Results: 206 patients were selected with most common diagnoses of melanoma (81%) or NSCLC (12%). Most patients (79%) also had stage 4 disease. There were 19 patients who had AKI, with a median age of 73 vs 68 in the non-AKI group (p = 0.057). There was no difference in HTN, DM, CKD stage, baseline creatinine, or baseline blood pressure between groups. There was no correlation between AKI and specific CPI therapy or combined CPI therapy. In the AKI group, there was a higher incidence of concomitant antihistamines (42% vs 15%, p = 0.003) and diuretics (37% vs 17%, p = 0.03). In the AKI group, 10 discontinued all CPI therapy due to disease status (progression or surveillance). 4 patients had AKI associated with autoimmune toxicity (2 colitis, 1 pancreatitis, 1 autoimmune nephritis) that resolved with steroids and stopping/changing CPI. 6 patients continued therapy without interruption, 4 had resolution of AKI. 5 patients had increasing SBP (>20 mmHg) at the time of AKI.

Conclusions: In our cohort, CPI therapy was well-tolerated from the standpoint of renal function. Of the 19 (9%) patients who experienced AKI, only 4 patients (1.9%) had AKI associated with autoimmune-related toxicity. Our data suggest the concomitant use of other potentially nephrotoxic drugs (e.g., antihistamines, diuretics) may be associated with increased risk of AKI.

SA-PO180

Incidence of Rash and Palmar-Plantar Erythrodysesthesia in Patients with Advanced Renal Cell Carcinoma Treated with First-Line Combination Therapy with Checkpoint Inhibitors

Wut yi Hninn,[1] Dia R. Waguespack,[6] Anita Sultan,[2] Vaqar Ahmed,[3] Maung htain K. Lin,[4] Thura W. Htut,[5] Kim Phung L. Nguyen,[7] Ala Abudayyeh,[8] Sriman Swarup,[9] Kyaw Z. Thein.[8,2] *[1]UTHealth, Houston, TX; [2]Texas Tech University Health Sciences Center, Lubbock, TX; [3]Dallas Nephrology Associates, Lubbock, TX; [4]Charles Wilson VA outpatient clinic, Houston, TX; [5]Aberdeen Royal Infirmary, Colchester, Essex, United Kingdom; [6]McGovern Medical School - UTHealth - Houston, Houston, TX; [7]University of Texas Health Science Center at Houston, McGovern Medical School, Houston, TX; [8]The University of Texas MD Anderson Cancer Center, Lubbock, TX; [9]Texas Tech University Health Science Center, Lubbock, TX.*

Background: Renal cell carcinoma (RCC) is the most common form of kidney cancer and clear cell RCC, the most common histology, harbors genetic abnormalities involved in angiogenesis via production of vascular endothelial growth factor (VEGF). Sunitinib has been the standard first-line treatment of advanced RCC for the past decade with notable dermatologic toxicities. We performed a combined analysis of randomized controlled trials (RCT) to determine the risk of rash and palmar-plantar erythrodysesthesia (PPE) with newer first-line combination therapies with checkpoint inhibitors.

Methods: PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through May 2019 were queried. RCTs utilizing upfront checkpoint inhibitors combination therapy in patients with advanced RCC were incorporated. The primary meta- analytic approach was a random effects model using the Mantel-Haenszel (MH) method. It was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI).

Results: Four phase III RCTs including 3758 patients with advanced RCC were eligible. The study arm used nivolumab+ ipilimumab, pembrolizumab+ axitinib, avelumab+ axitinib or atezolizumab+ bevacizumab while control arm utilized sunitinib. The randomization ratio was 1:1 in all studies. The I2 statistic for heterogeneity was 98%, suggesting some heterogeneity among RCTs. Any-grade rash was reported in 295 (15.8%) vs 205 (11.0%) in control group with RR of 1.43 (95% CI: 1.21 –1.69, P < 0.001). High-grade rash was noted in 13 (0.7%) in study arm vs 6 (0.3%) in control arm (RR, 1.41; 95% CI: 0.36 –5.51, P = 0.62). Any-grade PPE was 289 (15.5%) in study arm vs 741 (39.8%) in control arm. The pooled RR was statistically significant at 0.21 (95% CI: 0.06 –0.71, P = 0.01). High-grade PPE was noted in 47 (2.5%) vs 124 (6.6%) in control group with RR of 0.20 (95% CI: 0.03 –1.59, P = 0.13).

Conclusions: Upfront checkpoint inhibitors combination therapy notably decreased the risk of any-grade PPE, a major cause of morbidity and one of the feared dermatological toxicities, with a RR of 0.21, despite increasing the risk of any-grade rash.

Monoclonal Immunoglobulin Deposition Disease: Experience in a Single Institution

Yihe Yang,[1,2] Rushang Parikh,[1,2] Nina Haghi,[1,2] Purva D. Sharma,[1,2] Rimda Wanchoo,[1,2] Kenar D. Jhaveri,[1,2] Vanesa Bijol.[1,2] *[1]Northwell Health, Bayside, NY; [2]Zucker School of Medicine at Hofstra/Northwell, NY, Manhasset, NY.*

Background: Recently described proliferative glomerulonephritis with monoclonal immunoglobulin deposition (PGNMID) has become of interest as it typically has clinically significant course, with a membranoproliferative (MPGN) pattern on light microscope, and selective glomerular deposition of an entire monoclonal immunoglobulin by IF. There is often no hematologic malignancy to explain the findings, leading to therapeutic difficulties.

Methods: We reviewed our MIDD cases (7/1/2017-5/1/2019).

Results: The prevalence of MIDD is 3% (28/860), including entire monoclonal immunoglobulin or light and heavy chain deposition disease (L&HCDD, n=12), renal light chain (AL) amyloidosis (n=13), κ light chain deposition disease (KCDD, n=1), and γ heavy chain deposition disease (HCDD, n=2). The L&HCDD group had 9 cases of monoclonal IgG deposition disease (PGNMID), with a predominant MPGN pattern, and 3 cases of monoclonal IgA DD, with a predominant mesangial glomerular involvement. Bone marrow (BM) was biopsied in 6/12 of the L&HCDD cases; 3 showed abnormalities. Serologically, 6/12 had no M-spike; 1 case with M-spike had negative BM workup; 1 case had an M-spike without BM biopsy; and 1 case had no serological workup. 7/9 PGNMID cases received bortezomib based treatment. Pre- and post-treatment proteinuria was 8.76±9.95 and 1.75±2.06; creatinine was 1.97±0.64 and 1.94±0.81mg/dL. Other MIDD cases had a clear connection with BM malignancy: multiple myeloma in 9/13 amyloid cases and all HCDD and KLCDD cases;1 case had a negative BM evaluation but a IgG-λ circulating paraprotein.

Conclusions: L&HCDD is almost as common as AL amyloidosis, and much more common than LCDD or HCDD. Despite not identifying a monoclonal disease in many of our PGNMID cases, bortezomib based treatment resulted in good renal outcomes.

Table: Clinical and histological characteristics of monoclonal immunoglobulin deposition disease

	Overall	L&HCDD	KCDD	HCDD	Amyloidosis
N of patients	28	12	1	2	13
Age (y)	63.0±20.7	54.4±26.8	50****	65±5.7	71.5±11.6

Outcomes of Renal Transplantation in Monoclonal Immunoglobulin Deposition Disease

Avital Angel-Korman,[1] Vaishali Sanchorawala,[3] Andrea Havasi.[2] *[1]Boston Medical Center, Boston, MA; [2]Boston University Medical Center, Boston, MA; [3]Boston University School of Medicine, Boston, MA.*

Background: Renal involvement in monoclonal immunoglobulin deposition disease (MIDD) is close to 100%. Therapies have dramatically improved in the last 2 decades leading to deeper hematologic responses and longer disease-free survival, however renal organ survival is lagging behind and progression to end stage renal disease (ESRD) is frequent. Data on overall survival (OS) and renal transplant outcome in this patient population are limited.

Methods: We report the outcomes of 23 patients with MIDD of whom 6 patients underwent renal transplantation. All patients were followed in the Amyloidosis Center at Boston University School of Medicine between January 1989 and December 2018.

Results: At the time of diagnosis median age was 51.7 years, median eGFR was 22 mL/min/1.73m^2 (range, 4-91) and median proteinuria was 3g (range, 0.8-12). At censor, 9 of the 23 patients (39%) were deceased. One, 5 and 10-year survival from diagnosis were 95%, 78% and 65%, respectively. Renal organ response was achieved only in 5 patients (22%) after a median time of 1 year (range, 0.9-1.2) from diagnosis. One, 5 and 10-year renal survival from diagnosis were 72%, 36% and 21%, respectively. Twelve patients (52%) reached ESRD. Fourteen of the 18 patients (78%) who received first line treatment with high dose melphalan/stem cell transplantation (HDM/SCT) or bortezomib achieved a very good partial response or complete response. In the renal transplant patient group (n=6), shortest survival from diagnosis was 13.7 and the longest was 27.7 years. Three patients were still alive with functioning grafts at censor: 1.7, 2.8 and 6.5 years after renal transplantation. Grafts were lost either due to disease recurrence after 0.3 and 3.8 years or as a result of patient's death 20.3 years from renal transplantation. Median OS from diagnosis of patients who progressed to ESRD was significantly better for those who underwent renal transplantation vs. those who did not (19.8 vs. 8.3 years, p= 0.016). Median OS from dialysis initiation was also better in this group of patients; however the difference was not statistically significant (p=0.06).

Conclusions: Renal transplantation is a viable option for some patients with MIDD and these selected patients have improved OS.

SA-PO183

Impact of Autologous Stem Cell Transplantation on Renal Response in Multiple Myeloma Patients with Advanced Renal Failure

Jiwon Ryoo, Donghyuk Kang, Yun Jae Kwon, Yaeni Kim, Hyung Duk Kim, Ji Hee Lim, Eun Nim Kim, Yongjie Jin, Bumsoon Choi, Cheol Whee Park. *The Catholic University of Korea, Seoul, Republic of Korea.*

Background: This study aimed to evaluate the impact of autologous stem cell transplantation (ASCT) on renal outcomes of multiple myeloma (MM) patients who had advanced renal failure with estimated glomerular filtration rates (eGFR) ≤60 ml/min/1.73m^2 at the time point of transplantation.

Methods: In our ASCT database from July 2009 to September 2018, 76 MM patients with median eGFR of 36.6 (range, 5.4-59.8) ml/min/1.73m^2 at ASCT were included: 47 (61.8%) with eGFR ≥30 and <60ml/min/1.73m^2; 16 (21.1%) with eGFR ≥15 and <30ml/min/1.73m^2; and 13 (16.9%) with eGFR <15ml/min/1.73m^2 and/or hemodialysis-dependent. Myeloma and renal response after ASCT were evaluated using the international myeloma working group response criteria.

Results: During median follow-up of 37.3 (range 0.9-108.3) months, transplant-related mortality occurred in seven patients (9.1%). Overall myeloma response was achieved in 70 patients (92.1%): 6 (7.9%) of partial response (PR), 12 (15.8%) of very good partial response (VGPR), and 52 (68.4%) of complete response (CR). Median year-probability of myeloma progression-free survival (PFS) and overall survival were 23.2 (95% CI, 16.9-32.1) and 61.5 (95% CI, 43.6-69.8) months, respectively. Among 20 patients (26.3%) who achieved renal response, including 19 (25.0%) of renal CR and 1 (1.3%) of renal PR, median time to achieve partial response was 267 days (range, 3-2022). In subgroup (n=29) with baseline eGFR <30 ml/min/1.73m^2, 21 patients (53.8%) achieved renal response after median 53 (3-1756) days post ASCT. In multivariate analysis, IgA type, advanced eGFR (<30 ml/min/1.73m^2), and shorter duration from diagnosis to ASCT (<6.6 months) were associated with higher cumulative rate for achieving renal response.

Conclusions: Clinical outcome of myeloma patients after ASCT was favorable. Patients with advanced renal failure may benefit from early ASCT.

SA-PO184

Monoclonal Gammopathy-Associated Thrombotic Microangiopathy

Nelson Leung,[1] Ilya Glezerman,[3] Vanesa Bijol,[4] Daniel Garceau,[5] Hani Hassoun,[3] Angela Dispenzieri,[1] Kenar D. Jhaveri.[2] *[1]Mayo Clinic, Rochester, MN; [2]Northwell Health Sys, Great Neck, NY; [3]Memorial Sloan Kettering Cancer Center, New York, NY; [4]Northwell Health Hofstra University, Lake Success, NY; [5]IUCPQ, Lac Beauport, QC, Canada.*

Background: Thrombotic microangiopathy (TMA) is characterized by end-organ damage and classic histopathologic findings secondary to endothelial injury. Microangiopathic hemolytic anemia (MAHA) often accompanies the TMA. TMA in the setting of monoclonal gammopathy has been reported after hematopoietic stem cell transplant or with proteasome inhibitors in multiple myeloma (MM) but it is less clear if the monoclonal gammopathy itself may be involved in pathogenesis.

Methods: Cases were obtained from 6 institutions in the United States and Canada. TMA was confirmed histologically (kidney biopsy) or evidence of MAHA with thrombocytopenia (platelet count less than 150 x 10^9/L) and schistocytes, elevated lactate dehydrogenase (LDH), decreased haptoglobin, and indirect hyperbilirubinemia.

Results: Of the 9 patients, (33.3%) were female. The median age was 66 years. Five patients had MM (4 were treatment naive, 1 previously received melphalan and prednisone), one had Waldenstrom macroglobulinemia (WM), and 3 had monoclonal gammopathy of undetermined significance. The patient with WM had previously been treated with cyclophosphamide, rituximab and dexamethasone. No patient had otherwise received any medication associated with drug-induced TMA. All patients had renal involvement and a median creatinine of 3.3 mg/dl. Seven patients had a kidney biopsy and all demonstrated TMA. Median hemoglobin and platelet count were 108 g/L and 147 x 10^9/L, respectively. Six patients had thrombocytopenia but only 4 had evidence of MAHA. No patient had GI symptoms. ADAMTS13 level was only obtained in 1 patient and was non-deficient at 27%. Complement levels (C3, C4, total complement) were normal in 5 patients, and 1 patient had a low C4. Genetic testing for mutations in the alternative complement pathway were performed in 2 patients and were normal. Three patients were treated with plasma exchange, 1 patient initialy improved but died of multiorgan failure 6 days after presentation. One patient is awaiting treatment plan from hematology. The others have had resolution of TMA without recurrence after treatment of their disease. None of the patients received eculizumab

Conclusions: This study suggests that monoclonal gammopathies are assoicated with TMA. Disease-directed therapy should be considered first-line treatment of TMA, in addition to PLEX if there is ADAMTS13 deficiency.

SA-PO185

Tubulointerstitial Lesions Associated with Monoclonal Gammopathies of Renal Significance

Afonso Santos,[3] Ana Gaspar,[3] Anna Lima,[3] Rita Theias Manso,[1] Karina Soto.[3,2] *[1]Pathology, Hospital Fernando Fonseca, Lisbon, Portugal; [2]NOVA Medical School of Lisbon, CEDOC, Lisbon, Portugal; [3]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal.*

Background: Monoclonal gammopathy of Renal Significance (MGRS) is not a benign monoclonal disorder, neither a determined disease; abridge many kidney pathologies related to low proliferative small B-cell clone, being associated with kidney-end-organ damage, therefore requiring treatment. Herein we present a series of 11 patients who had monoclonal gammopathy (MG) and performed kidney biopsy, showing tubulointerstitial MGRS.

Methods: A retrospective analysis was performed. Patients with systemic lupus erythematous, HIV infection or Hemolytic Uremic Syndrome (with TMA) were excluded. Demographic, clinical, pathological and treatment data were collected from the admission to last follow-up. MGRS were defined according to the last categorization by the International Kidney and Monoclonal Gammopathy Research Group. Proximal Tubulopathies (PT) were classified as (a) PT without cytoplasmic inclusions; (b) PT associated with interstitial inflammatory reactions; (c) LCPT with crystals, (d) Crystal storing histiocytosis and (e) miscellaneous.

Results: From a total of 329 patients who performed kidney biopsy, 29 patients were initially excluded. Were also excluded 258 biopsied patients who did not had confirmed MG diagnosis, leading to a total of 40 patients. Of them, 14 had MM, 4SMM, 1WM, 2SWM and 15 MGUS, 2 amyloidosis, 1CLL and 1NHL indolent. Of all of them, 26 had MGRS criteria (65%). In the MM group most patients presented cast nephropathy (71%, n=10). In MGRS group most patients had glomerular lesions (n=17, 65%), while 11 (42%) had tubular lesions (2 patient with both lesions). The majority of these had (b) lesions (n=7, 64%); one patient had Fanconi Syndrome with lambda deposit crystals (c); one with (a) and cell vacuolization; one with (d) and one patient had AL tubular amyloidosis (e). Patients with MGRS had 66±2,9yo, most admitted with AKI. Median SCr of 2,5 mg/dL(IQR 1,61–5,55); proteinuria 2,52 g/d (IQR 1,41-6,49); ACR 0,5 g/g (IQR 0,14-2,58) and mean hemoglobin 12,1±2,84g/dL at admission.

Conclusions: The histopathological features of monoclonal gammopathies are broad, reflected in the proposed MGRS spectrum of renal lesions. In our series with monoclonal gammopathy patients tubular lesions were diverse, but none patient had been found with crystal-storing histiocytosis, but tubular deposits were found in immunofluorescence and electronic microscopy.

SA-PO186

Effect of Bortezomib and Male Sex on the Risk for Developing Tumor Lysis Syndrome in Patients with Multiple Myeloma: A Retrospective Study

Masahiro Kondo,[1] Yuji Hotta,[2] Karen Yamauchi,[2] Hirokazu Komatsu,[3] Shinsuke Iida,[3] Kazunori Kimura.[1,2] *[1]Department of Pharmacy, Nagoya City University Hospital, Nagoya, Japan; [2]Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [3]Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.*

Background: Tumor lysis syndrome (TLS) causes acute kidney injury and is a complication of cancer chemotherapy. TLS risk is classified by malignant disease type. Although multiple myeloma (MM) is a low-risk disease, treatment by novel therapies, including bortezomib, may increase TLS risk. This investigation was performed to obtain accurate information regarding TLS risk in MM patients.

Methods: We retrospectively investigated the incidences of laboratory and clinical TLS (LTLS and CTLS) in patients who received primary therapy for untreated symptomatic MM between May 2007 and December 2017. To identify potential TLS risk factors, we used univariate and multivariate logistic regression analyses to evaluate the associations between LTLS and several parameters hypothesized to be associated with an increased risk in prior reports.

Results: In total, 210 patients were included in this study. There were 17 (8.1%) and 7 (3.3%) patients with LTLS and CTLS, respectively; all CTLS patients were diagnosed due to elevated serum creatinine. Baseline characteristics were similar between patients with or without LTLS, although patients with LTLS tended to exhibit lower renal function. Multivariate analyses revealed that bortezomib-containing therapy (Bor-CT) was most strongly associated with LTLS (odds ratio (OR)=3.25, P=0.078) and male sex (OR=2.51, P=0.105). In subgroup analysis of patients treated with Bor-CT, male sex was significantly associated with increased risk of LTLS (OR=4.71, P=0.004, vs. other patients who received primary therapy) [Table].

Conclusions: Bor-CT may increase TLS risk, particularly among male patients with MM. Thus, TLS risk should be evaluated based on multifactorial.

Table. Odds ratios of laboratory TLS due to therapy regimen and sex in patients with multiple myeloma.

Therapy regimen	Sex	LTLS (+) n (%)	LTLS (-) n (%)	OR*	95% CI	OR*	95% CI
Bor-not containing	Female (n=42)	2 (4.8)	40 (95.2)	2.17	(0.19-25.50)		
	Male (n=38)	1 (2.6)	37 (97.4)	1.00	Referent	1.00	Referent
Bor-containing	Female (n=66)	3 (4.5)	63 (95.5)	2.04	(0.20-21.00)		
	Male (n=64)	11 (64.7)	53 (27.5)	8.33	(1.01-68.90)	4.71	(1.83-13.60)

TLS: tumor lysis syndrome, Bor: bortezomib, OR: odds ratio, CI: confidence interval.
*Adjusted for ISS stage 3, pretreatment serum creatinine level > upper normal limit.

SA-PO187

Assessment of Renal Impairment on the Prognosis of Newly Diagnosed Multiple Myeloma

Antonio Abel Portela Neto,[1] Marcella M. Frediani,[3] Renato A. Caires,[4] Elerson Costalonga,[4] Veronica Torres.[2] *[1]University State of São Paulo, São Paulo, Brazil; [2]Sao Paulo State Cancer Institute - USP, Sao Paulo, Brazil; [3]HC-FMUSP, Sao Paulo, Brazil; [4]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: The renal impairment (RI) at multiple myeloma (MM) ranged from 20 to 50% and RI is associated with reduced survival. The new criteria from the International Myeloma Working Group (IMWG) defined RI as serum creatinine (SCr) > 2.0 mg/dL or eGFR < 40 ml/min/1.73 m^2. If these definitions are associated to overall survival (OS) is still debatable.

Methods: All patients with newly diagnosed MM (up to three months) admitted for treatment at the Sao Paulo State Cancer Institute, between February 2012 and May 2016, were followed for a minimum of three years. Exclusion criteria were: age < 18 years; pts on dialysis; initiation of MM treatment before recruitment or exams; pts with follow up < 3 months. Chronic Kidney Disease (CKD) was diagnosed as eGFR < 60 ml/min/1.73 m^2. GFR was estimated by the CKD EPI formula. International Staging System (ISS) relyed on serum albumin (Alb) and $ß_2$ microglobulin (B2M).

Results: 255 pts were enrolled. Pts median age 61.70 ± 13.2 years (40.4% older than 65 yrs), 50.9% had hypertension and 20.4% diabetes. ECOG index was 0-2 in 61% of pts. Heavy chain IgG in 55.9% of pts and kappa light chain was in 65.8%. The Durie-Salmon stage III (DS-III) in 86.4% and ISS-III in 32.2% of pts. Exams associated with MM activity/prognosis were: 49% hemoglobin (Hb) < 10 g/dL; 13.3% total calcium (CaT) > 11 mg/dL; 45.9% Alb < 3.5 g/dL; 54.5% B2M > 3.5 mg/L; 30.6% elevated LDH. SCr was 1.06 (0.81 – 1.45) mg/dL and eGFR was 70.2 (44.5 – 91.7) ml/min/1.73 m^2. 14% of pts had RI with SCr > 2.0 mg/dL; CKD 3 was detected in 40.4% pts. Overall survival (OS) was 3.50 (1.74 – 4.95) years. No pts characteristics (age, performance, heavy of light chain type), CaT, Hb, Alb or DS-III were related to reduced OS. Neither was SCr > 2.0 mg/dL (P=0.730), eGFR < 40 ml/min/1.73 m^2(P=0.414). Variables related to low OS were CKD 3 (P=0.011), ISS-III (P=0.011) and B2M > 3.5 mg/L (P<0.0001). Elevated LDH value was marginally related to reduced OS (P=0.090). On Cox regression model, B2M > 3.5 mg/L (HR: 1.63 [1.02 – 2.63]) and abnormal LDH (HR: 1.61 [1.01 – 2.56]) were associated with lower OS.

Conclusions: KDIGO CKD definition seems to be superior to the IMWG criteria to assess the impact of RI on the prognosis of newly diagnosed MM pts. Markers of higher burden disease are strongly related to reduced survival.

SA-PO188

Impact of Autologous Stem Cell Transplant in Myeloma Patients on Renal Function, Progression-Free Survival, and Overall Survival: A Longitudinal Analysis

Ala Abudayyeh,[4] Omar Mamlouk,[1] Maen Abdelrahim,[2] Yan Heather Lin,[4] Arun Rajasekaran,[3] Paul W. Sanders,[3] Muzaffar Qazilbash.[4] *[1]University of Texas Health Science Center, Houston, TX; [2]Houston Methodist Cancer Center, Houston, TX; [3]University of Alabama, Birmingham, AL; [4]University of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Renal impairment has been negatively associated with progression free survival (PFS) and overall survival in patients diagnosed with multiple myeloma (MM). Autologous stem cell transplant (ASCT) has become a standard of care for treatment in MM. Most previous studies have assessed the safety of ASCT and the improvement in renal function in patients with MM. In our study we sought to understand how renal function was impacted over time, the predictors of renal function, progression free survival and overall survival after ASCT.

Methods: We performed a retrospective review of all MM patients who underwent ASCT at MDACC from January1, 2008 through December 31, 2013. A total of 885 none dialysis patients who received Melphalan alone as the conditioning regimen were identified. We collected demographic information, ISS stage, disease status at time of transplant (Day 0), and at last follow up. Creatinine, GFR (calculated using CKD Epi equation), calcium, and LDH were also collected at day 0, 100, 180, & 365. Given the longitudinal nature of the data, linear mixed effect models were used to study the change of GFR over time. A joint model approach for longitudinal, PFS and survival data was used to assess association of GFR with above variables. As sensitivity analyses, landmark analyses were conducted with day 0, 100, 180, and 365 days post-transplant as landmark time points.

Results: Patients' GFR at post-transplant time points were significantly higher ($p \leq 0.025$) compared to the day of ASCT. A higher ISS stage at diagnosis was significantly associated with a lower GFR ($p < .0001$) at all stages of chronic kidney disease. GFR value was not significantly associated with OS in any of the analyses described above. eGFR was not significantly associated with PFS when it was included in the models as a binary variable using median as the cutoff. However, disease status, ISS stage, response to induction prior to SCT were all associated with shorter OS.

Conclusions: The study demonstrates in a large cohort and in a longitudinal manner that MM patients who underwent ASCT did not have further decline in GFR over time. In addition, GFR was strongly associated with ISS stage. As far as OS, PFS, MM-related factors significantly impacted the survival while *GFR did not.*

Rate and Predictors of Developing Monoclonal Gammopathy of Renal Significance (MGRS) Lesion on Renal Biopsy in Patients with Positive Monoclonal Studies

Nattawat Klomjit, Nelson Leung, Fernando C. Fervenza, Sanjeev Sethi, Ladan Zand. *Mayo Clinic, Rochester, MN.*

Background: Monoclonal gammopathy (MG) can cause renal damage in a subset of patients known as MGRS. However, the rate of finding an MGRS lesion on a biopsy in a patient with MG and the clinical factors that would predict the likelihood of finding such lesions remains unknown

Methods: We identified all patients that had a positive serum MG based on a positive serum electrophoresis or immunofixation between 2013 through 2018 at the Mayo Clinic Rochester. We then excluded those patients who had a diagnosis of multiple myeloma, amyloidosis, or those with a renal transplant.

Results: We identified 4257 patients who met the inclusion criteria, of which 105 had a renal biopsy (2.47%). Of the 105 patients, 25 (23.8%) had an MGRS lesions. The most common MGRS lesions included proliferative glomerulonephritis with monoclonal immunoglobulin deposition (PGNMID) (n=10, 40%) followed by cryoglobulinemic vasculitis (n=5, 20%). In the remaining 80 patients, the most common lesions included arteriosclerosis (n=19, 23.75%), diabetic nephropathy (n=14, 17.5%), ANCA associated vasculitis (n=8, 8.8%) and IgAN (n=8, 8.8%). At the time of renal biopsy, there were no differences in age, sex, serum creatinine, hemoglobin and type of light chain between 2 groups. Compared to non-MGRS patients, MGRS patients had a significantly higher systolic blood pressure (p= 0.03) and more likely to have IgG heavy chain (p =0.05). Hematuria at time of the renal biopsy was the most significant predictor of finding an MGRS lesion with an OR of 6.21 (2.1-18.3, p=0.0003), followed by proteinuria >3.5 g/d with OR of 2.61 (1.01-6.7, p=0.04), and an elevated ratio of affected/unaffected light chain (OR= 1.08, 1.0-1.16, p=0.0001). Having a combination of hematuria and proteinuria≥2 g/day was also highly predictive with an OR of 5.67 (2.0-16.1, P=0.001).

Conclusions: Among patient with a positive MG who had a renal biopsy in the absence of amyloidosis, 75% had a lesion unrelated to the MG with arteriosclerosis and DN being the most common findings. Hematuria, nephrotic range proteinuria or high risk features (hematuria+proteinuria≥2 g) were the strongest predictors of finding an MGRS lesion.

Twenty-Eight Treatments of Acute Renal Failure Secondary to Multiple Myeloma (MM) with High Cutoff (HCO) Filters

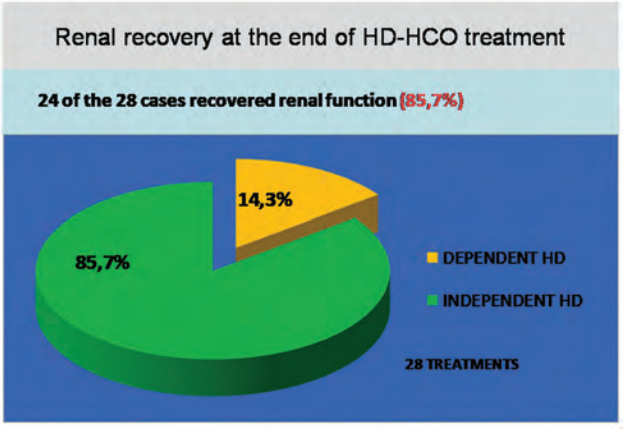
Ana Berni,[2] Rafael Alvarez lipe,[1] Ana Coscojuela otto,[1] Victoria Dourdil,[3] Pablo J. Inigo Gil.[1] *[1]Nephrology, Lozano Blesa University Hospital, Zaragoza, Spain; [2]Lozano Blesa University Hospital, Zaragoza, Spain; [3]Hospital Clinico Zaragoza, Zaragoza, Spain.*

Background: Our hospital is a reference in Spain for the treatment of acute renal failure secondary to multiple myeloma with HCO filters. We present our experience with 28 treatments.

Methods: Treatment indication required the diagnosis of MM, the presence of AKI requiring dialysis, a free light chains (FLC) level greater than 500 mg/L. The patients were analytically monitored by blood sampling at the start and the end of the hemodialysis session. The dialysis protocol used was the following: daily dialysis for 6 sessions, ultrapure water, HCO filter of 2,1 meters. To pass then to dialyze every other day until reaching sFLC levels below 500 mg/L, or until the recovery of a renal function. The duration of the sessions was 6 hours. 2 vials of 20% human albumin, 50 mL, were infused in a protocolized manner during the last half hour of dialysis.

Results: 28 treatments were performed on 25 patients. The average age of the patients was 60.2 years; 17 men and 8 women. The chemotherapy regimen was based on Bortezomib and Dexamethasone as first line. 24 of the 28 cases (85.7%) recovered renal function to allow independent dialysis. At 3 months, the number of patients who remain independent of dialysis was 21 of the 28 cases treated (75%), 13 patients presented MM with Lambda chains and 12 were Kappa. The average reduction of FLC by dialysis session was 63%. The reduction in sFLC beginning and the end of the treatment reached an average of 91%. Reviewing our data in May 2019, after 8 years of treatment, we have found that 52% of patients live independently of hemodialysis, we have also compared our results with the studies that more patients have treated and we have proven that our results are beter.

Conclusions: Given our experience, we believe that prolonged hemodialysis with HCO filters is effective, safe and with a high rate of renal recovery, Thelefore its hould be the treatment option chosen, together with chemotherapy, in all patients with multiple myeloma, cylinder nephropathy and acute renal failure requiring dialysis



SA-PO191

Incidence of Hypertension and Hypothyroidism in Patients with Advanced Renal Cell Carcinoma Treated with First-Line Combination Therapy with Checkpoint Inhibitors

Wut yi Hninn,[1] Anita Sultan,[2] Vaqar Ahmed,[3] Sriman Swarup,[2] Thura W. Htut,[4] Dia R. Waguespack,[5] Hanan A. Khairalla,[6] Jonathan D. Pankow,[9] Maung htain K. Lin,[8] Kyaw Z. Thein.[7,2] *[1]UTHealth, Houston, TX; [2]Texas Tech University Health Sciences Center, Lubbock, TX; [3]Dallas Nephrology Associates, Lubbock, TX; [4]Aberdeen Royal Infirmary, Colchester, Essex, United Kingdom; [5]McGovern Medical School - UTHealth - Houston, Houston, TX; [6]University of Texas, Houston, TX; [7]The University of Texas MD Anderson Cancer Center, Lubbock, TX; [8]Charles Wilson VA outpatient clinic, Houston, TX; [9]University of Texas Medical Center, Houston, TX.*

Background: Utilizing immunotherapies and antiangiogenic agents has become a fundamental paradigm shift in the treatment of advanced renal cell carcinoma (RCC). Inhibition of vascular endothelial growth factor (VEGF) has antiangiogenic and immunomodulatory effects. Combination of these therapies has also shown to have synergistic antitumor activities and survival benefits. Yet, there are considerable safety concerns. We conducted a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of hypertension and hypothyroidism.

Methods: PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through May 2019 were queried. RCTs utilizing upfront checkpoint inhibitors combination therapy in patients with advanced RCC were incorporated. The primary meta- analytic approach was a random effects model using the Mantel-Haenszel (MH) method. It was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI).

Results: Four phase III RCTs including 3758 patients with advanced RCC were eligible. The study arm used nivolumab+ ipilimumab, pembrolizumab+ axitinib, avelumab+ axitinib or atezolizumab+ bevacizumab while control arm utilized sunitinib. The randomization ratio was 1:1 in all studies. The I2 statistic for heterogeneity was 98%, suggesting some heterogeneity among RCTs. Any-grade hypertension was reported in 567 (30.4%) vs 746 (40.1%) in control group with RR of 0.54 (95% CI: 0.27 –1.07, P = 0.08). High-grade hypertension was noted in 273 (14.6%) in study arm vs 317 (17.0%) in control arm (RR, 0.63; 95% CI: 0.30 –1.30, P = 0.21). Any-grade hypothyroidism was 450 (24.1%) in study arm vs 388 (20.8%) in control arm. The pooled RR was not statistically significant at 1.22 (95% CI: 0.76 –1.95, P = 0.41). High-grade hypothyroidism was noted in 5 (0.27%) vs 4 (0.22%) in control group with RR of 1.23 (95% CI: 0.33 –4.67, P = 0.76).

Conclusions: Our meta-analysis demonstrated that there was no significant increase in the risk of hypertension and hypothyroidism in upfront combination therapy group compared to standard sunitinib arm, despite achieving higher survival benefits.

Graft vs. Kidney Disease in Recipients of Hematopoietic Stem Cell Transplantation: A Need for More Kidney Biopsies

Michelle L. Lubetzky,[2] Hannah Choe,[4] Victoria Gutgarts,[2] Steven Salvatore,[2] Koen Van besien,[2] Surya V. Seshan,[3] Thangamani Muthukumar.[1] *[1]Division of Nephrology and Hypertension, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medical Center, New York, NY; [4]The Ohio State University, Columbus, OH.*

Background: Kidney biopsies are seldom done in patients with AKI after Hematopoietic Stem Cell transplant (HSCT). Graft versus kidney disease (GVKD) has not been well described. We aimed to assess the clinical and pathologic findings of patients with AKI after HSCT who received a kidney biopsy.

Methods: We conducted a chart review of 15 HSCT patients who underwent 17 kidney biopsies for AKI.

Results: Clinical characteristics and pathology results are listed in Table 1. Most patients who underwent kidney biopsy had both AKI and proteinuria. The most common biopsy finding was a mix of interstitial inflammatory cell infiltrate (GVKD) combined with acute or chronic endothelial injury, TMA (n=7, 41%). Other biopsy diagnoses included acute and chronic TMA, GVKD, acute tubular injury, and polyomavirus BK nephropathy. Immunohistochemical staining for C5b-9 was done on 7 biopsies with acute or chronic TMA and was positive in all 7. In 3 patients with GVKD and interstitial cell infiltrate, staining for granzyme B and CD3 was positive. Figure 1 demonstrates the pathology findings of a patient with AKI and biopsy diagnosis of GVKD with inflammatory cell infiltrate and chronic TMA. IHC was positive for both granzyme B in the interstitium and C5b-9 in the glomeruli and arterioles (Figure 1).

Conclusions: There is a range of pathologic findings in patients with AKI after HSCT. To understand the pathogenesis and explore therapies for AKI in HSCT we recommend a lower threshold for kidney biopsy in these patients.

Characteristic	HSCT patients (n=15)
Age (mean±SD)	58.1±9.6
Gender (% Women)	9/15 (60%)
Hematologic Malignancy AML (9) MDS (n=1) T-cell Lymphoma (n=1) MPD (n=1) ALL (n=1) Non Hodgkin's Lymphoma (n=1)	 10/15 (66.7%) 1/15 (6.7%) 1/15 (6.7%) 1/15 (6.7%) 1/15 (6.7%) 1/15 (6.7%)

Death with GFR<15 or ESRD	4/7 (57.1%)

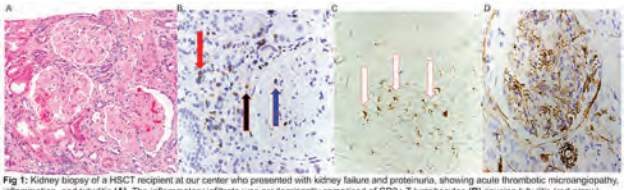

Fig 1: Kidney biopsy of a HSCT recipient at our center who presented with kidney failure and proteinuria, showing acute thrombotic microangiopathy, inflammation, and tubulitis (**A**). The inflammatory infiltrate was predominantly comprised of CD3+ T lymphocytes (**B**) causing tubulitis (red arrow), interstitial inflammation (black arrow), and glomerulitis (blue arrow). These cells were granzyme+ cytotoxic T-lymphocytes (white arrow in **C**). The glomeruli stained positive for terminal complement proteins C5b-9 (brown in **D**).

SA-PO193

Methotrexate-Induced AKI: A Retrospective Study

Mohit Gupta,[1] Sheron Latcha,[2] Elyn Riedel.[2] *[1]New York Presbyterian - Weill Cornell, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: High Dose Methotrexate (HD MTX) defined as ≥ 1000 mg/m^2 is used to treat several tumors including lymphomas, leukemias and osteosarcoma. In a multicenter study in patients with osteosarcoma treated with HD MTX, Widemann et al reported a rate of AKI (defined as elevation in Cr 1.5-3 X ULN)of 1.8%. We aimed to look at the rate of AKI in patients receiving HD MTX across the range of primary tumors for which it is indicated.

Methods: Data was collected on all adult patients (>18 years) who received HD MTX for all diagnoses from 01/01/2003 – 12/31/2013 at a single academic medical center. We excluded patients who had received prior or concurrent cisplatin/ ifosphamide. AKI with HD MTX was defined as 1.5 fold increase in baseline serum creatinine within 4 days after HD MTX. Clinical and demographic data were collected. Data on cumulative dose (CD) of HD MTX and number of cycles was obtained in both groups.

Results: The observed rate of AKI was 32.1% (282/880). The most common malignancies treated with HD MTX were lymphoma (75.0%) and leukemia (13.6%). Table 1 shows that advanced age (64 vs 57, p<0.0001) was associated with a higher rate of AKI. CKD III was associated with a lower rate of AKI (19.5 vs 80.5, p=0.01). The (CD) of HD MTX in patients who developed AKI was lower in comparison to those without AKI (13884 ± 10135 mg vs 22820 ± 16538 mg, p=0.0001). The number of cycles for HD-MTX was lower in patients who developed AKI (2.5 vs 4.4, p=0.0001).

Conclusions: This study is the largest single center report on the rate of AKI following HD MTX treatment across all tumor types for which the drug has an indication in adults. Lower eGFR corresponding to CKD III and shorter duration of treatment with HD MTX were associated with a lower rate of AKI. A lower (CD) of HD MTX was associated with a higher risk of AKI. These findings suggest that clinicians are reducing the dose of HD MTX in patients with CKD or following an episode of AKI. Future studies on the impact of AKI on long-term renal function in patients receiving HD MTX would assess whether such dose modification is necessary and what the effect is on long-term survivorship.

Table 1

Demographic Variables	AKI (n=282)	No AKI (n=598)	p-Value
Age (years)	64 (54-73)	57 (44-68)	<0.0001
Female (%)	32.7	67.3	0.72
Male (%)	6.86	31.4	
White (%)	32.9	67.1	0.40

SA-PO194

AKI in Allogeneic Hematopoietic Stem Cell Transplantation

Matthew Abramson,[1,2] Junting Zheng,[2] Victoria Gutgarts,[2] Josel D. Ruiz,[2] Molly A. Maloy,[2] Michael Scordo,[2] Edgar A. Jaimes,[2] Insara Jaffer Sathick.[2] *[1]New York Presbyterian-Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: The reported incidence of Acute Kidney Injury(AKI) after hematopoietic stem cell transplantation (HSCT) varies from 10 to 73%. The association between Graft vs Host Disease(GvHD), calcineurin inhibitors and risk for kidney injury remains controversial. We sought to describe the incidence of AKI and identify modifiable risk factors in patients undergoing allogeneic HSCT in our institution.

Methods: All patients undergoing allogeneic (non-cord) HSCT from 2014 to 2017 in our institution were included. Patient and graft characteristics associated with kidney injury were analyzed. AKI was defined using KDIGO criteria into grades 1, 2 and 3 including all serum creatinines obtained within the first 100 days after transplant. Differences across groups were assessed using either Wilcoxon rank-sum tests or Fisher's exact tests. AKI risk factors were estimated using cause-specific Cox proportional hazards regression.

Results: A total of 613 consecutive patients underwent allogeneic HSCT during the study period. Median age was 58(19-79) years, 59% male, 83% Caucasian. Indication for HSCT was leukemia in 49%, myelodysplastic syndrome in 16% and lymphoma in 17%. Median baseline creatinine was 0.8 (0.3-2.7) mg/dl. Median age-adjusted HCT-comorbidity index was 3(range 0-9). 97% patients engrafted with median time to engraftment of 12(8-33) days. Cumulative incidence of acute GVHD was 47%. By day100 postHSCT,143(23%) patients had grade 1 AKI, 153(25%) grade 2 AKI, and 78(13%) grade 3 AKI. Tcell depleted HSCT patients had a lower risk for AKI, hazard ratio 0.46 (0.35-0.62), p<0.001 (Table 1).

Conclusions: AKI in patients undergoing HSCT remains a major concern, affecting 61% of patients undergoing allogenic HSCT, with grade 2 and 3 AKI occurring in 25% and 13%, respectively. Patients undergoing T-cell depleted HSCT have lower incidence of AKI. Patients receiving GVHD prophylaxis with regimens including tacrolimus have a significantly higher risk for AKI, hazard ratio 2.63 (2.06-3.33). The effect of AKI after HSCT on long-term kidney function requires further prospective study.

Table 1: Risk factors for severe (grade 2-3) AKI

HSCT Regimen	N (%age)	Hazard Ratio (95% CI)	p-value
T-Cell Depleted	242 (39%)	0.46 (0.35, 0.62)	p<0.001
Conditioning			
Chemotherapy	461 (75%)	1	p=0.316
Total Body Irradiation	152 (25%)	0.86 (0.64, 1.16)	
GVHD Prophylaxis			
None	242 (39%)	1	p<0.001
Tacrolimus-based	263 (43%)	2.02 (1.62, 2.99)	
Tacrolimus/Sirolimus-based	37 (6.0%)	2.61 (1.58, 4.32)	
Cyclophosphamide-based	71 (12%)	1.84 (1.19, 2.84)	

SA-PO195

AKI in Critically Ill Patients After Oncological Surgery: Risk Factors and Mortality

Bertha M. Cordova-Sanchez,[1] Silvio A. Ñamendys- Silva.[1,2] *[1]Instituto Nacional de Cancerologia, Mexico, Mexico; [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Mexico, Mexico*.

Background: Acute kidney injury (AKI) is a frequent complication in critically ill patients, major surgery is the second most important cause of AKI. In cancer patients AKI is associated with increased mortality, therefore it is necessary to identify modifiable risk factors for its prevention. Previous scores aimed to predict AKI in general surgery have shown poor predictive value in patients undergoing oncological surgery, possibly because these scores do not consider previously administered radiotherapy or chemotherapy. The aim of this study was to evaluate the incidence, mortality and risk factors for AKI development, defined by KDIGO criteria in patients admitted to the intensive care unit (ICU) in the first 24 hours after major oncological surgery.

Methods: We conducted a retrospective analysis using a logistic regression model to evaluate the association between preoperative and intraoperative variables with AKI, and a Cox regression model to evaluate factors associated with 12-month mortality.

Results: We included 434 patients, with a median follow-up of 432 days. We included 171 men (39%), with a median age of 53 years (IQR 41-63). All patients had solid tumors, most from gastrointestinal origin (124 patients, 29%) and female reproductive system (98 patients, 23%), and 294 (68%) underwent abdominal surgery. We diagnosed AKI in 264 (60.8%) patients: 135 (31.1%) stage-1, 66 (15.2%) stage-2 and 63 (14.5%) stage-3 AKI. In multivariate analysis, abdominal radiotherapy (OR 2.57, 95%CI 1.25-5.29, p=0.010), abdominal surgery (OR 2.46, 95%CI 1.31-4.62, p=0.005), surgical packing (OR 4.12, 95%CI 1.97-8.61, p=0.000) and sepsis (OR 2.39, 95%CI 1.31-4.37, p=0.005) were independent risk factors for AKI development, while pre-surgical albumin (OR 0.45 95%CI 0.32-0.63, p=0.000) and intraoperative urine output (OR 0.81, 95%CI 0.70-0-94, p=0.006) were protective factors. During the 12-month follow-up 108 died, and stage 2 (HR 2.90, 95%CI 1.47-5.73, p=0.002) and stage 3 AKI (HR 5.85, 95%CI 2.89-11.88, p=0.000) were associated with mortality.

Conclusions: Almost 30% of patients developed stage 2 and 3 AKI, and the associated risk factors were abdominal radiotherapy, abdominal surgery, surgical packing and sepsis. Stage 2 and 3 AKI were associated with 12-month mortality.

SA-PO196

AKI After Radical Nephrectomy as Risk Factor for CKD: Retrospective Analysis from an Italian Cancer Center

Marina Foramitti,[1] Laura Cosmai,[2] Camillo Porta,[3] Meri Pedone,[4] Mimma Rizzo,[5] Nicole Gri,[6] Maurizio Gallieni,[7] Fabio Malberti.[8] *[1]ASST Cremona, Cremona, Italy; [2]San Carlo Borromeo Hospital, Milano, Italy; [3]University of Pavia, Pavia, Italy; [4]Nephrology, ASST Santi Paolo e Carlo Borromeo - Ospedale San Carlo Borromeo, Milan, Italy; [5]ICS Maugeri, Viggianello, Italy; [6]I.R.C.C.S. Istituti Cllinici Scientifici Maugeri, Pavia, Italy; [7]Ospedale San Carlo Borromeo - ASST Santi Paolo e Carlo - University of Milano, Milano, Italy; [8]Azienda Istituti Ospitalieri di Cremona, Cremona, Italy*.

Background: Radical nephrectomy is a significant risk factor for chronic kidney disease (CKD), and there are few reports on the renal outcome after radical nephrectomy for cancer. The aim of this study was to determine the incidence of AKI and whether postoperative AKI is associated with new-onset CKD after radical nephrectomy for renal cell cancer (RCC).

Methods: We conducted a retrospective study of 837 adult patients (>40 years old), from an Italian Cancer Centers with normal renal function who underwent unilateral radical nephrectomy for a solitary renal cortical tumor and were pathologically diagnosed with RCC between January 2010 and February 2019. Post-operative AKI was classed using risk, injury, failure, loss and end-stage kidney disease (RIFLE) criteria. CKD was defined as a decrease in estimated glomerular filtration rate (GFR) to <60 mL/min/1.73 m2.

Results: According with the RIFLE criteria, 250 of 278 patients fell into the AKI risk category 1, 21 patients fell into the AKI injury category and 6 patients fell into the AKI failure category. Multivariate analysis revealed as major result that higher preoperative GFR was an independent risk factor for postoperative AKI, although older age, male gender higher body mass index, smaller RCC size were independent risk factors too. New-onset CKD was more prevalent in the AKI risk group than in patients without AKI 1 year after surgery (56.1% versus 43.9%, respectively) and 3 years after surgery (52% versus 31%). Patients who experienced post-operative AKI had a 5.1-fold higher risk of new-onset CKD after multiple adjustments, that confirms other recent study.

Conclusions: AKI after radical nephrectomy in patients is a potent risk factor for new-onset CKD. Prevention of post-operative AKI, but also the assessment of kidney function pre-nephrectomy, is essential for reducing the incidence of CKD after nephrectomy.

SA-PO197

AKI in Patients with Haematological and Solid Organ Malignancy Receiving Chemotherapy

Reshma Shettigar. *Dunedin public Hospital, Dunedin, New Zealand*.

Background: The aim of this study was to look at the incidence of acute kidney injury and its clinical correlates in patients with haematological and solid organ malignancies receiving chemotherapy.

Methods: All patients, more than 18 years of age receiving outpatient chemotherapy for solid organ and haematological malignancies at our hospital from Jan 2016 to Dec 2016. Incidence of acute kidney injury was computed and its causes and clinical correlates were analyzed using univariate analysis and multivariate analysis.

Results: 592 patients were included in the study. Acute kidney injury during the one-year course of chemotherapy was seen in 158 patients (27.24%). Pre-renal acute kidney injury was seen in 82 patients (51.8%) and intrinsic renal in 20 patients (12.65%) and post renal cause in 35 patients (22.15%). Sepsis was the most common cause of acute kidney injury, followed by hypovolumia. There were 13 patients where the acute kidney injury was attributed to drugs. The drugs were NSAIDS, Lenalidomide, Methotrexate, Ibrutinib, Pamidronate, Gemcitabine, Vemurafinib and Crizotinib. Patients with acute kidney injury attributed to above drugs had either a dose reduction or change in chemotherapy regimen. None of the patients had a renal biopsy to confirm drug-induced pathology. However all of the patients had resolution of AKI after stopping the drug or changing the regimen. Also of note, only one patient with Pamidronate induced acute kidney injury was referred to nephrology service. Looking at individual cancer types, 5 out of 10 patients (50%) with RCC developed acute kidney injury followed by lymphoma, prostate and myeloma. Factors associated with acute kidney injury, higher ECOG score, diabetes and hypertension were associated with higher risk of developing acute kidney injury. Contrast to other published papers, having metastatic disease and ACE inhibitors was not associated with higher risk of acute kidney injury. Acute kidney injury is associated with increased mortality. We observed the same trend in our study. Without adjusting for confounding factors, mortality in the acute kidney group at 6, 12 and 18 months was 15%, 31% and 46% compared to Non AKI group, which was 5%, 26% and 43%.

Conclusions: AKI is common in patients with malignancies and its associated with high mortality.

SA-PO198

AKI and Mortality in Umbilical Cord Transplant Recipients

Sangeeta R. Hingorani,[1,2] Julie Chotivatanapong,[3] Emily C. Pao,[1] Kelsey Baker,[3] Filippo Milano.[3] *[1]Seattle Children's Hospital, Seattle, WA; [2]Pediatrics, University of Washington, Seattle, WA; [3]Fred Hutchinson Cancer Research Center, Timonium, MD*.

Background: Kidney injury occurs commonly after hematopoietic cell transplant (HCT) and negatively impacts outcomes. Umbilical cord blood transplantation (UCBT) is an established treatment for hematological malignancies. We sought to determine the incidence of, risk factors for, and outcomes in patients with AKI after UCBT.

Methods: Patients receiving a first UBCT at our Institution from 2006 to 2017 were included in this retrospective cohort study. AKI was defined by KDIGO stages 1-3 within the first 60 days post-transplant. Risk factors included age, gender, conditioning regimen, indication for transplant, graft vs. host disease (GVHD) prophylaxis, disease severity and clinical variables including acute GVHD, viral and bacterial infections. Cox regression models were used to identify risk factors for AKI and associations with non-relapse mortality.

Results: 276 patients were included in this study. 114 (41%) of patients developed Stage 1 AKI, 43 (16%) developed Stage 2 AKI, and 29 (11%) developed Stage 3 AKI. Risk factors prior to first episode of AKI stage 1 or higher included vancomycin use (HR=1.63; 95% CI 1.03-2.58), bilirubin rise of 1 mg/dL (HR=1.13; 95% CI 1.02-1.26), and cyclosporine level increase by 100 mg/dL (HR=1.23; 95% CI 1.13-1.34). Male gender and acute GVHD grade 2-4 were protective. Stage 2-3 and stage 3 AKI were associated with non-relapse mortality at 1 year (HR=3.26; 95%CI 1.65-6.45 and 42.41; 95%CI 16.18-111.18) respectively.

Conclusions: UCT recipients have a high frequency of stage 2 and 3 AKI. Risk factors for AKI appear to be different in the UCT population and further study is warranted to understand these differences.

AKI Associated with Immune Checkpoint Inhibitor Therapy: Incidence, Risk Factors, and Outcomes

Alejandro Y. Meraz-Munoz,[1] Eitan Amir,[2] Christopher T. Chan,[1] David Hogg,[2] Ron Wald,[3] Abhijat Kitchlu.[1] *[1]Nephrology, University Health Network, Toronto, ON, Canada; [2]Princess Margaret Cancer Centre, Toronto, ON, Canada; [3]St. Michael's Hospital, Toronto, ON, Canada*.

Background: Immune checkpoint inhibitors (ICI) are a novel and promising anti-cancer therapy. There is limited data on the incidence, risk factors and outcomes of acute kidney injury (AKI) in patients receiving ICI.

Methods: We conducted a retrospective cohort study of patients receiving ICI at our center between 2010 and 2017 via electronic health record. The primary outcome was AKI [an increase of at least 50% from baseline serum creatinine (sCr)]. Risk factors for AKI were assessed using logistic regression. Survival among those with and without AKI was compared using time-to-event analysis.

Results: Among 309 patients on ICI, 52 (17%) developed AKI (KDIGO Stages 1: 9%, 2: 4%, 3: 4%). AKI was associated with other immune-related adverse events (IRAE) [odds ratio (OR) 3.2 (95%CI: 1.6-6.1), p <0.001], hypertension [4.3 (1.8-6.1), p<0.001] and cerebrovascular disease [9.2 (2.1-40.0), p<0.001]. Baseline sCr, cancer and ICI type were not associated with AKI. Use of ACEi/ARB [OR 2.9 (1.5-5.7), p =0.002], diuretic [OR 4.3 (1.9-9.8), p <0.001] and corticosteroid treatment [OR 1.9 (1.1-3.6), p =0.03] were associated with AKI. In the multivariable analysis, AKI was associated only with other IRAE [2.82 (1.45-5.48) p=0.002] and hypertension [2.96 (1.33-6.59), p=0.008]. AKI was not associated with increased risk of mortality [hazard ratio 1.1 (0.8-1.6, p =0.67). ICI nephrotoxicity was attributed via biopsy or nephrologist assesment in 12 patients (6 intersitial nephritis, 2 membranous nephropathy, 2 minimal change disease, 2 thrombotic microangiopathy). Re-challenge with ICI occurred in 12 patients with AKI, 1 (8.3%) had recurrent AKI.

Conclusions: AKI incidence during ICI therapy may be greater than previously reported and several etiologies must be considered. A minority of patients undergo kidney biopsy. The development of other IRAE is associated with AKI risk. AKI was not associated with worse cancer survival.

Table 1: Logistic regression for risk factors associated with AKI

Variable	Odds Ratio	P value	95% CI

Partial Nephrectomy Was Associated with Increased Risk of Long-Term CKD in Kidney Cancer Patients

Gilberto J. Rodrigues,[1] Giuliano B. Guglielmetti,[1] Veronica Torres,[2] Renato A. Caires,[3] Elerson Costalonga,[4] Maurício Cordeiro,[5] William C. Nahas.[6]
[1]São Paulo State Cancer Institute, São Paulo, Brazil; [2]Sao Paulo State Cancer Institute - USP, Sao Paulo, Brazil; [3]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [4]School of Medicine, University of Sao Paulo, São Paulo, Brazil; [5]São Paulo Institute Cancer Center, São Paulo, Brazil; [6]University of São Paulo Brazil, Sao Paulo, Brazil.

Background: Few prospective studies assessed the risk of late kidney function impairment in kidney cancer (KC) patients (pts) after partial nephrectomy (PN) and most of them are based on measurement of serum creatinine level (SCr). The aim of this study is to perform a serial evaluation of radioisotopic glomerular filtration rate (rGFR) in patients (pts) with KC submitted to PN

Methods: Prospective evaluation of 97 outpts with KC admitted at the Sao Paulo State Cancer Institute between September 2012 and May 2018. All patients were submitted to PN and renal function was evaluated through ^{51}Cr-EDTA rGFR at three different moments: before surgery (pre-rGFR), at three months after surgery (rGFR-3Mo) and twelve months after surgery (rGFR-12Mo). Acute kidney injury was defined as an increase ≥ 50% at the baseline serum SCr. GFR was expressed as ml/min/1.73m^2. Chronic kidney disease (CKD) was defined as rGFR < 60

Results: Patients were 60 ± 12 years, 50.5% male. Hypertension was observed in 66% of pts and diabetes in 25.8%. CKD was observed in 16.5% of patients. KM had 3.30 (2.55-4.55) cm at largest diameter. Pre-operative exams were serum creatinine (SCr) 0.86 (0.75 – 1.06) mg/d and pre-rGFR 80.9 ± 27.3. Trans and immediate post-surgery period (next seven days) developed without serious complications: time of surgery was 120 (90-160) min, blood loss was 200 (100-500) ml, only three patients requiring blood transfusion. AKI was observed in 20.6% of pts, none of them required renal replacement therapy. rGFR-3Mo and rGFR-12Mo were reduced compared to pre-rGFR: 74.37 ± 23.2 (P<0.0001), and 73.23 ± 22.5 (P<0.0001), respectively. CKD prevalence increased at three (23.7%, P= 0.04) and twelve months (21.6%, P= 0.03) compared to the pre-surgery period

Conclusions: Uncomplicated PN was related with reduced rGFR and higher risk of CKD development at the long term in this group of KC patients

SA-PO201

Kidney Dysfunction in Head and Neck Squamous Cell Carcinoma Patients After Cisplatin-Based Concurrent Chemoradiation in a Long-Term (LT) Follow-Up: A Cross-Sectional Study

Thomás G. Rivelli, Veronica Torres, Gilberto Castro. *Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil.*

Background: Cisplatin-based concurrent chemoradiation (CRT) offers to head and neck squamous cell carcinoma (HNSCC) patients (pts) better overall survival, but is associated with significant acute and late toxicity. Here we aimed to study the frequency of kidney dysfunction in HNSCC pts treated with CRT with curative intent in a LT follow-up.

Methods: Cross-sectional study of pts treated at São Paulo State Cancer Institute under regular follow-up. Eligible pts had to be diagnosed with HNSCC and treated with CRT (adjuvant or definitive), with no evidence of disease (NED) for at least 2 years after CRT. Chronic kidney disease (CKD) was defined as glomerular filtration rate (eGFR) < 60ml/min/1.73m2. eGFR was estimated by the CKD-EPI equation.

Results: 120 pts were studied, median age 59 y.o. (21-78), being 88 (73%) male. The most common primary site was oropharynx (50 pts, 42%), followed by larynx (29 pts, 23%), oral cavity (23 pts, 19%), hypopharynx (9 pts, 8%) and nasopharynx (9 pts, 8%). Pts were staged as T3-T4 (87 pts, 75%) or N+ (86 pts, 72%). Comorbidities, such as hypertension or diabetes, were reported by 38 pts (32%). Most of the patients (107 pts, 97%) were ECOG-PS 0 or 1. CRT was administered either as adjuvant (59 pts) or definitive (61 pts) therapy, with a median RT dose of 70 Gy concurrently delivered with cisplatin (total median dose 300mg/m2, ranging from 100-300). Cisplatin-based induction chemotherapy was administered before CRT in 32 pts (total median cisplatin dose 225mg/m2, ranging from 75-300). In a median follow-up of 42 months (24-125) after CRT, we detected a significant increase of serum creatinine (1.01±0.35 mg/dL) in comparison with baseline values (0.84±0.18 mg/dL) (p < 0.001), and a decrease of eGFR (78±20 mL/min) versus baseline (93±19 mL/min) (p < 0.0001). Baseline (pre-treatment) eGFR was inferior to 60 mL/min in only 4 pts (3.4%). and in this analysis, eGFR was below 60 mL/min in 16 pts (14%) (p = 0.004). 44 pts (40%) had a decrease in eGFR above 5 ml/min/1,73m2/year. No clinically significant electrolyte abnormalities were detected and no pts were on dialysis at the end of follow up.

Conclusions: Chronic kidney disease features were frequently diagnosed in HNSCC pts with NED in a LT follow-up after CRT and may contribute to overall morbidity in these pts.

Mortality Rates and Geographic Distribution of Kidney Cancer in Peru

George Vasquez-Rios,[1] Junior S. Torres-Roman,[2] Carlo La vecchia,[4] Javier A. Neyra.[3]
[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]Universidad Nacional San Luis Gonzaga, Ica, Peru; [3]University of Kentucky Medical Center, Lexington, KY; [4]Università degli Studi di Milano, Saint Louis, MO.

Background: Recent data showed decreasing prevalence rates of kidney cancer in the world. However, the epidemiology of kidney cancer in South America remains poorly explored. This study aims to illustrate the case of Peru.

Methods: Secondary data analysis from the Deceased Registry of the Peruvian Ministry of Health (PMH) database (2010 – 2015), which included reports from health care facilities located in 24 provinces, grouped into 3 regions: coast, highlands, and rainforest. Code 189 was used to identify deaths from kidney cancer based on ICD 9th Revision. Deaths were classified according to the birthplace. Calculations were made assuming an underreporting rate of 40%, as estimated by the PMH. We computed age-standardized mortality rates (ASMR, world population) per 100,000 person-year. Cluster map was developed to visualize data across regions.

Results: A total of 2074 kidney cancer deaths in Peru were identified. ASMR (per 100,000 individuals) due to kidney cancer increased in men by 15.3%: from 1.30 (2010-2012) to 1.50 (2013-2015). Similarly, ASMR (per 100,000 individuals) increased among women by 22.6%: from 0.70 (2010-2012) to 0.86 (2013-2015). When stratified by regions, people in the coast had the highest ASMR, in both men (1.83 - 1.99 per 100,000 individuals) and women (0.94 - 1.14 per 100,000 individuals); mainly in the provinces of Lima and Tacna. In contrast, people in the rainforest had the lowest ASMR.

Conclusions: Mortality rates due to kidney cancer have increased in Peru. People from the coast had the highest mortality rates, particularly in Lima and Tacna. The lack of healthcare access for early detection and limited coverage for treatment may play a role in the observed kidney cancer-related mortality rates in Peru. Further studies are warranted to identify modifiable epidemiological risk factors associated with kidney cancer in this country and region.

Provincial, regional and national age-standardized kidney cancer mortality rates per 100,000 in men and women in 2010–2012 and 2012–2015, and rate percentage change

Gender		Men			Women	
	2010-2012	2013-2015	%change	2010-2012	2013-2015	%change
Peru	1.30	1.50	15.3	0.70	0.86	22.6
Coast	1.83	1.99	8.80	0.94	1.14	21.2
Highlands	0.47	0.48	1.60	0.34	0.28	-18.2
Rainforest	0.20	0.28	39.3	0.23	0.15	-32.8

SA-PO203

AKI and CKD Prevalence in Pediatric Neuro-Oncology Survivors

Elizabeth J. Rompies, Kelli A. Krallman, Ralph Salloum, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: In facing an oncologic diagnosis, the pediatric patient may face a host of concomitant diagnoses resultant of required treatments. These diagnoses will often influence life-long follow-up. The nephrologic impact of multimodal treatment regimens for childhood central nervous system (CNS) tumors is a topic of particular interest.

Methods: A pediatric CNS tumor survivor clinic follows patients who have been in remission for a minimum of 5 years. Medical records of 211 clinic patients were examined for renal sequelae of CNS tumor treatment. Patients were classified as having Acute Kidney Injury (AKI), using KDIGO definitions, if more than 2 serum creatinine (SCr) results were available over a 48hr period for trending. Patients were assessed for Chronic Kidney Disease (CKD) using nuclear or estimated GFR, positive proteinuria (PU) and/or microalbuminuria (MAU), and renal ultrasound. Stage I is defined as GFR>120, on 2+ measurements, with PU/MAU. Stage II is defined as GFR<90, and Stage III is defined as GFR<60. Patients with an abnormal renal ultrasound, or with PU/MAU but a normal or above normal GFR, were classified as having a marker of CKD.

Results: Survivors range in age from 7 to 53 years old, with the median age of 21. Eleven of the 211 patients could not be assessed for AKI due to inadequate SCr results. Of the remaining 200 patients, 11 (5.5%) experienced AKI. Evidence of CKD was observed in 62/211 patients (29.4%), six of whom previously had AKI. Of those with CKD, 15 (24.2%) had stage I, 27 (43.5%) had stage II, and 2 (3.2%) had stage III. The other 18 (29.0%) had either persistent PU/MAU with normal or above normal GFR and/or abnormal renal ultrasound.

Conclusions: Surveillance post AKI and mitigation of CKD after cancer remission helps to remove additional burden from pediatric cancer survivors. The high prevalence of CKD markers demonstrates that CNS tumor treatment regimens may cause significant subclinical renal damage during the acute treatment phase. Additional work should be done to assess the incidence of kidney disease in this population, and structure ideal follow-up.

	No CKD	Marker of CKD	CKD Stage I	CKD Stage II	CKD Stage III	Total
No AKI	144	17	14	24	1	200
Previous AKI	5	1	1	3	1	11
Total	149	18	15	27	2	211

SA-PO204

Cancer Risk and Mortality in Patients with CKD: A Population-Based Cohort Study

Abhijat Kitchlu,[1] Jennifer Reid,[6] Nivethika Jeyakumar,[6] Alejandro Y. Meraz-Munoz,[7] Christopher T. Chan,[4] Amit X. Garg,[3] Joseph Kim,[8] Eitan Amir,[5] Ron Wald.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]Toronto General Hospital, Toronto, ON, Canada; [5]Princess Margaret Cancer Centre, Toronto, ON, Canada; [6]ICES, London, ON, Canada; [7]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [8]Toronto General Hospital, University Health Network, Toronto, ON, Canada.*

Background: Patients with chronic kidney disease (CKD) may be at increased risk for cancer. CKD may also confer worse cancer outcomes. Existing data is limited and conflicting regarding the associations between kidney function and outcomes in specific malignancies.

Methods: We conducted a population-based cohort study of all Ontario residents 18 years of age or older with available serum creatinine data in the Ontario Laboratory Information System or inclusion in the Canadian Organ Replacement Register as chronic dialysis or kidney transplant patients between April 1, 2007 and October 31, 2016. We categorized patients according to CKD status [estimated glomerular filtration rate (eGFR) >60, 45-59, 30-44, 15-29, <15 mL/min/1.73m^2, dialysis and transplant recipients] and assessed overall and site-specific cancer incidence and mortality using multivariable Cox models, accounting for competing risks.

Results: Among 5,871,837 individuals with eGFR data, 29,809 on dialysis and 4,951 kidney transplant recipients there were 325,895 cancer diagnoses over 29,993,847 person-years of follow-up. Relative to patients with eGFR >60 mL/min/1.73m^2, total cancer incidence was increased in patients with CKD (stages 3a to 5), adjusted hazard ratios (aHR): 1.07, 95%CI: (1.05, 1.09), 1.04 (1.02, 1.07), 1.01 (0.98, 1.05), 1.13 (1.02, 1.25) on dialysis: 1.31 (1.25, 1.38), and transplant recipients: 1.22 (1.09, 1.36). The risks of bladder, kidney cancer and myeloma were particularly high in patients with CKD. Cancer-specific mortality was increased in CKD (stages 3a to 5), aHRs: 1.21 (1.17, 1.25), 1.30 (1.25, 1.35), 1.45 (1.37, 1.54), 1.41 (1.20, 1.67), dialysis: 1.36 (1.24, 1.49) and transplant: 1.46 (1.16, 1.84). Kidney cancer and myeloma mortality was observed to progressively increase with worsening baseline kidney function. Patients on dialysis had increased risk of mortality related to bladder, kidney cancer and myeloma.

Conclusions: Overall cancer incidence was increased in patients with CKD (stages 3a to 5) and end-stage kidney disease. CKD is associated with increased risks of bladder, kidney cancer and myeloma. Cancer-related mortality is also increased in patients with CKD, on dialysis and post-kidney transplant. Strategies to address the increased burden of cancer in the CKD population are needed.

SA-PO205

Predictors of Mortality in Patients with CKD and Cancer

Antonio Abel Portela Neto,[2] Marcella M. Frediani,[1] Renato A. Caires,[1] Fernanda O. Coelho,[1] Francisco Z. Mattedi,[1] Veronica Torres,[1] Elerson Costalonga.[1] *[1]Sao Paulo State Cancer Institute - USP, Sao Paulo, Brazil; [2]University State of São Paulo, São Paulo, Brazil.*

Background: Cancer patients have a high prevalence of chronic kidney disease (CKD). The aim of this study was to assess prognostic factors for death in cancer patients with CKD.

Methods: Among 516 outpatients with cancer referred to nephrology evaluation (2009-13), 251 had CKD according KDIGO definitions and at least 3 months of follow up. Clinical and biochemical data were retrieved from patient medical records. The Cox regression was used to examine the predictors of mortality.

Results: After a mean follow-up of 4.2±2 years, the mortality rate observed was 57%. The patients features are shown in Table1. In the Cox regression analyses, ongoing chemotherapy [aHR=2.4; CI 1.3-4.5, p=0.004], Karnofsky index < 80 [aHR=2.1; CI 1.1-3.9, p=0.025], and eGFR < 30 ml/min/1.73m^2 [aHR: 1.9; CI 1.0-3.6, p<0.03) were the independent predictors of mortality in our population. Of note, kidney dysfunction remained a independet risk factor for mortality even after adjustments for age and the presence of metastasis.

Conclusions: Patients with cancer and CKD have a poor prognosis. Ongoing chemotherapy, Karnofsky index, and an eGFR lower than 30 ml/min/1.73m^2 were independent factors associated to mortality.

Table 1. Baseline Features

	Death (n=142)	Surviving (n=109)
Age (yr)	67±12	65±11
Female (%)	25	31
Metastasis (%)	37	16*
Ongoing Chemotherapy (%)	50	23*
Karnofsky index < 80 (%)	38	20*
eGFR < 30 (%)	36	22*
Serum Albumin > 4 g/dL (%)	64	75*
Solid tumors (%)	86	82

Study of Relationship Between Etiology of ESRD and Cancer Incidence in Chronic Hemodialysis Patients

Leonid Feldman,[1,2] Anna Katkov,[1,2] Lusia Merkin,[2,3] Marieta Haimov,[1] Zvi Barnea,[1,2] Relu Cernes,[1,2] Ronen Brenner.[2,3] *[1]Nephrology and Hypertension Department, Wolfson Medical Center, Holon, Israel; [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Oncology Department, Wolfson Medical Center, Holon, Israel.*

Background: Previous research has shown that patients with end-stage renal disease (ESRD) treated with dialysis are at increased risk of cancer development. The aim of the present study was to examine a relationship between etiology of ESRD and cancer incidence in patients treated with chronic hemodialysis (HD).

Methods: We conducted a retrospective study of the cohort of hemodialysis patients over the age of 18 treated at teaching hospital between 2008 and 2017. Patients diagnosed with cancer prior to dialysis or with history of transplantation were excluded. Data on cancer diagnoses in the cohort population was collected from the National Cancer Registry. A multivariate analysis was conducted to examine the relationship between the various predictors and the incidence of cancer.

Results: The study included 333 patients, of whom 211 (63.4%) were males. The mean age at start of HD was 67.2±13.1 years. The etiology of ESRD was diabetes in 41%, hypertension in 31%, glomerulonephritis in 7%, cystic kidney disease in 5% and nephrolithiasis in 3% of cases. The median follow-up time was 4 (95%CI, 2.0-6.5) years. 28 patients (8.4%) developed 30 cases of primary malignancy during treatment with hemodialysis. The most common site of cancer was colon (33.3% of cases), followed by bladder (16.7%), kidney (10%) and prostate (10%). Higher patients' age was associated with cancer development: 72.3±7.7 years in patients that developed and 66.7±13.4 years in those that did not develop cancer (p=0.001). No statistically significant relationship was found between ESRD etiology and occurrence of malignancy.

Conclusions: We did not found association between ESRD etiology and cancer incidence in our cohort of hemodialysis patients.

SA-PO207

Dialysis Does Not Affect Outcomes in Stage IV Cancer Patients Admitted to the Intensive Care Unit with AKI at a Comprehensive Cancer Center

Ala Abudayyeh,[2] Maen Abdelrahim,[3] Juhee Song,[2] Sreedhar A. Mandayam,[2] Joseph L. Nates,[2] Alvin H. Moss.[1] *[1]West Virginia University, Morgantown, WV; [2]University of Texas MD Anderson Cancer Center, Houston, TX; [3]Houston Methodist Cancer Center, Houston, TX.*

Background: In advanced cancer patients, prolongation of life with treatment may incur substantial emotional and financial expense. Since acute kidney injury (AKI) in hospitalized cancer patients is known to be associated with poor survival, we investigated whether dialysis use in the intensive care unit (ICU) was a significant independent predictor of higher mortality or worse outcomes.

Methods: We retrospectively reviewed patients admitted in 2005-2014 who were diagnosed with stage IV solid tumors, had acute kidney injury and a nephrology consult. The main outcomes were survival from ICU admission, inpatient mortality and long-term survival after hospital discharge. Log-rank tests and Cox proportional regression were used to compare survival between dialysis and non-dialysis groups. Propensity score matched landmark survival analyses was performed with two landmark time-points chosen at day 2 and at day 7 from ICU admission.

Results: Of 465 patients, 176 needed renal replacement therapy. Landmark analyses at day 2 and day 7 indicated need for dialysis was not associated with worse mortality during ICU admission (HR, 0.926, p=0.6657), adjusting for age, baseline serum albumin, baseline creatinine, baseline, and baseline max SOFA. In the multivariate logistic regression model after adjusting for baseline serum albumin and baseline maximum SOFA, the patients who received dialysis were not less likely to be discharged alive than non-dialysis patients (p=0.9892). To evaluate the impact of dialysis on longer-term survival we evaluated 189 patients who were discharged alive. There was not a longer-term survival benefit after discharge for patients who received dialysis.

Conclusions: Our study found that receiving dialysis in the ICU did not adversely affect survival to discharge and longer-term survival after discharge for patients with stage IV cancer with AKI. Dialysis itself contributed little harm or benefit to survival after discharge of the patient. Prolongation of suffering with no meaningful longer-term survival should always be included in the shared decision-making discussion prior to reaching a decision about the initiation of dialysis in stage IV cancer patients with acute kidney injury.

SA-PO208

Calendar Trends in Cancer Incidence Among US Kidney Transplant Recipients

Christopher D. Blosser,[1,2] Gregory Haber,[3] Eric A. Engels.[3] *[1]University of Washington, Seattle, WA; [2]Seattle Children's Hospital, Seattle, WA; [3]National Cancer Institute, Bethesda, MD.*

Background: Kidney transplant recipients (KTRs) are at 2-4 times greater risk of cancer compared with the general population, and older recipients are at highest risk. Kidney allograft survival is improving with newer immunosuppression and allocation policies. We assessed the changes in incidence of cancers after kidney transplant over time.

Methods: We compared the incidence of cancer in first time kidney-only transplant recipients within three ten-year calendar intervals (1987-1996, 1997-2006, 2007-2016) characterized through linkage of SRTR and cancer registry databases from 17 U.S. states and regions in the Transplant Cancer Match Study. KTRs were excluded for a cancer diagnosis before or within 90 days post-transplant, if transplanted before cancer registry coverage, or HIV infection. First cancers were identified from cancer registries if <5 years of transplant. We analyzed overall cancer and post-transplant cancers: colorectal, lung, melanoma, breast, prostate, kidney, and non-Hodgkin lymphoma (NHL). Non-melanoma skin cancer is not reported to cancer registries. Poisson regression was used to compare incidence rate ratios (IRR) across time intervals among KTRs with the earliest era as the reference, and adjusted for risk factors including age at transplant, gender, primary cause of ESRD, time on transplant waiting list, BMI, type of kidney donor, and maintenance immunosuppression.

Results: The KTR population increased in age over the three decades - mean age 44.3, 48.6, and 50.9 years, respectively. Unadjusted IRR of overall cancer in KTRs appeared to increase over this period, but IRRs decreased after adjusting for age and other variables; Differences across decades were not significant. Adjusted IRRs for most common post-transplant cancers decreased nonsignificantly over time, except for kidney cancer, which appeared to increase.

Conclusions: Overall cancer incidence has trended downward amidst an older KTR population in the last three decades. Kidney cancer incidence may have risen over time while all other common cancer IRRs were stable or lower. The reasons for the age-adjusted decline over time may include better cancer screening, tighter transplant listing criteria, and changes in immunosuppression.

Risk Factors for Advanced Colorectal Neoplasia in CKD

Eric H. Au.[1,2] DETECT Study Investigators *[1]School of Public Health, Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.*

Background: Colorectal cancer is common in people with chronic kidney disease (CKD), but the risk factors are poorly understood. The aim of this study is to identify risk factors for advanced colorectal neoplasia in people with CKD (as a sub-study of DETECT).

Methods: People with CKD (stages III-V, dialysis and transplant) across eleven sites in Australia, New Zealand, Canada and Spain were screened for colorectal neoplasm using fecal immunochemical test (FIT). Advanced colorectal neoplasia was identified through a 2-step verification process with colonoscopy following a positive FIT and 2-year clinical follow-up for all patients. Potential risk factors for advanced colorectal neoplasia at different CKD stages were assessed using multivariable logistic regression.

Results: A total of 1706 patients received FIT screening (791 CKD III-V, 418 dialysis, 497 transplant). 323 (18.9%) had colonoscopy for positive FIT and 103 advanced colorectal neoplasia (44 CKD III-V, 31 dialysis, 28 transplant) were identified (overall detection rate 6%). At follow-up, 14 additional advanced neoplasia (10 CKD III-V, 3 dialysis, 1 transplant) were identified. Across CKD stages, older age and male sex were risk factors for advanced colorectal neoplasia (figure). Current smoking use was associated with advanced colorectal neoplasia among those with CKD III-V [odds ratio 2.3 (95% CI 1.1-4.9)]. For those on dialysis, patients with diabetes experienced 2.1 times greater odds of advanced colorectal neoplasia (95% CI 1.0-4.4). For kidney transplant recipients, daily anticoagulant use was associated with increased odds of advanced colorectal neoplasia [OR 4.5 (95% CI 1.5-13.4)].

Conclusions: Increasing age, smoking, male sex and having diabetes are associated with advanced colorectal neoplasia in patients with CKD. The observed increased risk associated with anticoagulation use in transplant recipients may be due to increased detection by FIT.

Increased Risk of Cutaneous Squamous Cell Carcinoma in Organ Transplant Recipients and Patients on Chronic Dialysis: A Cancer Registry-Based Study in Taiwan

Yuh-Mou Sue.[1,2] *[1]Department of Internal Medicine, Taipei Medical University-Wan Fang Hospital, Taipei, Taiwan; [2]Department of Internal Medicine, Taipei Medical University, Taipei, Taiwan.*

Background: Organ transplant recipients (OTRs), patients on chronic dialysis, and those with chronic kidney disease (CKD) have immune dysregulation and are at higher risk of skin cancers. However, the predominant histological skin cancer subtype in these populations has not been well-investigated among Asians. This study aimed to investigate the predominant histological skin cancer subtype among OTRs, patients on chronic dialysis, and those with CKD in Taiwan.

Methods: We obtained data between 2007 and 2014 from the Taiwan Cancer Registry Database and the National Health Insurance Research Database. The proportions of certain histological skin cancer subtypes in OTRs, patients on chronic dialysis, and those with

CKD were compared against those in the control group using a generalized estimating equation regression model.

Results: Among 23,644 patients with skin cancer, 53 were OTRs, 255 had chronic dialysis, 1,792 had CKD, and 21,544 were placed in the control group. The proportions of squamous cell carcinoma (SCC) were 52.8%, 47.8%, 40.1%, and 33.5%, respectively. Compared with the control group, OTRs (1.99-fold) and chronic dialysis patients (1.25-fold) were found to have higher risk of developing SCC than other skin cancers after adjustment for potential confounding factors. Other subgroups or covariates associated with increased SCC risk included CKD patients aged < 70 years (vs. control group; 1.3-fold), old age (vs. young age; 2.8-fold), male sex (vs. female sex; 1.1-fold), and south-Taiwan residency (vs. north-Taiwan residency; 1.1-fold).

Conclusions: OTRs and patients on chronic dialysis had a greater risk of developing SCCs than other skin cancer subtypes.

SA-PO211

Diversity of Nutritional Status in Patients with Cancer and CKD

Micheline T. Souza,[2] Luiz A. Gil,[5] Renato A. Caires,[4] George B. Coura-Filho,[1] Elerson Costalonga,[3] Marcelo T. Sapienza,[7] Andrew S. Levey,[8] Lesley Inker,[8] Emmanuel A. Burdmann,[6] Veronica Torres.[2] *[1]ICESP, São Paulo, Brazil; [2]Sao Paulo State Cancer Institute - USP, Sao Paulo, Brazil; [3]School of Medicine, University of Sao Paulo, São Paulo, Brazil; [4]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [5]ICESP/ FMUSP, SAO PAULO, Brazil; [6]University of Sao Paulo Medical School, Sao Paulo, Brazil; [7]HCFMUSP, Sao Paulo, Brazil; [8]Tufts Medical Center, Boston, MA.*

Background: Cancer patients (pts) constitute a population with heterogeneous range of nutritional status. There is scanty prospective data on nutrition aspects of cancer pts with chronic kidney disease (CKD).

Methods: A group of solid cancer pts with CKD (not in dialysis) admitted for treatment (AT) or already in follow-up (FU) at a cancer hospital in Brazil (São Paulo State Cancer Institute) was prospectively evaluated between April 2015 and October 2017. Patients underwent an evaluation including bioimpedance exam, weight, height and subjective nutritional assessment questionnaire (PG-SGA), assessment of the glomerular filtration rate through 51 Cr-EDTA (rGFR), serum creatinine (SCr) and albumin (Alb). Chronic Kidney Disease (CKD) was defined as rGFR <60 ml / min / 1.73 m2. Sarcopenia was defined when as Fat Free Mass Index ≤17.4kg/m2 for men and ≤15kg/m2 for women.

Results: One hundred sixty-one pts were enrolled. Pts characteristics were age 69.92 ± 10.46 years, 61.5% male, 72% AT. Most common tumor origins were: genitourinary tract 41%; gastrointestinal tract 12.4%, breast cancer 13.7%. ECOG was 0-1 in 89.5%, clinical stage III and IV comprised 53.4% of pts, with evidence of metastatic disease (MD) in 22.4%. Median rGFR was 49.9 (39.67 – 55.81) ml/min/1.73m2, SCr was 1.18 (0.96 – 1.44) mg/dL and Alb was 4.30 (4.10 – 4.60) g/dL. Nutrition evaluation revealed: weight 71 (62.6-80.35) Kg; body mass index (BMI) 25.71 (22.3 – 29.1); fase angle 5.20 (4.60 – 5.90); fat free mass 46.4 (39.4-56.25) Kg. BMI was < 23 in 29.8% and > 28 in 34.2% of pts. Sarcopenia was observed in 28.6% of pcts and 81.4% of pcts were considered well nourished by PG-SGA. AT and FU pcts presented no difference in either baseline variables (age, ECOG, MD, comorbidities, clinical stage, SCr, Alb) and in most of nutrition aspects (weight, sarcopenia, fase angle, fat free mass) (data not shown). FU pcts presented higher BMI (27.1 [24.2 – 30.20] vs 25.10 [22.2 – 28.7], P=0.330 and higher prevalence of well-nourished status by PG-SGA (93.3 vs 76.7%, P=0.015).

Conclusions: The nutritional status in cancer pts with CKD is diverse, ranging from significant malnutrition to expressive overweight both for AT and FU pts.

SA-PO212

Obesity and Renal Outcome in Patients with Renal Cell Carcinoma

Sewon Oh,[1] Kyungmi Lee,[1] Kijoon Lim,[1] Jihyun Yang,[2] Myung-Gyu Kim,[1] Sang-Kyung Jo.[3] *[1]Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea; [2]Korea university medical college, Seoul, South Africa; [3]Korea University Hospital, Seoul, Republic of Korea.*

Background: Epidemiologic studies has been shown obesity is associated with renal cell carcinoma (RCC). Obesity causes dysregulation of adipokines, activation of inflammatory cytokines, angiogenesis, and may lead to development RCC and renal injury. We evaluate the relationship of obesity with the risk of RCC and renal outcomes in urologic cancers. In addition, we evaluate the effect of inflammation on the risk of RCC.

Methods: A total of 6,218 patients were enrolled in patients diagnosed with urological cancer at two University Hospital from 2001 to 2019. Obesity was defined as body mass index (BMI) ≥ 30 kg/m^2.

Results: The mean age of the patients was 65.5± 12.0 years and 87.3% was male. Out of 6,218 patients, 1011 were diagnosed with RCC, 2002 with urothelial cancer, 136 with genital cancers and 2979 with prostate cancers. RCC was significantly related to younger age, diabetes, higher BMI, CRP and monocyte count. RCC showed 1.584-fold increased risk of obesity than prostate cancer (95% CI, 1.097-2.288). Compared than non-obese patients, obesity was associated with risk of RCC in urologic cancers (RR, 1.901, 95% CI, 1.326-2.724). Serum monocyte count is a stronger risk factor for the risk of RCC (RR, 3.461; 95% CI, 1.079-11.095) in obese patients than non-obese patients (2.714, 95% CI, 1.648-2.867). Obese patients showed higher incidence of 30% and 40% eGFR decline in urologic cancers during 7.7±1.2 years of mean follow up (P<0.05). Obesity was related to increased risk of 40% eGFR decline in urologic cancers by multivariate analysis (1.596, 95% CI, 1.074-2.371).

Conclusions: Obesity was significantly associated with the prevalence of RCC than other urologic cancers. Serum monocyte count is a stronger risk factor for the RCC in obese patients. Obese patients had significant worse renal outcomes in urologic cancers.

SA-PO213

Comparing Glomerular Filtration Rate Equations with ^{51}Cr-EDTA in Patients with Renal Tumors

Gilberto J. Rodrigues,[1] Giuliano B. Guglielmetti,[4] Veronica Torres,[2] Elerson Costalonga,[3] Maurício Cordeiro,[5] Renato A. Caires,[6] William C. Nahas.[7] *[1]ICESP - USP (Sao Paulo State Cancer Institute, University of Sao Paulo), São Paulo, Brazil; [2]Sao Paulo State Cancer Institute - USP, Sao Paulo, Brazil; [3]School of Medicine, University of Sao Paulo, São Paulo, Brazil; [4]São Paulo State Cancer Institute, São Paulo, Brazil; [5]São Paulo Institute Cancer Center, São Paulo, Brazil; [6]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [7]University of São Paulo Brazil, Sao Paulo, Brazil.*

Background: Assessment of glomerular filtration rate (GFR) is a crucial element to plan surgical strategies in patients with renal tumors. However, the estimate GFR (eGFR) trough equations was not validated in these patients. The aim of this study is to compare the performance of Chronic Kidney Disease Epidemiology Collaboration Equation (CKD-EPI), abbreviated Modification of Diet in Renal Disease (aMDRD) and Cockcroft-Gault (CG) equations with 51Cr-EDTA in patients with renal tumors eligible to surgical treatment.

Methods: Prospective evaluation of 142 outpatients with renal tumors and submitted to partial nephrectomy at Sao Paulo State Cancer Institute between April 2013 and November 2018. All patients were evaluated before surgery with ^{51}Cr-EDTA (rGFR) and serum creatinine (SCr), standardized to the isotope-dilution mass spectrometry reference method. rGFR and eGFR were expressed as ml/min/1.73 m^2.

Results: Patients were 59.4 ± 10.6 y, 50.2% male, 97.9% white. Renal tumor has 3.50 (2.70-4.72) cm at largest diameter and was malignant (histology confirmed post surgery) in 85% of cases. Comparing renal function before surgery, SCr was 0.86 (0.74 – 1.10) mg/d, rGFR was 81.1 ± 22.5 and rGFR < 60 was observed in 18% of pts. eGFRs using the CKD-EPI, aMDRD and CG equations were 80.6 ± 20, 77.3 ± 20.8, and 89.2 ± 30.6, respectively. CG and aMDRD showed significant differences in the means from the paired t-Test when compared to rGFR (P<0.05) (Figure 1 - Table 1). CKD-EPI equation demonstrated satisfactory precision and higher accuracy (Figure 1 - Table 2).

Conclusions: CG and aMDRD equations performed poorly compared with rGFR in this group of patients with renal tumors. CKD-EPI equation demonstrated adequate performance and should be considered when deciding upon surgical strategies in the setting of renal tumors.

Table 1: Mean bias rGFR vs eGFR

eGFR	Mean bias (entire group)	rGFR < 60	rGFR ≥ 60
CKD-EPI	+ 0.38	-7.91	+2.17
P value	*0.792*	*0.051*	*0.164*
aMDRD	+ 3.67	-6.21	+5.79
P value	*0.016*	*0.087*	*0.001*
CG	- 7.68	-5.86	-8.08
P value	*<0.0001*	*0.011*	*<0.0001*

If (-): eGFR overestimed rGFR. If (+): eGFR underestimated rGFR

Table 2: Percentage of studies with eGFR within 10 and 30% of the rGFR

	% within 10% of rGFR	% within 30% of rGFR
aMDRD	27.5	79.6
CKD-EPI	34.5	83.1
CG	29.6	71.8

SA-PO214

Dipstick Proteinuria and Cancer Incidence: A Nationwide Population-Based Study

Shin-Young Ahn,[1,2] Gang Jee Ko,[1,2] Young-Joo Kwon.[1,2] *[1]Korea University Medical Center, Korea University Guro Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Korea University College of Medicine, Seoul, Republic of Korea.*

Background: Proteinuria is a representative indicator of chronic kidney disease (CKD) and an independent risk factor for both cardiovascular and non-cardiovascular mortality. Given that a major cause of non-cardiovascular mortality is malignancy, the association between proteinuria and malignancy has been discussed for several decades. We evaluated the clinical implication of dipstick proteinuria as a predictor for malignancy using nationwide population-based data.

Methods: We included subjects who had undergone a medical examination in 2009 (index year). Among 10,505,818 participants, we excluded subjects who did not satisfy the inclusion criteria. Finally, 9,714,387 subjects were included in this study and were followed from the index year to December 31, 2017. We categorized the results of dipstick proteinuria into three groups; negative (-), trace (±), overt proteinuria (more than 1+).

Results: The participants with overt proteinuria were more likely to be older, have hypertension, diabetes, and dyslipidemia. During the follow up period, we observed that overt proteinuria at baseline correlated with the risk of overall cancer incidence, even after it was adjusted by age, gender, smoking history, degree of exercise and diabetes (HR 1.151, 95% CI, 1.133 – 1.169, referenced to no proteinuria). In terms of site-specific cancer, the risks of colorectal, liver, lung, cervical, esophagus, kidney, bladder, and prostate cancer incidence gradually increased in proportion to the degree of proteinuria. In order to observe the risk of cancer incidence according to the change in proteinuria, we used the same participant's records from the 2005 NHID (National Health Insurance Database). We demonstrated that the risk of cancer incidence increased proportionally according to the changes in dipstick proteinuria over four years.

Conclusions: We elucidated the dose-response relationship between the degrees of dipstick proteinuria and the graded risk of overall and site-specific cancer development. We also observed that the long-term risk of cancer incidence increased proportionally according to the changes in dipstick proteinuria over four years.

SA-PO215

Combining a Digital Platform and Point-of-Care (POC) Testing to Extend Kidney Patient Participation in Cancer Trials: Technical Feasibility and Patient Acceptability Study (IDecide Program)

Leanne A. Ogden,[1] Sandip Mitra.[2] Digital Experimental Cancer Research Team
[1]Manchester Royal Infirmary, Manchester, United Kingdom; [2]Manchester University Hospitals, UK, Sale, United Kingdom.

Background: Recruitment to cancer clinical trials is an ongoing challenge and usually limited to patients with preserved kidney function. Eligibility often restricts recruitment to those with an eGFR of >50ml/min, this is arbitrary and not a risk-based approach driven by current clinical science in nephrology. Due to increased survival rates for both conditions, there is a significant population with both cancer and reduced kidney function. The aim of this body of research is to assess whether new technological advances in POC creatinine meters and digital science can be used to modernise eligibility criteria in oncology clinical trials through personalised risk-based monitoring. We created an approach that explored the potential and acceptability of using a POC device, data capture via a smartphone, and risk-categorisation through an Acute Kidney Injury (AKI) algorithm, to enable decision-making and the first step in addressing this unmet clinical need.

Methods: Three POC devices were evaluated for usability, size and complexity. A smart phone app was developed, which captures device data and sends securely to a Cloud environment. Creatinine testing, calibration and patient acceptability in the hospital was conducted over a 2 week period with 17 interactions (patient/carer/nurse), including 2 patient focus group with 8 participants from oncology and nephrology backgrounds.

Results: The Nova Biomedical Creatinine StatSensor® was the device chosen to enable home creatinine readings with good end user feedback and stable performance characteristics. The app user interface design was acceptable with patients based on patient acceptability testing.

Conclusions: This initial proof of concept successfully demonstrated that creatinine can be measured by a POC device, the data captured by an app and reported in near-real time. We have now developed a clinical rules engine based on the NHS/NICE published algorithm for AKI; and will be applying this to a clinical trial to detect AKI in patients receiving chemotherapy to quantify the potential clinical benefits. We aim that this will be the first step in a body of work to challenge traditional eligibility criteria for clinical trials and improve outcomes for this population of patients, through first improving their recruitment to cancer clinical trials.

SA-PO216

Effect on Renal Function of Repeated Administrations of Contrast Media in Cancer Patients Nephrectomized for a Metastatic Renal Cell Carcinoma: A Retrospective Italian Study

Laura Cosmai,[1] Meri Pedone,[2] Camillo Porta,[3] Marina Foramitti,[4] Nicole Gri,[5] Maurizio Gallieni,[6] Mario Cozzolino.[7] *[1]San Carlo Borromeo Hospital, Milano, Italy; [2]ASST Santi Paolo e Carlo Borromeo - Ospedale San Carlo Borromeo, Milan, Italy; [3]University of Pavia, Pavia, Italy; [4]ASST Cremona, Cremona, Italy; [5]I.R.C.C.S. Istituti Cllinici Scientifici Maugeri, Pavia, Italy; [6]Ospedale San Carlo Borromeo - ASST Santi Paolo e Carlo - University of Milano, Milano, Italy; [7]Department of Health Sciences, University of Milan, Milan, Italy.*

Background: Patients with renal carcinoma (RCC) presents with concomitant chronic kidney disease (CKD) with a frequency which is about twice that of the general population; moreover, being often nephrectomised and therefore with a reduced renal functional reserve (RFR), they also present a higher incidence of acute kidney failure (AKI). Thus, we decided to evaluate the progression of renal impairment in metastatic RCC patients who underwent computed tomography (CT) scans every three months, being enrolled in experimental trials. The presence of risk factors for CKD and the possible correlation with the time elapsed between nephrectomy and the first CT scan showing the presence of metastatic disease was also evaluated

Methods: We analyzed a total of 76 patients, 59 males (78%) and 17 females (22%); 68 (89.5%) were nephrectomized for neoplasia (average age: 59.72, standard deviation (SD): 10.51; average Body Mass Index: 26.55, SD: 4.47). The trend of renal function was evaluated on the 40 mRCC patients for which all the data investigated at the following timepoints were available: T0 (i.e. baseline), T3, T6 and T9

Results: The eGFR trend (calculated by means of the CKD-EPI formula) was substantially stable, a drop of just 2 ml/min in 9 months having been observed. Intriguing, and statistically significant (p = 0.007), was the finding of a more marked worsening of eGFR (10 ml/min in 9 months) in hypertensive patients, worsening that is not observed in the other populations of patients considered, and that it could have been caused by the additional effect of the antiangiogenic drugs used. No correlations were found between renal function and the time elapsed between nephrectomy and the first CT scan

Conclusions: Even in nephrectomized patients, CT contrast medium appears to play a secondary role on the incidence of AKI, or on worsening of CKD. We should therefore be more liberal in the use of contrast medium, even in nephrectomized cancer patients

SA-PO217

Persistence of CKD and Hypertension at 12 Months After Cisplatin Therapy in Children

Asaf Lebel,[2] Kelly McMahon,[1] Vedran Cockovski,[2] Jasmine Lee,[2] Mariya Yordanova,[3] Louis Huynh,[4] Frédérik Crépeau-Hubert,[10] Tom D. Blydt-Hansen,[5] Cherry Mammen,[6] Maury N. Pinsk,[7] Shahrad R. Rassekh,[6] Kirk R. Schultz,[6] Ross T. Tsuyuki,[8] Michael Zappitelli.[2,9] *[1]Research Institute, McGill University Health Centre, Montreal, QC, Canada; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]Montreal Children's Hospital, Montreal, QC, Canada; [4]School of Medicine, Queen's University, Kingston, ON, Canada; [5]University of British Columbia, Vancouver, BC, Canada; [6]British Columbia Children's Hospital, Vancouver, BC, Canada; [7]University of Manitoba, Winnipeg, MB, Canada; [8]University of Alberta, Edmonton, AB, Canada; [9]University of Toronto, Toronto, ON, Canada; [10]McGill University, Montreal, QC, Canada.*

Background: Cisplatin (CisP) commonly causes acute kidney injury (AKI). Late CisP-nephrotoxicity (chronic kidney disease (CKD); hypertension (HTN)) is poorly characterized in children. We determined prevalence and progression of CKD and HTN 3 and 12 months (m) post-CisP therapy, and if CisP-AKI is associated with these outcomes.

Methods: 12 Canadian-site prospective cohort study. Protocol: Children treated with CisP were followed during cancer therapy (labs, clinical data) and at 3 and 12m post-CisP therapy completion (blood pressure [BP], blood and urine collection). AKI during cancer therapy: defined per KDIGO serum creatinine criteria. Outcomes: a) CKD: eGFR <90ml/min/1.73m^2 or urine albumin/creatinine ratio ≥3mg/mmol; b) elevated BP and HTN, per 2017 child HTN guidelines. Paired t-tests and McNemar's test used to determine if outcome prevalence differed from 3 to 12 m. Logistic regression (odds ratio [OR], 95% CI) used to determine relation of AKI with 3 and 12m CKD and HTN.

Results: Of 159 patients (50.3% male; median age 5.5 [IQR 2.4–11.9] yrs), 37 % developed AKI. Figure (1): There was no significant change in 3 *vs.* 12m prevalence (McNemar p-values all >0.05) of any outcomes (CKD: 44% and 39%, respectively; HTN: both 17%). eGFR was significantly lower at 12 *vs.* 3m (Figure (2), median [IQR] 135.8 [52.1] vs. 120.6 [37.4], respectively, p-value <0.001). AKI during CisP therapy was associated with 3 and 12m CKD (OR 2.2 [95% CI 1.2-4.4] and 2.8 [95% 1.4-5.6], respectively) but not HTN (OR 1.6 [95% CI 0.7-3.9] and 2.1 [95% CI 0.9-5.1], respectively).

Conclusions: CKD and HTN were common and persisted from 3m to 12m after cancer therapy completion. AKI was associated with later CKD but not HTN. Research on interventions to prevent AKI and reduce post-CisP CKD and HTN is needed.

Funding: Government Support - Non-U.S.

Anemia Management in Hemodialysis Patients: How Much Better Can We Do?

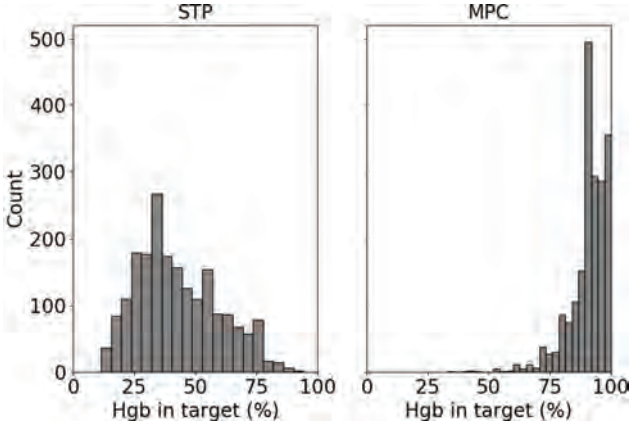
Sabrina Rogg,[1] Doris H. Fuertinger,[1] Stefan Fuertinger,[2] Alhaji Cherif,[3] Peter Kotanko,[3,4] Stefan Volkwein.[5] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Ernst Strüngmann Institute (ESI) for Neuroscience in Cooperation with Max Planck Society, Frankfurt am Main, Germany; [3]Renal Research Institute, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]University of Konstanz, Konstanz, Germany.*

Background: The goal of anemia management with erythropoiesis-stimulating agents (ESA) is to achieve target hemoglobin (Hgb) levels while keeping drug doses low. Built on a physiology-based mathematical model of erythropoiesis (Fuertinger et al., PLoS ONE 2018), we developed an optimal control algorithm for individualized methoxy polyethylene glycol-epoetin beta (Mircera®) dose optimization.

Methods: The designed algorithm is a model predictive controller (MPC) that aims to stabilize Hgb levels at 10.5 g/dl. We compared the MPC administration regimen to a standard treatment protocol (STP) in an in-silico study for 6,659 chronic hemodialysis (HD) patients over a period of one year. Based on the Hgb levels obtained by the protocol, the in-silico population was divided into Hgb cyclers (cycles with amplitude >1.5 g/dl and duration >8 weeks, at least two cycles per year) and non-cyclers as defined by Fishbane & Berns (Kidney Int., 2015) yielding 1,987 cyclers.

Results: For non-cyclers, the MPC and STP regimens produced similar outcomes with respect to achieving Hgb targets and ESA usage. However, for cyclers, the MPC outperformed the STP. Cyclers' percentage of Hgb values within the target range of 10-11.5 g/dl for both treatment approaches are shown in Figure 1. The MPC lead to 91% of cyclers with at least 80% of Hgb values within the range and lowered the monthly Mircera® dose on average by 30%.

Conclusions: Our analysis shows a clear potential for better anemia management in Hgb cyclers as a subpopulation of HD patients: The MPC stabilized Hgb levels with a significantly reduced amount of Mircera® in this in-silico study. For non-cyclers, the STP could not be outperformed. Clinical studies are warranted to validate these findings.



Cyclers' percentage of Hgb values within the target range of 10-11.5 g/dl for the MPC and STP regimen.

SA-PO219

Anemia Disrupts Renal Compensatory Responses After Uninephrectomy in Mice

Daisuke Nakano,[1] Akira Nishiyama.[2] *[1]Kagawa University, Kagawa, Japan; [2]Kagawa University Medical School, Kita-Gun, Japan.*

Background: Kidneys with functional nephrons are essential for our life, but the numerous factors could reduce the numbers of nephron day by day. Kidney has ability to adapt its size and function against the nephron loss to maintain total renal function, for example, in both donor and recipient in renal transplantation. However, the factors that regulate this compensation have not been fully clarified yet. Hereby we examined the effects of erythropoietin (EPO)/anemia on the compensatory renal hypertrophy in mice model of renal anemia.

Methods: The mice lacking renal EPO production were used.

Results: The anemic mice showed renal compensatory responses, such as GFR more than half and cell hypertrophy, similar to normoxemic mice at week 1 after unilateral nephrectomy (UNX). However, the compensation was disrupted only in anemic mice at week 4 after UNX; the mice lacking EPO receptor in the kidney showed successful compensation. The disruption was accompanied by the increased oxidized glutathione and sustainable phosphorylation of ribosomal protein S6, a marker of mTOR activation, which had been decreased after successful compensation in the normal mice. In the renal interstitium of anemic mice at week 4 of UNX, the number of cells promoting epo gene transcription (but disable to produce EPO protein in the mice) was reduced even under the anemia, and the number of α-smooth muscle actin-positive cells was increased, suggesting the transdifferentiation of EPO-producing cells. These changes were restored by the supplementation of rEPO.

Conclusions: Anemia does not affect the onset of compensatory renal hypertrophy after UNX, but disrupts the persistent compensation process.

Patient-Specific Characteristics of Erythropoiesis and Their Influence on Hemoglobin Stability

Doris H. Fuertinger,[2] Stefan Fuertinger,[4] Alhaji Cherif,[1] Sabrina Rogg,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Ernst Strüngmann Institute (ESI) for Neuroscience in Cooperation with Max Planck Society, Frankfurt am Main, Germany.*

Background: In hemodialysis (HD) patients treated with erythropoiesis-stimulating agents (ESA) maintaining hemoglobin (Hgb) levels within recommended ranges is difficult. Many patients express Hgb excursions above and below the target range over the course of a year. This Hgb variability is associated with clinical events and ESA dose changes. This study investigates differences in biological key characteristics of erythropoiesis in HD patients and its influence on Hgb stability.

Methods: We adapted a comprehensive mathematical model of erythropoiesis to individual HD patients treated with methoxy polyethylene glycol-epoetin beta to estimate key characteristics of their red blood cell (RBC) reproduction cycles (Fuertinger, Plos One 2018), including RBC lifespan, endogenous EPO levels, ESA half-life and ESA influence on apoptosis and maturation velocity of RBC progenitors. In-silico tests were performed to distinguish Hgb "cyclers" from "non-cyclers" (criteria per Fishbane & Berns, Kidney Int. 2005). Estimated physiological parameters are depicted as violin plots, groups are compared by t-test.

Results: We estimated patient-specific characteristics of erythropoiesis in 6659 HD patients (♀: 46 %, Black: 43 %, mean ± SD: age 64 ± 14 years, BMI: 29.4 ± 7.6 kg/m^2). 29.8% were categorized as Hgb cyclers. Figure 1 compares erythropoiesis characteristics between cyclers and non-cyclers. We observed a statistically significant difference between Hgb cyclers and non-cyclers in RBC lifespan (mean±SD: 72±18 vs 78±21 days), endogenous EPO levels (13±6 vs 18±8 U/l), ESA half-life (159±46 vs 115±57 hours) and anti-apoptotic effects.

Conclusions: Patient-specific parameter estimates suggest that certain underlying biological characteristics may predispose patients to Hgb cycling. A better understanding of these effects could permit tailoring anemia algorithms to this subgroup to improve their Hgb variability and eventually clinical outcomes.

The In Vitro Effect of Indoxyl Sulfate in Erythropoiesis of Human Hematopoietic Stem Cells: An Explanation of Anemia in CKD

Manoch Rattanasompattikul,[1,2] Aungkura Supokawej,[3] Moltira Promkan,[3] Sumana Masoodi,[3] Nuttawut Rongkiettechakorn.[1,2] *[1]Golden Jubilee Medical Center, Mahidol University, Nakhon Pathom, Thailand; [2]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [3]Faculty of Medical Technology, Mahidol University, Nakhon Pathom, Thailand.*

Background: The pathogenesis of anemia in chronic kidney disease (CKD) has been suggested to result from erythropoietin (EPO) insufficiency; however, several anemic CKD patients showed average to high plasma EPO levels. The presence of uremic toxins in patients with CKD has been suggested by several lines of evidence, including inhibition of erythroblast maturation. We suspected that EPO deficiency might not be the mainstay of anemia in CKD and then we focused on the effect of uremic toxins on the maturation of hematopoietic stem cells.

Methods: The effects of uremic toxin on red blood cell development was evaluated using hematopoietic stem cell (HSC) cultures. HSCs were isolated from umbilical cord blood using magnetic cell sorting to indicate CD34 positive cells. HSCs were then grown in differentiation medium combination with various concentrations of indoxyl sulfate (IS). Cell proliferation, viability, cell morphology, and erythrocyte specific markers were identified.

Results: The lower cell number in HSCs treated with IS was investigated in a dose-dependent manner. Proliferation and the percent viability of CD34 positive cells culture were observed with culture medium containing 0 (control), 25, 50, 100, and 200 ug/mL IS shown as Figure A. Erythrocyte differentiation tends to decline as demonstrated by lower numbers of CD235 and CD71 positive cells. Mature cells were counted using cell morphology assessments.

Conclusions: These findings conclude that uremic toxin (IS) appears to be a factor governing defective erythropoiesis. However, the pathogenesis of anemia involves multi-step processes that might be affected by the other types of uremic toxins and factors.

Funding: Government Support - Non-U.S.

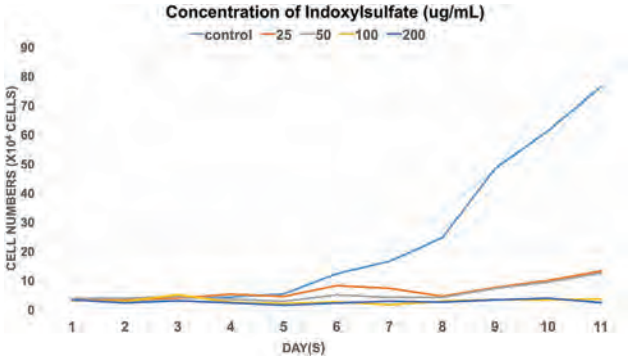

Figure A The proliferation of CD34 positive cells culture was observed for 11 days. Cells cultured with culture medium containing 0 (control), 25, 50, 100 and 200 ug/mL Indoxyl sulfate (IS)showed that all IS-treated cells decreased in cell number compared with control since day 6 of culture.

LDL Lipidome and Erythropoiesis Stimulating Agent Response in Hemodialysis Patients

Will Risinger,[1] Jordan T. Perkins,[1] Daniel W. Wilkey,[2] Brad H. Rovin,[3] Jonathan Himmelfarb,[4] Alfred A. Jacobs,[6] Jon B. Klein,[2,5] Michael E. Brier,[2] Michael Merchant.[2] *[1]University of Louisville School of Medicine, Louisville, KY; [2]University of Louisville Kidney Disease Program, Louisville, KY; [3]Ohio State University Wexner Medical Center, Columbus, OH; [4]Kidney Research Institute, Seattle, WA; [5]Robley Rex VAMC, Louisville, KY; [6]University of Louisville, Louisville, KY.*

Background: Anemia management in end-stage renal disease (ESRD) is difficult due to variable erythropoiesis stimulating agent (ESA) response. Hemodialysis alters lipoprotein composition. Additionally in-vitro erythropoietic burst assays respond to changes in lipoprotein supplementation; suggesting a role in RBC formation. We have previously shown HDL proteome differs with ESA response in maintenance hemodialysis (HD) patients. We hypothesized HD patients ESA response was associated with HDL/LDL composition.

Methods: HDL & LDL were isolated by dextran sulfate precipitation (n=105 patient samples). Purity was assessed by immunoblot and proteomics. Total cholesterol (Cho), phospholipid (PL) and triacylglycerol (TAG) were quantified by enzyme assay. Avanti SPLASH™ LipidoMix® standards were added before Bligh-Dyer LDL lipid extraction. LCMS analysis and informatics used Waters UPLC-Synapt G2-Si Q-Tof MSe (+/- ion modes) with Progenesis QI + LipidMAPS database. Data were normalized to internal spike-in and total Cho; results filtered based on mass accuracy (<15ppm), fragmentation score, and isotopic matching. Categorical differences (ESA naïve (38), ESA hyper (23)-, ESA normal (22)-, and ESA hypo-(22) responders) were compared by ANOVA, and continuous differences with Spearman correlation.

Results: LDL Cho but not HDL Cho was negatively correlated ($p<0.05$) with ESA utlization. Lipidomics identified 222 LDL-associated lipids including 36 different by ANOVA ($p<0.05$)- 22 increased and 3 decreased with EPO-dose response groupings; 11 lipids changed with EPO use relative to EPO naïve patients. Post-hoc ttest shows significant increase of four lipids (hyper-to-hypo-EPO response) including a cholesterol ester, ceramide, and a vitamin D3 analogue. Spearman analysis revealed LDL-lipid correlation to EPO dose (10), ESA response index (7), ferritin (12), hepcidin (3), and CRP (2); including polyunsaturated (PU)-ceramides, lysophosphatidylcholine, oxidized phosphoglycerolipid, Cho-esters and a statin.

Conclusions: In this study poor HD patient-ESA dose was associated with low LDL Cho levels suggesting ESA hypo-response is associated with LDL lipid composition including lipids associated cytotoxicity, proatherogenic pathways and a statin. Future/on-going work addresses anti-hyperlipidemic agents and ESA response.

ET-1-Dependent Impairment of Renal Iron Handling Leads to Iron Overload-Associated Tubular Injury in Sickle Cell Nephropathy

Malgorzata Kasztan, Kelly A. Hyndman, David M. Pollock. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Iron overload, a major consequence of the sickle cell disease (SCD), promotes renal iron deposition that correlates with albuminuria in SCD patients. Also, elevated plasma endothelin-1 (ET-1) levels reported in SCD correlate with microalbuminuria. Excessive renal iron deposition in humanized sickle cell (HbSS) mice is attenuated by endothelin A receptor (ET_A) blockade.Thus, we hypothesize that elevated ET-1 via ET_A receptor activity leads to dysfunctional tubular iron handling, iron overload, and resultant tubular injury in SCD nephropathy.

Methods: C57BL/6 mouse primary tubule (PT) cells and 14 weeks old HbSS mice were utilized in this study.

Results: ET-1 directly increased the expression of iron trafficking mediators in mouse PT cells. This includes transferrin receptor 1 (TfR-1) for cellular uptake and H-ferritin for storage. ET-1 also, decreases the expression of the iron exporter, ferroportin-1 ((FPN-1) and increases the expression of FPN-1 regulator, hepcidin (HAMP). Exposure of PT cells to 50 nM ET-1 and 0.1 μM heme for 24h increased cellular heme uptake compared to untreated cells (19.31±2.51 vs. 1.85±0.26 μM/mg protein). The ET_A antagonist, BQ123, prevented ET-1-induced alterations in all iron trafficking mediators. Moreover, plasma ET-1 concentrations were positively correlated with renal iron deposition in HbSS mice (R^2=0.72, $p<0.0001$). HbSS mice showed altered PT iron transporter expressions consistent with promoting PT iron accumulation. 10-week in vivo treatment with an ET_A receptor antagonist prevented the induction of cellular iron uptake transporter, DMT-1, preserved FPN-1, and reduced HAMP expression in PT cells from HbSS mice. A potential mechanism(s) of ET-1-mediated iron overload-associated tubular damage may involve ROS and/or mitochondrial dysfunction. PT cells exposed to FeS (500 μg/mL) have increased ROS production (12.52±1.31 vs. 0.14±0.01 AUCx10^3/mg protein). PT cells from HbSS mice exhibit mitochondrial dysfunction indicated by doubled expression of markers of mitochondrial stress PTEN-induced kinase 1 (PINK1), heat-shock protein 40 (mtHSP40), and mitochondrial fission 1 protein (Fis1).

Conclusions: These results uncover a novel role for ET-1 in PT iron trafficking and provide rationale for use of selective ET_A receptor blockade as a potential therapeutic approach in SCD nephropathy.

Hemodialysis Augments Red Blood Cell Death and Intracellular Hypoxia

Gabriela F. Dias,[1] Gabriela B. Andrade,[5] Sara S. Tozoni,[4] Nadja Grobe,[3] Roberto Pecoits-Filho,[2] Peter Kotanko,[3] Andrea N. Moreno-Amaral.[1] *[1]PPGCS/School of Medicine, Pontificia Universidade Católica do Paraná/PUCPR, Curitiba, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Renal Research Institute, New York, NY; [4]PPGCS/School of Medicine, Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; [5]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil.*

Background: Previous studies have shown that uremia increases red blood cell (RBC) death (eryptosis) in hemodialysis (HD) patients, possibly aggravating their anemia. The present study tests the hypothesis that hemodialysis (HD) triggers eryptosis, as indicated by phosphatidylserine (PS) exposure, and calcium influx into RBC. In addition, we explored levels of RBC intracellular hypoxia.

Methods: RBC were obtained from healthy subjects (CON-RBC; n=8) and ESRD patients (HD-RBC; n=10) pre- and post-HD. Using flow cytometry, PS exposure (Annexin-V), calcium influx (Fluo 3-AM probe), and intracellular level of hypoxia (Hypoxia Green probe) were determined. Results are expressed in mean fluorescence units (MFI). We compared these parameters between healthy controls and pre- and post-HD, respectively.

Results: The age of the healthy subjects was 34.8±17.3 years, 20% were male. The patients were 73% males, the age was 58.1±18.1 years. Compared to CON-RBC, PS exposure, calcium influx, and levels of intracellular hypoxia were increased in HD-RBC pre- and post-HD, respectively. In addition, HD treatment was associated with significantly increased PS exposure and intracellular hypoxia (Table 1).

Conclusions: Taken together, our results suggest that HD increases RBC hypoxia, eryptosis, and RBC calcium influx. Lower oxygen levels in HD-RBC could be due to either an impaired uptake or enhanced release of oxygen. Oxygen-sensitive intracellular responses may regulate RBC lifespan.

Eryptosis and oxygen levels in RBC from healthy controls (CON-RBC) and hemodialysis patients (HD-RBC) pre- and post-HD.

Parameters [in MFI units]	CON-RBC (n=8)	HD-RBC Pre-HD (n=10)	HD-RBC Post-HD(n=10)
Ca2+ influx	31.9±14.6	60.9±17.4***	74±15.8***
PS exposure	2.6±1.6	12.5±6**	27.2±7.2*** (#)
Hypoxia level	9.7±2.3	14.63±3.3*	22.15±4.9***(#)

Data are shown as mean±SD of the Mean Fluorescence Intensity (MFI).

*p<0.05, **p<0.01, ***p<0.001 correspond to the difference between HD-RBC and CON-RBC. (#) p<0.01 corresponds to the difference between pre-HD-RBC and post-HD-RBC.

SA-PO225

Two Phase 3, Multicenter, Randomized Studies of Intermittent Oral Roxadustat in Anemic CKD Patients on (PYRENEES) and Not on (ALPS) Dialysis

Ciro Esposito,[1] Botond Csiky,[2] Avtandil Tataradze,[6] Michael Reusch,[3] Cong Han,[4] Wladyslaw Sulowicz.[5] *[1]ICS Maugeri SpA, University of Pavia, Pavia, Italy; [2]FMC Dialysis Center, Pecs, Hungary; [3]Astellas Pharma Europe B.V., Leiden, Netherlands; [4]Astellas, Northbrook, IL; [5]Dept. of Nephrology, Jagiellonian University, Krakow, Poland; [6]National Center of Urology, Tbilisi, Georgia*.

Background: Roxadustat is an oral HIF-PHI in late-stage development for treatment of CKD anemia.

Methods: Two phase 3 European studies enrolled non–dialysis-dependent (NDD; ALPS) and dialysis-dependent (DD; PYRENEES) patients with CKD anemia. In the double-blind NDD study, patients with hemoglobin (Hb) ≤10 g/dL not treated with erythropoiesis-stimulating agents (ESAs) were randomized (2:1) to oral roxadustat or placebo for 52-104 weeks. In the open-label DD study, stable hemodialysis or peritoneal dialysis patients with Hb 9.5-12 g/dL treated with ESAs were randomized (1:1) to oral roxadustat or ESAs for 52-104 weeks. Primary endpoints were change of average Hb levels at Weeks 28-52 from baseline. Secondary endpoints included change of average low-density lipoprotein cholesterol (LDL) at Weeks 12-28 from baseline, time to use of rescue therapy (ie, transfusion, ESA, IV iron; NDD study), and mean monthly IV iron use through Week 36 (DD study). Occurrence of adverse events (AEs) was also assessed.

Results: The NDD study randomized 594 patients to roxadustat (n=391) or placebo (n=203); the DD study randomized 836 patients to roxadustat (n=415) or ESA (n=421). Mean (SD) change of average Hb levels at Weeks 28-52 from baseline was 1.988 (0.953) for roxadustat and 0.406 (0.979) for placebo (P<0.001) in NDD patients and 0.396 (0.773) for roxadustat and 0.183 (0.860) for ESA in DD patients (P<0.001). The LS mean difference (95% CI) in LDL was -0.701 (-0.83, -0.57; P<0.001) mmol/L vs placebo in NDD patients and -0.377 (-0.451,-0.304; P<0.001) mmol/L vs ESA in DD patients. In NDD patients, roxadustat was superior to placebo in time to use of rescue therapy (hazard ratio [95% CI], 0.238 [0.17, 0.33]; P<0.001). In DD patients, roxadustat was superior to ESA in mean monthly IV iron use (LS mean difference [95% CI], -31.9 [-41.4, -22.4]; P<0.001). Common AEs in both treatment groups were ESRD, hypertension, peripheral edema, and decreased GFR in NDD patients, and hypertension, arteriovenous fistula thrombosis, headache, and diarrhea in DD patients. Roxadustat safety data will be integrated across all trials.

Conclusions: Roxadustat was effective in achieving and maintaining Hb levels compared with placebo and ESA in NDD- and DD-CKD patients.

SA-PO226

Phase 3, Multicenter, Randomized, Open-Label, Non-Comparative Study of Intermittent Oral Roxadustat in ESA-Naive CKD Patients Not on Dialysis in Japan

Tadao Akizawa,[1] Tetsuro Otsuka,[2] Yusuke Yamaguchi,[2] Michael Reusch.[3] *[1]Showa University School of Medicine, Tokyo, Japan; [2]Astellas Pharma, Inc., Tokyo, Japan; [3]Astellas Pharma Europe B.V., Leiden, Netherlands.*

Background: Roxadustat, an oral HIF-PHI, is in late-stage development for treatment of chronic kidney disease (CKD) anemia. This phase 3 study evaluated efficacy and safety of oral roxadustat in erythropoiesis stimulating agent (ESA)-naïve non–dialysis-dependent (NDD)-CKD patients with anemia.

Methods: Multicenter, 24-week, Japanese study of NDD-CKD ESA-naïve anemic (hemoglobin [Hb] <10.5 g/dL) patients. Patients were randomized to roxadustat (initial dose of 50 mg or 70 mg) three times weekly; dose was adjusted to maintain Hb at 10-12 g/dL. Efficacy endpoints were response rate (Hb ≥10.0 g/dL and a Hb increase of ≥1.0 g/dL from baseline) at end of treatment; average Hb levels at Weeks 18-24; change of average Hb levels at Weeks 18-24 from baseline; maintenance rate of target Hb level (proportion of patients achieving average Hb level of 10-12 g/dL at Weeks 18-24); rate of rise in Hb (g/dL/week) from Week 0 to Week 4, time of discontinuation before Week 4, or time of dose adjustment before Week 4. Occurrence of adverse events (AEs) was assessed.

Results: Of 100 randomized patients, 99 started on 50 mg (n=49) or 70 mg (n=50) roxadustat. Response rate (95% CI) from baseline to end of treatment was 93.9 (83.1, 98.7) % and 100.0 (92.9, 100.0) % in the 50-mg and 70-mg groups, respectively. Mean (SD) of average Hb levels at Weeks 18-24 was 11.12 (0.57) g/dL and 11.23 (0.67) g/dL in the 50-mg and 70-mg groups, respectively. Mean (SD) change of average Hb levels at Weeks 18-24 from baseline was 1.39 (0.93) and 1.30 (0.80) g/dL in the 50-mg and 70-mg groups, respectively. Maintenance rate (95% CI) of target Hb level during Weeks 18-24 among patients with ≥1 Hb value at Weeks 18-24 was 88.6 (75.4, 96.2) % and 88.9 (75.9, 96.3) %, in the 50-mg and 70-mg groups, respectively. Mean (SD) rate of rise in Hb from Week 0-4 was 0.291 (0.197) g/dL/week and 0.373 (0.235) g/dL/week in the 50-mg and 70-mg groups, respectively. The most common AEs were nasopharyngitis (20.2%), hypertension (6.1%), diarrhea (5.1%), and hyperkalemia (5.1%).

Conclusions: Roxadustat was effective in achieving and maintaining Hb levels with the target range at both starting doses and in Japanese ESA-naïve NDD-CKD patients with a favorable safety profile. The rate of rise of Hb was dose dependent.

SIERRAS: A Phase 3, Open-Label, Randomized, Active-Controlled Study of the Efficacy and Safety of Roxadustat in the Maintenance Treatment of Anemia in Subjects with ESRD on Stable Dialysis

Chaim Charytan,[2] Roberto Manllo-Karim,[3] Edouard R. Martin,[4] Dylan Steer,[5] Marializa Bernardo,[6] Sohan L. Dua,[7] Moustafa A. Moustafa,[8] Gopal Saha,[1] Charles Bradley,[1] Meraf Eyassu,[1] Robert Leong,[1] Cameron S. Liu,[1] Lynda Szczech,[1] Kin-Hung P. Yu.[1] *[1]FibroGen, Inc., San Francisco, CA; [2]Nephrology Associates, PC, New Rochelle, NY; [3]South Texas Kidney Specialists, P.A., McAllen, TX; [4]South Florida Nephrology Associates, Lauderdale Lakes, FL; [5]Balboa Nephrology Medical Group, La Jolla, CA; [6]Southwest Nephrology Associates, Houston, TX; [7]Valley Renal Medical Group, Northridge, CA; [8]South Carolina Nephrology & Hypertension Center, Inc, Orangeburg, SC*.

Background: Roxadustat (FG-4592) is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and regulates iron metabolism.

Methods: Dialysis patients (pts) were randomized (1:1) to roxadustat (ROXA) or epoetin alfa (EPO). Oral iron was allowed; parenteral iron was restricted. ROXA was dosed thrice weekly. The initial ROXA dose was based on the pts' preceeding EPO dose. EPO was prescribed according to US Package Insert. An algorithm guided ROXA doses required to maintain Hb. The primary endpoint for US FDA was mean Hb change from baseline (BL) for Weeks (Wks) 28-52; the primary endpoint for the EU EMA submission was mean Hb change from BL to Wks 28-36. Safety and tolerability were assessed by adverse events, vital signs, electrocardiogram findings, and clinical laboratories.

Results: 741 pts (370=ROXA, 371=EPO) were randomized. The ROXA-treated pts were 44.6% Caucasian and 42.7% Black while the EPO-treated pts were 49.6% Caucasian and 42.0% Black. The percentage of pts with type-2 DM in the ROXA arm was 65.1% (n=241) and 65.8% (n=244) in the EPO arm. The mean Hb change from BL to the average over Wks 28-52 was 0.39 (ROXA) vs. -0.09 g/dL (EPO). The lower 95% CI for this difference was above the non-inferiority margin of 0.75 g/dL, and met the US criterion for superiority of ROXA over EPO (p<.0001). The mean Hb change from BL to the average over Wks 28-36 was 0.54 (ROXA) vs. -0.02 g/dL (EPO). ROXA met the non-inferiority criteria as the lower bound of 95% CI was above the non-inferiority margin of 0.75 g/dL compared with ESA. ROXA also achieved superiority, p<.0001. ROXA reduced RBC/blood transfusion risk by 33% compared with EPO (HR .67, p<.0037). The overall safety profile was consistent with results observed in prior ROXA trials and pooled safety findings will be submitted as a late breaker abstract.

Conclusions: ROXA was non-inferior and subsequently demonstrated superiority over EPO in the mean change in Hb from BL and in the rate of blood transfusions in dialysis pts.

ANDES: A Phase 3, Randomized, Double-Blind, Placebo Controlled Study of the Efficacy and Safety of Roxadustat for the Treatment of Anemia in CKD Patients Not on Dialysis

Daniel W. Coyne,[1] Simon D. Roger,[4] Sug kyun Shin,[8] Sung gyun Kim,[5] Andres A. Cadena,[7] Moustafa A. Moustafa,[6] Daniel Tak Mao Chan,[2] Willis Chou,[3] Charles Bradley,[3] Meraf Eyassu,[3] Anatole Besarab,[3] Robert Leong,[3] Tyson T. Lee,[3] Thomas B. Neff,[3] Lynda Szczech,[3] Kin-Hung P. Yu.[3] *[1]Washington University School of Medicine, St. Louis, MO; [2]Queen Mary Hospital, Pokfulam, HKSAR, China; [3]FibroGen, Inc., San Francisco, CA; [4]Renal Research, Gosford, NSW, Australia; [5]Hallym University, Chuncheon, Republic of Korea; [6]South Carolina Nephrology & Hypertension Center, Inc, Orangeburg, SC; [7]Clinica de la Costa, Barranquilla, Colombia; [8]Ilsan Hospital NHIS, Goyang-si, Republic of Korea*.

Background: Roxadustat (FG-4592; ASP1517; AZD9941) is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and regulates iron metabolism.

Methods: In this Ph3, randomized, double-blinded, placebo-controlled trial, the efficacy and safety of roxadustat vs. placebo was evaluated in patients (pt) with anemia and chronic kidney disease (stages 3-5) who were not dialysis-dependent (NDD-CKD). 922 pt were randomized (2:1) to receive oral roxadustat (n=616) or placebo (n=306) three-times weekly based on a tiered, weight-based scheme. Oral iron was allowed, IV iron was withheld except for rescue. Study drug dose was adjusted based on a dosing algorithm to correct and maintain hemoglobin (Hb). Primary efficacy endpoints were change in Hb from baseline (BL) to the average level during weeks (wk) 28-52 (for US [FDA]) and the proportion of subjects who achieve an Hb response at two consecutive visits during the first 24 wk of treatment without rescue therapy (for EU [EMA]). Safety and tolerability were assessed by adverse events, vital signs, ECG findings, and clinical laboratory values.

Results: Mean age was 64.9 years (yr) in the roxadustat arm and 64.8 in the placebo arm. Other BL characteristics were well balanced including BL Hb levels that averaged 9.1 g/dL in both arms. Treatment duration was up to 4.5 yr, with average duration of 1.7 yr. Mean change in Hb from BL to the average over wk 28-52 was 2.00 g/dL for roxadustat vs. 0.16 g/dL for placebo (p<0.0001). The proportion of pt who achieved an Hb response at two consecutive visits during the first 24 wk of treatment was 86.0% for roxadustat vs. 6.6% for placebo (p=0.0007). Roxadustat reduced the risk of rescue therapy by 81%

(HR=0.19) and the risk of blood transfusion by 74% (HR = 0.26), both p<0.0001. Pooled safety analysis will be submitted as a late breaking clinical trial abstract.

Conclusions: Roxadustat was superior to placebo in mean Hb change from BL to the average over wk 28-52 with a higher proportion of roxadustat-treated pt achieving an Hb response in the first 24 wk.

Funding: Commercial Support - Fibrogen Inc.

Randomized, Open-Label, Active-Controlled (Darbepoetin Alfa), Phase 3 Study of Vadadustat for Treating Anemia in Non-Dialysis-Dependent CKD Patients in Japan

Masaomi Nangaku,[1] Kazuoki Kondo,[2] Yoshimasa Kokado,[2] Kiichiro Ueta,[2] Genki Kaneko,[2] Masashi Shiosaka,[2] Yutaka Kawaguchi,[2] Yasuhiro Komatsu.[3] *[1]the University of Tokyo School of Medicine, Tokyo, Japan; [2]Mitsubishi Tanabe Pharma Corporation, Tokyo, Japan; [3]Gunma University, Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: This open-label, active-controlled Phase 3 study (NCT03329196) evaluates the efficacy and safety of vadadustat (VDT), an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, in 304 nondialysis dependent (NDD) chronic kidney disease (CKD) subjects with anemia in Japan for 52 weeks. Prespecified primary analysis results at 24 weeks are presented here.

Methods: NDD-CKD subjects with anemia receiving (conversion) or not receiving erythropoiesis stimulating agents (correction) were randomized to VDT (n=151) or darbepoetin alfa (DA) group (n=153). After initial VDT dose of 300 mg daily, doses were adjusted within 150–600 mg to achieve and maintain target hemoglobin (Hb) of 11–13 g/dL. Primary endpoint was average Hb at weeks 20 and 24. Noninferiority of VDT to DA was tested using mixed model for repeated measures. Iron parameters were measured. Safety was assessed up to 24 weeks.

Results: LSMean of the average Hb at weeks 20 and 24 was 11.66 (VDT: 95% CI, 11.49 to 11.84) and 11.93 (DA: 11.76 to 12.10) g/dL; 95% CI of both groups were within the target Hb of 11–13 g/dL. Difference in LSMean between the groups was –0.26 g/dL (–0.50 to –0.02); the 95% CI lower limit was above the predefined noninferiority margin of –0.75 g/dL, demonstrating the noninferiority of VDT to DA. VDT improved mean Hb from baseline of 10.68 to 11.27 g/dL at week 24 (conversion, n = 80) and 10.17 to 11.85 g/dL (correction, n = 71). VDT regimen was associated with significant increases in total iron-binding capacity and decreases in hepcidin from baseline to week 24, not found in the DA group. At least one adverse event (AE) was seen in 72.2% (VDT) and 73.2% (DA) subjects. The most common AEs in the VDT group were nasopharyngitis (VDT: 14.6%, DA: 12.4%), diarrhea (VDT: 10.6%, DA: 3.3%), and constipation (VDT: 5.3%, DA: 3.9%). The incidence rates of serious AEs were 13.9% (VDT) and 14.4% (DA). No serious AE was considered related to the study drug.

Conclusions: VDT was effective as DA in controlling Hb within the target range in both conversion and correction without new safety concerns, indicating the usefulness of VDT for treating anemia in Japanese NDD-CKD patients.

SA-PO230

An Open-Label Extension Study to Evaluate the Efficacy and Safety of Roxadustat for the Long-Term Maintenance Treatment of Anemia in Dialysis and Non-Dialysis Patients with CKD

Chao H. Sun,[3] Elizabeth A. Barranco,[2] Lona Poole,[1] Meraf Eyassu,[1] Cameron S. Liu,[1] Donna L. Kline,[1] Thomas B. Neff,[1] Kin-Hung P. Yu.[1] *[1]FibroGen, Inc., San Francisco, CA; [2]Ponce Maedical School Foundation Inc., Ponce, PR; [3]Nephrology Associates Medical Group, INC, Riverside, CA.*

Background: Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis via increasing endogenous erythropoietin, and regulates iron metabolism.

Methods: In this open-label, extension study, subjects with dialysis-dependent (DD-CKD) and non-dialysis-dependent chronic kidney disease (NDD-CKD) who have completed the treatment period of a phase 2 roxadustat anemia study in the U.S. were enrolled and treated with roxadustat. Subjects continued to receive roxadustat at the same dose and frequency unless a dose adjustment was required, followed by dose titration to Hb levels. Mean Hb values, total weekly roxadustat doses and dose frequencies over time were evaluated. Safety and tolerability were assessed by adverse events, vital signs, electrocardiogram findings, and clinical laboratory values.

Results: Fifteen subjects with NDD-CKD (n=14) and DD-CKD (n=1) were enrolled and treated. One subject with NDD-CKD who withdrew consent two weeks after enrollment and one other subject with DD-CKD were excluded from the analyses. Among the 13 NDD-CKD patients, mean age was 65.5 years; [range, 38 - 78 years], 61.5% (8/13) were female, and 100% (14/14) were white. Baseline Hb levels averaged 10.2 g/dL; [range, 8.7 - 11.2 g/dL], and eGFR averaged 26.1 mL/min; [range, 7.3 - 48.2 mL/min]. At the time of enrollment, 7.7% (1/13) of subjects were on TIW dosing regimen, 69.2% (9/13) on BIW, and 23.1% (3/13) on QW. Mean follow up was 3.7 years [range, 1.0 - 6.9 years]. Hb levels over time averaged 11.7 g/dL [range, 11.0 - 12.4 g/dL]. At patients' last dose, 7.7% (1/13) of subjects were on TIW dosing regimen, 69.2% (9/13) on BIW, 15.4% (2/13) on QW, and 7.7% (1/13) were on QOW dosing regimen. The mean total weekly dose of roxadustat was 241.2 mg; [range, 73.7 – 517.9 mg]. The safety and tolerability profiles observed were as expected for this patient population.

Conclusions: In this cohort of patients with NDD-CKD, long-term use of roxadustat for treatment of anemia resulted in continued efficacy in Hb maintenance in all patients with a safety profile consistent with the population of patients under study.

Long-Acting Erythropoiesis-Stimulating Agent (ESA) Induced the Physiological Erythropoiesis via an Improvement of Iron Availability

Takahiro Kuragano. *Internal Medicine Division of Kidney and Dialysis, Nishinomiya, Japan.*

Background: Maintenance hemodialysis (MHD) patients with a dysutilization of iron for erythropoiesis exhibited significantly higher risks of cardiovascular disease and all-cause death compared to other groups. Thus, anemia treatment that improves iron availability for erythropoiesis might attenuate the risk of adverse events of these patients. Recently, basic studies or short-term clinical studies reported that the long-acting erythropoiesis-stimulating agent (ESA) significantly suppressed the expression of hepcidin, which regulates iron availability. In this study, we compared the iron availability for erythropoiesis between short- and long-acting ESA during a long-term period.

Methods: Sixty-nine MHD patients with renal anemia (mean age: 69 yo, % of male: 65%, mean duration of HD time: 122±98 months) were enrolled in this study. All patients were treated with a short-acting ESA (epoetinα or epoetinβ) for the first 30 months (short-acting ESA period). Then, all patients were switched to a longacting ESA (continuous erythropoietin receptor activator-methoxy polyethylene glycol-epoetin beta) for the next 30 months (long-acting ESA period).

Results: The mean dose of the short-acting ESA and longacting ESA was 2795±259 IU/week and 82.6±14.7 μg/month, respectively. Compared with the short-acting ESA period, the mean Hb (10.3±0.2 vs.10.6±0.2 g/dL) and TSAT (15±2.9 vs. 25.9±3.5%) levels were significantly (p<0.05) increased in the long-acting ESA period. Additionally, the mean serum ferritin level (72.0±22.2 vs. 56.3±14.0 ng/mL) and the dose of IV iron (108.0±63.7 vs. 53.4±26.9 mg/month) were significantly (p<0.05) decreased in the long-acting ESA period.

Conclusions: In this study, anemia treatment of MHD patients with a long-acting ESA attenuated iron utilization for erythropoiesis (decreased serum ferritin and increased TSAT) and maintained target Hb levels without a higher dose of IV iron and ESA. From these results, we hypothesize that anemia treatment with a longacting ESA might induce more physiological erythropoiesis in MHD patients via improvements in iron metabolism compared to treatment with a short-acting ESA. To evaluate the effect of the long-acting ESA on the adverse events or survival of MHD patients, further randomized control studies are needed.

SA-PO232

Understanding Patient Perspectives of the Impact, Awareness, and Treatment of CKD Anemia: A US Patient Survey

Eirini Palaka,[1] Nicolas J. Guzman,[2] Alicia Dunn,[2] Eric T. Wittbrodt,[2] Susan Grandy,[2] Fredric O. Finkelstein.[3] *[1]AstraZeneca, Cambridge, United Kingdom; [2]Astrazeneca, Gaithersburg, MD; [3]Yale University, New Haven, CT.*

Background: Anemia is a common complication of CKD that may reduce patients' (pts) quality of life (QoL) and/or require them to seek treatment. The objective of this study was to assess the perceptions of US CKD pts with anemia with respect to QoL, disease understanding, and management of their anemia.

Methods: In August–September 2018, a quantitative online survey was administered to 500 US pt volunteers aged ≥18 years with self-reported CKD with or without anemia; pts with cancer were excluded. Pts were recruited via open requests to online communities and support groups, pt associations, and pt referrals. This survey explored pt knowledge of anemia and its management, impact on symptoms, and QoL. Data were aggregated and anonymized to protect pt confidentiality.

Results: Respondents were 69% female, mean age 52.2 years, and 68% confirmed they had CKD stages 3–5, 24% had CKD stage 1 or 2; the remaining 8% did not know the stage. Of the entire cohort, 57% (n=255) of pts reported being told they had anemia by a healthcare professional (HCP). However, only 66% (n=168) of these 255 pts knew about the relationship between anemia and CKD. Of the entire cohort, only 38% (n=170) knew their hemoglobin levels, but most were aware of the key symptoms associated with anemia, identifying fatigue (89%) or weakness (70%). Pts with anemia reported lack of energy (82%), feeling sad and/or depressed (53%), noting pain (52%), difficulty sleeping (53%), and worrying about worsening anemia (63%). Most pts (67%) stated that their anemia was well managed mostly with iron supplements (55% of those treated) or erythropoiesis-stimulating agents (30%), while 11% had received transfusions. Less than half felt confident that they knew the adverse effects of their treatment.

Conclusions: US pts with CKD perceived that anemia had a negative impact on their physical symptoms and emotional wellbeing; their knowledge and understanding of CKD anemia and its management varied. These findings emphasize the challenges HCPs and pts face concerning the need for further education on the association between CKD and anemia, symptoms associated with anemia, and the available treatment options for anemia.

Understanding Patient Perspectives of the Impact and Treatment of CKD Anemia: A Patient Survey in China

Chuan-Ming Hao,[1] Eric T. Wittbrodt,[2] Eirini Palaka,[3] Nicolas J. Guzman,[2] Alicia Dunn,[2] Susan Grandy.[2] *[1]Fudan University, Huashan Hospital, Shanghai, China; [2]AstraZeneca, Gaithersburg, MD; [3]AstraZeneca, Cambridge, United Kingdom.*

Background: Anemia is a common complication of CKD that may reduce patients' (pts) quality of life (QoL) and/or require treatment. The objective of this study was to assess the QoL burden, knowledge, and management of CKD anemia in a sample of Chinese pts.

Methods: In August–September 2018, a quantitative, online survey was administered to 500 Chinese pt volunteers aged ≥18 years with self-reported CKD with or without anemia; pts with cancer were excluded. Pts were recruited via online communities, pt associations, online support groups, and direct pt referrals. This 27-question survey explored pt knowledge of anemia, its management, impact on QoL, information sources for the condition, and effects on the healthcare practitioner–pt relationship. Data collected from the survey were aggregated and anonymized to protect pt confidentiality.

Results: Overall, data were evaluable for 456 pts, 44% female, mean age 41.0 years, and 23% reported receiving a CKD diagnosis stages 3–5, the remaining 77% had CKD stage 1 or 2, or did not know the stage. Of the entire cohort, 32% of pts reported being told they had anemia, 73% did not know their hemoglobin (Hb) level or had not had a blood test in the previous year. Of pts told they had anemia (n=148), most reported feeling ill (86%), lack of energy (75%), nausea (72%), pain (69%), and sadness and/or depression (61%). For these pts, a negative impact of CKD anemia on QoL was perceived: 66% reported less energy, 54% reported more sadness/depression, 50% felt they were more ill, 37% worried more that their condition was worsening, and 29% reported less ability to work. Awareness of the link between CKD and anemia was common (87%), and 71% thought that their anemia was well or very well managed: 64% reported taking iron supplements; 69% had received dietary advice; 26% were given erythropoiesis-stimulating agents; and 31% had received blood transfusions.

Conclusions: Chinese pts perceived that CKD anemia had a negative impact on their QoL. Although pt knowledge of anemia was varied, perceptions of its management were generally positive. There are opportunities for improving pt education on the association between CKD and anemia, improving Hb testing and monitoring, and increasing use of treatments to avoid blood transfusions.

Role of Nephrology Pharmacists in the Management of Anemia in Outpatient Dialysis Units: A Canadian Model

Wasim El Nekidy,[1] Terrence J. Lee-St. John,[4] Islam Ghazi,[3] Albert Kadri,[2] Nizar M. Attallah,[4] Derrick Soong.[5] *[1]Cleveland Clinic - Abu Dhabi, Windsor, ON, Canada; [2]Windsor Regional Kidney Care Center, Windsor, ON, Canada; [3]Philadelphia College of Pharmacy/University of the Sciences, Wayne, PA; [4]Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; [5]Windsor Regional Hospital, Windsor, ON, Canada.*

Background: Hemodialysis patients frequently suffer from anemia. Proper utilization of therapies such as iron and erythropoiesis-stimulating agents (ESAs) are crucial to attain established hemoglobin targets. The purpose of this study was to evaluate the clinical and financial impact of nephrology trained pharmacists on anemia management in these patients

Methods: A retrospective study of patients who received hemodialysis between Jan 2010 and Dec 2011 in the outpatient hemodialysis units. In Dec 2010, pharmacists were tasked to manage anemia under medical directive. Primary endpoints were compared across years (2010 vs. 2011) using a mixed-effects model strategy An unstructured random effects correlation matrix was utilized to capture patient-level variation in 2010 and 2011 separately

Results: Of 202 patients, 163 contributed in both years, 57% were males, age 65.18± 16.3 years. Hemoglobin levels were 10.95±0.95 and 10.83±0.94 mg/dL in 2010 vs. 2011 respectively, p=0.158, while the transfusion rate was 1.3% and 1.8%, respectively, p=0.196. Ferritin levels 273.5±215 and 317.1±123, p=0.0019, iron saturation 0.30±0.11 and 0.30± 0.05, p=0.838, and Iron dose 215.4±100.2 and 317.1±123.7 mg, respectively, p= 0.996. Finally, the average weekly ESA use in 2010 was higher and trending up as compared to 2011 where it significantly trended down. Erythropoietin alfa dose 12315.6±7591 vs. 11364.1±5150, respectively, p=0.556 (figure1) with expenditure of 2.8 million CAD in 2010 vs. 2.3 million in 2011.

Conclusions: The participation of a nephrology trained pharmacist resulted in favourable outcomes in dose optimization (process), decreased expenditure (financial) and positive trends in therapeutic goal achievement coupled with reduced consumption (clinical)

Figure 1. Effect of ESA dosing (a) and Iron Dosing in mg (b) on Hemoglobin trend over the study period

Anemia Nurse Manager in Peritoneal Dialysis: A Retrospective Study from Qatar

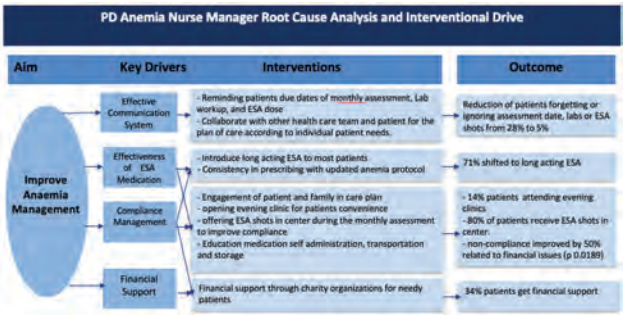
Abdullah I. Hamad, Hany E. Ismail, Michelle cruz Futotana, Rania A. Ibrahim, Fatma A. Ramadan, Shehab Mohamed, Vimala K. Lonappan, Hanaa Ahmed, Fadwa M. Al-Ali. *Hamad Medical Corporation, Doha, Qatar.*

Background: Anemia management is challenging in peritoneal dialysis (PD) patients (home-based with dependence on patients' compliance). We implemented a special anemia nurse manager (ANM) model with nephrologist's supervision in PD to achieve better hemoglobin (Hg) targets. We performed a retrospective study to evaluate outcomes and cost effectiveness of the new model.

Methods: Our PD ANM is a PD nurse who was trained for 4 months (8-12/2017) by a nephrologist. The program expanded gradually to include all PD patients by 1/2018. Our PDANM role includes lab review, medications adjustments, patients' education and act as a focal point for anemia. We reviewed patients record for 1 year (1/2018-12/2018). We tracked laboratory values and medications. We performed root cause analysis (RCA) routinely to analyze and resolve challenges to achieve goals.

Results: PD census mean was 180 patients during study period (1/2018-12/2018). ANM model achieved a significant improvement in PD patients with Hg in target range (10-12g/dL) (54% in 1/2018 vs 75% in 12/2018 p=0.0004). Number of patients with extreme Hg (<9 g/dl or >13 g/dl) improved from 18% to 12% in the same period (p=0.03). Patients in ferritin target (200-800) improved (55% vs 69% p<0.005) without affecting iron saturation. Weekly Aranesp dose was reduced with the ANM model from 45mcg to 39mcg and monthly Mircera dose from 151mcg to 127mcg. Simple cost effectiveness analysis (saving in ESA consumption-nurse salary) showed estimated annual cost saving of 70000 dollars. Our RCA showed that the main cause of failure was compliance with visits and ESA shots. Based on our RCA we built a unique anemia management algorithm for PD (Figure 1).

Conclusions: Anemia management in PD was successfully shifted to our new ANM model. We were successful to achieve and maintain patients within anemia targets. The model was cost effective. We collaborated with a hematologist to address challenges. Similar models are applied throughout our dialysis service.



SA-PO236

Association Between Serum Total Bilirubin Levels and Mortality in Dialysis Patients

Tsuyoshi Miyagi,[1] Hiroshi Kimura,[1] Ekamol Tantisattamo,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Serum bilirubin may have a potent antioxidant effect and may be associated with protection from cardiovascular disease (CVD) in non-dialysis patients. It is unknown if serum bilirubin levels (sTB) can predict subsequent mortality risk following dialysis initiation in patients at high risk of developing CVD.

Methods: We identified 3,769 patients who transitioned to maintenance dialysis in a large US dialysis organization (2007-2011) and had available sTB data at baseline. Patients with abnormally high (>1.3 mg/dL) and low (<0.1 mg/dL) sTB or liver disease were excluded from the cohort. We divided patients into 12 groups based on their sTB levels (0.1-<0.3 [ref.], 0.3-<0.4, 0.4-<0.5, 0.5-<0.6, 0.6-<0.7, 0.7-<1.3 mg/dL) and age (<65 years, ≥65 years). All-cause mortality risk was examined using Cox models with adjustment for case-mix (age, gender, race/ethnicity, hypertension, diabetes and CVD) and a fully adjusted model (case-mix model plus body mass index and 11 laboratory variables).

Results: The mean age was 62 ± 15 (mean ± SD) years, 56% of patients were male, and 48% were non-white. There were significant differences in all clinically relevant factors used for adjusted models among the non-elderly and elderly groups. In both the non-elderly and elderly patient groups, those with high sTB levels had the highest hazard ratio (HR) after full adjustment vs. the 0.1-<0.3 mg/dL group (HRs:1.68 [95% CI, 1.13-2.50] and 1.93 [95% CI, 1.41-2.64], respectively). [figure]

Conclusions: In contrast to conventional studies, higher sTB levels within normal ranges are associated with higher mortality in incident dialysis patients. Aging and uremia under dialysis might attenuate an antioxidant effect of bilirubin. Whether bilirubin can be used as an independent risk factor for mortality in dialysis patients warrants additional studies.

SA-PO237

CKD Anemia Epidemiology and Associated Outcomes in Non-Dialysis-Dependent Patients

Lois Lamerato,[1] Glen James,[2] Heleen van Haalen,[3] Katarina Hedman,[3] James A. Sloand,[4] Jerry Yee,[1] Eric T. Wittbrodt.[4] *[1]Henry Ford Health System, Detroit, MI; [2]AstraZeneca, Cambridge, United Kingdom; [3]AstraZeneca, Gothenburg, Sweden; [4]AstraZeneca, Gaithersburg, MD.*

Background: Anemia is a well-known CKD complication associated with increased risk of red cell transfusions (RBCs), low quality of life, and adverse outcomes such as cardiovascular events and mortality. Current treatments including erythropoietin-stimulating agents (ESAs) have not been shown to improve clinical outcomes in non-dialysis dependent (NDD) CKD patients. The aim of this study was to generate real-world evidence regarding the epidemiology and selected clinical outcomes of anemia and in NDD patients.

Methods: Data for this retrospective, observational study was extracted from Henry Ford Health System databases. Adults with NDD CKD (estimated GFR <60 ml/min/1.73m^2) between 01/01/13 to 12/31/17 were identified. Patients on renal replacement therapy or with active cancer were excluded. All patients were followed for ≥12 months and until 12/31/18. Outcomes included composites for CKD progression (end-stage CKD, 40% decrease in eGFR, CKD stage advancement, and doubling of serum creatinine) and major cardiovascular events (MACE). Logistic regression models, adjusted for baseline demographics and anemia, identified factors associated with MACE at 1 and 5 y.

Results: Study cohort (N = 55,447) demographics: median age 73 y (IQR 64, 82); 56% female; 63% White, 27% African American (AA), 2% Hispanic, 1% Asian, and 7% other/unknown race. Index CKD stages: 3A (60%), 3B (27%), 4 (10%), and 5 (3%). Baseline anemia prevalence, defined as Hb <10 g/dl, was 25%. Anemia treatments included iron (10%), RBCs (4%), and ESAs (1%). The 1- and 5-y cumulative incidences of CKD progression were 43% and 67%, respectively; for MACE, 8% and 37%, respectively. Baseline anemia (odds ratio (OR) 1.90) and AA race (OR 1.10) were associated with CKD progression risk at 1 y; both p <0.01. Both factors and strata of increasing age were modestly associated with CKD progression at 5 y. Increased risks of 1- and 5-y MACE were associated with baseline anemia (OR 3.22 and 3.02, respectively), male sex (OR 1.29 and 1.30, respectively), and increasing age (OR 1.32 and 1.50, respectively); all p <0.01, while AA race was slightly protective for 5-y MACE (OR 0.92, p <0.05).

Conclusions: Anemia is highly prevalent in NDD CKD patients, with a low frequency of treatment. Serum Hb <10 g/dL was associated with increased risk of CKD progression and MACE.

SA-PO238

Anemia, Iron Status, and Anemia Development in Relation to Body Mass Index in Nondialysis CKD Patients: The Results from the KNOW-CKD Study

Hyo Jin Kim,[1] Eunjeong Kang,[2] Minjung Kang,[2] Curie Ahn,[2] Kook-Hwan Oh.[3] *[1]Dongguk University College of Medicine, Gyeongju-si, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]SNU College of Medicine, Seoul, Republic of Korea.*

Background: Anemia and iron deficiency are frequent findings in obese subjects. However, there were inconsistent results in adult studies. We aimed to investigate anemia, iron status, and anemia development in relation to body mass index (BMI) in chronic kidney disease patients

Methods: This prospective study included 2,214 patients from the KNOW-CKD study (KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease), after excluding 24 patients without data on BMI. Participants were classified by BMI categories as underweight (<18.5 kg/m^2), normal weight (18.5 to <23 kg/m^2), overweight (23 to <25 kg/m^2), and obese (≥25 kg/m^2) according to Asia-Pacific classification. Central obesity was defined as a waist circumference according to Asian-Pacific threshold (male ≥90cm, female ≥80cm). Hemoglobin levels were measured yearly during a mean follow-up period of 37.5±22.1 months. Anemia was defined as hemoglobin <13.0 g/dL in men and 12.0 g/dL in women. Iron deficiency was defined as serum ferritin <100 ng/mL or transferrin saturation <20%.

Results: The prevalence of underweight, normal weight, overweight, and obese was 2.4%, 29.4%, 26.5%, and 41.7%, respectively. Overall, 44.0% of patients were anemic and 55.0% of patients had iron deficiency. Obese patients had the highest hemoglobin concentration compared with other BMI groups (P< 0.001). The prevalence of anemia (P< 0.001) and iron deficiency (P< 0.001) and usage of iron supplement (P< 0.001) and erythropoietin stimulating agent (P=0.015) were significantly decreased in high BMI categories. BMI was positively associated with hemoglobin in multivariable linear regression analysis with adjustment (β, 0.16; 95% confidence interval [CI], 0.22-0.61; P< 0.001). Central obesity was also positively associated with hemoglobin (P< 0.001). Among 1,165 patients without anemia at baseline, 414 (35.5%) patients developed anemia during a follow-up period. In multivariable Cox regression analysis after adjustment, obese patients had a significantly lower risk of anemia development than those in the normal weight patients (HR, 0.76; 95% CI, 0.58-0.99; P = 0.046).

Conclusions: Obese patients had the highest hemoglobin concentration and had a significantly lower risk of anemia development than those in the normal weight patients.

SA-PO239

Prevalence, Correlates, and Outcomes of Absolute and Functional Iron Deficiency Anemia in Non-Dialysis-Dependent CKD

Ahmed A. Awan,[2] Carl P. Walther,[1] Peter Richardson,[1] Wolfgang C. Winkelmayer,[1] Sankar D. Navaneethan.[1] *[1]Baylor College of Medicine, Sugar Land, TX; [2]Baylor college of medicine, Houston, TX.*

Background: Anemia contributes to adverse outcomes in those with chronic kidney disease (CKD). We examined the association of absolute and functional iron deficiency anemia (IDA) with adverse outcomes (hospitalization, dialysis and mortality) in those with CKD.

Methods: Non-dialysis patients followed in the Veterans Administration with hemoglobin level measured within 90 days of the date of the second eGFR < 60 ml/min/1.73m2 were included. Logistic regression, multivariate Cox proportional hazard and poisson regression models adjusted for demographics and comorbidities were used to assess following outcomes: a) prevalence and correlates of absolute (TSAT < 20%, ferritin <100ng/ml), functional IDA (TSAT < 20%, ferritin 100-800 ng/ml) and b) association of absolute and functional IDA, those with Ferritin >800 ng/ml with mortality, dialysis and cardiovascular hospitalization.

Results: Out of 933,463 CKD patients included, 21.6% were anemic. Among patients with anemia with TSAT/Ferritin data, 50% did not have iron deficiency, 30% had absolute IDA, and 19% had functional IDA. Median follow-up was 3.9 years for mortality and 3.6 years for dialysis. Absolute IDA was not associated with an increased risk of mortality and dialysis but had higher risk of 1-year (RR 1.18, 95% CI: 1.11-1.26) and 2-year cardiovascular hospitalization (RR 1.10, 95% CI: 1.04-1.16) [FIGURE]. CKD patients with functional IDA had a higher risk of mortality along with a higher risk of 1-year and 2-year cardiovascular hospitalization. Ferritin > 800 ng/ml (treated as a separate category) was only associated with an increased risk of mortality.

Conclusions: In a large population of CKD patients with anemia, functional IDA was associated with higher risk of mortality and cardiovascular hospitalization while absolute IDA was associated with a higher risk of hospitalization.

Funding: Commercial Support - Keryx Biopharmaceuticals

Table 1. Associations of absolute and functional iron deficiency anemia with outcomes in those with CKD

Outcome	Variable	Cause-specific hazard	
		HR & 95% CI	p-value
Death	No iron deficiency	1.0 (ref)	
	Absolute	1.01 (0.98 - 1.04)	0.45
	Functional	1.12 (1.08 - 1.15)	<.0001
	Ferritin > 800	1.64 (1.41 - 1.90)	<.0001
Dialysis	No iron deficiency	1.0 (ref)	
	Absolute	0.95 (0.89 - 1.02)	0.13
	Functional	1.01 (0.94 - 1.08)	0.75
	Ferritin > 800	1.24 (0.92 - 1.67)	0.16

SA-PO240

Prevalence and Risk Factors of CKD Anemia in the United States

Jill Davis,[1] Herve Caspard,[2] Dustin J. Little,[2] Robert M. Perkins,[1] Csaba P. Kovesdy.[3] *[1]Astrazeneca, Wilmington, DE; [2]AstraZeneca, Gaithersburg, MD; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: The most recent estimate to date of the prevalence of anemia in patients with chronic kidney disease (CKD) in the US is supported by data from US National Health and Nutrition Examination Survey (NHANES) in 2007-2010. We analyzed the NHANES database from 1999 to 2016 to update the prevalence of anemia among the US adult population with CKD and investigate risk factors.

Methods: CKD stage was assessed using the estimated glomerular filtration rate (eGFR) derived from serum creatinine using CKD-EPI equation. Anemia was defined as hemoglobin ≤13 g/dL in men and ≤12 g/dL in women, and severe anemia as hemoglobin (Hb) <10 g/dL (per KDIGO guidelines). Pregnant women were excluded. NHANES participants who had received dialysis treatment in the 12 months before the survey were considered as presenting CKD stage 5 but were excluded for estimation of prevalence of anemia. Associations between anemia and CKD stage, age, sex, race/ethnicity, smoking status, diabetes, hypertension, and body mass index were investigated. A logistic regression multivariate model was fit using a stepwise downward approach.

Results: Median age (yrs) of all the NHANES participants with CKD was 73.4 (interquartile range: 64.2-79.3); 59.4% (95% CI: 57.7-61.1) were female; 9.8% (95% CI: 8.4-11.1) were African-American; and 25.1% (95% CI: 23.3-26.8) reported diabetes mellitus. Prevalence estimates of anemia and severe anemia in 2015-2016 were 23.5% (95% CI: 19.4-27.7) and 1.2% (95% CI: 0.4-2.0), respectively. Association between CKD stage and anemia and severe anemia is shown in the Table.

Conclusions: Only a small fraction of CKD patients with anemia present with Hb <10 g/dL and are eligible for treatment. The risk of anemia and severe anemia is markedly increased in patients with lower eGFR.

Funding: Commercial Support - AstraZeneca

Table. Adjusted odds of anemia and severe anemia by CKD stage

CKD Stage	Prevalence of Anemia (%)	Prevalence of Severe Anemia (%)	Odds ratio [95% CI] of Anemia*	Odds ratio [95% CI] of Severe Anemia**
3A	12.6 [11.0;14.2]	0.59 [0.17;1.00]	Reference	Reference
3B	30.4 [27.0;33.8]	2.27 [1.21;3.32]	2.74 [2.19-3.44]	3.84 [1.60-9.21]
4	54.2 [47.6;60.9]	3.84 [1.22;6.46]	6.67 [4.87-9.12]	5.67 [2.04-15.77]
5	56.0 [41.7;70.3]	6.36 [0.96;11.76]	7.67 [4.11-14.33]	6.86 [2.07;22.71]

A Faster Decline of Residual Kidney Function and Erythropoiesis-Stimulating Agent (ESA) Hyporesponsiveness in Incident Hemodialysis Patients

Hiroshi Kimura,[1] Yusuke Okuda,[1,3] Connie Rhee,[1] Csaba P. Kovesdy,[2] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Kitasato University School of Medicine, Minato, Japan.*

Background: In dialysis patients, resistance to ESA is associated with worse outcomes such as higher death risk. Prior studies have demonstrated that a slower loss of residual kidney function (RKF) in the first year of hemodialysis (HD) is associated with improved survival and potentially a healthier profile. However, little is known about the relationship between RKF decline and resistance to ESA.

Methods: The odds of ESA hyporesponsiveness with RKF decline in the first year were examined across four strata of annual changes in residual renal urea clearance ([KRU], <-3.0, -3.0 to <-1.5, -1.5 to <0, ≥0 mL/min/1.73m^2) and urinary volume (<-600, -600 to <-300, -300 to <0, ≥0 mL/day). Logistic regression models adjusted for demographic, clinical characteristics and laboratory variables were used in 5,239 incident HD patients from a large US dialysis organization (2007-2011).

Results: The median (interquartile range) baseline values of the annual changes in KRU and urinary volume were -1.2 (-2.8, 0.1) mL/min/1.73m^2 and -250 (-600, 100) mL/day, respectively. A faster RKF decline in the first year of HD initiation was associated with higher odds of ESA hyporesponsiveness (Figure). These associations remained robust across adjustment for laboratory variables and consistent in subgroup analyses across strata of baseline RKF, age, sex, race, diabetes, congestive heart failure, hemoglobin, and serum albumin. Similar results were found using urinary volume as another index of RKF (Figure).

Conclusions: A faster RKF decline during the first year of dialysis was associated with hyporesponsiveness to ESA among incident HD patients. Future studies are necessary to explain the underlying mechanisms of this association.

Prevalence of CKD Anemia in Non-Dialysis-Dependent Patients Using Linked US Claims and Electronic Health Record Data

Eric T. Wittbrodt, Glen James, Supriya R. Kumar, Heleen van Haalen, Hungta (tony) Chen, James A. Sloand. *AstraZeneca, Gaithersburg, MD.*

Background: Novel strategies for the management of anemia, a complication of chronic kidney disease (CKD), are in development. Insights into CKD-related anemia burden, associated outcomes, and resource utilization are needed from representative non-dialysis dependent CKD populations receiving high-quality clinical care. The primary study objective was to describe baseline patient characteristics, comorbidities, and anemia prevalence in non-dialysis-dependent (NDD) CKD patients in US real-world practice.

Methods: This retrospective observational study evaluated the integrated Limited Claims and Electronic Health Record Data (IBM Health, Armonk, NY). The study cohort included patients aged ≥18 years with ≥2 eGFR measures <60 mL/min/1.73 m^2 at least 90 days apart. Anemia was defined as the first observed hemoglobin (Hb) <10 g/dl. The baseline period was defined as the date of the second confirmatory eGFR <6 months. Baseline anemia prevalence, demographics, comorbidities, laboratory measures, and selected medications were extracted and analyzed for the period from January 1, 2012 and September 30, 2017. Descriptive data were summarized, and no inferential statistics were performed.

Results: The study cohort (N = 33,088) was 57% female and mean (±SD) age was 70 (±13) years. The proportion of patients across CKD stages at baseline was: 3a (56%), 3b (23%), 4 (8%), and 5 (15%). Baseline comorbidities included type 2 diabetes mellitus (31%), cardiovascular disease (49%), heart failure (23%), and hyperlipidemia (62%). Median baseline (interquartile range) Hb was 12.4 (11, 13.6) g/dl, creatinine 1.3 (1.1, 1.7) mg/dl, ferritin 116 (53, 244) ng/ml, and total iron binding capacity 303 (254, 349). Baseline anemia prevalence was 30% (N = 9909/33,088). Erythropoiesis-stimulating agents (ESAs) were prescribed in 0.6% of all patients at baseline, and usage increased by worsening Hb strata (0.1% in Hb >12, 1.0% in Hb 10-11.9, 2.3% in Hb 8-9.9, and 2.6% in Hb <8 g/dl).

Conclusions: Anemia is a frequently observed complication of CKD in NDD patients and co-exists with other comorbidities. Baseline utilization of ESAs was very rare, and slightly increased use was associated with decreasing Hb in a large US cohort of NDD patients with anemia.

SA-PO243

A Rapid Decline of Residual Kidney Function and Anemia in Hemodialysis Patients

Hiroshi Kimura,[1] Yusuke Okuda,[1,2] Connie Rhee,[1] Csaba P. Kovesdy,[3] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Kitasato University School of Medicine, Minato, Japan; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Patients on dialysis commonly develop anemia due to the kidney's critical role in red blood cell production. Slower residual kidney function (RKF) decline on dialysis is associated with better outcomes. We hypothesized that a faster decline in RKF may be associated with a higher odds of developing anemia in the incident hemodialysis (HD) patients.

Methods: The associations of decline in RKF with anemia were examined retrospectively across four strata of annual change in RKF (residual renal urea clearance [KRU], <-3.0, -3.0 to <-1.5, -1.5 to <0, ≥0 mL/min/1.73m^2; urinary volume, <-600, -600 to <-300, -300 to <0, ≥0 mL/day) using logistic regression models adjusted for clinical characteristics and laboratory variables in 5,403 incident HD patients of a large US dialysis organization between January 1, 2007 and December 31, 2011.

Results: A total of 5,291 (98%) patients used erythropoiesis-stimulating agents (ESAs) during the first year of HD initiation. The median baseline values of the annual change in KRU and urinary volume were -1.2 (interquartile range [IQR]: -2.8 to 0.1) mL/min/1.73m^2 and -250 (IQR: -600 to 100) mL/day, respectively. Multivariate logistic regression models revealed that the fastest RKF decline in the first year of HD was associated with higher odds of anemia (Figure). These associations remained robust against adjustment for

laboratory variables and consistent across strata of baseline RKF, age, sex, race, diabetes, congestive heart failure, hemoglobin, and serum albumin. Analyses using urinary volume as another index of RKF showed consistent associations.

Conclusions: Rapid RKF decline during the first year of dialysis was associated with anemia among incident HD patients.

Iron Deficiency Anemia in Clinical Practice: Can Virtual Patient Simulation Improve Management?

Amy Larkin,[1] Donald Blatherwick,[2] Martin Warters,[1] Douglas Blevins.[3]
[1]Medscape Education, Nicholasville, KY; [2]Medscape, Medford, NJ; [3]Medscape, Durham, NC.

Background: We sought to determine if an online, virtual patient simulation (VPS)-based continuing medical education (CME) intervention could improve performance of nephrologists and primary care physicians (PCPs) in diagnosising and managing iron deficiency anemia (IDA).

Methods: The intervention comprised two patient cases where learners ordered lab tests, made diagnoses, and prescribed treatments similar to practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user's baseline (pre-CG) decisions using a 2-tailed paired t-test to determine *P* values. The activity launched May 10, 2019; data were collected for initial abstract submission through May 22, 2019.

Results: To date, 11 nephrologists and 47 PCPs have participated (larger sample size expected by ASN conference). Case 1: IDA diagnosis: 22% absolute improvement among nephrologists (22% pre-CG vs 44% post-CG; P=.18), 5% improvement among PCPs (53% pre-CG vs 58% post-CG; P=.16) Diagnosis of chronic kidney disease stage 5: 33% absolute improvement among nephrologists (0% pre-CG vs 33% post-CG; P<.001), 34% improvement among PCPs (16% pre-CG vs 50% post-CG; P<.01) Dialysis referral: 22% absolute improvement among nephrologists (22% pre-CG vs 44% post-CG; P=.18), 21% improvement among PCPs (21% pre-CG vs 42% post-CG; P<.05) Initiate oral iron supplement: 22% absolute improvement among nephrologists (22% pre-CG vs 44% post-CG; P=.18), 32% improvement among PCPs (39% pre-CG vs 71% post-CG; P<.01) Case 2: IDA diagnosis: 27% absolute improvement among nephrologists (27% pre-CG vs 54% post-CG; P=.08), 21% improvement among PCPs (30% pre-CG vs 52% post-CG; P<.01) Diagnosis of chronic kidney disease stage 4: 36% absolute improvement among nephrologists (27% pre-CG vs 63% post-CG; P<.05), 32% improvement among PCPs (17% pre-CG vs 49% post-CG; P<.01) Initiate oral iron supplement: 36% absolute improvement among nephrologists (36% pre-CG vs 82% post-CG; P=.01), 21% improvement among PCPs (9% pre-CG vs 57% post-CG; P<.01)

Conclusions: VPS that immerses and engages specialists in an authentic and practical learning experience can improve evidence-based clinical decisions related to diagnosis and management of IDA.

Ferric Citrate Hydrate on Anemia Management in Hyperphosphatemia Hemodialysis Patients with or Without Diabetes: ASTRIO Study Supplementary Analysis

Keitaro Yokoyama,[1] Masafumi Fukagawa,[2] Masaaki Nakayama,[5] Ito Kyoko,[3] Hideki Hirakata.[4] *[1]Harumi Toriton Clinic of The Jikei University Hospital, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan; [3]Torii Pharmaceutical Co., Ltd, Tokyo, Japan; [4]Fukuoka Renal Clinic, Fukuoka City, Japan; [5]Tohoku University, St Luke's International Hospital, Sendai City, Japan.*

Background: It is reported that patients with diabetes in hemodialysis (HD) tend to be treated with higher ESA dose. The relationship is bi-directional, iron affects glucose metabolism and glucose metabolism affects iron metabolism pathway. In ASTRIO Study, Ferric Citrate Hydrate (FC) reduced dose of ESA. The effect of FC on anemia management in hemodialysis diabetes patients has not been extensively evaluated.

Methods: ASTRIO was a prospective, randomized, multicenter, 24-week study. 93 hyperphosphatemia HD patients who had been taking non-iron based phosphate binders (PBs) were randomized to FC group (n=48) or Control group (n=45). In Control, patients maintained treatment with their existing PBs. Serum P and Hb were controlled within 3.5 to 6.0 mg/dL and 10.0 to 12.0 g/dL, respectively. Oral iron was prohibited in Control group. Intravenous iron was permitted if iron replacement therapy was required, at the physician's discretion. The primary endpoint was change in ESA dose from baseline to the end of treatment (EOT); we evaluated a stratified analysis for diabetes patients whose main underlying disease is diabetic nephropathy.

Results: Serum P and Hb were maintained in both groups. Regardless of whether patients have diabetes or not, ESA doses decreased in FC group.

Conclusions: The effect of FC on anemia management in hyperphosphatemia HD was comparable between diabetic and non-diabetic patients.

FC (n=46)*							
	Diabetes (n=19)			Non-Diabetes (n=27)			P value [a]
Mean	Baseline	EOT	Change	Baseline	EOT	Change

SA-PO246

Transferrin Saturation (TSAT) and Clinical Outcome in Patients with Advanced CKD

Xin Li,[1,2] Kristin Danielson Pistis,[1] Innas Forsal,[1] Ken Iseri,[1] Olof Heimburger,[1] Peter F. Barany,[1] Bengt Lindholm,[1] Abdul Rashid T. Qureshi,[1] Peter Stenvinkel.[1]
[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]Nephrology, Tongji Hospital of Tongji University, Shanghai, China.

Background: TSAT is frequently used in clinical practice as indicator of iron deficiency or overload, but its relationship with clinical outcomes in patients (pts) with advanced CKD is unclear. We investigated associations between TSAT and all-cause mortality in CKD5 non-dialysis (CKD5-ND) pts.

Methods: In 298 CKD5-ND pts (median age 56 years, 65% males, 38% cardiovascular disease, CVD, 31% diabetes, DM, median estimated glomerular filtration rate 6 (interquartile range, IQR, 5-8) ml/min/1.73^2), biomarkers of iron status (plasma iron, TSAT, transferrin and ferritin), presence of CVD and protein energy wasting (PEW; subjective global assessment), Framingham's CVD risk score (FRS; as a composite index of traditional CVD risk factors) and systemic inflammation (high-sensitivity C-reactive protein, hsCRP, and interleukin-6, IL-6) were assessed. During median follow-up of 23 months, 87 (29%) pts died and 129 (43%) pts underwent renal transplantation. Pts were stratified into high (n=74) and low (n=224) TSAT quartile groups. All-cause mortality risk was analyzed with competing risk regression with renal transplantation as competing risk.

Results: TSAT (median 21% (IQR 16-28%) was negatively associated with age, DM, CVD, FRS, white blood cell count, hsCRP, IL-6, use of erythropoietin stimulating agents and iron supplementation, and positively associated with hemoglobin (Hb), ferritin and s-albumin. In competing risk analysis, low TSAT (sHR 1.84, 95% CI 1.0-3.36) was associated with higher all-cause mortality, independent of FRS. However, after further adjustments for FRS, ferritin, Hb, hsCRP and PEW, the association was not significant (p=0.07; sHR 1.72, 95% CI 0.95-3.09).

Conclusions: TSAT was inversely associated with all-cause mortality in CKD5-ND pts, independent of traditional CVD risk factors represented by FRS, underlining the importance of iron status in CKD. Nevertheless, degree of anemia, inflammatory status and PEW should be considered when analyzing TSAT as risk factor for adverse clinical outcomes in non-dialyzed pts with advanced CKD.

SA-PO247

Potential Safety Concern of Daprodustat Compared with Injectable Erythropoiesis-Stimulating Agents in Patients with Anemia on Hemodialysis and Not on Dialysis: A Pooled Analysis

Takayuki Hamano,[2] Masaomi Nangaku,[3] Tadao Akizawa,[4] Yoshiharu Tsubakihara,[5] Takashi Nagakubo,[1] Taeko Yonekawa,[1] Toshifumi Kimura,[1] Yukihiro Endo,[1] Alexander R. Cobitz.[1]
[1]GlaxoSmithKline, Tokyo, Japan; [2]Osaka University Graduate School of Medicine, Suita, Japan; [3]the University of Tokyo School of Medicine, Tokyo, Japan; [4]Showa University School of Medicine, Tokyo, Japan; [5]Graduate School of Health Care Science, Jikei Institute, Yodogawa-ku, Osaka, Japan.

Background: Daprodustat is an oral hypoxia-inducible factor-prolyl hydroxylase inhibitor under development for treating anemia in hemodialysis (HD) and non-dialysis (ND) patients. Safety analyses were performed to evaluate potential safety concerns such as ocular, cardiovascular, and cancer related adverse events (AEs).

Methods: Post-hoc pooled analyses were conducted by using 2 open-label, randomized controlled trials (RCTs) compared to injectable erythropoiesis stimulating agent (ESA) in ND patients (ClinicalTrials.gov Identifier: NCT01977573, NCT02791763) and one open-label and one double-blind, RCTs compared to ESA in HD patients (NCT01977482, NCT02969655). The principal outcomes were frequencies of a subset of the predefined AEs of special interest (AESIs): ocular (proliferative retinopathy, macular edema, choroidal neovascularization), cardiovascular (all-cause death, myocardial infarction, stroke, heart failure, thromboembolic events, thrombosis of vascular access)

and cancer (cancer-related mortality and tumor progression and recurrence) related AEs, and ophthalmological findings by ophthalmologists during treatment.

Results: AEs in each AESI category were pooled from 549 patients (n=319; daprodustat, n=230; ESA) and 487 patients (n=313, n=174) in ND and HD patients, respectively. Median exposure (days, daprodustat vs. ESA) in ND and HD patients was 172 vs. 337 and 169 vs. 365, respectively. In ND patients, the incidence (daprodustat vs. ESA) of ocular, cardiovascular, and cancer related AEs were 3% vs. 3%, 3% vs. 6% and 1% vs. 1%, respectively. In HD patients, these were respectively 2% vs. 2%, 7% vs. 7% and <1% vs. <1%. The incidence of ophthalmological findings were 11% vs. 10% in ND patients and 6% vs. 8% in HD patients. There was no meaningful difference in the frequencies of these predefined AESIs and ophthalmological findings between the treatment groups in ND and HD patients.

Conclusions: Daprodustat showed no new safety concerns in these predefined AESIs in these clinical studies, but further investigation will be needed.

SA-PO248

Comparison Between a Novel Latex Immunoassay and LC-MS/MS for Hepcidin-25 Measurement

Daigo Kamei,[1] Masashi Nagano,[2] Norio Hanafusa,[1] Michio Mineshima,[1] Kosaku Nitta,[1] Ken Tsuchiya.[1] *[1]Tokyo Women's Medical University, Tokyo, Japan; [2]Nerima Sakuradai Clinic, Tokyo, Japan.*

Background: Hepcidin-25 is an iron regulatory factor in the in vivo evaluation of iron dynamics and plays an important role in determining the development and severity of anemia in patients with chronic kidney disease. Although the golden standard of measurement of hepcidin-25 is the LC-MS/MS method, results cannot be obtained immediately at the clinical site. However, the latex immunoassay (LIA) can be performed using general clinical laboratory equipment, and the results obtained quickly. Our aim was to measure hepcidin-25 by LIA and LC-MS/MS and compare the two methods.

Methods: Hepcidin-25 was measured by LIA and LC-MS/MS in 134 hemodialysis patients. We used a hepcidin-25 specific reagent (FUJIFILM Wako Pure Chemical Corporation) and the JCA-BM6050 automatic analyzer for LIA and the 4000 QTRAP LC-MS/MS system for LC-MS/MS. The results obtained by the two methods were compared by standard major axis regression.

Results: The standard major axis regression equation between the two methods was $y = 0.995x + 0.5$ ($r = 0.998$, $p < 0.001$). The correlation between the two methods was very strong and the measured values were almost identical.

Conclusions: The performance of LIA was equivalent to that of LC-MS/MS for hepcidin-25 measurement. LIA can be performed using general clinical examination apparatus and has a higher processing speed than LC-MS/MS. Therefore, measurement of hepcidin-25 by LIA may potentially be useful for routine laboratory testing.

SA-PO249

Hemoglobin Cycling Induced by Delayed Patient-Therapy Feedback During ESA Treatment

David J. Joerg,[1] Doris H. Fuertinger,[1] Peter Kotanko.[2,3] *[1]Fresenius Medical Care, Bad Homburg, Germany; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

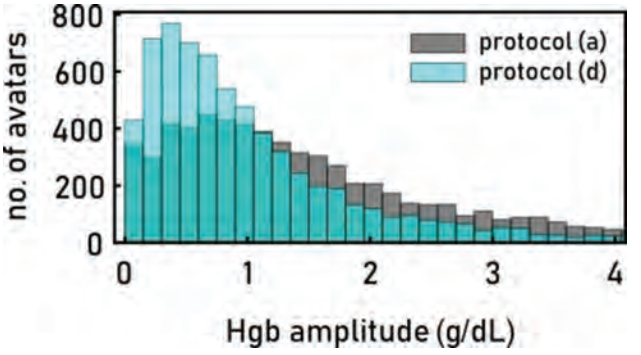
Background: Chronic kidney disease (CKD) commonly entails anemia, leading to poor patient outcomes. During treatment of anemia with erythropoiesis-stimulating agents (ESAs), patients frequently experience hemoglobin (Hgb) "cycling" periods during which the patient's Hgb levels periodically over- and undershoot a defined target range of 10–11.5 g/dL. Using a computational model of anemia treatment ("Virtual Anemia Trial"; Fuertinger et al., CPT Syst. Pharmacol. 7(4) 219, 2018), we aimed to detect treatment-related causes of this behavior.

Methods: We carried out Virtual Anemia Trials with 6659 virtual patients ("avatars") under 4 different anemia treatment protocols (a to d) for one simulated year of treatment. Avatars differed in endogenous EPO levels, total blood volume, and ESA half-life. Treatment protocols differed in ESA dosing charts (steps between doses and administration frequency) and the criteria that determine ESA dose recommendations based on the patient's Hgb history (i.e., critical Hgb levels and/or rates of change).

Results: The 4 treatment protocols yielded different distributions of Hgb amplitudes (difference between maximum and minimum Hgb in the second half of the simulated patient year), with mean ± s.d. given by (a) 1.7 ± 1.5 g/dL, (b) 1.7 ± 1.4 g/dL, (c) 1.6 ± 1.3 g/dL and (d) 1.1 ± 1.0 g/dL, respectively (see Figure). Except for (a) vs. (b), differences between the corresponding distributions were statistically significant when pairwise compared (Pearson chi-squared test; $p < 0.05$).

Conclusions: Our results suggest that certain treatment protocols can augment Hgb cycling instead of preventing it. Analysis of the differences between probed treatment protocols reveals two treatment-related causes for Hgb cycling: (i) too late ESA dose changes in response to falling/rising Hgb levels and (ii) too extreme dosing decisions (e.g., a complete ESA hold for a too long time) that prevent Hgb levels from remaining within target after transiently reaching it. Based on these insights, existing treatment protocols may be modified to reduce patients' Hgb cycling.

Funding: Commercial Support - Fresenius Medical Care Germany



SA-PO250

The Alteration of Non-Transferrin-Bound Iron (NTBI) and Malondialdehyde (MDA)-LDL After Single-Dose Oral Iron Administration (OIA) in Hemodialysis (HD) Patients

Noriko Saito,[1] Kazuhide Saito,[2] Hisaki Shimada,[1] Tetsuo Morioka.[1] *[1]Nephrology, Shinraku-en Hospital, Niigata, Japan; [2]Urology, Niigata University, Niigata, Japan.*

Background: OIA is not considered to increase NTBI because of slow iron adsorption rate. Aim of this study is to assess the alteration of NTBI and an oxidative stress marker, MDA-LDL after single dose OIA.

Methods: 25 HD patients without any iron load within 4 weeks, whose Hb<12g/dl, ferritin<100ng/ml and CRP<1.0mg/dl and 13 healthy volunteers received oral ferrous sulfate 105mg. 21 HD patients without OIA were as HD control. We evaluated the following markers before and at 1, 2, 3, 4 and 48 hours(hrs) after OIA : MDA-LDL, NTBI, Hepcidin-25(HPC), serum iron(Fe), TSAT, ferritin, selenium(Se) and standard hematological parameters. Vitamin C(VC) were measured before and at 4 and 48hrs. MDA-LDL was measured by ELISA. NTBI was measured by recently described reliable method(Clin Chim Acta437:129-135, 2014).

Results: Fe, TSAT and NTBI increased after OIA and reached the peak at 4hrs, ferritin also increased at 48hrs in both HD patients and healthy control. In HD control without OIA, they did not change. NTBI and HPC basal levels were higher in healthy control than in HD patients. MDA-LDL before OIA was not different between the two groups. MDA-LDL increased from 1 to 4hrs during HD and returned to the basal level at 48 hrs irrespective of OIA, however, in healthy control, no significant alteration was observed. In HD patients, Se level before OIA was a negative predictor for Log(MDA-LDL) before OIA by stepwise analysis(β=-0.459, p=0.021, R^2=0.21). In healthy control, NTBI before OIA was a predictor for Log(MDA-LDL) before OIA(β=0.768, p=0.002, R^2=0.589). Percentage of hypo-hemoglobinised (HypoHe) in HD patients (β=-0.443, p=0.027, R^2=0.196) and HPC in healthy control (β=-0.637, p=0.019, R^2=0.406) before OIA were negative predictors for the maximum level of NTBI after OIA, respectively. Antioxydants, Se and VC basal levels were lower in HD patients. Se level did not change during HD. VC level decreased after HD and recovered at 48 hrs.

Conclusions: NTBI significantly increased after OIA. However, MDA-LDL significantly increased during HD session irrespective of OIA, whereas it did not change in healthy control after OIA. Although OIA increase NTBI, it had little influence on the MDA-LDL level. This may result of the exquisite balance of the oxydative stress and the antioxydant activity.

SA-PO251

Impact of a Novel Dose Calculation Method for Erythropoiesis Stimulating Agents on Renal Anemia Therapy in Hemodialysis Patients

Tetsuya Fujikawa,[2] Tadashi Kuji,[1] Kazuhiko Shibata.[3] *[1]Yokodai Central Clinic, Yokohama, Japan; [2]Yokohama National University, Yokohama, Japan; [3]Yokohama Minami Clinic, Yokohama, Japan.*

Background: Patients with end-stage renal disease requiring dialysis therapy have poor prognosis compared with normal population. Renal anemia is a common comorbidity and is a major cause of morbidity and mortality among hemodialysis patients. For treatment of renal anemia, empiric erythropoiesis stimulating agents (ESA) dosing method is generally used in hemodialysis patients and standardized method are shown by Fishbane et al. in 2005. However, hemoglobin (Hb) levels are not always within target range for favorable prognosis according to anemia guidelines. We developed a new method for ESA dose determination that uses individual increase value and individual decrease value calculated from Hb variability. Individual increase value and individual decrease value mean real response of Hb increase under maximum ESA dose and natural Hb decrease without ESA per week, respectively. There has never been a reliable and valid method to calculate individual increase and decrease values before the new method. The aim of this study was to estimate effectiveness of the new method for ESA dosing.

Methods: This was a 6-month randomized, controlled, parallel-group study in hemodialysis patients with renal anemia treatment. Patients were assigned to two groups receiving epoetin beta (EPO) dosing by new method and standardized method. The target range of Hb was set at 10.0 to 11.0 g/dL. EPO doses for two weeks were determined at every two-week Hb measurement. Iron was administered when ferritin was below 100 ng/mL or transferrin saturation below 20%.

Results: One-hundred and two patients were enrolled (61 men, 41 women; mean age 68.9 ± 12.5 years). There was no difference in baseline characteristics between the two groups. At end of study, mean Hb levels were not different between the new method group and standardized method group (10.5 ± 0.7 g/dL vs. 10.5 ± 0.7 g/dL, P = 0.936). The ratio of patients with Hb levels within target range were significantly different between the new and standardized method groups (75% vs. 50%, P = 0.021 by chi-square tests). Required EPO dose were not different between the new and standardized method groups (2578.1 ± 1851.2 IU/w vs 3046.9 ± 2627.3 IU/w, P = 0.359). There were no adverse events related to the new method.

Conclusions: The new method for EPO dosing is superior to existing standardized EPO dosing method.

Modulation of Circulating Endothelial Progenitor Cells by Erythropoiesis-Stimulating Agent in Patients with Hemodialysis

Takashi Naito,[1] Kosaku Nitta.[2] *[1]Tokyo Rosai Hospital, Yokohama, Japan; [2]Tokyo Women's Medical University, Shinjuku-ku, Japan.*

Background: Recent studies have suggested that erythropoiesis stimulating agent (ESA) may accelerate not only angiogenesis but also vasculogenesis, beyond erythropoiesis

Methods: We conducted a 12-week prospective study in 42 dialysis patients; 11 patients were treated with recombinant human erythropoietin (rhEPO) (EPO group, 5487.5 ± 735.1 IU/week), 11 patients with darbepoetin (DA) (DA group, 41.6 ± 4.7 μg/week), 10 patients with epoetin β pegol (CERA group, 49.5 ± 16.5 μg/week) and 10 patients with no ESAs (no-ESA group). Vascular mediators comprising EPCs, vascular endothelial growth factor, matrix metalloproteinase-2 (MMP-2), and high-sensitivity C-reactive protein were measured at 0 and 12 weeks. EPCs were measured by flow cytometry as $CD45^{low}$ $CD34^{+}$ $CD133^{+}$ cells.

Results: In the EPO and CERA group, EPC count increased significantly from 0 to 12 weeks in a dose-dependent manner (EPO; r = 0.77, p = 0.01, CERA; r = 0.72, p = 0.01). In the DA group, the EPC number did not change at 12 weeks. Furthermore, the serum levels of the above biomarkers except EPC were not affected by ESA in all groups.

Conclusions: We speculate that the pleiotropic effects of each ESA types beyond their hematopoietic effects may differ in ESKD patients.

Model Predictive Control (MPC) for Iron Dosing for the Management of Anemia

Michael E. Brier,[1,2] Adam E. Gaweda,[1] Alfred A. Jacobs,[1] Vibha S. Nayak,[1] Eleanor D. Lederer.[3,1] *[1]University of Louisville, Louisville, KY; [2]Department of Veterans Affairs, Louisville, KY; [3]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

Background: Recent studies have shown that anemia management can be improved using computer based tools to determine the dose of an erythropoietic stimulating agent (ESA). We tested the hypothesis that similar improvements can be acheived for iron dosing.

Methods: A ferrokinetic model was developed based on published data from iron studies. The model predicts monthly change in TSat and Ferritin in response to a dose adjustment of iron sucrose. Using this model, a dose adjustment algorithm was designed using principles of Model Predictive Control. The dosing objective was to drive TSat to a physician-specified target value of 35 without exceeding an upper Ferritin threshold, also specified by the physician user. Ten subjects were enrolled into a pilot study to test the safety and efficacy of the proposed approach. Subjects will be followed for 6 months and have completed 3 months follow up. Iron dose, Tsat, ferritin and epoetin beta methoxy polyethylene glycol (ESA) doses are recorded.

Results: Results for the control period (M-2,M-1) and treatment period (M1,M2,M3) are shown in the table by month. Tsat values increased following the implementation of the MPC reaching the mid-pint of the target range at 3 months. Hb values also increased and ESA dose decreased over the same period. No recommended doses were over-ridden by the physicians monitoring the project.

Conclusions: MPC control of iron dosing can compliment the use of similar decision support tools used to dose ESA's. Optiimal anemia management would maximize the dose of ESA and Iron to achieve individualized patient care. These results demonstrate the potential of simultaneously determing ESA and Iron dose in the management of patients with anemia of chronic kidney disease.

Using a Predictive Algorithm to Provide Decision Support in Anemia Management

Lori Dunn,[1] Brendan T. Bowman,[2] Benjamin Lobo.[3] *[1]University of Virginia Health System, Charlottesville, VA; [2]University of Virginia School of Medicine, Charlottesville, VA; [3]Systems & Information Engineering, University of Virginia, Charlottesville, VA.*

Background: Anemia in hemodialysis is very common with most receiving erythropoietin stimulating agent (ESA) therapy. Most ESA dosing protocols are based on manufacturer recommendations and clinical experience. They are standardized across entire dialysis populations and do not account for individual response. To improve anemia management, we developed a predictive algorithm to forecast 1, 2 and 3 month hemoglobin (HGb) values as a way of providing decision support for monthly ESA dose adjustments.
Objectives: To determine if the addition of future HGb predictions to the information currently provided to anemia managers will result in a reduction in HGb variability, an increase in the number of HGb observations within the target range, and a decrease in the average per treatment ESA use.

Methods: We developed a predictive algorithm utilizing historic electronic medical record (EMR) data collected during the 2009-2017 time period. The data set included dialysis sessions, ESA administered, intravenous iron, HGb, ferritin, and transferrin saturation (Tsat %). Following algorithm development, we conducted a 10 month (July 2018 to April 2019) QI project with approximately 20 patients in an academic dialysis center. Each month, future hemoglobin predictions were provided for 1, 2, and 3 months based on the current monthly lab draw and patient's own historical data. These predictions were then provided to anemia managers along with interpretive guidance from the development team.

Results: Incorporation of this form of decision support into the anemia management process saw the number of HGb readings below 10 g/dL decrease from 23.7% pre intervention to 19.5% post intervention (p=0.44). There was an increase from 10.8 g/dL to 11.2 g/dL in the average patient mean HGb (p=0.09) and a 77.3% decrease in the average patient HGb variance (p<0.01). Overall, there was a 32.7% decrease in the average per treatment ESA dose (p<0.01).

Conclusions: Incorporating decision support from a predictive algorithm into an existing anemia management process resulted in a decrease in overall ESA use while decreasing patient HGb variability. Small study population was a limitation to this study.

SA-PO255

Contemporary Management of Anemia and Associated Risk Across the Spectrum of CKD: A Nationwide Analysis from the Swedish Renal Registry

Marie Evans,[1,4] Hannah Bower,[1] Elinor Cockburn,[3] Stefan H. Jacobson,[2] Peter F. Barany,[1] Juan J. Carrero.[1] *[1]Karolinska Institute, Stockholm, Sweden; [2]Danderyd Hospital, Stockholm, Sweden; [3]Astellas Pharma A/S, Kastrup, Denmark; [4]Karolinska University Hospital, Stockholm, Sweden.*

Background: The last decade has seen noteworthy changes in renal anemia guidelines. Here we explore the current management of renal anemia and associated cardiovascular (CV) risk in a contemporary nationwide cohort of chronic kidney disease (CKD) patients in Sweden.

Methods: Observational analysis from the Swedish Renal Registry, including nephrologist-referred adult CKD patients during 2015. The epidemiology and treatment of anemia across the spectrum of stage 3b-5 non–dialysis-dependent (NDD) and dialysis-dependent (DD) CKD were assessed. Logistic regression and Cox proportional hazard models were employed to explore the associations between anemia management, C-reactive protein (CRP), erythropoietin resistance index (ERI; [erythropoiesis-stimulating agent (ESA) dose/weight]/hemoglobin [Hb]), and subsequent risk of major adverse CV events.

Results: Data from 14,415 (NDD, 11,370; DD, 3,045) patients were included. Approximately 60% of NDD CKD patients had anemia (World Health Organization definition: Hb <12 g/dL for females; Hb <13 g/dL for males) compared with 93% of DD patients. The proportions of NDD patients who received iron (oral or intravenous) and/or ESA therapy were 21% and 24%, respectively; the proportions of DD patients were 62% and 82%, respectively. In both NDD and DD populations, about half of the patients receiving ESA had Hb levels between 10-12 g/dL; 27% had Hb >12 g/dL and 14% had

Hb <10 g/dL. Use of high-dose ESA (>6000 IU/week) was relatively common even among patients at earlier stages of CKD (~25%). The use of high versus low (<3000 IU/week)/medium (3000-6000 IU/week) dose ESA was associated with increased systemic inflammation in cross-section (CRP >5 mg/L) (odds ratio, 1.68 [95% CI: 1.45-1.94]), with a 40% higher risk of CV events (adjusted hazard ratio [HR], 1.40 [95% CI: 1.16-1.69]). Patients with high (0.81-12.0) versus low (0-0.4) ERI had a 2-fold higher risk of CV events (adjusted HR, 1.98 [95% CI: 1.61-2.43]). Treatment with iron was not associated with CRP levels or CV risk.

Conclusions: Anemia continues to be a highly prevalent complication among contemporary adults with CKD. Given the guideline recommendations, the use of iron was unexpectedly low. High doses of ESA and high ERI predicted increased CRP levels and subsequent CV risk.

SA-PO256

Evaluating Anemia of CKD in Acutely Ill Patients

Martha Catalina Morales Alvarez,[1] Nitzy N. Munoz casablanca,[1] Karen James,[2] Elliot M. Charen.[2] *[1]Department of Medicine, Icahn School of Medicine at Mount Sinai Beth Israel, New York, NY; [2]Nephrology and Hypertension, Icahn School of Medicine at Mount Sinai Beth Israel, New York, NY.*

Background: Anemia of chronic kidney disease (CKD) is one of the most common long-term complications as kidney failure progresses. The pathogenesis is multifactorial, but decreased erythropoietin production has a main role in later stages of CKD. The prevalence is approximately 33-67%. Treatment options include erythropoietin stimulant agents (ESA) once iron deficiency has been treated and contraindications have been evaluated. A decreased production of red blood cells is commonly seen in acutely-ill patients. We hypothesized that CKD/ESRD patients are at higher risk of worsening anemia even with adequate hemoglobin levels on admission.

Methods: We studied 53 patients with advanced CKD or ESRD admitted to our hospital between November 2017 and January 2018. Clinical data was obtained from chart review. Data incorporated in the analysis included: hemoglobin (Hb) on admission and upon discharge, outpatient treatment of anemia, and inpatient management of anemia such as transfusion, iron supplementation and ESA. Patients with acute bleeding during hospitalization were excluded.

Results: A total of 24 patients with Hb < 10 g/dl and 29 patients with Hb >10 g/dl on admission were included in our analysis. Patients with hemoglobin >10 g/dl on admission were noted to have significantly higher decrease in hemoglobin level upon discharge compared with patients with Hb < 10 g/dl (mean change from baseline Hb 0.9 vs -0.3, $p = 0.0014$). One third of patients with indication for ESA and no clinical contraindications for administration received EPO inpatient, while 33% of patients that were not treated with EPO received blood products.

Conclusions: Hospitalized patients with advanced CKD or ESRD are at high risk of worsening anemia despite adequate Hb levels on admission. We suggest considering a closer surveillance of hemoglobin for potential administration of ESA in order to prevent worsening anemia.

SA-PO257

Improving Rates of Epoetin Alpha Administration in ESRD Patients at Two Teaching Hospitals: A Quality Improvement Initiative

Xavier F. Parada,[1] Lorenz Leuprecht,[1] Karim El Hachem.[2] *[1]Medicine, Mount Sinai St Luke's and West, New York, NY; [2]Nephrology, Mount Sinai St Luke's and West, NY, NY.*

Background: Adequate management of anemia in ESRD has important clinical implications for both patients and the healthcare system at large. It improves quality of life, prevents readmissions, decreases the need for transfusions while simultaneously improving efficiency of care. Subcutaneous (SQ) Epoetin Alpha (EPO) provides a dose-sparing advantage over Intravenous (IV) EPO. In hospitals A and B, following a switch in the process of EPO administration from IV during dialysis to SQ on the general floors, we noted rates of 19.5% and 14.5% of missed EPO doses at hospitals A and B respectively. Unrefrigerated, un-administered EPO doses are discarded leading to a significant waste and worsening hemoglobin levels. The aim of this QI initiative was to understand the roots and reduce missed EPO doses to <10% over 9 months.

Methods: We utilized the PDSA performance improvement model to manage this project. A multidisciplinary team including Nephrology, Nursing, Pharmacy and IT was created. We identified the most common cause of missed doses as an inpatient dialysis schedule switch (from Monday/Wednesday/Friday to Tuesday/Thursday/Saturday or vice versa) without a coinciding change in the EPO order. Our first intervention was the creation of an EMR alert notifying nurses to administer the dose as ordered regardless of patients' dialysis schedule and asking them to discuss with nephrology if they were to hold a dose. At month 5, we tested a second intervention: a collaborative nursing education about anemia management at Hospital B only, facilitated by a nephrologist and a nurse educator.

Results: The results of the study are summarized in Figure1. Following the creation of an EMR alert, there was only a mild and unsustained improvement in our rates at both hospitals. After nursing education at Hospital B, we noted a sustained improvement in our rates at Hospital B but not at Hospital A.

Conclusions: While technology is an important tool providing scale and efficiency in QI initiatives, the role of targeted Nursing Education remains an effective measure to prevent waste and sustain change.

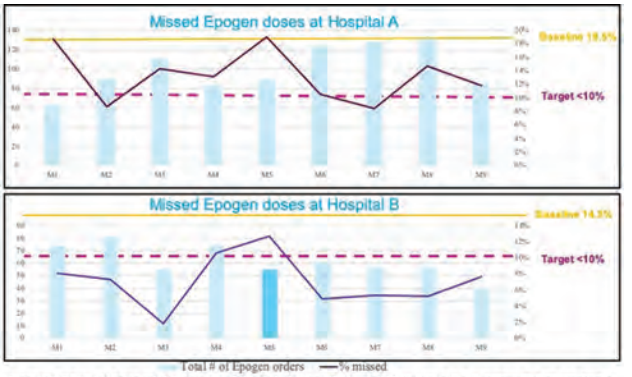

Figure1- Rates of missed doses at both Hospital A and B. M1 to M9 indicate the months 1 to 9 of the study. In addition to the EMR alert, Hospital B nurses underwent a series of **educational sessions** provided by a nephrologist focused on EPO administration and anemia management in ESRD patients starting at **Month 5**.

SA-PO258

24 Hydroxylase Deficiency: Comparison with Other Disorders of Vitamin D-Mediated Hypercalcemia

Sarah M. Azer, Lisa E. Vaughan, Peter Tebben, David J. Sas. *Mayo Clinic, Rochester, MN.*

Background: *CYP24A1* gene encodes 24-hydroxylase, an enzyme that converts $25(OH)D_3$ (25D) and $1,25(OH)_2D_3$ (1,25D) to inactive metabolites. Recent reports establish that loss of function mutations in *CYP24A1* are associated with 24 hydroxylase deficiency (24HD), characterized by hypercalcemia, nephrolithiasis, and/or nephrocalcinosis (NC). We retrospectively compared laboratory, imaging, and clinical characteristics of patients with suspected or confirmed 24HD to other disorders of vitamin D-mediated hypercalcemia: sarcoidosis (S), lymphoma (L), and exogenous vitamin D toxicity (EVT).

Methods: Patients seen at Mayo Clinic, Rochester between 1/1/08 and 12/31/16 were further evaluated if they met biochemical criteria: serum calcium ≥9.6 mg/dL, PTH <30 pg/mL, and 1,25D >40 pg/mL. Patients with 24HD were then identified if they met one of the following criteria: 1) positive genetic testing or 2) 25D:24,25D ratio ≥50. Patients with diagnosis of S, L, or EVT were identified by chart review. Patients with fungal infections were also identified but excluded from analysis due to lack of systemic involvement. Data were summarized and reported using median [IQR] for continuous variables and n(%) for categorical variables. Comparisons between disease groups were evaluated using the Fisher exact test for categorical variables and the Wilcoxon rank sum test for continuous variables.

Results: Comparison of 24HD (n=9) to all groups (n=28) revealed 24HD patients were younger at symptom onset (13.75 [1,35] vs 63 [56,79], p=0.001) and more likely to have family history (88.9% vs 20.8%, p<0.001), NC (88.9% vs 6.3%, p<0.001), lower lumbar spine Z-score (-0.50 [-0.80,0.70] vs 1.20 [0.80,2.10], p=0.011), and higher urine Ca:Cr ratio (0.24 [0.21,1.70] vs 0.17 [0.14,0.18], p=0.047).

Conclusions: Patients with 24HD have clinical and laboratory differences compared to other causes of vitamin D mediated hypercalcemia. 24HD should be suspected in hypercalcemic patients who present at a younger age, have a positive family history, and have nephrocalcinosis.

SA-PO259

Severe Hypercalcemia Mitigated by Etelcalcetide in Continuous Renal Replacement Therapy

Ashita J. Tolwani, Arun Rajasekaran. *University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Secondary hyperparathyroidism (SHPT) is associated with increased bone turnover, risk of fractures, vascular calcifications, and cardiovascular and all-cause mortality. We describe a critically ill ESRD patient with SHPT who developed hypercalcemia with prolonged immobilization managed with continuous renal replacement therapy (CRRT) using regional citrate anticoagulation (RCA) without calcium supplementation and treatment with intravenous etelcalcetide.

Case Description: A 51 year old lady with ESRD on hemodialysis (HD) underwent aortic and mitral valve replacement. She received maintenance HD for 10 days after cardiac surgery. Post-surgical course was complicated by hypoxic respiratory failure, mesenteric ischemia, and septic shock warranting mechanical ventilation, colectomy and vasopressor use. In the setting of SHPT with high turnover bone disease and prolonged immobilization, she developed pathological bilateral subcapital femoral neck fractures with diffuse osteopenia 2 months after admission. She had elevated systemic ionized calcium (1.6 mmol/L), phosphorus (6.7 mg/dl), ALP (426 U/L), bone-specific ALP (90 mcg/L), and PTH (780 pg/ml) levels. The patient was started on citrate based CRRT without the use of a calcium infusion 10 days after cardiac surgery; and was treated with intravenous etelcalcetide 5 mg thrice weekly to mitigate severe hypercalcemia. After 3 weeks, she had a reduction in systemic ionized calcium (1.1 mmol/L), phosphorus (3.5 mg/dl), ALP (316 U/L), and PTH (310 pg/ml) levels. She eventually died from worsening septic shock.

Discussion: Etelcalcetide, a novel second-generation calcimimetic, has made significant advances in managing SHPT via improved control of PTH and FGF-23 levels. It can be used in critically ill patients with severe hypercalcemia and SPHT on CRRT as no renal dosing is required. RCA provides anticoagulation for CRRT by chelating calcium in the circuit and requires a systemic calcium infusion to replace calcium. Patients with severe hypercalcemia can be managed effectively with citrate-based CRRT without the need for systemic calcium replacement as long as systemic ionized calcium levels are monitored frequently.

SA-PO260

Effect of Transition from Vitamin D2 to Vitamin D3 Supplementation on Serum 25(OH)D Levels in Patients on Chronic In-Center Hemodialysis

Andy Chuu, Madhuri Ramakrishnan, Daniel W. Coyne. *Washington University in St. Louis, St. Louis, MO.*

Background: Vitamin D deficiency (25(OH)D <12 ng/ml) can lead to osteomalacia in adults, and insufficiency (12 to 20 ng/ml) is associated with osteoporosis, increased falls, and possibly fractures. Clinical guidelines (KDIGO 2017) recommend correction of Vitamin D deficiency and insufficiency in all CKD 3-5D patients. Short-term pharmacokinetic studies in healthy adults have shown that Vitamin D2 (VitD2) is less effective at correcting 25(OH)D levels than Vitamin D3 (VitD3). We evaluated whether conversion from VitD2 therapy to VitD3 resulted in a meaningful change in 25(OH)D levels in hemodialysis (HD) patients.

Methods: Since 2006, we have directly administered 50,000 units of VitD2 monthly to all ~160 in-center dialysis patients. In June 2017, we converted to 50,000 units monthly of VitD3. We collected demographic and laboratory data from 2016 and 2017 (VitD2 dosing), and 2018-2019 (VitD3 dosing). 25(OH)D was measured each April at Quest laboratories. Assay detects both 25(OH)D2 and 25(OH)D3. Changes in 25(OH)D levels were analyzed, and relationships to demographic and other laboratory parameters were explored.

Results: 156 to 174 patients were included in each yearly analysis. Mean 25(OH) D levels (ng/ml) were 34.6 (2016) and 36.6 (2017) on VitD2. Levels increased to 52.9 (2018) and 53.7 (2019) on VitD3 (p<0.001). Use of VitD3 greatly reduced the proportion of patients with 25(OH)D 20-30ng/ml (29% pre; <1% post), but increased 25(OH)D levels >50 from 7% to 55%, and levels >80 from 0.3% to 4%. Among 96 patients present all 4 years, the results were similar (mean 35.2 on VitD2, and 55.0 on VitD3). There was no significant change in Calcium, PTH, or Alkaline Phosphatase

Conclusions: Consistent with short-term studies in healthy adults, at equal doses, VitD3 led to significantly higher 25(OH)D levels than VitD2. As 25(OH)D levels >20 ng/ml are sufficient to prevent osteomalacia, our data suggest use of either 50,000 units of VitD2 monthly, or a lower dose of VitD3 (likely 20-30,000 units monthly) is sufficient to prevent Vitamin D deficiency in HD patients.

Figure 1

	2016	2017	2018	2019	p-value
Vitamin D (ng/dL)	34.6	36.6	52.9	53.7	<0.001*
Calcium (mg/dL)	9.2	9.2	9.3	9.2	0.219
PTH (pg/mL)	450.2	517.2	471.1	575.5	0.217
Alk Phos (U/L)	94.3	97.6	89.2	96.4	0.542

Serial Change of Serum Calcium and Management of Hypocalcemia After Denosumab Treatment in Hemodialysis Patients: A Single-Center Experience

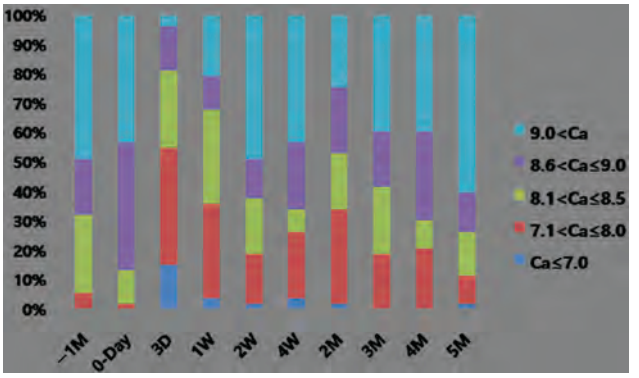
Jeongmyung Ahn,[1] Heeryong Lee,[1] Dong Ryeol Lee,[1] Mi young Jeon.[2] *[1]Division of Nephrology, Internal Medicine, Busan, Republic of Korea; [2]Maryknoll Medical Center, Busan, Republic of Korea.*

Background: Denosumab is a new drug of osteoporosis. It inhibits osteoclast formation and decreases bone resorption. Most common side effect is hypocalcemia. A prevalence of hypocalcemia after use of denosumab in HD patients is not clear.

Methods: We treated osteoporosis in HD patients with denosumab 60mg s.c. To prevent hypocalcemia, we gave Dicamax(cholecalciferol 1000 IU and calcium carbonate 1250mg) during a week before use of denosumab. After treatment, we checked serial serum calcium, every visit, during 2 weeks. When below 8mg/dL of serum calcium, patients was administrated with intravenous calcium gluconate(2g/20ml) according to our policy. We evaluated a serial change of serum calcium and prevalence of hypocalcemia after treatment. Also, We checked a percentage of patients who were replaced intravenous calcium.

Results: Total number of patients treated with denosumab was 53(female 43, 81.1%). Median age was 69 years old(45~83 years old). Median vintage of hemodialysis was 4.2 months(0.2~113.6months). Of 53 patients, there were 35(66%) diabetes and 19(35.8%) fractures. Basal calcium, phosphorus and iPTH were 9.1±0.53mg/dL, 4.1±1.34mg/dL, and 229.8±171.7pg/dL. Serial mean serum calcium was 8.4±0.80mg/dL, 8.8±0.82mg/dL, 8.9±1.14mg/dL, 8.6±1.11mg/dL, 8.9±1.03mg/dL, 9.1±1.13mg/dL and 9.2±1.01mg/dL, on the first day of 1st and 2nd week, 1st, 2nd, 3rd, 4st and 5st month later. Nadir calcium was detected during 2 weeks, 7.9±0.70mg/dL(6.5~9.2mg/dL). Patients who needed intravenous calcium, was increased during 2 weeks. 19patients(41.9%) was below 8mg/dL of serum calcium on the first day of 1st week after treatment. 21 patients(60.4%) were replaced intravenous calcium. One patient had hospitalization due to symptomatic severe hypocalcemia. After 2 months of using denosumab, serum calcium is stabilized to previous level.

Conclusions: Hypocalcemia is frequent in HD patients after use of denosumab. Intravenous calcium replacement is needed in patients with severe hypocalcemia.



SA-PO262

Assessment of the Confounding Factors to Affect Life Prognosis of Serum Magnesium in Hemodialysis Patients

Chie Ogawa,[1,3] Ken Tsuchiya,[2,3] Fumiyoshi Kanda,[1] Kunimi Maeda.[1,3] *[1]Maeda Institute of Renal Research, Kawasaki, Japan; [2]Department of Blood Purification, Tokyo Women's Medical University, Tokyo, Japan; [3]Biomarker Society, Inc., Kawasaki, Japan.*

Background: Recently, some studies reported that hypomagnesemia was associated with mortality and cardiovascular events. However, optimal levels of serum magnesium (s-Mg) is unknown in hemodialysis (HD) patients. We have measured s-Mg levels once a month in HD patients. So, to identify the appropriate s-Mg levels, a 9-year survey was performed to investigate the relationships between s-Mg levels and a prognosis in HD patients. Moreover, the factors to affect s-Mg level were examined.

Methods: 148 HD-outpatients under seventy years old were followed from January 2009 to December 2018. Patients were divided to two groups according to the mean s-Mg levels during the first year period. Cutoff-point of s-Mg levels was used 2.5mg/dL, upper value of normal range in healthy subjects. The outcome was all-cause mortality/hospitalization due to be impossible of HD-outpatient. Statistical analyses were used Kaplan-Meier, log-rank tests and the Cox proportional hazards model. Then, multiple regression analysis was performed to examine factors related to s-Mg levels.

Results: The range of mean s-Mg levels for the first year was 1.9-3.8mg/dL. The survival rate in the s-Mg levels ≤2.5mg/dL group was significantly lower than that in the s-Mg levels >2.5mg/dL group (39.0% vs 72.0%; P < 0.001). The multivariate Cox proportional hazards model (stepwise method) showed that the risk of mortality/hospitalization were significantly higher in the s-Mg levels ≤2.5mg/dL group compared with the s-Mg levels >2.5mg/dL group (hazard ratio; 1.89; 95% confidence interval, 1.08–3.28, P = 0.025). Multiple regression analysis showed that s-Mg levels were associated with age, serum albumin and corrected calcium [serum calcium (mg/dL) + 4.0 - serum albumin (g/dL)]

Conclusions: This study indicated the s-Mg levels ≤2.5mg/dL was associated with high mortality/hospitalization in HD patients. The optimal s-Mg levels in HD patients may be higher level than that in healthy subject. Moreover, s-Mg levels may be affected by age, nutritional condition and calcium metabolism.

Multiple stepwise regression analysis for serum magnesium

	β	95% confidence interval	P value	R2
(Intercept)		(-0.233 - 2.672)	0.100	0.17
age (years)	-0.008	(-0.014 - -0.002)	0.009	
serum albumin (g/dL)	0.267	(0.069 - 0.464)	0.008	
corrected calcium (mg/dL)	0.100	(0.003 - 0.195)	0.044	

SA-PO263

Soluble Klotho Modifies the Mortality Risk Associated with Hypomagnesemia in Patients with Hemodialysis

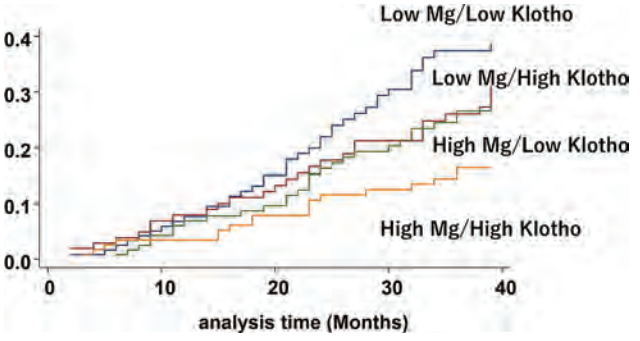
Akio Nakashima,[1] Ichiro Ohkido,[2] Keitaro Yokoyama,[3] Takashi Yokoo.[1] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [3]Harumi Toriton Clinic of The Jikei University Hospital, Tokyo, Japan.*

Background: Hypomagnesemia have been regarded as a risk factor of cardiovascular disease in patients with CKD. In vitro studies reported that hypomagnesemia induced downregulation of Klotho. We examined how soluble Klotho levels influence the association between serum magnesium levels and the risk of mortality in patients with hemodialysis.

Methods: This cohort study analyzed 1241 hemodialysis patients. We divided the study population into four groups based on serum soluble Klotho levels and magnesium levels. In this study, we defined the primary outcome was all-cause mortality. We used Cox proportional hazard model.

Results: Their mean age was 63.1 (±11,8) years, and median dialysis vintage was 84 (39 to 154) months. The distribution of Klotho levels was 325 (248 to 434) pg/ml. In addition, serum magnesium levels is 2.6 (± 0.46)mg/dl. During following period, 228 patients dead. Patients with lower magnesium (< 2.6mg/dl) and lower Klotho (325 pg/ml) were higher mortality than patients with higher magnesium and higher Klotho (HR 2.33,95%CI 1.37-3.97).

Conclusions: In this study, we found that lower magnesium and lower soluble Klotho is high risk of mortality in patients with hemodialysis.



SA-PO264

Circadian Rhythm of Plasma Magnesium in Patients with CKD Stage 3-4 and Healthy Controls

Alexanndra Jacobsen,[1,2] Iain O. Bressendorff,[1,2] Anders Nordholm,[2] Søren Egstrand,[3] Niklas R. Jørgensen,[4] Ewa Lewin,[5] Klaus Olgaard,[4] Ditte Hansen.[2] *[1]Department of Nephrology, Herlev Hospital, Copenhagen, Denmark; [2]Herlev Hospital, Herlev, Denmark; [3]Nephrological Department P, Rigshospitalet, Copenhagen, Denmark; [4]Rigshospitalet, Glostrup, Denmark; [5]University of Copenhagen, Copenhagen, Denmark.*

Background: Chronic kidney disease (CKD) is associated with vascular calcification leading to cardiovascular morbidity and mortality. Decreasing levels of plasma magnesium (Mg) are associated with increased risk of cardiovascular disease in patients with CKD, which might be amendable to Mg supplementation. Several biochemical parameters follow a circadian rhythm, which may affect the way these parameters should be measured and may be of importance for their physiological effects and interaction. The aim of this study was to identify the circadian rhythm of plasma Mg in CKD.

Methods: This was an investigator-initiated observational clinical trial. Subjects included were patients with CKD 3-4 without diabetes (n=10 (9 males)) and healthy controls (n=10 (5 males)). Venous blood and urine samples were collected non-fasting at 8 a.m. and every third hour during a 24-hour admission with the final collection in fasting state at 8 a.m. the following day.

Results: The baseline mean (± SD) eGFR was 27 ± 8 mL/min/1.73m^2 in patients with CKD and 105 ± 10 mL/min/1.73m^2 in healthy controls. The overall mean (± SD) plasma Mg in patients with CKD was not significantly higher than in healthy controls (0.88 ± 0.04 mmol/L versus 0.84 ± 0.07 mmol/L (p = 0.220)). Cosinor analysis revealed no significant diurnal variation in plasma Mg in either subjects with CKD (p = 0.23) or healthy controls (p = 0.29). There was no significant difference between plasma Mg levels (mean ± SD) in fasting and non-fasting state in patients with CKD (fasting 0.90 ± 0.13 mmol/L and non-fasting 0.90 ± 0.06 mmol/L (p = 0.907)) or healthy controls (fasting 0.84 ± 0.07 mmol/L and non-fasting 0.83 ± 0.09 mmol/L (p = 0.598)).

Conclusions: Plasma Mg exhibits no diurnal variation and is not affected by fasting in patients with CKD 3-4. Evaluation of plasma magnesium levels in patients with CKD 3-4 requires no special precaution concerning the time of the day for sampling or whether the patient is in fasting state.

SA-PO265

Chemical Plausibility of the Tradeoff-in-the-Nephron Hypothesis

Kenneth R. Phelps,[1,2] Darius Mason.[3] *[1]Research Service, Stratton Veterans' Affairs Medical Center, Albany, NY; [2]Medicine, Albany Medical College, Albany, NY; [3]Pharmacy, Methodist LeBonheur Healthcare, South Hospital, Albany, TN.*

Background: The tradeoff-in-the-nephron hypothesis attributes secondary hyperparathyroidism to events in the cortical distal nephron (CDN). The hypothesis suggests that high $[HPO_4^{=}]_{CDN}$ reduces $[Ca^{++}]_{CDN}$ and thus necessitates high [PTH] for normal Ca reabsorption (Nutrients 2017;9:427). We sought further evidence for the hypothesis with regressions of [PTH] on inferred values of $[HPO_4^{=}]_{CDN}$ and $1/[Ca^{++}]_{CDN}$.

Methods: Fasting data were obtained from 30 patients with CKD (mean eGFR 29.5) and 28 controls (mean eGFR 85.9). To estimate concentrations in the CDN, we assumed fractional delivery (k) of filtrate = 0.2 in controls and 0.35 in CKD; Ca delivery = 0.1(eGFR)$[Ca]_{uf}$, ($[Ca]_{uf}$ = plasma ultrafilterable Ca); and P delivery = urinary P excretion (E_p). We assumed pH in the CDN = 6.5 and pK of the $H_2PO_4^-$ Û $HPO_4^=$ equilibrium = 6.8. From the Henderson-Hasselbalch equation, we estimated delivery of HPO_4 to the CDN as 0.33(E_p). We calculated $[Ca]_{CDN}$ as (0.1)(eGFR$[Ca]_{uf}$)/k(eGFR) and $[HPO_4]_{CDN}$ as (0.33)(E_p/C_{cr})(eGFR)/k(eGFR), where E_p/C_{cr} = P excretion per volume of filtrate = $[P]_u[cr]_p/[cr]_u$. We assumed that $CaHPO_4$ Û Ca^{++} + $HPO_4^=$ in the CDN, with $K_{sp} = 10^{-7}$. Since equimolar amounts of Ca and P associate to form $CaHPO_4$, we let *complexed* [Ca] and $[HPO_4]$ = z. We calculated *ionized* $[Ca^{++}]_{CDN}$ as $([Ca]_{CDN} - z)$ and ionized $[HPO_4^=]_{CDN}$ as $([HPO_4]_{CDN} - z)$. Since $[Ca^{++}]_{CDN}$*$[HPO_4^=]_{CDN}$ = K_{sp}, we inferred that $([Ca]_{CDN} - z)([HPO_4]_{CDN} - z) = 10^{-7}$, and solved for z with the quadratic formula after algebraic manipulation. For CKD and controls, we examined linear regressions of [PTH] on $[HPO_4]_{CDN}$, $1/[Ca]_{CDN}$, $([HPO_4]_{CDN} - z)$, and $1/([Ca]_{CDN} - z)$.

Results: In CKD, regressions of [PTH] on $[HPO_4]_{CDN}$, $([HPO_4]_{CDN} - z)$, and $1/([Ca]_{CDN} - z)$ were significant; the regression of [PTH] on $1/[Ca]_{CDN}$ was not significant (see Table). In controls, only the regression of [PTH] on $1/[Ca]_{CDN}$ was significant.

Conclusions: In CKD (but not controls), [PTH] is related directly to ionized and total $[HPO_4]_{CDN}$, and inversely to ionized but not total $[Ca]_{CDN}$. The effect of $[HPO_4^=]_{CDN}$ on [PTH] appears to be mediated by $[Ca^{++}]_{CDN}$.

The Importance of Biologically Active Vitamin D for Mineralization by Osteocytes After Parathyroidectomy for Renal Hyperparathyroidism

Aiji Yajima,[2,1] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Tokyo Women's Medical University, Shinjuku-ku, Japan; [2]Anatomy and Cell Biology, Indiana University, School of Medicine, Indianapolis, IN.*

Background: Hypomineralized matrix is a factor determing bone mineral density. Increased perilacunar hypomineralized bone area is caused by reduced mineralization by osteocytes. The importance of vitamin D in the mineralization by osteocytes was investigated in hemodialysis patients who underwent total parathyroidectomy (PTX) with immediate autotransplantation of diffuse hyperplastic parathyroid tissue. No previous reports on this subject exist.

Methods: The study was conducted in 19 patients with renal hyperparathyroidism treated with PTX. In 15 patients, the serum calcium levels were maintained by subsequent administration of alfacalcidol (2.0 μg/day), intravenous calcium gluconate, and oral calcium carbonate for four weeks after PTX (Group I). This was followed in a suset of for patients in Group I by a reduced dose of 0.5 μg/day until one year following PTX; this was defined as Group II. In the remaining four patients, who were not in Group I, the serum calcium levels were maintained without subsequent administration of alfacalcidol (Group III). Transiliac bone biopsy specimens were obtained in all groups before and 3 or 4 weeks after PTX to evaluate the change of hypomineralized bone area. In addition, patients from Group II underwent a third bone biopsy one year folllowing PTX. And we did Raman measurements ffrom the same sections as those used for histology.

Results: A significant derease of perillacunar hypomineralized bone area was obsered 3 or 4 weeks after PTX in all Group I and II patients. The area was increased in the Group II patients one year following PTX. In Group III patients, an increase of hypomineralized bone area was observed four weeks after PTX. Mineral maturity, defined by the bone's carbonate and shown as CO_3^2-v1/PO_4^3-v1, did not change following PTX in Group I and Group III. Crystallinity of the mineral did not change after PTX in either Group I and Group III.

Conclusions: The maintenance of a proper dose of vitamin D is necessary for mineralization by osteocytes, which is important to increase bone mineral density after PTX for renal hyperparathyroidism. Mineral maturity and crystallinity are not expected within 3-4 weeks after PTX.

Vitamin D Status in CKD Patients Living in the Tropics: A Cohort in Thailand

Kraiwiporn Kiattisunthorn,[1] Muchima Rodchuae.[2] *[1]Siriraj Medical School, Mahidol University, Bangkok-noi, Thailand; [2]Faculty of Medicine Siriraj Hospital, Bangplad, Thailand.*

Background: Vitamin D deficiency is a key factor of secondary hyperparathyroidism in CKD and is recommended to be evaluated in the cases found persistently elevated PTH levels. Data survey during the last decade showed vitamin D deficiency among the general Thais for 6-30% compared to 60-70% in the Eastern Asians. Data of prevalent vitamin D deficiency in Thailand is scarce, but is seriously concerned in clinical practice to balance between standard of care and healthcare budget restraint. Therefore, the study is done to evaluate vitamin D status and predictors of vitamin D deficiency in CKD patients living in Thailand

Methods: 752 Stable CKD patients were included from CKD clinic and the outpatient section at Siriraj hospital. CKD is diagnosed based on KDIGO 2012 definition and GFR calculated with serum creatinine measured by using the enzymatic creatinine assay. Vitamin D levels were measured by using Elecsys® Vitamin D total (Roche Diagnostics, Germany). Albumin corrected serum calcium, phosphate, intact PTH, albuminuria were measured within 60 days of vitamin D levels, comorbidities and drugs related to vitamin D metabolism were collected.

Results: Mean age was 64.4±13.8 years old, 48% were female and 60.3% had diabetes mellitus. They were categorized to stage 1-2, 3a, 3b, 4 and 5 for 22.4, 18.7, 23.8, 24.1, and 11.0%, respectively. Prevalence of vitamin D deficiency (<20 ng/mL) and severe vitamin D deficiency (<10 ng/mL) were shown in Figure 1. Predicting factors of vitamin D deficiency in Thai CKD patients were stage 4-5 CKD 9.06 (3.64-22.58), albuminuria >1,500 mg/d 10.62 (3.97-28.41), calcium <9.0 mg/dL 3.99 (1.54-9.45), PTH >100 pg/mL 3.82 (1.54-9.49), diabetes 3.35 (1.33-8.46), and female 2.81 (1.19-6.62)

Conclusions: Vitamin D deficiency is highly prevalent in Thai stage 4-5 CKD patients. Considerations on GFR combined with serum calcium and PTH profiles and clinical characteristics would empower cost-effectiveness of 25-hydroxyvitamin D measurement in CKD population living in the tropic area.

1.25(OH)$_2$D Status in ESKD: Role of 25(OH)D and Residual Renal Function

Pieter Evenepoel,[1] Jan Vandewalle,[2] Bert Bammens,[1] Kathleen Claes,[3] Björn K. Meijers,[5] Maarten Naesens,[1] Ben Sprangers,[4] Dirk R. Kuypers.[1] *[1]University Hospitals Leuven, Leuven, Belgium; [2]University Hospitals KU Leuven, Leuven, Belgium; [3]University Hospital Gasthuisberg, Leuven, Belgium; [4]University of Hospitals Leuven, Leuven, Belgium; [5]UZ Leuven, Leuven, Belgium.*

Background: Recent insights into vitamin D regulation suggest that CKD is a state of stagnant vitamin D metabolism characterized by reduced 1.25(OH)$_2$D production (mediated by CYP27B1) and catabolism. The present study aimed to clarify whether this is caused by insufficient delivery of substrate or low nephron mass. As a secondary aim we investigated seasonal variation and long term trends of vitamin D levels in patients with ESKD.

Methods: We analyzed serum levels of 1.25(OH)$_2$D (LC MS/MS), 25(OH)D (RIA), along with other parameters of mineral metabolism (including PTH, FGF23, sclerostin), markers of inflammation in 518 adult patients (age 54.7 ± 12.8 yrs, males 60.6%) with ESKD between April 23, 2006 and December 21, 2013. Data on residual renal function (RRF) were available in 330 patients: 115 patients were anuric (24h urine output < 100 ml) and 21 patients were anephric.

Results: Median 25(OH)D and 1.25(OH)$_2$D levels in the overall cohort were 35.9 [24.0 – 48.6] µg/L and 26.8 [18.2 – 36.9] ng/L, respectively. 25(OH)D levels showed seasonal variation and increased by 16% along the study period (2006-2013), most probably as a result of more intense supplementation. A parallel 31% increase of 1.25(OH)$_2$D levels was noted. In regression analysis, only high 25(OH)D and low phosphate and sclerostin independently associated with high 1.25(OH)$_2$D levels. 25(OH)D was the most important determinant of 1.25(OH)$_2$D levels, explaining 30% of its variability. RRF did not correlate with 1.25(OH)$_2$D levels. Remarkably, 1.25(OH)$_2$D levels were only slightly lower in anephric patients (20.3 vs 27.3 ng/L, median, p=0.02). This suggests that non-renal tissues may contribute substantially to circulating 1.25(OH)$_2$D levels. In anuric patients, 25(OH) D levels, but not mineral metabolism hormones or inflammation were associated with 1.25(OH)$_2$D levels.

Conclusions: 1.25(OH)$_2$D levels in patients with ESKD are manifestly dependent on the delivery of 25(OH)D. Extrarenal CYP27B1 activity may sustain normal 1.25(OH)$_2$D levels, even in anephric patients. Substrate delivery thus seems to be much more important than nephron mass in maintaining adequate 1.25(OH)$_2$D level. Seasonal fluctuations and long term kinetics illustrate that both vitamin D generation in the skin and nutritional vitamin D supplements contribute to 25(OH)D stores in ESKD.

SA-PO270

Expression of Vitamin D Receptor, CYP27B1 and CYP24A1 Hydroxylases, and 1,25-Dihydroxyvitamin D3 Levels In Stone Formers

Thalita L. Melo, Priscila L. Esper, Lysien I. Zambrano, Milene S. Ormanji, Fernanda G. Rodrigues, Ita P. Heilberg. *Universidade Federal de São Paulo, Sao Paulo, Brazil.*

Background: The underlying pathophysiological mechanisms for hypercalciuria such as increased intestinal calcium absorption, reduced renal tubular reabsorption and increased bone resorption are influenced by calciotropic hormones. The levels of 1,25(OH)$_2$D$_3$ exceed the values of controls in some but not all hypercalciuric stone formers and the expression of vitamin D receptor (VDR) remains controversial in human studies. We aimed to evaluate the serum 1,25(OH)$_2$D$_3$ levels and the expression of VDR and the regulatory enzymes CYP27B1 (1α-hydroxylase) and CYP24A1, responsible for vitamin D degradation, in hypercalciuric stone formers (HSF) and compare to normocalciuric stone formers (NSF) and healthy subjects (HS).

Methods: Blood samples, 24-hour urine collection and a 3-day dietary record were obtained from 30 participants of each of the groups. The expression of VDR, CYP27B1 and CYP24A1 in monocytes were measured by flow cytometry.

Results: HSF presented a significantly higher mean urinary volume, sodium, magnesium, oxalate, uric acid, and phosphorus than NSF and HS. Mean daily calcium intake was lower in HSF versus NSF and HS (442±41 vs 594±42 and 559±41 mg, respectively, p=0.027). Ionized calcium was significantly lower in HSF than NSF (1.29±0.0 vs 1.31±0.0 mmol/L, p<0.01). Serum 1,25(OH)$_2$D$_3$ was significantly higher, even within normal ranges, in both HSF and NSF versus HS (22.5±1.2; 22.2±1.2 vs 17.4±1.2 pg/ml, p=0.007, respectively) but serum 25OHD$_3$, PTH, α-Klotho and plasma FGF-23 did not differ between groups. The VDR expression was higher in both HSF and NSF versus HS (80.8±3.2; 78.7±3.3 vs 68.6±3.2%, p=0.023). Although CYP27B1 and CYP24A1 expressions were similar among all groups, the ratio of 1,25(OH)$_2$D$_3$/CYP24A1 was higher in HSF and NSF than in HS (1.43±0.25 and 0.56±0.10 than 0.34±0.06, p=0.00).

