated with monoclonal gammopathy.

Case Description: A 50-year-old female with hypothyroidism and chronic kidney disease presented with presyncope, weakness and hypotension. She had a year history of on and off generalized body swelling unresponsive to diuretics and fluid restriction. She also had a prior admission for septic shock. Labs were significant for leukocytosis, polycythemia, hypercalcemia, low albumin, anion gap metabolic acidosis, elevated TSH and trace protein in the urine (200mg). Erythropoietin level, inflammatory markers and BNP were normal. Echo revealed preserved ejection fraction. A combination of hypotension, hemoconcentration and hypoalbuminemia was indicative of Capillary Leak Syndrome. Elevated paraproteins (kappa) were noted. A bone marrow biopsy revealed plasma cell myeloma and flow cytometry showed a clonal population of kappa-restricted plasma cell with CD56 expression. She was treated with pulse dose steroids and diuretics with improvement of her edema. She was subsequently discharged home on diuretics and to be started on chemotherapy outpatient.

Discussion: SCLS is a diagnosis of exclusion based on clinical findings. A rapid increase then drop in hematocrit and hypoalbuminemia are pathognomic. The capillary leak phase is characterized by severe intravascular fluid shifts presenting as generalized edema, compartment syndrome, ascites or effusions. Fatal circulatory shock may occur in this phase. This is followed by a fluid recruitment phase 1- 4 days later. Life-threatening pulmonary edema can develop here if fluid loss is over corrected. Several mechanisms such as vasoactive agents, endothelial receptors and signal transduction pathways have been suggested but the pathophysiology is poorly understood. No curative treatment is available but treatment with diuretics, steroids, theophylline, terbutaline, statins or immunoglobulins have been attempted with some success. Annual screening for lymphoproliferative disorders is also recommended. SCLS should be suspected in cases of shock with no clear source of infection. The immediate treatment should be focused on stabilizing the hemodynamic parameters because it can be potentially fatal otherwise.

PUB623

Renal Metastasis: Rare Initial Presentation of Ovarian Cancer

Kim Phung L. Nguyen,[1] Sara Faiz,[4] William F. Glass,[3] Jaya Kala.[2] *[1]University of Texas Health Science Center at Houston, McGovern Medical School, Houston, TX; [2]Ut Houston Medical Center, Houston, TX; [3]University of Texas – Houston Medical School, Houston, TX; [4]University of Texas Houston, Houston, TX.*

Introduction: Paraneoplastic glomerulonephritides are clinical manifestation of renal disease that are induced by products of tumor cells. Here we report a rare case of ANCA-associated glomerulonephritis as the initial presentation of ovarian cancer.

Case Description: A 79 years old woman with hypertension, diabetes mellitus, chronic kidney disease, diastolic heart failure, presented with worsening bilateral lower extremity edema, abdominal distension, dyspnea, hematuria and vaginal bleeding. She had history of left total mastectomy for invasive ductal carcinoma in remission. Her 8-year history of postmenopausal vaginal bleeding was evaluated to be negative for malignancy. Patient was started on diuretics for dyspnea and antibiotics for pyuria. Her baseline creatinine (Cr) was 1.3-1.5 mg/dL. On further evaluation, she had proteinuria of 2 gm/d without monoclonal bands; hepatitis panel, TB, and HIV were negative; urinalysis showed protein 2+, RBC 182/hpf, WBC 31/hpf and a few bacteria; ANA titer 1:640, C3 117, C4 44.8, MPO-ANCA 17.8, PR3-ANCA<3.5. Due to elevated MPO-ANCA levels and Cr 4.7 mg/dL with proteinuria, a kidney biopsy was obtained which surprisingly showed poorly differentiated high grade adenocarcinoma involving almost the entire sample, favoring high grade serous carcinoma of ovarian primary with positive staining for WT-1, P16, PAX-8, ER and P53. The light microscopy sample had one glomerulus that showed nodular diabetic glomerulosclerosis. Follow up pelvic ultrasound did not reveal any malignancy. CT abdomen showed calcification along right adnexa and prominent sized right ovary. CA-125 was found to be 31,684 U/mL. The presence of elevated anti-MPO antibody made us suspicious of ANCA-associated glomerulonephritis which was considered a paraneoplastic manifestation. She was started on mycofenolate and steroids. Due to her worsening uremia and oliguria she was started on dialysis. Her clinical condition continued to worsen and with poor performance status she was deemed unsafe to initiate chemotherapy for ovarian cancer. Patient was discharged to skilled nursing facility.

Discussion: To the best of our knowledge this is the first case reporting renal metastasis from ovarian malignancy. This highlights the importance of renal biopsy in patients with worsening renal function since this was the only way we were able to reach the diagnosis of ovarian malignancy in our patient.

PUB624

Multiple Myeloma in Association with Light Chain Deposition Disease in a 39-Year-Old: A Case Report

Amaresh R. Vanga,[1] Varun Malhotra,[2,1] Alamgir Mirza.[1] *[1]Nephrology, Eastern Virginia Medical School, Norfolk, VA; [2]Nephrology Associates of Tidewater, LTD, Virginia Beach, VA.*

Introduction: Multiple myeloma is a cancer of the elderly and most often the suspicion is raised in the older population. Only 2 percent of all cases of multiple myeloma present in patients younger than 40. Here we present a case of light chain deposition disease(LCDD) with features of cast nephropathy which is diagnostic of myeloma kidney in a 39-year-old male. Thus, recognition and knowledge of varied presentations can help in early diagnosis and treatment of the disease.

Case Description: A 39-year-old male with a history of hypertension presents with body aches for the past 2 weeks. He was mildly hypertensive at presentation (BP–152/90 mmHg). Data showed decreased HCT (20.7%); high BUN (78 mg/dl); increased serum creatinine (9.5 mg/dl), a mild increase in serum calcium (10.6 mg/dl). Protein/creatinine ratio was 4.19; normal serum albumin (4mg/dl). Urine dipstick was one plus for protein. Ultrasound was unremarkable. SPEP showed M protein of 0.4 g/dl. UPEP showed free k light chains in the gamma region. K/L ratio was 1670. Serologies for hepatitis B, hepatitis C, ANCA, anti-GBM, rheumatoid factor were negative. C3, C4 was normal. kidney biopsy was done. Among the ten glomeruli sampled, one showed global sclerosis with others showing no specific pathological alterations. Tubules were filled with dense lamellated casts, some of which were surrounded by multinucleated giant cells. Interstitium showed 30% fibrosis and tubular atrophy. Congo red stain was negative. Immunohistochemistry showed kappa chain positivity in tubular casts, basement membrane of tubules. Immunofluorescence for IgG, IgM, IgA, C3, and C1q was negative. Electron microscopy revealed finely granular deposits on tubular basement membrane with thickening. So based on clinical features, histopathology, electron microscopy and immunofluorescence a final diagnosis of light chain deposition disease with cast nephropathy was made.

Discussion: LCDD typically occurs in association with Multiple Myeloma (MM) or other lymphoplasmacytic disorders. The incidence of LCDD in patients with plasma cell dyscrasia is approximately 5%. Many patients with LCDD are associated with MM, but up to 50% of patients do not have concurrent MM. Though the incidence of these diseases is extremely uncommon in the younger population it still has to be considered for early diagnosis and effective treatment.

PUB625

Gemcitabine Drug-Induced Thrombotic Microangiopathy: A Clinical Diagnosis

Nihal Bashir, Khuloud A. Al mutawa. *Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates.*

Introduction: Thrombotic Microangiopathy (TMA) is a pathologic abnormalities in the arterioles and capillaries leading to microvascular thrombosis and diagnosis is made by tissue biopsy. 2 mechanisms are involved in D-TMA, immune-medicated, and dose or

duration related. Immune medicated D-TMA is related to recent onset within 21 days of a daily administered drug or within hours of intermittently administered drug.

Case Description: 34 year old female patient, Diagnosed with adrenocortical cancer in 2015, underwent multiple surgeries for tumor debulking, including right nephrectomy. Patient received multiple lines of chemotherapy including Platinum based chemo, and Gemcitabine for the last 2 years. In December 2018, she developed TMA picture after 3 days of receiving her chemotherapy (MAHA, Thrombocytopenia, AKI). Immune work up, Hepatitis B and C virus were negative. Complement levels showed normal C4 level and Low C3 of 0.81 (Normal value 0.9-1.80). Urinalysis : Positive for RBCs (1430 cell/micoL), no comment on Cast. Protein /Creatinine Ratio was : 10.5 g/g. Serum Albumin : 24 g. WBC: 1.9X10^9, HB: 90 g/L, Platelets : 13 X10^9. ADAMT13 activity was normal 114 %, (Normal Ref range 48-115), ADAMTS13 inhibitor : 1.9 U/ml (Normal value 1.8-7.1) Normal coagulation profile but high LDH. Peripheral blood smear showed (6%-10%) schistocytes. Patient's clinical picture was of Thrombotic microangiopathy (MAHA, Schistocytes, Thrombocytopenia, AKI) but kideny biopsy was not performed. Patient had daily plasma exchange sessions, 6 doses of eculizumab and 2 doses of Rituximab during her hospital stay. The plan of care included eculizumab 1200 mg every two weeks. Her recent blood tests showed normal bilirubin, normal platelets : 300X10^9 and LDH :385 IU/L. The patient remained on haemodialysis for three sessions per week.

Discussion: Gemcitabine induced TMA was first described in 1994 in phase II clinical trial in pancreatic adenocarcinoma patients. The estimated incidence is 0.015% to 1.4%. Mortality is up to 15%. It is associated with cumulative dose more than 20 000, or when doses are more than eighteen doses or duration more than 7 months but can occur within 5 days after the first dose. In view of normal ADAMTS 13 activity, features of TMA can be attributed to Gemcitabine in our patient. A clinical diagnosis can be made and a therapeutic trial can give the patient the benefit of doubt.

PUB626

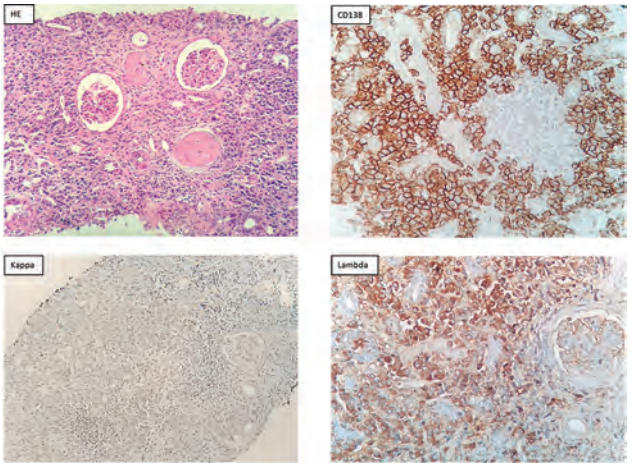
Differential Diagnosis on Kidney Impairment Related to Multiple Myeloma: A Case Report

Fabio M. Torres, Pablo A. Vale, Jeison Gois, Rafael A. Souza, Fábio A. Reis, Luiz V. Affonso, Guilherme P. Santa Catharina, Igor Smolentzov, Livia B. Cavalcante, Cristiane B. Dias, Luis Yu, Viktoria Woronik, Lectícia Jorge. *Nephrology, University of São Paulo, S, Brazil.*

Introduction: Kidney disease is one of the most common complications in Multiple Myeloma (MM), affecting approximately 50% on diagnosis. Renal impairment if often described due to Hypercalcemia, Cast Nephropathy and Amyloidosis. We present an unusual form of kidney injury associated with MM.

Case Description: Woman, 71 yo, previously hypertensive, complained of weight loss over the last year. During initial evaluation, presented the following laboratorial findings: Hemoglobin 5.1 g/dL; Reticulocytes 1.2%; SCr 2.78 mg/dL; BUN 16 mg/dL; Calcium 8.5 mg/dL; no hematuria and no leukocyturia at urinalysis; UPCR 3.76 g/g; SPEP with Gammaglobulin Monoclonal peak of 6.4 g/dL and Albumin 2.5 g/dL; Serum and Urine Immunofixation exhibit IgG/Lambda paraproteins; Bone marrow aspirate with 39.2% of clonal plasma cell, confirming MM diagnosis. Kidney biopsy showed an atypical monoclonal plasma cell infiltrate on renal parenchyma, confirmed by CD138 and Lambda positive immunostaining, with negative Kappa, associated with Cast Nephropaty. Immunofluorescence suggested Monoclonal Immunoglobulin Deposition Disease; Congo Red was negative. After 4 months of follow up and treatment with Cyclophosphamide and Dexamethasone, presents SCr 1.38 mg/dL; BUN 12 mg/dL; SPEP without monoclonal peak and UPCR 0.79 g/g.

Discussion: Cast Nephropathy is the single most common finding among patients with MM and clinical kidney involvement, leading to AKI. We report a patient with an unusual kidney involvement, with atypical monoclonal plasma cell infiltration of the renal parenchyma, which is often reported on advanced disease. Kidney biopsy is mandatory for diagnose and establishes the degree of activity and chronicity, in order to determine the treatment intensity and prognosis. On behalf of that, we decided to keep the chemotherapy in our patient.



PUB627

An Unusual Case of Acquired Fanconi Syndrome with Acute Myelogenous Leukemia

Robert C. Hartley, Matthew Gumbleton, Terrence S. Bjordahl, Josephine Abraham. *University of Utah, Salt Lake City, UT.*

Introduction: Acquired Fanconi syndrome is frequently associated with certain drugs and toxins, multiple myeloma and some autoimmune diseases. However, we present a case with a patient undergoing treatment for acute myelogenous leukemia (AML) who presented with Fanconi syndrome and imaging consistent with infiltrative disease in the kidneys.

Case Description: A 19-year-old woman with AML who was admitted for salvage chemotherapy. She was previously treated with cytarabine and daunorubicin, cladribine and mitotane and then decitabine. The salvage regimen consisted of vinorelbine, topotecan, thiotepa and clofarabine. Urine output ranged from 4-13 liters per day. Chemistry studies were notable for hypernatremia with serum sodium of 153 mmol/L, hypokalemia with potassium of 2.7 mmol/L, non-gap metabolic acidosis with serum bicarbonate of 10 mmol/L, hypomagnesemia with serum magnesium of 1.5 mg/dL, hypophosphatemia with serum phosphate of 1.2 mg/dL, hypouricemia with serum uric acid of 1.8 mg/dL, serum glucose of 106 mg/dL and a serum creatinine of 0.6 mg/dL. Urine studies showed glycosuria despite normoglycemia, elevated beta-2-microglobulin, elevated trans-tubular potassium gradient and elevated urine anion gap. Follow up studies showed atypical cells in urine cytology. Contrast enhanced CT-Imaging of the abdomen showed voluminous kidneys with decreased enhancement bilaterally. The patient's electrolytes and polyuria were treated with aggressive repletion and administration of desmopressin. She underwent bone marrow transplant, but contracted multiple opportunistic infections including mucormycosis sinusitis, fungemia and bacteremia. These progressed to septic shock ultimately leading to her death five weeks after the initial evaluation.

Discussion: Fanconi syndrome is classically associated with cisplatin, ifosfamide and plasma cell dyscrasias in hematologic malignancy, but not any of the agents used to treat this patient. Here, however, we present a case with findings consistent with Fanconi syndrome most likely secondary to infiltrative AML in the kidneys, as evidenced by nephromegaly and atypical cells on urine cytology. Similar cases have been reported in the pediatric literature associated with acute lymphocytic leukemia which resolved with treatment of the underlying disease.

PUB628

Nephrotic Syndrome: A Clue to Diagnosing Chronic Graft vs. Host Disease

Nirav Parikh,[1] Pooja D. Amarapurkar.[2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University Renal Division, Atlanta, GA.*

Introduction: Nephrotic range proteinuria (NRP) is a result of primary glomerulopathy, or renal manifestation of systemic diseases such as Diabetes Mellitus, Amyloidosis and Lupus Nephritis, to name a few. Complication of hematopoietic cell transplantation (HCT) such as Graft versus Host Disease (GvHD) is a less common yet well-established cause of NRP.

Case Description: We present a case of a 63-year-old male with a diagnosis of Myelodysplastic Syndrome. He was initially treated with chemotherapeutic agent azacitidine without response and eventually underwent an allogenic stem cell transplant with minimal residual disease. Maintenance immunosuppression was tacrolimus and low dose prednisone with gradually decreasing doses. His medical condition remained stable for about two years until he presented to the hospital with new onset anasarca. He had no other symptoms and serum creatinine level was within normal limits at that time. Hematological work up at the time was unrevealing. Evaluation of urinary protein excretion revealed greater than 13 grams of protein in 24 hours with a spot urine protein to creatine ratio that was greater than 8 grams. He was diagnosed with new onset Nephrotic Syndrome and was given intravenous Lasix with good response. A renal biopsy was performed to evaluate the cause of NRP. The renal pathology was reported as Membranous Nephropathy (MN) with features suggestive of a secondary cause. MN was thought to be the renal manifestation of GvHD. The patient was restarted on Tacrolimus 1mg twice daily and Prednisone dose was increased to 60mg daily. A bone marrow biopsy was not performed. The GvHD was presumed to be renal limited; the patient was continued on tacrolimus 1 mg twice daily with tapering doses of steroids with significant improvement of proteinuria.

Discussion: This case highlights an important aspect of recognizing NRP as a manifestation of Renal limited GvHD in order to prevent hematopoietic cell transplant complications. Occasionally NRP may be the only manifestation of GvHD which is a rather systemic process. Adjustment and or increase in the immunosuppressive regimen is necessary to manage such cases and thus can save the transplanted tissue from failure. More studies are needed to further understand this entity.

PUB629

Long-Term Management of Idiopathic Retroperitoneal Fibrosis Eventually Leading to Gout Medication

Eddy J. De Jesus, Justin Lee Loy, Gajapathiraju Chamarthi, I. D. Weiner. *University of Florida, Gainesville, FL.*

Introduction: Retroperitoneal fibrosis (RF) is a condition characterized by the presence of inflammatory and fibrous retroperitoneal tissue that often encases the ureters or abdominal organs. We present a case of retroperitoneal fibrosis that was treated with various immunosuppressive therapies over seven years with variable response to therapy.

Case Description: A 43-year-old male presented with abdominal pain; CT scan findings revealing circumferential soft tissue thickening around the abdominal aorta consistent with findings of RF. Prednisone was initiated, with improvement after 1 month followed by a steroid taper with recurrence of symptoms within 11-months. He was concerned for steroid side effects and opted for Cellcept. After 6 months he decided to be off medications and within a year, initial symptoms returned and restarted on high dose steroids. After tapering he was transitioned to Tamoxifen which later was switched to methotrexate and subsequently Imuran; all were discontinued due to GI intolerance. He opted for colchicine and 3 months into regimen he continued with no symptoms and stability of RF in repeat imaging.

Discussion: Management of RF is aimed to halt the progression of the fibrotic process and prevent a recurrence. In idiopathic cases, steroids as induction therapy should be initiated as soon as the diagnosis is made. In those who do not respond to steroid therapy or cannot tolerate the side effects, studies using Cellcept, Tamoxifen, Imuran, and Methotrexate have all been used with various degrees of success. For colchicine therapy, a case series involving seven patients were treated with colchicine plus prednisone, and after reaching a clinical response, the steroid dose was tapered, maintaining daily colchicine therapy with no recurrence or treatment failure observed during follow-up.

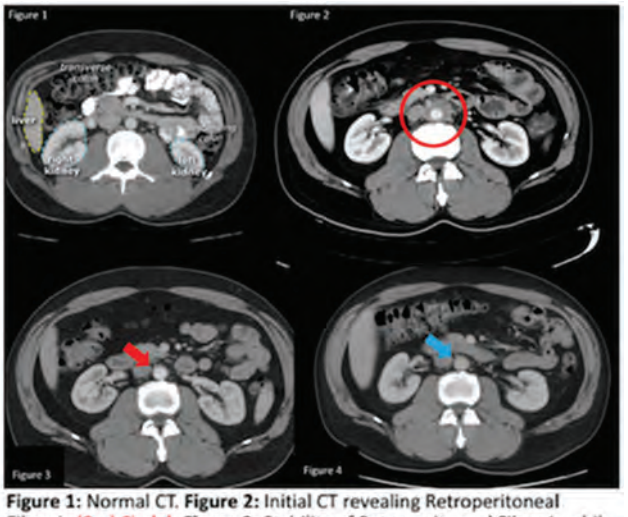


Figure 1: Normal CT. **Figure 2:** Initial CT revealing Retroperitoneal Fibrosis (Red Circle). **Figure 3:** Stability of Retroperitoneal Fibrosis while on Imuran therapy (Red Arrow). **Figure 4** Stability of Retroperitoneal Fibrosis while on Colchicine therapy for 3 months (Blue Arrow).

PUB630

Ifosfamide-Induced Fanconi Syndrome: A Rare Complication in Adults

Muhammad A. Ali, Mary O. Muoneke. *Emory University, Atlanta, GA.*

Introduction: Fanconi syndrome is a metabolic disorder characterized by severe proximal renal tubule dysfunction. It leads to impaired reabsorption of amino acids, glucose, phosphorus, potassium, urate and bicarbonate. Ifosfamide is used in the treatment of a variety of childhood and adult malignancies. Pathophysiology of its toxicity is unclear, but thought to be due to accumulation of the toxic metabolite chloroacetaldehyde in proximal tubular cells. Only a few cases have been reported in adults. We describe a case of an adult with diffuse large B cell Lymphoma who developed Fanconi Syndrome following Ifosfamide use.

Case Description: A 70-year-old Caucasian female with history of diffuse large B cell lymphoma presented to the ER with complaints of increased fatigue and confusion, which started a day after chemotherapy session with Ifosfamide. Physical exam revealed a confused female with trace pedal edema but otherwise normal exam. BP: 175/93, HR: 84/min, RR: 20/min, Temp: 36.6 C. Imaging studies were normal. Labs revealed Sodium 143, Potassium 2.5, HCO3 16, chloride 119, phosphorus 1.5mg/dl magnesium 1.3 mg/dL, creatinine 1.4, serum glucose109. She had a hyperchloremic metabolic acidosis and acute kidney injury with glycosuria with normal serum glucose. Fanconi's syndrome was suspected and 24 hour urine amino acid screen came back positive for Aspartic Acid, Threonine, Serine, Glutamic Acid, Glutamine, Glycine, Alanine, Cirulline, Valine, Cystine, Methionine and Isoleucine, amongst others A diagnosis of Ifosfamide induced Fanconi syndrome was made and aggressive electrolyte/bicarbonate and fluid repletion was started, Ifosfamide was discontinued and she improved remarkably after two weeks

Discussion: The mechanism of Ifosfamide induced renal injury is not completely understood. It is postulated that chloroacetaldehyde (CAA), a toxic metabolite is thought to deplete intracellular glutathione in the renal tubule, predisposing to cellular damage. Our patient had glycosuria in the presence of normal blood glucose, aminoaciduria, hypokalemia, hypophosphatemia and hyperchloremic acidosis which is consistent with Fanconi syndrome. Early detection and treatment is key to preventing further deterioration in renal function and mental status. Although uncommon, Fanconi syndrome can be fatal and should be considered in any patient with any degree of renal impairment on Ifosfamide.

PUB631

Oliguric AKI Following Laparoscopic Ablation of Liver Metastases

Aniesh Bobba, Andy Chuu, Tingting Li. *Washington University in St. Louis, St. Louis, MO.*

Introduction: Microwave ablation is a form of thermal ablation used for the treatment of solid liver lesions. With this therapy, the reported incidence of acute kidney injury (AKI) has been as high as 20% with tumor size > 5cm but AKI requiring dialysis is a relatively rare complication. AKI as a result of microwave ablation has gained increasing attention among surgeons in recent years but remains a relatively unknown phenomenon among nephrologists. We present a case of oliguric AKI requiring dialysis following microwave ablation of liver lesions.

Case Description: A 42-year-old male was admitted following laparoscopic microwave ablation of metastatic liver lesions from colon cancer. Ablation was performed on four liver lesions, with the largest measuring 1.5 cm. There was minimal blood loss and patient was hemodynamically stable during the intra-operative and post-operative period. He developed AKI on post-op day 1 with a rise in creatinine (Cr) to 2.51 mg/dL (1 mg/dL prior to ablation) accompanied by oliguria. A careful review of history (medications, IV contrast, etc) and search for potential causes (ANA, ANCA, anti-GBM antibody, complements, CPK) were unrevealing. Renal ultrasound with dopplers was unremarkable. Urinalysis was positive for 2+ protein, 3+ blood, 1+ glucose. Urine microscopy showed no granular casts or cells. Patient was given intravenous fluids for possible volume depletion but renal function continued to worsen. By day 3, his Cr was 8.1mg/dL and hemodialysis was initiated for oligoanuria and volume overload. Further testing revealed haptoglobin < 10 mg/dL and elevated LDH of 492 units/L. Hemoglobin dropped from 13.9 to 11.3 within the first 3 days post-op. Due to lack of recovery, a kidney biopsy was performed and pathology showed acute tubular injury with evidence of hemoglobin casts in the tubules.

Discussion: This case report highlights the importance of recognizing AKI related to hemolysis as a potential complication following microwave ablation. The liver is a highly vascular organ and carries an inherent risk of hemolysis resulting from exposure to adjacent thermal energy during ablation. Temperatures can reach as high as 100°C. Preventative measures including pre-op hydration, intra-op limits on the duration and applied energy, and close postop monitoring may help in prevention and early identification of AKI related to hemolysis secondary to microwave ablation.

PUB632

Plasma Exchange Therapy as Treatment for Myeloma Kidney

Cynthia Rivas,[1] Leonardo Pozo Garcia,[1] Brandon Cantazaro,[2] Sergio A. Trevino Manllo.[3] *[1]University of Texas Rio Grande Valley at Doctors Hospital at Rennaissance, McAllen, TX; [2]University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; [3]South Texas Kidney, McAllen, TX.*

Introduction: Multiple myeloma (MM) is characterized by a clonal proliferation of malignant plasma cell producing monoclonal proteins, which can lead to organ damage. Renal involvement is present 20-40% of MM. Severe acute kidney injury (AKI) related to intratubular cast formation is a common manifestation. Early reduction of serum free light chain (FLC) is associated with recovery of AKI. Survival of MM is related to kidney function. Plasma exchange therapy has been studied for myeloma kidney, although data is limited and current evidence is non-conclusive. We herein report a case of myeloma kidney with renal recovery after plasma exchange therapy.

Case Description: 84-year old female with history of multiple myeloma treated with 1 cycle of bortezomib and dexamethasone presented to the hospital with AKI. Labs upon presentation were showing a creatinine of 4.8 from baseline creatinine of 1.2. Serum kappa FLC of 7287 with a kappa/lambda ratio of 3259. Vital signs and physical examination were unremarkable. Patient received standard chemotherapy and fluid resuscitation. Given significant kidney dysfunction and severely elevated kappa FLC plasmapheresis was recommended. Patient received 3 sessions of plasma exchange. Before and after kappa FLC were measured. A significant decrease in creatinine and kappa FLC was observed by post-procedure day 4, with creatinine of 2.9 and kappa FLC of 2999. Patient was discharged and followed up at clinic.

Discussion: Our case demonstrates that plasma exchange therapy might provide a benefit to patients with severely elevated kappa FLC and significant kidney dysfunction. More clinical trials are needed to further establish the role of plasma exchange in Myeloma Kidney.

PUB633

Retroperitoneal Hematoma Manifesting as Pancreatic Adenocarcinoma in a Renal Allograft

Varsha reddy Pothula venkata,[2] Sandeep A. Padala,[1] Rajan Kapoor,[3] Imran Y. Gani,[4] Azeem Mohammed.[1] *[1]Augusta University, Augusta, GA; [2]Augusta university medical center, Augusta, GA; [3]Augusta University / Medical College of Georgia, Augusta, GA; [4]SELF, Augusta, GA.*

Introduction: A retroperitoneal mass could represent a hematoma, cyst or tumor. We present an unusual case of pancreatic adenocarcinoma presenting as retroperitoneal cystic mass in a renal transplant recipient.

Case Description: A 47-year-old African-American female with history of End Stage Renal Disease (ESRD) secondary to IgA nephropathy. She received her first renal transplant in 1999 which lasted till 2004. She received her second transplant in 2005. Her post-transplant course was uneventful for about 12 years until she presented with a left

abdominal palpable mass with pain for 2 weeks. CT scan of the abdomen/ pelvis revealed a large well-defined complex septated cystic mass 12 x13 x16 cm extending into the left lower quadrant without involving the surrounding structures. Upon resection, the mass yielded approximately 1.5 liters of old clotted blood. Sections of the tumor demonstrated cystic and solid areas with complex epithelial architecture including papillary and cribriform patterns and ovarian or ovarian-like stroma suggesting the possibility of an ovarian or gastrointestinal malignancy. PET CT showed increased uptake and thickening at the left psoas muscle at the posterior margin of the atrophied left native kidney. Final pathology of the rim was consistent with adenocarcinoma of unknown primary. The tissue stained positive for CK 7 and CK 20 making colonic primary less likely. CEA and CA-125 were normal. CA 19-9 was elevated, and the immunohistochemistry and gene expression profiling revealed pancreatic adenocarcinoma as the primary tumor. Despite aggressive chemotherapy, subsequent PET scans revealed disease activity in lungs, mediastinal lymph nodes and abdominal mesentery for which she is currently receiving palliative chemotherapy.

Discussion: The presentation of an isolated retroperitoneal hematoma initially thought to be a fluid collection in this case, was infact a malignant presentation. One possible hypothesis is that long-standing immunosuppression could have contributed to the malignant transformation. Given the difficulty in identifying the primary site and the unusual site of metastatic presentation, this case was a diagnostic challenge.

PUB634

Checkpoint Check-Up: Pembrolizumab and Interstitial Nephritis

Kyle E. Zoll,[1] Dhananjay P. Kulkarni.[2] *[1]St Vincent Hospital, Indianapolis, IN; [2]Indiana Nephrology and Internal Medicine, P.C., Indianapolis, IN.*

Introduction: Over the last few years, the FDA has approved pembrolizumab - one of the checkpoint inhibitors - for the treatment of several cancers. As the field of therapeutic immuno-oncology rapidly expands, enigmatic complications in conjunction with these agents are arising.

Case Description: We present a 52-year-old male with history of metastatic melanoma treated with pembrolizumab and no prior kidney disease who had recurrent relapses of acute kidney injury [AKI] due to acute tubulointerstitial nephritis [AIN]. He first presented with AKI six weeks after starting therapy. On admission his creatinine [Cr] was >9 and was thought to be due to excessive concurrent NSAID use. A two-month steroid taper was started and pembrolizumab was held until renal function normalized. Subsequently pembrolizumab was reinstated. He underwent a total 13/17 cycles without difficulty and stayed off NSAIDs. Unfortunately, seven months after restarting therapy he was readmitted with AKI and peak Cr > 9. This was about three weeks from his last pembrolizumab dose. A renal biopsy revealed AIN secondary to pembrolizumab. Patient was discharged on a 20-day taper of prednisone and pembrolizumab was discontinued in consultation with his oncologist. Two weeks later while still on the prednisone taper, the patient was admitted to the ICU for shock and AKI. His AKI was thought to be related to septic shock rather than worsening AIN, and at discharge he was continued on his previous prednisone taper. Unfortunately, he returned within one week with another AKI. It was concluded that his steroids were tapered too rapidly, and he was placed on high dose prednisone and renal function stabilized with plan for a prolonged taper over months. Remarkably, the patient never required dialysis and was not oliguric at any time.

Discussion: This case demonstrates the difficulty of establishing a treatment regimen for relapsing AIN with checkpoint inhibitor use. Case series point out a variable incidence of AIN from 0.2 to 5.1% associated with checkpoint inhibitor use. Per reports there were cases with AIN seen even weeks to months after conclusion of checkpoint inhibitor therapy. However, no consensus/guidance about duration of treatment is available to the best of our knowledge. This case highlights the need for prolonged treatment with steroids in case of relapsing AIN with checkpoint inhibitor use.

PUB635

Immune Checkpoint Inhibitor-Induced AKI

Mykel G. Tadros,[1] Wael A. Hanna,[1] Mohammad N. Saqib,[2] Sherif Roman.[3] *[1]Lehigh Valley Hospital, Breinigsville, PA; [2]Valley Kidney Specialists, PC, Orefield, PA; [3]Cairo University, Antioch, TN.*

Introduction: Drug-induced acute interstitial nephritis (DI-AIN) is a common cause of AKI, affecting about 20% of patients with unexplained AKI, and leads to CKD and ESRD. Cytotoxic T-lymphocyte antigen 4 (CTLA-4) and programmed cell death protein 1 (PD-1) are two essential immune checkpoint receptors that play an essential role in negatively regulating T cell activation. Immune checkpoint inhibitors (ICI) are widely being used in the treatment of several malignancies.

