JASN

Kidney Week Edition

Journal of the American Society of Nephrology

Abstract Supplement

KIDNEY WEEK 2019
Washington, DC | Nov. 5–10

Abstract Supplement

Abstract Publication
More than 4,600 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined.
For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 30, 2019: Page(s).

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

Abstract Disclaimer and Copyright
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). It is published as a service for the personal, noncommercial, and informational use only of its members and Kidney Week participants. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week program, which can be found on the ASN website and in the Kidney Week mobile app, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week to complete a disclosure form. Responses are listed on the ASN website.

Osmolarity-Dependent Gene Expression Enables Spatial Resolution of Cells from Whole Kidney Single Cell RNA Data

Christian Hinze,[1,2] Nikos Karaiskos,[3] Anastasiya Boltengagen,[3] Nina Himmerkus,[4] Markus Bleich,[4] Steven Potter,[5] Andrew Potter,[5] Christine Kocks,[3] Nikolaus Rajewsky,[3] Kai M. Schmidt-Ott.[1,2] *[1]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Nephrology and Medical Intensive Care, Charité-Universitätsmedizin, Berlin, Germany; [3]Berlin Institute for Medical Systems Biology Max Delbrück Center for Molecular Medicine, Berlin, Germany; [4]Institute of Physiology, CAU, Kiel, Germany; [5]Cincinnati Children's Hospital, Cincinnati, OH.*

Background: In whole organ single cell data, spatial information of cells is usually lost but can sometimes be restored if regional marker genes are identifiable. In the kidney, certain cell types exist in regions of different microenvironments along the corticomedullary axis. For instance, cells of the proximal tubule, thick ascending limb or collecting duct extend from the serum-isosmotic renal cortex into the hyperosmotic renal medulla. We hypothesized that differences in regional gene expression between cortex, outer and inner medulla driven by different microenvironments and osmolarity-dependent genes might provide information on the spatial origin of cells in single cell data.

Methods: We obtained mouse kidneys and prepared single cell suspensions of whole kidneys as well as of microdissected cortical, outer and inner medullary tissue and applied single cell RNA sequencing. We assigned cell type information based on known marker genes and systematically analyzed regional gene expression differences and differences in expression of osmolarity-dependent genes (osmogenes) within different tubular cell types. In addition, we developed an unsupervised algorithm based on osmogene expression and used this information to spatially assign cells in whole kidney single cell suspensions.

Results: Our data show that the expression of osmogenes is tubule segment-specific and increases towards the inner medulla. We show that osmogenes are substantial drivers of gene expression differences within a given cell type along the corticomedullary axis. They harbor spatial information especially for tubule cells present in the outer and inner medulla but also to a lesser extent for other cell types. Applying our algorithm to spatially assign whole kidney single cell data reveals an imbalanced composition of regional origin of kidney cells in whole kidney single cell suspensions with a marked underrepresentation of medullary kidney cells.

Conclusions: Osmolarity-dependent genes show cell type-specific regional expression patterns and harbor spatial information of kidney cells. They can be used to spatially assign cells within whole kidney single cell RNA sequencing data and uncover a previously unrecognized regional bias in whole kidney single cell preparations.

TH-OR002

The Hypertension Induced by Renal Snx5 Silencing Is Associated with Increased Renal Protein Abundance of NHE3, NaPi2, NKCC2, and NCC in Mice

Yanting Yu. *The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China.*

Background: Sorting nexin 5 (SNX5) plays an important role in the function of renal dopamine receptor subtype 1 (D_1R). The gene silencing of renal Snx5 by its siRNA decreases renal D_1R but increases blood pressure (BP) in rats; it also decreases renal expression of insulin receptor and insulin degrading enzyme and causes insulin resistance in mice.

Methods: In order to test the hypothesis that SNX5 deletion affects renal sodium absorption and develops hypertension, we measured BP, water and sodium balance, and renal protein expression of sodium transporters in C57BL6/J mice treated with siRNAs of SNX5 or mock. 8 male C57Bl6 mice (5-6 months old) were uninephrectomized 3 weeks prior to the infusion of SNX5-siRNA or mock-siRNA (3 mg/kg.day, n=4/group) via osmotic mini-pump into sub-capsular space for 1 week.

Results: In SNX5-siRNA-treated mice, systolic (119±5.2, mm Hg, under anesthesia) and diastolic BPs (91.8±7.3) were elevated, relative to mock-siRNA-treated mice (SBP=101.5±0.5, DBP=72±2.3). Food and water intake, body weight, urine volume and heart rate were similar in the two groups. The gene silencing decreased the protein expression of SNX5 and D_1R by 70% and 30% respectively (immunoblotting). In control mice, SNX5 and D_1R colocalized mainly in the apical membrane of the proximal tubules, thick ascending limbs of loop of Henle, but not in collecting ducts. The two proteins also co-immunoparticipated in mouse kidney homogenates and cell lysates from cultured mouse proximal tubule cells. The gene silencing of Snx5 increased renal protein expressions of NHE3 (172±30, % of control), NaPi2 (223±12), NKCC2 (286±54), NCC (177±23), but did not alter the protein expressions of ENaCs and Na^+K^+ATPase.

Conclusions: These findings suggest that inhibition of SNX5 by siRNA increases the apical sodium transporters in proximal and distal nephron segments, in which SNX5 and D1R were co-localized. This may cause the impaired sodium excretion that may be responsible for the increased blood pressure in SNX5-siRNA-treated mice.

Dietary Fructose Enhances Protein Kinase C Activity and Angiotensin II-Dependent Transport in Proximal Tubules

Jeffrey L. Garvin. *Case Western Reserve University, Cleveland, OH.*

Background: In both humans and model organisms fructose causes salt-sensitive hypertension. This is in part due to increasing the sensitivity of proximal nephron Na reabsorption to angiotensin II (Ang II) such that lower concentrations stimulate transport to a greater extent. Ang II stimulates Na transport in proximal tubules by activating protein kinase C (PKC) α, a calcium- and lipid-dependent kinase. We hypothesized that dietary fructose increases the ability of Ang II to elevate intracellular calcium (Cai) and, thereby, activate PKC α in proximal tubules. This, in turn, stimulates Na/H exchange activity, the primary transporter involved in Na reabsorption.

Methods: Rats were fed a diet of normal chow plus tap water or normal chow plus 20% fructose in drinking water for 7-8 days. The effect of Ang II on Cai was measured using Fura2 in isolated, perfused S2 segments of proximal tubules. Na/H exchange (NHE) activity was measured in perfused tubules using the pH-sensitive dye BCECF. PKC α activity was measured by separating particulate and soluble fractions, performing Western blots and recording the particulate to soluble ratio. Increases in this ratio was taken as activation.

Results: Basal Cai was 143±29 nM in proximal tubules from control rats while it was 160±30 nM in those given fructose, not significantly different. Ang II (1 nM) increased Cai by 43±10 nM in control tubules and by 148±53 nM in tubules from rats fed fructose ($p < 0.03$). A higher concentration of Ang II (100 nM) increased Cai by 237±100 nM in proximal tubules from rats fed fructose and by 190±34 nM in tubules from rats fed the control diet. Ang II increased the particulate to soluble ratio of PKC α by 0.134±0.026 in tubules from rats fed fructose ($p < 0.001$) but not significantly in control tubules (0.060±0.061). Finally we measured NHE activity. Ang II (1 pM) increased NHE activity by 0.7±0.1 fluorescent units/s in tubules from rats given fructose but had no effect on NHE activity in control tubules ($p<0.01$). With Go6976, a PKC $\alpha/\beta1$ inhibitor, Ang II was unable to stimulate NHE activity in tubules from rats fed fructose.

Conclusions: We concluded that dietary fructose increases the ability of Ang II to elevate Cai, and consequently PKCα. This, in turn, stimulates NHE activity which likely contributes to fructose-induced salt-sensitivity of blood pressure.

Potassium Directly Regulates WNK (With No Lysine Kinases)

Aylin R. Rodan,[1] Feng Zhang,[1] John Pleinis,[1] Jason O. Sosa,[1] John M. Humphreys,[2] Radha Akella,[2] Haixia He,[2] Elizabeth J. Goldsmith.[2] *[1]University of Utah, Salt Lake City, UT; [2]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Plasma potassium concentration is maintained within a narrow range, implying the ability to sense deviations from normal. WNK mutations in mice and humans result in abnormal potassium concentrations, and WNKs have been proposed to indirectly sense plasma potassium via effects on intracellular chloride. Here, we investigate whether WNKs are directly regulated by potassium. Our lab has previously shown that the WNK signaling cascade is conserved in *Drosophila* Malpighian (renal) tubules.

Methods: We used differential scanning fluorimetry and mass spectrometry to measure WNK kinase domain thermal stability and autophosphorylation *in vitro* in the presence of varying concentrations of potassium. We also examined the activity of DmWNK (*Drosophila* WNK) and HsWNK3 (human WNK3) activity in the *Drosophila* Malpighian tubule, using phosphorylation of transgenically expressed kinase-dead rat SPAK as a readout. We developed baths with varying extracellular potassium and fixed intracellular chloride concentrations (16 mM or 30 mM, measured using the transgenic sensor ClopHensor). We measured intracellular potassium in the tubule using inductively coupled plasma mass spectrometry.

Results: Potassium directly binds to the kinase domain of DmWNK (*Drosophila* WNK) and human WNK1 *in vitro*, as assayed by differential scanning fluorimetry. Potassium also inhibits autophosphorylation, required for kinase activation, of DmWNK and HsWNK3 (human WNK3) kinase domains *in vitro*. We also examined the activity of DmWNK or HsWNK3 in Malpighian tubules. Compared to the normal potassium bath, there was no change in DmWNK or HsWNK3 activity in low potassium bath, but there was no change in intracellular potassium under these conditions. Intracellular potassium was increased in the high potassium bath, and high potassium inhibited both DmWNK and HsWNK3 in both the 16 mM and 30 mM intracellular chloride conditions. High potassium bath also inhibited chloride-insensitive $HsWNK3^{L295F}$ activity in the tubule.

Conclusions: Our data suggest that potassium directly inhibits WNK kinases, in a manner that is additive to chloride inhibition, with implications for potassium sensing in the kidney and other organs.

Mg^{2+} Restriction Downregulates NCC Through NEDD4-2 and Prevents Its Activation by Hypokalemia

James A. McCormick,[1] Mohammed Z. Ferdaus,[1] Philip J. Blatt,[1] Jonathan W. Nelson,[1] Andrew Terker,[2] Olivier Staub,[3] Daohong Lin.[4] *[1]Oregon Health and Science University, Portland, OR; [2]Vanderbilt University, Nashvile, TN; [3]University of Lausanne, Lausanne, Switzerland; [4]New York Medical College, Valhalla, NY.*

Background: Hypomagnesemia is associated with lower kidney function and life-threatening complications, and sustains hypokalemia. The distal convoluted tubule (DCT) determines final urinary Mg^{2+} excretion, and via activity of the Na^+-Cl^- cotransporter (NCC) plays a key role in K^+ homeostasis by metering Na^+ delivery to distal segments. We previously showed that short-term (3 days) or long-term (14 days) Mg^{2+} restriction lowered abundances of total NCC (tNCC) and the active phosphorylated NCC (pNCC), but this did not involve the NCC-activating WNK-SPAK pathway.

Methods: We set out to further explore the mechanisms involved and determine interactions with K^+ restriction, a strong activator of NCC, by performing dietary manipulations in mice then Western blotting.

Results: We confirmed a previous report that long-term Mg^{2+} restriction does not alter NCC mRNA abundance, and found the same with short-term Mg^{2+} restriction. The E3 ubiquitin-protein ligase neural precursor cell expressed developmentally downregulated gene 4-2 (NEDD4-2) is known to target NCC for proteasomal degradation. We found that short-term Mg^{2+} restriction did not lower tNCC abundance in inducible nephron-specific NEDD4-2 knockout mice. We next examined interactions with K^+ restriction. tNCC and pNCC abundances were similar after short- or long-term Mg^{2+} or combined Mg^{2+}-K^+ restriction, but were dramatically lower compared with low K^+ diet, suggesting that Mg^{2+} restriction overrides the effects of K^+ restriction on NCC. After combined Mg^{2+}-K^+ restriction, adding back K^+ alone to the diet had no effect on tNCC abundance, but adding back Mg^{2+} either at the same time or after K^+ replenishment increased tNCC abundance. NEDD4-2 mediates degradation of the epithelial sodium channel (ENaC) during dietary K^+ restriction so we next examined the effect of Mg^{2+} restriction on ENaC by performing amiloride response tests. Compared with normal diet the natriuretic effect of amiloride was strongly blunted after K^+ restriction but not after Mg^{2+} restriction.

Conclusions: Together, these data suggest that NEDD4-2 mediates proteasomal degradation of NCC during Mg^{2+} restriction, Mg^{2+} restriction exerts differential effects on NCC and ENaC, and sustained NCC downregulation may enhance distal Na^+ delivery during states of hypomagnesemia, maintaining hypokalemia.

Angiotensin II Stimulates ENaC by an Aldosterone-Independent Mechanism

WenHui Wang,[1] Peng Wu,[2,1] Zhong-Xiuzi Gao,[2,1] Andrew Terker,[5] Dandan Zhang,[3] Daohong Lin,[1] David H. Ellison.[4] *[1]New York Medical College, Valhalla, NY; [2]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [3]New York Medical Collage, Valhalla, China; [4]Oregon Health & Science University, Portland, OR; [5]OHSU, Portland, OR.*

Background: Epithelial Na^+ channel (ENaC) is expressed in the aldosterone-sensitive distal nephron and both aldosterone and angiotensin II (AngII) have been shown to stimulate ENaC activity. The aim of the present study is to test whether AngII is able to stimulate ENaC by an aldosterone-independent mechanism.

Methods: We employed the patch-clamp technique and renal-Na^+ clearance method to study the effect of AngII on ENaC in the DCT and CCD of WT and kidney-specific mineralocorticoid receptor knockout (MR-KO) mice, where MR is knocked out in adult mice.

Results: High dietary K^+ (HK) intake stimulates ENaC in both DCT and CCD in WT mice but this effect is absent in MR-KO mice. In contrast, low sodium (LS) stimulates ENaC only in the CCD but not in the DCT and the effect of LS on ENaC in the CCD was completely absent in MR-KO mice. Under control conditions the amiloride-sensitive Na^+ currents (ENaC) in DCT2 were significantly higher than in the CCD. The deletion of MR partially inhibited ENaC in the DCT but completely abolished ENaC in the CCD. Furthermore, application of losartan (AT1R antagonist) inhibited ENaC in the DCT of both WT and MR-KO mice, suggesting the role of AT1R in regulating ENaC activity in the DCT. In contrast, losartan did not have a significant effect on ENaC in the CCD of WT mice. Infusion of AngII for 3 days increased ENaC activity in the DCT and in the CCD of WT mice. Moreover, AngII infusion still robustly increased ENaC currents in the DCT of MR-KO mice whereas the stimulatory effect of AngII on ENaC was modest in the CCD. Renal clearance study further demonstrated that angiotensin II infusion for three days augmented benzamil-induced natriuresis in MR-KO mice and increased the renal K^+ excretion. Consequently, the infusion of AngII completely corrected hyperkalemia of MR-KO mice.

Conclusions: Angiotensin II-induced stimulation of ENaC occurs mainly in the DCT and to a lesser degree in the CCD. In contrast, aldosterone plays a dominant role in determining ENaC activity in the CCD but to a lesser degree in the DCT. Thus, AT1R plays an important role in the regulation of ENaC activity in the DCT.

TH-OR007

Collecting System Specific Deletion of Kcnj10 Predisposes for Thiazide- and Low K^+ Diet-Induced Hypokalemia

David Penton Ribas,[1] Twinkle Vohra,[1] Eszter Banki,[1] Agnieszka Wengi,[1] Maria Weigert,[2] Anna-Lena Forst,[2] Sascha Bandulik,[2] Richard Warth,[2] Johannes Loffing.[1] *[1]University of Zurich, Zurich, Switzerland; [2]University of Regensburg, Regensburg, Germany.*

Background: The basolateral K^+ channel KCNJ10, is expressed in the renal distal convoluted tubule (DCT) and controls the activity of the thiazide-sensitive NaCl cotransporter (NCC). Loss-of-function mutations of KCNJ10 cause EAST/SeSAME syndrome with salt wasting and hypokalemia. KCNJ10 is also expressed in the principal cells of the collecting system (CS); however, its role in this segment has not been studied in detail.

Methods: To address this question, we generated the mouse model $AQP2^{cre}$:$Kcnj10^{flox/flox}$ with a deletion of Kcnj10 specifically in the CS (CS-Kcnj10-KO).

Results: CS-Kcnj10-KO mice responded normally to standard and high K^+ diet. However, CS-Kcnj10-KO exhibited a higher kaliuresis and lower plasma K^+ than control mice when treated with thiazide diuretics. Likewise, CS-Kcnj10-KO displayed an inadequately high kaliuresis and renal Na^+ retention upon dietary K^+ restriction. In this condition, CS-Kcnj10-KO mice became hypokalemic due to an insufficient downregulation of the epithelial Na^+ channel (ENaC) and the renal outer medullary K^+ channel (ROMK) in the CS. Consistently, the phenotype of CS-Kcnj10-KO was ameliorated by either pharmacological inhibition of ENaC or by genetic inactivation of ROMK in the CS.

Conclusions: In conclusion, KCNJ10 in the CS contributes to the renal control of K^+ homeostasis by regulating ENaC and ROMK. Impaired KCNJ10 function in the CS predisposes for thiazide- and low K^+ diet-induced hypokalemia and likely contributes to the pathophysiology of renal K^+ loss in EAST/SeSAME syndrome.

TH-OR008

Renal Inflammation, Vascular Pathology, and Splenomegaly Are Induced in a Mouse Model of Spontaneous Chronic Metabolic Acidosis

Jill W. Verlander,[1] Chao Chen,[1] Sharon W. Matthews,[1] Autumn N. Harris,[1,2] Hyun-Wook Lee,[1] Maria carmen Valero,[1] Michael F. Romero,[3] William L. Clapp,[4] I. D. Weiner.[1,5] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Veterinary Medicine, University of Florida, Gainesville, FL; [3]Mayo Clinic College of Medicine, Rochester, MN; [4]Pathology, University of Florida, Gainesville, FL; [5]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Background: Recent studies have shown that alkali treatment retards the progression of chronic kidney disease. However, whether long-term metabolic acidosis alone can cause development and progression of renal and vascular pathology is not known. We used a model of spontaneous chronic metabolic acidosis to examine this issue.

Methods: We used 4 and 8 month old female mice with proximal tubule $NaHCO_3^-$ cotransporter, NBCe1-A, deletion (KO) and their WT littermates. We used immunohistochemistry to determine inflammatory cell type (macrophage/monocyte, F4/80; B lymphocyte, B220; T lymphocyte, CD3).

Results: At both 4 and 8 mo KO mice had marked metabolic acidosis (4 mo, serum HCO_3^- WT, 25.4±0.8 vs KO, 12.5±1.5, n=4 per group; 8 mo, WT 21.8±1.5 vs KO 11.2±0.5 n=5 and 4). Urine albumin, measured at 8 mo, was increased significantly (WT 19.1±11.3 mg/d; KO 56.8±9.7, P<0.02); urea clearance was unaltered. Toluidine blue-stained semi-thin sections and transmission electron microscopy showed mesangial expansion with increased mesangial matrix deposition in KO at 4 and 8 mo compared to WT. Trichrome and picrosirius red stains showed mild-to-moderate increase in interstitial collagen in KO at 4 mo and 8 mo. Routine light microscopy showed mild cellular infiltrates, particularly in perivascular regions, in 4 mo KO kidney that was markedly increased at 8 mo. There was an increase in interstitial macrophages in KO cortex at 4 mo that was accentuated at 8 mo. The perivascular infiltrate in 8 mo KO kidney was predominantly T lymphocytes, but also included B lymphocytes and macrophages. The thoracic aorta had increased wall thickness with thickening and fragmentation of the elastin layers in 4 and 8 mo KO mice. KO mice had marked splenomegaly, which appeared due predominantly to increased macrophages in the splenic parenchyma.

Conclusions: Long-term metabolic acidosis induced by NBCe1-A deletion causes significant inflammatory activation, with renal inflammatory infiltrates and expansion of the splenic macrophage/monocyte population, along with development of mild mesangial expansion, renal interstitial fibrosis, and vascular defects. These data suggest chronic metabolic acidosis may independently contribute to the development and progression of renal and vascular disease.

Derivatives of FMP-API-1/27 Robustly Activate AQP2 Water Channels Independently of Vasopressin

Fumiaki Ando, Naofumi Yui, Shintaro Mandai, Kiyoshi Isobe, Takayasu Mori, Koichiro Susa, Naohiro Nomura, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Tokyo Medical and Dental University, Tokyo, Japan*.

Background: Congenital nephrogenic diabetes insipidus (NDI) is characterized by the inability of the kidney to concentrate urine. Congenital NDI is mainly caused by loss-of-function mutations in the vasopressin type 2 receptor (V2R), leading to impaired aquaporin-2 (AQP2) water channels activity in renal collecting ducts. Direct activators of protein kinase A (PKA) are novel therapeutic targets of congenital NDI. The intracellular distribution and activity of PKA are largely controlled by A-kinase anchoring proteins (AKAPs). We found that a low molecular weight compound, FMP-API-1/27, dissociated AKAPs binding to PKA and activated PKA/AQP2. We promoted further development of FMP-API-1/27 derivatives in terms of pharmaceutical potency and feasibility.

Methods: The effects of compounds on PKA/AQP2 were examined by a mouse cortical collecting duct (mpkCCD) cell line and a V2R-inhibited NDI mouse model.

Results: We examined the effects of screening compounds with similar structures to FMP-API-1/27 from TMDU Chemical Biology Database and derivatives of FMP-API-1/27 using mpkCCD cells. Hit compounds that increased PKA/AQP2 activity had similar chemical structures. We then developed compound X, which phosphorylated AQP2 at S269 to the same extent as vasopressin in mpkCCD cells. *In vivo*, compound Y significantly increased urine osmolality and decreased urine output in a V2R-inhibited NDI mouse model.

Conclusions: Derivatives of FMP-API-1/27 are promising therapeutic targets for congenital NDI caused by V2R mutations.

TH-OR010

Investigation of the Renal Phenotype of a Novel Mouse Model with Dent Disease

Imène B. Sakhi,[1,2] Yohan Bignon,[1,3] Nadia Frachon,[1] Nicolas Picard,[4] Stéphane Lourdel.[1,2] Renal physiology and tubulopathies *[1]INSERM U1138 Centre de recherche des Cordeliers, Paris, France; [2]Sorbonne Université, Paris, France; [3]INSERM U1147 Centre Universitaire des Saints-Pères, Paris, France; [4]LBTI CNRS U5305 Institut de Biologie et Chimie des Protéines, Paris, France*.

Background: Dent disease is a rare hereditary renal proximal disorder that predominantly affects young males. The disease is characterized by low molecular weight (LMW) proteinuria, hypercalciuria, kidney stones and progressive renal failure. Inactivating mutations of the *CLCN5* gene encoding the $2Cl^-/H^+$ exchanger ClC-5 have been identified in more than 60 % of patients with Dent disease. ClC-5 is essentially expressed in early endosomes of proximal tubules (PT) where it optimizes the function of the V-type H^+ ATPase to ensure an efficient endocytosis of LMW proteins, and therefore to avoid their loss into the urine. The functional consequences of *CLCN5* mutations have previously been investigated in heterologous expression systems. It has been shown that 60 % of the mutations lead to a defect in protein folding and processing, such as the previously published N340K pathogenic ClC-5 mutation. As a consequence, the misfolded ClC-5 are retained within the endoplasmic reticulum (ER). Here, we have investigated the consequences of the N340K mutation using a transgenic mouse model.

Methods: Daily food, water intake, body weight and urine excretion data were collected in metabolic cages for N340K and WT mice. Urine as well as blood samples were analysed for ions, proteins, glucose and creatinine to detect kidney dysfunction as observed in patients with Dent disease. Expression and localization of proteins involved in receptor-mediated endocytosis of LMW proteins were studied by Western blot and on kidney sections by immunofluorescence in WT and N340K male mice.

Results: The N340K mice showed an increased urinary calcium and glucose excretion, a decreased urinary pH, and a severe LMW proteinuria, recapitulating common features of Dent disease. Megalin, a multi-ligands receptor involved in the endocytosis of LMW proteins was less expressed at the apical border of N340K mouse PTs.

Conclusions: The present study validates a new Dent disease mouse model carrying a pathogenic mutation of ClC-5. It will help to better understand the molecular basis of Dent disease, such as the link between an altered ClC-5 and defective proximal tubule endocytosis. In the long term, our mouse model could be used to assess therapeutic approaches for the rescue of a proper proximal tubule cell function.

TH-OR011

Polyploidization Is Essential to Survive AKI but It Contributes to CKD Development

Letizia De Chiara, Elena Lazzeri, Maria Lucia Angelotti, Carolina Conte, Paola Romagnani. Romagnani Lab *Excellence Center for Research, Transfer and High Education Denothe, University of Florence, Florence, Italy*.

Background: Acute kidney injury (AKI) is a global health concern. If not lethal in the acute phase, AKI is considered reversible. However, even mild AKI episodes carry a risk of developing chronic kidney disease (CKD). Recently, we demonstrated that tubular epithelial cells (TECs) can undergo endoreplication-mediated hypertrophy after AKI. Endoreplications are incomplete cell cycles that lead to the formation of polyploid cells. As polyploid cells can provide increased cell function without restoring tissue integrity, we hypothesized that this mechanism is essential to survive AKI but it can be potentially maladaptive.

Methods: To address this hypothesis, we employed a series of *in vitro* and *in vivo* models based on the FUCCI technology to monitor cell cycle phasing in combination with YAP1 overexpression or downregulation. In the *in vivo* models, mice were subjected to unilateral ischemia reperfusion injury (IRI) to induce AKI. Polyploid cells have been then characterized by single cell RNAseq, cell sorting, super-resolution STED microscopy and transmission electron microscopy.

Results: *In vitro*, human renal tubular cells undergo polyploidization. The fraction of polyploid cells significantly decreases when YAP1 nuclear translocation is blocked. After AKI in mice, the inhibition of YAP1 significantly reduces the number of polyploid cells and worsens kidney function, while YAP1 overexpression leads to an increase in the number of polyploid cells up to 20% of all TECs. Electron microscopy and STED analysis revealed the presence of both mononucleated and binucleated polyploid cells with a chromatin distribution typical of actively transcribing cells. Strikingly, these mice appear to be more prone to develop tubulointerstitial fibrosis acquiring a marked senescent phenotype along with significant decline in renal function thus suggesting an association between polyploidization and CKD development. Indeed, isolation of polyploid cells proved that these cells actively transcribe and secrete pro-fibrotic and senescent factors thus confirming their role in CKD progression.

Conclusions: These data suggest that: 1) polyploidization is crucial to survive AKI by maintaining renal function in the acute phase and 2) polyploid cells are senescent and in the long run they are involved in the progression of AKI to CKD.

TH-OR012

A Comprehensive Single Nucleus RNA-Sequencing Atlas of Mouse and Human AKI

Yuhei Kirita, Haojia Wu, Benjamin D. Humphreys. *Washington University School of Medicine in St. Louis, Saint Louis, MO*.

Background: After acute kidney injury (AKI), many patients make an apparently full recovery ("complete repair") whereas others transition to chronic kidney disease (CKD, "failed repair"). To better define the cellular and molecular mechanisms of AKI and the AKI to CKD transition, we performed comprehensive single nucleus RNA-seq (snRNA-seq) on both mouse and human AKI.

Methods: We generated 122,828 single-nucleus transcriptomes from mouse kidney after IRI: 4 hours, 12 hours, 2 days, 14 days, 6 weeks and sham (n = 3 for each), and 37,636 nuclei from a healthy and AKI adult human kidney using the 10X platform and performed a comprehensive informatic analysis and gene expression validation.

Results: Mouse had on average 1317 and human 2007 unique genes/nucleus. We identified over 30 cell types including rare ones (juxtaglomerulus, macula densa) in both mouse and human datasets. We define transcriptional states that distinguish proximal tubule destined for successful vs. failed repair. Using receptor-ligand analysis, we identify and define profibrotic and pro-inflammatory signals secreted by failed repair epithelia to fibroblasts, endothelial cells and leukocytes, driving the AKI to CKD transition. We show that a scattered cell population in healthy kidney exists that recapitulates the epithelial repair signature and that likely represents the cell type that prior reports characterized as a fixed stem cell population. We define 9 stromal subtypes including four novel fibroblast and 3 novel pericyte cell types and find that a subset transiently upregulate aSMA after injury. These results were validated in the human AKI snRNA-seq dataset.

Conclusions: The first comprehensive snRNA-seq atlas of mouse and human AKI kidney revealed four novel insights: (1) injury-repair cycles occur in situ in single epithelial cells in healthy kidney, (2) a population of pro-fibrotic proximal tubule cells drives failed repair in a non cell-autonomous manner, (3) novel stromal subtypes are identified including a population with reversible expression of aSMA, suggesting plasticity amongst myofibroblast progenitors and (5) a receptor-ligand analysis between all major kidney cell types during injury and repair reveals dynamic intercellular communication patterns.

Sirtuin 5 Regulates a Metabolic Switch in Fatty Acid Oxidation That Protects Against AKI

Kevin Peasley,[1,2] Takuto Chiba,[1,2] Elina Mukherjee,[2] Eric S. Goetzman,[4] Sunder Sims-Lucas.[3] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA; [3]Children's Hospital of Pittsburgh, Pittsburgh, PA; [4]Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Background: There are currently no targeted drug therapies for the treatment of acute kidney injury (AKI). The proximal tubule compartment is particularly vulnerable to injury, owing to high energy demands. Fatty acids are a preferred energy source for proximal tubule cells and are oxidized at high rates through both the mitochondrial and peroxisomal fatty acid oxidation (FAO) pathways. Sirtuins are a class of enzymes which reverse post-translational lysine acylation and regulate many biological processes including FAO. Multiple sirtuins, including 1, 3, and 6 have been shown to play roles in AKI, but the role of mitochondrial-based Sirtuin 5 (Sirt5) during AKI has yet to be determined.

Methods: Male germline Sirt5 deficient mice (either +/- or -/-) and wild-type controls at 8-12 weeks old were subjected to two different AKI models: 1. unilateral ischemia-reperfusion injury (22 minutes) or 2. single high dose cisplatin-induced AKI (20 mg/kg). Mice were evaluated for injury by histopathological analysis and by serum chemistry. FAO was measured by the catabolism of ^{14}C-labeled palmitate to $^{14}CO_2$. Peroxisome-specific FAO was measured by inhibition of mitochondrial FAO via etomoxir (100uM). Primary mouse proximal tubule cells were isolated from Sirt5-/- or WT mice and exposed to 24 hours hypoxia (FiO_2 1%) or treated with 20μM cisplatin for 24 hours. hPTEC cells were exposed to combined glucose-oxygen deprivation with or without Sirt5 siRNA knockdown and evaluated for cell death by LDH efflux.

Results: No overt kidney phenotype was observed in Sirt5-/- mice at baseline. However, following IRI and cisplatin-induced AKI, Sirt5-/- and Sirt5+/- mice had significantly improved kidney function and less evidence of tissue injury compared with controls. The cell-based assays confirmed that knockdown of Sirt5 in proximal tubule cells was protective against both types of injury. This protection coincided with increased peroxisomal FAO and decreased mitochondrial FAO in the Sirt5-/- proximal tubules.

Conclusions: Subsequently, SIRT5 deficiency confers protection against multiple models of acute kidney injury. This identifies a therapeutically attractive mechanism whereby increased peroxisomal FAO and decreased mitochondrial FAO drives protection of kidneys from injury.

TH-OR014

High Mobility Group Box 1(HMGB1)-Induced Ferroptosis Accelerates Ischemia-Reperfusion-Incited AKI

Gang Xu,[2] Zhi Zhao,[3] Ying Yao,[2] Rui Zeng.[1] *[1]Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China; [2]Huazhong University of Science and Technology, Tongji Medical College, Tongji Hospital, Wuhan, China; [3]Department of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*.

Background: Regulated necrosis (RN), which is identified as cells death in a regulated manner but with the morphologic features of necrosis, has been implicated to be involved in the process of AKI and improve chronic kidney injury. The common hallmark of RN in kidneys is the rupture of tubular epithelial cell membrane and the release of the unprocessed intracellular components known as damage-associated molecular patterns (DAMPs) resulting in activation of immune system. As a representative DAMP molecular, high mobility group box-1 (HMGB1) involving in many inflammatory diseases has less determined on the effect of RN.

Methods: Mice with conditional alleles of HMGB1 were crossed with mice harboring Ksp-CreERT transgenes to knock out HMGB1 in renal tubular epithelial cells. 8-10 weeks old $HMGB1^{fl/fl}$; Ksp-$CreERT^{+/+}$ mice were randomly divided into two groups: KH+TMX group and KH+Vehi group. The two groups were injected with tamoxifen(TMX) at a dose of 100 mg/kg body weight and Vehicle for 5 consecutive days respectively. After two weeks of elution, the mice were subjected to 30 min of bilateral ischemia reperfusion (I/R). One day later, the mice were sacrificed and the serum, kidney, liver, and other organs were sampled for evaluating the role of HMGB1 in I/R.

Results: Renal tubular specific HMGB1 knockout mice underwent a pronounced pathological shift including decreased expression of KIM-1 and NGAL and upregulated expression of Klotho after I/R. Serum creatinine and urea nitrogen were reduced in KH+TMX group with less renal inflammatory cell infiltration. Ferroptosis and necroptosis are the most described in RN. We found that HMGB1 knockout ameliorated ferroptosis in I/R. KH+TMX group got a higher expression of GPX4 and lower level of ACSL4 in kidney with less accumulation of lipid peroxidation. However, the key enzymes of necroptosis, RIP1/RIP3/MLKL, have less changed in KH-TMX group compared to the control group. RNA-seq further indicated 710 genes differentially expressed between KH-TMX and KH-Vehi group. The results of GO analysis and the KEGG pathway analysis illustrated that a large amount of differentially expressed genes (DEGs) were involved in lipid metabolic and amino acid process which is tightly linked to the regulation of ferroptosis.

Conclusions: HMGB1-dependent ferroptosis impairs the ischemia-induced AKI, which might serve as a novel target for I/R treatment.

Optogenetic Stimulation of the Vagus Nerve Identifies Distinct Pathways That Mediate Kidney Protection from Ischemia-Reperfusion Injury

Shinji Tanaka,[1] Chikara Abe,[2,3] Shuqiu Zheng,[1] Daniel S. Stornetta,[2] Stephen Abbott,[2] Diane L. Rosin,[2] Ruth Stornetta,[2] Patrice G. Guyenet,[2] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Pharmacology, University of virginia, Charlottesville, VA; [3]Department of Physiology, Gifu University Graduate School of Medicine, Gifu, Japan*.

Background: We recently showed that electrical vagus nerve stimulation (VNS) in the neck protected mouse kidneys from ischemia-reperfusion injury (IRI) by activating the cholinergic anti-inflammatory pathway (CAP) (PMID: 27088805). Stimulation of vagal efferent neurons is believed to be essential in the activation of CAP. However, electrical stimulation of the cervical vagus nerve excites both the efferent (motor) and afferent (sensory) neurons. It is still unclear which pathway is important in ameliorating kidney injury.

Methods: Channelrhodopsin-2 (ChR2) is a light-sensitive, non-selective cation channel; the gate is opened only during blue light application. We generated choline acetyltransferase (*Chat*)-*ChR2* mice and vesicular glutamate transporter 2 (*Vglut2*)-*ChR2* mice, which express ChR2 in vagal efferent and afferent neurons, respectively. Thus, when the cervical vagus nerve is illuminated with blue laser, vagal efferent and afferent neurons are selectively stimulated in *Chat-ChR2* and *Vglut2-ChR2* mice, respectively. For selective ablation of C1 neurons, which are a group of lower brainstem catecholaminergic/glutamatergic neurons, *AAV2-flex-taCasp3-TEVp* was injected bilaterally into the rostral ventrolateral medulla (the area where C1 neurons are localized) of dopamine beta-hydroxylase (*Dbh*)-*Cre* mice 6 weeks before electrical afferent/efferent VNS. Optogenetic VNS with blue laser or electrical VNS was performed 24 h before bilateral renal IRI, and mice were euthanized 24 h after IRI.

Results: Optogenetic VNS protected kidneys from IRI in both *Chat-ChR2* mice (pCr: 1.53±0.20 vs. 0.48±0.05 mg/dL) and *Vglut2-ChR2* mice (pCr: 1.09±0.22 vs. 0.44±0.06 mg/dL), which was supported by improved kidney histology and decreased renal Kim-1 expression in the VNS groups. Next, based on our recent study (PMID: 28288124), we hypothesized that the C1 neurons mediate the afferent VNS pathway. Electrical VNS significantly increased the number of cFos-positive C1 neurons, and selective ablation of C1 neurons eliminated the protective effect of afferent VNS, but not efferent VNS.

Conclusions: Both stimulation of vagal efferent and afferent neurons protected the kidneys from IRI. C1 neurons in the lower brainstem were involved in the protective pathway elicited by afferent VNS.

A Functional Genomic Screen Identifies a CDKL5-SOX9 Regulatory Axis in Epithelial Cell Death and Kidney Injury

Ji Young Kim, Yuntao Bai, Laura A. Jayne, Navjotsingh P. Pabla. *The Ohio State University, Columbus, OH*.

Background: Numerous clinical conditions are associated with inflammatory, toxic, and hypoxic insults to tubular epithelial cells. The resulting epithelial cell dysfunction and cell-death are the hallmarks and underlying cause of acute kidney injury (AKI), a common disorder that predominantly develops in hospitalized patients. Importantly, the patients that recover from an episode of AKI are at increased risk of developing chronic kidney disease, end-stage renal disease and cardiovascular dysfunction- disorders that are associated with significant morbidity and mortality. To identify novel regulators of renal epithelial cell death and AKI, here, we have used a kinome-wide functional genomic screening to identify protein kinases that contribute to the pathogenesis of AKI.

Methods: An unbiased kinome-wide siRNA screen for regulators of renal epithelial cells was carried out in a murine epithelial cell line. Through subsequent in vivo validation experiments, we identified cyclin-dependent kinase-like 5 (CDKL5) also known as serine/threonine kinase 9 (STK9) as a key regulator of renal cell-death and injury. To directly define the role of CDKL5 in vivo, kidney tubule specific CDKL5 knockout mice were generated. In addition, a pharmacological inhibitor of CDKL5 kinase was evaluated in cisplatin nephrotoxicity and ischemia-associated AKI. Later proteomic studies were carried out to identify the transcription factor Sox9 as a bona fide Cdkl5 substrate and a key downstream target in renal epithelial cells.

Results: High-throughput siRNA screening and validation studies identified CDKL5 kinase as a crucial, previously unknown regulator of renal epithelial cell-death. In vivo studies showed that genetic or pharmacological ablation of CDKL5 function provides mitigates AKI in both cisplatin and ischemia-associated kidney injury. We also found that Sox9 is phosphorylated on the Ser-199 residue by Cdkl5 during kidney injury in vivo. Cdkl5-mediated phosphorylation reduced the stability of Sox9 protein.

Conclusions: Here we have found that Cdkl5 also known as Stk9 is a stress responsive kinase that controls epithelial cell fate during AKI. We propose that Cdkl5 activation promotes renal dysfunction through phosphorylation-mediated destabilization of pro-survival transcription factor Sox9.

Ubiquitin-Proteasome System Actively Maintains Homeostasis of Proximal Tubules

Keita Hirano,[1] Yoshitaka Tashiro,[2] Motoko Yanagita.[1] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*.

Background: Autophagy and ubiquitin-proteasome system (UPS) are two major protein degradation pathways essential for cellular protein homeostasis. While the role of autophagy in the kidney has been extensively analyzed in the proximal tubules of the kidney, the impact of UPS function in the maintenance the proximal tubules has been unclear.

Methods: In order to analyze the role of UPS function in the proximal tubule, we crossed conditional knockout mice of the proteasome subunit Rpt3 with proximal tubule specific inducible Cre (*Ndrg1-*Cre^{ERT2}), to generate *Rpt3fl/fl:Ndrg1-*Cre^{ERT2}(PT-Rpt3-CKO) mice, in which the expression of Rpt3 can be deleted in proximal tubules at desired time points by tamoxifen administration. Utilizing PT-Rpt3-CKO mice, we investigated how UPS regulates the maintenance of proximal tubules.

Results: As early as one day after tamoxifen administration for 5 consecutive days, proximal tubules of PT-Rpt3-CKO mice showed mild injury in light microscopy, whose mitochondria were fragmented in electron microscopy. Proximal tubule injury at this time point was also confirmed by the upregulation of Kim1, cleaved caspase 3, and gH2AX in immunostaining. Immunoblotting also revealed the upregulation of ubiquitin and p62, and downregulation of LC3 1/2ratio, indicating autophagy insufficiency. Four days after tamoxifen administration, serum creatinine and blood urea nitrogen (BUN) were elevated and proximal tubules were detached from the basement membrane. In addition to further upregulation of Kim1, cleaved caspase 3, and gH2AX, and p62 compared to those in day 1, the expression of p21was upregulated and cyclinD1 was downregulated indicating possible G1 cell cycle arrest. 8 days after tamoxifen administration, all PT-Rpt3-CKO mice died possibly due to renal insufficiency. The administration of the proteasome inhibitor MG-132 to a proximal tubule cell line NRK52E resulted in decreased mitochondrial membrane potential and oxygen consumption rate.

Conclusions: Our results provide strong evidence showing that the dysfunction of UPS rapidly triggers mitochondrial dysfunction, autophagy insufficiency, cell cycle arrest

and apoptosis of proximal tubules, leading to renal insufficiency and death. Compared to mild phenotypes of conditional knockout mice of autophagy related molecules in the proximal tubules, UPS plays a crucial role in the active maintenance of proximal tubules.

Organelle-Specific Oxidant Stress and CORE Disruption Mediate Proximal Tubule Cell Injury During Gentamicin Exposure

Chinaemere Igwebuike,[1] David Pimentel,[1] Hui Feng,[1] Joshua Campbell,[1] Michael Sherman,[3] Julia Yaglom,[3] Zhiyong Wang,[2] Andrea Havasi,[2] Steven C. Borkan.[2] *[1]Boston Univerisity School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Ariel University, Jerusalem, Israel.*

Background: The Cross-Organelle Stress Response (CORE) is an adaptive mechanism that maintains mitochondrial and endoplasmic reticulum (ER) proteostasis. We hypothesized that gentamicin causes nephrotoxic acute kidney injury (AKI) by causing both mitochondrial specific oxidative stress and fragmentation resulting in CORE disruption before activating the lethal unfolded protein response (UPR).

Methods: Mito HyPer, a mitochondrial-specific H_2O_2 probe, was used to detect early mitochondrial ROS accumulation in human proximal tubule epithelial cells (HK2) during gentamicin exposure. Mitochondria and ER were stained with MitoTracker and ER Tracker, respectively, and time course experiments were performed using a Nikon Super Resolution microscope. Mitochondrial-ER disassociation, mitochondrial morphology and immunoblots of CORE-associated mitochondrial pro-fission proteins (Total DRP1 and pDRP1) were used as surrogates of CORE function. Misfolded protein stains (Thioflavin T), protein ubiquitination, and immunoblots for whole cell oxidative stress (4HNE) were measured to assess proteotoxicity. The efficacy of preserving CORE on protein misfolding, lethal UPR activation (CHOP), and cell survival was assessed using geranylgeranylacetone (GGA), a protein chaperone inducer, prior to the introduction of gentamicin.

Results: Gentamicin exposure caused characteristic features of disrupted CORE, including mitochondrial-specific H_2O_2 accumulation, DRP-1 activation and organelle fragmentation, followed by mitochondrial-ER dissociation. Importantly, CORE disruption occurred before detectable changes in whole cell oxidative stress, protein ubiquitination, protein misfolding or lethal UPR activation (CHOP) were observed. GGA significantly decreased mitochondrial-specific oxidative stress, prevented fragmentation, preserved mitochondrial-ER association and ameliorated lethal UPR activation.

Conclusions: Gentamicin exposure causes early mitochondrial H_2O_2 accumulation and disrupts the CORE. These untoward events contribute to gentamicin-induced proteotoxicity and lethal UPR activation. GGA preserves the CORE and decreases subsequent lethal UPR activation that contributes to the proximal tubule cell injury caused by gentamicin.

TH-OR019

Matricellular Protein Tenascin C Has a Protective Effect in Renal Ischemia-Reperfusion Injury

Xiaoyi Mao, Chuan-Ming Hao. *Division of Nephrology, Huashan Hospital, Shanghai, China.*

Background: Interstitial microenvironment is critical in regulating cell proliferation and injury/repairing process. Tenascin-C is a matricellular protein which is transiently expressed during development and can be re-induced after injury, suggesting a potential role in tissue injury/repairing. The present study examined the role of TNC in acute kidney injury using a ischemia-reperfusion (IR) model.

Methods: A tenascin-C promoter driven inducible CreER2 knock-in mouse line with an eGFP reporter was generated. TNC-CreER$^{+/+}$ (TNC$^{-/-}$) mice were used to examine the role of TNC in of AKI.

Results: Following IR, TNC was markedly induced in the interstitium of the kidney as early as 3 hours and peaked at 24-48 hours. To examine the role of TNC in AKI, we used the TNC-CreER$^{+/+}$ (TNC$^{-/-}$) mice. Deletion of TNC in mice significantly aggravated IR induced AKI, showing significantly lower survival rate, higher BUN and more severe tubular injury after IR comparing to their wild type littermates. We Then examined the mechanism by which TNC is induced following injury. Four hypoxic response elements (HRE) were identified in the promoter region of TNC, suggesting a role of hypoxia-inducible factor(HIF). DMOG, a HIF stabilizer, significantly induced TNC expression both in mice and in primary cultured renal interstitial cells. Luciferase reporter assay showed that hif-2α promoted the transcription of TNC, while mutation of the HRE of the TNC luciferase reporter abolished this effect. The bindiong of hif-2α to endogenous TNC promoter was also supported by ChiP assay. To explore the mechanism by which TNC protects kidney from AKI, we isolated the primary tubular epithelial cells and treated the cells with commercially available TNC protein. TNC protected primary tubular epithelial cells from hypoxic injury. Our further experiments suggest that the EGF-like domain in TNC was involved in the protective effect via EGFR-STAT3 pathway.

Conclusions: TNC, which is immediately induced following IR, has a protective effect on ischemia-reperfusion injury.

TH-OR020

Enhancer and Super-Enhancer Dynamics in Repair After Ischemic AKI

Julia Wilflingseder,[2,3] Michaela Willi,[3] Hye kyung Lee,[3] Hannes Olauson,[4] Takaharu Ichimura,[2] Reinhold Erben,[1] M. Todd Valerius,[5] Lothar Hennighausen,[3] Joseph V. Bonventre.[2] *[1]University of Veterinary Medicine Vienna, Vienna, Austria; [2]Renal Division, Brigham and Women's Hospital / Harvard Medical School, Boston, MA; [3]Laboratory of Genetics and Physiology, National Institute of Diabetes, Digestive and Kidney Diseases / NIH, Bethesda, MD; [4]Division of Renal Medicine, Department of Clinical Sciences, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [5]Brigham and Women's Hospital, Boston, MA.*

Background: The endogenous repair process of the mammalian kidney allows rapid recovery after acute kidney injury (AKI) through robust proliferation of tubular epithelial cells. There is currently limited understanding of which transcriptional regulators activate these repair programs. Here we investigate the existence of enhancer dynamics in the regenerating mouse kidney.

Methods: RNA-seq and ChIP-seq (H3K27ac, H3K4me3, BRD4, Pol II) were performed on samples from repairing kidney cortex 2 days after ischemia/reperfusion injury (IRI) to identify activated genes, transcription factors, enhancer and super-enhancers associated with kidney repair. Further we investigated the role of super-enhancer activation in kidney repair through pharmacological BET inhibition using the small molecule JQ1 in acute kidney injury models in vivo.

Results: Response to kidney injury leads to genome-wide alteration in enhancer repertoire *in*-vivo. We identified 16,781 enhancer sites (H3K27ac/BRD4 positive, H3K4me3 negative) active in SHAM and IRI samples; 6,512 lost and 9,774 gained after IRI. The lost and gained enhancer sites can be annotated to 62% and 63% of down- and up-regulated transcripts, respectively. The top 3 transcription factor binding motifs enriched in lost enhancer sites are Hnf4a, Esrrb and PPARE and in gained enhancer sites Fra1, Fosl2 and Atf3. ChIP-seq profiles of selected transcription factors show specific binding at corresponding enhancer sites. Super-enhancer analysis revealed 164 lost and 216 gained super-enhancer sites at IRI day 2. 385 super-enhancers maintain activity during repair. Pharmacological inhibition of enhancer activity by BRD4 inhibition before IRI leads to suppression of 40% of injury-induced transcripts associated with cell cycle regulation and significantly increased mortality between days 2 and 3 after AKI.

Conclusions: This is the first demonstration of BRD4 enhancer and super-enhancer function in the repairing kidney. In addition, our data call attention to potential caveats for use of small molecule inhibitors of BET proteins that are currently being tested in clinical trials in cancer patients who are at risk for AKI. Our analyses of enhancer dynamics after kidney injury in vivo have the potential to identify new targets for therapeutic intervention.

HIMALAYAS: A Phase 3, Randomized, Open-Label, Active-Controlled Study of the Efficacy and Safety of Roxadustat in the Treatment of Anemia in Incident-Dialysis Patients

Robert Provenzano,[5] Shutov Evgeny,[6] Eremeeva Liubov,[3] Svitlana Korneyeva,[4] Amarnath A. Kathresal,[2] Lona Poole,[1] Gopal Saha,[1] Charles Bradley,[1] Meraf Eyassu,[1] Anatole Besarab,[1] Robert Leong,[1] Cameron S. Liu,[1] Thomas B. Neff,[1] Lynda Szczech,[1] Kin-Hung P. Yu.[1] *[1]FibroGen, Inc., San Francisco, CA; [2]Durham Nephrology Associates, Cary, NC; [3]LLC Fresenius Medical Care Kuban, Krasnodar, Russian Federation; [4]Zaporizhzhia regional clinical hospital, Zaporizhzhia, Ukraine; [5]DaVita Healthcare, Denver, CO; [6]Botkins hospital, Moscow, Russian Federation.*

Background: Roxadustat (FG-4592) is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and regulates iron metabolism.

Methods: ESA-naïve or limited prior use, incident dialysis pts were randomized (1:1) to roxadustat (ROXA) or epoetin alfa (EPO). Oral iron was allowed;parenteral iron was restricted. Oral ROXA was dosed thrice weekly. The initial roxadustat dose was weight-based. EPO was prescribed according to the country-specific product labeling. An algorithm determined ROXA doses. The primary endpoint for the US FDA was mean Hb change from baseline (BL) to Weeks (Wk) 28-52. The primary endpoint for EU EMA was the % of pts achieving a Hb response through Wk 1-24. An Hb response was defined at 2 consecutive visits during the first 24 Wk as achieving a Hb level of 11 and an increase of 1 g/dL if BL Hb was >8 gor 2 g/dL if baseline Hb was <8 g/dL. Safety and tolerability were assessed by adverse events, vital signs, electrocardiogram findings, and clinical laboratory values.

Results: 1,043 pts (522=ROXA, 521=EPO) ≥18 years old were randomized in 17 countries. Pts were majority Caucasian with 8.4% Black pts in the ROXA arm and 9.6% Black pts in the EPO arm. The % of pts with type 2 DM in the ROXA arm was 35.1% (n=183) and 34.4% (n=179) in the EPO arm. Mean BL Hb was 8.43 g/dL in the ROXA arm and 8.46 g/dL in the EPO arm. Mean Hb change from BL to the average over Wk 28-52 was 2.57 (ROXA) vs. 2.36 g/dL (EPO). The non-inferiority criteria were met as the lower bound of 95% CI was above the non-inferiority margin of -0.75 g/dL, and superiority over EPO was also achieved, p=.0005. ROXA pts had an Hb response rate of 88.2% compared with 84.4% in the EPO arm meeting EU's primary endpoint non-inferiority criterion. The overall safety profile was consistent with results observed in prior ROXA trials and pooled safety findings will be submitted as a late breaker abstract.

Conclusions: ROXA was non-inferior and subsequently demonstrated superiority over EPO in the mean change in Hb from BL in pts incident to dialysis.

ROCKIES: An International, Phase 3, Randomized, Open-Label, Active-Controlled Study of Roxadustat for Anemia in Dialysis-Dependent CKD Patients

Steven Fishbane,[1] Carol A. Pollock,[2] Mohamed A. El-Shahawy,[3] Elizabeth T. Escudero,[4] Anjay Rastogi,[5] Bui Pham van,[6] Lars Frison,[7] Mark T. Houser,[8] Maksym Pola,[9] Nicolas J. Guzman,[8] Pablo E. Pergola.[10]
[1]Northwell Health, Great Neck, NY; [2]The University of Sydney, Sydney, NSW, Australia; [3]Keck-USC School of Medicine, Los Angeles, CA; [4]Hospital Arzobispo Loayza, Lima, Peru; [5]University of California Los Angeles, Los Angeles, CA; [6]Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam; [7]AstraZeneca, Mölndal, Sweden; [8]AstraZeneca, Gaithersburg, MD; [9]AstraZeneca, Warsaw, Poland; [10]Renal Associates PA, San Antonio, TX.

Background: Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron absorption and utilization.

Methods: This Phase 3 trial evaluated roxadustat vs epoetin alfa (epo) in patients (pts) with ESRD and anemia receiving dialysis. Pts with baseline (BL) hemoglobin (Hb) of <12 g/dL if treated with an erythropoietin analog or <10 g/dL if not were recruited. Pts were randomized 1:1 to receive oral roxadustat or epo. For pts receiving epo at BL, initial roxadustat dose was based on epo dose; for epo-naïve pts initial roxadustat dose was weight-based. Roxadustat dose was constant for first 4 wks; a dose adjustment algorithm for roxadustat (20 mg qw–400 mg tiw to max 3 mg/kg) was used to maintain Hb between 10–12 g/dL. Oral iron was allowed; IV iron was used as standard-of-care in epo arm and with evidence of iron deficiency in roxadustat arm. Primary efficacy endpoint was mean Hb change from BL to Hb averaged over wks 28–52. Roxadustat safety data integrated across multiple appropriate dialysis trials will be reported separately.

Results: 2133 dialysis pts were randomized (1068 roxadustat, 1065 epo). Mean age was 54.0 years, 59% male, 57% white. Mean duration of dialysis was 37.5 months, 19.5% were incident pts (2 wks to 4 months). Mean (SD) BL Hb was 10.01 (1.22) g/dL. Mean Hb change from BL to average over wks 28–52 was higher with roxadustat (+0.77 g/dL) vs epo (+0.68 g/dL; p=0.036) in the overall cohort. Mean Hb change from BL to average over wks 28–52 in pts with elevated BL high-sensitivity C-reactive protein (hsCRP) was greater with roxadustat (+0.80 g/dL) vs epo (+0.59 g/dL; p=0.012). Roxadustat-treated pts had Hb ≥10 g/dL for a similar proportion of time over wks 28–52 vs epo-treated pts (79% vs 76%, respectively; p=0.045). Proportion of pts who received red blood cell transfusion was comparable between roxadustat and epo arms (HR=0.83; 95% CI: 0.64–1.07). Roxadustat-treated pts used less monthly IV iron from wk 36 to end of study (58.7 vs 91.4 mg, respectively; p<0.0001).

Conclusions: Roxadustat effectively increased Hb, overall and in pts with elevated hsCRP, and reduced IV iron use in pts with dialysis-dependent CKD.

OLYMPUS: A Phase 3, Randomized, Double-Blind, Placebo-Controlled, International Study of Roxadustat Efficacy in Patients with Non-Dialysis-Dependent (NDD) CKD and Anemia

Steven Fishbane,[1] Mohamed A. El-Shahawy,[2] Roberto Pecoits-Filho,[3] Bui Pham van,[4] Mark T. Houser,[5] Lars Frison,[6] Dustin J. Little,[5] Nicolas J. Guzman,[5] Pablo E. Pergola.[7]
[1]Northwell Health, Great Neck, NY; [2]Keck-USC School of Medicine, Los Angeles, CA; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam; [5]AstraZeneca, Gaithersburg, MD; [6]AstraZeneca, Mölndal, Sweden; [7]Renal Associates PA, San Antonio, TX.

Background: Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron absorption and utilization. Here, we report efficacy results for 1 of 3 trials for US and EU applications for treatment of anemia in patients (pts) with NDD CKD. Integrated safety will be reported separately.

Methods: Pts with NDD CKD stages 3–5 and anemia (hemoglobin [Hb] <10.0 g/dL) were randomized 1:1 to receive 70 mg oral roxadustat or placebo (PBO) three times weekly. A dose-adjustment algorithm was used to achieve and maintain Hb values of 10–12 g/dL. Primary efficacy endpoint was mean change from baseline (BL) Hb to average Hb over Wks 28–52 (US [FDA] submission) or proportion of pts with Hb response at two consecutive visits during the first 24 wks of treatment without anemia rescue therapy (EU [EMA] submission).

Results: 2781 pts were randomized (1393 roxadustat, 1388 PBO). Mean age was 61.7 years, 42% were male, 45% white, and 55% had type 2 diabetes. Mean (SD) BL Hb was 9.1 (0.7) g/dL and estimated glomerular filtration rate was 19.8 (11.7) mL/min/1.73 m^2. Mean (SD) study drug exposure was 19.6 (10.3; roxadustat) and 15.2 (10.5; PBO) months. Mean change in Hb from BL to the average over Wks 28–52 was +1.75 g/dL with roxadustat vs +0.40 g/dL with PBO (p<0.001). In 411 pts with BL elevated high-sensitivity C-reactive protein (hsCRP), changes from BL Hb were +1.75 g/dL (roxadustat) and +0.62 g/dL (PBO; p<0.001). Proportion of pts achieving Hb response at two consecutive visits without rescue during the first 24 wks was 77.0% with roxadustat vs 8.5% with PBO (p<0.001). Percentage of total time with interpolated Hb values ≥10 g/dL for Wks 28–52 was 82% with roxadustat vs 33% with PBO (p<0.001). Roxadustat reduced risk of rescue therapy by 74% (HR=0.26), including red blood cell transfusion by 63% (HR=0.37), IV iron by 59% (HR=0.41), and erythropoietin analog by 87% (HR=0.13; all p<0.001).

Conclusions: Roxadustat achieved prespecified primary endpoints for US and EU submissions, effectively increased Hb in the subgroup of pts with elevated hsCRP, and reduced rescue therapy use in pts with NDD CKD and anemia.

Randomized, Double-Blinded, Active-Controlled (Darbepoetin Alfa), Phase 3 Study of Vadadustat in CKD Patients with Anemia on Hemodialysis in Japan

Masaomi Nangaku,[2] Kazuoki Kondo,[1] Kiichiro Ueta,[1] Yoshimasa Kokado,[1] Genki Kaneko,[1] Hiroki Matsuda,[1] Yutaka Kawaguchi,[1] Yasuhiro Komatsu.[3]
[1]Mitsubishi Tanabe Pharma Corporation, Tokyo, Japan; [2]The University of Tokyo School of Medicine, Tokyo, Japan; [3]Gunma University, Graduate School of Medicine, Maebashi, Gunma, Japan.

Background: Vadadustat (VDT) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) being assessed in Japan and Global Phase 3 studies. This is the first result of phase 3 study (NCT03439137), evaluates the efficacy and safety of VDT for 52 weeks in 323 Japanese hemodialysis-dependent (HD) chronic kidney disease (CKD) subjects with anemia receiving erythropoiesis stimulating agents (ESA). Prespecified primary analysis results up to week 24 are presented here.

Methods: Subjects on maintenance hemodialysis receiving ESA were randomized to VDT (n=162) or darbepoetin alfa (DA) group (n=161). After the initial VDT dose of 300 mg daily, doses were adjusted to achieve a Hb target of 10–12 g/dL, within 150–600 mg. Primary endpoint was average Hb at weeks 20 and 24. Iron parameters were measured. Safety was assessed up to 24 weeks.

Results: The baseline Hb of both groups was 10.74 g/dL. The LSMean of average Hb at weeks 20 and 24 was 10.61 (95%CI: 10.45, 10.76) and 10.65 g/dL (10.50, 10.80) in the VDT and DA groups, respectively; 95% CI of both groups were within the target range of 10–12 g/dL. Difference in LSMean between the groups was –0.05 g/dL (–0.26, 0.17); the 95% CI lower limit was above the predefined noninferiority margin of –0.75 g/dL, confirming the noninferiority of VDT to DA. At week 24, 104 (75.4%) and 115 (75.7%) subjects in the VDT and DA groups, respectively, had Hb within the target range. VDT regimen was associated with significant increases in total iron-binding capacity and decreases in hepcidin from baseline to week 24, not found in the DA group. At least one adverse event (AE) was seen in 89.5% (VDT group) and 88.2% (DA group) subjects. The most common AEs in the VDT group were nasopharyngitis (VDT: 19.8%, DA: 28.6%), diarrhea (VDT: 10.5%, DA: 9.9%), and shunt stenosis (VDT: 8.0%, DA: 12.4%). The incidence rates of serious AEs (SAEs) were 13.0% (VDT group) and 10.6% (DA group). No SAE related to the study drug was considered.

Conclusions: VDT was generally well tolerated and effective as DA in maintaining Hb levels within the target range, indicating the usefulness of VDT for treating anemia in Japanese HD CKD patients converting from ESA.

Effects of Ziltivekimab, an Antibody to IL-6, on Inflammation, Nutritional Markers, and Anemia in Hemodialysis Patients: A Randomized, Double-Blind, Placebo-Controlled Trial

Pablo E. Pergola,[1] Rahul Kakkar,[4] Michel Chonchol,[2] Mark T. Smith,[5] Vandana S. Mathur,[3] Larry Lo,[4] Michael Davidson,[4] Matt Devalaraja.[4]
[1]Renal Associates, P.A., San Antonio, TX; [2]University of Colorado, Aurora, CO; [3]Mathur Consulting, Woodside, CA; [4]Corvidia Therapeutics, Waltham, MA; [5]Nephrology Associates, Augusta, GA.

Background: Patients with chronic kidney disease on hemodialysis (HD) and hyporesponsiveness to erythropoiesis stimulating agents (ESA) exhibit functional blockade in iron release from body stores due to inflammation-induced expression of hepcidin. We assessed the effects of ziltivekimab, a novel antibody against the proinflammatory cytokine interleukin (IL)-6, in HD patients with a genotypic variation in the *TMPRSS6* gene, hypothesized to induce a heightened susceptibility to IL-6-induced inflammation.

Methods: After a screening period documenting stable ESA and IV iron dosing, patients with high IL-6 (≥4 pg/mL) received double-blinded placebo or ziltivekimab at 2, 6 or 20 mg every 2 weeks during HD for 12 weeks. ESA dose adjustments were permitted after 4 weeks. Pharmacodynamic endpoints included markers of anemia, malnutrition and inflammation. Differences from placebo in changes from baseline were obtained from analysis of covariance with treatment as factor and baseline as covariate. Trend p-values for ordered dose treatment groups were calculated using Jonckheere-Terpstra test.

Results: 61 patients were randomized; 53 were included in the pharmacodynamic analysis population (12 received placebo; 16, 13 and 12 received 2, 6 and 20 mg, respectively). Across the treatment groups, baseline epoetin-equivalent doses ranged from 11,250-15,000 U/L, hemoglobin (Hgb) from 9-8-10.5 g/dL and high-sensitivity C-reactive protein (hsCRP) from 4-13 mg/L. Ziltivekimab significantly reduced hsCRP and increased serum albumin and Hgb while reducing ESA requirements in a dose-dependent manner (Table).

Conclusions: We demonstrated that IL-6 inhibition with ziltivekimab significantly improved markers of malnutrition-inflammation and reduced ESA requirements in hyporesponsive, inflamed dialysis patients.

Prognostic Evaluation by Different Target Hemoglobin Levels During Treatment with Epoetin Beta Pegol in Hemodialysis Patients with ESA Hyporesponsiveness: PARAMOUNT-HD Study

Ken Tsuchiya,[1] Takahiro Kuragano,[2] Nobuhiko Joki,[3] Kazuhiko Tsuruya,[4] Hirokazu Honda,[5] Takayuki Hamano,[6] Hideki Fujii,[7] Yukari Uemura,[8] Yasuo Ohashi,[9] Kosaku Nitta.[1] *[1]Tokyo Women's Medical University, Shinjuku-ku, Japan; [2]Hyogo College of Medicine, Nishinomiya, Japan; [3]TOHO University Ohashi Medical Center, Tokyo, Japan; [4]Nara Medical University, Kashihara, Japan; [5]Showa University Koto Toyosu Hospital, Tokyo, Japan; [6]Osaka University Graduate School of Medicine, Suita, Japan; [7]Kobe University Graduate School of Medicine, Kobe, Japan; [8]Tokyo University Hospital, Tokyo, Japan; [9]Chuo University, Tokyo, Japan.*

Background: The incidence of cardiovascular (CV) events is especially high in HD patients in association with hyporesponsive to erythropoiesis stimulating agents (ESAs). However, there is no recommended target ranges of hemoglobin for patients with ESA hyporesponsiveness.

Methods: We randomly assigned 304 HD, ESA-treated, patients with ESA hyporesponsiveness to a proactive treatment group (target hemoglobin [Hb] level; 11g/dL) and a maintenance treatment group (target Hb level; 9-10g/dL) by the use of epoetin beta pegol (CERA). The time from the date of study treatment initiation to the earliest CV event was evaluated as the primary endpoint. The CV events included cardiac death, heart failure requiring hospitalization, and acute coronary syndrome requiring hospitalization. The patients were followed for 24 months.

Results: The proactive and maintenance groups had a mean baseline Hb level of 9.34 and 9.32g/dL, respectively. Mean Hb levels during the observation period were 10.58 and 10.26g/dL (p=0.001) and mean length of Hb level of over 10.5g/dL were 11.5 and 8.6 months (p=0.0002), respectively. Median doses of CERA for 6 months after study treatment were 166.7 and 150.0μg/4 weeks (p=0.298). However, there was a significant difference in frequency CERA administration (once every 4 weeks: 10.9% and 26.4%; once every 2 weeks: 86.5% and 72.3% [p=0.0006], respectively). Kaplan-Meier analysis showed a significant difference in the primary endpoint between the two groups (9 and 18 events; log-rank test, p=0.033). Cox proportional hazards analysis showed a significant lower risk of CV events in the proactive group (Hazard ratio [HR], 0.429; 95% CI; 0.193-0.955). Also, the longer length of Hb level of over 10.5g/dL was associated with lower risk of CV events (HR, 0.919 per month; 95% CI; 0.865-0.977).

Conclusions: Our results suggest that targeting Hb level of 11g/dL with CERA reduces the incidence of CV events in HD patients with ESA hyporesponsiveness. Twice-monthly administration of CERA can maintain adequate Hb levels in these patients.

Maintenance Intravenous Iron Treatment on Erythropoietin Dose in Chronic Hemodialysis Patients: A Multicenter Randomized Controlled Trial

Paweena Susantitaphong,[1] Monchai Siribumrungwong,[2] Kullaya Takkavatakarn,[3] Songkiat Lewsuwan,[1] Pisut Katavetin,[4] Khajohn Tiranathanagul,[5] Sookruetai Lekhyananda,[7] Kriang Tungsanga,[6] Supat Vanichakarn,[7] Somchai Eiam-Ong,[1] Kearkiat Praditpornsilpa.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Lerdsin Hospital, Bangkok, Thailand; [3]Division of Nephrology, King Chulalongkorn Memorial hospital, Bangkok, Thailand; [4]King Chulalongkorn Memorial Hospital, Thai Red Cross Society and Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [5]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [6]King Chulalong Memorial lHospital, Bangkok, Thailand; [7]The Kidney Foundation of Thailand, Bangkok, Thailand.*

Background: Although the benefits of intravenous iron (IV) treatment in chronic hemodialysis (HD) patients were demonstrated in recent studies, IV iron regimens for optimal target levels of iron status are still not established in several guidelines. To explore these questions, we conducted a multicenter, randomized, open label study to demonstrate the effectiveness of IV iron supplement on erythropoietin dose in chronic HD patients.

Methods: Two hundred adult chronic HD patients with transferrin saturation less than 30%, and serum ferritin 200-400 ng/mL, receiving recombinant erythropoietin were randomized 1:1 for maintaining serum ferritin of 200-400 ng/mL (low serum ferritin group, N=100) or serum ferritin of 600-700 ng/mL (high serum ferritin, N=100). During 8-week titration period, subjects randomized to high serum ferritin group received total IV iron of 600 mg (100 mg every week), whereas the subjects in low serum ferritin group did not obtain initial IV iron. During 6-month follow up period, the dose of IV iron was adjusted following the protocol. The primary endpoint was to evaluate the efficacy of IV iron supplement on erythropoietin dose index [erythropoietin dose (unit/week) divided by hemoglobin level (g/dL)]. The study was registered with the Thai Clinical Trials Registry TCTR20180903003.

Results: The mean dose of IV supplement was 108.3±28.2 mg/month in low ferritin group and 192.3±36.2 mg/month in high ferritin group. The mean serum ferritin was 367.0±224.9 ng/mL in low ferritin group and 619.6±265.2 ng/mL in high ferritin group. At 3-month follow up, the erythropoietin index was significantly decreased in high serum ferritin group when compared with low serum ferritin group (921.4±369.1 vs. 756.1±372.2 unit/week/g/dL, P=0.002, and 873.8±329.4 vs. 767.9±392.1 unit/week/g/dL, P=0.05, respectively). At 6-month follow up, only high serum ferritin group showed a significant decrease of erythropoietin index from randomization (854.0±371.7 to 765.3±368.0 unit/week/g/dL, P<0.001).

Conclusions: Maintaining serum ferritin of 600-700 ng/mL by IV iron treatment approximately 200 mg per month can decrease erythropoietin dose in chronic HD patients.

Effect of Ferric Citrate on Erythropoiesis-Stimulating Agent (ESA) Use in ESRD Patients with Elevated Ferritin

Sreedhar A. Mandayam,[1] Omar Mamlouk,[3] Medha Airy,[2] Monica Rodriguez,[2] Jose J. Perez.[2] *[1]UT MD Anderson Cancer Center, Bellaire, TX; [2]Baylor College of Medicine, Houston, TX; [3]University of Texas Health Science Center at Houston, Houston, TX.*

Background: Iron deficiency anemia is common in ESRD patients on hemodialysis. Dialysis facilities infuse intravenous Iron to ESRD patients based on protocols. Patients with elevated serum Ferritin (>1000 mcg/dL) are poorly responsive to IV Iron and concerns about infection risks lead to withholding IV Iron for ESRD patients with Ferritin >1000 mcg/dL. We investigated the efficacy of orally available Iron (Ferric Citrate) used as a phosphate binder on Iron parameters and ESA use in ESRD patients that have low Transferrin Saturations (Iron deficient) but high Ferritins in a pragmatic pilot clinical trial.

Methods: Protocol was approved by the BCM IRB. All patients on hemodialysis for at least 3 months at the US Renal Care Scott Street Dialysis unit were eligible. Patients were included if: Mean Serum Ferritin >1000 on 2 consecutive samples in 3 months, TSAT <30% on 2 consecutive samples in 3 months. Information collected at enrollment: Ferritin, TSAT, hemoglobin, ESA dose, Calcium, Phosphorus, and PTH. Subjects given Ferric Citrate 210 mg 2 tabs to be taken with meals (minimum 6/day) for 3 months. Clinicians and dieticians were allowed to change the dose of Ferric Citrate as clinically indicated. Monthly monitoring for labs was performed. This is an interim report after 25 patients

Results: Mean serum Ferritin and mean TSAT at enrollment were1169 ng/ml and 23.3 %. After 90 days of Ferric Citrate, the mean TSAT increased to 36% (31% increase) and the mean serum Ferritin was 1075 ng/ml (15% decrease). ESA use decreased from 59 units/week to 28 units/week by the end of the trial representing a 52% reduction in mean ESA dose/week/patient. Adverse events were minimal with diarrhea being the most common. 1 patients withdrew before starting drug and another withdrew after 1 month on drug due to constipation.

Conclusions: Ferric Citrate is a phosphate binder that can increase iron stores in ESRD patients that have high Ferritin and low TSAT and appears to reduce ESA use by 50% in these patients. ClinicalTrials.gov Identifier:NCT03055598

Funding: Commercial Support - Keryx Bio-Pharmaceuticals

Effect of Ferric Citrate on ESA and Iron Parameters

Effect of Ferric Citrate vs. Ferrous Sulfate on Iron, Hemoglobin, and Mineral Metabolism in CKD

Rebecca L. Womack,[3] Bhupesh Panwar,[2] Orlando M. Gutierrez.[1] *[1]UAB School of Medicine, Birmingham, AL; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: Iron deficiency is common in CKD. Ferric citrate is a novel oral agent for treating iron deficiency anemia in CKD, but little is known about the efficacy of ferric citrate vs. ferrous sulfate (standard of care) in improving iron levels in CKD patients with iron deficiency.

Methods: 60 patients with stage 3b-4 CKD and iron deficiency (transferrin saturation [TSAT] <30% and ferritin <300 ng/ml) were randomized to ferric citrate (FC; n=30,2 grams tid with meals) or ferrous sulfate (FS; n=30,325 mg po tid) for 12 weeks. Primary outcomes were change in TSAT and ferritin. Secondary outcomes were change in hemoglobin, phosphate, and FGF23.

Results: There were no significant differences in baseline characteristics by treatment arm except FGF23, which was higher in the FS vs. FC arm (Table 1). A total of 25 patients in the FC arm and 26 patients in the FS completed all visits. There were no significant changes in TSAT or phosphate in either arm. Serum ferritin and hemoglobin significantly increased in the FC but not the FS arm (Fig.1). Intact FGF23 decreased 19% in the FC arm (P<0.001) and 3% in the FS arm (P=0.33), and c-terminal FGF23 decreased 15% in the FC

arm (P=0.08) and 14% in the FS (P=0.01) arm after 12 weeks. Adverse events were similar in both arms, and mostly involved gastrointestinal complaints.

Conclusions: As compared to FS, treatment with FC resulted in greater increases in ferritin and hemoglobin and a greater decrease in intact FGF23 in CKD patients.

Association of Erythropoietin Resistance and Fibroblast Growth Factor 23 in Dialysis Patients: Results from the J-DOPPS Study

Tomoko Usui,[1] Junhui Zhao,[2] Norio Hanafusa,[3] Takeshi Hasegawa,[4] Hiroshi Fujino,[5] Takanobu Nomura,[5] Jarcy Zee,[2] Eric W. Young,[6] Bruce M. Robinson,[2] Masaomi Nangaku.[1] *[1]the University of Tokyo School of Medicine, Tokyo, Japan; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Tokyo Women's Medical University, Shinjuku-ku, Japan; [4]Showa University, Yokohama, Japan; [5]Kyowa Hakko Kirin, Tokyo, Japan; [6]Arbor Research, Ann Arbor, MI.*

Background: High fibroblast growth factor 23 (FGF23) levels are associated with low hemoglobin levels and increased risk of anemia development in non-HD CKD patients. FGF23 negatively regulates erythropoiesis. We hypothesized that higher FGF23 levels would be associated with increased erythropoietin hyporesponsiveness among HD patients.

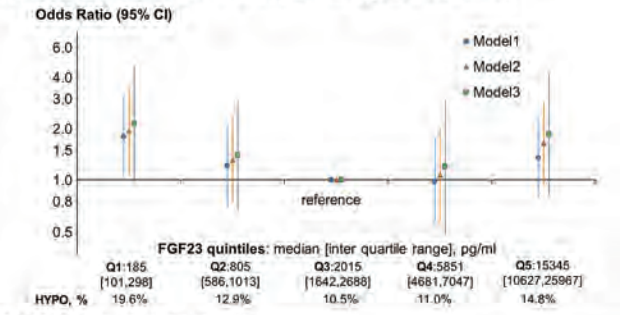
Methods: This study included 1048 patients from the Japanese Dialysis Outcomes and Practice Patterns Study (J-DOPPS) phase 5 (2012-2015). The outcome was erythropoiesis-stimulating agent (ESA) hyporesponsiveness, which was defined dichotomously as mean Hgb <10 g/dL and a standardized mean ESA dose >6,000 u/week over the 4 months following FGF23 measurement. The association between ESA hyporesponsiveness and FGF23 was estimated using multivariable adjusted logistic generalized estimating equation (GEE) regression models. We estimated the effect of FGF23 with increasing levels of covariate adjustment in three models for each outcome (See footnote in Figure).

Results: Patients with higher levels of FGF23 were younger and had higher levels of serum albumin, creatinine, albumin-corrected calcium, phosphorus, PTH, 25(OH)-Vitamin D and a higher percentage of IV iron, IV Vitamin D and cinacalcet use. ESA hyporesponsiveness was found in 144 patients (13.7%). Compared with the 3rd quintile of FGF23 levels, patients had increased risk of ESA hyporesponsiveness in the first (odds ratio [OR]=2.10, 95% confidence interval [CI]: 0.97-4.58) and fifth quintiles (OR=1.79, 95% CI: 0.79-4.04).

Conclusions: The lowest and highest levels of FGF23 were associated with increased ESA hyporesponsiveness in patients on maintenance HD.

Funding: Commercial Support - Kyowa Hakko Kirin Co. Ltd.

Figure. Association between FGF23 and ESA hyporesponsiveness



Model 1: accounting for facility clustering.
Model 2: model 1 + age, gender, vintage, summary comorbidities, post dialysis weight, body mass index, Kt/V, treatment time, hospitalization in past 3 months.
Model 3: model 2 + albumin, TSAT, ferritin, hemoglobin, creatinine, residual kidney function, phosphorus, CRP, PTH, and cinacalcet use.

To standardize the ESA dose between these different preparations, we converted Mircera doses to darbepoetin doses using a 1.2:1 ratio and converted darbepoetin doses to epoetin doses using a 250:1 ratio .

Application of 3D Kidney-on-a-Chip for the Evaluation of Contrast-Induced Nephropathy

Kipyo Kim, Suryeong Go, Yongjin Yi, Jong Cheol Jeong, Sejoong Kim, Ho Jun Chin, Ki Young Na, Dong-Wan Chae. *Seoul National University Bundang Hospital, Gyeonggi-do, Republic of Korea.*

Background: Among the pathogenic mechanisms of contrast-induced nephropathy (CIN), increased viscosity of concentrated contrast media (CM) in renal tubule can perturb renal hemodynamics and have a detrimental effect on tubular epithelial cells. However, the impacts of viscosity in CIN are still poorly understood. Conventional in vitro culture studies cannot reflect the rheological properties of CM. Therefore, we investigated the effects of CM viscosity on the renal tubule using kidney-on-a-chip and two different types of contrast media.

Methods: Renal proximal tubule epithelial cells (Ronza) were cultured in OrganoPlate (Mimetas), applying time-averaged shear stress of 0.13 dyne/cm². We treated the cells with two types of CM, low-osmolar agent (iopromide, LOCM) and iso-osmolar agent (iodixanol, IOCM), varying iodine concentrations (50-250mgI/mL). We evaluated cell viability of each group with WST-8 assay. The results of cell viability in Organoplates were compared with those in static conditions. Further, to examine the effects of viscosity-induced renal damage, we increased time-averaged shear stress to 0.52 dyne/cm². Numerical simulations were also performed with different fluid viscosities.

Results: Overall, increased cell viability was observed under physiological shear stress compared to the static condition. While both LOCM and IOCM decreased cell viability compared with the negative control, LOCM was significantly less viable than IOCM at high concentrations. However, highly increased shear stress resulted in reduced viability in IOCM; no difference between IOCM and LOCM was found under the shear stress of 0.52 dyne/cm². Numerical simulations revealed that high viscosity slowed the flow rate and augmented fluid shear stress. Viscosity-mediated damage was prominent in high shear stress condition, which may represent CKD conditions with increased single nephron GFR.

Conclusions: CM-induced cytotoxicity was reduced under physiological shear stress compared to static conditions. Nevertheless, under highly increased shear stress, CM viscosity-mediated cytotoxicity was prominent, showing similar viability between IOCM and LOCM.

Modeling the Renal Epithelial-Microvascular Niche with Perfusable, Pericyte-Lined Capillary Networks In Vitro

Jeffrey A. Beamish, David S. Cleveland, Likitha Nimmagadda, Andrew J. Putnam. *University of Michigan, Ann Arbor, MI.*

Background: Failed renal epithelial recovery after acute kidney injury is linked to decreased capillary density and expansion of pericyte-derived fibroblasts. How this altered microvascular niche contributes to epithelial regeneration is incompletely understood. Here we report an in vitro model to study how the microvascular niche alters the regeneration of renal epithelial cells.

Methods: Microvascular networks were generated from the self-assembly of human endothelial cells and fibroblasts under established vasculogenic culture conditions. Preformed, non-perfused networks were then co-cultured with renal proximal tubular epithelial cells using Transwell inserts. Next, a culture device was developed to study effects from microvascular perfusion. The device housed multiple polydimethylsiloxane culture chambers to increase experimental throughput. Each chamber contained a perfusable microvascular network formed between gravity-fed 300 μm channels just below a porous membrane. Epithelial cells were seeded on the membrane after network formation. Microvascular network function was assessed by perfusion of 70 kDa fluorescent dextran and immunostaining. Markers of renal epithelial phenotype were measured using real time RT-PCR and immunostaining.

Results: Networks of interconnected, lumenized endothelium developed in all models. Fibroblasts occupied the interstitial space and adopted a pericyte-like morphology around vessels. Co-culture of renal epithelial cells with non-perfused microvascular networks did not affect epithelial morphology or polarity but suppressed expression of SLC22A6, AQP1 and GGT1. In our custom culture device, microvascular networks had a vessel diameter of 18.6±1.7 μm and a density of 6.4±2.0 cm/cm^2, spanned 0.33 cm^2, were perfusable in 76% of chambers seeded, and could form within ~10 μm of the epithelia. Epithelial cells seeded adjacent to the perfused capillary networks formed polarized monolayers.

Conclusions: Co-culture with non-perfused microvascular networks reduced expression of proximal tubular epithelial differentiation markers. A model with perfusable microvasculature containing capillary-scale, pericyte-lined vessels in co-culture with epithelial cells in a high-throughput culture platform was developed to better mimic the epithelial-microvascular niche in vivo.

An Immunoprotected Bioreactor for Implanted Renal Cell Therapy

Rebecca C. Gologorsky,[1] Eun jung Kim,[1] Jarrett Moyer,[1] Ana Santandreu,[1] Charles Blaha,[1] Nathan Wright,[1] Benjamin W. Chui,[1] Paul R. Brakeman,[1] Shant M. Vartanian,[1] H. David Humes,[3] William H. Fissell,[2] Shuvo Roy.[1] *[1]University of California, San Francisco, San Francisco, CA; [2]Vanderbilt University, Nashville, TN; [3]University of Michigan Medical School, Ann Arbor, MI.*

Background: An implantable bioartificial kidney will use a bioreactor containing human cells to provide renal cell therapy. The bioreactor must provide an immunoprotected environment for renal tubule cells (RTC) that obviates the need for immunosuppression. Furthermore, RTC differentiation and functionality must be maintained in vivo.

Methods: We developed an immunoprotection chamber using silicon nanopore membranes (SNM) with sub-10nm wide slit pores and evaluated primary human renal epithelial cell viability and functionality in a benchtop model and in vivo. For the benchtop, we created a stacked dual-chamber vessel, with human RTC in the inferior chamber isolated by SNM. After exposure to 500ng/mL TNF-α, RTC were evaluated for viability and monolayer integrity using cell viability assay, transepithelial electrical resistance, and immunohistochemistry. Thereafter, we implanted an analogous bioreactor in a pig without systemic anticoagulation, with the device perifused by connections to the carotid artery and jugular vein. A static in vitro control was used for comparison. The device was explanted after three days for RTC evaluation. ELISA and quantitative PCR (qPCR) were used to examine RTC-specific markers that are surrogates for RTC functionality.

Results: Benchtop testing showed that isolated RTC were confluent and >90% viable, whereas cells directly exposed to TNF-α were nonviable. In vivo, there were no thrombi in the device. Cells were confluent with >90% viability and maintained intercellular interaction/signal transduction via tight junctions/diffuse expression of Zona Occludens-1 protein similar to static control. Implanted RTC had low *NAG*expression at <10% the rate of positive control indicating minimal damage to RTC while implanted. Expression of AQP1, 1a Hydroxylase, and NHE3 was up-regulated in implanted cells and twofold higher than static controls, suggesting greater functionality of implanted cells.

Conclusions: We present a kidney bioreactor tested in vivo that sustains implanted human renal cells in a xenogeneic environment without systemic anticoagulation. These data demonstrate the promise of a SNM-based bioreactor for use in implantable bioartificial kidney without immunosuppression.

Single Bioreactor Culture System for Mass Production of Kidney Organoids

Takuya Matsumoto,[1,3] Ryuji Morizane.[2,3] *[1]harvard medical school, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Wyss Institute, BOSTON, MA.*

Background: Pluripotent stem cell (PSC)-derived kidney organoids have great potential to recapitulate multicellular relationships and microenvironments of native kidneys, which can be used for drug screening, toxicology assays, disease modeling, and regenerative therapy. Mass production of kidney organoids by a robust, reproducible, and low labor-load approach is a prerequisite for the transition from laboratory to industrial applications. However, the process hasn't been established yet. Here, we employ stirred bioreactor culture system to manufacture kidney organoids and demonstrate a method of mass production of organoids with a well-established quality control.

Methods: We used Biott stirred bioreactor system. Bioreactors were inoculated with single cell suspension of human PSCs at optimal cell density in StemFit® Basic02 in a final 5-ml culture volume. Then, kidney organoids were differentiated by 6-step growth factor treatment which were modified from our previously reported protocols. Induction of nephron progenitor cells (NPCs) and kidney organoids were validated using a combination of immunostaining and qPCR.

Results: 500-1000 organoids were generated in a 5-ml bioreactor. Kidney organoids cultured in this system contained proximal tubular cells (LTL+), podocytes (NEPHRIN+), distal tubular cells (LTL-ECADHERIN+), interstitial cells (MEIS1/2+/ PDGFRβ+), and endothelial cells (CD31+). The sphere size at the beginning of differentiation was identified as a dominant factor which affected induction efficiency of NPCs and organoids. Optimization of CHIR concentration was also important for efficient NPC differentiation. Of note, higher expression of SIX2 at the NPC differentiation stage was positively correlated with more nephron structures in organoids which were viable for a longer time (>35 days) without apoptosis.

Conclusions: We established stirred bioreactor culture system for manufacturing kidney organoids whose yield was 10 times more efficient than the conventional culture system (96 organoids in 96 well culture plates). Our results also indicated SIX2 expression in NPCs is a predictive marker for production of high-quality kidney organoids. This process could be readily scaled up to support development of cell-products for clinical use at industry levels in the future.

A High-Throughput Microfluidic Renal Proximal Tubule Model to Study CKD and CVD Risk Factors

Erin M. Shaughnessey,[1,2] Timothy J. Haggerty,[2] Joseph L. Charest,[2] Lauren D. Black,[1] Else M. Vedula.[3] *[1]Tufts University, Medford, MA; [2]Draper, Cambridge, MA; [3]Draper, Cambridge, MA.*

Background: Chronic kidney disease (CKD) and cardiovascular disease (CVD) are highly interdependent conditions that share several risk factors, including hypertension. In the United States, hypertension affects nearly a third of CKD patients and is the second leading cause of kidney failure. However, the mechanisms contributing to the interdependency of CKD progression and hypertension are not fully understood, and platforms for studying the conditions *in vitro* are limited. An *in vitro* system capable of supporting kidney-specific function and mimicking vascular pathology in a replicable format has the potential to increase understanding of the physiological interplay and to provide a tool for drug development.

Methods: Draper has developed a high-throughput microfluidic platform, PREDICT96, that controls fluid flow to 96 independent bilayer tissue replicates. Here, we demonstrate the potential of the PREDICT96 platform for modeling renal proximal tubule responses to elevated flow rates with high fluid shear stress (5 dynes/cm^2). Human renal proximal tubule epithelial cells (hRPTEC) and human microvascular endothelial cells (hMVEC) were cultured in adjacent channels under different medium perfusion rates mimicking normal and elevated blood pressure (BP) in the renal microvasculature.

Results: After 7 days, tissue was characterized based on barrier function indicated by trans-epithelial electrical resistance (TEER) and expression of proteins involved in BP regulation including luminal sodium-hydrogen exchanger 3 (NHE3) and basolateral Na^+/K^+–ATPase, both previously found to be upregulated in hypertension. Preliminary data shows increased RPTEC barrier function, transporter expression and cell alignment with flow-induced shear stress in the renal and microvascular channels.

Conclusions: A high-throughput *in vitro* model of hypertension in the renal microvasculature will have powerful implications for studying interactions between CKD and CVD and for predicting toxicity responses of human tissue.

Kidney Proximal Tubule Engineering via Melt-Electrowriting

Katja Jansen,[1] Anne metje V. Genderen,[2] Marleen Kristen,[2] Joost van Duijn,[4] Tina Vermonden,[2] Jos Malda,[3] Rosalinde Masereeuw,[1] Miguel Castilho.[3] *[1]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands; [2]Utrecht University, Utrecht, Netherlands; [3]UMC Utrecht, Utrecht, Netherlands; [4]University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Tubular tissue engineering generally relies on large scaffolds (>1 mm) or smaller tubes within bulk hydrogels. However, for the engineering of kidney tubuli, these structures must preferably be both small-sized to increase surface area and freely

accessible for rapid waste removal. Here, we report on the fabrication of a small scale and self-standing living proximal tubule by combining well-organized tubular fiber scaffolds obtained by melt-electrowriting (MEW) with human kidney cells.

Methods: A custom-built MEW device was used to fabricate poly(ε-caprolactone) scaffolds with defined microarchitectures (square, rhombus or random) and inner Øs of 0.5-1 mm (Fig. 1A). Well-characterized human conditionally immortalized proximal tubular epithelial cells (ciPTEC) were seeded inside the scaffolds and tested for monolayer integrity, organization, matrix production and cell functionality.

Results: Scaffolds were manufactured by controlling acceleration voltage, dispensing pressure and mandrel rotation and translation speed. The pore resolution was 200-500 µm (Ø 5-10 µm microfibers, 400 µm scaffold thickness and inner Ø 0.5-1 mm) (Fig. 1B). ciPTEC formed tight monolayers in all scaffolds; rhombus shaped pores facilitated unidirectional cell orientation (Fig. 1C). The cells deposited extracellular matrix (ECM) directly after seeding, and collagen IV quantity increased over time. Viability was proven by enzymatic conversion of calcein-AM into calcein, and active uptake of RH-123; transport inhibitor sensitivity proved cell functionality.

Conclusions: Here, we present self-standing, small diameter kidney tubes that show cell functionality. Due to the well-organized tubular scaffold microstructure with large, interconnected pores, the self-produced ECM is the only barrier between the inner and outer compartment, facilitating rapid and active solute uptake. We are currently evaluating the potential for application in micro-physiological test systems and for fine-tuning towards implantable tissues with sufficient mechanical stability.

Funding: Government Support - Non-U.S.

Matrix Elasticity Regulates Multiple Podocyte Functions

Snehal Sant,[1] Samantha C. Schwager,[2] Monica A. Coode,[1] Cynthia A. Reinhart-King,[2] Nicholas J. Ferrell.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: The extracellular matrix provides biomechanical signals to adherent cells. Chronic kidney disease is associated with changes in the structural and mechanical properties of the glomerular basement membrane (GBM) that may be relevant to disease progression. The aim of this work was to use polyacrylamide hydrogels as GBM analogs to determine how variations from physiological substrate stiffness regulate podocyte proliferation, migration, and traction force generation. In addition, YAP activation, an established regulator of cellular mechanotransduction was evaluated in podocytes grown on hydrogels with varying levels of stiffness.

Methods: Conditionally immortalized mouse podocytes were cultured on soft (0.5 kPa) and stiff (10-50 kPa) polyacrylamide hydrogels. Podocyte force generation was measured using traction force microscopy (TFM). Podocyte proliferation was evaluated based on nuclear EdU incorporation. Cell migration rates were measured by live-cell imaging. YAP nuclear localization was determined by quantitative immunofluorescence staining. Gene expression for downstream targets of YAP activation were evaluated by qRT-PCR.

Results: TFM analysis showed that cell generated forces were orders of magnitude higher on stiff (10 kPa) compared to soft (0.5 kPa) hydrogels. Podocyte spreading was also significantly lower on soft gels. Tractions stresses were also higher on stiff hydrogel showing that increased force generation was not simply related to differences in cell spreading. Proliferation rate was nearly doubled on stiff gels compared to soft and the rate of podocyte migration was approximately 25 µm/hr on stiff substrates compared to <5 µm/hr on soft gels. Stiff substrates induced nuclear localization of YAP and resulted in up-regulation of gene expression for *CTGF, CYR61, ANKRD1,* and *BIRC5*, all which are known downstream targets of YAP activation.

Conclusions: These data show that the elasticity of podocyte substrata is important in regulating multiple podocyte functions that may be relevant to maintenance of normal physiological function and/or progression of chronic kidney injury. Additional work is needed to understand the pathological significance of changes in GBM stiffness in different chronic kidney injuries and to elucidate the molecular mechanisms that regulate stiffness-induced changes in cell behavior.

Application of a Newly Engineered Podocyte Culture System to Study Intracellular Complement Production and Activation

Abhigyan Satyam,[1,2] Rhea Bhargava,[1,2] Maria Tsokos,[1,2] George C. Tsokos.[1,2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Current technologies do not support long-term cell viability, differentiation and maintenance of podocytes. We developed a biophysical approach, termed macromolecular crowding(MMC), to create extracellular matrix(ECM)-rich tissue equivalents and decellularization. This approach generates decellularized grafts that scaffold podocytes to grow in an environment similar to native conditions. To show a potential application of this newly designed culture system we studied complement(C) activation in podocytes exposed to IgG from individuals with lupus nephritis(LN).

Methods: Human skin fibroblasts were cultured under MMC and then decellularized. Human immortalized podocytes were cultured on the decellularized matrix(DCM) at 33°C for 7 days and subsequently at 37°C for 14days. ECM deposition in the DCM-coated dishes was analyzed by SDS-PAGE, immunofluorescence(IF) and scanning EM and expression of podocyte markers by western blotting(WB) and IF. Podocytes were then exposed to IgG from patients with LN and C production and activation was studied.

Results: We found that DCM-coated dishes contained all major ECM molecules(laminin, fibronectin, collagen I & IV) and podocytes survived and differentiated on DCM-coated plates significantly better than on noncoated plates, as shown by development of interdigitating foot process (fig.a) and increased expression of nephrin and synaptopodin. Podocytes exposed to LN IgG displayed increased levels of C factors(C3, C4, C5, C5b9) and C3 activation products(fig.b).

Conclusions: Engineering *in vitro* microenvironment with DCM enhances podocyte viability, native physiology and morphology. This novel system enabled us to demonstrate increased C factor production by podocytes exposed to LN IgG and intracellular complement activation.

Hepatocyte Growth Factor-Producing Mesothelial Cell Sheets Reduce Apoptosis of Renal Tubular Epithelial Cells in Ischemia-Reperfusion Injury

Yoei Miyabe,[1] Sachiko Sekiya,[2] Naoko Sugiura,[1,2] Kazunori Karasawa,[1] Kosaku Nitta.[1] *[1]Tokyo Women's Medical University, Tokyo, Japan; [2]Institute of Advanced Biomedical Engineering and Science, Tokyo, Japan.*

Background: Ischemia-reperfusion injury (IRI) is a model of acute kidney injury and chronic kidney disease which are clinically important problems to be solved. We have recently reported that renal subcapsular transplantation of hepatocyte growth factor (HGF)-producing cell sheets improved renal IRI in rats from acute to chronic phase. However, the mechanism is not well understood. Therefore, we assessed the apoptosis of the renal tubular epithelial cells after IRI with or without transplantation of the HGF-producing cell sheets.

Methods: HGF-transgenic human mesothelial cells (HGF-tg MC sheet) were cultured in temperature-responsive dishes for 4 days to prepare cell sheets. At day 7 after right nephrectomyon a nude rat, two cell sheets were transplanted under the left renal capsule, and the left renal pedicle was clamped for 60 min. Reperfusion was performed after the ischemia, and the left kidney was harvestedat day 2, 14, and 28 after IRI. Terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) staining and caspase-3 staining were performed to evaluate apoptosis with paraffin-embedded sections of the kidney. HGF-tg MC sheet group was compared to other groups; a sham operation without IRI or treatment (Sham); IRI with no treatment (NT); IRI with intravenous administration of recombinant human HGF protein (IV HGF); or IRI with transplantation of non-transgenic MC sheets under the renal capsule (MC sheet).

Results: The number of caspase-3-positive cells was highest in the Sham group, lowest in the NT group, and somewhat higher in the other groups. WithTUNEL staining, positive cells were significantly suppressed in the HGF-tg MC sheet group and MC sheet group, compared to NT group and IV HGF group.

Conclusions: Transplantation of HGF-producing cell sheets under the renal capsule may reduce apoptosis in renal tubular epithelial cells. These results suggested that the suppression of apoptosis is one of the mechanisms to improve IRI by HGF-producing cell sheets.

Transdermal Delivery of Kidney-Targeting Nanoparticles

Nirmalya Tripathy,[1] Eun ji Chung.[1,2] *[1]Department of Biomedical Engineering, University of Southern California, Los Angeles, CA; [2]Division of Nephrology and Hypertension, Department of Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by cyst formation and kidney enlargement, resulting in end-stage renal failure. Most available therapies offer only controlling secondary consequences of ADPKD and are systemically administered via oral/intravenous routes in which drugs are eliminated by first pass metabolism, degraded by gastrointestinal tract, and cause off-target side effects. Herein, we aim to engineer a transdermal patch containing ADPKD treatment by combining 1) a dissolvable microneedle (DM) patch allowing controlled transdermal delivery of 2) kidney-targeted nanoparticles (KNP) with ADPKD-specific drugs. We hypothesize these KNP can deliver drugs specifically to diseased renal cells, thereby limiting systemic side effects while enhancing kidney bioavailability.

Methods: KNP were synthesized by self-assembly of DSPE-PEG(2000)-methoxy:DSPE-PEG(2000)-Folate:DSPE-PEG(2000)-FITC in 70:20:10 mol ratio and non-targeting NP consists of DSPE-PEG(2000)-methoxy:DSPE-PEG(2000)-FITC in 10:90 mol ratio. NP were studied by transmission electron microscopy (TEM), dynamic light scattering (DLS), and zeta potential. In vitro biocompatibility and binding were evaluated using MTS assay and confocal microscopy on human renal proximal tubule epithelial cells (RPTECs). The KNP incorporated DM (polyvinyl alcohol) patches were fabricated via micro-molding technique, evaluated for dissolution and NP release.

Results: Non-targeting and KNP exhibit a diameter of 15.0 ± 0.0 and 12.6 ± 1.2 nm as confirmed by TEM and DLS, and zeta potentials were found to be neutral (0.07 ± 0.2 and –0.32 ± 0.5 mV, respectively). When NP (1-100 μM) biocompatibility were assessed after 24 h on RPTECs, over 90% of cells were found to be viable and were comparable to the PBS-treated group. Additionally, KNP (100 μM) shown an enhanced binding as compared to non-targeting NP after 30 min. KNP incorporated DM patches consists of uniform microneedles of 600 μM height and 300 μM width. These patches showed complete dissolution within 120 ± 30 seconds in PBS at physiological pH 7.4, indicating potential for rapid transdermal release of NP.

Conclusions: Our transdermal delivery strategy of KNP offer a promising drug delivery system for ADPKD. Future studies will incorporate a library of drugs to test therapeutic efficacy in vivo.

High Fibroblast Growth Factor 23 Levels Induce Ventricular Arrhythmogenesis via Intracellular Ca^{2+} Mishandling

Jose A. Navarro-Garcia,[1] Carmen Delgado,[2] Maria Fernandez velasco,[3] Elena Rodríguez-Sánchez,[1] Jennifer Aceves-Ripoll,[1] Laura González,[1] Makoto Kuro-o,[4] Luis M. Ruilope,[1,5] Gema Ruiz-Hurtado.[1,6] Cardiorenal Translational Laboratory *[1]Cardiorenal Translational Laboratory, Research Institute 1+12, Hospital Universitario 12 de Octubre, Madrid, Spain; [2]Research Institute Alberto Sols, CSIC, Madrid, Spain; [3]Research Institute Idipaz, Hospital Universitario La Paz, Madrid, Spain; [4]Jichi Medical University, Shimotsuke, Japan; [5]National Instituto of Health, Spain, Madrid, Spain; [6]CIBER-CV, Hospital Universitario 12 de Octubre, Madrid, Spain.*

Background: Fibroblast growth factor (FGF)23 is a phosphaturic hormone synthesized as response to increased serum phosphate levels. FGF23 action requires the presence of its cofactor *Klotho* (KL). Chronic kidney disease patients show decreased soluble KL and high FGF23 levels. High FGF23 levels have been associated to renal dysfunction and recently considered as a non-conventional cardiovascular risk factor. However, it is unknown whether FGF23 might alter cardiac contractile function and rhythm. Our study analyze FGF23 effect on calcium (Ca^{2+}) handling, key regulator of contractile function and ventricular rhythm, and the Ca^{2+} handling in an animal model with high circulating levels of FGF23 (KL *hypomorphic* mice, *kl/kl*).

Methods: Isolated adult rat ventricular myocytes (ARVM) were perfused with FGF23 (100 ng/mL). To determinate FGF23-dependent pathways, ARVM were pre-incubated with the FGF-receptor inhibitor PD173074 (10 mM) or recombinant KL (rKL; 100 ng/mL). Adult mouse ventricular myocytes (AMVM) were isolated from Wildtype (WT, +/+) and *kl/kl* littermates mice. L-type Ca^{2+} current (I_{CaL}) was recorded by the whole-cell patch-clamp technique. Ca^{2+} handling and contractile function were analyzed using confocal microscopy.

Results: FGF23 reduced I_{CaL} ($p<0.001$), intracellular systolic Ca^{2+} transients amplitude ($p<0.01$) and sarcoplasmic reticulum (SR) Ca^{2+} load ($p<0.01$). These alterations were functionally translated to a deterioration of cellular contraction ($p<0.01$). FGF23 exposure increased diastolic Ca^{2+} leak ($p<0.01$) and ryanodine receptors activity. FGF23 perfusion induced a pro-arrhythmogenic phenotype in paced ARVM ($p<0.05$). FGF23 effects were blocked in PD173074- or rKL-pretreated ARVM. Moreover, *kl/kl* mice showed a significant increment of FGF23 serum levels versus WT ($p<0.001$). *kl/kl* AMVM presented a reduction of intracellular systolic Ca^{2+} transient amplitude ($p<0.001$), contraction ($p<0.001$) and SR-Ca^{2+} load ($p<0.05$). Diastolic Ca^{2+} release was increased in *kl/k* ($p<0.01$) which lead finally to a pro-arrhythmogenic phenotype in *kl/kl* AMVM ($p<0.001$).

Conclusions: Our study uncovers FGF23 as new target in the intracellular Ca^{2+} handling, able to induce contractile dysfunction and pro-arrhythmogenic phenotype in adult cardiomyocytes.

TH-OR042

A NPT2A-Selective Inhibitor Increases Phosphate Excretion in FGF23-Null and CKD Mice

Hiroshi Saito,[1] Monica Reyes,[1] Harald Jüppner.[2] *[1]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA; [2]Endocrine Unit and Pediatric Nephrology Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA.*

Background: The sodium-phosphate co-transporters NPT2a and NPT2c play key roles in reabsorbing filtered phosphate in proximal renal tubules thus contributing critically to phosphate (Pi) homeostasis. Expression of both transporters is regulated by parathyroid hormone (PTH) and Fibroblast Growth Factor 23 (FGF23). Consequently, inactivating mutations in FGF23, GALNT3, or KLOTHO lead to tumoral calcinosis because of increased tubular Pi reabsorption resulting in hyperphosphatemia. Increased plasma Pi levels are also observed in disorders with abnormal PTH synthesis or function, i.e. hypoparathyroidism and pseudohypoparathyroidism, respectively. Furthermore, acute and chronic kidney disease (CKD) typically leads to a significant elevation of plasma Pi and FGF23, which are associated with kidney disease progression and increased mortality.

Methods: A novel NPT2a-selective small molecule inhibitor, PF-06869206, which reduces phosphate uptake in human proximal tubular cells was given by oral gavage (10-500 mg/kg) to wild-type mice, to mice lacking either Npt2a, Npt2c, or Fgf23, and to mice with folic acid-induced AKI or adenine-induced CKD. Plasma Pi levels were measured at different time points after PF-06869206 administration, along with urinary Pi and creatinine.

Results: Administration of PF-06869206was well-tolerated and elicited a dose-dependent increase in fractional Pi excretion in wild-type mice that resulted in a reduction of plasma Pi levels by approximately3.0 mg/dl. The increase in urinary Pi excretion and the resulting reduction in plasma Pi after a single oral dose of PF-06869206 (300 mg/kg) was indistinguishable in wild-type mice and in animals lacking Npt2c, while no changes were observed in Npt2a-null mice. Furthermore, in Fgf23-null mice a single dose of the NPT2a inhibitor increased urinary Pi excretion by approximately 4-fold, which reduced plasma Pi levels from 15.8±0.84 to 11.6±0.49 mg/dl. In AKI and CKD mice, treatment with PF-06869206 increased urinary Pi excretion thereby reducing plasma Pi levels.

Conclusions: The selective pharmacological inhibition of NPT2a holds promise as a novel therapeutic option for genetic and acquired hyperphosphatemic disorders.

Calciprotein Particles Cause FGF23 Induction via TLR4 Stimulation in Osteoblasts

Kenichi Akiyama,[1] Kazuhiro Shiizaki,[2] Nobue Tanaka,[1] Norio Hanafusa,[1] Kosaku Nitta,[1] Ken Tsuchiya,[1] Makoto Kuro-o.[2] *[1]Tokyo Women's Medical University, Tokyo, Japan; [2]Jichi Medical University, Shimotsuke, Japan.*

Background: Calciprotein particles (CPP) are polydispersed colloidal nanoparticles composed of solid-phase calcium-phosphate (CaPi) and serum protein fetuin-A. Two types of CPP with different CaPi properties exist: Primary CPP contain amorphous CaPi, whereas secondary CPP contain crystalline CaPi. We previously reported that CPP induced FGF23 expression/secretion in cultured osteoblastic cells (UMR106). We also reported that a single dose of phosphate gavage in mice increased plasma CPP levels followed by increase in FGF23 expression in the bone and FGF23 levels in the blood. However, the mechanism by which osteoblasts sense CPP remains unknown. In this study, we tested the hypothesis that Toll-like receptor-4 (TLR4) might function as a receptor for CPP. We also determined which CPP, primary or secondary, contribute to FGF23 induction.

Methods: In vitro experiments: CPP were generated in the culture medium of UMR106 by increasing concentrations of calcium (Ca) and phosphate (P). To inhibit formation of secondary CPP, we added bisphosphonate (BP) to the medium (BP inhibits transition of CaPi from the amorphous phase to the crystalline phase) and measured physical properties of CPP in the medium by small angle X-ray scattering (SAXS). FGF23 mRNA levels were determined by quantitative RT-PCR. In vivo experiments: To inhibit formation of secondary CPP in vivo, we injected BP in wild-type (WT) mice fed high P diet for 10 days. To test if FGF23 induction might depend on TLR4, we administered a single dose of P by oral gavage in WT mice and mice lacking TLR4 (TLR4 KO). These mice were evaluated by measuring P, Ca, and FGF23 levels in the blood and FGF23 mRNA levels in the cranial bone.

Results: Secondary CPP with a hydrostatic diameter of approximately 35 nm were generated in the medium. In the presence of BP, these CPP disappeared and primary CPP with a diameter of around 9.2 nm were generated. FGF23 mRNA levels were much higher when BP was present in the medium. Administration of BP increased FGF23 levels in the blood, but suppressed FGF23 mRNA levels in the skull. A single dose of P ingestion increased FGF23 mRNA and circulating FGF23 levels in WT mice but not in TLR4 KO.

Conclusions: Primary CPP were a more potent inducer of FGF23 expression than secondary CPP. We also suggest that TLR4 is necessary for appropriate regulation of FGF23 expression/secretion.

TH-OR044

Calciprotein Particle (CPP)-Inhibition Explains Magnesium-Mediated Protection Against Vascular Calcification

Jeroen H. De Baaij,[1] Anique D. Ter Braake,[1] Coby Eelderink,[3] Lara W. Zeper,[1] Andreas Pasch,[2] Stephan J. Bakker,[3] Martin H. De Borst,[3] Joost Hoenderop.[1] NIGRAM2+ consortium *[1]Radboud University Medical Centre, Nijmegen, Netherlands; [2]University Hospital Bern, Bern, Switzerland; [3]University Medical Center Groningen, Groningen, Netherlands*.

Background: Phosphate (Pi) toxicity is a strong determinant of vascular calcification in chronic kidney disease (CKD). Pi induces the formation of calciprotein particles (CPP), which drive the calcification process. Magnesium (Mg^{2+}) may prevent vascular calcification, but the mechanisms are poorly understood. Here, we investigated the role of Mg^{2+} in calcification and crystal maturation induced by Pi and secondary crystalline calciprotein particles (CPP2).

Methods: Vascular smooth muscle cells were treated with high Pi or CPP2 and supplemented with Mg^{2+} and calcification was analyzed by medium absorbance, electron microscopy and energy dispersive spectroscopy. Effects of increased dietary Mg^{2+} intake on aortic calcification were assessed in Klotho knock-out mice. The effects of Mg^{2+} on calcification propensity (T_{50}) were measured in sera from CKD patients and healthy controls.

Results: Mg^{2+} supplementation prevented Pi-induced calcification in vascular smooth muscle cells. In contrast, Mg^{2+} failed to inhibit CPP2-induced calcification, indicating that it acts before the formation of CPP2. Increased expression of the osteogenic genes osteopontin and alkaline phosphatase remained stable after Mg^{2+} supplementation. In CPP2 cultures, Mg^{2+} dose-dependently delayed the maturation of CPP2 by several days *in vitro*. Elemental analysis showed that CPP2 contain 37 % oxygen, 19% Pi and 39% Ca^{2+}, all remaining stable upon Mg^{2+} supplementation in already matured CPP2. Furthermore, in Klotho knock-out mice, high dietary Mg^{2+} intake effectively prevented aortic calcification. In human serum, addition of 0.2 mmol/L Mg^{2+} increased T_{50} in healthy controls from 371 ± 16 minutes to 422 ± 20 minutes and in CKD patients from 323 ± 19 minutes to 367 ± 23 minutes (both $P < 0.05$). Each further 0.2 mmol/L addition of Mg^{2+} led to increases of ~40 minutes in both groups, resulting in a T_{50} of 566 ± 3 and 505 ± 21 minutes in healthy controls and CKD patients after addition of 1.0 mmol/L Mg^{2+}, respectively.

Conclusions: Our results demonstrate CPP2 mediate Pi-induced calcification. Mg^{2+} prevents CPP2 formation and thereby prevents Pi toxicity leading to calcification. Mg^{2+} supplementation, even at low dosages, is a potential therapeutic strategy to reduce vascular calcification in CKD.

Lipocalin 2 Regulates FGF23 Production in CKD

Guillaume Courbon,[1] Connor Francis,[1,2] Claire Gerber,[1] Maralee Capella,[1] Xueyan Wang,[1] Aline Martin,[1] Valentin David.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of Florida, Gainesville, FL*.

Background: Production of fibroblast growth factor 23 (FGF23) is increased during chronic kidney disease (CKD) progression and associated with left ventricular hypertrophy (LVH), cardiac failure, and mortality. *Lcn2*, encoding a pro-inflammatory and iron-shuttling molecule, is the topmost expressed gene in the kidneys of the *Col4a3*^{KO} mouse model of CKD. Serum Lcn2 and FGF23 levels are strongly correlated, suggesting that Lcn2 might control FGF23 production. Here, we investigated the role of Lcn2 in FGF23 regulation in health and CKD.

Methods: First, we injected WT mice with recombinant Lcn2 and measured serum FGF23 levels. Then, we crossed *Lcn2*^{KO} mice with *Col4a3*^{KO} (CKD) mice and analyzed the renal and cardiac functions of WT, *Lcn2*^{KO}, CKD, and CKD/*Lcn2*^{KO} littermates at 23 weeks of age. We next exposed WT and *Lcn2*^{KO} mice to 3 established models of FGF23 induction: acute inflammation, a low iron diet or a high phosphate diet- to identify if Lcn2 mediates the increase in FGF23 in response to these stimuli. In addition, we tested whether Lcn2 directly controls *Fgf23* transcription in osteoblast cultures.

Results: Administration of Lcn2 to healthy mice increased mRNA and serum FGF23 levels by 3-fold. As previously shown, mice with advanced CKD displayed impaired kidney function, increased levels of serum Lcn2, hyperphosphatemia, increased bone and serum FGF23, anemia, hypertension, LVH and reduced lifespan. Deletion of *Lcn2* in CKD mice partially improved kidney function and prevented hypertension. Compared to CKD mice, CKD/*Lcn2*^{KO} mice had normal levels of serum iron, ferritin and transferrin saturation. Importantly, CKD/*Lcn2*^{KO} mice displayed 90% reductions in *Fgf23* mRNA and serum FGF23 levels ($p<0.05$) and did not develop LVH. CKD/*Lcn2*^{KO} mice lived significantly longer than CKD littermates (+6.7 weeks, i.e. +30%, $p<0.05$). As expected, serum FGF23 levels increased in WT mice in response to acute inflammation, low iron diet and high phosphate diet. Interestingly, *Lcn2* deletion only prevented FGF23 elevations in response to acute inflammation. Finally, we showed that Lcn2 increased *Fgf23* transcription in cultured osteoblasts and we identified cAMP / PKA signaling as a pathway mediating the stimulation of FGF23 by Lcn2.

Conclusions: Our results show that Lcn2 is an important regulator of FGF23 production in CKD that might mediate FGF23 response to inflammation.

Physiologic Regulation of Systemic Klotho Levels by Renal CaSR Signaling in Response to CaSR Ligands and Extracellular pH

Joonho Yoon,[5,1] Zhenan Liu,[3] Eunyoung Lee,[4] Audrey N. Chang,[6] Orson W. Moe,[2,1] R. Tyler Miller.[1] *[1]University of Texas Southwestern Medical School, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX; [3]UT southwestern medical center, DALLAS, TX; [4]Medicine, UT Southwestern Medical Center, Dallas, TX; [5]UTsouthwestern medical center, Dallas, TX; [6]UTSouthwestern Medical Center, Dallas, TX*.

Background: Chronic kidney disease (CKD) progresses to end-stage renal disease accompanied by complications resembling the premature multi-organ failure akin to the Klotho-hypomorphic - mice (*Kl/Kl*). The kidney is the source of soluble Klotho (sKlotho), and as renal disease progresses serum and urine sKlotho levels fall, and patients acquire characteristics resembling the of *Kl/Kl* mice. Pharmacologic or dietary alkaline supplementation slows progression of CKD even in stages 3 and 4. The mechanism(s) by which HCO3 supplementation or alkaline diets work and physiologic mechanisms by which sKlotho levels might be regulated are unknown.

Methods: We measured: 1) urine and serum Kotho in mice treated with calcimimetics or alkali: 2) Klotho release in medium from minced mouse kidneys, and 3) medium Klotho from HEK-293 cells treated with calcimimetics, HCO_3, and ADAM protease inhibitors and expressing the calcium-sensing receptor (CaSR) and Klotho. The CaSR, Klotho, and ADAM10 were co-localized in mouse kidneys and in cells expressing the CaSR and Klotho using differential centrifugation, co-IP, and immunofluorescent staining visualized by confocal microscopy.

Results: In intact mice, minced kidneys, and cultured cells, (CaSR) activation with high Ca or calcimimetics increases sKlotho levels via ADAM10-mediated shedding. Alkaline pH values increase, and acid pH values decrease CaSR signaling. Alkali treatment increases serum and urine sKlotho in mice, Klotho shedding in mouse kidney homogenates and cultured cells in a CaSR-dependent manner. Oral K citrate for 72 hrs increases serum and urine Klotho in human volunteers. ADAM10-dependence was demonstrated using the ADAM10 inhibitor GI 254023X and siRNA. In HEK-293 cells the CaSR, Klotho, and ADAM10 form cell surface aggregates that disperse following CaSR activation, but not with ADAM10 inhibition.

Conclusions: We define a novel physiologic mechanism for regulation of sKlotho levels by the renal CaSR-ADAM10-Klotho pathway that can be modified by pH. We predict that acidosis accelerates, and alkalinization slows the rate of loss of renal function in CKD partly because acid decreases, and alkaline increases renal CaSR-stimulated Klotho shedding from the kidney.

TH-OR047

Novel Mechanism of Cardiac Hypertrophy Within the CKD-MBD

Matthew Williams, Keith A. Hruska. *Washington University in St. Louis, St Louis, MO*.

Background: Cardiac Hypertrophy is a predecessor of cardiac morbidity associated with CKD and caused by factors that are components of the CKD - MBD syndrome: vascular calcification (VC) and elevated levels of FGF23. In a murine model of Alport syndrome, we show that CKD causes cardiac hypertophy due to mechanisms independent of VC and FGF23 due to signaling through activin receptor type 2A (ActRIIA).

Methods: Cardiac size and function were determined by heart weight/tibial length (HW/TL) and echocardiography in 200 day old (do) Col4a5 deficient male mice on the C57Bl6J background. BUN, inulin clearance were used to measure kidney function. Aortic compliance was determined by pressure - diameter relationship. FGF23 levels were by Elisa. Mitochondrial morphometry was by electron microscopy, and OXPHOS was by respirometry. ActRIIA signaling was inhibited by an ActRIIA-Fc ligand trap.

Results: 200 do Alport mice had BUNs of 50 -90 and 70-85 % reduction in inulin clearance. Cardiac levels of psmad 2 and inhibin βa were increased in Alport mice and cardiac PGC1α levels were decreased. These effects of CKD were reversed by ActRIIA signaling inhibition. Aortic compliance was unchanged compared to WT mice, and elevated FGF23 levels were not altered by the ActRII-Fc treatment. HW/TL was 6.2 mg/mm in 200 do Alport mice compared to 4.7 in WT control mice, and 4.9 in ActRIIA-Fc treated Alport mice, $p<0.01$ (Fig.1). Cardiac hypertrophy was confirmed by echocardiography, but function was not significantly altered. Mitochondrial OXPHOS and morphology were significantly altered in 200 do Alport mice indicating a metabolic cause for the compensated hypertrophy.

Conclusions: Compensated cardiac hypertrophy in 200 do Alport mice was due in part to cardiac activation of ActRIIA signaling and prevented by its inhibition in the absence of vascular stiffness and without change in FGF23 levels.

TH-OR048

Identification of an Extracellular pH-Sensitive Residue in the Calcium-Sensing Receptor

Patricia Pacios centeno, Donald T. Ward. *The University of Manchester, Manchester, United Kingdom*.

Background: The calcium-sensing receptor (CaR) is the principal controller of parathyroid hormone (PTH) secretion. Mild acidosis (pH_o 7.2) inhibits CaR signalling in HEK-293 and bovine parathyroid cells, so permitting increased PTH secretion from human parathyroid cells [1]. Thus, acidosis could contribute to the CaR underactivation and secondary hyperparathyroidism of CKD but where the molecular site of the pH_o sensitivity remains unknown [1]. The crystal structure of the CaR reveals that CaR^{R62} and CaR^{R66} stabilize its active conformation. Therefore, here we investivated whether these residues mediate CaR pH_o sensitivity.

Methods: CaR activity was measured as $Ca^{2+}{}_i$ mobilization (Fura-2) and extracellular signal-regulated kinase (ERK) phosphorylation in HEK-293 cells transfected with (wild-type) CaR^{WT} or CaR^{R66A}. CaR stimulated with HEPES buffer containing the EC_{50} concentration for Ca^{2+} (3.5mM CaR^{WT}, 5 CaR^{R66A}) at either pH 7, 7.4 or 7.6.

Results: The CaR crystal structure predicts that following activation, CaR^{R66} creates a hydrogen bond with CaR^{S301} that is supported by a bound, negatively-charged bicarbonate ion (pKa 6.1). We hypothesize therefore that in pathophysiological acidosis, the more neutral bicarbonates will no longer bind CaR^{R66}, impairing the hydrogen bond and inhibiting CaR activity. Indeed we found that lowering pH_o from 7.4 to 7.0 inhibited CaR-induced $Ca^{2+}{}_i$ mobilisation in CaR^{WT} (-40 ±5%; P<0.001 ANOVA) whereas in CaR^{R66A} there was no significant effect (-14 ±9%; ns). Similarly, pH_o 7.0 inhibited CaR-induced ERK phosphorylation in CaR^{WT} (-86 ±5%; P<0.01) but not significantly in CaR^{R66A} (-30 ±12%; ns). Then in alkalosis, higher pH_o renders bicarbonate more negative which we hypothsize will better support the R66-S301 hydrogen bond, and thus enhance receptor activity. As predicted, raising pH_o from 7.4 to 7.6 stimulated CaR-induced $Ca^{2+}{}_i$ mobilisation in CaR^{WT} (+25 ±11%; P<0.001) but not in CaR^{R66A} (+3 ±12%; ns). Similarly, pH_o 7.6 enhanced CaR-induced ERK phosphorylation in CaR^{WT} (24±17%; P<0.05) but not in CaR^{R66A} (+9±12%; ns). Unlike for CaR^{R66A}, the CaR^{R62A} mutant retained its CaR^{WT}-like pH_o senstivity.

Conclusions: Together, these data identify CaR^{R66} as a site of pH_o sensitivity in CaR representing another potential contributor to the secondary hyperparathyroidism of CKD where acidosis is present. [1] Campion *et al* (2015) J Am Soc Nephrol 26, 2163-2171.

TH-OR049

In Vivo Deletion of Complex Genomic Enhancers Reveal a Kidney-Specific, Endocrine-Deficient Cyp27b1 Pseudo-Null Mouse and Loss of Reciprocally Regulated Cyp24a1 by FGF23 and PTH

Mark B. Meyer,[1] Nancy A. Benkusky,[1] Seong Min Lee,[1] Glenville Jones,[2] J. W. Pike.[3] *[1]University of Wisconsin-Madison, Madison, WI; [2]Queens University, Kingston, ON, Canada; [3]University of Wisconsin-Madison, Madison, Madison, WI.*

Background: *Cyp27b1* and *Cyp24a1* are reciprocally regulated in the kidney by the key hormones PTH, FGF23, and $1,25(OH)_2D_3$. Our recent genomic studies in mice identified a complex kidney-specific enhancer module located within the introns of adjacent *Mettl1* (M1) and *Mettl21b* (M21) genes that mediate basal and PTH induction of *Cyp27b1* as well as suppression by FGF23 and $1,25(OH)_2D_3$. Gross deletion of these segments in mice has severe consequences on skeletal health, but does not affect *Cyp27b1* regulation in non-renal target cells (NRTCs).

Methods: Using CRISPR/Cas9-mediated deletions of genomic enhancers (non-coding segments) in mice, we can separate tissue specific responses in both *Cyp27b1* and *Cyp24a1*. We used ChIP-seq from adult human kidney cortex to explore conservation to mouse.

Results: Our current studies reveal a bimodal activity in the M1 intronic enhancer with components responsible for induction of *Cyp27b1* by PTH and repression by $1,25(OH)_2D_3$. The deletion of both M1 and M21 submodules fully eliminates basal *Cyp27b1* expression and regulation in the kidney, leading to a systemic and skeletal phenotype similar to that of the *Cyp27b1*-KO mouse due to depletion of $1,25(OH)_2D_3$ and high PTH. *Cyp24a1* levels in the double KO mouse were low due to compensatory regulation by elevated PTH and reduced FGF23. However, expression of *Cyp27b1* and retention of its regulation by inflammation (LPS) in the NRTCs remained unperturbed. Importantly, dietary normalization of calcium, phosphate, PTH, and FGF23 rescues this aberrant phenotype and creates an ideal *in vivo* model with which to study NRTC production of $1,25(OH)_2D_3$ and its potential impact on disease. Using a separate set of mouse enhancer deletions, we found that basal as well as PTH and FGF23 regulation of *Cyp24a1* in the kidney was controlled by a set of downstream enhancers distinct from those that mediate $1,25(OH)_2D_3$. Finally, we confirm the presence of a conserved chromatin landscape for both *CYP27B1 and CYP24A1* in human similar to the mouse.

Conclusions: Collectively, these studies define a finely balanced homeostatic control mechanism employed by PTH and FGF23 with catastrophic toxicity protection from $1,25(OH)_2D_3$ in the genomic regulation of vitamin D metabolism and its accompanied control of mineral maintenance.

Nanomolar Potency Inhibitors of SLC26A3 (DRA) Anion Exchanger as First-in-Class Treatment of Enteric Hyperoxaluria and Nephrolithiasis

Onur Cil,[1,2] Sujin Lee,[2] Peter M. Haggie,[2] Alan S. Verkman.[2] *[1]Pediatrics, University of California San Francisco, San Francisco, CA; [2]Medicine, University of California San Francisco, San Francisco, CA.*

Background: Nephrolithiasis affects 9% of the US population in their lifetime. Two thirds of kidney stones are composed of calcium oxalate, for which hyperoxaluria is a major risk factor. Dietary oxalate is absorbed by intestine, and oxalate is also generated by liver as a metabolic end product. The majority of oxalate is excreted in urine with some excretion in stool. Gastrointestinal conditions such as bariatric surgery, inflammatory bowel disease and pancreatic insufficiency are associated with hyperabsorption of oxalate in colon (enteric hyperoxaluria). DRA (down-regulated in adenoma, SLC26A3) is an anion (Cl^-, HCO_3^-, oxalate) exchanger predominantly expressed in colon and is the main pathway for colonic oxalate absorption, with knock-out mice having 70% lower urine oxalate excretion. DRA is thus an attractive target for treating enteric and idiopathic hyperoxaluria, and calcium oxalate nephrolithiasis, by redirecting the majority of oxalate excretion through stool rather than urine.

Methods: We previously identified, by high-throughput screening, first-in-class DRA inhibitors (*JCI Insight* 2018; 3(14): 121370). The work herein includes the synthesis and characterization of a nanomolar potency (IC_{50} 40 nM) inhibitor (DRA_{inh}-A270), and demonstration of its efficacy in mouse models of hyperoxaluria and oxalate nephropathy.

Results: Single dose oral or intraperitoneal (ip) DRA_{inh}-A270 (10 mg/kg) gave predicted therapeutic levels in serum for at least 72 h in mice. In a model of acute hyperoxaluria, bolus oral administration of sodium oxalate (2.5 micromol/kg) produced approximately 3-fold increased urine oxalate/creatinine ratio that was largely prevented by DRA_{inh}-A270 treatment. In a diet-induced model of oxalate nephropathy involving a high-oxalate, low-calcium diet, vehicle-treated mice developed marked hyperoxaluria and renal failure by day 14; DRA_{inh}-A270 treatment (10 mg/kg, ip, BID starting day 0) largely prevented hyperoxaluria, renal failure (per serum creatinine), renal injury and calcium oxalate crystal deposition (per histology). In toxicity studies, one week high-dose DRA_{inh}-A270 administration did not affect CBC or serum chemistries.

Conclusions: DRA inhibition by DRA_{inh}-A270 represents a novel approach for treatment of enteric and idiopathic hyperoxaluria, and prevention of calcium oxalate nephrolithiasis.

Pragmatic Cluster-Randomized Trial of an Electronic Clinical Decision Support System (eCDSS) to Improve CKD Management in Primary Care

Carmen A. Peralta,[1] Andrew D. Robinson,[2] Jennifer Livaudais-Toman,[2] Marilyn Stebbins,[2] Rebecca Scherzer,[2] Lowell J. Lo,[2] Sarita Pathak,[3] Leah Karliner.[2] *[1]Cricket Health, UCSF, San Francisco, CA; [2]UCSF, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA.*

Background: Whether eCDSS improves CKD management in primary care is not well known.

Methods: We conducted a 12-month, 3-arm, pragmatic, cluster-randomized trial to evaluate feasibility and preliminary effectiveness of two eCDSS strategies to improve CKD management in primary care. We used electronic health record to identify participants, deliver intervention, and ascertain outcomes. We randomized 524 adults with two $eGFR_{Cr}$ <60 mL/min/1.73m^2 ≥90 days apart in clusters by primary care provider (PCP) to: (1) eCDSS; (2) eCDSS plus pharmacist; or (3) usual care. Intervention included risk

stratification with creatinine, cystatin C, albumin-to-creatinine ratio, followed by eCDSS embedded in EHR for individually tailored clinical guidance and patient education. eCDSS PLUS added a pharmacist follow up call. Primary clinical outcome was blood pressure (BP) change. Secondary outcomes were PCP CKD awareness, and appropriate use of ACEi/ARB and statin.

Results: All 81 eligible PCPs agreed to participate. Mean patient age was 70, 47% non-white, median $eGFR_{creat}$ 57 ± 0.6 mL/min/1.73m^2. At baseline, there was high use of ACEi/ARB (61%), statin (67%) and BP control (71%). Among intervention patients (n=336), 178 (53%) completed triple-marker labs and 138 (41%) had labs and PCP visit with eCDSS deployed. eCDSS was opened by the PCP for 102/138 (74%) eligible encounters, with at least one suggested order or education material signed for 83/102 (81%). Among eCDSS PLUS 29/40 (73%) completed pharmacist call. After 12 months, BP change (SBP: -2.0 ± 0.9 mmHg; DBP: -0.2 ± 0.4 mmHg), PCP CKD awareness (50%) and use of ACEi/ARB (49%) and statin (56%) were similar across groups. In as-treated analyses, PCP CKD awareness was higher in eCDSS and eCDSS PLUS (73% and 69%) vs. usual care (47%) at study end, adjusted p=0.01.

Conclusions: This tailored, automated CKD eCDSS embedded in the EHR was highly utilized by participating PCPs. Due to insufficient uptake of testing and high baseline guideline-concordant CKD care in the practice, we were unable to determine eCDSS effectiveness to improve CKD management. We did demonstrate increased PCP CKD awareness. This easily usable tool can be used in large pragmatic trials engaging PCPs to improve CKD management.

Patiromer vs. Placebo to Enable Spironolactone in Patients with Resistant Hypertension and CKD According to Baseline Kidney Function (AMBER Trial)

Rajiv Agarwal,[1] Patrick Rossignol,[2] Dahlia Garza,[3] Martha Mayo,[3] Suzette Warren,[3] Jia Ma,[3] Ansgar Conrad,[3] William B. White,[4] Bryan Williams.[5]
[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Lorraine and FCRIN INI-CRCT, NANCY, France; [3]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [4]University of Connecticut School of Medicine, Farmington, CT; [5]University College London, London, United Kingdom.

Background: Spironolactone (SPIRO) is effective at reducing BP in patients (pts) with resistant hypertension (RHTN); however, its use in pts with CKD is often limited by hyperkalemia. In AMBER, patiromer (PAT) enabled more persistent use of SPIRO in pts with RHTN and eGFR 25 to ≤45 mL/min/1.73 m^2. We report results in prespecified subgroups with eGFR <30 and ≥30 mL/min/1.73 m^2.

Methods: This was a randomized, double-blind, placebo (PBO)-controlled RCT in adults with eGFR 25-≤45 mL/min/1.73 m^2 and uncontrolled RHTN. Pts were assigned (1:1) to receive PBO or PAT, and SPIRO 25 mg QD, with dose titrations permitted after 1 wk (PAT) and 3 wk (SPIRO). The primary endpoint (between-group difference at wk 12 in the % of pts on SPIRO) was assessed in prespecified subgroups with eGFR <30 and ≥30 mL/min/1.73m^2.

Results: 295 pts were randomized, 66 (22.4%) and 229 (77.6%) with baseline (BL) eGFR <30 (median [Q1, Q3], 27 [25, 29]) and ≥30 (median [Q1, Q3], 38 [34, 42]) mL/min/1.73 m^2, respectively. BL mean (SD) automated office systolic BP (mmHg) was 143.7 (6.7) and 144.2 (6.8) and serum K^+ (mEq/L) was 4.78 (0.38) and 4.70 (0.36), respectively. Significantly more pts treated with PAT than with PBO remained on SPIRO at wk 12 in both subgroups (between treatment difference of 28.5% [*P*=0.0158] for pts with eGFR <30 mL/min/1.73 m^2 and 16.8% [*P*=0.0033] for pts with eGFR ≥30 mL/min/1.73 m^2) with *P*=0.46 for interaction between subgroups (**Figure**). Mean (SE) cumulative SPIRO dose was higher with PAT than PBO, by 732 (274) mg and 274 (140) mg in pts with eGFR <30 and eGFR ≥30 mL/min/1.73 m^2, respectively. Adverse events occurred in 56% (PBO) and 63% (PAT) with eGFR <30 and in 53% (PBO) and 54% (PAT) with eGFR ≥30. No pts had serum Mg <1.2 mg/dL; 1 PBO and 3 PAT pts (all with eGFR ≥30) had serum Mg 1.2 to <1.4 mg/dL.

Conclusions: PAT enabled more pts with advanced CKD and RHTN to continue treatment with SPIRO, regardless of whether eGFR is <30 or ≥30 mL/min/1.73 m^2.

Glomerular Hyperfiltration Predicts Cardiovascular Outcomes in Apparently Healthy Individuals

Marie-Eve Dupuis,[2] Annie-Claire Nadeau-Fredette,[3] Francois Madore,[1] Mohsen Agharazii,[4] Remi Goupil.[1] *[1]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [2]Université de Montréal, Montréal, QC, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]CHUQ-HDQ, Quebec City, QC, Canada.*

Background: Glomerular hyperfiltration (GHF) is associated with increased risk of cardiovascular (CV) diseases in high risk conditions, but its significance in low risk individuals is uncertain. The aim of this study was to determine the CV risk associated with GHF in apparently healthy individuals.