Conclusions: Stone-formers, regardless of urinary calcium levels, had higher VDR expression and 1,25(OH)$_2$D$_3$ levels compared to HS. Higher 1,25(OH)$_2$D$_3$/CYP24A1 ratio suggested a lower degradation of 1,25(OH)$_2$D$_3$ by CYP24A1 in HSF and NSF.

Stone Event Proximity Determines Health-Related Quality of Life (HRQoL) in Primary Hyperoxaluria (PH)

Frank Modersitzki,[1] Dawn S. Milliner,[3] Felicity T. Enders,[3] John C. Lieske,[3] David S. Goldfarb.[2] Rare Kidney Stone Consortium *[1]New York University School of Medicine, New York, NY; [2]New York Harbor VAMC, New York, NY; [3]Mayo Clinic, Rochester, MN.*

Background: We have shown previously that PH has better HRQoL compared to cystine stone formers and the US Standard Population. Now we show the first cross-sectional HRQoL profiles of PH patients.

Methods: PH participants were enrolled from the Rare Kidney Stone Consortium (RKSC) registry. The group of PH participants consist of PH 1, 2, 3, and PH-NMD (no mutation detected). PH-NMD met clinical criteria for PH. HRQoL was measured with the generic non-disease specific instrument (SF-36v2). Results were calculated as norm-based scores (NBS) based on US Standard Population (mean domain score = 50). We created three stone event groups (≤ 30 days, 31 – 365 days, ≥366 days). We compared HRQoL by last stone event for PH participants without a liver and/or kidney transplant. Group means < 47 indicate the presence of impaired functioning in associated dimensions.

Results: We used 184 surveys of adults with PH at different time points, adjusted for the last stone event, and compared SF-36 domain profiles. 56 participants were included with multiple surveys (PH1 26, PH2 8, PH3 13, PH-NMD 9; 30 males, 26 females; 42 years old, males 42 years, females 41 years). Lowest domain results were found in participants that experienced a stone event ≤ 30 days before the survey. Participants with no stone event within a year had the best HRQoL with domain scores above the US Standard Population. PH-NMD compared to PH1, PH2 and PH3 had the highest stone event rate within one year of the survey (58.1 vs 35 vs 3 vs 29.5%). All PH patients with a stone event within 30 days of the survey trended towards higher urine oxalate excretion and lower eGFR (underpowered, not significant). Figure 1 shows that time since the last stone significantly affected HRQoL.

Conclusions: PH participants as a group are not homogeneous and experience different HRQoL based on proximity to stone event. PH type is a covariate. Overall PH2 has fewer stone events compared to other PH participants, with an expected direct impact on HRQoL.

Plasma Oxalate as a Predictor of Kidney Function Decline in Primary Hyperoxaluria

Ronak J. Shah, Lisa E. Vaughan, Felicity T. Enders, Dawn S. Milliner, John C. Lieske. *Mayo Clinic, Rochester, MN.*

Background: This retrospective analysis investigated plasma oxalate (POx) as a potential predictor of end stage kidney disease (ESKD) among primary hyperoxaluria (PH) patients across varying stages of CKD.

Methods: PH patients with type 1, 2 and 3, age 2 or older, with estimated glomerular filtration rate (eGFR) and POx measures available during follow-up after PH diagnosis and prior to ESKD were identified in the RKSC PH Registry. Urinary oxalate (UOx) did not change across CKD stages 1-3, but POx increased with falling eGFR. Thus to maximize data for analysis of POx by eGFR stage, patients were further subdivided into CKD subgroups (stages 1, 2, 3a and 3b) such that a patient started in a given CKD stage subgroup on their first eGFR observed in that range, while also continuing to remain in any prior groups. ESKD was defined as an eGFR<15 ml/min per 1.73 m^2 or start of dialysis or renal transplantation. Hazard ratios (HRs) and 95% confidence intervals (95% CIs) for risk of ESKD were estimated using the Cox proportional hazards model with a time-dependent covariate.

Results: There were 118 patients in the CKD1 group (9 ESKD events during follow-up); 135 in CKD 2 (29 events); 72 in CKD3a (34 events); and 45 patients in CKD 3b (31 events). During follow-up, POx Q4 was a significant predictor of ESKD compared to Q1 across CKD2 (HR 14.2, 95% CI 1.8-115), 3a (HR 13.7, 95% CI 3.0-62) and 3b stages (HR 5.2, 95% CI 1.1-25), P<0.05for all. Within each POx quartile, ESKD rate was higher for more severe CKD stages, and within each CKD stage, ESKD rate was higher in Q4 compared to Q1-Q3, respectively.

Conclusions: Among patients with PH, higher POx concentration was a risk factor for ESKD, particularly in advanced CKD stages.

Proton Pump Inhibitors and Risk of Incident Nephrolithiasis: A Retrospective Cohort Study

Michael Simonov,[1,4] Erica A. Abel,[4] Ronald G. Hauser,[3] Cynthia A. Brandt,[5] Francis P. Wilson,[2] Loren Laine.[2,4] *[1]Yale New Haven Hospital, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Yale University School of Medicine, New Haven, CT; [4]VA Connecticut Healthcare System, West Haven, DC; [5]VA Connecticut, West Haven, CT.*

Background: Proton pump inhibitors (PPIs) have come under scrutiny given evidence of their association with various conditions including chronic kidney disease and fracture. Biochemically, the effect of PPIs and nephrolithiasis is unclear. PPIs decrease calcium gut absorption and decrease urine calcium and oxalate, which may be protective. However PPIs also decrease urine citrate which may increase stone formation. We studied the association of incident PPI use with nephrolithiasis in a large retrospective cohort.

Methods: Setting: Data were obtained from a large patient cohort from the Veteran's Health Administration (VHA). Data including demographics, encounters, comorbidities, medications, and laboratory values were obtained through querying the VHA system. Patients with prior nephrolithiasis or PPI usage were excluded. Matched Cohort: A cohort was developed with 1:1 fixed ratio matching for PPI users and non-users based on a propensity score developed from multivariate logistic regression of the patient's covariates. Kaplan-Meier survival analysis was used. Adjusted analysis was performed with Cox proportional hazards model from a robust set of covariates, including demographics, comorbidities, medications, and healthcare system interaction.

Results: Of 1,065,962 patients considered, 422,153 patients met eligibility criteria. 81,654 patients had exposure to PPIs at some point during observation. Of the 81,654 PPI users, 92% were matched based on propensity score to a non-PPI user. Over 660,426 patient-years of observation, PPI-exposed individuals developed nephrolithiasis at a higher rate compared to PPI-unexposed (62.3 versus 43.1 per 10,000 patient-years, relative risk ratio 1.43 (95% CI 1.33-1.54)). Under the Cox proportional hazards model PPI usage carried a hazard ratio of 1.32 (95% CI 1.23 - 1.42).

Conclusions: In our large retrospective cohort analysis, incident PPI usage was associated with a moderately increased risk of incident nephrolithiasis.

Nephropathic Cystinosis: A Distinct Model of CKD-MBD

Pablo Florenzano,[2] Carlos R. Ferreira,[3] Macarena Jimenez,[4] Sri harsha Tella,[5] Rachel Gafni,[6] Myles Wolf,[7] William Gahl,[9] Isidro B. Salusky,[1] Michael Collins.[8] *[1]Mattel Children's Hospital, Los Angeles, CA; [2]Pontificia Universidad Catolica de Chile, Santiago, Chile; [3]NHGRI, Bethesda, MD; [4]Pontificia Universidad Católica de Chile, Santiago, Chile; [5]University of South Carolina, Columbia, SC; [6]NIH, Bethesda, MD; [7]Duke University, Durham, NC; [8]NIHI, Bethesda, MD; [9]National Institutes of Health, Bethesda, MD.*

Background: Cystinosis is a rare autosomal recessive lysosomal storage disorder. Nephropathic cystinosis (NC) presents with Fanconi syndrome and CKD. Persistent phosphate wasting is a prominent feature; however, its impact on CKD-MBD has not been described. Thus, we compare CKD-MBD in NC (n=53) vs. non-NC (n=97).

Methods: eGFR, Ca, P, PTH, 1,25D, FGF23, and TRP were assessed. C-terminal FGF23 was measured by ELISA (Quidel), S-PTH and 1,25D by immunoassay. Subjects were grouped according to CKD stage; CKD 4 and 5 were analyzed together. Dialysis pts. were excluded. All NC patients were treated with cysteamine, phosphate supplementation, and 1,25D; non-NC with 1,25D and binders as needed. Statistical analysis included Spearman correlations and the Mann-Whitney U test.

Results: Age and eGFR were similar between the groups (**Table**). In NC across all CKD stages, TRP and FGF23 were lower, and 1,25D higher (**Figure**). PTH and S-PO4 were lower in NC stage 3. In NC, FGF23 was inversely associated with eGFR (r=-0.30, p<0.05) and positively associated with S-PO4(r=0.53, p<0.001). All hypophosphatemic NC subjects had normal FGF23 levels, independent of eGFR.

Conclusions: NC is characterized by a distinct CKD-MBD, with lower FGF23 and higher 1,25D levels. Persistent phosphate wasting may lead to this phenotype. Such findings may: 1) explain the long-term musculoskeletal complications and 2) support the concept for induction of phosphate excretion in non-NC pts. to lower FGF23 and raise 1,25D levels.

SA-PO275

Prevalence of Kidney Stones in the United States over the Past 10 Years

Api Chewcharat,[1] Gary C. Curhan.[2] *[1]Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA; [2]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: Kidney stones (KS) are common in the US and cost billions of dollars on treatment. The overall prevalence of kidney stones rose from 3.2% in 1980 to 10.1% in 2014. We examined the prevalence trends of KS in subgroups of age, sex and race in the US and identify laboratory factors associated with a history of KS using National Health and Nutrition Examination Survey (NHANES) data

Methods: We conducted a cross-sectional study among 28,209 US adults aged >=10 years old in the NHANES from 2007 to 2016. We calculated the percent prevalence of a self-reported history of KS by using weights and standardized to the 2010 US Census population using age adjustment. We also analyzed relevant laboratory values and compared them according to history of KS.

Results: The prevalence of KS decreased from 8.8% in 2007-2008 to 8.6% in 2009-2010 and 7.2% in 2011-2012 but then increased to 9.0% in 2013-2014 and 10.2% in 2015-2016. Prevalence of KS was highest in 2015-2016 in every age range except in women aged 20-39 years. Among different races, non-Hispanic whites had the highest prevalence of KS at 12.1% for the last cycle of 2015-2016 and the trend was increasing from 2011-2016. Non-Hispanic Asians had the lowest prevalence of KS at 4.5% for the last cycle. The prevalence of KS among non-Hispanic blacks increased over the last 3 cycles from 4.2% in 2011-2012 to 5.0% in 2013-2014 and 5.7% in 2015-2016. We presented relevant laboratory values in Figure 1.

Conclusions: Overall prevalence of KS has been increasing for the last 6 years but this may be random variability as the prevalence decreased then increased since 2007-2008. Men had higher prevalence of KS and Asians had the lowest prevalence. Stone formers had lower urine flow rate, eGFR, bicarbonate, phosphate, serum estrogen and testosterone while they had higher serum osmolality, creatinine, chloride and uric acid compared with non-stone formers.

Figure 1: Relevant laboratory factors comparing non-stone formers with stone formers

Characteristics	Kidney Stone		P Value
	Non-stone formers (n = 25601)	Stone formers (n = 2608)	
Serum creatinine (mg/dl)	0.87 (0.003)	0.90 (0.01)	**0.006**
eGFR (mL/min/1.73 m^2)	96.42 (0.24)	95.17 (0.53)	**0.008**
albumin-creatinine ratio (mg/g)	31.67 (3.23)	30.72 (4.91)	0.87
Urine flow rate (ml/min)	1.12 (0.01)	1.02 (0.03)	**0.009**
Serum uric acid (mg/dl)	5.40 (0.01)	5.52 (0.04)	**0.004**
Serum calcium (mg/dl)	9.41 (0.007)	9.40 (0.02)	0.46
Serum phosphate (mg/dl)	3.77 (0.007)	3.68 (0.02)	**0.0001**
Serum sodium (mmol/L)	139.15 (0.06)	139.18 (0.08)	0.66
Serum potassium (mmol/L)	3.97 (0.006)	3.96 (0.010)	0.50
Serum chloride (mmol/L)	103.83 (0.08)	104.12 (0.11)	**0.001**
Serum bicarbonate (mmol/L)	25.02 (0.06)	24.64 (0.09)	**<0.0001**
Serum osmolality (mmol/kg)	277.86 (0.11)	278.24 (0.18)	**0.004**
Serum vitamin D (25OHD2+25OHD3) (nmol/l)	68.65 (0.78)	69.33 (1.18)	0.52
Serum estrogen among female (pg/ml)	108.52 (9.70)	74.51 (0.48)	**0.003**
Serum testosterone among male (ng/dl)	420.12 (3.24)	395.45 (6.93)	**0.001**

Prevalence of Kidney Stones in Patients with Enteric Disorders

Gregory E. Tasian,[1] Brandon B. Wade,[2] Julia A. Gaebler,[2] Annamaria T. Kausz,[4] Joe Medicis,[3] Christina M. Wyatt.[5] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Health Advances, Weston, MA; [3]Allena Pharmaceuticals, Newton, MA; [4]Allena Pharmaceuticals, Newton, MA; [5]Duke University School of Medicine, Durham, NC.*

Background: Hyperoxaluria (HOx) is a serious metabolic disorder and a risk factor for kidney stone disease (KSD) and chronic kidney disease (CKD). Enteric HOx (EH) develops as a complication of increased intestinal oxalate absorption due to an underlying GI disorder (e.g., bariatric surgery, inflammatory bowel disease (IBD). The prevalence of EH is not well described, due in part to infrequent testing for risk factors of KSD and the lack of a specific diagnostic code for EH. We sought to estimate the prevalence of EH and the distribution of underlying enteric causes.

Methods: We developed a state-transition Markov model to estimate the current US prevalence of malabsorptive enteric disorders and the total number of stone-forming patients using data from the published literature and from a four-year claims analysis (6/2012-6/2016) from the IBM Truven Health Analytics system. Patients with a malabsorptive enteric disorders (Roux-en-Y Gastric Bypass, Short Bowel Syndrome, Inflammatory Bowel Disease (IBD), Chronic Pancreatitis, and Celiac Disease) who had KSD or KSD and CKD were considered to have EH.

Results: The 2019 prevalence was determined to be 249,048 and the most frequent malabsorptive enteric conditions were Roux-en-Y gastric bypass at 62% and inflammatory bowel disease at 20%.

Conclusions: EH is associated with serious consequences, yet its prevalence is poorly understood. Based on this analysis of data across various sources, there are approximately 250,000 EH patients with kidney stone disease in the US, including those who develop CKD. Additional epidemiological research and a specific diagnostic code could further improve efforts to understand and improve the recognition of EH.

Funding: Commercial Support - Allena Pharmaceuticals

Prevalence of enteric hyperoxaluria with kidney stones	
Roux-en-Y gastric bypass	154,722 (62%)
IBD	48,614 (20%)
Celiac disease	29,118 (12%)
Chronic pancreatitis	13,647 (5%)
Short bowel syndrome	2,947 (1%)
Total	249,048

NOSTONE Trial: Randomized Double-Blind Placebo-Controlled Trial Assessing the Efficacy of Standard and Low-Dose Hydrochlorothiazide Treatment in the Recurrence Prevention of Calcareous Nephrolithiasis

Nasser Dhayat,[1] Olivier Bonny,[2] Beat Roth,[4] Luca Tamò,[3,1] Daniel G. Fuster.[1] on behalf of the NOSTONE Investigators *[1]Department of Nephrology and Hypertension, Bern University Hospital, Bern, Switzerland; [2]Service of Nephrology, Department of Medicine, Lausanne University Hospital, Lausanne, Switzerland; [3]Clinical Trials Unit (CTU Bern), Medical Faculty, University of Bern, Bern, Switzerland; [4]Department of Urology, University of Bern, Bern, Switzerland.*

Background: Nephrolithiasis is a global healthcare problem with a current lifetime risk of up to 18.8 % in men and 9.4 % in women. Without specific treatment, 5- and 20-year recurrence rates are 40 % and 75 %, respectively. Given the high cost of medical treatments and surgical interventions as well as the morbidity related to symptomatic stone disease, medical prophylaxis for stone recurrence is an attractive approach. Efficacy of thiazides for kidney stone prevention was tested in 11 trials in the past. However, all these trials had major methodological deficiencies. Nowadays, thiazides are widely used in the treatment of recurrent nephrolithiasis and arterial hypertension, but at significantly lower doses. In the case of recurrent nephrolithiasis, however, this practice is not supported by randomized evidence. Thus, evidence for benefits and harms of thiazides in the prevention of kidney stones remains unclear.

Methods: NOSTONE is a multicenter, randomized, placebo-controlled, double-blind, parallel-group trial with the purpose to assess the dose-response relationship for three different dosages of hydrochlorothiazide (placebo, 12.5mg, 25.0mg, 50.0mg) in kidney stone prevention. The primary outcome is the incidence of stone recurrence (a composite of symptomatic or radiologic recurrence) at 3 years, a low-dose CT will be performed at the beginning and the end of the trial. A total of 416 patients from 12 hospitals throughout Switzerland will be included in the study.

Results: NOSTONE received all necessary approvals by the end of February 2017. Recruitment started in Bern on the 9th of March 2017, all study sites are operative since June 30th 2017. As of May 30th 2019, 270 patients were randomized in the trial (regular updates: www.nostone.ch). The end of recruitment is foreseen for August 2019. Baseline data concerning the study population will be available after the end of recruitment.

Conclusions: The NOSTONE study will provide critical information to physicians for the treatment of kidney stones. The impact of the results of this study will affect many patients currently treated with hydrochlorothiazide for the prevention of recurrent nephrolithiasis.

A Phase 3, Randomized, Placebo Controlled Trial of Reloxaliase in Enteric Hyperoxaluria (URIROX-1): Clinical Characteristics and Burden of Illness

John C. Lieske,[1] James E. Lingeman,[2] Pietro Manuel Ferraro,[3] Zhiqun Zhang,[4] Annamaria T. Kausz.[4] *[1]Mayo Clinic, Rochester, MN; [2]IU Health Physicians Urology, Indianapolis, IN; [3]Fondazione Policlinico Universitario A. Gemelli, Rome, Italy; [4]Allena Pharmaceuticals, Inc, Newton, MA.*

Background: Hyperoxaluria is a key risk factor for kidney stones (KS), and may lead to chronic kidney disease (CKD). Enteric hyperoxaluria (EH) results from excess gastrointestinal oxalate (Ox) absorption due to fat malabsorption. There are no approved therapies for EH; current recommendations are to reduce dietary Ox and increase calcium and fluid intake, calcium/citrate supplements, and thiazides. This phase 3 trial investigating reloxaliase, a first-in-class oral enzyme drug therapy that specifically degrades Ox within the gastrointestinal tract, for reducing urine Ox (UOx) excretion in patients with EH.

Methods: Adults with malabsorptive conditions, UOx ≥50 mg/d and eGFR >30 ml/min/1.73 m^2 were randomized to receive reloxaliase 7,500 U or placebo orally with food 3-5x/d for 28 d. The primary endpoint was percent change from baseline in 24-hour UOx during weeks 1-4, assessed from 24-hour urine collections obtained over 4 weeks. Clinical and 24-hour UOx data were summarized overall and by enteric condition.

Results: There were 88 subjects with available data, mean age 59 years, 48% female. The two most common enteric conditions were bariatric surgery (65%) and IBD (18%).

Recurrent kidney stones were reported by 70% (23% having more than 5 events in the past 5 yrs) while 23% had CKD stage ≥3. Mean baseline UOx was 91.5 mg/d, while 31% had UOx ≥100 mg/d. Patients with short bowel syndrome (SBS) had highest 24-hr UOx, whereas more patients with IBD had recurrent stones.

Conclusions: Patients with EH enrolled in the URIROX-1 trial from nephrologists and urologists had persistent and in some cases severe HOx and recurrent kidney stones, regardless of the type of underlying enteric condition. These clinical characteristics illustrate the limitations of existing therapeutic approaches, and the opportunity for a novel therapeutic approach to reduce oxalate burden on the kidney for patients with EH.

Funding: Commercial Support - Allena Pharmaceuticals, Inc

Enteric condition	N (%)	UOx (mg/d) – mean±SD	eGFR (mL/min/1.73m2) – Median (25th, 75th)	≥2 KS past 5 yrs
Bariatric surgery	57 (65%)	92.1±32.6	90 (73, 101.5)	63.2%
IBD	16 (18%)	90.6±32.4	59.5 (43.5, 81.8)	93.8%
Short bowel syndrome	9 (10%)	101.1±63.9	87 (56.5, 96)	66.7%
Pancreatic insufficiency	1 (1%)	92.5	67	100%
Other	5 (6%)	70.1±10.4	94 (63.5, 100)	80%

SA-PO279

Mediterranean Diet Adherence and the Risk of Kidney Stones

Pietro Manuel Ferraro,[2] Adrian Rodriguez,[1] Giovanni Gambaro,[5] Eric N. Taylor,[4] Gary C. Curhan.[3] *[1]Catholic University of the Sacred Heart, Roma, Italy; [2]Fondazione Policlinico Universitario A. Gemelli, Rome, Italy; [3]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [4]Maine Medical Center and Tufts University School of Medicine, Portland, ME; [5]University of Verona, Verona, Italy*.

Background: Diet plays an important role in kidney stone formation. Several individual components have been associated with an increased or decreased risk of kidney stones, but there is limited evidence about the role of healthful dietary patterns. The objective of this study is to examine prospectively the association of adherence to the Mediterranean diet and the risk of incident kidney stones.

Methods: We conducted a prospective study using three different cohorts: the Health Professionals Follow-up Study (n= 51,529 men), the Nurses' Health Study I (n= 121,700 women) and the Nurses' Health Study II (n=116,430 women). We assessed diet every four years using a food frequency questionnaire and calculated the adherence to a Mediterranean diet using the alternate Mediterranean Diet Score (aMED). The score considers: a high ratio of monounsaturated to saturated fatty acids; high intakes of: fruit, nuts, whole grains, vegetables, fish and legumes; low intake of red and processed meats; and a moderate alcohol consumption. The score ranges from 0 to 9, with higher scores for higher adherence to a Mediterranean diet. We used Cox proportional hazards regression to examine the independent association between the aMED and the incidence of kidney stones, adjusting for potential confounders.

Results: During more than 3 million person-years, 6,576 cases of incident kidney stones were identified. Participants with the highest aMED score (8/9) had lower BMI, lower percentage of hypertension, lower caffeine intake and higher intakes of supplements of vitamin C, calcium and total vitamin D. For participants in the highest aMED score category compared with participants in the lowest category, the risk of developing a kidney stone was between 20 and 43% lower in all the cohorts. The adjusted HR (95 % CI) for the highest category of the aMED score was 0.57 (0.38, 0.85) for HPFS (p-trend<0.001), 0.71 (0.45, 1.10) for NHS I (p-trend=0.001) and 0.80 (0.45, 1.10) for NHS II (p-trend= 0.003). When examining components of the score, high intake of fruits and whole grains, and moderate alcohol consumption, were associated with lower risk of kidney stone formation in all cohorts, while high intakes of legumes and nuts were associated with a lower risk in men, but not in women.

Conclusions: Adherence to a Mediterranean diet is associated with a lower risk of incident kidney stones.

Effect of Hydroxycitrate (HCA) on Urinary Risk Factors for Calcium-Based Kidney Stones

Avinash G. Adiga,[1] Briony L. Norris,[8] Ignacio Granja,[9] Kumar Rohit,[3] Frank Modersitzki,[4] James Borin,[10,4] David A. Bushinsky,[7] Jeffrey D. Rimer,[6] John R. Asplin,[5] David S. Goldfarb.[2,1] *[1]Nephrology, NYU School of Medicine, New York, NY; [2]Nephrology Section, New York Harbor VAMC, New York, NY; [3]New York University, Jersey City, NJ; [4]New York University School of Medicine, New York, NY; [5]Litholink Corp, Chicago, IL; [6]University of Houston, Houston, TX; [7]University of Rochester Medical Center, Rochester, NY; [8]The Royal Melbourne Hospital, Parkville, NSW, Australia; [9]Litholink Corporation, Chicago, IL; [10]NYU Langone Health, New York, NY*.

Background: Potassium citrate is a mainstay of treatment to prevent calcium stones. However, it can increase urine pH and calcium phosphate (CaP) supersaturation (SS). HCA, extracted from garcinia cambogia, is a potent inhibitor of calcium oxalate (CaOx) crystal growth *in vitro* and may not yield HCO_3. It is "generally regarded as safe" and available over the counter. We studied how HCA supplementation affects urine chemistry.

Methods: We enrolled 2 groups: calcium stone formers (SF) and non-stone forming (NSF) controls. Thiazides and potassium citrate were held for 2 weeks prior to study. Participants recorded a self-selected diet for 2 days and performed 24-hour urine collection on day 2. HCA 300 mg 3 times daily was taken orally for 7 days, and 24-hour urine collected on day 7 while the patient replicated the initial, self-selected diet.

Results: 13 people, aged 26 - 76 years, participated. There were 6 SF and 7 NSF, combined into 1 group of 13. Patients replicated their diets well, as urine Na, volume, and creatinine were similar (data not shown). Results presented in Table. HCA increased urine K and citrate ($P < 0.001$ and 0.013 respectively). Mean urine pH was unchanged (6.25 to 6.47, P=0.14), while urinary NH_4 fell ($P = 0.017$). 24h excretion of Ca and Ox did not change. SS of CaOx and CaP did not change. Serum values did not change: baseline HCO_3 and K were 23.5 ± 2.5 and 4.0 ± 0.2 meq/L and 23.7 ± 1.8 and 4.4 ± 0.6 meq/L after HCA.

Conclusions: Urine K excretion rose by 29 meq/day compared with an expected increase based on the label of 14 meq, suggesting the label was not accurate. Increased citrate and lower NH_4 suggest some K is in the form of alkali salts or that some HCA is metabolized to bicarbonate. There was no change in CaP or CaOx SS. The lack of effect on SS may not reflect the potential ability of HCA to inhibit calcium crystallization, as it inhibits Ca crystal growth in vitro in supersaturated media.

Funding: Commercial Support - Litholink Corp

Effect of HCA Supplementation on 24h Urine Chemistry; n=13, mean (SD)

	Ca	Ox	K	Cit	pH	NH4	SS CaOx	SS CaP

Oxalate Degradation Rates of Oxalobacter formigenes

Melody Ho,[1] Menghan Liu,[2] Steven L. Daniel,[3] David S. Goldfarb,[4] Lama Nazzal.[2] *[1]New York University, New York, NY; [2]New York University School of Medicine, New York, NY; [3]Eastern Illinois University, Charleston, IL; [4]New York Harbor VAMC, New York, NY*.

Background: Kidney stones commonly affect US adults. In recent years, there has been increasing interest in the human anaerobic colonic bacterium *Oxalobacter formigenes* because of its ability to metabolize oxalate, and its potential to protect against calcium oxalate kidney stones. Currently, there are two known groups of *O. formigenes* (Group 1 and Group 2) with only a few isolates from each group characterized. In our experiments, we aimed to isolate *O. formigenes* from subjects with primary hyperoxaluria (PH), enteric hyperoxaluria (EH) and healthy controls (HC) to compare their metabolic activities. Understanding these differences will help expand our knowledge about this important organism and its effect on oxalate homeostasis in humans.

Methods: We collected fecal samples from 37 patients via clinical trials at New York University Langone Medical Center and Mayo Clinic with PH, EH and HC. We cultured fecal samples in 25mM oxalate-rich selective media, then isolated *O. formigenes* by picking characteristic colonies from calcium oxalate agar. We identified and grouped isolates using PCR and Sanger sequencing of the *oxc* gene. We then tested their oxalate consumption via Oxalate Degradation Assay to compute mean oxalate degradation rates (ODR) for each group of isolates.

Results: We isolated 25 *O. formigenes* colonies from 14 subjects, with all isolates belonging to either HC (n=11) or PH (n= 14) patients, and none from EH patients. Based on oxc sequences, we identified Group 1 (n=17) and Group 2 (n=5) strains, and potentially a new taxonomic group Group 3 (n=3). We were able to regrow 13 (76%) of 17, 1 (20%) of 5, and 1 (33%) of 3 Group 1, 2, and 3 strains, respectively. All 14 PH patient colonies were identified as Group 1, while HC had a mix of all three groups. Mean ODR was significantly higher in Group 1 vs Group 2 isolates (8.5 ± 3.3 vs 2.8 ± 1.9 micromole/hour, p=0.02). Group 3 isolates had intermediate ODR (5.7 ± 3.1) values. As expected, the ODRs of our Group 1 isolates were similar to the control group 1 strain OXCC13 (11.1±1.2). Mean ODR between PH, EH and HC did not differ significantly.

Conclusions: We were able to isolate and characterize 25 colonies of *O. formigenes*, including a potential new group of *O. formigenes*. Group 1 strains appear to be most metabolically active *in vitro*, and were exclusively present in PH patients.

Suboptimal Screening of Primary Hyperparathyroidism Among Veterans with Urinary Stone Disease

Calyani Ganesan,[1] Benjamin C. Weia,[3] I-Chun Thomas,[4] Shen Song,[2] Ericka M. Sohlberg,[1] Christopher S. Elliott,[1] Simon Conti,[1] Joseph C. Liao,[1] Glenn M. Chertow,[2] John Leppert,[1] Alan C. Pao.[1] *[1]Stanford University, Palo Alto, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Stanford Healthcare, Palo Alto, CA; [4]VA Palo Alto, Palo Alto, CA.*

Background: The American Association of Endocrine Surgeons recommends parathyroidectomy in stone formers with primary hyperparathyroidism to prevent osteopenia, osteoporosis, and recurrent urinary stones. However, rates of screening for primary hyperparathyroidism among stone formers remain unknown. To address this knowledge gap, we determined the rate of parathyroid hormone (PTH) testing in a national cohort of stone formers with hypercalcemia in the Veterans Health Administration (VHA).

Methods: We identified stone formers as Veterans with one or more inpatient or two or more outpatient encounters for urinary stone disease (USD), or one or more stone procedures between 2008 and 2013 using the national VHA database. We excluded patients who were previously screened for hyperparathyroidism and those with an eGFR < 45 to avoid identifying Veterans with secondary hyperparathyroidism. We first identified the highest serum calcium measurement within a 6 month period before and after initial

stone diagnosis. We then identified associated serum PTH concentrations within 9 months of initial stone diagnosis.

Results: We identified 140,181 stone formers who met criteria of whom 94.7% (132,787 individuals) were men. Within this cohort, 85% (119,197 individuals) had a serum calcium level measured; of these, 1.8% (2,142 individuals) were found to have at least one serum calcium concentration > 10.5 mg/dL. Among patients with hypercalcemia, 24.4% (523 individuals) had a serum PTH measurement, and 51.8% (271 individuals) of these had serum PTH concentrations above the population reference range, suggesting primary hyperparathyroidism

Conclusions: Among Veterans with USD, hypercalcemia, and normal or near normal kidney function, fewer than one in four undergo PTH testing, and among those who do, more than half have evidence of primary hyperparathyroidism. The majority of stone formers with hypercalcemia and normal or near normal kidney function are not screened for primary hyperparathyroidism, a treatable cause of USD. This information should raise clinical awareness about deficits in guideline-concordant care and inform future quality-improvement efforts in USD care.

SA-PO283

Variation in Radiation Dose of Computed Tomography Examinations Used for Renal Imaging

Calyani Ganesan,[2] Philip W. Chu,[1] Rebecca Smith-Bindman.[1] *[1]UCSF, San Francisco, CA; [2]Stanford University, Palo Alto, CA.*

Background: Computed tomography (CT) is the most commonly used imaging modality for the assessment of renal related problems (e.g. kidney stones or masses.) Patients may be exposed to higher than needed doses of ionizing radiation, a known carcinogen. The objective of this study is to examine current practice and quantify variation in radiation doses for urinary stone, renal mass, and urogram CT as a first step toward informing future quality-improvement efforts to reduce patient exposure to ionizing radiation.

Methods: We identified computed tomography examinations within the University of California San Francisco International Radiation Dose Registry which prospectively assembled CT examinations from 152 institutions in 6 countries between 2015 and 2018 for renal indications including kidney stones and renal masses. We examined variation in mean effective dose by facility and variation in the technical parameters used for these examinations.

Results: We identified 90,459 urinary stone CT exams, 12,489 renal mass CT exams and 45,391 CT urograms. We found radiation dose varied with a threefold range in mean effective dose for urinary stone exams (4.9-13.6 mSv) and renal mass exams (12.7-41.2 mSv) and a sixfold range in mean effective dose for urograms (8.4-46.0 mSv). Adjusting for patient characteristics including size, and machine, make and model did not change these results and substantial variation in dose persisted.

Conclusions: Radiation dose varied substantially for urinary stone CT exams, renal mass CT exams and CT urograms, and these differences were not attenuated by adjusting for patient or machine factors. Doses could be substantially reduced if facilities adopted the protocols of the facilities where low dose protocols are used. This study highlights the need to adopt lower radiation dose protocols and standardize technical parameters to prevent patients from receiving unnecessarily high doses of ionizing radiation in the assessment of renal disease.

SA-PO284

The Study on Value of Bone Scan Technology in Early Diagnosis of Calciphylaxis

Yuqiu Liu, Xin Yang, Canlin Yang, Xiaotong Xie, Bi-Cheng Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China.*

Background: Current diagnostic criteria for calciphylaxis are based on ischemic necrosis and ulceration of skin and soft tissue. Nevertheless, once clinical diagnosis is confirmed, the disease progresses to the end stage with terrible prognosis. This study is aimed to investigate the early diagnostic role of bone scan technology in calciphylaxis patients undergoing dialysis, considering that this technology can reflect abnormal distribution of hydroxyapatite in eatra-osseous tissue.

Methods: Analyzed clinical data of 15 hemodialysis patients with calciphylaxis diagnosed by skin biopsy who had bone scan results in Zhongda Hospital Southeast University from Oct. 2017 to Dec. 2018. Meanwhile, non-calciphylaxis patients with the similar baseline values of clinical data were screened out (Ratio=1:2). Chi-square test was used to analyze the difference in positive rates of bone scan between two groups.

Results: General clinical data, including age, gender, dialysis time, history of diabetes and secondary hyperparathyroidism (SHPT), had no significant difference between two groups (P>0.05). In case group, 11 patients had positive result of bone scans and the positive rate was 73.3%. The positive results in calciphylaxis patients were mainly the increase in uptake or delay of clearance of radiotracer by soft tissue and the radiotracer under skin was linear or diffuse distributed. In control group, only 5 cases were positive with the rate being 16.7%, whereas the radiotracer was distributed in large patches, which was finally confirmed as SHPT-related metastatic calcification. The difference in the positive rate between two groups was significant (P<0.05). The sensitivity of bone scan for calciphylaxis was 73.3%, with the specificity being 83.3% and the Yoden index being 0.57, indicating bone scan had significant value in diagnosis of calciphylaxis. Moreover, its positive predictive value was 0.69, with the negative predictive value 0.86, suggesting that bone scan technology can be used in clinical work to screen high-risk patients in order to get clue for further examination such as skin biopsy to make early diagnosis of calciphylaxis.

Conclusions: Since bone scan has a high sensitivity and specificity in the diagnosis of calciphylaxis with a wide range of uptake for radiotracers by soft tissue, it has important application value in early diagnosis of calciphylaxis.

SA-PO285

The Specificity of Histology in Calciphylaxis

Carla L. Ellis,[2] Justin T. Cheeley,[3] W. Charles O'Neill.[1] *[1]Emory University, Atlanta, GA; [2]Emory University Hospital, Atlanta, GA; [3]Emory University School of Medicine, Atlanta, GA.*

Background: Calcific uremic arteriolopathy (CUA), also known as calciphylaxis, is a devastating skin lesion that occurs most commonly in end-stage renal disease (ESRD). We previously showed that many of the histologic findings considered diagnostic of CUA can also be seen in normal skin from amputations in unaffected ESRD patients, raising questions about their specificity. To address this with more appropriate control tissue, we compared affected and unaffected skin from patients with a clinical diagnosis of CUA.

Methods: Hospitalized patients were recruited by the consulting dermatologist, who then performed skin biopsies of the lesion and of normal skin on the contralateral extremity. Skin tissue was obtained at autopsy in 2 cases. Hematoxylin and eosin and von Kossa stains were examined on each specimen. Histologic findings were evaluated by a single pathologist and included small vessel calcification, small vessel thrombosis, intimal hyperplasia, and extravascular calcification.

Results: Paired skin samples were obtained from 7 patients, of whom 4 were female, 5 were diabetic, 3 were receiving warfarin, 6 were receiving hemodialysis, and 1 was receiving peritoneal dialysis. Age range was 39-77. Lesions were located on the leg (4), thigh (2), and penis (1). In the latter case, control tissue was obtained from the mons pubis. The prevalence of findings in affected skin were: 5/7 (71%) small vessel calcification, 3/7 (43%) small vessel thrombosis, and 2/7 (30%) intimal hyperplasia, and 2/7 (30%) extravascular calcification. None of these findings were present in two biopsies. At least 2 findings were present in each of the other 5 specimens. Unaffected skin showed no abnormalities in the biopsies and only vascular calcification in the autopsy samples.

Conclusions: Based on this small study, histologic findings associated with CUA are absent in biopsies of unaffected skin from patients with suspected CUA. While small vessel calcification was noted in normal skin in the autopsy cases (possibly due to the larger sampling size), none of the other findings were present. Thus, the presence of at least 2 histologic findings appeared to be specific for CUA. Reconciling this with our previous results using amputation specimens as controls, we conclude that CUA is associated with specific histologic findings but only in patients without peripheral arterial disease. However, additional cases are needed to confirm this.

A Novel Approach to Treat Calciphylaxis, A Deadly Disease

Mohammed I. Elsebaei. *Al Amiri, Kuwait City, Kuwait.*

Introduction: Calcific uremic arteriolopathy (CUA), also known as calciphylaxis, is a rare disease mostly occurring in patients with kidney disease (CKD). It is characterized by painful, indurated and ulcerative lesions often covered by dark eschar that is very tender and leads to necrosis following calcification and occlusion of small cutaneous arterioles. Lesions may be solitary or multiple, covering several body regions. The Prognosis is generally poor. Complications, septic episodes are common and explain the high mortality rate of about 45–80% particularly in patients with ulcerative disease [1]. We report a new therapeutic approach.

Case Description: A 66-years-old woman with known CKD stage 3 secondary to diabetic nephropathy, hypertension, coronary artery disease, hyperlipidemia and bronchial asthma. There was no history of any medication allergies. The patient presented to our hospital with urinary tract infection, which was complicated with acute deterioration of her renal function approaching ESRD. Her hospital stay was complicated with appearance of multiple red indurated skin lesions of variable sizes which were progressive. They were markedly painful and required strong Opiods for pain relief. These skin lesions were rapidly progressed to deep ulcers and were requiring multiple surgical debridement's. Skin biopsy was done and confirmed the diagnosis of calciphylaxis. She was supported with hemodialysis. Her labs showed. s PTH level of 30 pmol/l, scalcium was 2.4 u mol/l and s phos was 2.2 umol/l.

Discussion: The patient was Initially treated with intravenous sodium thiosulphate after each dialysis session, oral cinacalcet, oral sevelamer and low calcium dialysate. With These measures there was no relief of her lesions and pain. As a last resort Nitroderm patches (5 inches) and silver Alginate dressings were applied locally and she was given oral nifidepine 30 Mg LA once a day. Patient demonstrated a dramatic improvement over the subsequent months. Conclusions: This case illustrates that the local and systemic vasodilators including other general measures could be successfully used in managing resistant cases of calciphylaxis. This therapeutic approach should be evaluated in other such cases to revalidate.

Epidemiological Investigation of Calciphylaxis: Data from China

Yuqiu Liu, Canlin Yang, Xiaotong Xie, Bi-Cheng Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China*.

Background: Calciphylaxis is a serious life-threatening vascular disease commonly occurred in dialysis patients. Chinese research on calciphylaxis is still in its infancy without epidemiological data. A regional epidemiological study of calciphylaxis was initiated at first time in China to find out its prevalence and clinical characteristics in Chinese hemodialysis patients.

Methods: The project was initiated in Aug. 2018. Stratified sampling method was used to select 28 dialysis centers in four regions of Jiangsu Province in China with an estimated sample size of 6000. Inclusion criteria: a. age≥18 years; b. duration of dialysis≥6 months; c. informed consent. The study used a questionnaire included general information and calciphylaxis-related symptoms.

Results: As of Apr. 30, 2019, 3799 hemodialysis patients had completed questionnaires. 77.0% of patients hadn't heard of calciphylaxis, and another 9.2% only knew the name. Among them, 27 patients were diagnosed with calciphylaxis and unadjusted prevalence rate in hemodialysis patients was 0.71%. Of the diagnosed patients, 70.4% were male with an average age and duration of dialysis of 55.8±15.3 years and 86.0 (36.0, 144.0) months respectively. 13 patients had diabetes and 19 had secondary hyperparathyroidism [the median iPTH was 561.8 (312.9, 817.8) pg/mL]. Only one used warfarin therapy. Surprisingly, 383 of 3799 (10.1%) had different types of skin lesions, including rough skin (48.3%), sensory sensitivity or loss (15.6%), diffuse rash (14.6%), calcified nodules (6.5%), painful papules (3.7%) and livedo or purpura (15.4%). Lesions were mainly in lower limbs, reaching 56.9%. 116 patients (30.3%) noticed a progressive deterioration of skin damage with potential calciphylaxis risks. Nevertheless, skin biopsy rate of these patients was only 6.3%, which affected further diagnosis.

Conclusions: This is the first epidemiological data about calciphylaxis from China. The preliminary analyses show that prevalence of calciphylaxis in Chinese hemodialysis patients is 0.71%, which seems to be lower than that from other countries due to differences in races and medication habits. In particular, we find some dialysis patients have atypical skin lesions which don't rule out early manifestations of calciphylaxis. It's urgent to improve clinical understanding of calciphylaxis, and multifaceted diagnostic methods will be applied for early screening.

SA-PO288

A Case-Control Study on Risk Factors of Calciphylaxis: Data from Chinese Hemodialysis Patients

Yuqiu Liu, Xiaotong Xie, Canlin Yang, Bi-Cheng Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China*.

Background: Calciphylaxis (CUA) is a rare but potentially fatal disease that is commonly occurred in dialysis patients. Since there is no data based on Chinese population, the study is aimed to investigate risk factors of CUA in Chinese hemodialysis patients.

Methods: We retrospectively evaluated medical records of 20 hemodialysis patients who were newly diagnosed with CUA by skin biopsy admitted to Zhongda Hospital Southeast University from Oct.2017 to Dec.2018. Non-CUA dialysis patients with the same age and duration of dialysis were randomly selected as controls (Ratio=1:2).

Results: Most of CUA patients were male (80%) and elderly (55%), while 50% had a body mass index higher than 24. The mean time interval since start of dialysis to CUA diagnosis was 114.65±81.32 months, and the median time from appearance of skin lesion to diagnosis was 6 (2, 15) months. The incidence of hyperparathyroidism was higher in patients with CUA (80% vs 62.5%), but the differences of duration of elevated serum intact parathyroid hormone (iPTH) and its highest value were not significant compared with the controls. Warfarin therapy had no significant difference between two groups (15% vs 5%). Univariate logistic regression analysis indicated that male (OR 3.619, 95%CI 1.027-12.748), each 1 point increase in score of use of vitamin D and its analogues (OR 1.505, 1.029-2.201), each 1 mmol/L increase in corrected serum calcium level (OR 24.486, 1.570-381.873), each 1 mmol/L increase in serum phosphate level (OR 5.382, 1.767-16.389), each 1 pg/mL increase in iPTH level (OR 1.002, 1.000-1.003), each 1 g/L decline in serum albumin level (OR 1.181, 1.041-1.340), each 1 IU/L increase in serum alkaline phosphatase (ALP) level (OR 1.005, 1.000-1.009) and each 1 mg/L increase in hypersensitive c-reactive protein level (OR 1.029, 1.000-1.059) were significantly associated with CUA. Serum phosphate, albumin and ALP were still significant risk factors after multivariate analysis.

Conclusions: This is the first report of risk factors of CUA based on Chinese population. The results show that high levels of serum phosphate and ALP, low level of serum albumin are independent risk factors of CUA in Chinese hemodialysis patients. Unlike previous research from western countries, warfarin therapy didn't show an increased risk in this study, propably because of the low exposure rate of it in China.

SA-PO289

Outcomes Assessment in a Randomized, Double-Blind, Placebo-Controlled Phase 3 Trial of SNF472 for Treating Calciphylaxis

Smeeta Sinha,[1] Glenn M. Chertow,[2] Vincent Brandenburg,[3] Lisa Gould,[4] Stephan Miller,[5] Carolina Salcedo,[6] Claire S. Padgett,[5] Rekha Garg,[5] Alex Gold,[6] Joan Perelló.[6] *[1]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Rhein-Maas Klinikum, Würselen, Germany; [4]South Shore Hospital Center for Wound Healing, Weymouth, MA; [5]Sanifit Therapeutics, San Diego, CA; [6]Sanifit Therapeutics, Palma, Spain*.

Background: Calciphylaxis (calcific uremic arteriolopathy, CUA) is a severe form of vascular calcification characterized by painful necrotic skin ulcers and very high mortality. No approved therapies are available. SNF472, an intravenous formulation of myo-inositol hexaphosphate, inhibits formation and growth of hydroxyapatite crystals, the final common step in the pathophysiology of vascular calcification. The objective of this Phase 3 randomized, double-blind, placebo-controlled trial is to evaluate efficacy and safety of SNF472 for CUA. Efficacy outcomes will include wound healing, pain, and wound-related quality of life (QoL). Standard safety assessments will be conducted.

Methods: Planned enrollment is approximately 66 adult patients on maintenance hemodialysis with a clinical diagnosis of CUA with wound ulceration and wound-related pain. Patients will be randomized 1:1 to SNF472 (7 mg/kg) or placebo 3x/week for 12 weeks via infusion through the dialysis circuit. In a subsequent 12-week open-label period all patients will receive SNF472. Patients will also receive background care for CUA in accordance with the practices of each site.

Results: Wound healing will be assessed with the Bates-Jensen Wound Assessment Tool (BWAT), BWAT-CUA, and qualitative review of wound images. All 13 items comprising the BWAT will be assessed: size, depth, edges, undermining, necrotic tissue type, necrotic tissue amount, exudate type, exudate amount, skin color surrounding the wound, peripheral tissue edema, peripheral tissue induration, granulation tissue, epithelialization. BWAT-CUA is an 8-item targeted modification of BWAT focused on prototypical features of CUA lesions including necrotic tissue type and amount, exudate type and amount, skin color surrounding the wound, peripheral tissue edema and induration, and granulation tissue. External, independent wound care experts blinded to treatment assignment will determine BWAT scores based on review of standardized images, measurements from imaging software, and assessments by site investigators. Pain will be assessed on a visual analog scale. QoL will be assessed with the Wound-QoL questionnaire.

Conclusions: Efficacy and safety of SNF472 for CUA will be evaluated.

Whole-Kidney and Single-Tubule RNA Sequencing Reveal Changes of Cell Types and Signaling for Nephrogenic Diabetes Insipidus After Ureteral Obstruction

Chih-Chien Sung,[1] Shih-Hua P. Lin,[2] Mark A. Knepper.[3] *[1]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Tri-Service General Hospital, National Defense Medical Center, Neihu, Taiwan; [3]National Heart Lung and Blood Institute, Kensington, MD.*

Background: Unilateral ureteral obstruction (UUO) models in rodents are commonly employed in the study of CKD. Early stages of UUO are marked by polyuria with impaired urinary concentrating ability, associated with loss of aquaporin-2 (AQP2) expression. Most mechanistic work in UUO models has been done at relatively late time points, making it difficult to discriminate 'first cause' events from secondary, tertiary, etc. changes in gene expression.

Methods: Preliminary whole-kidney RNA-Seq studies were performed after 0, 3, 6, and 12 hrs of UUO. Based on whole-kidney findings, cortical collecting ducts (CCDs) and cortical thick ascending limbs of Henle (cTALs) were microdissected from rats 3 hrs after UUO. Single-tubule RNA-Seq was carried out independently in 4 UUO rats versus 4 controls.

Results: Whole kidney RNA-Seq time course experiments revealed that Aqp2 and other collecting ducts markers started to decrease between 2 and 6 hrs. Decreases were seen in markers of connecting tubule (Calb1), distal convoluted tubule (Slc12a3) and thick ascending limb (Slc12a1) were also seen within 3 hrs. However, there were no effects on transcripts coding for classical markers of podocytes and proximal tubules within 12 hours. Expression of renal non-epithelial cell markers showed B lymphocytes (Cd19, Cd80) rapidly increased at 3 hrs and decreased at 12 hrs followed by increased abundance of markers of monocytes (Fcgr2b, Sell), macrophages (Gata6), and chemokines (Ccl2, Ccl6, Cxcl14) at 6 to 12 hrs. Several aldosterone-regulated genes showed increases in mRNA including Sgk1, Scnn1a, and Tsc22d3 at 3 hrs. Single-tubuleRNA-Seq data (both CCD and cTAL) showed a large number of transcripts coding for transporters and receptors that were decreased. It also revealedthat immediate early gene transcripts were increased significantly more frequently than expected from random sampling from the full pool of transcripts at 3 hrs.

Conclusions: Whole-kidney RNA-Seq results are consistent with very early effects on the distal nephron but not proximal tubule or glomerulus in terms of gene expression and provided evidence for invasion or activation of inflammatory cell types. Single-tubule RNA-Seq showed cellular signaling changes in CCD and cTAL, consistent with activation of the immediate early response.

Single-Cell Transcriptomics of Enriched Human Intercalated Cells Exposed to Uropathogen Reveal Differential Innate Immune Signature in Intercalated Cell Subsets

Vijay Saxena, Andrew L. Schwaderer, David S. Hains. *Indiana University, Indianapolis, IN.*

Background: We have previously shown that intercalated cells (ICs) are important for innate immunity in murine model of urinary tract infection. Little is known about their role in human innate immune function. We explored the whole genome transcriptome after early 1 hour uropathogen vs saline exposure in enriched human intercalated cell at single cell level.

Methods: Human ICs were enriched from kidney biopsy samples using magnetic cell sorting with anti-human c-kit microbeads after removal of dead cells and $CD45^+$ immune cells. Enriched viable ICs were exposed to saline or UPEC for 1hr. Single cells were separated on 10x single cell instrument. Single cell gel beads containing barcoded oligonucleotides and reverse transcriptase reagents were generated with the v3 single cell reagent kit. Following cell capture and cell lysis, cDNA was synthesized and amplified. Illumina sequencing library was then prepared with the amplified cDNA. The resulting library was sequenced using Illumina NovaSeq 6000. 26 bp of cell barcode and UMI sequences and 91 bp RNA reads were generated. CellRanger 3.0.2 was utilized to process the raw sequence data generated. The R package Seurat development version 3.0.0.9 was used for the further gene expression analysis.

Results: Magnetically enriched $CKIT^+$ cells expressed higher levels of V-ATPase mRNA expression compared to $CKIT^-$ cells. 6 clusters of collecting duct cells identified including 4 alpha IC clusters with variable SLC4A1 (AE1) and innate gene including DEFB1 (anti-microbial peptide) expression, 1 beta IC cluster (showing no innate immune gene expression) and 2 PC vs transitional IC/PC clusters ($AQP2^{lo/hi}$ V-$ATPase^{lo}$) with distinct innate immune profile. Reactome pathway analysis predicted innate immune role for human ICs. Differential gene expression profiling found significantly upregulated gene with short UPEC exposure in IC clusters included Immunoglobulin lambda constant 3 (IGLC3) and adrenomedullin (ADM), an anti-microbial gene, integrin alpha E (ITGAE).

Conclusions: Innate immune function identified in murine models are conserved in human ICs. Enriched live human ICs can act as model system that can be used to determine human relevance of mouse findings. Single cell analysis reveals collecting cell types/subtypes are more diverse than previously recognized.

Novel Transcriptional Regulators of Tight Junction Biogenesis in Renal Collecting Ducts

Janna Leiz,[1,2] Christian Hinze,[1,2] Kai M. Schmidt-Ott.[1,2] *[1]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Charite - Universitaetsmedizin Berlin, Berlin, Germany.*

Background: The renal collecting duct is comprised of a tight epithelial barrier resulting in a strict separation of intraluminal urine and the interstitium. Disruption of this barrier leads to impaired water reabsorption and loss of adequate urine concentration ability. However, the overall transcriptional network controlling this process is only incompletely characterized. Using an integrated bioinformatics approach, we identified two transcriptional regulators (TRs), Tfap2a and Ncor1, potentially involved in this network. The transcription factor Tfap2a is a trans-regulatory factor implicated in epithelial differentiation and Tfap2a mutations have been associated with renal malformations. Ncor1 is a nuclear corepressor that assists nuclear receptors (such as thyroid hormone receptor) in the downregulation of gene expression. We hypothesize that Tfap2a and Ncor1 play a role in tight junction biogenesis and epithelial barrier formation in the CD.

Methods: Inner medullary collecting duct (IMCD3) cells were engineered to harbour CRISPR/Cas9-induced knock outs (KO) of either Tfap2a or Ncor1. Deregulated genes were identified by mRNA sequencing and confirmed with qPCR.

Results: Tfap2a and Ncor1 show predicted binding to promotors of several critical tight junction components and are highly expressed in IMCD3 cells and CD in mice. Crispr/Cas9-induced KO of Tfap2a and Ncor1 were confirmed with allele-specific sequencing validating frameshift mutations in the targeted areas. mRNA sequencing revealed a strong impact of Tfap2a and Ncor1 KO on the expression of important tight junction components. For example, two claudins, Cldn4 and Cldn8, showed massive downregulation in comparison to WT clones. Interestingly, the TR grainyhead-like 2 (Grhl2), which we previously identified as a critical regulator of tight junction biogenesis, was also highly downregulated in Tfap2a and Ncor1 KO clones. These findings were confirmed by qPCR. A detailed characterization of the transcriptional network is still ongoing.

Conclusions: Our data support our hypothesis that the candidates Tfap2a and Ncor1 are involved in the transcriptional network regulating tight junction biogenesis and barrier formation in the renal CD. A detailed understanding of the underlying network mechanisms controlling tight junction biogenesis might provide important insights into their potential involvement in kidney disease.

SA-PO293

A Comprehensive Transcriptome Database for Mouse Renal Tubule Segments

Lihe Chen,[1,2] Chung-Lin Chou,[1,2] Mark A. Knepper.[1,2] *[1]National Heart Lung and Blood Institute, Kensington, MD; [2]National Institutes of Health, Bethesda, MD.*

Background: The mammalian renal tubule is comprised of at least 14 segments, each with distinct cell types and unique sets of transcriptomes. Recent advances in RNA-seq techniques offer the ability to profile the transcripts at the level of single-microdissected tubules and single-cells. To better understand the mouse renal physiology and pathophysiology, a comprehensive transcriptome database for all the mouse renal segments/cells is needed.

Methods: Here, we microdissected all 14 mouse renal tubule segments and carried out single-tubule RNA-seq in each of them. These data were used to create an online database that allows for: 1) easy exploration of transcript expression; and 2) visualization of isoform distribution along the renal tubule through a genome browser, *JBrowse*. We also developed a flow-sorting procedure to enrich *Slc12a3*$^+$ distal convoluted tubule (DCT) cells and carried out single-cell RNA-seq (10X Chromium) to study their heterogeneity.

Results: We profiled at least 3 biological samples per segment and were able to detect more than 11,000 transcripts for each mouse renal tubule segment (mean TPM >1). We identified unique patterns of protein distribution along the renal tubule, including transcription factors, metabolic enzymes, and G protein-coupled receptors. Also, we incorporated JBrowse into the database, which allows for easy and intuitive visualization of exon usage for transcripts. Our data revealed distinct segment-specific isoforms of many genes including known isoforms of ROMK (*Kcnj1*), Wnk1, and SPAK (*Stk39*). This database allowed us to identify embigin (*Emb*) as a negative surface marker for proximal tubule cells, which was used to enrich non-proximal cell types by FACS sorting. We profiled ~2000 $embigin^+$ cells at a median depth of ~1000 genes. Single-cell RNA-seq analysis of Emb^+ $CD45^-$ $DAPI^-$ LTL^- PNA^- Kit^- cells indicated an enrichment of DCT cells (~1000 *Slc12a3*$^+$ cells). Initial results show evidence of heterogeneity of *Slc12a3*$^+$ cells separating into at least two independent clusters. Both clusters lacked AQP2 and 11β-hydroxysteroid dehydrogenase signals but a high percentage expressed ENaC subunits.

Conclusions: These data allowed us to create a resource in the form of a publicly accessible web page. They also expand our knowledge of the cell types that make up the DCT.

SA-PO294

Identification of MAP Kinases-Regulated Proteins in Downstream Signaling Pathways of Vasopressin V2 Receptor in Kidney Collecting Duct

Hyo-Ju Jang,[1] Hyun Jun Jung,[2] Hyo-Jung Choi,[1] Eui-Jung Park,[1] Hye-Jeong Park,[1] Tae-Hwan Kwon.[1] *[1]Kyungpook National University, Daegu, Republic of Korea; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Vasopressin signaling mediated by G protein-coupled V2 receptor (V2R) is critical in water and electrolyte transport in the kidney collecting duct (CD) cells. Stimulation of V2R affects several downstream signaling pathways, including PKA, PI3K/AKT, Wnt, and Ca^{2+}/calmodulin. MAP kinases are also involved as an apparent downstream signaling pathway of V2R, however, the roles and their substrates of MAP kinases in the vasopressin signaling are unclear.

Methods: Comprehensive substrates of MAP kinases were identified using bioinformatic analyses: 1) expression of MAP kinases were studied using database based on high-throughput profiles of transcriptome and proteome (https://hpcwebapps.cit.nih.gov/ESBL/Database/index.html); 2) MAP kinase substrates expressed in the CD were identified using multiple protein phosphorylation databases. The identified substrates were mapped on the downstream signaling of V2R. Trim28-mediated AQP2 regulation was examined using immunoblotting and immunohistochemistry.

Results: Five MAP kinases (ERK1, ERK2, ERK3, JNK2, and MAPK p38 alpha) were identified as the MAP kinases expressed in kidney CD cells. From multiple protein kinase-substrates databases, 189 proteins were identified as the substrates of five MAP kinases. Among them, 51 transcription factors, 15 transcription co-regulators, 30 kinases, 4 E3 ligases and 1 deubiquitinating enzyme were classified. In particular, sequential data mining revealed that serine 595 in the tripartite motif-containing 28 (TRIM28), as the substrate of MAP kinases, was the only one phosphorylation site downregulated by vasopressin. Since TRIM28 is a transcription cofactor and also E3 ligase, we examined whether TRIM28 is a mediator of MAP kinases action on AQP2 expression. Immunofluorescent labeling of mouse and rat kidneys revealed that TRIM28 was exclusively localized in the nuclei of the tubular epithelial cells, including CD. dDAVP-induced AQP2 up-regulation was significantly attenuated in mpkCCD cells with TRIM28 knockdown.

Conclusions: We identified MAP kinase substrates of the kidney CD mapped on the downstream signaling pathways of V2R. TRIM28 was identified as a substrate of MAP kinases that involves in vasopressin-mediated signaling pathways, including regulation of AQP2.

SA-PO295

Phosphorylation Profile of Human AQP2 in Urine Exosome Identified by LC-MS/MS Phosphoproteomic Analysis

Kenichi Ishibashi,[1] Yasuko Tanaka,[1] Sei Sasaki,[1] Tadashi Yamamoto.[2] *[1]Meiji Pharmceutical university, Kiyose, Japan; [2]Niigata University, Niigata, Japan.*

Background: AQP2 water channel is the key membrane protein which determines the water permeability of collecting ducts. Multiple phosphorylation sites at the C-terminal of AQP2 are identified including S256, S261 and S264. Interetingly, the amino acid at S269 of rodents AQP2 is Thr in human AQP2. The phosphorylation of S269 in rodents has been shown to be an important signal for the apical membrane accumulation. However, the phosphorylation of T269 in human is unknown. As AQP2 is excreted into the urine by the endocytosed exosomes, human AQP2 protein is easily obtained from the urine. The purpose of this study was to examine the phosphorylation status of human AQP2 from urine exosomes.

Methods: Human urine samples of volunteers were obtained from the morning first urine. Urine exosomes were isolated by differential centrifugations and digested with trypsin in solution. Tryptic peptides were purified by MonoSpin column (GL Sciences, Tokyo, Japan) and analyzed thrice by LC–MS/MS (Bruker Tims TOFpro). Western blots were used to detect the AQP2 phosphorylation with a usual and S256, S261, S264, and S269-phosphorylated AQP2-specific antibodies.

Results: Summation of thrice analysis identified total 185 PSMs (peptide spectrum match) of phosphorylated AQP2 at Ser and/or Thr. The most dominant form was S256 phosphorylated form (n=154), followed by S261 form (n=14). Small numbers of phosphorylation were observed at T244 (n=6), S264 (n=4), and T269 (n=2). Western blot of human urine exosomes detected dominant S256 and S261-phosphorylations and much lower S264 and T269-phosphrylations.

Conclusions: These results indicate that the all phosphorylation sites of human AQP2 including T269 are indeed phosphorylated and S256- and S261-phosphorylations play a dominant role in its urinary exosomal excretion. The newly identified T244 phosphorylation is intriguing and worth further studies.

Three-Dimensional Visualization of the Medullary Tubular-Vascular Relationship in Adult Mouse Kidneys

Jie Zhang,[1] Jie Yang,[1] Jesper S. Thomsen,[3] Arne A. Andreasen,[3] Ling Gu,[1] Shi-Jie Chang,[2] Erik I. Christensen,[3] Xiao-Yue Zhai.[1] *[1]Department of Histology and Embryology, China Medical University, Shenyang, China; [2]Department of Biomedical Engineering, China Medical University, Shenyang, China; [3]Aarhus University, Aarhus C, Denmark.*

Background: A close spatial relationship between renal tubules and blood vessels in the renal medulla forms the structural basis for urine concentration, but is also the site of acute and chronic kidney injury under certain pathological circumstances. Therefore, a comprehensive understanding of the structure of this area is indispensable for nephrologists.

Methods: The tubule-vessel arrangement through whole mouse medulla was investigated using serial sections with double immunofluorescent staining for CD34 and for either AQP-1 or AQP-2. Subsequently, 525 tubules and 333 vessels were traced with custom-made computer software, and ultrastructurally analyzed using EM.

Results: The main findings were: 1) Descending vasa recta (DVR) and ascending vasa recta (AVR) in the center of the vascular bundle (VB) of ISOM closely accompanied each other starting at the cortex-medulla transition towards the inner medulla and gradually draining into capillaries at papilla; 2) AVR arising from capillary nets of the different levels of the medulla always ran counter-currently in close contact with either descending thin limbs (DTL) or DVR in a VB or with collecting ducts (CD) in inter-bundle regions (IBR). AVR accompanying with type 3 short loop nephron-descending thin limbs (SLN-DTL) mainly drained into arcuate veins, while AVR in close contact with type 1 and 2 SLN-DTL often drained into the lobular veins in cortex; 3) Thick ascending limbs (TAL) from the longest long looped nephrons (LLN) entered into a VB, and ran mainly in proximity to and counter-current to the DVR that originated from same glomeruli; 4) The number of ascending and descending tubules and vessels were almost identical; and 5) In the inner medulla, DVR became thin-walled and fenestrated, closely related to the surrounding tubules or CD.

Conclusions: The present study shows a ubiquitous phenomenon that AVR is spatially arranged with DTL and DVR as well as CD in a counter-current way throughout the whole medulla. This contributes to an efficient reabsorption of water and electrolytes in the filtrate, and makes it sensitive to the damaging factors, such as hypoxia, hyperglycemia, cytotoxity, etc.

SA-PO297

Molecular Dynamics Simulations Reveal the Residues Involved in NBCe1 Ion Coordination

Hristina R. Zhekova,[2] Alexander Pushkin,[1] Rustam Azimov,[1] Natalia Abuladze,[1] Liyo Kao,[1] Debra Newman,[1] Sergei Noskov,[2] Ira Kurtz.[1] *[1]Medicine, UCLA, Los Angeles, CA; [2]University of Calgary, Calgary, AB, Canada.*

Background: We have recently solved by CryoEM the near atomic (3.9 Å) structure of NBCe1-A, an electrogenic Na^+-CO_3^{2-} cotransporter expressed on the basolateral membrane of the proximal tubule, which plays a key role in tubular bicarbonate absorption. Although our structure and functional mutagenesis data suggest that a set of residues from TMs 3, 8, 10 and their vicinity are likely involved in ion coordination, their exact roles cannot be determined given that 3.9 Å resolution was not sufficient to detect coordinated ions.

Methods: The NBCe1 membrane domain was placed in a cubic periodic box in a POPC bilayer using the CHARMM-GUI online server. MD simulations were performed with the CHARMM36 force field and the NAMD program, and ~600 ns long MD trajectories with 2-fs time steps were collected and used for analysis. Ion interactions with the NBCe1 residues were quantified as contact frequency (i.e. percentage of the MD trajectory steps, in which a given ion was found at 3.5 Å from a specific protein residue). Residues exhibiting high contact frequencies with respect to Na^+ and CO_3^{2-} were used for identification of the ion coordination sites.

Results: In the wild type NBCe1 protein, the Na^+ contact frequency was highest for residues D754 and T758 (TM8) and A799 (loop prior to TM10). The CO_3^{2-} contact frequency was highest for K924 (TM13), A800 (loop prior to TM10), T801 (TM10), with less interaction at T485 (loop prior to TM3), and G486 and P487 (TM3). Mutational data supported these results. The A799V mutation found in patients with proximal RTA affecting the Na^+ coordination site leads to significantly impaired protein-ion interactions for both Na^+ and CO_3^{2-}. Another proximal RTA causing mutation, G486R, affecting the CO_3^{2-} coordination site, demonstrates impaired Na^+ protein contacts and strong interaction between R486 and CO_3^{2-} with the arginine residue positioned away from the coordination site.

Conclusions: All-atom molecular dynamics simulations of the membrane domain of NBCe1 revealed that it binds stably Na^+ and CO_3^{2-}. Na^+ is coordinated by D754, T758, and A799. CO_3^{2-} is coordinated by K924, A800, A801, T485, G486, and P487. The proximal RTA patient mutations A779V and G486R drastically alter the coordination of Na^+ and CO_3^{2-}.

Water Loading Increases Urinary Extracellular Vesicle Size but Not Excretion Rate

Charles J. Blijdorp,[2] Thomas Hartjes,[2] Joost Hoenderop,[1] René J. Bindels,[1] Martin E. Van royen,[2] Catherina A. Cuevas,[2] David Severs,[2] Ewout J. Hoorn.[2] *[1]Radboud university medical center, Nijmegen, Netherlands; [2]Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Urinary extracellular vesicles (uEVs) are a promising source of kidney biomarkers, but the factors influencing uEV size and excretion rate are unknown. Here, we studied the effect of water loading on uEV size and excretion rate.

Methods: We performed a water loading test (20 ml/kg) in healthy men (n = 11) and isolated uEVs from whole urine at 6 time-points. uEVs were quantified using nanoparticle tracking analysis (NTA), a time-resolved fluorescence immunoassay that isolates CD9+ uEVs (CD9-TRFIA), and EVQuant, a novel technique that counts individual fluorescently labeled EVs after immobilization in a matrix.

Results: While EVQuant and CD9-TRFIA demonstrated that the excretion rate of uEVs was constant during water loading, NTA suggested a significant increase of 50% by the intervention ($p<0.0001$). Subsequently, we found on NTA that the size of uEVs generally increased ($p<0.0001$, Figure). This size increase was confirmed by EM (n= 4, $p<0.001$, Figure).

Conclusions: Water loading increases uEV size but not excretion rate. A lower urine osmolality may cause water to move into EVs. This phenomenon interferes with uEV quantification by NTA and is an important caveat in uEV studies.

Water Deprivation Shortens Primary Cilia Length in the Kidney Tubular Cells

Min Jung Kong,[2] Jee in Kim,[1] Kwon Moo Park.[2] *[1]Keimyung University, Daegu, Republic of Korea; [2]Kyungpook National University, Daegu, Republic of Korea.*

Background: The primary cilium, a microtubule-based cellular organelle, plays a key regulator for maintenance of cell homeostasis by sensing and transducing extracellular signals. In the kidney, the length of primary cilium links to the number of human kidney

diseases. Here, we investigated whether water deprivation affects the primary cilium homeostasis and its underlying mechanisms in the kidney tubule cells.

Methods: C57BL6 mice were dehydrated for 1 or 2 days. Some mice were administrated with tubastatin A (an inhibitor of histone deacetylase 6, HDAC6) or saline before restriction of drinking water supply.

Results: In this study, water deprivation significantly shortened primary cilia length in kidney tubular cells in mice along with increasing urine osmolality. The kidneys derived from water-restricted mice presented low levels of acetylated-α-tubulin, EXOC5, an exocyst complex, and α-tubulin transferase expression. In Madin-Darby canine kidney (MDCK) cells, high concentrations of NaCl or mannitol treatments shortened primary cilia length. This NaCl or mannitol treatment decreased the expression of acetylated-α-tubulin, EXOC5, and α-tubulin transferase. Treatment of tubastatin A prevented drinking water deprivation-induced shortening of primary cilia in the mice. In addition, this HDAC6 inhibitor treatment prevented the decrease of acetylated-α-tubulin, EXOC5, and α-tubulin transferase expression.

Conclusions: These findings demonstrate that the length of primary cilium in kidney tubule cells is associated with water supply and urine osmolality, suggesting that primary cilium may play an important role in body water homeostasis and regulation of urine osmolality.

Inactivation of the Mitochondrial Structural Protein Opa1 in Distal Tubules and Collecting Ducts in the Mouse Causes Nephrogenic Diabetes Insipidus

Laura Cassina,[1] Marco Chiaravalli,[1] Martina Maserati,[1] Valeria Mannella,[2] Giovanna Musco,[1] Alessandra Boletta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]IRCSS Policlinico San Donato, Milano, Italy*.

Background: Optic Atrophy-1 protein (OPA1) is a nuclear-encoded mitochondrial protein localizing in the inner mitochondrial membrane, where it participates to mitochondria fusion and supports cristae folding. Mitochondria in the kidney provide energy to the Na, K-ATPase that generates ion gradients for nutrient reabsorption, electrolyte and fluid balance (Bhargava 2017). Given their essential function in aerobic metabolism, mitochondria are of interest to the pathophysiology of diabetes. To study how mitochondria fitness contributes to kidney physiology, we inactivated *Opa1* gene expression in the kidney epithelium.

Methods: We generated a kidney-specific *Opa1$^{fl/fl}$* mouse model expressing the Cre recombinase under the kidney-specific cadherin 16 promoter (*Opa1* KO, for short). Mitochondria ultrastructure was analyzed by transmission electron microscopy (TEM), metabolomics analysis by NMR spectroscopy.

Results: *Opa1* KO mice die within the first three months of age. Mice were housed in metabolic cages and showed progressive polydipsia and polyuria, low urinary pH, decreased urinary electrolyte concentration but no gross alteration of total electrolyte excretion. We observed kidney enlargement from P30 onwards, which results from enhanced proliferation of *Opa1* KO epithelial cells of distal tubules and collecting ducts, where *Opa1* is inactivated, by Ki67 staining. Expression of markers of distal tubule subsegments is preserved indicating maintenance of cell identity, with the exception of aquaporin 2 that is reduced in *Opa1* KO collecting ducts, causing polyuria. We detected the expected alterations in mitochondria structure by TEM and decreased mitochondrial cytochrome *c* oxidase activity in *Opa1* KO epithelial cells. Metabolomics showed that these alterations result in a massive switch to glycolysis that sustains cell proliferation, ultimately resulting in renal dysfunction.

Conclusions: Inactivation of Opa1 induces kidney enlargement and a gross impairment of renal water reabsorption, thus recapitulating the key features of nephrogenic diabetes insipidus. Further investigations will clarify the molecular mechanisms that link mitochondria dysfunction to epithelial cell proliferation, a response that seems to be unique of the kidney.

Induction of the Intracellular Immunomodulator Toll-Interacting Protein (Tollip) Mediates Monophosphoryl Lipid A (MPLA)-Induced Protection Against Lipopolysaccharide in Medullary Thick Ascending Limb (MTAL)

Bruns A. Watts,[1] Esther Tamayo,[1] Edward R. Sherwood,[2] David W. Good.[1] *[1]University of Texas Medical Branch, Galveston, TX; [2]Vanderbilt University Medical Center, Nashville, TN*.

Background: LPS inhibits HCO_3^- absorption in the MTAL through activation of a basolateral TLR4-MyD88-IRAK-1-ERK pathway that is upregulated by sepsis. Recently we reported that pretreatment with the nontoxic immunomodulator MPLA prevents inhibition of HCO_3^- absorption by LPS through activation of a TLR4-TRIF-PI3K pathway that prevents LPS-induced activation of IRAK-1. Here, we examined the molecular mechanism by which MPLA pretreatment suppresses IRAK-1 activation. We investigated the role of Tollip, an inducible intracellular protein that negatively regulates LPS signaling by inhibiting activation of IRAK-1 downstream of TLR4. The expression and functional significance of Tollip in renal tubules are undefined.

Methods: .

Results: We found that treatment with MPLA in vitro increased Tollip protein level in mouse and rat MTALs and that the increase in Tollip expression occurs within a time frame (2 h) sufficient to account for the effect of MPLA pretreatment to inhibit LPS-induced IRAK-1 activation. The MPLA-induced increase in Tollip expression was prevented by PI3K inhibitors. In coimmunoprecipitation experiments in inner stripe of outer medulla, treatment with MPLA increased the amount of IRAK-1 stably bound to Tollip, an interaction shown to inhibit IRAK-1 activation after LPS stimulation. Treatment of mice with MPLA increased Tollip protein level in the MTAL and this increase was prevented by administration of a PI3K inhibitor. Thus, the ability of MPLA to upregulate Tollip expression in the MTAL in vitro translates to the MTAL in vivo.

Conclusions: We conclude that pretreatment with MPLA increases expression of Tollip in the MTAL through a PI3K-dependent pathway. Tollip, in turn, inhibits LPS-induced TLR4 signaling by suppressing activation of IRAK-1, thereby preventing downstream activation of ERK that inhibits HCO_3^- absorption. These results provide new evidence that MPLA induces immune reprogramming of MTAL cells that protects against LPS stimulation and that Tollip can function as an endogenous negative regulator of inflammatory TLR4-IRAK-1 signaling in renal tubule epithelial cells. Strategies targeted to manipulate Tollip expression may aid in protecting renal tubule function against infectious and inflammatory challenge.

SA-PO302

AQP11 Deficiency Impairs Thymus Development Possibly Through Defective Fat Metabolism

Kenichi Ishibashi,[1] Sei Sasaki,[1,2] Yasuko Tanaka.[1] *[1]Meiji Pharmceutical university, Kiyose, Japan; [2]Tokyo Medical and Dental University, Bunkyo-ku, Japan*.

Background: Aquaporin11 (AQP11) is a superaquaporin permeable to both water and glycerol. AQP11 null mice suffer from polycystic kidneys and die within a month after birth due to uremia. Although AQP11 is expressed widely, it is most abundantly expressed in the thymus and testis. The purpose of this study is to clarify the role of AQP11 in the thymus.

Methods: Immunohistochemistry and microarray analysis with RT-qPCR.

Results: The immunohistochemical analysis revealed the AQP11 expression at the stromal-epithelial cells in the thymus medulla. Surprisingly, the size of the thymus from AQP11 null mice was much smaller than that of the wild mice by half and sometimes by 10%. The vacuolated medullary epithelial cells were observed in the thymus of AQP11 null mice with a normal cortico-medullary structure. The microarray analysis of the gene expression in the thymus was compared between AQP11 null mice and the wild mice by the annotation analysis based on the David Bioinformatics Resources 6.8(beta). We identified 1.5 or more up-regulated 66 genes which mainly participate in the PI3K/Akt signaling pathways to promote metabolism, proliferation, cell survival, growth and angiogenesis. We also found 0.5 or less down-regulated 55 genes, some of which are regulated by the peroxisome proliferator-activated receptor (PPAR) signaling pathway which is activated by fatty acids and their derivatives. RT-qPCR analysis confirmed the enhanced expression of Egfr (Epidermal Growth Factor Receptor), Itgb4 (Integrin beta-4) and Il2ra (interleukin 2 receptor alpha) and the diminished expression of AQP7, Pck1 (Phosphoenolpyruvate carboxykinase 1) and Ucp1 (Mitochondrial uncoupling protein 1). The up-regulated genes for growth signaling may support the survival of the regressed thymus while the down-regulated genes may cause deleterious effects on fat-glucose-energy metabolism in the thymus. The decreased aquaglyceroporin AQP7 in AQP11 null thymus may further compromise the glycerol accumulation leading to the thymus regression.

Conclusions: As the role of AQPs to support memory T cells through glycerol transport has been reported (Cui G et al. Cell. 161:750, 2015), such may also be working in the thymus development. AQP11 may also play an important role in the metabolic control of the thymus.

SA-PO303

The CaSR Signals Through CDC42, MKK6, and p38 to Inhibit SP1, a Repressor of Claudin-14 Expression

Justin Lee, Jawad F. Alzamil, Saba Rehman, R. Todd Alexander. *University of Alberta, Edmonton, AB, Canada*.

Background: Urinary calcium (Ca^{2+}) excretion increases in direct response to elevated plasma [Ca^{2+}], independent of hormonal signalling, by attenuating paracellular Ca^{2+} reabsorption from the thick ascending limb (TAL). This occurs via sensing plasma [Ca^{2+}] by the calcium sensing receptor (CaSR) expressed in the basolateral membrane of the TAL. This increases expression of the tight junction protein claudin-14, which blocks paracellular Ca^{2+} reabsorption. This pathway is inappropriately activated in some kidney stone formers, causing their disease. However, the signalling pathway between CaSR activation and increased claudin-14 transcription is unknown.

Methods: We identified the renal *CLDN14* transcript variant regulated by CaSR activation via quantitative PCR, using specific primers to the different variants on cDNA isolated from kidneys of mice treated with cinacalcet. We cloned the promoter region of this gene into a luciferase reported construct. This region also contained elements responsive to cinacalcet. We used this tool to delineate the signalling pathway downstream of CaSR activation.

Results: The region 1500 bp 5' to the 1st transcript variant when transfected in HEK293 cells contained promoter activity. Further, this region displayed more than double reporter activity in the presence of the CaSR and cinacalcet, but not in the absence of the CaSR. Increasing extracellular [Ca^{2+}] similarly increased reporter activity in the presence, but not the absence, of the CaSR. A prior microarray found increased renal MKK6 and *CLDN14* expression in mice treated with cinacalcet. However, expression of MKK6 reduced *CLDN14* reporter activity after cinacalcet treatment. MKK6 can signal through JNK or p38 MAPK. Inhibition of p38 but not JNK enhanced the cinacalcet

mediated increase in CLDN14 reporter activity. Sp1, a known downstream effecter of p38, was down regulated by CaSR activation, and co-expression attenuated the effect on the reporter construct. Upstream activation of MKK6 is through CDC42, as dominant-negative CDC42 attenuated reporter activity.

Conclusions: CaSR activation increases *CLDN14* transcription via signalling through CDC42, MKK6 and p38 to attenuate the expression of SP1 a repressor of *CLDN14*.

Is Claudin 16 Required for the Effect of Parathyroid Hormone (PTH) and Calcium Sensing-Receptor (CaSR) on Calcium and Magnesium Reabsorption in the Cortical Thick Ascending Limb?

Caroline Prot-Bertoye,[1,2] Lucile Figueres,[1] Elsa Ferriere,[1] Gaëlle Brideau,[1] Camille Griveau,[1] Catherine Chaussain,[3] Claire Bardet,[3] Tilman Breiderhoff,[4] Dominik Müller,[4] Pascal Houillier.[1,2] *[1]INSERM, UMRS1138- CNRS- ERL8228, Paris, France; [2]Georges Pompidou Hospital; Paris Descartes University, Paris, France; [3]EA 2496, Laboratory Orofacial Pathologies, Imaging and Biotherapies, Dental School, Paris Descartes University, Paris, France; [4]Department of Pediatric Nephrology, Charité - Universitätsmedizin Berlin, Berlin, Germany*.

Background: The cortical thick ascending limb of the loop of Henle (CTAL) reabsorbs 25% of the filtered calcium (Ca) and 70% of the filtered magnesium (Mg), along the paracellular pathway. The expression of claudin 16 (Cldn16) at the tight junction is required for a normal paracellular permeability and selectivity to Ca and Mg. Loss-of-function mutations of Cldn16 in the CTAL cause familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC). No specific treatment has been developed so far. PTH increases Ca and Mg transport and CaSR decreases Ca transport across the CTAL but the mechanisms involved are imprecise. Recent studies suggested that both PTH and CaSR agonists act on Cldn14, which may control Cldn16 function and/or expression and, eventually, paracellular reabsorption of Ca and Mg. Our objective was to assess whether Cldn16 is actually involved in the effect of PTH and CaSR on Ca and Mg reabsorption in CTAL.

Methods: CTAL dissected from $Cldn16^{+/+}$ and $Cldn16^{-/-}$ male mice were microperfused *in vitro* to measure transepithelial ions absorption under symmetrical conditions. Measurements were made under control condition and after addition of PTH (10^{-10} M) or of the CaSR antagonist NPS2143 (10^{-6} M).

Results: PTH and NPS2143 increased Ca reabsorption in $Cldn16^{+/+}$ CTAL (+44 %, n= 5, p=0.06; and +23 %, n= 7, p=0.047, respectively) and $Cldn16^{-/-}$ CTAL (+37 %, n=8, p=0.02; and +59 %, n=7, p=0.02, respectively). PTH increased Mg reabsorption in $Cldn16^{+/+}$ CTAL (+57 %, n=7, p=0.03) and in $Cldn16^{-/-}$ CTAL (+27%, n=5, p=0.06). The effect of NPS2143 on Mg reabsorption is currently under study.

Conclusions: Cldn16 is not necessary for the effect of PTH and CaSR on Ca reabsorption by native CTAL. Cldn16 is not necessary for the effect of PTH on Mg reabsorption by native CTAL. Our results suggest that the current model describing the effect of PTH and CaSR on Cldn16 might not be accurate. Our results constitute a proof of concept to develop new therapeutic strategies based on CaSR inhibitor and/or PTH receptor agonist for FHHNC.

SA-PO305

Colocalization of Claudin-10 with Other Transport Proteins in Basolateral Infoldings of the Thick Ascending Limb

Catarina Quintanova,[1] Samuel L. Svendsen,[2] Otto Von schwerdtner,[1] Cosima Merkel,[1] Tilman Breiderhoff,[4] Dominik Müller,[4] Nina Himmerkus,[1] Dorothee Günzel,[3] Markus Bleich.[1] *[1]Institute of Physiology, Christian-Albrechts-University Kiel, Kiel, Germany; [2]Department of Biomedicine, Aarhus University, Aarhus C, Denmark; [3]Institute of Clinical Physiology, Charite University Berlin, Berlin, Germany; [4]Department of Pediatric Nephrology, Charite University Berlin, Berlin, Germany*.

Background: The nephron is the structural and functional unit of the kidney and is composed of renal tubular segments. The thick ascending limb (TAL) of the loop of Henle is the essential segment for salt homeostasis and urinary concentration. The TAL originates from medullary and cortical nephron and share the basic transcellular transport mechanism that involve cotransport of sodium (Na^+), potassium (K^+) and chloride (Cl^-) and paracellular cation permeability. The selectivity of the paracellular pathway is determined by the combination of claudin protein expression in the tight junctions (TJ). In the TAL, TJs showed a mosaic expression of either claudin-10 or claudin-3/claudin-16/claudin-19 in a complex. TJ dominated by claudin-10 confer mainly paracellular Na^+ permeability. Interestingly, claudin-10 immunofluorescence showed also an extra-junctional localization in the basolateral region of the cells.

Methods: Freshly isolated single murine TAL segments of C57Bl6 and kidney specific (Ksp-Cre) Claudin-10 knockout mice were investigated by immunofluorescence and analyzed by *stimulated emission depletion* (STED) and Airyscan confocal microscopy.

Results: We performed triple staining with claudin-10, Na^+/K^+-ATPase (NKA) and the chloride channel subunit Barttin, which are both known to be prominent proteins in the basolateral TAL membrane. Antibody staining revealed the localization of all proteins in the infoldings of the basolateral membrane. Claudin-10 thereby showed a dotted pattern.

Conclusions: Claudin-10 shows extra-junctional expression and colocalization together with tramsmebrane transport proteins NKA and Barttin in the basolateral infoldings of TAL. This suggests a functional complex that facilitates or regulates ion transport function.

SA-PO306

Claudin 10b Is a Target for Parathyroid Hormone (PTH) in the Cortical Thick Ascending Limb (CTAL)

Caroline Prot-Bertoye,[1,2] Lucile Figueres,[1] Elsa Ferriere,[1] Gaëlle Brideau,[1] Camille Griveau,[1] Catherine Chaussain,[3] Claire Bardet,[3] Tilman Breiderhoff,[4] Dominik Müller,[4] Pascal Houillier.[1,2] *[1]INSERM, UMRS1138- CNRS- ERL8228, Paris, France; [2]Georges Pompidou Hospital; Paris Descartes University, Paris, France; [3]3 EA 2496, Laboratory Orofacial Pathologies, Imaging and Biotherapies, Dental School, Paris Descartes University, Paris, France; [4]Department of Pediatric Nephrology, Charité - Universitätsmedizin Berlin, Berlin, Germany*.

Background: In the CTAL, 25% of the filtered calcium is reabsorbed, along the paracellular pathway; the reabsorption is driven by the lumen-positive transepithelial voltage (Vte). Vte depends on the back diffusion of sodium (Na) along the paracellular pathway. The expression of claudin 10b (Cldn10b) at tight junction makes the paracellular permeability to Na (P_{Na}) greater than that of chloride (P_{Cl}). PTH increases calcium reabsorption across the CTAL but the mechanisms involved are uncertain. We assessed whether the effect of PTH in the CTAL involves Cldn10b, which determines Vte and P_{Na}/P_{Cl}, and aimed at identifying the underlying mechanisms.

Methods: CTAL dissected from $Cldn10^{+/+}$ and $Cldn10^{-/-}$ male mice were microperfused *in vitro* to measure Vte and P_{Na}/P_{Cl} under asymmetrical conditions with 0.1 mM furosemide in the lumen. All measurements were made under control and/or after peritubular addition of PTH (10^{-10} M), phorbol 12-Myristate 13-Acetate (PMA, 10^{-6} M), dibutyryl cAMP (dbcAMP 5.10^{-4} M), ionomycin (10^{-7} M), PKI 14-22 amide (a protein kinase A inhibitor, 10^{-6} M), trifluoroperazine (TFP, a calcium-calmodulin kinase antagonist, 10^{-4} M), or Dyngo4a (a clathrin-mediated endocytosis inhibitor, 10^{-5} M). The ratio of permeabilities P_{Na}/P_{Cl} was calculated according to the Goldman-Hodgkin-Katz equation.

Results: PTH significantly increased P_{Na}/P_{Cl} in $Cldn10^{+/+}$ CTAL (p=0.0002) but not in $Cldn10^{-/-}$ CTAL. This effect was reproduced by dbcAMP (p=0.02) and ionomycin (p=0.047), but not by PMA. PKI, TFP and Dyngo4a inhibited the effect of PTH on P_{Na}/P_{Cl}.

Conclusions: We conclude that, in the mouse CTAL, PTH increases P_{Na}/P_{Cl} via a cAMP-, and calcium calmodulin kinase-dependent effect on Cldn10b. Inhibition of the clathrin-mediated endocytosis prevents this effect. Our results show that the properties of intercellular tight junctions can be directly and rapidly altered by intracellular signaling pathways and changes in intracellular protein trafficking.

Low Gut Microbiota Diversity and Dietary Magnesium Intake Are Associated with the Development of Proton Pump Inhibitor-Induced Hypomagnesemia

Joost Hoenderop,[1] Lisanne Gommers,[1] Thomas Ederveen,[1] Jenny Van der wijst,[1] Caro Overmars-Bos,[1] Jos Boekhorst,[2] René J. Bindels,[1] Jeroen H. De Baaij.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]NIZO, Ede, Netherlands*.

Background: Proton pump inhibitors (PPIs) are used by millions of patients for the treatment of stomach acid-reflux diseases. Long-term PPI intake has been associated with serious adverse effects including enteric and respiratory infections, acute kidney injury (AKI) and chronic kidney disease (CKD). In addition, it has become increasingly evident that long-term PPI use induces hypomagnesemia (serum magnesium (Mg^{2+}) levels < 0.7 mmol/L). Despite rising attention for this issue, the underlying mechanism is still unknown. Recent studies have identified associations between PPI use and gut microbiota. Here, we examined whether the gut microbiome is involved in the development of PPI-induced hypomagnesemia.

Methods: To assess the effects of the PPI omeprazole on Mg^{2+} homeostasis and gut microbiota, C57BL/6J mice were treated daily with omeprazole (20 mg/kg bodyweight) or placebo for four weeks under normal (0.22 % w/w) or low (0.05 % w/w) dietary Mg^{2+} availability. Subsequently, Mg^{2+} homeostasis was assessed by means of serum, urine and faecal electrolyte measurements, RT-qPCR to evaluate renal and intestinal Mg^{2+}-related genes, and gut microbiota composition was investigated by 16S rRNA gene sequencing.

Results: After four weeks of treatment, omeprazole significantly reduced serum Mg^{2+} levels in mice on a low Mg^{2+} diet. Renal *Trpm6* expression was increased as compensation for the low Mg^{2+} diet in placebo-treated mice, but expression of this Mg^{2+} channel was not changed in the omeprazole-treated group. Moreover, these mice did not exhibit urinary Mg^{2+} wasting. Overall, 16S rRNA gene sequencing revealed a lower gut microbial diversity in omeprazole-treated mice. Omeprazole induced a shift in microbial composition that was associated with a 3- and 2-fold increase in the abundance of *Lactobacillus* and *Bifidobacterium*, respectively. To examine the metabolic consequences of these microbial alterations, the colonic composition of organic acids was evaluated. Low dietary Mg^{2+} intake, independent of omeprazole treatment, resulted in a 10-fold increase in formate levels.

Conclusions: Our results imply that both omeprazole treatment and low dietary Mg^{2+} intake disturb the gut internal milieu and may pose a risk for the malabsorption of Mg^{2+} in the colon.

Impaired Lymphatic Vessel Function Contributes to Edema in Nephrotic Syndrome

Jianyong Zhong,[1] Elaine L. Shelton,[1] Haichun Yang,[1] Valentina Kon.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Edema is a cardinal feature of nephrotic syndrome (NS) although the underlying mechanisms are incompletely understood. Lymphatic vessels transfer fluids, solutes, and macromolecules from the interstitial space back into the circulation. We examined the structure and function of lymphatics in the puromycin aminonucleoside (PAN) model of NS.

Methods: PAN was induced in Sprague Dawley rats, while non-injected rats served as controls (Cont). Eight days later, blood, urine, renal and mesenteric lymph, kidney and ileum were analyzed. Renal lymphatic vessels were isolated, cannulated and mounted in a perfusion chamber to assess vasoactivity.

Results: PAN caused the expected proteinuria, hypoalbuminemia, hyperlipidemia and generalized edema including in the kidney and ileum. Compared to Cont, PAN increased lymphangiogenesis, reflected by significantly increased gene expression of podoplanin (1.7-fold), VEGFR3 (2.1-fold) and the number of lymphatic vessels. VEGF-C, the major growth factor for lymphangiogenesis was elevated (2.1-fold) and lymph contained significantly more VEGF-A (2.0-3.1-fold) in PAN vs Cont. Lymphatic endothelial cells (LEC) isolated from mesenteric collecting vessel showed significantly increased gene expression of VE-cadherin (2.2-fold) while ileal LECs had increased ZO-1 (2.7-fold) indicating intercellular junction transition from button to zipper type. Isolated renal collecting lymphatic vessels from PAN showed significantly increased vessel diameter (15%), deceased contraction frequency (30%), and reduced sensitivity to endothelial NO inhibitor (L-NAME), NO donor (sodium nitroprusside), and thromboxane A agonist (U46619).

Conclusions: Although edema-forming kidney injury increases the number of lymphatic vessels, this compensation is inadequate, and edema rather reflects impaired vessel function, e.g., reduced lymphatic vessel contractility and reabsorptive capacity that may be novel targets in edema-forming disorders.

Calcium Citrate Incorporated into Calcium Carbonate and Calcium Carbonate Nanoparticles Alleviate Cellular Injury from Acidosis

Thasinas Dissayabutra,[1] Tipagorn Udomsinsirikul,[2,1] Rojrit Rojanathanes,[1] Amornpun Sereemaspun.[1] Renal Biochemistry and Stone Disease Research Unit, Faculty of Medicine, Chulalongkorn University *[1]Chulalongkorn University, Pathumwan, Bangkok, Thailand; [2]NSTDA, Bangkok, Thailand.*

Background: Metabolic acidosis is a common complication found in patients with chronic kidney disease (CKD), and causes cellular dysfunctions, protein degradation, inflammation, oxidative stress and cell death. Current medication to treat metabolic acidosis is the supplementation of alkalinizing agents such as sodium bicarbonate and sodium citrate. We proposed new nanoparticles as the adjuvant therapy to mitigate the consequences of metabolic acidosis in CKD patients.

Methods: Calcium citrate incorporated into calcium carbonate nanoparticles (CCNP) and calcium carbonate nanoparticles (CNP) were synthesized from calcium chloride and sodium citrate. A HK-2 cells cultured in DMEM with pH 7.4 (normal environment) and 4.0-5.0 (acidosis environment) were used to study the cellular toxicity by Resazurin oxidative-reduction assay, intracellular reactive oxygen species (ROS) production by 2,7-dichlofluorescein-diacetate (DCFH-DA) test, and cell death by flow cytometry. Fluorescence isothiocyanate (FITC) conjugated CCNP and CNP were used to study cellular uptake. Intracellular and extracellular bicarbonate concentration were measured by automated biochemical analyzer. Sodium citrate (Nacit) was used as a standard drug in these experiments.

Results: CNP and CCNP had very low cytotoxicity at the concentration up to 1 mg/ml. The results showed that CNP and CCNP did not alter the extracellular pH, or extracellular and intracellular bicarbonate concentration, and they were freely uptake into the cell in normal and acidic condition. Pharmacological tests revealed that both CNP and CCNP can suppress ROS production better than sodium citrate treatment. In addition, CNP and CCNP treatment ameliorated acidosis-induced cell death and apoptosis.

Conclusions: CNP and CCNP mitigates the consequences of metabolic acidosis, as they could reduce ROS production and cell death in acidic environment. Because they did not alter pH and bicarbonate concentration, they could be potentially used as the adjuvant therapy with alkalinizing agents to treat metabolic acidosis in CKD patients. A study of *in vivo* effects of these nanoparticles is ongoing.

Interdialytic Creatinine Rise as a Predictor of Hospital Length of Stay and Cause of Shortness of Breath in ESRD Patients

Hamel Patel,[2,1] Carmen Smotherman,[1,3] Ljubomir M. Ilic.[1,3] *[1]UF Health Jacksonville, Jacksonville, FL; [2]University of Florida College of Medicine Jacksonville, Jacksonville, FL; [3]University of Florida, Jacksonville, FL.*

Background: The Interdialytic Creatinine Rise (IDCR), calculated as the change in serum creatinine over time, in mg/dL/h, has been proposed as a novel marker of volume status and mortality in patients with end-stage-renal-disease (ESRD). We wanted to determine if IDCR was associated with the hospital length of stay (LOS), a metric reflecting the opposing factors of hospital efficiency and patient risks. We also studied a subgroup of patients in order to evaluate the relationship of IDCR to the cause of their shortness of breath (SOB).

Methods: This was a prospective cohort study of 142 ESRD patients on hemodialysis admitted to our institution who were followed from admission until discharge. IDCR was calculated as the difference in two serum creatinine values divided by the time between the samples. LOS and potential confounders of age, gender, race, cirrhosis, active cancer, left ventricular ejection fraction (LVEF) <40%, and insurance status were recorded. A sub-cohort of 53 patients admitted due to SOB as documented in emergency room records was divided into two groups according to the cause of SOB documented in the discharge summary, as SOB due to volume excess or not. The data was analyzed using univariate analyses, multiple regression, and multiple logistic regression.

Results: IDCR is negatively associated with LOS (Spearman correlation= –0.245; p=0.003). Adjusting for the significant covariates of age, gender, race, LVEF<40 and insurance, IDCR is negatively associated with LOS; so that for every 0.021 mg/dL/h increase in IDCR, LOS decreases by 1 day (95%CI -1.6,-0.4; p=0.002). In the subset of patients with SOB, 11 patients had SOB unrelated to volume excess and 42 patients had SOB due to volume excess, with significantly different respective IDCRs of 0.09 and 0.06 (Wilcoxon's Rank Sum Test; p=0.018). Adjusting for the significant covariate of age, when IDCR increases by 0.03 the odds ratio of SOB being unrelated to volume excess is 2.45 (95% CI 1.23, 5.80; p=0.02).

Conclusions: Our study showed that ESRD patients with lower IDCR values due to volume overload or decreased creatinine production have increased LOS, likely due to their higher risk. In ESRD patients admitted with SOB, higher IDCR values are more likely to exclude hypervolemia as the cause of SOB.

The Role of the JAK2/STAT3 Pathway Activated by IL-22 in Angiotensin II-Induced Hypertensive Renal-Damage Mice

Rong Tang. *Xiangya Hospital, Central South University, Changsha, China.*

Background: $CD4^+$ T cells and the secreted inflammatory cytokines contribute to the progress of hypertensive renal damage. Previously, we found that blood Th22 cells and its effect factor IL-22 increased significantly in hypertensive renal damage patients, and were positively correlated with renal pathological damage. It is reported that IL-22 binds to receptor IL-22R and activates JAK2/STAT3 pathway. Th22 cells and its secreted cytokine IL-22 may play a promoting role in hypertensive renal damage, however the effects and mechanisms remain unclear.

Methods: Angiotension II (Ang II) was infused subcutaneously at a rate of 1.5 mg/kg/d to C57BL/6 mice for 28 days. Hypertensive mice were treated with recombinant IL-22 (rIL-22), anti-IL-22 neutralizing antibody, IgG control and JAK2/STAT3 pathway blocker AG-490. Blood pressure (BP), serum creatinine (Scr), urinary albumin/creatinine ratio (UACR) and renal histopathology were measured; renal Th22 cells proportion were detected by flow cytometry; inflammatory factors were evaluated by ELISA, and JAK2/STAT3, fibrotic related factors were detected by western blot.

Results: 1. Expression of IL-22/IL-22R and infiltrated Th22 cells proportion in kidney were elevated in Ang II-induced hypertensive mice; 2. Treatment with rIL-22 resulted in further elevated BP, UACR, renal Th22 and IL-22, renal pathological damage and inflammatory responses, and increased renal fibrosis and JAK2/STAT3 pathway activation, compared to hypertensive mice treated by Ang II alone; 3. In contrast, treatment with the anti-IL-22 antibody decreased BP, UACR, renal Th22 and IL-22 and renal pathological damage, also attenuated renal inflammation, fibrosis and JAK2/STAT3 pathway activation.

Conclusions: 1. Recombinant IL-22 may activate JAK2/STAT3 pathway by binding to IL-22R in kidney, increase BP, aggravate immune inflammation and renal fibrosis in Ang II infused hypertensive mice; 2. Anti-IL-22 neutralizing antibody can reduce BP, inflammation and renal fibrosis in hypertensive kidney damage, which may be through inhibiting the activation of JAK2/STAT3 pathway.

Whole-Exome Sequencing and Monogenic Hypertension in a Multiethnic Cohort

Ishan Paranjpe,[1] Kipp W. Johnson,[1] Steven G. Coca,[1] Lili Chan,[1] John C. He,[2] Barbara T. Murphy,[1] Ron Do,[1] Girish N. Nadkarni.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai School of Medicine, New York, NY; [3]Ichan School of Medicine, New York, NY.*

Background: A subset of hypertension (HTN) may be caused by monogenic mutations. We identified the prevalence of these mutations in a multiethnic cohort and determined their association with blood pressure, appropriate diagnosis, and adverse cardiovascular outcomes.

Methods: In 27,972 individuals from the Bio*Me* Biobank (8304 European, 6993 African, 9985 Hispanic, and 2690 Other ancestry), we identified ClinVar mutations pathogenic for secondary hypertension using exome sequencing. We conducted association analyses with mean arterial pressure and coronary artery disease (CAD)/congestive heart failure (CHF) and assessed whether individuals with mutations had appropriate diagnosis/evaluation.

Results: 3125 individuals (11.2%) had pathogenic mutations with a majority in genes associated with catecholamine excess (*SDHD, SDHB, TMEM127, RET*; n=1976) and sodium handling/hyperaldosteronism (*SCNN1G/ CYP11B1*; n=384). (Fig 1A,B). Individuals with mutations had elevated mean arterial pressure (b=0.7±0.6 mmHg;

p=0.03) and increased odds of CAD (adjusted OR=1.12, 95% CI 1.0 to 1.3, p=0.04) adjusting for sex, age, BMI, and 10 genetic principal components (PCs). Individuals with mutations in sodium handling/hyperaldosteronism genes had increased CHF (adjusted OR = 1.44, 95% CI 1.04 to 1.9; p=0.02) adjusted for age, sex, 10 PCs, and blood pressure. The majority of individuals with mutations were diagnosed with essential HTN (54.2%) and only 7.8% had appropriate diagnoses of secondary HTN or received appropriate biochemical evaluation. (Figure 1C)

Conclusions: Individuals with pathogenic mutations had higher blood pressures and elevated risk for CAD/CHF. The majority were not appropriately evaluated/diagnosed. These results suggest exome sequencing may have utility in hypertension diagnosis and management.

Funding: NIDDK Support

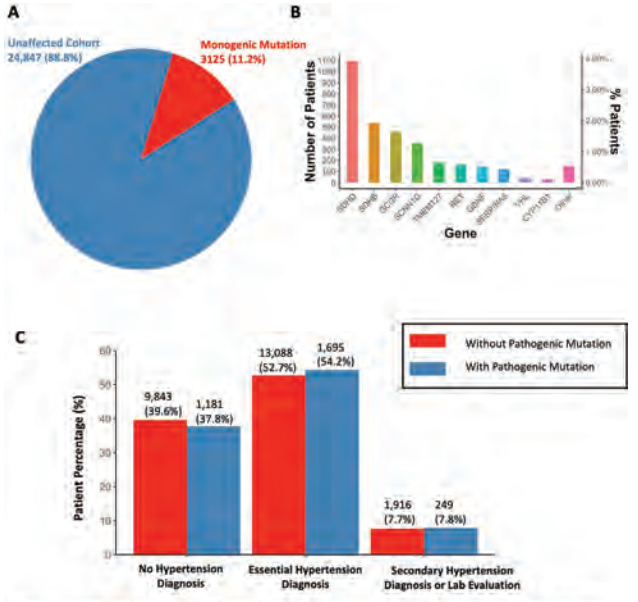

Figure 1 Prevalence of Pathogenic Mutations A. Proportion on individuals with mutation at least once loci cureated by ClinVar as pathogenic for secondary hypertension. **B.** Top 10 genes corresponding to mutations with greatest number of affected individuals. **C.** Percentage of individuals with no hypertension diagnosis, essential hypertension diagnosis, or secondary hypertension diagnosis/lab evaluation stratified by mutation status. Percentages indicate percent of individuals in each diagnosis group relative to the total number of people with or without pathogenic mutations.

SA-PO313

A Role for Toll-Like Receptors and Their Endogenous Ligands in CKD-Associated Cardiovascular Disease?

Anne-Catherine Raby. Wales Kidney Research Unit *Cardiff University, Cardiff, United Kingdom*.

Background: Cardiovascular disease (CVD) is greatly precipitated by chronic kidney disease (CKD). Overall, there is an approximately 20-fold increase in CVD mortality among CKD patients on dialysis compared with the general population. Traditional risk factors do not account for the high cardiovascular risk in CKD and standard clinical interventions are not always effective. CKD specific factors, such as anaemia, mineral metabolism disorders and the presence of uremic toxins are believed to be partially responsible. The inflammation associated with kidney tissue damage or the dialysis process has been suggested to play a substantial role in the onset and progression of CVD, however, it has yet to be demonstrated and the mechanisms elucidated. Kidney damage has been shown to lead to the local production of Damage Associated Molecular Patterns (DAMPs) that act as endogenous ligands of TLRs. We hypothesise that the TLR DAMPs being generated during CKD reach the circulation where they engage TLRs on the peripheral leukocytes and/or endothelial cells, inducing chronic vascular inflammation and dysfunction that promotes and/or accelerates CVD development.

Methods: Combination of ex vivo, in vitro and in vivo techniques

Results: A range of known TLR DAMPs were quantified in plasma from stage 5 CKD patients (n=40) at the start of PD and compared to the levels found in healthy individuals (n=30). Heat-shock protein (Hsp) 60, Hsp70, hyaluronic acid and calprotectin (S100A8/S100A9) were found significantly elevated in CKD patients. *In vitro* experiments were conducted to assess the ability of each of these TLR DAMPs to affect cellular responses related to initiation and progression of atherosclerosis. (expression of adhesion molecules by endothelial cells and monocytes, production of cytokines and chemokines, phagocytosis of oxidised LDL by macrophages). In preliminary *in vivo* experiments, chronic kidney injury was induced by repeated administration of the nephrotoxin aristolochic acid in mice prone to CVD development (LDL receptor deficient) to confirm the findings made *in vitro* and *ex vivo*.

Conclusions: Our preliminary results reveal significantly increased levels of several known TLR DAMPs in plasma from patients with late stage CKD. In ongoing work the role that these DAMPs and their interaction with TLRs may play in initiating or worsening atherosclerosis development is being investigated.

The Effect of the Sodium-Glucose Co-Transporter-2 Inhibitor in Angiogenesis of Diabetic Cardiovascular Disease

Jenq-shyong Chan,[1] Prabir Roy-Chaudhury,[2] Tao-cheng Wu.[3] *[1]Division of Nephrology, Department of Internal Medicine, Taoyuan Armed Forces General Hospital, Taiwan, Taoyuan, Taiwan; [2]University of North Carolina, Chapel Hill, NC; [3]Division of Cardiology, Department of Internal Medicine, Taipei Veterans General Hospital, Taipei, Taiwan*.

Background: Diabetic patients with peripheral arterial occlusive disease (PAOD) are at high risk from cardiovascular events, vascular death and ischemic ulceration. The most importantl induction of collateral vessels is essential to the initiation of angiogenesis. A sodium–glucose co-transporter-2 (SGLT-2) inhibitor (Dapagliflozin), is a novel class of antihyperglycaemic agent. In present study, we can evaluate the effects of SGLT2 inhibitors in diabetic mice with PAOD by cell and animal studies.

Methods: Chronic hind-limb ischaemia (15 mice) by ligating and transecting the left common femoral artery. **Laser Doppler measurement of tissue blood flow** to detect hind-limb blood flows **Human Endothelial progenitor cell culture** were cultured in 5% CO2 at 370C in cell growth medium. Cells from passages 4–8 were used for all experiments. **MTT assay** Cells were treated with variable concentration of dapagliflozin for 24 hours with hydrogen peroxide, washed with phosphate buffered solution, incubated in a conditioned medium for 1 hour with 2 μg/mL MTT, and then were lysed. Absorbance was measured at 570 nm using a spectrophotometric microplate reader (Multiskan EX, Labsystems; Helsinki, Finland). **EPC migration assay** was evaluated by a modified Boyden chamber assay. The magnitude of migration of late EPCs was evaluated by counting the migrated cells in six random high-power fields. **EPC tube formation assay** was performed with an In Vitro Angiogenesis Assay Kit(Chemicon). The average of the total area of complete tubes formed by cells was compared by using computer software, Image-Pro Plus.

Results: Dapagliflozin enhanced flow recovery in diabetic mice. Treatment of EPCs with dapagliflozin significantly increased tube formation and up-regulated impaired eNOS production and Akt action in hyperglycemic

Conclusions: SGLT-2 inhibitor improves blood flow recovery in diabetic mice with hind limb ischemia and promotes the functions of EPCs via NO-related pathways.

Myeloid PTEN Deficiency Exacerbates Renal Inflammation and Fibrosis in Angiotensin II-Induced Hypertension

Changlong An,[1] Jia Wen,[1] Baihai Jiao,[1] Zhaoyong Hu,[3] Yanlin Wang.[1,2] *[1]University of Connecticut Health Center, Farmington, CT; [2]Medicine, VA Connecticut Healthcare System, West Haven, CT; [3]Baylor College of Medicine, Houston, TX*.

Background: Hypertension is a major cause of chronic kidney disease, which is characterized by inflammation, tubular atrophy, and fibrosis. However, the molecular mechanisms that are responsible for the induction of inflammation and fibrosis are not fully understood. In the present study, we examined the role of phosphatase and tensin homolog (PTEN) in the pathogenesis of renal inflammation and fibrosis in an experimental model of hypertension.

Methods: We generated myeloid cell-specific PTEN knockout mice by crossing floxed PTEN mice with LysM-driven Cre mice. Both LysM-Cre-/-PTENf/f mice and LysM-Cre+/+PTENf/f mice were infused with angiotensin II at 1.5ug/kg/min or vehicle for 28 days. To accelerate renal injury, all mice were subjected to unilateral nephrectomy and received 1% sodium chloride in drinking water. Blood pressure was monitored by BP-2000 system. Renal function was evaluated by measuring serum creatinine. Proteinuria was quantified by measuring albumin and creatinine in the urine. Kidney sections were stained for histological and immunological analysis. Western blot analysis and

immunostaining were performed to detect the levels of fibronectin, collagen type I, and alpha-SMA in the kidneys. Sirius red staining was performed to examine total collagen deposition in the kidney.

Results: Both LysM-Cre-/-PTENf/f mice and LysM-Cre+/+PTENf/f mice had comparable blood pressure at baseline. Angiotensin II treatment led to an increase in blood pressure that is similar between LysM-Cre-/-PTENf/f mice and LysM-Cre+/+PTENf/f mice. Compared with LysM-Cre-/-PTENf/f mice, LysM-Cre+/+PTENf/f mice developed significantly worse renal dysfunction, proteinuria, and fibrosis following angiotensin II treatment. PTEN deficiency in myeloid cells enhanced myeloid fibroblast accumulation and myofibroblast formation associated with a significant increase in total collagen deposition and extracellular matrix protein production in the kidneys in response to angiotensin II. Immunohistochemical analysis revealed that PTEN deficiency in myeloid cells augmented infiltration of F4/80$^+$ macrophages and CD3$^+$ T cells into the kidneys of angiotensin II-treated mice.

Conclusions: PTEN plays a crucial role in the development of hypertensive kidney inflammation and fibrosis trough regulation of macrophage and T cell infiltration and myeloid fibroblast accumulation.

Grain vs. Casein-Based Diet Differentially Impact Angiotensin II Hypertension (AngII-HTN) Responses in Female vs. Male Sprague Dawley Rats

Brandon E. McFarlin,[1] Donna Ralph,[1] Luciana C. Veiras,[2] Alicia A. McDonough.[1]
[1]*Keck School of Medicine of USC, Los Angeles, CA;* [2]*Cedar Sinai Medical Center, W. Hollywood, CA.*

Background: We previously reported that the baseline renal transporter profile in females (F) is distinct from that in males (M), specifically: lower PT NHE3 activity, NaPi2, claudin 2 and AQP1, and higher DT NCC, SPAK, claudin 7 and cleaved γENaC abundance in F vs. M. We reported that F and M rats respond differentially to AngII-HTN (400 ng/kg/min for 14 days) when fed casein-based diet (Envigo TD 88239, 0.74% NaCl, 2% KCl). In F, abundance of cortical NHE3, NHE3p, NKCC2, and NKCC2p were increased, and NCC, NCCp, and cleaved γENaC were unchanged, while in M, abundance of cortical NHE3, NHE3p, NKCC2, NKCC2p were unchanged and NCC, NCCp and cleaved γENaC were increased (Fig A). Additionally, AngII-HTN increased proteinuria in M but not F despite similar HTN (~150 mmHg).

Methods: We aimed to determine if differential responses to AngII-HTN (as above) are also evident in SD rats fed grain based diet (LabDiet 5001), n=5 F and M.

Results: At baseline, in F fed casein (vs. grain) based diet, NHE3 and NHE3p are more abundant (1.27 ± 0.06 fold and 1.58 ± 0.15 fold) and NKCC2p and NCCp are less abundant (0.69 ± 0.04 and 0.7 ± 0.08), all p ≦ 0.01. M and F fed grain-based diet responded similarly to AngII-HTN (Fig B), with a pattern distinct from that in casein-fed rats: Cortical NHE3 decreased (M only), both M and F had significant decreases in abundance of medullary NHE3, NHE3p, NKCC2, NKA α1, and increases in cortical NKCC2, NKCC2p, NCC, NCCp and cleaved ENaC. Blood pressure and proteinuria were similarly increased in M and F on grain based diet.

Conclusions: In summary, diet impacts: 1) baseline Na transporter abundance, 2) Na transporters' regulation during AngII-HTN, and 3) AngII-HTN provoked proteinuria. Responses to AngII-HTN are similar in grain-based diet fed F and M.

High Sodium Intake Impairs Afferent Renal Sympatho-Depressory Pathways in Rats

Kristina Rodionova,[1,2] Franziska Fahrmeier,[1] Christian Ott,[1,2] Roland E. Schmieder,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken,[1,2] Tilmann Ditting.[1,2] [1]*Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany;* [2]*Paracelsus Private Medical School, Nuremberg, Germany.*

Background: Afferent renal nerve pathways are likely involved in the development of salt sensitive hypertension. We recently reported that intrarenal NaCl elicited a long-lasting sympatho-depression via a neuro-humoral TRPV1 dependent and tachykinin mediated renal afferent nerve pathway. We now wanted to test the hypothesis that high sodium intake impairs this afferent sympatho-depressory mechanism.

Methods: Respective groups were put on tap water, 0.9 % saline for drinking or chow containing 8% NaCl. Cultured dorsal root ganglion neurons (DRG Th11-L2) of rats with renal afferents were investigated in current clamp mode to assess action potential generation during current injection. Rats with femoral catheters for blood pressure (BP) & heart rate (HR) assessment, drug application, a renal arterial catheter for intrarenal administration (IRA) of NaCl boli (10 % NaCl, 10 µl) or Capsaicin (CAP 3.3, 6.6, 10, 33*10-7 M, 10 µl) and a bipolar electrode for renal sympathetic nerve activity (RSNA) recordings; eventually an intravenous (iv) bolus of the NK1-receptor blocker RP67580 (10*10-3M, 15 µl) was administered. Results are mean±SEM.

Results: In neurons from rats on 8% NaCl, but not on 0.9 % saline or controls the relation of tonic highly active neurons to less active neurons shifted towards less active units. (62% tonic neurons in the control group and 63% tonic neurons in the saline group vs. 40%* tonic neurons in the high salt group, * p<0.05, z-test, mean +/-SEM). However, cultured renal neurons from rats on 0,9% saline or on 8% NaCl exhibited increased action potential production upon stimulation (controls 13,3+/11,03 APs/600ms vs. 0.9% saline 19,8+/-2,33* APs/600ms vs. high salt diet 22,2+/-4,54 APs/600ms, * p<0.05, t-test, mean+/-SEM). 10% NaCl boli IRA induced decreases of RSNA from baseline 4.1±0.6 µV*sec to 2.2±0.8 µV*sec impaired in rats on 8% NaCl. (Suppressed RSNA by an i.v. NK1-inhibitor).

Conclusions: In rats on a high salt diet the number of highly active tonic neurons with renal afferents in vitro decreased at the expense of less active phasic neurons in spite of tonic neurons producing more action potentials upon stimulation in the group on 8% NaCl. The sodium inducible long-lasting sympatho-depression via a neuro-humoral tachykinin mediated afferent renal nerve pathway was eventually impaired.

SA-PO318

Late-Onset Presentation of Severe Hypokalemic Hypertension Resistant to Mineralocorticoid Antagonism

Ravi K. Thimmisetty,[1] Noreen F. Rossi.[2] [1]*Nephrology, Cape Girardeau, MO;* [2]*Wayne State University School of Medicine, Detroit, MI.*

Introduction: We are presenting rare case of secondary hypertension who presented with muscle cramps and severe hypokalemia treated with ENaC (epithelium sodium channel) blocker

Case Description: A 45-year-old Caucasian lady was referred to clinic for management of refractory hypokalemia, uncontrolled blood pressure and metabolic alkalosis. She was complaining of intermittent muscle cramps. She was a healthy patient until 2017, when she was diagnosed with hypertension. Home medications were spironolactone 50 mg once daily, potassium chloride 20 mEq four times daily, clonidine 0.2 mg three times daily, lisinopril 20 mg once daily, amlodipine 10 mg, hydralazine 100 mg three times daily. There had been several emergency room visits for muscle cramps and uncontrolled blood pressure. Family history revealed mother died of heart attack at the age of 54 years. Father had problems of low potassium and a heart attack at a young age. Vitals revealed temperature of 98F, blood pressure 143/100 mmHg, heart rate 87 bpm, respiratory rate 16 per minute breathing on room air. Examination showed no edema and no abdominal bruits. Review of labs over the previous 2 months showed Na141-143, K 2.8-3.6, bicarbonate 23-27 mEq/L, BUN 6 mg/dL, creatinine 0.56 mg/dL, aldosterone 4.6 ng/dL and 5.4 ng/dL, plasma renin activity <0.6 ng/mL/h (checked twice), random cortisol was 0.6 – 4.6 ug/dL, urine potassium 13.5mEq/L. Renal ultrasound along with renal artery doppler, Echocardiogram, CT scan of head, MRI and MRA of the head and neck revealed with in normal findings. Stopped spironolactone and started amiloride 5 mg daily. Over the next few days, blood pressure dropped to ~100-120's/60-80's. Lisinopril, hydralazine, spironolactone and potassium supplements were stopped and clonidine was weaned off. Follow up labs in one week after starting amiloride showed potassium 4.2. Subsequently patient was advised to check blood pressure twice per day and closely followed

Discussion: Epithelial sodium channel blockade improved blood pressure and electrolyte abnormalities significantly suggesting either Liddle syndrome (autosomal dominant) or apparent mineralocorticoid excess (autosomal recessive) which typically present in childhood. Our case illustrates a rare cause of hypertension having at this age which is associated with hypokalemia and metabolic alkalosis that is not amenable to mineralocorticoid blockade

SA-PO319

Dietary Salt Modifies the Blood Pressure Response to Renin-Angiotensin Inhibition in Experimental CKD

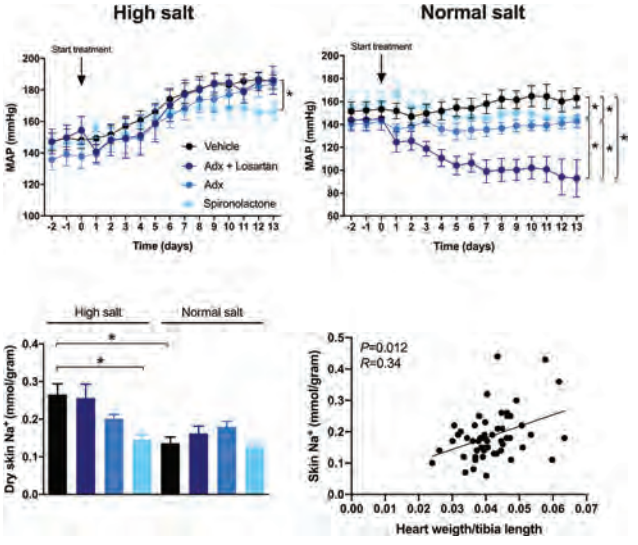
Dominique M. Bovee, Catherina A. Cuevas, Alexander H. Danser, Robert Zietse, Ewout J. Hoorn. *Erasmus Medical Center, Rotterdam, Netherlands.*

Background: Salt-sensitive hypertension is a hallmark of chronic kidney disease (CKD). The role of dietary salt and the renin-angiotensin system (RAS) in the pathogenesis of salt-sensitive hypertension in CKD is incompletely understood. Our aim was to dissect the role of dietary salt and the RAS in a rat model of hypertension and CKD.

Methods: Sprague Dawley rats were subjected to 5/6th nephrectomy, allowed to recover for four weeks, and subsequently subjected to one of four treatments: (1) vehicle, (2) adrenalectomy (Adx), (3) Adx + losartan (30 mg/kg/d), or (4) spironolactone (80 mg/kg/d). These interventions were performed either under normal dietary salt (0.4% NaCl) or high salt (4% NaCl) conditions. Mean arterial pressure (MAP) was measured by radiotelemetry, GFR by transcutaneous FITC-sinistrin clearance, and skin sodium (Na^+) by flame photometry after dissolving skins in nitric acid and hydrogen peroxide.

Results: 5/6th nephrectomy reduced GFR from 1.3 ± 0.4 to 0.4 ± 0.1 ml/min/100g. On a high salt diet, BP was resistant to RAS intervention, except for an attenuated BP rise in rats receiving spironolactone (Figure). On a normal salt diet, BP kept increasing with vehicle, but stabilized with Adx and spironolactone. Adx + losartan reduced BP remarkably. On a high salt diet, spironolactone prevented Na^+ accumulation in skin. For all groups, skin Na^+ correlated positively with heart weight.

Conclusions: High salt increases BP in CKD in part via direct effects on the mineralocorticoid receptor. Under normal salt conditions, however, hypertension in CKD depends on the combined effects of angiotensin II and aldosterone. Dietary salt modifies the BP response to RAS interventions in CKD, and accumulates in the skin. Our observations may have both therapeutic and prognostic implications for human CKD.



SA-PO320

The Effects of Sacubitril and/or Valsartan on Renal Disease Progression in Salt-Sensitive Hypertension

Mark Domondon, Iuliia Polina, Mikhail Fomin, Anastasia Sudarikova, Daria Ilatovskaya. *Medical University of South Carolina, Charleston, SC.*

Background: Available medications, such as diuretics and renin-angiotensin system (RAS) blockers, are often insufficient to control the blood pressure (BP) in the salt-sensitive (SS) hypertensive subjects. Abundant data support a pathogenic role for a low level of Atrial Natriuretic Peptide (ANP) in SS hypertension; ANP is known to promote salt excretion, vasodilation, and BP reduction. The goal of this project was to test if increasing the circulating ANP level using sacubitril in combination with a RAS blocker valsartan is beneficial for the alleviation of renal damage.

Methods: We performed chronic administration of sacubitril and/or valsartan at 75 ug/day to Dahl SS rats via an osmotic pump. All rats were fed a 0.4% NaCl (normal salt, NS) diet until 8 weeks of age, when they were challenged with a high salt (HS) 4% NaCl diet for 21 days. Vehicle, sacubitril (sacb), valsartan (val), or a 1:1 mix of both drugs (sacb/val) were administered together with HS diet; metabolic cage studies and GFR measurements were performed before the diet switch and at the end of the protocol.

Results: Upon a HS challenge, we observed renal hypertrophy reduction in the val group (p=0.047), and trend in the sac/val group (body weight was not affected). Urine flow was increased on HS diet compared to NS (p<0.01 for all groups), but not different between groups at the end of the protocol; we also observed a trend for lower water consumption in the sacb group. Upon a HS challenge, GFR was decreased in the control and elevated in the sacb/val and sacb groups; this increase was attenuated in the val treated animals. Interestingly, proteinuria was less pronounced in the sacb/val and val groups after 21 days on HS diet (vs control). In addition, we showed an increase in urinary KIM-1 in the control group, which was attenuated in the sacb/val and val animals.

Conclusions: Further mechanistic studies of the effects of sacubitril in the setting of SS hypertension are warranted in order to determine if pharmacological increase of circulating ANP level is a feasible therapeutic approach to interfere with the progression of the disease.

Adrenal Hyperplasia, Hormonal Disturbance, and Salt-Sensitive Hypertension in a Novel Rat Model with Glucocorticoid Resistance Syndrome

Paul emmanuel Vanderriele,[1] Qing Wang,[2] David Ancin,[3] Frederique Ino,[1] Denise V. Kratschmar,[4] Alex Odermatt,[4] Stephan Kellenberger,[1] Edith Hummler,[1] Sofia N. Verouti.[1] Professor Edith Hummler *[1]University of Lausanne, Lausanne, Switzerland; [2]CHUV, Lausanne, Switzerland; [3]UNIL, Lausanne, Switzerland; [4]University of Basel, Basel, Switzerland.*

Background: Glucocorticoid resistance is often due to glucocorticoid receptor (GR) haploinsufficiency, and is characterized by partial target tissue resistance to glucocorticoids. In human, an elevation in circulating glucocorticoids may cause the development of hypertension and, in some cases, obesity and sterility.

Methods: So far, no animal model mimics all features observed in human generalized glucocorticoid resistance. To address the impact of GR haploinsufficiency on adrenal gland function, steroid expression and development of hypertension, we generated rats carrying a deletion within the second zinc finger of the GR, named $GR^{+/em2}$ (Ponce de León. V *et al*; Plos One, 2014).

Results: Heterozygous mutant $GR^{+/em2}$ rats showed a monolateral adrenal hyperplasia with hyperkalemia, an increase of plasmatic aldosterone (0,47 ± 0,018 nM vs 0,39 ± 0,019nM pm, p<0,01), plasmatic corticosterone (576 ± 88,96 nM vs 332 ± 75,45 nM am, p<0,05; 1000 ± 61,41 nM vs 615 ± 99,11 nM pm, p<0,05), plasmatic 11-deoxycorticosterone (76,6 ± 5,24 nM vs 50,3 ± 5,97 nM am, p<0,001; 101,8 ± 4,02 nM vs 74,6 ± 5,63 nM pm, p<0,01) despite a normal activity of the 11-β-hydroxysteroid-dehydrogenase II ($GR^{+/+}$= 15, $GR^{+/em2}$= 8). Furthermore, $GR^{+/em2}$ mutant rats develop salt-sensitive hypertension followed by an increase of adrenal and kidney weight. In addition, RNA-seq analysis reveals disturbances in **41 genes** (21 up, 20 down regulated) implicated in e.g, adrenal gland architecture and steroid biosynthesis. We currently focus on these identified candidate genes implicated in adrenal gland function and we perform electrophysiological measurements on primary adrenal cells upon stimulation with angiotensin II and potassium chloride to determine the cell depolarization capacity in these cells.

Conclusions: In summary, we demonstrated that $GR^{+/em2}$ mutant rats **are useful to study GR haploinsufficiency** and the underlying mechanism leading to adrenal gland hyperplasia. We confirm the role of the GR in the development of **salt-sensitive hypertension**. We are currently studying identified new candidate genes leading to salt-sensitive hypertension in this rat model.

Finerenone Improves Cardiovascular Benefits After Diet Normalization in a Mouse Model of High-Fat Diet-Induced Obesity

Frederic Jaisser,[1] Marie Pieronne-Deperrois,[2] Benjamin Bonnard,[1] Lionel Nicol,[2] Anaëlle Marouchtchak,[2] Peter Kolkhof,[3] Paul Mulder,[2] Antoine Ouvrard-Pascaud.[2] *[1]INSERM U1138, Paris, France; [2]INSERM U1096, UFR Santé, University of Normandy, Rouen, France; [3]Bayer AG, Wuppertal, Germany.*

Background: Patients with obesity exhibit high prevalence of Heart Failure with preserved Ejection Fraction (HFpEF). We hypothesized that the non-steroidal mineralocorticoid receptor (MR) antagonist Finerenone further improves cardiac function after normalisation of the diet in obese mice.

Methods: B6D2 male mice were fed a High Fat Diet (HFD) (60%) or maintained on normal diet (CTL). After 16 weeks, obese mice were divided in 3 groups for 8 more weeks with either: *i)* HFD; *ii)* normal diet (HFD-STOP); *iii)* normal diet plus Finerenone 1 $mg.kg^{-1}.day^{-1}$ in the food (HFD-STOP+FINE).

Results: After 16 weeks of HFD, mice showed an increased cardiac filling pressure (LV-End-Diastolic-Pressure, LVEDP: CTL 2.73±0.1, HFD 4.73±0.34 mmHg; P<0.001) and impaired LV compliance (LV-End-Diastolic-Pressure-Volume-Relation, LVEDPVR: CTL 1.19±0.26, HFD 4.77±0.31 mmHg/RVU; P<0.001) (without alteration of the LV Fractional Shortening) and reduced exercise ability in a stress-test on treadmill. These features are typical of HFpEF. Decreased LV Fractional Shortening developed if HFD is continued for 8 weeks more. Switching HFD to normal diet from weeks 16 to 24 improved LV compliance which was further improved by FINE (LVEDPVR: HFD-STOP 3.44±0.39, HFD-STOP+FINE 2.28±0.23 mmHg/RVU; P<0.05) as well as the reduction in LV fibrosis (% fibrosis: CTL 0.21±0.02, HFD 0.47±0.12, HFD-STOP 0.28±0.03, HFD-STOP+FINE 0.23±0.02 mmHg; P<0.05). Only the FINE treatment on top of diet normalisation improved LV filling pressure (LVEDP: CTL 2.73±0.16, HFD 4.73±0.34, HFD-STOP 4.53±0.33, HFD-STOP+FINE 3.18±0.26 mmHg; P<0.05), Fractional Shortening, Cardiac Output, Coronary Reserve (CR: CTL 3.76±0.72, HFD 1.00±0.33, HFD-STOP 1.19±0.25, HFD-STOP+FINE 2.78±0.67 $ml.mg^{-1}.min^{-1}$; P<0.05) and total runing distance. Renal function is not altered by HFD. Expression of some renal injury markers are increased by HFD and improved by HFD STOP without further additional effects of FINE.

Conclusions: When administered on top of diet normalisation after HFD-induced obesity, Finerenone improved LV compliance, LV filling pressure, Coronary Reserve and

exercise performance thereby indicating benefit of Finerenone in HFpEF associated to HFD in mice.

Windkessel Modeling-Based Estimation of Intraglomerular Pressure Using Invasively Measured Renal Arterial Pressure and Flow Velocity in Humans

Didier Collard, Peter M. van Brussel, Lennart Van de velde, Liffert Vogt, Bert-jan Van den born. *University Medical Centers Amsterdam, Amsterdam, Netherlands.*

Background: Glomerular hyperfiltration due to a combination of failed autoregulation and progressive glomerulosclerosis is important in the pathogenesis of chronic kidney disease (CKD). Although prevention is widely recommend in current guidelines, up to now it is only possible to measure intraglomerular pressure (Pglom) directly in animal models. We hypothesized that renal arterial compliance and Pglom can be estimated from proximal renal arterial measurements.

Methods: Pressure and flow velocity were recorded in patients with a clinical indication for either coronary or renal angiography. The data was acquired under baseline conditions and after hyperemia induced by dopamine 30 µg/kg intrarenal. This was further analyzed using an adapted 3-element Windkessel model, consisting of compliance, impedance, afferent resistance and Pglom.

Results: We included 33 subjects with a median age of 58 years (IQR 52-65), eGFR of 85.9 ml/min/1.73m^2, 31% had microalbuminuria. In 4 patients, a renal artery stenosis was found. The model showed a mean Pglom of 47.7 mmHg at baseline. After induction of hyperemia, flow increased by 90 (95%CI 66-133)%. This resulted in a 172 (95%CI 81-309)% increase in compliance and a decrease of Pglom of 12.6 (95%CI 9.5-15.7) mmHg. Patients with diabetes had a significantly higher Pglom of 10.8 (95%CI 5.3-15.5) mmHg, after correction for a significant positive association with BMI (0.81, 95%CI 0.37-1.59) and renal perfusion pressure (0.40, 95%CI 0.22-0.59).

Conclusions: The model enables determination of parameters for the renal macro- and microcirculation using proximal pressure and flow measurements, which could be useful to identify patients at risk for CKD.

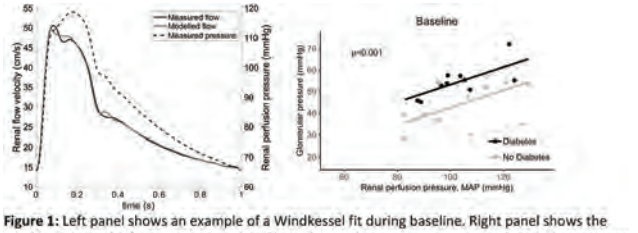

Figure 1: Left panel shows an example of a Windkessel fit during baseline. Right panel shows the results of the multiple regression model of intraglomerular pressure versus renal perfusion pressure under baseline, P value shows comparison of diabetes vs no diabetes.

Indole-3-Methanol, a Dietary Constituent, Suppresses Uremic Toxicity of Indoxyl Sulfate

Sean Richards,[1] Joshua A. Walker,[3] Nkiruka Arinze,[4] Stephen A. Whelan,[3] Norman Lee,[3] Lauren E. Brown,[3] Vipul C. Chitalia.[2] *[1]Boston University Medical Center, Boston, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University, Boston, MA; [4]Boston Medical Center, Boston, MA.*

Background: Indoxyl sulfate (IS), a bonafide uremic toxin, mediates its vasculotoxicity in chronic kidney disease (CKD) patients through activation of the Aryl hydrocarbon receptor (AHR)-tissue factor (TF) pathway in vessel walls. The management of patients with CKD focuses primarily on therapies to control the comorbidities associated with and contributing to CKD progression and recommends alterations in macronutrients. In essence, the current management of CKD patients completely lacks the strategies to directly target indolic toxins to prevent/retard the cardiovascular complications. The structural features of IS that impart toxicity and their therapeutic implications remain unknown.

Methods: A structure-activity analysis was conducted using an analog-by-catalogue approach, with the AHR-TF-thrombosis axis as a readout. A set of indolic compounds, including IS bioisosteres were analyzed in a three-tiered system along with validation in two human cohorts. This study employed three distinct animal models and two human cohorts to establish the role of the lead analog.

Results: Replacement of the sulfate moiety abrogated IS-mediated AHR-TF activation. Notably, of all the analogs, Indole-3-methanol (a.k.a. indole-3-carbinol or "I3M") showed a dose-dependent inhibition of the AHR-TF axis and suppressed IS-induced AHR activation and carotid artery thrombosis in discrete animal models. Mechanistically, I3M reduced TF protein without downregulating its mRNA. I3M suppressed TF in cells specifically in sera from CKD patients compared to the non-CKD controls, and the extent of TF suppression correlated with their levels of IS. I3Minhibited TF in vascular smooth muscle cells in response to pre-intervention sera from subjects who had developed post-angioplasty thrombosis from a sub cohort of a Thrombolysis in Myocardial Infarction-II trial.

Conclusions: This study demonstrates the importance of the IS sulfate group, and reveals I3M, as a suppressor of prothrombotic properties of IS. I3M is a naturally occurring phytochemical found in cruciferous vegetables that a rich source of indole-based glucobrassicin. These results can guide future campaigns to develop targeted therapies such as compounds against IS and plant-based diets that can be personalized to the blood IS levels in CKD patients.

Precision Medicine: Lanosterol Synthase Gene Polymorphisms Affect Body Na^+ in Salt-Sensitive Hypertension

Ermira Cuka,[1] Chiara Lanzani,[1] Marco Simonini,[1] Laura Zagato,[1] Lorena Citterio,[1] Elena Brioni,[1] John Hamlyn,[2] Simona Delli carpini,[1] Paolo Manunta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]University of Maryland, Baltimore, Baltimore, MD.*

Background: For decades, it has been widely accepted that initiation of salt-induced hypertension involves a type of kidney dysfunction (natriuretic handicap) which causes salt-sensitive subjects to excrete less of a sodium load than normal subjects and to undergo abnormal increases in cardiac output, and therefore in blood pressure (BP). Our research group has reported that a Lanosterol Synthase (LSS) gene variant influences both the salt sensitivity of BP and changes in circulating Endogenous Ouabain (EO) in response to a low salt diet. Aim of the study is to explore the role of LSS genotypic variants comparing salt-sensitive (SSH) with salt-resistant (SRH) hypertensive patients for their impact on body Na+.

Methods: A large cohort (n=807) of naïve hypertensive patients (NHP) was phenotyped for salt sensitivity by giving NaCl 308 mEq/2h/iv. Total body Na^+ at the end of infusion (T120) and after recovery (T240) was assessed by calculating the differences between Na^+ infused and urinary excretion.

Results: 516 SRH display a decrease in systolic BP (-0.6±0.32 mmHg), while in 291 SSH, SBP increases of 11.8±0.42 mmHg. Meanwhile, there was no difference in total body Na^+ in both groups, 254.75±1.41 mEq in SRH patient and 254.02±2.03 mEq in SSH group. Moreover, LSS rs225424 AA+AC carriers retained more body Na^+ both at T120 and T240 (256.81±1.52 and 255.9±1.6 mEq) than LSS CC wild-type subjects (252.66±1.72 and 251.4±1.6 mEq; p<0.01).

Conclusions: LSS gene contributes to maintaining a positive Na^+ balance in SSH. In the precision medicine era, LSS gene may be considered as a "natriuretic handicap" gene.

Different Forms of Afferent Nerve Input in Cardiac and Renal Disease in Rats?

Kristina Rodionova,[1,2] Tilmann Ditting,[1,2] Lisa Pickny,[1] Christian Ott,[1,2] Roland E. Schmieder,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2] *[1]Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany; [2]Paracelsus Private Medical School, Nuremberg, Germany.*

Background: Afferent nerve pathways form kidney and heart likely control sympathetic renal nerve activity. In renal disease (anti Thy1 nephtitis) the responsiveness of afferent renal nerve units was shifted from units with highly active primary neurons (tonic response pattern) to units with neurons of very low activity upon stimulation (phasic response pattern). Afferent renal nerve activity was likely decreased. Likewise, afferent vagal nerve activity in congestive heart failure (CHF) had a lower frequency at saturation than controls. Hence we wanted to test the hypothesis that in CHF the vagal afferent nerve pathway consists of a decreased number of highly active tonic sensory neurons in the nodose ganglion.

Methods: CHF was induced by coronary artery ligature, nephropathy by injections of an anti Thy1.1 antibody (OX7, 1.2mg/kg). After a respective time (CHF 21 days, nephropathy 7 days after induction) nodose ganglion neurons with cardiac vagal afferents from CHF rats or neurons form dorsal root ganglia with renal afferents from rats with nephropathy were cultured. Current clamp was used to characterize neurons as "tonic",

i.e. sustained action potential (AP) firing or "phasic", i.e. <5 APs upon current injection. Electrophysiological parameters and AP properties were determined in neurons from animals with CHF or nephropathy.

Results: In CHF rats, the number of neurons with a tonic, more active response pattern from CHF animals did not differ from controls (64% vs. 70 %, ns). However, tonic cardiac neurons from CHF rats exhibited an increased production of action potentials compared to controls (24.4+/-5.0 vs. 14.7+/-1.8 APs/10s; $p<0.05$; mean+/-SEM). In nephropathic rats, the number of neurons with a tonic response pattern decreased significantly (43% vs. 64 %, $p<0.05$), but there was no difference in action potential production as compared to controls.

Conclusions: In contrast to our hypothesis, in CHF the number of afferent neurons with a tonic response pattern was not altered, instead the action potential production of these neurons increased increased upon stimulation. Hence, in congestive heart failure vagal afferent neurons increase their sensitivity in the presence of impaired intracardiac receptors whereas in renal disease the responsiveness of the first part of the afferent pathway is impaired as a whole

SA-PO327

Afferent Peptidergic Nerve Fibers: Importance for the Salt Metabolism Beyond the Kidneys?

Tilmann Ditting,[1,2] Kristina Rodionova,[1,2] Christian Ott,[1] Roland E. Schmieder,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2] *[1]Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany; [2]Paracelsus Private Medical School, Nuremberg, Germany*.

Background: Sodium can be accumulated without commensurate water retention in the skin (non-osmotic sodium storage). Macrophages play a pivotal role in this context and their depletion can induce salt-sensitive hypertension. On the other hand renal afferent peptidergic nerves are involved. Since the skin is also densely innervated by afferent peptidergic nerves we hypothesized that high salt diet might enhance the release of neuropeptides from these nerve fibers

Methods: In a cross-over design, two groups of rats (n=4, each) were fed either low salt diet (LS; 0.2%) with free access to tab water for 14 days or high salt diet (HS; 8%) with free access to 0.9% saline as drinking water. After 14 days a skin sample (3x3mm) of the groin area was excised, and the diet was switched for another 14 days. Then a contralateral skin sample was taken. Tissue analyzed in an organ-bath and calcitonin gene related peptide (CGRP) content in the supernatant was measured with ELISA. After two baseline measurements within 5 min, the tissue was superfused with hypertonic saline (4.5%) for 5 min, and three further samples of the supernatant were taken every 5 min.

Results: Baseline CGRP release was similar with both diets (LS 11.9±1.5 vs HS 13.6±1.5ng/g skin). Maximum release was higher with HS diet (LS 17.5±1.8 5ng/g skin vs HS 29.8±1.3ng/g skin; *$p<0.05$). After diet switch the results were similar: baseline LS 9.4±1.2 ng/g skin vs HS 10.1± 1.1 ng/g skin, with HS diet the release was higher again (LS 19.7±2.1 vs HS 29.3±1.7*; *$p<0.05$).

Conclusions: High sodium diet sensitized neuropeptide release from peptidergic sensory nerves in the skin. Hence peptidergic afferent nerves might be an integrated body-wide system involved in sodium handling in very different target areas like skin and kidney. Putative peptidergic mechanisms (vasoregulation, chemotaxis) remain to be determined in this respect.

SA-PO328

Urinary Plasmin Plays Pathogenic Roles for the Development of Hypertension in Dahl Salt-Sensitive Rats

Yasunobu Iwata,[1] Yutaka Kakizoe,[1] Qinyuan Deng,[1] Terumasa Nakagawa,[1] Masataka Adachi,[1] Yuichiro Izumi,[1] Takashige Kuwabara,[1] Kenichiro Kitamura,[2] Masashi Mukoyama.[1] *[1]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Internal Medicine III, University of Yamanashi Faculty of Medicine, Yamanashi, Japan*.

Background: The epithelial sodium channel (ENaC) in the renal collecting duct plays pivotal roles in the regulation of sodium homeostasis and blood pressure. The proteolytic cleavage of γENaC by extracellular serine proteases is an important process for the full activation of this channel and is physiologically regulated by aldosterone. In the setting of proteinuria, proteases filtered through damaged glomeruli could activate ENaC leading to hypertension, independently of aldosterone. We reported that Dahl salt-sensitive (DS) rats with high-salt (HS) diet developed severe hypertension together with aberrant activation of γENaC by serine proteases. However, the role of plasmin in the hypertension of DS rats remain to be elucidated. In this study, we evaluated the relationship of proteinuria, urinary plasmin activity and hypertension, and the antihypertensive effect of a serine protease inhibitor camostat mesilate (CM) in DS rats.

Methods: Four-week-old DS rats were divided into normal-salt (NS) diet, HS and HS+CM (0.1% diet) groups. After systolic BP measurement and 24h urine collection were performed for 5 weeks, rats were sacrificed for biochemical examination. Urinary plasmin activities were evaluated by zymography and Western blotting.

Results: HS diet induced severe hypertension [SBP (mmHg): NS, 141.1±5.8; HS, 222.3±15.4; HS+CM, 199.5±5.0], marked proteinuria [U-TP (mg/day): NS, 23.8±12.1; HS 272.3±79.9; HS±CM, 135.1±27.4] and urinary plasmin activation, as well as the cleavage of urinary exosomal γENaC. The treatment with CM suppressed these changes, together with significantly reduced BP and proteinuria.

Conclusions: In conclusion, plasmin is associated with the pathogenesis of hypertension in DS rats, and serine protease inhibition could be a potential therapeutic strategy against salt-sensitive hypertension with proteinuria.

SA-PO329

Functional Impact of Proximal Tubule ATRAP in Blood Pressure Regulation

Kouichi Tamura,[1] Sho Kinguchi,[1] Kengo Azushima,[2] Kotaro Haruhara,[3] Takahiro Yamaji,[1] Takayuki Yamada,[1] Ryu Kobayashi,[1] Tetsuya Fujikawa,[4] Kohji Ohki,[1] Hiromichi Wakui.[1] *[1]Yokohama City University Graduate School of Medicine, Yokohama, Japan; [2]Duke-NUS Medical School, Singapore, Singapore; [3]The Jikei University School of Medcine, South Yarra, VIC, Australia; [4]Yokohama National University, Yokohama, Japan*.

Background: The angiotensin II (Ang II) receptor (AT1R)-associated protein (ATRAP) inhibits pathological activation of AT1R signaling in response to certain stimuli. We showed that systemic ATRAP knockout mice exhibits the exacerbation of Ang II-mediated hypertension via hyperactivation of distal tubule AT1R-ENaC pathway (Ohsawa Kid Int 2014; Kobayashi Kid Int 2017). Although ATRAP is also expressed abundantly in renal proximal tubules, little is known about a functional impact of proximal tubule ATRAP in blood pressure (BP) regulation in response to pathological stimuli.

Methods: We created proximal tubule-specific ATRAP knockout (PT-KO) mice using the Cre/loxP system with Pepck-Cre, and examined a functional role of proximal tubule ATRAP in angiotensin-mediated hypertension. For chronic Ang II stimulation experiments, Ang II (600 or 1000 ng/kg per minute) was infused subcutaneously in male WT and PT-KO mice (9–12 weeks old) for 14 days using an osmotic minipump (model 2002; ALZET).

Results: The ATRAP mRNA expression was decreased by ≈80% in renal proximal tubules of PT-KO mice compared with wild-type (WT) mice. The BP of PT-KO mice was comparable with that of WT mice at baseline. Moreover, in telemetry analysis, the 24-hour mean systolic BP was significantly and similarly increased in response to 2 weeks of Ang II infusion (1000 ng/kg per minute) in both PT-KO and WT mice (Ang II–infused PT-KO versus Ang II–infused WT mice, 2-way repeated measures ANOVA, F=0.04280, P=0.8407). Ang II infusion (1000 ng/kg per minute) for 2 weeks also significantly increased 24-hour mean systolic BP, not only in the light period but also in the dark period and to the same extent in both types of mice. The degrees of cardiac hypertrophy and albuminuria under Ang II -mediated hypertension were also similar in PT-KO and WT mice. In addition, the results of metabolic cage analysis showed that cumulative sodium balance during 2 weeks of Ang II infusion was comparable for PT-KO and WT mice.

Conclusions: Proximal tubule-specific down-regulation of ATRAP did not affect the Ang II-mediated hypertension *in vivo*. Since ATRAP is broadly expressed along renal tubules from proximal to distal tubules, proximal tubule ATRAP would be suggested to have a distinct function other than BP modulation in response to pathological stimuli.

SA-PO330

The Distal Convoluted Tubule Serves as a Potassium Switch in an Intracellular Chloride-Dependent Mechanism

Xiao-Tong Su,[1] Nathan Klett,[2,3] Charles N. Allen,[3,4] Chao-Ling Yang,[1] WenHui Wang,[5] David H. Ellison.[1,6] *[1]Division of Nephrology and Hypertension, Oregon Health and Science University, Portland, OR; [2]Centre for research in Neuroscience, McGill University, Montreal, QC, Canada; [3]Oregon Institute of Occupational Health Sciences, Oregon Health and Science University, Portland, OR; [4]Department of Behavioral Neuroscience, Oregon Health and Science University, Portland, OR; [5]Pharmacology, New York Medical College, Portland, OR; [6]Renal Section, Veterans Administration Portland Health Care System, Portland, OR.*

Background: The kidney plays a key role in the regulation of K^+ excretion and K^+ homeostasis. Previous studies have demonstrated that the thiazide-sensitive Na-Cl cotransporter (NCC) in the distal convoluted tubule (DCT) plays an important role in the regulation of renal K^+ excretion by controlling sodium and volume delivery to the distal nephron. It has been shown that NCC is inhibited when K^+ intake is high and activated when dietary K^+ intake is low. It is now generally accepted that WNKs (with-no-lysine kinases) plays a major role in NCC phosphorylation and activation. A large body of evidence has demonstrated that WNK1 and WNK4 are chloride-sensitive kinases, which are inhibited by high intracellular chloride concentration ($[Cl^-]_i$) and activated by low $[Cl^-]_i$. It has also been suggested that membrane voltage changes by extracellular K^+ concentrations are responsible for altering the $[Cl^-]_i$ thereby affecting WNK activity. The aim of our study is to test the hypothesis that changes in the basolateral cell voltage alter the $[Cl^-]_i$ in the DCT.

Methods: To determine the $[Cl^-]_i$ in the DCT, we have used isolated single DCT tubule of transgenic mice expressing *Cl-sensor*, a chloride-sensitive fluorescent protein modified from Chlomeleon. The *Cl-sensor* contains both a chloride-sensitive YFP moiety as well as a chloride-insensitive CFP moiety, allowing ratiometric estimation of $[Cl^-]_i$.

Results: We first measured the $[Cl^-]_i$ in the isolated DCT by establishing the calibration curve. Using this calibration curve, we estimated that basal DCT $[Cl^-]_i$ is 6.8 ± 2.3 mM (n=18). Changing the extracellular potassium concentration from 10 mM to 2 mM decreases the $[Cl^-]_i$. To test the role of the basolateral Kir4.1/Kir5.1 of the DCT in altering $[Cl^-]_i$, we examined whether inhibition of the basolateral K^+ channels with Ba^{2+} would increase the $[Cl^-]_i$ since Ba^{2+} has been shown to depolarize DCT membrane. Indeed, Inhibition of Kir4.1/Kir5.1 significantly increased the $[Cl^-]_i$ in the DCT bathed in a solution containing 2 mM K^+.

Conclusions: Our results indicate that the intracellular Cl^- concentrations of DCT cells are low at baseline and that the depolarization increases whereas hyperpolarization decreases the intracellular Cl^- concentrations. Thus, changes in DCT voltage are associated with alteration of intracellular Cl^- concentrations.

Assessment of Sublingual Microcirculation with the GlycoCheck System: Reproducibility and Examination Conditions

Marie Frimodt-Moller,[1] Mie K. Eickhoff,[1] Signe Abitz Winther,[1] Lars J. Díaz,[1] Frederik Persson,[1] Tine Hansen,[1] Peter Rossing.[1,2] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: The glycocalyx is an extracellular layer lining the lumen of the vascular endothelium including the glomerular capillaries. It protects the endothelium from shear stress and atherosclerosis and contributes to coagulation, immune response and micro-vascular perfusion. Degradation of the glycocalyx is a part of several renal disease processes and ultimately results in proteinuria. The GlycoCheck system is a new method to estimate the glycocalyx' thickness in vivo from perfused boundary region (PBR) and microvascular perfusion (red blood cell (RBC)-filling) via a video camera coupled to a computer with integrated software. We evaluate reproducibility and influence of examination conditions on measurements with the GlycoCheck system.

Methods: Open-labelled randomised, controlled study including 42 healthy smokers investigating day-to-day, side-of-tongue and inter-investigator variance and influence of smoking, high calorie meal and coffee on PBR and RBC-filling at intervals from 0-180 minutes.

Results: The mean(SD) age was 24.9(6.1) years and 52% were male. There was no significant intra- or inter-investigator variance for PBR or RBC-filling and no for PBR for side-of-tongue. A small variance was found for day-to-day, PBR (0.012μm, p=0.007)/ RBC-filling (0.003%, p=0.005) and side-of-tongue, RBC-filling (0.025%, p=0.009). Significant influence of cigarette smoking (from 40-180 minutes), high calorie meal intake and coffee consumption was found, the latter two peaking immediately and tapering off but remained significant up to 180 minutes, highest PBR changes for the three being 0.042μm ($p<0.05$), 0.183μm ($p<0.001$) and 0.160μm ($p<0.05$), respectively.

Conclusions: Measurements with the GlycoCheck system have an acceptable reproducibility, even with day-to-day variability. Smoking, diet and coffee had influence on measurements of up to 180 minutes, thus abstinence is recommended at least 180 minutes before measurements. Future studies will address impact of renal disease and reno-protective intervention on glycocalyx but should standardise measurement conditions.

SA-PO332

Impact of Oxidative Stress on Vascular Calcification in the Setting of Coexisting CKD and Diabetes Mellitus

Shuhei Watanabe, Hideki Fujii, Keiji Kono, Kentaro Watanabe, Shunsuke Goto, Shinichi Nishi. *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Vascular calcification is a crucial complication in patients with chronic kidney disease (CKD). Particularly, CKD patients with diabetes mellitus (DM) manifest severe vascular calcification but its precise mechanisms are poorly understood. It has been reported that oxidative stress plays a key role for the progression of vascular calcification. In the present study, we investigated the pathophysiological mechanisms of vascular calcification in the setting of coexisting CKD and DM particularly from the perspective of oxidative stress.

Methods: Sprague-Dawley rats were randomly divided into six groups as follows; (i) control rats (control group), (ii) 5/6 nephrectomized rats (CKD group), (iii) streptozotocin (STZ) injected rats (DM group), (iv) 5/6 nephrectomized and STZ injected rats (DM+CKD group), (v) DM+CKD rats treated with insulin (DM+CKD+INS group), (vi) DM+CKD rats treated with apocynin, which is an inhibitor of NADPH oxidase (DM+CKD+APO group). All groups were fed a high phosphate diet from 11 weeks of age. At 18 weeks, the rats were sacrificed for blood and urine analysis, histopathological analysis and evaluating mRNA expressions of oxidative stress and osteoblast differentiation-related markers in the aorta.

Results: Von Kossa-positive mineralized area and calcium content of aorta were significantly increased in the DM+CKD group compared to the control, CKD and DM groups at 18 weeks. However, despite high serum glucose levels control, apocynin treatment prevented the progression of vascular calcification. The mRNA expressions of RUNX2 and ALP and the number of RUNX2-positive cells in the aorta were significantly increased in the DM+CKD group compared to the control, CKD and DM groups. Similarly, these expressions were significantly reduced by apocynin treatment. As for the assessment of oxidative stress, urinary excretion of 8-hydroxydeoxyguanosine (8-OHdG), the number of 8-OHdG positive cells in the aorta, and the mRNA expressions of NOX4 and NADPH p22 phox were significantly decreased in the DM+CKD+APO group compared to the DM+CKD group.

Conclusions: Our results suggest that coexisting CKD and DM accelerates vascular calcification mainly by increased oxidative stress.

SA-PO333

c-Src and Caveolin-1 in Na-K-ATPase Signaling Complex: A Cys-Cys Crosslinking Analysis

Fang Bai,[1] Ying Nie,[2] Muhammad A. Chaudhry,[3] Rebecca Pratt,[3] Jiang Liu.[1] *[1]Marshall University JCE School of Medicine, Huntington, WV; [2]Marshall University, Huntington, WV; [3]Marshall University School of Medicine, Huntington, WV.*

Background: Activation of Na/K-ATPase signaling cascade regulates sodium handling in proximal tubule, systemic oxidative stress, and uremic cardiomyopathy. This study is to investigate the formation of the signaling complex, especially interactions amongst the α1 subunit, c-Src, and caveolin-1 (cav-1) under native condition in live cells.

Methods: Crosslinking studies were performed in resting live LLC-PK1 cells with Cys-Cys crosslinkers BMH (non-cleavable) and DTME (cleavable). Blue Native-PAGE was used to identify the molecular weight and protein components of the complexes under native condition. Capillary immunoblotting spectra analysis was used to determine the interactions amongst α1, c-Src, and cav-1, by comparisons between LLC-PK1 and cav-1-knockdown C2-9 cells (generated from LLC-PK1), as well as between triple Src kinase (c-Src, Yes, Fyn)-null mouse fibroblasts SYF cells and c-Src-rescued SYF cells, SYF+c-Src cells.

Results: (1) In Blue Native-PAGE, control samples showed a predominant complex around 480 kD (480-band), and crosslinked samples showed an additional complex around 720 kDa (720-band). Mass spectrometry analysis showed that, both the Na/K-ATPase α1 and β1 subunits were present in both 720-band and 480-band, in both control and BMH-crosslinked samples. Cav-1 was only present in the 720-band but not the 480-band. Moreover, in control samples, c-Src was detected in the 480-band, comparing with that c-Src was detected in the 720-band in BMH-crosslinked samples. (2) In spectra analysis of control and crosslinked samples, there were interactions between the α1 subunit and c-Src, and between the α1 subunit and cav-1. While depletion of c-Src or cav-1 clearly reduced the involvement of the α1 subunit in the crosslinked protein complexes, depletion of cav-1 did not affect the interaction of c-Src with other proteins including the α1 subunit. (3) Furthermore, there are multiple bands showing immuno-reactivity with the α1 subunit, c-Src, and cav-1, indicating the existence of different sizes of protein complexes that might contain different protein components with different functions.

Conclusions: In live cells, present study indicated that there are direct interactions between the α1 subunit and c-Src as well as between the α1 subunit and cav-1, but not likely between c-Src and cav-1. The α1 subunit functions as a bridge to link c-Src and cav-1.

Prevalence, Level of Awareness, and Hypertension Control in Africans

Titilayo O. Ilori,[1] Rulan S. Parekh,[2] Ifeoma I. Ulasi,[5] Lisa White,[1] Dwomoa Adu,[4] Akinlolu O. Ojo.[3] *[1]University of Arizona, Tucson, AZ; [2]The Hospital For Sick Children, Toronto, ON, Canada; [3]University of Arizona Health Sciences, Tucson, AZ; [4]University of Ghana, Accra, Ghana; [5]College of Medicine, University of Nigeria, Enugu, Nigeria.*

Background: Despite the availability of effective low-cost treatments, systemic hypertension continues to be a major cause of cardiovascular morbidity and premature death particularly in low resource countries where the overall prevalence of hypertension is increasing.

Methods: We estimated the prevalence, level of awareness and hypertension control in individuals the Human Hereditary and Health in Africa Kidney Disease Study (H3A-KDRN) in West Africa (n=8392). Using a standardized protocol, trained study staff measured three blood pressure in participants. We defined hypertension as systolic blood pressure ≥140 mmHg and/or diastolic blood pressure ≥90mmHg and/or self-reported antihypertensive medication use. We defined awareness of hypertension was defined using self-report and hypertension control as blood pressure <140/90mmHg.

Results: The prevalence of hypertension in the entire cohort was 53.7%. Of those with hypertension, 70.4% were aware of their diagnosis of hypertension, 54% were on medication on medication while 32.3% had controlled blood pressure to <140/90mmHg. Older individuals, those with lower eGFR, Ghanaians compared to Nigerians, obese individuals and alcohol drinkers were more likely to be aware of their hypertension diagnosis. Older age individuals, those with lower eGFR, and Ghanaians were all less likely to have a controlled blood pressure.

Conclusions: Despite the moderate level of awareness of hypertension in this cohort, the rate of hypertension control was suboptimal. There is need for programs to ensure for reliable and affordable access to the treatment of hypertension in Africa.

The Circadian Clock Provides Beneficial Effects Against the Endothelial Dysfunction to Promote Atherogenesis by Regulating Angiotensin II Generation and Vascular Endothelial Growth Factor Expression

Hideyuki Negoro. *Harvard Medical School, The Graduate School of Project Design, Tokyo, Japan.*

Background: The circadian clock is a molecular mechanism that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial

structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence growth factors, such as Angiotensin II or Vascular Endothelial Growth Factor (VEGF) which play an important part in the progression of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of Angiotensin II and VEGF expression in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was an increase in Angiotensin II and VEGF expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display premature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include Angiotensin II and VEGF, which are significantly elevated in Bmal1 KO mice. We also confirmed that PDGF levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating Angiotensin II and VEGF expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

A Novel and Reproducible Model of CKD-Induced Vascular Calcification in Mice

Farah Abou Daya,[1,2] Daryll R. Spangler,[1,2] Laurence M. Black,[1,2] Amie Traylor,[1,2] Abolfazl Zarjou.[1,2] *[1]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL.*

Background: Vascular calcification remains a frequent complication of advanced chronic kidney disease (CKD) and a leading cause of morbidity and mortality in this population. Various animal models have been introduced to induce CKD and study the pathomechanism of vascular calcification. The most commonly used such model in rodents is 5/6 nephrectomy followed by using high phosphate diet. However, the 5/6 nephrectomy in mice is markedly challenging and results are seldom consistent.

Methods: To address this challenge, we sought to examine a novel model of vascular calcification where ten-week-old mice with DBA2 background that are prone to vascular calcification, underwent unilateral ischemia reperfusion injury (UIRI) for 25 minutes followed by complete right nephrectomy after one week. The control group underwent sham surgery and both groups were fed high phosphate diet (0.6% Ca, 0.9% Pi) for twelve weeks at which point mice were sacrificed for analysis.

Results: While serum creatinine did not reveal significant changes (treatment group = 0.12 ± 0.01 mg/dL vs control group = 0.13 ± 0.03 mg/dL), glomerular filtration rate measurements (GFR) were lower in the treatment groups (treatment group = 187.68 ± 31.99 uL/min vs control group = 230.99 ±18.5 uL/min). Furthermore, protein analysis on aortae of the mice demonstrated significant upregulation of osteogenic markers including osteocalcin, alkaline phosphatase, and osteoblast specific transcription factor, cbfa-1.

Conclusions: Our findings suggest that UIRI followed by nephrectomy is a feasible and reproducible model of vascular calcification associated with CKD that would enable study of various transgenic mice to better understand the mechanistic pathways involved in mineralization of vascular tree and targeting novel therapeutics.

Bariatric Surgery Alters Fibroblast Growth Factor 21 and the Renin Angiotensin System in Patients with Obesity

Byung chul Yu,[2] Hyoshik Kim,[1] Yon hee Kim,[1] Hyunjin Noh,[1] Moo Yong Park,[2] Soon hyo Kwon.[1] *[1]Soonchunhyang University Seoul Hospital, Soonchunhyang University Medical College, Seoul, Republic of Korea, Seoul, Republic of Korea; [2]Soonchunhyang University Bucheon Hospital, Republic of Korea, Bucheon, Republic of Korea.*

Background: Obesity is associated with overactivation of the renin-angiotensin system (RAS). Recent studies have shown that fibroblast growth factor 21 (FGF21) prevents angiotensin II (Ang II) induced hypertension and vascular dysfunction by activation of the angiotensin-converting enzyme 2 (ACE2)/Angiotensin 1-7 (Ang (1-7))/MAS axis in hypertension. However, it is not certain whether bariatric surgery changes FGF21/RAS in morbid obesity. In this study, we examined the relationship between circulating FGF21 and Ang II/ACE2/Ang (1-7) in patients with obesity after bariatric surgery.

Methods: We prospectively enrolled obese patient who underwent bariatric surgery and age-sex matched healthy volunteers (HVs) (n=12 each). Serum FGF-21, Ang II, ACE2, and Ang (1-7) levels were measured by enzyme-linked immunosorbent assay kits. We measured also FGF-21, Ang II, ACE2, and Ang (1-7) 6 months after bariatric surgery in obese patients (n=12).

Results: Ang II and ACE2 levels were significantly higher in obese patients compared with HVs (931.9 ± 189.2 vs 615.2 ± 79.9 pg/mL, $p < 0.001$, 273.8 ± 45.0 vs 240.8 ± 42.3 ng/mL, $p = 0.020$, respectively). Ang II and ACE2 levels were significantly decreased after bariatric surgery ($p = 0.005$, 0.023, respectively). In obese patients, FGF 21 levels was higher compared with HV ($p = 0.034$) and decreased after bariatric surgery ($p = 0.002$). There was no significant difference in Ang (1-7) levels between obese patients and HVs ($p = 0.887$). Although Ang (1-7) levels did not change after bariatric surgery ($p = 0.480$), changes in Ang (1-7) levels were positively correlated with changes in body mass index (BMI) ($R^2 = 0.580$, $p = 0.048$)(Fig 1).

Conclusions: Bariatric surgery reduced the elevated systemic Ang II, FGF21 and ACE2 levels in obese patients. A decrease in BMI after bariatric surgery was associated with a reduction in Ang (1-7) levels.

Patrolling Monocyte Subsets in Patients with CKD and Coronary Heart Disease

Miguel Hueso,[4,1] Angela I. Casas Parra,[4] Adrián Mallén,[1] Jordi Guiteras,[1] Esther Castaño,[2] Beatriz Barroso,[2] Nuria Bolanos,[1] Arnau Blasco lucas,[3] Fabrizio Sbraga,[3] Estanislao Navarro,[1] Juan Torras.[4] *[1]IDIBELL, Hospitalet de Llobregat, Spain; [2]Biology Unit, CCiTUB, L'Hospitalet, Spain; [3]Cardiac Surgery, Hospital de Bellvitge, l'Hospitalet de Llobregat, Spain; [4]Nephrology, Hospital de Bellvitge, l'Hospitalet de Llobregat, Spain.*

Background: Chronic low-grade inflammation is prevalent in Chronic Kidney Disease (CKD) patients and plays a role in the development and progression of cardiovascular diseases. Monocytes are key factors in atherosclerosis progression and can be classified into subtypes based on their profiles of LPS co-receptor CD14 and FCgIII CD16 expression. The aim of this work is to analyze circulating monocytes subsets in CKD patients with atherosclerotic coronary artery lesions undergoing coronary Artery Bypass Surgery (CABG).

Methods: A prospective Case-Control study was conducted in CABG patients. Controls were patients with non-coronary lesions undergoing valve repair heart surgery. The expression of CD14+ and CD16+ antigens were analyzed by flow cytometry in peripheral blood mononuclear cells. A sample of perivascular adipose tissue and a punch from aorta were also obtained from patients included in the study.

Results: A total of 72 CABG patients (56 males) from which 40 suffered CKD (stages 3 to 5) and 26 non-coronary heart surgery controls (17 males) from which 11 patient suffered CKD were included. Here, we show the flow cytometry analysis. The proportion of classical CD14+CD16- monocytes (78.5±11% in CABG vs 75.9±12.1% in controls; p=0.3), CD14++CD16+ (10.8±8% in CABG vs 12.9±9.7 in controls; p=0.2) and CD14+CD16++ (10.9±6.6 vs 11.1±5.2 %: p=0.9) was similar in CABG than in controls. CKD was associated with a depletion of the CD14+CD16++ subset (CD14+CD16-: 76.4±12.5% in patients without CKD; n=50, vs 78.6±10.1% in CKD, n=48; p=0.4; CD14++CD16+: 11.2±8.1% without CKD vs 11.7±8.8% in CKD; p=0.4; and CD14+CD16++:12.4±7.2 vs 9.7±4.5 %: p=0.026). The depletion of CD14+CD16++ monocytes showed a significant negative correlation with systolic arterial pressure (R=-0.374, p=0.0001).

Conclusions: CKD and systolic arterial pressure were associated with a depletion in CD14+CD16++ monocytes in peripheral blood of patients. Next, we plan to study the expression of adhesion molecules in the surface of the CD14+CD16++ monocytes to determine their ability to adhere to endothelial cells.

Deficiency of the Anaphylatoxin Receptors C5aR2 and C3aR Aggravates Hypertensive Renal Injury

Marlies Bode,[1] Catherine Meyer-Schwesinger,[2] Christian Kurts,[4] Heimo Ehmke,[3] Joerg Koehl,[5] Ulrich O. Wenzel.[1] *[1]University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany; [2]University of Hamburg, Hamburg, Germany; [3]University Medical Centre Hamburg-Eppendorf, Hamburg, Germany; [4]Institute of Experimental Immunology, Bonn, Germany; [5]University of Luebeck, Luebeck, Germany.*

Background: Complement drives the host defense against microbes and mediates inflammatory responses. In addition, recent data also support a role for complement in arterial hypertension. During the activation and amplification of the complement cascade, the anaphylatoxins C3a and C5a are released and trigger pro inflammatory signaling

via their corresponding receptors. We recently described that C5a receptor 1 deficiency ameliorated hypertensive renal injury. However, the role of the second C5a receptor (C5aR2) and the C3a receptor (C3aR) in hypertension and hypertensive end organ damage remain unclear.

Methods: Expression of C5aR2 and C3aR on infiltrating and resident renal cells were determined using tandem tomato reporter mice for either C3aR or C5aR2 by flow cytometry and confocal microscopy. The hypertension model of angiotensin II infusion in combination with unilateral nephrectomy and high salt diet was induced in Balb/c wildtype, C5aR2- and C3aR-deficient mice. The glomerular filtration rate (measured with fitc sinistrin), albuminuria and glomerular damage were determined.

Results: Flow cytometric analysis of leukocytes isolated from the kidney of anaphylatoxin reporter mice showed C5aR2 expression on dendritic cells (34%), macrophages (30%) and neutrophils (14%) whereas dendritic cells are the major C3aR-expressing population (90%). C5aR2 and C3aR were also detected by confocal microscopy in the kidney only on infiltrating cells. Both anaphylatoxin receptor-deficient mice suffered from markedly increased renal injury after Ang II infusion with higher albuminuria, glomerular filtration rate and glomerular injury compared to hypertensive wildtype mice. The mortality in hypertensive C3aR-deficient mice was significantly higher than that observed in hypertensive wildtype or C5aR2-deficient mice and was associated with increased bleeding.

Conclusions: Our findings identify C5aR2 and C3aR expression on infiltrating (mainly dendritic cells, macrophages and neutrophils) but not on resident cells in the kidney. C5aR2 or C3aR deficiency was associated with strongly increased renal injury in response to arterial hypertension. Together, we propose that C5aR2 and C3aR mediate protective or homeostatic effects in hypertensive renal injury.

Indoleamine 2,3-Dioxygenase-1, a Novel Therapeutic Target in Thrombotic Uremic Toxicity

Joshua A. Walker,[1,3] Sean Richards,[2] Mostafa Belghasem,[1] Sung bok Yoo,[1] Nkiruka Arinze,[5] Stephen A. Whelan,[4] Norman Lee,[1] Vipul C. Chitalia.[3] *[1]Boston University, Boston, MA; [2]Boston University Medical Center, Boston, MA; [3]Boston University School of Medicine, Boston, MA; [4]Boston Univeristy, Boston, MA; [5]Boston Medical Center, Boston, MA.*

Background: Metabolites associated with chronic kidney disease (CKD) are highly thrombogenic. Emerging evidence validated CKD-specific mediators and definined the uremic solute-aryl hydrocarbon receptor (AHR)-tissue factor (TF) axis resulting in increased thrombosis. Given the importance of tryptophan metabolites in inducing thrombosis in CKD, we examined the role of Indoleamine 2,3-dioxygenase-1 (IDO), the rate limiting enzyme of the kynurenine pathway in CKD-mediated thrombosis.

Methods: Global IDO knock-out and wild type mice treated with 1-methyltryptophan (1-MT), a specific inhibitor of IDO, were used in an adenine-induced model of CKD. Plasma uremic solutes were measured by LC/MS. IDO protein and mRNA were examined in vascular smooth muscle cells (vSMCs) and in flow-loops. Prothrombic effects of IDO were further confirmed in clinical, Dialysis Access consortium (DAC)-fistual and Thrombolysis in Myocardial Infacrction (TIMI)-II.

Results: Compared to $IDO^{+/+}$ mice, $IDO^{-/-}$ mice showed a significantly increased time to occlusion (TTO) in both non-CKD and CKD mice models ($p<0.05$). $IDO^{+/+}$ mice administered 1-MT in a CKD model had increased TTO compared to controls, supporting the role of IDO in thrombosis. ($p<0.05$). Indoxyl sulfate (IS), a prothrombotic uremic solute, increased IDO expression in a dose-dependent manner in vSMCs *in vitro*and 3D flow loops. IDO protein and mRNA was upregulated by IS at concentrations observed in CKD patients. Polyubiquitination and proteasomal degradation of IDO was substantially inhibited by IS. IDO activity of sera samples was significantly higher in those patients who subseqently developed AVF thrombosis (DAC-fistula trial, p=0.001) and post-angioplasty thrombois (TIMI-II trial, p=0.008) compared to subjects without a thrombotic event.

Conclusions: We demonstrate a novel role for IDO as a contributor to CKD-mediated thrombosis and as a potential therapeutic target in post-interventional thrombosis in CKD patients. The current study further underscores a complex interplay of unique mediators triggered in the uremic milieu that impart thrombotic risk to CKD patients.

Mechanisms for Increased Cardiovascular Risk in Patients with ANCA Vasculitis in Long-Term Remission

Tariq E. Farrah. *University of Edinburgh, Edinburgh, United Kingdom.*

Background: Current treatments have improved the short-term survival of patients with ANCA-associated vasculitis (AAV), an autoimmune disease that often involves the kidneys. Long-term outcomes remain poor due to an increased risk of cardiovascular disease (CVD). AAV is defined by systemic endothelial injury but few clinical studies have robustly explored endothelial dysfunction as a contributor to CVD risk in these patients. We assessed brachial artery vasodilation and release of tissue plasminogen activator (tPA, an endogenous thrombolytic) as measures of endothelial function that predict CVD.

Methods: We recruited 32 AAV patients in long-term remission and 32 age- and sex-matched healthy controls into a prospective cohort study. Those with renal impairment, proteinuria, diabetes and overt CVD were excluded. Vasodilation was assessed by gold standard forearm blood flow during randomized intra-arterial infusions of acetylcholine (ACh, endothelium-dependent vasodilator, 7.5/15/30μg/min) and sodium nitroprusside (SNP, endothelium-independent vasodilator, 2/4/8μg/min). tPA release was measured during intra-arterial bradykinin (100/300/1000pmol/min).

Results: AAV patients had a mean±SD age of 55±13 years and 23 (72%) were male. The median (range) time from diagnosis was 4 (1-13) years and 17 (53%) were PR3+. 22 (69%) patients were prescribed a renin-angiotensin system blocker, and 21 (66%) were receiving a statin or ezetimibe. Forearm blood flow increased dose-dependently during all infusions. AAV patients had reduced ACh-mediated vasodilation compared to controls ($p<0.01$ at peak dose, ~25% difference in area under the curve). Responses to SNP did not differ. Compared to controls, AAV patients had lower mean±SD tPA release (125±50 *vs* 65±52 ng/100ml/min at peak dose, $p<0.001$). tPA release was lower in PR3+ *vs* MPO+ patients (52±40 *vs* 90±70 ng/100ml/min, $p<0.05$), and in patients on maintenance immunosuppression compared to those on no immunosuppression (91±43 *vs* 54±50 ng/100ml/min, $p<0.01$), who had similar tPA release to controls.

Conclusions: AAV patients in long-term remission have significant endothelial dysfunction, comparable to that seen following myocardial infarction or in advanced CKD; this may partly explain their increased CVD risk. Targeting these with existing and novel therapies may improve long-term outcomes in AAV.

SA-PO342

Lanosterol Synthase (LSS) Gene as a Predictor of Kidney Dysfunction in Hypertensive Patients

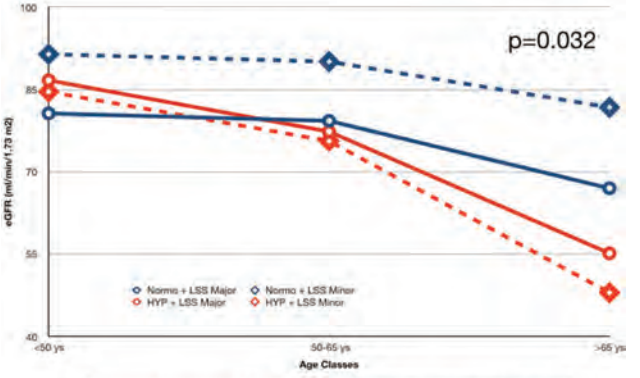
Marco Simonini,[1] Lorena Citterio,[1] Erika Salvi,[2] Chiara Lanzani,[1] Elisabetta Messaggio,[1] Simone Fontana,[1] Daniele Cusi,[3] Paolo Manunta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]Istituto Besta, Milan, Italy; [3]Bio4Dreams LifeSciences Incubator, Bresso, Italy.*

Background: Hypertension (HYP) is one of the main causes of chronic kidney disease (CKD). Recently we have proposed LSS as genotype-based risk stratification to predict accelerated eGFR decay in essential HYP patients. We tried to find a confirmation of this result in an observational study on general population.

Methods: We extracted clinical data of a general population from HYPERGENES Consortium. We also collected genetic data for LSS polymorphism that was already demonstrated as involved in kidney damage.

Results: A cohort of 3137 subjects was selected. Incidence of HYP and CKD was 49.8% and 9.1% respectively. Patients with well-known no-HYP / no-angiosclerosis related CKD (as diabetes, glomerulonephritis, ADPKD), were excluded. Population was divided into 3 classes according to age. At different age, HYP status have a deep impact on eGFR. Indeed in young (< 50ys) eGFR is higher in HYP vs control (86.2±19.3 vs 82.7±16.3 ml/min; p=0.04); vice-versa in elder (> 65ys) HYP have a reduction in eGFR (55.7±12.9 vs 71.0±12.9 ml/min; p<0.001). No direct influence of LSS polymorphism on eGFR was observed. When LSS is considered according to HYP status and age class it is possible to observe a preservation of age-associated eGFR reduction in normotensive patients (eGFR 91.4 vs 90.1 vs 81.8 ml/min for LSS risk allele); on the other side, LSS seems to enhance eGFR reduction associated with HYP status (eGFR 84.6 vs 75.6 vs 48.0 ml/min for LSS risk allele; p=0.032; fig. 1).

Conclusions: We confirmed on a large general population the involvement of LSS gene in enhanced eGFR loose in HYP patients. Indeed patients carrying the risk allele of this specific LSS polymorphism seem to express hyper-filtration if compared to their counterparts. When exposed to a specific pathological condition as HYP, with a further increase in eGFR in early phases, this could lead to an accelerated reduction in kidney function.



Age Class	Hypertension	LSS polymorphism	N	eGFR (ml/min/1.73m2)	
				Mean	S. D.
< 50 ys	Normo	Major	98	80.66	17.80
		Minor (risk)	8	91.43	12.85

Plasma Leucine-Rich Alpha-2-Glycoprotein 1 Predicts Cardiovascular Disease Risk in ESRD

Chia-Yu Liu,[1] Kai-Hsiang Shu,[2] Yen-Ling Chiu.[1] *[1]Far Eastern Memorial Hospital, New Taipei City, Taiwan; [2]National Taiwan University, Taipei, Taiwan.*

Background: Plasma Leucine-Rich alpha-2-Glycoprotein 1(LRG1) is an innovative biomarker for inflammation and angiogenetic diseases. End-stage renal disease (ESRD) is associated with adverse outcomes including inflammation, atherosclerosis, and premature mortality. However, whether levels of plasma LRG1 correlate with the co-morbidities of ESRD patients is unknown.

Methods: Plasma LRG-1 and high-sensitivity C-reactive protein were analyzed by ELISA in samples from 169 hemodialysis patients from the Immunity in ESRD study (iESRD study). Through history taking and detailed chart reviews, baseline co-morbidities were recorded. Peripheral blood monocyte and T cell subsets were assessed by multicolor flow cytometry.

Results: In the univariate analysis, LRG1 was found to be associated with the existence of cardiovascular disease (CVD) and peripheral arterial occlusive disease (PAOD). In multivariate-adjusted logistic regression models, higher LRG1 tertile was significantly associated with PAOD (odds ratio = 3.49), CVD (odds ratio = 1.65), but not with coronary artery disease, history of myocardial infarction, or stroke after adjusting for gender, hemoglobin, diabetes, hypertension, and level of C-reactive protein. In addition, the level of LRG-1 positively correlated with IL-6 and CRP and more advanced T cell differentiation, indicating the participation of LRG1 in the progression of atherosclerosis.

Conclusions: In the univariate analysis, LRG1 was found to be associated with the existence of cardiovascular disease (CVD) and peripheral arterial occlusive disease (PAOD). In multivariate-adjusted logistic regression models, higher LRG1 tertile was significantly associated with PAOD (odds ratio = 3.49), CVD (odds ratio = 1.65), but not with coronary artery disease, history of myocardial infarction, or stroke after adjusting for gender, hemoglobin, diabetes, hypertension, and level of C-reactive protein. In addition, the level of LRG-1 positively correlated with IL-6 and CRP and more advanced T cell differentiation, indicating the participation of LRG1 in the progression of atherosclerosis.

Potent Pro-Angiogenic Mediators Fail to Improve the Post-Ischemic Angiogenesis in the Uremic Milieu

Nkiruka Arinze,[1] Sean Richards,[1] Marc A. Napoleon,[1] Joshua A. Walker,[1] Mostafa Belghasem,[1] Chimera L. Lyle,[1] Stephan Anderson,[2] Jeffrey Siracuse,[1] Alik Farber,[1] Nader Rahimi,[1] Vipul C. Chitalia.[1] *[1]Boston University Medical Center, Boston, MA; [2]Boston University, Boston, MA.*

Background: Patients with chronic kidney disease (CKD) have been shown to have a 3-fold higher prevalence of peripheral arterial disease. Although CKD represents an independent risk factor for PAD, CKD-specific contributors remain unknown. The Wnt/beta catenin pathway is a potent pro-angiogenic pathway that increases endothelial cell proliferation and capillary permeability. Casitas b-cell lymphoma (c-Cbl) is a negative regulator of nuclear active beta catenin. We hypothesized that reduced activity of c-Cbl is likely to augment Wnt/beta catenin signaling in ischemia-induced angiogenesis in the uremic milieu.

Methods: Unilateral hindlimb ischemia (HLI) model was performed in 8-12 week old c-Cbl +/+ and c-Cbl +/- female mice under non-CKD and CKD conditions using the adenine-induced CKD model. Laser Doppler imaging was used to determine perfusion recovery over time. CD31 staining was used to determine capillary density. Capillary leakage was detected by dextran infusion. Both were quantitated as integrated density. Wnt/beta catenin activity was examined in primary human endothelial cells.

Results: On normal diet, c-Cbl$^{+/-}$ mice exhibited higher perfusion, capillary density, endothelial permeability and beta catenin expression in the ligated limb compared to c-Cbl$^{+/+}$ mice. Adenine diet significantly compromised all of these parameters in both c-Cbl$^{+/-}$ and c-Cbl$^{+/+}$ mice. Mechanistic probing revealed that the uremic milieu inhibited Wnt activity and the nuclear pool of active beta catenin in the endothelial cells, which was in part driven by P-cresyl sulfate.

Conclusions: This study demonstrates the detrimental effect of uremia on ischemia induced angiogenesis and suppression of Wnt/beta catenin signaling in endothelial cells by specific uremic solutes. These results provide the first potential link of uremic solutes with a potent pro-angiogenic Wnt/beta catenin pathway. This interaction warrants further exploration as a potential CKD-specific mediator of PAD.

Factors Determining Timing of Onset of Hypertension in Premature Infants

Randall Jenkins, Katherine Farnbach, Sandra Iragorri, Amira Al-Uzri, David J. Rozansky. *Oregon Health & Science University, Portland, OR.*

Background: We recently demonstrated that phthalate-exposed premature infants with unexplained hypertension (HTN) had evidence of inhibition of 11-BHSD2, and secondary activation of the mineralocorticoid receptor (MR). Neither HTN nor increased sodium transporter expression occurred until an adjusted age closer to term, despite phthalate exposure weeks earlier. We tested the hypothesis that other types of HTN in premature infants might also present with a similar timeframe.

Methods: We reviewed charts of all premature infants with HTN at two tertiary-care centers during the last 8 years, excluding infants with unknown phthalate exposures, and single case categories: neurology and renal vein thrombosis. Analyses included HTN incidence, time-course of HTN, and phthalate exposure.

Results: 106 infants with 107 episodes of HTN were found. In both AKI and thromboembolism groups, HTN developed at an early chronological and postmenstrual age. Their phthalate exposure was small. In all other categories HTN presented near 40 weeks postmenstrual age, usually with low renin. Phthalate exposures were large in the pulmonary and medications groups, and moderate in the CAKUT group.

Conclusions: The development of HTN in premature infants from AKI and thromboembolism is unrelated to phthalate exposure and to sodium transporter maturation. Onset of HTN for phthalate-exposed infant categories (pulmonary, medications, and CAKUT) occurs closer to an adjusted term age - more in line with activation and maturation of MR-dependent sodium transporter processes such as we reported for infants with unexplained hypertension. Phthalate exposure may be a major factor in influencing the onset of HTN amongst these categories of infant hypertension.

Diagnostic, time-course, and phthalate exposures by category for premature infants with hypertension

Categories	#	Plasma renin activity < 11.0 ng/ml/h #/n	Gestational age at birth weeks	DX of hypertension postmenstrual weeks	median IV fluid phthalate exposure ml (IQR)	Median respiratory phthalate exposure days (IQR)

The Post-Stenotic Human Kidney Shows Microvascular Dropout and Remodeling

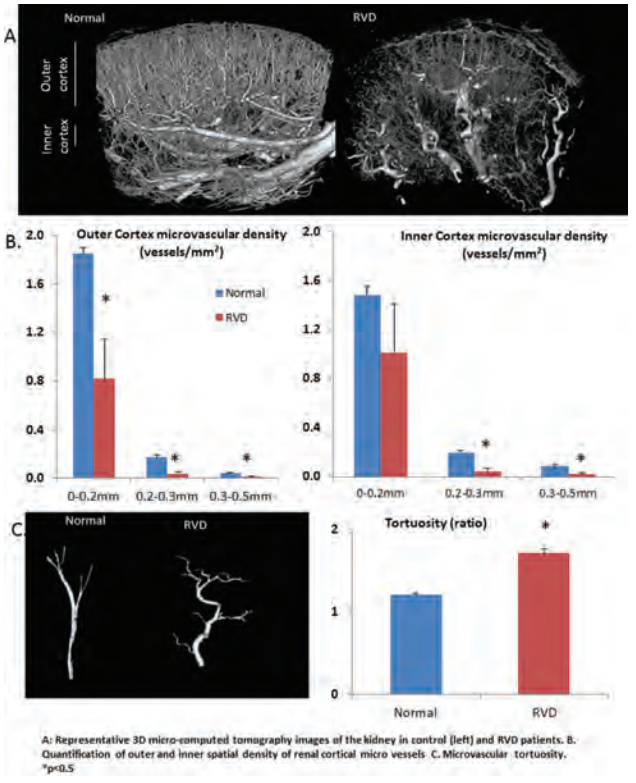
Aditya S. Pawar,[1] Alfonso Eirin,[1] Amrutesh S. Puranik,[4] Christopher M. Ferguson,[1] Xiang yang Zhu,[1] Seo Rin Kim,[2] Amir Lerman,[1] Stephen C. Textor,[1] Lilach O. Lerman.[3] *[1]Mayo Clinic, Rochester, MN; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [3]Mayo Clinic College of Medicine, Rochester, MN; [4]New York University Langone Health, New York, NY.*

Background: In animal models, post-stenotic kidney shows microvascular rarefaction, with loss of small outer cortical vessels correlating with limited kidney recovery after revascularization. However, whether stenotic human kidney shows microvascular loss is incompletely understood. We tested the hypothesis that Renal srtery stenosis (RAS) leads to microvascular remodeling in human kidneys

Methods: Nephrectomy samples from 4 patients with obstructive RAS, & 5 discard donor kidneys (Lifesource, MN) as controls were collected after IRB approval. The renal arteries were cannulated & perfused at physiological pressure with an intravascular radiopaque contrast agent. The kidney was segmented, scanned with micro-CT at 20μm resolution, & 3D images reconstructed. Microvascular diameter & spatial density were quantified (Analyze™). Cortical vessels were tomographically isolated to calculate tortuosity (ratio of path/linear length) as a measure of angiogenic activity & vascular immaturity.

Results: Age (55-65 yrs), sex, & body mass index were similar in both groups. Spatial density of medium & large cortical micro vessels (200-500μm in size) was significantly diminished in outer & inner cortex in Renovascular disease (RVD) compared with normal kidneys (Fig. 1A-B). RVD kidneys showed significant loss of small (<200μm) micro vessels in the outer cortex, as well as an increase in microvascular tortuosity compared with normal kidneys, suggesting remodeling & compensatory angiogenic activity

Conclusions: The post-stenotic human kidney shows cortical microvascular loss & remodeling. These alterations may magnify deterioration of renal function & interfere with renal ability to recover upon treatment, supporting development of pro-angiogenic strategies to preserve the kidney



A: Representative 3D micro-computed tomography images of the kidney in control (left) and RVD patients. B. Quantification of outer and inner spatial density of renal cortical micro vessels C. Microvascular tortuosity. *p<0.5

Hypertension Is Associated with Podocyte Hypertrophic Stress and Detachment Among a Healthy Living Donor Cohort

Abhijit S. Naik,[1] Dustin Le,[1] Milagros D. Samaniego-Picota,[2] Diane M. Cibrik,[3] Su Q. Wang,[1] Mahboob A. Chowdhury,[1] Roger C. Wiggins.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Henry Ford Health Services, Detroit, MI; [3]University of Kansas Hospital, Parkville, MO.*

Background: HTN is a major cause of ESKD. Kidney donors are a highly selected cohort with normal renal function. Podocyte depletion is a major process by which kidney disease progression occurs. Therefore we tested the hypothesis that Mean Arterial Pressure (MAP) would be related to rate of podocyte detachment.

Methods: 87 living donors that eventually donated were utilized. Two podocyte markers (podocin,nephrin) and a distal tubular/collecting duct marker (aquaporin2) were measured from urine pellet in spot samples normalized to creatinine. UPod:CR is a marker of podocyte detachment, Podocin to Nephrin ratio (UPod:Neph) of podocyte hypertrophic stress and Podocin to Aquaporin ratio (UPod:Aqp2) to understand relation of glomerular to tubular injury. Linear regression was adjusted for donor age, BMI, eGFR before donation.

Results: No donors were on antiHTN therapy. Mean SBP was 124±13, DBP was 73±10. See table and figure.

Conclusions: MAP is linearly related to podocyte detachment, hypertrophic stress and preferential glomerular injury even among healthy controls cleared for donation.

Funding: NIDDK Support

SNF472, a New Therapeutic Approach to Improve Outcomes in CKD Patients with Peripheral Artery Disease

Firas Bassissi,[1] Miquel D. Ferrer,[1,2] Maria del mar Perez,[1] Joan Perelló,[1,2] Carolina Salcedo.[1] *[1]Sanifit Therapeutics, Palma, Spain; [2]Universitat de les Illes Balears, Palma, Spain.*

Background: Peripheral Artery disease (PAD) is a common vascular disease associated with functional impairment and increased risk of cardiovascular events in Chronic Kidney Disease (CKD) patients undergoing dialysis. Poor limb salvage outcomes and high post-amputation mortality in hemodialysis (HD) patients highlight the need for earlier medical therapies. Cilostazol (SOC) use stays limited and requires caution in this population. Clinical studies demonstrate associations between arterial calcification and adverse outcomes in PAD patients. SNF472, a selective calcification inhibitor that interferes in the formation and growth of hydroxyapatite, is under development for calciphylaxis. We evaluated the effects of SNF472 on limb functional recovery and blood perfusion in a rat model with Vitamin D3 (VitD)-induced arterial calcification.

Methods: Arterial calcification was induced in 32 SD rats using (VitD) by 3 consecutives daily s.c. dosing of 120 kIU/kg. Rats were divided into four groups and treated during 12 days by: vehicle s.c, vehicle p.o, SNF472 (20mg/kg/day, s.c.) or cilostazol (20mg/kg/day, p.o.). An additional group of 8 rats without VitD received vehicle only (sham). Efficacy was evaluated at day 12 and 5 days after treatment stop. Posterior limb blood perfusion was measured using Laser Doppler Imaging and limbs walking ability were evaluated by measuring Maximum Walking Distance (MWD) and Maximum Walking Time (MWT) using a treadmill. Rats were sacrificed 10 days after treatment stop, and aorta was collected for calcium analysis.

Results: VitD-induced arterial calcification was associated with decreased blood perfusion and impairment of limb walking ability (MWT and MWD) compared to sham. SNF472 reduced aorta calcification by 41% compared to vehicle. No effects of cilostazol on vascular calcification were observed. The inhibition of calcification in SNF472 treated animals was associated with significant higher limb blood perfusion compared to vehicle or Cilostazol (1.28 and 1.37-fold higher, respectively at D12: p< 0.001) and translated into significant improvement in limbs walking ability compared to vehicle (515±114 meters vs 334±187 meters, respectively: p<0.05).

Conclusions: Our results evidence that SNF472 may present a promising new therapeutic approach to treat PAD associated with high vascular calcification such as in CKD and HD patients

SA-PO349

Carbamylated Homocitrulline Is Associated with Left Ventricular Hypertrophy in CKD: Results from the CAIN Study

Tzongshi Lu,[1] Kenneth Lim,[2] Michelle D. Song,[1] Jialing Liu,[1] Andrew M. Siedlecki,[1] Ravi I. Thadhani,[3] Sahir Kalim.[2] *[1]Brigham and Women's Hospital, Harvard Medical School, Natick, MA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [3]Cedars-Sinai, Los Angeles, CA.*

Background: Carbamylated proteins arise from post-translational modifications that accelerate with renal failure, can cause molecular and cellular dysfunction, and have been strongly associated to the presence of cardiovascular disease among patients with chronic kidney disease (CKD). To-date, it is unknown whether tissue levels of carbamylated proteins are linked to specific cardiac outcomes such as left ventricular hypertrophy (LVH). We hypothesized that carbamylated protein burden in cardiac tissue is associated with LVH in dialysis patients.

Methods: We analyzed 47 left ventricular (LV) human heart tissues collected in The CAIN (Cardiac Aging in CKD) Study Cohort. LV tissues from hemodialysis (HD; n=17), hypertensive (HTN; n=10) and healthy controls (n=20) were analyzed in a 3-arm cross-sectional controlled design. All tissues underwent gross pathologic exam. Tissue

carbamylation levels was assessed by western blotting using an antibody specific to homocitrulline as a marker (Cat. No. 22428, Cayman Chemical, MI, USA). Multiple regression analysis was performed to determine the association between carbamylated tissue levels and left ventricular free wall thickness (LVWT), an index of LVH.

Results: Across all 3 groups, there was no statistical difference in age (HD 46.2±11.2; HTN 55.9±5.0; control 49.2±15.3 yrs, p=0.2), gender (HD 59; HTN 60; control 50 % male, p=0.9) or BMI (HD 27.0±4.8; HTN 30.9±6.6; control 26.5±5.9 kg/m^2, p=0.1). HTN and HD patients had significantly greater LVWT standardized by body surface area on gross pathologic exam (p<0.0001). Basal homocitrulline was detected in LV tissues from control donors, however LV tissues from HTN patients exhibited increased homocitrulline levels (1.6-fold), while HD patients had even greater levels (2.3-fold) compared to control (P<0.0001). Multiple adjusted regression analysis showed that carbamylated homocitrulline levels was significantly associated with LVWT (p<0.05).

Conclusions: This present study is the first to assess carbamylated tissue levels in human hearts. We provide evidence that homocitrulline in LV tissues is associated with LVH as assessed by LVWT. Further studies are critically needed to determine the mechanisms involved.

Higher Type VI Collagen Formation Is Independently Associated with Increased Risk of Cardiovascular Events and Mortality in the Canagliflozin Cardiovascular Assessment Study (CANVAS)

Daniel Guldager Kring Rasmussen,[1] Timothy Jatkoe,[2] Nadja Sparding,[1,3] Joseph P. Blair,[1,3] Morten A. Karsdal,[1] David E. Gutstein,[4] Federica Genovese,[1] Michael K. Hansen.[4] *[1]Nordic Bioscience, Herlev, Denmark; [2]Janssen Research & Development, LLC., Raritan, NJ; [3]Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; [4]Janssen Research & Development, LLC., Spring House, PA.*

Background: Patients with type 2 diabetes are at significantly higher risk of experiencing cardiovascular complications. It has been shown that type VI collagen (COL VI) is markedly upregulated during pathogenic processes of the heart and vasculature. The role of COL VI biomarkers has been sparsely investigated in relation to cardiovascular events. We evaluated a novel biomarker of COL VI formation as a prognostic marker for cardiovascular events and mortality in patients with type 2 diabetes from the Canagliflozin Cardiovascular Assessment Study (CANVAS).

Methods: COL VI formation was assessed with the PRO-C6 enzyme-linked immunosorbent assay (ELISA), detecting a specific fragment of COL VI released upon deposition in the extracellular matrix. PRO-C6 levels were measured in baseline plasma samples from 3531 patients from CANVAS. Results from Cox proportional hazard regression models were reported as unadjusted or adjusted for the traditional risk factors age, sex, BMI, systolic and diastolic blood pressure, duration of diabetes, LDL cholesterol, HbA1c, eGFR, and albumin/creatinine ratio.

Results: In the unadjusted analysis, levels of PRO-C6 were significantly associated with heart failure (HF), cardiovascular death (CVD), a composite of HF and CVD, and all-cause mortality (Table, all P<0.0001). To assess the independent association of PRO-C6 with these outcomes, the analysis was adjusted for traditional risk factors. In the adjusted analysis, PRO-C6 was significantly associated with the listed outcomes (Table, all P≤0.0001).

Conclusions: In conclusion, this study reveals an independent association of the COL VI biomarker PRO-C6 with cardiovascular events and mortality in the CANVAS study.

Funding: Commercial Support - Janssen Research & Development, LLC

Deletion of the Gene for Transient Receptor Potential Canonical 1 (TRPC1) Channel Induces Diabetes and Cardiovasculopathy but Paradoxically Prevents the Cardiomyopathy from a High-Fat Diet (HFD)

Bonnie Eby,[1] Pedro Lozano,[1] Becky Pennington,[1] Alexander Lau,[1] Meghan M. Pantalia,[1] Kai Lau.[1,2] *[1]University of Oklahoma Health Science Center, Oklahoma City, OK; [2]Medical Service, Oklahoma City VA Hospital, Oklahoma City, OK.*

Background: TRPC1 is key in transducing Ca signal in the hypertrophic response to aortic constriction, but its natural role is unknown. Since +/- & -/- mice are hyperglycemic & since untreated diabetes induces cardiomyopathy, we tested if TRPC1 deficiency creates cardiovascular phenotypes & if 45% HFD aggravates these abnormalities.

Methods: In age-matched wild type, +/- & -/- males, we measured body weights (BW), heart weights (HW) & did echocardiographic studiies at ages 3, 7, 17 & 23 mon. At 7 mon, we measured blood pressure (BP) by tail cuffs & direct intraarterial readings of systolic (S) & diastolic (D) to get mean arterial BP (MABP). We studied aortic relaxation in chamber.

Results: In null mice, HW was 12-13% lighter at 2 mon & 7 mon. At 23 mon, HW remained 19% & HW:BW 23% lower, documenting cardiac hypoplasia. At 7 mon, in null mice, left ventricular (LV) end-diastolic (ED) volume (29 vs 56 μl) was down by 48%, ES volume (3 vs 11 μl) by 73%, stroke volume (26 vs 45 μl) by 42%, & stroke index (SI) (0.8 vs 1.4 μl/g BW) by 44%. Cardiac output (CO)(14 vs 21 ml/min) was 33 % down, as were SBP (113 vs 121 torr), DBP (77 vs 86 torr) & MABP (89 vs 98 torr). Systemic arterial resistance [MABP/CO], was elevated (7 vs 5 torr/ml/min). Pulse pressure was similar. Arterial stiffness [pulse pressure/SI] was up 2 fold as arterial compliance was down by 49%. Aortic relaxation, normal at 2 mon, was reduced at 23 mon in null mice. At 17 mon, LV fractional shortening (FS) was down by 16% in null & by 13% in +/-. LVEF was down by 7% in null. In wild type, HFD x 3 mon reduced FS by 17%, LVEF by 8% & SI by 26%. In contrast, HFD did not alter FS, LVEF, or SI in null mice, as if without TRPC1, the reduced cytosolic Ca blunts the activation of cardiac myocytes by HFD via the signaling pathway of Ca-calcineurin (CN)-NFAT. Indeed, SI in +/- mice with less impaired Ca homeostasis tended to fall with HFD.

Conclusions: Given the blunted cell Ca response to activation in all cells we studied in null mice, these data support the thesis that TRPC1 deficiency attentuates the intracellular CN-NFAT signaling to normal proliferative stimuli, producing cardiac hypoplasia & low CO. The same blunted Ca signaling prevents the cardiomyopathy induced by HFD and seen in wild types.

Normalization of Matrix Metalloproteinase Activity and Elastin Structure by Finerenone Reduces Arterial Stiffness in Mesenteric Resistance Arteries in a Rat Model of CKD

Maria S. Fernandez-Alfonso,[1] Marta Gil-Ortega,[4] Elena Vega martín,[5] Raquel G. Blázquez,[8] Gema Ruiz-Hurtado,[3] Angela Schulz,[6] Luis M. Ruilope,[7] Peter Kolkhof,[2] Beatriz Somoza,[4] Reinhold Kreutz.[6] *[1]Universidad Complutense de Madrid, Madrid, Spain; [2]Bayer AG, Wuppertal, Germany; [3]Hospital Universitario 12 de Octubre, Madrid, Spain; [4]San Pablo CE University, Alcorcón, Spain; [5]Facultad de Farmacia, Madrid, Spain; [6]Charité - Universitätsmedizin Berlin, Berlin, Germany; [7]National Instituto of Health, Spain, Madrid, Spain; [8]San Pablo Ceu University, Madrid, Spain.*

Background: Both albuminuria and arterial stiffness are independent predictors of cardiovascular morbidity and mortality associated to the progression of chronic kidney disease (CKD). This association supports a potential generalized vascular dysfunction with similar pathophysiologic mechanisms linking the cardiovascular-renal axis in patients with albuminuria. We aim to explore the effect of the mineralocorticoid receptor antagonist, finerenone (FIN), on vascular mechanics and structure in 2nd branch mesenteric resistance arteries (MA) from Munich Wistar Fromter (MWF) rats, a genetic model of non-diabetic CKD.

Methods: Wistar (W) and MWF rats were randomly grouped (n=10 per group) to receive either 10 mg/kg/day FIN (W-FIN; MWF-FIN) or vehicle (W-C; MWF-C) for 4 weeks by oral gavage. Mechanical and structural properties of MA were determined by pressure myography. Elastin organization in the internal elastic lamina (IEL) was analysed by confocal microscopy based on elastin autofluorescence. Metalloproteinase activity was assessed by gelatin zymography.

Results: FIN led to a significant reduction (>40%) in albuminuria in MWF. The stress/strain relationship curve in MA from MWF-FIN exhibited a significant right-shift, indicative of lower intrinsic arterial stiffness. No changes were observed in structural parameters (external and internal diameter, wall-to-lumen ratio, cross-sectional area and adventitial, medial and wall thickness) of MA. IEL from MWF-C animals showed significantly smaller fenestrae than W-C, without changes in total number of fenestrae. FIN significantly reduced fenestrae number in both W-FIN and MWF-FIN, and increased fenestrae area in MWF-FIN. Pro-MMP-2 activity was significantly lower in plasma samples from MWF-C rats compared with W-C rats, paralleled by higher levels of active MMP-2 and MMP-9 activities. FIN restored pro-MMP-2, MMP-2 and MMP-9 activities in MWF to control levels.

Conclusions: This study demonstrates the efficacy of FIN to ameliorate albuminuria and normalize circulating MMP activities, elastin structure and intrinsic arterial stiffness in MA from MWF rats.

Cellular Remodeling of Cardiomyocytes: An Unappreciated Phenotype of Congenital Proximal Renal Tubular Acidosis?

Clayton Brady,[1] Myles Pearson,[2] Aniko Marshall,[3] Mark Parker.[1] *[1]State University of New York at Buffalo, Buffalo, NY; [2]Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY; [3]SUNY Buffalo, Buffalo, NY.*

Background: Proximal renal tubular acidosis is caused by mutations in *SLC4A4* which encodes the electrogenic $Na^+/2HCO_3^-$ cotransporter variants NBCe1-A (predominantly renal and a major contributor to maintenance of plasma [HCO_3^-]) and NBCe1-B/C (predominantly non-renal and contributes to regulation of cardiomyocyte pH). Our laboratory has recently characterized a strain of Nbce1b/c-knockout (KO) mice that maintains Nbce1a in the kidney with widespread loss of Nbce1b/c elsewhere, allowing for the study of Nbce1 loss in non-renal organ systems in the setting of a normally maintained pH. To date no cardiac phenotype has been reported in pRTA patients (in fact Nbce1b/c blockade is considered to be cardioprotective under certain circumstances)

yet studies of cardiomyocytes isolated from spontaneously-hypertensive rats, in which Nbce1b/c activity is also impaired, reveal compensatory upregulation of the electroneutral Na^+/HCO_3^- co-transporter Nbcn1 and hypertrophy. Nbcn1 activity is predicted to impose a greater Na^+ load than Nbce1 activity. This is hypothesized to affect the activity of the Na^+-Ca^{2+} exchanger, decreasing Ca^{2+} extrusion, and ultimately activating Ca^{2+} dependent growth pathways. In the present study, we assess the hearts of Nbce1b/c-KO mice for signs of this pro-hypertrophic pathway.

Methods: Cardiac tissue from age and gender-matched C57 wild-type (WT) and KO littermates was weighed post-dissection and normalized to body weight for comparison. Cardiac tissue homogenates were prepared for RT-qPCR and western blot analysis of Nbcn1 expression.

Results: KO mice had 22 ± 8% larger heart-to-body weight ratios (n=5, p=0.03). Abundance of NBCn1 transcripts was 45 ± 10% greater in the KO compared to the WT (n=3, p=0.02). Abundance of NBCn1 protein was 85 ± 17% greater in the KO compared to WT mice (n=3, p<0.05).

Conclusions: Nbcn1 is upregulated both at the level of transcript and protein within cardiomyocytes of the enlarged hearts of Nbce1b/c-KO mice, consistent with the hypothesis that remodeling of acid/base transporter expression contributes to the enhanced growth of cardiac tissue.

High PTH Levels Inhibit Biorhythm of Human Vascular Smooth Muscle Cells In Vitro

Ningning Wang, Ying Cui, Qingting Wang. *Department of Nephrology, The First Affiliated Hospital with Nanjing Medical University, Nanjing, China*.

Background: In normal condition, vascular smooth muscle cells have self circadian rhythm. Here we observed the influences of high levels of parathyroid hormone (PTH) on circadian genes in human aortic vascular smooth muscle cells (hASMCs) *in vitro*.

Methods: Human ASMCs were divided into control and (1-84)PTH(10nmol/L) group. The timing of the beginning stimulated was counted as zeitgeber time 0 (ZT0). Thereafter, cells were collected every 4 hours for a total of 28 hours. The mRNA expressions of PPARγ, Bmal1, Per2 and Rev-erbα in different groups of cells at different time points were detected by quantitative polymerase chain reaction (qRT-PCR).

Results: mRNA expressions of PPARγ and clock genes Bmal1, Per2 and Rev-erbα showed circadian rhythms in the control group, and peaked at ZT4, ZT12, ZT4 and ZT20 respectively. High levels of PTH could inhibit the expression amplitudes of above genes, without affecting time phases of expressions.

Conclusions: High PTH levels could inhibit biorhythm of HASMCs, its relationships with vascular circadian rhythm abnormalities need further study.

G Protein-Coupled Receptor 37L1 Is Expressed on the Nuclear Envelope

Prasad Konkalmatt,[1] Ines Armando,[1] Pedro A. Jose.[2] [1]*George Washington University, Washington, DC;* [2]*George Washington University School of Medicine, Washington, DC*.

Background: G protein-coupled receptors (GPCRs), expressed on the plasma membrane, interact with various types of ligands, which trigger a cascade of signal transduction events leading to different intracellular responses that in turn manifest in physiological changes. Some GPCRs also reside and exert signals from intracellular organelles such as the nucleus, endoplasmic reticulum, and Golgi apparatus. Recently, we reported that G protein-coupled receptor 37L1 (GPR37L1) is expressed in the apical membrane of renal proximal tubule cells (RPTCs) and participates in luminal sodium transport and blood pressure regulation by regulating the renal expression of NHE3. However, the mechanism by which GPR37L1 regulates NHE3 expression and function in the RPTC has not been studied.

Methods: We employed Tandem affinity purification using GPR37L1 tagged with streptavidin and calmodulin binding peptides, followed by mass spectrophotometry (MS) analyses to identify the proteins interacts with GPR37L1. Subcellular location of GPR37L1 was determined by confocal fluorescence imaging and immunoblotting on the cells or the nucleus prepared from the RPTCs expressing GPR37L1 tagged with green fluorescence protein (GPR37L1-GFP).

Results: Tandem affinity purification of GPR37L1, combined with MS analyses, revealed the association of GPR37L1 with mediators of nuclear importing proteins, such as RAN-GTPase, importin-5, and importin-7. In silico analyses of GPR37L1 amino acid sequence revealed the presence of a potential nuclear localization signal at the N-terminus. Confocal fluorescence imaging of RPTCs expressing GPR37L1-GFP showed distinct nuclear membrane expression of GPR37L1. In addition, fluorescence imaging of nuclei isolated from the RPTCs expressing GPR37L1-GFP showed the expression on the nuclear envelope. Immunoblot analyses confirmed the presence of GPR37L1 in the nuclear protein prepared from the RPTCs expressing GPR37L1-GFP. The purity of the nuclear protein preparations was confirmed by the presence of histone deacetylase 2, a marker for nuclear protein, the absence of Na,K-ATPase, a marker for plasma membrane, and the absence of calnexin, a marker for endoplasmic reticulum.

Conclusions: Our results show that GPR37L1 also resides on the nuclear envelope and may play a critical role in the regulation of the expression of genes responsible for maintaining normal electrolyte balance and blood pressure.

Identification of X-Linked Alport Syndrome by Genetic Testing in a Girl Who Had Remained Undiagnosed After Two Kidney Biopsies Within a 10-Year Period

Yuko Fujii,[1] Hideki Matsumura,[1] Satoshi Yamazaki,[1] Tomoko Tanaka,[1] Akihiko Shirasu,[1] Hyogo Nakakura,[1] Kandai Nozu,[2] Kazumoto Iijima,[3] Akira Ashida.[1] [1]*Osaka Medical College, Takatsuki, Japan;* [2]*Kobe University, Kobe, Japan;* [3]*Dept. of Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Japan*.

Introduction: Girls with X-linked Alport syndrome (XLAS) are reported to show slower disease progression than boy patients, and most of them are asymptomatic carriers. Previous reports suggest that proteinuria begins at a median age of 7 years, finally resulting in end-stage kidney disease at a median age of 65 years. However, it is well known that the rate of disease progression in girls with XLAS cannot be predicted accurately, and that the clinical phenotype shows considerable variation, even among affected girls in the same family.

Case Description: We describe a girl with XLAS who showed hematuria and proteinuria in a kindergarten urine test at the age of one year, and who was followed up regularly thereafter. Her father had undergone kidney transplantation due to an unknown primary kidney disease when he was in high school. At the age of 7 years, the patient underwent initial kidney biopsy. Light microscopy revealed mesangial proliferation but an immunofluorescence study revealed no IgA deposition, and electron microscopy demonstrated no basement membrane abnormalities. The patient was therefore diagnosed as having non-IgA mesangial proliferative glomerulonephritis. As her proteinuria persisted at about urine protein-creatinine ratio; 0.5 g/gCr, therapy with a cocktail of prednisolone, mizoribine, warfarin, and dipyridamole was started at the age of 8 years, and this led to a gradual decrease of the proteinuria to 0.2 g/gCr. However, from the age of 13 years, the proteinuria and creatinine increased gradually to 1.0 g/gCr and 1.0 mg/dL, respectively, so we performed a second kidney biopsy which yielded results similar to the first one. Finally, at the age of 17 years, we conducted genetic testing of both the patient and her parents. This revealed that the patient had a heterozygous missense mutation in intron 7 of the *COL4A5* gene, and that her father was homozygous for the mutation.

Discussion: This girl showed relatively rapid progression of XLAS. Most girls with XLAS have no problem with ocular lesions or hearing, and those with decreased kidney function are very rare. Therefore, even today many clinical issues remain unclear, and diagnosis of XLAS in girls is sometimes very difficult without genetic testing.

SA-PO357

Spontaneous Remission of Genetic, Apparently Primary FSGS Presenting with Nephrotic Syndrome Challenges Traditional Notions of Primary and Genetic FSGS

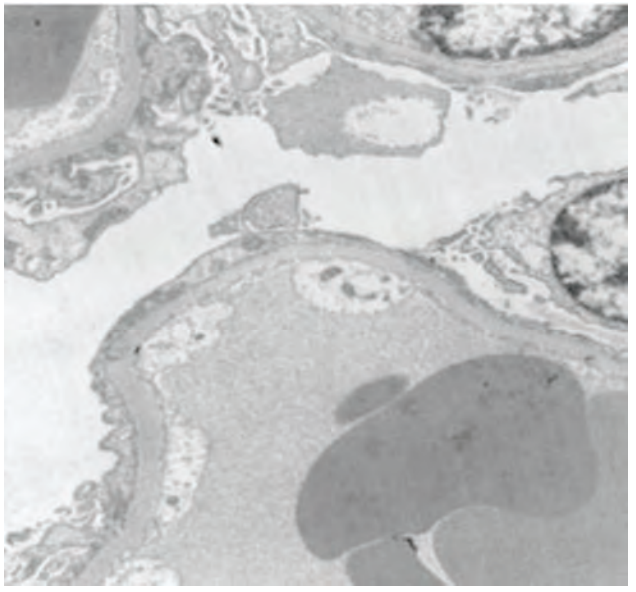
Swe Zin Mar Win Htut Oo,[1] Jayesh B. Patel,[1] Margaret E. Freese,[2] Christie P. Thomas.[3] [1]*Nephrology, University of Iowa, Iowa City, IA;* [2]*University of Iowa Hospitals & Clinics, Iowa City, IA;* [3]*University of Iowa College of Medicine, Iowa City, IA*.

Introduction: Focal segmental glomerulosclerosis (FSGS) presenting with nephrotic syndrome (NS) with focal sclerosing lesions and diffuse foot process effacement (FPE) is considered diagnostic of primary FSGS. KDIGO guidelines advise against genetic testing in adult idiopathic FSGS. We report a case of genetic FSGS that presented with NS and biopsy features of primary FSGS which resolved spontaneously.

Case Description: A 26-year-old healthy Caucasian female was referred for new onset NS. She had peripheral edema, a BP of 157/110 a urine protein creatinine ratio (UPC) of 9.04, a serum albumin of 2.3 mg/dl and a serum creatinine of 1.2 (eGFR 62). Other serological tests were negative. A kidney biopsy showed focal, segmental sclerosis in 2 of 47 glomeruli with diffuse FPE on EM consistent with primary FSGS. She declined corticosteroid treatment. She was treated with lisinopril/furosemide. Genetic testing showed a missense variant (p.Asn125Ser) in TRPC6. This missense variant is ultrarare, is predicted pathogenic and was previously reported in two pedigrees with FSGS with demonstrated gain of function *in vitro*. We continued conservative therapy and 8 months after diagnosis she has had complete remission with her UPC declining to 0.67, serum albumin improving to 4.3 and serum creatinine to 0.9 (eGFR 88).

Discussion: Most authors differentiate primary FSGS from all other causes including genetic and adaptive forms of FSGS. Our case demonstrates that genetic FSGS cannot be

differentiated clinically from primary FSGS and can undergo spontaneous remission. Given prognostic and therapeutic implications, we suggest that genetic testing be performed in any young adult with FSGS prior to a therapeutic trial with high dose steroids.



SA-PO358

X-Linked Alport Syndrome Caused by Synonymous Mutation, p.Pro-786Pro Inducing Incomplete Aberrant Exon Skipping in COL4A5

Yuya Aoto,[1] Kandai Nozu,[1] Tomoko Horinouchi,[1] Nana Sakakibara,[1] China Nagano,[1] Tomohiko Yamamura,[1] Yuko Shima,[2] Koichi Nakanishi,[3] Kazumoto Iijima.[1] *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan, Kobe, Japan; [2]Wakayama Medical University, Wakayama City, Japan; [3]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan*.

Introduction: X-linked Alport syndrome (XLAS) - a progressive hereditary kidney disease caused by mutations in COL4A5 gene coding type IV collagen α5 chain (α5(IV)), with the median age of developing end-stage renal failure in male XLAS patients of 25 years, and 70 or 90% of the patients had reached ESRD before the age 30 and 40 years, respectively. Additionally, patients with truncating mutations tend to show severe phenotypes.

Case Description: Two male siblings with mild phenotypes whose mother had hematuria, now 43, and 34 years old; both had hematuria since childhood. Their proteinuria appeared at 33, and 20 years, respectively. The elder recently developed ESRD, and the younger is still CKD-stage III b. The younger's kidney biopsy at 31 years of age, showed a thin glomerular basement membrane and normal α5(IV) expression. Gene analysis revealed both possessing only a novel hemizygous synonymous variant of c.2358A>G (p.Pro786Pro) in COL4A5 exon 29 among all 3 genes responsible for Alport syndrome. Further transcript analysis revealed this single base substitution caused aberrant splicing of exon 29 complete skipping which was shown both in peripheral lymphocytes and urinary sediments. Exon 29 is constituted by 151bp and the skipping of this exon leads to a frameshift mutation at the transcript level and supposed to be showing severe phenotypes. However, a small amount of normally spliced transcript was also detected in the transcript from urinary sediments which might be because of incomplete aberrant splicing by the variant.

Discussion: The synonymous mutation can cause aberrant splicing in COL4A5. However, relatively mild phenotypes were led by the presence of a small amount of normally spliced transcript along with aberrant splicing. By this normal transcript, α5(IV) expression was positive on glomerulus. In conclusion, synonymous mutations can have pathogenicity by causing aberrant splicing. Additionally, normal transcript production along with the aberrantly spliced transcript prevents the patients from presenting severe phenotype. Accurate genetic diagnosis would be required to elucidate the onset mechanism by synonymous variants or presentation of atypically milder phenotypes.

SA-PO359

A Novel Aquaporin 2 Insertion Mutation in a Chinese Family with Autosomal Dominant Nephrogenic Diabetes Insipidus and Chronic Renal Failure

Ping-Huang Tsai, Chih-Jen Cheng, Shih-Hua P. Lin. *Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan*.

Introduction: Mutations in aquaporin 2 (AQP2) cause mostly autosomal recessive or rarely autosomal dominant nephrogenic diabetes insipidus (NDI). Patients with autosomal dominant NDI usually exhibit less phenotype and have mutations in the carboxyl-terminal tail important intracellular routing of the AQP2. We described a family of autosomal dominant NDI carried a novel AQP2 mutation but presented a severe phenotype, which led to early-onset renal failure.

Case Description: A 26-year-old Chinese female manifested polyuria, polydipsia, and nocturia after birth. Her family history was non-revealing. She did not have non-obstructive hydronephrosis and never received NSAID or thiazide to treat her polyuria. Pertinent laboratory investigations showed abnormal renal function with serum creatinine 3.4 mg/dL, and hyperchloremic metabolic acidosis (chloride 115, HCO_3^- 19 mmol/L), persistently low urine osmolality (around 50-100 mOsm/kg.H_2O) and markedly increased serum von Willebrand factor and coagulation factor VIII in response to desamino-8-D-arginine AVP (DDAVP) test. Direct sequencing of *AVPR2* and *AQP2* gene showed two nucleotide GC insertion at c.755 of AQP2, resulting in a frameshift mutation (p.R253Dfs*82, +52 AA) and altering the amino acid sequence between R254 to A271. Of note, her one-year-old son also exhibited severe polyuria two days after birth and was found carrying the same mutation.

Discussion: We presented the first autosomal dominant NDI family with a severe phenotype, including early-onset polyuria in the neonatal period and renal failure in early adulthood. The functional experiment focusing on autosomal dominant AQP2 mutations in the C-terminal end is warranted.

SA-PO360

A Case of Classical Fabry Disease due to De Novo GLA Genetic Mutation That Showed Characteristic Findings in Both Renal and Nerve Biopsy

Mimiko Matsumura,[1] Rie Uni,[2] Akira Shimizu,[3] Hideki Takano.[1] *[1]Tokyo Teishin Hospital, Chiyoda-ku, Japan; [2]University of Tokyo, Tokyo, Japan; [3]Nippion Medical School, Tokyo, Japan*.

Introduction: Fabry's disease (FD) is an X-linked lysosomal storage disorder due to mutations in the alfa-galactosidase A(GLA). Most cases are related to GLA inherited mutations, cases of de novo onset occur rarely.

Case Description: A 53-year-old man has been pointed out proteinuria for 20 years, but the reason had been unclear. When he was 50 years old, he suffered from sick sinus syndrome and has been fitted pacemaker. 3 years later, his serum creatinine got worse to 1.5 mg/dl and urine protein 1.5 g/gCr. Kidney biopsy was done and diagnosed as FD due to de-novo GLA mutation (R112C). Enzyme replacement therapy (ERT) using agalsidase-alfa was started and the concentration of Lyso-Gb3 went down for 2 months. But his left leg's sensory neuropathy was obvious and nerve biopsy also showed peripheral neuropathy that could match to FD. Switching from agalsidase-alfa to agalsidase beta could lead to decrease the concentration of Lyso-Gb3.

Discussion: In Japanese FD's patient, genetic GLA de novo mutation is rare. After starting ERT, evaluation of organ damage is necessary, and if there were any problems, switching therapy may be suggested. There are few cases which both kidney and neuro biopsy were done. These findings emphasize the importance of early diagnosis, genetic analysis, and selecting appropriate enzyme replacement therapy to prevent irreversible organ damage that occurs during the course of the disease. In conclusion, early diagnosis, evaluating organ damage, and adequate ERT may be necessary for FD's patient to decrease Lyso-Gb3 that would be associated with good prognosis.

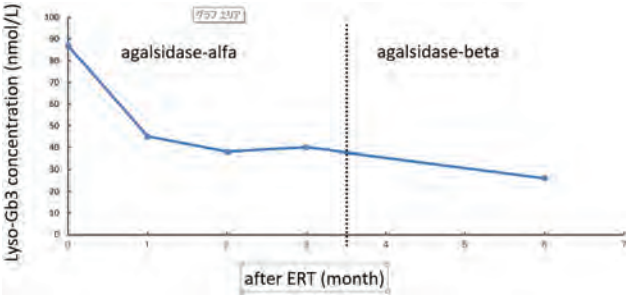


Figure 1 Lyso-Gb3 concentration after starting ERT

SA-PO361

An Unusual Case of Diffuse Proliferative Lupus Nephritis Presenting with Predominant C1q Deposition and No IgG Deposits That Is Responsive to Treatment

Samer Kareem,[1] Jay A. Pandav,[2] Michael Connery,[2] Sanjeev Gupta.[3] *[1]Nephrology, Westchester Medical Center, Valhalla, NY; [2]Westchester Medical Center, Valhalla, NY; [3]Westchester county medical center, Hartsdale, NY*.

Introduction: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disease, with nephritis as one of the most striking manifestations. Renal biopsy usually reveals glomerular deposits that stain predominantly for IgG and contain co-deposits of IgA, IgM, and C3. It is rare to have C1q as a dominant deposit with no IgG deposits on renal biopsy. We are presenting a case of lupus nephritis with predominant C1q deposits.

Case Description: 34-years-old female with history of idiopathic thrombocytopenia (10 years ago), SLE (1 year ago), antiphospholipid syndrome with history of stroke and one 2nd trimester miscarriage admitted with dyspnea, fever and AKI and suspicion of thrombotic thrombocytopenic purpura. Laboratory work up showed serum creatinine (SCr) of 2.13mg/dl, low complements C3/C4, positive cardiolipin IgM, anti-dsDNA and lupus anticoagulant. UA was positive for 2+ blood and 3+ protein with urine protein to

creatinine ratio of 3.2. Echocardiogram was suggestive of libman sachs endocarditis. Patient underwent kidney biopsy which revealed endocapillary proliferative GN (class IV lupus). It was negative for IgG but had 3+ C1q deposits, 2+ C3, 1+ IgA and trace IgM deposits. The patient was started on methylprednisone & mycophenolate and within a month her SCr returned to baseline with complete resolution of proteinuria and hematuria.

Discussion: C1q nephropathy is considered to be a variant of FSGS. It presents as mesangial proliferation with prominent C1q deposits on immunofluorescence microscopy and negative lupus serology. It typically has a poor response with immunosuppression. On the contrary, lupus nephritis presents as a 'full house pattern' with predominant IgG deposits. Our patient with predominant capillary and mesangial C1q deposits in lupus nephritis hasn't been described in the literature hence clinician needs to be aware that C1q deposits can be a variant of lupus nephritis and can be very responsive to immunosuppression.

SA-PO362

Tubulointerstitial Nephritis and Uveitis Unmasked by Decreasing Anti-TNF Alpha

Maria Clarissa Tio,[2] Pui Susan W. Cheung.[1] [1]*Massachusetts General Hospital, Boston, MA;* [2]*Brigham and Women's Hospital, Massachusetts General Hospital, Boston, MA.*

Introduction: Tubulo-interstitial nephritis and uveitis (TINU) is characterized by ocular and renal manifestations, and it could be associated with autoimmune, genetic, vascular, medication, and paraneoplastic etiologies. Here we present a case of TINU unmasked by decreasing anti-TNF alpha agent adalimumab.

Case Description: 55-year-old Caucasian male with history of hypertension on lisinopril and psoriatic arthritis on adalimumab admitted for acute renal failure. Four weeks prior to admission, patient presented to the ophthalmology clinic with sudden onset and progressively worsening bilateral blurring of his vision with symptomatic central vision loss. At that time, he was found to have a localized macular detachment with yellow choroidal lesions, and managed conservative with weekly follow up. Notable recent medication change was dose reduction of adalimumab from 40mg to 20mg every other week in the past year due to improvement of joint symptoms. On the day of admission at ophthalmology clinic, he was found to have an increase in retinal fluid and bilateral serous detachment with yellow/white choroidal lesions in the peripheral macula and fovea consistent with atypical uveitis. Routine labs showed sCr 12.3mg/dL (baseline 1.1 mg/dL 4 months ago), K 7.1mEq/L, HCO3- 14mEq/L, BUN 80mg/dL. Urinalysis showed 1+ leukocyte esterase, no blood or protein, urine microscopy showed WBC clumps. Despite medical management, and robust urine output, repeat K was 8.5 mEq/L required emergent hemodialysis. He was also initiated on prednisone for concerns of acute interstitial nephritis. Renal biopsy revealed acute interstitial nephritis with mononuclear cells and focal clusters of eosinophils. Other serologies showed CRP 23.7mg/L, ACE <5U/L, Lysozyme 9.9mcg/mL, ANA positive at 1:160, speckled, IgG4 negative. CT was negative for malignancy. His vision improved significantly after the first dose of prednisone. HD was discontinued on day 4 of admission, and prednisone was tapered over months. Discharge sCr was 6.76mg/dL and 2 weeks post discharge was 1.8mg/dL.

Discussion: In patient with TINU, uveitis can present as vision loss without apparent inflammation, and it often presents separately from interstitial nephritis. This patient has atypical posterior uveitis and biopsy-proven AIN consistent with TINU, likely unmasked by tapering of adalimumab.

SA-PO363

Syphilis-Associated Idiopathic Nodular Glomerulosclerosis

Sanjay A. Chandrasekhar, Sumit Gupta, Octavio Chavez, Elias Doumit, Claude Bassil. *University of South Florida, Winter Haven, FL.*

Introduction: Idiopathic nodular glomerulosclerosis (ING) is a rare entity in non-diabetics with a similar appearance on biopsy to diabetic nephropathy. ING has been associated with hypertension, dyslipidemia, and cigarette smoking; however, there is no known association with syphilis. Here we present a case of possible latent syphilis associated ING.

Case Description: A 73-year-old non-diabetic male with history of urothelial carcinoma, chronic kidney disease stage III, and mild hypertension presented due to worsening lower extremity swelling. Initial creatinine was elevated at 2.2 mg/dL. Urinalysis was notable for large blood and protein. Workup revealed urine protein of 6939 mg. Serologic workup was negative including C3, C4, ANA, dsDNA, ANCA, Hep B/C, and monoclonal antibodies. Of note, rapid plasma reagin and fluorescent treponemal antibody were positive. The patient was without signs of syphilis with a diagnosis of latent syphilis made. Light microscopy noted interstitial fibrosis, tubular atrophy, and globally sclerotic glomeruli. Immunofluorescence staining highlighted linear IgG accentuation. Electron microscopy revealed foot process effacement, increased mesangial matrix, and swollen endothelial cells. He was diuresed and discharged with continued follow-up in clinic with control of symptoms.

Discussion: ING presents in non-diabetics likely due to the formation of advanced glycation end products, angiogenesis, and altered renal hemodynamics. ING has an association with cigarette smoking, hypertension, dyslipidemia, and obesity. Our patient did not have a history of diabetes or smoking and was found to have markers positive for syphilis. Manifestations of syphilitic renal disease include but are not limited to membranous glomerulonephritis, focal segmental glomerulosclerosis, minimal change disease, and interstitial nephritis. However, a review of the literature has not shown a case of syphilis associated ING. ING is most commonly seen with cigarette smoking with concurrent hypertension. However, other pathophysiologic factors cannot be excluded. Given the new diagnosis of syphilis, syphilitic involvement must be considered as an etiology in conjunction with underlying mild hypertension given lack of diabetes history. While it cannot be shown that syphilis is responsible, clinical awareness of the possibility may allow for further identification of cases in the future.

SA-PO364

Thrombotic Microangiopathy as the Presenting Feature of Newly Diagnosed HIV Infection Treated with Eculizumab

Milagros Yunes, James M. Pullman, Molly Fisher. *Montefiore Medical Center, Bronx, NY.*

Introduction: Thrombotic microangiopathy (TMA) is a known complication of HIV infection. HIV infection precipitates endothelial injury and has been associated with increased complement activation. It may also trigger the onset of atypical HUS in patients with genetic predisposition. We present a case of severe kidney failure due to TMA in the setting of newly diagnosed HIV infection which was successfully treated with eculizumab.

Case Description: 58-year-old Hispanic male with history of hypertension presented with 1 month of diarrhea, lower extremity edema and oliguria. Initial labs revealed a serum creatinine 9.0 mg/dL, albumin <2.0 g/dL, urine protein/creatinine 8 g/g, platelet count 103,000, hemoglobin 7.9 g/dL, LDH 619 U/L and schistocytes on peripheral smear. Workup revealed newly diagnosed HIV/AIDS with a CD4 count of 40 cells/uL, viral load of 124,000 copies and coinfection with hepatitis B. Kidney biopsy demonstrated chronic active TMA with focally positive c4d staining of the glomerular capillaries and acute tubular necrosis. ADAMTS13 was normal and stool Shiga toxin was negative. He was found to have CMV viremia but immunostaining for CMV on kidney biopsy was negative. Genetic testing for complement abnormalities revealed a complement factor H receptor 5 variant of unknown significance but was otherwise negative. The patient was dialysis dependent at presentation. He was initiated on antiretroviral therapy and started on eculizumab infusions every 2 weeks for treatment of HIV-associated TMA. Although his CD4 count remained low at 70, his HIV viral load became undetectable, his hematologic parameters improved and creatinine clearance improved to 25 mL/min leading to discontinuation of dialysis after 2 months.

Discussion: In the modern era of antiretroviral therapy, TMA is a rare complication of HIV infection. Because uncontrolled HIV infection has been associated with increased complement activation, we hypothesized that HIV infection triggered dysregulation of complement activity in our patient and that treatment with eculizumab would be beneficial. Although our patient did not have a common gene mutation associated with atypical HUS, treatment with eculizumab in conjunction with ART resulted in hematologic remission as well as improvement in kidney function and discontinuation of dialysis.

SA-PO365

Hypocupremia: Cause or Effect of Nephrotic Syndrome?

Ahlim Al sanani, Sheena Surindran. *Marshall University SOM, Huntington, WV.*

Introduction: Nephrotic syndrome is well known to cause urinary loss of several factors including trace elements. Conversely, a rare association of copper deficiency with nephrotic syndrome (NS) has been reported in the literature with possible improvement in NS with correction of deficiency. Here we report an unusual presentation of Focal Segmental Glomerulosclerosis (FSGS) with worsening peripheral neuropathy and bicytopenia.