Case Description: A 70-year-old female with a past medical history of lung adenocarcinoma presented to the hospital with nausea, poor appetite, and lower extremity edema. The patient received a total of four cycles of Pembrolizumab which was started three months prior to presentation for stage IV lung adenocarcinoma. She has been using ibuprofen for years. On admission, she was found to have stable vital signs. Physical exam revealed mild leg edema without any lung rales or asterixis. Labs revealed SCr 10 mg/dl (baseline 0.7), BUN 55 mg/dl NA 134 mmol/L K 4.3 mmol/L and CO2 22 mmol/L. Urinalysis showed >100 WBC/HPF, >100 RBC/HPF, +++ protein with no casts. UPCR 6.64 g/g. ANCA ab, Anti GBM ab, and SPEP were negative. A renal biopsy revealed moderate inflammation of the interstitium with lymphocytic tubulitis and diffuse tubular injury. Trichrome staining was consistent with moderate interstitial fibrosis and edema. Pembrolizumab was promptly discontinued on admission. The patient was initiated on IV pulse dose steroids with significant improvement in renal function. SCr improved to 1.9 mg/dl after 3 weeks of steroids. She never required dialysis.

Discussion: AKI incidence rate is estimated to be of 2.1% in patients who received PD-1 inhibitor therapy. Acute interstitial nephritis induced by ICPIs is related to severe inflammatory cell infiltrates with or without granuloma. ICIs may reactivate exhausted drug-specific T cells previously primed by nephritogenic drugs, and consequently, due to loss of tolerance, memory T cells are activated against the drug. It is noteworthy that 14 out of the 19 patients reported by Cortazar et al.and Shirali et al.were on culprit drugs associated with ATIN (PPI and NSAIDs). Our patient has a history of NSAID use in the past but never developed AKI until she received Pembrolizumab. It is important to recognize early ICI-induced ATIN since a delay of steroid use may lead to irreversible renal fibrosis.

PUB636

The Use of Early Continuous Venovenous Haemofiltration and Glucarpidase Therapy in the Management of Methotrexate Toxicity

Suzanne D'Arcy. *Department of Nephrology, Cork University Hospital, Cork, Ireland.*

Introduction: Methotrexate (MTX) is a widely utilised anti-metabolite, however its use in extremely high doses (greater than 500mg/m2) is commonly the preserve of the oncologist. At toxic levels, its side effects include severe myelosuppression and acute kidney injury. MTX toxicity i.e; levels >1umol/L at 48 hours, are commonly observed, normally in the setting of impaired renal function. This case demonstrates the utility of combination therapy of early CVVH, leucovorin and glucarpidase therapy in the successful treatment of a patient with MTX toxicity.

Case Description: The 79 year old patient was diagnosed with stage 4 Non-Hodgkins Lymphoma and was commenced on R-CHOP therapy. He was admitted for iv MTX as an adjunct to his chemotherapy. At this time, his renal function was normal. He proceeded to treatment with iv isotonic bicarbonate and high-dose leucovorin. During his inpatient stay, he sustained a pre renal kidney injury. He required transfer to ICU for non invasive ventilatory support due to respiratory sepsis. At 48 hours post infusion his MTX levels were 19.61 umol/L. CVVH was started at a dose of 30 ml/kg/hr, within 52 hours of administration of MTX. The patient did not become oliguric and his peak creatinine was 1.89mg/dL. His MTX levels continued to fall over subsequent days. At hour 58 post infusion, the patient was administered glucarpidase, a recombinant bacterial enzyme which cleaves MTX into two non-cytotoxic metabolites. Of note is that immunoassay does not differentiate between the levels of active MTX and inactive metabolites. Due to this, CVVH was continued until MTX levels were below 1 umol/L. The patient was transferred from ICU after 9 days and was discharged following 29 days of admission with restored renal function.

Discussion: Previous cases reports have demonstrated the usage of CVVH in MTX toxicity when absolute indications arise for renal replacement therapy. However, here, CVVH was commenced with the express intent of reducing absolute serum MTX levels. The patient did not develop any haemorrhagic or infective complications of myelosuppression and continued to improve until his successful discharge after 29 days. This case demonstrates that combination therapy of early CVVH with glucarpidase therapy in conjunction with high dose leucovorin can be associated with promising outcomes in terms of therapy of MTX toxicity.

PUB637

Salt-Losing Nephropathy Associated with Use of Foscarnet in a Patient with Lymphoma

Cindy S. Yip,[2] Kathleen Speta.[1] *[1]UBMD Internal Med, Buffalo, NY; [2]SUNY University at Buffalo, Fort Erie, AB, Canada.*

Introduction: Salt losing nephropathy is an uncommon cause of hyponatremia. We report a case associated with the use of foscarnet.

Case Description: A 60 year old female with history significant for DLBCL status post Yescarta CD19 CAR-T cell therapy with Flu/Cy lymphodepleting regimen who presented with neurotoxicity related to her therapy. Work up revealed a HHV-6 encephalitis found in both plasma and cerebrospinal fluid. Patient was started on foscarnet for treatment of her HHV-6 encephalitis, however patient developed both hyponatremia and natriuresis. Subsequent investigation demonstrated hyponatremia due to salt-wasting nephropathy likely induced by foscarnet. Patient was started on salt replacement with both oral and IV sodium chloride to maintain her serum sodium above 130 meq/L. Urinary sodium losses were as high as 15 g/day. Unfortunately, foscarnet was unable to be discontinued as patient had persistent HHV-6 titer on LP three months into treatment and ganciclovir was added. Patient then cleared her HHV-6 a month later, and both medications were stopped. IVF were soon able to be stopped, but she continued to require sodium chloride replacement at time of discharge to maintain a normal serum sodium.

Discussion: Foscarnet is a pyrophosphate analog with antiviral properties which is used in the treatment of herpes encephalitis, varicella, and CMV. It can cause various electrolyte abnormalities including hypokalemia, hypomagnesia, hypocalcemia, and hypophosphatemia. We present a rare case of foscarnet causing hyponatremia due to salt wasting. The specific mechanism involved in the salt loss is unclear.

PUB638

Pseudolinear C4d Deposits in a Hereditary Glomerulopathy Caused by a Novel NC1 Collagen-4-Alpha-5 Missense Mutation: A "New Disease Entity?"

Sanjeet Roy,[1] Aasma Nalwa,[1] Lori Ramkissoon,[1] Jared N. Keith,[2] Karen E. Weck,[1] Harsharan K. Singh,[1] Volker Nickeleit.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Blue Ridge Nephrology and Hypertension, Boone, NC.*

Introduction: Glomerular C4d deposits in kidney biopsies are incompletely characterized and usually not used for diagnostic decision making. It was not until recently that isolated pseudolinear glomerular C4d deposits were identified as markers of structural glomerular capillary wall remodeling. Here we report a case that furthers our understanding of "pseudolinear-C4d-glomerulopathies": C4d beyond antibody and immune-complex mediated injury.

Case Description: We report a hypertensive, otherwise healthy 60 year-old male with a 5 month history of isolated nephrotic range proteinuria, no hematuria; normal serum creatinine, complement and ANA levels. Work-up showed MGUS (IgG/kappa restricted). A diagnostic renal biopsy to search for 'MGUS of renal significance' demonstrated thickened glomerular capillary walls with strong pseudolinear complement factor C4d deposits by immunofluorescence microscopy (IF; Fig. A); all other IF studies including stains for COL4A3 were unrevealing with only minor equivocal abnormalities seen for COL4A5. The unusual C4d staining of undetermined significance triggered electron microscopic studies uncovering a hereditary nephropathy with marked GBM remodelling (Fig. B). Genetic testing unveiled a novel single missense mutation in the NC1 domain of X-linked type-4 collagen, alpha-5 subunit (exon 51) with a single amino acid substitution (COL4A5 p.A1581S) that has thus far not been reported in hereditary nephropathies.

Discussion: We report a novel "Alport" COL4A5 NC1 missense mutation in a C4d positive hereditary nephropathy unexpectedly diagnosed in an older male presenting with isolated proteinuria. We provide further evidence of complement as building blocks in GBM remodelling and pseudolinear C4d deposits as morphologic signposts of architectural GBM disturbance that guided in-depth diagnostic work-up in our patient.

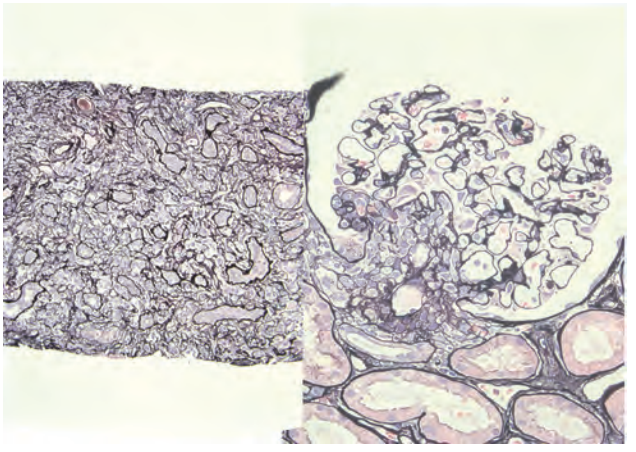
A Case of IgG4-Related Disease with Tubulointerstitial Nephritis and Glomerular Endocapillary Hypercellularity

Kyoko Tsujimoto,[1] Kentaro Koike,[1] Masahiro Okabe,[1] Kei Matsumoto,[1] Akira Fukui,[2] Tetsuya Kawamura,[1] Nobuo Tsuboi,[2] Takashi Yokoo.[2] *[1]Jikei Univ School of Medicine, Tokyo, Japan; [2]Jikei University School of Medicine, Minato-ku, Japan.*

Introduction: IgG4-related disease (IgG4RD) is an uncommon autoimmune disease that affects multiple organ systems. The most commonly affected organs are the pancreas, liver, gall bladder, lachrymal glands, salivary gland, lung, and kidney. Renal involvement of IgG4RD typically presents as IgG4-positive plasma cell-rich tubulo-interstitial nephritis and storiform fibrosis.

Case Description: A 61-year-old man with a history of asymptomatic pancreatic swelling and impaired renal function was referred to our hospital. Laboratory data showed an increased serum creatinine concentration (1.33 mg/dL) and a high serum level of IgG4 (1020 mg/dL). All autoimmune antibodies were negative, and the serum complement levels were within a normal range. Protein urine excretion was 0.69 g/day without microscopic hematuria. Abdominal magnetic Resonance imaging revealed enlargement of the pancreas and multiple bilateral renal parenchymal nodules with hypointensity in T2 image. A renal biopsy revealed storiform fibrosis and IgG4-positive plasma cell infiltration of the interstitium, which was consistent with IgG4-related kidney disease. Three out of 13 glomeruli exhibited segmental endocapillary hypercellularity. Of note, marked infiltration of monocytes to the vascular pole was observed, which is likely to be continuous to interstitial lesions. Immunohistochemistry and electron microscopic examination did not show any evidence of immune-mediated glomerular diseases including membranes nephropathy.

Discussion: We herein describe a case of IgG4RD with tubule-interstitial nephritis and focal endocapillary hypercellularity in the glomeruli. Although membranous nephropathy is a common glomerular presentation of IgG4RD, proliferative glomerulonephritis has only rarely been reportedpreviously. To our knowledge, this is the first case of glomerular endocapillary hypercellularity in a patient with IgG4RD.



PUB640

Gastrointestinal and Renal Allograft Involvement by Light Chain Deposition Disease: Report of Two Cases

Giovanni maria Rossi,[1] Francesca Costigliolo,[2] Lois J. Arend,[3] Avi Z. Rosenberg,[4] S.M. Bagnasco.[5] *[1]Pathology, Johns Hopkins, Baltimore, MD; [2]Pathology, Johns Hopkins School of Medicine, Baltimore, MD; [3]Johns Hopkins Hospital, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD; [5]The Johns Hopkins School of Medicine, Baltimore, MD.*

Introduction: Light chain deposition disease (LCDD) is a rare entity both in native and transplant kidneys, and concurrent involvement of the kidney allograft and other organs has been rarely described. We report two cases of post-transplant LCDD in which gastrointestinal symptoms preceded a diagnosis of LCDD initially made on kidney allograft biopsy, and subsequently detected on previous gastrointestinal biopsies.

Case Description: The first patient was a 59-year-old female with end-stage renal disease (ESRD) of unknown cause, who presented with chronic diarrhea and acute kidney injury (AKI), 1 year after kidney transplant (KT) from unrelated living kidney donor (LURT). Gastrointestinal (GI) endoscopy, as well as light microscopy of gastrointestinal biopsies were negative and the GI symptoms were ascribed to Mycophenolate mofetil (MMF) effect. MMF was discontinued with no benefits. Renal function kept worsening and an allograft kidney biopsy was performed, revealing LCDD, with a subsequent diagnosis of kappa light chain myeloma. The second patient was a 46-year-old male with ESRD of unknown cause, status-post KT from LURT, who presented 4 years post-transplant with chronic vomiting, diarrhea and AKI. Weeks-long recurrent episodes of nausea and vomiting, with non-bloody watery diarrhea, had been occurring for a year prior to admission. GI endoscopy as well as light microscopy of gastrointestinal biopsies were negative and the symptoms were ascribed to MMF effect. MMF was suspended with no benefits. Two subsequent allograft biopsies were diagnostic for LCDD. A work-up for plasma cell dyscrasias identified a clone secreting kappa light chains, consistent with monoclonal gammopathy of renal significance. We retrospectively stained previous GI biopsy specimens for light chains and found that both patients had kappa chain-restricted linear deposition along the basement membranes of gastric glands.

Discussion: These cases highlight (i) the rationale for screening kidney transplant recipients with serum protein electrophoresis for early diagnosis of plasma cell dyscrasias, (ii) the importance of full immunofluorescence staining panels and electron microscopy on allograft kidney biopsies after 6 months from KT, and (iii) the need to screen for extra-renal involvement by LCDD.

PUB641

Medullary Angiitis: Presentation and Diagnostic Challenges

Naga venkata rama krishna Vura,[2] Yeshwanter Radhakrishnan,[2] Jayaprakash R. Dasari,[1] Rupesh Raina.[3] *[1]Nephrology, Cleveland Clinic Akron General, Akron, OH; [2]Cleveland Clinic Akron General, Akron, OH; [3]Nephrology, Cleveland Clinic Akron General, Akron, OH.*

Introduction: When histopathologic exam of the native kidney is performed, conditions are diagnosed usually by microscopic examination of the renal cortex. Not many disease entities have been known to involve the renal medulla or have a medullary component. We present a very rare case of a subtype of small vessel vasculitis primarily involving the renal medulla that helps us understand the characteristic pathological features under microscopic examination and the challenges in establishing this diagnosis.

Case Description: A 75-year-old male with PMH of CKD Stage 3 with baseline serum creatinine (SCr) of 1.4, history of FSGS 18 years back, not on any medications and no other comorbidities came for evaluation of worsening SCr of 2.23. Labs were significant for creatinine, 2.23 mg/dl, with urinalysis showing hematuria, proteinuria without any RBC casts with urine protein creatinine ratio of 1400 mg/g. P-ANCA was positive but ANA, Anti dsDNA, serum protein electrophoresis, C-ANCA, HIV, Hepatitis B, and C were negative with normal serum complements. The renal US did not show any abnormalities. No history of skin or throat infections in the past. The biopsy was diagnostic of medullary angiitis which is

a subtype of small vessel vasculitis. The patient was started on prednisone 40mg per day with a plan to start rituximab infusions. In subsequent follow-ups, patient's SCr was stable at 2.2.

Discussion: Renal medullary angiitis was first described by Watanabe et al in 1983 and is an extremely rare condition with an incidence of 0.19%, which involves vasa recta of the renal medulla. Histopathological exam of the renal medulla has been described as the presence of interstitial hemorrhage with polymorphonuclear leukocyte infiltrate. Diagnosis of this condition is challenging, as most renal biopsies involve only the renal cortex and it can be misdiagnosed as acute interstitial nephritis due to the above microscopic features. Almost 63% of the reported medullary angiitis cases are ANCA positive and among non-ANCA related medullary angiitis, 20% have been reported to be due to IgA nephropathy. In fact, medullary angiitis may be the first systemic manifestation of an ANCA associated vasculitis and hence it should be differentiated from acute interstitial nephritis which has different etiologies.

PUB642

Non-Myeloma Hematologic Malignancies in Renal Biopsies: A Single Institution Experience

Meredith Parsons,[2] Danniele G. Holanda,[2] Prerna Rastogi.[1] *[1]University of Iowa, Iowa City, IA; [2]University of Iowa Hospitals and Clinics, Iowa City, IA.*

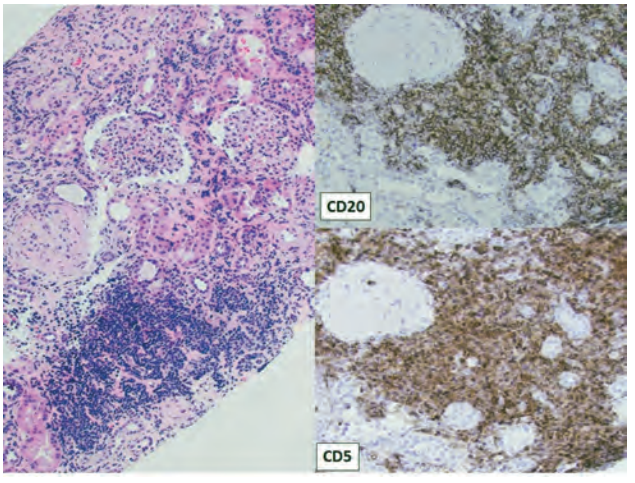
Introduction: Hematologic malignancies other than myeloma are relatively rare in renal biopsies. We present 5 diverse cases of hematologic malignancies with histologic, immunohistochemical, and immunofluorescent evidence of renal involvement. Consecutive native and transplant renal biopsies from year 2015 to 2018 were reviewed.

Case Description: Both lymphoid and myeloid malignancies were noted.

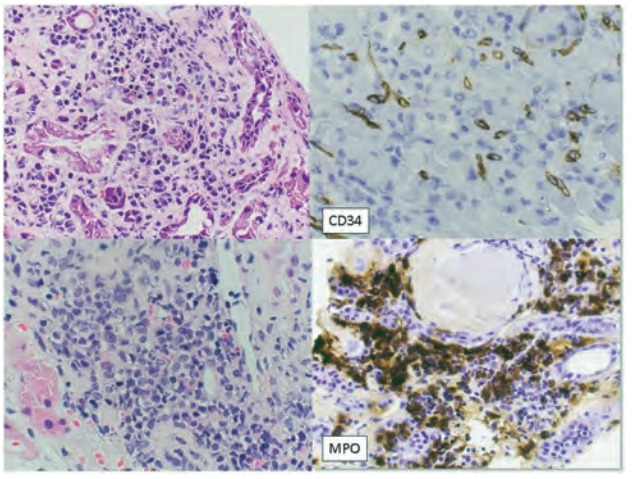
Discussion: This case series demonstrates that renal involvement is possible in any hematologic malignancy. Renal biopsy findings may sometimes direct evaluation for an unsuspected hematologic malignancy, possibly allowing for earlier detection and improving patient outcome.

Key Patient Findings in Renal Biopsy Specimens

Age (Years) / Sex / PMH	Non-renal symptoms	Renal symptoms	Hematologic findings in renal bx	Non-hematologic findings in renal bx	Treatment	Follow-up
64 / M/ HTN, Squamous cell CA of scalp, fatigue, chronic bronchitis	Lung nodules, splenomegaly, lymphadenopathy, thrombocytopenia	Nephrotic Syndrome	CLL/SLL	Moderate interstitial fibrosis and tubular atrophy	Rituximab based chemotherapy X 6 cycles	Periodic Follow up, no evidence of further decline
63 / M / DM2, HTN	Lower extremity swelling, nausea, emesis, fatigue, WBC: 83 K	Hypercalcemia, hyperkalemia, hyperuricemia; Cr: 3.1 mg/dl; UA: 2+ blood, 1+ protein	Mantle cell lymphoma	Diffuse membranoproliferative /C3 glomerulonephritis (MPGN)/C3GN	NORDIC chemotherapy regimen (maxi-CHOP/rituximab/ cytarabine; 6 cycles)	Complete remission after autologous stem cell transplant
50 / M / DDRT, for Tuberous Sclerosis	Fatigue, weight loss, liver and small bowel mass, anemia	AKI on CKD, Cr: 3.9 mg/dl, GFR <50	Diffuse Large B-cell lymphoma, germinal center subtype	Monomorphic PTLD, EBER Negative	R-EPOCH (2 cycles) and R-CHOP (4 cycles) chemotherapy	Clinical remission
69 / M/ HTN, HLD, DM2	Chest pain, MDS	Cr: 2.66 mg/dl GFR 55	Acute myeloid leukemia	ATI	Azacitidine Chemotherapy	Deceased
46 / M / CKD Stage III, HTN	None	AKI on CKD; Creatinine: 4.5 mg/dl, 3+ proteinuria	MPGN with IgM kappa deposits	cellular/fibrocellular crescents, moderate IFTA	Rx for HTN.	Negative hematology workup, regular clinical follow up



Case 1, H+E shows atypical lymphoid infiltrate. CD20 highlights the B-lymphocytes. CD5 (T-cell marker) is aberrantly expressed on the B-cells, consistent with CLL/SLL.



Case 4, H+E images show immature hematopoietic cells. CD34 and MPO stain them as myeloid blasts.

PUB643

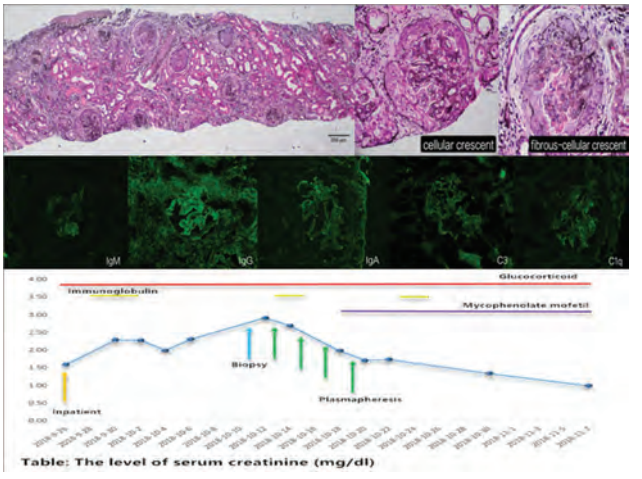
Lupus Encephalopathy and 87.5% Glomeruli with the Formation of Crescent in a Childhood-Onset Systemic Lupus Erythematosus: A Case Report

Jiahao Zeng,[1] Zhuojie Yuan,[1] Yenan Mo,[1] Haifeng Yang,[2] Wang L. Xin,[2] Xusheng Liu,[2] Zhiren He.[2] *[1]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; [2]Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China.*

Introduction: Systemic lupus erythematosus (SLE) associating with lupus encephalopathy and lupus nephritis has been reported in previous case reports. The crescent formation could be detected under the microscope at the same time. Here, we present a rare case that 87.5% glomerular crescent formation. Up to now, there have no report about crescent formation much more than this proportion in this type of patient.

Case Description: We report a case of a 14-year-old female who presented severe oliguric renal failure and uncoordinated movement. The highest serum creatinine reached 2.9mg/dl. She was diagnosed as lupus encephalopathy and severe diffuse proliferative lupus nephritis. A renal biopsy revealed that 18 of 21 glomeruli had crescent formation (11 cellular crescents, 5 fibrous-cellular crescents and 2 fibrous crescents), accounting for 87.5% of total. There were IgG, IgA, IgM, C3, C1q, both kappa and lambda light chains on Immunofluorescence staining. The patient was immediately treated with glucocorticoid, mycophenolate mofetil, immunoglobulin and plasmapheresis. She had symptomatic improvement and the serum creatinine also dropped to normal levels in 42 days later. No infection occurred during treatment. In addition, follow-up of 3 months after discharge showed stable kidney function and no recurrence of edema, oliguria or other symptoms.

Discussion: It's a rare case of lupus nephritis with 87.5% glomerular crescent formation accompanied by lupus encephalopathy. Such patients have a poor prognosis. However, renal function returned to normal after a series of aggressive treatments. It suggests that aggressive short-term combination therapy is beneficial for children with lupus nephritis with large amounts of glomerular crescent formation.



PUB644

Coexistence of Triple Viral Infection as a Trigger of Severe Rhabdomyolysis-Associated AKI in an Adolescent

Natalia Plotskaya,[1] Christina Irene Mejia,[1] Suzanne Boyle,[1] Olawunmi Ajelero,[2] Suganthi Soundararajan.[2] *[1]Nephrology & Hypertension, Drexel University College of Medicine, Philadelphia, PA; [2]Pathology, Drexel University College of Medicine, Philadelphia, PA.*

Introduction: Rhabdomyolysis has many triggers, including trauma, drugs, autoimmune disorders, infection and genetic mutations. Prevalence of viral-induced rhabdomyolysis is 38% in pediatric population. Here we describe a case of acute kidney injury (AKI) from rhabdomyolysis secondary to viral infection.

Case Description: An 18-year-old African American female college student with past medical history of febrile seizures, Kawasaki disease and obesity presented with a one-week history of myalgias, productive cough, abdominal pain and dark urine. She denied sick contacts, recent travel, rash, arthralgias, trauma. Physical examination revealed tachycardia, abdominal and lower extremities tenderness, inability to ambulate. On admission, creatinine (cr) was elevated at 1.56 mg/dl; potassium, 5 mmol/l; CK>200,000 IU/L, AST, 2033 U/L;ALT, 595 U/L. Urinalysis showed amber urine, 3+ blood, 2+ protein, 1-5 RBC and no casts. Drug screen was negative. Viral and bacterial serologies were negative with the exception of PCR-positive Parainfluenza and Epstein Barr virus (EBV), and Coxsackievirus group B antibodies (titer 1:32). Complement levels were normal, pANCA and cANCA <1:20. ANA titer was 1:160 with speckled pattern. On day 3, lower extremities MRI showed diffuse, symmetric muscle edema. Muscle biopsy demonstrated acute myonecrosis. PCR of muscle sample for EBV was negative. Stains for mitochondrial, glycogen, lipid storage myopathies were unremarkable. The patient was managed with intravenous volume resuscitation. On day 4, cr decreased to 1.25 mg/dl and CK decreased to 183,600 IU/L. On day 14, she was discharged home with normal renal function and CK of 617 IU/L.

Discussion: Coexistence of viral infections led to severe rhabdomyolysis in our patient. However, given the reported history of vasculitis, investigation of potential autoimmune etiology was pursued, and subsequently excluded. As a result, steroid therapy was withheld and resolution occurred with intravenous volume resuscitation alone. Clinicians should have a high index of suspicion for rhabdomyolysis in patients who present with muscle pain and weakness and elevated creatine. Further, timely investigation of the etiology of rhabdomyolysis, including viral, autoimmune, and genetic disorders, has implications for management and prognosis of AKI.

PUB645

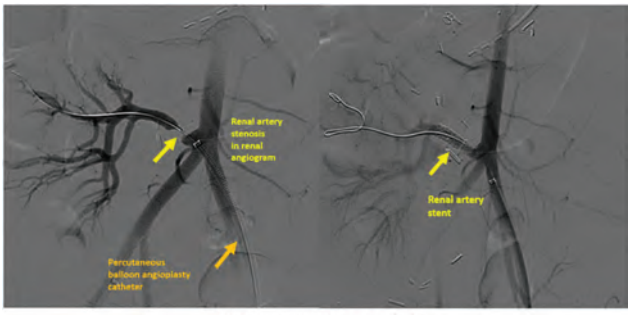
Transplant Renal Artery Stenosis in a Child with BK Nephropathy

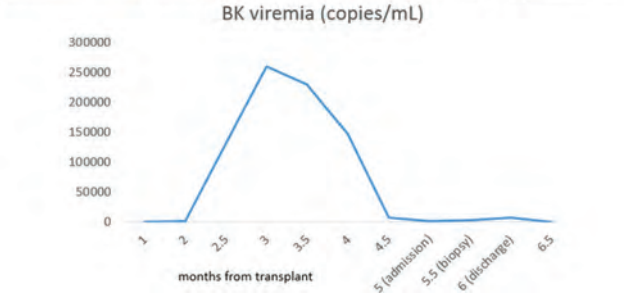
Sai Sudha Mannemuddhu,[1] Naile Tufan pekkucuksen,[2] Kiran K. Upadhyay.[1] *[1]University of Florida. College of Medicine., Gainesville, FL; [2]Pediatrics, University of FLorida, Gainesville, FL.*

Introduction: Transplant renal artery stenosis (TRAS) and BK nephropathy are known complications of renal transplantation, but the association has not been reported.

Case Description: A 2-year-old girl received a kidney transplant from a 20-year-old deceased donor, along with native nephrectomies. She had a delayed graft function due to a renal artery thrombus and required thrombectomy with reanastomosis, heparin and aspirin. Thymoglobulin, tacrolimus and mycophenolate were started. CMV and EBV DNA PCRs were negative but developed BK viremia at 2 months (peak 260,000 copies/mL). Serum creatinine remained stable at a baseline of 0.9 mg/dL. After immunosuppression reduction and leflunomide initiation, her BK load decreased to 1200 copies/mL after 4 months. There were no episodes of rejections, hydronephrosis or hematuria. Blood pressure (BP) was well controlled on low dose amlodipine. 5 months later, she presented with hypertensive emergency, following a respiratory infection. Her BPs remained refractory to 8 antihypertensive agents and required dialysis for oliguric acute kidney injury. Allograft biopsy showed evidence of BK nephropathy. Immunosuppression was further minimized. Doppler renal sonogram and duplex study of renal artery were both suggestive of TRAS. Angiogram showed severe proximal anastomotic TRAS (> 95% occlusion). Balloon angioplasty with stenting was done with immediate improvement in the blood flow and gradient reduction to 18 from 50 mm Hg. BPs and renal function normalized. 7 months post-transplant, she remains stable, with no BK viremia and while on 2 antihypertensives.

Discussion: Although ureteral and urethral stenosis are known to occur with BK infection, TRAS is an interesting association. Timely recognition and management of both is important to prevent uncontrolled hypertension and allograft dysfunction.





PUB646

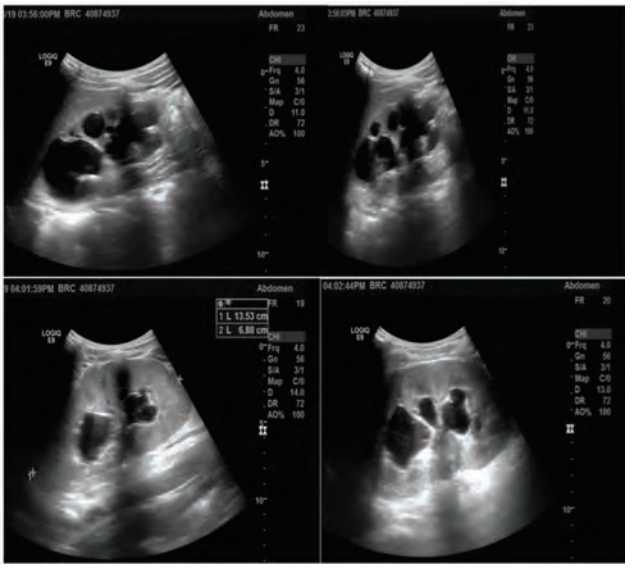
A Rare Etiology of Bilateral Hydronephrosis in Adolescents

Amal G. Ezzaiyani,[1,2] Arwa Nada.[1,2] *[1]Pediatric Nephrology, The Univesity of Tenneessee Health Science Center, Memphis, TN; [2]Pediatric Nephrology, Le Bonheur Children's Hospital, Memphis, TN.*

Introduction: Nonurological etiologies of bilateral hydronephrosis in children include external compression by a tumor, lymph nodes, retroperitoneal fibrosis, blood clots, and fungal ball

Case Description: A 14 years old male presented to the emergency department with nausea, vomiting, and decreased energy for a month. He was found to have stage III hypertension. Blood workup showed BUN of 58 mg/dL and creatinine of 5.4 mg/dL. Renal ultrasound showed severe bilateral hydronephrosis with cortical thinning (Image 1). CT abdomen showed 11.5 cm retroperitoneal mass encasing the aorta and right common iliac artery with obstruction of the right ureter and a hyperdense mass in the parapelvic left kidney (Image 2). Biopsy of the retroperitoneal and kidney mass was consistent with retroperitoneal fibrosis. It showed sclerotic fibrosis with lymphoplasmacytic, eosinophil, and macrophage infiltrates. Immunohistochemistry showed predominant CD3+ T-cells, CD20+ B-cells, eosinophils, plasmacytes, and S-100+ dendritic cells/macrophages. Fibrosis contained smooth muscle actin+ spindle cells. The number of CD3+ T cells were disproportionally higher than CD20+ B cells which suggests IgG related disease. IgG4:IgG ratio was normal. Work up for other etiologies is still ongoing

Discussion: The pathogenesis of retroperitoneal fibrosis (RF) can be due to asbestos, smoking, vasculitis, drugs, radiotherapy, neoplastic or infection. Idiopathic RF or Ormond's disease is a rare disease in all age groups. The first reported pediatric case in literature was in 1962. It is rare, with an incidence of 1.3 per 100,000 population/year with adult predilection. Its presentation is related to the organ involved, most commonly kidneys



PUB647

An Unusual Vintage: Wine-Colored Urine in a Postoperative Patient

Evan Zeitler,[1] Eva J. Stein,[2] Emily H. Chang.[1] [1]*UNC Kidney Center, Chapel Hill, NC;* [2]*University of Colorado-Denver, Denver, CO.*

Introduction: A variety of drugs and diseases may cause discoloration of urine. Some associations are well-known, but newer medications and novel uses for old medications may induce changes which can be disturbing to patients and providers. Laboratory abnormalities and dialysis machine dysfunction may also be associated as presented in this case of wine-colored urine.