Methods: 9,515 apparently healthy individuals without hypertension, diabetes, CV disease, stages 3-5 CKD and statin/aspirin with available follow-up data (governmental database) were identified from a large population study. From these, patients with GHF (eGFR > 95th percentile after stratification for sex/age) were compared to controls (eGFR 25th to 75th percentiles). Cardiovascular events (CVE) included CV mortality, myocardial infarction, unstable angina, heart failure, stroke and transient ischemic attack. CVE risk was assessed using Cox proportional hazard model and fractional polynomial regression.

Results: Baseline characteristics of individuals with GHF [eGFR 102 (95% CI 107, 115) ml/min/1.73m^2] and normal filtration [eGFR 92 (87, 97)] are presented in Table 1. During a median follow-up of 70 months, 245 CVEs occurred. GHF was associated with an increased risk of CVE [HR 1.78 (1.19, 2.64), p=0.005; Figure 1]. When evaluated continuously, only the highest eGFR percentiles were associated with increased CV risk (Figure 2).

Conclusions: GHF is independently associated with increased CVE risk in apparently healthy individuals. Whether this association is causal or not remains to be determined.

Table 1: Baseline characteristics

Baseline characteristics	Normal filtration (n=4,761)	Hyperfiltration (n=473)	p-value
Age	51 (46-56)	50 (43-53)	<0.001
Male sex	43%	43%	0.97
Afro-American race	1%	10%	<0.001
Body mass index (kg/m^2)	26 ± 5	26 ± 5	0.65
Lean body mass (kg)	52 ± 11	51 ± 11	0.027
Smoking (active)	19%	26%	<0.001
Glucose (mmol/L)	5.4 ± 1.0	5.2 ± 1.0	0.003
LDL-cholesterol (mmol/L)	3.2 ± 0.8	3.1 ± 0.8	0.003
Systolic BP (mmHg)	118 ± 11	118 ± 11	0.64
Heart rate (bpm)	67 ± 10	69 ± 10	0.001

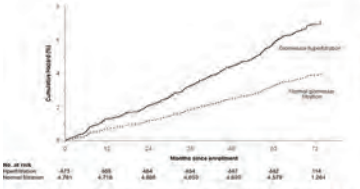

Figure 1: Cumulative incidence of CVE with a Cox proportional hazard model adjusted for age, sex, Afro-American race, active smoking, BMI, lean-body mass (bio-impedance), fasting glucose, LDL-c, total cholesterol, mean arterial pressure and heart rate.

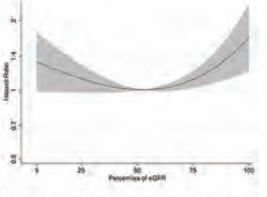

Figure 2: Fractional polynomial regression with HR of CVE occurrence for each 5 percentile increments of eGFR. Adjustments as described in Figure 1 legend.

TH-OR054

Acute Treatment Effects in Randomized Clinical Trials of CKD Progression

Lesley Inker, Hocine Tighiouart. Chronic Kidney Disease Epidemiology (CKD-EPI) Collaboration *Tufts Medical Center, Boston, MA.*

Background: Interventions in CKD trials often produce early short-term treatment effects on GFR slope (i.e. acute effect) that differ from its late long-term effects. The presence of acute effects complicates the design, interpretation and reduces statistical power of randomized clinical trials (RCT) with GFR slope as endpoint.

Methods: We computed the acute effect in past RCTs included in Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) using repeated measures models (N RCTs 57; N participants 60620). For the 30 studies with sufficient measurements prior to 18 months we truncated the follow-up time to 18 months to ensure that the long term trajectory did not overly influence the acute effect. We estimated GFR using the CKD-EPI 2009 creatinine equation. We included time since baseline, treatment, time by treatment interaction and baseline GFR as covariates and used an unstructured variance-covariance matrix to account for the correlated longitudinal measurements within each patient. We modeled time as a fixed effect using restricted cubic splines and then as a categorical variable with follow-up times fixed at each study specific scheduled visits.

Results: In the total set of CKD-EPI RCTs, the overall mean (SD) acute effect of 0.19 (1.27) mL/min/1.73 m^2 over 3 months but both negative and positive acute effects were observed with 95% confidence intervals ranging from -2.3 to 2.7 mL/min/1.73 m^2/3 months indicating large heterogeneity. The figure shows trajectories from baseline to 12 months for 6 example RCTs.

Conclusions: Acute effects are common but there is wide heterogeneity among RCTs. Understanding the timing, magnitude and nature of the acute effect of a specific intervention and population will inform optimal study design.

Funding: Private Foundation Support

Reduced Kidney Function Is Associated with a Greater Burden of Atrial Fibrillation: The KP-RHYTHM Study

Alan S. Go,[1,2] Jingrong Yang,[1] Kristi Reynolds,[3] Nigel Gupta,[3] Judith C. Lenane,[4] Elisha Garcia,[1] Sue hee Sung,[1] Teresa N. Harrison,[3] Matthew Solomon.[1] *[1]Kaiser Permanente Northern California, Oakland, CA; [2]Nephrology, University of California, San Francisco, San Francisco, CA; [3]Kaiser Permanente Southern California, Pasadena, CA; [4]iRhythm Technologies, Inc., San Francisco, CA.*

Background: Atrial fibrillation (AF) is the most potent risk factor for ischemic stroke. Previous studies have reported that reduced kidney function is associated with a higher risk of developing AF. Having a greater burden of AF (i.e., amount of time spent in AF is also an independent risk factor for stroke However, whether kidney function influences the burden of AF is unclear.

Methods: The Kaiser Permanente (KP) RHYTHM Study included all adult members of KP Northern and Southern California integrated healthcare delivery systems who underwent 14-day continuous, beat-to-beat ambulatory ECG monitoring using the ZIO® XT Patch between October 2011-October 2016. We identified patients who had known estimated glomerular filtration rate (eGFR) by CKD-EPI within the year before monitoring, who were not receiving renal replacement therapy, and who had AF detected during the monitoring period. Patient demographic characteristics and stroke risk factors were obtained from electronic health records. We examined the multivariable association of log-transformed AF burden (% analyzable wear time spent in AF) per 10 mL/min/1.73 m² decrease in eGFR.

Results: Among 1069 eligible adults with detected AF on continuous ambulatory monitoring, mean age was 69.1 years, 45% were women, and 25% were persons of color. Overall, median AF burden was 4% (IQR:1% to 13%). After adjustment for proteinuria, age, gender, race/ethnicity, heart failure, hypertension, diabetes mellitus, and prior stroke/transient ischemic attack, every 10 mL/min/1.73m² lower level of eGFR was independently associated with a 10% higher burden of AF (adjusted relative estimate 9.7%, 95% CI:1.1%-19.0%).

Conclusions: Among adults found to have AF on 14-day continuous ambulatory ECG monitoring, lower eGFR level was independently associated with a higher burden of AF. Reduced kidney function may contribute to excess risk of stroke through promoting both a higher incidence of developing AF as well as a greater burden of AF.

TH-OR056

Diminished Efficacy of the Angiotensin Receptor Blocker Losartan During High Potassium Intake in CKD Patients

Rosa D. Wouda,[1] Femke Waanders,[3] Dick de Zeeuw,[2] Gerjan Navis,[2] Liffert Vogt.[1] *[1]Academic Medical Center, Amsterdam, Amsterdam, Netherlands; [2]University Medical Center Grongingen, Groningen, Netherlands; [3]Isala Klinieken, Zwolle, Netherlands.*

Background: High potassium intake increases natriuresis and lowers blood pressure (BP). Whether these beneficial effects are also present in chronic kidney disease (CKD) patients and whether potassium intake affects BP and proteinuria-lowering efficacy of angiotensin receptor blockade (ARB) is unknown. We set out to address the effect of potassium intake on BP and proteinuria response to losartan in non-diabetic proteinuric CKD patients.

Methods: We performed a post-hoc analysis of a placebo-controlled interventional cross-over study in which 33 non-diabetic proteinuric patients (mean baseline proteinuria 3.8 g/d) were treated for 6 weeks with placebo, losartan 100mg, and losartan/hydrochlorothiazide (HCT) 100mg/25mg, respectively. Patients underwent the 3 interventions during both a habitual (~200 mmol/d) and low-sodium diet (<100 mmol/d), in randomized order. To analyze the effects potassium intake, we categorized patients based on median split of 24-hour urinary potassium excretion, reflecting potassium intake.

Results: Mean potassium intake was stable during all 6 treatment periods. Patients with high potassium intake (≥92 mmol/d) had similar BP reductions across all treatments as compared to low potassium intake (<92 mmol/d), whereas a lower proteinuria reduction (p=0.014) was observed for all treatments. Proteinuria reduction to losartan monotherapy and to losartan/HCT, respectively, was significantly lower during high potassium intake (20% vs 41%, p=0.011; and 48% vs 64%, p=0.036). These differences in antiproteinuric response abolished when adding a low sodium diet. In multiple regression analysis, potassium intake was a significant independent predictor of the antiproteinuric response to losartan monotherapy (-23%, 95%CI -37, -8%), but not to losartan combined with HCT.

Conclusions: In proteinuric CKD patients, the proteinuria, but not BP-lowering response to losartan was hampered during high potassium intake. Differences disappeared after low sodium diet, suggesting that intervention in sodium status outweighs the modulating effects of potassium intake on ARB efficacy.

ACEi/ARB Discontinuation and Adverse Outcomes in CKD

Carl P. Walther, Peter Richardson, Wolfgang C. Winkelmayer, Venkat Ramanathan, Salim S. Virani, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Treatment with ACEi/ARB is standard of care for CKD with albuminuria as it can slow disease progression. However, ACEi/ARB treatment can increase risk of hyperkalemia, hypotension, and acute kidney injury, especially in the setting of intercurrent illnesses. We investigated the association of ACEi/ARB discontinuation with patient characteristics and outcomes among VA patients with non-dialysis dependent CKD.

Methods: Patients followed at the VA who had eGFR<60ml/min/1.73 for >90 days, 2005-13, were identified; those with CKD G5 or ESKD were excluded. Patients entered the cohort at time of incident ACEi/ARB use, 2005-13; discontinuation (based on pharmacy fill data) was treated as a time-varying risk factor. Different durations of discontinuation (<90,90-180, >180 days) were investigated, and death and incident dialysis were the outcomes. We used Cox regression, adjusting for demographic and clinical factors.

Results: We identified 238,615 people who met the inclusion criteria; 96.7% were male, and mean age was 71±10 years. 69,544 deaths and 6,100 dialysis initiations were observed. ACEi/ARB discontinuation was associated with more than doubling the risk of subsequent mortality, with a <90 day discontinuation having a hazard ratio for mortality (compared to no discontinuation) of 2.74 (95%CI 2.67-2.81) on adjusted analysis. Longer discontinuation intervals were also associated more than doubling of mortality risk (Table). ACEi/ARB discontinuation was also associated with more than two-fold increased risk for incident dialysis, with a <90 day discontinuation having a hazard ratio of 2.36 (95%CI 2.17-2.56) on adjusted analysis, and longer durations having similar risk.

Conclusions: ACEi/ARB discontinuation was associated with increased subsequent risk of death and incident dialysis in an elderly male VA cohort. Additional investigation, including causes of discontinuation and outcome circumstances, will elucidate relative contributions of ACEi/ARB discontinuation as a cause of the poor outcomes or a marker of worsening health.

Table. Associations of ACEi/ARB discontinuation with mortality and dialysis initiation, adjusted models (HR [95% CI])

ACEi/ARB discontinuation	Mortality	Dialysis initiation
No discontinuation	1 (ref)	1 (ref)
<90 days	2.74 (2.67-2.81)	2.36 (2.17-2.56)
90-180 days	2.62 (2.54-2.71)	2.90 (2.53-3.09)
>180 days	2.12 (2.08-2.16)	2.52 (2.37-2.68)

TH-OR058

Autophagy Protects Podocytes from Diabetes-Related Glomerular Endothelial Dysfunction

Kosuke Yamahara,[1] Mamoru Yoshibayashi,[1] Shinji Kume,[1] Sho Sugahara,[1] Mako Yamahara,[1] Naoko Takeda,[1] Norihisa Osawa,[1] Masami Chin-Kanasaki,[1] Hideki Yokoi,[3] Masashi Mukoyama,[2] Shin-ichi Araki,[1] Hiroshi Maegawa.[1] *[1]Shiga University of Medical Science, Otsu, Shiga, Japan; [2]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [3]Kyoto University Graduate School of Medicine, Kyoto City, Japan.*

Background: In diabetic nephropathy, glomerular endothelial dysfunction is a primary event leading to albuminuria, and impaired podocyte autophagy is recently focused as a factor associated with progression to massive albuminuria. However, an interaction between these two events is still unclear. This study was designed to examine a renoprotective role of autophagy in podocyte injury during the development of diabetes-related glomerular endothelial dysfunction.

Methods: We generated tamoxifen (TM)-inducible podocyte-specific *Atg5*-deficient (TM-PodoAtg5KO) mice by crossbreeding *Atg5*-floxed (Atg5$^{f/f}$) mice and TM-inducible *Nphs2*-Cre transgenic mice. Age-matched TM-injected Atg5$^{f/f}$ mice (TM-Atg5$^{f/f}$) were used as the control group. Glomerular endothelial dysfunction was induced by a high-fat diet (HFD) feeding, crossbreeding with eNOS knockout mice, or an intravenous injection of neuraminidase that can remove endothelial glycocalyx.

Results: In both TM-Atg5$^{f/f}$ and TM-PodoAtg5KO mice, HFD-feeding induced glomerular endothelial dysfunction, which was characterized by increased urinary nitric oxide excretion, collapsed endothelial fenestrae, and decreased endothelial glycocalyx. HFD-fed TM-Atg5$^{f/f}$ mice showed slight albuminuria and nearly normal podocyte morphology. In contrast, HFD-fed TM-PodoAtg5KO mice developed massive albuminuria accompanied by severe podocyte injury. The severe podocyte damage in HFD-fed TM-PodoAtg5KO mice was observed in the podocytes adjacent to damaged endothelial cells. Interestingly, podocyte-specific autophagy deficiency did not exacerbated eNOS-deficiency-induced albuminuria, whereas it markedly exacerbated neuraminidase-induced albuminuria along with sever podocyte injury. Finally, we found that ER stress was accelerated in the podocytes of TM-PodoAtg5KO mice stimulated with neuraminidase, and that a treatment with molecular chaperone, TUDCA, was able to improve neuraminidase-induced severe podocyte injury in the mice.

Conclusions: Podocyte autophagy protects podocytes from diabetes-related endothelial structural dysfunction. Insufficient autophagy leads to severe podocyte injury and subsequent massive albuminuria via activation of ER stress during the development of endothelial dysfunction in diabetic nephropathy.

Unanticipated Effect of C3a Receptor Antagonist in the Podocyte Injury of Diabetes

Simona Buelli, Luca Perico, Daniela Corna, Monica Locatelli, Paola Cassis, Claudia Carminati, Carlamaria Zoja, Giuseppe Remuzzi, Ariela Benigni, Marina Morigi. *Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Bergamo, Italy.*

Background: Podocyte damage is a crucial determinant for the development of diabetic nephropathy (DN) and is associated with mitochondrial dysregulation. Activation of the complement (C) system and C3a generation at glomerular level have been described in patients with DN. We previously demonstrated that C3a promoted podocyte dysfunction, although the intracellular mechanism is still ill-defined. Given the causal link between C activation and the derangement of mitochondrial homeostasis in different cellular systems, here we studied whether abnormal glomerular C activation could cause podocyte injury through its harmful effect on mitochondrial functions in DN.

Methods: Changes in podocyte phenotype and mitochondrial structural and functional integrity were investigated in BTBR *ob/ob* mice treated with vehicle or C3a receptor (C3aR) antagonist SB290157 between 9 and 14 weeks of age, and in cultured podocytes treated with C3a (1μM, 6h).

Results: BTBR *ob/ob* mice exhibited increased albuminuria over time, podocyte loss and glomerular damage accompanied by increased C3 and C3a staining and C3aR overexpression. Decreased glomerular nephrin and a-actinin4 levels, coupled with induction of integrin-linked kinase, were observed. Treating DN mice with C3aR antagonist enhanced podocyte density and preserved their phenotype, thus limiting albuminuria (SB290157: 120±21 vs vehicle: 303±49 μg/day, $p<0.01$) and glomerular injury. Ultrastructural and functional mitochondrial changes in podocytes were associated with increased protein oxidation, and were normalized by SB290157. In cultured podocytes exposed to C3a, mitochondrial fragmentation and altered membrane permeability, associated with downregulation of the antioxidant SOD2, proved that C3a induced mitochondrial dysfunction directly. C3a also altered podocyte energy production without affecting the glycolytic pathway. Notably, C3a-induced podocyte motility was inhibited by SS-31, a peptide with mitochondrial protective effects, suggesting that disturbances in mitochondrial function in response to C3a affect podocyte adhesive properties.

Conclusions: These data indicate that C3a blockade is a novel therapeutic strategy in DN for preserving podocyte integrity through the maintenance of mitochondrial functions.

Gut Microbiome-Derived Phenyl Sulfate Contributes to Albuminuria in Diabetic Kidney Disease (Part 1)

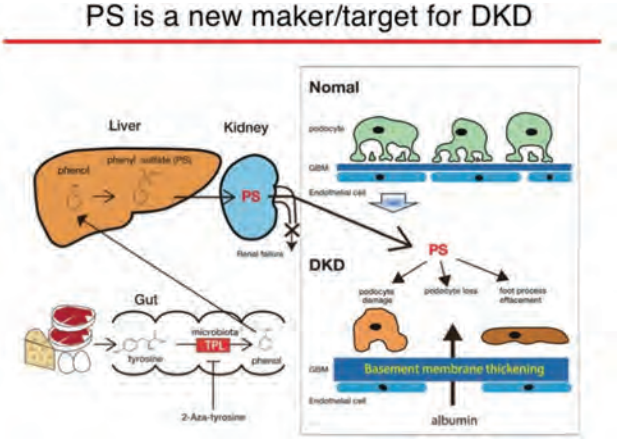
Koichi Kikuchi,[1] Daisuke Saigusa,[2] Yoshitomi Kanemitsu,[3] Yotaro Matsumoto,[3] Eikan Mishima,[1] Takafumi Toyohara,[1] Takehiro Suzuki,[1] Shizuko Nagao,[4] Shinji Fukuda,[5] Tomoyoshi Soga,[5] Yoshihisa Tomioka,[3] Takaaki Abe.[1] *[1]Tohoku University Graduate School of Medicine, Aoba-ku, Sendai, Japan; [2]Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; [3]Tohoku university Graduate school of Pharmaceutical Sciencies, Niigata, Japan; [4]Fujita Health University, Toyoake, Japan; [5]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan.*

Background: Diabetic kidney disease (DKD) is a major cause of renal failure in urgent of breakthrough in disease management. Type 2 diabetes causes significant changes in an array of plasma metabolites, and in humans, SLCO4C1 is the only transporter contributes to transport into urine. We generated transgenic (Tg) rats overexpressing SLCO4C1 in the proximal tubule, a typical human renal excretion model. Using this model, we characterize metabolites increased in diabetic wild type, but reduced in diabetic Tg rats.

Methods: Diabetes was induced by STZ. Untargeted metabolomics was performed by UHPLC-QTOF/MS. Phenyl sulfate (PS) and other uremic toxins were measured by LC/MS/MS. Mitochondrial function was analysis by Flux analyzer. The fecal 16S rRNA were analyzed by MiSeq.

Results: PS was increase with the progression of diabetes and was decreased in Tg rats with limited proteinuria. In diabetic mouse models, PS administration induced albuminuria and podocyte damage due to mitochondrial damage. By DKD cohort analysis, the PS level is correlated with basal and 2-year progression of albuminuria. Phenol is synthesized from dietary tyrosine by gut bacterial-specific tyrosine phenol-lyase (TPL) and absorbed phenol is metabolized into PS in the liver. Administration of TPL inhibitor reduced not only circulating PS level but also albuminuria in diabetic mice. Furthermore, TPL inhibitor ameliorated renal dysfunction in adenine-induced renal failure model. Because TPL inhibitor did not alter the major composition, the non-lethal inhibition of microbial-specific enzymes has a therapeutic advantage for the development of drug resistance.

Conclusions: PS is a modifiable cause and a target for the treatment of DKD. Chemical reduction of TPL should represent another aspect for developing drugs preventing DKD (Nat. Commun. 10: 1835, 2019).



TH-OR061

PLK1 Inhibitor Can Reverse the Diabetic Nephropathy in OVE26 Type 1 Diabetic Mice

Lu Zhang,[1,2] Kyung Lee,[1] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai, Newyork, NY; [2]Renal, Xiamen University Affiliated the First Hospital, Xiamen, China.*

Background: Diabetic kidney disease (DKD) remains the leading cause of ESRD. However, treatment options are very limited. Since DKD is caused by multiple factors and its pathogenesis is complicated, it would be important to apply the systems biology to analyze the major gene signatures which are responsible for DKD and therefore, we could identify drugs which could reverse these gene signatures as potential treatment of DKD.

Methods: We analyzed all public transcriptomic dataset L1000CDS2 as a LINCS L1000 characteristic signature search engine has been applied widely in repurposing drugs for treatment of various diseases. Using this, we analyzed all public transcriptomic datasets related to DKD and GEO2Enrichr analysis to identify potential drugs, which reverse the gene signatures in DKD. We validated the findings by in vitro and in vivo studies.

Results: Gene expression datasets from 24 studies that compared DKD to normal kidney tissue were identified from GEO and Nephroseq. Differential expression was analyzed with GEO2Enrichr. We further performed meta-analysis of 27 DKD signatures from 24 studies using GEN3VA. Then L1000CDS2 was employed with each signature to prioritize matching above signatures created from over 20,000 drugs treatments of multiple human cell lines. We selected BI2536 from the top 5 most consistent drugs across the L1000CDS2 results, also considering their novelty and applications in other fields. BI2536 is a PLK1 inhibitor which

can lead to cell cycle arrest and has been studied broadly in tumor treatments. We found PLK1 expression was increased in mouse glomeruli and localized mostly in mesangial cells. In vivo, we found that treatment of BI2536 attenuated albuminuria and renal histological changes, and expression of renal fibrosis and inflammation markers. We further compared the gene and pathways regulated in DKD but reversed by BI2536, which revealed Smad3 and NF-kB as the major pathways affected by BI2536. In vitro, we confirmed that BI2536 inhibited Smad3 and NF-kB phosphorylation in primary mesangial cells probably through direct interaction between PLK1 and these transcription factors.

Conclusions: Our data indicate that systems analysis could help to identify potential new drugs for treatment of DKD. BI2536 could be a potential drug which could reverse the gene signatures in DKD and the renal protective effect of BI2635 is validated in vivo animal model of DKD.

High Glucose and High Osmolarity Modulate Function of FRMD3/Protein 4.1O: A Candidate Gene of Diabetic Nephropathy

Eva Koenigshausen,[3] Sonja Rieckmann,[3] Aida Bajraktarevic,[3] Sinja Ohlsson,[3] Marie Schönberger,[3] Thorsten Wiech,[1] Ivo Quack,[4] Hermann G. Haller,[5] Lars C. Rump,[3] Mario Schiffer,[2] Lorenz Sellin.[3] *[1]Department of Pathology, University Hospital Hamburg Eppendorf, Hamburg, Germany; [2]University Hospital Erlangen, Erlangen, Germany; [3]Medical Faculty Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; [4]Klinikum Konstanz, Konstanz, Germany; [5]Nephrology, Medical Faculty, Hannover, Germany*.

Background: FRMD3 has been proposed as a candidate gene for susceptibility of diabetic nephropathy (DN) in type 1 diabetes. FRMD3 encodes for protein 4.1O, which is a member of the 4.1 protein family. The molecular function of FRMD3/protein 4.1O is unknown so far. Albuminuria is the earliest sign of DN and results from a defect in the glomerular filtration barrier. Linkage of the slit diaphragm protein nephrin to the actin cytoskeleton via adapter proteins are essential for the integrity of the glomerular slit diaphragm.

Methods: RNA was isolated from human podocytes and qPCR for FRMD3 was performed. Nephrin and protein 4.1O were stained in mouse glomeruli. In Cos7 cells, protein 4.1O and actin were visualized via immunofluorescence. Zebrafish larvae were treated with morpholinos against the orthologue of FRMD3 in zebrafish. Injection of fluorescently labeled FITC-dextran was monitored via eye fluorescence. A reduction of fluorescence was an indirect sign of glomerular tracer loss. Cells expressing protein 4.1O, its truncations and nephrin were subjected to cell lysis. Co-immunoprecipitation and Western blot analysis were performed. Kidney samples from patients with T1DN or T2DN were stained for protein 4.1O. Cells were treated with different glucose concentrations and mannitol for osmolarity control.

Results: Protein 4.1O is expressed in human podocytes. Protein 4.1O interacts with nephrin and actin*in vitro* and*in vivo*. Injection of *frmd3* paralogue morpholinos in zebrafish larvae leads to zebrafish yolk sac edema, slit diaphragm disruption and increase in glomerular permeability. The increase in glomerular permeability can be rescued by reconstitution of protein 4.1O AA 506-553, the nephrin binding domain. Protein 4.1O expression is increased in human T1 and T2DN. High glucose levels increase protein 4.1O expression while high osmolarity increases nephrin protein 4.1O interaction and protein 4.1O threonine phosphorylation.

Conclusions: Protein 4.1O is a novel linker of nephrin to the actin cytoskeleton and essential for the glomerular filtration barrier. High glucose increases expression of protein 4.1O while high osmolarity leads to posttranslational modifications on protein 4.1O mediating an increased interaction with nephrin.

TH-OR063

Short-Term Pulse Treatment with Nicotinamide Mononucleotide in Diabetic Nephropathy: Therapeutic Application of Metabolic Legacy Effect

Itaru Yasuda,[1] Kazuhiro Hasegawa,[1] Takashi Ono,[2] Shu Wakino,[1] Hiroshi Itoh.[1] *[1]Keio University, Tokyo, Japan; [2]Shionogi & Co., Ltd, Osaka, Japan*.

Background: We previously demonstrated that the derangement of nicotinamide adenine dinucleotide (**NAD$^+$**) metabolism and the inactivation of **Sirt1**, an NAD$^+$-dependent deacetylation enzyme, initiated diabetic nephropathy (**DN**) (Nat Med, 2013). Sirt1 is activated by NAD$^+$ precursor, nicotinamide mononucleotide (**NMN**). We tested short-term pulse treatment with NMN against DN.

Methods: We divided 8-week-old db/db and db/m mice into five groups: db/m + saline (**db/m**); db/db + saline (**db/db**); db/db + NMN 100 mg/kg (**NMN100**); db/db + NMN 300 mg/kg (**NMN300**); and db/db + NMN 500 mg/kg (**NMN500**). Short-term pulse treatment with NMN was performed via i.p. injection for two weeks. We terminated the treatment at 10 weeks of age and evaluated remote effects of NMN therapy at 10, 24, and 30 weeks of age. We also evaluated tissue NAD$^+$ metabolite levels and the expressions of some enzymes of NAD$^+$ metabolism, including **Nampt** that convert nicotinamide (NAM) into NMN and **Nmnat1** that converts NMN into NAD$^+$.

Results: At 24 weeks of age, db/db exhibited higher levels of HbA1c and albuminuria, as well as more foot process effacement and reduced expression of Sirt1 and Synaptopodin in renal histology as compared to those in the db/m. Although the HbA1c levels in the NMN500 and db/db were not different, NMN treatment resulted in lower albuminuria at even 14 and 20 weeks after the termination of therapy in a dose-dependent manner. NMN treatment ameliorated foot process effacement and preserved Sirt1 and Synaptopodin expressions. Renal NAD$^+$ levels reduced with age in both db/m and db/db. In contrast, the NMN500 maintained NAD$^+$ levels at 24 weeks of age. Nampt expression in the NMN500 was higher than those in the db/m and db/db. Nmnat1 expression was lower in the db/db than those in the db/m and NMN500, although Nmnat1 expression between the db/m and NMN500 was not different. These results indicated that the NMN treatment maintained renal NAD$^+$ concentration by increasing Nampt expression and maintaining Nmnat1 expression.

Conclusions: Short-term pulse treatment with NMN at the early phase of DN had long-lasting renoprotective effects via restoration of NAD$^+$ and preservation of Sirt1, Nampt, and Nmnat1 expressions independently of glycemic control. This intervention suggested the introduction of metabolic legacy effects during the course of DN.

TH-OR064

DcR2 Mediates Senescent Phenotype of Tubular Cell by Interacting with PRDX1: A Novel Mechanism of Renal Fibrosis in Diabetic Nephropathy

Jia Chen, Yani He. *Daping hospital, Chongqing, Chongqing, China*.

Background: Premature senescence of renal tubular epithelial cell (RTEC), which is involved in renal fibrosis, is a key event in the progression of DN. However, the underlying mechanism remains unclear. Our study investigated the role of Decoy receptor DcR2 in renal fibrosis and explored the mechanism of DcR2 mediated the senescent phenotype of RTEC.

Methods: 215 DN patients which diagnosed by renal biopsy were enrolled. Renal DcR2 and senescent markers, P16 and SA-β-gal were detected with confocal immunostaining. The degree of renal fibrosis and cell senescence were evaluated after regulation of DcR2 expression in vivo and vitro. Co-IP combining with LC-MS/MS were screened the DcR2-interaction proteins in renal tissue and high glucose (HG) induced-proximal tubular epithelial cells (PTECs). The interaction of DcR2 and PRDX1 was detected by Co-IP and pull down assay. Peroxidase activity of PRDX1 was assessed by the kits of ROS and specific 2-cys peroxidase activity. The level of PRDX1 phosphorylation was detected through WB.

Results: DcR2 was high specifically expressed in RTEC and associated with renal fibrosis. Confocal analysis indicated DcR2 co-expressed with senescent markers in the development of DN. Knockdown of DcR2 effectively decreased renal fibrosis and alleviated renal function in streptozotocin (STZ)-induced DN mice. Furthermore, DcR2 knockdown significantly inhibited RTEC senescence and promoted the secretion of senescence-associated secretory phenotype (SASP), such as IL-1β, MMP-2 and TGF-β1. However, DcR2 overexpression showed the opposite effects. In vivo and vitro studies revealed that DcR2 interacts with peroxiredoxin 1 (PRDX1) using quantitative proteomics, which have peroxidase and antioxidant activity in cytoplasm. Following study indicated PRDX1 was co-expressed with senescent phenotype, and PRDX1 knockdown accelerated whereas overexpression inhibited RTEC senescent phenotype. The interaction of DcR2-PRDX1 mediated RTEC senescent phenotype. Moreover, DcR2 inhibited the peroxidase activity of PRDX1 resulting in oxidative stress through promoting PRDX1 phosphorylation.

Conclusions: DcR2 interacts with PRDX1 and aggravates renal fibrosis by mediating RTEC senescent phenotype, suggesting DcR2 as a potential therapeutic target for the amelioration of DN progression.

Genetic Deletion of MIOX Ameliorates Obesity-Associated Tubulointerstitial Injury via Modulating O-GlcNAcylation of Sterol Regulatory Element Binding Protein (SREBP)

Isha Sharma,[1] Fei Deng,[1,3] Yingjun Liao,[1,2] Yashpal S. Kanwar.[1] *[1]Northwestern University Medical School, Chicago, IL; [2]Nephrology, Second Xiangya Hospital, Central South University, Changsha, China; [3]Urology, Third Xiangya Hospital, Central South University, Changsha, China*.

Background: Myo-inositol oxygenase (MIOX), a tubular enzyme, is involved in the pathogenesis of various forms of tubulo-interstitial injury

Methods: We assessed if genetic ablation of MIOX alone or in the background of ob*/ob* ameliorates obesity-associated tubulo-interstitial injury. Four weeks old Wild type (WT), MIOX overexpressing (MIOX-TG), and MIOX knockout (MIOX-KO) mice were fed HFD for four months. Also, double knockout (*MIOX$^{-/-}$/ob/ob*) mice were evaluated at five months of age.

Results: Increased proteinuria, serum creatinine and urea was observed in HFD-fed WT and MIOX-TG, and *ob/ob* mice, suggestive of renal injury. These pathophysiologic parameters were normalized in HFD-treated MIOX-KO and *MIOX$^{-/-}$/ob/ob* mice. The expression and activity of MIOX increased in the renal tubules of HFD-fed WT, MIOX-TG mice and *ob/ob* mice, which were associated with decreased levels of myo-inositol (MI); whereas MI levels remained relatively high in HFD-fed MIOX-KO and *MIOX$^{-/-}$/ob/ob* mice. MIOX overexpression was accompanied with accentuated ROS generation, DNA damage, lipid and protein peroxidation. These changes were minimally observed in HFD-fed MIOX-KO and *MIOX$^{-/-}$/ob/ob* mice. In addition, MIOX overexpression was accompanied with increased post-translational modification (O-GlcNAcylation) of cellular proteins via upregulating the expression of *O-GlcNAC* transferase in renal compartments in vivo. Likewise, such increase of modification of cellular proteins was observed in proximal tubular (HK-2 cells) treated with palmitate-BSA in vitro. Perturbation in cellular redox decreased the expression of various metabolic sensors, including p-AMPK, SIRT1, SIRT3, YY-1 and PGC1α, in HFD-treated MIOX-TG mice. These parameters were partially restored in HFD-fed MIOX-KO mice and *MIOX$^{-/-}$/ob/ob* mice. Interestingly, SREBP was heavily glycosylated in HK-2 cells treated with palmitate-BSA. The SREBP exhibited a strong binding to PAI-1 promoter in HFD-fed MIOX-TG mice, leading to an

increased synthesis of ECM. These aberrant metabolic and fibrogenic perturbations were normalized with MIOX gene disruption

Conclusions: In conclusion, these findings suggest that ablation of MIOX shields the kidney against obesity-induced tubulo-interstitial damage

Funding: NIDDK Support

Murine Diabetic Nephropathy at Single Cell Resolution

Haojia Wu,[1] Romer A. Gonzalez-Villalobos,[2] Xiang Yao,[2] Matthew M. Rankin,[2] Yuhei Kirita,[1] Matthew Breyer,[2] Benjamin D. Humphreys.[1] The Humphreys Lab *[1]Division of Nephrology, Washington University School of Medicine, Saint Louis, MO; [2]Janssen Research & Development, Cardiovascular Metabolism, Boston, MA.*

Background: Diabetic nephropathy (DN) is the most common cause of ESRD, but the transcriptional changes driving disease progression at the single cell level remain undefined. We hypothesized that single nucleus RNA-seq could provide insight into the cellular mechanisms of diabetic nephropathy.

Methods: We collected urine and kidney samples from control(n=2) and *db/db*(n=4) female mice at 17 weeks. We generated a total of 70,437 single nucleus transcriptomes and performed a comprehensive bioinformatics analysis.

Results: *db/db* mice had 255±35 μg/mg urine Alb:creatinine ratio compared to 24±6 in control. On average we detected 2,940 unique genes/nucleus. By unbiased clustering, we could identify 18 major cell types representing all major cell types, including macula densa, with differential expression of hundreds of genes across all clusters. Diabetic kidney had higher leukocyte infiltration including T cells, dendritic cells and macrophages. Diabetic macrophages upregulated the receptor Plxdc2, whose ligand PEDF ameliorates DN when administered exogenously. We generated a detailed diabetic glomerular intercellular communication map between podocytes, glomerular endothelium, mesangium and Cdh6+ parietal epithelia. This revealed podocyte – parietal epithelial cell signaling via b-catenin suppressive Igfbp4-Lrp6 signaling among others. We identified evidence for compensatory gene expression to combat podocyte damage, including downregulation of protein kinase C epsilon and upregulation of type 1 adenylate cyclase, proteins known to mediate susceptibility to proteinuria. Other upregulated podocyte genes included angiogenic EphA6 and Shroom3, a GWAS hit for CKD. Unexpectedly, diabetic stroma cells showed the largest gene expression changes including genes related to integrin linked kinase, cell adhesion and calcium signaling.

Conclusions: This is the first comprehensive single nucleus transcriptional atlas of a mouse model of DN. We demonstrate the utility of this approach by revealing (1) activated macrophage recruitment, (2) detailed diabetic glomerulus intercellular communication, (3) podocyte-specific expression of proteinuria susceptibility genes and (4) stromal cell activation.

Tankyrase Inhibition Upregulates Mitochondrial Master Regulator PGC-1α in the Kidney of db/db Mice

Sara Kuusela,[1] Hong Wang,[2] Eero Lehtonen,[2] Vincent Dumont,[1] Jo Waaler,[4] Nai-Wen Chi,[3] Sanna H. Lehtonen.[2,1] *[1]Medical Faculty, Research Program of clinical and molecular metabolism, University of Helsinki, Helsinki, Finland; [2]Department of Pathology, University of Helsinki, Helsinki, Finland; [3]UC San Diego, La jolla, CA; [4]Oslo University Hospital, Oslo, Norway.*

Background: Mitochondrial oxidative stress contributes to the cellular damage occurring in diabetic conditions. Peroxisome proliferator-activated receptor γ (PPARγ) coactivator 1α (PGC-1α) co-activates transcription factors that boost mitochondrial biogenesis and oxidative metabolism and interestingly, PGC-1α is downregulated in the kidney in diabetes. Tankyrase 1 and 2 (TNKS1 and TNKS2) are closely related homologs belonging to the poly-ADP-ribose-polymerase (PARP) family of proteins. TNKSs regulate their binding partners by post-translational modification (PARylation), typically increasing protein degradation. The aim of this study was to investigate whether pharmacological inhibition of TNKSs in *db/db* mice protects against kidney injury by regulating PGC-1α.

Methods: We treated 6 weeks old obese and diabetic *db/db* and non-diabetic *db/+* controls with the TNKS1/TNKS2-specific inhibitor G007-LK with 14 mg/kg/day dosing for 15 weeks and investigated the effect on systemic and kidney parameters.

Results: We found that TNKS inhibition reduces body weight gain and fat mass, and upregulates genes associated with β-oxidation in muscle in *db/db* mice. In cultured C2C12 myocytes TNKS inhibition stimulated fatty acid oxidation and impoved mitochondrial function. TNKS inhibitor treatment reduced glomerular area in the *db/db* mice albeit the albuminuria was not alleviated. Proximity ligation assay indicated that PGC-1α and TNKSs form a complex in the kidney cortex and that PGC-1α PARylation is decreased upon TNKS inhibition in renal tubules. This apparently increased the stability of PGC-1α leading to its upregulation. Additionally, immunoblotting of mitochondrial respiratory chain markers indicated that TNKS inhibition upregulates complex V ATP synthase subunit alpha (ATP5A) in *db/db* kidney cortices. Electron microscopy analysis of proximal tubule cells revealed that TNKS inhibitor treatment upregulates crista density of mitochondria. These data indicate that TNKS inhibition increases mitochondrial respiration rate.

Conclusions: We found that TNKS inhibition increases PGC-1α expression and improves oxidative metabolism. Along with existing clinical approaches, enhancing mitochondrial function by TNKS inhibition could offer an additional strategy to improve renal structural and functional parameters in diabetes.

TH-OR068

Electrocardiographic Manifestations of Acute vs. Chronic Hyperkalemia

Joshua Powell, Patrick J. Karabon, Aaron D. Berman, Paul S. Kellerman. *Oakland University William Beaumont School of Medicine, Royal Oak, MI.*

Background: Hyperkalemia from kidney failure may cause life-threatening arrhythmias. Patients with end-stage renal disease (ESRD) have been thought to better tolerate high potassium levels than those with acute hyperkalemia. Thus, we postulated that patients with chronic hyperkalemia from ESRD have fewer electrocardiography (ECG) changes and less arrhythmias than patients with acute hyperkalemia from acute kidney injury. This study aims to determine the incidence of ECG changes in all patients presenting with hyperkalemia, and tests for differences in the incidence of hyperkalemic ECG changes between chronic and acute hyperkalemic groups.

Methods: We reviewed 256 adult admissions to William Beaumont Hospital Royal Oak Emergency Center with primary or secondary diagnoses of hyperkalemia in patients with chronic hyperkalemia from ESRD, and patients with acute hyperkalemia without ESRD. Initial ECGs were assessed for hyperkalemic changes by a single blinded cardiologist. The overall incidence of ECG changes was measured, and differences between the two groups were assessed using unpaired t-tests, chi-square tests, and multivariate analysis with logistic regression.

Results: ECG changes attributed to hyperkalemia were seen in 32% of encounters. There was no difference in the incidence of ECG changes between chronic (ESRD) and acutely (non-ESRD) hyperkalemic patients. However, with univariate analysis, increased patient age (69.9 vs 61.7 years, p= 0.0003), increased serum potassium (7.05 vs 6.8, p= 0.0424), and history of ischemic heart disease (p= 0.03) increased the risk of ECG changes. Multivariate analysis additionally demonstrated that higher endogenous serum calcium levels were independently associated with less T-wave peaking (Odds ratio 0.68, p= 0.0235).

Conclusions: This study demonstrated no difference in ECG changes between acute and chronic hyperkalemic groups, thus did not support the hypothesis that clinical arrhythmias are less prevalent with chronic hyperkalemia. As expected, increasing age, increasing potassium levels, and prior ischemic heart disease predisposed patients to ECG changes. Although pharmacologic calcium is known to protect against hyperkalemic arrhythmias, this study is unique in finding less T-wave peaking with higher endogenous serum calcium levels, implying that higher nonpharmacologic calcium serum levels may be protective against arrhythmias.

ECG12Net: A Deep Learning Algorithm Capable of Suprahuman Detection of Hypokalemia and Hyperkalemia by Electrocardiography

Shih-Hua P. Lin,[1] Chih-Chien Sung,[1] Chien-Ming Lin,[2] Yu-Juei Hsu.[3] *[1]Tri-Service General Hospital, Neihu, Taiwan; [2]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [3]Division of Nephrology, Tri-Service General Hospital, Taipei, Taiwan.*

Background: Detection of dyskalemias (hypo- and hyperkalemia), important causes of sudden cardiac death, currently depends on laboratory tests. Since cardiac tissue is very sensitive to dyskalemias, electrocardiography (ECG) may be able to uncover clinically important dyskalemias before laboratory results. Our study aimed to develop a deep learning model, ECG12Net, to detect dyskalemias based on ECG presentation and to evaluate the logic and performance of this model.

Methods: Between May 2011 and December 2016, 66,321 ECG records with corresponding serum potassium (K^+) concentrations were obtained from 40,180 patients admitted to the emergency department. ECG12Net is an 82-layer convolutional neural network, which estimates serum K^+ concentration. Six clinicians (three emergency physicians and three cardiologists) participated a human-machine competition. We used sensitivity and specificity as evaluation measures to compare the performance of ECG12Net with these physicians.

Results: In a human-machine competition including 300 ECGs of different serum K^+ concentrations, the area under curve in detecting hypo- and hyperkalemia by ECG12Net was 0.926 and 0.958, respectively, which was significantly better than that of our best clinicians. Moreover, the sensitivities and specificities of detecting hypokalemia and hyperkalemia were 96.7% and 83.3%, and 93.3% and 97.8%, respectively. In the test set including 13,222 ECGs, ECG12Net had the same performance with sensitivities for severe hypokalemia/hyperkalemia achieving 95.6% and 84.5%, respectively with the mean absolute error of 0.531. The specificities of detecting hypokalemia and hyperkalemia were 81.6% and 96.0%, respectively.

Conclusions: A deep learning model based on 12-lead ECG may help physicians to promptly recognize severe dyskalemias and thereby reduce cardiac events.

TH-OR070

Is Tissue Sodium Storage Driving Systemic Inflammation in CKD? A Sodium Magnetic Resonance Imaging Study

Alireza Akbari,[1] Lisa Hur,[2] Jarrin D. Penny,[1] Elena Qirjazi,[3] Fabio R. Salerno,[2] Christopher W. McIntyre.[1] *[1]London Health Sciences Centre, London, ON, Canada; [2]Western University, London, ON, Canada; [3]Alberta Health Sciences, Calgary, AB, Canada.*

Background: Tissue sodium accumulation is intimately related to immune system function, and has been shown to occur in CKD patients due to impaired sodium elimination. However, the systemic effects of sodium accumulation, such as malnutrition

and inflammation, have not been explored in man. The aim of this study was to investigate the associations of tissue sodium accumulation in a sample of healthy controls and CKD patients using noninvasive 23-sodium (^{23}Na) magnetic resonance imaging (MRI).

Methods: Axial MR images of the lower leg were acquired in 10 controls and 35 CKD patients (eGFR 10-58 ml/min/1.73m^2) on a 3T MRI. Proton images for anatomical reference and ^{23}Na images for calculating mean tissue sodium concentration were acquired. Regions of interest included skin, pretibial tissue, bone, soleus, and gastrocnemius muscles (fig 1). Pearson correlation analysis between sodium concentration in different tissues and standard serum biomarkers was performed.

Results: Sodium concentration in all storage compartments was elevated in CKD patients relative to controls (data not shown), and significantly associated with serum albumin as a marker of malnutrition/inflammation complex (fig 2).

Conclusions: The negative association between serum albumin and tissue sodium concentration suggests that sodium accumulation may be a relevant factor driving systemic malnutrition/inflammation complex in the CKD population.

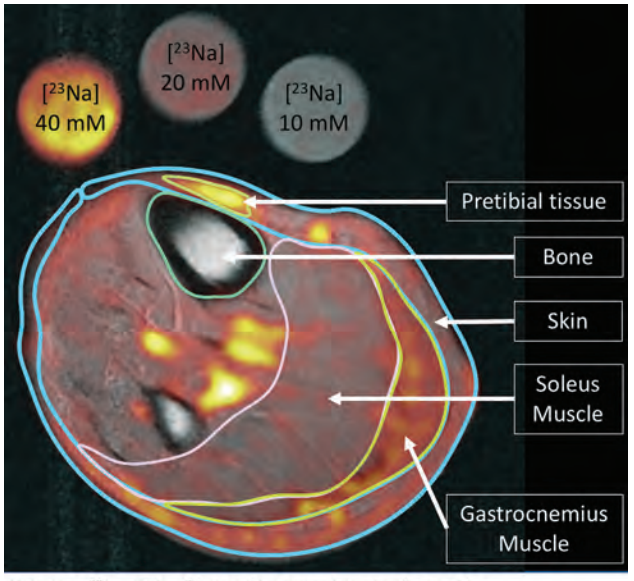

Figure 1. ^{23}Na MRI of lower leg superimposed over the corresponding anatomical proton MR image. The different tissues are represented by colored sections.

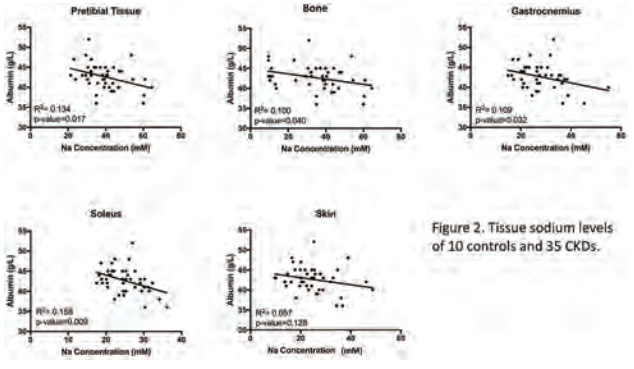

Figure 2. Tissue sodium levels of 10 controls and 35 CKDs.

Renoprotection by Long-Term Low-Dose Tolvaptan for Congestive Heart Failure Is Pronounced in Hyponatremia

Tatsufumi Oka,[1] Takayuki Hamano,[2] Yohei Doi,[1] Satoshi Yamaguchi,[1] Yusuke Sakaguchi,[2] Isao Matsui,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; [2]Inter-Organ Communication Research in Kidney Disease, Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Reportedly, tolvaptan (TLV), a selective vasopressin V2-receptor antagonist, did not lead to 1-year renoprotection in congestive heart failure (CHF), when its dose was set to be 30 mg/day. We aimed to examine the effects of its lower-dose therapy on long-term renal outcome in CHF.

Methods: In this retrospective cohort study, we enrolled hospitalized patients with acute decompensated heart failure (ADHF) in an educational hospital. TLV users were defined as patients receiving flexible doses of TLV for at least consecutive 180 days or those who continued TLV therapy until death, renal replacement therapy, implantation of a ventricular assist device, or heart transplantation, even if duration of the therapy was less than 180 days. We compared estimated glomerular filtration rate (eGFR) trajectories between TLV users and never-users, using multivariable mixed effects models with time-dependent eGFR as a dependent variable. We explored effect modification by baseline serum sodium levels for the relationship between TLV therapy and annualized eGFR slope, using a multivariable fractional polynomial interaction algorithm.

Results: Of total 584 patients, 78 TLV users were found. The median TLV dose, baseline B-type natriuretic peptide (BNP), and eGFR were 7.5 mg/day, 243 pg/mL, and 54 mL/min/1.73m^2, respectively. TLV users had higher eGFR trajectories than never-users (P <0.01) during a median follow-up period of 66 weeks (Figure 1). Additional adjustment for time-dependent BNP levels, ADHF hospitalization, and the number of loop diuretics' dose reductions extinguished the difference in eGFR. In hyponatremic patients, renoprotection by TLV was pronounced in terms of eGFR slope ($p_{interaction}$ =0.02) (Figure 2). This effect modification was extinguished when the analysis was restricted to patients without subsequent cardiac events or those receiving a stable dose of loop diuretics.

Conclusions: Long-term therapy of low-dose TLV is renoprotective in patients with CHF, in particular, hyponatremic patients, possibly by dose sparing in loop diuretics and improvement of CHF.

Impact of Fluid Status, Serum Sodium, and Their Interaction on Survival: A Study in an Interactional Hemodialysis Patient Cohort

Xiaoling Ye,[1] Mario Garbelli,[5] Jeroen Kooman,[2] Bernard J. Canaud,[3] Peter Kotanko,[1] Franklin W. Maddux,[4] Stefano Stuard.[4] *[1]Renal Research Institute, New York, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands; [3]FMC Deutschland GmbH, Bad Homburg, Germany; [4]Fresenius Medical Care, Waltham, MA; [5]Fresenius Medical Care Italia, Vaiano Cremasco, Italy.*

Background: While hyponatremia and fluid overload (FO) are associated with mortality in hemodialysis (HD) patients (pts), little is known about their interaction. We aimed to investigate whether the relation between serum sodium (SNa) and mortality differs in HD pts with different fluid status (FS) assessed by whole-body bioimpedance spectroscopy.

Methods: We included all incident in-center adult HD pts treated 01/2010 to 12/2018 in Fresenius Medical Care clinics in 18 European countries and with ≥1 pre-HD SNa and body composition measurements within the first 3 months on HD. We excluded pts with ≥1 SNa value outside 125 to 150 mmol/L. Baseline was defined as the first year on HD, follow-up comprised years 2 and 3. We averaged laboratory and clinical parameters during baseline. A smoothing spline analysis of variance Cox proportional hazard model was applied to explore the joint effects of SNa and FS on mortality (adjusted for age, gender, ultrafiltration rate(UFR), diabetes(DM), and CHF).

Results: Out of the 5938 pts, 4407(74%) were normovolemic, and 1531(26%) had FO. Compared with pts with normovolemic status, FO pts had lower SNa levels, higher Na gradient, higher UFR and DM prevalence (Table1). For normovolemic pts, higher SNa levels (≥138 mmol/L) were associated with better survival. Mortality risk was highest for pts with FO, independent of SNa (Figure1).

Conclusions: The relation between SNa and mortality is dependent on pre-HD FS. Whereas low SNa appears to be disadvantageous in normovolemia and FO pts, the relative effect of FO on outcome appears to be stronger than the effect of low SNa per se. In normovolemic pts the relation between SNa and outcome should be interpreted in the context of FS and not as an isolated risk marker.

Table 1. Patients with normal hydrated and over hydrated status

	Normovolemic	Fluid Overloaded	P-value
Number of patients	N = 4,407	N = 1,531	
Pre-HD serum sodium [mmol/L]	138.3 (136.8, 139.8) [a]	137.6 (136.1, 139.2) [a]	< 0.001
Pre-HD fluid [%]	7.5 (3.7, 10.7) [a]	17.9 (15.9, 21.3) [a]	< 0.001
Sodium gradient [mEq/L]	0.57 (3.1) [b]	1.1 (3.2)	< 0.001
Age [years]	61.0 (49.0, 71.0) [a]	61.0 (48.0, 70.0) [a]	0.004
Male [%]	63.0	57.0	< 0.001
Diabetic mellitus [%]	27.0	43.0	< 0.001
Congestive heart failure [%]	23.0	26.0	0.02
Ultrafiltration [ml/hour/kg]	2.5 (2.0, 3.0) [a]	2.8 (2.2, 3.4) [a]	< 0.001

*Fluid Overloaded defined as: >15% for Male, > 13% for Female.

Increased Short-Term and Long-Term Mortality in Community- and Hospital-Acquired Hypernatremia and in Patients with Delayed Sodium Correction

Charat Thongprayoon,[1] Wisit Cheungpasitporn,[2] Qi Qian.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: This study examined short- and long-term mortality (i) in a large cohort of general hospitalized adults with community- and hospital-acquired hypernatremia and (ii) in hypernatremic patients with and without serum [Na+] correction within three days of hospital stay.

Methods: Adult patients admitted to Mayo Clinic Rochester in a three-year (2011-2013) period were examined. Patients were categorized into 3 groups based on serum [Na^+] at admission and during hospitalization; 1) normal serum [Na^+], 2) community-acquired hypernatremia, and 3) hospital-acquired hypernatremia. Normal serum [Na^+] was defined as serum [Na^+] at admission and all during hospitalization within 138-142 mEq/L. Community-acquired hypernatremia was defined as serum [Na^+] at admission ≥ 143 mEq/L, whereas hospital-acquired hypernatremia was defined as serum [Na^+] at admission 138-142 mEq/L but any serum [Na^+] during hospitalization ≥ 143 mEq/L. Outcomes included hospital and 1-year mortality

Results: Of the total 25,781 patients, 44.7% (n=11,531) were normonatremic, 20.3% (n=5,229) were community-acquired hypernatremia and 35.0% were hospital acquired hypernatremia. In fully adjusted models, ORs (95% CIs) for hospital mortality and HRs (95% CIs) for one-year mortality were 4.91 (3.47-6.94) and 2.25 (2.01-2.53) for community-acquired and 4.11 (2.94-5.73) and 2.35 (2.12-2.60) for hospital-acquired hypernatremia. Hospital-acquired hypernatremia showed a higher hospital, but not one-year, mortality than community-acquired hypernatremia. Among patients with community-acquired hypernatremia, 36.1% (n=1,893) remained hypernatremic by hospital day three ([Na+] 145±3 mEq/L). Fully adjusted hospital- and one-year mortality were significantly increased in patients without [Na+] correction, 3.01 (2.01-4.49), 1.51 (1.26-1.81), respectively, compared to those with [Na+] correction.

Conclusions: Hypernatremia, regardless of acquisition origin, is associated with elevated short-term and long-term mortality. Hospital-acquired hypernatremia was more common and had a higher short-term mortality than community-acquired hypernatremia. Failure to correct hypernatremia by hospital day three is associated with increased morbidity and mortality.

TH-OR074

The Potential Utility of Urine Estimated Ammonium-to-Creatinine Ratio in Patients with CKD

Saeko Hatanaka,[1] Go Kanzaki,[1] Satoki Hatano,[2] Naoto Matsumoto,[1] Yasuyuki Nakada,[2] Yukio Maruyama,[1] Nobuo Tsuboi,[1] Takashi Yokoo.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Internal Medicine, Atsugi City Hospital, Kanagawa, Japan.*

Background: Renal ammonium (NH_4^+) excretion plays a critical role in the elimination of acid. Recent studies have reported that the impairment in urinary NH_4^+ excretion is an important determinant of the development of metabolic acidosis and is an independent factor for predicting loss of renal function. However, urine ammonium measurements are not widely available in routine diagnostic laboratories, and its clinical significance is still unknown. We hypothesized that urine estimated ammonium-to-creatinine ratio (u-eNH_4^+/u-Cr), as an indicator of urinary NH_4^+ excretion, would be surrogates for early metabolic acidosis in patients with CKD.

Methods: We measured u-eNH_4^+/u-Cr in outpatients without receiving oral alkali, hypokalemia, urinary acid-base imbalance, and negative value of urine anion gap (UAG) and urinary osmolar gap (UOG). The urine estimated ammonium concentration (u-eNH_4^+) from UOG was calculated as u-eNH_4^+ = 0.5 x (urine osmolality - 2[Na^+ + K^+] - [urea] - [glucose]). In a multiple regression model, the factors that had affected u-eNH_4^+/u-Cr ware examined. Receiver operating characteristic (ROC)-plot area under the curve (AUC) was used to show the effectiveness of u-eNH_4^+/u-Cr.

Results: A total of 464 outpatients were identified (Mean age, 66.4 ± 15.8 years old; Male, 57.7%; CKD, 58.8%; Hypertensives, 70.9%; Diabetes, 40.0%). u-eNH_4^+/u-Cr was associated positively with sex, eGFR, potassium, uric acid, blood glucose, UAG, and urine protein creatinine ratio. Interestingly, u-eNH_4^+/u-Cr was significantly lower in CKD stage 4-5 than in non-CKD groups, even though there were no overt metabolic disorders. Sex, eGFR, serum potassium level, and blood glucose were independently associated with u-eNH_4^+/u-Cr in a multiple regression model. In addition, AUC values for u-eNH_4^+/u-Cr had greater identity with the metabolic acidosis than ROC-plot AUC values for serum or urinary anion gap (mean ROC-plot AUC for u-eNH_4^+/u-Cr, 0.638; 95% CI, 0.550 to 0.726; p=0.007).

Conclusions: u-eNH_4^+/u-Cr is easily measured in clinical practice and would be more tightly linked with ammonium excretion than serum or urinary anion gap.

The Cystic Fibrosis Urine Test

Peder Berg,[1] Samuel L. Svendsen,[1] Mads V. Sorensen,[1] Soren Jensen-Fangel,[2] Majbritt Jeppesen,[2] Karl Kunzelmann,[3] Jens G. Leipziger.[1] *[1]Aarhus University, Aarhus C, Denmark; [2]Aarhus University Hospital, Aarhus N, Denmark; [3]University of Regensburg, Regensburg, Germany.*

Background: Cystic fibrosis (CF) patients commonly present with systemic electrolyte abnormalities and metabolic alkalosis, likely caused by renal dysfunction of base excretion. In mouse studies, we have identified the physiological mechanism of CFTR-dependent urine bicarbonate excretion in the collecting duct, which depends on functional pendrin and CFTR in β-intercalated cells. Remarkably, CFTR and pendrin knock-out mice cannot respond to increase their urine bicarbonate excretion during the first 3 hours following a defined acute gastric load.

Methods: We have developed a human, non-invasive *CF urine test* that is simple and quantifies the ability to excrete bicarbonate with the urine after oral intake of 79 mg/ kg BW NaHCO3.

Results: In human CF patients (homozygote for ΔF508, n=6), we can show a reduced ability (~ 40% as compared to normal) to excrete urinary bicarbonate after application of this *CF urine test*. We hypothesized that the *CF urine test* can verify and quantify therapy success in CF patients treated with the novel CF modulator drug Orkambi®. Currently, 6 CF patients have been studied before and after 4 weeks of treatment with Orkambi®. The results showed an appr. 2-fold increase of the urinary [HCO_3^-] in the treated CF group.

Conclusions: These results indicate that CFTR knock-out mice and human CF patients present with the inability/reduced ability to excrete a defined oral HCO_3^- load. Furthermore, the CF modulator drug Orkambi® can partially normalize the challenged urinary HCO_3^- excretion in CF patients.

TH-OR076

Intravenous Sodium Bicarbonate Replacement in Patients with Toluene Intoxication

Raul V. Enriquez,[2] Héctor R. Ibarra-Sifuentes,[1] Mara C. Olivo,[3] Juan fernando Gongora rivera.[2] *[1]Universidad Autonoma de Nuevo Leon, Monterrey, Mexico; [2]Hospital Universitario U.A.N.L., Monterrey, Mexico; [3]Hospital Universitaro, Monterrey, Mexico.*

Background: Toluene is widely available in over-the-counter products and is used as an inhaled abuse substance in developing countries. The treatment is not established and is expert opinion based on hydration and potassium replacement; however, acidosis treatment is not established.

Methods: Randomized single blind controlled clinical trial, in patients with toluene intoxication, in the emergency department. Inclusion criteria were patients >18 years, toluene poisoning clinical diagnosis, recently inhaled toluene history (<7 days), pH ≤7.25, and serum potassium between 1.1-5.5mmol/L. Patients were randomized to the administration on Group A, sodium bicarbonate (HCO3) and group B, No HCO3. Group A were given 100 mmol HCO3 as 4 hours infusion for up to 3 doses if the pH was still <7.30. In group B, HCO3 was not administered. All patients underwent serum electrolytes and venous or arterial blood gases every 4 hours since admission for up to 3 samples. The main outcome is to evaluate the time of metabolic acidosis resolution.

Results: In the study 19 patients were included, the mean age was 27 years, 53% were male. The resolution time of group A was 34.6 hours, while the group B was 19.5 hours, without significant difference (Table1). The hospital stay days (4.5 vs 3.2 days, p 0.14), the amount of potassium administered (568 vs 476 mEq, p 0.53) and the amount of fluid administered (8194 vs 7777 mL, p 0.859) were not significant between groups.

Conclusions: In the first clinical trial on toluene intoxication, there is no clear benefit of sodium bicarbonate intravenous replacement in patients with metabolic acidosis due to toluene intoxication. It is relevant to note no difference was found in the potassium administered between groups.

Table 1. Time to resolution, blood gases and serum potassium between groups.

Parameter	Group A	Group B	p
Time to resolution, h	34.7	19.6	0.344

TH-OR077

Development of a Novel Predictive Equation for Ionized Calcium in Hospitalized Subjects: Albumin-Corrected Calcium Equation Is Extremely Inaccurate

Juan Carlos Ramirez-Sandoval,[1] Fabian Gutierrez valle,[2] Sofia Ley,[2] Santiago Pastrana Brandes,[3] Ricardo Correa-Rotter,[4] Pablo Diener Cabieses.[2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México city, Mexico; [2]Universidad Panamericana, CDMX, Mexico; [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [4]Institutor Nacional de la Nutricion, Mexico City, Mexico*.

Background: In clinical practice total serum Ca is often corrected according to albumin (0.8mg/dL per each 1g/L Alb<4 g/L). Recently, hidden Ca disorders have been associated to higher mortality in dialysis. Our objective was to develop a novel-specific correction equation for ionized Ca.

Methods: We reviewed electronic data from all hospitalized patients of a single tertiary-care center (2017-2018). Hidden hypocalcemia and hidden hypercalcemia were defined as: normal Alb corrected-Ca & ionized Ca <4.3 or >5.2 mg/dL respectively.

Results: We analyzed 7,158 Ca samples from 5,618 subjects (age 54±18 y, female 55%, 44% with AKI or CKD). Hypercalcemia and hypocalcemia according to ionized Ca occurred in 3.8% (275/7158) and 28.8% (2059/7158) respectively. Alb corrected-Ca had a poor correlation with ionized Ca (r:0.56, p<0.001). Hidden hypercalcemia and hidden hypocalcemia occurred in 2.2% (160/7158) and 3.7% (271/7158) measurements respectively; 5.1% (362/7158) and 10.7%(766/7158) were erroneously diagnosed as hypercalcemia or hypocalcemia respectively when Alb corrected-Ca was employed. Agreement between Alb corrected-Ca for hypo, normo or hypercalcemia was poor (kappa 0.23). A novel laboratory-specific prediction equation was developed: *Ionized Ca* (mg/dL, reference value 4.3-5.2 mg/dL)=0.44*total Ca – 0.27*Alb (g/L) – 0.06*P(mg/dL) – 0.02*CO_2 (mEq/L) + 2.16. This new equation substantially improved adjusted R^2 to 0.81 (95% CI 0.78-0.82, p<0.001) when compared with Alb corrected-Ca equation (R^2=0.56). Area under ROC curve for hypercalcemia and hypocalcemia diagnosis with new equation were 0.98 (95% CI 0.97-0.99, p<0.001) and 0.86 (95% CI 0.84-87, p<0.001) respectively. In univariate models, SCr and eGFR were associated with Ca-status misdiagnosis (OR:18.1, p<0.001) yet this association disappeared when multivariate analysis was adjusted to P and CO_2 levels.

Conclusions: The novel equation proposed for prediction of ionized Ca is superior to the Alb corrected-Ca equation and could be useful when ionized Ca is not available. The conventional formulas currently used in practice are inaccurate and misclassify many patients, in particular when renal dysfunction with phosphorus or bicarbonate disturbances are present.

TH-OR078

Cell-Based Therapy and Podocyte Cell Fusion Rescue Type IV Collagen Composition in Alport Syndrome

Valerie Lebleu,[1,2] Joseph Alge,[10] Sara Lovisa,[3] Jiha Kim,[6] Yang Chen,[7] Keizo Kanasaki,[12] Yingqi Teng,[14] Behzad Gerami-Naini,[4] Hikaru Sugimoto,[3] Noritoshi Kato,[8] Ignacio Revuelta,[5] Caroline A. Miller,[9] Nicole Grau,[13] Jonathan Sleeman,[11] Shahin Rafii,[15] Raghu Kalluri.[2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of Texas MD Anderson Cancer Center, Houston, TX; [3]MD Anderson Cancer Center, Houston, TX; [4]Tufts University, Boston, MA; [5]Hospital Clinic. Barcelona, Barcelona, Spain; [6]North Dakota State University, Fargo, ND; [7]UT-MD Anderson Cancer Center, Houston, TX; [8]Nagoya University, Nagoya, Japan; [9]Indiana University, Indianapolis, IN; [10]Baylor College of Medicine, Houston, TX; [11]Heidelberg University, Mannheim, Germany; [12]Kanazawa Medical University, Kahoku, Japan; [13]Heidelberg University Hospital, Heidelberg, Germany; [14]Beijing Reciproca Pharmaceuticals Co. Ltd., Beijing, China; [15]Cornell, New York, NY*.

Background: Loss of function mutations in the genes encoding either of the three chains of type IV collagen forming the a3/a4/a5 protomer (*COL4A3*,*COL4A4*, and/or *COL4A5*genes) in Alport syndrome (AS) compromise the glomerular basement membrane (GBM) integrity and filtration function. Potential cure relies on restoring the missing chain(s) of type IV collagen; and cell-based therapies successfully delayed renal failure in mouse models of AS ($Col4a3^{KO}$).

Methods: To guide the development of cell-based therapies for AS, novel genetically engineered mouse models (GEMMs) were generated and used to define which glomerular cell(s) presents with rate-limiting function in GBM type IV collagen synthesis.

Results: In the new GEMMs, conditional deletion of *Col4a3* gene ($Col4a3^{cKO}$), following its breeding with a constitutively expressed Cre-recombinase transgene (CMV-Cre), proved functional and phenocopied the renal disease observed in $Col4a3^{KO}$ mice. Using endothelial cells (Cdh5-Cre) and podocytes (Podocin-Cre) transgenics, we find that podocytes, in contrast with endothelial cells, are requisite for functional type IV collagen GBM composition in AS. Exogenously administered cells (bone marrow derived-, embryonic, and induced-pluripotent stem cells (iPSC)) rescue the renal phenotype in AS mice by restoring a functional GBM a3/a4/a5 type IV collagen composition. Using lineage-tracing genetic strategies, we uncovered that cell-based therapies ensues from the formation of a heterokaryon with recipient podocytes and rescues GBM type IV collagen composition in AS mice.

Conclusions: Such fusion-dependent tissue regeneration was associated with TGFb1-dependent genetic reprogramming of the injured kidney glomerular cells and required de novo synthesis of the missing type IV collagen by the fused stem cells. These experiments highlight cell fusion as a mechanistic driver of stem cell-induced tissue regeneration.

TH-OR079

Lysosomal β-Mannosidase (Manba) Is a CKD Risk Gene

Xiangchen Gu,[1] Hongliu Yang,[2] Chengxiang Qiu,[1] Jihwan Park,[1] Shizheng Huang,[1] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]West China Hospital of Sichuan University, Chengdu, China*.

Background: Chronic kidney disease (CKD) is a complex gene-environmental disease affecting close to 10% of the population worldwide. Through the computational integration of CKD genome-wide association study (GWAS) variants and kidney compartment-based expression of quantitative trait loci (eQTLs) analysis, we identified lysosomal β-Mannosidase(Manba) as a candidate CKD risk gene. Manba is a lysosomal glycosyl hydrolase. Here we studied mice with genetic manipulation of Manba to understand the role of Manba in CKD.

Methods: We generated gene expression and genotype information and conducted eQTLs analysis on 121 microdissected human kidney glomerular and tubule samples. Bayesian colocalization method was performed to integrate the GWAS and eQTL data. We performed single cell RNA-sequencing on healthy mouse kidneys. We generated Manba knock-out mice and induced kidney disease by aging or by folic acid injection. We examined renal histology and gene expression. We analyzed lysosomes and autophagy in vivo and in cultured tubular epithelial cells in vitro.

Results: EQTLs analysis indicated that in human kidney tissue samples with CKD risk variant, the expression of Manba was significantly lower when compared to the reference allele kidneys. Manba was mostly expressed in kidney tubule cells including proximal tubules and principal cells in the mouse kidney single cell dataset. Double immunofluorescence staining confirmed its expression pattern. Aging (at 70 weeks age) Manba knock-out mice exhibited an increase in numbers of lysosomes and autophagic vacuoles in tubular cells. In FA-induced kidney fibrosis model, Manba knock-out mice showed more severe fibrotic changes by histological analysis and an increase in profibrotic genes by QRT-PCR. Manba knock-out mice and cultured Manba knock-out tubular cells demonstrated altered lysosomal dynamics. As lysosomes play a key role in autophagy, Manba knock-out mice also showed lower autophagic flux.

Conclusions: Taken together, these findings indicate that Manba is a CKD risk gene. Manba deficiency exacerbates kidney fibrosis, likely via lysosomal alterations and an impaired autophagic clearance.

TH-OR080

Novel Neuroendocrine Features of Macula Densa Cells Suggest Their Chief Role in Glomerular Tissue Remodeling

Georgina Gyarmati, Anne Riquier-brison, Urvi Nikhil Shroff, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: Macula densa (MD) cells are strategically positioned at the glomerular entrance and traditionally known to regulate renal hemodynamics and renin release. The present study aimed to explore the emerging new neuron-like and secretory function of MD cells and their role in glomerular angiogenesis and tissue maintenance.

Methods: A newly developed MD cell research toolbox was applied including MD-GFP, MD-GCaMP5, Cdh5-Confetti mouse models for tracking MD and endothelial genetic cell fate and $[Ca^{2+}]_i$ dynamics with intravital multiphoton imaging (MPM), freshly isolated single live MD cells, the newly established immortalized mouse MD cell line MD^{Geo}, and MD gene profiling.

Results: Mouse MD cell gene profile suggested axon guidance and growth as key MD cell functions, and high expression of secreted tissue remodeling and angiogenic factors Ccn1, Nov, Cxcl14, Pappa2, Sema3c. MD-GFP mice enabled the visualization of single MD cells in high detail and confirmed the presence of a dense network of long (up to 100 um) basal cell processes arborizing into the glomerular mesangium and vasculature, with highly dynamic features including rapid and extensive vesicular transport and outgrowth. MD^{Geo} cells showed high expression of nerve growth factor receptor (NGFR) and the regulation of nNOS and COX2 expression by NGF. In vivo MPM of MD cell $[Ca^{2+}]_i$ revealed that unlike in other renal epithelia, MD cells show robust (5-fold compared to baseline), rapid, and propagating calcium transients (2-4 s spikes) that were due to several

neuron-specific calcium entry, mobilization, and extrusion pathways. MD^{Geo} cells but not control M1 cells implanted under the renal capsule of Cdh5-Confetti mice induced within 4 days robust endothelial sprouting, neovascularization (angiogenesis). The radial pattern of new vessel growth towards the implanted MD cells' epicenter was formed by clonally expanding local endothelial precursor cells and contained circulating red blood cells.

Conclusions: The newly identified MD cell morphological and functional features suggest that the MD plaque is a single nephron-level ganglion of individual neuron-like MD cells that play chief sensory, effector, and neuroendocrine functions in the kidney. Novel MD-derived secreted angiogenic factors may contribute to glomerular tissue maintenance and repair after injury.

Extracellular Matrix Component Mediated DDR1 Activation Causes Podocyte Lipotoxicity and Progression of Renal Disease in Alport Syndrome

Jin Ju Kim,[1] Judith T. Molina David,[1] Sydney S. Wilbon,[1] Javier T. Varona Santos,[1] Marco Prunotto,[2] Sandra M. Merscher,[1] Jeffrey H. Miner,[3] Alessia Fornoni.[1] *[1]University of Miami, Miami, FL; [2]F. Hoffmann-La Roche Ltd., Basel, Switzerland; [3]Washington University School of Medicine, St. Louis, MO.*

Background: The GBM is primarily composed of laminin and Collagen type IV. *De novo* production of the collagen type I (Col I) has been observed in mouse models of Alport Syndrome (AS mice, Col4a3KO). Discoidin domain receptor 1 (DDR1) is activated by collagens. Deletion of DDR1 in AS mice was shown to improve survival and renal function. We reported that lipid (LD) accumulation in mice with AS contributes to disease progression. However, how DDR1 activation by aberrant collagen production may contribute to podocyte lipotoxic injury and proteinuria in AS is poorly understood

Methods: AS mice were obtained from the Jackson Laboratory for the determination of DDR1 phosphorylation and for the treatment with ezetimibe (EZ) or in combination with Ramipril (RM). Following Col I treatment (50ug/mL, 18hrs), podocyte lipid content was determined by BODIPY 493/503 and Cell Mask Blue staining. Free fatty acid (FFA) uptake was assessed using a fluorometric kit.

Results: We demonstrate that pDDR1 is increased in kidney cortexes of AS mice and pDDR1 levels correlate with blood urine nitrogen (BUN, R2 =0.7, p<0.01). *In vitro*, DDR1 is activated by Col I in human podocytes. Increased LD accumulation (p<0.05), FFA uptake (p<0.01) and triglyceride (TG) levels (p<0.01) were observed in Col I treated podocytes. DDR1 interacts with CD36, a protein involved in FFA uptake. Podocytes transfected with DDR1(DA) showed increased FFA uptake and TG level compared to cells transfected with WT and DDR1(DN) (p<0.05). A similar phenotype was observed in immortalized podocytes isolated from AS mice. We show that EZ interferes with the interaction between CD36 and DDR1 in HEK 293 cells. *In vivo*, administration of EZ or RM to AS mice preserves renal function. While EZ restores normal renal triglyceride content, we discovered an unexpected effect of RM, which lowered renal cholesterol content. Interestingly, we also observed an additive effect on renal fibrosis when a combination of EZ and RM was used compared to when either of the drugs was given to AS mice.

Conclusions: Our study suggests that Col I/DDR1-mediated lipotoxicity may represent a novel mechanism leading to podocyte injury in AS that is amenable to therapeutic intervention through a repurposing strategy of EZ.

Differential Expression of Parietal Epithelial Cell and Podocyte Extracellular Matrix Proteins in Focal Segmental Glomerulosclerosis and Diabetic Kidney Disease

Gek Cher Chan,[1,2] Diana G. Eng,[1] Jeffrey H. Miner,[3] Charles E. Alpers,[4] Kelly L. Hudkins,[4] Anthony Chang,[5] Jeffrey W. Pippin,[1] Stuart J. Shankland.[1] *[1]Division of Nephrology, University of Washington, Seattle, WA; [2]Division of Nephrology, National University Hospital, Singapore, Singapore; [3]Division of Nephrology, Washington University School of Medicine, St. Louis, MO; [4]Department of Pathology, University of Washington, Seattle, WA; [5]Department of Pathology, UChicago Medicine, Chicago, IL.*

Background: The differential expression of extracellular matrix (ECM) protein isoforms in focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy is not well defined. In activated parietal epithelial cells (PECs), upregulation of CD44 is associated with ECM expansion. PEC-derived ECM proteins include Laminin β1 (LAMB1), Perlecan and collagen type IV α2 (COL4A2). Podocyte-specific ECM proteins include Laminin β2 (LAMB2), Agrin and collagen type IV α4 (COL4A4). This study aimed to demonstrate differential ECM protein expression by PECs in experimental and human FSGS and diabetic nephropathy, and to determine if CD44 plays a role in regulating ECM protein expression.

Methods: FSGS was induced in CD44 null ($CD44^{-/-}$) and wild-type mice, using a cytotoxic podocyte antibody. Kidney tissues were obtained at baseline and day 28 of FSGS. Diabetic BTBR *ob/ob* mice with leptin deficiency obesity mutation, *ob*, in which severe hyperglycemia manifested resulting in advanced diabetic nephropathy at 24 weeks of age, were used. BTBR non-diabetic wild-type mice of similar age acted as controls. Human biopsies of normal kidney, FSGS and diabetic nephropathy were analyzed.

Results: In normal mouse and human glomeruli, PEC-derived ECM proteins were found along the Bowman's capsule while, podocyte-specific ECM proteins were found at the glomerular basement membrane. However, in experimental FSGS, LAMB1, Perlecan and COL4A2 staining were significantly increased in PECs, and there was *de novo* expressions of LAMB2 and Agrin along Bowman's capsule. In diabetic *ob/ob* mice, as well as in human biopsies with FSGS and diabetic nephropathy, similar findings were observed. Because our previous results showed lower ECM expansion in $CD44^{-/-}$ mice, we compared the difference of each ECM protein between $CD44^{-/-}$ and wild-type mice, to determine if ECM expansion was CD44-dependent. Perlecan, COL4A2, LAMB2 and Agrin were significantly lower in $CD44^{-/-}$ mice, but not LAMB1 or COL4A4.

Conclusions: Therefore, CD44 plays a role in regulating ECM protein expression. Activated PECs result in increased PEC-derived matrix production, and *de novo* production of podocyte-specific matrix.

TH-OR083

CD44 Impacts Glomerular Parietal Epithelial Cell Changes in the Aged Mouse Kidney

Hiroko Hamatani,[1,2] Diana G. Eng,[1] Keiju Hiromura,[2] Jeffrey W. Pippin,[1] Stuart J. Shankland.[1] *[1]Division of Nephrology, University of Washington, Seattle, WA; [2]Gunma University Graduate School of Medicine, Maebashi, Japan.*

Background: CD44, an activated parietal epithelial cell (PEC) marker, increases with aging, and colocalizes with pERK to increase extracellular matrix and epithelial-mesenchymal transition (EMT). The purpose of the current study was to determine the effect of CD44 on PECs with aging.

Methods: CD44 knockout and wildtype control mice at 4 or 24 months were used in this study. Immunohistochemistry and immunofluorescence staining were performed and glomeruli were assessed as follows; outer cortex (OC) vs. juxta-medulla (JM), young vs. aged, and wildtype (WT) vs. CD44 knockout (KO).

Results: Aged WT mice had an increase in segmental and global glomerulosclerosis in JM glomeruli, whereas aged CD44KO mice did not develop either segmental or global glomerulosclerosis. Bowman's capsule length increased with age and was longer in JM than in OC glomeruli. It was significantly less in aged CD44KO mice compared with WT mice in both OC (212.4±11.7μm vs. WT, 252.4±16.5μm, P<0.0001) and JM glomeruli (325.1±24.0μm vs. 373.1±32.2μm, P<0.0001). In WT mice, PEC number was higher in JM versus OC glomeruli, and was increased with age in JM glomeruli, while knockout of CD44 prevented this aged-related increase. PEC density was higher in JM than in OC glomeruli, and was lower in aged mice than in young mice, however there was no significant difference between WT and CD44KO mice. Glomerular tuft area was larger in JM than in OC and was significantly less in aged CD44KO mice versus WT mice, in both OC (2801±241μm2 vs. 4415±379μm2, P<0.0001) and JM glomeruli (6011±823μm2 vs. 8391±892μm2, P<0.0001). Podocyte number was higher in aged CD44KO mice versus WT mice in JM glomeruli. Podocyte density was higher in aged CD44KO versus WT mice in both OC and JM glomeruli. The expression of EMT markers, α-SMA and vimentin, and activated form of ERK (pERK) and a downstream target of mTOR, pS6RP was increased in aged WT mice especially in JM glomeruli, and was decreased in CD44KO mice.

Conclusions: We showed that knockout of CD44 attenuated age-related increase of glomerulosclerosis, Bowman's capsule length, glomerular hypertrophy, pERK, pS6RP, and EMT marker expression. Our data suggest that CD44 is involved in aged-related changes of glomeruli and CD44 is associated with activation of ERK and mTOR signaling.

TH-OR084

MAD2B Contributes to Parietal Epithelial Cell Activation and Crescentic Glomerulonephritis via Skp2

Chen Ye, Hua Su, Chun Zhang. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Mitotic spindle assembly checkpoint protein 2 (MAD2B), a well-defined anaphase-promoting complex/cyclosome (APC/C) inhibitor and a small subunit of DNA polymerase zeta, is critical for mitotic control and DNA repair. Previously, we reported that upregulation of MAD2B is involved in several renal diseases. However, the pathological role of MAD2B in crescentic glomerulonephritis (CGN) has not been fully elucidated.

Methods: The objects of this study included patients with CGN, anti-glomerular basement membrane (anti-GBM) rats and in vitro cultured mouse PECs. In vivo, the anti-GBM model was established by intravenous injection of sheep anti-GBM serum and intraperitoneal administration of recombinant human TNF receptor-Ig fusion protein (TNFR:Fc) and prednisolone (PNS) were adopted to slow down crescent formation. In vitro gene silence of MAD2B and Skp2 were carried out by small interfering (si) RNA.

Results: In the present study, we found an obvious MAD2B enhancement in glomeruli of CGN patients and anti-GBM rats, which mainly originated from PECs. Consistently, MAD2B was increased in tumor necrosis factor-α (TNF-α)-treated PECs in vitro, accompanied by cell activation, proliferation and extracellular matrix accumulation. Importantly, knocking down MAD2B with siRNA dramatically attenuated PECs activation. Furthermore, we found that the expression of Skp2, an APC/C-CDH1 substrate, was increased in glomeruli of anti-GBM rats and TNF-α-induced PECs, which could be suppressed by MAD2B depletion. Also, genetic deletion of Skp2 inhibited TNF-α-induced PECs activation. Lastly, the administration of TNFR:Fc and PNS in anti-GBM rats reversed MAD2B and Skp2 accumulation, PEC activation, and subsequent crescent formation.

Conclusions: Our data suggests a pivotal role of MAD2B in the pathogenesis of glomerular PEC activation, proliferation and crescent formation by inducing Skp2 expression. MAD2B-Skp2 axis may be a promising potential target for glomerular crescent formation interventions.

Fatty Acid Receptors GPR40/GPR84: Two Promising Targets in Kidney Fibrosis

Lyne Gagnon,[1] Jean-Francois Thibodeau,[1,2] Ming-Zhi Zhang,[3] François Sarra-Bournet,[1] Kathy Hince,[1] Mikaël Tremblay,[1] Lilianne Geerts,[1] Chris R. Kennedy,[2,4] Richard L. Hébert,[2,4] Alex Gutsol,[2] Chet E. Holterman,[2] Raymond C. Harris,[3] Brigitte Grouix.[1] *[1]Prometic Biosciences Inc., Laval, QC, Canada; [2]Kidney Research Centre, Ottawa, ON, Canada; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Ottawa, Ottawa, ON, Canada*.

Background: Numerous clinical conditions can lead to organ fibrosis and functional failure. There is a great need for therapies that could effectively target pathophysiological pathways involved in fibrosis. GPR40 and GPR84 are G protein–coupled receptors stimulated by free fatty acid ligands. Although both receptors have been associated with metabolic regulation and inflammation, they have not been previously linked to organ fibrosis. The dual GPR40 agonist/GPR84 antagonist PBI-4050 is a novel antifibrotic drug candidate entering phase III in idiopathic pulmonary fibrosis (IPF) and Alström syndrome. The aim of this study was to determine the role of GPR40 and GPR84 receptors and the effect of PBI-4050 treatment in models of acute kidney injury (AKI) and chronic kidney disease (CKD).

Methods: PBI-4050 was tested in cells involved in fibrosis (macrophages, fibroblasts and epithelial cells) and in various animal models of CKD/DKD (5/6-nephrectomized rat, *db/db* and *db/db* eNOS$^{-/-}$ mice, adenine-induced CKD), AKI (IRI, LPS, UUO, doxorubicin) and in GPR40- and GPR84-knockout mice.

Results: PBI-4050 acts on cells involved in the fibrotic pathway: macrophages, fibroblasts and epithelial cells by regulating cytokines, fibrotic and remodeling markers. GPR40 is also expressed in proximal tubules and collecting duct while GPR84 is mainly expressed in podocytes. In experiments using either GPR40- or GPR84-knockout mice in models of kidney fibrosis (UUO, IRI, and adenine-induced CKD), GPR40 was found protective and GPR84 deleterious. Through binding to GPR40 and GPR84, PBI-4050 significantly attenuated fibrosis in other models of AKI (doxorubicin, LPS) and CKD/DKD (5/6-nephrectomy, *db/db* mice). Moreover, in two phase II clinical trials (type 2 diabetes with metabolic syndrome, Alström syndrome) involving a total of 36 patients, PBI-4050 reduced kidney injury urinary biomarkers.

Conclusions: GPR40 and GPR84 may represent promising molecular targets in fibrosis pathways. We conclude that PBI-4050 is a first-in-class compound that may be effective for managing inflammatory and fibrosis-related kidney diseases.

TH-OR086

Endothelial Glycocalyx Hyaluronan Is Required for Glomerular Integrity and Is Determined by Shear Stress-Regulated Glucobiosynthesis

Bernard van den Berg,[1] Gangqi Wang,[3] Johan Van der vlag,[2] Ton J. Rabelink.[3] Division of Nephrology *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Radboud University Nijmegen Medical Centre; Dept of Nephrology, Nijmegen, Netherlands; [3]LUMC, Leiden, Netherlands*.

Background: Endothelial cells are covered by a glycocalyx envelop, both luminal and abluminal, which predominantly consists of proteoglycans and adhering proteins. Conditional EC loss of glomerular hyaluronan (HA) resulted in mesangiolysis and capillary ballooning and albuminuria. Over time this process develops into glomerular capillary rarefaction and glomerulosclerosis. Laminar shear stress is required to preserve glycocalyx expression, but how downstream cellular regulation of production and maintenance of glycocalyx hyaluronan occurs is unknown.

Methods: EC-HA production and expression were tested *in vitro* and *in vivo* using primary glomerular derived EC or conditional EC HAS2-KO mice by fluorescent staining for HA, CRISPR-CAS9 editing of the *HAS2* gene and NMR of ^{13}C labelled glucose to determine cellular glucose metabolite concentrations.

Results: Here, we show how biosynthesis of the major structural component of EC glycocalyx, hyaluronan (HA), is regulated by shear. Both *in vitro* as well as in *in vivo*, HA expression on the endothelial surface is increased upon laminar shear and reduced when exposed to oscillatory flow, which is regulated by KLF2. We demonstrate increased expression and translocation of HAS2 to the endothelial cell membrane during laminar shear. HA production by HAS2 was shown to be further driven by availability of the HA substrates UDP-glucosamine and UDP-glucuronic acid. KLF2 inhibits endothelial glycolysis and allows for glucose intermediates to shuttle into the hexosamine- and glucuronic acid biosynthesis pathways. In addition, we found that HA harbours a specific binding site for the key regulator of endothelial quiescence and maintenance in glomerular endothelial barrier function, angiopoietin 1 (Ang1), and show that endothelial loss of HA resulted in disturbed Tie-2 kinase dependent glomerular endothelial stabilization.

Conclusions: These data demonstrate how endothelial glycocalyx function and functional adaptation to shear is coupled to KLF2 mediated regulation of endothelial glycolysis and HAS2 expression and HA is a critical growth factor signaling platform enabling effective Ang1/Tie2 signaling. As such, glomerular endothelial hyaluronan is a hitherto unrecognised key ECM component required for glomerular structure and function, which is lost in diabetic nephropathy.

TH-OR087

Functional Intrarenal Alterations and Morphological Glomerular Basement Changes in Mice Deficient of the Angiotensinase Aminopeptidase A

Benedikt Marahrens,[1,2] Arndt Schulze,[1,2] Jan Wysocki,[1] Minghao Ye,[1] Yashpal S. Kanwar,[1] Juan Carlos Q. Velez,[3] Daniel Batlle.[1] *[1]Northwestern University Feinberg Medical School, Chicago, IL; [2]Charité University Medicine Berlin, Berlin, Germany; [3]Ochsner Clinic Foundation, New Orleans, LA.*

Background: Aminopeptidase A (APA) is an enzyme abundantly expressed in the kidney glomeruli and tubules which degrades both Angiotensin (Ang) I and Ang II and thereby potentially important for downregulating renal RAS overactivity. Our objective was to examine whether there is a kidney phenotype associated with APA deficiency.

Methods: Urinary albumin excretion rate (AER) and glomerular filtration rate (GFR) were evaluated in BALB/c mice with global APA deficiency (APA$^{-/-}$) and compared to wild-type (WT) mice. Kidneys harvested from 8-month-old mice were examined by light microscopy (LM) and electron microscopy (EM). Abundance of endogenous kidney Ang II and the ability of the kidneys to degrade exogenous Ang II *ex vivo* were evaluated. In addition, kidney Ang-converting enzyme (ACE) expression and activity were measured.

Results: APA$^{-/-}$ mice had normal urinary AER and a GFR similar to that of wild-type (WT) littermates. By LM, kidneys from APA$^{-/-}$ mice showed mild mesangial expansion and mild to moderate thickening of the glomerular basement membrane (GBM). By EM, the APA$^{-/-}$ also exhibited mild increase of the mesangial matrix and moderate thickening of the GBM with a striking appearance of knob-like structures and sub-endothelial expansion. Kidney lysates of APA$^{-/-}$ showed a markedly slower degradation of exogenous Ang II (10 μM) compared to those of WT as shown by residual Ang II levels after 30 minutes (48.6 ± 4 vs 16.0 ± 5 %, respectively, $p<0.001$). Endogenous Ang II levels in APA$^{-/-}$, however, were not different compared to WT kidneys (1.04 ± 0.2 vs 0.89 ± 0.3, fmol/mg, p=ns). In addition, kidney lysates of APA$^{-/-}$ mice showed a profound decrease in ACE activity (2981 ± 374 vs 10021 ± 897 rfu/μg, respectively, $p<0.001$), mRNA (RT-real time PCR) and protein (Western blot) levels. The downregulation of ACE by decreasing Ang II formation likely counterbalances the impaired Ang II degradation due to APA deficiency.

Conclusions: Deficiency of APA results in glomerular morphological alterations in the mesangial stalk and the GBM and functional adaptations in intrarenal ACE expression and activity. These findings support a role of APA in maintenance of glomerular structure and intrarenal Ang homeostasis.

TH-OR088

Adoption of Home Remote Monitoring to Improve Outcomes in Peritoneal Dialysis (PD) Patients

Martin J. Schreiber, Mike Gonzales, Shannon Roepe, Kevin Cahill, Bram Van hout, Jodi Holly-Kestel, Patricia Herzog, Michelle Cassin. *DaVita Inc, Denver, CO*.

Background: The use of virtual health technologies has the potential to transform care of end-stage renal disease patients, allowing ongoing biometric data capture and virtual in-home interactions between patients and the healthcare team. Tracking biometric data through home remote monitoring (HRM) platforms, especially for high-risk patients, can promote a more proactive approach to care management and may improve outcomes.

Methods: We examined the acceptance and utilization of HRM by high-risk PD patients of a large dialysis organization (LDO); patient risk status was determined using a predictive clinical algorithm in conjunction with care team clinical judgement. Each home dialysis facility's governing body approved the HRM protocol prior to use; patient consent and a physician's order was required to place a patient on the HRM protocol. Alerts were designed for all biometric values tracked (blood pressure, weight, temperature). Patients could also engage via an iPad in Daily Health Sessions, which included questions about symptoms as well as educational content designed to reinforce training concepts.

Results: Since April 2017, over 12,000 patients have used HRM and over 4700 patients were actively using the platform in May 2019; more than 1 million data points have been collected to date. Metrics tracked during implementation included: patient enrollment rate, consistency of patient data transmission, and speed of alert resolution by the care team. Adoption metrics were assessed by program, along with hospitalization rates and mean time on therapy.

Conclusions: HRM was shown to be feasible among high-risk PD patients of an LDO. Uncontrolled blood pressure, treatment weight > target weight, and an increase in positive answers to health questions could all be indicative of changes in patient health status that warrant action: use of HRM to track these metrics may help to drive action steps and improve outcomes. Areas of ongoing focus include improving adherence and adoption into clinic workflow, ensuring timely closure of HRM alerts, and consistency in targeting HRM to appropriate high-risk patients.

TH-OR089

A Transitional Start Unit (TSU) Improves Home Dialysis Adoption by Incident ESKD Patients

Subhasish Bose,[2,1] Brendan T. Bowman,[1] Lesley McPhatter,[3] Danielle Wentworth,[5] Carson L. Daniel,[4] Emaad M. Abdel-Rahman.[1] *University of Virginia Dialysis Program [1]University of Virginia School of Medicine, Charlottesville, VA; [2]Lynchburg Nephrology Physicians, Lynchburg, VA; [3]University of Virginia, Charlottesville, VA; [4]UVA/Lynchburg Dialysis, Lynchburg, VA; [5]University of Virginia Division of Nephrology, Charlottesville, VA.*

Background: Pre-dialysis education remains inadequate for incident ESKD patients. This is important as the first 90 days of dialysis is a vulnerable time with a high risk of hospitalization and death. To address this problem, we designed a pilot quality improvement program, the TSU, to orient, educate and empower incident patients on key aspects of ESKD. Here, we report results through 26 months.

Methods: The TSU program provides 4-6 weeks of 1:1 dialysis education on nutrition, access, finances, modalities and transplant delivered by an interdisciplinary team following a set curriculum. Setting was two University of Virginia academic dialysis units. Only in-center incident patients were eligible for enrollment. Exclusion criteria included: prior selection of home therapy, permanent long-term care residency, hospice, unstable living arrangements or severe cognitive disability. Patients received four times weekly dialysis on M/T/Th/F using NxStage S1 machines for 3-4 hours followed by the typical "long break". Modest prescription changes by the primary nephrologist were allowed. Primary outcome was uptake of home therapies. Secondary outcomes included: comparison of weekend interdialytic weight gain (WE-IDWG) during TSU and after TSU program for patients who remained on in-center hemodialysis (ICHD) and other relevant quality metrics.

Results: 81 patients enrolled in the TSU. Participants were 52% male, 60.9% black with median age of 62. ESKD cause included 35% type 2 diabetes, 34% hypertension. **After education in the TSU, 30.4% of participants chose home therapy** (23% PD and 7.4% home HD). Overall prevalence of home therapy in our program is 14.3% with adoption among in-center new starts lower at 5-10%. The above result represents a significant increase in home therapy adoption. **Average WE-IDWG was 32% less in the TSU (1.58 kg) versus subsequent thrice weekly ICHD (2.33 kg) (p-value < 0.01)**. **There were no hospitalizations for volume overload during the TSU program**. Antihypertensive medications were reduced 12% at the end of the TSU period.

Conclusions: A TSU education program significantly increases home therapy adoption among incident ESKD patients and reduces IDWG over the long weekend break. Larger studies are required to determine the effect on hospitalizations.

TH-OR090

Early Transitions from In-Center Hemodialysis to Home Dialysis

Sonny T. Nguyen,[1] Benjamin Lidgard,[1] Lucia Chen,[2] Jeffrey Perl,[3] Tiane Dai,[1] Anjali B. Saxena,[4] Jenny I. Shen.[5] *[1]Harbor UCLA Medical Center, Torrance, CA; [2]UCLA, Los Angeles, CA; [3]St. Michael's Hospital, Toronto, ON, Canada; [4]Stanford University / Santa Clara Valley Med Ctr, Los Altos, CA; [5]LaBiomed at Harbor-UCLA, Torrance, CA.*

Background: Most patients starting dialysis urgently and unplanned receive in-center hemodialysis (ICHD) but might prefer and have better outcomes on home dialysis. We identified those who transitioned from ICHD to home dialysis early following an unplanned dialysis start and determined whether those who transitioned early had a lower risk of death compared to those remaining on ICHD.

Methods: We identified adults in the USRDS who initiated ICHD from 2005-2013 with a central venous catheter and no maturing arteriovenous access who had no nephrology referral prior to dialysis. We used logistic regression to identify factors associated with an early transition to home dialysis (within 90 days of dialysis initiation). Among those who survived to day 90 of dialysis, we applied a Cox proportional hazards model to find the risk of death for those who transitioned compared to those who did not.

Results: Of 190,642 patients, 3923 (2%) transitioned to peritoneal dialysis (PD) and 853 (0.4%) to home HD (HHD) with an average time on PD and HHD of 413 and 224 days, respectively. Younger age, white race, private insurance, rural neighborhoods, and initiating dialysis in a unit that has a PD program were associated with higher odds of an early PD transition. In contrast, older age, frailty, urban neighborhoods, and initiating dialysis in a unit that has a HHD program was associated with making an early HHD transition. Those who had transitioned to PD at any time during the first 90 days were less likely to die compared to those who had never transitioned to home dialysis [adjusted HR 0.86; 95%CI: 0.82-0.91]. In contrast, transition to HHD in the first 90 days was associated with a higher risk of death compared to those who had never transitioned (adjusted HR 1.31, 95%CI: 1.19-1.44).

Conclusions: Few patients who start ICHD urgently and unplanned make an early transition to home dialysis. Initiating dialysis in a center with home dialysis may help facilitate these transitions by increased exposure, awareness and education about home dialysis. The different risk factors and demographics of patients transitioning to PD and HHD early suggest that these therapies may attract different types of patients and may explain the differences in outcomes between HHD and PD that we observed. However, further research is needed to understand the higher mortality among early transitions to HHD.

TH-OR091

The Effect of a Combined Resistance and Cardiovascular Exercise Program on Peritoneal Dialysis Patients: A Pilot Randomized Control Trial

Paul N. Bennett,[1,2] Michael G. West,[3,4] Wael F. Hussein,[1,5] Erick Smith,[1] Marc Reiterman,[1] Jignesh Patel,[3,6] Grace M. Alagadan,[3] Anna R. Carrasco,[1] Brigitte Schiller.[1,5] *[1]Satellite Healthcare, San Jose, CA; [2]Faculty of Health, Deakin University, Geelong, VIC, Australia; [3]Satellite Healthcare/Wellbound, Sacramento, CA; [4]College of Health and Human Services, California State University, Sacramento, CA; [5]Department of Medicine, Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; [6]Kaiser Permanente, Sacramento, CA.*

Background: Patients receiving peritoneal dialysis (PD) are physically inactive, resulting in poor physical function. The aims of this study were to test the feasibility, and measure the effect of a combined resistance and cardiovascular exercise program on physical function and patient reported outcome measures (PROMs).

Methods: Pilot randomized controlled trial (RCT). Intervention (I) group received monthly exercise physiologist consultations, exercise prescription (resistance and aerobic exercise program using exercise bands) and four phone calls over 12 weeks. Control (C) group received normal care. Feasibility outcomes were exercise adherence rates and adverse events. Physical function effect was measured by change in I compared to the C group in 30 second sit to stand test (STS), pinch strength test (PST) and the 8 foot timed up and go test (8TUG). PROMs were measured using the London Evaluation of Illness (LEVIL) instrument.

Results: From a single center with 75 PD patients, 18 (24%) did not meet inclusion criteria (7 unable to understand English, 4 PD<6 weeks, 3 significant amputations, 2 medically unstable, 2 unable to independently ambulate). 21 (28%) patients declined to participate resulting in a recruitment rate of 48% consisting of 36 patients randomized into 2 groups of 18 (1:1). 10 patients did not complete the study resulting in a retention rate of 72% and analyzable data for 26 patients (13 in each arm). 10 out of 13 (77%) intervention patients completed greater than 50% of sessions. No serious adverse events caused by the exercise program were reported. In all physical function measures the intervention exercise group improved more than the control group without reaching statistical significance. PROMs improved in the exercise group and worsened in the control group in the domains of wellbeing, fatigue, shortness of breath and appetite; sleep improved more in the exercise group; and pain worsened more in the control group.

Conclusions: This study is the largest reported US RCT demonstrating a resistance and cardiovascular exercise program is feasible and safe and can increase physical activity and physical function in PD patients. A future PDEx study using a larger sample size, is feasible in the US peritoneal dialysis context.

TH-OR092

Training Duration Is Associated with Adverse Events in Home Hemodialysis Patients

Isabelle Gionest,[2] Louis-Philippe Laurin,[1] Jean-Philippe Lafrance,[1] Annie-Claire Nadeau-Fredette.[1] *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Montreal University, Montreal, QC, Canada.*

Background: Home hemodialysis (HHD) training varies significantly at the center- and patient-levels. This study aimed to explore the clinical outcomes associated with HHD training length.

Methods: All HHD patients successfully trained in a single-center dialysis center between January 2006 and July 2017 were included. Poisson models were built to assess hospitalization rate after start of HHD in the home environment. Potential confounding were defined a priori and included age, sex, diabetes, cause of primary kidney disease and year of HHD start. Time to first adverse event (hospitalization, definitive transfer to in-center hemodialysis [CHD] or death) was evaluated using a Kaplan-Meier curve and log-rank P.

Results: Forty-nine patients graduated from HHD training in our program (1 patient was excluded due to delays related to dialysis machine unavailability). HHD training was offered using a thrice weekly schedule with a median duration of 86 (67-108) days. Mean hospitalization rate was 0.33 (95% CI 0.24-0.44) episode per patient-year. Longer training duration was associated with a trend toward higher hospitalization rates (unadjusted incidence rate ratio [IRR] 1.12 per month, 95% CI 0.99-1.27, p=0.07) and a statistically significant increase in hospitalization rates when adjusted for confounding (adjusted IRR 1.20, 95% CI 1.01-1.41, p=0.03). During the total follow-up time of 131 patient-year, 4 patients died on HHD, 9 were definitively transferred to HD, 18 received a kidney transplantation and 17 patients had a least 1 hospitalization. There was a trend toward lower event-free survival (hospitalization/ definitive transfer to CHD/ death) in the extended training group (≥4 months of training, log-rank p=0.09)

Conclusions: In this small cohort, patients with longer HHD training had more frequent hospitalizations. Enhanced home support could be offered to these more vulnerable patients once they graduate from HHD training.

Table1. Study cohort

Baseline Characteristics	n=48
Age	44 (37-55)
Male	35 (73)

Dialysis Modality Choice Among Healthcare Workers: A UK Perspective

Rizwan A. Hamer,[1] Jyoti B. Baharani,[2] Karen J. Jenkins,[3] Indranil Dasgupta.[2]
[1]University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; [2]Heart of England Foundation Trust, Birmingham, United Kingdom; [3]East Kent Hospitals NHS University Foundation Trust, Canterbury, United Kingdom.

Background: Whilst health care workers are closely involved in the decision making process of patients in regard to dialysis modality, very little is known about their personal preferences.

Methods: We conducted an anonymised online survey of UK renal healthcare workers on their preferred dialysis modality if they needed dialysis. In addition to collecting their baseline demographics, we asked "Assume you are an otherwise well 40 year old (and, separately, 75 year old) person approaching ESRD. You have no living kidney donor options at present. There are no contraindications to any of the following dialysis options. Which renal replacement therapy would you choose?"

Results: A total of 858 individuals participated in the survey. The median age 44.3 years, 70.2% were female, 37.4% were doctors, 31.1% senior nurses and 15.2% junior nurses or health care assistants. The remainder were allied healthcare staff including dietitians and pharmacists. Over 60% of respondents had been involved in renal healthcare for over 10 years. There was a preference for peritoneal dialysis (PD) over in-centre haemodialysis (50.47% v. 6.18%; p <0.001 for 40 year and 49.18% v. 17.83%%; p<0.001 for 75 year old assumption) and home haemodialysis (HHD) (50.47% v. 39.28%; p<0.001 for 40 year old and 49.18% v. 18.41% for 75 year old assumption). There was a preference for HHD over in-centre haemodialysis if the respondents assumed they were 40 years old (39.28% v. 6.18%; p <0.001) but not if they assumed they were 75 years old (18.41% v. 17.83% p=0.778). There was a preference for automated peritoneal dialysis over continuous ambulatory peritoneal dialysis for both assumptions, 40 years old (34.85% v. 15.62%; p <0.001) and 75 years old (36.48% v. 12.7%; p<0.001). There was no difference in choice of treatment between doctors and senior nurses. Junior nurses and health care assistants, however, preferred haemodialysis over PD (p<0.001). The area of work had an impact on choice of treatment with the more staff involved in the care of HHD choosing HHD when compared to staff looking after patients receiving PD (<0.01).

Conclusions: In conclusion this survey showed that most healthcare workers in renal medicine, irrespective of age, gender, role and experience would choose home-based dialysis, in contrast to current practice in the UK where less than 20% of dialysis patients are on home therapies.

TH-OR094

Patient and Caregiver Perspectives on Burnout in Peritoneal Dialysis

Justin O. Oveyssi,[1] Karine E. Manera,[2] Amanda Baumgart,[2] Yeoung Jee Cho,[6] Derek L. Forfang,[3] Anjali B. Saxena,[4] Allison Tong,[2] Jenny I. Shen.[5] *[1]St. Mary Medical Center, Long Beach, CA; [2]The University of Sydney, Westmead, NSW, Australia; [3]National Forum of ESRD Networks, San Pablo, CA; [4]Stanford University / Santa Clara Valley Med Ctr, Los Altos, CA; [5]LaBiomed at Harbor-UCLA, Torrance, CA; [6]The University of Queensland, Brisbane, QLD, Australia.*

Background: Peritoneal dialysis (PD) can offer patients more autonomy and flexibility compared with in-center hemodialysis. However, burnout – defined as mental, emotional, or physical exhaustion that leads to negative attitudes towards PD or an inability to perform PD safely – is associated with an increased risk of peritonitis or transfer to hemodialysis. We aimed to describe the perspectives of burnout among patients on PD and their caregivers.

Methods: 81 patients and 45 caregivers from 9 dialysis units in Australia, Hong Kong, and the US participated in 14 focus groups. Transcripts were analyzed thematically.

Results: We identified two themes. *Suffering an unrelenting responsibility* contributed to burnout as patients and caregivers felt overwhelmed by the daily regimen, perceived their life to be coming to a halt, tolerated the PD regimen for survival, and had to bear alone the burden and uncertainty of what to expect from PD. *Adapting and building resilience* encompassed establishing a new normal, drawing hope and support from family, relying on faith and hope for motivation, and finding meaning in other activities.

Conclusions: Patients on PD and their caregivers describe burnout as an unrelenting responsibility that they cope with by adapting and building resilience. Better informing patients and caregivers about the challenges of living with PD could prevent or delay burnout. Recognizing and providing resources to cope with burnout are essential to ensuring the well-being of patients on PD and their caregivers. Further research is needed to develop tools to screen for burnout and interventions for improved care and outcomes in patients on PD.

Illustrative Quotes

Theme	Subtheme	Quote
Suffering an unrelenting responsibility	Overwhelmed by the daily regimen	"Sometimes I feel like, when it comes to five or four times a day, five hours and then, sometimes I feel like I don't want to do it. Leave it. Let me die, I can't take this anymore."
	Life coming to a halt	"At the moment it's like a full stop. I can't move forward in my life."
	Tolerating PD regimen for survival	"And it's like, girl, you're dying. You don't have a choice."
	Bearing alone the burden and uncertainty of what to expect from PD	"You need social workers and psychologists for people that are feeling that way, they need to have counselling and support groups, because I can understand being in that frame of mind, where you would go okay, yeah, okay I've just had enough. I've had too much pain, I'm too tired, I'm too tired of fighting, right. They need support to know that there are still people here, and if it is their choice, then that's okay, and then the support to handle the side effects, the pain and the fear that they go through, dealing with it."
Adapting and building resilience	Establishing a new normal	"So it does depress you, it does do some things with you, but I'm still here, and my new normal is, I have to do dialysis. My new normal is, I have to have shots."
	Drawing hope and support from family	"I think if I hadn't have had supportive people around me at that stage and also being strong in myself, I could've gone no, bugger it, why go through this, why do dialysis every day, why put up with it."
	Relying on faith and hope for motivation	"I'm a strong believer in the Bible, so that gives me a foundation of hope."
	Finding meaning in other activities	"I notice for a caregiver that you have to make her happy. Sometimes I go to things, and it's a party...luau. I take them with me. That's the most happiest thing even if it's two hours just to be there and come back home."

TH-OR095

The Effect of Non-Visual Learning Preferences on Early Home Dialysis Adverse Events

Bourne L. Auguste,[2,1] Michael Y. Girsberger,[3,1] Claire Kennedy,[3,1] Thatsaphan Srithongkul,[3] Margaret E. McGrath-Chong,[3] Joanne M. Bargman,[3,1] Christopher T. Chan.[3,1] *[1]University of Toronto, Toronto, ON, Canada; [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [3]Toronto General Hospital, University Health Network, Toronto, ON, Canada.*

Background: Current approaches to home dialysis training are not individualized according to patients' learning preference. We hypothesize that visual learning preferences were associated with fewer adverse events in both peritoneal dialysis (PD) and home hemodialysis (HHD) patients within 6 months of training completion.

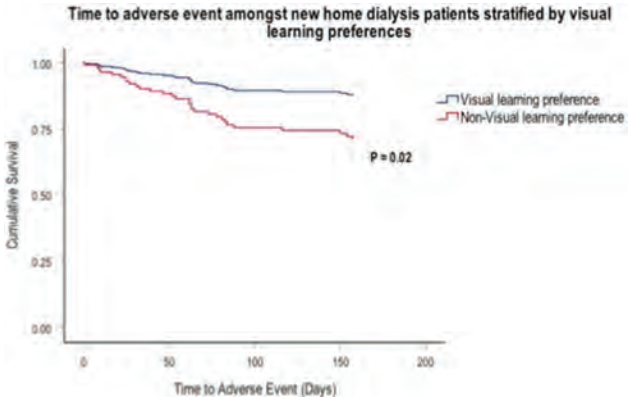
Methods: We performed a retrospective single centre cohort study at a large academic medical centre of prevalent HHD and PD patients. Patients received a VARK questionnaire at enrollment. VARK is a validated questionnaire that assesses a combination of individual learning preferences: visual (V), auditory (A), reading-writing (R) and Kinesthetic (K). Adverse events were defined as peritonitis, exit-site and tunnel infection, contamination episodes, access disruption along with needle dislodgement. We performed logistic regression analysis to determine the odds ratio of a single adverse event. We also performed multivariate cox regression analysis, adjusted for age, gender, modality, visual impairment, dialysis vintage, training duration and level of education.

Results: We enrolled 118 (78 HHD and 40 PD) patients with an average age of 52.0 ± 13.5 years. 38% (44) of study participants were non-visual learners. Thirty patients had at least one adverse event within 6 months of training completion; 63% (19) of these patients were non-visual learners. Non-visual learners were 4 times more likely to an adverse event, occurring sooner after training completion compared to visual learners (Table 1 & Figure 1).

Conclusions: Visual learning preference is associated with fewer adverse events in home dialysis patients within the first 6 months of completing training. Individualization of home dialysis training by learning preference is warranted.

Adverse Events

	Number of Patients N (%)	*Age (yrs,) mean ± SD*	*Weeks of Training mean ± SD*	*Patients with Any Adverse Event*	*Unadjusted OR*	*Adjusted OR*
Visual Learners (VARK, VAR, VAK, VRK, VK, VR, V)	*74 (63)*	*55.5 ± 14.4*	*6.6 ± 5.1*	*11 (36.7%)*		
Non-Visual Learners (ARK, AR, AK, K, R, RK)	*44 (37)*	*52 ± 14*	*6.2 ± 5.5*	*19 (63.3%)*	*4.35 (1.82-10.44) P = 0.001*	*4.04 (1.44 – 11.34) P= 0.008*



TH-OR096

Short-Term Gaps in Insurance Lead to Long-Term Disparities in Peritoneal Dialysis Use

Eugene Lin,[2] Glenn M. Chertow,[1] Jay Bhattacharya,[4] Darius Lakdawalla.[3] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]Internal Medicine - Nephrology, Keck School of Medicine of USC, Los Angeles, CA; [3]University of Southern California, Los Angeles, CA; [4]Stanford University, Stanford, CA.*

Background: Peritoneal dialysis (PD) offers improved quality of life over hemodialysis without compromising health outcomes. Uninsured patients do not become Medicare eligible until the first day of the fourth month of treatment. Using a quasi-experimental method, we studied whether short-term gaps in insurance were associated with long-term disparities in PD use.

Methods: Because Medicare eligibility starts on the first day of the fourth month of dialysis, patients starting dialysis at the end of the month have a shorter Medicare waiting period than patients starting dialysis at the beginning of the month. After identifying uninsured adults starting dialysis between 1/1/2006 and 12/31/2014 in the United States from a national registry, we studied whether starting dialysis at the end of the month was associated with higher PD use at day 360 than starting at the beginning of the month. Using two-stage least squares regression, we investigated whether gaps in insurance were associated with long-term disparities in PD use.

Results: The distribution of dialysis start day was distributed randomly (one-sample Kolmogorov-Smirnov, $p>0.05$). Patients starting dialysis in the first half of the month had a 10.7% (95% CI: 10.2-11.1%) probability of using PD at 360 days, while those starting in the last half of the month had an 11.8% (95% CI: 11.3-12.1%) probability (difference: 1.1% [0.5-1.7%]). Patients starting dialysis on the 31st had a 2.3% (95% CI: 1.1-3.5%) higher probability of PD use at day 360 than those starting on the 1st. Our second-stage regression showed that every 10 day gap without insurance was associated with a 1.0% (95% CI: 0.5-1.5%) absolute decrease in PD use at day 360. We projected that eliminating the Medicare waiting period entirely could increase the probability of long-term PD use in patients without insurance, from 11.2% to 19.8% (95% CI: 16.3, 23.3%).

Conclusions: Patients starting dialysis later in the month have shorter Medicare waiting periods and are more likely to use PD long-term. We exploited this difference to show that that longer periods of time without insurance lead to persistent decreases in PD use. Extending Medicare coverage to the first three months of dialysis or earlier could substantially improve PD penetration.

Use of Machine Learning to Inform Decision Making and Optimal Renal Replacement Therapy

Xiaoyan Wang,[1] Ollie Fielding,[1] Edward M. Lee,[1] Jung Hoon Son,[1] Chris Kipers,[1] Lauren A. Wiener,[1] Frank Liu,[2] Andrew Bohmart,[2] Jeffrey I. Silberzweig.[2] The PEAK team *[1]pulseData, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: We deployed a machine learning (ML) model to identify patients at risk of requiring RRT to support clinical care decision making in a multidisciplinary care (MDC) team. We compare the difference in optimal renal replacement therapy (RRT) starts pre and post implementation. To the knowledge of the authors, this is the first live application of ML to inform transition workflows.

Methods: An EHR database of 110,998 patients was used to create an ML model to predict progression to an eGFR <10 or RRT start in the next six months (see Kidney Week 2018 SA-PO953). The system calculates weekly risk scores for non-dialysis patients with an eGFR <35. For high risk patients an alert is sent to the patient's nephrologist suggesting prompt referral to the PEAK MDC team. The team reviews high risk patients and provides education to inform their decision making. Optimal dialysis starts were defined as outpatient starts with access via AV fistula, AV graft, or peritoneal dialysis catheter.

Results: Since deployment of the ML model in October 2018, 54% of patients enrolled in PEAK had an optimal dialysis start. This is almost three times the national average of 20% (USRDS 2018 data) and 14% better than the 47.3% rate prior to use of the ML model. PEAK home dialysis rates have increased 20% vs. before deployment (24% vs 20%), and is now eight times the NYC average 24% vs 2.5%. PEAK members also received pre-emptive transplants at a rate five times the NYC average 12.5% vs 2.5%. PEAK patients with optimal starts had significantly greater provider interactions, as measured by unique appointment days prior to dialysis, than non-optimal starts (3.9 vs. 2.5 appointments, $p<0.0001$, unequal variances t-test). Optimal start patients are also associated with earlier enrollment, defined as the time from the first PEAK appointment to dialysis (329 vs. 179 days, $p<0.02$, unequal variances t-test).

Conclusions: The PEAK MDC-pulseData partnership has improved optimal dialysis starts and home dialysis modality rates by 14% and 22% respectively. Enrollment to the PEAK program has increased by 22% since Oct. 2018. Our results demonstrate that purpose-built AI tools used by an MDC team can increase optimal RRT outcomes.

Efficacy and Safety of the Standard and Reduced Apixaban Dose Compared with No Anticoagulation in Dialysis Patients with Newly Diagnosed Atrial Fibrillation

Thomas Mavrakanas,[1,2] Katherine Garlo,[1] David M. Charytan.[3,1] *[1]Division of Nephrology, Brigham & Women's Hospital, Harvard Medical School, Boston, MA; [2]Department of Medicine, Geneva University Hospitals, Geneva, Switzerland; [3]New York University School of Medicine, Bronx, NY.*

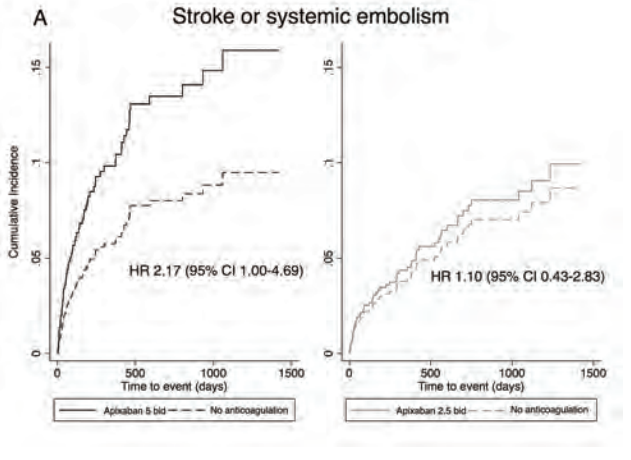
Background: The relative efficacy and safety of apixaban compared with no anticoagulation for atrial fibrillation (AF) has not been studied in dialysis patients.

Methods: This retrospective cohort study utilized 2012-2015 United States Renal Data System data. Dialysis patients with incident, non-valvular AF treated with apixaban (521 patients) were matched for relevant baseline characteristics with patients not treated with any anticoagulant agent (1561 patients). Competing risk survival models were used.

Results: Compared with no anticoagulation, apixaban was not associated with reduced risk of stroke or thromboembolism: HR 1.23, 95% CI 0.68-2.20, p=0.49. A significantly higher incidence of fatal or intracranial bleeding was observed with apixaban compared with no treatment: HR 2.48, 95% CI 1.25-4.90, p=0.009. A higher rate of stroke or systemic thromboembolism (**Figure**) and fatal or intracranial bleeding was seen in the subgroup of patients treated with the standard apixaban dose (5 mg twice daily) but not with the reduced apixaban dose (2.5 mg twice daily). A similar incidence of clinically significant bleeding events and major cardiovascular events was seen with apixaban compared with no treatment.

Conclusions: Randomized studies are needed to assess the efficacy of apixaban compared with no anticoagulation in chronic dialysis. Awaiting randomized data, prudence in prescribing apixaban to dialysis patients, especially at the standard dose, is warranted. Disclaimer The data reported here have been supplied by the United States Renal Data System (USRDS). The interpretation and reporting of these data are the responsibility of the authors and in no way should be seen as official policy or interpretation of the US government.

Funding: Private Foundation Support



Stroke or systemic embolism in patients treated with the standard and the reduced apixaban dose compared with no anticoagulation.

TH-OR099

Rivaroxaban vs. Warfarin for Prevention of Ischemic Stroke/Systemic Embolism (ISSE) in Patients with Non-Valvular Atrial Fibrillation (NVAF) and Stage 4-5 CKD

Matthew R. Weir,[1] Veronica Ashton,[2] Eric M. Ammann,[3] Kenneth T. Moore,[4] Shubham Shrivastava,[3] Eric D. Peterson.[5] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Janssen Scientific Affairs, Titusville, NJ; [3]Mu Sigma, Bangalore, India; [4]Janssen Medical Affairs, Titusville, NJ; [5]Duke University School of Medicine, Durham, NC.*

Background: There is limited evidence on the effectiveness and safety of direct-acting oral anticoagulants (DOACs) among patients with NVAF and advanced CKD. This study compared the risks of ISSE and major bleeding in patients with NVAF and stage IV-V CKD treated with rivaroxaban or warfarin.

Methods: Using data from the Optum Deidentified Electronic Health Record (EHR) Database, we selected patients with NVAF and stage IV-V CKD who initiated therapy with rivaroxaban or warfarin from November 1, 2011 through June 30, 2018. Selected patients were required to both be diagnosed with CKD and have an estimated creatinine clearance <30 mL/min and/or evidence of dialysis. Propensity score (PS) matching was used to balance rivaroxaban and warfarin patients on 97 measured baseline covariates. Hospitalizations for ISSE and major bleeding over 2 years following treatment initiation were ascertained with validated endpoint definitions. Outcomes were analyzed as time-to-event data using Kaplan-Meier survival estimators and Cox regression.

Results: 781 rivaroxaban patients were PS-matched to 1,536 warfarin patients; after matching, all baseline covariates were well balanced (absolute standardized difference<0.1). The mean patient age was 80 years; 62% were female; 82% and 18% had CKD stage IV and V, respectively. The relative hazard (HR) of ISSE associated with rivaroxaban use compared to warfarin use was 0.93 (95% CI: 0.46, 1.90; p=0.85), and the corresponding HR for major bleeding was 0.91 (95% CI: 0.65, 1.28; p=0.91).

Conclusions: No statistically significant difference in the risk of ISSE or major bleeding was found between patients treated with rivaroxaban or warfarin. While further study is needed, rivaroxaban appears to be a reasonable alternative to warfarin for ISSE prevention in the setting of NVAF and stage IV-V CKD.

TH-OR100

Effect of Evolocumab, an Anti-PCSK9 Antibody, on Vulnerable Coronary Plaque in CKD Patients Taking Statins

Keiji Hirai,[1] Shigeki Imamura,[2] Aizan Hirai,[2] Susumu Ookawara,[1] Yoshiyuki Morishita.[1] *[1]Saitama Medical Center, Jichi Medical University, Saitama, Japan; [2]Chiba cerebral and cardiovascular center, Chiba, Japan.*

Background: Coronary artery disease is a crucial complication in patients with chronic kidney disease (CKD). This study investigated the effects of evolocumab, a fully human monoclonal antibody against proprotein convertase subtilisin kexin type 9 (PCSK9), on vulnerable coronary plaques in CKD patients taking statins.

Methods: Vulnerable coronary plaques were defined by coronary computed tomography (CT) as having a density of <60 HU within the region of interest and remodeling index >1.1. Fifty-two CKD patients who had a vulnerable coronary plaque and who were taking stains (35 males, 17 females; mean age, 75.8 ± 7.0 years; mean estimated glomerular filtration rate, 51.4 ± 6.1 mL/min/1.73 m^2) were administrated evolocumab (140mg every two weeks) for 6 months. The change in 155 vulnerable coronary plaques from 52 CKD patients was evaluated before and after evolocumab administration. The changes in lipid metabolism were also evaluated.

Results: Evolocumab significantly increased the CT density (from 50.5 ± 9.9 HU to 102.4 ± 32.5 HU, p < 0.001) and reduced the remodeling index (from 1.28 ± 0.10 to 1.19 ± 0.09, p < 0.001) in vulnerable coronary plaques in CKD patients. Evolocumab also decreased low-density lipoprotein cholesterol (from 65.6 ± 22.2 mg/dL to 18.1± 11.8 mg/dL, p < 0.001), triglyceride (from 156.5 ± 172.3 mg/dL to 98.1 ± 61.4 mg/dL, p < 0.01), and lipoprotein (a) (from 23.9 ± 25.9 mg/dL to 14.5 ± 19.5 mg/dL, p < 0.001), and increased high-density lipoprotein cholesterol (from 52.5 ± 12.7 mg/dL to 57.8 ± 12.4 mg/dL, p < 0.001).

Conclusions: Evolocumab stabilized and reduced coronary vulnerable plaques and improved lipid metabolism in CKD patients taking stains. These results suggest that evolocumab has protective effects against coronary artery disease progression in CKD patients taking statins.

TH-OR101

Changes in eGFR After Left Ventricular Assist Device Implantation

Bethany Roehm, Lesley Inker, Amanda Vest, Hocine Tighiouart, Daniel E. Weiner. *Tufts Medical Center, Boston, MA.*

Background: Patients with advanced heart failure have a one-year survival of 25% which increases to more than 80% with left ventricular assist device (LVAD) support. Lower glomerular filtration rate (GFR), generally <30 ml/min/1.73m^2, is a relative contraindication to LVAD implantation. However reduced GFR may be secondary to decreased kidney perfusion that may improve after LVAD implantation. Our goal was to investigate kidney function following LVAD implantation.

Methods: We evaluated the change in eGFR among all patients at Tufts Medical Center who received an LVAD between 2010 and 2018 from baseline to 6 months, 1 year, and 2 years after implantation. Primary outcome was increase or decrease in eGFR by 30% or more, death on LVAD support, or heart transplantation, which were examined overall and by baseline eGFR category (>60, 30-59 and <30 ml/min/1.73m^2).

Results: Among 288 patients, mean baseline eGFR was 62 ±23 ml/min/1.73m^2. There were 144 patients with baseline eGFR ≥60, 122 with eGFR 30-59, and 22 with eGFR <30 ml/min/1.73m^2. Most LVAD recipients had an increase in eGFR or remained stable (Figure), and none with an eGFR <30 had a decline in eGFR. Death was also common, particularly in those with an eGFR<60. Among those with eGFR ≥60, 23% died within two years compared to 40% for those with eGFR <60 (p=0.004).

Conclusions: Substantial decreases in eGFR are rare in patients following LVAD implantation, even among patients with lowest baseline eGFR. One-year survival for patients with lower baseline eGFR is low, but remains better than reported one-year survival among LVAD eligible patients who do not receive LVAD support. Carefully selected patients with lower eGFR should not necessarily be excluded from receiving LVADs for treatment of heart failure.

Funding: Other NIH Support - NIH T32 grant

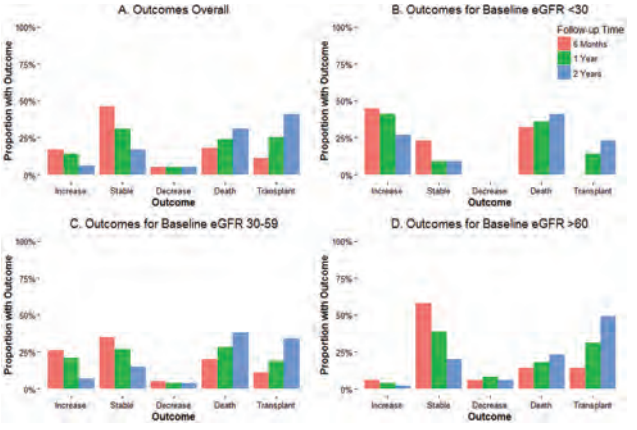

Figure: Outcomes over time post LVAD. Increase and decrease are defined as 30% increase or decrease in eGFR at follow-up.

Predictors to Identify Diuretic Resistance Early in Acute Decompensated Heart Failure (ADHF)

Shweta Bansal,[1,2] Kristina M. Munoz,[3] Sonja D. Brune,[4] Anand Prasad,[4] Chakradhar Velagapudi.[1] *[1]University of Texas Health at San Antonio, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX; [3]Central Michigan University College of Medicine, Mount Pleasant, MI; [4]UT Health San Antonio, San Antonio, TX.*

Background: Resistance to loop-diuretics occurs frequently in patients hospitalized for ADHF, resulting in inadequate decongestion, readmission and poor outcomes. Early identification of diuretic resistance during the hospital course may avoid delay in institution of appropriate therapies. We aimed to identify clinical biomarkers that predicted diuretic resistance in a study conducted to evaluate usefulness of high-dose spironolactone in loop-diuretic resistant ADHF patients.

Methods: The parent trial was a prospective, non-randomized trial in ADHF patients. Diuretic resistance was identified if subjects had weight loss<1lb/day despite intravenous furosemide>160mg/day (at least one dose of 80mg/day) or no change in dyspnea 48H after admission with usual care. Baseline clinical characteristics, blood chemistry including neurohormones and urine electrolytes were compared between diuretic-responsive and resistant subjects.

Results: Twenty of 47 enrolled subjects met loop-diuretic resistance criteria. The mean age was 61±15 yrs, 60% were male, and 50% were Hispanic. There was no difference in age, gender and race, co-morbidities, sign and symptoms of hypervolemia, renal function, EF%, presence of pulmonary HTN between diuretic-responsive and resistant subjects. However, serum sodium was lower (137[134,139] vs. 139[137,141]meq/L, p<0.03) and blood urea nitrogen was higher (11.42[7.60,3.18] vs. 7.68[5.71,8.92]mmol/l, p=0.009) in diuretic resistant compared to responsive subjects. Diuretic-resistant subjects had higher plasma renin activity (7.2[1.5,29.5] vs. 2[0.2,10.9]ng/ml/hr, p=0.03) and aldosterone (26.5[9.9, 56] vs. 5.2[3.7, 8.2] ng/dL, p<0.001), and lower urine sodium-potassium

ratio (2.63±1.2 vs. 8.2±4.8, p<0.001). Plasma aldosterone had an inverse relationship with urine sodium-potassium ratio and (r=-0.46, p=0.003), but not with serum sodium or urea nitrogen. Urine sodium-potassium ratio at admission predicted loop-diuretic resistance with an AUC (95%CI) 0.69 (0.68, 0.71). A cutoff value of 2.96 had a sensitivity of 76% and specificity of 65% to identify loop-diuretic resistance (lower the value, more the resistance).

Conclusions: The admission urine sodium-potassium ratio may serve as a surrogate for high aldosterone activity, and is an inexpensive and rapidly available biomarker to recognize diuretic resistance in ADHF patients.

Incorporating Kidney Disease Measures into Cardiovascular Risk Prediction: Evaluation Using Electronic Health Record Data from 37 Health Care Organizations

Nikita Stempniewicz,[1] Yingying Sang,[2] Kunihiro Matsushita,[2] Elizabeth Ciemins,[1] Shoshana Ballew,[2] Morgan Grams,[3] John K. Cuddeback,[1] Josef Coresh.[4,2] *[1]AMGA (American Medical Group Association), Alexandria, VA; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD.*

Background: Clinical guidelines for the primary prevention of atherosclerotic cardiovascular disease (ASCVD) increasingly use absolute risk to guide decision-making, often relying on the AHA/ACC Pooled Cohort Equation (PCE) for risk estimation. Two kidney measures, estimated glomerular filtration rate (eGFR) and urine albumin-to-creatinine ratio (uACR), are CVD risk enhancers but they are not included in the PCE. We hypothesize that when eGFR and uACR data are available, their inclusion will meaningfully enhance ASCVD risk assessment.

Methods: 836,047 patients in the OptumLabs® Data Warehouse's EHR-derived data with no evidence of baseline ASCVD and data on PCE variables plus eGFR and uACR, from 37 health care organizations (HCOs) were followed (mean (SD), 3.6 (2.4) years) for EHR evidence of ASCVD events (myocardial infarction and stroke). We developed a " CKD patch" to add eGFR and ACR data to the existing PCE.

Results: Patients were age 59 (10) (mean (SD)) years, had total cholesterol 175 (35) mg/dL, HDL 45 (15) mg/dL, SBP 128 (16) mmHg, eGFR 81 (21) ml/min/1.73 m^2, and uACR 10 (2-29) mg/g (median (IQR)), 51% were female, 74% had diabetes, and 4.5% were smokers. The original PCE predicted a 5-year risk of 8.4%, and observed rate of ASCVD was 4.2%. Adding eGFR and ACR to PCE improved the C-statistic by 0.022 (95% CI 0.020-0.024) overall, 97% of HCOs (36 of 37) improved by ≥ 0.01. Overall, reclassification of 5-year ASCVD risk from low (< 3.75%) to intermediate (3.75%–9.9%) risk and intermediate to high risk (≥ 10%) was 5.1% (range by HCO: 3.0–8.9%) and 6.2% (4.1 – 10.9%), respectively. ASCVD reclassification rates were higher with higher CKD risk (intermediate to high ASCVD risk: 2.6% at no CKD, 11.9% at intermediate-risk CKD, 15.8% at high-risk CKD and 20.4% at very high-risk CKD). Recalibrating PCE in each HCO prior to adding kidney measures yielded similar results.

Conclusions: CKD measures (eGFR and uACR) are often available, and their integration into the PCE is feasible and results in meaningful risk reclassification across HCOs, particularly among higher risk CKD. Implementation in EHRs should include rigorous validation, attending to limitations, e.g., EHRs are blind to events occurring outside the HCO.

TH-OR104

Trends in Hypertension Control in Those with and Without CKD in the United States: 1999-2016

Priya Vart,[1] Sri Lekha Tummalapalli,[2] Neil R. Powe,[3] Jennifer L. Bragg-Gresham,[6] Rajiv Saran,[6] Nilka Rios Burrows,[4] Sharon Saydah,[4] Deidra C. Crews.[5] CDC CKD Surveillance Team *[1]Radboud University, Nijmegen, Netherlands; [2]University of California San Francisco, San Francisco, CA; [3]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA; [4]Centers for Disease Control and Prevention, Atlanta, GA; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]University of Michigan, Ann Arbor, MI.*

Background: We examined temporal trends in hypertension (HTN) control overall and in those with and without CKD.

Methods: A total of 19,856 adults (≥20 years) with HTN from NHANES 1999-2000 to 2015-2016 were examined. HTN was defined as mean systolic blood pressure (BP) ≥130 or mean diastolic BP ≥80 or anti-hypertension medication use. HTN control was defined as BP <130/80 mmHg among hypertensives (as defined above). Age, sex and race adjusted estimates were obtained using logistic regression analysis. Restricted cubic splines were used to flexibly model trends over time, with predefined knots at 2004, 2008, and 2012. We tested the combined interaction of spline terms with reduced eGFR (<60 ml/min/1.73m^2) and elevated albuminuria (ACR ≥30mg/g), separately.