Case Description: A 57- year- old Caucasian female with history of hypertension, lower extremity edema and peripheral neuropathy of unknown etiology for several months admitted to the hospital for work up after outpatient testing revealed neutropenia and severe anemia. Hemoglobin on admission was 7.5g/dl (baseline hemoglobin of 12g/dl 6 months prior), WBC count of 1.5 x 109/L with absolute neutrophil count (ANC) of 0.4 x 10^9/L. Physical exam was unremarkable except for palor and sensory neuropathy lower extremities. Initial work up for bicytopenia was negative for evidence of hemolysis. Bone marrow biopsy showed megaloblastoid appearance. As part of megaloblastic anemia work up, levels of vitamin B12, folate, and zinc were within normal limits. However, serum Copper level was extremely low at 8 microgram/dl (72-166 microgm/dL). Urinalysis on admission with a bland urine and more than 300 mg/dl protinuria. Spot urine protein to creatinine ratio (UPC) of 14g/g, 24-hour urine protein excretion of 9 gram. Serum creatinine 0.5 mg/dl, serum albumin of 1.6 g/dl, and Triglyceride 232 mg/dl. Work up for NS included negative Hepatitis A, B and C panel, HIV, Syphilis T. Palladium antibodies, ANA, and Normal Complements levels. Copper gluconate supplement resulted in normalization of her anemia and leukopenia. Proteinuria improved from 9 grams to 6.8 grams after normalization of copper levels. A random kidney biopsy showed FSGS. Prednisone was started at 1 mg/kg daily with improvement in UPC ratio to 2.4g/g from 6.8g/g and serum albumin to 3.2 g/dl from 1.6g/dl at 12 weeks.

Discussion: FSGS is a diverse syndrome from several causes- some known and others unknown. There has been reports of urinary copper excretion correlated with urinary protein excretion in animal models. In our patient, severe copper deficiency likely explained sensory neuropathy and bicytopenia. It is open to debate weather NS started initially with urinary loss of copper leading to deficiency or copper deficiency exacerbated FSGS.

SA-PO366

Nephrocalcinosis Secondary to Excessive Oxalate Ingestion

Mengyao Tang, Jerald Cherian, Matthew Day, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Deposition of calcium oxalate or calcium phosphate within the renal medulla can lead to nephrocalcinosis. This most often occurs in the setting of hypercalciuria with or without hypercalcemia, but in rare instances, may occur due to hyperoxaluria. In the majority of cases, nephrocalcinosis is asymptomatic without progression to end stage renal disease, unless the underlying cause is left untreated. We present a case of renal failure secondary to nephrocalcinosis in the setting of prolonged secondary hyperoxaluria.

Case Description: A 68 year-old male with well-controlled hypertension presented to the emergency department after routine lab work at a yearly primary care visit revealed potassium 6.1 mEq/L, BUN 103 mg/dL, and creatinine 12.3 mg/dL. Corrected serum calcium was 8.2 mg/dL and 25-hydroxy vitamin D was 46.1 ng/mL. Two years prior to presentation, creatinine was 0.9 mg/dL, but had risen to 2.36 mg/dL one year prior to presentation. Four years prior to presentation, the patient had started a new diet consisting mainly of green beans, turnip greens, and broccoli. Review of previous urinalyses showed multiple instances of calcium oxalate crystals in his urine. Renal ultrasound showed decreased renal size bilaterally, as well as, bilateral non-obstructing renal calculi. CT abdomen and pelvis demonstrated bilateral nephrocalcinosis, likely secondary to hyperoxaluria in the setting of prolonged excessive dietary oxalate intake. Despite conservative medical management including initiation of a low oxalate diet, the patient did not recover renal function and became dialysis dependent.

Discussion: Once nephrocalcinosis is diagnosed, it is imperative to determine the underlying cause as to guide management. If standard laboratory testing does not reveal a cause, such as hypercalcemia or renal tubular acidosis, there should be increased suspicion for hyperoxaluria. Although secondary hyperoxaluria is most often due to fat malabsorption, a careful dietary history should also be taken to evaluate for chronic ingestion of excessive amounts of oxalate (e.g. rhubarb, spinach, green beans, etc.) or oxalate precursors (e.g. vitamin C), as highlighted by this case. In patients with secondary hyperoxaluria, dietary oxalate intake should be minimized, while calcium and fluid intake should be liberalized. If treated promptly, renal function often recovers.

SA-PO367

Fatal Hyperammonemia due to an Underlying Urea Cycle Disorder Unmasked by a High-Protein, Ketogenic Diet

Mina Sourial,[1,2] Maryanne Sourial,[1,2] Molly Fisher.[1,2] *[1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Introduction: Late-onset manifestations of urea cycle disorders may be difficult to recognize and if left untreated can lead to devastating, life threatening consequences. We present the tragic case of a young man who presented with acute hyperammonemic encephalopathy due to ornithine transcarbamylase (OTC) deficiency unmasked by a high protein, ketogenic diet.

Case Description: A 30-year-old male with no significant medical history presented with altered mental status. He was an avid hiker with recent tick exposure. Two months previously, he started a ketogenic diet and was taking high dose protein shakes and anabolic mimetics to build muscle. Initial workup including computed tomography (CT) of the head, magnetic resonance imaging of the brain, electroencephalography, urine toxicology screen, cerebrospinal fluid culture for bacterial meningitis and tick borne illness was negative. He was found to have an ammonia level of 215 umol/L with no evidence of liver failure and undetectable alcohol level. He received one hemodialysis session but quickly deteriorated, developing seizures requiring intubation and mechanical ventilation. Repeat ammonia level worsened to 430 umol/L and repeat CT head showed diffuse cerebral edema with impending herniation. He was treated with hypertonic saline, mannitol, an extraventricular drain was placed, and he was initiated on continuous-renal replacement therapy. Despite improvement in ammonia level to < 20 umol/L, the patient failed to make a meaningful neurologic recovery. Genetic testing for an underlying urea cycle disorder revealed OTC deficiency.

Discussion: Urea cycle defects result in the ability to breakdown protein and eliminate nitrogenous wastes, resulting in hyperammonemia. Symptoms vary from poor appetite, somnolence, and behavioral disturbances to rapid neurologic deterioration including seizures, coma, and death if not promptly recognized and treated. Although urea cycle disorders typically present shortly after birth, partial defects may manifest in adulthood in the context of increased catabolic stress. A high index of suspicion and rapid initiation of hemodialysis to remove ammonia is critical for a favorable outcome. We believe our patient's high protein diet and use of anabolic mimetics precipitated a hyperammonemic crisis in the setting of mild OTC deficiency which unfortunately proved fatal.

SA-PO368

Not All Severe Lactic Acidosis Implies an Ominous Prognosis

Nihal M. Ali, Jorge L. Castaneda. *UMC, Ridgeland, MS.*

Introduction: Glycogen Storage Disease (GSD) type 1, also knows as Von Gierke Disease is an inherited disorder caused by deficiencies of specific enzymes in the glycogen metabolism pathway. It comprises 2 major subtypes GSD 1a (deficiency of the enzyme Glucose 6 Phosphatase) and GSD 1b (deficiency of the transporter enzyme, Glucose 6 phosphatase translocase G6PT. GSD 1a results from mutation in G6PC gene on chromosome 17q21 that encodes G6Pase. GSD 1b results from mutations of SLC 37A4 gene on chromosome 11q23.3. Incidence is 1/100,000.

Case Description: This case is of 27 years old white female who was referred to clinic initially due to the following complaint metabolic acidosis and proteinuria of 3 gr/ 24 hr. Based on chart review, she has chronic lactic acidosis between 8-12 mmol/L and subsequent GAP metabolic acidosis. In addition, she has persistent hyperuricemia, hyperglycemia and hypertriglyceridemia. She used to have hypoglycemic episodes during childhood, however she has developed chronic pancreatitis and hyperglycemia due to glycogen deposition.

Discussion: GSD leads to accumulation of Glycogen and fat in the in Liver, kidney and intestinal mucosa is the final result. Initial laboratory findings include hypoglycemia, lactic acidosis, hyperuricemia, hypercholesterolemia and hypertriglyceridemia. Non-invasive molecular genetic testing that includes full gene sequencing of G6PC is preferred for making the diagnosis. Gene sequencing analysis has a detection rate of up to 100% however may miss certain mutations. Liver Biopsy has been also performed to demonstrate the glycogen deposition. Renal failure may occur from primary tubular or glomerular dysfunction. Glomerulosclerosis and podocytopaties have been described previously. The main targets for the management are the prevention of acute metabolic derangements, prevention of acute and long-term complications, attainment of normal psychological development and good quality of life. The main goal of this presented case that even though lactic acidosis is usually associated with poor short-term outcomes, the knowledge of metabolic pathways will help to approximate unusual etiologies of lactic acidosis in the adult population.

SA-PO369

Pharmacologic Management with Sodium Phenyl Acetate/Sodium Benzoate with or Without Dialysis for the Treatment of Hyperammonemia: A Case Study

Zubair B. Saeed Zafar,[1] Kostas Papamarkakis,[2] Whitney E. Besse.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT.*

Introduction: Hyperammonemia is an underrecognized indication for emergent renal replacement therapy in patients with inborn errors of metabolism. Duration of hyperammonemia correlates with neurologic consequences: seizures, intracranial hypertension, cerebral edema, and herniation. Dialysis decreases ammonia levels acutely, but has associated risks. Additionally, sodium phenylacetate/sodium benzoate is an FDA approved ammonia scavenger for treatment of hyperammonemia in patients with inborn errors of metabolism. There is no current study comparing the effectiveness of ammonia scavengers and dialysis for the acute management of hyperammonemia in adult patients. We present a case in which both treatments were utilized.

Case Description: The patient is a 21-year-old man with a diagnosis of pyruvate decarboxylase deficiency type A on chronic tube feeds who presented with lethargy after one loose bowel movement. Initial workup revealed a lactic acid of 5mmol/L, ammonia level of 447mmol/L, and creatinine of 0.6mg/dL. On exam, the patient had no focal motor or sensory deficits but was agitated and combative. A central venous line was placed for dialysis access and he underwent 2.5 hours of hemodialysis followed by approximately 12 hours of central venovenous hemodiafiltration, in addition to IV dextrose-containing fluids. The ammonia level fell to 34mmol/L. In consultation with the Genetics service, intravenous sodium phenylacetate with sodium benzoate were started and maintained normal levels of ammonia while his home feeding regimen was adjusted. Two weeks later, the patient was readmitted to the ICU with a similar presentation and serum ammonia level of 338mmol/L. This time, sodium phenylacetate with sodium benzoate was initiated rapidly. Ammonia levels were decreased to 47mmol/L over 7 hours without requiring dialysis.

Discussion: This case highlights the potential effectiveness of sodium phenylacetate/sodium benzoate. These ammonia scavengers combine with amino acids to form alternative products for urinary nitrogen excretion. While therapy with hemodialysis should be pursued, patients with normal renal function may achieve rapid resolution of hyperammonemia with volume resuscitation, feeding, and administration of sodium phenylacetate/sodium benzoate as a low risk and cost-effective treatment strategy.

SA-PO370

A Rare Cause of Resistant Hypertension

Amardeep Singh,[2] Atul Bali.[1,2] *[1]Nephrology, UVA Dialysis, Farmville, VA; [2]Nephrology, Centra Medical Group, Farmville, VA.*

Introduction: Resistant hypertension is defined as suboptimally controlled blood pressure despite concurrent use of three antihypertensive agents of different classes, including a diuretic. A thorough evaluation for secondary causes of hypertension is crucial to allow timely institution of treatment to limit end-organ damage and associated morbidity and mortality.

Case Description: A 66-year-old African American gentleman was referred for evaluation of uncontrolled hypertension and declining renal function. His antihypertensive regimen consisted of maximal doses of Valsartan, Verapamil ER and Clonidine. Diuretics were being held due to persistent hypokalemia despite potassium supplementation. Family history was notable for his father succumbing to renal failure of unclear etiology at age 50, his sister passing from her ESRD, and his mother having well controlled hypertension. Physical exam was otherwise unremarkable, with the patient appearing euvolemic. Lab review suggested progressive decline in GFR, equating to CKD stage 3 with minimal proteinuria, with mild but persistent hypokalemia and metabolic alkalosis. An arterial blood gas confirmed chronic metabolic alkalosis. Both plasma renin activity and aldosterone were undetectable. Based on the above findings, a diagnosis of Liddle syndrome was made. Amiloride was started and gradually uptitrated. He had a reassuring response to treatment which translated into stability of his GFR (Figure 1).

Discussion: Liddle Syndrome is a rare autosomal dominant disorder associated with a gain-of-function mutation involving the epithelial sodium channels, which mimics the manifestations of hyperaldosteronism, without a demonstrable elevation in serum aldosterone. Our case illustrates the benefits of prompt diagnosis and treatment to arrest the progression of hypertension mediated end-organ damage.

Amphetamine Toxicity Mimicking Pheochromocytoma

Amardeep Singh,[1] Atul Bali.[2,1] *[1]Nephrology, Centra Medical Group, Farmville, VA; [2]Nephrology, UVA Dialysis, Farmville, VA.*

Introduction: Pheochromocytoma is a catecholamine-secreting tumor with about 95% of the tumors located in the abdomen. A typical patient will present with the classic triad of episodic headaches, sweating, and tachycardia. Interestingly, patients with amphetamine toxicity can also present with a comparable clinical picture and differentiating the two can be a challenging conundrum.

Case Description: A 50-year-old Caucasian female with a history of nonepileptic seizure disorder presented to the ER with chest pain, nausea, and vomiting. She was found to be markedly hypertension with associated supraventricular tachycardia (SVT) which did not respond to intravenous adenosine or to cardioversion. She was placed on esmolol infusion, with improvement in heart rate. However, the patient developed acute pulmonary edema resulting in respiratory failure needing intubation and mechanical ventilation. Despite esmolol infusion, she had persistent hypertension with the systolic blood pressure in the 200s and was started on nitroglycerin infusion concomitantly. The resistant nature of hypertension led to concern for pheochromocytoma, and on further evaluation, she was found to have elevated urinary catecholamines, metanephrines, and vanillylmandelic acid. However, urine drug screen was also positive for amphetamines. One week after presentation, repeat testing of urinary and serum catecholamines showed marked reduction in these values. MRI of the abdomen (adrenal protocol) showed no concerning solid lesions. She was eventually tapered off the infusions and started on low dose oral metoprolol, primarily with the intent of preventing recurrence of SVT. These findings led to the conclusion that the patient's symptoms and laboratory findings were secondary to amphetamine toxicity.

Discussion: This case illustrates the strikingly similar presentations of amphetamine toxicity and pheochromocytoma, and highlights the importance of a good history, along with work up, to be able differentiate between two conditions with remarkably different clinical implications.

SA-PO372

Invasive Primary Mucormycosis: Renal Rhizopus

Tina Bui,[3] Christopher H. Girgis,[1] Pranay Kathuria.[2] *[1]Division of Nephrology, The University of Oklahoma - Tulsa, Tulsa, OK; [2]The University of Oklahoma College of Medicine, Tulsa, OK; [3]University of Oklahoma Internal Medicine, Tulsa, OK.*

Introduction: Mucormycosis is a known entity among diabetics and immunosuppressed patients. There are cases where the mucormycosis spectrum can involve individual organs, and in this case, the renal system. Treatment is difficult as this fungus is angio-invasive and can cause tissue infarction, which limits antifungal penetration to the affected tissues. The choice of antifungal therapy has traditionally been set to amphotericin B in regards to mucormycosis, whether in systemic or focal disease. However, in this case, posaconazole was a successful alternative treatment option to amphotericin.

Case Description: A 49 year white male with chronic kidney disease, uncontrolled diabetes, and a history of IV drug use presented to urgent care with right flank pain, dysuria, and hematuria, sent home with a subsequent visit to the emergency department. Hydronephrosis was noted on the right kidney and a ureteral stent was placed by urology. 2 weeks later, the patient followed up with urology to undergo uretero-renoscopy. However, this was postponed 2 weeks due to severe hyperglycemia. The patient underwent the uretero-renoscopy, revealing amorphous material within the right renal pelvis. MRI revealed a fungus ball with 60 percent of the volume of the right renal parenchyma consistent with pyelonephritis, as well as poor blood flow consistent with renal infarction. Biopsy revealed Rhizopus species, with repeat renal biopsy demonstrating fungal colonization. Urine and blood cultures were negative. The patient was started on posaconazole, as opposed to amphotericin B, due to a relatively normal left kidney and overall clinical stability. Due to the vascular and parenchymal invasion, nephrectomy was performed with pathology demonstrating extensive fungal pyelonephritis with abscesses. The patient continued with oral posaconazole for any microscopic remnants of the fungus for six weeks and did well with monitoring of CKD and diabetes.

Discussion: In most cases of reported isolated renal Rhizopus, amphotericin and nephrectomy are standard of care with an azole anti-fungal used as step down therapy or therapy in which the patient does not respond to amphotericin. With utilization of both posaconazole and nephrectomy, alternative to amphotericin B, the patient was able to maintain stable residual kidney function in an infection associated with high mortality and was successfully treated for isolated mucormycosis of the rhizopus group.

SA-PO373

Monoclonal Gammopathy of Renal Significance: Not Just a Disease of the Old

Bethany Roehm, Cindy Varga, Lesley Inker. *Tufts Medical Center, Boston, MA.*

Introduction: Immunotactoid glomerulopathy is a rare finding on kidney biopsy, reported in 0.06-0.1% of biopsies. It is characterized by subepithelial and subendothelial microtubules made of immunoglobulin deposits. Without clinical findings suggestive of lupus or cryoglobulinemia, monoclonal gammopathy of renal significance (MGRS) should be considered. MGRS can be caused by any B cell or plasma cell clonal proliferative disorder. Less than 2% of those diagnosed with monoclonal gammopathy of undetermined significance (MGUS) are under the age of 40 years. Of all patients with MGUS, 1.5% have MGRS.

Case Description: This is a 26 year old man who presented for evaluation of proteinuria and hematuria, found incidentally during work-up for an acute episode of diarrhea that subsequently resolved. Initial UPCR and UACR were 977 mg/g and 740 mg/g, respectively. Past medical history was notable only for "ear problems" requiring Eustachian tubes as a child. He was not on any medications or supplements. Blood pressure was 143/89, but there were no other abnormalities on physical exam. Complements, anti-dsDNA Ab, and CBC were normal. eGFR was 125 ml/min/1.73m^2. SPEP and UPEP were not initially done as he was deemed low risk for harboring a plasma cell dyscrasia at his age. Kidney biopsy showed immunotactoid glomerulopathy with dominant IgG Kappa. SPEP and UPEP with IFE were then done and neither showed any monoclonal bands. Bone marrow biopsy showed rare polytypic plasma cells with a small kappa-restricted plasma cell population on flow cytometry. Given his young age and the natural history of MGRS, the plan is to treat with plasma cell directed chemotherapy.

Discussion: MGRS can occur in younger patients presenting with proteinuria. When evaluating young patients with proteinuria, a broad differential should be considered. The most common causes in adults are diabetes, amyloidosis, lupus, minimal change disease, membranous nephropathy, and FSGS. We also considered IgA nephropathy and Alport's syndrome. MGRS was low on our differential, yet kidney biopsy showed immunotactoid glomerulopathy due to MGRS despite negative SPEP and UPEP. Kidney biopsy was key in obtaining a diagnosis in our patient. It is important even in young patients not to rule out potentially treatable causes of kidney disease based on age.

SA-PO374

A Unique Case of Malakoplakia of the Kidney

Manognya Muttineni,[1] Timothy A. Sutton,[1] Elizabeth Taber-Hight,[2] Richard N. Hellman.[3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University, Zionsville, IN; [3]Indiana University Division of Nephrology, Indianapolis, IN.*

Introduction: Malakoplakia is a rare inflammatory condition that has a gross and microscopic appearance resembling xanthogranulomatous pyelonephritis but with distinctive Michaelis-Gutmann bodies on pathology. Malakoplakia can affect any organ system but genitourinary tract involvement is the most common, particularly in immunocompromised individuals. We are presenting a unique case of malakoplakia presenting with AKI requiring dialysis and our treatment approach.

Case Description: A 40yo Caucasian female presented to a local hospital with altered mental status. She had a history of tobacco, alcohol, and cocaine abuse. There was no history of IV drug abuse or prior urinary tract infections. She was found to be in septic shock due to Escherichia coli bacteremia from a UTI that progressed to multiorgan failure requiring ventilatory support and AKI (SCr=7.2) that required renal replacement therapy. UA demonstrated pyuria and proteinuria. Renal US showed bilaterally enlarged kidneys. Clinical status improved with antibiotic treatment although there was no recovery in kidney function and fevers persisted. Renal biopsy was performed revealing sheets of macrophages, eosinophils and Michaelis Guttman bodies on EM characteristic of malakoplakia. Antibiotics were changed to ciprofloxacin and she was transferred to a tertiary care facility for further care. A multidisciplinary approach involving nephrology, urology, infectious diseases and immunology was initiated. Patient was started on methylprednisolone and consideration of bilateral nephrectomy for source control was discussed. Five weeks into the hospital course daily fevers subsided and evidence of kidney recovery ensued. Ultimately, she was discharged off of dialysis with improving kidney function, prolonged course of antibiotics, and steroid taper. Six months later she is off both antibiotics and steroids with stable kidney function (SCr=1.4).

Discussion: Renal malakoplakia must be kept in mind for patients presenting with AKI and bilaterally enlarged kidneys especially in the setting of E. coli bacteremia from a urinary source. It was a challenging case given her age and nephrectomy as potential treatment options. We learned that in such cases suppressing the inflammatory process as an adjunct to antibiotic therapy can salvage kidney function. A multidisciplinary approach was very useful in avoiding surgery and coming up with treatment plan.

SA-PO375

Extramedullary Hematopoiesis Misdiagnosed as Interstitial Nephritis in a Patient with Renal Dysfunction: A Case Report

Mea Asou, Makoto Araki. Suwa Central Hospital *Suwa Central Hospital, Chino, Japan*.

Introduction: Extramedullary hematopoiesis is widely known to occur in patients with primary myelofibrosis (PMF). Autopsy studies on individuals with PMF revealed that extramedullary hematopoiesis occurred in the kidneys in 35% of the cases. However, there is little awareness regarding such lesions.

Case Description: A 63-year-old man was diagnosed with PMF (Dynamic International Prognostic Scoring System: intermediate-1-risk group) with a JAK2 V617F gene mutation based on a detailed examination of persistent white blood cells (white blood cell count, >10,000 /μL). An examination of the patient's medical records revealed a correlation between leukocytosis and deterioration of renal function and urinary protein. Thus, a kidney biopsy was performed. Advanced lymphocyte invasion was recognized in the interstitial tissue, and the uriniferous tubule extensively disappeared. Glomerular lesions were investigated, and only some were determined to have resulted from mesangial proliferative glomerulonephritis. Based on these findings, the pathologist diagnosed the patient with interstitial nephritis. However, because of the large number of cells with nuclear atypia in the stroma, additional immunohistochemical staining was also performed, such as Glycophorin A, Napthol AS-D, Myeloperoxidase and CD42b. As a result, invasion of three lineages of immature cells, erythroblasts, megakaryocytes, and granulocytes, was identified. Renal dysfunction resulting from interstitial cellular infiltration due to extramedullary hematopoiesis was therefore diagnosed. Treatment with ruxolitinib was initiated after a renal biopsy. The patient's decrease in estimated glomerular function rate stabilized, and urinary protein concentration decreased slowly.

Discussion: Although, in myeloproliferative disorders, proliferative glomerular lesions are widely considered to be renal disorders, there is little awareness regarding interstitial lesions. Extramedullary hematopoiesis of the kidney in PMF is not uncommon, but 40% of cases are reportedly misdiagnosed as interstitial nephritis. Because extramedullary hematopoiesis can be controlled by treatment with ruxolitinib, early detection is important.

SA-PO376

A Case of Membranous Nephropathy in a Child with Immune Dysregulation, Polyendocrinopathy, Enteropathy, X-Linked (IPEX) Syndrome

Elizabeth Spiwak,[1] Corina Nailescu,[4] Amy C. Wilson,[1] Anne Kouri,[3] Neha D. Pottanat,[1] Myda Khalid.[2] *[1]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [2]Indiana University, Indianapolis, IN; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Riley Hospital For Children at Indiana University Health, Indianapolis, IN*.

Introduction: Classic IPEX syndrome is an autosomal recessive genetic disorder secondary to a mutation in the *FOXP3* gene. It is characterized by enteropathy, chronic dermatitis, type I diabetes mellitus (T1DM), hypoparathyroidism, antibody mediated cytopenias, and immune dysregulation. Up to 33% of patients with IPEX syndrome have renal complications, including tubulointerstitial nephritis, focal tubular atrophy, minimal change disease, membranous glomerulopathy and irregular granular immune deposits in glomeruli/tubular basement membranes. There are fewer than 10 reported cases in the literature.

Case Description: A 3-year-old female, with a history of IPEX (known gain of function mutation in *STAT3* gene), T1DM, hypothyroidism, nephrocalcinosis, and history of AKI presented with edema. Laboratory studies confirmed nephrotic syndrome: albumin of 1.6gm/dl, urine protein to creatinine ratio of 33. Renal function was normal. No abnormalities found on complement, ANA, or ANCA testing; renal biopsy demonstrated subepithelial electron dense deposits consistent with membranous glomerulopathy with autoantibodies to phospholipase A2 receptor (PLA2R-positive) on biopsy stain and negative serum PLA2R. She is currently treated symptomatically with twice weekly albumin infusions in addition to intermittent IVIG. Treatment with sirolimus was initiated based on successful outcomes reported in some case reports however it did not allow for remission of nephrotic syndrome after 9 weeks of treatment. Since non-autologous stem cell transplant allows for rapid clinical improvement, the aim is for this patient to receive a stem cell transplant from a sibling who will be born in a few weeks from the time of submission of this abstract.

Discussion: PLA2R-postive membranous nephropathy in the setting of IPEX syndrome is exceedingly rare and there is limited data in regards to treatment. Long-term immunosuppression and bone marrow transplantation are the current therapies utilized. IVIG and prophylactic antibiotics are often used adjunctively. Calcineurin inhibitors, mTOR inhibitors and/or steroids have been used to achieve long-term immunosuppression. As more cases are reported in the literature of PLA2R-positive membranous nephropathy in the context of IPEX syndrome better treatment options and outcomes may be established.

SA-PO377

Successful Pregnancies During Ongoing Complement Blockade in Two Patients with Complement Mediated Thrombotic Microangiopathy

Natalja Haninger-Vacariu,[1] Martina M. Gaggl,[1] Zoltan Prohaszka,[2] Christof Aigner,[1] Renate Kain,[1] Georg Bohmig,[1] Leah C. Piggott,[1] Raute Sunder-Plassmann,[1] Gere Sunder-Plassmann,[1] Alice Schmidt.[1] *[1]Medical University of Vienna, Vienna, Austria; [2]Semmelweis University, Budapest, Hungary*.

Introduction: In patients with pregnancy-associated complement gene variant mediated thrombotic microangiopathy (cTMA) terminal complement blockade is used for treatment of cTMA flares during pregnancy or following delivery. Data on pregnancies of cTMA patients during ongoing eculizumab (ECU) therapy, however, are scarce.

Case Description: We report pregnancy and delivery outcomes of two cTMA patients enrolled in the Vienna TMA cohort and measured complement related proteins and ECU concentrations at regular intervals during pregnancy, thereafter, and in cord blood. The first manifestation of cTMA occurred in both patients during childhood or young adulthood and was not related to pregnancy. One patient (genetic variants in *CFI, CD46, CFH, C3*) had a total history of 26 cTMA flares and of two uneventful pregnancies with prophylactic plasma infusions. She started ECU at her last cTMA flare, which was continued during her third pregnancy at the age of 27 yrs. The other patient (genetic variants in *CFH, CD46*), 29 yrs of age at her second pregnancy, had a history of recent early abortion during long-term ECU therapy following kidney transplantation, which was performed four years after her first manifestation of cTMA. ECU plasma concentrations were maintained in the therapeutic range during both successful pregnancies and were also detectable in the cord blood. Complement related tests did not indicate alternative pathway activation during pregnancies. Kidney function and blood pressure did not change substantially in both cases. However, proteinuria increased at the end of the third trimester in both patients. Both neonates were adequate for gestational age (weight: 3720 and 3082g; head circumference: 35 and 34 cm; length: 52 and 50 cm) with vaginal delivery in week 40+3 and 37+0 of gestation, respectively. Results of complement related tests in cord blood showed deficient complement activity, with low factor and regulator levels without overactivation, which most likely reflects the situation related to age and the presence of ECU in cord blood.

Discussion: Pregnancy and delivery outcomes with ongoing ECU therapy in two genetically high-risk cTMA patients with preserved native kidney and kidney transplant function were excellent.

SA-PO378

Hypokalemic Periodic Paralysis and Hypertension in Pregnancy: A Diagnostic Challenge

Tanuja Yalamarti,[1] K. Adu Ntoso,[4] Carmen Patrascu,[4] Shahrzad Zonoozi,[2] Timothy Barry.[3] *[1]Pennsylvania hospital of UPENN, Philadelphia, AL; [2]Pennsylvania Hospital, Philadelphia, PA; [3]UPHS, Philadelphia, PA; [4]Pennsylvania Nephrology Associates, P.C., Philadelphia, PA*.

Introduction: Geller syndrome is a rare autosomal dominant syndrome that causes new or worsening hypertension (HTN) during pregnancy associated with hypokalemia and metabolic alkalosis.

Case Description: We report the case of a 37-year-old Burmese female who presented at 24 weeks' gestation with a 3-day history of progressive lower extremity weakness leading to inability to walk. Her blood pressure (BP) was elevated at 180/90. Initial labs revealed serum potassium (K) 1.6 mMol/L with ECG changes of prolonged QT interval and U waves. Initial spot urine potassium was 5.7 mMol/L and sodium 54 mMol/L. A 24-hour urine potassium was 19.8 mMol/L. Following repletion of K both orally and intravenously, paralysis resolved. Initial diagnosis was hypokalemic periodic paralysis. She was started on nifedipine for HTN. Thyroid function was intact. Cortisol 3.4 mcg/dl (3.5-19.5 mcg/dl), renin <2.5 pg/ml (2.5-45.7 pg/ml), aldosterone <3.0ng/dl (4.0-31 ng/dl), and aldosterone/renin activity (A/RA) <3.8. Catecholamines were all normal. Moderate to severe hypokalemia recurred several times during the pregnancy, and urine K was not suppressed. BP remained high and she required addition of labetalol. She underwent cesarean delivery at 33 weeks' pregnancy due to severe pre-eclampsia. Amiloride was started postpartum. Hypokalemia and hypertension improved.

Discussion: Low renin and high aldosterone related HTN is mainly due to excess mineralocorticoid activity. Our patient experienced worsening HTN and severe hypokalemia during pregnancy, with low renin and low aldosterone levels. The improvement of HTN and hypokalemia postpartum suggests pregnancy-specific factors. Normally, activation of mineralocorticoid receptor (MR) causes renal salt reabsorption through the epithelial sodium channel (ENaC) activity. Progesterone binds to but does not normally activate the MR. Geller syndrome is caused by an activating mutation in the gene encoding the MR S810L. This allows progesterone (as well as spironolactone) to function as agonist, causing increases in BP, and hypokalemia during pregnancy. Liddle's syndrome was also considered as she responded well to amiloride. However, the age of the patient and the lack of family history argue against it. Geller syndrome is rare but should be considered in women with HTN and hypokalemia in pregnancy. Genetic testing is pending.

SA-PO379

Nutcracker Syndrome Treatment Complications

Rhyan Maditz,[1,2] Jonathan J. Taliercio.[2,1] *[1]Cleveland Clinic, Cleveland, OH; [2]Glickman Urological and Kidney Institute, Cleveland, OH.*

Introduction: Nutcracker syndrome is the clinical manifestation caused by the situation that the left renal vein suffers from pressure when passing through the angle between the abdominal aorta and the superior mesenteric artery. The syndrome is characterized by hematuria, albuminuria, lumbar pain, and varicocele. Indications for surgical treatment include severe unrelenting pain, significant hematuria, renal functional impairment, and inefficacy of conservative treatment after one year.

Case Description: 29-year-old female with a past medical history of migraines presented to nephrology clinic for evaluation of fatigue, hematuria, and severe left flank pain. She previously was a healthy endurance athlete. Her left flank pain occurs daily and she describes that pain as 10/10 in severity, debilitating, and sharp. CT kidney/pelvis results with a mild narrowing of the left renal vein as it passes between the SMA and aorta and a 1.4 cm left renal cyst. Renal artery duplex subsequently performed revealed left renal vein proximal narrowing and midsegment dilatation suggestive of Nutcracker phenomenon. Venogram performed revealed a 6 mmHg difference between the IVC and the left renal vein confirming the diagnosis of nutcracker syndrome. Patient underwent a left renal vein to inferior vena cava bypass. Unfortunately, the bypass thrombosed and her pain returned. She is currently being considered for autotransplantation of her left kidney. Risks of autotransplantation include a high risk of left nephrectomy in this patient due to a short renal vein segment.

Discussion: Management of Nutcracker Syndrome is a challenging endeavor. Non-surgical approaches include observation, especially in patients younger than 18 years of age since increase in intra-abdominal and fibrous tissue at the SMA origin during growth releases the obstruction of the left renal vein. In addition, weight gain increases the retroperitoneal adipose tissue, which leads to change in the positioning of the left kidney with reduction of tension on the left renal vein. Surgery is definitive treatment, but does not come without risks as seen in our patient. Surgical complications include deep venous thrombosis, retroperitoneal hematoma, ileus, and renal vein thrombosis. Complications of surgery should be extensively reviewed with patients prior to surgery. In retrospect, weight gain should have been trialed in this endurance athlete prior to surgical bypass.

SA-PO380

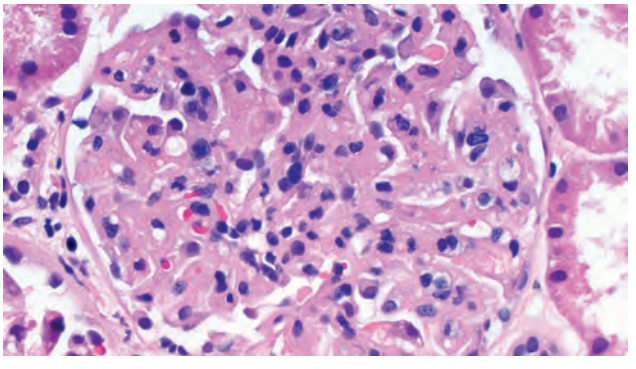
In Vitro Fertilization (IVF): Early-Onset Preeclampsia Before 16 Weeks' Gestation

Bilal shahzad azam Khan,[1] Yuvraj Sharma,[2] Sandeep S. Soman,[1] Mhd hussam Al jandali,[1] Snigdha Reddy.[1] *[1]Henry Ford Hospital, Detroit, MI; [2]Henry Ford Health system, Bloomfield Hills, MI.*

Introduction: Preeclampsia is a hypertensive pregnancy disorder diagnosed in women presenting with new onset hypertension and proteinuria > 20 weeks gestation. IVF has been suggested as a risk factor for preeclampsia. We describe a rare case of early onset preeclampsia < 20 weeks gestation conceived via IVF.

Case Description: A 38-year-old G2P0010 patient at 15w5d gestation conceived via IVF presented with headache and worsening bilateral lower extremity swelling. She was experiencing intermittent headaches and occasional foamy urine for a few weeks before presentation. No past or family history of renal disease. BP was 230/107mm Hg at presentation, UA showed >500 mg/dl protein with no hematuria, 24-hour urine protein was 18 gm/day, serum creatinine 0.76 mg/dl, ALT 88 IU/L, AST 55 IU/L, Platelets 165 K/μL. Transvaginal ultrasound(US) confirmed stated gestational age. Renal US was unremarkable. Relevant serologies were negative. Renal biopsy (see image) showed glomerular capillary endotheliosis and new subendothelial basement membrane (BM) formation creating BM double contours consistent with preeclampsia. The patient opted for termination of pregnancy at 17w2d. BP, transaminitis and proteinuria normalized after one week of pregnancy termination.

Discussion: Preeclampsia presenting before 20 weeks gestation is rare, and a case associated with IVF as a sole risk factor is unique. Other conditions like molar pregnancy, triploidy, lupus nephritis, antiphospholipid antibody syndrome, thrombotic thrombocytopenia, acute fatty liver of pregnancy, hemolytic uremic syndrome and fetal hydrops should be excluded. Common risk factors for preeclampsia are prior pre-eclampsia, chronic hypertension, pre-gestational diabetes, obesity and IVF. Embryo preservation, implantation techniques and placental development with IVF have been suggested as a cause for this serious systemic hypertensive disorder. This is the first reported case of early–onset preeclampsia before 16 weeks gestation with IVF.



SA-PO381

A 64-Year-Old Woman with Raccoon Eyes After Kidney Biopsy

Shuqin Mei,[1,2] Changlin Mei,[1] Bing Dai.[1] *[1]Shanghai Changzheng Hospital, Shanghai, China; [2]Tongji Hospital, Shanghai, China.*

Introduction: Raccoon eyes is caused by blood tracking into periorbital tissues, which are easliy recognized as a symptom of basal skull fractures. However, it may be a sign of health threatening situations such as multiple myeloma, amyloidosis and so on. Here we discuss a patient with raccoon eyes after the kidney biospy who was finally diagnosed as immunoglobulin light chain (AL) amyloidosis.

Case Description: A 64-year old woman presented to our clinic with 1-year proteinuria. Laboratory study showed Scr was 382 umol/L and 24-hour urine protein quantification was 2.4 g. The testing for monoclonal protein by serum revealed an M-peak in the λ fraction of IgA (Fig1a). The concentrations of κ and λ were 44.95 and 173 mg/L, respectively. The bone marrow cytology test was negative. Ultrasound report indicated the size of right kidney was 9.1×4.4 cm and the left one was normal. But unexpectedly, the patient showed periorbital purpura 24 hours later after kidney biopsy (Fig1b). Congo red staining was positive and also showed strongly λ deposition. EM showing expansion of the mesangium by amyloid fibrils.

Discussion: AL amyloidosis is the most common type of systemic amyloidosis. Renal involvement accounts for almost 70% and most presents as clinically apparent nephrotic syndrome. Sometimes it only presented with proteinuria and slowly progressive deterioration of renal function. So it is necessary to perform tissue biospy once the patients with unknown renal failure accompany with monoclonal M protein. The vascular infiltration of amyloid fibrils in blood vessels in patients with amyloidosis can cause bilateral periorbital ecchymosis by a Valsalva maneuver or minor trauma. Here we firstly reported this rare symptom after kidney biospy in a patient who was finally diagnosed as AL amyloidosis. During the kidney biopsy, the patient was asked to hold breath after inhalation, which mimicked Valsalva maneuver, and thus contribute to the periorbital purpura. Therefore, periorbital ecchymosis warrant more attention as an early cue of amyloidosis.

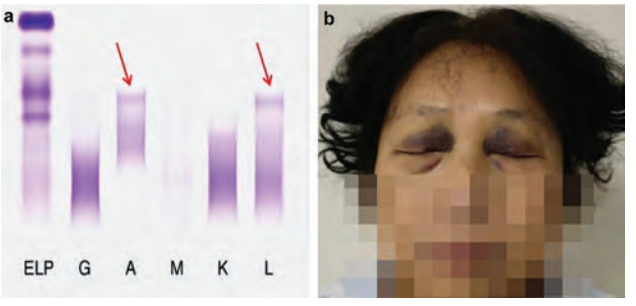


Fig1 (a) M-peak in the λ of IgA. (b) The patient showed bilateral periorbital ecchymosis.

SA-PO382

Hypervitaminosis D Secondary to Agaricus blazei Murrill Mushroom Supplementation: A Case Report

Sherida N. Edding, Monica Therese Cating-Cabral, Brian Michael I. Cabral. *Department of Medicine, St. Luke's Medical Center - Global City, Taguig City, Philippines.*

Introduction: Hypercalcemia secondary to hypervitaminosis D is extremely rare. Vitamin D intoxication usually occurs as a result of inappropriate use of vitamin D preparations and can lead to life-threatening hypercalcemia.

Case Description: Here we present a case of a 45-year-old female diagnosed with colon adenocarcinoma stage IV with liver, lung and bone (ribs) metastases, s/p FOLFOX x 6 cycles, s/p FOLFIRI x 2 cycles. She was admitted for 3rd cycle chemotherapy but hospitalization was complicated by development of pneumonia with worsening of kidney function and initiation of hemodialysis. Despite being on regular hemodialysis, her calcium levels were noted to be increasing. She was also noted to be feeling weaker, with decrease in sensorium attributed to hepatic encephalopathy. Workup for hypercalcemia revealed low normal PTH (21.50 pg/mL, N: 14.0-72), with a normal phosphorus level and elevated Vitamin D (104.28 ng/mL, N: 30-50). It was later revealed upon review of the patient's medications that her mother was giving her various herbal supplements, the latest of which was one that contained an extract from *Agaricus blazei Murrill*, a mushroom native to Brazil that allegedly aids in the treatment of a variety of diseases such as cancer, chronic hepatitis, diabetes, atherosclerosis and hypercholesterolemia.

Discussion: Mushrooms are one of the main dietary sources of vitamin D. The probable offending agent was discontinued and the patient was given IV hydrocortisone. Other therapies such as calcitonin and denosumab were not given due to the patient's history of anaphylactic reactions. Serial monitoring showed that the calcium levels steadily decreased, as well as the Vitamin D levels, although at a slower rate. This case highlights the importance of assessing the intake of all substances, not only prescribed medications, and the potential danger of the ingestion of unlicensed herbal supplements.

SA-PO383

Looking Beyond Tenofovir Renal Toxicity as the Cause of Bone Disease in HIV

Amita Maibam, Ana L. Castellanos, Alice Thornton, Madhumathi Rao. *University of Kentucky, Lexington, KY.*

Introduction: Chronic kidney disease (CKD) with tubular dysfunction from tenofovir therapy in HIV disease is frequently associated with bone disease. Here we present a patient referred for evaluation of osteoporosis.

Case Description: A 48-year-old African American phenotypic female with CKD stage 3a-A3 and sub-nephrotic proteinuria, was referred for osteopenia on bone densitometry in the setting of prior history of right hand fracture with minor trauma. Her past medical history was notable for HIV/AIDS diagnosed 24 years ago, for which she was on antiretroviral therapy (ART) including Tenofovir Disoproxil Fumarate (TDF) and protease inhibitors (PI). Upon evaluation, laboratory data showed serum creatinine of 1.5 mg/dL (eGFR 50 mL/min), low normal serum phosphorus with fractional excretion of phosphorus in the urine ~15% and glycosuria. There was mild elevation of serum alkaline phosphatase although bone alkaline phosphatase was normal. Other bone turnover markers (osteocalcin, C-Telopeptide and N-Telopeptide) were in the normal range. Patient underwent bone biopsy with double tetracycline labeling to evaluate turnover and mineralization; histological results showed high turnover osteoporosis with normal mineralization. Patient was started on anti-resorptive therapy with Alendronate. Patient was transitioned to combination ART (dolutegravir, abacavir, lamivudine) 2 years earlier, with improvements in renal parameters. Further review of medications revealed she was being treated with estradiol for gender dysphoria (male to female transition) and had levels below target; estradiol therapy was increased to better support hormone status and thereby mitigate bone loss.

Discussion: Although the impacts of HIV, ART with TDF and PI's, CKD, and tubular dysfunction contribute cumulatively to long-term consequences for bone health, in this patient, hypogonadism related to transgender status was likely a major contributing factor at the time of evaluation. This report highlights that bone disease in CKD patients with HIV is multifactorial and a potentially dynamic process over time in the context of evolving risk factors. Accurate diagnosis remains critical for optimal management.

SA-PO384

Dialysis for an Adult with Maple Syrup Urine Disease

Matthew Ray,[1] Alkesh Jani.[2] *[1]University of Colorado Denver, Aurora, CO; [2]University of Denver Colorado, Aurora, CO.*

Introduction: Maple syrup urine disease (MSUD) is a rare genetic defect in branched chain amino acid (BCAA) metabolism which, if untreated, leads to accumulation of isoleucine accompanied by significant neurologic decompensation and even death. MSUD predominantly affects children and there is little data regarding the utility of renal replacement therapy (RRT) to correct metabolic derangements in adults with MSUD.

Case Description: We present the case of a 39-year-old man who was admitted to our facility with acute encephalopathy as a consequence of decompensated MSUD secondary to acute gastrointestinal bleed likely from prolonged high-dose NSAID use. He was transferred with cerebral edema attributed to an elevated leucine level of 2900 umol/L. The patient's baseline levels of leucine, at which he had minimal symptoms, was ~ 1000umol/L. Given the encephalopathy and cerebral edema, he was initially started on CVVHD with monitoring of mental status and leucine levels. Despite RRT, the patient remained symptomatic, raising the possibility his leucine levels were still elevated. He was therefore switched to intermittent hemodialysis for four hours to facilitate rapid removal of leucine, followed by resumption of CVVHD. CRRT was continued for a further 12 hours, with improvement in his leucine levels to <800 and in mental status. The patient made a full recovery and was discharged home 4 days later.

Discussion: Maple syrup urine disease is an inborn error of metabolism of BCAA, characterized by mutations in genes that result in a deficiency of the branched-chain alpha-keto acid dehydrogenase complex that is required to metabolize BCAAs. The disorder gets its name because the urine of affected infants has sweet odor. A specialized diet can prevent accumulation of BCAAs in these patients. However, any hypercatabolic state, including stressors such as infection, injury, and a failure to eat (as occurred in our patient due to his GI bleed), can lead to a metabolic derangement with a rapid increase in amino acid levels and accompanied clinical deterioration. Much of the experience in treating such patients nests in pediatric academic centers and literature, and physicians caring for adult patients have little experience with these complicated cases. Our case therefore illustrates a successful approach to managing metabolic crisis in the setting of an acute metabolic decompensation in an adult patient with MSUD.

SA-PO385

Hyperbilirubinemia and Acquired Fanconi Syndrome

Juan P. Portocarrero caceres,[1] Shamikh E. Alghezawi,[2] Akika Ando,[3] Stephanie M. Toth-Manikowski,[3] Ragad Asmaro.[3] *[1]Loyola University MacNeal Hospital, Berwyn, IL; [2]Jordan University of Science and Technology, Irbid, Jordan; [3]University of Illinois Medical Center, Chicago, IL.*

Introduction: Bile cast nephropathy is characterized by renal dysfunction in the setting of severe hyperbilirubinemia. It is a rare condition that occurs as a result of direct toxicity from bile acids and from tubular obstruction by bile casts. Diagnosis requires a high degree of clinical suspicion and it should be differentiated from hepatorenal syndrome.

Case Description: A 32-year-old man with past medical history of alcoholic liver cirrhosis was admitted for generalized jaundice and dark-colored urine. He reported taking 1.5 grams of acetaminophen daily for 4 days prior to admission. He endorsed stopping alcohol intake 19 months prior to admission. Physical exam was significant for tachypnea, tachycardia, and generalized jaundice. He did not have neurological deficits. Laboratory studies demonstrated severe hypophosphatemia (<1 mEq/L), hypokalemia (2.3 mEq/L), non-oliguric kidney (creatinine of 1.6 mg/dL, unknown baseline), elevated anion gap (14), and hypoalbuminemia of 3 g/dL. Total bilirubin level was elevated at 49.7 mg/dL with a direct bilirubin >30 mg/dL. Blood urea nitrogen (BUN) level was 11 mg/dL. A urine sample revealed glucosuria. The urine sediment demonstrated bile casts. The calculated fractional excretion of phosphate in urine was 40%. He was initially treated for suspected acetaminophen toxicity and for decompensated liver failure with octreotide, midodrine, and albumin. He required aggressive intravenous infusion of phosphate and potassium. The patient was medically stabilized and all his electrolyte imbalances corrected. After peaking at 1.8 mg/dL, his creatinine improved to 1.4 mg/dL with supportive care.

Discussion: In this presentation, we attributed the cause of severe hypophosphatemia and non-oliguric acute kidney injury to bile cast nephropathy. Risk of bile cast formation increases when total bilirubin levels rise above 20 mg/dL. As a majority of filtered phosphate is reabsorbed in the proximal tubules (>80%), severe hyperbilirubinemia can lead to hypophosphatemia by way of proximal tubulopathy, more classically known as acquired Fanconi's syndrome. Previous case reports have reported that the degree of hypophosphatemia is inversely correlated with bilirubinemia. As bile cast nephropathy is partially reversible, therapy should be focused on treating the cause of liver failure and correcting metabolic derangements.

SA-PO386

Euglycaemic Diabetic Ketoacidosis in Type 2 Diabetes: A Rare Complication of SGLT-2 Inhibitors

Michael Toal. *Belfast City Hospital, Belfast, United Kingdom.*

Introduction: Diabetic ketoacidosis (DKA) is a commonly encountered condition worldwide, typically occurring in young patients with type 1 diabetes following a provoking illness. This case explores an atypical case of ketoacidosis in an elderly patient with type 2 diabetes, who was not on insulin treatment, providing a significant diagnostic challenge.

Case Description: An 81year old lady presented with a 48 hour history of poor oral intake, vomiting and dyspnea. Her past medical history was significant for schizophrenia and Type 2 Diabetes Mellitus. On examination she was dehydrated, but had an excellent urine output of over 100ml/hr. Investigations revealed a raised anion gap metabolic acidosis (pH 7.08, Anion gap = 23) and ketonaemia of 5.47 mmol/l. Blood glucose, lactate and renal function were within normal range and the patient denied ingestion of toxins. Chest X-ray showed evidence of pneumonia. Treatment with two litres of intravenous fluids and antibiotics did not correct the acidosis, the pH falling from an initial rise of 7.22 to 7.09 and blood glucose of 10.7 to 9.9 mmol/l (178 mg/dl). Dapagliflozin was identified in the drug history as a potential precipitant of euglycaemic diabetic ketoacidosis. Intravenous infusions of dextrose and insulin successfully corrected the blood pH to 7.36 with a resolution of ketonaemia over the course of twenty four hours.

Discussion: Euglycaemic diabetic ketoacidosis (euDKA) is defined as the clinical triad of a blood glucose <11.1mmol/l (< 200mg/dl), raised anion gap metabolic acidosis and the presence of ketones in blood or urine. Euglycaemic DKA has similar provoking factors to DKA, such as infection, fasting or surgery. This case is atypical as the patient was elderly and not on insulin treatment. The DECLARE (Dapagliflozin Effect on Cardiovascular Events) study with over 18,000 participants quoted an incidence of DKA in < 0.1% of patients on this treatment. The European Medicines Agency concluded in 2016 that life-threatening and fatal cases of diabetic ketoacidosis have been reported in patients treated with SGLT-2 inhibitors. SGLT-2 inhibitors act on the proximal convoluted tubule promoting urinary sodium and glucose excretion, inhibiting glucose reabsorption. Clinicians should be mindful of this potentially life-threatening complication and consider euDKA in challenging cases of acid-base disturbance.

SA-PO387

Ectopic Adrenocorticotropic Hormone Tumor Can Present as a Chloride-Depleted Metabolic Alkalosis

Neeharik Mareedu,[1] William L. Whittier.[2] *[1]Nephrology, Rush University Medical Center, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.*

Introduction: Metabolic alkalosis (MA) often presents with hypokalemia and is either Cl-depleted (CDMA, urine Cl<15 meq/L) or Cl-resistant (CRMA, urine Cl>15 meq/L). CDMA is due to sustained loss of Cl, most commonly from either renal or GI losses, leading to pendrin inhibition. CRMA is most often due to direct tubular stimulation from either apparent or actual hyperaldosteronism.

Case Description: A 67 year old man w/ PMH of HTN presents w/ lower extremity & scrotal swelling. No OTC, herbal, or dietary supplements. Meds: Lasix, Lisinopril-HCTZ, ASA and KCl. BP 186/100, 2+ LE & scrotal edema. Serum Na 140, K 1.8, Cl 82, HCO3 45, BUN 15, Cr 0.7. ABG pH 7.58/PCO2 52/HCO3 45. Urine pH 7.5, K 33 meq/L, Na<10meq/L, Cl<10meq/L, Cr 94mg/dL, Urine K:Cr 35.1meq/g. His CDMA and kaliuresis was attributed to remote use of HCTZ & Lasix. These were held, KCl & 0.9NS was initiated, but w/ only minimal improvement in his MA & hypokalemia. His edema & HTN was exacerbated by this therapy, & follow up labs revealed Plasma Renin 1.26 ng/ml, Aldosterone 2 ng/dl, Cortisol 114.2 mcg/dl and ACTH 231 pg/ml. Imaging revealed a lung mass with mets & biopsy confirmed metastatic small cell cancer. Spironolactone resolved his HTN, edema, hypokalemia, & MA, and he is currently undergoing chemotherapy for his malignancy.

Discussion: Though initially thought to be remote use of diuretic induced CDMA, our patient's lack of response to Cl repletion led us to search for an alternative diagnosis. After his aldosterone and renin levels returned low, we sent off ACTH & cortisol and found an ectopic ACTH producing tumor. His loop & thiazide diuretics had exacerbated his CMDA, but was not the sole underlying cause. At high concentrations, cortisol activates mineralocorticoid receptors (MR) in the cortical collecting duct, leading to epithelial Na channel (ENaC) & Na-K ATPase activation. This leads to Na reabsorption with K & H excretion through renal outer medullary K channels, thus causing HTN & hypokalemia. To maintain electrical neutrality, HCO3 is reabsorbed and Cl is secreted into the tubular lumen via pendrin. But contrary to expected, urine Cl was low in our case which makes it an unusual presentation of hypercortisolism. Treatment strategies in these patients should focus on eliminating the primary cause if possible (decreasing tumor burden) & using medications which inhibit MR (Spironolactone) or ENaC (Amiloride).

SA-PO388

SGLT2 Inhibitors Are a New String for Nephrologists' Bow: Time to Be Excited yet Exercise Caution

Ming-Jim J. Yang,[1] Eddy J. De Jesus,[1] Amer A. Belal,[1] Abhilash Koratala.[1,2] *[1]University of Florida, Gainesville, FL; [2]UT San Antonio, San Antonio, TX.*

Introduction: Diabetic ketoacidosis (DKA) is traditionally defined as a triad of hyperglycemia, anion gap metabolic acidosis, and ketosis. On the other hand, Euglycemic DKA (EDKA), associated with blood glucose levels of <200 mg/dL is a relatively rare variant that is being recognized more in the setting of sodium glucose cotransporter 2 (SGLT2) inhibitors use. With the recent CREDENCE trial showing that Canagliflozin (a SGLT2 inhibitor) portends better renal and cardiovascular outcomes in patients with type 2 diabetes mellitus, nephrologists need to be aware of EDKA, especially in the setting of acute kidney injury (AKI), which itself can contribute to metabolic acidosis and pose diagnostic challenge.

Case Description: A 69-year-old woman with a history of diabetes mellitus type 2, gastroparesis, hypertension and coronary artery disease presented with abdominal pain, nausea and vomiting for 3 days. She was on metformin 1000 mg twice a day and empagliflozin 25mg daily for her diabetes. She was found to have AKI with a serum creatinine of 4 mg/dL (baseline ~0.8). Other laboratory data was significant for hyperkalemia with a serum potassium level of 6 mmol/L and anion gap metabolic acidosis with a serum bicarbonate 10 mmol/L. There was no significant hyperglycemia and the blood glucose level was 150 mg/dL. Lactic acid level was near-normal. Her urinalysis was positive for ketones and plasma beta hydroxybutyrate level was found to be elevated at 3 mmol/L. She was diagnosed with EDKA and treated with intravenous insulin and fluids. Her ketosis and renal failure resolved subsequently.

Discussion: Despite euglycemia, EDKA remains a medical emergency and must be diagnosed in a timely manner. As the use of SGLT2 inhibitors is likely to increase considerably in near future, nephrologists should have high index of suspicion for their adverse effects including but not limited to EDKA, urinary tract infections, renal tubular acidosis, lower-limb ulcerations etc. Serum ketones should be obtained in any patient with nausea, vomiting, or malaise while taking SGLT2 inhibitors, and the drug should be discontinued if acidosis is confirmed. Moreover, other causes of metabolic acidosis such as acute kidney injury, metformin-associated lactic acidosis, superimposed Fanconi syndrome from SGLT2 inhibitors should be considered in the differential diagnosis.

SA-PO389

No Stone Unturned: A Case of Sjogren Syndrome Diagnosed by Recurrent Nephrolithiasis

Antonia Tharian,[1] John M. Carson.[2] *[1]NYU Winthrop, Manhasset, NY; [2]NYU Winthrop Hospital, Mineola, NY.*

Introduction: The cause of nephrolithiasis is idiopathic in the majority of cases. Patients who are young, form stones recurrently, or have high stone burdens warrant more thorough investigation into an underlying cause.

Case Description: 59 year old female with past medical history of hypertension, Raynaud's, gastric reflux, and recently diagnosed nephrolithiasis who presented with malaise, dysuria, fever, and chills after a seven day course of antibiotics for a urinary tract infection. She was evaluated in emergency department one month prior for right sided flank pain and was found to have a 4 mm obstructing stone in the proximal right ureter. This stone passed with medical expulsive therapy after which she continued to pass sandy urine sediment. On the current admission, imaging demonstrated a new 6 mm obstructing stone in the distal right ureter and a non-obstructing stone in the left renal pelvis not present a month earlier. Routine laboratory evaluation revealed a creatinine of 1.8mg/dL, non-anion gap metabolic acidosis, hypokalemia with elevated urinary potassium, and a urine pH of 6. The urine anion gap was positive and a distal renal tubular acidosis (RTA) was suspected. Further serologic testing was notable for a positive ANA (1:80), negative double stranded DNA, strongly positive anti SS-A and anti SS-B antibodies, low C3 and very low C4. Anti-Scl-70 was normal. A diagnosis of Sjogrens with possible systemic lupus erythematosus overlap was made. She was treated with antibiotics and urology removed the stone cystoscopically. Her creatinine improved from 1.8 to 1.1mg/dL on discharge. As expected, the composition of her stone was 98% calcium phosphate, 2% calcium oxalate. She was started on potassium citrate which improved her hypokalemia and acidosis significantly.

Discussion: Distal RTA increases stone risk due to alkaline urine, hypocitraturia, and hypercalciuria related to bone buffering in chronic acidosis. General causes of distal RTA from defects in the tubular transporters in the alpha intercalated cell of the renal collecting duct include genetic mutations, autoimmune diseases, and medications. Systematic evaluation of this patient's nephrolithiasis led to a diagnosis of distal renal tubular acidosis and ultimately an underlying systemic disease, Sjogren's syndrome.

SA-PO390

Severe Hyponatremia Associated with Autoimmune LGI1 Encephalitis, an Underrecognized Cause of SIADH

Maria Clarissa Tio,[2] Pui Susan W. Cheung.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Massachusetts General Hospital, Boston, MA.*

Introduction: SIADH is commonly caused by medications, malignancies, pain, and nausea, however autoummune encephalitis as a cause is often underrecognized. Here we present a case of severe SIADH secondary to autoimmune LGI-1 encephalitis.

Case Description: A 79-year-old male with hypertension on hydrochlorothiazide (HCTZ) presented to the ED 2 months prior for fatigue, and was found to have hyponatremia with serum Na (sNa) of 123mmol/L. It was attributed to HCTZ, and sNa improved to 127mmol/L after its discontinuation. A month later, patient was hospitalized for left arm twitching and recurrent hyponatremia with sNa 123mmol/L, sOsm 256mOsm/kg, uOsm 720mOsm/kg, serum Cr 0.81mg/dL. His twitches was associated with voluntary movements, occurred 3 times a day and each lasted for 10 seconds. Workups for SIADH were unrevealing. Given the concern for symptomatic hyponatremia with arm twitching, the patient was treated with ddavp and 3% saline for controlled sNa correction, and discharged with sNa 137mmol/L, on salt tablets, fluid restriction, and furosemide. Neurologic symptoms had improved. Patient returned to clinic 3 weeks after discharge, and reported recurrence of left arm and hand twitching with increased frequency and severity, and now with new onset facial clenching. Labs showed normal sNa of 135mmol/L, sOsm 280mOsm/kg, uOsm 681mOsm/kg, Ca 9.6mg/dL. Patient was referred to Neurology Dystonia Clinic, and the diagnosis of anti-LGI1 encephalitis was confirmed with positive Leucine-rich, glioma inactivated 1 protein IgG (LGI1) and positive Voltage gated potassium channel Ab (VGKC). He was promptly treated with pulse methylprednisolone with resolution of his neurologic symptoms and hyponatremia.

Discussion: It is estimated that 60% of the patient with autoimmune LGI-1 encephalitis presented first to health care providers with hyponatremia, and yet, it is an under-recognized cause of SIADH. LGI-1 is part of the voltage-gated potassium channel complex present in the hippocampus and temporal cortex, and LGI-1 encephalitis is characterized by hyponatremia, acute or subacute cognitive impairment, faciobrachial dystonic seizures, psychiatric disturbances and epileptic seizure. If left untreated, patient would progress rapidly to end stage dementia resulting in death. However, if treated early with steroids, it has low relapse rate and good clinical outcome.

SA-PO391

Unexplained Bromide Toxicity Presenting as Hyperchloremia and Negative Anion Gap

Hasan Iftikhar, Shailendra Sharma. *George Washington University Hospital, Washington, DC.*

Introduction: Brominev. is a deep red colored liquid primarily used in manufacture of chemical agents. Serum bromide concentration is difficult to quantify due to interference with other halogens, though when measured by x-ray fluorescence spectrometry is between 3.2 to 5.6 mg/L. Significant environmental exposure is mostly limited to industrial setting. Bromide toxicity was well recognized in early twentieth century when use of bromide containing drugs was widespread. Toxic effects of bromide include neuropsychiatric disturbances, tremors, gait imbalance, rash, and dermatitis.

Case Description: An 82-year-old male was seen in the emergency room with sudden cognitive decline, visual hallucinations, gait disturbance and multiple falls. His medical history was significant for squamous cell cancer of head and neck and Myasthenia Gravis. His medication list included scheduled infusion of IVIG every four weeks and ipratropium bromide 20 mcg inhaler two to three times daily. Notably, he was not on Pyridostigmine bromide. Physical examination was significant for blood pressure of 93/55 mm Hg, and fluctuating mental status. Serum chloride was found to be 163 mmol/L with anion gap of negative 65. Remaining serum chemistries, complete blood count, liver function tests, urinalysis, blood gas, TSH, Salicylate and Tylenol levels, B12 and cortisol levels were unremarkable. Multiple repeat labs continued to show high chloride concentration. Simultaneous chloride measurements were obtained employing indirect ion-selective and colorimetric method; serum values thus obtained were 135 mmol/L and 103 mmol/L respectively. Colorimetric method is less susceptible to interference from other halides. Concurrent serum bromide level was reported as 1100mg/L. Patient refused both saline diuresis and hemodialysis for bromide clearance, and expired at his home six weeks following discharge.

Discussion: Because of interference by other halogens in routine measurements, a high bromide level can masquerade as hyperchloremia with large negative anion gap. Thus when encountered, bromism should be kept in mind

SA-PO392

Fellow's Nocturnal "Natremic" Dilemma; True, Pseudo, or Both: Implications on Dialysate Sodium

Maria Andrievskaya, Bilal shahzad azam Khan, Sandeep S. Soman. *Henry Ford Hospital, Detroit, MI.*

Introduction: Hyponatremia is the most common electrolyte disturbance in patients admitted to the hospital. We report a case of combined true- and pseudohyponatremia in a patient who was on continuous renal replacement therapy (CRRT).

Case Description: A 46-year-old female with a history of end stage renal disease (ESRD) secondary to lupus was admitted to intensive care unit with peritonitis and septic shock. The patient weighted 50 kg, with calculated Watson's volume of 26 L. She was started on CRRT due to hemodynamic instability. Her serum sodium (SNa) levels were stable around 129-130 mmol/L while on CRRT with a CRRT dialysate Na of 132 (to avoid over-correction). This was thought to be related to a hypotonic solution she was receiving (D20 for severe hypoglycemia). Overnight, the SNa was noted to drop to 122 mmol/L while she was receiving CRRT with no added hypotonic solutions administered. On call nephrology fellow was contacted urgently to establish the cause of this acute worsening of SNa. On medication review it was found that the patient received intravenous immunoglobulin (IVIG) for immune thrombocytopenia in the evening prior to the SNa of 122 mmol/L. That fact raised a suspicion of pseudohyponatremia. Further workup revealed serum Osmolality of 281 mOsm/kg and anion gap of 1. Whole blood electrolytes were obtained and showed sodium level of 129 mmol/L.

Discussion: IVIG can cause hyponatremia by multiple mechanisms. Pseudohyponatremia results from increased percentage of protein in plasma, with a normal plasma water Na concentration. IVIG therapy can also result in true hyponatremia, arising from sucrose-induced translocation of water from the intracellular compartment (ICF) to the extracellular compartment (ECF). Even in the presence of underlying true hyponatremia, nephrologist should be cognizant of possibility of additional pseudohyponatremia. Therapeutic strategies should target whole blood Na in these situations.

SA-PO393

Gitelman Syndrome in Pregnancy: A Therapeutic Challenge with Outcomes Repercussions

Nathalie Jean,[1] Jay A. Pandav,[3] Savneek S. Chugh,[1] Sanjeev Gupta.[2] *[1]New York Medical College, Hartsdale, NY; [2]Westchester county medical center, Hartsdale, NY; [3]Westchester Medical Center, Valhalla, NY.*

Introduction: Gitelman Syndrome is an autosomal recessive disorder resulting in loss of function of the sodium chloride cotransporter (NCCT). Patient presents with metabolic alkalosis, hypokalemia and hypomagnesemia. It usually manifests in late childhood or adulthood; these symptoms can be exacerbated during pregnancy due to increased demand of potassium and magnesium. Here we present 2 difficult to manage cases of Gitelman syndrome with one manifesting and the other worsening during pregnancy.

Case Description: Case 1: 32-year old female with history of Gitelman syndrome on maintenance daily dose of 60 mEq KCl and 400 mg magnesium oxide oral supplementation. During the first trimester of her pregnancy, patient developed severe hypomagnesemia of 1.1 mg/dl and was subsequently started on amiloride 10 mg PO daily, increased dose of magnesium oxide to 800 mg PO twice daily and potassium 40 mg 3 times daily. Despite this intervention, she continue to have low magnesium of less than 1.3mg/dl requiring frequent hospitalization with intravenous and oral magnesium supplementation. Patient was eventually maintained on amiloride 10mg twice a day and maximum tolerable dose of 3200mg of magnesium oxide and 160meq of potassium chloride. Despite this she still gets admitted every week for intravenous magnesium supplementation to maintain levels more than 1.6 mg/dl. **Case 2:** 33-year old female with 32 weeks gestation presented with one day history of nausea, vomiting and severe leg cramping. She was found to have a potassium level of 2.7 mg/dL, calcium of 10.8 mg/dL and magnesium level of 1.3 mg/dL. She was started on oral Potassium chloride 40 mEq twice a day, Magnesium oxide 2400 mEq daily and Amiloride 10mg daily.

Discussion: Managing electrolyte abnormality in pregnant patients with Gitelman syndrome is very challenging. As we saw in our first case, patient remained hypomagnesemic despite maximum tolerable dose of 3200mg of magnesium, requiring multiple intravenous supplementations. The use of potassium sparing diuretics especially Amiloride (Class B in pregnancy) require close monitoring of amniotic fluid by obstetricians. To our knowledge, very few cases of pregnancy with Gitelman's syndrome are reported and these cases require a very close monitoring and managing by a multidisciplinary team of obstetricians and nephrologists

SA-PO394

Multiethnic GWAS for Idiopathic Nephrotic Syndrome in Adults and Children

Dina Ahram,[2] Michelle Mcnulty,[1] Adele Mitrotti,[2,9] Priya Krithivasan,[2] Gina ying Jin,[2] Monica Bodria,[14] Rik Westland,[7] Marijan Saraga,[3] Danko Milosevic,[4] Velibor Tasic,[5] Domenico Santoro,[6] Piergiorgio Messa,[15] Patricia L. Weng,[8] Gianluigi Zaza,[16] Loreto Gesualdo,[9] Enrico Fiaccadori,[12] Gerald B. Appel,[2] Andrew S. Bomback,[2] Francesco Scolari,[10] Yasar Caliskan,[13] Ali G. Gharavi,[2] Krzysztof Kiryluk,[2] Friedhelm Hildebrandt,[11] Matt G. Sampson,[1] Simone Sanna-Cherchi.[2] Sanna-Cherchi Lab *[1]Univeristy of Michigan, Ann Arbor, MI; [2]Division of Nephrology, Columbia University, New York, NY; [3]University Hospital in Split, Split, Croatia; [4]Zagreb School of Medicine, Clinical Hospital Centre Zagreb, Zagreb, Croatia; [5]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [6]Policlinico G Martino, Messina, Italy; [7]VU University Medical Center, Amsterdam, Netherlands; [8]UCLA, Los Angeles, CA; [9]University of Bari, Altamura, Italy; [10]University of Brescia, Montichiari (Brescia), Italy; [11]Boston Children's Hospital, Boston, MA; [12]Universita Degli Studi-Dip. Clinica Medica Nefrologia, Parma, Italy; [13]Division of Nephrology, Saint Louis University School of Medicine, St. Louis, MO; [14]Nephrology, Giannina Gaslini Children's Hospital, Genova, Italy; [15]Nephrology, Policlinico Milano, Milano, Italy; [16]Department of Medicine, Universita di Verona, Verona, Italy.*

Background: Common *HLA* variants have been associated with steroid sensitive nephrotic syndrome (NS) in small cohort studies. We conducted a genome-wide association study (GWAS) for NS in different ethnicities, ages of onset and response to steroid therapy.

Methods: We genotyped 2,639 NS cases and 16,765 genetically-matched controls. After imputation, we performed ancestry-specific GWAS using an additive model corrected for population stratification, followed by meta-analysis across 11 populations. Subsequent meta-analyses were performed stratified by: age of onset (Pediatric and Adults), race (Caucasians and Africans) and steroid responsiveness (Sensitive and Resistant).

Results: In the combined meta-analysis (2,639 cases), we discovered significant associations for the *APOL1* (OR=2.87, P= 7.68x10^{-31}), which were driven solely by African individuals (520 cases; OR=2.82, P=1.45x10^{-37}), the *HLA-DQA*1 locus (OR=1.43, P= 3.2x10^{-22}), and a novel locus on chr.1q42.2 (OR=1.34, P=3.29x10^{-08}). After conditional analysis on the top two SNPs at *APOL1* and *HLA*, a second independent *HLA* genome-wide significant signal was discovered (OR=1.36, P=2.18x10^{-10}). Among adult onset patients (n=1,391), the strongest signals were for *APOL1* (OR=3.14, P=1.82x10^{-21}) and a novel locus on chr.14q21.3 (OR=1.54, P=1.62x10^{-8}). The *HLA-DQA1* was the strongest signal among pediatric cases (n=1,195; OR=2.01, P=4.06x10^{-32}). Interestingly, the *HLA* signal in Caucasians was significant also in adults (OR=1.33; P=1.20x10^{-8}). Additional signals were found in adult and pediatric cohorts stratified by race and response to therapy.

Conclusions: Our results reveal novel NS loci, pleiotropic risk predisposing alleles across different subphenotypes, and signals specific to race and age of onset. Specifically, we can now implicate variation in the *HLA* locus as a major contributor to NS also in adults. Fine-mapping of *HLA* in children and adults and integrating these GWAS alleles with other NS-associated genetic factors (Mendelian alleles, CNVs) holds promise in further elucidating the genetic architecture of NS.

Funding: Other U.S. Government Support

SA-PO395

Genetic Risk Factors in a United Kingdom Paediatric Nephrotic Syndrome Cohort

Caroline J. Platt,[1] Gavin I. Welsh,[2] Ania B. Koziell,[3] Moin Saleem,[2] Agnieszka Bierzynska.[2] *[1]University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom; [2]University of Bristol, Bristol, United Kingdom; [3]Kings College London, London, United Kingdom.*

Background: Up to 30% of steroid resistant nephrotic syndrome (NS) patients have a genetic cause while the cause of the remaining group remains unknown. A yet unidentified 'circulating factor' (CF) has been attributed to the subset of patients who fail to respond to immunosuppression and in whom disease recurs post-transplant. There are emerging reports that apart from disease causing mutations in 'nephrotic' genes there are also common genetic variations in 'susceptibility genes' that may play important role in the development and/or disease progression of NS. We aimed to validate and add to the published findings on genetic variations in 'susceptibility genes'. We stratified patients into groups based on their clinical course and hypothesised that they may have different genetic 'signatures' in the selected genes.

Methods: We searched literature for previously published risk factor/modifier genes for NS/FSGS. We then screened the genes in 133 exome sequenced Caucasian patients with paediatric onset of NS. Phenotypic data was collected through a National Registry of Rare Kidney diseases. The frequency of detected single nucleotide variations (SNVs) in the cohort was compared with the 'general population'. Chi-squared test with Yates correction (2x2 contingency tables) was used. Sub-group analyses were performed for genetic SRNS and the presumed CF patients.

Results: number of previously described SNVs were enriched in our cohort when compared to the general population. We have also found several other SNVs to be significantly over-represented, that were not described before and which may therefore, be involved in susceptibility to the disease in some way. The identification of these variants provides new avenues for further exploration. By stratifying NS patients in the

case of *HLA-DRB1* and *HLA-DQA1* for example, we found a sub-set of variants that are specifically enriched in likely CF disease.

Conclusions: These results support and add to the hypothesis that there are a number of genetic variants (residing outside of the known 'nephrotic' genes) working alone or in combination, to modify the pathogenesis of NS.

SA-PO396

Reverse Phenotyping After Whole-Exome Sequencing Reveals Frequent Podocytopathy Phenocopies in Steroid-Resistant Nephrotic Syndrome

Francesca Becherucci,[1] Samuela Landini,[1] Benedetta Mazzinghi,[2] Marco Allinovi,[3] Francesco Guzzi,[1] Luigi Cirillo,[1] Hans J. Anders,[4] Sabrina Giglio,[1] Paola Romagnani.[1] *[1]University of Florence, Florence, Italy; [2]A.O.U Meyer, Firenze, Italy; [3]Careggi University Hospital, Firenze, Italy; [4]Klinikum der Universitat Munchen, Muenchen, Germany.*

Background: Primary idiopathic nephrotic syndrome (NS) is a typical presentation of genetic or non-genetic podocytopathies but occasionally other genetic nephropathies can present as clinically indistinguishable phenocopies. We hypothesized that such phenocopies of steroid resistant NS (SRNS) represent a relevant percentage of patients with primary NS explaining frequent multi-drug resistance.

Methods: All patients affected by primary NS referred to our center between 2000 and 2018 were included in the study. Whole-exome sequencing and *in silico* filtering of 298 nephropathic genes were combined with reverse phenotyping performed right after genetic diagnosis in all the patients and families.

Results: A total of 111 patients (64 SRNS and 47 steroid sensitive NS, SSNS) were included in the final analysis. Not a single pathogenic variant was detected in the SSNS group. As expected, 20/64 (31.3%) SRNS patients had pathogenic variants in podocyte genes. However, 17/64 (26.6%) showed pathogenic variants in many other genes related to clinically unrecognized genetic nephropathies, i.e. in the absence of clinical signs of the underlying disorder at onset. Reverse phenotyping permitted the identification of minor clinical signs of the underlying genetic nephropathy in the patient or the family, confirming the diagnosis and explaining multi-drug resistance. Genetic patients did not experience recurrence of post-transplant NS (0/11), while NS relapsed in 40% of the others (4/10).

Conclusions: Our unique interdisciplinary workflow based on extended genetic analysis and reverse phenotyping can significantly increase the diagnostic accuracy in patients referred with the diagnosis of SRNS, avoiding mistreatment and predicting outcome in a large percentage of these patients.

SA-PO397

Genetic Identification of Two Novel Loci Associated with Steroid-Sensitive Nephrotic Syndrome

Chris Cheshire,[1] Stephanie Dufek,[1] Adam P. Levine,[1] Matthew J. Stubbs,[1] Monika Mozere,[1] Sanjana Gupta,[1] Elena N. Levtchenko,[2] Jack F. Wetzels,[3] Jameela A. Kari,[4] Shenal Thalgahagoda,[5] Randula Ranawaka,[6] Asiri S. Abeyagunawardena,[7] Adebowale A. Adeyemo,[8] Rasheed A. Gbadegesin,[9] Daniel P. Gale,[1] Detlef Bockenhauer.[1] *[1]University College London, London, United Kingdom; [2]University Hospitals Leuven, Herent, Belgium; [3]Radboud University Medical Center, Nijmegen, Netherlands; [4]King abdulaziz University, Jeddah, Saudi Arabia; [5]Faculty of Medicine, University of Peradeniya, Peradeniya, Sri Lanka; [6]University of Colombo, Kiribathgoda, Sri Lanka; [7]University of Peradeniya, Sri Lanka, Peradeniya, Sri Lanka; [8]National Institutes of Health, Bethesda, MD; [9]Duke University Medical Center, Durham, NC.*

Background: Steroid-sensitive nephrotic syndrome (SSNS), the most common form of nephrotic syndrome in childhood, is considered an autoimmune disease with an established classical HLA association. However, the precise etiology of the disease is unclear. In other autoimmune diseases, the identification of loci outside the classical HLA region by genome-wide association studies (GWAS) has provided critical insights into disease pathogenesis. Previously conducted GWAS of SSNS have not identified non-HLA loci achieving genome-wide significance.

Methods: In an attempt to identify additional loci associated with SSNS, we conducted a GWAS of a large cohort of European ancestry comprising 422 ethnically homogeneous pediatric cases and 5642 ethnically matched controls.

Results: The GWAS found three loci that achieved genome-wide significance, which explain approximately 14% of the genetic risk for SSNS. It confirmed the previously reported association with the HLA-DR/DQ region (lead single nucleotide polymorphism [SNP] rs9273542, P=1.59×10-43; odds ratio [OR], 3.39), and identified two additional loci outside the HLA region, on chromosomes 4q13.3 and 6q22.1. The latter contains the calcium homeostasis modulator family member six gene CALHM6 (previously called FAM26F). CALHM6 is implicated in immune response modulation; the lead SNP (rs2637678, P=1.27×10-17; OR, 0.51) exhibits strong expression quantitative trait loci effects, the risk allele being associated with lower lymphocytic expression of CALHM6.

Conclusions: As CALHM6 is implicated in regulating the immune response to infection, this may explain the typical triggering of SSNS onset by infections. Our results suggest a genetically conferred risk of immune dysregulation may be a key component in the pathogenesis of SSNS.

Genetic Variants in Basement Membrane Genes Are Enriched in Nephrotic Syndrome

Agnieszka Bierzynska,[1] David R. Sherwood,[2] Moumita Barua,[3] Gavin I. Welsh,[1] Moin Saleem,[1] Rachel Lennon.[4] *[1]University of Bristol, Bristol, United Kingdom; [2]Duke University, Durham, NC; [3]Toronto General Hospital, Toronto, ON, Canada; [4]University of Manchester, Manchester, United Kingdom.*

Background: Basement membranes (BM) are essential for tissue formation and function. Core components include laminins, collagens and heparin proteoglycans. Genetic defects in BM components cause a spectrum of rare human diseases, however, recent large-scale genetic studies have shown that variants in BM genes associate with more prevalent disease including diabetic nephropathy. Whilst the role of core BM components have been linked to human disease, there are more BM components and interactors that are likely to have key roles in BM assembly and regulation. We hypothesised that BM integrity is key to kidney survival and that genetic variants in a wide spectrum of BM genes associate with disease. We aimed to identify genetic differences in BM genes between patients with nephrotic syndrome (NS) and controls.

Methods: We assembled a list of 110 genes, likely to be important for BM function. The list was derived from Gene Ontology classification, proteomic analyses of extracellular matrix, and functional screens in *C. elegans*. We used this list to screen 133 exome sequenced Caucasian patients with paediatric onset of NS. The frequency of detected single nucleotide variations (SNVs) in the cohort was compared with the general population (gnomAD controls, European non-Finnish). Randomly selected genes were also examined and used as control genes. Chi-squared test with Yates correction (2x2 contingency tables) was used.

Results: 25 SNVs were found to be significantly over-represented in the NS patients when compared to controls. 16 of those had the minor allele frequency (MAF) over 2x higher than in the general population. The biggest MAF differences were found in *HMCN2*, *SMOC1*, *LAMA5*, *MATN1*, *LAMA2* and *ADAMTS16* genes. No SNVs were enriched in the control genes. Furthermore, we screened 50 genes (BM and other) known to cause NS and identified 5 candidates that caused a BM rupture phenotype in *C. elegans* and this frequency was approximately 20-fold higher than randomly selected genes.

Conclusions: Overall these findings support our hypothesis that BM integrity is key to long term kidney survival.

SA-PO399

Incidence of Single Heterozygous Variants in "Nephrotic" Genes in Non-Genetic Paediatric Steroid-Resistant Nephrotic Syndrome

Caroline J. Platt,[1] Agnieszka Bierzynska,[3] Ania B. Koziell,[2] Gavin I. Welsh,[3] Moin Saleem.[3] *[1]University Hospitals Bristol NHS Foundation Trust, Bristol, United Kingdom; [2]Kings College London, London, United Kingdom; [3]University of Bristol, Bristol, United Kingdom.*

Background: Steroid resistant nephrotic syndrome (SRNS) is a rare condition in childhood associated with considerable morbidity, particularly in those with early onset disease. Up to 30% of children have a monogenic cause, and research is focusing on stratifying patients at an early stage in order to 'personalise' their treatments. Over 70 genes have been associated with SRNS to date, most of them are autosomal recessive (AR). Exome analysis will not infrequently identify single rare heterozygous variants within AR genes that can cause uncertainty. It is often speculated that a second variant was either missed or lies within the non-coding part of the gene. There are pathogenic single heterozygous variants within recessive 'nephrotic' genes in the general population ('carriers' for the disease). This pilot project aims to compare the incidence of rare variants in randomly selected AR 'nephrotic' genes in paediatric SRNS patients with the 'general' population.

Methods: 133 exome sequenced Caucasian SRNS patients and the ethnically matched 'general' population data (gnomAD, exomes) were used for the analysis. Rare (MAF<0.01) single nucleotide variants (SNVs) from the coding and splice-site regions were selected from the AR genes and their incidence was compared between the two cohorts. The data was analysed in 3 consecutive stages: 1. Rare SNVs regardless of zygosity. 2. Rare heterozygous SNVs (not found as homozygotes in any cohort). 3. Rare heterozygous SNVs + small indels, predicted to be likely pathogenic. SRNS patients with confirmed monogenic disease were excluded from this analysis.

Results: In this preliminary work we have found no statistically significant difference in the frequency of rare variants in NS genes (seen as homozygous or heterozygous (48.4% cohort / 53.1% control) / only as heterozygous (27.5% cohort / 24.6% control) / heterozygous and likely pathogenic (7.7% cohort / 8.1% control)) between SRNS patients and the control population.

Conclusions: Our preliminary findings suggest, for the case of the likely pathogenic single heterozygous variants, that these may be incidental and not indicative of a missing 'second hit' within the gene.

SA-PO400

Development of a High-Throughput Screening System to Evaluate Nephrin Expression on Plasma Membrane

Misato Kamura,[1,2] Haruka Kojima,[1] Mary Ann Suico,[1] Tsuyoshi Shuto,[1] Hirofumi Kai.[1] *[1]Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Program for Leading Graduate Schools "HIGO Program", Kumamoto University, Kumamoto, Japan.*

Background: Nephrin is an important component of the podocyte slit diaphragm and its dysfunction leads to severe proteinuria and nephrotic syndrome. Most nephrin mutants possibly lack export to the plasma membrane as a result of abnormal folding and post-translational modification. Although normalization of nephrin trafficking is considered as a novel therapeutic target, promising agents have not yet been found, due in part to a lack of suitable screening system for drugs that target nephrin regulation. Here, we established a high-throughput screening (HTS) system for discovery of agents that improve plasma membrane expression of nephrin.

Methods: To establish a high sensitive HTS system, we utilized split Nano-luciferase. NanoLuc fragment (HiBiT)-fusion nephrin was transfected into HEK293T cells and cell surface expression was detected by luminescence upon addition of a nonlytic reagent containing LgBiT fragment and substrate. Treatment with glycosylation inhibitor (Tunicamycin) or chemical chaperone (4-PBA), as well as comparison of clinically reported mutants (15 missense mutants) evaluated the validity of this system.

Results: HiBiT-Nephrin showed remarkable RLU compared to mock (> 200-fold). In addition, the retention of nephrin phosphorylation was confirmed by western blotting. Under this condition, tunicamycin treatment significantly reduced HiBiT-nephrin RLU (< 40%). In contrast, 4-PBA treatment significantly increased RLU (>150%). Furthermore, each of the 15 mutants of HiBiT-Nephrin showed unchanged (5) or reduced (10) expression on plasma membrane, most of which were augmented or recovered by 4-PBA treatment.

Conclusions: In this study, we succeeded in establishing a HTS system that can easily and sensitively quantify the expression of nephrin on the plasma membrane. Although the cell-based assay has limitations, this system reflected the characteristics of nephrin consistent with previous reports. With further optimization, this system will be used to screen for compounds that target nephrin.

SA-PO401

A GWAS of Congenital Anomalies of the Kidney and Urinary Tract

Tze Yin Lim,[1] Dina Ahram,[1] Miguel Verbitsky,[1] Rik Westland,[2] Priya Krithivasan,[1] Gina ying Jin,[1] Monica Bodria,[12] Shirlee Shril,[3] Byum hee Kil,[1] Enrico Fiaccadori,[10] Giuseppe Masnata,[11] Marijan Saraga,[5] Adele Mitrotti,[1] Domenico Santoro,[6] Fangming Lin,[7] Loreto Gesualdo,[9] Francesco Scolari,[4] Velibor Tasic,[8] Friedhelm Hildebrandt,[3] Krzysztof Kiryluk,[1] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]VU University Medical Center, Amsterdam, Netherlands; [3]Boston Childrens Hospital, Boston, MA; [4]University of Brescia, Montichiari (Brescia), Italy; [5]University Hospital in Split, Split, Croatia; [6]Policlinico G Martino, Messina, Italy; [7]Columbia University College of Physicians & Surgeons, New York, NY; [8]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [9]University of Bari, Altamura, Italy; [10]Universita Degli Studi-Dip. Clinica Medica Nefrologia, Parma, Italy; [11]Azienda Ospedale G. Brotzu, Cagliari, Italy; [12]Giannina Gaslini Children's Hospital, Genoa, Italy.*

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) are prevalent causes of pediatric renal failure. We investigated common risk variants that may be involved in the pathogenesis of diverse CAKUT.

Methods: A Genome-Wide Association Study (GWAS) was conducted on 2,894 ethnically and clinically heterogeneous CAKUT cases and 15,589 genetically matched controls. Association tests were performed on the imputed dosages of 10 subpopulations under the additive model with population stratification corrected and meta-analyzed.

Results: We identified a significant association on chr.21q.21.1 (P=1.91 x10^{-9}; OR=1.28) in *CHODL*, a gene that has been reported to be involved in motor axon differentiation in zebrafish models and has shown positive expression in the developing urogenital tract. We have found near genome-wide significant signals in 3 loci: *TMEM229B* (P=1.03 x10^{-7}; OR=1.25), previously reported as a suggestive locus associated to renal function measures and chronic kidney disease in a GWAS in children; *MARK1* (P=2.00 x10^{-7}; OR=1.21), a gene possibly implicated in autism and expressed in the pre and postnatal urinary tract; and chr.5p15.31 (P=1.07x10^{-7}; OR=1.43). Finally, we identified suggestive loci (P<1x10^{-5}) within or near essential renal development genes in human and mouse model, including *TWSG1*, *ROBO2*, *LAMA5*, and *GATA5*.

Conclusions: Our preliminary GWAS identified *CHODL* as a novel CAKUT candidate gene, and have shown suggestive associations of variants in critical renal development genes. Integration with a subphenotype analysis may allow us to refine these loci and prioritize candidate susceptibility genes in CAKUT.

SA-PO402

Estimation of Adenine Phosphoribosyltransferase Deficiency Prevalence Using Public Whole-Exome Sequencing Data

Hrafnhildur L. Runolfsdottir,[1,2] John A. Sayer,[3] Olafur S. Indridason,[2] Vidar O. Edvardsson,[4] Patrick Sulem,[5] Runolfur Palsson.[2,1] Rare Kidney Stone Consortium *[1]University of Iceland, Reykjavik, Iceland; [2]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [3]Newcastle University, Newcastle, United Kingdom; [4]Landspital - The National University Hospital of Iceland, Reykjavik, Iceland; [5]deCODE genetics, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase deficiency (APRTd) is a rare, hereditary cause of recurrent kidney stones and progressive chronic kidney disease (CKD). While treatment with allopurinol or febuxostat is effective, a delay in diagnosis frequently results in adverse outcomes. The small number of reported cases in countries other than France, Iceland and Japan suggests an extremely low prevalence, although missed diagnoses may significantly affect prevalence estimates. We assessed the prevalence of APRTd based on the frequency of mutated *APRT* alleles in public genomic databases.

Methods: Four databases containing genome sequencing data, the Genome Aggregation Database (gnomAD, n=141,353), the NHLBI GO Exome Sequencing Project (n=6503), the 100,000 Genomes Project (n=62,000) and the deCODE Genetics database (n=35,000) were searched for 64 reported *APRT* mutations and other potentially pathogenic variants. Minor allele frequencies (MAF) <0.01% were identified. The estimated prevalence of homozygous genotypes was calculated using the Hardy-Weinberg principle.

Results: A total of 30 disease-causing mutations with MAF <0.01% were detected in all databases. The variants with the highest allele counts are shown in Table 1. The p.Arg89Gln mutation was found to have a heterozygous frequency of 0.4087(%) in the South Asian population (n=1.3 billion), yielding an estimated 17.201 homozygotes, and a heterozygous frequency of 0.03714 (%) in the UK population (n=66 million) with an estimated 910 homozygotes. In the US, the p.Phe174 deletion had a heterozygous frequency of 0.3271 (%) in the European-American population (n=223 million), yielding an estimated 2408 homozygotes.

Conclusions: The data suggest a greater prevalence of APRTd in the Asian, UK and US populations than is reported in the literature. Based on these findings, APRTd appears to be a seriously underrecognized cause of kidney stones and CKD.

Funding: NIDDK Support

Table 1.

Database	Variant	Mutant Allele Frequency	Carrier frequency (1 in*)	Estimated prevalence (1 in*)
NHLBI, European-American	p.Phe174del	0.3271%	153	92,844
100.000 Genomes Project, UK	p.Arg89Gln	0.3714%	135	72,496
gnomAD, South Asia	p.Arg89Gln	0.4087%	123	59,864
gnomAD, East Asia	p.Ala116Thr	0.2307%	217	187,941
deCODE Genetics, Iceland	p.Asp65Val	1.2%	42	6874

Designing a Return of Genetic Results Workflow in Nephrology: Lessons Learned from a Pilot Study

Jordan G. Nestor, Maddalena Marasa, Hila Milo Rasouly, Ali G. Gharavi. *Columbia University, New York, NY.*

Background: Genetic testing is an emerging tool in nephrology practice. Actionable genetic findings can be identified as part of research or clinical care. However, no best practice exists for return of results (ROR) and clinical implementation of results, for renal patients.

Methods: We developed a workflow for ROR of primary diagnostic and/or medically actionable (secondary) findings for adults with all-cause chronic kidney disease, who underwent exome sequencing, through participation in a biobank study.

Results: We attempted to re-contact a diverse group of 50 participants with potentially diagnostic findings. Among them, 36 were contacted and we returned actionable genetic findings to 23 individuals. We identified 6 major elements in the ROR workflow for research participants: subject identification; re-contact; pre-test counseling for clinical testing; retesting for secondary validation; return of results with post-test counseling; and clinical implementation. We identified over 20 major challenges to ROR, which were iteratively addressed to optimize the workflow. Some common challenges included changes of address, death, lack of insurance for clinical validation of genetic data, lack of interest in receiving actionable findings, unwillingness to contact at-risk relatives, access to genetic counseling, and lack of standardized tools for patients and physician education. Importantly, the genetic result meaningfully impacted the clinical care of all cases.

Conclusions: The lessons learned from this study provide valuable information for return of genetic result in the setting of clinical care and research for nephropathies.

Diagnostic Utility of Next-Generation Sequencing in Patients Presenting for Percutaneous Renal Biopsy

Susan L. Murray,[1,2] Katherine A. Benson,[3] Ross P. Doyle,[4] Gianpiero Cavalleri,[6] Catherine Godson,[7] Peter J. Conlon.[5] *[1]Department of Nephrology & Transplantation, Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons In Ireland, Dublin, Ireland; [3]Royal College of Surgeons in Ireland, Dublin, Ireland; [4]Mater Misericordiae University Hospital, Dublin, Ireland; [5]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [6]RCSI, Dublin, Italy; [7]The Conway Institute of Biomolecular and Biomedical, Belfield, Dublin, Ireland.*

Background: Genetic testing is fast becoming a first line of investigation in many branches of medicine. Genetic causes of kidney disease may be under-recognised and exome sequencing has been shown to detect pathogenic mutations in up to 10% of patients with CKD. We aimed to genotype a cohort of patients undergoing renal biopsy.

Methods: We recruited adult patients attending for percutaneous kidney biopsy under investigation for acute or chronic kidney disease, over an eight-year period from 2010 to 2018. Patients undergoing post-transplant renal biopsy or patients whose renal biopsy showed diabetic nephropathy or pauci-immune vasculitis were excluded. Patients underwent next generation sequencing using a specially designed Roche NimbleGen HeatSeq panel, which sequenced for 227 genes associated with kidney disease. Data was analysed using an in-house bioinformatics pipeline and variants were classified using gold-standard American College of Medical Genetics and Genomics guidelines for variant pathogenicity.

Results: We sequenced 69 patients who had undergone native renal biopsy. These included 21 patients with a histological diagnosis of IgA nephropathy, 19 with other forms of glomerular disease, 14 with interstitial nephritis, and 15 with non-specific changes on histology. We identified a pathogenic variant for Alport Syndrome (*COL4A4*) in a single patient (1.5%). We also identified a variant of unknown significance in *CFH* in the same patient, which may be contributing to the patient's low complement levels. Additionally, we identified noteworthy variants of unknown significance in 39 patients including 12 loss-of-function variants and three truncating variants in genes previously established as contributing to renal disease.

Conclusions: Next generation sequencing may be a useful addition to renal biopsy in certain groups of patients. In an undifferentiated group of patients undergoing renal biopsy, we detected pathogenic mutations in 1.5%. This diagnostic yield may be improved when DNA is available from parents and other affected family members and with careful selection of patients sent for testing.

SA-PO405

Diagnostic and Clinical Utility of Whole-Exome Sequencing in a Cohort with Clinically Suspected Genetic Kidney Disease

Kushani C. Jayasinghe,[1] Andrew J. Mallett,[2] Catherine Quinlan.[3] Melbourne Genomics Renal Genetics Flagship part of the KidGen collaborative *[1]Monash Health, Clayton, NSW, Australia; [2]Royal Brisbane and Women's Hospital, Stafford, QLD, Australia; [3]The Royal Children's Hospital, Melbourne, VIC, Australia.*

Background: Genomic technologies enable rapid and cost-effective sequencing of DNA and have demonstrated a definitive diagnosis in several patient groups such as childhood syndromes and oncology. We sought to determine the diagnostic and clinical utility of WES in a cohort of adults and children with clinically suspected genetic kidney disease who were reviewed in multidisciplinary renal genetics clinic (RGC).

Methods: Sequential patients were prospectively recruited through five tertiary academic centres in Australia. Patients were referred by their treating nephrologist to a dedicated RGC. Following review by a multidisciplinary team consisting of a nephrologist, clinical geneticist and genetic counsellor, patients underwent genomic sequencing with analysis for a pre-determined phenotype specific list of genes of interest. We measured the diagnostic yield and the effect on short term clinical management. Full author list online at KidGen.org.au

Results: We performed WES in 204 patients (82 paediatric and 122 adults) with CKD. The median age at time of recruitment was 29 years (0-72). Preliminary results demonstrate a genetic diagnosis in 77 patients (38%). This includes (69) pathogenic variants and (25) likely pathogenic variants. When comparing the *a priori* clinical diagnosis at referral in patients with WES diagnoses, 48 (62%) had their suspected clinical diagnosis confirmed and 29 patients (38%) had a subsequent change in diagnosis. 42 patients (54%) with positive diagnoses had recommended changes to clinical management. This included the avoidance of immunosuppression, avoidance of renal biopsy, initiation of surveillance for extra-renal disease and facilitating transplant and reproductive decisions. In addition, at least 26 patients (13%) had a clinically relevant negative result with management implications.

Conclusions: To our knowledge this is the first study to report diagnostic and clinical utility of genomic sequencing in a pragmatic clinical setting. Our results confirm that in a clinically selected paediatric and adult cohort with kidney disease, WES is valuable for establishing a specific molecular diagnosis and demonstrates substantial quantifiable clinical utility.

Implementing Comprehensive Genetic Testing in Patients with Kidney Disease Improves Care by Identifying the Basis for a Wide Variety of Renal Phenotypes

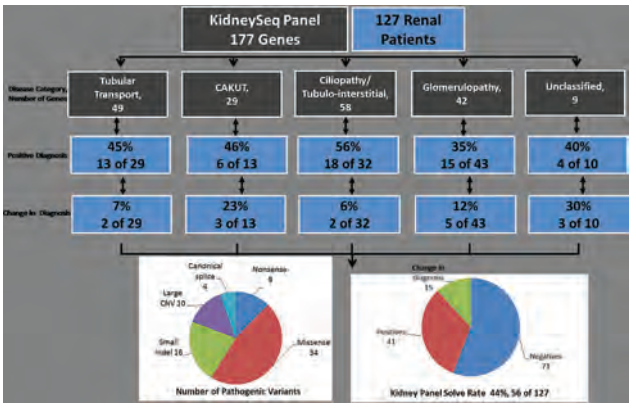
Christie P. Thomas,[2] M. Adela Mansilla,[2] Margaret E. Freese,[1] Mycah J. Kimble,[2] Colleen A. Campbell,[2] Richard J. Smith.[2] *[1]University of Iowa Hospitals & Clinics, Iowa City, IA; [2]University of Iowa, Iowa City, IA.*

Background: The clinical diagnosis of genetic renal diseases may be limited by the overlapping spectrum of manifestations between diseases or by the advancement of disease where clues to the original process is absent. The objective of this study was to determine whether genetic testing informs diagnosis and facilitates management of kidney disease patients.

Methods: We developed a comprehensive genetic testing panel (KidneySeq) to evaluate patients with various phenotypes including cystic diseases, congenital anomalies of the kidney and urinary tract (CAKUT), tubulointerstitial diseases, transport disorders and glomerular diseases. We evaluated this panel in 127 consecutive patients ranging in age from newborns to 81 years who had samples sent in for genetic testing.

Results: The performance of the sequencing pipeline for single nucleotide variants was validated using CEPH controls and for indels using Genome-in-a-Bottle. To test the reliability of the copy number variant analysis, positive samples were re-sequenced and analyzed. For patient samples, a multidisciplinary review board interpreted genetic results in the context of clinical data. A genetic diagnosis was made in 56 (44%) patients and ranged from 56% for ciliopathies/tubulointerstitial diseases, 46% for CAKUT, 45% for transport disorders and 35% for glomerulopathies. Pathogenic and likely pathogenic variants included 46% missense, 13% nonsense, 5% splice site variants, 22% insertion-deletions and 13% copy number variants. In 15 cases, the genetic result changed the clinical diagnosis.

Conclusions: Comprehensive genetic testing should be considered in the evaluation of renal patients as it complements other tests and provides insight into the underlying disease and its management.



Outcome of comprehensive gene panel testing in 127 renal patients

SA-PO407

Identifying New CKD Drug Targets from Genetic Analysis

Lisa Buvall, Anna Reznichenko, Anna Granqvist, Alex X. Zhou, Julie Williams, Linda Cederblad, Sophia Cameron-Christie, Mohammad Bohlooly, Carolina Haefliger, Pernille B. Laerkegaard Hansen. *AstraZeneca, Molndal, Sweden*.

Background: Identifying successful drug candidates to treat patients with Chronic Kidney Disease (CKD) is challenging due to the heterogenicity of the CKD population. As a result, no efficient treatment options to halt or reverse CKD development are today available. It's known that drug target genes associated with clinical phenotypes are more likely to succeed in pharmaceutical development. Thereby, in an unprecedent approach to identify CKD disease drivers we have performed whole exome sequence on 3315 CKD patients and 9563 controls to search for rare mutations in CKD patients.

Methods: Collapsing analysis generated a list with 417 enriched suggestive rare mutations in CKD patients. These genes where then prioritized through a comprehensive workflow aiming to validate the hits as potential drug targets. First the genes were filtered by bioinformatics analyses with genes being ranked and selected based on their gene expression correlating to renal function and CKD stage. In addition, integrative omics analyses were performed to give information on kidney enrichment and predict renal cell type expression.

Results: The analysis leveraged 93 genes with a strong CKD correlation. In the next step we ranked the genes based on literature data supporting a link to CKD relevant biology. The 31 genes with the highest scores went into experimental in vitro and in vivo validation. Loss of function phenotypes were investigated by siRNA KD in 2D and 3D human (organoid) renal cell systems. Gain of function phenotypes were investigated by overexpression or by studying KD protection in the presence of CKD stressors. In parallel, the importance of the genes on renal function was evaluated using CRISPR based gene knock-out of genes in zebrafish with the top ranked four genes being further processed using CRISPR knock-out mice.

Conclusions: This extensive workflow, that was processed within only one year, identified the first novel CKD target to have the potential to be first in class and as a result this gene entered our pipeline for drug discovery.

Unraveling the Genetic Contributions to Kidney Disease with the Kidney Genome Atlas

Thomas Soare,[1] Wei Zhang,[1] Adam Tebbe,[1] Vinay Mandal,[1] Diego Borges,[1] Niru Chennagiri,[1] Matthias Kretzler,[2] Girish N. Nadkarni,[3] Rasheed A. Gbadegesin,[4] Jamie L. Wenke,[5] Daniel G. Macarthur,[6] John F. Reilly,[1] Peter H. Mundel,[1] Liron Walsh,[1] Thomas T. Tibbitts.[1] *[1]Goldfinch Bio, Cambridge, MA; [2]U.Michigan, Ann Arbor, MI; [3]Ichan School of Medicine, New York, NY; [4]Duke University Medical Center, Durham, NC; [5]Nashville Biosciences, Nashville, TN; [6]Broad Institute, Cambridge, MA.*

Background: Focal segmental glomerulosclerosis (FSGS) is a progressive kidney disorder with limited treatment options. To discover novel drug targets for FSGS, we built the Kidney Genome Atlas (KGA), which currently contains whole-genome sequences (>30X) on 23000 individuals, including 3000 cases of FSGS, other proteinuric disorders, and diabetic nephropathy. Each patient genome is linked to longitudinal clinical records, and for a subset of 400 patients the KGA also includes matched transcriptomes from microdissected glomerular and tubulointerstitial samples. Our aim was to elucidate mechanisms of disease through genome-wide association studies (GWAS) of (1) disease severity in cases, (2) case-control status, and (3) gene expression in cases.

Methods: To measure disease severity, we calculated a combined Z-score based on age at presentation and eGFR slope, which was estimated using a Bayesian hierarchical linear model on 1797 patients with at least 3 eGFR measurements. Then we conducted an association study on this continuous phenotype with the burden of likely deleterious variants at the gene level. Additionally, we conducted a GWAS on case-control status and an expression quantitative trait loci (eQTL) analysis on a subset of 300 patients with transcriptomic data.

Results: As proof of principle, among all cases we found that two copies of APOL1 risk alleles were associated with earlier age at presentation (p=5e-6) and more rapid decline in eGFR slope (p=1e-2), and most strongly associated with the combined Z-score of age at presentation and eGFR slope (p=2e-8). A preliminary association test of the combined Z-score with variant burden in each of 15765 protein-coding genes showed one genome-wide significant association (FDR=0.01). A preliminary GWAS in AFR ancestry cases and controls (n=904) showed minimal impact of potential confounders, such as ancestry or sequencing batch differences (lambda=1.03). A preliminary eQTL analysis revealed 3562 genes had eQTLs in either microdissected glomeruli or tubules.

Conclusions: Integrating longitudinal clinical data, whole genome sequences, and transcriptomes from microdissected tissues is a promising approach to unraveling the molecular mechanisms of kidney diseases.

SA-PO409

Single-Cell RNA Sequencing Identifies Candidate Renal Resident Macrophage Gene Expression Signatures Across Species

Kurt Zimmerman, Zhang Li, James F. George, Michal Mrug, Bradley K. Yoder. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Resident macrophages are involved in homeostatic and disease processes in multiple tissues including the kidney. Despite the use of well-defined markers to identify these cells in mice, technical limitations have prevented the identification of a similar cell type across species.

Methods: As an entry point to determine novel markers that could identify resident macrophages across species, we performed single cell RNA sequencing (scRNAseq) analysis of $CD45^+$ innate immune cells in mouse, rat, pig and human kidney tissue.

Results: Using this approach, we identified multiple genes whose expression is enriched in mouse renal resident macrophages and in candidate resident macrophage populations across species. Further, we identified a novel set of possible cell-surface markers for these candidate kidney resident macrophages (Cd74, Cd81) and confirm using parabiosis and flow cytometry approaches that these proteins are indeed enriched in mouse resident macrophages. Our flow cytometry data also indicate there is a defined population of innate immune cells in rat and human kidney tissue that co-express CD74 and CD81, suggesting the presence of renal resident macrophages in multiple species. Finally, we show that we can use these novel resident macrophage markers to identify a population of cells that is independent of peripheral blood input in the rat.

Conclusions: Collectively, our data indicate that, based on transcriptional signatures, there is a conserved population of innate immune cells across multiple species that have been defined as resident macrophages in the mouse. In addition, we provide a proof of principle experiment showing that we can use our novel markers to identify a population of CD45+ innate immune cells that are independent of peripheral blood input in the rat.

More Than Half of Patients Clinically Diagnosed as Gitelman Syndrome in Adulthood Do Not Have Causal Mutations in Known Pathogenic Genes

Takayasu Mori, Motoko Chiga, Takuya Fujimaru, Shintaro Mandai, Azuma Nanamatsu, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

Background: Gitelman syndrome (GS) is an autosomal recessive kidney disorder characterized by hypokalemia, hypomagnesemia, hypocalciuria, and metabolic alkalosis. GS is caused by loss of function mutations in *SLC12A3* encoding Na-Cl cotransporters (NCC). Most of previous reports includes child-onset GS cases, and thus etiological profiles in adult GS have not been fully elucidated. The purpose of this study is to clarify mutation profiles of clinically diagnosed GS cases in adulthood, and to investigate the phenotypic difference between cases in which their genetic diagnoses were established or not.

Methods: A total of 84 genetically independent individuals who were referred to our institute with a clinical diagnosis of GS during 2012 to 2018 were retrospectively reviewed. Individuals who have any episodes of using loop or thiazide diuretics, or laxatives were not included. All of them received comprehensive genetic screening for known genes responsible for GS, Bartter syndrome, and hypomagnesemia (*SLC12A3, SLC12A1, KCNJ1, CLCNKB, BSND, CLCNKA, CASR, MAGED2, TRPM6, CLDN16, KCNJ10, etc.*). Twenty individuals were excluded because of the following reasons; 9 with insufficient clinical information, 5 under 18 years, 2 with only single heterozygous variant in *SLC12A3*, 3 with responsible mutations in *CLCNKB*, 1 with variants in *BSND*.

Results: Of the remaining 64 cases, 27 (42.1%) were genetically diagnosed as GS (solved cases). Thirty-seven (57.9%) did not have any responsible variants (unsolved cases). Unsolved cases were older (47.1 ± 15.2 vs. 37.3 ± 13.1 years, P = 0.01). Interestingly, most of unsolved cases were female (83.8% vs. 59.3%). Serum Mg was higher in unsolved cases (1.95 ± 0.47 vs. 1.67 ± 0.34, P = 0.02). There were no differences in serum K, HCO_3^-, FEK, urine Ca/Cr ratio between the groups. Regarding the causal mutations in *SLC12A3*, L858H (33.3%) and T180K (25.9%) were major, which are reported as hotspots in Japanese GS. In this study, R399C was also found in 11.1% cases.

Conclusions: More than half of the adult cases with GS phenotype were mutation-negative for known pathogenic genes. Phenotypic difference of the two was not evident other than age and serum Mg. Unsolved adult cases might have novel pathogenic genes responsible for their GS phenotype.

Metabolic Profiling of Urine from Patients with Cystinuria Provides New Insight into Disease Phenotype, Associated Microbiome Effects, and Treatment Efficacy

Matthew R. Lewis,[1] Elena Chekmeneva,[1] Caroline Sands,[1] Mark David,[1] Luke Whiley,[1] Ada Armstrong,[1] Lama Nazzal,[5] Amrik Sahota,[2] David S. Goldfarb,[3] Zoltan Takats,[1] John R. Asplin.[4] *[1]Imperial College London, London, United Kingdom; [2]Rutgers University, Piscataway, NJ; [3]New York Harbor VAMC, New York, NY; [4]Litholink Corp, Chicago, IL; [5]New York University School of Medicine, New York, NY.*

Background: Cystinuria is a disease of impaired absorption of cystine and dibasic amino acids (DAA) from the intestine and renal tubule leading to formation of cystine kidney stones. However, the metabolic impact of reduced amino acid absorption and excessive loss in the urine is poorly understood. We measured endogenous, gut microbial, and xenobiotic metabolites, providing insight into consequences of the disease and its treatment.

Methods: Urinary biochemicals were assayed using LC-MS in 293 urine specimens from patients with cystinuria or control urinary phenotypes. Multivariate statistical analyses were conducted to reveal statistically significant biochemical signatures of the disease and products of cysteine-binding thiol drugs (CBTDs). 16s rRNA gene sequencing was performed on fecal samples from 12 wildtype (WT) and 12 cystinuric (*Slc3a1* knockout; KO) mice to evaluate their gut microbial composition.

Results: Cystinuric urine samples had elevated levels of cysteine-γ-glutamyl cystine disulfide (glutathione precursor), indole-3-acetic acid (microbial tryptophan metabolism), and novel conjugated forms of putrescine (microbial DAA decomposition). Conversely, taurine (sulfur metabolism), indole-3-acetic acid-glucuronide, and novel urinary metabolite N-methyl pipecolic acid (lysine metabolism) were reduced in cystinuric urine. Where cysteine-bound CBTDs were observed, substantial amounts of "wasted" drug were also detected as CBTD homodimers, non-cysteine disulfides, and mixed drug disulfides. The differentiation of gut microbially-derived metabolites led us to evaluate the gut microbiome diversity and composition in a mouse model of cystinuria revealing clear beta diversity and taxa differentiation between WT and KO mice.

Conclusions: Cystinuria is associated with unique urinary metabolic profiles beyond hyperexcretion of cystine and DAA, indicating perturbed metabolic processes and potential gut microbial effects. Study of the gut microbiome of WT and KO mice provides the first evidence for them having distinct taxa, perhaps due to poorly absorbed DAA present in the intestinal lumen. Urinary profiles allow us to characterize the excretion profiles of CBTDs, providing insight which may be helpful to tailor treatment.

Familial Hypomagnesemia with Hypercalciuria and Nephrocalcinosis: Expression Pattern of Urinary Exosomal MiRNAs

Monica Vall,[2] Monica Duran,[2] Gema Ariceta,[3] Anna Meseguer.[1] Renal Physiopathology Group. VHIR *[1]Vall d'Hebron Institut de Recerca, Barcelona, Spain; [2]Renal Physiopathology, Vall d'Hebron Institut de Recerca, Barcelona, Spain; [3]Hospital Universitari Vall d' Hebron, Barcelona, Spain.*

Background: Familial hypomagnesemia with hypercalciuria and nephrocalcinosis (FHHNC) is a rare autosomal recessive tubulopathy caused by *CLDN16* or *CLDN19* genes mutations. FHHNC is characterized by urinary wasting of calcium and magnesium, nephrocalcinosis and progression to chronic kidney disease (CKD) and end-stage renal disease (ESRD). Also, some *CLDN19* patients develop ocular impairment. Patients homozygous for c.59G>A; p.G20D mutation in *CLDN19* gene, the most frequent in Spain, exhibit different progression to kidney failure, suggesting that other molecular events modulate disease evolution. In absence of biopsy availability, urinary exosome-like vesicles (uEVs) are a non-invasive source of information of the renal condition. In this work we analyzed the expression pattern of miRNAs obtained from uEVs of FHHNC patients.

Methods: uEVs isolation of non-transplanted FHHNC patients was performed by differential centrifugation and miRNA cargo was extracted with miRCURY RNA Isolation kit and analyzed through microarray assays. Statistical parameters were p-value<0,5 and an absolute logFC>1, except for renal progression comparison which was 0,5.

Results: Our cohort comprises 30 patients: 3 present mutations in *CLDN16* gene while 27 (90%) in *CLDN19*, of which, 63% (n=19) are p.G20D homozygous. Most patients (53%) exhibit a moderate renal phenotype whereas 17% and 30% are classified as severe and mild, respectively. In the ESRD group, 80% of patients were female, whilst in the non-ESRD group they represent only 40%. Comparisons revealed sets of deregulated miRNAs in FHHNC patients and specific miRNAs associated with the homozygous p.G20D mutation. Moreover, we identified two miRNAs differentially expressed in male patients and one related to renal disease progression.

Conclusions: The analysis of miRNAs defined a set of miRNAs commonly expressed in all FHHNC patients and other miRNAs exclusively associated with the homozygous p.G20D mutation in the *CLDN19* gene. Furthermore, gender of patients and renal disease progression were also associated with specific miRNAs each.

Phenotypic Expression of Primary Hyperoxaluria: Comparative Features of Types 1, 2, and 3

Prince Singh,[1] Jason K. Viehman,[2] Ramila A. Mehta,[2] Linda Hasadsri,[2] Andrea G. Cogal,[2] David J. Sas,[2] Peter C. Harris,[2] John C. Lieske,[2] Dawn S. Milliner.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN.*

Background: Primary hyperoxalurias (PH) are inborn errors of metabolism that result from 3 specific hepatic enzyme deficiencies leading to hepatic overproduction of oxalate that must be excreted by the kidneys. Recurrent calcium oxalate kidney stones, nephrocalcinosis and decreased kidney function are common. PH type 3 (PH3) accounting for 10% of known PH cases was most recently described and hence the clinical expression is less defined due to small patient numbers and shorter follow-up.

Methods: Demographic and clinical data were obtained from patients enrolled in the Rare Kidney Stone Consortium PH registry. PH diagnosis was by molecular diagnostic testing of *AGXT* (PH1), *GRHPR* (PH2) and *HOGA1* (PH3) genes. Demographic, clinical, and laboratory features were compared by PH type using a Chi-square test (categorical variables) and Kruskal-Wallis test (continuous variables).

Results: Though they tended to be younger at onset of symptoms and diagnosis, PH3 patients were more likely to have had stones prior to diagnosis (p=0.025), a lower prevalence of nephrocalcinosis (p=0.002), and lower urine oxalate, and higher urine calcium and citrate excretions than PH1 patients.(p <0.001) PH3 patients continued to experience recurrent stones throughout all decades of life. See Figure 1

Conclusions: Though more likely to have stones at presentation and higher urine calcium, nephrocalcinosis is less prevalent and kidney function better preserved in PH3 compared to PH1 and PH2. The lower Uox and higher urine citrate may contribute to preserved renal function, although the higher urine calcium may contribute to frequent stone events throughout the lifespan. The data suggest persistent stone activity throughout life in PH3 patients.

Funding: NIDDK Support

Interim Results from the Ongoing Phase 2 Open-Label Extension Study of Lumasiran, an Investigational RNA Interference (RNAi) Therapeutic, in Patients with Primary Hyperoxaluria Type 1 (PH1)

Tracy McGregor,[10] Sally Hulton,[3] Yaacov Frishberg,[1] Pierre Cochat,[2] Jaap Groothoff,[4] Daniella Magen,[5] Jerome Harambat,[6] Bernd Hoppe,[7] William van't Hoff,[8] Dawn S. Milliner,[9] John C. Lieske,[9] Patrick Haslett,[10] Sandeep Talamudupula,[10] David V. Erbe,[10] Georges Deschênes.[11] *[1]Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; [2]Université ClaudeBernard Lyon1-, Bron, France; [3]Birmingham Childrens' Hospital, Birmingham, United Kingdom; [4]Amsterdam UMC (Academic Medical Center), Amsterdam, Netherlands; [5]Rambam Health Care Campus, Haifa, Israel; [6]Bordeaux University Hospital, Bordeaux, France; [7]University Hospital Bonn, Bonn, Germany; [8]Great Ormond Street Hospital, Lond, United Kingdom; [9]Mayo Clinic, Rochester, MN; [10]Alnylam Pharmaceuticals, Cambridge, MA; [11]Hospital Robert Debre/Pediatric Nephrology, Paris, France.*

Background: PH1 is a rare genetic disorder characterized by persistent hepatic overproduction of oxalate. Oxalate crystalizes with calcium leading to recurrent kidney stones, nephrocalcinosis, progressive renal failure, and multiorgan damage from systemic oxalosis. Lumasiran is a subcutaneously-administered investigational RNAi therapeutic specifically designed to decrease oxalate production. In Phase 1/2, lumasiran demonstrated an acceptable safety profile and clinically significant urinary oxalate (UOx) lowering in patients with PH1. Emerging data from the ongoing Phase 2 open-label extension (OLE) study will be presented.

Methods: Phase 2 OLE includes patients who completed the Phase 1/2 randomized, placebo-controlled, multicenter trial, evaluating lumasiran in patients with PH1 ≥6 years old, UOx ≥0.7mmol/1.73m^2/day and eGFR >45mL/min/1.73m^2. Patients received 1 of 3 dosing regimens: 1mg/kg or 3mg/kg monthly x3 doses or 3mg/kg every 3 months x2 doses. After completing Phase 1/2, all patients enrolled in OLE, starting at their original dose unless a different dose was approved prior to dosing in OLE. Endpoints include safety and change in 24-hour UOx.

Results: The Phase 1/2 study enrolled 20 patients with PH1 at 9 sites in 5 countries; mean age 14.9 years (range: 6-43), mean baseline UOx 1.69mmol/1.73m^2/day (range: 0.83–2.97). As of February 2019, 18 patients were dosed in OLE for median of 4 months (range: 0.03–8.36). Continued dosing with lumasiran was well tolerated, with no discontinuations or drug-related serious adverse events. Adverse events were reported in 12/18 (66.7%) patients; majority were mild in severity and assessed as unrelated to study drug. Mean max reduction in UOx relative to Phase 1/2 baseline was 72% (N=9) and mean reduction at day 85 was 69% (N=7); all of these patients achieved normal or near normal levels of UOx.

Conclusions: To date, lumasiran has demonstrated an acceptable safety profile and clinically significant reduction in UOx in patients with PH1. A Phase 3 program evaluating efficacy and safety of lumasiran in patients with PH1 is ongoing.

SA-PO415

Alternative Promoter Type Influences the Expression of the GLA Gene in Human Kidney Cells

Mohammed A. Al-Obaide, Tetyana L. Vasylyeva. *Texas Tech University Health Sciences Center, Amarillo, TX.*

Background: Diagnostic genetic methods for Fabry disease focus on molecular screening for mutations in *GLA* exons. Intriguingly, alternative promoters are greatly influencing differential gene expression in tissues and malfunctions in many disease-associated genes [Trends Genet (2008) 24(4):167-177; Genome Res (2011) 21(8):1260-1272]. *GLA* expression is one of more than 50% of human genes that are controlled by alternative promoters. We aimed to investigate the influence of alternative promoters on *GLA* expression in three types of human kidney cells (embryonic, epithelial and glomerular cells).

Methods: The *GLA* alternative promoters were searched in TRED, EPD, PrESSto/FANTOM5, and Ensembl databases. RNA extracted from embryonic, epithelial and glomerular kidney cells by RNAzol method. RT q-PCR was used for the analysis of *GLA* expression. Expression data of *GLA* alternative promoters were normalized to reference gene *HPRT*1, and the fold-change in the *GLA* expression was calculated by Livak and Schmittgen mathematical method [Methods (2001) 25(4):402-8.].

Results: Nine *GLA* alternative promoters were identified in the databases with overlapping sequences at 5-prime side of the *GLA* locus. EPD database showed 31 transcription starting sites (TSSs) along 150 bases (-99 to +50) from the main TSS at position 0. Three primers sets (G1, G2, and G3) were designed to cover several TSSs and were used in the *GLA* expression analysis by RT q-PCR. The expression data showed *GLA* expression differences over a wide range in kidney embryonic, epithelial and glomerular cells. For example, in the kidney embryonic cells, the *GLA*-G2 expression was decreased 12.5-fold, and *GLA*-G3 was increased 15.3-fold compared with *GLA*-G1 expression. Promoter efficiency depends upon regulatory sequences specific to transcription factors, mutations in the alternative promoters can alter the binding capacity of transcription factors.

Conclusions: RT q-PCR data showed the influence of alternative promoter type on the expression of the *GLA* gene in human kidney cells. Alternative promoters and their variants may serve as diagnostic biomarkers and potential therapeutic targets for Fabry disease.

Variants in the Bidirectional Promoter of GLA and HNRNPH2 Associated with Fabry Disease

Mohammed A. Al-Obaide, Tetyana L. Vasylyeva. *Texas Tech University Health Sciences Center, Amarillo, TX.*

Background: Heterogeneous clinical presentation of Fabry disease is not yet completely understood. Although, heterozygous Fabry females generally show an attenuated form of Fabry disease; in some cases, they show a severe phenotype. A severe case of heterozygous female (HF) was attributed to CpG Island (CGI) methylation specifically at mutation site c.36C>A in the *GLA* gene exon 1, the patient's non-mutated allele C, which is prone to methylation, remained unchanged [Mol Genet Metab (2017) 120(3):173-179]. Even though the status of the CGI methylation in silencing genes' expressions is divisive, the overall view is that methylation can repress transcription factor binding. Genomic databases show overlapping sequence at 5-prime sides of *GLA* and *HNRNPH2* divergently paired loci. Mutations at the upstream of *HNRNPH2* sequence can cause Fabry disease. We aimed to investigate the molecular features of *GLA* and *HNRNPH2* predicted bidirectional promoter that control the expression of the two divergently paired genes and their association with Fabry disease.

Methods: Genomic databases and prediction tools for promoters, transcription factor binding sites and CGI were used to identify and analyze the intervening sequence for *GLA* and *HNRNPH2* and the bidirectional promoter.

Results: Most bidirectional promoters are GC rich and exhibit CGIs prone to methylation, and characterized by five transcription factors binding sites (TFSBSs) (GABPA/NRF2, NRF1, NFY, YY1, and ZNF143). The predicted *GLA* and *HNRNHP2* bidirectional promoter sequence located at chrX: 101,407,191-101,409,040 on the reverse strand composed of 1850 bps. We identified 831 bps intervening sequence for *GLA* and *HNRNHP2*-reverse complement. The five specific TFBSs were identified and marked along the predicted bidirectional promoter sequence. The lengths of four identified CGIs were between 100 and 323 bases. The criteria used for identification of CGI were: CGI size > 100, %G+%C Percent > 50.0, Obs/Exp CpG ratio > 0.6). Intriguingly, the c.36C>A variant of HF patient was mapped at NRF1 motif identified by our bioinformatic analysis. Methylation reduced binding of NRF1 transcription factor to those sites [Cell Rep (2017) 19(11):2383-2395].

Conclusions: The molecular characteristics of identified *GLA* and *HNRNHP2* bidirectional promoter define the role of upstream variants of the divergently paired *GLA* and *HNRNPH2* genes in Fabry disease.

Methyl-CG Erosion Define Core Pathways in the Progression of Diabetic Nephropathy

Assam El-Osta.[1,2] *[1]Central Clinical School, Monash University, Melbourne, VIC, Australia; [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Background: To apply systems level understanding of the role of DNA methylation, it is important to distinguish the essential sequence elements involved in regulating gene expression. This becomes a particularly challenging task for diabetic kidney disease (DKD) when reliable epigenetic markers such as DNA methylation are limited. While genome-wide methylation studies are typically performed using BeadChip array technology, this does not provide sufficient coverage to construct an integrated epigenetic regulatory network (ERN) important because diabetic nephropathy is considered a complex polygenic and multifactorial disorder. To address this knowledge gap, we examined DNA methylation using massive parallel sequencing to describe an ERN assessing methylation changes from multi-centre diabetes registries.

Methods: DNA methylation sequencing was used to define an epigenetic regulatory network in the Finnish Diabetic Nephropathy (FinnDiane) discovery cohort. DNA methylation changes were also assessed using independent replication cohorts from Hong Kong and Thailand. Methylation mediated gene regulation using primary human renal and vascular endothelial cells confirm functional methylation-dependent CTCF and Pol2B regulation of gene expression.

Results: Differential methylated regions (DMRs) in leukocytes are associated with DKD progression and integrative methylation analyses reveal 494 differentially methylated genes (DMGs) that intersect with CTCF binding sites (181 genes with increased- and 313 genes with reduced- methylation). Integration of DNA methylation and CTCF/Pol2B profiles confirm the major pathways associated with insulin receptor signalling, lipid metabolism and integrin cell interactions with the progression of DKD.

Conclusions: The progression of nephropathy in T1D remains unexplained, using multi-centre registries combined with functional studies using primary human renal cells we identify methylation indices and specifically erosion on core genes that functionally regulate pathways describing an epigenetic regulatory network.

Targeted Next-Generation Sequencing of Nephropathy Genes in Non-Diabetic and Diabetic Kidney Disease Patients Facilitates Clinical Diagnoses

Julio C. Fierro Morales, Andrew H. Wright, Scott G. Frodsham, Melissa H. Pezzolesi, Jose M. Lazaro guevara, Marcus G. Pezzolesi. *University of Utah, Salt Lake City, UT.*

Background: For patients with concomitant diabetes and chronic kidney disease (CKD), diabetes is often assumed to be the underlying cause of their kidney disease. Without histopathological evidence, however, it's unclear if such patients have diabetic

kidney disease (DKD), nondiabetic kidney disease (NDKD), or concurrent DKD and NDKD. To examine the utility of targeted next-generation sequencing (NGS) in facilitating clinical diagnoses in CKD, we coupled this technology with a custom nephropathy gene panel to determine the genetic cause of CKD in NDKD and DKD patients from the Utah Kidney Study.

Methods: Targeted NGS of 345 nephropathy genes was performed in 186 patients (87 NDKD and 99 DKD). Identified variants were prioritized by predicted effect on protein function, frequency (minor allele frequency (MAF) < 0.1%), and a CADD-based mutation significance cutoff (MSC) at the 95% confidence interval for ClinVar.

Results: After applying a MAF filter and MSC impact score cutoff, retaining only variants marked as highly likely to be deleterious, we identified 563 rare, functional variants, 113 of which are novel. These included 509 nonsynonymous, 20 nonsense, 24 frameshift, and 10 splicing variants. No enrichment of these variants was observed in NDKD patients when compared to DKD patients (*P*=0.55); there was, however, a modest, non-significant excess of novel rare variants in the NDKD cohort (P=0.15). An excess of rare variants was identified in the NDKD cohort in several genes, including *COL4A5* and *PKD2*. Conversely, variants in *DYNC2H1, ATP7B, NEK8,* and *ACE* were enriched in the DKD cohort. Interestingly, variants *PKHD1* and *CUBN* were nearly equally distributed between the two cohorts.

Conclusions: We identified many rare and novel variants in known nephropathy genes in both NDKD and DKD patients. Our findings suggest that many DKD patients likely have concomitant diabetes and non-diabetic CKD that can be attributed to a genetic cause. Our study suggests that targeted NGS may prove useful as a diagnostic tool to enable an accurate molecular CKD diagnosis, particularly in patients whose underlying CKD cause is incorrectly attributed to their diabetes.

Effects of the GLUT1 A-2841T Polymorphism on Proteinuria in CKD Patients Prior to the Onset of ESRD

Ljubomir M. Ilic,[1] Ian Tfirn,[2] Carmen Smotherman,[3] Charles W. Heilig.[3] *[1]University of Florida College of Medicine Jacksonville, Jacksonville, FL; [2]UF Health, Jacksonville, FL; [3]University of Florida, Jacksonville, FL.*

Background: The potential role of selected Glucose transporter 1 (GLUT1) single nucleotide polymorphisms (SNP)s in the pathogenesis of diabetic kidney disease has previously been published in human studies, with certain polymorphisms conferring a higher risk of nephropathy. We studied the effects of the GLUT1 A-2841T SNP in the promoter region on proteinuria in chronic kidney disease (CKD) patients prior to onset of their end-stage renal disease (ESRD).

Methods: This was a prospective cohort study of 127 ESRD patients whose GLUT1 A-2841T genotype was determined from their blood specimen and classified as: AA, AT or TT with the T polymorphism present in none, one or both alleles, respectively. Proteinuria was assessed by the highest protein to creatinine ratio within the 6-month period prior to ESRD onset, provided there was no sign of acute kidney injury. Covariates collected were patient age, race/ethnicity, gender, ESRD cause and date of onset as documented by their chronic dialysis unit, left ventricular ejection fraction <40%, smoking status, and presence of coronary/peripheral arterial disease. The gene analysis was performed by the UF Center for Biotechnology. Protein to creatinine ratio results were available in 78 patients. ESRD causes were categorized as type 2 or 1 diabetes mellitus, hypertension, polycystic kidney disease, glomerulonephritis or primary nephrotic syndromes, and other. The data were analyzed using Fisher's exact tests and multiple regression.

Results: The distribution of genotypes does not vary among the ESRD causes (p=0.54), but differs among the race/ethnicities (p=0.0002), with the TT genotype present in 50%(4/8), 7.7% (8/104), 10%(1/10) and 40%(2/5) of Hispanic, black, white and American Indian/other patients, respectively. Adjusting for the ESRD cause, the TT genotype is associated with 5.73 g/g more proteinuria than AA (95%CI 2.9,8.5;p=0.0001). The AT genotype is associated with 0.71 g/g more proteinuria than AA, but the results are not significant.

Conclusions: Proteinuria in CKD patients tends to increase with a single A to T allele change at the -2841 position of the GLUT1 gene and becomes very significant with A to T changes in both alleles, with the results applicable to all ESRD causes.

SA-PO420

Contribution of SLC22A12 on Hypouricemia and Its Clinical Significance for Screening Purposes

Sungkweon Cho,[1,2] Cheryl A. Winkler.[3] *[1]NCI, Frederick, MD; [2]SAIHST, Sungkyunkwan University, Seoul, Republic of Korea; [3]NCI, NIH, Frederick National Laboratory, Frederick, MD.*

Background: Renal hypouricemia (RHUC) is a rare inherited disorder strongly associated with genetic mutations of renal transporters genes. Despite its adverse complications (e.g. acute kidney failure and nephrolithiasis), differentiating between inherited renal hypouricemia and transient hypouricemic status is challenging. Here, we aimed to identify genetic variants in hypouricemia patients using whole-exome sequencing (WES) and assess the feasibility for genetic diagnosis in primary screening.

Methods: We selected all cases (N=31) with extreme hypouricemia (<1.3 mg/dl) from Korean urban cohort of 179,381 subjects; selection criteria included 1) abstinence from alcohol or smoking and 2) an absence of underlying conditions (i.e., hypertension, diabetes and taking anti-hypertensive medication). WES and corresponding downstream analyses were performed for the discovery of coding variants causal for hypouricemia. Two known causal variants within *SLC22A12* (p.Trp258*, pArg90His) were identified, we then directly genotyped the 2 *SLC22A12* variants in independent 50 hypouricemia subjects to assess the diagnostic utility of these two causal variants.

Results: For the discovery cohort who had undergone WES, 27 of 31 (87.1%) individuals harbored missense or nonsense variants in either the homozygous or compound heterozygous state in *SLC22A12*. 24 of 31 (77.4%) subjects were shown to have at least 1 copy of the truncating p.Trp258* and/or p.Arg90His. Four novel variants in *SLC22A12*, p.Asn136Lys, p.Thr225Lys, p.Arg284Gln, and p.Glu429Lys were discovered and were predicted to cause uric acid transport defects by molecular dynamics. Individuals (n=50) from an independent cohort were directly genotyped for the p.Trp258* and p.Arg90His variants, 47 of 50 cases (94%) were explained by only these two variants.

Conclusions: This is the first study to show the value of genetic diagnostic screening for hypouricemia in the clinical setting. Screening of just two ethnic-specific variants (p.Trp258* and p.Arg90His) identified 87.7% (71/81) of Korean patients with hypouricemia. Early genetic identification of constitutive hypouricemia may prevent acute kidney injury by avoidance of dehydration and excessive exercise.

Long-Term Renal Outcomes with Migalastat in Patients with Fabry Disease: Results from Phase 3 Trials

Daniel Bichet,[1] Eric L. Wallace,[7] Derralynn Hughes,[3] Nina Skuban,[6] Brian Lin,[2] Ulla Feldt-Rasmussen,[4] Raphael Schiffmann.[5] *[1]University of Montreal, Montreal, QC, Canada; [2]Amicus Therapeutics Inc, Cranbury, NJ; [3]University College London, Royal Free London NHS Foundation Trust, London, United Kingdom; [4]Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [5]Baylor Research Institute, Dallas, TX; [6]Amicus Therapeutics Inc, Cranbury, NJ; [7]University of Alabama at Birmingham, Birmingham, AL.*

Background: Fabry disease is a multisystem disorder of which nephropathy is an important feature, with untreated male patients experiencing a decline in glomerular filtration rate (GFR) of up to 12.2 mL/min/1.73 m^2 per year. Here, we assessed long-term changes in renal function in patients with Fabry disease and amenable mutations who were treated with migalastat in the phase 3 FACETS (NCT00925301) and ATTRACT (NCT01218659) trials.

Methods: In FACETS, enzyme replacement therapy (ERT)-naive patients were randomly assigned to 6 mo of double-blind miglastat 150 mg every other day (QOD) or placebo, followed by an additional 18 mo of migalastat. In ATTRACT, patients receiving ERT were randomly assigned to 18 mo of miglastat 150 mg QOD or continued ERT, followed by an additional 12 mo of miglastat. Patients could continue migalastat in separate long-term extension trials. Renal outcomes were evaluated using the beginning of migalastat treatment as the baseline, and were analyzed by sex, baseline $eGFR_{CKD-EPI}$, and baseline 24-h urine protein.

Results: Overall, mean (range) duration of migalastat exposure was 4.4 (0.1-7.8) years. Mean (SD) baseline $eGFR_{CKD-EPI}$ (mL/min/1.73 m^2) was 93.1 (24.4) in FACETS and 89.0 (20.4) in ATTRACTS. Annualized rates of change in $eGFR_{CKD-EPI}$ by baseline variables are shown in the table.

Conclusions: Data suggest that patients who received long-term treatment with migalastat experienced a rate of eGFR decline comparable to published data with ERT. In addition, starting treatment early may prevent irreversible renal progression.

Funding: Commercial Support - Amicus Therapeutics

Annualized Rate of Change in $eGFR_{CKD-EPI}$		FACETS (n=48)		ATTRACT (n=49)	
	Analysis group	Mean (SD)	n	Mean (SD)	n
Overall	—	-1.7 (3.8)	47	-1.6 (6.5)	49
Sex	Male	-2.6 (4.1)	18	-3.8 (6.8)	19
	Female	-1.1 (3.5)	29	-0.2 (6.0)	30
Baseline $eGFR_{CKD-EPI}$	>90 mL/min/1.73 m^2	-2.1 (4.0)	26	-2.0 (5.1)	24
	60-90 mL/min/1.73 m^2	-0.6 (2.7)	16	0.0 (6.9)	22
	>30 to <60 mL/min/1.73 m^2	-2.7 (5.3)	5	-10.0 (9.3)[a]	3
Baseline urine protein	<100 mg/24 h	-0.9 (1.4)	7	-2.3 (7.6)	12
	100-1,000 mg/24 h	-1.4 (4.0)	33	-1.6 (4.3)	25
	>1,000 mg/24 h	-3.9 (3.7)	7	-8.0 (11.7)[a]	3

[a]Each subgroup included one patient with an annual eGR decline of 20 mL/min/1.73 m^2.

Evaluation of Renal Biomarkers for Fabry Disease Patients with and Without Enzyme Replacement Therapy

Marcelo R. Bacci,[1] Fernando L. Fonseca,[1] Marion C. Braga,[2] Ana maria Martins,[2] Vania D'Almeida.[2] *[1]Faculdade de Medicina do ABC, Santo Andre, Brazil; [2]Universidade Federal de São Paulo, São Paulo, Brazil.*

Background: Renal follow-up is an important part of clinical monitoring in patients with Fabry disease(FD)with the aim of avoiding renal failure. Despite its limitations, creatinine is still the most used biomarker. While new renal biomarkers are described, their effectiveness has not yet been fully evaluated for FD. This study aimed to compare renal biomarkers generally and rarely used in the evaluation of FD patients receiving or not enzyme replacement therapy(TRE).

Methods: The usual biomarkers for renal monitoring (microalbuminuria, proteinuria and creatinine) and the proposed biomarkers (cystatin C, beta-2-microglobulin (B2M), NGAL were quantified in blood and/or urine samples of 40 patients with FD, 39 controls without renal disease paired by age and sex and 38 controls with renal disease undergoing hemodialysis.

Results: In FD group, 32.5% are men with mean age of 41 years old and mean age of 37.8 years of FD diagnosis. There was a statistical difference($p<0.05$)for proteinuria and microalbuminuria in isolated urine samples and, in results for both serum and plasma samples for cystatin C,NGAL,B2M, creatinine and GFR. All analytical parameters evaluated, including ROC curve, sensitivity, specificity and accuracy indicated B2M as the best biomarker, followed by cystatin C, proteinuria and microalbuminuria. Results of NGAL and urinary creatinine do not indicate good predictors of renal impairment. Although 72.5% patients were receiving ERT, similar results were found when comparing individuals with and without ERT with controls, suggesting that the treatment does not seem to have influences on the evaluated parameters. When comparing the results of FD receiving or not TRE with the control volunteers without kidney disease, there was a significant statistical difference for the results of NGAL, microalbuminuria and proteinuria. Microalbuminuria and proteinuria are widely accepted as one of the evidences for starting TRE in FD patients. Since NGAL has already been described as a potential biomarker of inflammation, it might help to explain the higher results of this biomarker in FD patients when compared to control groups.

Conclusions: Considering the biomarkers proposed, serum B2M was the best renal biomarker for renal follow-up in FD patients, followed by cystatin C. Moreover, TRE does not seem to have influences on biomarkers results.

SA-PO423

Family Screening Among CKD Patients with Fabry Disease: A Very Important and Underrated Task

Luciana S. Sodré,[1,2] Rosalia M. Huaira,[1] Fernando A. Colugnati,[2,1] Marcelo P. Coutinho,[3] Natalia M. Fernandes.[1,2] *[1]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil; [2]Interdisciplinar de Estudos e Pesquisas em Nefrologia, Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil; [3]Datagenno, Campos dos Goytacazes, Brazil*.

Background: Introduction: Fabry disease is a chronic, progressive and multi-systemic hereditary condition, related to a Xq22 mutation in X chromosome, which results in deficiency of acid alpha-galactosidase, hence reduced capacity of globotriaosylceramide (Gb3) degradation. Gb3 accumulates in lysosomes throughout virtually every organ, thus carrying considerable morbidity and mortality. **Objective**: Evaluate the prevalence of Fabry disease, as well as its signs and symptoms, among relatives of chronic kidney disease (CKD) patients diagnosed with Fabry disease during a previously conducted study, entitled "Clinical and epidemiological analysis of Fabry disease in dialysis centers in Brazil – the Brazil Fabry Kidney project".

Methods: Transversal study, interviewing the relatives of patients and performed blood tests for both Gb3 dosage and genetic testing.

Results: Among 1214 interviewed relatives, 115 (9.47%) were given the diagnosis of Fabry disease, with a predominance of women (66.10%). The most prevalent comorbidities were rheumatologic conditions and systemic hypertension (1.7% each), followed by heart, neurological and cerebrovascular disease, and depression, in 0.9% of individuals. Intolerance to physical exercise and tiredness were observed in 1.7%, followed by periodic fever, intolerance to heat or cold, diffuse pain, burn sensation or numbness in hands and feet, reduced or absent sweating, as well as abdominal pain after meals, in 0.9%.

Conclusions: Family screening of Fabry disease is highly indicated, since we found a prevalence of 9.47% of relatives of CKD patients with this condition, remarkably with a 66.1% predominance of women, which contrasts with previous reports.

SA-PO424

Natural Killer Subsets in Patients with Fabry Disease

Kultigin Turkmen,[1] Mehmet A. Karaselek,[2] Ismail Baloglu,[1] Seyma Celik,[2] Ismail Reisli,[2] Sukru Guner,[2] Sevgi Keles.[2] *[1]Necmettin Erbakan Universtity Meram School of Medicine, Konya, Turkey; [2]Pediatric Allergy and Immunology, Necmettin Erbakan University, Konya, Turkey*.

Background: Fabry Disease (FD) is a storage disorder which affects mostly kidney, kardio and serebrovascular systems. The lysosome, whose function is impaired in FD and also is an important compartment for the innate immune responses. To date, invariant natural killer (NK) T cell functions was found be impaired in FD. Hovewer, there is no data regarding NK cell subsets in patients with FD. We aimed to analyze subtypes of NK cell in patients with FD and compared these results with healthy subjects.

Methods: 15 patients with FD and 10 healthy subjects were included in the study. Of these 15 patients 8 patients were receiving agalsidase alfa or beta. Blood samples obtained from the patients with FD and healthy subjects were taken into 2 ml EDTA tube to evaluate peripheral NK cell subgroups according to CD56 and CD16. These cells were evaluated by flow cytometry technique.

Results: The characteristic and demographic features of patients with FD and controls are depicted in Table 1. According to flow-cytometric analysis, total percentage of NK cells of FD patients are similar to healthy controls (11.6% vs 10.7%, p: >0.05, respectively). When we analyzed subgroups of NK cells, we determined that $CD56^{dim}$ $CD16^{dim}$ and $CD56^{bright}$ $CD16^{dim}$ NK cells were increased, however, $CD56^{dim}$ $CD16^{bright}$ NK cells were decreased when compared with healthy controls (59% vs 38%, p:, 13.4% vs 7.3%, p:, 18.9% vs 49.2% p:0.025, respectively).

Conclusions: $CD56^{bright}$ $CD16^{dim}$ subtype of NK cells which can secrete cytokines in normal population are increased in patients with FD. Additionaly $CD56^{dim}$ $CD16^{dim}$ subtype of NK cells are also decreased in these patients which is closely associated with cellular cytotoxity in normal population. Further studies are needed to clarify the roles of NK cells in patients with FD.

Tunneling Nanotubes Shuttle Lysosomes with Low-Level α-Galactosidase A from Non-Fabry to Fabry Podocytes In Vitro

Frank Dastvan, Behzad Najafian. *University of Washington, Seattle, WA.*

Background: Fabry disease is an X-linked disease; however, females can suffer from serious complications. Biopsy studies are suggestive of no efficient cross-correction between non-Fabry and Fabry podocytes. We aimed to examine if there is any level of cross-correction between these cells in-vitro.

Methods: A conditionally immortalized human podocyte cell line with complete knock out of GLA (GLA-ko) using CRISPR-Cas9 was developed. Wild type (WT) podocytes were co-cultured with GLA-ko cells for a week, after which, GLA-ko and WT cells were separated by FACS sorting based on GFP expression in GLA-ko cells. Purity of sorted cells was confirmed by genotyping. Sorted co-cultured (CC) WT and GLA-ko, no co-culture (no-CC) WT and GLA-ko cells and culture media were tested for GLA-mRNA (qPCR), α-Gal-A [western blot (WB) and immunofluorescence (IF)], and α-Gal-A activity.

Results: GLA-mRNA in CC-GLA-ko cells was 2.6 fold less than WT podocytes, but 2.7 fold greater than no-CC-GLA-ko podocytes. No GLA-mRNA was detected in culture media. By WB, while no α-Gal-A protein was detected in no-CC-GLA-ko cells, this was present in CC-GLA-ko cells, albeit being 6 fold less than in WT podocytes, confirmed by IF for α-Gal-A. There was very scant α-Gal-A in media from WT and co-cultured podocytes by WB (31 fold and 15 fold less than intracellular WT, respectively). While there was almost no α-Gal-A activity in no-CC-GLA-ko podocytes, this was present in CC-GLA-ko cells, albeit being 6 fold less than in WT podocytes. There was no detectable α-Gal-A mRNA or enzyme activity in the media. A survival assay showed similarly reduced cellular proliferation in both CC-GLA-ko and no-CC-GLA-ko podocytes compared to CC-WT or no-CC-WT podocytes. IF staining showed tunneling nanotubes (TNTs) containing lysosomes and α-Gal-A running between the cells.

Conclusions: Our data suggest that there is small transfer of GLA-mRNA and α-Gal-A protein from non-Fabry to Fabry podocytes through TNTs. This low level cross-correction led to small increase in α-Gal-A activity in Fabry podocytes but was not enough to improve survival of these cells. It will be important to demonstrate if this phenomenon exists in-vivo and between other cells. These studies may lead to novel treatment options for females with Fabry disease.

Think, Rethink, Diagnose: Dent Disease Type 1

Carla Burballa,[4] Monica Duran,[4] Eduard Sarró,[4] Monica Vall,[4] Gema Ariceta,[3,1] Anna Meseguer.[1,2] Renal Physiopathology Group. VHIR *[1]Vall d'Hebron Institut de Recerca, Barcelona, Spain; [2]Biochemistry and Molecular Biology, Faculty of Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [4]Renal Physiopathology, Vall d'Hebron Institut de Recerca, Barcelona, Spain.*

Background: Dent's disease type 1(Dent1) is a rare X-linked tubulopathy with no cure at the present time. It affects mainly males and is characterized by low-molecular-weight proteinuria(LMWP), hypercalciuria, nephrolithiasis, nephrocalcinosis and progressive renal failure. There's a broad phenotypic variability unrelated to the different mutations. LMWP is not routinely tested so that it may go unnoticed and lead to misdiagnosis. The prevalence of Dent1 is unknown. The geographic dispersion and the lack of common registries make epidemiologic studies difficult. We aim to evaluate the Spanish Dent1 cohort and assess its genetic and clinical characterization.

Methods: We identified 18 patients with genetic confirmation of Dent1 diagnosed in 9 different hospitals in Spain. Only two individuals belonged to the same family; the rest to different families.

Results: Genetic analysis revealed 17 different mutations in *CLCN5* gene in the 18 patients. The median age at diagnosis was 15 months [IQR,11-108] and the main sign leading to diagnosis was proteinuria (40%). All patients had proteinuria measured by protein/creatinine ratio(pCOR), median 1600mg/g [IQR.715-1665]) and LMWP. During follow-up, 40% of patients presented with nephrocalcinosis and 11% with lithiasis. Mean creatinine at diagnosis was 0,37±0,18mg/dl and estimated glomerular filtration rate(eGFR) 140±59 ml/min. After follow-up, (median 6 years [IQR,3-12.25]) creatinine was 1,2±0,9 mg/dl and eGFR 88±44 ml/min. No patients required renal replacement therapy (Table 1).

Conclusions: One should suspect Dent1 in males with a history of lithiasis, nephrocalcinosis or bone disease. Although LMWP is the hallmark of Dent1, many

patients show albuminuria. LMWP should be tested in young males with albuminuria and no other sign/symptom of nephrotic syndrome. Common registries are important.

RNA Sequencing Profile of Circular RNAs in Mouse Kidney During Aging

Fanfan Gao, Hongli Jiang. *Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: Kidney aging is an important clinical problem, not only because normal aging reduces renal function but also because of the high frequency of ESRD, renal cancer, and renal failure in elderly people. At the present time, the molecular basis of renal aging is not clearly known. For example, the abundance and function of circular RNAs (circRNAs) in other disease have been reported, but their alterations in the biology of renal aging remain elusive.

Methods: Renal Specimens were collected from 3-month-old and 24-month-old C57BL/6 mice. Total RNA was extracted using Trizol reagent following the manufacturer's procedure. The circRNA expression was performed using secondary Sequencing. Quantitative real-time reverse-transcription polymerase chain reaction (qRT-PCR) was used to quantify the expression of circRNAs.

Results: A total of 134 distinct circRNA candidates were detected. Among them, we defined the statistical criteria for selecting aberrant-expressed circRNA using a p-value of < 0.05 with a fold change of > 2.0 or < 0.5. A total of 86 circRNA were upregulated and 48 circRNA were downregulated significantly in the 24-month-old tissues. Furthermore, an association of the circRNA-miRNA-mRNA was investigated, showing that 17 dysregulated circRNA successfully predicted an interaction with several age-related miRNAs-mRNAs. Finally, validation of down-regulation of circRNA6456 in 24-month-old compared to 3-month-old by qRT-PCR, indicating that circRNA6456 may delay renal senescence in mice.

Conclusions: This observational study demonstrated dysregulation of circRNA in age-related kidneys, which may have an impact on development of potential biomarkers in aging.

Amniotic Fluid Stem Cells Ameliorate Experimental Acute Renal Failure via Induction of Autophagy and Inhibition of Apoptosis

Ekta Minocha,[1] Rohit A. Sinha,[2] Manali Jain,[1] Chandra P. Chaturvedi,[1] Soniya Nityanand.[1] *[1]Hematology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [2]Molecular Medicine, Sanjay Gandhi Insitute of Medical Sciences, Lucknow, India.*

Background: Amniotic fluid stem cells (AFSC) have been shown to contribute in renal repair after Acute Renal Failure (ARF), however, the mechanism responsible for its renoprotective effects still remains unclear. Therefore, in the present study we evaluated the therapeutic efficacy of AFSC and investigated the underlying mechanisms responsible for its renoprotective effect.

Methods: To study the therapeutic potential of AFSC, ARF was induced in rats by a single dose of cisplatin. Five days after cisplatin injection, AFSC or normal saline were injected intravenously. On day 3 and 7 post-therapy, blood biochemical parameters, histopathological changes, apoptosis and expression of pro-apoptotic, anti-apoptotic and autophagy-related proteins in renal tissues were studied in both groups of rats. Furthermore, to confirm whether the protective effects of AFSC on cisplatin-induced apoptosis are dependent on autophagy, chloroquine, an autophagy inhibitor, was administered intra-peritoneally.

Results: Administration of AFSC in rats with ARF, resulted in improvement of renal function and attenuation of renal damage as reflected by decreased blood urea nitrogen and serum creatinine levels and alleviation in tubular cell apoptosis as assessed by lower Bax/Bcl2 ratio and decreased levels of pro-apoptotic proteins viz. PUMA, Bax, cleaved caspase-3 and cleaved caspase-9 as compared to saline-treated group. Furthermore, in the AFSC-treated group as compared to saline-treated group there was increased activation of autophagy as evident by increased expression of LC3-II, ATG5, ATG7, Beclin1 and phospho-AMPK levels with a concomitant decrease in phospho-p70S6K and p62 expression levels. Chloroquine administration led to significant reduction in the anti-apoptotic effects of the AFSC therapy and further aggravated the deterioration in renal structure and function caused by cisplatin.

Conclusions: This study suggests that induction of autophagy is essential for the renoprotective effects of AFSC against cisplatin-induced apoptosis. Collectively, our results show that AFSC ameliorate cisplatin-induced ARF through induction of autophagy and inhibition of apoptosis.

Engineered Bone Marrow Stem Cell-Sheets Alleviate Renal Fibrosis in a Chronic Glomerulonephritic Rat Model

Yufeng Huang. *Internal Medicine, Div. of Nephrology, University of Utah, Salt Lake City, UT.*

Background: Although mesenchymal stem cell (MSC)-based regenerative therapy is currently being developed for treatment of kidney diseases, it is ineffective due to a few functional cells present at the target tissue. Thus, we developed an MSC-engineered cell sheet technology using the temperature-responsive cell culture surfaces to release cultured MSCs as confluent living cell-sheets. We hypothesized that this new technology would improve MSC transplantation efficiency and therapeutically reduce kidney disease.

Methods: . Three experimental groups included normal, untreated disease control but received sham surgery, and allogeneic bone marrow-derived MSC-sheets treated diseased rats. The chronic glomerulonephritis was induced by two injections of anti-Thy 1.1 antibody (OX-7) in rats. The MSC-sheets were prepared and transplanted as patches onto the surface of the two kidneys of each rat in the treated group at 24h after the first injection of OX-7.

Results: At 4 weeks, retention of the transplanted MSC-sheets was confirmed and animals with MSC-sheets showed significant reductions in proteinuria, glomerular staining for periodic acid-Schiff positive materials, collagen III and fibronectin, and in renal TGFß1, PAI-1, collagen I and fibronectin mRNA and protein levels. Treatment also altered renal overexpression of KIM-1 and NGAL mRNAs and reversed disease induced reduction of WT-1, podocin and nephrin mRNAs. Furthermore, treatment enhanced regenerative gene expression, and IL-10, Bcl-2, and HO-1 mRNA levels but reduced TSP-1 levels, NF-kB and NAPDH oxidase production in the kidney, which were consistent with the reduction of glomerular macrophage cell infiltration and glomerular and tubular cell apoptosis.

Conclusions: These observations strongly support our hypothesis that MSC-sheets facilitated MSC transplantation and effectively retarded progressive renal fibrosis through paracrine or autocrine signaling involved cellular inflammation, oxidative stress, apoptosis and regeneration.

SA-PO430

Gene-Modified Urine-Derived Stem Cells Home to the Ischemic Kidney

Lauren E. Woodard,[1] Richard C. Welch,[3] Felisha M. Williams,[3] Neal Paragas,[4] Matthew H. Wilson.[2] *[1]Vanderbilt University Medical Center/VA, Charleston, SC; [2]Vanderbilt University, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Washington, Seattle, WA.*

Background: Acute kidney injury is a major cause of morbidity and mortality, with only half of those diagnosed surviving three months. The current therapies for acute kidney injury are supportive rather than regenerative. We sought to evaluate if human urine-derived stem cells were able to migrate to the kidney following ischemia/reperfusion injury in mice.

Methods: Urine is a practical and painless source of cells for gene and cell therapy applications. Urine-derived stem cells are adult human cells of renal origin that propagate in tissue culture in media containing growth factors on gelatin-coated plates. We have isolated, expanded, transfected, and tracked these cells following injection into live NSG immunocompromised mice order to assess their potential for regenerative gene and cell therapies.

Results: FACS characterization revealed that they expressed the characteristic marker panel (CD44, CD73, CD90, & CD146 + / CD31, CD34, & CD45 -). They differentiated into osteogenic and adipogenic lineages. Transfection was optimized to achieve 61% transfection. Five different *piggyBac* luciferase transposons were compared with the CMV and EF1-alpha giving the highest luciferase signals. When luciferase-modified urine-derived stem cells were injected directly into the renal pelvis of immunocompromised NSG mice they migrated to the surgical wound scar. To test the homing ability of the cells in the setting of ischemia reperfusion injury, we optimized the time of ischemia together with unilateral nephrectomy in immunocompromised NSG mice to be 22 minutes with 83% of mice having elevated creatinine. Urine-derived stem cells transfected with *piggyBac* transposons expressing luciferase were injected into the peritoneum of mice on Day 3 post-ischemia reperfusion injury. The cells were tracked via the InVivoPLOT

imaging gantry for quantitative tomographic optical live animal imaging. We found luciferase signal localized within 2 hours post-injection to the injured kidney with lower levels in the spleen.

Conclusions: Urine-derived stem cells represent an easily isolated, clinically relevant cell type that can be manipulated with non-viral genetic tools. We have found that the cells quickly migrate from their injection site to injured tissues. Next we will assess functional correction following injection of urine-derived stem cells into mouse models of acute kidney injury.

Bone Marrow Mesenchymal Stem Cells-Derived Exosomes Reduce Pericyte Transition by Inhibiting Core Fucosylation

Xuemei Hu,[1] Nan Wang,[1] Hong L. Lin.[2] *[1]Nephrology, The First Affiliated Hospital of Dalian Medical University, Dalian, China; [2]The First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: Renal interstitial fibrosis is the last common pathway to progression to end-stage renal disease. Myofibroblasts are a key event in renal interstitial fibrosis, and pericyte transition is one of the major sources of myofibroblasts. Our previous study found that CF (core fucosylation) mediated by FUT8 (α1,6-fucosyltransferase) could regulate the "fibrotic signaling pathway" such as TGFβ/Smad and PDGF/ERK regulate the pericytes -myofibroblasts transition in renal interstitial fibrosis. MSCs (Mesenchymal stem cells) can alleviate renal interstitial fibrosis and are potential therapeutic targets, but the mechanism is still unclear. The exosomes are an extracellular vesicle secreted by MSCs, and can transmit functional substances such as microRNAs and proteins through membrane ligand-cell receptor interaction. It is found that exosomes could regulate damage repair, but the mechanism is also unclear.

Methods: Primary culture of pericytes to establish a TGFβ1-stimulated pericyte transition model. After cell modeling, they were co-cultured with transwell upper MSCs, exosomes, CM, and CM for exosomes removal. Morphological changes of pericytes were observed by light microscopy. The levels of αSMA and LCA were observed by immunofluorescence. The levels of αSMA and FUT8 were observed by Western blot. The level of FUT8 was observed by HPLC (High Performance Liquid Chromatography).

Results: TGF-β1 stimulated pericytes to form spindle-shaped myofibroblasts, and the expression of αSMA, LCA and FUT8 increased, TGF-β/Smad and PDGF/ERK pathway activity increased. MSCs have an inhibitory effect, CM and exosomes have similar inhibitory effects, while CM for exosomes removal is ineffective. RT-PCR, immunofluorescence and Western blot confirmed that FUT8 was successfully transfected into pericytes. After FUT8 transfection, the degree of spindle-shaped myofibroblasts increased, and the expression of αSMA, LCA and FUT8 increased, the inhibition by MSCs,exosomes and CM was significantly weakened.

Conclusions: MSCs-derived exosomes reduce pericyte transition by inhibiting CF

Human Mesenchymal Stem Cells Modulate High Glucose-Induced Inflammatory Responses of Renal Proximal Tubular Cell Monolayers and Their Cross-Talk with Macrophages

Md Nahidul Islam,[1] Tomas P. Griffin,[3] Tara McMorrow,[4] Matthew D. Griffin.[2] *[1]National University of Ireland Galway, Galway, Ireland; [2]National University of Ireland, Galway, Galway, Ireland; [3]University College Hospital Galway, Galway, Ireland; [4]University College Dublin, Dublin, Ireland.*

Background: Renal proximal tubular epithelial cells (RPTEC) are dysfunctional in diabetic kidney disease (DKD). Mesenchymal stem cells (MSC) have been shown to modulate DKD pathogenesis. Having previously observed that soluble products of human MSC suppress high glucose (HG)-induced inflammatory responses of RPTEC/TERT1 stable monolayers, we aimed here to characterize the modulatory effect of MSC indirect co-culture on the transcriptional profile of RPTEC monolayers and to further explore the influence of MSC on RPTEC/Macrophage crosstalk.

Methods: Human RPTEC/TERT1 cells were cultured for 12 days to generate stable confluent monolayers. Normal medium or medium supplemented with 25mM D-Glucose (HG) or 25mM D-Mannitol (MAN) were applied for a further 5 days. Human bone marrow MSC were co-cultured 1:10 with RPTEC monolayers for the final 2 days in a trans-well system. RNA Sequencing, qRT-PCR and ELISA were performed on resulting samples. Conditioned Media from HG- and MAN-exposed RPTEC/MSC co-cultures were applied to monocyte-derived human macrophages under HG and MAN conditions.

Results: Bioinformatics analysis of RNA-sequencing data confirmed a predominant effect of HG on inflammation-related mediators and biological processes/KEGG pathways in RPTEC/TERT1 stable monolayers as well as the anti-inflammatory effect of MSC. KEGG pathway analysis showed HG-induced gene upregulation within the TNF-signalling, cytokine-cytokine receptor interaction and NOD-like receptor signalling. These gene expression signatures were modulated toward control expression by MSC co-culture. The HG-induced increase in RPTEC monolayer expression of transcripts for multiple cytokine (IL-1β, IL-6, IL-8, TNFα, MCP-1) and for NGAL as well as their counter-regulation by MSC were confirmed by qRT-PCR and ELISA. Conditioned medium from HG-exposed RPTEC/MSC transwell co-cultures attenuated secretion of inflammatory mediators (IL-8, TNFα, MCP-1) by macrophages compared to medium from HG-stimulated RPTEC alone.

Conclusions: Stable RPTEC monolayers demonstrate a delayed pro-inflammatory response to HG that is attenuated by close proximity to human MSC. In DKD, this MSC effect has potential to modulate hyperglycaemia-associated RPTEC/macrophage cross-talk - a key pathogenic mechanism of chronic interstitial inflammation.

SA-PO433

Mesenchymal Stem Cells Cultured in IFN-γ-Containing Medium Ameliorate Experimental Renal Fibrosis

Ryo Kanai,[2] Ayumu Nakashima,[1,2] Shigehiro Doi,[2] Naoki Ishiuchi,[2] Toshiki Doi,[2] Takao Masaki.[2] *[1]Hiroshima University, Hiroshima, Japan; [2]Hiroshima University Hospital, Hiroshima, Japan.*

Background: Mesenchymal stem cells (MSCs) have been reported to promote regeneration of damaged tissues and suppress fibrosis. Recently, interferon-γ (IFN-γ) was reported to enhance the paracrine activities of MSCs. In this study, we investigated the effect of MSCs cultured in IFN-γ-containing medium on inflammation and fibrosis using unilateral ureter obstruction (UUO) and ischemia-reperfusion injury (IRI) models.

Methods: At 4 days after the UUO operation, we injected rat MSCs (3×10^6 cells/rat) cultured in 10% FBS-containing DMEM (rMSCs) or IFN-γ-containing medium (IFN-γ rMSCs), or PBS only (Control) through the rat tail vein. In addition, we injected rats after an IRI operation through the abdominal aorta with PBS, rMSCs, or IFN-γ rMSCs (5×10^5 cells/rat). Next, we investigated the effect of IFN-γ human MSC (hMSC)-conditioned medium (CM) on TGF-β1-induced fibrotic changes by western blotting. As an anti-inflammatory mediator, we analyzed CM from IFN-γ hMSCs by an enzyme-linked immunosorbent assay.

Results: Immunohistochemical staining revealed that IFN-γ-rMSCs strongly ameliorated interstitial fibrosis. IFN-γ rMSCs also attenuated renal fibrosis and inflammation more significantly than rMSCs in IRI models. IFN-γ hMSCs-CM decreased the expression of phosphorylated Smad2 and αSMA compared with hMSCs-CM without IFN-γ stimulation. We found that prostaglandin E2 (PGE2) expression was significantly increased in IFN-γ hMSCs-CM. Knockdown of prostaglandin E synthase (PTGES), which is a synthetic enzyme of PGE2, weakened the anti-fibrotic effect of IFN-γ MSCs in IRI models.

Conclusions: Our findings indicate that IFN-γ potentiates the anti-fibrosis and anti-inflammatory abilities of MSCs and administration of MSCs cultured in IFN-γ-containing medium has the potential to be a useful therapy to prevent the progression of renal fibrosis.

SA-PO434

Hypoxia Preconditioning Modifies Mesenchymal Stem Cell Senescence and Epigenetics Mechanisms in Experimental Atherosclerotic Renal Artery Stenosis

Busra Isik,[1] Busra N. Bacik Goksu,[1] Sabena Conley,[1] Abdelrhman Abumoawad,[1] Xiang yang Zhu,[1] Alfonso Eirin,[1] LaTonya J. Hickson,[1] Andre J. Van wijnen,[1] Stephen C. Textor,[1] Lilach O. Lerman,[2] Sandra Herrmann.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic College of Medicine, Rochester, MN.*

Background: Atherosclerotic Renal Artery Stenosis(ARAS) is a contirbutor for hypertensive nephropathy(HN). Autologous mesenchymal stem cells(MSCs) is a promising therapy for ischemic nephropahty in patients with ARAS. However, MSCs from older ARAS patients are associated with impaired function, senescence, and DNA damage, possibly due to epigenetic mechanisms. Hypoxia preconditioning(HPC) exhibits beneficial effects on cellular proliferation, differentiation, as well as gene and protein expression. We hypothesized that HPC could influence MSC function, senescence and epigenetic mechanisms by modulating chromatin-modifying enzymes.

Methods: MSCs harvested from subcutaneous abdominal fat tissue of healthy(N=5) or ARAS(N=8)pigs were cultured under normoxia(20%O_2)or hypoxia(1%O_2) until 70-80% confluence. MSC function was measured by migration and proliferation assays, as well as cytokine levels in conditioned media. MSC senescence was evaluated by SA-β-gal activity and epigenetic markers, including HDAC activity and DNA hydroxymethylation using dot blot analysis.

Results: MSCs cultured under HPC had higher migratory and proliferative capacity as well as increased VEGF and IGF levels than normoxia-cultured MSCs(Figure). Under basal conditions, dot blot analysis showed lower DNA hydroxymethylation in ARAS. During HPC, MSC HDAC activity increased whereas DNA hydroxymethylation decreased, suggesting broad epigenetic changes. Furthermore, SA-β-gal activity fell, indicating lower senescence burden on HPC-MSCs.

Conclusions: HPC mitigates autologous MSC dysfunction, decreased MSC senescence and DNA hydroxymethylation in ARAS pigs. Future studies are needed to

determine the effect of HPC in MSCs of patients with other vascular nephropathies to optimize the potential use of autologous MSC therapy in this population.

Hypoxia-Preconditioned Mesenchymal Stem Cells Prevent AKI to CKD Progression

Naoki Ishiuchi,[1] Ayumu Nakashima,[2,1] Shigehiro Doi,[1] Ryo Kanai,[1] Toshiki Doi,[1] Takao Masaki.[1] *[1]Hiroshima University Hospital, Hiroshima, Japan; [2]Hiroshima University, Hiroshima, Japan.*

Background: Several studies have reported that mesenchymal stem cells (MSCs) promote regeneration of injured tissue via their paracrine activities, which are enhanced by hypoxic preconditioning. In this study, we examined the therapeutic efficacy of hypoxia-preconditioned MSCs for preventing acute kidney injury (AKI) to chronic kidney disease (CKD) progression using rat models of ischemia/reperfusion injury (IRI).

Methods: We injected rats through the abdominal aorta with hypoxia-preconditioned rat MSCs (1%O_2 rMSCs) or rat MSCs under normoxic conditions (21%O_2 rMSCs). We also administered hypoxia-preconditioned human MSCs (1%O_2 hMSCs) via the same procedure. In addition, we analyzed the conditioned medium from 1%O_2 hMSCs using ELISA kit and identified the humoral factor involved in anti-fibrotic abilities of MSCs.

Results: The administration of 1%O_2 rMSCs attenuated renal fibrosis induced by IRI more significantly than that of 21%O_2 rMSCs. 1%O_2 hMSCs also attenuated renal fibrosis and the anti-fibrotic effects of hypoxia-preconditioned MSCs were almost equivalent in bone marrow MSCs derived from rat and human. We also found that MSCs derived from rat and human were both observed in the kidney at day 21 post-IRI. Moreover, using flow cytometry, we confirmed that hypoxic preconditioning did not change the HLA expressions of MSCs. These results suggest that 1%O_2 hMSCs have low immunogenicity and may be a good candidate for allogeneic transplantation cell therapy. We also found that hypoxic preconditioning enhanced vascular endothelial growth factor (VEGF) and hepatocyte growth factor (HGF) secretion from MSCs. VEGF knockdown in 1% O_2 hMSCs by siRNA attenuated HGF secretion and the inhibition of TGF-β1 induced fibrotic changes in HK2 cells. It also weakened the suppression of renal fibrosis by 1%O_2 hMSCs in IRI models.

Conclusions: Our results indicate that hypoxia-preconditioned MSCs may be useful as an allogeneic transplantation cell therapy for preventing the progression of AKI to CKD.

Metformin Improves Dysfunction of Mesenchymal Stem Cells Associated with CKD via Protection from Senescence

Hyunjin Noh,[1,2] Mi ra Yu,[2] Hyoshik Kim,[1] Soon hyo Kwon.[1,2] *[1]Internal Medicine, Soon Chun Hyang Univ., Seoul, Republic of Korea; [2]Hyonam Kidney Laboratory, Soon Chun Hyang University, Seoul, Republic of Korea.*

Background: Mesenchymal stem cells (MSC) are promising source of cell-based regenerative therapy; however, adequate cell functionality is a critical factor for the success of autotransplantation. We previously reported a functional incompetence of CKD (chronic kidney disease) MSC.

Methods: In this study, we investigated the effects of metformin on CKD-associated cellular senescence using MSC isolated from sham operated and subtotal nephrectomized mice and further explored the protective role of metformin-treated CKD MSC in renal progression using unilateral ureteral obstruction (UUO) model and in vitro co-culture system.

Results: When compared to normal MSC, MSC isolated from CKD mice displayed reduced proliferation and early senescence as determined by enlarged cell morphology, increased oxidative stress, accumulation of DNA damage response marker p53 binding protein 1 (53BP1), phospho p53, $p16^{INK4a}$, and b-gal expression, and decreased cyclin-dependent kinase 4 (CDK4) and cyclin D. CKD MSC exhibited activation of NFκB resulting in expression of senescence-associated secretory phenotype (SASP) factors such as MCP-1, TNF-α, IL-6, and IL-1β compared to normal MSC. All of these changes were significantly prevented by metformin treatment. In vivo, metformin-treated CKD MSC attenuated inflammation and fibrosis in UUO kidney as compared to CKD MSC. Co-culture of LPS-treated HK2 cells with normal MSC almost completely rescued LPS-induced tubular expression of MCP-1 and TNF-α. Of note, metformin-treated CKD MSC markedly decreased tubular expression of MCP-1 and TNF-α when compared to CKD MSC suggesting paracrine action of CKD MSC enhanced by metformin treatment.

Conclusions: Taken together, our data suggest that metformin prevents cellular senescence of CKD MSC and improves their renoprotective effects.

Extracellular Vesicles from Human Bone Marrow Mesenchymal Stem Cells Repair Organ Damages Caused by Cadmium Poisoning in a Medaka Model

Tomoko Obara. *University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Treatment modalities for kidney disease caused by long-term exposure to heavy metals, such as cadmium (Cd), are limited. Often, chronic, long-term environmental exposure to heavy metal is not recognized in the early stages; therefore, chelation therapy is not an effective option. Extracellular vesicles (EVs) derived from stem cells have been demonstrated to reduce disease pathology in both acute and chronic kidney disease models.

Methods: To test the ability of EVs derived from human bone marrow mesenchymal stem cells (hBM-MSCs) to treat Cd damage, we generated a Cd-exposed medaka model that we treated with EVs.

Results: This model develops heavy metal-induced cell damage of various organs and tissues, and shows decreased survival. Intravenous injection of highly purified EVs from hBM-MSCs repaired the damage to kidney proximal tubules apical and basolateral membranes, and mitochondria, glomerulus podocytes, repaired bone deformation caused by Cd, and enhanced survival.

Conclusions: Our system serves as a model with which to study age- and sex-dependent cell injuries of organs caused by various agents and diseases. The effects of EVs on the tissue repair process, as shown in our Cd-exposed medaka model, may open new broad avenues for interventional strategies.

Extracellular Vesicles of Adipose-Derived Stem Cells from Obese Patients Drive ROS-Dependent Premature Senescence in Renal Tubular Cells

Ting Luo, Yu Meng. *The First Affiliated Hospital of Jinan University, Jinan University, Guangzhou, China.*

Background: Premature tubular cell senescence is characteristic of obesity-associated renal injury. Extracellular vesicles from adipose-derived stem cells (ADSC-EVs) are highly abundant, while their role in obesity-associated disorders remain unclear. We hypothesized that ADSC-EVs with obese patients were involved in renal tubular cell senescence, possibly via a ROS-dependent pathway.

Methods: ADSCs were isolated from the omental adopts from patients with morbid obesity and healthy volunteers (n=7 each). ADSC-EVs were co-cultured with HK-2 cells. The level of cellular senescence was assessed as senescence-associated β-galactosidase (SA-β-gal) activity using fluorescent quantitative detection, target gene expression using RT-PCR or western blot analysis, and reactive oxygen species (ROS) generation using CMH_2DCFDA staining. The next-generation mRNA sequencing was performed on ADSC-EVs to predict the enriched biological process (DAVID 6.8).

Results: Compared with the control, ADSC-EVs from obesity induced upregulation of SA-β-gal activity, $p16^{INK4A}$, TGFβ-1 and α-SMA in HK-2 cells. The mRNA levels of *IL-1β*, *IL-6*, and *TNF-α* also increased (Figure). Totally 56 up-regulated genes were found in ADSC-EVs from the obese compare to the control, and enriched the ROS-related biological processes (Figure). ADSC-EVs from obese patients could induce ROS formation in HK-2 cells. Conversely, ROS inhibitor N-acetylcysteine prevented the premature tubular cell senescence induced by ADSC-EVs from obese patients (Figure).

Conclusions: These findings suggest that EVs from the *ex vivo* ADSCs of obese patients induce premature tubular cell senescence through a ROS-mediated mechanism. Targeting ADSC-EV shedding may provide opportunities to limit the dysfunction of renal tubular cell post-obesity.

Funding: Government Support - Non-U.S.

Systematic Implantation of Dedifferentiated Fat Cells (DFAT) Ameliorated the Monoclonal Antibody 1-22-3-Induced Glomerulonephritis with Stimulation of TSG-6

Takashi Maruyama. *Nihon University School of Medicine, Tokyo, Japan.*

Background: Implantation of mesenchymal stem cells has recently been reported to repair tissue injuries through anti-inflammatory and immunosuppressive effects. We established dedifferentiated fat cells that show identical characteristics to MSCs.

Methods: We examined the effects of 10^6 of DFAT cells infused through renal artery or tail vein on monoclonal antibody 1-22-3-induced glomerulonephritis and adriamycin-induced nephropathy in rats. The mAb 1-22-3-injected rats were also implanted with 10^6 of DFAT cells transfected with TSG-6 siRNA through tail vein.

Results: Although DFAT cells transfused into blood circulation through the tail vein were trapped mainly in lungs without reaching the kidneys, implantation of DFAT cells reduced proteinuria and improved glomerulosclerosis and interstitial fibrosis. Implantation of DFAT cells through the tail vein significantly decreased expression of kidney injury molecule-1, collagen IV and fibronectin mRNAs, whereas nephrin mRNA expression was increased. Implantation of DFAT cells did not improve adriamycin-induced nephropathy, but significantly decreased the glomerular influx of macrophages, common leukocytes and pan T cells. However, the glomerular influx of helper T cells, was increased. Implantation of DFAT cells decreased expression of interleukin-6 and IL-12β mRNAs and increased expression of TNF-stimulated gene-6 mRNA in renal cortex from mAb 1-22-3-injected rats. The basal level of TSG-6 protein was significantly higher in DFAT cells than in fibroblasts. Expression of TSG-6 mRNA in MCs cocultured with DFAT cells was significantly higher than in mesangial cells or DFAT cells alone. Systematic implantation of DFAT cells with TSG-6 siRNA through tail vein did not improve proteinuria, renal dysfunction and renal degeneration in the mAb 1-22-3-injected rats.

Conclusions: Systematic implantation of DFAT cells effectively ameliorated mAb 1-22-3-induced glomerulonephritis through immunosuppressive effects accompanied by the suppression of macrophage infiltration and expression of IL-6, IL-10 and IL-12β, and increased production of serum and renal TSG-6 that improved the mAb 1-22-3-induced renal degeneration by the immunosuppressive effects of TSG-6. Thus DFAT cells will be suitable cell source for the treatment of immunological progressive renal diseases.

SA-PO440

The Extracellular Vesicles from Adipose Tissue-Derived Mesenchymal Stem Cells Attenuate the Renal Senescence via SP1/Klotho Pathway in Obesity

Yu Meng, Shuang Cui, Huanhuan Liu. *Department of Nephrology, First Affiliated Hospital, Jinan University, Guangzhou, China, Guangzhou, China.*

Background: Patients with obesity have a high risk of chronic renal disease and premature aging of the kidney has been proved as a major contributor. The extracellular vesicles from adipose tissue-derived mesenchymal stem cells (ADSCs-EVs) have therapeutic potential in many diseases. We aimed to investigate whether ADSCs-EVs could rejuvenate the senescent renal tubular cells in Obesity

Methods: ADSCs-EVs were isolated from the subcutaneous adipose tissues from healthy volunteers (n=6). The murine model with obesity was obtained after 8 weeks of the obese diet. ADSCs-EVs were injected to the obese mice in *vivo* and co-cultured with primary renal tubular cells from the obese mice *in vitro*. The level of senescence was assessed as P16, P21 with histological analysis and western blot. Next-generation mRNA sequencing (RNAseq) was performed to predict the key transcription factor. The expression of SP1 and Klotho were analyzed by PCR in cells.

Results: ADSCs-EVs treatment could rescue the obesity-induced senescence of renal tubular cells in *vivo* and in *vitro*. The expression of Klotho restored and the P16 was significantly ameliorated. Further study revealed the levels of SP1 and the Klotho were synergistically elevated after ADSCs-EVs treatment (Figure). RNA-seq identified five aging-associated genes upregulated after EVs treatment (fold change >2, p<0.05). The pathway analysis showed TGF- ß or ERK pathway could play a crucial role in ADSCs-EVs mediated rejuvenation through up-regulating transcription factor SP1 (Figure).

Conclusions: ADSCs-EVs ameliorate obesity-induced renal tubular injury by activating SP1 /Klotho and rescue senescence, thereby prevent the renal premature aging in obesity. ADSCs-EVs might be a natural nano-biomaterial for senescence-related diseases therapy.

Funding: Government Support - Non-U.S.

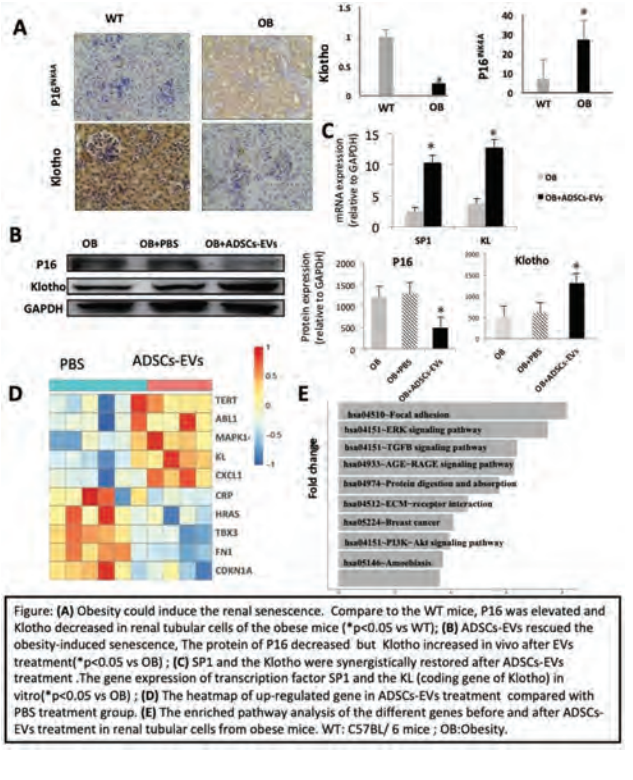

Figure: **(A)** Obesity could induce the renal senescence. Compare to the WT mice, P16 was elevated and Klotho decreased in renal tubular cells of the obese mice (*p<0.05 vs WT); **(B)** ADSCs-EVs rescued the obesity-induced senescence, The protein of P16 decreased but Klotho increased in vivo after EVs treatment(*p<0.05 vs OB) ; **(C)** SP1 and the Klotho were synergistically restored after ADSCs-EVs treatment .The gene expression of transcription factor SP1 and the KL (coding gene of Klotho) in vitro(*p<0.05 vs OB) ; **(D)** The heatmap of up-regulated gene in ADSCs-EVs treatment compared with PBS treatment group. **(E)** The enriched pathway analysis of the different genes before and after ADSCs-EVs treatment in renal tubular cells from obese mice. Spleen Is the Key Organ for the Renoprotective Potential of Adipose-Derived Mesenchymal Stromal Cells

Yuko Shimamura,[3] Kazuhiro Furuhashi,[1] Naotake Tsuboi,[2] Shoichi Maruyama.[3]
[1]Nagoya University, Nagoya, Japan; [2]Fujita Health University School of Medicine, Toyoake, Japan; [3]Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: Administration of mesenchymal stromal cells (MSCs), which exert immunomodulatory function, is considerable therapeutic agents for inflammatory disorders. However, it remains unknown where MSCs are distributed and act after administration. In this study, we evaluated the therapeutic efficacy of human adipose derived stromal cells (ASCs) on anti-GBM nephritis rats and where they exert therapeutic effects.

Methods: Anti-GBM nephritis was induced by monoclonal anti-glomerular basement membrane antibody, to female WKY/NCrj rats. We administrated human ASCs or bone marrow derived MSCs (BMMSCs) to them intravenously on day 0, 2, 4 and sacrificed on day 7. Therapeutic efficacy was evaluated by serum Cre, BUN, histological renal damage on day 7. To track MSCs, we also administrated MSCs labeled with DiD to the diseased rats and observed their distribution by flow cytometry and fluorescence microscope. Next, we inhibited MSCs accumulation in organs to reveal where they act.

Results: Human ASC-treatment decreased serum Cre and BUN in anti GBM antibody-induced renal dysfunction compared with BMMSCs. Histologically, crescent formation and accumulations of total macrophages in inflamed glomeruli were significantly decreased in ASC-treated groups. DiD positive cells are observed in lungs, kidneys, spleens and livers. The therapeutic efficacy was preserved even after reduction of

ASCs accumulation in lungs. Interestingly, splenectomy counteracted the effectiveness of ASCs completely, while sham operation did not affect their therapeutic effects.

Conclusions: Human ASCs have therapeutic potential for anti-GBM nephritis compared with BMMSCs. Spleen is a key organ for the therapeutic effect of MSCs. The elucidation of this mechanism would lead to the efficacy and safety of MSC based therapy.

SA-PO442

Cell Sheet Therapy to Suppress Renal Vascular Injury and Fibrosis in Rat Unilateral Ureteral Obstruction and Ischemia-Reperfusion Injury Models

Masatoshi Oka,[1,2] Aya Imafuku,[3] Kosaku Nitta,[2] Teruo Okano.[3,1] *[1]University of Utah, Salt Lake City, UT; [2]Nephrology, Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]Institute of Advanced Biomedical Engineering and Science, Tokyo Women's Medical University, Shinjuku-ku, Japan*.

Background: CKD is a growing and unsolved problem and a new strategy to suppress renal fibrosis is required. In CKD, lack of vasoprotective factors such as VEGF and HGF causes renal vascular injury and subsequent progressive fibrosis. Recently, many researchers reported that administration of vasoprotective factors or the cells producing those factors suppressed vascular injury and fibrosis in preclinical studies. However, the therapeutic effects were limited due to their short half-life in circulation or low retention of the transplanted cells in the kidneys. To solve this problem, we applied cell sheet technology for kidney diseases. We aimed to suppress renal vascular injury and fibrosis by long-term and direct supply of vasoprotective factors secreted form cell sheets.

Methods: Using a temperature responsive culture dish, HGF transgenic mesothelial cell sheet (HGF-tg MC sheet) and rat bone marrow derived mesenchymal stromal cell sheets (MSC sheet) were prepared. In rat UUO or IRI models, the renal capsule was removed and cell sheets were transplanted onto the kidney surface. We analyzed the behavior of the transplanted cells (immunostaining, in vivo imaging system), morphology of the kidney/renal microvascular density/ renal artery blood flow rate (US, CT), and renal fibrosis. The effects were compared between those in receiving intravenous administration of rHGF protein or MSCs.

Results: Transplantation of HGF-tg MC sheets significantly protected microvascular density, maintained renal artery blood flow, and suppressed renal fibrosis compared with intravenous administration of rHGF protein. Transplantation of MSC sheets showed superior survival of the donor cells in the kidney compared with intravenous administration of MSCs, resulted in strong suppression of renal fibrosis and protection of microvascular density in the whole kidney.

Conclusions: Transplantation of cell sheets onto the kidney surface ameliorated renal vascular injury and suppressed renal fibrosis in UUO and IRI by long-term and direct supply of vasoprotective factors secreted from grafted cells. Renal treatment with cell sheets would be a promising strategy.

Kidney Podocytes Generate Autonomous Calcium Transients That Regulate Glomerular Capillary Tuft Formation

Lydia Djenoune,[1] Iain A. Drummond.[1,2] *[1]Massachusetts General Hospital, Charlestown, MA; [2]Department of Genetics, Harvard Medical School, Boston, MA.*

Background: Podocytes are critical to maintaining the glomerular filtration barrier; mutations in nephrotic syndrome genes lead to defects in barrier function and can affect podocyte calcium signaling. The role of calcium signaling during podocyte development *in vivo* remains unknown however.

Methods: Using the genetically encoded biosensor GCaMP6s expressed in zebrafish podocytes we quantified intracellular calcium dynamics in differentiating podocytes *in vivo*.

Results: Immature podocytes (2.5 days post fertilization (dpf)) generate calcium transients that correlate with cell motility and podocyte interactions with forming glomerular capillaries. Calcium transients persist until 4 dpf and are absent when glomerular barrier formation is complete. Calcium transients are not affected by deficiencies in heartbeat (*tnnt2* morphant), endothelium (*cloche* mutant) or endoderm (*sox32* morphant), suggesting they may be generated cell autonomously. Dissociated, intact GCaMP6s-expressing glomeruli in short term *in vitro* culture continue to exhibit calcium transients similar to *in vivo* podocytes, indicating the transients are autonomously generated. Inhibitors of SERCA or IP3 receptor calcium-release channels block calcium transients, while lanthanum and medium EGTA are ineffective, indicating the source of calcium is podocyte ER stores. Blocking calcium release impacts glomerular shape and cell organization, suggesting further that calcium signaling guides glomerular morphogenesis.

Conclusions: Our results establish cell autonomous calcium signaling as a prominent feature of podocyte differentiation and present a model to decipher mechanisms leading to proper glomerular morphogenesis.

SA-PO444

Whole-Genome Bisulfite Sequencing Identifies Key Roles for Dnmt3a and Dnmt3b in Renal Tubular Cell Development

Yuting Guan, Hongbo Liu, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Cytosine methylation is an epigenetic mark that can stably repress gene expression. *De novo* DNA methyltransferases 3a (*Dnmt3a*) and 3b (*Dnmt3b*) play key roles in establishing cell type specific methylation patterns. However, their roles in kidney development are poorly understood.

Methods: We generated mice with genetic deletion *Dnmt3a* and *Dnmt3b* in nephron progenitor cells using $Six2^{Cre}$ and tubule cell specific cells using the Ksp^{Cre} ($Six2^{Cre}$ *Dnmt3a/3b* and Ksp^{Cre} *Dnmt3a/3b*, DKO). Next generation sequencing techniques, such as reduced representation bisulfite sequencing (RRBS), whole genome bisulfite sequencing (WGBS) and RNA sequencing (RNA-seq) were performed on whole kidney samples and on isolated and sorted renal tubule cells from 3-week-old mice. We induced kidney disease by folic acid injection at 8 weeks of age.

Results: Compared with littermate controls, no obvious developmental defect was identified in Ksp^{Cre} and $Six2^{Cre}$ *Dnmt3a*$^{f/f}$ and *Dnmt3b*$^{f/f}$ double knock-out mice. RRBS data showed significant methylation changes in both DKO mice consistent with Dnmt3a/b role in establishing *de novo* methylation pattern. More hypo-methylated regions (Hypo-DMR) were identified in $Six2^{Cre}$ DKO mice, suggesting the key role of Dnmt3a/b in establishing cell type specific methylation in development. To explore the genome wide effect of *Dnmt3a* and *Dnmt3b*, WGBS was performed on isolated Ksp positive renal tubule epithelial cells. Remarkable decreased in cytosine methylation was observed at genome wide level, especially affecting fetal enhancers which gain methylation in normal development. Motif enrichment analysis showed the significant enrichment of hypo-methylated regions in binding sites of kidney developmental transcription factors including *Six2*. Despite the broad changes in cytosine methylation, the effect of *Dnmt3a* and *Dnmt3b* loss on gene expression was less pronounced. DKO mice showed no differences when compared to control following kidney injury.

Conclusions: Our results indicate *Dnmt3a* and *Dnmt3b* are necessary for *de novo* methylation of enhancers which are active in fetal kidney and closed in adult kidney. Despite the significant methylation changes on enhancer regions, the effect of *de novo* methylation on gene expression regulation and phenotype was less pronounced.

Essential Roles of Testosterone in Male Kidney Maturation and Repair After Injury

Yuki Sato,[1,2] Eiichiro Uchino,[1,3] Akiko Oguchi,[1,4] Yuichiro Kitai,[1] Shushi Nagamori,[5,6] Yoshikatsu Kanai,[5] Yaushiro Murakawa,[4] Motoko Yanagita.[1] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Medical Innovation Center TMKP, Graduate School of Medicine Kyoto University, Kyoto, Japan; [3]Department of Medical Intelligent Systems, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [4]RIKEN, Yokohama, Japan; [5]Department of Pharmacology, Graduate School of Medicine, Osaka University, Osaka, Japan; [6]Nara Medical University, Kashihara, Japan*.

Background: The newborn kidneys are structurally and functionally immature. They mature after birth to adapt to extra-uterine life, yet the comprehensive changes of the kidney have not been defined. We investigated the structural and functional changes in the kidney after weaning and examined the effect of testosterone in this maturation process in male mice.

Methods: We performed phenotypic analysis of mouse kidneys utilizing a combination of histological analysis, bulk transcriptome analysis, charged metabolite analysis by CE-TOFMS and brush border membrane vesicles LC-MS/MS analysis.

Results: Bulk transcriptome analysis of postnatal 3 and 8 week male kidneys showed the gene sets enriched in 8w included those associated with metabolic process and transport in proximal tubule, and structural analysis revealed proximal tubule elongation and hypertrophy in 8 weeks. Most differentially expressed genes (DEGs) identified above were induced between postnatal day 28 and 40, a period of testosterone surge, and were closely correlated with DEGs between adult male and female kidneys. These structural and gene expression changes during maturation were mostly canceled by castration before testosterone surge. Proximal tubules expressed androgen receptor, and some gene expression changes were confirmed in cultured proximal tubules stimulated with testosterone. Consistent results with DEGs were also confirmed at protein levels and related metabolites in vivo. For instance, induction of cystine transporter SLC7A13 expression as well as the increase in cysteine and cysteine-glutathione disulphide-Divalent in the kidney were confirmed in this period. Fatty acid b-oxidation enzymes were also increased during this period. Some of the down-regulated genes across puberty were reactivated after injury and returned back with repair.

Conclusions: Proximal tubules are the main site of maturation after weaning and acquire the ability to absorb and metabolize a variety of filtered substances and increase energy metabolism, which were mainly driven by testosterone.

Ureteric Bud (UB) Prorenin Receptor (PRR) Directs UB Branching Morphogenesis by Regulating V-ATPase Activity and Autophagy in UB Cells

Ihor V. Yosypiv,[1] Renfang S. Taylor,[3] Nazih L. Nakhoul.[2] *[1]Pediatrics, Tulane University, New Orleans, LA; [2]Tulane Medical School, New Orleans, LA; [3]Southwest Baptist University, Bolivar, MO.*

Background: Targeted ablation of the *PRR* in the UB lineage in *Hoxb7*^{Cre}/*PRR*$^{flox/flox}$ (PRRUB-/-) mice causes severe defects in UB branching, leading to decreased nephron endowment and renal hypodysplasia. Since PRR is an accessory subunit of the vacuolar proton pump V-ATPase, we investigated the role of V-ATPase and autophagy in PRR-induced UB branching in mice.

Methods: *UB cells were FACS-isolated from Hoxb7*$^{Cre+/GFP+}$/*PRR*$^{flox/flox}$ (*PRR*$^{UB-/-}$) and control (*PRR*$^{UB+/+}$) littermates at birth (P0). V-ATPase subunit expression in isolated cells was determined by microarray and validated by real-time RT-PCR. PRR knockdown in immortalized UB cells (iUBc) was achieved with adenovirus-driven short hairpin RNA (shPRR). Effect of PRR knockdown on cell pH and V-ATPase activity was determined by staining with Lysotracker (a lysosomal pH marker) and from measurements of Na-independent cell pH recovery rates after intracellular acidification with a NH_4Cl prepulse.

Results: Expression of V-ATPase subunits Atp6ap2 (PRR), V0a4, V0b, V1b1 and V1g1 was reduced in *PRR*$^{UB-/-}$ compared to *PRR*$^{UB+/+}$ UB cells. shPRR decreased mRNA levels of PRR by 80-90% and of kidney-specific α4 V-ATPase subunit by 50% compared to control scrambled control PRR (scPRR) virus in iUBc. shPRR decreased Lysotracker fluorescence in iUBc compared to scPRR ($p<0.001$). Intracellular pH (pHi) measurements (by BCECF fluorescence) indicated slower recovery from acid loads in shPRR-treated cells due to reduced V-ATPase activity. Immunofluorescence of key autophagy protein LAMP2 was increased in the UB of *PRR*$^{UB-/-}$ compared to *PRR*$^{UB+/+}$ kidneys on E14.5, consistent with autophagic defects in UB cells in *PRR*$^{UB-/-}$ kidneys.

Conclusions: PRR knockdown decreases expression of α4 subunit of V-ATPase and suppresses V-ATPase activity in iUB cells in vitro, resulting in deacidification of intracellular vesicles. We propose that endogenous UB PRR regulates normal UB branching morphogenesis through stimulation of V-ATPase activity, control of lysosomal pH and appropriate autophagic flux in UB cells.

SA-PO447

Embryonic Stage Adam10/Notch Pathway Excessive Activation Promotes Ectopic Proximal Tubules Formation and Kidney Fibrosis

Bingjue Li, Jianghua Chen, Hong Jiang. *Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Chronic kidney disease (CKD) is an outstanding public health problem. It is important to elucidate the pathogenesis of CKD and researches on kidney development become a breakthrough. Studies have verified that Notch pathway plays a significant role in kidney development, it is widely believed that Notch promote the formation of proximal tubules. In addition to its role in kidney development, Notch was also found to be involved in kidney fibrosis. Here using prenatal chlorpyrifos (CPF) exposure mouse model we make a further study on the role of Notch in kidney development and fibrosis.

Methods: CPF 5mg/kg/d was administrated by subcutaneous injection in CPF-treated pregnant mice from gestation day 7.5-11.5 while the controls were injected with DMSO. RNA-seq was performed of E12.5, E14.5, E16.5 and E18.5 kidneys, RT-qPCR and WB were performed to verify gene expression. IF and IHC were performed to studied the protein levels and kidney structure changes of offspring mice (4 weeks, 8 weeks and 6 months). Masson staining and fibrosis factor detection were used to evaluate fibrosis. Kidney size and weight, Scr and Bun levels were measured to evaluate renal function.

Results: RNA-seq analysis revealed that Adam10/Notch and Aqp1 were increased in CPF group and nephron progenitor cell (NPC) marker Six2 was decreased. mRNA and protein levels were verified by RT-qPCR, WB, IF and IHC. IF and IHC showed the increasement of proximal tubules. Experiments of offspring mice kidneys showed abnormal embryonic kidney phenotypes persisted in adult kidneys. High activation of Notch also led to impaired kidney function and more severe renal fibrosis.

Conclusions: Excessive activation of Adam10/Notch pathway caused the depletion of $SIX2^+$ NPCs and ectopic proximal tubules formation and aggravate kidney fibrosis.

Toxicodendron vernicifluum Extract Ameliorates Renal Injury in Unilateral Ureteral Obstruction Mice

Dae Eun Choi,[1] Wonjung Choi,[1] Da bi Kim,[2,1] Eunji Kim,[2,1] Tae Woong Hwang,[1] Jwajin Kim,[1] Ki Ryang Na,[1] Kang Wook Lee,[1] Jin young Jeong,[2] Yoon-Kyung Chang.[3] *[1]Nephrology, Chungnam National University, Daejeon, Republic of Korea; [2]Department of Medical Science, Chungnam national university, Daejeon, Republic of Korea; [3]The Catholic University of Korea, Daejeon, Republic of Korea.*

Background: Toxicodendron†vernicifluumis used as a traditional herbal medicine in Asia. The physiological properties and antioxidative effects of Toxicodendron vernicifluum extract (TV) have been demonstrated in several experimental studies. The physiological properties and antioxidative effects of Toxicodendron vernicifluum extract (TV) have been demonstrated in several experimental studies. This study evaluated the possible renoprotective effects of TV on UUO induced tubular damage, as well as the mechanism through which it exerts antioxidative and antiapoptotic effects against UUO induced cell death.

Methods: Male Sprague–Dawley rats weighing 180–200 g each were assigned to one of two groups. The first group (UUO+TV) of rats drank TV for 2 weeks before surgery. The second group (UUO) of rats drank water for 2 weeks. Three days later, a morphologic evaluation of renal injury was conducted using hematoxylin and eosin and TUNEL staining. The renal protein expression of PCNA, caspase3, Nrf2, catalase, and phosphorylated p38 as markers of autophagy was determined by immunoblotting.

Results: Obstruction injury caused marked apoptosis and oxidative stress in the UUO group. It also increased the level of phosphorylated p38 and decreased the level of PCNA, suggesting delayed recovery from damage. The number of TUNEL positive cells, which were detected based on DNA fragmentation, was increased in the UUO group. Notably, there was a significant relationship with increased expression of cleaved caspase3, which was counteracted by TV treatment. Moreover, a comparison with the UUO group revealed that TV significantly enhanced the regulation of autophagy and autophagic flux.

Conclusions: Taken together, our findings suggest that the induction of autophagy protects against UUO induced apoptotic damage via ROS and a p38 regulated pathway in this in vivo model.

A Bottom-Up Approach to Reduce Animal Numbers in Compound Screening Targeting Renal Regeneration After AKI

Julian A. Marschner,[1] Zhibo Zhao,[1] Louise S. Platen,[1] Takamasa Iwakura,[1,2] Alexander Holderied,[1] Hans J. Anders.[1] AG Anders *[1]Klinikum der Universitaet Muenchen, Munich, Germany; [2]Iwata city hospital, Iwata, Japan.*

Background: Developing new therapeutic approaches to improve kidney regeneration after injury remains a hurdle in translational nephrology, since 96% of in vivo identified drugs drop out due to lack of efficacy or safety concerns in humans. We developed a highly efficient, cost- and animal-saving bottom-up approach to screen compound libraries for their pro-regenerative capacity in tubular cells.

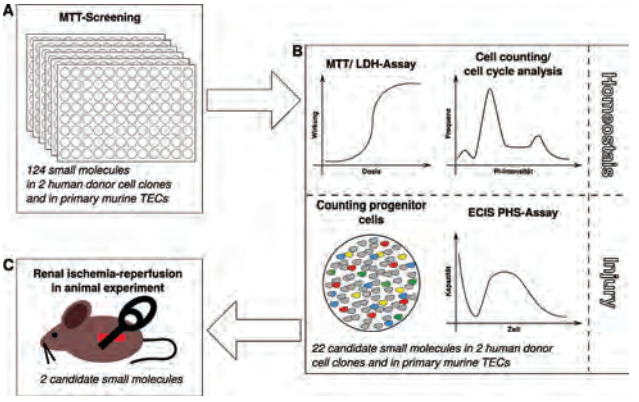
Methods: Using primary human renal progenitor cells (HPCs) and primary murine tubular epithelial cells (TECs) we tested 124 small molecules for their potential to induce

hypertrophy and hyperplasia during homeostasis. We then exposed the cells to PBS and histones (mimicking ischemia/ injury) followed by a return to normal culture conditions (mimicking reperfusion), to test for the compounds pro-regenerative effects. Electric cell impedance sensing and selective progenitor cell expansion were used to monitor effects on wound healing and target cell response, respectively. Only those compounds that proved pro-regenerative in human and murine cells alike were tested in a mouse model of unilateral IRI.

Results: We identified RKI-1447 and SB-525334 in vitro/ ex vivo, and tested both substances in male C57BL/6J, 8-10 weeks of age, at 10 mg/kg every 2nd day for a duration of 3 weeks starting from day 3 after IRI. Both molecules reduced intrarenal mRNA markers of injury, inflammation, and fibrosis. A corresponding trend towards less parenchymal loss and fibrosis was observed in histology.

Conclusions: We were able to show, that an appropriate setup of in vitro and ex vivo experiments using meaningful biological material is suitable for (a) efficiently screening of compound libraries, (b) significantly reducing animal numbers used and (c) predicting outcome in vivo.

Funding: Government Support - Non-U.S.



Bottom-up approach to identify pro-regenerative compounds, that have the capacity to enhance tubular cell healing after injury in human and murine tissue in vitro, ex vivo and in vivo.

Rapid and Efficient Method to Generate Donor Vectors for Homology-Directed Repair Mediated Genome Editing

Lioba Ester,[1,2] Kyle Mccracken,[3] Joseph V. Bonventre.[2] *[1]University of Cologne, Cologne, Germany; [2]Brigham and Women's Hospital, Boston, MA; [3]Boston Children's Hospital, Boston, MA.*

Background: Stem cell-derived kidney organoids are a powerful, tractable tool with numerous potential applications, including the investigation of complex processes underlying human kidney development. To further develop organoids as an embryologic model, it will be essential to generate genetic tools such as fluorescent reporters and lineage tracing systems, which have proven instrumental in rodent studies. With the emergence of CRISPR/Cas9 gene editing via homology directed repair (HDR) is becoming more common in pluripotent stem cells. However, construction of donor vectors that contain gene-specific homology regions remains a time-consuming and often costly endeavor. Thus, we simplified this process through the creation of a modular system to allow rapid and efficient cloning of homology arms into HDR donor vectors.

Methods: We designed and synthesized a plasmid with numerous features and cassettes that are easily interchangeable. These include fluorescent reporters, antibiotic resistance genes and an HSV-TK for use in negative selection. The genes for selection were contained in a floxed cassette to allow easy cre-mediated removal following successful integration. Gene-specific homology arms were created using high fidelity PCR, and final donor vectors were assembled using HiFi Cloning.

Results: To facilitate simultaneous dual and triple knock-in alleles, we used restriction cloning to generate a repertoire of vectors that pair different combinations of reporter and antibiotic resistance genes. The PCR primers designed to amplify the homology arms from genomic DNA of the cell lines of interest also contained sequences of overlap with the sites of insertion on the vector. Thus, in one step using HiFi cloning, we were able to assemble both homology arms into the double-digested vector. This process, including PCR of homology arms, cloning, and sequence validation, can be completed within one week at minimal cost.

Conclusions: Through creation of this vector collection and application of HiFi cloning, we have successfully devised an efficient, streamlined process for cloning donor vectors for use in HDR-mediated gene editing. Given the modular design, these plasmids can also be adapted to permit knock-in of any cDNA of interest. This approach is now broadly applicable for editing of any cell line, including human pluripotent stem cells and hPSC-derived kidney organoids.

Defects in the Exocyst-Cilia Machinery Results in Disease Development in the Kidney and Heart

Joshua H. Lipschutz, Diana B. Fulmer, Russell A. Norris. *Medical University of South Carolina, Charleston, SC.*

Background: Patients with polycystic kidney disease such as ADPKD and Joubert syndrome have elevated risk for bicuspid aortic valve disease (BAV). Non-syndromic BAV affects 1% of the population and often leads to aortic stenosis and the need for surgery. We have previously shown a link between these disorders and defects of organelles called primary cilia. Primary cilia are immotile projections of microtubules that act as signaling hubs for numerous pathways. We previously demonstrated in the kidneys that primary cilia are built by a highly-conserved octameric protein-trafficking complex, known as the exocyst. These studies leveraged the expression of the central exocyst protein, EXOC5. Knockdown of EXOC5 in MDCK cells inhibited ciliogenesis and, conversely, EXOC5 overexpression resulted in longer cilia.

Methods: We performed two human GWAS studies, generated two *exoc5*$^{-/-}$ zebrafish knockout lines and two conditional *Exoc5* mouse knockout lines. Phenotypes were characterized through immunohistochemistry, 3D reconstructions, confocal microscopy, and echocardiography.

Results: GWAS identified the exocyst as being near SNPs most associated with BAV. Next we noted that at three days post fertilization, *exoc5*$^{-/-}$ zebrafish embryos had cardiac edema and outflow tract stenosis. This phenotype was rescued in a dose dependent manner by injection of human *EXOC5* mRNA at the one cell stage; however, the rescue was significantly reduced with the introduction of a targeted mutation in the highly-conserved *EXOC5* VxPx ciliary targeting sequence. These findings prompted us to examine the cardiac phenotype following *Exoc5* deletion in mice. We previously reported altered ciliogenesis and nephrogenesis in *Exoc5*$^{f/f}$ mice when bred with a kidney-specific Cre. To examine the heart, we bred these mice with endocardial-specific *NfatC1-Cre*, and later endothelial-specific *Tie2-Cre*, lines This resulted in mice with highly-penetrant BAV and aortic valve calcification. Echocardiography also revealed aortic valve stenosis and increased aortic root diameter similar to what is seen in BAV patients. There was also evidence of significant cilia disruption, and conditional homozygous mutants were embryonic lethal by E15.5, likely due to cardiac defects.

Conclusions: These data for the first time link cilia, BAV, and the exocyst, and explain the clinical association of cardiac valve abnormalities with PKD.

Metabolic Syndrome (MetS) Upregulates the Tumour Necrosis Factor Alpha(TNF-α) Transcriptome and Proteome in Swine Adipose Tissue-Derived Mesenchymal Stem Cells (MSC)

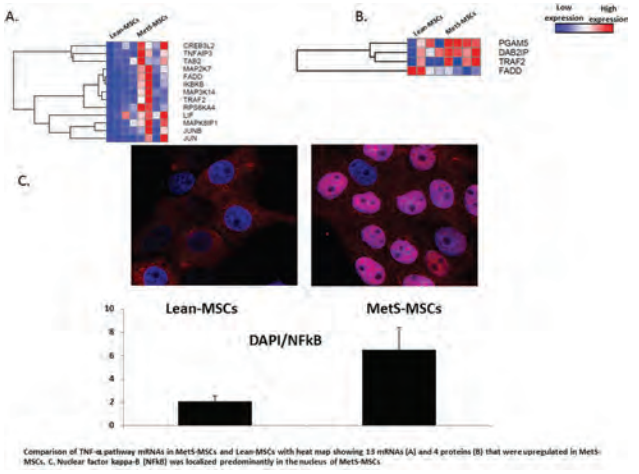
Aditya S. Pawar,[2,1] Alfonso Eirin,[2] Xiang yang Zhu,[2] Mohsen Afarideh,[2] Amir Lerman,[2] Lilach O. Lerman.[3] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic College of Medicine, Rochester, MN.*

Background: MSC have intrinsic reparative properties, & may serve as an exogenous therapeutic intervention in patients with chronic kidney disease (CKD). This microenvironment of MetS induces fat tissue inflammation, with upregulation of TNFα. MetS may also alter the transcriptome and proteome of adipose tissue-derived MSC, which might affect their reparative potency. We hypothesized that MetS upregulates MSC mRNA and proteins of the TNFα pathway.

Methods: Domestic pigs were fed a 16-week Lean or MetS diet (n=4 each), and MSC were then harvested from abdominal subcutaneous fat. Expression profiles of co-existing mRNAs and proteins in MSC were obtained by high-throughput sequencing and proteomics. DAVID 6.7 was used for functional annotation analysis to rank primary gene ontology categories for the mRNAs and proteins. Cellular location of the pro-inflammatory transcription factor nuclear factor (NF)-kB was evaluated by immunofluorescent staining.

Results: Differential expression after filtering for TNFα pathway genes revealed 13 mRNAs & 4 proteins upregulated in MetS compared to lean MSCs (fold change>1.4, $p<0.05$) (Fig. 1, A & B). Upregulated mRNAs were mostly involved in TNFα-1 receptor pathway. A similar pattern was observed in upregulated proteins, except for Traf2 involved in TNFα-2 receptor pathway. MetS induced changes in MSC TNFα signaling were associated with nuclear translocation of NF-kB(Fig 1, C).

Conclusions: MetS upregulates the TNFα transcriptome & proteome in swine adipose tissue-derived MSCs, leading to activation of NF-kB and inflammatory signaling. Hence, the MetS milieu may affect reparative function of endogenous MSC & limit their use as an exogenous regenerative therapy. Targeting the TNFα pathway might be a novel strategy to restore MSC expression patterns, & in turn function, and permit their use in subjects with MetS & CKD.



Comparison of TNF-α pathway mRNAs in MetS-MSCs and Lean-MSCs with heat map showing 13 mRNAs (A) and 4 proteins (B) that were upregulated in MetS-MSCs. C, Nuclear factor kappa-B (NFkB) was localized predominantly in the nucleus of MetS-MSCs.

SA-PO453

Isolation of Primary Cell Types from the Human Kidney Cortex

Kara Shumansky,[1] Laura Perin,[2] Stefano Da Sacco,[2] Casey Cossis.[1] [1]*Novabiosis, RTP, NC;* [2]*Children's Hospital Los Angeles, Los Angeles, CA.*

Background: In vitro studies can help elucidate kidney pathophysiology and nephrotoxicity. Cell lines and primary animal cells can be poor representatives of human cell biology. Primary human renal cells are essential tools for studying such mechanisms. Herein we describe isolation of primary cell types from the cortex of whole human kidneys.

Methods: Podocytes, Proximal Tubule Cells (PT), Mesangial, and Glomerular Endothelial Cells were isolated from non-transplantable human kidneys donated for research. The kidney cortex is surgically separated from the medulla, the tissue is minced, glomeruli are separated, and further digested using a collagenase based enzymatic blend to obtain a heterogenous single cell suspension. Cells are cultured and expanded in specialized media to enrich for the target cell populations. Homogenous cell isolates for a. proximal tubules (CD10/CD13) b. mesangial cells (PDGFRB) c. glomerular endothelial cells (CD31) d. podocytes (nephrin) are isolated by immunomagnetic sorting. Proximal tubular cells, mesangial cells and glomerular endothelial cells further expanded in specific media before undergoing a second round of selection to ensure purity. Podocytes are not expanded to avoid de-differentiation. Characterization of the isolated populations is performed by immunofluorescence and flow cytometry for cell-specific proteins.

Results: We successfully obtained pure human proximal tubular cells, podocytes, mesangial cells and glomerular endothelial cells using the outlined methodology. Each population was assessed for viability, attachment, proliferative ability. Purity and cell-specific marker expression were assessed by confocal fluorescent microscopy and flow cytometry; PT: AQ1, cytokeratin, Na/K-ATPase, and ENT1; Mesangial: PDGFRb, CD206, and Vimentin, GEC: EDH3, Ve Cadherin, and CD31; Podocytes: WT1, Synaptopodin, and Podocin. Proximal Tubular cells retained activity demonstrated by enzymatic GGT assay.

Conclusions: We have developed and optimized a streamlined method for isolating target populations from the human kidney. Our process yields highly pure homogenous cell populations that can proliferate in vitro and express population specific surface markers. Furthermore, isolated proximal tubule cells retained functionality and can be used in transporter assays.

Renovascular Disease Induces Mitochondrial Damage and Impairs the Reparative Capacity of Swine Scattered Tubular-Like Cells

Arash Aghajani Nargesi,[1] Xiang yang Zhu,[1] Sabena Conley,[1] John R. Woollard,[1] Ishran M. Saadiq,[1] Lilach O. Lerman,[2] Alfonso Eirin.[1] [1]*Mayo Clinic, Rochester, MN;* [2]*Mayo Clinic College of Medicine, Rochester, MN.*

Background: Scattered tubular-like cells (STC) contribute to repair neighboring injured renal tubular cells. Mitochondria mediate STC biology and function, but might be injured by the ambient milieu. We hypothesized that the microenviroment induced by the ischemic and metabolic components of renovascular disease (RVD) impairs STC mitochondrial structure and function in swine, which can be attenuated with mitoprotection.

Methods: CD24+/CD133+ STCs were quantified in pig kidneys after 16 weeks of metabolic syndrome (MetS) or Lean diet with or without renal artery stenosis (RAS) (n=6 each). Pig STC were isolated and characterized, and mitochondrial structure and membrane potential were assessed in cells untreated or incubated with the mitoprotective drug elamipretide (ELAM, 1nM for 6hrs). STC protective effects were assessed in-vitro by their capacity to improve viability of injured pig tubular epithelial (PK1) cells.

Results: The percentage of STC was higher in MetS, Lean+RAS, and MetS+RAS kidneys compared to Lean (Fig. A). STC isolated from Lean+RAS and MetS+RAS pigs showed decreased mitochondrial matrix density and membrane potential, which were both restored by mitoprotection (Fig. B). Furthermore, mitoprotection improved the capacity of MetS+RAS-STC to repair injured tubular cells in-vitro (Fig. C).

Conclusions: RVD in swine is associated with a higher percentage of STC, which was predominantly affected by MetS. Ischemia induces structural and functional alterations in STC mitochondria, which can be attenuated by mitoprotection. These observations suggest a key role for mitochondria in the renal reparative capacity of STC.

A. The percentage of CD24+/CD133+ STC in the pig kidney was higher in MetS, RAS, and MetS+RAS groups versus Lean. **B.** Mitochondrial matrix density and membrane potential (TMRE) improved after co-incubation with ELAM. **C.** ELAM also improved the capacity of MetS+RAS-STC to increase the viability of PK1 cells that were previously injured with 10ng/mL of tumor necrosis factor (TNF)-α and 10µM of antimycin-A (AMA). **p<0.05 vs. Lean; †p<0.05 vs MetS; ‡p<0.05 vs. Lean+RAS.*

SA-PO455

Mild AKI in a Murine Polymicrobial Sepsis Model and Its Value for Preclinical Testing of Human Cell Therapies

Barbara Fazekas,[1,2] Senthilkumar Alagesan,[2] Luke Watson,[2] Olivia Ng,[2,1] Callum M. Conroy,[2,1] Yolanda Garcia,[1] Stephen J. Elliman,[2] Matthew D. Griffin.[1] [1]*National University of Ireland Galway, Galway, Ireland;* [2]*Orbsen Therapeutics Ltd, Galway, Ireland, Galway, Ireland.*

Background: Even mild AKI greatly worsens the prognosis of sepsis. Allogeneic mesenchymal stem cells (allo-MSC) have potential therapeutic value in sepsis-associated (SA)-AKI but their optimal administration is undetermined. Improved analysis of human MSC effects in pre-clinical models of SA-AKI could improve future clinical trial design. We aimed to develop a model of mild SA-AKI in which to test a human allo-MSC cell product.

Methods: Caecal ligation and puncture (CLP) or Sham surgery with frequent post-procedural monitoring were performed in male C57BL/6 mice. Blood was sampled at 24, 48 and 72 hrs and kidney tissue collected at 72 hrs. Antibody-selected human umbilical cord (UC)-MSC were injected IV at 10^6 cells/animal 4 hours post-CLP. Plasma and renal tubular neutrophil gelatinase-associated lipocalin (NGAL) were quantified by ELISA and IHC. Renal lymphoid and myeloid cells were quantified by multi-color flow cytometry of collagenase/DNAase-digested kidney.

Results: CLP was associated with 10-15% body weight loss and low (10%) mortality by 72 hrs. Plasma liver enzymes were mildly increased in CLP vs Sham but BUN and creatinine were not raised. Plasma (p)NGAL was markedly increased in CLP versus SHAM animals (p<0.001), peaking at 24 hrs and remaing elevated at 48 & 72 hrs. NGAL staining intensity in renal tubular epithelial cells strongly discriminated between CLP and SHAM at 72 hrs (Mean score 2.6±1.2 vs. 0.0±0.0, p=0.0003) and correlated with pNGAL. Intra-renal immune cell profiling indicated that SA-AKI was associated with proportionatley reduced T-cells, increased neutrophils and a complex modulation of MHC II^+ mononuclear phagocytes (MP). A single administration of UC-MSC (compared to saline) resulted in less body weight loss (6.8±3.7% vs. 10.0±5.2%, p<0.05), trends toward lower pNGAL and renal NGAL staining intensity and reversal of SA-AKI-associated alterations to intra-renal T-cells, neutrophls and MP.

Conclusions: Mouse CLP with frequent post-procedural monitoring resulted in mild SA-AKI best detected by pNGAL, renal tubular NGAL staining intensity and altered

intra-renal immune cell repertoire. The model allowed for quantification of the kidney-specific effects of an investigational human allo-MSC product in the setting of subclinical SA-AKI.

Intrarenal Hh Signalling Mediates Fibrosis in Aged and Injured Kidneys

David A. Ferenbach,[1,2] Cuiyan Xin,[5] Eoin D. O Sullivan,[1] Laura Denby,[4] Joseph V. Bonventre.[3] *[1]Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom; [2]Department of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]University of Edinburgh, Edinburgh, United Kingdom; [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Kidney fibrosis is seen with physiological aging in man and is a feature common to all chronic kidney diseases (CKD), affecting 850 million people worldwide. Both aging and CKD are risk factors for renal injury, and there is an urgent unmet need for novel therapies to prevent subsequent progressive renal fibrosis and renal functional decline. We studied models of renal injury in singleton mice and parabiotic pairings between old and young mice to characterise factors associated with renal fibrosis.

Methods: Young and old C57BL/6J mice were obtained from the NIA. Kidney fibrosis, function and transcriptomes were assessed in baseline singleton and parabiotically paired mice - comparing YY, OY and OO pairings. Serum proteomics were quantified using SOMAscan aptamer panels. Fibrosis was assessed at both a transcriptome and protein level by RNAseq, qPCR and immunohistochemistry, after unilateral ureteric obstruction and ischemia reperfusion injury. Hh signalling was inhibited by the Smo antagonist Cyclopamine, and the Gli antagonist GANT61.

Results: Despite apparently normal function, kidneys from old mice have significantly altered transcriptomes (by RNA sequencing), basal fibrosis levels (by immunohistochemistry) and worsened fibrotic outcomes post injury (using the unilateral ureteric obstruction and ischaemia/reperfusion injury models). Old mice parabiotically paired to young animals demonstrate partial transcriptional normalisation to a young phenotype, revert five serum factors to 'young' levels, and show reduced fibrotic responses to injury. Hh ligands are the most significantly age-associated serum factor, and bulk and single cell transcriptomic assessments demonstrate upregulated renal hedgehog ligand production in the aftermath of injury. In vitro assays demonstrate that Hh induces canonical signalling via the Gli transcription factors leading to renal myofibroblast activation. Pharmacological Hh signalling blockade reduces fibrosis in both the ischaemia reperfusion injury and unilateral ureteric obstruction models of progressive renal fibrosis.

Conclusions: Renal Hh ligand production mediates fibrosis in aging and injury induced kidney disease, via induction of Gli signalling in renal myofibroblasts. The Hh pathway therefore represents a viable therapeutic target in kidney disease, with inhibitors already licenced for clinical use in cancer.

Urinary CRK1 Positive Vesicles Yield Novel Insight into Signaling Through Extracellular Vesicles in the Kidney

Inka C. Homeyer,[1] Victor G. Puelles,[1] Anja Obser,[1] Valerie T. Oberüber,[1] Sasha H. Shafikhani,[2] Tobias B. Huber,[1] Fabian Braun.[1] *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Rush Medical College, Chicago, IL.*

Background: While specific functions of extracellular vesicles (EVs) have been discovered in many fields of biology and medicine, very little is known about their role in kidney health and disease. Recently, a new subgroup of EVs was identified in human and murine cell culture as well as a model of glomerulonephritis. These vesicles are shed upon apoptosis and trigger proliferation in neighboring cells, hence named apoptotic compensatory proliferative signaling vesicles (ACPSVs). As these vesicles could be separated from kidney tissue, we aimed to determine whether a fraction is shed into the urine and further analyze their biological properties.

Methods: We established a protocol of differential centrifugation and filtration to separate ACPSVs from urine samples of healthy control subjects. Multiplex immunofluorescence microscopy, Western Blot and FACS were used to validate the presence of CRKI+ EVs, determine their cellular origin and assess the baseline characteristics of these urinary vesicles.

Results: The employed protocol lead to a robust isolation of spherical vesicles ranging between 800nm and 1,8µm in diameter with a subfraction containing the ACPSV marker protein CRKI. Further protein analysis revealed the presence of marker proteins for all segments of the nephron colocalizing with both CRKI positive and negative EVs. FACS analysis and multiplex immunofluorescence enabled us to determine and quantify the specific vesicle fractions originating from i.e podocytes, PECs and collecting duct cells.

Conclusions: Our study represents the first analysis of urinary CRKI containing vesicles of the ACPSV size range. Taken into account the presence of podocyte marker proteins in the separated vesicle fraction, we hypothesize, that these are not only shed upon apoptosis, hence would not call them urinary ACPSVs. Ongoing investigations aim to validate the potential to initiate proliferation on different renal cell types and to determine differences in their function and content in the state of renal diseases. As these vesicles can be easily isolated in a high purity, they also represent a valuable source for biomarker research in various nephropathies.

Interferon Regulatory Factor 5 Expressed in Kidney Resident Macrophages Promotes Polycystic Kidney Disease

Kurt Zimmerman,[1] Jifeng Huang,[3] Lan He,[3] Dustin Z. Revell,[1] Zhang Li,[1] Wayne R. Fitzgibbon,[4] Edward S. Hazard,[6] Gary Hardiman,[2] Michal Mrug,[3,5] Phillip D. Bell,[3] Bradley K. Yoder,[1] Takamitsu Saigusa.[3] *[1]Cell, Developmental, and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL; [2]Queen's University Belfast, Belfast, United Kingdom; [3]Medicine/Nephrology, University of Alabama at Birmingham, Birmingham, AL; [4]Medicine/Nephrology, Medical University of South Carolina, Charleston, SC; [5]VA Medical Center, Birmingham, AL; [6]Academic Affairs Faculty & Computational Biology Resource Center, Medical University of South Carolina, Charleston, SC.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by genetic mutations in *Pkd1* or *Pkd2*. Previous data indicate that pro-inflammatory cytokines including TNFα, IL-6, and MCP1, as well as their downstream signaling components, are associated with macrophages and accelerated cystogenesis. Recent data indicate that the *Irf5* transcription factor promotes a pro-inflammatory macrophage phenotype.

Methods: In these studies, we assess the importance of macrophage-derived *Irf5* during accelerated cystogenesis induced by unilateral nephrectomy (1K) in conditional *Pkd1* mice.

Results: Analyses of RNA sequencing, qRT-PCR, and flow cytometry data from whole kidney tissue collected three weeks post nephrectomy, a time point prior to the onset of severe cystogenesis, indicate an enriched inflammatory macrophage signature, including increased *Irf5* expression, in 1K *Pkd1* mice compared to controls. To determine the importance of *Irf5* in cyst progression, we injected scrambled or IRF5 antisense oligonucleotide (ASO) in 1K *Pkd1* mice and analyzed the effect on cytokine production and renal cystogenesis 6 weeks post nephrectomy. Our data indicate that IRF5 ASO treatment significantly reduced macrophage numbers, *Irf5* expression in resident, but not infiltrating, macrophages, and reduced the severity of cystic disease. In addition, IRF5 ASO treatment reduced the expression of the pro-inflammatory cytokine *Il6* in resident macrophages, which correlated with reduced STAT3 phosphorylation and downstream p-STAT3 target gene expression in 1K *Pkd1* mice.

Conclusions: These data indicate that *Irf5* expressed in resident macrophages promotes accelerated cystogenesis.

Funding: NIDDK Support, Veterans Affairs Support

Genetic Strain Influences Infiltrating Macrophage Subtype, Accumulation, and Gene Expression in the Liver of a Mouse Model of Hepatorenal Fibrocystic Disease

Kurt Zimmerman, Zhang Li, Michal Mrug, Bradley K. Yoder. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Hepatorenal fibrocystic disease (HRFCD) is a genetically inherited disorder in which patients display significant heterogeneity in disease severity and progression with varying levels of fibrosis, cyst development, and inflammation. Recent data indicate that macrophage subtypes promote renal cystic disease suggesting that the subtype of macrophage present controls phenotypic outcome.

Methods: Herein, we utilize a mouse model of HRFCD ($Ift88^{Orpk}$ mice) on the C57BL/6 and BALB/C inbred backgrounds to study the influence of genetic strain on macrophage accumulation and disease progression in the liver.

Results: Phenotypic analysis of liver tissue shows that C57BL/6 $Ift88^{Orpk}$ livers have increased cystic severity but reduced levels of fibrosis compared to BALB/c $Ift88^{Orpk}$ livers. Further, our data show that genetic strain influences the subtype of infiltrating macrophage present during normal postnatal liver development and in $Ift88^{Orpk}$ mice ($Ly6c^{lo}$ in C57BL/6 vs $Ly6c^{hi}$ in BALB/c). RNA sequencing data indicate that macrophages and cholangiocytes express unique ligand receptor pairs, dependent on genetic strain, that may facilitate epithelial cyst expansion or fibrosis. To test the importance of $Ly6c^{hi}$ infiltrating macrophages in promoting the fibrosis observed in BALB/c $Ift88^{Orpk}$ mice, we crossed these mice onto a CCR2-/- background. Our data indicate that CCR2 deficiency reduces $Ly6c^{hi}$ macrophage accumulation and prevents the increase in *Col1a1* and *Col3a1* gene expression in $Ift88^{Orpk}$ mice.

Conclusions: Collectively, our data suggest that the heterogeneity in the hepatic phenotype associated with ciliopathies is influenced by the subtype of infiltrating macrophage that is present.

Funding: NIDDK Support

SA-PO460

CD206+ Resident Macrophages Are Associated with Cyst Progression in Juvenile-Induced Cilia Mutant Mouse Models

Zhang Li, Kurt Zimmerman, James F. George, Michal Mrug, Bradley K. Yoder. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Abnormalities in the function (*Pkd1* or *Pkd2* mutation) or structure (*Ift88* mutation) of primary cilia result in renal cysts in animal models and human patients. Recent studies show that removing cilia in mouse models of *Pkd1*or *Pkd2* inactivation suppresses cyst growth suggesting a primary cilia-dependent suppressor function in cystogenesis. It has been reported that renal resident macrophages are associated with cyst formation; however, the importance of resident macrophage subsets in promoting renal

cyst formation and their relationship with cystic disease caused by mutations in proteins required for cilia formation (*Ift88*) or function (*Pkd2*) is unknown.

Methods: To test the association of resident macrophage subtypes with the type of cilia mutation, we performed flow cytometry analysis of kidneys harvested from juvenile induced conditional *Ift88, Pkd2*,or *Ifi88:Pkd2* mutant mice. We also used pharmacological (CSF1R kinase inhibitor) and genetic (CX3CR1$^{gfp/gfp}$) approaches to test the functional importance of resident macrophages in juvenile-induced cyst formation.

Results: Our data indicate that induction of cilia dysfunction (*Pkd2* mutation) in juvenile mice results in more severe cysts 21 days post induction compared to mice lacking primary cilia alone (*Ift88* mutation) or mice lacking both *Pkd*2 and *Ift88*. Analysis of flow cytometry data indicate that the number of CD206+ resident macrophages is directly correlated with the severity of cystic disease with juvenile-induced *Pkd2* deficient mice having the greatest number of CD206+ resident macrophages. Further, we show that *Ifi88:Pkd2* double mutant mice have an intermediate cystic severity and number of CD206+ resident macrophages compared to single *Ift88* and*Pkd2* mutant mice. Finally, our preliminary data indicate that inhibition of CD206+ resident macrophage accumulation using a CSF1R kinase inhibitor or genetic reduction of CD206+ resident macrophages using a CX3CR1$^{gfp/gfp}$ mouse reduced the severity of cystic disease in juvenile-induced *Ift88* mutant mice.

Conclusions: These data suggest that the type of primary cilia mutation controls the abundance of CD206+ resident macrophages and these resident macrophages are important in promoting cyst progression.

SA-PO461

Targeting Immunosuppressive Pathways Reduces ADPKD Progression in a Relevant Murine Model

Dustin Nguyen, Emily K. Kleczko, Berenice Y. Gitomer, Eric T. Clambey, Michel Chonchol, Jelena Klawitter, Raphael A. Nemenoff, Katharina Hopp. *University of Colorado Denver Anschutz Medical Campus, Aurora, CO.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) shares many parallels with cancer, where tumor microenvironmental immune cells considerably impact disease progression. Similarly, both macrophages and T cells within the cystic microenvironment (CME) regulate cystogenesis in ADPKD murine models. But, how the interplay among these cells impacts cyst progression remains elusive. The goal of this study was to understand this dynamic interplay better.

Methods: We utilized flow cytometry to quantify renal immune cells in the murine ADPKD C57Bl/6 *Pkd1* p.R3277C (RC) model, strain matched wildtypes (WT), and *Pkd1* RC mice treated with either an inhibitor to the CSF1 receptor (CSF1R) or IDO1 (treatment regimen: 30 days starting at 1-month of age). CSF1 binding to CSF1R regulates macrophage proliferation and IDO1 regulates T cell function.

Results: IDO1 levels were increased in our *Pkd1*$^{RC/RC}$ mice, a *Pkd1*$^{-/-}$ cell line, and in ADPKD patient cyst cells vs. controls. Further, resident macrophage numbers were significantly increased in *Pkd1*$^{RC/RC}$ vs. WT mice. These findings led us to investigate if CSF1R or IDO1 inhibition slows ADPKD and how targeting different immune cell populations modulates the CME. Intriguingly, blocking of either protein reduced PKD severity (%kidney weight [W]/body W) in our mild, slowly progressive model and altered the CME significantly. Both treatments significantly reduced renal resident but not infiltrating macrophage as well as T cell numbers; renal neutrophil or dendritic cell numbers were not impacted. Most interestingly, while overall significantly reduced, the CD4 T cell population shifted, with regulatory T cells (T_{Regs}; known to be immunosuppressive) being significantly reduced two-fold by both treatments. This is of notable importance as we found T_{Regs} to be significantly enriched four-fold in the CD4 population in early disease when comparing *Pkd1*$^{RC/RC}$ vs. WT mice.

Conclusions: Using a relevant disease model, we show that targeting resident macrophages or modulators of T cell function can reduce PKD progression. Inhibition of both pathways resulted in reduced numbers of renal T_{Regs}, suggesting that they may be a unifying key effector of cystogenesis and a viable target for ADPKD immune therapy.

Knockout of Caspase-1 Gene Restrains Polycystic Kidney Disease in Pkd1$^{RC/RC}$ Mice

Katherine Swenson-Fields,[1] Christopher J. Ward,[1] Anna L. Heimes Dillon,[1] Michael P. Vitek,[2,3] James D. Meisenheimer,[1] Darren P. Wallace,[1] Timothy A. Fields.[1] *[1]The Jared Grantham Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Resilio Therapeutics LLC, Durham, NC; [3]Duke University Medical Center, Durham, NC.*

Background: Two stimuli shown to accelerate disease in PKD model mice are acute kidney injury and exposure to commensal microbes. A commonality of these two stimuli is that they both promote activation of the inflammasome, a multi-protein scaffold that assembles in a range of cell types as an innate immune response to either microbe-associated or cell damage-associated molecular motifs. Inflammasome assembly results in activation of the protease Caspase 1. Activated Caspase 1 promotes the cleavage and secretion of multiple protein substrates to create an inflammatory environment that can be pathological. We hypothesized that inflammasome activation promotes disease progression during the natural course of PKD.

Methods: To identify whether inflammasomes were activated during PKD progression, the expression of known inflammasome sensors/markers was assessed by qRT-PCR and western blotting of samples from the kidneys of human ADPKD patients, cystic *jck* and *Pkd1*$^{RC/RC}$ mice, and from non-cystic human and mouse kidneys. The *jck* mice were treated during an early stage of disease with adenine (2.5% in the chow), an agent known to activate inflammasomes, and the effects on PKD progression were examined at PN43. Caspase-1 (*Casp1*) was knocked out in the *Pkd1*$^{RC/RC}$ mice (*Pkd1*$^{RC/RC}$:Casp1$^{\Delta/\Delta}$). The effects on cystic kidney disease in Pkd1$^{RC/RC}$ and Pkd1$^{RC/RC}$:Casp1$^{\Delta/\Delta}$ mice were assessed at 6 months of age.

Results: Elevated expression of inflammasome components was found in the *jck* and *Pkd1*$^{RC/RC}$ mice and human ADPKD kidneys (*Nlrp3, Nlrp10, Mefv, Casp1, Il1b,* NLRP3, CASP1 in *jck; Nlrp1, Nlrp3, Aim2, Mefv, Casp1, Il1b* in *Pkd1*$^{RC/RC}$; *NLRP1, NLRP3, NLP10, AIM2, CASP1, IL1B,* NLRP3, IL1β in ADPKD). Adenine consumption promoted elevated 2K/TBW and cystic index in *jck* mice. *Casp1* knockout lowered 2K/TBW (*Pkd1*$^{RC/RC}$ =2.2 ± 0.4, *Pkd1*$^{RC/RC}$*:Casp1*$^{\Delta/\Delta}$=1.8 ± 0.15, p=0.01; compared with WT=1.2 ± 0.13) and cystic index in *Pkd1*$^{RC/RC}$ mice.

Conclusions: These preclinical studies identify Caspase1 as a promoter of PKD progression and a potential therapeutic target for cystic kidney disease.