Case Description: A 38 year-old man with a history of chronic kidney disease stage 3 and flank pain was found to have a pheochromocytoma. He presented for left adrenalectomy and nephrectomy, complicated by both intra- and post-operative hypotension requiring pressor support. He received methylene blue (100 mg) and hydroxycobalamin (5 mg, CyanoKit) peri-operatively for vasoplegia. Nephrology was called on the 2nd post-operative day for evaluation of deep purple urine. Urine sediment revealed muddy brown casts, 25 RBCs/HPF and scattered WBCs, although creatinine remained near baseline of 2.8 mg/dL. The urine discoloration was due to the combination of methylene blue and high dose hydroxycobalamin. It resolved over the ensuing 14 days.

Discussion: Vasoplegia is an increasingly recognized complication of surgery, characterized by hypotension refractory to pressor support despite a normal cardiac output. There is evidence for the use of 2 agents, methylene blue and hydroxycobalamin, in the treatment of vasoplegia. Methylene blue causes a blue-green urine and is associated with serotonin syndrome in patients on SSRI. Hydroxycobalamin causes a deep red to purple discoloration of both urine and plasma, and is associated with falsely elevated creatinine, among other lab abnormalities. It can also cause a false blood leak alarm on certain dialysis machines leading to dialysis cessation. Recognizing these effects will be increasingly important for nephrologists caring for patients in the post-operative period as the recognition of vasoplegia and the use of methylene blue and hydroxycobalamin becomes more prevalent.

PUB648

Hydralazine-Induced ANCA-Associated Vasculitis

Mal P. Homan,[1] Mykel G. Tadros,[2] Wael A. Hanna,[2] Nelson P. Kopyt.[2] [1]*Lehigh Valley Health Network, Zionsville, PA;* [2]*Lehigh Valley Hospital, Bethlehem, PA.*

Introduction: Hydralazine is a potential cause of ANCA-Associated Vasculitis (AAV) resulting in crescentic glomerulonephritis. The following is a case of a patient found to have increased proteinase 3 (PR3) and myeloperoxidase (MPO) antibodies in the setting of worsening kidney function while taking hydralazine. We use this case to review the literature and highlight the importance of a high degree of clinical suspicion, early diagnosis, and prompt treatment for better clinical outcomes.

Case Description: A 78-year-old woman with a history of rheumatoid arthritis, hypertension, and gout was admitted for hypertensive urgency. She had been taking hydralazine 25mg three times each day for 6 years. Her kidney function had been declining within the past year (SCr rising from 1.1 mg/dL to 2.5 mg/dL). Urinalysis revealed microscopic hematuria and proteinuria. The urine protein-creatinine ratio (UPCR) was 2 g/g. Serology for hepatitis, C3, C4 and SPEP were negative. PR3 ANCA and MPO ANCA antibody titers were elevated at 56.4 u/mL and MPO 25.3 u/mL, respectively. A renal biopsy showed diffuse mesangial and focal endocapillary proliferative GN with IgM deposits, focal necrotizing features, and focal cellular crescents. After holding hydralazine, she was started on pulse-dose steroids and rituximab infusion weekly for four weeks. At follow-up, repeat ANCA levels were negative, UPCR was 0.53g/g, and SCr improved to a baseline of 1.8 mg/dL.

Discussion: Hydralazine-induced AAV has an incidence of 5.4% in patients on 100mg/day to 10.4% with 200mg/day for >3-years duration. Identifiable risk factors include a cumulative dose of more than 100g, female gender, and thyroid disease. In one retrospective study of 323 cases of AAV, 12 were exposed to hydralazine. Our patient's renal biopsy findings are most consistent with a mixed pattern of GN. Crescentic proliferative GN is due to Hydralazine-induced ANCA vasculitis while mesangial proliferative GN with IgM deposits is likely due to underlying rheumatoid arthritis. Hydralazine can cause AAV with both PR3 and MPO autoantibodies elevated. It is important to recognize hydralazine as a potential cause of worsening kidney function in the setting of chronic use so that it can be properly diagnosed and treated.

PUB649

Cefepime Neurotoxicity: At-Risk Population and Preferred Treatment Modality

Sheikh B. Khalid,[1] Clay A. Block,[2] Obiajulu Kanu.[3] [1]*UNC at Chapel HIll, Chapel Hill, NC;* [2]*University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC;* [3]*UNC Hospitals, Nephrology, Chapel Hill, NC.*

Introduction: Correct assessment of renal function in hospitalized patients is of paramount importance as it influences not only the choice of drug but also the specific route and dose. We present a case of cefepime neurotoxicity caused by incorrect dosing in a patient with unrecognized severe acute renal failure

Case Description: A 51-yr-old woman was admitted to the hospital with abdominal pain and chills. She was febrile to 38.8°C with low normal blood pressure. She had white blood cell count 23000/mm^3. Serum creatinine (Scr) 0.62 mg/dL. Vancomycin and piperacillin/tazobactam were begun. A contrast CT scan revealed a complex fluid collection in lower pelvis which was drained by interventional radiology. Two days after admission, SCr was 1.2 mg/dL with eGFR of 46 ml/min/1.73m^2. Because of the concern for nephrotoxicity, she was switched to cefepime. On the fourth day of hospitalization, she had progressive decline in mental status. She also had asterixis. SCr was 4.2 mg/dL with blood urea nitrogen 26 mg/dL prompting consultation with nephrology. It was noted that she had had received a total of 12 grams of cefepime over last 48 hours. The constellation of symptoms suggested cefepime neurotoxicity. Investigation for other causes of her neurologic decline was unrevealing. She was started on continuous venovenous hemofiltration (CVVH) with a replacement fluid (RF) flow rate of 20 ml/kg/hr. Over the ensuing few hours, she became more altered and developed expressive aphasia. For the concern for inadequate clearance, RF flow rate was increased to 30 ml/kg/hr. Improvement in her mental status was observed in the next 12-15 hours. She subsequently regained her baseline mental status and renal function

Discussion: The estimation of renal function is difficult in hospitalized patients as they are not always in a steady state. Despite that, eGFR estimation through Scr is still relied heavily upon. This patient had an anephric rate of rise in SCr, and eGFR grossly overestimated her true renal function and led to prescription of an excessive cefipime dose and subsequent toxicity. This case illustrates the importance of correct dosing based on active assessment of renal function. It also uderlines the pitfalls of using a laboratory eGFR in hospitalized patients. Cefepime is best cleared using conventional hemodialysis but requires RF flow rate of at least 30 ml/kg/hr with CVVH for adequate clearance

PUB650

Recurrence of Fibrinogen Alpha Amyloidosis in Transplant Kidney

Ayesha Ahmed. *Rwjmh, Piscataway, NJ.*

Introduction: Fibrinogen A alpha chain amyloidosis is an autosomal dominant disease associated with mutations in the fibrinogen A alpha chain (*FGA*) gene. Patients typically present with kidney impairment and progress to end-stage renal disease over a median time of 4.6 years. Variant fibrinogen is produced in the liver and solitary renal allograft fails in 1-7 years with recurrent amyloidosis. In the largest series to date recurrence was noted in 4/8 kidney transplants (50%). We present a case of recurrence of amyloidosis in transplant allograft in less than 2 years post-transplant.

Case Description: 55 year old man with history of ESRD secondary to fibrinogen-alpha amyloidosis had DDKT on 3/16/17. Creatinine post-transplant settled in the 1.0-1.3mg/dL range. His post -transplant course was complicated with bilateral DVTs and PEs. He also developed proteinuria up to 2.8 gm/gm on spot urine protein /Cr and a 24 hr urine collection showed 7.4g of protein. His serum Kappa/lambda free light chain ration was also elevated, which was suspicious for recurrent renal amyloidosis. He had a renal biopsy on 11/14/17 that demonstrated FSGS (likely due to hyperfiltration injury) and did not demonstrate amyloidosis. He was started on losartan and a repeat 24 hour urine collection showed 2249mg/24hr of proteinuria. He underwent a second renal biopsy for a rise in his creatinine in January 2019, which was positive for Congo red staining suggestive of disease recurrence. To confirm diagnosis mass spectrometry was done and it showed peptide profile consistent with fibrinogen alpha type amyloid deposition (Glu 526Val, HGVS:p.Glu545Val).

Discussion: Recurrence appears to be common in fibrinogen-alpha amyloidosis who receives a kidney transplant alone. In largest series, recurrence was noted in 4/8 successful kidney allograft. 3 were lost as direct result of recurrence (median 6 yrs). By comparison 7 patients undergone combined liver-Kidney transplantation and no recurrence has been found in 6 surviving patients. Even if reports are scarce, a fibrinogen-alpha amyloidosis recurrence could be a factor of poor prognosis and graft loss. As fibrinogen production is

exclusively hepatic, the only curative treatment of fibrinogen-alphaamyloidosis is liver transplantation. Combined liver-Kidneytransplantation should be considered as the first therapeutic option for patients with ESRD due to fibrinogen-alpha amyloidosis

PUB651

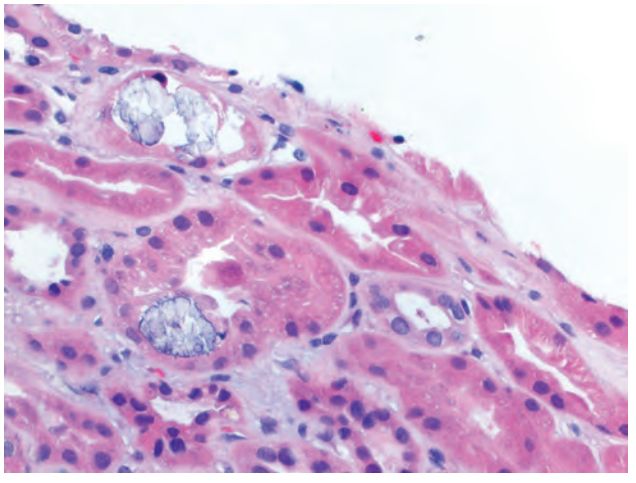
Undiagnosed Primary Hyperoxaluria in a Kidney Transplant Patient Resulting in Allograft Failure

Salim Bou Slaiman,[1] Rahul Bhardwaj,[1] Carla L. Ellis.[2] *[1]Emory University, Atlanta, GA; [2]Emory University Hospital, Atlanta, GA.*

Introduction: Primary hyperoxaluria (PH) is a rare disease that causes accumulation of oxalate in the kidneys, heart, nerves and other organs. It is responsible for 1-2% of end-stage renal disease(ESRD) in the pediatric population. Type1 PH is due to a defect in the gene AGXT and accounts for 80% of cases. Overproduction of oxalate leads to calcium oxalate stones, nephrocalcinosis, and renal failure.

Case Description: A 26-year-old man presented for a deceased donor kidney transplant (DDKT). He has ESRD secondary to obstructive uropathy from kidney stones and has been on dialysis for 3 years, as well as chronic polyneuropathy and heart failure. After receiving his DDKT the course was complicated by delayed graft function. His creatinine rose to 10.8 on post-op day(POD) 2, and he required dialysis on POD 3. An allograft kidney biopsy done on POD 7 showed oxalate nephropathy and tubulointerstitial inflammation meeting Banff criteria for borderline rejection. He was started on high calcium low oxalate diet, vitamin B6, calcium carbonate and sodium citrate; he received steroids for rejection. Dialysis was administered for 6 consecutive days initially. He was also given IV fluids. Serum oxalate and 24h urine oxalate came back as 49mcmol/L (normal <1.6) and 205mg/24h (normal 16-49). Genetic testing showed a missense mutation (508G>A) in the AGXT gene. The patient was taken off dialysis 3 months later. he is undergoing evaluation for a combined liver and kidney transplant.

Discussion: The recurrence of ESRD in PH is a definite outcome with kidney transplantation alone. Our patient had manifestations suggestive of PH with his congestive heart failure, neurologic disease, and urolithiasis that should have prompted to screen for PH. Screening is crucial in patients with high suspicion for the condition prior to kidney transplantation. In general, any patient younger than 40 with ESRD from urolithiasis should be screened for PH prior to transplantation.



PUB652

A Joint Dilemma: Tacrolimus Toxicity from Arthritis Treatment with Boswellia: A Case Report

Jonathan G. Lim,[1] Nityasree Srialluri,[1] Jennine Michaud.[2,1] *[1]Department of Medicine, Rutgers New Jersey Medical School, Newark, NJ; [2]Division of Nephrology, New Jersey Health Care System East Orange Campus, East Orange, NJ.*

Introduction: Bone and joint pain are a frequent complication of advanced renal disease with numerous over the counter (OTC) medications available with potentially dangerous active ingredients. Those which are inhibitors of CYP3A4 are associated with elevated tacrolimus levels. The present case describes an interaction between tacrolimus and *Boswellia serrata*, a CYP3A4 inhibitor. Boswellia is obtained from a tree resin indigenous to the Middle East, India, and Northern Africa and advertised to treat chronic inflammatory conditions. Its anti-inflammatory properties mainly stem from boswellic acid, a 5-lipooxygenase inhibitor.

Case Description: A 70 year old male with ESRD from IgA Nephropathy status post deceased donor renal transplant (DDRT), rheumatoid arthritis (RA), and hepatitis C (HCV) infection presents 26 days after renal transplant from an outside VA on a stable dose of tacrolimus 3mg q12h (tacrolimus level of 8.3 ng/mL), mycophenolate 1000 mg q12h, and prednisone 15 mg daily. His hospital course was complicated by a RA flare, treated with increasing his prednisone dose and oxycodone. After discharge, he initiated a glucosamine and chondroitin OTC supplement. When his care resumed at the home VA, his initial tacrolimus levels were 14.9 and 21 ng/mL. Additionally, his transaminases rose to twice the upper limit of normal and quadrupled from his baseline values. The supplement was discontinued, and tacrolimus levels decreased. However, he restarted the supplement for symptomatic relief and tacrolimus level rose to 18.7 ng/mL. While on the supplement, his tacrolimus dosage was decreased to 0.5 mg daily to achieve tacrolimus levels of 5.8 to 9.9 ng/mL. During evaluation for hepatitis C treatment, his glucosamine and chondroitin formulation was found to have *Boswellia serrata* extract. It was stopped, and his tacrolimus level decreased to 3.2 ng/mL. His subsequent tacrolimus levels stabilized on a total of 2.5 mg of tacrolimus a day, in 2 divided dosages, without Boswellia and his transaminases normalized.

Discussion: Common OTC preparations can cause severe morbidity and mortality in specific patient populations. Boswellia containing compounds may be effective in relieving joint pain but can have critical drug interactions. We report the first case of Boswellia induced tacrolimus toxicity in a renal transplant patient.

PUB653

Early BK Virus-Associated Nephropathy: A Double-Edged Sword and Unbeatable Barrier for Renal Allograft Survival

Kaushik Ivaturi, Ekamol Tantisattamo. *University of California, Irvine School of Medicine, Irvine, CA.*

Introduction: The prevalence of BK virus-associated nephropathy (BKVAN) in kidney transplant (KTx) recipients is estimated to be 1 to 10%. We report a case of young woman with the first KTx complicated by an early onset BKVAN contributing to renal allograft loss.

Case Description: A 30-year-old Hispanic woman with ESRD due to reflux nephropathy underwent a 2-A-B-DR mismatched deceased donor renal transplantation with antithymocyte globulin induction. She had an immediate renal allograft function and uneventful post-KTx. Baseline serum creatinine (SCr) was 0.8 – 1.1 mg/dL. Three months post-KTx, she developed new-onset BK viremia with a serum BK virus titer of 32,889 copies/ml. A 12-hour tacrolimus level ranged between 5.1 and 7.5 ng/mL. Even after lowering mycophenolate sodium (MPS) to 360 mg twice daily, BK titer increased to 315,000 copies/ml at 8 months post-KTx. MPS was discontinued and leflunomide was started. BK virus titers progressively increased to 2 million copies/ml by 11 months post-KTx. SCr was elevated to 2.4 mg/dL. A transplant renal biopsy revealed tubulointerstitial inflammation and diffuse SV40 immunostain positivity consistent with BKVAN without evidence of acute cellular (ACR) or antibody-mediated rejections (ABMR). Even after receiving IVIG, serum BK titers continued rapidly rising up to 15 million copies/ml at 13 months post-KTx with a worsening SCr of 3.5 mg/dL. All immunosuppressive medications were discontinued and serum BK titers decreased to 2,370 copies/ml, although renal allograft function progressively worsened. Repeat transplant renal biopsy showed evidence of ABMR and 1b ACR with moderate IFTA and negative SV-40. There was no additional escalation of immunosuppressive medication and hemodialysis was initiated at 16 months post-KTx.

Discussion: Early occurrence of highly elevated level of BK viremia causing BKVAN is very difficult to treat in kidney transplant patients. Immunosuppression post- KTx can lead to BKVAN which is common cause of allograft dysfunction contributing to renal allograft loss. Both, over-immunosuppression and de-escalation should be avoided, to mitigate the risk for BKVAN, and enhance the risk for rejection respectively. Initial over-immunosuppression led to BKVAN and subsequent de-escalation led to acute rejection and ultimately allograft loss in this patient.

PUB654

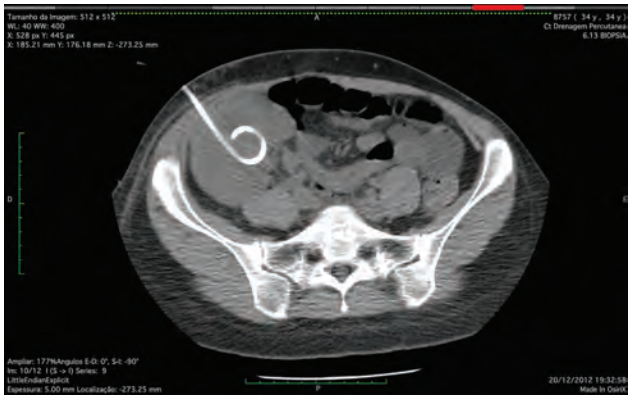
Graft Simple Cyst Infection in Late Transplantation

Priscila Dias goncalves,[1] Thiago A. Reis,[2] Geraldo R. Freitas.[3] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]CDRB - Clinica de Doencas Renais de Brasilia, Brasilia, DF., Brazil; [3]USP, Brasilia, Brazil.*

Introduction: Describe of a simple Cyst (SC)(Bosniak I) infection in a renal allograft is unprecedented in literature

Case Description: KM, 34-year-old female, presented end stage renal disease due to diabetes related nephropathy.14 months prior to the presentation she received a preemptive living donor kidney transplantation. Before implant, a 7cm Bosniak I cyst in kidney graft was marsupialized. Patient presented to the emergency departament with pain in the right iliac fossa, without fever or urinary symptoms. Beta HCG was negative, computed tomography (CT)showed small non-obstructive calculi in graft calyx and the patient was discharged. Within 6 days, she returned referring worsening of pain and spiking fever. Laboratory revealed leukocytosis with left upper shift and an acute kidney injure KDIGO 1. Graft Doppler ultrasound showed no vascular or perfusion changes, but heterogeneity and debris in the SC. With the mentioned findings, it was thought that the previously SC was infected. Ciprofloxacin with adjuctive ceftriaxone was started, however patient presented only partial clinical response with sustained leukocytosis. On the third day we performed a percutaneous CT-guided drainage of the SC with 170mL of purulent secretion. A drainage catheter was planted and maintained for 7 days and antibiotics we're not changed. Patient renal function and infectious parameters come back to normal.

Discussion: SC prevalence increases with age, occurring in up to 28-43% of kidney donor candidates. Despite the high occurrence, SC related complications are rarely reported. When facing a renal cysts infection, the antibiotic choice should take into account the cyst penetration profile (eg. Quinolone). Betalactamic association for synergism is controversial. SC infections requiring drainage are rare in native kidneys. The management was based on native kidney SC infections and ADPKD cyst infection reports.



CT guided percutaneus drainage of SC on graft with drainage catheter

PUB655

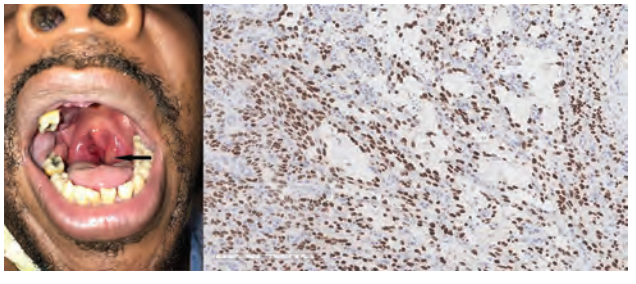
Kaposi Sarcoma of the Tonsils in a Renal Transplant Patient Treated with Resection and Sirolimus

John Howard, Ryan A. Thomas, Morgan Darrow, Ling-Xin Chen, Kuang-Yu Jen, Muna Alnimri. *University of California Davis Medical Center, Sacramento, CA.*

Introduction: Kaposi sarcoma (KS) is a locally aggressive vascular tumor which is strongly associated with human herpesvirus infection (HHV-8; also known as Kaposi sarcoma-associated herpesvirus or KSHV). KS is most often seen in patients with HIV infection, but can occur in patients who are on immunosuppressive therapy, particularly transplant recipients, with an incidence at least 9 fold greater than the general population. While skin and the oropharynx are the typical sites for KS accounting for 60% of cases, only 2% of these are confined to the mouth or oropharynx. Presentations involving the tonsils specifically are rare.

Case Description: We describe a case of tonsillar KS occurring in a kidney transplant patient. He presented 16 months post-transplant with dysphagia, odynophagia, and weight loss that developed over the preceding month. Oral examination revealed tonsillar hypertrophy with purple discoloration as well as friable exophytic lesions (figure 1). He underwent tonsillectomy with microscopic examination of the specimens showing a vascular proliferation which had immunohistochemical stain evidence of HHV-8, consistent with KS (figure 2). Serologic testing for HIV was negative.

Discussion: Reduction of immunosuppression is an important part of the treatment of KS, but alone can be insufficient for inducing remission in the majority of cases as well as placing patients at increased risk for rejection and graft failure. Other immunosuppressants, notably sirolimus, have been shown to improve outcomes. Extensive or refractory cases may still require chemotherapy. Clinicians should be aware of dysphagia and tonsillar enlargement as a rare presentation of KS in post-transplant patients, particularly during the first 2 years when most cases occur. Our patient was maintained on low dose tacrolimus and sirolimus, and he continues to have good graft function and stable disease 5 months post diagnosis.



PUB656

Monoclonal Gammopathy of Renal Significance in a Renal Transplant Patient

Shan Khan,[1] Barry M. Wall,[2,1] Shailesh Satpute,[4] Manish Talwar.[3,1] *[1]UTHSC, Memphis, TN; [2]Veterans Affairs Medical Center, Memphis, TN; [3]Methodist University Hospital, Memphis, TN; [4]Baptist Cancer Center, Memphis, TN.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) occurs due to abnormal secretion of a monoclonal immunoglobulin by a clonal population of plasma cells. MGRS has been rarely reported in renal transplant recipients.

Case Description: A 65-year-old male with a history of end-stage renal disease due to presumed diabetic nephropathy received a cadaveric kidney transplant. He was treated with mycophenolate mofetil, tacrolimus, and prednisone and had an uncomplicated post-op course. Four months later, he devloped difficult-to-control hypertension, lower extremity edema, and elevated serum creatinine (SCr) from a baseline of 1.6 mg/dL to 2.3 mg/dL. Tacrolimus toxicity was suspected, and, after dose adjustment, SCr decreased to 2.0 mg/dL. Two months later, the SCr increased to 2.5 mg/dL and urinalysis (UA) revealed pyuria and 1+ albumin. Spot urine protein:creatinine ratio (UPC) was 0.45. No anemia, hypercalcemia or bone pain was present. Allograft biopsy showed mild glomerulitis and peritubular capillaritis, acute tubular injury, and proximal tubules with intense lambda light chain restriction in cytoplasmic protein reabsorption droplets. C4d and Congo red stain were negative. Donor specific antibody (DSA) class I and II were negative. SPEP, UPEP, immunofixation (IFE), and serum free light chains (SFLC) revealed: SPEP had an M spike of 0.81 g/dL with IgG lambda restriction on IFE. UPEP had monoclonal protein, IgG lambda (6.43 mg/24 hours) with free lambda light chains (5.97 mg/24 hours). SFLC ratio was low at 0.25. Bone marrow (BM) aspirate and biopsy with flow cytometry revealed a hypercellular marrow with a lambda restricted plasma cell population that was 5% of total marrow cellularity. Hematology/oncology began bortezomib and dexamethasone. During follow-up SCr decreased from 2.5 mg/dL to 1.9mg/dL. The most recent UA showed no pyuria and a spot UPC of 0.44.

Discussion: Given the absence of hypercalcemia, bone pain, or anemia, the electrophoresis findings and the presence of only 5% lambda restricted plasma cells in the bone marrow would suggest a diagnosis of monoclonal gammopathy of unknown significance that would not warrant aggressive treatment. The histologic finding of proximal tubulopathy related to lambda restricted light chains in the allograft, however, led to the diagnosis of MGRS and the same treatment as given for multiple myeloma due to renal involvement.

PUB657

Thrombotic Microangiopathy in a Liver Transplant Patient on Tacrolimus

Harini Bejjanki, Gajapathiraju Chamarthi, Alfonso Santos. *University of Florida, Gainesville, FL.*

Introduction: Thrombotic microangiopathy (TMA) is a rare adverse reaction of calcineurin inhibitors. TMA is fatal in solid organ transplant patients, with a reported incidence of 0.5-3% and mortality of about 75%. We report the case of a 19-year-old woman with Tacrolimus (Tac) induced TMA treated with eculizumab (EZB).

Case Description: A 19-year-old female with autoimmune hepatitis status post Orthotopic Liver Transplant on Tacrolimus(Tac), Chronic Kidney Disease Stage III presented with diarrhea. Initial Labs: creatinine 12 mg/dl, platelet count 30,000/cu.m, hemoglobin 5.2 g/dl, elevated LDH 635 IU/L, haptoglobin (HG) < 30 mg/dl, many schistocytes on peripheral smear. ADAMTS-13 activity: 55%. Stool PCR:Negative for Shiga Toxin and E.Coli. Clinically, typical TTP was ruled out. HUS was diagnosed, supported by subsequent kidney biopsy finding of TMA. As Tac can cause TMA, it was switched to sirolimus. Treatment with EZB was instituted [900 mg IV weekly x four weeks, then 1200mg IV biweekly from doses 5 to 7]. By the 5th EZB dose, renal function improved (creatinine down to 2-3 mg/dl), LDH decreased to 388 IU/L, although haptoglobin remained<30 mg/dl. With ongoing hemolysis (elevated LDH and low HG), a 2nd renal biopsy was done following the 6th EZB dose, which showed FSGS. Due to persistent proteinuria and ongoing TMA, sirolimus was discontinued. After the 7th EZB dose, C3 level improved (68 to 128 IU/L), C4 was normal, LDH improved to 250 IU/L. Results of anti-complement H autoantibodies and aHUS genetic panel including C5 polymorphisms which is associated with poor response to EZB were negative; but, heterozygous variant (c.3287G>A, p. Arg1096His) in exon 25 of the ADAMTS13 gene was positive. The patient's renal function stabilized to creatinine of 2.1 mg/dl. In anticipation of discharge, outpatient EZB treatment was arranged; unfortunately, she developed cardiac arrest and passed away.

Discussion: The case highlights that EZB may improve Tac induced TMA without plasmapheresis. Per biopsy, patient's AKI was a combination of ATN and TMA, so it is unclear the extent EZB contributed to renal function improvement. Despite the finding of a heterozygous variant, the near-normal ADAMTS 13 activity and data from the clinvar database clarified that the variant is benign and common in the population. Thus, it is likely that this is a case of tac-induced TMA that responded to EZB treatment.

PUB658

To Be or Not to Be? Parvovirus B19 Causing Refractory Anemia After Kidney Transplant

Hameeda Khan, Aimen Liaqat. *Saint Barnabas Medical Center, West Orange, NJ.*

Introduction: Anemia is a common complication after transplantation and the reported incidence of Parvovirus induced anemia (PIA) is around 10%. The exact incidence is frequently underestimated because routine parvovirus screening is not performed and it is difficult to differentiate from drug adverse reaction.

Case Description: A 70-year-old male with a past medical history of G6PD deficiency, living donor transplant with induction presented 6 weeks later with dyspnea on exertion for 1 week. Labs showed hemoglobin of 7.4 g/dl (baseline 10), MCV 90 fl, Platelets 919 K/CMM, Creatinine 0.7mg/dl, Retic 0.3%, elevated Haptoglobin, fibrinogen, ferritin, erythropoietin levels 156 mIU/ml and LDH 510. CT scan was negative for retroperitoneal hematoma and pulmonary embolus was excluded. No evidence of bleeding was found. He was transfused units of packed red blood cells and treated with Aranesp. Hemoglobin improved to 9.7mg/dl prior to discharge. Outpatient follow up showed parvovirus PCR> 100 million copies. Mycophenolate was decreased to 180mg BID and intravenous immunoglobulin (IVIG) therapy was given (5 doses 0.7g/kg for 4 weeks). Parvovirus PCR decreased to 22000 and hemoglobin increased to 13.6mg/dl in 2 months.

Discussion: Parvovirus exhibits tropism for the erythroid progenitor cells resulting in pure red cell aplasia. Immunosuppression impairs the response to infection leading to prolonged viremia or chronic anemia. Clinical manifestation ranges from a normocytic anemia refractory to transfusions or erythropoietin, pancytopenia and thrombotic

microangiopathy. Clinical symptoms can be asymptomatic to life threatening organ dysfunction. Diagnosis is through positive polymerase chain reaction and confirmed by a bone marrow biopsy showing decreased erythropoiesis and giant pro-erythroblasts with nuclear viral inclusions. The recommended treatment is with intravenous immunoglobulins (IVIG) with or without reducing immunosuppression. The dose and duration of IVIG is much debated. Due to the severity of anemia, viral load should be frequently assessed pre and post-transplant till resolution is achieved. In conclusion PIA is a rare but serious complication and a higher index of suspicion is advised when a transplant patient presents with severe and refractory anemia.

PUB659

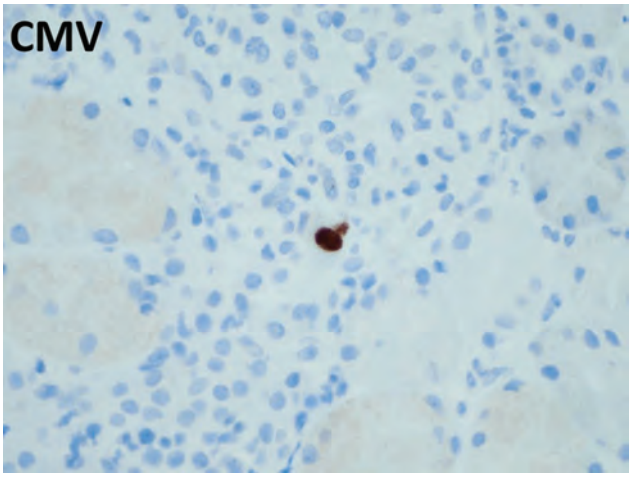
De Novo Collapsing FSGS Secondary to Cytomegalovirus Infection in a Deceased Donor Kidney Transplantation Recipient

Esmeralda Primeaux,[1] Muralidharan Jagadeesan,[2] Rohan S. Paul,[1] Renu Regunathan-Shenk.[1] *[1]Nephrology, George Washington University Hospital, Washington D.C, DC; [2]George Washington University, Washington, DC.*

Introduction: This case describes the case of a kidney transplant recipient, who developed collapsing FSGS in the setting of CMV infection two weeks after the standard CMV prophylaxis therapy was discontinued.