Results: HTN control improved overall between 1999-2000 and 2015-2016, from 9.1% to 25.2% (p<0.001). Greater improvement in HTN control was observed in the period from 1999-2000 to 2007-2008 (12.5%, p<0.001), than thereafter (3.5%, p=0.08). The temporal trend in HTN control differed by reduced eGFR status (p for interaction=0.02). HTN control was comparable in individuals with reduced and non-reduced eGFR until 2007-2008 and thereafter control improved more in those with reduced eGFR (Fig.1A). Difference in HTN control between those with and without reduced eGFR was -2.0% in 1999-2000 (p=0.07), 1.4% in 2007-2008 (p=0.4) and 7.0% in 2015-2016 (p=0.06). The temporal trend in HTN control by albuminuria status was similar to the overall trend (p for interaction=0.5) (Fig.1B). Persons with albuminuria had lower HTN control throughout. Difference in HTN control between those with and without albuminuria was -4.5% in 1999-2000 (p<0.001), -5.9% in 2007-2008 (p<0.001) and -8.5% in 2015-2016 (p=0.001).

Conclusions: Overall, improvement in HTN control has slowed in the last ten years, particularly among persons without reduced eGFR. Those with and without albuminuria experienced a similar trend in HTN control, though HTN control remained consistently lower in persons with albuminuria

White-Coat Hypertension Has a Predictive Role for Renal Outcome in Patients with Non-Dialysis CKD: Results from the C-STRIDE Study

Qin Wang, Jinwei Wang, Yu Wang, Luxia Zhang, Ming Hui Zhao. *Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China.*

Background: Data on the predictive value of white-coat hypertension (WCH) for renal and cardiovascular (CV) outcomes in patients with chronic kidney disease (CKD) is controversial.

Methods: Totally, 1734 CKD stage 1-4 patients with both ambulatory BP (ABP) and clinic BP (CBP) data from the Chinese Cohort Study of Chronic Kidney Disease (C-STRIDE) were enrolled in the present study. The BP pattern was categorized as normotension(NT), WCH, masked hypertension (MH) and sustained hypertension (SH) according to ABP and CBP values, respectively. The association of BP pattern with CKD outcomes, including initiation of renal replacement therapy and CV events, was evaluated by Cox regression model.

Results: The mean age of the cohort was 48.8±13.7 years with 43.2% females. The average value of ABP and CBP were 128±17/79±11mm Hg and 130±18/81±10mm Hg, respectively. And NT, WCH, MH and SH each had 678(39.1%), 83(4.8%), 538(31%) and 435(25.1%) patients. During a median follow-up of 4.7 years, 287 renal events and 128 CV events occurred, respectively. Compared with NT, the fully adjusted risk for renal events was significantly increased in WCH(hazard ratio [HR] 2.43; 95% confidence interval [CI] 1.38-4.31), MH (HR 2.42; 95%CI 1.66-3.50), and SH (HR 2.56; 95%CI 1.75-3.74), respectively. With regard to CV events, WCH, MH and SH also showed higher risk after adjusting for traditional CV risk factors (HR 2.53, 95%CI 1.21-5.29; HR 1.85, 95%CI 1.13-3.01; HR 2.63, 95%CI 1.63-4.25, respectively). After further adjusting baseline logarithm transformed 24h-urinary protein and estimated glomerular filtrationrate, only SH showed a significantly increased risk for CV events (HR 1.81; 95%CI 1.10-2.99).

Conclusions: WCH is independently associated with an increased risk for renal events in non-dialysis CKD patients.

TH-OR106

PRN Use of Antihypertensive Medications and Adverse Renal Outcomes: A Propensity Score-Matched Analysis

Rajesh Mohandas,[1,2] Shahab Bozorgmehri,[1] Gajapathiraju Chamarthi,[1] Ashutosh M. Shukla,[2,1] Rupam Ruchi,[1] Tezcan Ozrazgat-Baslanti,[1] Amir Kazory,[1] Azra Bihorac,[1] Mark S. Segal.[2,1] *[1]University of Florida, Gainesville, FL; [2]Renal Section, Gainesville VA Medical Center, Gainesville, FL.*

Background: Despite absence of data demonstrating a clear benefit, hospitalized patients are often treated with PRN antihypertensive medications (PRNBPMeds) for asymptomatic increases in blood pressure. We hypothesized that use of PRNBPMeds can be associated with abrupt lowering of blood pressures (BP) and worsening renal function.

Methods: Single center retrospective study of all adult patients admitted between Jan 2012 and April 2016 who received antihypertensive medications. We excluded those with possible hypertensive emergency, end stage renal disease and acute kidney injury (AKI) on admission. Patients who received PRN and scheduled antihypertensive medications were matched (1:1) by propensity scores which included systolic blood pressure on admission, demographic factors and comorbidities. Outcomes of interest were abrupt decrease in blood pressure, defined as >25% decrease in systolic blood pressures (SBP) within one hour of administration of PRN or scheduled medications and AKI.

Results: Mean age was 62±16 years. 52% were females, and 68% Caucasian. 82% of patients had hypertension. PRNBPMeds were used in 4,850 (13%) out of a total of 37,145 admissions. 93% of these patients had scheduled and PRN medications while 7% received PRNBPMeds alone. The propensity score-matched cohort included 3,707 patients each in the PRNBPMeds and scheduled antihypertensive groups. The abrupt decrease in SBP rates

were 11.6% and 3.5% for PRN and scheduled medications groups, respectively, (p<0.001). The AKI occurrence rates were 14.7% and 11.6% for PRN and scheduled medications groups, respectively, (p<0.001). Using the propensity score-matched analysis, the use of PRN medications was associated with 138% increased risk of abrupt decrease in SBP (OR, 2.38 [95%CI, 1.74-3.26]; p<0.001), and 29% increased risk of AKI (OR, 1.29 [95%CI, 1.13-1.47]; p<0.001).

Conclusions: To our knowledge, this is the first propensity-scored matched analysis of PRN vs scheduled antihypertensive medications. Our results suggest that use of PRNBPMeds is associated with increased risk of abrupt BP lowering and AKI. Pragmatic randomized controlled trials are required to assess the risk benefit of treating asymptomatic increases in BP in hospitalized patients.

TH-OR107

Resistant Hypertension Potentiates the Risk of ESRD in African Americans in the Million Veteran Program (MVP)

Elvis A. Akwo,[2] Cassianne Robinson-Cohen,[2] Peter W. Wilson,[5] Christopher J. O'Donnell,[4] Todd L. Edwards,[2] Csaba P. Kovesdy,[3] Adriana Hung.[1] *[1]VA & Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of Tennessee Health Science Center, Memphis, TN; [4]Boston Veterans Administration, Boston, MA; [5]Emory University, Atlanta, GA.*

Background: African Americans (AAs) are 4 times as likely as Whites to develop ESRD. Resistant hypertension (RH), a severe form of hypertension (HTN) is associated with increased risk of cardiovascular (CV) and renal outcomes. We investigated how ESRD risk is modified by race.

Methods: We designed a retrospective cohort of 240,038 veterans with HTN, enrolled in the MVP with a GFR >30 ml/min. The primary exposure was incident RH (time-varying). The primary outcome was incident ESRD during a 13.5 yr follow up: 2004-2017. Secondary outcomes were myocardial infarction (MI), stroke, and death. Incident RH was defined as failure to achieve outpatient BP <140/90 mmHg with 3 anti-HTN drugs, including a thiazide, or use of ≥4 drugs, excluding BPs when pain score was >5, when interfering medications or secondary HTN were present. Poisson models were used to estimate incidence rates (IR) and test biologic interaction with race. Cox (and competing-risks) models were used to identify independent effects.

Results: Median age was 60 yrs; 20% were African American and 6% were women with 23,385 incident RH cases (9.7%). RH patients had higher IR (per 1000 PY) of ESRD (4.5 vs. 1.3), MI (6.5 vs 3), stroke (16.4 vs 7.6) and death (12 vs 6.9) than non-resistant HTN (NRH). In Cox models adjusted for traditional CV risk factors; RH patients had a 2.0, 1.67, 1.9 and 1.14-fold higher risk of ESRD, MI, stroke, and death, respectively. In Poisson models, AAs with RH had a 2.5-fold higher risk of ESRD compared to AAs with NRH; 3-fold the risk of Whites with RH, and 9-fold the risk of Whites with NRH [p-interaction < 0.01].

Conclusions: RH was associated with a higher risk of ESRD (and CV outcomes), especially in AAs. Interventions (behavioral, drug choices) that improve reaching BP targets in RH patients, could have a major impact on ESRD incidence in this high-risk population, particularly in AAs.

Relationship Between Treatment Effects for Proteinuria and eGFR Slope over 2 Years in Patients with IgA Nephropathy

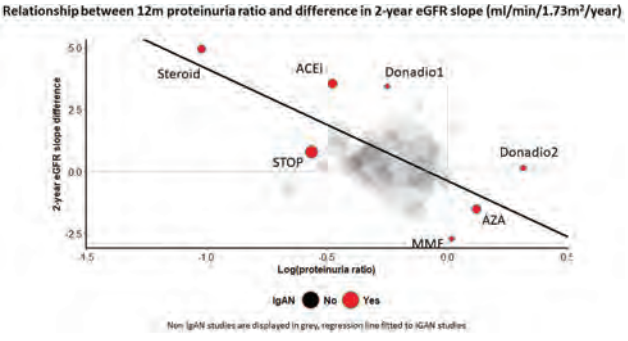
Andrew M. Stone,[1] Daniel C. Cattran,[2] Jürgen Floege,[3] Richard A. Lafayette,[4] Vladimir Tesar,[5] Hernan Trimarchi,[7] Brad H. Rovin,[6] Jens Kristensen,[8] Jonathan Barratt.[9] *[1]Stone Biostatistics Ltd, Crewe, United Kingdom; [2]Toronto General Hospital, Toronto, ON, Canada; [3]RWTH University of Aachen, Aachen, Germany; [4]Stanford University, Stanford, CA; [5]General University Hospital in Prague, Prague, Czechia; [6]Ohio State University Wexner Medical Center, Columbus, OH; [7]Hospital Britanico de Buenos Aires, Buenos Aires, Argentina; [8]Calliditas Therapeutics AB, Stockholm, Sweden; [9]University of Leicester, Leicester, United Kingdom.*

Background: A challenge for evaluating treatments for IgA nephropathy (IgAN) is the usually long time course for progression to ESKD. Recent meta-analyses have separately explored the role of proteinuria reduction and the rate/slope of eGFR decline as surrogate endpoints. In this meta-analysis we describe the relationship between treatment effects on proteinuria, recorded at 1 year, and 2-year eGFR (CKD-EPI) slope.

Methods: Study level data from 1037 patients in 12 IgAN studies, aggregated into 7 study groupings, were obtained from the databook provided at the March 2018 NKF/FDA/EMA workshop. A weighted linear regression was performed to quantify the relationship between baseline adjusted treatment effects for proteinuria, expressed as the log of the ratio of geometric means, and treatment effects for total 2-year eGFR slope, expressed as the difference in arithmetic means. Studies were weighted in inverse proportion to the variance of the 2-year eGFR slope treatment effect.

Results: There was a statistically significant association seen between treatment effects for proteinuria at 12 months and treatment effects for 2-year eGFR slope for the IgAN studies, p=0.043. On average, the between arm, annualized difference in the rate of decline in eGFR was estimated to increase by 4.53 ml/min/1.73m²/year (95%CI: 0.21, 8.84) for every 1 log (63%) reduction in the proteinuria treatment arm ratio.

Conclusions: In IgAN treatment effects on 12m proteinuria are reasonably likely to predict subsequent treatment differences in the rate of decline in eGFR over 2 years.



TH-OR109

Change in Proteinuria as a Surrogate End Point for GFR Slope: Individual Patient Meta-Analysis of 12 Randomized Clinical Trials in IgA Nephropathy

Lesley Inker. Chronic Kidney Disease-Epidemiology (CKD-EPI) Collaboration *Tufts Medical Center, Boston, MA.*

Background: A recent study demonstrated associations between treatment effects on urine protein (UP) and clinical endpoint (i.e. ESKD). Reasonably likely surrogate endpoints can be used as a basis for accelerated or conditional approval of therapies intended to treat serious or life-threatening conditions, such as IgAN. The clinical benefit of products approved under this program would need to be verified in a post-marketing confirmatory trial. For patients with IgAN, endpoints to such confirmatory trials may be GFR slope given the low likelihood of sufficient clinical endpoints.

Methods: Using a pooled dataset of 990 participants from 12 studies, we computed change in UP from baseline to 6 months (25th,75th 5.9, 6.9 month), and the GFR slope from randomization to 1, 2, and 3 years (total slope[TS]) as well as after excluding the initial 3 months after randomization (chronic slope[CS]). We performed Bayesian mixed models to relate the treatment effects on change in UP to GFR slope and to those on the clinical endpoint (CE), defined as ESKD, eGFR<15 or doubling of creatinine.

Results: Figure shows associations of treatment effects on change in UP compared to that of TS at 3 years and CS. Slopes are significant and intercepts are nonsignificant, supporting strong trial level associations. For TS, associations are consistent at 2 years [R^2 0.62 (0.01, 0.96)]. In sensitivity analyses, similar associations were noted for CS computed using truncated data with follow-up time of 18-24 months and when computing change in UP at 9 and 12 months. Associations between treatment effects on TS and CS to the clinical endpoint are very strong (e.g. TS 3 years R^2 0.99 (95% CI 0.28, 1.00)).

Conclusions: Our results suggest that treatment effects on early changes in UP confirmed by treatment effects on GFR slope might be a useful strategy for evaluation of treatment benefit in IgA.

The Clinical Utility of Immunosuppression Treatment Decisions Based on Personalized Risk Assessment from the International IgA Nephropathy Prediction Tool

Sean Barbour,[1] Mark Canney,[1] Rosanna Coppo,[6] Hong Zhang,[5] Yusuke Suzuki,[3] Dilshani Induruwage,[4] Heather N. Reich,[2] Daniel C. Cattran.[2] International IgA Nephropathy Network *[1]University of British Columbia, Vancouver, BC, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Juntendo University School of Medicine, Tokyo, Japan; [4]BC Provincial Renal Agency, Vancouver, BC, Canada; [5]Peking University First Hospital, Beijing, China; [6]Fondazione Ricerca Molinette, Torino, Italy*.

Background: The KDIGO guidelines recommend risk-stratifying patients with IgA nephropathy (IgAN) based on proteinuria ≧1g/day to guide immunosuppression treatment decisions. Because this approach does not accurately discriminate the risk of disease progression, we evaluated whether treatment decisions could be improved by using individual risk assessment from the International IgAN Prediction Tool, which estimates the 5-year risk of a 50% decline in eGFR or ESRD.

Methods: We used a net benefit and net reduction in treatment analysis, which for any given threshold probability of disease progression (P_t) balances correct decisions to give or withhold immunosuppression accounting for the relative harm to patients from incorrect decisions. In a multi-ethnic cohort of 3299 adults with biopsy-proven IgAN (median follow-up 5.1 years), decision rules for immunosuppression treatment were created based on proteinuria ≧1g/day or based on the Prediction Tool (predicted risk ≥P_t). The net benefit and reduction in treatment were calculated for all P_t from 0 to 1.

Results: Using proteinuria ≧1g/day to make treatment decisions was net harmful to patients for P_t ≥0.18 (Fig A). Compared to using proteinuria, decisions using the Prediction Tool had a larger net benefit and net reduction in treatment for P_t ≥0.09 and ≧0.08 (Fig B, C, D), and more accurately allocated or withheld immunosuppression in up to 23.4% and 35.1% more patients respectively.

Conclusions: These results demonstrate the benefit to patients from a precision-medicine approach to immunosuppression treatment using individual risk of disease progression from the International IgAN Prediction Tool instead of a single generic categorization of proteinuria.

Serum and Urine Biomarkers Related to Renal Fibrosis Predict Renal Outcome in Patients with IgA Nephropathy

Dita Maixnerova,[1] Nadja Sparding,[7] Michaela Neprasova,[2] Lenka Bartonova,[3] Eva Honsova,[8] Zdenka Hruskova,[4] Miloslav Suchanek,[5] Vladimir Tesar,[6] Federica Genovese.[7] *[1]Dept. of Nephrology, Prague, Prague, Czechia; [2]General Teaching Hospital in Prague, Dobris, Czechia; [3]Charles University, Prague, Czech Republic, Prague, Czechia; [4]Department of Nephrology, General University Hospital and First Faculty of Medicine, Charles University, Prague 2, Czechia; [5]University of Chemical Technology Prague, Prague, Czechia; [6]General University Hospital in Prague, Prague, Czechia; [7]Nordic Bioscience, Herlev, Denmark; [8]IKEM, Prague, Czechia*.

Background: IgA nephropathy (IgAN), the most common primary glomerulonephritis worldwide, has serious outcomes with end-stage renal disease developing in 30-50% of patients. Clinical predictors such as proteinuria, hematuria, hypertension as well as renal fibrosis may play a role in IgAN onset and/or progression. Here, we assessed serum and urine biomarkers related to renal fibrosis and histological findings in renal-biopsy specimens from patients with IgAN, ANCA associated vasculitis and compared with healthy controls.

Methods: We evaluated 46 patients with biopsy-proven IgAN, 45 patients with ANCA associated vasculitis, who were assessed at time of diagnosis for estimated glomerular filtration rate (eGFR), proteinuria, microscopic hematuria, hypertension, then followed prospectively and compared to 9 healthy controls (mean follow-up 51.8 months). Serum and urine samples collected at diagnosis were analyzed for biomarkers related to renal fibrosis using a novel enzyme-linked immunosorbent assay as well as histological evaluation of renal tissues at time of kidney biopsies were assessed. Linear discriminant analysis, logistic regression model and Kaplan-Meier (survival) analysis were used for statistic processing.

Results: We found serum and urine biomarkers such as EGF, PRO-C6, PRO-C3, which correlated with the level of histological fibrosis in kidney biopsies ($P<0.05$) and exactly predicted renal outcome of patients with IgAN ($P<0.05$). Moreover, addition of two other biomarkers such as serum LG1M and urine C3M completely differentiated patients with IgAN compared to patients with ANCA associated vasculitis and healthy controls (accuracy of classification 100 %).

Conclusions: In conclusion, serum and urine biomarkers related to renal fibrosis such as EGF, PRO-C6, PRO-C3 predicted renal outcome of patients with IgAN. Future studies are needed to validate these preliminary findings and to determine the power of these urinary and serum markers for assessment of responses to treatment.

TH-OR112

Association of IgM Deposition with Renal Outcomes in IgA Nephropathy: A Multicenter, Prospective, Observational Study

Li Tan,[1] Zhengxia Zhong,[2] Gaiqin Pei,[1] Wei Qin.[3] *[1]West China Hospital, Chengdu, China; [2]Affiliated Hospital of Zunyi Medical University, Guizhou, China, Guizhou, China; [3]West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

Background: The aim of this study was to investigate the relationships between co-deposition of IgM, clinicopathological features, and renal outcomes and whether IgM deposition is a novel marker for the response to patients with IgA nephropathy (IgAN).

Methods: A total of 1239 patients with primary IgAN diagnosed by renal biopsy were enrolled l from January 2013 to May 2018. The primary endpoint was the combined endpoint of a 50% decline in eGFR and/or ESRD. Responses to therapy included complete remission (CR), partial remission (PR), no response (NR) and ESRD. A 1: 1 propensity score matching (PSM) method was used to balance the covariates in all patients.

Results: Compared with IgM negative deposition(n=521), patients with IgM positive depositon (n=521) had higher level of Urine protein and higher proportion of M1, E1, C1/C2, deposition of IgG, C3, C4 and C1q (all P<0.05) at the time of biopsy. During the follow-up period (39.07±23.82 months), 76.39%, 60.08% patients in groups of IgM positive and negative deposition achieved CR or PR (P<0.001) respectively. According to Kaplan–Meier, renal survival rates in IgM negative and IgM positive groups were better both in unmacthed and matched cohort (both P<0.05). Furthermore, with 50% decline in eGFR and/or ESRD as the combined endpoint, multivariate Cox regression analysis of unmatched and matched cohort showed IgM deposition was an independent risk factors influencing renal survival.

Conclusions: IgM deposition in the glomerulus is associated with a poor renal outcome and severe pathologic features and did play a decisive role in renal progressio in IgAN patients.

TH-OR113

Analysis of 40-Year Prognosis of 1149 cases of IgA Nephropathy and Validation Study of Oxford Classification

Takahito Moriyama, Kosaku Nitta. *Tokyo Women's Medical University, Tokyo, Japan.*

Background: Half a century has passed since IgA nephropathy (IgAN) was firstly reported, however, very long term prognosis over 40 years has been unknown. In 2016, Oxford classification of IgAN was revised, and crescent formation was newly added. In this study, we showed 40 years prognosis of IgAN and validation study of Oxford classification in our cohort.

Methods: 1,149 IgAN patients diagnosed in our institution since 1974 were analyzed. At first, 40 years prognosis of whole cohort was analyzed. Then, 872 patients observed over 1 years and diagnosed by renal biopsy with more than 8 glomeruli were divided into two groups with or without immunosuppressant and evaluated about the Oxford classification.

Results: Renal survival rate of whole cohort was 86.8% in 10 years, 72.2% in 20 years, 58.2% in 30 years, and 49.9% in 40 years. In whole Oxford analysis cohort (n=872), only T lesion was related with 20 years renal prognosis (81.9 in T0, 58.7 in T1, and 34.7% in T2, P<0.0001). In group without immunosuppressant (n=416), 20 years renal survival rate was significantly higher in S0 than S1 (75.7 vs. 65.0%, P=0.04), in T0 than T1 and 2 (77.4 vs. 59.1 vs. 18.0%, P<0.0001), in C0 than C1+2 (71.9 vs. 60.1%, P=0.023), but not significant in M and E. In group with immunosuppressant (n=456), it was significantly higher in only T0 than T1 and 2 (87.3 vs. 55.7 vs. 54.7%, P<0.0001). Interestingly, survival rate in C1 (80.8%) was increased similar to C0 (76.6%) by immunosuppressant, but C2 was still low (58.8%). Multivariate Cox regression analysis showed lower eGFR and higher amount of proteinuria in every cohorts and T lesion in whole Oxford analysis cohort were independent risk factors. After propensity score matching (n=266/group), renal survival rate in group with immunosuppressant was significantly higher than without immunosuppressant (78.4 vs. 68.1%, p=0.0099), and it was also significantly higher than in M0 (83.0 vs. 70.1%, p=0.0277), E1 (85.2 vs. 65.1%, p=0.0051), S1 (80.0 vs. 63.5%, p=0.0031), T0 (91.6 vs. 81.6, p=0.003), T2 (62.5 vs. 0.0%, p=0.035), and C1 (82.5 vs. 62.5%, p=0.014).

Conclusions: Half of IgAN patients progressed to end stage within 40 years, and Oxford classification was evaluated to suspect prognosis especially T lesion, and immunosuppressant improved its prognosis especially in M0, E1, S1, T0, T2 and C1.

TH-OR114

Characterization of Recombinant IgG Autoantibody That Binds Galactose-Deficient IgA1 and Forms Immune Complexes Mimicking Those in IgA Nephropathy

Barbora Knoppova,[1] Zina Moldoveanu,[3] Stacy D. Hall,[1] Zhi qiang Huang,[1] Lea Novak,[2] Bruce A. Julian,[2] Jan Novak,[2] Todd J. Green.[2] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Immune complexes (IC) containing galactose-deficient IgA1 (Gd-IgA1) and Gd-IgA1-specific IgG autoantibodies (autoAbs) play a key role in the pathogenesis of IgA nephropathy (IgAN). However, the molecular interactions between autoAb and Gd-IgA1 in IgAN are not well understood. To gain a better insight, we used a recombinant IgG (rIgG) autoAb derived from an IgAN patient and assessed its structural and functional features.

Methods: rIgG autoAb was produced in Expi293F cells. Gd-IgA1 was isolated from plasma of a patient with IgA myeloma. Surface plasmon resonance was used for kinetic analysis of autoAb binding to Gd-IgA1. Fab of rIgG was used for crystallographic studies and the structure was solved by molecular replacement method. We formed *in vitro* engineered IC (EIC) that mimic those in IgAN patients by incubating Gd-IgA1 and rIgG in the presence of human serum. The formed EIC were isolated by size-exclusion chromatography and their biological activity was evaluated using human primary mesangial cells (MC). Furthermore, IC formed from purified Gd-IgA1 and rIgG were injected to immunodeficient mice and then the kidney histopathology was assessed.

Results: The rIgG formed complexes with Gd-IgA1. Kinetic analysis showed intermediate affinity of rIgG to Gd-IgA1 (KD=3.16 E-07 M). The structure of the Fab was solved at the resolution of 1.69 Å. The structure revealed a loop in the heavy chain that adopts a unique conformation, unveiling a surface-accessible pocket located in close proximity to the CDR3. Binding modes from an *in silico* docking study of a glycopeptide mimicking the hinge region of Gd-IgA1 showed potential binding to this region. The EIC, but not Gd-IgA1 alone, stimulated proliferation of cultured MC (2.88±0.69-fold increase over control). IC injected into immunodeficient mice increased glomerular cellularity (48.4±13.3 nuclei per glomerulus *vs.* 40.4±10.5 in control; p<0.0001; n=4 each).

Conclusions: This study provides the first structure of an autoAb that binds Gd-IgA1 and forms biologically active EIC. We envision that better understanding of the interactions of Gd-IgA1 and autoantibodies will enable design of inhibitors to block the formation of pathogenic IC in IgAN.

Mizoribine Prevents M2-Type Macrophage-Mediated Development of Chronic Lesions in Childhood IgA Nephropathy

Yohei Ikezumi,[1] Yuji Matsumoto,[1] Tomomi Kondo,[1] Naonori Kumagai,[1] Takeshi Yamada,[2] Hiroya Hasegawa,[2] David J. Nikolic-Paterson.[3] *[1]Fujita Health University School of Medicine, Toyoake, Japan; [2]Niigata University Medical and Dental Hospital, Niigata, Japan; [3]Monash Medical Centre, Clayton, VIC, Australia.*

Background: We have previously reported that CD163$^+$ M2-type macrophages (MQ) are associated with the development of chronic lesions such as glomerular matrix expansion and interstitial fibrosis in the progression of IgA nephropathy (IgAN). On the other hand, the immunosuppressant mizoribine (Miz) has been shown to reduce the progression of childhood IgAN. To investigate the mechanism of Miz protection, we examined the effect of Miz on MQ function.

Methods: A total of 73 children with IgAN were divided into groups treated with prednisolone (PSL) only (P group; n=33) or PSL plus Miz (PM group; n=40), and their

clinicopathological findings compared retrospectively. For in vitro studies, normal human monocyte-derived MQ were incubated with dexamethasone (Dex), or Dex plus Miz, for 48 hours and then analysed by DNA microarray.

Results: There were no differences in clinical and histological findings at the first (diagnostic) biopsy between the P and PM groups. Although there was no significant difference in the urinary findings, the protocol biopsy after 2-years of treatment showed that the number of sclerotic glomeruli, the degree of interstitial fibrosis, and the number of interstitial $CD163^+$ MQ were significantly reduced in the PM group, but not in the P group. Dex stimulation of cultured human MQ induced up-regulation of scavenger receptor characteristic of M2-type MQ (CD163). Dex also induced up-regulation of cytokines and growth factors associated with inflammation and fibrosis (CCL13, CXCL12, NOS1, NOS2, FGF-8, FGF-21 and CTGF) which was prevented by Miz. In addition, Miz inhibited expression of CD300e, an activating receptor capable of providing survival signals to prevent monocyte apoptosis and to regulate the innate immune response. Immunohistochemistry revealed expression of CD300e which co-localized with $CD163^+$ MQ in biopsies from IgAN patients treated with steroid which was reduced by Miz treatment.

Conclusions: Our data suggest that Miz suppresses M2-type MQ mediated interstitial fibrosis by inhibiting expression of profibrotic cytokines, and reducing MQ life-span by inhibiting steroid-induced CD300e expression.

Immunological and Genomic Analysis of Phenotype Discordant Monozygotic Twins Reveals a Novel Role of T-Follicular Helper Cells in IgA Nephropathy

Nicholas J. Steers, Zizhang Sheng, Jaclyn L. Wold, Swetha Kodali, Debanjana Chatterjee, Byum hee Kil, Maddalena Marasa, Gerald B. Appel, Andrew S. Bomback, Pietro A. Canetta, Jai Radhakrishnan, Wooin Ahn, Maya K. Rao, Krzysztof Kiryluk, Lawrence Shapiro, Ali G. Gharavi. *Columbia University, New York, NY.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis caused by deposition of IgA dominant immune complexes in the glomerulus. The cause of the excess IgA1 production is unclear, and has been attributed to self-proliferation of IgA antibody secreting cells (ASC) or an imbalance in the B-cell-T-cell interactions. T-follicular helper cells (T_{FH}) have been shown to play an essential role in antibody responses.

Methods: We studied 15 IgAN, 10 Lupus Nephritis (LN), 10 Polycystic Kidney Disease (PKD) patients, 20 healthy controls (HC), and 3 pairs of discordant monozygotic twins for IgAN, using flow cytometry and antibody repertoire sequencing.

Results: IgAN patients had a 3.6-fold increase in the IgA ASC, and 1.6-fold increase in the T_{FH}-like cells compared to HC and PKD patients, that correlated with the elevated plasma concentrations of IgA and IgA1. Immunoglobulin sequencing revealed no differences in the usage of heavy chain V, J and kappa genes. However, there was an enhanced usage of the lambda light chain IGLV2-8 gene in IgAN patients (12.9%) compared to HC (7.9%, $p<0.01$). Autologous co-culture experiments of the T_{FH}-like cells with naïve B-cells demonstrated an elevated IgA production for cells derived from IgAN patients (17.2±6.1 ng/ml) compared to HC, LN and PKD patients (5.8±1.3, 7.7± 2.9, and 7.0±1.7 ng/ml, respectively). We performed co-culture experiments in cells from IgAN discordant monozygotic twins. Co-culture of cells derived from the IgAN twins yielded significantly higher IgA production compared to the cells from the healthy twins. In addition, T_{FH}-like cells from the IgAN twins significantly increased IgA production in the naïve B-cells from their corresponding healthy twins (14.2±4.3 ng/ml). Whereas, T_{FH}-like cells from the healthy twins only elicited a baseline IgA production from naïve B-cells from their corresponding IgAN twins (6.7±1.1 ng/ml).

Conclusions: Our data demonstrates an essential interaction of naïve B-cells and T_{FH}-like cells in the augmented generation of IgA in IgAN patients, identifying a new pathway for intervention to reduce IgA production.

Enzymatic Inactive Ubiquitin C-Terminal Hydrolase L1 (UCH-L1) Promotes Antibody-Mediated Podocyte Injury

Julia Reichelt, Sandra Pohl, Gunther Zahner, Catherine Meyer-Schwesinger. AG Meyer-Schwesinger *University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Membranous nephropathy (MN) is an autoimmune disease of the glomerulus characterized by upregulation of the ubiquitin proteasome system (UPS) in podocytes. Thereby, ubiquitin C-terminal hydrolase L1 (UCH-L1) is among the highest upregulated UPS enzymes and *de novo* expressed in injured podocytes. Preliminary work demonstrates that proteasomal impairment and altered proteostasis depends on the enzymatic activity of UCH-L1 in naïve podocytes. We hypothesize that in MN oxidative-modification of UCH-L1 (secondary to oxidative stress) leads to the formation of a dysfunctional UCH-L1 enzyme, which perpetuates podocyte injury. Aim of this study is to understand the underlying mechanism for toxic loss of function of UCH-L1 in antibody-mediated podocyte injury.

Methods: *In vivo* experiments were performed by using unique mouse models with podocyte-specific overexpression of active UCH-L1 wildtype protein or inactive UCH-L1 I93M mutant protein (comparable to oxidative-modified UCH-L1). Mice were treated with anti-podocyte nephritis (APN) antibodies, sacrificed after 14 days, and analyzed by WB, enzyme activity assays, IHC and ELISA for proteinuria. For mechanistic studies, flag-tagged wildtype or mutant I93M UCH-L1 were cloned and transiently overexpressed in HEK-293T cells and used for proteasome interaction studies.

Results: Mice overexpressing dysfunctional UCH-L1 I93M protein exhibited an accelerated disease course with an increased accumulation of polyubiquitinated proteins accompanied by elevated expression of proteasomal and lysosomal proteins in isolated glomeruli. We also observed reduced levels of slit membrane proteins such as nephrin and α-actinin-4 correlating with podocyte loss. Contrastingly, mice overexpressing active wildtype UCH-L1 in podocytes exhibited milder proteinuria and stable expression of podocyte-specific proteins in response to anti-podocyte antibodies after 14 days. *In vitro* immunoprecipitation experiments demonstrated an interaction of wildtype UCH-L1 and UCH-L1 I93M with the proteasome, however only binding of UCH-L1 I93M decreased proteasomal activity.

Conclusions: These results strengthen the hypothesis that during MN a shift of UCH-L1 enzymatic activity to a dysfunctional protein negatively influences podocyte protein homeostasis by aberrant interactions with the proteasome.

TH-OR118

Common Risk Variants in NPHS1 and TNFSF15 Are Associated with Childhood Steroid-Sensitive Nephrotic Syndrome

Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Rasheed A. Gbadegesin,[2] Matt G. Sampson,[3] China Nagano,[1] Kandai Nozu,[1] Kenji Ishikura,[6] Pierre M. Ronco,[4] Hae Il Cheong,[5] Kazumoto Iijima.[1] *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan, Kobe, Japan; [2]Duke University Medical Center, Durham, NC; [3]University of Michigan, Ann Arbor, MI; [4]Hospital Tenon, Paris, France; [5]Seoul National University Children's Hospital, Seoul, Republic of Korea; [6]National Center for Child Health and Development, Tokyo, Japan.*

Background: Although steroid-sensitive nephrotic syndrome (SSNS) is the most common cause of glomerular disease in children, the pathogenesis remains unclear. Recent genome-wide association studies (GWASs) have shown that variants in the *HLA-DR/DQ* region are significantly associated with the disease in different populations. However risk loci outside of the *HLA* region are largely unknown.

Methods: We conducted a GWAS in 1,017 Japanese children with SSNS and 3,332 ancestry matched controls. We performed replication studies and trans-ethnic meta-analysis in Korean, South Asian, sub-Saharan African, European, and Hispanic populations.

Results: The most significant association was detected in *HLA-DR/DQ* region ($p=2.8 \times 10^{-33}$, odds ratio [OR]=2.49, 95%CI: 2.15-2.89). In addition, common variants in *NPHS1-KIRREL2* ($p=4.94 \times 10^{-20}$, OR=1.70, 95%CI: 1.66-2.18), *TNFSF15* ($p=2.54 \times 10^{-8}$OR=0.72, 95%CI: 0.64-0.81) and *TNFRSF11A* ($p=7.68 \times 10^{-8}$, OR=1.38, 95%CI: 1.23-1.56) regions achieved genome-wide or marginal genome-wide significance. Trans-ethnic meta-analysis confirmed the significant associations in *NPHS1* ($p_{meta}=7.06 \times 10^{-2}$, OR=1.91) and *TNFSF15* ($p_{meta}=4.05 \times 10^{-13}$, OR=0.72) loci. **Discussion:** *NPHS1* encodes nephrin and mutations in *NPHS1* cause congenital nephrotic syndrome of the Finnish type (CNSF). The two synonymous variants in *NPHS1* may induce aberrant splicing which could decrease the wild-type nephrin production and may affect the glomerular filtration barrier function. In addition, one of the two variants in *NPHS1* has been previously reported to induce *TRPC6* activation. *TNFSF15* encodes the TNF super-family member 15 (TNFSF15), ligand of death receptor 3. Activation of TNFS15 enhances the proliferation of human regulatory T cells (Tregs). The risk allele in *TNFS15* is associated with reduced expression of TNFSF15, which attenuate the proliferation of Tregs, consistent with findings reported in SSNS patients.

Conclusions: The present study markedly improves the understanding of genetic background of childhood SSNS, and provides another evidence that the gene responsible for a monogenic rare disease (CNSF) could be the susceptibility gene for a relatively common multifactorial disease (SSNS). Response to Intensified Immunosuppression in Genetically-Stratified SRNS Patients Predicts Outcomes and Indicates Distinct Underlying Mechanisms

Moin Saleem,[1] Anna E. Mason,[1] Ethan S. Sen,[1] Agnieszka Bierzynska,[1] Liz Colby,[1] Maryam Afzal,[1] Ania B. Koziell,[2] Olivia Boyer,[3] Gavin I. Welsh.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]Kings College London, London, United Kingdom; [3]Hopital Necker - Enfants Malades, Paris, France.*

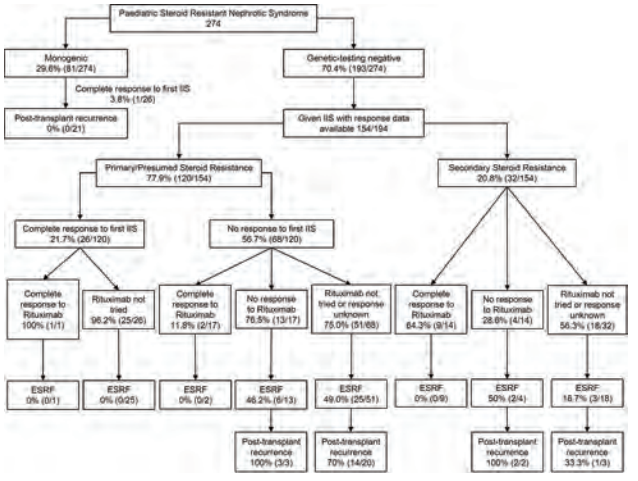
Background: We previously showed that secondary steroid resistance (SSR) in nephrotic syndrome is a reliable predictor of circulating factor disease that recurs post-transplantation. This follow-up study aimed to improve disease stratification by determining if response to intensified immunosuppression (IIS) in genetically-screened SRNS predicts disease progression and/or recurrence.

Methods: Paediatric patients with steroid resistant nephrotic syndrome (SRNS) were recruited via the United Kingdom RaDaR registry. 274 patients were whole genome, whole exome or SRNS-gene-panel sequenced. Complete response (CR) or partial response within six months of starting IIS was ascertained.

Results: Of 274 patients, 180 (93 male, median onset age 4.7 years, 99 focal segmental glomerulosclerosis) received IIS medications with responses available. 3.8% of monogenic disease patients showed CR, compared to 25.2% of genetic-testing negative (GTN) patients ($p=0.018$). None of the former recurred post-transplantation. In GTN patients, 97.4% with CR to first IIS showed no progression, whereas 43.2% of non-responders developed renal failure with 73.1% recurrence post-transplant. SSR had a higher CR rate than primary/presumed resistance (42.5% vs 23.0%, $p=0.0014$). Highest

CR rate was to Rituximab (64.3%). Biopsy findings showed no correlation with response to IIS or outcome.

Conclusions: This stratifies SRNS into three subgroups of prognostic utility based on genotype-phenotype correlation: monogenic disease responds poorly to IIS but doesn't recur, GTN SRNS that responding early to IIS with good long-term outcome, and multi-drug resistant GTN SRNS with poor renal survival and high post-transplant recurrence risk. This supports at least two different underlying immune mechanisms in non-genetic SRNS, able to determine disease outcome.



TH-OR120

Long-Term Efficacy of Rituximab and Mycophenolate Mofetil (MMF) Maintenance Therapy in Children with Steroid-Dependent Nephrotic Syndrome: RITURNS Trial Follow-Up

Franz S. Schaefer,[1] Biswanath Basu.[2] *[1]University of Heidelberg, Heidelberg, Germany; [2]NRS Medical College, Kolkata, India.*

Background: In the RITURNS study we demonstrated superior efficacy of Rituximab over Tacrolimus in children with steroid dependent nephrotic syndrome (SDNS), with 88 vs. 69 % relapse-free survival during a 12-month observation period (Basu et al. JAMA Pediatr 2018). Here we present the long-term outcomes of the patients in the Rituximab arm.

Methods: 59 of the 60 patients who had received a course of Rituximab (two infusions @375mg/m^2) in the RITURNS Study were available during a 2-year follow-up period after the end of the RITURNS study. Relapsing patients received a second course of Rituximab, either with (n=44) or without MMF co-treatment (n=15).

Results: During the extended follow-up, all patients developed relapses, with a median time to first relapse of 63 weeks for the entire cohort (Fig.1). Those patients who received co-treatment with MMF after the second course of Rituximab showed longer remission than those who received Rituximab alone (80% relapse-free survival 84 vs. 30 weeks) (Fig.2), whereas the total relapse rate (1.34 ± 0.75 vs. 1.47 ± 0.64) and cumulative prednisolone exposure (41.9 ± 35.0 vs. 45.5 ± 28.0 mg/kg) did not differ significantly. Both treatment protocols were equally well tolerated.

Conclusions: Recurrence of nephrotic syndrome occurred in all SDNS patients within 6 to 24 months following the first course of Rituximab. Co-treatment with MMF after Rituximab re-treatment substantially extended the duration of remission, with 75% of patients remaining relapse-free two years after the second Rituximab course.

Funding: Government Support - Non-U.S.

TH-OR121

A Global Anti B-Cell Strategy with Obinutuzumab and Daratunumab in Severe Pediatric Idiopathic Nephrotic Syndrome

Claire Dossier,[1] Benjamin Prim,[1] Christelle Moreau,[2] Theresa Kwon,[1] Anne Couderc,[1] Cambier Alexandra,[1] Veronique Baudouin,[1] Anne F. Maisin,[1] Georges Deschênes.[3] *[1]Pediatric Nephrology, APHP, Robert-Debre Hospital, Paris, France; [2]Pharmacy, APHP, Robert-Debre Hospital, Paris, France; [3]Hospital Robert Debre/Pediatric Nephrology, Paris, France.*

Background: The efficacy of B-cell depletion and Immunoglobulin adsorption in the treatment of patients with Steroid Dependant Nephrotic Syndrome (SDNS) and Steroid Resistant NS supports the involvement of B cells in the physiopathology of INS. However, rituximab (RTX) targets only CD20 positive B-cells and especially not plasma cells. Furthermore, RTX mediated B-cell depletion may paradoxically induce the settlement of autoreactive long-lived plasma cells which may account for some RTX failure. In this pilot study, we investigate in patients with severe SDNS the association of Obinutuzumab (OBZ), a 2nd generation anti CD20 monoclonal antibody, with higher in vitro B-cell cytotoxicity than RTX, with Daratumumab (DAR), an anti CD38 monoclonal antibody with high plasma cell cytotoxicity in addition to an immunomodulatory activity.

Methods: Patients received an infusion of 1000mg/1,73m^2 of obinutuzumab at day 0 and 1000mg/1,73m^2 of daratumumab at day 15. All other immunosuppressive treatments were discontinued within two months, and biological monitoring was performed monthly until B cell recovery.

Results: 9 patients with SDNS and resistance (n=3) or early relapse after prolonged B-cell depletion with rituximab (n=6) were included. Median ages at INS onset, first RTX and OBZ were respectively of 2.9, 7.7 and 10.9 years old. B-cell depletion was achieved in all patients. Median follow-up was 10 months (IQ 8.3-10.3), and all patients remained relapse-free. Six patients had still undetectable peripheral B-cells, while B-cell reconstitution occured at 7.9, 8.1 and 9.3 months in the 3 others. Mild infusion reactions were reported in 2/9 patient during OBZ and 3/9 during DAR infusions. Mild neutropenia (500-1000/mm^3) occured in 2/9 patients. 7/9 patients received IV immunoglobulins because of hypo-IgG. Hypo-IgA was noted in 8 patients and hypo-IgM in all patients. No severe infection was reported.

Conclusions: Global anti-B cell strategy with obinutuzumab and daratumumab induces prolonged peripheral B-cell depletion and nephrotic syndrome remission in children with severe SDNS. However, it induces frequent and profound hypogammaglobulinemia and further investigation of the safety and the long-term efficacy of this strategy is needed.

TH-OR122

Effect of Updated Hypertension Guidelines on Blood Pressure Staging in Pediatric Kidney Transplant Recipients

Rouba Garro,[1,2] Pamela D. Winterberg,[1,2] Mike Kelleman,[1] Roshan P. George,[1,2] Debora Matossian,[4] Joseph T. Flynn,[3] David K. Hooper.[5] *[1]Pediatrics, Emory University School of Medicine, Atlanta, GA; [2]Children's Healthcare of Atlanta, Atlanta, GA; [3]Seattle Children's Hospital, Seattle, WA; [4]Lurie Children's Hospital, Chicago, IL; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: In 2017, pediatric hypertension (HTN) guidelines were updated with 2 major changes compared to the 2004 NHBPEP 4th Report: normative blood pressure (BP) values excluded overweight children and simplified staging was provided for children ≥13 yo using the adult nominal cutoffs. This study evaluated the effect of the new guidelines on BP staging in children with kidney transplant (KT) using registry data from the Improving Renal Outcomes Collaborative (IROC).

Methods: We examined the last accurate BP measurement for patients <18 yo and >90 days post-KT in the IROC registry and compared BP staging using percentile (%tile) cutoffs in the 4th Report versus 2017 AAP HTN Guidelines. BP staging using AAP %tile versus adult nominal cutoffs for children ≥13 yo were also compared. Associations between overweight or short stature and change in BP staging were assessed with Chi-square tests, odds ratios (OR), and 95% confidence intervals (CI).

Results: A total of 563 patients met inclusion criteria. When applying AAP %tile cutoffs, 71/563 (13%) had increased BP stage compared to 4th Report classification, with most changing from normal to elevated or pre-HTN to stage 1 (see table). Overweight/obese children were more likely to have increased staging using AAP %tiles (OR 1.7, CI 1.05-2.90) compared to 4th Report cutoffs. When applying adult cutoffs for children ≥13 yo, BP stage decreased in 13% (31/241) compared to the %tile cutoffs in the AAP Guidelines. This age group had below-average height (median height %tile 11.2, IQR 1.9-38.5). Height percentile was a significant risk factor for decreased BP stage using adult cutoffs (p=0.01).

Conclusions: Short stature and obesity, which are common in pediatric KT recipients, affect BP staging when applying updated HTN guidelines. The application of adult BP cutoffs in children with kidney transplant ≥13yo may under-report uncontrolled BP, especially in those with short stature. Transplant physicians may consider applying percentile-based cutoffs until adulthood in this population with high cardiovascular risk.

Funding: NIDDK Support

Low Albumin Is Associated with Neonatal AKI During the First Post-Natal Week of Life: Report from the AWAKEN Study Group

Arwa Nada,[1] Linzi Li,[3] Russell Griffin,[3] Juan C. Kupferman,[4] Maroun J. Mhanna,[5] John D. Mahan,[2] David J. Askenazi.[3] On Behalf of the Neonatal Kidney Collaborative *[1]LeBonheur Children's Hospital, Memphis, TN; [2]Nationwide Children's Hospital, Columbus, OH; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Maimonides Medical Center, Brooklyn, NY; [5]Metro Health Medical Center, Cleveland, OH.*

Background: Hypoalbuminemia is an established risk factor for morbidity and mortality in adults and children. Adult studies showed an association between low albumin (alb) and acute kidney injury (AKI) in different settings. Low alb was found to be associated with AKI in children undergoing cardiac surgery. In this analysis of newborns (NB) enrolled in the Assessment of Worldwide Acute Kidney injury Epidemiology in Neonates (AWAKEN) we hypothesize that low alb is associated with increased risk of AKI in the first postnatal week of life. To our knowledge, this is the first study to examine this relationship in NB

Methods: AWAKEN included 2162 NB admitted to the neonatal intensive care units at 24 institutions (4 countries) from 01/14-03/14. Inclusion criteria: intravenous fluids for ≥48 hrs. Exclusion criteria: congenital heart disease repair at <7 days of life, lethal anomaly or death at ≤48 hrs. For this analysis, we excluded 1461 NB who had no alb levels documented, 19 NB who didn't have at least 2 serum creatinines or at least one day of urine output recorded during first postnatal week. Analysis was done for the entire cohort and for 3 stratified groups; <29 weeks (wks), ≥29 to <36 wks and ≥36 wks gestational age (GA)

Results: A total of 682 babies were included, 47.8% had at least 1 episode of AKI. Table 1 shows that mean minimum alb was significantly lower in AKI group versus the no-AKI group ($p < 0.0001$) for the entire cohort and for each of the 3 stratified groups. Mean maximum Alb was higher in the no-AKI group versus the AKI group ($p= 0.0001$) for the entire cohort and for the <29 wks and ≥39 wks groups. Low alb levels were independently associated with AKI. For every 1 g/dL decrease in alb the odds of developing AKI increased by 4%. Even after adjusting for confounders including fluid status; for every alb of 1 there was 4.6% higher odds of having AKI

Conclusions: AWAKEN describes for the first time the association between low alb and AKI in the first postnatal week. This association remained regardless of fluid balance and other potential confounders

Table 1: Mean and SD of Minimum and Maximum Albumin Levels Among Studied Groups

Effect of Erythropoietin (Epo) on Outcomes at 24-26 Months in Extremely Low Gestational Age Neonates (ELGAN)

Sangeeta R. Hingorani,[1,2] Robert Schmicker,[3] Kaashif A. Ahmad,[4] Maureen M. Gilmore,[5] Edmund F. Lagamma,[6] Sandra Juul,[7] David J. Askenazi.[8] *[1]Seattle Children's Hospital, Seattle, WA; [2]Pediatrics, University of Washington, Seattle, WA; [3]University of Washington Center for Biomedical Statistics, Seattle, WA; [4]MEDNAX National Medical Group, San Antonio, TX; [5]Johns Hopkins University, Baltimore, MD; [6]New York Med College - Maria Fareri Children's Hosp, Valhalla, NY; [7]University of Washington, Seattle, WA; [8]University of Alabama at Birmingham, Birmingham, AL.*

Background: Changes in EPO in premature infants may have a critical role in glomerulogenesis. The REPAIReD study examines kidney outcomes of ELGANS enrolled in PENUT, a randomized placebo-controlled trial of Epo. We compare prevalence and risk factors of chronic kidney disease (CKD), albuminuria, and hypertension at 24 months corrected gestational age (cGA) by treatment group.

Methods: Patients who survived to 24-26 months cGA with blood, urine or blood pressure at follow-up were included. We defined CKD as estimated glomerular filtration rate (eGFR) via the Schwartz cystatin C equation <90 ml/min/1.73m^2; hypertension as either systolic blood pressures (SBP) or diastolic (DBP) > 95%ile for height, age and gender; and albuminuria as a urine albumin/creatinine ratio ≥ 30 mg/g. Associations between baseline characteristics, maternal race and pre-eclampsia, and outcomes were assessed.

Results: 778 (84%) of enrolled babies had a 24-26 month follow up visit. 54 (16%) had an eGFR < 90mL/min/1.73m^2, 155 (36%) had albuminuria, 119 (24%) had systolic hypertension and 163 (33%) had diastolic hypertension. We found no difference by treatment group. An eGFR <90 was associated with lower birthweight ($p<0.001$), small for gestational age ($p<0.05$) and pre-eclampsia ($p<0.05$).

Conclusions: A low GFR, albuminuria, and hypertension are common in ELGANS and present at 24-26 months of age. Long-term kidney follow up of all premature infants less than 28 weeks GA is needed starting at 2 years old.

Funding: NIDDK Support

Stable Calcium Isotopes: A Novel Biomarker of Bone Mineral Density in Children with CKD

Rukshana Shroff,[1] Ana Kolevica,[2] Alexander D. Lalayiannis,[3] Dagmar-Christiane Fischer,[7] Aysun Bayazit,[8] Varvara Askiti,[5] Andromachi Mitsioni,[9] Augustina Jankauskiene,[6] Anton Eisenhauer.[4] *[1]Nephrology, Great Ormond Street Hospital, London, United Kingdom; [2]Geomar Helmholtz Centre for Ocean Research, Kiel, Germany; [3]Great Ormond St Hospital for Children NHS Foundation Trust, Birmingham, United Kingdom; [4]Geomar Helmholtz Institute for Ocean Research, Kiel, Germany; [5]Children's Hospital "P. & A. Kyriakou", Athens, Greece; [6]Children hospital, affiliate of Vilnius university hospital Santaros clinic, Vilnius, Lithuania; [7]University Hospital Rostock, Rostock, Germany; [8]Cukurova University, Adana, Turkey; [9]Children's Hospital "P&A Kyriakou", Athens, Greece.*

Background: In CKD dysregulated calcium (Ca) homeostasis is common and causally associated with reduced bone mineral content and vascular calcification. Currently available radiological measures and biomarkers do not allow an accurate evaluation of bone mineralisation.

Methods: We measured stable Ca isotope fractions ($\delta^{44/42}Ca$) by plasma ionization mass spectrometry in blood and urine as biomarkers for bone mineralization. The relationship between bone Ca gain and loss is described mathematically using a compartment model based on Ca kinetics. 104 children in CKD4-5 and on dialysis (CKD4-5D) and 40 matched controls underwent Ca isotope measurement, bone biomarkers, dual energy x-ray absorptiometry (DXA) and tibial peripheral quantitative CT scan (pQCT). pQCT accurately defines cortical and trabecular bone mineral density (BMD), and tibial cortical BMD Z-score is shown to predict fracture risk.

Results: Both the $\delta^{44/42}Ca_{Blood}$ and $\delta^{44/42}Ca_{Urine}$ were significantly different in children with CKD4-5D compared to healthy controls ($p<0.001$ for both). In healthy children the $\delta^{44/42}Ca_{Blood}$ and $\delta^{44/42}Ca_{Urine}$ were higher than values reported in adults (-0.27 vs -0.84 ‰ for $\delta^{44/42}Ca_{Blood}$ and 0.94 vs 0.35‰ for $\delta^{44/42}Ca_{Urine}$), reflecting avid Ca uptake during bone formation. There was a linear association between estimated GFR and $\delta^{44/42}Ca_{Urine}$ ($p<0.0001$) in CKD. $\delta^{44/42}Ca_{Blood}$ positively correlated with cholecalciferol ($p=0.01$) and alfacalcidol ($p=0.002$) doses, implying increased bone Ca uptake when Ca bioavailability is increased. $\delta^{44/42}Ca_{Blood}$ showed a linear association with established biomarkers of bone formation (alkaline phosphatase, $p=0.05$) and bone resorption (TRAP5b, $p<0.001$ and CTX, $p=0.006$). $\delta^{44/42}Ca_{Blood}$ strongly correlated with tibial cortical BMD Z-score ($p<0.0001$, $R^2=0.39$), and DXA hip Z-score ($p=0.02$). On multivariable linear regression analysis significant and independent predictors of tibial cortical BMD Z-score were $\delta^{44/42}Ca_{Blood}$ ($\beta=0.68$, $p=0.006$) and PTH ($\beta-0.39$, $p=0.04$), together predicting 67% of the variability in BMD.

Conclusions: Ca isotope ratios provide a novel, non-invasive method of assessing bone mineral density in children with CKD and may be used to guide safe and effective treatment that prevents Ca deficiency or overload.

Pediatric CKD Is Associated with Abnormal White Matter Integrity

Matthew A. Solomon,[3] Timothy R. Koscik,[1] Marci Novak,[1] Vincent Magnotta,[5] Susan L. Furth,[4,6] Patrick D. Brophy,[2] Peggy C. Nopoulos,[1] Lyndsay Harshman.[3]
[1]Psychiatry, University of Iowa, Iowa City, IA; [2]University of Rochester, Rochester, NY; [3]Pediatrics, Stead Family Children's Hospital, Iowa City, IA; [4]Division of Nephrology, The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Radiology, University of Iowa Carver College of Medicine, Iowa City, IA; [6]Pediatrics, Perelman School of Medicine at the University of Pennsylvania, Philidelphia, PA.

Background: Children with chronic kidney disease (CKD) are at risk for neurocognitive deficits. Neuroimaging studies provide an opportunity to accurately assess the brain and yield clues to the underlying mechanisms of observed neurocognitive abnormalities. To date, few published studies exist evaluating brain structure in pediatric CKD and often involve heterogenous samples with late CKD/end-stage populations of varying etiologies.

Methods: We describe the effect of mild to moderate CKD on brain white matter integrity (WMI) using quantitative MRI diffusion tensor imaging. Patients age 6-16 with congenital, non-glomerular causes of CKD (eGFR 30-90 ml/min/1.73m2) were invited to participate [N_{cases} = 20, $N_{control}$ = 26]. Participants completed a neurocognitive evaluation and MRI scan. WMI was calculated utilizing measurement of fractional anisotropy (FA). Voxel-wise linear regression models were calculated using R where FA values were predicted by CKD-status. Sex, age, blood pressure, and parental socioeconomic status were included as covariates.

Results: Relative to controls, CKD participants showed significant decreases in WMI within multiple brain regions including the right orbitofrontal cortex (Fig 1: t(54)=-3.74, p=0.000452, q=0.00722). Linear regression was performed to predict the relationship between regions with FA deficit and executive function. For males, lower FA within the right orbital frontal cortex was related to poorer executive function as measured by the Behavior Rating Inventory of Executive Function global executive composite (p = 0.006). In models adjusted for age, sex, participant type, and systolic blood pressure, lower FA within this region remained associated with poorer executive function (p = 0.011).

Conclusions: Our data demonstrate distinct white matter abnormalities in early pediatric CKD due to congenital anomalies of the kidney/urinary tract. Furthermore, these alterations in WMI are associated with executive function.

Funding: NIDDK Support

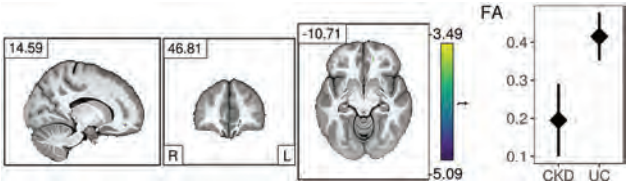

Figure 1: Localization of the right orbitofrontal WMI difference between cases (CKD) and controls (UC) [voxel coordinates xyz: 14.6, 46.8, -10.7].

Sleep Problems and Fatigue and Their Relationships with Emotional-Behavioral Symptoms and Neurocognitive Outcomes in Pediatric CKD

Rebecca J. Johnson,[1] Matthew Matheson,[3] Lyndsay Harshman,[5] Arlene C. Gerson,[4] Amy Kogon,[2] Marc Lande,[8] S. Shinnar,[6] Susan L. Furth,[2] Bradley A. Warady,[1] Stephen R. Hooper.[7]
[1]Children's Mercy Kansas City, Kansas City, MO; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD; [5]University of Iowa Children's Hospital, Iowa City, IA; [6]Montefiore Medical Center, Albert EInstein College of MEdicine, Bronx, NY; [7]University of North Carolina School of Medicine, Chapel Hill, NC; [8]University of Rochester Medical Center, Rochester, NY.

Background: Children with CKD are at risk for deficits in neurocognitive function. It is not known how sleep problems/fatigue within the context of CKD may contribute to these deficits.

Methods: Data from the Chronic Kidney Disease in Children (CKiD) study was used to evaluate the prevalence of sleep problems/fatigue among children with mild to moderate CKD, and to examine whether sleep problems or fatigue predict neurocognitive or emotional-behavioral outcomes. Four variables were created: fatigue, sleep disturbance, low energy, and trouble sleeping. Linear mixed models were used to determine if fatigue or sleep problems were associated with neurocognitive and emotional-behavioral outcomes. Each model was adjusted for sociodemographic and disease-related covariates.

Results: Baseline data was available for 1030 participants (median disease duration 6 years; 63% male; mean eGFR was 53 ml/min|1.73m^2). Prevalence was 26% (fatigue), 30% (sleep disturbance), 52% (low energy), 39% (trouble sleeping). Sleep disturbance (β=1.28, CI=0.25, 2.32; p=.02), low energy (β=1.85, CI=0.79, 2.9; p=.0006), and trouble sleeping (β=1.87, CI=0.87, 2.87; p=.0003) were significantly associated with worse parent ratings of overall executive functions. Low energy was significantly associated with lower working memory (Digit Span Forward β=-0.37, CI=-0.72, -0.01, p=.05; Digit Span Backward β=-0.48, CI=-0.87, -0.09, p=.02). Low energy was significantly associated with lower inhibition (B=-0.92, CI=1.57, -0.28, p=.0006) and lower problem-solving B=-0.67, CI=-1.25, -0.09, p=.02). Each of the four sleep measures was significantly related to more internalizing symptoms on a measure of emotional-behavioral functioning, and sleep disturbance, low energy, and trouble sleeping were associated with more externalizing symptoms.

Conclusions: A significant proportion of children with CKD report fatigue and problems with sleep. Sleep problems and fatigue were associated with lower executive functioning and increased emotional-behavioral symptoms over time after adjusting for key sociodemographic and CKD-related covariates. Assessing sleep problems/fatigue and treating co-morbidities may promote more positive emotional-behavioral and neurocognitive outcomes for children with CKD.

Economic Evaluation of Lifelong Medicare Immunosuppressive Drug Coverage for Kidney Transplant Recipients

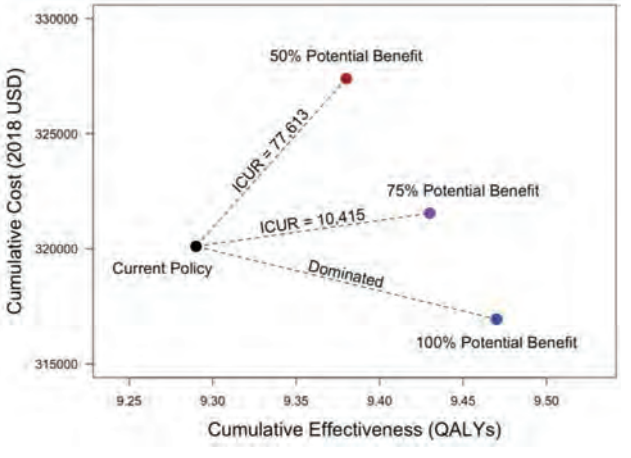
Matthew J. Kadatz,[1] John S. Gill,[2] Richard N. Formica,[3] Scott Klarenbach.[4]
[1]University of British Columbia, Vancouver, BC, Canada; [2](St. Paul's Hospital/ University of British Columbia), Vancouver, BC, Canada; [3]Yale School of Medicine, Bethany, CT; [4]University of Alberta, Edmonton, AB, Canada.

Background: Medicare coverage for kidney transplant recipients ceases 36 months after transplantation. This policy removes coverage for life-saving immunosuppressive medications essential to prevent rejection and maintain transplant function. A contemporary economic analysis of extending Medicare coverage for the duration of transplant survival using mean cost of immunosuppressant medications in the era of generic equivalents which accounts for that fact that many transplant recipients currently continue to receive Medicare coverage beyond 36 months due to medical disability is not available.

Methods: A Markov model was used to determine the incremental cost and effectiveness of extending Medicare coverage for immunosuppressive drugs for the duration of transplant survival compared with the current policy from the perspective of the Medicare payer. The model used contemporary mean costs of immunosuppressive medications, and incorporated assessment of continuation of Medicare coverage beyond 36 months in patients who are designated medically disabled. The expected graft survival of extending immunosuppressive drug coverage was estimated from a cohort of privately insured transplant recipients using multivariable survival analysis.

Results: Extension of immunosuppression coverage under Medicare for kidney transplant recipients led to lower costs of -$3,163 and 0.18 additional quality adjusted life years (QALYs). When the improvement in transplant survival associated with extending immunosuppressive coverage was reduced to 50% of that observed in privately insured patients, the strategy of extending drug coverage had an ICUR of $77,613/ QALY gained.

Conclusions: Extending immunosuppressive drug coverage under Medicare from the current 36 months to the duration of transplant survival will result in better patient outcomes and cost savings, and remains cost-effective if only a fraction of anticipated benefit is realized.



TH-OR129

Absence of Additional Predictive Ability Value of Preimplantation Biopsies for Long-Term Allograft Outcome

Olivier Aubert,[1,4] Marc Raynaud,[1] Gillian Divard,[1] Yassine R. Bouatou,[1,5] Denis Glotz,[5,1] Christophe M. Legendre,[4,1] Carmen Lefaucheur,[3,1] Peter P. Reese,[2] Alexandre Loupy.[1,4]
[1]Paris Translational Research Center for Organ Transplantation, Paris, France; [2]University of Pennsylvania, Ardmore, PA; [3]Saint-Louis Hospital, Paris, France; [4]Hôpital Necker, Paris, France; [5]Hopital Saint-Louis, Paris, France.

Background: A significant number of kidneys are discarded worldwide due to the suboptimal use of large kidney resources. The main cause of discard is the result of the preimplantation biopsy.

Methods: We included patients who underwent kidney transplantations from a deceased donor in 2 French referral centers between 2004 and 2014 with preimplantation biopsy. Two external validation cohorts were included: 1,107 deceased donors from Belgium and 1,103 discarded kidneys based on biopsy results from the US.

Results: A total of 1,629 patients were included in the development cohort. After adjusting for donor, recipient, and transplant characteristics as well as for preimplantation biopsy findings (IFTA, cv and ah Banff score, and glomerulosclerosis percentage) and baseline immunological parameters, we identified the KDRI score (HR=2.50; 95% CI, (1.38 to 3.40); p<0.001), the presence of circulating DSA on the day of transplantation (HR=1.76; 95% CI, (1.36 to 2.28); p<0.001), prior kidney transplantation (HR=1.34; 95% CI, (1.01 to 1.78); p=0.045), and the IFTA score (HR=1.51; 95% CI, (1.00 to 2.26); p=0.048) as the main independent determinants of long-term allograft loss. However, the biopsy results had no additional value to predict long term allograft outcome when compared to the model without the biopsy results. In the Belgium validation cohort, none of the biopsy results were associated with allograft loss. Kidneys discarded based on histology results in the US were matched to transplanted kidneys in France. French kidneys with similar histological results as discarded kidneys in the US did not have worse allograft survival compared to the unmatched transplanted kidneys (p=0.156).

Conclusions: Given this result and the fact that preimplantation biopsies increase the cold ischemia time, the current practice of discarding kidneys based on preimplantation biopsy results may not be optimal for allocation decision-making.

TH-OR130

Recipient Outcome After Declining a Deceased-Donor Kidney Offer

Dhriti Dosani, Rupert B. Bright, Anamika Adwaney, Emma C. Morganti, Damien Ashby. *Imperial College London, London, United Kingdom.*

Background: The decision to accept a deceased-donor kidney depends on organ quality, and also recipient factors, such as an estimate of mortality on dialysis, and the likelihood of receiving a more favourable offer. Whilst outcome after transplantation has been well studied, with several donor-related risk factors widely accepted, little is known about the outcome after declining a kidney, such as the influence of recipient factors on the chance of subsequent transplantation.

Methods: Over a 12 month period at a single UK centre, all potential recipients were identified for whom a deceased-donor kidney offer was declined, with subsequent transplant outcomes recorded.

Results: Kidneys were declined for 145 patients, aged 24 - 78 (mean 54.1), due to donor / organ quality (57.2%), recipient illness / unavailability (26.2%), and positive crossmatch (4.8%) with the remaining offers withdrawn (11.8%), largely due to delayed cardiac death. Over a mean follow-up of 12 months, 83 patients (57.2%) received at least one further offer. Second offers tended to be from slightly younger donors (53.5 vs 58.8 years, p=0.103) with the same HLA match (3.2/6 antigens matched). By the end of observation 59 (40.7%) had been transplanted, 46 (31.7%) remained on the wait-list, 38 (26.2%) were temporarily or permanently suspended from the wait-list, and 2 (1.4%) had died. Compared to those less sensitised, highly sensitised patients (calculated HLA reaction frequency over 75%) were less likely to be transplanted (23.1 vs 47.3%, p=0.025). Older patients (over 60) were more likely to be suspended (39.3 vs 22.0%, p=0.028) with a similar tendency also seen in those waiting over 4 years for their first offer (40.5 vs 25.3%, p=0.082).

Conclusions: After declining a deceased-donor kidney, around 40% of patients may expect to be transplanted during the following year, whilst around 25% may be suspended from the wait-list. Risk factors for suspension or non-transplantation include older age, longer wait-time and greater HLA sensitisation. These data will be helpful to patients and clinicians making kidney offer decisions.

TH-OR131

Decreasing Risks of Kidney Transplantation Using High KDPI Kidneys by Preferred Recipient Matching

Kyle R. Jackson, Jennifer D. Motter, Dorry L. Segev. Epidemiology Research Group in Organ Transplantation *Johns Hopkins Hospital, Baltimore, MD.*

Background: Kidneys with a high Kidney Donor Profile Index (KDPI, ≥ 85%) are often discarded due to an increased risk of mortality and graft loss. However, we hypothesized that some recipients might tolerate high KPDI kidneys well, and are therefore best suited to receive these grafts.

Methods: Using national registry data from SRTR from 2006-2017, we compared 10,361 kidney transplant recipients of high KDPI (≥ 85%) kidneys to 120,983 recipients of low KDPI (< 85%) kidneys. We identified recipient factors that amplified (or attenuated) the impact of high KDPI on mortality and graft loss using interaction analysis, classifying recipients without amplifying factors and with attenuating factors as preferred recipients. We compared mortality and graft loss with high KDPI versus low KDPI kidneys in preferred and non-preferred recipients using Cox regression.

Results: Preferred recipients were determined to be recipients who were ≥ 60 years old, non-white, with diabetes, and without glomerular or cystic disease as the cause of their ESRD. The increased mortality risk associated with high KDPI kidneys was 32% lower (interaction ratio: $_{0.62}0.68_{0.74}$, p<0.001) in preferred vs. non-preferred recipients, whereas the increased risk of graft loss was 21% lower (interaction ratio: $_{0.73}0.79_{0.85}$, p<0.001). This translated to a 1.37-fold higher mortality risk (HR: $_{1.26}1.37_{1.47}$, p<0.001) with a high KDPI kidney versus a low KDPI kidney in preferred recipients, compared to a 2.01-fold higher mortality risk (HR: $_{1.90}2.01_{2.13}$, p<0.001) for non-preferred recipients (Figure). Similarly, there was a 1.57-fold higher risk of graft loss (HR: $_{1.45}1.57_{1.69}$, p<0.001) with a high KDPI kidney versus a low KDPI kidney in preferred recipients, in comparison to a 1.96-fold higher risk of graft loss (HR: $_{1.88}1.96_{2.04}$, p<0.001) for non-preferred recipients (Figure).

Conclusions: The risks of kidney transplantation with high KDPI kidneys can be decreased by appropriate recipient selection.

TH-OR132

Cognitive Function and Waitlist Outcomes in Kidney Transplant Candidates With and Without Diabetes

Nadia M. Chu,[1] Zhan Shi,[2] Christine E. Haugen,[3] Dorry L. Segev,[2] Mara McAdams-DeMarco.[2] *[1]Johns Hopkins School of Medicine, Potomac, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins Hospital, Baltimore, MD.*

Background: Kidney transplantation (KT), while contraindicated for those with diagnosed dementia, improves cognitive function in ESKD patients. However, KT candidates may have unrecognized cognitive impairment, which can lead to difficulties navigating the health system and poor health behaviors that may prolong KT evaluation, elevate mortality risk, and hinder access to KT. Therefore, we estimated the burden of cognitive impairment at KT evaluation and its association with access to KT and waitlist mortality.

Methods: In a 2-center cohort study of 3,630 ESKD participants, we estimated adjusted chance of listing (Cox), risk of waitlist mortality (competing risks), and KT rate (Poisson) by cognitive impairment (3MS<80). Given potential differences in etiology in cognitive impairment in those with and without diabetes, we tested if associations differed by diabetes (Wald test).

Results: At evaluation, 6.4% had cognitive impairment, which was independently associated with 25% lower chance of listing (aHR=0.75, 95%CI:0.61-0.91); this association did not differ by diabetes ($p_{interaction}$=0.07). However, associations between cognitive impairment and waitlist mortality ($p_{interaction}$=0.02), as well as KT rates ($p_{interaction}$=0.048) differed by diabetes. In candidates without diabetes, those with cognitive impairment had 2.47-times (95%CI:1.31-4.66) greater risk of waitlist mortality and reduced KT rate (aIRR=0.58, 95%CI:0.36-0.93); cognitive impairment was not associated with these outcomes in candidates with diabetes.

Conclusions: Clinicians should screen for cognitive impairment in KT candidates, especially among those without predisposing conditions like diabetes, and identify interventions to improve access to KT so that these vulnerable patients can experience post-KT cognitive improvements.

Funding: NIDDK Support, Other NIH Support - National Institute on Aging (NIA)

Table. Cumulative incidence (%) and associations of listing, waitlist mortality, and kidney transplantation (KT) by global cognitive impairment. Participants were classified as cognitively impaired if they had a 3MS score <80. Adjusted associations were controlled for age, sex, race, diabetes, educational attainment, and the Charlson Comorbidity Index adapted for ESKD. To explore the association between waitlist mortality and cognitive impairment by diabetes status, an interaction term was added between cognitive impairment and diabetes status. Abbreviations: HR, hazard ratio; SHR, subdistribution hazard ratio; IRR, incidence rate ratio.

TH-OR133

Self-Reported vs. Measured Physical Function in Kidney Transplant Candidates at the Top of the Waitlist

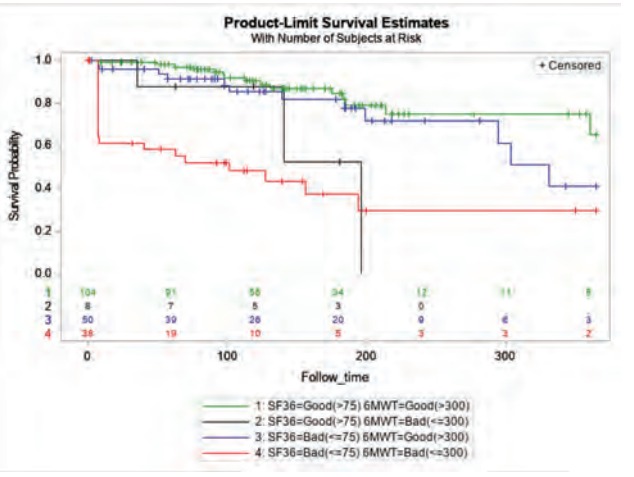
Daniel J. Watford,[1] Xingxing S. Cheng,[1] Jialin Han,[1] Margaret R. Stedman,[1] Khin N. Chan,[1] Jonathan N. Myers,[2] Jane C. Tan.[1] *[1]Stanford University, Palo Alto, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Background: Poor physical function of waitlisted kidney transplant candidates is associated with adverse waitlist outcomes, but the optimal metric is not known. We compared self-reported versus measured functional assessments in patients at the top of the waitlist.

Methods: Patients were evaluated from May 2017 to December 2018. Self-reported SF36 physical function subscale score (SF36 PF) was compared to results of the 6-minute walk test (6MWT) and sit-to-stand (STS) test by linear regression. We estimated the association between each metric and time to adverse waitlist outcomes (waitlist removal or death), with transplant as the competing event, by the Fine-Grey model, and adjusted for clinical covariates. We estimated model fit by AIC and likelihood ratios and compared hierarchically nested models, starting with demographics and comorbidities and sequentially adding physical assessment metrics.

Results: Out of 200 patients, the median SF36 PF, 6MWT, and STS results were 80, 396 meters, and 18, respectively. Physical function metrics were highly correlated (R^2=0.49 for STS-6MWT, 0.32 for STS-SF36 PF, and 0.54 for 6MWT-SF36 PF). Over median follow-up of 118 days, 29 patients were removed from the waitlist, 6 died, and 23 were transplanted. All three metrics were strongly associated with waitlist outcomes and improved model fit for adverse waitlist outcomes over standard exposures of demographics and comorbidities alone. 6MWT and SF36 PF results improved model fit more than STS. See figure.

Conclusions: Self-reported and measured assessments of physical function are strongly associated in kidney transplant candidates. Addition of SF36 and/or 6MWT results to standard exposures significantly improves association with waitlist outcomes. Combining self-reported and measured physical function metrics may provide the best assessment of global functional status in kidney transplant candidates.



TH-OR134

Living Kidney Donor Visceral Adipose Tissue Predicts Donor Histopathology and Post-Donation Kidney Functional Decline

Joshua J. Augustine,[1] Karen L. Stern,[1] Sherif Armanyous,[1] Ahmed M. Kamel,[3] Emilio D. Poggio.[2] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH; [3]Faculty of Pharmcay, Cairo University, Giza, Egypt.*

Background: Living kidney donors have become increasingly complex with increased obesity and older age. Given the association of visceral adipose tissue (VAT) and kidney functional decline in the general population, we hypothesized that VAT in living donors may predict baseline histopathology and post-donation kidney function.

Methods: We measured VAT in 170 living kidney donors using pre-donation computerized tomography (CT) imaging and computerized software at a single lumbar level: L3-L4 for females and L2-L3 for males. All donor kidneys had preimplantation biopsies. Chronic histologic findings were defined as 2 of 3 biopsy findings: >5% global glomerulosclerosis, any interstitial fibrosis with tubular atrophy, or the presence of any arteriosclerosis. Kidney function was recorded by estimated glomerular filtration rate (eGFR) pre-donation and at 1, 12, and 24 months post-donation. GFR decline was defined as the percent drop in eGFR at 12 months vs. pre-donation.

Results: Greater VAT by tertiles correlated with older donor age, male gender, smoking, higher blood pressure, lipid abnormalities, and body mass index (BMI), (TABLE). Donor glomerulosclerosis and interstitial fibrosis on biopsy also correlated with VAT (TABLE). The highest tertile of VAT also correlated with lower pre-donation eGFR and less GFR recovery (FIGURE). After controlling for all associated donor variables including age, gender, and BMI, donor VAT remained an independent predictor of chronic histologic findings (OR: 1.02, 95% CI 1.01-1.04, p<0.001), and GFR decline after donation (b = 0.04, 95% CI: 0.02 to 0.07, p=0.001).

Conclusions: Living kidney donor VAT using standardized CT measurements correlated independently with both histopathologic findings and kidney functional decline after donation. VAT measurement may allow for donor risk stratification and may identify donors at higher risk for long term kidney functional impairment.

Improvement in Waiting Times for Recipients of A_2 to B Kidney Transplants: Refining Our Understanding

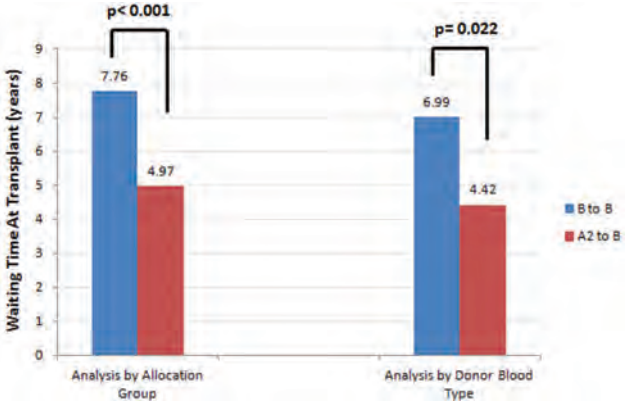
Alexander Gilbert,[1] Laurel Ormiston,[2] Shannon Radomski,[3] Gayle M. Vranic,[1] Beje S. Thomas,[1] Jack Moore.[4] *[1]MedStar Georgetown Transplant Institute, Washington, DC; [2]Georgetown University School of Medicine, Washington, DC; [3]Georgetown University Medical School, Washington, DC; [4]Washington Hospital Center, Kensington, MD.*

Background: The creation of a new allocation priority in the new Kidney Allocation System (KAS) for transplants from blood group A_2 donors to blood group B recipients has allowed more rapid transplantation of the group B list. However, no analysis has looked at the decrease in waiting times controlling for differences in sensitization or other priority factors (such as HIV or HCV positive kidneys). We undertook to do this type of robust analysis.

Methods: We conducted a retrospective analysis of 396 consecutive recipients who received a deceased donor kidney transplant in the time period from December 4, 2014 (the beginning of KAS) to November 1, 2018. We determined the waiting time based on the distribution pool in which the kidney was allocated and compared patients receiving kidneys in the local or regional blood type B for blood type A_2/A_2B donor only pools with those receiving kidneys within the local, regional, or national blood type identical or permissible pools.

Results: There were a total of 17 transplants of A_2/A_2B organs from deceased donors into blood group B recipients. 15 of the 17 were allocated within the A_2/A_2B pools (the other 2 were allocated in high cPRA pools). In the same period there were 57 B to B transplants of which 37 were allocated in the blood type identical or permissable pools. The 15 patients receiving A_2/A_2B organs had a mean waiting time of 4.97 ± 1.55 years, significantly lower than the 37 patients receiving standard B to B transplants (7.76 ± 3.91 years, p <0.001). This amounted to a 35.9% reduction in waiting time.

Conclusions: The benefits of A_2 to B transplantation in decreasing waiting times to transplant have been thus far underestimated due to the confounding factors of high sensitization and other high priority allocation. An A_2 to B transplant protocol can reduce waiting times by more than a third for hard to transplant patients.



Improvement in Waiting Times for Recipients of blood group A2 kidneys

Normothermic Ex Vivo Kidney Perfusion Preservation Reliably Improves Extreme Marginal Graft Function Compared with Hypothermic Machine Perfusion

Peter Urbanellis,[1,2] Dagmar Kollmann,[6] Ivan Linares,[4] Rohan John,[4] Istvan Mucsi,[2] Ana Konvalinka,[7] Lisa Robinson,[3] Markus Selzner.[5] *[1]University of Toronto, Toronto, ON, Canada; [2]Multi-Organ Transplantation, University Health Network, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada; [4]University Health Network, Toronto, ON, Canada; [5]Toronto General Hospital, Toronto, ON, Canada; [6]Medical University of Vienna, Vienna, Austria; [7]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: Normothermic ex-vivo kidney perfusion (NEVKP) is an emerging technique for renal graft preservation. We investigated whether NEVKP promoted improved marginal graft function compared to anoxic hypothermic machine perfusion (HMP) in a model of donation-after-cardiac-death (DCD).

Methods: Kidneys from 30kg-Yorkshire pigs were removed following 120min of warm ischemia (WI). These grafts were preserved with HMP (LifePort1.0, n=7) or NEVKP (n=7) for 8h prior to heterotopic autotransplantation.

Results: During NEVKP, 120min WI grafts cleared perfusion lactate (0h:10.48±0.93mmol/L vs 7h:1.48±0.85mmol/L,p<0.01), had decreasing intra-renal resistance (IRR) (0h:2.26±0.9mmHg/mL/min vs 7h:0.37±0.6mmHg/mL/min, p<0.01), and produced urine. IRR also decreased in HMP (0h:1.71±0.30mmHg/mL/min vs 7h:1.19±0.37mmHg/mL/min, p=0.01). Post-transplant, 120min WI grafts with NEVKP trended towards earlier and decreased serum creatinine (SCr) peak values compared to HMP (POD3:12.29±2.16mg/dL vs POD5:16.62±6.74mg/dL,p=0.13). From POD5-7, the HMP group demonstrated a bimodal distribution in SCr leading to increased variance compared to NEVKP (standard deviation = 6.74, 9.28, 9.38mg/mL vs 5.72, 6.25, 4.75mg/mL, respectively). In the HMP group, 4 of 7 grafts were poor performing with 2 developing renal vein thrombosis. Conversely, only 1 in 7 grafts was poor performing with NEVKP with no evidence of renal vein thrombosis (Figure 1). The consistent improvement in NEVKP vs heterogeneity in HMP was also observed through the variation in creatinine clearance (POD7: 26.31±11.54mL/min vs 16.8±18.9mL/min) and on histological analysis of tubular injury.

Conclusions: Marginal kidney grafts showed reliable improvement in function following 8h of continuous NEVKP compared to HMP where improvement was inconsistent. This suggests NEVKP would be a preferable storage strategy for DCD procured grafts with extended WI times.

Genome-Wide Non-HLA Donor-Recipient Mismatches in Intronic Regions Independently Associate with Graft Survival

Zhongyang Zhang, Zeguo Sun, Weijia Zhang, Ke Hao, Barbara T. Murphy, Madhav C. Menon. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Donor-recipient (D-R) mismatches at human leukocyte antigen (HLA) loci are used for management decisions. Recent work has showed the role of global non-HLA D-R mismatches, specifically exonic loci within genes coding transmembrane and secreted proteins in graft survival in Caucasian deceased donor cohorts. Since non-coding regions constitute ~98% of human genome, and these elements have demonstrable regulatory activity, we hypothesized that non-coding D-R genetic differences could also contribute to unchecked alloimmunity impacting graft survival.

Methods: We utilized genome-wide SNP array data on all D-Rs in the GOCAR study excluding HLA region (n=385 D-Rs). We quantified the genome-wide numbers of mismatches of all SNPs, and annotated those in non-coding regions, or exomes [divided further into nonsynonymous within genes coding transmembrane and secreted proteins] - all as separate continuous variables. Long-term death censored graft loss [DCGL] data were from UNOS/ANZDATA.

Results: Our multi-ethnic D-R cohort represented greater genetic diversity and included living donors vs published data. There were 73 DCGL events during median follow-up of 1824 days (IQR: 1392-2188 days). Genome-wide- & Tm-mismatches were all increased in inter-race vs intra-race transplants (p<0.001). The total numbers of SNP mismatches quantified as quartiles respectively impacted DCGL & all-cause GL in adjusted Cox models [Fig. 1A-B]. However, in multivariate Cox models after adjusting for protein-coding mismatches, non-coding D-R mismatches remained independently associated with graft survival. Surprisingly, non-HLA mismatch variables had no association with acute T-cell mediated rejection phenotypes (subclinical or clinical; with/without borderline lesions) in regression models.

Conclusions: Our data from a multi-ethnic cohort compliments recent work supporting the role of non-HLA D-R mismatches in long term allograft survival. In addition, we showed that non-coding loci based mismatches had independent impact on graft survival.

Preliminary Results of the PHYSICALFAV Trial

Ines Aragoncillo,[1] Jose manuel Ligero,[1] Silvia Caldés,[2] Yolanda Hernandez,[2] Yesika M. Amézquita orjuela,[2] Almudena Vega,[1] Ana M. Garcia Prieto,[1] Nicolas Macias,[1] Soraya Abad,[1] Jose Luno,[1] Maria Covadonga Hevia ojanguren.[3] *[1]Hospital Gregorio Marañón, Madrid, Spain; [2]Hospital Infanta Sofia, Madrid, Spain; [3]HU Infanta Sofía, S Sebastian de los Reyes.Madird, Spain.*

Background: Hemodialysis with autologous arteriovenous fistula (AVF) is associated with higher survival, lower costs, and fewer complications. Distal forearm AVF is the best option, but not all patients are good candidates for this approach and the primary failure rate ranges from 20% to 50%. The optimal AVF depends mainly on the anatomical and hemodynamic characteristics of the artery and the vein chosen for the anastomosis. These characteristics can be modified by performing physical exercise.

Methods: The PHYSICALFAV trial (NCT03213756) is an open-label, multicenter, prospective, controlled, randomized trial designed to evaluate the usefulness of preoperative isometric exercise (PIE) in pre-dialysis or prevalent hemodialysis patients who are candidates for a new AVF. Patients are randomized 1:1 to the PIE group (Exercises combining hand grip and elastic band for 8 weeks) or the control group (no exercise).

Results: After 20 months recruitment, 120 patients have been randomized. After 8 weeks of preoperative isometric exercise we have found significant differences on vein diameter (p<0.001), arterial peak systolic velocity and diameter (p 0.041- p 0.001) and maximum strength (p<0.001) on PIE group patients (table 1). We have been able to perform 76% of distal AVF in PIE group compared to 53% in the control group (p 0,043). Global primary failure rate was very low in both groups (6,9% PIE group vs 5,7% control group, pNS) and intervention free rate at 3 months was 82,8% PIE group vs 80% in control group (pNS).

Conclusions: Isometric preoperative exercise can improve vascular calipers and increase the possibility of performing distal AVF. The final results of this trial will be available in September 2019.

Funding: Other NIH Support - Grant founding from the Spanish Society of Nephrology.

Before and after exercise

	Baseline visit	After 8 weeks of exercise	p
Vein diameter (mm)	2,88 (1,05)	3,55 (0,97)	<0.001
Artery diameter (mm)	2,57 (0,90)	2,76 (0,89)	0.001
PSV (cm/sg)	66,67 (20,4)	72,84 (22,3)	0.041
Maximun strength(kg)	27,4 (10,3)	31,32 (11,9)	<0.001

Ferumoxytol MR Angiography vs. Doppler Ultrasound for Vascular Mapping Before Hemodialysis Arteriovenous Fistula Creation

Sokratis Stoumpos,[1,2] Alfred B. Tan,[3] Giles Roditi,[1] Patrick B. Mark.[2,1] *[1]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [2]Cardiovascular Research Centre, University of Glasgow, Glasgow, United Kingdom; [3]University Hospital Hairmyres, Glasgow, United Kingdom.*

Background: Doppler ultrasound (DUS) is routinely performed for vascular mapping prior to placement of a hemodialysis arteriovenous fistula (AVF) but can not adequately visualize the central vasculature. Ferumoxytol, an iron oxide nanoparticle, is an alternative to gadolinium for magnetic resonance angiography (MRA). We compared ferumoxytol-enhanced MRA (FeMRA) with DUS for assessment of the central and upper extremity vasculature in patients with renal disease due for autologous AVF creation.

Methods: In a prospective comparative study, paired FeMRA and DUS were obtained on the same day. Three readers independently assessed arterial and vein diameter and the presence of stenosis or occlusion (central or peripheral) with FeMRA and US. Interclass correlation coefficients (ICC) and Bland-Altman plots examined inter-reader variability. Based on accepted standards for the creation of an AVF, an algorithm was created to predict AVF outcome relying on mapping findings. Two binomial logistic regression models were created with AVF outcome as the dependent variable and age, sex, and US prediction algorithm (model 1) or FeMRA prediction algorithm (model 2) as the predictor variables.

Results: From the 59 patients that had FeMRA and DUS, 51 had an autologous AVF created. FeMRA showed excellent inter-reader repeatability (ICC 0.84-0.99). Vessel course, accessory veins, anatomical variants and the presence of stenosis or occlusion in arm vessels were better assessed with FeMRA. FeMRA identified 15 central vasculature stenoses (CVS). On multivariable regression analyses FeMRA mapping was an independent predictor of AVF outcome [odds ratio (OR): 6.49 (95% CI 1.7 - 24.8); p=0.02].

Conclusions: FeMRA prior to AVF creation better predicted outcome compared to DUS. Its value is not limited in identification of central vessels pathology but it also showed peripheral vascular disease under-recognized with US.

Funding: Commercial Support - AMAG Pharmaceuticals, Inc.

Inactivation of Lysyl Oxidase in Smooth Muscle Cells Improves Arteriovenous Fistula Function in Mice

Roberto I. Vazquez-Padron,[1] Diana R. Hernandez,[1] Laisel Martinez,[1] Marwan Tabbara,[2] Juan C. Duque,[1] Loay H. Salman.[3] Vazquez-Padron's team *[1]University of Miami, Miami, FL; [2]University of Miami, Miller School of Medicine, Miami, FL; [3]Albany Medical College, Albany, NY.*

Background: Over 400,000 patients in the U.S. depend on vascular access to receive hemodialysis (HD) and prolong their lives. Unfortunately, arteriovenous fistulas (AVFs), the preferred vascular access for HD, frequently fail (~40%) because venous stenosis compromises blood flow. We recently discovered that stenosis occurs due to excessive medial fibrosis and is aggravated by intimal hyperplasia. Herein, we hypothesize that it is possible to prevent AVF failure by targeting lysyl oxidase (LOX), a copper-dependent amine oxidase involved in collagen and elastin crosslinking and in the epigenetic control of gene expression in smooth muscle cells (SMCs).

Methods: We created a LOX conditional knockout mouse[$Lox^{f/f}$Myh11-$CreER^{T2}$] that is fertile, normal in size, and without any gross abnormalities. AVF were created by anastomosing the jugular vein to the nearby carotid artery. Mechanistic studies were performed with primary cultures of mouse venous SMC.

Results: Tamoxifen (TAM) injections significantly downregulated LOX gene expression[3 folds vs. control, p<0.01] and protein accumulation in the vasculature of conditional KO mice but not in those of control littermates[$Lox^{+/+}$Myh11-$CreER^{T2}$]. Inactivation of LOX in SMCs decreased immature collagen crosslinking in the aorta[1.3 ± 0.1 vs. 1.7 ± 0.1 HLNL+DHLNL/collagen], and reduced carotid pulse wave velocity[2.2 ± 0.2 vs. 2.9 ± 0.4 m/s] as determined by ultrasound microscopy. AVFs in mice with LOX-deficient SMCs showed higher distensibility and blood flow by day 21 post-surgery. Importantly, gene deletion caused aneurysms neither in the fistula nor in other parts of the vasculature. Mechanistically, we demonstrated that inhibition of LOX with BAPN increased H3K4me2 and H3K4me1 marks in the SMC genome, and specifically in the promoters of SMC contractile genes, to keep them in an open chromatin state and promote the binding of the SRF-myocardin transcription complex. We further confirmed the increased abundance of SRF in the CArG boxes of contractile gene promoters in SMCs treated with BAPN compared to the vehicle using a quantitative ChIP assay.

Conclusions: These data indicate, for the first time, the importance of LOX not only in post-operative vascular remodeling after AVF creation but also in the control of the SMC phenotype.

TH-OR141

Assessment of Fistula Flow Using Smartphone Video Analysis

Fansan Zhu,[1] Lin-Chun Wang,[1] Ohnmar Thwin,[1] Karen Lin,[1] Xia Tao,[1] Samir D. Patel,[1] Vaibhav Maheshwari,[1] Mia G. Garbaccio,[1] Stephan Thijssen,[1] Dean C. Preddie,[3] Norbert Shtaynberg,[3] Kamran Karimi,[3] Shadi Sallit,[3] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Azura Vascular Care, Brooklyn, NY.*

Background: Frequent, non-invasive assessment of arterio-venous fistula (AVF) blood flow (ABF) is desirable to timely detect access malfunction. Given the almost universal availability of smartphones with video capabilities, we assessed ABF by video image processing.

Methods: Fify-eight hemodialysis patients were studied after endovascular interventions where ABF was measured invasively using thermodilution (HVT100, Transonic, Ithaca, NY). A 1-minute video of the skin above the AVF was recorded (iPhone 6; Fig.1). Frame-to-frame pixel changes were quantified and followed over time. These time series were then transformed into the frequency domain. The frequency domain signal was characterized by the squared ratio of the maximal-to-median magnitude (M2; an example is shown in Fig.2). Forty randomly selected patients (derivation cohort) were

used to construct multiple regression models with ABF as dependent variable, 18 patients served as validation cohort.

Results: Visual inspection of the derivation cohort ABF vs. M2 scatterplot indicated 2 distinct populations, one with M2≤100 (n=30) and M2>100 (n=10; Table 1). In the validation cohort 17 patients had M2≤100, and 1 patient >100. In the derivation cohort a multiple regression model including M2, sex, body weight, and race explained 64% of the ABF variance in patients with M2≤100 (Fig 3A) and 44% in patients with M2>100 (Fig. 3B), respectively. In the validation cohort we predicted 51% of the ABF variance in patients with M2≤100 (Fig 4); the one patient with M2>100 was not analyzed.

Conclusions: Our results show that advanced mathematical analysis of smartphone videos may have the potential to assess AVF blood flow. If corroborated in more extensive clinical studies, smartphone video analysis provides an attractive and low-cost means to non-invasively evaluate AVF blood flow.

Funding: NIDDK Support

Automatic Classification of Arteriovenous Fistula Aneurysms Using Artificial Intelligence

Hanjie Zhang,[1] Murat Sor,[5] Elsie Koh,[5] Priscila Preciado,[1] Dugan Maddux,[2] Len A. Usvyat,[2] John W. Larkin,[3] Peter Kotanko.[1,4] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA; [3]Fresenius Medical Care, Waltham, MA; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Azura Vascular Care, Woodland Park, NJ.*

Background: Trained professionals examine arteriovenous fistulas and diagnose aneurysm (AVFA) stages, but there is no fully automated classification method. Our goal is to build a convolutional neural network (CNN) to automatically classify AVFA stages.

Methods: We collected 15-20 sec "panning" videos from 30 patients with two AVFA categories, 23 patients with AVFA stage 2 (enlarged AVF with hypopigmented skin) and 7 patients with AVFA stage 3 (enlarged fistula with open ulcer). The videos were collected against a white background. Patients had diverse skin tones. We extracted the video frames that then comprised our image set. Each image has three color channels, the image shape was 960 x 540 (Figure 1). We used 80% of the patients' videos for CNN training and the remainder for validation using the Amazon SageMaker machine learning platform (Amazon, Seattle, Washington).

Results: We trained the CNN in two modes. First, the transfer learning mode, utilized the pre-trained Amazon SageMaker image classification algorithm, fine-tuned to our image data set. Second, the full training mode, where the CNN was trained from scratch with our image data set. With both of these training modes, we were achieved a > 90% classification accuracy in the validation images.

Conclusions: CNN is able to automatically classify AVFA. Automation of that process is expected to reduce workload, provide timely AVFA diagnosis, and improve patient care.

TH-OR143

Comparison of Drug-Coated Balloon Angioplasty vs. Conventional Balloon Angioplasty for Arteriovenous Fistula Stenosis: A Meta-Analysis

Sohail Abdul Salim,[1] Charat Thongprayoon,[3] Wisit Cheungpasitporn,[1] Tibor Fulop.[2] *[1]University of Mississippi Medical Centre, Brandon, MS; [2]Medical University of South Carolina, Charleston, SC; [3]Nephrology, Mayo Clinic, Rochester, MN.*

Background: Arteriovenous fistula (AVF) is the most preferred form of vascular access for maintenance hemodialysis (HD) but access stenosis treated by balloon angioplasty are prone to restenosis due to neointimal proliferation. Multiple trials have been published with regards to use of paclitaxel coated balloon (DCB) to prolong lesion patency when compared to conventional balloon. Though DCB has theoretical appeal, its use has not been widespread with access centers nationwide due to factors related to cost and lack of large scale multicenter studies. We performed this meta-analysis to evaluate whether use of DCB outperforms conventional balloon to prolong target lesion patency.

Methods: Medical electronic databases, including PubMed/Medline, Clinical Trials. gov, EMBASE, Scopus, Web of Science and Cochrane Central were searched from inception through April 2019 for studies that investigated use of DCB in HD AVF. 15 studies (6 Randomized control trials (RCT) and 9 observational studies) were considered for qualitative and quantitative analysis.

Results: Ten studies were included in the final meta-analysis. 6 of the studies were RCTs and 4 were retrospective (cohort) studies. There were 915 participants with a mean age of 65.40 (+/-5.96) years and 61.89% were male. The outcome of interest was target lesion primary patency (TLPP), recorded at a longitudinal follow-up time, i.e. 1, 3, 6, 7, 12 and 24 months. Meta-analysis of all RCTs shows that drug-coated balloons (DCBs) did not statistically improve TLPP compared to traditional balloons at months 1 (OR 4.27, p-value 0.06), 3 (OR 0.9, p-value0.99), 6 (OR 0.80, p-value 0.54), 7 (OR 0.93, p-value 0.75), 12 (OR 0.61, p-value 0.17) and 24 (OR 0.69, p-value 0.15). The effect of DCBs was statistically significant for cohort studies at 6 months (OR 0.26, p-value 0.0007), 12 months (OR 0.21, p-value 0.0001) and 24 months (OR 0.23, p-value 0.01). Studies using AV-Graft were excluded. There was no publication bias as assessed by funnel plots.

Conclusions: Drug-coated balloons showed no statistically significant improvement over conventional balloons in decreasing fistula stenosis in meta-analysis of RCT at 1,3,6,7,12 and 24 months but were significant for cohort studies at all follow up months of 6, 12 and 24. Our analysis does not justify the use of DCB at this time.

Patient, Care Partner, and Provider Perspectives on Arteriovenous (AV) Access Creation Prior to Hemodialysis (HD) Initiation

Surya Manivannan,[1] Julia Narendra,[2] Shannon L. Murphy,[3] Christina Yule,[4] Heather Bonaparte,[5] L. Ebony Boulware,[6] Jamie A. Green,[7] Jennifer E. Flythe.[8] *[1]university of north carolina, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of North Carolina, Chapel Hill, NC; [4]Geisinger Health System, Danville, PA; [5]Geisinger, Danville, PA; [6]Duke University School of Medicine, Durham, NC; [7]Geisinger Medical Center, Danville, PA; [8]University of North Carolina Kidney Center, Chapel Hill, NC.*

Background: More than 80% of individuals in the U.S. start maintenance HD with a catheter, despite substantial evidence that starting HD with an AV access improves quality of life, lowers mortality, and decreases healthcare costs. Barriers to AV access creation prior to HD initiation have been under-investigated. We sought to identify patient, care partner, medical provider, and clinic personnel perspectives on the AV access creation process in the pre-HD period.

Methods: We conducted 4 focus groups (N=24 participants) and 16 semi-structured interviews across 2 diverse health systems (UNC and GH). Focus groups included advanced chronic kidney disease patients (GFR <20 mL/min/1.73m^2), and separately, HD patients within 1 year of HD initiation as well as care partners of such patients. Interviewees included nephrologists, surgeons, clinic nurses, imaging specialists, and other staff. Transcripts were coded independently by 3 researchers and thematically analyzed.

Results: Participants identified a range of patient- and healthcare system-related barriers to starting HD with an AV access. Key modifiable barriers included: siloed provider views of the AV access creation process; negative patient emotions (e.g. fear, denial, uncertainty); inadequate and inconsistent patient education; and lack of systematic approaches to tracking patients through AV access care processes. Key facilitators included: early and sustained dedicated vascular access education (i.e. separate from modality and transplant education); care partner inclusion in education; and positive peer interactions. Participants identified 4 essential aspects of pre-HD vascular access care: strong patient—provider relationships (trust, shared decision-making); focused, iterative multi-format education; peer support; and assistance in process navigation (e.g. care navigation, vascular access-specific electronic health record reports, consistent provider communication).

Conclusions: Programs aimed at improving rates of HD initiation with an AV access must address both patient- and healthcare system-related barriers. Key components include strong patient-provider relationships, targeted education, peer support, and care navigation.

TH-OR145

Ultrafiltration and Cerebral Microbleeds in Haemodialysis Patients

Yujun Qian,[1] Ke Zheng,[2] Xuemei Li.[2] *[1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Dongcheng District, Beijing, China; [2]Peking Union Medical College Hospital, Beijing, China.*

Background: Ultrafiltration of dialysis patients were variable. The detailed studies on the impact of different ultrafiltration are still rare. Variable ultrafiltration may contribute to brain lesions by inducing hemodynamic instability. Cerebral microbleeds (CMBs) in dialysis patients have recently attracted much attention. The risk factors of CMB in dialysis patients are not very clear. The association of dialysis ultrafiltration with CMB is unknown.

Methods: A total of 119 chronic haemodialysis patients were enrolled in our study. Demographic and Clinical Characteristics of Patients were recorded. Multiple ultrafiltrate information of every patient before MRI examination was recruited with Ultrafiltrate volume(UV) mean, UV standard deviation(SD), UV coefficient of variation(CV), the difference between UV mean and 6% of weight, the ratio of UV to weight mean, and the ratio of UV to weight SD. CV was calculated as the ratio of SD to the mean. CMBs were defined as small (2–10 mm) areas of homogeneous signal loss on susceptibility weighted imaging images. The correlation between ultrafiltration and CMB was investigated by logistic regression analysis.

Results: Recorded dialysis period ranged from 2.0 to 14.0 months, and recorded dialysis times ranged from 11.0 to 54.0. Urea removal ratio was 0.7±0.1, and Kt/V was 1.4±0.2. UV mean ranged from 0.2 to 4.6 kg, and UV CV ranged from 0.0 to 78.1 percent. The prevalence of CMBs was 35.3% in the total study population. Ten subjects (8.4%) suffered lobar CMBs, Nine subjects (7.6%) suffered mixed CMBs, and 23 subjects (19.3%) suffered deep group. UV mean, the difference between UV mean and 6% of weight, and the ratio of UV to weight mean were risk factors of CMB (OR=1.59, 1.48, and 1.31 respectively, p=0.031, 0.042, and 0.039 respectively) and mixed CMB (OR=2.23, 2.07, and 1.66 respectively, p=0.036, 0.057, and 0.030 respectively). UV CV was negatively associated with CMB(OR=0.96, p=0.022 respectively). The association of UV mean and UV CV with CMB was still significant after adjusting for gender, age, serum albumin, urea removal ratio, lacunes, and white matter hyperintensity(OR=1.72 and 0.96 respectively, p=0.044 and 0.046 respectively).

Conclusions: UV was closely associated with CMB in dialysis patients. Reducing UV may protect dialysis patients from CMB.

Trends in Use and In-Hospital Outcomes of Subcutaneous Implantable Cardioverter Defibrillators in Dialysis Patients: A Report from the National Cardiovascular Data Registry

Patrick H. Pun,[1] Craig S. Parzynski,[2] Daniel J. Friedman,[1] Gillian Sanders,[1] Jeptha P. Curtis,[3] Sana Al-Khatib.[1] *[1]Duke University, Durham, NC; [2]Yale New Haven Health, New Haven, CT; [3]Yale University School of Medicine, New Haven, CT.*

Background: Dialysis patients are at high risk of infectious and vascular complications related to implantable cardioverter defibrillator (ICD) implantation; many have advocated for the preferential use of subcutaneous (S-ICD) over transvenous devices (TV-ICD) due to the potential benefits of reduced risk of blood stream infection and interference with vascular access sites. We evaluated trends in use and in-hospital outcomes of S-ICD compared to TV-ICDs among dialysis patients in the United States

Methods: This was a retrospective analysis of 23,136 ICD implants among dialysis patients reported between 2012 and 2018 to the National Cardiovascular Data Registry ICD Registry, a nationally representative US ICD registry. We first examined the utilization and patient and procedure characteristics of dialysis patients receiving S-ICD. Next, among dialysis patients eligible to receive an S-ICD, we examined trends in S-ICD adoption as a proportion of all ICD implants and compared in-hospital outcomes (death, complications) among S-ICD and TV-ICD recipients using inverse probability weighted estimators.

Results: Of all ICDs implanted among dialysis patients during the study period, 3,195 (13.81%) were S-ICD. Among eligible first-time ICD dialysis recipients, the proportion of S-ICDs utilized increased yearly from 10.3% in 2012 to 68.5% in 2018. Compared to TV-ICD recipients, S-ICD recipients were more likely to be black (42.6% vs. 34.3%) and undergo implantation in teaching hospitals (62.8% vs 53.2%). In the inverse probability weighted estimators analysis of 3,327 patients, compared to TV-ICD, dialysis patients receiving S-ICDs had a higher rate of in-hospital cardiac arrest (1.53% vs 0.36%, p=0.002); in-hospital complications ((2.4% vs 1.48% p=0.08) and length of hospitalization ((1.57 vs. 1.24 days, p=0.08) were not significantly different between the 2 groups.

Conclusions: There has been a steady increase in the utilization of S-ICD among dialysis patients in the United States. The increased risk of in-hospital cardiac arrest in S-ICD recipients could have been due to residual confounding and selection bias, but randomized clinical trials are needed to definitively compare the outcomes of TV-ICD with S-ICDs in dialysis patients.

Intradialytic Hypotension and Incident Peripheral Artery Disease in Patients with ESKD on Hemodialysis

Eun Young Seong,[1] Sai Liu,[2] Sang Heon Song,[1] Nicholas J. Leeper,[2] Wolfgang C. Winkelmayer,[3] Maria E. Montez-Rath,[2] Tara I. Chang.[2] *[1]Pusan National University Hospital, Busan, Republic of Korea; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Baylor College of Medicine, Houston, TX.*

Background: Intradialytic hypotension (IDH) may decrease systemic circulation to the lower extremities, exacerbating symptoms of peripheral artery disease (PAD). We sought to evaluate the relationship between IDH and incident PAD among patients on hemodialysis (HD).

Methods: Using the data from USRDS linked to a large dialysis provider, we identified adults without pre-existing PAD who initiated HD between 2006-2011. Exposure: time-varying proportion of HD sessions with IDH, defined as nadir systolic blood pressure <90 mmHg, categorized as 0%, 1-14%, 15-29%, and ≥30% in 30-day intervals. Outcome: incident PAD, ascertained using PAD diagnosis codes or procedure codes for amputation or revascularization, in the subsequent 30-day interval. We estimated unadjusted and adjusted sub-distribution hazard ratios using Fine and Gray models with time specified in the counting-process style, assuming death and kidney transplant as competing events. Models were stratified by incident HD year and adjusted for baseline characteristics, comorbidities, healthcare use and laboratory values. Missing data were handled using multiple imputation by chained equations as implemented in R.

Results: In our cohort (N=45,489), patients with a more frequent IDH were more often women and of white race, and had a higher prevalence of diabetes, coronary artery diseases and heart failure. During 61,842 person-years of follow-up, 8,111 patients had incident PAD. We found a graded, direct association of IDH with incident PAD. For example, the presence of IDH in ≥30% of dialysis sessions was associated with an adjusted 36% increase in the hazard of incident PAD (95% CI, 27%-45%) compared to 0% IDH, in patients without PAD or who have experienced the competing events (Figure 1).

Conclusions: Patients with ESKD on HD with more frequent IDH have a higher hazard of incident PAD in the subsequent 30 days. Patients with more frequent IDH may warrant a careful examination for PAD such as foot examinations or other diagnostic testing.

Targeting the Cell Cycle in ADPKD: The Role of Cyclin-Dependent Kinase 1

Bruno Eduardo Pedroso Balbo,[2,4] Chao Zhang,[2] Xin Tian,[3] Yiqiang Cai,[2] Max Spitzer,[1] Rachel Gallagher,[2] Ke Dong,[2] Stefan Somlo.[1] *[1]Yale University, New Haven, CT; [2]Yale University School of Medicine, New Haven, CT; [3]Yale School of Medicine, New Haven, CT; [4]USP, Sao Paulo, Brazil.*

Background: Cilia ablation reduces cyst formation after polycystin inactivation, suggesting that a cilia-dependent cyst-activating (CDCA) mechanism is a driver in ADPKD. To investigate this pathway, we conducted transcriptomic profiling in adult-onset ADPKD models at an early stage following cyst initiation. We identified cyclin-dependent kinase 1 (*Cdk1*) as one of the most upregulated genes in incipient cyst cells following *Pkd1* inactivation and we investigated its role in ADPKD pathogenesis.

Methods: To enrich for transcriptomes from cells destined to form cysts in the kidney, we isolated RNA by translating ribosome affinity purification (TRAP). RNAseq profiling was performed in 10wk-old mice (4/group): *Pkd1$^{fl/+}$;R26^{Rpl10a};Pax8^{rtTA};TetO^{Cre}* (non-cystic; NC), *Pkd1$^{fl/fl}$;R26^{Rpl10a}; Pax8^{rtTA};TetO^{Cre}* (cystic, single KO; SKO) and *Pkd1$^{fl/fl}$;Kif3a$^{fl/fl}$;R26^{Rpl10a};Pax8^{rtTA};TetO^{Cre}* (non-cystic *Pkd1*-cilia double KO; DKO). Differential gene and KEGG pathway analyses were performed. Mouse models with early- (*Pkd1$^{fl/fl}$;Pkhd1^{Cre}*) and late-onset *Pkd1* deficiency (*Pkd1$^{fl/fl}$;Pax8^{rtTA};TetO^{Cre}*) were combined with the *Cdk1*-floxed allele, generating single KO (*Pkd1-KO*) and double KO (*Cdk1-Pkd1-KO*) models. The early and late onset groups were evaluated respectively on P24 and on the 18th wk of life (after doxycycline induction from P28-42).

Results: 155 genes were identified from the overlap between groups that shared differential expression in both NC vs SKO and SKO vs DKO groups. KEGG pathway analysis identified the cell cycle pathway as the most enriched and upregulated. *Cdk1* emerged as one of the most upregulated genes in this group. Polycystic kidney disease in *Cdk1-Pkd1-KO* group was significantly milder in both early onset and adult models when compared with *Pkd1-KO* models, as indicated by lower kidneys to body weight ratio, cystic index, and BUN. Cell proliferation rate (EdU incorporation) was significantly decreased in *Cre*-active tubule segments while no difference in apoptosis (TUNEL) was detected.

Conclusions: TRAP RNAseq on adult-onset ADPKD model at the early cystic stage has identified the cell cycle pathway as the most enriched one, suggesting that cell cycle changes occur early during the cyst formation. *Cdk1* emerged as one of the most upregulated cell cycle genes during cyst formation, and inactivation of *Cdk1* decreased cyst progression in ADPKD.

Single-Cell Transcriptomics Reveals Direct Target Genes Regulated by Pkd1 in Mouse Kidneys

Xiaoyan Li,[1] Hao Ding,[1] Xia Zhou,[2] James P. Calvet,[2] Xiaogang Li.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: While PKD gene mutations are known to be responsible for ADPKD, no study has yet been performed to tour the kidneys cell-by-cell to identify genes that are directly and significantly regulated by PKD mutations in individual kidney cells, and to address whether PKD mutation in a specific renal cell type affects gene expression profiles in neighboring cells with wildtype PKD genes. The recently developed technique of single-cell transcriptome analysis (scRNA-seq) can be used to monitor global gene regulation in thousands of individual cells at the same stage of the disease in the same kidney, to provide insights into the mechanisms that determine how PKD gene deletion results in cystogenesis.

Methods: We performed scRNA-seq with kidneys from *Pkd1$^{flox/flox}$;Pkhd1*-Cre (*Pkd1*-cKO) mice, in which the *Pkd1* gene is selectively deleted in collecting ducts, and *Pkd1$^{flox/flox}$* (*Pkd1*-WT) mice collected at postnatal day 7 (PN7) (before cyst initiation), day 14 (PN14) (after cyst onset) and day 21 (PN21) (later stage of cyst formation) (n ≥ 3 per group) to investigate the dynamic gene transcription profiles of each individual renal cell.

Results: Our scRNA-seq analysis indicated that the gene transcription profiles are affected in several PKD associated signaling pathways and in pathways not previously studied in PKD in collecting duct (CD) cells with *Pkd1* deletion. In addition, we found that the specific markers for principal cells (PCs) of the collecting duct, *Aqp2* and *Hsd11b2*, were upregulated in *Pkd1* knockout CD cell clusters, and the cell numbers of these clusters were also increased compared to the *Pkd1*-WT CD cluster, whereas the cell numbers of the clusters of intercalated cells (ICs) (marked by *Atp6v1g3* and *Atp6v0d2*) were decreased, suggesting that loss of *Pkd1* increases the transition of CD cells from ICs to PCs, possibly leading to renal metabolic acidosis and high blood pressure. Interestingly, we found that deletion of *Pkd1* did not affect the expression levels of *Pkd2* in most cell clusters, including the CD cell cluster. However, deletion of *Pkd1* in CD cells did affect the gene expression profiles in cell clusters of neighboring cells.

Conclusions: Deletion of *Pkd1* in collecting duct cells promotes cyst formation by affecting signaling pathways in CD cells and neighboring cells but not *Pkd2* gene transcription in most cell clusters.

The Polycystin Complex Is Essential for Cilia Disassembly

Vasileios Gerakopoulos, Peter Ngo, Leonidas Tsiokas. *University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetic disease, attributed almost exclusively to mutations in two genes, *PKD1* and *PKD2*, encoding a receptor-channel complex (Polycystins or PKD1/PKD2) at the cell surface and the primary cilium. However, how mutations in *PKD1* and/or *PKD2* contribute to cyst formation/progression is unknown. The primary cilium is an antenna-like organelle present in every cell, and excessive ciliary signaling has been linked to cyst progression in ADPKD. A unique feature of the primary cilium is that it is formed when cells exit the cell cycle and disassembled upon cell cycle re-entry. Moreover, acceleration or deceleration of cilia disassembly suppresses or exaggerates cystic growth, respectively. Here, we examined whether the Polycystin complex has an essential role in cilia assembly and disassembly.

Methods: **Mice** *Ubc-Cre^{ERT2};Pkd1$^{f/f}$* and *Pkd1$^{f/f}$* mice were induced by 4-Hydroxytamoxifen from P2-P6 and sacrificed at P21. **Immunofluorescence** Cilia or cells in S phase were labeled with an Arl13b antibody (1:500, Proteintech) or EdU (ThermoFisher), respectively. **Signaling pathways** Activity of signaling pathways was determined by the Cignal 45-pathway Reporter Array (Qiagen).

Results: Mouse embryonic fibroblasts, NIH3T3, or mouse inner medullary collecting duct (mIMCD3) cells lacking PKD1 or PKD2 showed severely delayed ciliary disassembly, whereas ciliary assembly was unaffected. These effects were specific to the deletion of *Pkd1* or *Pkd2* genes, as adding back wild type PKD1 or PKD2, but not pathogenic mutants, normalized ciliary disassembly. Consistently, the number of ciliated cells positive for EdU, an indicator of G1-S transition, was increased in mutant cells in cell culture and in the cystic epithelium of mice lacking *Pkd1*. An important intermediary was p53, which was induced in *Pkd1* mutant cells and kidneys and downregulation or inhibition of p53 restored delayed disassembly in *Pkd1/2*-null NIH3T3 cells. Consistent with delayed disassembly in *Pkd1/2*-null cells, several cilia-based pathways including the TGFβ/Smad pathway, which is causally linked to cyst progression, were overactivated in mutant cells.

Conclusions: Our studies identify an essential role of Polycystins in cilia disassembly. Delayed disassembly in cells lacking Polycystins leads to prolonged/excessive activation of ciliary pathways that could contribute to ADPKD progression.

FR-OR004

Deletion of Ift-A Gene, Thm1, in a Pkd2 Early-Onset ADPKD Mouse Model Has Renal Tubular-Specific Attenuating and Synergistic Effects

Wei Wang,[1,2] Pamela V. Tran.[1,2] *[1]Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS; [2]Jared Grantham Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: Primary cilia are signaling organelles that have emerged as powerful modifiers of ADPKD. Primary cilia are synthesized by intraflagellar transport (IFT) complexes B and A. Ift-B gene deletion in renal tubules in *Pkd1* or *Pkd2* conditional knock-out (cko) mice ablated primary cilia and attenuated renal cystic disease, suggesting that cilia-mediated signaling within an ADPKD background may be pro-cystogenic. In contrast to Ift-B gene deletion, which often results in cilia loss, Ift-A gene deletion causes shortened cilia with protein accumulation in bulbous distal tips and can have opposing effects on signaling. Thus we examined the effect of Ift-A deficiency on a *Pkd2* mutant background.

Methods: Using the ROSA-Cre^{ERT} recombinase, *Pkd2* and *Thm1* were globally deleted alone or together in mice at postnatal day (P) 0 generating early-onset disease models, which were analyzed at P21.

Results: At P21, *Thm1* cko kidneys were similar to those of control littermates. *Pkd2;Thm1* double knock-out (dko) mice had reduced KW/BW ratios and smaller collecting duct-derived cysts than *Pkd2* cko mice. Yet BUN levels were similar between *Pkd2;Thm1* dko and *Pkd2* cko mice. Unlike *Pkd2* and *Thm1* single mutants, *Pkd2;Thm1* dko mice developed proximal tubular-derived cysts. Additionally, *Pkd2;Thm1* dko kidneys showed enhanced fibrosis and STAT3 activation relative to *Pkd2* cko kidneys. In *Pkd2;Thm1* dko collecting ducts, many primary cilia were shortened with accumulation of IFT81 protein at the distal tip, characteristic of an IFT-A cilia mutant phenotype and in contrast to *Pkd2* cko collecting duct primary cilia, which were lengthened.

Conclusions: In *Pkd2;Thm1* dko mice, reduced KW/BW ratios and collecting duct-derived cysts indicate that IFT-A is required for a component of *Pkd2* renal cystogenesis. Yet the presence of proximal tubular-derived cysts reveals there is also synergy between *Pkd2* and *Thm1* deletion. Further, enhanced renal fibrosis and STAT3 activation indicate that *Thm1* deletion exacerbates *Pkd2*-mutant renal disease. Thus the role of *Thm1* or IFT-A deficiency on an ADPKD background may be renal tubular/cell-specific.

FR-OR005

Molecular Regulation of Polycystin TRP Channels

Paul G. DeCaen. *Northwestern University, Chicago, IL.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) causes progressive renal failure and can be caused by variants in the PKD2 genes which encode the polycystin-2 transient receptor ion channel (TRP). Despite our strong understanding of the genetic basis of ADPKD, we still do not know how polycystin-2 ion channel function is molecularly regulated. This basic question remains outstanding because polycystin-2 localizes to the primary cilium—an antenna-like organelle that requires innovative tools to study. Recently, our lab achieved the first heterologous and native electrophysiological characterization of TRPP2 in the primary cilia membrane. With our collaborators, we also published the first high-resolution structure of polycystin-2, which has provided a molecular context for understanding ADPKD variants and clues to its structural regulation.

Methods: We have developed novel methodologies which include: cilia electrophysiology, cilia-specific calcium sensors, super-resolution imaging, cryo-EM structural determination and ADPKD animal models to assay polycystin activity directly from the primary cilia membrane. We have deployed these state-of-the-art methods to provide the most accurate description of the biophysical regulation of polycystin-2 and the related polycystin-like (encoded by PKD2L1) channels, providing results in real-time and atomic resolution.

Results: We have interrogated multiple mutations within three structural domains within polycystin-2 and assessed their impact on the opening and closing of the ion

conductive pore, the oligomictic stability of the tetrameric channel and their trafficking to the primary cilia membrane.

Conclusions: Our results provide a biophysical framework for understanding of polycystin-2's molecular regulation. We have determined that polycystin-2 integrates polymodal stimuli to control the channels voltage dependent gating. Domains within the channel independently respond to stimuli (e.g. intra-ciliary calcium), but the final open step is ultimately controlled by four-helix bundle which senses membrane potential. Based on these structural observations, we propose mechanistic hypotheses regarding the impact variants found within these domains.

FR-OR006

Regulation of PKD2 Channel Function by PKD1

Biswajit Padhy, Sung Wan An, Jian Xie, Chou-Long Huang. *University of Iowa Carver College of Medicine, Iowa City, IA.*

Background: Mutations of PKD1 and 2 cause autosomal-dominant polycystic kidney disease (ADPKD). PKD1 peptide has a very large extracellular N-terminus (Nt), 11 transmembrane (TM) domains, and intracellular C-terminus (Ct). PKD2 is 6-TM domains channel with intracellular N and C-terminus. The function and relationship of PKD1 and PKD2 and in the pathogenesis of ADPKD remain elusive. Previous studies show PKD1 and PKD2 interact with its C-terminus. Recent cryo-EM structural studies reveal the last 6 TM of PKD1 can interact with PKD2 to form presumably non-functional channel complexes.

Methods: Wild-type (WT) PKD2 and phenylalanine-604 to proline (F604P) mutant PKD2 were expressed in Xenopus oocytes with or without WT and mutant PKD1. PKD2 channel function was studied by using two-electrode voltage-clamp. Extracellular Ca^{2+}-inhibitable inward K^+ currents were measured.

Results: We found that currents in oocytes expressing WT- PKD2 were not different from in control oocytes. WT-PKD1 itself did not produce currents, and had no effects on WT-PKD2 currents when coexpression with it. It is known that F604P mutation on the 5th TM domain of PKD2 leads to widening of the lower gate and constitutive activation of the channel. We then used F604P-PKD2 to study the regulation by PKD1. Oocytes expressing F604P-PKD2 showed ~3 fold higher currents than background currents in control oocytes, confirming gain-of-function of F604P. Coexpression with WT-PKD1 completely inhibited F604P-PKD2, to the level of control oocytes. To map regions of PKD1 that regulate PKD2, we made five PKD1 mutant constructs with deletion of Nt, deletion of Ct, deletion of the last 6 TM domains, deletion of both Nt and Ct or deletion of Nt as well as the first 5 TM domain. Comparing with WT-PKD1, deletion of Nt and/or the first 5 TM did not alter PKD1's ability to inhibit F604P-PKD2. Deletion of Ct or the last 6 TM resulted in partial reduction in the ability of PKD1 to inhibit F604P-PKD2.

Conclusions: PKD1 inhibits PKD2 channel activity. The C-terminus and last 6 TM domains of PKD1 are involved. The results support the implication of structural studies that PKD1 and PKD2 complexes are non-conducting. Further, they support the hypothesis that ligands or factors target PKD1 to activate channel activities of PKD1/PKD2 complexes.

The Role of Polycystin 1 in the Polycystin-1/Polycystin-2 Channel

Zhifei Wang,[1] Courtney Ng,[1] Xiong Liu,[2] Yan Wang,[1] R. Todd Alexander,[3] Feng Qian,[4] Xing-Zhen Chen,[2] Yong Yu.[1] *[1]Department of Biological Sciences, St. John's University, Queens, NY; [2]Department of Physiology, University of Alberta, Edmonton, AB, Canada; [3]Departments of Pediatrics and Physiology, University of Alberta, Edmonton, AB, Canada; [4]Department of Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in either polycystin-1 (PC1), a polycystic kidney disease protein, or Polycystin-2 (PC2), a transient receptor potential channel. PC1 and PC2 form a receptor-ion channel complex with a 1 (PC1) : 3 (PC2) stoichiometry. The molecular mechanism of the function of this complex, especially the role of PC1, is largely unknown.

Methods: Full-length or fragments of PC1 was co-expressed with a gain-of-function (GOF) mutant of PC2 (PC2-GOF) in *Xenopus laevis* oocytes. Ion channel activity and ion permeability of the PC1/PC2 channel was measured with a two-electrode voltage clamp (TEVC) method and compared with the homomeric PC2 channel. Co-immunoprecipitation (co-IP) and surface biotinylation were used to evaluate the interaction and surface expression level.

Results: Our results show that PC1 can form a channel with PC2-GOF with distinct properties from that of the homomeric PC2-GOF channel. Compared to the homomeric PC2-GOF channel, PC1/PC2-GOF channel is not blocked by extracellular divalent ions and has significantly higher Ca^{2+} permeability than PC2-GOF channel. We also found that the GPS cleavage-produced PC1 C-terminal fragment (PC1-CTF) has almost identical channel function as full-length PC1 when assembled with PC2-GOF. Further analysis shows that not only Ca^{2+}, a lot of other monovalent ions, including some big organic ions, also permeate better through the PC1/PC2-GOF channel, compared to that of the PC2-GOF channel, indicating a relatively larger pore of the complex channel. More importantly, mutations in the pore region of either PC1 or PC2 alter the ion permeability of the PC1/PC2-GOF channel, confirming that both proteins contribute to the formation of the ion-conducting pore.

Conclusions: Full-length PC1 can associates with PC2-GOF to form a GOF PC1/PC2 complex channel in *Xenopus* oocytes. We were able to successfully record the channel current from this channel and dissect the role of PC1. In this channel, the PC1 subunit directly contributes to the channel pore formation, and the PC1-CTF is sufficient for its channel activity. The PC1/PC2-GOF channel has a distinct ion-conducting pore from that of the homomeric PC2-GOF channel and is more Ca^{2+} permeable.

Ketosis Inhibits and Reverses Renal Cyst Growth in Polycystic Kidney Disease

Jacob A. Torres,[1] Samantha L. Kruger,[3] Caroline M. Broderick,[4] Tselmeg Amarlkhagva,[5] Shagun Agrawal,[5] Michal Mrug,[6] Leslie A. Lyons,[2] Thomas Weimbs.[3] *[1]University California Santa Barbara, Santa Barbara, CA; [2]College of Veterinary Medicine, University of Missouri, Columbia, MO; [3]University of California Santa Barbara, Santa Barbara, CA; [4]University of California, Santa Barbara, Goleta, CA; [5]UCSB, Goleta, CA; [6]University of Alabama at Birmingham, Birmingham, AL.*

Background: PKD cells have been shown to exhibit an altered metabolism, favoring aerobic glycoysis. Our lab recently found that a mild reduction in food intake slowed progression of PKD in a mouse model of the disease. We hypothesized that the effects we observed in the PKD mouse model were not due to calorie restriction per se, but were instead due to the effects brought on by the state of ketosis.

Methods: To test if ketosis was capable of ameliorating PKD, we use the Han rat model of PKD or the Nestin-Cre Pkd1 mouse model. Animals were treated beginning at age week 3 to week 8 or from week 8 to week 12 with induction of ketosis utilizing several methods including, 1-time-restricted feeding, 2-ketogenic diet, 3-acute starvation and 4-beta-hydroxybutyrate supplementation. Both male and female animals were tested using these approaches of inducing ketosis.

Results: Treatment using approaches that induce a state of ketosis produced profound effects in the animals tested, reducing or reversing the progression of PKD in treated animals. Interestingly, we found that supplementation with the ketone body, beta-hydroxybutyrate, was capable of eliciting the beneficial effects in a dominant way in the context of a normal rodent diet.

Conclusions: Our research shows that dietary interventions that induce a state of ketosis are capable of preventing PKD progression in a rodent model of PKD and that the small molecule beta-hydroxybutyrate underlies the effects observed by the diet. These findings have significant implications for the treatment of human ADPKD and may be readily transferrable to clinical practice.

Urinary Alanine/Citrate Ratio Associates with the Rate of Kidney Function Decline in ADPKD Patients

Shosha E. Dekker, Aswin Verhoeven, Darius Soonawala, Dorien J. Peters, Oleg Mayboroda, Johan W. De Fijter. *Leiden University Medical Center, Leiden, Netherlands.*

Background: The disease course of autosomal dominant polycystic kidney disease (ADPKD) is highly variable, and the option to prescribe renoprotective treatment make early risk stratification important. Therefore, novel biomarkers to select patients at high-risk of rapid progression are required. We applied metabolomics to evaluate whether changes in the urinary metabolome are associated with progressive loss of eGFR in ADPKD.

Methods: Targeted, quantitative metabolic profiling (^{1}H NMR-spectroscopy) was performed on single, spot urine samples using the KIMBLE workflow (Verhoeven et al, Anal Chim Acta, 2018). Multivariate linear regression analysis was used to dissect the association between urinary metabolites and the rate of disease progression, expressed as annual change in estimated glomerular filtration rate (eGFR; using CKD-EPI equation).

Results: A total of 309 patients with ADPKD were included (age 46±10 years, 57% female, median eGFR 62.1 ml/min/1.73m^2 [IQR 45 to 85]). From the NMR spectra, 29 known urinary metabolites were identified and quantified. In a model with annual change in eGFR (median -3.3 ml/min/1.73m^2 per year [IQR -5.3 to -1.3]) as a response variable and all quantified metabolites and their binary ratios (449 features in total) as predictors, the alanine/citrate ratio was found to be most strongly associated with eGFR decline (F=51.07, P=7.26e-12, r^2=0.15), and remained significant after adjustment for potential confounders. Moreover, it outperformed the model built on the clinical risk markers including baseline eGFR and height-adjusted total kidney volume (htTKV). When only young patients (age <35 years) with an eGFR ≥75ml/min/1.73m^2 were selected (n=33), this ratio was significantly higher in those with fast disease progression (rate of eGFR decline >3.3ml/min/1.73m^2 per year, n=16) as compared with slow progressors (n=17; P=0.015).

Conclusions: Urinary alanine/citrate ratio is associated with the rate of eGFR decline in ADPKD, and showed additional value beyond that of the conventional clinical risk markers. Based on this ratio in a single urine sample, early-stage ADPKD patients with fast disease progression could be identified when eGFR is still relatively preserved. Therefore, urinary alanine/citrate ratio is potentially useful as predictive marker for ADPKD progression.

Dissection of the Therapeutic Effect of Glucosylceramide Synthase Inhibition on Polycystic Kidney Disease Progression in Adult Pkd1 RC/RC Mice

Thomas A. Natoli,[1] Laurie A. Smith,[1] Nathan Kaplan,[1] Kelly A. Rogers,[2] Xiaoyou Ying,[1] Weiliang Qiu,[3] Oxana Beskrovnaya.[3] *[1]Sanofi, Framingham, MA; [2]Genzyme Corporation, Framingham, MA; [3]Sanofi Genzyme, Framingham, MA.*

Background: Glucosylceramide synthase inhibitors (GCSi) have been shown to inhibit cystogenesis in multiple preclinical models of PKD. To determine how GCSi treatment impacts kidney disease progression in an adult, orthologous mouse model of ADPKD over a sustained period, we have treated homozygous *Pkd1*$^{tm1.1Pcha}$ mice carrying the R3277C mutation (Pkd1 RC/RC) with a GCSi for one year. To assess the impact on liver cyst formation, we treated Pkd1 conditional knockout (cKO) mice with a GCSi from 7-36 days of age.

Methods: Pkd1 RC/RC mice were randomized into vehicle or GCSi treatment groups at 4 months of age. Genz-667161 was delivered ad libitum in feed (0.03% w/w) until sacrifice at 16 months of age. Periodic high-field (7T) Magnetic Resonance Imaging (MRI) analysis was used to determine total kidney volume (TKV) changes over time. Pkd1 cKO mice were treated with the GCSi Genz-123346 from 7-36 days of age. Kidneys and livers were isolated for histological analysis at the end of study for both Pkd1 RC/RC and cKO mice.

Results: Kidney volume in Pkd1 RC/RC mice was increased compared to wild-type mice prior to treatment at 4 months of age. GCSi treatment reduced the TKV of Pkd1 RC/RC mice within 1 month of treatment; in contrast, vehicle treated Pkd1 RC/RC mice showed a gradual increase in TKV over the same time period. This anti-cystic effect was observed for the duration of the study. At sacrifice, kidney/body weight ratio was significantly decreased in GCSi-treated animals compared to controls. Liver cyst growth was reduced in GCSi treated animals compared to vehicle controls.

Conclusions: GCSi treatment inhibits kidney and liver cyst growth in Pkd1-linked mouse models. Moreover, GCSis have a sustained effect on kidney cyst growth.