Autosomal Dominant Polycystic Kidney Disease Shows a Tumor-Like Microenvironment

Elisa Agnese Nigro, Maria Elena Steidl, Marco Chiaravalli, Alessandra Boletta. *San Raffaele Scientific Institute, Milan, Italy.*

Background: Polycystic kidney disease (PKD) is an inherited genetic disorder characterized by progressive growth of cysts in the kidneys. Despite not being a cancer, PKD shares many features with tumors. For instance, recent studies suggest a role of immune cells in PKD progression. Tumor modifies infiltrating cells functions to create the microenvironment favorable to tumor progression. Principal components of the Tumor Microenvironment (TME) are immune-inflammatory cells, Cancer-Associated Fibroblasts (CAFs), blood vessels and ECM. We investigated whether a similar environment might be present in PKD murine models.

Methods: We have characterized the renal tissue microenvironment of a *Pkd1*$^{flox/-}$*:TmCre* inducible and the *Pkd1*$^{flox/-}$*:KspCre* ADPKD mouse models. We have analyzed the presence of infiltrating immune cells and CAFs, and the state of the ECM through histological analysis and quantitative Real Time-PCR. In addition fluorometric analysis following dissociation of cells from total kidneys was used to analyze interstitial inflammation. For the *pan* macrophages quantification, we have performed an *in situ* quantification employing an F4/80 detection algorithm.

Results: We have detected a statistically significant increased level of CD45^{+} leukocytes in the ADPKD kidneys compared to the controls. In contrast, B and T lymphocytes could not be detected in late PKD models. Macrophages, activated myofibroblasts (potentially corresponding to CAFs), and extensive fibrosis in the kidneys of the ADPKD affected mice could be detected. In particular, while M1-macrophages (expressing *Nos2*) did not significantly change between the PKD kidneys and the controls, M2-macrophages (expressing *Arg1*) were found significantly increased in the kidneys of PKD mice compared to controls.

Conclusions: Our analysis on the kidneys of the ADPKD mouse models reveals the presence of a tumor-like microenvironment (T-LME), which could promote disease progression. The analysis of the crosstalk among the different components of the microenvironment might provide important insights into disease progression in PKD.

Peptides Derived from the Stalk Region of Polycystin 1 Function as Ligands to Activate Signaling by the C-Terminal Fragment and to Ameliorate Cystogenesis

Brenda S. Magenheimer, Robin L. Maser. *University of Kansas Medical Center, Kansas City, KS.*

Background: Polycystin-1 (PC1) modulates G protein signaling by as yet unknown regulatory mechanisms. Like the Adhesion class of GPCRs, PC1 undergoes auto-catalyzed cleavage at a GPS motif, which generates a large extracellular, N-terminal fragment and a membrane-embedded, C-terminal fragment (CTF) composed of 11 transmembrane domains preceded by an N-terminal extracellular stalk of 25 residues. We previously reported that PC1 CTF-mediated signaling to an NFAT reporter is dependent on the presence of the stalk, and is reduced by specific amino acid substitutions within its sequence. To determine if this stalk-dependent mechanism contributes to the inhibition of cyst formation, the ability of stalk-derived peptides to rescue signaling by a 'stalk-less' CTF expression construct (ΔCTF) and to ameliorate cAMP-driven cystogenesis was determined.

Methods: HEK293T cells transiently transfected with the ΔCTF construct lacking the first 21 residues of the stalk region were treated with soluble peptides (P) ranging from 7 to 21 residues in length whose sequences were derived from the stalk region. Activation of a co-transfected NFAT promoter-luciferase reporter was compared between ΔCTF- and empty expression vector control-transfected cells. Metanephric organ cultures derived from E15.5 Pkd1$^{RC/RC}$ fetal mice were stimulated with 8-Br-cAMP, and were treated with stalk peptides for up to 4 days in culture. The cystic area was compared between non-treated and peptide-treated kidneys.

Results: All of the stalk peptides (P7-P21) enhanced signaling from ΔCTF to the NFAT reporter, albeit to varying degrees, possibly due to differences in peptide structure. Peptides P7, P9, P13, P15 and P17 significantly reduced the cystic index of treated embryonic kidneys to different extents (e.g., ~25% for P7 to ~90% for P17), while P11 had no ameliorating effect. Treatment with P19 or P21 prevented kidney growth and decreased kidney survival. A mutant peptide containing a human ADPKD-associated missense mutation was also detrimental in organ culture unlike its wild type parental peptide.

Conclusions: These results support an Adhesion GPCR-like, stalk-dependent mechanism for regulation of signaling by PC1, implicate a physiological and disease-relevant role for this mechanism in renal tubulogenesis, and suggest a novel therapeutic avenue for ADPKD.

SA-PO465

RNA Helicase p68 Inhibits Pkd1 Transcription and Promotes Cyst Growth in ADPKD

Lu Zhang,[1] Xiaoyan Li,[1] Xia Zhou,[2] James P. Calvet,[2] Xiaogang Li.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations of PKD1 and PKD2, resulting in progressive deterioration of kidney function due to the formation of thousands of cysts. Expression of PKD1 is high in the fetal kidney, which is essential for kidney development, and then is reduced after nephron formation has completed. However, the transcriptional regulation of PKD1 remains elusive. In this study, we investigate the roles and underlying mechanisms of p68, a DEAD box RNA helicase, in regulating Pkd1 gene expression.

Methods: To understand the role of p68 in ADPKD, we examined the expression of p68 and its regulation in Pkd1 mutant renal epithelial cells and ADPKD patient kidneys by qRT-PCR, Western blot and immunostaining/immunohistochemistry, and investigated how p68 regulates cystic cell proliferation, oxidative stress and renal fibrosis. To investigate if and how p68 regulates the transcriptional and post-transcriptional processing of the Pkd1 gene, we performed co-IP and ChIP assays in renal epithelial cells with and without knockdown of p68.

Results: We found that p68 was upregulated in Pkd1 mutant renal epithelial cells compared to that in Pkd1 wild type control cells as examined by Western blot and qRT-PCR analysis. The level of p68 was also increased in cyst lining epithelial cells in kidneys from Pkd1 mutant mice and ADPKD patients. Knockdown of p68 increased Pkd1 gene transcription, whereas upregulation of p68 decreased Pkd1 transcription, which involved 1) interaction of p68 with p53 and Drosha to form a ternary complex on the promoter of the Pkd1 gene, and 2) increased p68 mediated microRNA 182 (miR182). Inhibition of miR182 increased Pkd1 mRNA and protein levels. In addition, we found that oxidative stress decreased Pkd1 expression in a p68-dependent manner. We further found that p68 regulated cystic epithelial cell proliferation via the activation of ERK, mTOR and Rb signaling, and regulated renal fibrosis via TGFβ1 signaling.

Conclusions: This is the first study to show that one of the RNA helicases, p68, inhibits the transcription of the Pkd1 gene and promotes cystic renal cell proliferation and the expression of fibrotic markers in these cells. Oxidative stress promotes renal cyst progression via p68 mediated Pkd1 downregulation. Targeting p68 with its inhibitor may be a potent therapeutic strategy for ADPKD treatment.

The Consequences of Decreased Cap-Dependent Translation in Polycystic Kidney Disease

Sara Holditch,[1] Carolyn N. Brown,[2] Daniel Atwood,[3] Katharina Hopp,[4] Charles L. Edelstein.[5] *[1]UC Denver Anschutz Medical Campus, Aurora, CO; [2]UC Denver Anschutz, Aurora, CO; [3]University of Colorado Anschutz, Aurora, CO; [4]University of Colorado Denver, AMC, Aurora, CO; [5]University of Colorado Denver, Aurora, CO.*

Background: Autosomal Dominant Polycystic kidney disease (ADPKD) is the most common life-threatening hereditary disease, characterized by cyst formation and growth. Unchecked proliferation of cystic epithelial cells is a major contributor to cyst growth. At the nexus of regulating proliferation is the 4E-BP1 pathway, a crucial checkpoint in cap-dependent protein translation and proliferation. We demonstrate on immunohistochemistry staining that ADPKD mice and rat models, ADPKD patient renal biopsies, and PKD1$^{-/-}$ cells exhibit hyperphosphorylated 4E-BP1, a biomarker of increased translation and proliferation. We hypothesized that expression of constitutively active 4E-BP1 constructs (4E-BP1^{F113A} and 4E-BP1R13A^{F113A}) would repress translation, decrease proliferation, and reduce cyst expansion.

Methods: In the orthologous ADPKD model, the C57BL/6 Pkd1$^{RC/RC}$ mouse, we determined the effect of 4E-BP1^{F113A} on cystic disease (on MRI scan).

Results: Unexpectedly, relative to controls, 4E-BP1^{F113A} resulted in increased cyst burden (%) (48±5 vs. 72±6*), decreased functional parenchyma (%) (46±7 vs 22±5*, suppressed TUNEL staining (% positive cyst epithelium, 24±9 vs. 36±14*), and increased Bcl-2 expression (relative densitometry units, 12±2 vs. 8±2*). Values are means of control treated, and 4E-BP1^{F113A} treated Pkd1$^{RC/RC}$ ± SEM, *p<0.05.

Conclusions: To determine the mechanism of 4E-BP1^{F113A} enhanced PKD, we performed *in vitro* studies in ADPKD patient cells. *In vitro*, 4E-BP1^{F113A} and 4E-BP1^{R13AF113A} significantly repressed cap-dependent translation as anticipated (57% mean reduction across 3 cyst cell lines). However, 4E-BP1 transduction increased mTOR signaling, enhanced proliferation, decreased apoptosis, impaired NADPH oxidoreductase activity and increased superoxide production. Reduced 4E-BP1 expression reversed the *in vitro* phenotype. These results demonstrate the importance of cap-dependent translation in PKD cyst lining epithelial cells

Elevated Calcium/Calmodulin-Dependent Protein Kinase IV (CaMK4) Promotes mTOR-Dependent Cell Proliferation in ADPKD

Yan Zhang, Emily A. Daniel, Yuqiao Dai, Gail Reif, Darren P. Wallace. *University of Kansas Medical Center, Kansas City, KS.*

Background: Mammalian target of rapamycin (mTOR), a central integration site for pathways involved in cell growth and proliferation, is abnormally activated in cyst-lining cells in ADPKD. mTOR inhibition reduces cell proliferation and PKD progression in rodents; however, the therapeutic value of targeting mTOR with rapalogues in ADPKD patients remains unclear due to dose-limiting side effects. The development of new therapies requires a better understanding of pathways responsible for aberrant mTOR activation in cystic epithelial cells. Calcium/calmodulin-dependent kinase type IV (CaM4) stimulates mTOR signaling in various cell types including hepatic cancer cells and immune cells; however, the role of CaMK4 on mTOR signaling and cyst growth in PKD has not been examined.

Methods: CaMK4 levels were measured in primary ADPKD and normal human kidney (NHK) cells, and in *Pkd1*$^{RC/RC}$ (slow onset), *Pkd1*$^{RC/RC}$*; Pkd2*$^{+/-}$ (rapid onset) and normal mouse kidneys by Western blot analysis. The effect of KN-93, a CaMK4 inhibitor, on mTOR signaling was evaluated in ADPKD cells. To determine if CaMK4 regulation of mTOR was dependent on the LKB1/AMPK pathway, we tested KN-93 on renal cells with an inducible knockout of *Lkb1*. *pcy/pcy* mice, a well-characterized PKD model, received 10 mg/kg KN-93 every day for one week to determine the effect of CaMK4 inhibition on renal mTOR signaling.

Results: CaMK4 levels were 2.5-fold higher in human ADPKD cells compared to NHK cells. Renal CaMK4 levels were also elevated in *Pkd1*$^{RC/RC}$ and *Pkd1*$^{RC/RC}$*; Pkd2*$^{+/-}$ mouse kidneys compared to age-matched normal littermates. Incubation with KN-93 decreased P-mTOR, P-S6K and P-S6, downstream targets of mTOR, and proliferation of ADPKD cells. mTOR inhibition by KN-93 was not affected by LKB1 knockout in renal epithelial cells, consistent with a direct effect of CaMK4 on the mTOR complex. CaMK4 inhibition with KN-93 decreased renal levels of P-S6 in *pcy/pcy* mice.

Conclusions: Elevated CaMK4 promotes mTOR signaling in PKD kidneys and may be a potential target to reduce mTOR-dependent cell proliferation and cyst growth.

SA-PO468

Polycystin 1 Regulates Cilia Length and Cyst Formation by Controlling Centrosomal ARHGAP35-Dependent RhoA Activation

Andrew J. Streets,[1] Philipp P. Prosseda,[1,2] Maya Boudiffa,[1] Albert C. Ong.[1] Kidney Genetics Group *[1]University of Sheffield, Sheffield, United Kingdom; [2]Stanford University, Palo Alto, CA.*

Background: Mutations in *PKD1* (encoding for PC1) account for most patients with ADPKD but it is still unclear how these result in the highly complex cellular phenotype of ADPKD. It had been reported that primary cilia length is normal in ADPKD cells implying an abnormality in function (flow-dependent signalling); however this hypothesis has been recently challenged. Unexpectedly, we observed consistently shorter cilia in patient-derived *PKD1* cystic cells compared to normal tubular cells and its correction by cytochalasin-D, an inhibitor of actin polymerisation.

Methods: RhoA activity (GST pulldown) and its localisation (RhoA biosensor) were determined in ciliated cells; siRNA knockdown of reported centrosomal ARHGAPs identified from ciliome and centrosome databases and their effect on cilia length; *PKD1* null human tubular cells were generated by CrispR/Cas9 mutagenesis; BioID proximity assay using a centrosome targeting sequence (PACT) to confirm centrosomal localisation of ARHGAPs; effect of a selective ROCK inhibitor (hydroxyfasudil) in a *Pkd1* mouse model.

Results: We confirmed that primary cilia are shorter *in vivo* (human ADPKD and mouse *Pkd1* kidneys) and in *PKD1* null CrispR cells. In ciliated cells, increased RhoA (but not Cdc42 or Rac1) activation was observed in *PKD1* cystic cells with a localised increase at the cilia base. Cilia length could be normalised by Rho kinase (ROCK) inhibitors or expression of dominant negative RhoA (but not Cdc42 or Rac1). Knockdown of several centrosomal ARHGAPs (5, 29, 35) resulted in shorter cilia but only ARHGAP35 centrosomal localisation was reduced in the absence of *PKD1*. Specific binding of ARHGAP35 to the PC1 C-terminal domain was shown by co-IP. Finally, we demonstrate that selective ROCK inhibition reduced cyst growth *in vitro* (*PKD1* human cystic cells) and *in vivo* (*Pkd1* mouse).

Conclusions: PC1 appears to regulate centrosomal RhoA activity through the recruitment or stabilisation of ARHGAP35. Mutations in *PKD1* lead to shorter cilia due to increased RhoA and ROCK activity. Interestingly a recently reported ARHGAP35 hypomorphic mouse develops shorter cilia and glomerular cysts. Inhibition of ROCK normalised cilia length and reduced cyst expansion suggesting that the RhoA/ROCK pathway is a potential new axis to develop therapies to inhibit cyst initiation in ADPKD.

SA-PO469

Genetic Reduction of Cilium Length by Targeting Ift88 Impedes Kidney and Liver Cyst Formation in Autosomal Polycystic Kidney Disease Mouse Models

Wassim El-Jouni,[2,1] Tapas Ranjan Behera,[3] Amrendra K. Ajay,[2] Jing Zhou.[2] Zhou Lab *[1]Massachusetts General Hospital, Charlestown, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Mutations in polycystin-1 (PC1) and -2 (PC2), products of the PKD1 and PKD2 genes, cause autosomal dominant polycystic kidney disease (ADPKD). They localize to the primary cilia; however, their ciliary function is in dispute. The loss of either the cilia or PC1 or PC2 causes cyst in orthologous mouse models. Cystogenesis is inhibited in the absence of both cilia and PC1 or PC2. How the cilia and PC1 or PC2 interact to regulate cystogenesis is still unknown. The role of intraflagellar transport proteins in Pkd1-deficient mice is also unknown.

Methods: In this study we used human and mouse kidney tissues to study the correlation between cilia length and cyst formation. We developed Pkd1 and Pkd2 single and double knockouts with Ift88 to thoroughly investigate the correlation between cilia length and cystogenesis in mice and to identify downstream signaling targets.

Results: 1) We report, for the first-time that cilium length is elongated in human ADPKD kidneys. 2) We found similar elongation in Pkd1 and Pkd2 knockout mice following polycystin inactivation. 3) We show that inactivating the intraflagellar transport protein Ift88 in Pkd1-deficient mice and Pkd2-deficient mice shortens the elongated cilia, impedes kidney and liver cystogenesis and reduces cell proliferation. 4) Multi-stage in vivo analysis of signaling pathways revealed a novel early, and sustained activator in disease onset and progression in Pkd2 single knockout (SKO) which is rescued in Pkd2 and Ift88 double knockout (DKO) mouse kidneys. 5) On the other hand, ERK pathway was activated in the SKO but no rescue was observed in the DKO mouse kidneys.

Conclusions: Our findings advocate an essential role of polycystins in the structure and function of the primary cilia and implicate a novel target as a key inducer of cystogenesis downstream of the primary cilia. These data suggest that modulating cilium length and/or its associated signaling events may offer novel therapeutic approaches for ADPKD.

SA-PO470

SMYD3: A Novel Regulator of Cystogenesis and Ciliogenesis in ADPKD

Ewud Agborbesong,[1] Xia Zhou,[1] Xiaogang Li.[2] *[1]University of Kansas Medical Center, Kansas City, KS; [2]Mayo Clinic, Rochester, MN.*

Background: Deregulation of lysine methylation signaling has emerged as a common aetiological factor in disease pathogenesis, such as cancers. We found that the lysine methyltransferase, SMYD3, is upregulated in ADPKD, a genetic and "ciliopathy" disease characterized by renal cyst formation and ciliogenesis defects. However, if and how SMYD3 regulates cyst formation and its relationship to ciliogenesis remains elusive.

Methods: We investigate the role of Smyd3 on renal cystogenesis by knockout of Smyd3 in *Pkd1* conditional knockout mouse kidneys, and investigate if Smyd3 regulates ciliogenesis in mIMCD3 and RCTE cells with and without knockdown of Smyd3 and in primary renal cells isolated from *Smyd3 fl/fl:Ksp-Cre* mouse kidneys. We determine the effect of Smyd3 on the localization of proteins on the basal body and ciliary axoneme by immunofluorescence.

Results: We found that knockout of Smyd3 delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, and cyst lining epithelial cell proliferation in Pkd1 mutant mice (all $p < 0.05$). We further found that knockout of Smyd3 decreased the activity of STAT3 and β-Catenin. In addition, we found that Smyd3 interacted with CDK2, a direct regulator of the cell cycle, and knockout of Smyd3 decreased the phosphorylation of CDK2 in *Pkd1* mutant mouse kidneys. We further found that Smyd3 is localized on the centrosome and basal body and silencing or knockout of Smyd3 inhibits primary cilia assembly in renal cells. Smyd3 is co-localized with centriolar distal appendage proteins, Cep164, C2CD3 and Ofd1, and interacts with Ofd1, Ift88 and TTBK2 proteins, known to play an essential role in ciliogenesis. Depletion of Smyd3 increased the recruitment of Ift140, but decreased the recruitment of Rab8a and Cep164 to the ciliary axoneme. Last, knockdown of Smyd3 regulated the expression of key distal appendage and trafficking related proteins at the transcript and protein levels.

Conclusions: Smyd3 regulates cystic renal epithelial cell proliferation via STAT3, β-catenin and Cdk2 signaling to promote cystogenesis, and regulates ciliogenesis by acting as a gate protein, controlling the trafficking of proteins in and out of the cilia. The interactions between Smyd3 and its novel binding partners provide novel mechanisms of Smyd3 in regulating cystogenesis and ciliogenesis in ADPKD.

SA-PO471

Protein Phosphatase 1 Alpha Interacts with Polycystin-1 and Regulates Polycystin-1 Targeting to Primary Cilium

Chong Luo,[1,2] Jianghua Chen,[1] Jing Zhou.[2] *[1]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]Brigham & Women's Hospital/Harvard Medical School, Boston, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary renal disease, which is mostly caused by mutations in *PKD1* or *PKD2* genes. However, how mutations in these two genes lead to ADPKD remains partially understood. Recent studies have indicated that defective ciliary trafficking of polycystin-1/2 (PC1/2, encoded by *PKD1* and *PKD2*, respectively) underlies the pathogenesis of a subgroup of ADPKD cases. We have recently identified a novel ciliary targeting sequence (CTS) in the C-terminus of PC1. We found that this CTS interacts with protein phosphatase 1-a (PP1a), a ubiquitously expressed phosphatase in the PPP family. Short hairpin RNA mediated knockdown of PP1a in IMCD3 cells results in reduced PC1 ciliary localization and elongated cilia without affecting GPS cleavage or protein maturation of PC1. Nevertheless, the precise mechanism under which PP1a regulates ciliary targeting of PC1 is still obscure.

Methods: Four PC1 constructs with phosphomimic or phosphodeficient mutantions were transfected into IMCD3 cells and co-stained with cilia marker. HA-tagged PC1 and flag-tagged PP1a were co-transfected into IMCD3 cells and then stained to detect the subcellular localization of PP1a/PC1 complex. PC1 and 2 were co-transfected into PP1a knockdown cells and then the ciliary targeting efficiency of PC1 was analyzed.

Results: Ciliary localization of all the four PC1 mutations was not affected compared with wild type control. PP1a and PC1 do not co-localize on the primary cilium but in the cytosol. Overexpression of PC2 is able to rescue the ciliary targeting defect of PC1 in PP1a knockdown cells.

Conclusions: Preliminary results suggest PP1a bind with PC1 in the cytosol and regulates PC1 trafficking. This regulation is probably not caused by PP1a mediated PC1 dephosphorylation. PP1a might function in this process via modifying PC2, a prerequisite for PC1 targeting to cilia. Further investigation is required to delineate the exact role of PP1a in PC1 trafficking.

SA-PO472

Pannexin-1 Mediates Fluid Shear Stress-Sensitive Purinergic Signaling and Cyst Growth in Polycystic Kidney Disease

Eric Verschuren,[1] Juan pablo Rigalli,[1] Charlotte Castenmiller,[1] René J. Bindels,[1] Dorien J. Peters,[2] Francisco J. Arjona,[1] Joost Hoenderop.[1] *[1]Radboud university medical center, Nijmegen, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands.*

Background: Tubular ATP release is regulated by mechanosensation of fluid shear stress (FSS), but the molecular mechanism mediating this process is poorly understood. Extracellular ATP is implicated in polycystic kidney disease (PKD), where polycystin-1/polycystin-2 (PC1/PC2) is dysfunctional. In health, PC1/PC2 functions as a mechanosensory complex in the kidney. This study aims to provide new insights into renal ATP signaling under physiological conditions and PKD.

Methods: Microfluidic setups, pharmacologic inhibition of mTORC1 and pannexin-1 by rapamycin and brilliant blue FCF, respectively, and CRISPR/Cas9 loss-of-function approaches were combined to assess the ATP release by renal cells. Acute water loading by healthy human subjects was used to evaluate the ATP release under variable urinary flow. PKD models, using inducible kidney-specific *Pkd1* knockout mice (iKsp-*Pkd1*$^{lox/lox}$) and zebrafish with translation blocking morpholino targeting the ortholog of human *PKD2* (*pkd2*), were employed to study *in vivo* the relevance of the mechanisms disclosed *in vitro*.

Results: Immortalized renal mouse distal convoluted tubule 15 (mDCT15) cells subjected to FSS displayed an increased ATP release. Furthermore, inhibition of mTORC1 amplified this FSS-modulated ATP release. Inhibition of pannexin-1 decreased the FSS-modulated ATP release by these renal cells. To translate this *in vitro* phenomenon to the *in vivo* situation, healthy human subjects were exposed to acute water loading resulting in an increased urine production and ATP excretion. In precystic iKsp-*Pkd1*$^{-/-}$ mice, increased renal pannexin-1 mRNA expression and urinary ATP were observed. Similarly, in renal *Pkd1*$^{-/-}$ mDCT15 cells, elevated ATP release was observed upon FSS mechanosensation. In these cells, inhibition of mTORC1 failed to enhance ATP extrusion, but an increase in pannexin-1 mRNA expression was observed compared to renal *Pkd1*$^{+/+}$ mDCT15 cells. Importantly, inhibition of pannexin-1 in a zebrafish PKD model decreased renal cyst growth.

Conclusions: Our results suggest that renal pannexin-1 channels mediate ATP release from epithelial cells towards the tubular lumen. The redundancy of this mechanism in PKD, where urinary ATP levels are elevated, presents pannexin-1 as a new therapeutic target to prevent cyst growth in PKD.

SA-PO473

Trans-Epithelial Fluid Pumping Performance of Renal Epithelial Cells and the Mechanistic Basis of Polycystic Kidney Disease

Mohammad ikbal Choudhury,[1,2] Feng Qian,[3] Owen M. Woodward,[3] Sean X. Sun.[1] Sean Sun Group *[1]Johns Hopkins University, Baltimore, MD; [2]Institute for NanoBioTechnology, Baltimore, MD; [3]University of Maryland School of Medicine, Baltimore, MD.*

Background: The epithelial cells lining nephrons in kidneys are highly efficient fluid reabsorption and secretion units. Imbalance in the trans-epithelial fluid flow leads to various renal diseases including polycystic kidney disease (PKD), which is characterized by development of numerous fluid-filled cysts in the renal tubules. Surprisingly, no work has been done so far to quantify the fluid pumping performance of renal epithelial cells in a physiologically relevant setup. To make progress, we developed a *micro-fluidic kidney pump* (MFKP) device, to measure the trans-epithelial fluid flow as a function of the hydrostatic pressure gradient generated by cells.

Methods: MFKP mimics a tubular segment of the nephron as it has two microfluidic channels separated by a porous membrane. A microcapillary connected to the basal side acts a sensor to measure both the trans-epithelial fluid flow (J) with a resolution of 0.31 μL and corresponding hydrostatic pressure gradient (ΔP) with a resolution of 10 Pa. This

setup was placed inside the incubator and fluid flow in the microcapillary was recorded using videography. J_0 is the fluid flow at $\Delta P = 0$ and ΔP^* is the stall pressure when $J = 0$.

Results: Here we report that normal human cells pump fluid from apical to basal side with J_0 in the range of 10 μL/min/cm^2 and ΔP^* of 250 Pa. Interestingly the PKD cystic cells pump fluid in the reverse direction (basal to apical) with J_0 of 5 μL/min/cm^2 and ΔP^* of -300 Pa. However, basolateral treatment with 1 nM Tolvaptan caused a decrease in both in J_0 and ΔP^*. The developed pressure gradient translates to a force of 50-100 nanoNewtons per cell, which can potentially expand the cyst lumen. In both normal and PKD cells, the trans-epithelial fluid flux (J) and the PPCs are modulated by mechanical (fluid shear stress), chemical (arginine vasopressin) and apical hypo-osmotic perturbations.

Conclusions: Our combined results offer insights into kidney fluidic pumping action and ADPKD cyst formation. To our knowledge this is the first demonstration of a decrease in secretory fluid flow and hydrostatic pressure gradient by PKD cells in response to a Tolvaptan. Our results demonstrate that secretory and absorptive functions of epithelia can generate significant mechanical forces, and maybe a general phenomenon in tubular morphogenesis in other contexts.

Defective Glomerulotubular Balance (GTB) in PKD2 Mutant and Conditional PKD2 Knockout Mice Before Renal Cyst Formation

Zhaopeng Du,[1] Xin Tian,[2] Ming Ma,[2] Alan M. Weinstein,[3] Stefan Somlo,[2] Tong Wang.[1] *[1]C. & M. Physiology, Yale University, New Haven, CT; [2]Nephrology, Yale University, New Haven, CT; [3]Physiology and Biophysics, Weill Medical College of Cornell University, New York, NY.*

Background: PC2 (*Pkd2*) is a nonselective calcium permeable cation channel belonging to the TRP channel family, at the cilia and ER, and functions as a Ca^{2+} channel in the ER. Previous studies showed *Pkd2* mutation or knockout resulted in an absence of IP3 receptor mediated calcium release from the ER. We have reported that blocking IP3 receptor abolished the flow-modulation of Na^+ and HCO_3^- transport in mouse proximal tubules. We investigated whether *Pkd2* has a physiological function in response to flow-mediated PT transport.

Methods: The flow-mediated Na^+ and HCO_3^- transport were studied by microperfusion of proximal tubules in vitro in WT, *Pkd2*$^{+/-}$ and *Pkd2* conditional KO (*Pkd2*$^{fx/fl}$*;Pax8-rtTA;Tet-O-Cre*) mice. The KO mice were induced with doxycycline from 4-6 and used 3-4 weeks after the end of induction (9-10 week old mice), before renal cysts have formed. Proximal tubules were perfused *in vitro*at low (5 nl/min) and high (20 nl/min) perfusion rates, and the fluid (J_v) and HCO_3^- (J_{HCO3}) absorption were measured by the changes of ^{3} H-Inulin and total CO_2 in the original and collected fluid. J_{Na} was estimated from the change of J_v and the assumption of isotonic transport.

Results: When perfusion was increased from 5 to 20 nl/min, J_v and J_{Na} increased 48% and J_{HCO3} doubled in WT. In contrast, the flow-stimulated component of J_v and J_{Na} could not be detected, and that of J_{HCO3} was significantly reduced in both *Pkd2*$^{+/-}$ and the *Pkd2*$^{-/-}$ mice, similar to the effect of the IP3 receptor antagonist (2-APB).

Conclusions: These results indicate that *Pkd2* is necessary for normal flow-mediated PT transport, and support the hypothesis that impaired GTB may contribute to renal cyst formation.

ATP Release into Renal Cysts Via Pannexin-1/P2X7 Channels Decreases ENaC Activity

Sergey N. Arkhipov, Tengis S. Pavlov. *Henry Ford Health System, Detroit, MI.*

Background: Genetic predisposition is necessary for polycystic kidney disease (PKD) initiation, although there are other, incompletely identified downstream processes that are required for cyst growth. Their characterization may provide a unique opportunity for clinical interventions. One of the poorly studied phenomena in PKD is high ATP content in cysts. Unfortunately, neither origins of uncontrolled ATP release, nor consequences of abnormal purinergic signaling in relation to epithelial transport are well explored in the polycystic kidney.

Methods: We tested the distribution of pannexin-1 (Panx1) and P2X7, two proteins potentially involved in ATP release, in the kidneys of the *Pkd1*$^{RC/RC}$ mice, a model of autosomal dominant PKD (ADPKD). To establish if pannexin-1 contributes to ATP release in the collecting ducts (CD), we measured luminal accumulation of ATP in M1 cell renal CD monolayers. Also, single channel patch clamp analysis of polarized M1 cells was employed to study how P2X stimulation affects ENaC activity.

Results: Abundance of both Panx1 and P2X7 proteins were abnormally increased in the cyst lining cells compared to non-dilated collecting ducts. Mechanical stimulation increases ATP release by polirized M1 cells to the luminal side and this effect was significantly blunted by treatment with probenecid, a pannexin-1 blocker. Patch-clamp studies reveal that apical stimulation of P2X receptors with αβ-MeATP acutely reduces ENaC activity.

Conclusions: We conclude that in ADPKD progression, an abnormal hyperexpression of both PANX1 and P2RX7 occurs in the cyst lining epithelial cells. High abundance of both proteins is not typical for non-dilated CDs but, when happens in cysts, pannexin1/P2X7 cooperation elevates ATP release into the luminal space. High ATP level is a pathogenic factor facilitating cystogenesis by reducing ENaC-mediated reabsorption from the lumen.

Novel PC2 Regulation of Ezrin in Renal Epithelia Reveals Insight into ADPKD Cystogenesis

Eryn E. Dixon, Carmen C. Leitch, Norann A. Zaghloul, Paul A. Welling, Owen M. Woodward. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Ezrin plays the role of master scaffold of the apical compartment in epithelial cells and is critical in regulation of polarity, cytoskeleton organization, and protein trafficking. Ezrin regulation and the downstream consequences of its disruption have not been elucidated. Investigation into the initiating events of cystogenesis in autosomal dominant polycystic kidney disease (ADPKD) revealed a dramatic change in ezrin, following loss of polycystin-2 (PC2). ADPKD is caused by loss of function mutations in *PKD1* and *PKD2*, which encode for transmembrane proteins PC1 and PC2, respectively.

Methods: Using an inducible *Cre* system (*Pkd2fl/fl Pax8rtTA TeTOCre*), PC2 loss in a three dimensional renal epithelial model resulted in decreased ezrin abundance. Furthermore, an *in vivo* mouse ADPKD model (*Pkd2fl/fl Pax8rtTA TetOCre*) of rapid cystogenesis exhibits significant changes in ezrin at the apical membrane of renal tubules after a short induction period of five days, and before the manifestation of cysts. Human ADPKD tissue also confirms changes in the structure of the apical compartment in emergent cystic cells, which correlated with significant alterations in the localization and abundance of ezrin in comparison to controls. A potential regulatory relationship between PC2 and ezrin is supported by experiments that demonstrated PC2 and ezrin interact in an overexpression system and share a similar phosphoinositide binding profile in a lipid overlay assay. Based on this novel regulatory relationship between PC2 and ezrin, as well as the antecedent loss of ezrin to cyst formation, human ezrin was overexpressed in the *pkd2* morpholino pronephric cyst model of zebrafish. Increased expression of ezrin abolished the formation of pronephric cysts.

Results: The interaction profile of PC2 and ezrin, disruption of ezrin in *Pkd2* inducible *in vitro* and *in vivo* model systems, changes in ADPKD patient tissue, and rescue of pronephric cysts in the *pkd2* MO suggest there is a significant role of ezrin in renal cystogenesis.

Conclusions: Understanding the relationship of a master scaffold, ezrin, with PC2 in renal epithelial cells will help elucidate the mechanism of ADPKD cystogenesis and define important downstream pathways necessary for epithelial functions.

SA-PO477

Myosin Activation as a Novel Therapeutic Strategy to Treat PKD in Human Kidney Organoids and Mice

Louisa Helms, Ivan G. Gomez, Nelly M. Cruz, Benjamin S. Freedman. *University of Washington, Seattle, WA.*

Background: Polycystic kidney disease (PKD) is an autosomal dominant disorder that manifests from loss of function mutations in *PKD1* or *PKD2*, encoding the proteins polycystin-1 (PC1) and polycystin-2 (PC2) respectively. The function of these proteins remain poorly understood and no curative therapeutics have been developed. Blebbistatin, a myosin inhibitor, was found to rapidly increase cyst proliferation in stem cell derived kidney organoids lacking PC1 or PC2. We hypothesize that non-muscle myosin II (NMII) activation will increase tubule epithelial cell contracility to reduce and prevent cystogenesis in PKD organoids and mice.

Methods: Stem cell derived kidney organoids genetically lacking PC1 or PC2 were differentiated over 18 days, picked, placed in suspension, and treated with blebbistatin or EMD, a small molecule myosin activator, every two days for two weeks. Organoids were measured for area, cystic index, stained for NMII, and toxicologically assessed. *Pkd1*$^{RC/RC}$ mice at 20 weeks were intra-peritoneally injected with EMD every two days for four weeks, with blood urea nitrogen (BUN) levels measured. Post-sacrifice, mice kidneys were dissected, imaged, measured for weight and cyst number and histologically analyzed.

Results: In pre-cystic PC2 null organoids, EMD was able to reduce the total number of cysts in the organoids, as well as inhibiting the growth of cysts treated with blebbistatin in tandem. Cystic PC1 null organoids were treated with EMD resulting in the halt of cyst progression and gradual cyst reduction. NMII was enriched at the apical surface of tubules and showed dramatic stretching upon cyst initiation. No added toxicity was observed from EMD treatment. In *Pkd1*$^{RC/RC}$ mice treated with EMD, EMD reduced the total burden of cysts, and reduced total kidney weight and BUN levels relative to their vehicle treated counterparts.

Conclusions: We have discovered a myosin activator that can prevent cysts from progressing in pre-cystic organoids, reduce cysts in post-cystic organoids, and shows efficacy in the *Pkd1*$^{RC/RC}$ mouse model. Collectively, this supports our hypothesis that NMII contractility counteracts PKD cyst formation by stabilizing tubules. Myosin activation has significant potential to spur therapeutic progress for PKD in humans, and elucidate new mechanisms linking myosin to PKD pathogenesis.

ADAM10-MMP14 Complex Regulates Adherens Junction Integrity at Renal Cystogenesis in Autosomal Dominant Polycystic Kidney Disease

Frank Xu,[2] Tianqing Kong,[2] Tzongshi Lu.[1] *[1]Brigham and Women's Hospital, Harvard Medical School, Natick, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common life-threatening genetic kidney disease and currently do not have relevant therapeutic methods, which eventually results in end-stage renal disease. We previous reported ADPKD is associated with mutations in polycystins, alterations in cell-cell junctions, and disruption of cell polarity in renal epithelial cells. Moreover, our data indicated that Gα12 increase the shedding of E-cadherin, and the inhibition of ADAM10 can block the cystogenesis in renal cells through the preservation of E-Cadherin. In addition, studies also indicate that Matrix metalloproteinase-14 (MMP14) promotes cystogenesis, which was blocked by its inhibitors. However, mechanisms of ADAM10 and MMP14 regulated cystogenesis in ADPKD are not fully understood. In this study, we investigate these two major sheddases association and their roles in renal cystogenesis

Methods: Immunoprecipitation, immunostaining and 3-dimensional (3D) cell culture technologies are used to analyze the interaction between metalloproteinase ADAM10 and MMP14 in Madin-Darby Canine Kidney (MDCK) cells.

Results: Our data shows that ADAM10 and MMP14 associated at hemopexin domain of MMP14 to form a complex, and activation of MMP14 is required for ADAM10 in shedding of E-Cadherin. The enzyme-inactive mutant MMP14^{E240A} (Glu240 to Ala) or the deletion of the catalytic domain of MMP14 (MMP14CAT) significantly decreases the sheddase activity of ADAM10. In addition, ectopic expression of MMP14 increases the proliferation of MDCK cells, alters the cell-cell adhesion and promotes the cystogenesis of renal epithelial cells in our 3D cell model, *in vitro*. Our data also shows that knockdown of MMP14 decreases the cleavage of E-Cadherin by ADAM10, and knockdown of ADAM10 enhances the activation of proMMP2 by MMP14. Furthermore, ectopic expression of the MMP14E^{240A} mutant promotes inhibition of cystogenesis in our 3D epithelial cell models.

Conclusions: Our study shows for the first time that ADAM10 form a unique, stable complex at hemopexin domain of MMP14, and the ADAM10-MMP14 complex play a pivotal role in regulation of their sheddase activity on various cell-cell junctional proteins and cystogenesis in renal epithelial cells. Our data provide a potential therapeutic target in ADPKD through the modulation of ADAM10-MMP14 complex.

Persistent Upregulation of Homologous Recombination Repair Signalling in Cystic Epithelial Cells in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Jennifer Zhang,[1] Sayanthooran Saravanabavan,[1] Alexandra Munt,[1] Irene Sangadi,[1] Annette Wong,[1] Peter C. Harris,[3] David Harris,[1,2] Yiping Wang,[1] Gopi Rangan.[1,2] *[1]Westmead Institute for Medical Research, The University of Sydney, Westmead, NSW, Australia; [2]Department of Renal Medicine, Westmead Hospital, Westmead, NSW, Australia; [3]Mayo Clinic, Rochester, MN.*

Background: In ADPKD, homologous recombination repair (HRR) of the *PKD* allele in response to DNA damage might explain the postnatal reduction in gene dose and triggering of focal kidney cyst formation. In this study, the hypothesis that HRR signaling is increased in ADPKD and correlates with kidney cyst formation, was investigated.

Methods: Markers of HRR [H2AX, γH2AX, phosphorylated Ataxia Telangiectasia and Rad3-related; pATR and AT Mutated; pATM] were assessed in immortalised ADPKD (WT9-7 and WT9-12) and normal (HK-2) kidney cells; *Pkd1$^{RC/RC}$* mice (1, 3, 6, 9 and 12 months), and end-stage human ADPKD. In addition, the expression of genes encoding proteins upstream (n=88) and downstream of HRR (n=355) was determined from normal and ADPKD kidney tissue [the latter divided into minimal cystic tissue, (MCT), small cysts (SC), medium cysts (MC) and large cysts (LC)] using public transcriptomic datasets (GSE7869; GSE9493).

Results: *In vitro*, pATR increased 1.7- and 2.2-fold in unstimulated WT9-7 and WT9-12 cells respectively compared to HK-2 cells (P<0.05). Similarly, pATM increased 9.6-(WT9-7) and 6.8-fold (WT9-12) compared to HK-2 cells (P<0.05). In *Pkd1$^{RC/RC}$* mice, cyst-lining epithelial cells (CECs) were positive for pATR and γH2AX at all timepoints, with higher frequency at 1 month of age. In end-stage human ADPKD tissue, CECs of kidney cysts were positive diffusely for pATR and pATM. Further analysis showed that dysregulation of HRR-related genes (>1.5-fold, q<0.05) varied by cyst size. The percentage of dysregulated genes encoding upstream HRR mediators (including *MRN*, *TOPBP1* and *RPA1*) increased 22% (in MCT), 47% (in SC) and 52% (in LC), compared to control kidneys. Similarly, genes encoding downstream HRR factors were also dysregulated according to kidney cyst size [MCT (12%), SC (36%), MC (37%) and LC (45%)]. *ATR* was highest in MCT (1.6-fold; q=0.01), and *H2AX* increased 1.4-fold (q=0.07) in MCT and 3.0-fold in LC (q=0.0001).

Conclusions: Kidney cystic epithelial cells exhibit DNA damage and the persistent upregulation of HRR signalling which correlates with cyst size. These data suggest that low-dose inhibition of HRR pathways using sub-lethal dose of ATR or ATM inhibitors could be used to selectively target kidney cyst growth.

Loss of Mitochondrial Transcription TFAM in Renal Tubular Epithelial Cells Is Associated with Cyst Development

Hanako Kobayashi,[1] Ken Ishii,[4] Kensei Taguchi,[2] Craig R. Brooks,[3] Volker H. Haase.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Department of Nephrology and Hypertension, Nashville, TN; [3]Vanderbilt University Medical Center/Division of Nephrology & Hpertension, Nashville, TN; [4]Daiichi Sankyo Co. Ltd., Tokyo, Japan.*

Background: Mitochondrial dysfunction plays an important role in the pathogenesis of kidney disease. In fact, certain kidney diseases are associated with genetic mitochondrial disorders, indicating that mitochondrial dysfunction can initiate and promote kidney disease.

Methods: In the kidney, mitochondria (mt) are highly abundant in renal tubular epithelial cells due to their high energy demands. In order to gain insights into mt function during renal pathogenesis, we inactivated the gene encoding mt transcription factor A (*TFAM*) in *Six2*-expressing progenitor cells, resulting in TFAM function loss in all nephron segments except collecting ducts; mutant mice are from hereon refered to as *Six2-Tfam$^{-/-}$* mutants. TFAM is required for mt DNA replication and gene transcription and is thus essential for the maintenance of mt mass and function.

Results: We found that *Six2-Tfam$^{-/-}$* mice developed severe renal cystic disease and died by postnatal day (P) 30 from renal failure (76.0 ± 3.46 mg/dL for mutants vs. 22.0 ± 2.0 mg/dL BUN for control; n=4 and n=3, respectively; p<0.0001). Although nephrogenesis was not affected (normal morphology at P0), the expression of proximal and distal renal differentiation markers was severely reduced by P7. Furthermore, *Six2-Tfam$^{-/-}$* mice were characterized by significant changes in mt morphology {EM and structured illumination microscopy (SIM)}, as well as alterations in cellular energy metabolism; increase in glycolysis and decrease in oxygen consumption in isolated proximal tubule epithelial cells using Seahorse XF-24 instrument. To investigate TFAM in autosomal dominant polycystic kidney disease (ADPKD), we examined two mouse models of ADPKD, ROSA26-Cre^{ERT}*Pkd1$^{-/-}$* and *Cys$^{cpk/cpk}$* mice as well as human nephrectomy tissues by immunohistochemistry and RNA in situ hybridization. We observed that TFAM as well as TFAM-regulated mt genes were signifcantly downregulated in cyst-lining epithelial cells in both mouse and human PKD tissues. Consistent with reduced TFAM expression was a decrease in mt volume in cyst-lining epithelial cells compared to non-cystic tubular epithelium using SIM.

Conclusions: Taken together, our data establish that loss of TFAM is associated with the development of polycystic renal disease providing strong rational for developing strategies that target mt function for ADPKD therapy.

SA-PO481

Investigating the Centrality of the Asparagine Synthetase Enzyme in the Metabolic Reprogramming and Glutamine Usage in ADPKD

Christine Podrini, Marco Chiaravalli, Alessandra Boletta. *San Raffaele Scientific Institute, Milan, Italy.*

Background: We showed that metabolic alterations in the TCA cycle and increased glutaminolysis interlinked with asparagine metabolism are important features of ADPKD (Podrini et al. Commun Biol, 2018). Tracing studies with labelled [$^{13}C_5$,$^{15}N_2$] glutamine showed that *Pkd1$^{-/-}$* cells increased glutamine uptake and ^{15}N-labelled asparagine, indicating a central role for asparagine synthase (ASNS). Indeed, *siAsns in vitro* abrogated glutamine contribution to the TCA cycle. Here, we explore ASNS as an ER-bound protein activator of the integrated stress response (ISR) sitting at the intercross of metabolic and ER stress response. Further, we propose ASNS as a novel therapeutic target for ADPKD.

Methods: Protein expression for ISR targets, metabolomics, tracing with *siAsns* in *Pkd1*-mutant cells. Given the absence of inhibitors for ASNS we developed a strategy using Antisense LNA GapmeRs to achieve stable downregulation *in vitro* and *in vivo.*

Results: Central to the ISR is the eIF2α/ATF4 axis which drive ASNS transcription. Elevated expression of ASNS was associated with increased ATF4 protein expression in cystic kidneys (*KspCre;Pkd1*) compared to controls. p-eIF2α, which promotes ATF4 synthesis, was increased in *Pkd1*-mutant cells. However, when *Pkd1*-mutant cells were deprived from glucose, p-eIF2α was decreased, suggesting the induction of a pathway involved in ROS production. This was supported by increased GSH (reduced glutathione) in metabolomics studies in cystic kidneys *(KspCre;Pkd1*) and *Pkd1*-mutant cells compared to respective controls. Further, amino acids availability for ROS production was significantly decreased, suggesting that eIF2α/ATF4 axis might be responsive to amino acids depletion. Importantly, downregulation of *Asns* in *Pkd1*-mutant cells causes cell death and rescues the accumulation of metabolites of the TCA cycle, suggesting a potential dual role for ASNS in glutaminolysis and cross-talk with ROS production. To validate ASNS as a therapeutic target, we have designed specifically the silencing of ASNS by LNA GapmeR. Initial testing *in vitro* was done in *Pkd1*-mutant cells on five different GapmeRs. The most effective is currently being tested *in vivo* in an inducible *Pkd1* KO mouse model.

Conclusions: Our data raises the possibility that asparagine metabolism interlinked with the ISR might offer a novel therapeutic intervention in PKD.

SA-PO482

Investigating the Role of Peroxisomal Metabolism in Polycystic Kidney Disease

Takeshi Terabayashi, Luis F. Menezes, Fang Zhou, Gregory G. Germino. *NIDDK, National Intitutes of Health, Bethesda, MD.*

Background: Our group recently reported impaired fatty acid oxidation and abnormal mitochondria in *Pkd1* mutants. However, how these phenomena contribute to cystogenesis in ADPKD is unclear. Peroxisomes interact with mitochondria physically and functionally, and congenital peroxisome biogenesis disorders cause developmental/metabolic phenotypes including renal cysts and aberrant mitochondria. Given the features observed in both PKD and the peroxisome diseases, we hypothesized *PKD1* might affect peroxisomal activity thus may alter mitochondrial behavior.

Methods: Peroxisome biogenesis in control and *Pkd1-/-* kidney epithelial cells was studied by evaluating the abundance of peroxisomes using staining of PMP70 and the peroxisome matrix import was assayed using GFP-SKL. We also investigated whether a tagged PC1 C-terminus (CTT) that localizes to mitochondria also co-localizes with peroxisome markers using live cell imaging. In addition, peroxisome-specific β-oxidation in control and *Pkd1-/-* cells was studied by mass spectrometry (MS) using deuterium-labeled behenic acid. Lastly, comprehensive analyzes of long-chain/very long-chain fatty acids were performed by MS of cystic kidneys of *Pkd1$^{fl/fl}$; Ksp-Cre* mice.

Results: There was no significant difference in peroxisomal abundance in control and *Pkd1 -/-* cells [peroxisome number per cell: 96784LTL WT 49.0±13.2 vs MUT 43.0±18.1 (p=0.4), 121112LTL WT 30.4±9.0 vs MUT 25.9±3.8 (p=0.2)]. GFP-SKL was equally well-recruited into peroxisomes in WT and MUT cells, suggesting peroxisome biogenesis is not defective. Exogenously expressed PC1 CTT exclusively localized to mitochondria. In the labeled behenic study, peroxisome β-oxidation was not significantlly different in *Pkd1-/-* cells (n=3 each cell line pair (each with 3–5 replicates), 89.6±6.7 vs 84.2±7.6%, p=0.3). In the kidney tissues, total levels of fatty acids (C10–C24) were lower in *Pkd1* mutant mice (control n=23, MUT n=12, 104.6±7.7 vs 83.9±7.1 μg/mg, p<6.3e^{-9}), while the ratio of C24:0/C22:0, used as a readout of peroxisome disorder was not changed in the mutant mice (0.56±0.11 vs 0.58±0.11, p=0.5).

Conclusions: These data suggest that peroxisome dysfunction is not responsible for the fatty acid oxidation defect previously described in *Pkd1* mutant cells. On the other hand, further study will be required to figure out the role of the observed reduction of fatty acids levels *in vivo*.

SA-PO483

Evidence for Genetic Compensation for Cilia Membrane Delivery Defects in cep290/NPHP6 Mutants

Magdalena Cardenas-Rodriguez,[1] Iain A. Drummond.[1,2] *[1]Massachusetts General Hospital, Charlestown, MA; [2]Harvard Medical School, Boston, MA.*

Background: Apical cilia move fluid and participate in sensing the extracellular environment. Cilia dysfunction or "ciliopathy" results from disruptions in cilia structure or failed localization of ciliary proteins. Mutations in the *centrosomal protein of 290* kDa (*CEP290/NPHP6*) gene are linked to ciliopathy syndromes including Juvenile nephronophthisis. CEP290 has been proposed to form a "ciliary gate" at the transition zone in *Chlamydomonas reinhardtii* however its roles in cilia appear to be more complex.

Methods: We generated antibodies to the cep290 N terminus and C terminus to assay localization in different cell types. cep290 was acutely disrupted using antisense morpholino oligos and phenotypes were compared with Enu or Crispr/Cas9-generated genetic *cep290* mutants. RNA Seq was performed to test for upregulation of compensatory gene expression in mutants.

Results: Cep290 was localized in different cell types to the transition zone or pericentriolar satellites. Pericentriolar satellite Cep290 correlated with axoneme length defects in photoreceptors and KV cilia of morphants and mutants. In cep290 mutants, photoreceptors showed an abnormal accumulation of cytoplasmic vesicles. Cilia length defects in the KV could be rescued by over-expression of exogenous cilia membrane protein mRNAs (pkd2 or sstr3). cep290 mutants, which show a mild phenotype compared to morphants, exhibited upregulation of multiple mRNAs encoding proteins essential for cilia membrane transport (Arl3, unc119b, Arl13b). Overexpression of upregulated mRNAs partially rescued cep290 deficiency phenotypes in cep290 morphants.

Conclusions: Cep290 plays a key role in facilitating cilia membrane transport, particularly in cells where it localizes to pericentriolar satellites. Long term vs. acute loss of cep290 induces upregulation of genes encoding proteins involved in cilia membrane transport, suggesting genetic compensation in cep290 mutants. Overexpression of cilia GTPases (Arl3, unc119b, Arl13b) in cep290 human patients may provide a new route to ciliopathy gene therapy.

SA-PO484

Fibrocystin Is Central to Cellular Control of Adhesion Forces and Epithelial Polarity

Wolfgang H. Ziegler, Birga Soetje, Lisa P. Marten, Fatima Hassan, Dieter Haffner. *Hannover Medical School, Hannover, Germany*.

Background: Mutations of the *Pkhd1* gene cause autosomal recessive polycystic kidney disease (ARPKD). *Pkhd1* encodes fibrocystin/polyductin (FPC), a ciliary type I membrane protein of largely uncharacterized function, suggested to affect adhesion signaling of cells. Contributions of altered epithelial cell adhesion and contractility to the disease process of ARPKD are elusive. Here, we study how loss of FPC (function) modifies epithelial cell response to adhesion stimuli and contractile force distribution leading to defective control of epithelial polarity.

Methods: To address FPC function in cells with renal collecting duct characteristics, we study *Pkhd1*-silenced Madin-Darby canine kidney cells (MDCKII) and human urine-derived renal epithelial cells (UREC) with normal and defective FPC. Consequences of FPC-deficiency are addressed by proteomics analysis and in cells studied in 2D/3D cell culture conditions, which includes micro-pattered chips and allows analysis of polarity, lumen formation and ciliogenesis in epithelial spheroids. Adhesion forces are studied via RhoA activation and myosin IIa phosphorylation and linked to adhesion signaling.

Results: FPC-mediated changes in epithelial cell characteristics, as revealed in proteomics-based pathway analysis, are linked to altered adhesion behavior and cellular capacity to form polarized epithelia. Their impact can be confirmed using selective inhibitors of cell contractility and FAK/Src signaling. FPC-deficient cells are characterized by defects in the formation of correctly polarized epithelial spheroids, which is restored upon transient reduction of cell contractility and adhesion forces during the initial phase of epithelial morphogenesis.

Conclusions: In FPC-deficient epithelial cells, altered control of pathway activity leads to enhanced integrin adhesion signals, impaired epithelial morphogenesis and by implication homeostasis, which are presumably related to progressive epithelial defects in ARPKD. Epithelial cell-based models with selective genetic alterations allow a better molecular understanding and furthermore may provide means to test pharmacological correction of epithelial defects in PKD.

Human and Mouse FPC-CTD Activate the MYC/Myc P1 Promoter: Implications for Renal Cystogenesis in ARPKD

Chaozhe Yang,[1] Naoe Harafuji,[1] Santiago Cuevas,[1] Maryanne Odinakachukwu,[1] Ljubica Caldovic,[1] Phillip D. Bell,[2] Marie Trudel,[3] Lisa M. Guay-Woodford.[1] *[1]Children's National Medical Center, Washington, DC; [2]University of Alabama, Birmingham, AL; [3]Institut de recherches cliniques de Montreal, Montreal, QC, Canada*.

Background: Human ARPKD (MIM 263200) results from mutations in *PKHD1*, but mouse *Pkhd1* models express limited or no renal cystic disease. The protein product, FPC, undergoes Notch-like processing with regulated membrane-release and nuclear translocation of the intracellular C-terminal domain (FPC-CTD) (Kaimori, 2007). We have previously shown that c-Myc is overexpressed in human ARPKD and mouse *Cys1^{cpk}* cystic kidneys, but not in *Pkhd1^{cyli}*, *Pkhd1^{del67}*, or *Pkhd1$^{del3-67}$* kidneys (ASN 2018). Trudel (2019) has demonstrated that c-Myc plays a dual role in *Pkd1*-induced pathogenesis, through *Myc*-mediated mechanisms and a feed-forward regulatory *Pkd1–Myc* loop. The current *in vitro* study was designed to compare *MYC*/*Myc* regulation by human and mouse FPC-CTD in collecting duct cell lines.

Methods: We generated immortalized normal human (hTERT) and mouse (mTERT) kidney collecting duct cell lines; V5-tagged hFPC-CTD and V5-tagged mFPC-CTD constructs; and luciferase constructs of the P1 promoter for human *MYC* and mouse *Myc*. Luciferase reporter assays were performed as previously described (Wu, 2013).

Results: Sequence analysis revealed 74% identity between the human *MYC* and mouse *Myc* P1 promoters and 55% identity between hFPC-CTD and mFPC-CTD. Combinatorial luciferase assays demonstrated that the hFPC-CTD and mFPC-CTD constructs enhanced *MYC* and *Myc* P1 promoter activity in both human and mouse collecting duct cell lines.

Conclusions: These *in vitro* data demonstrate that FPC-CTD activates *MYC/Myc* expression in both human and mouse collecting duct cells. Paradoxically, we have previously shown that loss of FPC-CTD leads to cystogenesis and c-Myc overexpression in human ARPKD kidneys, but not in mouse *Pkhd1* models. We speculate that in renal collecting duct cells, FPC-CTD regulation of *MYC/Myc* transcription is differentially modulated by species-specific mechanisms. In the mouse, we propose that in normal collecting duct cells, FPC-CTD function at the P1 promoter is constrained by mouse-specific co-factors and overexpression of mFPC-CTD would stimulate *Myc*-induced cystogenesis. Current efforts are focused on *ex vivo* studies in mouse metanephroi to test this model.

Intrahepatic Bile Duct Morphogenesis in Pkhd1 Mutant Mice

Patricia Outeda,[1] Terry J. Watnick.[2] *[1]University of Maryland, Baltimore, MD; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: ARPKD is a complex disease caused by mutations in the PKHD1 gene (encoding the Fibrocystin/Polyductin protein, or FPC). The predominant clinical manifestations are enlarged echogenic kidneys with distal tubule dilatation and cysts in the biliary tract with congenital hepatic fibrosis. The pathognomonic liver defect in ARPKD is the ductal plate malformation (DPM), which is characterized by the presence of increased numbers of tortuous, irregular bile ducts within the portal tract and fibrosis. In mice, as in humans, the biliary tract development is initiated by the induction of bi-potential hepatoblasts adjacent to the portal vein mesenchyme expressing Sox9 that eventually will form the primitive ductal structures (PDS) by recruiting Sox9– HNF4α+ cells from the surrounding parenchyma that will mature into symmetric structures with all the cells Sox9+ HNF4α–. From around E17 onwards, in a process termed ductal plate remodeling, these dilatations become surrounded by portal mesenchyme to eventually give rise to mature IHBD (intrahepatic biliary ducts). To date, few studies have characterized the DPM

associated with ARPKD in either humans or mouse models and the precise cellular defect remains undefined.

Methods: To gain insights into the mechanism altered during the development of the DPM we harvested livers from homozygous *Pkhd1*$^{\Delta 3\text{-}4}$ and control littermates at E18.5, P0, P7, and P15 and performed H&E staining.

Results: We observed dilated biliary ducts in homozygous mutants starting at P7. Immunofluorescence staining using Sox9 and Ki67 revealed an increased number of Sox9+ cells surrounding the portal vein in mutant homozygous mice although the number of proliferative cells Sox9+ was the same. In order to gain further insights into the role of FPC regulating the biliary tract development we isolated biliary duct cells using anti-EpCAM+ (cholangiocytes specific marker) coated magnetic beads from homozygous mutants and control littermates at P5 (N=16) and performed RNA sequencing (RNA-seq). We identified more than 50 genes that were differentially expressed (Log2 (FC)≤ ± 0.25 and a corrected p-value of <0.05).

Conclusions: Our study revealed that mutant mice develop a biliary expansion independent of the biliary precursors' proliferation. We also detected transcriptional changes in *Pkhd1* mutant cholangiocytes supporting the importance of FPC signaling in the biliary tract development.

The Impact of Uraemia on Oxidative Stress Signalling Pathways in the Presence of NPHP Mutations

Shabarni Gupta. Phillips and Atkin Laboratory, Faculty of Medicine and Health Sciences, Macquarie University *Biomedical Sciences, Macquarie University, Sydney, NSW, Australia*.

Background: Mutations in the *Nek8* gene, encoding a member of the serine/threonine protein kinase family related to NIMA (never in mitosis, gene A), are associated with nephronophthisis (NPHP9); a juvenile form of autosomal recessive cystic kidney disease. With the onset of cystic disease due to the genetic mutation, deteriorating renal health leads to accumulation and circulation of several toxins acting as a double-edged sword. This study investigates any synergistic effect between mutation in the *Nek8* gene and the uraemic toxin, indoxyl sulphate (IS) in driving an unfolded protein response (UPR) as an indicator of cellular stress.

Methods: Hek293 cells transiently expressing wild-type (WT) or H425Y mutant *Nek8* found in human NPHP patients were used. UPR was investigated by monitoring expression of BiP and XBP1s using protein and RNA, respectively, from cells expressing WT and H425Y Nek8 alone, and in the presence of 5mM IS for 8hr (n = 3). Tunicamycin treated Hek293 cells were used as positive control (2.5μg/ml, 4hr). Data was analyzed using 2-way ANOVA.

Results: Overexpression of H425Y *Nek8* did not result in elevating UPR markers (BiP and XBP1s) in comparison to WT. However, presence of IS, resulted in upregulation of BiP in WT by 1.45-fold and H425Y by 1.54-fold (calculated as mean ± SEM, $p < 0.05$, n=3) in comparison to untreated WT. XBP1s was upregulated by 2-fold in treated WT and 3.1-fold in treated H425Y cells (calculated as mean ± SEM, $p < 0.05$, n=3), in comparison to WT untreated cells, such that this increased expression was significantly greater in H425Y *Nek8* mutant cells.

Conclusions: Results from this study indicate that overexpression of the human variant of the *Nek8* mutation, as a standalone, is unable to trigger the UPR pathway. However, in presence of uraemic toxin IS, expressions of both BiP and XBP1s in WT and H425Y cells are elevated. The greater elevation of XBP1s expression in treated H425Y compared to treated WT cells is consistent with the hypothesis that UPR responses triggered by uraemic toxins are potentiated in presence of the *Nek8* mutation. Further studies examining additional markers of UPR and measures of cellular stress will further elucidate the impact of uraemic toxins and their interaction with PKD mutations and their potential impact on kidney function.

Proximal Tubular Intracellular Pathways Leading to Cystogenesis and Tubular Damage in Tuberous Sclerosis

Morris Nechama,[1] Oded Volovelsky.[1,2] *[1]Pediatric Nephrology Research Lab, Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Pediatric Nephrology Unit, Hadassah Hebrew University Medical Center, Jerusalem, Israel*.

Background: Tuberous sclerosis (TS) is a genetic disorder caused by inactivating mutations in either the *Tsc1* or *Tsc2* genes. These mutations induce mTOR activation resulting in cell growth and tumorigenesis. The renal presentation of TS includes angiomyolipoma and cystic disease and is associated with high morbidity and mortality. The exact molecular mechanisms leading to the tubular cell damage and cyst formation remain poorly understood.

Methods: *Tsc1* was deleted in nephron progenitor cells (NPCs) by mating Six2 *Cre*$^{tg/+}$ /*Tsc*$^{-/+}$ males with *Tsc1*$^{f/f}$ females. Tubular damage and cyst formation were examined by H&E staining of kidney sections and IHC for the proximal tubule marker LTL and the proliferation marker KI-67. c-Myc expression was examined by IHC and western blots. c-Myc - hamartin protein interaction was demonstrated by Co-Immunoprecipitation. Rapamycin (IP, 1 mg/kg every other day) was injected to pregnant females between gestation days E12.5-E16.5. For isolation of proximal tubule cells, kidneys from embryos at gestation date E18.5, were digested using Collagenase/Dispase and cells stained for Prominin1 (a marker for proximal tubule cells) and sorted by flow cytometry.

Results: *Tsc1* knockout in NPCs led to a lethal phenotype of severe renal cystic disease. The tubular damage was demonstrated already at E15.5 with a modified ciliary structure in the cyst lying epithelial cells. The tubular damage and cyst formation were associated with an increased proliferation as measured by Ki-67 staining, as well as c-Myc overexpression. Moreover, c-Myc interacted with hamartin which directly affects *c-Myc* expression. Rapamycin injection throughout pregnancy prevented tubular damage and cyst formation and prolonged offspring life span from P2 to P14 days. Rapamycin also prevented the increase in Ki67 and c-Myc overexpression. To uncover the molecular pathways involved in this process, we isolated embryonic proximal tubular cells from control and *Tsc1* KO mice without or with mTOR inhibition by rapamycin Expression profiling confirmed the increase in *c-Myc* expression, as above. In addition, it identified specific target genes that can contribute to the tubular cell damage and cytogenesis.

Conclusions: Tubular damage and cyst formation in TS correlate with increased cell proliferation and *c-Myc* expression, as well as modifications of specific molecular and biochemical pathways.

Pattern of Urinary Inflammatory Markers in Longstanding Type 1 Diabetes with and Without Diabetic Kidney Disease: Results from the Canadian Study of Longevity in Type 1 Diabetes

Jaya P. Ambinathan,[2] Leif E. Lovblom,[4] Vikas Sridhar,[2] Yuliya Lytvyn,[2] Petter Bjornstad,[1] Bruce A. Perkins,[5] Julie A. Lovshin,[5,3] David Cherney.[2,3] *[1]Department of Pediatrics, Division of Endocrinology, University of Colorado School of Medicine, Aurora, CO; [2]Department of Medicine, Division of Nephrology, University of Toronto, Toronto, ON, Canada; [3]Banting and Best Diabetes Centre, Toronto, ON, Canada; [4]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [5]Department of Medicine, Division of Endocrinology and Medicine, University of Toronto, Toronto, ON, Canada*.

Background: Diabetic kidney disease (DKD) contributes to significant mortality and morbidity in type 1 diabetes (T1D). Inflammation is a contributing factor to the pathogenesis of DKD, even during its early stages. Urinary inflammatory markers have been used to determine distinct urinary secretion phenotypes in different stages of DKD in T1D. The nature of urinary inflammatory markers in longstanding T1D is, however, unknown. Our objective was to study changes in urine inflammatory markers within the normal range of albuminuria in longstanding T1D, and to quantify the differential urinary excretion of inflammatory markers in participants with DKD versus those without DKD (resistors).

Methods: A 42-plex human urinary inflammatory markers was analyzed from participants of Canadian study of longevity in T1D of more than 50 years duration (n=74) and compared to age and sex matched comparators (n=73). Normoalbuminuric T1D participants (n=44) were categorized into tertiles of albumin:creatinine ratio (<0.8, 0.8-1.2, 1.2-2 mg/mmol). T1D subjects were grouped as those with and without DKD (n=25 vs. n=49).

Results: A stepwise increase was observed in 27 of 42 urine inflammatory markers across tertiles of normoalbuminuria. Urinary inflammatory marker excretion was *lower* in both DKD and DKD-resistors vs. controls. When comparing participants with DKD vs. DKD-resistors, IL-6, a potent inflammatory cytokine, was significantly different, with higher urinary excretion in DKD versus resistors (0.24±0.25 vs 0.13±0.16, P=0.03).

Conclusions: Urinary excretion of inflammatory markers increases with the degree of albuminuria within the normal range in participants with longstanding T1D. This is consistent with our previous observation in an adolescent T1D cohort with shorter disease duration. Lower urine inflammatory marker excretion in longstanding T1D versus comparators may represent as yet unidentified protective factors in these long-term survivors, irrespective of DKD status, and needs further exploration. DKD participants had higher urinary excretion of IL-6 compared to resistors, highlighting a possible role of inflammation in DKD risk.

SA-PO490

Tim-3 Aggravates Podocyte Injury in Diabetic Nephropathy by Promoting Macrophage Activation via the NF-κB/TNF-α Pathway

Huimin Yang,[1] Dengren Li,[2] Lei Liu,[1] Lichang Liu,[1] Xiangdong Yang.[2] *[1]Shandong University, Jinan, China; [2]Nephrology, Qilu Hospital of Shandong University, Jinan, China*.

Background: Macrophage-mediated inflammation plays a significant role in the development and progression of diabetic nephropathy (DN). However, the underlying mechanisms remain unclear. Studies suggest that T cell immunoglobulin domain and mucin domain-3 (Tim-3) has complicated roles in regulating macrophage activation, but its roles in the progression of DN are still completely unknown.

Methods: We downregulated Tim-3 expression in kidney (intrarenal injection of Tim-3 shRNA expressing lentivirus or global Tim-3 knockout mice) and induced DN by streptozotocin (STZ). We analyzed the degree of renal injury, especially the podocyte injury induced by activated macrophages in vitro and in vivo. Then, we transferred different bone marrow derived macrophages (BMs) into STZ-induced Tim-3 knockdown mice to examine the effects of Tim-3 on macrophages in DN.

Results: First, we found that Tim-3 expression on renal macrophages was increased in patients with DN and in two diabetic mouse models, i.e. STZ-induced diabetic mice and db/db mice, and positively correlated with renal dysfunction of DN patients. Tim-3 deficiency ameliorated renal damage in STZ-induced diabetes with concurrent increase in protein levels of Nephrin and WT-1. Similar effects were observed in mice with Tim-3 knockdown diabetic mice. Second, adoptive transfer of Tim-3-expressing macrophages,

but not Tim-3 knockout macrophages, accelerated diabetic renal injury in DN mice, suggesting a key role for Tim-3 on macrophages in the development of DN. Furthermore, we found NF-κB activation and TNF-α excretion were upregulated by Tim-3 in diabetic kidneys, and podocyte injury was associated with the Tim-3-mediated activation of the NF-κB/TNF-α signaling pathway in DN macrophages both in vivo and in vitro.

Conclusions: These results suggest that Tim-3 functions as a key regulator in renal inflammatory processes and serves as a potential therapeutic target for renal injury in DN.

Prolyl Hydroxylase Domain Inhibitor Protects Against Metabolic Disorder-Related Kidney Disease by Suppressing Monocyte Chemoattractant Protein 1 Expression in Mesangial Cells

Mai Sugahara,[1] Shinji Tanaka,[1] Yu Ishimoto,[1] Kenji Fukui,[1,2] Akira Shimizu,[3] Reiko Inagi,[1] Toshimasa Yamauchi,[4] Takashi Kadowaki,[4] Masaomi Nangaku,[1] Tetsuhiro Tanaka.[1] *[1]Division of Nephrology and Endocrinology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]JT CPRI, Osaka, Japan; [3]Department of Analytic Human Pathology, Nippion Medical School, Tokyo, Japan; [4]Department of Diabetes and Metabolic Diseases, The University of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: We previously showed that administration of a prolyl hydroxylase domain (PHD) inhibitor, enarodustat, improved glucose/lipid metabolism and restored adiponectin levels in BTBR *ob/ob* mice. It also reduced albuminuria and ameliorated glomerular epithelial and endothelial damage (TH-PO450, ASN Kidney Week 2016). To elucidate the mechanism of renoprotection, we performed transcriptome analysis of isolated glomeruli and *in vitro* experiments using murine mesangial cells.

Methods: Four-week-old male BTBR *ob/ob* mice were divided into vehicle and enarodustat groups. Enarodustat (0.005%; in feed) was administered from 4 weeks of age until euthanasia at 22 weeks. cDNA samples from isolated glomeruli were hybridized using Agilent SurePrint G3 Mouse GE Microarray 8x60K ver. 2.0. SV40 MES 13 cells were stimulated by palmitate with either enarodustat or AdipoRon (adiponectin receptor agonist).

Results: Enarodustat-treated mice tended to exhibit lower blood glucose (HbA1c: 8.9±0.3 vs 8.2±0.2%, p = 0.060) and significantly lower total cholesterol levels (260±26 vs 164±19 mg/dl, p = 0.019) with comparable intake. Plasma adiponectin was increased in enarodustat-treated mice (6.7±0.6 vs 9.8±0.8 ng/ml, p = 0.014). Enarodustat significantly decreased albuminuria (5.9±1.3 vs 2.3±0.5 mg/mgCr, p = 0.017) without affecting GFR. Electron microscopic examination revealed amelioration of glomerular epithelial and endothelial damage in enarodustat-treated mice. Transcriptome analysis of isolated glomeruli revealed reduced expression of monocyte chemoattractant protein-1 (MCP-1) in enarodustat-treated mice. Urinary MCP-1 was decreased in enarodustat-treated mice (317±62 vs 173±25 pg/mgCr, p = 0.064), accompanied by reduced glomerular macrophage infiltration (2.7±0.5 vs 1.1±0.2/glomerulus, p = 0.006). *In vitro* experiments demonstrated that both enarodustat and AdipoRon suppressed palmitate-induced MCP-1 production in mesangial cells. Enarodustat's suppressive effect was abolished when HIF-1α was knocked down by siRNA.

Conclusions: Enarodustat conferred renoprotection through both indirect and direct pathways: improvement in glucose/lipid metabolism and suppression of MCP-1 production in mesangial cells via HIF-1 activation.

Effects of Triptolide on Macrophage Function and Phenotype by Modulating Autophagy

Yuteng Jiang, Yu Zhao, Xiaodong Zhu, Beibei Wu, Yuqiu Liu, Bi-Cheng Liu, Xiaoliang Zhang. Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine *Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Macrophage infiltration process including capacity of adhesion migration and phenotype transformation are key points in diabetic nephropathy (DN). Triptolide (TP), a classic Chinese immunosuppressor, can alleviate macrophage infiltration effectively in renal inflammatory diseases. However, the relationships between autophagy and Triptolide are unknown. This study aims to investigate whether Triptolide affects macrophage function and phenotype through modulating autophagy.

Methods: RAW264.7 cells were divided into normal (NC) and high glucose treatment groups (HG). Triptolide (10.0ng/mL) was added to respective groups after 24 hours of cell incubated. Western blot and immunofluorescence staining were used to detect the expression of M1 macrophage marker (iNOS, TNF-α), M2 macrophage markers (MR, Arg-1) and autophagy markers (LC3, Beclin-1 and p62). The capacity of macrophage adhesion and migration with and without Triptolide treatment were assessed.

Results: Our study showed that macrophage autophagy was inhibited by HG, which results revealed a decrease expression of LC3 and Beclin-1, but increase expression of P62. Subsequently, the numbers of macrophage adhesion and migration were increased ($P<0.05$). HG induces M1 activation (with increase expression of iNOS and TNF-α) and inhibits M2 transformation (with increase expression of MR and Arg-1)($P<0.05$). However, TP recovers macrophage autophagy level that inhibited by HG (with increase expression of LC3 and Beclin-1, whereas a reduction expression of P62), which lead to inhibition of macrophage adhesion and migration under HG ($P<0.05$). In addition, TP inhibits M1 macrophage transformation (with decrease expression of iNOS and TNF-α) while induces M2 macrophage activation (with increase expression of MR and Arg-1) ($P<0.05$).

Conclusions: HG induces classical activation of M1 macrophages and promotes macrophage adhesion and migration, which is associated with decreased autophagy level. TP promotes M2 macrophage transformation under HG through reducing expression of inflammatory factors may affect macrophage adhesion and migration, which is related to the recovery of autophagy.

SA-PO493

Decay Accelerating Factor (DAF), a Local Complement Inhibitor, Protects from Streptozotocin (STZ)-Induced Diabetic Nephropathy (DN)

Chiara Cantarelli,[1,3] Sofia Andrighetto,[1,2] Susan Hartzell,[1] Chiara Guglielmo,[1] Enrico Fiaccadori,[3] Gianluigi Zaza,[2] Paolo Cravedi.[1] *[1]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]University of Verona, Verona, Italy; [3]Dipartimento di Medicina e Chirurgia, Università di Parma, Parma, Italy.*

Background: Glomerular deposition of complement components has been described in individuals with DN. Whether altered expression of DAF on podocytes mediates complement deposition in DN and affects disease severity is unknown.

Methods: We injected STZ (50 mg/kg, i.p.) into male WT and germline $DAF^{-/-}$ BALB/c mice and in B6 $DAF^{fl/fl}$ crossed to podocin Cre-transgenics (the B6 strain is resistant to STZ nephropathy). We serially measured urine albumin/creatinine ratio (ACR) and at 20 weeks we quantified histological injury and stained sections for C3b.

Results: STZ-induced nephropathy was associated with C3b deposition (**Fig. 1A**). In BALB/c mice, STZ caused more severe proteinuria in $DAF^{-/-}$ than in WT animals (**Fig. 1B**), a finding associated with more severe histological changes (**Fig. 1C**). Newly developed $DAF^{fl/fl}$-podocin-Cre^{POS} animals lacking DAF conditionally in podocytes showed albuminuria and histological changes of DN, while $DAF^{fl/fl}$-podocin-Cre^{NEG} did not develop the disease (**Fig. 1D-E**). DAF-deficiency-induced proteinuria correlated with glomerular staining for C3b (**Fig. 1E**), mechanistically implicating DAF-dependent restraint on complement activation in the disease process.

Conclusions: Podocyte-expressed DAF mediates resistance to STZ-induced glomerular injury in B6 mice. In the absence of DAF, STZ-induced kidney injury is propagated by local deposition of complement. These data provide the rationale for further studies addressing a role for DAF/complement in human diabetic nephropathy.

Funding: NIDDK Support

The Contact Pathway of Coagulation and Complement Activation Participates in the Progression of CKD in Obese Diabetic Rats

Katherine J. Kelly,[1,2] Jesus H. Dominguez.[1] *[1]Indiana University, Indianapolis, IN; [2]Medicine, Roudebush VA Medical Center, Indianapolis, IN.*

Background: Diabetic nephropathy is the leading cause of end stage renal disease. Obese diabetic ZS rats become nephrotic at age 12 weeks and develop advanced chronic renal failure (CKD), the hallmark of human diabetic nephropathy, by 24 weeks. We have proposed that episodes of ischemic acute kidney injury (AKI) are key in the progression of CKD. We have also found that, in AKI, disordered clotting and inflammation prevent reflow and promote ongoing ischemia, leading to loss of functional tissue and fibrosis. We hypothesize that activation of the contact pathway of intrinsic coagulation with complement activation is involved in the development of CKD.

Methods: Male lean (L) and obese, diabetic ZS rats were subjected to sham surgery (DS) or bilateral renal ischemia (DI) at 10 weeks of age (total n=24). The rats

were terminated at 28 weeks of age. Renal function and structure were assessed and comprehensive genomic sequencing was performed.

Results: The nephropathy in the diabetic rats postischemia was characterized by renal failure, the sin que non of human disease. The relevant renal transcripts (table) included activation of the contact pathway with increases in F9, 10, 12 and 13 as well as fibrinogen chains A, B, G, platelet MRNA pg1B, F2R, PF4 and C3.

Conclusions: This rat renal transcript profile strongly points to a persistent disorder of renal coagulation and immunity consistent with activation of renal contact pathway. This pathway is a critical juncture of coagulation and inflammation and has multiple therapeutic target opportunities for diabetic nephropathy.

Transcriptional Inhibitory Peptides of NFκB and JAK/STAT Pathways Improve Renal Damage in BTBR ob/ob Model

Lucas Opazo-Ríos,[1,2] Anita Plaza,[1] Yenniffer Sanchez,[1] Daniel Carpio,[1] Maria A. Droguett,[1] Jesus Egido,[2] Carmen Gomez-Guerrero,[2] Sergio A. Mezzano.[1] *[1]Unidad de Nefrología, Universidad Austral de Chile, Valdivia, Chile; [2]Renal, Vascular and Diabetes Research Lab, IIS-Fundación Jiménez Díaz. – Universidad Autónoma and Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), Madrid, Spain.*

Background: Diabetic nephropathy (DN) is the leading cause of chronic kidney disease and despite improvements in glycemic and blood pressure control by RAAS inhibitors, end-stage renal disease still remains a growing issue. Chronic inflammation plays a key role in the DN progression, but the underlying mechanisms are largely unknown. Therapeutic modulation of inflammation can be assessed by targeting soluble cytokines, their receptors or the involved cell signaling. In the BTBR ob/ob mice, a model of progressive DN that recapitulates the lesions seen in human DN, we have examined and compared the modulation of NFκB and JAK/STAT, two major inflammatory signaling pathways involved in the pathogenesis of DN. To do that we have employed inhibitory peptides targeting key domains of regulatory proteins such as Nemo-Binding Domain of IKK complex (NBD peptide) and the kinase-inhibitory region of SOCS1 (MiS1 peptidomimetic), which respectively prevent the nuclear translocation of p65 and STAT1/3 transcription factors.

Methods: Six-weeks old BTBR ob/ob mice were given intraperitoneal injections of active peptides (NBD, 6 and 10μg; MiS1, 2 and 4μg), inactive mutant peptides (10μg and 4μg, respectively) and vehicle for 7 weeks (n=6-8/group). At the end of the study, animals were sacrificed to obtain blood, urine and kidney tissue samples for further analysis.

Results: *In vivo* and *ex vivo* imaging revealed efficient peptide delivery and rapid systemic biodistribution, with selective renal metabolization in BTBR ob/ob mice. Although both active peptides significantly reduced albuminuria (ACR) in diabetic mice, a greater effect was observed with MiS1 (decrease 57% with 2μg and 66% with 4μg vs vehicle). Both NBD and MiS1 treatment improved glomerular and tubulointerstitial damage (49% with NBD and 48% with MiS1 vs vehicle) and increased the number of podocytes (46% with NBD and 55% with MiS1 vs vehicle), without changes in metabolic parameters (glycemia and lipid profile) and body weight. Additionally, high dose of MiS1 significantly reduced renal weight in compared to controls.

Conclusions: Transcriptional inhibitory peptides NBD and MiS1 significantly improve albuminuria and alleviate DN in BTBR ob/ob mice, being the inhibition of JAK/STAT pathway more effective in achieving these objectives.

SA-PO496

TNF-α Inhibition Protects Against Renal Tubulointerstitial Injury Associated with Suppressing NLRP3 Inflammasome in Diabetic Rats

Feng Wang,[1] Jianyong Yin,[1] Ting Zhao,[2] Yiwei Kong,[3] Xuanchen Liu.[4] *[1]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China; [2]Shanghai Sixth People's Hospital, Shanghai, China; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI; [4]Shanghai Jiao Tong University Afflicted Sixth People's Hospital, Shanghai, China.*

Background: Tubular injury exerts a pivotal role in the development of diabetic nephropathy (DN), but current therapies used to treat DN do not combat tubular injury. This study was conducted to investigate whether TNF-α inhibition protected against tubular injury in diabetic rats and examine the associated mechanisms.

Methods: Kidney biopsy tissues, taken from twelve patients with DN and five control subjects, were analyzed. STZ-induced diabetic rats were treated with a TNF-α inhibitor (Humira) for twelve weeks. Renal function, albuminuria, histological injury, renal TNF-α mRNA, and NLRP3 inflammasome was assessed.

Results: Diabetic patients with tubulointerstitial injury presented with higher renal tubular expression of TNF-α mRNA and NLRP3 inflammasome. TNF-α inhibition reduced albuminuria, glomerular injury, and tubular injury in STZ-induced diabetic rats. Importantly, TNF-α inhibition significantly reduced NLRP3 inflammasome in tubules. Moreover, TNF-α inhibition decreased expression of tubular IL-6 and IL-17A, which could activate NLRP3 inflammasome.

Conclusions: TNF-α inhibitor can protect against tubulointerstitial injury associated with suppressing NLRP3 inflammasome in diabetic rats.

SA-PO497

Comparison of Nrf2-Inducing Compounds on Renal Tubule Cell Responses Associated with Diabetes

Laura Davis, Madhavi J. Rane, Susan M. Isaacs, Michelle T. Barati. *University of Louisville, Louisville, KY.*

Background: The transcription factor Nrf2 regulates cell stress responses. Though many reports suggest the therapeutic potential of Nrf2 inducing compounds in models of kidney disease, use of these agents in clinical settings is limited. Our lab found disparate effects of two Nrf2 inducing compounds, Dimethyl fumarate (DMF) and Protandim (a dietary supplement with no previously reported findings in renal cells), on renal tubule cell morphology and actin cytoskeleton. Due to varying interactions of inducers with the Nrf2 inhibitor, Keap1, and ultimately Nrf2 target gene induction, this study tested the hypothesis that DMF and Protandim differentially regulate renal tubule cell responses associated with disease.

Methods: Human renal proximal tubule cells were treated with 5μg/ml Protandim or 10μM DMF, before or after culture in high glucose (HG; 25mM) concentrations to mimic diabetes. Cell viability was examined via MTT Assay (reduction of (3-(4, 5-dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide [MTT] in viable cells), matrix protein secretion tested via fibronectin immunoblot of cell culture medium, and cell structural proteins (E-Cadherin and α/β tubulin) analyzed via Immunofluorescent staining. Results analyzed by two-way ANOVA with post hoc.

Results: Culture in HG for 24h increased MTT reduction. When cells were treated with inducers for an additional 24h after culture in HG, DMF reversed the effects of HG on MTT reduction. When cells were instead pre-treated with inducers for 24h prior to culture in HG for an additional 24h, DMF again tended to reverse the effects of HG on MTT reduction. Pre-treatment with DMF and Protandim prior to culture in HG showed a trend (P=0.07) of lowering HG-induced fibronectin production. Alternatively, treatment with inducers after HG conditions exhibited the same trend with Protandim but an opposing trend with DMF. Expression of E-cadherin decreased with DMF and protein distribution was more punctate, while α/β tubulin expression and/or polymerization increased with Protandim.

Conclusions: Protandim and DMF differentially regulate renal tubule cell matrix protein secretion and cell structural protein expression and distribution, responses known to be altered with diabetes. The differential effects of Nrf2 inducers on renal cells may lead to different outcomes if/when used for treatment of kidney diseases.

Serpinc1/Antithrombin III Protects Against Diabetic Nephropathy

Feng Wang,[1,2] Yiwei Kong,[2] Xuanchen Liu,[2] Kristie Usa,[2] Aron M. Geurts,[2] Mingyu Liang.[2] *[1]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China; [2]Medical College of Wisconsin, Milwaukee, WI.*

Background: Antithrombin III (ATIII), encoded by the gene *Serpinc1*, is a serine protease inhibitor in the coagulation cascade and exhibits significant anti-inflammatory properties. Inflammation contributes to the development of diabetic nephropathy. The aim of this study was to investigate the effect of *Serpinc1*/ATIII on diabetic nephropathy.

Methods: ATIII activity was analyzed in patients with diabetic nephropathy. Kidney injury and inflammation were evaluated in streptozotocin (STZ)-treated *Serpinc1* heterozygous knockout (*Serpinc1*$^{+/-}$) rats and in db/db mice treated with adeno-associated virus (AAV, serotype 8) carrying *Serpinc1* gene. The effects of ATIII on macrophages and podocytes treated with high glucose were also examined in vitro.

Results: Diabetic patients with lower ATIII activities had a significantly higher incidence of macroalbuminuria and microalbuminuria (n=328, P<0.05). Albuminuria was exacerbated in STZ-treated *Serpinc1*$^{+/-}$ rats compared with STZ-treated wild-type littermates 8 weeks after diabetes induction (albuminuria 76.1±7.1mg/24hr in *Serpinc1*$^{+/-}$ rats vs 26.6±4.7mg/24hr in wild-type controls, n=6, P<0.05). *Serpinc1* heterozygous knockout significantly exacerbated renal infiltration of macrophages and increased renal NF-κB activity and IL-6 and MCP-1 mRNA abundance in rats with STZ-induced diabetes. *Serpinc1* overexpression in db/db mice reduced albuminuria (273.4±21.7μg/24hr in db/db mice treated with AAV-*Serpinc1* vs 430.9±26.8μg/24hr db/db mice treated with AAV-control, n=6, P<0.05) and attenuated renal infiltration of macrophages and decreased renal NF-κB activity and IL-6 and MCP-1 abundance. Treatment with high glucose (25mM) significantly increased NF-κB activation and IL-6 abundance in macrophages and podocytes in vitro. Treatment with ATIII protein attenuated these effects of high glucose.

Conclusions: In conclusion, *Serpinc1*/ATIII reduces inflammation and attenuates diabetic nephropathy.

Immunosenescence in Type 2 Diabetic Patients with Chronic Renal Disease

Kai-Hsiang Shu,[1,2] Fang-Yun Lay,[2] Szu-Yu Pan,[2] Yen-Ling Chiu.[2] *[1]National Taiwan University, Taipei, Taiwan; [2]Far Eastern Memorial Hospital, New Taipei City, Taiwan.*

Background: Immunosenescence is an important challenge for an aging population. It is known that patients with end-stage renal disease suffer from immunosenescence and premature T cell aging but whether such changes occur in diabetic patients with less severe chronic renal disease is unclear.

Methods: 832 patients with type 2 diabetes with different levels of renal function were recruited in this study. Immunosenescence was analyzed by staining peripheral blood with two immunophenotyping panels and analyzed by multicolor flow cytometry.

Results: Out of all the 832 participants, there were 171 patients with stage 3 CKD and 46 patients with 4/5 CKD. Compared to patients with eGFR>60 ml/min, patients with more severe CKD showed progressive decreased total CD3+ T cell and CD4+ and CD8+ T cell, but not monocyte numbers. In addition, immunosenescence, as defined by various phenotypic markers, showed significant upregulation in both stage 3 and stage 4/5 patients. However, immunosenescence was not associated with proteinuria level nor worse glucose control. In age and sex adjusted regression models, stage 3 CKD patients already exhibited significant elevated percentages of CD28-, CD127- and CD57+ cells among CD8+ T cells when compared to patients with eGFR>60 ml/min. In addition, stage 3 CKD patients exhibited depressed HLA-DR and CX3CR1 expression in specific monocyte subpopulations.

Conclusions: Level of immunosenescence is not significantly associated with proteinuria nor glucose control in type 2 diabetes patients. Both T cell and monocyte compartment exhibit characteristics of immunosenescence during renal function decline, starting from stage 3 CKD.

Targeted Transgenic Expression of Catalase to Mitochondria Reduces Reactive Oxygen Species and Ameliorates Diabetic Nephropathy in BTBR ob/ob Mice

Xianwu Li, Anna Batorsky, Alexander L. Holland, Peter S. Rabinovitch, Kelly L. Hudkins, Charles E. Alpers. *University of Washington, Seattle, WA.*

Background: Diabetes induced mitochondrial dysfunction from increased generation of reactive oxygen species (ROS) is pathogenic for diabetic complications including diabetic nephropathy (DN). Catalase is a major scavenger of ROS and prevents tissue damage from oxidative stress. To explore pathogenic mechanisms and to test a targeted ROS reduction strategy for treating DN, we created diabetic BTBR *ob/ob* mice with inducible transgenic human catalase expressed only in mitochondria (mCAT) to determine the efficacy of reducing mitochondrial ROS in a murine model of DN.

Methods: Transgenic Rosa 26 mice containing loxP-stop-loxP-mCAT and tamoxifen-inducible Cre mice (B6.129-Gt(ROSA)26Sor$^{tm1(cre/ERT2)Tyj}$/J) were backcrossed into the BTBR mouse strain. The heterozygous *ob*/+ mice of each strain were crossed to obtain *ob/ob* double transgenic mice. At 16 weeks of age, the mCAT gene expression was induced by oral administration of tamoxifen and the induced mice were referred as mCAT *ob/ob*. The double transgenic mice without tamoxifen treatment were used as control group (Rosa *ob/ob*). Fasting glucose levels were monitored and timed (6 hour) urine samples were collected at weeks of 18 and 24. At the end of the study (24wks), mice were sacrificed and blood and organs harvested.

Results: Both mCAT *ob/ob* and Rosa *ob/ob* were hyperglycemic (499.2 vs 566.7mg/dl) and obese. mCAT *ob/ob* mice exhibited a significant decrease in albumin-creatinine ratio (ACR) compared with control mice (196.1 vs 305.9 ug/mg, $p < 0.05$). Morphometry revealed a marked reduction of mesangial matrix accumulation assessed by collagen IV staining (15.4 vs 22.3% glomerular tuft area, $p < 0.01$). mCAT expression also reduced the extent of mesangiolysis vs. control mice (20.5 vs 29.4% of glomeruli, $p < 0.05$). The levels of urinary 8OHdG (a DNA/RNA marker of oxidative stress) were also reduced in mCAT *ob/ob* mice vs. Rosa *ob/ob* (72.9 vs 129.2 ng/mg creatinine, $p < 0.05$). Measures of podocyte density are pending.

Conclusions: Reduction of ROS specifically in mitochondria by targeted expression of catalase in BTBR *ob/ob* mice ameliorates albuminuria and dramatically improves mesangial expansion and mesangiolysis, thereby offering a new approach for DN therapeutics.

Lysyl Oxidase-Like 4 Acts as a Deacetylase to Regulate Mitochondrial Respiration in Diabetic Kidney Tubule

Qingqing Ke,[2] Yang Zhou,[1] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Dysfunctions in mitochondrial respiration and energy production are quite evident in the pathogenesis of diabetic kidney disease; however, the underlying mechanism remains unclear. Acetylation negatively regulates the activity of enzymes involved in the process of mitochondrial respiration. With the N-terminal scavenger receptor cysteine-rich (SRCR) repeats, lysyl oxidase-like 4 (LOXL4) may act as a deacetylase. In the present study, we aimed to investigate whether the LOXL4 regulates enzyme acetylation and mitochondrial respiration of renal tubular cells in diabetes.

Methods: Kidney biopsy samples were obtained from patients without or with diabetes. Protein acetylation was determined by mass spectrometry of isolated kidney tubule from control and STZ-induce diabetic mice. Mitochondrial respiration was measured by oxygen consumption rate (OCR) and extracellular acidification rate (ECAR). Protein expression and localization of LOXL4 were examined by western blot and immunofluorescence staining. Expression of LOXL4 was modulated by plasmid or siRNA in primary cultured tubular epithelial cells to determine the effect of LOXL4 on acetylation.

Results: In kidney tubule of diabetic mice, the acetylation was upregulated and downregulated in 588 and 105 proteins, respectively. Besides cyroplasm, abundant of these acetylated/deacetylated proteins locate in mitochondria. Bioinformatics analysis suggested that these proteins are evolved in mitochondrial respiration and probably regulate metabolic process and energy production. Consistently, mitochondrial respiration capacity was impaired in tubular cells treated with high glucose. The expression of LOXL4 was markedly increased in kidney tubule of both diabetic patients and mouse model. Moreover, immune staining showed the colocalization of LOXL4 and mitochondria. Modulation of the expression of LOXL4 regulated the acetylation of mitochondrial proteins and affected mitochondrial respiration and energy production.

Conclusions: Collectively, lysyl oxidase-like 4 may regulate the acetylation/deacetylation of mitochondrial proteins and protects mitochondrial respiration and function in diabetic kidney tubule.

CD248 Modulates Unfolded Protein Response in Diabetic Nephropathy

Shruthi Krishnan,[1,3] Ronald Biemann,[1,3] Sophie-Cecil Mathieu,[1] Jayakumar Manoharan,[1,3] Shrey Kohli,[1,3] Akshay Malhotra,[2] Michael Naumann,[2] Berend H. Isermann.[1,3] *[1]Institute for Clinical chemistry and Pathobiochemistry, Otto-von-Guericke University, Magdeburg, Germany; [2]Institute of Experimental Internal Medicine, Otto von Guericke University, Magdeburg, Germany; [3]Institute for Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, Leipzig University, Leipzig, Germany.*

Background: Diabetic nephropathy (DN) is a major cause of end-stage renal disease and a growing public health burden. Recently DN has been linked with maladaptive unfolded protein response (UPR) and sterile inflammation, but the underlying mechanism triggering the glucose induced maladaptive UPR and sterile inflammation remain poorly defined. We focused on CD248, a type I transmembrane glycoprotein expressed by pericytes, such as glomerular mesangial cells and tubulointerstitial fibroblasts whose expression correlates with renal fibrosis in chronic kidney disease. Hence, the aim of our study is to investigate the role of CD248 in regulating UPR and sterile inflammation in DN.

Methods: C57Bl/6 (WT) mice and CD248$^{-/-}$ mice were used for the study. Diabetes was induced using streptozotocin (STZ) and samples were obtained after 26 weeks. Albuminuria (UACR), PAS staining and WT-1 immunostaining of kidney sections were done to study development of renal disease. To evaluate mechanistic insights, genetic knockdown or overexpression of CD248 was done followed by immunoblotting and co-immunoprecipitation approaches.

Results: We detected a marked increase of renal CD248 expression after 26 weeks in diabetic mice versus nondiabetic controls. CD248 knockout protected mice from diabetes induced albuminuria, podocyte loss and mesangial expansion. In vitro, shRNA mediated CD248 knockdown in renal pericytes prevented high glucose induced maladaptive UPR signaling (lower levels of CHOP, ATF4, cATF6α), inflammasome activation (lower levels of NLRP3, cleaved IL-1β), SMAD2/3 phosphorylation and mTORC1 activation (lower levels of p-Raptor and p-p70S6Kinase). Vice versa, overexpression of CD248 amplifies these glucose induced cellular responses. Mechanistically, the chaperone HSP90 interacts with the transmembrane receptor CD248 and may thus transduce extracellular glucose-dependent stress signals to the ER via IRE-1α.

Conclusions: CD248 modulates hyperglycemia induced UPR, inflammasome activation and renal fibrosis. HSP90 appears to serve as the cytosolic mediator linking the receptor CD248 with ER membrane proteins such as IRE1α. Our findings identify pericyte-specific CD248 as a potential target for therapeutic interventions of DN.

SA-PO503

Spexin: Is It Another Bystander or a New Biomarker in Diabetic Kidney Disease?

Jin Joo Cha, Dae R. Cha, Jungyeon Ghee, Ji ae Yoo, Jeong-Taek Lim, Jungmin Joa, Young Sun Kang. *Korea University, Ansan, Republic of Korea.*

Background: Spexin is a highly conserved active neuropeptide that has been recently identified in the involvement of controlling appetite and energy balance. Although few is known regarding to the role of spexin, spexin level was noted to be significantly lower in obese and diabetic patients. Recent study has shown that spexin mRNA was significantly detected in human kidney tissue. Therefore, we investigated the expression of spexin in diabetic kidney disease in clinical and experimental model.

Methods: Serum samples from patients who were diagnosed as type 2 diabetes were examined for circulating spexin level using commercially available ELISA kit (Spexin/neuropeptide Q(NQP)). Serum and renal expression of spexin was examined in experimental mice models; ü1) normal control, 2) db/db mice, 3) fat chow diet induced obesity mice and 4) non-diabetic UUO-induced mice.

Results: Total 89 diabetic patients participated in the study. The circulating spexin level was significantly increased in patients on dialysis (both peritoneal and hemodialysis) compared to patients with estimated GFR ≥60 ml/min/1.73m^2. In diabetic patients with chronic kidney disease stage 1 to 3, spexin level was significantly increased in patients with overt proteinuria (urine protein to creatinine ratio). There was significant correlation between serum spexin and proteinuria, however no correlations were observed in age, gender, BMI, blood glucose, lipid profiles and HOMA-IR or estimated GFR with serum spexin level. Spexin was detectable in serum and kidney tissue of murine models. In experimental mice of obese type 2 diabetes (db/db), serum spexin level was significantly increased, whereas its renal expression was not significantly different compared to normal and obstructed kidney control.

Conclusions: The spexin expression in the kidney from experimental mice and circulating spexin level in diabetic patients may indicate that spexin may be a biomarker of diabetic kidney disease. However, further study is needed to elucidate the specific role and mechanism of spexin in metabolic kidney disease.

Hyperinsulinemia Contributes to High Fat-Induced Kidney Injury in Mice

Hak Joo Lee,[1] Meenalakshmi M. Mariappan,[1] Terry Bakewell,[1] Luke Norton,[1] Denis Feliers,[1] Sae Byeol Oh,[1] Andrew Donati,[1] Cherubina S. Rubannelsonkumar,[1] Isabelle Rubera,[2] Michel Tauc,[2] Stephen E. Harris,[1] Goutam Ghosh-Choudhury,[1] Manjeri A. Venkatachalam,[1] Kumar Sharma,[1] Ralph A. DeFronzo,[1] Balakuntalam S. Kasinath.[1] *[1]University of Texas Health San Antonio, San Antonio, TX; [2]Université Côte d'Azur, CNRS, LP2M UMR7370, Nice, France.*

Background: The mechanism of obesity-induced kidney injury is not well understood. We hypothesized that hyperinsulinemia activates kidney proximal tubular epithelial insulin receptor (IR) and contributes to obesity-induced kidney injury in high fat diet fed mice.

Methods: We generated kidney proximal tubule IR knock out (KPTIRKO) mice by crossing IR lox mice with Sglt2-Cre mice. We administered normal fat diet (NFD) or high fat diet (HFD) to 5-8 month old male Control and KPTIRKO mice for 4 months (n=9-10/group, 2 batches) and evaluated changes in albuminuria, blood pressure (BP), renal matrix proteins, signaling pathways and intraperitoneal GTT.

Results: KPTIRKO mice grew normally. In KPTIRKO mice renal cortical IR expression was decreased by more than 60% although it was unchanged in other tissues. Serum insulin, creatinine, urinary albumin to creatinine ratio (ACR) and renal cortical IGF-1 receptor expression in KPTIRKO mice were similar to Controls. On HFD, food consumption, increase in body weight and serum cholesterol were similar in Control and KPTIRKO mice. HFD increased the following in Control mice: renal cortical content of tyrosine phosphorylated IR indicating IR activation, matrix proteins laminin, fibronectin and collagen I, urinary and renal cortical KIM-1 content, urinary ACR, systolic BP; these changes were significantly ameliorated in HFD-fed KPTIRKO mice ($p<0.05$-0.001). HFD activated renal cortical IR-Akt axis in Control but not KPTIRKO mice. HFD increased serum insulin and C-peptide levels in Control but not in KPTIRKO mice. To explore if improved glucose tolerance was the reason for lack of hyperinsulinemia in KPTIRKO mice on HFD, GTT was done. KPTIRKO mice on NFD had lower fasting glucose and improved glucose tolerance; however, glucose intolerance was similar in Controls and KPTIRKO mice on HFD.

Conclusions: HFD-induced hyperinsulinemia activates renal cortical IR and contributes to kidney injury manifesting as albuminuria, elevated BP, and matrix protein accumulation in male mice. These results provide a mechanistic explanation for obesity-induced kidney injury. The reason for lack of hyperinsulinemia in HFD fed KTPTIRKO mice needs further investigation.

Deletion of Peroxisome-Proliferator-Activated Receptor δ in Mice Promotes High-Fat-Diet-Induced Renal Injury

Yongke You,[1,2] Hai-Yong Chen,[4] Yu Huang,[3] Hui Y. Lan.[1] *[1]1Department of Medicine and Therapeutics, and Li Ka Shing Institute of Health Sciences, The Chinese University of HongKong, Hong Kong, China; [2]Department of Nephrology, Shenzhen University General Hospital, Shenzhen, China; [3]School of Biomedical Sciences, Institute of Vascular Medicine, and Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Shatin, China; [4]School of Chinese Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China.*

Background: Peroxisome proliferator-activated receptor δ (PPARδ), the least studied member of the PPAR group in the nuclear receptor superfamily, plays a crucial role in cellular metabolic functions and other physiological processes. Recent evidence highlights the therapeutic potential of PPARδ agonists in obesity, dyslipidaemia, insulin resistance/type 2 diabetes. However, little is known the role of PPARδ in the pathogenesis of obesity related renal injury. It is reported that *PPAR*δ gene is a primary target of 1a,25-dihydroxyvitamin D3 (calcitriol), the aim of this study is to investigate the effects of calcitriol on the role of PPARδ in HFD-induced renal injury.

Methods: Diet-induced obese (DIO) micewere generated on *PPAR*δ KO, age-matched *PPAR*δ wildtype (WT) littermates at the 6 weeks of age and were fed with high-fat-diet (HFD) for 12 weeks. In addition, 12 weeks after HFD feeding, mice were treated with 1a, 25-dihydroxyvitamin D3 (calcitriol) or vehicle by intraperitoneal injection at the dosage of 100 ng/kg three times a week for 4 weeks. The effects of calcitriol on the role of PPARδ in HFD-induced renal injury were evaluated by real-time quantitative polymerase-chain-reaction (qRT-PCR), western blot analysis, as well as a histological examination.

Results: Compared with control mice on a normal diet, DIO *PPAR*δ WT mice exhibited significant renal injury, which were further exacerbated in DIO *PPAR*δ KO mice: including 1) obviously increased expression of kidney injury molecule-1 (KIM-1), as well as histological injury revealed by Masson's Trichrome &PAS Staining; 2) marked up-regulation of pro-inflammatory cytokines TNF-a; 3) exacerbated renal fibrosis as demonstrated by significantly up-regulation of fibrotic matrix proteins deposition, such as a-smooth muscle actin (a-SMA), collagen 1 and fibronectin. However, all these changes were dramatically attenuated after administration of calcitriol.

Conclusions: In conclusion, deletion of PPARδ promotes HFD-induced renal fibrosis and inflammation, and these changes could be partially attenuated by calcitriol treatment. Targeting *PPAR*δ gene may offer a new treatment approach for obesity-related renal injury.

SA-PO506

Increased Expression of NMN Transporter in the Kidneys in Diabetic Nephropathy

Itaru Yasuda,[1] Kazuhiro Hasegawa,[1] Takashi Ono,[2] Shu Wakino,[1] Hiroshi Itoh.[1] *[1]Keio University, Tokyo, Japan; [2]Shionogi & Co., Ltd, Osaka, Japan.*

Background: In diabetic nephropathy (**DN**) and aging kidney, renal tissue concentration of nicotinamide adenine dinucleotide (**NAD$^+$**) decreased, which is associated with renal dysfunction and albuminuria. The regulatory systems of NAD$^+$ and its precursor, nicotinamide mononucleotide (**NMN**) are considered to play a crucial role in the maintenance of tissue NAD$^+$ levels and the pathogenesis of DN. Recent study identified novel **NMN transporter,** Solute Carrier Family 12 Member 8 (**Slc12a8**). However, the role and location of NMN transporter in the kidneys as well as diabetic kidney remain unclear.

Methods: Type 2 diabetic db/db and **control db/m** mice were given regular chow diet ad libitum and euthanized at 24 weeks of age. We performed immunohistochemistry (IHC) of renal Slc12a8. Further, we measured serum and urinary NAD$^+$ metabolites at 24 weeks of age. We evaluated renal NAD$^+$ loss by calculating urine NAD$^+$ to creatinine ratio (**NAD$^+$/Cr**). NMN resorption was evaluated by the calculation of the fractional excretion of NMN (**FeNMN**).

Results: Tissue concentration of NAD$^+$ decreased in db/db mice as compared to that in db/m mice at the age of 8 weeks, although that of NMN was not different. Urine NAD$^+$/Cr ratios were higher in db/db mice than in db/m mice, suggesting an increased renal loss of NAD$^+$ in db/db mice. IHC revealed weak staining of Slc12a8 in the glomerulus and proximal tubules, while strong staining in the distal tubules. Slc12a8 expression was higher in db/db mice than in db/m mice. While the expression of Slc12a8 was detected mostly on the **basolateral** side in db/m mice, it was expressed on both **apical** and basolateral side in db/db mice. These findings suggested the increased translocation of Slc12a8 towards apical side of distal tubular cells in DN. Consistently, FeNMN was lower in db/db mice than that in db/m mice, indicating increased resorption NMN at the tubules in db/db mice.

Conclusions: Novel NMN transporter, Slc12a8 was dominantly expressed in the distal tubules. In DN, Slc12a8 translocation to apical side was enhanced, which can be the compensatory mechanism for NAD$^+$ loss in diabetic mice.

SA-PO507

Molecular Mechanism of Regulatory Effect of Vitamin D Receptor on Mitophagy of Proximal Tubular Epithelial Cells in Diabetic Nephropathy

Cheng Yang, Hao Zhang. *The Third Xiangya Hospital of Central South University, Changsha, China.*

Background: Vitamin D receptor (VDR) is a kind of nuclear transcription factor, which is widely expressed in proximal tubular epithelial cells (PTECs). Our previous study found that VDR has anti-inflammatory and anti-fibrotic effects. Given the previous evidence that the expression of VDR decreased in PTECs of DN patients and VDR can regulate the mitophagy, how VDR contribute to the development of renal tubulointerstitial mitophagy in diabetic nephropathy is not entirely clear. In this study, we tend to investigate the effect of VDR on mitophagy dysfunction in diabetic nephropathy and its molecular mechanism.

Methods: VDR-knockout mice in C57BL/6 background were generated and streptozotocin (STZ)-induced diabetic mice were used in these experiments. Mitophagy in the PTECs was observed by electron microscope, and the pathological changes of the kidneys were delineated by periodic acid–Schiff (PAS) staining. Immunohistochemistry and Western blotting were performed to identify the expression of VDR, Collagen 1, Fibrinogen, α-SMA,TGF-β, Drp1, mitofusin 2, Pink1 and Bnip3.

Results: 1. The blood glucose of the mice was significantly increased in the first week after the injection of STZ. 16 weeks after STZ injection, PAS staining revealed the glomerulomegaly and renal tubular injury of diabetic mice, suggesting that STZ-induced diabetic mice were generated successfully. 2. The accumulation of collagen in glomeruli and tubulointerstitium revealed the occurrence of renal fibrosis in the STZ-induced mice. The expression of Collagen 1, Fibrinogen and α-SMA in wild-type diabetic mice was lower than that in VDR-KO diabetic mice, thus confirming the anti-fibrotic effect of VDR in the pathogenesis of DN. In the diabetic model induced by STZ, there is severer mitophagy dysfunction in VDR-KO mouse than that in the wide type diabetic mouse, which indicates that VDR may regulate the mitophagy in diabetic nephropathy.

Conclusions: VDR can control the renal fibrosis and the progression of diabetics by regulating the mitophagy. VDR overexpression may act as a new target for the prevention and treatment of DN.

Funding: Government Support - Non-U.S.

Activation of Vitamin D Receptor Attenuates High Glucose-Induced Cellular Injury Partially Dependent on CYP2J5 in Murine Renal Tubule Epithelial Cell

Yan Liu, Hao Zhang. *The Third Xiangya Hospital of Central South University, Changsha, China*.

Background: Vitamin D receptor (VDR), have renoprotection effect against diabetic nephropathy (DN). Paricalcitol is a VDR activator. Epoxyeicosatrienoic acids (EETs) are cytochrome P450 (CYP) protecting against diabetes and DN. Our objective is to investigate whether activation of vitamin D receptor protect nephropathy partially dependent on CYP2J5 in murine renal tubule epithelial cell.

Methods: Adult male wile type (WT) and *Vdr*$^{-/-}$ mice were used,. STZ-induced diabetic nephropathy model was established and paricalcitol was injected. 12 weeks after the STZ injection, mice were sacrificed. Kidneys were collected for histology and immunohistochemistry staining. Murine kidney proximal tubule epithelial cell line (BU. MPT) was used in this study, incubated with high glucose and paricalcitol. supernatent, mRNA and protein were collected. Real-time PCR and Western blot were used to detect the RNA and protein levels.

Results: 1. STZ, VDR-/-,VDR-/-+STZ mice tubulointerstitial injury were more severe than WT, the expression of CYP2J5 and VDR decreased. But STZ mice treated with paricalcitol had attenuated tubulointerstitial injury and increased CYP2J5 and VDR than STZ 2. Activation of VDR attenuated high glucose-induced cellular injury in renal tubular epithelial cells partially though up-regulating CYP2J5 expression. High glucose treatment strongly reduced the CYP2J5 expression and the synthesis of 14,15-EET in murine renal tubular epithelial cells. Supplement of 14,15-EET significantly reduced the lactate dehydrogenase (LDH) release induced by high glucose in renal tubular epithelial cells. Treatment with an activator of VDR, paricalcitol, restored the expression of CYP2J5 reduced by high glucose treatment in renal tubular epithelial cells. And we found that paricalcitol attenuated cellular injury induced by high glucose partially dependent on the up-regulation of CYP2J5 in renal tubular epithelial cells 3. WT and a mutant-Cyp2j5 luciferase reporter plasmid were constructed. We found that paricalcitol treatment (0.1 mM) significantly increased relative luciferase activity in the WT plasmid, compared with the pGL3 basic plasmid

Conclusions: Activation of VDR attenuates high glucose-induced cellular injury partially dependent on CYP2J5 in murine renal tubule epithelial cells and paricalcitol may represent a potential therapy for DN.

The Potential Therapeutic Effect of Active Vitamin D Supplementation in Preventing Initiation and Progression of Diabetic Nephropathy in a Diabetic Mice Model

Tina Thawko,[4] Nakhoul Nakhoul,[2] Rula Nakhoul,[3] Farber Evgeny,[1] Farid M. Nakhoul,[1,2] Inbal Dahan.[4] *[1]Nephrology &Hypertension Division Baruch Padeh Poriya Medical Ctr, Lower Galilee, Israel; [2]Diabetes & Metabolism Lab Azrieli Faculty of Medicine, Ramat Gan, Israel; [3]Szejed Faculty of Medicine Hungary, Szeged, Hungary; [4]Diabetes &metabolism Lab Azrieli faculty of medicine, Lower Galilee, Israel*.

Background: Diabetiv Nephropathy (DN) is characterized by morphological changes in podocytes and proximal tubule cells (PCT), and are characterized by hyperfiltration, albuminuria, glomerular sclerosis to ESRD. DN mice suffer from an active vitamin D deficiency, which results in podocytopathy and PCT injury. We hypothesize that supplementation of **active vitamin D paricalcitol(P**) to DN mice may slow the development & progression of DN.

Methods: Renal injury in diabetic mice with and without **P** treatment (TX), and control mice, were evaluated for albuminuria, blood Creatinine and BUN levels. The kidney biopsies were subjected to PAS & IHD staining: of **vitamin D receptor (VDR) expression,** villin, nephrin, podocin and fibronectin proteins. We used 4 groups of mice:**(1)** CON-wild type **(2) DM group** after DM induction with STZ were treated with vehicle for 12 weeks.**(3) DM+P after STZ group** - diabetic mice treated with P **before** the onset of DN, and one week after DM induction, i.p. 3 times a W for 12 wkss, **(4) DM+P group** - 3 weeks **after** diabetes induction, the mice were treated with P i.p. 3 times a W for 12 wks.

Results: 1. VDR expression increased in DM+P after STZ (1.08±0.13) compared with DM+P group (0.59±0.13), **2**, **Renal villin expression of DM mice** was significantly decreased (0.53±0.09) compared with control mice (1.14±0.05, p<0.001), but **P** TX before and after the onset of DN (DM+P and DM+P after STZ groups) restored villin expression, **3. P** TX (DM+P and DM+P after STZ) **decreased fibronectin expression. 4. Nephrin expression levels were decreased in DM group** (0.5±0.11) compared with control group (1.03±0.09). **P treatment** (DM+P, DM+P after STZ) restore nephrin levels to normal (1.26±0.22) VS (0.99±0.04) respectively. 5. Renal expression of podocin was decreased in DM mice compared with control mice. **P** TX restore podocin expression in DM+P after STZ TX.

Conclusions: 1. Significant protective effect of Paricalcitol treatment in preventing the initiation and progression of DN in STZ-induced diabetic mice mode. 2. Increasing the expression of VDR and restoration of nephrin-podocine proteins with decreasing fibronectin, prevent the progression of DN **3**. Our findings can be proposed as a new approach to deal with DM complications by selective Vitamin D supplementation in early stages of DN.

Downregulation of EHHADH and Tubular Dysfunction in Diabetic Nephropathy

Jacob Whitman,[1] Haichun Yang,[1] Raymond C. Harris,[2] Agnes B. Fogo.[1] *[1]Department of Pathology, Microbiology & Immunology, Vanderbilt University Medical Center, Nashville, TN; [2]Division of Nephrology, Vanderbilt University Medical Center, Nashville, TN*.

Background: The pathophysiology of diabetic nephropathy (DN) is not well understood. In a previous study, we analyzed renal cortical tissue from the db/db/eNOS$^{-/-}$ murine DN model by RNA-seq, identified altered novel genes with human orthologs, and assessed mRNA expression of these genes in human DN versus control. Ehhadh was downregulated in human DN. Ehhadh encodes for a peroxisomal protein that catalyzes the second and third committed steps in the peroxisomal beta-oxidation pathway (PBO), which is responsible for oxidizing long-chain and complex fatty acids. We investigated the potential role of Ehhadh in DN.

Methods: Biopsies with mild (n=20), moderate (n=19), or severe (n=20) DN were compared to normal controls (n=20). Ehhadh protein expression and localization were scored and compared to morphologic lesions, clinical data, and follow-up. Multiplex analyses examined the relationship of Ehhadh and KIM1 expression. Subcellular localization of Ehhadh and peroxisomal membrane protein ABCD3 was analyzed via super-resolution microscopy (SIM). Ehhadh mRNA expression in a high-glucose assay of cultured human proximal tubular cells (PTC) was assessed by qPCR.

Results: In normal controls, Ehhadh protein was strongly expressed in tubular epithelium and was significantly reduced in moderate and severe DN groups versus control. Downregulation of tubular Ehhadh significantly correlated with increased interstitial fibrosis (r^2=0.587, p<0.0001), increased serum creatinine (r^2=0.488, p<0.0001), and increased UPCR (r^2=0.327, p<0.005). Ehhadh expression correlated positively with renal survival (p=0.054). Ehhadh exhibited complementary expression with KIM1 with no co-localization in tubules. SIM analyses of Ehhadh and ABCD3 indicated that tubular downregulation of Ehhadh in DN precedes loss of peroxisomal membranes. Ehhadh transcription was significantly downregulated in PTC under high-glucose conditions.

Conclusions: Ehhadh downregulation is associated with tubular injury and worse renal survival in human diabetic nephropathy. We postulate that the dysmetabolism caused by downregulation of Ehhadh and PBO promotes increased levels of complex lipid products in PTC, possibly contributing to progression and tubulointerstitial fibrosis.

Cell Proliferation of Proximal Tubular Epithelia Leads to Renal Hypertrophy in Early Diabetic Nephropathy

Noriko Uehara, Tetsuro Kusaba, Aya Tomita, Keiichi Tamagaki. *Department of Nephrology, Kyoto Prefectural University of Medicine, Kyoto, Japan*.

Background: The initial phenotypes of diabetic nephropathy are renal hypertrophy accompanying an increase in GFR, resulting in an increase in glucose reabsorption at proximal tubules. However, the detailed morphological changes and underlying mechanisms are not fully understood.

Methods: To investigate the proximal tubule-specific phenotypes in type 2 diabetic mice, we generated transgenic db/db mice carrying tamoxifen-inducible proximal tubule-specific tdTomato reporter genes (SLC34a1CreER/R26tdTomato). We isolated tubular epithelial cells by FACS from mice in which the proximal tubular epithelium was exclusively labeled by tdTomato, and evaluated the tubule-specific molecular mechanisms of the development of diabetic nephropathy. To assess the proliferation of tubular epithelial cells, we also performed lineage tracing analysis of single-labeled proximal tubular epithelial cells in db/db mice by low-dose tamoxifen injection.

Results: Histological analysis of 18-week-old diabetic mouse kidneys revealed expansion of the renal cortex and enlargement of the cross-sectional area in each tubule. The protein/DNA ratio, a marker of cellular hypertrophy, was not increased in FACS-isolated tubular epithelial cells from the diabetic mouse kidney. qPCR analysis revealed that SGLT2 and GLUT2 expression in isolated tubular epithelial cells was not increased in diabetic mice. Lastly, lineage tracing analysis of single-labeled proximal tubular epithelia cells revealed significant clonal expansion of the labeled epithelium in db/db mice, suggesting increased cell proliferation during the observational period.

Conclusions: Our study using a proximal tubule-specific reporter demonstrated that cell proliferation, rather than cellular hypertrophy, plays a role in the enlargement of the tubular lumen and subsequent kidney hypertrophy in early diabetic nephropathy. This suggests that the increase in glucose reabsorption under diabetic conditions is due to the proliferation of proximal tubular epithelial cells, which predominantly express SGLT2, and not to the overexpression of SGLT2 in individual cells.

SA-PO512

VEGFR2 Blockade Improves Renal Damage in the Experimental Model of Diabetic Nephropathy

Anita Plaza,[1] Carolina Lavoz,[1] Daniel Carpio,[1] Marta Ruiz-Ortega,[2] Sergio A. Mezzano.[1] *[1]Universidad Austral de Chile, Valdivia, Chile; [2]Universidad Autonoma, Madrid, Spain.*

Background: Chronic inflammation is the main feature of progressive kidney disease, including Diabetic Nephropathy (DN). Among the potential therapeutic targets of renal damage induced by diabetes, a pathogenic role for Gremlin has been described. Recent

studies in our group have described that Gremlin activates the vascular endothelial growth factor-2 receptor (VEGFR2) associated with renal inflammation. The animal model BTBR ob/ob has been widely used for the study of DN, since it develops histological characteristics that resemble the human DN. In these mice, Gremlin expression increases at week 8 and remains elevated until week 20 of life. This model offers an opportunity to study the mechanisms that could lead to more specific therapies that lead to the regression of the DN. Our aim was to evaluate the role of VEGFR2 blockade in the progression of the DN in the BTBR ob/ob model.

Methods: In this animal model, VEGFR2 was blocked with the pharmacological inhibitor SU5416. The inhibitor was administered to mice of 15 weeks of life, 3 times a week for 5 weeks and then sacrificed (0.1 mg per mouse, i.p). The parameters of weight and glycemia, the ratio of Albumin/Creatinine (ACR) in urine, glomerular and tubulointerstitial damage at the microscopic and ultrastructural level, as well as inflammatory and podocyte damage markers by real-time PCR and IHC were evaluated in non-diabetic, diabetic and diabetic SU5416-treated groups. (n:6-8 animals per group).

Results: VEGFR2 blockade improved the ACR during all period of study compared to diabetic group. At glomerular level, SU5416-treated mice showed lower cellularity and lower mesangial matrix expansion and decreased thickening of the glomerular basement membrane. Also, in the tubulointerstitial compartment, the inflammatory infiltrate decreased and some foci of tubular atrophy were observed. In response to VEGFR2 blockade, there was a downregulation in the kidney damage markers (KIM1 and Ngal), in podocyte markers WT-1, Nphs-1 and Nphs2 and in the pro-inflammatory factors MCP-1, Rantes, IL-17A and IL-6. However, Gremlin levels were not affected. Decreased inflammatory infiltrating cells in SU5416-treated mice was histologically observed.

Conclusions: These data show that the Gremlin/VEGFR2 axis would be involved in kidney damage mediated by diabetes and could be a new therapeutic target for ND.

Soluble Klotho Anchors TRPV5 on Membrane Independent of FGFR1 by Binding TRPV5 and Galectin 1 Simultaneously

Jinho Lee,[1] Tsogbadrakh B. Bodokhsuren,[1] Hyunjin Ryu,[1] Eunjeong Kang,[1] Minjung Kang,[1] Curie Ahn,[1] Kook-Hwan Oh.[2] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]SNU College of Medicine, Seoul, Republic of Korea.*

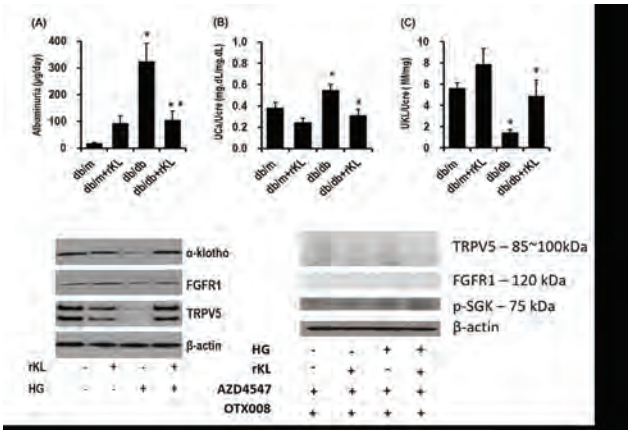
Background: Hypercalciuria is one of the early disturbances of diabetic nephropathy (DN). This is partially due to decrease of renal transient receptor potential vanilloid type 5 (TRPV5) expression, which is responsible for renal calcium reabsorption. Soluble klotho was previously known to increase TRPV5 by cleaving sialic acid, causing TRPV5 to bind to a membrane protein galectin 1. However, recent study showed that soluble klotho binds to a2-3-sialyllactose - where sialic acid is located - on TRPV5, rather than cleave it.

Methods: We injected recombinant soluble klotho protein(rKL) into db/db and db/m mice for 8 weeks, and collected urine and the kidney. We treated rKL, AZD4547 (FGFR1 inhibitor), and OTX008 (Galectin 1 inhibitor) to mouse distal tubular cells, with or without 30mM high glucose (HG) exposed.

Results: db/db mice showed increased renal calcium excretion, and decreased renal TRPV5 expression. rKL treatment reversed this change. In vitro, TRPV5 expression in distal tubular cells decreased in HG situation, and rKL successfully upregulated TRPV5 with or without AZD4547. Also, immunofluorescence for klotho, TRPV5 and glaectin 1 are the same location in distal tubule cells, suggesting that klotho binds to both TRPV5 and galectin 1. However, when AZD4547 and OTX008 are both treated, rKL failed to increase TRPV5 in HG condition.

Conclusions: rKL binds to both TRPV5 and galectin1, thereby tethers TRPV5 on apical membrane. This soluble klotho-mediated holding TRPV5 on apical membrane is FGFR1 independent, but galectin 1 dependent.

Funding: Government Support - Non-U.S.



in db/db mice, rKL increased renal TRPV5 and decreased urinary calcium excretion. In vitro, rKL failed to increase TRPV5 when both FGFR1 and galectin 1 are inhibited.

SA-PO514

Function of Protein X as a Novel Regulator of NADPH Oxidase 4 in Diabetic Nephropathy

Sae rom Lee, Yun soo Bae. *Ewha Womans University, Seoul, Republic of Korea.*

Background: Several lines of evidence indicate that NADPH oxidase (Nox)-derived excessive reactive oxygen species (ROS) play important role in diabetes complication such as diabetic nephropathy. It has been reprted that Nox4 isozyme is major source of ROS in pathological stage of kidney. Nox4, the isozyme highly expressed in kidney, is known to be constitutively active, but its activity is associated with diabetic nephropathy. We recently identified a novel regulator of Nox4, PX which interacts and activates Nox4. Here, we show that association of Nox4 with PX is involved in chronic kidney disease.

Methods: Eight week-old male wild type (WT), PX KO, Nox4 KO mice were subjected into the development of type I diabetes by injection of streptozotocin (STZ). Kidney tissues of the mice were analyzed with histological analyses, PAS-staining and collagen with immunohistochemistry (IHC) staining. Oxidative stress was assessed with urinary 8-isoprstane. Furthermore, renal functions were investigated by measurement of urinary albumin excretion and creatinine clearance rate (CCR).

Results: Mesangial expansion as a marker of glomerulosclerosis was reduced in PX KO and Nox4 KO mice. Albumin to creatinine ratio (ACR), urinary albumin excretion, and blood urea nitrogen (BUN) of protein X KO and Nox4 KO mice markedly decreased, compared to diabetic WT. Extracellular matrix (ECM) including collagen type I, type IV, TGF-β and α-SMA were significantly reduced in PX KO and Nox4 KO mice. Levels of H_2O_2 and urinary 8-isoprostane were suppressed in PX KO and Nox4 KO mice, compared to diabetic WT. To investigate clinical significance of PX-induced H_2O_2 generation, we evaluated the level of PX expression in type II diabetic patients. Interestingly, significantly elevated levels of PX were seen in type II diabetic patients. It strongly suggests that PX is involved in renal damage in type II diabetic patients.

Conclusions: In conclusion, PX as a Nox4 regulator plays important role in progression of diabetic nephropathy.

SA-PO515

Thioredoxin-Interacting Protein (TXNIP) Promotes GAPDH Nuclear Translocation by High Glucose

Lexy (huize) Zhong,[1,2] Ling Xia,[3,2] Ivan G. Fantus.[2,1] *[1]Medicine, University of Toronto, Toronto, ON, Canada; [2]Metabolic Disorders and Complications Program (MeDiC), Montreal, QC, Canada; [3]Research Institute-McGill University Health Center(RI-MUHC), Montreal, QC, Canada.*

Background: Thioredoxin-interacting protein (TXNIP) is a multifunctional protein that regulates glucose metabolism and the cellular redox state, the latter by binding and inhibiting the endogenous antioxidant thioredoxin. TXNIP is markedly upregulated by high glucose and we previously showed that STZ-induced diabetic TXNIP-/- mice are protected from developing features of Diabetic Nephropathy (DN). The pathogenesis of diabetes complications involves the oxidative inhibition of the glycolytic enzyme GAPDH, resulting in aberrant glucose metabolism. However, nitrosylation and oxidation (N/O) of GAPDH was found in neuronal cells to cause its nuclear translocation by binding the E3 ligase Siah1, followed by activation of proapoptotic gene expression. We postulated that TXNIP would promote GAPDH N/O and nuclear translocation in HG by inhibiting redox balance.

Methods: To study TXNIP signalling in vitro, primary mesangial cells (MCs) from TXNIP+/+ (WT) and TXNIP-/- (KO) mice were cultured in normal (5mM) and high glucose (25mM; HG). GAPDH activity, GAPDH/Siah1 nuclear translocation, caspase-3 cleavage, and Bax/Bcl-2 expression were examined via immunoblotting. To test our hypothesis in vivo, STZ-induced diabetic DBA/2J mice were orally treated with deprenyl, a drug used in Parkinson's disease and shown to inhibit GAPDH-Siah1 binding, or the vehicle as a control. Structural outcomes including glomerular mesangial expansion and fibrosis, basement membrane thickening, podocyte foot process effacement, and NOX4 expression were assessed by histology. Functional outcomes such as albuminuria were assessed by ELISA.

Results: In vitro, exposure of primary cultured WT MCs to HG significantly decreased GAPDH activity, caused nuclear localization of both GAPDH and Siah1 at 24h and 48h, and increased caspase-3 cleavage and the Bax/Bcl-2 ratio at 12h and 24h, while TXNIP-/- MC showed no HG-mediated effect. In vivo, deprenyl treatment significantly reduced diabetes-induced albuminuria, glomerular mesangial expansion and fibrosis, basement membrane thickening, podocyte foot process effacement, and NOX4 expression.

Conclusions: These data suggest that GAPDH has a direct pathogenic role in DN via the GAPDH-Siah1 signalling pathway and that TXNIP is a critical modulator of this pathway that promotes DN.

L-Homoarginine Supplementation Prevents Diabetic Kidney Damage

Michael Wetzel,[1] Ting Gao,[2] Manjeri A. Venkatachalam,[1] Sidney M. Morris,[3] Alaa S. Awad.[1,2] *[1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Penn State College of Medicine, Hershey, PA; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Diabetes is the major cause of end stage renal disease, with heavy burden for the health care system. L-homoarginine (**HA**) is an endogenous, non-proteinogenic amino acid that is associated with renal and cardiovascular disease. Specifically, low HA levels are associated with cardiovascular diseases, stroke and reduced kidney function. However, the role of HA in diabetic nephropathy is unknown.

Methods: Six-week-old diabetic DBA *Ins2*^{Akita} and their controls were treated with or without HA supplementation via drinking water or mini osmotic pump for twelve weeks.

Results: Plasma and kidney HA levels were significantly reduced by 25% (p<0.05) and 65% (p<0.05) in *Ins2*^{Akita}; respectively compared to control mice. Vehicle-treated *Ins2*^{Akita} mice showed significant increases in urine albumin excretion (UAER) (p<0.01), renal histological changes (score: 1.5 vs. 0.25), glomerular macrophage recruitment (p<0.01), inflammatory KC-GRO/CXCL1 (p<0.0005), and urinary TBARS (p<0.0001); a marker of oxidative stress, along with reduction in kidney nitrate and nitrite levels (p<0.01) compared to non-diabetic controls. HA supplementation by either drinking water or osmotic pumps for 12 weeks in *Ins2*^{Akita} mice significantly reduced UAER (p<0.05), renal histological changes (score: 0.625 and 0.375), glomerular macrophage recruitment (p<0.05), KC-GRO/CXCL1 (p<0.005), and urinary TBARS (p<0.05), along with significant increase in kidney nitrate and nitrite levels (p<0.05) compared to vehicle-treated *Ins2*^{Akita} mice.

Conclusions: These data demonstrate that L-homoarginine supplementation attenuates specific features of diabetic nephropathy in mice and could be a potential new therapeutic tool for treating diabetic patients.

Parkin Accelerates Tubular Cell Senescence Through GATA4/GAS1 in Diabetic Nephropathy

Kehong Chen, Jia Chen, Yani He. *Daping hospital, Chongqing, China.*

Background: Accelerated senescence of renal tubular epithelial cell (RTEC) plays a fundamental role in the pathogenesis of diabetic nephropathy (DN). Gene mutation of Parkin, an E3 ubiquitin ligase, can accelerate neuron degeneration in familial aging-related diseases. We investigated the role of Parkin in accelerating senescence of RTEC and its mechanism.

Methods: 149 cases of patients with DN diagnosed by renal biopsy were recruited in our study. 32 normal kidney samples were obtained from renal carcinoma as control. Renal Parkin expression was detected by immunohistochemistry. In vivo, we used C57BL/6 Parkin$^{-/-}$ knockout mice, Parkin overexpression mice and wild-type controls with or without streptozotocin-induced diabetes over 5 months of follow-up. In vitro, mouse primary RTEC were exposed to high glucose (HG) for 48h. Moreover, co-immunoprecipitation and ubiquitination experiments were applied to evaluate the relationship of GATA4 with Parkin.

Results: Expression of Parkin was gradually decreased with development of tubulointerstitial injury and positively correlated with eGFR. Parkin KO+STZ mice showed significantly higher plasma BUN, SCr and urinary NAG than those in wild-type STZ mice. The degree of renal interstitial fibrosis in the STZ+Parkin overexpression group was significantly lower than that in STZ mice. The proportion of P16-positive renal tubular cells and renal P21 expression in Parkin overexpression + STZ group were significantly lower than those in STZ group. In vitro, overexpression of Parkin attenuates high glucose-induced tubular senescence and GATA4 accumulation. Parkin co-immunoprecipitated with GATA4 in renal biopsy samples of DN patients and mouse tubular cells. Furthermore, Parkin ubiquitinated GATA4 in vivo and in vitro. Parkin KO diabetic nephropathy mice have significantly higher GAS1 mRNA and protein levels in kidneys than WT mice. Overexpression of GATA4 enhanced GAS1 mRNA and protein levels in renal tubular cells. Overexpression of GAS1 can directly inhibit the expression of a key negative regulator of cell senescence, cyclin dependent kinase 2 (CDK2) and inhibit the anti-senescence effect of Parkin in mouse primary RTCs stimulated by high glucose.

Conclusions: Parkin inhibits RTEC senescence in diabetic nephropathy by inhibiting GATA4/GAS1 pathway. Parkin is a potential anti-senescence factor in the development of diabetic nephropathy.

Funding: Government Support - Non-U.S.

Tubular Secretory Clearance Is Associated with Whole-Body Insulin Clearance

Matthew P. Huber,[1] Leila R. Zelnick,[3,2] Ian H. de Boer,[2,3] Bryan R. Kestenbaum.[2,3] *[1]University of Washington, Seattle, WA; [2]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [3]Kidney Research Institute, Seattle, WA.*

Background: The kidneys eliminate insulin via glomerular filtration plus tubular reabsorption and by extraction from the basolateral surface of proximal tubule cells. The relative contributions of each mechanism are incompletely understood. We tested associations of proximal tubular secretory clearances and estimated glomerular filtration rate (eGFR) with whole-body insulin clearance.

Methods: The Study of Glucose and Insulin in Renal Disease performed the hyperinsulinemic-euglycemic clamp in 57 non-diabetic persons with CKD (eGFR <60 mL/min/1.73m^2) and 38 persons without kidney disease or diabetes (eGFR ≧60 mL/min/1.73m^2). We defined insulin clearance as the intravenous insulin infusion rate divided by the steady-state plasma insulin concentration. We measured plasma and 24-hour urine concentrations of 7 tubular secretory solutes using targeted liquid chromatography-tandem mass spectrometry. We estimated GFR using the CKD Epidemiology Collaboration equation.

Results: Mean age was 63 ± 13 years and mean insulin clearance was 924 ± 228 mL/min. After adjustment for demographics and body composition, lower eGFR and lower kidney clearances of 3 solutes were associated with lower insulin clearance accounting for multiple comparisons (Table). Lower kidney clearances of isovalerylglycine and xanthosine remained associated with lower insulin clearance after further adjustment for eGFR.

Conclusions: Lower kidney clearances of tubular secretory solutes are associated with lower insulin clearance, suggesting an important role of tubular secretory pathways in renal insulin metabolism.

Funding: NIDDK Support

Associations of kidney functions with insulin clearance

	Insulin Clearance (mL/min)

Effects of RAAS Activation on Intrarenal Inflammation and Intrarenal Hemodynamics: Results from the Canadian Study of Longevity in Type I Diabetes

Vikas Sridhar,[1] Jaya P. Ambinathan,[1] Leif E. Lovblom,[5] Yuliya Lytvyn,[1] Petter Bjornstad,[3] Bruce A. Perkins,[4] David Cherney,[1,2] Julie A. Lovshin.[4,2] *[1]Department of Medicine, Division of Nephrology, University of Toronto, Toronto, ON, Canada; [2]Banting and Best Diabetes Centre, Toronto, ON, Canada; [3]Department of Pediatrics, Division of Endocrinology, University of Colorado School of Medicine, Aurora, CO; [4]Department of Medicine, Division of Endocrinology and Metabolism, University of Toronto, Toronto, ON, Canada; [5]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada.*

Background: Inflammation and pro-fibrotic pathways are implicated in the pathogenesis of diabetic kidney disease (DKD) and are activated by chronic hyperglycemia and renin angiotensin aldosterone system (RAAS) stimulation. Quantification of urinary inflammatory markers has been used in type I diabetes (T1D) to determine renal tissue inflammation. The relationship between RAAS activation, intrarenal inflammation and hemodynamics is unknown. To study this, we measured the excretion of urine inflammatory markers and GFR in participants with longstanding T1D compared to adult comparators without diabetes following exogenous RAAS activation.

Methods: A urinary cytokine 42-plex panel adjusted for urine creatinine was analyzed from participants of the Canadian Study of Longevity in T1D of more than 50 years duration (n=74) and compared to age and sex matched adult comparators without diabetes (n=73). Renal hemodynamic function was measured using inulin and *p*-aminohippurate (PAH). Changes in urinary inflammatory marker excretion post angiotensin II (AngII) infusion were compared between comparators, and T1D participants with and without DKD (resistors). Renal hemodynamic function was correlated with urinary inflammatory markers independent of A1c, T1D duration, and systolic blood pressure.

Results: The renal hemodynamic response to AngII in this cohort has been previously published, with an attenuated response in DKD vs. DKD resistors and controls, likely signifying high baseline RAAS activation. Conversely, in this analysis, RAAS activation stimulated a significant increase in the urinary excretion of 31 inflammatory markers in both DKD and DKD resistors, compared to adults without diabetes (p<0.05). There were no differences in inflammatory marker excretion between participants with DKD and resistors. $Inulin_{GFR}$ inversely correlated with urinary excretion of proinflammatory markers (IL-18, IP-10, & RANTES), growth factor receptors (PDGF-AA & VEGFAA), and chemokines (Eotaxin & MCP-1).

Conclusions: RAAS activation was associated with increased markers of intrarenal inflammation in T1D participants with and without DKD, suggesting a consistent role for RAAS activation at the renal tissue level leading to inflammation even after longstanding T1D.

SA-PO520

ManNAc Improves Nephropathy but Worsens Hyperglycemia in Diabetic Rats by Inducing O-GlcNAcylation

Joubert B. Kharlyngdoh,[1] Maria Del Nogal Avila,[1] Ranjan Das,[1] Hector Donoro blazquez,[1] Eduardo Molina-Jijon,[1] Lionel C. Clement,[1] Camille E. Mace,[1] Carmen Avila-Casado,[2] Sumant S. Chugh.[1] *[1]Rush University Medical Center, Chicago, IL; [2]University Health Network, University of Toronto, Toronto, ON, Canada*.

Background: The sialylation inducing compound N-acetyl Mannosamine (ManNAc) improved renal function in Nephrotic syndrome rats model (Clement LC et al Nature Medicine Jan 2011). We compared the overall efficacy and side effect profile of ManNAc with another sialylation inducing compound GDT01 in diabetic rats.

Methods: MManNAc study: 5 month old ZDF male rats (n = 5 rats / group) were treated for 5 months with tap water or ManNAc in drinking water. Changes in proteinuria, BUN, creatinine, hyperglycemia and histology were assessed. GDT01 study: 5 month old male ZSF1 rats (n = 6 rats / group) were treated with plain tap water or GDT-01 over a period of 7 months. Same parameters as above were assessed. Muscle protein content of the diabetogenic sugar O-GlcNAc was assessed using 1D and 2D gel Western blots for both studies. O-GlcNAcylation occurs at the same amino acid residues as O- glycosylation and phosphorylation.

Results: ManNAc reduces proteinuria in ZDF rats significantly ($P<0.05$, $P<0.01$) when compared to water control group. The blood glucose level in ManNAc treated animals was also significantly ($P<0.05$) increased. GDT01 treated rats showed a significant reduction in proteinuria ($P<0.05$ to $P<0.01$) without any increase in blood glucose levels. Analysis of BUN and creatinine levels showed no significant changes in the ManNAc study, but improved in the treated group in the GDT01 study ($P<0.05$, $P<0.01$). In addition, renal histology was remarkably better in GDT01 treated rats. Assessment of O-GlcNAc showed increased levels in skeletal muscle in ManNAc treated rats, but no change in GDT01 treatment. This suggests that shuttling of ManNAc into O-GlcNAc induces diabetogenic changes, that negate otherwise potentially beneficial effects in treating diabetic nephropathy. It is likely that this phenomenon is noted also in non-diabetic rats, suggesting "diabetes like" side effect profile in the absence of diabetes.

Conclusions: The sialic acid precursor ManNAc is diabetogenic and should be avoided as a sialylation inducing agent. GDT01 improves diabetic CKD without being diabetogenic, and remains the preferred sialylation inducing agent

Urinary L Type Fatty Acid Binding Protein Reflects the Degree of Renal Hypoxia in Spontaneously Diabetic Torii Fatty Rats

Jun Tanabe,[1] Daisuke Ichikawa,[1] Kenjiro Kimura,[2] Yugo Shibagaki,[1] Atsuko Ikemori.[1,3] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [2]Tokyo Takanawa Hospital, Tokyo, Japan; [3]Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan*.

Background: Tubulointerstitial damage is known to be strongly associated with renal prognosis in diabetic kidney disease (DKD). Because renal hypoxia is an aggravated factor for the tubulointerstitial damage, urinary marker which is capable of detecting the renal hypoxia, is useful for monitoring the DKD. The aim of this study is to reveal the correlation between urinary liver-type fatty acid binding protein (L-FABP) and renal hypoxia using novel model of type 2 diabetes with obesity.

Methods: Male spontaneously diabetic torii (SDT) fatty rats (n =6) were used as an animal model of type 2 diabetes with obesity. Age- and sex-matched Sprague–Dawley rats (SD) (n = 8) were used as controls. Body weight, systolic blood pressure and blood glucose levels were measured at 8, 12, 16 and 24 weeks of age. Urine samples, serum and kidney tissues were obtained at 24 weeks of age. Microvascular blood flow index (BFI) in renal cortex was measured using diffuse correlation spectroscopy (DCS) before removing the kidney at 24weeks of age.

Results: Obesity, hyperglycemia and hypertension were observed in the SDT fatty rats. Mild glomerular hypertrophy and sclerosis, moderate interstitial inflammation and fibrosis, and accumulation of renal oxidative protein were significantly observed in the SDT fatty rats compared to the SD rats. While frequency of peritubular endothelial cells and phospho- endothelial nitric oxide synthase levels were similar between the SDT fatty rats and the SD rats, the degrees of renal hypoxia-inducible factor-1a expression significantly increased and renal vascular endothelial growth factor expression levels did not increase in the SDT fatty rats compared to the SD rats. Urinary L-FABP levels in the SDT fatty rats were significantly higher and renal microvascular BFIs in the SDT fatty rats were significantly lower compared to the SD rats. The levels of urinary L-FABP were significantly positively correlated with renal HIF-1a expression levels and were negatively correlated with renal microvascular BFIs.

Conclusions: Urinary L-FABP levels reflected the degree of renal hypoxia in DKD of type 2 diabetic animal model. In clinical practice, urinary L-FABP may be useful for monitoring DKD in type 2 diabetic patients as a renal hypoxic marker.

SA-PO522

A Protective Role of Renalase in Nephropathy

Feng Wang,[1] Jianyong Yin,[1] Yiwei Kong,[2] Xuanchen Liu,[1] Ting Zhao,[3] Niansong Wang.[3] *[1]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China; [2]Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China; [3]Shanghai Sixth People's Hospital, Shanghai, China*.

Background: Renalase, a recently discovered secreted flavoprotein, exerts anti-apoptotic and anti-inflammatory effects against renal injury in acute and chronic animal models. However, whether Renalase elicits similar effects in the development of diabetic nephropathy (DN) remains unclear. The studies presented here tested the hypothesis that Renalase may play a key role in the development of DN and have therapeutic potential for DN.

Methods: Renalase expression was determined in human kidney biopsies with diabetic nephropathy. The role of Renalase in the development of diabetic nephropathy were examined using Renalase heterozygous knockout mice with db/db background and db/db mice with Renalase overexpression. In addition, the effects of Renalase on high glucose induced podocytes were investigated.

Results: Renalase was downregulated in human diabetic kidneys compared with healthy controls. Our data demonstrated that Renalase heterozygous knockout resulted in elevated albuminuria and increased renal mesangial expansion in db/db mice. However, overexpression of Renalase significantly ameliorated renal injury in db/db mice. Renalase could inhibit high glucose-induced podocyte injury in vitro.

Conclusions: This study suggested that Renalase protected against the progression of DN and Renalase may represent as a novel therapeutic target for the treatment of DN.

SA-PO523

The Role of ABCA1 on the Glomerular Lipid Accumulation and Renal Injury in Diabetic Kidney Disease

Jimin Park,[1] Seonghun Kim,[1] Boyoung Nam,[1] Tae-Hyun Yoo.[2] *[1]Yonsei University, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea*.

Background: Glomerular lipid accumulation is one of the pathologic characteristics of diabetic kidney disease (DKD). Recent evidences suggested that ATP-binding cassette transporters A1 (ABCA1) has a particular effect on the cellular lipid homeostasis. We aimed to evaluate the role of ABCA1 on the lipid accumulation in glomeruli and podocyte under the diabetic conditions.

Methods: *In vitro,* mouse podocytes were stimulated with high glucose (HG) and palmitic acid (PA), and treated an GW683965, agonist of ABCA1. In vivo, C57BL/6 and ABCA1 knockout (KO) mice were maintained with high fat diet for 12 weeks with low dose streptozocin intraperitoneal injection. GW683965 was administered via osmotic pump in *db/m* or *db/db* mice. Urinary albumin-to-creatinine ratio (ACR), total cholesterol and triglyceride in kidney tissues were measured. RhoA activity and BODIPY 493/503 staining were performed in the kidney. Foot process effacement in glomeruli was evaluated by transmission electron microscopy. Apoptosis, mitochondrial morphology and energy metabolic key enzymes were evaluated both *in vitro* and *vivo*.

Results: Blood glucose, ACR, serum cholesterol and triglyceride were significantly increased and foot process effacement was prominent in diabetic mice. These changes were exaggerated in the ABCA1 KO mouse with diabetes, whereas abrogated by GW683965 treatment. Renal cholesterol and triglyceride contents were higher in ABCA1 KO mice with diabetes or lower in GW683965 treated mice than those in control and diabetic mice. Mitochondrial morphology and the expression of energy metabolic enzymes were changed in the kidneys of diabetic ABCA1 KO mice or GW683965 treated mice. In vitro, the intracellular lipid contents were increased and apoptosis combined with mitochondrial swelling and crista disruption were also increased in podocytes with HG and PA stimuli. All of these changes were ameliorated through GW683965 treatment.

Conclusions: These findings suggest that ABCA1 plays an important role in the glomerular lipid accumulation and renal injury under diabetic conditions and that ABCA1 can be a promising therapeutic target in patients with DKD.

Intrarenal Enhancement of Leucine-Rich α-2-Glycoprotein-1 in the Early Stage of Diabetic Nephropathy

Hiromichi Wakui,[1] Tomohiko Kanaoka,[1] Shingo Urate,[2] Kengo Azushima,[3] Takayuki Yamada,[1] Takahiro Yamaji,[2] Kotaro Haruhara,[4] Kohji Ohki,[2] Kazushi Uneda,[1] Ryu Kobayashi,[2] Sho Kinguchi,[1] Yoshiyuki Toya,[1] Kouichi Tamura.[2] *[1]Yokohama City University, Yokohama, Japan; [2]Yokohama City University Graduate School of Medicine, Yokohama-shi, Kanagawa-ken, Japan; [3]Duke-NUS Medical School, Singapore, Singapore; [4]The Jikei University School of Medcine, South Yarra, VIC, Australia*.

Background: Abnormal angiogenesis plays a major role in the development of early stage diabetic nephropathy. Vascular endothelial growth factor (VEGF) is a classical proangiogenic factor that regulates abnormal glomerular angiogenesis linked to glomerular hypertrophy in the early stage of diabetic nephropathy. Very recently, Leucine-rich α-2-glycoprotein-1 (LRG1), a novel proangiogenic factor expressed in endothelial cells, has been reported to be involved in the development of diabetic nephropathy. The aim of this study was to compare glomerular expression of the classical proangiogenic factor VEGF and novel proangiogenic factor LRG1 in the early stage of diabetic nephropathy.

Methods: We investigated intrarenal expression of VEGF and LRG1 in a mouse model of diabetes (*db/db* mouse) by immunohistochemistry and a laser capture microdissection method, and compared the changes in expression at 16 and 24 weeks of age to evaluate their association with diabetic nephropathy development.

Results: At 16 weeks, diabetic *db/db* mice exhibited glomerular hypertrophy with abnormal angiogenesis characterized by endothelial cell proliferation, which was concomitant with an increase in LRG1 expression of glomerular endothelial cells. However, glomerular VEGF expression was not increased at this early stage. At 24 weeks, the features of early diabetic nephropathy in *db/db* mice had developed further, along with further enhanced glomerular LRG1 expression. At this late stage, glomerular VEGF and fibrosis related-gene expression was also significantly increased compared with nondiabetic *db/m* mice.

Conclusions: These results suggest that LRG1 plays a pivotal role in the initial development of diabetic nephropathy by promoting abnormal angiogenesis, thereby suggesting that LRG1 is a potential preemptive therapeutic target of diabetic nephropathy.

Deletion of Endothelial Nitric Oxide Synthase in BTBR ob/ob Mice Enhances Mesangiolysis and Worsens Diabetic Nephropathy

Xianwu Li, Kelly L. Hudkins, Alexander L. Holland, Shreya Swaminathan, Charles E. Alpers. *University of Washington, Seattle, WA.*

Background: Leptin receptor deficient *db/db* mice with endothelial nitric oxide synthase (eNOS) deficiency and leptin deficient BTBR *ob/ob* mice have been useful models of moderately advanced diabetic nephropathy (DN). eNOS is essential for maintaining integrity and health of endothelial cells and podocytes. We postulated eNOS deficiency in BTBR *ob/ob* mice would exacerbate the severity of DN, allow testing of whether intact eNOS is essential or not to enable regression of DN with leptin replacement.

Methods: CRISPR/Cas9 was used to delete eNOS in BTBR *ob* +/- heterozygous mice. The resultant BTBR *ob* +/- /eNOS-/-mice were crossed to obtain BTBR *ob/ob*/ eNOS-/- homozygous mice (eNOS *ob/ob*), and control BTBR wt eNOS-/- mice (eNOS BTBR). At 18 weeks, fasting glucose levels and timed (6 hour) urine samples were collected. The mice were then euthanized, and blood, urine and tissue samples collected.

Results: eNOS *ob/ob* mice exhibited robust hyperglycemia (517.5 mg/dl) and a marked increase in urine albumin-creatinine ratio (ACR) (791.9 vs 172.3 ug/mg in eNOS BTBR, $p < 0.01$). Compared to control mice, eNOS *ob/ob* mice had significantly higher mesangial matrix accumulation (29.5% vs 15.9%, $p < 0.01$, assessed as fraction of collagen IV staining of glomerular tuft area). Silver methenamine stain revealed striking mesangiolysis, affecting 31.1% of glomeruli in eNOS *ob/ob* vs. 9.5% in control mice ($p < 0.01$). Podocyte density decreased in eNOS ob/ob compared to control mice (90.5 vs 149.8 podos/x10^6 um^3, $p < 0.01$). In addition, significantly higher amounts of urinary 8OHdG (a DNA/RNA marker of oxidative stress) were detected in eNOS *ob/ob* mice than in control mice (511.2 vs 35.9 ng/mg creatinine, $p < 0.05$).

Conclusions: BTBR *ob/ob* mice with further knockout of eNOS exhibit dramatic albuminuria, reduced podocyte density, mesangial expansion and more extensive mesangiolysis than is featured in other models of murine DN including BTBR *ob/ob* mice of similar age. These characteristics more closely resemble advanced human DN. This mouse model could be useful for the development of drugs targeting mesangiolysis as well as for understanding the pathogenesis of DN.

Low Expression of Autophagy-Related Protein 5 (ATG5) Leads to Suppression of Autophagy in Patients with Diabetic Nephropathy and Retinopathy

Rola Nakhoul,[4] Nakhoul Nakhoul,[1,2] Farber Evgeny,[1,2] Farid M. Nakhoul,[3,2] Remah Abass.[1,2] *[1]Baruch padeh Poriya Medical center, Lower Galilee, Israel; [2]Nephrology & diabetes and metabolism Lab, Lower Galilee, Israel; [3]Azrieli faculty of Medicine, Lower Galilee, Israel; [4]Szeged Faculty of Medicine, Szeged, Hungary.*

Background: Autophagy is a catabolic mechanism that involves lysosomal-dependent degradation of unnecessary or dysfunctional intracellular components, plays role in diabetic nephropathy (DN) and retinopathy (DR). ATG5 is one of the most important participants in the autophagy mechanism. Our study's aim was to investigate if aberrant expression of ATG5 protein/ *Atg5* gene is associated with DN or DR.

Methods: The study included 120 human participants in 4 groups – Healthy, diabetic (DM), DN and DR; 10 mice in 2 groups – healthy and DN. Western blot analyses of ATG5 and its downstream collaborator LC3-II were performed on human white blood cell lysates and murine renal lysates. Immunohistochemical analysis was performed on mice renal tissues. qRT-PCR analysis of ATG5 was performed on total mRNA isolated from human WBC.

Results: 1. ATG5 protein expression was decreased in DM patients, with and without complications [0.66 ± 0.06 A.U in DM patients (n=30) $p < 0.01$), 0.62 ± **0.06** A.U in DN, (n=30) $p<0.001$), 0.67± 0.05 A.U in DR patients (n=30) $p<0.01$)], compared with the healthy control 0.97 ± 0.04 A.U. **2. A** 2.5-fold decrease in the percentage of ATG5-stained areas in the PCT of DN mice (4.42 ± 1.08%) compared with W.T mice (10.87 ± 1.01%). **3.** The expression of *Atg5* gene between the groups by qRT-PCR analyses: in the DN (0.0069 ± 0.0005) and DR patients (0.0069 ± 0.0004) was down regulated at the mRNA levels, compared with healthy controls (0.0083 ± 0.0008). **4. Decreased** LC3-II levels in DM patients (0.50 ± 0.04 A.U (n=18) $p < 0.001$) DN patients (0.44 ± 0.05 A.U, (n=19) $p < 0.001$) and DR patients (0.43 ± 0.05 A.U (n=18) $p < 0.001$) compared with the healthy control (0.81 ± 0.05 A.U (n=19). 5. The renal LC3-II protein expression was found to be greatly decreased in the tubules of DN mice when compared with W.T mice.

Conclusions: 1. ATG5, as well as its downstream collaborator LC3-II, are down-regulated in DN & DR patients, which contributes to deficiencies in autophagy process. 2. Impairment of this process can lead to accumulation of abnormal proteins and molecules that can lead to the development and progression of DN &DR. 3. Therapeutic potential of ATG5 modulations as a novel treatment strategy for DN/DR patients through the autophagy mechanism may serve as a goal in the development of drugs for diabetic complications.

Semicarbazide-Sensitive Amine Oxidase (SSAO) Inhibition Ameliorates Albuminuria and Glomerulosclerosis but Does Not Significantly Improve Tubulointerstitial Fibrosis in Diabetic Nephropathy

May Y. Wong,[1] Muh Geot Wong,[1] Amgad Zaky,[1] Anthony J. Gill,[2] Carol A. Pollock,[2] Sonia Saad.[1] *[1]Kolling Institute of Medical Research, St Leonards, NSW, Australia; [2]University of Sydney, St Leonards, NSW, Australia.*

Background: SSAO is an enzyme known for its dual function in mediating inflammation and reactive oxygen species production. However, the role of SSAO inhibitors in chronic kidney disease is unclear. We aimed to determine the effectiveness of a SSAO inhibitor (PXS4728A) as an antifibrotic agent using a diabetic model of chronic kidney fibrosis.

Methods: A streptozotocin-induced diabetic model in male $eNOS^{-/-}$ mice on a C57BL/6 background. Diabetic mice were treated with SSAOi for 24 weeks and outcomes compared with untreated diabetic mice and telmisartan treated animals as a comparator of current standard of care.

Results: Albuminuria, the extracellular matrix marker fibronectin, inflammatory marker expression of CD45 and oxidative stress, assessed by nitrotyrosine staining, were lower in diabetic mice treated with SSAOi compared with untreated diabetic mice. Glomerulosclerosis was reduced to a greater extent by SSAOi compared to telmisartan.

Conclusions: The effect of SSAO inhibition in diabetic mice resulted in a significant reduction in inflammation, oxidative stress, glomerulosclerosis and associated albuminuria compared to untreated diabetic mice. However, the effect of SSAOi was less obvious in the tubulointerstitial compartment than in the glomeruli. Therefore, SSAOi may be a potential target for diabetic glomerulosclerosis.

Parameters of studied animals

n=6-8	Control	Control + SSAOi	DM	DM+ SSAOi	DM + Telmi	DM+ Telmi+ SSAOi
Fasting Blood glucose level (mmol/L)	9.5±0.44	10.2±0.41	20.0±0.60*	20.7±0.77*	24.2±1.06*	20.2±1.0*
HbA1c (%)	4.3±0.05		7.0±0.26*	7.1±0.49*	7.7±0.40*	7.9±0.44*
Weekly Insulin requirement (IU)			0.1±0.05	0.04±0.02	0.3±0.09	0.1±0.04

Chloride Channel Accessory 1 (CLCA1)-TMEM16A-Chloride Current Axis: A Novel Kidney Injury Pathway in Aging and Diabetes

Hak Joo Lee,[1] Yuyang Sun,[1] Andrew Donati,[1] Christopher G. Kevil,[2] Adam Salmon,[1] Muniswamy Madesh,[1] Goutam Ghosh-Choudhury,[1] Brij Singh,[1] Kumar Sharma,[1] Balakuntalam S. Kasinath.[1] *[1]University of Texas Health San Antonio, San Antonio, TX; [2]LSU Health Shreveport, Shreveport, LA.*

Background: CLCA1 activates TMEM16A, a Ca^{++}-dependent chloride channel. RNA Seq showed increased expression of CLCA1 in renal cortex of old vs. young mice. We have reported that renal changes in aging and diabetes are associated with deficient generation of hydrogen sulfide (H_2S) (Lee, 2012, Lee, 2018). We studied role of CLCA1 in kidney injury in aging and diabetes.

Methods: We employed young and aging mice (n=10 per group). We also studied aging mice treated with (n=20) or without sodium hydrosulfide (NaHS) (n=14), a source of H_2S. Diabetic db/db mice with littermate controls (n=3 per group) were studied after being treated with or without NaHS. We overexpressed human CLCA1 (hCLCA1) in proximal tubular epithelial MCT cells.

Results: In aging mice renal CLCA1 expression was increased but not TMEM16A in association with mTORC1 activation, senescence associated secretory phenotype (SASP, consisting of increase in p53, p21, p16, IL-1and IL-6), albuminuria and fibrosis; all these were ameliorated by NaHS administration. Overexpression of hCLCA1 in MCT cells resulted in increase in chloride current by patch clamp, mTORC1 activation, induction of SASP and increase in matrix protein fibronectin. TMEM16A inhibitor and NaHS individually abolished these changes. In diabetic mice renal cortical expression of CLCA1 and TMEM16A was increased in association with mTORC1 activation, SASP, albuminuria, and matrix increase; these changes were ameliorated by NaHS. In MCT cells, high glucose augmented renal cortical expression of CLCA1 and TMEM16A. siRNA against CLCA1 and TMEM16A individually abolished high glucose-induced fibronectin and collagen 1 protein increase. Patch clamp showed high glucose increased chloride current that was abolished by NaHS and TMEM16A inhibitor.

Conclusions: Renal cortical H_2S deficiency in aging and diabetes is associated with increased CLCA1 expression; it is ameliorated by H_2S administration. Overexpression of hCLCA1 activates chloride current, mTORC1, induces SASP and matrix protein increase in renal cells. High glucose induced mTORC1 and matrix increase requires activation of CLCA1-TMEM16A-chloride current. These data suggest that CLCA1-TMEM16A-chloride current pathway is a novel contributor to kidney injury in aging and diabetes.

Redosing of Dysglycemic, Diabetic Mice with Neo-Islets, Aggregates of Adipose Stem Cells and Pancreatic Islet Cells, Achieves Euglycemia: Relevance to the Therapy of Diabetic Dogs

Christof Westenfelder,[2,1] Anna Gooch.[1] *[1]Research, SymbioCellTech, Salt Lake City, UT; [2]University of Utah School of Medicine, Salt Lake City, UT.*

Background: We demonstrated that allogeneic, ip administered "Neo-Islets" (NIs), aggregates of cultured islet cells and immune- and cyto-protective Adipose Derived Stem Cells, reestablished durable normoglycemia through omental engraftment and splenic and omental upregulation of Tregs, in autoimmune T1DM NOD mice without immunosuppressive agents (*SCTM* 2017;6:1631). Similarly, our FDA pilot study in insulin dependent pet dogs (INAD 012-0776) demonstrates that allogeneic NI therapy (i) is effective in significantly improving both glycemic control and the need for insulin (> 1 year); and (ii) does so without eliciting an allo-immune response (see abstract this session). Because the need for insulin is not eliminated in dogs, the current study was conducted to test whether redosing, independent of modulating an allo-immune response, is effective in further reducing the need for insulin. Redosing was therefore tested using Streptozoticin-diabetic (STZ) NOD/SCID mice.

Methods: Blood glucose levels were initially controlled with insulin pellets (Linbits) in 12 STZ-diabetic mice prior to i.p. NI or vehicle treatment (2x10e5 NIs/kg bw) (n=6 per group). Mice were followed (blood glucose; weight, ip Glucose Tolerance Test [GTT]) for ~8 weeks.

Results: No mice in the treated group died vs. 4 controls. NI therapy significantly improved glycemic control without achieving euglycemia vs controls x50 days. Therefore, on day 60, mice were redosed and followed as detailed above. This second dose of normalized both blood glucose levels and GTTs.

Conclusions: We conclude that these data support the planned redosing of dogs whose need for insulin has been reduced but not eliminated through allogeneic NI treatment, as initial allogeneic treatment of these dogs failed to elicit an immune response. We expect that doing so may lead to insulin independence, i.e., in analogy to islet transplant recipients who require several doses of islets but who are, however, treated with anti-rejection drugs.

SA-PO530

Allogeneic "Neo-Islets" Composed of Adipose-Derived Stem and Islet Cells Durably Reduce Diabetic Pet Dogs' Insulin Needs Without Requiring Immunosuppression (INAD 012-776)

Anna Gooch,[2] Christof Westenfelder.[1,3] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]Research, SymbioCellTech, Salt Lake City, UT; [3]Research, SymbioCellTech, Salt Lake City, UT.*

Background: We demonstrated that allogeneic, ip administered "Neo-Islets" (NIs), aggregates of cultured islet cells (ICs) and immune- and cyto-protective Adipose Derived Stem Cells (ASCs), reestablished durable normoglycemia through omental engraftment and splenic and omental upregulation of Tregs, in autoimmune T1DM NOD mice without immunosuppressive agents (*SCTM* 2017;6:1631). Comparable euglycemia was achieved with dog- or human-derived NIs in STZ-diabetic NOD/SCID mice. Here we update our report on an FDA supervised study using NI therapy in diabetic pet dogs.

Methods: Insulin dependent, diabetic pet dogs were included; 8 enrolled; 6 treated; and 4 followed for ≥ 6 mos. Pre-treatment serum samples were tested for islet autoantibodies. Comorbidities and blood glucose levels were treated. Allogeneic NIs were given once ip (2.5x10e5/kg bw). No encapsulation or antirejection agents were used. Blood glucose levels, insulin need and antibody responses were monitored.

Results: Prior to treatment 3 dogs had islet autoantibodies indicating autoimmunity. NIs appear to engraft, redifferentiate and physiologically produce insulin, and are neither rejected by auto- or allo-immune attacks, as evidenced by (i) an absent IgG response to the administered NIs, and (ii) progressively, durably (≥ 12 mos) and improved glycemic control, achieved with an up to 50% reduction in daily insulin need paralleled by a fall in serum glucose (See Figure). No adverse events attributable to therapy have been observed to date. While no dog has achieved insulin independence, preclinical results using human NIs indicate that redosing could accomplish this.

Conclusions: Allogeneic NI therapy is feasible, safe, and durably effective. We conclude that this therapy has significant translational relevance for dog and human T1DM.

Funding: Commercial Support - SymbioCellTech, LLC

Hyperglycemia Reduced DUSP4 Expression Leads to JNK MAPK Activation, Increased NOX4 Expression, and Insulin Resistance in Podocytes and Diabetic Nephropathy

Marina Rousseau,[1] Benoit Denhez,[1] Farah Lizotte,[1] Pedro M. Geraldes.[2] *[1]University of Sherbrooke, Compton, QC, Canada; [2]University of Sherbooke, Sherbrooke, QC, Canada.*

Background: Podocyte dysfunction is an early event in the development of diabetic nephropathy (DN) with multiple causes including insulin resistance and increased oxidative stress (ROS via NOX4) which lead to the activation of p38 and JNK MAPK pathways. A previous study has shown that JNK activation leads to serine 307 (ser307) phosphorylation of IRS1 (inhibitory phosphorylation) in insulin-resistant ob/ob mice. Our laboratory recently reported a decrease in the expression of DUSP4, a dual specificity phosphatase known to inhibit the MAPKs, which was associated with elevated JNK activation and NOX4 expression in podocytes exposed to high glucose. Thus, we hypothesized that hyperglycemia-induced DUSP4 expression reduction leads to insulin resistance in podocytes and DN via JNK activation and NOX4 expression.

Methods: Cultured podocytes were exposed to normal (5.6 mM) or high (HG; 25 mM) levels of glucose for 72h with either an overexpression of DUSP4 (adenovirus) or an inhibition of JNK (JNK inhibitor SP600125). *In vivo*, insulin injection was performed 15min prior to euthanasia where renal cortex was extracted from nondiabetic and diabetic ($Ins2^{+/C96Y}$) mice, with or without a deletion of DUSP4 ($Dusp4^{-/-}$).

Results: Podocytes exposed to HG showed reduced DUSP4 expression, increased JNK activation and increased ser307 phosphorylation of IRS1, which contributed to a decrease in the phosphorylation of Akt after insulin stimulation. Both DUSP4 overexpression and JNK inhibition blocked ser307 phosphorylation of IRS1 induced by HG and reestablished downstream insulin signaling cascade (tyrosine 612 phosphorylation of IRS1 and Akt phosphorylation). HG reduced DUSP4 expression was prevented using antioxidant N-acetyl cysteine and HG increased NOX4 expression was diminished with DUSP4 overexpression

and JNK inhibition in podocytes. *In vivo*, DUSP4 reduction in renal cortex of *Ins2*$^{+/C96Y}$ mice correlated with JNK activation, increased ser307 phosphorylation of IRS1 and reduced Akt phosphorylation, reduction exacerbated in *Ins2*$^{+/C96Y}$ mice deficient for DUSP4.

Conclusions: HG induced JNK activation by reduced DUSP4 expression mediates an increase in the production of ROS via NOX4 as well as insulin resistance in DN.

SA-PO532

Transgenic LPA Expression Does Not Exacerbate Albuminuria in Diabetic Mice

Amal O. Dadi,[2] Jennie Lin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL.*

Background: Lipoprotein(a) [Lp(a)] is a unique primate-specific and liver-specific lipoprotein consisting of a low-density lipoprotein molecule covalently bonded to an apo(a) protein. Genetically elevated circulating Lp(a) has been identified as an independent causal risk factor for developing coronary heart disease and stroke. We previously showed in a cross-sectional study of patients with type 2 diabetes mellitus that elevated baseline Lp(a) associates with steeper eGFR decline, although no causal link has been firmly established. Here we describe kidney phenotypes resulting from transient adenovirus-induced expression of two different Lp(a) isoforms in diabetic mice.

Methods: In 26-week old DBA/2J mice fed a high-fat diet for 14 weeks, we induced transient liver-specific expression of Lp(a) (truncated or full-length isoform) by adenovirus delivery under a TBG promoter. These sizes were tested due to the proposed role of isoform size in altering Lp(a) plasma concentrations. Plasma and urine samples were serially collected and assayed for metabolic analytes.

Results: Within seven days of adenovirus injection, mice receiving plasmid encoding the truncated LPA isoform or the full-length isoform had robust induction of circulating Lp(a) compared to mice receiving the null plasmid control (1693 +/- 714.3 mg/dL and 207.8 +/- 132.4 mg/dL, respectively, vs. < 6 mg/dL). Baseline mean fasting glucose, blood urea nitrogen, and urinary albumin to creatinine ratios (ACR) were 206.4 mg/dL, 20.3 mg/dL, and 202.9 ug/mg, respectively. Although all mice had increased urinary ACR 4 days post-adenoviral injection, no significant increases in urinary ACR for LPA-expressing mice were seen on days 2, 4, 6, and 7. Consistent with this result, we also did not observe changes in BUN between the LPA-expressing mice and control. No structural differences were observed on histology of kidneys collected 7 days after injection.

Conclusions: Taken together, our results suggest that transient overexpression of Lp(a), does not induce significant worsening of renal function in the short-term. Further studies are needed establish whether a more significant causal effect would be observed with chronic overexpression.

SA-PO533

Clinicopathological Features of a Rapid Decliner in Diabetic Nephropathy

Kengo Furuichi,[1] Miho Shimizu,[2] Tadashi Toyama,[2] Hitoshi Yokoyama,[2] Takashi Wada.[2] *[1]Kanazawa Medical University, Kahoku-Gun, Japan; [2]Kanazawa University, Ishikawa, Japan.*

Background: Declining speed of kidney function in diabetic nephropathy is different in each case. It is well known that there are characteristic groups; “rapid decliner” and “no or slow decliner”. Although, many studies of kidney prognosis and cardiovascular events in cases of diabetic nephropathy have been reported, clinical and pathological features of these groups are unclear so far.

Methods: Biopsy proven 600 diabetic nephropathy cases were enrolled in this study. Among them, 385 cases were able to calculate the eGTR decline speed 3 years after kidney biopsy. The cases were classified into 4 groups in accordance with the eGFR declining speed. The first quartile, that is the fastest declining speed group, contains 97 cases, and the fourth quartile, that is the slowest declining speed group, contains 96 cases. Clinical data and kidney biopsy data of these two groups were evaluated. The pathological findings (Nine glomerular lesions, two interstitial lesions, and two vascular lesions) were followed by the previous paper (Nephrol Dial Transplant. 2018;33:138-148).

Results: Declining speed op the first quartile group (rapid declining) was 13.9 mL / min / 1.73 m 2 / year or more (median 21.3), and that of the fourth quartile (slow declining) group was 1.9 mL / min / 1.73 m 2 / year or less (median -1.96). The incidence of renal composite events and renal deaths, 40.0 and 4.6 (100 persons / year) in the first quartile, and 3.12 and 0.5 in the fourth quartile, respectively. In background analysis at biopsy, ten pathological factors and three clinical factors were statistically difference between two groups. Using multivariate logistic analysis showed that three pathological factors (nodular lesion, mesangiolysis, and polar vasculosis) and one clinical factor (urinary albumin) were statistically significant, and odds ratio of these factors were 4.4, 3.0, 6.9 and 4.0, respectively. We evaluate the cohort with tertile, in the same way of the quartile as the tertile. The result of tertile analysis an almost similar to the results of quartile.

Conclusions: Through this analysis, large amounts of urinary albuminuria, and three pathological findings (nodular lesion, mesangiolysis, and polar vasculosis) were characteristic features of patients with rapid kidney function declining.

Diversity of Biopsy-Proven Kidney Diseases in Japanese Patients with Diabetic Kidney Disease

Satoshi Inotani,[2] Taro Horino,[1] Yoshiko Shimamura,[1] Shimpei Fujimoto,[2] Yoshio Terada.[1] *[1]Kochi Medical School, Kochi University, Kochi, Japan; [2]Kochi University, Nankoku, Japan.*

Background: Diabetic kidney disease (DKD), including diabetic nephropathy (DN), is the leading cause of chronic kidney disease worldwide including Japan. However, there is also increasing recognized diagnosis of non-diabetic renal diseases (NDRD) in diabetic patients, which may influence in the different treatments and outcomes. This study reported the spectrum and clinical characteristics of NDRD and NDRD superimposed DN in Japanese diabetic population.

Methods: Clinical data of the diabetic patients with aged > 18 years undergone kidney biopsy in Kochi Medical School hospital during 2001-2017 were collected. These data including the and laboratory data together with renal biopsy pathological findings.

Results: The 165 from 872 patients were recruited in this study; 108 cases were male (65.4%). The mean age was 61.1±1.1 years, and the median serum creatinine was 1.86 mg/dL (0.96-2.76). The 48 cases (29.0%) were diagnosed NDRD, while 50 cases (30.3%) were diagnosed NDRD superimposed DN. The rest of the patients were diagnosed isolated diabetic nephropathy; DN (40.6%). IgA nephropathy was either the most prevalent glomerular disease in NDRD (39.5%) and NDRD superimposed DN (34.0%). The second and third kidney biopsy findings in NDRD were lupus nephritis (18.7%), membranous nephropathy (12.5%), respectively. In NDRD superimposed DN, membranous nephropathy (18.0%), and ANCA associated vasculitis (14.0%) were the second and third pathological findings. The serum creatinine levels were higher in DN than in NDRD and NDRD superimposed DN (2.47 mg/dL, 1.25 mg/dL, and 1.63 mg/dL, respectively). Nephrotic syndrome was more common in NDRD superimposed DN, following DN and NDRD (38.0%, 37.3%, and 31.2%, respectively, $p<0.05$). Moreover, the quantity of proteinuria was found to be higher in DN and NDRD superimposed DN than in NDRD (4.0, 3.2, and 2.8 g/gCr, respectively, $p<0.05$).

Conclusions: This study disclosed the diversity and prevalence of NDRD that was diagnosed in almost 60% of DKD in Japanese diabetic patients. Presence of nephrotic syndrome was the more suggestive diagnosis of DN or NDRD superimposed DN. Kidney biopsy is the important means for the definite diagnosis and the proper treatment of glomerular disease in diabetic patients.

SA-PO535

Synergistic Effects of Glomerular Lesion and Interstitial Lesion on Increased Proteinuria But Not on Renal Prognosis

Masahiro Eriguchi,[1] Takaaki Kosugi,[1] Masatoshi Nishimoto,[1] Hideo Tsushima,[1] Kaori Tanabe,[1] Katsuhiko Morimoto,[3] Masaru Matsui,[2] Miho Tagawa,[1] Ken-ichi Samejima,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kashihara, Japan; [2]Nara Prefecture General Medical Center, Nara, Japan; [3]Nara Prefecture Western Medical Center, Ikoma-gun, Nara, Japan.*

Background: Diabetic kidney disease (DKD), a recently proposed concept, is associated with various proteinuria level and heterogeneous renal prognosis; however, these patients are rarely examined by renal biopsy. We have biopsy-proven diabetic nephropathy (DN) cohort including many patients with relatively mild proteinuria. That encouraged us to examine the association between histological findings and variation in proteinuria level and renal prognosis in DKD.

Methods: This is a longitudinal study of 396 adults with biopsy-proven DN from 1981 to 2014. Predictors were renal pathological findings. DN was evaluated by two renal pathologists according to 13 histological findings (9 glomerular lesions, 2 tubulointerstitial lesions and 2 vascular lesions). Cross-sectional association with proteinuria level was examined with multivariable general linear model and two-way analyses of covariate and variance, and longitudinal association with renal prognosis was examined with Cox regression model.

Results: Median proteinuria level was 0.5 g/day (25th and 75th percentile: 0.2 and 2.6 g/day) at the time of renal biopsy. During mean follow-up of 9.7 years, 99 patients reached end-stage kidney disease (ESKD). Among thirteen histological findings, nodular lesion (NL) and interstitial fibrosis and tubular atrophy (IFTA) were significant predictors for proteinuria levels after adjustment for clinical risk factors. Among patients with NL or >25% IFTA, 31% of patients had only IFTA and 20% had only NL. NL and IFTA had a synergetic effect on increased proteinuria after adjustment with clinical parameters (p for interaction=0.07). Cox regression analysis showed NL and IFTA were significantly associated with a development of ESKD but there was not a synergetic effect on renal prognosis between these two factors (p for interaction=0.94).

Conclusions: These data suggest the fluctuation in the balance between glomerular and interstitial damages could interpret various degrees of proteinuria and heterogeneous renal prognosis in DKD.

Implications of Solidified Glomerulosclerosis and Extracapillary Hypercellularity in Chinese Patients with Type 2 Diabetes and Diabetic Nephropathy

Lijun Zhao,[1] Fang Liu,[1] Lin Li.[2] *[1]Division of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China, Chengdu, China; [2]Division of Pathology, West China Hospital of Sichuan University, Chengdu, China.*

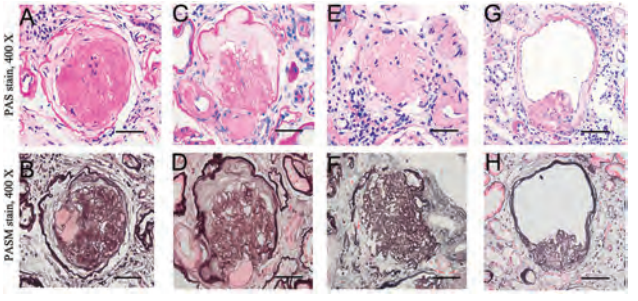
Background: This study was aimed to determine nephropathologic markers for time to end-stage renal disease (ESRD) in Chinese patients with type 2 diabetes and diabetic nephropathy (DN).

Methods: This retrospective cohort study recruited 322 Chinese type 2 diabetic patients from 2003 to 2017 with biopsy-proven diabetic nephropathy who received follow-up over 12months. All kidney biopsy specimens were fully assessed under a uniform scale. Competing risk models with death as the competing risk was used to estimate the sub-distribution hazard ratios (SHRs) for ESRD.

Results: During a median follow up of 26.0 months, 144 (44.7%) patients progressed to ESRD and 17 (5.3%) patients died before entering ESRD. Global glomerulosclerosis was further separated into three categories: solidified glomerulosclerosis (Figure 1 A-B), ischemic obsolescent glomerulosclerosis (Figure 1 C-D) and not otherwise specified glomerulosclerosis (Figure 1 E-H). Pathological parameters in Renal Pathology Society system were associated with ESRD in univariate analysis but failed to predict ESRD in multivariable models. After adjusting for parameters of demographics, baseline kidney functions, nutritional status, and medications in the multivariable model, solidified glomerulosclerosis and extracapillary hypercellularity (SHR, 1.77; 95% CI, 1.11-2.80; and SHR, 2.48; 95% CI, 1.58-3.90, respectively) were identified as risk factors for ESRD. Moreover, patients in RPS class III with a higher proportion of solidified glomerulosclerosis had a lower 5-year renal survival rate than class IV.

Conclusions: In Chinese type 2 diabetic patients with DN, solidified glomerulosclerosis and EXHC were prognostic indicators for ESRD. Solidified glomerulosclerosis contributed partly to the worse renal outcome of patients in class III.

Funding: Government Support - Non-U.S.



A-B, Solidified glomerulosclerosis. **C-D,** Ischemia obsolescent glomerulosclerosis. **E-F,** One type of not otherwise specified glomerulosclerosis. **G-H,** Another type of not otherwise specified glomerulosclerosis. Bar= 50 μm.

SA-PO537

Association Between Renal Fibrosis and Early Renal Decline in Type 2 Diabetes

Katsuhito Ihara,[1,2] Jan Skupien,[3] Kristina V. O'Neil,[1] Jonathan M. Wilson,[4] Kevin L. Duffin,[4] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]Medicine, Harvard Medical School, Boston, MA; [3]Jagiellonian University Medical College, Krakow, Poland; [4]Eli Lilly and Company, Indianapolis, IN.*

Background: The association between fibrosis and early progressive renal decline in diabetes is unclear. Recently, MMP-7 (Matrilysin) and WFDC2 (WAP four-disulfide core domain protein 2) were postulated to be markers of renal fibrosis. We hypothesized that renal fibrosis may be involved in early renal decline in type 2 diabetes (T2D).

Methods: Patients for this nested case-controls study were selected from among those participating in the 2nd Joslin Kidney Study with T2D, CKD stage 1 and 2, and normo-/microalbuminuria at enrollment. Patients were followed for 6-12 years. The primary outcome was eGFR decline defined as eGFR slope ≤-5 mL/min/1.73m^2/year. We developed the fibrosis index by integrating serum and urinary MMP-7 and plasma WFDC2 into a predictive probability model of renal decline using logistic regression, after verifying that these markers were not highly correlated between each other. To estimate the effect of fibrosis index on eGFR decline, multivariable logistic regression was applied adjusting for eGFR, ACR, plasma TNF-R1, plasma KIM-1, and urinary EGF/MCP-1 ratio at baseline. The markers included in our model were based on our previous prediction model (Nowak et al. Kidney Int 2018).

Results: One hundred sixty patients were enrolled. Median age was 57.5, 43.1% were women, 75.6% were Caucasian, median HbA_{1c} was 7.7%, and median duration of diabetes was 10.0 years. eGFR and ACR at baseline were 97.0 mL/min/1.73m^2 and 24.1 mg/g, respectively. One hundred patients experienced eGFR decline, and 60 were non-decliners. In comparison with non-decliners the group of eGFR decline at baseline had elevated plasma TNF-R1, KIM-1, WFDC2, serum and urinary MMP-7, whereas urinary EGF/MCP-1 ratio was decreased. Quartile change of the fibrosis index was significantly associated with eGFR decline [odds ratio (OR) 2.04; 95% confidence interval (CI) 1.38-3.03] and was consistent in patients with normoalbuminuria (OR 5.18; 95% CI 2.00-13.41) and microalbuminuria (OR 2.33; 95% CI 1.38-3.96). The effects of the fibrosis index on eGFR decline were robust across sex, HbA_{1c}, duration of diabetes, and use of renin-angiotensin system inhibitors in subgroup analyses.

Conclusions: Renal fibrosis is associated with early progressive renal decline in type 2 diabetes, even in patients without albuminuria.

SA-PO538

Effects of Tubulointerstitial Plasmocyte Infiltration on Hard Clinical Renal Outcomes in Subjects with Diabetic Kidney Disease

Junlin Zhang. *West China Hospital of Sichuan University, Chengdu, China.*

Background: Identification of the tubulointerstitial inflammatory features has the potential to the prediction of renal prognosis of diabetic kidney disease (DKD); however, the influence of plasmocyte infiltration on the DKD is unclear. This study was conducted to determine the association between the tubulointerstitial plasmocyte infiltration and DKD in a cohort of Chinese patients with type 2 diabetes mellitus (T2DM).

Methods: We enrolled 226 adult patients with biopsy-proven DKD for a follow-up time more than 12 months. Tubulointerstitial plasma cells in kidney biopsy tissues were detected by immunohistochemistry and immunofluorescence. The patients then were divided into two groups based on tubulointerstitial plasmocyte infiltration: plasmocyte group (n=117) and non-plasmocyte group (n=109). Hard renal outcome was defined as end stage renal disease (ESRD). A comparison of the baseline features and renal prognosis between the two groups was performed.

Results: The accumulation of tubulointerstitial plasma cells was found to be related with more serious anemia, heavy proteinuria, renal function decline, and more serious glomerular, interstitial and arterial lesions. During the follow up (12-85 months), 42.5% (96) of patients developed ESRD. Patients in plasmocyte group exhibited a high percentage of incident ESRD (53%) than those (31.2%) in non-plasmocyte group ($p<0.05$). A Cox regression showed that the plasmocyte infiltration had a significant effect on the renal endpoint (HR, 1.969; 95%CI, 1.292-3.000), though it was not an independent risk factor.

Conclusions: As one of contributors to the renal inflammatory response, the tubulointerstitial infiltration of plasmocyte was associated with severity of glomerular, interstitial, and arterial lesions as well as DKD hard clinical renal outcome.

SA-PO539

Impact on Kidney Function with Focal and Segmental Glomerulosclerosis (Tip) in Patients with Diabetic Nephropathy

Ivan Rosero,[1] Diego F. Argudo sanchez,[1] Virgilia Soto,[2] Rafael Valdez-Ortiz,[1] Adrian R. Matias.[1] *[1]Hospital General de Mexico, Mexico City, Mexico; [2]INC Ignacio Chavez, Mexico City, Mexico.*

Background: Type 2 Diabetes Mellitus is the first cause of end stage kidney disease (ESKD). Focal and Segmental Glomeruloesclerosis (FSG) is the most common glomerulopathy in western world. Tip variant is the most common glomerulopathy associated with Diabetic Nephropathy (DN). By now, only mathematic and experimental models tried to explain the association between DN and FSG (tip) without including the clinical impact and the prognosis of these patients. This study is the first in Mexico which evaluates this combination and the clinical impact.

Methods: Retrospective cohort with patients over 18 years with renal biopsy who at that moment, didn't had ESKD. We did descriptive and analytic statistics and a survival analysis with Kaplan Meier. We considered as primary outcome, the need of dialysis, lowering glomerular filtration rate (GFR) >50% of basal value and/or doubling the basal serum creatinine.

Results: 41 patients included, 64% (26) male, 73% (30) had hypertension at the moment of the biopsy, 83% (34) had nephrotic syndrome, the chronic changes score (CCS) were moderate or severe in >90% of patients. The age was 51±13, follow up of 18±12 months, the initial proteinuria was 8.8±4.3 gr/24h in the group without FSG and 8.3±5.7 gr/24h in the other group. The proteinuria at 6 months after the biopsy was different between groups (p= 0.03). The group without FSG had worse GFR, but with no difference in the analysis of the primary outcome, (Figure 1)

Conclusions: There was no difference between groups in the primary outcome, but we observe some clinical differences. The CCS did evaluate better the outcomes than the histologic changes in both groups. Maybe further studies with more patients, could find a difference in the impact of FSG on kidney function proposed in our study.

Figure 1. Survival analysis according the presence or not of FSG tip variant, complex outcome and GFR lowering >50%

Interstitial Eosinophilic Infiltration in Diabetic Nephropathy Is Indicative of Poor Prognosis with No Therapy Benefit from Steroid

Wenyan Wu,[2] Xujie Zhou,[2,1] Pingping Sun,[2] Yu Xiaojuan,[2,1] Su-xia Wang,[2,3] Lane Qu,[2,1] Fan Zhang,[2,1] Yi Ma,[2,1] Gang Liu,[2,1] Li Yang.[2,1] *[1]Renal Pathology Center, Peking University First Hospital, Beijing, China; [2]Renal Division, Peking University First Hospital, Beijing, China; [3]Laboratory of Electron Microscopy, Pathological Centre, Peking University First Hospita, Beijing, China*.

Background: Recent data suggested that eosinophils in diabetes might be associated with severity of diabetic nephropathy (DN). In a retrospective study of 102 Chinese patients with biopsy proven DN, we aimed to evaluate relationships of both blood and renal eosinophils(Eos) to the severity of DN, and check whether it can be served as an independent indicator of prognosis as well as therapeutic effect of steroids in these patients.

Methods: A total of 102 patients with a single diagnosis of glomerulopathy with DN were enrolled. Demographical and clinical data as well as histopathological scores were associated. Interstitial eosinophilic aggregates (IEA) were defined as the presence of ≥10 Eos in at least one high-power field (×400). End stage renal disease was defined as the end point. Urinary eosinophil cationic protein (ECP) levels were also analyzed to evaluate its biomarker role in DN

Results: We observed that $\log_2$(blood eosinophil counts) correlated with neutrophil counts, proteinuria and interstitial inflammation. IEA was observed in 33.3% of the DN patients and was associated with higher serum creatinine (2.3 vs. 1.5mg/dL, p=0.021), lower estimated glomerular filtration rate (39.8 ± 27.3 vs. 51.9 ± 30.3ml/min/1.73 m^2, p=0.053), higher proteinuria (7.5 ± 4.8 vs. 4.9 ± 3.6g/d, p=0.004), more prevalence of hematuria (82.4% vs. 43.9%, p<0.001), higher HbA1c (7.5 ± 1.9% vs. 6.7 ± 1.4%, p=0.026), higher blood eosinophil counts (0.22×10^9 vs. 0.16×10^9/L, p=0.001), severer tubulointerstitial injury including tubular injury (p=0.004), interstitial inflammation(p=0.004), tubular atrophy (p= 0.007) and interstitial fibrosis (p=0.020). IEA was associated with worse renal prognosis (HR 2.424, p=0.008). Consistently, urine ECP (ng/mgCr) was associated with renal injury and poor renal prognosis (HR 1.160, p=0.024). Patients with IEA were more likely to be treated with steroid (IEA vs. non-IEA, 47.1% vs. 14.7%, p=0.001) but did not show renal benefit.

Conclusions: It suggested that both blood and renal infiltrated eosinophils were prevalent in DN and associated with severity of DN. But IEA in renal pathology showed better fit in correlation with renal prognosis. Treatment with steroid/immunosuppressant showed no significant improvement regarding renal prognosis.

The Feasibility and Safety of Obtaining Research Kidney Biopsy Cores in Patients with Diabetes: An Interim Analysis of the TRIDENT Study

Jonathan J. Hogan,[2] Jonathan G. Owen,[12] Katalin Susztak,[13] Shweta Bansal,[4] Harold M. Szerlip,[3] Shikha Wadhwani,[5] Michael J. Ross,[6] Salem Almaani,[7] Deep Sharma,[9] Samir M. Parikh,[10] Rupali S. Avasare,[11] Randy L. Luciano,[8] Amy K. Mottl.[1] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Hospital of the University of Pennsylvania, Haddonfield, NJ; [3]Baylor University Medical Center, Dallas, TX; [4]University of Texas Health at San Antonio, San Antonio, TX; [5]Northwestern University Feinberg School of Medicine, Chicago, IL; [6]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [7]The Ohio State University Wexner Medical Center, Columbus, OH; [8]Yale University School of Medicine, New Haven, CT; [9]Montefiore Medical Center, Old Tappan, NJ; [10]BIDMC/Harvard Medical School, Boston, MA; [11]Oregon Health & Science University, Portland, OR; [12]University of New Mexico, Albuquerque, NM; [13]University of Pennsylvania, Philadelphia, PA.*

Background: Obtaining additional kidney tissue for research is essential for advancing the understanding and treatment of kidney disease. The Transforming Research in Diabetic Nephropathy (TRIDENT) Study is a multi-center, longitudinal, observational cohort study for adults with diabetes who are undergoing a clinically indicated kidney biopsy, and requires an additional research biopsy core. We present an interim analysis of the feasibility and safety of obtaining research kidney biopsy cores in the TRIDENT study.

Methods: The TRIDENT database was analyzed for data acquired as of May 1, 2019. Data on adverse events (AEs) were obtained for cases where a research core was successfully obtained and a central pathologist confirmed the histologic diagnosis (N=134). Clinical and demographic data was obtained at the enrollment visit, which occurred within 45 days of biopsy. We defined AEs as hematoma >5cm, gross hematuria and prolonged hospital stay. Serious AEs included unplanned blood transfusion, transfer to an intensive care unit (ICU), respiratory distress requiring intubation or vascular radiology intervention to halt bleeding.

Results: As of May 1, 2019, 160 patients were consented and underwent kidney biopsy at 15 centers, with a research biopsy core successfully obtained in 143 cases (89%). Diabetic glomerulopathy was found in 110 (82%) of cases. Patients had a mean age of 54.7 (SD 12.6) years, with 45% female, 32% African American race and 34% Hispanic ethnicity. The mean serum creatinine was 2.9 (SD 1.9) mg/dL. A 16 gauge needle was used in 72 (54%) of biopsies and the mean number of biopsy passes was 3.6 (SD 1.0). Serious AEs occurred in 4 patients (3%): blood transfusion in 2 (1.5%), post-biopsy aspiration leading to respiratory failure and prolonged hospitalization in 1 (0.7%)) and ICU observation in 1 (0.7%). Post-biopsy hematoma >5 cm was noted in 7 (5.2%), 2 developed transient gross hematuria (1.5%) and 5 (3.7%) patients required a prolonged hospital stay.

Conclusions: This interim analysis of the TRIDENT study suggests that obtaining tissue for research purposes in adults with diabetes undergoing clinical kidney biopsies is feasible and is associated with an acceptable complication rate.

SA-PO542

Incidence in Kidney Failure from Diabetes Among Native Americans, 2000-2016

Nilka Rios Burrows, Yan Zhang, Israel Hora, Meda E. Pavkov, Giuseppina Imperatore. *Division of Diabetes Translation, Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Diabetes-related end-stage renal disease (ESRD-D) among Native Americans (NAs) declined from 1996 to 2013. We assessed recent data to determine if the rates have continued to decline.

Methods: From the US Renal Data System, we obtained the number of NA adults and adults of other races (whites, blacks, Asians, Native Hawaiians/Pacific Islanders, and others) aged ≥18 years with newly treated ESRD-D (with diabetes listed as primary cause of ESRD) between 2000 and 2016. ESRD-D rates by age and sex were calculated using general population estimates from the US Census and age-adjusted based on the 2000 US standard population. Joinpoint regression was used to assess trends and estimate the annual percentage change (APC).

Results: From 2000 to 2016, the number of US adults starting ESRD-D therapy decreased from 878 to 825 for NAs and increased from 40,632 to 56,170 for other races. For NAs, the age-adjusted ESRD-D rate decreased from 66.7 per 100,000 population in 2000 to 30.3 in 2013 (APC= -5.6%, p<0.001) and then leveled off (Figure). Trends for NA men and women were similar to the overall trend. For other races, the age-adjusted rate increased slightly from 2000 to 2006 (from 19.7 to 20.7, APC=0.6%, p=0.04), decreased from 2006 to 2012 (20.7 to 19.1, APC= -1.1%, p=0.007), and again increased from 2012 to 2016 (19.1 to 20.3, APC=1.5%, p=0.009). By age group, ESRD-D rates showed no change for NAs aged 18-44 (from 7.7 in 2000 to 7.6 in 2016), declined for NAs aged 45-64 (from 108.3 in 2000 to 45.2 in 2013, APC= -5.8%, p<0.001) and 65-74 (from 231.2 in 2000 to 88.6 in 2012, APC= -7.6%, p<0.001) and then leveled off, and declined throughout the period for NAs aged ≥75 (119.3 to 61.9, APC= -4.2%, p<0.001).

Conclusions: From 2000 to 2016, ESRD-D continued to decline in NAs aged ≥75 years but, after an initial decline, has leveled off in more recent years in NAs aged 45-74 years. During the period, the disparity gap between NAs and other races was reduced more than 2-fold. Continued efforts might be considered to sustain and improve ESRD-D trends in NAs.

Genetic Determinants of CKD Progression Among Individuals with Diabetes: The Million Veteran Program

Adriana Hung,[1] Hua-Chang Chen,[2] Cecilia P. Chung,[2] Edward D. Siew,[5] Elvis A. Akwo,[2] Ayush Giri,[2] Otis D. Wilson,[2] Todd L. Edwards,[2] Christopher J. O'Donnell,[3] Peter W. Wilson,[4] Ran Tao,[2] Cassianne Robinson-Cohen.[2] *[1]VA & Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Boston Veterans Administration, Boston, MA; [4]Emory University, Atlanta, GA; [5]Vanderbilt University School of Medicine, Nashville, TN*.

Background: The rate of CKD progression among individuals with diabetes varies widely and is incompletely explained by known risk factors. While the genetic determinants of cross-sectional eGFR have been identified, only one small analysis of longitudinal change in eGFR among individuals with CKD has been conducted.

Methods: We performed a genome-wide association study of the relative rate of decline in estimated glomerular filtration rate (eGFR, % decline/year) among individuals with CKD and diabetes participating in the Million Veteran Program. Our study included participants

with genetic data available from the MVP second data release, with 351,510 participants from whom 91,523 individuals had type 2 diabetes. Analyses were stratified by race.

Results: There were 28,368 individuals with CKD and diabetes. 21% (n=5904) were of non-hispanic black race /ethnicity. Mean (SD) eGFR at baseline was 51.1 (±8.1) ml/min/1.73m^2 and median relative kidney function decline was -0.5%/year. Trans-ethnic meta-analysis uncovered 6 SNPs from only one region significantly associated with decline in kidney function. The SNP with the strongest association, rs6047460, lies 45kb upstream of *UGT2A1*; every additional minor allele was associated with a 1%/year faster decline in eGFR ($p=1.1 \times 10^{-7}$). Among blacks, we were able to replicate one of four previously identified SNP, rs116356141, which lies between *SH2D4B* and *NRG3* (p=0.03). Among whites, we were able to replicate 2 of 11 SNPs previously associated with incident CKD, rs12917707 (near *UMOD*, $p=6x10^{-4}$) and rs7805747 (intronic for *PRKAG2*, $p=9x10^{-3}$).

Conclusions: Our data suggest that while there is genetic basis for diabetic kidney disease progression, the discovery of the genetic variants involved has been difficult. The etiological heterogeneity of the phenotype could preclude true associations from being detected.

Poor Renal and Cardiovascular Outcomes in Patients with Biopsy-Proven Diabetic Nephropathy

Niansong Wang, Ying Fan, Yiyun Wang, Ting Zhou. *Department of Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China, Shanghai, China.*

Background: Despite high level of mortality related to cardiovascular disease (CVD) in diabetic patients with renal injury, few studies have compared cardiovascular characteristics and outcomes between patients with diabetic nephropathy (DN) and non-diabetic renal disease(NDRD).

Methods: A total of 370 T2DM patients with renal biopsy were assigned to one of three groups (DN, NDRD, and NDRD with underlying DN). Echocardiography and Doppler ultrasound were performed to evaluate left ventricle hypertrophy(LVH) and peripheral atherosclerosis disease(PAD). Renal and cardiovascular survival rates were compared between the DN and NDRD groups by Kaplan-Meier analysis (medium follow-up, 29 months). Risk factors for renal and cardiovascular events were identified by Cox proportional hazards model.

Results: DN patients were more vulnerable to developing LVH than NDRD patients (37.3% vs 6.8%, $P < 0.001$). PAD was more severe in DN group, with thicker intima-medium and more atherosclerotic plaques ($P < 0.001$). Poorer renal (log Rank $X^2 = 22.089$, $P < 0.001$) and cardiovascular (log Rank $X^2 = 9.346$, $P = 0.002$) prognosis were seen in DN group. Low estimated glomerular filtration rate at baseline was associated with renal events (HR = 0.962 [0.942–0.983], P = 0.001), while elevated levels of glycosylated hemoglobin A1c (HR = 1.599 [1.256–2.635], P = 0.041) and postprandial blood glucose (HR = 1.321 [1.072–1.626], P = 0.009) were identified as risk factors for cardiovascular events.

Conclusions: Patients with DN had more severe CVD along with poorer renal and cardiovascular prognosis than those with NDRD.

Association of Urinary Acidification Function with the Progression of Diabetic Kidney Disease in Patients with Type 2 Diabetes

Yanggang Yuan,[1,3] Chang Ying Xing.[2,3] *[1]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [3]Nephrology, Jiangsu Province hospital, Nanjing, China.*

Background: Although diabetic kidney disease (DKD) has been considered as a glomerulocentric disease in the past few decades, growing evidence demonstrated that tubular damage is indispensable in its pathogenesis and progression. This study was designed to investigate the association of urinary acidification dysfunction with the progression of DKD in type 2 diabetic patients.

Methods: Here we measured the urinary acidification function from 80 participants with renal biopsy-proven DKD. The different kinds of renal tubular transportation dysfunction were analyzed by urinary acidification function, including the dysfunction of bicarbonate reabsorption, titratable acid secretion, and ammonium secretion. In addition, patients were followed up for 17 (interquartile range, 11-32) months to evaluate the effect of urinary acidification dysfunction in the progression of DKD.

Results: The dysfunction of ammonium secretion was the most common, accounting for 53.75%. The more proteinuria excretion and the lower glomerular filtration rate (GFR) were observed in the urinary titratable acid secretion disorder group than the normal group, and the same results were obtained for ammonium secretion disorder. Urine titratable acid was positively correlated with eGFR whereas it was inversely correlated with proteinuria, serum creatinine, and BUN. Moreover, 24h urine protein, serum creatinine, BUN and cystatin C increased from DKD stage II to stage IV, whereas the eGFR and urine titratable acid decreased in the same way. Furthermore, Kaplan-Meier analysis and Cox regression showed that the dysfunction of titratable acid secretion was an independent risk factor of DKD progression.

Conclusions: The dysfunction of titratable acid secretion is a potential biomarker for the severity of proteinuria, eGFR and glomerular lesions in patients with DKD. Moreover, the titratable acid secretion disorder is an independent risk factor of the DKD progression.

SA-PO546

Influence of Metabolic Phenotype and Non-Alcoholic Fatty Liver Disease in the Evolution of Renal Function in Diabetic Patients

Lucia Aubert, Justo Sandino Perez, Teresa Bada Bosch, Hernando Trujillo Cuellar, María Fernández vidal, Elizabeth Canllavi fiel, Enrique Morales. *Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: It has been described the albuminuric and normoalbuminuric phenotypes in diabetic nephropathy (DN). However, there is little information on the influence of non-alcoholic fatty liver disease (NAFLD) and metabolic syndrome (MSd) on renal function in patients with type 2 diabetes mellitus (DM). The aim of this study was to compare the effect on renal function and proteinuria in patients with type 2 DM according to the presence of MSd.

Methods: Retrospective and observational study, including patients with type 2 DM, < 70 years of age and estimated glomerular filtration rate (eGFR) > 30 ml/min/1,73 m^2. MSd was defined as: obesity (body mass index > 30 kg/m^2), hypertension and dyslipidaemia. Patients were classified according to the presence or absence of MSd. We analysed different clinical and analytical variables along the follow up.

Results: A total of 90 patients were included (61% males) with mean age of 57.9 7.6 years. The median evolution of type 2 DM was 64.8 months (38.7 – 117.8 months). When comparing patients with (group 1, n=39) and without (group 2, n=51) MSd at the beginning of this study, we found no significant difference in eGFR (80.5 39.7 ml/min vs 71.3 29.4 ml/min), proteinuria (1.4 1.1 g/24h vs 2.2 3.1 g/24h) and glycated haemoglobin (7.4 1.7% vs 6.8 1.2%). After a mean follow-up time of 74 months, we found significant differences in the loss of eFGR (group 1 4.9 ml/min/year vs group 2 2.6 ml/min/year; .013) and in increase of proteinuria (2.7 3.5 g/24h vs 1.0 1.3 g/24h; .02). We found an increase in incidence of chronic kidney disease in group 1 (26%) vs group 2 (16%). There were no differences in the need to initiate renal replacement therapy or all-cause mortality. On a post hoc analysis, we evaluated the influence on renal function and proteinuria of NAFLD. Twenty eight out of 59 patients had NAFLD, observing a significant difference in loss of eFGR between those with and without NAFLD (32.7 ± 4.9 vs 29.7 ± 5.3; .03). There was also an increase in incidence of chronic kidney disease (32% vs 10%).

Conclusions: Metabolic phenotype and NAFLD in type 2 DM caused a mayor decline in renal function and increase in 24-hour proteinuria. Therefore, we should stratify patients with DKD to optimise treatment of associated risk factors.

SA-PO547

Prognostic Importance of Serum Alkaline Phosphatase in Type 2 Diabetic Patients with Diabetic Nephropathy

Lijun Zhao,[1] Fang Liu.[2] *[1]Division of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China, Chengdu, China; [2]West China Hospital of Sichuan University, Chengdu, China.*

Background: This study was aimed to investigate the impact of circulating alkaline phosphatase (ALP) on renal outcomes in type 2 diabetic patients with diabetic nephropathy (DN).

Methods: This longitudinal observational study enrolled 299 type 2 diabetic patients with biopsy-proven diabetic nephropathy. Patients were divided into two groups: nephrotic-range proteinuria group (NPU, 24h proteinuria≥3.5 g/d, n=179), and non nephrotic-range proteinuria group (non-NPU: 24h proteinuria<3.5 g/d, n=121). Multivariable adjusted Cox models were used to estimate the association of serum ALP with end-stage renal disease (ESRD).

Results: During a median follow up of 26.0 months, 133 (44.5%) patients progressed to ESRD. The median ALP was much higher in NPU group than non-NPU group (87 IU/L vs. 76 IU/L, P=0.009). In NPU group, higher ALP levels were incrementally associated with higher risks of ESRD after adjusted for demographics, kidney functions, nutritional status and medications. The highest quartile of ALP was associated with a hazard ratio for ESRD of 3.37 [95% confidence interval (CI), 1.41-8.07] (Figure 1). Moreover, ALP level was positively correlated with proteinuria (r=0.21) and interstitial fibrosis and tubular atrophy (r=0.37). In non-NPU group, only the highest ALP quartile was associated with a hazard ratio for ESRD of 2.94 (95% CI, 1.08-9.36).

Conclusions: Elevated serum ALP was an independent predictor for time to renal events in type 2 diabetic patients with nephrotic-range proteinuria. Our findings suggested ALP might play a role in kidney fibrosis and interstitial injury. Further studies are warranted to clarify the potential mechanisms.

Diabetic Retinopathy and Progression of Diabetic Kidney Disease in Asians

Charumathi Sabanayagam,[1,2] Rehena sultana Ganguly,[2] Simon Nusinovici,[1] Cynthia C. Lim,[3] Gavin Tan,[4] Tien Yin Wong.[1] DYNAMO *[1]Singapore Eye Research Institute, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]Singapore General Hospital, Singapore, Singapore; [4]Singapore Nationa Eye Centre & Singapore Eye Research Institute, Singapore, Singapore*.

Background: Diabetic kidney disease (DKD) and diabetic retinopathy (DR) share similar risk factors and pathogenic mechanisms. We examined the prospective relationship between DR and incidence and progression of DKD in a multi-ethnic Asian population in Singapore.

Methods: We analysed data from 2981 Chinese, Malay and Indian adults with diabetes aged 17-90 years who attended annual screening visits (3-6 visits) at primary care clinics from 2010-2015 as part of the Singapore Integrated DR Screening Program (SiDRP). DR (n=297) was assessed from retinal photographs graded using a standard protocol and defined as presence of mild/moderate/severe DR. Incident DKD was defined as an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2+ 25% decrease in eGFR at follow-up in those with eGFR≥60 at baseline and DKD progression as decline in eGFR by ≥30% from baseline to follow-up. We examined the association between DR and incidence/progression of DKD using logistic regression models adjusted for age, sex, ethnicity, systolic blood pressure (SBP), baseline eGFR, HbA1c, and duration of diabetes. We assessed if addition of DR improved prediction of DKD incidence or progression to traditional risk factor model by comparing the area under the receiver operating characteristic curve (AUC-ROC).

Results: The 3-5 year cumulative incidence and progression of DKD were 6.4% and 2.1%. Progression was significantly higher in Malays compared to Chinese and Indians (4.4%, 1.9%, 1.9%, p=0.04), incidence was not significantly different (7.1%, 6.8%, 3.8%, p=0.09). In multivariable models, DR was significantly associated with both incident and progressive DKD, (odds ratio [95% confidence interval] = 2.29 [1.50-3.48]) and 2.20 [1.18-4.09]) compared to no DR. Addition of DR, did not significantly improve prediction of incidence (AUC= 0.824 vs. 0.818, p=0.1) or progression (0.737 vs. 0.726, p=0.4) compared to traditional model, probably due to the small number of events. Other than DR, SBP and baseline eGFR were significant predictors for incidence and progression and Malay ethnicity for progression (all p<0.05).

Conclusions: We found that presence of DR was independently associated with increased risk of onset and progression of DKD. Our findings emphasize the importance of assessing DR status in DKD management and control of blood pressure in DR patients.

SA-PO549

Relationship Between Waist Circumference and Renal Function Decline Rate

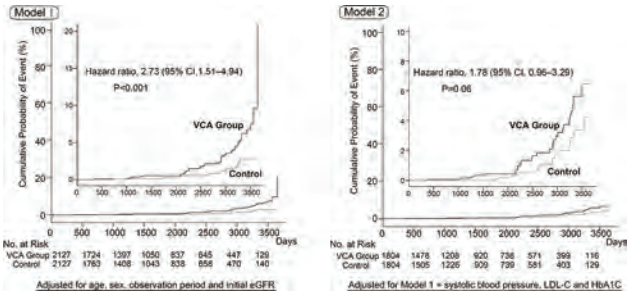
Makoto Araki. *Suwa Central Hospital, Chino, Japan*.

Background: As hyperinsulinemia correction is one of the renal protective effects of SGLT2 inhibitors, we hypothesized that hyperinsulinemia-insulin resistance deteriorates renal function. Therefore, we investigated the relationship between waist circumference, a marker of visceral fat and an indicator of insulin resistance, and renal function decline rate.

Methods: In this single-institutional observational study in Japan, subjects were selected from those who underwent creatinine and waist circumference measurements at annual health examinations from 2008 to 2018. Subjects had undergone examinations for ≥2 years; their estimated glomerular filtration rate (eGFR) in the first year was > 60 ml/min/1.73 m^2. The subjects were divided into two groups: visceral adiposity group (VCA group) and control group, by the initial abdominal circumference based on diagnostic criteria for metabolic syndrome in Japan. We adjusted for the following baseline variables: model 1: age, sex, observation period, and initial eGFR; model 2: model 1 + systolic blood pressure, low-density lipoprotein cholesterol, and hemoglobin A1C during the observation period. We evaluated both groups by time-to-event analysis for 30% eGFR decline.

Results: Totally, 8390 subjects (56.4% men, mean age: 47.7 years, mean observation period: 1751.1 days) met the criteria. The mean waist circumference was 77.0 cm in the control group and 92.3 cm in the VCA group. When adjusted using propensity score, 2127 (model 1) and 1804 (model 2) subjects in each group were extracted. In the time-to-event analysis for 30% eGFR decline, there was a significantly difference in model 1 (hazard ratio, 2.73 [95% CI, 1.51-4.94]; P<0.001), but not model 2 (hazard ratio, 1.78 [95% CI, 0.96-3.29]; P=0.06).

Conclusions: Excess visceral fat is associated with decreased renal function. However, after adjustment for hypertension, lipids, and glucose intolerance, this study failed to establish a relationship between hyperinsulinemia-insulin resistance and decreased renal function.



SA-PO550

Development of an Exhaustive-Risk-Prediction System Using Deep Learning and Different Patterns of Diabetic Kidney Disease Progression Based on Patient Characteristics

Eiichiro Kanda,[1] Atsuyuki Tokuyama,[1] Seiji Itano,[1] Hajime Nagasu,[1] Bogdan I. Epureanu,[2] Naoki Kashihara.[1] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]University of Michigan, Ann Arbor, MI*.

Background: Diabetic kidney disease (DKD) is a risk factor for end-stage kidney disease (ESKD) and death. An accurate prediction of these risks at an individual level is required to improve DKD patients' prognosis. In this study, we developed a new system for the prediction of chronic kidney disease (CKD) progression using deep learning (DL) and the CKD big database in Japan, and investigated DKD progression patterns based on their characteristics.

Methods: The associations among patients' characteristics, laboratory data and an outcome (ESKD or death) in five years were evaluated by DL. The kidney disease progression risk for a virtual patient was simulated using the trained DL model.

Results: Among the patients (n=3877, 83701 measured data), 53.0% were male; average age, 59.8±17.9 years; estimated glomerular filtration rate (eGFR), 51.1±29.0 ml/min/1.73 m^2; and diabetes mellitus, 18.8%. In the test dataset, the accuracy of DL was 0.95, which was higher than those of multivariate logistic regression models (0.84) and support vector machine models (0.84). Then, various patterns of characteristics of a 60-year-male patient were evaluated. The predicted risk of the outcome is shown in heat maps (Figure 1), and various patterns are observed. A basic pattern (e.g., CKD severity category) shows high risks in categories of low eGFR and high urinary protein level. And, the nephrosclerosis-like pattern shows higher risks at low urinary protein levels than at high urinary protein levels. Moreover, DKD shows a mix pattern, which suggests that DKD patients are a heterogenous population.

Conclusions: We developed a new exhaustive risk-prediction system using DL and found different patterns of kidney disease progression based on patient characteristics. This system may be useful for identifying patients at an increased risk of DKD progression for early treatment.

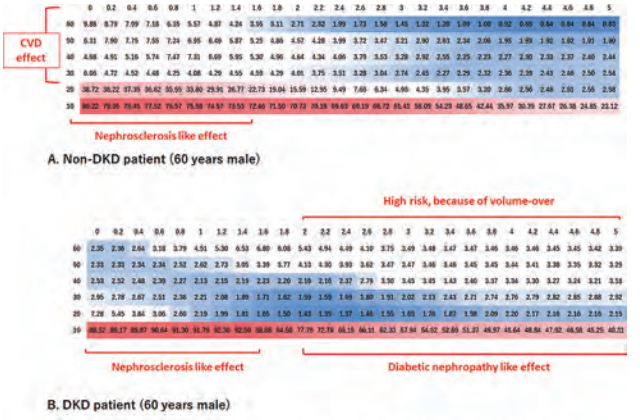


Figure 1 Risks of CKD progression predicted on the basis of patients' characteristics

SA-PO551

Trimethylamine-N-Oxide and Renal Complications, Cardiovascular Disease, and Mortality in Individuals with Type 2 Diabetes and Microalbuminuria

Signe Abitz Winther,[1,2] Jens C. Øllgaard,[1,2] Tine Hansen,[1] Bernt Johan Von Scholten,[1,2] Peter Gaede,[6,7] Hans-Henrik Parving,[5] Oluf Pedersen,[3] Peter Rossing.[1,4] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Novo Nordisk A/S, Måløv, Denmark; [3]Novo Nordisk Foundation Center for Basic Metabolic Research, København Ø, Denmark; [4]University of Copenhgaen, Copenhagen, Denmark; [5]Rigshospitalet, Copenhagen, Denmark; [6]Slagelse Hospital, Denmark, Denmark; [7]University of Southern Denmark, Odense, Denmark.*

Background: Trimethylamine-N-Oxide (TMAO) is suggested as an independent gut microbiota derived risk marker for several diseases. We investigated associations between plasma TMAO concentrations and all-cause mortality, cardiovascular disease (CVD) and deterioration in renal function in individuals with type 2 diabetes and microalbuminuria.

Methods: Plasma TMAO was measured at baseline in 311 individuals with type 2 diabetes and microalbuminuria. All-cause mortality and CVD (fatal and non-fatal) were tracked from national registries. Yearly p-creatinine was measured after baseline in 166 of the participants, the renal endpoint was defined as eGFR-decline of >30%. Associations between TMAO and events were analyzed using Cox regression models. Adjusted models included age, sex, HbA1c, systolic blood pressure, total cholesterol, urine albumin excretion rate and eGFR.

Results: Baseline mean (SD) age was 57.2 (8.2) years, 75% were male and median [IQR] of TMAO was 5.87 [3.79-9.04] μM. TMAO was negatively associated with eGFR at baseline (R^2=0.108, p<0.0001). Follow-up was up to 21.8 years for all-cause mortality and CVD events (median 6.8 and 6.5 years) and for renal events up to 5.8 years (median 4.6 years). We recorded 106 cases of mortality, 116 CVD events and 41 renal events. Higher plasma TMAO concentrations were associated with renal events in unadjusted analyses (p=0.03), but not after adjustment p=0.17. TMAO was not associated with mortality (unadjusted p=0.53; adjusted p=0.87) or CVD events (unadjusted p=0.14; adjusted p=0.24).

Conclusions: In individuals with type 2 diabetes and microalbuminuria, plasma TMAO was negatively correlated with eGFR at baseline. Moreover, higher plasma TMAO was in unadjusted analysis associated with renal events, but not after adjustment. Plasma TMAO was not associated with mortality and CVD events.

SA-PO552

Visit-to-Visit Variability of Albuminuria and eGFR as Risk Markers for Renal Complications, Cardiovascular Events, and Mortality in Type 1 Diabetes

Viktor Rotbain Curovic,[1] Simone Theilade,[2] Signe Abitz Winther,[1] Nete Tofte,[1] Anders Jorsal,[4] Hans-Henrik Parving,[3] Frederik Persson,[2] Tine Hansen,[2] Peter Rossing.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Steno Diabetes Center, Hellerup, Denmark; [3]Rigshospitalet, Copenhagen, Denmark; [4]Aarhus University Hospital, Aarhus, Denmark.*

Background: Clinicians strive towards determining stable and reliable measures for monitoring risk of diabetic complications. The impact of visit-to-visit variability (VVV) of albuminuria (ALB) and eGFR needs further clarification. We investigated VVV in ALB and eGFR as risk markers of renal complications, cardiovascular events (CVE), and mortality in subjects with type 1 diabetes (T1D).

Methods: 1077 individuals with T1D a range of albuminuria were included. VVV was defined as the standard deviation (SD) of the residuals in individual linear regression models, calculated using all measures of ALB or eGFR from 1998-2016. Data on end-stage renal disease (ESRD), CVE and mortality were gathered through national registers. eGFR and ALB was traced through laboratory records from ambulatory care. Endpoints were ESRD (CKD stage 5, dialysis or transplantation), eGFR-decline ≥30%, CVE (cardiac death, myocardial infarction, stroke and arterial interventions) and mortality. Hazard ratios (HR) were calculated using Cox models and are presented per doubling of VVV. Adjustment included sex, age, total cholesterol, HbA_{1c}, systolic blood pressure, body mass index, smoking, 24h ALB, eGFR, and the intercept and slope of the respective linear models.

Results: Median follow-up ranged from 6.1-13.4 years for ALB and 6.8-16.2 years for eGFR, depending on endpoint. Subjects had a mean (SD) age and diabetes duration of 47 (13) and 27 (13) years, respectively, at baseline. Depending on availability of data, between 848-1077 subjects were included in the respective models. Adjusted HR (95% CI, p) for ALB VVV were 1.68 (1.38-2.05, p<0.001), 1.34 (1.25-1.44, p<0.001), 1.12 (1.04-1.20, p=0.002) and 1.10 (1.01-1.19, p=0.029) for development of ESRD, eGFR decline ≥30%, CVE and mortality, respectively. Adjusted HR (95% CI, p) for eGFR VVV were 1.78 (1.29-2.45, p<0.001), 2.02 (1.68-2.43, p<0.001), 0.96 (0.85-1.08, p=0.091) and 0.93 (0.79-1.11, p=0.424) respectively.

Conclusions: We demonstrate an independent association between long term VVV in ALB and development of renal complications, CVE and mortality in T1D, and in eGFR VVV for development of renal complications. Studies addressing stabilization of VVV and reduction of endpoints, are warranted.

SA-PO553

Poor Glycemic Control Increases Mortality in Elderly Dialysis Patients with Diabetes: A Nationwide Prospective Cohort in Korea

Jangwook Lee,[1] Jung Nam An,[2] Jeonghwan Lee,[2] Jae Yoon Park,[4] Yong Chul Kim,[1] Jang-Hee Cho,[3] Yun Kyu Oh,[2] Yong-Lim Kim,[3] Chun Soo Lim,[2] Jung Pyo Lee.[2] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Seoul, Republic of Korea; [3]Kyungpook National University Hospital, Daegu, Republic of Korea; [4]Dongguk University Ilsan Hospital, Gyeonggido, Republic of Korea.*

Background: Glycemic control, defined as glycated hemoglobin (HbA1c), was known to be an important factor for mortality in diabetic end-stage renal disease (ESRD) patients. However, the clinical impacts of glycemic control had not been fully elucidated in the elderly diabetic ESRD patients. We investigated whether glycemic control had clinical impact on all-cause mortality of elderly dialysis patients with diabetes.

Methods: A total of 755 elderly diabetic patients (≥ 65 years) who had a value of HbA1c at the time of cohort enrollment were extracted from a nationwide prospective ESRD cohort in Korea between August 2008 and February 2015. The patients were divided into three groups according to the degree of glycemic control (< 6.5%, 6.5-7.9%, and ≥ 8.0%).

Results: The patients in the highest group of HbA1c (≥ 8.0%) were 132 (17.5%), which were younger, had higher vintages of dialysis, and higher percentage of peritoneal dialysis than the other two groups. Mortality rate was 57.2% during the median follow-up of 56.3 months. Patients with poor glycemic control (≥ 8.0%) had a higher risk of mortality compared with those in the HbA1c < 6.5% (hazard ratio [HR] 1.37; 95% confidence interval [CI] 1.06-1.77; P = 0.016). In subgroup analysis by dialysis modality, HbA1c ≥ 8.0% was a risk factor for mortality in the patients on peritoneal dialysis (HR 1.66; 95% CI 1.02-2.70; P = 0.041). Multivariate analysis adjusting for age, sex, comorbidity, dialysis vintage, and dialysis modality verified a significant association between poor glycemic control (≥ 8.0%) and mortality rate in the elderly diabetic ESRD patients (HR 1.53; 95% CI 1.17-2.00; P = 0.002).

Conclusions: Poor glycemic control was significantly associated with mortality in the elderly dialysis patients, which suggests that lowering HbA1c to at least less than 8.0% might decrease mortality rate.

SA-PO554

Hypoglycemia and Mortality Risk in Incident Hemodialysis Patients

Duk-Hee Kang,[2] Elani Streja,[3] Amy S. You,[4] Yong kyu Lee,[1] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh,[6] Connie Rhee.[1] *[1]University of California Irvine, Huntington Beach, CA; [2]Ewha University College of Medicine, Seoul, Republic of Korea; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California, Irvine, Orange, CA; [5]University of Tennessee Health Science Center, Memphis, TN; [6]University of California Irvine, School of Medicine, Orange, CA.*

Background: Hypoglycemia is a frequent occurrence in chronic kidney disease (CKD) patients due to alterations in glucose and insulin metabolism. Yet there are sparse data examining the predictors and clinical implications of hypoglycemia, including mortality risk, among incident hemodialysis patients.

Methods: Among 58,304 incident hemodialysis patients receiving care from a large national dialysis organization over the period 2007-2011, we first examined clinical characteristics associated with risk of hypoglycemia, defined as a blood glucose concentration of <70 mg/dL, in the first year of dialysis using expanded case-mix and laboratory-adjusted logistic regression models. We then examined the association between hypoglycemia during the first year of dialysis with all-cause mortality risk using expanded case-mix and laboratory adjusted Cox models.

Results: In the first year of dialysis, hypoglycemia was observed among 16.8% of diabetic and 6.9% of non-diabetic incident hemodialysis patients. In adjusted logistic regression models, clinical characteristics associated with higher risk of hypoglycemia included younger age, female sex, African-American race, presence of a central venous catheter, lower residual renal function, and longer dialysis session length. In the overall cohort, patients who experienced hypoglycemia had a higher risk of all-cause mortality (reference: absence of hypoglycemia): adjusted HR (95% CI) 1.08 (1.04, 1.13). In stratified analyses, hypoglycemia was also associated with higher mortality risk in the diabetic and non-diabetic subgroups: adjusted HRs (95% CIs) 1.08 (1.04-1.13) and 1.17 (0.94-1.45), respectively.

Conclusions: Hypoglycemia was a frequent occurrence among both diabetic and non-diabetic hemodialysis patients, and was associated with higher mortality risk. Further studies are needed to identify approaches that ameliorate risk of hypoglycemia in hemodialysis patients.

SA-PO555

Diabetic Retinopathy and the Risk of Renal, Cardiovascular, and Death Events: Results from a Longitudinal Japanese Cohort of 232 Patients with Type 2 Diabetes and Biopsy-Proven Diabetic Kidney Disease

Masayuki Yamanouchi,[1,2] Junichi Hoshino,[1,2] Yoshifumi Ubara.[1,2] *[1]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [2]Okinaka Memorial Institute for Medical Research, Tokyo, Japan.*

Background: The predictive value of diabetic retinopathy on end-stage kidney disease (ESKD), cardiovascular disease (CVD), and death has not been fully addressed in patients with type 2 diabetes and diabetic kidney disease.

Methods: We studied 232 patients with type 2 diabetes and biopsy-proven diabetic kidney disease, stratified into five groups according to the International Clinical Disease Severity Scale for Diabetic Retinopathy. The association between retinal grading and kidney lesions was examined. The risks of ESKD, CVD, and all-cause death, were explored using Cox regression analyses adjusted for known risk demographic and clinical variables. The incremental prognostic value of ESKD was assessed by adding diabetic retinopathy to the clinical variables.

Results: The severity scale of diabetic retinopathy positively correlated with all scores of renal lesions, especially with the glomerular-based classification (r =0.41), and scores of interstitial fibrosis (r =0.41) and diffuse lesion (r =0.47). During median follow-up of 5.7 years, 114 patients developed ESKD, 45 patients developed CVD, and 42 patients died, respectively. Compared to patients with no apparent retinopathy, the adjusted hazard ratio (HR) for ESKD were 1.96 (95% confidence interval (CI), 0.62-6.17) for patients with mild non-proliferative diabetic retinopathy (NPDR), 3.10 (95% CI, 1.45-6.65) for patients with moderate NPDR, 3.03 (95% CI, 1.44-6.37) for patients with severe NPDR, and 3.43 (95% CI, 1.68-7.03) for patients with proliferative diabetic retinopathy, respectively. The risks of CVD and all-cause mortality were not shown to be significant. The global chi-square statistic increased from 155.21 to 164.48 (p <0.001) with the addition of diabetic retinopathy severity scale to the clinical model alone.

Conclusions: Diabetic retinopathy appeared to be associated with developing ESKD but not with developing CVD or all-cause mortality. Since diabetic retinopathy and diabetic kidney disease share the same magnitude of microvascular changes, diabetic retinopathy may predict renal prognosis in patients with diabetic kidney disease.

SA-PO556

Prevalence and Risk Factor Analysis of Microalbuminuria in Type 2 Diabetic Patients: Data from Nationwide Registry of Primary Care Cohort of Thailand

Manoch Rattanasompattikul,[1] Sukit Raksasuk,[3] Nuttawut Rongkiettechakorn,[1] Moltira Promkan,[2] Sumana Masoodi,[2] Kanyaphak Ngerninta,[1] Aungkura Supokawej.[2] *[1]Golden Jubilee Medical Center, Faculty of Medicine Siriraj Hospital, Mahidol University, Nakhon Pathom, Thailand; [2]Faculty of Medical Technology, Mahidol University, Salaya, Phutthamonthon, Thailand; [3]Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Background: Microalbuminuria (MAU), an indicator of glomerular injury, is associated with an increased risk of progressive renal deterioration, cardiovascular disease, and mortality. However, the prevalence of MAU in Asian populations is unclear, especially during various stages of chronic kidney disease (CKD). Thus, we examined the prevalence of microalbuminuria and its associated risk factors in Asian patients with type 2 diabetes mellitus (T2DM).

Methods: This study evaluated patients between 18 and 85 years old from the most extensive National Health Security System (NHS) of Thailand from 2011 to 2014. Multivariate regression analyses, including linear and logistic regression, were performed to assess the association between MAU and risk factors.

Results: A total of 7,587 T2DM patients were included. Sixty-four percent were female. The mean age was 63 ±11 years old. The prevalence of MAU was presented by percentage and 95% confidence interval (CI): CKD stage G1 32% (30–34); stage G2 34% (32–35); stage G3a 41% (39–44); stage G3b 47% (43–50); stage G4 70% (63–77); and stage G5 73% (60–82) **(Figure1)**. The multivariate analysis identified the odds ratio (OR) of time-average systolic blood pressure (adjusted OR; 95% CI; P-value) as an independent risk factor for MAU presence. After adjusting for age, gender, body mass index, occupation, provinces, religions, categories of cholesterol, and % glycosylated hemoglobin, the resulting levels were 1.12; 0.94–1.32; 0.20 (<120 mm Hg group), reference group (120–140 mm Hg group), 1.21;1.07–1.36; 0.003 (140–160 mm Hg group), and 1.45; 1.21–1.75; <0.0001 (>160 mm Hg group).

Conclusions: Several factors demonstrated independent correlations with MAU in Asian populations. Higher time-average systolic blood pressure was associated with MAU, which may lead to further target organ damage in T2DM. MAU has also been observed to be much more prevalent in later CKD stages.

The Association Between Vitamin D Level and Microvascular Complications in Persons with Type 2 Diabetes

Ninna H. Tougaard,[1] Tine Hansen,[1] Peter Rossing.[1,2] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Copenhagen, Copenhagen, Denmark.*

Background: The objective of this study is to examine the association between vitamin D level and presence of microvascular complications in persons with type 2 diabetes.

Methods: Cross-sectional study including 789 persons with type 2 diabetes followed at Steno Diabetes Center Copenhagen with information on plasma concentration of vitamin D and relevant clinical data. Peripheral neuropathy was defined as bilaterally decreased sensibility of vibration and minimum one symptom.

Results: The cohort included 378 persons with normoalbuminuria (NA) (mean (SD) age 63.7 (11.5) years), 260 with moderately increased albuminuria (MA) (mean age 68.3 (10.9) years) and 148 with severely increased albuminuria (SA) (mean age 67.2 (11.0) years). The overall prevalence of vitamin D deficiency (25-49 nmol/L) and severe deficiency (<25 nmol/L) was 19.3% and 6.6%, respectively. In persons with NA, MA and SA, the mean (SD) of vitamin D level was 78.1 (35.7), 75.7 (33.6) and 65.2 (35.0) nmol/L, respectively. There was no difference between the NA and MA group (p=0.41), but the difference between the NA and SA group was significant both unadjusted (p=0.0002) and after adjustment for age, sex, seasonal variation, HbA_{1c}, smoking, BMI, systolic BP and eGFR (p=0.005). In linear regression analysis, vitamin D level was negatively associated with albuminuria unadjusted and after adjustment (both p<0.0001). When stratified into CKD stage 1 to 5; including 254, 309, 195, 20 and 11 persons, respectively, the mean (SD) vitamin D level was 70.3 (34.5), 78.6 (33.9), 74.2 (36.7), 81.5 (43.7) and 67.4 (25.9) nmol/L in stage 1 to 5. There was no difference between groups (p=0.25). The mean (SD) vitamin D level was 81.4 (41.2) nmol/L in persons with proliferative retinopathy (n=48) and 75.3 (35.0) nmol/L in persons without (n=621) (p=0.25). In persons with peripheral neuropathy (n=153), the mean (SD) vitamin D level was 74.3 (34.4) nmol/L, and 74.7 (35.4) nmol/L in persons without (n=470) (p=0.91).

Conclusions: Among persons with type 2 diabetes, persons with severely increased albuminuria had a lower vitamin D level; moreover, an inverse relationship between vitamin D level and albuminuria was demonstrated. Interestingly, no association between vitamin D level and CKD stage, proliferative retinopathy or peripheral neuropathy was observed.

SA-PO558

The Target Glycated Albumin Level May Differ According to Dialysis Patients' Nutritional Status and Use of Hypoglycemic Agents: A 3-Year Nationwide Cohort Study

Junichi Hoshino,[2,1] Masanori Abe,[2,3] Takayuki Hamano,[2,4] Takeshi Hasegawa,[2,5] Atsushi Wada,[2,9] Yoshifumi Ubara,[1] Kenmei Takaichi,[1] Shigeru Nakai,[2,6] Ikuto Masakane,[2,7] Kosaku Nitta.[2,8] JSDT Renal Data Registry Committee
[1]Toranomon Hospital, Tokyo, Japan; [2]Renal Data Registry Committee, The Japanese Society for Dialysis Therapy, Tokyo, Japan; [3]Nihon University School of Medicine, Tokyo, Japan; [4]Osaka University Graduate School of Medicine, Osaka, Japan; [5]Showa University, Tokyo, Japan; [6]Fujita Health University School of Health Sciences, Aichi, Japan; [7]Honcho-Yabuki Clinic, Yamagata, Japan; [8]Tokyo Women's Medical University, Tokyo, Japan; [9]Kitasaito Hospital, Asahikawa, Japan.

Background: We previously reported a J-shaped association between glycated albumin (GA) and mortality in diabetic patients on dialysis. However, it remains unclear what GA level is associated with the cause-specific mortality among patients taking or not taking hypoglycemic agents and among those with or without malnutrition.