Case Description: A 59 year-old African American man with a history of deceased donor kidney transplant due to ESRD secondary to hypertension presented to the ER with an acute febrile illness seven months following his transplant surgery. Symptoms included two weeks of diarrhea, anorexia, fever, cough and decreased urine output. Transplant history: CPRA 90 %; Immediate graft function; CMV status D+/R. For induction received Velcade, Thymoglobulin and Simulect. Prophylaxis included nystatin and Bactrim. Valgancyclovir for six months post-operation. Maintenance immunosuppression consisted of tacrolimus, mycophenolate and prednisone. In the ER he was found hemodynamically stable, ill-appearing, benign cardiopulmonary and abdominal exams and no edema. Initial lab remarkable for leukopenia, thrombocytopenia, acute kidney injury, nephrotic range proteinuria. Renal allograft ultrasound was normal. Initial management included IV fluids and empiric antibiotics. Flexible sigmoidoscopy performed which was negative for gross lesions. CMV PCR results positive for 895,000viral copies. Immediately started on Ganciclovir and MMF dose was reduced. Due to worsening renal function the patient underwent kidney allograft biopsy which revealed: Colapsing FSGS. Stain for CMV was positive. The viral load downtrended in the first week of induction therapy. Patient made a symptomatic recovery and his creatinine improved.

Discussion: This case describes a kidney transplant recipient who developed CMV infection despite completing the appropriate prophylaxis and developed secondary FSGS of the allograft as a result. This case is notable for nature of the renal allograft injury and the fact that he recovered allograft function through treatment of his CMV infection.



PUB660

Central Diabetes Insipidus Unmasked After Kidney Transplant: A Case Report

Sherida N. Edding, Brian Michael I. Cabral. *Department of Medicine, St. Luke's Medical Center - Global City, Taguig City, Philippines.*

Introduction: Patients who undergo pituitary surgery are prone to develop Central Diabetes Insipidus (CDI) post-operatively on top of other hormonal deficiencies. CDI is characterized by decrease in release of antidiuretic hormone (ADH) and present clinically with polyuria, nocturia and polydipsia. In patients with End Stage Renal Disease (ESRD) and on maintenance dialysis, CDI may be masked and then unmasked after transplantation. To the best of our knowledge, there have only been 4 published studies with regards unmasking of CDI post-kidney transplantation.

Case Description: We report a case of a 62 year old male with history of resection of a pituitary macroadenoma and ESRD secondary to Diabetic Nephropathy on maintenance dialysis, admitted for living non-related kidney transplantation. Pre-transplantation, he was on desmopressin for CDI but when he developed ESRD, CDI was masked and desmopressin was discontinued. His kidney transplant went uneventful. Post-transplantation, he developed polyuria, increasing serum sodium levels, borderline high serum osmolality and low urine osmolality. In lieu of measuring plasma ADH levels, fluid restriction was done which resulted to increase sodium levels. A diagnosis of CDI was made. He was started on oral desmopressin with noted improvement of symptoms. He was eventually discharged improved. On succeeding outpatient consults, patient's daily urine output exceeded to 4L/day and his dose of desmopressin was increased to 100mcg twice daily. Thereafter, he remained clinically stable with average daily urine output of 3L/day, normal sodium levels and good renal allograft function.

Discussion: Successful kidney transplantation leads to unmasking of pre-existing CDI, which when missed may lead to rapid dehydration and hypernatremia. Frequent monitoring is necessary for early detection and management of CDI. Furthermore, CDI is not a contraindication for transplant as long as patient is closely monitored for adequate titration of fluids and prompt management with desmopressin.

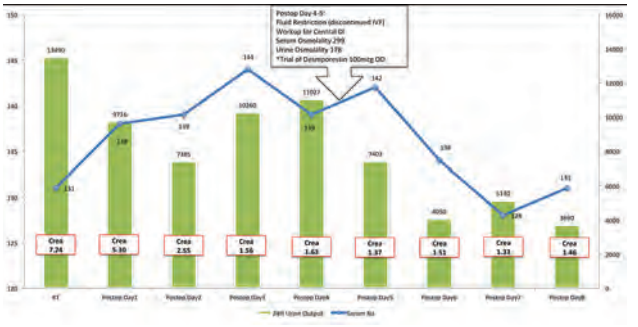


Fig 1. Clinical Timeline From Day of Transplant until Postop Day 8

PUB661

More Than Meets the Eye: Acute Cellular and Antibody-Mediated Renal Allograft Rejection Associated with Donor-Specific Antibodies (DSA) Angiotensin II Type 1 Receptor (AT1R) Antibodies

Hanan A. Khairalla,[1] Wut yi Hninn,[2] Angelina Edwards.[3] *[1]University of Texas, Houston, TX; [2]UTHealth, Houston, TX; [3]University of Texas at Houston Health Science Center, Houston, TX.*

Introduction: Kidney transplant is associated with improved survival in end stage renal disease (ESRD) patients and although 1 year allograft survival rates continue to improve, long term allograft survival remains low. Immune-mediated graft loss remains a challenge and non-HLA antibodies increasingly are recognized as contributing to allograft dysfunction. We present a case of a deceased donor renal transplant (DDRT) patient who presented with acute kidney injury from mixed cellular and antibody mediated rejection.

Case Description: An 18 year old woman with ESRD from neurogenic bladder received a 2A2B2DR HLA mismatch DDRT, low immunologic risk without DSA, with basiliximab induction and maintenance immunosuppression with mycophenolate mofetil, tacrolimus and prednisone. She had a history of spina bifida and repaired meningomyelocele necessitating self-catheterization, with unfortunately increased urinary tract infections. At age 12, she had bladder augmentation with small bowel and ureteral re-implantation, with continued intermittent self-catheterization. Post-transplant course was complicated by recurrent, multidrug-resistent UTIs, leading to reduction in maintenance immunosuppression and nonadherence to medications by the patient. On post-op month 5, she was noted to have an acute kidney injury with Cr increase from 1 mg/dL to 4.47 mg/dL. A renal biopsy was obtained which showed acute T cell mediated rejection and C4d negative antibody mediated rejection. DSA was positive and non-HLA testing was pursued which was negative for endothelial cell and MICA antibodies but positive for AT1R. Treatment with ATG, plasma exchange, IVIG, steroids and Rituximab was given. Patient was started on Losartan for AT1R antibody. Her Cr improved to baseline and she remains with stable allograft function.

Discussion: *In addition to the common factors that contribute to allograft injury such as infection and non-adherence*, non-HLA antibodies are becoming increasingly more relevant in renal allograft dysfunction, contributing to graft loss. AT1R antibodies are usually associated with ABMR histopathology and lead to cytokine release. They further enhance vascular inflammation and allograft dysfunction. They should always be considered when rejection is diagnosed in the absence of HLA antibodies.

PUB662

Undiagnosed Anti-GBM Antibodies Causing Rapid Loss of a Kidney Transplant

Bonnie Ann Sarrell, Paisit Paueksakon, Meghan E. Kapp, Vadim Pedchenko, Billy G. Hudson, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Many patients have renal dysfunction attributed to co-morbid conditions. Depending on the clinical scenario, a serologic workup or renal biopsy for definitive diagnosis may not be deemed necessary. However, definitive diagnosis may be crucial for the success of a subsequent kidney transplant. Here we present a case of a young man with unknown etiology of his native kidney disease who received a kidney transplant that failed rapidly due to the presence of undiagnosed circulating anti-GBM antibodies.

Case Description: This is a 33yo CM with HTN and tobacco use who presented with 3 weeks of vomiting, diarrhea, and weakness. He was anuric with a creatinine of 25 mg/dL and was started on chronic dialysis. Two years later, he underwent a living unrelated kidney transplant. He received alemtuzumab, solumedrol, tacrolimus, and mycophenolate mofetil. Surgery was uncomplicated but after 12hrs his urinary output started to decline and creatinine plateaued. Transplant ultrasound was normal. DSA was negative. UA had 100 mg/dL protein, 30 WBC, 921 RBC. Urine PCR was 1g/g. Renal biopsy was performed which showed 17/25 glomeruli with active lesions – 13 with cellular crescents and 4 with fibrinoid necrosis. Immunofluorescence showed diffuse, global, linear capillary loop staining for polyclonal IgG and C3. Anti-GBM level was 213 AU/mL. He was treated with steroids, plasmapheresis, and cyclophosphamide without response and required re-initiation of dialysis. His course was further complicated by septic shock due to *Bacteroides fragilis* bacteremia to which he ultimately succumbed 6 weeks post-transplant. Stored serum collected 1 week prior to transplant subsequently tested positive for anti-GBM antibodies, specifically a3,5 collagen IV antibodies.

Discussion: In this case, the rapid and unexpected failure of a newly transplanted kidney was caused by circulating anti-GBM antibodies. Their presence was unsuspected due to the lack of definitive diagnosis for his native kidney disease and absence of common clinical features of anti-GBM disease at the time of transplant. Presumably, the patient suffered from anti-GBM disease causing failure of his native kidneys. This compelling case suggests that in a young male with undiagnosed etiology of kidney failure, a test for the presence of anti-GBM antibodies should be considered before transplantation.

PUB663

Great Threat from a Benign Drug: Vitamin C Causing Severe AKI in a Renal Transplant Patient

Catarina Regis,[1,2] Saul N. Gonzalez Montalvo,[1,2] Naveen Punchayil narayanankutty,[1,2] Ragi Philips,[1,2] Luis A. Vazquez Zubillaga,[1,2] Phillip Ruiz,[3] Javier Pagan.[1,2] University of Miami Katz Family Division of Nephrology and Hypertension *[1]Nephrology, University of Miami, Miami, FL; [2]Jackson Memorial Hospital, Miami, FL; [3]University Of Miami, Miami, FL.*

Introduction: Ascorbic acid (AA) is an essential and relatively harmless vitamin if taken in doses less than 2g/day. Despite the lack of randomized controlled trials validating its efficacy, the use of high doses of Vitamin C has been increasing in the intensive care unit(ICU) setting as part of septic shock treatment. AA metabolizes to oxalate and once excreted by the kidneys can deposit in the tubules leading to oxalate nephropathy. In this report, we highlight a case of allograft nephropathy related to oxalate deposition in the setting of high dose of vitamin C use to treat septic shock.

Case Description: 70-year-old female, with history of end stage renal disease due to autosomal dominant polycystic kidney disease, underwent dual deceased donor kidney transplant. On postoperative(POD) day 9, patient developed septic shock from pneumonia, was started on empiric antibiotics, stress dose steroids, vasopressors, IV AA 1.5g every 6 hs and IV thiamine 200 mg every 12hs. In total, a 5-day course of IV Vitamin C (6g/day) was given. Hospitalization further complicated by another septic shock from intraabdominal abscess and secondary peritonitis when IV AA 6g/day was prescribed again for 5 days. She had a prolonged and complicated ICU stay, with sustained stage 3 acute kidney injury (AKI) requiring hemodialysis. Progressively, patient improved clinically but there were no signs of allograft recovery after 2 months from the transplant. A kidney biopsy was performed and showed moderate acute tubular injury with tubular crystal deposition, resembling calcium oxalate crystals. Creatinine levels went back to baseline after discontinuation of AA.

Discussion: The patient described had a complicated postoperative course following renal transplantation requiring prolonged ICU stay due to two episodes of septic shock and respiratory failure. During that time, high doses of IV AA (6g/day) for 10 days was given as adjunct therapy for septic shock. After prolonged AKI, renal biopsy was performed which showed tubular crystal deposition and moderate tubular injury. Clinicians should be aware that high doses of Vitamin C (>2g/day) can cause oxalate nephropathy and a careful assessment of risk and benefits should be made, especially in patients with history of renal disease and kidney transplant.

PUB664

Neurotoxoplasmosis After Kidney-Pancreas Transplantation

Jayesh B. Patel, Swe Zin Mar Win Htut Oo, Patricia A. Kirby, Melissa L. Swee. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Toxoplasmosis is a potentially life-threatening infection that is strongly associated with immunosuppression, such as after solid organ transplantation. Although most cases occur during induction of immunosuppression, reactivation or de novo infection may occur in those with a remote history of solid organ transplantation. We report a case of cerebral toxoplasmosis that mimicked malignancy.

Case Description: A 71-year-old male with end-stage kidney disease status post kidney-pancreas transplantation 21 years ago on mycophenolate mofetil, tacrolimus, and prednisone presented with three weeks of left sided weakness. Vital signs were stable and examination was remarkable for 4/5 strength of the left upper and lower extremities. A right parietotemporal mass lesion with surrounding edema concerning for malignancy was found on MRI. Chest, abdomen, and pelvis PET/CT scan showed no FDG-positive lesions. Five days later, his mental status acutely worsened. Repeat MRI showed an acute right temporal lobe infarction with transtentorial herniation, requiring urgent mass resection. Histopathologic examination showed necrosis with toxoplasma tachyzoites and cystozoites. Immunohistochemistry stains for HSV, VZV, SV-40, CMV, as well as Gram, AFB and Gommori trichrome stains, were negative. HIV serology was negative. Toxoplasma IgG was positive, and IgM was indeterminate. Immunosuppression was discontinued and pyrimethamine-sulfadiazine was initiated. He was discharged to an acute rehabilitation facility after 2 weeks.

Discussion: Toxoplasmosis is a parasitic infection that may present variably as encephalitis, brain abscess, or retinitis. Because of its heterogeneous presentation, a high index of clinical suspicion and close collaboration between the nephrologist, radiologist, pathologist, and microbiologist is required. Early identification is critical since treatment depends on reversal of immunosuppression and initiation of appropriate antimicrobial coverage, such as pyrimethamine-sulfadiazine.

Is Cidofovir an Option for Refractory BK Nephropathy?

Aravindan V. Jeyarajasingam,[1] Julien Sanon,[3] Gitana Bradauskaite,[4] Yamuna Yoganathan,[2] John P. Knorr.[4] *[1]Renal Transplant, Einstein Medical Center, Philadelphia, PA; [2]Windsor University School of Medicine, Caledon, ON, Canada; [3]Einstein Healthcare Network, Cheltenham, PA; [4]Einstein Medical Center, Philadelphia, PA.*

Introduction: BK human polyomavirus typically seroprevalent in humans however BK appears to affect immunocompromised patients and cause clinical disease. In Kidney transplant patients, degree of immunosuppression is associated with BK viremia and nephropathy (BKVN) and has a prevalence of approximately 5 % in post kidney transplant patients. We present the case of a patient who underwent diseased donor renal transplant and developed BK viremia within a month of receiving her transplant. BK viremia was refractory to a reduction in the dose of her immunosuppressive agents, IVIG as well as Leflunomide. BK viremia responded significantly after initiation of intravenous cidofovir.

Case Description: 42 year old female with past medical history including end stage renal disease due to diabetic nephropathy who underwent diseased donor renal transplant and patient had immediate graft function. Maintenance immunosuppression including Tacrolimus, Mycophenolate and Prednisone. She developed BK viremia with in first month after transplant; subsequently mycophenolate was discontinued, and she was started on Leflunomide and IVIG infusion. She received total of eight doses of IVIG. Due to worsening creatinine, patient underwent transplant graft biopsy #1 which showed stage A BK nephropathy with polyoma viral load (PVL) 1-10 %. Second renal biopsy four months later showed stage B BK nephropathy with a PVL > 3 % and SV 40 positive in cortex > 10%. Patient was started on Cidofovir intravenous infusion 0.5 mg/kg every 2 weeks with normal saline pre-treatment infusion 500 ml. The patient's BK viremia started to trend down after initiation of cidofovir (figure 1).

Discussion: BK virus affects immunocompromised renal transplant patients. Transplant graft biopsy will give the definite diagnosis of BKVN with positive for SV40. BKVN thought to be secondary to over immunosuppression. The initial treatment for BK viremia includes lowering immunosuppression followed by IVIG as well as Leflunomide. In patients who are refractory to initial treatment, cidofovir can be a treatment option.

PUB666

Who's to Blame? Angiotensin II Type Receptor Antibodies (AT1R): A Lurking Cause of Sudden Graft Dysfunction in a Patient with Donor-Specific Antibody

Ruchi H. Naik, Serban Constantinescu, Dina Abdelwahab, Iris J. Lee. *Temple University School of Medicine, Philadelphia, PA.*

Introduction: AT1R has been linked to refractory humoral rejection and poor transplant outcomes. Vascular inflammation on biopsy, typically without C4d is commonly reported. The signs, histologic presentation, and mechanisms of AT1R mediated graft dysfunction are not well understood and require further study. We discuss an atypical

presentation of AT1R mediated graft dysfunction associated with pre-existing DSA highlighting the need to recognize the potential for multiple mechanisms for graft injury and develop screening protocols post-transplant.

Case Description: A 56 year old African American female with end-stage renal disease due to lupus nephritis received a standard criteria deceased donor kidney transplant. She had a 100% panel reactive antibody and a borderline B cell positive crossmatch due to pre-existing class II DSA with low mean fluorescent intensity (MFI) (900-1600). On post-op day 1 she started 5 sessions of plasma exchange (PP) followed by GammaGard intravenous immunoglobulins. Graft function was immediate, but on day 15, acute kidney injury (AKI) occurred with an abrupt increase in creatinine (3.26 mg/dl to 7.07 mg/dl). Allograft biopsy lacked features of cellular or humoral rejection, was C4d negative and showed only severe ischemic tubular injury (ATN). Given DSA with low stable MFI, and absence of any ischemic event to explain ATN, AT1R titer was measured. Pre-PP titers were (>40units/ml) and remained high despite initial PP. With continued PP and titers (<16 units/ml) her creatinine improved to 1.12 mg/dl.

Discussion: Our patient had persistent low level class II DSAs in a range not expected to cause sudden graft dysfunction and severe AKI. Furthermore, her biopsy had no evidence of humoral or cellular rejection. Only severe ischemic ATN was observed without an obvious cause. As described in preeclampsia, we propose AT1R may impart signals leading to endothelial cell dysfunction and sustained vasoconstriction leading to poor perfusion and ischemia. We argue that AT1R can present without significant inflammation and can function as an agonistic antibody that may be internalized once ligated to membrane bound receptor, thereby avoiding severe complement mediated inflammation and damage.

PUB667

Pulmonary Necrotic Rhodococcus equi Infection in a Kidney Pancreas Transplant Recipient: A Rare Case Treated Without Surgical Intervention

Khawaja O. Omar, Tim E. Taber, Muhammad S. Yaqub, Oluwafisayo O. Adebiyi, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Rhodococcus equi has emerged as a serious pathogen in solid organ transplant recipients. Primary pulmonary involvement is the most common presentation. However, this opportunistic pathogen is often not considered in the differential diagnosis of pneumonia in transplant recipients. Approximately less than 30 cases in renal transplants and only 2 in pancreas transplants have been reported with up to 20-25% mortality.

Case Description: 57-year-old white male who had received his 3rd renal transplant 2 years and 1st pancreas transplant 12 years earlier. At the time of presentation, he was on tacrolimus, mycophenolate mofetil, prednisone and basiliximab for immunosuppression. He presented with a 2 month history of a cough and weight loss. He had been prescribed azithromycin, doxycycline, and ciprofloxacin by his local providers with no improvement. Chest x-ray showed necortic 5cm cavitary right middle lobe lung lesion. On evaluation he was positive for influenza virus, corona virus and aspergillus. Bronchoscopy with BAL and lymph node biopsy cultures showed Rhodococcus Equi. He was started on IV vancomycin, meropenem for 6 weeks and his symptoms improved. He was switched to oral azithromycin and linezolid for another 6 months which was later held for cytopenias. He was then given minocycline after 6 months, while the azithromycin prophylaxis was continued. He was also given voriconazole for his aspergilllus for 12 months. Repeat chest imaging near total improvement in the cavitary lesion and his symptoms resolved over the next 6-9 months. Although surgery was considered an option, due the pericardial location of the lesion it was not pursued. His immunosuppressants were reduced and basiliximab was stopped. His creatinine remained stable around 2.4. Over the following year his pancreas function experienced elevation of lipase which was successfully reversed with steroids and resuming his mycophenolate.

Discussion: R.equi is a unique Acid fast positive cocci and a intracellular pathogen. Here we report a very rare case of Rhodococcus infection in a kidney pancreas transplant recipient which was successfully treated without surgical intervention. Choice of antibiotics were challenging while maintaining dual organ transplant function and avoiding acute rejection.

PUB668

Extended Spectrum Beta-Lactamase Producing Escherichia Coli-Associated Necrotizing Fasciitis in a Kidney Transplant Recipient

Aju Jose, Apaar Dadlani, Nitender Goyal, Jeff Cooper. *Tufts Medical Center, North Attleboro, MA.*

Introduction: Necrotizing fasciitis (NF) is a life-threatening soft tissue infection. NF is usually polymicrobial and can be caused by aerobic, anaerobic, gram-positive, or negative bacteria. Although Escherichia coli (E.coli) associated NF is usually polymicrobial, there have been few case reports of monomicrobial NFassociated with E. Coli. Even fewer are reports of extended-spectrum beta-lactamase (ESBL) producing NF.

Case Description: A 57-year-old African American male kidney transplant recipient presented 2 weeks after transplant with fever, altered mental and scrotal pain. Clinical examination revealed warmth, erythema, and swelling over the transplant kidney incision site that tracked down a grossly enlarged erythematous, warm and tender scrotum. He was intubated due to the inability to protect the airway, fluid resuscitated and started on empiric antibiotics and antifungals vancomycin, cefepime, and micafungin. The patient was emergently taken to the operating room (OR) for wound exploration, and the one-liter perinephric purulent fluid collection was drained. His vitals started improving following drainage, and he came off vasopressors. In the next 24 hours, clinical condition deteriorated with the increasing vasopressor requirement. Cefepime was discontinued, and Piperacillin/Tazobactam and Clindamycin were added. The perinephric fluid and blood culture came back positive for ESBL producing E. Coli, and meropenem was initiated. He developed severe pain to palpation on bilateral thighs and crepitus in the groin region, tracking to the left medial thigh. He was taken back to OR for debridement, and 70% of the scrotal skin was debrided with an onrush of purulent material. He developed dependant new areas of blistering, erythema and worsening crepitus in the groin, thigh, and hip for which he underwent bedside debridement. Despite aggressive resuscitation, the patient died on the third day of hospitalization.

Discussion: Several reports have emphasized importance of Gram-negative rods in NF. To our knowledge, only 3 cases of E. Coli associated NF have been previously described in kidney transplant recipients. Ours is the only case of ESBL producing E.coli NF in kidney transplant recipients. It is important to note that monomicrobial ESBL producing E. coli infection can lead to necrotizing NF, and appropriate antibiotic selection on initial presentation is critical.

PUB669

Zebra Bodies in a Kidney Transplant Recipient

Stefano Coppola fasick, Neeraj Singh, Adrian P. Abreo, James O. Onyirimba. *Nephrology, Ochsner LSU Health Shreveport, Shreveport, LA.*

Introduction: Fabry disease is an X-linked genetic disorder due to deficiency of lysosomal enzyme α-galactosidase A characterized by glycosphingolipids accumulations within body cells and development of concentric lamellar bodies or zebra bodies. It is associated with renal and extra-renal manifestations including angiokeratomas, hypohidrosis, hearing loss, corneal opacity, neurological and cardiac involvement.

Case Description: A 63 year-old Asian male with kidney transplant (10 years ago) due to end stage renal disease secondary to hypertension presented with a 2-week history of lower extremity edema. Clinical findings was remarkable for 2+ pedal edema, and laboratories with slightly elevated serum creatinine, 2.3 mg/dl, a spot urine protein to creatinine ratio of 7.6 grams/gram of creatinine, and tacrolimus level of 4.7 ng/ml. The serum α-galactosidase A level was normal; BK virus PCR and donor specific anti-HLA antibodies were negative. Medications consisted of mycophenolate mofetil, tacrolimus, prednisone, sertraline, nifedipine and vitamin D3. One month post-transplant, he had one episode of biopsy proven rejection without complications. The biopsy of the transplanted kidney revealed focal mild to moderate interstitial fibrosis/tubular atrophy, glomeruli with lobulation of tufts, large endothelial cells with foamy cytoplasm, glomerular capillary endothelial cells and mesangial cells containing lamellar and dense cytoplasmic inclusions or myelin bodies, and chronic rejection related thickening of glomerular basement membrane. No rejection or viral cytopathic effects, immune complex deposits or fibrils were identified. The stain for polyoma virus and the C4d were negative. In addition to chronic transplant glomerulopathy, the diagnosis of glomerular phospholipidosis was entertained.

Discussion: Renal phospholipidosis post-kidney transplant is rarely known. The diagnosis is based on clinical signs and symptoms, confirmed by low enzyme activity in peripheral blood or in leukocytes, or by genetic mutation analysis. Recurrence in allograft post-kidney transplant from non-Fabry Disease donors is rare, therefore awareness among transplant providers of drug induced renal phospholipidosis is important as it can result in post-transplant renal dysfunction and proteinuria.

PUB670

Darling's Disease Presenting with Hypercalcemia in a Kidney Transplant Recipient

Enrique Acosta,[1] Jose A. Castillo-Lugo,[2] Roberto L. Collazo-Maldonado.[2] [1]*Methodist Dallas Medical Center, Dallas, TX;* [2]*Dallas Nephrology Associates, Dallas, TX.*

Introduction: Histoplasmosis is an infection caused by a fungus called *Histoplasma*. The fungus lives in the environment, particularly in soil. Spread occurs mainly by aerosolization of spores. Most people that are exposed to *Histoplasma* do not display symptoms. Those who do typically have fever, cough, and fatigue. Most infections resolve spontaneously without treatment. Infection may be severe in people that are immunosuppressed.

Case Description: A 61-year-old man with previous ESRD due to hypertension, second kidney transplant recipient, history of left transplant nephrectomy due to left renal mass presented with complaints of fever, worsening fatigue, dyspnea on exertion, anorexia, and unintentional weight loss of 11 lbs (in the last 2 months) a year after his second kidney transplant. He was admitted to the hospital with suspected pneumonia as worsening bilateral reticular nodular opacities were present on chest radiographs. CT scan of the chest showed innumerable bilateral micro nodules along with dense focal area of consolidation in the right base along with mild mediastinal adenopathy. Empiric cefepime and azithromycin was started for coverage of atypical pneumonia. Bronchoscopy with broncho alveolar lavage (BAL) was done by Pulmonary service and serological workup was sent. (1,3)-Beta-D-Glucan and Histoplasma Galactomannan Urine Antigen were positive. Serum calcium was high normal on admission but peaked at 12.5 mg/dL. Vitamin D 25-OH was 56 ng/mL and Vitamin D 1,25-OH was markedly elevated at 104 ng/mL suggesting exogenous production. Pulmonary histoplasmosis was diagnosed. Mycophenolate was discontinued. Induction with amphotericin B liposomal with pentoxifylline was started and he completed 14 days of treatment. After induction, maintenance oral itraconazole was started with goal length of treatment of 9-12 months. Rare *Histoplasma capsulatum* was isolated in BAL washings fungal culture after 3 weeks. Vitamin D 1,25-OH levels and Histoplasma Galactomannan Urine Antigen concentration has decreased on 1 month follow up.

Discussion: This is a classic case of pulmonary histoplasmosis in an immunocompromised patient in Texas, where *Histoplasma* is only mildly endemic. The proposed mechanism for hypercalcemia in patients with granulomatous disease (e.g. Histoplasmosis) is increased 1-alpha-hydroxylase production by alveolar macrophages.

PUB671

Metabolism Matters: An Interesting Case on Immediate Tacrolimus Metabolism in a Renal Transplant Recipient on Ritonavir-Boosted Antiretroviral Therapy

Arvind K. Singh. Derriford Hospital Renal team *Renal Medicne, Derriford Hospital NHS Trust, Plymouth, United Kingdom.*

Introduction: Access to solid organ transplantation in the setting of human immunodeficiency virus (HIV) infection has been increasing. HIV positive solid organ transplant recipients are at increased risk of acute rejection – partly because of drug interactions. Multiple studies report serious interactions between tacrolimus and ritonavir-boosted HIV-1 protease inhibitors (PIs). The conventional approach is to reduce the tacrolimus dose to around ten percent of the standard dose and anticipate a ritonavir 'washout period' of up to ten days. Local experience managing liver transplant recipients with HCV at this centre have led to the conclusion that the interaction period is much shorter. They therefore advocate less aggressive tacrolimus dose reductions in view of the even higher risks of early rejection if tacrolimus levels are low.

Case Description: We present an interesting case of a patient undergoing haemodialysis who was matched to a deceased brain dead donor through the national organ sharing scheme in the United Kingdom. The patient was on antiretroviral therapy with ritonavir and their HIV viral load had been undetectable for several years. The HIV specialist team recommended a change to a non-tacrolimus interacting regimen at the time of transplantation. The last dose of ritonavir was taken 40 hours before the first administration of tacrolimus. Induction was with basiliximab and maintenance therapy was with tacrolimus (Adoport), mycophenolate mofetil and prednisolone. Whole blood tacrolimus concentrations were measured at the time of first administration (standard single 0.05 mg/kg dose) and at 30, 60, 120, 240, 360, 480 and 720 minutes. Please see the attcahed graph image below

Discussion: Although there is concern about concomitant use of ritonavir and tacrolimus, this case suggests minimal interaction only 40 hours after the last dose, with appropriate tacrolimus concentrations and an exposure to tacrolimus (area under the curve of 91.2 ng.h/mL) comparable to patients receiving tacrolimus not on ritonavir. We conclude that if a patient on antiretroviral therapy is taken off a ritonavir-boosted protease inhibitor regimen when starting or taking tacrolimus therapy, the standard dosing should be considered at the time of the change along with close therapeutic drug monitoring.

PUB672

PTH-Independent Severe Hypercalcemia Secondary to Pneumocystis jiroveci Pneumonia in a Renal Transplant Recipient: A Case Report

Sravanthi Paluri, Dhiren Kumar, Irfan A. Moinuddin. *Nephrology, Virginia Commonwealth University Health System, Richmond, VA.*

Introduction: Hypercalcemia following renal transplant is a common finding due to preexisting hyperparathyroidism. Pneumocystis Jirovecii Pneumonia (PJP) is an opportunistic infection in solid organ transplant with rare incidence in renal transplant recipients. We report a case of hypercalcemia due to PJP following a change in immunosuppression.

Case Description: 55 year old male, who is a non-sensitized recipient of a second DDKT 34 years ago. He now has CKD stage 3 of the allograft with no prior history of rejection. He presented with a 3 week history of dry cough, hypoxia, lethargy, progressive weakness, 10 pound weight loss associated with diarrhea. He was previously on maintenance immunosuppression with cyclosporine and azathioprine. 6 months prior to presentation, azathioprine was changed to mycophenolate in order to accommodate allopurinol for gout treatment and prevention. He was found to be positive for influenza, clostridium difficile and low grade CMV viremia (2000 IU/ml). Chest x-ray showed multifocal infiltrates. Labs showed calcium of 16mg/dl, ionized calcium of 1.83, PTH of 30pg/ml (baseline 110pg/ml), PTHrp <2pmol/L, calcitriol of 66pg/ml and 25-OH vitamin D of 35ng/ml. He underwent bronchoscopy, BAL was positive for PJP and he was started on IV Bactrim and steroids. He was initially given IV fluids and calcitonin for the hypercalcemia but his calcium levels did not improve. After a week of initiation of IV Bactrim, his ionized calcium decreased to 1.2.

Discussion: The prevalence of hypercalcemia ranges from 8.5 to 71% in renal transplant patients, it is most likely secondary to hyperparathyroidism. Case reports have shown the association of PJP pneumonia and hypercalcemia. Hypercalcemia in PJP is thought due to PTH-independent extra-renal production of 1,25 di-hydroxy vitamin D by activated alveolar macrophages. Previous case series have reported that risk factors associated with PJP pneumonia in solid organ transplant recipients are mycophenolate use, CMV viremia, lymphopenia (<750/mm3) and age >65 years. We believe that switching to mycophenolate led to over immunosuppression which resulted in him developing opportunistic infections, particularly PJP pneumonia. PJP pneumonia is a rare cause of hypercalcemia and should be considered in immunocompromised patients presenting with pneumonia.