Membrane Filtration of Contaminated Water with Used Dialyzers Reduces the Incidence of Diarrhea in Rural Communities in Developing Countries

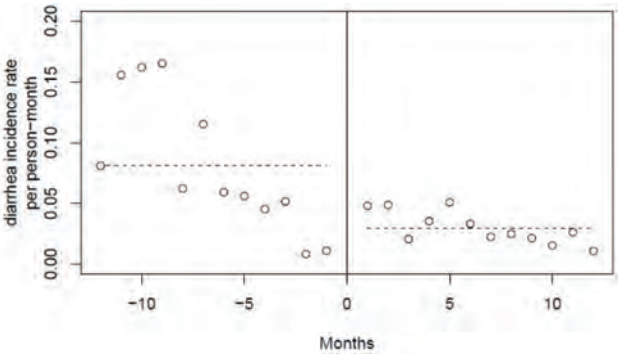
Jochen G. Raimann,[1,2] Joseph M. Boaheng,[2] Philip K. Narh,[5] Seth Johnson,[2] Linda L. Donald,[2] Hongbin Zhang,[3] Friedrich K. Port,[4,2] Nathan W. Levin.[2] *[1]Renal Research Institute, New York, NY; [2]Easy Water for Everyone, New York, NY; [3]Graduate School of Public Health and Health Policy, New York, NY; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Ghana Health Service, Ada Ghana, Ghana.*

Background: Access to clean water remains unavailable for a large fraction of the world population. Consequent infectious diarrhea, dehydration and acute kidney injury too often leads to death. Membrane filtration using recycled hemodialyzers is a recent innovation. We quantified its effect on health outcomes in rural communities in Ghana.

Methods: From 2015 to 2018 we provided membrane filtration devices (NUFiltration Israel) to 9 communities in Ghana (Greater-Accra region). We calculated incidence rates of self-reported diarrhea and compared monthly counts for 12 months before and 12 after implementation by negative binomial and Poisson regression (Pois) with the log(exposure time) as the offset. Models were compared by likelihood ratio test (LRT) and Akaike Information Criterion (AIC). Logistic regression for recurrent events on a subject-level (LogReg) was used to determine the effect of device implementation and seasonality (rainy versus dry season).

Results: We studied 2605 villagers (10.4% younger than 5 and 5.1 % older than 65 yrs). Incidence rates were significantly lower after device implementation (0.08 versus 0.03; P<0.01). LRT and AIC determined Pois to fit best and Pois showed a significant treatment effect [0.4 (95% CI 0.3 to 0.5)]. LogReg confirmed a lower OR of diarrhea after implementation [0.3 (95% CI 0.2 to 0.3)] with a higher OR of 1.1 (95% CI 1.0 to 1.3) during the rainy season. Lower rates during Month -1 and -2 can possibly be explained by concomitant handwashing and hygiene education initiatives.

Conclusions: Our data shows decrease in the incidence rates and odds of contracting infectious diarrhea with the use of membrane filtration device in rural villages in West Africa. A possible effect of seasonality should be recognized as a potential risk factor. These data emphasize the remarkable public health effect achievable by provision of these low-cost devices.



FR-OR012

Relationship of Acute Kidney Disease (AKD) to Long-Term Outcomes After AKI

Isma Kazmi,[1] Rebecca A. Packington,[2] John Monaghan,[3] Nicholas M. Selby.[1,2] ARID study investigators *[1]Centre for Kidney Research and Innovation, University of Nottingham, Derby, United Kingdom; [2]Department of Renal Medicine, University Hospitals of Derby and Burton, Derby, United Kingdom; [3]Department of Clinical Biochemistry, University Hospitals of Derby and Burton, Derby, United Kingdom.*

Background: Acute Kidney Disease (AKD) is a term that has been advocated by the Acute Disease Quality Initiative (ADQI) and others to describe ongoing renal dysfunction after AKI that persists beyond 7 days. Currently there is very little available epidemiological data regarding AKD. We sought to study its relevance to long term renal and patient outcomes.

Methods: All patients from the AKI arm of a large parallel group cohort study of AKI were included in this study. Participants were recruited following hospitalisation and followed up prospectively. Renal function, proteinuria and patient outcomes were assessed at 3 months, 1 year and 3 years after AKI. CKD progression was defined as a ≥25% decline in eGFR from baseline with a decline in eGFR stage. Patients were categorized into three groups depending on duration of AKI: AKI that resolved in <48hours (rapid recovery, r-AKI), AKI duration of 2-6 days (persistent AKI, p-AKI) and AKD (AKI duration ≥7 days). Outcomes were compared across these three groups.

Results: In total, 506 patients with AKI were studied. There were 109 (22%) in r-AKI group, 302 (60%) in p-AKI group and 95 (19%) with AKD. Patients in the AKD group had lower baseline eGFR and a higher proportion of AKI stage 3. CKD progression was more common in AKD group as compared to other two groups. At one year, CKD progression was 46% in AKD group versus 11% (r-AKI) and 22% (p-AKI), p<0.001. eGFR was lower in AKD group at all time-points; at year 3, eGFR was 66.9±23ml/min, 60.1±20ml/min and 53±20ml/min in r-AKI, p-AKI and AKD groups respectively, p<0.001. Proteinuria was more common and more severe in AKD. Hospital readmission occurred more frequently in the AKD group. Using binary logistic regression analysis adjusting for age, gender, diabetic status, baseline eGFR, AKI stage and biochemical variables, AKD remained independently associated with CKD progression at 1 (OR 5.4, 95% CI 2.2-13.2, p<0.001) and 3 years (OR 2.2, 95%CI 1.0-4.6, p=0.04).

Conclusions: AKD is common and is associated with a number of clinical variables including chronic comorbidities and markers of AKI severity. However, AKI duration remains an important independent determinant of subsequent progression of kidney disease, and AKD appears to be a useful way to categorize this to identify patients at higher risk of long-term adverse outcomes.

FR-OR013

Renal Recovery Patterns After AKI Influence Mortality

Alexander Zarbock,[6] Etienne Macedo,[1] Ashita J. Tolwani,[3] Marlies Ostermann,[4] Josee Bouchard,[5] Ravindra L. Mehta.[2] STIRS group *[1]University of California San Diego, San Diego, CA; [2]University of California San Diego Medical Center, La Jolla, CA; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Guy's & St Thomas' Hospital, London, United Kingdom; [5]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [6]University Hospital Münster, Münster, Germany*.

Background: Renal recovery from acute kidney injury (AKI) in hospitalized patients is variable and non-recovery has been associated with an increased mortality and resource utilization. There is limited information on different patterns of renal recovery following AKI in the ICU setting. We hypothesized that the AKI course and duration in the ICU influences the length of stay and mortality.

Methods: A retrospective multinational cohort study of critically ill adult patients admitted to 4 centers in Germany, UK, and USA was conducted between Jan2014 and Dec2017. We excluded patients who stayed <72hrs in the ICU, patients with ESRD and kidney transplant. AKI was defined by sCr KDIGO criteria and the course characterized as a single episode (SE) or stuttering course (SC) if the patient had multiple AKI during the ICU stay. Recovery of AKI was defined as no longer meeting criteria for even stage 1 AKI. No recovery was defined as an episode of AKI during ICU stay and the last recorded sCr higher than the patient's reference sCr. The primary outcome was ICU and hospital mortality.

Results: Of 20,560 eligible patients, 9,712 (47.2%) developed AKI, 5,303 (25.8%) at Stage 1, 3,358 (16.3%) Stage 2, 2,290 (11.1%) Stage 3 and 9,613 (46.7 %) no AKI. 2,156 patients (10.5%) received dialysis. 7,086 (74 %) patients had a SE while 2,494 (26 %) patients had a SC. Overall, more than half of the patients recovered from AKI (6,128; 65.9%); 65% in SE versus 58.5% in the SC. Amongst dialyzed patients, 51.8% recovered from AKI; 61.7% of the patients with a SE, 42.1% in the SC. The development of AKI significantly increased length of hospital stay (no AKI: 14.2 (±17.4), SE: 20.3 (±21.1); SC: 40.1 (±38.8) days; p<0.001). Patients with AKI had significantly higher mortality which was influenced by the course (no AKI: 8.2%, SE 14.5%, SC: 19.9%; p<0.001). Patients who recovered from AKI had significantly lower hospital mortality (10.9% versus 25.6%; p<0.05). However, mortality in patients with non-recovery was similar in SC 27.9% and SE (24.6%). Overall, we observed four recover patterns.

Conclusions: We have identified four distinct recovery patterns on the basis of the clinical course. These phenotypes may identify patients amenable to therapeutic intervention. The pattern of renal recovery from AKI in the ICU influences resource utilization and mortality.

Hospitalizations, AKI, and Longitudinal Kidney Function in HIV+ Patients

Ani Chilingirian,[6] Anthony N. Muiru,[6] Anna Rubinsky,[6] Rebecca Scherzer,[3] Erin Madden,[5] Jose M. Monroy-Trujillo,[4] Richard Moore,[4] Chirag R. Parikh,[4] Michael Shlipak,[2] Michelle M. Estrella.[1] *[1]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [2]San Francisco VA Medical Center, San Francisco, CA; [3]UCSF, San Francisco, CA; [4]Johns Hopkins University, Baltimore, MD; [5]NCIRE, San Francisco, CA; [6]University of California, San Francisco, San Francisco, CA.*

Background: Whether AKI contributes to the excess CKD burden in HIV+ persons or simply marks poor overall health is unclear. We conducted a substudy in the Johns Hopkins HIV Clinical Cohort to examine if hospitalizations with and without AKI were each associated with longitudinal eGFR.

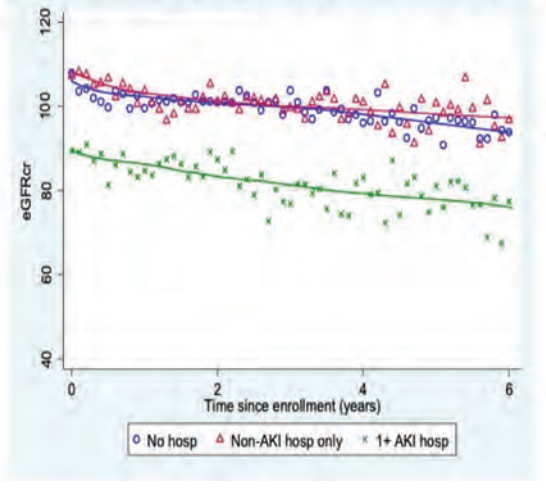
Methods: We included HIV+ persons followed from 1/2005-5/2016 and had baseline eGFR ≥15 ml/min, ≥3 eGFRs and sufficient creatinine (Cr) data to assess AKI status. We classified patients into 3 mutually exclusive groups: never hospitalized, hospitalized without AKI or hospitalized with AKI (≥0.3 mg/dL Cr rise within 48h or max inpatient Cr ≥50% above outpatient baseline). We used mixed effects models, adjusted for demographics, comorbidities, serum albumin, BMI, proteinuria, HIV factors and number of primary care visits.

Results: Among 1731 HIV+ persons, mean age was 43y, 77% were black, and 70% were on antiretrovirals at baseline. During a median follow-up of 3.7y, 730 had ≥1 hospitalization, of whom 43% had ≥1 complicated by AKI. Versus other groups, the hospitalized AKI group was more likely to have IV drug use history, greater comorbidity burden, lower CD4 count, less HIV suppression and lower mean eGFR at baseline (96 vs. 107-109 ml/min) at baseline. In adjusted models, there was little difference in annual eGFR change in those with non-AKI hospitalizations vs. no hospitalizations (Δ 0.12 ml/min; 95%CI: -0.46, 0.71). Conversely, patients with hospitalized AKI vs. no hospitalizations had faster eGFR decline (Δ -1.68 ml/min; 95%CI: -2.69, -0.67) (Figure). This association weakened in sensitivity analyses with inverse weighting for death (Δ -0.85; 95%CI: -1.83, 0.14).

Conclusions: Hospitalized AKI is associated with faster kidney function decline, but hospitalization without AKI had no association. These findings underscore AKI as a potential pathway leading to CKD in HIV+ persons.[Figure]

Funding: NIDDK Support

Figure. eGFR trajectories among HIV+ persons, by hospitalization and AKI status



FR-OR015

Nephrologist Follow-Up vs. Usual Care After an AKI Hospitalization (FUSION): A Randomized Pilot Trial

Samuel A. Silver,[1] Christopher T. Chan,[3] Ron Wald.[2] *[1]Queen's University, Kingston, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: Survivors of AKI are at increased risk of CKD and death but few patients see a nephrologist post-discharge. Our objectives were to determine the feasibility of randomizing survivors of AKI to structured follow-up with a nephrologist or usual care, as well as to collect data on clinical outcomes for event rate calculations.

Methods: We performed a 52-week randomized pilot trial in patients hospitalized with KDIGO stage 2-3 AKI in 4 hospitals in Toronto, Canada. We randomized patients to usual care or nephrologist-led follow-up within 90-days of discharge, which consisted of a standard assessment that emphasized blood pressure control, cardiovascular risk reduction, and medication safety. The feasibility outcome was the proportion of patients recruited. The primary clinical outcome was a major adverse kidney event, which is a composite of death, chronic dialysis, or a sustained decrease in eGFR≥25%, at 52-weeks post-discharge.

Results: We screened 269 patients and randomized 71 (26%) from July 2015 to June 2017 (37 to usual care and 34 to nephrology follow-up). The most common reasons for declining to participate were patient fatigue (33%) from recent hospitalization and reluctance to see additional specialists (30%). Baseline characteristics included age 65±10 years (mean, SD), 30% female, baseline eGFR 76±22mL/min/1.73m^2, 47% admitted to the ICU, and median length of stay 14 (IQR 13) days. The median time from hospital discharge to nephrology follow-up was 48 (IQR 40) days, and 22/34 (65%) patients in the intervention group attended their nephrology appointment. The primary outcome occurred in 18/37 (49%) patients in the usual care group and 17/34 (50%) patients in the intervention group (P=0.91). There were no differences between usual care and the nephrology follow-up group in death (8% vs 18%, P=0.23), ≥25% decrease in eGFR (46% vs 38%, P=0.51), or rehospitalization for AKI (24% vs 24%, P=0.94). No patients in either group received maintenance dialysis.

Conclusions: Patient recruitment was lower than anticipated primarily because of patient fatigue and resistance to in-person visits post-discharge, which suggests a more pragmatic intervention may be needed that actively engages patients in its development. The high number of major adverse kidney events observed suggests more work is warranted to improve patient follow-up after AKI.

FR-OR016

Clinical Outcomes and Disparities Associated with ESKD due to AKI in the United States

Silvi Shah,[1] Anthony C. Leonard,[1] Karthikeyan Meganathan,[1] Annette Christianson,[2] Charuhas V. Thakar.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is associated with increased mortality. Mortality in end-stage kidney disease (ESKD) patients is highest during the first year of dialysis. ESKD due to AKI is common, but little is known about the rate of recovery and its impact on long-term outcomes in incident dialysis patients.

Methods: We evaluated a retrospective cohort of 1,045,540 incident ESKD patients from the United States Renal Data System. Using Cox proportional hazard models, we examined the impact of AKI as the ESKD cause on the primary outcome of all-cause mortality. Additionally, we determined the impact of sex and race on renal recovery and associated mortality in patients with AKI as the ESKD cause.

Results: Mean age was 63±15 years. Of the study cohort, 3.3% had ESKD due to AKI. The majority were men (58.1%) and white (75.8%). One-year all-cause mortality was 21.8%. Compared to ESKD due to diabetes (46% of the sample, the most common cause), ESKD due to AKI was associated with changes in the adjusted mortality across the follow-up period – higher adjusted hazards of mortality in first 0-3 months following dialysis initiation (HR, 1.27; 95% CI, 1.23-1.31) and 3-6 months (HR, 1.15; 95% CI, 1.11-1.20), followed by lower adjusted hazards of mortality at 6-12 months (HR, 0.93; 95% CI, 0.90-0.97) that continued to decrease through 84-96 months of follow up (HR, 0.46; 95% CI, 0.41-0.52). Of the patients with ESKD due to AKI, 35.3% eventually recovered their kidney function. The median time of recovery was 2 months (IQR, 1.2-3.5 months). Women had lower adjusted hazards of renal recovery than did men (HR, 0.86; 95% CI, 0.82-0.89). As compared to whites, blacks (HR, 0.67; 95% CI, 0.65-0.71), Asians (HR, 0.77; 95% CI, 0.66-0.90), and Hispanics (HR, 0.80; 95% CI, 0.74-0.86) had a lower likelihood of renal recovery. Heart failure and diabetes were other risk factors associated with non-recovery.

Conclusions: About one-third of patients with ESKD due to AKI recover kidney function. Mortality risk changes across the follow-up period in patients with ESKD due to AKI. Women have a 14% lower likelihood of recovery than men. Black, Asian, and Hispanic patients have a lower likelihood of recovery than do white patients. The study suggests that the need for customized dialysis care in patients with ESKD due to AKI.

FR-OR017

Outcomes of AKI Patients Receiving Dialysis in ESRD Facilities

Jonathan H. Segal, Claudia Dahlerus, Shu Chen, Tempie H. Shearon, Aaron Pearson, Sun Yating, Jennifer Sardone, J. M. Messana. *University of Michigan, Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

Background: Medicare beneficiaries with Acute Kidney Injury (AKI) have received dialysis in outpatient end stage renal disease (ESRD) facilities since 2017 as a result of a CMS policy change allowing payment for dialysis services provided to AKI patients. Outcomes of AKI patients relative to ESRD patients have not been reported.

Methods: AKI patients were identified from 2017 Medicare claims with at least one bill type 072x with condition code 84 (Dialysis for AKI), CPT G0491 (Dialysis for AKI without ESRD) or a select group of ICD-10 codes. We determined patient transition to ESRD from CROWNWeb and other sources; vital status was obtained from the Medicare Enrollment Database. Patients were followed through 3/31/18. We used Cox proportional hazards modeling to compare survival between AKI and non-AKI Medicare incident ESRD patients.

Results: 10,717 of 399,936 (2.7%) patients on dialysis had at least one AKI claim. AKI patients were more likely to be white (72% v. 47%) and age 60+ (82% v. 61%) than ESRD patients. Overall 64% of AKI patients developed ESRD, 13% died without developing ESRD, 17% were alive without ESRD, and 6.1% were lost to follow up. Hospital based facilities had a larger proportion of AKI claims relative to free standing facilities (mean 1.9% v. 0.7% of all dialysis claims). After adjustment for age, race, sex, and ethnicity, AKI patients had a 27% higher mortality risk compared to incident ESRD patients (HR 1.27, p<0.0001).

Conclusions: Patients with AKI represented a small proportion of patients in ESRD facilities in 2017. Almost two-thirds developed ESRD during our limited follow-up. Mortality in the AKI population was higher compared to incident ESRD patients suggesting additional investigation is needed to understand the differences and monitor their outcomes.

FR-OR018

Incidence and Clinical Outcomes of Outpatient Dialysis for AKI Among Medicare Beneficiaries

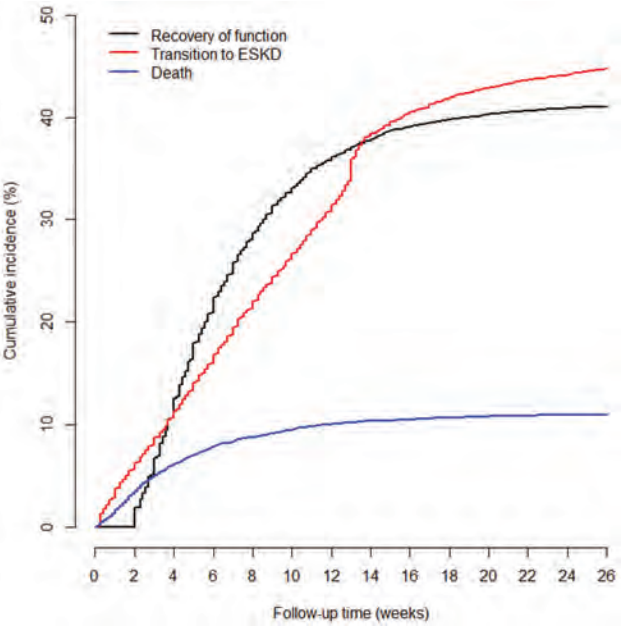
Eric D. Weinhandl,[1,2] Lorien S. Dalrymple.[1] [1]*Fresenius Medical Care North America, Waltham, MA;* [2]*University of Minnesota, Minneapolis, MN.*

Background: As of January 1, 2017, Medicare Part B covers outpatient (OP) dialysis for acute kidney injury requiring dialysis (AKI-D). We analyzed Medicare claims to describe the incidence and clinical outcomes of beneficiaries initiating OP dialysis for AKI-D in 2017.

Methods: We analyzed the 100% sample of institutional claims in 2014–2017 Medicare Limited Data Sets. To identify initiation of OP dialysis for AKI-D, we located the first OP dialysis facility claim in 2017 with condition code 84 and HCPCS code G0491. We excluded patients with Medicare claims history of OP dialysis for end-stage kidney disease (ESKD), dating to January 1, 2014. We followed patients from initiation of OP dialysis for AKI-D to the earliest of recovery of kidney function (≥2 weeks without OP dialysis for AKI-D), transition to ESKD (OP dialysis facility claim with condition code 71–74), death, or December 31, 2017.

Results: We identified 9634 Medicare beneficiaries undergoing OP dialysis for AKI-D and 9070 (94%) satisfying inclusion criteria. Mean age was 69.9 ± 11.2 years, 24% were age 20–64 years, 76% were white, 16% were black, 44% were female, and 27% were enrolled in Medicaid. During follow-up, 3208 (35%) recovered kidney function, 3381 (37%) transitioned to ESKD, and 896 (10%) died. The cumulative incidence of these events is displayed. At 13 weeks after initiation of OP dialysis for AKI-D, 37% had recovered function, 36% had transitioned to ESKD, and 10% had died. In 7485 patients who reached any endpoint, mean (median) days between first and last OP dialysis sessions were 45 (34) and mean (median) number of sessions was 17 (13).

Conclusions: Most Medicare beneficiaries who initiate OP dialysis for AKI-D recover kidney function or transition to ESKD within 3 months. Long-term follow-up of those who recover function is needed.



FR-OR019

Electronic Alert and a Bundle of Care Reduces Progression and Mortality of AKI Patients

Ana carolina N. Tome, Bianca Ponte, Helga Agostinho, Karise F. Dos santos, Mauricio Machado, Mario Abbud-Filho, Rodrigo J. Ramalho, Emerson Q. Lima. *Nephrology Division, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil.*

Background: Acute kidney injury (AKI) is potentially preventable but its early diagnosis is essential to ensure appropriate management. The aim of this study was to evaluate the impact of an electronic AKI alert and a bundle of care (BoC) in the progression and mortality of patients with AKI.

Methods: An algorithm examined all serum creatinine reported by the laboratory. An alert was issued in the electronic medical record (accessed by physicians and nurses) and a BoC was suggested in case of AKI (KDIGO criteria). Prescription audit was performed by a clinical pharmacist. Individuals > 18 years were included and patients in palliative care, nephrology and renal transplantation wards were excluded. The study was divided in two periods: pre-alert initiation group (PRE, January-June/2018) and post-alert group (POS, July-December/2018).

Results: 3174 patients developed AKI (8.3% of hospitalizations). The PRE (n= 1613) and POS (n=1561) groups were similar in age, gender, serum creatinine, baseline glomerular filtration rate (GFR) and ICU admission rate. Dialysis was performed in 514 patients (15%) and was not different between groups (PRE 14.9% vs POS 15.1%; NS). At the time of AKI alert, the prevalence of KDIGO I was similar between groups (PRE 73.5% vs. POS 75.1%; NS), but a higher number of patients remained at this stage in POS (PRE 51% vs. POS 56.1%, P=0.004). Lower percentage evolved to KDIGO III in POS (PRE 33.3% vs POS 30%, P=0.04). Nephrologist was called to 832 patients (26.2%) and the median time to the consultation was lower in the POS (PRE 1.0 day vs POS 0.0 day; P=0.04). The 30-day mortality was 33.6% and was lower in POS (PRE 36.7% vs 30.5%, P <0.001). The independent 30-day mortality risk factors were: age 40 to <65 years (HR 1.37; CI 1.04-1.81, P = 0.02); age 65 to <75 years (HR 1.72; CI 1.29-2.3, P <0.001), age ≥ 75 years (HR 2.36; CI 1.77-3.14, P = 0.003), ICU admission (HR 1.24; CI 1.08-1.43, P = 0.003), baseline GFR (each increase of 10 mL/min) (HR 0.96; CI 0.94-0.98, P <0.001) and AKI eletronic alert (HR 0.87; CI 0.77-0.98, P = 0.02).

Conclusions: An electronic AKI alert and a multidisciplinary BoC reduced progression and 30-day mortality of patients with AKI.

FR-OR020

Development of Machine Learning Models for Predicting AKI Onset Using Electronic Medical Records

Eiichiro Uchino,[1,2] Kazuki Kume,[4] Kazuki Iwamoto,[4] Tatsuo Hayakawa,[4] Noriaki Sato,[3,2] Yoshinori Tamada,[1] Motoko Yanagita,[2] Yasushi Okuno.[3] *[1]Department of Medical Intelligent Systems, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Department of Biomedical Data Intelligence, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [4]Fujitsu Ltd., Tokyo, Japan.*

Background: Acute kidney injury (AKI) is a common disease associated with high morbidity and mortality, and the prediction of its onset will help the prevention and appropriate intervention. Recent studies have reported some machine learning models for predicting onset of AKI up to 72 hours in general patient population using electronic medical records (EMR), but studies for predicting in a relatively longer period such as one week have been limited.

Methods: We used the EMR data of adult patients who presented to Kyoto University Hospital, a tertiary teaching hospital in Japan, and received a measurement of renal function between January 2006 and November 2018. Based on the KDIGO guideline, the onset of stage 1 or severer AKI was determined by serum creatinine (sCr) values. Baseline sCr values were calculated by averaging within the windows according to KDIGO's 48-hour and 7-day AKI definitions. The comprehensive results of blood tests, medications, and vital signs were used as explanatory variables. By using random forest algorithm, seven models were constructed to classify whether or not to develop AKI during day 1 to day 7. The models were constructed and validated by 5-fold cross-validation in the cohort. The performance of the models was evaluated by area under the curve (AUC) of receiver operating characteristic curve.

Results: Of the 154,745 patients included in the analysis, it was determined that 10,460 patients (6.8%) had developed AKI. The amount of data with positive and negative labels was considered sufficient for training and validation of the seven models (positive labels, 2,528 ± 274; negative labels 8,571 ± 470 [mean ± standard deviation]). The AUC values were 0.910 ± 0.013, 0.885 ± 0.006, and 0.853 ± 0.012 in predicting onset of AKI after 1 day, 3 days, and 7 days, respectively.

Conclusions: Our models showed high performance equivalent to previous studies with AUC of more than 0.9 in prediction of onset after 1 day. In addition, the models achieved near performance even after periods of up to 7 days, which are longer in compared to previous studies. In future studies, implementing these predictive models in a clinical decision support system that presents risk scores may lead to appropriate interventions to prevent AKI.

FR-OR021

Macrophage COX-2 Protects Against AKI via Promotion of M2 Polarization and Efferocytosis

Yu Pan,[1] Guannan Jin,[1] Sungjin Chung,[2] Yinqiu Wang,[1] Suwan Wang,[1] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] *[1]Vanderbilt University Medical School, Nashville, TN; [2]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Efferocytosis, the clearance of apoptotic cells by macrophages, plays a key role in recovery from acute kidney injury (AKI) by promoting the production of anti-inflammatory cytokines. Our previous studies show that macrophage cyclooxygenase-2 (COX-2) plays an essential role in polarization and maintenance of a macrophage alternatively activated, tissue-reparative M2 phenotype. Macrophages with an M2 phenotype exhibit higher efferocytotic capacity and play a pivotal role in recovery from AKI. We examined the role of macrophage COX-2 in efferocytosis, recovery from AKI and subsequent development of fibrosis.

Methods: Wild type (COX-$2^{f/f}$) or CD11b-Cre; COX-$2^{f/f}$ mice (male, 8 weeks, FVB background) were uninephrectomized, immediately followed by unilateral ischemia-reperfusion with 29-min renal pedicle clamping. Mice were sacrificed at different time points after AKI. Renal macrophages were isolated with a mixture of CD11b and CD11c microbeads and used for efferocytosis assay with phagocytosing fluorescent beads or apoptotic neutrophils.

Results: Compared to WT mice, CD11b-Cre; COX-$2^{f/f}$ mice had delayed recovery after AKI, as indicated by BUN and creatinine and had subsequent increases in renal fibrosis as indicated by Masson's Trichrome and Sirius red staining, increased profibrotic and fibrotic components, and increased renal macrophage and lymphocyte infiltration. In WT mice, renal proinflammatory cytokines such as iNOS, TNF-α, CCL3, and IL-23α increased 6 hours after AKI, peaked at 16 hours, and returned to baseline at day 3. In CD11b-Cre; COX-$2^{f/f}$ mice, these cytokines increased to a greater extent and were still elevated 7 days after AKI. Two days after AKI, CD11b-Cre; COX-$2^{f/f}$ mice had increased proinflammatory Th1/M1 but decreased anti-inflammatory Th2/M2 cytokines, in association with decreased expression levels of components of efferocytosis, including TIM4, Axl, and Tyro3 and Gas6. Renal macrophages isolated from CD11b-Cre; COX-$2^{f/f}$ mice 2 days after AKI showed significantly decreased efferocytotic ability in both the fluorescent bead phagocytosis assay and the neutrophil efferocytosis assay.

Conclusions: Macrophage COX-2 protects against AKI and development of renal fibrosis after severe AKI, at least in part due to COX-2-derived PGE2-mediated macrophage M2 polarization and efferocytosis.

FR-OR022

Genetically Augmenting Renal Lymphangiogenesis Protects Against Inflammation Following AKI

Gaurav Baranwal,[1] Joseph M. Rutkowski.[2] *[1]Medical Physiology, Texas A&M College of Medicine, College Station, TX; [2]Texas A&M College of Medicine, College Station, TX.*

Background: Acute kidney injury (AKI) is a major cause of patient mortality and experimental data suggest AKI as an increased risk factor for progression to chronic kidney disease (CKD). The pathological transition from AKI to CKD is not well understood. Not only the degree of the initial AKI inflammatory response, but also how well it resolves - both in time and in function - are likely factors dictating the potential for future CKD progression. Lymphatic vessels and lymphangiogenesis (LAG) are necessary to maintain tissue homeostasis through fluid, macromolecule, and immune cell clearance. Inflammation-associated LAG is necessary for a timely resolution of peripheral inflammation. What roles renal lymphatics play in AKI recovery or CKD progression is largely unknown.

Methods: We have recently characterized transgenic mice that overexpress the potently lymphangiogenic signal VEGF-D only in the kidney upon doxycycline administration. These conditional "KidVD" mice exhibit marked lymphangiogenesis throughout the kidney. To test if a kidney-specific increase in lymphatic density was protective in AKI, we utilized KidVD mice in the well-characterized surgical bilateral ischemia reperfusion (I/R) model. We also crossed KidVD mice to the POD-ATTAC mouse line, a model of inducible podocyte apoptosis and proteinuria.

Results: First, we identified an endogenous upregulation of lymphatic growth factors VEGF-C and VEGF-D with a small degree of inflammation-associated LAG in both models absent genetic LAG induction. Second, when renal LAG was first induced on the KidVD background prior to injury, we found reduced expression of inflammatory cytokines and matrix fibrosis at 7 days post insult in both models. POD-ATTAC x KidVD mice demonstrated reduced interstitial fibrosis and reduced immune cell numbers 28 days following podocyte loss. Interestingly, despite improvements in inflammation, serum creatinine and eGFR were not improved in KidVD mice in either AKI model and KidVD mice demonstrated increased sodium excretion.

Conclusions: These data suggest that specifically increasing renal LAG signaling may reduce inflammation and fibrosis, but may concurrently disturb transport homeostasis. Renal lymphatic density in response to AKI may thus be predictive in identifying and targeting inflammatory CKD progression.

FR-OR023

Neutrophil Extracellular Traps Are Triggered by C3 and Contribute to AKI

Jian-xin Wan. *The First Affiliated Hospital of Fujian Medical University, Fuzhou, China.*

Background: Infiltration neutrophils can be stimulated to formed neutrophil extracellular trap (NETs), which may lead to renal injury. Complement C3 play a prominent role in inflammatory processes, its activation exacerbates AKI. But the relationship between the formation NETs and activation C3 in IR injury-induced AKI was not clear.

Methods: C57BL/6 mice (WT) were subjected to renal IR injury-induced AKI model by clamping both renal pedicle for 45 min. To deplete neutrophil, mice were treated with intraperitoneal injection of anti-Ly6G IgG (1A8) or control IgG 24h and 2h before bilateral IR injury. C3KO mice were subjected to renal IR injury. The level of renal neutrophils were evaluated by MPO, LY6G and ICAM-1 immunohistochemistry. NETs formation was defined by the colocalization of diffused DAPI, Ly6G and CitH3 signal by immunofluorescence and protein level of CitH3 by western blot. The expression of C3 in renal were estimated by immunofluorescence, qPCR and ELISA. In vitro, neutrophil were isolated from normal individuals and were assessed by Wright-Giemsa stain. Neutrophils in RPMI were simulated with PMA and C3a.

Results: The expression of neutrophil, NETs and C3 of each temporal point after IR increased obviously. At 24h, post-ischemic kidneys represent positivity for DAPI, CitH3 and Ly6G colocalizing of NETs in the outer medulla. Injection of 1A8 suppressed the increase in BUN and Scr 24h after renal IR injury, with a concomitant reduction of neutrophils infiltration and NETs formation, while there were no significant differences in the expression of C3 in mice with and without neutrophil depletion. Compared with WT-sham group, C3KO can ameliorate the accumulation of neutrophil and protect renal against IR injury. Kidney sections from C3KO mice contained less NETs formation with WT mice, corroborating the CitH3 western blot. In vitro, neutrophils were assessed to be >90% pure. After 4h of incubation, 0.1 μM C3a simulated the formation of NETs which reflected by amorphous extracellular DNA structures that colocalized with CitH3 and MPO. PMA altered neutrophil phenotype with decondensed chromatin, while C3a remained intact neutrophil phenotype with lobulated nuclei.

Conclusions: C3 activation can stimulate neutrophil motivation and lead to the formation of NETs in renal IR injury.

FR-OR024

IL-6-Mediated Hepatocyte Production Is the Primary Source of Plasma and Urine Neutrophil Gelatinase-Associated Lipocalin (NGAL) During AKI

Nataliya Skrypnyk,[1] Sarah Faubel.[2] *[1]University of Colorado, Denver, CO; [2]University of Colorado Denver, Denver, CO.*

Background: NGAL (*Lcn2*) is the most widely studied biomarker of acute kidney injury (AKI); however the ability of NGAL to predict AKI has been mixed, possibly because it is produced by cell types outside of the kidney or in response to other stimuli

such as systemic inflammation. In the present study, we investigated renal and extra-renal NGAL production in response to the proinflammatory cytokine IL-6.

Methods: Mice: C57Bl/6J (WT)/ B6.IL6<tm1Kopf>/J (*IL-6*$^{-/-}$), hepatocyte specific *Lcn2* deficient (*Lcn2*$^{hep-/-}$)/cre- littermates. Procedures: sham, kidney ischemia reperfusion (IR) (27 minutes bilateral renal pedicle clamping); bilateral nephrectomy (Bnx). Injections: anti-mouse Ly6G clone 1A8/rat IgG2a isotype control clone 2A3 500μg, IP; recombinant murine (rm)IL-6 (200 ng, IV). Measurements: BUN, plasma creatinine, Kim1 mRNA, NGAL mRNA (liver kidney, spleen and lung); NGAL protein concentrations (liver, kidney, spleen, lung, plasma and urine).

Results: Plasma NGAL was increased in WT 4 and 24 hours after sham, IR, and BNx and was decreased in *IL-6*$^{-/-}$ mice in all three conditions; similarly, urine NGAL was increased after sham and IR in WT and decreased in *IL-6*$^{-/-}$ mice. Kidney function was similar between WT and *IL-6*$^{-/-}$ mice as judged by serum creatinine, BUN, and kidney histology. NGAL mRNA was most upregulated in the liver (versus the kidney, lung, and spleen) 4 and 24 hours after sham, IR, and BNx, and reduced in *IL-6*$^{-/-}$ mice. IV injection of recombinant IL-6 to normal mice resulted in a significant increase in hepatic, but not renal, NGAL mRNA and an increase in plasma and urine NGAL. In vitro, addition of recombinant IL-6 to hepatocytes resulted in a significant increase in NGAL levels in the supernatant. To further examine the specific contribution of hepatocytes to plasma and urine NGAL levels, mice with hepatocyte specific NGAL deletion (*Lcn2*$^{hep-/-}$) were studied; plasma and urine NGAL were 90% and 80% reduced, respectively, after IR. Neutrophil depletion after IR did not affect plasma and urine NGAL levels after sham and IR.

Conclusions: IL-6 mediates hepatic production of NGAL during AKI. The results of these experiments shed new insights into the mechanism behind the increases in plasma and urine NGAL after AKI.

Lung Double Negative (αβ+CD4-CD8-) T Cells Respond to AKI and Can Directly Protect from Lung Injury: A Protective Mediator During Kidney-Lung Cross-Talk?

Errol L. Bush,[2] Joshua Hsu,[1] Mohanraj Sadasivam,[1] Abdel Hamad,[1] Hamid Rabb.[3] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Kidney-lung cross talk during AKI contributes to the high mortality and reveals key interactions between lung and kidney. CD4-CD8- (double-negative; DN) αβ T cells have been recently described in kidney and rapidly respond to local ischemia reperfusion injury (IRI) with a protective anti-inflammatory cytokine profile, but the response to remote injury is unknown. We hypothesized that DN T cells serve a potential protective role as an immunologic mediator of kidney-lung crosstalk following remote as well as local injury.

Methods: B6 Wild type (WT) mice were subjected to IRI on either kidney or in lung by a established methods. Lymphocytes from lung was isolated and analysed by flow cytometry. H&E staining was performed with lung tissue to assess lung edema. Immunoblotting with cleaved caspase-3 was evaluated for apoptosis. To test the role for DN T cells in lung IRI, adoptive transfer of DN T cells prior to lung IRI was performed.

Results: Our data show that the frequency of lung DN T cell was significantly increased following both lung (39.1%) and kidney IRI (23.5%), $p<0.05$, compared to sham (10.7%). Immunoblotting of cleaved caspase-3 revealed higher levels of apoptosis at 3 and 6 hours of both renal and lung IRI. Evans blue extravasation demonstrated that adoptive transfer of DN T cells significantly decreased interstitial thickening and lung permeability (39.5 μg vs. 28 μg, $p<0.05$). Quantitative analysis of cleaved caspase-3 immunoblotting showed that DN T cell transfer attenuated cellular apoptosis (3.2 vs. 0.8, $p<0.01$). To assess the human relevance of lung DN T cells, lung samples were studied during implantation of lung transplants which were exposed to ischemia reperfusion, and DN T cells were also found in the human lungs (18.4% at ischemia, 39.2% at reperfusion).

Conclusions: These data demonstrate that DN T cells are a potential immunologic mediator of kidney-lung cross talk, and studies in lung IRI extend the role of DN T cells from kidney IRI to importance in lung injury as well. Further studies are needed to elucidate the mechanism of this potentially immunoregulatory response and human correlates

CD4 T Cell-Derived Neutrophil Gelatinase-Associated Lipocalin (NGAL) Mediates Ischemia Reperfusion-Induced AKI

Sul A Lee,[1] Sanjeev Noel,[1] Johanna T. Kurzhagen,[1] Mohanraj Sadasivam,[1] Phillip M. Pierorazio,[2] Lois J. Arend,[3] Abdel Hamad,[1] Hamid Rabb.[4] *[1]Johns Hopkins University, Baltimore, MD; [2]Brady Urological Institute, Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins Hospital, Baltimore, MD; [4]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: T cells mediate tissue injury and repair processes following ischemia reperfusion (IR) and nephrotoxin induced acute kidney injury (AKI). While exploring underlying mechanisms involved in T cell mediated AKI/repair, we unexpectedly identified lipocalin 2 (*Lcn2*) as the most upregulated gene in post IR kidney CD4 T cells. Functional studies of *Lcn2* encoded neutrophil gelatinase-associated lipocalin (NGAL), a biomarker for early detection of AKI, showed important role in T cell mediate AKI pathophysiology.

Methods: WT mice were subjected to IR and kidney CD4 T cells flow sorted after 24 hours. An unbiased RNA sequencing was carried out to determine transcriptional effects of IRI on kidney CD4 T cell response. Flow cytometry and ELISA was performed to validate RNA-seq data. Adoptive transfer studies were performed using NGAL KO, CD 4 KO and WT mice. Pre and post clamp human kidney samples from RCC nephrectomies were also evaluated.

Results: RNA-seq analysis showed *Lcn2* mRNA as the top upregulated (60-fold) gene in CD4 T cells from post IR mouse kidney. RT-PCR validated RNA-seq data and showed increased *Lcn2* expression ($P< 0.05$) in post IR renal CD4 T cells. ELISA showed increased NGAL protein in renal CD4 T cells (244±24 vs 8±5 ng/mg; $p < 0.001$) and spleen CD4 T cells (261±44 vs. 42±19 ng/mg; $p < 0.01$) post IR compared to controls. Adoptive transfer of splenic CD4 T cells from NGAL KO mice significantly increased serum creatinine (SCr) than CD4 T cell from WT mice or the PBS in CD4 KO recipients (1.80±0.26; 1.06±0.21 and 0.97±0.25 mg/dL respectively; p=0.04) and in the WT recipients (1.47±0.17; 0.93±0.17 and 0.73±0.17 mg/dL respectively; p=0.02). *In vitro* simulated hypoxia increased *Lcn2* (1.7-fold) and *Ifn*-γ (8.8- fold) mRNA expression in CD4 T cells from NGAL KO mice compared to CD4 T cells from WT mice. NGAL increased significantly (38.8±3.9 % vs.15.4±5.9 %, $P < 0.05$) in post clamp human kidney T cells compared to pre clamp.

Conclusions: These data show that kidney CD4+ cell *Lcn2*/NGAL responds rapidly to IRI, directly mediates kidney structural and functional responses to ischemic AKI, and modifies CD4 cell *Ifn*-γ. NGAL, traditionally thought to be a candidate biomarker for AKI, is an important molecular regulator of the CD4+ T cell response during ischemic AKI

Autophagy Stimulation of FGF2 in Tubular Cells Activates Renal Fibroblasts and Promotes Interstitial Fibrosis During AKI-CKD Transition

Man J. Livingston,[1,2] Zheng Dong.[1,2] *[1]Augusta University Medical College of Georgia, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA.*

Background: The mechanisms that trigger AKI-CKD transition are poorly understood. We recently reveal an autophagy-mediated tubular maladaptive repair and its contribution to renal fibrosis after ischemic AKI. However, it is unclear how autophagy in renal tubules promotes interstitial fibrosis.

Methods: We generated a doxycycline-inducible, conditional *Atg7* knockout mouse model (i*Atg7* KO) with *Atg7* specifically deleted from renal tubules at a desired time after ischemic AKI without affecting initial injury. We also exposed proximal tubular cells to TGFB1 and collected conditioned medium (CM) to treat renal interstitial fibroblasts. Using these models we examined how tubular cell autophagy regulates fibrosis with a focus on tubular paracrine activation of fibroblasts.

Results: Autophagy was activated in proximal tubules during post-ischemic fibrosis in wild-type (WT) mice. i*Atg7* KO blocked tubular autophagy and suppressed fibrosis. Along with autophagy, the expression of several profibrotic cytokines (TGFB1, FGF2, CTGF and PDGFB) was increased in WT fibrotic kidneys. Among them, only the expression of FGF2 (both mRNA and protein) was reduced in i*Atg7* KO mice. In WT kidneys FGF2 accumulated predominantly in the basolateral cytoplasm of atrophic tubules, which was suppressed in i*Atg7* KO mice. Costaining of FGF2 in autophagy reporter mice further revealed a partial colocalization of FGF2 with LC3 puncta in autophagic tubules. In cultured mouse proximal tubular cells, TGFB1 induced the production of FGF2, CTGF and PDGFB, and also enhanced tubular secretion of FGF2 and CTGF. Defective autophagy by *Atg7* KO reduced both the production and tubular secretion of FGF2, but not CTGF or PDGFB. CM from TGFB1-treated WT tubular cells induced proliferation and activation of renal fibroblasts and accumulation of ECM proteins, whereas these effects were attenuated in fibroblasts treated with *Atg7* KO tubular cell-CM. FGF2 neutralizing antibody recapitulated the inhibitory effects of *Atg7* KO tubular cell-CM on renal fibroblasts, further supporting a role for FGF2 in autophagy-dependent tubular paracrine activation of fibroblasts.

Conclusions: Dysregulated autophagy in renal tubules may specifically stimulate tubular production and secretion of FGF2. This autophagy-mediated paracrine then activates interstitial fibroblasts and promotes kidney fibrosis after AKI.

Inactivation of Endothelial HIF Polyhydroxylases Following Ischemic AKI Promotes Kidney Fibrosis

Ratnakar Tiwari, Michael P. Schonfeld, Pinelopi P. Kapitsinou. *KUMC - University of Kansas Medical Center, Kansas City, KS.*

Background: Key regulators of hypoxic vascular responses are Hypoxia-Inducible-Factors (HIF)-1 and -2, transcription factors whose activity is negatively regulated by prolyl-hydroxylase domain proteins 1 to 3 (PHD1 to PHD3). Little is known about endothelial cell (EC) specific functions of PHDs in response to acute kidney injury (AKI), a common problem associated with significant morbidity and mortality. Here, we used a genetic approach to investigate the function of endothelial PHDs in renal ischemia-reperfusion injury (IRI).

Methods: Cdh5(PAC)CreER^{T2} inducible system was used to induce conditional deletion of PHD1,2,3 in ECs (Cdh5(PAC)CreER^{T2}; Phd1$^{f/f}$Phd2$^{f/f}$Phd3$^{f/f}$ referred as EC-PHD1/2/3 mutants) while the recombination efficiency was assessed by crossing Cdh5(PAC)-CreER ^{T2} transgenic mice to ROSA26-ACTB-tdTomato,-EGFP reporter mice. Mice were subjected to unilateral IRI and at Day 1 post IRI they were started on tamoxifen (total of 4 doses) to inactivate PHDs. Samples were collected at day 14 after IRI.

Results: The Cdh5(PAC)CreER^{T2} showed efficient recombination in the kidney endothelium based on FACs analysis and imaging of kidney tissue from the reporter mice. Immunofluorescence analysis of PHDs showed persistent expression of PHDs following IRI. Post-ischemic inactivation of endothelial PHDs (1-3) exacerbated infiltration of inflammatory cells and tubular damage at day 14 after IRI assessed by histopathological analysis of injured kidneys. EC-PHD1/2/3 mutants showed increased expression levels of profibrotic genes *Loxl2* (n=6-8, P= 0.03). and *Tgf*-β (n=6-8, P= 0.005). Significant deposition of matrix in interstitial spaces was observed in kidneys of EC-PHD1/2/3 mutants compared to Cre-controls as indicated by Sirius red staining. Transmission electron microscopic examination showed prominent endothelial cell damage in the kidney of EC-PHD1/2/3 mutants, which was associated with peritubular capillary rarefaction as indicated by endomucin staining. Furthermore, treatment of human ECs with a PHD inhibitor following the induction of hypoxia-reoxygenation led to significant suppression of EC-proliferation.

Conclusions: Our data show a critical role for endothelial PHDs following ischemic AKI. Inactivation of endothelial PHDs following ischemic AKI promotes kidney inflammation, peritubular capillary rarefaction and fibrosis.

ATR Deletion Drives TOR-Autophagy Spatial Coupling Compartment (TASCC) Formation and Kidney Fibrosis

Craig R. Brooks,[1] Seiji Kishi,[3] Kensei Taguchi,[4] Joseph V. Bonventre.[2] *[1]Vanderbilt University Medical Center/Division of Nephrology & Hpertension, Nashville, TN; [2]Brigham and Women's Hospital, Boston, MA; [3]Kawasaki Medical School, Kurashiki, Japan; [4]Department of Nephrology and Hypertension, Nashville, TN.*

Background: Acute kidney injury (AKI) occurs in ~20% of hospitalized patients. While the kidney can functionally recover from AKI, AKI predisposes patients to subsequent chronic kidney disease (CKD), which effects 13% of the global population. Our lab, and others, have shown the AKI-CKD transition involves maladaptive repair leading to G2/M arrest regulated by DNA damage response (DDR) genes. Recently, we have identified target of rapamycin–autophagy spatial coupling compartments (TASCCs) as components of the secretory response in G2/M arrested cells. To determine how the DDR modulates AKI-CKD transition, we tested if the loss of ataxia telangiectasia and Rad3-related (ATR) regulates TASCC formation and fibrosis.

Methods: 1: ATR flox/flox mice were breed to SLC34a1-Cre-ERT2 mice to generate proximal tubular cell (PTC) specific ATR deletion (ATR$^{RPTC-/-}$) upon tamoxifen injection. ATR floxed mice lacking the Cre acted as control (ATR^{Ctrl}). ATR^{Ctrl} and ATR$^{RPTC-/-}$ received unilateral ureteral obstruction (UUO). Kidneys were taken at day 7 and analyzed for fibrosis, G2/M arrest markers, injury markers and TASCC formation by immunostaining. TASCCs were identified by super-resolution microscopy. 2: Fucci2a mice were breed to γGT-Cre mice to generate PTC specific Fucci2a expression. The PTCs were then isolated and treated with aristolochic acid (AA), with/without the ATR inhibitor VE-821. Cells were analyzed for increased connective tissue growth factor (CTGF) by western blot.

Results: Inhibition of ATR in PTCs resulted in increased numbers of G2/M arrested cells following AA treatment, as measured by the Fucci cell cycle reporter, and greater production of CTGF, *in vitro*. *In vivo*, ATR$^{RPTC-/-}$ mice had more sever and rapidly progressing fibrosis compared to ATR^{Ctrl} mice. Deletion of ATR from PTCs resulted in increased tubular cell injury, caspase 3 staining, and G2/M arrest in response to UUO. G2/M arrest was associated with formation of TASCCs in PTCs. ATR$^{RPTC-/-}$ mice had greater numbers of TASCC/cell compared to controls.

Conclusions: ATR deletion sensitized PTCs to injury and G2/M arrest, which drove TASCC formation and production of CTGF. These data indicate the DDR modulates the AKI-CKD transition through a pathway involving G2/M arrest, TASCC formation and profibrotic factor secretion, as well as identifying novel targets for therapeutic intervention.

FR-OR030

Long-Acting Thioredoxin Prevents AKI to CKD Transition via Its Anti-Oxidative and Anti-Inflammatory Action

Hiroshi Watanabe, Kento Nishida, Rui Fujimura, Toru Maruyama. *Department of Biopharmaceutics, School of Pharmacy, Kumamoto University, Kumamoto-shi, Japan.*

Background: Renal fibrosis is common finding in CKD and is induced by the sustained oxidative stress and inflammation after AKI. Therefore, an effective strategy is highly desirable for preventing AKI to CKD transition. Thioredoxin-1 (Trx) is a redox-active protein that has anti-oxidative and anti-inflammatory properties. Although, Trx has great potential for use as a therapeutic agent against several types of oxidative stress-related diseases, its short half-life limits its clinical application. To overcome this problem, we produced a recombinant fusion protein that is comprised of human serum albumin and Trx (HSA-Trx), and examined its preventive effect against AKI to CKD transition.

Methods: Recombinant HSA-Trx was expressed using Pichia expression system. AKI to CKD transition model mice were generated by renal ischemia-reperfusion (IR).

Results: From day 1 to day 14 after renal IR, recovery of renal function and body weight were accelerated by HSA-Trx administration. HSA-Trx ameliorated excessive extracellular matrix deposition and the increase in hydroxyproline content and Col1a2 mRNA expression in the kidney on day 14 after renal IR. HSA-Trx also suppressed epithelial-endothelial transition, is known as the process of fibrosis progression. To elucidate the suppressive mechanism of HSA-Trx on AKI to CKD transition, we examined at the early phase of fibrogenesis (day 7) after renal IR. HSA-Trx treatment ameliorated renal histological alterations and decreased the increase in renal mRNA expression of Kim-1 and Sox9, which is injury marker and regeneration marker in renal tubule, respectively. In addition, the increase in oxidative stress, pro-inflammatory cytokine expression, and the number of macrophages in the kidney of PBS-treated mice were suppressed by HSA-Trx. Similarly, HSA-Trx treatment inhibited G2/M cell cycle arrest and apoptosis in renal tubule cells, which are involved in CKD progression. While renal Trx protein level were significantly decreased by renal IR, HSA-Trx suppressed the decrease in renal Trx protein level, suggesting that HSA-Trx exerts renoprotective effect partially due to preserve renal Trx protein level.

Conclusions: HSA-Trx has potential for use in the treatment of AKI to CKD transitionvia its extended effects of modulating oxidative stress and inflammation.

FR-OR031

A Randomized Trial of Optimal Phosphate Range for Coronary Artery Calcification in Dialysis Patients

Yoshitaka Isaka,[1] Takayuki Hamano,[1] Hideki Fujii,[2] Satoshi Teramukai,[3] Yoshihiro Tsujimoto,[4] Ryoichi Tanaka,[5] Noriyuki Tomiyama,[1] Fuminari Tatsugami,[9] Terumasa Hayashi,[6] Atsushi Yamauchi,[7] Yoshiharu Tsubakihara.[8] *[1]Osaka University Graduate School of Medicine, Suita, Japan; [2]Kobe University Graduate School of Medicine, Kobe, Japan; [3]Kyoto Prefectural University of Medicine, Kyoto, Japan; [4]Inoue hospital, Osaka, Japan; [5]Iwate Medical University, Iwate, Japan; [6]Osaka General Medical Center, Osaka, Japan; [7]Osaka Rosai Hospital, Sakai-city, Japan; [8]Graduate School of Health Care Science, Jikei Institute, Yodogawa-ku, Osaka, Japan; [9]Hiroshima University, Hiroshima, Japan.*

Background: In dialysis patients, mortality risk due to cardiovascular diseases is remarkably high and prognosis is poor; coronary artery calcification (CAC) is considered one of the major contributing factors. It is known that hyperphosphatemia is associated with CAC. Therefore, controlling serum phosphate level could improve the poor prognosis of dialysis patients. However, the optimal phosphate level in dialysis patients remains unknown; hence, this study was planned to compare the effects of two types of non-calcium-based phosphate binders, and examine the effect of strict control of phosphate on CAC.

Methods: Evaluate the new Phosphate Iron-based binder Sucroferric Oxyhydroxide in Dialysis patients with the goal of advancing the practice of E.B.M. (EPISODE) study is a randomized, open-label, multi-center, interventional trial with a two-by-two factorial design (UMIN000023648). We enrolled 160 hemodialysis patients, who were randomized to the sucroferric oxyhydroxide (SO) or lanthanum carbonate (LC) group in order to reduce serum phosphate to two target levels (3.5 - 4.5 mg/dL in strict group and 5.0 - 6.0 mg/dL in standard group) for 12 months. The primary endpoint was percent change in CAC score (% CACS change).

Results: Median CAC score was 840 (IQR 270-2705) at baseline. In 160 dialysis patients, 115 patients were analyzed as full analysis set. There was no significant difference in % CACS change between two phosphate binders (SO; median 12.46% [IQR -2.78-24.12], vs. LC; 13.23% [4.87-30.19], P=0.369) at 12 months. On the contrary, strict phosphate control (achieved phosphate level; 4.98±0.11 mg/dL) significantly suppressed % CACS change (median 7.57% [IQR -1.84-23.93], vs. 20.16% [9.85-30.19], P=0.020) compared with standard control (phosphate level; 5.61±0.11 mg/dL). Strict phosphate control significantly decreased c-terminal FGF23 (-130.31±327.65 pmol/L) compared with standard control (168.69±730.73, P=0.012). Of interest is that therapeutic effect of strict phosphate control was observed even in dialysis patients with baseline-CAC score>1000 (strict; 4.87% [IQR -3.90-4.87], vs, standard; 11.88% [IQR 5.78-21.41], P=0.030).

Conclusions: Strict phosphate control may retard the progression of CAC among dialysis patients.

Effects of Long-Term Burosumab, a Fully Human Monoclonal Antibody Against FGF23, on Phosphorus, Calcium, and Nephrocalcinosis in Adults with X-Linked Hypophosphatemia

Anthony A. Portale,[1] Thomas Carpenter,[2] Erik Imel,[3] Suzanne Jan de beur,[4] Lin Zhang,[7] Linda Rees,[5] Ting Chang,[8] Javier San martin,[6] Karl Insogna.[2] *[1]University of California San Francisco, San Francisco, CA; [2]Yale University, New Haven, CT; [3]Indiana University School of Medicine, Indianapolis, IN; [4]John Hopkins University, Balitmore, MD; [5]Ultragenyx Pharmaceutical Inc., Novato, CA; [6]ultragenyx, Novato, CA; [7]Ultragenyx Pharmaceutical Inc, Novato, CA; [8]Ultragenyx, Novato, CA.*

Background: In XLH, nephrocalcinosis and hyperparathyroidism are complications of treatment with oral phosphate and active vitamin D. Burosumab significantly improved serum phosphorus, fracture/pseudofracture healing, stiffness, and physical functioning compared to placebo in a Phase 3, double-blind, multicenter study in adults with XLH (CL303, NCT02526160). Here, we evaluate the effects of long-term burosumab on nephrocalcinosis and related measures using data from the completed trial.

Methods: 134 subjects were randomized 1:1 to receive burosumab 1 mg/kg or placebo subcutaneously every 4 weeks. At Week 24, subjects receiving placebo crossed-over to receive burosumab, and all subjects remained on burosumab up to Week 96, remaining blinded to prior treatment. Groups were combined for the Week 96 analysis.

Nephrocalcinosis score determined by ultrasound, ranging from 0 (normal) to 4 (stone formation), was assessed by central readers blinded to treatment.

Results: 90% (121/134) of subjects had previously received oral phosphate and active vitamin D. At baseline, nephrocalcinosis was present in 54% (73/134) of subjects, with scores of 1, 2, and 3 observed in 41%, 12%, and 1%, respectively. At Week 96, nephrocalcinosis score remained unchanged from baseline in most subjects (101/120, 84%), decreased by 1 in 9 subjects (8%), and increased by 1 in 10 subjects (8%). Serum phosphorus levels and TmP/GFR increased significantly with burosumab. Serum calcium and GFR remained stable, and mean PTH decreased modestly. Urine calcium trended upward, with 4 (3%) subjects having values above the ULN at Week 96.

Conclusions: In adults with XLH receiving burosumab for 96 weeks, renal phosphate reabsorption and serum phosphorus increased significantly and PTH decreased toward normal levels. Mean urine calcium excretion increased slightly, but nephrocalcinosis scores were not significantly changed.

Visit	Serum Calcium, mg/dL	Serum PTH, pg/mL	Serum 1,25(OH)2D, pg/mL	Urine Calcium Excretion, mg/24-hour	Serum Phosphorus, mg/dL	TmP/GFR, mg/dL
Baseline	9.15 (0.45)	97 (51)	33 (14)	102 (57)	1.98 (0.31)	1.64 (0.39)
Week 48	9.09 (0.44)	87 (40)	40 (14)	117 (66)	2.47 (0.47)	2.21 (0.56)
Week 72	9.12 (0.40)	78 (39)	38 (14)	124 (63)	2.49 (0.45)	2.19 (0.52)
Week 96	9.10 (0.40)	79 (36)	34 (11)	145 (99)	2.42 (0.46)	2.07 (0.52)

Data are mean (SD); Measurements were assessed at the end of the dose interval

EOS789, a Novel Pan-Inhibitor of NaPi-IIb/PiT-1/PiT-2, Decreased Intestinal Phosphate Absorption in Hemodialysis Patients Measured by Sensitive and Direct Method Using 33P: A Phase 1b Clinical Trial

Sharon M. Moe,[1] Laurie Trevino,[1] Ranjani N. Moorthi,[1] Simit Doshi,[1] Meryl E. Wastney,[2] Nozomi Hisada,[3] Takei Kake,[3] Yoshitaka Ogita,[3] Naohisa Fujii,[3] Yuya Matsuda,[3] Jotaro Sato,[3] Kathleen M. Hill Gallant.[4] *[1]Indiana University, Indianapolis, IN; [2]Metabolic Modeling Services, Blenheim, New Zealand; [3]Chugai Pharmaceutical, Chuo-ku, Tokyo, Japan; [4]Purdue University, West Lafayette, IN.*

Background: Elevated serum phosphorus (P) remains problematic in dialysis patients. EOS789, a novel pan-phosphate transporter inhibitor (NaPi-IIb, PiT-1, PiT-2), showed increased fecal phosphate excretion in healthy subjects in phase 1 study. Here we report safety and efficacy of EOS789 in hemodialysis (HD) patients (pts).

Methods: We conducted two cross-over, randomized sequence studies of identical design. The first compared EOS789 50 mg to placebo tid with meals. The second compared EOS789 100 mg vs EOS789 100 mg + 1600 mg sevelamer carbonate tid with meals. Pts undergoing thrice weekly HD, with a rise in serum P of 0.5 mg/dL after 15-19 days without a phosphate binder were eligible. Pts consumed a standardized diet containing 900 mg of P for 2 weeks. Study drug was given on days 4 to 14 with the diet. On day 10 subjects were admitted to the CRC for 3 days. Pts had pre-dialysis blood drawn, dialysis treatment, a meal with an oral dose of 10 uCi of 33P, and the next day they received 10 uCi 33P by IV. Serial blood draws were taken over 48h post-oral 33P dose, serum was analyzed for 33P activity, and percent P absorption was determined by kinetic modeling.

Results: A total of 12 to 14 patients were randomized to each study; 10 completed all assessments. There were no study drug related SAEs. Eight patients had gastrointestinal disorders (2 patients in each group). For efficacy, percent P absorption was 56% for placebo vs. 51% for EOS 50 mg (p=0.52) and 40% for EOS 100 mg vs. 36% for EOS 100 mg + sevelamer (p=0.45). Within each individual cross over study, these differences did not reach significance. When the 6 pts that completed both studies awere analyzed, percent P absorption was significantly lower with EOS 100 mg (44%) compared with placebo (63%) (p=0.013) and trended lower compared with EOS 50 mg (55%, p=0.12).

Conclusions: In this phase 1b study in HD pts, EOS789 was well tolerated. There was a significant decrease in intestinal P absorption at EOS789 100 mg tid. Importantly, 33P is a sensitive and direct measure of intestinal absorption, and is a superior method to serum P that is confounded by dialysis P clearance and bone remodeling.

FR-OR034

Fractional Phosphorus Absorption Is Inappropriately Normal and Does Not Correlate with 24-Hour Urine Phosphorus in Patients with Moderate CKD Compared with Healthy Adults

Elizabeth Stremke,[1] Gretchen Wiese,[1] Meryl E. Wastney,[3] Sharon M. Moe,[2] Ranjani N. Moorthi,[2] Kathleen M. Hill Gallant.[1,2] *[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Metabolic Modeling Services, Blenheim, New Zealand.*

Background: Intestinal phosphorus (P) absorption in patients with CKD is understudied, yet current therapies focus on reducing intestinal P absorption to lower the risk of cardiovascular dysfunction and mortality. Rodent studies suggest that intestinal P absorption remains inappropriately normal in early CKD, despite elevations in FGF23 and declining calcitriol. We have previously shown that 24h urine P is not related to net P absorption from metabolic balance studies in CKD patients (Stremke et al. CJASN 2018), and thus more direct measures of absorption are needed.

Methods: In this controlled feeding study, we aimed to determine P absorption in patients with moderate CKD vs healthy subjects using a 33P radioisotope tracer method. CKD and controls were matched for age (+/-10y), sex, and race. Subjects ate a controlled study diet of ~1500 mg/d P, ~1400 mg/d Ca, ~3200 mg/d K, ~2400 mg/d Na, and 0.8 g/kg/d protein for 1 week. The final two study days consisted of a clinical research center (CRC) inpatient P absorption test utilizing oral and IV doses of 33P. Fractional P absorption was determined by multi-compartment kinetic modeling. 24h urine P (uP) was determined by ICP-OES as a 2-day average. Paired analyses were performed to determine differences between CKD and controls. The relationship between fractional P absorption and 24h uP was determined by Pearson's correlation.

Results: N=6 CKD patients (eGFR=29-55 mL/min/1.73m^2) and N=6 controls completed the study. Fractional P absorption was similar between CKD patients and controls (0.68 vs 0.66, p=0.91). 24h uP also did not differ (856 vs 878 mg/d, p=0.91). 24h uP did not relate to fractional P absorption overall (r=0.07, p=0.37), nor within either group (CKD, r=0.09, controls, r=0.11, p>0.50).

Conclusions: Fractional P absorption is similar between moderate CKD patients and healthy control subjects consuming a controlled diet. This supports the animal data that P absorption is maintained at inappropriately normal levels in early/moderate CKD despite hormonal changes that should suppress P absorption. We also show no association between CRC collected 24h uP and fractional P absorption supporting that 24h uP is not reflective of P intake or net P absorption in CKD.

FR-OR035

Prevalence, Progression, and Implications of Breast Artery Calcification in Patients with CKD

Pieter Evenepoel,[1] Brecht Van Berkel,[2] Chantal Van ongeval,[3] Amaryllis H. Van Craenenbroeck,[1] Katrien D. Vusser.[3] *[1]University Hospitals Leuven, Leuven, Belgium; [2]KU Leuven, Sint-Truiden, Belgium; [3]UZ Leuven, Leuven, Belgium.*

Background: Breast artery calcification (BAC) is increasingly recognized as a specific marker of medial calcification. In this retrospective observational cohort study, we aimed to define the prevalence and progression rate of BAC in CKD patients across disease stage, to identify clinical and biochemical correlates of BAC and to explore the association of BAC with incident cardiovascular morbidity and overall mortality.

Methods: Presence and extent (BAC score) were determined on mammograms in 311 females (58.7 ± 10.8 yrs, Caucasian) with CKD across disease stage (CKD 2-5D n=133; transplant recipients [Tx]: n=178). In a subset of 88 patients (CKD5D n=14, Tx n=74), a repeat mammography was performed after a mean interval of 3.5 ± 2.2 years, allowing to calculate the annualized BAC rate. Relevant clinical and laboratory parameters, including parameters of mineral metabolism and inflammation, and outcomes were extracted from electronic files. Survival analysis was performed in the TX group by Kaplan-Meijer analysis.

Results: BAC was observed in 34.7% of the patients. Prevalence and extent of BAC increased parallel to the decline of kidney function. In the overall cohort, patients with BAC were older, suffered more from CVD and inflammation, had higher pulse pressure, and borderline higher prevalence of diabetes. The BAC progression rate was significantly higher in patients with CKD5D as compared to Tx patients (2.2 ± 1.2 vs 1.0 ± 0.4 mm/yr, mean ± SE; p=0.02). Progressors were characterized by more inflammation, worse kidney function and higher BAC score at baseline. In the Tx subcohort, progressors moreover showed higher serum phosphate levels at baseline. Presence of BAC associated with poor overall (Log-Rank p=0.0007) and cardiovascular event free (Log-Rank p=0.007) survival in Tx.

Conclusions: BAC is common among CKD patients, progresses at a slower pace in Tx as compared to CKD5D, and associates with dismal (cardiovascular) outcomes. BAC score, kidney function and serum phosphate at baseline are important determinants of progression. Measurement of BAC may offer a personalized, non-invasive approach to risk-stratify CKD patients for cardiovascular disease at no additional cost or radiation since a majority of women over the age of 40 undergo regular breast cancer screening.

FR-OR036

Sevelamer Therapy Associates with a Disturbed Microbial Metabolism in Patients with ESRD

Lu Dai,[1] Björn K. Meijers,[2] Bert Bammens,[3] Henriette De loor,[4] Abdul Rashid T. Qureshi,[1] Peter Stenvinkel,[1] Pieter Evenepoel.[3] *[1]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]UZ Leuven, Leuven, Belgium; [3]University Hospitals Leuven, Leuven, Belgium; [4]KULeuven, Leuven, Belgium.*

Background: Sevelamer is a commonly used phosphate binder (PB) in patients(pts) with ESRD. Gastrointestinal discomfort and constipation are frequently reported by sevelamer users, which raises the hypothesis that sevelamer may disturb microbial metabolism. Here we investigate if sevelamer therapy is associated with microbial metabolism in ESRD pts.

Methods: We analyzed serum levels of indoxyl sulphate (IndS) and trimethylamine-N-oxide (TMAO) (as important representatives of colonic microbial metabolism) in a large cohort of ESRD pts (n=423, 65% males, median age 54 years) listed for renal transplantation in Leuven (Belgium, n=347) or Stockholm (Sweden, n=76). Since gut microbial metabolism besides nutritional intake is an important source of VitK, we measured desphospho-uncarboxylated Matrix Gla-Protein (dp-ucMGP) levels, as a proxy of VitK status. Pts treated either with non-calcium containing PB other than sevelamer or VitK antagonist were excluded. Relevant demographics and biochemistry data were extracted from electronic files. Descriptive and multivariate linear regression analyses were performed to define the role of sevelamer therapy.

Results: Compared with sevelamer non-users, pts treated with sevelamer were characterized with younger age, higher BMI, worse phosphate control, lower albumin,

higher serum creatinine, higher serum IndS, TMAO and higher dp-ucMGP levels. In multivariate regression models adjusted for age, gender, phosphate control, serum calcium, calcium containing PB users, dialysis vintage and cohort, sevelamer therapy was identified as an independent determinant of IndS (Odds ratio, [OR 1.41; 95% confidence interval [95%CI], 1.15 to 1.71] and dp-ucMGP (OR[95%CI], 1.46 [1.17 to 1.83]), but not TMAO (1.19 [0.97 to 1.47]). A further adjustment of dp-ucMGP showed that dp-ucMGP is associated with IndS (1.32 [1.19 to 1.46]) and TMAO (1.20 [1.08 to 1.33]).

Conclusions: Sevelamer therapy associates with poor VitK status and an unfavorable microbial metabolism pattern, characterized by high IndS levels. Though the design of our study precludes causal inference, present findings point to a disturbed gut microbial metabolism and VitK deficiency as potential trade-offs of sevelamer therapy and should be considered a call for caution.

FR-OR037

Serum Sclerostin: A Useful Biomarker of CKD-MBD

Annelies De maré,[1] Patrick D'Haese,[1] Geert J. Behets,[1] Pierre Delanaye,[3] Etienne Cavalier,[4] Anja Verhulst,[1] Pieter Evenepoel.[2] *[1]University of Antwerp, Antwerp, Belgium; [2]University Hospitals Leuven, Leuven, Belgium; [3]University of Liège, Liège, Belgium; [4]University of Liege, CHU Sart-Tilman, Liege, Belgium.*

Background: Sclerostin is a glycoprotein secreted by osteocytes and antagonizing the bone catabolic effects of the wnt/beta-catenin pathway. Mounting evidence indicates that circulating sclerostin may qualify as a biomarker of CKD-MBD. In this study we report data from a clinical study in which correlations between circulating sclerostin, skeletal sclerostin expression, bone histomorphometric parameters and serum markers of bone metabolism were investigated.

Methods: A transiliac bone biopsy was taken and serum samples were collected in a cohort of 68 ESRD patients (19 males) at the time of transplantation. Serum sclerostin levels were measured using 4 different commercially available assays (BioMedica, Diasorin, Tecomedical and R&D). Skeletal sclerostin expression was evaluated on immunohistochemically stained tissue sections by counting the % of sclerostin positive osteocytic lacunae. Quantitative bone histomorphometry was performed on Goldner stained undecalcified tissue sections. Different serum markers of bone metabolism were analysed using commercially available kits.

Results: 43 ± 13% of the osteocytic lacunae were positive for sclerostin expression. Median; interquartile range (IQR) serum sclerostin concentrations (pg/ml) with the 4 assays were: 213; 159 (R&D), 1155; 848 (Diasorin), 1687; 1501 (Tecomedical), 3109; 2524 (BioMedica). Despite these large inter-assay variation, significant correlations with the skeletal sclerostin expression were found for the 4 assays under study with the Biomedica assay showing the best correlation: Rs=0.3989, p<0.001. Furthermore, both skeletal and serum (except for the Diasorin assay) sclerostin levels negatively correlated with static bone histomorphometric and serum parameters reflecting bone metabolism (formation/-turnover/-mineralization) i.e. osteoid width (p<0.05), osteoblast perimeter (p<0.05), bone-specific alkaline phosphatase (p<0.05), N-terminal propeptide of type I collagen (p<0.01), PTH (p<0.01).

Conclusions: In ESRD patients, circulating sclerostin levels significantly correlate with skeletal expression of the protein and can be regarded as a metabolic bone marker. Further research investigating extra-osseous production (e.g. calcifying vascular smooth muscle cells) of sclerostin is warranted since variation in circulating sclerostin cannot be explained by its variation in skeletal expression only.

Impact of Kidney Transplantation on Bone Microarchitecture: A Longitudinal Study

Catarina Meng,[1,4] Geert J. Behets,[2] Patrick C. D'Haese,[3] Henriette De loor,[1] Pieter Evenepoel.[1] *[1]University Hospitals Leuven, Leuven, Belgium; [2]University of Antwerp, Antwerp (Wilrijk), Belgium; [3]University Antwerp, Edegem, Belgium; [4]Department of Nephrology, São João Hospital Center, Porto, Portugal.*

Background: Patients with chronic kidney disease (CKD) who undergo kidney transplantation experience increased risk of fracture. Bone microarchitecture is a major contributor to overall bone strength. High bone remodeling has been reported to be associated with cortical bone loss in CKD. The present prospective observational study aimed to investigate the impact of kidney transplantation on cortical and trabecular microarchitecture.

Methods: Bone biopsies were performed in 49 patients (56 yrs, males 69%) at the time of transplantation, with paired samples available in 30 patients 1 year after transplantation. Structural parameters were analysed by histomorphometry (trabecular bone only) and micro-CT including trabecular bone volume, thickness (TbTh), separation (TbSp) and cortical thickness (CtTh) and porosity (CtPo). Cortical region of interest was independently defined in baseline and follow-up scans. Parameters of mineral metabolism (including PTH, sclerostin, FGF23) and bone turnover markers (BTMs, including trimeric N-terminal propeptide [P1NP] and tartrate-resistant acid phosphatase 5b [TRAP5B]) were monitored as well.

Results: Changes of parameters of mineral metabolism were as expected (e.g. 1-84 PTH 320 vs 85 ng/ml, median, pre vs post) and bone turnover markers showed a significant decrease after transplantation (e.g. P1NP 109 vs 60 µg/L; TRAP5B 6.2 vs 3.9 U/L, median). Parameters of microarchitecture, overall remained stable, with only TbTh (as assessed by µCT) showing a modest but significant decline. Parameters of mineral metabolism and BTMs failed to correlate with parameters of microarchitecture. µCT and histomorphometry derived parameters of microarchitecture showed moderate correlation (r between 0.4 and 0.6).

Conclusions: Contemporaneous kidney transplantation has no or minimal impact on bone microarchitecture, noteworthy on cortical indices. This beneficial outcome may be a reflection of (adequate) suppression of bone remodeling following transplantation.

	parameter	Baseline	Year 1	p-value
Histomorphometry	BAr/TAr (%)	18.0 (13.4-24.2)	18.9 (14.5-23.7)	1.0
	TbTh (µm)	134.9 (113.1-148.6)	124.1 (110.9-140.5)	0.7
	TbSp (µm)	409.0 (303.5-504.1)	383.7 (313.7-949.6)	0.2
µCT	BV/TV (%)	16.2 (13.5-21.6)	14.5 (11.5-17.8)	0.02
	TbTh (µm)	134.7 (118.2-151.9)	125.3 (115.2-129.4)	0.03
	TbSp (µm)	677.8 (557.0-754.5)	653.6 (596.3-763.2)	0.9
	CtPo (%)	10.2 (8.0-16.3)	9.5 (7.3-14.6)	0.2
	CtTh (mm)	0.676 (0.548-0.853)	0.610 (0.507-0.941)	0.5

FR-OR039

Vitamin D3 Repletion Improves Vascular Function, as Measured by Full-Length Osteopontin, in a High-Risk African American Cohort

Susanne B. Nicholas,[2] Satyesh K. Sinha,[1,2] Ling Sun,[4] Michelle Didero,[7] Jae eun Lee,[5] Yuan-Xiang Meng,[6] Jung hye Sung,[8] Keith C. Norris.[3] *[1]Charles R Drew University of Medicine and Science, Los Angeles, CA; [2]UCLA Medical Center, Los Angeles, CA; [3]UCLA, Marina Del Rey, CA; [4]Xuzhou Central Hospital, Xuzhou, China; [5]Jackson State Univerity, Madison, MS; [6]Morehouse School of Medicine, East Point, GA; [7]University of California, Los Angeles, Los Angeles, CA; [8]Jackson State University, Jackson, MS.*

Background: Vitamin D deficiency is common among patients with chronic kidney disease (CKD). African Americans (AAs) suffer disproportionately fromCKD and cardiovascular (CV) disease, and 80% of AAs are vitamin D deficient. The effects of vitamin D on vascular and renal health in patients with CKD have been contradictory, in part due to different study designs. Hence, the impact of vitamin D therapy on CV health in CKD patients, especially AAs is unknown. We examined the effect of vitamin D supplement on the cardio-renal biomarkers: full-length osteopontin (flOPN), c-terminal fibroblast growth factor-23 (cFGF23), and plasminogen activator inhibitor-1 (PAI-1), which have been implicated in the pathology of both vascular and renal function in CKD.

Methods: We performed a randomized, placebo-controlled study of high-risk, overweight AAs with controlled hypertension, normal renal function and vitamin D deficiency, treated with 100,000 IU vitamin D3 (N=65) or placebo (N=65) every 4 weeks for 12 weeks. We measured renal function (CKD-EPI eGFR, urinary albumin-to-creatinine ratio (ACR)), and quantified plasma cFGF23, PAI-1 and flOPN by ELISA, vascular function (pulse wave velocity (PWV), augmentation index, waist circumference (WC), and 24h-ambulatory blood pressure (BP)). We performed multiple regression controlling for the placebo-treated group to understand the relationship between the log values of flOPN, cFGF23, and PAI-1 with cardiovascular and renal risk factors.

Results: Compared to placebo vitamin D3 repletion did not change eGFR and BP values. Vitamin D3 levels increased 2-fold (p<0.0001) and iPTH levels decreased 13% (p=0.007) with repletion, which was associated with a 10% reduction in log-flOPN levels (p=0.03). There were no significant changes in log-cFGF23 or log-PAI-1 with vitamin D3 repletion. Multiple regression analysis indicated that flOPN was associated with reduced PWV (p=0.04) and diastolic BP (p=0.02), while cFGF-23 was associated only with reduced diastolic BP (p=0.05), and a trend for increased eGFR (p=0.06).

Conclusions: Vitamin D3 repletion may improve vascular function in a subset of AAs with controlled hypertension and vitamin D3 deficiency. Compared to cFGF-23 and PAI-1, flOPN may be a more sensitive vascular function biomarker in this population.

Phosphate Lowering to Treat Vascular Dysfunction in CKD

Anna J. Jovanovich,[1] Zhiying You,[2] Taylor Struemph,[8] Beverly Farmer,[3] Mikaela R. Malaczewski,[4] Moshe Levi,[5] Gregory G. Schwartz,[6] Kristen L. Nowak,[7] Michel Chonchol.[3] *[1]Denver VA / University of Colorado, Denver, CO; [2]UC Denver, Aurora, CO; [3]University of Colorado, Aurora, CO; [4]No, Aurora, CO; [5]Georgetown University, Washington, DC; [6]Rocky Mtn Regional VA Med Ctr and University of Colorado School of Medicine, Aurora, CO; [7]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [8]University of Colorado, Denver, Aurora, CO.*

Background: Individuals with CKD exhibit vascular endothelial dysfunction and arterial stiffness, independent predictors of cardiovascular disease (CVD) events. Elevated serum phosphorus, even within the normal range, is associated with CVD and mortality in CKD. An acute increase in serum phosphorus impairs endothelial function and increases vascular oxidative stress. We hypothesized that lowering serum phosphorus would improve vascular function and endothelial markers of oxidative stress in CKD.

Methods: We randomized 52 participants with CKD 3b-4 and serum phosphorus within normal limits to receive 12 weeks of lanthanum carbonate or placebo. Primary endpoints were change in brachial artery flow-mediated dilation (FMD_{BA}) and aortic pulse-wave velocity (aPWV). Secondary endpoints were change in FMD_{BA} and aPWV after ascorbic acid infusion and vascular endothelial cell protein expression of NADPH oxidase and NFκB.

Results: Mean age was 65±8 years and mean eGFR was 38±14 mL/min/1.73m^2. Baseline serum phosphorus (3.44±0.47 mg/dL) in the lanthanum carbonate group did not change after 12 weeks (p=0.94) while serum phosphorus increased (3.42±0.80 mg/dL to 3.74±1.26 mg/dL; p = 0.09) after 12 weeks in the placebo group. Randomization to lanthanum carbonate did not improve FMD_{BA} or aPWV compared to placebo: lanthanum carbonate baseline FMD_{BA} 3.13%±2.87% and 12-week FMD_{BA} 2.73%±2.48% *vs.* placebo baseline FMD_{BA} 3.74%±2.86% and 12-week FMD_{BA} 3.09%±2.49%; p=0.52; and lanthanum carbonate baseline aPWV 1214±394 cm/sec and 12-week aPWV 1216±322 cm/sec *vs.* placebo baseline aPWV 993±289 cm/sec and 12-week aPWV 977±254 cm/sec; p=0.66. Supraphysiologic infusion of ascorbic acid to inhibit superoxide production did not differentially change FMD_{BA} or aPWV between groups at the end of the study (p>0.1 for all). Vascular endothelial cell protein expression of NADPH oxidase and NFκB did not change in either group (p>0.6 for all groups).

Conclusions: Compared to placebo, lanthanum carbonate did not improve vascular endothelial function or stiffness nor did it change endothelial markers of oxidative stress among participants with CKD 3b-4. Infusion of ascorbic acid to inhibit oxidative stress did not differentially affect FMD_{BA} or aPWV.

FR-OR041

Disruptions to Neurovascular Patterning Affect Kidney Development and Adult Function

Samuel E. Honeycutt, Deanna M. Hardesty, Lori L. O'Brien. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Kidney neurovascular networks are critical to maintaining mammalian physiology and homeostasis. Despite their important roles, we know little about how they form and pattern in the embryonic kidney or how neurovascular interactions affect kidney development. Netrin-1 (*Ntn1*) is a secreted ligand critical for neurovascular guidance during embryogenesis and is highly expressed by stromal progenitors. Therefore, netrin-1 is an ideal candidate for regulating these processes during kidney development. In turn, the neurovascular networks can release factors important for development and maturation of tissues. We set out to identify candidate angiocrine factors released by the kidney endothelium and confirm their role in renal development.

Methods: We conditionally deleted *Ntn1* from kidney stromal progenitors. We utilized immunofluorescent staining, lightsheet and confocal microscopy, and cellular analyses to interrogate the embryonic phenotype. Adult kidneys were assessed for EPO and Renin production, subjected to histological analyses, and blood collected from animals for clinical chemistry. Additionally, we developed a novel vascular labeling and imaging methodology to generate 3D images for our adult analyses. We utilized publicly available single-cell RNA-seq and array data to identify putative angiocrine factors produced by the developing kidney vasculature.

Results: Conditional deletion of *Ntn1* results in hypoplastic kidneys and aberrant patterning of the neurovascular networks. Nephron progenitor proliferation is reduced and nephrogenesis is extended. Vasculature mis-patterning persists in the adult *Ntn1* mutant kidney. These animals have altered EPO and red blood cell production, and abnormal histology. Utilizing expression data, we identified Insulin-like growth factor 1 (*Igf1*) as a putative angiocrine factor in the developing kidney. Current efforts focus on conditional *Igf1* deletion from the kidney vasculature and assessing the effects on development.

Conclusions: Taken together, our studies provide novel insights into the establishment of neurovascular networks in the developing kidney and implications for adult function. Such findings will help inform regenerative strategies and efforts to engineer kidneys de novo, where establishing proper kidney filtration and nephron function will be essential.

Observation of Renin Lineage Cell Migration Following Local Laser Damage by Longitudinal Intravital Multiphoton Microscopy

Lisa Raith,[1] Michael Gerlach,[2] Jan Sradnick,[1] Vladimir T. Todorov,[1] Christian Hugo.[1] *[1]University Hospital CGC, Dresden University of Technology, Dresden, Germany; [2]Core Facility Cellular Imaging, TU Dresden, Dresden, Germany.*

Background: Several studies demonstrate intraglomerular migration of renin lineage cells (RLC) after antibody-induced damage of glomeruli. The aim of our study was to trigger and trace RLC migration patterns by non-systemic, spatially defined glomerular injury. Using an inducible transgenic RLC reporter mouse strain we were able to track cell migration by intravital 2-photon microscopy.

Methods: Renin lineage reporter mice expressing tdTomato (mRen-rtTAm2-LC1-tdT) were induced for 16 days. 24 hours before initial microscopy, abdominal body windows were implanted to allow repeated kidney imaging without further surgery. Single glomeruli were longitudinally examined six times (d0, d1, d2, d3, d6, d10) by 2-photon laser scanning microscope. Blood plasma was visualized by FITC dextran injection. Spatially defined damage was induced by intraglomerular scanning with a femtosecond pulsed 2-photon laser at high zoom factor, with a second observation 10 minutes after injury. Neighbouring non-damaged glomeruli in the same animal served as controls. Data was 3D analysed with Bitplane Imaris. Glomerular volume, total volume of intraglomerular tdTomato positive cells and maximal migration distance from the juxtaglomerular apparatus to tdTomato positive area were evaluated.

Results: RLC migration into the injured glomeruli could be observed as early as day 3 after damage. The total glomerular volume was reduced by injured glomerular over time. Compared to controls, intra-glomerular tdTomato positive cell volume continuously elevated on day 3, day 6 and day 10 (0.4 ±0.7%, 2.4 ±2.2%, 7.3 ± 7.8%). Maximal migration distance also progressively increased during observed times (day 3: 7.1 ± 6.7 μm, day 6: 21.3 ±11.9 μm and day 10: 26.8 ± 14.1 μm).

Conclusions: We were able to evaluate the temporal and spatial migration pattern of RLC into single glomeruli, starting as early as 3 days after injury. Moreover, we quantitatively assessed this process by 3D analysis. This new approach gives us the opportunity to characterize the migratory path of RLC after glomerular injury and evaluate the impact of local signalling due to spatially restricted damage.

FR-OR043

Differentiation of Stromal Cells to Renin Cells During Embryonic Vascular Development

Vidya K. Nagalakshmi, Maria Luisa S. Sequeira Lopez, Roberto Ariel Gomez. *University of Virginia, Charlottesville, VA.*

Background: Kidney arterioles are formed by the assembly of different cell types such as smooth muscle cells, endothelial cells and renin cells. Foxd1 positive stromal cells are precursors of all mural cells of the renal vasculature including the renin producing cells. How the Foxd1 cells convert to renin cells is not known. Therefore, we aimed to understand the cell fate changes during differentiation of renin producing cells from their $Foxd1^+$ stromal cell precursors throughout kidney development using single cell genomic approaches. In the current study we analyzed the transcriptome profile of GFP^+ cells FACS sorted from the kidneys of E15.5-Foxd1Cre.mTmG mice embryos.

Methods: Single cell capture was performed using the Fluidigm C1 platform and subsequent RNA sequencing was done using Illumina HiSeq4000.

Results: Sequencing analyses with Fluidigm-Singular software revealed that within the Foxd1 lineage cells, cells specific for various mural cell lineage markers clustered separately, indicating the unique molecular repertoire acquired by them during their differentiation from a common precursor population. Approximately 7.5% of the Foxd1 lineage single cells captured from E15.5 kidneys were renin positive. Unsupervised hierarchical clustering was able to identify renin positive cells as a distinct cell cluster separated from the rest of the group. Pathway analyses using the PANTHER classification system for differentially expressed genes between renin positive and negative cells detected pathways critical for vascular morphogenesis such as Angiogenesis (*Dlk1, F2r, Rhob, Crk*), Wnt signaling (*Smarcb1),* and Notch signaling (*Dlk1*) only in renin positive cells. *Smarcb1* regulates actin cytoskeleton network and loss of *Smarcb1* enhances the migratory potential of the cells. Earlier studies in our lab showed that disruption of Notch pathway in renin cells and Foxd1 precursor cells results in deregulation of genes associated with vascular smooth muscle cells and defective vascular morphogenesis. The non-canonical Notch ligand Delta-like 1 (*Dlk1*) exhibits an inhibitory role in the regulation of angiogenesis and its precise role in renin producing cells needs to be investigated further.

Conclusions: Our results suggests that Notch and Wnt pathways govern the differentiation of stromal cells to renin cells as they assemble to form the kidney vasculature.

Funding: NIDDK Support

FR-OR044

Tubule Interconnection After Zebrafish Kidney Injury

Caramai N. Kamei,[1] Iain A. Drummond.[1,2] *[1]Massachusetts General Hospital, Charlestown, MA; [2]Harvard Medical School, Boston, MA.*

Background: Nephrons made during kidney development and newly made during zebrafish kidney regeneration must establish tubule lumen interconnections with the collecting system. The zebrafish adult kidney regenerates after gentamicin injury from an adult progenitor cell population, forming 20-100 new nephrons that subsequently invade and "plumb into" the pre-existing collecting system and restore renal function. Using the zebrafish adult kidney as a model of synchronous nephron-collecting duct fusion, we investigated the role of growth factor signaling pathways in this process.

Methods: *Tg(TCFLef-miniP:dGFP)* Wnt reporter expression was used to reveal high Wnt signaling domains in new nephrons. The Wnt inhibitors IWR1 and IWP2 were applied to injured adult zebrafish to test requirements for Wnt signaling. Homozygous adult Crispr/Cas9 indel mutants in *fzd9b* and *wnt9b* were generated.

Results: We find that new nephron aggregates are patterned by canonical Wnt signaling. High canonical Wnt signaling cells formed a single cell thick dome within cell aggregates and polarized to form rosettes with an apical constriction predicting the site of future tubule lumen. Cells at the distal end of the new nephron extend invasive processes or invadopodia into the underlying tubular epithelium. Short term inhibition of Wnt signaling using the chemical inhibitors IWR1 and IWP2 inhibited invadopodia formation and blocked tubule interconnection events. Adult homozygous *fzd9b* mutants exhibit ectopic distal cell proliferation and a failure of convergent extension in new nephrons after injury while *wnt9b* mutants produce fewer new nephrogenic aggregates. A quantitative RT-PCR screen of candidate genes highly upregulated in both zebrafish nephron progenitors after injury and human cancer metastasis implicates new pathways involved in the invasion process.

Conclusions: Wnt signaling is required for tubule invasion and correlates with expression of multiple genes associated with metastatic cell invasiveness. Manipulation of Wnt signaling is an opportunity to engineer kidney tubule interconnections.

Distinct States of Chromatin Accessibility and MicroRNA Expression in Nephron Progenitor Cells During Development

Andrew S. Clugston,[1,2] Andrew J. Bodnar,[1] Jacqueline Ho,[1] Dennis Kostka.[2,3] *[1]Department of Pediatrics, UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Developmental Biology, University of Pittsburgh, Pittsburgh, PA; [3]Computational and Systems Biology, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Mammalian nephrons develop from a multipotent and self-renewing population of nephron progenitors (NPs) during kidney development. All nephrons are formed prior to birth in humans, and the number of nephrons formed is largely dependent on the number of nephron progenitors during kidney development. Low nephron endowment predisposes individuals to chronic kidney disease and hypertension. NPs that exist early in nephrogenesis are known to be transcriptionally distinct from those in later nephrogenesis. We hypothesize that changes in chromatin accessibility and microRNA (miRNA) expression contribute to developmental age-related changes in the NP transcriptome.

Methods: NP cells were isolated from mouse kidneys using magnetic-activated cell separation with positive selection of Integrin alpha 8 (Itgα8) at embryonic day 14.5 (E14.5), E16.5 and postnatal day 0. To measure transcriptional activity at regulatory features genome-wide, a proportion of the NP cells were assayed for transposase-accessible chromatin (ATAC-seq). Total RNA from remaining NP cells was sequenced using small-RNA sequencing (smRNA-seq).

Results: A total of 35,172 regions of accessible chromatin were identified based on the irreproducible discovery rate (IDR = 0.1), 1,800 of which underwent a statistically significant change in read depth between age groups (FDR = 0.05). More changes in DNA accessibility are observed between E14.5 and E16.5 than between E16.5 and P0 (1,788 and 12, respectively), and a majority of these early changes (79%) represent a reduction in accessibility over time. Findings corroborate published features including reduced activity at the *Lin28b* gene promoter during nephrogenesis. 1,243 known miRNAs were detected across all NP samples, of which 170 underwent significant changes in expression between the measured time points (padj. ≤ 0.05). These include most members of the let-7 family, which see increased expression coincident with the reduced expression of Lin28b, a published let-7 repressor.

Conclusions: Chromatin accessibility and miRNA expression appear to be distinct in early versus late nephrogenesis.

Mass Spectrometric Analysis of the Extracellular Matrix During Renal Development

Sarah N. Lipp,[1] Kathryn R. Jacobson,[1] David S. Hains,[2] Andrew L. Schwaderer,[2] Sarah Calve.[1] *[1]Purdue University, West Lafayette, IN; [2]Indiana University, Zionsville, IN.*

Background: The extracellular matrix (ECM) is a network of macromolecules that interacts with renal cells to regulate development, physiology, and pathology. Defects in specific ECM associated genes affect metanephric kidney initiation, branching, tubulogenesis, terminal differentiation of intercalated cells, and integrity of the glomerular basement membrane. However, global changes in the composition and turnover of kidney ECM as a function of development are unknown.

Methods: We used mass spectrometry (MS) to analyze embryonic (E18.5) and adult murine kidney proteins fractionated by differential solubilities and decellularization techniques for ECM 3D visualization using confocal microscopy

Results: We resolved increased expression of COL4A3, COL4A4, COL4A5, LAMA5, and LAMB2, which are critical for the integrity of the glomerular basement membrane in the adult. Additionally, FREM1, FREM2, and FRAS1, which are necessary for metanephric induction, were selectively upregulated at E18.5 (Fig 1a). The ECM of decellularized kidneys from different developmental stages could be visualized in 3D using confocal microscopy (Fig 1b).

Conclusions: Together, this work shows that the ECM changes during development can be resolved by MS. We aim to observe how global protein abundance determined by MS correlates to 3D spatiotemporal organization in ECM proteins in the kidney. This information can be used to tailor the scaffold environment in regenerative medicine applications.

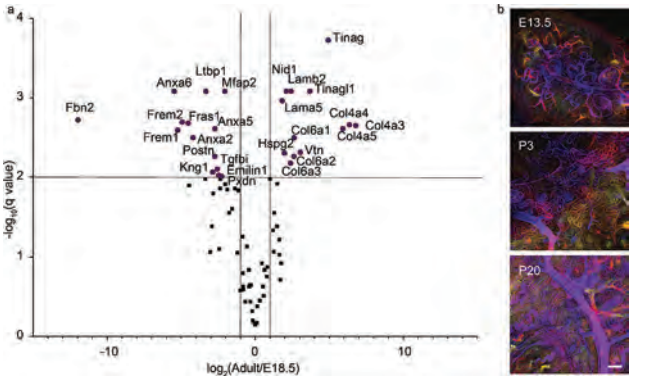

Figure 1: (a) Volcano plot comparing ECM of E18.5 and adult murine kidneys. Proteins that are different between time points (>2-fold difference with a false discovery rate of 1%) are indicated with a circle. (b) Decellularization enables the 3D visualization of E13.5-P20 kidneys stained with wheat germ agglutinin to visualize the ECM. Color portrays depth (blue to yellow), scale bar=100 μm.

FR-OR047

Generation of Functional Human Kidney Tissues from Metanephric Nephron Progenitors and Ureteric Bud Cells Separately Differentiated from Human iPS Cells

Hiraku Tsujimoto, Toshikazu Araoka, Makoto Ryosaka, Shin-ichi Mae, Kenji Osafune. *Center for iPS Cell Research and Application, Kyoto University, Kyoto City, Kyoto, Japan.*

Background: Chronic kidney disease (CKD) affects more than 10% of the global population. The lack of effective curative options has led to research on regenerative therapies using stem cells. Accordingly, recent studies using human induced pluripotent stem cells (hiPSCs) have developed protocols to induce kidney-lineage cells and reconstruct kidney organoids. However, no reports have generated human kidney tissues by recapitulating nephrogenesis using metanephric nephron progenitors (NPs) and ureteric bud (UB) cells induced separately from hiPSCs, in which NP-derived glomeruli and renal tubules and UB-derived collecting ducts are interconnected. Furthermore, no *in vivo* imaging studies have directly demonstrated that hiPSC-derived kidney organoids produce urine.

Methods: We separately and efficiently induced metanephric NPs and UB cells from hiPSCs in the original 2D differentiation culture conditions, co-cultured these two progenitors using bioreactors and performed immunofluorescent analysis using the CUBIC tissue clearing method. In addition, we transplanted mixed aggregates from the two progenitors into immunodeficient mice and examined them using *in vivo* multiphoton microscopy.

Results: After co-culture of the two progenitors, NPs constructed SIX1(+) active nephrogenic niches close to UB tips and S-shaped body-like structures. They further organized kidney structures that contained glomeruli, proximal and distal tubules, Henle's loops and collecting ducts *in vitro* and *in vivo*. By using two hiPSC lines that constitutively express fluorescent reporter proteins (GFP or mCherry), we demonstrated that the connecting points of GFP(+) NP-derived distal tubules and mCherry(+) UB-derived collecting ducts showed a marker expression pattern consistent with their counterparts in human embryonic kidneys, indicating that they were functionally interconnected. Furthermore, the intravenous injection of fluorescent-conjugated dextran confirmed that the hiPSC-derived glomeruli were functionally integrated with the host vasculature. Moreover, we observed urine-like dextran accumulation in the hiPSC-derived Bowman's space *in vivo*.

Conclusions: Our culture system should contribute to the mechanistic elucidation of human nephrogenesis and the development of regenerative therapies against kidney diseases.

Application of Cellular Extrusion Bioprinting to Improve Kidney Organoid Patterning

Jessica M. Vanslambrouck,[1] Kynan T. Lawlor,[2] James W. Higgins,[3] Sara E. Howden,[1,7] Ker sin Tan,[2] Sean Wilson,[1] Pei Xuan Er,[6] Alexander N. Combes,[6] Derek Arndt,[3] Benjamin Shepherd,[4] Alice Chen,[5] Melissa H. Little.[1,7] *[1]Murdoch Childrens Research Institute, Parkville, VIC, Australia; [2]Murdoch Children's Research Institute, Parkville, VIC, Australia; [3]Organovo, Inc., San Diego, CA; [4]Organovo, Inc, San Diego, CA; [5]Organovo, Inc., San Diego, CA; [6]Murdoch Children's Research Institute, Parkville, VIC, Australia; [7]Departments of Pediatrics and Anatomy and Neuroscience, University of Melbourne, Melbourne, VIC, Australia*.

Background: Organoids derived from induced pluripotent stem cells (iPSCs) are now being exploited as a model system for a variety of organs, especially for structurally complex organs such as the kidney. iPSC-derived kidney organoids show great potential for modelling kidney diseases and improving our understanding of disease pathogenesis. However, they do not yet accurately recapitulate the cellular maturity and compartmental organisation of the human kidney *in vivo*. Changes in culture format may allow for improved patterning by altering biophysical properties, cell-cell interactions and growth factor gradients. Here we report the application of 3D cellular extrusion bioprinting to i) improve quality control and ii) modify organoid morphogenesis and maturation.

Methods: A series of fluorescent reporter iPSC lines designed to report the formation of specific cellular compartments of the kidney, such as podocytes, proximal tubule and distal nephron/ureteric epithelium, were subjected to monolayer differentiation as previously described (Takasato *et al*, 2016). Generation of organoids was performed using extrusion-based NovoGen Bioprinter® MMX technology (Organovo), with variations in cell density and printing configuration, and compared to manually pelleted organoids. Organoids were analysed via live imaging for fluorescent reporters, confocal immunofluorescence and quantitative image analysis.

Results: Bioprinting facilitated rapid, uniform and highly reproducible organoid production. Organoids were well-patterned and comprised all kidney cell types and compartments previously described using the manual technique. Changes in cell density, organoid shape and thickness also modified nephron number, patterning and the formation of off-target populations.

Conclusions: Here we demonstrate that biophysical properties of organoids at the time of their generation can have a significant impact of their morphogenesis and differentiation, potentially affecting cellular maturity and differentiation trajectory. Further research into the variables of organoid generation will be fundamental to achieve and maximise future downstream applications.

Improved Human Pluripotent Stem Cell-Derived Kidney Organoids for Modeling Collecting Duct Biology and Tubular Injury

Kohei Uchimura, Haojia Wu, Benjamin D. Humphreys. *Washington University School of Medicine, Saint Louis, MO*.

Background: Maximizing the potential of human kidney organoids for drug testing, regenerative medicine and to model development and disease requires addressing cell immaturity, the lack of a branching collecting system and off target cell types.

Methods: We separately induced posterior intermediate mesoderm and anterior intermediate mesoderm from human iPS and ES cells and combined them on day 7. For the next five days, the combined organoids were incubated in a cocktail including FGF9, heparin, GDNF, retinoic acid and EGF. At day 12, we compared organoids left to mature in basal medium vs. medium supplemented with aldosterone, vasopressin and the NTRK2 inhibitor K252a. Organoid cell diversity and maturation state was assessed by scRNA-seq, immunofluorescence, AQP2 trafficking assays and nephrotoxicity responses.

Results: Our new protocol induced a definitive ureteric bud-derived branching collecting duct system interconnected to more proximal nephron segments. The hormones aldosterone and vasopressin were critical to promote maturation of collecting duct cell types including both principal and intercalated cells. The resulting principal cells express aquaporin-2 protein which undergoes translocation to the apical membrane after vasopressin or forskolin stimulation. By scRNA-seq (35,954 cells total), we define all cell types present, define their maturity and demonstrate superior proximal tubule maturation. Compared to organoids differentiated with existing protocols generated in parallel, this new protocol results in superior downregulation of progenitor cell types, substantially reduced off-target cell types and improved modeling of tubular injury.

Conclusions: We developed a new protocol for the separate induction of both metanephric mesenchyme and ureteric bud from hPSC. This results in robust collecting system development. We report that aldosterone and vasopressin drive the maturation of collecting duct cell types, including principal cells complete with vasopressin-stimulated AQP2 trafficking and the emergence of intercalated cells for the first time. Our scRNA-seq analysis demonstrates that the protocol also results in more mature nephron segments, appropriate downregulation of progentors and improved injury modeling.

An Approach for Improving iPSC-Derived Ureteric Epithelial Identity In Vitro

Sara E. Howden,[1] Sean Wilson,[1] Ker sin Tan,[2] Lakshi T. Starks,[1] Kynan T. Lawlor,[2] Jessica M. Vanslambrouck,[1] Melissa H. Little.[1] *[1]Murdoch Childrens Research Institute, Parkville, VIC, Australia; [2]Murdoch Children's Research Institute, Parkville, NSW, Australia*.

Background: We previously described a protocol for generating iPSC-derived human kidney organoids containing segmented nephrons, renal interstitium, endothelium and a CDH1+/GATA3+/PAX2+/CALB1+ ureteric epithelium (UE). Recent single cell analyses of mouse and human fetal kidney have identified expression of many presumed UE marker genes, including *GATA3* and *HOXB7*, within the distal nephron and connecting segment. This has raised questions about the true identity of GATA3+ epithelium within kidney organoids. Here we describe the transcriptional profile of GATA3+ epithelium isolated from organoids both prior to and after *in vitro* culture.

Methods: Kidney organoids were generated from iPSCs harboring an mCherry fluorescent reporter gene within the endogenous *GATA3* locus. We used fluorescent activated cell sorting (FACS) to isolate GATA3+/mCherry+ epithelium for subsequent culture in conditions previously shown to promote expansion of mouse UE. Immunofluorescence and RNAseq-based transcriptional profiling was performed to evaluate cell identity pre- and post-culture.

Results: We observed extensive proliferation and branching of FACs-isolated GATA3+/mCherry+ cells cultured in conditions known to promote propagation of mouse UE. GATA3/mCherry expression was maintained even after several rounds of dissociation and re-plating. Additional UE markers (KRT8, PAX2, SOX9, CALB1) were detected by immunofluorescence. Although global RNAseq of GATA3+/mCherry+ epithelium at the time of isolation suggested a cellular identity more akin to distal tubule, cultured GATA3+/mCherry cells showed loss of *KCNJ1* and induction of *WNT11* and *RET* expression. Single cell transcriptional analysis of cultured cells revealed 3 clusters representative of tip (RET+/GFRα1+/ETV4+), stalk (AQP2+) and a putative medullary compartment (UPK1A+). Notably, *WNT9B* expression was evident at a level consistent with that observed in human fetal kidney.

Conclusions: Our results redefine the identity of the GATA3+/CDH1+ epithelium within kidney organoids to early connecting segment/distal tubule. However, when cultured in appropriate conditions, this can transition to a more recognizable collecting duct fate. The capacity to expand and propagate a branching epithelial compartment with ureteric identity may represent a useful approach for the generation of collecting duct tissue.

Association Between Ambient Fine Particulate Matter Air Pollution and Death due to CKD

Benjamin C. Bowe,[1] Yan Xie,[1] Hong Xian,[2,1] Yan Yan,[3,1] Ziyad Al-Aly.[1,3] Clinical Epidemiology Center, VA Saint Louis Health Care System *[1]VA Saint Louis Health Care System, Saint Louis, MO; [2]Saint Louis University College for Public Health & Social Justice, St. Louis, MO; [3]Washington University Medical School, Saint Louis, MO*.

Background: Experimental and epidemiologic evidence suggest that ambient fine particulate matter ($PM_{2.5}$) is a risk factor for chronic kidney disease (CKD). However, no studies have investigated whether $PM_{2.5}$ is associated with mortality due to CKD, nor quantified the burden in the US.

Methods: Data from the Environmental Protection Agency, Department of Veterans Affairs, and National Death Index were linked. Non-linear exposure response functions were built using an ensemble survival modeling approach, and CKD death rates associated with $PM_{2.5}$ exposure were estimated.

Results: A cohort of 4,522,160 US veterans was followed for a median of 10 years. There were 29,016 deaths due to CKD during follow-up. The median $PM_{2.5}$ exposure at baseline was 11.8 ($\mu g/m^3$) (IQR: 10.0-13.8). As $PM_{2.5}$ levels increased, an increase in risk of death due to CKD was observed. In the contiguous US in 2017, it was estimated that 7,175.2 (Uncertainty Interval (UI): 5910.2-8371.9) CKD deaths were associated with $PM_{2.5}$ exposure, corresponding to an age-standardized rate of 1.9 (UI: 1.5-2.2) deaths due to CKD per 100,000 persons. Geographic heterogeneity in age-standardized rates of CKD deaths associated with $PM_{2.5}$ was observed (Figure), where states with the highest rates (per 100,000 persons) included Mississippi (3.14), Georgia (2.9), and Indiana (2.9), while states with the lowest rates included Vermont (0.31), Wyoming (0.46), and Washington (0.56). In those of black or African American race, the age-standardized CKD death rate associated with $PM_{2.5}$ was estimated to be 2.1 per 100,000 persons, 16.4% higher than the estimate in those not of black or African American race (1.8 per 100,000 persons).

Conclusions: Elevated levels of $PM_{2.5}$ is associated with increased risk of death due to CKD. The burden is disproportionately borne by those of black or African American race.

Particulate Matter, Albuminuria, and CKD: The ARIC Study

Matthew F. Blum,[1] Aditya L. Surapaneni,[1] James Stewart,[4] Duanping Liao,[3] Jeff D. Yanosky,[3] Eric A. Whitsel,[4] Melinda Power,[2] Morgan Grams.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]George Washington University, Washington, DC; [3]Pennsylvania State University College of Medicine, Hershey, PA; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Exposure to particulate matter less than 2.5 mm in diameter ($PM_{2.5}$) has been linked to detrimental health effects. This study describes the relationship between long-term exposure to $PM_{2.5}$ and estimated glomerular filtration rate (eGFR), albuminuria, and incident chronic kidney disease (CKD).

Methods: The study included 10,856 participants from the Atherosclerosis Risk in Communities cohort followed from 1996 through 2017. Monthly mean $PM_{2.5}$ concentrations (ug/m^3) were estimated at participant addresses, then averaged over 12-, 60-, and 120-month periods preceding participant examination. Covariate-adjusted cross-sectional associations of $PM_{2.5}$ with eGFR and log-transformed urinary albumin-creatinine ratio (ACR) were estimated using linear regression. $PM_{2.5}$-incident CKD associations were estimated using Cox proportional hazards regression. Modeling was stratified by ARIC site, and stratum-specific estimates were combined in random-effects meta-analyses.

Results: There was no significant $PM_{2.5}$-eGFR association at any exposure averaging period. $PM_{2.5}$ averaged over the 12- and 60-, but not 120-month periods was associated with higher log(ACR) after adjusting for demographics, socioeconomic status, and clinical covariates. Incident CKD was higher with higher 12-, but not 60- and 120-month mean $PM_{2.5}$ concentrations (Table).

Conclusions: Exposure to higher 12- and 60-month mean $PM_{2.5}$ concentrations was associated with higher albuminuria, and exposure to higher 12-month mean $PM_{2.5}$ concentration was associated with higher risk for incident CKD.

Adjustment model	eGFR, β (CI)	log(ACR), β (CI)	Incident CKD, HR (CI)
12-month: Model 1	2.05 (-2.62, 6.73)	0.80 (0.33, 1.27)†	1.96 (1.31, 2.93)†
12-month: Model 2	0.98 (-2.45, 4.40)	0.66 (0.26, 1.05)†	1.95 (1.14, 3.33)†

FR-OR053

Environment-Wide Association Study on CKD in the National Health and Nutrition Examination Survey (1999-2016)

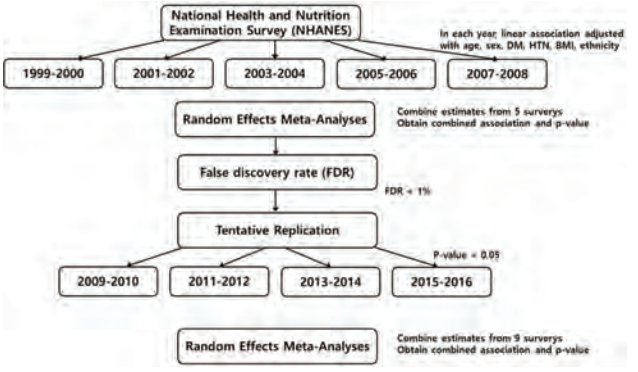
Jeonghwan Lee,[1] Lilin Li,[2] Jung Pyo Lee.[3] *[1]Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Boramae Medical Center, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Effects of environmental chemicals on the development of CKD are not well-investigated. We aimed to investigate which environmental chemicals are significantly associated with the development of CKD.

Methods: A total of 53,348 adult aged above 18 years old participants, who participated in the NHANES surveys over 18 years, were enrolled. The association between environmental chemicals and CKD was tested and validated using the environmental-wide association study (EWAS) methodology. CKD was defined as three categories (albuminuria, urinary albumin to creatinine ratio above 30 mg/g; glomerular filtration rate (GFR), GFR below 60 ml/min/1.73m^2; and composite of albuminuria and GFR).

Results: A total of 299 environmental toxins were included in the analysis. Blood lead, urinary antimony and cobalt, blood 1,2-Dichlorobenzene and nitrobenzene were positively associated with CKD defined by albuminuria. In the contrary, perfluorooctanoic acid, perfluorooctane sulfonic acid, urinary nitrate and thiocyanate were negatively associated with CKD defined by albuminuria. Blood lead and cadmium showed positive association with CKD defined by GFR. Other 31 significant environmental factors were all negatively associated with CKD defined by GFR. Blood lead, urinary tungsten, blood 1,2-dichlorobenzene and nitrobenzene, 2,4,5-trichlorophenol, mono-n-butyl phthalate, mono-benzyl phthalate were positively associated with CKD defined both albuminuria and GFR. Urinary mono-benzyl phthalate is associated with increased prevalence of CKD in various categories of albuminuria and GFR.

Conclusions: Urinary mono-benzyl phthalate as well as blood lead are consistently associated with CKD defined by various range of albuminuria, glomerular filtration rate, and composite categories. Increased exposure to lead or mono-benzyl phthalate can be associated with increased prevalence of CKD.



Schematic representation for the association analysis of environmental toxins with chronic kidney disease.

Genetic Determinants of CKD Progression Among Individuals Without Diabetes: The Million Veteran Program

Cassianne Robinson-Cohen,[1] Hua-Chang Chen,[1] Ran Tao,[1] Otis D. Wilson,[1] Ayush Giri,[1] Elvis A. Akwo,[1] Cecilia P. Chung,[1] Todd L. Edwards,[1] Peter W. Wilson,[2] Christopher J. O'Donnell,[3] Adriana Hung.[4] on behalf of the Million Veteran Program *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Emory University, Atlanta, GA; [3]Boston Veterans Administration, Boston, MA; [4]VA & Vanderbilt University, Nashville, TN.*

Background: The rate of CKD progression among individuals with diabetes varies widely and is incompletely explained by known risk factors. While the genetic determinants of cross-sectional eGFR have been identified, only one small analysis of longitudinal change in eGFR among individuals with CKD has been conducted.

Methods: We performed a genome-wide association study of the relative rate of decline in estimated glomerular filtration rate (eGFR, % decline/year) among 41,348 individuals with CKD and free of diabetes at baseline participating in the Million Veteran Program. Analyses were stratified by race; 5,818 participants were of non-Hispanic Black race/ethnicity.

Results: Mean (SD) eGFR at baseline was 51.1 (±8.1) ml/min/1.73m^2 and median relative kidney function decline was -0.7%/year. In trans-ethnic meta-analysis, we uncovered 48 SNPs from 2 independent regions associated with decline in kidney function. The SNP with the strongest association, rs13329952, is an intronic variant in *UMOD*; every additional minor allele was associated with a 1%/year faster decline in eGFR ($p=1.7x10^{-13}$). Our GWAS also identified a novel locus associated with CKD progression (top SNP rs12805797 near *LINC02098* ($p=5.0x10^{-8}$)). Among blacks, the presence of two high-risk *APOL1* variants was associated with a 3%/year faster decline in eGFR, relative to individuals with no high-risk variants.

Conclusions: Our data suggest that CKD progression has a genetic basis beyond that of baseline eGFR alone. Better understanding of the contribution of inherited genes to CKD progression could help to build the foundation for genetic diagnosis and personalized treatment of this common condition.

FR-OR055

Kidney Function Decline Among African Americans with Sickle Cell Trait and Sickle Cell Disease

Kabir O. Olaniran,[1] Andrew S. Allegretti,[1] Sophia Zhao,[1] Nwamaka D. Eneanya,[2] Ravi I. Thadhani,[4] Sagar U. Nigwekar,[1] Sahir Kalim.[3] *[1]Massachusetts General Hospital, Boston, MA; [2]University of Pennsylvania, Philadelphia, PA; [3]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA; [4]Cedars-Sinai, Los Angeles, CA.*

Background: Sickle cell trait (SCT) and disease (SCD) are felt to be independent risk factors for chronic kidney disease (CKD) among African Americans (AA). However, the understanding of the trajectory of kidney function decline and its predictors in patients with SCT/SCD remains limited. We aimed to describe longitudinal kidney function decline and associated risk factors among adult AA with SCT/SCD.

Methods: We performed a multi-center observational study of adult AA patients with hemoglobin electrophoresis to ascertain the presence of SCT or SCD (exposure) and normal hemoglobin phenotype (reference). We included patients with a baseline estimated glomerular filtration rate (eGFR) ≧29 ml/min/1.73m^2, at least 3 eGFR values between 2005-2018 and at least 1 year between the first and last eGFR values. Outcomes of interest were the difference in the mean change in eGFR per year (evaluated using linear mixed models) and incident stage 3 CKD (described using Cox proportional hazards).

Results: We identified 10,210 patients (1,251 SCT, 230 SCD and 8,729 reference) with a median follow-up of 8 (IQR 5-11) years and a median of 17 (IQR 10-30) eGFR values. The mean age was 36 (±13) years, 86% were female and baseline eGFR was 113 (±27) ml/min/1.73m^2. Compared to the reference, eGFR declined 0.45 ml/min/1.73m^2/year faster in SCT (p<0.01) and 1.28 ml/min/1.73m^2/year faster in SCD (p<0.01). SCD patients' eGFR declined 0.83 ml/min/1.73m^2/year faster (p<0.01) than the SCT patients. These results were consistent after multivariable adjustment. Compared to the reference, incident stage 3 CKD was higher in SCT (hazard ratio [HR] 1.26; 95% confidence interval (CI), 1.05-1.51), and SCD (HR 2.37; 95% CI, 1.43-3.93) after multivariable adjustment. Males, diabetes mellitus, and a baseline eGFR ≥90ml/min/1.73m^2 were associated with faster eGFR decline in SCT/SCD.

Conclusions: SCT/SCD is associated with a significantly faster eGFR decline compared to normal hemoglobin phenotype among AA patients. A dose-response relationship between sickle hemoglobin and kidney dysfunction may exist. Prospective and mechanistic studies are needed to develop best practices to attenuate eGFR decline in AA patients with SCT/SCD. Physicians caring for AAs need to consider SCT/SCD status and SCT/SCD interactions with comorbidities when evaluating CKD risk.

FR-OR056

Sickle Cell Trait (SCT) and CKD Progression Among African Americans in the Chronic Renal Insufficiency Cohort (CRIC) Study

Vimal K. Derebail,[1] Jesse Y. Hsu,[4] Abhijit V. Kshirsagar,[1] Nigel S. Key,[1] Sankar D. Navaneethan,[2] Chi-yuan Hsu,[3] Hyacinth I. Hyacinth,[5] Yulan Liang,[6] Harold I. Feldman.[4] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Baylor College of Medicine, Sugar Land, TX; [3]University of California San Francisco, San Francisco, CA; [4]University of Pennsylvania, Philadelphia, PA; [5]Aflac Cancer and Blood Disorder Center, Emory University., Atlanta, GA; [6]University of Maryland, Baltimore, MD.*

Background: SCT has been identified as a risk factor for CKD in prior epidemiologic cohort studies. The influence of SCT upon progression of established CKD has not been previously evaluated.

Methods: SCT was imputed from genetic data in AA CRIC participants. We excluded those with hemoglobin C trait. Mixed effects models were used to analyze estimated glomerular filtration rate (eGFR) decline. Association of SCT and the CRIC composite renal outcome (end-stage renal disease or halving of eGFR) was assessed by Cox regression. Models were constructed in stepwise fashion and included demographics, African ancestry, clinical site, baseline eGFR, education, income, insurance status, nephrologist use, ACE-I/ARB use, systolic blood pressure, body mass index, diabetes, hemoglobin A1c, smoking and 24-hour urine protein. Analyses were also stratified by APOL1 risk status.

Results: We included 1,468 participants, of whom 218 (14.9%) had SCT. Median follow up was 8.6 years (IQR 6.7 - 9.6). Baseline characteristics including eGFR were similar between the SCT and non-SCT groups (TABLE) as was the unadjusted eGFR decline (-1.37 [1.43] v. -1.44 [1.55]). In the fully adjusted model, no difference was noted in eGFR slope comparing SCT to non-SCT (-0.031 [-0.567, 0.504] ml/min/1.73m^2/year, p=0.91). SCT was not associated with the composite renal outcome (HR 1.19 [95% CI 0.89 - 1.61], p=0.24). When stratified by APOL1, no association was noted between SCT and the outcomes of interest.

Conclusions: SCT is present in 8-10% of the general AA population but was enriched among AAs in the CRIC Study suggesting it may confer risk for *developing* CKD. In contrast to prior findings in population-based cohorts, SCT was not associated with *progression* of renal disease when evaluated in individuals with CKD.

FR-OR057

Progressive CKD and Mortality as Predicted by Renal Histology After Radical Nephrectomy

Hisham Elsherbiny, Aleksandar Denic, Camden Lopez, R. houston Thompson, Luisa M. Ricaurte Archila, Ramya Narasimhan, Mariam P. Alexander, John C. Lieske, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: Nephron hypertrophy and nephrosclerosis may be important determinants of mortality and kidney failure. However, the study of adverse outcomes with renal histology has been limited to select patient populations with small tissue specimens.

Methods: We studied patients who underwent a radical nephrectomy for tumor between 2000 and 2012. Wedge sections distal to the tumor were stained and scanned into high resolution images. The areas of cortex and glomeruli (sclerotic and non-sclerotic) were annotated to calculate glomerular volume and percentage globally sclerotic glomeruli (%GSG). The percentage luminal stenosis (arteriosclerosis) and interstitial fibrosis/tubular atrophy (IFTA) of the cortex were morphometrically measured. Patients were followed with annual visits or phone calls for non-cancer death or kidney failure, censoring at cancer death. Progressive chronic kidney disease (CKD) was defined as dialysis, kidney transplant, or a 40% decline in estimated glomerular filtration rate (eGFR) from the post-nephrectomy baseline. Models adjusted for age, sex, BMI, hypertension, diabetes, smoking, and eGFR.

Results: There were 712 patients (mean age 63y, 64% male, 64% hypertension, 14% diabetic, and mean postoperative eGFR 48 ml/min/1.73 m^2) with a mean follow-up of 8.0±4.2 years, 77 progressive CKD events, 170 non-cancer deaths, and 104 cancer deaths. Larger non-sclerotic glomerular volume predicted progressive CKD, but this was no longer evident after adjustment for proteinuria. Higher %GSG and more severe arteriosclerosis predicted progressive CKD, which persisted with adjustment for proteinuria. Higher %IFTA predicted non-cancer morality, and this persisted with adjustment for proteinuria. No kidney structural finding predicted cancer mortality.

Conclusions: Larger nephron size predicts kidney failure along the same pathway as proteinuria. Subclinical glomerulosclerosis and arteriosclerosis predict kidney failure, whereas subclinical IFTA predict non-cancer mortality.

Funding: NIDDK Support

Hazard ratio of outcomes by renal histology (p-values)

	Predicted progressive CKD	Non-cancer Mortality	Cancer Mortality
Glomerular volume, log	2.17 (0.003)	1.11 (0.52)	1.18 (0.44)
IFTA %	1.07 (0.25)	1.16 (0.0002)	1.04 (0.43)
%GSG	1.32 (0.01)	1.11 (0.18)	0.98 (0.81)
Luminal stenosis %	1.90 (0.02)	1.39 (0.10)	0.95 (0.81)

FR-OR058

Effects of Different Serum Bicarbonate Levels on Muscle Mass and Renal Function Among CKD Patients with Metabolic Acidosis: A Randomized Controlled Trial

Somrath Srijaruneruang,[2] Piyawan Kittiskulnam,[1] Kearkiat Praditpornsilpa,[3] Somchai Eiam-Ong.[3] *[1]Chulalongkorn university, Bangkok, Thailand; [2]Chulalongkorn, Bangkok, Thailand; [3]Chulalongkorn University, Bangkok, Thailand.*

Background: Treatment of metabolic acidosis to target high serum bicarbonate level may downregulate muscle protein degradation and retard GFR decline among CKD patients. We conducted a study to test the effects of increased bicarbonate level on muscle parameters and renal function in pre-dialysis CKD patients.

Methods: This was a randomized, controlled study. CKD stage 3-4 patients with serum HCO_3^-<22 mmol/L were randomized to either receive oral sodium bicarbonate with target bicarbonate level of 25±1 or standard level of 22±1 mmol/L as control group using the protocol-based titration of dosage adjustment. The change of muscle mass measured by bioelectrical impedance analysis (BIA), muscle strength by hand grip dynamometer, eGFR using CKD-EPI equation, nutritional markers, and muscle-related biomarkers were determined. Baseline data and after 6 months of sodium bicarbonate supplementation were compared between groups using t-test or Chi-square test as appropriate.

Results: Forty-two patients completed the study (n=21 per group). The mean age and eGFR were 61.2±9.8 years and 32.4±14.1 ml/min, respectively. Baseline data including age, sex, diabetes, serum bicarbonate level, muscle mass, and blood pressure were similar. After 6 months of treatment, the average serum bicarbonate levels in both group were 24.8 and 21.2 mmol/L. Both BIA-derived total-body muscle mass and appendicular lean balance were significantly increased at 6 months in the higher bicarbonate group (26.0±5.4 to 26.7±5.7 kg, p=0.04 and 19.8±4.1 to 20.6±4.5 kg, p=0.03, respectively) despite comparable energy and protein intake. The higher bicarbonate group also had 36% lower serum myostatin, a surrogate for muscle degradation, but unaltered insulin-like growth factor-1 level as the mediator of muscle cell growth (133.8±43.6 vs 121.3±52.7 ng/mL, p=0.3) compared to the control group. Muscle strength, eGFR as well as serum albumin were not significantly different between two groups (p>0.05). Neither worsening hypertension nor heart failure was found throughout the study.

Conclusions: Bicarbonate supplementation to achieve the serum level ~25 mmol/L demonstrates better muscle mass preservation in patients with pre-dialysis CKD. The impact of alkaline therapy on renal function may require longer period of study.

Impaired Sleep Quality Is Associated with Incident Albuminuria in Hispanics/Latinos: Findings from the Hispanic Community Health Study/Study of Latinos (HCHS/SOL)

Sajid Q. Ansari,[1] Ana C. Ricardo,[1] Jinsong Chen,[8] Phyllis C. Zee,[2] Sylvia E. Rosas,[3] Gregory A. Talavera,[4] Elizabeth M. Cespedes feliciano,[5] Jianwen Cai,[6] Nora Franceschini,[6] Sanjay R. Patel,[7] Martha L. Daviglus,[1] James P. Lash.[1] *[1]University of Illinois at Chicago, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Joslin Diabetes Center, Boston, MA; [4]San Diego State University, Chula Vista, CA; [5]Kaiser Permanente Northern California, Oakland, CA; [6]University of North Carolina at Chapel Hill, Chapel Hill, NC; [7]University of Pittsburgh, Pittsburgh, PA; [8]Medicine, University of Illinois at Chicago, Chicago, IL.*

Background: Emerging evidence suggests that short duration and poor quality sleep may be associated with progression of chronic kidney disease (CKD). Little is known about the relationship of sleep duration/quality with incident albuminuria.

Methods: Analyses included data from 1662 U.S. Hispanic/Latino adults aged 18-64 years enrolled in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) Sueno Sleep Ancillary Study, who completed 7 days of wrist actigraphy (2011-2013) and a follow-up visit (2014-2017), and did not have CKD (estimated glomerular filtration rate [eGFR] ≥ 60 ml/min/1.73m^2 and urine albumin-to-creatinine ratio [ACR] <30 mg/g) at baseline. Incident albuminuria was defined as ACR ≥30 mg/g. Validated computer software algorithms were used to assess sleep duration and sleep fragmentation (calculated by summing the percentage of the sleep period that is spent moving and the percentage of the number of immobile phases that last 1minute or less). Poisson regression with follow-up years as an offset was used accounting for HCHS/SOL complex sampling design.

Results: At baseline, mean age was 37.5 years and 51.9% were female. In 5.7 years median follow-up, 71 individuals developed incident albuminuria. Higher sleep fragmentation was associated with higher incident rate of albuminuria after adjusting for center, age, sex, education, diabetes, systolic blood pressure, body mass index, cardiovascular disease, depression, eGFR, and ACR (Table). Sleep duration was not associated with new-onset albuminuria.

Conclusions: Among US Hispanic/Latinos, fragmented sleep was associated with new-onset albuminuria. These findings could have implications for preventive strategies in a population which experiences a high burden of CKD.

Funding: NIDDK Support, Other NIH Support - National Heart, Lung, and Blood Institute

Predictor	Incident Density Ratio (95% CI)
Sleep duration (per 1 hr decrease)	0.91 (0.71, 1.17)
Sleep fragmentation index (per 10% increase)	1.38 (1.02, 1.85)

Effect of Medicaid Expansion on the Incidence of ESRD Among Nonelderly Adults

Rebecca Thorsness,[1] Shailender Swaminathan,[2] Yoojin Lee,[2] Benjamin Sommers,[3] Rajnish Mehrotra,[4] Kevin Nguyen,[1] Daeho Kim,[2] Amal Trivedi.[2] *[1]Brown University School of Public Health, Providence, RI; [2]Brown University, Providence, RI; [3]Harvard University, Boston, MA; [4]University of Washington, Seattle, WA.*

Background: End stage renal disease (ESRD) can be prevented or delayed with effective management of chronic disease, particularly diabetes and hypertension. However, the uninsured have limited ability to finance health services and may forego preventive and chronic disease care. We examined the impact of Medicaid expansion on the incidence of ESRD in the non-elderly adult population.

Methods: A quasi-experimental differences-in-differences study of the incidence rate of ESRD in the non-elderly adult population in the US (annual average of 194,793,035 persons aged 19-64 years). We calculated quarterly incidence rates by geolocating incident patients (347,288 persons over the study period) within Public Use Microdata Areas (PUMAs), which are contiguous geographic areas of at least 100,000 persons nested within states. We estimated linear models comparing pre- vs post-expansion changes in the incidence rate in PUMAs in expansion vs non-expansion states. Models were adjusted for age group, sex, race/ethnicity, time-varying PUMA-level economic characteristics with fixed effects for year-quarter, season, and PUMA. We confirmed parallel pre-policy trends between expansion and non-expansion PUMAs.

Results: The mean quarterly ESRD incidence rate for the 19-64 population in 2012 and 2013 was 67.8 cases per million in expansion states and 78.5 cases per million in non-expansion states. While incidence increased in both expansion and non-expansion states over the study period, Medicaid expansion was associated with 1.7 fewer incident ESRD cases per million (95% CI: -3.28 to -0.17), relative to concurrent trends in non-expansion states. This observed effect represents a 2.5% relative reduction in incidence. These findings were robust to exclusion of early- and late-expanding states, and time-varying covariates.

Conclusions: The ACA's Medicaid expansions were associated with a small but meaningful reduction in incidence of ESRD in the non-elderly adult population. The findings also demonstrate the potential for expansions of Medicaid coverage to generate offsetting reductions in spending in the Medicare program, the primary payer for the ESRD population in the US.

A Novel Therapeutic Strategy for Autosomal Dominant Tubulointerstitial Kidney Disease

Moran Dvela levitt,[1,2] Maria Alimova,[1] Maheswarareddy Emani,[1] Eva Kohnert,[1] Rebecca L. Thompson,[1] Eriene-Heidi Sidhom,[2] Ana Rivadeneira,[1] Julie Roignot,[1] Gregory Papagregoriou,[3] Anthony J. Bleyer,[4] Stanislav Kmoch,[5] Seth L. Alper,[6] Astrid Weins,[7] Anna Greka.[2] *[1]Broad Institute of MIT and Harvard, Cambridge, MA; [2]Harvard Medical School, Brookline, MA; [3]University of Cyprus, Nicosia, Cyprus; [4]Wake Forest University School of Medicine, Winston-Salem, NC; [5]Institute of Inherited Metabolic Disorders, Prague, Czechia; [6]Beth Israel Deaconess Medical Center, Boston, MA; [7]Brigham & Women's Hospital, Boston, MA.*

Background: MUC1 kidney disease (MKD) is an autosomal dominant tubulo-interstitial kidney disease caused by a frame-shift mutation in the MUC1 gene (MUC1-fs). The disease is characterized by slowly progressive tubulo-interstitial damage that leads to end-stage renal disease. No treatment is currently available. Affected individuals require dialysis or kidney transplantation in the third to seventh decade of life. The main goal of this study was to investigate the cellular and molecular mechanisms by which MUC1-fs causes alteration in epithelial cell function, and to develop a mechanism-based therapy for this disease.

Methods: To investigate the biological mechanism responsible for MKD, three different model systems were developed: a patient-derived cell line, a knock-in mouse model and patient iPSC-derived kidney organoids. In order to identify a possible treatment for MKD, a high content screen (HCS) composed of 4,000 compounds was developed to detect the removal of mutant MUC1-fs protein from kidney epithelial cells.

Results: Immunofluorescence studies indicated that while MUC1-wt was located at the cell surface, the mutated protein MUC1-fs was accumulated intracellularly, where it induced ER stress by activation of the unfolded protein response (UPR). The HCS identified BRD, a small molecule that cleared MUC1-fs not only from patient cells, but also from kidneys of knock-in mice and from patient kidney organoids. Importantly, BRD showed no overt toxicity at any concentration tested, and in fact, it rescued cells from ER stress-induced cell death.

Conclusions: These results indicate that intracellular accumulation of MUC1-fs induces ER stress- related cell toxicity, a pathologic mechanism likely responsible for the progressive renal damage associated with the MUC1 mutation. Our findings reveal BRD as a promising lead for the treatment of MKD.

High Prevalence of C-Terminal CUBN Variants Associated with Chronic Proteinuria and Normal Renal Function in Humans

Matias Simons,[1] Mathilda Bedin,[1] Olivia Boyer,[2,5] Aude Servais,[5] Yong Li,[4] Tarunveer S. Ahluwalia,[3] Anna Kottgen,[4] Carsten Bergmann,[4] Corinne Antignac.[2,5] *[1]Institut Imagine, Paris, France; [2]Imagine Institute/ Laboratory of Hereditary Kidney Diseases, Paris, France; [3]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [4]Medical Center - University of Freiburg, Freiburg, Germany; [5]Necker University Hospital, Paris, France.*

Background: Proteinuria is considered as an unfavorable clinical condition that accelerates renal and cardiovascular disease. However, it is not clear if all forms of proteinuria are damaging. Mutations in *CUBN* cause Imerslund-Gräsbeck syndrome (IGS) featured by intestinal malabsorption of vitamin B12 and in some cases proteinuria. *CUBN* encodes for cubilin, an intestinal and proximal tubular uptake receptor containing 27 CUB domains for ligand binding.

Methods: We used next-generation sequencing for renal disease genes to genotype cohorts of patients with suspected hereditary renal disease and chronic proteinuria. *CUBN* variants were analyzed using bioinformatics, structural modeling and epidemiological methods.