Methods: We examined 40,417 diabetic patients on maintenance hemodialysis in a cohort studied by the Japanese Society for Dialysis Therapy (female, 30.8%; mean age, 67.3±11.2 years; mean dialysis duration, 5.4±4.6 years) and followed up for 3 years from 2013-2016. GLIM criteria were used to assess malnutrition. Patients on PD, who had history of kidney transplantation, or who did not have data of baseline GA or hypoglycemic agent use were excluded. We used Cox regression to calculate adjusted hazard ratios (HRs) and 95% confidence limits (95% CL) for 3-year mortality after adjusting for 18 potential confounders. Subdistribution hazard ratios (SHRs) were used to explore cause-specific mortality.

Results: Using GA levels of 15.9–17.2% as the reference, patients not taking hypoglycemic agents in the lowest GA deciles (≤15.8%) had slightly worse mortality (HR 1.10 [0.94–1.30]), mainly due to increased deaths from cancer (SHR 1.64 [0.99–2.68]), which was not observed in those patients taking hypoglycemic agents. Malnourished patients taking hypoglycemic agents in the lowest GA deciles had slightly worse mortality (HR 1.05 [0.75–1.46]), mainly due to increased deaths due to infections (SHR 1.31 [0.70–2.44]). In addition, their lowest mortality was observed at a GA level of around 21.5%, which was higher than that seen in other patients.

Conclusions: These data suggests that GA levels may differ according to patients' hypoglycemic agent use, nutritional status, and cancer status. Target GA levels in malnourished patients may be higher than in other diabetic patients, and a very low GA level in dialysis patients not taking hypoglycemic agents may be associated with an increased risk of cancer.

Predictors of CKD Progression, Mortality, and Cardiovascular Outcomes in Patients with and Without Diabetes

Tope Olufade,[1] Lois Lamerato,[2] Like Jiang,[1] Stephen Nolan,[1] Rubeen K. Israni.[1]
[1]AstraZeneca, Wilmington, DE; [2]Henry Ford Health System, Detroit, MI.

Background: Diabetes and CKD are a growing burden for health systems, both in the US and internationally. Diabetes is thought to be responsible for approximately half of all end-stage renal disease (ESRD) cases. Also, the number of people with diabetes and CKD has increased dramatically along with the increase in diabetes itself. The role of albuminuria in CKD progression and cardiovascular (CV) outcomes is still underappreciated. This study examines CKD progression and CV outcomes in a contemporary real-world setting.

Methods: This retrospective cohort study used administrative data in Henry Ford Health System. eGFR lab results were used to identify patients with stage 2-4 CKD (index date) from 2006-2016 and followed through 2018. A second eGFR >90 days from index date excluded acute kidney injury. Patients with a history of renal transplant, death within 30 days of index date, or progression to ESRD within 6 months of index date were excluded. Logistic regression models were used to identify factors associated with ESRD and occurrence of a composite of myocardial infarction (MI), stroke, and all-cause mortality at 5 yrs of follow-up.

Results: The final cohort consisted of 29,303 patients. The population was 45% male, 38% African American (AA), 48% white, and had a mean age of 61 yrs. At baseline, 72% of patients had stage 2 CKD and 64% had type 2 diabetes (T2D). At 5 yrs of follow-up, ESRD occurred in 3.8%, heart failure (HF) in 17.6%, and the composite outcome in 17.5% (MI 5.8%, stroke 5.0%, all-cause mortality 9.4%). In the ESRD regression model, male gender, AA race, baseline eGFR, and diabetes were associated with high risk, and older age with lower risk. For the composite outcome, male gender, AA race, older age, T2D, and baseline eGFR were all associated with greater risk. In additional models examining the subset of patients with UACR (48% of patients), elevated UACR became the strongest predictor, with a 4-fold increased risk for both ESRD and the composite outcome.

Conclusions: There was a moderate risk of progression to ESRD, but a significant risk of the CV composite and HF outcomes over a 5-yr period. Traditional factors (eg, male gender, increasing age) were observed, but albuminuria was further identified as a strong independent risk factor.

SA-PO560

Modifiable Factors Associated with Health-Related Quality of Life in Patients with Diabetic Kidney Disease

Suhyun Kim, Mee yeon Park, Hyo jin Boo, Hye Ryoun Jang, Wooseong Huh, Yoon-Goo Kim, Dae joong Kim, Jung eun Lee. *Nephrology Division, Department of Internal Medicine, samsung medical center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Poor health-related quality of life (HRQOL) is associated with increased cardiovascular risk and mortality in patients with kidney disease. Therefore, it is critical to identify potentially modifiable clinical factors contributing to poor HRQOL. This study examined clinical factors associated with poor HRQOL in patients with diabetic kidney disease (DKD) focusing on depression, anxiety, sleep quality, and physical activity.

Methods: Between April 2017 and March 2018, 141 adults (aged ≥18 years) with DKD were recruited in single tertiary hospital. HRQOL was assessed at baseline with the Short Form 36 (SF – 36) Health Survey Questionnaire. Poor HRQOL was defined as baseline scores blow the median value. Depression and anxiety were assessed with the Hospital Anxiety and Depression Scale (HADS). Sleep quality and physical activity were measured using Korean version of the Pittsburgh Sleep Quality Index (PSQI-K) and Short form of Global Physical Activity Questionnaire (GPAQ) respectively.

Results: The age was 65 [57-72] years old, and 73% (n=103) of participants were men. Prevalence of anxiety and depression were 17% (n=24) and 7% (n=10) respectively. Forty-eight (34%) subjects corresponded to poor sleepers and 40 (28%) subjects showed low physical activity. SF-36 scores were decreased with advanced CKD stages (stage 3, 79 [71-82]; stage 4, 71 [56-82]; stage 5, 70 [57-82]; $p = 0.029$ for trend). Anxiety, depression, and poor sleep quality were negatively correlated with SF-36 scores ($p < 0.05$). eGFR and physical activity were positively correlated with HRQOL scores ($p < 0.05$). In multivariable logistic analysis, depression scores were associated with poor HRQOL independently of age, sex, comorbidity, eGFR, anemia, sleep quality, anxiety and physical activity (odds ratio per 1-score increment, 1.51; 95% CI, 1.27-1.80, $p < 0.001$).

Conclusions: In patients with DKD, depression was a major determinant of poor HRQOL among the modifiable clinical factors such as anxiety, sleep and physical activity. Active surveillance of depression and psychosocial intervention should be considered to improve the well-being of these patients.

Characterization of Extracellular Vesicles Derived from Human Amniotic Fluid Stem Cells (hAFSC-EVs) and Their Therapeutic Effect in Alport Syndrome

Laura Perin,[2] Paola Aguiari,[2] Charmi Dedhia,[2] Astgik Petrosyan,[1] Valentina Villani,[2] Hasmik Soloyan,[2] Jo-Anna Reems,[3] Sargis Sedrakyan.[2]
[1]Saban Research Institute- Children's Hospital Los Angeles, Los Angeles, CA; [2]Children's Hospital Los Angeles, Los Angeles, CA; [3]University of Utah, Salt Lake City, UT.

Background: Alport Syndrome (AS) is an inherited disease characterized by a loss of glomeruli cells and kidney function. Based on our previous results that EVs from AFSC modulated glomerular crosstalk, we proposed that AFSC-EVs might represent a new therapeutic approach to treat AS. In light of clinical translation, we characterized AFSC-EVs of human origin and evaluated whether they would present a therapeutic effect in an AS mouse model.

Methods: Human clonal AFSC were derived from amniotic fluid collected after volunteer donors provided consent. EVs were obtained from AFSC and characterized by RNA-seq and proteomics. hAFSC-EVs were injected into Alport mice and their therapeutic effect was studied by evaluation of renal function and life-span. RNA-seq was performed on glomeruli obtained from injected and non-injected mice.

Results: Proteomic profiling identified 675 intact proteins and RNA-seq data identified 2,535 miRs in hAFSC-EVs. hAFSC-EV "fingerprint" was assessed by performing GO analysis on the 100 most highly expressed proteins and miRs. The results identified pathways involved in tissue homeostasis, the mTOR pathway, and TGFβ and VEGF pathways. When injected in vivo into AS mice, biodistribution studies showed hAFSC-EVs localized in the kidney, corrected proteinuria and prolonged the life-span of treated mice. No side effects (including teratoma) were noted in the treated mice. RNA-seq of glomeruli obtained from treated AS mice showed similar gene expression patterns to WT, by cluster analysis. Our data indicated that hEVs highly modulated pathways involved in collagen deposition remodeling, in addition to downstream targets of VEGF, FGF, TNF, angiotensin and preserved glomerular cells structure and function.

Conclusions: Our protocol for hEVs derivation is reproducible and allows derivation of EV lots with the same identity (specific cargo of proteins and miRs), purity (absence of contaminants) and potency (present therapeutic effect in AS). hAFSC-EVs modulated signaling pathways that are central to maintaining glomerular homeostasis and preserved glomeruli structure with improved kidney function. This suggests the possibility of using hAFSC-EVs as a new therapeutic option for treating AS in humans.

Macula Densa mTOR Signaling Regulates Renin Cell and Glomerular Endothelial Remodeling

Urvi Nikhil Shroff, Anne Riquier-brison, Audrey Izuhara, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: Macula densa (MD) cells are critical regulators of glomerular filtration rate, renal blood flow and renin release via paracrine signaling that involves MD MAP kinases ERK1/2 and p38, and the MD-specific enzymes COX2 and nNOS. The mTOR complex is known to act as a central mediator, integrating the downstream effects of several cell signaling pathways to promote cell growth and protein synthesis. The present study aimed to examine the role of mTOR signaling in regulating MD cell function and its effect on glomerular tissue remodeling.

Methods: An MD-specific genetic mouse model for upregulated mTOR signaling was developed by crossing nNOS Cre mice and mice with a truncated form of TSC2 that upon tamoxifen induction results in mTOR gain-of-function in MD cells (MD-mTOR^{gof}). Changes in expression of MD molecular players controlling renin release (ERK1/2, COX2, mPGES1, etc.) was quantified in renal cortical tissue homogenates. To test the effect of MD-mTOR signaling on renal tissue remodeling, kidney slices were stained for endothelial cell (Meis2 and CD34) and podocyte markers (WT1) using 3D tissue clearing and histological analysis.

Results: Compared to control WT mice, a significant increase in glomerular diameter, robust expansion of the glomerular mesangium, and hypercellularity at the glomerular vascular pole were observed in MD-mTOR^{gof}mice. MD-mTOR^{gof}mice had increased expression of ERK1/2, phospho ERK1/2, COX2 and mPGES1, as well as increased renin expression quantified with immunofluorescence labeling for renin granules and on immunoblots. MD-mTOR^{gof}mice featured significantly increased number of Meis2^{+} glomerular endothelial cells as well as CD34^{+} endothelial precursor cells with the highest density close to the MD.

Conclusions: In summary, upregulation of MD-mTOR signaling has robust effects on both the traditional MD cell functions (renin control), and their newly emerging role in long-term glomerular tissue remodeling. Since MD-mTOR signaling significantly affects the glomerular architecture, it may be targeted to develop future therapeutic strategies for endogenous tissue remodeling and repair in glomerular diseases.

SA-PO563

Extent of Glomerular Filtrate Determines the Pattern of Podocyte Detachment

Nobuyuki Saga,[1] Taiji Matsusaka,[2] Michio Nagata.[1] *[1]University of Tsukuba, Tsukuba, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Podocyte detachment is a hallmark of segmental glomerulosclerosis. In ASN Kidney Week 2018, we presented that the cell detachment occurred locally and dominantly at the side of urinary pole even in diffuse cell injury in NEP25 mouse. In addition, by adding unilateral ureter obstruction (UUO) in the mouse model, we showed that glomerular filtrate was essential for detachment. In the present study, we focused on the effects of hyperfiltration to the changes of detachment pattern in diffuse podocyte injury model.

Methods: We used NEP25 mouse, a model of podocyte-specific injury by immunotoxin (LMB2) injection. We performed UUO at 5 days or uninephrectomy (UNx) at 1 day after LMB2 injection. Whole glomerular profiles were photographed by TEM from LMB2+UUO contralateral kidney (61 glomeruli, n=3) and LMB2+UNx model (65 glomeruli, n=3) and compared with the data from LMB2 model (47 glomeruli, n=4). Entire GBM in all glomeruli were classified into normal, foot process effacement or detachment and each length per glomerulus was measured. This method enabled us to identify the localization, continuity and relationship of each change. The relationships between the depth of the glomerulus and the severity of detachment were also analyzed in all models.

Results: The average lengths of detachment were significantly longer in both LMB2+UUO contralateral kidney (12.27%) and LMB2+UNx model (14.21%) than in LMB2 model (5.20%). The tendency of detachment to occur near the urinary pole was enhanced in LMB2+UUO contralateral kidney. By contrast, detachment occurred globally without the tendency in LMB2+UNx model. Detachment was most severe not at the deepest area (750-1000 um) but at 500-750 um from the surface in all models. In comparison with LMB2 model, detachment was severer at all range of the depth of the glomeruli in LMB2+UUO contralateral kidney and LMB2+UNx model.

Conclusions: Extent of glomerular filtrate may regulate the length and the localization of detachment of injured podocyte. Up to some threshold, increase in glomerular filtrate may enhance the tendency of the lesion as a local event. Excessive glomerular filtrate beyond the autoregulation by glomerulus, as presumed in LMB2+UNx model in the study, may change the pattern of podocyte detachment that accelerates FSGS.

SA-PO564

Dynamic regulation of macrophage subpopulations in mouse models of kidney injury

Johannes Nordlohne,[1] Ilona Hulsmann,[1] Svenja Schwafertz,[1] Frank Eitner,[1] Michael S. Becker.[2] *[1]Bayer AG, Wuppertal, Germany; [2]Bayer, Wuppertal, Germany.*

Background: Macrophages are key drivers of kidney fibrosis and therapeutic efforts have been made to manipulate immuno-regulatory macrophage functions *in vivo*. However, the moderate success of these approaches might be explained by a poor understanding of macrophage kinetics, functional relevance of distinct macrophage subpopulations, and model specific differences.

Methods: We analyzed kidney macrophages in healthy mice and two models of kidney damage, unilateral ureteral obstruction (UUO) and ischemia reperfusion injury (IRI) by a flow cytometry strategy. We identified five kidney macrophage subpopulations with distinct expression of myeloid markers CD11b and CD11c, based on a strategy by Kawakami et al. (2013; J Immunol.).

Results: All macrophage populations, particularly CD11b^{high} CD11c^{high} macrophages, were increased in diseased mice compared to healthy mice. Model specific differences revealed 8-fold more blood-derived monocytes (CD11b^{high} CD11c^{low}) after eight days of UUO than after six days of IRI (840 vs 110 cells/mg kidney). Surface markers MHCII and CD206 allowed further distinction between more pro-inflammatory "M1"- and immuno-regulatory "M2"-like macrophages, illustrating dynamic contribution of each of the five macrophage populations. Treatment with the VEGF receptor tyrosine kinase inhibitor tivozanib effectively reduced total numbers of MHCII-positive and CD11b^{high} CD11c^{high} macrophages after eight days of UUO.

Conclusions: In conclusion, we were able to reveal kinetic and model specific changes in kidney macrophage subpopulations occurring under damage. Being able to monitor and understand the dynamics of different macrophage subsets within diseased organs could help in finding new therapeutic angles.

SA-PO565

Anti-KITLG Therapy in Renal Injury

Debra L. Walter,[1] Hongyu Zhang,[1] Cindy Chu,[1] Christopher L. O'Connor,[1] Paul D. Killen,[1] Martin D. Phillips,[2] Wenjun Ju,[1] Nicholas W. Lukacs,[1] Markus Bitzer.[1] *[1]University of Michigan, Milan, MI; [2]Opsidio LLC, Bryn Mawr, PA.*

Background: Activation of TGFB signaling promotes organ fibrosis. KIT/KITLG signaling regulates inflammation and fibrosis in humans and animal models and cross-talks with TGFB signaling, but its role in mediating kidney fibrosis remains unclear. Isoform-specific anti-KITLG-antibody therapy is in preclinical development. Therefore, we examined the effect of KITLG inhibition on glomerulosclerosis and interstitial fibrosis in ALB-TGFB1 transgenic mice (TGFB1-TG).

Methods: Ten-day old TGFB1-TG mice were treated biweekly with a monoclonal antibody against KITLG (aKITLG) (n=17) or control-IgG (IgG) (n=15) and euthanized after two weeks. Six wild-type mice were used as non-diseased controls. Pathologic phenotype was assessed blindly by an experienced nephropathologist using trichrome stained sections. RNA-sequencing was performed on HiSeq4000 and analyzed using dseq2 and limma-voom, and further assessed using Ingenuity pathway analysis (IPA). IgG and aKITLG-treated mice were separated into mild (n=6) and severe (n=9-10) groups using previously published parameters (PMID 19465643) and principal component analysis of gene expression profiles. Podocyte density, mesangial index and glomerulosclerosis were quantitated morphometrically and plasma KITLG (pKITLG) levels measured by ELISA.

Results: Severe IgG mice had significantly higher pKITLG and mesangial index and lower podocyte density compared to mild IgG mice ($p<0.01$). pKITLG levels significantly correlated to podocyte density (inversely) and mesangial index (positively) ($p<0.05$). aKITLG mice had no change in body weight and trended towards improved survival. aKITLG mice demonstrated significantly reduced fibrosis and mesangial index ($p<0.05$) and a trend towards improved podocyte density compared with IgG mice. Expression of extracellular matrix genes *Col1a1*, *Col3a1* and *Col6a3* was significantly reduced in kidney cortex of aKITLG vs IgG mice ($p<0.05$). IPA identified several candidate signaling pathways altered by aKITLG.

Conclusions: Our findings that pKITLG increased with severity and aKITLG antibody ameliorated kidney damage in TGFB1-TG mice support aKITLG therapy as a candidate intervention for fibrotic kidney disease. Studies examining human biofluids and aKITLG therapy in other mouse models of kidney injury are ongoing.

Inhibition of Human Antigen R Reduces Glomerular Injury in Experimental Glomerulonephritis

Simeng Liu, Zhimin Huang, Yufeng Huang. Internal Medicine, Div. of Nephrology, University of Utah *University of Utah School of Medicine, Salt Lake City, UT.*

Background: Recent identification of a mRNA-binding protein (human antigen R (HuR)) that regulates mRNA turnover and translation of numerous genes involved in immune response, inflammation, fibrosis and oncogenic signaling and is abnormally elevated in varied kidney diseases offers a novel target for the treatment of renal fibrosis. Thus, we hypothesized that therapy with a selective inhibition of HuR function with a small molecule, KH3, would reduce inflammation and profibrotic factors thereby improving glomerulosclerosis in experimental glomerulonephritis.

Methods: Three experimental groups included normal, untreated disease control, and KH3-treated nephritic rats. Disease was induced in rats with monoclonal anti-thy 1.1 antibody. KH3 was given via daily intraperitoneal injection from day 1 after disease induction at the dose of 50mg/kg BW/day.

Results: At day 6, animals treated with KH3 showed significant reductions in proteinuria, podocyte injury determined by ameliorated podocyte loss and glomerular podocin expression, glomerular staining for periodic acid-Schiff positive material (41%), fibronectin (52%) and collagen IV (48%) and in collagen and fibronectin mRNA levels and protein production. Treatment with KH3 also reduced disease-induced increases in

renal TGF-ß1 and PAI-1 mRNA levels and protein levels. Additionally, a marked increase in renal production of NF-kb-p65 and Nox4 and glomerular macrophage cell infiltration observed in disease control group was largely reversed by treatment with KH3.

Conclusions: These observations strongly support our hypothesis that inhibition of HuR with KH3 has therapeutic potential for reversing glomerulosclerosis by inhibiting inflammatory cell infiltration, decreasing local NAPDH oxidase-mediated oxidative stress, and TGFß and PAI-1's expression and action.

SA-PO567

D-Site Binding Protein Regulates Cell Proliferation Through Mediating Cell Cycle Progression in Rat Mesangial Cells

Lei Chen,[1] Jie Li,[2] Ning Qu,[2] Hua Liu.[2] *[1]Xi'an Jiaotong University, Xi'an, China; [2]First Affiliated Hospital of Medical College of Xi'an Jiaotong University, Xi'an, China.*

Background: Over proliferation of glomerular mesangial cells (MCs) disturbs mesangial homeostasis and leads to renal damage in mesangioproliferative glomerulonephritis. It is documented that transcriptional factors may be involved in the proliferation of MCs. This study aims to identify the key transcriptional factor that prevents the MCs from over proliferation and to clarify its regulatory mechanism.

Methods: Glomeruli were isolated from rats subjected to anti-Thy1 antibody or phosphate-buffered saline. Total RNA was extracted and subjected to microarray analysis. Lentiviral transfection and siRNA transfection were used to obtain D-site binding protein (DBP)-over expressed and DBP-knockdown rat primary MCs, respectively. The cell proliferative capacity was measured by 5-Ethynyl-2′-deoxyuridine (EdU) assay. Flow cytometry was conducted for cell cycle analysis. Histology, immunohistochemistry, and western blot analysis were performed to detect the expression of selected gene and cell cycle regulators.

Results: The cell cycle pathway was the most enriched pathway in the anti-Thy1N model, and the DBP ranked first in the cluster of transcription factors, which was markedly decreased accompanied by an over proliferation of MCs in anti-Thy1N model rats. The knockdown of DBP significantly promoted the proliferation of primary rat MCs, whereas the DBP over expression inhibited the MCs' proliferative capacity in vitro, compared to that of the control cells. DBP arrested G1/S-phase transition by inhibiting the expression of p21, p27 and inducing the Cyclin D1 expression in MCs.

Conclusions: DBP effectively inhibits the proliferation of MCs through G0/G1 phase arrest, and the decrease of DBP may induce mesangial over proliferation in the anti-Thy1N model.

SA-PO568

Integrin β6 Knockout Ameliorates Glomerular Sensitization to Podocyte-Specific Injury

Jiayi Wang,[1,2] Xin Li,[4] Taiji Matsusaka,[3] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Nephrology, Second Xiangya Hospital, Central South University, Changsha, China; [3]Tokai University School of Medicine, Isehara, Japan; [4]The Medicine College of Shanghai JiaoTong University, Shanghai, China.*

Background: We previously showed that even mild tubulointerstitial injury sensitized glomeruli to subsequent podocyte-specific injury. We also showed that tubulointerstitial fibrosis was decreased in integrin $\beta6^{-/-}$ mice. Integrin avβ6 is expressed on some tubular epithelial cells, including macula densa, but not on glomerular tufts, and activates latent TGFβ. We aimed to investigate whether $\beta6^{-/-}$ mice had ameliorated sensitization to glomerular injury induced by initial tubular injury, and possible mechanisms of β6 in tubuloglomerular crosstalk.

Methods: Wild type (WT) or $\beta6^{-/-}$ mice were mated with NEP25 mice which express human CD25 on podocytes that can be injured with specific toxin (LMB2) injection. A sequential tubular-glomerular injury model was performed by inducing acute tubular injury by aristolochic acid injection at wk 0, followed by podocyte injury by LMB2 injection at wk 8, when tubular injury had functionally recovered. Uninephrectomy was performed at wk 9 and mice sacrificed at wk 12. Effects of β6 on tubuloglomerular feedback were assessed by adding high salt from wk 6 in subgroups.

Results: KIM-1 expression in tubules was decreased in $\beta6^{-/-}$ at wk 8 after tubular injury but with only numerically reduced interstitial fibrosis (Sirius red morphometry). However, even this minor tubulointerstitial protection by β6 deficiency resulted in a marked effect on glomerular sensitization to podocyte injury. $\beta6^{-/-}$ mice had less albuminuria and glomerulosclerosis with more preserved GFR and $WT1^{+}$ cells vs WT, with less TGFβ activation. Further, WT subgroups treated with high salt had greater increase in urinary sodium excretion, compared to normal salt, vs $\beta6^{-/-}$. High salt increased calculated single-nephron GFR (SNGFR) in $\beta6^{-/-}$ but not in WT, with less decrease in renin RNA and protein in $\beta6^{-/-}$. NKCC2 activity (measured by OXSR1 and VAMP2 expression), adenosine formation enzyme (ecto-5–nucleotidase) and A1 adenosine receptor were lower in high salt exposed $\beta6^{-/-}$ vs WT.

Conclusions: We conclude that integrin $\beta6^{-/-}$ show very mild amelioration of acute tubular injury and interstitial fibrosis vs WT, but still show markedly less glomerular sensitization to subsequent podocyte-specific injury, which is contributed to by blunted tubuloglomerular feedback. We postulate that β6 may, in addition to effects on tubulointerstitial injury, also modulate macula densa function.

Funding: NIDDK Support

SA-PO569

PBI-4050 Reduces Renal Injury in a Mouse Model of Aristolochic Acid-Induced Nephropathy

Jean-Francois Thibodeau,[1,2] Amélie Blais,[2] François Sarra-Bournet,[1] Brigitte Grouix,[1] Alex Gutsol,[2] Martin Leduc,[1] Francois A. Leblond,[1] Richard L. Hébert,[2,3] Lyne Gagnon,[1] Chris R. Kennedy.[2,3] *[1]Prometic Biosciences Inc., Laval, QC, Canada; [2]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [3]Department of Cellular and Molecular Medicine, University of Ottawa, Ottawa, ON, Canada.*

Background: PBI-4050 is a novel therapeutic compound with excellent safety and efficacy profiles in both experimental and clinical settings. Treatment with PBI-4050, a dual GPR40 agonist and GPR84 antagonist, is beneficial in diseases where sustained inflammation and fibrosis are involved, including chronic kidney disease (CKD). Here we used the aristolochic acid (AA) model of CKD and tested whether treatment with PBI-4050 could mitigate renal injury progression.

Methods: Eight-week old male C57BL/6 mice were challenged with AA (4 days, 3.5 mg/kg/day, i.p.) and were treated with PBI-4050 (200 mg/kg/day, p.o.) or vehicle (H_2O) seven days later for four weeks. Plasma creatinine was measured weekly by HPLC. Twenty-four hour urine collection was performed at endpoint. Tubulointerstitial injury was assessed using Sirius-red and PAS-stained kidney sections. Lipid accumulation was observed using Oil Red-O stained frozen kidney sections.

Results: At endpoint, renal function was significantly improved in PBI-4050 treated AA-mice, as plasma creatinine and urea were reduced compared to vehicle treated mice. This was accompanied by significant improvements in polyuria and tubular function as fractional excretion of Na^{+}, K^{+}, Ca^{2+} was maintained by PBI-4050. Moreover, AA-induced reduction in hematocrit was significantly improved as early as one week-post treatment with PBI-4050 and maintained until endpoint. Consistent with improved renal function, tubulointerstitial fibrosis (% collagen area) was apparent in AA-mice and was significantly reduced in PBI-4050-treated mice. Interestingly, AA-challenged mice had significant lipid deposition in kidney tissue along with reduced PGC1α mRNA expression, and this effect was also improved by PBI-4050. Finally, inflammatory cell infiltration and F4/80 mRNA levels were decreased in PBI-4050 treated AA-mice.

Conclusions: Overall, treatment with PBI-4050 improved several key renal functional and structural abnormalities in AA-induced CKD including anemia, fibrosis, renal lipid handling and functional decline. Results from the above and previous studies suggest treatment with PBI-4050 has the potential to slow the progression of CKD due to various diseases with different etiologies.

Persistent Mechano-Growth Factor (MGF) Upregulation in Glomeruli of Diabetic or MGF-Transgenic Mice Induces Mesangial Cell (MC) Glucose Transport, PKC Activation, and Extracellular Matrix Production

Yongxin Gao,[1] Hongwei Li,[4] Virin R. Ramoutar,[3] Sarah T. Suliman,[1] Ljubomir M. Ilic,[2] Charles W. Heilig.[1] *[1]University of Florida, Jacksonville, FL; [2]University of Florida College of Medicine, Jacksonville, FL; [3]UF Health, Jacksonville, FL; [4]Southern Medical University, Guangzhou, China.*

Background: Mechano-Growth Factor (MGF) is expressed at baseline in normal mouse glomeruli, and is increased in type 2 and type 1 diabetic mice. Here we investigated glomerular MGF expression at both 18 and 26 weeks of Type 2 diabetes mellitus in db/db mice vs db/+ controls and the role of MC glucose uptake and PKC in this process. Mice overexpressing MGF in the glomerular MC were produced to determine its role in glomerulosclerosis (GS).

Methods: IHC for glomerular proteins using specific antibodies, with 0-4+ scoring. P<.05 for changes. 3H2-Deoxyglucose glucose uptake rates in cultured MC. PAS stain for GS. Western analyses for MC proteins.

Results: Db/db Type 2 diabetic mice had developed GS at 18 and 26 weeks of age (increased 45%). They also had 1.9-fold increased glomerular GLUT1 and 1.7-fold increased active PKCß1, resulting in 2.4-fold excess Fibronectin (FN) and 1.7-fold excess Collagen Type IV (Col-IV). Glomerular MGF increased > 3-fold in the diabetic mice at 18 and 26 weeks. MGF-overexpression in cultured MC (i.e. MGF-S) increased GLUT1 2.6-fold, with a 67% increased glucose uptake rate and increased fibronectin (FN) 95%. 0.1mM Phloretin inhibited the excess glucose uptake in MGF-S by 57%, and suppressed the excess FN by 43%. This implicated MGF-induced glucose uptake in the excess FN production of MGF-S. 1μM Staurosporine (PKC inhibitor) suppressed the excess GLUT1 in MGF-S by 77%, and suppressed the excess glucose uptake rate by 64%. This implicated PKC activation in MGF-induced GLUT1 expression and glucose uptake. Transgenic overexpression of MGF in mouse glomerular MC's in vivo by 2.7-fold vs controls, led to 2.3-fold increased glomerular GLUT1 and 2.4-fold increased fibronectin (FN) accumulation. MGF-transgenic adult mice exhibit 2-fold increased GS on PAS staining.

Conclusions: 1. Glomerular MGF is induced in Type 2 diabetic mice at age 18 weeks and persists at 26 weeks, with increased PKCB1, GLUT1, FN and Col-IV. 2. Enhanced glucose uptake and PKC activation are involved in MGF-induced GLUT1 and FN expression in MC; 3. Transgenic mice overexpressing MGF in glomerular MC exhibited increased glomerular GLUT1 and GS with excess FN, similar to diabetic GS where glomerular MGF is also elevated.

Lipopolysaccharide from Gut Microbiota Contributes to Pathogenesis of Murine Lupus Nephritis

Caleb C. Chan, Jing Yu, Susan Yung, Daniel Tak Mao Chan. *The University of Hong Kong, Hong Kong, China*.

Background: Bacterial products from the gut may enter the circulation and induce inflammatory responses at distant sites, and gut microbiota has been implicated in the pathogenesis of autoimmune diseases. Lipopolysaccharide (LPS) is a component of the outer wall of Gram-negative bacteria. We previously showed that lupus nephritis patients had higher circulating LPS levels compared with healthy subjects. We investigated the role of LPS in the pathogenesis of murine lupus nephritis

Methods: NZB/W F1 mice at 16-wk were randomized to receive saline or LPS (0.5 mg/kg body weight) once daily for 4 weeks, and their renal and colonic histopathology was examined. Intestinal mucosal permeability was investigated with LPS-FITC. Expression of LPS-binding protein (LBP), CD14 and TLR-4 was investigated with cytochemistry.

Results: Serum LPS level was significantly higher in NZB/W F1 mice with active nephritis compared with age-matched BALB/c mice ($P<0.05$). Histopathologic features of active nephritis in NZB/W F1 mice were accompanied by increased LBP, CD14 and TLR-4 expression in proximal renal tubular epithelial cells. Mice with active nephritis also showed increased gut permeability, with orally fed LPS-FITC detected in renal proximal tubules. NZB/W F1 mice that received LPS showed increased proteinuria, and increased IgG and collagen deposition in glomeruli, compared with controls that received saline. Mice given LPS also showed decreased neutral mucin expression in goblet cells, and reduced ZO-1 and LBP expression, in the colonic epithelium, and also increased α-smooth muscle actin expression in the lamina propria.

Conclusions: The data demonstrate that active murine lupus nephritis is associated with increased circulating LPS likely of gut origin, which may contribute to the pathogenesis of renal histopathologic features.

Kidney Biopsy in Initial Presentation of Markedly Reduced Kidney Function: Is It Safe? Will It Make a Difference?

Fatima B. Eltayeb, Dr. Shaefiq B. Thappy, Essa Abuhelaiqa, Omar Fituri, Hassan A. Al-Malki, Mohamad M. Alkadi. *Hamad Medical Corporation, Doha, Qatar*.

Background: One of the dilemmas faced by nephrologist is a patient presenting for the first time with elevated creatinine and unknown baseline renal function. It is usually unclear whether this represents an acute or chronic kidney disease, especially when the size of kidneys is normal and immunologic workup is negative. The aim of this study is to retrospectively determine the risks and benefits of obtaining a kidney biopsy in patients presenting with elevated creatinine and negative immunologic workup.

Methods: We included patients who presented with serum creatinine higher than 4.5 mg/dL and underwent kidney biopsy between April 1st, 2017 and April 1st, 2019. Patients who had known baseline creatinine or positive serologic studies were excluded from the study.

Results: 52 patients were included in the study and their baseline characteristics are summarized in Figure 1. 54% of patients were initiated on chronic hemodialysis during hospitalization. All kidney biopsies were ultrasound-guided and were done with blood pressure <140/80. 29% of kidney biopsies were considered suboptimal or inadequate to make a diagnosis. Only two biopsies (4%) showed treatable acute pathology (1 multiple myeloma and 1 proliferative GN). All the remaining biopsies had at least moderate IFTA and 86% had diffuse global glomerulosclerosis. IgA nephropathy was the most common etiology (n=11; 21%) followed by hypertension (n=5) and diabetic nephropathy (n=4). 13 patients (25%) developed hematoma post procedure: 6 patients (46%) required no intervention, 6 patients (46%) required blood transfusion, and 1 patient (8%) required embolization to control bleeding. Figure 1 compares kidney size and incidence of hematoma.

Conclusions: Initial presentation of markedly reduced renal function with insignificant history and negative work up are at high risk for native kidney biopsy complications and have low yield to diagnose a reversable disease even if kidney size is normal. Benefits and risks of kidney biopsy should be carefully discussed with patients.

Table 1.

Baseline characteristics	N = 52
Age at presentation, years, median (IQR)	32.5 (29-40)
Male gender, n (%)	39 (75)
Asian ethnicity, n (%)	43 (83)
Diabetes, n (%)	8 (15)
SBP on presentation, mm Hg, median (IQR)	174 (160-190)
DBP on presentation, mm Hg, median (IQR)	105 (97-114)
Serum creatinine at presentation, mg/dL, median (IQR)	8.8 (5.8-13.2)
Hemoglobin, g/dL, median (IQR)	8.95 (7.4-10.9)
Serum Calcium, mg/dL, median (IQR)	8.52 (8-9.6)
Serum Phosphorus, mg/dL, median (IQR)	5.9 (4.9-7.5)
PTH, pg/mL, median (IQR)	371 (250-649)
Urine protein: creatinine ratio, mg/mmol, median (IQR)	572 (361-705)
Serum C3, mg/dL, median (IQR)	99 (84-114)
Serum C4, mg/dL, median (IQR)	32 (27-40)
Hematuria, n (%)	36 (69)
Right kidney size, cm, Median (IQR)	9.7 (9.3-10.1)
Left kidney size, cm, Median (IQR)	9.7 (9.2-10.1)
Dialysis during hospitalization, n (%)	28 (54%)

MiRNA-424 in Exosomes from Podocytes Promote Apoptosis of Renal Tubular Epithelial Cells Through p38 Activation

Soon hyo Kwon,[1] Hyoshik Kim,[1] Hyunjin Noh,[1] Yon hee Kim,[1] Byung chul Yu.[2] *[1]Soonchunhyang University Seoul Hospital, Soonchunhyang University Medical College, Seoul, Republic of Korea, Seoul, Republic of Korea; [2]Soonchunhyang University Bucheon Hospital, Republic of Korea, Bucheon, Republic of Korea.*

Background: Tubular injury and fibrosis is associated with progressive kidney function decline in advanced glomerular disease. Glomerulo-tubular crosstalk is believed to contribute to tubular injury. Exosomal micro RNAs (miRNAs) are capable of modulation of distant cells. We hypothesized the exosomal miRNAs derived from injured podocyte lead to tubular epithelial cell damage.

Methods: As proof of concept, tubular epithelial cells (HK2 cell) were cultured with exosomes from puromycin-treated human podocytes or healthy podocytes. Damage to the HK2 cells was assessed. Through sequencing we identified the miRNA repertoire from podocyte exosomes. To validate the effect of the miRNAs, HK2 cells were treated with miRNA mimics.

Results: Exosomes from injured podocytes induced apoptosis and p38 phosphorylation of HK2 cells. RNAseq identified up-regulated 63 miRNAs in the exosomes from puromycin treated podocytes. Among them, 5 miRNAs (miR-149, 424, 542, 582 and 874) were selected as candidate miRNAs for tubular apoptosis according to a literature-based search. miRNA-424 mimics led to apoptosis of HK2 cells.

Conclusions: Exosomes from injured podocytes lead to damage in tubular epithelial cells. This may contribute to the development of tubular injury in glomerular disease.

SA-PO574

Cell Fraction Changes Show Strong Correlation with Kidney Disease Severity in Mice and in Patients

Yawen Yang,[1,2] Jihwan Park,[1,2] Rojesh Shrestha,[1,2] Seungyub Han,[3] Xin Sheng,[1,2] Mingyao Li,[4] Junhyong Kim,[3] Katalin Susztak.[1,2] SUSZTAK LAB *[1]Renal-Electrolyte and Hypertension, University of Pennsylvania, Philadelphia, PA; [2]Institute for Diabetes, Obesity, and Metabolism, University of Pennsylvania, Philadelphia, PA; [3]Department of Biology, University of Pennsylvania, Philadelphia, PA; [4]Biostatistics and Epidemiology, University of Pennsylvania, Philadelpiha, PA.*

Background: A revolution in cellular measurement technology is under way. While prior studies have only been able to analyze averaged outputs from whole kidneys, now we can accurately monitor genome-wide gene expression, regulation, function, cellular history and cellular interactions in thousands of individual cells in a single experiment. We used single cell RNA analysis to unravel the kidney and immune cell diversity and cell plasticity in healthy and diseased kidneys.

Methods: Five to 8-week-old male FvB wild-type mice underwent ligation of the left ureter and were sacrificed on day 7. Single cell RNA sequencing was performed using the 10X Genomics Chromium System. Data was aligned using Cell Ranger Software and processed using the Seurat package.

Results: We analyzed the transcriptome of 59,609 individual cells from 6 control and 2 UUO kidneys. We identified 30 different major cell populations and multiple subpopulations. Specifically, we found that immune cell diversity was much greater in disease tissue compared to control animals and we identified 16 different immune cell types, including neutrophils, basophils, macrophages, B-cells, plasma cells, CD4 T cells, Th17 cells, T regulatory cells, NK cells, CD8 cells, CD8 effector cells, dendritic cells and plasmacytoid dendritic cells. We found that the fraction of immune cells were also significantly increased in UUO kidneys by single cell analysis. In silico cell deconvolution analysis of bulk RNA sequencing further confirmed loss of epithelial cells and increased in immune cell numbers in UUO mice. Cell-cell interaction analysis indicated that cytokines secreted by injured epithelial cells play key role in immune cell recruitment into disease samples, for example the expression of CD34 responsible for myeloid cell recruitment, Cxc10 and Cxc16 for lymphocyte recruitment. In silico cell deconvolution analysis of 91 human kidney biopsy samples indicated significant cell proportion changes in patient samples. We found that cell proportion changes correlated with the degree of kidney disease such as GFR or fibrosis.

Conclusions: Comparing to health kidneys, UUO kidneys are characterized by increase cell diversity and cell type specific changes. Cell fraction changes show strong correlation with the degree of fibrosis in mice and in patients.

Kidney Expression of Quantitative Trait Analysis Identified Tubule Caspase9 as a Kidney Disease Gene

Tomohito Doke,[1,2] Shizheng Huang,[1,2] Matthew J. Seasock,[1,2] Chengxiang Qiu,[1,2] Katalin Susztak.[1,2] Susztak's lab *[1]Renal-Electrolyte and Hypertension Division, Department of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Institute for Diabetes, Obesity, and Metabolism, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.*

Background: Genome-wide association studies (GWAS) have identified sequence variations associated with kidney disease. However, finding causal genes, cell types and biological mechanisms underlying these associations remains a challenge. We generated expression of quantitative trait (eQTL) information for human kidney compartments to identify likely causal genes. Computational integration of the GWAS and eQTL datasets

identified caspase 9 as a kidney disease risk gene. Caspase 9 is an initiator caspase in the apoptosis pathway found in many cells. Here we analyzed the role of caspase9 in kidney disease development.

Methods: We used a Bayesian colocalization method to integrate kidney eQTL data from 151 healthy individuals of European descent with CKD GWAS. We complemented our compartment-based eQTL studies with kidney-specific epigenome maps and single-cell specific RNA-sequencing results. We generated mice with heterozygous loss of caspase 9 (Casp9+/-). We characterized wild type and Casp9+/- mice at baseline and following folic acid induced kidney injury. Transcript levels for Caspase9 and fibrosis markers were determined by qPCR. Histological changes were characterized by Sirius Red and PAS staining.

Results: We found that the CKD risk variant of rs12124078 was associated with higher expression of caspase9 in microdissected human kidney glomerular and tubule samples. Similarly, in the folic acid kidney fibrosis model and in the APOL1 transgenic mouse model but not in the UUO induced kidney fibrosis model, the expression of cleaved Caspase9 was increased. Caspase 9 heterozygous mice appeared healthy without renal abnormalities. In the folic acid induce kidney injury model, not only the expression of cleaved Caspase9, but other effector caspases such as caspase3, caspase7, and expression of profibrotic genes were lower in Caspase 9 heterozygous mice.

Conclusions: GWAS and eQTL integration identified caspase 9 as CKD risk gene. Heterozygous loss of Caspase9 decreases apoptosis and fibrosis in models of kidney injury, indicating that Caspase9 is a kidney disease risk gene.

The Dual AT_1R/ET_AR Blocker Sparsentan Slows Renal Disease, Improves Lifespan, and Prevents Hearing Loss in Alport Mice

Dominic E. Cosgrove,[1] Brianna M. Dufek,[1] Duane C. Delimont,[1] Daniel T. Meehan,[1] Gina C. Samuelson,[1] Grady Phillips,[2] Flint Boettcher,[2] James Hasson,[3] Celia P. Jenkinson,[3] Radko Komers,[3] MichaelAnne Gratton.[2] *[1]Boys Town National Research Hospital, Omaha, NE; [2]Washington University, St. Louis, MO; [3]Retrophin, Inc., San Diego, CA.*

Background: In Alport syndrome (AS), ET_AR activation in mesangial cells results in subendothelial invasion of glomerular capillaries by mesangial filopodia and induction of inflammatory cytokines culminating in glomerulosclerosis (GS) and tubulointerstitial fibrosis (TIF). Hearing loss in AS is also a consequence of ET_AR-mediated changes in the inner ear. We compared the effect of sparsentan (SP) with AT_1R blocker losartan (LS) on the development of nephropathy and explored the effect of SP on hearing loss-associated inner ear pathology in Alport (AP) mice.

Methods: Wild type (WT) and AP mice were treated daily with vehicle (V), 120 mg/kg SP, or 10 mg/kg LS in 3 studies; early intervention (EI) from 3-7 weeks of age (W) (n=7-8), late intervention (LI) from 5-7W (n=8), or for lifespan (n=10). Proteinuria (UP/C) was assessed weekly, and immunostaining for fibronectin and collagen 1 was used to assess GS and TIF. Glomerular basement membrane dysmorphology was examined by electron microscopy (EM). For hearing, WT and AP mice were treated with V or SP in EI (n=5). Strial capillary basement membrane (SCBM) width was analyzed by EM. Hearing was assessed at 7W (n=5) by auditory brainstem response pre- and 5 days post-exposure to noise.

Results: SP or LS treatment in AP mice in EI ($p<0.05$ vs APV) attenuated increases in UP/C observed in APV at 7W and showed little to no TIF or GS. In LI, SP but not LS prevented a significant increase in GS compared to 5W untreated AP mice and significantly attenuated ($p<0.05$ vs APV 7W) UP/C and TIF compared to APV. Lifespan was significantly longer ($p<0.05$) for both SP- and LS-treated AP mice compared to APV. SP prevented both SCBM thickening and post-noise hearing loss at 16 kHz in AP mice (mean SCBM width±SD nm: 57.8±2.1 WTV, 67.6±5.5 APV, 54.7±2.4 APSP [$p<0.05$ APSP vs APV]; hearing loss: $p<0.05$ APSP vs APV).

Conclusions: In the LI studies, SP provided significant nephroprotection in AP mice, and to a greater extent than in the LS group. SP also significantly attenuated inner ear pathologies. Results from this study, if translated to the clinic, may present a therapeutic approach to reduction in both hearing and renal injury for AS patients.

SA-PO577

Acetate from Microbiota Contributes to the Pathogenesis of Murine Lupus Nephritis

Susan Yung, Jing Yu, Caleb C. Chan, Young Lo, Ellen Wong, Daniel Tak Mao Chan. *The University of Hong Kong, Hong Kong, China.*

Background: Pathogenesis of lupus nephritis is complex, and involves both genetic and environmental factors. Emerging evidence suggests that translocation of microbial products from the gastrointestinal (GI) tract into the circulation may have impact on distant organs. Acetate is a short chain fatty acid (SCFA) generated by gut microbiota. We previously showed that lupus nephritis patients had higher serum acetate levels compared to healthy subjects, and serum acetate level correlated with lupus disease activity. We investigated the role of acetate in the pathogenesis of murine lupus nephritis.

Methods: Eight week old NZB/W F1 mice were randomized to receive (a) drinking water, (b) sodium acetate, or (c) ampicillin and neomycin for 20 weeks. Intestinal mucosal permeability was investigated with dextran-FITC administration, and ZO-1 and claudin-1 expression. Expression of SCFA receptors GPR-41 and GPR-43 was investigated with cytochemical staining. The effect of acetate on mediators of inflammation was investigated in HK-2 cells.

Results: Serum acetate level was significantly higher in NZB/W F1 mice with active disease compared with age-matched BALB/c mice ($P<0.05$). Renal histology in untreated NZB/W F1 mice showed mesangial expansion, immune cell infiltration, progressive glomerulosclerosis, tubular atrophy and interstitial fibrosis; and increased GPR-41 and GPR-43 expression in proximal renal tubular epithelial cells. Also, active lupus nephritis was accompanied by increased gut permeability and decreased ZO-1, claudin-1, GPR-41 and GPR-43 expression in colonic epithelium. 16S rRNA analysis showed a progressive decrease in Gram-positive bacteria phyla *Actinobacteria* and *Firmicutes* and an increase in Gram-negative bacteria phyla *Bacteroides* and *Proteobacteria* as lupus nephritis progressed. Mice fed acetate showed higher level of proteinuria and reduced survival. In contrast, antibiotic treatment attenuated abnormalities observed in the colon and kidney, and significantly decreased serum acetate level and proteinuria ($P<0.05$, for both). HK-2 cells exposed to acetate for 24h showed induction of IL-6, IL-8, TNF-α, TGF-β1 and SNAIL mRNA.

Conclusions: The data demonstrate that murine lupus nephritis is associated with a change in gut microbiota and increased circulating microbial acetate, which may contribute to renal tubulo-interstitial inflammation and fibrosis.

SA-PO578

Irradiation-Induced Glomerular Endothelial Cellular Senescence May Contribute to the Senescence-Associated Secretory Phenotype by Activating the NF-kB Signaling Pathway

Sae Aratani,[1] Akiko Takahashi,[4] Masako Tagawa,[3] Tze mun Loo,[5] Yukinao Sakai,[1] Akira Shimizu,[2] Shuichi Tsuruoka.[3] *[1]Nippon Medical School Hospital, Tokyo, Japan; [2]Nippion Medical School, Tokyo, Japan; [3]Nippon Medical School, Tokyo, Japan; [4]Japanese Foundation for Cancer Research, Tokyo, Japan; [5]The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo, Japan.*

Background: Cellular senescence is one of the major risk factors for chronic kidney disease. We recently reported that ionizing radiation (IR) can cause cellular senescence in the kidney and lead to kidney dysfunction. In this report, we investigated the precise characteristics of radiation-induced cellular senescence in glomerular endothelial cells.

Methods: Male 7-8-week-old rats received unilateral IR of 18 Gy on the kidney (irradiated kidney) or sham IR (normal kidney). We analyzed the presence of cellular senescence and pathological changes until 9 months post IR. In an in vitro experiment, rat glomerular endothelial cells received a single dose of 20 Gy (irradiated cells). Cellular senescence was defined by the combination of senescence-associated β-galactosidase (SA-β-gal), p21, p53, p16 and the senescence-associated secretory phenotype (SASP). The DNA damage response (γH2AX, a marker of DNA double strand breaks) and nuclear factor-kappa B (NF-κB) signaling pathway were also evaluated.

Results: As previously reported, irradiation-induced cellular senescence was demonstrated in the irradiated kidneys. Notably, glomerular endothelial cells in irradiated kidneys displayed more cells that were positively stained for p21 at an earlier time (from 3 months) compared to podocytes. In vitro, irradiation-induced cellular senescence in glomerular endothelial cells was also confirmed. Recent studies reported that the DNA damage response could trigger the NF-kB signaling pathway, resulting in a cascade of inflammation. In our study, irradiated cells showed DNA damage response, and a gradual increase in the expression level of NF-kB mRNA. Irradiated cells also showed nuclear localization of NF-κB and positive staining for phosphorylated IκBα. Once IκBα is phosphorylated, IκB proteins are released from NF-κB. Subsequently, NF-κB translocates to the nucleus and transactivates the expression of target genes. Following the activation of the NF-κB pathway, the various SASP was upregulated at days 20.

Conclusions: Taken together, these data suggest that IR could cause cellular senescence in the kidney. In particular, glomerular endothelial cells may play an important role in production of SASP that might be triggered by the activated NF-kB signaling pathway.

SA-PO579

DCR2, a Cellular Senescent Molecule, Is a Novel Marker for Assessing Tubulointerstitial Fibrosis in Patients with Immunoglobulin A Nephropathy

Jia Chen, Yani He. *Daping hospital, Chongqing, Chongqing, China.*

Background: DcR2 is a senescent marker expressed exclusively in senescent tubular epithelia. We calculated the ratio of urinary levels of Dcr2 to creatinine (uDcr2/Cr) and renal tissue DcR2 levels, in order to analyze the relationship between DcR2 levels and the severity of tubulointerstitial fibrosis (TIF) in patients with immunoglobulin A nephropathy (IgAN).

Methods: This study included 210 IgAN patients and 80 healthy volunteers, with uDcR2 levels measured using enzyme-linked immunosorbent assay. Renal DcR2 expression was quantified by immunohistochemistry. Co-expression of DcR2 with senescent (interleukin-6 [IL-6], tissue inhibitors of metalloproteinase [TIMP]-2) and fibrotic markers (α-smooth muscle actin [α-SMA], collagen III) were analyzed by confocal microscopy. We examined the relationship among uDcR2/Cr levels, renal function, and pathological findings, using the area under the curve (AUC) approach to predict tubulointerstitial fibrosis.

Results: Levels of uDcR2/Cr were significantly higher in IgAN patients and in those with more severe TIF, compared with healthy controls. Serum DcR2 levels were similar across groups. The proportion of IgAN patients with stage 1-2 chronic kidney disease (CKD) and T0 was highest among those with uDcR2/Cr < 130 ng/g. In contrast, the majority of those with uDcR2/Cr > 201 ng/g had stage 4-5 CKD and T2. Levels of uDcR2

were positively associated with urinary albumin/creatinine ratio (ACR), N-acetyl-β-D-glucosaminidase (uNAG)/Cr, and TIF scores. Levels of uDcR2 were negatively associated with estimated glomerular filtration rate (eGFR). uDcR2/Cr, uNAG, ACR and eGFR were independent predictors for TIF, with AUC of 0.907 for uDcR2/Cr. This AUC value was higher than that observed for eGFR, uNAG/Cr, or ACR. The sensitivity and specificity of uDcR2/Cr in predicting TIF were 87.0% and 80.5%, respectively. Renal DcR2 co-expressed with IL-6 and TIMP-2 in tubules and co-localized with α-SMA and collagen III in the kidneys of IgAN patients.

Conclusions: Levels of uDcR2/Cr were closely associated with the severity of TIF and renal function parameters. uDcR2/Cr represents a potential biomarker for predicting chronic TIF in IgAN patients.

Epigenetic Factors Regulate APOL1-miR193a Axis in Parietal Epithelial Cells

Vinod Kumar,[1] Himanshu Vashistha,[4] Kamesh R. Ayasolla,[1] Harsha Adnani,[1] Ashwani Malhotra,[3] Pravin C. Singhal.[2] *[1]Medicine, Feinstein Institutes for Medical Research, Manhasset, NY; [2]Medicine, Feinstein Institute of Research, Manhasset, NY; [3]Feinstein Institutes for Medical Research and NSLIJ, Manhasset, NY; [4]Medicine, Ochsner Health System, New Orleans, LA.*

Background: Bifunctional APOL1-mIR193 axis plays a vital role in the podocyte renewal during normal physiology and pathological states. Parietal epithelial cells (PECs) serve as progenitor cells for podocytes in juvenile. We have recently demonstrated the role of APOL1 wild-type (G0) in the transition of PECs. Since PECs have a higher expression of miR193a, they do not express APOL1. However, downregulation of miR193a induces APOL1 expression in PECs. We hypothesize that epigenetic factors regulate APOL1-miR193 axis through modulation of miR193a expression in PECs.

Methods: Immortalized human PECs underwent several experimental designs: PECs were transduced with either vector (V) or HIV (NL4 (n=4); PECs were incubated in media containing variable concentration of IFN-γ (0, 5, 10, and 20 nM) for 48 hours (n=4); PECs were treated with either empty vector (EV) of a specific miR193 inhibitor (20 nM) for 48 hours (n=4); PECs were treated with either buffer, azacytidine (5 μM, a demethylating agent), or SAHA (10μM, an histone deacetylation inhibitor) for 48 Hours (n=4). Protein blots were probed for APOL1, DNMT 1-3, HDAC 1-4, H3K27me3, H3K4me3, H3K8/9ac, and reprobed for actin. cDNAs were amplified for DNMT1-4, HDAC1-4, and APOL1. RNAs were assayed for miR193a. ChiP assay was carried out to evaluate histone acetylation at miR193a promoter. The RIP-ChIP assay was performed to examine the binding of miR193a at APOL1 gene promoter. In PECVs and PECHIVs, methylation of CpG islands at miR193a gene was detected by Bisulphite sequencing.

Results: HIV, as well as IFN-γ, induced APOL1 expression in PECs. PECHIV and IFN-γ-treated PECs showed 2.0-2.5-fold decrease in miR193a expressions, respectively; inhibition of miR193a in PECs by a specific miR193a inhibitor also resulted in the induction of APOL1 expression. The treatment of PECs with either azacytidine or SAHA induced the expression of APOL1 as well as decreased (three-fold) miR193a levels. HIV and IFN-γ enhanced the expression of DNMT3b, HDAC4, HK4me3, and H3K27me3 but down-regulated the expression of H3K8/9ac. ChIP assay revealed histone methylation at 27 lysine residues. RIP-ChIP assay confirmed the binding of miR193a on APOL1 gene promoter. Bisulfite sequencing displayed enhanced methylation of CpG islands at miR193a gene in PECHIV.

Conclusions: Epigenetic factors regulate APOL1-miR193a axis in PECs.

SA-PO581

Efficacy of Low-Intensity Pulsed Ultrasound on Renal Fibrosis and Progression of CKD in a Mouse Model

Chih-Kang Chiang,[3,2] Shing-Hwa Liu,[3] Kuan-Yu Hung.[1,4] *[1]Department of Internal Medicine, National Taiwan University, Medical College, Taipei, Taiwan; [2]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; [3]Institute of Toxicology, School of Medicine, National Taiwan University, Taipei, Taiwan; [4]National Taiwan University Hospital Hsin-Chu Branch, Hsin-Chu, Taiwan.*

Background: The prevalence of chronic kidney disease (CKD) has been increasing in recent years. Proliferation of fibroblasts and excessive deposition of extracellular matrix including collagen in renal tissues after ischemia/reperfusion injury (IRI) contribute to renal fibrosis and progression of CKD. Low intensity pulsed ultrasound (LIPUS) has been recognized to elevate bone fracture repair process and help in some soft tissues healing such as cartilage and cardiac tissues. Here, we tested the prevention of renal fibrosis and progression of CKD by LIPUS in a mouse model of unilateral IRI with contralateral nephrectomy.

Methods: Animals were randomized into the sham, IRI, and IRI+LIPUS groups. In the IRI group, the left renal artery was isolated and clamped fir 30 mins. They were sacrificed 14 days after IRI as an AKI to CKD transition model in the presence or absence of LIPUS treatment (3 MHz, intensity 0.1 W/cm^2, 20 min, 50% duty factor) 5 days before and 14 days after IRI. Serum biochemical measurement, including BUN, Cr and Cystatin C, Histological analysis, Immunoblotting, including GRP78, Chop, Bax, cleaved caspase-3, p21, Sirtuin-1, E-cadherin, vimentin, catalase, superoxide dismutase 1 (SOD1), Klotho, etc., and Malondialdehyde (MDA) were examined

Results: LIPUS treatment significantly alleviated the increases in the serum levels of BUN, creatinine, and fibroblast growth factor (FGF)-23, and renal pathological changes and fibrosis (n=8, p<0.05). The development of epithelial-mesenchymal transition was alleviated by LIPUS treatment (n=8, p<0.05). LIPUS treatment could also inhibit the induction of renal senescence-related molecular signals such as p53, p21, and p16 (n=8, p<0.05). Interestingly, LIPUS significantly reversed the decreased α-Klotho protein expression in the kidneys (n=8, p<0.05). LIPUS treatment significantly reversed the decrease in renal endogenous antioxidant enzymes (n=8, p<0.05). Taken together, LIPUS treatment showed the benefits for renal protection in IRI mice.

Conclusions: These findings suggest that LIPUS therapy may be used to serve as an auxiliary tool for the management of renal fibrosis and progression of CKD.

Remodeling of the Glomerular Tuft in Proteinuric Kidney Disease

Michelle Liu,[1] Itzhak D. Goldberg,[2] Prakash Narayan.[3] *[1]Angion, Uniondale, NY; [2]Angion Biomedica Corp., Uniondale, NY; [3]Angion Biomedica Corp, Uniondale, NY.*

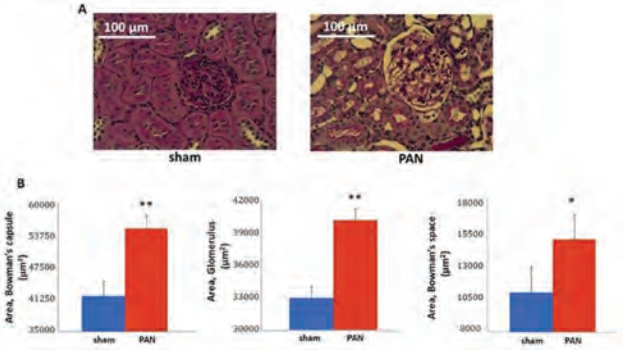
Background: Glomerular hypertrophy is associated with proteinuric kidney disease and progression to renal failure. The present study sought to quantify the association between remodeling of the glomerular tuft and proteinuria.

Methods: Adult male Wistar rats (sensitive strain, ~75 g) were administered puromycin aminonucleoside (PAN, 167 mg/kg, n=8) or water (n=3, sham cohort). On Day 14 after PAN administration, 24-hour urine was collected for determination of proteinuria. Left kidneys were removed, sectioned and stained with hematoxylin-eosin and glomeruli (14 per kidney) photographed at 40X. Areas of the Bowman's capsule and glomeruli were measured using ImageJ by an observer blinded to the experiment groups and the area of the Bowman's space calculated.

Results: Compared to the sham cohort, PAN-administered animals exhibited a 3-fold increase in proteinuria (p<0.01) and changes in glomerular tuft morphology (A). Significant increases (B) were observed in the areas of the Bowman's capsule (**, p<0.01), the glomerulus (**, p<0.01), and the Bowman's space (*, p<0.05) with PAN administration.

Conclusions: Remodeling of the glomerular tuft, including hypertrophy of the Bowman's capsule and glomerulus, and an increase in Bowman's space, accompanies proteinuric kidney disease. These findings might be an important consideration in the development of therapies for the treatment of kidney disease.

Funding: Private Foundation Support



The PAN model of proteinuric kidney disease is associated with an increase in the area of the Bowman's capsule, hypertrophy of the glomerulus, and an increase in the Bowman's space.

Molecular Mechanisms of Renal Fibrosis in Alport Syndrome

Kenneth Minor, Kristin M. Joly, Denise L. Schwabauer, Craig F. Plato. *Plato BioPharma, Inc., Westminster, CO.*

Background: Alport Syndrome is a rare hereditary disease caused by mutations in glomerular basement membrane (GBM) type IV collagen and characterized by progressive renal fibrosis and early onset ESRD. Collagen IV dysregulation and loss of GBM integrity allows passage of albumin to the tubular lumen causing injury and ultimately tubulointerstitial fibrosis in advanced Alport Syndrome. To date, the signaling pathways and molecular targets in albuminuria-induced fibrosis in Alport Syndrome have not been elucidated.

Methods: We evaluated the kinetics and potential mechanisms of renal fibrosis in Col4a3 knock out (Col4a3KO) mice, a model of autosomal recessive Alport Syndrome compared to age-matched Wild Type (WT) controls. Approximately equal numbers of male and female Mice were studied from 5–10 wks age to evaluate the renal fibrotic response to progressive albuminuria. At 6, 8 and 10 wks, representative cohorts of mice were euthanized and kidneys were harvested for biochemical and histological analyses. mRNA expression was analyzed using a Quantigene pro-inflammatory and fibrotic gene multiplex (MCP-1, CTGF, TGF-β1, α-SMA, FN1 and Collagens 1a1 and 3a1). Renal cortical hydroxyproline (OH-P) content and Collagen Volume Fraction (CVF) via Picrosirius Red (PSR) histology were also evaluated. Renal cortical lysates were evaluated for TGF-β1 content and phospho- p38, JNK and Erk to elucidate potential pathways in albuminuria-induced fibrosis.

Results: Col4a3KO had age-dependent polyuria and fulminant albuminuria (5 wks: 360-fold; 10 wks: ~2,500-fold) compared to WT. Renal cortical OH-P content was not increased by 6 wks but increased thereafter. Associated with progressive albuminuria, CVF was age-dependently increased in Col4a3KO (8 wks: 10-fold; 10 wks: 25-fold). Although pro-inflammatory and fibrotic mRNA species were increased by 6 wks in Col4a3KO, peak expression occurred at 8 wks, in advance of peak fibrosis. Renal cortical TGF-β1 content was age-dependently increased while pJNK and pERK peaked at 8–10 wks.

Conclusions: This study demonstrates albuminuria precedes renal fibrosis in the Col4a3KO model of Alport Syndrome and identifies potential mechanisms related to disease progression. These results enable future investigations of inflammatory and stress-signaling pathways in Alport Syndrome, and evaluation of novel therapies to attenuate albuminuria-induced renal fibrosis.

Established Human Mesenchymal Stem Cell Lines Stably Secreting Matrix Metallopeptidase 7 to Treat Glomerulosclerosis in Light Chain Deposition Disease

Xiuyan Feng,[1] Chun Zeng,[4] Jiamin Teng,[2] Hui Cai,[3] Guillermo A. Herrera.[4] *[1]LSU Shreveport, Shreveport, LA; [2]University of South Alabama, Mobile, AL; [3]Emory University School of Medicine, Atlanta, GA; [4]Louisiana State University Health Sciences Center, Shreveport, LA.*

Background: Light chain deposition disease (LCDD) is a rare systemic disorder, caused by the overproduction and extracellular deposition of monoclonal immunoglobin light chain. The clinical manifestation is dominated by renal disease. The affected glomeruli are enlarged. The deposition of PAS-positive material produces capillary wall thickening and nodular expansion of the mesangium. The extent of glomerular involvement can vary from minimal mesangial expansion to a fully developed nodular glomerulosclerosis. Although the pathogenesis of the glomerulosclerosis in LCDD is not entirely clear, experimental studies have shown that mesangial cells incubated with monoclonal light chains obtained from patients with LCDD produce transforming growth factor β, which triggers the production of extracellular matrix proteins. Tenascin is the most common protein in expanded mesangium in LCDD and is degraded mostly by Matrix Metallopeptidase 7 (MMP7). This finding suggests that inducing MMP7 secretion by stem cells might be a possible therapeutic intervention to reverse nodular glomerulosclerosis in LCDD. In this study, we aimed to establish stable stem cell lines to facilitate degradation of tenascin.

Methods: 1) pcDNA3-GFP-MMP-7 plasmid was purified using ***QIAprep Spin Miniprep Kit.*** The products are confirmed by gel electrophoresis. 2) HMSC was cultured in 6-well plate with 5% FBS specific medium. When 80% confluences was reached, the HMSCs were transfected by purified GFP-MMP7 plasmid using ***lipofectinamine 2000***. Immunofluorescence microscopy was used to test the transfection efficiency. 3) 48 hours after transfection, the HMSCs were transferred into 10cm dishes. 72 hours later, G418 600ug/ml was added in to medium. Cell clones formed in 3-4 weeks and then were picked up to amplify. Confocal microscopy and western blot analysis were used to identify MMP-7 expression and secretion.

Results: 1) GFP-MMP-7 plasmid was successfully amplified and purified. 2) HMSC were successfully transfected by GFP-MMP7 plasmid using *lipofectinamine 2000*. The transfection efficiency was about 30%, including 10% highly expressed cells.

Conclusions: We successfully established HMSC cell lines which highly express and secret MMP7. In our future study, the cell line will be used to treat kidney diseases caused by LCDD in animal model.

SA-PO585

IL-17 Signaling in CD4$^+$ T Cells Controls TH17 Immune Response

Tilman Schmidt,[1] Jonas Lübbe,[1,2] Jan-Hendrik Riedel,[1] Christoph Kilian,[1,2] Christian F. Krebs,[1] Hans-Joachim Paust,[1,2] Ulf Panzer.[1,2] *[1]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Section of Translational Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: The IL-17/IL-17 receptor system plays a crucial role in autoimmune and chronic inflammatory diseases. The biological effects on residential cells are mediated through a heterodimeric receptor complex consisting of IL-17RA and a ligand specific IL-17 receptor subunit (IL-17RB - IL-17RE). However, the expression and function of IL-17 receptors on hematopoietic cells as CD4$^+$ T cells have not been elucidated.

Methods: Crescentic GN (NTN), Psoriasis and C. rodentium colitis were induced in IL-17RA$^{-/-}$, IL-17RC$^{-/-}$ and in IL-17A, IFNγ and Foxp3 triple-reporter mice for *in vivo* cell sorting of CD4$^+$ T cell subsets. Single cell RNAseq of CD4$^+$ T cells from the nephritic kidney was performed using the 10X single cell system. pLIVE-plasmid was used to induce IL-17A overexpression *in vivo*. Moreover, we generated T_H17 cell specific IL-17RA gene-deficient mice to study the role of IL-17 signaling in T_H17 cells in the NTN model.

Results: Induction of inflammation in the kidney, skin and intestine in IL-17RA$^{-/-}$ mice resulted in an aggravated T_H17 cell immune response. Transfer of IL-17RA$^{-/-}$ bone marrow cells in irradiated WT mice indicated IL-17 signaling on hematopoietic cells. CD4$^+$ IL-17 producing WT cells from the inflamed kidney, analyzed with single cell RNAseq, demonstrated a highly activated IL-17 signaling score. mRNA expression analysis of FACS-sorted T cells revealed predominant expression of IL-17RC and IL-17RE by IL-17A$^+$ T_H17 cells, whereas IL-17RA is ubiquitously expressed by all CD4$^+$ T cell subsets, demonstrating a T cell specific expression pattern of IL-17 receptors. Systemic overexpression of IL-17A showed a reduction of CD4$^+$ IL-17A$^+$ cells in the kidneys of nephritic mice. Moreover, competitive adoptive transfer experiments of wildtype and IL-17RA$^{-/-}$ or IL-17RC$^{-/-}$ CD4$^+$ T cells into nephritic Rag1$^{-/-}$ mice showed that IL-17 signaling on CD4$^+$ T cells is critically for the control of the pathogenic T_H17 response. Mice specifically lacking the IL-17RA receptor in IL-17A$^+$ cells also present an enhanced T_H17 cell immune response.

Conclusions: Our findings indicate intrinsic IL-17RA/RC signaling on CD4$^+$ T cells, which regulates the T_H17 cell immune response. This novel mechanism might lead to more efficient therapeutic options in targeting IL-17 signaling pathways.

SA-PO586

Establishment of a Preparative Method and Gating Strategy for Renal Mononuclear Phagocytes (rMophs) and Analysis of rMophs in CD11c-Specifc Shp-1 Knockout Mice

Mitsuharu Watanabe,[1] Yoriaki Kaneko,[1] Masato Kinoshita,[1] Shreya Shrestha,[1] Yuko Ohishi,[1] Toru Sakairi,[1] Hidekazu Ikeuchi,[1] Yoshihisa Nojima,[2] Keiju Hiromura.[1] *[1]Nephrology and Rheumatology, Gunma University Graduate School of Medicine, Maebashi, Japan; [2]Inoue Hospital, Takasaki, Japan.*

Background: Recent studies demonstrated the existence of renal mononuclear phagocytes (rMophs), which express both macrophage markers, CD11b and F4/80, and dendritic cell marker, CD11c. However, standardized procedures to isolate and characterize rMophs have not been adopted; therefore, the function of rMophs is not fully understood. In this study, we aimed to provide a preparative method of rMophs and optimize gating strategy for flow cytometry (FCM). We further examined the contribution of rMophs in renal injury by inducing nephritis in CD11c-specific Shp-1 knockout mice (Shp-1 CKO), in which certain population of rMophs lack Shp-1, a negative regulator of hematopoietic cell signaling.

Methods: C57BL/6J mice were used to establish the preparative method of rMophs. To induce nephritis, Shp-1 CKO and control littermates mice (Ctrl) at the age of 8-10 weeks were immunized by subcutaneous injection with bovine serum albumin (BSA) at 2-week intervals.

Results: We first determined the efficacy of renal cell collections from the mouse kidney. Higher yield of CD45.2$^+$ cells and F4/80^{high} cells was achieved by collagenase digestion compared to simple mechanical dissociation. We then characterized the isolated cells by FCM. A significant number of neutrophils, which expressed Ly6G, mixed up into F4/80^{low} cells. Therefore, isolated renal cells expressing CD45.2 and CD11b, but not Ly6G, could be referred as rMophs. These CD45.2$^+$ CD11b$^+$ Ly6G$^-$ rMophs were, then, divided into 3 subpopulations: F4/80^{high} CD11c^{int} rMophs, F4/80^{low} CD11c^{high} rMophs and F4/80^{low} CD11c^{low} rMophs. In animal experiments, Shp1-CKO developed proteinuria at 6-8 weeks after the first BSA injection, when Ctrl did not develop proteinuria yet. Proliferative glomerulonephritis was also developed at this early time point in Shp-1 CKO. Finally using the isolation and gating methods, the FCM analysis revealed that proportion as well as absolute number of F4/80^{high} rMophs increased in Shp-1 CKO treated with BSA.

Conclusions: We found that the use of collagenase digestion is necessary to collect rMophs and the gating strategy of eliminating neutrophils is important for the analysis of rMophs. We also showed that Shp-1 may regulate rMophs and protect against renal injury.

SA-PO587

Neutrophil Elastase-Deficient Mice Are Protected from Experimental Myeloperoxidase Anti-Neutrophil Cytoplasmic Antibody Vasculitis

Kim M. O'Sullivan,[1] Poh-Yi Gan,[2] A. Richard Kitching,[3] Stephen R. Holdsworth.[4] Autoimmune Kidney Disease and Vasculitis Research Group *[1]Monash University, Clayton, VIC, Australia; [2]Monash University, Monash Medical Centre, Melbourne, VIC, Australia; [3]Monash University, Monash Health, Clayton, VIC, Australia; [4]Monash Health, Clayton, VIC, Australia.*

Background: Neutrophil extracellular trap (NETs) are implicated in the pathogenesis of myeloperoxidase anti neutrophil cytoplasmic antibody vasculitis (MPO-AAV). Neutrophil elastase (NE) is implicated in initiating NET formation through proteolytic degradation of the nuclear envelope, histone degradation and chromatin decondensation in concert with other neutrophil enzymes to facilitate DNA release. NETs are decorated with multiple proinflammatory enzymes including MPO (the autoantigen in this disease) and NE. NE released through degranulation is degraded by endogenous NE inhibitors, however NE bound to NET derived DNA is protected providing a reservoir of proteolytic NE enabling tissue destruction, microvascular injury and further recruitment of neutrophils. This study investigates the pathogenic contribution of NE release through NET formation in experimental MPO-AAV using animals deficient in neutrophil elastase.

Methods: A 20 day experimental model of anti-MPO GN was induced in B6.129X1-Elane^{tm1Sds}/J mice (neutrophil elastase knock out mice) and wild-type (WT) litter mate controls by myeloperoxidase (MPO) immunisation and GN triggered using a sub-nephritogenic dose of anti-glomerular basement membrane globulin (anti GBM Ig), [*n*=10 (WT) and *n*=10 (*Elane*-/-)].

Results: *Elane*-/- animals were protected from excessive NET production and glomerular injury with significantly reduced numbers of glomerular neutrophils, extracellular MPO deposition, CD4 T cells and macrophages influx (all, P <0.05 compared to WT). Histological assessment of kidneys demonstrated a reduction in segmental necrosis in the *Elane*-/- group compared to the WT group (P<0.05). Functional injury measured by creatinine/albuminuria ratio was significantly reduced in the *Elane* -/- group compared to the WT group (P=0.04). Systemic autoimmunity to MPO was significantly reduced in *Elane*-/- mice with reduced frequency of MPO specific CD4 effector T cells from the draining lymph nodes and a significant reduction in dermal DTH, measured by a 24 hour footpad challenge with MPO (P<0.05, compared with WT).

Conclusions: Reduced NET formation in *Elane -/-* mice attenuated glomerular injury through the reduction in NET associated MPO and NE. This data provides proof of concept evidence that targeting NE therapeutically may be of potential benefit in MPO-AAV.

SA-PO588

Urinary Treg and Th17 Cells Identify Active Renal Disease in Patients with ANCA-Associated Vasculitis

Janis Sonnemann, Jan Klocke, Philipp Enghard, Kai-Uwe Eckardt, Adrian Schreiber. *Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Background: ANCA-associated vasculitides (AAV) cause necrotizing crescentic glomerulonephritis which is a major contributor to morbidity and mortality in AAV. As therapy relies on immunosuppressive agents with potential adverse effects, a reliable non-invasive biomarker of disease activity is needed to determine the right balance between over- and undertreatment. Since the pathogenic role of Tcells in AAV is emerging, we hypothesized that these subsets are increased in urine in active renal AAV and represent a reliable biomarker of disease activity.

Methods: Levels of Tcells and their subsets were measured in peripheral blood and urine samples from patients with active renal AAV (n=39), active non-renal AAV (n=9), AAV in remission (n=22), and healthy controls (n=9) using flow-cytometry. Urinary metabolites and cytokines (MCP-1, sCD163, sCD25, and C5a) were quantified by multiplex-analysis.

Results: Patients with active renal vasculitis show significantly higher urinary T cell counts than active non-renal, inactive, and healthy controls. In particular CD4+ T cells, T regulatory cells, and Th17 cells are significantly elevated compared to all controls. No significant difference could be shown for CD8+ T cells between active renal and remission. The only significant difference for Th1 cells was was found between active renal vasculitis and healthy controls. sCD163, MCP-1, and C5a all show a significantly elevated concentration compared to patients in remission only sCD163 reaches significance for active renal vs. active non-renal. Analysis of receiver operator characteristics (ROC) reveals that urinary T cells identify active renal vasculitis with at least comparable diagnostic accuracy, CD3+, CD4+, CD8+ and Treg outperform soluble markers based on area under the curve (Treg AUC 0.93, sensitivity 79%, specificity 95%; CD3 Tcells AUC 0.95; sensitivity 92%, specificity 95%; MCP-1 AUC 0.9; sensitivity 60% specificity 100%, sCD163 AUC 0.92, sensitivity 96%, specificity 85%).

Conclusions: Urinary Tcells are significantly elevated in active renal AAV and reliably determine renal disease activity. Biomarker performance for Tregs is comparable to published results of urinary MCP-1 and sCD163 and exceeds sCD25 and C5a while Th17 outperforms only sCD25 and C5a. Hence, urinary Tregs and Th17 are new potential biomarkers in AAV.

SA-PO589

Fostamatinib Treatment of a New Model of Myeloperoxidase-ANCA Vasculitis

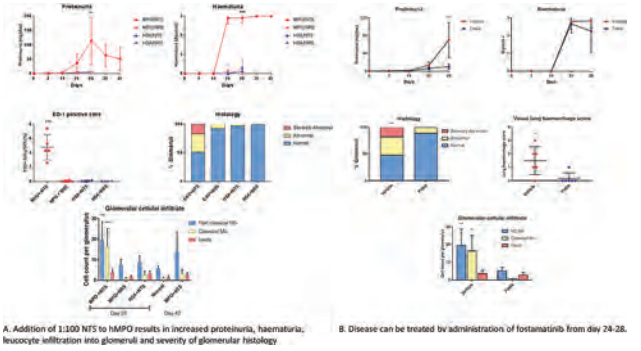
Maria Prendecki, Stephen P. McAdoo, Tabitha Turner-Stokes, H. Terence Cook, Frederick W. Tam, Charles D. Pusey. *Imperial College London, London, United Kingdom.*

Background: EAV is a model of MPO-AAV induced by immunising rats with human myeloperoxidase (hMPO). Animals develop lung haemorrhage and proliferative GN, but disease is milder than human AAV. To augment disease severity, we immunised animals with an additional subnephritogenic dose of rabbit nephrotoxic serum (NTS). Fostamatinib, a small molecule Syk inhibitor, was used to evaluate therapeutic manipulation in this new model.

Methods: WKY rats were immunised IV with diluted NTS to establish a subnephritogenic dose. For EAV+NTS experiments, animals were immunised IM with hMPO (or human serum albumin (HSA)) on day 0 and 1:100 NTS IV (or normal rabbit serum (NRS)) at day 14. When fostamatinib was used, this (or vehicle) was administered by oral gavage from day 24-27, and animals culled on day 28. Infiltrating glomerular leucocytes were isolated and analysed by flow cytometry.

Results: A sub-nephritogenic dose of NTS was identified as a 1:100 dilution. Animals immunised with hMPO and 1:100 NTS had significantly more proteinuria and glomerular abnormalities at day 28 than the hMPO+NRS group or HSA controls (Fig1A). There was no detectable immune deposits by immunofluorescence or electron microscopy in any of the groups. In animals immunised with hMPO and 1:100 NTS, there were significantly more infiltrating glomerular leukocytes with greater increase in classical compared to non-classical monocytes (Fig1A). Fostamatinib treatment significantly reduced lung haemorrhage, glomerular, urinary abnormalities and infiltrating gloemrular leucocytes (Fig1B).

Conclusions: A subnephritogenic dose of NTS 14 days after hMPO significantly augments disease severity without evidence of deposited antibody or immune complexes. Characterisation of glomerular infiltrating cells shows significant infiltration of classical monocytes and we suggest it may be these cells which are stimulating crescent formation. Administration of fostamatinib for 4 days was sufficient to significantly decrease disease severity.



A. Addition of 1:100 NTS to hMPO results in increased proteinuria, haematuria, leucocyte infiltration into glomeruli and severity of glomerular histology

B. Disease can be treated by administration of fostamatinib from day 24-28.

SA-PO590

In ANCA Vasculitis, Low-Density Neutrophils Express High Levels of Autoantigen Genes, but Expression in Normal-Density Neutrophils Correlates with Activation by ANCA

Christian Agosto-Burgos,[1] Carolina A. Herrera,[1] Britta E. Jones,[1] Joshua Starmer,[2] William Bass,[1] Caroline J. Poulton,[1] Lauren N. Blazek,[1] Candace D. Henderson,[1] Yichun Hu,[1] Susan L. Hogan,[1] Peiqi Hu,[3] Hong Xiao,[3] J. Charles Jennette,[3,1] Meghan E. Free,[1] Ronald J. Falk,[1,4] Dominic J. Ciavatta.[1,2] *[1]UNC Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Pathology and Laboratory Medicine, Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

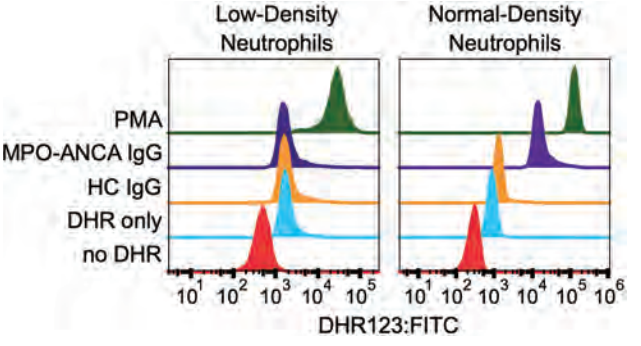
Background: Neutrophils are a heterogenous cell population, a primary source of expression of autoantigen genes in ANCA vasculitis, and central to the pathology of ANCA vasculitis; however, it is unclear the impact neutrophil heterogeneity and expression has on disease pathology.

Methods: Low-density neutrophils (LDNs) and normal-density neutrophils (NDNs) were isolated from peripheral blood of 137 ANCA vasculitis patients and 54 healthy controls (HC). Expression of *MPO* and *PRTN3* was measured by quantitative RT-PCR. LDNs were immunophenotyped by flowcytometry. Oxidative burst in response to MPO-ANCA was measured with dihydrorhodamine assay in LDNs and NDNs without *in vitro* priming.

Results: Increased *MPO* and *PRTN3* expression was detected in LDNs and NDNs from patients during active disease compared to HC, with the largest difference in LDNs. Surface markers CD10 and CD15 revealed LDNs contained mature and immature neutrophils; both contributed to autoantigen expression. The frequency of LDN subtypes was similar between HC and patients regardless of disease activity. The frequency of immature LDNs did not correlate with *MPO* or *PRTN3* expression in LDNs. LDNs were refractory to MPO-ANCA induced oxidative burst, while MPO-ANCA induced robust activation of NDNs, that correlated with *MPO*expression.

Conclusions: LDNs may be a bystander of chronic inflammation or contribute to alternative mechanisms of disease pathology. In NDNs the association between *MPO* gene expression and MPO-ANCA induced NDN activation argues autoantigen gene expression influences disease pathogenesis and a therapeutic strategy could be suppressing expression.

Funding: NIDDK Support



Oxidative burst in LDNs (left) and NDNs (right) from ANCA vasculitis patients. Histograms show DHR fluorescence following activation with HC IgG (organge), MPO-ANCA IgG (purple), or PMA (green).

SA-PO591

Platelet Activation Is Induced via Myeloperoxidase Production and Anti-Myeloperoxidase Antibodies Primed by Thrombin

Di Miao. *Peking University First Hospital, Beijing, China.*

Background: In addition to their central role in hemostasis and thrombosis, platelets involve in inflammatory responses. Anti-neutrophil cytoplasmic autoantibodies (ANCAs) directed to myeloperoxidase (MPO-ANCAs) are the main serological markers of ANCA-associated vasculitis.

Methods: Platelets were stimulated by purified total IgG and MPO-ANCA from patients with or without low doses of thrombin. The fragments from MPO-ANCAs, $F(ab')_2$ and Fc, were digested and isolated, then incubated with thrombin-primed platelets. The $F(ab')_2$ pull-downed proteins were analyzed using mass spectrometry. The concentration of MPO was detected in active platelets and AAV patients.

Results: The current study demonstrated that MPO-ANCAs caused normal human platelets to activate, primed by low doses of thrombin. Purified immunoglobulin G, MPO-ANCAs and their $F(ab')_2$ fragments evidently increased the CD62P expression of platelets compared with controls. The existence of MPO in platelets was confirmed with mass spectrometry technology, after analyzing the $F(ab')_2$ fragment pull-downed proteins. After thrombin priming, platelets not only expressed MPO on the surface with an activation-dependent manner, but also released the enzyme to extracellular space. These effects markedly enhanced the activation of platelets. Additionally, there was no apparently increased CD62P-expression on platelets in MPO-ANCAs group compared with controls when adding MPO inhibitor, proving that primed platelets have ANCA antigen at their surfaces interacting with the autoantibodies.

Conclusions: These findings suggest a previously unappreciated character for platelets as immune cells and the autoantibodies-induced activation in an acute inflammatory disease.

SA-PO592

SUMO1 Promote Mesangial Cell Proliferation Through Inhibiting Autophagy in a Cell Model of IgA Nephropathy

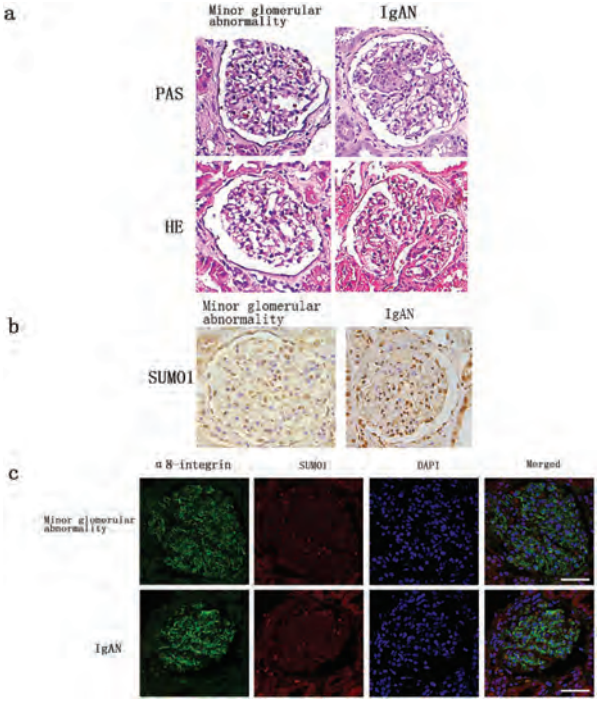
Hong Liu, Xia Tan. *The Second Xiangya Hospital, Central South University, Changsha, China.*

Background: IgA nephropathy(IgAN) is a common form of primary glomerulonephritis and its main pathological changes are mesangial cell proliferation and matrix expansion. Autophagy inhibition may result in its mesangial cell proliferation and renal lesions. SUMOylation is a eukaryotic-reversible post-translational modification where SUMO are covalently attached to target proteins to regulate their properties. It is largely unclear if SUMOylation contributes to the pathogenesis of IgAN.

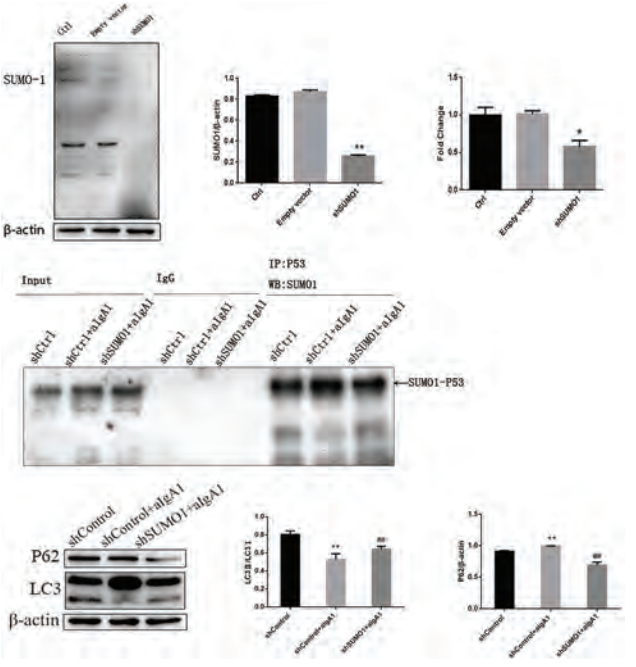
Methods: This study was designed to investigate the change of protein SUMO1 in mesangial cells of IgAN and its association with autophagy.

Results: We found the expression of SUMO1 was up-regulated in IgAN and aIgA1 stimulated mesangial cells. In aIgA1 stimulated mesangial cell model, we tested LC3 and p62, the autophagy-related proteins suggested the inhibition of autophagy. Silencing SUMO1 could down-regulate SUMO1 and SUMO1-p53, promote autophagy and lessen cell proliferation.

Conclusions: In the mesangial cells stimulated with aIgA1, SUMO1 may contribute to its cell proliferation through inhibited autophagy and SUMO1-p53 may play a role in this process.



The expression of SUMO1 in IgAN patients.



The expression of autophagy related proteins in mesangial cells stimulated with aIgA1.

IgA1 from Sera of Patients with IgA Nephropathy, but Not Purified Monomeric or Polymeric IgA1, Associates with Cultured Primary Human Mesangial Cells and Induces Cellular Signaling

Zhi qiang Huang, Stacy D. Hall, Bruce A. Julian, Jan Novak. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Circulating immune complexes (CIC) containing galactose-deficient IgA1 (Gd-IgA1) bound by Gd-IgA1-specific autoantibodies play a key role in the pathogenesis of IgA nephropathy (IgAN). Using a model of cultured primary human mesangial cells (hMC), we have previously shown that Gd-IgA1-containing CIC are biologically active, as they activate multiple protein-tyrosine kinases, lead to ERK1/2 phosphorylation, and stimulate cellular proliferation. In this study, we assessed how purified IgA1 of different molecular forms and serum IgA1 associate with and activate hMC.

Methods: Monomeric and polymeric forms of Gd-IgA1 were isolated from plasma of a patient with multiple myeloma by size-exclusion chromatography. IgA concentrations in serum samples from IgAN patients were measured by ELISA. Primary hMCs were incubated for 15 min at 37°C with 5% sera from IgAN patients or with the corresponding amount of monomeric or polymeric IgA1; hMC without any IgA1 served as a negative control. Cell lysates obtained after the incubation were used for pull-down using antibody specific for integrin β1 followed by protein G agarose. Cell lysates and pull-down samples were subjected to SDS-PAGE/Western blotting to detect IgA and phospho-ERK1/2.

Results: Purified monomeric as well as polymeric Gd-IgA1 exhibited minimal interactions with hMC, as only small amounts of IgA1 appeared in the hMC lysates and no induction of ERK1/2 phosphorylation was observed. In contrast, when sera from IgAN patients were used, we observed more IgA1 in hMC lysates (4 times more compared to monomeric Gd-IgA1, 8 times more compared to polymeric Gd-IgA1) as well as robust ERK1/2 phosphorylation. Preliminary pull-down experiments indicated that a fraction of IgA1 was associated with integrin β1, a previously described hMC receptor for IgA1. Moreover, we found that hMC formed α1β1 and α5β1 integrin complexes.

Conclusions: IgA1 from sera of IgAN patients, but not free monomeric or polymeric Gd-IgA1, associates with hMC and activates hMC. Integrin β1 may be involved in this process and may provide clues for development of future targeted therapy of IgAN.

Funding: NIDDK Support, Private Foundation Support

SA-PO594

C-Reactive Protein Is Renoprotective in Experimental IgA Nephropathy

Ann Chen,[1] Shuk-Man Ka.[2] *[1]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taipei, Taiwan; [2]National Defense Medical Center, Taipei, Taiwan, Taipei, Taiwan.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis in the world. Although the pathogenesis of the renal disorder remains largely unknown, NLRP3 inflammasome-mediated IL-1b production and subsequent activation of adaptive immunity is implicated in the development of IgAN. C-reactive protein (CRP) is a serum biomarker for various inflammatory conditions and has been shown to inhibit the activation of the NLRP3 inflammasome.

Methods: In the present study, we examined the role that CRP could play in the evolution of IgAN using an experimental model of IgAN in CRP knockout (KO) mice, and dissected the mechanisms involved.

Results: The results show that the experimental IgAN in CRP KO mice revealed significantly increased magnitudes in **(1)** renal pathology, including marked mesangial cell proliferation and mononuclear leukocyte infiltration in the glomeruli and peri-glomerular interstitial tissue, **(2)** glomerular deposition of IgA and C3, **(3)** NLRP3 inflamamsome activation in the kidney, and **(4)** renal function impairment and proteinuria compared to their wild type (WT) counterparts equally induced of IgAN. Moreover, IL-10 levels in both sera and renal tissues were significantly elevated in IgAN in CRP KO mice, compared with WT counterparts.

Conclusions: In conclusion, CRP may serve as a protective role in the development of IgAN by inhibiting NLRP3 inflammasome and enhancing the production of IL-10. The results suggest that CRP may be a potential therapeutic agent for IgAN.

Tris DBA Ameliorates IgA Nephropathy by Blunting the Activating Signal of NLRP3 Inflammasome Through SIRT1- and SIRT3-Mediated Autophagy Induction

Wu Chung-Yao,[1] Ann Chen.[2] *[1]Graduate Institute of Life Scieces National Defense Medical Center, Taipei, Taiwan; [2]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taipei, Taiwan.*

Background: Tris (Dibenzylideneacetone) dipalladium (Tris DBA), a small molecule palladium complex, can inhibit cell growth and proliferation in pancreatic cancer, lymphocytic leukemia and multiple myeloma. Given that this compound is particularly active against B cell malignancies (Chronic lymphocytic leukemia and multiple myeloma), we hypothesized that it can alleviate immune complex-mediated conditions, including IgA nephropathy (IgAN)

Methods: C57BL/6 mice were induced IgAN by consecutive 28 daily injections of purified IgA anti-phosphorylcholine antibodies and pneumococcal C-polysaccharide antigen (PnC), followed by clinical, pathological, and molecular mechanism analyses. On day 7 after disease induction, the mice were divided into 2 groups and administered daily either Tris DBA (30 mg/kg body weight) or vehicle (KATIMIN) via an intraperitoneal route throughout the study. The animals were killed at days 14 and 28, respectively. Cultured of macrophages were analysis for activating signal of NLRP3 inflammasome and SIRT1- and SIRT3-mediated autophagy induction.

Results: In the present study, we examined the therapeutic effects of Tris DBA on glomerular cell proliferation and renal inflammation in a mouse model of IgAN. The results show that treatment of IgAN mice with Tris DBA resulted in markedly improved renal function, albuminuria and renal pathology, including glomerular cell proliferation, neutrophil infiltration, sclerosis and peri-glomerular inflammation in the renal interstitium, together with [1] reduced mitochondrial ROS generation; [2] differentially regulated autophagy and NLRP3 inflammasome, [3] inhibited phosphorylation of JNK, ERK, and p38 MAPK signaling pathways, and priming signal of the NLRP3 inflammasome, and [4] blunted NLRP3 inflammasome activation through SIRT1- and SIRT3-mediated autophagy induction, in renal tissues or macrophages.

Conclusions: Tris DBA was able to effectively ameliorate the mouse IgAN model; this beneficial effect involves blunting of mitochondrial ROS production, a MAPK (ERK, JNK)-mediated priming signal of the NLRP3 inflammasome, and differentially regulating the autophagy/NLRP3 inflammasome axis through SIRT1 and SIRT3. Thus, Tris DBA can be considered a therapeutic candidate for IgAN.

Quantitative Assessment of Sites with Galactose-Deficient O-Glycans in the Hinge Region of IgA1

Yukako Ohyama,[1] Hisateru Yamaguchi,[1] Kazuki Nakajima,[1] Hiroki Hayashi,[1] Shigehisa Koide,[1] Daijo Inaguma,[1] Midori Hasegawa,[1] Jan Novak,[2] Yoshiyuki Hiki,[1] Naotake Tsuboi,[1] Yukio Yuzawa,[1] Kazuo Takahashi.[1] *[1]Fujita Health University, Toyoake, Japan; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Serum level of IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans (Gd-IgA1) is elevated in patient with IgA nephropathy (IgAN) and the glomerular immunodeposits of IgAN patients are enriched for Gd-IgA1. Lectins and a monoclonal antibody (mAb) specific for Gd-IgA1 have been used in ELISA to measure Gd-IgA1 serum levels. mAb specific for Gd-IgA1 stained glomerular immunodeposits in IgAN, further supporting the role of Gd-IgA1 in pathogenesis of IgAN. As mAb for Gd-IgA1 recognizes Gal-deficient *O*-glycans at a specific site(s), quantitative assessment of Gal-deficient sites is needed to identify disease-specific IgA1 HR *O*-glycoforms. Here, we describe a new method for quantitative assessment of sites with Gal- deficient *O*-glycans in IgA1 HR.

Methods: IgA1 from sera of 5 healthy controls was purified by affinity chromatography. After neuraminidase treatment and trypsin digestion, IgA1 HR glycosylation heterogeneity was analyzed by liquid chromatography-high-resolution mass spectrometry (LC-MS). Area under the peaks of extracted ion chromatogram (XIC) of identified IgA1 HR *O*-glycopeptides was calculated and expressed as relative abundance (RA) for each glycopeptide. The sites with Gal-deficient *O*-glycans were identified after selective quantitative removal of galactosylated *O*-glycans with *O*-glycanase by electron-transfer dissociation (ETD) tandem MS.

Results: Approximately 60% of IgA1 HR *O*-glycoforms contained one to three Gal-deficient *O*-glycans. ETD tandem MS unambiguously identify sites with Gal-deficient *O*-glycans and XIC based on isomeric glycoforms enabled quantitative assessment of Gal-deficient sites. The most common Gal-deficient sites included T^{236} followed by S^{230}, S^{232}/T^{233} and T^{228}. HR *O*-glycoforms with 2 or 3 Gal-deficient *O*-glycans predominantly included combinations of Gal-deficient sites at S^{230}, T^{233}, and/or T^{236}.

Conclusions: The quantitative assessment of sites with Gal-deficient *O*-glycans in IgA1 HR of healthy controls will enable future differentiation of IgAN *vs.* controls and identification of disease-specific IgA1 HR *O*-glycoforms associated with IgA1 glomerular deposition.

Characteristics of B Cells in IgA Nephropathy Model Mice

Yoshihito Nihei, Yusuke Fukao, Hitoshi Suzuki, Yusuke Suzuki. *Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: The pathogenesis of IgA nephropathy (IgAN) is associated with dysregulation of immune system, however the characteristics of B cells that are responsible for production of nephritogenic IgA have been elusive. Recently, we have reported the abnormal B cells expressing APRIL are present in tonsils of human IgAN (JASN 28; 1227, 2017). Since abnormal antibody production seems to be the key feature in the pathogenesis of IgAN, we investigated characteristics of B cells in IgAN model mice, gddY mice, which we have established. Furthermore, we recently developed a novel culture system mimicking germinal center in mucosa, by which nearly 50 % of B cells undergo class switch (CS) to IgA. Therefore, the present study aimed to evaluate characteristics of B cells in gddY mice by using this novel culture system. First, we analyzed the proliferation of splenic B cells upon stimulation in vitro. Next, we examined their CS to IgA.

Methods: The proliferation of splenic B cells upon stimulation with membrane-bound IgM and CD40 were evaluated by Thymidine-uptake analysis. Naïve B cells from wild type mice and gddY mice were cultured for seven days by using newly developed culture system and the IgA CS was evaluated by flow cytometry.

Results: We found that B cells of gddY mice exhibited elevated proliferation rate than those of wild type mice in response to stimuli through CD40 and membrane-bound IgM. There was no significant difference in the frequency of CS to IgA between splenic B cells from gddY mice and those from wild mice.

Conclusions: These data indicate B cells in gddY mice may be hyper-sensitive to stimuli by antigen and T-cell help without increasing the frequency of IgA CS and suggest such a B-cell intrinsic factor may be involved in the pathology of IgAN.

A New Insight into the Pathogenesis of IgAN: Dissecting the Disease in Single Cells

Sonia Zambrano Sevilla,[1] Toshiki Kano,[3] Yusuke Suzuki,[2] Jaakko Patrakka.[1] *[1]Karolinska Institutet, Huddinge, Sweden; [2]Juntendo University School of Medicine, Tokyo, Japan; [3]Juntendo University, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. Molecular mechanisms driving glomerular damage in the disease are poorly understood. In this study, we analysed individual glomerular cell from ddY mice, a well-established genetic model of IgAN, by using scRNA-seq.

Methods: 5 control (non-proteinuric) and 5 IgAN (proteinuric) ddY mice were included in the study. Animals were sacrificed at 4 weeks of age and glomeruli isolated using the perfusion of magnetic beads. The glomeruli were treated mechanically and enzymatically to obtain single cells. Viable single cells of enriched glomeruli were unbiasedly sorted to 384-well plates and scRNA-seq performed using the Smart-seq2 protocol.

Results: A total of 3096 cells passed Quality Control. Unsupervised cell clustering demonstrated the inclusion of 11 cell types in both control and IgAN (glomerular endothelial (GEC), mesangial, parietal epithelial, podocyte, juxtaglomerular, macrophage, NK, T and B cells, as well as small contamination with tubular cells). The results showed a significant loss of podocytes in IgAN animals and revealed a number of new IgAN-associated genes/pathways in individual cell types. In podocytes, the Gene Ontology analysis revealed the emission of chemoattractant and pro-inflammatory cytokines, a role classically attributed to mesangial cells in this disease. In GECs, several cell subpopulations were detected and they showed a proinflammatory phenotype in IgAN, including for instance the up-regulation of selectin and MHC class 2 molecules. Mesangial cells seemed to be get activated and gain a migratory phenotype, which included, for instance, the up-regulation of ACTA2 expression. Moreover, several novel ligand-receptor pairs were identified in glomerular cells that are likely to play a role in the disease progression.

Conclusions: The preliminary analysis of our data suggests a crucial role of podocytes and GECs in the initiation of glomerular injury in ddY IgAN mice. Further analyses are ongoing to understand the crosstalk between the different glomerular cell types in both disease and healthy state.

Intravenous Infection with Cnm-Positive Streptococcus mutans, a Dental Pathogen, Induces IgA Nephropathy-Like Lesions in Rats

Taro Misaki,[1,2] Shuhei Naka,[6] Kaoruko Wato,[3] Yoshitaka Shimizu,[1] Yasuyuki Nagasawa,[4] Seigo Ito,[5] Ryota Nomura,[3] Michiyo Matsumoto-Nakano,[6] Kazuhiko Nakano.[3] *[1]Seirei Hamamatsu General Hospital, Hamamatsu, Japan; [2]School of Nursing, Seirei Christopher University, Hamamatsu, Japan; [3]Osaka University Graduate School of Dentistry, Suita, Japan; [4]Hyogo College of Medicine, Nishinomiya, Japan; [5]National Defense Medical College, Tokorozawa, Japan; [6]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: IgA nephropathy (IgAN) is one of most common types of primary glomerulonephritis worldwide, but its precise pathogenesis remains unclear. Previously, we reported that *Streptococcus mutans*, a major pathogen of dental caries was frequently isolated from the oral cavity of IgAN patients; these isolates showed surface expression of collagen-binding protein (Cnm). However, there is no direct evidence that Cnm-positive *S. mutans* induces IgAN. In the present study, we evaluated renal lesions in rats that were intravenously infected with Cnm-positive *S. mutans* isolated from an IgAN patient.

Methods: Cnm-positive *S. mutans* strain SN74, isolated from the saliva of an IgAN patient, was intravenously administered to 4-week-old male specific pathogen-free Sprague-Dawley rats. At 15, 30, 45, and 60 days post-infection, kidney specimens were evaluated. Periodic acid-Schiff staining and fluorescent immunostaining with IgA, C3, and CD68 antibodies was performed; electron microscopy analysis was also performed.

Results: Proteinuria in the *S. mutans* group was significantly elevated, compared with that in the control group at 30 days post-infection ($p < 0.05$). Histopathological examinations revealed increased presence of mesangial cells and matrix at 30 days post-infection in the *S. mutans* group. Immunochemical examinations demonstrated that combined IgA/C3 deposition in mesangial cells was significantly greater in the *S. mutans* group than in the control group at 45 days post-infection ($p < 0.05$). Electron microscopy analysis showed electron-dense deposits in the mesangial area and hump in subepithelial areas in the *S. mutans* group at 45 days post-infection. Furthermore, the numbers of CD68-positive cells (i.e., macrophages) in the glomeruli of the *S. mutans* group were significantly higher than those in the control group at 30, 45, and 60 days post-infection ($p < 0.01$).

Conclusions: Intravenous infection with Cnm-positive *S. mutans* isolated from an IgAN patient could induce IgAN or infection-related glomerulonephritis in rats.

Upregulation of miR-98-5p Enhance the Level of Galactose-Deficient IgA1 Through Chemokines in IgA Nephropathy

Di Liu, Hong Liu. *The Second Xiangya Hospital, Central South University, Changsha, China.*

Background: The increase of galactose-deficient IgA1 (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). The aim of this study was to find the miRNA which could affect the pathogenesis of IgAN and reveal its regulation mechanism of Gd-IgA1 expression in peripheral blood.

Methods: The differentially expressed miRNAs in peripheral blood mononuclear cell (PBMC) between IgAN patients and healthy controls were screened by high-throughput sequencing. Confirm the results of the sequencing in a larger sample size. And explore the mechanism of the regulation of Gd-IgA1 caused by miRNA through transfecting miRNA mimic and related plasmid.

Results: High-throughput sequencing results showed that miR-98-5p is highly expressed in PBMC of IgA nephropathy patients compared with healthy controls, and the luciferase reporter gene system confirmed that miR-98-5p may target CCL3. miR-98-5p was increased and CCL3 was decreased in PBMC of IgAN patients were confirmed in a larger sample size, which was consistent with the sequencing results. It was confirmed by transfecting si-CCL3 that the decrease of CCL3 can affect the expression of interleukin-6 (IL-6) and C1GALT1. The overexpression of miR-98-5p in PBMC through transfecting the miR-98-5p mimic led to a reduction in CCL3 and C1GALT1 levels and an increase in IL-6 and Gd-IgA1 levels. But when co-transfected with the CCL3 plasmid, these changes in PBMC could be attenuated.

Conclusions: Hsa-miR-98-5p may be involved in the development of IgA nephropathy and is expected to become a biomarker and a new therapeutic target.

SA-PO601

Macrophage Interactions with Collecting Ducts May Contribute to the Interstitial Fibrosis Observed in IgA Nephropathy Progression

Izabella Z. Pawluczyk,[1] Maria F. Soares,[2] William A. Barratt,[1] Jeremy R. Brown,[1] Haresh Selvaskandan,[3] Jasraj S. Bhachu,[4] Yiqing Zeng,[1] Rishi Sarania,[1] Karen Molyneux,[5] Jonathan Barratt.[1] *[1]University of Leicester, Leicester, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [3]University Hospitals of Leicester, Leicester, United Kingdom; [4]University Of Leicester, Leicester, United Kingdom; [5]Leicester University, Leicester, United Kingdom.*

Background: Tubulo-interstitial fibrosis is a powerful predictor of future progression in IgA nephropathy (IgAN). Proximal tubules, in concert with infiltrating macrophages, are regarded as the *agents provocateurs* for driving this process. However, evidence is now emerging for a contributory role of the distal nephron. The aim of this study was to examine the potential influence of macrophages on renal collecting ducts (CDEC) in the progression of IgAN.

Methods: Macrophage-conditioned media (MCM) were generated from U937 and THP-1 cells, cultured in the presence or absence of 100μg/ml IgA1. Collecting duct epithelial cells (CDEC) exposed to the MCMs were analysed for evidence of inflammation and fibrosis.

Results: Staining of IgAN biopsies for the macrophage marker CD68 demonstrated that macrophages were principally observed in and around proximal tubules. However, CD68+ macrophages were also observed in areas of medullary collecting ducts and within their lumens. CDEC exposure to THP-1-IgA-MCM exhibited markedly increased expression of the tubular injury marker neutrophil-associated gelatinase (NGAL) and raised levels of IL1β, TNFα, IL6 and IL8; effects that were replicated by 5ng/ml IL1ß alone. U937-IgA-MCM, on the other hand, significantly increased MCP-1 and fibronectin levels and reduced E-cadherin mRNA expression. Exosomes extracted from THP-1-IgA-MCMs stimulated similar increases in NGAL and cytokine expression to the source MCM, while in cross over experiments exosomes extracted from CDECs induced IL1β and IL6 mRNA expression in macrophages. MiRnome analysis using nanostring technology revealed that miR-146a was expressed more than 2 fold in CDECs treated with THP-1-IgA-MCM compared to THP-1-MCM. Enforced miR-146a suppression with a specific inhibitor further enhanced NGAL expression in CDECs in the presence of MCM while ectopic miR-146a over expression down-regulated it. Both NGAL mRNA and miR-146a were found, by RT-PCR, to be upregulated in the biopsies of progressive forms of IgAN compared to CKD controls.

Conclusions: Taken together these data suggest that macrophages and collecting ducts could interact to contribute to the tubulo-interstitial fibrosis and inflammation found in progressive forms of IgAN.

SA-PO602

CARD9 Risk Allele and IgA Nephropathy

Fateh O. Kadhim,[1,2] Karen Molyneux,[3] Izabella Z. Pawluczyk,[5] Hong Zhang,[4] Wang Yanna,[4] Xujie Zhou,[4] Jonathan Barratt.[5] *[1]Cardio Vascular Sciences, University of Leicester, Leicester, United Kingdom; [2]College of Veterinary Medicine, University of Kerbala, Kerbala, Iraq; [3]Leicester University, Leicester, United Kingdom; [4]Peking University First Hospital, Beijing, China; [5]University of Leicester, Leicester, United Kingdom.*

Background: IgA nephropathy (IgAN) is a common cause of primary glomerulonephritis and is most prevalent in East Asian populations. The pathogenesis of IgAN is not well understood. IgAN GWAS studies have revealed an association with rs4077515, a SNP within the coding sequence of CARD9, an essential mediator of the innate immune system. However the place of CARD9 in the pathogenesis of IgAN has yet to be defined. The aim of this study was to investigate the expression of CARD9 in the kidney and determine whether it has an intrarenal role in IgAN.

Methods: Screening kidney cell lines for synthesis of CARD9 by western blotting revealed greatest CARD9 synthesis in human mesangial cells (hMC). To test the significance of the risk allele we incubated hMC that were heterozygous or homozygous negative or positive for the risk allele rs4077515-T with IgA1 isolated from 5 individuals (3 IgAN, 2 healthy subjects) and measured IL-6 synthesis using ELIZA.

Results: We observed increased expression of CARD9 mRNA in whole kidney biopsies in IgAN compared to kidney disease controls ($p<0.005$). Immunohistochemistry demonstrated CARD9 protein in both the glomerular and tubulointerstitial compartments in IgAN. The presence of rs4077515-T resulted in significantly increased production of the pro-inflammatory cytokine IL-6 following exposure to IgA1 ($p<0.0001$: TT:CC and $p<0.001$: CT:CC). In parallel, similar increases were seen in mRNA coding for IL-6 IgA1 ($p<0.001$: TT:CC and $p=0.0109$: CT:CC), the signal transducer, IL-6ST ($p<0.0001$: TT:CC and $p<0.0023$: CT:CC) and monocyte chemoattractant protein 1 ($p<0.0001$: TT:CC and

p=0.0004: CT:CC). This *in vitro* data suggests that the presence of rs4077515-T could result in a greater inflammatory response to mesangial IgA deposition in IgAN and therefore rs4077515-T may play a role in determining the rate of renal function decline in IgAN. To test this hypothesis we analysed the association of rs4077515-T with renal function outcome in 1,279 Chinese IgAN patients. There was a significant association between rs4077515-T and the likelihood of renal function decline in this population (HR values of 1.85 (95% CI 1.17-2.93) TT:CC and 1.33 (95% CI 0.98-1.82) CT:CC).

Conclusions: This data suggests intrarenal CARD9 may play a significant role in determining mesangial response to IgA deposition in IgAN and ultimately influence the likelihood of renal function decline.

SA-PO603

The Role of Angiogenin/miR-141 Axis in Glomerular Injury of IgA Nephropathy

Chunhua Weng. *the First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China.*

Background: IgA nephropathy (IgAN) is the most common primary chronic glomerular disease worldwide. Gal-deficient IgA1 (Gd-IgA1) containing immune complex is the important factor involved in the pathogenesis of IgAN, which mechanism has not yet been clarified. Angiogenin is a secreted ribonuclease, and it plays biological functions through selectively cutting RNA substrates, including miRNAs.

Methods: The concentration of Angiogenin in plasma and cell medium was examined by Elisa. Overexpression of Angiogenin was conducted by infection of lentivirus with Angiogenin overexpression plasmid. Knockdown of Angiogenin was conducted by infection of lentivirus with shRNA. Cell proliferation activity was carried out by CCK-8. Cell apoptosis was carried out by Flow cytometry. The protein were measured by western blotting, mRNA and miRNA were measured by RT-qPCR. The cleavage of miR-141 by Angiogenin was carried out by a cell-free cleavage assay.

Results: The level of Angiogenin in plasma was elevated in IgAN patients than healthy controls. When the glomerular mesangial cell was stimulated by Gd-IgA1 immune complex, the secretion of Angiogenin and some inflammatory cytokines were upregulated. When the expression of Angiogenin in mesangial cell was knock-down by shRNA, the proliferative activity of mesangial cells was inhibited. The expression level of miR-141 was affected by Angiogenin expression in mesangial cells, high expression of Angiogenin downregulated miR-141 and knockdown of Angiogenin upregulated the level of miR-141. In addition, Angiogenin digest miR-141 as an endoribonuclease *in vitro*.

Conclusions: Angiogenin was upregulated in IgAN. Gd-IgA1 complex stimulation increased the secretion of Angiogenin and inflammatory cytokines of mesangial cell. Down-regulation of Angiogenin inhibits the proliferative activity of mesangial cells. Angiogenin regulates the level of miR-141 in mesangial cell and digests miR-141 as an endoribonuclease *in vitro*. Thus, Angiognein/miR-141 axis may regulate IgAN through affecting mesangial cell proliferation and inflammatory cytokines secretion.

TLR3 Activation Contributes to Pathogenesis of Mesangial Proliferative Glomerulonephritis

Syuhei Watanabe,[1,2] Ying Zhang,[1] Hidenori Yasuda,[1] Yoshiyasu Fukusumi,[1] Junichiro J. Kazama,[2] Hiroshi Kawachi.[1] *[1]Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Fukushima Medical University, Fukushima, Japan.*

Background: It is assumed that Toll-like receptor (TLR) is activated by ligands released from damaged tissue, and the TLR-mediated signaling is involved in the development of mesangial proliferative glomerulonephritis (MGN). However, how TLR detects signals from the damaged tissue and the pathogenic mechanism initiated by the TLR activation in MGN are poorly understood. Thy1.1. GN, a widely used rat experimental model for MGN, is caused by the injection of the antibody against Thy1.1 expressed on mesangial cell surface. Thy1.1. GN is characterized by diffuse mesangiolysis at 24h and consequent accumulation of inflammatory cells and mesangial cell proliferation.

Methods: The kinetics of the expression of TLR2, TLR3, TLR4 in Thy1.1. GN were analyzed by RT-PCR and immune-histochemical analyses. The cells expressing TLRs were analyzed.

Results: The increase in mRNA expression of TLR3 was already detected at 1 h (3.4 times to control) and the increase is promoted on day 7 (11.4 times to control). However, such a clear increase is not detected in TLR2 or TLR4. Immunostaining of TLR3 was not detected in normal glomeruli, and the clear positive staining of TLR3 was detected at mesangial area at 1h, and at 24h and day 7 the positive staining was detected at the expanded mesangial area and in capillary lumen. In Thy1.1. GN at the early recovery phase after mesangiolysis Thy1.1. negative cells were mainly accumulated in mesangial area and the population of Thy1.1 positive cells gradually increased with time. ED1+ macrophage (4.3±0.45/glom.), ED3+ activated macrophages (4.5±0.90/glom) and NKRP1+ NK cells (1.6±0.45/glom) were accumulated in glomeruli on day 7 of Thy1.1. GN. Dual labeling immune-histochemical analysis showed that TLR3 was detected on Thy1.1. negative cells localized at mesangial area but not detected on Thy1.1. positive cell, and some portions of ED3+ cells express TLR3 but no NKRP1+ cells express TLR3. mRNA expression IFN-β, which is mainly activated by TRL3-mediated signaling, was increased (2.8 times to control) in this GN model.

Conclusions: Not TLR2 or TLR4 but TLR3 was dominantly activated in Thy1.1. GN. It is conceivable that TLR3 responds to molecules released by damaged mesangial cell, and TLR3-mediated signaling participates in the pathogenesis of mesangial proliferative nephritis.

THSD7A Knockout Mice as a Valuable Tool for the Generation of Domain-Specific Monoclonal Antibodies

Larissa Seifert,[1] Gunther Zahner,[1] Catherine Meyer-Schwesinger,[2] Thorsten Wiech,[3] Tobias B. Huber,[1] Friedrich Koch-nolte,[4] Nicola M. Tomas.[1] *[1]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Institute of Physiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Institute of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Autoantibodies against multiple domains in THSD7A cause membranous nephropathy (MN). However, the function of THSD7A in podocytes, the precise mechanisms of antibody-induced glomerular injury and the role of the targeted epitopes are largely unknown.

Methods: Embryonic stem cells for generation of THSD7A-ko first mice were purchased from UCDavis KOMP. Since ko first mice were found to contain residual expression of THSD7A in podocytes, mice were further bred to obtain a true constitutive THSD7A ko status (THSD7A$^{-/-}$). For the generation of poly- and monoclonal antibodies (MABs), 12w-old THSD7A$^{-/-}$ mice were immunized using the purified murine antigen fragments d1_d2 and d15_d16, corresponding to the domains most frequently recognized by patient autoantibodies. Spleen and lymph nodes were collected 7w after immunization and fused with SP2/0 myeloma cells. Cell clones expressing anti-THSD7A antibodies were selected using an immunofluorescence test on THSD7A-transfected CHO cells. Positive clones were cultured and IgG was purified from cell culture supernatant.

Results: THSD7A$^{-/-}$ mice showed no glomerular expression of THSD7A in immunofluorescence and Western blot. Glomeruli appeared normal in PAS staining and no ultrastructural changes were observed by EM. Mice had no proteinuria by the age of 1y. Immunization of THSD7A$^{-/-}$ mice induced high levels of domain-specific anti-THSD7A antibodies. Fusion of splenic cells with myeloma cells resulted in 3 clones producing antibodies against THSD7A. One MAB recognized d1_d2 (IgG1) and two MABs recognized d15_d16 (IgG1 and IgG2b). These MABs were suitable for the detection of THSD7A in immunofluorescence, Western and dot blot. Transfer of individual MABs to WT BALB/c mice resulted in glomerular binding of mouse IgG, but no complement deposition and no proteinuria.

Conclusions: In preliminary investigations, THSD7A$^{-/-}$ mice do not show significant glomerular alterations, suggesting that THSD7A expression is not integral for basal glomerular function or that other unidentified molecules can compensate for the lack of THSD7A. THSD7A$^{-/-}$ mice are a powerful tool for the generation of poly- and monoclonal antibodies and these antibodies can potentially be used to dissect the mode of antibody-induced glomerular damage and the role of targeted epitopes in MN.

SA-PO606

IL233 Regulates Mitochondrial Function and WNT Signaling for Lupus Glomerulonephritis Remission

Rajkumar Venkatadri,[2,3] Vikram Sabapathy,[2,3] Murat Dogan,[2,3] Saleh Mohammad,[2,3] Shu man Fu,[1,3] Rahul Sharma.[2,3] *[1]Center for Immunity, Inflammation and Regenerative Medicine, Division of Rheumatology, Charlottesville, VA; [2]Center for Immunity, Inflammation and Regenerative Medicine, Division of Nephrology, Charlottesville, VA; [3]University of Virginia, Charlottesville, VA.*

Background: We showed that the hybrid cytokine IL233 induced persistent remission in ongoing lupus glomerulonephritis (GN) in NZM2328 mice. The progression of GN in NZM2328 animals involves stages of acute (aGN), transitional (tGN) and chronic GN (cGN). As a means to further understand the mechanisms involved in IL233-rendered protection, we investigated modulation of mitochondrial function and canonical Wnt signaling that is understudied in the setting of aGN to cGN progression, utilizing both *in vitro* and *in vivo* approaches.

Methods: Mouse glomerular endothelial cells (mGECs) and proximal tubular TKPTS cells were treated with varying concentrations of IL233 and investigated for mitochondrial membrane potential and for genes and proteins associated with mitochondrial function. *In vivo*, kidney lysates from treated NZM2328 animals were screened for transcripts of mitochondrial genes by real time PCR. Canonical Wnt signaling proteins were studied by Western blotting. Seahorse XF Cell Mito Stress assay was performed with isolated regulatory T cells (Tregs) from treated animals.

Results: IL233 treatment induced a marked elevation of genes related to mitochondrial function and biogenesis (*Pgc1α*, *Mfn1*, *Nrf1*, *Nrf2*, *Tfam* and *Drp1*) in mGECs and TKPTS cells indicating a direct regulation of mitochondrial function. These cells also displayed higher mitochondrial membrane potential by flow cytometry. IL233-treated mice with established GN had higher expression of genes related to mitochondrial function and biogenesis, thus, complementing *in vitro* observations. Levels of canonical Wnt activators (*LRP6* and *Dvl3*) and □□-catenin were significantly reduced in IL233 treated kidneys. Tregs isolated from saline, IL-2, IL-33, IL2+IL-33 and IL233 treated animals were investigated for oxidative respiration with Seahorse. Although there was a trend of a higher rate of oxidative respiration in mice treated with IL-2 or IL-33 only or the combination of IL-2 and IL-33, the Tregs isolated from IL233 treated mice had a significantly higher basal and burst respiration rate.

Conclusions: We present evidence for the use of IL233 for therapy of lupus GN in a murine model. *In vitro* and *in vivo* data reveals enhancement of mitochondrial function and modulation of canonical Wnt signaling as possible mechanisms of IL233-mediated remission from lupus GN.

Epidermal Growth Factor Receptor-Dependent TLR7 Signaling in Macrophages Promotes Kidney Injury in Crescentic Glomerulonephritis

Narihito Tatsumoto,[2] Daniel N. Leal,[2] Ian R. Rifkin,[3] Moshe Arditi,[1] Michifumi Yamashita.[1] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Cedars Sinai Medical Center, Los Angeles, CA; [3]Boston University School of Medicine, Boston, MA.*

Background: Epidermal growth factor receptor (EGFR) has been shown to promote glomerular injury in crescentic glomerulonephritis (CRGN) and we showed that EGFR plays pivotal roles in the signaling of endosomal Toll-like receptors (TLRs): TLR3 (*Sci Signal. 2012*), TLR4 (*EMBO Rep. 2015*), and TLR9 (*J Immunol. 2018*). Polymorphisms in TLR7, a sensor for endogenous danger signal, are linked with the development of SLE, and TLR7 activation is implicated in lupus nephritis. Here, we show that EGFR has a critical role in macrophages (MΦs) for TLR7-dependent CRGN.

Methods: To induce nephrotoxic serum nephritis (NTN), a model of CRGN, C57Bl/6 (WT) mice or TLR7-/- mice were immunized with normal rabbit IgG and IFA, and injected with nephrotoxic serum (NTS). These mice were also treated with or without treatment of Gefitinib, an EGFR inhibitor. Seven days after NTS injection, kidney injury was analyzed by proteinuria and histology. In cell culture system, TLR7-mediated gene induction, cytokine production, and cell migration were assessed using bone marrow-derived MΦs and RAW 264.7 cells. The physical interaction between EGFR and TLR7, and tyrosine phosphorylation of TLR7 were analyzed by immunoprecipitation assay.

Results: TLR7-/- mice were resistant to NTN compared to WT mice: TLR7-/- mice showed less severe proteinuria, GBM rupture, crescent formation, and less number of Mac-2 positive MΦs infiltration into glomeruli. None of the glomerular resident cells expressed TLR7 confirmed by protein expression and functional assays *in vitro* and *ex vivo*. Only inflammatory MΦs expressed significant amount of functional TLR7. Mechanistically, upon a TLR7 ligand stimulation, TLR7 physically interacted with EGFR in MΦs by co-immunoprecipitation, and tyrosine residue(s) of TLR7 is phosphorylated. However, such a TLR7 phosphorylation is completely blocked by Gefitinib, an EGFR kinase inhibitor. In addition, Gefitinib blocked subsequent cellular function (e.g. cell migration) and cytokine production (e.g. IL-6 production). Finally, Gefitinib treatment on TLR7-/- mice did not show significant additional protective effects on NTN at an early time point (Day 7), compared to TLR7-/- mice without Gefitinib.

Conclusions: These results indicate that regulation of TLR7 signaling in MΦs by EGFR has a critical role in the early pathogenesis of CRGN.

Glomerular Endothelial Cell Heterogeneity and Contribution to Kidney Disease

Sargis Sedrakyan,[1] Hasmik Soloyan,[1] Matthew E. Thornton,[2] Valentina Villani,[1] Patrick Khatchadourian,[1] Georgina Gyarmati,[2] Janos Peti-Peterdi,[2] Roger E. De Filippo,[1] Laura Perin.[1] GOFARR Laboratory for Organ Regenerative Research and Cell Therapeutics in Urology *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Glomerular endothelial dysfunction plays a key role in the development of chronic kidney disease (CKD), but its impact on Alport syndrome (AS, characterized by mutations in collagen IVα3α4α5) is unknown. In AS, we reported structural changed and upregulation of VEGF pathway in the glomerular endothelial cells (GEC) in the early stage of the disease and we hypothesized that GEC dysfunction is important in AS pathogenesis.

Methods: To test our hypothesis, we generated GEC specific (Tek-Cre driven) *td*Tomato reporter AS mice and isolated GEC by FACS. We studied GEC by flow cytometry, WB, and by multiphoton and confocal microscopy, and by RNA-seq analysis. Data were analyzed and AS-GEC compared to WT-GEC in terms of their morphology and gene expression.

Results: *td*Tomato signal identified two distinct GEC subsets (*bright* and *dim*) in both wild type and AS mice, which presented with transcriptional heterogeneity in ECM and glycocalyx-associated proteins, immune cell activation and cellular metabolism. In AS-GEC vs WT-GEC, genes with a well-established functional role in mitochondrial dysfunction, glucose and lipid metabolism, and inflammation were most significantly enriched. In particular, the *bright* cells were enriched in (upregulated) genes controlling cytoskeleton organization and inflammatory cell-cell adhesion (such as Icam1, Vcam1, Ccl2, Spon2, Sele, etc). In contrast, the *dim* cells were highly enriched in (upregulated) genes related to chemokine signaling but downregulated for genes and pathways associated with mitochondrial function. Both *bright* and *dim* cells were enriched in downregulated genes linked to glucose and lipid metabolism. In terms of cell-ECM interactions, Itgβ9 was highly reduced in both subsets in AS. Among other differentially expressed genes related to ECM composition, Svep1 expression was highly increased in the *bright* cells and Col17α1 in the *dim* cells exclusively.

Conclusions: In conclusion, we identified two GEC subpopulations and showed glomerular endothelial dysfunction in the early stages of AS. Importantly, GEC subsets contributed to endothelial dysfunction differently. A better understanding of the functional role of the glomerular endothelium could lead to the development of targeted new therapies for the treatment of CKD.

APL-2 Prevents Both C3 and C5 Convertase Formation and Activity: A Potential Therapeutic for Renal Diseases

Noémie Simon-Tillaux,[2] Sophie Chauvet,[2] Delphine El mehdi,[1] Pascal Deschatelets,[1] Veronique Fremeaux-Bacchi.[2] *[1]Apelllis Pharmaceuticals, Crestwood, KY; [2]Hôpital Européen Georges Pompidou, Paris, France.*

Background: C3 glomerulopathy (C3G) is a group of renal diseases characterized by isolated glomerular deposits of C3 fragments as a result of an uncontrolled activation of the complement alternative pathways (AP). The excessive activation of C3 and C5 convertases leading to C3b production and formation of the membrane attack complex is associated with renal function impairment. About 50% of the patients progress to end stage renal disease within 10 years of the diagnosis. The disease is caused either by genetic abnormalities in complement regulatory proteins or by the presence of autoantibodies, C3 or C5 nephritic factors (NeFs), that bind and stabilize the convertases. APL-2 is a small, synthetic, cyclic peptide that binds and inhibits C3 and C3b. The objective of this study was to better understand the impact of APL-2 on the formation of the AP C3 and the C5 convertases and on the activity of pre-formed convertases. We also evaluated the ability of APL-2 toinhibit NeFs-mediated overactivation of both convertases.

Methods: This study was performed in *in vitro*model of hemolysis using C3b-recovered sheep erythrocytes and purified complement proteins. IgG positive for C3NeF (n=14) and C3/C5NeF (n=9) were isolated from patients with C3G and added with or without APL-2 (25 μg/ml).

Results: APL-2 prevents the formation of AP C3 and C5 convertases and inhibits the activity of both pre-formed convertases. APL-2 also decreased the prolonged convertase activity mediated by C3NeF and C5NeF. In 6/14 C3NeF and 7/9 C5NeF the stabilizing effect of the autoantibodies became undetectable demonstrating that APL-2 is still effective to inhibit the convertase hyperactivity in the presence of NeFs.

Conclusions: APL-2 is a C3 inhibitor that also interrupts the formation and inhibits the activity of pre-formed AP C3 and C5 convertases, therefore blocking the activation of both C3 and C5. The effect of APL-2 on the convertases occurs also in the presence of NeFs. This data supports potential therapeutic effects of APL-2 in patients with C3G as well as for other renal diseases associated with overactivation of complement.

Micromanaging Autoimmune Nephritis: miR-17-92 Modulates T_{FH} Development and Regulatory T Cell Activity

Huang-Yu Yang. *Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: T follicular helper (T_{FH}) cell provide crucial growth signals to germinal center (GC) B cells supporting antibody production. Tight control of T_{FH} numbers maintains self-tolerance. Regulatory T (Treg) cells play a critical role in maintaining self-tolerance and controlling the magnitude of physiologic immune response. The Treg transcription factor forkhead box P3 (Foxp3) works in concert with other co-regulator molecules to determine suppressive phenotype of Treg. Compiling evidence show that aberrant T_{FH}, GC responses and deficiencies of Treg are associated with systemic lupus erythematousand autoantibody production.

Methods: We generated T cell specific miR-17-92 knockout (miR-17-92-/-) mice, followed by induction of pristane nephropathy in miR-17-92 -/- and wild type littermates. By bioinformatics study, possible targets of mir-17-92, related to Treg function was evaluated. Luciferase reporter assay was utilized for verification. Forced expression and knockdown of miRNA in Treg and TFH was performed by lentivirus.

Results: We induce pristane nephropathy on T cell specific miR-17-92 knockout (miR-17-92$^{-/-}$) mice. Mir17-92 CD4 T cell specific deficiencymitigates pristane induced-lupus nephropathy in mice. The mice showed less T_{FH} cells, less GC B cells and lower autoantibody formation. Consistent with the reduction in autoantibody production, histological analysis revealed a lower mean renal histopathology score and less IgG deposition. We further demonstrate that the miR-17 regulates T_{FH} development by targeting Akt pathway. Moreover, miR17-92 mitigate the suppression function of Tregs

by targeting Foxp3 co-regulators. Ectopic expression of miR-17 downmodulates the suppression functions of Tregs in the colitis model. In addition, Tregs from patient with lupus nephritis and lupus mice both showed increased miR-17 expression.

Conclusions: Our studies suggest that miR-17-92 modulates aberrant immune response through critical regulation in T cells subsets, unveiling the future therapeutic potential of microRNA manipulation in lupus nephritis.

Evaluation of the Renoprotective Role of Endogenous Galectin-3 and Mechanism in Lupus Nephritis

Shin-Ruen Yang,[2] Shuk-Man Ka,[2] Wu Chung-Yao,[2] Ann Chen.[1] *[1]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taipei, Taiwan; [2]National Defense Medical Center, Taipei, Taiwan, Taipei, Taiwan.*

Background: Lupus nephritis (LN) is a major complication of systemic lupus erythematosus. Current therapeutic regimens to control the acute onset of LN progression include high doses of corticosteroids, cytotoxic agents and disease-modifying antirheumatic drugs. However, there is still a major concern about the potential, systemic adverse events of these drugs. Thus, the development of pathogenic pathway-based new therapies with much fewer and more tolerable side effects is clinically warranted. Galectin-3 (Gal-3) is a β-galactoside-binding protein and implicated in diverse biological processes in macrophages, dendritic cells (DCs), activated lymphocytes, and epithelial cells. However, the role of Gal-3 and exact mechanisms involved in the development and progression/deterioration of LN has yet to be determined, although renal expression of the protein is observed in LN patients.

Methods: Gal-3 KO-Y chromosome-linked autoimmune acceleration (Yaa) mutation was introduced in KO1 strain (KO1.Yaa) mice, a spontaneous mouse model of LN, which is deficient of Gal-3 were generated to investigate the renoprotective effects of Gal-3 in two complementary LN mouse models. Moreover, lupus-like nephritis in Gal-3 KO mice induced by LPS injections. Renal function, pathology and pathogenesis-based experiments galactoside-binding.

Results: In the present study, the results show that [1] the distribution and expression levels of Gal-3 were increased in renal biopsy specimens from LN patients, compared to normal control subjects; [2] deficiency of endogenous Gal-3 resulted in markedly increased severity in clinical and pathological alterations in both the LPS-induced LN in Gal-3 KO mice and spontaneous LN in Gal-3 KO-KO1. Yaa mice, compared to their respective wild type counterparts that equally induced of or developed galactoside-binding; and [3] greatly enhanced activation of T cells and B cells as well increased monocytosis in peripheral blood mononuclear cells were observed in the spontaneous LN in Gal-3 KO-KO1. Yaa mice, compared to KO1.Yaa mice.

Conclusions: Gal-3 played a protective role in the development of LN, and justify the protein as a potential drug candidate for LN.

SA-PO612

Urinary Levels of CD11b and CD163 Determine Rapid Responders to Remission Induction Therapy in Proliferative Lupus Nephritis

Munetoshi Karasawa,[3] Asaka Hachiya,[1] Naotake Tsuboi,[2] Shoichi Maruyama,[3] Kazuhiro Furuhashi.[1] *[1]Nagoya University, Nagoya, Japan; [2]Fujita Health University School of Medicine, Toyoake, Japan; [3]Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Drastic elevations of urinary CD11b (U-CD11b), α_m subunit of integrin Mac-1, and CD163 (U-CD163), a scavenger receptor for hemoglobin-haptoglobin complex, have been demonstrated in proliferative lupus nephritis (LN). The current study aims the further verifications of U-CD11b and U-CD163 as the potential LN biomarkers to predict longitudinal response of proliferative LN patients to the remission induction therapy.

Methods: We examined CD11b and CD163 by enzyme-linked immunosorbent assay in urine samples collected from proliferative LN class III or IV patients confirmed by renal biopsy in Nagoya Kidney Disease Registry (N-KDR) cohort between 2004 and 2014, and retrospectively analyzed those associations with longitudinal achievement of complete remission (CR) following the remission induction therapy. Based on the cut-off values of U-CD11b and U-CD163 respectively determined by receiver operation curves to predict CR, univariate analysis by log-rank test and multivariate analysis by cox proportional hazards regression model were performed to evaluate patient susceptibility to the remission induction therapy.

Results: Among 63 patients with proliferative LN for 52 months observation period on average, U-CD11b and U-CD163 levels were significantly higher in patients who achieved CR within 3 months ($p<0.001$ in U-CD11b, $p=0.003$ in U-CD163) and 12 months ($p=0.02$ in U-CD11b, $p=0.03$ in U-CD163) compared with those who did not. In univariate analysis, the cumulative CR rates within 3 months in patients presenting low levels of U-CD11b and U-CD163 were significantly higher than their respective high levels. Multivariate analysis revealed low level of U-CD11b (hazard ratio [HR], 5.68; 95% confidence interval [95% CI], 1.65 to 19.4) and eGFR per 10ml/min/1.73m^2 (HR, 1.30; 95% CI, 1.11 to 1.52) as independent predictors for the achievement of CR within 3 months. Moreover, low level of U-CD11b (HR, 4.69; 95% CI, 1.35 to 16.2) still demonstrated the significance even in the subpopulation with preserved renal function.

Conclusions: U-CD11b, rather than U-CD163, serve the clinical values for the prediction of early response to the remission induction therapy in LN patients.

The Role of Plasmacytoid Dendritic Cells in Pathogenesis of Systemic Lupus Erythematosus

Hiroki Kitai,[1] Noritoshi Kato,[1] Shoichi Maruyama,[3] Yoshio Funahashi,[2] Takuji Ishimoto,[3] Tomoki Kosugi,[3] Takahiro Maeda,[4] Shintaro Komatsu.[1] *[1]Nagoya university, Nagoya, Japan; [2]65 Tsurumaicho showa-ku, Nagoya University, Nagoya, Japan; [3]Nagoya University Graduate School of Medicine, Nagoya, Japan; [4]Nagasaki Univesity, Nagasaki, Japan.*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease accompanied by production and deposition of immune complexes (IC) in multiple organs. Especially in the kidney, lupus nephritis (LN) due to deposition of IC occurs in about 40-70% of SLE patients, and about 10-30% of these patients progress to end stage renal disease. Plasmacytoid dendritic cells (pDCs) which recognize viral nucleic acids by endosomal toll-like receptor (TLR) 7/9 and secrete large amounts of IFN- I are considered as important mediators of antiviral responses, while inappropriate recognition of self nucleic acids with IFN- I responses is linked to autoimmunity. Therefore, this subset of DCs are attracting an attention for novel therapeutic target. But so far, little is known about the mechanisms how pDCs contribute pathogenesis of SLE and LN. TLR7 agonist, imiquimod (IMQ) induced mice SLE model is deeply involved with IFN- I secretion, and present LN which is similar to those of human. With this model, we investigated pathogenesis of SLE focusing on pDCs.

Methods: We isolated pDCs from spleen of 4weeks IMQ model, and performed miRNA array. We extracted miRNA which was up or down-regulated, and searched mRNAs target of these miRNAs on database. Then predicted mRNA targets were confirmed by qPCR. Using human pDCs cell line, CAL-1, we performed TLR7, 9 and IC stimulation experiment.

Results: As a target of miRNAs that shows down-regulation, we found zinc finger transcription factor: Kruppel-Like Factor 4 (KLF4). By qPCR, we confirmed that KLF4 was up-regulated in mice pDCs. Similar results were observed in the pristine-induced mice SLE model. We found that the protein levels of KLF4 was also up-regulated in TLR7 stimulation group compare with control group.

Conclusions: The production of autoantibody in SLE requires sustained production of IFN- I, but the pathogenesis of sustained IFN- I production in pDCs is not fully understood. From our study, it was suggested that the up-regulation of KLF4 in pDCs plays some roles in the pathogenesis of SLE. Further studies are needed to elucidate the precise roll of KLF4 in pDCs.

SA-PO614

Circulating MiRNAs as Potential Biomarkers of Kidney Damage in Patients with Systemic Lupus Erythematosus

Gustavo Aroca Martinez,[1] Henry J. Gonzalez Torres,[3] Lorena Gomez Escorcia,[3] Elkin Navarro.[2] *[1]Universidad Simon Bolivar / Clinica de la Costa, Barranquilla, Colombia; [2]Universidad Simón Bolívar, Barranquilla, Colombia; [3]Universidad Simon Bolivar, Barranquilla, Colombia.*

Background: Renal involvement is one of the most severe manifestations of systemic lupus erythematosus (SLE). Renal biopsy is the gold standard when it comes to knowing whether a patient has lupus nephritis and the degree of renal disease present. However, the biopsy has various complications, bleeding being the most common. Therefore, the development of alternative, non-invasive diagnostic tests for kidney disease in patients with SLE is a priority. Micro RNAs (miRNAs) are differentially expressed in various tissues, and changes in their expression have been associated with several pathological processes. The aim of this study was to identify changes in the abundance of miRNAs in plasma samples from patients with lupus nephritis that could potentially allow the diagnosis of renal damage in SLE patients.

Methods: This is an observational case-control cross-sectional study, in which we characterized the differential abundance profiles of miRNAs among patients with different degrees of lupus compared with SLE patients without renal involvement and healthy control individuals.

Results: We found 89 miRNAs with changes in their abundance between lupus nephritis patients and healthy controls, and 17 miRNAs that showed significant variations between SLE patients with or without renal involvement. Validation for qPCR of a group of miRNAs on additional samples from lupus patients with or without nephritis, and from healthy individuals, showed that five miRNAs presented an average detection sensitivity of 97%, a specificity of 70.3%, a positive predictive value of 82.5%, a negative predictive value of 96% and a diagnosis efficiency of 87.9%.

Conclusions: These results strongly suggest that miR-221-5p, miR-380-3p, miR-556-5p, miR-758-3p and miR-3074-3p are potential diagnostic biomarkers of lupus nephritis in patients with SLE. The observed differential pattern of miRNA abundance may have functional implications in the pathophysiology of SLE renal damage.

SA-PO615

Pneumococcal Polysaccharide Vaccine Regulates Murine Lupus

Chiara Cantarelli,[1,2] Chiara Guglielmo,[1] Susan Hartzell,[1] Fadi Salem,[4] Sofia Andrighetto,[1] Enrico Fiaccadori,[2] Ioannis Tassiulas,[3] Paolo Cravedi.[1] *[1]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Dipartimento di Medicina e Chirurgia, Università di Parma, Parma, Italy; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Mount Sinai Medical Center, New York, NY.*

Background: Current guidelines suggest the use of anti-pneumococcal vaccine Prevnar13 in patients with lupus, but the effects of such vaccination on disease severity are unknown.

Methods: We injected Prevnar13 (0.5 ml) or vehicle control into 8wk-old female MRL-*lpr* that spontaneously develop lupus. After 3mo, we measured circulating anti-PS IgG. In another set of animals, we quantified disease severity at 3 mo after Prevnar13 injection, including albuminuria, renal histology, and skin lesions. We also measured phenotype and function of splenocytes from treated and untreated mice, as well as renal STAT1 and STAT3 protein levels (WB).

Results: Prevnar13 induced the formation of anti-pneumococcal IgG (**Fig. 1A**). Prevnar13 treated animals showed less albuminuria, renal histological lesions, and milder dermatitis compared to controls (**Fig. 1B-D**). Improved disease severity in Prevnar13-treated animals was associated with reduced T follicular helper cells (T_{FH}) and more T follicular regulatory cells (Tfr) and regulatory T cells (Treg) (**Fig. 1E**). After aCD3/aCD28 stimulation, T lymphocytes from vaccinated mice showed less IL-17 and IL-4 production than non-vaccinated controls, while IL-10 production was significantly increased. Vaccinated mice had significantly decreased expression of STAT1 compared to controls, whereas STAT3 levels did not differ.

Conclusions: Anti-pneumococcal vaccination elicits anti-pneumococcal antibody response and ameliorates disease severity in MRL-*lpr* mice, which associates with increased fewer T_{FH} and increased Tregs. These data strongly support the use of Prevnar vaccination in individuals with lupus.

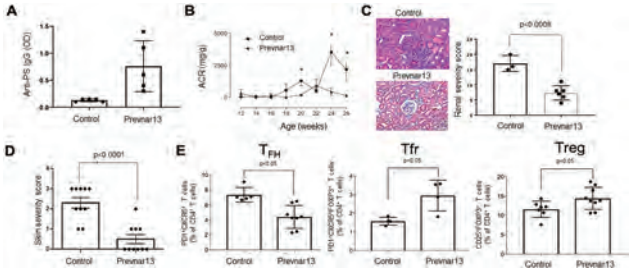

Fig. 1. Anti-PS IgG in MRL-*lpr* mice at 3 months after Prevnar13 injection (**A**). Urinary albumin/creatinine ratio (ACR) at serial time points after vehicle control or Prevnar13 injection in MRL-*lpr* mice (**B**). Representative H&E staining and kidney (**C**) and skin (**D**) severity score at 3 months after injection. T_{FH}, Tfr, and Treg in the spleens of the same mice (**E**). *P < 0.05 vs. control at the same time-point.

SA-PO616

Patients with Membranous Nephropathy Show Increased Circulating T Follicular Helper (T_{FH}), T_H17, and Exhausted T Cells (T_{EXH}): Results from a Cross-Sectional Study Including Healthy and CKD Controls

Chiara Cantarelli,[1,2] Susan Hartzell,[1] Andrea Angeletti,[1,3] Joaquin Manrique,[4] Lisa Anderson,[1] Emilie Chan,[5] Chiara Donadei,[3] Enrico Fiaccadori,[2] Gaetano La Manna,[3] Paolo Cravedi.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Dipartimento di Medicina e Chirurgia, Università di Parma, Parma, Italy; [3]Nephrology Dialysis and Renal Transplantation Unit, S. Orsola University Hospital, Bologna, Italy; [4]Complejo Hospital de Navarra, Pamplona, Spain; [5]Mount Sinai Hospital, New York, NY.*

Background: Primary membranous nephropathy (MN) is characterized by the presence of antibodies to the podocyte, but studies characterizing abnormalities in circulating T and B cell populations are limited and generally include only healthy controls.

Methods: We performed a comprehensive flow-cytometric analyses of 38 T and B lymphocyte subpopulations, including intracellular staining for IFN-g, IL-4, and IL-17 production in 27 patients with MN (before initiating immunosuppressive therapy) and compared them with 12 healthy individuals and 22 patients with non-immune mediated chronic kidney disease (CKD) including diabetic nephropathy, hypertension, and APKD. We also measured 19 serum cytokines in MN patients and healthy controls.

Results: 9 T and B cell subsets varied between MN and healthy subjects, but the only ones that differed between MN and both healthy and CKD controls included: $CD4^+$ $CXCR5^+$ $PD1^+$ T follicular helper (T_{FH}), $CD4^+$ $PD1^+$ $CD57^-$ T exhausted (T_{EXH}), and $CD4^+$ $IL17^+$ T cells (T_H17) that were significantly higher in MN patients (**Fig. 1A-D**). TNF-a and IL-7 were also significantly higher in MN patients than in healthy controls (**Fig. 1E-F**).

Conclusions: Patients with MN display a unique immune phenotype characterized by increased T_{FH}, T_{EXH}, and T_H17 cells. Despite the associative nature of the study, inclusion of both healthy and CKD controls, strongly supports a pathogenic role for these cells.

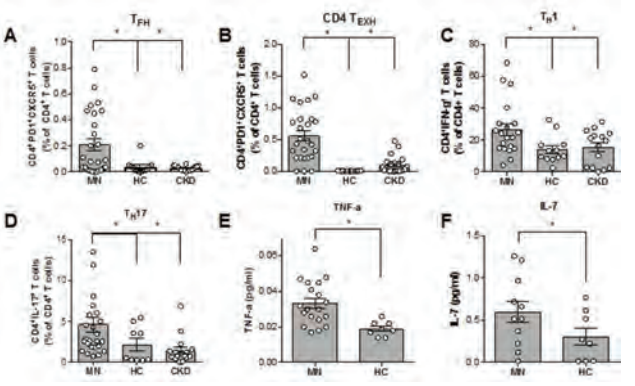

Fig. 1. Percentages of T_{FH} (**A**), $CD4^+$ T_{EXH} (**B**), T_H1 (**C**), T_H17 (**D**) cells in patients with membranous nephropathy (MN), in healthy controls (HC), and in patients with non-immune mediated chronic kidney disease (CKD). Serum TNF-a (**E**) and IL-7 (**F**) levels in MN patients and in HC.

SA-PO617

Ablation of MRP8 in Myeloid Cells Ameliorates Glomerulonephritis by Affecting Macrophage Characterization

Yusuke Hata,[1] Takashige Kuwabara,[1] Kiyoshi Mori,[3] Shuro Umemoto,[1] Tomoko Kanki,[1] Daisuke Fujimoto,[1] Yoshihiko Nishiguchi,[1] Yutaka Kakizoe,[1] Yuichiro Izumi,[1] Hideki Yokoi,[2] Masashi Mukoyama.[1] *[1]Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Kyoto University Graduate School of Medicine, Kyoto City, Japan; [3]University of Shizuoka, School of Pharmaceut Sci, Shizuoka, Japan.*

Background: We previously reported that toll-like receptor 4 (TLR4) and its endogenous ligand, myeloid-related protein 8 (MRP8, S100A8), play important roles in the progression of diabetic nephropathy in mice. During these experiments, we unexpectedly observed that glomerular-infiltrated macrophages (MΦ) expressed MRP8 much more robustly than tubulointerstitial MΦ. However, the mechanisms and roles remain elusive.

Methods: We generated myeloid-lineage cell-specific MRP8 knockout mice (MyM8KO), and induced experimental nephrotoxic glomerulonephritis (NTN). Co-culture of MΦ with mesangial cells (Mes) or proximal tubular cells (PT) was performed to investigate the potential cellular crosstalk within glomeruli. Phalloidin staining was performed to evaluate the effects of MRP8 on bone marrow-derived MΦ (BMDM) generated from MyM8KO. BMDM was characterized as the M1/M2 ratio (M1/M2) determined by real-time PCR. Cell surface markers of peripheral leukocytes and glomerular-infiltrated MΦ were analyzed by flow cytometry (FCM). For effective sorting of MRP8-targeted cells, MyM8KO were crossed with floxed-STOP ZsGreen transgenic mice (MyM8KO-ZsG).

Results: In the NTN mice, ablation of MRP8 in myeloid-lineage cells significantly ameliorated glomerulonephritis as indicated by the reduction in proteinuria, glomerular exudative lesions, pro-inflammatory gene expressions and M1 dominancy in isolated glomeruli. In vitro, MRP8 expression was markedly induced in BMDM by co-culture with Mes but not with PT. This finding was recapitulated by stimulation with Mes-cultured supernatant (Mes-sup). Moreover, Mes-sup stimulation increased M1/M2 in wild-type BMDM, but such effect was blunted in BMDM obtained from MyM8KO. In BMDM stimulated with Mes-sup, deletion of MRP8 resulted in less stress fiber formation. FCM revealed that MyM8KO-ZsG NTN mice exhibited less ICAM-1 expression in both peripheral blood monocytes and glomerular-infiltrated MΦ.

Conclusions: These results indicate that myeloid-lineage cell-derived MRP8 could potentially contribute to glomerular injury upon NTN through intraglomerular cell-cell crosstalk, affecting MΦ characterization.

SA-PO618

A Modified Peptide Derived from Goodpasture Autoantigen Arrested and Attenuated Kidney Injuries in Experimental Anti-GBM Glomerulonephritis

Yue Shi. *Peking University First Hospital, Beijing, China.*

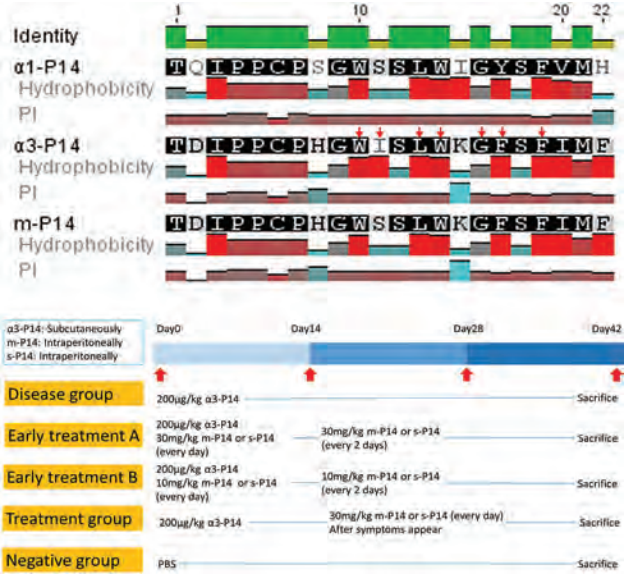
Background: P14 ($\alpha3_{127\text{-}148}$) was a nephritogenic epitope on human α3(IV)NC1, inducing EAG with its core motif $W_{136}I_{137}L_{139}W_{140}G_{142}F_{143}F_{145}$. Based on the sequences of α1-P14 and α3-P14, a modified peptide (m-P14) was designed by the substitution of $\alpha3\text{-}I_{137}$ to $\alpha1\text{-}S_{137}$.

Methods: m-P14 was injected into P14-immunized WKY rats either on immunization or upon disease onset. PAS staining, ELISA, Flow cytometry, ELISpot were also applied in this study.

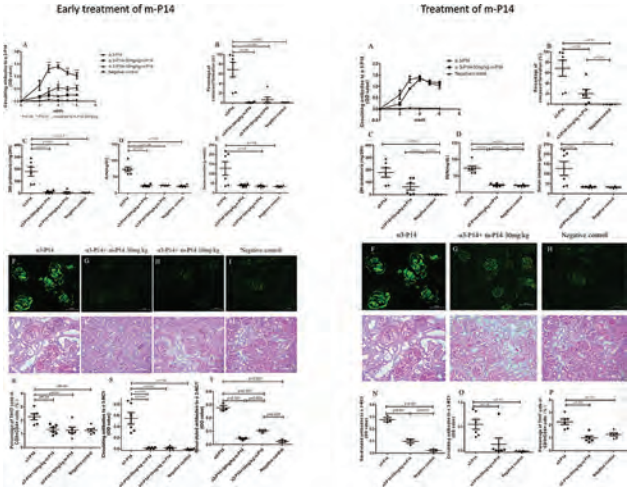
Results: m-P14 intervention attenuated the α3-P14 induced anti-GBM disease in early-treatment groups and treatment group with decreased crescent formation(30mg/kg m-P14: 0.5±0.4 *vs.* 68.8±15.4 %; *P*=0.002; 10mg/kg m-P14: 6.3±5.6 *vs.* 68.8±15.4%, *P*=0.009; treatment: 20.1±8.4 *vs.* 68.8±15.4%, *P*=0.026). m-P14 could inhibited the binding of α3-P14 to MHC molecules and abated the forming of splenic Th17 in

intervention groups. m-P14 also inhibited the binding between α3-P14 to antibodies and impeded intra-molecular epitope spreading.

Conclusions: m-P14 could arrest and attenuate the kidney injuries of anti-GBM disease in rat model through cellular and humoral immunity regulation. This approach confirmed the feasibility of modulating T cell activation for the treatments of Goodpasture's disease.

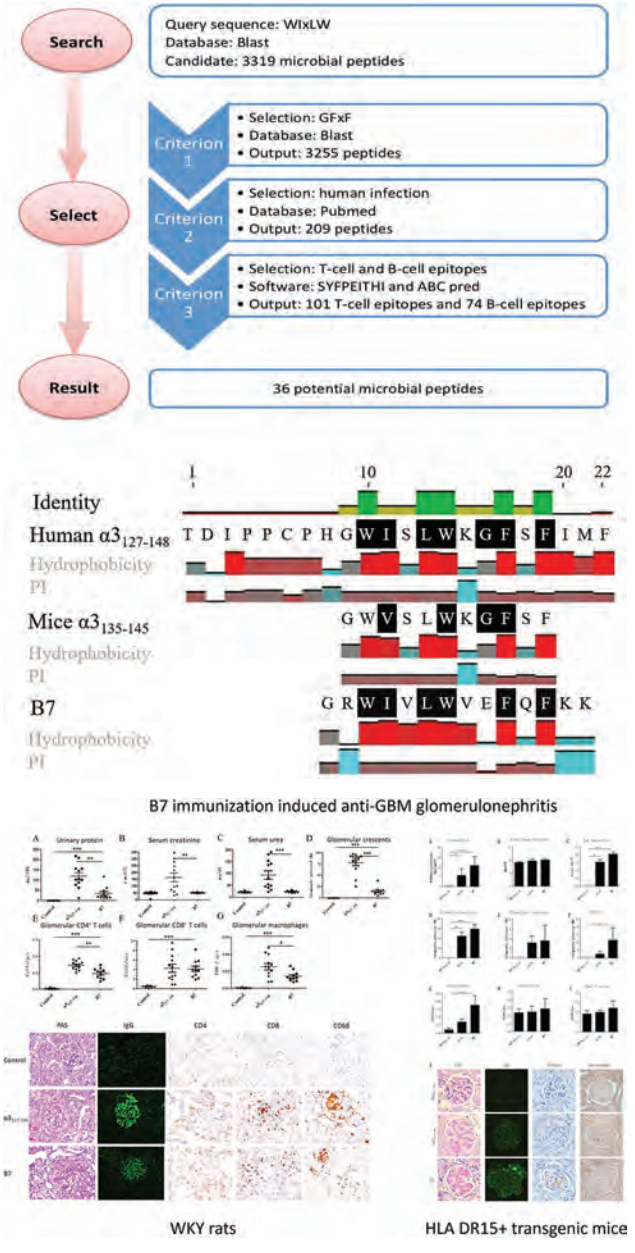


The design of m-P14 and the flowcharts of m-P14 intervention in experimental anti-GBM disease.



Early-treatment and treatment of m-P14 in experimental anti-GBM glomerulonephritis.

HLA-DR15 transgenic mice. These results indicate that infections may initiate anti-GBM disease through molecular mimicry.



SA-PO619

Experimental Anti-Glomerular Basement Membrane Glomerulonephritis Induced by a Peptide from Actinomyces

Yue Shi. *Peking University First Hospital, Beijing, China.*

Background: P14 ($\alpha3_{127}$-$_{148}$) was a nephritogenic epitope for anti-GBM disease, with its core motif $W_{136}I_{137}L_{139}W_{140}G_{142}F_{143}F_{145}$. Infections has been suspected as the "second hit" for the onset of anti-GBM disease. We aimed to search for mimicking microbial peptides that may participate in anti-GBM disease.

Methods: Blast, SYFPEITHI, ABCpred were used for searching P14-mimic microbial peptides. WKY rats and HLA-DR15$^+$ transgenic mice were immunized with peptide B7. IHC staining, ELISA and ELISpot were applied.

Results: Peptide B7 derived from actinomyces was screened from 3319 microbial peptide under the criteria of containing the critical motif of P14, related with human infection, included both T cell and B cell epitope and high recognition for sera of anti-GBM patients. All B7-immunized rats exhibited linear deposits of IgG on the GBM. The percentage of crescent formation in glomeruli was 14.6±2.7%. For HLA-DR15$^+$ transgenic mice, all mice immunized with B7 exhibited linear IgG deposits along the GBM and focal glomerular necrosis, two of them (28.6%) developed glomerular crescent formation. B7 also had cross-reaction with $\alpha3_{135-145}$ immunized rat splenocytes on T cell level for WKY rats model.

Conclusions: We found one microbial peptide derived from actinomyces could induce crescentic anti-GBM glomerulonephritis in both WKY rats and humanized

Human Hypoxic Proximal Tubule Epithelial Cells (PTECs) Trigger NLRP3 Inflammasome Activation in CD1c$^+$ Dendritic Cells (DC)

Helen G. Healy,[1,2] Kurt T. Giuliani,[1,2] Xiangju Wang,[1] Josephine M. Forbes,[3] Andrew J. Kassianos.[1,2] *[1]Conjoint Kidney Research Laboratory, Pathology Queensland/RBWH, Brisbane, QLD, Australia; [2]Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; [3]Mater Research Institute, University of Queensland, Brisbane, QLD, Australia.*

Background: Chronic kidney disease (CKD) is characterised by inflammation and tubulointerstitial fibrosis. Hypoxia is a key driver of this pathology. Kidney proximal tubule epithelial cells (PTEC) are particularly susceptible to oxygen imbalances due to their high rates of aerobic respiration. We have reported activated CD1c$^+$ dendritic cells (DC) adjacent to PTEC in fibrotic kidney tissue, where they are well positioned to sense PTEC-derived danger signals via the NLRP3 inflammasome. In this study, we examined the hypoxic response in human PTEC and their functional role in CD1c$^+$ DC activation.

Methods: Primary human PTEC were cultured under normoxia (21% O_2) or hypoxia (1% O_2) and assessed for mitochondrial function, proliferation and viability. PTEC-CD1c$^+$ DC interactions were examined by *in vitro* co-culture in the absence or presence of NLRP3 inflammasome inhibitor MCC950. DC activation was assessed by mRNA profiling and cytokine secretion. *In vivo* cellular interactions in fibrotic kidney tissue were examined by immunofluorescence microscopy.

Results: Hypoxic PTEC displayed significant mitochondrial dysfunction, significantly reduced proliferation and significantly increased cell death compared to normoxic PTEC. $CD1c^+$ DC matured in the presence of hypoxic PTEC showed increased NLRP3 mRNA expression and secreted significantly elevated levels of inflammasome-related cytokines (IL-1β, IL-18). Notably, this pro-inflammatory response was significantly reduced in the presence of the NLRP3 inflammasome inhibitor, MCC950. Immunofluorescence staining of fibrotic kidney tissue identified PTEC co-localized with $CD1c^+$ DC expressing downstream signalling markers of NLRP3 inflammasome activation (active Caspase-1).

Conclusions: Our data demonstrate that hypoxic PTEC trigger and activate $CD1c^+$ DC via the NLRP3 inflammasome, resulting in the secretion of pro-inflammatory cytokines. Future studies will examine the putative role of mitochondrial danger signals generated by hypoxic PTEC for therapeutic targeting in human CKD.

HIV-Induced Podocyte Pyroptosis Contributes to Proliferation of Parietal Epithelial Cells

Harsha Adnani,[2] Vinod Kumar,[2] Himanshu Vashistha,[3] Kamesh R. Ayasolla,[4] Xiqian Lan,[4] Maleeha Qayyum,[6] Sushma Chinnapaka,[6] Ashwani Malhotra,[5] Karl Skorecki,[7] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Medicine, Feinstein Institute of Research, Manhasset, NY; [3]Ochsner Health System, New Orleans, LA; [4]Feinstein Institute for Medical Research, Manhasset, NY; [5]Feinstein Institute Medical Research and NSLIJ, Manhasset, NY; [6]Northwell health, Hicksville, NY; [7]Rambam Health Care Campus, Haifa, Israel.*

Background: The lack of or abundance of proliferating parietal epithelial cells (PECs) in Bowman's space determines the glomerular phenotype in focal segmental glomerulosclerosis. Proliferating PECs in Bowman's space characterize the HIV-associated nephropathy. The involved mechanism of PECs proliferation in HIV milieu is not understood. Interleukin (IL)-1 β has been reported to stimulate PECs proliferation. We have recently demonstrated that HIV infection stimulates the generation of IL-1β by podocytes. We hypothesize that massive injury of HIV-infected podocytes would stimulate PECs proliferation.

Methods: Immortalized human podocytes were differentiated and transduced with either vector (V-PDs) or HIV (NL4-3, HIV-PDs) and evaluated for pyroptosis (morphologic assay). V-PDs and HIV-PDs were incubated in serum-free media for 24 hours. Incubation (conditioned, C) media was collected and stored at -80°C. PECs were incubated in serum-free media containing 10% of control (V-PDs), and experimental (HIV-PDs) conditioned media for 48 hours. In another set of experiments, PECs were incubated in serum-free media containing 10% control and experimental media with or without IL-1β (neutralizing) antibodies for 48 hours. Cells were evaluated for proliferation by MTT cell viability assay. To establish an interaction, PECs were grown in outer wells, and V-PDs/HIV-PDs were seeded into inner wells (Trans-well plates). After 48 hours,-PDs were assayed for IL-1β by ELISA. Additionally, PECs grown on coverslips were treated with 10% control and experimental media for 48 hours, followed by immunolabeling for either PCNA or Ki67.

Results: HIV-PDs showed a higher percentage of pyroptosed cells ($P<0.01$ vs. V-PDs). Cellular lysates and incubation media of HIV-PDs showed increased ($P<0.05$ vs.V-PDs) generation of IL-1β. Conditioned media of HIV-PDs stimulated PECs proliferation; however, anti-IL-1β antibody partially inhibited HIV-PDs conditioned media-mediated proliferation. PECs growing in outer wells of trans-well plates containing HIV-PDs showed increased proliferation. PECs treated with HIV-PDs conditioned media showed a higher percentage ($P<0.01$ vs. V-PDs) of PCNA/Ki67 +ve cells.

Conclusions: HIV-induced podocyte pyroptosis contributes to PECs proliferation.

Glomerular Gene Coexpression Networks Suggest Pathogenic Mechanisms in a Mouse Model of HIV-Associated Nephropathy

Agustin Gonzalez-Vicente,[3] Zhenzhen Wu,[3] Viji Nair,[1] Laura Barisoni,[2] Matthias Kretzler,[1] Leslie A. Bruggeman,[3,4] John R. Sedor,[3,4] John F. O'Toole.[3,4] *[1]University of Michigan, Ann Arbor, MI; [2]Duke University, Durham, NC; [3]Cleveland Clinic, Cleveland, OH; [4]Case Western Reserve University, Cleveland, OH.*

Background: HIV-associated nephropathy (HIVAN) is an important cause of renal failure in African-Americans. The Tg26-transgenic mouse replicates key features of HIVAN including podocyte dedifferentiation. We hypothesize that glomerular gene coexpression networks from Tg26 mice will provide insights into HIVAN pathogenesis.

Methods: Glomerular-transcriptomes were obtained from 6-week old wild-type and Tg26-HIVAN4 mice of both sexes. Preliminary analysis demonstrated a strong sex effect on gene expression. In order to control the covariate sex, two networks were generated using weighted gene-correlation network analysis (WGCNA): 1) all mice sex-adjusted, 2) Consensus network between unadjusted gene expression form female and male mice. Coexpression modules significantly correlated with HIV-transgenes in both analysis were compared, identifying overlapping gene lists. These lists were evaluated for canonical pathway enrichment with IPA.

Results: 1113 overlapping genes were found between 2 consensus and 5 sex-adjusted modules significantly correlated with HIV transgenes. Intersecting genes were pooled into 4 functional groups based on pathways enrichment. The first group represented the initial response to HIV transgenes with pathways leading to the activation of macrophages and secretion of chemoattractant molecules. The second group represented the migration of immune cells to the "infection" site and the activation of the inflammasome. The third group was enriched with integrin signaling pathways. As integrin interactions are widely used by migrating immune cells, this group likely supports the immune response on groups 1 and 2. Finally, the fourth functional group was largely enriched with cell cycle pathways, reflecting that in collapsing forms of focal segmental glomerulosclerosis such as HIVAN, differentiated glomerular cells are recruited back into the cell cycle.

Conclusions: Gene-coexpression network analysis detected modules matching the chain of events in the progression of HIVAN in the Tg26-HIVAN4 mice. We also identified sex as a strong driver of gene expression. However, this sex effect did not impact disease pathways in Tg26-HIVAN4 mice, but could be relevant in understanding sexual dimorphism in other kidney diseases.

APOL1 and JAK1/2 Are Required for Interferon Gamma-Stimulated Inflammatory Responses in Human Kidney Cells

Hongyu Zhang,[1] Matt G. Sampson,[1] V. Vega-Warner,[1] Wenjun Ju,[1] Frank C. Brosius.[2,1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Arizona, Tucson, AZ.*

Background: Chronic inflammation contributes to progression of glomerular diseases including diabetic kidney disease (DKD). Recent data suggest that APOL1 and JAK1/2 signaling contribute to the pro-inflammatory milieu in FSGS and DKD, respectively. Based on systems genetic and transcriptomic analyses of humans and of murine models of glomerular diseases, the expression of CXCL9, a T-cell chemoattractant belonging to the CXC chemokine family, is increased by APOL1 high risk genotype expression in FSGS and by JAK2 overexpression in diabetic podocytes. We therefore determined whether and how APOL1 and JAK signaling interact to stimulate CXCL9 in a human kidney cell.

Methods: Human kidney 2 (HK-2) cell monolayers were grown to confluence and treated with interferon gamma (IFNg) (30ng/ml), interleukin-6 (10ng/ml), or tumor necrosis factor-alpha (10ng/ml) from 30 min to 48 hr. Levels of JAK2, APOL1 and CXCL9 mRNAs were determined in response to agonists. Inhibition of JAK1 and JAK2, with baricitinib (500nM) or siRNA knockdown of APOL1 expression was performed in some experiments befpre IFNg exposure. Effects of APOL1 knockdown on IFNg-stimulated gene expression were examined. These genes were identified by transcriptomic analysis of IFNg-treated podocytes.

Results: HK-2 cells express APOL1, JAK2 and CXCL9. Stimulation of HK-2 cell monolayers with IFNg, but not IL-6 or TNF, resulted in a rapid and sustained 4-50-fold increase in mRNA expression of JAK2, APOL1 and CXCL9. These increases were largely abrogated by pretreatment with the JAK1/2 inhibitor as were IFNg-induced increases in STAT3 phosphorylation and APOL1 protein levels. APOL1 knockdown resulted in an 80% reduction in CXCL9 expression and a 40-50% reduction in interferon-induced guanylate-binding protein 2, HLA class II histocompatibility antigen, DR alpha chain and ubiquitin D. Expression of other IFNg-stimulated genes was not consistently affected by APOL1 knockdown.

Conclusions: In cultured human kidney cells, IFNg triggered responses in kidney cells resulting in increased expression of pro-inflammatory mediators and APOL1. This cascade was largely abrogated by specific inhibition of JAK1/2 signaling and selectively inhibited by knockdown of APOL1. These findings suggest that APOL1 plays an important role in the IFNg-mediated inflammatory response in kidney cells.

Lipoxins Promote Tissue Repair And Regeneration

Darrell C. Andrews,[1] Monica de Gaetano,[1] Eoin P. Brennan,[1] Catherine Godson.[2] *[1]University College Dublin, Dublin, Ireland; [2]The Conway Institute of Biomolecular and Biomedical, Belfield, Dublin, Ireland.*

Background: Inflammation and its timely resolution is essential in maintaining tissue homeostasis during injury and infection. Chronic low-grade inflammation contributes to the pathogenesis of CKD and failure to resolve this leads to impaired tissue repair. Conventional therapeutics such as steroids and non–steroidal anti-inflammatory drugs target the key drivers of the inflammation to dampen the inflammatory response but fail promote inflammation resolution or tissue repair. The resolution phase of inflammation is dynamically regulated by endogenously generated mediators including bioactive lipids such as lipoxins and deficits in these mediator networks may underlie chronic inflammation. We have previously demonstrated reno-protection by lipoxins in experimental models of acute and chronic renal injury (Brennan et al, JASN 2018). Now we wish to explore the therapeutic potential of lipoxins to promote tissue repair and regeneration.

Methods: To investigate the potential of lipoxins to promote tissue repair and regeneration the median tail fin of wild-type 3dpf zebrafish larvae was transected. 4 hours post-injury larvae were treated with LXA4 or vehicle and tissue regeneration tracked by time lapse imaging over 48 hours. The effect of lipoxins on the activation and recruitment of PMNs during tail fin injury was monitored using fluorescent imaging in the transgenic zebrafish lines Tg(mpx:EGFP) and Tg(MPEG1:mCherry). The effect of lipoxins on macrophage subsets was further investigated in human THP-1 derived macrophages treated with TNFα.

Results: Treatment with LXA4 significantly enhanced tail fin regeneration and promoted the resolution of inflammation in the zebrafish model. Furthermore, in THP-1 derived macrophages LXA4 treatment significantly reduced TNF induced inflammation, reprogramming macrophages towards a pro-resolution phenotype as evidenced by up-regulation of IL-4 and MRC1.

Conclusions: These findings suggest that lipoxins promote tissue repair and regeneration by reprogramming macrophages towards a pro-resolution phenotype and may have therapeutic potential for the treatment of chronic inflammation associated with diseases such as CKD.

Mitochondrial Damage in Tubule Cells Activates the cGAS-STING Innate Immune Pathway and Leads to Fibrosis

Poonam Dhillon,[1,2] Kiwung Chung,[1,2] Shizheng Huang,[1,2] Xin Sheng,[1,2] Rojesh Shrestha,[1,2] Chengxiang Qiu,[1,2] Jihwan Park,[1,2] Matthew Palmer,[3] Katalin Susztak.[1,2] Susztak's Lab *[1]Renal-Electrolyte and Hypertension Division, Department of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Institute for Diabetes, Obesity, and Metabolism, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [3]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA.*

Background: Mitochondrial damage, defective bioenergetics, and immune system activation play key role in chronic kidney disease (CKD) and fibrosis. As the mitochondria retained ancient circular bacterial DNA, we hypothesized that the mitochondrial defects observed in kidney fibrosis lead to cytoplasmic leakage of the mitochondrial DNA and then recognized by the intracellular bacterial DNA recognition pathway; cGAS-STING signaling cascade resulting in activation of inflammatory pathways and CKD.

Methods: Here, we analyzed gene expression data by RNA sequencing of 433 microdissected human kidney tissue samples with varying degree of kidney fibrosis and kidney function. To model mitochondrial damage, we generated mice with tubule-specific mitochondrial transcription factor (*Tfam)* deletion (Ksp-Cre/Tfam$^{f/f}$). To explore the role of STING we crossed these mice with STING knock-out mice and treated with STING inhibitor. To understand the therapeutic potential of STING inhibition in CKD, we examined the renal phenotype of the STING knock-out mice following folic acid (FA) induced kidney injury and treated mice with a STING inhibitor.

Results: We found that expression of mitochondrial genes and its transcriptional regulator TFAM was significantly decreased in patients and mouse models with kidney disease. *Ksp-Cre/Tfam $^{f/f}$* developed severe mitochondrial loss and decline of ATP content by 6 weeks of age. Progressive azotemia, kidney fibrosis and death of the animals was only observed after 12 weeks of age. Mechanistic studies demonstrated that aberrant mtDNA packaging upon TFAM deficiency in tubule cells resulted in escape of mtDNA into the cytosol, activation of the cytosolic DNA sensing pathway, STING, resulting in cytokine expression and immune cell recruitment. Genetic deletion or pharmacological inhibition of STING ameliorated TFAM-loss induced kidney fibrosis. Genetic deletion of STING and to lesser degree the STING inhibitor ameliorated kidney fibrosis in the FA induced model of kidney disease.

Conclusions: We concluded that in addition to its essential role in metabolism, TFAM sequesters mtDNA to prevent the activation of innate immune pathways and fibrosis. Cytosolic aberrant DNA in CKD activates the cGAS-STING pathway. Limiting STING activity can ameliorates kidney disease development.

Decreased Monocyte Costimulatory Molecule CD86 Expression in Focal Segmental Glomerulosclerosis Predicts Early Relapse Following Rituximab Therapy

Chang-Yien Chan,[1] Sharon Teo,[3] Isaac Liu,[1] Kong Peng Lam,[2] Kar Hui Ng,[1] Hui Kim Yap.[1] *[1]National University of Singapore, Singapore, Singapore; [2]Bioprocessing Technology Institute, A*STAR, Singapore, Singapore; [3]KTP-NUCMI, NUHS, Singapore, Singapore.*

Background: We recently reported a subgroup of focal segmental glomerulosclerosis (FSGS) patients bearing an immunological signature of T-cell hyporesponsiveness who responded to rituximab treatment. This study aimed to characterize the immunological subsets in FSGS patients who responded to treatment in order to predict early relapse within the first year following rituximab therapy.

Methods: A total of 29 FSGS patients (median age 14.7 years, range 6.1-25.0 years) receiving rituximab were recruited in this study. Rituximab was administered to patients at a dose of 375 mg/m^2 fortnightly to a maximum of 4 doses, and followed up longitudinally. Immunological subsets were monitored at baseline, and 6 months post-rituximab. Statistical analyses was done using Mann-Whitney U test and Wilcoxon signed rank test for paired analysis prior and 6-months post-rituximab. Receiver-operating characteristic (ROC) curve analysis was used to determine predictive utility of the subset for early relapse.

Results: 51.7% (15/29) responded to rituximab therapy with characteristic significant downregulation of IFNγ (P<0.01) following PMA/ionomycin stimulation. Of the 15 FSGS patients who responded to treatment, 60% (9/15) had no relapses within the first year post-rituximab (Group I), while 40% (6/15) relapsed (Group II) with comparable median B-cell recovery of 6.0 months and 5.0 months respectively (P=0.41). Patients in Group II had significant lower percent CD86 (75.5±7.0%) on monocytes compared with Group I (91.8±2.5%) (P=0.03). ROC analysis showed that monocyte expression of CD86 (AUC 0.88, 95% CI 0.67-1.00) fared well as a good predictor for relapse (sensitivity 80.0%, specificity 87.5%, PPV 80.0%, NPV 87.5%, with discriminatory threshold <90.2%). CD86 expression in Group II was significantly upregulated 6-months post-rituximab treatment (91.6±2.1%), (P=0.04).

Conclusions: We identified a distinct immunological subset of FSGS patients with decreased monocyte CD86 (B7-2) expression at baseline, who are likely to relapse within a year post-rituximab therapy and hence could benefit from early re-treatment with rituximab. CD86 is a receptor which provides costimulatory signal to T-cell activation, deciding between T-cell fate of immunity or anergy. The role of monocytes in FSGS however remains to be elucidated.

SA-PO627

Differential Roles of RAGE Species for Renal Tubular Damages

Taro Miyagawa,[1] Yasunori Iwata,[1] Hisayuki Ogura,[1] Koichi Sato,[1] Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[1] Norihiko Sakai,[1] Miho Shimizu,[1] Kengo Furuichi,[2] Yasuhiko Yamamoto,[3] Takashi Wada.[1] *[1]Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan; [2]Kanazawa Medical University, Kahoku-Gun, Japan; [3]Kanazawa University Graduate School of Medical Sciences, Kanazawa, Japan.*

Background: Receptor for advanced glycation end-products (receptor for AGEs, RAGE) is a transmembrane and multiligand pattern recognition receptor, which binds AGEs, S100 proteins, and high mobility group box 1 protein (HMGB1), eliciting inflammatory signal transductions. Soluble and decoy forms of RAGE (sRAGE) are, otherwise, generated by a cleavage of RAGE or by an alternative splicing, which forms an endogenous secretary RAGE (esRAGE). However, roles of sRAGE in the pathogenesis of kidney diseases remains unclear. We here examined whether RAGE and sRAGE could be implicated in renal tubular damages using a mouse kidney ischemia/reperfusion (I/R) model.

Methods: Unilateral renal I/R was introduced in RAGE knockout (*Ager$^{-/-}$*) mice with or without administration of sRAGE. Tubular damages, interstitial cell accumulation and fibrosis were assessed at day 2 or 7. We also assessed tubular damages using anti-glomerular basement membrane nephritis models with or without sRAGE treatment at day 7. We checked the expression of genes coding RAGE, esRAGE and proinflammatory mediators after hypoxia using murine renal proximal tubular epithelial (mProx24) cells. Cellular damages and proliferation were also assessed in hypoxia-induced mProx24 cells with or without an sRAGE addition.

Results: We found that tubular damages were severer in *Ager$^{-/-}$* mice than in *Ager$^{+/+}$* mice at day 2 and 7 after I/R. Kidney fibrosis and macrophage infiltration were also exaggerated in *Ager$^{-/-}$* mice at day7. In vitro, hypoxia-exposure decreased the expression of genes coding RAGE and esRAGE in mProx24 cells, while *Hmgb1* and *Tnfa* mRNAs were paradoxically upregulated. However, an sRAGE addition significantly decreased *Hmgb1* and *Tnfa* mRNA expressions and induced the proliferation in hypoxia-induced mProx24 cells. Moreover, an sRAGE administration protected from tubular damages of I/R-performed mice and of the anti-GBM glomerulonephritis models.

Conclusions: We demonstrated that the hypoxic condition could induce the downregulation of genes coding RAGE and esRAGE in renal tubular cells. Administration of sRAGE could protect the kidney from I/R injury.

Detection and Characterization of Prolonged Classical Pathway Convertase Activity: C4 Nephritic Factor and a Non-Autoantibody Serum Factor

Marloes Michels,[1] Nicole Van De Kar,[1] Marcin Okroj,[4] Anna Blom,[3] Sanne van Kraaij,[2] Lambertus P. Van den heuvel,[1,2] Elena Volokhina.[1,2] on behalf of the COMBAT consortium *[1]Pediatric Nephrology, Amalia Children's Hospital, Radboud university medical center, Nijmegen, Netherlands; [2]Laboratory Medicine, Radboud university medical center, Nijmegen, Netherlands; [3]Medical Protein Chemistry, Translational Medicine, Lund University, Malmö, Sweden; [4]Medical Biotechnology, Intercollegiate Faculty of Biotechnology, Medical University of Gdansk, Gdansk, Poland.*

Background: C3 glomerulopathy (C3G) is a renal disease caused by overactivity of the complement system, particularly of the alternative pathway (AP). Autoantibodies such as C3 nephritic factors (C3NeFs) or mutations in complement genes are commonly found as pathogenic causes. Recent findings also reveal the presence of C4 nephritic factors (C4NeFs) in some C3G cases. By stabilizing the convertases of the classical pathway (CP), these autoantibodies contribute to the complement dysregulation in C3G. In this study, we investigated C4NeF activity in a cohort of patients with complement-mediated renal diseases.

Methods: We used a recently described hemolytic method to measure convertase activity directly in serum, using a C5-blocker to separate the CP into 2 steps: a time-variable first step for convertase formation out of test serum and a standardized second step for hemolysis readout.

Results: Serum samples of 17 healthy controls and 47 patients with (suspected) C3G and closely related complement-mediated disorders were analyzed. Convertase activity levels in controls consistently returned to background levels after 10 min. In contrast, convertase activity was significantly prolonged until 20 min in 2/47 (4%) patients (P1 and P2), indicating the presence of CP convertase-stabilizing factors. Addition of purified Igs from P1 to control serum supported prolonged convertase activity, confirming the autoantibody nature of the stabilizing factor. Previously, the Igs of this patient were also shown to have AP convertase-stabilizing activity, i.e. C3NeF activity. Further investigation showed that both the C3NeF and C4NeF activity resided in the Ig fractions of the kappa light chain type. In addition, both the AP and CP convertase-stabilizing activities remained present over the disease course of the patient. In contrast to P1, the Igs of P2 did not support convertase stabilization when added to control serum, indicating a non-autoantibody factor caused the increased convertase half-life. The nature of this factor, possibly genetic, is currently under investigation.

Conclusions: This study offers new opportunities for the detection and characterization of (previously unrecognized) CP convertase-dysregulating factors in patients with complement-mediated renal diseases.

SA-PO629

Trending Complement C3 in C3 Glomerulopathy Patients Before and After Renal Transplant

Monica D. Hall,[2] Nicolò Ghiringhelli Borsa,[2] Amanda O. Taylor,[1] Bertha Martin,[1] Renee X. Goodfellow,[2] Jill J. Hauer,[2] Amy E. Weaver,[2] Yuzhou Zhang,[2] Richard J. Smith,[2] Carla M. Nester.[2] *[1]Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; [2]University of Iowa, Iowa, IA.*

Background: C3 Glomerulopathy (C3G) is characterized by dysregulation of the alternative pathway of complement. Most patients will approach ESRD within 10 years of diagnosis. Recurrence in renal transplants is as high as 84%. Little is known about the natural history of transplant recurrence or predictors of poor renal outcome. The degree of C3 consumption (represented by a low C3) has been postulated as a predictor of disease activity in the setting of native kidney disease. Whether C3 abnormality plays a similar role in the transplant setting is unknown. Similarly, the predictive value of other complement biomarkers is unknown.

Methods: We studied a sub-cohort of the University of Iowa's C3G Natural History Study. All patients met biopsy criteria for C3G. Reviewed patients had at least 3 pre-transplant and 3 post-transplant C3 values. Using our standard assays, we tested all patients in the cohort for complement gene abnormalities and for longitudinal nephritic factor trend. Phenotypic results were correlated with recurrence of C3G in a renal allograft.

Results: Average age at diagnosis was 24 years. Average time to ESRD was 2 years. Drivers of disease included nephritic factors (NF, n=5), gene mutations (n=2), and a monoclonal protein (n=1). Median follow-up time post-transplant was 5 years. At transplantation, 6 patients had a low C3 level. In the five patients with a NF at the time of transplant, the NF remained positive at follow-up. Disease recurrence was noted in 2 patients (both within the first year of transplant). One was positive for a nephritic factor, one has a C3 mutation. One patient had histologic recurrence. This patient was both nephritic factor negative and with normal genetics. All patients with recurrence had a low C3 at the time of recurrence. All nonrecurring patients have a normal C3.

Conclusions: Considering this preliminary data, having a low C3 appears to predict risk for C3G recurrence. It remains unclear what role a persistent nephritic factor titer may have. Our data suggest the impact of this titer may change over time. We have extended the collection of the clinical parameters and the complement biomarker evaluation for each subject in this cohort - with the express goal of creating a predictive model for C3G recurrence.

Risk Factors for Biopsy Complications in Initial vs. Subsequent Biopsies in Native and Transplant Kidneys

Björn Peters,[1,2] Salar abbas Maitlo,[1] Henrik Hadimeri.[1] *[1]Nephrology, Skaraborg Hospital, Skövde, Sweden; [2]Public Health and Clinical Medicine, Umeå University, Umeå, Sweden.*

Background: There are few studies about risk factors for complications in initial (ib) versus subsequent (sb) biopsies. Biopsy complications are divided in major (require an intervention) and minor (resolve without intervention). The aim of the study was to explore the risk factors for complications in ib versus sb in native (nkb) and transplant kidney biopsies (tkb) which may serve as predictors for biopsy complications.

Methods: In a multi-center study, 2830 nkb (4.3% sb) were analyzed for major and 667 tkb (29% sb) for major and minor complications. No death or nephrectomy was described. Fisher's exact, t-test (mean values) and $\chi 2$ test were used. A two sided p-value <0.05 was considered significant.

Results: In nkb, the frequency for major biopsy complications was 5.6% in ib and 4.9% in sb. In tkb, the biopsy complication frequency was 4% major and 2.3% minor in ib; in sb 3.5% major and 3.5% minor. In initial nkb, the frequency of major complications were higher in women compared to men (7.1% vs 4.6%;Odds Ratio 1.6, Confidence Interval 1.1-2.2), in younger patients (50 vs 54years, p=0.007) and in patients with lower weight (78 vs 82kg, p=0.005). In subsequent nkb, patients with major complications had a higher systolic blood pressure (145 vs 132mmHg, p=0.03). In initial tkb, biopsies with major complications had less glomeruli in the biopsy (17 vs 24, p=0.046) and biopsies with minor complications were from younger patients (42.5 vs 52years, p=0.027) and patients with lower BMI (22 vs 26, p=0.049). Risk factors for overall complications in initial txb were younger age (46 vs 52years, p=0.028) and less glomeruli in the biopsies (18 vs 24, p=0.04). In subsequent tkb, patients with major complications had a higher systolic (151 vs 136mmHg, p=0.03) and diastolic blood pressure (93 vs 79mmHg, p=0.003). For minor and overall complications in subsequent nkb, no risk factors were found. In nkb, in sb there was a higher number of SLE-nephritis (12% vs 4.6%, p=0.001), a lower number of nephrosclerosis (4.3% vs 10.3%, p=0.02) and diabetic nephropathy (3.4% vs 9.3%, p=0.02) compared to ib; in tkb no differences were found.

Conclusions: The different types of risk factors for biopsy complications in initial versus subsequent biopsies in native and transplant kidneys could be important for the clinicians to improve patients' safety.

Infection-Related Glomerulonephritis and Analysis of Clinical Outcomes: Experience in South India

Sree B. Raju. *Shiloh House, Hyderabad, India.*

Background: There has been a major shift in the causative agents, clinical presentation, epidemiology and the treatment outcomes of IRGN in the developing nations.

Methods: A retrospective analysis of 100 IRGN consecutive cases were studied from our hospital records. percutaneous renal biopsy was done in all the patients and the tissue has been processed for LM IF and EM after appropriate staining for clinical and pathological characteristics

Results: A retrospective analysis of 100 IRGN consecutive cases were studied from our hospital records. percutaneous renal biopsy was done in all the patients and the tissue has been processed for light microscopy, immunofluorescence and electron microscopy after appropriate staining for clinical and pathological characteristics Results: A total of 73 patients were analyzed after exclusion. The mean age of the presentation was 41.89±14.58 years. 51% were males. Common infection sources were UTI (33%) and foot ulcer (33%). Most common clinical presentations were shortness of breath (45%), Anasarca (38%) and fever (36%). All the patients had micro hematuria (100%). The mean creatinine at presentation was 3.37± 2.47 mg/dl with an average proteinuria of 2.43 ± 1.28 g/24hr. 94% had low C3, 8% had low C4,8 % had low C3+C4.55% c4d negative out of c4d negative, 38% are c3 codominant and 63% are c3 dominant. Mean serum creatinine at presentation 4.1±2.6 and 3.3±2.5 (p value:0.8). Proteinuria between two groups was statistically significant. On light microscopy, the most common histological pattern of injury is endocapillary proliferation with neutrophil in mesangial tufts. Immunofluoresence pattern revealed immunoglobulin and C3 dominant staining commonly. Mean GBM thickness was seen in 358.95±99.2. Diffuse effacement was seen in 13 patients, focal effacement was seen in 27 patients. 23% patients needed hemodialysis and 8% needed plasmapheresis at presentation. 20% patients needed immunosuppression. At the end of 12months, 35% patients had persistent hypertension and 30% patients had persistent renal dysfunction. Persistent proteinuria was noted in 17 % of patients and persistent hematuria was seen in 30 % of patients at 1 year follow up. Spot PCR and creatinine between C4d negative C3 dominant and codominant groups was not significant at 1 year.

Conclusions: Male sex, age>40 years, creatinine>5 mg/dl, dialysis requirement at presentation were independently associated with poor renal outcomes.

SA-PO632

Success and Safety of Native Kidney Biopsies Guided and Performed by Nephrologists

Jith Palacherla, W. Charles O'Neill. *Emory University, Atlanta, GA.*

Background: Percutaneous kidney biopsy is a key procedure in nephrology and a requirement for training, but is often not performed by nephrologists, even in training programs. The reasons are manifold but include concerns about competence and safety, particularly the perceived need for real-time ultrasound guidance. To address this, we examined the outcomes of ultrasound-guided biopsies performed in their entirety by nephrologists at this institution.

Methods: All native kidney biopsies performed by the Renal Division at Emory University Hospital for clinical indications from 1/1/2008 to 9/30/2018 were identified from a database of ultrasound studies performed by the Division. Medical records were reviewed to determine clinical characteristics and outcomes. Large hematomas, gross hematuria, hypotension, transfusion, or endovascular intervention were considered clinically important complications.

Results: We identified 422 biopsies that were performed by 70 trainees (1-12 procedures each; median: 5) with the supervision or assistance of 22 faculty (1-105 procedures each; median: 5). Forty three were performed by faculty alone. Patient age was 45.6 + 0.8 (13-84) and body mass index (BMI) 27.2 + 0.3 kg/m^2 (16.2-52.3). All biopsies were performed with a Monopty 18g device with a 1.7 cm sampling length (Bard Peripheral Vascular, Tempe, AZ). In 93%, the kidney was located by ultrasound prior to but not during the biopsy, with an 18.8 cm, 20g needle used to confirm the location and provide deep anesthesia. In 7%, ultrasound was used during the procedure (real-time guidance). Other characteristics of the biopsies were: left kidney 91%; prone position 99%; end-inspiration 51%; end-expiration 44%; depth 5.4 + 0.08 cm (2-11). Tissue was obtained in 98.6% (adequate for diagnosis in 96.9%) with 3.56 +0.07 (1-10) passes and 2.54 + 0.04 (1-5) tissue cores. The BMI was 40 kg/m^2 or greater in 2 of the 6 unsuccessful procedures. Clinically significant complications occurred in 7 patients (1.7%), requiring transfusions in 3 and intervention in 2. These patients did not differ in characteristics or biopsy parameters from those with no complications.

Conclusions: Percutaneous renal biopsies can be performed in their entirety by nephrologists with excellent success and complication rates. Real-time ultrasound guidance is not essential and should not deter nephrologists from performing this important procedure.

The Effect of Intravenous Tranexamic Acid in Percutaneous Renal Biopsy: A Randomized Controlled Trial

Junichi Izawa,[1,2] Keiichi Matsuzaki,[1] Yoshihiko Raita,[3,4] Genta Uehara,[3,5] Norihiro Nishioka,[3,1] Hiroyuki Yano,[3] Ko Sudo,[3] Masato Katsuren,[3,6] Tomohiro Ohigashi,[7,8] Takashi Sozu,[7] Takashi Kawamura,[1] Hitoshi Miyasato.[3] The TRANEPSY Trial Group *[1]Kyoto University, Kyoto, Japan; [2]University of Pittsburgh, Pittsburgh, PA; [3]Okinawa Chubu Hospital, Uruma, Japan; [4]Harvard Medical School, Brookline, MA; [5]Kanto Rosai Hospital, Kawasaki, Japan; [6]Okinawa Hokubu Hospital, Nago, Japan; [7]Tokyo University of Science, Tokyo, Japan; [8]Tsukuba Clinical Research & Development Organization, University of Tsukuba, Tsukuba, Japan.*

Background: Tranexamic acid is an anti-fibrinolytic agent, and the evidence of its benefit for major surgery and trauma has accumulated. We aimed to assess whether intravenous tranexamic acid reduces hematoma sizes after percutaneous renal biopsy.

Methods: We conducted a randomized, triple-blind, placebo-controlled trial at a teaching hospital in Japan between January 2016 and July 2018. We included adult patients who had a clinical indication of percutaneous renal biopsy. High-dose tranexamic acid (500 mg), low-dose tranexamic acid (250 mg) or counterpart saline (placebo) was intravenously injected twice, with bolus just before the biopsy and continuous infusion initiated just after the biopsy. On the morning of the biopsy day, patients were randomly assigned to either of the three groups. The primary outcome was the post-biopsy perirenal hematoma size measured by ultrasound on the next morning of the biopsy. According to the predefined protocol, a closed testing procedure with Wilcoxon rank sum test was used to adjust the multiple comparisons of the tranexamic acid groups (high-dose and low-dose) with the placebo control group. Thus, if the high-dose group was statistically significant against the control group, the low dose group was compared with the placebo group. All analyses were done on an intention-to-treat basis. The trial was registered with UMIN-CTR, number UMIN000019830.

Results: We randomly allocated 56 patients into the three groups: 20 in the high dose group, 19 in the low dose group, and 17 in the placebo group. The median post-biopsy hematoma sizes were 200 mm^2 (IQR 21–650) in the high dose group, 52 mm^2 (0–139) in the low dose group, and 0 mm^2 (0–339) in the placebo group. The results of Wilcoxon rank sum test for the comparison of the high dose group with the placebo group was p=0.047 and that of the low dose group with the placebo group was p=0.80.

Conclusions: High dose tranexamic acid compared to placebo increased perirenal hematoma size after percutaneous renal biopsy. Since the mechanism of increased bleeding in this drug is unknown, we need to confirm the findings in further large randomized controlled trials.

Biofluid MicroRNA Expression Patterns in Three Types of Naturally Occurring Canine Models for Glomerular Disease

Candice P. Chu,[1] Rachel Cianciolo,[2] Jessica Hokamp,[2] George E. Lees,[3] Mary B. Nabity.[1] *[1]Texas A&M University, College Station, TX; [2]The Ohio State University, Columbus, OH; [3]Retired, Lakeland, FL.*

Background: The majority of proteinuric dogs with naturally-occurring chronic kidney disease (CKD) have one of three categories of glomerular diseases: immune complex-mediated (often membranous glomerulopathy [MGN]), glomerulosclerosis (GS), or amyloidosis (AMYL). As in humans, proper treatment of glomerular disease relies on an accurate diagnosis largely based on a renal biopsy and comprehensive pathologic examination. We hypothesized that the expression pattern of biofluid microRNA (miRNAs) would correlate with disease progression and categorization.

Methods: Archived serum and urine samples from 24 dogs, 6 proteinuric dogs from each glomerular disease category (MGN, GS, and AMYL) and 6 clinically healthy dogs were selected. Within each glomerular disease category, equal numbers of non-azotemic and azotemic dogs were included. Circulating and urinary miRNAs were isolated and profiled using small RNA sequencing.

Results: Overall, 38 circulating miRNAs and 16 urinary miRNAs were differentially expressed (DE) in CKD dogs versus controls. When all CKD dogs were combined regardless of glomerular disease category, no circulating DE miRs were identified between azotemic and non-azotemic CKD dogs. However, DE urinary miR-182, miR-21, and miR-486 were identified comparing azotemic dogs versus non-azotemic CKD dogs. Notably, the distinctive expression of urinary miR-126, miR-335, and miR-128 could correctly group azotemic, proteinuric dogs into MGN, GS, or AMYL.

Conclusions: This unique finding supports that urinary miRNAs might help establish a diagnosis in azotemic dogs with suspected glomerular disease. These highly conserved miRNAs are potential non-invasive biomarkers for human patients.

Differentially expressed miRNAs in proteinuric dogs with three types of glomerular disease

SA-PO635

Percutaneous Native Kidney Biopsy in Obese Patients: Feasibility and Histological Findings

Guilherme P. Santa Catharina, Igor Smolentzov, Cristiane B. Dias, Luis Yu, Viktoria Woronik, Roberto Zatz, Lectícia Jorge. *University of Sao Paulo (USP), Sao Paulo, Brazil.*

Background: Body Mass Index (BMI) > 30 kg/m^2 is an independent risk factor for proteinuria and Chronic Kidney Disease. There are few studies on kidney biopsy of obese patients (OP). This study assessed the results of renal biopsies and their complications in this group as compared to nonobese patients (NOP).

Methods: This is a retrospective cohort study of native kidney biopsies performed between January/2009 and December/2018 at a tertiary university center. Clinical and laboratory data were collected at the time of the procedure. Biopsy indication, sample quality, procedural complications and histological diagnoses were analyzed, comparing OP and NOP.

Results: A total of 171 biopsies were performed in OP (mean BMI 33.1±2.8 kg/m^2) and 780 in NOP (mean BMI 23.8±3 kg/m^2). When compared to NOP, we found a higher proportion of women (68% x 60%, p=0.04) and higher age (45±14 x 39±16, p<0.001) in OP. The indications for biopsy did not differ significantly between groups. Although a higher number of OP required more than 3 needle shots (23% x 12%, p=0.0002), the representativeness of samples did not differ between groups: an average of 17±9 glomeruli for light microscopy and 11±8 for immunofluorescence was obtained in OP, compared to 18±9 and 11±8 in NOP (p>0.05). The incidence of complications such as hematuria (6% x 7%), need for arteriography (1% x 2%) and blood transfusion (2% x 3%) was also similar in OP and NOP (p>0.05). The most common histological diagnoses in OP were Lupus Nephritis (LN, n=42, 25%); Focal Segmental Glomerulosclerosis (FSGS, n=33, 19%); Membranous Glomerulopathy (MG, n=20, 12%); Diabetic Nephropathy (n=13, 8%) and IgA Nephropathy (IgAN, n=13, 8%), whereas in NOP LN (n=128, 16%); FSGS (n=79, 10%); MG (n=45, 6%) and IgAN (n=34, 4%) were the main diagnoses.

Conclusions: Kidney biopsy of obese patients is safe, feasible and effective. In our cohort, despite the need for more needle shots, the representativeness of samples and the rate of complications were similar between OP and NOP. Of note, FSGS was not the most frequent histologic finding. A broad spectrum of patterns was observed, implying equally variable therapeutic schemes and reinforcing the appropriateness of performing renal biopsies in this particular group of patients.

SA-PO636

The Impact of Desmopressin on Native Kidney Biopsy Complications

Simon Leclerc,[1,2] Naoual Elftouh,[3] Jean-Philippe Lafrance,[1,2] Annie-Claire Nadeau-Fredette,[1,2] Vincent Pichette,[1,2] Louis-Philippe Laurin.[1,2] *[1]Nephrology Division, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Department of Medicine, Université de Montréal, Montreal, QC, Canada; [3]Hôpital Maisonneuve Rosemont, Montreal, QC, Canada*.

Background: As bleeding is a feared complication of native kidney biopsy (NKB), nephrologists often prescribe desmopressin in an attempt to lower its occurrence, especially for patients with reduced estimated glomerular filtration rate (eGFR) at risk of uremia-related platelet dysfunction. However, only one randomized study has analyzed its effect before NKB on patients with eGFR >60 mL/min/m^2 whereas retrospective studies on patients with eGFR <60 mL/min/m^2 are contradictory.

Methods: This study aims to evaluate the impact of desmopressin on complications after NKB. We reviewed medical records of every adult patient who had a NKB at our tertiary teaching hospital from April 2013 to April 2018. We collected data concerning the medical history of each patient and their clinical parameters before and after each NKB. We used multivariate logistic regressions to evaluate the effect of desmopressin on the occurrence of hemoglobin fall, transfusions, hypotension, acute kidney injury (AKI), hematomas and additional radiologic examinations.

Results: Among the 413 NKB analyzed, 79.4% were done after a dose of desmopressin. Patients who received desmopressin had more severe chronic kidney disease at baseline (eGFR 39 vs 54 mL/min/m^2; p=0.0003) and were more often hospitalized before the biopsy (48% vs 32%; p=0.009). There was a tendency for a reduction in symptomatic hematomas (OR=0.34; 95%CI: 0.11-1.19; p=0.08) and a significant reduction of post-biopsy additional radiologic examinations (OR=0.22; 95%CI: 0.07-0.73; p=0.01) in the desmopressin group. Desmopressin had a neutral effect on other complications (see table) and on hyponatremia.

Conclusions: Our results were affected by an indication bias, because sicker patients were more likely to receive desmopressin and IV fluids causing hemodilution. However, after adjustment for potential cofounders, desmopressin seems to reduce post-biopsy symptomatic hematomas and additional radiologic examinations, implying important clinical and financial benefits.

	OR	CI 95%	p
Hemoglobin fall > 15	1.54	[0.78;3.23]	0.23
Hemoglobin fall > 20	1.29	[0.58;4.36]	0.43

SA-PO637

Proximity of Residence to Silica Mines as a Risk Factor for Anti-Neutrophil Cytoplasmic Antibody-Associated (ANCA) Vasculitis

Kirsten S. Hepburn,[1] Gianna Pastore,[1] Dev K. Jegatheesan,[2] Dwarakanathan Ranganathan.[1] *[1]Nephrology, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia*.

Background: Anti-neutrophil cytoplasmic antibody-associated (ANCA) vasculitis is a rare necrotizing vasculitis affecting small to medium-sized vessels, with renal involvement usually presenting with a rapidly progressive glomerulonephritis. There is evidence to suggest that silica exposure is associated with the development of ANCA vasculitis. The incidence of ANCA vasculitis in Queensland, Australia was 0.47 per 100,000 people/year from 2002 to 2011; and there is a high density of silica mines, with approximately 2 per 1,000,000 population in 2011. The aim of the study was to examine whether residing close to silica mines is associated with development of ANCA vasculitis.

Methods: This retrospective cohort study compared patients with a biopsy-proven diagnosis of ANCA vasculitis and a control cohort of IgA nephropathy (IgAN) from 2009 to 2011. IgAN was selected as there is no known association between silica exposure and its development. A pathology database of renal biopsies was used to identify cases of ANCA vasculitis and IgAN. Age, gender, postcode and suburb of the patient at the time of biopsy were obtained. The distance between the suburb and closest silica mine in Queensland was calculated using Quantum GIS 3.4 software. Distance to silica mines was categorised into ≤50km, 51-99km and ≥ 100km. SPSS was used, with a X^2 test for independence to determine association between distance to silica mines and ANCA vasculitis.

Results: 135 patients were identified, with a mean age of 48 years and 60% were male. There were 44 cases of ANCA vasculitis and 91 cases of IgAN. Patients diagnosed with ANCA vasculitis were significantly older (63.5 years v 40.9 years, p<0.05). 50% of ANCA vasculitis patients resided within 50km of a silica mine, compared to 44% of patients with IgAN. 20.5% and 29.5% of ANCA vasculitis patients resided 51-99km and ≥ 100km respectively; compared to 22% and 34.1% of patients with IgAN respectively. There was no evidence of association between distance from suburb to silica mine and ANCA vasculitis ($X^2_{(2,135)}=0.45$, p=0.8).

Conclusions: There was no evidence that proximity of residence to silica mines was associated with ANCA vasculitis compared to IgAN in this cohort of patients. Limitations include small sample size and inability to account for patient relocation prior to biopsy.

SA-PO638

Urine Aquaporin-2 Messenger RNA Predicts Global Glomerulosclerosis and Renal Outcome in Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis

Masao Kikuchi,[1] Akihiro Fukuda,[4] Akihiro Minakawa,[2] Yuji Sato,[3] Shouichi Fujimoto.[1] *[1]University of Miyazaki, Kiyotake, Japan; [2]Miyazaki university, Miyazaki, Japan; [3]University of Miyazaki Hospital, Miyazaki, Japan; [4]Oita University, Yufu, Japan*.

Background: Despite substantial progress in the treatment for anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), the prognosis of patients with AAV has not sufficiently improved. The poor prognosis is not only caused by the activity of AAV but also caused by adverse events due to the therapeutic agents. Avoiding excessive immunosuppression can lead to an improvement in the prognosis. Useful and noninvasive predictor for renal outcome is needed. We recently announced that urine aquaporin 2 (U-AQP2), which is a water channel localized in the renal collecting ducts, mRNA predicts the renal outcome in AAV at the 56th ERA-EDTA Congress in Budapest, 2019. Here, we examined the association between U-AQP2 mRNA and renal biopsy tissue.

Methods: We enrolled 33 patients with AAV diagnosed at Miyazaki University Hospital from January 2009 to March 2016. Their U-AQP2 mRNA levels at the onset of AAV were evaluated by real-time polymerase chain reaction, and normalized by urine creatinine concentration. We divided them into two groups (High U-AQP-2 group (n=7) and Low U-AQP-2 group (n=26)) based on mean value of U-AQP2 mRNA and performed Kaplan-Meier analysis to assess renal survival in two groups. We also examined the renal biopsy tissues of each group.

Results: High U-AQP2 group showed poorer renal prognosis than Low U-AQP2 group (p<0.001). In analysis of renal biopsy tissue, the percentage of global glomerulosclerosis in High U-AQP2 group was significantly higher than in Low U-AQP2 group (32.9 % vs. 16.8 %, p=0.02). The percentage of crescentic lesions in High AQP2 group was not significantly different from Low AQP2 group (39.8 % vs. 33.3 %, p=0.44). The degree of tubulointerstitial lesion in High AQP2 group was also not significantly different from Low AQP2 group. Urinary NAG concentration, which is an indicator of tubular injury, did not change between the two groups.

Conclusions: This result could suggest severe glomerular damage caused by AAV affects distal nephron. U-AQP2 mRNA may be able to detect deep lesions that are difficult to diagnose in kidney biopsy tissue. U-AQP2 could predict irreversible damage by AAV.

SA-PO639

Improved Survival due to Better Renal Outcomes in Danish Patients with Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitis (AAV) During the Years 2000-2015: A Nationwide Study

Karl E. Nelveg-Kristensen,[1] Wladimir M. Szpirt,[2] Nicholas Carlson,[1] Hans H. Dieperink,[3] Elizabeth Krarup,[4] Per R. Ivarsen,[5] Jon W. Gregersen,[6] Christian Torp-Pedersen,[6] Martin Egfjord.[7] *[1]Rigshospitalet, Copenhagen, Denmark, Cambridge, United Kingdom; [2]Rigshospitalet P2132, Copenhagen, Denmark; [3]Odense University hospital, Odense, Denmark; [4]Herlev Hospital, 2730 Herlev, Denmark; [5]Nephrology, Aarhus University Hospital, Aarhus, Denmark; [6]Aalborg University Hospital, Aalborg, Denmark; [7]Rigshospitalet, Copenhagen, Denmark*.

Background: AAV (Granulomatosis with polyangiitis and microscopic polyangiitis) carries significant risk of morbidity and mortality, notwithstanding adequate treatment. Contemporary large-scale descriptive studies have been challenged by the rare occurrence of these diseases. Accordingly, by use of Danish nationwide healthcare registries, we examined the temporal progression of incidence and prognosis of AAV during 2000-2015.

Methods: All patients with incident AAV, regardless of primary organ manifestation were included by use of ICD10 diagnostic codes (positive predictive value of > 90%) and grouped in five-year intervals (P1: 2000-2004, P2: 2005-2009, P3: 2010-1015). Absolute risk ratios (ARR) adjusted for age, sex and advanced disease severity (>10 days of initial hospital stay), as well as cumulative incidences were computed in R version 3.5.0.

Results: We identified 1634 patients (52% male), corresponding to an overall incidence of 18.2 persons/million/year (P1: 12.1; P2: 16.3; P3: 21.0), and 425 (26% [P1: 34.6%; P2: 28.5%; P3: 19.4%]) met the criteria of advanced disease severity. Mean age was 60.3 (IQR 21.0) years and mean follow-up was 5.9 (IQR 4.0) years. 571 (34.9%) patients died (uncensored 5-year mortality of 20.3%) resulting in an ARR for P2 and P3 as compared to P1 of 0.80 (CI 0.65-0.97, P=0.028), and 0.40 (CI 0.30-0.51, P<0.001). 274 patients developed end-stage renal disease (16.8 % [P1: 23.3%; P2: 17.6%; P3: 12.5%]), similarly with ARR decreasing over time: P2 0.62 (CI 0.43-0.89, P=0.009) and P3 0.54 (CI 0.37-0.78, P=0.001) relative to P1. The overall risk of death associated with need of dialysis or chronic kidney involvement within 30 days of discharge as compared to no renal involvement was 1.81 (CI 1.41-2.33, P<0.001) and 1.39 (CI 1.11-1.76, P=0.005). During follow-up 526 (32.2% [P1: 39.6%; P2: 30.4%; P3: 29.3%]) patients developed chronic kidney disease.

Conclusions: AAV remain a group of diseases associated with high morbidity and mortality; however, although incidence of AAV is increasing, the absolute risk of death appears to be declining, putatively in part due to earlier detection of incident episodes and better renal outcomes.

SA-PO640

Predictors of Renal Involvement in ANCA-Associated Vasculitis

David R. Jayne,[7] Andreas Kronbichler,[1] Jae Il Shin,[2] Daiki Nakagomi,[3] Luis F. Quintana,[4] Martin Busch,[5] Raashid A. Luqmani,[6] Gert J. Mayer,[1] Richard Watts.[8] *[1]Medical University Innsbruck, Innsbruck, Austria; [2]Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Yamanashi University, Yamanashi, Japan; [4]Hospital Clinic de Barcelona. Fundacio Clinic per la Recerca Biomedica, Barcelona, Spain; [5]University Hospital Jena, Jena, Germany; [6]Rheumatology Department, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [7]University of Cambridge, Cambridge, United Kingdom; [8]University of East Anglia, Ipswich, United Kingdom.*

Background: Renal involvement in the context of anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitis (AAV) is associated with significant morbidity and higher mortality rates. This study examined predictive factors associated of renal involvement in AAV within a large, international cross-sectional cohort.

Methods: Univariate and multivariate analyses were performed to identify risk factors associated with renal disease, which was defined as i) an increase of serum-creatinine > 30%; ii) a fall in creatinine-clearance < 25%; or iii) haematuria attributable to active vasculitis.

Results: Of the 1230 patients eligible, 723 patients (58.8%) presented with renal involvement. The majority of patients with microscopic polyangiitis (82.2%) and granulomatosis with polyangiitis (58.6%) had renal involvement, while 26.4% with eosinophilic granulomatosis with polyangiitis presented with renalvasculitis. The following clinical factors were more common among patients with renal disease that among patients without renal disease. Older age (p=0.001), fever (p<0.001), fatigue (p=0.005), weight loss (p=0.001), polyarthritis (p=0.036), petechiae/purpura (p=0.022), pulmonary haemorrhage (p=0.014), gastrointestinal symptoms (p=0.002), serum albumin below 30 g/L (p<0.001), higher CRP (p=0.038), low C3 at baseline (p=0.015), ANCA positivity (p<0.001), myeloperoxidase-ANCA (p<0.001) and proteinase 3-ANCA (p=0.020). Patients with proptosis/exophthalmos (p=0.001), saddle nose deformity (p=0.015), nasal polyps and nasal septal defect/perforation (p<0.001 each), respiratory distress/pulmonary fibrosis/asthma (p<0.001) or wheeze/obstructive airway disease (p<0.001) had a lower likelihood of developing renal involvement.

Conclusions: In this large international study, we identified clinical factors associated with renal involvement in AAV, including concomitant pulmonary alveolar haemorrhage, low C3, and elevated C-reactive protein. Further large studies arenecessary to confirm our findings.

SA-PO641

Chorioretinal Thickness Reflects Disease Activity in ANCA-Associated Vasculitis

Tariq E. Farrah. *University of Edinburgh, Edinburgh, United Kingdom.*

Background: ANCA-associated vasculitis (AAV) is characterised by autoimmune-mediated injury of small blood vessels and often requires renal biopsy for diagnosis. A non-invasive means of detecting this microvascular injury would be of major clinical value. The eye acts as a window to the systemic microvasculature. Retinal optical coherence tomography (OCT) provides cross-sectional imaging of the retina and highly vascularized choroid with near-histological resolution. We have shown that systemic and renal inflammation associates with choroidal thinning. We hypothesized that OCT metrics would reflect disease activity in AAV and be modified with treatment.

Methods: We prospectively recruited 50 patients with active AAV and 50 age-and sex-matched healthy controls, excluding those with diabetes and previous eye disease. AAV patients were studied prior to receiving immunosuppression and once in disease remission, defined by a Birmingham Vasculitis Activity Score (BVAS) of 0 for a least 2 months on low dose steroid. All subjects were imaged with the Heidelberg SPECTRALIS® OCT device. Choroidal thickness was measured blinded at three locations: 2mm nasal to fovea (location I), subfoveal (location II) and 2mm temporal to the fovea (location III), Figure 1.

Results: AAV patients had a mean (±SD) age of 60±14 years, 20 (50%) were male and 24 (60%) were PR3+. Median (range) BVAS at entry was 13 (3-21). 30 (75%) patients were new presentations and 26 (65%) had renal involvement. Mean (±SD) choroidal thickness was thinner in active AAV patients compared to health: location I 202±84 *vs.* 248±76mm; location II 279±90 *vs.* 331±69mm; location III 276±90 *vs.* 309±65mm; all p<0.05. Choroidal thickness correlated negatively with baseline BVAS, *r*=0.57, p<0.05. Following disease remission, choroidal thickness increased by ~10% compared to active disease, p<0.01 at all locations, Figure 1.

Conclusions: Active AAV is associated with choroidal thinning compared to health. This improves with successful treatment. OCT-derived metrics may be a novel means of assessing disease activity and treatment response in AAV. Larger studies will explore these findings further.

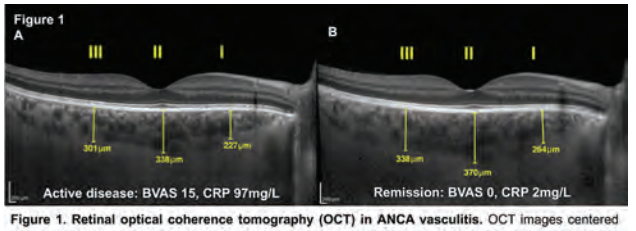

Figure 1. Retinal optical coherence tomography (OCT) in ANCA vasculitis. OCT images centered over the macula of the right eye from the same patient with ANCA vasculitis during active disease (**A**) and following successful treatment and disease remission (**B**). OCT images taken at the level of the macula. Yellow callipers indicate choroidal thickness measured at locations I, II and III.

SA-PO642

Venous Thromboembolisms in ANCA-Associated Vasculitis: Incidence and Risk Factors

Brad Isaacs,[2] Philip Seo,[2] Eric J. Gapud,[2] Brendan Antiochos,[2] Duvuru Geetha.[1] *[1]John Hopkins Bayview Medical Center, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: The incidence of venous thromboembolism (VTE) is increased in ANCA associated vasculitis (AAV). We aimed to assess the frequency of VTEs observed in our center and identify risk factors.

Methods: VTEs in 155 AAV patients with diagnosed Granulomatosis with Polyangiitis and Microscopic Polyangiitis were analyzed. Baseline demographics, clinical and serologic data were extracted. Univariate and multivariate analyses were performed to identify factors associated with VTE in AAV.

Results: Of the 155 AAV patients, the mean age was 55.1 ± 17.5 years, 61% females, 55% PR3-ANCA positive, 45% MPO-ANCA, with a total mean BMI of 28.9 ± 6.3 kg/m^2. The mean Birmingham Vasculitis Activity Score (BVAS) was 14.3 ± 6.0. VTEs occurred in 21 (14%) patients and the mean time to VTE was 1.8 months. Univariate analyses identified PR3-ANCA as significantly associated with the onset of VTE (17/85, p=0.02). In multivariate models, each adjusted for age, sex, hyperlipidemia/hypertension medications, smoking status, diagnosis (GPA/MPA), **the associations of PR3-ANCA (p=0.018), BMI (p=0.0015), and RPGN (p=0.015) with VTE incidence remained significant, while there was no statistically significant correlation of alveolar hemorrhage or BVAS severity with VTE.**

Conclusions: The incidence of VTE in AAV was 21/155 (14%). PR3-ANCA, RPGN, and increased BMI are risk factors for developing VTEs. BVAS severity or alveolar hemorrhage does not increase risk of venous thromboembolic events. Further studies are needed to confirm these findings.

Logistic Regression				
Coefficients:	**Estimate**	**Standard Error**	**z-value**	**Pr(>|z|)**
BMI (kg/m^2)	0.14869	0.04680	3.177	0.0015 **
ANCA Serology (PR3/MPO)	-1.64706	0.69727	-2.362	0.018 *
RPGN	1.59363	0.65311	2.440	0.015 *
Alveolar Hemorrhage	0.81914	0.75023	1.092	0.27
Age of diagnosis	0.02996	0.01863	1.608	0.11
BVAS < 10	0.85613	1.84096	0.465	0.64
10 < BVAS < 20	0.82044	1.76084	0.466	0.64
20 < BVAS < 30	1.82693	1.90066	0.961	0.34

BMI (kg/m^2), ANCA serology (PR3 vs MPO), RPGN are significantly correlated with incidence of venous thromboembolisms. BVAS severity and presence of alveolar hemorrhage do not appear to contribute to VTE risk.

SA-PO643

Outcomes by Etiology in Pediatric Glomerulonephritis with Crescents

Juhi A. Gor,[8] Joseph T. Flynn,[3] Cynthia G. Pan,[4] David T. Selewski,[5] Michelle N. Rheault,[6] Katherine Twombley,[5] Loretta Reyes,[7] William E. Smoyer,[2] Scott E. Wenderfer,[1] Guillermo Hidalgo.[9] *[1]Baylor College of Medicine, Houston, TX; [2]Nationwide Children's Hospital, Columbus, OH; [3]Seattle Children's Hospital, Seattle, WA; [4]Children's Corporate Center, Milwaukee, WI; [5]Medical University of South Carolina, Mount Pleasant, SC; [6]University of Minnesota, Minneapolis, MN; [7]Emory University School of Medicine, Atlanta, GA; [8]Brody School of Medicine at East Carolina University, Greenville, NC; [9]Eastern Carolina University, Greenville, NC.*

Background: Etiologies of Glomerulonephritis (GN) with crescents in Pediatrics differ from those in adults. Many of the typical etiologies can be categorized into diseases with or without involvement of immune complex (IC) deposition leading to damage and inflammation of glomeruli. Our previous work had identified a composite risk index, involving 4 disease markers: % crescents, presence of fibrous crescents, HTN, and eGFR at biopsy. However, it is unknown whether these 4 markers predict 1 year outcomes in specific classes of glomerulonephritis.

Methods: We reviewed the Pediatric GN with crescents registry which is a multicenter, retrospective (2004-2016) review of subjects < 21 y, with GN with crescents, followed for at least 12 mo. across the US as part of the Midwest Pediatric Nephrology Consortium. Crescentic GN was defined as > 1 crescent per core biopsy according to local pathologist read. Primary outcome of interest was end stage kidney disease (ESKD) at 1 year.

Results: We reviewed records on 305 patients, mean age 11 y, 58% female. There were 53 with pauci immune GN (17%) and 252 with IC GN (82%). 21% of patients in the pauci-immune group reached ESKD at 1 year, as compared to 9.5% in the immune complex group (p-value 0.031). On bivariate analysis in the pauci immune group, variables at time of biopsy associated with ESKD at 1 y. were estimated glomerular filtration rate (eGFR) <15 ml/min/1.73m2 (58 vs. 10% p= 0.001), hypertension (44 vs. 8.6%, p= 0.006), and > 43% crescents (39 vs. 6.7%, p=0.006). Percentage drop in eGFR at 1 year was also higher in the pauci-immune group (20 vs. 10.7%), as compared to the immune complex group, but these results were not statistically significant. In the immune complex group, variables at time of biopsy associated with ESKD at 1 y. were estimated glomerular filtration rate (eGFR) below 15 ml/min/1.73m2 (59 vs. 5.1% p< 0.001), presence of fibrous crescents (16 vs. 6.9% p = 0.034), hypertension (17 vs 3.1% p < 0.001), > 43% crescents (33 vs. 3.9%, p<0.001), and presence of generalized edema (17 vs 5.7% p=0.007

Conclusions: Pauci-immune GN, which constituted only 17% of our cohort, was associated with a significant risk of ESKD at 1 year. Different risk factors at time of biopsy are associated with ESKD at 1 year in pauci immune GN compared to IC GN.

SA-PO644

Benefit or Burden: A Systematic Review and Meta-Analysis of Treatment Outcomes of ANCA-Associated Vasculitis in Patients Older Than 75 Years

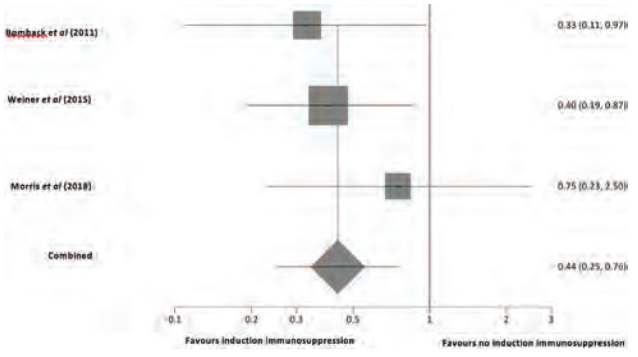
Adam Morris, Mohamed Elsayed, Mark Brady, Arvind Ponnusamy, Ajay P. Dhaygude. *Renal Medicine, Royal Preston Hospital, Lancashire NHS Foundation Trust, Preston, United Kingdom*.

Background: Despite a peak incidence of 64-75 years, the benefit of treating ANCA-associated vasculitis (AAV) in older patients remains unclear with most published studies defining elderly as ≥65 years. This study aims to determine outcomes of induction immunosuppression in patients aged ≥75 years.

Methods: A cohort aged ≥75 years with biopsy proven AAV was constructed from a single centre between 2006–2016. Follow up was to two years or death. Analysis included multivariate Cox regression to compare mortality and ESRD based on induction immunosuppression therapy. A systematic review of outcome studies was subsequently undertaken amongst this patient group through Pubmed, Cochrane and Embase databases from inception until 13/09/18.

Results: From 145 patients, 59 were ≥75 years, of which 51 had completed data. Mean age was 78.9±2.7, 54.9% were male and mean modified Charlson comorbidity index was 1±1.3. 76% (n=39) received induction therapy. The systematic review identified 1943 citations. Four studies were eligible for inclusion, yielding a combined total of 274 patients inclusive of our cohort. The aggregated one year mortality irrespective of treatment was 36% (CI 27–47%). Within our cohort, induction immunosuppression therapy was associated with a lower two-year mortality risk, although not statistically significant [HR 0.75 (95% CI 0.23–2.49)]. However, the pooled HR by meta-analysis revealed a significant risk reduction for death [HR 0.44 (95% CI 0.25–0.76), I^2=0%]. Treated patients had a lower pooled rate of ESRD, but was not statistically significant [HR 0.76 (95% CI 0.37–1.59)].

Conclusions: This meta-analysis suggests that patients ≥75 years with AAV do benefit from induction immunosuppression with a significant survival benefit. Age should not be a limiting factor when considering treatment. Further trials are required to better evaluate renal outcomes amongst this age group.



Forest plot of mortality risk in patients with AAV ≥75 years based on the use of induction immunosuppression

SA-PO645

ANCA-Associated Vasculitis with AKI: KDIGO AKI Stage, Short-Term Recovery, and Long-Term Outcome

Xiaohan Huang, Liangliang Chen, Yanhong Ma, Binfeng Yu, Fei Han. *The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China*.

Background: To study KDIGO AKI stages and its association with short-term and long-term outcome in patients with ANCA associated vasculitis.

Methods: We retrieved data of 154 patients who combined with AKI (including AKI on chronic kidney disease) and not requiring maintaining renal replacement therapy 3 months after admission. In these 154 patients, 14 were lost to follow up. The remaining 140 patients were staged from 1 to 3 according to AKI criteria based on KDIGO guideline. Short-term recovery was assessed according to the serum creatinine level change, and patients were divided in to 2 groups: ≥30% decline(G1), and <30% decline or rise (G1) at 3 month comparing to pre-episode baseline. Long term renal endpoint was defined as: reaching an eGFR level of <15ml/min/1.72m2 or requiring maintaining renal replacement therapy for more than 3 months. Univariate analysis and multivariate analysis were used to compare the outcome.

Results: At admission, 49(35%) were in AKI stage 1, 53(37.0%) in stage 2 and 38(27.1%) were in stage 3. Three months after admission, there were 75 patients in G1, and 65 patients in G2(including 24 patients with rising serum creatine level). No significant differences in age and gender(p>0.05) were found. AKI stage(p<0.001), 24h urine protein(p=0.012) and urine red blood cell per μl(p=0.015) were found associated with short-term recovery. Twenty-three patients reached the renal endpoint during the median follow-up duration of 54(32,79) months. The renal survival rates of AKI stage 1 patients were 91.90%, 79.07 % in stage 2 and 71.80% in stage 3, Kaplan-Meier analysis suggested significant difference (p=0.034). Additionally, renal survival rates were 90.7% in G1 and 75.4% in G2, and Kaplan-Meier analysis showed significant difference between the two groups (p=0.013). The COX model suggested that high AKI stage (OR=5.765, 95%CI 1.886-17.619; p=0.002), high baseline serum creatine (OR=1.008,95%CI 1.001-1.016, P=0.027), and G1(OR=0.084, 95%CI 0.019-0.37) were independent risk factors of renal outcome in patients with ANCA associated vasculitis.

Conclusions: In patients with ANCA associated vasculitis, AKI stage, 24h urine protein and hematuria were associated with short-term outcome; AKI stage, baseline scr, and serum creatinine recovery level at 3 months were independent risk factors of long-term renal outcome.

SA-PO646

Analysis of Clinical Features in ANCA-Associated Vasculitis with Rapidly Progressive Glomerulonephritis: Thirty-Five Years of a Single-Center Experience

Soko Kawashima,[1] Hiroko Uchida,[2] Yoshinori Komagata,[1] Shinya Kaname.[1] *[1]Kyorin University School of Medicine, Mitaka, Japan; [2]Kyorin Univercity, Tokyo, Japan*.

Background: The clinical features of AAV, with respect to renal involvement, may have been changing recently in Japan, where MPO-ANCA-associated vasculitis (MPO-AAV) are dominant in contrast to the Western countries. Thus, we retrospectively analyzed the clinical database of the141 AAV-patients with RPGN who were admitted to our hospital for the last 35 years.

Methods: At the onset, all patients fulfilled the Chapel Hill Consensus Conference (CHCC) classification criteria for MPA, GPA and EGPA. 141 patients (56 male, 85 female: MPA 118, MPO-GPA 12, PR3-GPA 7, EGPA 4) who underwent initial treatment diagnosed with AAV and presented rapidly progressive glomerulonephritis (RPGN) at our hospital from 1983 to 2018. We divided the AAV patients into the 3 groups(Group1 (1983-2000: 31 cases), Group2 (2001-2010: 56 cases), 3 (2011-2018: 54 cases)), and compared the clinical features and renal prognosis.

Results: The frequencies of RPGN in AAV were 76% (31/41) in group1, 50% (56/111) in group2 and 47% (54/115) in group 3, respectively. The average ages at the first onset were 67.2 ± 10.9, 69.1 ± 12, 75.4 ± 9.1 years (mean±SD). The BVAS were 24.8 ± 3.9, 22.8 ± 8.1, and 17.8 ± 4.7. Serum creatinine levels (mg/dl) were 6.5 ± 4.2, 4.6 ± 3.5, 3.2 ± 2.1, and the frequencies of renal death were 71% (22/31), 46% (26/56), 22% (12/54). The dialysis withdrawal rates were 0% (0/22), 7% (2/28), 20% (3/15). The immunosuppressants were used in the 19% (6/31), 25% (14/56), 44% (24/54) of the patients in initial treatment. Cyclophosphamide (CY) was used for 16% (5/31), 23% (13/56), 33% (18/54) of the patients. RTX was used only in group III for 9% of the patients (5/54). PE were used 3% (1/31), 2% (1/56), 6% (3/54). One-year survival rates were 52% (16/31), 85% (47/55), 88% (36/41), with the survival observation period for 40.0 ± 56.2 months, 47.3 ± 42.7 months, 29.6 ± 29.5 months, respectively. Death due to vasculitis was seen in 30% (8/27), 17% (4/24), 11% (1/9), and death due to infection in 30% (8/27), 21% (5/24), 56% (5/9). Relapse rates were 32% (10/31), 21% (12/56), 11% (6/54).

Conclusions: These results clearly show the changing features of ANCA-associated renal vasculitis, with an earlier detection and the improvement of renal and patient survival during the last decades in Japan.

SA-PO647

ANCA-Associated Glomerulonephritis Without Crescent Formation Has Atypical Clinicopathological Features: A Multicenter Retrospective Study

Kazuyuki Suzuki,[2] Takeshi Zoshima,[1] Fae Suzuki,[4] Satoshi Hara,[4] Mitsuhiro Kawano.[3] *[1]Kanazawa University Hospital, Kanazawa, Japan; [2]Kanazawa University, Kanazawa, Japan; [3]Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan; [4]Kanazawa University Graduate School of Medicine, Kanazawa, Japan*.

Background: The most typical histopathological feature of ANCA-associated glomerulonephritis (ANCA-GN) is crescentic GN. However, ANCA-GN sometimes includes tubulointerstitial or vascular-dominant inflammation without crescent (C) formation. Few reports have focused on ANCA-GN without C in a large multicenter study. We aimed to identify the clinicopathological features of ANCA-GN without C.

Methods: We enrolled 147 Japanese ANCA-GN patients who were subjected to renal biopsy in 17 hospitals from 2001 to 2018. We measured various clinical parameters at the time of renal biopsy, and determined the presence of comorbidities. We also measured serum Cr and eGFR at the last patient visit, and recorded medications prescribed for ANCA-GN. We retrospectively compared these clinical and histological findings between those with C (C+ group) and without C (C- group). The endpoint was the cumulative percentage of patients who died from any cause.

Results: Of 147 patients (76 females; mean age 69.2 years; observational period 39.5 months), 25 (17.1%) were in C- group. Although C- group had less proteinuria (0.7±0.8 vs 1.7±1.6 g/gCr, p<0.01) and hematuria (75.0% vs 99.1%, p<0.01) with better renal function (eGFR; 53.9±28.7 vs 32.2±24.6 ml/min/1.73m^2, p<0.01), they had higher CRP levels (10.9±7.9 vs 6.6±6.1 mg/dl, p<0.01) than C+ group. There were no significant differences in any other clinical findings including ANCA serology. In histological findings, C- group had a higher frequency of arteritis (41.7% vs 17.5%, p=0.01), while other histological findings such as arteriolitis and tubulointerstitial lesions did not differ. Corticosteroid was less often prescribed in C- group (84.0% vs 100%, p<0.01). There was no significant difference in observational period, and C- group had better latest renal function (eGFR;

53.9±32.1 vs 40.6±29.4 ml/min/1.73m^2, p=0.05) than C+ group. However, overall survival rate did not differ (76.0% vs 79.6%, p=0.78).

Conclusions: ANCA-GN without C had specific clinicopathological features including higher systemic inflammation and frequency of renal arteritis than ANCA-GN with C. Though renal function throughout the clinical course was better in ANCA-GN without C, overall survival rate was similar with ANCA-GN with C.

SA-PO648

The Clinical and Pathological Features of Patients with Antineutrophil Cytoplasmic Antibody-Associated Vasculitides Concomitant with IgG4-Related Disease

Liangliang Chen, Yanhong Ma, Fei Han. *The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China*.

Background: Antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitides (AAV) and IgG4-related disease (IgG4-RD) have similarities in clinical features. The characteristics and the pathogenesis of the concomitant AAV and IgG4-RD disease have not been elucidated.