PUB673

Arterial Thrombosis from Vascular Clamp Injury: Magnetic Resonance Angiography for Evaluation

Aju Jose, Nitender Goyal, Jeff Cooper. *Tufts Medical Center, North Attleboro, MA.*

Introduction: The most common vascular complications after kidney transplant are renal artery and renal vein thrombosis. Imaging studies with contrast are often avoided immediately after transplant because of concern of nephrotoxicity with iodinated contrast and risk of nephrogenic systemic fibrosis with gadolinium. We present a case of thrombosis of external iliac artery due to vascular clamp injury diagnosed using non-contrast magnetic resonance angiography (MRA).

Case Description: A 68 year old female with end-stage renal disease presumed due to diabetes and hypertension underwent deceased donor kidney transplant after 8 years of dialysis. Operative course was uneventful. Donor kidney biopsy showed severe vasculopathic changes with concentric fibrointimal hyperplasia. Post-operative course was complicated by delayed graft function and renal ultrasound (US) revealed decreased flow of the main renal artery and vein with resistive index of 0.88-1.0. Repeat US on post-operative day (POD) 2 revealed parvus tardus waveforms in both main renal arteries and minimal arterial perfusion of the transplanted kidney. Non-contrast MRA was obtained, which showed the loss of signal in the proximal right external iliac artery just above the arterial anastomosis, concerning for vascular clamp injury versus thrombosis. Right common iliac arteriogram subsequently showed filling defect in the proximal right external iliac artery at the origin of the upper renal artery transplant anastomosis and retrograde filling of lower renal artery. Attempt at suction thrombectomy was unsuccessful and exploration of allograft showed intramural hematoma in external iliac artery proximal to anastomosis. The patient underwent right external iliac local endarterectomy and reanastomosis of donor renal artery to native external iliac artey. Repeat US on POD 4 revealed improved perfusion of the transplanted kidney. Allograft function improved and the patient came off dialysis on POD 8.

Discussion: Vascular clamp injury is a rare complication after kidney transplantation. Due to impaired renal function, diagnostic imaging with contrast is usually avoided. In the case described above, non-contrast imaging study was used to arrive at the diagnosis of clamp injury induced thrombus. Non-contrast MRA can be helpful early post-transplant to identify vascular complications when contrast study is not an ideal choice because of impaired kidney function.

PUB674

Proliferative Glomerulonephritis with Monoclonal Immune Deposition in a Transplanted Kidney

John T. Ludwig, Scott Buchowski. *University of Michigan, Ann Arbor, MI.*

Introduction: Proliferative glomerulonephritis is known recur or develop de-novo in the transplanted kidney, and can lead to graft failure. MPGN is a diagnosis of exclusion, and various other diagnoses based on etiology can lead to this pathologic lesion. One cause is immune deposition disease, for which the differential includes SLE, cryoglobulinemic, infection-related, C3 GN, or monoclonal immune deposition disease (MIDD). We present a case of MIDD with proliferative glomerulonephritis in a transplant, with discordant kappa free light chains and plasma cell restriction vs lambda glomerular deposition on biopsy.

Case Description: 58 yo female with history of ESRD from nephrotic syndrome of unclear etiology, multiple myeloma, and DM type 2. She received chemotherapy for myeloma in 2012 with good response. Kidney biopsy in 2012 after initiating hemodialysis, but before myeloma treatment, showed no evidence of paraprotein deposition. The patient was monitored for smouldering myeloma with serial bone marrow exams. She was cleared for transplant and received deceased-donor kidney March 2018. Stable serum Cr 1.0-1.5 and spot urine prot/creat <0.5, until she presented Nov 2018 with acute onset hematuria, edema, AKI, and nephrotic range proteinuria. No other systemic signs or symptoms of myeloma. Serum kappa free light chains elevated with elevated kappa/lambda ratio. Renal biopsy showed acute proliferative glomerulonephritis with lambda predominant IgG immune deposition. Pulse-dose steroids were given, and she was initiated on CyBorD chemotherapy for myeloma. The patient had rapid improvement in renal function to baseline and resolution of proteinuria.

Discussion: We present a rare case of proliferative glomerulitis with monoclonal IgG immune deposits in a transplanted kidney. This syndrome has been characterized as monocolonal gammopathy of renal significance, or "MGRS". The case is notable for discrepancy between lambda light chain deposition on renal biopsy and kappa restricted plasma cells in bone marrow as well as serum free light chains. In this patient, there was rapid recovery of transplant kidney function following treatment for myeloma.

PUB675

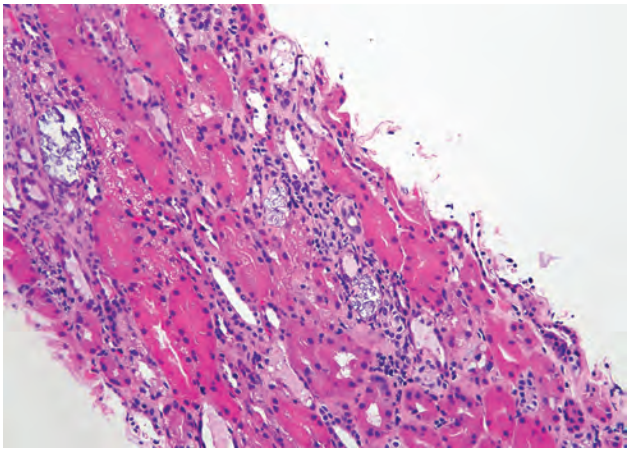
Atypical Case of Calcium Phosphate Deposits in Renal Allograft

Sheetal Koul,[1] Dina Abdelwahab,[1] Serban Constantinescu,[2] Iris J. Lee.[2] *[1]Temple University Hospital, Philadelphia, PA; [2]Temple University School of Medicine, Philadelphia, PA.*

Introduction: Calcium phosphate crystals have been observed in renal allografts within the first six months of transplantation in patients with hyperparathyroidism prior to transplant. Calcium phosphate deposits correlate significantly to mineral metabolism abnormalities. We report a case of persistent renal allograft dysfunction secondary to calcium phosphate crystals with no evidence of hyperparathyroidism or other known risk factors

Case Description: A 38 y.o male PMH of ESRD secondary to Diabetes Mellitus underwent a simultaneous kidney pancreas transplant. Post-transplant allograft biopsies were done at 15,18,21 months for persistent renal function impairment. All biopsies were noted to have heavy calcium phosphate deposits in the renal tubules and persistent severe acute tubular injury. Post-transplant serum calcium ranged between 9.1-9.6 mg/dl, phosphorous 2.7-3.4 mg/dl which were similar to pretransplant levels, calcium excretion ratio showed no hypercalciuria, serum PTH was decreased from a pretransplant value of 587 to 156 pg/ml. Despite normal calcium and phosphorous levels, along with decreasing PTH, heavy calcium phosphate deposits persisted in the allograft. Serum creatinine has remained in the range of 1.8-2.2 mg/dl suggesting calcium phosphate deposits as underlying etiology. Immunosuppression regimen included mycophenolate mofetil, extended release tacrolimus(envarsus) and sulfamethoxazole trimethoprim as prophylaxis

Discussion: Calcium phosphate deposits in the renal allograft have been typically noted in patients with persistent hyperparathyroidism post-transplant. However, in our patient this was observed with normal calcium phosphate product and in setting of decreasing PTH levels. The mechanism of calcium phosphate deposits in this setting is unclear suggesting possible drug induced due to new drugs as extended release tacrolimus(envarsus)



PUB676

Third Renal Transplant in a Patient with Prune Belly Syndrome

Sandeep A. Padala,[1] Rajan Kapoor,[2] Imran Y. Gani,[3] Muhammad I. Saeed,[4] Peter Drevets.[1] *[1]Augusta University, Augusta, GA; [2]Augusta University / Medical College of Georgia, Augusta, GA; [3]SELF, Augusta, GA; [4]Augusta University Medical Center, Augusta, GA.*

Introduction: Prune belly syndrome (PBS) is most characterized by the lack of abdominal wall musculature, genitourinary defects, and cryptorchidism. 97% of patients with PBS are male and is frequently associated with End Stage Renal Disease (ESRD). The graft survival rate is similar compared to the general population. We present an exceptionally rare case of a PBS who had undergone a third transplant in our institution.

Case Description: 33-year-old African-American male with PBS was evaluated for renal transplant evaluation after two previous failed transplants. He received his first transplant at the age of 10 and it failed due to chronic allograft dysfunction. His right native kidney was removed at the time of the first transplant and the transplant kidney placed in the right lower quadrant. During the second transplant, the kidney in the right lower quadrant was removed and a transplant kidney placed in the left lower quadrant. It failed due to non-compliance with the immunosuppressive therapy. Due to the patient's history of prior transplant's and need for intra-abdominal allograft implantation, cavoplasty was not performed. We performed an end-to-end anastomosis of the donor renal vein to the inferior vena cava and the transplant renal artery to the right common iliac artery. The ureter was implanted into the bladder utilizing double-J ureteral stents. The bladder was tacked to the anterior abdominal wall. There were no adverse post-operative events and he was discharged home in a stable condition the follow up labs revealed normal indices.

Discussion: Third renal transplants are technically challenging from a surgical standpoint. However, the survival is improved when compared to continued dialysis. The transplant provided to the above-described patient will improve both quality of life and survival, justifying the increased surgical risk taken in performing the procedure. In conclusion, we believe that renal transplantation is a viable option for PBS patients with prior donor-organ failure.

PUB677

Persistently Elevated Beta Human Chorionic Gonadotropin in a Non-Pregnant Premenopausal Patient with ESRD

Kelly Walters,[1] Jose L. Zabala-Genovez,[2] Sindhu L. Joseph.[3] *[1]Chicago Medical School, Chicago, IL; [2]Loyola Medicine MacNeal Hospital, Hoffman Estates, IL; [3]MacNeal Hospital, Riverside, IL.*

Introduction: b-hCG has clinical uses in detection of pregnancy, abnormalities in pregnancy, and monitoring trophoblastic diseases and malignancies. Elevated post-menopausal physiologic hCG levels and decreased renal clearance are thought to play a prognostic role in chronic kidney disease, however elevated hCG levels have also been reported in premenopausal women with established ESRD. This age group is especially important due to possibility of pregnancy. Here report a case of persistently elevated b-hCG over several menstrual cycles in a premenopausal woman with ESRD.

Case Description: A 27 year-old woman with ESRD on hemodialysis was hospitalized several times for recurrent abdominal pain in a 50 day period and found to have intermediate range (5 – 15 IU/mL) hCG levels at each of her visits. The patient has a complex medical history including congenital absence of one kidney, past renal transplant, heart failure with reduced ejection fraction and hypertension. The cause of her abdominal pain was never diagnosed but believed to be secondary to either gastritis or hepatic congestion from her congestive heart failure. Her hCG levels showed no obvious associations with timing of hemodialysis sessions or menstrual cycle, or creatinine levels.

Discussion: Very few cases of elevated b-hCG in a non-pregnant premenopausal female with ESRD. Our case had several unique and new findings, including consistently lower hCG levels not meeting the positive threshold but in the intermediate range. Our case also covers the longest timespan of elevated hCG measurements for ESRD patients and only report throughout several menstrual cycles, suggesting that hCG is chronically elevated. The patients multiple organ disease have unclear significance at this time but may contribute information about characteristics of patients with elevated hCG. Her age and lack of hCG correlation with creatinine levels suggests another mechanism for elevated hCG apart from increased postmenopausal levels and decreased renal clearance. This case provides further evidence that special consideration should be given to patients with elevated b-hCG levels who have chronic kidney disease, including women of reproductive age.

PUB678

Unilateral Renal Fibromuscular Dysplasia Presenting as Macroscopic Hematuria in an Normotensive Elderly Female

Jason Cummings,[1] Marc Richards.[2,1] *[1]Florida Atlantic University Charles E. Schmidt College of Medicine, Delray Beach, FL; [2]South Florida Kidney Disease and Hypertension, Boca Raton, FL.*

Introduction: Fibromuscular dysplasia (FMD) is a nonatherosclerotic, noninflammatory, hyperplastic disorder that affects medium and small arteries. It occurs predominantly in young females and usually involves the renal and carotid arteries. Classically, renal FMD presents as early onset or difficult to control hypertension.

Case Description: Our patient is a 77-year-old Caucasian female with normal renal function and no history of hypertension who presents to an outpatient nephrology clinic with a several month history of painless gross hematuria. Prior urologic evaluation inclusive of computed tomography (CT) of the abdomen/pelvis showed no masses, no hydronephrosis, a right (R) kidney measuring measuring 6.5cm, a left (L) kidney measuring 9.7cm, multiple renal cysts and apparently patent renal arteries and veins. Cystoscopy suggested bleeding from the R ureteral orifice. Subsequent ureteroscopy revealed inflammatory changes of several R renal calyces and a clot in the R ureteral orifice. Biopsies were obtained and negative for neoplasia. In our clinic, her blood pressure was normal and physical exam benign. Urinalysis noted gross hematuria with many monomorphic red blood cells observed on urine microscopy. Renal ultrasound substantiated the CT findings of a R smaller than L kidney without findings to support renal artery stenosis. Ultimately, a magnetic resonance angiogram of the renal arteries showed hemodynamically significant stenosis in the R renal artery. Bilateral renal angiogram followed which elucidated an irregularity involving a R renal artery branch consistent with FMD that was successfully balloon angioplastied resulting in resolution of her hematuria both grossly and microscopically which has continued for several months following the procedure.

Discussion: Despite renal FMD typically presenting with hypertension in the young, our elderly patient presented with normal blood pressure and unilateral hematuria. Hematuria is a common medical problem and several renal vascular pathologies have been associated with hematuria, including renal FMD, which causes microscopic hematuria in about 50% of cases. Conventional contrast angiography remains the gold standard in confirming this rare diagnosis. Percutaneous renal artery revascularization is currently considered the optimal treatment option with good outcomes in the majority of cases, including our own.

PUB679

Dysnatremia from Vasopressinase in Pregnancy: A Case Series

Yuvaram N. Reddy,[1,2] Naoka Murakami,[1,2] David B. Mount.[1] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Massachusetts General Hospital, Boston, MA.*

Introduction: Sodium homeostasis in pregnancy dramatically differs from that a non-pregnant state. Vasopressinase is a hormone secreted by trophoblasts. Here, we report cases of hyper/hyponatremia in gestation and discuss the pathophysiologic role of vasopressinase.

Case Description: Case 1 (hypernatremia): 28-year-old woman (G3P2, 37 week) with no known past medical hstory presented with one week of abdominal pain, vomiting, excessive thirst and polyuria for 2 weeks. BP 148/100mmHg. Laboratory data was significant for: AST 739U/L, ALT 387U/L, bilirubin 3.0mg/dL, Cr 1.77mg/dl, Na 148mmol/L, K 4.5mmol/L, plasma Osm 307mOsim/kgH20, albumin 2.4g/dL, urine protein 1.6g/gCr. She underwent emergent C-section. Perioperative course was notable for persistent polyuria with urine output of 200-600cc/hr with urine osmolarity (UOsm) 113mOsm/kgH_2O. Diagnosed with gestational diabetes insipidus (DI), she was started on ddAVP 10 mcg intranasally and her Na stabilized ~139mmol/l with UOsm 300mEq/L. **Case 2 (hyponatremia):** 40-year-old woman (G1P0, 27 week) with no past medical history presented with abdominal pain, vaginal bleeding, hypertension and leg edema. She developed hypertension around 22-weeks and mild abnormality in liver function tests since 24-weeks. Vital signs were notable for HR 75, BP 158/102. Laboratory data significant for Na 118mmol/L, K 4.3mmol/L, Cr 0.51mg/dL, urine protein 0.39g/gCr, Psom 240mOsm/kgH2O, UOsm 500mOsm/kgH2O, UNa82 mmol/L. Urine output remained 20-50cc/hr. Diagnosed with SIADH and initiated 3% NaCl infusion perioperatively. She underwent C-section due to fetal distress. Postoperatively her Na remained low ~120 mmol/L. Eventually Na corrected to ~139 mmol/L with fluid restriction.

Discussion: These cases highlight the role of vasopressinase in pregnancy. Gestational DI is rare (2-4 in 100,000 pregnancies), and is felt to be due to impaired degradation of vasopressinase. It is degraded in the liver and is associated with HELLP syndrome. Vasopressinase cleaves AVP but not the synthetic version, ddAVP. Increased vasopressinase levels lasts up to 6-weeks post-partum. In contrast, there have been only several case series of gestational SIADH. This is thought to be related to preeclampsia-associated SIADH with defective placenta producing insufficient vasopressinase. This results in higher ADH levels, causing hyponatremia.

PUB680

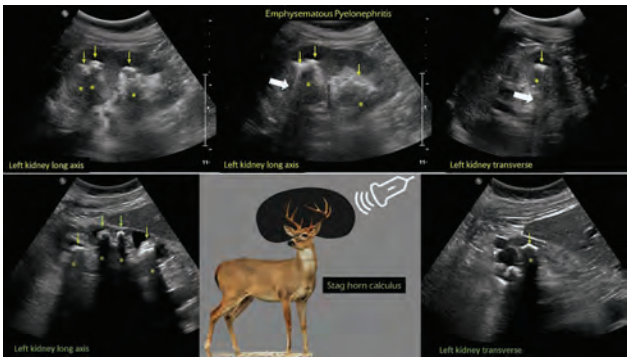
Emphysematous Pyelonephritis: An Ultrasound Look-Alike of Staghorn Calculus

Joan J. Morales Lappot, Harini Bejjanki, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Introduction: Emphysematous pyelonephritis (EPN) is a gas producing, necrotizing infection involving the renal parenchyma and surrounding tissue that is associated with high mortality and morbidity. On a sonogram, it appears as multiple hyperechoic foci with posterior acoustic shadowing mimicking a staghorn calculus. With growing interest in point of care ultrasonography (POCUS) among nephrologists, it is important to be aware of and consider this condition in the differential diagnosis of nephrolithiasis, especially in diabetic patients.

Case Description: A 22-year-old woman with a history of uncontrolled type I diabetes mellitus and hypertension presented with fever and left flank pain for three days. She denied any history of nephrolithiasis. Laboratory data was significant for a serum creatinine of 3.1 mg/dL (last available was 1.3 three years before) and hemoglobin A1c of 12. Urine microscopy showed >50 WBC/hpf, 10 RBC/hpf, and numerous bacteria suggestive of infection. A bedside renal sonogram demonstrated hyperechoic ill-defined material with shadowing throughout the left collecting system suggestive EPN [Figure, top panel]. CT scan without contrast confirmed the diagnosis and excluded extension to extrarenal space. The patient was treated with intravenous antibiotic therapy and showed clinical improvement. A repeat sonogram four days after presentation demonstrated resolution of the emphysematous changes.

Discussion: On a sonogram, both gas and calcified structures appear hyperechoic, the major difference being the echogenic foci caused by gas exhibit posterior "dirty shadowing" as opposed to distinctive echo-free "clean shadow" [Figure, asterisks indicate shadowing] distal to a calculus. Moreover, foci of gas tend to be ill-defined. Ring-down artifacts, when seen, suggest gas in the collecting system. They appear as vertical hyperechoic lines analogous to B-lines on lung POCUS [white arrows]. In patients where POCUS suggests EPN, a non-contrast CT scan should be obtained to confirm the diagnosis and to provide details regarding the extent of infection.



PUB681

Pregnancy-Associated Atypical Hemolytic-Uremic Syndrome

Daniel Guevara,[1] Robin H. Lo.[2] *[1]Nephrology, University of Connecticut, Farmington, CT; [2]University of Connecticut, Trumbull, CT.*

Introduction: Pregnancy-associated atypical hemolytic-uremic syndrome (p-aHUS) is characterized by microangiopathic hemolytic anemia, thrombocytopenia, and acute kidney injury. Triggered by pregnancy, uninhibited activation of the alternative pathway of the complement cascade induces endothelial host cell damage and results in a thrombotic microangiopathy.

Case Description: A 20 year old African American female with history of sickle cell disease was admitted for severe preeclampsia and was treated in the postpartum period at our facility for severe thrombocytopenia and acute kidney injury. The patient was treated for suspected pregnancy induced HUS with plasmapheresis and IV steroids with improvement of renal function and normalization of platelets levels.

Discussion: Pregnancy-associated atypical hemolytic-uremic syndrome (p-aHUS) is a rare condition. The pathogenesis and presentation of P-aHUS remain ill-defined. Diagnosis of p-aHUS is challenging, as it can mimic various diseases found during pregnancy and the postpartum period. Correct diagnosis and timely management are crucial to improve outcomes. Comprehensive genetic and molecular study of the alternative complement pathway are recommended to confirm the diagnosis and to identify patient at risk for aHUS in subsequent pregnancies.

PUB682

Improvement in Cervical Radiculopathy by Erenumab During the Preventive Treatment of Migraine in a Patient with CKD

Alexander M. Swan, Jr.,[1] Htun M. Aung,[1] Htet Htet Kyaw,[1] Tracy T. Swan,[1] May T. Tun,[1] Aye M. Thida,[1] Alexander M. Swan.[2,1] *[1]Department of Medicine, Nephrology Hypertension Renal Transplant & Renal Therapy, LLC., Avenel, NJ; [2]Department of Medicine, Rutgers New Jersey Medical School, Newark, NJ.*

Introduction: Pain control of chronic kidney disease (CKD) patient can be challenging especially in those with multiple comorbidities. We present the incidental finding of improvement in cervical radiculopathy in a CKD patient receiving erenumab for the preventive treatment of migraine.

Case Description: A 75-year-old lady with HTN, DM2, CKD, CHF, peripheral vascular disease, osteoarthritis, osteoporosis and migraine presented with a sharp, intermittent, shooting neck pain, which was 7/10 in intensity, radiating to both arms, aggravated by movement of the neck, without a motor deficit. She was taking pantoprazole, sacubitril/valsartan, metoprolol, clonidine, aspirin, linagliptin, pravastatin, alirocumab, denosumab, gabapentin, pentoxifylline, calcitriol, erythropoietin, sevelamer and pain medications including narcotics. Physical exam revealed severe paresthesia from neck to arms, significant neck spasms, loss of cervical lordosis and reduced deep tendon reflexes. MRI of the cervical spine revealed mild nerve root impingement. Appropriate pain medications with gabapentin, non-narcotic and narcotic medications were used without success. The pain progressively worsened within 3 weeks, the intensity being 9/10. Surgery was considered high-risk due to multiple comorbidities. Meanwhile, erenumab was initiated for the preventive treatment of migraine. Neuropathic neck pain intensity concomitantly decreased from 10/10 to 3/10 within a week of erenumab treatment without administering any pain medications, resulting in improvement in her quality of life.

Discussion: Erenumab, a human immunoglobulin G2 (IgG2) monoclonal antibody and a calcitonin gene-related peptide (CGRP) receptor antagonist, has been indicated for the preventive treatment of migraine in adults. CGRP mediates the trigeminovascular pain transmission from intracranial blood vessels to the central nervous system, as well as the vasodilatory component of neurogenic inflammation. Improvement in her cervical radiculopathy during preventive treatment of migraine may be due to inhibition of CGRP, a major mediator of neurogenic inflammation and vasodilation. This incidental finding may suggest additional use of CGRP-inhibitor for the treatment of radiculopathy. Therefore, further researches are necessary to prove this hypothesis.

PUB683

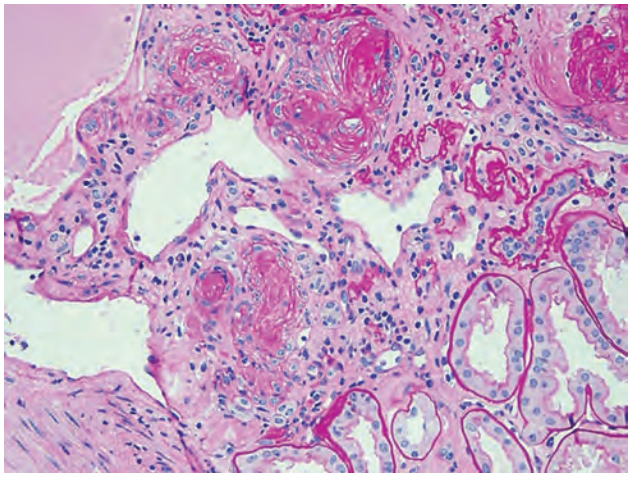
Severe Arteriosclerosis in a Young Patient

Houssam Mhanna. *Nephrology, University of Michigan, Ann Arbor, MI.*

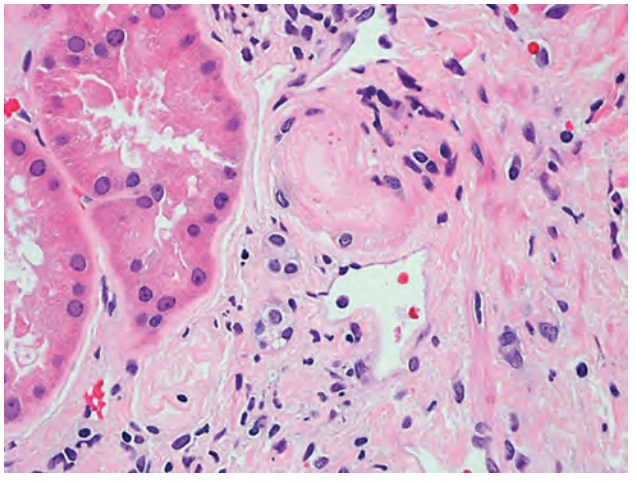
Introduction: Progressive renal failure and HTN in a young patient warrants thorough investigation in an attempt to identify treatable causes.

Case Description: 32 y/o F with HTN and primary hyperPTH s/p partial parathyroidectomy. Had episodes of "Panick attacks" with evidence of episodic and then persistent HTN. PE was normal. Her serum Cr in January 2015 was 1.05 mg/dL, gradually increased over 2 years to 2 mg/dL. UPCR 0.38. No hemauria. urine sediment was unremarkable. CBC normal, Imunological serologies and Secondary HTN w/u were unrevealing Renal biopsy: severe arteriolosclerosis with glomerular obsolescence (19/42) and commensurate tubular atrophy and interstitial fibrosis; no evidence of glomerulonephritis. The larger arterioles had moderate fibrous intimal thickening which narrows the vascular lumen, and many small arterioles have completely obliterated vascular lumens. No arteritis or thrombosis is identified. Schistocytes in the walls of small arteriols were seen, indicating arteriolar TMA.

Discussion: This is a case of progressive renal failure and HTN in a young previously healthy patient. The findings in the arterioles in a woman of this age were striking according to expert renal pathologists and likely are the cause of the glomerular obsolescence and tubular atrophy and interstitial fibrosis. However, the etiology of her vascular disease is less clear. HTN is a possible cause of the renal failure, On the other hand, pt may have a primary renal disease that is not completely understood caused HTN. Arteiolar TMA was a pathological diagnosis.



Completely obliteralted arterioles



Schistocytes in small arterioles

Pooled Efficacy and Cardiovascular (CV) Analyses of Roxadustat in the Treatment of Anemia in CKD Patients on and Not on Dialysis

Robert Provenzano,[1] Steven Fishbane,[2] Lee-Jen Wei,[3] Lynda Szczech,[4] Robert Leong,[4] Khalil G. Saikali,[4] Ming Zhong,[4] Tyson T. Lee,[4] Mark T. Houser,[5] Lars Frison,[5] John Houghton,[5] Thomas B. Neff,[4] Kin-Hung P. Yu.[4] Dr. Provenzano and Dr. Fishbane contributed equally. *[1]Wayne State, Detroit, MI; [2]Northwell Health, Commack, NY; [3]Harvard University, Boston, MA; [4]FibroGen, Inc., San Francisco, CA; [5]AstraZeneca, Mölndal, Sweden.*

Background: Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that regulates erythropoiesis & iron metabolism. Integrated Phase 3 analyses examine efficacy & safety of roxadustat in CKD patients (pts).

Methods: Phase 3 studies comparing roxadustat to placebo (pbo), in pts with Stage 3-5 non-dialysis-dependent CKD (NDD) & epoetin alfa in dialysis-dependent (DD) patients were pooled. Death, MI, & stroke (MACE), & heart failure or unstable angina requiring hospitalization (MACE+) were adjudicated. Efficacy analyses assessed Hb & rescue therapy (transfusion, IV iron & ESA). CV endpoints included MACE & MACE+.

Results: In NDD, 4270 pts were randomized (2386 roxadustat;1884 pbo). The primary endpoint (mean Hb CFB; Wks 28-52) was +1.85(.94)g/dL in the roxadustat group v. +.13(±1.01)g/dL in pbo (p<.0001) with lower risk of rescue therapy HR(95% CI)=.19 (.16,.23;81% reduction, p<.0001) in roxadustat. Using ITT long-term follow-up, the HR for time to MACE was 1.08(95%CI .94,1.24) for roxadustat vs. pbo, & 1.04(95% CI .91,1.18) for MACE+. In the subgroup with eGFR>10 (n=3431), MACE HR(95% CI)=.99(.84,1.16) & MACE+ HR=.98 (.85,1.14), for roxadustat v. pbo. In DD, 3917 patients were randomized (1960 roxadustat;1957 epoetin alfa). The primary endpoint (mean Hb CFB Wk 28-52) was 1.21 in roxadustat v. .95 g/dL in EPO (difference .26 g/dL;95%CI .20,.33) in pooled analysis; roxadustat was noninferior & superior to EPO (p<.0001). The roxadustat group received fewer transfusions, 9.5 v.12.8%; HR(95%CI) =.82(.679,.997). Comparing roxadustat with EPO, HR for MACE = .95 (95% CI .81,1.12) & for MACE+ HR=.84 (.73,.97;p=.02) in DD pts. Of 1526 incident pts (dialysis <4 months), HRs for MACE & MACE+ =.70 (95% CI .51,.97) (p=.03) & .66 (95%CI .50,.89)(p=.005).

Conclusions: These integrated Phase 3 analyses provide evidence for roxadustat superiority in anemia correction with transfusion reduction & acceptable CV safety profile.

Effect of Angiotensin-Neprilysin Inhibition on Renal Outcomes in Heart Failure with Preserved Ejection Fraction

Finnian R. McCausland,[1,2] Brian Claggett,[2,3] Nagesh Anavekar,[9] Mauro Gori,[10] Pardeep Jhund,[4] Martin P. Lefkowitz,[7] Martina M. McGrath,[8] John McMurray,[4] Marc A. Pfeffer,[5] Victor Shi,[7] Dirk J. Van veldhuisen,[11] Faiez Zannad,[6] Scott D. Solomon.[5] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Cardiology Division, Brigham and Women's Hospital, Boston, MA; [4]University of Glasgow, Glasgow, United Kingdom; [5]Brigham and Women's Hospital, Boston, MA; [6]Inserm, CHU & Université de Lorraine, Vandoeuvre les Nancy, France; [7]Novartis, East Hanover, NJ; [8]Harvard University, Chestnut Hill, MA; [9]University of Melbourne, Melbourne, VIC, Australia; [10]ASST Papa Giovanni XXIII Bergamo, Bergamo, Italy; [11]UMC Groningen, Groningen, Netherlands.*

Background: Chronic Kidney Disease (CKD) confers an increased risk of cardiovascular (CV) and renal events in patients with heart failure and preserved left ventricular ejection fraction (HFpEF). We assessed the long-term renal effects of angiotensin/neprilysin inhibition, a prespecified secondary outcome, in patients with HFpEF enrolled in the PARAGON-HF trial.

Methods: In this randomized, double-blind, parallel group, active controlled, event-driven trial, we assigned 4,822 patients with chronic HFpEF to receive sacubitril/valsartan or valsartan. Key exclusion criteria included a baseline eGFR <30mL/min/1.73m2. The prespecified renal outcome, a key secondary endpoint, was the time to first occurrence of either a ≥50% reduction in eGFR relative to baseline, attainment of end-stage renal disease, or renal death. We also evaluated the effect of treatment on the change in eGFR during follow up, and the influence of eGFR on the efficacy of sacubitril/valsartan for reducing the primary composite outcome.