Results: We identified 39 patients, in whom biallelic pathogenic variants in the *CUBN* gene are associated with chronic isolated proteinuria with childhood onset. Since the proteinuria displayed a high proportion of albuminuria, glomerular diseases such as steroid-resistant nephrotic syndrome or Alport syndrome were often the primary clinical diagnosis, motivating renal biopsies and proteinuria-lowering treatments. Yet, renal function was normal in all cases. By contrast, we did not find any biallelic pathogenic *CUBN* variants in patients with reduced renal function or focal segmental glomerulosclerosis. Unlike the more N-terminal IGS mutations, 37 out of the 41 proteinuria-associated *CUBN* variants led to modifications or truncations after the vitamin B12-binding domain. By structural modeling, we further demonstrate that all these C-terminal variants affect stability or ligand binding of CUB domains. Finally, we show that four C-terminal *CUBN* variants are associated with albuminuria and significantly higher eGFR in meta-analyses of large population-based cohorts.

Conclusions: Collectively, our data suggest an important role for the C-terminal half of cubilin in renal protein reabsorption. Defective reabsorption could be an unexpectedly common benign condition that does not require any treatment and may even have renoprotective effects. Therefore, cubilin can be defined as a safe drug target in human renal disease.

FR-OR063

Phenome-Wide Association Study (PheWAS) of Common Genetic Variants for UMOD in the Million Veteran Program (MVP) Participants

Elvis A. Akwo,[2] Cassianne Robinson-Cohen,[2] Hua-Chang Chen,[2] Edward D. Siew,[1] Ran Tao,[2] Christopher J. O'Donnell,[3] Cecilia P. Chung,[2] Adriana Hung.[1] *[1]VA & Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Boston Veterans Administration, Boston, MA.*

Background: Uromodulin (UMOD) is synthesized exclusively in the kidney and is the most abundant protein in ordinary urine. Common variants for UMOD have been considered an adaptation to protect against urinary tract infections (UTIs). Several GWAS studies of estimated glomerular filtration rate (eGFR) have shown SNPs in UMOD top hits; these variants have also been associated with chronic kidney disease (CKD) progression, ESRD and blood pressure, highlighting shared genetic pathways between these traits. In clinical settings, serum UMOD is increasingly considered a more sensitive indicator of functional kidney mass than filtration markers like eGFR, and has been associated prospectively with cardiovascular outcomes and mortality. Hypertension, vascular calcification and arterial stiffness are hypothesized mechanisms.

Methods: We tested common variants in UMOD and their association with clinically diagnosed phenotypes in a phenome-wide association study (PheWAS) in 188,008 White European Americans from the MVP. Using logistic regression adjusted for sex and 10 principal components, we regressed 1813 phenotypes against our 13 SNPs in models adjusted (and not adjusted) for eGFR.

Results: Eight of the common variants had significant associations for CKD (**Table 1**), renal failure, hypertensive heart or kidney disease and urinary calculus, and two with UTIs. Other significant associations were with premenstrual syndrome. In the eGFR-adjusted models, the strongest associations were with urinary calculus and disease groupings related to congestive heart failure, including non-hypertensive congestive heart failure.

Conclusions: This PheWAS confirms that UMOD variants are associated with CKD and ESRD. Other observed associations included kidney stones and UTIs. Mendelian Randomization studies of haplotypes for UMOD variants are underway to further elucidate the role of UMOD in vascular health.

Funding: Veterans Affairs Support

De Novo Truncating TRIM8 Mutations Cause a Novel Pediatric Neuro-Renal Syndrome and Abrogate Protein Localization to Nuclear Bodies

Amar J. Majmundar,[2] Patricia L. Weng,[1] Kamal Khan,[3] Tze Yin Lim,[4] Shirlee Shril,[2] Nina Mann,[2] Gina ying Jin,[4] John L. Musgrove,[3] Vimla Aggarwal,[6] Ana C. Onuchic-Whitford,[5] Florian Buerger,[2] Bodo B. Beck,[7] Marcus R. Benz,[8] Julia Hoefele,[9] Vivette D. D'Agati,[4] Erica Davis,[3] Friedhelm Hildebrandt,[2] Simone Sanna-Cherchi.[4] *[1]UCLA, Los Angeles, CA; [2]Boston Children's Hospital, Boston, MA; [3]Duke University Medical Center, Durham, NC; [4]Columbia University, New York, NY; [5]Boston Children's Hospital / Brigham and Women's Hospital, Boston, MA; [6]CUIMC, New york, NY; [7]University of Cologne Medical Center, Cologne, Germany; [8]Pediatric Nephrology Dachau, Dachau, Germany; [9]Klinikum rechts der Isar, Technical University of Munich, School of Medicine, Munich, Germany.*

Background: Genetic forms of pediatric focal segmental glomerulosclerosis (FSGS) are usually caused by recessive mutations. The contribution of dominant *de novo* mutations (DNMs) to this trait is unknown.

Methods: We performed genetic studies using exome sequencing (ES) in 43,146 individuals. We conducted studies in tissue and human podocytes transfected with *TRIM8* cDNA constructs.

Results: A 4 year old child with epilepsy presented with FSGS. ES in the patient and unaffected parents identified a novel DNM in *TRIM8* (p.Q459*). To establish a link between *TRIM8* and FSGS, we conducted ES at Columbia University and Boston Children Hospital. We identified 6 additional *TRIM8* truncating mutations in 2,051 FSGS children as compared to 0/35,885 controls (P=2.5x10^{-8}). Parental data was available for 4/6 cases and in all instances the mutations were *de novo* (P=2.6x10^{-10}), establishing *TRIM8* as a novel FSGS gene. Review of clinical data showed that all 6 cases also had epilepsy, indicating that *TRIM8* DNMs define a novel neuro-renal syndrome. Consistent with this, we identified additional *TRIM8* mutations in 2/5,209 epilepsy patients. TRIM8 spans 551 amino acids. All mutations clustered between amino acid positions 410-460 in the last exon, predicted to escape non-sense mediated decay. TRIM8 was strongly expressed in podocytes and while overexpressed wildtype TRIM8 localized to nuclear bodies, constructs harboring patient-specific mutations (p.Q411* and p.Q459*) localized diffusely to the nucleoplasm.

Conclusions: Dominant *TRIM8* DNMs cause a novel pediatric neuro-renal syndrome due to its aberrant nuclear localization, implicating nuclear bodies in FSGS pathogenesis. Work in zebrafish and mouse is ongoing.

Homozygous Variants in NOS1AP from a Patient with Steroid-Resistant Nephrotic Syndrome Cause Podocyte Polarity Dysregulation and Aberrant Glomerulogenesis in Human iPSC Kidney Organoids

Thomas A. Forbes,[1,2] Sara E. Howden,[1] Amar J. Majmundar,[3] Florian Buerger,[3] Michelle Scurr,[1] Ker sin Tan,[1] Lakshi T. Starks,[1] Kynan T. Lawlor,[1] Melissa H. Little,[1] Friedhelm Hildebrandt.[3] *[1]Murdoch Children's Research Institute, Parkville, VIC, Australia; [2]Dept of Nephrology, Royal Children's Hospital, Parkville, VIC, Australia; [3]Boston Children's Hospital, Boston, MA.*

Background: Kidney organoids generated from human induced pluripotent stem cells (hiPSC) represent an emerging disease modelling platform for the study of genetic kidney diseases. Genomic sequencing is increasing the rate of novel disease gene discovery, and over 60 genes have been identified to cause steroid resistant nephrotic syndrome (SRNS). *Nitric oxide synthase 1 adaptor protein* (*NOS1AP*) is a novel gene for SRNS, whose encoded protein regulates actin cytoskeleton remodelling by promoting CDC42 activation. CDC42 regulates PAR3-PAR6-aPKC complex maintenance of apicobasal polarity. This PAR complex colocalises with the slit diaphragm in podocytes and either CDC42 or aPKC deficiency in mice causes severe proteinuria. Here, we characterise the effect of a homozygous *NOS1AP* SRNS patient variant on glomerulogenesis in hiPSC kidney organoids.

Methods: A homozygous, patient-derived *NOS1AP* variant (c.428G>A) was gene-edited into a wild type hiPSC cell line using CRISPR-Cas9. *NOS1AP* homozygous and wild-type (WT) hiPSC clones were differentiated to kidney organoids in paired experiments. Organoids were examined by blinded and semi-automated analysis of histology, immunofluorescence and electron microscopy imaging.

Results: Histology sections of WT organoids demonstrated tufts of podocyte monolayers lining an established basement membrane. In contrast, *NOS1AP* homozygous organoids showed disorganised podocyte collections with poorly established basement membranes and pyknotic nuclear figures which were CASP-3 positive. Foot process effacement was evident on electron microscopy of *NOS1AP* homozygous organoids. Whole mount immunofluorescence showed disorganisation of slit diaphragm markers and reduced aPKC expression in *NOS1AP* homozygous glomeruli suggesting dysregulation of the PAR complex.

Conclusions: A novel, SRNS patient-derived, homozygous variant in *NOS1AP* causes abnormal glomerulogenesis in kidney organoids and highlights the utility of this 3D, human, *in vitro*, functional genomic model. We propose that pathogenic variants in *NOS1AP* reduce active CDC42 which impairs polarity complex expression and foot process formation in hiPSC kidney organoid glomeruli.

FR-OR066

Exon Skipping Therapy for COL4A5 Gene Truncating Variant Rescued Progression of Kidney Failure in X-Linked Alport Syndrome

Tomohiko Yamamura,[1] Kandai Nozu,[1] Tomoko Horinouchi,[1] China Nagano,[1] Nana Sakakibara,[1] Yuya Aoto,[1] Misato Kamura,[2] Hirofumi Kai,[3] Kazumoto Iijima.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Kuamoto University, Kumamoto, Japan; [3]Kumamoto University, Kumamoto, Japan.*

Background: X-linked Alport syndrome (XLAS) is a hereditary disease caused by mutations of *COL4A5* gene. Affected male patients generally develop end-stage renal disease in early or middle adulthood and patients with truncating variants show severer phenotype than those with non-truncating variants. In recent years, exon skipping (ES) therapy, which induces truncating variants into non-truncating variants, has been applied clinically in muscular dystrophy, etc. Here we applied the ES therapy for XLAS model mice and evaluated clinicopathological findings.

Methods: We generated C57B/6 mice with nonsense mutation in Col4a5 gene exon 21 (R471X) using CRISPER/Cas9 technique and clinicopathological features of this model was confirmed as typical for XLAS. In addition, we determined the antisense sequence (ASO) showed highest ES effect for exon 21 and administrated percutaneously to this model mouse once or twice a week from 4 weeks to 20 weeks of age. The effectiveness was evaluated both clinically and pathologically at 21 weeks of age.

Results: With clinical parameters, urinary albumin creatinine ratio was remarkably suppressed in ASO-treated group (n=5) compared to saline-treated group (n=6). At 21 weeks of age, serum BUN and creatinine levels were remarkably low in ASO treated group compared to vehicle treated group. With pathological evaluation by electron microscope, although even ASO-treated mice show thin basement membrane, they did not

show severe thickening with lamellation of GBM as shown in saline-treated group. With immunofluorescence, α5(IV) was completely negative in vehicle group, but it expressed clearly on tubular basement membrane and even on GBM although expression is not linear but partially on GBM. No clear side effect was recognized in the ASO-treated group.

Conclusions: It was clarified that the clinical-pathological findings of the XLAS model mouse was remarkably improved by ES therapy using ASO. ES therapy is expected to be an effective therapy for XLAS patients with truncating variants.

Copy Number Variation and Genome-Wide Association Studies Identify Risk Loci with Large Effects on Vesicoureteral Reflux

Miguel Verbitsky,[1] Priya Krithivasan,[2] Maddalena Marasa,[17] Byum hee Kil,[17] Adele Mitrotti,[17] Matt G. Sampson,[3] Monica Bodria,[19] Shirlee Shril,[4] Loreto Gesualdo,[5] Giuseppe Masnata,[6] Francesco Scolari,[7] Rik Westland,[8] Joanna Van Wijk,[18] Marijan Saraga,[9] Domenico Santoro,[10] Pasquale Zamboli,[11] Velibor Tasic,[12] Craig S. Wong,[13] Enrico Fiaccadori,[14] Fangming Lin,[15] Friedhelm Hildebrandt,[16] Krzysztof Kiryluk,[2] Cathy Mendelsohn,[20] Simone Sanna-Cherchi,[2] Ali G. Gharavi.[17] *[1]Medicine-Nephrology, Columbia University, New York, NY; [2]Columbia University, New York, NY; [3]University of Michigan, Ann Arbor, MI; [4]Boston Childrens Hospital, Boston, MA; [5]University of Bari, Altamura, Italy; [6]Azienda Ospedale G. Brotzu, Cagliari, Italy; [7]University of Brescia, Montichiari (Brescia), Italy; [8]VU University Medical Center, Amsterdam, Netherlands; [9]University Hospital in Split, Split, Croatia; [10]Policlinico G Martino, Messina, Italy; [11]Second University of Naples, Naples, Italy; [12]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [13]UNM, Albuquerque, NM; [14]Universita Degli Studi-Dip. Clinica Medica Nefrologia, Parma, Italy; [15]Columbia University College of Physicians & Surgeons, New York, NY; [16]Boston Children's Hospital, Boston, MA; [17]Columbia University, New York, NY; [18]Vrije Universiteit University Hospital Amsterdam, Amsterdam, Netherlands; [19]Istituto G. Gaslini, Genoa, Italy; [20]Columbia University Medical Center, New York, NY.*

Background: Vesicoureteral reflux (VUR) is a highly familial disease caused by malfunction of the vesicoureteral junction, resulting in retrograde flow of urine from the bladder into the ureters and kidney and accounts for 25-30% of pediatric ESRD worldwide. Very few genetic risk factors for VUR have been identified to date.

Methods: We undertook a Copy Number Variant (CNV) study on 1,737 VUR cases compared to 24,765 controls and GWAS on 1,395 unrelated VUR cases of European ancestry and 5,366 matched population controls, under additive, recessive and dominant models; we also performed sex-specific analyses.

Results: We found a significant excess of large, rare gene-intersecting CNVs in VUR cases ($P = 1.87 \times 10^{-7}$). We identified distinct known pathogenic CNV in 35 (2.01%) of cases vs. 0.65% of controls (OR = 3.12; 95% CI = 2.10 - 4.54; $P = 6.35 \times 10^{-8}$). The VUR cases were enriched for 1q21.1 deletions, 16p11.2 deletions, 22q11.21 deletions and duplications, and triple X syndrome. Our GWAS identified 3 study-wide significant ($P<7.58 \times 10^{-9}$) and 5 suggestive ($P<1.52 \times 10^{-7}$) loci with large effects (ORs = 1.41 to 3.65). The top SNPs for each of these associations were within or near genes known to be important in embryonic development and/or kidney disease (*WDPCP, OTX1, BMP5, WNT5A, VANGL1*). In addition, we estimated genetic heritability to be 15% based on the additive model results from all SNPs tested, and 4% based on a genotypic risk score from only the top 8 signals from all models. In situ hybridization confirmed that the top candidate genes are expressed in the ureter or vesicoureteral junction during mouse genitourinary development.

Conclusions: This study identifies multiple rare CNV disorders and common variants which impart large effects on the risk of VUR and implicate multiple canonical developmental pathways in the pathogenesis of disease.

Genome-Wide Polygenic Score and Urinary Tract Stone Diagnosis in a Multiethnic Cohort

Ishan Paranjpe,[1] Manish Paranjpe,[2] Lili Chan,[1] John C. He,[3] Steven G. Coca,[1] Ron Do,[1] Mantu Gupta,[4] Girish N. Nadkarni.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Harvard Medical School, Boston, MA; [3]Mount Sinai School of Medicine, New York, NY; [4]Mount Sinai, New York, NY.*

Background: Urinary tract stones are highly heritable and clinical risk factors only explain a portion of stone occurrence. Additionally, urinary tract stones may occur in the absence of risk factors. We aimed to develop a polygenic score for association with urinary tract stones.

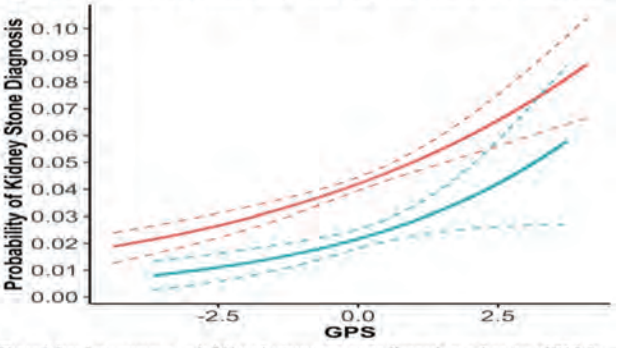
Methods: We used genome-wide association studies (GWAS) summary statistics for urinary tract stones from the UK Biobank (n=361,141), to generate polygenic scores with increasing number of single nucleotide variants (SNVs). We then determined the association of the best performing polygenic score with urinary tract stone diagnosis in individuals with and without clinical risk factors (diabetes, hypertension, gout and obesity) in a biobanked cohort using imputed genotyping data (Bio*Me* Biobank, 1208 cases, 30,233 controls) and calculated adjusted odds ratios (aOR) with 95% confidence intervals (CI) adjusting for age, sex and genetic ancestry.

Results: A genome wide polygenic score (GPS_{stone}) utilizing the most SNVs (~7 million) explained the highest variance and was chosen for further analysis. In individuals with at least one risk factor, every standard deviation (SD) increase in GPS_{stone} was associated with a 14% increase in odds of diagnosis (aOR 1.14; 1.08 – 1.22; $p = 4.3 \times 10^{-5}$). In individuals without clinical risk factors, every SD increase in GPS_{stone} was associated with a 30% increase in odds of diagnosis (aOR 1.3; 1.1 – 1.5; $p = 4.7 \times 10^{-3}$, Figure 1). In these individuals, the top 10% had four-fold increased odds of diagnosis relative to the lowest 10% (aOR 3.7; 95% CI 1.7 – 9.3; p = 0.003).

Conclusions: We developed a genomic wide risk score, GPS_{stone}, that is associated with urinary tract stones overall and even in the absence of known clinical risk factors identifies a subgroup with genetic risk comparable to a monogenic mutation.

Funding: NIDDK Support

Figure 1 Association of GPS with Kidney Stone Diagnosis Stratified by Clinical Risk.



The teal function represents probability of urinary tract stone diagnosis as a function of GPS for individuals with no clinical risk factors (BMI <25, no hypertension, no type 2 diabetes, and no gout). The red function represents probability of urinary tract stone diagnosis as a function of GPS for individuals with at least one clinical risk factor. We estimated probability of urinary tract stone diagnosis using an adjusted logistic regression function with GPS, age, sex and 10PCs.

FR-OR069

Next-Generation Sequence Analysis of Genetically Unsolved Primary Hyperoxaluria (PH) or Dent-Diagnosed Patients Resolved 10% of Cases with 11 Genes Implicated

Ronak J. Shah, Andrea G. Cogal, David J. Sas, John C. Lieske, Peter C. Harris. *Mayo Clinic, Rochester, MN.*

Background: Due to phenotypic overlap between patients with monogenic stone diseases, gene specific analysis of patient groups can result in under diagnosis. Here we employed a targeted next generation sequencing (tNGS) approach to analyze primary hyperoxaluria (PH) or Dent diagnosed patients that were genetically unresolved after analysis of the respective known genes by Sanger analysis.

Methods: A cohort of genetically unresolved patients with a presumptive diagnosis of PH (PHN, n=236) and Dent disease (DN, n=61) were screened employing a 90 gene panel that included known monogenic causes of stone disease and candidates. Variants were assessed considering American College of Medical Genetics and Genomics guidelines. Their presence was determined in disease-specific databases, Human Gene Mutation Database (HGMD) and ClinVar, and the frequency in normal populations, GnomAD, plus using variant assessment tools and by analysis of multisequence alignments. Sanger sequencing was used to confirm changes and test segregation.

Results: Biallelic pathogenic variants were found in 11 different genes and accounted for 30 patients (10.1%). Recurrent genes included ones encoding claudins, *CLDN16* [6PHN, 1DN] & *CLDN19* [1PHN, 1DN] (familial hypomagnesemia with hypercalciuria and nephrocalcinosis), the cystinuria gene, *SLC7A9* [5PHN], *CYP24A1* [4PHN], *SLC34A3* [1PHN, 2DN] (hypophosphatemic rickets with hypercalciuria), and APRT [2PHN]. The genes *ATP6V1B1* [1DN], *SLC12A1* [1DN] and *SLC34A1* [1DN] account for just one family. Mutations to *CLDN16, CLDN19, SLC34A3,* and *KCNJ1* were found to account for both PH and Dent diagnosed patients. Two additional patients were found to have copy number variants, a 72 gene deletion [1PHN] or 2 duplicated regions [1DN], that may be phenotypically significant.

Conclusions: The phenotype of monogenic stone diseases overlaps greatly. Given the emerging therapies for these disorders, including siRNA approaches for PH, making the correct diagnosis is crucial for enrollment in clinical trials and selecting the correct therapy. It is also essential to identify cohorts of patients with poorly recognized disorders, in order to better understand the natural history, and assemble cohorts for future trials.

FR-OR070

Nationwide Diagnostic Yield of Clinical Genomics in Patients with Suspected Genetic Kidney Disease

Kushani C. Jayasinghe,[1] Catherine Quinlan,[3] Andrew J. Mallett.[2] Australian and Melbourne Genomics Renal Genetics Flagships part of the KidGen collaborative *[1]Monash Health, Clayton, NSW, Australia; [2]Royal Brisbane and Women's Hospital, Stafford, QLD, Australia; [3]The Royal Children's Hospital, Melbourne, VIC, Australia*.

Background: With increased understanding of genetic kidney disease (GKD), genomic testing is translating from research to clinic. Rigorous evaluation of clinical practice and patient outcomes is required to guide value-based healthcare. We aimed to describe diagnostic outcomes of clinically accredited genomic testing delivered by nationwide multidisciplinary team (MDT) clinics for patients with suspected GKD.

Methods: Sequential incident patients undergoing clinically indicated genomic testing for presumed GKD from 18 Australian MDT clinics 2016-19 were analysed (HREC/16/MH/251). A molecular diagnosis constituted clinical reporting of pathogenic and/or likely pathogenic variant/s in gene/s associated with the patient kidney phenotype with concordant inheritance. All genomic testing included restriction of variant analysis to a phenotype-derived gene list. Full author list online at KidGen.org.au

Results: Of 824 patients, 52.1% were female. Median age was 26 years. A molecular diagnosis was made in 43.7%. A further 15.4% had a variant/s of uncertain significance (VUS), of which 23.6% were clinically compelling but require further functional validation or additional segregation. The diagnostic yield for whole genome (WGS n=92, 41.3%), whole exome (WES n=231, 40.7%) and clinical exome (CES n=392, 42.3%) sequencing was similar (p=0.91). Median age at test request for WGS (42yrs) was significantly older ($p<0.00001$) than WES (27yrs) and CES (18yrs). Of all patients with a genetic finding, 53.6% involved variation in 7 genes (COL4A3, COL4A4, COL4A5, PKD1, PKD2, PKHD1, HNF1B). Stratifying by age at test request, the diagnostic rate was not significantly different between 0-15yrs (41.8%), 16-25yrs (48.5%) and 26+yrs (44.2%) (p=0.25). The gender mix in these age groups was significantly different (female 45.8% vs 51.5% vs 56.7%, p=0.015).

Conclusions: Clinical genomics delivered by MDT clinics are diagnostically effective for suspected GKD. Neither sequencing approach nor age group at test request appear to impact diagnostic yield though WGS patients in this cohort were older and gender mix changed with increasing patient group age. Clinical utility studies are required to clarify impact of these diagnostic outcomes.

Circadian BP Rhythm as a Possible Key Target of SGLT2 Inhibitors for DKD: Yokohama Add-on Inhibitory Efficacy of Dapagliflozin on Albuminuria in Japanese T2DM Patients (Y-AIDA) Study

Kouichi Tamura,[1] Sho Kinguchi,[1] Hiromichi Wakui,[1] Yuzuru Ito,[2] Kengo Azushima,[3] Uru N. Osada,[4] Tamio Iwamoto,[5] Toshihiro Misumi,[1] Takayuki Yamada,[1] Kazuki Orime,[1] Ryu Kobayashi,[1] Kohji Ohki,[1] Kotaro Haruhara,[6] Yoshinobu Kondo,[2] Tadashi Yamakawa,[7] Gen Yasuda,[8] Takeharu Yamanaka,[9] Yasuo Terauchi.[1] *[1]Yokohama City University Graduate School of Medicine, Yokohama, Japan; [2]Yokohama City University Medical Center, Yokohama, Japan; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Saiseikai Yokohamashi Nanbu Hospital, Yokohama, Japan; [5]Saiseikai Yokohama Nanbu Hospital, Yokohama, Japan; [6]The Jikei University School of Medcine, South Yarra, VIC, Australia; [7]Yokohama City Unieversity Medical Center, Yokohama, Japan; [8]Yokohamahigasigutijin Clinic, Yokohama, Japan; [9]Yokohama City Univ., Yokohama, Japan*.

Background: In treating T2DM, it is important to appropriately manage glucose and lipid metabolism, body weight and BP and to suppress the development and progression of diabetic complications to restore the quality of life to a level comparable with healthy subjects. The Y-AIDA study was designed to investigate the renal and home BP modulating effects of add-on dapagliflozin treatment in Japanese T2DM individuals with albuminuria.

Methods: This study was a prospective, multicenter, single-arm study. A total of 86 T2DM (HbA1c 7.0-10.0%) individuals with albuminuria (UACR ≧ 30 mg/gCr) were enrolled, and 85 participants were administered with add-on dapagliflozin for 24 weeks. The primary and key secondary endpoints were change from baseline in the natural logarithm of UACR over 24 weeks and change in home BP profile at week 24. This study was registered at UMIN Clinical Trials Registry (UMIN000018930; http://www.umin.ac.jp/ctr/index-j.htm). All participants provided written informed consent prior to initiation of the study.

Results: Baseline median UACR was 181.5 mg/gCr (interquartile range 47.85, 638.0). Baseline morning, evening and nocturnal home systolic/diastolic BP were 137.6/82.7 mmHg, 136.1/79.3 mmHg, and 125.4/74.1 mmHg, respectively. After 24 weeks, the logarithm of UACR decreased by 0.37±0.73 ($P<0.001$). In addition, changes in morning, evening and nocturnal home BP from baseline were morning systolic/diastolic BP -8.32±11.42/-4.18±5.91 mmHg (both $P<0.001$), evening systolic/diastolic BP -9.57±12.08/-4.48±6.45 mmHg (both $P<0.001$) and nocturnal systolic/diastolic BP -2.38±7.82/-1.17±5.39 mmHg ($P=0.0079$ for systolic BP, $P=0.0415$ for diastolic BP). Furthermore, the reduction in UACR after 24 weeks significantly correlated with the improvement of home BP profile, but not with changes in other variables including office BP.

Conclusions: In Japanese T2DM individuals with albuminuric DKD, dapagliflozin not only lowered albuminuria but also improved home BP profile, suggesting that circadian BP rhythm estimated by out-of-office home BP monitoring as a possible key target of SGLT2 inhibitors for DKD.

FR-OR072

Activation of G Protein-Coupled Estrogen Receptor Ameliorates Proteinuria in Dahl Salt-Sensitive Female Rats

Eman Y. Gohar, Rawan N. Almutlaq, Carmen De Miguel, Elizabeth M. Daugherty, Chunhua Jin, Jennifer S. Pollock, David M. Pollock. *University of Alabama at Birmingham, Birmingham, AL*.

Background: Recent evidence implicates a central role for the G protein-coupled estrogen receptor (GPER) in the maintenance of cardiovascular and renal health in women. The current study tested whether GPER activation ameliorates salt-induced elevation in blood pressure and renal damage in female Dahl salt-sensitive (SS) rats.

Methods: 12-14 weeks old female rats were implanted with telemetry transmitters and osmotic minipumps releasing G1 (GPER agonist, 400 μg/kg/day, IP) or its vehicle for 28 days. Two weeks after pump implantation, rats were shifted from a normal salt diet (NS, 0.4% NaCl, AIN-76A Purified Rodent Diet) to a matched high salt diet (HS, 4% NaCl) for two weeks. 24-hour urine samples were collected while on NS and HS diets.

Results: 24-hr mean arterial pressure (MAP) markedly increased in response to HS in vehicle-treated rats in comparison to NS baseline values (141±3 vs. 124±1 mmHg, respectively, n=5, $p<0.05$). This salt sensitivity was evident also in G1-treated rats (MAP: 144±4 vs. 124±2 mmHg, n=6). No differences were observed in diastolic, systolic blood pressure, heart rate or locomotor activity between G1- and vehicle-treated rats. Body weight, food intake, water intake, urine flow and urinary sodium excretion were not significantly altered by G1. HS significantly increased urinary excretion of protein, albumin, nephrin (podocyte damage marker) and KIM-1 (proximal tubule injury marker) in vehicle-treated rats, compared to NS (protein: 63.9±16.2 vs. 22.8±3.8 mg/day, albumin: 52.6±19.9 vs. 12.4±5.1 mg/day, nephrin: 65.9±8.7 vs. 16.4±5.3 ng/day, KIM-1: 30.2±7.2 vs. 16.6±1.7 ng/day, n=7, $p<0.05$). Importantly, GPER activation prevented HS-induced proteinuria, albuminuria and increase in KIM-1 excretion (n=6, $p<0.05$), but not nephrinuria suggesting that systemic GPER activation protects against HS-induced proximal tubular damage in female Dahl SS rats.

Conclusions: Collectively, we found that GPER activation ameliorates salt-induced renal damage, but not salt sensitive hypertension, in female Dahl SS rats. Our data suggest that GPER elicits a protective effect against HS-induced renal damage, specifically proximal tubular damage, in a blood pressure-independent manner.

Sex-Related Differences in the Intratubular Renin-Angiotensin System (RAS) in 2-Kidney 1-Clip Hypertensive Rats

Yang gyun Kim,[1] Sangho Lee,[1] Su Woong Jung,[1] Won-Hee Cho,[1] Kyung hwan Jeong,[2] Ju young Moon.[1] *[1]Kyung Hee University Hospital at Gang-Dong, Seoul, Republic of Korea; [2]Kyung Hee University College of Medicine, Gangdong-gu, Seoul, Republic of Korea*.

Background: The intratubular renin-angiotensin system (RAS) is thought to play an essential role in hypertensive renal disease, but information regarding sex-related differences in this system is limited. This study investigated the sexual differences in the intratubular RAS in 2-kidney 1-clip (2K1C) rats.

Methods: A 2.5-mm clip was placed on the left renal artery of Sprague Dawley rats, and the rats were euthanized 3 or 5 weeks following the operation.

Results: Systolic blood pressure (SBP) increased in 2K1C rats of both sexes but was significantly higher in males than in females, and an antihypertensive effect disappeared in 2K1C ovariectomized(OVX) female rats. Intratubular angiotensin-converting enzyme (ACE) and Ang II were repressed, and intratubular ACE2, Ang 1-7, and MasR were increased in both kidneys of 2K1C female rats at five weeks after surgery compared with those of male 2K1C rats. Intratubular mRNA levels of ACE and AT_1R were augmented in OVX female rats regardless of clipping surgery at three weeks after operation in comparison with those in male and female rats. The AT_2R was upregulated in female rats with or without OVX; thus, the AT_1/AT_2 ratio was higher in female rats than in male rats.

Conclusions: Female rats were protected from hypertensive injury after renal artery clipping. An increase in intratubular nonclassic RAS (ACE2/angiotensin 1-7/MasR) and a decrease in the AT_1/AT_2 ratio could limit the adverse effects of classic RAS during renovascular hypertension in female rats, and estrogen is suggested to have a primary role in regulating intratubular RAS components.

FR-OR074

Central EP3 Receptors Mediate Salt-Sensitive Hypertension and Immune Activation

Liang Xiao,[1] Richard M. Breyer,[2] David G. Harrison.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN*.

Background: Prostaglandin E_2 (PGE_2) has been implicated in the generation of reactive oxygen species and inflammation associated with hypertension. Proteins oxidatively modified by reactive isolevoglandins (isoLGs) accumulate in dendritic cells (DCs) leading to subsequent activation of T lymphocytes. The local signals that stimulate DCs to accumulate isoLG adducted proteins remain undefined. We hypothesized that PGE_2 via its EP3 receptor contributes to DC activation in hypertension.

Methods: $EP3^{-/-}$ mice and wild type (WT) littermates were exposed to sequential hypertensive stimuli involving an initial exposure to the nitric oxide synthase inhibitor L-NAME (LN) in drinking water, a 2 week washout period, and a subsequent 4% high salt diet (HS). Lentiviral vectors encoding shRNA targeting EP3 receptor were administered intracerebroventricularly to knockdown EP3 receptor expression in the central nervous system.

Results: In WT mice, this protocol increased systolic pressure from a baseline of 123±2 to 148±8 mmHg ($p<0.05$), and renal $CD4^+$ and $CD8^+$ effector memory T cells by 2 to 3 fold. This was associated with marked increases in superoxide production in the kidney and a striking accumulation of isoLG protein adducts in splenic DCs. The increases in blood pressure, renal T cell infiltration, renal superoxide production and DC isoLG formation were completely prevented in $EP3^{-/-}$ mice. Interestingly, we found that EP3 receptor, among all EP receptors, is highly expressed in the organum vasculosum laminae terminalis (OVLT) in the brain, LNHS treatment induced an upregulation of COX-2 expression and downregulation of EP3 receptor in the OVLT. To test the hypothesis that central EP3 receptor contributes to the LNHS induced hypertension and renal inflammation, WT mice received intracerebroventricular injection of lentiviral vectors encoding shRNA targeting EP3 receptor and then subjected to the same LNHS treatment. These mice were also protected from salt induced hypertension and renal inflammation like the $EP3^{-/-}$ mice.

Conclusions: These findings provide new insight involving EP3 receptor in the central nervous system and sympathetic activation in salt induced hypertension and provide additional information as to how PGE_2 modulates inflammation in this conditions.

FR-OR075

Mutation of the Furin Cleavage Site in the (Pro)Renin Receptor Attenuates Angiotensin II-Induced Hypertension and Albuminuria

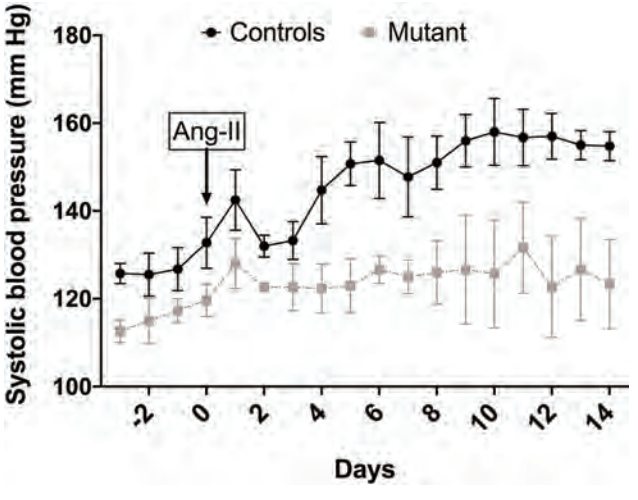
Nirupama Ramkumar,[1] Deborah Stuart,[3] William Wheatley,[1] J. D. Symons,[1] Donald E. Kohan.[2] *[1]University of Utah, Salt Lake City, UT; [2]University of Utah Health Sciences Center, Salt Lake City, UT; [3]University of Utah Health Sciences, Salt Lake City, UT.*

Background: Cleavage of the extra-cellular domain of the (pro)renin receptor (PRR) yields a soluble fragment (sPRR) which can promote angiotensin-II (Ang-II) formation. Although alterations in plasma sPRR levels have been reported in hypertension, the causal role of sPRR in hypertension is unknown.

Methods: To investigate this, we mutated the furin cleavage site (R276A, R279A) of the PRR using CRISPR/Cas9. Because the gene encoding PRR is on the X-chromosome and male mutant mice are infertile, only male mice were studied.

Results: Mutant mice had markedly lower plasma sPRR levels (control: 16.2 ± 0.3 vs mutant 0.2 ± 0.03 ng/ml). Mutant mice had normal survival and development and no histological renal abnormalities up to 12 months of age. During normal salt intake, no differences in blood pressure, body weight, urinary water or Na^+ excretion, or acid-base status were observed between control and mutant mice. Compared to controls, mutant mice had an attenuated hypertensive response to 2 weeks of Angiotensin-II infusion (400 ng/kg/min) (Figure 1). Mutant mice also had lower albuminuria (control: 327 ± 114 vs mutant: 58 ± 8 μg/day) at day 7 post Ang-II infusion. No differences in urinary Na^+ excretion were detected between control and mutant mice after 7 days of Ang-II infusion (control: 33.6 ± 3.1 vs mutant: 35 ± 2.7 μmol/day/gram body weight). Mesentric arteries isolated and studied ex-vivo using isometric tension procedures showed an attenuated vascular response to Ang-II (10^{-8} M) compared to controls (internal diameter control: 115 ± 7 μm vs mutant 125 ± 8 μm).

Conclusions: These results suggest that sPRR plays a role in Ang-II induced hypertension and renal injury.



FR-OR076

Connexin40 (Cx40) Knockout Rat Has Impaired Renal Autoregulation

William A. Cupples,[1] Branko Braam.[2] *[1]Simon Fraser University, Burnaby, BC, Canada; [2]University of Alberta, Edmonton, AB, Canada.*

Background: Renal autoregulation is mediated by the generic myogenic response (MR), modulated by the kidney-specific tubuloglomerular feedback (TGF). Recent studies have indicated that TGF acts on a larger scale than individual nephrons and that the well-known synchronization of TGF dynamics operates on macroscopic scales, communicating electrically along the vasculature via gap junction intercellular communication.

Methods: A Wistar Kyoto (WKY) rat lacking Cx40 was made at the Genome Editing Rat Resource Center (https://rgd.mcw.edu/wg/gerrc/). Heterozygous parents produce wild type (WT), heterozygous (HET), and knockout (KO) offspring in Mendelian ratios. In anesthetized rats, surface perfusion of renal cortex in all genotypes was studied by laser speckle contrast imaging (LSCI) in an area 2.75×2.75 mm. ROIs captured blood flow dynamics in star vessels. Synchronization was assessed by phase coherence (PC) between all possible ROI pairs (Scully et al. IEEETBME 2014; 1989-97). Blood pressure (BP) and renal blood flow (RBF) were monitored. Data are reported as mean±SEM. Significance testing was not done because N is not yet sufficient for it to be meaningful.

Results: In WT and HET rats (N = 3 each) BP and RBF were similar (WT: 100±2 mmHg, 6.57±0.56 mL/min; HET: 98±4 mmHg, 6.12±1.84 mL/min) while in KO rats (N = 3) BP appeared higher and RBF lower (123±6 mmHg, 4.52±0.86 mL/min). There was a pronounced gene dosage effect on TGF synchronization. In N=6 WT rats 86±10% of possible connections had statistically significant PC and of those 37±14% had PC >0.6 which is considered to be significant for autoregulation. In N=6 HET rats 95±4% of possible connections were significant and of those 18±10% had PC >0.6. In N=5 KO rats 62±16% were significant and 5±2 had PC >0.6. Renal autoregulation assessed by transfer functions was visibly impaired.

Conclusions: We report a new knockout rat on the normotensive Wistar Kyoto background that lacks Cx40. Wildtype, heterozygote, and Knock-out are bred in Mendelian ratios. As expected from the Cx40 knockout mouse, KO rats appear to be hypertensive, probably due to dis-regulated renin secretion. TGF synchronization is, and autoregulatory effectiveness appears to be, grossly impaired in the absence of Cx40.

FR-OR077

Myocardial Infarction in an Inducible Hypertensive Rat Model: Does Spironolactone Reduce Renal Fibrosis?

Catherine Leader, Robert J. Walker. *University of Otago, Dunedin, New Zealand.*

Background: Hypertension is a leading cause of myocardial infarction (MI), and is strongly associated with renal injury. However, superposition of MI on renal injury secondary to hypertension is not clearly defined. Likewise mineralocorticoid blockade (e.g. spironolactone; SP) has been shown to reduce cardiac fibrosis and improve cardiac outcomes post MI, but consequences for renal function are not known. We aimed to explore the effects of SP on renal fibrosis, post MI, in established hypertensive rats.

Methods: Hypertension was induced and maintained using male Cyp1a1Ren2 rats (n=20) by addition of 0.167% (w/w) indole-3-carbinol to the rat chow, and established for two weeks prior to treatment or surgical intervention. Rats (10 weeks of age) were divided into four groups: hypertensive controls (H), hypertensive controls fed SP daily (4.4mg/kg/day; H-SP), hypertensive with MI (permanent left anterior coronary ligation; H-MI) and H-MI plus daily SP (H-MI-SP). Physiological data and tissue was collected four weeks after MI for analysis.

Results: Systolic blood pressure (SBP) did not differ significantly between groups. Ejection fraction (EF) was significantly ($p<0.001$) reduced by MI induction (42±10%), but not improved by SP treatment (43±10%). MI significantly increased global cardiac fibrosis (2.2±0.5%) and renal cortical fibrosis (3.1±0.9%) when compared to hypertensive animals (1.3±0.5% and 2.6±0.9% respectively), while SP therapy post infarct significantly reduced cardiac interstitial fibrosis (1.5±0.6%) and kidney cortical fibrosis (1.4±0.6%). The reduction in fibrosis was associated with decreased expression of αSMA, TGFβ, reduced expression of MCP1 and a significant reduction in interstitial macrophages. SP significantly reduced ($p<0.01$) glomerulosclerosis in both H-SP group (from 1.2±0.07 in hypertensive controls to 0.9±0.04) and from 1.5±0.1 (H-MI) to 1.2±0.2 in the H-MI-SP group.

Conclusions: The addition of MI significantly worsened the extent of hypertension-induced renal fibrosis and glomerulosclerosis. SP treatment resulted in significant improvement in renal fibrosis and GSI scores in hypertensive animals with or without MI. Further work will aim to further define the relationship between cardiac injury and renal damage.

FR-OR078

Experimental Renovascular Disease Induces Endothelial Cell Mitochondrial Damage and Impairs Endothelium-Dependent Relaxation of Renal Artery Segments

Arash Aghajani Nargesi,[1] Kyra L. Jordan,[1] Amir Lerman,[1] Lilach O. Lerman,[2] Alfonso Eirin.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic College of Medicine, Rochester, MN.*

Background: Endothelial cell (EC) mitochondria produce energy, control redox status, and support EC function, but may be damaged during renal disease. We hypothesized that the ischemic and metabolic constituents of swine renovascular disease (RVD) induce mitochondrial damage and impair the function of renal artery EC.

Methods: Domestic pigs were studied after 16 weeks of diet-induced metabolic syndrome (MetS), renal artery stenosis (RAS), or coexisting MetS and RAS, and Lean pigs served as control (n=6 each). Mitochondrial morphology (electron microscopy), membrane potential (TMRE staining), and production of reactive oxygen species (MitoSOX) were measured in isolated primary renal artery EC. Vasoreactivity of renal artery segments was characterized in an organ bath.

Results: Lean-RAS and MetS-RAS developed significant stenosis and hypertension (Table), and showed increased mitochondrial area and decreased matrix density (Fig. A). Mitochondrial membrane potential similarly decreased in MetS, Lean+RAS, and MetS+RAS groups, whereas production of reactive oxygen species increased in MetS vs. Lean, but further increased in both RAS groups (Fig. B). Endothelial-dependent relaxation of renal artery segments was blunted in MetS vs. Lean, but further attenuated in Lean+RAS and MetS+RAS (Fig. C).

Conclusions: MetS and RAS damage mitochondria in pig renal artery EC, which may impair EC function. However, the coexistence of MetS and RAS did not aggravate EC mitochondrial injury and dysfunction in the short time of our in-vivo studies. These findings suggest that mitochondrial injury might be implicated in the pathogenesis of RVD-induced vascular damage.

FR-OR079

Opposite Regulation of Renal and Cerebral Microarteriolar Angiotensin II Contractility by Specific Endothelial Prostaglandin Pathways

Christopher S. Wilcox,[1] Lingli Li,[2] Enyin Lai,[2] William J. Welch.[2] *[1]Georgetown University Medical Center, Washington, DC; [2]Georgetown University, Washington, DC.*

Background: The kidney requires robust angiotensin II (Ang II) responsiveness for regulation of body fluids whereas the cerebral circulation requires resilience to Ang II to prevent cerebral ischemia and dementia. RNAseq of single cerebral microarterioles (CAs) versus renal afferent arterioles (Affs) detected >30-fold greater gene expression for COX2 and >3000-fold greater expression for lipokalin type prostaglandin D synthase (LPGDS) and DP1 receptor in CAs yet Affs expressed more thromboxane synthase. We reported enhanced contractility of Affs by thromboxane (*Circulation research* 94: 1436-1442, 2004). Therefore, we hypothesized that expression of different PGs accounts for regional differences in Ang II responsiveness.

Methods: Individual mouse microarterioles (8-15μm) from the intraparenchymal frontal cerebral cortex were compared to renal cortical Affs, perfused at 40 mmHg and change in diameter (%) assessed with Ang II (10^{-12} to 10^{-6} M).

Results: Normal CAs were entirely unresponsive to 10^{-6} Ang II (0±0.03%) whereas Affs were highly responsive (-49±1 %). Ang II responses of CAs from COX1 -/- vs +/+ mice were enhanced (-15±2 vs 0±0.1% P<0.001) and enhanced further by COX2 blockade with parecoxib (-20±2 vs -15±2%; P<0.05) similar to effects of LPGDS blockade with AT56 in normal mouse arterioles (-15±4%). In contrast, COX-blockade reduced Ang II contractions of Affs. The DP1R agonist, BW450c reduced Ang II contractions of CAs from COX-blocked mice, yet was ineffective in Affs. Deendotheliaization of CAs enhances Ang II contractions in normal mouse CAs (0±0.1 vs 17.2±1.9%; P<0.001) but did not increase contractions further in COX-blocked CAs (19.8±1.5 vs 22.5±1.9%; NS).

Conclusions: The normal complete resilience of CAs to Ang II contractions depends on constitutive endothelial expression of COX1 and 2 and LPGDS generating vasodilator PGD_2 that activates DP1 whereas the robust Ang II responsiveness of Affs is independent of PGD_2 but depends on vasoconstrictor COX products. Thus, strong expression of PGD_2 protects the cerebral circulation from ischemia with Ang II but strong expression of vasoconstrictor PGs renders the renal circulation highly Ang II responsive.

Sox6 Ablation in Renin Expressing Cells Has Protective Function Against Renovascular Hypertension and Kidney Damage

Mohammad Saleem,[1] Liang Xiao,[1] Luz A. Saavedra,[2] Jose Gomez.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VUMC, Nashville, TN.*

Background: Renal artery stenosis (RAStenosis) is an interactable problem affecting about 6% of the people over 65 and in up to 40% of the people with coronary or peripheral vascular disease. The renin angiotensin aldosterone system (RAAS) is implicated in RAStenosis. Renin controls rate-limiting step in RAAS and is a key driver in RAStenosis induced hypertension. Sox6 is a transcription factor important for cell fate determination of muscle, bone, neurons among others.

Methods: A new transgenic mice the $Ren1d^{Cre}/Sox6^{fl/fl}$ (Sox6 KO), in which Sox6 is knockout in renin expressing cells was used to determine the impact of Sox6 ablation on renin expression and hypertension during RAStenosis. Two time-point studies, 3 weeks, and 3 days were conducted. Blood pressure was measured by tail-cuff method. The kidney injury markers KIM1, creatinine, albumin, and urea were measured using commercially available kits. Superoxide was measured using HPLC.

Results: *In 3-week study*; systolic and mean arterial blood pressure were significantly lower in Sox6 KO compared to wild-type mice. When stenosed kidneys were compared, renin expression levels were significantly lower in Sox6 KO compared to wild-type. Urine creatinine clearance was significantly higher in Sox6 KO compared to wild-type. *In 3-day study*; renin, STAT3, HIF1-α, N-Gal, and Sox6 serine-threonine phosphorylation levels were lower in the stenosed kidney of Sox6 KO compared to wild-type. This indicates that phosphorylated Sox6 triggers renin expression increase in RAStenosis and indicates that HIF1-a and STAT3 may control Sox6 expression in RAStenosis. Superoxide levels in stenosed kidney were lower in Sox6 KO compared to wild-type mice. Urine creatinine clearance was significantly higher in Sox6 KO compared to wild-type animals. KIM1, urea, and albumin levels were not different between the groups in both time-point. Altogether, our data suggest that Sox6 KO mice were protected from developing hypertension and kidney damage during RAStenosis.

Conclusions: Our data indicates that Sox6 has a new function modulating renin expression, renovascular hypertension and kidney damage induced by RAStenosis. Identification of this novel pathway and its regulators may lead to new therapies for hypertension and associated cardiovascular disease.

Investigating the Role of CD40-CD154 Interactions in Lupus Nephritis

James Rush,[1] Barbara Nuesslein-Hildesheim,[1] Frédérique Lafossas,[1] Grazyna Wieczorek,[1] Melanie Ceci,[1] Swann Gaulis,[1] Giovanni Palla,[3] Katriona Mcmichael,[1] Enrico Ferrero,[1] Sabina Pfister.[2] *[1]Novartis Institutes for Biomedical Research, Basel, Switzerland; [2]Novartis Pharma AG, Basel, Switzerland; [3]Novartis Institute for BioMedical Research, Basel, Switzerland.*

Background: Disease pathology in lupus nephritis (LN) has been linked to a variety of different immune pathways, including CD40-CD154 interactions. This pathway has been shown to regulate the activation of B lymphocytes as well as macrophages and activated renal epithelia, and thus blockade of this pathway could provide therapeutic benefit in individuals with LN.

Methods: We evaluted the expression and activation of the CD40-CD154 pathway in kidney tissue from LN patients. Additionally, we evaluted the therapeutic effect of a blocking, non-depleting anti-mouse CD40 mAb (GOT40) in the NZB/W F1 model of lupus nephritis.

Results: Histological analysis of kidney biopsies from patients with proliferative LN revealed evidence of CD40 and CD154 on B cells, macrophages and T cells respectively. These results suggested that there might be ongoing T-B cell collaboration in LN kidneys and we subsequently examined whether there was evidence of CD40 pathway expression and activation in situ. Using published scRNA-seq data from LN kidney biopsies we could demonstrate evidence of CD40 transcript expression by B cells and myeloid cells and CD154 expression by subsets of CD4+ T cells. To directly address the role of CD40-CD154 in LN, we used GOT40, a novel, blocking, non-depleting anti-CD40 antibody in the NZB/W F1 model of lupus nephritis. Therapeutic treatment for 9-77 days of NZB/W F1 mice aged 24 to 37 weeks and individually enrolled into treatment groups with proteinuria ≥3 mg/ml resulted in suppression of established proteinuria and extended survival in GOT40 treated animals in comparison to isotype control treated animals. Serum autoantibody and CXCL13 levels were reduced by GOT40 treatment compared to isotype control. Similar to current treatments, we observed only minimal (not significant) reduction in various histological parameters with GOT40 treatment at this advanced stage of kidney injury, despite evidence of complete, systemic pathway blockade at the transcriptional level and suppression of a kidney gene expression with GOT40 treated animals.

Conclusions: Our data support the notion that CD40-CD154 pathway signaling may contribute to pathology in LN and that anti-CD40 treatment could provide therapeutic benefit in individuals suffering from this disease.

Modified Immune Cell (MIC) Therapy Ameliorates Murine Lupus Nephritis and Induces Regulatory B Cells In Vivo

Claudius Speer, Florian Kälble, Christian Nusshag, Martin G. Zeier, Christian Morath, Matthias Schaier. *University Hospital Heidelberg, Heidelberg, Germany*.

Background: MICs are mononuclear cells that gain immunosuppressive properties after incubation with mitomycin C (MMC). We recently showed that syngeneic MIC therapy controlled experimental autoimmune encephalitis (EAE). In addition, allogeneic MICs prevented rejection in rat heart and hindlimb as well as pig kidney transplantation. We wanted to translate these encouraging findings to the prevention and treatment of lupus nephritis.

Methods: Splenocytes of syngeneic BWF1 donor mice were incubated with MMC and injected into recipient's tail vein after matching for disease activity. Group 1 received no therapy, group 2 standard-dose MIC therapy with $1.5x10^8$/kg BW and group 3 high-dose MIC therapy with $1.5x10^8$/kg BW at week 1, 2 and 3. Group 4 received MIC infusions before disease onset as preemptive treatment approach. Disease activity was monitored by body weight, protein excretion, serum creatinine and dsDNA. Primary endpoint was day 40, protein excretion >3g/l and >20% loss of body weight. Kidney histopathology with PAS/HE staining was performed. Regulatory cell subsets and cytokine concentrations were measured.

Results: MIC therapy prevented the progression of lupus nephritis. Protein excretion, serum creatinine and dsDNA were lower in standard-dose and preemptive group compared to control group whereas repeated MIC therapy after disease onset had no effect. The endpoint was reached significantly more often in control group (67%) compared to groups 2 (14%), 3 (14%) and 4 (0%). Renal architecture was preserved in different MIC treatment groups with decreased glomerular and tubular damage scores. The frequency of $CD5^+CD1d^{high}$ regulatory B cells was higher in MIC-treated compared to control animals, whereas double negative T cells were markedly reduced. IL-6 serum concentration was significantly decreased in group 2 and 4.

Conclusions: MIC therapy inhibits progression of active lupus nephritis. Preemptive MIC therapy delayed the onset of disease with no significant disease activity at completion of the study. In accordance with our EAE experiments and a first in-human clinical trial in kidney transplantation (TOL-1 study), MIC therapy was able to induce regulatory cell subsets in-vivo. This clinically applicable cell therapy may control lupus nephritis by specifically silencing deleterious autoimmune responses.

Adeno-Associated Virus-Mediated Factor H Gene Therapy in a Murine Model of Complement-Dependent Thrombotic Microangiopathy and Systemic Thrombophilia

Daisuke Ito,[1,2] Hangsoo Kim,[1] Damodara Gullipalli,[1] Yoshiyasu Ueda,[1,3] Takashi Miwa,[1] Sayaka Sato,[1] Lin Zhou,[1] Matthew Palmer,[4] Jun Xie,[5] Guangping Gao,[5] Wen-Chao Song.[1] *[1]Department of Systems Pharmacology and Translational Therapeutics, University of Pennsylvania, Philadelphia, PA; [2]Seirei Hamamatsu general hospital, Hamamatsu, Japan; [3]Osaka general medical center, Osaka, Japan; [4]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA; [5]Horae Gene Therapy Center, University of Massachusetts Medical School, Worcester, MA.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a form of thrombotic microangiopathy (TMA) caused by complement dysregulation. It is characterized by thrombocytopenia, hemolytic anemia and renal injury, with up to 50% patients eventually progressing to end stage renal failure. Mutation in the C-terminal domain of factor H (FH), a critical plasma complement inhibitor, is the most common genetic cause of aHUS. Eculizumab, a humanized anti-C5 mAb, is effective for aHUS but whether lifetime treatment with Eculizumab is needed and what is the optimal length of therapy remains unknown. Here we tested the hypothesis that adeno-associated virus (AAV)-mediated FH gene therapy can correct complement dysregulation and replace anti-C5 therapy in FH mutation-related aHUS.

Methods: We used $FH^{R/R}$ mice which carried a homozygous mutation (W1206R) in FH. $FH^{R/R}$ mice developed characteristic TMA as well as macro-vessel thrombosis in multiple organs, and approximately 50% died prematurely. Twice weekly treatment of 4-week old $FH^{R/R}$ mice with an anti-mouse C5 mAb for 4 weeks prevented disease development as indicated by normal platelet counts and blood hemoglobin levels. The treated mice were then randomized to receive either control AAV vector or AAV-sFH encoding a mouse FH construct comprising short consensus repeats 1-4, 6-8 and 19-20 (1×10^{12} gene copies/mouse)and anti-C5 mAb treatment was discontinued one week later.

Results: When examined at 5 weeks after AAV gene therapy (4 weeks after stopping anti-C5 mAb treatment), TMA features including thrombocytopenia, low plasma hemoglobin and elevated reticulocyte count returned to control AAV-treated but not AAV-sFH-treated mice. Six months after AAV gene therapy, 9/10 AAV-sFH-treated mice were still alive whereas only 7/20 control AAV-treated mice survived. Furthermore, severe glomerular injury and fibrin deposition in the kidney, and macro-vessel thrombosis in extra-renal organs, were detected in terminally sacrificed control AAV-treated $FH^{R/R}$ mice but were almost absent in AAV-sFH-treated $FH^{R/R}$ mice.

Conclusions: These results demonstrate that AAV-mediated FH gene transfer can replace anti-C5 mAb treatment to provide curative therapy for TMA and other pathologies associated with FH point mutations.

Urinary Soluble CD163: A Non-Invasive Biomarker of Activity for Lupus Nephritis

Juan M. Mejia-Vilet,[1] Xiaolan Zhang,[3] Mayra L. Cano verduzco,[2] Cristinoc Cruz,[2] John P. Shapiro,[3] Luis E. Morales-Buenrostro,[1] Brad H. Rovin.[3] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Toriello Guerra, Mexico; [3]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Distinction between lupus nephritis (LN) patients with active inflammation and those with chronic kidney damage is challenging. Soluble CD163 derives from cleavage of the CD163 M2c-macrophage receptor, can be quantified in urine and may reflect intra-renal inflammation. We tested urine sCD163 as a biomarker of LN activity.

Methods: The cross-sectional diagnostic yield and the longitudinal course of urinary sCD163 (usCD163) was assessed in two large LN cohorts. We recruited 113 (Mexican cohort) and 129 (OSU cohort) active LN (aLN) patients with prospective follow-up. Patients with other diseases, inactive LN (iLN), and healthy donors were included as controls. ROC curves were obtained from the cross-sectional data. Then 86 LN flares from the Mexican and the OSS study cohort were followed with repeated samples and response to therapy (RTT) evaluated at 6- and 12-months. Linear mixed models were fitted to evaluate the association between usCD163 and RTT.

Results: The highest levels of usCD163 were found in aLN in the Mexican (1805ng/mmol, 760-4334) and OSU (1358ng/mmol, 811-2356) cohorts compared to iLN (10ng/mmol, 0-40, p<0.001) and other diseases. UsCD163 was higher in class IV Vs. other classes and correlated with the histologic activity index (r=+0.527, p<0.001). A usCD163>100ng/mmol differentiated aLN from iLN with 95% sensitivity and 93% specificity. UsCD163 increased from 6-months pre-flare to flare and then diminished to <500ng/mmol at 12 months in 88% of RTT, while usCD163 remained >500ng/mmol at 12-mo in 88% of non-responders. Diagnostic yield of usCD163 to discriminate 12-month RTT was better than that of currently-used biomarkers (Table 1). After adjusting for other predictors, the usCD163 slope was associated with RTT.

Conclusions: UsCD163 reflects LN renal inflammation and varies over time with LN activity and treatment. Its levels increase pre-flare and then parallel RTT, being independently associated with response to therapy.

Funding: Other NIH Support - National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), Government Support - Non-U.S.

Diagnostic performance of usCD163 and serological biomarkers to discriminate 12-month responders from non-responders

	Sensitivity	Specificity	PPV	NPV	+LR	-LR

Proliferation and Changes in Cellular Signatures in Memory B Cells from Lupus Nephritis Patients Receiving Mycophenolate or Azathioprine Maintenance

Desmond Y. Yap,[1] Paul Lee,[2] Cheryl Tam,[2] Irene Yam,[2] Susan Yung,[2] Daniel Tak Mao Chan.[1] *[1]Queen Mary Hospital, Hong Kong, China; [2]The University of Hong Kong, Hong Kong, China.*

Background: Mycophenolate mofetil (MMF) and azathioprine (AZA) are standard maintenance treatments for lupus nephritis (LN), and recent data suggested lower risk of relapse with MMF maintenance. Memory B cells have been implicated in LN relapse, and miRNA148a, BACH1, BACH2 and PAX5 can regulate memory B cell homeostasis. The effects of MMF and AZA treatment on these memory B cell signatures remain unclear.

Methods: Memory B cells were isolated from clinically stable LN patients receiving low-dose corticosteroid and MMF (n=10) or AZA (n=9) maintenance, and the cell proliferation and intracellular miRNA148a, BACH1, BACH2 and PAX5 expressions on Day 3 after *ex vivo* stimulation were compared.

Results: MMF group showed lower memory B cell proliferation on Day 3 (8.5±1.2%, compared with 20.3±2.0% in AZA group, p<0.001) (Figure 1, A). MMF group also showed lower miRNA148a expression (10-fold decrease compared to health controls (HC), vs. 2-fold decrease in AZA group, p<0.001) (Figure 1, B), but higher BACH1, BACH and PAX5 expression in memory B cells (8.2±0.8, 7.2±1.8, and 7.6±1.1 fold increase compared to HC respectively, vs. 4.0±0.7, 2.9±0.6, and 3.4±0.4 fold increase in the AZA group, p<0.001, MMF vs. AZA) (Figure 1, C).

Conclusions: LN patients receiving MMF maintenance showed reduced memory B cell proliferation and a distinct cellular signature, which may account for the lower risk of relapse observed clinically.

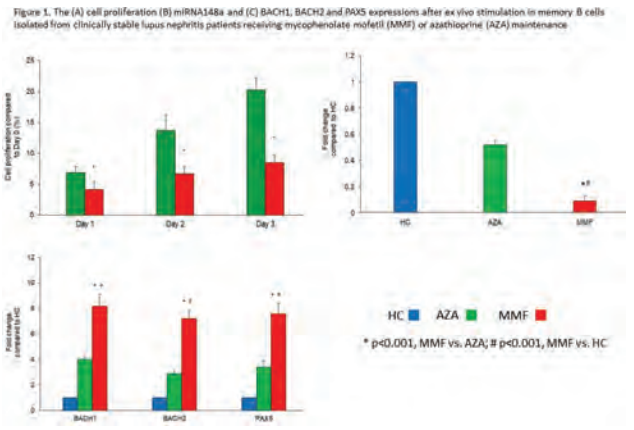

Figure 1. The (A) cell proliferation (B) miRNA148a and (C) BACH1, BACH2 and PAX5 expressions after ex vivo stimulation in memory B cells isolated from clinically stable lupus nephritis patients receiving mycophenolate mofetil (MMF) or azathioprine (AZA) maintenance

FR-OR086

Kidney Biopsy-Based Management of Maintenance Immunosuppression in Lupus Nephritis

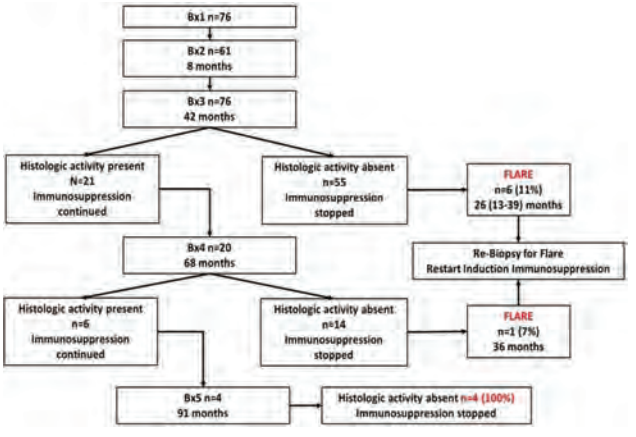
Ana Malvar,[1] Valeria G. Alberton,[1] Bruno J. Lococo,[1] Matias Ferrari,[1] Pamela Delgado,[1] Brad H. Rovin.[2] *[1]Hospital Fernandez, Buenos Aires, Argentina; [2]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: The optimal duration of maintenance immunosuppression (MIS) for proliferative lupus nephritis (LN) is unknown. Management of MIS therapy must balance the risk of LN flare after IS withdrawal against the toxicities of long-term IS. We postulated that information from a protocol kidney biopsy done when withdrawal of IS is being contemplated could attenuate LN flares and improve long-term kidney outcomes, and tested this hypothesis in a large LN cohort.

Methods: A cohort of 76 Caucasian Hispanic SLE patients initiated IS for kidney-biopsy proven (Bx1) LN, was followed prospectively, re-biopsied after induction (Bx2) and again during MIS therapy (Bx3). Bx3 was done after a minimum of 36 months of IS in patients stable for at least 12 months, who had achieved a complete renal response and had no extra-renal SLE activity. Biopsies were graded using the NIH activity index (AI). If AI=0 MIS was tapered off and patients were followed for LN flare. If AI was ≥1 MIS was continued for 24 months, and patients were re-biopsied around month 68 (Bx4). If Bx4 AI=0 MIS was withdrawn; if Bx4 AI was ≥1, MIS was continued for 24 months and the decision to withdraw MIS was based on re-biopsy (Bx5).

Results: Patient outcomes are shown in the Figure. After a median follow-up of 50 months between Bx3 and last visit only 7 patients (9.2%) experienced an LN flare, no patient died, and no patient progressed to ESKD.

Conclusions: These data extend the observation that clinical remission and histologic remission even after several years of IS may be discordant. Management of MIS by histologic activity of protocol biopsies resulted in an LN flare rate of 0.012 events/patient-year, significantly better than the reported flare rates of 0.02-0.81 events/patient-year in international LN cohorts. Protocol kidney biopsies during MIS may help guide treatment duration, minimizing exposure to toxic medications and risk of LN relapse.



FR-OR087

Validation of C3 Glomerulopathy Histopathologic Index in a Large Multicenter Cohort Study

Fernando Caravaca-Fontan,[1] Teresa Cavero escribano,[1] Laura Lucientes,[2] Elena Goicoechea de jorge,[3] Manuel Praga.[1] on behalf of GLOSEN group *[1]Hospital Universitario 12 de Octubre, Madrid, Spain; [2]Universidad Complutense de Madrid, Madrid, Spain; [3]Complutense University Madrid, Madrid, Spain.*

Background: C3 Glomerulopathy Histopathologic Index (C3G-HI) has been recently proposed as a tool for assessing both activity and chronicity of kidney biopsies in patients affected with C3 glomerulopathy (C3G). The aim of this study was to evaluate the utility and reproducibility of C3G-HI for predicting renal prognosis in C3G.

Methods: Multicenter, retrospective cohort study in 37 nephrology departments belonging to GLOSEN group. All patients fulfilling diagnostic criteria of C3G were included. Kidney biopsies were evaluated by each participating center, and lesions were scored according to the C3G-HI. Demographic, clinical and biochemical parameters of prognostic interest were recorded and used to analyze the main determinants of disease progression and response to different therapeutic regimens.

Results: The study group consisted of 134 patients: 114 C3 glomerulonephritis (C3GN) and 20 dense deposit disease (DDD). Membranoproliferative glomerulonephritis was the most predominant pattern of injury. No significant differences were observed in the parameters of activity across age groups, except for interstitial inflammation that was greater in older patients. However, pediatric patients had a significant lower degree of glomerulosclerosis, tubular atrophy and interstitial fibrosis. No significant clinicopathological differences were observed between C3GN and DDD patients. During a median follow-up of 43 months, 53 patients (40%) developed end-stage renal disease (ESRD). Renal survival was significantly worse in patients in the lower tertiles of Total Chronicity Score. By Cox regression analysis, the main determinants of ESRD were: age (hazard ratio [HR]: 1.019; C.I.95%:1.003–1.034; p=0.016), serum creatinine at baseline (HR:1.131; C.I.95%:1.037–1.235; p=0.006), proteinuria at baseline (HR:1.076; C.I.95%:1.007–1.151; p=0.031), Total Chronicity Score (HR:1.326;C.I.95%:1.118–1.480;p<0.0001) and therapy with mycophenolate mofetil plus steroids (HR: 0.344; C.I.95%: 0.150–0.787; p=0.012).

Conclusions: C3G-HI provides useful predictive information in C3G, being chronicity parameters the main pathologic determinants of renal prognosis. Older age, elevated serum creatinine and proteinuria are the main clinical determinants of renal survival, whereas treatment with steroids and mycophenolate mofetil was associated with better outcome.

FR-OR088

National Observational Study Monitoring the Restrictive Regimen of Eculizumab Therapy in aHUS in the Netherlands

Romy N. Bouwmeester,[1] Caroline Duineveld,[1] Kioa L. Wijnsma,[1] Jack F. Wetzels,[2] Nicole Van De Kar.[3] CUREiHUS Study Group *[1]Radboudumc, Nijmegen, Netherlands; [2]Radboud University Medical Center, Nijmegen, Netherlands; [3]UMC St. Radboud Nymegen, Nijmegen, Netherlands.*

Background: Nowadays eculizumab is the cornerstone of treatment in atypical hemolytic uremic syndrome (aHUS). The optimal treatment strategy in aHUS is still unknown. In October 2016, a Dutch guideline promoting a restrictive eculizumab regimen in aHUS, was implemented. Here we report the preliminary results of the CUREiHUS study, monitoring this guideline.

Methods: The data of pediatric and adult Dutch aHUS patients included in CUREiHUS study from 1-10-2016 till April 2019 were evaluated. Patients were divided in two groups; a historical cohort containing aHUS patients already on eculizumab treatment before October 2016 (n=13) and aHUS cohort who started with eculizumab after October 2016 (n=24).

Results: In the historical cohort eculizumab could be withdrawn in 5 of the 13 aHUS patients (median duration treatment 6,6 months). Four patients are treated with interval elongation ranging from 3 to 6 weeks). Three patients are on two-weekly interval dosage. In two of the 24 patients who started eculizumab after October 2016 aHUS was diagnosed <3 months and are receiving the standard two-weekly regimen according to the Dutch guideline. In 22 of these 24 aHUS patients the follow up is > 3 months. In 13 patients the eculizumab therapy could be withdrawn. The median duration of treatment was 3,2 months (range 0,3-10 months). The median follow-up after the last gift of eculizumab was 17 months (range 1-35 months). Tapering of eculizumab was seen in 6 patients (interval 3-6 weeks). Additional three patients are treated with the standard two weekly regimen treatment. Relapse of HUS occurred in 14 patients and were treated immediately with eculizumab. In total 8/34 (24%) are at the moment treated with eculizumab biweekly. Eculizumab therapy is withdrawn in 38% (5/13) and 62% (13/21) in patients with onset of aHUS before and after implementation of the guideline, respectively.

Conclusions: The majority of aHUS patients do not need eculizumab biweekly and can be safely switched to an extended interval or withdrawal of therapy. Continuous monitoring and further determination of contributing or predictive factors to relapse(s) are necessary.

FR-OR089

Evaluation of the Endothelin A Receptor Antagonist Zibotentan in Systemic Sclerosis-Associated CKD

Edward Stern,[1] Lauren V. Host,[1] Katherine J. Escott,[2] Peter S. Gilmour,[2] Ivy Wanjiku,[3] Rachel Ochiel,[3] Aine Burns,[3] Robert J. Unwin,[1] Voon Ong,[1] Christopher P. Denton.[1] *[1]University College London, London, United Kingdom; [2]AstraZeneca, Royston, United Kingdom; [3]Royal Free Hospital, London, United Kingdom.*

Background: Systemic sclerosis (SSc) causes scleroderma renal crisis (SRC) and chronic kidney disease (SSc-CKD). A previous open label trial of bosentan suggested possible benefit for CKD following SRC. We report the results of a placebo-controlled trial of zibotentan, a highly selective endothelin A receptor antagonist, in SSc-CKD.

Methods: ZEBRA-1 was a double-blind randomised placebo-controlled trial in SSc-CKD (eGFR 45-60 ml/min) comparing oral zibotentan 10 mg/day and placebo over 26 weeks with final assessment at 52 weeks (Clinical Trials NCT02047708). eGFR and candidate urinary molecular markers of SSc-CKD were measured at each time point and safety was a key secondary endpoint.

Results: 16 patients consented with 3 screen failures due to ineligible eGFR on re-testing. 7 patients received placebo and 6 zibotentan. Baseline renal function was well-matched between groups—median eGFR in placebo 51 (44-58); zibotentan 50.5 (49-59). Renal function remained equal at 26 weeks—placebo 53 (37-58); zibotentan 54 (50-58)—but significantly improved in the active treatment group at 52 weeks—placebo 50 (36-55) zibotentan 60.5 (50-74), p=0.0082 (**Figure 1**). Our previous work identified high urinary MCP-1 as a marker of SSc-CKD. In ZEBRA-1 levels declined on zibotentan but not on placebo. Median baseline MCP-1:creatinine (pg/mg/L) was 7.1 (5.2-21.9) in placebo and 5.4 (3.1-28.9) for zibotentan, increased to 8.8 (6.3-33.5) at 26 weeks on placebo and reduced to 4.4 (2.9-11.2) on zibotentan. At 52 weeks MCP-1:creatinine for placebo was 7.5 (6.4-15.8) and was significantly lower at 4.5 (4.1-6.0; p=0.0095) for zibotentan. There were 46 reported adverse events (26 placebo and 20 zibotentan) with 6 serious adverse events (3 in each arm).

Conclusions: This is the first placebo-controlled clinical trial in renal SSc. Zibotentan treatment was safe and associated with improved eGFR and reduced urinary MCP-1 at 52 weeks compared to placebo. These prelimanary results suggest potential benefit from targeting endothelin A in SSc-associated CKD.

Risk Factors for Infection in Patients with Glomerular Disease: An Analysis of the Cure Glomerulonephropathy (CureGN) Study

Dorey A. Glenn,[1] Candace D. Henderson,[2] Yichun Hu,[3] Michelle M. O'Shaughnessy,[4] Larry A. Greenbaum,[5] Jarcy Zee,[6] Andrew S. Bomback,[7] Laura H. Mariani,[8] Keisha L. Gibson,[2] Susan L. Hogan,[9] Ronald J. Falk,[2] Amy K. Mottl.[9] CureGN Consortium *[1]Nephrology and Hypertension, University of North Carolina, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]UNC Kidney Center & Divisions of Nephrology & Hypertension, Chapel Hill, NC; [4]Stanford University, Palo Alto, CA; [5]Emory University, Atlanta, GA; [6]Arbor Research Collaborative for Health, Ann Arbor, MI; [7]Columbia University, New York, NY; [8]University of Michigan, Ann Arbor, MI; [9]University of North Carolina, Chapel Hill, NC.*

Background: Infections are an important contributor to patient morbidity and mortality in glomerular disease (GD). We sought to understand risk factors for infection among patients in the Cure Glomerulonephropathy (CureGN) study.

Methods: CureGN is a prospective multi-center cohort study of patients with biopsy-proven minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), or IgA nephropathy/vasculitis (IgAN/IgAV). Risk factors for time to first infection-related hospitalization or ED visit were identified using Cox proportional hazards regression. Cox models were adjusted for patient characteristics at enrollment, including demographics [age, race, sex], immunosuppression exposure, GD subtype, number of comorbid conditions, smoking status, time from initial biopsy, and laboratory measurements [eGFR, urine protein to creatinine ratio (UPC), and serum albumin].

Results: Of 1917 participants (43% female, 42% less than 20 years, 67% white), 165 subjects (9%) experienced a first infection over a median follow-up of 15.5 (IQR 7.5 – 24.9) months. In adjusted multivariate models, age < 10 or 20-59 (versus >60) years, black race, and a higher number of comorbidities were significantly (p<0.05) associated with an increased hazard for infection (Table). An association with corticosteroid exposure was of borderline significance (p=0.06).

Conclusions: Among CureGN participants, younger age, black race, and more comorbidities were independently associated with time to first infection-related hospitalization or ED visit. These findings might inform the development of strategies aimed at preventing infection in patients with GD.

Clinical Exome Sequencing for Renal Disorders

Parker C. Wilson,[1] Latisha Love-gregory,[2] Meagan Corliss,[2] Samantha N. Mcnulty,[2] Jonathan Heusel,[2,3] Joseph Gaut.[1,4] *[1]Division of Anatomic and Molecular Pathology, Department of Pathology and Immunology, Washington University in St. Louis, Saint Louis, MO; [2]Division of Laboratory and Genomic Medicine, Department of Pathology and Immunology, Washington University in St. Louis, Saint Louis, MO; [3]Department of Genetics, Washington University in St. Louis, Saint Louis, MO; [4]Divison of Nephrology, Department of Medicine, Washington University in St. Louis, Saint Louis, MO.*

Background: Next-generation sequencing is a valuable tool for evaluating patients with suspected genetic renal disease. Clinical practice relies on targeted gene sets that are ordered based on patient phenotype and physician knowledge of the utility of genetic testing. We report the diagnostic yield of four clinically-established gene sets and employ a retrospective analysis of an expanded set of genes to characterize patients with pathogenic variants in genes that were not part of the ordered gene set.

Methods: In total, 324 patients underwent clinical exome sequencing based on physician-ordered gene sets for atypical hemolytic uremic syndrome (n=224), nephrotic syndrome/FSGS (n=56), cystic renal disease and nephronophthisis (n=26), Alport syndrome (n=13), or a custom panel (n=5). Also, patients referred for aHUS genetic testing were assessed for *CFHR3-CFHR1* deletion by multiplex ligation-dependent probe amplification. Subsequently, all patients underwent retrospective analysis using an extended panel of 309 genes to detect additional potentially pathogenic variants according to ACMG 2015 guidelines.

Results: We identified 42 pathogenic and likely pathogenic variants in 97 of 324 patients and an additional 101 patients with a variant of uncertain significance. *CFHR3-CFHR1* homozygous deletion was detected in 22 aHUS patients without a pathogenic or likely pathogenic variant. Overall, the diagnostic yield of the clinical gene sets was 20% and varied between groups (aHUS=18%, NS=16%, NPHP=46%, AS=23%). The extended gene set revealed 18 additional pathogenic or likely pathogenic variants and 8 patients with a high-risk *APOL1* genotype, increasing the overall yield to 30%.

Conclusions: These results highlight the importance of a broad and collaborative approach between the clinical laboratory and their physician clients that employs additional analysis when the ordered gene set of kidney-disease-causing genes does not return a clinically meaningful result.

Proliferative Glomerulonephritis with Monoclonal Light Chain Deposits

Samih H. Nasr,[1] Christopher P. Larsen,[6] Christophe Sirac,[5] Jason D. Theis,[1] Jonathan J. Hogan,[2] Samar M. Said,[1] Surendra Dasari,[1] Julie A. Vrana,[1] Ellen D. Mcphail,[1] Lynn D. Cornell,[1] Vivette D. D'Agati,[4] Nelson Leung,[1] Frank Bridoux.[3] *[1]Mayo Clinic, Rochester, MN; [2]Hospital of the University of Pennsylvania, Haddonfield, NJ; [3]Hôpital Jean Bernard, CHU Poitiers, Poitiers, France; [4]Columbia University College of Physicians and Surgeons, New York, NY; [5]CNRS, Limoges, France; [6]Arkana Laboratories, Little Rock, AR.*

Background: Most cases of proliferative glomerulonephritis with monoclonal immunoglobulin (MIg) deposits (PGNMID) are of the IgG isotype (particularly IgG3).

Methods: We describe the first clinicopathologic and proteomic series of PGNMID with MIg light chain (LC) deposits (PGNMID-LC).

Results: This multicenter cohort consisted of 18 patients (median age 60 years, 72% male) who presented with nephritic or nephrotic syndrome. The underlying hematologic condition was MGRS (72%) or multiple myeloma (28%). MIg was identified by serum and urine immunofixation in 61% and 69% of patients, abnormal serum FLC in 77%, and corresponding nephritogenic plasma cell clone in the bone marrow in 88%. Renal biopsy showed MPGN in most patients; glomerular deposition of MIg LC (κ in 67% and λ in 33%) and C3 (100%), without extraglomerular deposits, IgG, IgA, or C1q deposits, by immunofluorescence (IF); and subendothelial (100%), mesangial (100%) and subepithelial (72%) granular electron dense deposits by electron microscopy. Paraffin IF done in 39% of cases showed similar results to IF on frozen tissue. Laser microdissection/mass spectrometry performed on 4 cases of κ PGNMID-LC revealed spectra for Ig κ constant and variable domains and complement alternative pathway (CAP) and terminal complex proteins (particularly C3 and C9) in 3 without spectra for Ig γ, α, μ, λ, or classical complement pathway proteins. In contrast, 6 cases of κ LCDD analyzed did not show spectra for complement proteins. Complement functional assays in 1 patient revealed that a serum fraction enriched with the monoclonal Vl3 LC induced CAP activation in normal human serum. Follow up (median 66 months) was available in 16 patients. Renal response occurred in 6 of 10 patients treated with plasma cell-directed chemotherapy but not in 6 who did not. Hematologic response was evaluable in 8. All 6 with hematologic complete response achieved renal response while the 2 with hematologic partial or no response did not.

Conclusions: PGNMID-LC is a variant of PGNMID with higher detection rate of the nephritogenic plasma cell clone. Proper recognition is crucial as plasma cell clone-directly therapy appears to improve renal prognosis. Activation of CAP by MIg LC likely plays a central role in its pathogenesis.

FR-OR093

Prevalence of Exostosin 1/Exostosin 2-Associated Membranous Lupus Nephritis

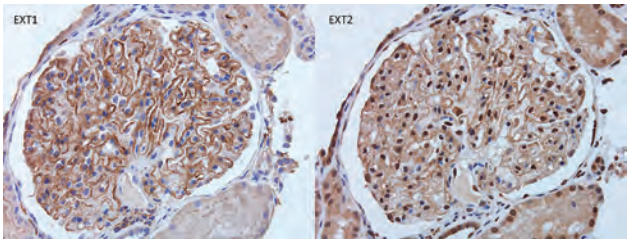
Aishwarya Ravindran, Fernando C. Fervenza, Benjamin J. Madden, Cristine Charlesworth, Sanjeev Sethi. *Mayo Clinic, Rochester, MN.*

Background: Membranous nephropathy (MN) is classified as primary and secondary. Primary MN is associated with PLA2R antigen in 70-80% cases and THSD7A in 1-5% cases. The target antigens are unknown in 20-25% cases of primary MN and all of secondary MN. Two novel proteins, Exostosin1 and Exostosin 2 (EXT1/EXT2) were recently identified as likely target antigens in a small cohort of MN with an underlying autoimmune etiology (Sethi et al, JASN 2019). In this study, we validate the EXT1/EXT2 findings in a large cohort of patients with lupus membranous nephritis (LMN).

Methods: We studied 374 cases of biopsy-proven LMN from 2003 to 2018. Immunohistochemical studies (IHC) using antibodies against EXT1/EXT2 were performed on paraffin-embedded sections. Laser microdissection and mass spectrometry (MS) were performed on a subset of these cases.

Results: Of the 374 LMN cases, 122 (32.6%) were EXT1/EXT2 positive (figure 1) and 252 (67.4%) were EXT1/EXT2 negative by IHC. Among the 122 cases, 86.9% were female. At presentation, the median serum creatinine and proteinuria were 0.8 mg/dL (range: 0.4-14.7) and 4 g/day (range: 0.4-13.5). Kidney biopsies revealed an average of 16.6 glomeruli (SD: ±10.0) with an average of 1.7 globally sclerotic glomeruli (SD: ±3.3). Interstitial fibrosis and tubular atrophy was minimal (<10%) in 89 (72.9%), mild (11-25%) in 21 (17.2%), moderate (26-50%) in 8 (6.6%), and severe (>50%) in 4 (3.3%) cases, respectively. Further, 30 (24.6%) patients had proliferative features (Class III/IV). MS was performed on 8 cases which showed high spectral counts for EXT1 (average: 88.6, SD:± 37.2) and EXT2 (average: 66.1, SD:± 34.6), thus confirming the IHC findings. Among the 252 EXT1/EXT2 negative cases, 81 (32.1%) patients showed proliferative features. MS was performed in 7 of these 252 cases and was negative for EXT1/EXT2.

Conclusions: We validate our previous findings in a large cohort of LMN. Approximately one-third (32.6%) of LMN patients are positive for EXT1/EXT2, of which approximately one-fourth (24.6%) have coexisting proliferative features.



EXT1/EXT2 positive LMN

FR-OR094

Renal Polyvinylpyrrolidone Deposition from Illicit Drug Use Is Associated with Tubulointerstitial Nephropathy

Ida V. Stalund,[1,2] Heidi Grønseth,[1] Finn P. Reinholt,[4] Erik H. Strom,[4] Einar Svarstad,[2,3] Hans-Peter Marti,[2,3] Sabine Leh.[1,2] *[1]Department of Pathology, Haukeland University Hospital, Bergen, Norway; [2]Department of Clinical Medicine, University of Bergen, Bergen, Norway; [3]Department of Medicine, Haukeland University Hospital, Bergen, Norway; [4]Department of Pathology, Oslo University Hospital, Rikshospitalet, Oslo, Norway.*

Background: Polyvinylpyrrolidone (PVP) is a water-soluble polymer used as an excipient in drugs for oral use. When injected, high molecular weight PVP can neither be metabolized nor excreted by glomerular filtration and will accumulate in the body, resulting in PVP deposition disease. From 2009 to 2016, we observed 25 kidney biopsies with PVP deposition in Norway. All biopsies were from patients with opioid addiction and chronic kidney disease (CKD). The most likely source of PVP in these patients is illicitly injected, PVP-containing opioid substitution drugs intended for oral use.

Methods: We collected clinical data from the Norwegian Kidney Biopsy Registry and from affiliated medical records. We reviewed the biopsies, assessed light microscopy, immunohistochemistry and electron microscopy, and obtained additional pathological parameters using quantitative methods.

Results: The cohort consisted of 25 adults with a mean age of 37. All were suffering from opioid addiction with a known history of injecting opioids regularly, and 22 of them were prescribed opioid substitution drugs. 22 (88%) of the patients had positive hepatitis C virus serology and none were HIV-positive. All patients had CKD with a mean serum creatinine of 205 mole/L and mean estimated glomerular filtration rate of 35 mL/min/1.73m2 (Range 14-58). The majority (64%) had stage 3b CKD. Four patients had slightly to moderately increased urinary protein:creatinine-ratio. All biopsies revealed widespread areas of tubular atrophy and interstitial fibrosis with a mean proportion 64% (Range 32-86). The interstitium of these areas contained single and grouped histiocytes with characteristic bluish vacuoles indicating PVP deposits (fig. 1). Apart from one patient with lupus nephritis, the biopsies showed no evidence of other diseases that could explain the widespread atrophy.

Conclusions: Opioid drug addiction is associated with a high burden of morbidity and various renal diseases. This large case series illustrates that PVP deposition might be a rare cause of chronic renal insufficiency in these patients.

Funding: Government Support - Non-U.S.

Chronic Interstitial Nephritis in Agricultural Communities (CINAC): A Toxin-Induced Proximal Lysosomal Tubulopathy

Benjamin A. Vervaet,[1] Cynthia C. Nast,[2] Channa Jayasumana,[3] Gerd Schreurs,[4] Frank Roels,[10] Chulani A. Herath,[5] Nika Kojc,[6] Anne S. Rodrigo,[5] Swarnalata Gowrishankar,[7] Christiane I. Mousson,[11] Rajeewa T. Dassanayake,[8] Carlos M. Orantes,[9] Patrick C. D'Haese,[1] Marc E. De Broe.[4] *[1]University Antwerp, Antwerp, Belgium; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]Faculty of Medicine, Anuradhapura, Sri Lanka; [4]University of Antwerp, Antwerp, Belgium; [5]Sri Jayawardenepura General Hospital, Colombo 5, Sri Lanka; [6]Medical faculty Ljubljana, Ljubljana, Slovenia; [7]Apollo Hospitals, Hyderabad, Hyderabad, India; [8]General hospital Polonnaruwa Sri Lanka, Polonnaruwa, Sri Lanka; [9]National Direction of Non-communicable diseases of Ministry of Health, San Salvador, El Salvador; [10]Ghent University, Gent, Belgium; [11]University Hospital Dijon, Dijon, France*.

Background: There is no consensus on the etiology of CINAC. Heat stress/dehydration and toxic exposure are the two most likely etiologies. There are no direct diagnostic criteria to identify CINAC patients.

Methods: Renal CINAC biopsies (18 Sri Lanka, 10 El Salvador, 1 India, 3 France) were examined by light (LM) and electron microscopy (EM) in comparison to normal kidneys at implantation and 6 and 12 months of calcineurin inhibitor (CNI) therapy, transplant patients on CNI with indication biopsies (n=24), proteinuric nephropathies (n=15), light chain disease (n=4), cases on nephrotoxic drugs (lomustine, clomiphene, lithium, tenofovir, cisplatinum) and CKD of various causes (n=20). A rat study compared histopathology of heat stress with cyclosporine nephrotoxicity.

Results: There was a unique constellation of proximal tubular cell (PTC) findings: cellular/tubular atrophy, cell fragment shedding, weak to non-proliferative capacity of the PTC and dysmorphic lysosomes increased in size and number with a light-medium electron-dense matrix containing dispersed dark electron-dense non-membrane bound "aggregates". Identical lesions were observed in 55-80% of renal transplant protocol biopsies at 6 and 12 months of CNI therapy and in indication biopsies. In implantation biopsies the prevalence was 6%. Several cases of nephrotoxic drugs (lomustine, clomiphene, lithium) and some patients with light chain disease, all conditions linkable to CNI, presented the same lesion. Controls (n=66) of normal kidney, toxic nephropathies (tenofovir, cisplatinum), and overt proteinuric patients of different etiology to some extent could demonstrate the tubular cell changes observed by LM, but not or very rarely those by EM. Rats treated with cyclosporine for 4 weeks developed similar PTC lysosomal alterations, that were absent in a dehydration group.

Conclusions: A sensitive constellation of renal PTC lesions was detected associated with CINAC and CNI nephrotoxicity in several countries, suggesting a common new paradigm where CINAC patients are experiencing a tubulotoxic mechanism similar to CNI nephrotoxicity, the latter also being known as a direct or indirect effect of pesticides.

FR-OR096

Integrative Analysis of Single Cell and Bulk Transcriptomic Data Identifies FSGS Subgroup with Endothelial Cell Activation

Rajasree Menon,[1] Edgar A. Otto,[1] Paul J. Hoover,[6] Sean Eddy,[1] Laura H. Mariani,[1] Celine C. Berthier,[1] Abhijit S. Naik,[1] Felix H. Eichinger,[1] Wenjun Ju,[1] Jennifer L. Harder,[1] Brad A. Godfrey,[5] Viji Nair,[1] Laura Barisoni,[2] Jarcy Zee,[3] Jinghui Luo,[1] Virginie Royal,[4] Jeffrey B. Hodgin,[1] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Duke University, Durham, NC; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [5]The University of Michigan, Ann Arbor, MI; [6]Broad Institute, Cambridge, MA*.

Background: Single cell RNA sequencing (scRNA-seq) generates transcriptomic data at cellular resolution allowing the identification of both known and novel cell-type specific markers. These markers enable to investigate the role of distinct cell types in kidney disease. In this study, we used glomerular endothelial cell type markers identified by scRNA-seq to analyze micro-dissected glomerular mRNA data from FSGS patients in NEPTUNE Consortium.

Methods: As part of the Kidney Precision Medicine Project (KPMP), single cell analysis (10x Chromium) was performed on unaffected kidney tissue from 16 tumor-nephrectomy and 10 surveillance transplant biopsy samples. Integrated analysis was performed on the single cell data from these 26 reference datasets including normalization, batch correction, unsupervised clustering and cell-specific marker identifications. Cell specific markers were used to cluster glomerular RNA transcriptomic data from 74 NEPTUNE FSGS patients followed by functional analysis.

Results: 37 kidney cell-type clusters were identified including glomerular, tubular and immune cell types as well as 3 distinct endothelial cell types (arteriolar, peritubular and glomerular). The glomerular endothelium-specific markers were then used to sort bulk tissue gene expression from FSGS patients resulting in two main groups, 1 (n=44) and 2 (n=30). Group 2 demonstrated significant enrichment of glomerular endothelial activation markers. Higher hazards of a composite progression endpoint (>40% reduction eGFR reduction or ESRD) indicated poor prognosis for Group 2. Differentially expressed genes (DEGs) up-regulated in group 2 were involved in type-1 interferon response, ras-protein signaling, and response to endothelin receptor antagonists in model systems.

Conclusions: Glomerular endothelial marker genes identify a subgroup of patients with poor prognosis and establish a molecular correlate for the endothelin treatment response observed in clinical trials in FSGS.

Evaluation of a Computer-Aided Quality Assessment of Whole Slide Images for Computational Pathology

Yijiang Chen,[1] Jarcy Zee,[2] Abigail R. Smith,[2] Catherine P. Jayapandian,[1] Jeffrey B. Hodgin,[3] David Howell,[4] Matthew Palmer,[5] David B. Thomas,[6] Clarissa A. Cassol,[7] Alton B. Farris,[8] Kathryn R. Perkinson,[9] Stephen M. Hewitt,[12] Anant Madabhushi,[1,11] Laura Barisoni,[10] Andrew Janowczyk.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]The University of Michigan, Ann Arbor, MI; [4]Duke University and Durham VA Hospitals, Durham, NC; [5]University of Pennsylvania, Philadelphia, PA; [6]IYM Health Financial Services, LLC, Durham, NC; [7]The Ohio State University, Columbus, OH; [8]Emory University, Atlanta, GA; [9]Duke University Medical Center, Durham, NC; [10]Duke University, Durham, NC; [11]Louis Stokes Cleveland Veterans Affair Medical Center, Cleveland, OH; [12]National Cancer Institute, Bethesda, MD*.

Background: The establishment of computational image analysis has uncovered inconsistency in quality of whole slide images (WSI) across pathology laboratories, due to pre-analytic (fixation and tissue processing) and analytic (cutting, staining and scanning) variations. While pathologists train themselves to read through artifacts, computational pathology systems are not trained to adjust to such variability. Our group developed a pipeline aided by an open-source computer-based quality control tool (HistoQC) to identify heterogeneity, qualify WSI for computational image analysis (see Figure 1-A), and output tissue masks (see Figure 1-B) that exclude the artifacts. The aim of this study is to test whether HistoQC can efficiently and reliably qualify WSI based on artifact detection.

Methods: 1814 WSIs (458 H&E, 470 PAS, 438 silver, 448 trichrome) from 512 NEPTUNE digital renal biopsies were analyzed by HistoQC and reviewed for disqualification. Disqualified (extreme outliers) WSIs and 10% of the qualified WSIs, randomly selected, were manually scored by 2 reviewers for the presence of glass slide, tissue, and scanning artifacts. Principal component analysis (PCA) of HistoQC metrics and logistic regression was used to evaluate the association between HistoQC and human assessment.

Results: 151 WSIs were considered extreme outliers by HistoQC. Only 318 (151 disqualified + 167 qualified) of the 1814 WSIs required human review. PCA components based on HistoQC metrics demonstrated good to strong prediction of human identified artifacts (C-index range 0.64-0.83, see Figure 1-C).

Conclusions: HistoQC can aid in the identification of pre-analytic and analytic artifacts and of variations in WSI presentation. Furthermore, this pipeline may enable efficient curation of digital pathology repositories and reduce computational image analysis variability.

Assessment of Renal Function by Advanced Light Sheet Microscopy and 3D Image Analyses: Quantification of Albumin Filtration/Reabsorption at the Single-Nephron Level in Rodents

Mette V. Østergaard, Urmas Roostalu, Annemarie A. Pedersen, Tanja X. Pedersen, Lisbeth N. Fink, Jacob L. Skytte, Niels Vrang, Jacob Hecksher-Sørensen. *Gubra ApS, Hørsholm, Denmark*.

Background: Drug development in diabetic kidney disease (DKD) and chronic kidney disease (CKD) is halted by poor translatability of preclinical animal models. Using 3D imaging techniques, we aimed to develop a new method for quantification of renal function, glomerular filtration and proximal tubular albumin absorption to assess the morphology and functionality of populations of single nephrons in preclinical rodent models of kidney disease.

Methods: Healthy mice and rats as well as 5/6 nephrectomised (Nx) rats were perfused with fluorescently labelled lectin, albumin, and 10 kDa dextran under terminal anesthesia, and intact kidneys were cleared for scanning by light sheet microscopy (LSM). Using 3D image analysis, distribution of glomerular size and nephron morphometry were determined, while proximal tubular albumin absorption was quantified based on albumin-intensity. To characterize kidney function using standard methodologies, 2D histology, plasma, and urine analyses were applied.

Results: In healthy mice and rats, LSM and 3D nephron reconstruction revealed intact nephrons with glomeruli connected to proximal then distal tubules extending from the cortex into the medulla. Juxtaglomerular proximal tubules were clearly delineated by tubular epithelial cells that were fluorescently labelled by absorbed albumin and followed by tubular epithelial cells labelled by dextran. In sharp contrast, imaging analyses suggested functional defects in the kidney remnants of 5/6 Nx rats. Nephrons in 5/6 Nx rats appeared fragmented and with limited tubular absorption of albumin and dextran, which obstructed tubular tracking from the cortex to the medulla. These findings were corroborated by albuminuria, plasma urea and creatinine, and 2D renal histopathology in 5/6 Nx vs sham-operated rats.

Conclusions: Development of advanced microscopy and 3D imaging technologies allows for assessment of renal function at a single-nephron level and by characterization of populations of single nephrons. Thereby, this 3D imaging technique can support 2D end-point histological analyses and functional endpoints in rodent models to refine the use of rodent models to study disease mechanisms and test novel therapies for DKD and CKD.

FR-OR099

Visualizing the N-Linked Glycome within Human Kidney Biopsies Using Mass Spectrometry Imaging

Christopher R. Anderton,[1,2] Dusan Velickovic,[1] Guanshi Zhang,[2] Arunima Bhattacharjee,[1] Ljiljana Pasa-Tolic,[1] Theodore Alexandrov,[3] Kumar Sharma.[2] for the KMPM Consortium *[1]Pacific Northwest National Laboratory, Richland, WA; [2]University of Texas Health San Antonio, San Antonio, TX; [3]European Molecular Biology Laboratory, Heidelberg, Germany*.

Background: The current study is a part of the NIDDK Kidney Precision Medicine Project (KPMP). The observed alterations in protein glycosylation attributed to disease development has stemmed major interest in studying glycans (e.g., higher HbA1c in type 1 diabetes is associated with changes in the serum N-glycome). Currently, a limited number of methods are available for interrogating clinical tissue samples for variations in protein glycosylation. An emerging approach is on-tissue enzymatic N-glycan releasing (OtER) followed by matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI), which positionally conserves the location of N-glycan moieties and allows their composition to be registered to histological information. This method can be performed on archival, formalin-fixed paraffin-embedded (FFPE), clinical sample tissue.

Methods: We optimized the OtER MALDI-MSI workflow on FFPE preserved health human biopsy tissue provided by the KPMP. Tissue was sectioned and mounted on conductive glass slides, deparaffinized by washing with xylenes, rehydrated with EtOH:H_2O solutions, and then antigen retrieved (citraconic buffer). On-tissue application of Peptide-N-Glycosidase F was applied with a robotic sprayer, followed by incubation in a humidified environment (40 ºC). Finally, matrix (cyanohydroxycinnamic acid) was applied to samples and MALDI was performed.

Results: Several high mannose, hybrid, and paucinomannose N-glycans were spatially detected in the human kidney tissue, and many showed co-localization with different histological features, as revealed through pre- and post-MALDI autofluorescence and H&E images. MALDI performed using the high mass resolution 15T Fourier transform ion cyclotron resonance MS gave confident matches of N-glycans in the ChEBI database and with those previously reported. We were able to separate isomeric N-glycans using pre-mass analysis ion mobility separation in our MALDI-MSI method.

Conclusions: This highlights the value of using this workflow for mapping the N-glycome, where the location of species can be registered to different anatomical compartments and cell types within the human kidney. We anticipate this method can provide the ability to distinguish diseased from healthy kidney biopsies, by identifying aberrant N-glycosylation patterns.

Iterative Indirect Immunofluorescence Imaging for Tissue (4iT): The First Step Towards Spatial Proteomic Maps

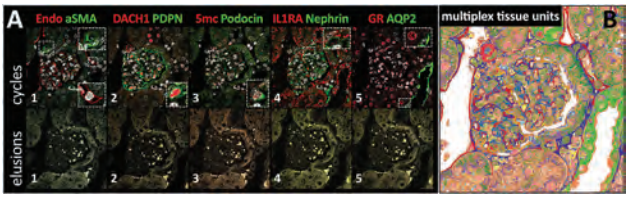
Victor G. Puelles,[1] Lukas Gernhold,[1] Jacobo Sarabia del Castillo,[2] Catherine Meyer-Schwesinger,[3] Ann-Christin Gnirck,[1] Fabian Braun,[1] Jan-Eric Turner,[1] Lucas Pelkmans,[2] Tobias B. Huber.[1] *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]University of Zurich, Zurich, Switzerland; [3]University of Hamburg, Hamburg, Germany*.

Background: With the rapid development of multi-omics techniques, there is an increasing need for methods that can localize proteins with high spatial resolution. This is particularly important in a complex system like the kidney; where a large number of interacting cell-types coexist.

Methods: We present 4iT, a new method for highly multiplexed protein measurements in paraffin-embedded tissue based on the principle of cyclic immunolabelling, including conventional indirect immunofluorescence, high-resolution fluorescence imaging, and elusion of primary and secondary antibodies. Five glomeruli and periglomerular spaces were serially imaged per mouse (n=4 controls and n=8 crescentic glomerulonephritis) for a total of 40 cycles (1 antibody per cycle). Multiplexed protein maps were generated using an in-house unsupervised integration tool based on artificial neural networks that identified shared and unique pixel profiles.

Results: We successfully identified endothelial cells, mesangial cells, basement membranes, podocytes, parietal epithelial cells, proximal tubuli, collecting ducts, immune cells, fibroblasts, innervation, subcellular units (ie. lysosomes, ER and mitochondria), and dynamic changes of extracellular matrix, integrins, tight-junctions, extra/intracellular receptors, phosphorylation sites, cell activation, and post-translational modifications. Multiplexed protein maps generated functional/pathological clusters based on proximity profiles.

Conclusions: 4iT can be used to identify functionally relevant single-cell states in paraffin-embedded tissue, providing a new roadmap for molecular tissue analysis with high spatial resolution, and thereby personalized medicine.



4iT generates complex proteomic maps with high spatial resolution. (A) Example of 5 cycles with a total of 10 proteins identified in different kidney cells - first row shows stainings and second row shows the same glomerulus after elusion. (B) Proteomic map after deep learning and cluster/proximity analyses.

FR-OR101

Effect of Automated Wearable Artificial Kidney (AWAK) Device on Toxin Clearance and Safety in Peritoneal Dialysis Patients

Marjorie W. Foo,[1] Htay Htay,[1] Sheena Gow,[2] Mandar Gori,[2] Mathini Jayaballa,[1] Siti N. Huda,[2] Jason T. Lim,[2] Elizabeth L. Oei,[1] Suresha B. Venkataraya,[2] Sin yan Wu.[1] *[1]Singapore General Hospital, Singapore, Singapore; [2]AWAK Technologies Pte Ltd, Singapore, Singapore*.

Background: Patients undergoing dialysis face mobility and logistic challenges due to limited progress in dialysis technological advancement. Dialysate regeneration through use of sorbent technology led to the development of Automated Wearable Artificial Kidney Peritoneal Dialysis (AWAK PD) device.

Methods: The first-in-human (FIH) study was conducted in Singapore between March 2016 and October 2018. The study aimed to evaluate safety of AWAK PD in 15 prevalent peritoneal dialysis (PD) patients who underwent up to 9 AWAK PD therapies over 3-4 consecutive days. Incidence of adverse event was monitored and serum and dialysate samples were collected. Study also aimed to examine weekly peritoneal urea. Patients were followed up weekly up to a month.

Results: Of 15 patients with median age 65.5 [Range Min, Max: 35, 73] years, male (67%), Chinese (80%), presence of coronary artery disease (27%), anuria (33%), with a median PD duration of 21 [4-147] months, none experienced any serious adverse events during or post AWAK PD therapy. The reported adverse events included abdominal discomfort (71%), presence of fibrin in the drain (36%) and bloating (36%). There was no significant difference in pre and post therapy weight. All patients who completed at least 1 valid therapy (n=14) achieved weekly peritoneal $Kt/V_{urea} \geq 1.7$ with median weekly peritoneal Kt/V_{urea} =3.04 [IQR: 2.19-4.75]. Significant reduction in solute concentrations was observed with AWAK PD therapy **(Table 1)**. Stable serum sodium (136[134-139] mmol/L), potassium (4.0[3.6-4.4] mmol/L), and bicarbonate (24.2[23.1-25.5] mmol/L) levels were reported during the study.

Conclusions: This FIH study showed that AWAK PD device was shown to be safe on 15 PD patients with appropriate solute clearance and no observed water retention.

Funding: Commercial Support - AWAK TECHNOLOGIES PTE LTD, Government Support - Non-U.S.

Inhibition of Hyperglycolysis in Mesothelial Cells Prevents Peritoneal Fibrosis

Meijun Si,[1,2] Wenbo Zhao,[1] Yin Li,[1] Hongchun Lin,[1] Tan-qi Lou,[1] Zhaoyong Hu,[2] Hui Peng.[1] *[1]The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [2]Baylor College of Medicine, Houston, TX*.

Background: Progressive peritoneal fibrosis is a dreaded problem for patients receiving peritoneal dialysis (PD) because it has no reliable treatment. There also are disagreements about the identification of mechanisms that initiate and sustain peritoneal fibrosis. To overcome these problems, we developed a strategy that prevents peritoneal fibrosis by suppressing PD-stimulated mesothelial to mesenchymal transition (MMT).

Methods: We evaluated single-cell transcriptomes of mesothelial cells obtained from normal peritoneal biopsy and effluent from PD-treated patients. We then examined the metabolic reprogramming in the peritoneal fibrogenesis in mouse model and mesothelial cells using metabolomics and cellular respiration tests. We finally developed a triad of AAV1 encoded microRNA therapy, and evaluated its therapeutic potential to treat peritoneal fibrosis.

Results: We analyzed 96,446 single cell transcriptomes including cells dissociated from normal peritoneum, peritoneal cells from effluent of short-term PD and from

long-term PD patients. We found the expression of glycolytic enzymes was increased during the development of MMT. Using gene expression profiling and metabolomics analyses, we confirmed that PD fluid induces metabolic reprogramming, characterized as hyperglycolysis in peritoneum. We found that transforming growth factor β1 (TGF-β1) can substitute for PD fluid to stimulate hyperglycolysis. The mechanism involves suppressing mitochondrial respiration in mesothelial cells. Blockade of hyperglycolysis with 2-deoxy-glucose inhibited PD fluid-induced profibrotic cellular phenotype and fibrogenesis in mice. We developed a triad of adeno-associated viruses that overexpresses microRNA-26a and microRNA-200a plus inhibitor of microRNA-21a, which targets both hyperglycolysis and fibrotic signaling. Intraperitoneal injection of the viral triad in mice significantly inhibited the development of peritoneal fibrosis induced by PD fluid.

Conclusions: We conclude that hyperglycolysis is responsible for MMT and peritoneal fibrogenesis. This aberrant metabolic state can be principally corrected by modulating microRNA levels in the peritoneum. These results could provide a novel therapeutic strategy to combat peritoneal fibrosis.

Identifying MiRNA Biomarkers for Diagnosis of Encapsulating Peritoneal Sclerosis

Chiu-Ching Huang,[1] Nianhan Ma,[2] An-Lun Li,[2] J. B. Chen,[3] Chin Chung Tseng.[4] Taiwan EPS Consortium *[1]China Medical University and Hospitals, Taichung, Taiwan; [2]National Central University, Zhongli District, Taiwan; [3]Chang Gung Memorial Hospital-Kaohsiung, Kaohsiung Hsien, Taiwan; [4]National Cheng Kung University Hospital, Tainan, Taiwan.*

Background: Encapsulating peritoneal sclerosis(EPS) is a serious complication of chronic peritoneal dialysis (PD). Late diagnosis is associated with high mortality. With the advance of new diagnostic technology, such as microRNA (miRNA), we attempted to develop a non-invasive test to assist the diagnosis of EPS.

Methods: We examined miRNAs expression profiles of PD fluids from patients with or without EPS by high-throughput and quantification real-time PCR array. We used the high-throughput miRNA array cards as primary screen tool for analysis. The analysis of miRNA was conducted using the Running TaqMan® Low Density Arrays on Vii7 RealTime PCR Systems. Candidate miRNAs were selected to verify in another group of patients by single qRT-PCR assay. The model for EPS prediction was developed by multiple logistic regression.

Results: We collected overnight PD fluids from 72 non-EPS (controls) and 25 EPS patients. The **screening set** included PD fluids from 28 patients (20 of non-EPS vs. 8 of EPS-ongoing cases). We compared the ratio values of two miRNA expression levels between EPS and non-EPS samples. Eight candidate miRNAs were selected. The **training set** was conducted using 69 samples (52 of non-EPS vs 17 of EPS-ongoing) to produce the good area under curve (AUC) value of diagnostic miRNA classifier. The miRNA combination ratios with the top five ROC values were selected to calculate the combined AUC by logistic regression. The value of AUC to distinguish EPS from non-EPS with five miRNAs in PD fluid was 0.9723 (Figure 1). From results of the training set, six different miRNA expressions and two ratios of two miRNA expressions in the PD fluid showed significant difference between EPS and non-EPS patients.

Conclusions: We identify a miRNA classifier with the combination of top five miRNAs' expression in PD fluids to assist the diagnosis of EPS.

Funding: Government Support - Non-U.S.

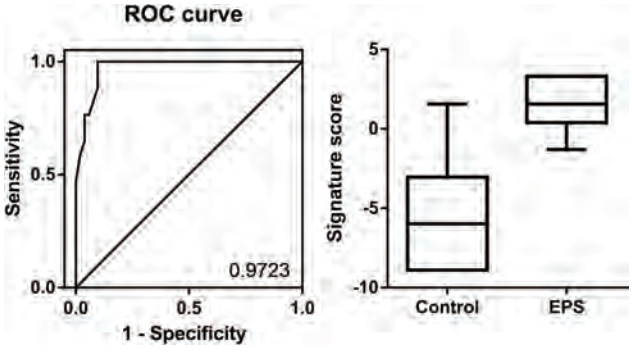

Figure 1. The ROC analysis of the EPS miRNA classifier with the combination of top five miRNAs expressions and the box plots showed that the score of non-EPS and EPS miRNA classifier distribution.

Lung Ultrasound B-Lines and Oxygen Status in Automated Peritoneal Dialysis Patients

Christos Argyropoulos,[1] Maria-Eleni Roumelioti,[1] Zhi Xu,[1] V. Shane Pankratz,[2] Mark L. Unruh.[1] *[1]University of New Mexico, Albuquerque, NM; [2]UNM Health Sciences Center, Albuquerque, NM.*

Background: Patients undergoing automated PD (APD) are frequently fluid overloaded, while anuric dialysis patients with low fluid removal depict uncontrolled hypertension, LVH and worse survival. In this report, we aim to explore the correlation of overhydration (B-lines) as detected using lung ultrasound (LUS) in APD patients with their vital signs and weight.

Methods: Fourteen chronic APD patients were recruited at the Dialysis Clinic Inc. (DCI) PD center in Albuquerque, NM and completed their first visit of the pilot study LUMIFY-PD (Lung Ultrasonography to Measure Interstitial Fluid in Your Peritoneal Dialysis patients). Demographics, personal history, and laboratory values were collected from their electronic medical records. A pre-trained physician performed LUS with a handheld scanner (Phillips©Lumify, 2-5 MHz phased-array probe). Examination of the anterolateral chest was performed with longitudinal LUS scans (28 total sectors per exam, supine position). LUS exams were scored for the presence and number of B-lines.

Results: Study participants had a mean age of 41.5 (± 3.4) years and were mostly males (52.9%), whites (57.1%) and Hispanics (50%). They were on PD for a mean of 9.9 (± 7.3) months. The two main causes of kidney disease were DM and hypertension. 57% exhibited at least 1 B-line in their LUS while 21.4% had mild lung congestion (at least 3 B-lines) (Figure). All patients with detectable B-lines had normal physical exams. A statistically significant correlation was found between age and number of antihypertensives (p=0.05) as well as between number of B-lines in LUS and % of arterial oxygen saturation (p=0.002). A negative correlation was found between number of B-lines and residual renal function volume (Pearson correlation -0.65).

Conclusions: In this report the number of LUS B-lines correlated with oxygen saturation and residual renal function volume. Larger studies are needed. Portable LUS can optimize the assessment of prescribed "dry weight" and thus improve outcomes of incident APD patients.

FR-OR105

Initiation of Peritoneal Dialysis in Patients with Cardiorenal Syndrome Reduces Subsequent Hospitalization

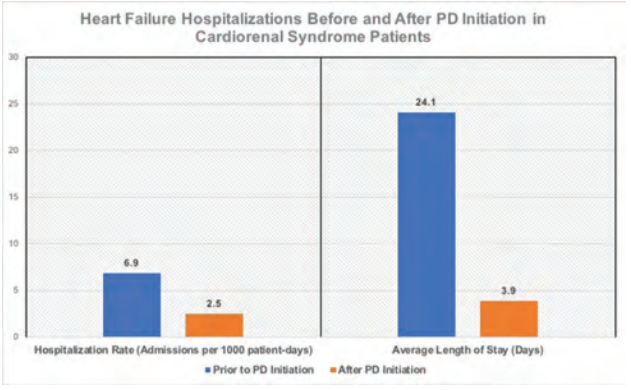
Bourne L. Auguste,[3,1] Ali Z. Ibrahim,[2,1] Michael Y. Girsberger,[2,1] Zita C. Abreu,[2] Arnav Agarwal,[1] Rory F. McQuillan,[1] Joanne M. Bargman.[2,1] *[1]University of Toronto, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Background: Inotropic dependence and diuretic resistance in patients with cardiorenal syndrome (CRS) leads to frequent hospitalizations and is associated with high mortality. Peritoneal dialysis (PD) offers a smoother hemodynamic profile with effective volume removal for these patients. There is little data on this approach in the North American literature. The aim of our study was to determine if volume overloaded CRS patients on maximal doses of diuretic therapy had reduced heart failure hospitalization following PD initiation.

Methods: We reviewed CRS patients receiving a bedside catheter and starting PD urgently within 2 weeks of insertion at the University Health Network from January 1, 2013 to December 31, 2018. Data for heart failure-related hospitalizations and length of stay 6 months before and after PD initiation was collected. Patients who died, switched to hemodialysis or were transferred to another facility within 6 months of starting PD were excluded from analysis of the hospitalization rates.

Results: We identified 31 CRS patients who had a beside PD catheter inserted. The average age of patients was 66.0 ± 13.0 years. There were 7 (22.6%) deaths and 4 (12.9%) transfers to other programs or hemodialysis within 6 months of catheter insertion. After exclusion, we analyzed the hospitalization and length of stay data for 20 patients. The hospitalization rate 6 months prior to PD initiation was 6.9 admissions per 1000 patient-days. This decreased to 2.5 admissions per 1000 patient-days after PD initiation (Figure 1). Additionally, there was also a striking reduction in the average length of stay (24.1 to 3.9 days; p= .001).

Conclusions: Volume overloaded CRS patients receiving maximal diuretic therapy have lower hospitalization rates and shorter stays after PD initiation. Adopting quality improvement strategies such as bedside PD catheter insertions can serve as a means to facilitate acute start dialysis in this population.



FR-OR106

Associations Between Body Mass Index, Kt/V, and Outcomes Among Patients Treated with Peritoneal Dialysis

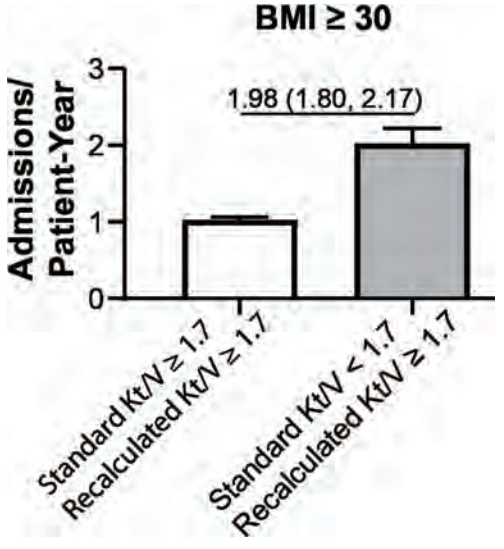
Scott Sibbel,[1] Dena E. Cohen,[1] Carey Colson,[1] Francesca Tentori,[1] Steven M. Brunelli,[1] Martin J. Schreiber.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita, Inc, Denver, CO.*

Background: Among patients treated with peritoneal dialysis (PD), achievement of Kt/V ≥ 1.7 indicates adequate dialysis. The volume of urea distribution (V) is based on bodyweight. Because the water content and metabolic activity of fat mass differ from that of lean, V may be over-estimated in obese patients, such that Kt/V under-estimates adequacy. Recalculation of V based on lean body mass might enable more accurate estimation of dialysis adequacy in such patients.

Methods: Data were derived from deidentified records of adults (body mass index [BMI] 15-45 kg/m^2) who initiated PD with a large dialysis organization Jan 2016 – June 2018. Patients were followed from PD start until death, censoring, or study end (Dec 2018). Kt/V was calculated on the basis of bodyweight or estimated lean body mass. Associations between time-updated values of BMI, Kt/V, and outcomes were estimated using Poisson models that included an interaction term for BMI and Kt/V.

Results: At baseline, among 16,443 patients, mean BMI was 28.1 ± 5.8 kg/m^2, Kt/V was 2.4 ± 0.7, and 16.1% of patients had Kt/V < 1.7. Across BMI categories, lower Kt/V was associated with higher hospitalization rate; no interaction between Kt/V and BMI was observed (p>0.05). Similar results were obtained when Kt/V was recalculated on the basis of estimated lean body mass. Among patients with BMI≥30 and recalculated Kt/V ≥ 1.7 but standard Kt/V < 1.7, hospitalization rates were 1.98-fold (95% confidence interval 1.80 – 2.17) higher than among patients with Kt/V ≥ 1.7 by both measures.

Conclusions: Associations between Kt/V and outcomes do not differ on the basis of BMI. Calculation of Kt/V on the basis of estimated lean body mass may over-estimate dialysis adequacy, with potential negative consequences for patient outcomes.



FR-OR107

Prognostic Significance of Carotid Plaque Presence in Peritoneal Dialysis Patients and Its Association with the Apolipoprotein B/Apolipoprotein A1 Ratio

Yun Chen,[1] Da Shang,[1] Shuqi Dai,[1] Chuan-Ming Hao,[2] Tongying Zhu.[1] *[1]Huashan hospital, Fudan university, Shanghai, China; [2]Huashan Hosp., Shanghai, China.*

Background: Atherosclerosis has been reported as a risk factor for cardiovascular disease in the general population. As a phenotype of atherosclerosis, carotid plaque and its influence factors are rarely discussed,especially among dialysis patients. The study aimed to investigate the prognosis-predictive significance of carotid plaques in patients on peritoneal dialysis (PD), and explore risks factors for carotid plaque presence.

Methods: It was designed as an observational, prospective study. Patients that had undergone stable peritoneal dialysis for at least 3 months were recruited and divided into two subgroups: group with carotid plaques and group without carotid plaques. Cox regression model was used to identify independent predictors of all-cause mortality, cardiovascular events and cardiovascular mortality. Risk factors correlated to the plaque-occurrence were explored by logistic regression and verified by receiver operating characteristic curve (ROC) analysis.

Results: A total of 233 PD patients (141 men) with a mean age of 56.4±16.1 years were recruited. The cohort was followed for up to 86 months (median: 36.3 months; interquartile range: 21.3 months). In the multivariable Cox regression analysis, the carotid plaque presence turned out to be an independent risk factor both of cardiovascular events (HR:2.420; 95%CI:1.157-5.064; p=0.019) and cardiovascular mortality (HR:3.346; 95%CI:1.079-10.375; p=0.036). Multivariable logistic regression showed that the apolipoprotein B/apolipoprotein A1 ratio was significantly associated with the presence of carotid plaques. ROC analysis indicated that the AUC of the apoB/apoA1 ratio was 0.640, and it was higher than that of the traditional lipid metabolism index, the non-HDL-C/HDL-C ratio (p=0.012).

Conclusions: Carotid plaque presence can predict cardiovascular events and cardiovascular mortality in PD patients. The ApoB/ApoA1 ratio is significantly correlated to the plaque presence and it can be a more sensitive monitoring marker for predicting the presence of carotid plaques in this population than traditional lipid metabolism parameters.

FR-OR108

Peritoneal Dialysis (PD) Modality and Interference in Daily Life: Results from the PDOPPS

Thyago P. Moraes,[1] Junhui Zhao,[2] Douglas S. Fuller,[2] Keith McCullough,[2] Brian Bieber,[2] Bruce M. Robinson,[2] Ronald L. Pisoni,[2] Simon J. Davies,[3] Jeffrey Perl.[4] on behalf of PDOPPS Dialysis Prescription and Fluid Management working group *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University Hospital of North Midlands, Stoke-on-Trent, United Kingdom; [4]St. Michael's Hospital, Toronto, ON, Canada.*

Background: Patient-reported outcomes (PROs), including quality of life and life participation activities, are important considerations for patients receiving peritoneal dialysis. The relative effects of automated (APD) vs. continuous ambulatory (CAPD) modalities on PROs remain controversial.

Methods: We analyzed cross-sectional clinical and patient-reported data from the PD Outcomes and Practice Patterns Study (PDOPPS; 2014-2017; Australia, Canada, Japan, New Zealand, UK, US). Patients rated dialysis interference with 9 aspects of daily life on a 7-point Likert scale. Linear and logistic regressions were used to estimate associations of PD modality with the interference item scores (mean and grouped as response levels 4-6 vs 0-3), KDQOL Mental Component Summary (MCS), Physical Component Summary (PCS) scores, and the 10-item CES-D depression screening scale (scale scores grouped as ≥10 vs <10), adjusted for demographic, comorbidity, and treatment variables.

Results: The analysis included 1800 APD and 892 CAPD patients. After adjustment, APD (v. CAPD) patients had 0.04 higher mean interference score (95% CI=-0.09, 0.18), 0.05 lower MCS (-1.19, 1.09), 0.73 lower PCS (-1.73, 0.26), and 1.17 (0.94, 1.45) higher odds of CES-D ≥10 vs <10. APD (v. CAPD) patients reported less interference with employment (adjusted OR=0.83, 95% CI=0.62-1.12) and total PD time (0.86, 0.68-1.08), and greater interference with intimacy (1.18, 0.96-1.46) and the lives of family/friends (1.36, 1.09-1.70).

Conclusions: Summary PROs were generally similar for APD and CAPD patients, potentially due to non-randomized modality choice. However, domain specific differences in interference scores were observed that may be informative for patients when choosing PD modality type. Across both modalities, PD appears to interfere for the majority in domains of travel and employment suggesting that these are important areas to reduce the overall interference of PD with life activities.

International PD Training Practices and the Risk of Peritonitis

Jeffrey Perl,[2] Douglas S. Fuller,[1] Neil Boudville,[6] Yasuhiko Ito,[8] Talerngsak Kanjanabuch,[7] Beth M. Piraino,[5] Ronald L. Pisoni,[1] Cheuk-Chun Szeto,[3] Isaac Teitelbaum,[9] Graham Woodrow,[10] David W. Johnson.[4]
[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]The Chinese University of Hong Kong, Shatin, China; [4]Princess Alexandra Hospital, Brisbane, QLD, Australia; [5]University of Pittsburgh, Pittsburgh, PA; [6]University of Western Australia, Nedlands, WA, Australia; [7]Chulalongkorn University, Bangkok, Thailand; [8]Aichi Medical University, Nagakute, Aichi, Japan; [9]University of Colorado, Aurora, CO; [10]Renal Unit, St James University Hospital, Leeds, United Kingdom.

Background: Patient training for peritoneal dialysis (PD) is vital in reducing the risk of complications, including PD-related peritonitis. We describe variation in training practices across countries and assess their impact on peritonitis risk.

Methods: Using Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS; 2014-2017) data from Australia and New Zealand (A/NZ), Canada (CA), Japan (JP), Thailand (TH), the UK, and the US (non-large dialysis organization facilities), we report variation in facility-reported PD training practices and estimate associations with peritonitis using proportional rates models adjusted for patient and facility factors.

Results: 183 out of 204 facilities with peritonitis data available returned a PDOPPS Unit Practices Survey (US, n=83; other, n=14-26). Nearly all facilities reported using unit-affiliated training nurses only (UK, 72%; other, >95%), a standard training curriculum (UK, 65%; JP, 79%; other, >90%), individualized training (TH, 41%; other, >88%) and a single nurse per patient (JP, 28%; A/NZ, 71%; other, >89%). All facilities required successful technique demonstration; 50% (US, 88%; other, 4-36%) required a written test, and 55% (CA, JP, UK, 24-40%; A/NZ, TH, US: 57-70%) required an oral test. Peritonitis rate was associated with the timing of training relative to catheter insertion (HR=1.12 [95% CI=0.87, 1.44], HR=1.34 [1.04, 1.72], and HR=1.47 [1.11, 1.96] for 1, 2, or 3 weeks after catheter insertion, respectively, vs. prior to insertion; p<0.01 for trend) and longer duration of training (HR=1.04 [0.86, 1.24] and HR=0.84 [0.69, 1.02] for 4-5 and ≥6 days, respectively, vs. 2-3 days; p=0.06 for trend).

Conclusions: Variation in PD training practices was seen across PDOPPS countries. Given the patient-centered nature of PD, earlier and longer training periods may reduce peritonitis risk.

FR-OR110

Combination of Once Weekly Hemodialysis with Peritoneal Dialysis Is Associated with Lower Mortality Compared with Peritoneal Dialysis Alone: A Longitudinal Study

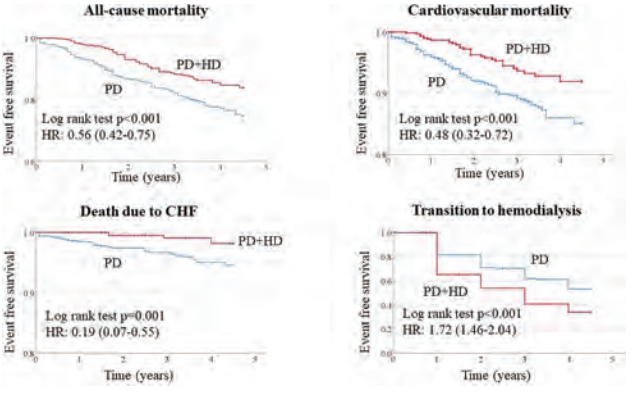
Miho Tagawa,[1] Takayuki Hamano,[3] Masanori Abe,[2] Ikuto Masakane.[4]
[1]Nephrology, Nara Medical University, Nara, Japan; [2]Nihon University School of Medicine, Tokyo, Japan; [3]Osaka University Graduate School of Medicine, Suita, Japan; [4]Honcho-Yabuki Clinic, Yamagata, Japan.

Background: Combination of once weekly hemodialysis with peritoneal dialysis is a unique type of renal replacement therapy available in Japan. Outcomes of this therapy compared with peritoneal dialysis alone has not been reported in a large cohort.

Methods: This is a longitudinal study based on Japanese Renal Data Registry (JRDR). Those on peritoneal dialysis from 2010 to 2014 in the JRDR database were included. The end of observation period was at the end of 2015. Exposure of interest was combination of once weekly hemodialysis with peritoneal dialysis compared with peritoneal dialysis alone. Outcomes were all-cause mortality, cardiovascular mortality, and death due to congestive heart failure. Those who initiated combination therapy from 2011 to 2014 were matched with those on peritoneal dialysis alone by propensity score derived from the data of previous year. The data were analyzed using Kaplan-Meier curves and Cox regression models.

Results: Six hundred and eight patients on combination therapy were matched with 869 on peritoneal dialysis alone. During median follow-up of 2.5 years, there were 224 death, 123 cardiovascular death, and 35 death due to congestive heart failure. All-cause mortality (HR [95% CI]: 0.56 [0.42-0.75]), cardiovascular mortality (HR: 0.48 [0.32-0.72]), and death due to congestive heart failure (HR: 0.19 [0.07-0.55]) were significantly lower among combination therapy group. Transition to hemodialysis was significantly earlier in combination therapy group (HR: 1.72 [1.46-2.04]). There was no effect modification by age, dialysis vintage, diabetic status, or baseline urine volume. The decrease in body weight was larger in combination group (p<0.001 by mixed effects model) in combination therapy group, suggesting better fluid removal.

Conclusions: Combination of once weekly hemodialysis with peritoneal dialysis was associated with lower mortality compared with peritoneal dialysis alone.



FR-OR111

Aptamer-Based Plasma Proteomic Profiling Reveals Candidate Proteins Associated with Slow or No Renal Decline in CKD Stage 3 Diabetic Patients

Zaipul I Md Dom,[1,2] Eiichiro Satake,[1,2] Jan Skupien,[3] Katsuhito Ihara,[1,2] Andrzej S. Krolewski.[1,2]
[1]Research Division, Joslin Diabetes Center, Boston, MA; [2]Department of Medicine, Harvard Medical School, Boston, MA; [3]Jagiellonian University Medical College, Krakow, Poland.

Background: Patients with diabetes and chronic kidney disease (CKD) stage 3 are at high risk of developing end-stage renal disease (ESRD). However, the rate of renal decline leading to onset of ESRD varies tremendously among these patients. This study aimed to identify biomarkers associated with slow or no renal decline (slow decliners) in two independent cohorts of diabetic patients with CKD stage 3.

Methods: The study comprised an exploratory cohort of 214 individuals with Type 1 diabetes (T1D) with 129 slow decliners, and a replication cohort of 144 individuals with Type 2 diabetes (T2D) with 96 slow decliners. Both cohorts were followed for 7-10 years. Serial measurements of serum creatinine were used to estimate the rate of eGFR decline. Slow renal decline was defined as eGFR slope of ≥ –5 ml/min/year. Baseline plasma specimens were assayed by the SOMAscan proteomics platform. Relationships of plasma proteins with eGFR slopes were evaluated based on Spearman's rank correlation coefficients. Multivariable logistic regression models investigated the odds ratio (OR) between plasma proteins and being a slow decliner.

Results: In slow decliners, the median (25th, 75th percentiles) eGFR slope was -2.4 (-3.5, -1.3) and -1.8 (-3.1, -0.1) ml/min/year in T1D and T2D cohorts, respectively. In the exploratory cohort, 76 plasma proteins were significantly and positively associated with eGFR slope (FDR P<0.005). Eighteen of these proteins were replicated in the T2D cohort (P<0.05). Multivariable logistic analyses in the combined cohorts with T1D and T2D demonstrated that all proteins were significantly associated with slow renal decline in models adjusted for type of diabetes, eGFR and HbA1c. In models further adjusted for

TNF-R1, the ORs remained statistically significant for 11 of the 19 proteins. TNFSF12 (OR (95% CI): 1.46 (1.2, 1.9), *P*=0.0017) was the most significant independent predictor of slow or no renal decline with higher TNFSF12 plasma levels protecting against progressive renal decline.

Conclusions: Our findings suggest that several circulating plasma proteins are associated with slow or no renal decline in both types of diabetes, and these proteins may represent new targets that can be used therapeutically for slowing the progression of renal function decline.

Notch Signaling Proteins as Key Factor in the Progression to ESRD in Diabetes

Hiroki Kobayashi, Eiichiro Satake, Zaipul I Md Dom, Andrzej S. Krolewski. *Joslin Diabetes Center, Harvard Medical School, Boston, MA.*

Background: It has been reported that Notch signaling proteins might regulate interstitial fibrosis development in the kidneys of mice and humans. The objective of this study was to investigate an association of circulating Notch signaling proteins on the development of ESRD in subjects with diabetes during long-term follow-up.

Methods: Using the modified aptamer-based SomaScan platform, 4 proteins including Notch1, delta like protein 1 (DLL1), delta like protein 4 (DLL4), and Jagged 1 protein (JAG1) were measured in baseline plasma specimens obtained from 363 Caucasian subjects with diabetes and CKD stage 3 (CKD3); including 219 with Type 1 diabetes (T1D) and 144 with Type 2 diabetes (T2D). Additionally, the 4 proteins were also measured in 190 T1D patients with CKD stage 1 and 2 (CKD12). All patients were followed for 10 years to ascertain onset of ESRD.

Results: In Cox regression analysis, DLL1, DLL4, and JAG1 were strongly associated with progression to ESRD in T1D patients with CKD3 ($P=1.6*10^{-10}$, $p=5.1*10^{-8}$, and $p=2.0*10^{-5}$, respectively) and in T2D patients with CKD3 ($p=3.6*10^{-4}$, $p=1.9*10^{-4}$, and $p=6.1*10^{-4}$, respectively). Importantly, this significant association with ESRD for DLL1 and JAG1 were also found in T1D patients with CKD12 ($p=2.8*10^{-6}$ and $p=4.1*10^{-2}$), and DLL1 was the strongest predictor for ESRD in the combined panel, even after adjustment for relevant covariates (Hazard Ratio 1.48, $p=8.4*10^{-6}$) (Table 1).

Conclusions: There were few previous reports about the association between circulating Notch signaling proteins and kidney diseases. Our finding is novel in that circulating ligands for Notch receptors, especially DLL1, are strongly associated with progression to future ESRD. Regulation of the specific circulating Notch ligands could become the new therapeutic targets to retard progression to ESRD in diabetes.

Multicentre Prospective Validation of a Urinary Peptidome-Based Classifier for the Diagnosis of Type 2 Diabetic Nephropathy

Nete Tofte,[1] Morten Lindhardt,[1] Gemma Currie,[2] Marie Frimodt-Moller,[1] Heiko E. von der Leyen,[4] Christian Delles,[2] Harald Mischak,[3] Peter Rossing.[1] PRIORITY Study Group *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Glasgow, Glasgow, United Kingdom; [3]Mosaiques Diagnostics, Sehnde, Germany; [4]Hannover Medical School, Hannover, Germany*.

Background: Diabetic kidney disease (DKD) is a major late complication of diabetes. The 'Proteomic prediction and Renin angiotensin aldosterone system Inhibition prevention Of early diabetic nephRopathy In TYpe 2 diabetic patients with normoalbuminuria trial' (PRIORITY) is the first prospective study to evaluate the early detection of DKD in subjects with type 2 diabetes (T2D) and normal urinary albumin creatinine ratio (UACR) (<30 mg/g) using a urinary proteome-based classifier (CKD273).

Methods: Prospective multicentre observational study. The CKD273 classifier was assessed at baseline. The primary endpoint was development of confirmed microalbuminuria (moderate albuminuria) in 2 of 3 first morning urine samples (UACR >30 mg/g and with ≥30% increase (geometric mean) from baseline). For subjects with estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73m^2 at baseline, development of CKD3: eGFR <60 ml/min/1.73m^2 was a secondary outcome. Mean follow-up time was 2.57 years with a minimum of 7 days and a maximum of 4.33 years.