Methods: We included 92 AAV patients with renal biopsy results. Among them, 10 patients met both AAV and IgG4-RD criteria (concomitant group). The IgG subclasses of myeloperoxidase (MPO)-ANCA in both serum and renal tissue were measured and complement activation components were detected in serum.

Results: Patients in concomitant group had both elevated serum IgG4 level and positive MPO-ANCA. They had higher levels of eosinophil counts, serum globulin, IgG, IgE and CRP than patients in AAV alone group. All 10 patients had glomerulonephritis with crescents and 7 patients also had segmental necrosis of glomerular capillary wall. Most of them also presented storiform fibrosis and lymphoplasmocytic infiltration in renal interstitium with IgG4 positive plasma cells more than 10/HPF. The percentages of glomerular global sclerosis and crescent were 36.6%±25.7% and 23.2%±15.4% respectively. Eight patients received combined therapy of glucocorticoids and cyclophosphamide, one patient received glucocorticoids only and another patient received glucocorticoids and rituximab. Eight patients achieved remission with improved renal function, the other two patients were on maintaining dialysis. The IgG4 subclass of MPO-ANCA was higher in concomitant group than that in AAV alone group. A merge of IgG4 and MPO immunofluorescence was observed in parts of glomerular mesangium of concomitant AAV and IgG4-RD patients. For complement components, Bb and mannose-binding lectin (MBL) were elevated in serum of concomitant AAV and IgG4-RD patients.

Conclusions: We showed a new overlap syndrome of AAV and IgG4-RD, in which the IgG4 subclass of ANCA may be a pathogenic factor, and alternative complement pathway and MBL pathway may be involved.

SA-PO649

Histopathological Findings and Clinical Outcomes of ANCA-Negative vs. ANCA-Positive Pauci-Immune Glomerulonephritis

Adam Morris, Mohamed Elsayed, Lauren Floyd, Mark Brady, Arvind Ponnusamy, Ajay P. Dhaygude. *Renal Medicine, Royal Preston Hospital, Lancashire NHS Foundation Trust, Preston, United Kingdom*.

Background: It has been suggested that pauci-immune small vessel vasculitis exhibits a different spectrum of disease in the absence of detectable ANCA. We investigated differences in clinical phenotypes, renal histology and clinical outcomes amongst patients with or without ANCA positive disease.

Methods: A cohort with biopsy proven pauci-immune glomerulonephritis was constructed from a single centre between 2006-2016 and followed until December 2018. Patients were stratified by ANCA status at the time of diagnosis with comparative analysis of demographics, clinical characteristics and histopathological variants. Multivariate survival and logistic models compared remission rates, ESRD and mortality risk.

Results: From 143 patients, 20% (n=29) had ANCA negative disease with a male predominance of 66% (n=19) and a younger mean age at diagnosis compared to those with positive ANCA serology; 53±19 years vs. 66±12 years respectively (p=<0.001). The presence of extra-renal disease with ENT and constitutional symptoms occurred more frequently in ANCA positive patients; 25% (n=27) vs. 0% (p=0.0012) and 27% (n= 30) vs. 3% (n=1) (p=0.0049) respectively. Conversely, ANCA negative serology was associated with renal limited disease (p=0.039). There was no association between histological features on biopsy and ANCA serology (Table 1). ANCA positive disease was associated with a significantly higher remission rate [OR 3.9 (95% CI 1.12-13.5)]. However, this did not confer any renal or overall survival benefit; [HR 0.45 (95% CI 0.15 – 1.33)] for ESRD and [HR 0.68 (95% CI 0.25 – 1.81)] for death.

Conclusions: Our single centre experience suggests that ANCA negative disease tends to occur in younger patients, with a higher rate of renal limited disease and no significant differences in histopathologial variants. Seronegative disease is less likely to remit, but is associated with similar survival risks in compassion to ANCA positive disease.

Table 1: Histopahtological Variants by ANCA status

Histological feature	ANCA negative	ANCA positive	p-value
< 10% Normal Glomeruli	10 (34.48%)	22 (19.30%)	0.22
Berden Classification:	.	.	.
Crescentic class	3 (10.34%)	21 (18.42%)	0.73
Sclerosed class	2 (6.90%)	5 (4.39%)	0.73
Focal class	13 (44.83%)	47 (41.23%)	0.73
Mixed class	11 (37.93%)	41 (35.96%)	0.73
Extra-glomeruli arteritis	4 (13.79%)	16 (14.04%)	1
Vessel wall necrosis	4 (13.79%)	11 (9.65%)	0.51
>50% IFTA	0	3 (2.63%)	0.53

SA-PO650

Absence of Fibrinoid Necrosis in ANCA-Glomerulonephritis Is Associated with Increased Risk of Vasculitis Relapses

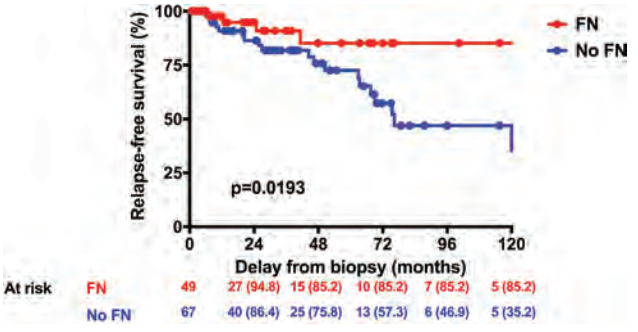
Jean francois Augusto,[1] Samuel Wacrenier,[4] Giorgina B. Piccoli,[2] Benoit Brilland,[3] Jean-Francois Subra,[1] Anne-Sophie Garnier.[5] *[1]CHU Angers, Angers, France; [2]University of Torino, Torino, Italy; [3]CHU d'Angers, Angers, France; [4]Nephrology, CHU Angers - CH Le Mans, Angers, France; [5]Angers University Hospital, Angers, France*.

Background: Fibrinoid necrosis (FN) is a cornerstone lesion of ANCA-associated glomerulonephritis (ANCA-GN). However, its significance in kidney biopsy of ANCA-GN patients has not yet been fully established. The objective of the present study was to analyze its association with baseline characteristics and outcomes of ANCA-GN patients.

Methods: All consecutive AAV patients diagnosed between 2000 and 2018 from the Maine-Anjou ANCA-associated vasculitis (AAV) registry with a contributive kidney biopsy showing pauci-immune glomerulonephritis at onset or relapse of AAV were included in the present study. Among the 146 patients on the registry, 116 patients fulfilled the inclusion criteria and were analyzed.

Results: Patients were predominatly males with a mean age of 63.7 years-old and a mena eGFR at diagnosis of 33.1mL/min/1.73m^2. FN was detected at kidney biopsy in 42.2% of patients. Patients with FN had lower eGFR (p=0.008), needed more frequently renal replacement therapy at kidney biopsy (p=0.018) and had a lower rate of AAV relapse (p=0.005) as compared to patients without FN. Attack and maintenance regimen, and extra-renal involvment was not significantly different between groups. FN was not significantly associated with other glomerular lesions. Relapse-free survival was significantly higher in patients with FN at biopsy, as was the survival-free of major and renal relapses. Univariate analysis showed granulomatosis with polyangiitis (GPA; HR 2.32, p=0.045), ear-nose-throat involvement (HR 2.47, p=0.032) and absence of FN (HR 3.35, p=0.027) to be significant risk factors of relapse. In multivariate Cox analysis, absence of FN at kidney biopsy conferred a 3-fold increased risk of developing relapse, after adjustment for other risk factors.

Conclusions: FN could be a reliable marker to assess the risk of AAV relapse and we propose that it should be evaluated as a tool to manage immunosuppressive regimen, especially in the long term.



Relapse-free survival according to FN status

SA-PO651

C3 Dominant Deposition in ANCA-Associated Glomerulonephritis

Rina Oba,[1] Go Kanzaki,[1] Takaya Sasaki,[1] Yusuke Okabayashi,[1] Kotaro Haruhara,[2] Kentaro Koike,[1] Keita Hirano,[3] Nobuo Tsuboi,[1] Takashi Yokoo.[1] *[1]The Jikei University School of Medicine, Minato-ku, Japan; [2]The Jikei University School of Medcine, South Yarra, VIC, Australia; [3]Ashikaga Red Cross Hospital, Ashikagas-shi, Tochigi prefecture, Japan.*

Background: It has been reported that Anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (ANCA-GN) is characterized by necrotizing crescentic glomerulonephritis with few immune and complement deposits. Several recent studies have implied that complement activation plays an important role in the pathogenesis of ANCA-GN. However, the clinical and pathological significance of C3 deposits in patients with ANCA-GN has not been fully elucidated. This current study investigated the characteristics of C3 dominant deposition in ANCA-GN.

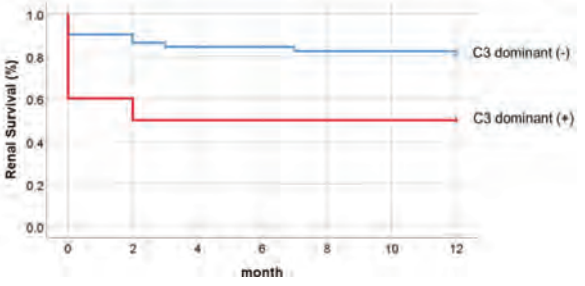
Methods: Kidneys specimens from 61 subjects with ANCA-GN were retrospectively evaluated at Jikei University School of Medicine Hospital, Atsugi City Hospital and Japanese Red Cross Ashikaga Hospital, Japan, during biopsy performed between 2004 and 2019. Clinical and histopathological data at kidney biopsy were compared between the patients with and without C3 deposits. The dominant deposition was defined as the presence of C3 for at least 1+ in a 0–3+ scale without other immune and complement deposits.

Results: **Figure** provides clinical and histopathological data for the ANCA-GN patients with and without C3 dominant deposits. Demographic data, estimated glomerular filtration rate (eGFR), and urine protein were similar between the two groups, indicating that renal function at biopsy was unlikely to associate with C3 deposition. Compared with patients without C3 dominant deposition, patients with C3 dominant deposition had a higher level of C3 (P=0.003) and a poorer renal outcome at one year after biopsy (P=0.025). Although there was no difference in the rate of glomerular cellular crescent

formation or global sclerosis, the patients with C3 dominant deposition had a higher percentage of fibrocellular or fibrous crescent.

Conclusions: These results suggest that C3 deposition and complement activation would be associated with chronic histological changes and poor renal outcome in ANCA-GN.

Figure : Kaplan-Meier plot of the renal survival curve comparing C3 dominant and negative



SA-PO652

Prognostic Impact of Interstitial Fibrosis for Progression to ESRD in ANCA-GN

Lars S. Bostad,[4] Leif Bostad,[5] Anne-Siri Fismen,[3] Rune Bjoerneklett.[1,2] *[1]Emergency Care Clinic, Haukeland University Hospital, Bergen, Norway; [2]Clinical Medicine, University of Bergen, Bergen, Norway; [3]Western Norway University of Applied Sciences, Bergen, Norway; [4]Emergency Care Clinic, Haukeland University Hospital, Bergen, Norway; [5]Pathology, Haukeland University Hospital, Bergen, Norway.*

Background: Interstitial fibrosis (IF) is a well-known risk factor for progression to ESRD in patients with glomerulonephritis (GN). However, few studies have reported its role as an independent risk factor as determined by multivariate analysis on patients with ANCA-GN.

Methods: Patients with ANCA-GN and IF graded as none-mild focal (<25%)/severe focal (25-50%)/diffuse (>50%) and other base-line risk factors, were obtained from the Norwegian Kidney Biopsy Registry. The observation period was from the date of biopsy to date of ESRD/death/end of 2013. ESRD and deaths during follow-up were identified by record linkage with The Norwegian Renal Registry. The primary end-point of the study was progression to ESRD within 3-years after diagnosis of ANCA-GN. Cox-regression statistics with and without adjustment for eGFR, glomerular classification (focal/crescentic/mixed/sclerotic), age, gender, ANCA sero-type was used to calculate HR's of ESRD between the different grades of IF.

Results: Two-hundred-fifty patients were identified of whom 43 progressed to ESRD within 3-years after diagnosis of ANCA-GN. Severe focal versus mild focal IF: Unadjusted HR 3.1 (1.6-6.1) p<0.001 and adjusted HR 2.1 (1.0-4.2) p=0.04. Diffuse versus mild focal IF: Unadjusted HR 5.7 (2.6-12.6) p<0.001 and adjusted HR 2.3 (0.9-5.6) p=0.07. Diffuse or severe focal versus mild focal IF: Unadjusted HR 3.8 (2.1-7.0) p<0.001 and adjusted HR 2.0 (1.1-3.9) p=0.03. Diffuse versus severe focal: Unadjusted HR 1.9 (0.9-4.4) p=0.11 and adjusted HR 0.8 (0.3-2.0) p=0.63.

Conclusions: Unadjusted, increasing degrees of IF is a strong risk factor for progression to ESRD in ANCA-GN. Adjusted for other known risk factors IF < versus ≥25% is a moderate independent predictor of progression to ESRD in ANCA-GN. Our finding suggests that IF should be included in multi-factor models aiming at predicting risk of progression to ESRD in ANCA-GN.

SA-PO653

Histopathologic Predictors for Renal Outcome in Crescentic Glomerulonephritis

Hee-Yeon Jung,[1] Jeong-Hoon Lim,[1] Man-hoon Han,[1] Ji-Young Choi,[1] Jang-Hee Cho,[1] Chan-Duck Kim,[1] Yong-Lim Kim,[1] Hajeong Lee,[2] Kyung chul Moon,[2] Yong-Jin Kim,[1] Sun-Hee Park.[1] *[1]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Crescentic glomerulonephritis (CGN) results in serious decline of renal function, but the prognostic factors are not known in detail. We evaluated the long-term renal outcome and prognostic predictors of CGN according to histopathologic information obtained by renal biopsy.

Methods: Among 133 patients diagnosed as CGN between 2010 and 2018 from two university-based hospitals, we retrospectively analyzed 117 patients whose biopsy specimen contained more than 10 glomeruli. Specimens were categorized into four classes according to anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis classification. The severity of arterial fibrointimal thickening was assessed by semi-quantitative method between grade 0 and 3. Cox proportional analysis was used to calculate hazard ratio (HR) for renal survival and linear regression analysis was performed for one-year estimated glomerular filtration rate (eGFR).

Results: The mean age was 60.9 ± 15.5 years and male was 49.6%. The mean eGFR was 19.5 ± 16.5 mL/min/1.73m^2 and hemodialysis was required in 38 patients (32.5%) initially. Ninety-one patients (77.8%) showed positive for ANCA and 11 patients (9.4%) showed positive for anti-glomerular basement membrane antibody. Fifty-nine patients (50.4%) had advanced to end-stage renal disease (ESRD) during the mean follow-up of 34.1 month. Patients with sclerotic type had worse renal survival than focal type (HR, 3.30 [95% CI, 1.18–9.17], *P*=0.022), and moderate to severe arterial fibrointimal thickening was also associated with poor renal survival (grade 2: HR, 2.51 [95% CI, 1.18–5.37], *P*=0.017; grade 3: HR, 2.82 [95% CI, 1.21–6.57], *P*=0.016). Tubulointerstitial rounded dense lymphocyte aggregation was observed in 42 patients (35.9%) and was also a prognostic factor for ESRD (HR, 1.76 [95% CI, 1.03–2.99], *P*=0.039). In the multivariate linear regression analysis, sclerotic type, severe tubular atrophy, age, and baseline eGFR were independent predictors of eGFR at one year after biopsy (all, *P*<0.05).

Conclusions: Specific histopathologic findings, such as higher proportion of sclerotic glomeruli, moderate to severe arterial fibrointimal thickening, and presence of tubulointerstitial lymphocyte aggregation, provide helpful information for predicting the renal outcome in patients with CGN.

SA-PO654

Validation of a New Renal Risk Score for Patients with ANCA-GN

Lars S. Bostad,[4] Leif Bostad,[5] Anne-Siri Fismen,[3] Thomas Knoop,[6,2] Rune Bjoerneklett.[1,2] *[1]Emergency Care Clinic, Haukeland University Hospital, Bergen, Norway; [2]Clinical Medicine, University of Bergen, Bergen, Norway; [3]Western Norway University of Applied Sciences, Bergen, Norway; [4]Emergency Care Clinic, Haukeland University Hospital, Bergen, Norway; [5]Pathology, Haukeland University Hospital, Bergen, Norway; [6]Medicine, Haukeland University Hospital, Bergen, Norway.*

Background: A new predicting model, renal risk score in ANCA associated GN, was published by Brix et al. in Kidney International Dec. 2018. It is a general principle that prognostic models need external validation for determination of generalizability.

Methods: Patients with ANCA-GN and risk factors included in the prognostic model; GFR > (G0) vs ≤15 ml/min/1,73m^2(G1), IF ≤ (T0) vs >25%(T1), and percentage of normal glomeruli (N0 >25%/N1 10-25%/N2 <10%), were identified in the Norwegian Kidney Biopsy Registry. According to the model, risk score points were assigned: G1=3, N1=4, N2=6, T1=2. Further, risk stratification was performed according to the model as follows: Low risk = 0-point, intermediate risk = 2-7 point, high-risk 8-11. Observation period was from the date of biopsy to date of ESRD/death/3 years post biopsy. ESRD during follow-up were identified by record linkage with The Norwegian Renal Registry. Kaplan-Meier and the ROC statistics were used to evaluate the prognostic performance of the model.

Results: We identified 250 patients with ANCA-GN of whom 43 progressed to ESRD during follow up. At 3-years of follow up cumulative risk of ESRD was 3.3% in low-, 22.4% in intermediate- and 44.0% in the high-risk group, p<0.001. In the ROC analysis AUC was 0.77 when assessed as 3 risk groups and 0.78 when assessed according to number of risk points.

Conclusions: We demonstrate that the prognostic value of this new prediction model for patients with ANCA-GN is good with an AUC of nearly 0.8 in the ROC analysis. However, the use of percentage normal glomeruli instead of glomerular classification (focal/crescentic/mixed/sclerotic) needs confirmation in larger cohorts. Further, the choice of grading initial eGFR in only 2 groups > versus ≤15 ml/min/1.73 m2 can also be questioned. It is also slightly surprising that demographic risk factors like age and gender are not included.

SA-PO655

Pauci-Immune Glomerulonephritis (PIGN) with Low Clearance at Clinical Presentation: Predictors of Treatment Response and Long-Term Outcomes

Sophia Lionaki, Smaragdi Marinaki, Petros Kalogeropoulos, Georgios Liapis, Helen Kapsia, Harikleia Gakiopoulou, Athanasios Tzioufas, John N. Boletis. *Laiko Hospital, Athens, Greece.*

Background: Pauci-immune vasculitis often presents with severe kidney involvement requiring hemodialysis. Considering the poor prognosis in this setting, we aimed to explore the factors which are associated with response to therapy.

Methods: Patients were included if they had biopsy proven PIGN with estimated GFR<20 ml/min/1.73 m^2 or required dialysis at presentation, received standard immunosuppression and had a follow up > 6 months. We recorded clinical, laboratory and histopathological parameters at diagnosis, at 3 months, at 1 year and at the end of follow up. Outcomes of interest included response to treatment, ESKD, and death. Treatment response was defined by the ability to come off dialysis with an eGFR>20 ml/min/1.73 m^2 with no signs of vasculitis. Histopathological evaluation included arteriosclerosis, % of normal glomeruli, activity index, chronicity index.

Results: A total of 77 patients, with a mean age of 60.6(16.05) years were included. There were, 42 males (54.5%). After 3 months, 55 patients (74.6%) had responded to immunosuppressive therapy, 15 (20%) were dialysis depended, 5(6.7%) died and 2 were lost in follow up. By the end of the 1st year, 54 patients (71.4%) achieved remission, 15(20%) ended up in ESKD and 6(8%) died. Factors which were associated with treatment response included MPO-ANCA positivity [odds ratio OR:3.9, 95%CI(1.13-13.37) p=0.03], eGFR>10ml/min/1.73m^2 at presentation [OR:2.5, 95% CI(0.86-7.30), p=0.009], normal glomeruli >10% [OR:3.8, 95%CI(1.24-12.1), p=0.02], and chronicity index more than 6 [OR:6.2, 95% CI(1.77-22.4), p=0.004]. Risk factors associated with ESKD included non-response to immunosuppressive therapy [Relative Risk RR:0.05, 95%CI(0.01-0.2) p<0.0001)], normal glomeruli<10% in the diagnostic biopsy [RR: 2.9, 95% CI(1.38-6.32), p=0.005] and age>75 years [RR:3.2, 95% CI(0.9-10.6) p=0.055]. Two of the 6 deaths were disease related.

Conclusions: A significant proportion of patients with PIGN who presented with severe renal dysfunction, responded to immunosuppresive therapy and recovered renal function approximately 3 months after initiation of therapy. Risk factors for ESKD were age>75 years, <10% normal glomeruli in the diagnostic biopsy and non-response to immunosuppressive therapy.

SA-PO656

Long-Term Outcomes of Patients with ANCA-Associated Vasculitis (AAV) Presenting with Severe Renal Dysfunction

Anisha Tanna, Stephen P. McAdoo, Amy Kang, Kavita Gulati, Sultana Azam, Jeremy B. Levy, Megan Griffith, Tom Cairns, Frederick W. Tam, Charles D. Pusey. *Imperial College Healthcare NHS Trust, London, United Kingdom.*

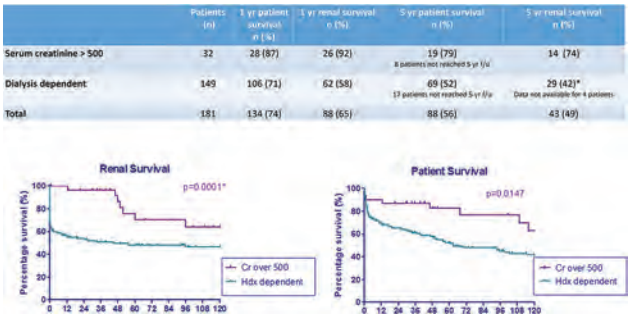
Background: Rapidly progressive glomerulonephritis (RPGN) is an important cause of morbidity and mortality in AAV. Few studies have specifically addressed the outcome of patients presenting with severe RPGN, traditionally defined as dialysis-dependence or a serum creatinine (SCr) of over 500µmol/l, and in particular the benefit of plasma exchange (PEX). Recent research has challenged the role of PEX in this patient set. Here we describe the long-term patient and renal outcomes in a large cohort of patients with severe RPGN treated with PEX at our centre.

Methods: This is a retrospective analysis of patients treated from 1977-2017 with newly presenting AAV and severe RPGN. Patients were classified as being dialysis-independent with a sCr>500µmol/l or as dialysis-dependent (defined as the need for dialysis within 72 hours of admission). Patients were treated consistently with steroids, cyclophosphamide and plasma exchange (with Rituximab post 2011) and with azathioprine as first line maintenance.

Results: Data were obtained for 181 patients, 149 of whom presented with dialysis-dependence. There were no demographic or treatment differences between the two groups. Patients who were not dialysed at presentation had significantly improved renal and patient survival at 1 and 5 years when compared to patients who presented dialysis dependent (Figure 1).

Conclusions: Renal and patient outcomes were favourable compared to other studies of this patient group. There was a striking difference in outcomes for dialysis-dependent patients when compared to those who had a sCr of >500µmol/l with independent renal function; it may be relevant to analyse patients with severe renal dysfunction according to these criteria in future therapeutic trials.

	Patients (n)	1 yr patient survival n (%)	1 yr renal survival n (%)	5 yr patient survival n (%)	5 yr renal survival n (%)
Serum creatinine > 500	32	28 (87)	26 (92)	19 (79) 8 patients not reached 5 yr f/u	14 (74)
Dialysis dependent	149	106 (71)	62 (58)	69 (52) 13 patients not reached 5 yr f/u	29 (42)* Data not available for 4 patients
Total	181	134 (74)	88 (65)	88 (56)	43 (49)



SA-PO657

A Dutch Consensus Statement on the Diagnosis and Treatment of ANCA-Associated Vasculitis

Ebru Dirikgil,[1] Peter Verhoeven,[2] Sander W. Tas,[3] Abraham Rutgers,[4] Hein J. Bernelot moens,[5] Willem Jan W. Bos,[6] Yoe Kie Onno Teng.[1] Arthritis Research and Collaboration Hub *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Vasculitis Stichting, Maarssen, Netherlands; [3]Amsterdam UMC, location AMC, Amsterdam, Netherlands; [4]UMCG, Groningen, Netherlands; [5]Ziekenhuisgroep Twente, Hengelo, Netherlands; [6]St. Antonius Hospital, Nieuwegein, Netherlands.*

Background: Several guidelines have been published on the diagnosis and treatment of anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV). These guidelines provide an evidence-based approach to support clinical-decision making and adequate implementation is needed to improve care. As part of an implementation strategy, national consensus meetings in the Netherlands were initiated in order to establish consensus on broad aspects of the diagnosis and treatment of AAV based upon the recently published guidelines, relevant to daily clinical practice.

Methods: A national, multidisciplinary working group of physicians (nephrologists, rheumatologists, immunologists, pulmonologist, pathologist) with expertise on AAV addressed the broad spectrum of diagnosing, treating and organisation of care for AAV patients. Consensus was established using a Delphi-based method in a national conference in conjunction with a nationally distributed online consensus survey. This survey was distilled from the current published international guidelines. Cut-off for consensus was 70% (dis-)agreement.

Results: Ninety-eight professionals were involved in the Delphi procedure to assess consensus on 52 statements regarding diagnosis, treatment and organisation of care for AAV patients. From 52 statements, consensus was achieved for 39 statements (75%). Consensus was achieved on aspects of AAV disease definition, nomenclature, distinct disease states through follow-up, treatment algorithm and organisation of care for AAV. No consensus was achieved on the necessity of histopathological evidence, regular blood testing for ANCAs and standard BVAS, VDI and PROMs assessment.

Conclusions: This study describes the results of a national consensus statement on diagnosing and treatment of AAV patients as part of an implementation strategy in the Netherlands of (inter-)national guideline-derived recommendations. Future studies should evaluate whether the consensus statement has facilitated local implementation, reduced clinical practice variation and, ultimately, improved care for AAV patients in the Netherlands.

SA-PO658

A Proposal of a Stepwise Algorithm for Therapeutic Intervention Using a Modified EUVAS Classification

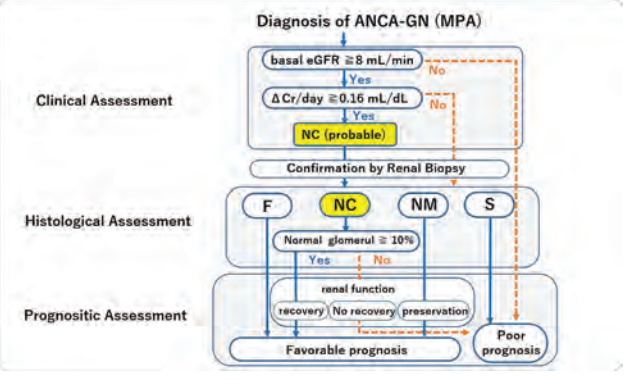
Takahisa Kobayashi,[1] Yayoi Ogawa,[2] Wako Yumura,[3] Kensuke Joh,[4] Daisuke Nagata.[1] *[1]Jichi Medical University, Shimotsuke, Japan; [2]Hokkaido Renal Pathology Center, Sapporo, Japan; [3]Tohoku Medical and Pharmaceutical University Hospital, Sendai, Japan; [4]The Jikei University School of Medicine, Tokyo, Japan.*

Background: Prediction of treatment's response is useful for minimizing the side effects of immunosuppression therapy for elderly patients. We proposed the Modified EUVAS histological classification of ANCA-associated glomerulonephritis (AAGN), in which New Crescent class (NC) was categorized by active crescents with more than 50% after eliminating a number of global sclerosis and the rest was categorized as New Mixed class (NM) (ASN2018). The purpose was to produce a stepwise algorithm consisting of clinical, histological, and prognostic assessments using the modified EUVAS classification.

Methods: The 51 patients with MPO-AAGN (male 45%, 68 +-9.1years old), who were followed more than 2 years were the cohort in the present retrospective study. All patients were treated according to the Japanese guideline (JSN 2011). In the clinical assessment, cut off values of basal eGFR and increases in sCr per day (ΔCr/day) predicting NC were decided using ROC analysis. In the second step, prognosis as well as treatment's response of each subclass of modified EUVAS classification was analyzed.

Results: F:NC:NM:S was 18:11:11:11, respectively. In clinical assessment, 8 mL/min of $eGFR_0$ and 0.16 mg/dL/day of ΔCr were cut off values for renal prognosis and estimation of NC, respectively. In subtype NC, the proportion of normal glomeruli more than 10% was valuable indicator for prediction of treatment response ($\Delta eGFR_{0\text{-}2}$). The renal function of NM was preserved without correlation with the proportion of normal glomeruli.

Conclusions: Patient with F or S will be treated conventionally. However, histological quantative assessment of NC and NM provides an idea of concrete immunosuppressant's therapy. Stepwise algorism consisting of clinical, histological and prognostic assessment as shown in Figure, is useful for minimizing the side effects of immunosuppression therapy for elderly patients.



Stepwise Algorithm using the modified EUVAS classification.

SA-PO659

Glucocorticoids for Remission Induction in Incident ANCA-Associated Vasculitis (AAV) Patients in Real-World Practice: High Exposure and Temporal Relationship to Adverse Events

Peter A. Rutherford, Dieter K. Goette. *Vifor Pharma, Glattbrugg, Switzerland.*

Background: Rapid induction of remission in AAV is desirable and typically includes high dose glucocorticoids (GC). While achieving remission is critical, patients are also at risk from GC-related adverse events (AEs) leading to long term organ damage as well as acute morbidity and mortality. This study examined GC prescribing, AAV response and AEs in incident AAV patients managed in routine clinical practice

Methods: 929 incident AAV patients from 4 European countries (399 physicians) were diagnosed between 2014-17 and data collected at baseline, 1, 3, 6 and 12 months following induction therapy start were reviewed

Results: 54% of patients had granulomatosis with polyangiitis, and 46% had microscopic polyangiitis; mean age was 56.82 years (SD 14.2) with 53.7% male. Physicians reported 12% patients as mild/localized, 54% as moderate systemic and 34%

as severe life threatening vasculitis. 83% of patients received GCs – 49% IV followed by oral, 17% oral only and 17% IV only. 43% used cyclophosphamide and GC, 13% rituximab and GC, 10% only GC with remainder using other regimes. As BVAS was not used, full clinical response was assessed as no vasculitis activity and GC taper on track. Most patients remained on GCs over 12 months, AAV response was incomplete and AEs were common especially in first 3 months when GC dose highest. Dose change practice varied and more UK patients had GC reductions at 3 (55%) and 6 months (46%) compared to other countries. At 12 months, of the 61% patients still receiving GCs, 34% were taking < 5mg, 56% 5-10mg, 9% 10-20mg and 2% > 20mg. 67% had no AAV activity, 17% local disease only, 11% mild/moderate systemic disease and 6% moderate/severe systemic disease

Conclusions: Most incident AAV patients receive high dose GCs, commonly IV, and most remain on GCs over 12 months. AEs and infections are common especially in the first months when GC dose is high. Remission is variable and only a minority of patients at 12 months have full control of AAV without steroids. New treatments are needed to address this unmet medical need

Funding: Commercial Support - Vifor Pharma

	1 month	3 months	6 months	12 months
Full response %	22	43	61	68
Still receiving GC %	82	79	67	61
Decrease/stop GC at visit %	38/1	45/4	38/5	26/8

SA-PO660

Maintenance Treatment in ANCA-Associated Vasculitis (AAV): Definition, Clinical Outcomes, and Significant Burden of Disease in Real-World Clinical Practice

Peter A. Rutherford, Dieter K. Goette. *Vifor Pharma, Glattbrugg, Switzerland.*

Background: After remission induction AAV is a relapsing remitting long term condition and patients are at risk of organ damage from both active AAV and therapy in particular glucocorticoids (GC). This maintenance phase of AAV is critical for good long term outcomes. This retrospective study examined the definition of maintenance, therapies and clinical outcomes in AAV patients in routine clinical practice.

Methods: AAV patients from 4 European countries (310 physicians) who completed induction therapy for organ/life threatening AAV and initiated maintenance therapy between 2014-16 were studied. Data were collected from when maintenance was determined to begin by the physician and at 6, 12, 18 and 36 months.

Results: 929 patients were studied - 51% had granulomatosis with polyangiitis, mean age 54 years with 54% male. 49% were incident AAV patients and 51% relapsing. Physicians defined maintenance beginning at mean of 5.6 months from induction start on basis of fixed time point 38%, starting of new drug for maintenance 27%, reaching full remission 26% and no specific criteria 9%. At this time 45% were in full remission vs 49% in partial and 6% refractory. Over 36 months after maintenance was defined, 84% were still in remission but 10% had major relapse requiring re-induction and left follow up, 6% died (2/3 at time of relapse). There is variation in maintenance drug regimes, initially in 929 patients GC 62%, Azathioprine 37%, Rituximab 19% and MMF 18%. At 36 months, 9% of AAV patients were receiving renal replacement therapy and CKD was reported as a comorbidity in 17% vs 7% at start of remission induction therapy.

Conclusions: Maintenance therapy in AAV is variably defined but typically 6 months after start of remission induction. Relapse severity varies and is still a problem and many patients require ongoing GC therapy to maintain remission. Infections and renal complications are an unmet need in AAV maintenance. There is a need for new targeted therapies in AAV to improve clinical outcomes in the maintenance phase.

Funding: Commercial Support - Vifor Pharma

SA-PO661

ANCA Response on Rituximab or Cyclophosphamide in ANCA-Associated Vasculitis Patients

Laura S. van Dam, Ebru Dirikgil, Edwin Bredewold, Ton J. Rabelink, Cees van Kooten, Yoe Kie Onno Teng. Lupus, Vasculitis and Complement Center of Expertise (LuVaCS) LUMC Leiden *LUMC, Leiden, Netherlands.*

Background: Recent studies have demonstrated that in patients with anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) with successful remission-induction (RI) after cyclophosphamide (CYC), maintenance treatment with ANCA-guided rituximab (RTX), improved relapse free survival (RFS). However, current recommended RI therapy is RTX, CYC or the combination. As yet it is unclear how these different RI therapies affect ANCA levels. Therefore, this study aimed to investigate the potential of RTX, CYC, or RTX+CYC to achieve an ANCA-negative status and its effect on RFS to further improve the insight on ANCA-guided treatment in AAV patients.

Methods: This retrospective cohort study involved 129 ANCA-positive AAV patients treated with 200 remission-induction regimens, including RTX (n=109), CYC (n=66), or RTX+CYC (n=25) between 1990 – 2018 with a mean follow-up of 328 weeks. ANCA serum levels and major RFS were assessed.

Results: Within 6 months, 23% of RTX-treated, 50% of CYC-treated and 40% of RTX+CYC-treated AAV patients achieved an ANCA-negative status (p=0.0001). Time to ANCA negativity was significantly shorter after CYC+/- RTX (mean±SD: 11±6 weeks) as compared to RTX (16±6 weeks; p=0.02). ANCA reappearance within 1 year after achieving ANCA negativity, occurred in 9 out of 31 (29%) RTX-treated, 17 out of 43 (39%) CYC-treated and 2 out of 12 (17%) RTX+CYC-treated patients (p=0.2), which happened significantly faster in CYC-treated patients at an average of 18 weeks as compared to RTX+/- CYC at an average of 30 weeks (p=0.003). Both 1yr and 2yr major RFS was significantly less for RTX-treated (86% and 68%) as compared to CYC-treated (97% and 91%) and RTX+CYC-treated patients (100%, 91%) (p=0.02, p=0.005). Overall, patients that reached an ANCA-negative status had a better 2yr-RFS. ANCA reappearance associated with major relapses in RTX-treated group (67% vs 0%; p=0.001) but not in CYC-treated group (12% vs 4%; p=0.38).

Conclusions: This study demonstrates that an ANCA-negative status was achieved more frequently and quicker with CYC +/- RTX as compared to RTX and associated with a better 2yr-RFS. ANCA reappearance was associated with relapses in RTX-treated patients but not in CYC-treated patients. Thus, monitoring ANCAs to guide tailored maintenance treatment is most relevant in RTX-treated AAV patients.

SA-PO662

Harmful Effects of Cyclophosphamide on Japanese Patients with Renal Vasculitis Associated with Myeloperoxidase-Antineutrophil Cytoplasmic Antibody-Positive Microscopic Polyangiitis

Izaya Nakaya,[1] Mizuho Morooka,[1,2] Kei Takahashi,[1,3] Yoshinori Tsuchiya,[3] Masashi Iwabuchi,[3] Jun Soma.[1] *[1]Department of Nephrology and Rheumatology, Iwate Prefectural Central Hospital, Morioka, Japan; [2]Department of Nephrology, National Hospital Organization Chiba-East-Hopsital, Chiba, Japan; [3]Department of Nephrology, JCHO Sendai Hospital, Sendai, Japan.*

Background: In Europe, combination of glucocorticoid (GC) and cyclophosphamide (CY) or rituximab is recommended as an induction therapy in patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis. However, many Japanese patients with myeloperoxidase (MPO)-ANCA-positive microscopic polyangiitis (MPA) are treated with only GC.

Methods: We retrospectively reviewed patients with newly diagnosed MPO-ANCA-positive MPA in two Japanese institutes between April 2000 and March 2017. Patients with serum creatinine levels > 5.0 mg/dL or those <20 years of age were excluded. Patients were divided into two groups based on whether they received combination therapy of GC plus CY (CY group), therapy with only GC, or GC plus other therapies excepting CY for remission induction (non-CY group). Primary endpoint was a combination of death and end-stage renal disease (ESRD). Pairwise 1:2 propensity-score matching was used to assemble a cohort of patients with similar baseline characteristics.

Results: Among 121 eligible patients, 27 [17 men (63.0%), average age 66.9 ± 10.2 (mean ± SD) years] were assigned to the CY group, whereas 54 [32 men (59.3%), average age 67.0 ± 14.7 years] were assigned to the non-CY group. Both groups had similar propensity scores. In the CY group, 22 patients were treated with oral CY and five with intravenous CY. In the non-CY group, 42 patients were treated with GC alone and 12 with a combination of GC and other therapeutics, including intravenous immunoglobulin, mizoribine, and lymphocyte apheresis. No patient was treated with rituximab. Fifteen primary endpoints (8 deaths and 7 ESRDs) occurred in the CY group, whereas 14 (10 deaths and 4 ESRDs) occurred in the non-CY group. The 1- and 5-year survival rates were 0.89 and 0.60 in the CY group and 0.93 and 0.79 in the non-CY group (p = 0.039), respectively. Hazard ratio in the CY group was 2.14 (95% confidential interval, 1.02–4.52) as compared with the non-CY group.

Conclusions: Induction therapy with CY increased the risk of death and ESRD by 114% as compared with therapy without CY in Japanese patients with renal vasculitis associated with MPO-ANCA-positive MPA. Therefore, CY should not be used for induction therapy in these patients.

SA-PO663

The Use of Rituximab in ANCA-Negative Pauci-Immune Small Vessel Vasculitis: A Comparative Analysis

Adam Morris, Mohamed Elsayed, Lauren Floyd, Mark Brady, Arvind Ponnusamy, Ajay P. Dhaygude. *Renal Medicine, Royal Preston Hospital, Lancashire NHS Foundation Trust, Preston, United Kingdom.*

Background: Rituximab has been established as an effective treatment strategy for induction-remission of ANCA associated vasculitis, although little is known about its use in the absence of detectable circulating ANCA with respect to its accepted mechanism of action. Due the rare nature of the disease and even smaller subcategory of patients with ANCA negative disease, trials in this area are likely to be challenging. This study aims to determine the treatment outcomes of rituximab as induction therapy in ANCA negative disease.

Methods: A cohort of patients treated with rituximab for induction-remission of pauci-immune small vessel vasculitis was constructed from a single centre between 2006-2018 and followed up until May 2019. Multivariate Cox regression was used to compare treatment outcomes of rituximab between patients with or without detectable circulating ANCA. Primary study outcomes were patient survival, renal survival and disease remission.

Results: 58 patients with active disease who required treatment with rituximab were identified. Mean age was 59±14 with a male predominance of 53%. 29% (n=17) had ANCA negative disease at the time of treatment. The overall remission rate irrespective

of ANCA serology was 91% (n=53), with a relapse rate of 23% (n=12). On comparative multivariate analysis, ANCA negative disease was not associated with a lower likelihood of remission [HR 0.6 (95% CI 0.19 - 1.85)]. There was no significant difference in subsequent relapse rates between ANCA positive and ANCA negative patients; 21% vs. 27%, respectively (p=0.67). Moreover, the risk of death [HR 2.65 (95% CI 0.32 – 21.76)] and ESRD [HR 0.25 (95% CI 0.03 – 2.04)] were similar between the two groups. Adverse events did not differ between the two groups (p=0.96).

Conclusions: Our centre experience suggests that the use of rituximab is an effective treatment for induction-remission of ANCA negative pauci-immune small vessel vasculitis. To our knowledge, this is the largest cohort analysis of rituximab therapy in seronegative disease reported to date.

SA-PO664

Rituximab-Associated Hypogammaglobulinemia in ANCA Vasculitis: Incidence and Time Course

Anam Tariq, Ayobami Akenroye, Antoine Azar, Philip Seo, Eric J. Gapud, Duvuru Geetha. *Johns Hopkins University, Baltimore, MD.*

Background: Rituximab (RTX) is approved for remission induction (I) and maintenance (M) in ANCA vasculitis (AAV). RTX depletes B cells that express CD20 but does not affect B cell precursors or antibody producing plasma cells. Persistent production of protective antibodies and replenishment of peripheral B cells by B cell precursors renders RTX a relatively safe and effective treatment option. However, several observational studies have demonstrated a decline in serum immunoglobulin (IgG) in AAV patients treated with RTX. We evaluated the risk of hypogammaglobulinemia (Hypo-IgG) among RTX-treated AAV patients.

Methods: AAV patients treated with RTX were included in this single-center observational study. Demographics, clinical and post RTX IgG levels were extracted and analyzed. Severity of Hypo-IgG was defined as mild (501-700mg/dL), moderate (301-500mg/dL), and severe (≤300mg/dL). Descriptive data are presented as mean with SD and median with IQR.

Results: Between 2013 to 2018, we investigated 105 RTX treated AAV patients, with mean (SD) age 56 (16) years, 84% Caucasians, 57% females and 64% diagnosed with Granulomatosis with Polyangiitis. Post RTX IgG were measured in 74 patients of which 50 had repeat IgG. 27 patients received RTX for remission I, 8 for remission M and the remainder received RTX for remission I and M. Hypo-IgG occurred in 43 (58%) patients and 19 (44%) had moderate to severe hypo-IgG. Overall, IgG remained stable over time (Figure). Of the 50 patients with repeat IgG, 11 (36%) had moderate to severe hypo-IgG. Infections requiring hospitalization occurred in 10 patients with hypo-IgG.

Conclusions: Hypo-IgG is common in RTX treated AAV patients. Although limited by sample size, IgG trend suggests that nadir IgG levels occur during I dosing and the IgG levels remain stable or increase over time in those receiving M.

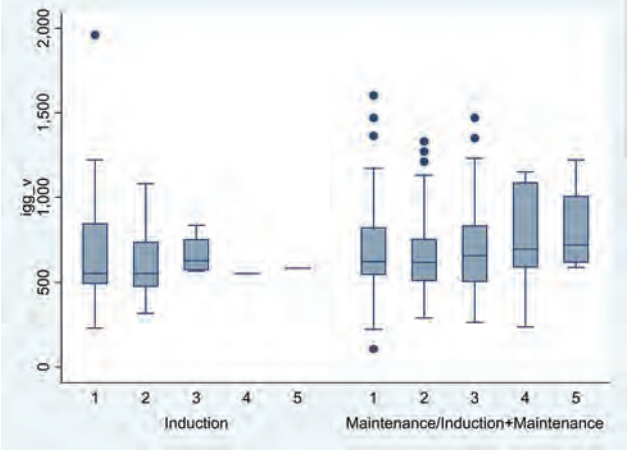

Figure: IgG levels over time in patients receiving induction and continous Rituximab

The Factors for Maintenance of B Cell Depletion After Use of Rituximab in Renal Disorders

Binfeng Yu, Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: The duration of B-cell depletion(BCD) after rituximab administration may be related to the disease recurrence. We aimed to explore the factors which may influence the duration of BCD(CD19 positive B cell count<5/μL) after the use of rituximab in patients with kidney diseases.

Methods: Patients received rituximab for renal causes and were regularly monitored every 2-3 months on B cell counts were enrolled. Prognostic factors for maintenance of BCD were identified through Cox proportional hazards model where the optimal cutoff values were determined using an online statistical tool Cutoff Finder.

Results: There were 47 patients who received a median of 900mg (range,300-1500mg) of rituximab with 100% achieving BCD and 49% experiencing B cell reconstitution during follow-up. The optimal cutoff value of dose to body-surface-area ratio (DBR) was 529.5mg/m^2 in total and that of circulating T helper (Th) cell count was 978.5/μL. In multivariate analyses, high DBR(>529.5mg/m^2) was identified as an independent protective factor (HR0.42,p=0.024) and high circulating Th cell count (>978.5/μL) was identified as an independent risk factor (HR2.98,p=0.037) for maintenance of BCD. High Th cell count (>978.5/μL) was also associated with manifestation of nephrotic syndrome, increased CD19 positive B cell counts and T killer cell counts.

Conclusions: DBR and Th cell counts were of predictive values for maintenance of BCD after use of rituximab in patients with renal disorders.

The Short-Time Efficacy and Safety of Immunoadsorption onto Protein A, Compared with Plasma Exchange, in the Treatment of Severe Immunological Nephropathy

Xiaoxin Chu, Gang Xu, Rui Zeng. *Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: The efficacy and safety of immunoadsorption onto protein A (IA), compared to plasma exchange (PE), in the treatment of severe anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV) and lupus nephritis (LN), are few reported.

Methods: The clinical data of 42 patients with severe immunological nephropathy, including 21 treated with IA from Nov 1, 2016 to Nov 31, 2018 and 21 treated with plasma exchange (PE) from Nov 1, 2014 to Nov 31, 2018 in our hospital were retrospectively analyzed. IA or PE was combined glucocorticoid, with or without immunosuppressant regimen as induction immunosuppression. IA was performed 10 cycles every time and was done 3-7 times. PE was performed 3-6 times with plasma and albumin. All the patients were followed up prospectively for 3 months.

Results: In AAV patients, Hb, PLT, Glb, SCr, IgA, IgG, IgM, C3, C4, Fg and BVAS were significantly decreased after IA treatment, $P<0.05$. The decline of ANCA and IgG were 46.11% and 53.76% after the first time IA treatment. After the 3-7 times IA treatment, ANCA and IgG decreased by 82.48%, 77.81%, respectively. In LN patients, Glb, SCr, IgA, IgG, IgM, Fg and SLEDAI-2k were significantly lower after IA treatment, $P<0.05$, while eGFR was increased, $P<0.05$. After IA treatment, the reduction rates of anti-dsDNA Ab and IgG were 72.14%, 44.31%, respectively. There was no significant change in PT and INR in IA group, but in PE group PT and INR were longer than that before treatment, $P<0.05$. The Fg decline in IA and PE group were 46.74±25.32%, 66.01±13.98%, respectively, $P<0.05$. There were 4 patients in the PE group who were transfused with cryoprecipitate due to

poor coagulation function but no one in IA group, *P*<0.05. The main adverse event of IA treatment is hypotension during processes, but for PE treatment is allergies, manifested as rashes. There was no difference in the incidence of adverse events, *P*>0.05. After 3 month follow-up, albumin in IA group was higher than that in PE group, *P*<0.05.

Conclusions: IA combined with glucocorticoid, with or without immunosuppressant, resulted in similar rapid removement of pathogenic autoantibodies and similar rapid improvement of renal function as PE did in the short term, but IA treatment induced less coagulation disorders, which potentially decreased the risk for bleeding, compared to PE treatment.

SA-PO667

Rescue Therapy with Extracorporeal Membrane Oxygenation (ECMO) for Diffuse Alveolar Haemorrhage in Patients with Systemic Vasculitis

Jorge Jesus Silva, Ricky Bell, Peter S. Topham, Reem Al-Jayyousi. *John Walls Renal Unit, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

Background: Diffuse alveolar haemorrhage (DAH) is a life threatening condition and common causes include autoimmune diseases, infections and medications among others. DAH is a severe manifestation of systemic vasculitis, particularly in patients with ANCA and anti-GBM antibodies. This is mediated through inflammation, occupation and destruction of the alveoli. In extreme cases, even mechanical ventilation is ineffective and ECMO is required to oxygenate the blood whilst the immunosuppressive treatment takes effect.

Methods: We performed a retrospective review of the patients with confirmed DAH which required ECMO at our centre between 01/2016 and 04/2019. Each case was reviewed and we assessed baseline characteristics, cause of vasculitis, duration of ECMO, immunosuppressive therapies used, renal outcome and mortality.

Results: 8 patients met the inclusion criteria making this the largest single centre case series to date of patients with DAH requiring ECMO. 6 patients were female and 2 male with a median age of 42.5 years. 6 patients had ANCA associated vasculitis (5 PR3, 1 MPO), 1 had systemic lupus erythematosus (SLE) and 1 was ANCA and anti-GBM negative. After commencing ECMO, 7 patients survived; of those 4 received IV cyclophosphamide, and 5 received rituximab; all had IV methylprednisolone and plasmapheresis (PLEX). 6 of the 8 patients presented AKI and 5 required continuous renal replacement therapy (CRRT); at discharge 5 patients had renal recovery with a GFR back to baseline.

Conclusions: The majority of cases with catastrophic DAH are related to AAV and in those failing invasive mechanical ventilation, ECMO would appear to be a valid rescue therapy with good overall outcomes. Immunosuppression with IV CYC and/or IV RTX appears to be safe and effective in this setting. Despite a high incidence of AKI requiring RRT, the majority of patients achieved renal recovery.

Gender	Age	Aetiology	Days ECMO	CRRT	Immunosuppression	PLEX sessions	ICU length of stay	Renal recovery	Survival
M	47	AAV	7	Yes	MPDN + CYC	7	21	Yes	Yes
M	48	AAV	7	Yes	MPDN + RTX	7	14	No	Yes
F	24	SLE	4	No	MPDN	3	5	No	No
F	36	MAHA	6	Yes	MPDN + RTX	7	13	Yes	Yes
F	38	AAV	5	No	MPDN + CYC	7	13	Yes	Yes
F	34	AAV	4	No	MPDN + RTX	7	10	Yes	Yes
F	63	AAV	10	Yes	MPDN + CYC + RTX	7	23	No	Yes
F	50	AAV	5	Yes	MPDN + CYC + RTX	7	11	Yes	Yes

Clinical Features and Outcomes in Anti-Glomerular Basement Membrane Glomerulonephritis Patients with Onset of Noninfectious Fever

Xiaoxiao Shi, Lei Xu, Huanhuan Yin, Yu bing Wen, Xuemei Li, Limeng Chen. *Department of Nephrology, Chinese Academy of Medical Sciences & Peking Union Medical College Hospital, Beijing, China.*

Background: To summarize the clinical features and outcomes of anti-glomerular basement membrane (anti-GBM) glomerulonephritis (GN) with onset of non-infectious fever.

Methods: We retrospectively reviewed the clinical records and follow-up data of 58 patients with anti-GBM GN in our hospital from May 2010 to May 2019.

Results: Among the 58 anti-GBM GN patients, 39 patients (67.2%) presented with fever initially. After careful screening of serological and urinary tests, pathogenic cultures, and CT scans, 28 (48.3%) patients had no evidence of infections. These non-infectious febrile patients had a female/male ratio of 1.3:1, and the average age was 46±18 years old. Six (21.4%) patients were complicated with pulmonary hemorrhage. Compared to the non-febrile anti-GBM GN patients (n=19), they showed higher CRP levels (65.4 vs. 24.5 mg/L, *P*=0.045) and higher anti-GBM antibody titers (175±41 vs. 132±62 EU/ml, *P*=0.012). In kidney, they presented milder proteinuria (2.51±2.51 vs. 4.69±2.41 g/d, *P*=0.016), despite similar serum creatinine (906±414 vs. 995±604 μmol/L) and eGFR (4.66 vs. 4.40 mL/min/1.73m^2) levels (*P*>0.05). Crescentic GN was diagnosed in 11 (84.6%) of 13 patients who had renal biopsy. At onset, 82.1% patients were treated by antibiotics which didn't work. All patients received immunosuppressive treatment later, and 26 of them had combined plasma exchange therapy. They received more plasma exchanges (7.2±3.9 vs. 4.0±3.5, *P*=0.006) and had a longer hospital stay (42±21 vs. 29±15 days, *P*=0.020) compared to the non-febrile group. During follow-up, the renal survival rate at 1, 3 and 5 year was 20.8%, 13.6% and 10.0%, which were similar with the non-febrile group (18.8%, 7.1%, 0%) (*P*>0.05). Among all the 58 anti-GBM GN patients, Kaplan-Meier survival analysis showed that oliguria, pulmonary hemorrhage, initial eGFR, and anti-GBM antibody titers were prognostic factors for renal outcome (*P*<0.05), but fever was not a predictor of it. Multivariate Cox regression analysis showed higher initial eGFR was an independent risk factor for ESRD (RR=0.80, 95%CI (0.69, 0.93), *P*=0.004).

Conclusions: Fever in anti-GBM GN may be part of systemic inflammations instead of infections. Anti-GBM GN patients with onset of non-infectious fever presented more severe systemic inflammations and needed more intensive treatment.

SA-PO669

Anti-Glomerular Basement Membrane Disease: A Real-World Experience

Jennifer Scott,[1] Zdenka Hruskova,[2] Sarah Van der laan,[1] Julio L. Chevarria,[1] Avi Z. Rosenberg,[3] Lenka Bartonova,[4] Doubravka Frausova,[4] Mark A. Little,[1] Duvuru Geetha.[5] *[1]Trinity Health Kidney Centre, Dublin, Ireland; [2]Department of Nephrology, General University Hospital and First Faculty of Medicine, Charles University, Prague 2, Czechia; [3]Johns Hopkins University, Baltimore, MD; [4]Charles University, Prague, Czech Republic, Prague, Czechia; [5]John Hopkins Bayview Medical Center, Baltimore, MD.*

Background: Anti-glomerular basement membrane (Anti-GBM) disease is associated with deleterious renal outcomes, with the majority of patients remaining dialysis dependent. There is a paucity of evidence regarding optimal treatment and factors predicting outcomes in this cohort. We aim to describe our real-world experience and evaluate factors associated with end-stage renal disease (ESRD).

Methods: A multi-centre, retrospective cohort study was performed using existing databases from 3 centers in Ireland, Czech Republic and North America (N= 52). All patients, recruited between 1998-2018, had biopsy proven Anti-GBM disease. We describe the clinical characteristics and evaluate factors associated with ESRD using chi-square and independent sample t-tests.

Results: 48 (92%) were Caucasian and 33 (64%) female, with a mean (SD) age of 58 (16) years. Table 1 depicts baseline characteristics for the total cohort stratified for presence of ESRD. 43 (83%) required renal replacement therapy (RRT) at presentation and 22 (42%) displayed ANCA positivity. Patients reaching ESRD had higher need for RRT at entry, were more often ANCA negative and had a lower percentage of normal glomeruli compared to those who did not. Overall, renal recovery occurred in 14 (33%), over a median follow-up of 39 months (IQR 79.5).

Conclusions: The need for RRT at diagnosis, ANCA negativity and a lower percentage of normal glomeruli are associated with an increased trend towards ESRD. Renal recovery occurred in 1/3 of patients, suggesting a possible beneficial role in modulating acute renal inflammation, even with apparent poor prognostic features. Individualization of treatment, stratified by prognostic factors is paramount and requires larger scale collaborative studies to explore this further.

Variable	ESRD Yes (n = 31)	ESRD No (n = 21)	p value
Female (%)	51	48	0.12
RRT requirement at diagnosis (%)	72	28	0.0001
Alveolar haemorrhage (%)	47	53	0.23
eGFR (MDRD) at diagnosis, ml/min/1.73m2 (SD)	7 (6)	14 (15)	0.06
ANCA negative (%)	70	30	0.08
Percentage normal glomeruli (SD)	5 (8)	15 (22)	0.05
Crescentic Berden class (%)	67	33	0.07
Immunosuppression use (%)	58	42	0.24
Plasmapheresis use (%)	60	40	0.89

SA-PO670

Intravenous Cyclophosphamide for Treatment of Anti-GBM Disease

Nathan R. Lorde,[1] Fiona E. Harris,[1] Marie B. Condon,[3] Bhrigu Raj Sood,[1] David Makanjuola.[2] *[1]Epsom and St Helier University Hospitals NHS Trust, Sutton, United Kingdom; [2]St. Helier Hospital, Carshalton, United Kingdom; [3]Imperial College Healthcare, Surrey, United Kingdom.*

Background: Anti-GBM disease is a condition caused by antibodies to type IV collagen. We report a single centre experience of the use of pulsed intravenous cyclophosphamide (IV Cyc), steroids and plasma exchange (PEX) for induction treatment. There is a paucity of data on the use of IV Cyc for induction. Standard therapy involves daily oral cyclophosphamide.

Methods: Retrospective review of patient records from Jan 2006 to Dec 2018. Primary aim was to compare the outcomes of our treatment regimen on mortality and preservation of renal function with published outcomes.

Results: 33 patients were identified. Complete data was not available in 4. Of the remaining 29, 24 had renal disease, 2 had pulmonary disease and 3 had both renal and pulmonary involvement. Iv Cyclophosphamide was dosed adjusted for age and renal function. Maintenance was predominantly with steroids and Azathioprine. The median age was 67 years (range 17-86), 41% were female. Plasma exchange was done in 25 patients who received between 4 and 25 sessions. 14 patients were dialysis dependent at presentation. Renal survival was 10% in dialysis dependent patients and in those who did not require dialysis, it was 75%. Patient survival was 90% at 1-year for treated patients. 8 out of 29 patients were deemed too frail to receive induction therapy. 14 of 27 (52%) with renal involvement required dialysis at the time of discharge after their first presentation. 3 of the 13 dialysis independent patients later went on to require dialysis.

Conclusions: Published data suggests 1 year patient survival of 87 to 100% and 1 year renal survival of 94% in those with creatinine < 500 umol/[1-3]. Our cohort had higher proportion of patients who were dialysis dependent at presentation. Our data suggest that pulsed intravenous cyclophosphamide is as effective a therapy as oral cyclophosphamide with comparable outcomes at 1 year. This may make it a suitable option when consideration to cumulative dose exposure is made. As it is a rare disease further collaborative prospective study with other centres will likely be needed. 1. Therapy and Outcome of Anti-Glomerular Basement Membrane Disease: A Single-Center Experience

Ping Lan, Liyi Xie. *Department of Nephrology, Kidney Hospital, the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: Patients with anti-glomerular basement membrane (GBM) disease are at high risk of morbidity and mortality from renal failure or severe complications. Reviews revealed one-third patients have circulating anti-neutrophil cytoplasmic antibodies (ANCA). Phospholipase A_2 receptor (PLA_2R) antibody can also be positive. The aim of this study was to analyze the therapy differences of patient and renal outcomes in anti-GBM disease with or without ANCA or PLA_2R antibody.

Methods: We screened the patients from December 2014 to April 2019 in the First Affiliated Hospital of Xi'an Jiaotong University. The patients with anti-GBM disease were reviewed. Renal biopsies were scored for the presence of active and chronic lesions. The correlation between survival with clinical characteristics and regimens were analyzed.

Results: A total of 40 patients (18 M/ 22 F) were identified with anti-GBM glomerulonephritis. The average age was 57.4±16.8 years old. The duration of symptoms before diagnosing was 1.3±1.5 months. 35 patients (87.5%) presented with rapidly progressive glomerulonephritis. The SCr level was 10.0±5.2 mg/dL. Serological screening showed anti-GBM antibody titer 180.2±87.4 RU/mL, 11 cases with ANCA positivity (27.5%, 10 cases of pANCA-MPO, 1 case of cANCA-PR3), 5 cases with PLA_2R antibody positivity (12.5%). 23 patients accepted renal biopsy. 82.6% were compatible with crescentic glomerulonephritis. 30 patients (75%) received Plasmapheresis (PE). The patients were followed up for 9.98±10.5 months (range 0.5-28.5 months). Except 3 cases lost data and 14 death, 14 patients underwent maintenance hemodialysis, 2 patients underwent peritoneal dialysis, 3 cases had kidney transplantation, renal function recovered in 4 cases and 4 cases to chronic kidney disease. Multivariate Cox regression revealed female (hazard ratio [HR], 3.21; 95% confidence interval [95% CI], 1.41 to 7.30; *P*=0.005) and regimen with PE (HR, 2.89; 95% CI, 1.32 to6.35; *P*=0.008) were independent predictors of survival. SCr >6mg/dL was a risk factor for the ESRD and all-cause mortality.

Conclusions: Unlike previous data, our study shows that 55% of the patients with anti-GBM disease were female (considered a district bias). Multivariate analysis reveals female and PE therapy are predictors of renal and patient survival while high SCr (>6mg/dL) is associated with poor renal outcome and high risk of all-cause mortality.

Predictors of Kidney Function Recovery in Glomerular Disease After Dialysis Initiation

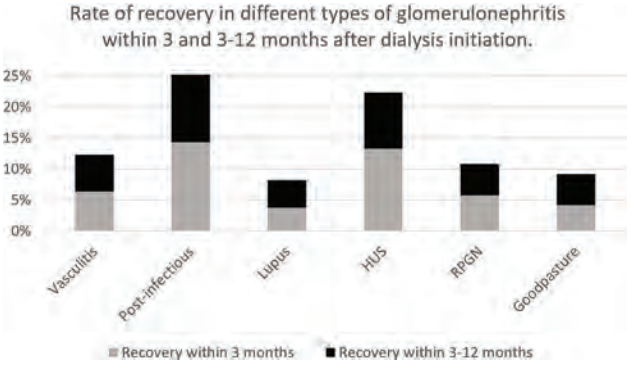
Mohammad Kazem Fallahzadeh Abarghouei, Raymond K. Hsu, Kathleen D. Liu, Delphine S. Tuot, Charles E. McCulloch, Elaine Ku. *University of California San Francisco, San Francisco, CA.*

Background: Many patients with glomerulonephritis (GN) may require dialysis acutely, but the proportion of patients who recover kidney function has not been well-described. We examined characteristics of patients with GN who initiated outpatient dialysis and recovered sufficient function to become dialysis independent as well as trends in rates of recovery by GN type over time.

Methods: We performed a retrospective cohort study of adults ≥18 years who initiated outpatient dialysis between 1995-2015 and had a GN as cause of ESKD according to the USRDS. We defined recovery as a 60-day dialysis-free period and alive for at least 90 days after stopping dialysis within one year of dialysis initiation. We used adjusted Cox models to examine predictors of recovery.

Results: Of 173,348 patients, 4.6% recovered renal function and 13.3% died within one year after dialysis initiation. Recovery within the first 90 days of dialysis initiation was most likely among those with post-infectious GN or hemolytic uremic syndrome (HUS) [Figure]. Younger age, female gender, non-Hispanic white race, and having post-infectious, lupus and vasculitis as the cause of ESKD were associated with higher odds of recovery [Table].

Conclusions: Nearly one in four patients who initiated outpatient dialysis due to post-infectious and HUS diagnoses recovered kidney function within one year. Close follow-up after dialysis initiation is warranted.



Odds of kidney function recovery in adjusted model.

Predictors of Treatment Resistance and Relapse in Childhood-Onset ANCA-Associated Vasculitis: A Nationwide Japanese Survey

Daishi Hirano,[1] Tomoaki Ishikawa,[3] Mai Sato,[2] Aya Inaba,[5] Shuichi Ito.[4] *[1]The Jikei university school of medicine, Tokyo, Japan; [2]National Center for Child Health and Developement, Tokyo, Japan; [3]Nara Medical Universtty, Nara, Japan; [4]Department of Pediatrics, Graduate School of Medicine, Yokohama City University, Yokohama, Japan; [5]Yokohama City University Medical Center, Yokohama, Japan.*

Background: Treatment resistance and relapse in childhood-onset antineutrophil cytoplasmic antibody (ANCA)–associated vasculitis (AAV) are major challenges for pediatricians. The aim of this study was to assess the predictive factors for treatment resistance and relapse in a nationwide cohort of Japanese patients with childhood-onset AAV.

Methods: Forty-five consecutive patients with childhood-onset AAV were recruited for inclusion in this study. The value of various demographic and clinical parameters for the prediction of treatment resistance and relapse were analyzed.

Results: The cohort consisted of 45 children; 34 (76%) were female, 36 (80%) had MPA, 9 (20%) had GPA, 78% were MPO-ANCA-positive, 20% were PR3-ANCA-positive. After the induction phase treatment, treatment resistance occurred in 20 (44%). Multivariable logistic regression models revealed that decreased estimated glomerular filtration rate (eGFR) at presentation predicted treatment resistance (odds ratio [OR] 30.71, 95% confidence interval [95% CI] 2.30-410.43, P = 0.010). Relapse occurred in 14 (31%) of 45 patients in whom remission was achieved and was independently associated with PR3-ANCA (OR 6.95, 95% CI 1.05-46.04, P = 0.044). Although not significant, male tended to be associated with relapse (p = 0.05).

Conclusions: Our findings highlight the important effect of severity of renal disease at presentation as predictors of treatment resistance. Increased risk for relapse appears to be related to the presence of anti-PR3 antibody seropositivity.

SA-PO674

The Role of TNFα/TNF Receptor 2 Pathway Activation in the Modulation of Childhood Nephrotic Syndrome

Dor Fisher,[1] Michal Herman-Edelstein,[2] Miriam Davidovits.[1] *[1]Nephrology, Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [2]Felsenstein Medical Research Center and Department of Nephrology, Rabin Medical Center, Petah Tikva, Israel.*

Background: Primary Nephrotic Syndrome (NS) is considered T cell pathology; however, the pathogenesis still remains poorly defined. There is increasing evidence pointing to the important role of tumor necrosis factor-alpha (TNFα), a key inflammatory mediator, in pediatric nephrotic syndrome. We recently showed that elevated serum TNFα levels were associated with worse prognosis and lack of response to corticosteroids in children with NS. TNFα exerts its biological effect via interaction with two main cell surface receptors: tumor necrosis factor receptor 1 (TNFR1), and tumor necrosis factor receptor 2 (TNFR2), that contribute differently to glomerular inflammation. The aim of the present study was to investigate the expression and the role of different TNFα receptors and TNFα signaling pathways in kidney biopsies of children with steroid responsive and steroid resistant nephrotic syndrome.

Methods: TNFα and TNFα receptors expression were studied by immunofluorescence staining and RNA isolation from formalin-fixed, paraffin-embedded (FFPE) renal biopsies of children with nephrotic syndrome who were treated in our department (n=40) versus normal kidneys (n=12).

Results: TNFα and TNFR2 expression was significantly elevated in both children with steroid sensitive and resistant nephrotic syndrome, versus control group. Furthermore, TNF protein and mRNA abundancey were increased in steroid resistant nephrotic syndrome kidneys compared with steroid sensitive nephrotic syndrome kidneys. TNFα and TNFR2 but not TNFR1 expression positively correlated with steroid resistance and disease progression. In addition, TNFα signaling proteins (TRAF1, TRAF2, CCL2, CCL4, CCL10, CCL11, MMP2, MMP9, TIMP1, ADAM17, IL1b, IL6 and others) were also increased in children with NS and predicted prognosis and steroid responsivness.

Conclusions: As yet there is little information regarding the pathogenesis and optimal treatment of pediatric nephrotic syndrome, our results may indicate that TNFα pathway has a role in the pathogenesis of steroid resistant nephrotic syndrome, and may serve as a target for future therapy.

SA-PO675

Efficacy of a Gluten-Free Diet (GFD) in Children with Difficult-to-Manage Nephrotic Syndrome (NS)

Howard Trachtman,[1] Laura Jane Pehrson,[2] Suzanne M. Vento,[7] Laura Malaga-Dieguez,[11] Debbie S. Gipson,[3] Kevin V. Lemley,[4] Katherine M. Dell,[8] Tarak Srivastava,[5] Frederick J. Kaskel,[9] Kevin E. Meyers,[10] Christian Faul.[6] *[1]NYU Langone Health, New York, NY; [2]NYU School of Medicine, New York, NY; [3]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [4]Childrens Hospital Los Angeles, Pasadena, CA; [5]Childrens's Mercy Hospital, Kansas City, MO; [6]The University of Alabama at Birmingham, Birmingham, AL; [7]NYU Langone Medical Center, New York, NY; [8]Cleveland Clinic Children's, Cleveland, OH; [9]Children's Hospital at Montefiore, Bronx, NY; [10]The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [11]New York University School of Medicine, New York, NY.*

Background: Zonulin (ZON) increases gut permeability after exposure to gliadin in children with celiac disease. Plasma zonulin levels are increased in children with NS. Protease activated receptor-2, which mediates ZON effect in enterocytes, is present on podocytes. Thus, gluten-induced elevations in ZON may affect glomerular permeability and mediate proteinuria in children with NS. We conducted this study to assess the efficacy of a GFD in controlling disease in children with difficult-to-manage NS.

Methods: This multicenter, open-label trial tested the efficacy of a GFD in children with steroid-responsive, difficult-to-manage NS. The Treatment Period was 6 months. A positive response was defined as ≥50% reduction in relapse rate versus the prior 6 months or discontinuation of ≥1 immunosuppressive medication. The following data were tabulated: age, gender, race/ethnicity, serum creatinine, proteinuria, histopathology if available, and treatment. Serum was collected prior to and at completion of the Treatment Period to assess the effect on the glomerular cytoskeleton in vitro. Data are provided as mean±SD.

Results: 14 children (8F:6M) were enrolled, age 7.8±4.6 yr, baseline serum creatinine 0.46±0.12 mg/dl, and Up/c 0.45±0.49 (mg:mg). There were 11 Whites, 1 Black and 3 other racial groups and 2 children were Hispanic/Latino. The underlying disease was MCD in 10 and FSGS in 4 cases. At the end of the Treatment Period, 4 participants had a positive response (2 reduced relapse rate and 2 reduced medication burden), 5 had no benefit (2 withdrew before 6 months), 3 patients are in the 6-month Treatment Period, and 1 child was lost to follow-up. One adolescent had no change in relapse rate but responded to corticosteroids more rapidly on the GFD. Baseline plasma zonulin concentration was 19.4±1.7 vs 13.4±0.9 pg/mL in non-responders (n=4) vs GFD responders (n=2), respectively, P=0.01.

Conclusions: Up to a third of patients with difficult-to-manage NS have a favorable response to implementation of a GFD. An elevated plasma zonulin level may predict a poor response to the maneuver. A trial of this dietary intervention may be warranted in children with frequently relapsing or steroid dependent NS to minimize the need for immunosuppressive agents.

SA-PO676

Unbiased Transcriptional Analysis of the Nail-Patella-Like Renal Disease Inducing LMX1B R246Q Variant Reveals Dysregulation of Several Genes Critical to Homeostasis of Podocytes and the Glomerular Basement Membrane

Brandon M. Lane,[1,3] Gentzon Hall,[2,3] Guanghong Wu,[1,3] Megan Chryst-Stangl,[1,3] Robert F. Spurney,[2] Rasheed A. Gbadegesin.[1,3] *[1]Pediatrics, Duke University School of Medicine, Durham, NC; [2]Medicine, Duke University School of Medicine, Durham, NC; [3]Duke Molecular Physiology Institute, Durham, NC.*

Background: While most genetic variants in LIM Homeobox Transcription Factor 1 Beta (*LMX1B)* are associated with the development of Nail Patella Syndrome, select variants such as *R246Q* produce renal limited phenotypes known as Nail Patella Like Renal Disease (NPLRD). Using a targeted analysis of key podocyte genes, we have previously identified several candidates that are downregulated by *R246Q* in cultured human podocytes. However, a more comprehensive transcriptional analysis is needed to understand the pathological mechanisms driving kidney specific disease development in NPLRD patients and to identify possible theraputic targets.

Methods: Differentiated conditionally immortalized human podocytes cell lines stably overexpressing equivalent levels of wild type *LMX1B* or the *R246Q* variant were analyzed using Illumina RNAseq technology.

Results: The analysis of *LMX1B R246Q* revealed significant reductions in genes that have been previously implicated in renal disease, including *SULF1* and *CLIC5*, (fold changes of -7.6, and -7.1 respectively). These genes as well as *FIBIN* (-24.1), *COL3A1* (-4.6), *ODAM* (-5.3), *TNIP3* (-5.2), *PRKG2* (-5.0), *RGS5* (-3.3), *ADRA1D* (-3.1), and *CDH11* (-2.8) were the most highly downregulated targets by the *R246Q* variant in a kidney focused analysis of the data. The most highly upregulated genes include *ANKHD1* (2.9), *CCL2* (2.1), *C8ORF4* (2.1), *ST14* (2.0), *MMP9* (1.7), *MMP2* (1.7), *MMP7* (1.7), and *CSF2* (1.7). A kidney focused pathway analysis of the transcriptional data in this study revealed that Matrix Metalloproteinase (MMP) inhibition was the top candidate pathway affected.

Conclusions: While downregulation of key podocyte genes was observed in the transcriptional analysis of *LMX1B R246Q*, the milieu of affected genes suggest additional pathogenic mechanisms may exist. The upregulation of *MMP* genes as well as a downregulation of critical basement membrane genes including *SULF1* and *COL3A1* suggests that glomerular basement membrane (GBM) modification is a key component of *R246Q* mediated renal disease.

CD44 Isoform Status Predicts Response to Treatment in Childhood Nephrotic Syndrome

Michal Herman-Edelstein,[1] Dor Fisher,[2] Benaya Rozen-zvi,[1] Miriam Davidovits.[3] *[1]Nephrology, Rabin Medical Center, Ramat-Gan, Israel; [2]Nephrology, schneider children's medical center, Ramat-Gan, Israel; [3]Schneider Children's Medical Center of Israel, Petah Tiqva, Israel.*

Background: Standard CD44 (sCD44) and variant (vCD44) isoforms are hyaluronic receptors, known as stem cell markers that play a role in stem cell activation, migration, and shaping of extracellular matrix and fibrosis. De-novo expression of CD44 is a marker of activated glomerular parietal cells (PECs), which predicts the development of focal segmental glomerulosclerosis (FSGS). Upregulation of CD44 in nephrotic syndrome (NS) has been linked to poor prognosis in minimal-change disease (MCD) and has been shown to be an early marker of glomerular sclerosis prior to the development of visible lesions by light microscopy. Multiple CD44 isoforms are known to produce by alternative RNA splicing with different functions related to cell-cell, cell-matrix interaction and also to renal fibrosis, however, there are no reports on which isoforms are expressed on activated PECs in NS and whether changing profile of CD44 isoforms expression is associated with renal disease progression. This study was addressed to investigate the role of different CD44 splicing variant isoforms expression in pediatric kidney biopsies of steroid responsive vs steroid resistant NS.

Methods: Here we investigate the expression patterns of CD44S (which does not contain any alternative exon) and CD44 splice variants using rtPCR in RNA isolated from formalin-fixed, paraffin-embedded (FFPE) of renal biopsies from children with nephrotic syndrome (n=40) versus normal kidneys (n=12), all were treated in our department.

Results: The expression of CD44S and CD44 splice variants CD44v2, CD44v6, and CD44v9/10, were significantly higher in NS kidneys compeerd with normal kidneys and were negatively correlated with disease progression and overall immunosuppressive response. In contrast, there was no significant difference in the expression of CD44v3, CD44v4/5, and CD44v7.

Conclusions: These data indicate that certain standart CD44 and CD44 splice variants may contribute to NS pathology and to disease progression and glomerulosclerosis.

SA-PO678

Response to Glucocorticoids Remains a Valid Approach to Initial Evaluation of Children with Idiopathic Nephrotic Syndrome

Agnieszka Swiatecka-Urban,[1] Deepti Narla.[2] *[1]Children's Hospital of Pittsburgh of UMPC, Pittsburgh, PA; [2]Akron children's Hospital, Akron, OH.*

Background: The therapeutic approach to childhood Idiopathic Nephrotic Syndrome (INS) is based on the ISKDC and APN studiesfrom the 1960's and 1970's. Because most patients had minimal change disease (MCD) sensitive to glucocorticoids, the therapeutic response to the medication was recommended for initial evaluation and therapy. Since the 1990's, several single-center studies have reported greater frequency of resistance to glucocorticoids among MCD patients and of Focal Segmental Glomerulosclerosis (FSGS). The trend is concerning, causes are unknown, and data are limited. Although initially considered a resistant lesion, more aggressive therapy can induce a response in more than 50% of FSGS patients. However, unnecessary exposure to long-term glucocorticoid therapy in resistant patients may cause side effects without a benefit. Our objective was to determine whether response to glucocorticoids remains a valid approach to initial evaluation of INS children.

Methods: A retrospective review identified 110 patients with INS treated at our center. Glucocorticoid doses and definitions of steroid sensitive (SS) and steroid resistance (SR) INS were according to ISKDC. Statistical analysis was performed by fisher exact test.

Results: The mean age was 5.9 years with equal number of males and females. Caucasians (80%) and African Americans (15%) were the predominant ethnicities. The proportion of SRINS in our study was higher, compared to ISKDC (33% vs. 20%). However, it has not been increasing with time (35% during 2003-2007 compared to 30% during 2008-2012). MCD was almost 3 times as common among the SRINS patients in our study, compared to ISKDC (52% vs. 18%). FSGS was similar among SRINS patients, compared to ISKDC (39% vs. 36%). Among patients with kidney biopsy, SSINS characterized 77% of MCD and 42% of FSGS, compared to 93-98% and 17-30% in the ISKDC studies.

Conclusions: In summary, despite the changing characteristics and different study populations, the therapeutic response to glucocorticoids is a valid approach for the initial evaluation and therapy for INS children at our center. An international study would help to monitor the changing characteristics and elucidate the role of patient demographics, ethnicity, and environmental factors that cannot be assessed by smaller studies.

SA-PO679

Pioglitazone (Pio) in Pediatric Nephrotic Syndrome (NS)

Tracy E. Hunley,[1] Kar Hui Ng,[4] William E. Smoyer,[3] Guillermo Hidalgo.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Eastern Carolina University, Greenville, NC; [3]Nationwide Children's Hospital, Columbus, OH; [4]National University of Singapore, Singapore, Singapore.*

Introduction: Thiazolidinediones (TZD) may exert direct protective effects on injured podocytes. PPARγ agonists have been shown to reduce proteinuria in adults with non-diabetic kidney disease. We report our experience with off label, adjuvant use of Pio in pediatric patients with NS.

Case Description: Case 1 A 4 yr old boy was diagnosed with steroid resistant NS (biopsy minimal change). Despite ongoing treatment with prednisone (Pred), lisinopril, tacrolimus, mycophenolate (MMF), losartan, rituximab (Ritux), and Acthar he required twice weekly admissions for diuresis. Pio 15 mg/day was added and increased after 4 wks to 30 mg/day. U P/C decreased from 6 - 8 to 0.2 - 1 mg/mg over the next 7 months and cumulative immunosuppression was decreased considerably. Case 2 A 13 yo female with obesity was found to have NS (Ur P/C 11 mg/mg, S_{Alb} 1.7 g/dL, S_{creat} 0.56 mg/dL), normal C3, and negative ANA. Biopsy showed collapsing FSGS. Glomerular size was normal. She was treated with Pred 40 mg, valsartan 80 mg, simvastatin 20 mg, and Pio 15 mg daily. After 7 wks, U P/C was 3.8 mg/mg and edema had resolved. Pred was decreased to 20 mg and Pio increased to 30 mg daily. After 6 months of treatment, U P/C was 0.5 mg/mg. Case 3 A 6½ yo boy was diagnosed with NS and renal dysfunction after 3 months of intermittent edema (4+ proteinuria, S_{Alb} 1.2 g/dL, S_{creat} 0.93 mg/dL [eGFR 51 ml/min/1.73 m^2]). He was born at 29 weeks gestation with a single right kidney. After 1 1/2 weeks of Pred 2 mg/kg/day, he was readmitted with anasarca and worse renal dysfunction (S_{creat} 2.02 mg/dL [eGFR 24 ml/min/1.73 m^2]. Biopsy showed collapsing FSGS. HIV and parvovirus evaluations were negative. Pred was continued and daily Pio 7.5 mg and pravastatin 20 mg were added. He received 2 doses of Ritux. Renal dysfunction progressed and he required dialysis 3 wks later, 6 ½ wks after presentation. During Pio, blood glucose ranged 93 – 159 mg/dL. Case 4 A 5 yo boy was diagnosed with steroid sensitive but dependent NS. Addition of MMF did not allow Pred taper which was kept at 30 mg/d. Pio 15 mg daily was added for 16 weeks. During this time, Pred was successfully tapered to 5 mg qod while maintaining remission.

Discussion: In pediatric NS, the addition of Pioglitazone may improve proteinuria and allow reduction in corticosteroid and other immunosuppressant medications. In this case series, no hypoglycemia or other adverse events occurred.

SA-PO680

Initial Steroid Resistance Is Not Predictor of a Worst Prognosis in Children with Nephrotic Syndrome Sensitive to Calcineurin Inhibitors

William Morello, Yashika Narang, Luciana Ghio, Giovanni Montini. *Pediatric Nephrology, Dialysis and Transplant Unit, Fondazione IRCCS Ca" Granda Ospedale Maggiore Policlinico Milano, Milan, Italy.*

Background: Children with steroid resistant nephrotic syndrome (SRNS) have a high risk of progressing to end-stage renal disease (ESRD). While Calcineurin inhibitors (CNIs) effectively induce remission in >30% patients, long-term management of SRNS presents a significant clinical challenge. Very little is known about the evolution of SRNS in children, prognosis and the potential role of cortisteroid for relapse(s).

Methods: We performed a retrospective observational study of all paediatric patients treated with CNI for SRNS at our institution between 2008 and 2018. The data was collected about remissions achieved with CNIs, subsequent relapses, their treatment and remission, and long-term renal function.

Results: 54 patients were included (41% males), with a median age of 12.5 years. After a median follow-up of 49 months, 38/54 patients (70.37%) achieved remission with CNIs, while the remaining 16 patients (29.63%) were unresponsive.18/38 patients (47.4%) had one or more relapse(s), (range:1-7). The total number of relapses was 48, out of which, 46 (95.8%) achieved remission. Of these, 38/46 (82.60%) were treated with corticosteroids only, 2/46 were treated with an increased dose of CNI only (>50% of initial dose), 5/46 (10.87%) were treated with both increased CNI dose and corticosteroids, and 1 patient achieved remission with mesenchymal stromal cell infusion. In total, 43 relapses were treated with steroids and 41 of these achieved a new remission. 2/48 relapses did not achieve remission despite different lines of treatment, but none had an impairment of renal function.

Conclusions: SRNS patients responsive to CNIs appear to have a good long-term prognosis, with no patient developing chronic kidey disease after a median follow-up of 49 months. 41/43 (95.3%) relapses were sensitive to corticosteroid therapy, despite the patient being SRNS at the onset of the disease. Therefore, corticosteroids can be considered an option for relapses of SRNS patients sensitive to CNIs. Steroid-sensitive and steroid-resistant NS responsive to CNIs are essentially a part of the spectrum of the same disease.

SA-PO681

Oval Fat Bodies in Urinary Sediment Microscopy Can Be a Convenient Prognostic Marker for Idiopathic Nephrotic Syndrome in Children

Hideki Matsumura,[1] Satoshi Yamazaki,[1] Yuko Fujii,[1] Akihiko Shirasu,[1] Tomoko Tanaka,[1] Hyogo Nakakura,[1] Motoshi Hattori,[2] Akira Ashida.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan.*

Background: Recently, genetic testing for steroid-resistant nephrotic syndrome has been applied to diagnosis and treatment, but it is not a simple test because of the time and cost. Meanwhile, urine microscopy is the oldest and one of the most commonly used tests for diagnosis of kidney disease. It is generally considered that oval fat bodies and fatty casts in urine sediments are seen in nephrotic syndrome, but in fact oval fat bodies and fatty casts are rarely detected in pediatric idiopathic nephrotic syndrome, and sometimes they are detected in steroid-resistant nephrotic syndrome. However, the significance of oval fat bodies and fatty casts in pediatric idiopathic nephrotic syndrome has rarely been investigated. In this study, we investigated whether oval fat bodies and fatty casts could be a prognostic predictor of steroid-resistant nephrotic syndrome in children with idiopathic nephrotic syndrome.

Methods: We retrospectively reviewed medical records of pediatric patients with idiopathic nephrotic syndrome who were being treated at our department. The study items were steroid sensitivity in the nephrotic syndrome, the grade of CKD, and the presence of oval fat bodies and fatty casts in the urine sediments at the onset and recurrence.

Results: Of the 45 patients, 11 had oval fatty bodies and/or fatty casts. These sediments were present in 8/13 (62%) of patients with steroid-resistant nephrotic syndrome versus only 3/32 (13%) of patients with steroid-sensitive nephrotic syndrome. In patients with CKD, they were observed continuously in all patients, while in those with steroid-sensitive nephrotic syndrome, they were observed only once or twice.

Conclusions: In children with idiopathic nephrotic syndrome, those who continue to have oval fat bodies or fatty casts are more likely to be steroid-resistant and have a poor kidney prognosis. In the present study, oval fat bodies and fatty casts in the urine sediment were found to be poor prognostic markers in children with idiopathic nephrotic syndrome.

SA-PO682

A Pilot Study of Urinary Podocyte-Derived Microparticles (MP) as a Marker for Podocyte Injury in Youth with Type 1 Diabetes

Katie Sullivan,[2] James W. Scholey,[1] Rahim Moineddin,[1] Yesmino Elia,[2] Thalia Medeiros,[3] Pusha Sadi,[4] Brandy Wicklow,[4] Etienne B. Sochett,[2] Dylan Burger,[3] Farid H. Mahmud,[2] Allison Dart.[4] *[1]University of Toronto, Toronto, ON, Canada; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]Kidney Research Centre, The Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [4]University of Manitoba, Winnipeg, MB, Canada.*

Background: Podocyte injury plays a crucial role in the development of diabetic nephropathy. Recent animal and clinical studies have shown that podocytes release microparticles under conditions of stress, and may be an early marker of podocyte injury.

Our objectives were to assess MP in youth with Type 1 (T1DM) and healthy controls (HC), and investigate associations with clinical characteristics, including glycemia and renal function. We included youth with T1DM (n= 53), mean age of 14.7 ±1.6 years and age matched (12.9±1.9years) healthy control (HC) subjects, (n=52).

Methods: MP were extracted from first am urine, processed immediately and frozen. MP were identified as of podocyte origin by co-labelling with Annexin V and Podoplanin. ACR was measured on two sets of first morning samples, albuminuria defined as >3.5mg/mmol in males and >4mg/mmol females. eGFR was calculated using the Larsson Equation, previously validated in the Type 1 population. MP numbers were normalised to urinary creatinine (MP/umol Cr). Data distribution was skewed, so groups were compared using non parametric analyses, and expressed as median (IQR).

Results: There was no difference observed in MP number between T1DM with no albuminuria, T1DM with albuminuria and HC 8.28 (8.87), 6.39 (8.90), & 10.39 (8.93); p=0.1530. Unexpectedly, there was only a modest positive correlation between MP number and blood glucose levels (r=0.21, p=0.04) in the T1DM subjects, and trends for MP number and eGFR (r=0.25, p=0.07). A modest positive correlation was also seen for HDL level (r=0.30, p=0.03). There was a more robust negative correlation with serum uric acid (r= -0.46, p=0.0007). Finally, MP number correlated with the urinary albumin excretion rate (r = 0.48, p=0.0029) in T1DM, but only in subjects with normal albumin excretion rates.

Conclusions: Podocyte-derived MP numbers are similar in youth with early T1DM and age-matched healthy subjects, although within the T1DM cohort, MP numbers associate with both glycemia and ACR. These findings suggest that podocyte injury cannot be detected by MP enumeration in the urine at this early stage of diabetes. Future will be necessary to define changes in podocyte MPs over time and their relationship to long term kidney outcomes.

SA-PO683

Urine Exosome Protein Signatures Differentiate Disease Type and Activity in Children with Steroid-Resistant Nephrotic Syndrome

Ivana Bensa,[1] Alev Yilmaz,[3] Augustina Jankauskiene,[2] Dusan Paripovic,[4] Zeynep Yuruk yildirim,[3] Franz S. Schaefer,[1] Klaus Kratochwill.[5] PodoNet Consortium *[1]University of Heidelberg, Heidelberg, Germany; [2]Children's Hospital, affiliate of Vilnius University Hospital Santaros Clinic, Vilnius, Lithuania; [3]Istanbul University Faculty of Medicine, Istanbul, Turkey; [4]University Children's Hospital, Belgrade, Serbia; [5]University of Vienna, Vienna, Austria*.

Background: Steroid resistant nephrotic syndrome (SRNS) is an etiologically and prognostically heterogeneous condition. In 40-50% of children with SRNS remission is achieved by intensified immunosuppressive (IIS) therapy, 20-25% suffer from hereditary podocytopathies, and 30-40% turn out multidrug resistant (MDR) without an identifiable genetic cause. Long-term renal outcomes are excellent for IIS, poor for genetic, and intermediate for MDR-SRNS. No biomarkers differentiating these entities early in the disease course are available to date. Urinary exosome analysis is a promising non-invasive methodology to obtain information about pathobiological processes in the cells lining the nephron.

Methods: Urine samples were obtained from patients with IIS-SRNS (n=4) and MDR-SRNS with or without an identified genetic cause (n=4 each). IIS patients were studied both during relapse and in remission. Exosomes were isolated by ultracentrifugation followed by size exclusion HPLC. Protein isolates were digested with trypsin and LysC, labeled with isobaric tags (TMT 10-plex) and subjected to two-dimensional LC-MS analysis. Ingenuity software was used to identify enriched pathways and functions.

Results: We identified 2,713 proteins with high confidence in urinary exosomes. Comparison of samples from patients with active disease (IIS-relapse/MDR/genetic) vs remission yielded 739 differentially abundant proteins, respectively, with glomerular and tubular cell damage as the most prominent disease functions. Exosomal fractions from active IIS and MDR/genetic patients differed in 124 proteins (most prominently of complement and coagulation pathways and proteins indicating glomerular and proximal tubule damage), whereas only 16 proteins were differentially abundant in MDR with and without an identified genetic cause. Biomarker filter analysis for individual proteins discriminating between disease states yielded highly significant candidates.

Conclusions: Urinary exosome analysis is technically feasible and provides a reflection of disease-related tissue alterations on the proteome level. The deregulated molecular pathways identified in this study might allow to differentiate etiologically and prognostically distinct entities in SRNS.

SA-PO684

Obinutuzumab in Pediatric Idiopathic Nephrotic Syndrome Resistant to Rituximab

Benjamin Prim,[1] Claire Dossier,[1] Christelle Moreau,[2] Theresa Kwon,[1] Anne Couderc,[1] Cambier Alexandra,[1] Veronique Baudouin,[1] Anne F. Maisin,[1] Georges Deschênes.[1] *[1]Pediatric Nephrology, APHP, Robert-Debre Hospital, Paris, France; [2]Pharmacy, AP-HP, Robert-Debre Hospital, Paris, France*.

Background: B-cell depletion with rituximab (RTX) induces sustained remission in children with Steroid Dependant or Frequent Relapsing Nephrotic Syndrome (SD/FRNS). However, most patients relapse after B-cell recovery and some patients do not achieve B-cell depletion. Obinutuzumab (OBZ) is a 2nd generation glycoengineered anti CD20 monoclonal antibody, with higher in vitro B-cell cytotoxicity, that might be more effective in patients with autoimmune diseases. We report the results of a pilot study of OBZ in pediatric patients with FR/SDNS aiming at assessing both the safety and efficacy of OBZ in patients with prior resistance, intolerance or failure to rituximab.

Methods: Patients received an infusion of 300mg/1,73m^2 of obinutuzumab, after premedication. All other immunosuppressive therapies were discontinued within two months, and biological monitoring performed monthly until B-cell recovery.

Results: 12 patients with SD/FRNS were included and followed for a median duration of 8.0 months [IQ 5.9-12.1]. Median ages at INS onset, first RTX and first OBZ injection were of 3.8, 8.8 and 9.3 years old, respectively. Indication for OBZ were intolerance to RTX (n=1), no B-cell depletion (n=4) or short depletion <3 months (n=4) or early relapse after prolonged B-cell depletion (n=3). B-cell depletion was achieved in all patients. At last follow up, B-cell recovery had occurred in 7 patients after a median depletion of 6 months [IQ 5.2-7.9]. B-cell depletion after OBZ was longer in all patients compared to prior RTX (p = 0,0013). 6/7 patients remained relapse-free with median follow up of 3.6 months after B-cell recovery. Mild infusion reactions were reported in 3/12 patients. Neutropenia within 500-1000/mm^3 occurred in 3/12 patients. 2 patients received IV immunoglobulins because of hypo-IgG and 5 patients had hypo-IgM. One patient was hospitalised for pneumonia, with negative bacterial and viral testing and improved with antibiotics.

Conclusions: Obinutuzumab induced peripheral B-cell depletion in SD/FRNS patients resistant to rituximab. A single low dose injection resulted in longer B-cell depletion compared to rituximab. However, short term and long term immunological and infectious side effects have to be closely monitored.

SA-PO685

Bloody Diarrhea and Shiga Toxin-Producing Escherichia coli Infection in Children: Data from the ItalKid-HUS Network

Gianluigi Ardissino,[1] Rosaria Colombo,[2] Laura Daprai,[2] Valentina Capone,[1] Antonella Dodaro,[2] Francesca Tel,[3] Ilaria Possenti,[1] Sara Testa,[1] Fabio Paglialonga,[1] Mario V. Luini,[4] Maurizio Brigotti,[5] Chiara Vignati,[2] Carla Masia.[2] *[1]Center for HUS Prevention Control and Management, Pediatric Nephrology, Dialysis and Transplant Unit, Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milano, Italy; [2]Center for HUS Prevention Control and Management, Laboratory of Microbiology, Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milano, Italy; [3]Department of Pediatrics, Vittore Buzzi Children's Hospital, Milano, Italy; [4]Lombardia and Emilia Romagna Experimental Zootechnic Institute (IZSLER), Lodi, Italy; [5]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy*.

Background: Shiga toxin-producing Escherichia coli (STEC) are responsible for STEC-HUS. The few days before the development of the renal complication, when bloody diahrrea (BD) is the only symptom, represent a window of therapeutic opportunities for preventing or mitigating HUS.

Methods: In order to identify patients at risk for HUS early in the course of the disease, a network connecting >60 pediatric hospitals in Northern Italy (12 millions gp; 2.3 million children) has been developed since May 2010, aimed at identifying patients with STEC infections with the aim of an early management of the severe renal complication. Children (<18 yrs old) with BD were centrally screened for the presence of Stx genes in stools using a Reverse Dot blot assays (Genotype EHEC-Arnika) until 2018 and Real-Time PCR (RIDA Gene-Relab) thereafter.

Results: Out of 4239 analyzed samples, 216 (5.1%) were positive for Stx (1: 63 (29.2%), 2: 92 (42.6%) and 1&2: 61 (28.2%)). Forty patients (0.9% of BD) developed HUS (Stx1 alone was found in 1 eHUS only). The most frequent serogroup identified was the O26 (29%), followed by the O157 (19%) and the other top5 (18%), while a significant proportion were "non top5" (19.7%). In late Summer, the probability that BD is associated with Stx, increases from the year average of 5.1% to around 15%. BD was more common in younger children (85% of cases < 10 yo) but the likelihood that BD was caused by STEC infection was not different in different age groups. Finally, the probability of developing HUS in case of STEC infection decreases with age.

Conclusions: The present analysis provides important information about the epidemiology of BD and gives the evidence that STEC is everything but a rare cause of BD that should therefore always be screened for Stx given the severity of its complication.

SA-PO686

Disease Risk Among Family Members of Patients with aHUS Carrying Complement Regulatory Gene Abnormality

Gianluigi Ardissino,[2] Bice Strumbo,[1] Valentina Capone,[2] Donata C. Cresseri,[3] Selena Longhi,[2] Laura Martelli,[2] Giulia Loffredo,[1] Luigi Porcaro,[1] Piergiorgio Messa,[3] Silvana Tedeschi.[1] *[1]Center for HUS Prevention, Control and Management, Laboratory of Medical Genetics, Fondazione IRCCS Ca' Granda- Ospedale Maggiore Policlinico, Milano, Italy; [2]Center for HUS Prevention Control and Management, Pediatric Nephrology, Dialysis and Transplant Unit, Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milano, Italy; [3]Center for HUS Prevention, Control and Management, Nephrology, Dialysis and Kidney Transplant Unit, Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milano, Italy*.

Background: Atypical hemolytic uremic syndrome (aHUS) is a severe thrombotic microangiopathy mainly due to mutations in complement regulatory genes (MCRG) with a dominant pattern (heterozygous can exhibit the disease) but incomplete penetrance thus a number of healthy carriers (HC) can be identified in any family of aHUS patients but it is not clear which, when or why HC will eventually turn into patient. Patients with aHUS referred to our Center are screened for all of the known MCRG and once a genetic

abnormality is identified, the search is extended to all the at-risk family members interested in being tested.

Methods: Among all the patients with primary aHUS diagnosed at or referred to our centre, only those with a documented MCRG and their relatives were included: 276 subjects (141 females) with 104 aHUS patients and 172 HC, from 75 families.

Results: Fourteen families(18.7%) experienced multiple cases, 9 subjects had multiple mutations. The mean age at presentation (for patients) or at the time of analysis was 35.2+24.1 years. Over a cumulative observation period of 6408 patient-year, only 29 family members carrying gene mutations experienced aHUS (overall penetrance of 14.4%) leading to a disease rate of 4.5 events for 1000 patient-year. The disease rate was 13.4 among siblings, 10.7 among offsprings and only 3.5 among parents.

Conclusions: In conclusion, the overall penetrance of aHUS seems a lot lower than previously reported, the risk of developing the disease in any given relative carrying MCRG is low but it is not equally distributed among generations: siblings and the offspring of patients have a much greater disease risk compared to parents. This piece of information is very important for genetic counseling and clearly supports the concept of a second hit as a cofactor of aHUS which, most likely, should be searched for in the parent who does not carry the MCRG.

Biomarkers of Disease Activity in Childhood-Onset Lupus Nephritis

Jessica M. Greco,[1,2] Xiaolan Zhang,[4] John Sinclair,[4] Sherene Mason,[6] Larry A. Greenbaum,[7] Mahmoud Kallash,[8] Scott E. Wenderfer,[5] Brad H. Rovin.[3] *[1]Ohio State Wexner Medical Center, Columbus, OH; [2]Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH; [3]Ohio State University Wexner Medical Center, Columbus, OH; [4]The Ohio State University, Columbus, OH; [5]Baylor College of Medicine, Houston, TX; [6]Connecticut Children's Medical Center, New Haven, CT; [7]Emory University, Atlanta, GA; [8]Nationwide Children's Hospital, Hilliard, OH.*

Background: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that affects children and adults, but is more severe and more often involves the kidneys in children. The traditional clinical signs of renal injury do not adequately reflect kidney histology in lupus nephritis (LN), but repeating biopsies frequently is not practical. In adults with LN urine levels of CD163 and epidermal growth factor (EGF) correlate with histologic activity and chronic damage, respectively. These putative biomarkers were examined in a cohort of SLE patients from the Midwest Pediatric Nephrology Consortium.

Methods: Urine was collected prospectively from 37 pediatric patients with active LN, 27 with active extra-renal lupus, and 34 with inactive SLE. Urine CD163 (uCD163) and urine EGF (uEGF) were measured by ELISA and analyzed using JMP14 Pro.

Results: uCD163 was higher in children with active LN compared to those with active non-renal lupus and inactive disease (p=0.0011, p=0.0004, respectively). uCD163 fell significantly in patients who had a complete renal response or in whom renal inflammation resolved on repeat biopsy after 6 months of treatment (328±350 ng/mg urine creatinine vs 15±31 ng/mg, P<0.03). uCD163 correlated with the biopsy NIH activity index (r^2=0.452, p=0.002), and specifically capillary hypercellularity, WBC infiltration, hyaline deposits, karyorrhexis, and interstitial inflammation. uCD163 did not correlate with chronic damage. uEGF was significantly lower in children with active LN compared to those with active non-renal lupus and inactive disease (p=0.0008, p=0.0004, respectively). In patients with eGFR <60 ml/min/m^2 uEGF was 24±8 ng/mg compared to 129±44 ng/mg in those with eGFR >60 (p<0.0001). In the patients with eGFR <60, the biopsy chronicity index (CI) was 0 (n=2), 2 (n=1), 3 (n=1). uEGF did not correlate with CI, interstitial fibrosis, or tubular atrophy. uEGF tended to increase in treated patients as eGFR improved (p=0.06).

Conclusions: uCD163 reflects histologic activity in pediatric patients with LN. In children uEGF does not reflect histologic chronicity, but appears to be a marker of acute kidney injury.

SA-PO688

Silent Lupus Nephritis vs. Overt Lupus Nephritis in a Pediatric Lupus Cohort

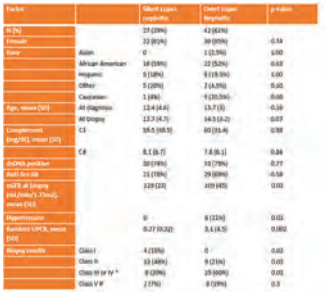
Sai Sudha Mannemuddhu,[1] Roberto E. Borgia,[1] Nirupama Gupta,[3] Renee Modica.[2] *[1]University of Florida. College of Medicine., Gainesville, FL; [2]Univeristy of Florida, Gainesville, FL; [3]University of Florida- College of Medicine, Gainesville, FL.*

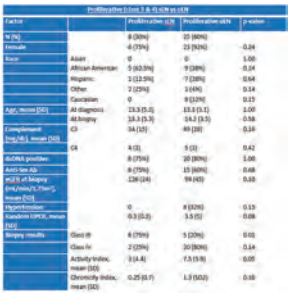
Background: Lupus nephritis (LN) is seen in 20–75% of childhood onset Systemic Lupus Erythematosus (cSLE) and is a predictor of poor prognosis. LN may present with active urinary sediment and/or renal impairment (overt LN- oLN) or be apparent only upon renal biopsy (silent LN-sLN). There is limited data regarding sLN in pediatric lupus. We describe and compare features of sLN and oLN.

Methods: Our retrospective review included patients followed at the University of Florida, Gainesville, diagnosed with cSLE < 18 years of age (≥ 4/11 ACR and/or ≥ 4/11 SLICC classification criteria) who underwent renal biopsy between January 2011 and October 2018. Continuous variables were compared using Student's t test and categorical variables were compared using Fisher's test.

Results: Out of 69 patients, 39% (n=27) were found to have sLN and 61% (n=42) had oLN. The most common histopathology [ISN/RPS] was Class II LN in sLN group (48%, n=13) and proliferative Class III/IV LN in oLN group (60%, n=25). However, 30% (n=8) of sLN had proliferative LN [Class III/IV]. The two groups had similar demographic features. Most of the patients were African American in both groups. There was no significant differences in C3, C4 levels and anti ds-DNA titers. Patients with oLN had more hypertension (p=0.01), deceased eGFR (p=0.03) and higher UPCR (p=0.002) when compared to sLN group. (refer to tables).

Conclusions: In our pediatric cohort, 39% were found to have sLN and 30% of them had proliferative LN, which was more prevalent in African American females with low C3. Renal biopsy should be considered in patients with very low C3 and before development of renal manifestations like hypertension, and decreased eGFR. However, more studies are needed to see if early diagnosis and treatment would modify the long-term renal outcomes.





SA-PO689

Clinical Characteristics and Risk Factors for Thrombotic Microangiopathy in Children with Lupus Nephritis

Lei Yin,[1] Wei Zhou,[1] Youying Mao,[2,1] Yanliang Jin.[1] *[1]Nephrology and Rheumatology Department, Shanghai children's Medical Center, Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Boston children's hospital, Boston, MA.*

Background: Thrombotic microangiopathy (TMA) presents with the most severe clinical manifestations and high mortality. The aim of this study is to find the risk factors for TMA in children with lupus nephritis (LN) after analyzing their clinical characteristics.

Methods: We retrospectively reviewed the clinical data of 12 LN patients complicated with TMA hospitalized from January 2006 to December 2018.

Results: TMA occurred in 8.28% (12/145) of the hospitalized patients with LN. Four patients were boys and 8 patients were girls. One boy was 6-year-old and the other 11 patients were from 11 to 18-year-old. Their SLEDAI scores ranged from 14 to 31, 92% of them were in severe activity. Renal biopsy was performed in 11 patients, and the results of renal pathology showed all of them had type IV or type IV plus type V LN (type IV, n=8; type IV+V, n=3). All the patients were diagnosed with TMA within 1 week to 2 months after admission. At the beginning of the hospitalization, seven of them (58%) had both anemia and thrombocytopenia, while 5 patients (42%) only had moderate anemia. All of them had obvious hypocomplementemia. Especially in all of the 8 patients with first onset of SLE, there serum levels of C3 were lower than 0.18g/L and C4 were lower than 0.07g/L. Moreover, GFR of them were much lower than normal range. Most of the patients had heavy proteinuria (11/12) and positive anti-ds-DNA antibody (10/12). All of the patients accepted the treatment of methylprednisolone pulse therapy, ten of the them were treated with cyclophosphamide, five patients were treated with plasmapheresis (PE). After 6 months of treatment, five patients obtained complete response, five patients obtained partial response. One patient relieved after 3 times of PE but died during the fourth PE may because of intracranial hemorrhage. The other patient was unwilling to accept renal biopsy and the diagnosis of TMA was not confirmed until 2 months after onset. Although she was treated with PE for 10 times and two doses of Rituximab, she deteriorated continuously.

Conclusions: Children with LN complicated with TMA are mostly in severe disease activity, and the main pathological change of them is type IV LN. Anemia and extremely low level of serum complement occur simultaneously maybe the risk factors for TMA in children with LN whether they have thrombocytopenia or not.

SA-PO690

Recapitulating Shiga Toxin-Mediated Renal Injury in Engineered Microvessels

Russell S. Whelan,[1,2] Jonathan Himmelfarb,[3] Ying Zheng.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington, Seattle, WA; [3]Kidney Research Institute, Seattle, WA.*

Background: Hemolytic-Uremic Syndrome (HUS) presents as a severe form of thrombotic microangiopathy (TMA), and the endothelial injuries that precipitate HUS/TMA are caused by a wide range of insults, including metabolic, immunologic, pharmacologic, and infection-associated etiologies. Shigatoxin-producing E. Coli HUS (STEC-HUS) is an infectious TMA that results in renal injury, leading to AKI, permanent renal damage and death, and is the leading cause of dialysis initiation in otherwise healthy children. Despite severe long-term consequences with STEC-HUS, no targeted therapies to-date have demonstrated any clinical benefit. Use of perfusable vascular models previously developed in our lab provide physiologically relevant platforms to evaluate specific cellular injury mechanisms responsible for the endothelial injury in STEC-HUS. These models also provide a well-controlled and efficient platform for evaluating novel therapeutic interventions.

Methods: Human primary renal endothelial cells were treated with Stx1 and Stx2, the principal toxins responsible for STEC-HUS, and evaluated for cell death, cell injury, and morphology. Studies were performed in both 2D tissue culture and 3D microvessel platforms.

Results: Treatment of isolated human primary renal endothelial cells with either Stx1 or Stx2 demonstrated effective binding, toxin internalization and death. Significant increases in both apoptosis and necrosis were appreciated in a dose-dependent manner in these microvascular cells, with non-renal endothelial cell lines demonstrating insensitivity to Stx1 or Stx2 treatment at equivalent or higher doses. Engineered microvessels using primary renal endothelial cells were generated and maintained under flow for several days. In these models, treatment with Stx1 and Stx2 demonstrated effective binding to luminal endothelia, with evidence of a greater degree of endothelial injury and endothelial denudation observed with Stx2 than Stx1.

Conclusions: Human primary renal endothelial cells exhibit dose-specific responses to Shigatoxin consistent with clinical presentation of STEC-HUS. Notably, engineered renal microvessels also exhibited endothelial injury consistent with Shigatoxin toxicity. Ongoing phenotypic and transcriptional studies will use these models to delineate the specific injury pathways responsible for endothelial injury that result in vascular damage and progression to TMA.

SA-PO691

Immunostaining for Galactose-Deficient IgA1 in Routine Kidney Biopsies

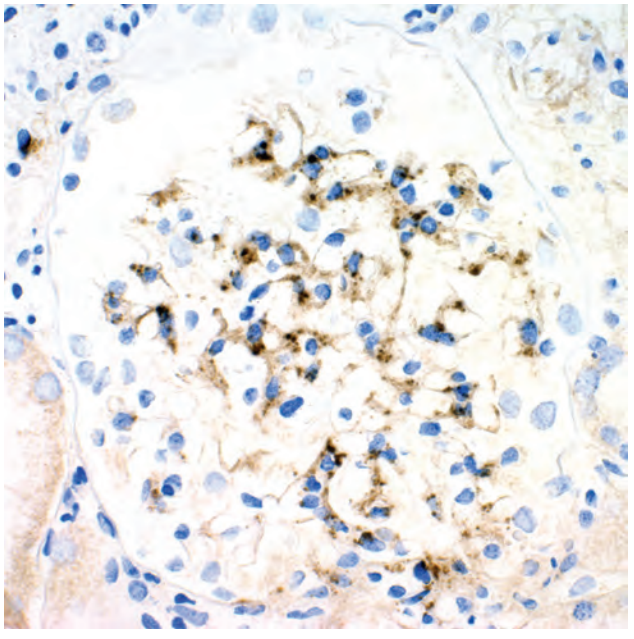
Jan U. Becker,[1] Bernd Hoppe,[2] Roman-Ulrich Mueller,[3] Peter Hoyer.[4] *[1]University Hospital Cologne, Köln, Germany; [2]University Hospital Bonn, Bonn, Germany; [3]Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany; [4]University Hospital Essen, Essen, Germany.*

Background: Recently, an antibody against galactose-deficient IgA1 (gdIgA1) became commercially available. Very little is known about the specific staining patterns of this KM55 antibody in routine diagnostics. Here we report the staining pattern in routine native and transplant biopsies with various forms of IgA-codominant glomerulonephritis and controls.

Methods: We established a protocol for formalin-fixated paraffin embedded (FFPE) tissue with protease antigen retrieval (Fast Enzyme, Zytomed Systems, Germany). Primary antibody KM55 was incubated overnight at 1:5 dilution and visualized with a standard peroxidase system and reported as 0, 1+, 2+, 3+ on 58 consecutive renal biopsies with IgA-codominant glomerular staining (50 native, 8 transplant) and controls (7 IgM glomerulopathy, 3 infectious associated glomerulonephritis) together with immunostaining for IgA1 and IgA2.

Results: 26/43 (60%) primary IgA-GN (pIgA-GN), 7/9 (78%) Henoch-Schönlein Purpura (HSP) and 2/4 (50%) cirrhotic IgA-GN (cirrhIgA-GN), 0/1 (0%) staphylococcus-associated GN (staphGN), 0/1 (0%) monoclonal IgA-GN were positive for gdIgA1. IgA1 was dominant over IgA2 in 40/43 pIgA-GN, 7/9 (78%) HSP, 4/4 (100%) cirrhIgA-GN, 1/1 (100%) staphGN; IgA2 over IgA1 in 1/43 (2%) pIgA-GN, 0/9 (0%) HSP and 0/4 (0%) cirrhIgA-GN. gdIgA1 was negative in all controls. Repeat biopsies in transplants showed consistent staining.

Conclusions: We report an immunohistochemical staining method for gdIgA on FFPE kidney biopsies. Together with serum tests for gdIgA1 and anti-gdIgA1 autoantibodies, this ancillary staining method could be useful for a pathogenesis-driven classification of glomerular diseases with IgA-codominant deposits.



3+ mesangial staining (brown) for gdIgA1 in a FFPE biopsy which was classified as primary IgA-GN. Immunoperoxidase, original magnification x400.

SA-PO692

Circulating Endothelial Microparticles and Correlation with MEST-C Scores in IgA Nephropathy

Vinita Agrawal,[1] Niharika Bharti,[1] Vikas Agarwal,[2] Narayan Prasad.[3] *[1]Pathology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [2]Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [3]Nephrology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.*

Background: Renal endothelial injury or activation can lead to a cascade of pathways that contribute to loss of renal function and fibrosis. Recent reports suggest that endothelial injury may play a role in the pathophysiology of IgAN. Microparticles (MPs) are 0.1 to 1.0 μm membrane vesicles shed from the damaged or activated cell surface following injury. Microparticles derived from endothelial cells are called endothelial microparticles (EMPs) and play an important role in promoting endothelial dysfunction. They can act as biomarkers of disease state and progression. The aim of this study was to study the presence and quantify the levels of circulating MPs of endothelial origin in plasma from patients with IgAN and healthy controls.

Methods: 25 biopsy-proven IgA nephropathy (Mean age=32.8±8.2 years) and 25 healthy controls (Mean age=30±7.6 years) were recruited in this study. Platelet-poor-plasma from citrated blood was isolated and centrifuged at 20,000g (90 min) at 4 degree C. EMPs were analyzed by Flow cytometry using EMP specific antibodies for antiCD31-FITC and antiCD146-PE. All quantification related to size and number was done by using cell count beads of known concentration. The levels of circulating endothelial MPs were correlated with renal biopsy features of the Oxford classification (MEST-C scores). The study was reviewed and approved by the Institutional Ethics Committee.

Results: There are significantly higher levels of total circulating MPs and EMPs in IgAN compared to healthy controls ($p<0.05$). EMPs levels were increased in patients with hypertension and correlated with presence of mesangial and endocapillary hypercellularity ($p<0.05$) on renal biopsy (Table 1).

Conclusions: IgAN shows evidence of significant endothelial injury/dysfunction. A non-invasive method of detection of levels of circulating EMPs can predict the severity of glomerular injury and may be a simple method useful for monitoring endothelial injury in IgAN.

Funding: Government Support - Non-U.S.

Table 1. Correlation of Circulating Endothelial Microparticle (EMP) counts with MEST-C scores in IgAN

MEST-C score on Renal Biopsy	MPs/μl plasma	Circulating EMPs/μl plasma (CD31+/CD146+)	P value
Mesangial Proliferation M0 M1	105±12 187±107	21±2.8 44±27	0.04
Endocapillary Proliferation E0 E1	141±49 242±141	31±14 60±33	0.001
Segmental sclerosis S0 S1	168±93.3 188±116	40±26 43±26	0.614
Tubular Atrophy Absent Present	126±34 156±89	37±13 44±29	0.433
Crescent Absent Present	164±82 200±140	39±26 45±27	0.512

SA-PO693

Histological Classifications in IgA Nephropathy Should be Considered for Predicting Not Only Renal Functional Decline but Also Treatment Response

Kensuke Joh,[1] Akinori Hashiguchi,[2] Akira Shimizu,[3] Ritsuko Katafuchi,[4] Satoshi Hisano,[5] Tetsuya Kawamura.[1] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Keio University School of Medicine, Tokyo, Japan; [3]Nippion Medical School, Tokyo, Japan; [4]National Hospital Organization Fukuokahigashi Medical Center, Koga, Fukuoka, Japan; [5]University of Occupational and Environment Health, Kitakyushu, Japan.*

Background: In IgA nephropathy, Oxford classification (Oxford) (MESTC) and Japanese Histological Grade Classification (JHGC) (Gr1-Gr4, A: active crescent, C: global or segmental sclerosis) are evidence-based classification, which have been produced for predicting renal functional decline (RFD). However, clinical parameters are also selected as independent parameters besides histological parameters for RFD. The purpose was to detect the histological parameters, which show a significant correlation with these clinical parameters, because the detected histological parameters can be main indicators for the choice of therapy.

Methods: The 906 Japanese patients with IgA nephropathy (male : 49%, median age: 38 yrs) were prospectively followed for a median of 62 months. First, histological and clinical parameters were evaluated by multivariate Cox regression analysis for 1.5 time's increase of serum creatinine to find clinical independent parameters. Thereafter, structural equation modeling (SEM) (STATA, Light Stone, USA) was used to find histological parameters which correlate with the independent clinical parameters for RFD.

Results: Besides M, T1, T2 in Oxford and Gr1-Gr4 in JHGC as the independent histological parameters, amount of proteinuria at renal biopsy (PU0) and steroid therapy (ST) were selected as the independent clinical parameters in both classifications. In SEM, histological parameters which correlated with ST were S(coefficient 0.10), C1(0.20), C2(0.30), and E(0.11)in Oxford and AorA/C(0.27)in JHGC for renal functional

improvement (RFI: 0.75 in Oxford and 0.81 in JHGC). The histological parameters which correlated with PU0 were C1 (0.39), M(1.08) and eGFR0 (-0.01) in Oxford and Gr3(1.03), Gr4(1.61), eGFR0 (-0.01), AorA/C(0.27)in JHGC for RFD (-0.06 in Oxford and -0.06 in JHGC).

Conclusions: Since S, C1, C2, and E in Oxford and AorA/C in JHGC were treatment's targets for ST resulting in RFI, these histological parameters in each classification are reasonable indicators for a choice of ST. The histological parameters, which correlated with PU0, consisted of ST-related parameters and non-ST related parameters. Therefore, both histological classifications can be more practical considering aforementioned histology-based choice of therapy.

SA-PO694

Validation of the Renal Risk Score for ANCA-Associated Glomerulonephritis

Maria Wester Trejo,[7] Emma Van Daalen,[7] Franco Ferrario,[16] Kensuke Joh,[9] Yayoi Ogawa,[1] Suzanne Wilhelmus,[2] Miriam J. Ball,[15] Eva Honsova,[10] Zdenka Hruskova,[3] Renate Kain,[4] Andreas Kronbichler,[5] Xavier Puéchal,[11] Steven Salvatore,[12] Wladimir M. Szpirt,[8] Vladimir Tesar,[6] Ron Wolterbeek,[7] Willem Jan W. Bos,[13] Jan A. Bruijn,[14] Ingeborg M. Bajema.[7] *[1]Hokkaido Renal Pathology Center, Sapporo, Japan; [2]Pathan B.V., Rotterdam, Netherlands; [3]Department of Nephrology, General University Hospital and First Faculty of Medicine, Charles University, Prague, Czechia; [4]Medical University of Vienna, Wien, Austria; [5]Medical University Innsbruck, Innsbruck, Austria; [6]General University Hospital, Prague, Czechia; [7]Leiden University Medical Center, Leiden, Netherlands; [8]Rigshospitalet P2132, Copenhagen, Denmark; [9]The Jikei University School of Medicine, Tokyo, Japan; [10]IKEM, Prague, Czechia; [11]National Referral Centre for Rare Systemic Autoimmune Diseases, Paris, France; [12]Weill Cornell Medical College, New York, NY; [13]St. Antonius Hospital, Nieuwegein, Netherlands; [14]Pathology, Leiden University Medical Center, Leiden, Netherlands; [15]Ipswich Hospital NHS Trust, Ipswich, United Kingdom; [16]Nephropathology, San Gerardo Hospital, Monza, Italy.*

Background: Recently, Brix *et al*. proposed a clinicopathologic score to predict renal outcome in ANCA-associated glomerulonephritis (AAGN). This score was based on data from 205 German patients. We here show results of a validation study of this risk score in an international cohort of patients.

Methods: This study included 143 adult patients with AAGN from centers in the U.S., Europe and Asia. Percentage of normal glomeruli (>25%, 10-25% or <10%), percentage tubular atrophy and interstitial fibrosis (≤25% or >25%) and estimated glomerular filtration rate at the time of diagnosis (>15 or ≤15) were determined for each patient. Following the risk score, each parameter was assigned points, resulting in a low, intermediate or high risk to develop end-stage renal disease.

Results: At 36 months follow-up, renal survival in our cohort was substantially higher compared to the Brix *et al*. cohort (table 1). Although renal survival differed significantly between the three risk groups (P<0.001), the clinical relevance between low and medium risk is doubtful, being 100% and 96% respectively. In the high risk group, there was a substantial difference in the renal survival of our cohort (77%) in comparison to the reported renal survival from the Brix study (32%). Only one patient from five with the maximum risk score of 11 developed ESRD in our cohort versus all patients with a maximum score in the German cohort.

Conclusions: In this international cohort, we validated the renal risk score proposed by Brix *et al*. and demonstrated significantly different renal survival between the three risk groups. The renal survival in our cohort was much higher than in the cohort from Brix. Their relatively poor renal survival might result from the German practice of early dialysis initiation which questions the applicability of the renal risk score to other populations.

Table 1. Renal survival at 36 months in our cohort and the cohort of Brix et al.

	The present cohort		The training cohort by Brix et al.	
Risk group	N of patients	Renal survival 36 months	N of patiens	Renal survival 36 months
Low (0 points)	6	100%	30	100%
Medium (2-7 points)	90	96%	64	84%
High (8-11 points)	47	77%	21	32%

SA-PO695

The Clinicopathologic Characteristics and Complement Activation of Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitides with Glomerular IgA Deposition

Yanhong Ma, Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: The renal injury caused by anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are characterized by few or no immune deposits in glomerulus. A growing number of AAV patients with glomerular IgA deposits have been reported.

Methods: We retrospectively investigated all AAV patients with glomerular IgA deposits diagnosed in our center. Serum Galactose-deficient IgA1 (Gd-IgA1) level and glomerular Gd-IgA1 and IgA staining were measured. Moreover, we detected complement pathway components in their sera.

Results: A total of 168 AAV patients were enrolled, including 26 patients with glomerular IgA deposition and 142 patients with pauci-immune complex deposition. The AAV patients with IgA deposition had a tendency of lower systemic disease activity, presenting with lower ESR, lower MPO-ANCA, tendency of lower CRP and BVAS. For renal injury, there were no significant differences in clinical data, renal pathological parameters or renal outcome between groups. The serum level of Gd-IgA1 and intensity of glomerular Gd-IgA1 staining in IgA deposition AAV patients were similar with IgA nephropathy patients. All patients in IgA nephropathy group, AAV groups with or without IgA deposition had the activation of alternative complement pathway, while AAV patients with IgA deposition also had the activation of classical complement pathway. Correlation analysis showed serum C1q level correlated directly with serum globulin and IgA levels.

Conclusions: AAV patients with IgA deposition had the basis of IgA nephropathy, and may present lower systemic disease activity. But it differs from pauci-immune AAV or IgA nephropathy by the possible activation of classical complement pathway.

SA-PO696

The Modern Spectrum of Kidney Biopsy Findings in HIV-Infected Patients

Satoru Kudose, Dominick Santoriello, Andrew S. Bomback, Ibrahim Batal, Michael B. Stokes, Glen S. Markowitz, Vivette D. D'Agati. *Columbia University Medical Center, New York, NY.*

Background: The epidemiology of HIV-associated kidney disease is evolving rapidly. However, few North American studies address modern trends and none has applied the pathologic classification proposed by the 2018 Kidney Disease Improving Global Outcomes (KDIGO) consensus.

Methods: To characterize the modern spectrum, we performed a retrospective analysis of all HIV-positive patients (pts) with kidney biopsy interpreted at Columbia University from 2010-2018 using KDIGO guidelines.

Results: The biopsy cohort of 437 HIV pts had median age 53 years, including 66% male, 78% on anti-retroviral therapy (ART), 27% with hepatitis C (HCV), 6% with hepatitis B coinfection, 57% with hypertension, and 31% with diabetes. Race, known in 308 pts, included 179 African American (AA), 77 White, 51 Hispanic and 1 Asian. The frequency of diabetic nephropathy and immune complex (IC)GN each outnumbered classic HIVAN, followed by tenofovir nephrotoxicity (Table 1). However, classic HIVAN was the most common disease in ART-naïve or noncompliant pts (43%) and associated with AA race (95%). The association of FSGS (NOS) with AA race (62%) and ART (79%) suggests that some FSGS (NOS) may represent an attenuated form of HIVAN. The most common ICGNs were IgA nephropathy and membranous GN, both associating with ART (>90% pts). Of the 26 cases of unclassified ICGN, 54% were not on ART and 54% lacked an identifiable etiology, a subset of which may represent true HIVICK. IgM-dominant ICGN was most common in hypocomplementemic and HCV-infected pts. The presence of dual diagnoses in 88 (20%) pts underscores lesion complexity.

Conclusions: ART is changing the landscape of HIV-associated kidney diseases in the U.S. towards diabetic nephropathy, diverse ICGN and tenofovir nephrotoxicity, but has not eradicated classic HIVAN.

Table 1. Kidney Biopsy Findings in HIV-infected Patients (N=437).

Diagnosis		N (%)
Glomerular-dominant		**190 (43%)**
Podocytopathy		**116 (28%)**
	Classic HIVAN	64 (15%)
	FSGS NOS in the setting of HIV	49 (11%)
	Minimal change disease in the setting of HIV	3 (1%)
Immune complex-mediated glomerular disease		**74 (17%)**
	IgA nephropathy in the setting of HIV	21 (5%)

Clinicopathologic Features and Outcomes of Endocarditis-Associated Glomerulonephritis (ECGN)

Jane K. Nguyen, Leal C. Herlitz. *Cleveland Clinic, Cleveland, OH.*

Background: ECGN is a well-documented entity but may be under recognized due to its overlapping features with other glomerulonephridities. The aim of this study was to analyze clinical and pathologic characteristics of patients with ECGN.

Methods: Clinical and renal histopathologic data of 12 patients from a single center with biopsy-proven ECGN from 2009 to 2019 were retrospectively analyzed.

Results: Among the 12 patients with ECGN, all presented with acute kidney injury, the male-to-female ratio was 5:1 and mean age was 60 years. Mean serum creatinine at the time of presentation was 4.8 mg/dL. On urine dipstick, 92% of the patients presented with at least 2+ hematuria and 84% had 1+ proteinuria. There were no known cardiac abnormalities in 7 of 12 patients. The most common comorbidities were cardiac valve disease (42%), intravenous drug abuse (17%), and hepatitis C (8%). Infective bacteria were *Bartonella* (5/12), *Staphylococcus* (4/12), *Enterococcus* (2/12) and *Streptococcus* (1/12). All cases associated with hypocomplementemia (5/10) and/or ANCA antibody (5/10) in the patients tested were found in association with the following bacteria: *Bartonella*, *Enterococcus* or *Streptococcus viridans*. Cryoglobulins were positive in 9 of 11 patients tested. Light microscopy showed either focal or diffuse endocapillary proliferative features in 92% of the cases and 83% of cases showed at least focal necrotizing crescent formation. An active tubulointerstitial infiltrate was seen in 67% of the cases. No cases showed arteritis. Immunofluorescence revealed either dominant or co-dominant C3 staining (10/12 cases) and IgM was the most commonly deposited immunoglobulin with polyclonal 2-3+ staining seen in 58% of the cases. Strong IgM staining was associated with all tested cases of *Bartonella* (5), *Enterococcus* (1) and *Streptococcus* (1). Treatment included long term antibiotics (12/12), heart valve replacement (6/12), immunosuppression (4/12) and dialysis (4/12).

Conclusions: ECGN most commonly presents with AKI. Particularly in subacute endocarditis, positive ANCA serologies and biopsy findings of crescentic GN can lead to missed diagnosis. Strong staining for IgM as well as C3 was seen commonly in cases of ECGN associated with *Bartonella* and other subacute organisms. A high index of suspicion on renal biopsy was important to timely diagnosis as *Bartonella* is not detectable on routine blood culture.

SA-PO698

Gender, Ethnicity, and Outcome in Thrombotic Microangiopathy (TMA) on Renal Biopsy: A Retrospective Study Evaluating the Demographic and Etiologic Spectrum

Shu Lui, Jason Cobb, Alton B. Farris, Carla L. Ellis. *Emory University School of Medicine, Atlanta, GA.*

Background: TMA is a systemic disease with diverse etiologies, characterized histologically by endothelial injury. Studies have reported an increased incidence and mortality rate in African American (AA) females with TMA. Our study seeks to determine if this finding is reproducible in a population of patients with evidence of TMA on renal biopsy.

Methods: A retrospective search of our pathology data system was conducted to identify all renal biopsies with a diagnosis of TMA from January of 2015 to May of 2018. Groups were analyzed in terms of gender, ethnicity, native versus allograft, presence of associated rejection and cause of ESRD in the allograft population. The presence of ESRD or a doubling of the serum creatinine from the time of the biopsy until the latest follow up date was defined as an unfavorable outcome.

Results: Sixty-six cases were reviewed with the demographic data. Number of total and (allograft) biopsies is shown in the table. There was no statistically significant difference between the groups in terms of gender, ethnicity, unfavorable or favorable outcome, numbers of native versus allograft biopsies or the presence or absence of cell or antibody mediated rejection in biopsies showing histopathologic findings of TMA. However, in allograft biopies, 9/14 males and 2/12 females had ESRD due to HTN and/or DM (p=0.014). Other cases of ESRD in women included scleroderma, SLE, complications of pregnancy, drug toxicity, multiple myeloma and polycystic kidney disease.

Conclusions: In summary, we found that kidney biopsies showing histologic findings of TMA are indeed, more common in AA females, but this was not associated with a significantly worse outcome as the data suggests. We also note that in the transplant population of biopsies with TMA, hypertension and/or diabetes was a more common cause of ESRD in males of either ethnicity, rather than mirroring the general population with a higher preponderance in AA overall. This finding suggests that in women, allograft associated TMA could be related to predisposing factors. Further investigation with a larger cohort is required to support these findings.

Results

	Males (# allograft)	Females (# allograft)
AA	13 (8)	28 (10)
C	14 (6)	11 (2)

Lithium Nephrotoxicity Is Associated with Dysmorphic Proximal Tubule Cell Lysosomes

Cynthia C. Nast,[1] Benjamin A. Vervaet,[2] Gerd Schreurs,[2] Channa Jayasumana,[3] Aude Servais,[4] Marc E. De Broe.[2] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]University of Antwerp, Antwerp, Belgium; [3]Faculty of Medicine, Anuradhapura, Sri Lanka; [4]Necker University Hospital, Paris, France.*

Background: Long term lithium (L) use is associated with tubulointerstitial fibrosis, renal dysfunction and ESRD in select patients. The mechanisms resulting in parenchymal fibrosis are not well understood. We have described proximal tubular cell (PTC) dysmorphic lysosomes (DLs) in calcineurin inhibitor (CNI) toxicity and chronic interstitial nephritis in agricultural communities (CINAC), suggesting this is a marker of tubulotoxic exposure. Similar lysosomes were identified in cases of chronic interstitial nephritis due to lithium toxicity (LT) used as controls for our CINAC studies, prompting further assessment of this finding.

Methods: 9 kidney biopsies from patients with clinical LT were reviewed, Ki67 staining was performed and clinical data were obtained from the medical records.

Results: Patient data are in the Table. 7 patients discontinued L for 0.15 to 31 years prior to biopsy. All biopsies showed tubulointerstitial fibrosis and tubular microcysts diagnostic of LT. 7 biopsies had PTCs with cytoplasmic large DLs containing electron dense aggregates, identical to patients with CINAC and CNI toxicity. Ki67 staining showed no to few positive proximal and distal tubular cells in 8 biopsies, demonstrating reduction in tubular cell proliferation and repair. The 1 patient with moderate numbers of Ki67 positive tubular cells had scattered PTC DLs and had discontinued L 14 years before biopsy, possibly indicating evolving tubular cell repair. The patient off L for 31 years had no DLs or Ki67, suggesting completed recovery from LT.

Conclusions: PTC DLs are a marker of tubulotoxic exposure to L and are associated with a reduction in PTC regenerative capacity. In the setting of LT, PTCs are senescent and the DLs may persist for up to 14 years after drug discontinuation. As tubular cell mitotic arrest has been associated with tubulointerstitial fibrosis, further evaluation of the relationships between DL development, DL cargo, and loss of PTC proliferative capacity may help elucidate mechanisms of L-induced tubulointerstitial fibrosis, which currently are poorly understood.

Clinical and Biopsy Data

PT dysmorphic lysosomes	Age	Gender	Time on L	L stopped before biopsy	Cr (mg/dL)	Tubulointerstitial fibrosis
Yes (n=7)	46+/-18	2M:5F	7->25 yrs	0-14 yrs	1.8+/-0.1	35+/-15%
No (n=2)	67+/-25	2M	15->25 yrs	0-31 yrs	2.8+/-0.8	27.5+/-10.5%

SA-PO700

Renal Oxalosis in Adult Patients: A Relatively Common Entity of Often Unclear Etiology

Yihe Yang,[1,2] Purva D. Sharma,[1,2] Vinay Nair,[1] Kenar D. Jhaveri,[1,2] Deepa A. Malieckal,[1,2] Rimda Wanchoo,[1,2] Jordan L. Rosenstock,[1,2] Vanesa Bijol.[1,2] *[1]Northwell Health, Bayside, NY; [2]Zucker School of Medicine at Hofstra Northwell, Great Neck, NY.*

Background: The prevalence, manifestation and outcome of secondary oxalate nephropathy have not been extensively studied.

Methods: Retrospectively reviewed kidney biopsy cases with oxalate deposition (7/1/2017-12/31/2018).

Results: The prevalence of oxalate deposition on a kidney biopsy was 4.07%(25/615). Prior to biopsy, oxalate was anticipated in only 1 case. The etiology of oxalosis was clarified retrospectively in 14 cases, most commonly due to GI surgery (n=10) and increased oxalate intake (n=4). In 11 cases, etiology remained unknown, although at least 3 cases were exposed to antibiotics associated with secondary oxalosis. There was no significant clinical/pathological or survival difference between known vs. unknown cause groups. Multivariate COX regression showed that Cr at the time of biopsy (HR1.79,95%CI 0.71-4.51), background histological chronicity change(HR1.82, 95%CI 0.70-4.72) and oxalate density (HR2.27,95%CI 0.49-10.55) are associated with ESRD and patient death(-2LogLikelihood: 20.15 to 16.99, forward selection).

Conclusions: Oxalate deposition is common but rarely anticipated biopsy finding. Nephrologists need to consider surgical history and other secondary causes of oxalosis as causes of AKI and CKD.

Table 1: Clinical and histological characteristics of patients with renal oxalosis

	Overall	Oxalosis with known etiology	Oxalosis with unknown etiology	p
N of patients	25	14	11	
N of renal biopsy	27	14	13	
Age (y)	63.6 ± 9.1	64.6±9.7	62.4±8.5	0.54
Male sex	13 (52%)	6 (42.9%)	7 (63.6%)	0.32
BMI (kg/m^2)	30.6±8.6	29.9±9.3	31.8±8.4	0.64
Diabetic	16 (64%)	10 (71.4%)	6 (54.5%)	0.38
Hypertension	19 (76%)	10 (71.4%)	9 (81.8%)	0.55
Cr at renal biopsy (mg/dL)	6.31±3.23	5.92±3.43	6.86±3.04	0.50
Cr at last follow-up (mg/dL) *	2.86±1.53	2.71±1.59	3.09±1.57	0.66
Follow-up time (months)**	3.1±4.7	3.7±5.1	2.4±4.2	0.48
ESRD or Death	6 (24%)	4 (26.8%)	2 (18.2%)	N.A.
Histological Parameters				
Presence of diabetic nephropathy	8 (29.6%)	6 (42.9%)	2 (15.3%)	0.12
Presence of acute tubular injury	17 (63.0%)	7 (50%)	10 (76.9%)	0.15
Presence of acute interstitial inflammation	9 (33.3%)	3 (21.4%)	6 (46.2%)	0.09
Presence of interstitial fibrosis	3 (11.1%)	2 (14.3%)	1 (7.7%)	0.59
Global sclerosis (%)	26.27±20.60	29.92±20.53	21.90±20.89	0.38
Tubular atrophy (%)	37.27±20.80	47.50±19.25	25.00±15.81	0.01
Mild artery and arteriolar sclerosis	2 (7.4%)	2 (14.3%)	0	0.38
Moderate artery and arteriolar sclerosis	9 (33.3%)	3 (21.4%)	6 (46.2%)	
Severe artery and arteriolar sclerosis	11 (40.7%)	7 (50%)	4 (30.8%)	
Oxalate density (per cm)	15.49±18.68	19.20±23.65	11.45±10.86	0.33

*only patients not progressed into ESRD are included in this calculation.

**time from renal biopsy to the last follow-up or ESRD/death.

Clinicopathologic Spectrum of Renal Lesions Following Anti-TNF Alpha Inhibitor Therapy: A Single-Center Experience

Joichi Usui,[1] Steven Salvatore,[2] Kunihiro Yamagata,[1] Surya V. Seshan.[3] *[1]University of Tsukuba, Tsukuba, Japan; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medical Center, New York, NY.*

Background: Anti-tumor necrosis factor (TNF)-alpha inhibitors, as biological agents, are used in a number of chronic immune mediated inflammatory states such as rheumatoid arthritis (RA), psoriatic arthritis (PA), and Crohns disease. This therapy can induce several autoimmune serologic markers and disorders including systemic vasculitis and lupus-like diseases, which may affect the kidney.

Methods: We studied the clinicopathologic features of kidney disease from our renal biopsy files from 2000-2018 and categorized them into pathogenic groups.

Results: 45 patients using anti-TNF alpha inhibitors had renal biopsies, RA in 30, PA in 6, Crohns disease 7, RA and PA 1, RA and Crohns 1. Among these, 21 received etanercept, 16 adalimumab, 8 infliximab and 4 had 2 kinds of anti-TNF alpha inhibitors. The patients presented mostly with nephritic syndrome or CKD plus 1 case of AKI and 6 nephrotic syndrome. The main renal lesions on biopsy were classified into 3 groups: autoimmune and anti-TNF alpha induced lesions in 15, autoimmune disease-only 8, a variety of renal lesions unrelated to autoimmune or anti-TNF alpha therapy in 22 (diabetic nephropathy, interstitial nephritis, acute tubular injury, infection-related GN). Crescentic glomerulonephritis was seen in 6, 5 being pauci-immune type with 4 ANCA positive serology. Lupus or lupus-like nephritis was diagnosed in 6: ISN/RPS 2018 class II-2, class V-2, class III+V-1, class IV+V-1. Concurrent fibrillary GN, scleroderma renal crisis and renal amyloidosis were noted in 3 cases. In addition, active or chronic thrombotic microangiopathy was noted in 5, possibly associated to scleroderma or antiphospholipid antibodies, and nephrotic syndrome secondary podocytopathy in 2 cases.

Conclusions: The renal lesions during anti-TNF alpha therapy may have an autoimmune basis such as lupus, lupus-like or ANCA mediated disease, as well as secondary to endothelial or podocyte injury or related to the primary underlying systemic disease.

SA-PO702

Pathological Value of Lysozyme Staining for Diagnosing Renal Sarcoidosis

Satoru Sanada, Shohei Yoda, Toshinobu Sato. *Japan Community Health Care Organization Sendai Hospital, Sendai, Japan.*

Background: Sarcoidosis is a systemic inflammatory disease of unknown etiology. Pathological findings of the kidney show interstitial fibrosis with or without granulomatous formation, whereas low detection rates of granulomas make it difficult to diagnose renal sarcoidosis. We have found positive lysozyme staining of kidney tubular cells in sarcoidosis and assessed the diagnostic value of lysozyme staining for sarcoidosis.

Methods: Kidney biopsy specimens of 41 cases of pathological diagnosed tubulointerstitial nephritis (TIN) obtained in Japan Health Care Organization Sendai Hospital between 2013 to 2019 were analyzed retrospectively by immunohistochemistry. Diagnosis of sarcoidosis was made by clinical, radiational, and histopathological examinations. Samples of representative skin sarcoidosis were also stained by lysozyme. Three specimens from sarcoidosis, chronic myelomonocytic leukemia (CMML) and IgG4-related nephritis were analyzed by electron microscopy.

Results: All six cases of sarcoidosis showed positive staining of lysozyme in proximal tubular cells (100%), however, 25 TIN specimens, including drug-induced, IgG4-related, aristolochic acid toxicity, ischemia and Sjogren syndrome showed blunted stains (0%). The specimen of CMML-related TIN, representative of lysozyme-induced nephropathy, showed strikingly positive lysozyme staining in the proximal tubules. Among nine idiopathic TIN, two cases revealed lysozyme positive. These cases did not meet the diagnostic criteria of sarcoidosis clinically, but the possibility of sarcoidosis cannot be denied. In electron microscopy, an increased number of lysosomes in proximal tubules was observed in CMML and sarcoidosis, however, no lysosome was found in IgG4-related nephritis. In skin sarcoidosis, positive lysozyme staining was shown in basal layer of epidermis and dermis while no stain was found in skin samples from different subjects.

Conclusions: Lysozyme staining can aid in the diagnosis of renal sarcoidosis by distinguishing from sarcoidosis to other TIN diseases. Lysozyme induced tubular injury could be an underlying mechanism of TIN in sarcoidosis. In addition, this method could be a useful tool to detect clinically underdiagnosed sarcoidosis including skin and kidney lesions.

SA-PO703

Endothelial Cell Injury Can Be Significant in Cases of Membranoproliferative Glomerulonephritis with Monoclonal IgG Deposition

Anri Sawada,[1,2] Kunio Kawanishi,[3] Sekiko Taneda,[2] Shohei Fuchinoue,[2] Kazunari Tanabe,[2] Junki Koike,[5] Kazuho Honda,[4] Akira Shimizu,[1] Kosaku Nitta,[2] Yoji Nagashima.[2] *[1]Nippon Medical School, Tokyo, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan; [3]University of Tsukuba, Tsukuba, Japan; [4]Showa University School of Medicine, Tokyo, Japan; [5]St. Marianna University, Kawasaki, Japan.*

Background: Pathological and clinical features of proliferative glomerulonephritis with monoclonal IgG deposition (PGNMID) are not fully revealed. This study focused on glomerular endothelial alterations characterized by plasmalemmal vesicle associated protein-1 (PV-1) and Weibel–Palade body. PV-1 is a component of caveolae and considered an indicator of endothelial injury and Weibel–Palade body.

Methods: A total of 23 cases of PGNMID were compared with cases of lupus nephritis (n = 52), primary membranoproliferative glomerulonephritis (MPGN) (n = 7), and IgA nephropathy (n = 25). Informed consent from the patients and ethical approval from Tokyo Women's Medical University was obtained. PV-1 expression in the glomerular endothelium was evaluated using PAL-e antibody to verify endothelial changes in both PGNMID and control groups. Further, we compared monoclonal IgG patterns and complement deposition. We also examined histological types of MPGN and endothelial alterations as Weibel–Palade body using electron microscopy.

Results: Histological analysis in PGNMID group revealed MPGN type I (n = 10), MPGN type III (n = 8), membranous nephropathy (n = 3), endocapillary proliferative glomerulonephritis, and minor glomerular abnormality (n = 1). Deposit patterns were identified as IgG1 (IgG1κ, n = 6), IgG2 (IgG2λ, n = 1), and IgG3 (IgG3κ, n = 13; IgG3λ, n = 3). Further, 16 cases showed C1q deposition, and 21 cases showed C3 deposition. Electron dense deposits were located in subepithelial (n = 11), intramembranous (n = 16), subendothelial (n = 21), and mesangial (n = 19) sites. The percentage of PAL-e antibody-positive patients was significantly higher in PGNMID group (69.6%, n = 23) than in control groups (19.0%, n = 84). Weibel–Palade body density and caveolae were considerably elevated in PGNMID groups.

Conclusions: These results suggest that PGNMID-related damage is characterized by glomerular endothelium alterations; further studies are required to investigate whether such endothelial alterations are associated with clinical prognosis.

SA-PO704

Monoclonal IgG Deposit on Tubular Basement Membrane in Original Kidney

Anri Sawada,[1,2] Masayoshi Okumi,[2] Sekiko Taneda,[2] Shohei Fuchinoue,[2] Hideki Ishida,[2] Motoshi Hattori,[2] Kazunari Tanabe,[2] Kazuho Honda,[4] Kosaku Nitta,[2] Junki Koike,[3] Yoji Nagashima,[2] Akira Shimizu.[1] *[1]Nippon Medical University, Tokyo, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan; [3]St. Marianna University, Kawasaki, Japan; [4]Showa University School of Medicine, Tokyo, Japan.*

Background: Tubular basement membrane immune deposit (TBMID) are often observed during renal biopsies. We recently reported that monoclonal IgG TBMID is associated with the progression of interstitial fibrosis and tubular atrophy (IFTA) in renal allografts; however, its significance in original kidneys remains unclear.

Methods: This retrospective study includes 3,126 patients who underwent native renal biopsy and 1,724 patients who underwent 0-hour biopsy between 2008 and 2018 at Tokyo Women's Medical University. We performed light microscopic, electron microscopic, and immunofluorescence studies.

Results: IgG TBMID was identified in 164 (5.2%) patients who had undergone native renal biopsy and in six (0.4%) patients who underwent 0-hour biopsy. The IgG subclass was identified in 94 patients. Monoclonal IgG TBMID was found in seven patients, including three patients who underwent 0-hour biopsy. Pathological diagnosis was that of IgA nephropathy (n = 3, including one patient who underwent of 0-hour biopsy), minor glomerular abnormalities (n = 2), antineutrophil cytoplasmic antibody-related vasculitis (n = 1), and light and heavy chain deposition disease (LHCDD) (n = 1). Upon IF, glomerular IgG deposition was negative for all patients. The combinations of IgG subclass and light chain were IgG1κ (n = 2), IgG1λ (n = 3), and IgG2κ (n = 2). Complement C3, C4, and C1q staining in the tubular basement membrane (TBM) was negative for all patients. Upon electron microscopy (EM), all patients showed a powdery electron-dense deposition (EDD). Median IFTA was 5% (range: 0–30%). Based on bone marrow examination, the diagnosis of monoclonal gammopathy of undetermined significance was

made in one patient, which was different from the patient with LHCDD. Median follow-up period from biopsy was 3.5 (range: 0.5–6) years. Although one patient with LHCDD developed renal graft failure, all other patients had stable renal function.

Conclusions: Unlike cases of renal allograft, IgG TBMID in the original kidneys does not appear to be associated with renal prognosis. However, it is necessary to investigate for hematological disorders and evaluate the type of deposit in the TBM by EM.

SA-PO705

Adenovirus Immunohistochemistry in Renal Transplantation

Maria Wester Trejo,[1] Mariet Feltkamp,[1] Els Wessels,[1] Jan A. Bruijn,[2] Hans J. Baelde,[1] Ingeborg M. Bajema.[1] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Human adenovirus, a linear double-stranded DNA virus, is a common cause of mild respiratory and gastrointestinal disease in otherwise healthy people. In immunocompromised patients, such as renal transplant patients, it may cause severe infections including hemorrhagic cystitis, hepatitis and interstitial nephritis. Adenovirus immunohistochemistry is a technique frequently used in the clinic to aid the diagnosis of adenovirus infections, next to PCR. Based on clinical experience, we recently questioned the specificity of immunohistochemical adenovirus detection in renal tissue as currently used in laboratories worldwide.

Methods: Adenovirus immunohistochemistry was performed on 25 pre-transplantation biopsies of donor kidneys, eight autopsy controls and one renal allograft which was removed as a result of renal failure caused by infection. Adenovirus PCR targeting Adenovirus species A, B, C, E and F was performed in quadruple on those biopsies staining positive for adenovirus. In addition, electron microscopy was performed on the renal allograft.

Results: The renal allograft and 4 out of 25 pre-transplantation kidney biopsies were positive for adenovirus on immunohistochemistry, showing typical nuclear and perinuclear staining in tubular epithelium as previously reported in the literature. However, adenovirus PCR remained negative in all cases. Electron microscopy of the renal allograft showed particles with a width ranging from 75 to 95 nm, which could be compatible with adenovirus virions.

Conclusions: In cases in which adenovirus infection is clinically suspected and a positive immunohistochemical staining for adenovirus supports this notion, an additional workup (PCR and/or EM) is usually not performed. It appears that by immunohistochemistry, positivity for adenovirus is present in normal donor kidney samples without clinical suspicion for adenovirus infection. Because of lack of confirmation by PCR, we question whether immunohistochemistry for adenovirus is specific and clinically relevant. Alternatively, adenovirus could be present (latently?) in the otherwise healthy population – but little is known about its prevalence.

SA-PO706

Kidney Function and Histopathology in Patients Undergoing Nephrectomy

Shruti Gupta,[1] Ping Li,[3] Suraj Sarvode Mothi,[5] Sushrut S. Waikar,[2] Gearoid M. McMahon.[4] *[1]BWH, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Chinese PLA General Hospital, Beijing, China; [4]Brigham and Women's Hospital, Brookline, MA; [5]Brigham and Women's, Boston, MA.*

Background: Existing data on kidney histopathologic findings and estimated glomerular filtration rate (eGFR) are derived largely from studies from kidney donor nephrectomy specimens. Our objective was to use non-neoplastic tissue from nephrectomy specimens to examine the association between eGFR and the degree of glomerulosclerosis (GS), interstitial fibrosis/tubular atrophy (IF/TA), and arteriosclerosis (AS).

Methods: We reviewed non-neoplastic kidney pathology reports from patients who underwent nephrectomy between 1999 and 2018 (n=1,195). We used linear regression models to determine the association between the degree of GS, IFTA, and AS, with eGFR at the time of nephrectomy. We also assessed the relation between age and eGFR, stratifying by the degree of GS, IFTA, and AS.

Results: Greater %GS, IFTA, and AS were associated with lower eGFR (Figure 1). After MV-adjustment, eGFR was most strongly associated with greater degrees of IFTA [-29.0 ml/min/1.73m^2 (95% CI -34.2, -24.0), p <0.001 among those with >50% vs <10% IFTA]. The slope of decline in eGFR within each category of GS, IFTA, AS, and chronicity score did not differ based on age (Figure 2) (interaction term p >0.05).

Conclusions: Independent of age, lower eGFR was associated with a greater severity of histopathologic changes.

SA-PO707

Percutaneous Renal Biopsy Using an 18-Gauge Automated Needle Is Not Optimal

George Sousanieh, William L. Whittier, Stephen M. Korbet. *Rush University Medical Center, Chicago, IL.*

Background: As percutaneous renal biopsies (PRB) are increasingly performed by interventional radiologists, an increase in the use of the smaller 18-gauge (G) automated biopsy needle has been observed. The use of smaller needles stands to compromise biopsy adequacy, ideally >20 glomeuli per biopsy. We compare the adequacy and safety of PRB with a 14, 16 and 18G automated needles.

Methods: PRB of native (N) kidneys (N-557) and transplant (T) kidneys (N-991) was performed by a Nephrologist or supervised Fellow at Rush University Medical Center from 1/2002 to 12/2018 using automated biopsy needles and with real-time ultrasound guidance. Baseline clinical and laboratory data, biopsy data (number of cores, glomeruli on light (LM) and immunofluorescence (IM) microscopy, total glomeruli (LM+IM) and total glomeruli per core (LM+IM)/cores)) and outcome data (hematoma on renal US 1-hr post-PRB, complications and procedures post-PRB) was collected prospectively. PRB with N14G (n=337) vs N16G (n=220) vs T16G (n=892) vs T18G (n=99) needles were compared. A P value of <0.05 was significant.

Results: PRBs with an 18G needle were less likely to be performed by fellows (N14 vs N16 vs T16 vs T18G: 94% vs 85% vs 62% vs 22%, <0.0001). Despite this, PRB with an 18G needle was associated with the lowest number of glomeruli on LM (23±11 vs 20±10 vs 26±14 vs 16±10, <0.0001), IM (9±5 vs 9±5 vs 8±5 vs 6±, <0.0001) and LM+IM (32±13 vs 29±12 vs 34±6 vs 22±12, <0.0001). PRBs with an 18G needle were less likely to have >10 (99% vs 98% vs 98% vs 89%, <0.0001) and >20 (81% vs 79% vs 83% vs 48%, <0.0001) total glomeruli (LM+IM) per biopsy. The total glomeruli per core ((LM+IM)/cores) was also significantly less with an 18G needle (15±8 vs 14±6 vs 13±6 vs 10±5, <0.0001). A hematoma by renal US 1-hr post-PRB was similar for native biopsies (14G-35% vs 16G-29%, P=0.16), and transplant biopsy (16G-10% vs 18G-10%, P=0.71) irrespective of needle size. The complication rate for native biopsies (14G-8.9% vs 16G-7.2%, P=0.53), and transplant biopsies (16G-4.6% vs 18G-2.0%, P=0.30) and the transfusion rate for native biopsies (14G-7.7% vs 16G-5.9%, P=0.49), and transplant

biopsies (16G-3.8% vs 18G-1.0%, P=0.25) were not significantly different irrespective of needle size.

Conclusions: The use of 18G biopsy needles significantly compromise the adequacy and thus, quality of the PRB while not significantly enhancing safety.

SA-PO708

Necessity Drives Innovation: Using Transjugular Liver Biopsy Sets for Renal Biopsies

Paul M. Adams,[1] Sadiq Ahmed,[1] Virgilius Cornea.[2] University of Kentucky *[1]Nephrology, University of Kentucky, Lexington, KY; [2]University of Kentucky, Lexington, KY.*

Background: Renal biopsies are a cornerstone of nephrology, providing valuable diagnosis and treatment information. In some cases, traditional percutaneous biopsies are limited by factors such as obesity, coagulopathy and critical illness. Previously, an intravascular transjugular approach using a renal biopsy set from Cook Medical (Bloomington, IN) was used. However, the Cook set was discontinued in 2016, leaving few options for such patients in the United States. As a solution to this problem, our institution has employed a liver biopsy set manufactured by Argon Medical Devices (Frisco, TX). Our case series describes the novel and successful use of a transjugular liver biopsy set for renal biopsies in complex patients.

Methods: We reviewed patients undergoing transjugular renal biopsy using the Argon liver biopsy set at our center from 2017-2018. Indications, demographics, and outcomes were noted. Briefly, the procedure involves catheterization of the right internal jugular vein and subsequent right renal vein catheterization with renal cortex identification by venography. Biopsy specimens are then obtained using the Argon core biopsy needle set.

Results: Eighteen patients underwent a transjugular renal biopsy with the liver set. Biopsy adequacy was 95% as judged by interpreting pathologists. Complications were rare, with only one patient experiencing bleeding which was self-limited. Results are summarized in Table 1.

Conclusions: Our novel case series demonstrates that a transjugular liver biopsy set is safe and effective for renal biopsies in patients unsuitable for percutaneous biopsy. These findings are significant as there are limited options for transjugular renal biopsies in the United States. Hopefully this will lead to wider use of such techniques.

SA-PO709

The Accuracy of Equations That Estimate Glomerular Filtration Rate Compared with Measured Creatinine Clearance in Critically Ill Patients

Abdulmajeed Alsadhan,[2] Hasan M. Al-Dorzi,[3] Ayman S. Almozaini,[2] Ali Alamri,[2] Hani Tamim,[4] Lolowa Alswaidan,[2] Yaseen M. Arabi.[1] *[1]King Saud Bin Abdulaziz University for Health Sciences, King Abdulaziz Medical City, Riyadh, Saudi Arabia; [2]King Abdulaziz Medical City-Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia; [3]King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [4]American University of Beirut, Beirut, Lebanon.*

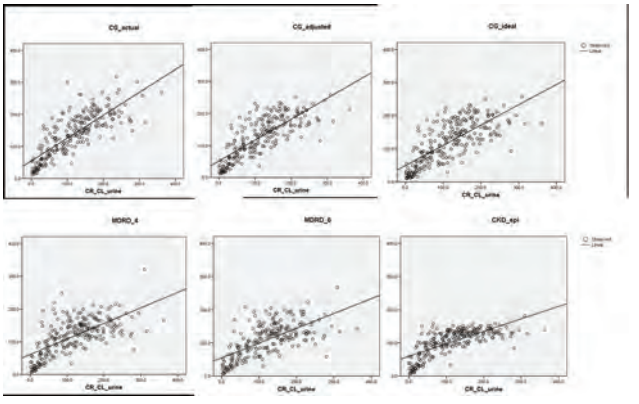
Background: The accuracy of glomerular filtration rate estimates has been questioned. This study compared estimates of GFR by commonly used equations with creatinine clearance measured by 24-hour urine collection in critically ill patients.

Methods: This sub-study of the PermiT trial included the patients enrolled at KAMC-Riyadh who had 24-hr urine collection. We estimated GFR using the Cockroft–Gault (CG), Modification of Diet in Renal Disease(MDRD4-MDRD6) and Chronic Kidney Disease Epidemiology Collaboration(CKD-EPI) equations. For the CG equation, we entered actual weight in one calculation(CG actual-wt), and for BMI ≥30 kg/m2, the ideal body weight and the adjusted body weight in two calculations.

Results: The cohort consisted of 238 patients (age 45.2±20.2 years, DM 31.9%, CKD 2.9%, APACHE II 20.3±8.1, mechanical ventilation 98.7% and serum Cr 214±128 micromol/L). The measured CrCl24h-urine was 117.0±75.0 ml/min. The correlations between the different formulae were all significant (p<0.0001).

Conclusions: There was a modest correlation between the formulae estimating GFR with CrCl24hr-urine. CGactual-wt had the best correlation. Strength of correlation changed within the different ranges of CrCl24h-urine.

	Estimated GFR(ml/min)	Correlation(r) with CrCl(24h-urine)
CG (Actual-wt)	138.3 67.2	0.80
CG(Ideal-wt)	121.0 62.4	0.74
CG(Adjusted-wt)	127.9 62.4	0.78
MDRD-4	116.8 54.1	0.66
MDRD-6	109.2 51.0	0.65
CKD-EPI	103.5 39.5	0.71



CrCl24h-urine (ml/min)	Correlation (r) based on the equation
20-60 (ml/min)	CKD-EPI (r=0.42) MDRD-4 (r=0.37)
60-130 (ml/min)	$CG_{ideal-wt}$ (r=0.29) $CG_{adjusted-wt}$ (r=0.29)
> 130 (ml/min)	$CG_{actual-wt}$ (r=0.41) $CG_{adjusted-wt}$ (r=0.35)

SA-PO710

Performance of StatSensor Point-of-Care Device for Measuring Creatinine in Patients with CKD or Post-Kidney Transplantation

Melissa S. Nataatmadja,[1,2] Angela Fung,[3] Beryl E. Jacobson,[4] Eva Bernstein,[5] Paul Komenda,[8] Andre Mattman,[3] David Seccombe,[4] Adeera Levin.[6,7] *[1]Department of Nephrology, Sunshine Coast University Hospital, Birtinya, QLD, Australia; [2]School of Medicine, The University of Queensland, Herston, QLD, Australia; [3]Department of Pathology and Laboratory Medicine, St. Paul's Hospital, Vancouver, BC, Canada; [4]CEQAL Inc, Vancouver, BC, Canada; [5]Providence Health Care Research Institute, Vancouver, BC, Canada; [6]Division of Nephrology, St. Paul's Hospital, Vancouver, BC, Canada; [7]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [8]University of Manitoba, Winnipeg, MB, Canada.*

Background: The StatSensor measures creatinine in "fingerstick" capillary blood samples. Previous studies reported a negative bias at higher creatinine concentrations. The current accuracy-based study evaluates the use of this device in kidney transplanted patients and those with CKD.

Methods: Duplicate StatSensor creatinine measurements were performed on direct fingerstick samples from 60 participants (mean age 61.9 years, 55% male, 33% transplant, mean plasma creatinine 137 μmol/L) and compared to plasma creatinine values obtained from simultaneous venous blood sampling using a Roche Integra 400 mainframe analyser.

Results: Bland-Altman analysis indicated a positive mean difference (bias) of 25.4 μmol/L between StatSensor fingerstick creatinine measurement and plasma creatinine. Comparison of eGFR (CKD-EPI) calculated from the StatSensor fingerstick creatinine versus plasma creatinine revealed misclassification across all KDIGO CKD stages (Figure 1). Post-analytical correction of the bias did not improve misclassification. Use of mean of duplicate StatSensor creatinine results did not improve performance compared to use of singlet results.

Conclusions: Our results suggest that the limiting characteristics of the StatSensor are not only bias, but also imprecision. The level of imprecision observed would likely

influence clinical decision making and limits the StatSensor's usefulness as a CKD screening tool. If choosing to utilise it for either screening for or monitoring CKD, it is essential that clinicians understand the limitations of point-of-care devices and apply this knowledge to test interpretation.

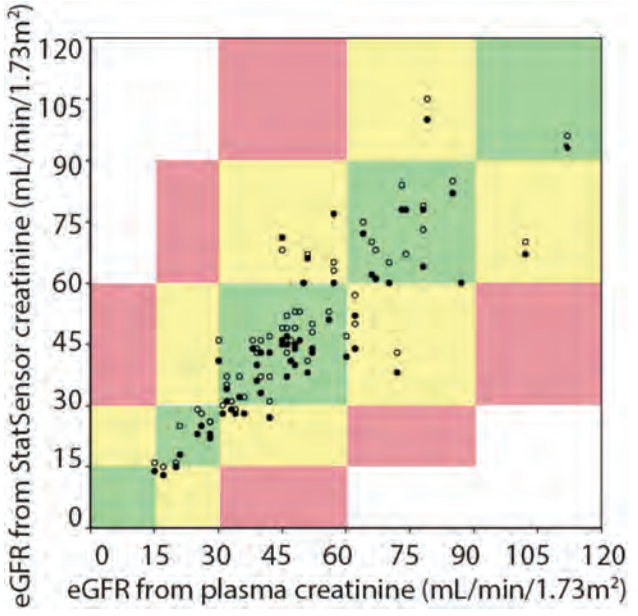


Figure 1. eGFR with StatSensor creatinine vs plasma (● Uncorrected creatinine; ○ Bias corrected creatinine)

SA-PO711

B and T Cell Subsets in Patients with Membranous Nephropathy: Comparison of Frozen Stored vs. Freshly Collected Blood Samples

Coralien Vink- van Setten, Anne-Els van de Logt, Jack F. Wetzels. *Radboud University Medical Center, Nijmegen, Netherlands*.

Background: It is suggested that characterisation of B and T cell subsets may provide relevant information in auto-immune diseases. Rosenzwajg et al (Kidney Int 2017; 92,277-237) studied B and T cell subsets in Rituximab treated patients with primary membranous nephropathy (pMN). They observed a decrease of regulatory T cells as well as NK cells in active disease, whereas numbers of naive B cells were increased. The increase in Treg after Rituximab predicted treatment response. In the literature B and T cell subsets are evaluated using frozen peripheral blood mononuclear cells (PBMCs) or freshly isolated blood samples. We compared these conditions, a comparison which is lacking in the literature.

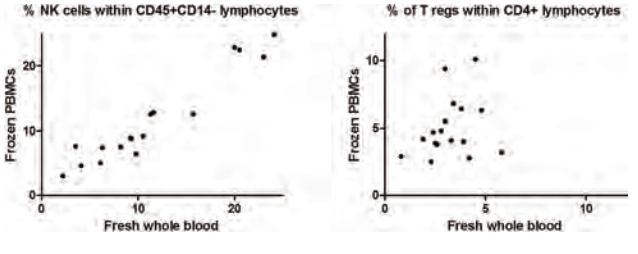
Methods: In 18 patients with pMN, we collected 20 mL of EDTA plasma. 10mL was used for fresh whole blood analysis and 10mL was used for isolation of PBMCs, and samples were stored in liquid nitrogen for 6 – 12 months. We characterised immune cell subsets with flowcytometry with fluorescently labelled cell surface markers: CD3, CD4, CD5, CD8, CD14, CD16, CD19, CD20, CD24, CD25, CD27, CD38, CD45, CD45 RA, CD45RO, CD56, CD127, HLA-DR, IgD, IgM.

Results: The distribution of the various B and T cell subsets when comparing both conditions showed a good correlation(table). The figure shows the correlation for NK cells and Tregs respectively. Our data show a weak correlation specifically within the Treg subset.

Conclusions: Our study suggests that frozen PBMC samples can be used for the characterisation of T and B lymphocytes and NK-cells, except for the Treg population. This may be improved by intracellular staining techniques. Further validation is needed.

Comparison of fresh and frozen immune cell subsets

Cell type	Fresh whole blood	Frozen PBMCs	Spearman correlation coefficient (P value)
Monocytes	20.3%	31%	0.631 (0.005)
Lymphocytes	79.7%	69%	0.631 (0.005)
total T-cells (within lymphocytes)	73.4%	67.9%	0.811 (0.000)
CD4 (within T-cells)	69.2%	68.1%	0.934 (0.000)
Treg (within T-cells)	3.1%	4.4%	0.421 (0.082)
CD8 (within T-cells)	26.6%	27.6%	0.935 (0.000)
total B-cells (within lymphocytes)	3.8%	6.5%	0.824 (0.000)
NK-cells (within lymphocytes)	10.9%	9.0%	0.939 (0.000)



SA-PO712

Vasculopathy Plays an Essential Role During the Development and Relapse of Encapsulating Peritoneal Sclerosis in Conventional PD Solutions

Mitsuhiro Tawada,[1,2] Yasuhiko Ito,[3] Ting Sun,[2] Yasuhiro Suzuki,[2] Masashi Mizuno,[2] Makoto Yamaguchi,[3] Takayuki Katsuno,[3] Masataka Banshodani,[4] Hideki Kawanishi.[4] *[1]Koujyukai Kasugai Hospital, Kasugai, Japan; [2]Department of Nephrology and Renal Replacement Therapy, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Aichi Medical University, Nagakute, Aichi, Japan; [4]Tsuchiya General Hospital, Hiroshima, Japan*.

Background: Encapsulating peritoneal sclerosis (EPS) is a rare, but life-threatening complication of peritoneal dialysis (PD) therapy. The precise pathogenesis remains unknown, making it difficult to prevent the development of EPS. The aim of this study is to examine the peritoneal samples of EPS patients and identify the association of the peritoneal pathology with different clinical factors.

Methods: Peritoneal samples were obtained at the time of surgical enterolysis in Tsuchiya General Hospital from 1993 to 2016. Total 283 peritoneal samples were screened. This study used pathological and immunopathological techniques to assess EPS peritoneum samples.

Results: 214 in 283 samples were evaluable. In conventional PD solution group, the ratio of lumen diameter to vessel diameter (L/V ratio) was significantly smaller (P<0.01) and less angiogenesis (P=0.014). Lower L/V ratio was also found to be related to the relapse of EPS (P=0.014). Univariate analysis demonstrated that L/V ratio was significantly associated with EPS relapse (P=0.024). Multivariate logistic regression analysis suggested that more sever vasculopathy with low L/V ratio was identified as a risk factor of EPS relapse (per 0.1 increase, HR 0.87, P= 0.025)

Conclusions: Pathophysiology of the development of EPS was different between conventional solution and pH-neutral solution. Vasculopathy was related to the development and relapse of EPS in conventional solutions.

SA-PO713

Assessing Bleeding Risk in CKD Using Global Coagulation Assays

David Langsford,[1,3] Brandon Lui,[3] Timothy J. Pianta,[1,3] David Barit,[1,3] Harshal Nandurkar,[2,3] Prahlad W. Ho,[2,3] Yin H. Lim.[2,3] *[1]Department of Nephrology, Northern Health, Melbourne, VIC, Australia; [2]Department of Hematology, Northern Health, Melbourne, VIC, Australia; [3]University of Melbourne, Melbourne, VIC, Australia.*

Background: Later stage CKD patients are often clinically hypocoaguable. Current coagulation studies do not sufficiently assess this risk. Global coagulation studies (GCA) are functional studies that can better describe bleeding and thrombosis risk. GCA includes whole blood thromboelastography (TEG), platelet-poor calibrated automated thrombogram (CAT), overall haemostatic potential (OHP). TEG is well established in the management of major haemorrhage and massive transfusion. We aim to evaluate using GCA in CKD patients to help define bleeding or thrombosis risks.

Methods: We prospectively recruited 2 groups of stable CKD patients. Pre-dialysis with eGFR<30 ml/min/1.73m² (n=24) and dialysis patients (n=46 haemodialysis, n=10 peritoneal dialysis) were compared to healthy controls (n=138). Baseline renal, hematological investigations and GCA were compared using t-test and chi-square statistics.

Results: Compared to controls (67% female, mean age 42, creatinine 70umol/L) predialysis CKD (46% female, mean age 70, creatinine 237umol/L, urea 18.6mmol/L, eGFR 22 ml/min/1.7m2) had increased von Willebrand factor (VWF) antigen (223 vs 102%, p<0.001), factor VIII (208 vs 108%, p<0.001) and D-dimer (1188 vs 430, p<0.001). Pre-dialysis CKD were prothrombotic with increased maximum amplitude (MA, a measure of clot strength) of 68 vs 60mm (p<0.01) compared to controls. In predialysis CKD, there was no association between urea or eGFR and MA. Thrombin generation (peak thrombin 269 vs 219nM, p<0.01) and fibrin generation (OHP 41 vs 29, p<0.01) were increased with impaired fibrinolysis (OFP 42 vs 50%, p<0.01) compared with controls. Dialysis patients (38% female, mean age 66) also had increased clot strength (MA 70mm, p<0.01) and reduced fibrinolysis (OHP 41 U, OFP 40%, p<0.01) compared to controls. Measures of clot strength and overall fibrinolysis were not significantly different between pre-dialysis and dialysis patients.

Conclusions: Contrary to expectation, pre-dialysis CKD and dialysis patients were not found to be hypocoaguable using functional coagulation tests. Both groups were found to have markers conferring increased prothrombotic risk: elevated vWF, increased TEG measures and impaired fibrinolysis. The clinical significance of these results and the use of GCA to stratify both thrombotic and bleeding risk warrants further investigation.

SA-PO714

Usefulness of Urinary-Soluble CD163 as a Biomarker of Disease Activity in Patients with Glomerulonephritis

Hidenori Yamazaki, Tsutomu Koike, Hayato Fujioka, Kota Kakeshita, Shiori Kobayashi, Ayako Takashima, Koichiro Kinugawa. *The Second Department of Internal Medicine, University of Toyama, Toyama, Japan*.

Background: Although histopathological examination of kidney tissues can be useful for understanding of disease activity of glomerulonephritis, there are undiagnosed cases because of the difficulties in performing invasive biopsies. Therefore, noninvasive

biomarkers are needed to reflect disease activity and monitor response to therapy in patients with glomerulonephritis. Recently, it is suggested that the level of urinary soluble CD163 (sCD163), a marker of M2 macrophage infiltration, associated very tightly with active renal vasculitis, but the usefulness of urinary sCD163 as a surrogate marker of disease activity in glomerulonephritis is unclear. In this study, we investigated whether urinary sCD163 is useful for reflecting disease activity and monitoring response to therapy in patients with glomerulonephritis.

Methods: Subjects were forty-five patients with biopsy-proven glomerulonephritis including IgA nephropathy (n=24), IgA vasculitis (n=7), ANCA-associated glomerulonephritis (n=8), and lupus nephritis (n=6). In all patients, urinary excretion of sCD163 and protein, and quantitative urinary occult blood were measured at two points (baseline and follow-up). The relationships between change in urinary sCD163, reflecting follow-up value minus baseline value, and changes in other measurements were evaluated.

Results: Patients except for 8 cases of IgA nephropathy were treated with steroid therapy. At the point of follow-up, urinary sCD163 significantly decreased compared with baseline (6582±10827 to 1837±4510 pg/mgCr, p <0.01). Change in urinary sCD163 positively correlated with change in urinary protein (r = 0.60, p <0.01), whereas change in urinary sCD163 did not associate with change in urinary occult blood. ROC curve analysis revealed that a reduction of urinary sCD163 by more than 60% predicted remission of proteinuria defined as urinary protein < 0.3 g/gCr (71.4% sensitivity and 87.1% specificity), and a reduction of urinary sCD163 by more than 86% predicted remission of hematuria remission (86.4% sensitivity and 54.5% specificity).

Conclusions: Urinary sCD163 levels reflected disease activity of glomerulonephritis and thus may be useful for monitoring disease activity in patients with glomerulonephritis.

SA-PO715

In Situ Visualization of C3/C5 Convertases: A New Diagnostic Tool to Differentiate Complement Activation in Kidney Biopsies

Thorsten Wiech,[1] Fermin Person,[3] Sonia Wulf,[5] Franziska Buescheck,[4] Sergey Biniaminov,[7] Wilfrid Fehrle,[5] Jun Oh,[6] Christine Skerka,[2] Peter F. Zipfel.[2] *[1]Department of Pathology, University Hospital Hamburg Eppendorf, Hamburg, Germany; [2]Leibniz Institute for Natural Product Research and Infection Biology, Jena, Germany; [3]Insitute of Pathology, University Hospital Basel, Basel, Switzerland; [4]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, Hamburg, Germany; [5]UKE, Hamburg, Germany; [6]University Childrens Hospital, Hamburg, Germany; [7]HS Analysis, Karlsruhe, Germany*.

Background: Deregulated complement activation contributes to or drives the pathogenesis of various kidney diseases. Currently, the diagnosis of complement activation in kidney diseases is primarily based on detection of complement activation products in glomerular tissue and of consumption of complement components or generation of split products in plasma. Up to now a method to directly identify, localize and differentiate complement convertases in tissue has been lacking.

Methods: We established a new *in situ* method for the detection of the assembled C3/C5-Convertases of the classical/lectin and alternative pathways using the bright field proximity ligation assay. We compared kidney biopsies derived from cases of systemic lupus nephritis (SLE, n=10) with cases of thrombotic microangiopathy (TMA, n=9) due to atypical hemolytic syndrome, using zero hour transplant biopsies as normal controls (n=5).

Results: As expected, SLE cases revealed a higher density of classical pathway C3/C5 convertases, while TMA cases showed less classical pathway enzymes and a higher density of alternative pathway C3/C5 convertase signals.

Conclusions: We introduce the first methodological workflow for the visualization, differentiation and quantification of classical/lectin and alternative C3/C5 convertases directly within the tissue specimen.

SA-PO716

Massive Ex Vivo C5b9 Formation on Endothelium Indicates Complement Defects and a Clinical Response to Complement Inhibition in Patients with Thrombotic Microangiopathy

Sjoerd Timmermans,[1] Pieter van Paassen.[2] Limburg Renal Registry *[1]Maastricht University Medical Center, Maastricht, Netherlands; [2]Maastricht University Medical Center/Nephrology and Clinical Immunology, Maastricht, Netherlands.*

Background: The syndromes of thrombotic microangiopathy (TMA) are extraordinarily diverse, some of which have been linked to defects in complement regulation. The correct recognition of such defects in patients with TMA is critical for treatment and prognosis, although challenging in patients with coexisting conditions, i.e., so-called secondary TMAs. We evaluated the clinical value of an *ex vivo* test to detect complement defects in a well-defined cohort of patients with TMA.

Methods: Sixty-three patients with TMA on kidney biopsy and/or peripheral blood smear were analyzed for serum-induced *ex vivo* C5b9 formation on microvascular endothelial cells and compared to pooled normal human serum. Patients with TMA also were screened for rare variants in genes linked to complement regulation. In addition, renal survival at 1 year was assessed.

Results: At diagnosis, massive *ex vivo* C5b9 formation was found in *n*/*N*=40/63 (63%) patients with TMA, including *n*/*N*=15/15 with atypical hemolytic uremic syndrome, *n*/*N*=17/25 with hypertensive emergency, *n*/*N*=6/6 with pregnancy, *n*/*N*=1/1 with invasive Streptococcus pneumonia infection, and *n*/*N*=1/1 after an endovascular aortic repair, but neither in those with coexisting autoimmunity (n=9) nor thrombotic thrombocytopenic purpura (n=6). Patients with massive *ex vivo* C5b9 formation presented with severe acute kidney injury (median serum creatinine of 538 versus 197 μmol/L, *P*<0.01) and a high prevalence of rare variants in complement genes (23 [58%] versus 0, *P*<0.001) as compared to those with normal *ex vivo* C5b9 formation. Seventeen patients with massive *ex vivo* C5b9 formation were treated with eculizumab (median number of treatment was 14); renal survival at 1 year was *n*/*N*=14/17 (82%) and *n*/*N*=9/23 (39%) for treated and untreated patients (*P*<0.01), respectively. Notably, 3 patients with normal *ex vivo* C5b9 formation who had been treated with eculizumab progressed to end-stage renal disease.

Conclusions: Massive *ex vivo* C5b9 formation indicates defects in complement regulation as the dominant cause of TMA, including TMAs that present with coexisting conditions. Patients with TMA and massive *ex vivo* C5b9 formation may benefit from complement inhibition.

SA-PO717

Direct and Indirect Effects of Macrophage Compartmental Localization and Salt Concentration in the Kidney Graft

Janis Casper,[1] Jessica Schmitz,[1] Jan H. Braesen,[2] Abedalrazag A. Khalifa,[2] Bernhard M. Schmidt,[1] Hermann G. Haller,[1] Sibylle Von Vietinghoff.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Medizinische Hochschule Hannover, Hannover, Germany*.

Background: Recent data have delineated a role for sodium chloride in immune regulation. The kidney is characterized by a marked cortico-medullary salt gradient. A better understanding of local immunoregulatory mechanisms is especially relevant in the transplanted kidney, where the balance between detrimental inflammation in rejection and beneficial inflammation for host response is frequently lost.

Methods: Primary human macrophage and tubular cell culture single and co-cultures was performed in defined sodium chloride and urea concentrations serving as osmolarity control with an without therapeutic dose calcineurin inhibitors and analyzed by flow cytometry, qPCR and microscopy. In a cohort of 112 adult renal allograft recipients, renal cortical and medullary macrophage polarization markers and MCP-1 chemokine production were analyzed by digitally assisted immunohistology of surveillance biopsies. Incidence of urinary tract infection during five years after transplantation was extracted from the records.

Results: Under defined conditions in vitro, an elevated sodium chloride concentration dose-dependently increased chemotactic cytokine MCP-1 production in human renal tubular epithelial cells and also in monocyte derived macrophages. Patients who received loop diuretic therapy, which depletes the renal cortico-medullary salt gradient, had significantly lower MCP-1 serum levels and no gradient between renal medullary and cortical MCP-1 protein, in contrast to patients without diuretic therapy, where it was significant. The renal medullary M1/M2 macrophage marker ratio decreased with increasing loop diuretic dose. Clinically, diuretic therapy significantly correlated with urinary tract infection rate in uni- and multivariable regression analysis in this cohort of renal allograft recipients.

Conclusions: Renal medullary M1/M2 macrophage marker ratio and MCP-1 gradient significantly associated with loop diuretic therapy as did urinary tract infection rate. Modulation of the renal salt gradient should be considered and further investigated in patients at a high risk of urinary tract infections.

From Baseline Serum Creatinine to Creatinine-Based AKI: Different Definitions for Different Results

Sara Samoni,[6,1] Anna Lorenzin,[6] Silvia De Rosa,[6] Nicola Marchionna,[6] Massimo de Cal,[6] Luis I. Bonilla,[3] Gianluca Villa,[5] Monica Zanella,[2] Alessandra Brendolan,[2] Claudio Ronco.[4] *[1]Institute of Life Sciences, Sant'Anna School of Advanced Studies, Vicenza, Italy; [2]San Bortolo Hospital, Vicenza, Italy; [3]IRRIV, Vicenza, Italy; [4]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy; [5]University of Florence, Florence, Italy; [6]IRRIV - San Bortolo Hospital, Vicenza, Italy*.

Background: The lack of consensus on the definition of baseline serum creatinine(bsCr) influences the creatinine-based acute kidney injury(AKI) diagnosis, leading to problems relating to both research and clinical purpose. Pre-admission bsCr, measured in a time-period of a maximum of 365 days and minimum of 7 days from hospitalization, is considered the gold standard, but is rarely available in unscheduled patients. Our study aims at evaluating sensitivity and specificity of different bsCr.

Methods: We retrospectively enrolled patients admitted to our intensive care unit(ICU) over 6-month period. Inclusion criteria were:(i)availability of pre-admission bsCr;(ii)length of ICU stay≧72hrs. According to the bsCr definitions derived from literature, we recorded:(i)sCr measured at ICU admission(admission bsCr);(ii)the lowest sCr achieved during the first 3 days of ICU stay(nadir bsCr);(iii)sCr calculated using the MDRD equation(back-estimation formula)(estimated bsCr), thus resulting 4 different bsCr for each patient. The occurrence of AKI was evaluated according to KDIGO criteria considering each of the 4 bsCr.

Results: Of 490 patients, 195 had pre-admission bsCr. 14 patients were excluded because daily sCr was not available. Using pre-admission bsCr, we identified 79 patients who developed AKI(43.6%). Results are summarized in table 1.

Conclusions: Admission bsCr, frequently used in ICU, has the lowest sensitivity for AKI, missing almost entirely the diagnosis of community-acquired AKI. In previous studies, estimated bsCr has been demonstrated to overestimate the incidence of AKI in patients with pre-existent chronic kidney disease. In the absence of pre-admission bsCr,

nadir bsCr seems to be the most accurate bsCr for diagnosis of AKI. Future efforts should focus on identifying a shared definition of bsCr.

	pre-admission bsCr	admission bsCr	nadir bsCr	estimated bsCr
AKI(pts)	79	37	63	69
no AKI(pts)	102	96	86	91
sensitivity(%)		46.8	87.3	79.7

New Approach to the Urinary Sediments: Strange Crystals in Urine

Makoto Abe,[1] Akihiro Tojo,[1] Shohei Yokoyama,[1] Mayu Uchida,[1] Yoshiki Murayama,[1] Takehiro Ohira,[1] Hiroshi Satonaka,[1] Toshihiko Ishimitsu.[2] *[1]Department of Nephrology & Hypertension, Dokkyo Medical University, Mibu, Japan; [2]Dokkyo Medical Univ, Mibu Tochigi, Japan.*

Background: Low vacuum scanning electron microscopy (LVSEM) is a non-perturbing technology that requires minimal sample preparation. Compared with conventional SEM, it is possible to observe wet samples directly without freeze-drying and vacuum evaporated carbon deposition process, thus, there is no loss of small parts of the samples during processing and can obtain more detail structure.

Methods: LVSEM was used to study the 3D structure of the urinary sediment from the patients undergone renal biopsy. Ten mL urine samples from renal biopsy patients were fixed with 1mL of 10% formalin and centrifuged at 500g for 5 minutes. The urinary sediments were stained with 1% Ponseau solution and mounted on the carbon filter membrane and observed with the LVSEM (Hitachi TM4000 Plus, Tokyo, Japan).

Results: Typical bipyramids calcium oxalate crystals and dodecahedrons crystals of various sizes were observed by LVSEM. Interestingly, dodecahedral calcium oxalate crystal shows multilayer configuration resembling a thread winding. Urine samples collected from the bladder catheter's bag showed curious honeycomb and tubular structures with spikes. It revealed that these structures were shed from the luminal walls of bladder catheter. These walls are composed of silicon-elastomer coated rubber to strengthen the tube.

Conclusions: LVSEM is a useful tool to obtain 3D views of the urinary sediment and can provide a new understanding of the urinary sediment, especially of the urinary crystals.

Clinical Verification of Urine Protein/Creatinine Ratio Instead of 24-Hour Urinary Protein Evaluated the Different Levels of Proteinuria in Children

Yanjie Huang, Xiaoqing Yang. *The First Affiliated Hospital of Henan University of Traditional Chinese Medicine, Zhengzhou, China.*

Background: To evaluate the correlation and consistency between urine protein/creatinine ratio (UPCR) and 24 hour urinary protein (24hUP) in children, and to determine cutoff values of UPCR relative to 24hUP at 150mg(>150mg is pathological proteinuria) and 50mg/kg (>50mg/kg is nephrotic-range proteinuria) respectively.

Methods: 370 children were enrolled, including 85 normal children, 109 Henoch-Schönlein purpura nephritis, 167 nephrotic syndrome, 5 IgA nephropathy, and 4 lupus nephritis. These patients were divided into three groups: normal group: 24hUP≤150mg, *n* =85; non-nephrotic range proteinuria group: 150mg<24hUP≤50mg/kg, *n* =120; nephrotic-range proteinuria group: 24hUP>50mg,kg, *n* =165. Clinical symptoms and laboratory examination data were collected. The correlation between UPCR and 24hUP were evaluated by spearman correlation analysis. The consistency between UPCR and 24hUP was analyzed by Bland-Altman technique. The cutoff values of UPCR in predicting non-nephrotic range proteinuria group and nephrotic-range proteinuria were determined using receiver operating characteristics (ROC) curve, respectively.

Results: UPCR was positively correlated with 24hUP (r =0.885, *P*<0.01). Bland-altman diagrams showed that UPCR and 24hUP had good consistency, and >95% spots of UPCR and 24hUP were within the 95% consistency area. Relative to 24hUP (150mg), the cutoff value (0.23g/g Cr) with the highest sensitivity (92.8%) and specificity (92.9%) was close to the UPCR>0.2g/g Cr proposed by American rheumatic society in 2006 as the diagnositic standard of pathological proteinuria. Relative to 24hUP (50mg/kg), the cutoff value (2.09g/g Cr) with the highest sensitivity (94.5%) and specificity (88.6%) was close to the UPCR>2.0g/g Cr proposed in 2012 KDIGO guidelines as the diagnositic standard of nephrotic syndrome and nephrotic-range proteinuria.

Conclusions: There are good correlation and consistency between UPCR and 24hUP. UPCR can be used to evaluate the different levels of proteinuria in children.

Alteration of Structural and Functional Connectivity in Neurologically Asymptomatic Patients with ESRD

Seong M. Jun, Yoo jin Lee, Bongsoo Park, Sihyung Park, Yang Wook Kim. *Haeundae paik hospital Inje University, Busan, Republic of Korea.*

Background: The aim of this study was to evaluate the alterations of structural and functional connectivity using graph theoretical analysis in the neurologically asymptomatic patients with end-stage renal disease (ESRD). In addition, we investigated the prevalence of cognitive impairment (CI) in the patients with ESRD, and analyzed the association between the network measures of brain connectivity and cognitive function.

Methods: We prospectively enrolled neurologically asymptomatic 40 patients with ESRD and 40 healthy controls, and all of the subjects underwent diffusion tensor imaging (DTI) and resting state functional MRI (rs-fMRI). We calculated the measures of structural and functional connectivity based on DTI and rs-fMRI, respectively, and investigated the differences between the patients with ESRD and healthy controls. We assessed cognitive function in the patients with ESRD with the MMSE, MoCA, and CERAD neuropsychological battery.

Results: The patients with ESRD had decreased global structural and functional brain connectivity, and they had also alterations of network hubs compared to healthy controls. About 70% of patients with ESRD had CI. Even without CI, patients with ESRD had decreased global connectivity and alterations of network hubs. Furthermore, there was significant positive association between measures of brain connectivity and cognitive function.

Conclusions: We found that patients with ESRD had decreased structural and functional brain connectivity, and there was significant association between brain connectivity and cognitive function. These alterations of brain network may contribute to the pathophysiological mechanism of CI in the patients with ESRD.

SA-PO722

Brain Structural and Functional Dissociated Connectivity Patterns Between ESRD Patients with Peritoneal Dialysis and Hemodialysis

Seong M. Jun, Yoo jin Lee, Bongsoo Park, Sihyung Park, Yang Wook Kim. *Haeundae paik hospital Inje University, Busan, Republic of Korea.*

Background: The aim of this study was to investigate and compare the alterations of structural and functional connectivity between peritoneal dialysis(PD) patients and hemodialysis (HD) patietnts.

Methods: We prospectively enrolled neurologically asymptomatic 20 maintenance PD patients, 20 maintenance HD patients and 40 healthy controls, and all of the subjects underwent diffusion tensor imaging (DTI) and resting state functional MRI (rs-fMRI) to investigate the alterations of structural and functional connectivity. We calculated the measures of structural and functional connectivity based on DTI and rs-fMRI, respectively. We assessed cognitive function in the patients with ESRD with the MMSE, MoCA, and CERAD neuropsychological battery.

Results: The main findings of our study were that PD patients had decreased global structural connectivity compared to healthy controls and HD patients had decreased global functional connectivity compared to healthy controls. In addition, we found that there are many regions in the alteration of local structural and functional connectivity between PD patients compared to healthy subjects and HD patients compared to healthy subjects.

Conclusions: We found that patients with ESRD had decreased structural and functional brain connectivity, and there are important differences of the structural and functional connectivity in brain networks according to the dialysis modality

SA-PO723

Prediction of Baseline Renal Function in Lupus Nephritis Using Deep Learning on Histology Images

Olivier Moindrot,[1] Solange Moll,[2] Charles Maussion,[1] Wei Tew,[3] Pierre Courtiol,[1] Gilles Wainrib,[1] Marco Prunotto.[4] *[1]Owkin, Paris, France; [2]University Hospital of Geneva, Geneva, Switzerland; [3]Genentech Inc, South San Francisco, CA; [4]F. Hoffmann-La Roche Ltd., Basel, Switzerland.*

Background: Lupus nephritis (LN) is a heterogeneous disease that might be an ideal case to use artificial intelligence such as deep learning (DL) to provide a more precise and objective assessment of biopsy. The aim of the study is to assess DL performance on kidney biopsy whole-slide images in predicting baseline renal function in LN stage II-IV patients.

Methods: Kidney biopsies from 98 LN patients were used to train an agnostic DL algorithm called Chowder using multitask learning. Additionally, a Mask Region-based Convolutional Neural Network instance segmentation model was used to segment renal structures, trained using expert annotations and validated before applying it to patient biopsies. Histomic features from the algorithm predictions were extracted to predict renal function. Cross-validation AUC was calculated.

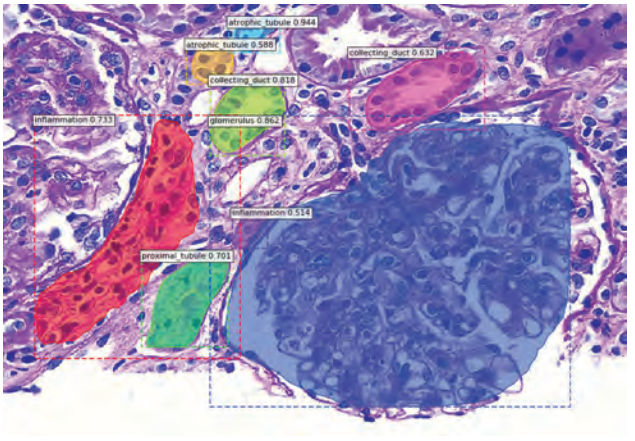
Results: Chowder was able to predict baseline eGFR and creatinine (Table). The structure segmentation model has an average precision of 0.68 and 0.76 for proximal tubules and glomeruli, respectively (Figure). Histomic feature of inflammation area outperforms Chowder in proteinuria and tubulointerstitial fibrosis prediction (Table).

Conclusions: Preliminary results show that DL on renal biopsy can predict baseline renal function. Histomic features from structure segmentation prediction provided additional insights into histological manifestations. This methodology can be extended to disease outcome prediction.

Funding: Commercial Support - Hoffmann-La Roche Ltd

Renal function prediction performances. AUC values shown.

Renal Function	ISN/RPS Grade	Chowder	Histomics (inflammation area)
eGFR (<60 ml/min/1.73m2)	0.70	0.91	0.77
Serum Creatinine (>83 µmol/l)	0.64	0.74	0.74
Proteinuria (>0.35 g/l)	0.82	0.62	0.75
Tubulointerstitial fibrosis (>10%)	0.69	0.55	0.75



An example of structure segmentation prediction on a test image in validation set. Classes and confidence values shown.

Urine Red Blood Cell-Derived Microparticle by Flow Cytometry as a Novel Biomarker for Diagnosis of Glomerular Hematuria

Pongpratch Puapatanakul, Awirut Charoensappakit, Kearkiat Praditpornsilpa, Duangdao Palasuwan. *Chulalongkorn University, Bangkok, Thailand.*

Background: Differentiating glomerular hematuria (GH) from non-glomerular hematuria (NGH) is based on the identification of dysmorphic red blood cell (RBC) by bright field microscopy which is operator-dependent and insensitive. Whether the detection of RBC-derived microparticle (RMP) by flow cytometry which indicates specific injury to RBC can differentiate GH from NGH has never been validated.

Methods: Spot urine was collected from patients with GH, NGH, and healthy non-hematuria volunteers. GH patients were patients with biopsy-proven glomerular disease diagnosed within 3 months while NGH were patients with urinary tract cancer, nephrolithiasis, and post-operative bleeding. Urine was submitted for microscopic study to identify percentage of dysmorphic RBC, and flow cytometry to detect urine RMP. RMP was defined by size (<1 μm) and positive labeling for CD235a and annexin V. The RMP number was normalized by total RBC number (RMP/RBC ratio). All analyses were performed by blinded technician within 2 hours after specimen collection. Receiver Operating Characteristics (ROC) curve analysis was used to demonstrate diagnostic performance of RMP/RBC ratio in diagnosing GH.

Results: There were 29, 29, and 19 participants in GH, NGH, and healthy groups. The most common diagnoses in GH group were lupus nephritis (48.3%), ANCA-associated glomerulonephritis (13.8%), and IgA nephropathy (10.3%) while majority of NGH group were post-operative hematuria (55.2%) and urinary tract cancers (17.2%). RMP was not present in urine from healthy volunteers but were detected in both GH and NGH patients. The RMP/RBC ratio was significantly higher in GH compared to NGH patients (1.06±0.19 vs 0.18±0.04; p<0.001). RMP/RBC ratio at a cut point of 0.40 provided a sensitivity and specificity of 82.8% and 82.8% for diagnosis of GH, respectively. Performance of RMP/RBC ratio was better than the conventional use of dysmorphic RBC percentage according to the area of under the curve of ROC curve analysis (0.90 vs 0.87).

Conclusions: Measurement of urine RMP/RBC ratio by flow cytometry is a more accurate biomarker for diagnosing GH. This biomarker is operator-independent and can serve as a useful test for clinical practice.

SA-PO725

A Nuclear Magnetic Resonance-Based Biomarker Constellation for GFR Prediction Enables Metabolic Phenotyping

Jochen H. Ehrich,[1] Laurence Dubourg,[2] Sverker Hansson,[3] Katharina Schäffler,[4] Tobias Steinle,[4] Jana Fruth,[4] Sebastian Höckner,[4] Eric Schiffer.[4] *[1]Hannover Medical School, Hannover, Germany; [2]Hospices Civils de Lyon - Université Claude Bernard Lyon 1-INSERM U 820, Lyon, France; [3]Sahlgrenska University Hospital, Göteborg, Sweden; [4]numares AG, Regensburg, Germany.*

Background: Assessment of kidney function does either entail high burden for patients as part of clearance measurements (mGFR) or estimated GFR by moderately-performing equations (eGFR). Recently, we developed a novel method for accurate prediction of mGFR, based on a serum biomarker constellation of creatinine, myo-inositol, valine and dimethyl sulfone (DMS) analyzed by nuclear magnetic resonance (NMR) spectroscopy. This metabolomic constellation was tested and validated in three separate cohorts in a multi-center study.

Methods: In order to characterize the role of these biomarkers in renal dysfunction and pathogenesis of CKD and to test their value for metabolic phenotyping, biomarker profiling was applied to sets of three age-, sex-, and mGFR-matched male patients with CKD stage II during end-stage liver disease. To compare the obtained profiles, measured biomarker concentrations were transformed into z-scores and plotted into a radar chart with four axes, one each for creatinine (marker for filtration), dimethyl sulfone (marker of oxidative stress), myo-inositol (marker of uremia), and valine (marker of metabolic acidosis).

Results: Within these age-, sex-, and mGFR-matched sets, the metabolic profiles of clinically similar patients differed significantly concerning single markers reflecting filtration, uremic toxins, oxidative stress, and acidosis. An exemplary set of patients with an mGFR of 62 ml/min/1.73m^2 is depicted in the figure where every color indicates the distinct metabolic profile of one matched patient.

Conclusions: These observations suggest that the set of renal biomarkers enables molecular phenotyping of clinically highly selected age-, sex-, and mGFR-matched patients of homogenous clinical etiology providing further insights into their individual renal comorbidities based upon complex design thinking and a single diagnostic method using one serum sample.

Artificial Intelligence Is Useful for Quantitative Analyses of Human Kidney Biopsy Images

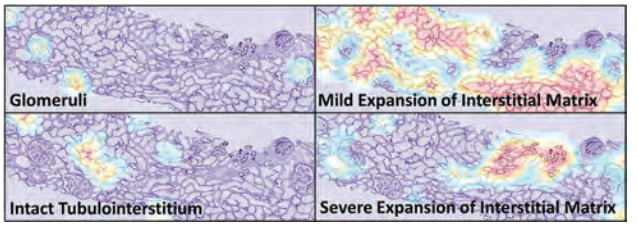
Ayumi Matsumoto,[1] Isao Matsui,[1] Karin Shimada,[2] Nobuhiro Hashimoto,[1] Seiichi Yasuda,[1] Sachio Kajimoto,[3] Yohei Doi,[1] Satoshi Yamaguchi,[1] Tatsufumi Oka,[1] Keiichi Kubota,[1] Yusuke Sakaguchi,[1] Tomoko Namba,[1] Kazunori Inoue,[1] Takayuki Hamano,[1] Yoshitaka Isaka.[1] *[1]Osaka University Graduate School of Medicine, Suita, Japan; [2]Graduate School of Medicine, Osaka University, Osaka, Japan; [3]Osaka university, Osaka, Japan.*

Background: The kidney biopsy is a valuable clinical examination that provides profound insight into the diagnosis, prognosis, and treatment of kidney diseases. However, appropriate quantitative analyses of the kidney biopsy images require trained nephrologists and pathologists. Artificial intelligence, an emerging technology in the field of computer science, may help analyses of pathology images.

Methods: PAS, PAM, or Masson-stained human kidney biopsy samples were obtained from four hospitals in Japan. The kidney biopsy images were digitalized by virtual slide system. Convolutional neural network (CNN), a deep neural network for computer vision, was trained to segment the kidney biopsy images.

Results: The CNN was almost well trained to identify glomerular and global sclerosis regions in various kidney diseases. However, Kimmelstiel-Wilson nodules were tended to be identified as global sclerosis. The CNN could also segment kidney biopsy images into intact tubulointerstitium, mild expansion of interstitial matrix, severe expansion of interstitial matrix, inflammation, arteries, and capsule of the kidney. Because PAS, PAM, and Masson-staining techniques were slightly different among the four hospitals, the training of the CNN required data from all four hospitals to obtain better accuracy of segmentation.

Conclusions: The artificial intelligence could segment human kidney biopsy images. The segmentation by artificial intelligence can provide novel quantitative methods for the analyses of human kidney biopsy images.



Segmentation of kidney biopsy images by artificial intelligence

SA-PO727

Primary and Secondary Podocyte Infolding and Microparticles: An Ultrastructural Diagnosis

Vinita Agrawal. *Pathology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.*

Background: Podocyte Infolding Glomerulopathy (PIG) is a recently described pathologic entity with ultrastructural alterations of glomerular basement membrane (GBM) and podocytes. It is characterized by the presence of podocyte invaginations, podocyte infolding, spherical microparticles and microtubules in the GBM. It was first reported from Japan. Since then there are case reports describing it more commonly among women with membranous nephropathy and autoimmune diseases. This study describes the author's experience of finding PIG-like changes in a spectrum of glomerular diseases.

Methods: The ultrastructural features in renal biopsies received for routine electron microscopy during a 6-month period, in a tertiary care referral center in North India, were evaluated for PIG-like changes. Biopsies showing both podocyte infolding and microtubules and microparticles were included. The changes were evaluated as segmental/global and focal/diffuse.

Results: On ultrastructure, focal and segmental podocyte infolding and microparticles were seen in four biopsies including Membranous Nephropathy with FSGS (n=2), post-transplant IgAN with transplant glomerulopathy (n=1), and unspecified connective tissue disease (n=1). Electron dense deposits were present in all. Mean age was 29 years (range 20-47) with three males. Diffuse PIG was seen in a renal biopsy from a 43-year old woman, diagnosed as FSGS on light microscopy. No electron dense deposits were seen. The microparticles were round or oval and the size varied widely, measuring 40-170 nm. All biopsies showed diffuse foot process effacement and evidence of GBM remodeling with lamellation and splitting of lamina densa. Nephrotic proteinuria was present in all patients.

Conclusions: As is true for other pathological morphological entities in renal glomerular diseases like FSGS, MPGN etc., PIG is also a morphological; pattern which may exist in a primary diffuse form with no electron dense deposits, predominantly in females and a secondary form with focal and segmental changes associated with other glomerular diseases with electron dense deposits without any gender predilection. It is useful to recognize that PIG-like changes can be seen in various glomerular diseases and this may be referred to as focal and segmental-PIG (FSPIG) instead of PIG.

SA-PO728

Podocytic Infolding Glomerulopathy: The Clinical Secrets of Hidden Disease

Anvesh G. *NIMS, Hyderabad, India.*

Background: Several cases of Podocytic infolding glomerulopathy (PIG) has been reported from Japan as a new disease entity since 2008. It is a rare glomerular abnormality seen predominantly among women in associaciation with membranous nephropathy and autoimmune diseases involving glomerular basement membrane (GBM) bubbling visualised by light microscopy (LM), invagination of the podocyte membrane, and the presence of microspheres viewable by electron microscopy (EM). The clinical features and pathogenesis of this condition are still unclear. We reviewed clinical, biochemical, and pathological features of cases of PIG at our institute.

Methods: We retrospectively analysed cases of PIG as per the diagnostic criteria during preceding two years.

Results: Seven cases of PIG have been reported from our institute. The mean age of the patients was 48, (43-65) years, and all were men. Both hypertension and diabetes were seen in five, one each had hypertension and diabetes. Four patients had nephrotic range proteinuria and two had insignificant proteinuria. All had increased creatinine with a mean of 4.3mg%. Autoimmune workup and viral markers were negative in all. LM showed diabetic nephropathy (DN) in 5 cases and hypertensive changes in 1 case and secondary FSGS in 1 case. Microspheres were present in all but podocyte infolding was present in 1 and cluster formation of microspheres was found in 3 cases

Conclusions: PIG in our case series differs from that of Japan in male preponderance and is associated with diabetic nephropathy. The clinical significance of PIG in south Indian population is yet to be elucidated.

SA-PO729

Single-Cell RNA Sequencing of Myofibroblasts to Identify Therapeutic Targets in CKD

Liqun He,[2] Christer Betsholtz,[2,1] Marie Jeansson.[1,2] *[1]Karolinska Institutet, Huddinge, Sweden; [2]Uppsala University, Uppsala, Sweden.*

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in activated cells, myofibroblasts, which produce and deposit extracellular matrix. This project aim at an in depth analysis of myofibroblasts to further understand the progression of fibrosis and to identify novel targets for development of therapeutics.

Methods: Mice with Pdgfra-GFP and Pdgfrb-GFP reporters were utilized to identify pericytes, fibroblasts and myofibroblasts. Mice were subjected to unilateral ureter obstruction (UUO) and analyzed at different time points after UUO. GFP positive cells from UUO and contralateral (CL) kidneys were enzymatically digested and sorted into 384-well plates by FACS for single cell RNA-seq using SmartSeq2. Cluster analysis was performed with BackSPIN and Pagoda2.

Results: Pdgfra-GFP and Pdgfrb-GFP positive cells were significantly increased after UUO and colocalized with markers of fibrosis (ASMA and vimentin). Analysis of the single cell transcriptomes from Pdgfra-GFP and Pdgfrb-GFP cells clustered CL cells and UUO cells separately. Several genes were exclusively expressed in cells from UUO kidneys, while some genes were seen in CL kidneys but lost in UUO kidneys. Ongoing studies include trajectory analysis from the different time point as well as confirmation of results with immunohistochemistry and RNAScope.

Conclusions: Our study will give insight into the temporal changes of fibroblast and pericytes transcriptomes on the single cell level during fibrosis progression.

Funding: Private Foundation Support, Government Support - Non-U.S.

Endoglin Promotes Interstitial Fibrosis in CKD

Tessa Gerrits, Meilin Berkhoff, Isabella J. Brouwer, Jan A. Bruijn, Hans J. Baelde, Marion Scharpfenecker. *Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Tubulointerstitial fibrosis is a common process leading to chronic renal damage. It is characterized by extracellular matrix (ECM) deposition and pathological scar formation driven by transforming growth factor beta (TGF-β). Inhibiting excessive ECM production could be a strategy to reduce the functional decline of the kidney and thereby the progression towards end-stage renal disease. Endoglin, a co-receptor of the TGF-β-receptor, could be an interesting target to inhibit fibrosis formation.

Methods: Biopsies of patients with kidney diseases characterized by interstitial fibrosis, such as focal segmental glomerular sclerosis (FSGS; n=48), diabetic nephropathy (DN; n=11) and chronic allograft dysfunction (CAD; n=43) were selected; healthy kidneys were used as controls (n=8). Sections were stained for endoglin and the positively-stained area was measured. DN and CAD sequential sections were stained for Sirius Red, a marker for interstitial fibrosis. Endoglin mRNA expression in whole kidney tissue of another DN cohort (n=23) was measured with qPCR; healthy kidneys were used as controls (n=12). Lastly, collagen type I production was measured with western blot in TGF-β stimulated lentivirally transduced fibroblasts that were either wild type or knock down for endoglin.

Results: Endoglin was increased in the interstitium of patients with FSGS, DN and chronic allograft dysfunction compared to controls ($p<0.001$). The endoglin-positive area colocalized with the Sirius Red-positive area. qPCR showed upregulation of endoglin mRNA in patients with DN compared to healthy controls ($p<0.05$). The western blot analysis demonstrated that collagen type I production after TGF-β stimulation was less upregulated in the endoglin knockdown fibroblasts compared to wild type fibroblasts.

Conclusions: We show that endoglin is overexpressed in different patient cohorts with interstitial kidney fibrosis and that it colocalizes with Sirius Red-positive areas. We also show that lowering endoglin levels reduces TGF-β-induced collagen type I production. These results suggest that endoglin could be a potential target reduce the development of fibrosis. This offers an interesting opportunity to treat patients with declining renal function.

SA-PO731

Hypothermic Protection Attenuates Renal Fibrosis After Renal Ischemia-Reperfusion

Da bi Kim,[2] Eunji Kim,[2] Jin young Jeong,[2] Jwajin Kim,[1] Yoon-Kyung Chang,[3] Wonjung Choi,[1] Dae Eun Choi,[1] Ki Ryang Na,[1] Kang Wook Lee.[1] *[1]Nephrology, Chungnam National University, Daejeon, Republic of Korea; [2]Department of Medical Science, Chungnam national university, Daejeon, Republic of Korea; [3]The Catholic University of Korea, Daejeon, Republic of Korea.*

Background: Hypothermia attenuates acute renal injury including tubular necrosis, detachment, and apoptosis after ischemia-reperfusion. However, it remains unknown whether hypothermia improve renal fibrosis. Although some reports showed cold ischemia activate TGF-bata signals, it is unclear that it induce the renal fibrosis. We evaluated the hypothermia reduced the renal fibrosis after renal ischemia-reperfusion injury.

Methods: C57Bl/6 mice were divided into the following groups: sham-operated (cold, 32C) vs normal temperature (37C); ischemia-reperfusion mice (32C vs 37C). Kidneys were harvested 20 minutes after induction of renal ischemia, 4hr, 24 hours, 72hr, and 168hr after ischemiareperfusion injury. Functional and molecular markers of kidney injury were evaluated. To explore the molecular mechanism involved the expression levels of renal HIF-1 and associated proteins were evaluated.

Results: The blood urea nitrogen and serum creatinine levels and the histologic renal injury scores were significantly lower in 32C ischemia-reperfusion than 37C ischemia-reperfusion kidneys (all P values < .05) at 24hr and 72hr after IR. Microscopic evaluation showed that renal fibrosis were significantly decrased in the kidneys of 32C compared to 37C ischemia-reperfusion mice at 4hr and 24hr after IR. The expression levels of Bax and caspase-3 and the extent of TUNEL and 8-OHdG cell positivity decreased, whereas the renal Bcl-2 level increased, in 32C ischemia-reperfusion compared to 37C ischemia-reperfusion mice. ERK and HIF1 phosphorylation was significantly increased in the kidneys of 32C compared to 37C ischemia-reperfusion mice at 4hr and 24hr after IR. However, TGF beta, SOX9, fibronectin, and collagen IV were significantly decrased in the kidneys of 32C compared to 37C ischemia-reperfusion mice at 4hr and 24hr after IR.

Conclusions: Hypothermic Protection increased the HIF1 and ERK phosphorylation. however it decreased the SOX9 and TGF beta signals. Hypothemia reduced the renal fibrosis after IR renal injury.

Effects of AMPK Deficiency and Sex-Differences in Kidney Parameters Post Uninephrectomy

Nuria M. Pastor-Soler, Kenneth R. Hallows, Jessica Pham, Daniel Rivera, Biagio Saitta. *Keck School of Medicine of USC, Garden grove, CA.*

Background: Living donor (LD) kidney transplant is the preferred therapy for end-stage kidney disease. LDs have generally excellent outcomes, yet some show that in the first year post-UNX there is an increased risk of hypertension and microalbuminuria. It is unclear whether compensatory kidney changes are beneficial to the LD long term. In some chronic kidney disease (CKD) models activity of the metabolic sensor AMP-activated kinase (AMPK) is lower compared to healthy kidneys. We hypothesized that low AMPK activity pre-UNX could worsen CKD post-UNX when combined with a high-Na^+ diet in both male and female mice. Our work aims to inform mechanisms that could lead to protective interventions for LDs with AMPK activation.

Methods: We used adult male and female mice with double-floxed AMPK alpha subunit (AMPKfl) and ± tamoxifen-driven (tam) expression of Cag-Cre recombinase (Cre+ vs. Cre-AMPKfl). Mice underwent UNX 5 wks post-Tam (vs. Sham surgery) and were all placed on a high-Na^+ (HNa) diet at that time (intervention). We measured GFR, urine albumin and plasma electrolytes at different time points. Kidneys were examined by immunoblot and qPCR.

Results: Cre+AMPKfl males and females kidneys had significant AMPK knockdown (KD) compared to Cre-AMPKfl mice after tam. Females. AMPK-KD (Cre+ mice) females had a significant increase in albuminuria compared to AMPK-sufficient mice, although we did not detect such change in males. AMPK-KD mice had significantly worse anemia compared to AMPK-sufficient mice in both males and females. Although we found that GFR increased after UNX+HNa in AMPK-sufficient females, this compensatory hyperfiltration was not evident in the AMPK-D female mice. In male mice that were AMPK-sufficient we did not observe compensatory hyperfiltration post UNX+HNA (as estimated by blood urea nitrogen (BUN). In contrast, in AMPK-D mice, UNX+HNa had a detrimental effect on BUN.

Conclusions: AMPK KD in both male and female mice worsens kidney injury in a model of kidney donation and HNa diet. These findings implicate AMPK as an important target for potential pharmacological interventions to prevent CKD in men and women LDs.

SA-PO733

Renal Epithelia Regulate Clearance and Homeostasis of Amyloid-β

Bjoern Tampe, Michael Zeisberg. *University Medical Center Goettingen, Goettingen, Germany.*

Background: Accumulation of circulating amyloid-β (Aβ) molecules is associated with accelerated Aβ deposition in the brain, thereby accelerating cognitive impairment and dementia. Aβ molecules undergo renal clearance to ensure proper Aβ homeostasis. In chronic kidney disease (CKD), impaired kidney function contributes to accumulation of circulating Aβ and accelerates cognitive impairment. Based on these prerequisites, we here aimed to elucidate molecular mechanisms contributing to impaired renal clearance of Aβ molecules.

Methods: Aβ transporters including P-glycoprotein, LRP1, LRP2 and RAGE were analyzed in multiple mouse models of acute/chronic renal failure, human kidneys and cultures of tubular epithelial cells. Genome-wide array datasets was analyzed using NephroSeq database (GSE69438).

Results: We show that Aβ transporters including P-glycoprotein, LRP1, LRP2 and RAGE are present and polarized in tubular compartments in the kidney. Progressive CKD is associated with loss and/or mislocalization of tubular Aβ transporters, implicating that tubular clearance regulates Aβ homeostasis. Finally, analysis of human kidneys and genome-wide array datasets confirmed that Aβ transporters are equally present in human renal epithelia and lost during progressive CKD.

Conclusions: In summary, we here show that Aβ transporters are present and polarized in tubular compartments in the kidney. Furthermore, we provide evidence that CKD is associated with loss of tubular Aβ transporters and impaired renal Aβ clearance. Because impaired kidney function contributes to accumulation of circulating Aβ and accelerates cognitive impairment, these findings provide insights into molecular mechanisms underlying clearance and homeostasis of Aβ.

1,25-Dihydroxy-Vitamin D3 Regulates M2 Macrophage Polarization via the VDR-PPARγ Signaling Pathway in Lupus Nephritis Mice

Jia Wang,[1] Jiong Zhang.[2] *[1]Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, China; [2]Renal Department, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, China.*

Background: Lupus nephritis (LN) is one of most serious manifestation of systemic lupus erythematosus (SLE). Recent studies have shown besides autoantibodies and complement activation, macrophage polarization play a major role in the pathogenesis of LN. 1,25-Dihydroxyvitamin D (1,25(OH)2D3) has immunomodulatory activity, and 1,25(OH)2D3 deficiency is correlated with SLE, especially with activity of LN. This study aimed to explore whether 1,25(OH)2D3 modulates macrophage polarization in LN and its underlying mechanism.

Methods: We compared the levels of 1,25(OH)2D3, renal injury (proteinuria, serum urea), and inflammatory cytokines (TNF-α, interleukin (IL)-10) in MRL-*Fas*^{lpr} mice expressing VDR and VDR knockout (KO) MRL-*Fas*^{lpr} mice. Infiltration with M1-like (iNOS+/CD68+), M2-like macrophages (CD163+/CD68+) in renal tissue were detected using immunohistochemical analysis. Peripheral blood monocytes were isolated in MRL-*Fas*^{lpr} mice, and were incubated with or without 1,25(OH)2D3 (10^{-8} mol/L). M1 and M2 macrophages in vitro were induced by treating cells with 100 U/mL IFNγ + 5 ng/mL LPS or 10 ng/mL IL-4, respectively. In order to explore the underlying mechanism, these cells were treated with VDR siRNA and the PPARγ antagonist. mRNAs expression levels of iNOS, MR and Arg-1 were assessed by RT-PCR.

Results: In vivo, compared with VDR KO MRL-*Fas*^{lpr} mice, more positive for CD68 and iNOS cells were infiltrated in renal tissues in expressing VDR mice, a phenotype suggestive of M1 macrophages. 1,25(OH)2D3 and IL-10 levels were also observed higher than VDR KO MRL-*Fas*^{lpr} mice, whereas TNF-α, proteinuria, serum urea levels were lower. In vitro, pretreatment with 1,25(OH)2D3 significantly inhibited M1 activation, enhancing M2 macrophage activation. Moreover, it upregulated the expression of anti-inflammatory cytokine IL-10 and MR, Arg-1 mRNA but downregulated the expression of iNOS mRNAs. However, cells treated with VDR siRNA and PPARγ antagonist were decreased the tendency toward M2 polarization. Moreover, the expression of PPARγ was decreased when cells treated with VDR siRNA.

Conclusions: The above results demonstrate that 1,25(OH)2D3 promoted M1 phenotype switching to M2 via the VDR-PPARγ pathway in LN. 1,25(OH)2D3 treatment ameliorated LN-associated renal inflammatory injury.

IL-6-Mediated Phosphorylation of STAT3 at Tyrosine 705 Leads to Proliferation of Pericytes and Fibroblasts

Li Zhao,[1,2] Amrendra K. Ajay,[1] Li-Li Hsiao.[1] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Renal Division, Dongzhimen Hospital affiliated to Beijing University of Chinese Medicine, Peking, China.*

Background: Fibrosis is a final common pathway that leads to progressive chronic kidney disease (CKD) and end stage renal disease. Inflammation is one of the many events occurrs during the progression of CKD. IL-6, an inflammatory cytokine, contributes to kidney disease by enhancing the signaling response of tubular epithelial cells to profibrotic cytokines. STAT3 is known to be activated following phosphorylation at tyrosine 705 in response to IL-6, which plays a key role in many cellular processes such as cell proliferation and apoptosis. The role of IL-6/STAT3 pathway in the differentiation of specific cell types and its outcome in kidney fibrosis remains largely unknown.

Methods: We used the mouse pericyte cell line 10T1/2 and human fibroblast cells. We treated these cells with different doses (20 ng/ml to 300 ng/ml) of recombinant IL-6 for different time points. Phosphorylation of STAT3 was evaluated by western blot and immunofluorescence using anti-phospho-STAT3 specific antibody. To assess the cellular proliferation, we used MTS assay. The cellular migration was examined by trans well chamber method. The expression of pro-fibrotic markers was detected by RT-PCR, immunofluorescence and western blot analysis.

Results: IL-6 induced the activation of STAT3 in 10T1/2 and human fibroblast cells, and up-regulated the phosphorylation of STAT3 (Tyr705) in a dose and time dependent manner. The dose of IL-6 for activation of STAT3 was different in these two cell types (10T1/2 and human fibroblasts showed pSTAT3 at 20 and 300 ng/ml respectively). After phosphorylation, STAT3 was translocated to the nucleus, which is crucial for its transcriptional activity. IL-6 mediated phosphorylation of STAT3 caused cellular proliferation of human fibroblasts (at 72 hours by 123.88% and of mouse pericytes 10T1/2 (at 96 hours by 131.71%) as compared to respective control cells. pSTAT3 increased the expression levels of α-SMA, Collagen 1 and fibronectin.

Conclusions: IL-6/STAT3 pathway may participate in cellular proliferation of pericytes and fibroblasts during fibrosis development and its inhibition may reduce the proliferation of these cells leading to reduced fibrosis.

IL34-Induced M2-Like Macrophage Polarization Promotes Renal Interstitial Fibrosis via Macrophage-to-Myofibroblast Transition

Qian Yang, Gang Xu, Rui Zeng. *Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: M2-like macrophages play important roles during the injury and repair phases in kidney diseases. However, the relationship between M2-like macrophages and fibrosis is still controversial, with some studies showing pro-fibrotic effects while others showing anti-fibrotic effects.

Methods: Here, we used the Cre/LoxP system to generate renal tubular epithelial cells-specific IL34-overexpression mice (Cdh16-Cre; LSL-IL34 mice and Tamoxifen-induced Cdh16-iCreERT2; LSL-IL34 mice).

Results: We found that Cdh16-Cre; LSL-IL34 mice spontaneously experienced weight loss, renal injury, decreased survival rates and declined renal function after birth. Furthermore, they automatically developed into renal fibrosis, which was marked by notable intrarenal infiltration of M2-like macrophages. The similar results were also found in the Tamoxifen-induced Cdh16-iCreERT2; LSL-IL34 kidneys. The proteome and transcriptome analysis of Cdh16-Cre; LSL-IL34 kidneys showed a high degree of relationship between the extracellular matrix deposition and the infiltrated macrophages. Meanwhile, transcriptome sequencing of isolated macrophages from Cdh16-Cre; LSL-IL34 kidneys revealed the infiltrated macrophages in Cdh16-Cre; LSL-IL34 kidneys were predominantly M2-like ($CD204^+$ $CD206^+$ $CD163^+$) and characteristically exhibited

a myofibroblast phenotype (Fibronectin$^+$ Acta2$^+$ Collagens$^+$). The M2-like macrophage polarization and macrophage-to-myofibroblast transition were further supported by flow cytometry, immunofluorescence and confocal fluorescence microscopy. On the contrary, Clodronate Liposomes (CLs)-mediated depletion of renal M2-like macrophages in Cdh16-Cre; LSL-IL34 mice alleviated the renal injury and fibrosis.

Conclusions: Tubular IL34 specifically activates M2-like macrophages, which can directly transdifferentiate into myofibroblasts (MMT) and in turn promote renal interstitial fibrosis.

Development of a New Macrophage-Specific TRAP Mouse (Mac^{TRAP}) and Definition of the Renal Macrophage Translational Signature

Andreas Hofmeister,[4] Maximilian Claudius Thomassen,[2] Sabrina Markert,[3] André Marquardt,[5] Mathieu Preußner,[4] Joachim Hoyer,[3] Benjamin D. Humphreys,[1] Ivica Grgic.[4] *[1]Washington University School of Medicine, Clayton, MO; [2]Universitätsklinikum Marburg, Marburg, Germany; [3]Philipps Universität Marburg, Marburg, Germany; [4]Philipps-Universität Marburg, Marburg, Germany; [5]Universitätsklinikum Würzburg, Würzburg, Germany.*

Background: Tissue macrophages play an important role in organ homeostasis and immunity as well as pathogenesis of inflammatory-driven diseases including organ fibrosis, atherosclerosis and autoimmune disorders. One major challenge has been as how to selectively study resident macrophages *in vivo* in highly heterogeneous organs such as kidney.

Methods: To address this problem, we adopted a *translational ribosome affinity purification* (TRAP) - approach and designed a transgene that expresses an enhanced green fluorescent protein (eGFP)-tagged ribosomal protein (L10a) under the control of the macrophage-specific c-fms promoter, a driver of the macrophage colony-stimulating factor 1 receptor (Csf1r), to generate c-fms-eGFP-L10a transgenic mice (Mac^{TRAP}).

Results: Rigorous characterization and validation found no gross anatomical, behavioral or developmental abnormalities in Mac^{TRAP} mice and confirmed transgene expression across various organs. Immunohistological analyses of Mac^{TRAP} kidneys identified eGFP-L10a-expressing cells in the tubulointerstitial compartment that stained positive for macrophage marker F4/80. Following induction of kidney fibrosis we observed a robust upregulation of eGFP-L10a along with classical macrophage and fibrotic markers, validating Mac^{TRAP} responsiveness upon proinflammatory challenge. Using TRAP, we successfully extracted macrophage-specific polysomal RNA from Mac^{TRAP} kidneys and conducted RNA sequencing followed by extensive bioinformatical analyses, hereby establishing a comprehensive *in vivo* gene expression and pathway signature of resident renal macrophages and closely related dendritic cells.

Conclusions: In summary, we have created, validated and applied a novel and responsive macrophage-specific TRAP mouse line, defining the translational profile of renal macrophages and dendritic cells. This new and broadly applicable tool may be of great value for the study of macrophage biology in different organs and various models of injury and disease.

Disruption of CD40 Attenuates Renal Injury Induced by Acute High Salt Intake in Experimental Hypertensive Renal Disease

Shungang Zhang,[1] Fatimah K. Khalaf,[1] Apurva Lad,[2] Andrew Kleinhenz,[2] Deepak K. Malhotra,[1] David J. Kennedy,[3] Steven T. Haller.[2] *[1]University of Toledo, Toledo, OH; [2]University of Toledo College of Medicine and Life Sciences, Toledo, OH; [3]University of Toledo Health Science Campus, Toledo, OH.*

Background: We have recently shown that circulating levels of the pro-inflammatory receptor CD40 predict progression of renal dysfunction in patients with hypertensive renal disease and the soluble ligand for CD40 (sCD40L) is significantly elevated in this setting. In our CD40 knockout (KO) model developed on a background prone to hypertensive renal disease (Dahl S rat), we demonstrated significantly reduced renal fibrosis and improved renal function following a chronic high salt diet. To test the hypothesis that disruption of CD40 attenuates early indicators of renal injury and reduces inflammation, we performed the following acute high salt study.

Methods: Seven-week old Dahl S wild-type and Dahl S CD40KO male rats (n=8 per group) were given a high salt diet (2% NaCl) for 1 week. Blood pressure, urinary protein excretion (UPE), and plasma creatinine were measured. Kidneys were assessed for evidence of inflammation and injury.

Results: After acute high salt diet, blood pressure and plasma creatinine between wild-type Dahl S rats and Dahl S CD40KO rats were similar. UPE was significantly reduced in the Dahl S CD40KO compared to Dahl S rats (33.7±6.8 mg/24h vs. 106.9±28.6 mg/24h, $p<0.05$). Renal cortex gene expression of kidney injury molecule-one (KIM-1) ($p<0.05$), monocyte chemoattractant protein-1 (MCP-1) ($p<0.001$), and chemokine (C-X-C motif) ligand 2 (CXCL-2) ($p<0.05$) were significantly lower in Dahl S CD40KO rats compared to Dah S rats as assessed by quantitative PCR.

Conclusions: Disruption of CD40 significantly reduced proteinuria, KIM-1, and markers of inflammation following acute high salt induced renal injury. Our results indicated that CD40 may serve as a therapeutic target to inhibit acute renal injury and prevent the progression of hypertensive renal disease.

SA-PO739

Protein-Bound Uremic Toxins Induce NLRP3 Inflammasome Activation in Proximal Tubule Cells

Milos Mihajlovic,[2] Daria Andreeva,[2] Sonja Steenhuis,[2] Luuk Hilbrands,[1] Rosalinde Masereeuw.[2] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.*

Background: Protein bound-uremic toxins (PBUTs) are not efficiently removed by hemodialysis in chronic kidney disease (CKD) patients. Their accumulation can lead to cellular dysfunction, inflammation and oxidative stress. Moreover, it has been shown that increased intrarenal expression of the NLRP3 receptor and IL-1β are associated with reduced kidney function, suggesting a critical role for the NLRP3 inflammasome in CKD progression. Here, we evaluated the effect of PBUTs on NLRP3 inflammasome activation in human conditionally immortalized proximal tubule epithelial cells (ciPTECs).

Methods: NLRP3 activation was studied after exposing cells to LPS, ATP, indoxyl sulfate (IS), and a mixture of eight anionic PBUTs (UT-mix). Expression levels of inflammasome components (NLRP3, caspase-1, IL-1β), IL-1β secretion, caspase-1 activity and production of reactive oxygen species (ROS) were evaluated.

Results: Exposure to a combination of LPS (1 µg/ml; 24h) and ATP (5 mM; 30 min) showed 3-fold ($p<0.01$) increase in IL-1β secretion, and 2-fold ($p<0.05$) increase in caspase-1 activity, suggesting that the NLRP3 pathway is functional in ciPTECs. Next, 24h exposure to increasing concentrations of IS increased mRNA expression of NLRP3 (2.3-fold; $p<0.01$), caspase-1 (2.2-fold; $p<0.01$) and IL-1β (24-fold; $p<0.01$). Similar results were observed for UT-mix: NLRP3 (1.7-fold increase; $p<0.05$), caspase-1 (1.8-fold increase; $p<0.05$) and IL-1β (4.5-fold increase; $p<0.001$). In addition, exposure to IS and UT-mix led to 10-fold ($p<0.001$) and 3-fold ($p<0.001$) increases in IL-1β secretion, respectively. Similarly, there was 1.9-fold ($p<0.01$) increase of caspase-1 activity upon treatment with IS and 1.8-fold increase after exposure to UT-mix. Furthermore, IS and UT-mix induced the production of intracellular ROS (2.6-fold increase for IS and 1.9-fold increase for UT-mix; $p<0.05$). Finally, IL-1β secretion was reduced when the N-acetylcysteine (1.8 mM; 24h) was added as a pre-treatment (47% reduction for IS and 35% reduction for UT-mix; $p<0.05$), suggesting that inflammasome activation is ROS-mediated.

Conclusions: PBUTs are able to induce NLRP3 inflammasome activation in proximal tubule cells via oxidative stress, suggesting their involvement in a local inflammatory response in kidney disease.

Mint3 Mitigates Renal Fibrosis After Ischemia-Reperfusion Injury Through Protection of Tubular Epithelial Cells from Apoptosis via Upregulation of NF-κB

Takahisa Kawakami,[1,2] Kahori Nasu,[2] Akinari Shinohara,[2] Shinya Kaname,[1] Masaomi Nangaku.[2] *[1]Department of Nephrology and Rheumatology, Kyorin University School of Medicine, Tokyo, Japan; [2]the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Tubulointerstitial fibrosis is a hallmark of chronic kidney disease (CKD), and initiated by tubular epithelial cell (TEC) injury. Hypoxia promotes tubular cell death, fibrosis, and CKD progression. Munc18-1-interacting protein 3 (Mint3) is a molecule that activates hypoxia-inducible factors (HIFs) by binding and suppressing factor inhibiting HIF-1 (FIH). However, the role of Mint3 in tubulointerstitial fibrosis remains unknown.

Methods: We induced fibrosis of the kidney after unilateral ischemia-reperfusion injury (uIRI) in Mint3-knockout and littermate wild-type mice. The function of Mint3 was further investigated by using mouse cortical tubular (MCT) cells, which were treated with Mint3 and/or FIH siRNA and exposed to hypoxia. Apoptosis was assayed with cleaved caspase-3 and TUNEL staining, and flow cytometry with Annexin-V and 7-AAD.

Results: We found that Mint3 was mainly expressed in TECs with immunostaining of the kidney. Knockout of Mint3 did not affect the acute injury induced by uIRI, but exacerbated the tubulointerstitial fibrosis, accompanied by an increase in TEC apoptosis. Consistently, hypoxia-induced apoptosis of MCT was aggravated by Mint3 knockdown. Unexpectedly, the additional knockdown of FIH did not suppress the increase in apoptosis by Mint3 knockdown, demonstrating the irrelevance of the FIH/HIF pathway. Hence, we focused on NF-κB, a transcription factor which has an anti-apoptotic role, as well as a well-known proinflammatory role. While NF-κB forms a dimer and usually promotes transcription, a homodimer of p50 or p52, which lacks a transactivation domain, can suppress transcription. Indeed, the expression of the inhibitory NF-κB p50 and the protein in nuclei were increased by knockdown of Mint3 in the TECs and by its knockout in the kidney, along with the decreased expressions of the NF-κB-targeted anti-apoptotic genes.

Conclusions: This study demonstrated the importance of TEC injury as a primary event leading to renal fibrosis, as well as unexpected relationship of Mint3 and NF-κB. Mint3 protects the cells from apoptosis by decreasing inhibitory effects of NF-κB, leading to fibrosis suppression. This new pathophysiology of tubulointerstitial fibrosis can be a target of the future therapy for CKD.

SA-PO741

Nrf2 Deletion Attenuates Kidney Injury Caused by Cullin Ring Ligase Dysfunction

Ryan J. Cornelius, Jonathan W. Nelson, Chao-Ling Yang, David H. Ellison. *Oregon Health and Science University, Portland, OR.*

Background: Nrf2 is postulated to play a protective role in oxidative stress-induced kidney injury; conversely, multiple studies have shown that aberrant Nrf2 activity can be damaging. Nrf2 abundance is determined by cullin-RING ligases (CRLs), which control the regulated degradation of proteins through the ubiquitin proteasome system. CRLs, in turn, are regulated by the COP9 Signalosome (CSN). We previously reported that nephron-specific CSN disruption (KS-*Jab1*$^{-/-}$ mice) causes progressive renal injury, with increased Nrf2. Here, we tested the hypothesis that direct Nrf2 accumulation exacerbates kidney injury in this model, using KS-Jab1 and Nrf2 double knock out mice (DKO).

Methods: The Pax8-rtTA mouse system was used to generate inducible mice with genetic deletion of the catalytically active CSN subunit, *Jab1*, only along the nephron (KS-*Jab1*$^{-/-}$). KS-*Jab1*$^{-/-}$ were bred to mice with global and constitutive deletion of Nrf2 (DKO). Kidney damage was evaluated at 1 week (early) and 8 weeks (late) after *Jab1* deletion.

Results: KS-*Jab1*$^{-/-}$ showed an increase in Nrf2 activity which was attenuated in DKO at both time points. Early KS-*Jab1*$^{-/-}$ demonstrated an increase in blood urea nitrogen (BUN; 34 ± 2 vs. 26 ± 1 mg/dl in controls), and kidney weight (6.8 ± 0.3 vs. 5.3 ± 0.2 mg/g BW in controls). Analysis of the proximal tubule injury marker KIM-1 (kidney injury molecule-1) via Western blot revealed an increase in KS-*Jab1*$^{-/-}$ compared to controls. Furthermore, immunofluorescent staining using antibodies against the proliferation marker Ki-67 demonstrated an increase in the number of proliferating cells located in kidney medulla (208 ± 27 vs. 42 ± 4 cells/field in controls). Nrf2 deletion in early DKO significantly attenuated the rise in BUN (29 ± 2 mg/dl), KIM-1 abundance, and medullary Ki-67 positive cells (96 ± 13 cells/field). Kidney weight trended lower (6.0 ± 0.5 mg/g BW), but was not significantly different. Late DKO showed no significant differences in BUN, kidney weight, or KIM-1 abundance compared to time-matched KS-*Jab1*$^{-/-}$.

Conclusions: Disrupting the CRL pathway in mouse tubules, which leads to kidney damage, also increases Nrf2 activity. Nrf2 deficiency reduces kidney injury after *Jab1* deletion early, but not at later time points. The results suggest that treatment via modulation of Nrf2 activity in progressive kidney disease may have unexpected effects.