Results: The mean age was 73±8 years; 52% were female. At baseline, mean (+/- SD) eGFR was 63±19 mL/min/1.73m2; 2,341 participants (49%) had CKD (eGFR <60 mL/min/1.73m2) and 43% had diabetes. At study closure, the composite renal outcome had occurred in significantly fewer patients in the sacubitril/valsartan group compared with the valsartan group (HR 0.50, 95% CI 0.33, 0.77, p = 0.002), and the mean decline in eGFR during follow up was less for the sacubitril/valsartan group (full results will be available for the ASN annual meeting). Patients with lower eGFR derived greater benefit from sacubitril/valsartan for reducing the primary composite outcome of total heart failure hospitalization or CV death.

Conclusions: In patients with chronic HFpEF, sacubitril/valsartan reduced the risk of clinically important renal events, and slowed the progression of kidney disease, compared with valsartan. (Funded by Novartis; PARAGON-HF ClinicalTrials.gov number, NCT01920711.)

The Dapagliflozin in Heart Failure with Reduced Ejection Fraction Trial (DAPA-HF): Outcomes in Patients with CKD and Effects on Renal Function

Scott D. Solomon,[1] Pardeep Jhund,[3] Mikhail Kosiborod,[2] Subodh Verma,[4] Silvio E. Inzucchi,[5] Anna Maria Langkilde,[6] Felipe Martinez,[7] Olof Bengtsson,[8] Kieran F. Docherty,[3] Lars Køber,[9] Mikaela Sjostrand,[8] Marc S. Sabatine,[10] John McMurray.[11] DAPA-HF Executive Committee *[1]Brigham and Women's Hospital, Boston, MA; [2]Saint Luke's Mid America Heart Institute, Kansas City, MO; [3]BHF Glasgow Cardiovascular Research Centre, Glasgow, United Kingdom; [4]St. Michael's Hospital, Toronto, ON, Canada; [5]Yale University School of Medicine, New Haven, CT; [6]AstraZeneca, Gothenburg, Sweden; [7]DAMIC Institute, Cordoba, Argentina; [8]Astrazeneca, Molndal, Sweden; [9]Rigshospitalet, Copenhagen, Denmark; [10]TIMI Study Group, Boston, MA; [11]University of Glasgow, Glasgow, United Kingdom.*

Background: A substantial proportion of patients with heart failure and reduced ejection fraction (HFrEF) have or develop chronic kidney disease (CKD). SGLT-2 inhibitors have been shown to delay the progression of kidney disease and reduce the incidence of cardiac events in patients with type 2 diabetes (T2D) and CKD. Dapagliflozin (DAPA) was shown in the DAPA-HF Trial to reduce the primary composite outcome of a worsening heart failure event or cardiovascular death in patients with HFrEF, both with and without T2D

Methods: We randomized 4744 patients with NYHA class II-IV heart failure, LVEF ≦40%, elevation in natriuretic peptides and optimal background HFrEF therapy to DAPA 10mg qd or placebo (PBO). The primary outcome is described above. The prespecified secondary renal outcome was a sustained ≥50% reduction in eGFR, end-stage renal disease or death from renal causes. We also prespecified an analysis of the effect of DAPA, compared to PBO, in patients with and without CKD (eGFR <60 ml/min/1.73m^2 at baseline).

Results: Overall, 45% of patients had T2D and 55% did not. The baseline eGFR was 65.8 ± 19.4 ml/min/1.73m^2 and 1926 (40.6%) patients had CKD. A worsening heart failure event or cardiovascular death (the primary end point) occurred in 386 patients (16.3%) in the DAPA group and 502 patients (21.2%) in the PBO group: hazard ratio [HR] 0.74; 95% confidence interval [CI], 0.65-0.85; P<0.001. DAPA reduced the primary outcome by a similar magnitude in patients with CKD (HR 0.72, 95%CI 0.59-0.86) and without CKD (HR 0.76, 95%CI 0.63, 0.92) - results to be shown at ASN. The composite renal endpoint was observed in 28 (1.2%) patients in the DAPA group vs 39 (1.6%) in the PBO arm (HR 0.71, 95% CI 0.44, 1.16). Renal serious adverse events and investigator reported acute kidney injury were significantly less common in the DAPA group. Additional results, including eGFR over-time, will be shown at the ASN annual meeting.

Conclusions: In this trial including HFrEF patients with and without T2D, DAPA reduced the composite of a worsening heart failure event or cardiovascular death, both in participants with CKD and in those without CKD. The absolute benefit in patients with CKD was substantial.

FR-OR134

Efficacy and Safety of Difelikefalin in Patients Undergoing Hemodialysis with Pruritus: Results from a Phase 3 Randomized, Controlled Study (KALM-1)

Steven Fishbane,[1] Aamir Z. Jamal,[2] Warren Wen,[3] Catherine Munera,[3] Frederique Menzaghi.[3] *[1]Northwell Health, Commack, NY; [2]North America Research Institute, San Dimas, CA; [3]Cara Therapeutics, Inc., Stamford, CT.*

Background: There is an unmet need for effective treatments for pruritus associated with chronic kidney disease (CKD-aP or uremic pruritus), a debilitating condition prevalent in patients undergoing hemodialysis (HD). Difelikefalin (DFK; CR845) is a novel, peripherally restricted kappa opioid receptor (KOR)-specific agonist in development for treatment of pruritus. Here we report on the first Phase 3 study of DFK in HD patients with CKD-aP.

Methods: Patients with moderate-to-severe CKD-aP undergoing HD (N=377) were randomized 1:1 to receive an IV bolus of DFK 0.5 mcg/kg (N=189) or placebo (PBO) (N=188), thrice weekly post dialysis, over 12 weeks. The primary endpoint was the proportion of patients achieving ≥3-point improvement from baseline (BL) to Week 12 in the weekly mean of 24-hr daily Worst Itching Intensity Numerical Rating Scale (WI-NRS) scores. Secondary endpoints included the change in itch-related QoL measured by 5-D Itch and Skindex-10 questionnaires and the proportion of patients achieving ≥4-point WI-NRS score improvement from BL to Week 12. Safety was assessed based on vital signs, clinical laboratory results, ECG, and adverse event (AE) reporting.

Results: The primary and all secondary efficacy endpoints were met. BL mean WI-NRS scores were 7.1 and 7.3 in DFK and PBO groups. Percentages of patients with ≥3-point improvement and ≥4-point improvement in mean WI-NRS scores at Week 12 were 51% vs 28% (p<0.001; odds ratio (OR) 2.7) and 39% vs 18% (p<0.001, OR 2.9) for DFK vs PBO. Separation from PBO in WI-NRS score change from baseline was observed at Week 1. All QoL measures were significantly improved vs PBO (p<0.001). Serious AE incidence was similar for DFK vs PBO; most common treatment emergent AEs were diarrhea (9.5% vs 3.7%), dizziness (6.9% vs 1.1), and vomiting (5.3% vs 3.2%).

Conclusions: This study demonstrated that DFK significantly reduced itch intensity in HD patients. Patients treated with DFK were about 3 times (based on OR) more likely to have a clinically meaningful reduction in itch intensity vs PBO and had significant improvements in QoL. DFK was generally well tolerated with an acceptable safety profile. DFK could represent an important advance for treatment of pruritus in HD patients.

Mycophenolate Mofetil vs. Azathioprine in Kidney Transplant Recipients on Steroid-Free, Low-Dose Cyclosporine Immunosuppression: The ATHENA Trial

Paolo Cravedi,[1] Piero L. Ruggenenti,[3] Francesco Peraro,[4] Annalisa Perna,[5] Giuseppe Remuzzi.[2] For the ATHENA Study Group, Italy *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Bergamo, Italy; [3]Azienda Socio-Sanitaria Territoriale Papa Giovanni XXIII, Bergamo, Italy; [4]Istituto Mario Negri, Albino, Italy; [5]Mario Negri Institute, Milano, Italy.*

Background: Registration trials with old sandimmune formulation of cyclosporine (CsA) suggested that Mycophenolate Mofetil (MMF) prevents acute cellular rejection (ACR) more effectively than Azathioprine (AZA), but multiple trials with standard-dose of more stable microemulsion formulation of CsA (Neoral) did not confirm this. The safety/efficacy of MMF and AZA in kidney transplant recipients on steroid-free, low-dose CsA Neoral is unknown.

Methods: The ATHENA trial (NCT00494741) was a randomized, prospective, multicenter trial comparing THe Effect on chronic allograft Nephropathy prevention of mycophenolate mofetil versus Azathioprine as the sole immunosuppressant for kidney transplant recipients. All patients were induced with low-dose Thymo + basiliximab. Those with stable graft function, no previous ACRs and no infiltrates at 1-yr surveillance biopsy underwent CsA tapering to half of the initial dose. Primary endpoint was cumulative incidence of chronic allograft nephropathy (CAN) at 3 yrs.

Results: We included 233 patients (119 on MMF; 114 on AZA). At 3 yrs, 38 patients on MMF (31.9%) vs 37 on AZA (32.4%) developed CAN (**Figure**); 22 on MMF (18.5%) vs 24 on AZA (21.1%) had biopsy-proven ACR (p=0.72); 11 on MMF (9.2%) and 8 on AZA (7.0%) had sub-clinical (sCreat increase <10% during previous 3 mo) ACR at 1-yr surveillance biopsy (p=0.47); 6 on MMF (5.0%) vs 7 on AZA (6.1%) had graft failure (p=0.54). 3-yr eGFR was similar between MMF and AZA groups (53.8±20.2 vs 51.4±18.8 ml/min/1.73m^2, p=0.50). 19 patients on MMF (16.0%) vs 21 on AZA (18.4%) successfully tapered CsA doses, with only one ACR episode per arm. Post-tapering eGFR was stable.

Conclusions: In kidney transplant recipients on low-dose CsA and no steroids, AZA and MMF are associated with similar incidence of CAN, of clinical or subclinical ACR, and similar graft survival and function. AZA represents a valuable, less expansive, alternative to MMF also on low-dose maintenance immunosuppression.

A Phase 2 Randomized, Controlled Study of Obinutuzumab with Mycophenolate and Corticosteroids in Proliferative Lupus Nephritis

Brad H. Rovin,[1] Gustavo Aroca Martinez,[2] Analia Alvarez,[3] Hilda E. Fragoso loyo,[4] Adolfina E. Zuta,[5] Richard Furie,[6] Paul G. Brunetta,[9] Thomas Schindler,[7] Imran Hassan,[8] Matthew Cascino,[9] Jay P. Garg,[9] Ana Malvar.[10] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Universidad Simon Bolivar / Clinica de la Costa, Barranquilla, Colombia; [3]CEMIC, Buenos Aries, Argentina; [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [5]Instituto de Ginecologia y Reproduccion, Lima, Peru; [6]Northwell Health, Great Neck, NY; [7]F. Hoffmann-La Roche AG, Basel, Switzerland; [8]Hoffmann-La Roche Limited, Mississauga, ON, Canada; [9]Genentech, Inc., South San Francisco, CA; [10]Organizacion Maedica de Investigacion, Buenos Aires, Argentina.*

Background: Type I anti-CD20 antibodies such as rituximab fail to achieve complete B-cell depletion in lupus nephritis (LN). NOBILITY tested whether enhanced B-cell depletion with the type II anti-CD20, obinutuzumab (OBI), could improve responses in LN compared to placebo (PBO). (NCT02550652)

Methods: Patients with active Class III/IV LN (n=125) received standard-of-care mycophenolate and steroids and were randomized to OBI or PBO and followed for 104 weeks. The primary endpoint (EP) was complete renal response (CRR) at week 52. Key secondary EPs included overall renal response (ORR) and modified CRR (mCRR). Results through week 76 are reported. The two-sided alpha level was 0.2.

Results: Baseline mean urine protein:creatinine ratio (UPCR) and serum creatinine were 3.1 g/g and 0.84 mg/dL. OBI was associated with increased renal responses vs. PBO at weeks 52 and 76 (**Table**). 80% of OBI pts and 0% of PBO pts had CD19+ count <0.441 cells/μL at week 52. Significant improvements in anti-dsDNA, C3, and C4 were observed with OBI vs. PBO. Through week 76, serious adverse events (OBI 24% vs. PBO 29%) and serious infections (6% vs. 18%) were not increased with OBI. Nonserious infusion-related reactions were more common with OBI (16% vs. 10%). There were 5 deaths (1 OBI, 4 PBO).

Conclusions: NOBILITY met its primary and secondary efficacy EPs. OBI was superior to PBO for the achievement of renal response at 12 and 18 months in proliferative LN patients treated with mycophenolate and steroids. There were no unexpected safety findings.

Preventing Early Renal Loss in Diabetes (PERL) Study: Outcome of a 3-Year Trial of Serum Uric Acid Reduction with Allopurinol

Alessandro Doria,[1,4] Andrzej Galecki,[3] Cathie Spino,[3] Michael Mauer.[2] PERL Consortium *[1]Joslin Diabetes Center, Boston, MA; [2]University of Minnesota, Minneapolis, MN; [3]University of Michigan, Ann Arbor, MI; [4]Harvard Medical School, Boston, MA.*

Background: Observational studies have shown that higher serum uric acid (SUA) is associated with a higher risk of diabetic kidney disease (DKD) in type 1 diabetes (T1D). PERL (NCT02017171) evaluated whether lowering SUA with allopurinol could slow glomerular filtration rate (GFR) decline in patients with T1D and mild to moderate DKD.

Methods: This double-blind, placebo-controlled, multicenter, international trial randomized 530 persons with T1D, estimated GFR (eGFR) 40-99.9 mL/min/1.73 m^2, SUA ≥4.5 mg/dL, and micro- to macroalbuminuria (79.1%) or normoalbuminuria with historical eGFR decline ≥3 mL/min/1.73 m^2/year (20.9%) to allopurinol (A, n=267) or placebo (P, n=263). The primary outcome was baseline-adjusted iohexol GFR (iGFR) after 3 years of treatment plus a 2-month drug washout period. Treatments were compared by means of a linear model with correlated errors using the intention-to-treat population.

Results: Participants were 66% male and 84% white. Baseline median age was 52 years, T1D duration was 35 years, and HbA1c was 8.0 %; 93% had hypertension and 90% were on RAS blockers. These factors were balanced between A and P. The mean (± SD) baseline iGFR was 68.7 ± 17 in A and 67.3 ± 17 mL/min/1.73 m^2 in P. Baseline SUA was 6.1 ± 1.5 mg/dL in both groups. During the trial, SUA averaged 4.1 ± 1.2 in A and 6.2 ± 1.3 mg/dL in P (p <0.0001). Baseline-adjusted iGFRs at the end of the drug washout period were virtually identical in A and P (least square mean ± SE = 61.2 ± 1.6 mL/min/1.73 m^2 in both, p=0.99). Rates of iGFR decline over the 3 years of treatment were -3.0 in A and -2.5 mL/min/1.73 m^2/year in P (p=0.25), at or close to the loss of -3.0 mL/min/1.73 m^2/year expected in untreated subjects. No statistically significant treatment differences were seen in the secondary outcomes of iGFR before drug washout, eGFR slope, or time to serum creatinine doubling or ESKD. Albuminuria levels at washout were higher in A than in P (baseline-adjusted geometric means: 42.9 vs. 31.7 μg/min, p=0.035).

Conclusions: PERL – the largest CKD trial of allopurinol to date – found no significant benefit of SUA reduction on kidney outcomes in T1D persons with mild to moderate GFR reduction and SUA levels above the median. Secondary analyses are in progress to assess whether results are similar across pre-specified clinical sub-groups.

Effects of Vitamin D and Omega-3 Fatty Acid Supplementation on Kidney Function and Damage in Type 2 Diabetes

Ian H. de Boer,[1] Leila R. Zelnick,[2] Andrew N. Hoofnagle,[3] Ravi I. Thadhani,[4] Joann E. Manson.[5] VITAL-DKD Research Group *[1]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]University of Washington, Seattle, WA; [4]Cedars-Sinai, Los Angeles, CA; [5]Brigham and Women's Hospital, Harvard, Boston, MA.*

Background: Vitamin D and omega-3 fatty acid supplements are readily available and safe interventions that may help prevent the development and progression of diabetic kidney disease. Preclinical and observational studies suggest that vitamin D suppresses the renin-angiotensin system, reduces renal inflammation and fibrosis, and exerts direct pro-survival effects on podocytes, while omega-3 fatty acids have potentially beneficial anti-inflammatory, antithrombotic, and vascular properties.

Methods: We performed a randomized clinical trial of 1,312 adults with type 2 diabetes to test whether supplementation with vitamin D_3 or omega-3 fatty acids for five years prevents the development or progression of CKD. The study was completed as an ancillary study to the VITamin D and OmegA-3 TriaL (VITAL). In a 2-by-2 factorial design, participants were randomly assigned to vitamin D_3 (2000 IU daily) or placebo and to omega-3 fatty acids (eicospentaenoic acid and docosahexaenoic acid, 1 g daily) or placebo. The primary outcome was change in glomerular filtration rate estimated from serum creatinine and cystatin C (eGFR) from baseline to year 5.

Results: Baseline mean age was 67.6 (SD 6.9) years, 46% of participants were women, and 31% were racial or ethnic minorities. Baseline mean (SD) eGFR was 85.8 (22.1) mL/min/1.73m^2, and mean change in eGFR from baseline to year 5 was -12.7 (SD 14.6) mL/min/1.73m^2. There was no significant difference in change in eGFR comparing vitamin D_3 to placebo (difference in change 0.8 (95% CI -0.8, 2.5) mL/min/1.73m^2) or omega-3 fatty acids to placebo (difference in change 0.8 (95% CI -0.8, 2.4) mL/min/1.73m^2). Null results were robust in analyses restricted to participants with complete data or to participants who were highly adherent to study medications. No significant difference was observed in secondary outcomes, including change in eGFR after 2 years of treatment, a composite outcome of loss of eGFR ≥40% from baseline or kidney failure (N=85 events), and change in urine albumin excretion.

Conclusions: Neither vitamin D nor omega-3 fatty acid supplementation reduced the development or progression of kidney disease among adults with type 2 diabetes.

Kidney Protection Using the RenalGuard® System in Cardiac Surgery (KIDNEY Study): A Randomised Control Trial Assessing AKI Rate

Heyman Luckraz,[1] Ramesh Giri,[2] Benjamin J. Wrigley,[2] Kumaresan Nagarajan,[2] Lawrence Beare,[2] Eshan Senanayake,[2] Emma L. Sharman,[2] Alan M. Nevill.[3] *[1]American Hospital Dubai, Dubai, United Arab Emirates; [2]The Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom; [3]University of Wolverhampton, Walsall, United Kingdom.*

Background: Acute kidney injury (AKI) after cardiac surgery occurs in up to 30% of patients & is associated with significant morbidity & mortality. RenalGuard® system (RG) has been shown to reduce AKI rates in patients undergoing Percutaneous Cardiac Intervention (PCI, TAVR). This study investigated the efficacy & safety of balanced forced diuresis using the RenalGuard® system in cardiac surgical patients requiring cardiopulmonary bypass (CPB)

Methods: Patients at risk of developing AKI during cardiac surgery (history of diabetes &/or anemia, e-GFR < 60 ml/min/1.73m^2, anticipated CPB time > 120 minutes, Log EuroScore >5) were randomized to either RG (n=110) or managed as per current management strategy (control=110). Primary end-point was the development of AKI, defined by RIFLE criteria, within first 3 days of surgery. (Trial registration:NCT02974946)

Results: There were no significant differences in patients' pre & intra-operative characteristics (age, gender, LVEF, surgery type, Log EuroScore, pre-op creatinine & e-GFR levels, CPB & cross-clamp times & pre-op history of diabetes, peripheral vascular disease & renal impairment) between the 2 groups. Post-operative AKI rates were significantly lower in RG group compared to control (10% (11/110) v/s 20.9% (23/110), p=0.025). Binary logistic regression analysis confirmed RG system to be independently associated with significant AKI reduction (OR 2.82, 95%CI 1.20 – 6.60, p=0.017). The mean volumes of urine produced during surgery (2337+/-896 ml v/s 766+/-557 ml) & within first 24 hours post-op (3297 +/- 1298 ml v/s 2053 +/- 802 ml) were significantly higher in RG group (p<0.01). There was no significant difference in the incidence of blood transfusions, atrial fibrillation, infections, cerebro-vascular events, median ICU and in-hospital stays between the two groups. One patient in the RG group & two patients in the control group died prior to hospital discharge. The number needed to treat (NNT) with the RG system to prevent AKI was 9 patients

Conclusions: In patients at-risk for AKI, undergoing cardiac surgery with the CPB, the RenalGuard® system significantly reduced the incidence of AKI and can be used safely & reproducibly. Larger studies will be required to assess the cost benefit of this device

TH-PO1184

Results of the START-CKD Trial (Strategies Using Darbepoetin Alfa to Avoid Transfusions in CKD)

Robert D. Toto,[1] Jeffrey Petersen,[4] Jeffrey S. Berns,[3] Eldrin F. Lewis,[6] Qui Tran,[5] Matthew R. Weir.[2] *[1]University of Texas Southwestern Medical Center, Dallas, TX; [2]University of Maryland School of Medicine, Baltimore, MD; [3]University of Pennsylvania School of Medicine, Philadelphia, PA; [4]Amgen, Thousand Oaks, CA; [5]Amgen Inc, Newbury Park, CA; [6]Brigham and Women's Hospital, Boston, MA.*

Background: Exposure to high doses of an erythropoiesis stimulating agent (ESA), high cumulative dose, wide Hb excursions, and rapid hemoglobin (Hb) rises may contribute to cardiovascular adverse events with ESA use. Thus, there is a desire to define an ESA dosing strategy that minimizes red blood cell transfusion and limits dose. The START-CKD trial evaluated such a dosing strategy using darbepoetin in anemic subjects with stage 3-5 CKD using a fixed dosing (FD) strategy of 0.45 µg/kg Q4 wks or a Hb-based titration dose (TD) algorithm (per US prescribing information (USPI).

Methods: This was a US phase 3, multicenter, randomized, double-blind, parallel group study (N=756; ClinicalTrials.gov, NCT01652872) with 377 subjects randomized to the TD and 379 to the FD treatment for up to 2 years. The primary endpoint was the percentage of subjects transfused. Transfusions, per protocol, were performed as deemed necessary by the treating physician and were prospectively adjudicated.

Results: Mean age of the subjects, baseline Hb and eGFR: 69 yrs., 9.0 g/dL and 22 ml/min/1.73m^2, respectively and were balanced between arms. The % of subjects transfused was 24.1% vs 24.4% in the FD and TD groups, respectively, with similar time to first transfusion (HR 1.01, Figure A). Average Hb achieved was greater in the TD group compared to the FD group, 9.7 vs 9.4 g/dL respectively (Figure B). Average cumulative dose of darbepoetin per 4 wks was less in the FD group, 30.8 µg vs 50.7 µg.g.

Conclusions: In this study, minimizing RBC transfusion can be achieved using a low fixed-dose of darbepoetin with lower cumulative dose than use of Hb-based dose titration approach.

Funding: Commercial Support - Amgen, Inc.

Phase 3 Study to Compare the Efficacy and Safety of Enarodustat (JTZ-951), an Oral HIF-PH Inhibitor, with Darbepoetin Alfa in Anemic Patients with CKD Not Requiring Dialysis

Tadao Akizawa,[1] Atsushi Matsui,[2] Yuya Miyazawa,[2] Ryosuke Koretomo.[2]
[1]Showa University School of Medicine, Tokyo, Japan; [2]Pharmaceutical Division, Japan Tobacco Inc., Tokyo, Japan.

Background: This phase 3 study was conducted to verify the efficacy (non-inferiority to darbepoetin alfa (DA)) and safety of enarodustat in Japanese anemic patients with CKD not requiring dialysis in randomized, open-label, parallel-arm comparison manner for 24 weeks.

Methods: Patients were respectively randomized in 1:1 ratio to receive either enarodustat orally once daily or DA subcutaneously every 2 or 4 weeks. The doses were adjusted every 4 weeks to maintain Hb levels within a target range (10-12 g/dL). The primary endpoint was difference in mean Hb level between arms during the evaluation period defined as Week 20-24 (non-inferiority margin: -0.75 g/dL). Other assessments included proportion of patients whose Hb level was within the target range, iron-related parameters, renal function-related parameters, and NT-pro BNP.

Results: 216 patients were randomized to receive either enarodustat (n=107) or DA (n=109). The mean Hb level of each arm during the evaluation period was 10.96 g/dL (95% CI: 10.84, 11.07) with enarodustat arm and 10.87 g/dL (95% CI: 10.75, 10.99) with DA arm. The difference between arms in the mean Hb level was 0.09 g/dL (95% CI: -0.07, 0.26), confirming the non-inferiority to DA. Proportions of patients whose Hb level was within the target range during the evaluation period were 89.6% in enarodustat arm and 90.6% in DA arm. Increase of TIBC and decrease of hepcidin were observed in enarodustat arm. No apparent difference between arms in the incidence of AEs including CV events and hypertension-related events were observed. There were no negative effects of enarodustat on NT-pro BNP or renal function-related parameters.

Conclusions: Enarodustat, administered orally, was as effective as DA, administered subcutaneously, in maintaining Hb levels in Japanese anemic patients with CKD not requiring dialysis. No new safety concerns were identified when compared with DA.

Funding: Commercial Support - Japan Tobacco Inc.

TH-PO1186

Phase 3 Study to Compare the Efficacy and Safety of Enarodustat (JTZ-951), an Oral HIF-PH Inhibitor, with Darbepoetin Alfa in Anemic Patients with CKD Receiving Maintenance Hemodialysis

Tadao Akizawa,[1] Kazuo Maeda,[2] Yuya Miyazawa,[2] Ryosuke Koretomo.[2]
[1]Showa University School of Medicine, Tokyo, Japan; [2]Pharmaceutical Division, Japan Tobacco Inc., Tokyo, Japan.

Background: This phase 3 study was conducted to verify the efficacy (non-inferiority to darbepoetin alfa (DA)) and safety of enarodustat in Japanese anemic patients with CKD receiving maintenance hemodialysis in randomized, double-blind, parallel-arm comparison manner for 24 weeks.

Methods: Patients, who have been receiving a stable dose of ESAs and have protocol specified Hb criteria (Hb level of 9.5≥ g/dL and <12.0 g/dL), were randomized in 1:1 ratio to receive either enarodustat orally once daily or DA intravenously every week after switching from ESAs. The doses were adjusted every 4 weeks to maintain Hb levels within a target range (10-12 g/dL). Intravenous iron preparations were prohibited during the screening period and the initial treatment period (Week 0-4). The primary endpoint was difference in mean Hb level between arms during the evaluation period defined as Week 20-24 (non-inferiority margin: -1.0 g/dL). Other assessments included proportion of patients whose Hb level was within the target range and iron-related parameters.

Results: 173 patients were randomized to receive either enarodustat (n=87) or DA (n=86). The mean Hb level of each arm during the evaluation period was 10.73 g/dL (95% CI: 10.56, 10.91) with enarodustat arm and 10.85 g/dL (95% CI: 10.72, 10.98) with DA arm. The difference between arms in the mean Hb level was -0.12 g/dL (95% CI: -0.33, 0.10), confirming the non-inferiority to DA. Proportions of patients whose Hb level was within the target range during the evaluation period were 78.2% (95% CI: 67.4, 86.8) in enarodustat arm and 88.8% (95% CI: 79.7, 94.7) in DA arm. Increase of TIBC and decrease of hepcidin were observed through Week 4 in enarodustat arm albeit after switching from ESAs. Proportions of patients who experienced any AEs or SAEs were 87.4% and 14.9% in enarodustat arm and 83.7% and 14.0% in DA arm, respectively.

Conclusions: Enarodustat was proved to be non-inferior to DA in the treatment of anemia in Japanese CKD patients receiving maintenance hemodialysis, and was generally well-tolerated.

Efficacy of Tenapanor in Combination with Phosphate Binders in CKD Patients on Dialysis with Uncontrolled Hyperphosphatemia While on Phosphate Binders Alone

Pablo E. Pergola,[1] Yang Yang,[2] David P. Rosenbaum,[3] Glenn M. Chertow.[4]
[1]Renal Associates, P.A., San Antonio, TX; [2]Ardelyx, Fremont, CA; [3]Ardelyx, Inc., Fremont, CA; [4]Stanford University School of Medicine, Palo Alto, CA.

Background: Tenapanor (TEN) is a first-in-class, non-binder, phosphate absorption inhibitor being developed to treat hyperphosphatemia in dialysis patients. It has a unique mechanism of action and acts locally in the gut to inhibit the sodium-hydrogen exchanger 3 (NHE3). This results in the tightening of the epithelial cell junctions, reducing paracellular uptake of phosphate, the primary pathway of phosphate absorption, and thereby reducing serum P concentrations.

Methods: 4-week, randomized, double-blind, placebo (PBO)-controlled study with a 2 to 4-week standard of care run-in period. Patients on maintenance dialysis, on stable phosphate binder (BIND) therapy who had a serum P≥5.5 and ≤10.0 mg/dL at screening and the end of the run-in period were randomized 1:1 to receive TEN+BIND or PBO+BIND. Patients' dose of BIND remained stable during both washout and treatment periods. The primary endpoint was the change from baseline in serum P at week 4 between the TEN+BIND and PBO+BIND arms. (NCT 03824587)

Results: 511 patients were screened, and 236 patients were randomized to treatment. Mean age was 54.5 years, 58.9% male, 49.6% white, 43.2% Black, BMI 32.1 kg/m^2. Mean (±SD) baseline P was 6.73±1.32 mg/dL and 6.93±1.37 mg/dL for TEN+BIND and PBO+BIND groups respectively. At week 4, the mean change in serum P was more pronounced in the TEN+BIND arm (-0.84 mg/dL v. -0.19 mg/dL in the PBO+BIND arm, p=0.0004). When added to BIND therapy, TEN resulted in statistically significant decreases in serum P during all four weeks of treatment ranging from 0.84 to 1.21 mg/dL. Twice as many patients achieved P<5.5 mg/dL with TEN+BIND than with PBO+BIND (up to 49.1% v. up to 23.5%, p<0.01). TEN+BIND resulted in a 24% relative reduction in serum intact FGF23 (p=0.0027) at week 4. For patients on TEN, the only adverse event with a placebo-adjusted rate over 3% was loose stools/diarrhea (36%); 4.3% of patients discontinued the study while on TEN+BIND v. 2.5% on PBO+BIND. There were no serious adverse events related to TEN.

Conclusions: In patients on dialysis who have uncontrolled phosphorus despite BIND treatment, adding TEN results in improvement in P levels and a significantly higher percentage of patients achieving phosphorus levels <5.5 mg/dL.

Funding: Commercial Support - Ardelyx, Inc.

TH-PO1188

Phase 2 Trial of Phytonadione in Calciphylaxis

Sagar U. Nigwekar. On behalf of VitK-CUA trial investigators *Massachusetts General Hospital, Boston, MA.*

Background: Calciphylaxis is a rare, life-threatening disorder characterized by calcific occlusion of cutaneous microvessels resulting in extremely painful skin lesions. There are no approved therapies for calciphylaxis and randomized controlled trials (RCTs) are lacking. Vitamin K deficiency is implicated in calciphylaxis via reducing gamma-carboxylation of matrix Gla protein (MGP)- a calcification inhibitor.

Methods: We performed a phase 2, double-blind, placebo-controlled trial of phytonadione (vitamin K1) in adult hemodialysis patients with calciphylaxis (NCT02278692) to examine pharmacodynamics (reduction in plasma uncarboxylated MGP levels), efficacy, and safety. Patients were randomly assigned to receive either oral phytonadione 10 mg or placebo thrice weekly for 12 weeks.

Results: Baseline characteristics and co-treatments were comparable between the two groups (N=26 patients [13 in each group]). The median change in uncarboxylated MGP level between baseline and 12-weeks was -1014 pmol/L (IQR: -1429 to -614 pmol/L) with phytonadione and 753 pmol/L (IQR: -315 to 1360 pmol/L) with placebo (p<0.001). Compared with placebo, treatment with phytonadione demonstrated greater improvements in the size of the largest skin lesion (p=0.02), the combined size of all lesions (p<0.001), and pain intensity (p<0.001). [Figure] The reduction in uncarboxylated MGP correlated with a reduction in the combined size of all lesions (r=0.56, p=0.01). At 12-weeks, mortality rates were 0% and 31% in phytonadione and placebo groups, respectively (p=0.03). One patient treated with phytonadione developed hepatic thrombosis.

Conclusions: In this phase 2 RCT of patients with calciphylaxis, oral phytonadione reduced uncarboxylated MGP and demonstrated clinical efficacy. A larger phase 3 study is now planned to establish the efficacy and safety of this agent in calciphylaxis.