Results: A total of 1775 participants from 15 centres were included, with 12 % (n=216) of these having a high-risk proteomic pattern. At baseline, participants in the high-risk group were more likely to be men, were older, had longer diabetes duration, lower eGFR and higher UACR than those in the low-risk group (n=1559, p<0.02). Numerical differences were small and univariate regression analyses showed weak associations (R2<0.04) of CKD273 with each baseline variable. Development of persistent microalbuminuria was seen in 28% of high risk and 8.9% of low risk subjects (p<0.0001), resulting in a hazard ratio (HR (95% CI)) of 3.924 (2.902-5.304) in a crude Cox-model; and 2.441 (1.766-3.374, p<0.0001) when adjusted for baseline age, sex, diabetes duration, HbA1c, systolic blood pressure, retinopathy, eGFR and UACR. For development of CKD3, HR (high vs. low risk) was 3.932 (2.811 – 5.499) in a crude model; and 4.089 (2.878 – 5.811, p<0.0001) adjusted.

Conclusions: In normoalbuminuric subjects with T2D, the urinary proteomic classifier CKD273 prospectively predicts progression to microalbuminuria and impaired renal function, independent of clinical characteristics.

FR-OR114

Urinary Biomarkers of Injury and Repair and Risk for Kidney Function Decline or Mortality: Results from VA NEPHRON-D

Teresa K. Chen,[1] Steven G. Coca,[2] Heather Thiessen Philbrook,[3] Hiddo J. L Heerspink,[6] Wassim Obeid,[4] Joachim H. Ix,[5] Chirag R. Parikh.[3] CKD Biomarkers Consortium (BioCon) *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Johns Hopkins University, Newton, MA; [4]John Hopkins University, Baltimore, MD; [5]UCSD, San Diego, CA; [6]University Medical Center Groningen, Groningen, Netherlands*.

Background: Diabetes is the leading cause of ESRD worldwide. Biomarkers of kidney injury and repair may prognosticate diabetic kidney disease beyond that of eGFR and albuminuria.

Methods: Baseline urinary biomarkers of tubular injury and repair (neutrophil gelatinase-associated lipocalin [NGAL], kidney injury molecule-1 [KIM-1], interleukin-18 [IL-18], monocyte chemoattractant protein-1 [MCP-1], chitinase-3-like protein-1 [YKL-40]) were measured by multiplex immunoassays. Using Cox proportional hazards models, we studied the associations of each biomarker with kidney function decline (first occurrence of absolute decrease in eGFR≥30 ml/min/1.73 m^2 if randomization eGFR≥60, relative decrease ≥50% if randomization eGFR<60, or ESRD) and all-cause mortality. Covariates included age, sex, race, BMI, blood pressure, HgbA1c, treatment arm, eGFR, and UACR.

Results: We included 1136 VA NEPHRON-D participants with available baseline urine samples. Mean age was 65 years, 99% were male, mean eGFR was 56 ml/min/1.73 m^2, and median UACR was 840 mg/g. Over a median follow-up of 2.2 years (IQR 1.3, 3.1), 148 (13%) experienced kidney function decline and 103 (9%) died. In unadjusted models, the hazard risk of kidney function decline was ~20-30% higher per two-fold greater baseline level of urine NGAL, IL-18, MCP-1, and YKL-40. These associations attenuated and were no longer significant after adjusting for baseline eGFR and UACR. Higher levels of urine NGAL, MCP-1, and YKL-40 were independently associated with higher risk of death (Table).

Conclusions: Among diabetic individuals with CKD, baseline values of urinary biomarkers of tubular injury and repair were associated with risk of death but not kidney function decline.

Proximal Tubular Uptake of Free Fatty Acid (FFA) by Kidney Injury Molecule-1 (KIM-1) Mediates Tubulointerstitial Damage in Diabetic Kidney Disease (DKD), Which Is Attenuated by a Novel Inhibitor

Yutaro Mori,[1] Amrendra K. Ajay,[1] Jae Hyung Chang,[1] Huiping Zhao,[1,6] Seiji Kishi,[2] Jiahua Li,[1] Pierre Galichon,[1] Craig R. Brooks,[1,3] Sheng Xiao,[4] Venkata Sabbisetti,[1] Suetonia Palmer,[1] Joel M. Henderson,[5] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Division of Renal Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Department of Nephrology, Graduate School of Biomedical Sciences, Tokushima University, Tokushima, Japan; [3]Division of Nephrology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; [4]Center for Neurologic Disease, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [5]Department of Pathology and Laboratory Medicine, Boston University School of Medicine, Boston, MA; [6]Department of Nephrology, Peking University People's Hospital, Beijing, China*.

Background: DKD is associated with tubulointerstitial damage. KIM-1, a scavenger receptor, is the most upregulated proximal tubule protein in many forms of kidney injury. Dyslipidemia is a primary feature of DKD. We hypothesized that KIM-1-mediated uptake of FFAs contributes to tubulointerstitial damage in DKD.

Methods: Human DKD renal biopsy samples were analyzed. Renal epithelial cells expressing KIM-1 (LLC-PK1 cells overexpressing KIM-1, and mouse and human primary cells) were exposed to palmitate followed by measurement of FFA uptake, cell death and pro-inflammatory and pro-fibrotic effects determined *in vitro*. To clarify the role of FFA uptake by KIM-1 *in vivo*, a DKD model induced by unilateral nephrectomy, streptozotocin and high fat diet (UNx-STZ-HFD) was studied in wild-type (WT) or KIM-1$^{\Delta mucin}$ (functional knockout of KIM-1) mice. A second new model was created whereby KIM-1 was upregulated by aristolochic acid and the effect of subsequent injection of FFA was determined (AA-FFA model). An inhibitor for KIM-1-mediated endocytosis was screened from >14,000 compounds and tested both *in vitro* and *in vivo*.

Results: KIM-1 expression in DKD patients was positively correlated with tubulointerstitial inflammation and fibrosis. FFA was taken up by the WT-KIM-1 expressing cells causing IL-1β production through activation of inflammasomes and cell death. Conditioned media from FFA-treated WT cells stimulated greater αSMA expression in mouse fibroblasts, than did media from KIM-1$^{\Delta mucin}$ cells. In the UNx-STZ-HFD model, WT mice showed greater proximal tubular atrophy, macrophage infiltration, fibrosis and albuminuria than KIM-1$^{\Delta mucin}$ mice. In the AA-FFA model, WT mice showed more macrophage infiltration, αSMA expression and loss of brush border than KIM-1$^{\Delta mucin}$ mice. Both *in vitro* and *in vivo* our newly identified compound prevented FFA uptake and injury only on WT, not on KIM-1$^{\Delta mucin}$.

Conclusions: KIM-1 mediates the proximal tubular uptake of FFA, leading to pro-inflammatory and pro-fibrotic responses and increase in cell death. Our findings support the role of KIM-1 as a target for DKD and introduce a new candidate therapeutic agent.

A Metabolomics-Based Pathway Analysis for How Dapagliflozin May Slow Kidney Function Decline in Patients with Type 2 Diabetes

Skander Mulder,[1,2] Ann Hammarstedt,[3] Sunil Belur nagaraj,[1] Peter J. Greasley,[3] Jonatan Hedberg,[3] Viji Nair,[2] Wenjun Ju,[2] Jan W. Eriksson,[4] Jan Oscarsson,[3] Hiddo J. L Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]University of Michigan, Ann Arbor, MI; [3]AstraZeneca, Mölndal, Sweden; [4]Uppsala University, Uppsala, Sweden*.

Background: Sodium glucose cotransporter 2 inhibitors (SGLT-2i) slow progression of diabetic kidney disease (DKD). The underlying mechanisms are not fully elucidated. We examined which metabolic pathways are targeted by the SGLT-2i dapagliflozin (DAPA) to explore the molecular processes involved in the renal protective effects with DAPA.

Methods: An unbiased serum metabolomics assay was performed on baseline and follow-up (week 12) samples from the EFFECT II trial in type 2 diabetes patients with non-alcoholic fatty liver disease (NCT02279407; Eriksson Diabetologia 2018), using the DAPA 10 mg/day treatment arm (n=19). Transcriptomic signatures from tubular compartments were identified from kidney biopsies collected from patients with DKD and healthy controls from the European Renal cDNA Biobank (ERCB). Serum metabolites that were significantly changed after 12 weeks of DAPA treatment were selected and mapped to a metabolite-protein interaction network. These proteins were then linked with intra-renal transcripts that were associated with DKD or eGFR. The impacted metabolites and their protein coding transcripts were analyzed for enriched pathways.

Results: Of all measured (n=812) metabolites, 108 changed ($p<0.05$) during DAPA treatment and 74 could be linked to 367 unique proteins with corresponding coding genes. Intra-renal mRNA expression analysis of the genes encoding the metabolite-associated proteins using kidney biopsies resulted in 105 genes that were significantly associated with eGFR in patients with DKD from the ERCB cohort, and 135 genes that were differentially expressed between patients with DKD and controls. The combination of metabolites and transcripts identified four enriched pathways that were affected by DAPA and associated with eGFR: Glycine Degradation (Creatine Biosynthesis) [mitochondrial function]; TCA Cycle II [energy metabolism]; L-carnitine Biosynthesis [energy metabolism] and Superpathway of Citrulline Metabolism [nitric oxide synthase and endothelial function].

Conclusions: The observed molecular pathways targeted by DAPA and associated with DKD suggest that modifying molecular processes related to energy metabolism, mitochondrial function, and endothelial function may contribute to the renal protective effects of DAPA.

FR-OR117

Assessing Glomerular Cellularity in Diabetic Human Kidney Biopsies with 3D Tissue Cytometry: Implications for Disease Progression

Angela R. Sabo,[2] Michael J. Ferkowicz,[1] Michael T. Eadon,[3] Carrie L. Phillips,[2] Katherine J. Kelly,[1] Timothy A. Sutton,[2] Pierre C. Dagher,[1] Seth Winfree,[2] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University Division of Nephrology, Indianapolis, IN*.

Background: Diabetic nephropathy (DN) is a leading cause of kidney disease worldwide. At the tissue level, DN has been classified by morphology including glomerular size and cellularity. Large scale 3D multi-fluorescence imaging and 3D tissue cytometry (3DTC) provides a unique and efficient way to quantitate and characterize the cellularity of glomeruli. Here, we examined the changes in cellular density across multiple kidney biopsy specimens with DN, compared to reference nephrectomy tissue. We also sought to determine whether the changes in cellularity are indicative of a focal or diffuse response.

Methods: 5 non-DN reference nephrectomy specimens and 5 kidney biopsy specimens with DN were stained with 4 to 8 markers and imaged by confocal fluorescence microscopy. Glomeruli were isolated digitally and analyzed using 3DTC with Volumetric Tissue Exploration and Analysis (VTEA) software. Cell density and immune cell subtypes were determined for each glomerulus within each specimen.

Results: When comparing all glomeruli from diabetics to those from the reference specimens, the average cellular density was increased in the diabetic group: 592715 ± 116469 vs. 259556 ± 8107 cells/mm^3, respectively ($p < 0.05$). When comparing between individual specimen, there were no significant differences seen in glomerular cellular density across reference tissues, but three of the five diabetic specimens showed significant increases in cellularity, albeit to different levels ($p<0.05$ using one-way ANOVA compared to reference). Interestingly, within each biopsy with DN, the cellular densities in all glomeruli were comparable. When examining cell subtype, the contribution of immune cells to the increased cellularity in diabetes was minimal.

Conclusions: 3DTC using VTEA is a powerful and efficient tool to assess glomerular cellularity in biopsy specimens. Using this tool, we detected an increase in glomerular cell density in DN. Importantly, our data suggest that diabetes uniformly alters the cellularity across all glomeruli within a biopsy specimen, rather than a selective effect on a subset of glomeruli. These findings increase our understanding of the dynamics of the progression of diabetic kidney disease and may aid pathologists' interpretation of specimens.

Regional Transcriptomic Profiling of the Human Kidney Uncovers Major Signature Shifts in the Interstitium During Diabetes

Daria Barwinska,[1] Yinghua Cheng,[2] Ricardo Melo ferreira,[1] Michael J. Ferkowicz,[1] Seth Winfree,[2] Blue Lake,[7] Rajasree Menon,[3] Edgar A. Otto,[3] Kimberly S. Collins,[2] Ken Dunn,[1] Katherine J. Kelly,[1] Timothy A. Sutton,[2] Brad H. Rovin,[4] Samir V. Parikh,[5] Pierre C. Dagher,[1] Tarek M. El-Achkar,[1] Michael T. Eadon.[6] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of Michigan, Ann Arbor, MI; [4]Ohio State University Wexner Medical Center, Columbus, OH; [5]Ohio State University Medical Center, Columbus, OH; [6]Indiana University Division of Nephrology, Indianapolis, IN; [7]UCSD, San Diego, CA.*

Background: The expression signature of the renal interstitium is less well characterized than that of the glomerulus and tubules. Here, we examine gene expression of the human renal interstitium in reference nephrectomies and diabetic kidney biopsy specimens using laser micro-dissection (LMD).

Methods: We used LMD to collect cortical kidney interstitium from reference nephrectomies (N=9) and diabetic renal biopies (N=6). Rapid stain with DAPI, OG-Phalloidin, and Tamm-Horsfall protein antibody identified relevant renal structures. LMD excluded tubules, glomeruli and large vessels. Transcriptomic data was obtained using RNAseq on Illumina platform, and analyzed with R studio. The gene signature was compared to existing platforms such as snRNAseq and scRNAseq datasets.

Results: Our laser micro-dissected interstitial regions did not show significant expression of known tubular or glomerular markers (eg. *NPHS1, LRP2, UMOD, AQP2*). In contrast, we identified a set of markers specific to the interstitium in reference nephrectomy samples. While some of them were novel (eg. *FABP2, ADGRD1*), others were commonly expressed across all three platforms (*LTBP1, ELN, SYNM, ADCY5, COL4A1, C1R)*. The expression of these genes was localized to expected cell types such as stromal, vascular and immune cells. The renal interstitium from diabetic biopsies revealed differential expression in many pathways including extracellular matrix organization ($p=0.0037$) and chemokine signaling ($p=0.0065$).

Conclusions: We successfully isolated the interstitium of human kidney samples using LMD. Gene expression from our samples correlated well with vascular, immune and stromal cell clusters from scRNAseq and snRNAseq data. Therefore, our LMD approach allows rich deconvolution of transcriptomic signatures from single cell datasets and facilitates backmapping of unidentified clusters to the interstitium. Dramatic changes in the gene expression in diabetic kidney interstitium suggest that this compartment may be an important player in the pathophysiology of diabetic nephropathy.

Single Nucleus RNA Sequencing of Early Human Diabetic Nephropathy Reveals Transcriptional Changes That Promote Potassium Secretion

Parker C. Wilson,[1] Haojia Wu,[2] Yuhei Kirita,[7] Kohei Uchimura,[3] Helmut G. Rennke,[4] Sushrut S. Waikar,[5] Paul A. Welling,[6] Benjamin D. Humphreys.[3] *[1]Pathology and Immunology, Washington University in St. Louis, St. Louis, MO; [2]Renal Division Washington University School of Medicine, Saint Louis, MO; [3]Washington University School of Medicine, Saint Louis, MO; [4]Brigham and Women's Hospital, Boston, MA; [5]Harvard Medical School, Boston, MA; [6]University of Maryland School of Medicine, Baltimore, MD; [7]Washington University School of Medicine in St. Louis, Saint Louis, MO*.

Background: Diabetic nephropathy is characterized by damage to both the glomerulus and tubulointerstitium, but relatively little is known about cell-specific transcriptional changes. We hypothesized that single nucleus RNA sequencing (snRNAseq) of cryopreserved human diabetic kidney samples would reveal genes and signaling networks in early diabetic nephropathy.

Methods: We analyzed three diabetic and three healthy human kidney samples. Diabetics had elevated A1c (mean = 7.9 +/- 1.5%) and two of three patients had proteinuria. Baseline serum creatinine (mean = 1.06 +/- 0.23 mg/dl) was not different

between groups. Nuclear preparations of cryopreserved samples were processed using 10x Genomics Chromium 5' kit and sequenced by NovaSeq. Reads were counted with zUMIS v2.0 and analyzed with Seurat v2.3.

Results: A total of 23,980 single nuclei were sequenced representing all glomerular and tubulointerstitial cell types. Infiltrating T-cells and B-cells were increased in diabetic samples. Side by side comparison showed cell-type-specific transcriptional changes important for ion transport, angiogenesis, and immune cell activation. In particular, the diabetic loop of Henle, late distal convoluted tubule, and principal cells show gene changes consistent with increased potassium secretion, including alterations in Na-K^+-ATPase, *WNK1*, *NEDD4L*, and mineralocorticoid receptor (Figure 1; green=upregulated, red=downregulated). These effects were accompanied by increased expression of *CASR* and decreased expression of *CLDN16* in the loop of Henle, which regulate calcium and magnesium reabsorption. We also identify strong angiogenic signatures in glomerular cell types, proximal convoluted tubule, distal convoluted tubule and principal cells.

Conclusions: Early diabetes induces gene expression changes in the distal nephron coordinate to promote potassium secretion and angiogenesis.

Characterizing the Bioenergetic Profile of Kidney Mitochondria in Human Diabetes

Melinda T. Coughlan,[1,3] Cesare Granata,[1] Elif Ekinci,[2] Adrienne Laskowski,[3,1] Mark E. Cooper,[1] Scott Wilson.[3,1] Glycation, Nutrition and Metabolism Laboratory; Department of Diabetes, Monash University *[1]Monash University, Melbourne, VIC, Australia; [2]University of Melbourne, Heidelberg West, VIC, Australia; [3]Alfred Health, Melbourne, NSW, Australia*.

Background: Optimal mitochondrial respiration is central to renal function. We have shown a decline in mitochondrial respiratory function in the kidney in experimental diabetes prior to development of characteristic kidney lesions. Despite a large body of work focussing on the role of mitochondrial dysfunction in diabetic kidney disease (DKD), the majority of studies have been performed in the kidneys of animal models and no study to date has determined if there is a defect in mitochondrial bioenergetics within the renal cortex of individuals with diabetes.

Methods: Renal cortical tissue was obtained after informed patient consent from the macroscopically/microscopically healthy portion of tumor nephrectomies. Renal cortices were freshly collected from non-diabetic controls (ND, n=15) and patients with diabetes (D, n=12). Oxygen consumption rates were determined with a substrate-uncoupler-inhibitor titration protocol by high resolution respirometry (Oxygraph-2k respirometer, Oroboros Instruments) in saponin-permeabilized tissue. In addition, respiration rates were also measured for a subset of specimens (n=12 ND, n=9 D) in mitochondria isolated by differential centrifugation.

Results: In permeabilized renal cortex, fatty acid-induced mitochondrial respiration was increased in patients with diabetes compared to non-diabetic patients. Coupled maximal mitochondrial respiration with electron input through electron transfer flavoprotein, complex I (CI) and CII was greater in patients with diabetes compared to non-diabetic patients. The uncoupled state of maximal respiration, experimentally induced by FCCP to collapse the proton gradient across the mitochondrial inner membrane and to measure the capacity of the electron transfer system was also increased in the setting of diabetes. Intriguingly, in isolated mitochondria, the opposite was observed in that there was a decrease in mitochondrial respiration in patients with diabetes, using all three protocols, suggesting that per unit mitochondria, there is an overall decline in mitochondrial respiratory function.

Conclusions: Our findings demonstrate for the first time that patients with diabetes display a profile of altered renal mitochondrial respiratory control. Further studies are required to determine defective sites within the mitochondria.

Funding: Government Support - Non-U.S.

FR-OR121

Non-HLA Antibodies Targeting Angiotensin II Type 1 Receptor and Endothelin 1 Type A Receptors Induce Endothelial Injury via β2-Arrestin Link to mTOR Pathway

Duska Dragun,[3] Rusan Catar,[1] Oskar Wischnewski,[2] Claudia Rutz,[5] Ralf Schülein,[4] Angelika Kusch.[1] *[1]Charité, Universitätsmedizin Berlin, Berlin, Germany; [2]Charite, Berlin, Germany; [3]University Hospital Charite, Campus Virchow, Berlin, Germany; [4]Leibniz-Forschungsinstitut für Molekulare Pharmakologie, Berlin, Germany; [5]Leibniz-Forschungsinstitut für Molekulare Pharmakologie (FMP), Berlin, Germany*.

Background: Functional non-HLA antibodies targeting G protein-coupled receptors (GPCR) Angiotensin II Type 1 receptor (AT1R) and Endothelin-1 Type A receptor (ETAR) are implicated in the pathogenesis of transplant vasculopathy. While ERK signaling may represent general cellular response to agonist stimulation, the molecular link between receptor stimulation and development of vascular obliteration has not been fully established yet. We hypothesized the involvement of β-arrestins and PI3K/mTOR signaling and assessed functional consequences of AT1R- and ETAR-activation by non-HLA antibodies.

Methods: Human microvascular endothelial cells (HMEC) were stimulated with AT1R-Ab and ETAR-Ab IgG isolated from kidney transplant patients with chronic vasculopathy. Phospho-specific antibodies against ERK and mTOR downstream targets were used to assess activation of mTORC1 and mTORC2. β-arrestin involvement was investigated using RNA silencing and laser scanning microscopy studies in ARRB2. GFP and ETA.myc.Cherry-transfected HEK293 cells. Scratch assay was employed to study effect of non-HLA-antibodies on endothelial repair. Involvement of AT1R/ETAR activation was addressed by use of specific inhibitors.

Results: Signaling activity of both, mTORC1 and mTORC2, was increased after treatment with patient IgG compared to cells treated with IgG from healthy controls. This effect could be inhibited by specific AT1R-/ETAR- blockers. Activation of mTORC1 and mTORC2 were PI3K-dependent and independent from ERK. mTOR inhibitor rapamycin completely abolished activation of mTORC1 and in addition mTORC2 after long term treatment induced by receptor antibodies. Imaging studies revealed that β2- and not β1-arrestin was recruited to ETAR in response to ET1 and transplant patient IgG. Furthermore, AT1R and ETAR downstream signaling to ERK1/2 and mTORC2 was significantly reduced in β2-arrestin silenced HMECs. Non-HLA antibodies impaired endothelial repair by AT1R and ETAR induced mTORC2 signaling.

Conclusions: We provide evidence that functional AT1R-/ETAR-Abs induce ERK1/2 and mTOR signaling involving β2-arrestins in human microvascular endothelium. Our data may provide a translational rationale for mTOR inhibitors in combination with receptor blocker in patients with non-HLA receptor recognizing antibodies.

FR-OR122

Tissue Resident Memory T Cells in Mouse Renal Transplantation

Khodor Abou Daya, Martin H. Oberbarnscheidt, Fadi G. Lakkis. *Starzl Transplantation Institute, University of Pittsburgh, Pittsburgh, PA*.

Background: The newly identified tissue resident subset of memory T cells (T_{RM}) provides immune surveillance in the tissue and first response against infections. They are functionally, transcriptionally, and phenotypically distinct from circulating effector and central memory T cells. The role of T_{RM} in transplantation is unknown. In this study, we investigated the formation and function of T_{RM} in a mouse kidney transplantation model.

Methods: Syngeneic B6 or allogeneic (B6xBALB/c) F1.ova kidneys were transplanted to B6 recipients and 1 million OT-I effector T cells were transferred on day 2. Graft, blood, bone marrow, SLO, and liver tissues were harvested 4 and 8 wks after transplantation. Serum creatinine was measured using i-Stat analyzer. T_{RM} were identified phenotypically as $CD44^{hi}CD62L^{low}CD69^{+}$ $CD103^{+/-}$ cells after excluding *in vivo* labeled T cells. OT-I and polyclonal T_{RM} were transcriptional characterized using scRNAseq. We tested T_{RM} residency in the graft by performing parabiosis between 4-wk transplanted CD45.1 B6 mice that contained OT-I effectors and CD45.2 B6 parabionts that had received F1.ova kidneys but no OT-I. Whether T_{RM} are sufficient for rejection was tested in a re-transplantation model using splenectomized LTBR-/- mice as secondary recipients of F1.ova grafts containing T_{RM}. Depletion experiments are underway to further establish causal relationship between T_{RM} and rejection.

Results: Mean serum creatinine (mg/dl) was significantly higher in allogeneic vs syngeneic group at wk 8 (0.8 vs 0.2, $p<0.05$). Graft histology showed mixed acute and chronic rejection in the allogeneic group. Flow analysis of allograft cells demonstrated T_{RM} cells among OT-I and endogenous T cell populations at 4 & 8 wks. The OT-I population was exclusively T_{RM} phenotype by flow and scRNAseq, rapidly produced IFNg upon re-stimulation, and was not detected anywhere else. There was no significant difference in mean number of OT-Is between wk 4 and wk 8 (125k vs 79k, $p=0.94$). OT-I T cells could not be detected in the parabiont kidney graft or tissues or in the secondary host outside the re-transplanted kidney, indicating that the T_{RM} are indeed resident in the graft and do not re-circulate. Chronic rejection progressed in re-transplanted kidneys that harbored T_{RM}.

Conclusions: Our findings show that donor-specific T_{RM} form in kidney allografts, are functional, and could contribute to rejection.

Single Cell RNA Sequencing of Antibody-Mediated Rejection and Control Kidney Transplant Biopsies Reveals Endothelial, T-Cell, and Monocyte Intercellular Communication and Host-Donor Chimerism

Andrew F. Malone, Haojia Wu, Ashima Chadha, Benjamin D. Humphreys. *Washington University School of Medicine, Clayton, MO.*

Background: Antibody mediated rejection (AMR) is one of the major causes of allograft failure yet current treatment strategies are suboptimal reflecting our poor understanding of this disease. We performed single cell(sc)RNAseq on biopsies from patients with AMR and compared them to non-AMR biopsies.

Methods: The 10X platform was used for library preparation. Sequencing depth was ~50k reads/cell. CellRanger, R and Seurat were used to make gene-cell matrices and for downstream analyses. Donor and recipeint exome sequencing was also performed. IRB approved.

Results: 96,547 cells (avg=1292 genes detected/cell) from 7 kidney transplant biopsies were included in the integrated analysis using UMAP. 21 cell clusters were identified and included all major tubular types (PT,LOH,PC,IC), stroma, endothelium, lymphocytes (T and B cells) and monocytes (figure). In AMR biopsies, monocytes expressed the B cell activator BAFF and B cells upregulated expression of its cognate receptors TACI and BMCA, suggesting monocyte driven B cell activation. Endothelial cells in AMR showed increased expression of cytokines that recruit T cells such as CXCL9, as well as the chemokine receptor ACKR1, suggesting that endothelial cells amplify the immune response. Of note, we could distinguish host from donor leukocytes based on expressed SNVs defined by exome sequencing. Whether donor-derived leukocytes exhibit differential gene expression compared to their host counterparts is under analysis.

Conclusions: Comprehensive scRNAseq of human AMR suggests that monocytes drive B cell activation and that endothelial cells recruit T cells. We also show, for the first time, that donor leukocytes persist even years after transplantation. Whether donor-derived leukocytes differentially regulate AMR represents a new and potentially important direction in transplantation research enabled by scRNAseq.

Modulation of Ischemia-Reperfusion Injury (IRI) Post-Renal Transplantation in Estrogen Receptor-α Knockout (ERα-KO) Mice and by Selective Estrogen Receptor Modulators (SERM)

Paul T. Hernandez,[1] Seth Concors,[1] Zhonglin Wang,[1] Guanghui Ge,[1] David D. Aufhauser,[3] Lauren Krumeich,[3] Wayne W. Hancock,[2] Matthew H. Levine.[1] *[1]Hospital of the University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA.*

Background: IRI is a major contributor to early allograft dysfunction(EAD) post-kidney transplantation. We have demonstrated lower rates of EAD among female renal transplant recipients in UNOS, and using a murine model, showed improved IRI tolerance after administration of 17β-estradiol in both warm and cold renal IRI. We now investigate the contribution of ERα to this protection, and the utility of SERM administration in wild type mice.

Methods: Female C57BL/6(B6) and ERα-KO mice were used. We transplanted kidneys from B6→B6, ERα-KO→B6, and B6→ERα-KO, followed by native nephrectomy. All groups were treated with 17β-estradiol(1 mg/kg) and subsequently underwent temperature-controlled IRI(28min at 36°C). In a separate experiment, B6 mice received either Lasofoxifene(LAS), Raloxifene(RAL), Tamoxifen(TAM), Bazedoxifene(BAZ), or vehicle (all 10mg/kg in DMSO) prior to warm IRI. Serum creatinine(Cr) was measured at 24-hour intervals post-surgery in both experiments.

Results: Mice in the B6→ERα-KO group had significantly higher Cr compared to B6→B6 and ERαKO→B6 groups(Figure 1a). Mice treated with LAS prior to IRI had significantly lower Cr compared to controls(Figure 1b). RAL, TAM, or BAZ did not provide significant protection(Figure 1c).

Conclusions: Loss of estrogen-derived protection from warm IRI in the B6→ERα-KO group indicates that the mechanism for this protection is extrinsic to the kidney. Protection from IRI in the LAS-treated group demonstrates that selective ERα activation outside the breast and uterus, potentially sparing off-target effects, is sufficient for protection from IRI. Lack of significant protection from IRI after RAL, TAM, and BAZ is likely due to differential affinity of each drug for ERα in extra-renal tissues. Collectively, these data provide new insights into the mechanisms by which estrogen-based therapy can improve early outcomes in renal transplantation.

Protective Role of Kynurenine 3-Monooxygenase in Kidney Allograft Rejection

Youli Wang,[1] Andrew Harner,[1] Xuexiu Fang,[1] Todd D. Merchen,[1] Chak-Sum Ho,[2] Daniel T. Kleven,[1] Thomas Z. Thompson,[1] N. Stanley Nahman.[1] Augusta University, Augusta, GA *[1]Augusta University, Augusta, GA; [2]Gift of Hope Organ & Tissue Donor Network, Itasca, IL.*

Background: Rejection of a transplanted kidney is a complex adaptive immune response and is the primary driver of graft loss. Kynurenine 3-monooxygenase (KMO) is an oxidoreductase involved in the kynurenine pathway of tryptophan metabolism and has been associated with inhibition of T cell proliferation. Our previous study demonstrated that indoleamine 2,3-dioxygenase (IDO) was upregulated in rejecting allografts, and was associated with reduced KMO expression. Herein, we investigated the role of KMO in preventing rejection in a pig model of kidney transplantation, and in protecting renal cortical epithelial cells (RCEC) following exposure to cytokines common to inflammation.

Methods: Outbred Yorkshire pigs underwent mismatched kidney transplants as we have described (Transplant Immunol 42:40). No immunosuppression was used and the tissue was studied 72 hours post-transplant. Immunohistochemistry (IHC) was performed to measure allograft expression of KMO. Cultured RCEC were utilized measure KMO, IDO, and the epithelial-mesenchymal transition markers E-cadherin and tight junction protein 1 (TJP1), following cytokine activation with and without treatment with the product of KMO, 3-hydroxykynurenine (3HK, 20mg/ml).

Results: RCEC-specific KMO staining was down-regulated by approximately 10-fold in rejecting allografts when compared to normal kidney. Following cytokine activation of RCEC, KMO was silenced, and the expression of E-cadherin and TJP1 was blunted. The addition of 3HK completely restored E-cadherin and TJP1 expression. In additional studies, we showed that high dose 3HK (100ug/ml) effectively inhibits human peripheral blood pan-T cell prolifereation.

Conclusions: KMO may be a key modulator of allograft immune responses as suggested by its downregulation in rejecting allografts. Moreover, KMO, through the generation of 3HK, may exert cytoprotective effects through preservation of normal renal parenchymal architecture, by retained expression of E-cadherin and TJP1 and inhibition of T cell proliferation. Inducing KMO, with the generation of 3HK in renal allografts, may provide an avenue for novel therapies in renal transplantation.

FR-OR126

Tertiary Lymphoid Organs in Renal Chronic Allograft Rejection

Khodor Abou Daya, Martin H. Oberbarnscheidt. *Starzl Transplantation Institute, University of Pittsburgh, Pittsburgh, PA.*

Background: Chronic allograft rejection remains a major obstacle to long-term allograft survival. Tertiary lymphoid organs (TLOs) are ectopic lymphoid structures that arise in non-lymphoid tissues in the setting of chronic inflammation. They have been documented extensively in human renal allografts and have been associated with chronic rejection. Their immunologic role in allograft rejection is unclear. Therefore, fundamental understanding of TLO function is necessary. Here, we employed a chronic renal allograft rejection model in mice and intravital time-lapse 2-photon microscopy to investigate the function of TLO in transplant rejection.

Methods: CB6F1 RIP-LTα (preformed TLO) or CB6F1 (no TLO) kidney grafts were transplanted to WT B6 recipients and survival monitored. To investigate immunologic function of TLO, we adoptively transferred B6-RIPLTα CD11c-YFP mice with 10e6 naïve dsRed OT-I T cells or 10e6 CTR-labeled NP-specific B cells + 10e6 CFP$^+$ OT-II cells and immunized with NP-OVA + alum. Intravital 2P imaging of renal TLO was performed at time points 0, 3, 6, 24 or 72 hours after immunization. Three-dimensional

image analysis was performed and mean speed, displacement, arrest coefficient (AC) and contact times (CT) with DC were calculated for OT-I, OT-II and NP-B cells.

Results: CB6F1 RIP-LTα grafts rejected significantly faster (MST= 54) than CB6F1 grafts (MST= 225), demonstrating that TLO contribute to allograft rejection. Grafts from both groups harvested at the time of rejection demonstrated interstitial fibrosis, lymphocytic infiltrates and TLO, positive for B, T and HEV-marker PNAd. CB6F1 RIP-LTα grafts contained similar numbers of, but larger TLO than CB6F1 grafts. Mean speed and displacement of OT-I and OT-II cells significantly decreased over time after immunization while AC and mean CT significantly increased. B cell mean speed, displacement and AC increased after immunization. These data are consistent with B cell activation and productive T cell-DC interactions and mirror previously reported data in secondary lymphoid organs.

Conclusions: We provide first evidence that TLO provide a local structure for T and B cell activation that might propagate anti-graft immune responses in the setting of chronic rejection. Further studies will elucidate the formation and maintenance of TLO and the consequences of local T and B cell activation.

Deciphering Shared Gene Expression Patterns by Whole-Genome Transcriptomics of Urinary Cells and Kidney Allograft Biopsies

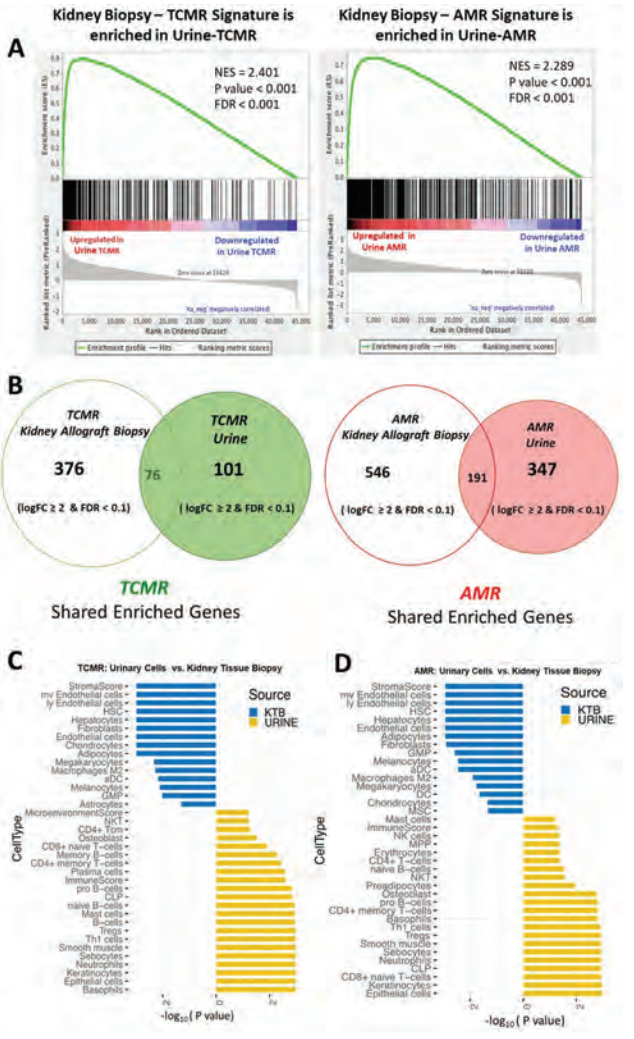
Michelle L. Lubetzky,[1] Thangamani Muthukumar,[1] John R. Lee,[1] Darshana Dadhania,[1] Michael F. Cassidy,[2] Surya V. Seshan,[3] Steven Salvatore,[1] Manikkam Suthanthiran.[1] *[1]Weill Cornell Medical College, New York, NY; [2]Weill Cornell Medicine, New York, NY; [3]Weill Cornell Medical Center, New York, NY.*

Background: Urinary cell mRNA profiling to interrogate kidney allograft (KTx) status is based on the premise that the allograft can function as an in-vivo flow cytometer and sort graft destructive/protective T cells into the urinary space. We used RNA-Seq of urinary cells to demonstrate that urinary cell mRNA profiles mirror intragraft events and urinary cells are enriched for immune cells in acute rejection

Methods: We performed global RNA-seq to characterize mRNA transcriptomes of urinary cells from 57 KTx recipients with T Cell Mediated Rejection (TCMR), n=22, Antibody Mediated Rejection (AMR), n=8, Normal, n=27, and allograft tissues from 49 KTx recipients (ACR n=12, AMR n=17, and Normal n=20). We analyzed the urine and biopsy profiles using Gene Set Enrichment Analysis (GSEA) and a gene-signature expression based cell-type deconvolution tool xCell.

Results: By GSEA analysis, genes upregulated in the KTx biopsies with TCMR and AMR were upregulated in the urinary cells with TCMR and AMR (FDR-P<0.01). There were 76 differentially expressed mRNAs that were shared between urine and biopsy profiles in TCMR, and 191 differentially expressed mRNAs that were shared between urine and biosy AMR. Deconvolution analysis revealed higher enrichment of stromal cell score in the biopsies compared to urine, whereas immune cell types were enriched in the urine.

Conclusions: GSEA of RNA-seq data from urinary cells and kidney allografts demonstrate enrichment of genes related to immune cells in urine that is undiluted by the stromal component. Our data support the use of urine as an excellent biospecimen for biomarker discovery and development as well as for deciphering the anti-allograft repertory.



(Figure 1, Panel A: GSEA, Panel B: Venn Diagram Shared Genes, Panel C&D: xCell immune cell types in TCMR and AMR, Blue=Biopsy and Yellow=urine)

FR-OR128

Altered Gut Microbial Fermentation and Colonization with Methanobrevibacter smithii in Renal Transplant Recipients

Tim J. Knobbe, Rianne M. Douwes, Daan Kremer, J.c. Swarte, Michele F. Eisenga, Antonio W. Gomes Neto, Marco van Londen, H. Blokzijl, Hermie Harmsen, Ilja M. Nolte, Stephan J. Bakker. *University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands.*

Background: The gut microbiota of kidney transplant recipients (RTR) differs from that of healthy controls (HC). This may have consequences for gut microbial fermentation. Breath hydrogen (H_2) and methane (CH_4) concentrations are markers of fermentation in the gut, of which CH_4 is mainly produced by *Methanobrevibacter smithii* (*M. smithii*). We aimed to investigate (1) whether breath H_2 and CH_4 concentrations differs between RTR and HC, (2) whether the presence of *M. smithii* in faeces differs between RTR and HC and (3) whether presence of *M. smithii* is related to breath H_2 and CH_4.

Methods: All study subjects participated in the TransplantLines biobank cohort study. Organ donors served as HC. Breath H_2 and CH_4 concentrations were analysed using solid state-sensor gas-chromatography. Presence of *M. smithii* in faeces was determined with real-time PCR.

Results: A total of 152 RTR and 77 HC were included. Breath H_2 concentrations of RTR were not significantly different from HC (median [IQR] 11.3 [4.0-30.0] ppm vs. 10.5 [4.5-28.3] ppm, p=0.92). However, RTR had significantly lower breath CH_4 concentrations compared to HC (7.5 [3.9-10.6] ppm vs. 16.0 [8.0-45.5] ppm, p<0.001). In addition, *M. smithii* was found less frequently in RTR compared to HC (86.4% vs. 28.6%, p<0.001). In absence of *M. smithii*, there was a significant positive correlation between breath H_2 and CH_4 (r = 0.88; p<0.001). There was no correlation if *M. smithii* was present (r = 0.09; p=0.50).

Conclusions: Breath CH_4 concentrations and the prevalence of *M. smithii* in faeces were significantly lower in RTR compared to HC, which indicates RTR have altered microbiota and altered gut microbial fermentation. In absence of *M. smithii*, CH_4 is highly

dependent on H_2 production, while this is not the case in the presence of *M. smithii*. These findings provide novel insight in the alterations of gut microbiota secondary to renal transplantation and the use of immunosuppressants.

Extracellular Vesicles Mediate Complement Activation and Tubular Senescence in Renal Antibody-Mediated Rejection

Giuseppe Castellano,[1] Rossana Franzin,[1] Chiara Divella,[2] Alessandra Stasi,[2] Fabio Sallustio.[2] *[1]Department of Emergency and Organ Transplantation (DETO), University of Bari, BARI, Italy; [2]University of Bari, Bari, Italy.*

Background: Renal Antibody-Mediated Rejection (AMR) is characterized by a strong complement activation that can lead to a premature senescence in tubular epithelial cells (TEC). EVs (Extracellular vesicles), circulating microparticles able to mediate cell-to cell communication, are emerging as pivotal in different kidney diseases. The aim of this study was to investigate whether AMR derived-EVs could induce tubular inflammaging aging and complement activation.

Methods: Renal biopsies, serum and serum-isolated-EVs from 10 Acute and Chronic AMR patients were collected. TEC culture were incubated with EVs ($5E^{+4}$EVs/cells target for 24h); then to assess cellular senescence qPCR for *p21*, *p53*, *Klotho* and *CYP1B*1 and SA-β-gal staining were performed. mRNA level of *C3* and *CFH* were also measured. Inflammaging ($p16^{INK4a}$ and Klotho) markers were evaluated by IHC. Endothelial cells were grown in serum free media, incubated with AMR derived-EVs for 24h, then C4d IF was performed.

Results: Renal AMR biopsies showed significant tubular senescence as indicated by $p16^{INK4a}$ expression; $p16^{INK4a}$ was significantly upregulated in Chronic compared with Acute AMR biopsies ($p<0.05$). *In vitro*, the exposure of TEC to AMR serum induced senescence as observed by the upregulation of *p21* and *p53* gene levels ($p<0.05$). Furthermore, EVs exposed-TEC were characterized by significant increase in *p21, p53* and *CYP1B1* gene expression and down-regulation of *Klotho* ($p<0.05$) indicating that EVs can induce tubular senescence. In accordance, EVs induced a higher number of SA-β-gal+ TEC compared with control serum ($p<0.05$); the cells appeared larger and polynucleated indicating typical senescence phenotype. Finally, EVs from AMR patients induced a significant increase in *C3* gene expression with concomitant downregualtion in *CFH in TEC associated with* C4d deposition on endothelial cells in serum free medium.

Conclusions: In AMR patients, circulating EVs induced accelerated inflammaging in TEC via dys-regulation of Complement system at cellular level. This new pathogenic process might help to identify new targets for therapeutic intervention.

FR-OR130

Distinct Metabolic Signatures of Murine Kidney Allograft Rejection and Ischemia-Reperfusion Injury (IRI)

Erum A. Hartung,[1,4] Ulf H. Beier,[1,4] Seth Concors,[2] Paul T. Hernandez,[3] Zhonglin Wang,[6] Michelle Denburg,[5,4] Terence P. Gade,[6] Matthew H. Levine.[6] *[1]Division of Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania Health System, Philadelphia, PA; [3]Hospital of the University of Pennsylvania, Philadelphia, PA; [4]Department of Pediatrics, University of Pennsylvania, Philadelphia, PA; [5]Division of Nephrology, The Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Pennsylvania, Philadelphia, PA.*

Background: Acute rejection is an important complication of kidney transplant, and must be distinguished from other causes of allograft dysfunction such as IRI. We hypothesized that tissue metabolomic profiling could identify biomarkers of rejection and IRI in murine models.

Methods: Mismatched kidney transplants were performed using C57BL/6 donors into BALB/c recipients (n=10). Allografts were harvested after 14d when rejection is prominent (TK), with BALB/c recipient kidneys as controls (NK). Separately, unilateral warm IRI was induced in C57BL/6 mice by clamping the renal pedicle for 28 mins. IRI and contralateral control (Ctrl) kidneys were harvested at 24 h, during peak IRI (n=10 each). Kidneys were snap frozen and stored at -80°C prior to mass spectrometry-based non-targeted metabolomic profiling of 879 biochemicals (Metabolon, Inc.). FDR-adjusted t-tests were used to test differences between TK vs. NK, IRI vs. Ctrl, and TK vs. IRI.

Results: Rejecting kidneys had significantly higher levels of metabolites related to the glutathione antioxidant response (GSSG; ophthalmate), tryptophan derivatives (kynurenine, quinolinate), and the TCA cycle derivative itaconate. IRI kidneys had significantly higher levels of saccharopine, 2-aminoadipate (lysine metabolism), fructose, β-citrylglutamate (mitochondrial iron carrier), and (3'-5')-adenylyladenosine (Fig.1). Key metabolites characterizing rejection and IRI, respectively, were itaconate, an immunometabolite released by activated macrophages, and saccharopine, a lysine catabolite reported to cause mitochondrial injury that is potentially relevant to IRI mitochondrial dysfunction.

Conclusions: Acute rejection and IRI have distinct tissue metabolomic signatures. These findings may help in the future development of non-invasive biomarkers to detect rejection and IRI in kidney transplant patients.

SA-OR001

Multicenter Study of Immune Checkpoint Inhibitor-Associated AKI

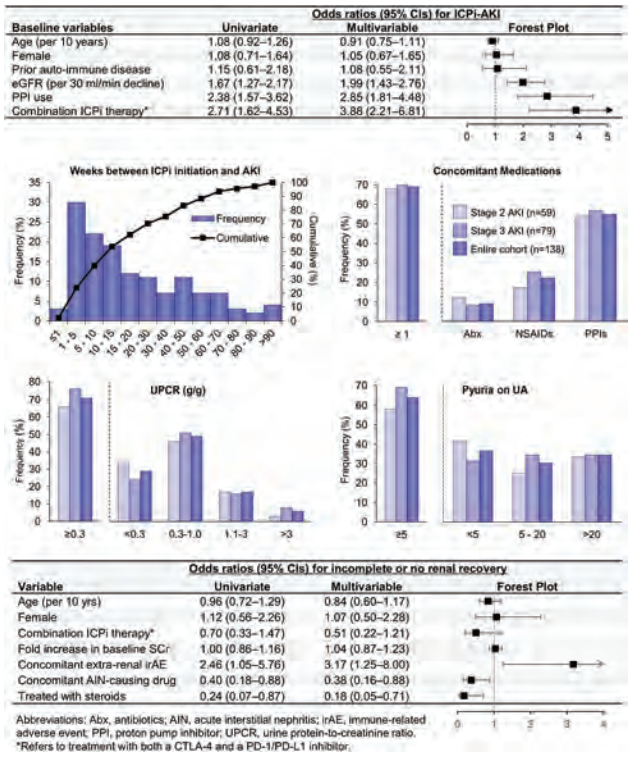
Zoé A. Kibbelaar,[1] Frank B. Cortazar,[2] David E. Leaf.[1] ICPi-AKI Working Group *[1]Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Immune checkpoint inhibitor-associated AKI (ICPi-AKI) is an increasingly frequent complication of immunotherapy. However, existing data on ICPi-AKI are limited to small, mostly single-center studies.

Methods: We contacted nephrologists and oncologists at >20 major cancer centers across the U.S. and Canada, and identified 138 patients from 18 institutions with ICPi-AKI. All patients were required to have at least a doubling of serum creatinine or need for dialysis, along with a clinical diagnosis of ICPi-AKI by the provider. Detailed data were collected using a standardized case report form. We also collected data on 276 control patients who received ICPis but did not develop AKI. Multivariable logistic regression was used to determine risk factors for development of ICPi-AKI and prognostic factors for its recovery.

Results: Lower baseline eGFR, concomitant use of a PPI, and combination ICPi therapy were each associated with a greater risk of ICPi-AKI. The median time from initiation of an ICPi to AKI was 14 (IQR, 6–37) weeks. An extra-renal immune-related adverse event (irAE) occurred concomitantly with AKI in 43% of patients. Most patients had proteinuria and pyuria. A kidney biopsy was obtained in 43% of patients, with acute interstitial nephritis (AIN) found in 93%. Overall, 87% of patients were treated with steroids, of whom 43%, 43%, and 13% had complete, incomplete, and no renal recovery, respectively. Concomitant extra-renal irAEs were associated with worse renal prognosis, while concomitant AIN-causing medications and treatment with steroids were associated with improved renal prognosis. ICPi re-challenge occurred in 22% of patients, of whom 23% developed recurrence of AKI.

Conclusions: Using a multicenter approach, we present the largest clinical study to date to describe the clinical and pathologic features of ICPi-AKI.



SA-OR002

Safety of Immune Checkpoint Inhibitors for Cancer Treatment Among Kidney Transplant Patients: A Systematic Review

Sandhya Manohar,[1] Charat Thongprayoon,[1] Wisit Cheungpasitporn,[2] Sandra Herrmann.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Mississippi Medical Center, Jackson, MS.*

Background: The use of immune checkpoint inhibitors have significantly improved outcomes in multiple cancer types. Kidney Transplant (Ktx) recipients are excluded from trials due to the concern of allo-immunity and possible allograft rejection. Aim of this systematic review was to assess the safety of checkpoint inhibitors among KTx patients.

Methods: Literature search was conducted utilizing MEDLINE, EMBASE and Cochrane Database from inception through April 2019. We included studies that reported outcomes of kidney transplant recipients who received immune checkpoint inhibitors for cancer therapy. Outcomes of interest were allograft rejection and/or allograft failure, The protocol for this meta-analysis is registered with PROSPERO (International Prospective Register of Systematic Reviews; no. CRD42019126777).

Results: 27 articles with a total of 44 KTx patients treated with immune checkpoint inhibitors were identified. Of 44 KTx patients, 18 were reported to have acute rejection of renal allograft. Among those with acute allograft rejection following the treatment, 83% were males with mean age of 62 +/- 13 years. 8 (44%) patients received nivolumab, 3 (17%) received pembrolizumab, 2 (11%) received ipilimumab, 2 (11%) received ipilimumab followed by pembrolizumab, 2 (11%) received ipilimumab followed by nivolumab, and 1 (6%) received pembrolizumab followed by nivolumab. Cancer types were melanoma (66%), lung cancer (17%), and metastatic squamous cell carcinoma of skin (12%), respectively. 3 patients had a partial remission (17%), a patient achieved cancer response (6%) and 5 patients had stable disease (28%). Median time from immune checkpoint inhibitors to acute rejection diagnosis was 24 (IQR 10-60) days. Reported types of acute allograft rejection were cellular rejection (33%), mixed cellular and antibody mediated rejection (17%), and unspecified type (50%). 15 (83%) had allograft failure and 8 (44%) died.

Conclusions: The findings of our study raise awareness of the potential risk of acute allograft rejection/failure following immune checkpoint inhibitors for cancer treatment among KTx patients. Future large-scale clinical studies are required to appraise the pathogenesis and plan optimal therapy that helps sustain graft tolerance without discouraging clinical benefits of immune checkpoint inhibitors for cancer treatment.

SA-OR003

Predictors of AKI in Patients Undergoing CAR T-Cell Therapy

Sherif Metwally,[1] Salma Shaikhouni,[2] Udayan Y. Bhatt,[2] Jason Prosek.[3] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]The Ohio State University, Dublin, OH; [3]The Ohio State University Medicial Center, Columbus, OH.*

Background: Chimeric Antigen Receptor T-cell therapy (CAR-T) is an emerging immunotherapy used to treat certain malignancies. Organ dysfunction, including acute kidney injury (AKI), has been described, and hypothesized to be due to cytokine release syndrome (CRS). Predictors of AKI in patients receiving CAR-T cell therapy have not been adequately studied. We conducted a retrospective cohort study of patients receiving CAR-T cell therapy at our institution, in an attempt to identify those patients who are at risk of developing AKI after receiving this therapy.

Methods: We reviewed the charts of patients who received CAR-T between 5/2016 and 9/2018. A total of 58 patients were included in the study. Development of AKI was defined as increase in creatinine of at least 0.3 above baseline. 32% of patients (N = 19) developed AKI. Univariate analyses were conducted to delineate significant differences between patients who developed AKI compared to those who did not with regards to baseline characteristics, inflammatory markers (CRP, ferritin, albumin), markers of organ dysfunction (AST, bilirubin), and the use of any steroids or tocilizumab.

Results: Univariate analysis revealed comparable age, gender, ethnicity, as well as prevalence of hypertension and diabetes in the two groups. Patients with AKI tended to have a higher BMI (p=0.002) and baseline Cr (p=0.03). Ferritin peaked at a significantly higher level in the AKI group (p=0.008). There was no significant difference in peak CRP or albumin nadir between groups. Patients who developed AKI developed higher AST and Bilirubin levels (p=0.05, p=0.025 respectively). There was no significant difference in the rate of administration of steroids or tocilizumab in the AKI group compared to the other patients. The AKI group had a higher rate of death at 6 months after therapy (47% compared to 13%, p=0.008).

Conclusions: CAR-T cell therapy is gaining increased use for various malignancies. Models have been proposed to predict, diagnose and manage CRS, but not specifically AKI. Our findings indicate that baseline patient characteristics and inflammatory response markers, particularly ferritin, may play a role in predicting worse renal outcomes. Future work may focus on creating a broader predictive model that can help identify and guide management of patients receiving CAR-T who are at risk of AKI.

SA-OR004

AKI and Electrolyte Abnormalities in Patients Receiving Chimeric Antigen Receptor T-Cell (CAR-T) Therapy

Shruti Gupta,[1] Harish Shanthanu Seethapathy,[3] Shveta S. Motwani,[4] Samir M. Parikh,[6] Gary C. Curhan,[5] Kerry Reynolds,[3] David E. Leaf,[2] Meghan E. Sise.[3] *[1]BWH, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]Brigham and Women's Hospital and Dana-Farber Cancer Institute, Newton, MA; [5]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [6]BIDMC/ Harvard Medical School, Boston, MA.*

Background: CAR-T therapy targets tumor antigens using genetically engineered cytotoxic T-cells, and is a breakthrough treatment for hematologic malignancies. Cytokine release syndrome (CRS), a systemic inflammatory response, is a known complication of CAR-T. CRS can lead to acute kidney injury (AKI); however, scant data exist on AKI in adults. We aimed to define the incidence, clinical features, and outcomes of AKI and electrolyte abnormalities in adults receiving CAR-T.

Methods: We performed a retrospective review of adults with lymphoma treated with CAR-T at 2 major cancer centers in Boston. Baseline demographics, laboratory data, and clinical outcomes were obtained from electronic health records. AKI was defined using KDIGO criteria.

Results: Among 78 patients receiving CAR-T, CRS occurred in 85%, of whom 62% required treatment with tocilizumab. AKI occurred in 15 patients (19%): 8 were pre-renal azotemia; 6 acute tubular necrosis; and 1 urinary obstruction related to disease progression. Patients with AKI were more likely to experience higher grades of CRS (grades 3,4). The association between the underlying cause of AKI and length of stay (LOS)/mortality are shown in Figure 1. All 3 patients requiring dialysis died during the hospitalization during which they received CAR-T. Electrolyte abnormalities in the first week after CAR-T were common: hypophosphatemia < 2.0 mg/dL occurred in 51% and hyponatremia < 130mEq/L in 15%.

Conclusions: In the largest report of adverse kidney events associated with CAR-T in adults, AKI and electrolyte abnormalities occur commonly in the context of CRS.

Carfilzomib-Associated Nephrotoxicity: A Systematic Review and Meta-Analysis

Harini Bejjanki, Chintan Shah, Ankur Jain, Rohit Bishnoi, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: There has been growing interest in the field of onco-nephrology with the advent of novel antineoplastic treatments, many of which portend nephrotoxic properties. Emergence of proteasome inhibitors (PI) has resulted in significant improvement in survival of patients with multiple myeloma (MM). Carfilzomib (CFZB) is a second-generation PI currently approved for relapsing or refractory MM. We sought to explore whether CFZB is associated with nephrotoxicity (NTX).

Methods: The present review was performed according to Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement. Articles cited in PubMed, Web of Science, and Clinical Trials Registry, using keywords "Carfilzomib" and "Kyprolis" were searched. A meta-analysis was performed. Cumulative incidence and odds ratios (OR) were calculated using random effect model. We used Common Terminology Criteria for Adverse Events to grade NTX.

Results: A total of 22 studies including 2489 patients were selected. The cumulative incidence of all -grade NTX (grade 1[mild] to grade 5[death]) was 15.5% (CI:11.1-22.1%); high-grade NTX, (grades 3- 5 [life-threatening or resulting in death]) was 4.7 % (CI: 3.3-6.77%). Estimated overall OR of all-grade NTX was 1.81 (CI: 1.09-3.02, p =0.02.). Similarly, the OR of high-grade NTX was 1.85 (CI: 0.93-1.75, p = 0.08). We found no difference in the incidence of all-grade (p =0.38) and high-grade (p = 0.46) NTX between newly diagnosed, relapsing, or refractory MM groups. The high dose of CFZB did not change the incidence of NTX compared to standard dose (p=0.66 and p=0.61 respectively). Similarly, the incidence of NTX was not significantly different when CFZB was used alone or in combination (p=0.63 and p=0.44 respectively). However, concomitant use of immunomodulators significantly increased the incidence of all-grade (p =<0.001), but not high-grade, CFZB-related NTX (p = 0.89).

Conclusions: Currently available data supports the notion that CFZB use is associated with increased risk of NTX. While the risk does not seem to be dose-dependent, it does increase with concomitant use of immunomodulators. Clinicians need to be aware of this complication when considering CFZB use and possibly consider alternative options in patients at risk of renal injury or for those who develop NTX. These results also call for rigorous monitoring of renal function with CFZB use.

SA-OR006

Characterization of the Acute eGFR Response to SGLT2-Inhibition with Empagliflozin

Christoph Wanner,[1] Bettina J. Kraus,[1] Matthew R. Weir,[2] George L. Bakris,[3] David Cherney,[4] Hiddo J. L Heerspink,[5] Silvio E. Inzucchi,[6] Bernard Zinman,[7] Ivana Ritter,[8] Michaela Mattheus,[9] Maximilian von Eynatten,[8] Audrey Koitka-Weber.[8] *[1]University Hospital, Wuerzburg, Germany; [2]University of Maryland School of Medicine, Baltimore, MD; [3]The University of Chicago Medicine, Chicago, IL; [4]University of Toronto, Toronto, ON, Canada; [5]University Medical Center Groningen, Groningen, Netherlands; [6]Yale University School of Medicine, New Haven, CT; [7]Mount Sinai Hospital, Toronto, ON, Canada; [8]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [9]Boehringer Ingelheim Pharma GmbH & Co.KG, Ingelheim, Germany.*

Background: Empagliflozin (EMPA) reduces cardiovascular (CV) and renal risk in type 2 diabetes patients with established CV disease. As shown with RAAS blockade, EMPA also causes an acute eGFR decrease after treatment initiation. Although considered hemodynamic and reversible, it needs to be better understood to avoid premature drug discontinuation.

Methods: In EMPA-REG OUTCOME®, 6,668 participants who received at least one dose of study drug and had an eGFR value at both baseline and week 4 were categorized by % acute eGFR change to: >10% decrease, >0% to ≤10% decrease, ≤0% decrease. eGFR over time was analyzed using mixed model repeated measures. Acute renal failure (ARF) incidence was based on investigator-reported adverse events according to the narrow standardized MedDRA query.

Results: As expected, there were more patients with a >10% decrease in EMPA (28.3%) than in PBO (13.4%); however, an acute eGFR drop >30% with EMPA was rare (1.4%). After initial dynamics, long-term eGFR remained stable in all categories on EMPA (Figure). In multivariate regression analyses, KDIGO risk category (elevated UACR/low eGFR) and diuretic use at baseline were independent predictors of an acute eGFR decrease >10% with EMPA. From baseline to week 4, irrespective of the magnitude of the eGFR decrease, overall adverse events (AEs) and serious AEs were similar or lower with EMPA than PBO. ARF was more frequent in patients experiencing an acute eGFR decrease >10% in both groups, however most were reported as 'renal impairment'. During chronic treatment, overall and renal safety profiles were similar between PBO and all categories on EMPA.

Conclusions: Given the known renal protection with SGLT2 inhibition, our data demonstrate a relatively modest acute eGFR decrease with treatment, less likely to cause discontinuation of this reno-protective therapy.

Renin-Angiotensin-Aldosterone System Blockade Is Associated with Higher Risk of Contrast-Induced AKI in Patients with Diabetes: A Multicenter Propensity Score-Matched Study

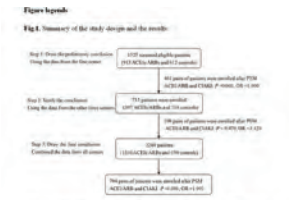
Mengqing Ma. *Sir Run Run Hospital, Nanjing, China.*

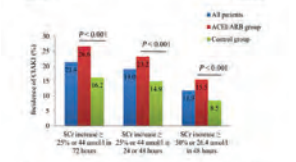
Background: CIAKI is a relatively common complication after treatment of coronary angiography (CAG) and percutaneous coronary intervention (PCI). The role of ACEIs or ARBs on CIAKI is controversial.

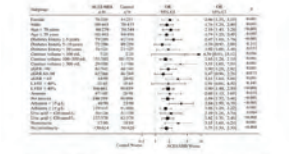
Methods: A retrospective, multi-center design with propensity score matching (PSM) was used to evaluate the effect of ACEIs/ARBs on the occurrence of CIAKI in diabetic patients undergoing CAG and PCI. The primary endpoint CIAKI was defined as an increased serum creatinine level of ≥ 25% or 44 μmol/l (0.5mg/dl) over the baseline level within 72 hours after contrast agent exposed.

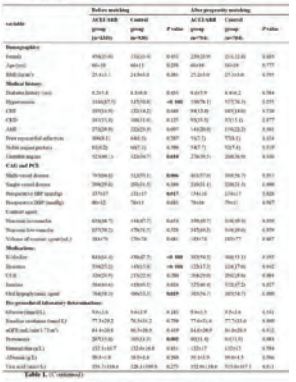
Results: A total of 2240 patients from four centers met the inclusion criteria. On the basis of PSM, 704 patients with ACEIs/ARBs were successfully matched to the control group. The incidence of CIAKI in the ACEIs/ARBs group was significantly higher than that in the control group (26.6% vs.16.2%, P< 0.001), no matter which kind of medicine was used in subgroups. In-hospital endpoints, patients with CIAKI had a higher risk of worsening heart failure (2.3% vs. 1.0%, P= 0.068). However, patients in the control group had an increased risk of overall adverse cardiovascular events (death, myocardial infarction, worsening heart failure, stroke) after PCI (3.8% vs. 1.8%, P= 0.034).

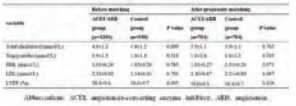
Conclusions: The ACEI/ARB was associated with an increased risk of CIAKI in patients with diabetes, but beneficial for early cardiovascular outcomes.

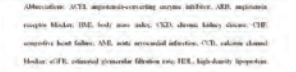


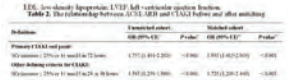


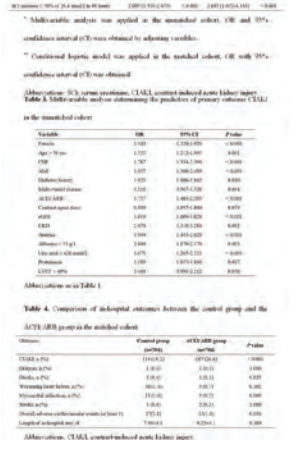












SA-OR008

Risk of AKI Among Critically Ill Patients with Concomitant Use of Vancomycin and Piperacillin-Tazobactam: A Meta-Analysis

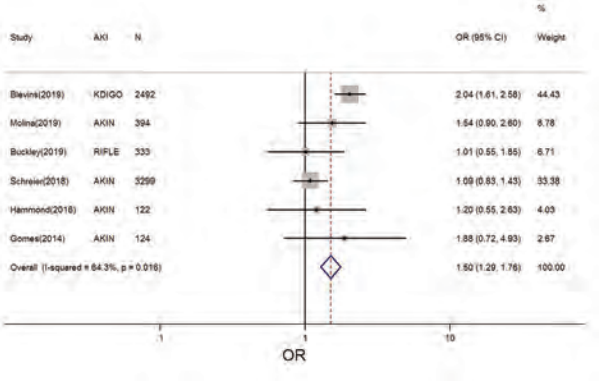
Mengyao Tang,[1] Jerald Cherian,[1] Sahir Kalim.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA.*

Background: Multiple studies have demonstrated that the combination of vancomycin and piperacillin-tazobactam (VPZ) is associated with increased risk of AKI compared to the combination of vancomycin and cefepime (VC) in the general population. Whether this holds true for critically ill patients is particularly important, given that AKI is very common in this population and is associated with increased mortality. Currently the data in critically ill patients is limited and the effect of VPZ in this population is controversial. Thus, the goal of this study was to determine the association between VPZ and AKI in critically ill adults.

Methods: A meta-analysis of observational studies that enrolled critically ill patients receiving VPZ or VC in the ICU setting was conducted. Electronic databases (PubMed, Cochrane and Embase) were searched through April 2019. Effect estimates and 95% CIs were pooled using the random effects model in STATA. The primary outcome was AKI as defined by the individual study. The secondary outcome was time to AKI.

Results: Literature search identified 6 published studies with 6764 patients. The definition of AKI was based on RIFLE, KDIGO or AKIN criteria. The odds of AKI in the VPZ group were higher compared to the VC group (odds ratio, 1.50; 95% CI 1.29-1.76; p<0.001) (Figure 1). There was no difference in the time to AKI between the VPZ group and the VC group (mean difference, -0.06; 95% CI, -0.09 to 0.74 days).

Conclusions: In critically ill patients, concomitant use of vancomycin and piperacillin-tazobactam is associated with an increased risk of AKI just as in the general population. This finding should be taken into consideration when choosing empiric antimicrobial coverage for critically ill patients. The included studies demonstrated some heterogeneity. Thus, future research regarding the use of VPZ in critically ill patients is warranted to confirm these findings.



Forest plot demonstrating the odds ratio of AKI in critically ill patients

Does Erythropoietin (Epo) Protect Extremely Low Gestational Age Neonates (ELGANs) Against AKI?

David J. Askenazi,[1] Robert Schmicker,[3] Russell Griffin,[1] Patrick J. Heagerty,[5] Patrick D. Brophy,[4] Sandra Juul,[5] Stuart Goldstein,[2] Sangeeta R. Hingorani.[6] PENUT Investigators *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]University of Washington Center for Biomedical Statistics, Seattle, WA; [4]University of Rochester, Rochester, NY; [5]University of Washington, Seattle, WA; [6]Seattle Children's Hospital, Seattle, WA.*

Background: The Recombinant Erythropoietin for Protection of Infant Renal Disease (REPAIReD) study is a randomized, placebo-controlled study designed to test the hypothesis that infants randomized to Epo will have lower rates of severe AKI than placebo-treated infants. Secondary outcomes include severity of AKI, AKI at different timepoints (postnatal days 3-7, days 8-14, and days >14), and SCr/Cystatin C values at 7, 9 and 14 postnatal days.

Methods: 936 infants were randomized to Epo vs. placebo. Those who died on days 0, 1, 2 are excluded (n=13) leaving 923 for analysis. Infants recevied EPO 1000 U/kg or placebo IV every other day x 6 doses and then Epo 400 U/kg SQ or sham infections every Monday, Wednesday and Friday until 33 weeks post-menstrual age. AKI is defined by the Neonatal KDIGO classification using the lowest prior SCr as the baseline value. As the first postnatal days reflect maternal SCr, day 3 was first possible AKI day. Severe AKI was defined as doubling of SCr from baseline (stage 2 or 3 AKI). GEE models including gestational age, sex, site and sibship clustering were used for analysis of our primary outcome.

Results: No maternal or neonatal differences by treatment group were observed. 374/923 (40.5%) had at least one epidose of AKI, of which 191/ 374 (51%) had severe AKI. We found no differences in the rates of severe AKI between treatment groups

(Figure 1). GEE models showed no differences in severe AKI rates between treatment groups after controlling for potential confounders (OR [95%CI] = 0.75 [0.53, 1.06]). No difference between treatment groups was seen in our secondary outcomes.

Conclusions: Up to 40% of ELGANS have at least one episode of Neonatal AKI. Epo is not protective for AKI in ELGANS. Whether Epo impacts urine kidney biomarkers or long-term CKD remains an area of investigation.

A Novel Targeting Strategy That Can Prevent Cholesterol Crystal Embolism-Induced AKI and Kidney Infarction

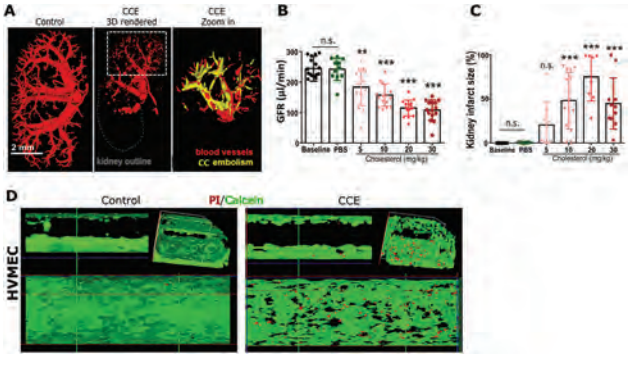
Chongxu Shi,[1] Tehyung Kim,[1] Stefanie Steiger,[1] Barbara M. Klinkhammer,[2] Peter Boor,[2] Hans J. Anders.[1] *[1]Klinikum der Universitat Munchen, Muenchen, Germany; [2]RWTH University Aachen, Aachen, Germany.*

Background: Cholesterol crystal embolism(CCE) is a life-threatening complication of advanced atherosclerosis and often missed as a cause of AKI. Due to the lack of a suitable animal model, little is known about the pathophysiology of CCE.

Methods: We injected the left kidney of C57/BL6 mice with cholesterol crystals(CC). Primary endpoint: GFR. Secondary endpoints: infarct size, kidney injury, vascular injury, vascular occlusions, territorial hypoperfusion and perifocal edema(3D imaging: MRI and microCT). 2D and 3D in vitro studies CC with neutrophils, platelets, and endothelial cells.

Results: CC injection induced CCE in interlobar, arcuate, and interlobular arteries(A). Not CC alone but CC-induced clots obstructed arteries and caused a tight dose-dependent GFR decline(B), i.e. CCE-related AKI, while infarct size showed a higher variability(C). Deficiency of *Mlkl* protected mice from kidney infarction but not AKI, suggesting only targeting crystal clots but not kidney infarct may prevent AKI. Crystal clots were made of fibrin, neutrophils, platelets, and extracellular DNA. Fibrinolysis with rtPA and recombinant DNase all reduced arterial occlusions, GFR loss, and infarct size. For DNase the window-of-opportunity was 3h after CCE. To maximize the renoprotective effect in a clinically potentially feasible manner we tested a single prophylactic dose of necrostatin-1s before CCE and gave DNase 3h after CCE, which entirely prevented AKI and kidney infarction(D, E). In vitro, CC activated platelets, triggered NETs formation, and killed endothelial cells(F). All these mechanisms lead to the DNA release into extracellular space.

Conclusions: CCE induces kidney infarction but AKI develops independently from infarction due to obstruction of pre-glomerular vessels. Not CC but CC-induced clots lead to vascular obstruction. The extracellular DNA as a critical component in CC-induced clots. The window-of-opportunity for DNase therapy is 3h. A 2-step dual targeting strategy can entirely prevent AKI and infarction.



SA-OR011

Pregnancy-Related AKI and Diabetes: Hospitalizations and Clinical Outcomes

Silvi Shah,[1] Karthikeyan Meganathan,[1] Anthony C. Leonard,[1] Annette Christianson,[2] Charuhas V. Thakar.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA, Cincinnati, OH.*

Background: Pregnancy-related acute kidney injury (AKI) is a public health problem and is associated with significant maternal and fetal morbidity and mortality. Clinical outcomes in pregnancy-related AKI, especially in women with diabetes are not well studied.

Methods: Using data from the 2012-2015 Nationwide Inpatient Sample, we identified hospitalizations for pregnancy, acute kidney injury (AKI), and diabetes mellitus using ICD-9-CM and DRG codes in women aged 15-49 years. We compared AKI rates, mortality, and home discharge rates in pregnancy-related AKI in women according to their diabetic status.

Results: We identified 15,550,459 pregnancy-hospitalizations in the study cohort. Rate of pregnancy-related hospitalization involving AKI was 0.1% and increased from 0.09% in 2012 to 0.12% in 2015. Women with pregnancy-related AKI were older than those who did not develop AKI (mean age, 40y vs. 30 y). Pregnancy-related AKI occurred at a higher rate in black women (0.25%) than white women (0.07%, p<0.0001) and at a higher rate in southern and midwest geographical regions (0.12%) than in northeast region (0.09%, p<0.0001). Higher rate of pregnancy-related AKI was observed in urban teaching hospitals (0.14%) than in urban non-teaching hospitals (0.07%) and rural hospitals (0.04%, p<0.0001). Women with pregnancy-related AKI had higher in-hospital mortality than those without AKI (2.6% vs. 0.01%). Overall, 1.3% of women were diabetic. Women with diabetes had higher pregnancy-related AKI hospitalizations than did women without diabetes (1.1% vs. 0.1%). Rate of pregnancy-related hospitalization involving AKI in diabetic women increased from 0.9% in 2012 to 1.2% in 2015. Diabetic women with pregnancy-related AKI did not differ with in-patient hospital mortality compared to pregnancy-related AKI in women without diabetes (3.2% vs. 2.5%) and with discharge to home (76% vs 78%).

Conclusions: Rate of pregnancy-related hospitalization involving AKI has increased overall and in diabetic women. In-hospital mortality is 260-fold higher in women with pregnancy-related AKI than those with no AKI. Women with diabetes have a 10-fold higher risk of AKI during pregnancy than those without diabetes but are not associated with a higher risk of mortality.

SA-OR012

Use of Urinary Neutrophil Gelatinase Associated Lipocalin (NGAL) to Rule Out AKI in Children with High Nephrotoxic Medication Exposure

Stuart Goldstein,[1] Kelli A. Krallman,[1] Alexandra Schmerge,[1] Lynn Dill,[2] Bradley S. Gerhardt,[3] David J. Askenazi.[2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Alabama at Birmingham, Birmingham, AL; [3]CCHMC, Cincinnati, OH.*

Background: Nephrotoxic medication (NTMx) exposure is one of the most common causes of AKI in hospitalized children. We have demonstrated sustained reductions in NTMx exposure and associated AKI by implementation of the Nephrotoxic Injury Negated by Just in time Action (NINJA) program at our institutions. The NINJA program puts processes in place to identify high NTMx exposure and implements daily SCr assessment in exposed patients. Daily blood draws for SCr can be burdensome for the healthcare system and patients. We tested the hypothesis that daily urine NGAL assessments could be used to screen for NTMx AKI, allowing for a more limited SCr assessment.

Methods: This was a 2 center prospective study of children identified with high NTMx exposure (3 or NTMx on the same day or ≥3 days of IV vancomycin or an IV aminoglycoside). Patients had daily SCr drawn as standard of care for the NINJA program. Urine for NGAL measurement (The NGAL Test™, Bioporto, Denmark) was obtained for the first 7 days of high NTMx exposure. AKI was defined by the SCr based KDIGO criteria, and severe AKI (sAKI) was defined as KDIGO Stage 2 or 3 AKI.

Results: 117 patients had 498 urine samples available for analysis. 27 patients had AKI; 9 patients had severe AKI. The performance of NGAL at various concentrations (ng/ml) to predict AKI and severe AKI is shown in the table.

Conclusions: Urine NGAL level < 150 ng/ml has high NPV for any AKI and sAKI. We suggest NGAL can be used to complement SCr as part of the assessment for NTMx AKI, limiting the burden on providers and patients associated with a daily blood draw.

Funding: Commercial Support - Bioporto Diagnostics, Inc

NGAL level/AKI	Sensitivity	Specificity	PPV	NPV
50/Any AKI	35% (14-62%)	72% (62-80%)	18% (9-30%)	87% (82-90%)
150/Any AKI	24% (7-50%)	92% (85-96%)	33% (14-60%)	88% (84-90%)
300/ Any AKI	0% (0-20%)	96% (90-99%)	0	85% (84-85%)
50/Severe AKI	50% (7-93%)	71% (62-80%)	6% (2-15%)	98% (94-99%)
150/Severe AKI	25% (0-81%)	90% (83-95%)	8% (2-35%)	97% (95-98%)
300/Severe AKI	0% (0-60%)	96% (91-99%)	0	96% (96-97%)

Association Between Urinary Dickkopf-3, AKI, and Subsequent Loss of Kidney Function in Patients Undergoing Cardiac Surgery: An Observational Cohort Study

Stefan J. Schunk,[1] Alexander Zarbock,[4] John A. Kellum,[3] Danilo Fliser,[2] Thimoteus Speer,[1] Stephen Zewinger.[1] *[1]Saarland University Hospital, Homburg/Saar, Germany; [2]Department of Internal Medicine IV, Saarland University, Homburg/Saar, Germany; [3]University of Pittsburgh, Pittsburgh, PA; [4]University Hospital Münster, Münster, Germany.*

Background: Cardiac surgery is associated with a high risk of postoperative acute kidney injury (AKI) and subsequent loss of kidney function. We explored the clinical utility of urinary dickkopf-3 (DKK3), a renal tubular stress marker, for preoperative identification of patients at risk for AKI and subsequent kidney function loss.

Methods: The study comprised consecutive patients who had elective cardiac surgery at the Saarland University Medical Centre (Homburg, Germany; derivation cohort) and

those undergoing elective cardiac surgery who were enrolled in the prospective RenalRIP multicentre trial (validation cohort) and who were randomly assigned to remote ischaemic preconditioning or a sham procedure. The association between the ratio of preoperative urinary concentrations of DKK3 to creatinine (DKK3:creatinine) and postoperative AKI, and subsequent kidney function loss was assessed.

Results: In the 733 patient in the derivation cohort, urinary concentrations of DKK3 to creatinine that were higher than 471 pg DKK3 per milligram of creatinine were associated with significantly increased risk for AKI (OR 1.65, 95% CI 1.10–2.47, p=0.015), independent of baseline kidney function. High urinary DKK3:creatinine concentrations were independently associated with significantly lower kidney function at hospital discharge and after a median follow-up of 820 days. In the RenalRIP trial, preoperative urinary DKK3:creatinine concentrations higher than 471 pg/mg were associated with a significantly higher risk for AKI (OR 1.94, 95% CI 1.08–3.47, p=0.026), persistent renal dysfunction (OR 6.67, 1.67–26.61, p=0.0072), and dialysis dependency (OR 13.57, 1.50–122.77, p=0.020) after 90 days compared with DKK3:creatinine concentrations of 471 pg/mg or less. Urinary DKK3:creatinine concentrations higher than 471 pg/mg were associated with significantly higher risk for AKI and persistent renal dysfunction only in patients having a sham procedure, but not remote ischaemic preconditioning.

Conclusions: Preoperative urinary DKK3 is an independent predictor for postoperative AKI and for subsequent loss of kidney function. Urinary DKK3 might aid in the identification of patients in whom preventive treatment strategies are effective.

SA-OR014

The Association Between Intraoperative Fluid Balance and Postoperative AKI in Noncardiac Surgery

Masatoshi Nishimoto,[1] Miho Tagawa,[1] Maiko Kokubu,[3] Takayuki Hamano,[2] Masaru Matsui,[3] Masahiro Eriguchi,[1] Ken-ichi Samejima,[1] Yasuhiro Akai,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kashihara, Japan; [2]Osaka University Graduate School of Medicine, Suita, Japan; [3]Nara Prefecture General Medical Center, Nara, Japan.*

Background: Insufficient fluid administration may cause prerenal acute kidney injury (AKI) though excess fluid administration was reported to be associated with postoperative AKI in cardiac surgery. Little is known about the association between intraoperative fluid balance (IFB) and postoperative AKI in non-cardiac surgery.

Methods: This is a retrospective cohort study on adults who underwent non-cardiac surgery under general anesthesia from 2007 to 2011 at Nara Medical University. Exclusion criteria were urological or obstetric surgery, those with missing data for analyses, and preoperative dialysis. The exposure of interest was IFB and outcome variable was postoperative AKI, defined as KDIGO criteria, within 1 week after surgery. IFB was defined as (amount of fluid administration – urine output – amount of bleeding) / body weight. Data were analyzed using logistic regression models.

Results: Data for 5,168 subjects were available for analyses. Median age was 63, 46.7% were male, and baseline eGFR was 78.2. AKI was observed in 309 (6.0%). Higher IFB (per 1 SD) was independently associated with postoperative AKI after adjustment for baseline characteristics, intraoperative blood pressure, and intraoperative use of medications (Table 1). A subgroup analysis indicated the association between higher IFB and AKI was similar across intraoperative urine output or amount of bleeding (p for interaction = 0.27 and 0.43, respectively). There were no effect modifications by age, sex, preoperative renal function, or prior history of cardiovascular disease.

Conclusions: Higher IFB was independently associated with postoperative AKI. Association was similar across urine output. These results suggest that the association was not due to decrease in intraoperative urine output. Excessive fluid administration might cause renal congestion and subsequent AKI.

Table 1. Odds ratio for postoperative AKI associated with per 1 SD increase of intraoperative fluid balance.

Model	Odds ratio (95% CI)
Unadjusted	1.33 (1.22–1.45)
Model 1	1.20 (1.09–1.33)
Model 2	1.19 (1.08–1.32)
Model 3	1.19 (1.08–1.32)
Model 4	1.18 (1.07–1.31)
Model 5	1.18 (1.07–1.31)

Model 1 ; Adjusted for age, sex, body mass index, hypertension, diabetes mellitus, cerebrovascular disease, cardiovascular disease, type of surgery, emergency surgery, surgery of malignancy, regular use of ACE–I or ARB, other anti–hypertensive agents, diuretics, NSAIDs, contrast agents, preoperative hematocrit, serum albumin, logCRP, estimated GFR, and preoperative proteinuria.
Model 2 ; Model 1 + lowest intraoperative systolic blood pressure (SBP) (per 1 SD).
Model 3 ; Model 2 + maximum intraoperative delta SBP* (per 1 SD).
Model 4 ; Model 3 + intraoperative use of diuretics.
Model 5 ; Model 4 + intraoperative use of vasopressor.
* delta SBP = SBP at the beginning of surgery − lowest intraoperative SBP

SA-OR015

Plasma Biomarkers to Identify Patients at Increased Risk of CKD Following an Episode of AKI

Nicholas M. Selby,[1,2] Michelle Hutchinson,[3] Rebecca A. Packington,[2] Eibhlin M. McCole,[4] Mary Jo Kurth,[5] Ciaran Richardson,[4] Peter Fitzgerald,[5] Rosamonde E. Banks.[3] *[1]Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom; [2]Department of Renal Medicine, University Hospitals of Derby and Burton, Derby, United Kingdom; [3]University of Leeds, Leeds, United Kingdom; [4]Randox Teoranta, Donnegal, Ireland; [5]Randox Laboratories Ltd, Antrim, United Kingdom.*

Background: The long-term sequelae of acute kidney injury (AKI) on renal function and mortality are increasingly appreciated, but there remains the need for prospective studies to develop strategies to identify those at greatest risk. We aimed to test whether biomarkers improve prediction of long-term outcomes of AKI.

Methods: In a single centre, participants were identified using a hospital-wide electronic AKI detection system. Plasma samples were collected at 3months after hospitalisation and a panel of 14 biomarkers were measured using a multiplex biochip array method. This was done firstly in a discovery cohort (112 AKI patients) with the most promising markers assayed in the remaining 388 AKI patients (validation cohort). Measures of renal function, proteinuria and survival were assessed at 1 and 3 years. CKD progression was defined as ≧25% decline in eGFR from baseline (pre-AKI) with a decline in eGFR stage.

Results: Median age was 70yrs (IQR 14), AKI episodes were predominantly stage 1 with median duration 3 days (IQR 3) and 29% had pre-existing CKD. There was no difference in age, gender or smoking status between discovery and validation cohorts. The proportion of AKI patients with CKD progression was 21% and 22% at year 1 and 3 respectively. Mortality was 4.3% at year 1 and 15.8% at year 3. Clinical factors associated with CKD progression included eGFR at 3months, albuminuria, severity and duration of AKI. In the discovery cohort, four markers were associated with CKD progression, including NGAL and cystatin C. Multiplexed models were developed to include biomarkers and clinical variables; when the models derived in the discovery cohort were applied to the validation cohort, AUC's improved e.g. AUC of best performing model in validation cohort 0.81 (95% CI 0.75 to 0.87) to discriminate those with CKD progression at 1 year.

Conclusions: Non-recovery of renal function is common following AKI, even in a general hospital population with predominantly AKI stage 1. We present data evaluating the utility of a panel of biomarkers to identify those at highest risk.

Arterial Stiffness Independently Predicts AKI in SPRINT

Nina Bispham,[2] Kristen L. Nowak,[3] Zhiying You,[4] Mark A. Supiano,[5] Michel Chonchol,[2] Anna J. Jovanovich.[1] *[1]Denver VA / University of Colorado, Denver, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [4]UC Denver, Aurora, CO; [5]University of Utah Geriatrics Division, Salt Lake, UT.*

Background: Arterial stiffness is associated with increased risk for kidney function decline and cardiovascular disease in both healthy and chronic kidney disease populations, independent of blood pressure. An episode of acute kidney injury (AKI) is also associated with increased risk for kidney disease progression and cardiovascular disease. However, it is unclear if arterial stiffness predicts AKI. We hypothesized that higher arterial stiffness at baseline was independently associated with time to incident AKI among participants in the Systolic Blood Pressure Intervention Trial (SPRINT).

Methods: Arterial stiffness was measured as carotid to femoral pulse-wave velocity (CFPWV) in 613 older adults at high risk for cardiovascular events who participated in an ancillary study of SPRINT. Cox proportional hazards analysis was used to examine the association between baseline CFPWV and time to incident AKI.

Results: Mean±sd age was 72±9 years and 40% (n=244) of participants were female. Mean±sd baseline CFPWV was 10.8±2.7 m/s in the whole cohort. In the 593 individuals who did not have an AKI event, baseline CFPWV was 10.7±2.7 m/s. In the 20 participants who had incident AKI, baseline CFPWV was 12.5±2.7 m/s ($p<0.01$) and median (IQR) time to AKI was 453 (289-724) days. After adjusting for demographics, randomization group, comorbidities, smoking, number of antihypertensive medications, baseline estimated glomerular filtration rate, urinary albumin to creatine ratio, and systolic blood pressure, risk of an AKI event was 32% higher for each m/s increase in baseline CFPWV (HR: 1.32, 95% CI: 1.13-1.53).

Conclusions: Greater large-elastic artery stiffness is a strong independent predictor of incident AKI in older adults at high risk for cardiovascular events. Clinical assessment of arterial stiffness may represent a useful tool to predict AKI, as well as a potential therapeutic target.

SA-OR017

Predicting Severe AKI, Fluid Overload, and Renal Replacement Therapy with the Renal Angina Index in Critically Ill Children

Kelli A. Krallman, Jean-Philippe Roy, Ranjit S. Chima, Alexandra Schmerge, Bradley S. Gerhardt, Lin Fei, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: The Renal Angina Index (RAI) and urinary Neutrophil Gelatinase Associated Lipocalin (uNGAL) can be used to risk stratify patients for development of severe AKI (sAKI). Our research has focused on combining the RAI and NGAL for early detection and acute kidney injury (AKI) prediction.

Methods: Patients admitted to the Pediatric Intensive Care Unit (PICU) from 7/1/18 to 11/30/18, underwent an automated RAI assessment 12 hours after admission. RAI+ patients were defined by RAI ≥ 8 and had uNGAL assessed. A cutoff value of 150ng/mL was used to stratify patients with the primary outcome measure the development of sAKI (KDIGO Stage 2 or 3) through PICU day 4. Secondary outcomes included fluid overload (FO) and renal replacement therapy (RRT) at PICU day 7, as well as PICU length of stay (LOS).

Results: Over our study period 1103 RAIs resulted from 1022 patients. After excluding patients with ESRD and with admissions less than 2 days, 627 RAIs from 569 patients were examined, of which 63 (10.0%) were RAI+. The incidence of Day 2-4 sAKI was higher in the RAI+ cohort compared to RAI- patients (38% vs. 1.8%, *p<0.001*). With the addition of uNGAL, the rate of sAKI in RAI+NGAL+ was higher than in RAI+NGAL- or RAI- patients (55.5% vs 17.6% vs 1.8%, *p<0.0001*). RAI+ patients had a higher need for RRT compared to RAI- patients (13% vs. 0.4%, *p<0.001*). PICU and hospital length of stay were also longer in RAI+ patients: PICU LOS 4.6 vs 3.1 days (*p<0.02*), Hospital LOS 17.8 vs 7.5 days (*p<0.001*). There was no significant difference between RAI+/- patients in the occurrence or duration of FO (*p=0.14, p=0.11*).

Conclusions: The RAI alone continues to be a good rule-out test for sAKI in the PICU, and addition of NGAL is promising for improved sAKI prediction. Additional research needs to be conducted on a larger sample size to better assess the clinical relevance of the RAI NGAL model in predicting sAKI and other relevant outcomes.

Funding: NIDDK Support

Performance of RAI and NGAL in Predicting sAKI

	RAI ≥ 8 on Day 2-4 sAKI	RAI ≥ 8 + NGAL ≥ 150ng/mL on Day 2-4 sAKI
Negative Predictive Value (NPV)	98.2% (97.1% to 99.0%)	97.8% (96.7% to 98.5%)
Positive Predictive Value (PPV)	38.1% (29.8% to 47.2%)	55.2% (39.6% to 69.8%)
Sensitivity	70.6% (52.5% to 84.9%)	55.2% (35.7% to 73.6%)
Specificity	93.4% (91.1% to 95.3%)	97.8% (96.2% to 98.8%)

Hemoglobin A1c and Major Adverse Kidney Events After Cardiac Surgery

Samuel Short,[1] Gregory L. Hundemer,[1] James Rawn,[1] Andrea L. Axtell,[2] David E. Leaf.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Diabetes mellitus (DM) is a well-known risk factor for acute kidney injury (AKI). However, nearly all prior studies in the setting of AKI assessed DM as a dichotomous variable. We investigated whether hemoglobin A1c, assessed categorically and continuously, associates monotonically and independently with AKI following cardiac surgery.

Methods: We performed a retrospective cohort study in 15,892 patients who underwent cardiac surgery at two medical centers in Boston, MA, between 2008-2018. The primary exposure was the most recent A1c within 6 months prior to surgery. We assessed A1c in 6 categories: low (<5%), reference (5–5.6%), prediabetes (5.7–6.4%), well-controlled DM (6.5–6.9%), moderately-controlled DM (7–8.9%), and poorly-controlled DM (≥9%). The primary endpoint was any Major Adverse Kidney Event occurring within 7 days of surgery (MAKE7), defined as an increase in serum creatinine ≥50%, dialysis, or death. We used multivariable logistic regression to adjust for potential confounders.

Results: The incidence of MAKE7 was 12%. Compared to the reference group, we observed a monotonic increase in the risk of MAKE7 with higher A1c categories. Patients with an A1c ≥9 vs. 5–5.6% had a nearly two-fold higher risk of MAKE7 in unadjusted models (odds ratio, 1.99; 95% CI, 1.56 to 2.53). We found similar results in multivariable adjusted models that included 13 key variables (Figure). We also found similar results in models that assessed higher stages of AKI. When assessed as a continuous variable, the adjusted odds ratio for MAKE7 per 1-percent increase in A1c was 1.10 (95% C, 1.05 to 1.15). Finally, patients with an A1c <5% also appeared to be at increased risk of MAKE7.

Conclusions: Both higher and lower hemoglobin A1c values are independently associated with higher risk of MAKE7 following cardiac surgery.

Funding: NIDDK Support

Contrast-Associated AKI Is Not Reflective of Intrinsic Injury

Caroline Liu,[1] Steven D. Weisbord,[2,4] James S. Kaufman,[3] Heather Thiessen Philbrook,[1] Maria K. Mor,[2,5] Paul M. Palevsky,[2,4] Chirag R. Parikh.[1] PRESERVE Trial Study Group *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]Division of Nephrology, VA New York Harbor Healthcare System, New York, NY; [4]University of Pittsburgh School of Medicine, Pittsburgh, PA; [5]Department of Biostatistics, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA.*

Background: There is controversy regarding the mechanism of contrast-associated acute kidney injury (CA-AKI). Biomarkers may provide insight into whether the etiology of CA-AKI is mediated by nephron injury. The PRESERVE trial followed participants for CA-AKI and 90-day major adverse kidney events and death (MAKE-D) after contrast angiography. In this sub-study, we evaluated the association of the absolute changes (Δ) and relative ratios of urine and plasma biomarkers with CA-AKI and MAKE-D.

Methods: We measured injury (KIM-1, NGAL, IL-18) and repair (MCP-1, UMOD, and YKL-40) proteins in urine and plasma at baseline and 2-4 hours post-angiography in a subset of PRESERVE trial participants. We calculated the absolute Δ and relative ratio between post-operative and baseline levels. We then assessed the association between absolute Δs and relative ratios with CA-AKI and MAKE-D.

Results: Participants (n=922) were predominately male (96%), diabetic (82%) with mean±sd age of 70±8 years. 73 and 60 participants experienced CA-AKI and MAKE-D, respectively. The absolute Δs and relative ratios were not statistically different by CA-AKI status (**Figure**). The majority of participants experienced an insignificant decrease in biomarkers regardless of CA-AKI or MAKE-D status. Findings remained after indexing urine biomarkers to urine creatinine and after adjusting for baseline eGFR and urine albumin to creatinine ratio.

Conclusions: The lack of significant differences in injury and repair biomarkers in patients by CA-AKI and MAKE-D status suggests that CA-AKI is not mediated by intrinsic nephron injury. While our findings need to be validated, our results can help advance pharmacological developments for the prevention of CA-AKI.

ACE-I/ARB Use and Outcomes After Hospitalized AKI

Sandeep Brar,[1] Kathleen D. Liu,[2] Alan S. Go,[3] Raymond K. Hsu,[4] Vernon M. Chinchilli,[7] Paul L. Kimmel,[5] James S. Kaufman,[6] Chi-yuan Hsu.[1] ASSESS-AKI study investigators *[1]University of California San Francisco, San Francisco, CA; [2]University of California at San Francisco School of Medicine, San Francisco, CA; [3]Kaiser Permanente Northern California, Oakland, CA; [4]University of California, San Francisco, San Francisco, CA; [5]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [6]VA New York Harbor Healthcare System, New York, NY; [7]Penn State College of Medicine, Hershey, PA.*

Background: The risk-benefit ratio of ACE-I/ARB therapy after an AKI episode is unclear.

Methods: We studied 1570 patients recently discharged from hospital and enrolled in a multi-center prospective cohort study (ASSESS-AKI). Follow-up began 3 months after index hospitalization and continued through November 2018. Half of the participants had AKI during the index hospitalization. ACE-I/ARB use and covariates were ascertained 3 months after discharge from the index hospitalization. We used multivariable Cox regression adjusting for demographics, cardiovascular disease, diabetes mellitus, heart failure (HF), blood pressure, urine protein to creatinine ratio, and eGFR to examine the association between ACE-I/ARB use and subsequent death, AKI (≥50% difference between peak and nadir inpatient serum creatinine), renal progression (ESRD or halving of eGFR), and adjudicated HF events.

Results: Among study participants who did not have AKI during index hospitalization (N=806), mean age was 65 years, mean eGFR 74 ml/min/1.73m^2, and 45% self-reported use of ACE-I/ARB 3 months after hospitalization. Among study participants who did have AKI during index hospitalization (N=764), mean age was 64 years, mean eGFR 65 ml/min/1.73m^2, and 50% self-reported use of ACE-I/ARB 3 months after hospitalization. Mean follow-up time was 3.6 years. ACE-I/ARB therapy 3 months after an AKI hospitalization was associated with a lower risk of another hospitalized AKI event and a lower risk of death (Table).

Conclusions: Use of ACE-I/ARB in survivors of hospitalized AKI was not associated with increased risk of subsequent AKI but was associated with lower risk of death.

Funding: NIDDK Support

Outcomes beyond 3 months after index hospitalization (no. of events)	Adjusted HR for ACE-I/ARB use 3-months after index hospitalization (95% CI)		P-value for interaction between ACE-I/ARB use 3 months after index hospitalization and AKI during index hospitalization
	AKI during index hospitalization (N=764)	No AKI during index hospitalization (N=806)	
AKI (442)	**0.75 (0.58, 0.97)**	1.23 (0.90, 1.67)	0.01
Death (320)	**0.73 (0.55, 0.97)**	0.69 (0.46, 1.04)	0.29
Renal progression (139)	**0.81 (0.55, 1.21)**	0.49 (0.23, 1.07)	0.74

Clonal Hematopoiesis in ANCA-Associated Vasculitis

Marlene Weiss,[3] Anthony Rousselle,[5] Lars Bullinger,[6] Kai-Uwe Eckardt,[4] Ralph Kettritz,[7] Frederik Damm,[2] Adrian Schreiber.[1] *[1]Charite Berlin, Berlin, Germany; [2]Department of Hematology, Oncology, and Tumor Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Charité Berlin, Germany, Berlin, Germany; [4]Charité – Universitätsmedizin Berlin, Berlin, Germany; [5]ECRC, Berlin, Germany; [6]Charité University Medicine, Berlin, Germany; [7]Universitatsmedizin Berlin, Berlin, Germany*.

Background: Antineutrophil cytoplasmic autoantibodies (ANCA)-associated vasculitides (AAV) are induced by binding of ANCA IgG to myeloid cells and their subsequent activation. Autoantigen expression has been described to be dysregulated on both molecular and protein expression level in AAV patients. Recently, clonal hematopoiesis of indeterminate potential (CHIP), which is defined by the presence of a somatic mutation in the peripheral blood of individuals without evidence of hematologic neoplasms, has been linked with increased risk of hematologic cancer and cardiovascular disease. Here we aimed to characterize CHIP in patients with AAV.

Methods: 112 patients with AAV (median age 64, range 18-84) were screened for CHIP using targeted sequencing. mRNA expression of PR3 and MPO in peripheral blood leukocytes was quantified by qPCR, ANCA autoantigen expression and neutrophil reactive oxygen generation were measured by flow-cytometry.

Results: CHIP was discovered in 34 out of 112 AAV patients (in total of 46 somatic mutations), which is a higher prevalence than expected in age-matched healthy controls (30.4% vs. 13.5%, p<0.001). The overall frequency of CHIP increased with age, however, 18.2% of patients <55 years had CHIP. The most frequently mutated genes were *DNMT3A* (19/46=39.1%), *TET2* (7/46=15.2%), and *ASXL1* (4/46=8.7%). CHIP was not associated with disease activity, ANCA subtype, or therapy. No differences in blood counts, creatinine levels, comorbidities, the development of malignancies, disease activity status, and AAV relapse risk were observed. However, disease manifestation patterns differed: CHIP^{positive} GPA patients showed less renal (68.2% vs. 88.5%, p=0.049) and nervous system involvements (0% vs. 19.2%, p=0.028). Longitudinal analysis of 23 CHIP clones in 19 selected patients revealed that more than 25% of patients showed an increase in clone size over time. Finally, a downregulation of both PR3 and MPO mRNA in peripheral blood leukocytes and significant less ROS production after ANCA IgG stimulation of neutrophils from CHIP^{positive} AAV patients compared to CHIP^{negative} patients (stimulation-index aMPO 7.8±5.4 vs. 15.5±9.3 and aPR3 6.8±3.1 vs. 13.2±7.7) was found.

Conclusions: Our findings provide novel experimental evidence of CHIP in AAV patients. Additionally, we found a functional impact of CHIP on ANCA-related neutrophil functions.

SA-OR022

Staphylococcus Aureus-Induced Tissue Resident Memory T Helper 17 Cells ($T_{RM}17$ Cells) Drive Renal Autoimmune Disease

Christian F. Krebs,[2] Daniel Reimers,[2] Yu Zhao,[2] Patricia Bartsch,[1] Alina Borchers,[1] Malte Hellmig,[1] Christoph Kilian,[6] Leon U. Enk,[1] Jan-Hendrik Riedel,[4] Tobias B. Huber,[2] Jan-Eric Turner,[3] Ulf Panzer,[2] Hans-willi Mittrücker.[5] *[1]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]University Medical Center Hamburg, Hamburg, Germany; [4]UKE, Hamburg, Germany; [5]Institute for Immunology, Hamburg, Germany; [6]UKE, Hamburg, Germany*.

Background: Tissue resident memory T (Trm) cells represent a new type of memory cells that reside in peripheral organs without recirculating. They provide rapid on-site immune protection against previous exposed pathogens. However, it remains to be clarified whether Trm cells also interfere with responses unrelated to the primary infection, such as organ-specific autoimmunity.

Methods: To study Trm cells, we used a combined approach of flow cytometry, histology and single cell RNA-sequencing. Human kidney tissue was obtained from tumour-nephrectomies. In mice, renal Th17 cells were induced by S. *aureus* infection. GN was induced with the nephrotoxic sheep serum or by immunisation with a fragment of the α3 chain of type IV collagen. We also used *Listeria monocytogenes* in another infection model.

Results: We found high frequencies of CD4$^+$ CD69$^+$ Trm cells of the Th17 phenotype, which we identified based on homology to published core transcriptional and protein data sets. We operationally named them Trm17 cells. CD4$^+$ Th17 cells are involved in the response to major human pathogens such as *S. aureus*, and play a critical role in autoimmunity such as crescentic glomerulonephritis (cGN). We established a mouse model of *S. aureus* infection that resulted in initially high renal bacteria titres and a profound accumulation of Th17 cells

in the kidney. Renal Th17 cells persist long-term (>100 days) after clearance of the infection, present with the phenotype of Trm cells and partially protect against re-infection. Induction of autoimmune kidney disease (cGN) in mice, which recovered from *S. aureus* infection, resulted in a more rapid and aggravated renal Th17 response and consequently developed a more severe course of cGN. By labelling renal cells in photoconvertible Kaede-transgenic mice, we were able to demonstrate that *S. aureus* induced Trm17 cells contribute significantly to the enhanced local IL-17 immune response in cGN.

Conclusions: Thus, pathogen-induced Trm17 cells in peripheral tissues are capable of rapidly responding to an antigenic unrelated challenge thereby driving renal autoimmune diseases. Our data suggest that Trm cells might have a previously unknown role in amplifying organ-specific autoimmunity.

Infiltrating Citrullinated Histone (CitH3)-Positive Neutrophils May Be Involved in Active Glomerular and Interstitial Lesions in ANCA-Related Vasculitis

Hidehito Kimura,[2] Akiko Mii,[1] Yusuke Arakawa,[1] Shuichi Tsuruoka,[1] Akira Shimizu.[3] *[1]Nippon Medical School, Tokyo, Japan; [2]Nippon medical school, Tokyo, Japan; [3]Nippion Medical School, Tokyo, Japan.*

Background: Activated neutrophils release neutrophil extracellular traps (NETs), resulting in cell death called NETosis. NETs formation has been reported to be involved in the onset of systemic lupus erythematosus and ANCA-related vasculitis (AAV). However, the precise mechanism is unknown. Citrullination of histones is an essential step for NETs formation, and the presence of citrullinated histones (CitH3) in neutrophils may be involved in disease induction and activity. We examined an association between infiltrating neutrophils with/without CitH3 and disease specificity and activity in various glomerulonephritis (GN).

Methods: We selected following cases, who presented proliferative GN with neutrophil infiltration; AAV (n=8), lupus nephritis (LN) (n=5), Henoch schonlein purpura nephritis (HSPN) (n=5), and post-streptococcal acute GN (PSAGN) (n=5). We assessed clinical characteristics and histopathological findings and examined myeloperoxidase (MPO)-positive (+) infiltrating neutrophils with or without CitH3 in glomeruli and interstitium and association with the necrotizing and crescentic glomerular lesions and tubulointerstitial lesions.

Results: Number of MPO+ neutrophils in glomeruli was significantly higher in PSAGN, LN and HSPN than in AAV. In LN, MPO+ neutrophils were found mainly on the margin of glomerular tufts which formed wire-loop lesions. In part of them, CitH3+ neutrophils were seen. In PSAGN and HSPN, many MPO+ infiltrated in glomeruli, however, only a few CitH3+ neutrophils. In contrast, the frequency of CitH3+ neutrophils in AAV was significantly higher while the number of MPO+ neutrophils was significantly lower than in other diseases. CitH3+ neutrophils were observed in necrotizing lesion along glomerular capillaries. Moreover, the frequency of CitH3+ neutrophils was significantly higher not only in glomeruli but also in interstitium than in the others. In addition, peritubular capillaritis with CitH3+ neutrophils was remarkable.

Conclusions: CitH3 immunostaining was useful tool for identifying activated neutrophils. In AAV cases, the frequency of CitH3+ neutrophils in both glomeruli and interstitium was significantly higher. The frequency of CitH3+ neutrophils is not only a disease specific marker but also a possibility of becoming a marker for disease activity in AVV.

CFHR5 Deposition in ANCA-Associated Glomerulonephritis

Silke R. Brix,[1,2] Kajal Patel,[7] Martin Busch,[3] Christine Skerka,[6] Rolf A. Stahl,[5] Thorsten Wiech.[4] *[1]Manchester University NHS Foundation Trust, Manchester Royal Infirmary, Manchester, United Kingdom; [2]University of Manchester, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; [3]University Hospital Jena, Jena, Germany; [4]Department of Pathology, University Hospital Hamburg Eppendorf, Hamburg, Germany; [5]University of Hamburg, Hamburg, Germany; [6]Leibniz Institute for Natural Product Research and Infection Biology, Jena, Germany; [7]University of Manchester, Manchester, United Kingdom.*

Background: The complement system has been found to play a role in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis. Complement factor H (CFH) is a negative regulator of complement C3 activation. Complement factor H related protein 5 (CFHR5) competitively binds factor 3 yet enables further complement activation. We hypothesized CFHR5 facilitates more aggressive renal ANCA disease.

Methods: Here, we investigated CFHR5 deposition in biopsies of patients with ANCA-associated glomerulonephritis (GN) from a multicenter cohort (n=207) and correlated it with clinical outcome. Granular mesangial and endothelial deposition was scored semiquantitatively (0-3).

Results: Initial renal function at time of diagnosis did not correlate with CFHR5 staining. Patients, however, who reached end stage kidney disease during-follow up were found to have a more prominent CFHR5 deposition than patients who remained dialysis independent ($p<0.0001$). Patients suffering from renal relapsing disease and patients who died during follow-up showed a stronger CFHR5 positivity as well ($p=0.01$, $p=0.03$).

Conclusions: Glomerular CFHR5 positivity is associated with renal outcome in ANCA-associated GN and may serve as a prognostic marker in the disease.

SA-OR025

Induction of Eosinophilic Granulomatosis with Polyangiitis by Myeloperoxidase-ANCA in Mice with Allergic Airway Disease

Peiqi Hu,[1] Hong Xiao,[1] Marco A. Alba,[3] Ronald J. Falk,[2] J. Charles Jennette.[3] *[1]UNC-Chapel Hill, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a phenotype of ANCA vasculitis associated with asthma, and blood and tissue eosinophilia. EGPA is characterized by eosinophil-rich infiltrates, granulomatous inflammation, necrotizing vasculitis and pauci-immune crescentic glomerulonephritis (CGN). We hypothesized that EGPA can be induced by injecting anti-MPO into mice with asthma-like disease.

Methods: Ovalbumin (OVA) or house dust mites (HDM) were used to induce acute allergic airway inflammation in C57Bl6 mice that were injected either intraperitoneally (i.p.) with 20ug OVA on days -21 and -7 and administered intranasally (i.n.) 1% OVA in saline on days 1-5; or administrated 25ug HDM protein i.n. in 20ul PBS for 5 days, followed by 2 days of rest, then repeated for another week, followed by 2 daily HDM doses. Thereafter, mice received 75ug/g body weight anti-MPO IgG i.p. Mice were sacrificed 6 days after anti-MPO injection.

Results: Control mice receiving OVA(n=3) or HDM(n=3) but no anti-MPO developed mild eosinophil-rich pulmonary airway inflammation without pulmonary hemorrhage, granulomatous lesions, or CGN. Mice receiving anti-MPO without OVA or HDM (n=3) developed CGN but no lung lesions. Six days after iv injection of anti-MPO IgG, OVA(n=3) or HDM (n=3) treated mice developed more extensive eosinophil-rich pulmonary inflammation, acute capillaritis with hemorrhage and granulomatous inflammation containing numerous eosinophils with admixed multinucleated giant cells. All mice receiving anti-MPO had similar levels of serum anti-MPO and developed similar CGN severity (avg. crescents with OVA 18.7%, HDM 18.7% and anti-MPO alone 18%); whereas control mice treated with OVA or HDM alone had no CGN.

Conclusions: Mouse models of anti-MPO induced EGPA can be generated in mice with acute allergic airway disease. We hypothesize that respiratory tract neutrophils primed by the allergic airway disease are activated by anti-MPO IgG, and amplify the eosinophil-rich inflammation resulting in pulmonary capillaritis and granulomatosis. These models provide useful tools for studying pathogenesis and therapeutic strategies for EGPA.

Cathepsin C as a Treatment Target in ANCA Vasculitis

Ralph Kettritz,[1] Uwe Jerke,[1] Claudia Eulenberg-Gustavus,[8] Anthony Rousselle,[1] Stefan Kreideweiss,[2] Marc A. Grundl,[3] Paul Nicklin,[4] Peter Eickholz,[5] Katrin Nickles,[7] Adrian Schreiber,[1] Brice Korkmaz.[6] *[1]Medical Faculty of the Charité, Experimental and Clinical Research Center (ECRC), 13125 Berlin, Germany; [2]Boehringer Ingelheim Pharma, Biberach, Germany; [3]Boehringer-Ingelheim Pharma GmbH&Co, Biberach, Germany; [4]Boehringer Ingelheim, Biberach an der Riss, Germany; [5]Johann Wolfgang Goethe-University Frankfurt, Frankfurt, Germany; [6]INSERM U-1100, Tours, France; [7]Poliklinik für Parodontologie, ZZMK Carolinum, Goethe University Grankfurt, Frankfurt an Main, Germany; [8]Experimental and Clinical Research Center (ECRC) Campus Buch, Berlin, Germany.*

Background: Neutrophil serine proteases (NSPs) of neutrophils and monocytes contribute to ANCA-associated vasculitis (AAV). Cathepsin C (CatC) proteolytically activates pro-NSPs in the bone marrow (BM) producing mature neutrophil elastase (HNE), cathepsin G (CatG), and PR3 - a major ANCA antigen. We showed previously that CatC gene-deficient mice were protected from AAV, implicating CatC as a treatment target.

Methods: We characterized NSPs and NSP-mediated functions in healthy individuals and Papillon-Lefèvre syndrome (PLS) patients with CatC loss-of-function mutations and developed a highly specific CatC inhibitor to reduce NSPs in a human neutrophil stem cell model and in mice.

Results: NSP proteins and proteolytical activity were abrogated in neutrophils and monocytes from PLS patients. PLS cells gave a negative PR3-ANCA, showed reduced membrane-PR3 (mPR3) on viable and apoptotic neutrophils, and supernatants (SN) from activated PLS neutrophils caused less endothelial cell (EC) damage. We developed the pharmacological CatC-inhibitor BI01169740 that strongly reduced NSP proteins (by 80% for PR3, 94% for HNE, and 99% for CatG) and the corresponding proteolytic activity (by 98% for PR3, 88% for HNE, and 79% for CatG) in differentiated neutrophils without affecting cell differentiation. mPR3 on viable and apoptotic differentiated neutrophils was diminished, viable cells showed less respiratory burst to PR3-ANCA, and SN caused less EC damage. Finally, 12-day treatment of Bl6 mice with increasing CatC inhibitor BI01169740 doses (0.05, 0.5, and 5 mg/kg/qd) lead to increasing compound plasma exposure (15±1, 164±26, and 1195±57 nM) and BM (478±52, 512±25, and 1680±190 nM), respectively. The highest dose strongly reduced NSP proteins and activity in BM cells, and reduced HNE activity in neutrophils from bronchoalveolar lavage fluid.

Conclusions: CatC gene-deficiency down-regulates NSPs and NSP-dependent neutrophil functions with relevance to ANCA. CatC inhibition with the novel BI01169740 compound recapitulates these effects in a stem cell model *in vitro* and effectively reduces NSP proteins and proteolytical activity in mice. These findings provide us with the opportunity to explore pharmacological CatC inhibition as a treatment strategy in AAV disease models and ultimately in AAV patients.

Long-Term Follow-Up of a Glucocorticoid-Minimising Regimen for Remission Induction in ANCA Vasculitis (AAV)

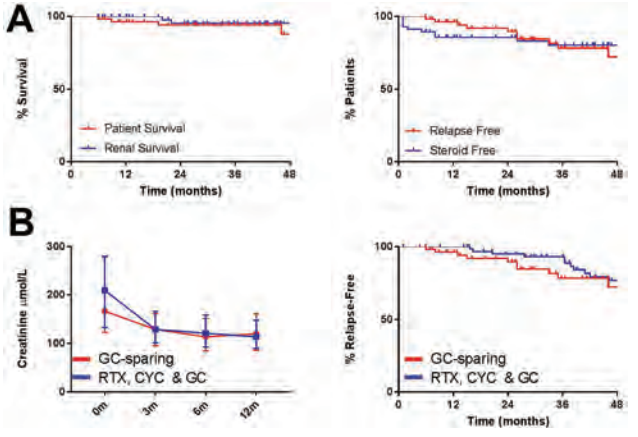
Stephen P. McAdoo,[1] Ruth Pepper,[6] Sally Hamour,[7] Aine Burns,[2] Mark A. Little,[3] Tom Cairns,[4] Alan D. Salama,[5] Charles D. Pusey.[1] *[1]Imperial College London, London, United Kingdom; [2]Centre for Nephrology Royal Free NHS Trust, London, United Kingdom; [3]Trinity College Dublin, Dublin, Ireland; [4]Imperial College Healthcare, London, United Kingdom; [5]University College London, London, United Kingdom; [6]Royal Free Hospital, London, United Kingdom; [7]UCL, Royal Free Campus, London, United Kingdom.*

Background: Glucocorticoids (GC), though a mainstay of treatment for AAV, have significant adverse effects. We previously reported successful short-term outcomes using a GC-sparing treatment regimen. Here, we report long term outcomes in an extended cohort of patients treated with this protocol.

Methods: Patients were treated at 2 centres with rituximab (RTX) 2x1g, low-dose iv cyclophosphamide (CYC), and a short course of oral GC of <2 weeks duration, followed by maintenance azathioprine/MMF. Data reported as median ± IQR.

Results: 58 patients with new (84%) or relapsing (16%) AAV are included, with average follow up of 37 (23-46) months. 65% were MPO-ANCA+ve, 29% PR3-ANCA, 5% ANCA negative. Initial BVAS, CRP and creatinine were 14 (12-19), 46 (11-90) mg/L, and 176 (131-270) μmol/L, respectively. 90% had biopsy-proven renal involvement. The median dose of GC during induction was 960 (781-1276) mg. 5 patients (9%) required re-introduction of GC during the first 3 months for active disease; all patients subsequently achieved remission by 3 months, which was sustained in 91% at month 12. At 3 years, 96% were alive, 95% with independent renal function.19% had relapsed, however the majority (80%) remained free of GC (Figure 1A). There were no significant differences in renal or relapse-free surival compared to a previous cohort treated with a comparable RTX+CYC regimen, along with standard steroid dosing (Figure 1B).

Conclusions: Rapid GC withdrawal was safe and effective in the majority of cases following induction with RTX+CYC. Long-term patient, renal and relapse-free survival are comparable to published cohorts treated with standard GC. A small proportion required early re-introduction of GC, such that careful monitoring is required, though GC avoidance was feasible in the majority. Controlled studies are warranted to compare the efficacy of this regimen to current standards of care.



SA-OR028

A Randomized Controlled Trial of Rituximab (RTX) vs. Azathioprine (AZA) After Induction of Remission with RTX for Patients with ANCA-Associated Vasculitis (AAV) and Relapsing Disease

Rona M. Smith,[2,1] David R. Jayne,[3] Peter A. Merkel.[4] RITAZAREM trial investigators *[1]Cambridge University Hospitals, UK, Cambridge, United Kingdom; [2]University of Cambridge, Cambridge, United Kingdom; [3]University of Cambridge, Cambridge, United Kingdom; [4]University of Pennsylvania, Philadelphia, PA.*

Background: RTX is an effective remission induction therapy in AAV. However, the effect of RTX is not sustained, and relapse rates are high, especially in patients with a history of relapse. The RITAZAREM trial is an international, open label, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy, after remission induction with RTX, of repeat dose RTX or AZA as relapse prevention strategies.

Methods: Patients with relapsing AAV received induction therapy with RTX and glucocorticoids (GC). If remission was achieved by month 4, patients were randomized 1:1 to receive RTX (1000mg every 4 months for 5 doses) or AZA as maintenance therapy. Patients were followed for a minimum of 36 months, with a primary outcome of time to disease relapse.

Results: 190 patients were enrolled and 170 randomized at month 4 (85 to RTX; 85 to AZA). Data are complete on all patients up to at least month 24. Median age was 59 years (range 19-89), with a prior disease duration of 5.3 years (0.4-38.5). 123/170 (72%) of patients were historically positive for anti-PR3 ANCA; 104 (61%) were enrolled after a major relapse, and 48 (28%) received a higher dose GC induction regimen. 114 (67%) patients had prior renal involvement. RTX was superior to AZA in preventing relapse with a preliminary overall HR estimate of 0.36 (95% CI 0.23-0.57, p<0.001) and a during-treatment HR estimate of 0.30 (95% CI 0.15-0.60, p<0.001) (Figure 1). By 24 months after entry, 20 months after randomization, 11/85 (13%) patients in the RTX group had experienced a relapse compared to 32/85 (38%) in the AZA group. 9 (22%) patients in the RTX group and 31 (36%) patients in the AZA group experienced at least one severe adverse event.

Conclusions: RTX was superior to AZA in the prevention of relapse in patients with AAV with a prior history of relapse following induction of remission with RTX

SA-OR029

In Vivo Pooled CRISPR/Cas9 Screening with Single Cell Transcriptome Readout to Analyze Genetic Modifications in Primary Murine T Cells in Crescentic Glomerulonephritis

Leon U. Enk,[1] Kristoffer Riecken,[2] Christoph Kilian,[1] Hans-Joachim Paust,[1] Sonja Kapffer,[1] Alina Borchers,[1] Malte Hellmig,[1] Patricia Bartsch,[1] Michael Zinke,[1] Ulf Panzer,[1] Boris Fehse,[2] Christian F. Krebs.[1] AG Krebs *[1]Translational Immunology, III. Medical Departement, UMC Hamburg-Eppendorf, Hamburg, Germany; [2]Research Dept. Cell and Gene Therapy, Dept. of Stem Cell Transplantation, UMC Hamburg-Eppendorf, Hamburg, Germany.*

Background: CRISPR/Cas9-based screening approaches usually lack the analysis of transcriptional perturbations caused by genetic modifications. In contrast, investigation of individual genetic modifications is time consuming and expensive. Therefore, CRISPR droplet sequencing (CROP-seq) has been developed to perform in vitro pooled CRISPR screening with single-cell transcriptome readout. However, examining changes in the cellular phenotype due to genetic modifications is strongly dependent on the local micro-environment. To address this, we have established an approach to target renal T cells in a mouse model of crescentic glomerulonephritis (cGN) to investigate transcriptional perturbations at the single cell level under the influence of a genetic modification in the context of renal autoimmunity.

Methods: CD4+ T cells from Il17a^{Cre} x Cas9^{Gfp} mice were polarized towards a Th17 phenotype and transduced with lentiviral vectors encoding BFP and individual guide-RNAs (gRNAs) targeting IL17A, CD2 or scrambled-control. In another set of experiments, cells were transduced with a pool of gRNAs targeting 28 genes. Subsequently, cells were transferred into Rag1-deficient mice and experimental cGN (nephrotoxic nephritis) was induced. At day 10 renal T cells were analyzed by flow cytometry for protein expression in case of individual gRNAs or FACS-sorted and subjected to Single Cell RNA-seq in the pooled approach.

Results: Using individual gRNAs, we identified a highly significant reduction of IL17A producing cells after treatment with anti-Il17a gRNA and of cells' surface expression of CD2 after treatment with anti-CD2 gRNA, while scrambled-gRNA had no effect on IL-17A and CD2. Furthermore, we show that a pool of gRNAs targeting 28 genes can be used to identify individual transcriptional profiles of cells with defined gene knockdowns.

Conclusions: In vivo CROP-seq is a new technique that enables CRISPR-screens with single cell transcriptome read-out in experimental mouse models for the first time. This approach might be of major interest for the investigation of genetic modifications not only in the context of T cell-driven autoimmunity but also in a broader range of applications.

RNA Sequencing of Microdissected Kidney Biopsies Differentiates HIV+ FSGS from HIV-Negative FSGS

Weijia Zhang,[3] Christina M. Wyatt,[4] Michelle M. Estrella,[2] Zhengzi Yi,[3] Jonathan P. Troost,[5] Brad A. Godfrey,[5] Felix H. Eichinger,[5] Mohamed G. Atta,[6] Derek M. Fine,[6] Avi Z. Rosenberg,[6] Michael J. Ross.[1] *[1]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [2]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [3]Icahn School of Medicine at Mount Sinai, Elmhurst, NY; [4]Duke University School of Medicine, Durham, NC; [5]University of Michigan, Ann Arbor, MI; [6]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Antiretroviral therapy (ART) has reduced the incidence of "classic" HIV-associated nephropathy (HIVAN), characterized by rapidly progressive proteinuric CKD from underlying collapsing focal glomerulosclerosis and severe tubulointerstitial (TI) disease including tubular microcysts. Whether FSGS without other histologic findings of HIVAN in HIV+ persons represents a partially treated HIVAN phenotype or FSGS unrelated to HIV infection is unclear. We therefore compared gene expression in kidney biopsies from HIV+ persons with non-HIVAN FSGS to biopsies from HIV- persons with FSGS.

Methods: 27 kidney biopsies from HIV+ persons with FSGS were microdissected, and glomerular and TI RNA were analyzed by RNAseq. We compared RNA expression from these samples to that of 22 HIV-negative FSGS biopsies which were matched for eGFR, demographic, and histologic variables. RNAseq data were processed and analyzed using the pipeline consisting of raw data processing, normalization, batch correlation and differential analysis based on LIMMA test. Differentially expressed genes were subjected to enrichment analysis for gene ontology function and KEGG pathways.

Results: Principal component analysis demonstrated that glomerular and TI RNA from HIV+ FSGS biopsies clustered separately from HIV- FSGS biopsies. 1081 genes were differentially expressed by 1.5 fold in glomeruli from HIV+ vs. HIV- biopsies, and 607 genes were differentially expressed in TI from HIV+ vs. HIV- biopsies. Pathway analysis revealed that the predominant cellular pathways represented by differentially expressed genes from HIV+ biopsies have roles in metabolism, solute transport, and cell cycle regulation. HIV sequences were detected in the majority of HIV+ biopsies and were detected in more glomerular than TI samples.

Conclusions: These results suggest that FSGS occurring in HIV+ persons may have a different molecular pathogenesis than FSGS occurring in HIV- persons and may reflect residual effects of HIV not fully treated by ART. Future studies are needed to determine whether new treatment strategies targeting deleterious effects of HIV can improve kidney outcomes in this population.

HIF Stabilizer Decreases Mitochondrial Oxygen Consumption in Skeletal C2C12 Myotube

Koji Takemura,[1] Hiroshi Nishi,[2] Takaaki Higashihara,[1] Masaomi Nangaku.[2] *[1]The University of Tokyo Graduate school of medicine, Tokyo, Japan; [2]the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Erythropoietin (EPO) and hypoxia-inducible factor (HIF) stabilizers (PH inhibitors) are efficient therapeutic modalities against anemia in CKD. However, extra-renal action of PH inhibitors has not been fully investigated. Previous reports caution us about the actual misuse of PH inhibitors in doped athletes, but nonhematopoietic effects on skeletal muscles remain controversial.

Methods: To study direct pharmacological effects of roxadustat on skeletal muscles, cultured muscle cells were assessed from multiple perspectives including cell viability, myotube differentiation and glucose metabolism. Murine C2C12 myoblasts were cultured in media containing 2% horse serum, for differentiation. Quantitative PCR was applied for expression analysis of myogenin (Myog), differentiation marker, Myh-7, encoding a slow-twitch muscle isoform, Myh-1, 2, and 4, encoding fast-twitch isoforms and glycolytic enzymes such as lactate dehydrogenase (LDH), phosphoinositide-dependent kinase-1 (Pdk1), and glycogen synthase-1 (Gys1). Biochemical quantitative assay of lactate was also utilized. Glucose and mitochondrial metabolic profile was quantified with extracellular flux analyzer.

Results: Culture in the low serum media stimulated C2C12 myoblasts to differentiate and to fuse into multinucleated myotubes with enhanced expression of Myog and Myh-1, 2, 4, and 7. Roxadustat treatment did not affect myotube viability, morphology, or increase differentiation marker expression. However, 2-deoxyglucose uptake was enhanced. The treatment also elevated expression of Ldha, Pdk1, and Gys1, and promoted glycolytic rate with culture lactate concentration increased. By contrast, the treatment decreased the ratio of mitochondrial/nuclear DNA and down-regulated mitochondrial respiration, which lentivirus-mediated genetic silencing of HIF-1α in C2C12 cells reversed. Electron microscopic evaluation showed mitochondrial fragmentation in roxadustat-treated myotubes.

Conclusions: Roxadustat, a PH inhibitor to stabilize HIF that is beneficial for renal anemia treatment, may exert a direct effect on skeletal muscles. Although it did not affect cellular viability or morphology, roxadustat compromised the ability of cells to undergo oxidative phosphorylation, which action was mediated by HIF-1α, and directed cells to acceleration of glycolytic process and lactic acid generation.

SA-OR032

Hyperphosphatemia Contributes to Inflammation and Iron Dysregulation in Models of Normal and Impaired Renal Function

Brian A. Czaya, Beatrice Richter, Christopher Yanucil, Isaac D. Campos, Kylie Heitman, Dominik Kentrup, Christian Faul. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Fibroblast growth factor (FGF) 23 is a phosphaturic hormone that targets the kidney to promote urinary phosphate excretion. In patients with chronic kidney disease (CKD), serum concentrations of phosphate (Pi) and FGF23 gradually increase as renal function declines and associate with various pathologies, including systemic inflammation and anemia. Our previous studies revealed FGF23 contributes to inflammation by directly targeting hepatocytes via FGF receptor 4 (FGFR4) and inducing phospholipase Cg (PLCg) signaling and the expression of inflammatory cytokines. Experimental studies have shown Pi can accelerate CKD-associated pathologies, but direct effects of Pi on the liver are not well described. Here we compare the effects of Pi versus FGF23 on hepatocytes and determine their respective contributions to inflammation and anemia in the context of CKD.

Methods: We subject mice with global deletion of FGFR4 and wild-type littermates to increasing dietary Pi load (0.7%, 2.0%, or 3.0%) or an adenine-rich diet (used as a CKD model) in order to examine systemic inflammation and alterations in iron metabolism in the setting of normal and impaired renal function. In addition, we study primary mouse hepatocytes treated with FGF23 and increasing Pi concentrations and examine the activation of downstream signaling events and expression levels of specific target genes. Furthermore, we determine if co-treatment with inhibitors of Pi uptake and downstream signal mediators block the observed effects.

Results: A 3% Pi diet as well as an adenine-rich diet promote inflammation and iron dysregulation in mice. These effects are exacerbated in FGFR4 knockout mice. In cultured hepatocytes, expression of inflammatory cytokines, hepcidin and FGF23 are induced by Pi in a dose-dependent manner. Furthermore, Pi activates NFkB signaling and the inhibition of Pi uptake and of NFkB protects from Pi-induced effects.

Conclusions: We postulate that in CKD, gradual elevations in serum Pi promote inflammation and anemia by targeting the liver to induce gene programs which regulate the inflammatory response and iron metabolism. Our study indicates Pi effects may be independent of FGF23. Pharmacological approaches targeting hyperphosphatemia or hepatic Pi actions might alleviate various CKD-associated pathologies.

PBI-4610 Improves Renal Function, Anemia, and Histopathological Abnormalities in an Adenine-Induced CKD Model

Jean-Francois Thibodeau,[1,2] Kathy Hince,[1] Amélie Blais,[2] Ramon Corpuz,[1] Francois A. Leblond,[1] Brigitte Grouix,[1] Martin Leduc,[1] Richard L. Hébert,[2,3] Chris R. Kennedy,[2,3] Lyne Gagnon.[1] *[1]Prometic Biosciences Inc., Laval, QC, Canada; [2]Kidney Research Centre, Ottawa, ON, Canada; [3]Department of Cellular and Molecular Medicine, University of Ottawa, Ottawa, ON, Canada.*

Background: Adenine-supplementation is an effective tool to study the onset and progression of fibrosis and CKD-associated sequelae. Prometic's PBI-compounds show excellent safety and efficacy in both experimental models and in human studies. Here we tested a second-generation orally active PBI compound, PBI-4610, in adenine-induced renal injury.

Methods: Six to eight-week old male C57BL/6 mice were fed a regular (Control, n=9) or custom diet consisting of regular chow supplemented with 0.25% adenine for 30 days. After 7 days, mice were administered vehicle (H_2O, n=9) or PBI-4610 (100 mg/kg, n=10) by daily oral gavage. Blood sampling was done at day 0, 7 and 30. Reticulocytes were quantified by FACS analysis. Serum urea and creatinine levels were measured at endpoint by ELISA and HPLC respectively. Renal histology was assessed using H&E and Masson's trichrome stained kidney sections.

Results: Adenine decreased bodyweight, which was significantly improved by PBI-4610 at days 17, 21 and 24. Anemia was apparent as hematocrit (Hct) began to decline as early as 7 days post-adenine, however this was significantly improved by PBI-4610 at day 14, 21 and 30. FACS revealed reduced reticulocyte counts in vehicle-treated adenine mice compared to Control mice at day 14, however at day 30, levels were increased. PBI-4610 treatment maintained reticulocyte counts to normal levels. Similarly, hemoglobin was decreased in adenine-fed mice, but levels in PBI-4610 mice trended higher (p=0.059). At endpoint, blood urea nitrogen and serum creatinine were increased by adenine-feeding, however treatment with PBI-4610 significantly reduced these levels. Tubulointerstitial fibrosis, collagen deposition, tubular dilatation and inflammation were all significantly reduced by PBI-4610. Finally, survival rate in PBI-4610 treated mice increased from 30% in the vehicle group to 80%.

Conclusions: Taken together, PBI-4610 improves several key renal functional and structural abnormalities in adenine-induced CKD including anemia, fibrosis and renal function decline leading to improved survival rates. Although the mechanism of action remains incompletely resolved, the above findings suggest treatment with PBI-4610 may represent a novel therapeutic modality in CKD.

C-FGF23 Peptide Protects Against Severe Hypoferremia During Acute Inflammation

Guillaume Courbon, Vikas Chonira, Maralee Capella, Xueyan Wang, Aline Martin, Valentin David. *Northwestern University - Feinberg School of Medicine, Chicago, IL.*

Background: Inflammatory stimuli induce functional iron deficiency, by increasing the expression of the hepatic iron regulatory peptide, hepcidin. Acute inflammation stimulates fibroblast growth factor 23 (FGF23) production in bone and leads to a dramatic increase in both *Fgf23* transcription and FGF23 cleavage and paradoxically leads to excess in C-terminal FGF23 peptides (cFGF23), but not intact hormone (iFGF23). This questions the physiological need for increased *Fgf23* transcription in this context and we hypothesized that cFGF23 peptides might actively participate in the regulation of iron metabolism by regulating hepcidin expression.

Methods: We induced acute inflammation in WT, FGF23-null and FGF23-DMP1^{cKO} mice using a single dose of 250ng/g of interleukin 1 beta (IL1b) and we analyzed the effects on iron homeostasis. We next used recombinant cFGF23 peptides as bait in cultured osteoblasts to immunoprecipitate (IP) and to identify binding partners by mass spectrometry (MS). We also verified binding between FGF23 peptides and putative partners using bio-layer interferometry (BLI). Finally, we administered cFGF23 to verify its impact on iron metabolism.

Results: As expected IL1b administration to WT mice led to low serum iron and transferrin saturation (TSAT) due to high hepcidin levels, and increased bone *Fgf23* expression and secretion of cFGF23 peptides ($p<0.05$). FGF23-DMP1^{cKO} mice had 90% lower FGF23 levels ($p<0.05$), but exhibited further reductions in serum iron and TSAT compared to IL1b-treated WT, due to higher serum hepcidin and liver *Hamp* (encoding hepcidin) mRNA, suggesting that cFGF23 reduces Hepcidin production. Using IP/MS, we next identified binding of cFGF23 peptides to members of the bone morphogenic protein (BMP) family, BMP2 and BMP9, established inducers of hepcidin, and we confirmed binding of BMP2 and BMP9 to cFGF23 by BLI. In WT mice, co-administration of cFGF23 and BMP2 or BMP9 prevented the increase in *Hamp* mRNA and circulating hepcidin levels resulting in normal serum iron levels and TSAT. In addition, injection of cFGF23 increased serum iron levels and TSAT in WT and FGF23-null mice.

Conclusions: This is the first study to provide a new direct role for bone-produced cFGF23 peptides to antagonize the inflammation-induced BMP signaling in the liver and inhibit the secretion of the iron regulatory peptide, hepcidin.