Unilateral Ureter Obstruction (UUO)-Induced Renal Fibrosis Is Attenuated by Suppression of Indoxyl Sulfate (IS) Accumulation in Sulfotransferase (Sult)1a1-Deficient Mice

Hou Huixian,[1] Rika Fujino,[2] Yuya Hayashi,[2] Jumpei Unoki,[1] Keisuke Matsushita,[1] Nao Gunda,[1] Hirofumi Jono,[2,1] Hideyuki Saito.[2,1] *[1]Clinical Pharmaceutical Sciences, Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Pharmacy, Kumamoto University Hospital, Kumamoto, Japan.*

Background: Obstructive nephropathy is the result of functional or anatomic lesions located in the urinary tract, and renal interstitial fibrosis is a common finding associated with long-term nephropathy. Many factors are involved in the pathogenesis of renal fibrosis, such as macrophages, growth factors, oxidative stress and inflammatory cytokines. Indoxyl sulfate (IS), a typical sulfate-conjugated uremic solute, accumulates markedly in serum and kidney of drug or ischemic AKI models, thereby inducing oxidative stress. IS is produced predominantly in the liver by CYP2A6/2E1-mediated oxidative metabolism of gut microflora-derived indole to indoxyl, followed by Sult1a1-mediated sulfate transfer to indoxyl. Thus, we established Sult1a1 gene-deficient (KO) mice to investigate the pathological role of IS in UUO-induced renal interstitial fibrosis.

Methods: The left ureter of C57BL/6J mice (wide type, WT, 8wks-old) and KO (8wks-old) were obstructed last for 2 weeks. IS concentration in serum and renal tissue was determined by LC-MS/MS. BUN was determined as renal damage marker. Changes in interstitial fibrosis formation was histologically examined by Sirius red staining. Renal fibrosis-related factors(Col1a1, α-SMA,TGF-β1)were detected by Western blot analysis or quantitative qRT-PCR.

Results: Elevated BUN in WT-UUO mice was significantly reduced in KO-UUO mice (1.44-fold). By UUO treatment, IS accumulation in serum, kidney and liver were markedly elevated in WT-UUO mice, which were suppressed in KO-UUO mice. IS accumulation in the unobstructed kidney was also decreased in KO-UUO mice. Remarkable interstitial fibrosis was observed in the kidney of WT-UUO, but was partly prevented in the kidney of KO-UUO mice. The medulla portion in the kidney of KO-UUO mice exhibited alleviated atrophy compared with that in WT-UUO mice. The high expression of Col1a1, α-SMA and TGF-β1 in the kidney of WT-UUO was suppressed in KO-UUO mice, 1.40-fold, 2.30-fold and 1.68-fold, respectively.

Conclusions: Sult1a1-deficient mice showed suppressed IS accumulation in the serum and kidney after UUO treatment, suggesting that Sult1a1 is the enzyme responsible for IS production. Renal IS accumulation during progression of UUO nephropathy could enhance interstitial fibrosis.

SA-PO743

Ablation of Polyamine Catabolic Enzymes Protects Against Renal Damage and Fibrosis due to Long-Term Cisplatin Treatment

Kamyar A. Zahedi,[1,2] Marybeth Brooks,[1,2] Sharon L. Barone,[1,2] Manoocher Soleimani.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH.*

Background: Cisplatin is a highly effective anti-neoplastic agent against a variety of solid tumors; however, complications associated with its use such as nephrotoxicity limit its effectiveness. While cisplatin's main anti-tumor activity is via the formation of DNA adducts and disruption of cell cycle progression, its general toxicity is mediated by the induction of oxidative stress. Enhanced polyamine catabolism, mediated via increased expression and activity of spermidine/spermine N1-acetyltransferase (SAT1) and spermine oxidase (SMOX), and generation of toxic products of polyamine degradation (acrolein, H_2O_2 and aldehydes) is important in the mediation of acute kidney injury in mice treated with a single high dose of cisplatin (20mg/kg). We hypothesized that the inhibition of polyamine catabolism will reduce the severity of chronic renal injury caused by long-term cisplatin treatment.

Methods: Using a multiple low dose cisplatin (single weekly cisplatin injection of 7mg/kg for 4 weeks) which more closely simulates the course of cisplatin treatment in cancer patients, we examined the effect of inhibition of polyamine catabolism on the severity of renal injury. The onset and severity of renal damage was determined by assessment of renal function (serum creatinine and blood urea nitrogen levels), damage to the tubular epithelium and renal fibrosis.

Results: Treatment of mice with multiple low doses of cisplatin led to renal tubular damage, interstitial fibrosis and deterioration of renal function. This was associated with increased expression of polyamine catabolizing enzymes *Sat1* and *Smox* transcripts. Comparing the effect of multiple low dose cisplatin treatment in wild type (Wt), *Smox*-KO and *Sat1*-KO mice revealed that *Sat1*-KO and *Smox*-KO mice are significantly protected against renal tubular injury, interstitial fibrosis and loss of renal function.

Conclusions: These studies indicate that: 1) the expression and activity of *Smox* and *Sat1* increase in animals treated with multiple low doses of cisplatin; and 2) the ablation of these genes reduces the severity of renal injury, interstitial fibrosis and loss of renal function. These results suggest that modulating the activity of polyamine catabolic enzymes or neutralizing the toxic products of polyamine catabolism protects against cisplatin-induced chronic renal injury.

SA-PO744

Discovery and Validation of Intestinal Microbiota as Gut Biomarkers for Mirroring Disease Progression and Circulating Nephrotoxin Levels in CKD

I-Wen Wu,[1] Chan-Yu Lin,[3] Hsin-Chih Lai,[2] Shih-Chi Su.[1] *[1]Chang Gung Memorial Hospital, Keelung, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan; [3]Kidney Research Center, Chang Gung Memorial Hospital, Chang Gung University, Taoyuan City, Taiwan.*

Background: The interplay of the gut microbes with gut-producing nephrotoxins and the renal progression remains unclear in cohorts with different stage of chronic kidney disease (CKD) patients.

Methods: Analysis of intestinal microbiota (16S rRNA gene sequencing) and circulating p-cresyl sulfate/indoxyl sulfate were conducted in 92 (31 mild, 30 moderate and 31 advanced) CKD patients and 30 controls (discovery cohort), and further validated in a cohort comprising 22 controls and 76 peritoneal dialysis patients. Spearman's correlation was used to determine the association of major genera (>0.1% abundance and present in >90% of samples) with serum biomarkers and disease severity. Chao1 index and Bray-Curtis distance were used to assess microbial community diversity. Functional composition of metagenomes was predicted from 16S rRNA data by the phylogenetic reconstruction of unobserved states (PICRUSt).

Results: Significant differences in bacterial composition and diversity were noted among controls and patients at different disease stages. A core CKD-associated microbiota consisted of 7 genera (Escherichia_Shigella, Dialister, Lachnospiraceae_ND3007_group, Pseudobutyrivibrio, Roseburia, Paraprevotella and Ruminiclostridium) and 2 species (Collinsella stercoris and Bacteroides eggerthii) were identified to be highly correlated with the stages of CKD. Paraprevotella, Pseudobutyrivibrio and Collinsella stercoris were superior in discriminating CKD from the controls than the use of urine protein/creatinine ratio, even at very early-stage of disease. The performance was further tested in validation cohort. Bacterial genera highly correlated with indoxyl sulfate and p-cresyl sulfate levels were identified, and predicting the functional capabilities of microbial communities by PICRUSt showed that microbial genes related to the metabolism of aromatic amino acids (phenylalanine, tyrosine, and tryptophan) were differentially enriched among the control and different CKD stages.

Conclusions: Our results provide solid human evidence of the impact of gut-metabolite-kidney axis on the severity of CKD and highlight a usefulness of specific gut microorganisms as possible biomarker or therapeutic target of this global health burden.

Probiotic Bifidobacterium animalis subsp. lactis Bi-07 Protects Intestinal Barrier by Alleviating Intestinal Oxidative Stress in Uremic Rats

Meng Wei,[1] Kehui Shi,[2] Hua Liu,[2] Hongli Jiang.[2] *[1]Dialysis Department of Nephrology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: To investigate whether oral administration of probiotic *Bifidobacterium animalis subsp. lactis Bi-07*(*B. animalis subsp. lactis Bi-07*)could protect intestinal barrier in uremic rats and to explore whether it could alleviate oxidative stress in intestinal tissues.

Methods: Thirty SD rats were randomly divided into 3 groups (n=10). The sham operation group only opened the renal capsules. The uremia group underwent 5/6 nephrectomy. Uremia+probiotics group: *B.animalis subsp. lactis Bi-07* was administered daily to the rats for 5 weeks after 5/6 nephrectomy. Determination of 99mTc-DTPA in blood and urine after intragastric administration of 99mTc-DTPA solution evaluated Intestinal permeability. At the end of the intervention, the intestinal segments were retrieved. The ultrastructure of the intestinal epithelial tight junction (TJ) complex was observed by scanning electron microscopy (SEM) combined with lanthanum nitrate staining. After preparation of intestinal homogenate, malondialdehyde (MDA) content and superoxide dismutase (SOD) activity were detected.

Results: SEM showed that microvilli structure of the intestinal epithelial cells in the uremia group was disordered, sparse and shed. Lanthanum nitrate dye could penetrate into the intestinal epithelial cells gap. Compared with the uremia group, microvilli were neatly arranged and TJ was structurally intact. Little of lanthanum nitrate penetrated cell gap in uremia+ probiotics group. Compared with uremic group, *B. animalis subsp. lactis Bi-07* can significantly reduce intestinal permeability (P<0.05). The content of MDA of the ileal tissue was significantly increased in the uremia group (P<0.05), SOD activity was significantly decreased (P<0.05). Compared with the uremia group, the uremia +probiotic group significantly increased SOD levels, suggesting that *B. animalis subsp. lactis Bi-07* protects the intestinal barrier by alleviating oxidative stress.

Conclusions: The probiotic *B. animalis subsp. lactis Bi-07* can protect the intestinal barrier in uremic rats. The mechanism may be to alleviate intestinal oxidative stress and reduce intestinal barrier damage in uremia.

Funding: Government Support - Non-U.S.

SA-PO746

The Expression of Intestinal Mir-223/NLRP3 Axis in Uremic Rats and the Intervention of Probiotics

Hua Liu,[1] Lei Chen,[3] Shanshan Liang,[4] Meng Wei,[4] Lingshuang Sun,[4] Jinhong Xue,[1] Meng Wang,[2] Hongli Jiang.[2] *[1]Blood Purification, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [3]Xi'an Jiaotong University, Xi'an, China; [4]Dialysis Department of Nephrology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: To investigate the role of chronic inflammatory response mediated by NLRP3 inflammasome in uremia intestinal barrier dysfunction by detecting the changes of mir-223 /NLRP3, and to observe the effect of probiotic intervention on it.

Methods: Seventy SD rats were randomly divided into 3 groups and 20 sham group (SH group). 5/6 Nephrectomy was performed on 50 rats in the uremic model group, and the final histopathology confirmed the successful modeling, which were randomly divided into the uremic group (UR group, n=20), probiotics intervention group (UP group, n=20), and intestinal tissue were extraction. The expression of miR-223 mRNA of each group was detected by RT-qPCR. Expression of NLRP3, caspase-1, IL-1β, tight junction protein in intestinal epithelial cells were detected by Western blotting. Bioinformatics software was used to predict the binding site of mir-223-3p and NLRP3 gene. The 3'UTR sequence of NLRP3 gene and its mutants were cloned into the dual luciferase reporter gene vector, and the wild-type and mutant recombinant double luciferase reporter plasmid vector were constructed. PCR and gene sequencing were used to determine whether the vector was successfully constructed, and 293 cells were used for grouping transfection and cell luciferase detection.

Results: Compared with SH group, the expression of miR-223 mRNA in the ileal tissues of the UR group was significantly decreased, while that of UP group was significantly increased (*P*<0.05). Western blotting showed that the expressions of NLRP3, caspase-1 and IL-1β of the UR group were significantly higher than those of the SH group (*P*<0.05), while the expressions of JAM-1, Occludin and claudin-1 proteins were significantly lower (*P*<0.05). However, after probiotics intervention, the expressions of NLRP3, caspase-1 and IL-1b was decreased (*P*<0.05), and the expressions of JAM-1, Occludin and claudin-1was improved. After 293 cells co-transfected with miR-223-3p mimic or inhibitor, NLRP3-3 'UTR wild-type had decreased or increased luciferase activity, with statistically significant differences (P < 0.05).

Conclusions: Probiotics can improve the intestinal barrier function of uremia, which may involve the miR-223 /NLRP3 pathway. The conclusion of this study may provide a new treatment idea for the intestinal barrier dysfunction of uremia and chronic inflammation.

SA-PO747

Omega-3 Polyunsaturated Fatty Acids Reduce Intestinal Inflammation and Enhance Intestinal Motility Associated with Reduced Nitric Oxide Production in CKD

Chao Yu,[1] Feng Liu,[3] Shougang Zhuang.[1,2] *[1]Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China; [2]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [3]Shanghai East Hospital, Shanghai, China*.

Background: Previous studies have shown that chronic kidney disease (CKD) could elicit an intestinal inflammation and result in intestinal dysmotility followed by many complications. Increasing evidence suggests that omega-3 polyunsaturated fatty acids can reduce intestinal inflammation and improve intestinal function in many diseases. In this study, we therefore investigated the effect of omega-3 polyunsaturated fatty acids on intestinal inflammation and intestinal motility in CKD and the underlying mechanism.

Methods: CKD was induced by the 5/6 kidney resection, and omega-3 polyunsaturated fatty acids enriched diet or standard diet was administrated for six weeks. Intestinal motility was assessed by charcoal transportassay, and intestinal inflammation was assessed by analyzing myeloperoxidase activity and concentrations and gene expression of TNF-α,IL-1β, and IL-10 in the intestinal tissue. The nitric oxide production was assessed in the intestinal tissue.

Results: The results showed that CKD resulted in a marked delay in intestinal motilityand was associated with a significant increase of intestinal levels of inflammatory parameters (*P*<0.05). However, compared to the standard diet, omega-3 polyunsaturated fatty acids enriched diet administration markedly reduced intestinal inflammatory response, and resulted in a significant improvement in intestinal motility(*P*<0.05). In addition, the intestinal nitric oxide production was inhibited by omega-3 polyunsaturated fatty acids enriched diet treatment (*P*<0.05).

Conclusions: These results suggest that omega-3 polyunsaturated fatty acids could reduce intestinal inflammation and enhance intestinal motility in CKD, and the underlying mechanism may be associated with reduced nitric oxide production.

The Effects of Allopurinol on Xanthine Oxidase Activity and Expression in CKD

Nicole G. Lacina,[1] Diego Scerbo,[1] Nicholas Kruse,[2] Mingyao Sun,[1] Eric Taylor,[1] Diana I. Jalal.[1] *[1]The University of Iowa, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA*.

Background: Allopurinol lowers uric acid levels and may improve vascular function in chronic kidney disease (CKD). It is unclear whether the effects of allopurinol are mediated by xanthine oxidase (XO) inhibition, uric acid-lowering, or both. We hypothesized that allopurinol suppresses serum XO activity and reduces endothelial XO protein expression.

Methods: We anlayzed serum and endothelial cells samples from 45 CKD patients who participated in a randomized controlled trial of allopurinol vs placebo. Serum XO activity was determined and the expression of endothelial XO protein was evaluated (immunofluorescence). Serum xanthine levels were measured via mass spectrometry. Change from baseline was compared for both study groups.

Results: Baseline serum uric acid correlated with baseline CKD-EPI estimated GFR (r = 0.57, p value <0.0001) but not with serum XO activity (r =0.10, p value 0.52) or endothelial XO protein expression (r =0.2, p value=0.56). There was no correlation between serum XO activity or endothelial XO protein expression with baseline brachial artery flow-mediated dilation (BA-FMD) or CKD-EPI estimated GFR. As shown in the Table, allopurinol lowered serum uric acid levels and increased serum xanthine levels significantly. However, allopurinol did not decrease serum XO activity or the expression of endothelial XO protein. Change in XO activity and XO protein expression did not correlate with change in BA-FMD.

Conclusions: Our data suggest that allopurinol effectively lowers serum uric acid levels by inhibition of XO activity in the liver. However, contrary to our hypothesis, allopurinol does not significantly affect serum XO activity or XO protein expression in the endothelium. In addition our findings suggest that the main factor for increased serum uric acid in CKD is reduced kidney function.

Funding: NIDDK Support

Allopurinol Alters the Metabolome of CKD Patients Beyond Uric Acid-Lowering

Mingyao Sun,[1] Nicole G. Lacina,[1] Nicholas Kruse,[2] Jane Buchanan,[1] Diana Zepeda-Orozco,[1] Eric Taylor,[1] Diana I. Jalal.[1] *[1]The University of Iowa, Iowa City, IA; [2]The University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Allopurinol, a xanthine oxidase (XO) inhibitor, is the most commonly prescribed uric acid-lowering agent in patients with chronic kidney disease (CKD). Although experimental evidence suggests allopurinol has broader effects on the metabolome, these potential effects have not been characterized in CKD. Here, we sought to evaluate the effects of allopurinol on the metabolome of CKD patients.

Methods: Gas chromatography mass spectrometry (GC-MS) was performed on the serum of 31 subjects who participated in a 12-week randomized clinical trial of allopurinol vs placebo. Metabolites of central carbon metabolism included the TCA cycle, glycolysis, the pentose phosphate pathway, amino acid metabolism, neurotransmission, reactive oxygen species defense, and energetics. Metabolites were compared at baseline to the end of study for allopurinol and placebo (paired t test). MetaboAnalyst software was utilized to identify metabolic pathways.

Results: Of the 90 metabolites evaluated by GC-MS, 6 were significantly altered after allopurinol treatment but not placebo (Table). MetaboAnalyst indicated the pentose phosphate (PP) pathway and purine and pyrimidine metabolism were the top pathways affected by allopurinol. Allopurinol inhibited purine metabolism, resulting in decreased serum uric acid (-3.7 ± 1.0mg/dL) vs placebo (0.1 ± 1.5 mg/dL) ($p<0.0001$) and increased the precursor xanthine. Allopurinol inhibited PP pathway activity as downstream product ribose-5-phosphate decreased and upstream precursor glucose-6-phosphate increased.

Conclusions: We describe, for the first time, important effects of allopurinol on the metabolome of CKD patients. Specifically, PP pathway inhibition is known to contribute to oxidative stress and pyrimidine pathway inhibition is known to increase ammonia. These findings should be confirmed in larger studies and the clinical implications of these broad effects should be explored.

Funding: NIDDK Support

Hydrogen Sulfide Attenuates CKD Progression by Inducing TET-Dependent DNA Demethylation on Klotho Promoter

Yulu Gu, Xiaoqiang Ding, Xiaoyan Zhang. *Zhongshan Hospital, Fudan University, Shanghai, China.*

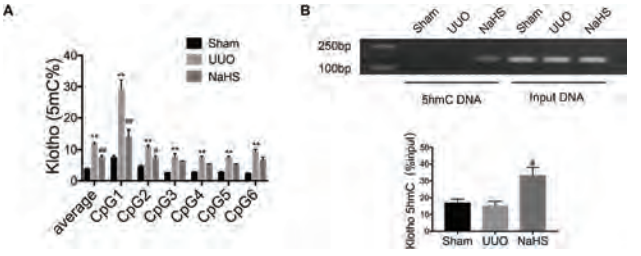
Background: Hydrogen sulfide has been reported to attenuate renal fibrosis. A recent study shows hydrogen sulfide can demethylate its target genes by upregulating TET1 expression in regulatory T cells. Our previous study revealed Klotho hypermethylation in CKD patients, suggesting possible involvement of Klotho promoter hypermethylation in the development of CKD This study aims to investigate whether H_2S can directly change TET hydroxylase expression or activity as well as subsequent DNA demethylation in renal fibrosis.

Methods: C57BL/6 mice underwent unilateral ureter obstruction(UUO) with or without NaHS treatment. Multiple techniques were used to analyze the extent of tubulointerstitial fibrosis and renal hypoxia, the methylation and hydroxymethylation level of renal Klotho promotors, and the expression and activity of TETs. In vitro, HK2 cells received hypoxia treatment. The level of cellular ROS and ferrous ion was examined to further explore the role of hypoxia on TETs enzyme activity and Klotho methylation.

Results: Evidenced by Masson staining and the expression of α-SMA and Fibronectin, NaHS treatment reduced renal fibrosis in UUO mice. Also, it upregulated Klotho expression, decreased Klotho methylation level and increased Klotho hydroxymethylation level, along with increased TETs activity, rather than TETs expression. Moreover, NaHS reduced hypoxic areas of UUO-injured kidney. In vitro, hypoxia increased Klotho methylation level and decreased TET activity. In hypoxic HK2 cells, the level of total ROS and nuclear ROS were raised. Both H_2O_2 and hypoxia reduced the concentration of cellular Fe^{2+}. While ascorbate rescued hypoxia-induced decrease of TETs activity.

Conclusions: Hypoxia causes Klotho hypermethylation by decreasing TETs enzyme activity through ROS-induced Fe^{2+} reduction. And hydrogen sulfide attenuates renal fibrosis by improving hypoxia and enhancing TETs enzyme, which induces Klotho demethylation and restores Klotho.

Funding: Government Support - Non-U.S.



NaHS administration demethylates Klotho in UUO mice.

The Differential Expression Research of Circular RNAs in Exosomes from Serum and Urine in Patients with Idiopathic Membranous Nephropathy

Hualin Ma. *Shenzhen People's Hospital, Shenzhen, China.*

Background: To further explore the pathogenesis of IMN, the technique of gene-sequencing was uesd to analyze the differentially expressed circRNAs in exosomes from both the serum and urine of patients with IMN, which may lay the foundation for research of circRNAs as a new class of exosome-base IMN diagnosis biomarkers.

Methods: Ten patients with IMN and ten normal controls were recruited as experimental subjects in our study. The exosomes were extracted from the collected serum and urine. Then, pure circRNAs were extracted from the exosomes with a series of enzymatic reactions. Afterwards, the significantly differentially expressed circRNAs were chosen by the method of gene-sequencing.

Results: Compared with normal controls. the circRNAs were reduced in the exosomes from serum of patients with IMN, which mostly originated from intron gene regions. Meanwhile, a total of 89 circRNAs were significantly differentially expressed, which were also mostly derived from intron gene regions. including 49 up-regulated and 40 down-regulated genes. However, the species were increased in the exosomes from the urine of patients with IMN compared to normal controls, and they mainly originated from exon gene regions. Simultaneously, a total of 60 circRNAs were significantly differentially expressed, which primarily belonged to intron gengeregions, including 54 up-regulated and 6 down-regulated regions.

Conclusions: The significant differential and specific expression of circRNAs in the exosomes from patients with IMN were. For example, MUCA, which originated from chr7:100550808/100551062, could be considered a potential diagnostic biomarker of IMN. Furthermore, these figures may be used as a reference or supplement in the research of the pathogenesis of IMN. Number

Dietary Phosphate Disturbs of Gut Microbiome In Mice

Naoko Oda,[1] Kohei Sugihara,[3] Miho Ikeda,[1] Yuho Higashimura,[1] Takashi Uebanso,[2] Hirokazu Ohminami,[1] Kohta Ohnishi,[1] Masashi Masuda,[1] Hisami Yamanaka-Okumura,[1] Yutaka Taketani.[1] *[1]Tokushima University, Tokushima, Japan; [2]Institute of Medical Nutrition, Tokushima Uiverisity, Medical School, Tokushima City, Japan; [3]Tokushima University Graduate School, Tokushima, Japan.*

Background: Disorder of phosphate metabolism is a common pathological condition in chronic kidney disease (CKD) patients. Excessive intake of dietary phosphate deteliorates CKD and various complications including cardiovascular disease. Recent reports have demonstrated that gut microbiome disturbance is associated with both the etiology and progression of CKD. However, the relationship between dietary phosphate and gut microbiome remains unknown. Here, we examined the effects of excessive intake of phosphate on gut microbiome.

Methods: Five-week-old male C57BL/6J mice were fed either control diet (0.4% phosphate; CP) or high phosphate diet (1.2% phosphate; HP) for eight weeks. Stool samples were collected at eight weeks. After amplifying the V3-V4 region of 16S ribosome RNA by PCR, analysis of the gut microbiota was carried out using MiSeq next generation sequencer (NGS).

Results: Compared with CP diet group, HP diet group significantly decreased in body weight and epididymal fat weight, plasma calcium level, and increased in urinary phosphate excretion. In analysis of gut microbiota, HP diet group increased in *Firmicutes* phylum and decreased in *Bacteroidetes* phylum by PCR and NGS analysis. In particular, significant increase in *Erysipelotrichaceae* genus and decrease in *Clostridia* genus were observed in HP diet group, and NGS analysis showed the decrease in bacterial diversity in HP diet group. In addition, HP diet group decreased colonic tight junction marker mRNA levels.

Conclusions: These results suggest that the excessive intake of dietary phosphate disturbs gut microbiota and decreased in bacterial diversity. Furthermore, it may affect the intestinal barrier function. Such a disturbance may be related to progression of CKD. Adequate management of dietary phosphate would be required to keep healthy environment in gut.

Improvement of the Effect of HIF-1α Stabilizer on the Destruction of Tight Junctions in Intestinal Epithelial Cells Induced by Homocysteine

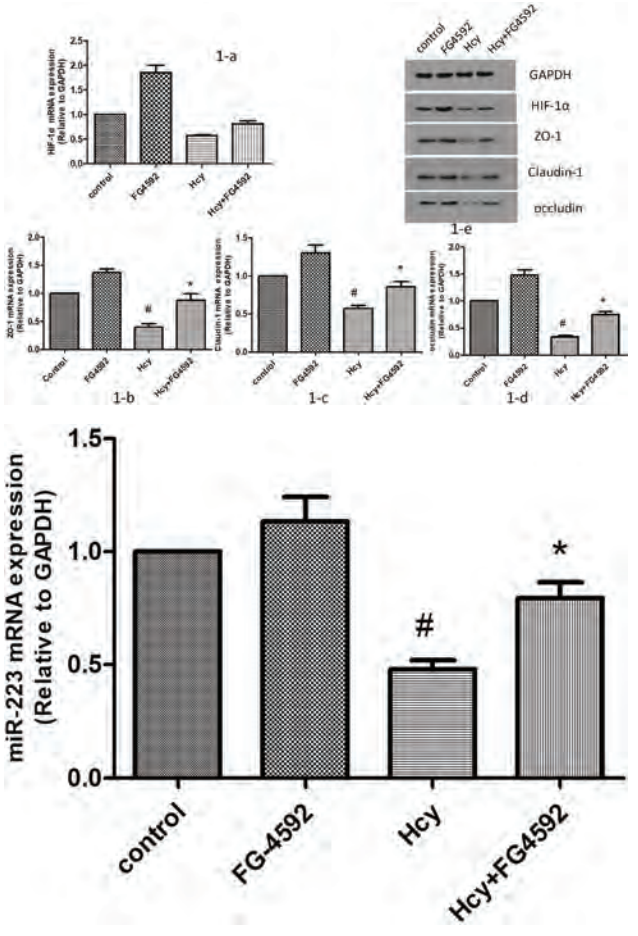
Hua Liu,[1] Lei Chen,[2] Shanshan Liang,[3] Jinhong Xue,[1] Hongli Jiang.[4] *[1]Blood Purification, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]Xi'an Jiaotong University, Xi'an, China; [3]Dialysis Department of Nephrology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [4]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: Based on previous findings that homocysteine (Hcy) can increase the permeability of intestinal epithelial Caco2 cell and lead to decreased expression of tight junction molecules, the role of HIF-1α in intestinal barrier dysfunction caused by homocysteine and the mechanism of intervention of HIF-1α stabilizer (FG-4592) on these effects were explored.

Methods: Caco2 cells was cultured and divided into four groups: normal control group, FG4592 group, homocysteine group (Hcy group), Hcy+FG4592 group. mRNA and protein expression levels of HIF-1α, ZO-1, claudin-1, occludin were detected by RT-qPCR and Western blotting. The expression level of miR-223 was detected by RT-qPCR.

Results: Hcy (0.5 mM) can reduce the expression of HIF-1α, claudin-1, occludin and ZO-1mRNA and protein in Caco2 cells, and FG-4592 can improve the expression of these induced by Hcy (P<0.05) through the RT-qPCR or Western bloting method (Fig.1). Hcy can reduce the expression of miR-223 mRNA (P<0.05), while the FG-4592 can increase the expression of miR-223 mRNA (P<0.05) (Fig.2).

Conclusions: miR-223 may be involved in the maintenance of intestinal epithelial barrier function in the experiment of using uremic serum to stimulate Caco2 cells. HIF-1α stabilizer can improve the Hcy-induced reduction expression of HIF-1α, ZO-1, claudin-1, Occludin, up-regulate the expression of miR-223 and down-regulate the expression of NLRP3, the mechanism may involve the mir-223/NLRP3 pathway.



SA-PO754

Effect of Hypoxia-Inducible Factor-1α Stabilizers on the Destruction of Tight Junctions in Uremic Intestinal Epithelial Cells

Hua Liu. *the blood purification, the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China*.

Background: Hypoxia-inducible factor-1α (HIF-1α) plays an important role in maintaining the structure and function of the intestinal mucosal barrier and is involved in regulating the expression of intestinal epithelial tight junction proteins. In this study, based on the previous findings, the role of HIF-1α in intestinal barrier dysfunction caused by ureima toxins and the effect of intervention of HIF-1α stabilizer (FG-4592) on the above effects were explored.

Methods: Caco2 cells was cultured and divided into 3 groups, the normal control group, the uremic serum stimulation group, and the uremic serum + HIF-1α stabilizer (FG-4592) intervention group. RT-qPCR and Western blotting method was used to detect the expression of HIF-1α, ZO-1, claudin-1, Occludin, and NLRP3 inflammasome in each group. RT-qPCR was used to detect the effect of miR-223 mimimc and siNLRP3 on NLRP3 expression stimulated by uremia serum. Transfection of miR-223-mimics or miR-223-inhibitor to Caco2 cells followed by downstream gene expression analysis is performed to elucidate the targets and roles of mir-223.

Results: Compared with the control group, the application of uremia serum to Caco2 cells can significantly decrease the expression of HIF-1α, ZO-1, claudin-1, occludin mRNA and protein (P < 0.05), while FG-4592 intervention could reverse the above changes (P < 0.05). On the contrary, stimulation of Caco2 cells by uremia serum can significantly increase the expression of NLRP3, caspase-1 and IL-1β mRNA and protein, while FG-4592 intervention can down-regulate the expression of NLRP3 inflammasome. At the same time, while uremic serum stimulation can increase NLRP3 expression, application of miR-223 mimic or siNLRP3 can reduce NLRP3 expression (P < 0.05). The mRNA and protein expression of NLRP3, caspase-1 and IL-1β of Caco2 cells transfected miR-223-mimic decreased but that increased for tight junction protein, while transfection of miR-223-inhibitor, we got opposite results.

Conclusions: HIF-1α stabilizer (FG-4592) increases the decrease of HIF-1α expression under the stimulation of uremic serum, and its improvement of the expression mechanism of tight junction protein may play a role in the down-regulation of NLRP3 inflammasome caused by the up-regulation of miR-223 expression, thus improving the intestinal barrier function, which needs further experimental verification

SA-PO755

A Guanylate Cyclase C Agonist Linaclotide Reduces Trimethylamine N-Oxide in an Adenine-Induced CKD Model

Fumika Hara,[1,6] Yoshitomi Kanemitsu,[2] Koichi Kikuchi,[1] Daisuke Saigusa,[3] Eikan Mishima,[1] Takehiro Suzuki,[1] Tomoyoshi Soga,[4] Yoshihisa Tomioka,[2] Shinji Fukuda,[5] Takaaki Abe.[1] *[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Tohoku University Graduate School of Pharmacutical Sicineces, Sendai, Japan; [3]Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; [4]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan; [5]Keio University, Tsuruoka, Japan; [6]National Agriculture and Food Research Organization, Tsukuba, Japan.*

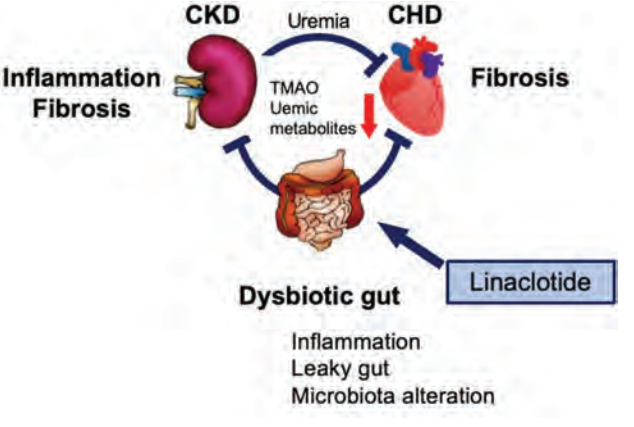
Background: Cardiorenal syndrome is a major cause of mortality in CKD patients. Trimethylamine-*N*-oxide (TMAO), which is a hepatic metabolized product of trimethylamine (TMA) generated from dietary phosphatidylcholine or carnitine derived by gut microbiota, directly linked to the progression of cardiovascular disease and renal dysfunction. Therefore, targeting TMAO may be one of a novel strategy for the prevention of CVD and CKD.

Methods: A guanylate cyclase C agonist linaclotide was administered to adenine-induced renal failure model and the changes of renal function and gut-derived uremic toxins as well as gut microbiota community were analyzed using metabolomic and metagenomic analyses.

Results: Linaclotide decreased the plasma TMAO level at a clinically used dose (10 μg/kg) in an adenine-induced renal failure mouse. In additon, linaclotide (100 μg/kg), significanlty improved renal function and reduced various uremic toxins. Linaclotide reduced renal inflammation and fibrosis, cardiac fibrosis as well as collagen I, TGF-β, galectin-3 and ST2 gene expressions. The plasma galectin-3 and ST2 were also reduced. In the small intestinal crypt, F4/80-positive macrophages were abundant in renal failure and theexpression was decreased by linaclotide. Reduced colonic claudin1 was also restoredby linaclotide, suggesting that linaclotide ameliorated "leaky-gut" in the renal failure. By metagenome analysis, microbial order Clostridiales may have been responsible for the change in TMAO.

Conclusions: Linaclotide reduced TMAO and uremic toxin levelsand be a potent tool for the cardio-renal syndrome by modification of the "gut-cardiorenal axis"

Funding: Government Support - Non-U.S.



gut-cardiorenal axis

Impaired Secretion of Uremic Solutes in Advanced CKD

Robert Mair, Sheldon Leong, Natalie Plummer, Tammy L. Sirich, Timothy W. Meyer. *Stanford University/VAMC Nephrology, Palo Alto, CA.*

Background: The normal kidney clears many solutes efficiently by proximal tubular secretion. Clearance values are observed to be particularly high relative to the glomerular filtration rate (GFR) when the clearances of protein-bound solutes are calculated in terms of their free, unbound concentrations. This study examined the extent to which high secretory clearances are maintained when kidney function is markedly reduced.

Methods: Simultaneous urine and blood samples were collected from patients with stage V chronic kidney disease not on dialysis (CKD, n=16) and control subjects (control, n=17). The normally secreted and protein-bound solutes indoxyl sulfate (IS) and p-cresol sulfate (PCS) were assayed by LC/MS/MS. Clearances relative to the GFR (fractional clearances) were then estimated by dividing the urine to free plasma concentration ratios for these solutes by the urine to plasma concentration ratio for creatinine.

Results: GFR values estimated by the CKD-EPI equation were 7 ± 2 ml/min/1.73 m^2 in the CKD patients and 86 ± 17 ml/min/1.73 m^2 in the controls. Fractional clearances of IS and PCS were very high in controls in accord with prior results. Fractional clearances for both solutes were greatly reduced in CKD indicating impaired secretion (IS: 5 ± 2 vs. 28 ± 7, p<0.001; PCS: 3 ± 1 vs. 10 ± 3, p<0.001). Impaired kidney secretion was accompanied by prominent plasma accumulation in CKD patients with plasma concentrations of IS and PCS averaging 59 and 27 times greater than those in control subjects as compared to a 9 times greater creatinine concentration.

Conclusions: Secretory clearance of IS and PCS was impaired out of proportion to glomerular filtration in patients with advanced CKD. Prominent accumulation of these and other normally secreted solutes may contribute to uremic illness.

Association of Tubular Solute Clearances with the Glomerular Filtration Rate and Complications of CKD: The CRIC Study

Yan Chen,[1] Leila R. Zelnick,[11] Ke Wang,[1] Ronit Katz,[1] Chi-yuan Hsu,[2] Alan S. Go,[3] Harold I. Feldman,[4] Rupal Mehta,[5] James P. Lash,[6] Sushrut S. Waikar,[10] L. Lee Hamm,[9] Jing Chen,[8] Tariq Shafi,[7] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]University of California San Francisco, San Francisco, CA; [3]Kaiser Permanente Northern California, Oakland, CA; [4]University of Pennsylvania, Philadelphia, PA; [5]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [6]University of Illinois at Chicago, Chicago, IL; [7]University of Mississippi Medical Center, Jackson, MS; [8]Tulane School of Medicine, New Orleans, LA; [9]Tulane University School of Medicine, New Orleans, LA; [10]Harvard Medical School, Boston, MA; [11]Kidney Research Institute, Seattle, WA.*

Background: The secretion of organic solutes by the proximal tubules is an essential intrinsic kidney function. However, the degree to which secretory solute clearance corresponds with the glomerular filtration rate (GFR) and potential implications of net secretory clearance are largely unknown.

Methods: We evaluated 1240 participants who underwent ^{125} I-iothalamate clearance (iGFR) measurements of GFR in the Chronic Renal Insufficiency Cohort (CRIC) Study. We used targeted mass-spectrometry to quantify 11 secretory solutes in 24-hour urine and plasma samples. We used correlation and linear regression to determine cross-sectional associations of secretory clearances with iGFR and common metabolic complications.

Results: Correlations between iGFR and secretory solute clearances ranged from ρ = 0.21 (p-cresol sulfate) to ρ = 0.55 (kynurenic acid). Lower clearances of most secretory solutes were associated with higher serum concentrations of parathyroid hormone (PTH), triglycerides, and uric acid (Figure). Each 50% lower kynurenic acid clearance was associated with a 16.1 pg/mL higher serum PTH concentration and an 18.2 mg/dL higher serum triglyceride concentration after adjustment for iGFR, albuminuria, and other potential confounders. Secretory solute clearances were not associated with meaningful differences in serum calcium, phosphate, hemoglobin, bicarbonate, or C-reactive protein concentrations.

Conclusions: Patients with CKD differ in their tubular secretory clearance for a given level of GFR. Lower net secretory clearances are associated with higher levels of PTH, triglycerides, and uric acid independent of GFR and albuminuria, suggesting potential clinical and biological relevance of this kidney function.

Funding: NIDDK Support

Variations in Gut Microbiota May Correlate with Lipid Metabolism in UMOD Knockout Rats

Na Wang. *Renal Division, Peking University First Hospital Institute of Nephrology, Peking University, BeiJing, China.*

Background: Tamm-Horsfall protein (THP, uromodulin, UMOD) is an important protective factor during kidney injury. Although it was mainly expressed in the thick ascending limb, uromodulin still can be detected in the serum and in other tissue cells. Study has revealed a crucial role of uromodulin on the M-cell surface for the uptake of SlpA-positive lactic acid bacteria into M cells, possibly leading to subsequent delivery of the bacteria to dendritic cells closely associated with M cells for immunomodulation. In this study we investigated the change of gut microbiome in UMOD ablation rats.

Methods: 10wild type SD male rats and 10 UMOD knockout SD rats (THP-/-) were housed under controlled environment for10 weeks. Same water and diet were provided. All of the rats were anesthetized to collect fecal samples from large intestine directly. The bacterial composition was analyzed based on 16S ribosomal DNA pyrosequencing. Bioinformatics tools, including sequence alignment, abundance, and taxonomic diversity, were used in microbiome data and its products analyses.

Results: There was no difference in mean weight between two groups. The serum triglyceride (TG) decreased significantly in THP-/-rats (0.632&1.473mmol/L, p<0.05). The microbial richness and diversity in composition were different in THP-/- rats compared with WT (PCoA analysis, p=0.036). At the phylum level, there were obvious reductions in Elusimicrobia and Actinobacteria in THP-/- rats (p<0.05). At the genus level, five genera were obviously increased in THP-/- rats(p<0.05), including Helicobacter, Lactobacillus, Roseburia, Clostridium XI and Phascolarctobacterium. While four genera, including Alloprevotella, Elusimicrobium, Intestinimonas and Ruminococcus decreased (p<0.05). Among those changed genera, Ruminococcus and Elusimicrobium presented positive correlation with TG, while Phascolarctobacterium, Lactobacillus and Alloprevotella were negative correlated with TG (P<0.05). Obvious variations were identified in 33 microbial metabolites with the change of microbiota. 22 out of 33 microbial metabolite products were fatty acid.

Conclusions: UMOD ablation led to significant variations in composition of gut microbiota in SD rats. The change of gut microbiota correlated with serum TG, suggested other pathways may be involved the abnormal lipid metabolism in chronic kidney disease

SA-PO759

Carbamylation of Albumin Results in Structural Changes That Minimize Binding to Cubilin and FcRn Resulting in More Rapid Serum Clearance

Shiv Pratap S. Yadav, Sudhanshu Kumar, Ruben M. Sandoval, Silvia B. Campos-bilderback, George Rhodes, Mark C. Wagner, Bruce A. Molitoris. *Indiana University School of Medicine Division of Nephrology, Indianapolis, IN.*

Background: Chronic kidney disease results in high serum urea concentrations and leads to increased cardiovascular disease. An increase in urea results in excessive protein carbamylation which has been associated with increased mortality. We hypothesized carbamylation would alter the structure of albumin leading to reduced binding to cubilin and or FcRn resulting in increased serum clearance.

Methods: To test this hypothesis rats were injected at time 0 with RSA or RSA modified with KCN 30min, 2hr or 4hr to induce increasing amounts of carbamylation. Increased serum clearance was observed in a dose dependent fashion. To determine the mechanism we quantified the number of lysine residues modified on RSA using MALDI TOF and showed increasing Lys residues modified with longer KCN incubation times. We then asked whether increased clearance was the result of decreased binding to cubilin, which would result in reduced PTC uptake, and or FcRn which would reduce transcytosis of albumin. Using Microscale Thermophoresis to quantify changes in binding affinity values, Kd, we observed a reduction in both cubilin and FcRn binding with carbamylated RSA, compared to RSA.

Results: Specifically, the Kd of cubilin 7,8 increased from 0.01 mM for unmodified RSA to 1.2 mM for 30min, 1.7 mM for 2hr and 10 mM for 4hr carbamylated RSAs, respectively. For FcRn the Kd for albumin was10 mM for unmodified albumin, while 2hr carbamylated RSA was >100 mM and 4hr had no binding. The decreased binding to both cubilin 7,8 and FcRn can explain the increased serum clearance and is also consistent with our observed increase in carbamylated albumin in the urine. To better understand the changes to albumin mediated by carbamylation we performed a structural characterization analysis of modified albumin using small-angle X-ray scattering (SAXS) to evaluate shape changes with carbamylation. Guinier and P(R) analyses yielded the radius of gyration (R_g) and D_{max} with longer carbamylation time.

Conclusions: These data indicate carbamylation of albumin results in an altered structure that mediates reduced binding to cubilin and FcRn. This results in reduced proximal tubule uptake and transcytosis of albumin resulting in more rapid serum clearance and lysosomal accumulation of carbamylated albumin.

The Mechanism of Glutamine Catabolism in the Activation of Renal Fibroblasts

Yang Cai,[1] Min Han,[3] Gang Xu.[2] *[1]Tongji Hospital of Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China; [2]Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, China; [3]Tongji Hospital, Tongji Medical College, Wuhan, China.*

Background: Glutamine catabolism enhances the activity of tricarboxylic acid cycle and synthesizes key intermediate metabolites required for amino acids. This study will explore the role of glutamine catabolism in the activation of fibroblasts.

Methods: Activation of fibroblasts was induced by TGF-β1, changes of metabolites during fibroblast activation were detected by non-targeted metabolomics. The expression of GLS1, the key enzyme of glutamine catabolism, was detected by western blot. After the inhibition of GLS1 by specific inhibitors or siRNA, the proliferation, activation and migration of fibroblasts were detected. Glutamine was deprived during fibroblast activation, and the effects of glutamine on mitochondrial function were detected by measuring mitochondrial content, morphology, membrane potential, and oxygen consumption rate. The effects of supplementation with α-ketoglutarate after deprivation of glutamine on proliferation, activation, migration and mitochondrial function of fibroblasts were observed. In vivo experiment, intraperitoneal injection of BPTES after the UUO model was constructed, and the effect of BPTES on renal fibrosis was determined by pathological staining and immunohistochemistry.

Results: After TGF-β1 treatment, non-targeted metabolomics suggested that glutamate content increased significantly and pathway analysis highlighted significant enhancement of glutamine metabolism. The expression of GLS1 was significantly increased during fibroblast activation. After inhibition of GLS1, the proliferation, activation and migration of fibroblasts were significantly inhibited. After deprivation of glutamine during fibroblast activation, the mitochondrial content was significantly reduced, mitochondria were fragmented, the mitochondrial membrane potential, mitochondrial oxygen consumption rate, and ATP generation were all significantly reduced. After deprivation of glutamine and supplementation with α-ketoglutarate, the proliferation, activation and migration of fibroblasts were increased, and the mitochondrial content and mitochondrial membrane potential was partially recovered. In UUO model, BPTES could inhibit the activation of renal fibroblasts and alleviate renal fibrosis.

Conclusions: Glutamine catabolism plays an important role during fibroblast activation. Inhibition of glutamine catabolism can inhibit the proliferation and activation of renal fibroblasts and improve renal fibrosis.

Knockdown of Central (Pro)Renin Receptor Attenuates Renal Injury in a High-Salt-Load CKD Rat Model

Jiawen Li, Aiqing Li. *Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: High-salt promotes renal injury in chronic kidney disease (CKD) through activating the RAS axis of the brain and kidney. Simultaneously, (pro)renin receptor (PRR) can exert local physiological effects in brain. However, the mechanism of central PRR in regulating salt-induced renal injury in CKD remains unclear. Therefore, we investigate the role of central PRR on renal injury in salt-loaded CKD rats in this study. Furthermore, we also investigate the potential mechanism of central PRR ameliorating renal injury.

Methods: Protocol A, First, we screened out the sequences that inhibit the central PRR expression in vitro. After the CKD model, which was established by 5/6 nephrectomy, was successfully prepared, intraventricular injection of lentivirus-packaged shRNA was used and a high-salt diet was given for 4 weeks. Finally, renal pathologic change was detected. Protocol B, U0126, Wortmannin and Losartan were used to inhibit MAPK/ERK1/2, PI3K/Akt signaling pathway, and ACE1-Ang II-AT1 axis in CKD model by continuous central administration and a high-salt diet was given for 4 weeks, respectively. Finally, we investigated the central and renal pathological changes.

Results: High-salt diet could aggravate kidney damage and fibrosis, increased RAS activation, oxidative stress, and inflammation. After successful inhibition of central PRR expression, the activity of the sympathetic nervous system (SNA) was decreased, kidney damage, renal fibrosis, RAS activation, oxidative stress, and inflammation were diminished. Furthermore, phosphorylation of ERK1/2 and Akt in central were inhibited. Central administration of U0126, Wortmannin, and Losartan was performed. The results revealed that these interventions ameliorated kidney damage, inflammation, oxidative stress, fibrosis, and SNA. However, decreased phosphorylation of ERK1/2 and Akt signaling in the brain had no significant effect on the expression of PRR, but knocking down PRR can inhibit the phosphorylation of these pathways. It suggested that central PRR may affect renal pathology through these signaling pathways.

Conclusions: Centrally knockdown of PRR expression can ameliorate salt-induced renal damage, as well as reduce RAS activation, inflammation, and oxidative stress, thereby slowing down the progression of CKD. Central PRR may affect renal pathology through the ACE1-Ang II-AT1 axis as well as MAPK/ERK1/2 and PI3K/Akt signaling pathways.

A Whole-Genome CRISPR Knockout Positive Screen Reveals Pathways Regulating APOL1-Induced Cytotoxicity

Francesca Oltrabella,[1] Ted Lau,[2] Jonathan Cooper,[3] Marinella Callow,[2] Benjamin Haley,[4] Scott Martin,[2] Michael Costa,[2] Suzie J. Scales.[1] *[1]Immunology, Genentech, South San Francisco, CA; [2]Discovery Oncology, Genentech, South San Francisco, CA; [3]Molecular Oncology, Genentech, South San Francisco, CA; [4]Molecular Biology, Genentech, South San Francisco, CA.*

Background: In humans two genetic variants of Apolipoprotein L1 (APOL1), G1 and G2, are common in African Americans and are strongly associated with chronic kidney disease (CKD). However, little is known about their pathological mechanism(s). APOL1 G1 and G2 are generally more toxic than wild type upon overexpression, with evidence for cellular mechanisms ranging from mitochondrial dysfunction, ER stress, endosome or autophagosome maturation defects, impaired cholesterol efflux, altered suPAR:integrin binding to cation efflux. It is unlikely that all these are primarily responsible for CKD, so an unbiased approach to identifying pathways and/or co-factors that mediate APOL1 variant cell killing should aid our understanding of the actual disease mechanism.

Methods: A pooled genome-wide CRISPR knockout screen, where each cell is deleted of a single gene prior to a phenotype-based selection, is one such powerful unbiased technique, which APOL1-induced *in vitro* cell death renders possible. Here, we show how we performed a genome-scale CRISPR-Cas9 loss-of-function screen in HEK293 cells to discover genes that influence APOL1-induced cell killing. We generated *Tet* inducible APOL1 G0, G1 and G2 HEK-293 cells expressing Cas9-GFP and carefully titrated APOL1 variant dose-dependent cell killing. These cells were infected with a genome-wide lentiviral guide RNA library, followed by APOL1 induction to the pre-determined level.

Results: The cells surviving APOL1 selective pressure were subjected to next-generation sequencing of the integrated sgRNA cassettes. With this approach we identified new and existing pathways affecting APOL1-mediated cell killing.

Conclusions: Here we demonstrated how APOL1 variants over-expression could be used as a selective pressure in a CRISPR KO positive screen to reveal pathways that are directly or indirectly involved in APOL1-induced cell toxicity. The same pathways have the potential to become druggable targets for patients that develop CKD linked to APOL1 variants. Validation and characterization analysis of the discovered factors will be essential to confirm our findings and to demonstrate the feasibility of our screening approach.

Putative Endothelial Progenitor Cells Protected Mice from Ischemia-Reperfusion-Induced Renal Fibrosis by Suppressing the Activation of PDGFR-β$^+$ Pericytes via Paracrine Way

Meng Wang, Ying Yao, Rui Zeng. *Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: Putative Endothelial progenitor cells (pEPCs) are defined as a group of stem cells which have the potential capacity to differentiate into endothelial cells. When tissues suffer from injury, they secrete factors to recruit pEPCs from bone marrow to injured site, involving in the vascular repair and protecting tissues from damage. However, the mechanism of pEPCs acting on ischemic organs, especially kidneys, is still not clear. Some studies showed that pEPCs participated in angiogenesis by directly intervening in vascular walls and differentiating into endothelial cells. Other studies claimed that pEPCs regulated long-distance targeting recipient cells via paracrine way. This study aimed to investigate the role and mechanism of pEPCs in ischemia reperfusion (IR)-induced renal fibrosis.

Methods: Mice were infused with pEPCs extracted from bone marrow of GFP mice 6 hours after IR surgery and sacrificed at day 5, 10 and 28. GFP+ pEPCs were tracked by immunofluorescence and flowcytometry. The pEPCs-cultured medium (pEPCs-CM) were infused to investigate the paracrine role of pEPCs. Platelet derived growth factor-BB (PDGF-BB), the ligand for platelet derived growth factor receptor-β (PDGFR-β), which is the specific surface receptor on pericytes, was adopted, in a selective pericyte knockout mice (DTR expression in PDGFR-β$^+$ cells), to detect the relationship between pEPCs and pericytes in the progression of IR-induced kidney disease.

Results: The results demonstrated that the adoptive transfer of pEPCs promoted the renal angiogenesis and attenuated renal fibrosis. Cell tracking experiments showed that few pEPCs were detected in IR kidney, suggesting the involvement of paracrine mechanism. We further found the injection of pEPCs-CM had an equal protective effect on kidney as pEPCs did. The transfer of pEPCs or pEPCs-CM inhibited IR-induced PDGFR-β expression, pericyte-endothelial detachment, pericyte proliferation and

pericyte-myofibroblast transition. These protective effect of transferred pEPCs on capillary rarefaction and renal fibrosis was blocked by conditional PDGFR-β^+ cell knockout.

Conclusions: The adoptive transfer of pEPCs ameliorated IR-induced capillary rarefaction and renal fibrosis by suppressing the activation of PDGFR-β^+ pericytes via paracrine way.

Basigin/CD147 Facilitates Uptake of Protein into Renal Tubular Epithelium

Tomoharu Watanabe,[1] Tomoki Kosugi,[2] Akihiro Ryuge,[2] Kayaho Maeda,[2] Yuka Sato,[2] Noritoshi Kato,[1] Sawako Kato,[2] Shoichi Maruyama.[2] *[1]Nagoya University, Nagoya, Japan; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: CD147/Basigin (Bsg), a glycosylated transmembrane protein, plays a crucial role in processes such as cancer development, inflammation and immune system regulation. We have so far demonstrated that Bsg is involved in the pathogenesis of acute kidney injury and renal fibrosis. In the injured kidneys, this expression is induced strongly in the basolateral sides of TECs, infiltrating inflammatory cells. In a series of prior clinical studies, proteinuric kidney diseases such as minimal change nephrotic syndrome, showed marked increases in urinary Bsg levels, and a close relationship between proteinurea and urinary Bsg levels. Aberrant molecular mechanisms involving Bsg-mediated intracellular metabolism may be a crucial determinant of proteinuric tubular injury. In this study, we investigated whether Bsg deficiency maintains intracellular homeostasis by inhibiting uptake of protein into TECs.

Methods: As a clinical study, diabetic kidney disease (DKD) patients (N=52) registered with UMIN Clinical Trials Registry (8016) were treated with spironolactone 25 mg once daily for 8 weeks. The relationships between urinary Bsg values and clinical indicators were examined. We then induced tubulointerstitial injuries in wild-type ($Bsg^{+/+}$) or Bsg-deficient ($Bsg^{-/-}$) mice using intraperitoneal injections of a large amount of protein for 14 days. Immortalized proximal tubule epithelial cell line from normal adult human kidney (HK2) was exposed to high glucose (40mM) or bovine serum albumin (BSA).

Results: In DKD patients, plasma and urinary CD147 levels showed a correlation with eGFR or proteinuria, but not HbA1c, respectively. In biopsy tissues of patients with DKD, marked CD147 induction was detected in injured lesions representing renal inflammation. In a basic study, $Bsg^{-/-}$ mice induced by protein overload ameliorate the development of tubulointerstitial injuries and kidney dysfunction. In $Bsg^{+/+}$ kidneys with protein overload, several apoptotic factors were enhanced with increased Bsg expression. Bsg silencing in HK2 exposed to BSA suppressed uptake of BSA into the epithelium, and decreased heme oxygenase-1 expression as a marker of oxidative stress. Exposure of high glucose wasn't affected.

Conclusions: Bsg is involved in the pathogenesis of tubulointerstitial injuries by protein overload through promoting uptake of protein into TECs.

SA-PO765

Mechanism of Action of Veverimer, a First-in-Class, Orally Administered, Nonabsorbed, Counterion-Free Hydrochloric Acid Binder for the Treatment of Metabolic Acidosis in CKD

Jun Shao, Kalpesh N. Biyani, Matthew Kade, Paul Kierstead, Randi Gbur, Scott Tabakman, Son H. Nguyen, Jerry M. Buysse, Gerrit Klaerner. *Tricida, Inc., South San Francisco, CA.*

Background: Current management of metabolic acidosis in patients with CKD relies on dietary protein restriction to reduce metabolic acid production or neutralization of retained acid with orally administered bicarbonate. Veverimer is being developed to provide a novel treatment modality for metabolic acidosis: endogenous acid removal. Veverimer is a free-amine polymer designed to combine high capacity and high selectivity for binding and removing HCl from the GI tract. It does not deliver sodium or other counterions and may therefore be appropriate for all patients with CKD and metabolic acidosis, including those with common sodium-sensitive comorbidities.

Methods: The binding capacity of veverimer and its selectivity for chloride over other anions were assessed in vitro in matrices mimicking the pH and ionic conditions of the human GI tract. Proof-of-concept of the efficacy of veverimer to increase serum bicarbonate was provided using a rat model of adenine-induced nephropathy and chronic metabolic acidosis. The bioavailability of veverimer was assessed in ADME studies in rats and dogs dosed with ^{14}C-labeled veverimer.

Results: In vitro, veverimer had a maximum binding capacity of 10.7 ± 0.4 mmol HCl per gram of polymer with significant binding capacity (> 5 mmol/g) across the entire range of physiologically relevant human GI pH (1.5 to 7). Upon protonation, veverimer bound chloride with high specificity, with little to no binding of phosphate, citrate or taurocholate. Administration of veverimer to rats with adenine-induced nephropathy and chronic metabolic acidosis resulted in a significant increase in fecal chloride excretion and a dose-dependent increase in serum bicarbonate to within the normal range, compared to untreated controls. ADME studies demonstrated that veverimer was not absorbed from the GI tract into the systemic circulation.

Conclusions: Endogenous acid removal through binding to veverimer, an orally-administered, non-absorbed polymer that is then excreted, provides a potential new mechanism for treating metabolic acidosis in patients with CKD.

Klotho Protein Supplementation Retards Renal Injury in 5/6-Nephrectomized Rats

Tsuneo Takenaka,[1] Hiroyuki Kobori,[4] Tsutomu Inoue,[2] Naohito Ishii,[3] Matsuhiko Hayashi.[5] *[1]International University of Health and Welfare, Sanno Hospital, Tokyo, Japan; [2]Saitama Medical University, Iruma-gun, Saitama, Japan; [3]Kitasato University, Sagamihara, Japan; [4]Tulane University Hypertension and Renal COE, New Orleans, LA; [5]Kawakita General Hospital, Suginami-ku, Japan.*

Background: We have previously reported that ronacaleret, a calcilytic agent, retards renal injury by increasing endogenous klotho expression in remnant kidney model (Am J Physiol Renal Physiol. 2015;309:F216-26). Recent studies have demonstrated that FGF23 transduces its signal using klotho as co-receptor to increase renal abundance of Egr-1 and phosphorylated ERK, both of which may control the expression of bone morphogenetic protein (BMP) 7.

Methods: In the present study, the effects of exogenous klotho protein supplementation on renal injury was compared between two groups of rats (n=6 for each group); 5/6-nephrectomized Wister rats (Nx), those treated with klotho (20 μg/kg/day) (Nx+K). Three months later, rats were killed with over-anesthesia, and harvested remnant kidney for analysis.

Results: Albuminuria was lower in Nx+K (42±6 mg/day) than Nx group (132±14 mg/day, $p<0.05$). Glomerular filtration rate and serum calcium were similar between 2 groups. However, fractional phosphate excretion was increased in Nx+K group (13±2 %) than Nx group (7±1 %, $p<0.05$). Serum phosphate (8.1±0.3 mg/dl (Nx+K) vs 9.8±0.3 mg/dl (Nx), $p<0.05$).and FGF23 (361±17 pg/ml (Nx+K) vs 480±31 pg/ml (Nx), $p<0.05$) were reduced in Nx+K group. RT-PCR analysis revealed that compared to Nx ($p<0.05$), renal expressions of klotho (1.8 fold) and BMP7 (1.7 fold) were elevated in Nx+K group. In contrast, renal expression of TGF-β in Nx+K group (2.1±0.2) was lower than Nx group (3.2±0.3, $p<0.05$). Western blot analyses showed that renal abundance of Egr-1 and phosphorylated ERK in Nx+K group was higher than Nx group. Pathological examination revealed that fibrosis index in Nx+K group was smaller than Nx group, and that endogenous klotho and BMP7 were co-localized in both renal tubular and interstitial cells.

Conclusions: The present data indicate that klotho supplementation reduced albuminuria, serum phosphate and FGF23 in 5/6-nephroctomized rats. Our findings demonstrate that exogenous klotho supplementation prevented the declines in endogenous klotho expression to recover normal FGF23-klotho signaling that facilitates phosphate excretion. Finally, the current results provide the evidence that klotho protein, which inhibits renal fibrosis, counteracts against TGF-β in itself as well as induces BMP7 expression by elevating the abundance of Egr-1 and phosphorylated ERK. in remnant kidney.

SA-PO767

NAD$^+$ Metabolite, 2-Py Has a Potent Anti-Fibrotic and Anti-Inflammatory Activity in the Mouse Unilaterally Ureter-Obstructed Kidney

Norito Yoshimura,[1] Katsutoshi Yamada,[1] Takashi Ono,[1] Mitsuru Notoya,[1] Shingo Sakamoto,[2] Hideo Yukioka,[1] Rina Takahashi,[3] Takeshi Kanda,[3] Shu Wakino,[3] Hiroshi Itoh.[3] *[1]Shionogi & Co., Ltd., Osaka, Japan; [2]Shionogi TechnoAdvance Research Co., Ltd., Osaka, Japan; [3]Keio University, School of Medicine, Tokyo, Japan.*

Background: Renal fibrosis is a common pathogenic feature in chronic kidney diseases. Several studies have suggested NAD$^+$ metabolism may be disturbed in the kidney diseases, and we have found that the plasma levels of NAD$^+$ metabolites, N-methyl-2-pyridone-5-carboxamide (2-Py) and 4-Py were markedly increased in the unilateral ureter obstruction (UUO) mice and CKD patients. However, the effect of NAD$^+$ metabolites on renal fibrosis has not been fully elucidated.

Methods: Effects of 2-Py, 4-Py, and NNO (nicotinamide N-oxide) on TGFβ1 (5 ng/mL)-induced fibrosis-related genes (Col1a1, Col3a1, Col4a1, Acta2) and inflammatory gene (IL-6) were evaluated in rat fibroblast cells (NRK49F) and human tubular cells (HK-2). In vivo study was performed by administering 2-Py (300 mg/kg, bid, plus 5 or 10 mg/mL in the drinking water) to the UUO mice. Body weight and food intake were monitored during this study. At day 7, plasma parameters, gene expression, hydroxyproline content in the kidney were analyzed. Fibrotic area was evaluated using Masson's trichrome stained sections.

Results: In NRK49F, 2-Py strongly attenuated TGFβ1-induced Col3a1 expression (IC_{50} 750 μM), and 4-Py showed weak but significant reduction. NNO had no effect. In HK-2, 2-Py prevented TGFβ1-induced Col1a1 expression. 2-Py inhibited TGFβ1-mediated IL-6 gene induction in NRK49F and HK-2. In the UUO mice study, food intake and body weight were not affected by 2-Py treatment, and abnormal behaviors were not observed. At day 7 after UUO treatment, gene expressions of Col1a1, Col3a1, Acta2, IL-6 and TNFα in the kidney were significantly attenuated, and hydroxyproline content and histological fibrotic in the kidney area were significantly lower in the 2-Py-treated group as compared to those in UUO mice with vehicle treatment.

Conclusions: We provide a novel evidence that NAD$^+$ metabolite, 2-Py ameliorates renal fibrosis and inflammatory response in renal tubular and fibroblast cells as well as in UUO mice.

SA-PO768

The Bidirectional Relationship Between CKD and Sleep Disordered Breathing

Saima Mansuri, Fernando Figueroa rodriguez. *Beaumont Health, Troy, MI.*

Background: The prevalence of Sleep Disordered Breathing (SDB) is higher in Chronic kidney disease (CKD) patients compared to the general population. The relationship between these two diseases is complex and bidirectional. SDB is linked to increased risk of hypertension, atherosclerosis and systemic inflammation which can accelerate the deterioration of renal function. On the other hand, CKD is associated with volume overload, metabolic abnormalities and hypertension contributing to the pathogenesis of SDB. Recognizing the association between them can lead to early treatment, better clinical outcomes and higher quality of life.

Methods: A retrospective study included 385 Beaumont Health System patients from 01/01/2012 to 12/31/2017 with diagnosis of both CKD and SDB. The objective was to observe the association of SDB across the CKD stages and proteinuria and to assess the relationship with sleep parameters identifying common predictors associated with these two conditions. SDB was confirmed by polysomnography. CKD diagnosis was based on Glomerular Filtration Rate (GFR) and urine albumin creatinine ratio (UACR).

Results: In patients with both SDB and CKD, there was an association between Apnea Hypopnea Index (AHI) and GFR (p=0.08) but not with UACR (p=0.59). 70 % of the patients with stage G2 & G3 CKD had moderate to severe AHI. The median decline in GFR was 5.5 ml/min/1.73 m2 per year and 12% had accelerated decline in GFR. There was a strong association between Nocturnal Hypoxia (NH) and AHI (p<0.0001) in CKD patients but none with GFR (p=0.60) or UACR (p=0.52). Patients on Renin Angiotensin System (RAAS) inhibitors and on Non-Steroidal Anti-inflammatory (NSAIDs) showed trend towards less severe AHI (p=0.03) and (p=0.06) respectively; those with systolic heart failure (HF) trended towards worse UACR values (p=0.02). There was no evidence that body mass index, gender, antidepressant or narcotic use is related to AHI severity or NH in CKD patients.

Conclusions: Overall, the severity of SDB tended to get worse with advanced CKD and vice versa: patients on RAAS inhibitors and NSAIDs showed less severe AHI, supporting the role of systemic inflammation and hypertension in the pathogenesis of SDB. It was also noted that patients with nocturnal hypoxia tended to have worse AHI and those with systolic HF had higher levels of proteinuria.

Phenotype or Environment: Mechanisms of CKD Skeletal Muscle Wasting

Tom O'Sullivan, Luke A. Baker, Alice C. Smith, Emma L. Watson. Leicester Kidney Lifestyle Team *University of Leicester, Leicester General Hospital, United Kingdom.*

Background: Despite its prevalence and impact, mechanisms of skeletal muscle wasting in non-dialysis dependent chronic kidney disease (NDD-CKD) are unclear. The current investigation used human primary skeletal muscle cells (HDMCs) to investigate the effect of CKD derived serum on HDMC proliferation and differentiation *in-vitro*.

Methods: Biopsies were taken from the vastus lateralis of NDD-CKD (n=3, 45.3yrs, eGFR 16ml.min.1.73m^2) and healthy controls (HC, n=3, 48.3yrs, eGFR>90 ml.min.1.73m^2). Isolated HDMCs were cultured for 4 days in medium supplemented with foetal bovine serum (FBS, 20%), HC (sHC) or CKD (sCKD) derived serum (10%). Proliferation was assessed using AlamarBlue™ assay. To assess differentiation, cells were grown to confluence in FBS, followed by 7 days in either 2% horse serum (HS), sHC or sCKD and myotube morphology was analysed.

Results: Proliferation increased significantly from baseline in all conditions in HC and CKD. There was a significant effect of sera in HC, with greater proliferation in sCKD from D2 compared to FBS and D3 compared to sHC (Fig.1a). There was no effect of sera on CKD proliferation (Fig.1b). Fusion index (Fig.1c) and myotube diameter (Fig.1e) was generally higher in CKD, but only significantly in sHC and HS, respectively. There was no significant effect of sera on either outcome. There was no effect of donor or sera on desmin index (Fig.1d).

Conclusions: Preliminary findings indicate similar rates of proliferation between HC and CKD. sCKD increased proliferation compared to FBS and sHC in HC but not CKD. There was no effect of sera on measures of differentiation/maturation. Future work will seek to determine what factors increase HDMC proliferation which may inform targets for therapeutic intervention.

Funding: Government Support - Non-U.S.

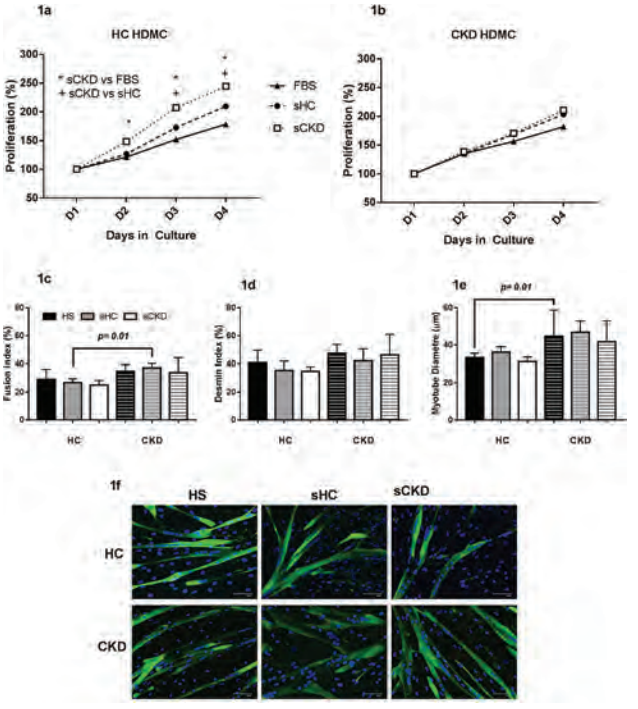

Figure 1. The effect of sCKD on proliferation in HC (a) and CKD (b) and differentiation (c-e).

SA-PO770

Discovery and Validation of Skeletal Muscle MicroRNA Expression in Non-Dialysis CKD

Kate A. Robinson, Luke A. Baker, Matthew P. Graham-Brown, Robert U. Ashford, Emma L. Watson. *University of Leicester, Leicester, United Kingdom.*

Background: Skeletal muscle (SM) wasting is a common complication of chronic kidney disease (CKD), and is significantly associated with an increased risk of morbidity and mortality. The precise mechanisms of SM wasting are not fully defined, but multiple studies have identified a major contribution of aberrant microRNA (miR) expression and regulation. The involvement of miRs has been described in animal models of CKD SM wasting, however there is no evidence for their involvement in human CKD SM wasting. Therefore, we investigated SM miR expression in non-dialysis CKD patients compared to matched healthy controls (HCs).

Methods: Next Generation Sequencing (NGS) was performed on lower limb (LL) SM biopsies collected from 5 CKD patients stage 3b-5 (mean eGFR 22.0 ± 8.1 ml/min/1.73m^2; mean age 59.2 ± 9.4 years) and 5 HCs (mean age 54.7 ± 7.9 years). MiR expression was then validated in LL SM biopsies collected from a further 10 CKD patients stage 3a-5 (mean eGFR 30.8 ± 13.6 ml/min/1.73m^2; mean age 61.6 ± 11.8 years) and 10 HCs (mean eGFR 83.2 ± 4.4 ml/min/1.73m^2; mean age 61.5 ± 13.4 years) by qPCR with let-7f as an internal control. Relative expression was calculated by 2^{-DCT}).

Results: NGS identified differential expression of 15 miRs in SM of CKD patients compared to HCs (fold-change ≥1.5; increased: miR-128, 148a, 182, 21, 22, 29c, 92a; decreased: let-7a, 7e, miR-100, 191, 206, 486, 99a, 99b). Upon validation in a larger sample, miR-148a expression was significantly decreased in CKD patients compared to HCs (p=0.03), and there was a non-significant trend towards decreased miR-191 expression in CKD patients (p=0.061). No further differences were maintained upon validation of the other miRs.

Conclusions: Patients with non-dialysis CKD exhibit altered SM miR expression compared to HCs. However, the miR signature reported here does not reflect those previously reported in animal models of CKD SM wasting. For the first time, we report that miR-148a expression is significantly decreased in SM in CKD. Future work will explore the role of dysregulated miR-148a in CKD SM wasting, thus providing a rational for use as a potential therapeutic target in this population.

SA-PO771

Heparin Infusions Contribute to Cardiovascular Damage in CKD by Promoting Pathologic Effects of FGF-23

Christopher Yanucil, Dominik Kentrup, Isaac D. Campos, Beatrice Richter, Brian A. Czaya, Kylie Heitman, Christian Faul. *University of Alabama, Birmingham, AL.*

Background: Fibroblast growth factor (FGF) 23 is a bone-derived hormone that increases phosphate excretion by targeting the kidney via klotho and FGF receptor (FGFR) 1. Most FGF family members interact with heparin as a co-factor for efficient FGFR activation. Endocrine FGFs, such as FGF23, have reduced heparin binding affinity

and instead require the transmembrane protein klotho as FGFR co-receptor. Patients on hemodialysis (HD) have extremely high serum FGF23 levels and receive high amounts of heparin to prevent blood clotting. We have shown that FGF23 causes cardiac hypertrophy by directly targeting cardiac myocytes via FGFR4 in the absence of klotho, and here we test whether heparin affects this pathologic process.

Methods: We have developed a multi-well assay to measure FGFR binding affinities of FGF23 and test effects of heparin co-incubations. We co-treat cultured cardiac myocytes with FGF23 and heparin and analyze changes in signaling events and in cell area as a readout for hypertrophy. Finally, mimicking a HD-like administration pattern, we inject heparin via the tail vein into two mouse models of FGF23 elevation, i.e. adenine diet-induced kidney failure and repetitive injections of recombinant FGF23.

Results: While purified FGF23 and FGFR4 proteins show only a weak interaction, co-incubation with patient grade heparin increases their binding affinity 10-fold. Heparin increases FGF23-induced signaling and hypertrophic growth of cardiac myocytes. Both mouse models with elevated serum FGF23 levels show increased cardiac hypertrophy when heparin is administered.

Conclusions: We show that heparin can increase the FGFR binding affinity and cellular effects of FGF23. Specifically, heparin aggravates the klotho-independent FGFR4-mediated actions of FGF23 on cardiac myocytes and thereby cardiac injury in mice with systemic FGF23 elevations. Our experiments suggest that in HD patients, administered heparin acts as a biologically active, circulating co-receptor for FGF23 that increases FGF23 affinity for FGFR4 thereby aggravating the pathologic actions of FGF23 on the heart and contributing to the increased cardiovascular mortality.

Novel Truncated ACE2 Fusion Protein with Extended Half-Life Is Delivered to the Kidney and Ameliorates Angiotensin II-Induced Hypertension

Jan Wysocki, Arndt Schulze, Pan Liu, Minghao Ye, Chad R. Haney, Ming Zhao, Daniel Batlle. *Northwestern University, Chicago, IL.*

Background: ACE2 converts angiotensin (Ang)II to the renoprotective peptide, Ang (1-7), thereby providing a mechanism to downregulate the renin-angiotensin system (RAS). Targeting kidney RAS using native ACE2 might not be effective due the large size (~110 kDa) that prevents its glomerular filtration and subsequent tubular uptake.

Methods: To circumvent this limitation, ACE2 truncate (ACE2 1-619) was generated through C-terminal truncation of the native ACE2 and subsequently fused with albumin binding domain (ABD). Enzyme activity of the chimeric protein was confirmed using ACE2-specific substrate Mca-APK-Dnp and its inhibition by MLN-4760 (ACE2-specific inhibitor).

Results: In Western blot the fusion protein appeared as a single band at the apparent molecular weight of ~75 kDa, as expected from its amino acid sequence. In keeping with the goal of our original design, ACE2 1-619ABD exhibited a markedly extended circulatory residence longevity than naked ACE2 1-619 or native ACE2 1-740. The extended in vivo half-life was confirmed in a model of angiotensin II-induced hypertension whereby an increase in SBP was mitigated by the ACE2 1-619ABD for up to 7 days after a single i.p. bolus injection (1 ug/g BW) (Figure). In SPECT/CT imaging, after i.v. injection of ^{Tc99m}-labeled ACE2 1-619ABD, there was a significant retention in kidney cortex (6.3 ±0.5% of whole body (WB) radioactivity) as compared to trace retention generated by the native ^{Tc99m}-ACE2 1-740 (1.2±0.2% WB).

Conclusions: The novel ACE2 truncate fused with ABD is enzymatically active, exhibit an extended in vivo half-life, and is taken up by kidney cortex. These features might be potentially favorable for developing a new approach to target kidney disease with intrarenal RAS overactivity.

Cardio-Renal Protective Effect of the Xanthine Oxidase Inhibitor Febuxostat in the 5/6 Nephrectomy Model with Hyperuricemia

Hiroki Omizo,[1] Yoshifuru Tamura,[3] Osamu Yamazaki,[1] Shunya Uchida,[3] Yoshihide Fujigaki,[2] Shigeru Shibata.[3] *[1]Teikyo University, Tokyo, Japan; [2]Teikyo University School of Medicine, Department of Internal Medicine, Tokyo, Japan; [3]Teikyo University School of Medicine, Tokyo, Japan.*

Background: Previous studies have shown that hyperuricemia can cause cardiovascular dysfunction and chronic kidney disease progression; however, the mechanisms remain unclear. In this study, we addressed the cardio-renal protective effects of xanthine oxidase (XO) inhibition in the rat remnant kidney model with hyperuricemia (RK+HUA).

Methods: Male Sprague-Dawley rats received 5/6 nephrectomy and were fed oxonic acid, the uricase inhibitor, according to the previously described methods (Kang et al., J Am Soc Nephrol 2002; Asakawa et al. Oxid Med Cell Longev 2017). XO inhibitor febuxostat was administered orally via drinking water (30 mg/l). Blood pressure and urinary albumin excretion were monitored during the course of the experiment. At 8 weeks, heart and kidney were removed for the histological evaluation.

Results: Compared with control group, RK+HUA showed significant increase in urinary albumin excretion. However, febuxostat significantly reduced albuminuria in this model, along with the reduction in serum uric acid levels. PAS-stained kidney section revealed that febuxostat attenuated glomerular and tubulointerstitial injury, confirming the renoprotective effects of XO inhibition. There was no significant difference in blood pressure levels between RK+HUA rats and RK+HUA rats that received febuxostat. However, histopathological analysis using HE-stained cardiac sections indicated that left ventricular wall thickness was reduced by febuxostat. Furthermore, quantitative evaluation of myofiber cross-sectional areas in wheat germ agglutinin (WGA)-stained sections revealed that individual myofiber hypertrophy was significantly alleviated. In addition, cardiac fibrosis was also reduced in RK+HUA with febuxostat compared with RK+HUA rats.

Conclusions: XO is involved in the cardiac and renal injury observed in the remnant kidney model with hyperuricemia. These effects can at least in part be mediated through non-hemodynamic mechanisms.

Elevated Left Ventricular Cardiac LIM Protein (CSRP3) in ESRD

Michael Hutchens,[1,2] Susan B. Gurley,[3] Mahaba B. Eiwaz,[3] Tzongshi Lu,[4] Kenneth Lim.[5,6] *[1]Portland VA Medical Center, Portland, OR; [2]Anesthesiology & Perioperative Medicine, Oregon Health & Science University, Portland, OR; [3]Oregon Health and Science University, Portland, OR; [4]Brigham and Women's Hospital, Harvard Medical School, Natick, MA; [5]Massachusetts General Hospital, Boston, MA; [6]Harvard University, Boston, MA.*

Background: Emerging evidence suggest that cardiac cytoskeletal components are involved in the pathogenesis of cardiorenal syndromes. We recently identified the cardiomyocyte transcription factor CSRP3 as an endocrine cardiorenal connector in mice. CSRP3 is a critical component of the cytoskeleton and contractile apparatus in the heart. Mutations of CSRP3 have been detected in patients with cardiomyopathy, however the role of CSRP3 in human cardiorenal disease is unknown.

Methods: We analyzed human Left Ventricular (LV) tissues from donors with end-stage renal disease (ESRD, n=15) compared to hypertensive (HTN, n=11) and healthy controls (n=18) in a 3-arm cross-sectional controlled study using The CAIN (Cardiac Aging in CKD) Cohort. All tissues underwent gross pathologic examination. LV free wall thickness (LVWT) was assessed as an index for left ventricular hypertrophy (LVH). RNASeq, immunoblotting, and qPCR were performed. Confirmatory tissue qPCR studies were performed in a rodent model of advanced nephropathy, Akita(*Ins2c96y*)-ReninTg (Akita-RenTg) mice and controls.

Results: Groups were well-matched and there was no statistical difference in age (ESRD 46.4±10.7; HTN 56.3±4.9; control 49.7±15.7 yrs, p=0.1) or sex (ESRD 60; HTN 64; control 58 % male, p=0.9). HTN patients had slightly higher BMI (HTN 31.5±6.6 vs ESRD 26.2±4. vs. 26.3±5.8 kg/m2, p=0.1). HTN and ESRD patients had significantly greater left ventricular wall thickness normalized to body surface area (p<0.0001). RNASeq of left ventricular tissue revealed that csrp3 is among the top 1000 genes dysregulated by ESRD. Immunoblotting for CSRP3 revealed increased LV CSRP3 in HTN patients (2.2-fold). ESRD patients had even greater levels (4.4-fold, p<0.0001) compared to controls; this was independent of LVH. These results were consistent with advanced nephropathy Akita-RenTg mice; cardiac CSRP3 mRNA was increased relative to controls (~14-fold).

Conclusions: We provide the first translational data demonstrating CSRP3 is greatly elevated in the hearts of humans with ESRD. Data from an experimental model of advanced nephropathy suggest that this cardiorenal crosstalk is conserved. We postulate that upregulation of CSRP3 may function as a stress signal in kidney failure and further studies are critically warranted to elucidate its role.

Myocardiocyte Transcription Factor Cardiac LIM Protein (CSRP3) Mediates Renal Tubular Transcription

Michael Hutchens,[1,2] Mahaba B. Eiwaz,[2] Katsuyuki Matsushita.[3] [1]*Portland VA Medical Center, Portland, OR;* [2]*Anesthesiology & Perioperative Medicine, Oregon Health & Science University, Portland, OR;* [3]*Anesthesiology, Kyushu University Hospital, Kyushu, Japan*.

Background: Cardiac LIM Protein (CSRP3, molecular weight 21 kD), is released from the heart into the systemic circulation after myocardial injury; we recently identified it as an endocrine cardiorenal connector. We hypothesized that modeled release of CSRP3 would alter tubular epithelial cell transcription of renal fibrosis-related genes in vivo and in vitro.

Methods: Cardiac arrest was induced with potassium chloride, and terminated with cardiopulmonary resuscitation (CA/CPR, a model of cardiac injury leading to acute cardiorenal syndrome). CA/CPR or sham procedure was performed in male, 8-12 week old male mice (WT mice). Mice were killed 10h, 24h, 72h, or 7 days later and plasma CSRP3 quantified by ELISA. Recombinant CSRP3 (rCSRP3) was purchased and 1 μg injected intravenously to WT mice. Mice were killed and plasma CSRP3 quantified by ELISA. Curves were fit to model pharmacokinetics. Following injection, mice were perfusion-fixed; the right kidney was snap-frozen and prepared for mRNA measurements and the left paraffin-embedded for immunofluorescence. qPCR for lef1 and tgfb1 mRNA, and CSRP3 immunofluorescence were performed on kidney tissue. Human kidney cells were exposed to 1 μM rCSRP3 or vehicle in translational relevance studies.

Results: CA/CPR resulted greatly increased plasma CSRP3 (max 20.3±3.3 *vs.* 1.4±0.2 in sham, ng/mL, p=0.04) and remained detectable in plasma at 7 days (5.6±1.6 ng/mL). The 7-day area-under the curve (AUC) was 65 ng/mL*day. The $t_{1/2}$ for injected rCSRP3, was 86 minutes, and the AUC for a single 1μg dose was 15 ng/mL*days. Immunofluorescence demonstrated CSRP3 within tubular epithelial cell nuclei following injection. Renal tissue mRNA for transforming growth factor beta (tgfb1) was 1.7-(±0.28-fold) increased 6h after rCSRP3 injection, while lef1 mRNA was not regulated. In human tubular epithelial cells, 16h exposure to 1 μM CSRP3 upregulated lef1 mRNA 1.8±0.15-fold compared to vehicle control (p=0.02).

Conclusions: CSRP3, highly specific to cardiomyocytes, is released into the circulation after cardiac injury, and mediates renal transcription of fibrosis-related genes *in vivo* and *in vitro*. We postulate this cardiomyocyte transcription factor may play a role in AKI-CKD transition following acute cardiac illness such as cardiac arrest or myocardial infarction.

Chronic, Combined Cardiac and Renal Dysfunction Exacerbates Renal Venous Pressure-Induced Suppression of Systemic Blood Pressure and Renal Function in Rats

Shereen M. Hamza,[1] Tayyaba Zehra,[1] William A. Cupples,[2] Branko Braam.[1] [1]*University of Alberta, Edmonton, AB, Canada;* [2]*Simon Fraser University, Burnaby, BC, Canada*.

Background: Coexisting cardiac/renal dysfunction may be perpetuated by increased renal venous pressure (RVP) in this condition. We previously showed that acute RVP elevation depresses renal blood flow (RBF), GFR and induces renal vasoconstriction in the absence of changes in blood pressure in healthy rats. We established a rodent model of combined cardiac/renal dysfunction and tested whether an acute, superimposed RVP elevation would impair cardiovascular stability, baseline renal perfusion and exacerbate renal dysfunction.

Methods: Male rats were subjected to 5/6 renal mass resection (Nx or Sham) and 6% high salt diet to induce renal dysfunction followed 7 weeks later by ligation of the left anterior descending coronary artery (CL or Sham). Four experimental groups were as follows: CL+Nx (n=11); Sham CL+Nx (n=9); CL+ Sham Nx (n=3); Sham Control (n=4). 8 weeks post-recovery, rats were anesthetized and subjected to an acute experiment whereupon mean arterial pressure (MAP), heart rate (HR), RVP, RBF and GFR were measured at baseline and during partial left renal vein occlusion to increase RVP to 20-25 mmHg for 120 min.

Results: Baseline MAP, HR, RBF and renal vascular conductance (RVC) were comparable between all experimental groups. Baseline GFR was significantly depressed in CL+Nx and Sham CL+Nx groups compared to Sham Control and CL+Sham Nx groups. Upon RVP increase, an early, rapid and pronounced reduction in MAP occurred in CL+Nx, Sham CL+Nx and CL+Sham Nx compared to Sham Control (p<0.001); MAP fell to the same extent in all groups at the end of the recording period. HR fell gradually with the increase in RVP in all experimental groups to the same extent. RVP increase exacerbated the reduction in RBF in CL+Nx compared to Sham Control (p<0.001) with intermediate responses in Sham CL+Nx and CL+Sham Nx groups. Similarly, RVP increase virtually eliminated GFR in CL+Nx (-99%), Sham CL+Nx (-95%) and CL+Sham Nx (-100%) groups compared to Sham Control (-82% from baseline; p<0.001). Renal vascular conductance dropped significantly but comparably upon RVP increase in all experimental groups.

Conclusions: Combined cardiac/renal dysfunction impairs cardiovascular stability in response to elevated RVP; MAP instability impairs the ability to maintain RBF and GFR considering preserved intrarenal responses.

SA-PO777

Pericyte-Specific Manipulation of Hypoxia-Inducible Factors Regulates Erythropoiesis Without Aggravating Renal Fibrosis

Szu-Yu Pan,[1,2] Pei-Zhen Tsai,[3] Tzong-Shinn Chu,[2] Shuei-Liong Lin.[2,3] [1]*Far Eastern Memorial Hospital, New Taipei City, Taiwan;* [2]*National Taiwan University Hospital, Taipei, Taiwan;* [3]*National Taiwan University College of Medicine, Taipei, Taiwan*.

Background: Stabilizers of hypoxia-inducible factor (HIF) have been shown to be effective on treatment of anemia in patients with chronic kidney disease (CKD). Increased erythropoietin (EPO) production and enhanced erythropoiesis are known to be the major mechanisms responsible for the treatment effects. However, the effect of HIF stabilization on renal fibrosis is controversial. We created animal models characterized by CKD and pericyte-specific or non-selective stabilization of HIF to examine the effects of HIF on renal fibrosis and erythropoiesis.

Methods: *Gli1*$^{CreERT2/+}$*;Egln1*$^{F/F}$, *Gli1*$^{CreERT2/+}$*;Vhl*$^{F/F}$, and *Gli1*$^{CreERT2/+}$*;Hif1a*$^{F/F}$*;Hif2a*$^{F/F}$ mice were generated to study the effects of pericyte-specific overexpression or knockout of *Hif*. *Tg(UBC-CreERT2);Egln1*$^{F/F}$, *Tg(UBC-CreERT2);Vhl*$^{F/F}$, and *Tg(UBC-CreERT2);Vhl*$^{F/F}$*;Hif1a*$^{F/F}$*;Hif2a*$^{F/F}$ mice were generated to study the effects of non-selective stabilization of HIF. Unilateral ureteral obstruction (UUO) was used to induce CKD. The severity of fibrosis was determined by Picrosirius red stain and *Col1a1* mRNA level in the kidney.

Results: Pericyte-specific stabilization of HIF resulted in increased serum EPO level, augmented splenic erythropoiesis, and polycythemia, while the severity of renal fibrosis was not affected. In line with these findings, pericyte-specific knockout of *Hif1a* or *Hif2a* did not result in significant change of renal fibrosis. We further examined the role of HIF stabilization in mice with postnatal global stabilization of HIF. Surprisingly, unexpected mortality developed along with dramatically increased serum EPO levels in a HIF-dependent manner.

Conclusions: Our study endorses the neutral effects of pericyte-specific HIF stabilization on renal fibrosis. However, the possible risks of artificially increased serum EPO level warrant further study.

The Effect of Increased Blood MicroRNA on Apoptosis in Cardiac Cells and Cardiac Complications in CKD

Kyoung Hye Kong,[1,2] Hyung Jung Oh,[3] Dong-Ryeol Ryu.[4] [1]*Ewha Women's University, Yangcheon-gu, Seoul, Republic of Korea;* [2]*Nephology, Ewha Medical Research, Seoul, Republic of Korea;* [3]*Ewah Womans' University, Mokdong Hospital, Seoul, Republic of Korea;* [4]*Ewha Womans University, Seoul Hospital, Seoul, Republic of Korea*.

Background: Increased cardiovascular morbidity and mortality is the conundrum in chronic kidney disease (CKD). Although hemodynamic change has been blamed for the extremely high incidence of cardiovascular disease in CKD, the retention of uremic toxins might be directly associated with it, including decreased heart function and induction of serious arrhythmia. This study aimed to investigate the association between the cardiac fibrosis and uremic toxin in CKD. Furthermore, we will try to investigate the role of the alteration of blood microRNA (miRNA) levels like other uremic toxin on cardiac fibrosis.

Methods: We induced CKD in rats by 5/6-STNx. We investigated the changes in the renal function and the levels of blood miRNA by affymetrix miRNA array. Renal and cardiac fibrosis was evaluated by Masson's trichrome(MT) staining. We also isolated sinus nodal cells from cardiac atria of C57BL/6 mice, and treated a representative protein-bound uremic toxin, indoxyl sulfate (IS) and probenecid into the cells for 48 h, and evaluated the changes in the expression of fibrosis-related molecules.

Results: Serum creatinine(Cr) and blood urea nitrogen(BUN) were significantly higher in the 5/6-STNx than controls, while echocardiography were lower in the 5/6-STNx. The miRNA profiles of blood serum of 5/6-STNx were significantly different compared to controls. We focus on the significant decrease in the level of miRNA let-7 family for now. Additionally, MTstaining for the assessment of fibrosis showed the increased fibrosis in the heart and kidney of 5/6-STNx compared with controls. In vitro, protein expressions of fibronectin, phospho-p38 MAP kinase and Bax/bcl2 ratio after IS stimulation were significantly higher at 48 h, which was blocked by organic anion transporter inhibitor, probenecid.

Conclusions: These findings suggested that there was a direct effect of uremic toxin on the induction of fibrosis by MAPK activation in sinus nodal cells. The relationship between miRNA and cardiac fibrosis would be investigated down the road.

SA-PO779

Insignificant Renal Artery Stenosis Is Associated with a Decrease in Renal Perfusion and Function

Arkadiusz Lubas, Stanislaw Niemczyk. *Military Institute of Medicine, Warsaw, Poland*.

Background: Renal artery stenosis (RAS) exceeding 50% of vascular diameter is known as hemodynamically significant and can result in hypertension and deterioration of renal function, thus can require an invasive treatment. On the other hand, RAS < 50% of the diameter is thought to be safe. The study aimed to investigate whether renal artery narrowing < 50% of the diameter could influence renal perfusion and function.

Methods: Twenty-seven kidneys evaluated in an enhanced by contrast multidetector computed tomography (CE-MDCT; GE Discovery 750 HD) in 17 patients (6F, 11M; age 62.5 ±19.7 y) with hypertension and RAS 0-49% of the diameter were included to the study. Renal Parenchymal Perfusion (RPP), and renal function (eGFR) were evaluated.

Results: Mean eGFR was 52.4 ±26.1 mL/min/1.73m^2, and RPP 222.7 ±78.7 mL/s/100g. In twelve stenotic kidneys mean RAS was 30.0 ±8.8% of the diameter. Fifteen renal arteries were normal. The severity of RAS correlated significantly ($p<0.05$) with RPP ($r= -0.39$) and eGFR ($r= - 0,41$). In non-stenotic kidneys RPP and eGFR were significantly higher than in those having RAS (256.4 ±82.5 vs 189.5 ±49.9 mL/s/100g; $p=0.010$ and 62 ±27 vs 43 ±21 mL/min/1.73 m2; $p=0.045$, respectively).

Conclusions: Even mild renal artery stenosis can contribute to the decrease in renal perfusion and renal function. Due to the negative correlation of mild RAS with renal perfusion, the definition of significant RAS should be revised.

Patient Engagement in Knowledge Translation: A Collaborative Model for Moving Kidney Health Research into Practice

Mary Beaucage,[1] Selina Allu,[1] Meghan J. Elliott.[2] Can-SOLVE CKD Network *[1]Can-SOLVE CKD Network, Vancouver, BC, Canada; [2]University of Calgary, Calgary, AB, Canada*.

Background: Effective knowledge translation is the process of moving research evidence into clinical practice. Can-SOLVE CKD is a pan-Canadian patient-oriented kidney research network with an established Knowledge User (KU) and Translation (KT) Committee that includes two patient partners. This committee provides guidance, expertise, and direction for all KT activities undertaken by research projects within the network and ensures KT approaches are patient-centered. This research defines key concepts related to KT, outlines the role of the KU/KT Committee in supporting kidney health research, and highlights the contributions of patient partners on this committee.

Methods: The KU/KT Committee provides core infrastructure support for 18 research projects within the Can-SOLVE CKD Network. Membership includes national representation of patients living with kidney disease, policymakers, health care professionals and researchers with KT expertise. In alignment with our strategic framework, we co-developed two KT reporting templates for research teams to complete, reviewed project KT plans, and discussed our KT assessments among the committee. The committee also provides ongoing support for stakeholder engagement and helps projects tailor their KT strategies for communicating, implementing and sustaining their findings in practice.

Results: As the main stakeholders in health research, there are opportunities for patients to participate in KT. Two patient partners act as full KU/KT committee members and maintain links with the Network's Patient Council and Indigenous Peoples' Engagement & Research Council (IPERC). Although all committee members share the responsibility of assessing project KT plans and identifying relevant KT strategies, the patient partners are uniquely positioned to understand real-world implications of the research findings. Continued acknowledgment of the patient voice in KT will help encourage ongoing relevant research, novel approaches to KT, and the translation of evidence into practice.

Conclusions: Our multi-stakeholder KU/KT Committee promotes patient-oriented research supporting the translation of kidney health research into practice. Patients can identify unique KT considerations, provide meaningful feedback to research teams, and encourage the generation and application of relevant research evidence.

Sleep Deprivation Induces Metabolic Reprogramming in Kidney

Xiaoming Mao, Lei Jiang, Jing Luo, Junwei Yang. *Nanjing Medical University, Nanjing, China*.

Background: Sleep is critical to human being. Sleep deficiency, or sleep deprivation, is an increasingly important global issue of human health, and has been linked to obesity, diabetes, and cardiovascular disease. Many findings published has addressed the interaction between sleep and metabolism, and metabolic health relies strongly on sleep. Sleep deprivation is known to promote the development of chronic kidney disease. Individuals with shorter time of sleep were more likely to have proteinuria, and faster decline of glomerular filtration rate, yet little is known about the mechanism by which sleep deprivation deteriorate renal function.

Methods: Wild-type male C57BL/6J mice were housed in a 12:12 hr light/dark cycle (light on 8:00 A.M. to 8:00 P.M) at a constant temperature (22±1°C) with free access to food and water. For sleep deprivation, mice were placed in a chamber with a sweep bar moving along the bottom of the cage every 1 min for 20 hours (ZT0-8, ZT12-24) and shut-off for 4 hours. Control mice received no disruption during sleep were living with stationary sweep bars. Mice were sacrificed after the procedure of sleep deprivation lasts for 4 weeks at ZT0 and ZT12.

Results: Though body weight and food/water intake did not differ from SD group to control group, biochemical analysis revealed statistical differences in serum albumin, AST, SOD, STB, phosphorus ($p<0.05$) between SD mice and control. Oil Red O staining indicated larger lipid droplets in SD kidney. No difference in urinary albumin excretion was observed between the two groups, while a tendency towards higher urine albumin-creatinine ratio was seen in SD group. Transcription analysis identified altered gene expression most significantly involved in lipid metabolism and biosynthesis, insulin signaling pathway, and circadian rhythm. Protein expression confirmed by Western blot (CPT1α, ACADL, FASN, ADFP, CD36, PDK4, PDH) indicated depressed fatty acid oxidation, increased lipid accumulation and glycolysis.

Conclusions: Sufficient sleep is associated with kidney metabolic homeostasis. More lipid utilization might be occurred in kidney during sleep than waking state. Metabolism disorder caused by chronic sleep deprivation may be concerned in the progression renal function decline or proteinuria.

SA-PO782

Apabetalone Downregulates Alkaline Phosphatase and Improves Cardiovascular Risk

Dean Gilham,[1] Laura Tsujikawa,[1] Sylwia Wasiak,[1] Christopher Halliday,[1] Li Fu,[1] Chris Sarsons,[1] Phoebe S. Ho,[1] Stephanie Stotz,[1] Brooke D. Rakai,[1] Kenneth E. Lebioda,[1] Ravi Jahagirdar,[1] Michael Sweeney,[3] Jan O. Johansson,[1] Norman C. Wong,[1] Kamyar Kalantar-Zadeh,[2] Mathias Haarhaus,[4] Ewelina Kulikowski.[1] *[1]Resverlogix, Calgary, AB, Canada; [2]University of California Irvine, School of Medicine, Orange, CA; [3]Resverlogix, San Francisco, CA; [4]Karolinska University Hospital, Stockholm, Sweden*.

Background: Apabetalone is an inhibitor of BET proteins - epigenetic readers modulating gene expression. In phase 2 trials, apabetalone reduced major adverse cardiac events (MACE) in patients with cardiovascular disease (CVD) & improved eGFR in those with chronic kidney disease (CKD). Elevated serum alkaline phosphatase (ALP) is a risk factor for MACE, as it contributes to vascular calcification & endothelial dysfunction. We examined apabetalone-mediated effects on ALP in CVD patients post-hoc & determined apabetalone's impact on tissue non-specific ALP (TNAP) expression in cell culture systems.

Methods: Circulating ALP was measured in CVD patients receiving apabetalone in the 3-month (ASSERT) and 6-month (SUSTAIN & ASSURE) trials. Apabetalone's effect on expression of TNAP (gene symbol *ALPL*) was determined in cultured primary human hepatocytes (PHH), HepaRG, HepG2, calcifying vascular smooth muscle cells (VSMCs) & vascular endothelial cells. Protein abundance & ALP enzyme activity were also measured.

Results: In phase 2 trials, baseline serum ALP correlated with MACE ($R^2=0.87$). In ASSERT, apabetalone dose dependently reduced serum ALP ($p<0.001$ vs placebo). In ASSURE & SUSTAIN, patients on apabetalone (n=331) had greater reduction in serum ALP than placebo (n=166; median % change -3.2 vs -11; $p<0.001$), including those with CKD, i.e. eGFR<60 (apabetalone n=35 placebo n=13 median % change -6.3 vs -14; $p<0.02$). In vitro, apabetalone suppressed *ALPL* expression in PHH, HepaRG & HepG2 cells by 60-80%. Trans-differentiation of VSMCs to calcifying cells resulted in 2.5-fold increase in *ALPL* gene expression. Apabetalone countered calcium deposition & suppressed *ALPL*/TNAP gene expression, protein levels & enzyme activity. Apabetalone also downregulated *ALPL* in aortic endothelial cells, umbilical vein endothelial cells & brain microvascular endothelial cells 50-70%.

Conclusions: In phase 2 trials, apabetalone lowered serum ALP. Mechanistically, apabetalone downregulates *ALPL*/TNAP expression in multiple cell types, which may contribute to reductions in MACE observed in patients. The impact of apabetalone on biomarkers, renal function & CVD outcomes is being evaluated in the phase 3 BETonMACE trial.

Funding: Commercial Support - Resverlogix

SA-PO783

Short Time of Resistance Training Attenuates the Renal AKT Pathway; Improves Physical Capacity, Renal Function, and Glomerulosclerosis; and Decreases Mortality Rate in Rats with CKD

Rafael Luiz,[2] Alexandre Saud,[2] Maria A. Gloria,[2] Rodolfo R. Rampaso,[2] Daniela M. Chiloff,[3] Beatriz P. Martinez,[4] Giovanna M. Zavadzki,[2] Marina L. Ramires,[5] Miguel Angelo Goes.[1] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]UNIFESP, São Paulo, Brazil; [3]Escola Paulista de Medicina - UNIFESP, São Paulo, Brazil; [4]Centro Universitário das Américas, São Paulo, Brazil; [5]FICSAE, Sao Paulo, Brazil*.

Background: The aim of this study was to evaluate if 4 weeks of resistance training (RT) attenuates renal AKT Pathway, improves physical capacity (strength gain and VO_2 peak), renal function, glomerulosclerosis and mortality in rats with chronic kidney disease (CKD) by nephrectomy 5/6 (Nx5/6).

Methods: Adult Wistar rats were divided in four groups (n=8): Sedentary (S) Exercise (E), Nx 5/6 + Sedentary (NS), Nx 5/6 + Exercise (NE). We evaluated (by multiplex) renal AKT Pathway (IGF1R, TSC2, AKT, Mtor and PS706SK), creatinine clearance (CrCl), proteinuria (uProt), blood urea nitrogen (BUN), glomerulosclerosis, mean arterial pressure (MAP) as well mortality rate. Exercise periods were as follows: 6 to 12 climbs/day, 5 days a week, during 4 weeks, 40 to 60% of maximal load test (MLT). The physical capacity was performed with maximal load test (MLT), ergoespirometry test (Vo_2 peak) and maximal exercise test (MEtest).

Results: The Renal AKT Pathway was increased in NS vs all group in all protein analyzed (IGF1R, TSC2, AKT, Mtor and PS706SK), CrCl was improve in NE (43%) vs NS group, ($p<0.05$). Proteinuria was different in NS and NE vs S and E groups but not in NS vs NE. BUN was higher in NS and NE vs S and E. Glomerulosclerosis was different in NS vs NE ($p<0.05$). The MAP was lower in NE vs NS group ($p<0.05$). Physical Capacity (MLT, VO_2 peak and Mtest) was increased in NE vs NS. A higher mortality rate was observed in NS (30%). Results suggested that the 4 weeks of RT minimize the impact of 5/6Nx IN renal AKT pathway by increase in physical capacity (MLT, VO_2 peak and Mtest), reduce the impact on CrCl (43%) and improve in glomerulosclerosis (44%).

Conclusions: These parameters indicate that exercise could have a protective effect, especially under this experimental protocol. Thus, this study suggests that the exercise plays a preventive role in mortality and could be an additional strategy to be employed in CKD.

SA-PO784

CKD Is Associated with a Pro-Angiogenic and Inflammatory Profile Even in Post-Transplant CKD

Diana I. Jalal,[1] Brandon Renner,[2] Patrick Ten eyck,[1] Jennifer Laskowski,[3] James E. Cooper,[4] Mingyao Sun,[1] Massimo Attanasio,[1] Joshua M. Thurman.[3] *[1]University of Iowa, Iowa City, IA; [2]University of Colorado Denver Med Campus, Aurora, CO; [3]University of Colorado School of Medicine, Greenwood Village, CO; [4]University of Colorado at Denver, Denver, CO.*

Background: Cardiovascular disease (CVD) is the most common cause of death in native and post-transplant chronic kidney disease (CKD). Circulating microparticles (MP) are increased in CKD and may reflect vascular injury and inflammation, important non-traditional risk factors for CVD. Here, we sought to identify novel biomarkers of vascular injury and inflammation common in both native and post-transplant CKD.

Methods: Proteomic analyses were conducted on plasma and MP of 9 healthy controls, 9 stage 3/4 native CKD patients, and 9 stage 3/4 post-transplant CKD patients. Somalogic SOMAscan assay, a highly sensitive assay that uses aptamers to quantify >1,300 proteins, was used. Ingenuity pathway analyses (IPA) were conducted.

Results: We identified 44 plasma proteins common to both native and post-transplant CKD vs healthy controls; the most significant being angiogenic proteins. IPA indicated Ephrin receptor signaling, serine biosynthesis, and transforming growth factor (TGF)-β as the top pathways activated in both CKD groups. The MP analyses indicated higher levels of 18 proteins common in both native and post-transplant CKD patients vs healthy controls. These proteins included cystatin C, β2-microglobulin, and renin precursor protein. Biomarkers of inflammation and fibrosis were most pronounced with IPA indicating acute phase response, insulin-like growth factor-1, tumor necrosis factor-α, and interleukin-6 signaling activation.

Conclusions: We have identified new putative pathways of vascular injury and inflammation in CKD. Pathways of angiogenesis and inflammation were significantly activated in CKD patients' plasma and MPs, respectively. Considering the high levels of MP renin precursor protein, the MPs most likely originated in the kidney. The activated pathways common in both native and post-transplant CKD suggest similar mechanisms of CVD in both groups of CKD.

Myokine SIRPα Causes Insulin Resistance Promoting Organ Cross-Talk in CKD

Maryam K. Saeed,[1] Jiao Wu,[1] William E. Mitch,[1] Sandhya S. Thomas.[1,2] *[1]Nephrology, Baylor College of Medicine, Houst, TX; [2]Nephrology, Michael E. Debakey VAMC, Houston, TX.*

Background: Signal regulatory protein alpha (SIRPα), a substrate for tyrosine phosphatases, promotes insulin resistance. SIRPα regulation in skeletal muscle and systemic responses to distant organs is largely unknown. Here we examine the influences of circulating SIRPα induced by chronic kidney disease (CKD) or hyperglycemia on disturbing insulin signaling pathways related to metabolism.

Methods: CKD was induced in muscle-specific and fat-specific SIRPα KO mice and compared to control mice and serum levels of SIRPα were evaluated. Next, acute hyperglycemia was induced in control and organ-specific SIRPα KO mice and serum levels of SIRPα were evaluated. Next, exogenous administration of recombinant SIRPα was utilized to treat control mice and skeletal muscle insulin signaling was determined. Finally, serum samples were obtained from CKD patients prior to peritoneal dialysis catheter placement and healthy control samples were obtained from blood donors.

Results: In control mice with CKD serum SIRPα levels were increased, while in muscle-specific SIRPα KO mice with CKD, we uncovered that serum SIRPα levels ($p<0.05$) were suppressed and associated with improved insulin signaling both in skeletal muscles and adipose tissue. However, in adipose-specific SIRPα KO mice with CKD, levels of serum SIRPα were increased over 2-fold ($p<0.05$) while muscle losses were minimally inhibited. Additionally, when acute hyperglycemia was induced in control mice and and organ-specific SIRPα KO mice, serum SIRPα levels were significantly increased in response to hyperglycemia in control and adipose-specific SIRPα KO, but not muscle-specific SIRPα KO mice. Next, recombinant SIRPα was injected into mice and skeletal muscle insulin signaling was significantly impaired by exogenous administration. Finally, SIRPα signaling is clinically relevant as suggested by our findings that include increased serum SIRPα expression in the serum of patients with CKD (2.4-fold, $p=0.000017$ vs. Healthy Controls).

Conclusions: SIRPα plays an important role as an anti-insulin myokine regulating insulin-mediated pathways. In muscle-specific KO mice with CKD, changes in serum SIRPα levels improve insulin signaling in muscle and adipose tissue, suggesting organ crosstalk. Therefore, targeting SIRPα may prevent metabolic dysregulation and insulin resistance in patients with CKD.

Nephrogenic Systemic Fibrosis (NSF) Is Induced in High-Phosphate-Diet CKD Rats Exposed to Gadolinium Gd^{3+}-Binding Contrast Agents: Role of Bone ASARM Peptides

Peter S. Rowe, Timothy A. Fields, Aditi Gupta, Ellen T. McCarthy. *University of Kansas Medical Center, Kansas City, KS.*

Background: High contrast Magnetic Resonance Imaging (MRI) requires the use of Gadolinium Binding Contrast Agents (GBCAs). Subsets of chronic kidney disease (CKD) patients exposed to GBCAs develop Nephrogenic Systemic Fibrosis (NSF), a progressive disease that leads to acute morbidity and death. Our previous work showed circulating ASARM-peptides bind to GBCAs and induce release of toxic Gd^{3+}. Bone-derived ASARM peptides induce hypophosphatemia and bone-mineralization abnormalities. We hypothesize increased levels of acidic ASARM-peptide exacerbates release of free Gd^{3+} resulting in an NSF pathology with reduced ectopic mineralization defects.

Methods: To test our hypothesis, we used a rat 5/6 Nephrectomy CKD disease model (NEPHREX). Male rats (16 wk, 250 gm) were fed a high phosphate diet (2% P, 200IU Vit D and 0.8% Ca; TEKLAD 170496). ASARM peptide was infused continuously for 4 weeks using subcutaneous implantation of osmotic pumps. As controls, co-implanted osmotic pumps were used to co-infuse SPR4 peptide - a peptide that neutralizes ASARM. Sera collections were taken at the beginning and end of the study. Three consecutive, daily bolus injections of Gd^{3+}-containing contrast agent (Omniscan™, gadodiamide) were given 3 days after pump implantation through surgically implanted jugular-vascular-catheters.

Results: NEPHREX rats treated with Omniscan™ and ASARM developed severe skin pathology, behavioral abnormalities, and joint abnormalities that were consistent with NSF. Computed tomography (CT) showed renal, brain, heart dermal metastatic calcifications and bone defects in Omniscan™ treated Rats. ASARM peptide treatment corrected the Omniscan™ induced skin, bone and soft tissue mineral abnormalities and corrected the hyperphosphatemia.

Conclusions: Our study shows CKD rats fed a high phosphate diet and treated with Omniscan™ develop severe NSF like pathology. ASARM infusion prevents Omniscan™ induced subdermal calcification, corrects mineral defects and hyperphosphatemia. In conclusion, ASARM peptides induce release of free Gd^{3+} from GBCAs but reduce mineralization pathology. These findings have clinical importance for GBCA use in inherited or acquired renal bone-mineral loss disorders with increased circulating ASARM-peptides.

Uremia Modulates the Action of Simvastatin on the ABCA1 (ATP-Binding Cassette Transporter-1) in Endothelial Cells

Silmara F. De melo,[2] Renata Nakamichi,[2] Maria Dalboni,[2,3] Beata M. Quinto,[2] Marcelo C. Batista.[2,1] UNIFESP *[1]Hospital Israelita Albert Einstein, São Paulo, Brazil; [2]Universidade Federal de São Paulo, São Paulo, Brazil; [3]Universidade Nove de Julho, São Paulo, Brazil.*

Background: Ligands of the retinoid X receptor (RXR) and liver X receptor (LXR) activate ABCA1 in endothelial cells at levels of both promoter activation and mRNA induction. ABCA-1 has a broad specificity in cholesterol efflux in endothelial cell and is highly modulated by statins. Chronic kidney disease (CKD) drives an epidemic cardiovascular burden due to neurohumoral dysfunction related with uremic state. We investigated the role of sinvastatin on ABCA1 modulation by LXR-β/RXR-α pathway in HUVEC cells exposed to uremic serum of patients under regular hemodialysis.

Methods: Previously characterized HUVEC cells were pre-treated with statin and stimulated with uremic serum for the same period. TNF-α and IL-10 levels were measured in cell supernatant. The expression of ABCA-1, LXR-β and RXR-α was analyzed by real-time PCR. Transfection of HUVEC cells was performed for analysis of ABCA-1 and promoter activation mediated by LxR-β and RxR-α, evaluation was carried out by flow cytometry and Western blot.

Results: In HUVEC cells, uremic state reduced the expression of LXR-β and RXR-α receptors without changing ABCA-1 expression. Simvastatin reversed the decrease of LXR-β and RXR-α expression observed in HUVEC cells incubated with uremic serum leading to a significant increase in ABCA-1 expression. The 3-HMCoA reductase inhibitor

reversed the TNF-α increased secretion observed under uremic state without modifying IL-10. Sinvastatin-treated cells had a significant increase in transcription activation of LxR-β/RxR-α inducing ABCA-1 expression gene. Uremic state promoted a significant reduction in ABCA-1 transcription activation which was reversed by simvastatin.

Conclusions: We demonstrated that sinvastatin reduced inflammatory response of HUVEC cells exposed to uraemia by decreasing TNF-α secretion. We sugest that attenuation of inflammation observed by the 3-HMCoA reductase inhibitor is promoted through LxR-β/RxR-α pathway activation and consequent upregulation of ABCA-1 expression. Our study provides a potential role of statins on endothelial protection in CKD patients.

Collaborative Peer-Review Model: Patient Partners as Equal and Contributing Voices in Patient-Oriented Research

David Hillier,[1] Mila Tang,[7] William F. Clark,[8] Carol Connolly,[1] Malcolm King,[1] Joel Singer,[1] Adeera Levin,[2] Braden J. Manns,[3] Ana Konvalinka,[4] James W. Scholey,[6] Norman D. Rosenblum.[5] Can-SOLVE CKD Network *[1]Can-SOLVE CKD Network, Vancouver, BC, Canada; [2]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [3]Foothills Medical Center, Calgary, AB, Canada; [4]University Health Network, University of Toronto, Toronto, ON, Canada; [5]The Hospital for Sick Children, Toronto, ON, Canada; [6]University of Toronto, Toronto, ON, Canada; [7]St. Paul's Hospital, Vancouver, BC, Canada; [8]London Health Sciences Center, London, ON, Canada*.

Background: Can-SOLVE CKD is a pan-Canadian network seeking solutions and innovations that will transform kidney health in Canada through 18 patient-centered projects. The Research Operations Committee (ROC) performs annual peer-review on all projects to provide guidance for successful implementation. The Patient-Oriented Research (POR) Collaborative Peer-Review Model employed by ROC and facilitators enables patient partners to participate as equal and contributing voices in the process.

Methods: Membership includes patients, Indigenous partners, experts on research methodology/clinical research. Reviewed aspects include design, feasibility of implementation plan, risk-mitigation, patient engagement, knowledge translation (KT) and Indigenous cultural safety and engagement. A review package includes a progress update by the project team, Knowledge Users and KT Committee review feedback, POR Training log, patient engagement check-in calls and survey report. A researcher is a primary reviewer, focusing on scientific methods, a patient partner is a secondary reviewer, focusing on patient engagement, and a reader contributes to the discussion. Reviewers complete an evaluation checklist and attend a session to agree on recommendations that are relayed back to the project team. Network supports may be dispatched to facilitate recommendations. Concerns require project teams to address and respond to ROC with possible interim reporting.

Results: The involvement of patient partners in the peer-review process is a new addition to what has traditionally been a highly technical, closed format. Patient partners play prominent roles in the review. Effective patient partner reviewers are 1) "comfortable with themselves" and not afraid to voice opinions, and 2) motivated and interested in the work. An environment that cultivates engagement includes respectful and inclusive facilitation at meetings, a forum for peer support to share learning and provide the opportunity to learn on the job.

Conclusions: The Collaborative Peer-Review Model ensures accountability of POR principles encouraging research outputs to have a high impact. This can be considered and adapted for other organizations for patient partners to have a prominent role in monitoring and governance of POR.

SA-PO789

Association of Lower Dietary Potassium Intake with Higher Death Risk in a Prospective Hemodialysis Cohort

Yoko Narasaki,[2,1] Yusuke Okuda,[3] Sara S. Kalantar,[1] Amy S. You,[3] Alejandra Novoa,[7] Elani Streja,[4] Tracy Nakata,[5] Sara Colman,[6] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine, Huntington Beach, CA; [2]Tokushima University, Irvine, CA; [3]University of California, Irvine, Irvine, CA; [4]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [5]UC Irvine, Orange, CA; [6]DaVita, Huntington Beach, CA; [7]UC Irvine Health, Orange, CA.*

Background: Among hemodialysis patients, clinical practice guidelines recommend dietary potassium restriction given concerns about potential hyperkalemia leading to malignant arrhythmias and mortality. Yet there are sparse data informing recommendations for dietary potassium intake in this population. We thus sought to examine the relationship between dietary potassium intake and death risk in a prospective hemodialysis cohort.

Methods: Among 415 hemodialysis patients from the prospective "Malnutrition, Diet, and Racial Disparities in Chronic Kidney Disease" cohort recruited across 16 outpatient dialysis clinics, information regarding dietary potassium intake was obtained using Food Frequency Questionnaires (FFQ's) administered over 2011 to 2015. We first examined associations of baseline dietary potassium intake categorized as tertiles with mortality risk using Cox regression. We then examined clinical characteristics associated with low dietary potassium intake (defined as the lowest tertile) using logistic regression.

Results: In expanded case-mix Cox analyses, patients whose dietary potassium intake was in the lowest tertile had higher mortality (ref: highest tertile): adjusted HR (aHR) (95%CI) 1.74 (1.14, 2.66). These associations had even greater magnitude of risk following adjustment for laboratory and nutritional covariates: aHR (95%CI) 2.65 (1.40, 5.04). In expanded case-mix restricted cubic spline analyses, there was a monotonic increase in mortality risk with incrementally lower dietary potassium intake. In expanded case-mix logistic regression models, female sex; higher serum bicarbonate; and lower dietary energy, protein, and fiber intake were associated with low dietary potassium intake.

Conclusions: In a prospective cohort of hemodialysis patients, lower dietary potassium intake was associated with higher mortality risk. These findings suggest excessive dietary potassium restriction may be deleterious in hemodialysis patients, and further studies are needed to determine the optimal dietary potassium intake in this population.

SA-PO790

Proactive Identification and Nutritional Management of Hyperkalemia via Electronic Health Record Phenotyping

Jung Hoon Son,[1] Lauren A. Wiener,[1] Ollie Fielding,[1] Tia Y. Yu,[1] Frank Liu,[2] Jeffrey I. Silberzweig.[2] PEAK Team at The Rogosin Institute *[1]pulseData, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: Hyperkalemia is common chronic kidney disease (CKD) patients and is often associated with adverse cardiac events. Patients with CKD are at increased risk of hyperkalemia due to impaired potassium homeostasis. CKD patients on long-term RAAS inhibitors and/or potassium-sparing diuretics are at increased risk of hyperkalemia, as are those with history of hyperkalemia who are not treated with potassium-binding agents. Targeted nutritional guidance is a low-cost, low-risk intervention for reducing hyperkalemic events.

Methods: Using longitudinal data of 110,998 patients from the Rogosin Institute, a rule-based cohorting criteria (Fig 1) was created using a custom web-based interface provided by pulseData to identify patients who are hyperkalemic or are at risk of hyperkalemia. A two-step workflow was developed: 1) EHR data-driven identification of patients at risk for hyperkalemia and 2) targeted delivery of a nutritional flyer to high-risk patients.

Results: 1) *Data-driven identification*: We developed a method to systematically identify high-risk patients and facilitate targeted delivery of the nutritional intervention. On retrospective review, this query identifies on average 10 patients each week. 2) *Nutritional Guidance*: A nutritional flyer was created to inform the identified patients on which high-potassium foods which should be avoided. Using a flyer is a less costly resource than an appointment with a nutritionist and can be brought with the patient to the grocery store.

Conclusions: A proactive, data-driven method was developed for delivery of nutritional guidance to high-risk patients to reduce future hyperkalemic events. This workflow will be implemented at The Rogosin Institute. Data will be collected on subsequent hyperkalemia events.

Variability of Serum Phosphate and Markers of Malnutrition and Inflammation in Hemodialysis Patients

Xiaoling Ye,[1,2] Jeroen Kooman,[2] Jochen G. Raimann,[1] Franklin W. Maddux,[3] Peter Kotanko.[1,4] *[1]Renal Research Institute, New York, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands; [3]Fresenius Medical Care, Waltham, MA; [4]Icahn School of Medicine at the Mount Sinai Hospital, New York, NY.*

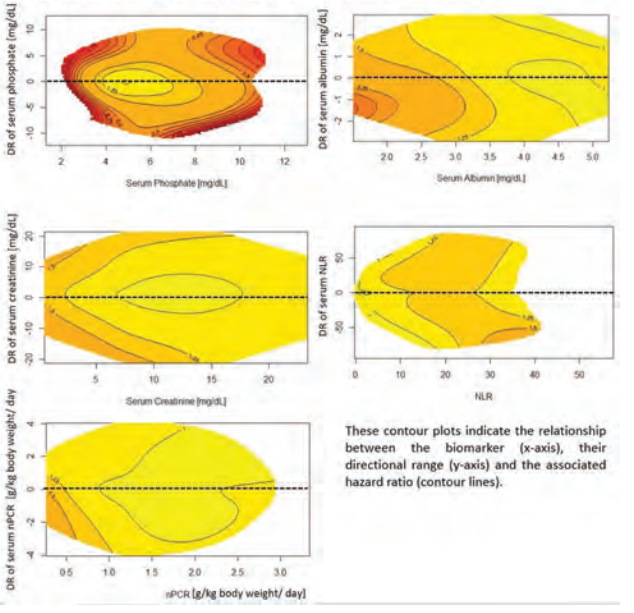
Background: Several biomarkers show significant short- and long-term variability. Here we assessed the variabilities of phosphate(P), albumin(alb), creatinine (creat), nPCR, and neutrophil-to-lymphocyte ratio(NLR) and their associations with outcome.

Methods: All incident in-center HD pts treated in Fresenius Medical Care North America clinics from 10/2010 to 10/2018 were enrolled. The 6-months (mo) baseline (mo 4 to 9) preceded a 12-mos follow-up (mos 10 to 21). Biomarker baseline variability was described by several metrics:(i) standard deviation (SD); (ii) average real variability (ARV = $1/(N-1) * \sum_{(i=1 \sim N-1)} | X_{i+1} - X_i|$; N is number of valid lab measurements); (iii) the directional range (DR), it is positive when the minimum antedates the maximum, otherwise negative. Cox proportional hazards models with spline terms were employed to investigate the association between these variables, their variability indicators, and all-cause mortality. ANOVA Cox proportional hazard models (adjusted for age, gender, race, diabetic, congestive heart failure) were built to study the interactions of these variables and their variability with outcome during follow-up.

Results: We enrolled 159703 patients, 17037 died during follow-up. Baseline P was 5.1 mg/dL, median serum P SD, ARV, and DR were 0.91, 0.95, -0.91 mg/dL, respectively. The relation between P variability and all-cause mortality was consistent across a wide range of P levels. For alb, nPCR and creat the highest mortality was observed in patients with low P levels and negative DR.

Conclusions: The direct relation between P variability and mortality is present across levels of nutrition and inflammation. A high P variability should prompt the search for underlying causes, such as poor nutrition and inflammation, and potential interventions.

Figure: Interaction of laboratory markers and their DR with all-cause mortality.



SA-PO792

Dietary Modification Improves FGF-23, KLOTHO, PTH, and Serum Phosphorous Levels in CKD Stages 1 and 2

Anita Saxena. SGPGI Renal Nutrition Group *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Dietary phosphorus restriction is a potential therapy for improving cardiovascular outcomes. Aim: To examine effect of dietary counselling and dietary modifications on FGF-23, klotho, PTH levels and phosphorous in CKD Stage 1 and Stage 2 patients.

Methods: 100 subjects aged 35.37 ± 10.98 years with eGFR 83.55+16.53 ml/minute and BMI 24.74 ±2.18 were recruited in the study. 24 hour dietary recall was taken at baseline, Based on dietary phosphorous intake patients were divided into two groups. Group 1: low phosphorous diet and Group 2: high. phosphorous diet. Controls were 30 healthy subjects, aged 43.83±10.11 ml/min with eGFR 126.11+10.26 ml/min and BMI 24.06 ±2.09. FGF-23, soluble α-Klotho, iPTH were measured (ELISA)

Results: The independent t test showed that iPTH, serum creatinine, FGF-23, serum phosphorous, total cholesterol and VLDL were significantly higher in CKD patients compared to controls(p=0.000),. Hemoglobin (p=0.046), vitamin D(p=0.008), klotho (p=0.000) and HDL (p=0.000) were lower in CKD patients compared to controls (n=30). GFR showed a positive significant correlation with klotho (r=0.696, p=0.000) and a negative significant correlation with serum phosphorous (r=-0.494, p=0.000), iPTH (r=-0.751, p=0.000), FGF-23 (r=-0.638, p=0.000), urinary phosphorous (r=-0.476, p=0.000) and dietary phosphorous intake (r=-0.678, p=0.000). Urinary phosphorous showed a significant positive correlation with dietary phosphorous (r=0.488, p=0.000) After dietary counselling and diet modifications in group 2, dietary phosphorous decreased from 1384.74±117.32 to 1027.69±101.39 (p=0.008; serum phosphorus 3.89±0.57 to3.59±0.63 p **0.008**), FGF-23 (169.80±50.96 to 159.45±58.66; p **0.023**), klotho (351.77±134.88 to 316.83±167.25 p **0.037**) and iPTH decreased from 88.48±10.55 to 85.49±15.25; p **0.033**. There was decline in protein intake from 0.67±0.130.to 60±0.11g/kg/d p **0.010.** FGF-23 showed a strong significant negative correlation with klotho (r=0.754, p=0.000) i.e. as the levels of FGF-23 decreases, the levels of klotho increases after the diet modification in group 2 when they were advised to be strictly on a low phosphorous diet.

Conclusions: Both diet counselling and diet modification can bring down levels of FGF-23, Klotho, iPTH, serum phosphorous, urinary phosphorous which can be instrumental in slowing the progression of CKD and preventing cardiovascular disease.

SA-PO793

Hyperphosphatemia: Barriers to Treatment Adherence in Dialysis Patients

Wei Xiang Wong, Wina Yousman, Jennifer Aranas, Lance Bechtold, Kussay Samkari, Bijin Thajudeen, Frank C. Brosius. *University of Arizona, Banner Medical University Tucson, Tucson, AZ.*

Background: Hyperphosphatemia in end-stage renal disease is associated with increased morbidity and mortality. One important cause of hyperphosphatemia is non-compliance with low phosphate diet and phosphate binders. The primary objective of our study is to evaluate the adherence to prescribed treatment and barriers in accomplishing adherence.

Methods: We collected data from 2 dialysis units in Tucson. A questionnaire was designed to assess dialysis patient's access to nutritional resources, knowledge of medications as well as dietary restrictions and barriers to access appropriate care.

We included patient >18 years old who had phosphorus >5.5mg/dl in the preceding 3 months prior to screening. From the gathered information we identified the top 6 factors responsible for uncontrolled phosphorus and designed strategies to improve patient compliance and accessibility. Data were analyzed using SPSS.

Results: 38 patients were included in the final analysis. Mean age of participants was 52.9±16.3 year. Our cohort consisted of 63% male and 53% Hispanic population. 6 most common reasons are represented in figure 1. In 55% of subjects, budget affects the preference of food. 42%, 74% and 39% could not answer low phosphorus drink, snack and meal respectively. 74% suggested that the use of pamphlets for diet education could improve compliance. Reasons for noncompliance: education does not fit food habits, concern for own/family nutrition, fast food.74% not aware of the importance of phosphorus control. 74% not satisfied with doctor's explanation about phosphorus. 76% complained about phosphorus binders. Most common complaint about binders was size of the pill. Based on the findings, an intervention strategy was designed.

Conclusions: ESRD patients require a multidisciplinary approach to mobilize more local and national resources to achieve good phosphorus control. Diet changes, educational approach, reminder techniques, binder type should be tailored to the individual patient. Patients appreciate doctor's involvement in the management of phosphorus (it should not be completely left to the dietician.)

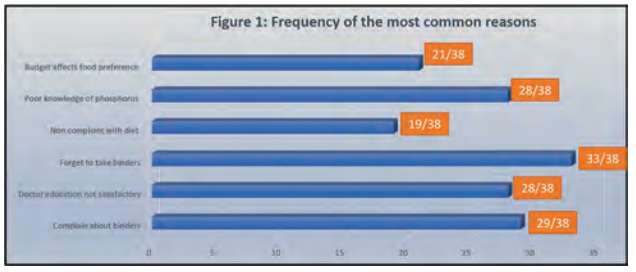


Figure 1

SA-PO794

Low Protein Intake Is Associated with Severe Fatigue in Stable Outpatient Renal Transplant Recipients

Antonio W. Gomes Neto,[1] Marit Geelink,[1] Rianne M. Douwes,[1] Iris Van vliet,[2] Adrian Post,[1] Judith Rosmalen,[1] Monica L. Joustra,[1] Hans Knoop,[3] Stefan P. Berger,[1] Gerjan Navis,[1] Stephan J. Bakker.[1] *[1]Department of Internal Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Dietetics, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]Department of Medical Psychology, University of Amsterdam, Academic Medical Center, Amsterdam, Netherlands.*

Background: Severe fatigue is a frequent complaint in renal transplant recipients (RTR) that is often accompanied by functional impairment and poor quality of life. Low protein intake may lead to protein-energy malnutrition and thereby contribute to fatigue in RTR. We aimed to (1) compare the prevalence of severe fatigue between RTR and healthy controls, (2) investigate impact of severe fatigue on quality of life in RTR, and (3) investigate the association of protein intake with severe fatigue in RTR.

Methods: We included 601 stable RTR with a functioning graft >1 year and 237 prospective kidney donors from the TransplantLines Study. Overall fatigue was assessed using the Checklist Individual Strength (CIS) Questionnaire. A CIS-score >76 is commonly considered to indicate severe fatigue and was used as cut-off in this study. Quality of Life (QoL) was assessed with the RAND-36 Questionnaire. The Maroni formula was used to calculate protein intake from 24-hr urinary urea excretion. Chi-Square was used to test differences in prevalence of severe fatigue in RTR and donors. Mann-Whitney U was used to test differences in QoL of RTR with and without severe fatigue. Logistic regression was used to analyze the association between protein intake and presence of severe fatigue.

Results: RTR were 55 ± 13 years old, 347 (58%) were male and mean eGFR was 50 ± 18 ml/min/1.73m^2. Thirty-three percent of RTR were severely fatigued compared to 6% of kidney donors (P<0.001). QoL was significantly lower in RTR with compared to RTR without severe fatigue (median QoL-score 40 [30-60] *vs* 60 [50-75], P<0.001). Mean protein intake in RTR was 1.0 ± 0.3 g per kg bodyweight per day. Protein intake was inversely associated with severe fatigue in RTR (OR 0.17; 95%CI 0.07-0.40 per g/kg/d, P<0.001). This association remained materially unchanged after adjustment for potential confounders, including age, sex, eGFR, BMI, and anaemia (OR 0.20; 95%CI 0.08-0.51 per g/kg/d, P=0.001).

Conclusions: Severe fatigue is highly prevalent in RTR and a determinant of poor quality of life. Low protein intake is associated with higher risk of severe fatigue in RTR, independent of potential confounders, including age, sex, eGFR, BMI, and anaemia.

SA-PO795

Dietary Protein Intake, Kidney Function, and Mortality in a Nationally Representative Cohort

Yoko Narasaki,[2] Yusuke Okuda,[3] Linda W. Moore,[4] Amy S. You,[3] Tracy Nakata,[5] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[6] Connie Rhee.[1] *[1]University of California Irvine, Huntington Beach, CA; [2]Tokushima University, Irvine, CA; [3]University of California, Irvine, Irvine, CA; [4]Houston Methodist Hospital, Houston, TX; [5]UC Irvine, Orange, CA; [6]University of California Irvine, School of Medicine, Orange, CA.*

Background: In the general population, high protein diets (Paleo, Atkins, ketogenic) have gained popularity as a means to promote weight loss and avoid excess carbohydrate consumption. Yet in chronic kidney disease (CKD), evidence suggests low dietary protein intake (DPI) leads to attenuation of kidney function decline, although there remains concern about risk of protein-energy wasting. We thus sought to examine the association of DPI with mortality risk in a nationally representative cohort stratified by estimated glomerular filtration rate (eGFR).

Methods: We examined the association of daily DPI normalized to actual body weight (g/kg actual weight [AW]/day) ascertained by 24-hour dietary recall, with all-cause mortality among 27,604 continuous NHANES adult participants (1999-2010) stratified by low vs. normal eGFR (<60 vs. ≥60ml/min/1.72m^2, respectively) in adjusted Cox models. We also examined the relationship between high biologic value (HBV) protein consumption with mortality.

Results: In participants with low eGFR (N=1999), high DPI ≥1.4g/kg AW/day was associated with higher death risk, while lower DPI levels were not associated with mortality (ref: 0.6-<1.0): HRs (95%CI): 1.09 (0.90, 1.32), 1.03 (0.82, 1.29), and 1.37 (1.02, 1.85) for DPI <0.6, 0.6-<1.0, 1.0-<1.4, and ≥1.4g/kg AW/day, respectively. Yet in those with normal eGFR (N=25,605), low DPI <0.6g/kg AW/day was associated with higher mortality, whereas higher DPI levels were not associated with death. In those with low eGFR, the highest two tertiles of HBV consumption were associated with higher death risk (ref: lowest tertile), whereas no association of HBV intake with mortality was observed with normal eGFR.

Conclusions: In participants with low eGFR, higher DPI and HBV consumption were associated with higher mortality, whereas lower DPI was associated with higher mortality in those with normal eGFR. Further studies are needed to elucidate the specific pathways between higher DPI and HBV consumption and mortality in those with CKD.

SA-PO796

Decline in Renal Function After Withdrawing Ketoanalogue Supplementation: A Randomized Clinical Trial

Anita Saxena. SGPGI Group *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Studies have reported preservation of renal function and nutritional status in patients with a low protein diet supplemented by ketoanalogues. Our group reported preservation of renal function and nutritional status in patients who were supplemented with ketoanalogues. The aim of the study was to evaluate if the renal function is maintained after withdrawing ketoanalogue supplementation despite continuing on the same diet.

Methods: Forty CKD patients were randomized into two groups: Group 1 (Intervention) patients were supplemented with 6 tablets of ketoanalogue for 10 months. Patients were advised very low protein diet 0.4 g/kg/day. Group 2 (Control) patients were given conservative treatment with 0.6 g/kg/d protein restriction. Dietary assessment was done at visit 1 and at visit 2 (10 months). Nutritional assessment was evaluated with SGA score. GFR and serum albumin were evaluated at baseline and at 10 months. After 10 months ketoanalogue supplementation was stopped and patients were followed up for four years with same dietary intake.

Results: At baseline, the GFR was higher in controls (51.14±15.1 ml/minute). compared to supplemented group (47.79±13.2 ml/minute). After 10 months in control group, in GFR decline by 15.54 ml/min (51.14 to 35.5±7.94 ml/minute) and serum albumin decreased from 3.8±0.90 g/dL to 3.09±0.38 g d/l. In supplemented group the GFR and albumin remained stable at 47.79±13.2 ml/minute and 4.11±0.43 respectively. In ketoanalogue group patients did not comply to low protein diet, in stead they consumed normal protein diet 0.62±0.24 g/kg/d. In supplemented group serum creatinine decreased from 1.61±0.52 to 1.40±0.52 but increased to 2.2 mg% after stopping ketoanalgue. After stopping supplementation at 10 months patients were followed up for four years. Gradual decline was observed in GFR (47.79±13.2 to 28.0 ml/minute) and albumin (4.11±0.43 to 3.6 g/dL). Some patients progressed to ESRD. After stopping ketoanalogues, the dietary intake remained the same

Conclusions: Low protein diet supplemented with ketoanalogues preserves renal function and nutritional status in predialysis patients. However, a rapid decline in renal function is observed after stopping ketoanalogue supplemention.

Urinary Proteomics in CKD Associated with Glomerular Endothelial Cell Injury

Ji Eun Kim,[1] Jinseon Jeong,[1] Jong joo Moon,[1] Yong Chul Kim,[1] Seung Hee Yang,[2] Yon Su Kim.[3] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: A number of studies have been conducted on the identification of urinary proteomics associated with the progression of chronic kidney disease (CKD). In the course of CKD, any injury to the glomerular structure is likely to affect the glomerular endothelial cell. In this study, we sought to identify proteomic markers that increase in CKD with endothelial cell injury.

Methods: Label-free quantitative proteomic analysis based on liquid chromatography-tandem mass spectrometry (LC-MS/MS) was performed on urine samples obtained from 9, 11, and 10 patients in CKD stage 1, 3 and 5, respectively. Quantitative proteomic analysis based on Tandem mass tag (TMT) was also performed for primary cultured glomerular endothelial cells (GECs) before and after inducing hypoxia injury through maintenance in hypoxia chamber for 24 hours. Selection of differentially expressed proteins (DEPs) was based on false discovery rate-adjusted p-value <0.05.

Results: The mean estimated glomerular filtration rate of patients with CKD stages 1, 3, and 5 were 110.1 + 17.9, 43.2 + 12.5, and 10.5 + 3.0, respectively. We identified 65, 198, and 650 DEPs between CKD 1 and CKD 3, between CKD 3 and CKD 5, and between CKD 1 and CKD 5, respectively, when the urinary proteins were identified in these CKD patients. When comparing the proteins expressed before and after hypoxia injury in the GEC cell, we identified 4032 DEPs in the first experimental set and 3194 DEPs in the second set. Only 8 of these proteins showed significant results in both urine of CKD patients and endothelial cells. Among these 8, there were only 5 significant results between CKD 3 and 5 and between CKD 1 and 5, and there were no significant results between CKD 1 and 3. Among the significant proteins, IGFBP3, APOL1, and PROS1 increased more than 1.5 fold with hypoxia injury on GEC and increasing CKD stages, whereas HILPDA and MUC1 increased with GEC injury and decreased with increasing CKD stages.

Conclusions: We have identified specific urinary proteins that change with endothelial cell injury and CKD progression, and further analysis of the diagnostic value of these proteins for chronic renal failure and endothelial cell damage is needed.

SA-PO798

Metabolomics of Dietary Protein Sources and CKD Progression in Children

Casey Rebholz,[1] Jingsha Chen,[1] Alison G. Abraham,[1] Yunwen Xu,[6] Aisha Betoko,[1] Bradley A. Warady,[2] Eugene P. Rhee,[3] Susan L. Furth,[5] Josef Coresh,[4] Michelle Denburg.[5] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Children's Mercy Kansas City, Kansas City, MO; [3]Massachusetts General Hospital, Newton, MA; [4]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]Johns Hopkins School of Public Health, Baltimore, MD.*

Background: Recent evidence suggests that source of dietary protein may influence kidney disease risk. We aimed to characterize the plasma metabolome of plant and animal sources of protein and to determine whether dietary protein-related metabolites were associated with CKD progression in children.

Methods: Metabolites were measured using an untargeted platform (Metabolon) in baseline plasma specimens from 488 Chronic Kidney Disease in Children (CKiD) participants. We assessed the cross-sectional association between protein source (plant, animal) and metabolites using linear regression adjusted for age, sex, race, BMI, glomerular vs. non-glomerular diagnosis, and eGFR, and statistical significance was determined using a false discovery rate <0.05 to account for multiple comparisons. Metabolites that were significantly associated with protein were included in the prospective analysis with CKD progression (renal replacement therapy or ≥50% eGFR decline) after accounting for proteinuria, anemia, hypertension, and serum albumin in addition to the same covariates in the cross-sectional analysis.

Results: A total of 94 (9.9% of 949) known serum metabolites were significantly associated with animal protein and 45 (4.7% of 949) metabolites were significantly associated with plant protein. Only one metabolite was significantly associated with both animal and plant protein: phenylacetate. For the prospective analysis, 23 animal protein-related metabolites (24.5% of 94) and 8 plant protein-related metabolites (17.8% of 45) were associated with CKD progression, including 21 lipids, 3 amino acids, 3 cofactors and vitamins, 2 xenobiotics, 1 peptide, and 1 nucleotide (p<0.05; **Table**).

Conclusions: An untargeted metabolomic platform identified multiple blood metabolites that were associated with animal and plant protein consumption and CKD progression. These findings could inform more nuanced dietary recommendations for children with CKD regarding protein source.

Funding: NIDDK Support

Dietary Results from the CKD Observational Database (CKDOD) in China

Zhao Hu,[6] Junwu Dong,[8] Hao Zhang,[2] Detian Li,[7] Fuyuan Hong,[9] Yuxin Wang,[11] Junlan Liu,[10] Yanlin Zhang,[10] Xinjian Li,[12] Miao Yu,[4] Peter C. Koch,[3] Hrishikesh G. Kulkarni,[3] Jianmei Wang,[4] Aike T. Schweda,[5] Talat Alp Ikizler.[1]
[1]Vanderbilt University Medical Center, Nashville, TN; [2]The Third Xiangya Hospital of Central South University, Changsha, China; [3]Fresenius Kabi Deutschland GmbH, Bad Homburg, Germany; [4]Fresenius Kabi Pharmaceutical Co.,Ltd, Beijing, China; [5]DBM Wissen schafft, Wiesloch, Germany; [6]Qilu Hospital of Shandong University, Shandong, China; [7]China Medical University, Shenyang, China; [8]Wuhan puai hospital, Wuhan, China; [9]Fujian Provincial Hospital, Fuzhou, China; [10]The First Affiliated Hospital of Xiamen University, Xiamen, China; [11]Xiamen Medical College, Xiamen, China; [12]Jining Medical University, Jining, China.

Background: Protein restricted diets (PRD) with or without ketoanalogue (KA) supplementation are an established dietary treatment option in chronic kidney disease (CKD). The aim of this study was the evaluation of specific types of protein restriction for management of CKD in China and assessment of associations between different nutritional protein interventions and estimated glomerular filtration rate (eGFR) changes over time.

Methods: 733 non-dialysis CKD patients were observed for median 1.1 year in this registry from routine care in China. Demographics and dietary prescriptions were analyzed descriptively. A mixed-effects model adjusting for demographics, CKD stage, and primary cause of CKD was used for longitudinal analysis of eGFR changes.

Results: Time since diagnosis of CKD was 1.1 [0.1; 3.1] years. 15% of patients were in stage 1-2, 35% stage 3, 20% stage 4, and 24% stage 5. PRD were mainly used in stages 3 and 4 (Figure 1A), with 90% of these patients receiving an advice for target of protein intake of 0.6-0.8 g/kg/d (LPD). Higher protein recommendations (0.8-1.0 g/kg/d, intermediate protein diet (IPD)) were more common in earlier CKD stages, e.g., in stage 2, 58% received recommendation for PRD with 25% of these for IPD. KA were prescribed more frequently with lower dietary protein intake (72% LPD, 38% IPD, p<0.001). Mixed effects regression suggested that lower protein intake is associated with slower eGFR decline compared to IPD or normal protein intake (Figure 1 B).

Conclusions: In this select Chinese population cohort, the use of protein restricted diets with or without KA supplementation in advanced stages of chronic kidney disease might be associated with a trend towards slower eGFR decline.

Low-Protein Diet for Patients Older Than 70 Years with CKD due to Benign Nephrosclerosis Is Effective in Suppressing Its Progression Without Causing Sarcopenia and Frailty

Yoshihiko Inoue,[1] Naoto Kawata,[1] Tomoaki Miyazaki,[1] Shinya Omiya,[1] Kiyoko Inui,[1] Ashio Yoshimura,[2] Fumihiko Koiwa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan; [2]Shinyokohama Daiichi Clinic, Yokohama, Japan.*

Background: Restriction of protein intake delays or stops the progression of CKD. However, the effect of low-protein diet (LPD) in the elderly CKD patients is not well understood because of risk for malnutrition and other concerns. We studied the effect of LPD on them.

Methods: Patients with CKD stage 3-4 due to benign nephrosclerosis (BNS) were studied. All of them were 70 years old or older. Nutritional guidance of energy 30-35 Kcal/kgBW/day, protein intake 0.6-0.8 g/kgBW/day, salt intake 6g/day was given to patients. Protein intake was evaluated using the Maroni's formula by 24-hour urine sample. We studied for 3 years after the start of the LPD and also evaluated renal function and nutritional status.

Results: 50 patients were included in this study. Majority of patients were male (64%). The average age of patients is 75.5±5.39 years. 33 (LPD group) out of 50 patients were able to achieve less than 0.8g/kgBW/day (average: 0.60±0.10g/kgBW/day) of dietary protein in the evaluation of the Maroni's formula. 87.8% patients of the LPD group used low protein rice as a special low protein food. The LPD group showed significant improvement in eGFR, salt intake compared with the non-LPD group (n=17). The LPD group also did not have body weight loss, trouble climbing stairs, poor balance, weakness and not decrease walking speed, hemoglobin, albumin, T-cho and BMI (table 1). Four patients in the LPD group decreased eGFR. These four patients had significantly more amount of urine protein since the start of the study.

Conclusions: Even in the elderly, application of LPD is possible and effective in CKD stage 3-4 patients due to BNS. LPD in the elderly does not cause sarcopenia/frailty if it contains enough energy. Use of special protein-restriction foods is important in success of continuation of low protein diet.

Table 1

	Non-LPD group (>0.8g/kgBW/day, n=17)			LPD group (< 0.8kg/kgBW/day, n=33)		
	Baseline	End of the study (3-year)	P	Baseline	End of the study (3-year)	P
Protein intake (g/kgBW/day)	1.42±0.12	1.03±0.13	<0.05	1.35±0.10	0.60±0.10	<0.05

SA-PO801

Adherence to a Low-Protein Diet (LPD) Is Associated with Slower Rate of eGFR Decline in Patients with CKD

Andrea Angeletti,[1] Fulvia Zappulo,[1] Miguel Fribourg,[2] Samira S. Farouk,[2] Chiara Guglielmo,[2] Sofia Andrighetto,[2] Susan Hartzell,[2] Chiara Cantarelli,[4] Joaquin Manrique,[3] Gaetano La Manna,[1] Paolo Cravedi.[2] *[1]Nephrology Dialysis and Renal Transplantation Unit, Sant'Orsola-Malpighi Hospital, Bologna, Italy; [2]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Complejo Hospital de Navarra, Pamplona, Spain; [4]Dipartimento di Medicina e Chirurgia, Università di Parma, Parma, Italy.*

Background: LPD is considered an effective strategy to defer transition to dialysis in patients with CKD through azotemia reduction. However, whether dietary protein intake impacts the rate of kidney function decline remains controversial.

Methods: We included 135 patients with an eGFR between 20 and 60 mL/min/1.73m^2 who started LPD (0.6-0.7g/kg/d) between 2015 and 2017 and retrospectively collected clinical history (diabetes status and RAASi therapy), serial eGFR (CKD-EPI), proteinuria, and urinary phosphorus. Dietary energy intake was >30Kcal/Kg/d. eGFR and 24h proteinuria were collected at the time of LPD initiation and at 6 and 12mo before and after LPD initiation. These time points were used to generate eGFR slopesbefore and after starting LPD. Adherence to LPD was estimated based on phosphaturia at 6mo after starting LPD. Patients on immunosuppressive therapy were excluded.

Results: There was a significant decrease in the rate of eGFR decline after LPD initiation (eGFR slopes: -0.35 ± 0.007 vs. -0.02 ± 0.003 ml/min/1.73m^2/month before vs. after LPD; p = 0.0007) (**Fig. 1**), though proteinuria did not significantly change. Univariate analyses showed that phosphaturia was the only variable significantly (p = 0.05) associated with rate of eGFR change, while diabetes status, RAASi therapy, and proteinuria at baseline were not. In a multivariate analyses, phosphaturia retained an independent association.

Conclusions: This retrospective, single center study shows that adherence to LPD is independently associated with ameliorated kidney function decline. These data support strategies to increase patient adherence to LPD. Further studies are needed to elucidate mechanisms by which LPD exerts renoprotection.

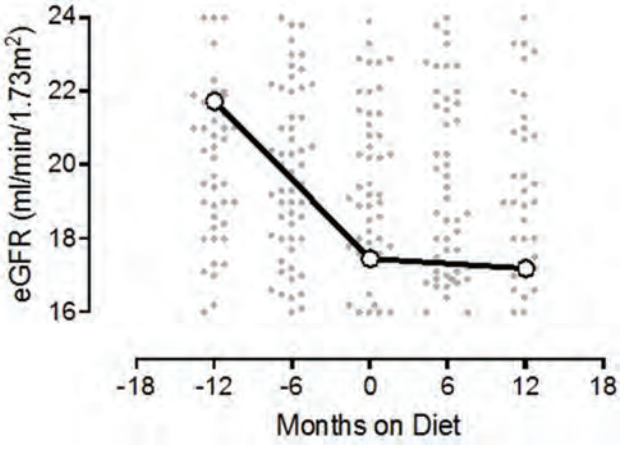

Fig. 1. Average eGFR at different time points before and after low-protein diet initiation. Grey dots represent single patients.

SA-PO802

High Plasma Branched-Chain Amino Acids Are Associated with Higher Risk of Post-Transplant Diabetes Mellitus in Renal Transplant Recipients

Maryse C. Osté,[1] Jose L. Flores-Guerrero,[1] Dineke Gruppen,[2] Lyanne M. Kieneker,[1] Margery Connelly,[3] James D. Otvos,[3] Robin Dullaart,[2] Stephan J. Bakker.[1] *[1]Nephrology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Endocrinology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]LabCorp, Morrisville, NC.*

Background: Post-transplant diabetes mellitus (PTDM) is a serious complication in renal transplant recipients (RTR). Branched-chain amino acids (BCAAs) are involved in the pathogenesis of insulin resistance and may predict new onset diabetes in the general population. Here, we prospectively determined the association of plasma BCAAs which comprise the amino acids valine, leucine, and isoleucine, with PTDM.

Methods: Adult RTR (≥ 18 y) recruited between November 2008 and May 2011 with a functioning graft for ≥1 year were eligible. Plasma BCAAs were measured in 518 RTR using nuclear magnetic resonance spectroscopy. We excluded RTR with a history of diabetes, leaving 368 non-diabetic RTR eligible for analyses. Cox proportional hazards analysis was used to assess the association of BCAAs with the development of PTDM.

Results: In 368 non-diabetic RTR (mean±SD age: 52.7±13.0 y, 53.7% men), fasting plasma BCAA was 377.6±82.5 μM. During median follow-up of 5.3 (IQR, 4.2-6.0) y, 38 (9.8%) RTR developed PTDM. RTR developed PTDM more frequently in the highest tertile of total BCAA (17.3%) when compared to the lowest two tertiles (8.0%; p=0.02). Total BCAAs were associated with a higher risk of developing PTDM (HR: 1.42, 95% CI 1.08-1.89) per SD change (p=0.01), independent of age and sex. Adjustment for other potential confounders did not significantly change these associations.

Conclusions: High concentrations of plasma BCAAs are associated with developing PTDM in RTR.

SA-PO803

High Circulating Concentrations of Very-Long-Chain Saturated Fatty Acids Are Associated with Low Risk of Premature Mortality in Renal Transplant Recipients

Fabian Vogelpohl,[1] Antonio W. Gomes Neto,[1] Ingrid Martini,[2] Camilo G. Sotomayor,[1] Stefan P. Berger,[1] Gerjan Navis,[1] Ido Kema,[2] Stephan J. Bakker.[1] *[1]Department of Internal Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Laboratory Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.*

Background: Recent epidemiological studies indicate that high exposure to very long chain saturated fatty acids (VL-SFA), present in peanuts and canola oil, is associated with positive health effects. Despite successful transplantation, health of renal transplant recipients (RTR) remains fragile, resulting in high risk of premature mortality. We hypothesized that high circulation concentrations of VL-SFA in RTR are associated with low risk of premature mortality in RTR.

Methods: We included 680 stable RTR with a functioning graft >1 year. Plasma behenic acid (C22:0) and lignoceric acid (C24:0) were measured by Agilent gas chromatography with flame ionization detector. Dietary data were collected using a Food Frequency Questionnaire. Correlations between dietary intake and C22:0 and C24:0 were analyzed by Spearman's Rho. Cox regression was used to analyze the association of VL-SFA on mortality and to estimate mortality risk across tertiles of VL-SFA concentrations.

Results: Age was 53±13 years, 57% were male and eGFR 52±20 ml/min/1.73m^2. Plasma concentrations of C22:0 and C24:0 were 73.7±17.7 and 62.5±16.3 nmol/L, respectively. C22:0 and C24:0 concentrations were correlated with intake of peanuts (r=0.13; *P*=0.001 and R=0.16, *P*<0.001, resp.) and peanutbutter (r=0.11, *P*=0.008 and R=0.11, *P*=0.005, resp.). During median follow-up of 5.4 years, 146 (22%) RTR died. Plasma C22:0 and C24:0 were inversely associated with mortality, independent of potential confounders, including age, sex and eGFR (HR 0.84 [95%CI 0.76-0.93], *P*=0.001 and HR 0.82 [95%CI 0.74-0.92], *P*=0.001, reps.). Moreover, RTR in the 3rd tertile of plasma C22:0 and C24:0 had significantly better survival compared to RTR in the 1st tertile (Table1).

Conclusions: Plasma VL-SFA is inversely associated with mortality in RTR. Increasing intake of foods containing VL-SFA, such as peanuts, may improve patient survival in RTR.

Mortality risk according to tertiles of C22:0 and C24:0

	C22:0		C24:0	
	Hazard Ratio (95%CI)	P-value	Hazard Ratio (95%CI)	P-value
Tertile 1	Reference	n/a	Reference	n/a
Tertile 2	1.07 (0.74-1.55)	0.74	0.76 (0.52-1.10)	0.15
Tertile 3	0.51 (0.33-0.80)	0.003	0.41 (0.27-0.64)	< 0.001

Lipoatrophy and Metabolic Disturbance in Mice with Adipose-Specific Deletion of Kindlin 2

Huanqing Gao, Guozhi Xiao. *Southern University of Science and Technology, Shenzhen, Comoros.*

Background: Kindlin-2 regulates the integrin-mediated cell adhesion and migration on the extracellular matrix. Our recent studies demonstrate important roles of Kindlin-2 in regulation of mesenchymal stem cell differentiation and skeletal development.

Methods: In this study we generated adipose tissue-specific conditional knock-out Kindlin-2 mice by using the Adipoq-Cre BAC transgenic mice. We used GTT to assess the glucose tolerance and ITT to assess insulin sensitivity.

Results: The results showed that deleting Kindlin-2 expression in adipocytes in mice caused a severe lipodystrophy with drastically reduced adipose tissue mass. Kindlin-2 ablation elevated the levels of blood nonesterified fatty acids (NEFA) and triglyceride, resulting in massive fatty livers in the mutant mice fed with high fat diet (HFD). Furthermore, HFD-fed mutant mice displayed type II diabetes-like phenotypes, including elevated levels of fasting blood glucose, glucose intolerance, and peripheral insulin resistance. Kindlin-2 loss dramatically reduced the expression levels of multiple key factors, including PPARg, mTOR, AKT, and b-catenin proteins, and suppressed adipocyte gene expression and differentiation. Finally, Kindlin-2 loss drastically reduced leptin production and caused a high bone mass phenotype.

Conclusions: Our study established a critical role of Kindlin-2 in control of adipogenesis and lipid metabolism as well as bone homeostasis.

Lipoprotein Abnormalities Are Associated with Mitochondrial Function and Intermuscular Adipose Tissue in Patients with CKD

Jorge Gamboa,[1] Dungeng Peng,[1] Aseel Alsouqi,[1] Baback Roshanravan,[2] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California Davis, Davis, CA.*

Background: Dyslipidemia such as increased LDL cholesterol and triglycerides levels, and decreased HDL levels frequently occurs in patients with CKD. There are limited data regarding the changes in lipoprotein composition and lipoprotein subfractions (based on density and size) in patients with CKD. Mitochondrial dysfunction may contribute to dyslipidemia and dyslipoproteinemia in patients with CKD including ectopic fat in skeletal muscle, i.e. intermuscular adipose tissue (IMAT). We now tested wheter lipoprotein abnormalities are associated with mitochondrial function and IMAT in patients with CKD.

Methods: In a cross-sectional study, we evaluated 63 patients (20 with CKD 3-4, 22 with CKD 5 on hemodialysis (HD), and 21 matched controls). Composition of lipoprotein subfractions was determined in plasma from proton nuclear magnetic resonance spectra (NMR). Mitochondrial function was evaluated by ^{31} phosphorus magnetic resonance spectroscopy (^{31} P-MRS). IMAT was evaluated in the quadriceps muscle using magnetic resonance images.

Results: Groups were matched by gender, body mass index, and history of diabetes and hypertension. We identified changes in lipoprotein composition in patients with CKD, particularly in the mature (the smallest and most dense) HDL subfraction 4 (HDL-4) including increased triglyceride content, loss of apolipoproteins (AI and AII), and a decrease in cholesterol (free and esterified) and phospholipids (**Figure 1**). Mitochondrial dysfunction was associated with HDL triglycerides content (ρ=0.47, p<0.001) and HDL-4 Apolipoprotein AII (ρ=-0.43, p=0.001). IMAT accumulation was associated with HDL triglycerides content (ρ=0.65, p<0.001) and HDL-4 phospholipids (ρ=-0.36, p=0.009).

Conclusions: HDL composition is altered in patients with CKD and it is associated with mitochondrial dysfunction and IMAT accumulation. Dysfunctional HDL is unable to efficiently remove lipids from peripheral tissues and may contribute to IMAT accumulation. Likewise, changes in HDL apolipoproteins may affect mitochondrial function. Further studies should evaluate the interrelation among lipoproteins, mitochondrial function, and IMAT in patients with CKD.

SA-PO806

High Circulating Concentrations of Marine-Derived N-3 Polyunsaturated Fatty Acids Are Associated with Low Risk of Premature Mortality in Stable Renal Transplant Recipients

Fabian Vogelpohl,[1] Antonio W. Gomes Neto,[1] Ingrid Martini,[2] Camilo G. Sotomayor,[1] Maryse C. Osté,[1] Stefan P. Berger,[1] Gerjan Navis,[1] Ido Kema,[2] Stephan J. Bakker.[1] *[1]Department of Internal Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Laboratory Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.*

Background: Cardiovascular disease contributes significantly to high rates of premature mortality in renal transplant recipients (RTR). Plasma marine derived omega-3 poly-unsaturated fatty acids (N-3 PUFA) have been shown to have a positive effect on cardiovascular risk in the general population. The benefit of marine derived N-3 PUFA in RTR is unclear as most studies relied on intake derived from food frequency questionnaires rather than on plasma concentrations.

Methods: We included 680 stable RTR with a functioning graft >1 year. Plasma EPA and DPA were measured by Agilent gas chromatography with flame ionization detector. We used linear regression analyses to investigate the association of plasma EPA+DHA with log-transformed plasma concentrations of N-terminal Pro Brain Natriuretic Peptide (NT-proBNP). Cox regression analyses were used to analyze the prospective association of EPA+DHA on mortality.

Results: RTR were 53 ± 13 year old, 386 (57%) were male and mean eGFR was 52 ± 20 ml/min/1.73m^2. Mean plasma concentrations of EPA+DHA were 0.28 ± 0.12 µmol/L. Median NT-proBNP concentrations were 249 [IQR 105-625] ng/L. EPA+DHA was inversely associated with NT-proBNP, independent of potential confounders, including age, sex and eGFR (st.β -0.080, *P*=0.02). During 5.4 years of follow-up, 146 (22%) RTR died. In prospective analyses, we observed EPA+DHA was inversely associated with risk of premature mortality, independent of potential confounders (HR 0.24; 95%CI 0.06-0.98, *P*=0.047).

Conclusions: High circulating concentrations of marine derived N-3 PUFA (EPA+DHA) are associated with low circulating concentrations of NT-proBNP, consistent with beneficial effects on cardiovascular health and low risk of premature mortality in RTR. These results support advices for increased intake of N-3 PUFAs in RTR.

SA-PO807

The High Dietary Polyunsaturated Fatty Acid Level Is Associated with Lower Prevalence of CKD: A Population-Based Cohort Study

Jimin Park,[1] Seonghun Kim,[1] Boyoung Nam,[1] Shinchan Kang,[2] Tae-Hyun Yoo.[2] *[1]Yonsei University, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: There have been steady interests in the effects of polyunsaturated fatty acid (PUFA) on health and several studies have proved PUFA is associated with lower risk of hypertension and diabetes. However, the effect of dietary PUFA on renal function in general population has been relatively unexplored, yet. Therefore, we aimed to evaluate the relationship between dietary PUFA intake and renal function in a nationwide nutritional survey.

Methods: Data were retrieved from the Korea National Health And Nutrition Examination Survey (KNHANES). Among 39,225 subjects collected from 2013 to 2017, 22,079 subjects were included in final analysis, after exclusion of those who were under 18 or whose baseline data were missing. FPF (fraction of PUFA among dietary fat intake) was defined as percentage of daily PUFA intake (g) relative to daily total fat intake (g). The subjects were categorized into quartiles according to the FPF. Primary outcome was defined as a prevalent chronic kidney disease (CKD) with estimated glomerular filtration rate (eGFR) by Korean version of CKD-EPI < 60 mL/min/1.73 m^2 and composite outcome was eGFR < 60 mL/min/1.73 m^2 or the presence of proteinuria, defined as ≥ 1+ by dipstick urine test.

Results: The mean age and eGFR of the subject were 51.1 ± 16.4 years and 94.6 ± 18.8 mL/min/1.73 m^2, respectively. The mean FPF was 26.4 ± 10.0 %. Interestingly, the subjects in higher FPF group tended to be older and have slightly lower eGFR compared to those in lower FPF group. Moreover, they had lower daily fat intake and higher prevalence of HTN, DM and dyslipidemia. Total 899 subjects were found to have prevalent CKD and 1,106 subjects had composite outcomes. Multivariable logistic regression analyses revealed that the risk of CKD was lower in the group with the highest FPF compared to the lowest FPF group after adjustment for confounding factors [odds ratio (OR) 0.71, 95% confidence interval (CI) 0.58-0.88, P = 0.002]. This finding was consistent in terms of composite outcome (OR 0.75, 95% CI 0.62-0.90, P = 0.002).

Conclusions: The risk for CKD was lower in the subjects with the high dietary PUFA. Fraction of PUFA among dietary fat may affects renal function in healthy population.

SA-PO808

The Effects of Omega-3 Fatty Acids on Proteinuria Among Diabetic Patients: A Meta-Analysis of Randomized Controlled Trials

Api Chewcharat,[1] Pol Chewcharat,[2] Anawin Rutirapong,[2] Stefania Papatheodorou.[1] *[1]Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA; [2]Chulalongkorn Hospital, Bangkok, Thailand.*

Background: Long-chain omega-3 fatty acids including eicosapentaenoic acid (EPA) and docosahexaenoic acids (DHA) have been the focus of experimental studies in humans. There are clinical trials studying in various types of kidney diseases including IgA nephropathy and lupus nephritis. However, the effects of omega-3 fatty acids on diabetic kidney disease have not been studied adequately.

Methods: We conducted electronic searches in Pubmed, Embase and Cochrane Central Register of Controlled Trials from January 1960 to April 2019 to identify RCTs, which examined the effects of omega-3 fatty acids on proteinuria, eGFR and metabolic biomarkers among diabetic patients.

Results: Ten RCTs with 344 participants were included in our meta-analysis. Omega-3 fatty acids reduced the progression of proteinuria among type 2 diabetes mellitus (type 2 DM) and type 1 diabetes mellitus (type 1 DM). This association was only significant among type 2 DM (SMD = -0.29 (95% CI: -0.54, -0.03; p = 0.03). Only studies with duration of intervention of 24 weeks or longer demonstrated a significant decline in proteinuria comparing omega-3 fatty acids to placebo group (SMD = -0.30 (95% CI: -0.58, -0.02; p = 0.04). There was a slower decline in eGFR for both type 1 and type 2 DM groups, however, the effect was not statistically significant. Regarding, serum LDL-cholesterol and HbA1C, there was no significant difference comparing omega-3 fatty acids to placebo group. There was a non-significant systolic blood pressure reduction in the omega-3 fatty acids supplementation group compared to placebo.

Conclusions: Omega-3 fatty acids could help diminish proteinuria among type 2 DM who received omega-3 supplementation for at least 24 weeks without adverse effects on HbA1C and serum LDL-cholesterol.

SA-PO809

Lipidomics of Feces in Hemodialysis Patients and Some Potential Biomarkers

Ning Qu,[1] Hongli Jiang,[1] Lei Chen.[2] *[1]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]Xi'an Jiaotong University, Xi'an, China.*

Background: Earlier studies have demonstrated that chronic kidney disease (CKD) results in profound changes in lipid. Serum lipid profile of CKD patients has been determinated at many studies, but few studies have measured fecal lipid profile of CKD patients. To gain an in-depth insight into the fecal lipid profile of CKD, we performed a fecal lipidomics study of patients receiving hemodialysis (HD).

Methods: Ultra-performance liquid chromatography/mass spectrometry was used to investigate the fecal lipid profiles of 16 healthy controls and 26 patients receiving regular hemodialysis. Principal component analysis (PCA) and orthogonal-partial least squares analysis (OPLS-DA) were used for multivariate statistical analysis to screen potential biomarkers related to diseases.

Results: A total of 478 lipid species were identified from positive and negative ion modes. Out of 478, 52 identified lipid species were significantly altered in patients with ESRD(all P<0.05). According to the VIP value of OPLS-DA model, 46 lipid molecules with VIP > 1 were screened. There were only 4 lipid molecules satisfying the condition of VIP > 1 and P < 0.05, including DG(18:0/18:3)+NH4, TG(18:1/18:1/22:0)+NH4, TG(20:1/18:1/18:1)+NH4 and TG(18:1/18:2/22:0)+NH4. They were all decreased compared with the healthy controls. TG(18:1/18:1/22:0)+NH4, TG(20:1/18:1/18:1)+NH4 and TG(18:1/18:2/22:0)+NH4 are all triglycerides which participate in pathways including fat digestion and absorption, vitamin digestion and absorption and regulation of lipolysis in adipocytes that could be searched at the KEGG website. DG (18:0/18:3) +NH4 is diglyceride involved in adipocytokine signaling pathway which is correlated with leptin production.

Conclusions: Fecal lipidomics uncovered the lipid metabolism disorder of HD patients, especially disturbances in the gut. The 4 lipid species could be potential biomarkers of ESRD. Aa reported, the incidence rate of cardiovascular and cerebrovascular diseases (CCDs) is now increasingly high in CKD patients and high cholesterol is closely related to CKD. Our study indicated that ESRD patients had lower triglycerides and diglycerides in feces than healthy controls and we considered that CKD patients may absorb more glycerides which promote to the development of CCDs. However, the exact mechanism still needs to be studied further.

SA-PO810

Diploid Gene Deletion of Transient Receptor Potential Canonical 1 (TRPC1) Channel Produces Metabolic Syndrome (MetS) but Prevents Further Liver Steatosis and Dyslipidemia Induced by a High-Fat Diet (HFD)

Muhammad B. Mahmood,[1] Bonnie Eby,[1] Lindsay J. Barron,[1] Alexander Lau,[1] Meghan M. Pantalia,[3] Usman A. Khan,[1,2] Chris D. Skaggs,[4] Kai Lau.[1,2] *[1]University of Oklahoma Health Science Center, Oklahoma City, OK; [2]Medical Service, Oklahoma City VA Hospital, Oklahoma City, OK; [3]Columbia University, New York, NY; [4]OU Medical Center, Moore, OK.*

Background: There is growing evidence for the role of TRPC1 in regulating glucose & lipid metabolism. Secretion of insulin, leptin & adiponectin is sensitive to cell free Ca. TRPC1 may mediate the effects of leptin in anorexigenic hypothalamic neurons. TRPC1 iwas found low in diabetes & we recently found hyperglycemia in null mice. We tested if TRPC1 deficiency produces MetS & if 45% HFD x 3 mon aggravates it.

Methods: In age-matched TRPC1 +/+. +/-, & -/- mice, we measured glucose & lipids using standard methods & insulin, leptin, & adiponectin by mouse ELISA. We did glucose tolerance test (GTT) by IP glucose (2 mg/kg) after 13 h fast.

Results: From 4-30 week, null mice ate & weighed more than +/- & wt. At 4 mon, HOMA-insulin resistance (IR) was up 60% & HOMA β down 40%. By 12 mon, HOMA-IR was up 8 fold. At 7 mon, by GTT, both TRPC1 +/- & -/- mice were diabetic. In null, adiponectin was down 11% but leptin up 77%. At 2 mon, total cholesterol was 85% hgher in null, their liver 36% heavier, & triglyceride content (TGC) 47% higher. Liver echogenicity was up by 50-150% at 7, 11, & 22 mon, confirmed by 140% higher liver TGC. At 12 mon, only null mice had hyperlipidemia (cholesterol up 30%, LDL up 60%, & TG up 200%). In +/- & wt, lipids, liver density at 12 & 19 mon, & liver TGC at 19 mon were all normal. Fasting glucose was high only in null from 1 through 16 mon). Thus on a normal fat diet (NFD), 1 wt allele prevented hyperphagia, obesity, MetS & hepatic steatosis. As expected, HFD vs NFD stimulated leptin & insulin, similarly in all 3 genotypes without altering adiponectin. Unlike NFD, HFD increased liver density in +/- & wt, but not in null. HFD induced the highest HOMA-IR in wt (3.1 vs 1.3 x in +/-) & the largest liver TGC hike in wt (3.3 vs 1.6 x in null). During GTT, AUC for glucose vs time was the highest in wt vs null.

Conclusions: 1. Diploid TRPC1 deletion produces hyperphagia, obesity & Met S, all resolvable by caloric restriction, implying hypothalamic resistance to leptin in null mice. 2. HFD raises the risks of dyslipidemia & hepatic steatosis, only in the presence of 1-2 wt alleles, as if deficiency would block the pathogenic Ca-CM-NFAT signaling pathway. 3. TRPC1 -/- is a good model to study MetS.

SA-PO811

Higher Fruit Intake Is Associated with Albuminuria in a Nested United Kingdom Biobank Case Control Cohort

Gareth J. McKay, Euan N. Paterson, Alexander P. Maxwell. *Queen's University Belfast, Belfast, United Kingdom.*

Background: Fruit and vegetable (F&V) consumption is associated with better renal function and lower risk of CKD. These associations may be explained by the protective effects of antioxidant vitamins and phytonutrients, nitric oxide precursors, and other active substances present in F&V. The potential negative consequences of increased fruit intake on renal health however have not been extensively studied. Fruit is an important dietary source of the monosaccharide fructose that has been implicated as an environmental toxin contributing to gout, acute kidney injury and chronic kidney disease. This study evaluated associations between F&V consumption and albuminuria in the United Kingdom Biobank (UKBB www.ukbiobank.ac.uk).

Methods: A nested case-control design included cases defined by urinary albumin to creatinine ratio (ACR) ≥ 3mg/mmol and controls with ACR < 3mg/mmol, matched for age, sex and ethnicity. Typical daily F&V intake was assessed by touch screen food frequency questionnaire. Associations between fruit, vegetable or F&V intake and ACR were tested using binary logistic regression adjusted for potential confounders age, sex, ethnicity, systolic blood pressure (SBP), diabetes, smoking, blood pressure medication, waist circumference and alcohol consumption.

Results: In a sample of 6998 participants (3499 case-control pairs), the mean age was 59 years (standard deviation [SD] 8), 53% were female, and 86% were white. SBP was 150 mmHg (SD 22) for cases and 144 mmHg (SD 20) for controls (24% of cases and 16% of controls used BP lowering medication). Twice as many cases (16%) had diabetes compared to controls. In adjusted models, no significant association was found between vegetable intake and ACR. Greater fruit, and combined F&V intake, were significantly associated with ACR ≥ 3mg/mmol (fruit: odds ratio [OR] = 1.03, 95% confidence intervals [CI]: 1.01, 1.05; P = 0.005; Combined F&V intake: OR = 1.02, CI: 1.00, 1.03; P = 0.01).

Conclusions: In the UKBB population, vegetable intake alone was not significantly associated with albuminuria. However, increased fruit intake was significantly associated with a greater risk of albuminuria. These findings are consistent with previous associations between fructose intake and renal damage.

Fewer Daily Fruit and Vegetable (FV) intake in Adults with CKD May Increase the Risk of ESRD

Tanushree Banerjee,[1] Juan J. Carrero,[2] Charles E. McCulloch,[1] Nilka Rios Burrows,[3] Karen R. Siegel,[4] Hal Morgenstern,[5] Rajiv Saran,[5] Neil R. Powe.[6] *[1]University of California San Francisco, San Francisco, CA; [2]Karolinska Institutet, Stockholm, Sweden; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]CDC, Atlanta, GA; [5]University of Michigan, Ann Arbor, MI; [6]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA.*

Background: Previous studies have examined the overall FV intake and the effect on CKD progression. However, the association between the number of servings of FVs per day with kidney functional decline is relatively unexplored. We examined the relation between daily number of servings of FV and risk of ESRD in adults with CKD stage 3 and 4.

Methods: We analyzed a cohort of 1084 adults with CKD stage 3-4 (eGFR 15-59 ml/min/1.73m^2) aged≥ 20 years in the 1988-1994 National Health and Nutrition Examination Survey linked with the US Renal Data System, allowing for assessment for ESRD over a follow-up of 14 years. Daily FV servings were ascertained using a food frequency questionnaire. We examined the association between sex-specific quintiles for FV servings and incident ESRD using a Fine Gray competing risk model with age as time scale and cardiovascular mortality as the competing event. We adjusted for age, sex, socio-economic status (SES), total caloric intake, meat and fish intake, A1C, systolic BP, baseline eGFR, and urinary albumin–to-creatinine ratio (ACR).

Results: Mean age was 76.1 years; 47.8% were men. Those in quintile 1 (fewest servings of FV per day) were more likely to have lower SES; those in highest quintile (most servings of FV per day) were more likely to have DM and hypertension. 120 participants (11.1%) developed ESRD during follow-up. Compared to quintile 5, those in lowest quintiles had a greater risk of ESRD--for quintile 4: relative hazard [RH, 95% CI] = 1.07[0.84-1.40], for quintile 3: 1.11[0.89-1.36], for quintile 2: 1.56[1.18-1.98] and for quintile 1: 1.39[1.10-1.72]. Sex modified the estimated effect of FV quintile (p-interaction=0.03), the RH for the lowest vs highest quintile was (2.10[1.71-2.64]) for women and (1.24[0.90-1.57]) for men.

Conclusions: Fewer servings of FVs per day, with a threshold value corresponding to servings less than quintile 3 (<4.5 servings/day in men and women), is independently associated with a higher risk of ESRD. Since dietary restrictions in the setting of CKD result in a lower intake of FVs, a randomized trial to evaluate potential benefits and harms of higher FV servings may provide guidance for effective dietary recommendations.

SA-PO813

Cycles of a Fasting Mimicking Diet Restore Renal Function in a Rat Model of PAN Nephrosis

Laura Perin,[1] Valentina Villani,[1] Camille H. Nicolas frank,[2] Roberta Buono,[3] Charmi Dedhia,[1] Valter Longo.[3] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]The Saban Research Institute, Los Angeles, CA; [3]USC, Los Angeles, CA.*

Background: A major hallmark of end-stage renal disease (ESRD) is the irreversible loss of the glomerular filtration barrier, the structure in charge of the blood ultrafiltration. The only treatment options for ESRD are dialysis or transplantation. To date, no cure is available to restore kidney function in ESRD patients. While dietary recommendations are currently given to patients with kidney disease to minimize the burden of the disease itself and slow down its progression, no diet has proven effective in restoring renal function. Animals have evolved adaptive mechanisms to fasting that are associated with stress resistance, reduced inflammation, longer lifespan. The fasting mimicking diet (FMD) was developed to induce similar metabolic changes as observed during fasting and FMD has been clinically proven to be extremely efficient in various human disease settings (including diabetes and cancer) by activating endogenous regenerative mechanisms.

Methods: We tested the potential of FMD to treat kidney disease. Sprague Dawley rats were injected with puromycin aminonucleoside (PAN) to induce chronic nephrosis. Multiple cycles of FMD have been applied to PAN-induced rats to determine their effect on renal function and structure. Rats were monitored for renal physiological parameters, histological and WB analysis of glomerular and tubular structures were performed.

Results: We observed amelioration of proteinuria and reduced levels of BUN in rats undergoing 6 cycles of FMD compared to the PAN group. The effect was sustained long term up to 6 weeks after the last dietary cycle. Histological characterization showed preservation of the renal structure including tubular and glomerular structures in rats treated with FMD in contrast to PAN-induced rats. Podocyte number in FMD treated rats was comparable with that of healthy animals, while a significant reduction was noted in the PAN group. WB also revealed mitochondrial function protection measured by the level of mtTFA protein expression (mitochondrial transcription factor A) associated with the post re-feeding time after only one cycle of diet.

Conclusions: These results support the application of multiple cycles of FMD to restore renal function and as a possible treatment of chronic kidney disease.

Skipping Breakfast and Dinner and Incidence of Proteinuria: A Retrospective Cohort Study

Ryohei Tomi,[2] Ryohei Yamamoto,[1] Maki Shinzawa,[3] Ryuichi Yoshimura,[4] Shingo Ozaki,[3] Yoshiyuki Fujii,[3] Yoshiki Kimura,[5] Kaori Nakanishi,[3] Manabu Taneike,[3] Makoto Nishida,[3] Takashi Kudo,[3] Keiko Yamauchi-Takihara,[6] Katsunori Aoki,[3] Yoshitaka Isaka,[4] Toshiki Moriyama.[6] *[1]Health and Counseling Center, Osaka University, Suita, Japan; [2]Nephrology, Osaka University, Toyonaka, Japan; [3]Osaka University, Suita, Japan; [4]Osaka University Graduate School of Medicine, Suita, Japan; [5]National Hospital Organization Osaka National Hospital, Osaka, Japan; [6]Osaka University, Health Care Center, Toyonaka, Japan.*

Background: Chronic kidney disease (CKD) caracterized by proteinuria and low glomerular filtration rate (GFR), is one of the major risk factors of end-stage kidney disease, cardiovascular disease (CVD), and mortality. Recent studies showed that skipping breakfast was associated with type 2 diabetes (T2D) and CVD. Regarding CKD, little information is available about a clinical impact of skipping breakfast on CKD. The aim of the present study was to assess an association between breakfast frequency and incidence of proteinuria in a retrospective cohort study, along with lunch and dinner frequency.

Methods: The present study included 7,881 employees of Osaka University, one of the largest national university in Japan, who underwent their annual health checkups between April 2004 and March 2013, and had nagative or trace result of dipstick urinary protein and estimated GFR (eGFR) ≧60 ml/min/1.73m^2 at their baseline visit. Main exposure of interest was self-reported frequency of breakfast, lunch and dinner at their baseline visit: almost every day vs. irregularly. The associations of irregular breakfast, lunch, and dinner with the incidence of proteinuria defined as 1+ or more of dipstick urinary protein, using a Cox proportional hazards model adjusting for clinically relevant factors.

Results: Baseline clinical characteristics of 7,881 employees: age, mean 35 ± SD 9 years; body mass index, 21.6 ± 3.2 kg/m^2; eGFR 92 ± 15 ml/min/1.73m^2; current treatment for hypertension and CVD, 6.5% and 0.2%, respectively. During median 4.8 (interquartile range 2.1-7.7) years of the observational period, 582 (13.2%) males and 446 (12.9%) females developed proteinuria. In females, irregular breakfast and dinner was significantly associated with the incidence of proteinuria in a multivariable-adjusted model, whereas not irregular lunch (adjusted incident rate ratio of irregular breakfast, lunch, and dinner: 1.49 [1.22-1.81], 1.21 [0.82-1.79], and 1.41 [1.01-1.97], respectively). In contrast, no association was observed in males (0.95 [0.75-1.21], 1.00 [0.69-1.46], and 0.88 [0.50-1.56]).

Conclusions: Skipping breakfast and dinner were risk factors of proteinuria in females, not males.

SA-PO815

Dietary Oxalate Ingestion, Urinary Oxalate Levels, and Response to Reloxaliase in Three Phase 2 Studies

Craig B. Langman,[1] Linda H. Easter,[2] Zhiqun Zhang,[3] Annamaria T. Kausz,[3] Sagar U. Nigwekar.[4] *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Wake Forest School of Medicine, Kernersville, NC; [3]Allena Pharmaceuticals, Inc, Newton, MA; [4]Massachusetts General Hospital, Cambridge, MA.*

Background: Over-absorption of oxalate from dietary oxalate can lead to hyperoxaluria (HOx) in patients with malabsorptive gastrointestinal (GI) conditions {enteric HOx (EH)}. Reloxaliase is an oral enzyme that degrades oxalate within the GI tract, resulting in less oxalate absorbed and lower urinary oxalate (UOx) excretion. We hypothesized that patients with greater baseline levels of UOx may show increased responsiveness to a therapy that degrades dietary Ox. Data on patients with EH in three phase II trials were analyzed to examine this hypothesis.

Methods: A composite analysis of data from three Phase 2 studies of reloxaliase was performed to include: an uncontrolled study with 5 EH subjects treated for 4d (NCT02289755), an RCT with 11 EH subjects treated for 28d (NCT02547805) and an ongoing open label study in EH patients with advanced CKD (NCT03391804). Ox intake was assessed via dietary recall in studies 396 and 713. UOx levels were assessed serially as part of the respective protocols.

Results: There was a consistent effect seen in EH subjects with higher UOx levels across three Phase 2 clinical trials. All EH patients demonstrated an average reduction of at least >20 mg/d across all three studies. On average, patients who had a >50 mg/24h baseline UOx, demonstrated a >30 mg/d or ≥24% reduction in UOx across all studies. The results of these Phase 2 studies support the design of the ongoing Phase 3 program for UOx in EH.

Conclusions: Consistent with the mechanism of action of reloxaliase, patients with higher baseline UOx appear to benefit from a therapy that degrades oxalate in the GI tract before systemic absorption.

Association Between Probiotic Intake and Inflammation in CKD Patients

Sandra Wagner,[1,2] Thomas Merkling,[1] Marie Metzger,[3] Maurice Laville,[4,2] Luc Frimat,[5] Christian Combe,[6] Ziad Massy,[7,2] Benedicte Stengel,[8,2] Denis Fouque.[9,2] *[1]University of Lorraine, INSERM CIC 1433, Nancy CHRU, Inserm U1116, Nancy, France; [2]FCRIN INI-CRCT, Nancy, France; [3]CESP U1018, INSERM, Villejuif, France; [4]Department of Nephrology, Centre Hospitalier Lyon-Sud, Université de Lyon, UCBL, Carmen, Pierre-Bénite, France; [5]Nancy University Hospital, Vandoeuvre les Nancy, France; [6]CHU de Bordeaux, Bordeaux, France; [7]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [8]CESP, Inserm U1018, Kidney and Heart Team, Villejuif, France; [9]University Claude Bernard, Pierre Benite, France.*

Background: Little is known about the effect of probiotics on inflammation in chronic kidney disease (CKD) and results are inconsistent. Our study aims to investigate the association between probiotic intake and inflammation in patients with CKD.

Methods: This study is based on 900 patients with moderate or advanced CKD from the French CKD-REIN cohort. The intake of both dietary supplements and yoghurts was assessed from a food frequency questionnaire, and divided in 3 classes: probiotics (yoghurts or dietary supplement), regular yoghurts (which contains 2 regulated bacteria strains), and none. Inflammation was defined as CRP>5mg/l. Multivariable logistic regression was performed to assess the cross-sectional association between probiotic intake and inflammation.

Results: Patients' median (IQR) age was 70(63-78) years, eGFR, 31.1(22.8-40.7) ml/min/1.73m^2, CRP, 3.0(1.6-7.2) mg/L and 34% had inflammation. 30% consumed probiotics, 58% regular yoghurts and 12% none. Compared to non-consumers, patients consuming probiotics or regular yoghurts were less likely to have inflammation, although it did not reach significance [OR (95% CI): 0.64 (0.40;1.01), P = 0.05, and 0.75(0.49;1.15), P = 0.2, respectively]. After adjustment for co-morbidities, socio-demographics and nutrients intake, probiotic intake was associated with a significant decrease in the risk of inflammation [0.57 (0.35;0.94); P = 0.03], while the association was weaker and non-significant for regular yoghurts [0.67(0.43;1.04); P = 0.08].

Conclusions: Probiotic intake, but not regular yoghurts, was found to be associated with lower odds of inflammation.

SA-PO817

Dietary Fiber Intake Is Associated with Indoxyl Sulphate in Hemodialysis Patients

Denise Mafra,[1] Natalia A. Borges,[1] Lia S. Nakao.[2] Nutrição em Nefrologia *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]UFPR, Curitiba, Brazil.*

Background: Gut microbiota imbalance is a common complication in chronic kidney disease (CKD) patients. This dysbiosis is linked to increased gut-derived uremic toxins production such as indoxyl sulphate (IS), involved with inflammation and oxidative stress in these patients. Lifestyle modifications may have significant favorable effects on reduction of uremic toxins from the gut microbiota, as increased dietary fiber intake which seems to be associated with gut microbiota modulation and reduction on uremic toxins production. The aim of this study was to verify a possible relationship between fiber intake and IS plasma levels in hemodialysis (HD) patients.

Methods: In this cross-sectional study, 50 HD patients were evaluated. Indoxyl sulphate plasma levels were measured by Reversed-Phase High-Performance Liquid Chromatography (HPLC) and, the food intake was assessed using a 3-day 24-hour dietary recall.

Results: Table 1 shows the characteristics and food intake parameters of the HD patients evaluated. The IS plasma levels were negatively correlated with fiber intake (r = - 0.32, p = 0.02, Figure 1).

Conclusions: Our results suggest that increasing dietary fiber intake the IS plasma levels can be reduced in hemodialysis patients, probably due the gut microbiota modulation.

Funding: Government Support - Non-U.S.

Table 1. Characteristics and food intake parameters of the HD patients.

Parameters	Results
Age (years)	54.1 ± 10.4
BMI (kg/m2)	26.2 ± 4.8
Time on HD (months)	47 (28 -78)
Kt/V	1.4 ± 0.3
Energy Intake (Kcal/Kg/day)	19.0 ± 8.0
Protein Intake (g/Kg/day)	1.0 ± 0.3
Fiber Intake (g/day)	16.0 ± 7.6
Indoxyl sulfate (mg/dL)	28.0 ± 14.2

Resistant Starch Supplementation Attenuates Inflammation in Hemodialysis Patients

Denise Mafra,[1] Bruna Paiva,[1] Marta Esgalhado,[1] Natalia A. Borges,[2] Julie ann Kemp,[1] Ludmila F. Cardozo,[3] Jessyca S. Brito,[2] Paulo emílio C. Leite,[5] Renata D. Macedo,[3] Gutemberg G. Alves.[4] Nutrição em Nefrologia *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Universidade Federal Fluminense, Rio de Janeiro, Brazil; [3]Federal Fluminense University, Niterói, Brazil; [4]Fluminense Federal University, Rio de Janeiro, Brazil; [5]INMETRO, Rio de Janeiro, Brazil.*

Background: Dysbiosis in chronic kidney disease (CKD) is linked to oxidative stress and inflammatory response. Researchers have investigated strategies capable of reestablishing the symbiosis of the gut microbiota in CKD, and suggested that resistant starch (RS) can promotes many benefits, including immunomodulatory effects. The aim of the study was to evaluate the impact of RS supplementation on levels of some inflammatory markers in hemodialysis (HD) patients.

Methods: A double-blind, placebo-controlled, randomized trial was conducted with sixteen HD patients [55.3 ± 10.0 years, BMI, 25.9 ± 5.42 kg/m^2, 56% men, time on dialysis 38.9 ± 29.2 months] that were equally divided in RS (16 g of RS HI-MAIZE 260, Ingredion®) or placebo (manioc flour) groups, to receive alternately 9 cookies/day (dialysis days) and 1 sachet/day (non-dialysis days) for 4 weeks. Cytokines and growth factors plasma levels were evaluated by XMap-labeled magnetic microspheres based multiparametric immunoassay (LuminexCorp, USA), before and after supplementation.

Results: After RS supplementation there was a reduction of Normal T Cell Expressed and Secreted (RANTES) (p<0.001), Platelet-derived growth factor two B subunits (PDGF-BB) (p=0.014) and Interferon-inducible protein 10 (IP-10) (p=0.027) (Fig 1). The other parameters did not change significantly.

Conclusions: The results of this randomized study suggested that supplementation with prebiotic, specifically RS, was able to minimize the inflammation in CKD patients on HD. These findings support the hypothesis that the use of prebiotics can be an effective non-pharmacological intervention in reducing the inflammatory state in CKD patients.

Effects of Anti-Inflammatory and Insulin Sensitizing Agents on Markers of Inflammation and Protein Turnover in Maintenance Hemodialysis (MHD) Patients

Aseel Alsouqi,[1] Serpil muge Deger,[4] Adriana Hung,[2] Edward D. Siew,[3] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA & Vanderbilt University, Nashville, TN; [3]Vanderbilt University School of Medicine, Nashville, TN; [4]Vanderbilt University Faculty of Medicine Department of Nephrology, Nashville, TN.*

Background: Systemic inflammation and insulin resistance are associated with increased protein catabolism leading to protein energy wasting in MHD patients.

Methods: We studied the metabolic effects of a PPAR-gamma agonist (pioglitazone-TZD 30 mg daily, N=9) and an Interleukin-1 receptor antagonist (anakinra subcutaneous injections 3 times weekly during hemodialysis, N=7) versus placebo (n=8) over 3 months in MHD patients through a randomized placebo-controlled trial. Whole body and skeletal muscle protein turnover, inflammatory markers and body composition were measured at baseline and 12 weeks after intervention in all patients (Total N = 24). The primary outcome was change in whole-body protein balance (WBPB) measured by stable isotope technique. Inflammatory markers and lean body mass (LBM) were secondary outcomes.

Results: There were no significant demographic or clinical differences at baseline between groups. There were no statistically significant differences in whole-body protein balance between groups over 3 months (Table 1). Patients in the pioglitazone group demonstrated a significant decline in HsCRP concentrations compared to placebo (p= 0.03), but there were no statistically difference in changes in IL-6 for either group. There were no statistically significant differences between groups regarding changes in lean body mass or fat mass in any of the study groups.

Conclusions: In this pilot mechanistic trial, we were not able to demonstrate a significant change in whole body protein balance and lean body mass with 3-month administration of anakinra or pioglitazone in MHD patients. While these results indicate a lack of efficacy of the anti-inflammatory and insulin sensitizing interventions tested in this study, our analyses could be limited by relatively small number of subjects and duration of intervention.

Low Dietary Fiber Consumption Contributes to Gut Dysbiosis with Increased Fecal Indole and Circulating Indoxyl Sulfate in CKD Patients

David Chih-Yu Yang,[1,2] Der-Cherng Tarng.[1] [1]*Taipei Veterans General Hospital, Taipei, Taiwan;* [2]*Institute of Clinical Medicine, National Yang-Ming University School of Medicine, Taipei, Taiwan.*

Background: Recent advances in the understanding of the role of gut microbiota and its function and composition in health and disease have revealed previously unappreciated effects of CKD-associated colonic pathology on the development of uremic complications. We aim to investigate the relationship between dietary content, gut microbiota, fecal bacterial metabolites, and circulating gut-derived uremic toxins in CKD patients.

Methods: We obtained dietary frequency questionnaires, blood, and stool samples for patients in CKD stage 5, and healthy controls. We examined and analyzed their gut microbiome by 16S rRNA sequencing and fecal indole amount. Also, we successfully developed a method for quantification of the indole level in human fecal samples.

Results: We enrolled 62 patients, among which 40 patients were CKD stage 5. Compared to healthy controls (n = 22), and we found a distinct gut microbiome between groups. Next, we stratified study subjects into age-matched subgroups, and we found that though the most dominant phylum was *Bacteroides* within each group, its relative abundance in the CKD group was much higher than the other two control groups. Second, three genera *Fusobacterium, Shewanella*, and *Erwinia* were present in the CKD group, but not in the others (Fig. 1). Besides, in contrast to the sum of relative abundance of the common top 10 genera in the control groups and the top 10 genera within individuals, the microbial composition of the fecal community were much diverse in a CKD patient than in the controls (Fig. 2). Furthermore, we also found that dietary fiber consumption is less, and fecal indole is higher in CKD patients (Fig. 3). Interesting, through combining FFQ and nutrient quantification, we identified that the circulating levels of total p-cresol sulfate negatively correlated with fiber-rich and ascorbic acid-rich diet intake.

Conclusions: Vegetables and fruits are enriched with dietary fibers but were instructed to be restricted in patients with advanced CKD to avoid hyperkalemia. Our data proved that such fiber-restricted diet creates an intestinal environment which is unfriendly for beneficial microbial flora with subsequent local and systemic inflammation as evidenced by increased fecal indole and increased the circulating level of indoxyl sulfate.

SA-PO821

Effect of Cranberry Extract (Vaccinium macrocarpon) on Inflammation, Oxidative Stress, and Uremic Toxins in CKD Patients

Denise Mafra, Laís G. Moreira, Natalia A. Borges, Ludmila F. Cardozo, Jessyca S. Brito, Bruna Paiva, Viviane O. Leal, Karla thais R. Teixeira, José C. Carraro-Eduardo. Nutrição em Nefrologia *Federal Fluminense University, Niterói, Brazil.*

Background: Chronic kidney disease (CKD) patients present many complications that potentially could be linked to increased cardiovascular risk such as inflammation, oxidative stress and high levels of uremic toxins from gut microbiota. Bioactive compounds from food may reduce these complications, such as polyphenols present in fruits like cranberry, which have antioxidant, anti-inflammatory and prebiotics properties.

Methods: In this randomized, double-blind, placebo-controlled study, 30 non-dialysis CKD patients were randomized to receive cranberry dry extract (1000 mg/day containing 72mg of proanthocyanidins) or placebo (1000mg/day of corn starch) for 2 months. Blood samples were collected at baseline and after intervention. The mRNA expression of factor erythroid 2-related factor 2 (Nrf2) and nuclear factor-kappa B (NF- κB) was evaluated by real-time PCR. Uremic toxins plasma levels [indoxyl sulfate (IS), p-cresyl sulfate (PCS), and indole-3-acetic acid (IAA)] were obtained by Reversed-Phase HPLC and, the analysis of thiobarbituric acid reactive substances (TBARS) were also performed.

Results: Twenty-seven patients concluded the study: 13 patients in the cranberry group (55.7 ± 7.5 years, 5 males) and 14 in the placebo group (57.7 ± 5.7 years, 4 men). Treatment adherence was above 96% in both groups. There was no significant difference in NF-κB or Nrf2 mRNA expression after cranberry supplementation [0.91 (0.62 – 1.19) to 1.20 (0.75 – 1.80), p=0.21 and 1.31 (0.59 – 2.95) to 0.99 (0.61 – 1.25), p=0.57), respectively]. TBARS levels did not change after cranberry supplementation. The uremic toxins plasma levels also did not change [IS: 2.97 (1,28 – 4.42) mg/L to 2.86 (1.32 – 4.14) mg/dL, p=0.53; PCS: 14.94 mg/L (7.12 – 23.53) to 17.63 (5.74 – 23.50)mg/L, p=0.48; IAA: 758.99 (608.5 – 1237.4) μg/L to 664.5 (500.5 – 1592.3) μg/L, p=0.58). There were no significant differences in the placebo group.

Conclusions: Short-term cranberry dry extract supplementation does not appear to influence inflammation, oxidative stress and uremic toxins in non-dialysis CKD patients. Long-term studies with different doses are needed to determine whether cranberry dry extract may affect these markers in CKD patients.

Effect of the Dietary Antioxidant Supplement Alpha Lipoic Acid on Nuclear Reduced Glutathione Levels in Kidney Cortex and Medulla from Young Rats

Marianna J. Zamlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN.*

Background: Supplementation with antioxidants, such as alpha lipoic acid, are thought to be beneficial since they can increase the level of reduced glutathione (GSH) inside cells. GSH is the major antioxidant inside cells and provides protection against damage by free radicals produced as a consequence of oxidative metabolism. Previous studies have reported that GSH levels in mitochondria from kidney, liver and heart are significantly increased with alpha lipoic acid supplementation in old rats, but not in young rats. This suggest that dietary antioxidant supplementation may not always be beneficial in young rats. The purpose of this study was to determine whether the nucleus in kidneys from young rats does respond to alpha lipoic acid supplementation with an increase in GSH levels.

Methods: Young female Experimental Lewis rats (3 months of age; n=7) received alpha lipoic acid (100 mg/Kg) via i.p injection for one week. Age-matched Control rats (n=4) did not receive any supplementation. The kidneys were harvested from anesthetized rats, and the cortex and medulla were separated and homogenized. The nuclear fractions were isolated using differential centrifugation. The GSH and total glutathione (Tot GLUT; GSH plus oxidized GSH) were measured with a spectrophotometric assay. The GSSG (oxidized GSH) levels were determined from the difference between Tot GLUT and GSH levels, and then divided by 2. Comparisons were done using a Student's T Test.

Results: There was a significant increase in nuclear GSH levels in the kidney cortex and medulla with dietary supplementation with alpha lipoic acid. This was accompanied by a significant decrease in nuclear GSSG levels. Nuclear Tot GLUT levels did not change or were decreased following supplementation.

Conclusions: The nucleus in kidney cells from young rats does respond to alpha lipoic acid supplementation with an increase in GSH levels.

Effect of Alpha Lipoic Acid on Nuclear GSH Levels in Young Rat Kidney

Changes in Metabolic Syndrome Components Affect the Incidence of ESRD in the General Population: A Nationwide Cohort Study

Eun Sil Koh,[1] Jongho Son,[1] Sungjin Chung,[1] Seok Joon Shin,[2] Cheol Whee Park,[1] Chul Woo Yang,[3] Hyuk-Sang Kwon.[1] [1]*The Catholic University of Korea College of Medicine, Seoul, Republic of Korea;* [2]*Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Incheon, Republic of Korea;* [3]*Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: Few studies have investigated the impact of a change in metabolic syndrome (MetS) components on clinical renal outcomes in the general population.

Methods: Using nationally representative data from the Korean National Health Insurance System, 13,310,924 subjects without chronic kidney disease who underwent two health examinations over 2 years and were free from end-stage renal disease (ESRD) from 2009 to 2012 were followed to the end of 2016. The subjects were divided into four groups according to the change in MetS components between the two visits over 2 years: no MetS (–/–), post-MetS (–/+), pre-MetS (+/–), and both MetS (+/+).

Results: The proportion of patients in the no-MetS (–/–), post-MetS (–/+), pre-MetS (+/–), and both-MetS (+/+) groups was 61.3%, 10.8%, 8.3%, and 19.5%, respectively. After a median follow up of 5.11 years, 18,582 incident ESRD cases were identified. In the multivariate adjusted model, the hazard ratio (HR) and 95% confidence interval (CI) for the development of ESRD in the both-MetS (+/+) group compared with the no-MetS (–/–) group was 5.65 (95% CI, 5.42–5.89), which was independent of age, sex, and baseline estimated glomerular filtration rate. Additionally, the HR for the pre-MetS (+/-) group versus the no-MetS (–/–) group was 2.28 (2.15–2.42). In subgroup analysis according to renal function, the impact of a change in MetS on the incidence of ESRD was more pronounced in individuals with advanced renal dysfunction.

Conclusions: Subjects with resolved MetS components had a decreased risk of ESRD, but not as low as those that never had MetS components. This provides evidence supporting the strategy of modulating MetS in the general population to prevent the development of ESRD.

Abdominal Fat, Physical Function, and Their Associations with Insulin Resistance, Inflammation, and Adipokines in CKD

Sankar D. Navaneethan, John P. Kirwan, Erick M. Remer, Erika Schneider, Bryan Addeman, Susana Arrigain, Jeffrey C. Fink, James P. Lash, Charlie Mckenzie, Mahboob Rahman, Panduranga S. Rao, Jesse D. Schold, Tariq Shafi, Jonathan J. Taliercio, Raymond R. Townsend, Harold I. Feldman. *CRIC VAP Study team, Houston, TX*.

Background: Adiposity and physical inactivity are major drivers of cardiometabolic risk, and may confer differential metabolic risk profile in CKD. We examined the associations of visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT) and physical function with inflammation, insulin resistance, adipokines in those with CKD.

Methods: We obtained MRI of the abdomen and pelvis, and 400m walk test to assess the VAT, SAT volume and physical function among 419 CRIC study participants using a standardized protocol. We also measured markers of inflammation (IL-beta, IL-6, TNF-R1, and TNF-R2), insulin resistance (HOMA-IR), and adipokines (adiponectin- total and HMW, resistin, and leptin). We evaluated the associations between VAT, SATvolume and physical function, and individual markers (log-transformed values) adjusting for relevant confounders.

Results: Mean age of the study population (n=419) was 64.3 years; 40% were females, and the mean eGFR was 55.7 (+/- 18.4) ml/min/1.73 m^2. Over 85% of them were overweight or obese, and 39% were diabetics. Each SD higher VAT and SAT were associated with lower levels of total and HMW adiponectin, and higher levels of leptin and insulin resistance [Figure]. However, higher 400m walk time was associated only with higher levels of plasma IL-6 and TNFR-1 [Figure].

Conclusions: The observations that greater adiposity is associated with altered adipokine profile and insulin resistance, while lower levels of physical function are related to enhanced inflammation in CKD are intriguing. A deeper understanding of the reasons for these differential associations may lead to new approaches to management of patients with CKD.

Associations Between Visceral Obesity and Renal Impairment in Medical Checkup Participants

Yoshikazu Miyasato,[1] Koji Oba,[1] Shinji Yasuno,[2] Yutaka Matsuyama,[1] Izuru Masuda.[3] *[1]The University of Tokyo, Tokyo, Japan; [2]The Jikei University School of Medicine, Tokyo, Japan; [3]Takeda Hospital, Kyoto, Japan.*

Background: Obesity has been reported to be a risk factor for chronic kidney disease, which is now considered one of the most important public health issues worldwide. We aimed to evaluate the relationships between obesity indicators (visceral fat area [VFA], body mass index [BMI], waist circumference, waist-to-height ratio, and visceral-to-subcutaneous fat ratio [VSR]) and changes in kidney function and the risk of proteinuria, and to determine the most sensitive obesity indicator to predict a decline in kidney function and new-onset proteinuria.

Methods: Design: Retrospective cohort study. **Setting:** Routine medical check-up program at two Japanese hospitals. **Participants:** Subjects who underwent VFA measurements during medical checkups in 2012 at Takeda Hospital Group Medical Examination Centers were included. The follow-up period was from April 2012 to March 2018. **Exposures:** Obesity was defined using a separate baseline value of each indicator: VFA (≥100 cm^2), BMI (≥25 kg/m^2), waist circumference (≥85 cm for men and ≥90 cm for women), waist-to-height ratio (≥0.5), and VSR (≥0.4). **Main outcomes measures:** Changes in estimated glomerular filtration rate ($eGFR_{cr}$) and time to new-onset proteinuria were measured. **Statistical analysis:** The relationships between obesity indicators and $eGFR_{cr}$ were evaluated using a linear mixed effects model. The relationships between obesity indicators and new-onset proteinuria were evaluated using Poisson regression analysis.

Results: Analysis was performed on 2,753 subjects (mean age 50.3 years [standard deviation 10.0], 1,419 men, 1,334 women). The VFA ≥100 cm^2 group exhibited a significantly larger difference in the annual change in $eGFR_{cr}$ (-0.24 mL/min/1.73 m^2, p=0.03) than the <100 cm^2 group. Furthermore, there was a significant difference in the proteinuria incidence ratio, which was 1.54 times higher in the VFA ≥100 cm^2 group (95% confidence interval: 1.01 to 2.35). Significant correlations were not observed with any of the other obesity indicators.

Conclusions: VFA ≥100 cm^2 was significantly associated with a greater annual decline in $eGFR_{cr}$ and the higher incidence of new-onset proteinuria. VFA is suggested as the most sensitive obesity indicator for the decline in kidney function and new-onset proteinuria.

The Effect of Bilateral Nephrectomy on Gene Expression of Hypothalamic Neuropeptides Regulating Feeding Behaviors

Kazutoshi Nakazono,[1] Hiromichi Ueno,[2] Kenya Sanada,[3] Yoko Fujimoto,[2] Yoichi Ueta,[2] Yutaka Otsuji,[2] Tetsu Miyamoto.[4] *[1]University of Occupational and Environmental Health, Japan, Kitakyuusyuu-shi, Japan; [2]University of Occupational and Environmental Health, Kitakyushu, Japan; [3]University of Occupational and Environmental Health, Japan, Kitakyushu-shi, Japan; [4]Second Department of Internal Medicine, Kitakyushu, Fukuoka, Japan.*

Background: Anorexia is one of the most widespread eating disorders that appears to contribute to malnutrition in patients with advanced kidney dysfunction. Previously, many neuropeptides synthesized in the hypothalamus have been shown to regulate feeding behavior. While several mechanisms underlying uremic anorexia have been proposed, the hypothalamic neuropeptides that regulate feeding in the hypothalamus of patients with kidney dysfunction are poorly understood.

Methods: The gene expressions of hypothalamic neuropeptides controlling feeding behaviors were evaluated after bilateral nephrectomy, which is a model of acute kidney dysfunction, by *in situ* hybridization histochemistry. Adult male rats received bilateral nephrectomy or a sham operation under anesthesia. The rats were decapitated at 6, 12, and 24 h after treatment. The gene expression of corticotrophin-releasing hormone (CRH) in the paraventricular nucleus (PVN); proopiomelanocortin (POMC), cocaine- and amphetamine-regulated transcript (CART), neuropeptide Y (NPY), agouti-related peptide (AgRP) in the arcuate nucleus; and melanin-concentrating hormone (MCH) and orexin in the lateral hypothalamic area, were quantified by *in situ* hybridization histochemistry. After treatment, cumulative food intake, water intake, and body weight were measured.

Results: Food consumption decreased markedly in bilateral nephrectomized rats. The mRNA levels of *CRH*, *POMC*, *CART*, which suppress feeding behavior, were significantly higher in bilateral nephrectomized rats than in sham-operated rats. On the other hand, the mRNA levels of *NPY*, *AgRP*, *MCH*, and orexin, which promote feeding behavior, were significantly lower in bilateral nephrectomized rats than in sham-operated rats.

Conclusions: The results suggest that hypothalamic neuropeptides regulating feeding behaviors may be involved in the development of anorexia in bilateral nephrectomized rats. This report is the first step to elucidating the physiological mechanisms of anorexia in patients with kidney dysfunction.

SA-PO827

Obestatin Response to a Meal and Association with Subsequent Appetite Sensations in Maintenance Hemodialysis Patients

Ilia Beberashvili,[1] Ada Azar,[2] Ramzia Abu hamad,[1] Shai Efrati.[1] *[1]Nephrology Division, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Nutrition, Assaf harofeh medical center, Zerifin, Israel.*

Background: Obestatin, a physiological opponent of acylated ghrelin, linked to the regulation of appetite reducing food intake in mice but its anorexigenic property in human is controversial. We aimed to investigate a potential role of obestatin in dietary intake regulation by examining response to a meal in maintenance hemodialysis (MHD) patients.

Methods: In this case-control study we have investigated the response of obestatin around a fixed calorie meal (500 kcal) in 21 MHD patients (age 69.2±13.1 years, 10 women, with body mass index 27.2±5.5 kg/m^2). Parallel changes in serum obestatin and insulin levels and subjective scores of appetite (visual analogue scales for hunger, satiety, fullness and prospective food consumption) were recorded on fasting and 30, 60 and 120 min after meal.

Results: In a linear mixed effects model controlling for baseline demographics and clinical parameters including serum insulin concentrations, postprandial levels of obestatin did not change significantly from baseline in response to the meal. The response was the same in MHD patients treated with high or low flux dialyzers. However, postprandial obestatin levels were associated with the rate of change in sensation of fullness (linear estimate: 11.60 (95% confidence interval 0.17 to 23.04, P<0.05). The remained sensations of appetite did not correlate with postprandial obestatin levels in time.

Conclusions: Obestatin levels do not change acutely with food administration in MHD patients, but associate with the changes in sensation of fullness. This supports the possible role of obestatin in the long-term regulation of appetite in MHD population.

SA-PO828

Protective Effect of Leuconostoc in Renal Damage Induced by Obesity

Andrea Sanchez-Navarro,[1,2] Diana C. Castro,[2] Rosalba Pérez-villalva,[1,2] Miguel A. Martinez-Rojas,[1,2] Elena Zambrano,[2] Norma Bobadilla.[1,2] *[1]Molecular Physiology Unit IIB/UNAM, México, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion SZ, Mexico City, Mexico.*

Background: There is enough evidence showing that obesity promotes kidney damage. Probiotics might help in improving several diseases. Mexican honey water contains bacteria known as *Leuconostoc* that have anti-obesity activity. However, its role in prevention of renal injury induced by obesity still unknown.

Methods: Forty three C57BL6 male mice were divided into four groups: control diet, 3.41 Kcal/g (n=10), probiotic control, $2x10^9$ CFU, IG, (n=10), hypercaloric diet, 4.9 Kcal/g, (n=11), and hypercaloric diet+probiotic (n=12). The groups were studied for 3 months and a half. Weekly measurements of weight and caloric intake were made. At the end of the follow-up, the determination of body fat and water was carried out using nuclear magnetic resonance (NMR). Urine was collected to analyze renal function and biomarkers. Tissue was stored for molecular analysis and the other kidney was fixed for histopathological analysis.

Results: At the end of the study, the hypercaloric diet induced a significant increase by 52.1% in body weight (BW) and by 3-fold in body fat (BF), with a reduction in lean mass by 27.4%. Also renal damage was observed that was characterized by a significant increase in: albuminuria, oxidative stress and KIM-1 levels, as well as, kidney inflammation, and TGF-b up-regulation. *Leuconostoc* administration significantly reduced the increase in BW and BF by 14.2% and 42.8%, respectively, with the same food intake. *Interestingly, albuminuria, oxidative stress, and KIM-1 levels in the hypercaloric+probiotic group were similar to control groups. Effects that were accompanied by restoration of IL-6, TNFa, and TGF-b mRNA levels.*

Conclusions: These results show that hypercaloric diet induced metabolic and renal alterations. While, *Leuconostoc* was efficient in preventing weight gain, renal injury, and oxidative stress, as well as, profibrotic and inflammatory pathways activation. Therefore, this probiotic seems to be a feasible and useful tool for the treatment of renal injury induced by obesity; however, controlled clinical studies are required to prove this hypothesis.

Noninvasive Measures of Visceral Adiposity and Risk of Kidney Function Decline

Ujjala Kumar,[1] Orlando M. Gutierrez,[2] Holly J. Kramer,[5] Mark J. Sarnak,[3] Joachim H. Ix,[1] Ronit Katz,[4] Suzanne E. Judd,[2] Mary Cushman,[6] Pranav S. Garimella.[1] *[1]UCSD, San Diego, CA; [2]UAB School of Medicine, Birmingham, AL; [3]Tufts Medical Center, Boston, MA; [4]University of Washington, Seattle, WA; [5]Loyola University Medical Center, Maywood, IL; [6]University of Vermont, Colchester, VT.*

Background: Measures of visceral obesity are better markers of adverse outcomes than body mass index (BMI) and waist circumference (WC). Lipid accumulation product (LAP) and visceral adiposity index (VAI) are novel, non-imaging markers of visceral adiposity calculated by using BMI, WC and serum lipids. We hypothesized that LAP and VAI will be associated with adverse kidney outcomes independent of traditional risk factors.

Methods: Using data from Reasons for Geographic and Racial Differences in Stroke (REGARDS) study, we evaluated the association of LAP, VAI, BMI and WC with (a) 1127 cases of incident CKD, defined as reaching an eGFR <60ml/min/1.73m^2 with at least 25% decline between visit 1 and 2; (b) 1452 cases of >30% eGFR decline using logistic regression; and (c) 353 cases of incident ESRD using Cox regression.

Results: Mean age was 65 years, 54% were women, and 41% were African American. The median time between visit 1 and 2 was 9.4 years. After adjusting for confounders, the top quartiles of VAI, LAP, BMI and WC were associated with higher odds of incident CKD and progressive eGFR decline compared to bottom quartiles. VAI and LAP were associated with an increased risk of ESRD after demographic and risk factor adjustment (HR 1.94; 95% CI, 1.37 to 2.76) but this association was no longer significant after adjusting for baseline eGFR and albuminuria.

Conclusions: Adiposity assessed by measures of generalized and visceral obesity is associated with higher risk of incident CKD and eGFR decline. VAI and LAP are not more strongly associated with CKD and eGFR decline compared to BMI and WC. However, for incident ESRD, VAI and LAP may be valuable for providing useful information beyond BMI and WC (in the models that do not include eGFR/ACR).

Table. 1 Association of adiposity measures with kidney outcomes

	Exposure type	Incident CKD OR (95% CI)*	Progression of eGFR decline OR (95% CI)	Incident ESRD HR (95% CI)
VAI*	Q4 vs. Q1 ≥ 5.92 vs. ≤ 2.31	1.26 (1.02, 1.55)	1.20 (1.00, 1.44)	0.72 (0.50, 1.03)
	Continuous model (per doubling)	1.12 (1.04, 1.20)	1.11 (1.04, 1.18)	0.93 (0.82, 1.04)
LAP**	Q4 vs. Q1 ≥ 339.58 vs. ≤ 124.89	1.51 (1.22, 1.87)	1.36 (1.13, 1.63)	0.82 (0.56, 1.20)
	Continuous model (per doubling)	1.21 (1.13, 1.29)	1.18 (1.11, 1.26)	0.89 (0.81, 0.99)
BMI	Q4 vs. Q1 ≥ 40.0 vs. 18.5 - 24.9	1.74 (1.26, 2.41)	1.45 (1.09, 1.92)	0.58 (0.40, 0.82)
	Continuous model (per doubling)	1.23 (1.14, 1.33)	1.16 (1.09, 1.24)	0.85 (0.76, 0.95)
WC	Q4 vs. Q1 ≥108 (w); ≥122 (m) vs. <80(w); <94 (m)	2.16 (1.68, 2.77)	1.68 (1.36, 2.10)	0.55 (0.39, 0.78)
	Continuous model (per doubling)	1.22 (1.14, 1.32)	1.18 (1.10, 1.25)	0.81 (0.72, 0.91)

* VAI: M= WC/[39.68 + (1.88×BMI)]×TG/1.03×1.31/HDL
F= WC/[36.58 + (1.89×BMI)]×TG/0.81×1.52/HDL
** LAP: M= (WC-65) x TG
F= (WC-58) x TG
+ Adjusted for age, sex, race, CAD, stroke, HTN, DM, smoking, eGFR, UACR

Comparative Study on the Prognostic Value of Body Composition Parameters in Hospitalized Patients with Dialysis

Huijuan Mao,[1] Buyun Wu.[2] *[1]First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Nanjing medical University, Nanjing City, China.*

Background: Body composition is essential to the prognosis of dialysis patients, but comparison of prognostic value of different nutritional and fluid load parameters in the hospitalized patients with dialysis are limited.

Methods: We conducted a prospectively observational study to assess the association of different parameters in body composition with all-cause mortality in dialysis inpatients. The body composition was measured by bioelectrical impedance within the first 3 days after admission and hemodialysis patients should be measured before dialysis session. The parameters in fluid volume included overhydration (OH), the ratio of OH to extracellular water (OH/ECW), the ratio of extracellular water to body cell mass (ECW/BCM), the ratio of extracellular water to intracellular water (ECW/ICW); the parameters in nutritional status included fat tissue index (FTI), lean tissue index (LTI) and body cell mass index (BCMI).

Results: Of the 832 study patients, 191 (23.0%) died during a median follow-up of 31 months. In multivariable adjusted Cox models, higher ECW/BCM (adjusted hazard ratio per 1-SD, 1.30; 95% CI, 1.09 to 1.54) were associated with a significantly greater risk of death, as were lower LTI (adjusted odds ratio per 1-SD, 0.70; 95% CI, 0.59 to 0.83) and BCMI (adjusted hazard ratio per 1-SD, 0.72; 95% CI, 0.62 to 0.84). BMI, FTI and BCM/weight were also associated with death, but the magnitude of the association was greatest for ECW/BCM, LTI and BCMI. When ECW/BCM, LTI and BCMI were added to the fully adjusted model, only LTI improved the predictability for all-cause mortality (net reclassification index =0.15, P=0.04; integrated discrimination improvement =0.02, P=0.01).

Conclusions: ECW/BCM was the most relevant to mortality in fluid volume indices, and LTI and BCMI were most two relevant to mortality in nutritional status indices. Higher LTI was significantly associated with a lower risk of death and exhibited a stronger association with mortality than ECW/BCM, BCMI and other body composition parameters in dialysis inpatients.

SA-PO831

Effect of Age and Gender on the Relation Between Body Fat Area and Kidney Outcomes in Patients with CKD

Kiyomi Osako, Yugo Shibagaki, Tsutomu Sakurada. *Division of Nephrology and Hypertension, Department of Internal Medicine, St Mariannna University of Medicine, Kawasaki, Japan.*

Background: Increase in body fat area has been noted as a risk factor for progression of chronic kidney disease (CKD) as well as cardiovascular disease and death. Similarly, obesity has been shown to be associated with CKD progression, but this association might be interacted with patient's characteristics. Here, we examined obesity assessed by body fat area is related to kidney outcomes in patients with CKD with possible interaction by age and gender.

Methods: We included 367 patients who completed CKD educational program between January 2011 and February 2017. Patients were classified into four groups: male patients under 75yo, (n=164), female patients under 75yo(n=52), male patients 75yo or older(n=98), and female patients 75yo or older(n=53). Body fat area was measured at the level of the umbilicus using an CT-image analysis system. Kidney outcomes was defined as initiation of renal replacement therapy or incidence of 50% reduction in estimated glomerular filtration rate.

Results: The overall mean age of the patients was 73.0 (65.0-78.0) years old, of whom 262 patients (71.4%) were male, and the median estimated glomerular filtration rate based on plasma cystatin C (eGFRcys) was 26.9 mL / min / 1.73 m^2. During the observation period [median 1.7 year (0.7-3.5)], 187 patients reached kidney outcomes. In both univariate and multivariate Cox regression analysis, VFA and SFA were not associated with increased kidney outcome in overall population. However, in males under 75yo, multivariate Cox regression analysis showed SFA but not VFA as significant risk for kidney outcomes (SFA: HR 1.06, 95% CI: 1.02-1.11). In turn, VFA but not SFA was significantly associated with decreased kidney risk in female under 75 yo (VFA: HR 0.83, 95% CI: 0.71-0.97). Moreover, in patients 75yo or older in both sex, multivariate Cox regression analysis failed to show the significant association with kidney outcomes in both VFA and SFA.

Conclusions: Obesity as assessed by body fat area was not a significant risk for CKD progression in very old patients with CKD. In younger patients with CKD, high SFA in males was a significant risk factor for CKD progression, whereas high VFA in females was a significant renoprotective factor. When we consider obesity as a potential risk for CKD progression, we need to consider age and gender.

SA-PO832

Change in Glomerular Filtration Rate After Bariatric Surgery Varies by Baseline Kidney Function

Alex R. Chang,[1] Lesley Inker,[3] Andrew S. Levey,[3] Josef Coresh,[4] Morgan Grams.[2] *[1]Geisinger Medical Center, Danville, PA; [2]Johns Hopkins University, Baltimore, MD; [3]Tufts Medical Center, Boston, MA; [4]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD.*

Background: It is unclear whether GFR decreases after bariatric surgery in individuals with lower baseline GFR who may lack renal functional reserve.

Methods: GFR was measured by plasma iohexol clearance in 27 adults at multiple research visits before and after bariatric surgery (twice pre-surgery, ~6 and 12 months post-surgery). We examined whether changes in GFR after bariatric surgery varied by pre-surgery GFR using generalized estimating equations, clustered by individuals.

Results: Pre-surgery, mean values of body mass index (BMI) and body surface area (BSA) were 49.4 kg/m^2 and 2.42 m^2. Mean unindexed and indexed GFR were 117.3 ml/min (range 57.4 to 206.0) and 84.1 ml/min/1.73m^2 (range 44.3 to 138.0), respectively. Six months after surgery, BMI decreased by 13.9 kg/m^2 (95% CI: -15.9, -11.8) and BSA decreased by 0.30 m^2 (95% CI: -0.34, -0.27). Post-surgery changes in GFR varied by pre-surgery GFR ($p<0.001$ for interaction). Those in the middle and upper tertiles of pre-surgery GFR had declines in unindexed GFR at 6 months post-surgery (upper tertile: -22.6 ml/min, -36.0, -9.2; middle tertile: -12.74, -23.1, -2.4). By contrast, individuals in the lowest tertile (GFR <100 ml/min) did not have a decline in unindexed GFR (8.9 ml/min, -2.2, 20.0). Indexed GFR was unchanged 6 months after surgery in the upper 2 tertiles whereas indexed GFR increased by 15.3 ml/min/1.73m^2(95% CI: 6.4, 24.3) in the lowest tertile. Overall, albuminuria tended to decrease (-41%, 95% CI: -67%, 4%). Findings were consistent in additional analyses accounting for regression to the mean, using GFR measurements from the other visits.

Conclusions: GFR did not decrease after bariatric surgery in severely obese individuals with GFR < 100 ml/min. This may reflect less capacity for physiologic changes in GFR, though we lack the ability to discern physiologic from pathologic decline in GFR.

Changes in GFR after Bariatric Surgery, by Baseline Tertile of GFR

SA-PO833

Dietary Zinc Amount Is Associated with Incident CKD in General Population

Dae-Suk Han, Wonji Jo, Hyung Woo Kim, Youngu su Joo, Ki heon Nam, Jung Tak Park. *Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Previous study suggests that zinc is associated with diabetes. No studies have undergone the association of incident chronic renal disease (CKD) and zinc consumption amount in a preserved renal function population. Data from the Korean Genome and Epidemiology Study, a prospective community-based cohort study were used to assess the between zinc consumption amount and incident CKD.

Methods: Zinc consumption amount was calculated by a 24-h dietary recall Food Frequency Questionnaire and converted into relative zinc consumption amount with energy-adjust method. A. total 7821 participants were analyzed with a primary of incident CKD that defined as estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2.

Results: The mean age was 52.1 ± 8.8 years, 47.5% were male, and mean eGFR was eGFR was 92.1 ± 16.1 ml/min/1.73m^2. The mean daily zinc consumption amount was 8.6 ± 3.4 mg. During a median follow up of 11.5 (1.6 – 13.0) years and 71417 person-year observation, CKD developed in 1428 (18.3%) participants. When the participants were categorized into quartiles according to energy-adjusted zinc intake, the lowest quartile was significantly associated with the development of incident CKD compared to third lowest quartile group in multivariable cox hazard analysis (Hazard ratio; 1.19; 95% Confidence Interval 1.02 – 1.39; P = 0.027) and this finding was consistent after further adjustment. The U shaped hazard association was noted between zinc consumption and incident CKD in restricted cubic spline analysis.

Conclusions: Thus, low zinc consumption was associated with the increased risk for CKD.

SA-PO834

Low Serum Zinc Concentration Is Associated with Infection Events in CKD Patients

Yosuke Saka, Tomohiko Naruse. *Department of Nephrology, Kasugai Municipal Hospital, Kasugai, AIchi, Japan.*

Background: Zinc plays an important role in immune function. Several studies reported the association between zinc deficiency and infection. Infectious disease is one of major complications in CKD patients. We investigated whether serum zinc concentration is associated with infection risk in stage 5 CKD patients.

Methods: We retrospectively analyzed 232 patients in whom serum zinc concentration was measured to evaluate renal anemia between January 2013 and December 2016. Of the 232 patients, 9 patients receiving zinc supplementation at the time of measurement were excluded. We followed up the remaining participants after enrollment. The endpoint was infection-related hospitalization. The length of infection-related hospitalization was also analyzed. Participants were divided into two groups according to the median of serum zinc concentration, categorized as low or high (Zn ≤ 50 and > 50 μg/dl, respectively). Data were analyzed using the Kaplan-Meier method and Cox hazards models.

Results: The median follow-up period was 36 months. During follow-up, 40 patients were hospitalized due to infection. Low serum zinc concentration was associated with a higher rate of infection-related hospitalization (low vs. high: 23.3% vs. 12.6%; p=0.042), and also associated with long-term hospitalization (more than 20 days) due to infection (low vs. high: 17.9% vs. 7.2%; p=0.016). After adjustment in Cox hazards models, low serum zinc concentration remains an independent risk factor for infection-related hospitalization (HR 2.11, 95% CI 1.06–4.21, p < 0.034).

Conclusions: Patients with low serum zinc concentration are at high risk of infection-related hospitalization, which also causes long-term hospitalization.

SA-PO835

Impact of Sodium Bicarbonate ($NaHCO_3$) on Systemic and Urine Metabolites in Patients with and Without CKD

Julia J. Scialla,[1] Jennifer L. Modliszewski,[1] James R. Bain,[1,3] Michael Muehlbauer,[1,3] Olga Ilkayeva,[1,3] Shirin Pourafshar,[2] Crystal C. Tyson,[1] Laura P. Svetkey,[1] David L. Corcoran,[1] Pao-Hwa Lin.[1] *[1]Duke University, Durham, NC; [2]University of Virginia, Charlottesville, VA; [3]Duke Molecular Physiology Institute, Durham, NC.*

Background: Net acid excretion (NAE) falls in early stages of CKD, yet systemic metabolic acidosis (MA) occurs in late CKD. Homeostasis may be maintained by compensatory decrease in acid production. As conjugate bases of endogenously produced acids, organic anions (OAs) lost in the urine are markers of acid production. Modulation of OA excretion may defend against MA and alkalosis. Here we explore changes in urine OAs and potential consequences for systemic metabolism after alkali in a cross-over trial.

Methods: The Acid-Base Compensation in CKD Study was a cross-over trial evaluating 7-days of $NaHCO_3$ vs. 7-days of NaCl supplementation in the setting of fixed diet in adult, non-diabetic patients with (n=8) and without CKD (n=6). 24h urine, and fasting and 90-minute postprandial plasma were collected at the end of each period. We used nontargeted GC/MS metabolomics to explore the excretion of urine OAs and systemic metabolism in plasma. Linear mixed-effects models and discriminant analyses (sparse PLS-DA) were used to identify metabolites that vary with $NaHCO_3$ treatment independently in CKD and non-CKD subjects and overall.

Results: We found 15 urine metabolites higher with $NaHCO_3$ at a nominal p-value <0.05 in CKD participants and 13 lowered in non-CKD. Rise in 3-indoleacetic acid, citric

acid/isocitric acid, and glutaric acid in CKD participants were the only significant changes after false discovery rate (FDR) correction (each p=0.01). These changes were not detected in those without CKD. There were no changes in plasma metabolites overall or in any group after FDR correction. A primary component including higher fatty acids and lower leucine, asparagine, serine and lysine, among others, was identified by sparse PLS-DA in fasting plasma samples from the CKD group after $NaHCO_3$. A component loading directly on fructose, phosphate, urea, valine, leucine and aminomalonic acid, among others, was higher in post-prandial samples overall after $NaHCO_3$.

Conclusions: Several urine OAs were increased by alkali in CKD suggesting possible increased acid production. Changes in sugars, mineral ions, and protein metabolites in the fed state suggest concurrent changes in nutrient metabolism which could represent an additional response to acid-base manipulation.

SA-PO836

Metabolic Acidosis Is Associated with Failure to Thrive and Fractures and Falls in Patients with CKD

Nancy L. Reaven,[1] Susan E. Funk,[1] Vandana S. Mathur,[2] Navdeep Tangri.[3] *[1]Strategic Health Resources, La Canada, CA; [2]Mathur Consulting, Woodside, CA; [3]University of Manitoba, Winnipeg, MB, Canada.*

Background: Metabolic acidosis causes muscle-wasting and bone loss in experimental animal and human studies. However, its association with clinical outcomes in epidemiological studies is unknown. Here we assess the role of metabolic acidosis as an independent predictor of adverse muscle, bone and functional outcomes in patients with non-dialysis CKD.

Methods: De-identified electronic medical records (Optum® EMR), 2007–2017 were queried to identify non-dialysis CKD patients with ≥2 consistent serum bicarbonate test values 28–365 days apart, ≥3 eGFR values >10 and <60 mL/min/1.73m^2 and ≥2 years of post-index data or until death. Patients were followed for 2 years for adverse outcomes using ICD codes: failure to thrive (muscle/functional outcome); composite of hip, spine, pathological fractures or falls (bone outcome). Metabolic acidosis and normal serum bicarbonate groups were defined by two serum bicarbonate values between 12 and <22 mEq/L and 22-29 mEq/L, respectively. Logistic regression was used to examine serum bicarbonate as an independent predictor of 2-year outcomes and possible demographic and comorbidity confounding factors.

Results: 51,558 patients qualified for this longitudinal observational study. The incidence of adverse outcomes was significantly higher in patients with metabolic acidosis during the 2-year follow-up compared to patients with normal serum bicarbonate: muscle outcomes: 6.5% vs. 1.9%, p<0.0001; bone outcomes: 17.3% vs. 11.6%, p<0.0001, respectively. Serum bicarbonate was a significant predictor of both types of outcomes; odds ratios for failure to thrive, 0.883, CI: 0.869-0.898, and for fracture/fall, 0.948; CI: 0.939-0.956, independent of age, sex, race, eGFR, diabetes, hypertension, heart failure, coronary artery disease, peripheral vascular disease, hemoglobin and serum albumin. Each 1 mEq/L increase in serum bicarbonate was associated with a 12% decrease in failure to thrive and a 5% decrease in fracture/fall risk.

Conclusions: In this analysis of > 51,000 non-dialysis CKD patients followed for 2 years, metabolic acidosis was independently associated with increased incidence of failure to thrive and the composite endpoint of fractures (hip, spine, or pathological) and falls.

Impact of a Virtual Multidisciplinary Care Management Program for Advanced CKD on Patient Knowledge, Dialysis Modality Choice, and Planned Dialysis Start

Carmen A. Peralta,[2] Paulina Kaiser,[1] Olivia Pipitone,[1] Dixie R. Jackson,[1] Anthony Franklin,[1] Chris R. Dubuque,[4] Elizabeth A. Moore,[1] Anthony C. DeMory.[3] *[1]Samaritan Health Services, Corvallis, OR; [2]Cricket Health, UCSF, San Francisco, CA; [3]Samaritan Kidney Specialists, Corvallis, OR; [4]Good Samaritan Regional Medical Center, Grants Pass, OR.*

Background: Among persons with advanced chronic kidney disease (CKD), education and preparation for renal replacement therapy (RRT) remain suboptimal. We conducted a pilot study to evaluate the impact of a virtual multidisciplinary care program including a nurse, dietitian, pharmacist, and peer mentors for patient education, monitoring, and managing transitions to RRT.

Methods: We invited adults with eGFR <30 ml/min/1.73m^2 not on RRT from a community-based nephrology clinic into Cricket Health's online multidisciplinary care program. We compared CKD knowledge, confidence in disease self-management, and first choice of RRT modality before and after education. Then, in a matched prospective cohort design, we evaluated the association of program participation with planned RRT initiation (in-hospital vs. outpatient planned) after 9 months using conditional logistic regression. For each participant, we identified 1 to 2 controls from the same clinic, matched on age, gender, baseline eGFR, diabetes, and heart failure status.

Results: Among 50 invited, 37 (74%) enrolled, with average age 66 (SD=13), eGFR 19 ml/min/1.73m^2 (SD=6), 68% female, and 53% diabetic. 36 participants (97%) completed a pre-program survey, and 23 (62%) completed a post-education survey. After education, the average percent correct on a 7-item CKD knowledge assessment increased from 52% to 89%, p<0.001. The percent reporting confidence in self-care dialysis was 83% after education, compared with 64% prior, p=0.22. Before education, 50% were unable to choose a RRT modality. After education, 91% of respondents made a choice, of whom 76% preferred a home RRT modality. At 9 months, 5 program participants and 5 controls started RRT. A total of 4 of 5 program participants (80%) started RRT as outpatients with planned starts, compared with 1 of 5 controls (20%) (OR=6.3, 95% CI=0.7-57, p=0.06).

Conclusions: A virtual multidisciplinary care program for persons with advanced CKD improves patient CKD knowledge, confidence in self-care, and interest in home RRT. Our findings also suggest this virtual multidisciplinary care program may increase the likelihood of planned RRT initiation.

Validation of a Smartphone-Based Proteinuria Testing Solution

Alan S. Go,[1,2] Chi-yuan Hsu,[2,1] Hui-Ling Koh,[3] Stephen Chen,[3] Pavel Bozdog,[3] Kate M. Horiuchi,[1] Ellen N. Boyer,[1] Thida C. Tan.[1] *[1]Kaiser Permanente Northern California, Oakland, CA; [2]Nephrology, University of California, San Francisco, San Francisco, CA; [3]Scanwell Health, Los Angeles, CA.*

Background: Proteinuria is a potent risk factor for ESRD. Guidelines recommend screening and monitoring for urinary protein in those with or at high-risk for CKD, but this involves lab or clinic procedures that contribute to undertesting. A valid smartphone-based testing solution could facilitate widespread testing.