Efficacy of phytonadione in calciphylaxis

TH-PO1189

Effect of Etelcalcetide in Patients on Hemodialysis with Secondary Hyperparathyroidism: The DUET Trial

Yuya Itano,[5] Sawako Kato,[5] Hirotake Kasuga,[4] Masato Tsuboi,[3] Makoto Kuro-o,[2] Yachiyo Kuwatsuka,[1] Masahiko Ando,[1] Shoichi Maruyama.[5] *[1]Nagoya University, Nagoya, Japan; [2]Jichi Medical University, Shimotsuke, Japan; [3]Anjo Kyoritsu Clinic, Anjo, Japan; [4]Nagoya Kyoritsu Hospital, Nagoya, Japan; [5]Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Etelcalcetide is a second-generation calcimimetic agent approved for treatment of Secondary Hyperparathyroidism (SHPT). The DUET trial (jRCTs041180108) was designed to clarify the efficacy of etelcalcetide, and to identify sensitive markers for vascular calcification.

Methods: The DUET study was a 12-week multicenter, open-label, randomized (1:1:1), parallel-group study in SHPT patients undergoing maintenance hemodialysis. Patients were randomly assigned to etelcalcetide + active vitamin D (Group E+D), etelcalcetide + oral calcium preparation (Group E+Ca), or control groups (Group C). The primary end point was to compare the proportion of patients with a 50% reduction from baseline in intact parathyroid hormone (iPTH) levels and iPTH levels ≤240 pg/mL at the 12-week time point after the trial start. Secondary end points included to compare changes in calciprotein particles (CPPs) and fibroblast growth factor 23 (FGF23).

Results: A total 124 patients (men 67.6%, 66.6 years) were randomized in this trial. The achievement proportion (95% confidential interval: CI) of the primary end point (iPTH 50% reduction and iPTH ≤240 pg/mL) were 90.0% (76.3-97.2) in Group E+D, 56.8% (39.5-72.9) in Group E+Ca, and 19.5% (8.8-34.9) in Group C, respectively. When compared the achievement proportion of the primary end point between the groups treated with etelcalcetide and the control groups by logistic regression analysis with iPTH, corrected serum calcium and phosphate at baseline as covariates, treatment of etelcalcetide demonstrated significant increase in achievement proportion (odds ratio 13.4; CI 5.10-35.3, P = 0.000). Next, when compared between Group E+D and Group E+Ca, achievement proportion in Group E+Ca was significantly inferior to that in Group E+D (odds ratio 0.16; CI 0.04-0.56, P = 0.004). The decrease in CPPs was estimated -59949 (AU) in patients treated with etelcalcetide and -37584 (AU) in controls in a linear mixed model, respectively. Similarly, the decrease in FGF23 was estimated -3044.9 (pg/mL) and -186.4 (pg/mL). However, the both decrease in CPPs and FGF23 could not reach significant differences between two groups by Tukey-Kramer multiple-comparison test.

Conclusions: Among maintenance hemodialysis patients with SHPT, the use of etelcalcetide showed good control of iPTH.

IMpact of Phosphate Reduction on Vascular End-Points in CKD (IMPROVE-CKD): A Randomized, Placebo-Controlled Trial

Nigel D. Toussaint,[1,2] Eugenia Pedagogos.[3,2] IMPROVE-CKD investigators *[1]The Royal Melbourne Hospital, Parkville, VIC, Australia; [2]University of Melbourne, Parkville, VIC, Australia; [3]Alfred Health, Melbourne, VIC, Australia.*

Background: Hyperphosphatemia is associated with increased fibroblast growth factor 23 (FGF23), arterial calcification, arterial stiffness and increased cardiovascular (CV) mortality in patients with chronic kidney disease (CKD). Due to these associations, clinical guidelines recommend lowering serum phosphate levels towards the normal range. However, the effect of phosphate-lowering medications on markers of vascular calcification and arterial stiffness in non-dialysis CKD patients remains uncertain. The aim of IMPROVE-CKD was to assess the effects of a non-calcium-based phosphate binder, lanthanum carbonate, on intermediate CV markers in patients with CKD.

Methods: In this double-blind, multi-centre, randomized controlled trial, patients with stage 3b or 4 CKD were randomized to lanthanum carbonate 500mg or matched placebo three times daily for 96 weeks. The primary outcome was change in carotid-femoral pulse wave velocity (PWV, SphygmoCor). Intention-to-treat analysis was used with linear mixed models for repeated measures. Secondary outcomes included aortic calcification (AC, computed tomography), and serum and urine markers of bone and mineral metabolism.

Results: 278 participants from Australia, Malaysia and New Zealand were randomized to lanthanum carbonate (n=138) or placebo (n=140) (mean age 63.1±12.7yrs, 69.4% male, 63.9% white; 33% stage 3b CKD, 67% stage 4 CKD, mean eGFR 26.6±8.3ml/min/1.73m^2; 45% diabetes, 32.1% CV disease). Mean serum phosphate was 1.25±0.20mmol/L, mean PWV 10.8±3.6m/s and 81.3% had AC at baseline (median [IQR] 1535 [63.2, 5744] Hounsfield Units [HU]). At 96 weeks, change in PWV did not differ significantly between the groups (diff [95%CI] +0.7 [-0.2, 1.6] m/s, p=0.13). Change in AC score was also not significantly different (+154 [-334, 641] HU, p=0.53) and there were no differences in serum phosphate, c-terminal and intact FGF23, and 24-h urinary phosphate excretion between the groups. Serious adverse events were reported in 63 (46%) and 66 (47%) participants on lanthanum and placebo respectively.

Conclusions: In stage 3b/4 CKD patients, treatment with the phosphate-lowering agent lanthanum carbonate over 96 weeks did not result in any difference in change in arterial stiffness or aortic vascular calcification.

A Precision Medicine Approach to Treatment of Osteoporosis in CKD-5D

Hartmut H. Malluche, Florence Lima, Katelyn M. Hellman, Tara L. Spach, Jin Chen, Daniel Davenport. *University of Kentucky, Lexington, KY.*

Background: This prospective stage II proof-of-concept randomized controlled study uses different treatments for osteoporosis in low vs. non-low bone turnover (Low TO vs. Non-low TO) CKD-5D patients.

Methods: In 36 dialysis clinics across Kentucky, 96 CKD-5D patients with established Low TO and Non-low TO osteoporosis were enrolled. Low TO was determined by serum measurements of PTH, PTH ratio, and TRAP-5b below race-specific normal ranges histologically validated by our laboratory. In Low TO patients, teriparatide combined with cinacalcet was given to stimulate bone formation. In Non-low TO patients, alendronate was administered to reduce bone resorption. The primary endpoint was 1-year change in bone mineral density (BMD) measured by QCT.

Results: Patient status is shown in the Table. In Low TO patients, change in Total Hip BMD demonstrated a positive effect of treatment (Treatment: 12.6 mg/cm^3 [SE 5.8] n=8; Control: -14.1 [SE 12.7] n=8; p=.076). The mortality rate was 17% (10/60) in Non-low TO patients with no deaths in Low TO patients (Figure, p=.003). Only two Non-low TO control patients survived to complete the study, thus group comparisons are not yet feasible; Non-low TO treated patients had bone loss of only 4.0 mg/cm^3. In Low TO patients identified through blood tests, teriparatide has a positive effect on reversing bone loss in CKD-5D.

Conclusions: This study demonstrates better survival in Low TO vs. Non-low TO CKD-5D osteoporotics; supporting the precision medicine approach.

TH-PO1192

A Randomized Crossover Trial of Ultrafiltration (UF)-Profiled Hemodialysis (HD) for UF Rate-Related Harm

Jennifer E. Flythe,[1] Matthew J. Tugman,[1] Julia Narendra,[1] Magdalene M. Assimon,[1] Quefeng Li,[1] Yueting Wang,[1] Steven M. Brunelli,[2] Alan L. Hinderliter.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]DaVita Clinical Research, Needham, MA.*

Background: Rapid UF is associated with adverse outcomes among HD patients. UF profiling, the practice of varying UF rates to maximize fluid removal during periods of greatest hydration and oncotic pressure, may reduce UF rate-related complications.

Methods: In this 4-phase, blinded crossover trial, participants (UF rates >10 mL/h/kg in ≥30% of screening treatments) were assigned in random order to receive HD with conventional UF *vs.* UF-profiled HD; each 3-wk treatment period was followed by a 1-wk washout period. Participants crossed into each treatment arm twice (2 phases/arm). Each patient was their own control. The primary outcomes were intradialytic hypotension (IDH, nadir systolic BP <90mmHg), rise in serum troponin T from pre- to post-HD (≥10%), and change in left ventricular global longitudinal strain (GLS) from baseline to peak intra-HD stress (%). Secondary outcomes included intra-HD symptoms and blood volume monitor-measured plasma refill (hematocrit fall by ≥0.5%), a volume status measure.

Results: On average, the 34 randomized patients (mean age 56y, 24% female, mean HD vintage 6.3y) had UF rates ≥10 mL/h/kg in 56% treatments during the 4-wk screening period. All but 2 patients completed the 15-wk study (long hospitalization, transplant). With UF-profiled HD, patients had significantly lower odds of light-headedness and plasma refill (i.e. less post-HD hypervolemia) compared to HD with conventional UF. There was no significant difference in IDH. There was a non-significant trend toward a lower odds of troponin T rise with UF-profiled HD.

Conclusions: UF-profiled HD did not reduce the odds of IDH or troponin T rise but did reduce the odds of light-headedness and post-HD plasma refill.

Funding: NIDDK Support

Selected outcomes

Outcome	Odds ratio (95% confidence interval), UF-profiled HD vs. conventional HD*
Intradialytic hypotension	1.2 (0.8, 1.7)
Troponin T rise (%)	0.5 (0.2, 1.3)
Left ventricular GLS change (%)	Results pending
Cramping	0.9 (0.4, 2.1)
Light-headedness	0.2 (0.06, 0.9)**
Plasma refill	0.2 (0.05, 0.9)**

* Difference of outcomes between the UF-profiled intervention arm and the conventional UF control arm were assessed with likelihood ratio tests using various generalized linear mixed models depending on outcome type.

** $p<0.05$.

Multicenter RCT of Vitamin K Antagonist Replacement by Rivaroxaban with or Without Vitamin K2 in Hemodialysis Patients with Atrial Fibrillation: The Valkyrie Study

An S. De Vriese,[1] Rogier Caluwé,[2] Lotte Pyfferoen,[3] Dirk De Bacquer,[4] Koen De Boeck,[5] Joost L. Delanote,[3] Didier P. De Surgeloose,[6] Bruno Van Vlem,[2] Francis Verbeke.[7] *[1]Nephrology, AZ Sint-Jan Brugge - Oostende AV, Brugge, Belgium; [2]Nephrology, OLV Hospital Aalst, Aalst, Belgium; [3]Medical Imaging, AZ Sint-Jan Brugge-Oostende AV, Brugge, Belgium; [4]Public Health, Ghent University, Ghent, Belgium; [5]Nephrology, ZNA Middelheim, Antwerpen, Belgium; [6]Medical Imaging, ZNA Middelheim, Antwerpen, Belgium; [7]Nephrology, University Hospital Ghent, Ghent, Belgium.*

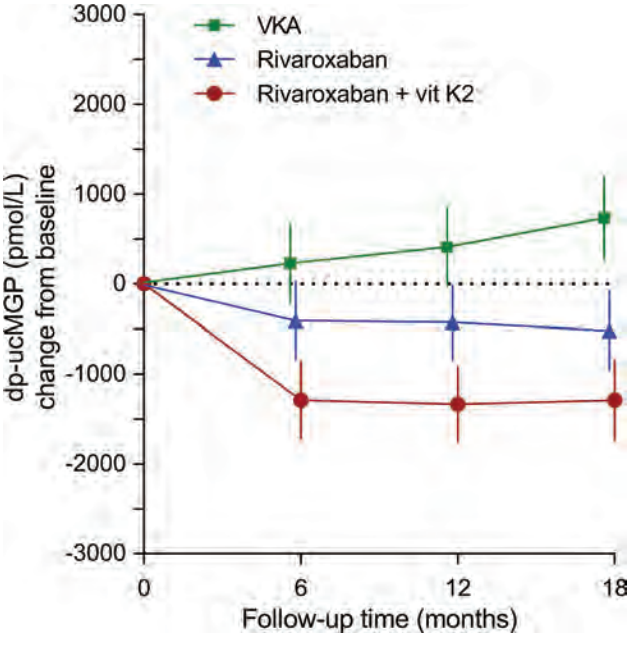
Background: Vitamin K antagonists (VKA) have been incriminated as probable cause of accelerated vascular calcification (VC) in hemodialysis patients. Functional vitamin K deficiency may further contribute to their susceptibility for VC. We investigated the effect of vitamin K status on VC progression in 132 hemodialysis patients with atrial fibrillation treated with VKA or qualifying for anticoagulation.

Methods: Patients were randomized to VKA, rivaroxaban 10 mg od, or rivaroxaban plus vitamin K2 2000 µg trice weekly during 18 months. Systemic dp-ucMGP levels were quantified to assess vascular vitamin K status. Cardiac and thoracic aorta calcium scores and pulse wave velocity were measured to evaluate VC progression.

Results: Initiation or continuation of VKA increased dp-ucMGP, while levels decreased in the rivaroxaban group and to a larger extent in the rivaroxaban+vitamin K2 group, but remained nevertheless elevated (Figure). Changes in coronary artery, thoracic aorta and cardiac valve calcium scores and pulse wave velocity were not different among the treatment arms. All cause death, stroke, cardiovascular event and bleeding rates were not significantly different between the groups. The incidence of life-threatening and major bleeding was significantly lower in the pooled rivaroxaban arms than in the VKA arm.

Conclusions: Withdrawal of VKA and high-dose vitamin K2 improve vitamin K status in hemodialysis patients, but have no significant favorable effect on VC progression. Severe bleeding complications may be lower with rivaroxaban than with VKA.

Funding: Commercial Support - Kaydence Pharma



Estimated marginal mean changes in dp-ucMGP levels from baseline (95% CI).

Effects of Exercise Training on Psychosocial Health and Cognition in Elderly Hemodialysis Patients

Khin N. Chan,[1] Ralph Rabkin,[1] Yu Chen,[1] Atul A. Nagare,[2] Tieming Niu,[1] Yiming Lit,[1] Manjula Kurella Tamura,[1] Jonathan N. Myers.[1] *[1]VA Palo Alto Health Care System/Stanford University, Palo Alto, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Background: The impact of exercise training on health-related quality of life (HRQOL) and cognition in chronic kidney disease has not been fully explored. We aimed to determine the effects of 12-weeks of home-based exercise training on psychosocial health and cognition outcomes among elderly maintenance hemodialysis (MHD) patients.

Methods: Fifty-six patients (66± 7 years; exercise [Ex]: n=28, usual care [UC]: n=28) with end-stage renal disease on MHD (mean years of MHD: 4±4; mean Kt/V=2.1) were studied using the SF-36 v2, Kidney Disease and Quality of Life (KDQOL) and a battery of cognitive function tests as part of a randomized trial. Ex subjects underwent a home-based aerobic and resistance training program for 12 weeks. Eight components of the SF-36 v2 (bodily pain, general health, mental health, physical functioning, role physical, role emotional, social functioning, vitality), and 5 components of the KDQOL (burden of kidney disease, symptoms, effects, physical component score [PCS], and mental component score [MCS]) were assessed. Tests of cognitive function assessing general cognition, executive function, memory and verbal learning were obtained.

Results: Ex patients improved peak VO_2 by 11% (p=0.01), while no differences were observed among UC. A 20-point increase in general health was observed among Ex (p=0.04), and trends were observed for increases in physical functioning and role emotional (p=0.08). No other HRQOL measures differed between EX and UC patients. KDQOL symptoms improved in Ex (p=0.05). PCS increased slightly from 38% ± 12 to 45% ± 10 (p=0.12) in EX. KDQOL measures were unchanged in UC. There were no significant changes in cognition within or between groups.

Conclusions: Home-based exercise training promotes health-related quality of life and some symptom metrics but did not affect cognition.

Safety and Efficacy of the Tablo System: Results from a Prospective, Multi-Center, Cross-Over Study of a First-in-Class Hemodialysis Device in the Home

Troy J. Plumb,[1] Luis Alvarez,[2] Dennis L. Ross,[3] Joseph J. Lee,[4] Jeffrey Mulhern,[8] Graham E. Abra,[7] Sarah S. Prichard,[5] Glenn M. Chertow,[6] Michael A. Aragon.[9] *[1]University of Nebraska Medical Center, Omaha, NE; [2]Palo Alto Medical Foundation, Menlo Park, CA; [3]Kansas Nephrology Physicians, P.A., Wichita, KS; [4]Nephrology Associates Medical Group, Riverside, CA; [5]Independent Consultant, Montreal, QC, Canada; [6]Stanford University School of Medicine, Palo Alto, CA; [7]Satellite Healthcare, San Jose, CA; [8]Tufts University School of Medicine, Boston, MA; [9]Outset Medical, San Jose, CA.*

Background: Home dialysis is in critical need of new technology to facilitate its delivery, as evidenced by the recent Advancing American Kidney Health initiative. The Tablo™ Hemodialysis System (Tablo) is the first new technology expanding to home use in nearly 15 years, designed to simplify patient self-care through automation, integrating on-demand water purification and dialysate production. This investigational device exemption (IDE) study assessed the safety and efficacy of Tablo managed in-center by healthcare professionals and in-home by patients or caregivers.

Methods: We conducted a prospective, multicenter, open label, cross-over trial comparing in-center and in-home hemodialysis using Tablo. Dialysis was prescribed four times per week during four treatment periods: 1-week Run-In, 8-week In-Center, approximately 4-week Transition and 8-week In-Home. The primary efficacy endpoint was achieving weekly standardized $Kt/V_{urea} \geq 2.1$. The secondary efficacy endpoint was delivered ultrafiltration within 10% of prescribed. We also collected safety and usability data.

Results: Thirty participants enrolled, and 28 completed all trial periods. Adherence to the four treatment per week prescription was 96% in-center and 99% in-home. The average prescribed and delivered treatment session lengths were 3.4 hours for the In-Center and In-Home periods. The primary efficacy endpoint was achieved in 199/200 (99.5%) measurements during the In-Center period and 168/171 (98.3%) In-Home. The average weekly standardized Kt/V_{urea} was 2.8 in both periods. The ultrafiltration endpoint was achieved in 94% of patients during both the in-center and in-home periods. No pre-specified adverse events related to Tablo occurred during any trial period. The resolution time of alarms was 14 seconds in-center and 12 seconds in-home.

Conclusions: Tablo exceeds the target $stdKt/V_{urea} \geq 2.1$ for in-center and home care settings with highly accurate ultrafiltration. With patient-centric design, infrequent and easy to resolve alarms, and a demonstrated safety profile, Tablo provides a new option for expanding home dialysis in the United States, aligning with ambitious targets recently set by policymakers.

TH-PO1196

A Randomized Cross-Over Trial Using Intradialytic MRI to Compare the Effects of Standard vs. Cooled Haemodialysis on Cerebral Blood Flow and Cardiac Function

Venkata R. Gullapudi,[1,4] Eleanor Cox,[3] Charlotte E. Buchanan,[1] Sebastian C. Coleman,[1] Kelly White,[4] Bernard J. Canaud,[2] Maarten W. Taal,[1,4] Susan Francis,[3] Nicholas M. Selby.[1,4] *[1]University of Nottingham, Derby, United Kingdom; [2]FMC Deutschland GmbH, Bad Homburg, Germany; [3]Sir Peter Mansfield Imaging Centre, Nottingham, United Kingdom; [4]University Hospitals Derby and Burton, Derby, United Kingdom.*

Background: Ischemic end-organ damage during haemodialysis (HD) is a significant problem that may be ameliorated by intradialytic cooling. We performed a randomized trial to compare acute hemodynamic effects of standard HD (SHD) and cooled HD (CHD), using intradialytic magnetic resonance imaging (MRI) to provide concurrent assessments of cerebral blood flow (BF) and cardiac function.

Methods: 12 prevalent HD patients were randomly allocated to receive 4 hours either SHD (dialysate temperature 37°C) or CHD (programmed cooling using BTM device). All other HD prescription and operating conditions remained constant. Participants were exposed to initial modality for two weeks before undergoing serial multiparametric MRI (Phillips 3T Ingenia) of the heart and brain pre, during (30min and 180min) and 30min post HD. Cognitive function was assessed pre and post HD. Participants then crossed over to the other modality and the study protocol repeated.

Results: Median age of participants was 59.5yrs (IQR 25), 3 had diabetes and dialysis vintage was 18.5months (IQR 52). Participants were significantly cooled during CHD (CHD -0.40±0.31°C vs SHD 0.28±0.24°C; p=0.02). Ultrafiltration rate was 7.5±2.6ml/kg/hr in CHD vs 6.9±2.7ml/kg/hr in SHD (p=0.3). BF velocities fell in carotid (-19±2%, p<0.001) and basilar arteries (-16±3%, p=0.004) during HD and reached nadir in the 4th hour, as did cardiac index and stroke volume index (-29±2% and -32±2%, both p<0.001). Reductions in left ventricular diastolic filling time and volume were also observed. Changes in cerebral BF and cardiac function were not different between CHD and SHD. Reduction in carotid BF was associated with higher ultrafiltration volumes (R^2=0.43, p=0.005) and slower completion of trail making test: part B (R^2=0.33; p=0.03). Pre-HD myocardial T_1 and left ventricular wall mass were lower after two weeks of CHD as compared to SHD (1281±14ms vs 1308±18ms, p=0.03; 128±12g vs 137±12g, p=0.003).

Conclusions: HD and fluid volume reduction adversely affects cardiac function, carotid and basilar artery BF, with acute changes similar during SHD and CHD. However, lower myocardial T_1 and left ventricular mass may indicate reduced myocardial tissue oedema with CHD.

Background: Hyperuricemia is a common finding in chronic kidney disease (CKD) and associated with increased risk of progression of CKD. The effect of urate-lowering therapy on CKD progression remains uncertain. We therefore assessed whether allopurinol attenuates the decline of estimated glomerular filtration rate (eGFR) over 2 years in people with high CKD-progression risk.

Methods: In this double-blind randomized controlled trial, adults with CKD stage 3 or 4, urinary albumin-to-creatinine ratio (UACR) ≥30 mg/mmol or decrease in eGFR ≥3.0 mL/min/1.73 m^2 in the preceding ≤12 months, and no history of gout, were randomized to allopurinol (100-300 mg once daily) or placebo. The primary outcome was change in eGFR (mL/min/1.73 m^2/yr) up to 104 weeks. The key secondary endpoints were 40% reduction in GFR, progression to end-stage kidney disease (ESKD), blood pressure, albuminuria, and adverse events.

Results: 369 participants were randomised to the allopurinol group (n=185) or placebo group (n=184). Six withdrew before the baseline visit (3 in each group). The rate of eGFR decline did not differ significantly between the allopurinol (-3.33 mL/min/1.73 m^2/yr, 95% CI -4.11 to -2.55) and placebo (-3.23 mL/min/1.73 m^2/yr, 95% CI -3.98 to -2.47) groups (difference -0.10 mL/min/1.73 m^2/yr, 95% CI -1.18 to 0.97, P=0.85). 63 (35%) and 51 (28%) participants in the allopurinol and placebo groups experienced a secondary composite endpoint of 40% eGFR decline, ESKD, or death from any cause (RR 1.23, 95% CI 0.90 to 1.67). There were no significant differences in change in UACR (P=0.25), and systolic blood pressure (P=0.30) between the two groups. Serum urate was significantly lower in the allopurinol group (mean difference -0.16 mmol/L, 95% CI -0.17 to -0.15, P<0.001). Serious adverse events were reported in 84 (46%) and 79 (44%) participants in the allopurinol and placebo groups, respectively (P=0.63).

Conclusions: In CKD patients with elevated CKD-progression risk, urate-lowering treatment with allopurinol did not result in slower eGFR decline than placebo. These results do not support the use of urate-lowering therapy to slow CKD progression.

A Phase 3 Randomized Controlled Trial on the Effect of Losartan vs. Add-On Aliskiren in CKD

Sydney C. Tang,[1] Kam wa Chan,[1] Desmond Y. Yap,[2] Gary C. Chan,[2] Kar Neng Lai.[1] *[1]The University of Hong Kong, Hong Kong, China; [2]Queen Mary Hospital, Hong Kong, China.*

Background: The potential long-term safety and efficacy of aliskiren in non-diabetic CKD is unknown.

Methods: Non-diabetic CKD stages 3-4 patients were randomized to receive aliskiren added on to losartan (maximal tolerated dose) or losartan alone. The primary outcome was the slope of eGFR at 3 years, along with other secondary endpoints. Composite renal outcomes of doubling of baseline serum creatinine (sCr) or a 40% reduction in eGFR or incident end-stage renal disease (ESRD) or death was analysed as post-hoc analysis.

Results: After follow-up of 144 weeks in 76 subjects (Table 1), there was no difference in the slope of eGFR (Fig 1). 6 patients receiving aliskiren and 7 control patients reached the renal composite endpoint (16.2% *vs.* 17.9%, *P*=0.84). Cardiovascular events rate was 10.8% *vs.* 2.6%, *P*=0.217. Hyperkalemia rate was 18.9% *vs.* 5.1% (Fig 2).

Conclusions: Compared to losartan alone, add-on aliskiren conferred no further renoprotective benefit but increased hyperkalemia risks in non-diabetic CKD patients.

Baseline demographics

	Aliskiren Group (N=37)	Control Group (N=39)

TH-PO1200

Safety and Efficiency of Nephroprotective Therapy with Ramipril in Children

Oliver Gross. GPN-study group and EARLY PRO-TECT Alport investigators *University Medicine Goettingen, Goettingen, Germany.*

Background: Children with Alport syndrome (AS) develop renal failure early in life. The safety and efficacy of preemptive nephroprotective therapy is uncertain.

Methods: In an investigator-initiated, double-blinded, randomized, placebo-controlled trial, we treated pediatric patients with Ramipril. Pretreated children and patients whose parents refused randomization versus placebo were treated open label. Prospective data from the US-Alport registry (NCT00622544) were added to substantiate our results in a Bayesian evidence synthesis approach. The primary endpoints were safety: *adverse drug reactions before disease progression* and efficacy: *time to progression*.

Results: Sixty-six oligosymptomatic children with (yet) normal renal function entered the up to 6-year treatment phase with a total of 216.4 patient-years on Ramipril. Most important, Ramipril was safe (hazard ratio 1.00, 95%CI 0.83-1.21). Efficacy analyses, though not significant, cumulated evidence in favor of Ramipril: in the randomized arm, Ramipril decreased the risk of disease progression by >40% (0.51; 95%CI 0.12–2.20), diminished the slope of albuminuria progression and the loss of glomerular filtration rate. Only 27.3% (3/11) of Ramipril-treated, but 55.6% (5/9) of placebo-treated children progressed. Efficacy was confirmed by comparison of untreated children from the US with participants treated open label, in whom Ramipril again reduced disease progression by >40% (0.53; 95%CI 0.23-1.24).

Conclusions: Early initiation of Ramipril therapy in children with AS is safe and can be expected to slow renal failure by many years, underlining the value of preemptive therapy in this CKD. Thus, screening programs for glomerular hematuria in children and young adults should include genetic testing for AS-gene variants. (Funded by the German Federal Ministry of Education and Research; EARLY PRO-TECT Alport ClinicalTrials.gov number, NCT01485978).

Double-Blind, Randomized Phase 3 Study Comparing Esaxerenone with Placebo in Type 2 Diabetes Patients with Microalbuminuria (ESAX-DN Study)

Naoki Kashihara,[1] Sadayoshi Ito,[2] Kenichi Shikata,[3] Masaomi Nangaku,[4] Takashi Wada,[5] Yasuyuki Okuda,[6] Tomoko Sawanobori.[6] *[1]Kawasaki Medical School, Kurashiki City, Japan; [2]Katta Hospital, Shiroishi, Japan; [3]Center for Innovative Clinical Medicine, Okayama University Hospital, Okayama, Japan; [4]The University of Tokyo School of Medicine, Tokyo, Japan; [5]Kanazawa University, Ishikawa, Japan; [6]Daiichi Sankyo Co., Ltd., Tokyo, Japan.*

Background: The progression of kidney disease in type 2 diabetes mellitus (T2DM) is not always adequately controlled by renin-angiotensin system inhibitors. In preclinical studies, Esaxerenone (ESAX), a non-steroidal mineralocorticoid receptor blocker, showed kidney protective effects; it may be effective for diabetic kidney disease. Here, the efficacy and safety of ESAX were evaluated in comparison with placebo in 455 Japanese patients with type 2 diabetes mellitus with microalbuminuria.

Methods: ESAX-DN Study was a multicenter, randomized, double-blind, placebo-controlled, phase 3 study. Hypertensive T2DM patients treated with ACEi or ARB with microalbuminuria (UACR ≥45 to <300 mg/g Cr in at least two measurements) and an estimated glomerular filtration rate ≥30 mL/min/1.73 m^2 were eligible. Patients were randomized to ESAX (1.25mg to 2.5mg) or placebo groups for 52 weeks with a follow-up of 4 weeks. The primary endpoint was the proportion of patients of UACR remission, defined as a reversal of UACR to normoalbuminuria (<30 mg/g Cr) and a decrease in UACR by ≥30% from baseline at the end of treatment. Secondary endpoints were the change in UACR from baseline, comparison of the transition rate to overt albuminuria at the end of treatment, and safety assessed in terms of adverse events (AEs).

Results: ESAX significantly reduced UACR (-58.3%) compared with placebo (8.4%) (61.6% reduction relative to placebo, P<0.0001), showed a significantly higher UACR remission rate (22.1% vs. 4.0%) and a significantly lower transition rate to overt albuminuria (1.4% vs. 7.5%) compared with placebo (P<0.0001, P=0.0016). Incidence of

Underline represents presenting author/disclosure.

AEs was similar, ESAX vs. placebo (78.3% vs. 77.3%). The proportion of subjects with serum potassium ≥6.0 mEq/L or with two consecutive readings ≥5.5 mEq/L was higher with ESAX (8.8% vs. 2.2%); patients recovered with ESAX dose adjustment and showed a recovery tendency after the end of the treatment.

Conclusions: This study demonstrated the efficacy of ESAX for UACR remission and a decrease in the transition to overt albuminuria in T2DM patients with microalbuminuria receiving ACEi or ARB. Although the serum potassium increase was higher with ESAX than placebo, all patients tended to recover after treatment and were clinically acceptable.

Background: The CREDENCE trial demonstrated that the SGLT2 inhibitor CANA significantly reduced kidney failure and cardiovascular (CV) events in participants with type 2 diabetes and chronic kidney disease. During the study, participants continued treatment until initiation of dialysis or kidney transplantation. The efficacy and safety of CANA in the subgroup of participants with BL eGFR <30 mL/min/1.73 m² were evaluated.

Methods: While eligibility, in part, required a screening eGFR of 30-90 mL/min/1.73 m², BL assessment of eGFR performed at the randomization visit could fall outside of the indicated range. Efficacy and incidence of selected adverse events were examined in those with a BL eGFR <30 mL/min/1.73 m², a subgroup defined post hoc. Effects of on-treatment eGFR slope were analyzed using a piecewise, 2-slope linear mixed effects model with a knot at week 3, with compound symmetry fitted where unstructured models did not converge. Treatment effects for other renal outcomes are expressed hazard ratios (HRs) with 95% CI.

Results: Overall, 174 (4%) participants had BL eGFR <30 mL/min/1.73 m². Mean annual change in eGFR for placebo- and CANA-treated participants was –4.00 and –1.50 mL/min/1.73 m² (placebo-subtracted difference: 2.50 mL/min/1.73 m², 95% CI: 0.55–4.44). Numerical trends favoring CANA were noted for ESKD (HR: 0.67; 95% CI: 0.35–1.27], primarily driven by risk reduction in time to eGFR <15 mL/min/1.73 m² (HR: 0.50; 95% CI: 0.25–1.02) as compared to initiation of dialysis/kidney transplantation (HR: 0.90; 95% CI: 0.39–2.06). Doubling of serum creatinine similarly favored CANA (HR: 0.72; 95% CI: 0.34–1.54). CV outcomes were not different between groups, although results were broadly consistent with the overall population. Acute kidney injury events were similar for CANA compared with placebo (10.7% and 11.1%).

Conclusions: Among a subgroup of participants with BL eGFR <30 mL/min/1.73 m², CANA reduced the rate of eGFR decline and slowed progression to ESKD. The renal and CV outcome comparisons were consistent with results in the overall study population.