Enteral Ferric Citrate Absorption Is Dependent on Ferroportin

Mark R. Hanudel, Victoria R. Gabayan, Bo Qiao, Kristine Chua, Elizabeta Nemeth, Tomas Ganz. *UCLA, Los Angeles, CA.*

Background: Ferric citrate (FC) is approved as an iron replacement product in CKD non-dialysis patients with iron deficiency anemia. FC-delivered iron is enterally absorbed, but the specific mechanisms involved have not been specifically evaluated. The absorption of dietary iron and conventional supplements requires duodenal ferroportin (FPN). To assess whether or not enteral FC absorption is dependent on FPN, we evaluated the effects of FC in a tamoxifen-inducible, enterocyte-specific FPN knockout (KO) murine model (Villin-Cre-ERT2, FPN$^{flox/flox}$).

Methods: We assessed three groups: uninduced mice, induced mice (FPN KO), and induced mice (FPN KO) supplemented with 1% FC. Mice were injected with vehicle (uninduced group) or tamoxifen (induced groups) at ~7 weeks of age, then terminally assessed 7-8 weeks later. The treated induced mice had their diets supplemented with 1% FC for ~19 days pre-euthanasia.

Results: The FPN KO was effective, as 6 weeks after tamoxifen injection, the induced mice had ~4000 fold lower duodenal FPN mRNA expression than uninduced mice and undetectable FPN protein on the duodenal tissue Western blot. Confirming that 1% FC prevents anemia, uninduced mice placed on iron-deficient 4 ppm diets for 7 weeks (n=5) became anemic, but uninduced mice placed on iron deficient 4 ppm diets for 4 weeks, then supplemented with 1% FC for 3 weeks (n=6), were rescued from anemia (mean (SD) terminal hemoglobin of 13.8 (0.7) vs. 7.6 (0.8) g/dL, $p<0.001$). FPN KO mice on iron-sufficient 50 ppm diets developed anemia whether or not they were supplemented with 1% FC. The FPN KO groups had higher duodenal intracellular iron staining, lower liver iron concentration, lower hemoglobin, lower mean corpuscular volume, and higher red cell distribution width vs. the uninduced group (**Figure 1**). There were no differences between the untreated and 1% FC-treated FPN KO groups.

Conclusions: The 1% FC diet does not rescue iron deficiency anemia caused by enterocyte FPN KO. Enteral FC absorption is dependent on conventional enterocyte iron transport by FPN.

Colchicine Does Not Affect Anemia or Inflammation in a Mouse Model of CKD

Daniel Landau,[2] Yael Segev,[1] Nehorai Shukri.[1] *[1]Ben Gurion University, Beer-Sheva, Israel; [2]Tel Aviv University, Petach Tikva, Israel.*

Background: Previous studies point for a significant role of low grade inflammation mediated by the innate immune system in CKD and its complications. We have recently shown that anemia of CKD is associated with such increased inflammation, which impairs both HIF2-EPO-EPOR signals as well as iron homeostasis. Colchicine is a safe drug for long term use in humans, including children, mainly for the prevention of familial Mediterranean fever attacks, as well in gouty arthritis. In addition, colchicine attenuated both glomerular sclerosis and interstitial fibrosis without affecting systemic blood pressure in a model of CKD by 5/6 nephrectomy (Guan T et al, AJP 2013).

Methods: 7-8 wk old C57BL/6 mice were divided into 4 groups (C, C-Col, CKD, CKD-Col). CKD or control states were induced by adenine (0.3-0.2%) or control diet. Colchicine (30ukg/kg/day, IP) or saline were injected for 3 weeks, until sacrifice.

Results: Systemic inflammation (liver CRP, IL6, plasma platelet count) was elevated in CKD animals (140±15%, 151±37% and 239±27% respectively) but was unaffected by colchicine. Serum urea and creatinine were increased by ~ 50% in CKD animals but without differences between CKD-Col and CKD. Kidney IL6 and pSTAT3 were increased in both CKD groups but without differences between them. Anemia developed in this model of CKD (63±5% of C), in association with decreased iron (62±6% of C) and transferrin saturation (55±4% of C), decreased renal EPO (37±5% of C) and renal HIF2 mRNA (55±4% of C) but without differences between the uremic groups.

Conclusions: In this model of CKD associated anemia and inflammation (systemic and renal) colchicine was inefficient in preventing these complications, despite previous reports. Therefore, inflammation control through other pathways (sucj as IL1) may be needed.

SA-OR037

Preclinical Characterization of Vadadustat (AKB-6548), an Oral Small Molecule Hypoxia Inducible Factor Prolyl-4-Hydroxylase Inhibitor, for the Potential Treatment of Renal Anemia

Anna Zuk,[1] Zhihai Si,[2] Sally Loi,[2] Santhosh K. Bommegowda,[2] Sanjay Danthi,[2] Gyongyi Molnar,[2] Michael Rabinowitz.[1] *[1]Akebia Therapeutics, Inc., Natick, MA; [2]Akebia Therapeutics Inc., Cambridge, MA.*

Background: We summarize preclinical pharmacological characterization of the small molecule hypoxia inducible factor-prolyl-4-hydroxylase (HIF-PHD) inhibitor, vadadustat (AKB-6548), an investigational drug in phase 3 development for the treatment of anemia in patients with chronic kidney disease (CKD). Pharmacological inhibition of PHD enzymes lead to the stabilization of hypoxia-inducible factor (HIF), a transcription factor which activates target genes that increase erythropoietin (EPO) synthesis, resulting in the production of new red blood cells.

Methods: Enzymatic IC50 values of vadadustat against the full-length human PHD isoenzymes, PHD1, PHD2, and PHD3, were measured by time-resolved fluorescence resonance energy transfer assay. Stabilization of HIF-1α and HIF-2α in the human hepatocarcinoma cell line Hep3B was measured by meso scale discovery technology. EPO and vascular endothelial growth factor (VEGF) were quantitated by ELISA. In vivo studies measured the pharmacokinetics and pharmacodynamics of vadadustat.

Results: Vadadustat inhibits PHD1, PHD2 and PHD3 at approximately equivalent nanomolar concentrations. Vadadustat metabolites are approximately 100-200 fold less potent for PHD2 compared to the parent compound. Moreover, vadadustat shows 2-oxoglutarate competitive inhibition against the human HIF-PHDs and vadadustat activity is insensitive to the presence of added iron. In Hep3B cells, PHD inhibition by vadadustat leads to the time-dependent stabilization of both HIF-1α and HIF-2α, which in turn results in the synthesis and secretion of EPO; stimulation of VEGF was not detectable. In vivo, single dose administration of vadadustat potently increases circulating levels of EPO, but not VEGF. Moreover, once daily oral dosing in mice and rats significantly increases hemoglobin, hematocrit and reticulocytes. Vadadustat exhibits a relatively short half-life in all non-clinical species evaluated and does not accumulate upon repeat dosing.

Conclusions: The pharmacology and safety of vadadustat support development for renal anemia. Vadadustat is an equipotent pan-PHD inhibitor which activates erythropoiesis through stabilization of both HIF-1α and HIF-2α without stimulation of VEGF in the preclinical setting.

The Association of sTNFR-1 and sTNFR-2 with Histopathologic Lesions and Progression to ESRD: The Boston Kidney Biopsy Cohort Study

Anand Srivastava,[1] Ragnar Palsson,[2] Venkata Sabbisetti,[2] Insa M. Schmidt,[2] Isaac E. Stillman,[4] Helmut G. Rennke,[2] Sushrut S. Waikar.[3] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The relationship of soluble tumor necrosis factor-1 (sTNFR-1) and sTNFR-2 with histopathologic lesions and progression to ESRD in individuals with biopsy-confirmed kidney disease is unknown.

Methods: We measured plasma sTNFR-1 and sTNFR-2 levels in 523 individuals enrolled into a prospective, observational cohort study of patients undergoing native kidney biopsy at three tertiary care hospitals. Two experienced renal pathologists adjudicated biopsy specimens for semiquantitative scores of histopathology. Linear regression models tested the association between biomarkers and histopathologic lesions. Proportional hazards models tested the association between biomarkers and risk of progression to ESRD.

Results: Mean age was 53±17 years and mean baseline eGFR was 56±36 ml/min/1.73m^2. sTNFR-1 and sTNFR-2 correlated with eGFR (R_s = -0.70 and -0.62, P<0.001, respectively). After adjustment for age, sex, race, and eGFR, sTNR-1 and sTNFR-2 levels were highest among individuals with glomerulopathies and diabetic nephropathy (Figure). sTNFR-1 and sTNFR-2 followed slightly different patterns of injury after multivariable adjustment (Figure). Both biomarkers were associated with more severe interstitial fibrosis/tubular atrophy and mesangial expansion. Only sTNFR-1 associated with more severe acute tubular injury and presence of inflammation in the nonfibrosed interstitium. Only sTNFR-2 associated with presence of endocapillary glomerular inflammation and segmental sclerosis. During a median follow-up time of 25 months, 78 individuals progressed to ESRD. sTNFR-1 and sTNFR-2 were each independently associated with greater than 2-fold increased risk of progression to ESRD (Figure).

Conclusions: Higher levels of sTNFR-1 and sTNFR-2 are independently associated with increased risk of progression to ESRD across a diverse set of biopsy-confirmed kidney diseases.

Funding: NIDDK Support

Differences in sTNFR-1 and sTNFR-2 by Clinicopathologic Diagnosis (top) and Histopathologic Lesion (bottom)

Primary Clinicopathologic Diagnosis	sTNFR-1	sTNFR-2
Proliferative glomerulonephritis	73.3**	44.8*
Non-proliferative glomerulonephritis	101**	91.6**
Paraprotein disease	20.9	-7.7
Diabetic nephropathy	87.8**	49.2
Vascular disease	24.6	24.6
Tubulointerstitial disease	16.2	-5.8
Advanced Chronic Changes	31	20.9

Percent differences are derived from multivariable linear regression models of natural log-transformed sTNFR-1 and sTNFR-2, respectively.
Models are adjusted for age, sex, race, and eGFR.

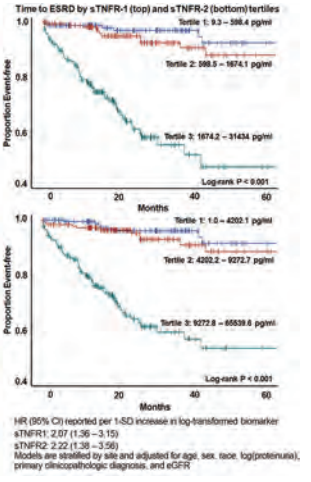
[c] Reference is 0-25% of cortical volume affected
P<0.05*
P<0.001**



HR (95% CI) reported per 1-SD increase in log-transformed biomarker
sTNFR1: 2.07 (1.36 – 3.15)
sTNFR2: 2.22 (1.38 – 3.56)
Models are stratified by site and adjusted for age, sex, race, log(proteinuria), primary clinicopathologic diagnosis, and eGFR

SA-OR039

Two-Year Change in Galectin 3 and MMP-2 and Risk of ESRD: The Chronic Renal Insufficiency Cohort (CRIC) Study

Amanda H. Anderson,[1] Paula F. Orlandi,[2] Wei Yang,[2] Robin L. Baudier,[1] Katalin Susztak,[2] Anand Srivastava,[3] Ana C. Ricardo,[4] Mirela A. Dobre,[5] Rajat Deo,[2] Jing Chen,[6] Jiang He,[7] Tariq Shafi,[8] Hsiang-Yu Chen,[11] Dawei Xie,[9] Nisha Bansal,[10] Harold I. Feldman.[2] *[1]Tulane University, New Orleans, LA; [2]University of Pennsylvania, Philadelphia, PA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]University of Illinois at Chicago, Chicago, IL; [5]Case Western Reserve University, Cleveland, OH; [6]Tulane School of Medicine, New Orleans, LA; [7]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [8]University of Mississippi Medical Center, Jackson, MS; [9]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA; [10]Kidney Research Institute, Seattle, WA; [11]The Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA.*

Background: Galectin-3 and matrix metalloproteinase-2 (MMP-2) have both been associated with kidney fibrosis, however, the relationship of these markers with chronic kidney disease (CKD) progression remains unclear.

Methods: A case-cohort study including a randomly selected sample of 1300 CRIC participants was conducted to characterize the association of two-year change in plasma galectin-3 and MMP-2 with subsequent development of end-stage renal disease (ESRD; N=542). Weighted Cox proportional hazards regression models used data from up to 8 years of follow-up, adjusted for sociodemographic, clinical and biochemical factors including eGFR and proteinuria in addition to galectin-3 or MMP-2 values from baseline.

Results: Two-year change in galectin-3 ranged from -51 to + 56 ng/mL with an overall mean change of 4.3 ng/mL, while change in MMP-2 ranged from -455 to +654 ng/mL (mean change: 25.4 ng/mL). Restricted cubic splines demonstrate non-linear associations for both markers (**Figure**). Increases in galectin-3 over two years did not appear to increase ESRD risk, but decreases may trend toward reduced risk of ESRD. The hazard ratio for MMP-2 reductions of 400 ng/mL was 0.2 (95% CI: 0.1-0.5).

Conclusions: Decreases in MMP-2 over two years are strongly and independently associated with marked reduction in the risk for ESRD among patients with established CKD. This pathway should be studied further to investigate possible interventions to reduce CKD progression risk.

Funding: NIDDK Support

The Pro-Fibrotic Serum Marker MMP7 Predicts Accelerated GFR Loss in the General Population

Inger Therese T. Enoksen,[1] Dmitri Svistounov,[1] Jon V. Norvik,[2] Marit D. Solbu,[1,2] Bjorn O. Eriksen,[1,2] Toralf Melsom.[1,2] Metabolic and Renal Research Group, UiT The Arctic University of Norway *[1]The Arctic University of Norway, UiT, Tromsø, Norway; [2]University Hospital of North Norway, Tromsø, Norway*.

Background: Age related loss of glomerular filtration rate (GFR) is a major contributor to the global chronic kidney disease (CKD) epidemic. CKD is associated with increased morbidity and mortality and there is a need for novel biomarkers that identify at risk persons at an early stage to delay or prevent CKD onset. Matrix Metalloproteinase (MMP) 2 and 7 are key players in interstitial remodeling and mediate renal fibrosis development in animal models. We investigated whether serum MMP2, MMP7 and their inhibitor TIMP1, were associated with accelerated age-related GFR decline and incident CKD in middle-aged individuals from the general population.

Methods: In the Renal Iohexol Clearance Survey (RENIS) we performed GFR measurements (using iohexol clearance) in 1627 subjects, aged 50-62 years, from the general population without self-reported diabetes, kidney or cardiovascular disease. 1324 (81%) had follow-up measurements after a median of 5.6 years. The biomarkers were analyzed in baseline serum samples with a Bioplex 200 machine. Using multiple logistic regression analysis, we evaluated the risk of accelerated GFR decline (defined as subjects with the 10% steepest GFR slope) and incident CKD (defined as GFR <60ml/min/1.73m^2).

Results: After adjustment for age, sex, baseline GFR and urinary albumin-creatinine ratio (ACR), higher levels of MMP7 were associated with an increased risk of accelerated GFR decline (Odds ratio (95% confidence interval)) per one SD increase in MMP7: 1.68 (1.39-2.04) and incident CKD: 1.71 (1.25-2.34). The results were attenuated, but remained significant in the fully adjusted model (1.48 (1.20-1.81) and 1.53 (1.08-2.18)). Prediction of accelerated GFR decline improved after addition of MMP7 to a model with age, sex, baseline GFR and ACR (aera under the ROC curve increased from 0.72 to 0.75 (p=0.054), continuous net reclassification improvement: 0.34 CI: 0.16-0.52). Similar results were obtained using alternative definitions of accelerated GFR decline such as ≤-3.0 ml/min/1.73m^2/year or a GFR decline rate twice the cohort mean (≤-1.68 ml/min/1.73m^2/year). MMP2 and TIMP1 showed no association with GFR decline.

Conclusions: The pro-fibrotic biomarker MMP7 was independently associated with increased risk of accelerated GFR decline and incident CKD in middle-aged persons from the general population.

Relation of a Parsimonious Model of Factors Derived from 10 Biomarkers of Kidney Tubule Health with Decline in eGFR in the SPRINT Trial

Alexander Bullen,[1] Ronit Katz,[5] Alexandra K. Lee,[2] Michelle M. Estrella,[3] Michael Shlipak,[4] Joachim H. Ix.[1] *[1]UCSD, San Diego, CA; [2]Kidney Health Research Collaborative, UCSF & VA, San Francisco, CA; [3]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [4]San Francisco VA Medical Center, San Francisco, CA; [5]University of Washington, Seattle, WA.*

Background: To move towards assimilation of the various information gained from multiple biomarkers, we have evaluated 10 urine biomarkers of kidney tubule health measured at baseline among SPRINT participants with chronic kidney disease (CKD). In prior analyses, we created summary scores of different dimensions of kidney tubule

health using unsupervised exploratory factor analyses. Four factors were derived and found to be strongly associated with CVD events; associations that were stronger than individual markers. The goal of the current study was to evaluate if these 4 factors of tubule health are related with progression of CKD in SPRINT.

Methods: The factors comprised Factor 1: "tubule injury/repair" (urine NGAL, IL-18, & YKL-40); Factor 2: "tubule injury/fibrosis" (urine KIM-1 & MCP-1); Factor 3: "tubule reabsorption" (urine alpha-1 microglobulin & beta-2 microglobulin); and Factor 4: "tubular reserve" (urine umod & serum iPTH & iFGF-23). We selected SPRINT participants with eGFR <60 ml/min/1.73m^2 at baseline and used linear mixed models to examine the association of the 4 factors of kidney tubule health with decline in kidney function.

Results: Among 2351 SPRINT participants two factors of tubule health, "tubule injury/fibrosis" and "tubular reserve" were associated with mean eGFR decline (percentage decrease per year), independent of baseline eGFR and albuminuria (Table). The magnitude of the association between these two factors and longitudinal eGFR changes was lower than the one seen with albuminuria (Table).

Conclusions: Assessment of tubule health by integrating tubule injury, fibrosis, and reserve factors provides information on CKD progression independent of baseline eGFR and albuminuria in persons with non-diabetic CKD.

Metabolomics of CKD Progression in CRIC and AASK

Eugene P. Rhee,[1] Zihe Zheng,[2] Morgan Grams,[3] Dawei Xie,[4] Sushrut S. Waikar,[5] Casey Rebholz,[6] Michelle Denburg,[7] Paul L. Kimmel,[8] Josef Coresh,[9] Harold I. Feldman.[2] CKD Biomarkers Consortium *[1]Massachusetts General Hospital, Newton, MA; [2]University of Pennsylvania, Philadelphia, PA; [3]Johns Hopkins University, Baltimore, MD; [4]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA; [5]Harvard Medical School, Boston, MA; [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [7]The Children's Hospital of Philadelphia, Philadelphia, PA; [8]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [9]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD.*

Background: Non-targeted metabolomics is a promising tool for the identification of novel markers of CKD progression, with the goal to improve CKD diagnosis, prognosis, and therapy.

Methods: We examined the association between blood metabolites and CKD progression, defined as subsequent development of ESRD or eGFR halving. Discovery analysis was performed with the Broad Institute platform in 1800 randomly selected participants of the CRIC study. We fit Cox proportional hazards models, adjusting for age, gender, center, race/ethnicity/APOL1, CVD, smoking, alcohol, physical activity, SBP, diabetes, BMI, UPCR, and eGFR. Statistical significance was determined at a FDR <5%. For replication, we examined data generated with the Metabolon platform for 962 participants of the AASK study, adjusting for age, sex, study arm, smoking, CVD, BMI, SBP, UPCR, and mGFR.

Results: In CRIC, >160 of 547 metabolites were associated with the composite of ESRD or eGFR halving in unadjusted analysis, but only 9 metabolites remained significant following full adjustment (Fig). This attenuation in associations was driven by adjustment for eGFR. A subset of 7 of these metabolite were also measured in AASK, 3 of which were associated with CKD progression (Table): pseudouridine, 4-acetamidobutanoate, and guanidinoacetate.

Conclusions: In this large metabolomics study of CKD progression, 3 metabolites significantly associated with ESRD or eGFR halving, with discovery and replication performed in independent cohorts using different metabolomics platforms. More work is required to explore clinical utility and biologic implications.

Association Between Urine 6-Bromotryptophan and ESKD in the German CKD Study

Peggy Sekula,[1] Adrienne Tin,[5] Ulla T. Schultheiss,[1] Seema Baid-Agrawal,[4] Robert P. Mohney,[2] Inga Steinbrenner,[1] Bing Yu,[3] Eric Boerwinkle,[3] Kai-Uwe Eckardt,[4] Josef Coresh,[5] Morgan Grams,[5] Anna Kottgen.[1,5] *[1]Medical Center - University of Freiburg, Freiburg, Germany; [2]Metabolon, Inc., Durham, NC; [3]University of Texas Health Science Center, Houston, TX; [4]Charité – Universitätsmedizin Berlin, Berlin, Germany; [5]Johns Hopkins University, Baltimore, MD.*

Background: Higher serum 6-bromotryptophan has been associated with lower risk of chronic kidney disease (CKD) progression, but its levels in urine have not yet been studied. We studied determinants of urine 6-bromotryptophan and its association with CKD risk factors and incident end-stage kidney disease (ESKD) in 4,843 CKD patients.

Methods: 6-bromotryptophan was measured from spot urine samples using mass spectrometry. Genetic determinants of 6-bromotryptophan levels were assessed using genome-wide association studies (GWAS) in European ancestry cohorts. The associations between urine 6-bromotryptophan and CKD risk factors were assessed by univariate tests. The risk for ESKD, defined as incident dialysis, kidney transplantation, or kidney-related death, by 6-bromotryptophan levels was assessed using Cox regression.

Results: Urine 6-bromotryptophan was detected in 57% of the patients and categorized into three groups: undetectable, low (<median), and high (≥median). GWAS of urine 6-bromotryptophan levels detected two significant loci likely related to its generation and tubular reabsorption, illuminating its biological determinants (near *SLC6A19*, p=3.2x10^{-12}; near *GPR137C*, p=2.4x10^{-14}). The locus near *GPR137C* possibly related to its generation was also associated with serum 6-bromotryptophan in an independent general population-based cohort (p=7.3x10^{-9}). Patients with higher levels of urine 6-bromotryptophan had higher baseline estimated glomerular filtration rate (eGFR, p<0.001). After four years of follow-up, we observed 216 ESKD events. Compared with the undetectable group, higher 6-bromotryptophan levels were associated with lower risk of ESKD in unadjusted models and when adjusting for all ESKD risk factors other than eGFR (low group cause-specific hazard ratio [HR]: 0.7, 95% confidence interval [CI]: 0.51 to 0.97; high group HR: 0.5, 95% CI: 0.34 to 0.74). With the addition of baseline eGFR, this association became insignificant.

Conclusions: Higher urine 6-bromotryptophan levels were associated with lower risk of ESKD, which was attenuated when adjusting for baseline eGFR. The protective direction of association is noteworthy, because higher levels of most other metabolites, such as creatinine, are associated with higher risk of ESKD.

SA-OR044

Carbamylation and the Risk of CKD Progression in the Chronic Renal Insufficiency Cohort (CRIC)

Sahir Kalim,[1] S. Ananth Karumanchi,[2] Andrew S. Allegretti,[7] Sagar U. Nigwekar,[7] Anand Srivastava,[3] Dominic S. Raj,[4] Anne Frydrych,[8] Jing Chen,[9] Tariq Shafi,[5] Matthew R. Weir,[6] Sophia Zhao,[7] James H. Sondheimer,[10] Rajat Deo,[11] Ravi I. Thadhani,[12] James P. Lash.[8] *[1]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA; [2]Cedars-Sinai Medical Center, Los Angeles, MA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]GWU Medical Faculty Associates, Washington, DC; [5]University of Mississippi Medical Center, Jackson, MS; [6]University of Maryland School of Medicine, Baltimore, MD; [7]Massachusetts General Hospital, Cambridge, MA; [8]University of Illinois at Chicago, Chicago, IL; [9]Tulane School of Medicine, New Orleans, LA; [10]Wayne State University School of Medicine, Detroit, MI; [11]University of Pennsylvania, Philadelphia, PA; [12]Cedars-Sinai, Los Angeles, CA.*

Background: Carbamylation is a posttranslational protein modification caused, in part, by exposure to urea's dissociation product cyanate. While carbamylation associates with cardiovascular outcomes and mortality in ESRD, its effects in earlier stages of CKD are unknown.

Methods: In 2 independent nested case-control studies within CRIC, we first matched 75 subjects demonstrating CKD progression (cases, 50% reduction of eGFR or reaching ESRD) to 75 people not meeting this definition (controls, matched on baseline eGFR, 24-hour proteinuria, age, sex, and race). Regression models compared baseline levels of carbamylated albumin (C-Alb, a validated measure of total body carbamylation burden) between the groups. With the same matching approach, we next compared baseline C-Alb in 75 subjects who died during follow up (mortality cases) to 75 survivors (mortality controls).

Results: Table 1 shows baseline characteristics of the study groups. Other than urea (CKD progression) and smoking status (both CKD progression and mortality), there was no difference in any matched or other parameter. Adjusting for baseline differences, the top tertile of C-Alb was associated with an increased risk of CKD progression (OR [95% CI] 7.9 [1.9-32.8], P= 0.004) and mortality (OR 3.4 [1.0-11.4], P= 0.05) when compared to the bottom tertile.

Conclusions: In this first report of carbamylation and clinical outcomes in CKD patients not on dialysis, our data suggest carbamylation predicts CKD progression, beyond GFR and proteinuria. Impact on mortality was less robust in this small sample. Additional study is warrented as carbamylation is considered a modifiable risk factor.

Funding: NIDDK Support

Blood and Urine Biomarkers and CKD After Cardiac Surgery

Steven Menez,[3] Dennis G. Moledina,[1] Amit X. Garg,[7] Heather Thiessen Philbrook,[3] Eric McArthur,[8] Yaqi Jia,[2] Caroline Liu,[3] Wassim Obeid,[9] Sherry Mansour,[1] Jay L. Koyner,[4] Michael Shlipak,[5] Francis P. Wilson,[1] Steven G. Coca,[6] Chirag R. Parikh.[2] TRIBE-AKI Consortium *[1]Yale School of Medicine, New Haven, CT; [2]Johns Hopkins University, Newton, MA; [3]Johns Hopkins University School of Medicine, Baltimore, MD; [4]University of Chicago, Chicago, IL; [5]San Francisco VA Medical Center, San Francisco, CA; [6]Icahn School of Medicine at Mount Sinai, New York, NY; [7]London Health Sciences Centre, London, ON, Canada; [8]Institute for Clinical Evaluative Sciences, London, ON, Canada; [9]John Hopkins University, Baltimore, MD.*

Background: The use of blood and urine biomarkers of injury, inflammation and repair in the post-operative period following cardiac surgery may help identify patients at increased risk for longer-term adverse kidney outcomes. We investigated the independent associations between candidate biomarkers and CKD incidence or progression following cardiac surgery.

Methods: We prospectively enrolled adult patients undergoing cardiac surgery (CABG or valve) in 2 academic centers from 2007–2010 as part of the TRIBE-AKI Study. The cohort was separated into exploration (Canada n=613) and replication (USA n=310) cohorts due to differences in outcome ascertainment and lack of data integration. Top biomarkers were identified from candidate post-operative biomarkers (32 blood, 8 urine) in the exploration cohort and confirmed in the replication cohort, thereby reducing model selection bias. Our primary outcome was a composite of CKD incidence or progression. In those with a pre-operative eGFR≥60, CKD incidence was defined as a 25% reduction in eGFR and a fall below 60. In those with a pre-operative eGFR<60, CKD progression was defined as a 50% reduction in eGFR or a fall below 15.

Results: 172 (28.1%) patients in the exploration cohort developed the primary outcome after a median (IQR) follow-up of 5.61 (4.30-6.84) years. 8 biomarkers were associated with the primary outcome, of which 3 remained significant after full adjustment. Each log increase in post-operative levels of bFGF (HR 1.52 [1.19, 1.93]), N-terminal pro-BNP (HR 1.19 [1.01, 1.41]), and TNF-r1 (HR 1.75 [1.18, 2.59]) were independently associated with the primary outcome (Table 1). Similar estimates were found in the replication cohort, with pooled estimates showing little heterogeneity (I^2=0).

Conclusions: Elevated post-operative levels of bFGF, NT pro-BNP, and TNF-r1 were associated with the CKD outcome. These biomarkers provide additional value in evaluating CKD incidence and progression after cardiac surgery.

Photoacoustic Ultrasound: A New Way to Assess Kidney Fibrosis

Xiaolin He,[1,3] Eno Hysi,[2,3] Adriana Krizova,[4] Michael C. Kolios,[2,3] Darren A. Yuen.[1,3] *[1]Keenan Research Centre for Biomedical Science of St. Michael's Hospital, Toronto, ON, Canada; [2]Department of Physics, Ryerson Univesity, Toronto, ON, Canada; [3]Institute for Biomedical Engineering, Science and Technology (iBEST), a partnership between Ryerson University and St. Michael's Hospital, Toronto, ON, Canada; [4]Laboratory Medicine, St. Michael's Hospital, Toronto, ON, Canada.*

Background: Despite advances in imaging technology(conventional ultrasound, CT, MRI), the only method for assessing fibrosis is by biopsy. Biopsy is limited by its invasiveness and the fact that it samples < 1% of the kidney. Here we show that combining ultrasound with laser technology (photoacoustic (PA) ultrasound) allows imaging of kidney fibrosis by directly measuring collagen content.

Methods: Kidneys of mice undergoing UUO (left kidney) or sham surgery were imaged ex vivo using a VevoLAZR-X PA ultrasound imaging system at 15 MHz at day 7 and 14 post surgery(n=5 per time point). Human kidney samples were obtained from the non-cancerous pole of radical nephrectomies(n=6). Spectral unmixing was performed on the collected images to produce a PA collagen score for each image. For mouse kidneys, a total of 60 PA ultrasound frames were acquired along the largest longitudinal cross-section. Human kidney cortex specimens were scanned in 60 perpendicular cross-sections(separated by 150 μm increments) to obtain a 3D representation of the collagen distribution across the entire sample. Histology was acquired at 3-4 locations within the mouse and human kidneys stained with picrosirius red (PSR) and an antibody direct against α-SMA. The relationship between PA-derived collagen scores and the above histological parameters was then analyzed by univariate linear regression.

Results: The average PSR score for UUO mouse kidneys increased with time post-surgery [day 7 (0.14±0.01) and day 14 (0.27±0.03]], and was higher than sham kidneys (0.002±0, p<0.001). α-SMA staining increased by 18.8% from 7 to 14 days post-surgery and was 26x higher than sham kidneys by 14 days. PA-derived collagen scores correlated strongly with histologic parameters of fibrosis (PSR, r^2=0.98, p<0.05; α-SMA, r^2=0.91, p<0.05), suggesting that PA imaging can accurately quantify murine renal collagen content. Human kidney specimens exhibited a 30% variation in PSR staining, which was also strongly correlated with the PA estimates of collagen (r^2=0.90, p<0.05). The technique was also capable of generating 3D collagen maps across the entire specimen with sub-mm spatial resolution across the entire kidney cortex.

Conclusions: PA ultrasound can be used to accurately quantify renal collagen content. This non-invasive, easy-to-use technique offers the potential for renal fibrosis imaging in both the pre-clinical and clinical settings.

Increase of Extracellular Fluid Volume over Time Is Associated with ESKD and Mortality in Patients with CKD

Anne-Laure Faucon,[1] Emmanuelle Vidal-Petiot,[10,11] Martin Flamant,[10,11] Marie Metzger,[1] Pascal Houillier,[2,6] Jean-Philippe Haymann,[7,13] Francois Vrtovsnik,[4,11] Jean-Jacques Boffa,[9,13] Eric Thervet,[8,12] Benedicte Stengel,[1] Karen Leffondre,[3] Guillaume Geri.[5,1] Renal and Cardiovascular Epidemiology *[1]CESP, INSERM U1018, Villejuif Cedex, France; [2]Department of Physiology, Hopital Europeen Georges Pompidou, Paris, France; [3]ISPED, INSERM U1219, University of Bordeaux, Bordeaux, France; [4]Department of Nephrology, Hopital Bichat, Paris, France; [5]Intensive Care Unit, Hopital Ambroise Pare, Boulogne-Billancourt, France; [6]INSERM U1138, Paris-Descartes University, Paris, France; [7]Department of Physiology, Hopital Tenon, Paris, France; [8]Department of Nephrology, Hopital Europeen Georges Pompidou, Paris, France; [9]Department of Nephrology, Hopital Tenon, Paris, France; [10]Departement of Physiology, Hopital Bichat, Paris, France; [11]INSERM U1149, Paris Diderot University, Paris, France; [12]Paris-Descartes University, Paris, France; [13]INSERM U1155 Pierre et Marie Curie University, Paris, France.*

Background: Data on the association between longitudinal change in extracellular fluid volume (ECF) and end-stage kidney disease (ESKD) and mortality are lacking. The aim of the present study was to analyze whether ECF over time was associated with ESKD and mortality, in patients with chronic kidney disease (CKD).

Methods: 1588 patients of the hospital-based tricentric NephroTest cohort with CKD stage 1-4 were included. ECF and glomerular filtration rate (GFR) were measured using the distribution volume and clearance of ^{51}CrEDTA, respectively. ESKD was defined by initiation of chronic dialysis or pre-emptive transplantation. Joint models with shared random-effect were used to jointly analyze individual trajectories of ECF and the competing risks of ESKD and mortality. Time-to-event sub-model of the joint models was adjusted for age, gender, site, ethnicity, cardiovascular risk factors, underlying renal disease, measured GFR (mGFR), proteinuria, 24-h urinary sodium excretion, diuretics and renin-angiotensin system inhibitors.

Results: At baseline, patients (mean age 58.7±15.1 years, 67% men) had a mean mGFR of 44±19 mL/min/1.73m^2, and ECF was 16.1±3.6 L. After a median follow-up of 5.3[IQR: 3.0;7.4] years with a median number of ECF measurement of 2 [IQR: 1;4] per patient, the mean rate of ECF increase was 117 mL/year 95%CI [90;144]. Between the first and the last visit, the percentage of patients treated by diuretic increased from 47.6 to 50.9% and mean 24-h urinary sodium excretion decreased from 155±73 to 150±73 mmol/d. ESKD occurred in 324 (20.4%) patients and 185 (11.6%) patients died before

ESKD. In multivariable analysis, a higher current value of ECF was associated with an increased hazard of ESKD (adjusted hazard ratio [aHR] per 1L increase in ECF was 1.12 95%CI [1.06;1.18], p<0.001) and with mortality (aHR=1.08 [1.01;1.15], p=0.02).

Conclusions: In this large cohort of CKD patients, ECF over time was independently associated with ESKD and mortality. This highlights the need for a close monitoring and adjustment of treatments in these patients.

Discovery of Novel Podocyte Endoplasmic Reticulum Calcium Stabilizers to treat Nephrotic Syndrome

Sun-Ji Park,[2] Yeawon Kim,[2] Shyh-Ming Yang,[1] Mark J. Henderson,[1] Wei Yang,[3] Maria Lindahl,[4] Fumihiko Urano,[5] Ying M. Chen.[2] *[1]National Center for Advancing Translational Sciences (NCATS), NIH, Rockville, MD; [2]Division of Nephrology, Washington University in St. Louis, St Louis, MO; [3]Department of Genetics, Washington University in St. Louis, St Louis, MO; [4]Institute of Biotechnology, University of Helsinki, Helsinki, Finland; [5]Division of Endocrinology, Metabolism, and Lipid Research, Washington University in St. Louis, St Louis, MO.*

Background: Podocyte injury is the hallmark of primary nephrotic syndrome (NS), a leading cause of chronic kidney disease affecting approximately 500 million people worldwide. Despite the importance of podocyte endoplasmic reticulum (ER) stress in the pathogenesis of NS, currently no treatment targets the podocyte ER. For the first time, we have developed a new class of drugs-podocyte ER calcium channel stabilizers, to treat NS.

Methods: We have developed a podocyte ER stress-induced monogenic NS mouse model with an engineered human C321R mutation in laminin β2, which is synthesized and secreted by podocytes. Western blot and RNA sequencing of isolated mouse glomeruli or cultured primary podocytes were utilized to determine accelerated ER calcium efflux-mediated pro-apoptotic pathway. Moreover, a *Gaussia* luciferase-based assay utilizing secreted ER calcium-monitoring proteins (SERCaMPs) was performed to monitor ER calcium depletion in primary podocytes and to screen for novel ER calcium stabilizers. Lastly, our mouse model was exploited to test the therapeutic effect of an identified drug.

Results: We have identified a novel therapeutic target, podocyte ER type 2 ryanodine receptor/calcium release channel (RyR2). It was phosphorylated at Ser2808 under ER stress, resulting in podocyte ER calcium leak and cytosolic calcium elevation. The altered intracellular calcium homeostasis led to activation of calcium-dependent cytosolic protease calpain 2 and cleavage of its important downstream substrates, including the apoptotic molecule procaspase 12 and podocyte cytoskeletal protein talin 1. More importantly, we have identified a chemical compound K201 and a novel biotherapeutic protein mesencephalic astrocyte-derived neurotrophic factor (MANF), which can reduce RyR2 phosphorylation and inhibit pro-apoptotic calpain 2-caspase 12 signaling in podocytes undergoing ER stress. Most excitingly, K201 treatment attenuated proteinuria and improved kidney function in our podocyte ER stress-induced NS mouse model.

Conclusions: Podocyte RyR2 remodeling contributes to ER stress-induced podocyte injury. Podocyte ER calcium channel stabilizers, including K201 and MANF, could be emerging therapies for the treatment of podocyte ER stress-induced NS.

Combined Single Cell Epigenomic and Transcriptomic Analysis of Healthy vs. FSGS Adult Human Kidney

Yoshiharu Muto, Andrew F. Malone, Haojia Wu, Yuhei Kirita, Joseph Gaut, Benjamin D. Humphreys. *Division of Nephrology, Department of Medicine, Washington University School of Medicine, St.Louis, MO.*

Background: Unraveling the pathogenesis of human FSGS requires a detailed understanding of the distinct cell types, cell specific transcriptomes, chromatin status and cell state changes in healthy and FSGS kidneys. We hypothesized that combined single nucleus RNA-seq and ATAC-seq on a single human biopsy would allow definition of FSGS-specific transcriptional changes and the DNA regulatory variation driving them, at cellular resolution.

Methods: We performed combined scATAC-seq and snRNA-seq on healthy kidney from partial nephrectomy, and on each half of a human kidney biopsy from a 42 year-old transplant patient with new onset proteinuria (2.4g) and preserved renal function (Cr 0.8 mg/dL). Histologic read on the biopsy was FSGS with 30% podocyte foot process effacement by EM. Informatics was by standard workflows.

Results: After quality control, 4,626 cells (8 clusters) and 6,459 cells (13 clusters) were included in the scATAC-seq analysis from the FSGS and healthy kidney, respectively. For snRNA-seq these numbers were 4,672 cells (13 clusters) and 4524 cells (17 clusters). A matrix of cell type specific differentially accessible regions and transcription factor motifs across cell types revealed 580 significantly enriched TF motifs in healthy, and 435 in FSGS. We generated a multimodal, harmonized kidney single cell atlas using all datasets to better understand how transcription and chromatin accessibility are regulated in FSGS. This revealed strong podocyte upregulation of PRKCI, aka atypical PKC, which is required for maintenance of slit diaphragms, and decreased podocyte – mesangial NPNT-ITGA8 signaling in FSGS. The most strongly enriched TF motifs in FSGS endothelium were for ETS family members (ETS1, ETV1,3-5, ELK3-4, ERG), which are downstream of VEGF signaling, whereas snRNA-seq from podocytes showed enhanced VEGFA expression, suggesting active podocyte-endothelial signaling in FSGS.

Conclusions: A multi-omics approach in human FSGS was successfully applied, revealing that that the cell-specific landscape of chromatin accessibility changes dramatically in human FSGS. Combining this epigenome data with snRNA-seq data allows inference of intercellular communication pathways driving disease pathogenesis.

A Human Model of Membranous Nephropathy on-a-Chip

Stefano Da Sacco,[1] Astgik Petrosyan,[1] Paolo Cravedi,[2] Valentina Villani,[1] Andrea Angeletti,[2] Joaquin Manrique,[3] Roger E. De Filippo,[1] Laura Perin.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]Mount Sinai Nephrology, Pianoro, Italy; [3]Complejo Hospital de Navarra, Pamplona, Spain.*

Background: Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults worldwide. MN pathogenesis involves the deposition of auto-antibodies against podocyte-expressed antigens in the glomerular subepithelial space, causing podocyte injury and initiating progressive renal damage which leads to kidney failure in approximately one third of patients. While the role of complement has been confirmed, many questions are still unanswered and the study of mechanisms responsible for MN pathogenesis is challenged by the lack of in vitro systems that recapitulate human disease.

Methods: We have developed a novel glomerulus-on-a-chip system (GOAC) using primary, immortalized and amniotic fluid derived podocytes together with glomerular endothelial cells (GEC) in combination with OrganoPlates and assessed the functional response to human MN serum. Human podocytes were seeded on microfluidic chips with human GEC. Immunofluorescence and WB were performed for podocyte, endothelial and GBM markers. Barrier selective-permeability was investigated. Chips were cultured with serum from MN patients or healthy individuals. Functional response was assessed by albumin permeability assay. IgG/IgG4 deposition was assessed by immunofluorescence while mechanisms of action were explored by Western Blotting and immunostaining.

Results: This system recapitulates salient characteristics and functions of the in vivo glomerular filtration barrier. The GOAC is permeable to inulin and impermeable to albumin. When exposed to serum of subjects affected by MN, the chip displayed deposition of IgG and complement C3 on podocytes and loss of permselectivity to albumin to an extent correlated to urinary protein loss in respective patients. Moreover, we have found evidence suggesting that activation of ILK/MAPK/SNAIL signaling pathway in podocytes might contribute to injury during MN pathogenesis.

Conclusions: We have successfully developed a glomerulus-on-a-chip system that closely mimics the GFB structure and provides a powerful tool for studying pathophysiology of MN. This system will increase our ability to individualize treatments and facilitate drug discovery, thus ultimately benefiting patients affected by this and potentially other glomerular diseases.

Inflammasome-Mediated Cell Death Plays a Key Role in APOL1 Risk Variant-Induced Kidney Disease

Archana Raman, Ziyuan Ma, Dorottya Laczko, Matthew J. Seasock, Katalin Susztak. Susztak Lab *University of Pennsylvania, Philadelphia, PA.*

Background: Apolipoprotein L1 (APOL1) coding variants, termed as G1 and G2 are associated with increased kidney disease risk. We developed a mouse model by conditional and inducible expression of reference (G0) or risk (G1 or G2) variants of APOL1. Mice with podocyte-specific G1 or G2 APOL1 expression develop albuminuria, glomerulosclerosis and renal failure recapitulating the human disease condition. However, molecular pathways leading to kidney disease development in this model remains poorly understood. We hypothesized that APOL1 risk alleles induced inflammasome-mediated pyroptotic cell death contributed to the phenotype development.

Methods: We generated cells with stable or inducible G2 APOL1 expression and used inhibitors of apoptosis, necrosis, and pyroptosis to determine pathways mediating cytotoxicity. To define the role of inflammasome-mediated cell death *in vivo*, we crossed G2 APOL1 transgenic mice (Nphs1rtTA-TRE APOL1) with caspase-1 (Casp1-/-) or NLRP3 (Nlrp3-/-) knockout mice and induced podocyte G2 APOL1 expression with a 21-day doxycycline diet. Histological changes were evaluated by PAS, fibrosis was quantified using Sirius red staining. Albuminuria was determined by ELISA. Inflammasome markers were quantified by immunoblotting.

Results: We found that expression of inflammasome markers cleaved caspase-1, NLRP3, and IL-1B were higher in mice expressing risk variant APOL1. These results were recapitulated in cultured cells expressing risk variant APOL1, while pyroptosis inhibitors decreased inflammasome signaling and cytotoxicity. Nphs1rtTA-TRE APOL1/Casp1-/- mice showed a 90% reduction albuminuria, and a 73% decrease in renal fibrosis compared to Nphs1rtTA-TRE APOL1 mice. Nphs1rtTA-TRE APOL1/Nlrp3-/- mice showed an 80% reduction in albuminuria, and ~ 75% reduction in renal fibrosis, compared to G2 APOL1 littermates. Kidney histology examined by PAS and Sirius red staining showed significant improvement in kidney structure damage. Additionally, NLRP3 or caspase-1 knockout interchangeably decreased markers of inflammasome signaling and cell death.

Conclusions: Our data suggest that caspase-1 and NLRP3 inflammasome plays an important role in the development of G2 APOL1 induced kidney damage. Our results raise the possibility that inflammasome inhibition could be a potential therapeutic approach for APOL1-associated kidney disease.

A Novel Small Molecule Therapy for Nephrotic Syndrome Caused by a Common Podocin Mutation

Valeryia Kuzmuk,[1] Iwona Pranke,[5] Wen Y. Ding,[2] Geraldine Mollet,[4] Corinne Antignac,[3] Rebecca R. Foster,[2] Richard Coward,[2] Gavin I. Welsh,[2] Aleksander Edelman,[5] Moin Saleem.[2] *[1]Univeristy of Bristol, Bristol, United Kingdom; [2]University of Bristol, Bristol, United Kingdom; [3]Imagine Institute/ Laboratory of Hereditary Kidney Diseases, Paris, France; [4]Inserm U1163, Paris, France; [5]INSERM U1151, Paris, France.*

Background: There are currently no targeted therapies for the ever-increasing number of podocyte diseases. Currently, there are over 60 different genetic disorders causing SRNS - the commonest of these by far is that of mutations in the *NPHS2* gene encoding podocin. Podocin is a key scaffolding protein of the slit diaphragm essential for intact glomerular filtration. The most frequent podocin mutation in European children is R138Q, causing retention of the protein in the ER.

Methods: A conditionally immortalized patient cell line with the R138Q mutation was used to study podocin trafficking and biology and to characterize the nature of R138Q-K8 interaction in podocin's cell type, the kidney podocyte. A conditional podocin knock-in mice carrying R140Q mutation, the mouse analogue of human R138Q, was created using doxycycline-inducible Cre-recombinase technology allowing to study the effects of the mutation in postnatal life and representing an ideal model for pharmacological studies.

Results: We provide evidence that a protein-protein interaction of misfolded podocin R138Q (but not wt podocin) with the intermediate filament K8 prevents its correct trafficking to the PM. We have also identified a small molecule that interrupts this interaction and rescues mutant protein mis-trafficking. This results in functional rescue of podocin in both human patient R138Q mutant podocyte cell line, and in a mouse inducible knock in model of the R138Q mutation. In the mouse, complete rescue of proteinuria and histological changes are seen, when the molecule is administered at disease induction, and also after proteinuria has commenced (F1).

Conclusions: Altogether, this data provided constitutes the first therapeutic option for NS patients bearing the R138Q mutation.

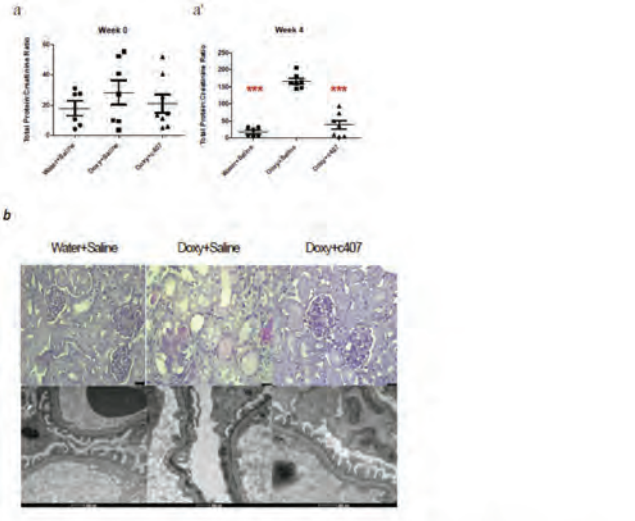

Figure 1. (a) Rescue of proteinuria. Induced control mice developed severe proteinuria at 4 weeks after doxycycline induction, which was prevented in c407 mice (treated via minipump with c407 for 4 weeks, inserted at a time of doxycycline induction). **(b)** Podocytes effacement and glomerular sclerosis were observed in doxy saline mice, while normal histology and podocyte ultrastructure were seen upon treatment with c407.

An iPSC platform for Human Preclinical Evaluation of Kidney Disease Targeting Compounds

Amy D. Westerling-Bui,[1] Thomas Soare,[1] Wei Zhang,[1] Srinivasan Venkatachalan,[1] Maheswarareddy Emani,[2] Alyssa Fanelli,[1] Evan Murray,[1] Grinal M. Corriea,[1] Hien G. Hoang,[1] Sergii Kyrychenko,[1] Maolin Yu,[1] Matthew Daniels,[1] Goran Malojcic,[1] Xin-Ru Pan-Zhou,[1] Thomas T. Tibbitts,[1] Jean-Christophe Harmange,[1] John F. Reilly,[1] Peter H. Mundel.[1] Goldfinch Bio *[1]Goldfinch Bio, Inc., Cambridge, MA; [2]Broad institute of MIT and Harvard, Cambridge, MA.*

Background: A major challenge in drug target validation and assessment of efficacy is the limited translation between preclinical animal models and human diseases, which is often invoked to explain the failure of investigational drugs to produce the expected therapeutic benefit. Human iPSC-derived cells and organoids offer an opportunity to complement preclinical animal models, but their systematic use remains challenging due to the technical complexity associated with consistent cell culture and scalability.

Methods: Here, we report a robust, reproducible and scalable platform for generating iPSC derived human podocytes and kidney organoids to enable target validation and preclinical assessment of therapeutic agents targeting the kidney. The organoid platform was characterized by immunofluorescence analysis of kidney differentiation markers and by assessing transcriptomic changes during organoid differentiation *in vitro* and following *in vivo* transplantation under the rat kidney capsule using single-cell RNA sequencing.

Results: Here, we report three examples supporting the use of these models by – a) providing a mechanistic basis for the antiproteinuric effects of cyclosporine A via protective effects on podocytes from Rac1-mediated cytoskeletal injury *in vitro*, b) exploring of the effects of disease-causing genetic mutations, and c) demonstrating the protective effect of a novel TRPC5 channel blocker, GFB-887. *In vivo* transplantation resulted in vascularization of human iPSC derived kidney organoids, with functional perfusion confirmed by pharmacokinetic measurement of GFB-887 in the organoid after dosing by oral gavage.

Conclusions: Our kidney disease-targeted human iPSC platform provides a valuable complement to pre-clinical models for target validation and assessment of drug efficacy.

SA-OR054

Proteomic Analysis of Clathrin-Coated Vesicles from Podocytes Identifies Cargo Proteins

Marwin Groener,[1,2] Kazunori Inoue,[3,2] Elizabeth Cross,[2] Shuta Ishibe.[2] *[1]Department of Nephrology and Hypertension, University Clinic Erlangen, Erlangen, Germany; [2]Yale University School of Medicine, New Haven, CT; [3]Osaka University Graduate School of Medicine, Suita Osaka, Japan.*

Background: Clathrin-mediated endocytosis (CME) plays a crucial role in podocyte health. Knockout of proteins involved in CME resulted in severe albuminuria and foot process effacement in mice. However, the cargo of clathrin-coated vesicles (CCVs) in podocytes is unknown. The goal of this study was to isolate CCVs from podocytes and identify their cargo by proteomic analysis.

Methods: Kidneys were isolated from *Podocin-Cre Rosa-DTR^{flox}* mice. The glomeruli were seeded and treated with diphtheria toxin to obtain pure primary podocyte cultures. After cell harvesting, CCVs were isolated by D_2O-sucrose density gradient centrifugation using multiple ultracentrifugation steps. Enrichment of CCVs was assessed by immunoblotting and electron microscopy (EM). LC-mass spectrometry (LC-MS) was performed for proteomic analysis. Proteins with higher abundance than transferrin receptor protein 1 were evaluated for CCV cargo potential by comparison to published impurities in CCV preparations, podocyte proteomic databases, and by searching the literature for CME-association.

Results: Immunoblotting for multiple protein markers of CME revealed enrichment in the CCV fraction. Enrichment of CCVs amongst other small vesicles was observed on electron microscopy. Clathrin-heavy chain was the fourth-most abundant protein in LC-MS analysis of the vesicle fraction. Proteomics yielded a total of over 1700 proteins. After adjustment for impurities and upregulation from whole cell expression, over 50 potential cargo proteins were identified. Among those are fibronectin, receptor of activated protein C kinase, thrombospondin-1, and vigilin.

Conclusions: This is the first time CCVs were enriched from podocytes. Enrichment was confirmed by immunoblotting, EM and LC-MS analysis. Proteomic analysis of CCV cargo and adjustment for impurities identified the most abundant cargo proteins in podocytes. These findings help to elucidate the importance of endocytic trafficking for podocyte health and disease.

SA-OR055

Mechanism of Albuminuria in Kidney Disease

Linus Butt,[1] David Unnersjö-Jess,[5] Martin Höhne,[4] Markus M. Rinschen,[3] Hjalmar Brismar,[5] Bernhard Schermer,[4] Thomas Benzing.[2] *[1]University Hospital of Cologne, Cologne, Germany; [2]University of Cologne, Köln, Germany; [3]The Scripps Research Institute, La Jolla, CA; [4]University Hospital Cologne, Cologne, Germany; [5]Royal Institute of Technology, Solna, Sweden.*

Background: Albuminuria is regarded as the most important predictor of progression in a variety of glomerular diseases including Focal-Segmental Glomerulosclerosis (FSGS). Investigating the events causing the occurrence of albuminuria is of utmost importance for future preventive and therapeutic strategies.

Methods: *NPHS2* encodes for the PHB-domain protein podocin and is the most frequently mutated gene in patients with a Steroid-Resistant Nephrotic Syndrome (SRNS) and FSGS. Using CRISPR/Cas9 mediated genome editing, we inserted two separate point mutations into the murine *Nphs2* gene which, in combination, cause late-onset SRNS and FSGS in patients. Disease occurrence and development was assessed using histological and clinical parameters. In addition, changes in the podocytes' foot process morphology and slit diaphragm integrity were investigated using Stimulation Emission Depletion (STED) microscopy.

Results: Compound-heterozygous mice exhibit a mild-onset phenotype reminiscent of patients with the equivalent mutations. FSGS lesions are detectable in young adult mice and lead to end-stage renal disease starting as early as 15-20 weeks. Investigation of the podocyte and the slit diaphragm with STED microscopy showed several distinctive morphological changes like foot process length and width and slit diaphragm length which progress over time. Strikingly, some of the changes correlate tightly with albuminuria and precede the overt onset of disease, podocyte loss and glomerular scarring. We provide evidence that shortening of the slit diaphragm reduces the podocytes' ability to counteract the hydrostatic pressure within the capillaries. This leads to a decreased compression of the glomerular basement membrane (GBM) which results in albuminuria.

Conclusions: We have generated a new mouse model that mimicks the course of disease in patients with a hereditary late-onset SRNS and FSGS. This new mouse model allows the investigation of early disease stages prior to the onset of podocyte depletion, glomerular scarring and massive proteinuria. Based on our data of foot process morphology and slit diaphragm integrity, glomerular filtration rate and albuminuria, we developed a model that attributes the occurrence of albuminuria to a decreased compression of the GBM. In addition, the proposed mechanism of albuminuria can be adapted to other albuminuric pathologies.

SA-OR056

APOL1 Risk Variants Affect Podocyte Lipid Homeostasis and Energy Production in FSGS

Mengyuan Ge,[1] Gloria Michelle Ducasa,[1] Judith T. Molina David,[1] Maarten Hoek,[2] Jeffrey B. Kopp,[3] Flavia Fontanesi,[1] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Merck & Company, Inc., Kennilworth, NJ; [3]NIDDK, NIH, Bethesda, MD.*

Background: Focal segmental glomerulosclerosis (FSGS) is the most common primary glomerular disorder causing chronic kidney disease. Susceptibility to FSGS in African Americans is associated with the presence of genetic variants of the Apolipoprotein L 1 gene (APOL1) named G1 and G2. We recently published that mice with a podocyte-specific, doxycycline (Dox)-inducible expression of constitutively active NFATc1nuc (NFAT;Podocin-rtTA, DT) represent a valuable new model for FSGS.

Methods: Human urinary podocyte-like epithelial cells (HUPECs) carrying different APOL1 genetic variants were established from patients with FSGS and used for *in vitro* studies and human BAC transgenic mice expressing the APOL1 genetic variants (G0, G1 or G2) under the endogenous promoter for *in vivo* studies. DT mice were expanded for consecutive breeding to G0, G1 or G2 mice to generate triple transgenic mice (TT). NFATc1nuc transgene expression was induced by feeding of Dox chow (200 ppm) for 4 months.

Results: HUPECs carrying G1/G2 alleles are characterized by lipid droplet remodeling in association with decreased oxygen consumption, ATP generation and reduced mitochondrial membrane potential, while an increased abundance of super complexes was observed. *In vivo*, we tested the relative contribution of APOL1 risk variant expression to podocyte injury in APOL1 transgenic mice at baseline as well as in TT mice. Glomerular expression of APOL1 mRNA was similar among transgenic mice carrying APOL1 G0 and G1, but significantly lower in G2 carrying mice and these mice did not develop proteinuria at least up to 7 months of age (G2 mice were then excluded due to the low APOL1 mRNA levels). Meanwhile, TT mice carrying the G1 allele showed increased proteinuria, less body weight gain, higher serum BUN levels, more severe glomerulosclerosis and kidney cortex fibrosis when compared with G0 TT and their DT littermates. A strong correlation between serum BUN and kidney cortex cholesterol esters was observed.

Conclusions: Our data reveal that APOL1 risk variant expression may play a role in modulating lipid homeostasis and energy production in podocytes. APOL1 risk variant expression in mice does not impair kidney function at baseline whereas APOL1 G1 expression may contribute to APOL1 mediated susceptibility in NFAT-mediated FSGS.

Adeno-Associated Virus Gene Therapy Prevents Progression of Kidney Disease in Genetic Human and Mouse Models of Nephrotic Syndrome

Wen Y. Ding,[1] Sarah Hunter,[1] Abigail C. Lay,[1] Bryony Hayes,[1] Valeryia Kuzmuk,[1] Matthew F. Beesley,[3] Jenny Hurcombe,[1] Fern Barrington,[1] Catrin Masson,[1] Geraldine Mollet,[4] Colin J. Chu,[1] Richard Coward,[1] Corinne Antignac,[2] Gavin I. Welsh,[1] Moin Saleem.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]Imagine Institute/Laboratory of Hereditary Kidney Diseases, Paris, France; [3]NHS, Cheltenham, Gloucestershire, United Kingdom; [4]Inserm U1163, Paris, France.*

Background: Gene therapy targeting the kidney has proven challenging thus far. Adeno-Associated Virus (AAV) has been used successfully for gene therapy targeting other organs, with particular success demonstrated in targeting monogenic diseases. Here we aimed to advance gene therapy in the kidney by targeting a monogenic disease of the kidney. The commonest cause of genetic nephrotic syndrome in children is a mutation in *NPHS2* encoding podocin. Here, AAV-mediated gene therapy was tested on a conditional podocin knock-out mouse model (iPod $NPHS2^{fl/fl}$), and on human podocytes with the commonest podocin mutation, R138Q.

Methods: AAV 2/9 expressing mouse podocin with a podocyte-specific promoter (either a mouse or human nephrin promoter) was delivered via tail vein injection to iPod $NPHS2^{fl/fl}$. AAV serotypes LK03 and 2/9 were used to transduce immortalised human kidney cell lines to test for transduction efficiency. AAV LK03 expressing human podocin with a minimal nephrin promoter was used to transduce immortalised R138Q podocin mutant human podocytes.

Results: AAV 2/9 expressing podocin demonstrated successful transduction of podocytes in iPod $NPHS2^{fl/fl}$. Treated mice showed a significant improvement in urinary albumin creatinine ratio (n=9/group, p<0.001 at day 42) and prolonged survival (n=3-4/group, p=0.049). *In vitro*, AAV LK03 transduced the human podocyte with a transduction efficiency of close to 100%. Transduction of the R138Q podocin mutant human podocyte with AAV LK03 expressing podocin demonstrated functional rescue *in vitro*.

Conclusions: This is the first study demonstrating successful gene transfer using AAV 2/9 in a monogenic kidney disease in a mouse model. AAV LK03 demonstrated highly efficient transduction of the human podocyte, making it a promising potential serotype for translation of gene therapy targeting the podocyte.

Consolidation in the Dialysis Industry in the Era of Health Reform, 2006-2013

Caroline E. Sloan,[1,3] Abby Hoffman,[2] Matthew L. Maciejewski,[2,3] Cynthia Coffman,[5,3] Linda L. Sanders,[5] Richard A. Hirth,[4] Shoou-Yih D. Lee,[4] Virginia Wang.[2,3] *[1]Division of General Internal Medicine, Duke University, Durham, NC; [2]Department of Population Health Sciences, Duke University, Durham, NC; [3]HSR&D, Durham VAHCS, Durham, NC; [4]University of Michigan, Ann Arbor, MI; [5]Duke University Medical Center, Durham, NC.*

Background: In the last 15 years, the dialysis industry has become dominated by two for-profit large dialysis organizations (LDO) that control 85% of the market. For-profit LDOs have been shown to have higher costs, greater use of expensive medications, lower transplant rates and higher mortality rates. We describe trends in dialysis industry consolidation in the current era of health reform, 2006-2013, and identify factors that put small dialysis chains and independently-owned facilities at risk of closure or acquisition by LDOs.

Methods: We conducted a retrospective cohort study of non-federal US outpatient dialysis facilities that were independently-owned or affiliated with small chains (<20 facilities) for ≥1 year in 2006-2013. These facilities were deemed to be eligible for acquisition by large dialysis organizations. We used data from Center for Medicare and Medicaid Services, US Renal Data System and Area Health Resource File to evaluate facility and market characteristics throughout the study period. The outcome of interest was change in dialysis facility ownership (i.e. acquisition) or facility closure. We used a generalized estimating equation with a logit link, clustered at the regional level, to examine the association between facility characteristics and closure or acquisition.

Results: Overall, 1686 dialysis facilities (27% of all US facilities) were eligible for acquisition for at least one year of the study period; 61% were independently-owned and 39% were affiliated with small chains. The number of independently-owned and small chain-affiliated facilities declined by 192 from 2006 to 2013 (1356 to 1164), while LDO-affiliated facilities increased by 1473 (3214 to 4687). Facilities at highest risk of acquisition or closure were not-for-profit (p<0.001), smaller in size (p=0.02), and in regions with lower hospital density (p=0.001) and more monopolistic markets (p=0.006).

Conclusions: Small dialysis chains and independent facilities retain a declining share of the dialysis market. Policy makers should work to maintain (or even increase) the current diversity of dialysis organizations and help maintain competition in markets at risk of antitrust violation. Efforts should be directed toward facilities that are particularly vulnerable to acquisition and closure.

Patient Experience with Care as a Critical Component of the Medicare ESRD Quality Incentive Program (QIP)

Katherine Hanslits,[1] Shannon Griffin,[2] Jeffrey Pearson,[1] Alissa Kapke,[1] Licia Gaber baylis,[2] Adebola O. Adeleye,[4] Andrew Breck,[2] Dominick Esposito,[2] Marc Turenne,[1] Eric W. Young,[3] Alan B. Leichtman.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Insight Policy Research, Arlington, VA; [3]Arbor Research, Ann Arbor, MI; [4]CMS, Woodlawn, MD.*

Background: Medicare has long required dialysis facilities to assess patient experience as a condition for Medicare participation. More recently, the ESRD QIP introduced the In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH-CAHPS) pay-for-reporting measure in payment year (PY) 2014, shifting to pay-for-performance starting in PY18. The ICH-CAHPS performance measure is based on patient-reported data from 3 global ratings and 3 composite ratings from 35 survey questions.

Methods: We used facility ICH-CAHPS survey results reported in the ESRD QIP Performance Score Summary Reports and CROWNWeb data during 2012-18 to examine facility eligibility and ICH-CAHPS performance from PY14-19. We evaluated ICH-CAHPS performance by facility case-mix and by receipt of payment reduction using linear regression.

Results: In PY18 and 19, <50% of QIP-eligible facilities were scored on ICH-CAHPS. Over 2,200 facilities were not scored due to obtaining <30 complete surveys. Among scored facilities, scores increased slightly from PY18 to PY19; the share of facilities receiving a score of 0 decreased from 8.5% to 4.2%. Performance was highest on the composite "providing information to patients" and lowest on the global rating of nephrologists. Important determinants of low ICH-CAHPS scores included facility

case-mix (e.g. patient race and Medicaid eligibility) and ownership by the two large dialysis organizations. On average, facilities with PY19 payment reductions scored 2.5 points lower on ICH-CAHPS in PY19. Similarly, facilities penalized in PY18 had lower ICH-CAHPS scores in PY19.

Conclusions: Patient experience with care is an important component of the CMS Meaningful Measures framework, and by extension, the ESRD QIP. The use of ICH-CAHPS results in the Medicare ESRD QIP was limited to about half of facilities in PY18 and 19; improving survey response rates in moderately sized facilities may include more facilities. Survey results varied by facility case-mix and ownership. QIP-penalized facilities had lower ICH-CAHPS scores in the performance year and the subsequent year.

Urban Segregation and Hospitalization Outcomes in Patients on Hemodialysis

Ladan Golestaneh,[1,2] Kerri L. Cavanaugh,[5] Angelo Karaboyas,[4] Michal L. Melamed,[2] Tanya S. Johns,[2] Keith C. Norris.[3] *[1]Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, New York, NY; [3]UCLA, Marina Del Rey, CA; [4]Arbor Research Collaborative for Health, Ann Arbor, MI; [5]Vanderbilt University Medical Center, Nashville, TN.*

Background: Patients receiving hemodialysis treatments in communities with a high percentage of Black residents have worse morbidity and mortality outcomes. To better understand drivers of this increased risk, we analyzed data from the United States cohort of the Dialysis Outcomes and Practice Patterns Study (US-DOPPS).

Methods: This analysis included 4567 patients on hemodialysis from 154 facilities in 127 zip codes from the US-DOPPS phases 4-5 (2010-2015) linked to American Community Survey (ACS) data. Negative binomial regression was used to test the association of community, defined by tertile of percent Black residents in dialysis facility zip code, with hospitalization rates, while adjusting for multiple confounders.

Results: The hospitalization incidence rate was 1.18 per year. Patients receiving dialysis in facility zip codes located in communities with a higher (tertile 3: ≥14.4%) vs. lower (tertile 1: ≤1.8%) percentage of Black residents were more likely to be younger, Black, live in urban areas, of lower socio-economic class, more likely to have a catheter as a vascular access, and had fewer comorbidities. These tertile 3 facilities were more likely for-profit and had higher patient counts, but did not differ with respect to clinical quality benchmarks or dialysis adherence. Compared to tertile 1, the covariate-adjusted IRR (95% CI) for hospitalization was 1.32 (1.13-1.55) for tertile 2 and 1.32 (1.14-1.54) for tertile 3 of percent Black residents. This association remained significant in multiple strata examined.

Conclusions: Patients receiving dialysis in communities with a high percentage of Black residents have higher adjusted hospitalization rates, despite having equivalent dialysis care benchmarks. Prospective studies to assess the role of social support, access to pre-ESRD and specialty service care, and patient engagement strategies from healthcare systems and nephrologists caring for these vulnerable populations are warranted.

Sodium Zirconium Cyclosilicate (SZC) Improves Potassium Balance in Hyperkalemic Hemodialysis Patients: Results from the Phase 3b, Randomized, Placebo-Controlled DIALIZE Study

Steven Fishbane,[1] Martin L. Ford,[2] Masafumi Fukagawa,[3] Kieran Mccafferty,[4] Anjay Rastogi,[5] Bruce S. Spinowitz,[6] Konstantin Staroselskiy,[7] Konstantin Vishnevskiy,[8] Vera Lisovskaja,[9] Ayman Al-shurbaji,[10] Nicolas J. Guzman,[11] Sunil Bhandari.[12] *[1]Department of Medicine, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Department of Renal Medicine, King's College Hospital NHS Trust, London, United Kingdom; [3]Division of Nephrology, Endocrinology and Metabolism, Department of Internal Medicine, Tokai University School of Medicine, Isehara, Japan; [4]Department of Nephrology, Barts Health NHS Trust, London, United Kingdom; [5]Department of Medicine, David Geffen School of Medicine, Los Angeles, CA; [6]Department of Medicine, NewYork-Presbyterian Queens, Queens, NY; [7]Department #2, B. Braun Avitum Russland Clinics, St Petersburg, Russian Federation; [8]Propedeutics of Internal Diseases Chair, First Pavlov State Medical University of St Petersburg, St Petersburg, Russian Federation; [9]Biometrics and Information, AstraZeneca, Gothenburg, Sweden; [10]Global Medicines Development, AstraZeneca, Gothenburg, Sweden; [11]Global Medicines Development, AstraZeneca, Gaithersburg, MD; [12]Department of Renal and Transplant Medicine, Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom.*

Background: Patients (pts) with end-stage renal disease frequently have persistent predialysis hyperkalemia (HK) despite hemodialysis (HD). The phase 3b, randomized, double-blind, placebo (PBO)-controlled DIALIZE trial (NCT03303521) investigated the effect of SZC on predialysis serum potassium (sK^+) after the long interdialytic interval in HD pts with HK. To further examine the effect of SZC, several post hoc analyses were conducted.

Methods: In DIALIZE, 196 pts of mean age 58.1 [SD 13.7] years were randomized 1:1 to receive PBO (n=99) or SZC (n=97) 5 g once daily starting dose on non-dialysis days for 8 weeks, comprising a 4-week SZC dose-titration phase (max 15 g) to achieve target predialysis sK^+ 4.0–5.0 mmol/L, and 4-week stable-dose evaluation phase (SZC 0, 5, 10 or 15 g). Post hoc analyses included assessment of the number of visits at which pts had sK^+ of 4–5 mmol/L and 3.5–5.5 mmol/L, and the maximum sK^+ during the evaluation phase. Change in K^+ gradient (difference between the predialysis sK^+ and dialysate K^+ [dK^+]) from baseline to end of evaluation phase was also assessed by cross tabulation of categorized dK^+ (dK^+ 2–3, 3–4, 4–5 and ≥5 mmol/L).

Results: A high sK^+ to dK^+ gradient at the start of HD permits rapid lowering of sK^+ but can also be associated with a greater risk of adverse events, such as cardiac arrhythmias and hospitalizations. SZC was associated with more pts achieving sK^+ 4.0–5.0 mmol/L and being maintained at sK^+ 3.5–5.5 mmol/L vs PBO for 1, 2, 3 and 4 visits. 56 pts had severe predialysis HK (sK^+ ≥6 mmol/L) in the PBO group during the evaluation period, compared with only 14 in the SZC group. A shift in K^+ gradient towards values below the reported higher risk threshold of 3 mmol/L was observed in the SZC group, with 30.6% of pts (n=11/36) moving from gradient 4–5 to 2–3 mmol/L and 55.6% (n=25/45) from 3–4 to 2–3 mmol/L.

Conclusions: These findings suggest that treatment with SZC improves management and reduces the frequency of severe HK in HD pts, which could potentially modify the risks associated with these factors.

Hospitalization Risk Among Younger Adult Hemodialysis Patients: Psychosocial Predictors in the ACTIVE-ADIPOSE Study

Nancy G. Kutner,[1] Yijian Huang.[2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University, Atlanta, GA.*

Background: Association of younger age with hospitalization burden and 30-day readmission risk among adult hemodialysis (HD) patients is an unexpected observation in recent national studies, and predictors may be psychosocial in nature (Lin et al. 2019; Chan et al. 2017). Smoking reflects individuals' priority on health maintenance, and hospitalization risk is known to be elevated among HD patients who smoke, especially younger persons (Li et al. 2018). A dataset that captures granular patient-level data including smoking status and HD treatment adherence facilitates examination of age-stratified risk predictors.

Methods: The ACTIVE-ADIPOSE Study (AAS) is a USRDS special study of a multi-center cohort of prevalent HD patients aged 20-92 conducted 2009-2013 at 14 outpatient dialysis clinics in the Atlanta GA and San Francisco areas. Institutional review boards (Emory University, University of California San Francisco) approved the study and all participants provided written informed consent. Study coordinators conducted patient interviews and abstracted patient medical records. In a multivariable regression analysis adjusted for AAS participants' sociodemographic characteristics and comorbidity, we estimated the association of age, smoking, and HD treatment adherence with all-cause hospitalization burden.

Results: Among 759 AAS participants with data for all variables, younger age was associated with increased odds for hospitalization ($p = 0.02$). Smoking was associated with 30% increased odds ($p = 0.03$), and higher frequency of HD sessions skipped was associated with 20% increased odds ($p < 0.001$), for hospitalization. Compared with non-smokers (n=621), AAS participants who were current smokers (n=138) were younger

(52.1 [11.4] vs. 58.2 [14.5]; p <0.001) and more often reported elevated depressive symptoms (36% vs. 22%; p <0.001), and the mean number of HD treatment sessions skipped by smokers compared with non-smokers was twice as high (p = 0.02).

Conclusions: A validated risk score incorporating psychosocial factors may be useful for targeting interventions to reduce HD patients' risk of hospitalization and 30-day unplanned readmissions (Chan et al. 2017). Younger age, smoking, depression, and treatment non-adherence were prominently associated with hospitalization risk among adult HD patients who participated in the AAS.

SA-OR063

Timing of Intradialytic Exercise and Its Impact on Intradialytic Hypotension: A Randomized Crossover Study

Krista F. Rossum,[1] Stephanie E. Thompson,[3] Evelyn K. Hancock,[4] Victoria Riehl-Tonn,[6] Ranveer S. Brar,[4] Silvia J. Leon mantilla,[5] Jennifer M. MacRae,[6] Clara Bohm.[1,2] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [3]University of Alberta, Edmonton, AB, Canada; [4]Seven Oaks General Hospital, Winnipeg, MB, Canada; [5]Seven oaks General Hospital. Chronic Disease innovation Center, Winnipeg, MB, Canada; [6]University of Calgary, Calgary, AB, Canada.*

Background: Intradialytic cycling improves physical function and quality of life in hemodialysis and appears safe. Due to concerns regarding increased intradialytic hypotension (IDH), experts recommend that intradialytic cycling be completed during the first half of treatment. However, this recommendation limits the use of intradialytic cycling as a therapeutic tool to improve intradialytic symptoms, which are more common in the latter half of treatment. We compared the rate of IDH while cycling during the first half of hemodialysis (early) versus the second half (late).

Methods: We performed a multi-centre randomized crossover study in adults (≥ 18 years old) on chronic (>3 months), in-centre hemodialysis who were participating in a clinical intradialytic cycling program at three Canadian academic centres between July 1, 2018 and Mar 31, 2019. Group A cycled in the first half of hemodialysis for 2 weeks and then in the second half for the subsequent 2 weeks. In Group B, the exercise schedule was reversed. Blood pressure was measured every 15 minutes throughout hemodialysis. We compared *rate of IDH* (episodes IDH/100 hemodialysis hours) with early and late intradialytic exercise. IDH was defined as a >20 mmHg drop from baseline BP OR a drop in systolic BP to <90 mmHg during hemodialysis. Data was analyzed using a general linear mixed model with random intercept and negative binomial regression.

Results: Eighty-four participants were included in the analysis. Group A (n=43, 32.6% female, 64.5 ±11.9 years) had a mean time on hemodialysis of 3.93 (0.26) hours and exercised for an average of 54.7 minutes. Group B (n=41, 41.5% female, 52.6 ± 13.5 years) had a mean time on hemodialysis of 3.90 (0.23) hours and exercised for an average of 50.2 minutes. The rate of IDH per 100 hemodialysis hours was 35.7 and 37.6 when cycling during the first half and second half of hemodialysis, respectively; p=0.11.

Conclusions: There was no association between IDH and the timing of intradialytic cycling. Exercise late in hemodialysis will facilitate expansion of intradialytic cycling programs by optimizing resource use and will enable the use of cycling as a potential non-pharmacological means of improving hemodialysis-related symptoms.

SA-OR064

The Effects of a 6-Month Structured Programme of Intradialytic Cycling on Cardiovascular Remodelling, Myocardial Fibrosis, and Aortic Stiffness: Results from the CYCLE-HD Study

Matthew P. Graham-Brown,[1] Daniel S. March,[2] Katherine L. Hull,[3] Joanne V. Wormleighton,[4] Robin Young,[5] Gerry P. Mccann,[2] James Burton.[2] *[1]Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom; [2]University of Leicester, Leicester, United Kingdom; [3]University Hospitals of Leicester NHS Trust, Coventry, United Kingdom; [4]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [5]University of Glasgow, Glasgow, United Kingdom.*

Background: Cardiovascular disease (CVD) is the leading cause of death in patients on haemodialysis (HD). Traditional and non-traditional risk factors drive pathological changes in cardiovascular structure that relate directly to outcomes, including elevated LV mass (LVM), adverse LV remodelling (LVM/LVEDV), myocardial fibrosis (MF) and aortic stiffness. Exercise improves many of the risk factors that drive these processes. In this study we assessed the effects of a 6-month programme of intra-dialytic cycling (IDC) compared to usual care on prognostically significant measures of CVD in HD patients using cardiac MRI (CMR).

Methods: In an open-label, blinded end-point, cluster randomised controlled trial, adults undergoing maintenance HD were assigned to either a 6-month structured programme of IDC or usual care. Subjects underwent CMR scanning with assessment of LVM, LVM/LVEDV, native T1 mapping and aortic pulse wave velocity (aPWV) at baseline and study completion. Outcomes were analysed as intention-to-treat, using linear mixed-effects models, adjusted for baseline value.

Results: 130 subjects completed baseline assessments (65 per group) with 101 completing the study protocol (control group n=50, IDC group n=51). Patient demographics were well matched between groups. There was a significant between group reduction in LVM of -11.1g (95% CI -15.8,-6.4, p<0.001) with reverse LV remodelling (LVM/LVEDV) -0.07g/ml (95% CI -0.12,-0.07, p<0.01) favouring the IDC group. There was a significant reduction in native T1 between groups over the study period of -32.2ms [95% CI -46.1,-18.3, p<0.001), with significant reductions in septal native T1 (-23.8ms [95% CI -37.2,-10.3]) and non-septal native T1 (-37.5ms [95% CI -54.3,-20.7]) favouring the IDC group (both p<0.001). There was a significant improvement in aPWV between groups over the study period of -2.07ms^{-1} (95% CI -3.16,-0.99, p<0.01) favouring the IDC group.

Conclusions: A 6-month programme of IDC associated with significant reductions in LVM and reverse LV remodelling, as well as reductions in native T1 and aPWV. These data suggest IDC is associated with beneficial LV remodelling, improvements in extent of MF and severity of aortic stiffness compared to usual care HD.

SA-OR065

Effect of a Pedometer-Based Intervention on Body Composition in ESRD

Anoop Sheshadri,[1] Piyawan Kittiskulnam,[3] Jennifer C. Lai,[4] Kirsten L. Johansen.[2,1] *[1]Nephrology, University of San Francisco, California, San Francisco, CA; [2]Hennepin Healthcare, Minneapolis, MN; [3]Chulalongkorn university, Bangkok, Thailand; [4]Hepatology, University of California, San Francisco, San Francisco, CA.*

Background: A randomized trial of a pedometer-based intervention with weekly activity goals led to a modest increase in step count among dialysis patients. However, the effect of this intervention on body composition parameters has not been determined.

Methods: 60 dialysis patients were randomized to standard care or a 3-month intervention program with pedometers and weekly step count targets. We obtained bioelectrical impedance spectroscopy (BIS) data on 54 of these patients (28 control, 26 intervention) at baseline, at 3 months, and 6 months and used linear mixed modeling (adjusted for sex and dialysis modality) to estimate differences in change in total-body muscle mass (TBMM) adjusted for height^2, fat mass (kg), and body mass index (BMI) (kg/m^2) between control and intervention groups.

Results: At baseline, there was no significant difference between groups in age, BMI, race, or body composition. There was no statistically significant difference in change between groups in muscle mass, fat mass, or BMI at 3 months. However, at 6 months, participants in the intervention had a significantly greater increase in TBMM of 0.4 kg/m^2 (95% CI 0.02, 0.09) (Figure 1), decrease in fat mass (-4.5 kg [95% CI -8.5, -0.49]) and decrease in BMI (-0.8 kg/m^2 [95% CI -1.7, -0.01]) relative to controls. Each increase of 1,000 steps from 0 to 3 months was associated with a 0.4 kg decrease in fat mass (95% CI 0.03, 0.7) but there was no dose-response relationship with TBMM/ht^2 or BMI.

Conclusions: Patients assigned to a pedometer-based intervention lost weight compared with patients who did not engage in the intervention. Weight loss was driven primarily by changes in fat mass with relative preservation of muscle mass. The between-group differences appear to reflect a combination of negative changes in the control group as well as decrease of fat mass and increase of muscle mass in the intervention group. Achieved changes in step counts were correlated with changes in fat mass. These data support the use of our intervention in improving body composition measures in this population.

Development of an Automatic Risk-Prediction System for Hemodialysis Patients Using Artificial Intelligence: A Nationwide Dialysis Cohort Study in Japan

Eiichiro Kanda,[1] Yuki Tsuruta,[6] Kan Kikuchi,[2] Naoki Kashihara,[1] Masanori Abe,[3] Ikuto Masakane,[4] Kosaku Nitta.[5] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]Shimoochiai Clinic, Tokyo, Japan; [3]Nihon University School of Medicine, Tokyo, Japan; [4]Honcho-Yabuki Clinic, Yamagata, Japan; [5]Tokyo Women's Medical University, Shinjuku-ku, Japan; [6]Tsuruta Itabashi Clinic, Tokyo, Japan.*

Background: Dialysis patients are at high risks of death and cardiovascular disease. An accurate prediction of these risks at an individual level is required to improve the prognosis of dialysis patients. In this study, we developed a new system for predicting five-year death using machine learning and big data from a nationwide prospective cohort study of the Japanese Society for Dialysis Therapy Renal Data Registry.

Methods: We categorized hemodialysis patients in Japan into new clusters generated by k-means clustering method. The associations between clusters and an outcome (death) in five years were evaluated using multivariate Cox proportional hazards models. Then, the accuracy of the prediction of five-year mortality was compared among the machine learning models.

Results: Among the hemodialysis patients (n=78,854); average age, 65.7±12.2 years; male, 61.5%; and diabetes mellitus, 32.8%. The k-means clustering method using baseline characteristics in the training dataset automatically generated three new groups. Hazard ratios of the high- and middle-risk groups were 45.2 (95% confidence intervals 40.8, 50.0) and 4.8 (4.4, 5.4), respectively. In the test dataset, the accuracy of the cluster was 0.79, which was higher than those of multivariate logistic regression models including baseline characteristics (0.76). The accuracies of deep learning and support vector machine (SVM) models including baseline characteristics were 0.88 and 0.91, respectively. Moreover, that of the SVM model with the cluster was improved to 0.93.

Conclusions: It was found that artificial intelligence can categorize hemodialysis patients on the basis of their characteristics, which reflects their prognosis. This system is useful for identifying high-risk patients at an early stage.

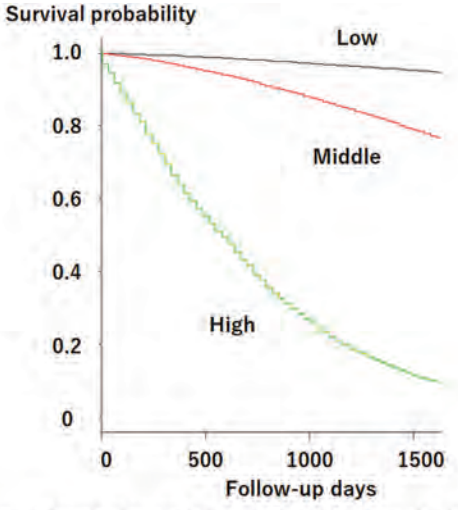

Figure 1 Survival probabilities determined on the basis of new clusters generated by k-means method

SA-OR067

Hyperkalemia Excursions and Mortality in Hemodialysis Patients: Results from the DOPPS

Angelo Karaboyas,[1] Bruce M. Robinson,[1] Glen James,[6] Katarina Hedman,[6] Carol P. Moreno Quinn,[7] Patricia De Sequera,[3] Thomas Weinreich,[4] Zhaohui Ni,[5] Fayez F. Alhejaili,[8] Kosaku Nitta,[2] Roberto Pecoits-Filho.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]University Hospital Infanta Leonor, Madrid, Spain; [4]Nephrologisches Zentrum, Villingen Schwenningen, Germany; [5]Renji Hospital Shanghai Jiaotong University School of Medicine, Shanghai, China; [6]AstraZeneca, Cambridge, United Kingdom; [7]MedImmune, Cambridge, United Kingdom; [8]King Fahad National Guard Hospital, Riyadh, Saudi Arabia.*

Background: Hyperkalemia (HK) has been associated with adverse clinical events in hemodialysis (HD) patients when analyzing a single potassium (K) measurement or time-averaged K values, but the mean value of serial pre-dialysis K measurements does not reflect variability or excursions out of K target range.

Methods: We used data from 21 countries in phases 4-6 (2009-2018) of the Dialysis Outcomes and Practice Patterns Study (DOPPS), a prospective cohort study. We assessed the number of HK excursions over 4-month periods using 3 definitions – serum K >5.0, >5.5, and >6.0 mEq/L – and investigated the association with all-cause mortality over the subsequent 4 months using Cox regression and adjusted for potential confounders, including hypokalemia (K <4.0) excursions and other markers of malnutrition.

Results: We studied 243,886 4-month periods across 61,897 HD patients; The prevalence of at least 1 HK excursion over a 4-month period was 58%, 30%, and 12%, respectively, for serum K >5.0, >5.5 and >6.0 mEq/L. HK excursions >5.5 were most common in Russia (68%) and least common in the US (25%). Patients with HK excursions tended to be younger, with longer HD vintage and higher serum levels of albumin and phosphorus. Compared to 4-month periods with no HK excursions, adjusted models showed that the mortality rate over the subsequent 4 months was 10-20% higher with exactly 1 HK excursion (even at only >5.0 mEq/L), and 20-30% higher with 2+ HK excursions (Figure).

Conclusions: A clear association between one or more HK excursions and all-cause mortality was observed regardless of the hyperkalemic threshold. This method to assess target K achievement may be more sensitive at identifying patients with greater mortality risk over short-term intervals at lower thresholds (5.1-5.5 mEq/L) than previously reported, prompting reassessment of existing HK severity ranges and exploration of strategies to avoid HK excursions.

Identification of Dicarbonyl and L-Xylulose Reductase (DCXR) as a Therapeutic Target in Human CKD

Paul Perco,[1] Wenjun Ju,[2] Julia Kerschbaum,[1] Johannes Leierer,[1] Rajasree Menon,[2] Catherine Zhu,[2] Matthias Kretzler,[2] Gert J. Mayer,[1] Michael Rudnicki.[1] *[1]Medical University Innsbruck, Innsbruck, Austria; [2]University of Michigan, Ann Arbor, MI.*

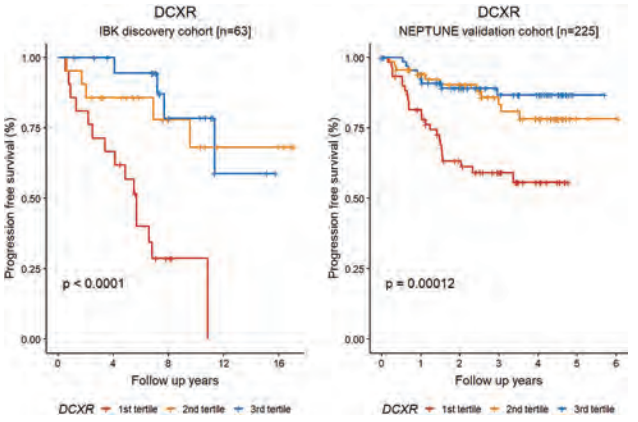
Background: Deregulation of renoprotective factors contributes to development and progression of chronic kidney disease (CKD).

Methods: Renal gene expression profiles of 197 renoprotective factors were analyzed in a cohort of 63 CKD patients. Median follow-up time was 6.9 years and association with disease outcome was assessed in Kaplan-Meier analysis and log-rank statistics. The multicenter NEPTUNE study served as validation cohort [n=225]. Associations with histological and clinical parameters were evaluated for the most significant renoprotective factor DCXR. The impact of SGLT2 inhibition on DCXR levels was furthermore assessed in human renal proximal tubular cells.

Results: DCXR was significantly associated with outcome in the discovery cohort (p-val < 0.0001) and the NEPTUNE validation cohort (p-val = 0.0001). Reduced expression of DCXR was significantly associated with the degree of histological damage as well as with lower estimated glomerular filtration rate and increased urinary protein levels. DCXR expression was positively correlated to enzymes involved in dicarbonyl stress detoxification. The SGLT2 inhibitors canagliflozin and empagliflozin showing a beneficial effect on renal proximal tubular cells under diabetic stimuli enhanced DCXR gene expression up to 2.35 and 2.22 fold.

Conclusions: Lower expression of the renoprotective factor DCXR is associated with more severe disease and worse outcome in human chronic kidney disease.

Funding: Government Support - Non-U.S.



Dicarbonyl and L-xylulose reductase (DCXR) was significantly associated with disease outcome in the discovery cohort (p-value < 0.0001) as well as in the NEPTUNE validation cohort (p-value = 0.00012) in Kaplan Meier analysis and log-rank test statistics.

SA-OR069

NLRP3 Inflammasome Inhibition Attenuates Cisplatin-Induced Renal Fibrosis by Decreasing Oxidative Stress and Inflammation

Li Shu, Qisheng Lin, Xinghua Shao, Zhaohui Ni. Department of Nephrology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University *Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China*.

Background: The mechanisms of cisplatin-induced chronic kidney disease are ill-defined.

Methods: Renal fibrosis was induced via a series of three injections of cisplatin to male C57BL/6 mice (7.5mg/kg body weight), and mice were euthanized at 6 weeks after the first cisplatin treatment. To validate the protective effect of NLRP3 inflammasome inhibition, MCC950 or gene deletion was used.

Results: Male C57BL/6 mice were administered three doses of cisplatin. BUN and serum creatinine increased time-dependently, accompanied tubular interstitial fibrosis. The protein level of NLRP3, ASC, and caspase-1 maturation was upregulated, and expression of IL-1β was markedly increased in renal tubular epithelium. MCC950, the specific inhibitor of NLRP3 inflammasome, was daily injected into multiple-cisplatin-treated mice intraperitoneally(20mg/kg body weight) for 14 days, starting from 4 weeks after the third dose of cisplatin. MCC950 reduced renal dysfunction, tubular damage, interstitial collagen deposit, and the expression of profibrotic parameters. MCC950 treatment also alleviated oxidative stress and inflammation. Furthermore, NLRP3 gene knockout halted the progression of cisplatin-induced renal fibrosis.

Conclusions: The activation of NLRP3 inflammasome promoted renal dysfunction and interstitial fibrosis induced by multiple injections of low-dose cisplatin. Blockade of NLRP3 inflammasome, by a selective inhibitor of NLRP3 inflammasome, MCC950, or by genetic NLRP3 deficiency, attenuated cisplatin-induced oxidative stress, inflammation, renal injury and fibrosis.

Macrophage Mitophagy Deficiency Promotes Experimental and Human Kidney Fibrosis

Divya Bhatia,[1] Kuei-Pin Chung,[1,2] Kiichi Nakahira,[1] Edwin Patino,[1] Michelle C. Rice,[1] Lisa K. Torres,[1] Thangamani Muthukumar,[1] Augustine M. Choi,[1] Oleh M. Akchurin,[1] Mary E. Choi.[1] *[1]Weill Cornell Medicine, New York, NY; [2]National Taiwan University Hospital, Tapei, Taiwan*.

Background: Mitochondrial quality control by mitophagy is critical for normal kidney function. We examined the role of PINK1, Mitofusin 2 (MFN2) and Parkin-mediated mitophagy in macrophage-induced kidney fibrosis, using experimental models of adenine diet (AD) or unilateral ureteral obstruction (UUO) and in human kidney fibrosis.

Methods: Kidney fibrosis in *Pink1*$^{-/-}$ or *Prkn*$^{-/-}$ mice was induced by AD or UUO. Role of MFN2 was studied using *LysM-Cre*$^{+/-}$*Mfn2*$^{fl/fl}$ mice. Kidney tissues and primary macrophages were analyzed by flow cytometry, confocal and electron microscopy, qPCR, western blot, ELISA, and MitoStress test. PBMCs, plasma and kidney biopsies from patients with severe-CKD (GFR<30 ml/min/1.73m^2,*n*=15) or biopsy-proven interstitial fibrosis & tubular atrophy (IFTA,*n*=6) were compared to patients with mild/moderate-CKD (GFR>30,*n*=8) or controls (no CKD,*n*=9).

Results: Expression of PINK1, MFN2, and Parkin was decreased in kidneys and renal macrophages after AD or UUO, as well as in TGF-β1-treated bone-marrow-derived macrophages (BMDMs), human renal macrophages, and THP-1-cells. Kidneys from *Pink1*$^{-/-}$ and *Prkn*$^{-/-}$ mice showed higher fibronectin, collagen-I, TGF-β1, galectin-3, and arginase-I after AD or UUO *vs* corresponding wild-type mice. Renal macrophages from AD-fed *Pink1*$^{-/-}$ mice had a higher number of abnormal mitochondria. Ly6C^{low}CD11b+, F4.80+CD206+ cells and CCL2 levels were increased in blood and kidneys from *Pink1*$^{-/-}$ and *Prkn*$^{-/-}$ mice after AD or UUO. Mitochondria from TGF-β1-treated *Pink1*$^{-/-}$ BMDMs showed lower respiration, higher mitochondrial ROS (mROS), and reduced colocalization with LC3. Mitophagy inhibition by *Pink1*-siRNA or Mdivi-1 resulted in decreased phosphorylation of downstream MFN2 and increased fibrotic response by human macrophages. *LysM-Cre*$^{+/-}$*Mfn2*$^{fl/fl}$ macrophage mitochondria displayed lower recruitment of Parkin and mitophagy. Plasma, PBMCs, and kidney biopsies from patients with severe-CKD and IFTA showed higher CCL2 and mROS, and lower *PINK1*, *MFN2* and *PRKN* expression.

Conclusions: Our study is the first to demonstrate that deficiency of *PINK1*/*MFN2*/*PRKN*-mediated mitophagy promotes macrophage-induced oxidative stress and fibrotic response, and is associated with human kidney fibrosis. Therapeutically targeting macrophage mitophagy pathway may protect against kidney fibrosis.

The PAR-1 Antagonist Vorapaxar Ameliorates Kidney Injury and Tubulointerstitial Fibrosis in Experimental Obstructive Nephropathy

Sarah W.Y. Lok,[1] Wai Han Yiu,[1] Wing han Liu,[2] Hongyu Li,[1] Rui Xue,[1] Loretta Y.Y. Chan,[3] Joseph C K Leung,[1] Kar Neng Lai,[1] Sydney C. Tang.[1] *[1]The University of Hong Kong, Hong Kong, China; [2]The University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [3]Queen Mary Hospital, Hong Kong, China*.

Background: In addition to its role in tumor invasiveness and metastasis, protease-activated receptor-1 (PAR-1) has emerged as an inducer of kidney fibrosis. Whether it can be exploited as a therapeutic target remains unknown.

Methods: We assessed the effect of direct inhibition of PAR-1 on renal fibrosis by vorapaxar (a PAR-1 antagonist), a drug currently undergoing clinical trials for cardiovascular disease, in murine unilateral ureteral obstruction (UUO) model, and in cultured rat renal proximal tubular epithelial cells (NRK-52E). PAR-1 signaling was studied by real-time quantitative PCR, Western blotting and immunohistochemical staining.

Results: In UUO kidneys, PAR-1 and its activator, thrombin, were highly expressed in tubular cells. Mice treated with vorapaxar showed diminished renal fibrotic changes with attenuated fibronectin, α-smooth muscle actin and collagen expression versus control. Macrophage infiltration and ERK1/2 activation were also reduced in vorapaxar treated UUO kidneys. In NRK-52E cells, vorapaxar inhibited PAR-1 signaling, ameliorated thrombin-induced ERK1/2 activation and suppressed the downstream TGF-β signaling via both Smad-dependent and non-Smad-dependent MAPK signaling pathways.

Conclusions: Vorapaxar protects against kidney fibrosis in UUO model, partly via inhibition of thrombin/TGF-β/Smad signaling. This PAR-1 targeted therapeutic strategy may provide a novel treatment approach for chronic renal fibrotic diseases. **Funding:** Health and Medical Research Fund (HMRF) of Hong Kong (grant no. 05163596), Research Grants Council of Hong Kong (Collaborative Research Fund, grant no. C7018-16G), and Hong Kong Society of Nephrology/HK Kidney Foundation Research Grant 2018.

A New Therapeutic Target for CKD: Activins Facilitate TGF-β1 Profibrotic Signaling in Kidney Mesangial Cells

Asfia Soomro,[1,3] Neel Mehta,[1,3] Bo Gao,[3] Joan C. Krepinsky.[2] *[1]McMaster University, Hamilton, ON, Canada; [2]McMaster University, St. Joseph's Hospital, Hamilton, ON, Canada; [3]St. Joseph's Hospital, Hamilton, ON, Canada*.

Background: Chronic kidney disease (CKD) is a rising health issue for approximately 11% of the North American population and is characterized by progressive renal fibrosis and loss of kidney function leading to end-stage renal disease requiring dialysis or transplantation. The profibrotic cytokine TGFβ1 is a central mediator of kidney fibrosis in CKD; blocking it is not feasible due to adverse effects thereby requiring alternate therapeutic approaches. We have shown that TGFβ1 requires activins, a TGFβ superfamily member, for its profibrotic effects. However, since they both signal via the same canonical Smad pathway, how activins enable TGFβ1-induced fibrosis is not known and was investigated here.

Methods: Primary mouse mesangial cells were used. Activin A (AA) and B (AB) were inhibited with a neutralizing antibody, follistatin or siRNA to their receptor, ALK4. Smad3 transcriptional activity was assessed using a CAGA12 luciferase reporter.

Results: TGFβ1 induced strong early activation (60min) of Smad3, while AA/AB caused later activation (48h). TGFβ1 also induced the secretion of AA, with minimal effect on AB. Inhibition of AA, but not AB, decreased TGFβ1-induced Smad3 activation, assessed by phosphorylation and nuclear accumulation, and its transcriptional activity. This demonstrated a requirement for AA for canonical Smad3 signaling by TGFβ1. However, activin inhibition also decreased TGFβ1-induced activation of the α-smooth muscle actin (SMA) promoter more effectively than Smad3 transcriptional activity. Since SMA is a well-known Smad3-mediated TGFβ1 target which also requires non-canonical signaling, these data suggest that AA adds to TGFβ1 signaling activation via a non-canonical pathway. The transcription factors YAP/TAZ are known Smad3 comediators of SMA. Interestingly, activin inhibition prevented TGFβ1-induced YAP, but not TAZ, activation and upregulation. Finally, we confirmed that TGFβ1-induced expression of the extracellular matrix proteins fibronectin and collagen IV were prevented by activin inhibition in mesangial cells. Future experiments will investigate the relevance of Activin-induced TGFβ1 profibrotic signalling in a mouse model of CKD.

Conclusions: AA facilitates TGFβ1 profibrotic effects through regulation of both canonical and non-canonical signaling. Thus, targeting AA represents a novel antifibrotic treatment approach for CKD.

A Computational Drug Screening Approach to Identify Compounds Targeting Renal Age-Associated Molecular Profiles

Paul Perco,[1] Christian Koppelstaetter,[1] Johannes Leierer,[1] Michael Rudnicki,[1] Julia Kerschbaum,[1] Andreas Kronbichler,[1] Anette Melk,[2] Gert J. Mayer.[1] *[1]Medical University Innsbruck, Innsbruck, Austria; [2]Hannover Medical School, Hannover, Germany*.

Background: Aging is a key driver for chronic kidney disease (CKD) and counterbalancing of renal aging processes depicts a way of preventing development and progression of CKD.

Methods: We generated a set of renal age-associated genes (RAAGs) making use of two transcriptomics datasets complemented by information extracted from scientific literature and dedicated aging databases. We evaluated the association of RAAG expression with CKD progression in an independent trancriptomics dataset of 63 CKD patients with a median follow-up time of 6.9 years. Genes showing concordant expression in aging and CKD were used to computationally screen for compounds reversing expression patterns using the L1000 Characteristic Direction Signature Search Engine. The impact on gene expression of key RAAGs in a human renal proximal tubular cell culture model of renal aging was validated for selected compounds.

Results: 31 of the 634 identified RAAGs were significantly associated with CKD progression. 23 RAAGs (74%) showed concordant regulation with CKD progression, i.e. being upregulated in progressive CKD patients as well as with increasing age or vice versa. Among the top-ranked compounds reversing expression of these RAAGs were drugs being in use in the clinical setting in the context of diabetes and kidney disease, namely rosiglitazone, valsartan, captopril, and atorvastatin. All four compounds significantly affected gene expression in a beneficial way in the cell culture model of renal aging. Rosiglitazone had the strongest impact on RAAG expression in HK2 cells significantly downregulating levels of TNFRSF11B (p-value < 0.001), MMP7 (p-value = 0.007), CFB (p-value < 0.001), LTF (p-value = 0.029), and C3 (p-value = 0.002) as compared with untreated controls.

Conclusions: We have (i) generated a list of RAAGs, (ii) identified a subset being also associated with CKD progression, and (iii) identified compounds that have a positive impact on expression levels of the RAAG/CKD signature in renal proximal tubular cells.

Single Cell Landscapes of Human Kidney in Health and Disease

Katherine A. Vernon,[1] Ayshwarya Subramanian,[1] Yiming Zhou,[2] Astrid Weins,[3] Anna Greka.[4] *[1]Broad Institute, Cambridge, MA; [2]Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [3]Brigham & Women's Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: Chronic kidney disease is a global health concern and yet therapies to prevent or halt its progression remain scarce. The emergence of single-cell genomics has provided the opportunity to simultaneously characterize the transcriptomic profile of thousands of individual cells and their respective states, revealing differences previously hidden by bulk analyses. As part of an effort to expand knowledge of regional cell identity, function and diversity within the kidney as a basis to understand and treat disease, we set out to catalog the cell types in different regions of the kidney and the perturbations seen with disease. The detailed identification of cellular landscapes across a variety of kidney diseases using single-cell and single-nucleus RNA sequencing (RNA-seq), aims to illuminate therapeutic targets for the development of precision therapies.

Methods: Macroscopically normal, fresh kidney tissue from patients undergoing tumor nephrectomies and frozen tissue sampled from diagnostic renal biopsies, were used to generate single cell and nuclei suspensions respectively. Droplet-based single-cell or single-nucleus RNA-seq libraries were prepared, amplified by PCR and sequenced. Established computational analytical techniques and a panel of canonical marker genes curated in our laboratory, were used to cluster the different cell types present.

Results: We identified heterogeneous cell populations characteristic of expected kidney cell types and detected regional differences predicted from known anatomy. The changing landscape in the setting of disease was revealed by changes such as the presence of additional immune cell populations.

Conclusions: Having established single-cell dissociation and single-nuclei isolation protocols for fresh and frozen human kidney specimens, this study represents an unprecedented cell mapping effort to identify disease-specific pathophysiological mechanisms and reveal novel therapeutic opportunities. The ability to prevent the potentially inexorable decline to kidney failure would represent a major advance and revolutionize the outlook for renal patients worldwide.

Capillaries Are Primary Targets in CKD and Loss of Tie2 Signaling Increases Vascular Injury

Marie Jeansson,[1] Christer Betsholtz.[2,1] *[1]Karolinska Institutet, Huddinge, Sweden; [2]Uppsala University, Uppsala, Sweden*.

Background: Progressive renal diseases are associated with capillary rarefaction of peritubular capillaries, but the functional alterations and mechanisms are not well described. In both mouse models and patients a decline in endothelial tyrosine kinase receptor (Tie2) signaling can be seen in CKD. Here, we investigate the role of Tie2 signaling on capillary function and fibrosis in models of CKD.

Methods: Tie2 floxed mice were crossed with tamoxifen inducible endothelial specific Cadh5-Cre and a reporter line expressing TdTomato upon Cre-activation (Tie2 ECKO). This line enables both an endothelial specific KO of Tie2 and an endothelial lineage tracer. Mice were induced at 4 weeks of age to avoid developmental effects from the knockout. To study the role of Tie2 signaling in progressive renal disease we utilized the unilateral ureter obstruction (UUO) model. Additional lines (Pdgfra-H2b-GFP, Pdgfrb-GFP) were crossed into the line, resulting in reporters of myofibroblasts.

Results: Endothelial injury started already 1 day after UUO and was significantly worse in Tie2 ECKO mice compared to WT mice, including reduced capillary density, capillary fenestrations and vessel perfusion, increase tubular vacuolization and hypoxia. Blood pressure was not different between WT and Tie2 ECKO mice. Later than the endothelial injury was tubulointerstitial fibrosis starting 3 days after UUO. Fibrosis could be seen 3 and 10 days after UUO with significantly more fibrosis in Tie2 ECKO mice at each time point. Although capillary markers decreased and capillary morphology changed, the number of endothelial nuclei, as measured by the lineage tracer TdTomato, did not change. To investigate if the endothelial lineage had undergone endothelial-mesenchymal transition we utilized a myofibroblast reporter, Pdgfra-GFP, to investigate if GFP and TdTomato would colocalize after UUO. Investigation 3 and 10 days after UUO show no colocalization with TdTomato lineage although the up to 3-fold increase in total number of Pdgfra-GFP cells reflect the onset of fibrosis. Ongoing studies are analyzing single cell transcriptomes from the endothelial lineage in the above experiments.

Conclusions: Our results suggest that blood vessel function is central in progressive renal disease and that Tie2 signaling affects blood vessel function and that pro-Tie2 signaling could be an interesting therapy.

Heat Shock Proteins Prevent Mitochondrial Dysfunction In Uremic Cardiomyopathy: Results from the CAIN Study

Michelle D. Song,[2] Arvin Halim,[2] Li-lun Ho,[5] Thomas F. Hiemstra,[3] Kenneth Lim,[4] Tzongshi Lu.[1] *[1]Brigham and Women's Hospital, Harvard Medical School, Natick, MA; [2]Brigham and Women's Hospital, Arlington, MA; [3]University of Cambridge, Cambridge, United Kingdom; [4]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [5]Massachusetts Institute of Technology, Quincy, MA*.

Background: Uremic cardiomyopathy is a life-limiting condition that occurs in chronic kidney disease (CKD). Emerging evidence has shown that mitochondrial dysfunction is critical in the pathogenesis of the failing heart. We previously showed that impairment of mitochondrial bioenergetics, fusion and division activities is a cardinal event in heart failure in CKD. Heat Shock Protein (HSP) 70 is an inducible HSP that has been shown to exert self-cytoprotective effects. We previous report that HSP70 prevents vascular calcification in uremic conditions and mitochondrial dysfunction in various stress models. In this study, we hypothesized that induction of HSP70 can prevent mitochondrial dysfunction in the failure heart in CKD.

Methods: Human left ventricular tissues collected from advanced CKD on dialysis (n=15) and healthy donors (n=15) were subjected to RNA sequencing, *ex vivo*. We developed a digital cell sorting study model using deconvolution method to enhance interpretation of heterogenous transcriptomic profiles inherent of mixed-cell type tissue. Primary human cardiac myofibroblast were treated with uremic serum and calcification medium (CM, 5 mM calcium chloride and 5 mM β-glycerolphosphate disodium), *in vitro*. Cells were placed into an incubator for heat shock treatment (HST) at 43°C for 30 min to induce HSPs.

Results: Our data shows that HSP70, as well as HSP27 and HSP90 were significantly down-regulated in CKD hearts compared to control group ($p<0.01$). Additionally, cytoprotective mtHSP70 (HSPA9) and the HSP70 co-chaperone, Bcl2 associated Athanogene 1 (BAG1) were highly expressed in healthy control hearts compared to CKD. However, mitochondrial fusion regulation genes MFN1 and OPA1 were down-regulated in CKD hearts ($p<0.01$). Analysis of primary human cardiac myofibroblast treated with CM and uremic serum revealed the same pattern of changes, in vitro. Induction of HSP70 by HST in cardiac myofibroblasts significantly prevented mitochondrial dysfunction, *in vitro* ($p<0.01$).

Conclusions: Our data shows that mitochondrial dysfunction and downregulation of HSPs are involved in the development of uremic cardiomyopathy. Induction of HSP70 prevents mitochondrial dysfunction in cardiac cells under uremic stress. Further studies are critically warranted to investigate therapeutic strategies targeting HSP70 in uremic cardiomyopathy.

Inhibition of Urea Transporter A Attenuates Uremic Cardiomyopathy in CKD Mouse

Akihiro Kuma,[1,2] Xiaonan H. Wang,[1] Janet D. Klein,[1] Jeff M. Sands.[1] *[1]Emory University Renal Division, Atlanta, GA; [2]Second Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan*.

Background: Chronic kidney disease (CKD) induces retention of water, sodium, and urea within the body, and is strongly related to the cardiovascular disease named uremic cardiomyopathy. Our previous study found that urea transporter (UT)-A protein was increased in hearts from CKD mice. We hypothesize that downregulation of UT-A could attenuate volume overload, which could be a new therapeutic strategy for uremic cardiomyopathy.

Methods: The CKD model was generated by uninephrectomy (Nx) in C57BL/6 wild-type (WT) and UT-A1/A3$^{-/-}$ (KO) mice. Blood pressure (BP) was determined by the tail cuff method. Echocardiography was performed on lightly anesthetized mice using the VisualSonics system. Heart tissue was harvested for protein and mRNA analysis by Western blot, histology and real-time PCR.

Results: BUN was 29.2 mg/dL (WT-sham), 52.3 mg/dL (WT-Nx), 26.3 mg/dL (KO-sham), and 55.1 mg/dL (KO-Nx), which proved the success of the CKD model. In WT mice, systolic BP (SBP) in Nx mice was higher than sham mice at 8 weeks; 92.5 mmHg vs 121.2 mmHg (P=0.0012), but not in KO mice; 102.0 mmHg vs 106.1 mmHg (P=0.128). The heart to brain weight ratio increased in WT mice (1.03 mg/mg (WT-sham) vs 1.18 mg/mg (WT-Nx); P=0.027), but showed no significant difference for KO mice. In KO-Nx mice, 24 hr urine volume increased (P=0.014) with decreased urine osmolality (P=0.029) compared with KO-shams, but WT-shams vs WT-Nx mice showed no differences. Echocardiography showed that ejection fraction decreased (57% vs 42%; P=0.0193) and left ventricular end-diastolic volume, which indicates preload, increased in WT-Nx mice vs WT-shams (53 μL vs 62 μL; P=0.0433). Gene expression of angiotensin converting enzyme was increased 1.26-fold in WT-Nx heart compared with WT-sham (P=0.0076), but showed no significant difference between KO-Nx and KO-sham.

Conclusions: Deletion of UT-A may reduce volume retention and suppress increased SBP and renin-angiotensin system activity that accompany CKD. UT-A inhibitors may be attractive diuretics for uremic cardiomyopathy.

Funding: NIDDK Support

Renal, Cardiovascular, and Safety Outcomes of Canagliflozin (CANA) According to Baseline Kidney Function: A CREDENCE Secondary Analysis

Meg J. Jardine,[1,2] Kenneth W. Mahaffey,[3] Rajiv Agarwal,[4] George L. Bakris,[5] James S. Baldassarre,[6] Barry M. Brenner,[7] Scott Bull,[6] David M. Charytan,[8] Tom Greene,[9] Adeera Levin,[10] Bruce Neal,[1] Norm Rosenthal,[6] Tao Sun,[6] Rose Qiu,[6] Hong Zhang,[11] Zien Zhou,[1,12] Bernard Zinman,[13] Vlado Perkovic.[2,14] *[1]The George Institute for Global Health, UNSW, Newtown, NSW, Australia; [2]Concord Repatriation General Hospital, Sydney, NSW, Australia; [3]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [4]Indiana University School of Medicine and VA Medical Center, Indianapolis, IN; [5]The University of Chicago Medicine, Chicago, IL; [6]Janssen Research & Development, LLC, Raritan, NJ; [7]Renal Division and Department of Medicine, Brigham and Women's Hospital, Harvard Medical School and Baim Institute for Clinical Research, Boston, MA; [8]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, Boston, NY; [9]Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; [10]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [11]Renal Division of Peking University First Hospital, Beijing, China; [12]Department of Radiology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [13]Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada; [14]The Royal North Shore Hospital, Sydney, NSW, Australia*.

Background: CANA is approved in people with type 2 diabetes and eGFR ≥45mL/min/1.73m^2. We assessed its efficacy and safety according to eGFR strata including the 30-<45mL/min/1.73m^2 stratum.

Methods: The CREDENCE study enrolled 4401 participants with eGFR 30-<90mL/min/1.73m^2 and urinary albumin:creatinine ratio >300-5000mg/g, randomizing them within eGFR-based strata to CANA 100mg daily or matching placebo. Primary and prespecified secondary composites and safety outcomes were analyzed using Cox proportional hazards regression within each screening eGFR stratum 30-<45, 45-<60 and 60-<90mL/min/1.73m^2.

Results: At screening, 1313 (29.8%), 1279 (29.1%), and 1809 (41.1%) participants had an eGFR 30-<45, 45-<60 and 60-<90ml/min/1.73m^2. Overall, CANA reduced the primary outcome, the renal composite of ESKD, sustained doubling serum creatinine (SCr) or renal death, a range of CV outcomes and serious adverse events with no impact on fractures or amputations. There was no evidence the impact of CANA differed between eGFR subgroups (all P-interaction >0.11, Figure). The benefits of CANA were individually significant in people with a screening eGFR 30-<45ml/min/1.73m^2 for the primary composite, renal composite and composite of CV death or hospitalization for heart failure (95%CI upper limit <1.00).

Conclusions: CANA safely reduces the risk of renal and CV events in people with type 2 diabetes and substantial albuminuria, and these benefits are preserved across a spectrum of eGFR 30-<90ml/min/1.73m^2, including eGFR 30-<45/min/1.73m^2.

Canagliflozin and Renal-Related Adverse Events in Type 2 Diabetes and CKD: Results from CREDENCE

Hiddo J. L Heerspink,[8] Hong Zhang,[1] Kenneth W. Mahaffey,[2] Jingwei Li,[3] Rajiv Agarwal,[4] Barry M. Brenner,[5] George Capuano,[6] David M. Charytan,[7] Jagriti Craig,[6] Dick de Zeeuw,[8] Adeera Levin,[9] Bruce Neal,[3,10] David C. Wheeler,[11] Yshai Yavin,[6] Vlado Perkovic.[3,12] *[1]Renal Division of Peking University First Hospital, Beijing, China; [2]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [3]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [4]Indiana University School of Medicine and VA Medical Center, Indianapolis, IN; [5]Renal Division and Department of Medicine, Brigham and Women's Hospital, Harvard Medical School and Baim Institute for Clinical Research, Boston, MA; [6]Janssen Research & Development, LLC, Raritan, NJ; [7]Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY; [8]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [9]Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; [10]Imperial College London, London, United Kingdom; [11]Department of Renal Medicine, UCL Medical School, London, United Kingdom; [12]The Royal North Shore Hospital, Sydney, NSW, Australia*.

Background: Canagliflozin (CANA), a sodium glucose co-transporter 2 inhibitor, has been shown to reduce the risk of major renal outcomes in patients with type 2 diabetes and chronic kidney disease (CKD) in the CREDENCE trial. The aim of this analysis was to examine the incidence of renal-related adverse events (AEs) during treatment with CANA.

Methods: The CREDENCE trial randomly assigned 4401 participants with type 2 diabetes, CKD, and urinary albumin:creatinine ratio >300-5000mg/g to CANA 100 mg/day or placebo (PBO). Rates of renal-related AEs were analyzed using an on-treatment approach overall and by screening eGFR strata (30-<45, 45-<60, and 60-<90 ml/min/1.73m^2).

Results: The incidence rate of renal-related AEs was lower in the CANA versus the PBO group (Table), with consistent results for the majority of specific AEs, including acute kidney injury, azotemia, blood creatinine increased, glomerular filtration rate decreased, nephropathy toxic, renal failure, and renal impairment. The incidence rate for serious renal-related AEs was also lower in the CANA compared to the PBO group (Table). The incidence rates of renal-related AEs were lower with CANA relative to PBO across three eGFR strata (HRs of 0.73, 0.60, and 0.81 for eGFR 30-<45, 45-<60, and 60-<90, respectively; P-interaction=0.31). Renal-related serious AEs were also lower with CANA relative to PBO across the three eGFR strata (Table).

Conclusions: CANA decreased the incidence of serious and non-serious renal-related AEs in patients with type 2 diabetes and CKD. These data highlight the renal safety of CANA in this population.

Funding: Commercial Support - Janssen Research & Development, LLC

Cost Effectiveness Analysis of Sodium-Glucose Cotransporter 2 (SGLT2) Inhibitors Treatment in Patients with Diabetic Kidney Disease for Cardiovascular and Renal Protection in Singapore

Adrian Liew,[1] Wanting Weng,[1] Yee Ang,[2] Pradeep paul George,[2] Bee hoon Heng,[2] Chee Kong Lim.[3] *[1]Tan Tock Seng Hospital, Singapore, Singapore; [2]National Healthcare Group, Singapore, Singapore, Singapore; [3]National Healthcare Group Polyclinics, Singapore, Singapore*.

Background: Diabetic Kidney Disease (DKD) is a major cause of end stage kidney disease (ESKD) in Singapore. Whilst major trials showed that SGLT2 inhibitors (SGLT2i) improve renal and cardiovascular outcomes in patients with DKD, drug cost is a significant deterrent. We aim to analyse the cost effectiveness of SGLT2i treatment, when added to standard therapy in patients with DKD, for the reduction of cardiovascular and renal events in Singapore.

Methods: All patients with Type 2 diabetes and CKD stages 1 to 3B on follow up with 9 primary care facilities between January 2008 to January 2011 were included in the study population. Incidence of acute myocardial infarct (AMI), ESRD and all-cause mortality were determined and the annual cost of AMI and ESRD requring dialysis and the cost of SGLT2i were calculated using data from the Regional Healthcare System (RHS) Database. Results of the risk reduction for the above outcomes were obtained from CREDENCE, CANVAS, DECLARE and EMPA-REG trials to determine the incremental cost effectiveness ratio (ICER) if SGLT2i were initiated on this historical cohort.

Results: 6281 patients with Type 2 DM and CKD stages 1 to 3B were included in the study. The rates of AMI, all-cause mortality and ESRD was 7.9/1000, 75.2/1000 and 18.1/1000 patient-year respectively. If SGLT2i were initiated, the cost to prevent 1 mortality and 1 ESRD ranged from USD $11 857-40 174 and USD $19 888-63 356 respectively but the cost to prevent 1 AMI was substantially higher. ICER of less than USD $57 827 (equivalent to GDP per capita) was determined to be cost effective in the study. Addition of SGLT2i to standard therapy to reduce cardiovascular and renal events seems cost effective for preventing deaths and progression to ESRD. (Table 1)

Conclusions: Addition of SGLT2i to standard therapy in our diabetic CKD patients can potentially improve outcomes and may be cost effective for preventing deaths and progression to ESRD.

	ICER (Cost/QALY gained) in USD	
AMI	Canagliflozin 300mg (CANVAS)	$2,396448
	Empagliflozin (EMPA-REG)	$783 038
	Dapagliflozin (DECLARE)	$636 886
All-cause mortality	Canagliflozin 300mg Canagliflozin 100mg(CREDENCE)	$155 064 $26 471
	Empagliflozin	$21 889
	Dapagliflozin	$20 473
ESRD	Canagliflozin 300mg Canagliflozin 100mg	$238 999 $46 042
	Empagliflozin	$27 812
	Dapagliflozin	$97 987

Clinical Events in Type 2 Diabetes and Moderate-to-Severe CKD by Albuminuria Status: Dulaglutide vs. Insulin Glargine

Katherine R. Tuttle,[1] Brian Rayner,[2] Mark Lakshmanan,[3] Brad Woodward,[3] Anita Kwan,[3] Manige Konig,[3] Fady T. Botros.[3] *[1]University of Washington School of Medicine, Spokane, WA; [2]Division of Nephrology and Hypertension, Groote Schuur Hospital and University of Cape Town, Cape Town, South Africa; [3]Eli Lilly and Company, Indianapolis, IN.*

Background: In participants with type 2 diabetes and moderate-to-severe chronic kidney disease (CKD), in the AWARD-7 trial, treatment with dulaglutide (DU) compared to insulin glargine (IG) led to slower estimated glomerular filtration rate (eGFR) decline at similar levels of glycemic control and blood pressure.

Methods: To determine risk of a composite endpoint of ≥40% eGFR decline or end-stage kidney disease (ESKD) by albuminuria status, this *post hoc* analysis used Cox proportional hazards modeling for time to first event. Participants were randomized (1:1:1) to DU 0.75 mg or 1.5 mg weekly versus titrated IG daily for one year. eGFR was calculated using the CKD-epidemiology (EPI) creatinine and cystatin C equations.

Results: At baseline, treatment groups had similar eGFR within albuminuria subgroups (Table). Through the 1-year treatment period, the majority of events occurred in patients with macroalbuminuria; the incidence rate of the composite endpoint was significantly lower for DU 1.5 mg compared to IG in those with macroalbuminuria (Table). Consistent results were obtained when eGFR was calculated using either CKD-EPI creatinine or cystatin C equations.

Conclusions: The risk of the composite endpoint of ≥40% eGFR decline or ESKD was lower by approximately half for DU 1.5 mg compared to IG, which was mainly driven by effects in participants with macroalbuminuria.

Renoprotection with Semaglutide and Liraglutide: Direct or Indirect Effects?

Johannes F. Mann,[1] John Buse,[2] Thomas Idorn,[3] Lawrence A. Leiter,[4] Richard E. Pratley,[5] Soren Rasmussen,[6] Tina Vilsbøll,[7] Benjamin Wolthers,[8] Vlado Perkovic.[9] *[1]Friedrich Alexander University of Erlangen, Erlangen, Germany; [2]University of North Carolina School of Medicine, Chapel Hill, NC; [3]Novo Nordisk A/S, Søborg, Denmark; [4]St. Michael's Hospital, University of Toronto, Toronto, ON, Canada; [5]AdventHealth Translational Research Institute for Metabolism and Diabetes, Orlando, FL; [6]Novo Nordisk A/S, Søborg, Denmark; [7]Steno Diabetes Center Copenhagen, Gentofte; University of Copenhagen, Hellerup, Hellerup, Denmark; [8]Novo Nordisk A/S, Søborg, Denmark; [9]The George Institute, UNSW, Sydney, NSW, Australia.*

Background: The SUSTAIN 6 and LEADER cardiovascular (CV) outcome trials indicated that the glucagon-like peptide-1 analogues semaglutide and liraglutide may provide renal as well as CV benefits. This post-hoc analysis investigated the degree to which the observed renoprotective effects could be mediated by glycated hemoglobin (A1C), systolic blood pressure (SBP) and body weight (BW).

Methods: SUSTAIN 6 (N=3297, NCT01720446) and LEADER (N=9340, NCT01179048) assessed CV, renal and safety outcomes for semaglutide and liraglutide versus placebo in patients with type 2 diabetes and high CV risk. A prespecified secondary outcome in these trials was a renal composite of new onset persistent macroalbuminuria, persistent doubling of serum creatinine, need for continuous renal-replacement therapy or death due to renal disease. We performed counterfactual mediation analyses of A1C, SBP and BW using absolute values at each trial visit. The direct contribution of semaglutide/liraglutide to time to first renal event was estimated assuming that the mediator values changed to those observed in the placebo group (from baseline to 2 and 3 years in SUSTAIN 6 and LEADER, respectively). In the adjusted model for A1C, both SBP alone and in combination with BW were included as confounders. Due to the limited number of events in SUSTAIN 6, 95% confidence intervals (CIs) could not be calculated.

Results: In SUSTAIN 6 and LEADER, the rate of a renal event was reduced by 36% (95% CI 12%;54%; P=0.005) and 22% (95% CI 8%;33%; P=0.003) in the semaglutide and liraglutide groups, respectively, versus placebo. A1C was estimated to mediate 26% and 25% (95% CI -7.1;67.3) of the benefits of semaglutide and liraglutide, respectively, whereas the contributions of SBP (22% and 9% [95% CI 2.8;22.7]) and BW (-8% and 9% [95% CI -7.9;35.5]) were smaller. In adjusted analyses, the contribution of A1C increased to 36% (SBP as confounder) and 30% (95% CI -4.5;81.1; SBP and BW as confounders) in the semaglutide and liraglutide groups, respectively.

Conclusions: The renal benefits of semaglutide and liraglutide appear mediated to a modest extent by changes in A1C, SBP and BW, and are therefore likely to be also driven by other, potentially direct, mechanisms.

Combination Therapy of Empagliflozin and Linagliptin vs. Metformin and Insulin Glargine on Intra- and Renal Hemodynamics in Type 2 Diabetes

Christian Ott, Dennis Kannenkeril, Susanne Jung, Roland E. Schmieder. *Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany.*

Background: Combination of insulin with oral antidiabetic drugs is a valid option, but oral combination therapy emerged as an alternative treatment in type 2 diabetes (T2DM). However, the intra-, and renal hemodynamic profile of such combinations therapies has not been evaluated so far.

Methods: In this study 101 patients with T2DM were randomized to receive either empagliflozin 10mg and linagliptin 5mg (E+L group) orally or metformin and insulin glargine (M+I group, with dose adjustments according to glucose levels), for 3 months. Renal hemodynamics were assessed with the "gold-standard", namely constant-infusion input-clearance technique with para-aminohippuric acid and inulin for renal plasma flow (RPF) and glomerular filtration rate (GFR). Intrarenal hemodynamics were calculated according the model established by Gomez.

Results: Due to the multiple dose adjustment of insulin glargine, reduction in HbA1c was greater in M+I than in E+L group (p=0.001), hence all analyses between M+I and E+L were HbA1c-adjusted to evaluate the glucose independent effects between the 2 therapies. In E+L group, body weight (p<0.001), body mass index (p<0.001) and both ambulatory 24-h systolic and diastolic BP (p=0.004/0.036) were reduced compared to M+I group. Treatment with E+L reduced GFR (127±13 vs. 120±14 ml/min, p=0.003), but RPF remained unchanged (623±114 vs. 615±115 ml/min, p=0.536). In contrast, treatment with M+I not only reduced GFR (127±15 vs. 120±13 ml/min, p=0.001), but also resulted in a significant reduction of RPF (653±150 vs. 600±121 ml/min, p<0.001) that was different between the 2 groups (p<0.001). Analysis of intrarenal hemodynamics revealed that E+L did not significantly impact on resistance of afferent arteriole (R_A) (p=0.116), but diminished resistance of efferent arteriole (R_E) (p=0.001), whereas in M+I group R_A was reduced (p=0.006) and R_E remained unchanged (p=0.538). Thus, the effects on R_A (p<0.001) and on R_E (p<0.001) were significantly different between the 2 groups.

Conclusions: As expected combination therapy with E+L reduced GFR, whereas M+I resulted in both reduction of GFR and RPF. Analysis of intrarenal hemodynamics identified different underlying hemodynamic mechanism, with E+L (surprisingly) mainly decreasing R_E and M+I affecting R_A.

Risks of eGFR Decline Thresholds by CKD, Diabetes, and Albuminuria Status

Kenn B. Daratha,[1] Cami R. Jones,[3] Katherine R. Tuttle.[2] *[1]Providence Health Care, Colbert, WA; [2]University of Washington School of Medicine, Spokane, WA; [3]Providence St. Joseph Health, Spokane, WA.*

Background: Thresholds for estimated glomerular filtration rate (eGFR) decline are increasingly used as chronic kidney disease (CKD) outcomes and clinical trial endpoints. eGFR decline thresholds of 30%, 40%, and 50% predict end-stage kidney disease. However, data from large clinical populations to determine risks of reaching these thresholds among patients with and at-risk of CKD [diabetes mellitus (DM), pre-DM, and hypertension (HTN)] and by DM or albuminuria status among patients with CKD are lacking.

Methods: CURE-CKD is a meticulously curated registry of clinical and administrative data extracted from health records of two major healthcare systems in the western United States. eGFR (CKD-EPI) was calculated as the mean value during a 90-day baseline and for each subsequent year (2006-2017). Adults with baseline eGFR ≥15 mL/min/1.73m^2 and at least two follow-up years were included. Albuminuria was defined as urine albumin-to-creatinine ratio ≥30 mg/g. Time-to-event models examined eGFR decline thresholds, controlling for age, gender, race/ethnicity, baseline eGFR, and medication use. An alpha of p<0.001 was chosen *a-priori.*

Results: A total of 1,005,986 patients with mean follow-up of 5.4 years were included (table 1). For patients with established CKD compared to those at-risk of CKD, adjusted hazard ratios (aHRs) for eGFR decline thresholds (30%, 40%, 50%) were increased (1.93, 2.05, 2.16). For patients with CKD, those with DM compared to without DM had increased aHR (1.57, 1.71, 1.75). For patients with CKD and DM, aHR were increased for those with albuminuria compared to without albuminuria (1.38, 1.41, 1.44). Among patients with CKD and no DM, aHR were increased for those with albuminuria compared to without albuminuria (1.81, 1.93, 1.97).

Conclusions: Patients with CKD had increased risk of reaching clinically relevant eGFR decline thresholds compared to patients at-risk with DM, pre-DM, or HTN. Among patients with CKD, DM or, albuminuria independently predicted thresholds of eGFR decline. Study findings inform the design of observational studies and clinical trials in patients with and at-risk of CKD.

Funding: Private Foundation Support

CKD Progression for Patients with Diabetes and Reduced eGFR Treated with Metformin or Sulfonylurea

Adriana Hung,[1,2] Marie Griffin,[1,2] Jonathan Chipman,[1,2] Amber J. Hackstadt,[1,2] Carlos g. Grijalva,[1,2] Robert Greevy,[3] Jea young Min,[1,2] Christianne Roumie.[1,2]
[1]VA Tennessee Valley healthcare System; Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University, Nashville, TN.

Background: Safety concerns limit metformin use in kidney disease. We compared the incidence of renal events between metformin and sulfonylureas users with reduced estimated glomerular filtration rate (eGFR).

Methods: A retrospective cohort combined Veterans Administration, Medicare, and National Death Index data. Metformin or sulfonylurea users were followed from renal function threshold (eGFR <60 ml/min/1.73m^2) until a renal event, treatment change, loss to follow up, death or study end. Renal event was defined as persistent decline in eGFR from baseline of 40% or more (eGFR event) or a diagnosis of end-stage renal disease (ESRD). The analysis compared renal event hazard for metformin vs. sulfonylurea users and estimate cumulative risk in a propensity score matched weighted cohort accounting for the competing risks of non-persistence or death.

Results: There were 74,101 and 28,976 persistent metformin and sulfonylurea users, respectively, who reached renal threshold. The weighted cohort included 24,886 metformin vs. 24,990 sulfonylurea patients; 98% male; 84% white, median (IQR) age 71 years [64, 78]. Median eGFR was 56 ml/min [51.4, 58.0], 10% of the patients had a eGFR <45 ml/min/1.73m^2 and HbA1c 6.6% [6.1, 7.2]. Metformin users had lower cause-specific hazard of renal events vs. sulfonylurea (adjusted HR 0.81, 95%CI (0.68, 0.98)).

Conclusions: Compared to sulfonylureas, metformin use in patients with reduced eGFR was associated with a lower risk of kidney function decline or ESRD.

Verinurad Plus Febuxostat Rapidly Reduces Albuminuria in Type 2 Diabetes Independent of Preexisting Kidney Disease

Austin G. Stack,[1] Nalina Dronamraju,[2] Joanna Parkinson,[3] Susanne Johansson,[3] Eva K. Johnsson,[3] Fredrik Erlandsson,[3] Robert Terkeltaub.[4] *[1]Graduate Entry School of Medicine & Health Research Institute, University Hospital Limerick, Limerick, Ireland; [2]AstraZeneca R&D, Gaithersburg, MD; [3]AstraZeneca R&D, Gothenburg, Sweden; [4]Division of Rheumatology, Allergy, and Immunology, University of California, San Diego, CA.*

Background: Elevated serum uric acid predicts new-onset albuminuria, the earliest clinical indicator of kidney disease. We evaluated the effects of intensive uric acid lowering on albuminuria by combining verinurad with febuxostat in patients with type 2 diabetes mellitus (T2DM) and albuminuria.

Methods: In a phase 2, parallel group, multicenter, randomized, double-blind, placebo-controlled trial (NCT03118739), adults with T2DM, albuminuria, and hyperuricemia were randomized to verinurad 9 mg plus febuxostat 80 mg once daily, or placebo, and followed for 24 wks. The primary outcome was reduction in urinary albumin to creatinine ratio (UACR) at 12 wks compared with baseline. Changes in UACR were evaluated according to baseline characteristics including UACR and estimated glomerular filtration rate (eGFR).

Results: Baseline UACR was 459 (±825) mg/g in the verinurad plus febuxostat group (n=32) and 412 (±548) mg/g in the placebo group (n=28). Improvement in UACR with verinurad plus febuxostat was rapid, sustained over time, and met prespecified criteria for significance, with 39%, 39%, and 49% reductions vs placebo at wks 1, 12, and 24, respectively (wk 12 90% CI –62%, –4%; *P*=0.0747). Reduction was consistent across subgroups including those based on UACR and eGFR (**Figure**). Verinurad plus febuxostat was well tolerated.

Conclusions: Intensive urate lowering with verinurad plus febuxostat significantly reduced UACR in patients with T2DM, albuminuria, and hyperuricemia. Reduction was rapid, sustained, and similar regardless of baseline eGFR and degree of albuminuria. A larger study is underway to determine which patient groups might benefit most from verinurad combination therapy.