Methods: We prospectively evaluated the feasibility and accuracy of a smartphone-based urinary protein testing platform in a sample of adults with CKD not receiving dialysis enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study at Kaiser Permanente Northern California/UCSF. The urinary protein testing solution involves a smartphone-based app combined with a color-calibration card and urinalysis dipstick (Scanwell Health, Inc.)(**Figure**). Participants provided a urine sample that was tested using (1) the smartphone-based testing platform and (2) Clinitek urine dipstick analyzer. Test results were reported as negative, trace, 1+, 2+ or >=3+ proteinuria.

Results: Eighty-seven participants were enrolled, with mean (SD) age 70 (9) years, 53% women, 31% black, 8% Asian, 5% Hispanic, 24% with diabetes and mean (SD) eGFR 57 (17) ml/min/1.73 m^2. Based on results from the clinical Clinitek analyzer, 32 (37%) had evidence of proteinuria. The smartphone-based testing solution exactly matched the categorical result in 61% of patients, while 82% were within one category level of proteinuria compared with the Clinitek analyzer result.

Conclusions: We found a high level of concordance for a semi-quantitative smartphone-based proteinuria testing platform compared with a clinical standard within a diverse sample of adults with CKD. Our study supports the utility of a smartphone-based testing solution to expand proteinuria screening and monitoring.

Smartphone-based urinary protein testing solution

SA-PO839

Evaluation, Classification, and Identification of CKD Progression in Rhesus Macaques

Zunyuan Yang,[1] Yinan Liang,[1] Li Gong,[1] Wen Zeng,[1] Barbara Hansen.[2] *[1]Sichuan Primed Shines Bio-tech Co., Ltd., Chengdu, China; [2]Dept Int Med, Univ of So Florida, Tampa, FL.*

Background: Chronic kidney disease (CKD) is characterized by progressive reduction in kidney function, and with accelerated cardiovascular disease and increased mortality. The goal of the present study was to characterize naturally occurring CKD in rhesus monkeys in comparison to the CKD of humans, to explore the relationship between CKD and CVD, and to evaluate the response of rhesus monkeys with combined CKD-CVD to the angiotensin receptor blocker, Valsartan.

Methods: Plasma biomarkers (Creatinine (Cr), Cystatin-C (CYSC), and Blood Urea Nitrogen (BUN)) were measured in 1198 adult rhesus monkeys (*Macaca mulatta*, 7-22 yrs). Four hr urine collections were obtained from 100 of these monkeys in order to measure urine albumin and urine creatinine for calculation of the urine albumin/creatinine ratio (UACR). Monkeys with eGFR (CKD-EPI) 30-59 ml/min/1.73m^2 and/or UACR≥10mg/g were defined as having CKD (Grade G3a-3b). Blood pressure and cardiac function were measured, monkeys with LVEF<50%, e'<8 cm/s and E/e'>10 were defined as having CVD. A colony of 37 adult male monkeys received medical examinations and direct GFR measurements (Iohexol clearance). Eight monkeys with combined CKD-CVD were enrolled in the validation study and divided into the Valsartan group (n=4)(3 mg/kg, Bid) and the vehicle group (n=4). Cardiac function, blood pressure and UACR were measured before and after 8 weeks treatment. Cr, CYSC, BUN and eGFR were measured every 2 weeks.

Results: Among the 1198 adult rhesus monkeys studied, 52 monkeys (4.3%) had eGFR 30-59 ml/min/1.73m^2 and/or UACR≥10mg/g. Among the 52 monkeys with CKD, 30 monkeys had confirmed CVD. With Valsartan treatment, average eGFR increased by 23.31%; average UACR decreased by 76.45%; and average SBP decreased by 14.40%. All of these biomarkers differed significantly compared to the vehicle group (p's<0.05). The cardiac ultrasound parameters remained stable.

Conclusions: The 4.3% incidence of CKD in adult rhesus monkeys was similar to that in adult humans, and 58% of those with CKD also had CVD as in patients. Valsartan increased eGFR, and also decreased UACR and BP in monkeys. The extent of change in rhesus monkeys was similar to that observed in clinical trials. These monkey models, therefore, provide important new opportunities to understand the pathogenesis of CKD and predict the human response to new therapeutic agents.

SA-PO840

Use of Kidney Disease Progression Model Care Planning Report Associates with Lower Dialysis Catheter Rates at the Initiation of Hemodialysis

Yue Jiao,[1] Nelson P. Kopyt,[5] Ravindra Bollu,[5] Kylene Casey,[2] Sam Gopal,[2] John W. Larkin,[1] Peter Kotanko,[3] Yuedong Wang,[4] Jeffrey L. Hymes,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Acumen Physician Solutions, Durham, NC; [3]Renal Research Institute, New York, NY; [4]University of California - Santa Barbara, Santa Barbara, CA; [5]Valley Kidney Specialists, A Division of Kidney Care Specialists, Allentown, PA.*

Background: Approximately 80% of end stage kidney disease (ESKD) patients use a central venous catheter (CVC) at the initiation of hemodialysis (HD) (USRDS 2018). A healthcare organization developed a CKD Forecaster Tool for nephrologists to use for prognostic clinical decision support and patient education in care planning for the transition from CKD to ESKD. We assessed CVC rates at the initiation of HD based on the nephrologists' level of utilization of the CKD Forecaster Tool.

Methods: We used data from CKD patients treated by nephrology practices using Acumen Electronic Health Record system who progressed to ESKD during April 2018 to October 2019. The CKD Forecaster Tool uses an artificial intelligence modelling of historic eGFR values to predict the trajectory of eGFR values in the future. We assessed CVC rates at HD initiation in patients who progressed to ESKD stratified by the frequency of their nephrologist accessing the CKD Forecaster Tool. Only nephrologists with ≥15 CKD patients who transitioned to ESKD were used for the analysis. Frequent users accessed the tool on >1% of their CKD patients, occasional users accessed the tool on >0-1% of their CKD patients, and non-users did not use the tool.

Results: Among a population of 106,915 CKD patients treated by 309 nephrologists, we analyzed data on 6,917 patients who progressed from CKD to ESKD (this includes only nephrologists with ≥15 CKD patients who transitioned to ESKD). A total of 30 nephrologists were frequent users of the CKD Forecaster Tool, 39 were occasional users, and 240 were non-users. Patients treated by nephrologists who used the CKD Forecaster Tool exhibited 1% to 2% lower CVC rates at HD initiation (Figure 1).

Conclusions: Nephrologists who used the CKD Forecaster Tool had slightly less patients transitioning to HD with a CVC. Further assessments are needed to determine if greater adoption and consistent use of the CKD Forecaster Tool over time is associated with larger improvements.

SA-PO841

Added Value of Census Tract Measures of Socioeconomic Status to Identify Patients at High Risk of CKD in the Twin Cities Metro Area

Lama Ghazi, Paul E. Drawz. *University of Minnesota, Saint Paul, MN.*

Background: CKD is associated with low socioeconomic status (SES); however, guidelines do not recommend screening low SES patients for CKD. Our objective was to assess whether adding census tract level SES status to the traditional CKD screening approach improves our ability to detect patients with CKD.

Methods: Electronic health records of 256,212 patients with outpatient serum creatinine available who received primary care at a health system serving the 7 county Minneapolis/St Paul metro area. CKD was defined as having an estimated glomerular filtration rate <60 ml/min/1.73m^2 or proteinuria. We compared 3 screening approaches: Approach 1(traditional), screening patients with diabetes(DM) or hypertension(HTN); Approach 2A, DM, HTN, or low census tract SES-housing (quartile 1 of the median value of owner occupied housing units); Approach 2B, DM, HTN, or low census tract SES-education (quartile 1 of percent of residents >= 25 years with complete college education); Approach 3A, screening patients with low census tract SES-housing; Approach 3B: screening patients with low census tract SES-education.

Results: In our cohort, 34,489 patients had CKD. Adding low census tract SES (Approach 2A and 2B), significantly increases the sensitivity of detecting CKD (Table1). Number needed to screen to detect 1 CKD case was 4, 5, 5, 8, and 7 for Approaches 1, 2A, 2B, 3A, and 3B, respectively.

Conclusions: Adding an individuals' residence SES status to traditional risk factors improved our ability to detect individuals at risk of CKD who may benefit from interventions to reduce risk of cardiovascular disease and progression of CKD.

Table 1. The sensitivity, specificity, positive predictive and negative predictive value of the screening approaches for detecting CKD.

	Number of CKD cases detected	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
Approach 1	17,117	50	77	25	91
Approach 2A	18,769	54	69	22	91
Approach 2B	19,192	56	68	21	91
Approach 3A	3,439	10	90	13	87
Approach 3B	4,303	13	88	14	87

SA-PO842

Outcomes from Development of a Unique Statewide Platform to Improve CKD Care

Andrea K. Easom,[1] Nadia M. Alqurini,[4] Nishank Jain,[3] John M. Arthur,[4] Manisha Singh.[2] *[1]Nephrology, UAMS, Little Rock, AR; [2]University of Arkansas For Medical Sciences, Little Rock, AR; [3]Little Rock VA Hospital, Little Rock, AR; [4]University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: The division of Nephrology at University of Arkansas for Medical Sciences (UAMS) and Arkansas health department faculty co-investigated a pilot project identifying barriers to chronic kidney disease (CKD) awareness in the State of Arkansas (AR). These included a lack of infrastructure and patient and provider education. To address these barriers, our core investigators reached out to potential stakeholders. We invited a multidisciplinary team of health-care professionals to partner with non-profit organizations and CKD patients, creating the platform of the Arkansas State CKD Advisory Committee (ARCKDAC), with a mission to increase CKD awareness, detection and education through community engagement activities. We also provided baseline AR data to improve systems of care and generate data for future research.

Methods: ARCKDAC focused on 4 projects: 1) Analysis of end-stage renal disease (ESRD) incident data provided by ESRD Network-13 identifying regional differences. 2) Compile a cost/saving analysis of health-care dollars spent on CKD in AR 3) Develop model continuous quality improvement (CQI) projects based on Healthy People 2020 CKD objectives, clinical indicators and targets 4) Improve patient, provider and public education.

Results: Result highlights by projects include: 1) There was a 2% decrease in incident ESRD patients in 2017and an increase from 13.6% to 18.9% incident peritoneal dialysis in the central region which has dedicated CKD education programs. 2) Costs for transplantation and dialysis are lower in AR than national averages. AR spends $7K less per patient/per year for transplants and $10K less for dialysis. 3) Two CQI models were developed for future use: CKD detection by ICD10 codes and Targeted education of providers assessing practice improvement using claims data. 4) Compiled resources for patients and increased provider education by live and web-based education, published articles in the state physician and nursing magazines and development of a "Know-Your-Kidney-Number"

campaign. A white paper detailing data, resources, and recommendations for each project is available electronically to all providers and stakeholders.

Conclusions: From our knowledge, this unique statewide approach to CKD care is the first of its kind in the country and can serve as a model targeting efforts for improving CKD outcomes.

SA-PO843

The Relationship Between County-Level Contextual Determinants and Risk of CKD

Yan Xie,[1] Benjamin C. Bowe,[1] Yan Yan,[3] Hong Xian,[2] Ziyad Al-Aly.[1] *[1]VA Saint Louis Health Care System, Saint Louis, MO; [2]Saint Louis University College for Public Health & Social Justice, St. Louis, MO; [3]Washington University School of Medicine, Saint Louis, MO.*

Background: Multiple studies described geographic variation in the burden of chronic kidney disease (CKD) in the United States, and evidence suggests that this variation cannot be fully explained by individual level risk factors. We aimed to examine the relationship between county level contextual determinants and individual risk of incident eGFR<60 ml/min/1.73 m^2.

Methods: We built a cohort of 2,456,853 US veterans with eGFR>60 ml/min/1.73 m^2 and followed for up to five years. Contextual determinants were curated from County Health Ranking databases. High dimensional propensity score method was used to estimate prognostic score for CKD based on individual level risk factors. Logistic regression analyses were conducted to examine the association between contextual determinants and incident eGFR<60 ml/min/1.73 m^2, controlling for individual risk factors.

Results: Within 38 contextual determinants, the top 5 determinants which have strongest univariate association with incident eGFR<60 ml/min/1.73 m^2 included physical inactivity, injury deaths, some college or above degree, health care costs and median household income. After controlling for sumarized pronostic score, physical inactivity, injury deaths, health care cost and median household income associated with eGFR<60 ml/min/1.73 m^2 independent of individual risk factors (table). Interaction analyses suggested that association between individual risk factors and incident eGFR<60 ml/min/1.73 m^2 was modified by county level contextual determinants including physical inactivity, health care costs and median household income.

Conclusions: Contextual determinants are associated risk of eGFR<60 ml/min/1.73 m^2 independent of individual risk factor. In addition, they could modify the relationship between individual risk factors and eGFR<60 ml/min/1.73 m^2. Contextual determinants may play important role in burden of CKD; their role should be reflected in the national discussion about reducing CKD burden.

Funding: Veterans Affairs Support

Association between contextual determinats and incident eGFR<60 ml/min/1.73 m2

Contextual determinants	Unit	Univariate OR	OR controlling for individual risk factor	Interaction between contextual determinants and individual risk factors
Physical inactivity	5%	1.08 (1.08, 1.08)	1.05 (1.04, 1.05)	P<0.001
Injury deaths	Per 100 in 100,000	1.31 (1.29, 1.33)	1.16 (1.14, 1.17)	P=0.16
Some college or above	5%	0.97 (0.97, 0.97)	0.99 (0.99, 0.99)	P=0.65
Health care costs	Per $10000	1.50 (1.47, 1.53)	1.36 (1.33, 1.40)	P<0.001
Median household income	Per $10000	0.96 (0.96, 0.96)	0.96 (0.96, 0.96)	P<0.001

SA-PO844

Housing Insecurity and Healthcare Engagement Among People with CKD

Tessa K. Novick,[3,4] Dingfen Han,[1] Delphine S. Tuot,[2] Elizabeth A. Jacobs,[3] Alan B. Zonderman,[5] Michele K. Evans,[6] Deidra C. Crews.[4] *[1]Johns Hopkins University, Baltimore, MD; [2]University of California, San Francisco, San Francisco, CA; [3]University of Texas Dell Medical School, Austin, TX; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]Intramural Research Program, NIA, NIH, Baltimore, MD; [6]National Institutes of Health/National Institute on Aging, Baltimore, MD.*

Background: Housing insecurity is characterized by high housing costs or unsafe living conditions. Among persons with CKD, we examined whether housing insecurity was associated with postponing medical care.

Methods: We performed a cross-sectional analysis of data from the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study (Baltimore, MD) during study visit 4. We used multivariable log binomial and Poisson regression with robust estimate of variance clustered on neighborhood to quantify associations between housing insecurity (self-report of inability to afford a suitable home or difficulty paying rent/mortgage payments) and self-report of postponing medical care that was felt to be needed among individuals with CKD (eGFR <60 ml/min/1.73m^2 or albumin-to-creatinine ratio ≥30 mg/g).

Results: Among 355 HANDLS participants with CKD, 135 (38%) reported housing insecurity. Individuals with housing insecurity were younger (mean [SD] age 57.8 [9.1] years versus 61.1 [8.3] years), more likely to be male (48.9% versus 38.6%), less likely to have a high school degree (60.5% versus 72.3%) and more likely to lack health insurance (6.7% versus 4.1%) than stably housed persons. Overall, 85 (23.9%) participants reported postponing medical care that was felt to be needed. Housing insecurity was associated with increased risk of postponing medical care even after adjusting for demographics, clinical variables, health insurance status, CKD awareness, food insecurity and education level (**Table**).

Conclusions: Individuals with CKD experiencing housing insecurity may be more likely to postpone medical care, which could increase their risk of poor clinical outcomes.

Funding: Other NIH Support - National Institute on Aging, National Institute of Health

Association Between Housing Insecurity and Postponement of Medical Care Among People with CKD

Regression Model	Incidence Rate Ratio (95% CI)
Unadjusted	1.92 (1.44 – 2.56)
Model 1	1.73 (1.34 – 2.23)
Model 2	1.69 (1.34 – 2.15)
Model 3	1.59 (1.20 – 2.10)

Model 1: adjusted for demographics (age, race, sex, and poverty level).

Model 2: adjusted demographics and clinical variables (baseline eGFR, urine albumin-creatinine ratio, blood pressure, and diabetes).

Model 3: adjusted for demographics, clinical variables, health insurance, CKD awareness, food insecurity and education level.

SA-PO845

Documenting CKD in the Primary Care Electronic Health Record

Claudine T. Jurkovitz,[1] Sarahfaye Dolman,[2] Richard Caplan,[1] Rubeen K. Israni,[3] Sidney J. Swanson.[1] *[1]Christiana Care Health System, Newark, DE; [2]MedStar Health Research Institute, Washington, DC; [3]AstraZeneca, Newark, DE.*

Background: The KDOQI guidelines recommend 2 measurements of glomerular filtration rate (GFR) <60 mL/min/1.73m^2 or evidence of kidney damage at 3 months intervals or more to establish the diagnosis of chronic kidney disease (CKD). We examined whether the diagnosis of CKD in an outpatient primary care setting was documented in the Electronic Health Record (EHR) according to the GFR-based KDOQI criteria.

Methods: We used the CKD-Epi equation to assess GFR from the serum creatinine records of patients seen in a network of primary care offices from 2011 to 2015. Our study population was defined as patients 18+ with at least one GFR<60 and at least one followup visit. We excluded patients with an initial GFR<15, those in renal replacement therapy and those with a known CKD diagnosis. Followup began at the time of the first GFR<60. We calculated the time interval between the first GFR<60 and the second GFR and stratified patients into 3 categories according to their first GFR (GFR 15-<30; 30-<45; 45-<60). We used the Systematized Nomenclature of Medicine (SNOMED) codes to ascertain documentation of CKD.

Results: Our final study population included 7098 patients. Of those, 37% were male, 84% white, 15% black; 3%, 18%, and 78% had a first GFR 15-<30, 30-<45 and 45-<60 respectively. Mean age was 70. Overall 63% had a second GFR<60. A total of 4669 patients did not have a CKD diagnosis during followup. Of those, 65% met the KDOQI criteria and CKD should have been documented in the EHR. Of the 2429 patients assigned a CKD code, 41% met the KDOQI criteria, 12% had a second GFR≥60, 27% were given the diagnosis prior to the second GFR measurement, 20% had a second GFR measured within 3 months. Of our study population (n=7098), 43% met the KDOQI criteria but did not receive a documented diagnosis and 20% had a documented diagnosis but did not meet KDOQI criteria.

Conclusions: CKD diagnosis was not appropriately documented in a large number of patients. Algorithms used to identify CKD patients for population health management should not rely only on diagnosis codes but also include measurements of GFR. More resources should be developed to assist primary care physicians to enter the appropriate code in the EHR. The lack of albuminuria information in our dataset limits the interpretation of the apparent over CKD coding of those who did not meet the GFR-based KDOQI guidelines.

SA-PO846

Kidney Disease Knowledge, Health Literacy, and Self-Care in CKD

Sarah J. Schrauben,[1] Kerri L. Cavanaugh,[3] Angela Fagerlin,[4] Talat Alp Ikizler,[3] Ana C. Ricardo,[2] Nwamaka D. Eneanya,[1] Julie Wright.[5] *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Illinois at Chicago, Chicago, IL; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Utah, Salt Lake City, UT; [5]University of Michigan, Ann Arbor, MI.*

Background: Research is needed to better understand the links between health literacy and kidney disease knowledge on patient self-care behaviors in order to guide interventions to improve self-care in chronic kidney disease (CKD).

Methods: Among study participants with CKD stage 1-5, validated surveys assessed level of health literacy (Rapid Estimate of Adult Literacy in Medicine [REALM]), perceived kidney disease knowledge (Perceived Kidney Knowledge Survey [PiKS]), objective kidney disease knowledge (Kidney Disease Knowledge Survey [KiKS]), and self-care behaviors (modified Summary of Diabetes Self-Care Activities Assessment [SDSCA]). A summary score of self-care was constructed utilizing the SDSCA scoring system. Multivariable adjusted linear regression estimated the association of self-care scores with health literacy (inadequate vs. adequate, determined by REALM score ≤59 vs. >59, respectively) and PiKS and KiKS scores (per SD). Health literacy was also explored as a potential effect modifier.

Results: Of the 401 participants: mean age was 57 years; 47% female, 38% diabetes; 77% CKD stage 3-5. The prevalence of inadequate health literacy was 18%. The median KiKS score (range 0-1) was 0.7 (interquartile range [IQR] 0.6-0.8), and median PiKS score (range 0-4) was 2.6 (IQR 2.1-3.0). After full adjustment, a PiKS score was positively associated with self-care scores (β=1.0, 95% confidence interval: 0.3-1.7). Health literacy and KiKS scores were not associated with self-care. There was evidence of effect modification by health literacy; a KiKS score appeared to positively associate with self-care scores only among those with inadequate literacy, but this did not reach statistical significance (**Figure**).

Conclusions: Objective kidney knowledge is likely necessary, but not sufficient for self-care, and may be particularly helpful to those with inadequate health literacy. Perceived kidney knowledge has a strong positive association with self-care, offering a novel target to support self-care among patients with non-dialysis dependent CKD.

Association of Knowledge and Self-Care by Health Literacy Level.

SA-PO847

A Tale of Two Neighborhoods: Association of Neighborhood-Level Social and Environmental Contexts with High CKD Prevalence

Dinushika Mohottige,[2,3] Pamela J. Maxson,[3] Nrupen A. Bhavsar,[2] Michelle J. Lyn,[1,3] Clarissa J. Diamantidis,[2] L. Ebony Boulware.[2,3] *[1]Duke University, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]Duke University, Center for Community and Population Health Improvement, Durham, NC.*

Background: Although CKD risk has been linked to neighborhood income, its association with other neighborhood contexts is less clear.

Methods: We estimated the 2017 prevalence of KDIGO CKD 3-5 among adults age 30 and older living in 153 Durham County census block groups (i.e. 'neighborhoods'). Data were derived from the Durham Neighborhood Compass, a publicly available platform which integrates local electronic health record data with social and environmental data from 153 neighborhoods in Durham County, North Carolina-- a diverse US county of 295,373 residents. We characterized differences in neighborhood contexts reflecting social cohesion, economic stability, safety, transportation and the built environment among neighborhoods with 'high' CKD prevalence (above median county CKD prevalence among residents age 30-64 and age 65+) vs. 'low' CKD prevalence. In logistic regression models, we quantified the association of specific contexts with 'high' (vs. 'low') neighborhood CKD prevalence while adjusting for neighborhood median age and % black population.

Results: Among all 153 neighborhoods, the mean (SD) prevalence of CKD 3-5 was 2 (1.1)% and 11.7 (4.3)% among those age 30-64 and 65+, respectively. Nearly a quarter (22%) of neighborhoods (27,619 residents) had 'high' CKD prevalence. Contexts of 'high' and 'low' CKD prevalence neighborhoods varied substantially. After adjustment, neighborhoods with above median violent crimes, evictions, and impervious areas had greater odds of 'high' (vs. 'low') CKD prevalence; neighborhoods with above median household income and primary election participation had lower odds of 'high' (vs. 'low') CKD prevalence.

Conclusions: Durham neighborhoods with high and low CKD prevalence had substantially different social and environmental contexts. Further study of the influence of these factors on CKD risk is warranted.

Funding: NIDDK Support, Other NIH Support - Duke CTSI UL1TR002553

Table
Social and Environmental Contexts in Durham Neighborhoods with 'high' and 'low' CKD prevalence

Determinant of Health	Neighborhoods with 'high' CKD prevalence N=34	Neighborhoods with 'low' CKD prevalence N=119	p	Adjusted* Odds Ratio [95% CI] for 'high' versus 'low' CKD prevalence**	p
Violent crimes per square mile, Median [IQR]	125.9 [60.6-194.2]	12.6 [4.3-47.8]	<0.01	12.7 [3.21-50.0]	<0.01

Predicted Risk of Renal Replacement Therapy at Time of Referral for Arteriovenous Fistula Placement in CKD

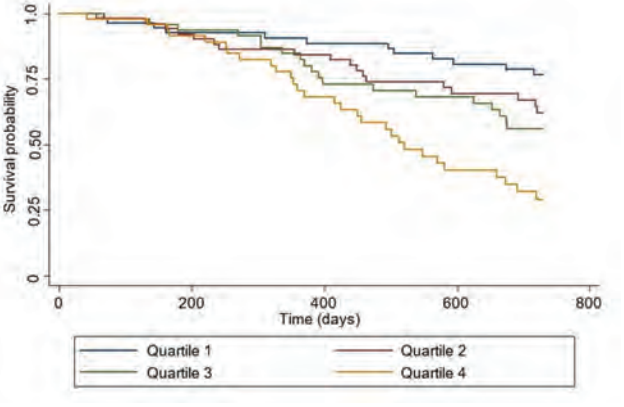
Ken J. Park,[1] Jose G. Benuzillo,[1] Erin Keast,[4] Micah L. Thorp,[2] David Mosen,[3] Eric S. Johnson.[2] *[1]Kaiser Permanente, Salem, OR; [2]Northwest Permanente, Portland, OR; [3]Kaiser Permanente Northwest, Portland, OR; [4]Kaiser Permanente Center for Health Research, Portland, OR.*

Background: The complexity in predicting which and when patients with chronic kidney disease (CKD) will progress to renal replacement therapy (RRT) contributes to 80% of patients starting hemodialysis without a functioning permanent access. This has been associated with higher mortality, morbidity, and cost. A prediction model developed at Kaiser Permanente Northwest may help guide timing of AVF placement.

Methods: 398 CKD stage 4 patients followed by nephrology were classified into AVF referral group (n = 199) and non AVF referral group (n = 199). The non-referral group was randomly selected and matched 1:1 on age, gender, and eGFR. Patients were followed for up to two years and censored if they died or discontinued coverage. Survival analyses were performed for overall hemodialysis initiation.

Results: The average age was 68.5 years in the AVF referral group and 68.1 years in the non AVF referral group. The mean eGFR among the AVF referral group was 16.8 mL/min and 17.2 ml/min in the non AVF referral group. The average 2-year predicted risk of progression to RRT was 47.7% in the AVF referral patients and 44.1% in the matched controls. Hemodialysis initiation occurred at a significantly higher rate in the AVF referral group than in the non AVF referral group (43.7% vs. 23.6%, HR = 1.9, $p < 0.001$). The AVF referral group was stratified into quartiles based on predicted risk of progression to RRT. The lowest quartile (average risk 17.6%) had a 78% lower risk of hemodialysis initiation than the highest quartile (average risk 84.3%); HR = 0.22, $p < 0.001$.

Conclusions: In patients with CKD stage 4, a computer-generated risk score identified a subgroup of AVF referred patients with a low predicted risk to RRT that may have been referred too early.



Kaplan-Meier curve of dialysis free survival by 2 years risk for renal replacement therapy divided into quartiles

SA-PO849

Association of Educational Attainment with Incidence of CKD: Coronary Artery Risk Development in Young Adults (CARDIA) Study

Swetapadma Tripathy,[1] Xuan Cai,[3] Carmen A. Peralta,[5] Holly J. Kramer,[4] David R. Jacobs,[6] Tamara Isakova.[2] *[1]Northwestern University feinberg school of medicine, Chicago, IL; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]Northwestern University, Chicago, IL; [4]Loyola University Medical Center, Maywood, IL; [5]Cricket Health, UCSF, San Francisco, CA; [6]University of Minnesota School of Public Health, Minneapolis, MN.*

Background: Chronic kidney disease (CKD) is a major public health challenge that is greatly impacted by social determinants of health, including education. There are limited data on relationship of low educational attainment with incidence of CKD in young adults.

Methods: We evaluated the association of education with incident CKD and with change in estimated glomerular filtration rate (eGFR) over 20 years in 3140 participants of the Coronary Artery Risk Development in Young Adults (CARDIA) Study. We categorized education into low (high school and below), medium (college), and high (masters and professional studies) groups. Incident CKD was defined as new development of estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2, or urine albumin to creatinine ratio (ACR) ≥ 30 mg/g.

Results: At baseline (year-10 study visit), mean age was 35 ± 3.6 years, mean eGFR was 110.2 ± 16.0 ml/min/1.73m^2, and median ACR was 3.9 (interquartile range, 2.7 – 5.9) mg/g. Participants with lower educational attainment were less likely to have health care access and engage in healthy lifestyle, and had more comorbidities. Over 20 years, 407 participants (13%) developed CKD. Compared to individuals with low educational attainment, those with medium educational attainment had an unadjusted hazard ratio (HR) for CKD of 0.79 (95% confidence intervals [CI] 0.65 – 0.97) and those with high

educational attainment had a HR of 0.44 (95%CI 0.30 – 0.63). This association was no longer significant after adjusting for health care access, lifestyle, and comorbid conditions. Low educational attainment remained significantly associated with change in eGFR, although the relationship was attenuated with adjustment for covariates.

Conclusions: Health care access, lifestyle, and comorbid conditions likely help explain the association between low educational attainment and incident CKD in young adults.

SA-PO850

Developing a Clinical Decision Support Software to Monitor and Tailor Treatment of CKD Patients

Ulla T. Schultheiss,[3,7] Michael C. Altenbuchinger,[2] Kai-Uwe Eckardt,[1,6] Peter J. Oefner,[2] Wolfram Gronwald,[2] Anna Kottgen,[3] Johannes Raffler,[4] Helena U. Zacharias.[5] GCKD investigators *[1]Department of Nephrology and Medical Intensive Care, Charité – Universitätsmedizin Berlin, Berlin, Germany; [2]Institute of Functional Genomics, University of Regensburg, Regensburg, Germany; [3]Institute of Genetic Epidemiology, Medical Center - University of Freiburg, Freiburg, Germany; [4]Institute of Bioinformatics and Systems Biology, Helmholtz Center Munich, Neuherberg, Germany; [5]Department of Psychiatry and Psychotherapy, University Medicine Greifswald, Greifswald, Germany; [6]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany; [7]Renal Division, Medical Center - University Freiburg, Freiburg, Germany.*

Background: CKD is a complex disease with several therapeutic challenges: silent onset; different: etiopathologies, progression patterns, prognosis and comorbidities; polypharmacy. Clinical decision support (CDS) software may improve CKD management.

Methods: Within the German Chronic Kidney Disease (GCKD) study, a multi-center, prospective, observational CKD stage 3 cohort study, demographic, phenotypic, and clinical parameters of 5,217 Caucasian patients have been collected. We will model these data and variable dependencies by state-of-the-art machine learning methods to predict the risk of adverse endpoints, to interpret the results in the context of current biomedical knowledge, and to use the estimated models as a backbone for a CDS software, which will be provided as a user-friendly app to nephrologists (CKDNapp).

Results: CKDNapp, based on mathematical models and enriched by state-of-the-art literature (**Fig 1** (1)), will assess patient parameters in one consistent framework, schematically represented by a network (**Fig 1** (2)). Only the mathematical models will enter the app (**Fig 1** (3)) ensuring data security. Nephrologists will be able to use CKDNapp as a CDS system (**Fig 1** (4)), entering patient data like clinical parameters and disease history. CKDNapp will integrate all provided patient information and return personalized adverse event / disease progression prediction, support medication management, and offer in silico modification of patient parameters exploring effects of future treatment strategies.

Conclusions: The overall goal of CKDNapp is to facilitate personalized CKD patient treatment. First results will be available for presentation at ASN Kidney Week 2019.

Funding: Government Support - Non-U.S.

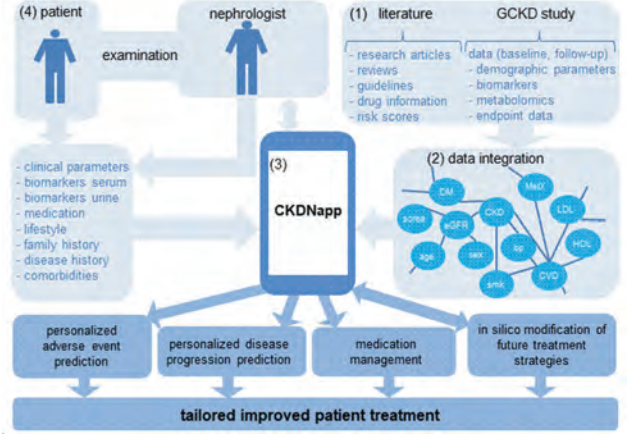


Figure 1 Schematic workflow of the development and application of CKDNapp.

The Keeping Kidneys Program: Baseline Results from a New Model of Care for Community Kidney Health

Pedro H. Gois,[1,3] Louise Purtell,[2,1] Ann Bonner,[2,1] Gary K. Chang,[1] Vinod Lal,[1] Alexandra Cation,[1] Adrian L. Kark,[1] Helen G. Healy.[1,3] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Queensland University of Technology, Brisbane, NSW, Australia; [3]Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia.*

Background: Intervention in early-stage CKD slows rate of progression. First contact healthcare providers like general practitioners (GPs) are at the forefront of detection and management of the early stages of CKD. Keeping Kidneys (KK) was implemented in 2018 to augment kidney care skills of GPs in a less-privileged socio-economic area of Queensland, Australia, where access to specialized kidney care was not available. Here we describe the characteristics of patients referred to this program.

Methods: Two GPs were recruited and trained in a specific subset of CKD skills. Training included didactic knowledge acquisition and clinical detailing by a nephrologist. Demographic and clinical data were extracted from electronic medical records; patient-reported outcomes (CKD knowledge and self-management) were completed at KK entry. Data were analysed descriptively (frequency distributions and mean/median as appropriate).

Results: 140 patients were referred to KK in the first 8 months. Median age was 76 years (67-81). Most patients were in CKD stage 3B (54%) or 3A (22%). Hypertension and diabetes were the leading CKD causes but 33% had no aetiological diagnosis at entry. Most patients had low-average scores for CKD knowledge (13±14/28) and CKD self-management (46±6/116). Median Charlson comorbidity score was 7, predicting survival of <10 years. Mean haemoglobin (Hb) was 12.6±2 g/dL and 5% of patients had Hb<10g/dL. Mean parathyroid hormone, calcium (Ca^{++}) and phosphate (PO^4) were respectively 94±81 pg/mL, 9.6±0.5 and 3.4±0.5 mg/dL. Prevalence of hypoCa^{++} and hyperPO_4 were respectively 1% and 2%. Median urine albumin:creatinine ratio was 38 (12-75) mg/g. One patient was referred for renal biopsy and one for bone marrow biopsy. Patients travelled, on average, 25 minutes less for their appointments, with 72% seen within 15 km of their homes.

Conclusions: KK focuses on the interface between patients, GPs and specialists. Trained GPs were capable of staging severity of kidney disease, initiating the work up of the cause/s of the kidney disease and screening for complications. They managed a cohort of patients with CKD that were elderly, had intermediately advanced CKD and complex co-morbidities in their communities.

Improving Care by Targeting High-Risk Communities in North Carolina (NC)

Koyal Jain,[1] Jill Powell,[1] Caroline J. Poulton,[1] Keisha L. Gibson,[1] Ronald J. Falk,[1] Abhijit V. Kshirsagar,[2] Susan L. Hogan.[2] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC.*

Background: Nearly one million in NC have chronic kidney disease (CKD), not including end-stage kidney disease. A goal of the UNC Kidney Center's Kidney Education and Outreach Program (KEOP) is to understand potential healthcare barriers faced by rural communities. The objective of this study was to describe characteristics of screening participants and their access to physician care.

Methods: The KEOP conducted 206 screenings, predominantly in rural communities, collecting urinalysis and surveys (10/2005-11/2015). This exploratory data analysis compared participants who had seen their regular doctor in the past year to those without a regular doctor or who had not seen one in over a year. Characteristics examined included, age, gender, race, diabetes (DM), hypertension (HTN), income status and others. Proteinuria was assessed by dipstick (negative, trace, 1+, 2+, and 3+).

Results: 5512 were screened; 53% were Black, 55% and 26% had HTN and DM, respectively. 8% had > trace proteinuria, among whom 92% were unaware of a kidney problem, and 50% fell below the NC poverty line. 18% reported not having a regular physician or not seeing a provider for >1 year (Figure); and although younger, reported a worrisome presence of DM (13%) and HTN (30%), with 45% reporting no health insurance and 20% Hispanic.

Conclusions: NC is the 9th largest state; 40% rural. It is abysmal that nearly 1-in-5 screened reported no regular medical care despite having common CKD risk factors. Community medical resources in rural NC were unavailable or under-utilized. Obviating financial and language barriers is critical to connect this high-risk group to chronic disease care.

Figure

Characteristics % or as noted	No Regular physician or Last visit > 1 year (N=929) (18%) *	Saw Regular physician in < 1 year (N=4298) (82%) *
Mean Age (SD)	47 (15.2)	59 (15.5)
Race/Ethnicity**		
Black	49%	55%
Hispanic	20%	3%
Female gender	59%	76%
Less than high school education	25%	16%
Income (<40,000 annually)	78%	65%
DM	13%	30%
HTN	30%	62%
History of kidney disease	3%	4%
> Trace proteinuria	7%	8%
BMI (Mean, Std Dev.)	29.4 (7)	30.8 (7)
Smoked 100 cigarettes	37%	37%
No Health Insurance	45%	10%

*<5% missing except for income (6%); table excludes missing values; **mutually exclusive groups with the remaining participants predominantly White non-Hispanics.

SA-PO853

Physician Practice Characteristics Associated with Quality of CKD Care

Sri Lekha Tummalapalli,[1,2] Salomeh Keyhani,[4] Michelle M. Estrella.[3] *[1]Division of Nephrology, Department of Medicine, University of California, San Francisco, San Francisco, CA; [2]Kidney Health Research Collaborative, San Francisco, CA; [3]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [4]Division of General Internal Medicine, San Francisco VA Health Care System, San Francisco, CA.*

Background: Improving the quality of CKD care has important implications for delaying disease progression and preventing ESKD. Understanding physician practice characteristics associated with high quality CKD care is critical to provide insight into effective care delivery for CKD.

Methods: We performed a serial cross-sectional study of visits to office-based ambulatory care practices for adults with diagnosed CKD using National Ambulatory Medical Care Survey data. Our predictors were physician practice characteristics: geographic region, metropolitan area, solo practice, type of specialty, practice ownership, employment status, and physician compensation. Outcomes were quality indicators: 1) uncontrolled hypertension; 2) uncontrolled diabetes; 3) ACEi/ARB use; and 4) statin use if age ≥50. Using multivariable logistic regression, we determined the association of physician practice characteristics with quality indicators, adjusting for patient age, sex, race, and comorbidities (hypertension, diabetes, congestive heart failure, and coronary artery disease).

Results: In 2006-2014, there were 9554 unweighted visits for CKD patients representing 232,899,670 weighted visits. Patients seen in medical specialty vs. primary care had nearly 2-fold odds of uncontrolled diabetes (95% CI: 1.11–2.86). Patients in metropolitan vs. non-metropolitan areas had higher use of ACEi/ARBs (41% vs. 33%, p=0.021), but there was no statistically significant association in adjusted analyses. CKD patients aged ≥50 seen in non-solo vs. solo practice had lower odds of statin use (aOR=0.81; 95% CI 0.66–0.99). Those seen in practices owned by insurance companies or health plans had 1.5-fold odds of statin use (95% CI 1.03–2.08), compared with practices with other ownership. Practice characteristics were otherwise not associated with CKD quality indicators.

Conclusions: In a nationally representative subset of outpatient visits for patients with diagnosed CKD, we found that few physician practice characteristics were associated with CKD quality indicators. Further studies are needed to determine optimal care delivery models based on practice-level characteristics.

Utilising Mobile and Web-Based Technology for Capturing Patient-Specific Information: Methods from the DISCOVER CKD Program

Glen James,[1] Jenny Wei,[1] Eric T. Wittbrodt,[1] Carol P. Moreno Quinn,[1] Alaster Allum,[1] Katarina Hedman,[1] Hungta (tony) Chen,[1] Esther Pascual,[1] Björn Holmqvist,[1] Peter Fenici,[2] Juan J. Carrero,[3] Gary C. Curhan,[4] Steven Fishbane,[5] Hiddo J. L Heerspink,[6] Eiichiro Kanda,[7] Naoki Kashihara,[7] Mikhail Kosiborod,[13] Lam S. Carolyn,[12] Roberto Pecoits-Filho,[8] Carol A. Pollock,[9] Peter Stenvinkel,[10] David C. Wheeler.[11] *[1]AstraZeneca, Cambridge, United Kingdom; [2]AstraZeneca, Cambridge, United Kingdom; [3]Karolinska Institutet, Stockholm, Sweden; [4]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [5]Northwell Health, Commack, NY; [6]University Medical Center Groningen, Groningen, Netherlands; [7]Kawasaki Medical School, Kurashiki, Japan; [8]Arbor Research Collaborative for Health, Ann Arbor, MI; [9]The University of Sydney, St. Leonards, NSW, Australia; [10]Karolinska University Hospital Huddinge, Stockholm, Sweden; [11]University College London, London, United Kingdom; [12]National Heart Centre Singapore, Singapore, Singapore; [13]Saint Luke's Mid America Heart Institute, Kansas City, MO.*

Background: Chronic kidney disease (CKD) is a global health problem associated with cardiovascular complications, impaired health-related quality of life (HRQoL) and high mortality. New ways of capturing patient experiences and burden of disease in settings outside of the clinic through mobile or web-based technology are becoming more widely used, but not within CKD real-world data.

Methods: DISCOVER CKD is an enriched hybrid observational study utilising a novel cloud-based IT platform to integrate retrospective and prospective data from patients with estimated glomerular filtration rate (eGFR) <75 ml/min/1.73 m² through to end stage kidney disease from the UK, US, Italy, Denmark, Sweden, China and Japan. Prospective data will be captured over a 3-year period from >1,000 CKD patients. Data collected by validated instruments including HRQoL (SF-36), physical activity (RAPA), work productivity (WPAI), diet (food diary), and other patient-reported outcomes will be captured in a bespoke mobile/web-based application to be completed by the patient before, during or after their routine clinical visit. The application will be available, validated and user-tested in multiple languages.

Results: Capturing patient-reported information outside of the clinic setting provides an innovative patient-centric approach for understanding the burden and journey of CKD from a patients' perspective. Initial results are anticipated in 2020.

Conclusions: Utilising mobile/web-based technology to collect patient experiences has the potential to increase the understanding of a disease, with easier communication, minimising burden of data collection in the clinic from a patient, physician and eCRF perspective while improving the consistency and validity of data that patients enter.

Where Patients Get Their CKD Information: Perceptions Vary by Individual Demographics

Julie Wright,[1] Andrea L. Oliverio,[1] Amy B. Pai,[1] Silas Norman,[3] Angela Fagerlin.[2] *[1]University of Michigan, Ann Arbor, MI; [2]University of Utah, Salt Lake City, UT; [3]University of Michigan Health Systems, Ann Arbor, MI.*

Background: Patient education is a critical first step in the pathway to improved outcomes. Little data is available about sources of CKD information that patients perceive as most useful, and whether perceptions vary with patient characteristics.

Methods: Adults with CKD Stages 1-5 were enrolled in a cross-sectional survey. Eleven questions assessed patient ratings (1=not at all helpful to 5=extremely helpful) of specific sources of kidney information (e.g. healthcare providers, peer mentors, internet). Patients also answered questions about their perceptions of communication by providers and how well they thought providers communicate with each other (0=do not communicate at all to 4=outstanding communication). Associations between patient demographics and summarized patient ratings were examined using linear regression.

Results: 245 patients enrolled with a mean age of 60 years, mean eGFR of 34 mL/min/1.73m², 49% were men, 80% White, 15% African American, 5% other and/or multiple races. Summarized patient ratings for each source of kidney information were: Kidney doctors (mean 4.7, SD 0.9), PCPs (3.4, 1.5), nurses (2.8, 1.9), dieticians (2.6, 2.1), Internet (2.2, 1.8), handouts/brochures (1.8, 1.6), social workers (1.6, 1.9), family/friends (1.2, 1.7), classes (1.1, 1.7), news (0.9, 1.2), peer mentoring (0.7, 1.3). Most patients reported it was NOT difficult to talk with their doctors about CKD (213, 92%), and rated overall communication fair (mean 2.9, SD 1.1). In analyses adjusted for age, sex, race, education, income, and eGFR the following were significantly associated with summarized patient ratings: 1. Women rated kidney doctors higher compared to men (β 0.26, p=0.03), higher eGFR predicted lower ratings for dieticians (-0.02, 0.01), higher income predicted lower ratings for social workers (-0.20, 0.01), Nonwhite race predicted higher ratings for family/friends (0.78, <0.01) for brochures/handouts (0.36, 0.02) and a trend for peer mentors (0.26, 0.07), older age predicted lower ratings (-0.03, <0.01) and more education higher ratings (0.20, 0.03) for Internet.

Conclusions: Patient perceptions about the usefulness of kidney information from different sources vary significantly by patient demographics. More work is needed to explore reasons for, and interventions to improve, disparities in these perceptions.

SA-PO856

No Independent Relationship Between Socioeconomic Status and CKD Progression in South Korea: Results from the KNOW-CKD Cohort

Eunjeong Kang,[1] Hyunjin Ryu,[1] Minjung Kang,[3] Yeji Hong,[1] Jayoun Kim,[1] Curie Ahn,[1] Kook-Hwan Oh.[2] *[1]Medical Research Collaborating Center, Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Socioeconomic status (SES) has long been conjectured to be associated with the incidence and progression of chronic kidney disease (CKD). However, prospective studies from Asian data for impact of SES on renal progression were less. We revealed the association between SES and renal progression in CKD patients especially in South Korea where medical insurance is well established.

Methods: Data were collected from the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD, NCT01630486 at http://www.clinicaltrials.gov). SES was characterized based on monthly income which was divided into three strata; ≥$4,500, $1,500-4,000, <$1,500. Patients who underwent baseline tests but did not have follow-up visits thereafter or who did not respond to questionnaires regarding SES were excluded. The outcome was a composite of estimated glomerular filtration rate (eGFR) halving or the onset of end-stage renal disease (ESRD). ESRD was defined as the initiation of maintenance dialysis or kidney transplantation. Cox or time-dependent cox regression analysis were conducted as appropriate. Age, sex, cause of CKD, baseline eGFR by CKD-EPI (cr) equation, hemoglobin, albumin, uric acid, calcium, phosphorus, mean blood pressure, 24hr sodium intake calculated by 24hr urine sodium was included as covariates in multivariable analysis.

Results: Total 1,732 patients were enrolled in this study. Mean age was 52.9 ± 12.0 years and 61.5% were men. Higher monthly income was associated with higher educational attainment (*P* for trend <0.001). There is an incremental tendency of CKD progression according to lower monthly income level ($1,500 to $4,500, adjusted hazard ratio [HR] 1.55, 95% confidence interval [CI] 0.86-2.77, *P*=0.144; <$1,500, adjusted HR 1.75, 95%

CI 0.93-3.29, *P*=0.080; ≥$4,500 group as reference), but the statistical significance was not observed, event after the subgroup analysis according to age ≥ 50 years or below.

Conclusions: In the Korean CKD population, there is no definite association between SES classified by monthly income level and renal progression. We speculate that this is because health care accessibility is high regardless of the SES in Korea due to Korean National Health Insurance Service. Further studies are needed to confirm this phenomenon.

Development and Initial Analysis of a Nationwide Multicenter Electronic Health Record Database of CKD in Japan (J-CKD-DB)

Naoki Nakagawa,[1] Tadashi Sofue,[2] Eiichiro Kanda,[3] Hajime Nagasu,[3] Hirokazu Okada,[4] Naoki Kashihara.[3] Steering committee of Japan CKD database, Japan *[1]Asahikawa Medical University, Asahikawa, Japan; [2]Kagawa University, Kita-gun, Japan; [3]Kawasaki Medical School, Kurashiki, Japan; [4]Saitama Medical University, Saitama, Japan*.

Background: Chronic kidney disease (CKD) is not only a precursor of end stage renal disease but also a strong risk factor for various adverse outcomes like cardiovascular disease and dementia. To collect clinical data from CKD patients in Japan, the Japanese Society of Nephrology in collaboration with the Japan Association for Medical Informatics has embarked on the Japan Chronic Kidney Disease Database (J-CKD-DB) project.

Methods: J-CKD-DB is a large-scale, nation-wide registry based on electronic health record (EHR) data from university hospitals in Japan. Using a standardized exchangeable information storage (the Standardized Structured Medical Information eXchange 2), J-CKD-DB succeeded to efficiently compile clinical data of CKD patients across hospitals despite their different EHR systems. CKD was defined as dipstick proteinuria ≥1+ and/or estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 based on both out- and inpatient laboratory data.

Results: As an initial analysis, we analyzed 40,409 CKD outpatients from 7 university hospitals and observed that majority of them were older than 65 years old, with the most prevalent age category 70-79 years in both sexes. Median age was 71 years (IQI 62–79), 54.8% were men, median eGFR was 50.2 mL/min/1.73 m^2 (42.6–57.5). The number of patients with a CKD stage G1, G2, G3a, G3b, G4 and G5 were 929 (2.3%), 3,972 (9.8%), 23,333 (57.7%), 8,357 (20.7%), 2,710 (6.7%) and 1,108 (2.7%), respectively. Although proteinuria data were available in 19,725 cases (48.8%) of all patients, the number of patients with a CKD stage A1 [dipstick proteinuria (-)], A2 [dipstick proteinuria (±)], and A3 [dipstick proteinuria ≥1+] were 10,360 (52.5%), 3,049 (15.5%) and 6,316 (32.0%), respectively. Younger CKD patients in J-CKD-DB tended to be at more advanced stages than older patients.

Conclusions: In the present study, we have constructed the J-CKD-DB which is a comprehensive nationwide CKD database. This registry will be a platform for a number of analyses, for example, mortality and morbidity risk, by clinical diagnoses, lab data, or medication data and may be able to fill important knowledge gaps surrounding CKD care.

SA-PO858

Detecting Lifestyle Risk Factors for CKD with Comorbidities: An Association Rule-Mining Analysis

Suyuan Peng,[1] Xusheng Liu,[2] Andrew Wen,[3] Feichen Shen.[3] *[1]Peking University Health Science Center, Beijing, China; [2]The Second Affiliated Hospital, Guangzhou University of Chinese Medicine, Guanghzou, China; [3]Mayo Clinic, Rochester, MN*.

Background: The rise in the number of patients with chronic kidney disease (CKD) and consequent end-stage renal disease (ESRD) necessitating renal replacement therapy has placed significant strain upon healthcare. The burden of CKD is substantial. According to WHO global health estimates, 864,226 deaths (or 1.5% of deaths worldwide) were attributable to this condition in 2012. The rate of progression of CKD is influenced by both modifiable and unmodifiable risk factors. Identification of modifiable risk factors such as lifestyle choices has been vital in informing strategies towards renoprotection as modification of unhealthy lifestyle choices lessens the risk of CKD progression and associated comorbidities. However, the lifestyle risk factors and modification strategies may vary due to different comorbidities and studies on suitable lifestyle interventions for CKD patients with comorbidities are sparse.

Methods: We applied ARM to identify lifestyle risk factors for CKD progression with comorbidities using questionnaire data for 450,000 participants collected from the Behavioral Risk Factor Surveillance System (BRFSS) 2017, a web-based resource, including demographic information, chronic health conditions, fruit and vegetable consumption, sugar or salt-related behavior, among others. To enrich the BRFSS questionnaire, the Semantic Medline Database (SemMedDB) was also mined to identify lifestyle risk factors.

Results: The results suggest that the lifestyle modification of CKD varies among different comorbidities. For example, the lifestyle modification of CKD with cardiovascular disease (CVD) needs to focus on increasing aerobic capacity by improving muscle strength or functional ability. For CKD patients with chronic pulmonary disease (CPD) or rheumatoid arthritis (RA), lifestyle modification should be high dietary fiber intake and participation in moderate-intensity exercise. Meanwhile, the management of CKD patients with diabetes focuses on exercise and weight loss predominantly.

Conclusions: We have demonstrated the use of ARM to identify lifestyle risk factors for CKD with common comorbid chronic conditions using data from BRFSS 2017. Our methods can be generalized to advance chronic disease management with more focused and optimized lifestyle modification of NCDs.

SA-PO859

Quality of CKD Management in the Canadian Primary Care System

Aminu K. Bello. On behalf of CKD-CPCSSN Team *University of Alberta, Edmonton, AB, Canada*.

Background: Although patients with chronic kidney disease (CKD) in Canada are routinely managed in primary care settings, no nationally representative study has assessed the quality of CKD care received by these patients. We evaluated the current state of CKD management in Canadian primary care practices leveraging guideline-concordant quality of metrics.

Methods: This cross-sectional study leveraged electronic medical record data from the Canadian Primary Care Sentinel Surveillance Network (CPCSSN) from 2010–2015. We examined the proportion of CKD patients meeting a set of 12 quality indicators in six domains: (a) detection and recognition of CKD, (b) testing and monitoring of kidney function, (c) use of recommended medications, (d) appropriate monitoring after initiation of ACEIs/ARBs, (e) management of blood pressure, and (e) glycemic control in patients with CKD. We also analyzed predictors of divergence from these quality indicators.

Results: The baseline cohort comprised 46,162 patients with CKD Stages 3–5 (defined as those with at least two eGFR measurements < 60mL/min/1.73m^2 within a period of at least three months, but not more than 18 months apart). Results show that only four out of 12 quality indicators were met by ≥ 75% of the study cohort: one in the testing and monitoring of kidney function domain (i.e., follow-up serum creatinine measurements), two in the blood pressure management domain, and one in the glycemic control domain. Indicators in the domains of detection and recognition of CKD, testing and monitoring of kidney function (specifically, urine albumin creatinine ratio [UACR] testing), use of recommended medications, and appropriate monitoring after initiation of ACEIs/ARBs were not met. Only 18.4% of patients with CKD received a urine albumin test within six months of their qualifying eGFR measurement and 39.4% had a second measurement within six months of an abnormal baseline urine test (UACR > 2.5mg/mmol).

Conclusions: Management of CKD in primary care settings varies according to quality indicator. Over 75% of patients with CKD received quality-concordant (or guideline concordant) testing and monitoring of kidney function, and achieved blood pressure and glycemic control. Prevalence of albuminuria detection and use of recommendation medications were much lower. These findings reveal priority areas for quality improvement initiatives in primary care.

SA-PO860

An Innovative, Community-Based Screening Strategy Identifies High Rates of Advanced CKD in Asymptomatic Individuals Living in a Low-Income, Largely African-American Community

Aisha H. Montgomery,[2] Heather Kitzman,[2] Winfred C. Parnell,[3] Kenneth Halloran,[2] Abdullah A. Mamun,[2] Donald E. Wesson.[1] *[1]Baylor Scott and White Health and Wellness Center, Dallas, TX; [2]Baylor Scott & White Health, Dallas, TX; [3]Baylor Scott & White, Dallas, TX*.

Background: The USRDS most recently (2018) reported a statistically significant increasing prevalence of more advanced stages (3-5) of chronic kidney disease (CKD). Individuals with early CKD are generally asymptomatic and so remain largely unidentified until presenting to health systems with symptomatic, far advanced, CKD at which time kidney-protective interventions offer limited benefit to delay progression to end-stage kidney disease. Reducing prevalence of advanced CKD must include proactive screening to identify asymptomatic individuals with early CKD while in their routine living environments.

Methods: As part of a grant (R21DK113440) we tested an innovative screening strategy to identify asymptomatic individuals with CKD through community-level screening in settings trusted by community members including churches, community-based organizations, and community events in low-income, largely African American communities that studies show to be at high CKD risk. We met with these community-based organizations to describe our study testing the effectiveness of education regarding preparation of provided fruits and vegetables compared to providing the fruits and vegetables alone. We then dispatched the screening team to those that agreed to allow dipstick measurements of urine albumin concentration (Ualb).

Results: To date, we screened 282 participants, finding 83% (N= 234) with albumin > 30 mg/l, the level designated as "positive". The first 55 individuals who completed measures had mean (SD) age of 55.4 (11.1) years, 30.9% were male, and had mean eGFR (CKD-EPI creatinine-based) of 50.3 (13.2) ml/min/1.73m^2 with 0% CKD 1, 20% CKD 2, 76% CKD 3a/b, and 2% CKD 4. This proportion of measured participants with CKD stage 3 was much higher than anticipated based on NHANES 2001 – 2016 data (~47%).

Conclusions: This innovative screening strategy found high rates of both albuminuria and subnormal eGFR in asymptomatic individuals living in communities at high CKD risk through leveraging trusted community organizations. The strategy should be explored further to identify asymptomatic individuals with early CKD who are candidates for kidney protective interventions designed to reduce the increasing prevalence of advanced stages of CKD.

Urine Testing of Community Residents in a Region of Nicaragua with a High Burden of Mesoamerican Nephropathy Reveals That Background Systemic Inflammatory Signs Rapidly Increase in Younger Ages

Anna Strasma,[1] Sreedhar A. Mandayam,[2] Chandan Vangala,[1] Rebecca S. Fischer.[3] *[1]Baylor College of Medicine, Houston, TX; [2]UT MD Anderson Cancer Center, Bellaire, TX; [3]Texas A&M Health Science Center, Houston, TX.*

Background: A large and ongoing epidemic of kidney disease of unknown etiology affects the rural poor from Mexico to Panama and has resulted in greater than 50,000 deaths. Mesoamerican nephropathy (MeN) is a devastating and rapidly progressing disease that affects primarily young agriculture workers who are otherwise healthy and lack traditional risk factors for kidney disease. Very little is known about renal function in the community-at-large, especially among children.

Methods: Urine specimens were collected from individuals of all ages at health fairs in 4 rural, agricultural communities in the Pacific lowland areas of Nicaragua, a region heavily affected by MeN and where morbidity and mortality due to the epidemic has more than quadrupled since its emergence. Semi-quantitative dipstick and microscopic analysis were performed on fresh specimens. We generated descriptive statistics and tested for differences by age and community by Chi-squared and ANOVA in Stata 15.

Results: Urine from 471 community residents, ages 3 months to 89 years (median 21 years) were analyzed. Almost all individuals (99%) were shedding leukocytes, many (21%) with >5 per field. Renal cell shedding (11%), hematuria (13.4%) were also noted. Proteinuria was rare (3.2%). Hematuria and leukocyturia varied by locale ($p<0.05$). Leukocyturia was more common in adults than children ($p<0.05$). Leukocyturia increased with age, which was driven by the age group 12-33 years.

Conclusions: In this community-based sample, clinical urine specimens indicate an underlying prevalence of markers of impaired renal function. These markers increase in adolescence and young adulthood. Further investigations into MeN should target populations other than agricultural workers and should specifically look at renal function in children. Geographic differences in clinical indicators may also point to the highest risk communities.

SA-PO862

CKD Detection Might Benefit from an Ethnic-Specific Screening Approach: Results from the HELIUS Study

Brechje Huisman, Bert-jan Van den born, Charles Agyemang, Marieke Snijder, Liffert Vogt. *Academic Medical Centre, Amsterdam, Netherlands.*

Background: Screening for chronic kidney disease (CKD) is currently recommended for patients with a history of diabetes mellitus, hypertension or cardiovascular disease (CVD). This approach may not identify all individuals with CKD. Ethnicity, age and socio-economic status (SES) have been described to affect CKD risk and these factors may influence CKD detection in the general population. We studied whether the addition of criteria for age and socio-economic status may improve CKD detection in a multiethnic population.

Methods: Baseline data from the HELIUS study, a multiethnic cohort study conducted in the city of Amsterdam, were used. Analyses were conducted among 21,617 partcipants (mean age 44 years, 43% male) of Dutch (n=4564), South-Asian Surinamese (n=3043), African Surinamese (n=4151), Ghanaian (n=2339), Moroccan (n=3614) and Turkish (n=3906) ethnic origin. Detection success of three screening approaches was investigated in each ethnic group. Respectively, approaches I, II and III consisted of the traditional approach (i.e, screening when a history of diabetes mellitus, hypertension or CVD was present); the traditional approach combined with age >50 yr; and the traditional approach combined with low SES (i.e, none or elementary schooling only). We defined CKD as eGFR (CKD-EPI formula, < 60ml/min/1.73m^2) or albuminuria (A2/A3).

Results: In our cohort, 2284 (10.6%) participants had CKD. Overall, compared to approach I, approach II increased detection success with 6.7% and approach III with 6.3%. Detection success of approach I among the ethnic groups varied from 38.8 to 70.3%. Detection improvement by using approach II and III showed ethnic specific differences. In participants of Dutch origin, approach II significantly increased the detection rate with 15.1%, while in participants of Turkish and Moroccan origin approach III significantly increased detection rates (8.9 and 14.1%, respectively).

Conclusions: Addition of age and SES criteria to the currently advised screening approach results in higher CKD detection. This improvement varies among ethnic groups. Addition of an age criteria improved detection in Dutch participants, while adding a SES criterium improved detection in Turkish and Moroccan participants. Our results may prompt for development of a different set of CKD screening criteria in a multiethnic population.

SA-PO863

The Association of Physical Activity with Poor Health Outcomes in Patients with Advanced CKD

Ranveer S. Brar,[2,1] Clara Bohm,[2,1] Claudio Rigatto,[2,1] Paul Komenda,[2,1] Bhanu Prasad,[3] Navdeep Tangri.[2,1] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [3]Internal Medicine, Regina Qu'Appelle Health Region, Winnipeg, MB, Canada.*

Background: Chronic kidney disease (CKD) disproportionately affects older adults, and is known to be associated with low physical activity levels. In the general population, low physical activity level is associated with an increased risk of all-cause mortality and other adverse outcomes. This association also exists in patients with moderate CKD and those on dialysis; however this has yet to be explored in patients with advanced CKD (G4-G5). The primary aims of this study were to determine the association of physical activity level with all-cause mortality, as well as the assocation with progression to dialysis and future fall risk in patients with advanced CKD.

Methods: Individuals with advanced CKD (G4-G5) were identified from the CanFIT cohort, a multicenter, prospective study of frailty, between October 2012 and July 2018 (n=592). Self-reported physical activity was assessed at baseline by the Physical Activity Scale for the Elderly (PASE). PASE scores were stratified by tertiles (0-40 (Low Activity); 41-90 (Light Activity); >90 (Moderate-High activity). Baseline clinical characteristics and comorbidities were obtained through chart review. Our primary outcome of all-cause mortality and secondary outcome of progression to dialysis were analyzed using Cox proportional hazard models. Logistic regression was performed for our secondary outcome of future fall risk.

Results: We had 121 participants die during the study (mean follow-up 1193 days) and 215 participants progressed to dialysis (mean follow-up 896 days). Compared with low physical activity level, higher levels of physical activity were associated with a reduction in all-cause mortality (HR 0.56 [95% CI: 0.33-0.94]) when adjusted for age, sex, and comorbidities. Of 472 participants with follow-up assessing falls, 131 (28%) had a fall event. Level of baseline physical activity did not predict progression to dialysis or future falls.

Conclusions: In advanced CKD, higher levels of physical activity were associated with a 50% reduction in all-cause mortality. Although progression to dailysis and future fall risk were not associated with baseline physical activity level, the impact in the change of physical activity level on these outcomes requires further investigation.

SA-PO864

Automated Urinary Albumin Creatinine Testing in Stage 3 CKD and Effect on Prescriptions of ACE Inhibitors and ARBs

Ken J. Park,[1] Micah L. Thorp,[2] Robert Unitan.[3] *[1]Kaiser Permanente, Salem, OR; [2]Northwest Permanente, Happy Valley, OR; [3]Noorthwest Permanente, Portland, OR.*

Background: Kidney Disease Improving Global Outcomes recommends assessing for albuminuria annually in patients with chronic kidney disease (CKD). Despite this recommendation, many patients with CKD do not undergo annual testing for albuminuria. We were interested in whether automated testing in CKD for annual urinary albumin creatine (ACR) testing improved ACR testing and prescribing of ACE inhibitors and ARBs.

Methods: We defined a CKD 3 cohort registry in April 2018 in Kaiser Permanente Northwest. We compared ACR testing and filled ACE inhibitor and ARB prescriptions in the year before and after April 2018 after implementing a quality improvement project targeting patients with stage 3 CKD based on eGFR criteria or ICD-10 codes. A web-based tool examined the registry and ordered an ACR in those patients that did not have an ACR checked within the past year. In those patients not on an ACE inhibitor or ARB who had a renal indication, primary care providers received an alert in the electronic health record (EHR) which recommended initiation. Renal indications for an ACE inhibitor or ARB were hypertension and an ACR > 30 mg/g with diabetes mellitus (DM) or an ACR > 300 mg/g without DM.

Results: There were 11,229 patients in the initial CKD registry with index date of April 2018. Average age was 72.7 years, 37.4% had DM, 79.4% had hypertension, and mean eGFR was 46.8 ml/min. One year after implementation of annual ACR testing, the registry decreased to 10,934. Average age was 73 years, 37.1% had DM, 79.4% had hypertension, and mean eGFR was 47.4 ml/min. One year after implementation of ACR testing, rate of ACR testing increased from 25.1% to 83% ($p < 0.001$). In patients with renal indication, ACE inhibitor or ARB use increased from 77.4% to 80.2% but was not significant ($p = 0.07$). Maximum dose ACE inhibitors or ARB use increased from 26.8% to 32.1% ($p = 0.02$) in patients with A3 grade albuminuria and hypertension.

Conclusions: In patients with stage 3 CKD, a population-based tool that automated testing of ACR linked with EHR alerts resulted in a significant increase in ACR testing but did not result in a significant increase in ACE inhibitor or ARB prescriptions in patients who had a renal indication. However, prescribing of maximum dose ACE inhibitors or ARBs did increase in patients with A3 grade albuminuria and hypertension.

SA-PO865

The Effects of a Participatory Structured Group Educational Program on the Development of CKD: A Population-Based Study

Tadashi Sofue,[4] Yuka Okano,[2] Nao Matsushita,[3] Masahiro Moritoki,[4] Akira Nishiyama,[1] Tetsuo Minamino.[4] *[1]Department of Pharmacology, Kagawa University, Kita-gun, Japan; [2]Kagawa National Health Insurance Organization, Takamatsu, Japan; [3]Health and Welfare Department, Marugame City, Marugame, Japan; [4]Division of Nephrology and Dialysis, Department of Cardiorenal and Cerebrovascular Medicine, Kagawa University, Kagawa, Japan.*

Background: The type of lifestyle guidance that is effective for preventing development of chronic kidney disease (CKD) is unknown. Here, we aim to investigate the effects of a participatory structured group education (SGE) program on the development of CKD in a population-based study.

Methods: We retrospectively analyzed 1,060 adult special health check-up examinees with CKD. Examinees with an estimated glomerular filtration rate (eGFR) from 50 to 60 mL/min/1.73 m^2 and/or proteinuria 1+ were encouraged to attend an SGE program.

The SGE program included participatory small group discussions on the attendees' remaining risk factors. The primary outcome of this study was the change in eGFR per year.

Results: The changes in eGFR in examinees who attended the SGE program (n = 209, +2.9 mL/min/1.73 m^2/year [95% confidence interval (CI) +1.9–+3.9]) significantly improved compared with control (n = 383, +1.2 mL/min/1.73 m^2/year [95%CI +0.5–+1.9], p = 0.006). Attending an SGE program was independently and positively related to the changes in eGFR at 1 year after attendance, after adjusting for classical covariates (β = 1.55 [95%CI 0.37–2.73], p = 0.01). In subgroup analysis, attending an SGE program was effective for the examinees with a lower eGFR compared with those with only proteinuria.

Conclusions: Our SGE program showed the beneficial effects of preventing the development of CKD, independent of classical factors. The type of SGE program that is more effective for preventing development of CKD should be investigated in a long-term analysis.

SA-PO866

CKD Awareness Among US Adults by Future Risk of ESKD, 1999-2016

Chi Chu,[1] Charles E. McCulloch,[1] Meda E. Pavkov,[2] Nilka Rios Burrows,[2] Brenda W. Gillespie,[3] Rajiv Saran,[3] Neil R. Powe,[1] Delphine S. Tuot.[1] CDC CKD Surveillance Team *[1]University of California, San Francisco, San Francisco, CA; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of Michigan, Ann Arbor, MI.*

Background: Individuals with chronic kidney disease (CKD) are often unaware of their disease. Efforts to improve CKD awareness would have the most benefit if focused on individuals at highest risk of progression to end-stage kidney disease (ESKD). Therefore, we examined CKD awareness by future risk of ESKD in a representative sample of US adults.

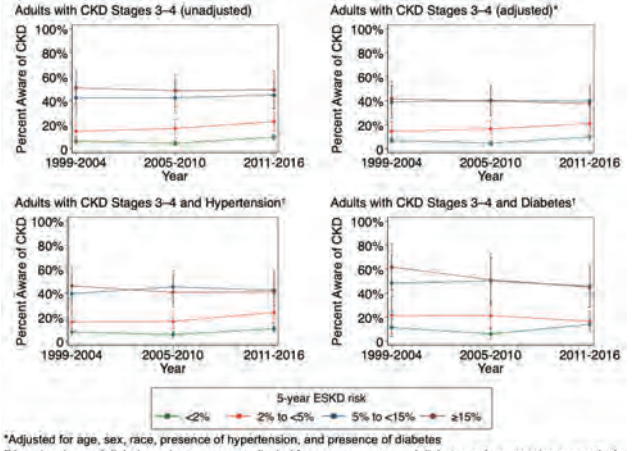
Methods: We assessed the prevalence of CKD awareness among non-pregnant adults (≥ 20 years) with CKD stages 3-4 who participated in the National Health and Nutrition Examination Survey (NHANES) between 1999 and 2016 (n=3,668). CKD awareness was defined by a "yes" answer to the question, "Have you ever been told by a doctor or other health professional that you had weak or failing kidneys?". The 5-year probability for ESKD was estimated by the 4-variable Kidney Failure Risk Equation. ESKD risk was categorized as minimal (<2%), low (2% to <5%), intermediate (5% to <15%), or high (≥15%). Unadjusted and adjusted trends in prevalence of CKD awareness by ESKD risk group were computed using logistic regression with complex sample survey methods.

Results: Unadjusted CKD awareness was less than 10% among adults with minimal risk and was higher in the intermediate and high ESKD risk groups (approximately 45% and 50%, respectively). CKD awareness within each risk group was stable over time. Similar results were obtained when adjusted for age, sex, race, hypertension status, and diabetes status, and when analysis was limited to the subgroup with hypertension (Figure). Among adults with diabetes, awareness within each risk group was greater but was also stable over time.

Conclusions: Among adults with CKD stages 3–4 with over 15% 5-year risk of ESKD, approximately half were unaware of having kidney disease. CKD awareness was stable over time, demonstrating the need for intensified efforts to increase CKD awareness.

Funding: NIDDK Support, Other U.S. Government Support

Figure: CKD awareness among adults with CKD stages 3-4 by 5-year ESKD risk



*Adjusted for age, sex, race, presence of hypertension, and presence of diabetes
†Hypertension and diabetes subgroups were adjusted for age, sex, race, and diabetes or hypertension respectively.
CKD = chronic kidney disease; ESKD = end-stage kidney disease

SA-PO867

Technology Use, Interest in Mobile Health Technology, and eHealth Literacy in CKD

Sarah J. Schrauben,[1] Lawrence J. Appel,[7] Claudia M. Lora,[2] James P. Lash,[2] Jing Chen,[4] L. Lee Hamm,[4] Jeffrey C. Fink,[5] Alan S. Go,[6] Raymond R. Townsend,[1] Rajat Deo,[1] Laura M. Dember,[1] Harold I. Feldman,[1] Clarissa J. Diamantidis.[3] *[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [2]University of Illinois at Chicago, Chicago, IL; [3]Duke University School of Medicine, Durham, NC; [4]Tulane University School of Medicine, New Orleans, LA; [5]University of Maryland, Baltimore, MD; [6]Kaiser Permanente Northern California, Oakland, CA; [7]Johns Hopkins Medical Institutions, Baltimore, MD.*

Background: Mobile health (mHealth) technologies improve patient-provider communication and increase information accessibility. eHealth literacy is needed to effectively find and appraise health information from electronic sources. Using a mixed methods approach, we assessed technology use, mHealth interest, and eHealth literacy among those with CKD.

Methods: We utilized data from Chronic Renal Insufficiency Cohort Study participants who completed a technology survey (N=424) and an eHealth Literacy Scale (eHEALS) (N=633). We report technology use (Internet/email/smartphone), interest in mHealth (Internet/email/ smartphones/mHealth applications [apps]), and level of eHealth literacy, determined by the eHEALS score. We examined the association of participant characteristics with technology use, mHealth interest, and eHealth literacy by estimating prevalence ratios (PRs) and 95% confidence intervals (CI). We conducted a thematic content analysis of open-ended survey responses to augment the quantitative findings.

Results: Study participants (N=932): mean age 68 years, 59% male, mean eGFR 54 ml/min/1.73^2. About 70% currently use Internet/email/smartphones; only 27% had adequate eHealth literacy (eHEALS score ≥32). Participants <65 years (vs. older), of White (vs. non-White) race, and with high school education (vs. lower) had more Internet/ email use. Those of non-White (vs. White) race had more interest in mHealth apps (see **Table** for more results). Three themes emerged from the content analysis: opposing views on using mHealth, concerns about losing the patient-provider face-to-face interaction, and barriers to mHealth use.

Conclusions: Many people with CKD currently use and are interested in mHealth, but few have adequate eHealth literacy. Leveraging mHealth represents a potential opportunity to engage individuals with CKD, especially minorities since they had more interest in mHealth apps, compared to non-minorities.

Funding: NIDDK Support

Patient Characteristics and Technology Use, Interest, and eHealth Literacy. Prevalence ratios (PR) and 95% CI reported.

	Internet/Email Current Use	Smartphone Current Use	Interest in Internet/Email/Smartphone Use	Interest in mHealth application Use	Adequate eHealth Literacy
Age ≥65 vs <65 years	0.68 (0.64-0.72)	0.61 (0.57-0.65)	0.74 (0.69-0.79)	0.95 (0.87-1.03)	0.56 (0.69-0.79)
White vs. Non-White race	1.28 (1.19-1.38)	0.99 (0.91-1.07)	1.16 (1.06-1.28)	0.82 (0.75-0.90)	1.25 (0.97-1.62)
High school or more vs. Less than	2.69 (2.09-3.45)	1.60 (1.33-1.92)	1.96 (1.43-2.69)	1.02 (0.92-1.14)	4.11 (2.16-7.79)

The Role of Renal Pharmacists in the Management of Patients with Renal Conditions

Ragi Philips,[1] Catarina Regis,[1] Vasuki N. Venkat,[4] Daniel J. Soberon,[2] Maribel T. Garcia,[3] Marco A. LadinoAvellaneda.[4] *[1]Jackson Memorial Hospital, Miami, FL; [2]Bruce W. Carter VA Medical Center, Hialeah, FL; [3]Miami VA Medical Center, Miami, GA; [4]Miami VA Medical Center/University of Miami/ Jackson Memorial Hospital, Plantation, FL.*

Background: The review of the renal pharmacist role in assisting in the management of CKD is not clear. Our review is the first evaluation in the United States that tests the renal pharmacist as part of the interdisciplinary team in the management of patients with renal conditions.

Methods: This retrospective study assessed the clinical outcomes after the intervention of our renal pharmacist in the Nephrology clinic at the Miami VA Medical Center. The patients were initially evaluated in the outpatient clinic by the nephrologist and the renal pharmacist; medications were changed to decrease the progression of CKD, for the management of hypertension (HTN), immunosuppression and CKD complications. The renal pharmacist followed the patients according to the changes in medical care.

Results: Fifty-six patients were assigned to the renal pharmacist in a 3-month period. Fifty patients (89%) were male; six patients (11%) were female. In 20 patients (35.7%) that had CKD III, HTN, and proteinuria, ACEIs or ARBs were started with close monitoring of the renal function, electrolytes, and proteinuria. In 10 patients (17.9%) that had uncontrolled HTN and CKD, BP medications were added and adjusted. In 9 patients (16.1%) that had a kidney transplant, tacrolimus dosages needed modification to achieve levels. In 15 patients (26.7%) that had CKD IV and V with anemia, erythropoietin stimulating agent dose was adjusted to reach appropriate hemoglobin (HB) levels. In 2 patients (3.6%) that had hypomagnesemia, magnesium supplements and amiloride were added to their medication regimen with close follow up of electrolytes and renal function. The interventions that were made in the 56 patients were successful (Proteinuria decreased, BP was controlled, tacrolimus levels achieved goal, HB levels reached goal), and patient adherence increased

Conclusions: The intervention from renal pharmacists has improved the quality of care in our patients not just by close monitoring of potential adverse effects from therapies, but also by improving BP goals, electrolyte management, and medication adherence. These changes may reduce the progression of CKD, improve cardiovascular outcomes, lower hospital admissions, and decrease the risk of death.

SA-PO869

Screening and Recognition of CKD in Primary Care Clinics in the VA Health Care System and Its Impact on Delivery of Care

Shweta Bansal,[2,1] Michael J. Mader.[3] *[1]Renal Section, South Texas Veterans Health Care System, San Antonio, TX; [2]University of Texas Health at San Antonio, San Antonio, TX; [3]South Texas Veterans Health Care System, San Antonio, TX.*

Background: The successful implementation of interventions targeted to improve kidney disease outcomes requires early identification of CKD. Early identification involves screening at-risk population as well as recognizing CKD. We determined CKD screening and recognition rate in at-risk veterans enrolled in Vertically Integrated Service Network (VISN) 17, and evaluated the impact of CKD awareness on processes of care.

Methods: We interrogated VISN 17 corporate Data Warehouse for Veterans seen at least twice in primary clinics with ICD-9 codes for hypertension (HTN) and diabetes (DM). The final cohort of 220,229 subjects (55.6% HTN, 6% diabetes and 38.4% both) was examined for serum creatinine/eGFR reported at least twice 90 days apart, urine protein and ICD-9 for CKD. Presence of CKD was defined as eGFR <60ml/min at least twice 90 days apart and/or urine albumin creatinine ratio (uACR) of >30 mg/g. BP readings from last two visits were averaged to evaluate HTN control. Prescription rate for statins and non-steroidal anti-inflammatory agents (NSAIDs) were assessed.

Results: Overall, 173,966 (79%) patients had one or other screening procedure done. Patients with isolated hypertension were less likely to have any screening procedure (72.8%) as compared to DM (81.1%) or both conditions (87.6%). Only 40.3% of total patients had urine protein in the chart, worse in HTN (18.3%) compared to DM (62.6%) or both (68.5%). Of 173,966 patients, 73,965 (42.5%) had lab evidence of CKD. However, only 19,317 (26.1%) did have a documented ICD-9 CKD diagnosis. Many of these unrecognized CKD patients (30.5%) had CKD based on uACR criteria. There was no clinically significant difference between recognized vs. unrecognized CKD groups in terms of age, sex and race. Moreover, blood pressure control and statin prescription rate were also not different. Of note, patients with BP >140/90 mmHg consistently had high rates of uACR >300 mg/g irrespective of CKD documentation. Diuretics prescription was higher (66.7% vs 58%) and NSAIDs was lower (11.4% vs. 22.9%) in documented vs undocumented CKD groups.

Conclusions: While overall CKD screening rate was 79%, identification of albuminuria was suboptimal and despite screening procedures the recognition of CKD was low in VISN 17 population with HTN and DM. Early awareness of CKD may improve processes of care.

Funding: Veterans Affairs Support

SA-PO870

Renal, Cardiac, and Safety-Related Events with Alpha Blockers in Patients with CKD

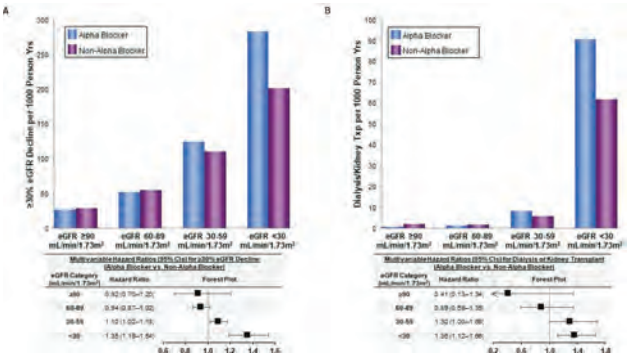
Gregory L. Hundemer,[1] William Petrcich,[2] Swapnil Hiremath,[1] Marcel Ruzicka,[1] Manish M. Sood.[1,2] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Ottawa, ON, Canada.*

Background: Alpha-blockers (ABs) are commonly prescribed as add-on therapy for blood pressure (BP) control in patients with and without chronic kidney disease (CKD). However, the association between AB use and renal, cardiac, mortality, and safety-related outcomes by CKD stage remains unknown.

Methods: Population-based, retrospective cohort study of Ontario (Canada) residents ≥66 years old with a diagnosis of hypertension from 2007 to 2015. Patients newly prescribed an AB (doxazosin, terazosin, prazosin) were matched to patients newly prescribed a non-AB BP-lowering medication using a high dimensional propensity score. Cox proportional hazards models examined the association of AB use with renal (≥30% eGFR decline, need for renal replacement therapy [RRT]), cardiac, mortality, and safety (hypotension, syncope, falls, fractures) outcomes compared to AB non-use by baseline eGFR categories (≥90, 60-89, 30-59, <30 mL/min/1.73m^2).

Results: From 329,799 eligible patients, 18,460 were dispensed ABs and matched 1:1 to non-AB users. Among patients with CKD, AB use was associated with a higher risk of the following adverse renal outcomes compared with non-AB use: (**See Figure**) ≥30% eGFR Decline: eGFR 30-59 mL/min/1.73m^2: HR 1.10 [95%CI 1.02-1.18] eGFR <30 mL/min/1.73m^2: HR 1.35 [95%CI 1.19-1.54]; p-interaction <0.001 RRT: eGFR 30-59 mL/min/1.73m^2: HR 1.30 [95%CI 1.00-1.68] eGFR <30 mL/min/1.73m^2: HR 1.36 [95%CI 1.12-1.66] There were no significant differences in cardiac, mortality, or safety-related events between AB users and non-users by CKD stage.

Conclusions: ABs are associated with a higher risk of adverse renal outcomes in patients with CKD compared with other BP-lowering medications.



Adverse Kidney Outcomes in Alpha-Blocker Users vs. Non-Users

SA-PO871

Nephrotoxin Exposure After Hospital Discharge Predicts Development of CKD Among AKI Survivors

Diana J. Schreier,[1] Kianoush Kashani,[1] Andrew D. Rule,[1] John C. Lieske,[1] Sandra Kane-Gill,[2] Alanna Chamberlain,[1] Kristin C. Mara,[1] Erin F. Barreto.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Survivors of acute kidney injury (AKI) are at high risk of progression to chronic kidney disease (CKD). A potentially modifiable risk factor for subsequent CKD is exposure to drugs with potential nephrotoxicity. The objective of this study was to evaluate the association between the prescription of potentially nephrotoxic medications in AKI survivors at hospital discharge and the subsequent risk of new or worsening CKD, readmission with AKI or death.

Methods: We conducted a population-based cohort study of adult Olmsted County, MN residents who developed AKI while hospitalized between 1/1/2006 and 12/31/2014 using data from the Rochester Epidemiology Project (REP). The REP links medical records across care providers in Olmsted County, making population-based studies possible. The cohort included those with a hospitalization complicated by AKI who survived to discharge. Discharge medication lists, prescription records, and clinical notes were queried for prescription of potentially nephrotoxic medications over the 3 years after discharge. New or worsening CKD was identified by both diagnosis codes and calculated estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2. Cox proportional hazards models were fit to evaluate the association between exposure to potentially nephrotoxic medications and the study outcomes. A validated CKD risk prediction score was used to adjust the Cox models for the baseline risk of CKD following AKI.

Results: Among 2,894 AKI survivors, 2143 (74%) received a potentially nephrotoxic medication at discharge. Those that received these drugs experienced a significantly higher risk of new or worsening CKD during 3-years of follow-up (cumulative incidence 71% vs. 57%; HR 1.44: 95% CI 1.28, 1.63). Patients prescribed potentially nephrotoxic medications after discharge also experienced a significantly greater risk of the composite endpoint of CKD, AKI readmission, or death within 3 years of discharge (HR 1.32: 95% CI 1.20, 1.46).

Conclusions: In this population-based cohort study, we observed that AKI survivors prescribed potentially nephrotoxic medications at hospital discharge were at significantly greater risk for CKD development, AKI readmission, and death in the 3 years following hospitalization.

SA-PO872

Baclofen and the Risk of Encephalopathy in Older Adults with CKD: A Population-Based Cohort Study

Flory T. Muanda,[1] Amit X. Garg.[2] ICES-KDT *[1]Western University/ICES KDT, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada.*

Background: Importance: Baclofen, a popular muscle relaxant, undergoes renal clearance and can accumulate in patients with low kidney function. Over 30 case reports link baclofen use to encephalopathy in patients with chronic kidney disease (CKD). Objectives: The primary objective was to compare the 30-day risk of encephalopathy in patients with CKD newly prescribed a high vs low dose of baclofen (≥20 vs <20 mg/day). The secondary objective was to compare the risk in baclofen users vs non-users.

Methods: Design: Population-based cohort study using linked healthcare data. Setting: Ontario, Canada (2007–2018). Participants: Older adults with CKD (defined as an estimated glomerular filtration rate [eGFR] <60 mL/min/1.73 m^2 but not on dialysis). The primary cohort was restricted to new baclofen users; the secondary cohort included both new users and non-users. Exposure: Oral baclofen (≥20 mg/day vs <20 mg/day). Main Outcome and Measure: Hospital admission with encephalopathy, defined as a main diagnosis of delirium, disorientation, transient cerebral ischemic attack, alteration of awareness, or dementia. Inverse probability of treatment weighting on the propensity score was used to balance comparison groups on indicators of baseline health. Weighted risk ratios (wRR) were obtained using modified Poisson regression and weighted risk differences (wRD) using binomial regression.

Results: The primary cohort included 15,942 patients with CKD (61% women; median age 77); 9707 (61%) patients started baclofen at ≥20 mg/day and 6235 (39%) at <20 mg/day. The primary outcome, hospital admission with encephalopathy, occurred in 108 (1.11%) patients in the high-dose group and in 26 (0.42%) patients in the low-dose group. The wRR was 3.54 (95% CI, 2.24–5.59) and the wRD was 0.80% (95% CI, 0.55%–1.04%). In subgroup analysis, the absolute risk increased progressively as eGFR declined. In patients with eGFR<30 mL/min/1.73 m^2, the wRR was 4.26 (95% CI, 1.77–10.25) and the wRD was 2.90% (95% CI, 1.30%–4.49%). In the secondary comparison with 284,263 non-users, both low-dose and high-dose users had a higher risk of encephalopathy: wRR, 5.90 (95% CI, 3.59–9.70) and 19.8 (95% CI, 14.0–28.0), respectively.

Conclusions: Baclofen should be used cautiously or avoided in patients with CKD.

Immunosuppressive Agents for Treating IgA Nephropathy: An Updated Cochrane Review

Suetonia Palmer,[1] Marinella Ruospo,[2] Patrizia Natale,[2,3] Jorgen B. Hegbrant,[2] Giovanni F. Strippoli.[2,3] *[1]University of Otago, Christchurch, New Zealand; [2]Diaverum, Lund, Sweden; [3]University of Bari, Bari, Italy.*

Background: IgA nephropathy (IgAN) is the most common glomerular disease worldwide. High certainty evidence for effective interventions has been impeded because due to the rarity of patient-centred endpoints such as end-stage kidney disease (ESKD) and heterogeneity in clinical progression and disease severity. As several recent trials have reported, we updated the Cochrane review evaluating the benefits and harms of immunosuppression for the treatment of IgAN.

Methods: A Cochrane systematic review with meta-analysis was updated to include randomized controlled trials in which adult and children with biopsy-proven IgA nephropathy were randomly allocated to immunosuppressive agent versus placebo, no treatment/standard care, or other non-immunosuppressive agent. Treatment effects were estimated by random-effects meta-analysis. Evidence certainty was adjudicated using GRADE methodology.

Results: 54 studies (3730 patients) were included. Median follow-up was 24 months. Risk of bias was generally high or unclear. Steroid treatment probably prevents progression to ESKD (RR 0.41, 95% CI 0.26-0.65; moderate certainty evidence) and annual GFR loss (MD -5.40 ml/min/1.73m2, 95% CI -2.25 to -8.55; moderate certainty evidence), and may induce complete remission (RR 1.76, 95% CI 1.03-3.01; low certainty evidence). The addition of cytotoxic therapy to steroids had uncertain effects as did regimens containing mycophenolate mofetil (MMF), or calcineurin inhibitors as monotherapy on background steroid treatment. Adverse effects of treatment, especially infections, were uncertain due to a lack of data and heterogenous results in studies.

Conclusions: Steroid therapy probably prevents progression of ESKD and annual GFR loss and may induce complete remission. The effects of other treatments for treating IgA nephropathy were very uncertain and adverse events are poorly understood.

SA-PO874

Inpatient Admissions Account for the High Medical Costs of CKD

Gregory A. Nichols,[1] Anastasia Ustyugova,[2] Anouk Deruaz-Luyet,[2] Kimberly Brodovicz.[3] *[1]Kaiser Permanente Northwest, Portland, OR; [2]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [3]Boehringer Ingelheim, Ridgefield, CT.*

Background: Chronic kidney disease (CKD) results in high medical costs typically attributed to renal dialysis but excess costs begin to accumulate in earlier CKD stages. Better understanding of medical costs and its determinants may help to optimize patient care in resource-constrained settings. We evaluated annual medical costs in patients with CKD across types of care and in subgroups of patients with and without diabetes, cardiovascular disease, and heart failure.

Methods: We used the electronic medical records of Kaiser Permanente Northwest to identify 21,252 patients with CKD in 2016 or 2017 and examined non-mutually exclusive groups according to presence of comorbidities. We used 1 year of follow-up data to calculate the annual outpatient, inpatient, emergency, pharmaceutical, dialysis, and total medical care costs by KDIGO-defined stages of CKD adjusted for age, sex, non-white race, and within subgroups of patients with selected comorbidities.

Results: Inpatient costs accounted for 42%, 50%, 57% and 29% of total costs for stages G3a, G3b, G4, and G5, respectively (figure). Nearly 30% of all hospitalizations were CVD-related. Patients with CKD and 1 or more comorbidities incurred 2.4 to 4-fold greater medical costs than those with no comorbidities. Inpatient costs accounted for 35%-66% of the total in stages G3a, G3b and G4, and 23%-37% in stage G5.

Conclusions: Inpatient costs consistently accounted for over 40% of the total costs of care for CKD patients prior to reaching end-stage kidney disease regardless of the presence of comorbidities. Considering the significant economic burden evident in early CKD stages, development and implementation of effective measures to reduce the need for inpatient care is critical.

Predictors of Hyperkalemia in Patients with Advanced CKD

Ankur A. Dashputre,[1] Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Oguz Akbilgic,[1] Suryatapa Kar,[1] Yoshitsugu Obi,[2] Fridtjof Thomas,[1] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Identifying predictors of hyperkalemia will help clinicians in managing patients with advanced CKD at a greater risk for future hyperkalemia events.

Methods: In 20,657 US Veterans with eGFR <30 ml/min/1.73m^2 and with ≥1 year of follow-up prior to dialysis initiation, we identified predictors of plasma potassium [K^+] >6.0 mEq/l using multivariable logistic regression models with backward-selection based on Akaike's information criterion, adjusted for demographics, comorbidities, vital signs, laboratory tests and medications. The sample was split (70%:30%) into training set (n=14,461) and test set (n=6,196). We conducted model cross validation using the leave one out cross validation method (LOOCV). We assessed model predictive discrimination using the area under the receiver-operator curve (AUC).

Results: The mean (SD) age of the patients was 67 (10) years; 98% were male, 29% were African American, with a mean (SD) baseline K^+ of 4.6 (0.6) mEq/l, and baseline eGFR of 23.6 (4.7) ml/min/1.73m^2. At least one event of [K^+] >6.0 mEq/l was experienced by 7.4% of the patients. Our final model included 16 predictor variables. The AUC (95% CI) estimates for training, test, and LOOCV were 0.765 (0.751-0.780), 0.761 (0.738-0.784), and 0.762 (0.749-0.774), respectively (Figure). Baseline K^+ (OR [95%CI], 3.09 [2.83-3.39]), baseline Na polystyrene sulphonate use (2.51 [2.16-2.93]), and age (0.97 [0.96-0.98]) were the strongest predictors of hyperkalemia.

Conclusions: We developed and tested a prediction model with good discrimination ability to identify future hyperkalemia in patients with advanced CKD. Accurate prediction of future hyperkalemia could help implement preventive measures and may have a beneficial impact on outcomes.

Plasma Potassium Trajectories and Associated Post-Transition Mortality in Patients with Advanced CKD Transitioning to ESRD

Ankur A. Dashputre,[1] Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Suryatapa Kar,[1] Yoshitsugu Obi,[2] Fridtjof Thomas,[1] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Potassium (K^+) homeostasis is impacted by reduced kidney function, but the pre-ESRD trajectory of plasma K^+ concentration and the associated post-ESRD mortality is unknown.

Methods: In 34,167 US Veterans who transitioned to dialysis between 2007-2014 and had ≥1 K^+ measurement in each year over the last three years prior to dialysis initiation, we examined K^+ trajectory (slope) for both the entire three-year and for each of the three one-year pre-ESRD periods, using linear mixed effects models adjusted for fixed (age, sex, race, diabetes and congestive heart failure) and time-varying (RAAS inhibitor, sodium-polystyrene sulphonate, loop diuretics and mineralocorticoid receptor antagonist use, and eGFR) covariates with patient as the random effect. Quadratic spline and Cox regression models were used to assess the multivariable adjusted association between K^+ slope and all-cause mortality within 6 months of dialysis initiation.

Results: The mean (SD) age of the cohort was 67 (11) years; 98% were male, 29% were African American, and 77% were diabetic. The unadjusted mean (95% CI) K^+ slope was 0.008 (0.006, 0.011) mEq/l/year, which reversed after multivariable adjustment, especially for eGFR levels (adjusted mean [95% CI] K^+ slope, -0.10 [-0.13, -0.07] mEq/l/year). Most of the change over time in plasma K^+ was observed in the last year prior to dialysis. A reverse J-shaped association was observed between K^+ slope and mortality (Figure).

Conclusions: The average intraindividual plasma K^+ trajectory is remarkably stable in patients nearing ESRD, likely as a result of physiologic mechanisms and therapeutic interventions which counteract the progressively limited ability of the failing kidneys to excrete K^+. A declining slope, but not an increasing slope, is associated with higher mortality risk.

Higher Discharge Serum Creatinine Is Associated with CKD Among Survivors of AKI

Binbin Wu, Yi Yang, Jianghua Chen. *Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Despite many studies showing patients have higher risk of developing chronic kidney disease (CKD) after a hospitalization with acute kidney injury (AKI), data on the prognostic value of discharge serum creatinine (SCr) are limited. The aim of this study is to explore the association between discharge SCr and CKD risk among survivors of AKI.

Methods: From January 2011 through December 2011, patients hospitalized with AKI in the First Affiliated Hospital, College of Medicine, Zhejiang University without known CKD were screened. The primary endpoint was CKD progression within 5 years. The association between discharge SCr and CKD was assessed by multivariate logistic regression. The net reclassification improvement(NRI) and integrated discrimination improvement (IDI) statistics were applied in statistical analysis.

Results: 673 patients was enrolled and 526 (78.1%) progressed to CKD in 5 years' follow-up. After adjusting for age, gender, stage of AKI, diabetes, hypertension, coronary heart disease, proteinuria and baseline SCr, the odds ratio(OR) rose with the increase of discharge SCr. Multivariable model showed prognostic significance, with the area under the receiver operating characteristic curve (AUC) of 0.77. The addition of discharge SCr to established risk factors improved risk prediction of CKD (AUC of 0.841; NRI of 18.18%; IDI of 10.12%, all P < 0.01).

Conclusions: Higher levels of discharge SCr were associated with increased risk of CKD among survivors of AKI, indicating that discharge SCr could be a predictor independent of established conventional risk factors.

Table 1. Discharge SCr concentrations prediction of CKD with AUC.

	AUC					
Endpoint	Discharge SCr	Risk factors	Risk factors with discharge SCr	Incremental area (P)	NRI (P)	IDI (P)
CKD	0.763	0.77	0.841	0.071 (P < 0.01)	0.182 (P < 0.01)	0.101 (P < 0.01)

Established risk factors including age, gender, stage of AKI, diabetes, coronary artery disease, hypertension, proteinuria and baseline SCr.

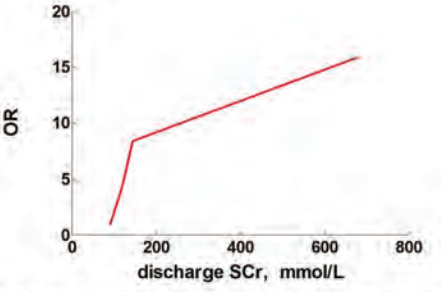

Figure 1. Adjusted OR of CKD according to discharge SCr concentrations.

ORs were adjusted for age, gender, stage of AKI, diabetes, hypertension, coronary artery disease, proteinuria and baseline serum creatinine.

SA-PO878

Pre-Operative Biomarkers and Risk for CKD After Cardiac Surgery

Steven G. Coca,[1] Steven Menez,[4] Dennis G. Moledina,[2] Eric McArthur,[3] Yaqi Jia,[4] Wassim Obeid,[4] Caroline Liu,[4] Sherry Mansour,[2] Heather Thiessen Philbrook,[4] Michael Shlipak,[5] Amit X. Garg,[6] Chirag R. Parikh.[4] TRIBE-AKI Consortium *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale School of Medicine, New Haven, CT; [3]Institute for Clinical Evaluative Sciences, London, ON, Canada; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]San Francisco VA Medical Center, San Francisco, CA; [6]London Health Sciences Centre, London, ON, Canada.*

Background: The associations between various biomarkers and long-term kidney outcomes after cardiac surgery are unknown.

Methods: In patients undergoing cardiac surgery who were enrolled in the TRIBE-AKI study, we assessed the associations of 32 plasma and 8 urine biomarkers measured pre-operatively with the composite kidney endpoint of incident CKD or progression of existing CKD. The cohort was separated into exploration (Canada, n=613) and replication (USA, n=310) cohorts due to differences in outcome ascertainment and lack of data integration of the two cohorts. In the exploration cohort, top biomarkers were identified from the 40 candidate biomarkers. Results were confirmed in the replication cohort, thereby reducing resubstitution and model selection biases. Estimates were pooled for biomarkers that were statistically significant in both the derivation and replication cohorts. Cox proportional hazard regression models adjusted for age, sex, AKI stage, pre-op albuminuria, pre-op SCr, discharge SCr estimated the relationship of the biomarkers with the CKD outcome.

Results: After a median (IQR) follow-up of 5.6 (4.3-5.8) years, a total of 172 (28%) patients experienced the CKD endpoint. 7 plasma and 0 urine biomarkers were independently associated with the CKD endpoint in the exploration cohort, of which 4 biomarkers retained statistical significance in the replication cohort and upon pooling. The pooled HRs (95% CI) per natural log increase were as follows: TNFR1 2.3 (1.6, 3.2), TNFR2 1.7 (1.2, 2.3), KIM1 1.8 (1.3, 2.4), NT-proBNP 1.2 (1.1, 1.4) (**Table**).

Conclusions: Pre-operative plasma TNFR1, TNFR2, KIM-1 and NT-proBNP were associated with incidence and progression of CKD several years after cardiac surgery. As in other clinical settings, these biomarkers may provide prognostic value for long-term kidney outcomes after cardiac surgery.

Plasma Potassium Variability and Associated Post-Transition Mortality in Patients with Advanced CKD Transitioning to ESRD

Ankur A. Dashputre,[1] Praveen Kumar Potukuchi,[1] Keiichi Sumida,[1] Suryatapa Kar,[1] Yoshitsugu Obi,[2] Fridtjof Thomas,[1] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

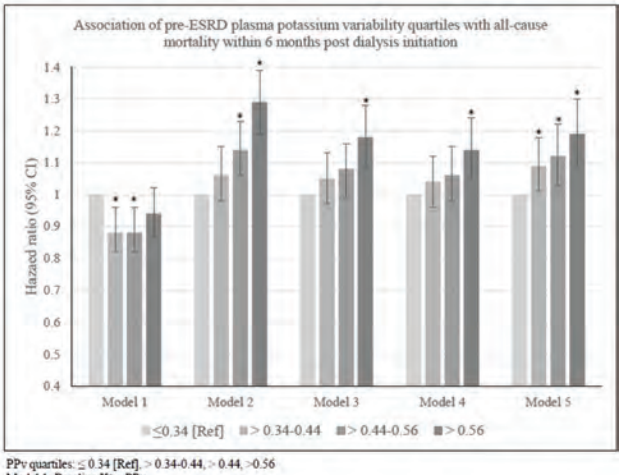
Background: Both higher and lower plasma potassium (K^+) levels are associated with increased mortality, but it is unclear if a propensity for higher plasma K^+ variability (i.e. more frequent or extreme deviations in plasma K^+) prior to dialysis initiation is associated with post-ESRD adverse outcomes independent of baseline K^+ levels.

Methods: In 34,167 US Veterans who transitioned to dialysis between 2007-2014 and had ≥1 plasma K^+ measurement in each year over the last three years prior to dialysis initiation, we examined the association of plasma K^+ variability (PPv, defined as the standard deviation of intra-individual K^+ values over the three-year study period and expressed as quartiles) with all-cause mortality within 6-months after dialysis initiation, using Cox proportional hazard models with adjustment for baseline K^+, demographics, comorbidities, cumulative length of hospital stay, medications, and average eGFR and number of K^+ measurements (median [IQR]: 19 [8-35]) over the three-year study period.

Results: The mean (SD) age of the cohort was 67 (11) years; 98% were male, 29% were African American, and 77% were diabetic. After adjusting for potential confounders, higher PPv quartiles were consistently associated with increased risk of all-cause mortality within 6 months of dialysis initiation (adjusted HRs [95% CI] for quartiles 2-4 [vs. quartile 1], 1.09 [1.01-1.18], 1.12 [1.03-1.22], and 1.19 [1.09-1.30] in model 5; Figure)

Conclusions: Greater pre-ESRD PPv is associated with higher all-cause mortality within 6 months of dialysis initiation. Clinical trials are needed to determine if measures used to stabilize plasma K^+ can improve patient outcomes.

Funding: NIDDK Support



PPv quartiles: ≤ 0.34 [Ref], > 0.34-0.44, > 0.44, >0.56
Model 1: Baseline K^+ + PPv
Model 2: Model 1 + demographics
Model 3: Model 2 + comorbidities + cumulative length of hospital stay
Model 4: Model 3 + medications
Model 5: Model 4 + eGFR + baseline K^+ counts

SA-PO880

Impact of ACE Inhibitor/ARB Discontinuation After an Episode of Hyperkalemia in Patients with CKD

Silvia J. Leon mantilla,[1,3] Reid Whitlock,[1,3] Claudio Rigatto,[2,3] Paul Komenda,[2,3] Navdeep Tangri.[2,3] *[1]Community Health Sciences, University of Manitoba, Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Department of Internal Medicine, University of Manitoba, Max Rady College of Medicine, Winnipeg, MB, Canada; [3]Chronic Disease Innovation Centre, Winnipeg, MB, Canada.*

Background: Angiotensin-converting-enzyme inhibitors (ACEi) and angiotensin II receptor blockers (ARB) are recommended in diabetic and proteinuric nondiabetic chronic kidney disease (CKD). However, therapy with ACEi/ARBs is also associated with an increased risk of hyperkalemia (HK+) that ranges from mild to life-threatening. After an acute episode of hyperkalemia is treated, physicians are faced with the important clinical decision of whether to discontinue ACEi/ARBs. With this study we aim to evaluate the effect of discontinuation of ACEi/ARBs after an episode of HK+ in patients with CKD.

Methods: We performed a retrospective cohort study using administrative health data from Manitoba, Canada. We included all adults (≥ 18 years) with an episode of de novo HK+ (defined as serum potassium ≥ 5.5 mmol/L) between January 1st, 2007 and December 31, 2016. We identified a subgroup of patients with CKD who were current ACEi/ARB users at the time of their HK+ episode. Discontinuation was defined as the absence of a new prescription for an ACEi/ARB within 90 days of the index date among surviving patients. Cox proportional hazards were used to examine the association of ACEi/ARB discontinuation and all-cause and cardiovascular mortality, and initiation of dialysis.

Results: In our cohort, 37,633 episodes of hyperkalemia were identified. Among those, 10,273 had CKD and were current ACEi/ARB users at the time of the hyperkalemia episode. Ninety days after the episode of hyperkalemia, 7,699 surviving patients were included for analysis. A total of 1,707 (22.3%) patients discontinued the ACEi/ARB. ACEi/ARB discontinuation was associated with a more than 2-fold higher risk of all-cause and cardiovascular mortality [hazard ratio (HR) 2.15, 95% CI: 1.99-2.32] for all-cause mortality and [HR 2.04, 95% CI 1.81-2.31] for cardiovascular mortality. Discontinuation of ACEi/ARB was not associated with initiation of dialysis [HR 0.76, 95% CI: 0.49-1.18].

Conclusions: ACEi/ARB discontinuation was associated with a more than 2-fold higher rate of all-cause mortality compared with those who continued ACEi/ARB. Newer therapies for hyperkalemia may be better tolerated and can allow patients to stay on ACEi/ARB therapy.

The Impact of Prevalent Stroke at Critical Junctures in the Care for Patients with Kidney Disease

James Tollitt,[1,2] Aghogho Odudu,[2] Rajkumar Chinnadurai,[3,2] Emma Flanagan,[5] Craig J. Smith,[2] Philip A. Kalra.[4,2] *[1]Salford Royal NHS Trust, Salford, United Kingdom; [2]University of Manchester, Manchester, United Kingdom; [3]Salford Royal NHS Foundation Trust, Manchester, United Kingdom; [4]Salford Royal Hospital NHS Trust, Salford, United Kingdom; [5]Salford Care Organisation, Salford, United Kingdom.*

Background: Chronic kidney disease is an independent risk factor for stroke in the general population. The impact of a prior stroke on important outcomes for CKD patients is less well characterised. We examined associations between prior stroke and clinical outcomes in a large UK CKD cohort at study recruitment and at time of dialysis commencement

Methods: 3060 participants of the Salford Kidney Study (a large UK CKD longitudinal epidemiological cohort study recruiting since October 2002) were included in the analysis. Multivariable cox regression survival analyses, adjusted for competing risks, was performed to examine the effects of prevalent stroke on endpoints of death, end stage renal disease (ESRD) and non-fatal cardiovascular events (NFCVE). Similar methodology was used to examine the impact of prior stroke on survival in patients who commenced dialysis

Results: Of 3060 study recruits 227 had suffered a stroke prior to recruitment (table 1). Stroke was independently associated with mortality (HR 1.20 95%CI 1.0-1.43, p=0.05), reaching ESRD (HR 1.34 95%CI 1.06-1.69, p=0.02) and future NFCVE (HR 1.54 95%CI 1.12-2.11, p=0.01) after adjustment for age, gender, eGFR, diabetes, hypertension, myocardial infarction, heart failure, atrial fibrillation, smoking history and peripheral vascular disease. 579 patients reached ESRD and commenced dialysis. Stroke prior to dialysis commencement (N=48) was significantly associated with mortality (HR 1.47 (95%CI 1.01-2.14 P=0.05) after adjustment for the same factors (except eGFR) over median 25 months follow up.

Conclusions: Sroke prior to study recruitment was independently associated with mortality, ESRD and future NFCVE. Similarly, stroke was independently associated with mortality in patients who commenced dialysis. This large observational study indicates that stroke alters cardiovascular risk in CKD patients and emphasises the importance of kidney brain crosstalk.

Comparison between patient outcomes (Prevalent stroke v no prevalent stroke)

Outcome	No Stroke at Recruitment N=2833	Stroke at Rectuitment N=227	
Stroke	81 (2.9%)	20 (8.8%)	<0.001
Myocardial Infarction	154 (5.4%)	24 (10.6%)	0.001
End Stage Renal Disease	887 (31.3%)	92 (40.5%)	0.004
All cause mortality	1275 (45%)	157 (69.2%)	<0.000
Death from cardiovascular disease	174 (43.5%)	31 (57.5%)	<0.001

SA-PO882

Association of Laxative Use with Change in eGFR in Patients with Advanced CKD

Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Ankur A. Dashputre,[1] Suryatapa Kar,[1] Fridtjof Thomas,[1] Yoshitsugu Obi,[2] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Constipation is highly prevalent in advanced CKD and is associated with adverse kidney outcomes potentially through altered gut microbiota. Laxatives are typically used for constipation management; however, little is known about the effect of laxatives on kidney function in advanced CKD patients.

Methods: We examined the association of laxative use with change in eGFR (slope) over the last two years before dialysis initiation in 25,140 US veterans transitioning to dialysis from 2007-2014. Laxative use was defined as having ≥2 prescriptions of laxatives of ≥30-day supply each during the two-year prelude period. eGFR slopes were estimated by linear mixed effects models using all available outpatient eGFR measurements in the same period. Associations were examined in multinomial logistic regression models with adjustment for demographics, comorbidities, medications, nephrology care, cumulative length of hospital stay, vascular access type, and clinical variables.

Results: The mean (SD) age of the cohort was 70 (11) years; 98% were male; 26% were African American; and 75% were diabetic. Patients with (vs. without) pre-ESRD laxative use were at lower risk of experiencing more progressive eGFR decline and also had higher risk of increasing eGFR even after accounting for various potential confounders (fully adjusted multinomial odds ratios [95% CI] for eGFR slope <-10, -10-<-5, and ≥0, vs. -5-<0 mL/min/1.73 m^2/year, 0.86 [0.78-0.94], 0.59 [0.54-0.65], and 1.26 [1.03-1.52], respectively; Figure).

Conclusions: The use of laxatives may have potential renoprotective benefits in advanced CKD patients, in whom the gut gains importance in the acid-base and mineral homeostasis and the disposal of nitrogenous waste products. Further studies are needed to elucidate the underlying mechanisms and to evaluate its clinical effectiveness.

SA-PO883

Patterns of Care for Lipid Management in CKD Stage 3-5 Patients: Results from CKDopps

Daniel G. Muenz,[1] Stephanie R. Reading,[2] Keith McCullough,[1] Viviane Calice-Silva,[4] Paul Dluzniewski,[2] Ziad Massy,[3] Kiran Philip,[2] Helmut Reichel,[5] Bruce M. Robinson,[1] Roberto Pecoits-Filho.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Amgen, Los Angeles, CA; [3]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [4]Pro-Kidney Foundation, Joinville, Brazil; [5]Nephrological Center Villingen-Schwenningen, Villingen-Schwenningen, Germany.*

Background: Current KDIGO guidelines recommend conducting a lipid profile upon diagnosis for chronic kidney disease (CKD) and treating patients ≥50 years with a statin +/- ezetimibe. However, these guidelines do not provide target lipid levels for treatment. Thus, we aimed to evaluate current nephrologist care practice patterns for lipid management, including perceptions of target levels of LDL-cholesterol (LDL-C), statin/ezetimibe prescription, and achieved LDL-C using the CKD Outcomes and Practice Patterns Study (CKDopps).

Methods: We analyzed patient-level treatment and LDL-C levels and nephrologist-specified target LDL-C upper limits from CKDopps clinics in Brazil, Germany, and the United States (2013-2018). Patients were ≥18 years old with eGFR <60ml/min at enrollment. P-values were obtained from a logistic model of the prevalence of treatment with statins +/- ezetimibe by age (< or ≥50), country, and CKD stage; and a linear model of mean LDL-C by treatment, country, and CKD stage. Both models used generalized estimating equations to account for patient clustering by clinic.

Results: Statin/ezetimibe treatment was more prevalent among CKD patients ≥50 years-old (p<0.0001) and differed significantly by country (p=0.001; Figure 1a). LDL-C was lower among treated patients (p<0.0001) and differed significantly by country (p<0.0001; Figure 1b). Neither patient-level outcome varied significantly by CKD stage (p≥0.2). Between 7-23% of untreated patients in each country had LDL-C ≥160 mg/dL. Only 7-17% of nephrologists believed that LDL-C should be <70 mg/dL.

Conclusions: There is substantial variation in practice patterns regarding lipid-lowering therapies across countries, but not across CKD stages. Treated patients appear to benefit with regard to LDL-C lowering, yet a significant proportion of hyperlipidemia patients are not receiving treatment.

Treatment Preferences of Patients with CKD in Acute Coronary Syndrome: A Discrete Choice Experiment

Todd Wilson,[1] Glen Hazlewood,[1] Stephen B. Wilton,[1] Tolulope Sajobi,[1] Pantea Amin javaheri,[1] Juli Finlay,[1] Winnifred (winnie) E. Pearson,[2] Carol Connolly,[3] Matthew T. James.[1] Alberta Provincial Program for Outcome Assessment in Coronary Heart Disease (APPROACH) and Can-SOLVE CKD Network project team *[1]University of Calgary, Calgary, AB, Canada; [2]Alberta Health Services, CALGARY, AB, Canada; [3]Can-SOLVE CKD Network, Calgary, AB, Canada*.

Background: Chronic kidney disease (CKD) is associated with a high incidence of acute coronary syndrome (ACS) and related morbidity and mortality. Treatment choices for patients with CKD involve tradeoffs in potential benefits and harms of invasive management options.

Methods: To design, pilot and field a discrete choice experiment (DCE) to quantify preferences of patients with CKD towards invasive heart procedures. Attributes of invasive versus conservative treatment for ACS were identified through semi-structured qualitative interviews. Levels for each attribute were determined from CKD subgroup analyses of early invasive versus conservative management clinical trials and cohort studies. The DCE was co-developed with physicians and patient input. Eligible patients for the study included those with CKD over 18 years of age, recruited from two multidisciplinary CKD clinics in Calgary, Alberta. Patients were recruited for the pilot study from September to November 2018 and the full study commenced in January 2019. Average importances for treatment attributes were quantified using Hierarchical Bayes estimation, and scaled on a 0-100 scale to reflect their relative importance.

Results: Among 64 patients who provided consent to participate in this full study, 59 (92%) completed the survey. Participants had an average age of 67 years, with 41% female, and mean eGFR 18mL/in/1.73m^2. The most important attributes were risk of death within one-year (32.0, 95% CI [28,6, 35.4]) and end stage renal disease (20.5, 95% CI [17.3, 23.7]). The attributes AKI requiring dialysis, risk of another heart attack within one year and invasive procedures (versus conservative management) were of lesser importance (17.2, 95% CI (14.8, 19.7); 15.8, 95% CI (14.2, 17.5); and 14.5 95% CI (11.0, 18.0), respectively).

Conclusions: These results demonstrate the feasibility of conducting a DCE to quantify preferences of patients with CKD. Preliminary findings suggest patients with CKD are most risk averse towards death, however, end-stage kidney disease is a strong consideration. Measurement of these patient preferences can be used to inform the strength of clinical guideline recommendations and to improve shared-decision making approaches for cardiovascular disease for patients with CKD.

Statin Prescription in CKD Patients Aged ≥50 Years Without Prevalent Coronary Heart Disease

Jung-Im Shin,[1] Yao (Lucy) Qiao,[1] Lesley Inker,[3] Josef Coresh,[1] Alex R. Chang,[2] Morgan Grams.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Geisinger Medical Center, Danville, PA; [3]Tufts Medical Center, Boston, MA.*

Background: According to the 2013 Kidney Disease Improving Global Outcomes (KDIGO) guideline, statins are recommended in adults aged ≥50 years with chronic kidney disease (CKD) stages 3-5, not on dialysis. Our objective was to examine whether there was a change in prescription prevalence after publication of the KDIGO guideline in November 2013 in two real-world populations.

Methods: We created one-year period prevalence cohorts for each year in the Geisinger Health System (2004-2016) and Johns Hopkins Medicine (2013-2016), including patients with CKD stages 3-4 (to be conservative so as not to inadvertently include end-stage kidney disease), age ≥50 years, and without prevalent coronary heart disease (another indication for statin use that could confound interpretation).

Results: At Geisinger (N=54,788, mean age 72 years, 65% female, 99% white, mean eGFR 50 ml/min/1.73 m^2), statin prescription increased from 28% to 41% from 2004 to 2007 (p<0.001), but then remained relatively stable (**Figure**). There was no significant change in statin prescription after the KDIGO guideline was published; prevalence of statin prescription in 2016 was 47%. At Hopkins (N=19,682, mean age 70 years, 61% female, 67% white, mean eGFR 50 ml/min/1.73 m^2), statin prescription did not change after the KDIGO guideline; prevalence of prescription in 2016 was 52%.

Conclusions: Despite the 2013 KDIGO's recommendation that all adults with CKD aged ≥50 years should be prescribed statins, nearly half of the patients were not prescribed for statin in 2016 in two real-world settings. We need to understand better why adherence to KDIGO guideline on statin use is low in this high-risk population.

Funding: NIDDK Support

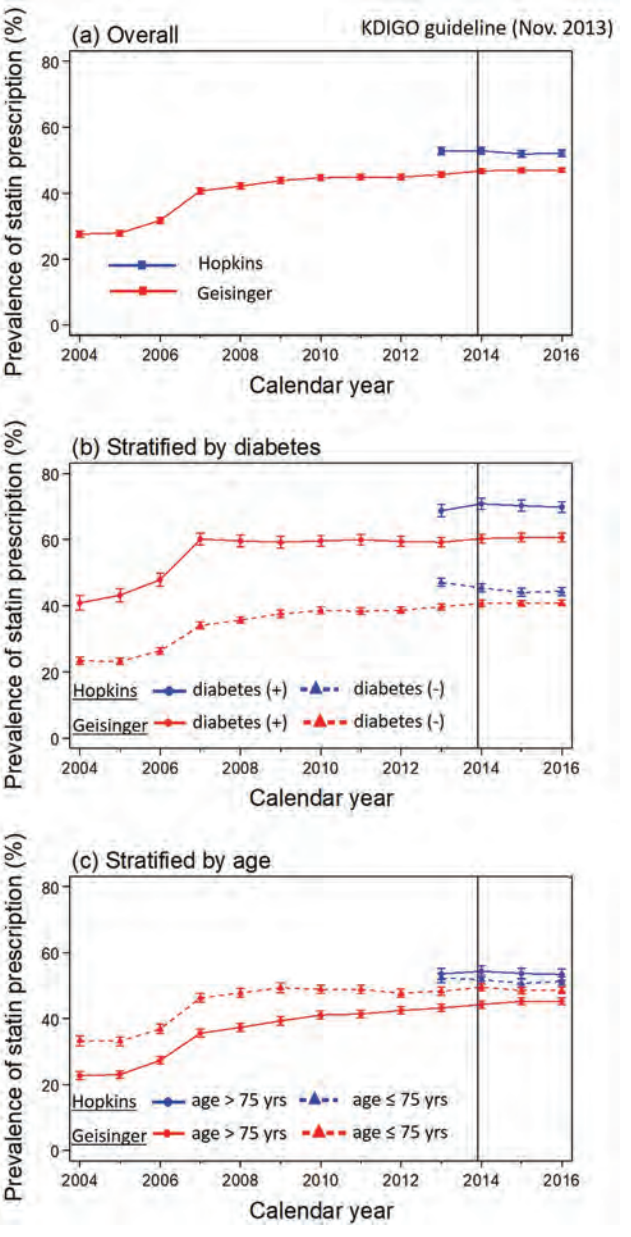

Figure. Prevalence of statin prescription in CKD G3-4 patients aged ≥ 50 years without prevalent coronary heart disease

Hospitalization with Major Infection and Incidence of ESRD: The Atherosclerosis Risk in Communities (ARIC) Study

Junichi Ishigami,[1] Logan T. Cowan,[2] Ryan Demmer,[5] Morgan Grams,[3] Pamela L. Lutsey,[5] Josef Coresh,[4] Kunihiro Matsushita.[6] *[1]Johns Hopkins School of Public Health, Baltimore, MD; [2]Georgia Southern University, Statesboro, GA; [3]Johns Hopkins University, Baltimore, MD; [4]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [5]University of Minnesota, Minneapolis, MN; [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*.

Background: Animal studies have suggested deleterious impacts of infection on the kidney. Whether incidence of infection increases long-term risk of incident ESRD has not been systematically evaluated in the general population.

Methods: In 10,293 participants of the ARIC Study who attended visit 4 (1996-1998), we evaluated the association of incident hospitalization with major infection (pneumonia, urinary tract infection, bloodstream infection, and cellulitis/osteomyelitis) with subsequent risk of ESRD. Hospitalization with major infection was entered into multivariable Cox models as a time-varying exposure to estimate the HRs.

Results: The mean age was 63 years, 56% were female, 22% were black, and 7% had eGFR < 60 ml/min/1.73m^2. During a median follow-up of 17.4 years, there were 2,910 incident hospitalizations with major infection and 279 cases of ESRD (209 cases

after hospitalizations with major infection). The risk of ESRD was higher following major infection compared to while free of major infection (crude incidence rate, 5.0 vs. 0.6 per 1,000 person-years) (Table). In multivariable time-varying Cox analysis, hospitalization with major infection was associated with 3.4-fold increased risk of ESRD (HR, 3.41 [95%CI, 2.61-4.46]) (Table). The association was similar across pneumonia, urinary tract infection, bloodstream infection, and cellulitis/osteomyelitis and stronger among participants with a concurrent diagnosis of acute kidney injury (HR, 4.30 [95%CI, 3.00-6.18]) compared to those without (HR, 2.06 [1.57-2.72]).

Conclusions: Hospitalization with major infection was independently and robustly associated with subsequent risk of ESRD. Whether preventive approaches of infection have beneficial impacts on kidney outcomes may deserve future investigations.

Funding: NIDDK Support, Other U.S. Government Support

The hazard ratios for incident ESRD

	All major infection (2,910 events)	Pneumonia (1,499 events	Urinary tract infection (1,422 events)	Bloodstream infection (910 events)	Cellulitis and osteomyelitis (602 events)
IR per 1,000 person-years while free of hospitalization	0.6 (0.5-0.8)	1.1 (0.9-1.3)	1.3 (1.1-1.5)	1.2 (1.1-1.4)	1.4 (1.3-1.6)
IR per 1,000 person-years following hospitalization	5.0 (4.3-5.7)	6.0 (5.0-7.1)	4.6 (3.7-5.6)	7.5 (6.2-9.2)	6.8 (5.3-8.8)
Hazard ratio (95%CI)					
Model 1	5.20 (4.03-6.72)	4.31 (3.21-5.78)	4.05 (3.01-5.45)	4.72 (3.26-6.83)	3.69 (2.57-5.28)
Model 2	3.41 (2.61-4.46)	2.84 (2.11-3.83)	2.61 (1.92-3.54)	3.11 (2.15-4.51)	2.37 (1.64-3.44)

Model 1 adjusted for age, sex, race, BMI, smoking, ever drink, education, sBP, anti-HTN, DM, eGFR, ACR, CRP, CVD, COPD and cancer. Model 2 additionally adjusted for incident CVD.

SA-PO887

Proton Pump Inhibitor Use in Ambulatory Care Setting in Patients with CKD: A Patient Safety Project

Bidyut K. Sarker,[1] Charuhas V. Thakar,[2,3] Anthony C. Leonard.[2] *[1]Division of Nephrology/Kidney C.A.R.E Program, University of Cincinnati, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH; [3]Division of Nephrology/Kidney C.A.R.E Program, Veteran Affairs Medical Center, University of Cincinnati, Cincinnati, OH.*

Background: Proton pump inhibitors (PPI) are widely prescribed medications, and recent observational studies suggest that PPI exposure increases the risk of adverse renal outcomes including acute kidney injury (AKI), chronic kidney disease (CKD), and progression to end-stage renal disease (ESRD). Timely cessation of PPI therapy may improve patient safety and health care costs. **Objective:**To assess PPI use in the absence of indications, the missed opportunities to deprescribe, and to develop strategies for sustainable quality improvement (QI).

Methods: As a requirement of the clinical QI program during nephrology fellowship training, we performed an audit of records spanning September 1, 2018 to May 31, 2019 in an academic outpatient Nephrology clinic. We selected patients with estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2 and used FDA recommendations and American College of Gastroenterology (ACG) consensus derived guideline for PPI indications. We counted the total number of outpatient clinic visits that patients attended during the study period. Comparisons between groups were tested using Wilcoxon tests to get two-tailed p-values.

Results: 116 consecutive clinic patients with eGFR<60 were audited .99% were Male, 23% Black, mean age was 72(standard deviation/SD 9). Mean eGFR was 39(SD 11) ml/min/1.73 m^2 and mean BMI was 31(SD 5.6). 53% of patients were diabetic, 91% were hypertensive and 53% had proteinuria. 38% (44/116) patients were on PPI. Of those on PPI, 68% did not have an indication to be on it. Average duration of PPI prescription was 434(SD 145) days in the indicated group compared to 482 (SD 266) days in the non-indicated group (p=.6). PPI were prescribed by PCPs for 77% of patients, with other providers prescribing for 23%. PPI users averaged 8 outpatient clinic visits during the time audited; for indicated patients the average was 8.3, while for non-indicated patients the average was 7.9 visits, which were considered as missed opportunities for PPI deprescription.

Conclusions: Knowing the adverse outcomes associated with PPI use, 68% CKD patients were on PPI despite lack of a clear indication. There were several subsequent missed opportunities to de-prescribe these non-indicated medications. A concerted multidisciplinary program to de-prescribe PPI in high-risk CKD patients can improve patient safety and outcomes.

SA-PO888

Association Between Proton-Pump Inhibitors and CKD in Japanese Patients

Taro Horino,[1] Yutaka Hatakeyama,[2] Keitaro Nagata,[3] Tatsuki Matsumoto,[3] Yoshio Terada,[4] Yoshiyasu Okuhara.[4] *[1]Kochi Medical School, Kochi University, Kochi, Japan; [2]Kochi medical school, Nankoku-shi, Kochi, Japan; [3]Kochi University, Nankoku, Japan; [4]Kochi Medical School, Nankoku-city, Japan.*

Background: Proton-pump inhibitor (PPI) use has been reported to be a risk factor for chronic kidney disease (CKD), potentially mediated by recurrent acute kidney injury (AKI). We aimed to estimate the progress rate of renal dysfunction in patients taking PPI in real clinical settings and to compare the results with those of patients taking histamine-2 receptor antagonist (H2RA) and those taking neither PPI nor H2RA.

Methods: We retrospectively reviewed patients' data collected from Kochi Medical School Hospital's information system between 2001 and 2017. Patients were classified into the PPI, H2RA, and CONT (control patients without PPI/H2RA use) groups, and their data were compared. Survival time was defined as the time between drug administration date (zero hour) and a 30% decrease in estimated glomerular filtration rate (eGFR; primary endpoint).

Results: We initially evaluated 92,585 Japanese individuals. According to the study protocol, the final analysis evaluated data of 5,849 patients, including 3,211 patients in the PPI group and 2,638 patients in the H2RA group. The mean age was 58±18.5, 67.4±14.1, and 63.8±15.8 years for the CONT, PPI, and H2RA groups, respectively. On survival analysis, the PPI and H2RA groups had a significantly higher survival rate ($p<0.001$) than the CONT group, whereas no significant difference was found between the PPI and H2RA groups. When the CONT group was set as a reference, PPI use, or H2RA use were associated with high HRs at 1.2861, and 1.5437, respectively. Frequencies of male sex, older age, CKD (G3a, G3b, G4), and diabetes mellitus (DM) were significantly higher in the PPI group, followed by the H2RA group, then the CONT group. Our cohort had higher frequencies of male sex, older age, DM, and AKI history, associated with high HRs at 1.1015, 1.025, 1.219, or 12.7142, respectively.

Conclusions: PPI or H2RA use was significantly associated with an increased risk of CKD development. H2RA use was associated with CKD development. PPI or H2RA users may include patients with CKD risk factors. Given that CKD risk was not different between Japanese PPI and H2RA users, PPIs may not be more involved in CKD development than H2RAs.

SA-PO889

Characteristics and Symptom Severity of Patients Reporting CKD in the PatientsLikeMe Online Health Community

Elisabeth Nyman, Glen James, Jonatan Hedberg, Cathy E. Emmas. *AstraZeneca, Cambridge, United Kingdom.*

Background: Online health communities and research networks such as PatientsLikeMe (PLM) may provide important insight into understanding the real-world experiences of patients with chronic diseases, including chronic kidney disease (CKD).

Methods: Retrospective cross-sectional observational study using the PLM online health network database. Inclusion criteria were registration with PLM between 2011-2018, aged ≥18 years at registration, with self-reported CKD within 30 days of registration and not receiving dialysis. Information reported by patients within 30 days of registration was used to assess demographics, clinical history, comorbidities, treatments and patient reported symptoms, both general (prompted for all PLM patients) and other symptoms.

Results: 1848 patients met the inclusion criteria. The median age at registration was 56 years (IQR 45-64), most patients were female (66%), and US residents (87%). The 1496 patients who recorded race were predominately Caucasian (80%) and African-American (9%). Median age at diagnosis was 47 years (IQR 33-56, N=578) and the median age of first symptom onset was 43 years (IQR 28-54, N=378). Most patients (74%, N=1374) reported at least one comorbidity (median 3 (IQR 0-4)), the most common being type 2 diabetes (57%), hypertension (48%), hypercholesterolemia (32%) and diabetic neuropathy (27%). Less than half of patients (41%) entered any symptom within 30 days of registration. General symptoms were reported by 487 patients and rated as moderate or severe by 72% for fatigue, 58% for pain, 48% for insomnia, 41% for anxious mood, and 41% for depressed mood. Additional symptoms reported by more than 15% of patients and rated moderate or severe by >30% were problems concentrating, nerve pain, and feet tingling (N=315-338). Treatments were reported by 1369 (74%) patients, the most common were for diabetes (51%) and hypertension (27%).

Conclusions: Characteristics of CKD patients in the PLM community are broadly consistent with the general US CKD population, although the percentage of females is slightly higher. PLM provides a unique source of real-world information on the patient experience beyond the clinical environment that can be utilized to improve understanding of the patient-level impact of CKD.

Identification of Symptom Clusters and Their Association with Clinical Characteristics and Quality of Life Outcomes in CKD: A Multicenter Study

Thomas J. Wilkinson, Daniel Nixon, Alice C. Smith. Leicester Kidney Lifestyle Team *University of Leicester, Leicester, United Kingdom.*

Background: Renal patients suffer from an overwhelming symptom burden including fatigue, dyspnea, sleep problems and depression. Research into symptom *clusters* (co-occurrence of symptoms) is emerging although primarily limited to end stage renal disease. Whilst individual symptoms are established contributors to poor quality of life (QoL), no research has investigated the role of symptom *clusters* on these outcomes.

Methods: Self-reported symptoms of 876 CKD pre-dialysis patients (44% females, age 67±16 years, eGFR 40±25ml/min) were assessed using the Kidney Symptom Questionnaire. Clusters were derived based on the frequency of the 13 symptoms using Principle Component Analysis (minimum factor loading 0.4, KMO=.925). Associations between clusters, QoL (EQ5D), and physical function (Duke Activity Status Index) was analysed using generalized regression modeling (age and sex used as co-variants).

Results: Symptom clusters based are shown in Figure 1. Cluster 1-type patients were older (β=.297, P<.001) whilst cluster 2 patients were younger (β=-.211, P<.001). Sex had no effect on symptom clustering. Symptom cluster 1 was the *greatest* predictor of reduced

QoL (using the EQ5D index; β=-.465, P<.001) and physical function (β=-.407, P<.001). Cluster 3 was *least* predictive of poor QoL (β=-.108, P=.044) and cluster 4 least predictive of physical function (β=-.079, P=.015), although both significant. Worsening of eGFR was associated with cluster 2 symptoms only (β=-.142, P=.001). Higher inflammation (CRP) was associated with cluster 1 symptoms (β=.181, P=.040).

Conclusions: We identified 4 unique symptom clusters in patients with non-dialysis dependent CKD. QoL was primarily affected by physiological symptoms relating to muscle and joint pain, dynapenia and dyspnea. Routine clinical assessment and management strategies targeted at cluster level could have synergistic effects in reducing the burden of CKD symptoms.

SA-PO891

Disability and Its Association with Chronic Diseases, Especially Early CKD

Dong-Young Lee, Hyeonjeong Kim. *VHS Medical Center, Seoul, Republic of Korea.*

Background: In older people muscle weakness, defects in the organs of the body are common, and in severe cases help is needed for daily life. In addition, vision, hearing are reduced, walking disorders occur, and in this condition, they are called disabled. People with disabilities need continued support from family and community people, and people with disabilities have a higher mortality rate. Disabilities are known to occur and worsen when accompanied by chronic diseases such as stroke, ischemic heart disease, arthritis, diabetes and hypertension. Plantinga et al reported that disability is also associated with chronic kidney disease (CKD) and it can be induced from early CKD. We evaluated the association between disability and various chronic diseases, especially CKD, in older Koreans.

Methods: The subjects of this study were 3rd KNHANES participants who were over 65 years old. 3rd KNHANES did not conduct a microalbuminuria test, so the definition of CKD was defined as estimated glomerular function rate<60 ml/min/1.73 m2 regardless of urine test, and the CKD stage followed the KDIGO. Disabilities included abnormal activity of daily living (ADL), instrumental ADL and vision, hearing, walking impairment.

Results: The prevalence of abnormal ADL in CKD stage 3a, stroke, arthritis, DM and hypertension were 52.2%, 42.6%, 20.1%, 25.3% and 18.7%, respectively (Table 1). The prevalence of CKD stage 3a for vision, hearing and walking impairment was significantly higher and as high as that of other chronic diseases. In multivariate logistic regression analysis, abnormal ADL is significantly associated with CKD 3a (Odds ratio, 1.78 [95% confidence interval, 1.03-3.09]).

Conclusions: CKD was associated with the disorder from the early state, and was as frequent as the previously known chronic diseases.

Prevalence of disabilities between CKD and other comorbidities

	Abnormal ADL (%)	Abnormal IADL (%)	Visual impairment (%)	Hearing impairment (%)	Walking impairment (%)
DM	25.3†	43.2	60.4†	32.9	51.7
Hypertension	18.7†	39.2	52.6	29.1	49.8†
Arthritis	20.1†	46.8	58.2†	39.8†	63.4†
Cancer	8.9	37.8	46.7	31.1	60.0
Stroke	42.6†	62.3†	57.4	37.7	78.7†
IHD	17.9	44.6	64.3	33.9	75.0†
CKD 3a	52.2†	47.3†	59.8†	34.3†	52.0†

Efficacy and Safety of Direct-Acting Antiviral Based Treatment in HCV-Infected Patients with Chronic Renal Function Impairment: Updated Systemic Review and Meta-Analysis

Yunlin Feng,[1] Hongling Yang,[2] Pu Lei,[3] Song Ren.[2] *[1]Sichuan Provincial People's Hospital, Chengdu, China; [2]Sichuan Academy of Sciences & Sichuan Provincial People's Hospital, School of medicine, University of Electronic Science and Technology of China, Chengdu, China; [3]Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.*

Background: To further determine the efficacy and safety of direct acting antiviral (DAA) -based treatments in hepatitis C virus (HCV) infected patients with renal function impairment.

Methods: MEDLINE, EMBASE, and the Cochrane Library were searched for relevant studies. All studies assessing the efficacy and safety of DAA -based treatments against HCV infection in patients with renal impairment and HCV infection were eligible for inclusion. Outcomes assessed included efficacy outcomes and safety outcomes. Summary estimates were obtained using an inverse-variance weighted random effect model and Freeman-Tukey double arcsine transformation.

Results: 27 studies (n= 1048 participants) were included. The majority of included studies were of fair quality with Newcastle–Ottawa scale scores between 4-6. The pooled virologic response rates at the end of treatment or 4, 12, 24 weeks after treatment (i.e. EOTR, SVR4, SVR12 and SVR24 rates) were 97.0% (95% CI, 94.0%-99.0%), 80.9% (95% CI, 49.3%-98.7%), 94.1% (95% CI, 91.6%-96.3%), and 89.6% (95% CI, 75.5%-98.1%), respectively. The pooled relapse rate was 6.4% (95% CI, 3.4%-10.4%). The pooled incidence of adverse events and severe adverse events leading to discontinuation were 47.6% (95% CI, 35.0%-60.4%) and 2.9% (95% CI, 1.4%-5.0%), respectively. High heterogeneity among studies exist for SVR4 and SVR24 rates. Formal statistical testing did not identify the presence of publication bias for all measured outcomes except the relapse rate.

Conclusions: The results support the efficacy and safety of DAA -based treatments in this population. Future studies with better design, larger sample size and longer follow up will be the next step.

SA-PO893

The Prevalence of Subtypes of Substance Use Disorder in Patients with Advanced Kidney Disease

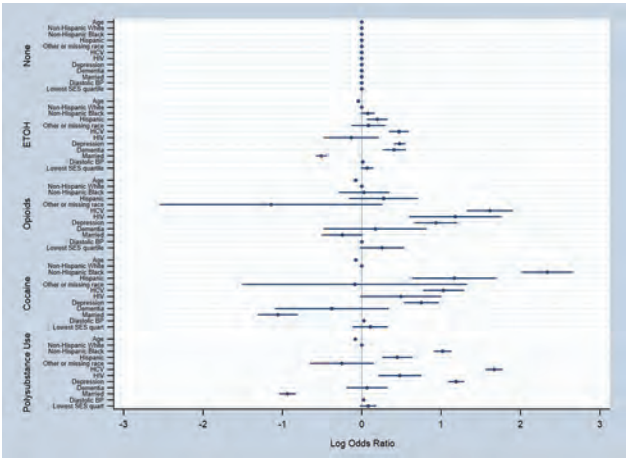
Meaghan S. Roche,[1] Jordana B. Cohen,[1] Harold I. Feldman.[2] *[1]University of Pennsylvania School of Medicine, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Previous studies have shown that illicit drug use in patients on hemodialysis is associated with poor outcomes. The prevalence and characteristics of different types of substance use disorder (SUD) have not been well-described in patients with advanced chronic kidney disease (CKD).

Methods: Diagnostic codes were used to characterize the prevalence of different types of SUD in a national cohort of veterans with incident stage 4 CKD from 2003 to 2014. Subtypes of SUD were grouped as alcohol, opioid, cocaine, or polysubstance use disorders. Their clinical and demographic characteristics were compared to those among veterans without SUD using multinomial logistic regression.

Results: Among 57,874 veterans with incident stage 4 CKD, the prevalence of alcohol use disorder was 7.0%, opioid use disorder 0.4%, cocaine use disorder 0.6%, and polysubstance use disorder 4%. See Figure for adjusted relative differences in demographic and clinical characteristics by subtype of SUD (with no SUD as the reference group). The prevalence of non-Hispanic black race and Hispanic ethnicity were higher with cocaine (aOR 10.38, 95% CI 7.51-14.35 and aOR 3.21, 95% CI 1.89-5.46, respectively) and polysubstance (aOR 2.78, 95% CI 2.48-3.10 and aOR 1.56, 95% CI 1.30-1.89, respectively) use disorders.

Conclusions: Demographic and clinical characteristics vary significantly across different subtypes of SUD in veterans with stage 4 CKD. Future research is needed to evaluate the differential association of these SUD subtypes with CKD progression and mortality.



Baseline Characteristics, Grouped by SUD Subtype, Among Veterans with Stage 4 CKD

SA-PO894

Cannabis Use and Its Association with Incidence of Ischemic Stroke in Advanced CKD Patients Transitioning to ESRD

Praveen Kumar Potukuchi,[1] Keiichi Sumida,[1] Miklos Z. Molnar,[1] Abduzhappar Gaipov,[2] Frank Park,[7] Cameron M. Kaplan,[1] Hamid Moradi,[3] Fridtjof Thomas,[1] Justin Gatwood,[1] Ankur A. Dashputre,[1] Yoshitsugu Obi,[4] Elani Streja,[5] Kamyar Kalantar-Zadeh,[6] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]National Scientific Medical Center, Astana, Kazakhstan; [3]University of California, Irvine, Orange, CA; [4]University of California Irvine, Irvine, CA; [5]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [6]University of California Irvine, School of Medicine, Orange, CA; [7]University of Tennessee Health Sciences Center, Memphis, TN.*

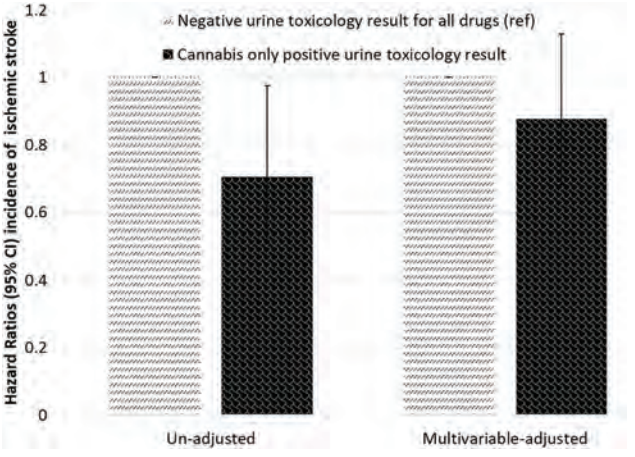
Background: The risk of stroke is especially high in patients with CKD/ESRD. The effects of cannabis use on incidence of stroke in patients with advanced CKD are unclear.

Methods: We examined 3,615 US veterans who transitioned to dialysis during 2007-2014 and had undergone urine toxicology tests up to one year prior to dialysis. We compared patients whose toxicology tests were positive for cannabis alone (N=202) with those whose tests were negative for all drugs (N=3,413). We examined the association of cannabis use with incident ischemic strokes (defined using ICD-9-CM codes) using Cox proportional hazards model adjusted for sociodemographics, comorbidities, medications, vital signs and time dependent dialysis initiation. We applied conditional repeated measures in Cox regression (modeling the full time-course of the recurrent events) to handle the occurrence of multiple strokes in the same patient.

Results: The mean (SD) age of the cohort was 61.4 (10.3) years; 97% were male, 41% were African American, and 73% had diabetes. Ischemic stroke occurred in 18% of the cohort (N=661) with a median (IQR) follow up time of 2 (1-4) years (one stroke event N=311 and ≥ 2 stroke events N=350). Cannabis use was associated with lower risk of stroke in unadjusted analysis [Figure]. However, the protective effect of cannabis use was attenuated in multivariable adjusted models [hazard ratio (95%CI): 0.88 (0.68-1.13)].

Conclusions: Cannabis use in advanced CKD patients is not significantly associated with the incidence of ischemic strokes.

Funding: NIDDK Support



SA-PO895

Association Between Pre-ESRD Opioid Use and Post-ESRD Mortality

Praveen Kumar Potukuchi,[1] Keiichi Sumida,[1] Christina A. Spivey,[1] Ankur A. Dashputre,[1] Abduzhappar Gaipov,[2] Suryatapa Kar,[1] Fridtjof Thomas,[1] Justin Gatwood,[1] Yoshitsugu Obi,[3] Miklos Z. Molnar,[1] Elani Streja,[4] Kamyar Kalantar-Zadeh,[5] Marie Chisholm-Burns,[6] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]National Scientific Medical Center, Astana, Kazakhstan; [3]University of California Irvine, Irvine, CA; [4]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [5]University of California Irvine, School of Medicine, Orange, CA; [6]University of Tennessee Health Science Center College of Pharmacy, Memphis, TN.*

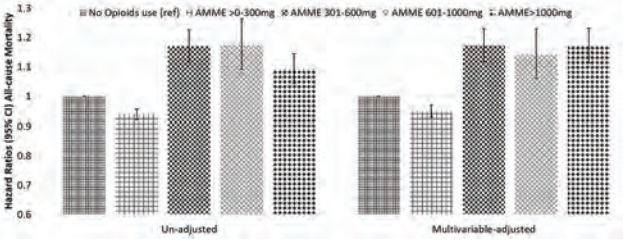
Background: Opioids are frequently used for chronic pain management in patients with advanced CKD. The relationship between pre-ESRD opioid use and post-ESRD mortality is unclear.

Methods: In a national cohort of 69,765 US veterans who transitioned to dialysis during 2007-2014 we assessed the association between pre-ESRD opioid use and post-ESRD all-cause mortality. Opioid use was defined as receiving opioids within a year prior to dialysis initiation (N=31,472) and divided into four groups based on the cumulative received dose, expressed as annual morphine milligram equivalent (AMME): >0-300 mg (N=25,282), 301-600 mg (N=2,499), 601-1000 mg (N=993) and >1000mg (N=2,698). Associations were examined using Cox proportional hazards models adjusted for demographics, smoking status, comorbidities, nephrology care, number of outpatient visits, and cumulative length of hospitalizations.

Results: The mean (SD) age of the cohort was 71 (12) years, 93% were male, 24% were African American, and 64% had diabetes. Opioid users (AMME >300 mg) displayed significantly higher mortality compared to non-users [Figure]. The multivariable adjusted hazard ratios (95%CI) associated with the four incrementally higher AMME categories (vs. no opioid use) were 0.95 (0.93-0.97), 1.17 (1.12-1.23), 1.14 (1.06-1.23), and 1.17 (1.11-1.23), respectively.

Conclusions: Pre-ESRD opioid use was associated with higher post-ESRD mortality in patients with AMME >300 mg. Further studies are needed to determine whether this association is confounded by indication or whether part of the increased risk can be mitigated.

Funding: NIDDK Support



SA-PO896

Extended and High-Dose Nonsteroidal Anti-Inflammatory Drug Use Is a Risk Factor for CKD Incidence

Kabir Jalal,[1] Rocco C. Venuto,[2] Andre F. Charest.[3] *[1]University at Buffalo, Amherst, NY; [2]Erie County Medical Center, Buffalo, NY; [3]UBMD Internal Medicine, Getzville, NY.*

Background: The use of non-steroidal anti-inflammatory drugs (NSAIDS) and its risk for CKD progression is well known. However, risks for onset of CKD have not been definitively established. This study examined the extended use of NSAIDS and the extended use of high-dose NSAIDS among patients from a third-party insurer for risk of CKD development.

Methods: Serial observations from 2007 through 2017 were examined. Patients with valid serum creatinine measurements and complete supporting data, including other lab values (albumin, bilirubuin, calcium, sodium, potassium, hemoglobin, glucose, chloride, and carbon dioxide), medication use (NSAIDS, angiotensin converting enzyme inhibitors, angiotensin receptor blockers, proton pump inhibitors, hydralazine, and antihistamines), and comorbid conditions (diabetes, hypertension, cardiovascular diseases, congestive heart failure, proteinuria) were included for analysis. In addition to chi-squared tests of association between NSAIDS use and CKD development, Kaplan-Meier survival analysis of time to CKD onset was stratified by NSAIDS use and log-rank tests were performed on the full sample and 1:1 matched samples of patients with 1) NSAIDS use in over 50% (NSAIDS-50) of their prescription history matched to similar controls; and 2) evidence of high-dose oral NSAIDs usage (NSAIDS-H) matched to similar NSAIDS-50 controls.

Results: 80,619 patients qualified for the full data analysis, with 4,185 patients developing CKD, and 4,086 NSAIDS-50 patients (chi-sq p-value < 0.0001). In the NSAIDS-50 matched analysis, 514 of 8,172 patients develped CKD, 282 of which were NSAIDS-50 patients (chi-sq p-value = 0.0255). 755 patients were identified as NSAIDS-H patients with 54 developing CKD, while 34 of 755 controls developed CKD (chi-sq p-value = 0.0363). The full sample showed differences in log-rank tests of survival curves between NSAIDS and non-NSAIDS groups (p < 0.0001), as in the matched NSAIDS-50/non-NSAIDS-50 sample (p = 0.0033) and the matched NSAIDS-H/non-NSAIDS-H sample (p = 0.0167).

Conclusions: While establishing firm dosing and exposure guidelines requires further research, this study suggests that extended and/or high-dose usage of NSAIDS carries an increased risk of CKD onset. Additional multivariate analysis to confirm the reliability and extent of these findings is underway and will be presented.

SA-PO897

Emergency Department Utilization by Patients with Advanced CKD and Dialysis

Ruchi Chhibba,[5] Silvia J. Leon mantilla,[1,3] Thomas W. Ferguson,[4,2] Navdeep Tangri,[4,2] Paul Komenda,[4,2] Claudio Rigatto.[2,4] *[1]Seven oaks General Hospital. Chronic Disease innovation Center, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [3]Department of Community Health Sciences, Max Rady College of Medicine, University of Manitoba, Winnipeg, MB, Canada; [4]Department of Internal Medicine, Max Rady College of Medicine, University of Manitoba, Winnipeg, MB, Canada; [5]University of Manitoba, Winnipeg, MB, Canada.*

Background: Chronic Kidney Disease (CKD) is a potent risk factor for kidney failure, cardiovascular events and all cause hospitalizations. In addition to higher outpatient resource use, patients with CKD may present more frequently to the emergency department (ED) and may be more likely to be admitted for hospitalization. In Manitoba, we previously demonstrated an 8-fold increase in the frequency of ED presentations by patients on dialysis as compared to a non-dialysis population. Comparable data on ED visits remain sparse for patients with CKD G3-G5, not on dialysis. Here, we aim to describe the frequency of ED visits and highlight differences in reasons for visit in patients with CKD stages G3-G5 and Those on dialysis when compared to a non-CKD population.

Methods: We performed a retrospective cohort study using administrative health data from the Winnipeg Regional Health Authority, Canada. We included all adults (≥ 18 years) with CKD stages G3-G5 and patients undergoing dialysis between January 1st, 2010 and December 31, 2014. Secular trends in the in the rates of ED visits were calculated for those with CKD, those on dialysis and in the non-CKD population.

Results: Over the study period, patients undergoing dialysis had the highest incidence of ED visits, followed by patients with CKD and those with normal kidney function (150 vs 106 vs 34 per 100 persons per year respectively). These rates were stable over the period studied. Among the non-CKD population, the most common reasons for an ED visit were musculoskeletal complaints (25.6%), followed by gastrointestinal (11.04%) and cardiovascular complaints (10.26%). In the CKD and dialysis cohort, ED visits were more commonly secondary to cardiovascular complaints (21.54% and 18.99% respectively), followed by respiratory and gastrointestinal complaints. Admission to hospital was higher in CKD and dialysis populations than in the non-CKD population (29.56%, 26.07% vs 10.61%, respectively).

Conclusions: Patients with CKD present frequently to the ED, and are often admitted after presentation. Cardiovascular and respiratory complaints are more common in the CKD population.

SA-PO898

Associations of Opiate Use and Mortality Risk by Estimated Glomerular Filtration Rate in the NHANES Cohort

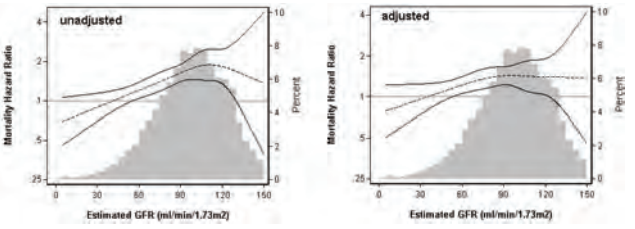
Emily N. Batcheller,[1] Taryn B. Benson-Hernandez,[2] Rachel H. Fitt,[3] Connie Rhee,[4] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Harold Simmons Center, Bishop, CA; [3]BUHS, Big Pine, CA; [4]University of California Irvine, Huntington Beach, CA.*

Background: A previous study from the National Health and Nutrition Examination Survey (NHANES) cohort revealed that adults with chronic kidney disease (CKD) had a higher likelihood of having an active prescription for opioid medication. Although it is known that opioids are associated with a higher mortality risk, it is unknown if that risk differs according to estimated glomerular filtration rate (eGFR) or CKD stage. We sought to examine the association of opioid use with mortality risk across eGFR in the NHANES cohort.

Methods: We examined associations of opioid use with mortality risk in 42,041 NHANES adult participants between 1999-2014 using Cox proportional hazards models with adjustment for demographics, body mass index, serum albumin and indicators of comorbid conditions such as cancer, diabetes, and hypertension. eGFR was estimated from serum creatinine using the CKD-EPI equation. Data on mortality up to year 2015 were downloaded from the corresponding CDC website. Effect modification by continuous eGFR using restricted cubic splines were modeled.

Results: The mean±SD age of the cohort was 47±19 years and was comprised of 52% females and 21% non-Hispanic black patients. Patients reporting opioid use were slightly older and were more likely to have a lower eGFR or eGFR<60 mL/min/1.73m^2. Overall opioid use was associated with a 27% higher risk of mortality in fully adjusted models (HR: 1.27, 95%CI: 1.13, 1.32). Hazard Ratios for eGFR 90+, 60-<90, and <60 were [HR:1.47, 95%CI: 1.20, 1.81; HR:1.32, 95%CI: 1.11, 1.58; HR: 1.06, 95%CI: 0.87, 1.29], respectively in fully adjusted models (p-for interaction eGFR-category and opioid use: p=0.067). In both unadjusted and adjusted models, restricted cubic splines show that the risk estimates of opioid use with mortality risk decline with lower GFR [figure].

Conclusions: In the NHANES cohort, mortality risk with opioid use appears to decline with lower eGFR or worsening CKD. Further studies should investigate these relationships in larger CKD cohorts with the ability to address potential confounding by indication, and impact of opioid dose, and opioid type.



SA-PO899

Laxative Use in Patients with Advanced CKD Transitioning to Dialysis

Keiichi Sumida,[1] Ankur A. Dashputre,[1] Praveen Kumar Potukuchi,[1] Suryatapa Kar,[1] Fridtjof Thomas,[1] Yoshitsugu Obi,[2] Miklos Z. Molnar,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Constipation, typically managed by laxatives, is one of the most prevalent conditions in primary care settings and associated with poor quality of life and adverse outcomes. Constipation is highly prevalent in dialysis patients; however, little is known about laxative use in patients with advanced CKD transitioning to dialysis.

Methods: In 67,377 US veterans transitioning to dialysis from 10/2007-3/2014, we examined the proportion of patients who filled a prescription for any type of laxatives within each 6-month time period over 36 months pre- and post-transition to ESRD. Prescribed laxatives were ascertained using both inpatient and outpatient prescriptions sourced from CMS Medicare Part D and VA pharmacy dispensation records. We also identified factors associated with pre-ESRD laxative use by multivariable logistic regression.

Results: The proportion of patients prescribed laxatives was 14% in -36 to <-30 months pre-transition to ESRD and gradually increased as patients progressed to ESRD. Laxative use markedly increased immediately prior to ESRD transition and reached the highest proportion (28%) in the first 6 months post-transition. The proportion remained relatively stable at ~23% throughout the rest of the post-transition period (Figure). The use of antihistamines (OR [95%CI], 3.12 [2.89-3.37]), antacids (2.06 [1.96-2.17]), and K-lowering agents (1.73 [1.65-1.82]) were the strongest factors associated with pre-ESRD laxative use after multivariable adjustment.

Conclusions: Laxative use increased considerably and peaked at 28% as patients neared transition to ESRD and remained fairly stable thereafter, likely mirroring the increasing burden of drug-induced constipation during the transition period. Further studies are needed to elucidate the underlying causes of this trend and the clinical implication of constipation management in advanced stages of CKD.

SA-PO900

Trends in Use of Antidiabetic Drugs Among Diabetic Patients with and Without CKD in the United States (2006-2016)

Yun Han,[1] Brenda W. Gillespie,[2] Nilka Rios Burrows,[3] Stephen R. Benoit,[3] Delphine S. Tuot,[4] Neil R. Powe,[5] William H. Herman,[1] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of California, San Francisco, San Francisco, CA; [5]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA.*

Background: Since 2006, several new antidiabetic drugs have been introduced and shown to be safe in patients with chronic kidney disease (CKD) and metformin's use among CKD patients has been expanded. How these have changed the prescription of diabetes therapy plans is not clear. Our study compares trends in the use of ten different classes of antidiabetic drugs among diabetic (DM) patients with and without CKD in the US.

Methods: Analysis included 4,281,223 commercially insured members from Optum Clinformatics™ aged 20-64 years from 2006 to 2016. ICD-CM diagnosis codes were used to identify DM and CKD. Antidiabetic drug use by year was measured as the proportion of patients prescribed the specified medications. OLS model is used to compare changes in antidiabetic therapy between DM patients with and without CKD.

Results: Newer antidiabetic drugs, including SGLT2 inhibitors and two incretin-based therapies (DDP-4 inhibitors and GLP-1 agonists) are increasingly being used for DM patients regardless of kidney function (Fig.1, all p<0.001). There was a notable decline in the use of thiazolidinediones and sulfonylureas in both populations over the same time period (all p<0.001). The decrease in use of sulfonylureas was greater among those without CKD (p<0.05). From 2006-16 metformin use increased considerably from 30% to 44% among individuals with CKD and from 47% to 56% among individuals without CKD. In 2016, metformin became the most common therapy for both populations, followed by insulins. Insulin use slightly decreased after 2014, from 44% to 40% among those with CKD and 25% to 23% in those without CKD (p<0.01).

Conclusions: Use of SGLT2 inhibitors, incretin-based therapies, and metformin increased among individuals with and without CKD, suggesting that safety data has driven evidence-based practice. Nevertheless, substantial treatment differences exist in diabetes therapy among those with and without CKD suggesting that other strategies may be needed to accelerate translation of evidence to practice.

SA-PO901

The Effects of Testosterone Replacement Therapy (TRT) in Patients' Established CKD

Aditi Gupta,[1] Peter S. Wiegmann,[2] Virginia J. Savin,[3] Mukut Sharma,[4] Archana Goel,[4] Mariana Garcia-Touza,[6] Thomas Wiegmann.[5] *[1]University of Kansas Medical Center, Kansas City, KS; [2]Midwest Biomedical Research Foundation, Kansas City, MO; [3]KC VA Medical Center, Kansas City, KS; [4]KCVA Medical Center, Kansas City, MO; [5]VA Medical Center, Kansas City, KS; [6]Kansas City VA, Kansas City, MO.*

Background: We have previously shown that TRT provides significant survival benefits and reduces CKD progression in hypogonadic men. Testosterone deficiency is common in CKD but the benefits of TRT are disputed. Here we examined if TRT slows CKD progression, cardiovascular disease and all cause mortality in patients with established CKD.

Methods: Data from a large cohort of veterans diagnosed with low total testosterone (n=57,985) were used to determine the effect of TRT on the CKD progression, cardiovascular diseases and all-cause mortality in patients with CKD. Data were extracted using the Veterans Administration Informatics and Computing Infrastructure (VINCI), and analyzed using SAS. Propensity score matching was used to adjust for age, vascular disease and follow up time. Results were compared by means tests, frequency tables, odds ratio and p values (p=<0.01).

Results: Of the 3,627 patients with CKD, 2,469 received TRT, and of the 54,358 controls without CKD 41,965 received TRT. Mean baseline serum creatinine was 1.97 mg/dl in CKD and 0.98 mg/dl in controls. TRT reduced new cardiovascular accident (CVA) in CKD (OR 0.86, 95% CI 0.76-0.98), and in controls (OR 0.86, 95% CI 0.77-0.94), and reduced all-cause mortality in CKD (OR 0.749, 95% CI 0.66-0.85) and controls (OR 0.71, 95% CI 0.68-0.74). New myocardial infarction (MI) in CKD were higher with TRT (OR 1.37) and lower in controls (OR 0.79). Prior cardiovascular disease was more common with CKD (% difference CKD/Control), coronary artery disease (130), congestive heart failure (284), CVA (111), hypertension (92), MI (162), peripheral artery disease (265). Average follow up was 6.1 years.

Conclusions: The protective effect of TRT on CKD progression in hypogonadic men appears to taper off in patients with established CKD. CKD is associated with a higher burden of cardiovascular disease. TRT reduces all-cause mortality in established CKD (and controls) but the beneficial effect on cardiovascular events is blunted in CKD, underscoring importance of early TRT.

Opioid Utilization for Pain Management Among Medicare Fee-for-Service Beneficiaries with ESRD in 2016

Matthew L. Maciejewski,[1,2] Lindsay Zepel,[5] Virginia Wang,[3,2] Clarissa J. Diamantidis,[4] Serene Olin,[8] Jacquelyn Blaz,[7] Shondelle Wilson-Frederick,[6] Valerie A. Smith.[5,1] *[1]VA HSR&D, Durham, NC; [2]Population Health Sciences, Duke University, Durham, NC; [3]Durham VA Health Care System, Duke University, Durham, NC; [4]Duke University School of Medicine, Durham, NC; [5]Duke University, Durham, NC; [6]CMS, Baltimore, MD; [7]National Committee for Quality Assurance, Washington, DC; [8]NCQA, Washington, DC.*

Background: Opioid misuse has raised concerns about opioid utilization under the Part D drug prescription benefit for Medicare beneficiaries. It is important to understand whether Medicare Fee-for-Service (FFS) beneficiaries with end-stage renal disease (ESRD) are more likely to utilize opioids compared to other beneficiaries.

Methods: We assembled a 100% Medicare FFS sample (n=20,880,490) with 12-month Part A, B, and D coverage between 1/1/2016-12/31/2016 to examine patient factors associated with 2 opioid utilization outcomes. We used a two-part model to estimate the probability of opioid utilization in 2016 via logistic regression and the level of average daily dose (ADD)≥120 morphine milligram equivalents (MME) via a generalized linear model with a gamma distribution and identity link in those with >1 opioid prescription. Beneficiary characteristics (age, disability, ESRD, dual eligibility, race and ethnicity, rurality, 16 chronic conditions) were adjusted.

Results: 35% of FFS beneficiaries had 1 or more opioid prescription fills in 2016 and 1.5% had ADDs≥120 MME. Compared to age-eligible beneficiaries without ESRD, beneficiaries were more likely to fill opioids if they were disabled with ESRD (odds ratio (OR)=2.57, 95% confidence interval (CI): 2.53, 2.61) or without ESRD (OR=1.43, 95% CI: 1.42, 1.43), age eligible with ESRD (OR=1.99, 95% CI: 1.96, 2.02), or eligible due to ESRD alone (OR=2.31, 95% CI: 2.25, 2.37). Beneficiaries who were disabled without ESRD (OR=2.99, 95% CI: 2.95, 3.03) or with ESRD (OR=1.34, 95% CI: 1.29, 1.40) had higher odds of having ADDs≥120 MME, while beneficiaries who were age-eligible with ESRD (OR=0.71, 95% CI: 0.66, 0.76) had lower odds compared to those age-eligible without ESRD.

Conclusions: Beneficiaries who are vulnerable due to ESRD filled opioid prescriptions at higher rates than other beneficiaries and at ADDs ≥120 MME. Based on recently endorsed opioid-related quality metrics and more restricted policies on opioid dispensing, these beneficiaries should be prioritized for opioid optimization strategies to balance pain management and adverse event risk.

SA-PO903

Acceptance Measured as Psychological Flexibility Protecting Against Depression Among Different Severities of CKD

Hidekazu Iida,[1,2] Noriaki Kurita,[2] Takafumi Wakita,[3] Tomo Suzuki,[4] Masahiko Yazawa,[5] Yoshitaka Ishibashi,[6] Hiroo Kawarazaki,[7] Yugo Shibagaki.[8] *[1]You Home Clinic, Ishinomaki, Japan; [2]Department of Clinical Epidemiology, Fukushima Medical University, Fukushima, Japan; [3]Kansai University, Suita, Japan; [4]Kameda Medical Center, Kamogawa, Japan; [5]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [6]Japanese Red Cross Medical Center, Tokyo, Japan; [7]Division of Nephrology, Department of Internal Medicine, Inagi Municipal Hospital, Inagi, Japan; [8]St Marianna University Hospital, Kawasaki, Japan.*

Background: Depression is associated with poor survival among chronic kidney disease (CKD) patients. Psychological flexibility (PF) is conceptualized as "the ability to contact the present moment more fully (i.e., accept any physical or emotional experiences without controlling them) and to change, or persist in, behaviors to pursue identified values." Although PF is often measured as acceptance in clinical settings and its reduction by behavioral therapy is associated with reduced depression in the general population, this concept has not been examined in CKD patients.

Methods: This multicenter cohort study included five hospitals in Japan and patients with non-dialysis stage 3-5 CKD or stage 5D CKD receiving hemodialysis or peritoneal dialysis. The main exposure was PF measured by a 7-item Acceptance and Action Questionnaire (AAQ-II). The inverse mean of its summation score was used (ranging from 1 [low PF] to 7 [high PF]). The outcome was depression defined as a Center for Epidemiologic Studies Depression (CES-D) questionnaire score of 16 points or higher. The association between PF and presence of depression among all CKD patients, and between PF and incidence of depression after one year among CKD patients without baseline depression were analyzed by logistic regression models, with adjustment for age, sex, performance status, primary renal disease, treatment modality, presence of family, work status, and comorbidities.

Results: The cross-sectional and longitudinal analyses included 433 and 195 patients, respectively. The means (standard deviations) of age, PF, and CES-D were 67.2 (13.8) years, 5.64 (1.14) points, and 13.4 (8.6) points, respectively. Higher PF was associated with lower likelihood of depression (per 1 point increase, adjusted odds ratio [AOR] 0.44, 95% confidence interval [95%CI] 0.35-0.55) and lower likelihood of developing depression (per 1 point increase, AOR 0.50, 95%CI 0.33-0.75) after one year.

Conclusions: PF measured by the AAQ-II was associated with lower prevalence and incidence of depression. Nonpharmacological interventions to improve PF, such as acceptance and commitment therapy, could be useful for preventing depression in patients with different severities of CKD.

SA-PO904

Cognitive Impairment, Vascular Dysfunction, and Sedentary Behavior Differ Between Older Adults with and Without CKD

Mary Hannan,[1] Eileen Collins,[2] Shane Phillips,[3] Alana D. Steffen,[1] Ulf G. Bronas.[1] *[1]University of Illinois at Chicago, Chicago, IL; [2]UIC, Hines, IL; [3]University of Illinois, Chicago, Chicago, IL.*

Background: Chronic kidney disease (CKD) is common in older adults and is associated with numerous complications, including cognitive impairment and vascular dysfunction. Additionally, older adults have lifestyle factors that can negatively influence health, including being sedentary- a phenomenon associated with cognitive impairment, vascular dysfunction, and mortality in the general population. The objective of this study was to determine if there are differences in cognitive impairment, vascular dysfunction, and sedentary behavior between older adults with and without CKD. We hypothesized that older adults with CKD would exhibit cognitive and vascular impairment and be more sedentary, compared to those without CKD.

Methods: Utilizing a cross-sectional approach, 48 older adults (24 with CKD, age 68.4(5.6), eGFR 43.9(11.6)ml/min; 24 without CKD, age 68.5(5.5), eGFR 82.7(12.3) ml/min) were evaluated for performance on a test of global cognition and executive function (Montreal Cognitive Assessment (MoCA)), vascular function via carotid-femoral pulse wave velocity (cfPWV)) and ultrasound (carotid compliance, flow mediated vasodilation), and sedentary behavior via actigraphy. Data was analyzed utilizing t-tests and OLS regression.

Results: Older adults with CKD had higher levels of cognitive impairment and vascular dysfunction and higher sedentary time. In regressions including CKD and the covariates of age, years of education, history of smoking, and gender, the variance was significantly explained for total MoCA score, MoCA executive function score, cfPWV, indicators of carotid compliance, and sedentary time per day.

Conclusions: Cognitive impairment, vascular function, and sedentary behavior in older adults with CKD are different compared to those without CKD. This represents a possible unique phenotypic presentation in this at-risk population.

Central Systolic and Pulse Pressures as Predictors of Cardiovascular Events: A Prospective Study

Florence Lamarche,[1] Louis-Charles Desbiens,[2] Fabrice Mac-Way,[3] Mohsen Agharazii,[4] Francois Madore,[1] Remi Goupil.[1] *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]Université Laval, Québec, QC, Canada; [3]CHU de Quebec, Hotel-Dieu de Quebec Hospital, Quebec, QC, Canada; [4]CHUQ-HDQ, Quebec City, QC, Canada.*

Background: Central blood pressure (BP) is proposed as a better predictor of cardiovascular (CV) burden than peripheral BP. Nevertheless, its clinical value remains to be determined. This study aims to characterize the role of central BP in CV risk stratification.

Methods: We included 15,923 CARTaGENE participants with available central BP (SphygmoCor Px; type I device) and prospective data from an administrative healthcare database. Major adverse CV events (MACE) included myocardial infarction, stroke, heart failure with hospitalization and CV death. The associations between of brachial and central BP parameters with MACE were assessed using Cox regressions adjusting for: age, sex, BMI, smoking, diabetes, known CV disease, HbA1c, LDL-c, eGFR, uric acid, heart rate, use of beta-blockers, renin-angiotensin system blockers, calcium channel blockers, diuretics, aspirin, clopidogrel and anticoagulants. Restricted cubic splines were performed to account for nonlinear associations.

Results: 1,399 MACE occurred over a median follow-up of 70 months. Significant associations between central and brachial systolic and pulse pressures (PP) and MACE were found (Figure 1). Increments of 5 mmHg in brachial and central systolic BP were both associated with increased risk [HR 1.04 (95%CI 1.01-1.06), p<0.005, for both], which was significant at BPs greater than 130 mmHg and 140 mmHg respectively. HRs remained similar at higher values of systolic BP and PP.

Conclusions: There is a significant association between MACE and both central and brachial systolic BP and PP. There appears to be a similar relationship between central and brachial BP parameters and CV risk but with different thresholds. In this regard, central BP alone estimated with SphygmoCor may not provide an added benefit in CV risk stratification compared to brachial BP.

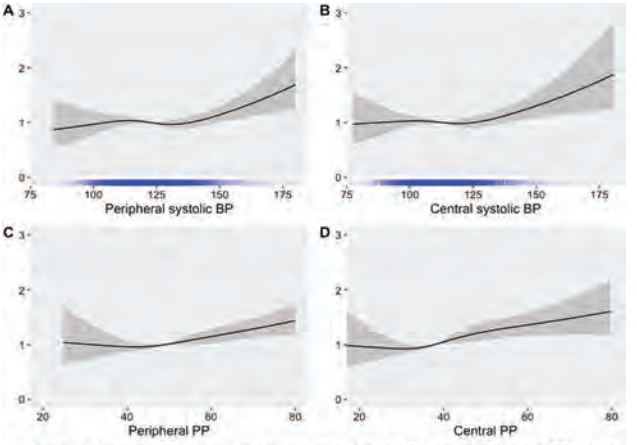

Figure 1. Relationship between central and brachial BP parameters and MACE for A) Brachial systolic BP, B) Central systolic BP, C) Brachial PP and D) Central PP. Hazard ratios with 95% confidence intervals. Marginal rug on X axis representing the distribution of systolic BP. BP; blood pressure, PP; pulse pressure.

Iohexol Renal Measurement In Uro-Oncological Patients: Ready to Quit Pandora's Box?

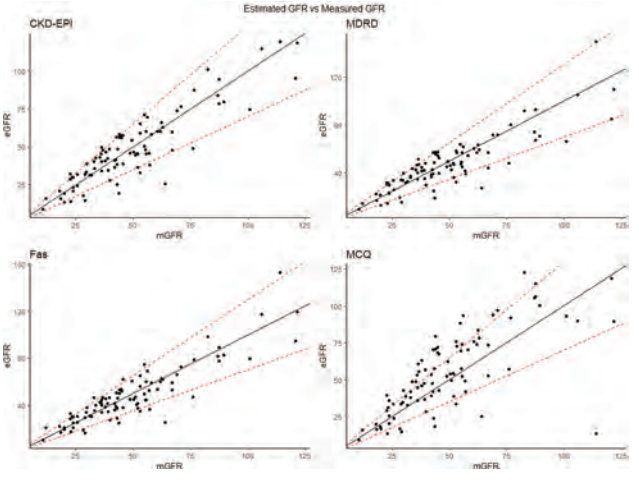
Francesco Trevisani,[1] Federico Di marco,[1] Massimo Locatelli,[2] Giorgio Pizzagalli,[2] Alessandro Larcher,[1] Umberto Capitanio,[1] Arianna Bettiga,[1] Alessandra Cinque,[1] Esteban Porrini,[3] Alberto Briganti,[1] Andrea Salonia,[1] Francesco Montorsi.[1] *[1]Urological Research Institute, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]University Hospital of the Canary Island, La Laguna, Spain.*

Background: An accurate assessment of renal function in urological and oncological patients should be mandatory to define the most appropriate urological surgery technique (nephron sparing vs radical nephrectomy) and to decide the correct dose for each type of chemo-immuno therapy. Unfortunately, the most used method to measure GFR in clinical practice is represented by the estimated glomerular filtration rate (eGFR) which harbours error in comparison to gold standards methods (mGFR). The objective of this study is to determine the extent of the error of eGFR in the oncological and urological pts category.

Methods: A prospectively consecutive cohort of 91 pts affected by uro-oncological neoplasm was collected comparing eGFR with mGFR using iohexol renal measurement. Four estimated GFR formulas were used for this study: CKD-EPI, MDRD, MCQ, FAS. The agreement them was evaluated taking in account Bias, expressed as median of percent difference between mGFR and eGFR and overall accuracy as P_{30} representing the percent of estimates within 30% of measured GFR.

Results: The agreement between formulas and mGFR was poor. The Bias for MDRD was -1%, for CKD-EPI was 0%, for FAS was 1% and for MCQ was -19% indicating that, except for the latter, those formulas don't harbour systematic errors. Different information was provided by the accuracy parameter: the P_{30} was 81% for CKD-EPI, 76% for MDRD, 82% for FAS and 58% for MCQ.

Conclusions: In our cohort study we observed that formulas equally over or underestimate mGFR resulting in unbiased methods; however the magnitude of the over/underestimations is not negligible, at least ± 20 mL/min/1.73 m^2, and could led to errors in clinical management.



eGFR formulas vs mGFR: Black line represents identity; red dotted lines represent P_{30} boudaries

SA-PO907

Association Between Kidney Function and the Risk of Cancer: Results from the China Health and Retirement Longitudinal Study (CHARLS)

Lili Liu,[3] Qinqin Meng,[2] Yafeng Wang,[2] Luxia Zhang,[1] Yaohui Zhao,[2] Ming Hui Zhao.[3] *[1]Peking University Institute of Nephrology, Beijing, China; [2]Peking University, Beijing, China; [3]Peking University First Hospital, Beijing, China.*

Background: Increased cancer risk after dialysis or transplantation has been recognized, but studies of cancer in pre-dialysis chronic kidney disease are extremely limited. Therefore, we aim to investigate the risk of cancer in individuals with reduced kidney function.

Methods: Our study was based on a nationally representative sample of population aged 45 years or older from China Health and Retirement Longitudinal Study (CHARLS) conducted between June 2011 and March 2015. Altogether 17,708 participants were randomly chosen using a multistage sampling scheme. For the current analyses, 11,508 eligible individuals with measurement of kidney function and without cancer at baseline were included. Then, 104 participants without follow-up and 392 died of causes unrelated to cancer during follow up were excluded. Estimated glomerular filtration rate (eGFR) was calculated using Chronic Kidney Disease Epidemiological Collaboration equation. Reduced kidney function was defined as eGFR <60 ml/min/1.73m^2. Incident cancer cases diagnosed by doctors were documented in the biennial questionnaire of CHARLS. Poisson regression was used to examine the association between kidney function and the risk of cancer.

Results: Altogether 11,012 participants with an average of 58.6 years were included. Participants with eGFR≥90, 60 to 89, and <60 ml/min/1.73m^2 accounted for 63.4%, 33.4% and 3.2%, respectively. During 43,854 person-years of follow-up, 217 new cases of cancer were recorded. Compared to participants with eGFR ≥90 ml/min/1.73m^2, those with eGFR <60 ml/min/1.73m^2 was associated with the increased risk of cancer, with fully adjusted relative risk of 2.04 (95% confidence interval 1.20 to 3.46).

Conclusions: Reduced kidney function is associated with a higher risk of cancer and therefore should be integrated into the risk-stratification of cancer management.

RRs and 95% CIs for cancer risk in different eGFR groups.

Effect of Statins on Cardiovascular Complications in CKD Patients: A Network Meta-Analysis

Seon Deok Hwang,[1,2] Seoung woo Lee,[2,1] Jin ho Lee.[3] *[1]Inha University College of Medicine, Incheon, Republic of Korea; [2]Inha University Hospital, Incheon, Republic of Korea; [3]Bong Seng Memorial Hospital, Busan, Republic of Korea.*

Background: It is well known that cardiovascular mortality and morbidity increase in advanced chronic kidney disease **(**CKD), and that mild to moderate CKD is also associated with an increase in cardiovascular events. Statins have been shown to reduce cardiovascular events, and in this study we investigated the lipid-lowering effect of different statins in CKD patients.

Methods: We searched CENTRAL, MEDLINE, Embase, and Science Citation Index Expanded databases from 1970 until February 2019 to identify cardiac events, cardiac mortality, and all-cause mortality affect in CKD patients according to statin types and doses. We performed direct and indirect network meta-analysis in Bayesian models and generated rankings of the different lipid-lowering agents via generation mixed treatment comparison.

Results: We analyzed the network meta-analysis of 19 studies (N = 45,863) for commonly used statins. Compared with placebos, pravastatin 40 mg groups showed a statistically significant decrease in patient mortality(odds ratio0.66 [95% confidence interval, 0.46 to0.91]). In reducing cardiac events, atorvastatin 80 mg, fluvastatin 40 mg, lovastatin 20 mg, pravastatin 40 mg, and simvastatin 40 mg showed statistically significant effects. In rank probability, pravastatin was ranked first in all-cause mortality rate. In cardiac events, lovastatin, fluvastatin, and pravastatin ranked first, second, and third, respectively.

Conclusions: We found that pravastatin 40mg reduced mortality and cardiovascular events CKD patients receiving statin therapy of hyperlipidemia. In addition, drugs that reduce cardiovascular events appeared effective in the order, lovastatin 20 mg, fluvastatin 40 mg, and pravastatin 40 mg.

Continuous System Improvements to Reinstate Kidney Patients Lost to Follow-Up

Lowell J. Lo. UCSF Nephrology and Hypertension Faculty Practice Team *Internal Medicine, University of California San Francisco, San Francisco, CA.*

Background: In chronic disease clinics, reducing the number of patients who are lost to recommended follow-up (LTFU) may improve outcomes. We designed a method to identify LTFU patients and trigger a procedure to schedule appointments. Using this system at our nephrology clinic, we reduced the number of LTFU patients from 24% to 3.8% in one year. MDs activated an electronic medical record (EMR) trigger indicating follow-up (FU) time frame for 77% of visits. We sought to explore reasons for incomplete MD EMR triggers use and persistent LTFU patients.

Methods: We generated a monthly LTFU report that identifies patients who did not return to clinic in the recommended FU time frame. Clinical staff called these patients and classified them into three groups: "scheduled" (appointment made successfully); "no need to return" (patients transitioned to dialysis, transferred to another nephrologist, declined appointment, or died); or "active" (i.e. actively trying to reconnect). We aimed to increase MD use of the EMR trigger by faculty meeting reminders and administrative assistant prompts. Lastly, we identified explanation categories for patients persisted on the "active" list.

Results: We had 5730 patient visits from 1/31/2018 to 3/31/2019. MDs successfully used the EMR trigger on 3598 (62.8%) of the visits. The most common barriers for using the EMR trigger were: rotating trainees not familiar with this system; MDs running behind on charting; and MDs short on time during clinic. We identified 460 (12.8% of total visits) LTFU patients among whom 252 (54.8%) were "scheduled,"114 (24.8%) were designated "no need to return," and 94 (20.4%) as "actively trying to reconnect." Among the 94 patients, reasons we were unable to reach patients included homelessness; inaccurate contact information; and having multiple stressors at home causing postponement of routine care.

Conclusions: Retention in care is associated with improved outcomes. Our team has identified a method by which patients LTFU were identified and reconnected. A future goal may be to make MD trigger activation mandatory via EMR validation point. For the difficult to reconnect patients who may be the most vulnerable, a team approach with case management may improve the chances of reconnection. Limitations of our study are that we lack outcome data on patients who were LTFU and the development and implementation of the system is time-intensive.

SA-PO910

Resistance Exercise Training in CKD: A Randomized Pilot Trial

Akika Ando, Georgios Grigoriadis, Jillian Caldwell, Neil Mcmillan, Tracy Baynard, Eunice Carmona, Sajid Q. Ansari, Walaa S. Dabbas, Jinsong Chen, Bo Fernhall, Ana C. Ricardo. University of Illinois at Chicago, Nephrology Department *University of Illinois at Chicago, Chicago, IL.*

Background: Resistance exercise training has been shown to improve vascular function and cardiovascular risk factors in healthy individuals, but studies in patients with chronic kidney disease (CKD) are lacking.

Methods: We randomly assigned adults with mild-to-moderate CKD to a 12-week resistance exercise training intervention (45-minutes sessions, twice per week) or to control (educational material regarding the benefits of physical activity). The primary outcomes were aortic pulse-wave velocity (PWV), carotid artery stiffness and systolic blood pressure (BP), measured at baseline, 6 weeks and 12 weeks. Intention-to-treat analyses with repeated measures ANOVA were used.

Results: Of the 32 individuals included in the analyses (15 randomized to the intervention group and 17 to the control group), mean (SD) age was 57 (1.8) years, 47% were male, 94% African American, and 27% had diabetes; mean (SD) eGFR was 42 (14) ml/min/1.73m^2. Of those randomized to the resistance exercise intervention, 67% completed at least half of the training sessions. No adverse effects were observed with the intervention. There was a decrease in PWV, carotid stiffness and systolic BP among participants randomized to resistance exercise training, but these changes were not statistically significant when compared with controls (Table).

Conclusions: Resistance exercise training is feasible and safe among patients with CKD, and has the potential of improving vascular function in this population.

SA-PO911

Effect of Sodium Bicarbonate on Acid Excretion and BP in Patients with and Without CKD: The Acid-Base Compensation in CKD (ABC) Study

Crystal C. Tyson,[1] Pao-Hwa Lin,[1] Alison Luciano,[5] Jenifer M. Allen,[1] Cassandra Bowman,[1] Joseph Gung,[1] John R. Asplin,[3] Jane F. Pendergast,[2] Laura P. Svetkey,[1] Julia J. Scialla.[1,4] *[1]Medicine, Duke University Medical Center, Durham, NC; [2]Bioinformatics and Biostatistics, Duke University, Durham, NC; [3]Litholink Corp, Chicago, IL; [4]Duke Clinical Research Institute, Durham, NC; [5]Center for the Study of Aging and Human Development, Duke University, Durham, NC.*

Background: As kidney function worsens, net acid excretion (NAE) diminishes resulting in subclinical, then overt, metabolic acidosis (MA). Treatment with alkali may improve outcomes in CKD even when overt MA is not present. Our goal was threefold: 1) evaluate NAE and response to alkali in the setting of controlled diet acid load; 2) compare response in those with and without CKD; and 3) evaluate change in 24h BP as a potential mechanism of benefit.

Methods: We enrolled 14 non-diabetic adults in a random order, cross-over feeding study; 8 had CKD and 6 did not. After a 3-day run-in, participants consumed a 7-day controlled acid load diet supplemented with $NaHCO_3$ tablets (alkali; 31 or 39 mEq/day based on weight) and an identical 7-day diet supplemented with NaCl as table salt (control), in random order. We assessed NAE and other acidification markers from two 24h urines, and measured 24h ambulatory BP at the end of each period. We estimated the alkali effect using mixed models adjusted for CKD status, study period, and intervention order, and tested for interaction between alkali and CKD.

Results: Mean age was 68, 64% were women, and 57% were white. In the control period, mean NAE and urine citrate were lower for those with CKD (29.6±7.7 mEq/d and 388.4±213.5 mg/d) vs. non-CKD (40.4±18.6 mEq/d and 687.5±218.6 mg/d) on identical diets. Overall, alkali lowered NAE and urine ammonium and increased urine pH, HCO_3 and citrate. Response in urine pH and citrate to alkali differed by CKD status. Alkali increased urine pH more in patients with vs. without CKD (p-int=0.17), whereas urine citrate increased only among those with CKD (p-int=0.05). Alkali had no effect on 24h BP (**Table**).

Conclusions: Despite identical diets, NAE and urine citrate are lower in CKD vs. non-CKD suggesting that NAE in CKD has non-diet determinants. $NaHCO_3$ decreases NAE; however, it increases, thereby restoring, lower urine citrate in CKD. Urine citrate may be a useful marker of early, subclinical acidosis in CKD that responds to therapy.

Funding: NIDDK Support

Nitrite, Isoquercetin, and Endothelial Dysfunction Trial (NICE trial): Design and Preliminary Data

Jing Chen,[1] L. Lee Hamm,[2] Joshua D. Bundy,[3] Damodar R. Kumbala,[4] Shirisha Bodana,[5] Chung-shiuan Chen,[6] Charlton C. Starcke,[6] Erin Mahone,[6] Aarti Vadalia,[6] Katherine M. Obst,[6] Syed Rizwan A. Bokhari,[1] Arnold B. Alper,[7] Ivo Lukitsch,[8] Myra A. Kleinpeter,[2] Hua He,[9] Jiang He.[10] *[1]Tulane School of Medicine, New Orleans, LA; [2]Tulane University School of Medicine, New Orleans, LA; [3]Northwestern University Feinberg School of Medicine, Evanston, IL; [4]Renal Associates of Baton Rouge, LLC, Metairie, LA; [5]Ochsner Clinc Foundation, Metairie, LA; [6]Tulane University, New Orleans, LA; [7]Tulane University Helath Science Center, New Orleans, LA; [8]Ochsner Healt Center, New Orleans, LA; [9]School of Public Health and Tropic MedicineTulane University, New Orleans, LA; [10]Tulane School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: Endothelial dysfunction may be an early etiology for chronic kidney disease (CKD) and cardiovascular disease in CKD. We studied the safety and efficacy of combination treatment with sodium nitrite and isoqercetin on endothelial dysfunction, inflammation and oxidative stress in CKD patients.

Methods: This double blind, randomized, placebo-controlled trial enrolled 70 CKD patients. 35 patients were randomly assigned to oral combination of immediate-release sodium nitrite (40 mg twice daily) and isoquercetin (225 mg, once daily) or placebo for 3 months. The primary endpoint was changes in flow-mediated dilation (FMD) from baseline. The secondary endpoints were changes in biomarkers of endothelial function, inflammation, oxidative stress, eGFR, and urine albumin. The follow-up rate was 97%. Mixed-effects models were used to assess the treatment effects.

Results: Baseline characteristics were similar between groups. FMD increased by 1.13% (95% confidence interval [CI], -0.07 to 2.32) vs. 0.34% (95% CI, -0.86 to 1.53) in treatment vs. placebo group (p=0.35). The level of von Willebrand factor (vWF) decreased by 695 pg/mL (95% CI, -3793 to 2403) vs. increased by 2768 pg/mL (95% CI, -300 to 5838) in treatment vs. placebo group (p=0.047). There were statistically insignificant reductions between treatment and placebo groups in other biomarkers of endothelial dysfunction (intercellular adhesion molecule-1, vascular adhesion molecule-1, E-selectin, and Endothelin-1), oxidative stress (oxidized low-density lipoprotein and nitrotyrosine), and urine albumin. Additionally, there were no differences in changes of inflammatory biomarkers (C-reactive protein, tumor necrosis factor-α, interleukin [IL]-6, and monocyte chemoattractant protein-1) except IL-17 (1.35 [95% CI, 0.87 to 1.82] vs. 1.98 [95% CI, 1.50 to 2.45] in treatment vs. placebo group, p=0.05). There was no significant change in eGFR between groups. Methemoglobin and side effects were not different between groups.

Conclusions: The combination treatment significantly reduces vWF and IL-17 and may potentially improve endothelial dysfunction, inflammation, oxidative stress, and proteinuria. Larger trial is warranted to confirm those findings.

SA-PO913

Correspondence of Ankle-Brachial Index and Doppler Ultrasound Findings in Patients with CKD

Moh'd Sharshir,[1] Mohammad Atari,[1] Shuo Bai,[2] Syed Rizwan A. Bokhari,[1] Talal Nakkar,[1] Halil K. Erol,[1] Jing Chen.[1] *[1]Tulane School of Medicine, New Orleans, LA; [2]Tulane University, New Orleans, LA.*

Background: Ankle-brachial index (ABI) is used to diagnose peripheral artery disease (PAD). ABI may be artificially high among patients with chronic kidney disease (CKD) due to increased arterial calcification and stiffness. It is not well studied how ABI and toe-brachial index (TBI) are correlated with more accurate diagnostic measures of doppler ultrasound in evaluating PAD in CKD.

Methods: We conducted retrospective chart review among pre-dialysis CKD patients in Tulane Hospital in New Orleans, Louisiana. Total of 251 were included in the study. De-identified demographic information, clinical measures, ABI, TBI, and doppler ultrasound findings were extracted into the study forms. The correlations of ABI, TBI, doppler waveforms, and peak systolic velocity (PSV) were analyzed. PSV is calculated as percentage change of measured PSV from normal value.

Results: Among patients with ABI ≤ 0.9, 73% had normal US waveform, 24% had biphasic waveform, and 3 % had monophasic waveform; 54% had TBI ≤ 0.7. Among those with ABI > 1.4, 77% had normal waveform, 23% had biphasic waveform, and 0% had monophasic waveform; 0% had TBI≤ 0.7. Among those with TBI ≤ 0.7, 50% had normal waveform, 43% had biphasic waveform, and 7% had monophasic waveform. In addition, ABI ≤ 0.9 or >1.4 and TBI ≤ 0.7 were poorly corelated with a ≥30%- <100% or ≥ 100% increase in PSV.

Conclusions: These data indicate that the ABI and TBI diagnostic criteria for PAD needs to be further evaluated in CKD. Larger study is warranted to confirm these study findings.

SA-PO914

Correlation of Raised NT proBNP Levels and Left Ventricular Filling Pressure in CKD Patients with Acute Decompensated Heart Failure (ADHF)

Syeda H. Zartash,[1] Sidra Saleem,[1] Zain Rasool,[1] Shahbaz Sarwar,[1] Nimra N. Zaman,[1] Shahryar A. Sheikh,[1] Shamila Afshan,[2] Shahmeer M. Nawaz,[1] Abeera Mansur.[1] *[1]Doctors Hospital and Medical Centre, Lahore, Pakistan; [2]Punjab Institute of Cardiology, Lahore, Lahore, Pakistan.*

Background: Left ventricular filling pressures (LVFP) and N-Terminal pro brain natriuretic peptide (NT-proBNP), both of which are well known indicators of poor prognosis, are elevated in ADHF. The relationship of NT pro-BNP with LVFP in CKD patients is not well documented. Therefore, the aim of our study is to find integrative utility of measuring NT-pro BNP levels with LVFP in patients with acute dyspnea enabling their utilization as diagnostic and prognostic markers in the management of CKD patients with ADHF.

Methods: From 1st May, 2018 through 30th April, 2019, 450 patients who presented in Emergency department of Doctors Hospital Lahore with acute dyspnea and potential fluid overload were assessed. Out of these, 85 patients who underwent simultaneous echocardiography and NT Pro BNP measurement were included in the study. Charts were analysed by a nephrologist and cardiologist. Both CKD(66) and non CKD(19) patients with reduced LV ejection fraction (LV EF <40%:HFrEF), Midrange (LV EF:40-50%: HFmrEF) and preserved ejection fraction(LV EF >50%:HFpEF) were included. eGFR was measured using the CKD-EPI(Chronic kidney disease Epidemiology collaboration) equation. Data was analysed using SPSS version 25.

Results: Echo parameters were compared with different NT pro-BNP levels in this study group. The mean value of NT pro BNP was much higher(1895.74±10.57 pmol/L) in CKD patients with ADHF as compared to non CKD patients(550.66 pmol/L). As shown in the image, in patients with eGFR<60ml/min with ADHF and NT Pro- BNP > 1000, 51.8% had EF less than 40%(14/27)(p-value :0.014) 74% of patients had increased LVFP(20/27) (p-value:0.028), 85.1% had PCWP more than 15 mmHg (23/27)(p-value:0.031), and 76.9% had Grade II/III Diastolic dysfunction (20/26)(p-value:0.051).

Conclusions: NT pro-BNP is a rapid and reliable marker for accurate and early diagnosis of ADHF since it has a significant correlation with LVEF and LVFP in CKD patients with ADHF.

NT pro-BNP Levels(pmol/L)			<100	100-500	500-1000	>1000	p-value

SA-PO915

Effects of a 16-Week Physical Training on Mortality, Quality of Life, and CKD Progression: NEPHROS Post-Trial Follow-Up

Franklin C. Barcellos,[2,1] Maristela Bohlke,[2] Rafael B. Orcy,[3] Larissa R. Ribeiro.[2] *[1]School Hospital, University Federal of Pelotas, Pelotas, Brazil; [2]Universidade Católica de Pelotas, Pelotas, Brazil; [3]Universidade Federal de Pelotas, Pelotas, Brazil.*

Background: The NEPHROS is a randomized controlled trial which applied a 16-week aerobic and resistance training to patients with chronic kidney disease (CKD) and high blood pressure and found an improvement in functional capacity, inflammatory status and metabolic profile, compared with usual care. The current report describes a long-term post-trial observational follow-up study, comparing survival, health-related quality of life (HRQoL) and estimated glomerular filtration rate (eGFR) change between the intervention and control groups, and according to in-trial cardiovascular (CV) risk factors. Clinicaltrials.gov NCT01935297.

Methods: After three years of the original trial, the NEPHROS participants were revaluated. Cox proportional hazards was used to compare survival time and linear regression to compare the change in eGFR and physical and mental HRQoL summary scores, between intervention and control groups, and according to age, sex, and in-trial eGFR, hs-CRP, fasting plasma glucose, lipids, ankle-brachial index (ABI), functional capacity and blood pressure (BP).

Results: Of the 150 participants of NEPHROS, 128 individuals were included in the long-term analysis. There were 13 deaths, no patient needing renal replacement therapy, and none reported maintaining regular exercise. No effect of the previous exercise training on survival, eGFR or HRQoL change was observed. Baseline in-trial eGFR (HR 0.95; 95% CI 0.92 to 0.98) and ABI (HR 0.03; 95% CI 0.002 to 0.43) were positive independent predictors for survival. Lower ABI (coef. 9.00; 95% CI 0.43 to 17.5) and higher systolic blood pressure (coef. -0.13; 95% CI -0.24 to -0.03) were independent predictors for eGFR decline.

Conclusions: We conclude that **l**ower eGFR and ABI, and higher systolic BP were associated with poorer prognosis among CKD patients. A sixteen-week exercise program had no long-term effect on survival, quality of life or glomerular filtration change in patients with CKD stages 2 to 4. This finding highlights the scant usefulness of short-lasting structured exercise interventions if not associated with long-term lifestyle changes.

SA-PO916

What Is the Best Predictable Subfraction for Cardiovascular Outcomes in Patients with CKD?

Yaerim Kim,[2] Jin hyuk Paek,[2] Woo Yeong Park,[3] Kyubok Jin,[2] Seungyeup Han,[2] Hajeong Lee,[4] Jung Pyo Lee,[5] Kwon Wook Joo,[1] Chun Soo Lim,[5] Yon Su Kim,[4] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Keimyung University School of Medicine, Daegu, Republic of Korea; [3]Dongsan Medical Center, Daegu, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Dyslipidemia is an important parameter for prediction of cardiovascular disease (CVD). We aimed to investigate the most valuable subfraction of lipid for predicting CVD in patients with chronic kidney disease (CKD).

Methods: We retrospectively reviewed the National Health Insurance Service (NHIS) database for a people who received nationwide health check-up in 2009. The population was divided as control, early CKD (eGFR 45-60 ml/min/m^2), and advanced CKD (eGFR <45 ml/min/m^2) by estimated glomerular filtration rate. Each subfraction of lipid profile including LDL, TG, HDL, and TG/HDL was categorized by decile, and the reference was the fifth decile. The end-point of the study was major adverse cardiovascular events (MACCE) such as fatal, non-fatal myocardial infarction, revascularization, acute ischemic stroke, and heart failure. The hazard ration (HR) of MACCE was calculated using Cox regression models after adjustment of multiple covariates.

Results: A total of 3,634,915 examiners were included in this study with 66,810 (1.8%) and 404,315 (11.1%) in advanced and early CKD, respectively. For all populations, LDL, TG, and TG/HDL showed a linear relationship to MACCE, the tenth decile for each subfraction showed highest adjusted HR: 1.45 (1.42-1.49) in LDL; 1.25 (1.22-1.28) in TG; 1.30 (1.27-1.33) in TG/HDL. Moreover, HDL showed inversed relation with lowest HR 0.88 (0.85-0.90) in the tenth decile. In the subgroup analysis for LDL and TG/HDL, control and early CKD showed similar patterns for HR with significantly increasing from the sixth decile. In advance CKD, TG/HDL showed significant HR in the tenth decile as 1.19 (1.05-1.34). However, there was no significance of LDL for MACCE in advanced CKD.

Conclusions: The pattern and significance of lipid subfraction were different according to the grade of renal function. Thus, TG/HDL should be additionally considered with LDL as a target variable in patients with advanced CKD.

SA-PO917

Outcomes in Patients with Renal Impairment and Myocardial Infarction Identified by High-Sensitivity Cardiac Troponin Testing: A Prespecified Analysis of the High-STEACS Trial

Peter J. Gallacher. High-STEACS Investigators *University of Edinburgh, Edinburgh, United Kingdom.*

Background: Patients with renal impairment are at increased risk of myocardial infarction (MI), but the interpretation of cardiac troponin in this context is challenging. Using a high-sensitivity cardiac troponin I (hs-cTnI) assay that has been widely adopted into clinical practice, we describe the diagnosis and outcomes of patients with MI, stratified by renal function.

Methods: In a pre-specified secondary analysis of a stepped-wedge cluster-randomised controlled trial, consecutive patients with suspected acute coronary syndrome (ACS), a hs-cTnI concentration greater than the sex-specific 99th centile and renal impairment (defined as an estimated glomerular filtration rate [eGFR] of <60 mL/min/1.73m^2) were identified between June 2013 and March 2016. Diagnoses of type 1 or type 2 MI were adjudicated and classified according to the 4th Universal Definition of Myocardial Infarction. The primary outcome of type 1 MI or cardiovascular death was compared in patients with and without renal impairment at 1 year.

Results: eGFR was available in 46,927 (97.1%) patients. 38,994 (83.1%) patients had an eGFR ≥60, 6,627 (14.1%) had an eGFR 30-59 and 1,306 (2.8%) had an eGFR <30. Plasma hs-cTnI concentrations were raised in 47.9% of patients with and 16.2% without renal impairment. Patients with renal impairment were less likely to be diagnosed with type 1 MI (35.2% [1,336/3,800] *vs* 56.3% [3,556/6,311]) but more likely to be diagnosed with type 2 MI (12.6% [480/3,800] *vs* 9.8% [619/6,311]; P<0.001 for both) than patients with normal renal function. In patients with hs-cTnI concentrations >99th centile, the risk of subsequent MI or cardiovascular death at 1 year was significantly increased in patients with renal impairment compared to those without it (24.9% [945/3,800] *vs* 12.0% [757/6,311]; adjusted hazard ratio [aHR] 1.56, 95% CI 1.34 to 1.82; P<0.001). This risk increased as eGFR declined: 30-59 mL/min/1.73m^2 (23.2% [674/2,905]; aHR 1.51, 95% CI 1.28-1.78); <30 mL/min/1.73m^2 (30.3% [271/895]; aHR 1.74, 95% CI 1.39-2.19) (P<0.001 for both).

Conclusions: Almost half of all patients with suspected ACS and renal impairment had a hs-cTnI greater than the sex-specific 99th centile. This was associated with a poorer prognosis, especially in those with an eGFR <30mL/min/1.73m^2.

A Cardiovascular Risk Mitigation Strategy on the Safety of Bardoxolone Methyl Post-BEACON

Glenn M. Chertow,[1] Gerald B. Appel,[2] Geoffrey A. Block,[3] Melanie Chin,[3] Daniel W. Coyne,[4] Angie Goldsberry,[3] Hironori Kanda,[5] Colin J. Meyer,[3] Pablo E. Pergola,[6] Stuart M. Sprague,[7] Peter Stenvinkel,[8] Christoph Wanner,[9] Peter A. McCullough.[10] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [3]Reata Pharmaceuticals, Inc., Irving, TX; [4]Division of Nephrology, Washington University School of Medicine, St. Louis, MO; [5]Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan; [6]Renal Associates, P.A., San Antonio, TX; [7]NorthShore University HealthSystem University of Chicago, Chicago, IL; [8]Karolinska University Hospital Huddinge, Stockholm, Sweden; [9]University Hospital, Wuerzburg, Germany; [10]Baylor University Medical Center, Dallas, TX.*

Background: Bardoxolone Methyl Evaluation in Patients with Chronic Kidney Disease and Type 2 Diabetes (BEACON) was a multinational, randomized, double-blind, placebo-controlled Phase 3 trial that enrolled patients with type 2 diabetes (T2D) and stage 4 CKD. The BEACON trial was terminated due to a significant increase in the risk of heart failure occurring within the first four weeks of treatment with bardoxolone methyl (Bard). Post-hoc analyses identified a history of heart failure and elevated baseline serum concentrations of B-type natriuretic peptide (BNP) as risk factors for these events. Four subsequent clinical trials in other disease states have excluded patients with these clinical characteristics. Additionally, BNP and NT-proBNP were measured as safety parameters over the course of these trials. Safety data from these trials will be presented.

Methods: Data from four studies were included: a 48-week, open-label Phase 2 study in patients with Alport syndrome (CARDINAL; NCT03019185); a 12-week, open-label Phase 2 study in patients with autosomal dominant polycystic kidney disease, IgA nephropathy, focal segmental glomerulosclerosis, or type 1 diabetes CKD (PHOENIX; NCT03366337); a 16-week, randomized, placebo-controlled, double-blind Phase 2 study patients with T2D and CKD in Japan (TSUBAKI; NCT02316821); and a 16-week, randomized, placebo-controlled, double-blind, global Phase 2 study of pulmonary hypertension (PH) (LARIAT; NCT02036970).

Results: A total of 423 patients were enrolled in four studies that were initiated after the termination of BEACON. There were no fluid overload-related serious adverse events in any patients treated with Bard in any of these studies. Treatment with Bard was not associated with increases in mean blood pressure in any of these studies. Mean decreases in body weight were apparent by Week 12 of treatment with Bard and were more pronounced in patients with higher baseline BMI.

Conclusions: In four clinical studies that enrolled over 400 patients without elevated BNP or a history of heart failure, Bard did not result in an increased differential risk of heart failure, other signs of overt fluid overload or subclinical measures of fluid retention (increases in blood pressure or weight).

SA-PO919

Increased Heart Rate Reflects Intrarenal Renin-Angiotensin System Activation in CKD Patients but Not in Subjects Without CKD

Naro Ohashi,[1] Shinsuke Isobe,[1] Sayaka Ishigaki,[1] Taro Aoki,[1] Takashi Matsuyama,[1] Tomoyuki Fujikura,[1] Akihiko Kato,[2] Hideo Yasuda.[1] *[1]Hamamatsu University School of Medicine, Hamamatsu, Japan; [2]Hamamatsu University Hospital, Hamamatsu, Japan.*

Background: A higher heart rate is one of the risk factors for heart failure and cardiovascular disease as well as accelerated glomerular filtration rate (GFR) decline. Activation of the intrarenal renin-angiotensin system (RAS) plays an important role in the development of hypertension and renal damage. However, the association between heart rate and intrarenal RAS activation is unclear.

Methods: We investigated the relationship between heart rate and urinary angiotensinogen (AGT) excretion, a surrogate marker for intrarenal RAS activity, in 10 subjects without chronic kidney disease (CKD) [age 50.1 ± 6.4 years, 4 men and 6 women, serum creatinine (sCr) 0.71 ± 0.13 mg/dL, urinary protein excretion 35.6 ± 15.3 mg/day, and urinary AGT excretion 7.22 ± 4.69 μg/day] and 72 CKD patients who were not taking medications that influence heart rate and RAS blockers [age 50.0 ± 17.4 years, 27 men and 45 women, sCr 1.85 ± 2.71 mg/dL, urinary protein excretion 1.27 ± 2.63 g/day, and and urinary AGT excretion 747.4 ± 2714.6 μg/day]

Results: As heart rate is influenced by behavior and emotion, we divided it into daytime and nighttime. Heart rate had a significant positive association with sCr levels during daytime and nighttime in CKD patients but not in non-CKD subjects. Moreover, although heart rate was not associated with urinary AGT excretion levels in non-CKD subjects during daytime ($r = 0.39$ and $p = 0.28$) and nighttime ($r = 0.34$ and $p=0.38$), it was associated with urinary AGT excretion levels during daytime ($r = 0.23$ and $p = 0.047$) and nighttime ($r = 0.45$ and $p < 0.01$) in CKD patients. Multiple linear regression analysis revealed that heart rate had a significant positive association with the urinary AGT excretion levels during nighttime, but not daytime, after adjustments for age, sex, body mass index, and sCr in CKD patients ($\beta = 0.31$ and $p = 0.034$).

Conclusions: Heart rate is associated with urinary AGT excretion levels, especially during the nighttime, in CKD patients but not in non-CKD subjects. Heart rate measurement may be a convenient surrogate marker for intrarenal RAS activation in CKD patients.

Comparison of Heart-Type Fatty Acid Binding Protein with Troponin T for Prediction of Cardiovascular Events in the German CKD Study

Markus P. Schneider,[1,2] Christoph Wanner,[3] Vera Krane,[3] Jürgen Floege,[4] Turgay Saritas,[4] Martin Busch,[7] Helena Stockmann,[6] Heike Meiselbach,[2] Florian Kronenberg,[5] Kai-Uwe Eckardt.[6,2] *[1]Nephrology and Hypertension, Klinikum Nuremberg, Nuremberg, Germany; [2]Nephrology and Hypertension, Universitätsklinikum Erlangen, Erlangen, Germany; [3]Nephrology, University Hospital Wurzburg, Wuerzburg, Germany; [4]Nephrology, RWTH University of Aachen, Aachen, Germany; [5]Medical Genetics, Molecular and Clinical Pharmacology, Innsbruck Medical University, Innsbruck, Austria; [6]Nephrology and Medical Intensive Care, Charité – Universitätsmedizin Berlin, Berlin, Germany; [7]Nephrology, University Hospital Jena, Jena, Germany.*

Background: Measurement of heart-type fatty acid binding protein (H-FABP) is more sensitive than high-sensitive troponin T (hs-TNT) in the early detection of myocardial injury. H-FABP also improves prediction of long-term cardiovascular (CV) outcomes in patients with acute coronary syndrome. We have investigated the ability of H-FABP in comparison with hs-TNT to predict all-cause mortality and long-term CV outcomes in patients with CKD.

Methods: H-FABP (ELISA, Hycult biotech) and hs-TNT (Cobas system) levels were measured from baseline samples of patients enrolled into the German Chronic Kidney Disease (GCKD) study (n=5127). The associations of H-FABP and hs-TNT with all-cause death, CV death, combined major adverse cardiovascular events (MACE) and hospitalization for heart failure were evaluated by cox regression analyses adjusted for demographics, estimated glomerular filtration rate, urinary albumin excretion rate, CV risk factors, use of statins and renin angiotensin inhibitors. Cardiac structure was examined by magnetic resonance imaging (MRI) in a subgroup of 290 patients.

Results: Both H-FABP and hs-TNT levels were inversely related with renal function. Over a follow-up period of 4 years, there were 345 deaths, 117 CV deaths, 329 MACE and 224 patients were admitted for heart failure. The hazard ratios (HRs) for prediction of these events were greater with hs-TNT than with H-FABP. When both markers were entered simultaneously, only hs-TNT remained a significant predictor in each of the models (e.g. HR for CV death for 1SD increase on the log10 scale: 1.96 (CI 95% 1.54-2.40) for hs-TNT and 0.88 (CI 95% 0.65-1.20) for H-FABP). In the subgroup with MRI measurements, only hs-TNT was related with left ventricular hypertrophy and concentricity (both $P<0.001$).

Conclusions: In this large prospective cohort of CKD patients, hs-TNT clearly outperformed H-FABP in the prediction of all-cause mortality and CV outcomes. As a potential explanation for these findings, only hs-TNT was associated with altered cardiac structure in a deep-phenotyped subgroup of CKD patients.

SA-PO921

Peak Oxygen Consumption Is Reduced at All Levels of CKD in Chronic Heart Failure Patients

Knut Asbjørn R. Langlo,[1,2] Kari M. Lundgren,[2] Elisa Cittanti,[2] Stein I. Hallan,[2] Havard Dalen.[2] *[1]St. Olavs Hospital HF, Trondheim, Norway; [2]NTNU, Trondheim, Norway.*

Background: There is an increasing body of literature showing reduced Cardiorespiratory Fitness (CRF) in CKD. This is mainly proven in CKD stages 4 and 5, but increasing knowledge suggests that this is the case in earlier stages as well. Chronic heart failure (CHF) is characterized by the hearts inability to meet tissues blood demands, mainly during exercise. We wanted to see if CKD affected peak oxygen consumption (VO_{2peak}) in CHF.

Methods: Participants were enrolled from two regional CHF clinics with similar access for all phenotypes of HF and all levels of renal insufficiency without any upper age limit. Echocardiography was performed at inclusion. Left ventricular and left atrial volumes and ejection fraction (EF) were measured in 4- and 2-chamber view. HF phenotype was classified according to the 2016 European Society of Cardiology Guidelines. All participants underwent testing for VO_{2peak} on a treadmill. Hemoglobin (Hb) was analyzed with a photometric method whereas creatinine was measured enzymatically. Analysis were performed in hospital routines. Estimated Glomerular Filtration Rate (eGFR) was calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula. For statistical analysis we used multiple linear regression.

Results: 59 participants (10 female) had valid test results for Hb (mean 13.3, SD 1.8), VO_{2peak} (mean 17.9, SD 4.6) and eGFR (mean 57.6, SD 24.2). In a multiple regression analysis, VO_{2peak} showed a strong association with eGFR after correcting for Hb of -0.078 ml/min/kg per 1 ml/min/1.73 m^2 drop in eGFR (95% CI -0.031 - -0.123, p=0.001).

Conclusions: Lower eGFR is a major predictor of poor cardiorespiratory fitness even in a chronic heart failure population where VO_{2peak} is already severely reduced. This relation holds for eGFR ranging from ESRD to normal renal function. Whether reduced renal function is caused by the severity of the heart failure and thereby lower VO_{2peak}, or reduced renal function leads to worsening heart failure with lower VO_{2peak} is not known from our cross-sectional design.

SA-PO922

The Association of Diastolic Dysfunction with CKD in Patients with Heart Failure

Knut Asbjørn R. Langlo,[1,2] Kari M. Lundgren,[2] Elisa Cittanti,[2] Stein I. Hallan,[2] Havard Dalen.[2,1] *[1]St. Olavs Hospital HF, Trondheim, Norway; [2]NTNU, Trondheim, Norway.*

Background: Chronic Kidney Disease (CKD) is tightly connected to cardiac disease, including Chronic Heart Failure (CHF) through different Cardiorenal Syndromes (CRS). CHF caused by hypertension and CKD often presents with left ventricular hypertrophy, stiffening and increasing filling pressures depicted as Chronic Renocardial Syndrome, whereas CHF caused by primary myocardial disease display dilation of left ventricle with venous congestion leading to reduced renal perfusion in the Chronic Cardiorenal Syndrome. This heterogeneity in CRS complicates the study of its pathophysiology, and studies comparing echocardiographic features of diastolic function in CHF between CKD and non-CKD patients are scarce.

Methods: Patients from two regional heart failure clinics were included if they had stable CHF and were medically optimized. Echocardiographic recordings, analyses and estimation of filling pressure and grade of diastolic dysfunction were based on latest recommendations. Estimated glomerular filtration rate (eGFR) was calculated based on creatinine, using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula.

Results: Mean age of the 67 participants was 68 (65.6-71.1) years (82 % male). eGFR⟨60 ml/min/1,73m^2 was present in 46 %. Three patients were in dialysis and 1 had a renal transplant. NYHA class II and III was present in 77 % and 23%, respectively. Patients with elevated filling pressure had lower eGFR than patients with normal filling pressure (-14.8 ml/min/1.73m^2, $p = 0.03$). Indexed left atrial end-systolic volume was significantly larger in HF patients with eGFR⟨60 ml/min/1.73m^2 compared to those with better renal function (11 ml/m^2, $p = 0.02$). Patients with grade I diastolic dysfunction had a higher eGFR compared to grade II (18 ml/min/1.73m^2, $p = 0.01$). The differences between grade I and III, and II and III diastolic dysfunction did not reach statistical significance.

Conclusions: Reduced renal function was associated with increased filling pressures and larger left atrial volumes in a general heart failure population. This shows a common trait in CKD-patients with CHF despite the otherwise heterogeneity in clinical presentation.

Intraventricular Septum Thickness (IVST) Increases Depending on the Decline of eGFR in AL Renal Amyloidosis

Shinichi Nishi, Hideki Fujii, Shunsuke Goto, Keiji Kono, Kentaro Watanabe. *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: In advanced AL amyloidosis, cardiac walls show thickening and cardiac functions reveal deterioration. It is unclear whether renal dysfunction and hypertension affect cardiac walls and functions in AL amyloidosis. We aimed to study the relationship between CKD progression and the ultrasound cardiac parameters in patients with AL amyloidosis.

Methods: The Amyloidosis Research Group, supported by funds from the Ministry of Health, Labour and Welfare in Japan surveyed the patients with AL amyloidosis in 2015. We could collected clinical data concerning renal and cardiac functions from 353 cases.

Two hundred forty patients had positive urine protein and 113 patients had negative urine protein.

Results: In urine protein positive group, eGFR showed a significant negative correlation with IVST and LVPWT (p<0.05), while did not with LAD, EF, and E/e'. The cardiac ultrasound parameters showed no significant differences between hypertension positive and negative groups. Multiple linear regression analysis showed IVST and LVPWT showed independently significant relationship with eGFR but not with hypertension. In urine protein negative group, eGFR showed no significant relationship with IVST and LVPWT. IVST and LVPWT showed significant differences between hypertension positive and negative group. The both parameters were significantly thicker in hypertension positive group (p<0.05).

Conclusions: In AL amyloidosis with urine protein, IVST and LVPWT became significantly thick according to the decline of renal function but the thickening of cardiac walls had no relationship with hypertension. In urine protein negative group, these results were up and down. From the present data, we suspected the cardiac amyloid deposition might begin from the appearance of urine protein in AL amyloidosis. The progression of cardiac wall thickening might not depend on hypertension in AL renal amyloidosis.

SA-PO924

Right Coronary Artery (RCA) Dominant Distribution of Coronary Artery Lesions in the Development of CKD Stage

Miho Tsukada,[1] Toshihide Hayashi,[2] Nobuhiko Joki,[3] Shiko Gen,[1] Naofumi Ikeda.[1] *[1]Saitama Sekishinkai Hospital, Saitama, Japan; [2]Toho university ohashi medical center, Meguro, Japan; [3]TOHO University Ohashi Medical Center, Tokyo, Japan.*

Background: It is reported that a more proximal lesions in RCA was observed in CKD patients compared with non-CKD patients (Kidney International (2009) 75, 80–87). CKD may affect the location and/or distribution of coronary atherosclerosis. The characteristics of coronary artery disease in CKD patients, however, have not entirely been clarified. We elucidate the relationship between the progression of CKD and the distribution of coronary artery stenosis diagnosed by coronary artery angiography.

Methods: Among the 13391 cases of coronary artery angiography performed in our hospital from 2003 to 2017, we characterized coronary artery lesions in predialytic phase of CKD patients. The inclusion criteria was the patients who had been treated with the first elective PCI. The patients with previous revascularization, acute myocardial infarction, unstable angina pectoris, coronary artery bypass imaging after coronary artery bypass grafting, or hemodialysis or unknown renal function were excluded in this study. Finally, 3268 CKD patients were enrolled into this study.

Results: The average age was 71 (64-77) years, and average eGFR was 65 (53-77) ml/min. A single lesion was observed in 2168 cases and multiple lesions were observed in 1085 cases. location of the lesion was the right coronary artery (RCA) in 914 cases, left main trunk in 101 cases, left anterior descending artery (LAD) in 1832 cases, and left circumflex artery in 733 cases. The prevalence of RCA lesion significantly increases in parallel with the development of CKD stage, however this phenomenon disappeared in LAD and LCX lesion. In multivariate logistic regression analysis, odds ratios of RCA for stage 4 and 5 were 1.79 (C.I. 1.10 to 2.94, p=0.019) and 4.21 (C.I. 1.90 to 9.29, p<0.001) respectively compared with the reference of CKD1. After adjusting for age, male, diabetes, hypertension, and dyslipidemia, this strong association remained statistically significant.

Conclusions: It is still unclear the mechanism, it is possibility that progression pattern is different between three major coronary arteries. The deterioration of renal function may affect the progression of atherosclerosis more in RCA than LAD or LCX.

SA-PO925

Maximisation of Renin-Angiotensin-Aldosterone System Inhibition (RAASi) in CKD Patients with Heart Failure (HF): Experience from a CKD-HF Clinic

Mai Nguyen,[2] Samir A. Rumjaun,[2] Debasish Banerjee.[1] *[1]St Georges Hospital and St Georges University of London, Wimbledon, United Kingdom; [2]St Georges University Hospital NHS Foundation Trust, London, United Kingdom.*

Background: CKD-HF patients suffer from high hospitalisation and mortality rates, which may improve with maximum RAASi- often avoided by physicians due to fear of worsening renal function and hyperkalaemia. This study reports impact of a novel multidisciplinary cardiology-nephrology clinic for RAASi maximisation in CKD-HF patients.

Methods: Clinical, biochemical data and medications were obtained from electronic patient records and clinical letters on 97 patients seen and followed up in CKD-HF clinic from 23/03/17 to 11/04/19. Daily doses of each medication were classified into None, Low, Medium (≥50% maximum dose) and Maximum dose. Medication dose groups and blood test results were compared between the first and last clinic visit.

Results: Patient characteristics were: median age 78.5 years (IQR 66.8-84.3 years), male 71.1%, diabetes mellitus 53.6%, mean ejection fraction (EF) 38.6±13.7%, HFrEF 48.5% and CKD stages 3 (56.7%), 4&5 (43.3%). Median follow up time was 302 days (IQR 178-479 days). 15 patients died during follow up. At the end of follow up: 78.4% patients remained same or milder CKD group. There was a difference in the number of RAASi patients were on, between first and last visit (p=0.02): none (41.2% vs 29.9%), one (45.4% vs 50.5%), both ACEi/ARB and MRA (13.4% vs 19.6%). ACEi/ARB dose was increased in 33.0% patients and MRA dose in 17.5% of patients. Proportion of patients on each dose category between first and last visit for ACEi/ARB was not different (p=0.11): none (45.4% vs 39.2%), low dose (26.8% vs 26.8%), medium dose (16.5% vs 20.6%), maximum dose (11.3% vs 13.4%); for MRAs, it was different (p=0.02): none (82.5% vs 71.1%), low dose (7.2% vs 13.4%), medium dose (10.3% vs 12.4%), maximum dose (0% vs 3.1%). There was no change in serum Na, K, creatinine in patients with ACEi/ARB or MRA dose increase between first and last visit. The change of eGFR was significant in patients with MRA dose increase (p=0.03), however, it was small (34.5 vs 32.1 ml/min/1.73m2). There was no significant correlation between RAASi dose increase and the likelihood of patients having CKD progression (p=0.64 for ACEi/ARB; p=0.66 for MRA).

Conclusions: A combined CKD-HF clinic was effective in maximising RAAS inhibition in a high-risk group of patients without clinically significant hyperkalaemia or deterioration in renal function.

SA-PO926

The Influence of Vascular Endothelial Dysfunction on the Prognosis of CKD and Its Possible Related Influencing Factors

Jing Qian,[1] Shaojun Liu,[2] Chuan-Ming Hao,[1] Lingyun Lai.[2] *[1]Huashan Hospital, Shanghai, China; [2]Huashan Hospital, Fudan University, Shanghai, China.*

Background: Vascular endothelial dysfunction may be involved in progression of renal fibrosis in CKD patients. Asymmetric dimethylarginine(ADMA) is an endogenous nitric oxide synthase(NOS) inhibitor, which plays an important role in the pathophysiological process of endothelial dysfunction. Elevated circulating ADMA level is one of the primary biomarkers of endothelial dysfunction. This study will explore the associated factors leading to endothelial injury in CKD patients and the relationship between vascular endothelial dysfunction and CKD prognosis.

Methods: 77 adults in CKD stage 1–5 were enrolled. Baseline demographic data including age, gender and etiology of kidney disease were all recorded. Serum ADMA, α-klotho and phosphorus levels were measured and immunohistochemical staining was carried out. Patients were divided into two groups by the median serum ADMA level and were followed up for 6 years. The primary outcome was initiation of renal replacement therapy.

Results: The mean serum ADMA level of all patients was 64.3±34.6ng/mL. Serum ADMA level increased with declining renal function(r=–0.267, p=0.020). It was negatively correlated with serum α-klotho(r=0.–233, p=0.042) and positively correlated with phosphorus(r=0.243, p=0.037) levels. The expression of α-klotho in renal perforation tissues of CKD patients was decreased by immunofluorescence staining. The expression of sodium-phosphorus synergistic transporter(NaPi) in renal tubules, which promoted phosphorus reabsorption and the expression of dimethylarginine-dimethylamine hydrolase(DDAH), which regulated ADMA level, were significantly decreased, consistent with the clinical results. Kaplan-Meier analyses showed that the incidence of renal replacement therapy initiation in high ADMA group was significantly higher than that in low ADMA group(35.9%vs13.2%, p=0.029, log rank test).

Conclusions: Serum ADMA level increased with deterioration of renal function and increase of CKD stage. Low serum α-klotho and high phosphorus levels are associated with increased circulating ADMA levels, which implies that they may be involved in the pathogenesis of endothelial dysfunction in CKD patients. High serum ADMA level predicts the occurrence of end-stage renal failure. Alleviating endothelial injury and improving endothelial dysfunction in patients with CKD may delay the progress of CKD.

SA-PO927

Incidence of Cardiovascular Events and Mortality in Korean Patients with CKD: Results from KNOW-CKD Cohort

Hyunjin Ryu,[1] Jayoun Kim,[1] Eunjeong Kang,[1] Minjung Kang,[1] Yeji Hong,[1] Curie Ahn,[1] Kook-Hwan Oh.[2] KNOW-CKD Study Group *[1]Seoul National University Hospital, JongNo-Gu, seoul, Republic of Korea; [2]SNU College of Medicine, Seoul, Republic of Korea.*

Background: There are lack of studies regarding the incidence of major adverse cardiovascular events (MACE) in Asian pre-dialysis population. This study was conducted to analyze the incidences of MACE and death in Korean chronic kidney disease (CKD) population, using the data from a multicenter prospective cohort.

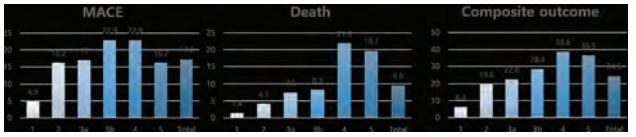
Methods: This is a longitudinal analysis from a multicenter prospective cohort study, entitled KNOW-CKD. Among a total 2,238 patients enrolled, 59 patients without follow-up data were excluded and, finally, 2,179 patients were included. MACE was defined as any of the cardiovascular events occurred during the follow-up. The composite outcome was defined as MACE and all-cause death.

Results: Mean age was 53.6±12.2 years and 38.7% were female. At enrollment, mean eGFR was 53.2±30.7 ml/min/1.73m² and the prevalence of cardiovascular disease and diabetes were 6.0% and 33.4%, respectively. During median 4.1 years of follow-up, the incidences of MACE, death and composite outcome were 17.2, 9.6 and 24.5 per 1,000 patient-year (PY). All outcome incidences were higher in diabetic patients compared

to non-diabetics (p<0.001). The incidence rate increased as CKD stages advanced, for MACE (p=0.001), death (p<0.001) and composite outcomes (p<0.001). In the multivaraite regression model, CKD stage G4 and G5 showed increased HR of 2.5 and 3.2 for MACE compared to G1 adjustment for age and sex. However when other confounding factors were adjusted, the significance disappeared. For the composite outcome, CKD stage G4 and G5 showed significant increased HR of 2.9 and 4.3 over G1, even after other confounding factors were adjusted. When the incidence rate of composite outcome was compared to general population using National Health Insurance service – National, sample cohort, this CKD population had increased HR of 1.5 (CI 1.31-1.72, p<0.001) compared to general population.

Conclusions: The incidence rate of MACE, death and composite outcome in Korean non-dialysis CKD patients were 17.2, 9.6 and 24.5 per 1,000 PY, respectively, which were similar to Japan cohort data but lower than western cohorts data.

Funding: Government Support - Non-U.S.



Incidence of outcomes according to CKD stages

SA-PO928

Effect of Blood Pressure Variability and Arterial Stiffness for Renal Outcome in Patients with CKD Stage 3 or 4

Yun Hee Park,[1] Yunmi Kim,[1] Sunwoo Kang,[2] Yeong Hoon Kim,[3] Taehee Kim.[2] *[1]Inje University Busan Paik Hospital, Busan, Republic of Korea; [2]Inje University, Busan, Busan, Republic of Korea; [3]Inje University Medical School, Busan, Republic of Korea.*

Background: Previous studies have reported that higher visit-to-visit blood pressure (BP) variability is higher risk of decreased renal function in hypertensive individuals. Arterial stiffness is associated with decline of renal function. We examined the association between BP variability and renal outcome in patients with chronic kidney disease (CKD) stage 3 or 4, and whether theses renal outcomes were associated with arterial stiffness.

Methods: Among 2238 CKD patients in Korea in 2011 through 2017, 1241 patients who had CKD stage 3 or 4, and measured BP more than 3 times during follow-up period were included. BP variability was defined as standard deviation (SD) of systolic BP across 3 to 8 visits. SD was divided into quintiles. Composite renal outcome included ≥ 50% reduction of eGFR, dialysis or transplantation. Arterial stiffness was measured with brachial-ankle pulse wave velocity (baPWV). We calculated adjusted hazard ratio (AHR) for composite renal outcome across SD quintile and analyzed the effect of baPWV.

Results: Mean age was 53.6±11.1 years, 37% was women, and mean estimated glomerular filtration rate was 36.9±12.2 ml/min/1.73m^2. Median follow-up was 3.0 years and 391 outcomes occurred. The AHR for composite renal outcome were 1.10 (95% confidence interval [95% CI]: 0.77-1.58), 1.19 (95% CI: 0.84-1.68), 1.30 (95% CI: 0.92-1.83), and 1.62 (95% CI: 1.15-2.28) for second through fifth versus the first quintile of SD. baPWV >15 m/s was significantly higher risk for renal outcomes in fifth compared to the first quintile (AHR: 1.75, 95% CI: 1.08-2.80).

Conclusions: Higher visit-to-visit BP variability are associated with rapid deterioration of renal function. Furthermore, there are different association between BP variability and renal outcome depending on arterial stiffness such that higher BP variability has a strong association with CKD progression among patients with high arterial stiffness.

SA-PO929

Short-Term Systolic Blood Pressure Variability Predicts Renal Events in CKD: Results from the C-STRIDE Study

Qin Wang, Jinwei Wang, Yu Wang, Luxia Zhang, Ming Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China.*

Background: Whether short-term blood pressure variability (BPV) correlates with renal and cardiovascular (CV) events is controversial in patients with chronic kidney disease (CKD).

Methods: A total of 1421 CKD stage 1-4 patients with ambulatory BP (ABP) data from the Chinese Cohort Study of Chronic Kidney Disease (C-STRIDE) were enrolled in the present study. Short-term BPV was evaluated by calculating 24-hour standard deviation (SD) andthe weighted SD (w-SD) of systolic BP (SBP). The association of short-term BPV with CKD outcomes, including initiation of renal replacement therapy and CV events, was evaluated by Cox regression model. The adjustment included age, gender, smoking, diabetes, anti-hypertensive treatment, body mass index, serum albumin, estimated glomerular filtration rate, logarithm transformed low-density lipoprotein cholesterol and logarithm transformed urine protein.

Results: The mean age of the cohort was 49.4±13.7 years with 56% males. The average value of 24-hour SBP SD and w-SD were 13.9±4.8mmHg and 12.6±4.4mmHg, respectively. During a median follow-up of 4.8 years, 236 renal events and 93 CV events occurred, respectively. Both 24-hour BP SD (hazard ratio [HR]: 1.04, 95% confidence interval [CI]: 1.01-1.06) and w-SD (HR: 1.05, 95%CI: 1.02-1.08) showed a greater hazard for renal events in fully adjusted model. Compared with the bottom tertile group, the risk for renal events was significantly increased in top tertile group for both 24-hour SBP SD (HR:1.58, 95%CI:1.11-2.24) and w-SD (HR:1.48, 95%CI: 1.07-2.06), respectively. Neither 24-hour SBP SD nor w-SD showed a significant relationship with CV events when expressed as a continuous variable (HR: 1.04, 95% CI: 0.99–1.08 and HR: 1.03, 95% CI: 0.99–1.08, respectively). Similar findings were found with tertiled 24-hour SBP SD and w-SD.

Conclusions: In CKD patients, short-term systolic blood pressure variability increases the risk for renal events independently.

Clinical Burden of Complications Associated with CKD: A Novel Cardio-Renal Risk Tool

Eirini Palaka,[1] Oliver T. Darlington,[2] Philip McEwan,[2] Susan Grandy.[3] *[1]AstraZeneca, Cambridge, United Kingdom; [2]Health Economics and Outcomes Research Ltd., Cardiff, United Kingdom; [3]AstraZeneca, Gaithersburg, MD.*

Background: The prevalence of chronic kidney disease (CKD) is growing worldwide. CKD affects approximately 15% of Americans. CKD patients are a complex and comorbid population. Complications are frequent in people with CKD and represent an important component of the associated disease burden. This study aimed to synthesize evidence reporting associations between two common complications of CKD, hyperkalemia (HK) and anemia, and risk of adverse outcomes including death and cardiovascular (CV) events in a novel risk tool to encourage a holistic approach to evaluating the associated disease burden.

Methods: Systematic literature reviews were conducted to identify studies reporting risk of either HK or anemia in people with CKD including those receiving dialysis, and studies associating the incidence of HK or anemia with clinical outcomes including mortality, hospitalization and CV events. Reported evidence was then incorporated in a Cardio-Renal Risk Awareness and Impact Tool developed in Excel to characterize the risks of HK, anemia and associated adverse outcomes in people with CKD.

Results: A total of 314 studies were identified that reported the risk of HK (n=123) or anemia (n=191), or the association between each complication and patient outcomes. For male patients aged 65 years with CKD stage 3b, the estimated 5-year risk of a HK event (potassium>5.5mmol/L) was 11.9%. Separately, the prevalence of anemia (Hb<11g/dL) was 35.0%. For a patient with HK the estimated relative risks (RR) of death, hospitalization and CV events were 1.50, 1.20 and 1.08, respectively. For a patient with anemia corresponding RRs were 1.13, 1.47 and 1.12. Furthermore, estimated RRs increased with the severity of each complication; RRs of death, hospitalization and CV events increased to 2.19, 1.73 and 1.14 for a patient with potassium>6.0mmol/L and to 1.13, 1.72 and 1.24 for a patient with Hb<10g/dL, respectively.

Conclusions: HK and anemia are both consistently and independently associated with increased risk of adverse outcomes in CKD patients. This study uniquely synthesizes the growing body of evidence on the epidemiology and impact of complications such as HK and anemia in CKD patients. This novel risk tool can be used to communicate the importance of timely diagnosis and management of these conditions to reduce the burden of disease in this population.

Osteoprotegerin Is Associated with Development of Coronary Artery Calcification but Not Severity and Progression in Non-Dialysis CKD: Results from the KNOW CKD Study

Seon Ha Baek,[1] Sun Ryoung Choi,[1] Jang Won Seo,[1] Ja-Ryong Koo,[1] Sejoong Kim,[2] Ho Jun Chin,[2] Dong-Wan Chae.[2] KNOW CKD group *[1]Internal Medicine, Hallym University Dongtan Sacred Heart Hospital, Hwaseong-si, Gyeonggi-do, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, GyeonGgi-Do, Republic of Korea.*

Background: Coronary artery calcifications (CAC) are recognized as a predictor of all-cause and cardiovascular mortality in chronic kidney disease (CKD). Osteoprotegerin (OPG) could be a marker of vascular calcification presence and extent. The purpose of this study was to evaluate relationships between OPG levels and presence/severity/progression of CAC score in non-dialyzed CKD patients.