Soluble Tumor Necrosis Factor Receptor 1 (sTNFR1) Is Prognostic for ESRD over 48 Weeks in a Randomized Clinical Trial in Moderate to Advanced Diabetic Kidney Disease (DKD)

Jacqueline Tarrant,[1] Lene Vestergaard,[1] Emon Elboudwarej,[1] Yuan Tian,[1] Fang Chen,[1] Scott D. Patterson,[1] Uptal D. Patel,[1] Pablo E. Pergola,[2] Glenn M. Chertow,[3] Jan Skupien,[4] Andrzej S. Krolewski.[5] *[1]Gilead Sciences, Inc., Foster City, CA; [2]Renal Associates, P.A., San Antonio, TX; [3]Stanford University School of Medicine, Palo Alto, CA; [4]Jagiellonian University Medical College, Krakow, Poland; [5]Joslin Diabetes Center, Boston, MA.*

Background: Serum sTNFR1 associates with progression to ESRD in natural history studies of DKD. A predefined sTNFR1 cutpoint has been proposed as a potential patient selection criterion for clinical trials. We conducted a pre-planned retrospective analysis of the prognostic power of sTNFR1 over 48 weeks (48W) in a Phase 2 trial of selonsertib (SEL) in patients with DKD at high risk of progression based on estimated glomerular filtration rate (eGFR) and albuminuria.

Methods: The Phase 2 SEL trial comprised 333 patients randomized 1:1:1:1 to receive SEL (2, 6, or 18 mg) or matching placebo for 48W. Serum sTNFR1 and UACR cut-points previously described in Joslin type 1 DKD (T1DKD n=279) and T2DKD (n=221) cohorts (Yamanouchi M, et al. Kidney Int 2017;92:258) were applied to evaluate risk of the composite endpoint: ESRD, 40% decrease in eGFR, or nonrenal death. Cox proportional hazards models compared event rates by sTNFR1. Results were then evaluated in propensity score matched patients by age, sex and race.

Results: The proportion of the Phase 2 SEL trial patients categorized as high risk based on sTNFR1 >4.3 ng/mL was higher than the Joslin cohorts combined (60% vs 33%, p<0.001 as was the high risk subgroup with UACR > 1900mg/g and sTNFR1 >2.9≤4.3ng/mL (8% vs 6%, p<0.01. In the SEL trial, we observed 32 events, with annualized event rates of 15% vs 3% in patients above or below sTNFR1 4.3 ng/mL, respectively (p=0.002). Comparable event rates were observed in the subpopulation of matched SEL trial and Joslin T2DKD patients (n=121 pairs, 21% vs 4% and 21% vs 8%, respectively). Further, each standard deviation increase of sTNFR1 was associated with a higher risk of the composite endpoint in the full SEL trial (HR 1.64, 95% CI 1.12-2.41) and full Joslin T2DKD cohort (HR 1.76, 95% CI 1.31-2.38).

Conclusions: We validated a predefined cutpoint of serum sTNFR1 associated with a higher event rate in a DKD trial population already selected for high risk based on eGFR and albuminuria criteria. sTNFR1 may improve the efficiency of DKD trial design as a patient stratification or selection biomarker.

Wheeler,[14] Hong Zhang,[15] Bernard Zinman,[16] Vlado Perkovic.[1,17] *[1]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [2]Concord Repatriation General Hospital, Sydney, NSW, Australia; [3]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [4]Indiana University School of Medicine and VA Medical Center, Indianapolis, IN; [5]Janssen Research & Development, LLC, Raritan, NJ; [6]Department of Medicine, University of Chicago Medicine, Chicago, IL; [7]Cardiovascular Division, Brigham & Women's Hospital and Baim Institute for Clinical Research, Boston, MA; [8]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, Bronx, NY; [9]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [10]Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; [11]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [12]The Charles Perkins Centre, University of Sydney, Sydney, NSW, Australia; [13]Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St. Leonards, NSW, Australia; [14]Department of Renal Medicine, UCL Medical School, London, United Kingdom; [15]Renal Division of Peking University First Hospital, Beijing, China; [16]Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada; [17]The Royal North Shore Hospital, Sydney, NSW, Australia.*

Background: SGLT2 inhibitors were developed to lower glucose. Renal and cardiovascular (CV) protection from CANA in CREDENCE was seen in participants with type 2 diabetes overall, and in those with reduced eGFR in whom systemic glycemic effects are attenuated suggesting clinical benefits are not entirely mediated by glycemic improvements. We explored this by assessing the impact of CANA on eGFR slope in participants with HbA1c<7% vs those with HbA1c≥7%.

Methods: Relative and absolute effects of CANA on renal and CV outcomes were estimated using Cox proportional hazards regression. Effects of on-treatment eGFR slope were analyzed using a piecewise, 2-slope linear mixed effects model with a knot at week 3.

Results: At baseline, 650 (14.8%) participants had HbA1c<7% (mean 6.6%) and they had lower eGFR than the HbA1c≥7% cohort (53.5 vs 56.7 mL/min/1.73m²). CANA resulted in an acute drop in eGFR in those with HbA1c<7% (CANA vs placebo: 3.8±0.4 vs 0.5±0.4; Diff: 3.3 [95% CI: 2.1–4.5] mL/min/1.73m²) and HbA1c≥7% (3.3±0.2 vs 0.4±0.2; Diff: 2.9 [95% CI: 2.4–3.5] mL/min/1.73m²; **Figure**). CANA thereafter attenuated annualized eGFR decline in those with HbA1c<7% (2.3±0.4 vs 4.0±0.4; Diff: 1.8 [95% CI: 0.8–2.8] mL/min/1.73m²/year) and HbA1c≥7% (1.9±0.2 vs 4.9±0.2; Diff: 3.0 [95% CI: 2.5–3.4] mL/min/1.73m²/year). Primary and secondary outcomes were consistent in those with HbA1c<7% and ≥7%.

Conclusions: CANA appears to slow renal function loss in those with optimized HbA1c consistent with non-glucose mediated mechanisms of benefit.

Prevention of CKD with Dapagliflozin: Analysis of the DECLARE-TIMI 58 Trial

Ofri Mosenzon,[1] Hiddo J. L Heerspink,[3] Jamie P. Dwyer,[8] Avivit Cahn,[1] Erica L. Goodrich,[4] Sabina A. Murphy,[4] Aliza Rozenberg,[7] Ilan Yanuv,[7] Thomas A. Zelniker,[10] Deepak L. Bhatt,[13] Lawrence A. Leiter,[6] Darren K. Mcguire,[5] John P. Wilding,[11] Ingrid A. Gause-Nilsson,[2] Anna Maria Langkilde,[12] Martin Fredriksson,[12] Peter A. Johansson,[12] Marc S. Sabatine,[4] Stephen Wiviott,[9] Itamar Raz.[7] *[1]Hadassah Hebrew University Hospital, Jerusalem, Israel; [2]AstraZeneca, Gothenburg, Sweden; [3]University Medical Center Groningen, Groningen, Netherlands; [4]TIMI Study Group, Boston, MA; [5]UT Southwestern Medical Center at Dallas, Dallas, TX; [6]St. Michael's Hospital and University of Toronto, Toronto, ON, Canada; [7]Hadassah Hebrew University Medical Center, Jerusalem, Israel; [8]Vanderbilt University Medical Center, Nashville, TN; [9]TIMI Study Group/Brigham and Women's Hospital, Boston, MA; [10]TIMI Study Group, Cardiovascular Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [11]University of Liverpool, Liverpool, United Kingdom; [12]AstraZeneca, Mölndal, Sweden; [13]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Patients with early stage kidney disease incur low rates of hard renal endpoints, limiting the ability to demonstrate drug efficacy in this population. Consequently, the regulatory agencies including Federal Drug Administration and European Medicines Agency now consider eGFR based endpoints as acceptable surrogates. In the DECLARE-TIMI-58 study, dapagliflozin showed robust reduction in cardiorenal and renal specific composite outcomes in the overall population.

Methods: 17,160 patients with type 2 diabetes were randomly assigned to dapagliflozin or placebo and followed for a median of 4.2 years. The baseline eGFR was 85.3 ml/min/1.73m^2 and only 7% of patients had an eGFR <60 ml/min/1.73m^2. We analyzed eGFR slopes from randomization to end of treatment with dapagliflozin vs. placebo.

Results: Dapagliflozin attenuated the eGFR decline overall in the trial and in subgroups based on eGFR, UACR, use of ACEi/ARB and diuretics (table). Fewer patients experienced an eGFR decline of 30%, 40% or 50% to eGFR<60 with dapagliflozin vs. placebo, HR (95% CI): 0.68 (0.58, 0.79); 0.54 (0.43, 0.67); 0.57 (0.40, 0.81) respectively, all p<0.002.

Conclusions: Dapagliflozin slowed the progression of renal disease across all subgroups of patients with type 2 diabetes, even in patients with normal kidney function and in patients with normo-albuminuria, highlighting its potential for primary prevention of chronic kidney disease.

Randomized Controlled Trial of Tacrolimus vs. Prednisolone Monotherapy for Adults with De Novo Minimal Change Disease

Megan Griffith,[1] Nicholas R. Medjeral-Thomas.[2] MInTac Study Investigators *[1]Renal Medicine, Imperial College NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Background: Standard treatment of de novo nephrotic syndrome secondary to Minimal Change Disease with high dose corticosteroids is associated with the risk of adverse side effects. However there is a paucity of Clinical Trials to guide the use of steroid free alternative regimens in this rare disease in adults. This multicentre prospective, open-label, randomised controlled trial (EudraCT 2009-014292-52, ClinicalTrials.gov NCT00982072) involving 6 nephrology units across the UK investigated whether tacrolimus monotherapy without corticosteroids would be effective for the treatment of de novo minimal change disease. We hypothesised nephrotic syndrome remission rates would be non-inferior for tacrolimus monotherapy compared to corticosteroids

Methods: Adult patients with first presentation of minimal change disease and nephrotic syndrome were randomised to oral tacrolimus at 0.05mg/kg twice daily, or prednisolone at 1mg/kg daily up to 60mg daily. 50 patients completed the trial

Results: There were no significant differences between the tacrolimus and prednisolone treated cohorts in the proportion of patients in complete remission at 8 weeks (primary outcome; 21 of 25 (84%) for prednisolone and 17 of 25 (68%) for tacrolimus (p=0.32)), at 16 weeks (23 of 25 (92%) for prednisolone and 19 of 25 (76%) for tacrolimus (p=0.25)), or at 26 weeks (23 of 25 (92%) for prednisolone and 22 of 25 (88%) for tacrolimus (p>0.99)). Likewise there was no difference in total remission rates (complete or partial) at 4 weeks (20 of 25 patients (80%) in the prednisolone and 19 of 25 patients (76%) in the tacrolimus cohort (p>0.99), or at the subsequent time points. There was no significant difference in relapse rates (17 of 23 (74%) for prednisolone and 16 of 22 (70%) for tacrolimus (p>0.99)), in the time from complete remission to relapse, or in changes from baseline serum creatinine.

Conclusions: Tacrolimus monotherapy treatment for adults with newly presenting minimal change disease was non-inferior to oral prednisolone in achieving remission from nephrotic syndrome. This is the 1st multicentre randomised controlled trial demonstrating an effective alternative for patients wishing to avoid steroid therapy. This heralds a new era in the management of adults with minimal change disease.

TH-PO1207

A Phase 2 Open-Label Trial Evaluating the Efficacy and Safety of Daratumumab in Treatment of Patients with Proliferative Glomerulonephritis with Monoclonal Immune Deposits (PGNMID)

Ladan Zand, Nelson Leung, Sanjeev Sethi, S. Vincent Rajkumar, Fernando C. Fervenza. *Mayo Clinic, Rochester, MN.*

Background: PGNMID is the result of the direct deposition of monoclonal proteins in the kidney and the ensuing inflammation. There are no proven therapies available. Rituximab or combination of cyclophosphamide, bortezomib & dexamethasone have been used with variable success.

Methods: In this trial we evaluated the safety & efficacy of daratumumab (an anti-CD38 plasma therapy). The primary safety end point was incidence of major infections, grade 3 or 4 pancytopenias. The primary efficacy end point was rate of complete remission (CR) (proteinuria <300 mg & <10% drop in eGFR) or partial remission (PR) (50% reduction in proteinuria & <30% drop in eGFR). Patients were treated with daratumumab IV at a dose of 16mg/kg once weekly for 8 weeks followed by once every other week for an additional 8 doses.

Results: Total of 9 patients were recruited. The mean age was 53.6±20.3 years. There were 5 males. Two withdrew from the study. At the end of treatment (6 m) the median 24hr urinary protein (UP) declined from 6.0g (IQ 4.4-8.2) to 0.64g (0.5-3.0), p=0.003 with a corresponding rise in serum albumin from 2.98±0.63 to 3.75±0.84 g/dL (p=0.03). Serum creatinine showed improvement from 1.52 ± 0.52 to 1.39 ± 0.47 mg/dL (p=0.1). At 6m, of the 7 patients, 1 achieved CR and 4 achieved PR. In 5 patients who had 12m data available, median 24hr UP at 6m was 3.0g (IQ 0.5-4.3) which decreased significantly from baseline, p=0.01. Median 24hr UP at 12 m was lower at 1.29 (IQ 0.3-4.0), p=0.01. Mean serum creatinine at 12 m was 1.15 ± 0.32 and unchanged from 6m (1.18±0.35, p=0.1). Four of the 5 achieved PR at 12 m. There were two serious adverse events. One was acute glaucoma which occurred 45 min into 1st infusion (patient was withdrawn). Another was eye chemosis/headache after receiving one infusion. Patient withdrew, but 2 m after, the 24hr UP showed no proteinuria (baseline of 2.3 g/24hr). The most common side effects were infusion-related reactions. There were no major infections or pancytopenias.

Conclusions: In this trial, daratumumab was shown to be effective in reducing proteinuria dramatically in patients with PGNMID along with stabilization of renal function. The effect is sustained at 12 m. In conclusion daratumumab is a promising therapy for treatment of patient with PGNMID.

Intensive Supportive Care Plus Immunosuppression in IgA Nephropathy: Long-Term Renal Outcomes

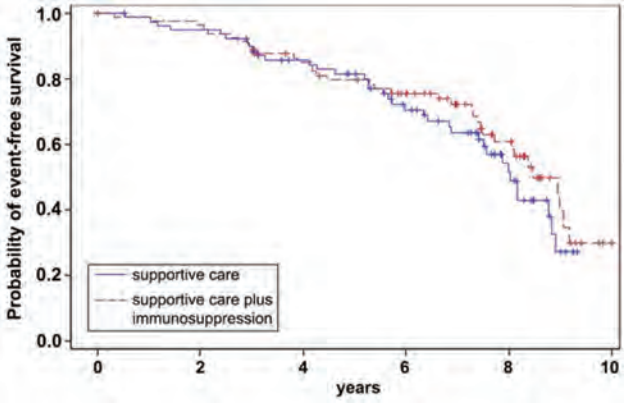
Jürgen Floege,[10] Stephanie Wied,[10] Christina Fitzner,[13] Frank Eitner,[10,1] Claudia Sommerer,[2] Martin G. Zeier,[2] Britta Otte,[8] Ulf Panzer,[9] Klemens Budde,[3] Urs Benck,[14] Peter R. Mertens,[7] Uwe Kuhlmann,[11] Oliver Witzke,[4] Oliver Gross,[12] Volker Vielhauer,[5] Johannes F. Mann,[6] Ralf-dieter Hilgers,[10] Thomas Rauen.[13] for the STOP-IgAN investigators *[1]Bayer AG, Wuppertal, Germany; [2]University Hospital of Heidelberg, Heidelberg, Germany; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]University Duisburg-Essen, Essen, Germany; [5]Ludwig-Maximilians-University Munich, Munich, Germany; [6]KfH Nierenzentrum, München, Germany; [7]Nephrology, Otto-von-Guerricke University, Magdeburg, Germany; [8]Universitätsklinikum Münster, Muenster, Germany; [9]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [10]RWTH Aachen University, Aachen, Germany; [11]Klinikum Bremen Mitte, Bremen, Germany; [12]University Medicine Goettingen, Goettingen, Germany; [13]RWTH Aachen University Hospital, Aachen, Germany; [14]University Medicine Mannheim, Mannheim, Germany.*

Background: Our randomized, controlled STOP-IgAN trial in patients with IgA nephropathy (IgAN) and substantial proteinuria failed to detect a benefit of immunosuppression added on top of supportive care on the decline in estimated glomerular filtration rate (eGFR) over 3 years. We now evaluated long-term renal outcomes after observational follow-up.

Methods: We obtained information on serum creatinine, proteinuria, end-stage renal disease (ESRD) and death as censored by 03/31/2018. The primary endpoint was the time to first occurrence of a composite of all-cause death, ESRD or eGFR decline by ≥40% as compared to baseline, i.e. randomization in the STOP-IgAN trial (Cox-regression).

Results: Long-term data were available for 149 STOP-IgAN participants (i.e. 92% of the patients originally randomized). Median follow-up after randomization was 7.4 years (IQR 5.7-8.3 years). The primary endpoint was reached in 36 patients (50.0%) originally randomized to supportive care and 35 patients (45.5%) of those receiving additional immunosuppression (HR 1.20; 95%-CI 0.75 to 1.92; p=0.45). ESRD occurred in 17 patients (23.6%) in the supportive care arm and in 20 patients with additional immunosuppression (26.0%). An eGFR loss ≥40% occurred at the same rate in both arms and annual eGFR loss also did not differ significantly. Two patients in the supportive-care arm and three in the arm with additional immunosuppression died during follow-up.

Conclusions: Over a follow-up of up to 10 years, we failed to detect differences in key clinical outcomes in IgAN patients randomized to receive added immunosuppression on top of supportive care versus supportive care alone (ClinicalTrials.gov number, NCT03488368).



Primary endpoint analysis. Kaplan-Meier curves showing survival without occurrence of the primary endpoint in the STOP-IgAN cohort.

The Gut-Kidney Axis in Man: GLP-1's Natriuretic Action Is Abolished by the GLP-1 Receptor Antagonist Exendin 9-39

Ali Asmar,[1,2] Per K. Cramon,[2] Meena Asmar,[7] Lene Simonsen,[2] Charlotte M. Sorensen,[3] Sten Madsbad,[4] Peter Hovind,[2] Jens J. Holst,[5] Boye Jensen,[6] Jens Bülow.[3] *[1]Rigshospitalet, Copenhagen, Denmark; [2]Bispebjerg University Hospital, Copenhagen, Denmark; [3]University of Copenhagen, Copenhagen, Denmark; [4]Hvidovre Hospital, Hvidovre, Denmark; [5]The Panum Institute, University of Copenhagen, Copenhagen N, Denmark; [6]University of Southern Denmark, Odense C, Denmark; [7]Steno Diabetes Center, Odense, Denmark.*

Background: We have recently demonstrated that extracellular fluid volume expansion in healthy participants uncovered a natriuretic action of GLP-1 probably via a tubular mechanism secondary to suppression of angiotensin II (ANG II). In the current study, we designed an additional study day to investigate whether GLP-1's natriuretic effect is mediated via activation and signaling of the GLP-1 receptor.

Methods: Under fixed sodium intake for 4 days before each study day, 6 healthy male participants were recruited from our recent study (1) and examined during a 3-hour infusion of GLP-1 (1.5 pmol/kg/min) together with a 3.5-hour infusion of the GLP-1 receptor antagonist, exendin 9-39 (Ex 9-39) (900 pmol/kg/min), initiated 30 minutes before start of GLP-1 infusion. Timed urine collections were conducted throughout the experiments. Renal plasma flow (RPF), glomerular filtration rate (GFR), and uptake and release of hormones and ions were measured via Fick's principle after catheterization of a renal vein.

Results: During co-infusion of GLP-1 and Ex 9-39, urinary sodium and osmolar excretions remained at baseline levels compared to a mean 2-fold natriuretic effect during GLP-1 infusion alone. Arterial plasma ANG II levels were unaffected during co-infusion of GLP-1 and Ex 9-39, whereas ANG II decreased significantly during GLP-1 alone. Arterial plasma renin levels decreased similarly on the two study days, and arterial aldosterone levels remained unchanged on both days. RPF and GFR remained unchanged on both days.

Conclusions: GLP-1's natriuretic action is abolished by the GLP-1 receptor antagonist Ex 9-39, probably via the antagonized GLP-1-mediated ANG II suppression.

Concordance Between AKI and Blood Pressure (BP) Assessment in Routine Clinical Practice and Research: Results from the SPRINT Electronic Health Record (EHR) Ancillary Study

Paul E. Drawz,[1] Mahboob Rahman,[2] Delphine S. Tuot,[3] Michael V. Rocco,[4] Nicholas M. Pajewski.[4] *[1]University of Minnesota, Minneapolis, MN; [2]Case Western Reserve University, Cleveland, OH; [3]University of California, San Francisco, CA; [4]Wake Forest School of Medicine, Winston-Salem, NC.*

Background: In SPRINT, intensive BP lowering was associated with increased risk for AKI. However, AKI ascertainment was based in part on billing codes and was limited to ER visits and hospital admissions. Additionally, it is unknown how BPs obtained using a standardized protocol in SPRINT compared to BPs in routine clinical practice.

Methods: Participant level EHR data were obtained from 15 SPRINT clinical sites. We merged these data with trial data to compare creatinines and BPs obtained in routine clinical practice with data obtained in SPRINT. AKI was defined by a 1.5 fold or greater increase in creatinine from the most recent SPRINT value. The primary outcome was inpatient or outpatient AKI. We used Cox models to assess the effect of intensive BP lowering on AKI events. We also report the difference between SPRINT and EHR BPs.

Results: Out of 9361 randomized participants, at least one EHR creatinine or BP value was available for 3827 participants. Among these, 87 in the intensive and 54 in the standard arm had an AKI event as adjudicated in SPRINT (HR 1.58, 95% CI 1.1 to 2.2). Using EHR-based creatinines, 147 in the intensive and 127 in the standard arm had an inpatient/ER AKI event (HR 1.15, 95% CI 0.9 to 1.5). For our primary outcome, 246 participants in the intensive and 170 in the standard arm had either an inpatient or outpatient AKI event (HR 1.49, 95% CI 1.2 to 1.8). Mean systolic BP in the EHR from 6 to 18 months after randomization was 7.2 (± 11.1) mm Hg higher than BPs obtained in SPRINT in the intensive arm and 4.7 (± 11.7) mm Hg higher than SPRINT BPs in the standard arm. Bland-Altman limits of agreement were wide.

Conclusions: Using linked EHR and SPRINT data, we demonstrate: a) a higher rate of AKI using data from routine clinical practice compared to clinical trial data, b) the increased risk for AKI with intensive BP lowering shown in SPRINT was attenuated using data obtained in routine clinical practice; this is the first report of the effect of an intervention on outpatient AKI, and c) BPs obtained in routine clinical practice were higher than readings obtained in SPRINT; though, the concordance between these BPs varied widely. These findings should inform the translation of SPRINT results into clinical practice.

Lack of Concordance Between Changes in the Serum Creatinine and Measured GFR in Patients with Acute Decompensated Heart Failure

Jutta S. Swolinsky,[1] Enkhtuvshin Tuvshinbat,[1] Fabian Knebel,[5] Edis Gasanin,[6] Daniel Meier,[2] Kai-Uwe Eckardt,[1] Bruce A. Molitoris,[3] Kai M. Schmidt-Ott.[1,4]

Background: The impact of serum creatinine-based episodes of acute kidney injury (AKI) on outcomes in patients with acute decompensated chronic heart failure (ADHF) is currently unknown. Unfortunately, creatinine and estimated GFR (eGFR) may not accurately reflect renal function under non-equilibrium conditions and might be affected by shifts in volume distributions in the context of decongestive therapy. In this study we measured plasma volume (PV) and GFR (mGFR) in patients undergoing treatment for ADHF and correlated them with creatinine dynamics and AKI based on KDIGO.

Methods: In a prospective cohort study in 50 hospitalized subjects with ADHF, PV and GFR were measured using a two-component intravenous visible fluorescent injectate (VFI) at two time points 48h apart during the course of treatment. Serum concentrations of a high molecular weight dextran component of VFI were measured 15, 60 and 180min after a single injection to quantify PV using the indicator-dilution principle. At the same time, concentrations of a low molecular weight dextran were measured to determine mGFR based on PV-normalized plasma pharmacokinetics. Linear correlation and Bland-Altman plots were used to compare changes in eGFR (CKD-EPI) and mGFR and to correlate changes in mGFR and eGFR. 38 patients had complete serial data regarding GFR dynamics during 48h of treatment.

Results: While eGFR and mGFR correlated well at the time of study inclusion (r=0,829, p<0,01), changes of eGFR and mGFR during 48h of ADHF treatment correlated poorly (r=0,3; p=0.08). 7 patients (18%) showed a decrease of mGFR by >=25% during 48h of treatment, but only one of these patients showed a corresponding decrease of creatinine-based eGFR by >=25%. Conversely, ten patients (26%) had a >=0.3mg/dl increase of creatinine within the 48h of treatment indicating a diagnosis of AKI by KDIGO, but only three of these patients (30%) had a decrease of mGFR by >=25%.

Conclusions: In patients hospitalized for ADHF undergoing recompensation, changes of measured GFR displayed a remarkable disconnect from estimated GFR predictions. Serum creatinine-based KDIGO AKI criteria frequently provided GFR-independent false-positive signals, indicating a need for improved diagnostics to identify worsening GFR in these patients.

Water Intake and Blood Pressure in Children: Results from the SPA Project

Gianluigi Ardissino,[1] Michela Perrone,[5] Silvia A. Ghiglia,[2] Patrizia Salice,[2] Francesca Tel,[2] Valentina Capone,[2] Sandra Piantanida,[3] Silvia Di michele.[4]
SPA Project *[1]Center for HUS Prevention, Control and Management, Milano, Italy; [2]Fondazione Ca' Granda Osp. Maggiore Policlinico, Milano, Italy; [3]Polo Materno Infantile- Ospedale F. del Ponte - Varese, Comerio, Italy; [4]UOC Pediatria Ospedale di Pescara, Pescara, Italy; [5]Pediatric Nephrology and Dialysis Unit, Milano, Italy.*

Background: Sodium (Na) intake (I) is involved in the development of hypertension (HPT); to reduce NaI is important in the treatment of HPT, but also the increase in renal Na excretion (E) might be a potential preventive and/or therapeutic opportunity. The SPA Project studied blood pressure (BP) in relation to water (H2O) and NaI with the working hypothesis that an increased H2O I can improve renal Na handling.

Methods: 339 healthy, non-overweight children (166 girls), 5.7 years old (IQR: 5.3-6.2) were characterized for: BP (using standardized multiple office BP measurement), Na and H2O I (by means of urinary Na and creatinine from 4 samples taken in 4 days). After categorizing subjects as low/high Na I and low/high water I (based on median value), BP was compared.

Results: Among children with higher NaI, those introducing more H2O, showed a significantly (p<0.001) lower BP (both systolic and diastolic) compared to those who drink less (fig.). This difference was not observed among children with lower NaI.

Conclusions: Our findings support the hypothesis that an increased H2O I, reduces BP perhaps by increasing Na renal E. We speculate that this simple, highly acceptable, inexpensive and harmless measure might have a role in preventing and minimizing the epidemics of HPT and related morbidities.

ANG-3777 Improves Outcomes in Patients with Delayed Graft Function: A Randomized, Double-Blind, Placebo-Controlled Phase 2 Trial with 12-Month Follow-Up

Jonathan Bromberg,[1] Matthew R. Weir,[2] Ahmed O. Gaber,[3] Barry Browne,[4] Itzhak D. Goldberg,[5] Michael A. Yamin,[5] Tracy J. Mayne,[5] Matthew Cooper.[6]
[1]University of Maryland, Baltimore, MD; [2]University of Maryland School of Medicine, Baltimore, MD; [3]Houston Methodist Hospital, Houston, TX; [4]Balboa Nephrology Medical Group, San Diego, CA; [5]Angion Biomedica Corp., Uniondale, NY; [6]Medstar Georgetown Transplant Institute, Washington, DC.

Background: Delayed graft function (DGF) is associated with lower graft survival & higher mortality. ANG-3777 is a hepatocyte growth factor mimetic shown in animal models to enhance tissue repair & function in damaged organs.

Methods: Kidney transplant patients producing <50cc urine/H over 8 consecutive hours post-transplant, or with CRR <30% at 24H, were randomized to ANG-3777 (2mg/kg IV QD x 3D; N=19) or Placebo (PBO, N=9). Primary endpoint: median time to ≥1200cc urine/24H.

Results: Study arms were generally balanced, though history of CVD was higher in PBO (ANG-3777=79%, PBO=100%). Kidney/Donor characteristics were similar: Donation after brain death (ANG-3777=68.4%; PBO=77.8%); time from procurement to transplant (ANG-3777= 23.7H±9.2; PBO=23.7H±10.3); DGF incidence (ANG-3777=73.6%; PBO=66.6%). Figure 1: ANG-3777 was more likely to achieve ≥1200cc urine/24H (ANG-3777=79%, median 5 days; PBO=44%, median 14 days). Figure 2: ANG-3777 had higher eGFR at Days 14, 28, 168, 365. Number of dialysis sessions was equivalent (ANG-3777=1.9 Days±1.3; PBO=1.8 Days±1.5), but ANG-3777 had shorter duration of dialysis (4.1±5.5 vs 6.0±8.4 Days) & transplant hospitalization (7.6±2.3 vs 11.4±9.7 Days). PBO had 2 graft failures vs 0 in ANG-3777 (Log Rank χ^2=4.6, p=0.03). Treatment Emergent Serious Adverse Events (TESAEs) were similar (ANG-3777=42.1%; PBO=44.4%); TESAEs/subject was higher in PBO (ANG-3777=2.0; PBO=4.3). No TESAEs were drug related.

Conclusions: ANG-3777 showed better short & long-term graft function, and similar safety to PBO.

Durable Donor Hematopoietic Stem Cell (HSC) Chimerism Is Associated with Protection from Native Renal Autoimmune Disease Recurrence in Recipients of Combined Stem Cell/Kidney Transplants

Joseph R. Leventhal,[3] John P. Galvin,[4] Lorenzo G. Gallon,[3] Dianne S. Belshe,[3] David Tollerud,[2] Suzanne T. Ildstad.[2,1] *[1]U of Louisville, Louisville, KY; [2]Talaris Therapeutics Inc., Louisville, KY; [3]Northwestern University, Chicago, IL; [4]University of Illinois Chicago, Chicago, IL.*

Background: Recurrence of autoimmune disease (AD) that caused ESRD has been observed in standard of care (SOC) renal transplants (KTx). Since 2009 we have conducted a Phase 2 trial of combined stem cell/living donor kidney transplantation in mismatched related and unrelated subjects with the goal of establishing durable donor chimerism. Our phase 2 is now closed and we have analyzed disease-recurrence in durably chimeric vs. transiently chimeric subjects

Methods: We hypothesized that durable chimerism will protect against native AD recurrence. Our protocol is based on tolerogenic $CD8^{+}/TCR^{-}$ facilitating cells (FC) and 200 cGy TBI-based nonmyeloablative conditioning with fludarabine (30mg/m2/dose, days -5,-4,-3), cyclophosphamide (50mg/kg/dose, day-3 and+3), 200 cGy TBI (day-1) followed by a living donor KTx (day0). A G-CSF mobilized apheresis product was collected from the donor >2 weeks pre-KTx, processed to remove graft-versus-host disease-producing cells yet retain HSC and FC (FCRx), and cryopreserved until infusion on day+1 post-KTx. 36 subjects are more than 1 year post-KTx (12-105 months). Subjects ranged in age from 18-65 years and were from 6/6 HLA matched related to 0/6 matched unrelated: 16 unrelated and 20 related donors. MMF and tacrolimus immunosuppression (IS) was weaned and discontinued at 1 year post-KTx if chimerism, normal renal function and normal KTx biopsy were noted.

Results: 12 subjects had AD as the cause of ESRD (6 IgAN, 2 FSGS, 2 Membranous GN, 2 Alport's). 7 had durable chimerism, allowing full withdrawal of IS; none had disease recurrence, including 2 with FSGS. 3 subjects had transient chimerism. In that cohort, Membranous GN recurred in 1 subject. 2 had no donor chimerism; 1 IgAN recurrence which resolved with corticosteroids. There were no graft losses or patient deaths in these 12 subjects. Renal function (eGFR) has been excellent (eGFR range 56-102 ml/min). In conclusion, durable chimerism using the FCR001 approach protects against recurrent AD.

Conclusions: The FCR001 approach may be particularly suited for patients at high risk for disease recurrence post-KTx, such as FSGS.