Correction of Anemia by Dapagliflozin in Patients with T2D

Bergur V. Stefansson,[1] Hiddo J. L Heerspink,[2] David C. Wheeler,[3] David Sjostrom,[1] Peter J. Greasley,[1] Peter Sartipy,[1] Ricardo Correa-Rotter.[4] *[1]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [2]Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [3]Department of Renal Medicine, University College London, London, United Kingdom; [4]Institutor Nacional de la Nutricion, Mexico City, Mexico.*

Background: Type 2 diabetes (T2D) is one of the most common causes of chronic kidney disease (CKD) and the most frequent cause of renal anemia. Most patients (pts) with T2D show no overt symptoms of renal impairment, consequently, unrecognized anemia is common. Increased hemoglobin (Hb) levels have been observed with dapagliflozin (DAPA) treatment. This study investigated the efficacy and safety of DAPA 10mg in pts with and without anemia at baseline.

Methods: This post-hoc analysis evaluated the effect of the sodium-glucose cotransporter 2 inhibitor, DAPA 10mg, on Hb over 24 weeks (w) across 14 placebo (PBO)-controlled studies in T2D pts with or without anemia (women Hb<12.0 g/dL; men Hb<13.0 g/dL).

Results: A total of 5324 pts were included, 700 (13%) pts had anemia at baseline. There were 1168 (22%) pts with CKD (eGFR<60 mL/min/1.73m^2), 324 (28%) had anemia at baseline. As expected, pts with anemia vs those without anemia were older (mean age:63 vs 59y), had a longer duration of T2D (14 vs 9y) and more advanced CKD (mean eGFR: 66.3 vs 78.6 mL/min/1.73m^2 and mean UACR: 274 vs 89 mg/g). Longitudinal repeated measures analysis showed an Hb increase at w 24 in the DAPA 10mg anemia and no-anemia subgroups (**Fig.1A**). Anemia: (Mean g/dL(SEM)[95% CI], DAPA 0.81(0.066) [0.68,0.93], PBO 0.28(0.067)[0.15,0.41]; difference vs PBO 0.53(0.076)[0.38,0.68]). No-anemia: (DAPA 0.56(0.017)[0.53,0.60] and PBO -0.20(0.018)[-0.23,-0.16]; Difference

vs PBO 0.76(0.024)[0.72, 0.81]). DAPA 10mg corrected anemia in more pts than PBO; DAPA 10mg 52% vs PBO 26% (**Fig.1B**). Overall, DAPA 10mg was well tolerated.

Conclusions: Unrecognized anemia is common in pts with T2D. DAPA 10mg corrected anemia by increasing Hb over 24w and was well tolerated. This effect may be driven by a reduction in blood volume but the increase in Hb beyond w 4 may be explained by other mechanisms.

Polycystin 1 Regulates Actomyosin Contraction and the Cellular Response to Extracellular Stiffness

Elisa Agnese Nigro,[1] Gianfranco Distefano,[1] Marco Chiaravalli,[1] Vittoria Matafora,[2] Maddalena Castelli,[1] Angela Pesenti Gritti,[1] Angela Bachi,[2] Alessandra Boletta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]IFOM-FIRC Institute of Molecular Oncology, Milano, Italy*.

Background: The Polycystins (PC-1 and PC-2) are the products of the genes mutated in Autosomal Dominant Polycystic Kidney Disease. PC-1 is a receptor with a large extracellular extendible domain postulated to act as a mechanosensor. It associates with PC-2 to form a receptor/channel complex possibly activated by the mechanical stimulus of ciliary bending and resulting in calcium influx. This model has recently been challenged, leaving the open question of what mechanical stimuli activate the polycystins.

Methods: To identify interactors of PC-1, we immunoprecipitated (IP) endogenous tagged PC-1 in mouse embryonic fibroblasts derived from *Pkd1*$^{HA/HA}$ or *Pkd1*$^{WT/WT}$ embryos, followed by liquid chromatography mass-spectrometry (LC-MS). We used SILAC (Stable Isotopes Labeling by Aminoacids in Cell culture) followed by either in-gel proteins digestion or protein digestion directly on the beads prior to LC-MS. Each assay was performed in two experiments.

Results: We identified 316 proteins, 30 of them significantly enriched in the IP versus the control in both SILAC studies. Both approaches yielded similar results. The list of binding partners all pointed to a central role for PC-1 in regulation of the actomyosin contraction machinery. Using *Pkd1* gain and loss of function cellular models, we found that PC-1 reduces myosin light chain phosphorylation (pMLC), the main regulator of actomyosin contraction. Furthermore, we confirmed that PC-1 inhibits cell contractility using a collagen disc contractility assay. Given the role of the actomyosin pathway in the response of cells to mechanical stimuli, we used hydrogels or graded epithelial density conditions to mimic different extracellular rigidity states, ranging from 0.4 to 40 kPa. We found that PC-1 negatively regulates Yes-Associated Protein (YAP) activation in response to extracellular stiffness. Finally, in an orthologous murine model of PKD we found increased pMLC, and enhanced YAP nuclear translocation and transcriptional activity, both reversed by the ROCK-inhibitor Fasudil. Notably, treatment with this compound ameliorates disease progression.

Conclusions: Our data suggest a possible direct role for PC-1 as a mechanosensor able to negatively regulate the cellular response to extracellular stiffness.

SA-OR089

Polycystin 1 Acts as an Atypical Adhesion G-Protein-Coupled Receptor (GPCR) That Responds to Non-Canonical WNT Signals and Inhibits GSK3?

Nikolay P. Gresko,[1] Michael J. Caplan,[1] Kavita Mistry,[2] David Merrick.[3] *[1]Yale University School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT; [3]University of Pennsylvania, Philadelphia, PA.*

Background: A recent study demonstrates that polycystin-1 (PC1) serves as a receptor for Wnt ligands. We find that PC1 responds to Wnt9b by shedding its 350kD N-terminal fragment (NTF), which bears a striking resemblance to the activation mechanism of an adhesion GPCR (aGPCR). For aGPCRs, NTF removal liberates a short peptide sequence near the GPS cleavage site called stachel, which then interacts with an internal binding site and engages a G protein signalling cascade.

Methods: Biosensor kinase assay, western blot, morpholino in zebra fish

Results: We find that Wnt9b induces a PC1-dependent phosphorylation and inhibition of the GSK3β kinase through the RhoA GTPase-ROCK kinase pathway. Expression of a "constitutively active" aGPCR form of PC1 that lacks its NTF (NTF PHS) leads to profound suppression of GSK3β activity that is dependent upon Gα13, RhoA and ROCK. Furthermore, a form of the NTF PHS that lacks the putative "stachel" peptide (NTF PH) is unable to inhibit GSK3β kinase, indicating the importance of "stachel" peptide for the active participation of PC1 in this signalling pathway. Interestingly, GSK3β is an important negative regulator of the HIPPO/non-canonical Wnt signalling target TAZ(WWTR1), lack of which leads to the development of severe renal cysts. Furthermore, recent data show that pharmacological inhibition of GSK3β is beneficial in mouse models of ADPKD. We find that exogenous expression of an active form of TAZ in PC1 null cells or in PKD1a/b morphant zebrafish suppresses the development of relevant phenotypes. We also demonstrate that pharmacological inhibition of GSK3β leads to accumulation of the TAZ protein and to reduced cystogenesis in a 3D matrigel assay employing PC1 null cells. TAZ abundance and activity have been shown to be upregulated through the non-canonical Wnt signalling pathway. We find that HEK293 cells that express PC1 and PC2 respond to Wnt9b treatment by significantly increasing TAZ abundance as compared to the wild type HEK293 cells treated in the same manner.

Conclusions: Taken together, our data suggest that PC1 can act as an aGPCR-like receptor for non-canonical Wnt ligands and that it participates in a novel signalling pathway by linking non-canonical Wnt ligands to the GSK3β-dependent regulation of TAZ, a multifaceted signalling molecule whose absence is sufficient to induce renal cystic disease.

Inhibition of Drp1, the Master Regulator of Mitochondrial Fission, Ameliorates Polycystic Kidney Disease Progression

Laura Cassina, Marco Chiaravalli, Alessandra Boletta. *San Raffaele Scientific Institute, Milan, Italy*.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disorder caused by mutations in *PKD1* gene. We reported the remodeling of glucose utilization for energy production and a wide metabolic rewiring in mouse *Pkd1* mutant cells and kidneys (Rowe 2013, Podrini 2018). Alterations in mitochondrial structure and mitochondrial respiration have also been described (Ishimoto 2017, Podrini 2018, Lin 2018). We investigated mitochondrial morphology and function in a PKD mouse model to elucidate their possible contribution to disease progression.

Methods: We analyzed mitochondria structure by transmission electron microscopy (TEM) and respiratory complexes by *in situ* activity staining on kidney sections from control and *Ksp-Cre;Pkd1*$^{fl/-}$ mice. Control and cystic mice were treated with daily intra-peritoneal injection of vehicle or Mdivi-1 (25mg/kg) from P6 to P8.

Results: We measured the number of mitochondria, their size and shape in epithelial cells of cystic kidneys from *Ksp-Cre;Pkd1*$^{fl/-}$ mouse model at P4 by TEM and, in line with previous reports, we detected a decrease in the mitochondrial mass and aberrant mitochondria in cystic kidneys in comparison to controls. Inactivation of *Pkd1* results also in the decreased activity of mitochondrial respiratory chain complexes cytochrome *c* oxidase and succinate dehydrogenase in DBA-positive cystic epithelia. Most mitochondria are in a round shape indicating fragmentation of the network in the epithelial cells of the cystic kidneys. We measured the amount of mitochondrial fusion/fission proteins by western blot and immunofluorescence and we found increased pro-fission Drp1 and decreased pro-fusion Opa1 and Mfn1 proteins in *Ksp-Cre;Pkd1*$^{fl/-}$ kidneys. In line with this, treatment with the Drp1-specific inhibitor Mdivi-1 reduces the cystic phenotype and the kidney to body weight ratio (vehicle, n=8, 7,28 ± 0,83%; Mdivi-1, n=9, 6,48 ± 0,64%, p<0,05), with amelioration of kidney function (BUN, vehicle, 233,3 ± 58,58 mg/dl; Mdivi-1, 187,9 ± 36,43 mg/dl, p<0,05).

Conclusions: Our data indicate that deletion of polycystin 1 in the kidney epithelium results in a reduction of mitochondrial respiration and increased mitochondrial fragmentation. Inhibition of the last ameliorates the PKD phenotype, indicating that mitochondrial fragmentation is a modifier of PKD progression.

ALG9 Mutation Carriers Develop Kidney and Liver Cysts

Whitney E. Besse,[1] Alex R. Chang,[2] Jonathan Z. Luo,[2] William J. Triffo,[2] Ashima Gulati,[1] Marcus Jones,[3] Vicente E. Torres,[4] Tooraj Mirshahi,[2] Stefan Somlo.[1,5] *[1]Internal Medicine, Section of Nephrology, Yale School of Medicine, New Haven, CT; [2]Geisinger Clinic, Danville, PA; [3]Regeneron Pharmaceuticals, Tarrytown, NY; [4]Mayo Clinic, Rochester, MN; [5]Genetics, Yale School of Medicine, New Haven, CT*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic kidney disease. Mutations in *PKD1* or *PKD2* cause typical ADPKD. Dominantly inherited polycystic kidney and liver diseases on the ADPKD spectrum are also caused by mutations in at least six other genes required for protein biogenesis in the endoplasmic reticulum (ER) whose loss results in defective production of the low abundance complex polytopic membrane protein polycystin-1 (PC1), the *PKD1* gene product.

Methods: Whole exome sequencing in a cohort of 122 patients with genetically unresolved clinical diagnosis of ADPKD or polycystic liver disease was used to identify a candidate gene, *ALG9*. This candidate was functionally validated using in vitro cell-based assays of PC1 protein maturation. For further validation, we identified carriers of *ALG9* loss of function mutations (cases) and non-carrier controls matched by gender, ethnicity, age and CKD stage at time of imaging, imaging type and year, in a large exome-sequenced population-based cohort of >92,000 individuals. We assessed kidney and liver lesions in a blinded fashion using pre-specified radiographic criteria.

Results: Two patients in the clinically-defined cohort had rare loss of function variants in *ALG9*. *ALG9* encodes an ER protein required for addition of two mannose molecules to the lipid-linked oligosaccharide precursors for asparagine-linked glycosylation. In vitro assays showed that inactivation of *Alg9* results in impaired maturation and defective glycosylation of PC1. We found 21 carriers of heterozygous *ALG9* loss of function

mutations. Eleven of these had abdominal imaging. Seven of 11 (64%) had at least 4 kidney cysts, including 7 of 8 (88%) of those over age 50, compared with none in the 22 matched controls without *ALG9* mutations ($P = 7.7 \times 10^{-5}$, $P = 2.3 \times 10^{-5}$ respectively).

Conclusions: *ALG9* is a novel disease gene in the genetically heterogeneous ADPKD spectrum. It may be considered when clinically diagnosed ADPKD or isolated polycystic liver disease remain genetically unresolved. This study supports the utility of genotype-driven validation and analysis of candidate disease gene phenotypes in the era of precision medicine.

CD4 T Cells Promote Renal Cystic Disease

Kurt Zimmerman, Michal Mrug, Bradley K. Yoder. *University of Alabama at Birmingham, Birmingham, AL.*

Background: The majority of renal cystic diseases are caused by mutations in proteins associated with primary cilia formation or function. Previous data indicate that mice with dysfunctional primary cilia have an enhanced innate immune response following injury and that these cells are required for accelerated cyst formation. Despite this knowledge, little work has studied the complementary adaptive immune system during injury induced cyst formation.

Methods: Herein, we set out to identify and determine the importance of adaptive immune cells, particularly CD4 T cells, during injury induced rapid cyst formation in conditional *Ift88* mice (here after referred to as cilia mutant mice) and in the *Ift88*^{Orpk} and adult induced conditional *Ift88* slowly progressive models of cystic disease.

Results: Our data show that the number of T cells, including CD4, CD8 and double negative (DN) T cells, are increased in injured cilia mutant mice compared to controls. In addition, we show that the number of CD4, CD8, and DN T cells are also increased in the *Ift88*^{Orpk} and adult induced, non-injured conditional *Ift88* mouse models of slow cystogenesis. Further subtyping of CD4 T cells in these models shows that the number and percentage of Foxp3+ Tregs is increased in all 3 models of cystic disease compared to their respective controls. To test our hypothesis that adaptive immune cells are promoting cystic disease, we crossed our cystic mouse models to RAG1-/- mouse that lack all adaptive immune cells. Our data indicate that loss of adaptive immune cells reduces cyst formation in the rapid injury-induced model of cystogenesis but not in the slowly progressive models. To test the hypothesis that CD4 T cells were the adaptive immune cell type driving rapid cystogenesis following injury in cilia mutant mice, we injected conditional *Ift88* and *Pkd2* mice with an IgG or CD4 depleting antibody. Our data indicate that CD4 depletion reduces renal cystogenesis in both mouse models. Finally, analysis of human patients indicate that the number of Tregs is increased in autosomal dominant polycystic kidney disease patients compared to controls.

Conclusions: Our results suggest that CD4 T regulatory cells promote cystic kidney disease.

The Ciliary Phosphoinositide Pathway Controls the Dosage of Polycystins in Cilia

Chuan Chen. *Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN.*

Background: ADPKD is a progressive genetic disorder characterized by the development of fluid-filled renal cysts. It is mainly caused by mutations in *PKD1* and *PKD2* genes encoding respectively PC1 and PC2. PC1 and PC2 function as a complex and localize predominantly in primary cilia. However, the molecular mechanism underlying the trafficking and maintenance of PC1/PC2 in cilia is unclear. PIs are a group of signaling phospholipids that regulate membrane trafficking and organelle identity. Abnormal phosphoinositide metabolism correlates with variant human diseases. Recent studies showed that PI(4)P and PI(4,5)P_2 exhibit unique compartmentalization in the ciliary membrane and regulate the ciliary trafficking and signaling, suggesting this PI pathway may function in the trafficking of polycystins to cilia.

Methods: We manipulate the PI contents and determine the ciliary level of PC1 and PC2 using IF. The global protein levels are determined by immunoblotting. We use the 3D spheroid model and the embryonic kidney culture to determine the effect of the ciliary PI pathway on renal cystogenesis. Moreover, *in vitro* cellular assays are used to monitor cell survival and proliferation.

Results: We found increased PI(4,5)P2 level in ciliary membrane increases the ciliary level of PC2 in normal cells. Moreover, in renal epithelial cells carrying ADPKD mutations, the ciliary level of PC1 and PC2 can also be restored by increasing PI(4,5)P_2 in cilia. Then, we utilized 3D culture and embryonic kidney culture assays to detect the renal cystogenesis, and discovered that our specific inhibitor reduced the cyst formation both *in vitro* and *ex vivo*. In addition, the inhibitor showed no obvious effect on phosphated AKT or ERK expression, as well as cell proliferation in MTT assays, suggesting that the impaired cystogenesis were very likely resulted from recovered ciliary polycystins.

Conclusions: The effective treatment of ADPKD is extremely limited and Tolvaptan as the only FDA approved drug shows limited benefits with substantial side effects. The functional dosage of polycystins directly influences the disease severity in ADPKD patients. We found that manipulating the ciliary PI pathway as well as their products increases the ciliary polycystins, and exhibits suppression effects on cystogenesis. These results suggest that the ciliary PI pathway could be a novel therapeutic target for ADPKD.

SA-OR094

Aurora A Kinase Is Required for Development of Renal Cysts in a Ciliopathy Model

Ian Smyth, Denny L. Cottle, Mingshen Tham, Allara Zylberberg, Lynelle K. Jones, Kieran M. Short, Sarah E. Conduit, Christina A. Mitchell. *Monash University, Clayton, VIC, Australia.*

Background: Aurora A Kinase (AURKA) is classically regarded as a mitotic cell kinase necessary for progression through the cell cycle. It is also associated with disassembly of the primary cilium. We have previously shown that in vitro inhibition of AURKA is sufficient to reverse many of the cyst associated phenotypes in cultured cells lacking the Joubert Syndrome gene, INPP5E. This raises the possibility that therapies aimed at limiting AURKA actions may represent an approach to preventing cyst development in this and other ciliopathies.

Methods: To investigate a casuative role for AURKA in renal cyst initiation and progression we have independently inhibited its kinase activity (using Alisertib) and deleted the Aurka gene in a mouse model of PKD development in Joubert Syndrome. We have then studied the impact of these alterations on cystogenesis and cell signaling.

Results: We find that treatment with Alisertib results in the generation of more, rather than less, renal cysts and provide evidence that the drug actually increases the amount of AURKA protein in kidney cells. Conversely, we find the while AURKA deletion does not affect the development or homeostasis of the collecting duct system, its co-deletion with Inpp5e is able to almost completely prevent PKD - over the long term. Analysis of these models indicates that AURKA over-expression in PKD is associated with increased AKT signalling and that genetic deletion of AURKA normalises this pathway and cyst associated DNA damage. Furthermore, we find that AKT and AURKA directly interact and co-localise to the primary cilium in a dynamic manner associated with the activation of growth factor signaling.

Conclusions: These studies demonstrate that while AURKA is dispensible for renal development and tubule homeostasis, it acts as a key driver of cyst formation. The failure of Alisertib to ameliorate cyst formation contrasts with the profound prevention of disease mediated by AURKA gene deletion. Taken together, these findings that suggest that kinase independent functions of AURKA are central to cystogenesis. The correction of AKT signaling and the close functional association identified between AURKA and AKT highlights dysregulation of this pathway as being critically important for cyst initiation, suggesting a potential avenue for therapeutic development.

Carbonic Anhydrase II (CAII) and Intercalated Cells (ICs) Drive Kidney Cystogenesis in Tuberous Sclerosis Complex (TSC)

Sharon L. Barone,[1,2] Kamyar A. Zahedi,[1,2] Marybeth Brooks,[1,2] Alicia A. McDonough,[3] Stefan Somlo,[5] Elizabeth P. Henske,[4] Jane J. Yu,[1] Manoocher Soleimani.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH; [3]Keck School of Medicine of USC, Los Angeles, CA; [4]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [5]Yale University, New Haven, CT.*

Background: TSC is caused by mutations in either TSC1 or TSC2 genes and affects multiple organs, including kidney, lung and brain. In the kidney, TSC presents with benign tumors (angiomyolipomas) and cysts, which eventually lead to kidney failure. Little is known about the factors that promote cyst generation and enlargement in tuberous sclerosis.

Methods: Principal cell (PC) specific inactivation of Tsc-1 or Tsc-2 was accomplished by crossing mice with either a Tsc-1 or Tsc-2 floxed construct with mice expressing cre recombinase under the control of Aqp-2 promoter.

Results: Tsc-1 KO as well Tsc-2 KO (Physiol. Report 2019) develop numerous cortical cysts, which are overwhelmingly (>95%) comprised of A-ICs, as identified by strong apical expression of V H^+-ATPase B subunit and basolateral AE1 (Slc4a1), with remaining cells (<5%) expressing Aqp-2, a marker of PCs. ICs lining the cysts expressed intact Tsc-1 gene and exhibited vigorous proliferation and mTORC1 activation. RNA-seq and confirmatory northern hybridization and/or immunohistochemical studies demonstrated the robust expression of the transcription factor Foxi1, a master regulator of ICs H^+-ATPase, Cl^-/HCO_3^- exchanger AE1 and CAII in cyst epithelia in Tsc-1 KO mice, but not in Pkd1 mutant mice. Given the vital role of CAII in H^+-ATPase activity and ICs viability/proliferation, we tested the hypothesis that CAII may play a critical role in the cytogenesis in TSC.

Conclusions: Our studies demonstrate that CAII deletion in Tsc-1 KO mice profoundly inhibited the cyst burden (see image). Compared with Tsc-1 single mutant mice, CAII/Tsc-1 double mutant mice displayed much smaller cysts, with significantly fewer proliferating ICs, and decreased mTORC activity. We propose that the H^+-ATPase and CAII are critical to cystogenesis, and their inhibition or inactivation is associated with significant protection against cyst generation/enlargement in TSC.

Innate Immunity Contributes to Tubular Cell Senescence in Nephronophthisis Type 7 Knockout Mouse Kidneys

Heng Jin,[1,2] Yan Zhang,[1,2] Qiong Ding,[1] Dingxiao Liu,[1] Prerna Rastogi,[1] Peter Igarashi,[3] Massimo Attanasio.[1] *[1]University of Iowa, Iowa City, IA; [2]Tianjin Medical University General Hospital, Tianjin, China; [3]University of Minnesota, Minneapolis, MN.*

Background: Nephronophthisis (NPHP), an autosomal recessive disease, is the most frequent monogenic cause of chronic renal failure during the first three decades of life. Mutations in over 25 genes have been identified as causes of this disease and in several cases, like in NPHP type 7, result in chronic DNA damage. Cell senescence is a frequent outcome of chronic DNA damage. We showed that kidney tubular cells undergo cell senescence in the *Glis2* mouse model of NPHP type 7. Senescent cells secrete pro-inflammatory molecules that can induce further senescence in neighboring non-senescent cells through the activation of the Toll-like receptor/interleukin 1 receptor/NF-kB (TLR/IL-1R/NF-kB) signaling pathway. We previously reported that NF-kB is activated in kidney tubular cells of the *Glis2* knockout mice. We hypothesized that inducing apoptosis of senescent cells would protect from inflammation and fibrosis, and that genetic inhibition of the TLR/IL-1R/NF-kB signaling axis would decrease tubular cell senescence in *Glis2*-knockout kidneys. We hypothesized that inducing apoptosis of senescent cells would protect from inflammation and fibrosis, and that genetic inhibition of the TLR/IL-1R/NF-kB signaling axis would decrease tubular cell senescence in *Glis2*-knockout kidneys.

Methods: To this end we used the senolytic drug FOXO4-DRI to induce apoptosis of senescent cells, and generated two mouse lines: a double knockout line lacking both *Glis2* and *Tlr2* in all tissues (*Glis2*$^{-/-}$;*Tlr2*$^{-/-}$); and a line in which a kidney-specific promoter (Ksp) is used to conditionally inactivate the adaptor myeloid differenziation protein 88 (MyD88) downstream of TLR/IL-1R receptors in tubular cells of *Glis2*-null mice (*Glis2*$^{-/-}$;^{KspCre}*Myd88*$^{f/f}$).

Results: We found that pharmacologic elimination of senescent cells results in reduced kidney damage, fibrosis, and apoptosis in *Glis2*-knockout kidneys. Noticeably, in *Glis2*, *Tlr2* double knockouts and, to a lesser extent, in *Myd88*, *Glis2* knockout mice senescence was reduced and tubular-cell proliferation was increased, suggesting that loss of TLR2/IL-1R activity improves the regenerative potential of tubular cells.

Conclusions: Our results further suggest that a combination of TLR/IL-1R inhibition and senolytic therapy may delay the disease progression in NPHP type 7 and other forms of this disease.

The Pathogenic Role of NEK8 RCC1-Domain Mutations in Inversin Compartment Assembly

Doaa A. Attia,[2] Anjali Misra,[1] Peter G. Czarnecki.[3] *[1]University College Cork, Cork, Ireland; [2]Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Background: The Inversin compartment (IC) is a protein module located at the proximal end of the primary cilium that consists of four known components, inversin (INVS), NEK8, ANKS6 and NPHP3. Missense mutations in inversin compartment genes, including NEK8, give rise to a wide spectrum of disease phenotypes, including Nephronophthisis (NPHP), polycystic kidney disease (PKD), as well as complex multiorgan malformation syndromes with embryonic lethality. In our previous work, we have shown that NEK8 kinase-domain mutations that specifically affect the phosphorylation mechanism give rise to cystic kidney phenotypes and randomization of embryonic L-/R-asymmetry determination. We have also shown that the NEK8 RCC1-domain is necessary for recruitment of NPHP3 to the ciliary inversin compartment. The mechanism how NEK8 RCC1-domain mutations and mutations in NPHP3 produce NPHP- and PKD-like phenotypes remains unexplained.

Methods: We cloned affinity-tagged versions of NEK8 and NPHP3 in expression vectors for transient expression in 293T cells and for stable lentiviral transduction in mIMCD3 cells. We knocked out NEK8 and NPHP3 genes in IMCD3 cells by CRISPR/Cas9. We introduced pathogenic mutations into the NEK8 ORF by fusion PCR. We analyzed protein expression levels by Western-Blot, protein localization to primary cilia by immunofluorescence and protein-protein interactions by immunoprecipitation and Western-Blot.

Results: We found that pathologic missense mutations in the NEK8 RCC1 domain fall into three categories: (1) Mutations that destabilize NEK8 protein lead to reduced or absent expression and no detectable localization to the cilium; (2) Mutations that produce soluble and detectable levels of NEK8 protein, but fail to properly localize to the primary cilium; (3) Mutations that allow NEK8 protein to localize to the cilium, but have reduced affinity to NPHP3 binding. While mutations of categories (1) and (2) correlate with NPHP phenotypes, mutations of category (3) correlate with PKD phenotypes.

Conclusions: We demonstrate that hierarchical defects in inversin compartment assembly correlate with the phenotypic spectrum of kidney disease. Reduced NEK8 and NPHP3 localization leads to NPHP-like disease, whereas proper NEK8 localization and reduced NPHP3 affinity leads to PKD.

SA-OR098

Ultra-Short-Duration Direct-Acting Antiviral Prophylaxis to Prevent Hepatitis C from Viremic Donors to Hepatitis C-Negative Kidney Transplant Patients

Gaurav Gupta,[1] Idris Yakubu,[1] Anam Alam,[2] Dhiren Kumar,[1] Anne L. King,[2] Layla Kamal,[2] Le Kang,[4] Irfan A. Moinuddin,[1] Chandra S. Bhati,[3] Amit Sharma,[4] Adrian Cotterell,[2] Marlon F. Levy,[4] Richard Sterling.[2] *[1]Virginia Commonwealth University Health System, Richmond, VA; [2]Virginia Commonwealth University, Midlothian, VA; [3]VCU Health system, Richmond, VA; [4]VCU, Richmond, VA.*

Background: Direct-acting anti-viral drug (DAA) prophylaxis of of less than twelve weeks initiated at the time of transplant could have the potential to reduce the cost of deceased HCV-infected viremic donor to non-HCV-infected transplants (D+/R-). In our recently concluded single-center trial (ClinicalTrials.gov: NCT03249194; to be presented at ATC 2019; manuscript under peer review) we reported a HCV transmission rate of 13% with an ultra-short course of DAA prophylaxis given over the first 4 days of transplant. Here we present initial data on our extension open-label clinical protocol [REFORM HEPC (REgistry For the study of ORgan transplants froM HEPatitis C infected donors].

Methods: Waitlisted HCV negative adult kidney transplant candidates without significant liver fibrosis, as assessed by transient elastography, were enrolled. After administration of ultra-short course (4 days) prophylactic Sofusbuvir/Velpatasvir (SOF/VEL), patients were screened for HCV RNA at Days 7, 14, 21 and Month 3. Development of viremia (defined as two consecutive positive RNAs) triggered a full 12 week course of DAA therapy.

Results: Over a period of 4 months (Jan-April 2019), 88 patients were enrolled. Of these, 22 (25%) received D+/R- transplants. The mean wait time to transplant from enrollment was 19 days and the mean donor KDPI was 64%. Of the data available on 11 donors (50%), the median donor viral load was 2.6E+06 IU/mL (IQR:2.5E+02-7.3E+06). A majority were genotype (GT) 1a donors (88%). At a median follow-up of 97 days (IQR: 30-150 days) post-transplant, both patient and graft survivals were 100%. There were no cases of liver dysfunction. Average kidney function as measured by eGFR was 52±25mL/min/1.73m2. There were no episodes of acute rejection or de-novo donor specific antibody formation. Viral transmission rate was 4.5% (1/22; GT1a). The only patient with viremia has a declining viral load on glecapravir/pibrentasvir after 4 weeks of initiating therapy.

Conclusions: Our data suggests that ultra-short duration DAA prophylaxis is highly effective in preventing donor-derived HCV transmission and has the potential of resulting in significant cost-savings by avoiding DAA therapy in a majority of D+/R- transplants.

Greater Impact of Pre-Transplant Dialysis Exposure on Transplant Survival in Regions with Higher Dialysis Mortality

John S. Gill,[1] Stephanie Clark.[2] *[1](St. Paul's Hospital/University of British Columbia), Vancouver, BC, Canada; [2]Providence Health Care - St. Paul's Hospital, Vancouver BC, BC, Canada.*

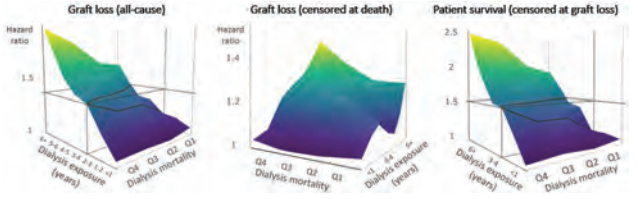
Background: Longer pre-transplant dialysis exposure is associated with a higher risk of transplant failure. Mortality rates on dialysis are known to vary between regions, and may in part reflect differences in the quality of dialysis care. We hypothesized that the association of dialysis exposure with transplant failure would be higher in patients treated in regions with higher rates of dialysis mortality.

Methods: Adult patients in the United States Renal Data System who initiated maintenance hemodialysis after May 1995, and received a kidney-only deceased donor transplant by Dec 2010 were studied (n=63,610). Dialysis mortality (per 100 patient years), adjusted for differences in patient age, sex, and race, was determined by state of residence and time period of dialysis, and grouped into quartiles. The association between the duration of dialysis exposure (years), dialysis mortality quartile and post transplant outcomes was determined in Cox regression models. Each model adjusted for differences in patient age, gender, race, cause of end stage kidney disease, body mass index, year of transplant, PRA, comorbid conditions and included an interaction term of dialysis exposure (years) with quartile of dialysis mortality.

Results: The association of different combinations of dialysis exposure (years) and dialysis mortality (quartiles), compared to the reference group of patients with <1 year

dialysis exposure treated in a region with the lowest quartile of dialysis mortality, with the outcomes of graft loss from all causes including death, death censored graft loss, and death with a functioning graft are shown in Figure 1. Longer durations of dialysis exposure were associated with a higher risk of each outcome, and this risk of dialysis exposure was magnified in regions with higher dialysis mortality.

Conclusions: The risk of pre-transplant dialysis exposure on transplant failure is higher in regions with higher rates of dialysis mortality. The findings support better integration of dialysis and transplant care, and indicate that regional differences in dialysis mortality should be accounted for in evaluation of transplant center performance metrics.



SA-OR100

Lack of Association Between Pre-Transplant Donor-Specific Antibodies and Kidney Outcomes in Simultaneous Liver-Kidney Transplant Recipients

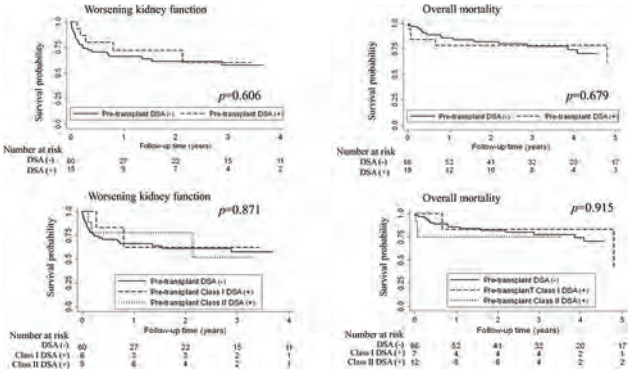
Masahiko Yazawa,[1,3] Orsolya Cseprekál,[6,1] Ryan A. Helmick,[1,2] Manish Talwar,[1,2] Vasanthi Balaraman,[1,2] Pradeep S. Podila,[9,10] Sallyanne Fossey,[8] Uchenna Agbim,[1,2] Sanjaya K. Satapathy,[7] Keiichi Sumida,[5] Csaba P. Kovesdy,[5,4] James D. Eason,[1,2] Miklos Z. Molnar.[1,2] METEOR (MEthodist Transplant EpidemiOlogy Research) Group *[1]Division of Transplant Surgery, Department of Surgery, University of Tennessee Health Science Center, Memphis, TN; [2]James D. Eason Transplant Institute, Methodist University Hospital, Memphis, TN; [3]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [4]Nephrology Section, Memphis Veterans Affairs Medical Center, Memphis, TN; [5]Division of Nephrology, Department of Medicine, University of Tennessee Health Science Center, Memphis, TN; [6]Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary; [7]Northshore University Hospital/Northwell Health, Manhasset, NY; [8]DCI, Inc, Nashville, TN; [9]Faith & Health Division, Methodist Le Bonheur Healthcare, Memphis, TN; [10]Division of Health Systems Management & Policy, School of Public Health, The University of Memphis, Memphis, TN.*

Background: The impact of pre-transplant donor-specific antibodies (DSA), especially class II DSA, on kidney allograft outcomes remains unclear in simultaneous liver-kidney transplantation (SLKT) recipients.

Methods: We examined 85 recipients who underwent SLKT between 2009-2018 in our center. Associations between the presence of pre-transplant DSA [pre-transplant DSA (+)], including class of pre-transplant DSA ([Class I DSA (+)] and [Class II DSA (+)]), and worsening kidney function (WKF), composite kidney outcome (WKF or antibody-mediated rejection or death censored allograft kidney loss), death with functioning graft, and overall mortality were examined in unadjusted and age, sex, and race-adjusted Cox proportional hazards regression and competing risks regression models. WKF was defined as eGFR decrease of 30% or greater from baseline, or two or more episodes of proteinuria, at least 90 days apart from each other.

Results: The mean age at SLKT was 56 years old and 62% of the recipients were male. Nineteen recipients (22%) had pre-transplant DSA at the time of SLKT. For the WKF, the median follow-up time was 9.6 months. The incidence rate was 148/1,000 person-years in the DSA (+) group and 169/1,000 person-years in the DSA (-) group with a non-significant difference. Pre-transplant DSA (+) groups had similar risk of not only WKF (unadjusted model: HR=0.77, 95%CI: 0.29-2.05 and adjusted model: HR=0.36, 95%CI: 0.12-1.08) but also the other outcomes compared to DSA (-) group. We found similar results when comparing different DSA sub-classes with recipients without DSA.

Conclusions: Neither pre-formed DSA nor class II DSA was associated with worse kidney allograft outcomes or patient mortality in SLKT recipients.



SA-OR101

Tertiary Lymphoid Tissues in Protocol Biopsies Predict Progressive Graft Dysfunction in Kidney Transplant Recipients

Yu ho Lee,[2,3] Yuki Sato,[3,7] Mitsuru Saito,[5] Shingo Fukuma,[4] Nobuhiro Fujiyama,[6] Shigeru Satoh,[6] Sangho Lee,[1] Tomonori Habuchi,[5] Motoko Yanagita.[3,8] *[1]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [2]Department of Nephrology, CHA University, Sungnam, Republic of Korea; [3]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]Human Health Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan; [5]Urology, Akita University Graduate School of Medicine, Akita, Japan; [6]Center for Kidney Disease and Transplantation, Akita University Hospital, Akita, Japan; [7]Medical Innovation Center TMK Project, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [8]Institute for the Advanced Study of Human Biology (ASHBi), Kyoto, Japan.*

Background: Tertiary lymphoid tissues (TLTs) are inducible ectopic lymphoid tissues found in chronic inflammatory organs. Previous studies have documented TLT formation in transplanted kidneys with rejection, but their clinical relevance remains controversial. Moreover, the evidences of TLTs in transplanted kidney without rejection are limited. In this study, we examined the frequency and staging of TLTs in protocol biopsy samples without the sign of rejection, and analyzed their effects on renal function in stable kidney transplant recipients.

Methods: A total of 181 patients who lacked clinical risk factors for poor graft survival, such as biopsy-proven acute rejection, were selected among those who underwent living donor kidney transplantation. We analyzed serial protocol biopsies (0-hour, 1-month, 6-month, and 12-month) and evaluated TLTs using novel staging methods we had recently established. TLTs were defined as organized lymphocyte aggregates with signs of proliferation, and their stages were determined by the absence (stage I) or presence (stage II) of follicular dendritic cells, which support the formation of B cell area.

Results: Although only 5.1% of patients exhibited TLTs at 0-hour biopsy, the prevalence increased to almost 50% at 1-month after transplantation and was maintained at the similar levels for one year. Stage II TLTs increased gradually over time, from 2.8% at 1-month to 18.0% at 12-month biopsy. Patients with no or stage I TLTs had stable graft function over 5 years, whereas those with stage II TLTs exhibited progressive graft dysfunction. (Figure 1) These advanced TLTs were associated with severe tubular inflammation and atrophy at 1 year post-transplantation. Finally, pre-transplantation rituximab dramatically attenuated the development of stage II TLTs.

Conclusions: TLTs were commonly found in protocol biopsies of transplanted kidneys, and stage II TLTs predict progressive decline in graft function in kidney transplant recipients even in the absence of rejection

Serum Expression of Selected MiRNAs Distinguish Recurrence of Glomerulonephritis and Antibody-Mediated Rejection in Kidney Transplant Recipients

Spela Borstnar,[1] Emanuela Bostjancic,[5] Damjan Kovac,[2] Zeljka Veceric Haler,[3] Nika Kojc.[4] *[1]Department of Nephrology, Universal Medical Centre Ljubljana, Ljubljana, Slovenia; [2]University Medical Centre Ljubljana, Ljubljana, Slovenia; [3]University Clinical centre Ljubljana, Komenda, Slovenia; [4]Medical faculty Ljubljana, Ljubljana, Slovenia; [5]University of Ljubljana, Faculty of Medicine, Insitute of Pathology, Ljubljana, Slovenia.*

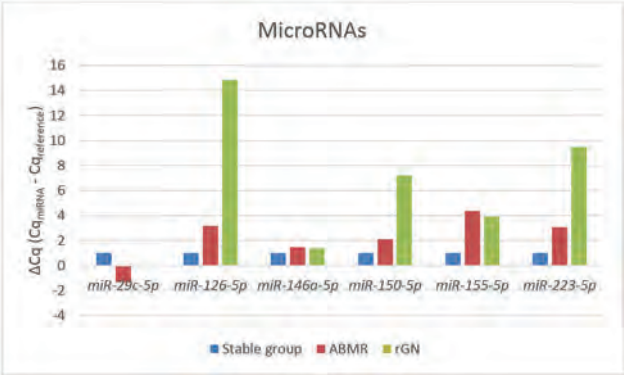
Background: Recently, many miRNAs (small non-coding regulatory RNAs) were found to be involved in pathological processes that can occur following kidney transplantation. The purpose of current study was to investigate the potential significance of different circulating miRNAs in predicting acute antibody mediated rejection (ABMR) and glomerulonephritis recurrence (rGN) regardless of the stage of renal impairment.

Methods: Total RNA was isolated from serum of 50 kidney transplanted patients with varying degrees of kidney graft failure, but stable function as estimated with CKD EPI equations (eGFR CKD-EPI), as well as precisely measured using chromium-51 labelled ethylenediamine tetraacetic acid clearance (mGFR CrEDTA). Expression of 6 selected miRNAs (*miR-29c*, *miR-126*, *miR-146a*, *miR-150*, *miR-155*, *miR-223*) was determined by qPCR, using *miR-103a-3p* as reference gene.

Results: Selected candidate miRNAs *miR-126* (p=0.002), *miR-155* (p=0.004) and *miR-223* (p=0.028) distinguished ABMR (n=6) from the stable patient group – patients without ABMR or rGN (n=41). *MiR-126* (p=0.008), *miR-150* (p=0.009) and *miR-223*

(p=0.033) distinguished rGN (n=3) from stable patient group. *MiR-126* (p=0.048), *miR-150* (p=0.024) and potentially *miR-223* (p=0.09) distinguished ABMR from rGN. Additionally, *miR-29c* expression was not detected in rGN and it was down-regulated in ABMR compared to stable group. Expression of *miR-146a* did not show association to any of the group of patients. None of the tested miRNA was associated with mGFR CrEDTA, only *miR-150* weakly correlated to eGFR CKD EPI.

Conclusions: Four of the tested miRNAs (*miR-126, miR-29, miR-155, miR-223)* are not associated with kidney graft function, but may discriminate AMBR and rGN and therefore can be used as a non-invasive biomarker to distinguish between pathologies.



Different expression of selected miRNA in stable patient group, ABMR and rGN group.

SA-OR103

Characteristics and Dysbiosis of the Gut Microbiome in Renal Transplant Recipients

J.c. Swarte,[1] Rianne M. Douwes,[2] Michele F. Eisenga,[1] Marco van Londen,[3] Antonio W. Gomes Neto,[3] Rinse Weersma,[1] Hermie Harmsen,[4] Stephan J. Bakker.[3]
[1]University Medical Centre Groningen, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, The Netherlands, Groningen, Netherlands; [3]University Medical Center Groningen, Groningen, Netherlands; [4]University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Background: Renal transplantation is life-changing in many aspects. This most likely also includes the gut microbiome, particularly because of the inevitable exposure to immunosuppressive drugs and antibiotics. As a consequence, Transplantation patients frequently suffer from intestinal dysbiosis. We aimed to investigate the gut microbiome of renal transplant recipients (RTR) and compare it with healthy controls.

Methods: We included 110 RTR and 79 healthy renal donors participating in the TransplantLines Biobank and Cohort Study (NCT03272841). We analyzed the gut microbiome using 16s rRNA sequencing and compared the composition of the gut microbiome of RTR with healthy renal donors using the Mann Whitney U-test with false discovery rate correction. Linear discriminant effect size (LEfSe) and multivariate association with linear models (MaAsLin) were used to study the relationship between the gut microbiome and the occurrence of diarrhea and the use of medication.

Results: Fecal samples of 110 RTR (38.3% female, mean age: 54.6 ± 12.0 years) and 79 healthy renal donors (34.0% female, age: 59.6 ± 11.0 years) were collected. Median time after transplantation of RTR was 1.08 [2.0-13.0] years., with a range of 1 to 26.4 years. Microbiome composition of RTR was significantly different from that of healthy donors (P=0.001). RTR had a lower diversity of the gut microbiome (P<0.001). Significantly higher levels of Proteobacteriae, Enterobacteriaceae, Streptococcus and E. coli were found in RTR (P<0.05). The levels of commensal, butyrate producing bacteria, including Clostridium spp., Eubacterium spp., Coprococcus spp. and Gemmiger formicilis were significantly lower in RTR (P<0.05). The microbiome of RTR with diarrhea contained lower levels of Ruminococcaceae and higher levels of Actinobacteria (P<0.05).

Conclusions: This study shows the gut microbiome of RTR is significantly different from the gut microbiome of healthy renal donors. RTR suffer from dysbiosis characterized by a loss of diversity and there is a preponderance towards lower levels of butyrate producing species, which may have detrimental effects on gut health in RTR.

SA-OR104

^{18}F-FDG PET/CT Imaging at 3 Months Post Transplantation Disproves Subclinical Rejection in Kidney Transplant Recipients

Oriane Hanssen,[1] Laurent E. Weekers,[1] Pierre Lovinfosse,[1] Alexandre Jadoul,[1] Alexandre Huynen,[2] Catherine Bonvoisin,[1] Antoine Bouquegneau,[1] Roland Hustinx,[1] Francois Jouret.[1] *[1]University of Liège Hospital (ULiège CHU), Liège, Belgium; [2]University of Liège, Liège, Belgium.*

Background: Subclinical kidney allograft acute rejection (SCR) corresponds to "the histological documentation of unexpected evidence of acute rejection (AR) in a stable patient". SCR detection relies on surveillance biopsy. Still, non-invasive approaches may help avoid biopsy-associated complications and limitations. Positron emission tomography (PET) coupled with computed tomography (CT) after injection of F^{18}-fluorodeoxyglucose (^{18}F-FDG) may be an option.

Methods: From 11/2015 to 01/2018, we prospectively performed ^{18}F-FDG-PET/CT in adult kidney transplant recipients (KTR) who underwent surveillance transplant biopsy at ~3 months *post* transplantation. Banff-2017 classification was used. The ratio of the mean standard uptake value (mSUVR) between kidney graft cortex and psoas muscle was measured. One-way analysis of variance (ANOVA) followed by Student t-tests was performed using the Python library SciPy to compare mSUVR among groups. Additionally, the R-squared statistic assessed the correlation between mSUVR and acute composite Banff score or total inflammation. Finally, the receiver operating characteristic (ROC) curve was built using Python programming language.

Results: In our 95-patient cohort, the median age of recipients was 57 years [min 37; max 68], with a gender ratio (M/F) of 2 and a mean BMI of 27±5kg kg/m^2. The cohort was categorized into 3 groups upon Banff-based histology: normal (n=70); borderline (n=16); AR (n=6). Three cases were excluded for PCR-proven BK nephropathy (n=2) or uninterpretable histology (n=1). No clinical or biological difference was observed between groups. The mSUVR reached 1.87±0.55, 1.94±0.35 and 2.41±0.54 in normal, borderline and AR groups, respectively. A significant difference of mSUVR was found among groups. Furthermore, mSUVR was significantly higher in AR *versus* normal (p, 0.02) or borderline (p, 0.02) groups. The area under the ROC curve (AUC) was 0.79, with 83% sensitivity and 87% specificity using mSUVR threshold at 2.4. The mSUVR positively correlated with total-i (r ^{2}=0.05; p, 0.02) and acute composite Banff score (r^2=0.04; p, 0.05).

Conclusions: ^{18}F-FDG-PET/CT imaging helps non-invasively detect SCR, with a negative predictive value of 98% using 2.4 as mSUVR threshold.

Galectin 3 and Graft Failure in Kidney Transplant Recipients: A 10-Year Prospective Cohort Study

Camilo G. Sotomayor,[1] Charlotte A. te Velde - Keyzer,[1] Marco van Londen,[1] Reinold O. Gans,[1] Ilja M. Nolte,[2] Martin H. De Borst,[1] Stefan P. Berger,[1] Ramon Rodrigo,[3] Stephan J. Bakker.[1] *[1]Department of Internal Medicine, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Epidemiology, University Medical Center Groningen, Groningen, Netherlands; [3]Molecular and Clinical Pharmacology Program, Institute of Biomedical Science, Faculty of Medicine, University of Chile, Santiago, Chile.*

Background: Galectin-3 is associated with kidney fibrosis and kidney function decline in the general population. We aimed to study the association of galectin-3 with long-term risk of graft failure in a cohort of extensively phenotyped kidney transplant recipients (KTR).

Methods: We performed a longitudinal cohort study in 561 KTR without heart failure and with a functioning graft ≥1 year. Kaplan-Meier curve, log-rank test, and multivariable-adjusted Cox proportional-hazards regression analyses were performed to assess the prospective association of baseline serum galectin-3 with death-censored graft failure (defined as restart of dialysis or re-transplantation). Subgroup prospective analyses were performed according to significant effect-modifiers.

Results: Median galectin-3 was 21.1 (IQR, 17.0-27.2) ng/mL. During a median follow-up of 9.5 (IQR, 6.2-10.2) years, 72 KTR developed graft failure, with significantly different distribution of events across tertiles of galectin-3 (P<0.001). In multivariable Cox regression analyses, galectin-3 associated with graft failure (HR, 2.13 per 1-SD increase; 95% CI, 1.61-2.80, P<0.001), independent of well-established general and transplant-specific risk factors, including eGFR and proteinuria. Particularly strong associations were found in patients with systolic blood pressure ≥140 mmHg (HR, 2.29 per 1-SD increase; 95% CI 1.80-2.92, P<0.001) and in former or current smokers (HR, 2.56 per 1-SD increase; 95% CI 1.95-3.37, P<0.001).

Conclusions: In stable KTR, galectin-3 levels are elevated and independently associated with higher risk of graft failure at 10-years of follow-up. These results underline novel opportunities to monitor patients, target pharmacological therapy, and decrease the burden of long-term graft failure in stable KTR.

Funding: Government Support - Non-U.S.

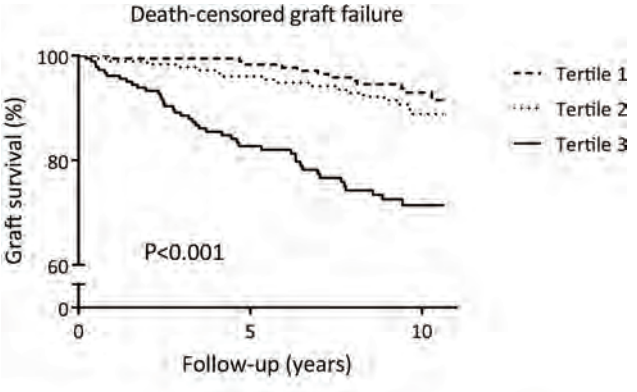

Figure 1. Kaplan–Meier curve for death-censored graft failure according to tertiles of galectin-3 in KTR. Tertile 1: 15.4 (IQR, 13.4-17.0) ng/mL; tertile 2: 21.1 (IQR, 19.8-22.9) ng/mL; tertile 3: 29.5 (IQR, 27.1-35.6) ng/mL. P value was calculated by Log-rank (Mantel cox) test.

SA-OR106

Potential for Recovery of Bone Density and Structure Following Renal Transplantation

Susan Ziolkowski,[2] Jin Long,[1] Simin Goral,[3] Babette Zemel,[3,4] Mary B. Leonard.[2,5] *[1]Stanford University, Palo Alto, CA; [2]Stanford School of Medicine, Stanford, CA; [3]University of Pennsylvania, Bryn Mawr, PA; [4]Children's Hospital of Philadelphia, Philadelphia, PA; [5]Pediatrics, Stanford University, Palo Alto, CA.*

Background: Fracture rates increase early following renal transplant (RTxp) and then decline. The objective is to determine if trabecular and cortical bone mineral density (BMD) and cortical structure recover following RTxp treated with glucocorticoids (GC).

Methods: We enrolled 60 incident RTxp recipients, ages 20-60 yr, with DXA and peripheral quantitative CT (pQCT) scans at RTxp, 6, 12, and 24 months. Bone outcomes and DXA appendicular lean mass index (ALMI) were expressed as age and sex-specific Z-scores using concurrent controls. Regression models identified correlates of change for bone outcome Z-scores.

Results: 58 and 53 RTxp completed the 12 and 24 month visit, respectively. At transplant, DXA total hip, femoral neck, and ultradistal radius BMD, and pQCT trabecular and cortical BMD, and cortical thickness BMD Z-scores were lower in RTxp vs. controls (all $p<0.05$). Prednisone was typically tapered to a maintenance dose of 5 mg/day by 4 weeks. During the first 6 months, DXA spine and pQCT trabecular BMD decreased significantly (e.g. trabecular BMD Z from -0.53 to -0.60) then were unchanged through 24 months. Radius 1/3rd BMD was stable but ultradistal BMD Z-scores decreased from baseline onwards. Greater GC exposure was associated with decreases in DXA spine and ultradistal radius BMD and pQCT trabecular BMD Z-scores (all $p<0.01$). Cortical BMD Z-scores increased across 24 months (from -0.51 to -0.33, $p<0.01$) in association ($p = 0.02$) with decreasing PTH. Endosteal circumference increased and cortical thickness decreased progressively over 24 months (both <0.01). DXA total hip and femoral neck BMD Z-scores were unchanged during the first 6 months, then increased marginally. ALMI Z-scores increased but were not associated with changes in bone outcomes. Gains in cortical BMD were associated with gains in total hip and femoral neck BMD ($p<0.01$). Renal function, physical activity and mineral metabolites were not associated with bone outcomes.

Conclusions: RTxp is associated with early loss of trabecular bone without subsequent recovery on low dose GC. Cortical BMD recovers in association with decreases in PTH levels and may explain the marginal increase in hip BMD. Given that cortical thinning progresses following RTxp, strategies are needed to preserve cortical structure in CKD.

SA-OR107

Post-Transplant Recurrence of IgA Nephropathy: HLA as a Predictive Factor

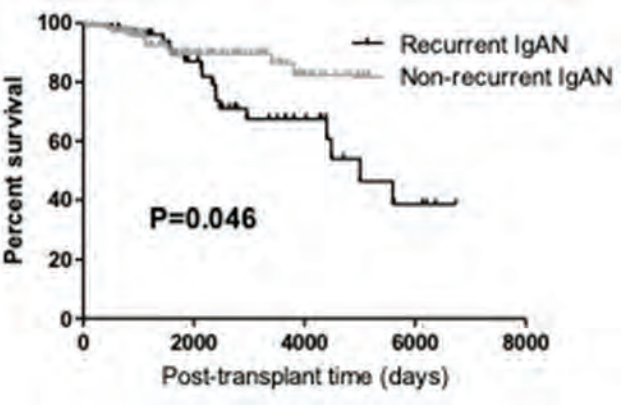
Catherine R. Kavanagh, Namrata G. Jain, Jeanne Kamal, Elena R. Vasilescu, Ibrahim Batal. *Columbia University Irving Medical Center, New York, NY.*

Background: In the native kidney, studies have suggested that specific Human Leukocyte Antigen (HLA) alleles have increased risk or protective effects for the development of IgA Nephropathy (IgAN). There remains limited knowledge of the clinical significance and specific factors that contribute to recurrence of IgAN in the kidney allograft. We aimed to study whether the degree of HLA matching and the presence of certain HLA loci in the donor and recipient can contribute to recurrence.

Methods: A retrospective cohort of 159 recipients with ESRD secondary to IgAN who were transplanted at our center between 1995 and 2017 were evaluated for recurrent disease. Clinical characteristics and HLA typing were analyzed in both donor and recipient.

Results: Of the 159 patients identified, 53 (33%) had biopsy-proven recurrent IgAN. On follow-up, 16/53 (30%) of patients with recurrent IgAN developed graft failure compared to 11/106 (10%) of patients without proven recurrence (P= 0.046, See Figure). Univariate Cox proportional hazards analysis has identified that younger recipient age at transplantation, receiving allograft from living donors, higher degree of HLA matching, recipient HLA-DR15, and donor HLA-DR3 to be significantly associated with recurrence. By multivariable Cox analysis, younger recipient age [HR 0.97 (95% CI: 0.94 – 0.99), P= 0.016], HLA mismatch [0.83 (0.70- 0.98), P=0.03], presence of HLA-DR15 in the recipient [2.58 (1.36-4.88), P= 0.004], as well as the presence of HLA-DR3 in the donor [2.57 (1.23-5.37), P= 0.012] were independently associated with recurrent IgAN.

Conclusions: Recurrence of IgAN is associated with decreased graft survival. In an effort to improve long-term outcome, it is imperative to consider factors that increase recurrence risk when evaluating potential donors, such as higher HLA matching and the presence of HLA-DR3 in the donor. Recipient variables of younger age and HLA-DR15 were also independent predictors for recurrent IgAN.



Graft Survival

SA-OR108

Novel Experimental Model of Poor Pregnancy Outcomes After Recovery from Ischemia-Reperfusion Injury

Ellen E. Gillis,[1] Jennifer C. Sullivan.[2] *[1]Physiology, Augusta University, Augusta, GA; [2]Augusta University, Evans, GA.*

Background: Recent clinical studies have reported that women with a history of acute kidney injury (AKI) have a greater incidence of maternal and fetal adverse outcomes during pregnancy, despite fully recovering renal function prior to conception. The mechanisms contributing to these adverse outcomes in pregnancy after AKI are not yet understood. In the current study, a rodent model of recovered AKI (r-AKI) was developed in an effort to elucidate the mechanisms contributing to adverse pregnancy outcomes after AKI. We hypothesize that female Sprague Dawley (SD) rats will have poor pregnancy outcomes after recovery from ischemia reperfusion (IR) injury, our experimental model of AKI.

Methods: IR surgery was performed on female SD rats (10 wks age) by clamping both renal arteries for 45 minutes. Rats were then allowed to recover for 1 month before they were mated. Recovery from IR was confirmed by plasma creatinine and urinary protein excretion (UPE). Vaginal smears were performed daily once mating began, with sperm on the slide indicative of day 1 of pregnancy. Rats were then sacrificed during late pregnancy on gestational day 20.

Results: UPE, a crude marker of renal injury, was significantly higher in r-AKI dams in late pregnancy (Table, *$p<0.05$, T-test). r-AKI dams also had significantly higher plasma creatinine and urea levels than control dams, suggesting that subclinical injury after IR leaves these dams unable to handle the hemodynamic changes in pregnancy, resulting in renal insufficiency (Table). In addition to adverse maternal outcomes, fetal outcomes were also significantly worse in r-AKI dams, as measured by decreases in fetal weight and an increase in fetal death (Table).

Conclusions: Pregnancy after recovery from AKI resulted in maternal renal insufficiency and significant impairments in fetal growth in the current study. This mimics what has recently been reported in the clinical population, indicating that this model is a useful tool to further explore the alterations in kidney function after AKI in females. Ongoing studies in the lab are further exploring the maternal syndrome in these rats, focusing on alterations in renal immune cells.

A Population Study of Pregnancy Outcomes by Pre-Conception GFR

Jessica S. Tangren,[1] Amit X. Garg,[2,3] Stephanie Dixon,[3] Jade Dirk,[3] Megan K. Mccallum,[3] Ayub Akbari,[5] Michelle A. Hladunewich.[4] *[1]Massachusetts General Hospital, Boston, MA; [2]London Health Sciences Centre, London, ON, Canada; [3]Institute for Clinical Evaluative Sciences, London, ON, Canada; [4]University of Toronto, Toronto, ON, Canada; [5]University of Ottawa, Ottawa, ON, Canada.*

Background: Chronic kidney disease is a known risk factor for adverse pregnancy outcomes including preeclampsia and preterm delivery, however studies on CKD pregnancies are small, outdated and contain few subjects with moderate or advanced stage CKD. Our objective was to investigate the association of pre-conception GFR with the risk of adverse pregnancy outcomes in a large population-based cohort with more than 400 pregnancies in women with pre-existing moderate or advanced stage CKD.

Methods: A population-based cohort study of women in the province of Ontario, Canada, who had an obstetric delivery between 2007 and 2017. Administrative health databases linked using unique identifiers at ICES were used to capture all hospital births in Ontario and a majority of outpatient laboratory testing. Women with a serum creatinine measured within 2 years of conception were included for analysis.

Results: The mean pre-conception eGFR among the 458,206 pregnancies included in the analysis was 114 ± 14 ml/min/1.73 m^2, of which 28,232 were 60 to <90 ml/min/1.73 m^2, 330 were 45 to <60 ml/min/1.73 m^2 and 97 were <45 ml/min/1.73 m^2. There were no maternal deaths among women with eGFR < 60 ml/min/1.73 m^2. Rates of gestational hypertension, preeclampsia and preterm delivery increased monotonically across pre-conception eGFR categories (Figure 1). Maternal admission rate to the ICU during pregnancy or within 90 days after delivery was 7% among women with an eGFR < 45 ml/min/1.73 m2 compared with 1% in women with eGFR > 90 ml/min/1.73 m2.

Conclusions: In this population-based study of pre-conception CKD, low pre-conception eGFR was associated with high rates of maternal morbidity and adverse pregnancy outcomes. Absolute risk was highest in women with eGFR < 45 ml/min/1.73 m2, however even women with mildly impaired eGFR were at higher risk for adverse pregnancy outcomes.

Funding: NIDDK Support

Effects of Pregnancy on Kidney Allograft Outcomes

Andrea G. Kattah, Fernando G. Cosio, Vesna D. Garovic. *Mayo Clinic, Rochester, MN.*

Background: Women with chronic kidney disease are often counseled to wait until after a successful kidney transplant (TX) to pursue pregnancy. However, pregnancy after kidney TX is still high risk and the effects on graft function and long-term graft survival are unclear.

Methods: We identified all kidney TXs in women ages 18 to 44 at all three Mayo clinic sites (MN, FL and AZ) from 1996 to 2014 who had a graft that functioned for at least 2 years. We reviewed records to identify pregnancies and evaluated the risk graft failure, death-censored graft loss, doubling of urine protein and a decrease in eGFR by 50% in women with post-TX pregnancies as compared to matched controls (matched on parity and age at TX and year of TX). Cox proportional hazards models were used to calculate hazard ratios (HR) and 95% confidence intervals (CIs). Biopsies before and after pregnancy were reviewed.

Results: There were 818 women identified, of which 33 had at least 1 pregnancy lasting > 20 weeks gestation post-TX. The median time from TX to first delivery was 61 months (interquartile range (IQR) 35.5-76.5). Women with pregnancies were more likely to have pre-emptive TXs (51.5% vs. 24.2%, p=0.03) and lower nadir proteinuria post-TX (median 102 mg/24 hrs (IQR 67-153) vs. 135 mg/24 hrs (IQR 104-133), p=0.005) than women without pregnancies. There was no significant increase in the risk of graft failure (HR 0.49, 95% CI 0.12-1.23), death-censored graft loss (HR 0.60, 95% CI 0.23-1.57), or decrease in eGFR by 50% (HR 0.95, 95% CI 0.42-2.14) in women with pregnancies post-TX as compared to those without, even after adjusting for preemptive TX and baseline proteinuria. When adjusted for baseline proteinuria, there was a significant risk of doubling of proteinuria (adjusted HR 3.30, 95% CI 1.05-10.3). There was an increase in the number of biopsies with segmental sclerosis post-pregnancy (2 vs. 8). There was a significant mean (standard deviation) decrease in eGFR after pregnancy of 9 ml/min/1.73 m^2 (22.1) (p=0.03) and increase in women with eGFR < 45 ml/min/1.73 m^2 (3% vs. 37.5%, p=.002).

Conclusions: Women with preganancies after TX were more likely to have preemptive TXs and had lower baseline proteinuria than those without pregnancies. While pregnancy did not increase the risk of graft loss, there was a significant reduction in eGFR after pregnancy and an increased risk of doubling of proteinuria when adjusted for baseline values.

Serum Transforming Growth Factor β1 Is a Sex-Specific Risk Factor for Accelerated GFR Decline in the General Population

Jon V. Norvik,[1] Inger Therese T. Enoksen,[3] Wenjun Ju,[2] Marit D. Solbu,[1] Viji Nair,[2] Matthias Kretzler,[2] Bjorn O. Eriksen,[1] Toralf Melsom.[1] *[1]University Hospital of North Norway, Tromsø, Norway; [2]University of Michigan, Ann Arbor, MI; [3]UiT - The Arctic University of Norway, Tromsø, Norway.*

Background: The health burden of chronic kidney disease (CKD) is increasing worldwide, and there is a need for novel biomarkers that can identify those at CKD risk for early preventive measures. There are sex differences in the progression of CKD and several risk factors seem to affect CKD risk differently in men and women. We investigated the association between serum transforming growth factor β1 (TGF-β1), a key mediator in kidney fibrosis development, and risk of accelerated loss of glomerular filtration rate (GFR) in women and men from the general population.

Methods: In the Renal Iohexol Clearance Survey in Tromsø 6 (RENIS-T6), we measured GFR by iohexol-clearance in 826 women and 801 men between 50 and 62 years of age without self-reported diabetes, cardiovascular or kidney disease. Of these, 1,324 (81%) had a follow-up GFR measurement after a median of 5.6 years in the RENIS-Follow Up. We used a multiple logistic regression model to examine the association between serum TGF-β1 and accelerated GFR decline (defined as subjects with the 10% steepest GFR slope).

Results: After adjusting for CKD risk factors, 1 SD increase in TGF-β1 levels was associated with higher odds of accelerated GFR decline in women (odds ratio (OR) 1.38 (95% confidence interval (CI) 1.01 to 1.89)), but not in men (p for interaction 0.03). Women with TGF-β1 in the upper quartile had an OR of 2.74 (95% CI 1.05 to 7.17) compared to women with TGF-b1 in the lower quartile.

Conclusions: Higher baseline TGF-β1 was independently associated with accelerated GFR decline in women, but not in men.

Sirtuin 3 Mediates Sex Differences in Ischemia-Reperfusion Kidney Injury

Jenny S. Pan,[1,2] Huiyun Shen,[1] Qingtian Li,[1] David Sheikh-Hamad.[1,2] *[1]Medicine-Nephrology, Baylor College of Medicine, Houston, TX; [2]Renal, Michael E. DeBakey VAMC, Houston, TX.*

Background: Biologic sex influences susceptibiity to AKI, a common condition with limited therapies. Mitochondrial dysfunction and oxidative stress play key roles in the pathogenesis of ischemic AKI. Our observations reveal higher baseline kidney expression of mitochondrial SIRT3 (mtSIRT3), a major mitochondrial deacetylase, in female vs male mice. We hypothesize that SIRT3 confers protection and mediates sex differences in response to kidney ischemia-reperfusion injury (IRI).

Methods: Male and female wild-type (WT), SIRT3 transgenic (Tg), or inducible kidney tubule-specific SIRT3 knockout (KO) mice were subjected to bilateral kidney IRI (clamping of renal pedicles for 30 min). HEK cells were treated with 17β-estradiol (E2), testosterone or veh.

Results: We observe higher mtSIRT3 expression in kidneys of WT female vs. male mice; mtSIRT3 declines with age but sex differences persist. At age 6-months, SIRT3 Tg male mice display less tubular vacuolization and ROS vs similarly aged WT males. Male Tg mice demonstrate resistance to IRI [preserved creatinine clearance (CrCl) and morphology; less ROS] and better survival vs WT males; outcomes similar to WT females. In contrast at age 6-months, SIRT3 KO males display greater tubular injury vs WT males. SIRT3 KO mice demonstrate increased susceptibility to IRI [decreased CrCl; worse morphological changes; increased ROS] and worse survival vs WT. In WT females, kidney mtSIRT3 correlates positively with plasma E2 and negatively with testosterone (T) levels. In WT males, kidney mtSIRT3 only correlates negatively with plasma T. In HEK cells, E2 treatment increases SIRT3 mRNA, and whole cell- and mtSIRT3 protein; T decreases mtSIRT3 protein with no effect on whole cell SIRT3 or SIRT3 mRNA. We previously showed that LRP2 shuttles intracrine proteins to the mitochondria and physically associates with SIRT3. Current observations show higher baseline kidney expression of LRP2 in WT female vs male. Testosterone treatment decreases LRP2 protein expression. In vitro LRP2 knockdown decreases mtSIRT3 protein.

Conclusions: 1) SIRT3 ameliorates kidney IRI, and decreased SIRT3 in males mediates the increased susceptibility to ischemic injury; 2) sex steroids regulate mtSIRT3 expression; estrogen via transcriptional regulation and testosterone via inhibition of LRP2-mediated mitochondrial targeting; 3) sex differences in AKI pathophysiology need to be studied.

SA-OR113

Association of Reproductive Lifespan Duration and CKD in Postmenopausal Women

Shinchan Kang,[1] Seonghun Kim,[2] Byounghwi Ko,[1] Wonji Jo,[1] Yooju Nam,[1] Jung Tak Park.[1] *[1]Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Yonsei University, Seoul, Republic of Korea.*

Background: Although animal studies have suggested estrogen to offer renoprotective effects, clinical evidence remains scarce. This study sought to investigate the relationship between endogenous estrogen exposure and renal function. Considering female reproductive lifespan duration (RLD) to be a surrogate of lifetime exposure to

endogenous estrogen, the association of RLD and chronic kidney disease (CKD) was analyzed in postmenopausal women.

Methods: Data were retrieved from the Korean Genome and Epidemiology Study_ Health Examinees cohort. A total of 57,505 postmenopausal women were included in the analysis. The RLD for each participant was determined by subtracting the age at menarche from the age at menopause. The participants were divided into groups according to RLD quartile. The association between RLD and CKD, defined as an estimated glomerular filtration rate (eGFR) of less than 60 mL/min/1.73m^2, was examined.

Results: The mean age and eGFR of the study subjects were 57.7 ± 6.1 years and 88.0 ± 16.7 mL/min/1.73m^2, respectively. The mean RLD was 34.2 ± 4.1 years. A total of 1,664 (2.89%) women were found to have CKD. The prevalence of CKD tended to decrease in groups with longer RLDs. Logistic regression analysis revealed that the odds ratio for CKD was lower in groups with longer RLDs as compared to the shortest RLD group. This finding was significant even following adjustments for confounding factors.

Conclusions: The prevalence of CKD was significantly lower in subjects with longer RLDs. The amount of endogenous estrogen exposure could be a determining factor for renal function in postmenopausal women.

Sex Differences in Vascular Access

Jennifer M. MacRae,[1] Sofia B. Ahmed,[1] Meghan J. Elliott,[1] Robert R. Quinn,[1] Matthew T. James,[1] Swapnil Hiremath,[2] Kathryn M. King--Shier,[1] Matthew J. Oliver,[3] Brenda Hemmelgarn,[1] Nairne W. Scott-Douglas,[1] Pietro Ravani.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Ottawa, Ottawa, ON, Canada; [3]Sunnybrook Health Sciences Center, Toronto, ON, Canada.*

Background: Although fistulas are actively promoted, studies report fewer women receive and use a fistula. Whether women undergo similar efforts at fistula creation and procedures as men is unknown. We sought to describe differences between men and women for probability of receiving a fistula attempt, achieving independent fistula use, remaining catheter-free over time, and the rate of access-related procedures as a function of sex in a cohort of Canadian incident hemodialysis patients.

Methods: Prospectively collected vascular access data on incident dialysis patients from five Canadian programs using Dialysis Measurement Analysis and Reporting (DMAR) system to determine differences in fistula related outcomes between women and men. Probability of receiving a fistula attempt and the probability of successful fistula use was determined using binary logistic regression. Catheter and fistula procedure rates were described using Poisson regression. We studied time to fistula attempt and time to fistula use accounting for competing risks of death, transplant and recovery of kidney function.

Results: We included 1,446 (61%) men and 929 (39%) women. Men had a lower body mass index (p<0.001) and were more likely to have coronary artery disease (p<0.001) and peripheral vascular disease (p<0.001) than women. 688 (48%) men and 403 (43%) women received a fistula attempt. After accounting for confounders (age, diabetes, cardiovascular disease, inpatient starts), men were more likely to receive a fistula attempt (OR 1.29 [1.08-1.54] and to achieve catheter free use of the fistula at one year (OR 2.62 [1.88-3.65]. We found an average of 2.30 procedures per person-year after start of dialysis, with no significant difference between men and women (IRR 1.04 [0.93-1.15]). Following a fistula attempt, women received more procedures (IRR men v women: 0.86 [0.77-0.96]) attributed to an increased number of catheter procedures (IRR men vs women: 0.67 [0.56-0.79]. Men received more fistula procedures IRR 1.20 [1.04-1.37]).

Conclusions: We found that, as compared to men, fewer women undergo a fistula attempt and after adjusting for comorbidities this disparity increases. Not only do women have fewer fistula creations, but they are less likely to successfully use their fistula without a catheter in place.

Clinical, Angiogenic, and Immune System Markers Predict Preeclampsia in Women with CKD During Pregnancy

Nadia Sarween,[1,2] James Hodson,[3] Ellen M. Knox,[4] Mark T. Drayson,[2] Graham W. Lipkin.[1] *[1]Department of Renal Medicine, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [2]Department of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom; [3]Institute of Translational Medicine, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [4]Department of Obstetrics, Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom.*

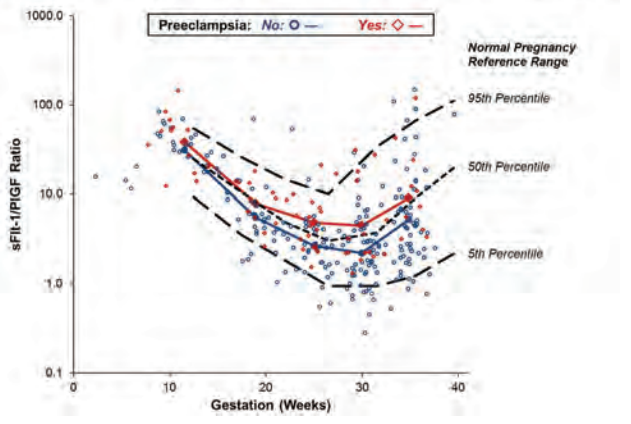
Background: Pre-eclampsia (PE) is associated with immune activation and altered circulating angiogenic factors (with elevated soluble FMS-like tyrosine kinase-1/placental growth factor or sFLT-1/PlGF ratio). There are currently limited data in pregnant women with CKD. Longitudinal changes of markers inflammation, immunity & angiogenic factors during CKD pregnancy were assessed in this study & their relationship to the development PE explored.

Methods: Women with CKD were recruited from a UK renal-obstetric clinic between 2011-2016. Baseline demographics, serial serum samples and pregnancy outcomes were recorded. Samples were analysed for IgG/A/M, high-sensitivity CRP, serum free light chains (sFLC), Beta-2 Microglobulin (B2M), complement factors 3 & 4 (C3/4), uric acid (UA), creatinine, cystatin-C & sFLT-1/PlGF using the Roche Cobas® platform. Gestational periods were split into five groups.

Results: PE was diagnosed in 23% of the 164 pregnancies (136 women) with rates increasing with CKD stage (p=0.011). White ethnicity, non-smoking, SLE, chronic hypertension and previous PE were independent predictors of PE. sFLC, B2M, creatinine, cystatin-C & UA increased significantly over the antenatal period and were higher in the PE group. The greatest predictive accuracy for PE was seen at 16-21 weeks, for sFLC & cystatin-C (AUROC 0.745, 0.810 respectively). Antenatal levels of C3 increased (p<0.001) and IgA fell (p=0.015) more rapidly in the PE vs. non-PE group. The sFlt-1/PlGF ratio was predictive for PE developing at 22-27 weeks gestation (AUROC=0.728, p=0.005) (figure 1).

Conclusions: In women with CKD, an elevated sFLT-1/PlGF ratio is predictive of PE at 22-27 weeks gestation, but not at later gestations. Its predictive accuracy is comparable to markers of kidney function, sFLC and B2M levels.

Figure 1: sFLT-1/PlGF ratio by gestation in patients that did and did not develop PE



SA-OR116

Black and Hispanic Women Are at Increased Risk of Hypertension After Preeclampsia

Dana M. Larsen,[1] Camille E. Powe,[2] Sushrut S. Waikar,[2] S. Ananth Karumanchi,[3] Ravi I. Thadhani,[3] Jessica S. Tangren.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Cedars-Sinai Medical Center, Los Angeles, MA.*

Background: Preeclampsia is a leading cause of maternal mortality and associated with increased risk of hypertension (HTN) in later life. Black and Hispanic women are at increased risk for pregnancy-related mortality compared to non-Hispanic white women in the United States. We sought to investigate whether long-term complications of preeclampsia are differentially impacted by race/ethnicity. We tested the hypothesis that black and Hispanic women have an increased risk of incident HTN after preeclampsia compared to non-Hispanic white women.

Methods: We analyzed a longitudinal observational cohort of black, Hispanic and non-Hispanic white women who had at least one pregnancy between 1998 and 2014 and were subsequently followed at an academic network of primary care practices through 2018. Patients were followed until incident HTN, using validated diagnostic criteria, or their last encounter in the hospital system. Multivariable Cox proportional hazards models were used to examine the independent association between preeclampsia and risk of incident HTN after delivery. Analyses for effect modification between preeclampsia and non-white race on the risk of HTN were performed.

Results: There were 20,864 women with a pregnancy in the cohort of which 4,959 (23%) and 1,412 (6%) were of self-reported Hispanic or black race/ethnicity, respectively. Preeclampsia developed in 524 (2.5%) of pregnancies. Preeclampsia was associated with an increased risk of incident hypertension after pregnancy in all groups, with higher rates in non-white women (adjusted HR 2.8 [1.9-4.2] p<0.01 for Hispanic women, adjusted HR 2.7 [1.3-5.7] p = 0.01 for black women and adjusted HR 1.8 [1.2-2.8] p<0.01 for non-Hispanic white women. There was evidence of effect modification between non-white race/ethnicity, preeclampsia and incident hypertension (p-interaction=0.04).

Conclusions: Preeclampsia is a major risk factor for later life HTN, particularly among black and Hispanic women.

Maternal Pregnancy Outcomes in Women with Complement-Mediated TMA: Update of the Vienna TMA Cohort

Martina M. Gaggl, Natalja Haninger-Vacariu, Christof Aigner, Gere Sunder-Plassmann, Alice Schmidt. *Medical Universitiy of Vienna, Vienna, Austria*.

Background: Pregnancy is a high-risk scenario to trigger complement pathway dysregulation. Presentation of paternal antigens activates the maternal alternative pathway and in women with malfunctioning complement regulatory proteins or C3 life-threatening thrombotic microangiopathy (TMA) can develop.

Methods: As of 2015 we reported outcomes of 27 pregnancies in 14 women with complement-mediated TMA (cTMA) enrolled in the Vienna TMA cohort (VTC). This work presents an update on this open cohort as of May 2019: Outcomes are CKD stage at last follow-up, incidence of dialysis or kidney transplantation (KTX) and death.

Results: In 32 women of the VTC the mean age at first cTMA presentation was 30 ±16 years (figure 1). Up until 2019 in 25 women a total of 55 pregnancies were observed: 6 women 1, 9 women 2, 6 women 3, 2 women 4, 1 woman 5 pregnancies. In 14 women pregnancy occurred before diagnosis of cTMA (26 pregnancies, 6 abortions) with 8 pregnancies afterwards in 5 women. Pregnancy-associated cTMA (p-cTMA) happened in 11 women: 6 during first, 3 during second and 2 during a later pregnancy. Five women had 11 pregnancies following KTX. Thirty-nine (71%) pregnancies were untreated and not complicated by p-cTMA. Four women received preventive plasma therapy for 6 pregnancies (2 KTX; 1 p-cTMA), 2 became pregnant during ongoing eculizumab therapy (3 pregnancies,1 KTX; 0 p-cTMA), 5 received therapeutic plasma therapy for p-cTMA (1 KTX), and 2 were switched to eculizumab (0 ESRD). At last follow-up 20 had eGFR ≥60ml/min per 1.73m^2, 6 eGFR <60, 2 needed dialysis and 4 had died.

Conclusions: In summary, VTC data demonstrates good maternal outcome (1) in the majority of untreated pregnancies in women with a diagnosis of cTMA and (2) in specifically treated cTMA patients in a specialized center.

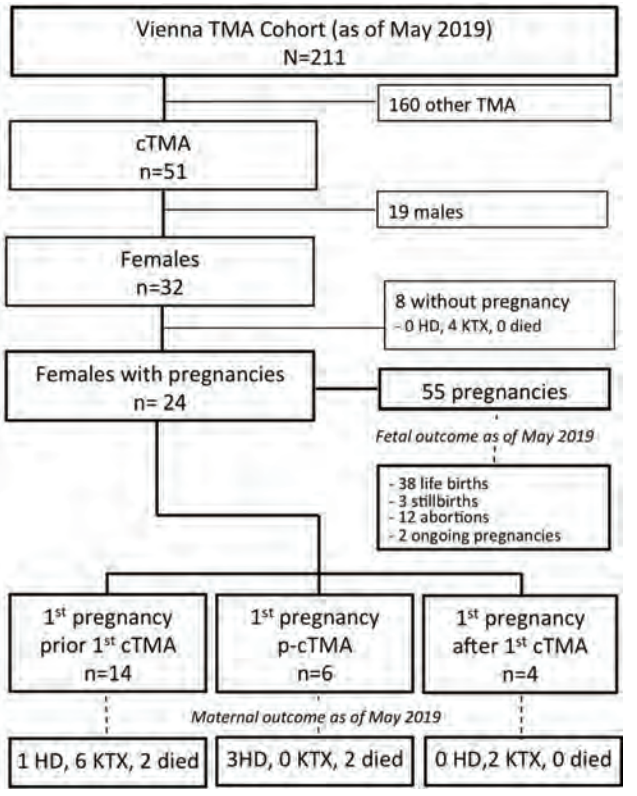

Figure 1.

Transiently Dedifferentiated eR1-Active Proximal Tubule Cells Clonally Expand and Repair Proximal Tubules in Severe Injury

Yuichiro Kitai, Motoko Yanagita. *Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: It is well accepted that injured proximal tubules (PT) are restored by the proliferation of surviving PT cells. However, whether this process depends on stochastic proliferation or expansion of a PT subpopulation, and how severity of injury affects repair process is uncertain. A Runx1 enhancer named Runx1+24mCNE (eR1) was shown to be active in adult long-term hematopoietic stem cells and gastric stem cells, but the role of eR1 in the kidney is unknown.

Methods: We explored the behaviors of PT cells with high eR1 activity, in 30-(moderate) and 60-min (severe) ischemia reperfusion injury (IRI), utilizing eR1-EGFP and eR1-Cre^{ERT2} mice.

Results: PT cells showed a higher rate of BrdU incorporation in 60-min IRI than in 30-min IRI, and a significant proportion of the PT cells showed RUNX1 expression after 60-min IRI, but not after 30-min IRI. In eR1-EGFP mice, after 60-min IRI, but not after 30-min IRI, EGFP$^+$ PT cells accounted for 20% of total PT cells of the superficial cortex. In eR1-EGFP:eR1-Cre^{ERT2}:R26-tdTomato mice subject to 60-min IRI, EGFP$^+$ and tdTomato$^+$ PT cells mostly overlapped in acute phase even without tamoxifen. This suggested that eR1-Cre^{ERT2} mice showed leaky Cre^{ERT2} activity when eR1 was highly activated after injury, and could be used to trace the fate of PT cells with high eR1 activity. In acute phase of 60-min IRI, tdTomato$^+$ PT cells showed a higher rate of BrdU incorporation compared to other PT cells, and clustered with several tdTomato$^+$ cells. Consistently, eR1-Cre^{ERT2}:R26-Confetti multicolor reporter mice revealed the clonal expansion of eR1-active PT cells after 60-min IRI. RNA-seq data of eR1^{CreERT2} lineage-labeled PT cells after 60-min IRI showed higher expression of genes associated with cell cycle progression and DNA replication. Notably, tdTomato$^+$ PT cells in acute phase were mostly positive for Kim-1 and vimentin, and negative for differentiation markers. In chronic phase, however, the percentages of PT cells positive for Kim-1 and vimentin were not different between tdTomato$^+$ and tdTomato$^-$ PT cells, indicating the re-differentiation capacity of this population even after severe injury.

Conclusions: eR1 marks a subpopulation of PT cells of the superficial cortex with different transcriptomic profiling, highly proliferative after severe injury.

TH-PO002

Caspase-11-Mediated Tubular Epithelial Pyroptosis Underlies Contrast-Induced AKI

Zhen Zhang, Xinghua Shao, Zhaohui Ni. *Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China*.

Background: Contrast-induced acute kidney injury (CI-AKI) is a serious complication in patients after administration of iodinated contrast media. Pyroptosis is a form of programmed lytic cell death that is triggered by inflammatory caspases (caspase-11), but little is known about its role in tubular epithelial cells (TECs) death and CI-AKI.

Methods: 1. The primary mouse and human renal TECs were treated with iohexol and isosmotic mannitol in separate experiments. Experiments were performed in triplicate. The protein expression of Caspase-4/5/11, IL-1β and Gsdmd in cells by assessed by Western Blot, respectively. Caspase-4/5, and IL-1β mRNA expression in cells detected by real-time PCR. ELISA was used to detected the concentration of IL-1β in cell culture supernatants and a CytoTox 96 Non-Radioactive Cytotoxicity Assay measured cell death. 2. The model of CI-AKI mice was established. Mice were killed 24 hours after iohexol or other drugs injection, and blood and kidney tissue specimens of mice were collected. Scr and blood BUN was assessed by an automatic biochemical analyzer; the protein expression of Caspase-11, IL-1β and Gsdmd in mouse kidney was assessed by Western Blot; Acute kidney injury biomarkers (KIM-1, IL-18) and inflammatory cytokines IL-6 mRNA expression was detected by real-time PCR. H&E staining and immunolabelling were used to evaluate degree of renal tubular injury and expression of caspase-11, and IL-1β in kidneys, respectively.

Results: Here, we show that systemic exposure to contrast media causes severe tubular epithelial pyroptosis that is mediated by the inflammatory caspases, caspases 4/5 in human TECs, or the murine homolog caspase-11 in mice in vivo and in mouse TECs in vitro. Knockdown of caspase-4/5 preserved human TECs from cell death and reduced the release of mature IL-1β, and in caspase-11-deficient mice, contrast-induced acute kidney injury was abrogated, indicating a central role for caspase-11 in acute kidney injury. Additionally, deletion of caspase-11 in TECs reduced Gsdmd cleavage, which is the key process for execution of pyroptosis.

Conclusions: These results establish the requisite role of caspase-11–mediated epithelial pyroptosis in CI-AKI and suggest that epithelial inflammatory caspases are an important therapeutic target for AKI.

Role of NLRP3 in Rhabdomyolysis-Induced AKI

Won-Hee Cho,[1] Su Woong Jung,[1] Kyung hwan Jeong,[2] Ju young Moon,[1] Sangho Lee,[1] Yang gyun Kim.[1] *[1]Kyung Hee University Hospital, Gang-Dong, Seoul, Republic of Korea; [2]Kyung Hee University, College of Medicine, Seoul, Republic of Korea*.

Background: NOD-like receptor, pyrin domain containing-3 (NLRP3) has been suggested to contribute to various kidney through inflammasome-depedent or –independent pathways. Recent evidence showed the association of NLRP3 inflammasome in the pathogenesis of rhabdomyolysis-induced AKI (RIAKI); However, underlying mechanisms was not clarified yet. We investigated the role of NLRP3 in RAKI and evaluated the possibility of NLRP3 as the treatment target of RIAKI.

Methods: HK-2 cells and THP-1 cells were treated with ferrous myoglobin to mimic the rhabdomyolysis environment in vitro. A glycerol was injected intramuscularly to the gluteal area of the mice to generate RIAKI model in NLRP3 KO and WT ones. Selective NLRP3 inhibitor (MCC950) was used as a therapeutic agent.

Results: NLRP3 KO mice showed a marked decrease in serum creatinine, KIM-1, and tubular injury compared with WT mice although muscular injury was not different. Apoptosis markers and inflammatory cytokines, which were increased in the kidneys of WT mice, were mitigated in the kidneys of NLR3 KO mice. AKI was attenuated by the MCC950 treatment before glycerol injection. Ferrous myoglobin caused to increase apoptotic signals and to translocate NLRP3 from cytoplasm to mitochondria in HK-2 cells. NLRP3 knock down HK-2 cells identified significant decrease of apoptosis. Also, ferrous myoglobin activate NLRP3 inflammasome in THP-1 cells. Cleaved IL-1β was reduced in siNLRP3 treated THP-1 cells.

Conclusions: The deficiency of NLRP3 protected kidneys from RAKI by both inflammasome-independent and -dependent ways. NLRP3 could play the essential role in RIAKI and and be a candidate as a treatment target.

Kynureninase Is Essential for Protection from AKI by Caloric Restriction

Karla J. Hoyer-Allo, Martin R. Späth, Franziska Grundmann, Felix C. Koehler, Bernhard Schermer, Thomas Benzing, Volker R. Burst, Roman-Ulrich Mueller. *Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany*.

Background: Experimental work shows that preconditioning by caloric restriction (CR) or hypoxia (HP) prevents acute kidney injury (AKI) reliably. Recently, we have identified *Kynu* as one of the top gene candidates conveying organ protection in a transcriptome analysis of renal tissue after preconditioning. Here, we further characterize the impact of *Kynu* in a mouse model of renal ischemia-reperfusion-injury (IRI).

Methods: We generated a conventional Knockout (KO) of *Kynu* using CRISPR/Cas9 mediated genome editing and *non-homologous end joining* (NHEJ) in C57Bl6 mice. Following a functional and histological phenotyping, wildtype and KO mice were preconditioned by CR and subsequently were subject to IRI.

Results: *Kynu* encodes kynureninase, which represents a key player in tryptophan metabolism. We confirmed the knockout of our newly generated mouseline by immunoblot, immunhistochemistry and mass spectrometry. The basal phenotyping of the KO mice did not differ from that of wildtype mice (appearance, weight, kidney function, histology). Renal function as well as histological features of AKI 24h after IRI were similar in KO mice without preconditioning and wildtype mice. However, while wildtype mice were effectivly protected from AKI after CR, this effect was significantly diminished in the *Kynu* KO animals after CR.

Conclusions: The induction of *Kynu* is associated with HP and CR. Our results confirm the pivotal role of *Kynu* as a key player of preconditioning-mediated renal protection. Further investigations to determine the mechanistic features of *Kynu* are required now.

TH-PO005

Kidney-Centered Radiotherapy Attenuates Renal Ischemia-Reperfusion Injury in Mice

Badr Khbouz,[1] Pascal Rowart,[2] Jean-Marie H. Krzesinski,[1] François Lallemand,[1] Francois Jouret.[1] *[1]University of Liège Hospital (ULiège CHU), Liège, Belgium; [2]Children's Hospital of Pittsburgh, Pittsburgh, PA*.

Background: Whole-body irradiation has been associated with renal ischemic preconditioning in mice. Here, we investigate the functional and fundamental impact of radiotherapy centered on the kidneys before renal ischemia/reperfusion (I/R) in mice.

Methods: Experience1: Animals (n=6) were anesthetized and placed in the irradiator. Two beams of X-rays (225Kv, 13 mA) specifically targeted both kidneys to deliver a dose a 8,56Gy. One month later, a right nephrectomy was performed, and a left renal ischemia was induced for 30min. After 48 hours of reperfusion, the left kidney was collected, as well as blood. Control group (n=6) underwent a similar renal I/R procedure, with no prior irradiation. Experience 2: Unilateral irradiation of the left kidney (8.56 Gy) was performed in mice (n=10). One month later, the left (irradiated) kidney was collected. Additionally, the left kidneys were collected from non-irradiated mice (n=5). Total RNAs were extracted from irradiated and control kidneys to perform comparative high-throughput RNA-Seq. BaseSpace Sequence Hub Illumina was used. Functional enrichment analysis was performed using DAVID program. Both experimental protocols have been approved by the IACUC of ULiège, Liège, Belgium.

Results: Following kidney I/R, blood urea nitrogen (BUN) levels were significantly lower in pre-irradiated mice (148.4±93.1) compared to controls (495.7±33.3, $p<0.01$). The number of PCNA-positive proliferating cells was significantly lower in pre-irradiated mice (130.8±52.7) compared to controls (545.4±257.3, $p<0.001$). The renal infiltration by inflammatory CD11b-positive cells (90.2±32.2 *vs.* 414.5±148.6) and F4-80-positive macrophages (80.6±22.9 *vs.* 178.5±68) was significantly reduced in pre-irradiated animals *vs.* controls. Comparative transcriptomics showed a significant up-regulation of various signaling pathways, including angiogenesis (*HMOX1*) and stress response (*HSPA1A*, *HSPA1B*), and a down-regulation of oxidoreduction (*NOX4*).

Conclusions: Kidney irradiation induces ischemic preconditioning in mice, with improved renal function and decreased inflammation following renal I/R. The aforementioned signaling pathways may play a role in irradiation-associated kidney resistance to I/R.

TH-PO006

Renal Protective Effect by Vagus Nerve Stimulation After Kidney Injury

Rie Uni, Tsuyoshi Inoue, Bongkod Surattichaiyakul, Wachirasek Peerapanyasut, Sho Hasegawa, Hiroshi Maekawa, Masaomi Nangaku, Reiko Inagi. *The University of Tokyo Graduate School of Medicine, Tokyo, Japan*.

Background: We previously reported that the macrophages with vagus nerve stimulation (VNS) before bilateral ischemia-reperfusion injury (IRI) protect the kidney from the injury by activating the cholinergic anti-inflammatory pathway (CAP) in mice. Clinically, it would be more beneficial if VNS after injury could protect the kidney. We evaluated the effect of VNS after the injury both in vitro and in vivo model.

Methods: <LPS model> Both murine macrophage cell line RAW 264.7 and primary peritoneal macrophages were administered LPS (100 ng/ml). Human monocyte cell line U937 also received LPS (1 μg/ml). Because a7 nicotinic receptor plays an important role in the CAP, all of the cells were treated with a7nicotinic receptor agonist GTS-21 (50 mM for each) 4 and 6 hours after LPS administration, followed by assessment of the inflammatory status (TNF-α, IL-1β). In vivo, C57BL/6 mice were injected with LPS (5 mg/kg) intraperitoneally, and GTS-21 (10 mg/kg) was administered 4 and 6 hours later. Cytokine levels such as systemic TNF-α and splenic IL-1β and kidney injury markers such as Kim-1 were evaluated 8 hours after LPS administration. <IRI model> C57BL/6 mice underwent unilateral IRI (uniIRI). Followingly, VNS or sham stimulation was performed 3 times a week for 2 weeks, then the extent of kidney fibrosis (a-SMA, Masson's trichrome staining) was evaluated 2 weeks after the injury.

Results: GTS-21 decreased TNF-α expression level induced by LPS in macrophages / monocyte we used. In vivo, GTS-21 significantly suppressed LPS-induced kidney injury such as increased Kim-1 expression, as well as inflammation such as increased plasma TNF-α and splenic IL-1β. The progression of kidney fibrosis was also suppressed in VNS-treated uniIRI mice, compared to the sham stimulation-treated group.

Conclusions: CAP activation after injury could also exert organ protective effect.

Human Recombinant α-1-Microglobulin Protects Against AKI in Rat Models of Ischemia-Reperfusion Injury (IRI)

Magnus Gram,[2] Tobias E. Larsson,[3] Silvia B. Campos-bilderback,[4] Ruben M. Sandoval,[1] Bruce A. Molitoris.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]A1M Pharma AB, Lund, Sweden; [3]A1M Pharma, Lund, Sweden; [4]Indiana University, Indianapolis, IN.*

Background: Acute kidney injury (AKI) is a global health concern associated with high morbidity, mortality, and progressive chronic kidney disease (CKD). RMC-035, a recombinant human α_1-microglobulin (A1M), has demonstrated protective antioxidant effects in several injury models. The principal mechanisms of RMC-035 are heme binding, reductase activity, radical scavenging and protection of mitochondria. RMC-035 is being developed for the prevention of cardiac surgery associated-AKI, and are currently evaluated in a Phase 1 study. We present preclinical data for RMC-035, supporting its protective effect in ischemic AKI and AKI on a CKD background.

Methods: RMC-035 (0-5 mg/kg, i.v.) was administered at various time-points and doses prior and/or post renal ischemia in rats exposed to unilateral nephrectomy followed by a 30 minute pedicle clamp ischemia. AKI was evaluated at 1-5 days post injury by serum creatinine (sCr), BUN and 24 hr urinary creatinine clearances (CrCl). Furthermore, RMC-035 (2 mg/kg, i.v.) was administered prior to and post renal clamp ischemia in rats previously subjected to unilateral and renal ischemia ("AKI on CKD model"). Texas Red-x labeled RMC-035 (TR-RMC-035) trafficking and handling by proximal tubule cells (PTC) was studied via intravital imaging.

Results: RMC-035 caused a dose-dependent decrease in AKI measured as reduced proteinuria, sCr and BUN levels, and improved 24 hr CrCl, in rats subjected to a single renal IRI episode. RMC-035 given prior and post renal IRI was more effective for protection vs a single dose given either before or after IRI. In a CKD model with two successive episodes of AKI over 28 days, RMC-035 given at the second IRI episode significantly reduced renal injury by sCr and CrCl. TR-RMC-035 was rapidly filtered and bound to the apical brush border in PTC. Accumulation of RMC-035, tubular-vesicular extensions and vesicular trafficking was seen from 30 minutes through 24 hr post infusion. Cytosolic release was seen as early as 70 minutes.

Conclusions: RMC-035 demonstrates dose-dependent protective effects against AKI in multiple IRI models including AKI on CKD, had a prolonged PTC half-life including release into the cytosol, thus being a novel and promising therapeutic candidate for the treatment of cardiac surgery associated-AKI.

TH-PO008

A Novel Angiotensin-Converting Enzyme 2 Truncate Markedly Improves Ischemic AKI

Mina Shirazi, Jan Wysocki, Minghao Ye, Chad R. Haney, Ming Zhao, Yashpal S. Kanwar, Zheng J. Zhang, Daniel Batlle. *Northwestern University Feinberg Medical School, Chicago, IL.*

Background: RAS is overactive in AKI and therefore RAS blockers could be beneficial. Their use, however, is usually avoided because of their hypotensive and hemodynamic effects. An alternative approach to blocking the formation or action of angiotensin II (Ang II) is to foster its degradation. ACE2 is a tissue enzyme that degrades Ang II to Ang 1-7. Due to its large size, native ACE2 is not filterable. We therefore used a novel ACE2 truncate (1-619) to test the therapeutic potential in a unilateral model of ischemia-reperfusion injury (IRI).

Methods: IRI was induced in C57 mice by clamping the left renal pedicle for 30 min. ACE2 1-619 or vehicle (PBS) was administered 20 min prior to, and 5-6 h and 30 h after IRI. Renal function and tubular injury were assessed 24h and 48h post IRI. Filtration and renal uptake of 1-619 was assessed by SPECT/CT imaging.

Results: In 1-619-treated mice, GFR was higher at 24h (103±16 vs. 63±11 μl/min, $P<0.05$) and 48h (93±22 vs 38±93 μl/min, $P<0.01$) post IRI as compared to vehicle mice. Consistent with a better preserved GFR, BUN and Cr were lower in the 1-619-treated group as compared to their vehicle counterparts at 24h and 48h post IRI. ACE2 1-619 attenuated injury to the renal tubules as reflected by an improved tubular injury score and reduced kidney NGAL at 48h post IRI compared to vehicle mice. SPECT/CT showed comparable parenchymal activity of infused 1-619 in a mouse subjected to IRI 24h prior to imaging and an Nx control mouse. ACE2 activity was increased in kidneys of 1-619-injected mice as compared to vehicle mice at 48h post IRI (66±4 vs. 46±3 RFU/μg protein/h, $P<0.01$).

Conclusions: We conclude that the use of our novel ACE2 truncate downregulates the kidney RAS and provides a preventative/therapeutic approach to attenuate AKI.

Knockout of Leucine Rich α-2 Glycoprotein Protects Against Renal Ischemia-Reperfusion Injury Through Reduction of Fibrosis and Apoptosis

Kahio Takeshi,[1] Yoshio Terada,[2] Shimpei Fujimoto,[3] Yoshinori Taniguchi,[3] Masami Ogasawara,[3] Taro Horino,[4] Hirofumi Nishikawa,[3] Yoshiko Shimamura,[4] Tatsuki Matsumoto.[3] *[1]Kochi Medical School Hospital, Nankoku-shi, Japan; [2]Kochi Medical School, Nankoku-city, Japan; [3]Kochi University, Nankoku, Japan; [4]Kochi Medical School, Kochi University, Kochi, Japan.*

Background: Leucine-rich α-2 glycoprotein (LRG) is one of serum glycosylated proteins with 347 amino acids, and serum LRG is reported as a novel disease activity biomarker for inflammatory bowel disease. However, little is known about the role of LRG in acute kidney injury (AKI) pathogenesis. We examined renal LRG expression and urinary LRG level using mice AKI model and clinical samples.

Methods: We evaluated LRG function in the bilateral renal ischemia-reperfusion injury (IRI) AKI model by using LRG knockout (KO) and wild-type (WT) mice. We at first evaluate the localization of LRG in AKI of WT mice. The effects of LRG on phosphorylation of Smads were examined in primary cultured renal tubular cells. In clinical study, we measured urine LRG in AKI patients, and immunohistological examination of LRG in AKI and minimal change renal biopsy sample.

Results: In WT mice with IRI-induced AKI, renal mRNA and protein expression of LRG were induced from 6 h and 12 h and peaked at 24 h and 48 h after IRI, respectively. In control mice kidney, only a very few expression of LRG was observed. Urine and serum LRG are increased after IRI in WT mice. Immunohistological examination showed that LRG expression was observed mainly in renal distal tubular cells in AKI mice. LRG KO mice had significantly lower PCr (0.61+0.13 versus 1.67+0.38 mg/dl), BUN (102.3+21.8 versus 234.5+48.5 mg/dl) at 48h after IRI compared to WT mice. Immunohistological examination showed mild tubular injury, fibrotic change, collagen IV deposition, and fewer KIM-1 positive and apoptotic cells in LRG KO mice. In primary cultured renal tubular cells, TNF-a and LPS stimulated LRG expression. LRG KO reduced TGF-b stimulated-phosphorylation of Smad2. Notably, in contrast media-induced AKI patients, urinary LRG levels were increased from 6 h. LRG staining were enhanced in AKI renal-biopsy samples.

Conclusions: Our results demonstrate that LRG is up-regulated in renal tissues in both mice and human AKI, and that urine and serum LRG are increased in early phase of AKI. Inflammatory cytokines such as TNF- a stimulates expression of LRG in renal tubular cells. Thus, LRG could serve as a potential early biomarker in AKI, and LRG blockage could serve as a potential therapeutic target in AKI.

Mineralocorticoid Receptor Antagonism Counteracts the Acute and Chronic Effects of Renal Ischemic Injury in Rodents and the Large White Pig

Frederic Jaisser,[4,5] Gabriel R. Estrela,[4] Sebastien Giraud,[1] Sihem Kaaki,[1] Thierry Hauet,[1] Peter Kolkhof,[2] Jonatan Barrera-Chimal.[3] *[1]INSERM U1082-CHU de Poitiers, service de biochimie, Poitiers, France; [2]Cardiology Research, BAYER AG, Wuppertal, Germany; [3]Instituto de Investigaciones Biomédicas, UNAM and Instituto Nacional de Cardiología Ignacio Chavez, Mexico City, Mexico; [4]INSERM, UMRS 1138, Team 1, Centre de Recherche des Cordeliers, Sorbonne University, Paris Descartes University, Paris, France; [5]INSERM, Clinical Investigation Centre 1433, French-Clinical Research Infrastructure Network (F-CRIN) INI-CRCT, Nancy, France*.

Background: Mineralocorticoid receptor antagonists (MRA) prevent ischemic acute kidney injury (AKI) and its transition to chronic kidney disease (CKD) through macrophage polarization modulation. The specific contribution of interleukin-4 (IL-4) signaling to this effect is unknown. Whether the MRA protective effect reported in rodents can be translated to the human remains to be elucidated. Here, we explore the role of IL-4 signaling in the protective effect of Finerenone and we evaluate the effect of MRA against the acute and chronic effects of ischemic AKI in the Large White pig.

Methods: Male C57/B6 mice (24) were divided in: sham, renal ischemia for 22.5 min (IR), IR plus the non-steroidal MRA finerenone (10 mg/kg) at -48, -24 and -1 h before IR and IR-finerenone plus Tofacitinib (15mg/kg), a JAK3 inhibitor. The mice were followed-up for 4 weeks to evaluate the AKi to CKD transition. Large White male pigs (18) were divided in: sham, bilateral renal ischemia for 60 min + vehicle and IR + Soludactone (potassium canreonate-7mg/kg, i.v.) at 48 h, 24 h and 30 min before the induction of the ischemia and 24 h and 48 h after reperfusion.

Results: In mice, the AKI to CKD transition was evidenced by a 40% increase in plasma creatinine, interstitial fibrosis and increased mRNA levels of α-SMA, fibronectin and collagen I. Finerenone protected against these alterations while the JAK3 inhibitor partially reversed this protective effect. In the Large White pig, tubular injury protection by canrenoate was evidenced by a significant reduction in urinary protein (Vehicle: 1±0.08 g/mmol vs canrenoate: 0.49±0.02 g/mmol), L-FABP (Vehicle: 39±2 ng/mL vs canrenoate: 19±.1.5 ng/mL), NAG excretion (Vehicle: 109±3 U/L vs canrenoate: 59±2 U/L) and by the recovery of the urinary concentration capacity after 24 h of renal ischemia. After 3 months, the untreated pigs presented proteinuria (0.03±0.01 g/mmol) which was absent in the canreonate-treated pigs (0.01±0.01 g/mmol).

Conclusions: MR antagonism prevents the acute and chronic IR-kidney effects in the mice and in the Large White pig. The IL-4 receptor-JAK3 signaling pathway is involved in the benefit of the MRA finerenone. These findings support clinical trials testing the potential benefits of MRAs in the kidney transplantation setting.

The V1a Receptor Activator Terlipressin (TLP) Attenuates Hemorrhagic Shock (HS)-Induced AKI

Leticia U. De Castro, Denise A. Otsuki, Talita R. Sanches, Mirela Santinho, Irene L. Noronha, Lucia Andrade. *University of Sao Paulo School of Medicine, Sao Paulo, Brazil*.

Background: Although HS is still the leading cause of mortality, early vasopressor use can restore hemodynamic parameters and organ perfusion, reducing the need for aggressive fluid therapy and avoiding fluid overload. In shock, TLP improves hemodynamics, decreasing pulmonary capillary leak and avoiding fluid overload. The AVP/V1a receptor system also stimulates RAS activity and inhibits apoptosis. This study aimed to compare levels of lactated Ringer's (LR) fluid therapy: aggressive (LR 3× the blood volume removed, 3LR), conservative (2LR), and minimal (1LR)—with or without TLP—in rats with HS-induced acute kidney injury (AKI).

Methods: We induced rats to HS, maintaining MAP at 30-40 mmHg for 60 min, and evaluated 4 groups of rats—control (no intervention); 3LR; 1LR+TLP (10 μg/100 g BW, iv); and 2LR+TLP. At 15 min after LR/TLP administration, we used the drawn blood to resuscitate the rats with HS. We measured MAP at various time points, studying other variables at 24 h after HS induction. Data are mean±SEM.

Results: MAP was restored in all three study groups. p21 protein expression was significantly higher in 3RL rats than in 1LR+TLP and 2RL+TLP rats (144±3.4 vs. 116±0.9 and 110±2.8%; P<0.05), and PCNA+ cell counts were lower in 3RL rats (1.1±0.1 vs. 1.8±0.7 and 2.2±0.6 cells/0.087 mm²). CD68+ cell counts were higher in 3RL rats than in 1LR+TLP and 2RL+TLP rats (10±2.2 vs. 6.3±0.7 and 5.3±0.7 cells/0.087 mm²). TUNEL+ cells counts were significantly lower in 2LR+TLP and 1LR+TLP rats than in 3LR rats (0.6±0.1 and 1.6±0.3 vs. 4.5±2.5 cells/0.087 mm²; P<0.05), as was BAX protein expression (105±5.4 and 107.5±5.2 vs. 153±14.5%, P<0.05).

Conclusions: TLP could be a viable therapy for HS-induced AKI. TLP might attenuate AKI by modulating the inflammatory response and apoptosis via the V1a receptor. (FAPESP)

S100A8/S100A9 Diminishes Acute Tubular Injury After Ischemia-Reperfusion

Timm H. Westhoff,[1] Felix S. Seibert,[1] Kai M. Schmidt-Ott.[2] *[1]University Hospital Marien Hospital Herne, Herne, Germany; [2]Charite - Universitaetsmedizin Berlin, Berlin, Germany*.

Background: Urinary calprotectin (S100A8/S100A9) has recently been identified as a promising biomarker in acute kidney injury (AKI). It is a mediator of the innate immune system and acts as a danger associated molecular pattern protein (DAMP). It remains elusive, however, whether calprotectin plays a pathophysiological role in AKI. Recently, there was first evidence that it might participate in the control of macrophage-mediated renal repair following ischemia/reperfusion. The present work examines whether calprotectin modulates acute I/R injury by means of a S100A9 -/- mouse model.

Methods: Since S100A8 -/- mice are not viable, S100A9 -/- knockout mice were established on a C57BL/6 background. I/R injury was induced by 25 min of unilateral ligation of the renal artery in S100A9 -/- and wildtype (WT) mice. The extent of tubular injury was assessed by a histological score and neutrophil gelatinase associated lipocalin (NGAL) and kidney injury molecule 1 (KIM-1) mRNA expression.

Results: Histological tubular injury was comparable between S100A9 -/- and WT controls at 24h, while transition to fibrosis was aggravated in S100a9-/- mice. After 24h KIM-1 mRNA concentrations were higher in S100A9 -/- than in WT mice. The increase in NGAL mRNA expression was highly significantly larger in S100 A9 -/- than in WT mice at 24h. The difference of both KIM-1 and NGAL expression between the two mice strains disappeared by day 7. Sham operated animals did neither show any tubular injury nor an increase in KIM-1 or NGAL expression.

Conclusions: S100A9 deficiency is associated with increased I/R injury. Acting as an alarm signal, calprotectin may initialize tubular protective mechanisms after the induction of I/R.

TH-PO013

Aryl Hydrocarbon Receptor Agonist FICZ Alleviated Rhabdomyolysis-Induced AKI by Regulating Inflammation and Apoptosis

Sibei Tao,[1] Liang Ma,[2] Ping Fu.[3] Kidney Research Lab, Division of Nephrology, West China School of Medicine, West China Hospital of Sichuan University, Chengdu, China. *[1]Kidney Research Lab, Division of Nephrology, West China Hospital of Sichuan University., Chengdu, China; [2]Kidney Research Institute, Division of Nephrology, West China Hospital of Sichuan Univeristy, Chengdu, China; [3]West China Hospital of Sichuan University, Chengdu, China*.

Background: Aryl hydrocarbon receptors (AhR) are ubiquitous in the cytoplasm of various cells in various organs. They can bind to multiple ligands and affect different downstream pathways. Previous studies have found that activating AhR could alleviate inflammation and apoptosis through the NFκB pathway in ulcerative colitis, psoriasis and metabolic diseases induced by high-fat diet. However, whether AhR agonist FICZ can alleviate acute kidney injury (AKI) remains unclear. Thus, we explored the role of FICZ in AKI and its related mechanisms through rhabdomyolysis-induced AKI model.

Methods: C57BL/6 mice were randomly divided into three groups: control, glycerol and glycerol+FICZ. The glycerol group were injected group were injected with glycerol at bilateral back limbs. The glycerol+FICZ group was administered intraperitoneally for 3 days before the glycerol injection. The mice were sacrificed at 24h after the glycerol injection, blood and organs were collected. Renal histological injury was measured by PAS staining. Renal tissues of mice were analyzed by immunohistochemical, immunofluorescence, western blot and qPCR assay.

Results: Immunofluorescence staining and western blot showed that AhR was mainly expressed in proximal renal tubular epithelial cells, and the expression of AhR was decreased in rhabdomyolysis-induced AKI. Activation of AhR by FICZ pretreatment significantly reduced serum creatinine (Scr), urea and creatine kinase (CK) levels, as well as attenuated renal tubular damage in glycerol-injured kidneys. AhR activation also resulted in reduced TUNEL-positive tubular cells, suppressed cleaved caspase-3, BAX levels, and preserved Bcl-2, Bcl-XL expression, indicating that FICZ regulated tubular cell apoptosis. Moreover, the expressions of p-P65, p-iκBα and inflammatory factors IL-6, IL-1β and TNFα in the glycerol+FICZ group were significantly reduced, comparing with the glycerol group. The transcription levels of those inflammatory factors, MCP1 and IFNγ genes were detected by qPCR. These data suggested that FICZ showed renoprotective effects also by regulating inflammation via the NFκB pathway.

Conclusions: In summary, our findings demonstrated that AhR agonist FICZ protects against rhabdomyolysis-induced AKI via the regulation of inflammation and apoptosis in tubular epithelial cells.

TH-PO014

Effect of Bortezomib on Proximal Tubule Cells Exposed to Free Light Chains Isolated from the Urine of Multiple Myeloma Patients

Rohit Upadhyay, Vecihi Batuman. *Medicine (Nephrology), Tulane University Medical School, New Orleans, LA.*

Background: Bortezomib (BTZ, also known as Velcade® and PS-341) is the first 20S proteasome inhibitor used as a drug for Multiple myeloma (MM) patients. Although, BTZ has markedly improved the treatment outcomes of MM patients; several adverse events, including acute kidney injury (AKI) can occur due to off-target effects of BTZ. Kidney proximal tubule cells (PTCs) are a primary target of a vast array of nephrotoxic compounds but direct effects of BTZ on PTC have not been explored in the presence of free light chains (FLCs) derived from the urine of MM patients.

Methods: Human kidney PTCs cultures (RPTECs and HK2 cell lines) were exposed to BTZ, κ, or λ FLCs. Cell supernatant and pellets were used for ELISA and gene expression studies. Cell proliferation, viability, cytotoxicity and apoptosis were evaluated using standard procedures. Immunofluorescence and Western blotting were used to localize NFkβ translocation in subcellular fractions. Mitochondrial membrane potential was measured using TMRE (tetramethylrhodamine, ethyl ester) assay. Data were analyzed using one-way ANOVA with post hoc Tukey test and P values <0.05 were considered significant.

Results: BTZ (50nM) alters cell morphology, significantly decreases proliferation and induces apoptosis in HK2 cells irrespective to FLCs exposure. Toxic effect of BTZ was also apparent from substantial overexpression of LCN2, a known kidney injury marker, and TLR9 upregulation. Additionally, NFkβ phosphorylation was evident in BTZ treated cells, which was further supported by the increased IKKα/β expression and decreased expression of IKβα. BTZ induced LCN2 and NFkβ showed possible immunomodulatory effects in PTCs. Our results indicate probable ROS-mediated mitochondrial injury and activation of TLR9 and LCN2, which may be unique pathway leading to injury in PTCs.

Conclusions: These results show a novel off-target, and potentially toxic action of BTZ in human PTCs.

TH-PO015

Alpha-1 Acid Glycoprotein Ameliorates Hemolysis-Induced Renal Oxidative Stress Via Accelerating Plasma Free Hemoglobin Clearance Through CD163 Induction

Rui Fujimura,[1,2] Hiroshi Watanabe,[1] Kento Nishida,[1] Jing Bi,[1,2] Toru Maruyama.[1] *[1]Department of Biopharmaceutics, School of Pharmacy, Kumamoto University, Kumamoto-shi, Japan; [2]Program for Leading Graduate Schools "HIGO(Health life science: Interdisciplinary and Glocal Oriented) Program", Kumamoto, Japan.*

Background: In hemolysis-induced kidney disease such as paroxysmal nocturnal hemoglobinuria, increased free hemoglobin (Hb) contributes to the renal vascular endothelium injury and renal oxidative stress which play a role in the progression of AKI and CKD. In hemolytic condition, CD163, hemoglobin scavenger receptor, expressed on monocytes and macrophages takes up plasma free Hb or Hb-haptoglobin (Hp) complex. We previously found that the an acute-phase protein, alpha-1 acid glycoprotein (AGP) increased the expression of CD163 in macrophages (Komori et al. J Biol Chem 2012). The purpose of this study is to investigate the effect of exogenously administered AGP on plasma free Hb level and renal oxidative stress in hemolysis-model mice.

Methods: Hemolysis model mice were generated by intraperitoneally administered phenylhydrazine (PH). AGP was intraperitoneally administered at 24 hr and 48 hr before PH administration. The mice were sacrificed at 24 hr after PH administration.

Results: Administration of AGP to PH mice reduced plasma free Hb level and renal oxidative stress (malondialdehyde). In the same experimental condition, we found that AGP treatment increased CD163 expression in kidney and liver. In healthy mice, administration of AGP also increased the expression of CD163 in kidney and liver, but it did not affect the plasma Hp level. These data suggested that the effect of AGP on free Hb clearance could be due to the induction of CD163. In *vitro* experiments using human monocyte-derived macrophages (dTHP-1 cells), AGP treatment increased the expression of CD163 and also increased the intracellular uptake of Hb-Hp complex.

Conclusions: AGP ameliorates hemolysis-induced renal oxidative stress *via* accelerating plasma free hemoglobin clearance through CD163 induction.

TH-PO016

Treprostinil Inhibits Apoptosis During Rat Renal Ischemia-Reperfusion Injury

Nisanne S. Ghonem,[1] Meiwen Ding,[1] Mark Birkenbach,[2] Fatemeh Akhlaghi,[1] Reginald Y. Gohh.[2] *[1]University of Rhode Island, Kingston, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: Kidney transplantation (KTx) is the optimal treatment for end-stage renal diseases. Ischemia-reperfusion (I/R) injury, an unavoidable process during KTx, is a major cause of delayed graft function, carrying a high mortality rate if patients are not re-transplanted immediately. No pharmacological treatment for I/R injury is available. Treprostinil (Remodulin®), an FDA-approved prostacyclin analog, has potent vasodilatory and anti-platelet aggregatory effects. We recently demonstrated the efficacy of treprostinil in reducing acute kidney injury during bilateral rat renal ischemia. The objective of this study is to determine the inhibitory role of treprostinil on renal apoptosis during rat renal I/R injury.

Methods: Male Sprague Dawley rats were randomly divided into four groups: control, sham, I/R-placebo and I/R-treprostinil groups and subjected to 45 minutes of bilateral renal ischemia followed by reperfusion for 1-168 hours. Placebo or treprostinil (100 ng/kg/min) was administered subcutaneously via an osmic mini-pump. Blood and kidney tissue were collected for analysis.

Results: Treprostinil significantly reduced elevated SCr vs. placebo (0.93 ± 0.17 mg/dl vs. 0.41 ± 0.04 mg/dl, p<0.001) and BUN (150.87 ± 20.38 md/dl vs. 74.06 ± 6.41 mg/dl, p<0.001) at 24 hr post-I/R injury. Treprostinil also reduced renal mRNA expression of kidney injury markers *Kim-1* (5.4-fold, p<0.001) and *Ngal* (8.9-fold, p<0.001) at 48 hr post-I/R injury. Histopathological analysis showed that treprostinil reduced proximal tubular necrosis by 24 hours post-reperfusion. Treprostinil reduced lipid peroxidation byproduct malondialdehyde (7.30 ± 1.43 to 3.84 ± 0.48 μM/mg protein, p<0.05) and renal pro-inflammatory cytokines *Ccl2*, *Il-6* and *Il-1*β by 2.0- (p<0.05), 2.1- (p<0.01) and 3.3-fold (p<0.001), respectively at 6 hrs post-I/R injury. Additionally, treprostinil reduced protein expression of pro-apoptotic Bax, cleaved caspase-3, and -9 by 1.4- (p<0.05), 1.8- (p<0.05), and 1.3-fold (p<0.05), respectively, at 24 hr after I/R injury.

Conclusions: Our results demonstrate that treprostinil improves renal function and inhibits renal inflammation and apoptosis after renal I/R injury. These results suggest a potential therapeutic application of treprostinil in protecting the kidney against I/R injury during KTx.

Tet2 Contributes to Repression of Cisplatin-Induced AKI by Regulating Metabolic Pathway and Inflammation Response

Mengqiu Bai, Fei Han, Jianghua Chen. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Ten eleven translocation (Tet) methylcytosine dioxygenase family members is known to catalyze 5-methylcytosine to 5-hydroxymethylcytosineas. Previous studies have demonstrated that Tet2 was involved in various pathological process, including leukemia, atherosclerotic cardiovascular diseases and inflammation. However, the role of Tet2 in AKI remains largely unknown.

Methods: We established AKI animal model by Intraperitoneal injecting 22mg/kg cisplatin into male C57BL/6 mice. To explore the role of Tet2 in cisplatin-induced AKI, we generated Tet2 systemic knockout mice by using the cre-loxp system. Serum creatinine and BUN were measured in $Tet2^{-/-}$ mice at 48h and 72h after cisplatin injection to indicate the renal functional changes. 2mg/kg mouse Tet2 catalytic domain expression vector or Tet2 mutant catalytic domain vector or empty vector was administered intravenously for 3 days before cisplatin treatment by hydrodynamic based gene transfer technique to investigate the role of Tet2 in cisplatin-induced AKI. To broaden the role of Tet2 in repressing renal injury caused by cisplatin, we analysed dynamic expression patterns of different genes in renal RNA sequencing (RNA-seq) data of healthy and cisplatin-injected mouse.

Results: We found that Tet2 is highly expressed in healthy kidney and decreased in cisplatin-induced AKI. Exacerbation of cisplatin-induced AKI in Tet2 knock-out mice, and also administration of the Tet2 plasmid could protect Tet2 deficient mice from cisplatin-induced nephrotoxicity. Additionally, renal sequencing results showed that in cisplatin-induced AKI, Tet2 deletion was associated with down-regulation of metabolic-related genes such as the PPAR pathway and increased expression of inflammatory cytokines.

Conclusions: Tet2 may play a role in cisplatin-induced AKI by modulating metabolic and inflammatory responses.

The Role of Cysteine Cathepsins in Lipopolysaccharide-Induced Preconditioning in the Mouse Kidney

Peter Hamar,[2,3] Pál Tod,[1] Robert Vidmar,[4] Matej Vizovisek,[4] Beáta Róka,[1,5] Gábor Szénási,[1] Marko Fonovic,[4] Boris Turk.[4] *[1]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [2]Institute of Clinical Experimental Research; Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [3]Institute of Translational Medicine, University of Pécs, Budapest, Hungary; [4]Biochemistry and Molecular and Structural Biology, Jozef Stefan Institute, Ljubljana, Slovenia; [5]Institute of Clinical Experimental Research, Semmelweis University, Budapest, Hungary.*

Background: Cysteine cathepsins along with legumain are associated with diverse biological processes, e.g. antigen processing and presentation. Several studies investigated the potential role of cysteine cathepsins in preconditioning in the brain and heart. The aim of our study was to examine their probable involvement in LPS-induced preconditioning in the kidney.

Methods: Kidney samples were collected from male NMRI mice injected with LPS at 40 mg/kg i.p. and sacrificed at 1.5 and 6 hours (early preconditioning, EP) or at 10 mg/kg i.p. and sacrificed at 24 and 48 hours (late preconditioning, LP). Control animals received an equal volume of saline. Renal function was assessed by plasma urea levels and NGAL mRNA expression. The inflammatory response to LPS was evaluated by TNF-α and IL-6 mRNA expression levels. Cathepsin B, H, Z (Cat B, H, Z) and legumain protein levels were measured by HPLC-MS/MS and Western blot (WB), mRNA expression was quantified using real-time PCR and legumain activity was evaluated using an enzyme assay.

Results: LPS administration induced acute kidney injury and provoked a strong inflammatory response. Only the Cat B mRNA was elevated in EP but no alteration in any Cat protein or legumain expression was detected. Cat B and Z mRNA expression peaked

at 24 hours and begun to decrease at 48 hours compared to the saline group. In align with these observations Cat B and Z protein levels were elevated at both time points. Legumain mRNA expression gradually increased after LPS administration and was markedly elevated at 6 hours in EP and 24 and 48 hours in LP. A significant increase in legumain protein levels was detected by MS at 48 hours and validated by WB. Legumain activity showed a marked increase at 48 h in comparison to the saline group.

Conclusions: The current results suggest that cysteine cathepsins and legumain may play a role only in the late phase of LPS-induced preconditioning.

Modeling of Tacrolimus Nephrotoxicity Using Kidney Organoids Derived from Human iPS Cells

Jinwon Kim,[1] Benjamin S. Freedman,[2] Yong Kyun Kim.[3] *[1]Cell death and disease reserch center, Catholic university of Korea, Seoul, Republic of Korea; [2]University of Washington, Seattle, WA; [3]Catholic University of Korea, Seoul, Republic of Korea.*

Background: Tacrolimus, a calcineurin inhibitor, was clinically used as an immunosuppressive agent in organ transplantation or glomerulonephritis. Despite the therapeutic benefits, tacrolimus's use is limited due to its nephrotoxicity. To reduce tacrolimus nephrotoxicity, the effective experimental models are essential. Recently, we and others have established protocols for the generation of kidney organoids from human pluripotent stem cells, containing nephron-like structures with podocytes, proximal tubules, and distal tubules. Here, we recapitulated tacrolimus nephrotoxicity using kidney organoids and investigated its pathogenic mechanism.

Methods: Kidney organoid differentiated from the CMC11 iPSC cell line (human male donor). Kidney organoids were re-seeded in 96-well plates and tacrolimus was treated at doses of 0 μM, 30 μM, 60 μM, or 120 μM for 24 h.

Results: The size of kidney organoids decreased at dose-dependent manner. Cell viability assessed by CCK-8 assay and live/dead cell staining decreased at dose-dependent manner. Proximal tubular cells as well as distal tubular cells were decreased according to the concentration of tacrolimus. Podocyte loss and injured podocytes with unplolarized and diffuse pattern of ZO-1 tracks were observed after treatment of tacrolimus. Ultrastructural analyses showed the vacuoles throughout the cytoplasm of tubule-like structures, which were similar to those of human tacrolimus nephrotoxicity. Autophagic activity was enhanced after treatment with tacrolimus in kidney organoids, which were similar patterns in mouse model of tacrolimus nephrotoxicity. Rapamycin, as an autophagy inducer, attenuated cell death in kidney organoids model of tacrolimus nephrotoxicity, whereas 3-methyladenine, as an autophagy inhibitor, accelerated cellular toxicity.

Conclusions: Our data suggest that human iPSC-derived kidney organoids can recapitulate tacrolimus nephrotoxicity and serve the effective in vitro model to investigate its pathogenic pathway.

Spatiotemporal ATP Dynamics In Podocytes During Ischemic Reperfusion Injury Predicts Later Foot Process Effacement

Masahiro Takahashi, Shigenori Yamamoto, Masamichi Yamamoto, Motoko Yanagita. *Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Mitochondrial dysfunction, genetic or postnatal, is closely related to podocyte injury, suggesting the possibility that hypoxia or oxidative stress during ischemic AKI causes podocyte injury. Indeed, some studies report proteinuria after kidney transplantation, however, little is investigated regarding pathophysiological changes of podocytes during AKI. Here we investigated the dynamics of adenosine 5' triphosphate (ATP) in podocytes during ischemic AKI, because ATP is essential for stabilization of foot process.

Methods: To enable spatiotemporal ATP imaging, we utilized ATeam mice, which expressed the FRET-based ATP biosensor systemically, and monitored ATP changes of podocytes during IRI by multi-photon microscopy. Furthermore, we performed microstructural analysis of podocytes two weeks after IRI, and assessed the correlation between the ATP recovery in acute phase and morphological change in chronic phase.

Results: While the ATP levels of podocytes gradually decreased to the plateau level in twenty minutes after ischemia induction, they recovered rapidly in less than five minutes after reperfusion. The % ATP recoveries after 15, 30, 37, 45 and 60 minute-ischemia were 95%, 93%, 87%, 84% and 80% respectively, and were dependent on the length of ischemia. Electron microscopy two weeks after IRI revealed significant foot process effacement and mitochondrial fragmentation in mice subjected to severer IRI. Foot process widths were 367, 361, 381, 450 and 480 nm, and mitochondrial circularities, an indicator of mitochondria fragmentation, were 0.80, 0.80, 0.83, 0.86 and 0.88 after 15, 30, 37, 45 and 60 minute-ischemia, respectively. Mitochondrial circularities were strongly correlated with foot process widths, supporting the importance of energy metabolism in the maintenance of foot processes. Notably, the % ATP recoveries in acute phase were well correlated with the foot process widths and mitochondrial circularities in chronic phase.

Conclusions: We, for the first time, succeeded in visualizing ATP dynamics of podocytes during IRI. Our results show the close link between podocyte energy metabolism and ultrastructural changes during and after AKI, and provide the basis for understanding the mechanism of proteinuria after AKI or kidney transplantation.

TH-PO021

A Novel Kidney Slice Culture System Visualizing Intrarenal ATP and Segment-Dependent Energy Metabolism

Shigenori Yamamoto, Shinya Yamamoto, Masamichi Yamamoto, Motoko Yanagita. *Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: The kidney constantly utilizes adenosine 5' triphosphate (ATP), and ATP depletion plays a crucial role in the progression of kidney diseases. Recently, we generated a mouse line, which expresses the FRET-based biosensor systemically, and reported spatiotemporal ATP dynamics in the kidney during AKI model using two-photon microscope. In our previous observation from the kidney surface, however, deeper nephron segments such as S3 segment of proximal tubules (PTs), glomeruli, and thick ascending limbs of Henle (TALs) cannot be observed. Additionally, we cannot analyze ATP dynamics in the presence of the reagents with systemic effects *in vivo*.

Methods: We established ATP imaging system using the kidney slice culture of ATP visualizing mice and evaluated ATP dynamics in the presence of pharmacological inhibitors of oxidative phosphorylation (OXPHOS) and glycolysis. We also evaluated ATP dynamics after cisplatin administration in this system.

Results: While the ATP levels of PTs, TALs and DTs rapidly and significantly decreased by the administration of 4mM NaN3, an OXPHOS inhibitor, those of podocytes were well maintained as long as 60 min after the administration. On the other hand, the administration of 0.2mM phloretin, a glucose transporters inhibitor, decreased ATP levels in podocytes, but not apparently in PTs, TALs, and DTs. When the kidney slice was incubated in the buffer containing 1mM cisplatin, the ATP levels of PTs and DTs decreased after 60 min, while those of podocytes and principle cells showed no apparent changes even after 120 min. Interestingly, mitochondrial cristae deformation were observed by electron microscopy in the slice incubated with cisplatin for 120min.

Conclusions: Utilizing this novel slice culture system, we, for the first time, directly demonstrated the segment-specific changes in ATP metabolism. While PTs, TALs and DTs are more or less dependent on OXPHOS for ATP production, suggesting their possible vulnerability to ischemia, podocytes rely more on glycolysis for ATP production than on OXPHOS. In addition, we succeeded in demonstrating the different sensitivity to cisplatin among nephron segments. This method could be useful for the elucidation of the metabolic changes in the pathophysiological conditions and for screening of renal toxic drugs.

Pannexin 1 Channels Regulate Mitochondrial Function, Autophagy, and Cell Survival During Kidney Ischemia-Reperfusion Injury in Mice

Nabin Poudel,[1] Jakub Jankowski,[1] Sho Morioka,[2] Colleen Schinderle,[1] Shuqiu Zheng,[1] Diane L. Rosin,[1] Mark D. Okusa.[1] *[1]Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; [2]Department of Microbiology, Immunology, and Cancer Biology, University of Virginia, Charlottesville, VA.*

Background: Pannexin 1 (Panx1) channels are membrane associated non-selective channels that are activated by mechanical/physiological stimuli during injury and serve as a conduit for release of small molecules, including ATP. We have previously shown that pharmacological inhibition or genetic deletion of Panx1 in mice is protective against renal ischemia reperfusion injury (IRI), and Panx1 deficiency in murine proximal tubule-derived (TKPTS) cells results in reduced extracellular ATP and concomitant increase in intracellular ATP (PMID: 29866797). While the effects of extracellular ATP released from cells via Panx1 during injury have been extensively studied, the physiological role of Panx1 in cellular homeostasis is unknown.

Methods: Mice were subjected to IRI (26 mins of ischemia and 24 hrs of reperfusion) to assess plasma creatinine and kidney ATP levels. Control and *Panx1* deficient TKPTS cells were subjected to hypoxia reperfusion (HR). Mitochondrial biogenesis and autophagy were assessed using real-time PCR and western blotting. Mitochondrial membrane potential was assessed by flow cytometry. Mitochondrial respiration was assessed using an Agilent Seahorse® assay. Cyclic AMP levels were measured using cAMP biosensor. For ATP depletion studies, cells were pretreated with 100 nM oligomycin prior to HR.

Results: *Panx1*$^{-/-}$ mice have higher kidney ATP levels 24 hours after IRI than control mice. *Panx1*$^{-/-}$mice have higher levels of p62 in kidneys. *In vitro* findings show that *Panx1* deficient cells retain more intracellular ATP after HR and have better survivability. *Panx1* deficient cells have reduced mRNA expression of *Pgc1a* and *Tfam*, increased intensity of Mitotracker Red CMXRos® staining, and reduced cAMP-dependent signaling.

Conclusions: Our findings demonstrate that *Panx1* deficiency leads to increased intracellular ATP, reduced cAMP signaling, reduced autophagy, increased mitochondrial function, and better cell survival during hypoxia. We conclude that deficiency of Panx1 leads to improved mitochondrial health and increased tubule cell survival during hypoxia resulting in protection during IRI. The development of selective pharmacological inhibitors of Panx1 could provide a novel approach to the treatment of acute kidney injury by maintaining mitochondrial health during stress and injury.

TH-PO023

Effects of Tubular Mitochondrial Pyruvate Carrier 1 Deletion on Redox Metabolism

Emily J. Steinbach, Adam J. Rauckhorst, Hsiang M. Wen, Kranti A. Mapuskar, Bryan Allen, Douglas R. Spitz, Mitchell C. Coleman, Eric Taylor, Diana Zepeda-Orozco. *University of Iowa, Iowa City, IA.*

Background: Kidney injury results in mitochondrial dysfunction, oxidative stress, change to tubular glycolytic metabolism, and disruption of lactate and pyruvate metabolism. Pyruvate treatment is protective in different kidney injury models. The Mitochondrial Pyruvate Carrier 1 (MPC1) transports pyruvate from the cytosol into the mitochondrial matrix and mediates the metabolic decision committing glycolytic carbon to mitochondrial oxidative phosphorylation. Understanding the implication of impaired tubular mitochondrial pyruvate transport may provide critical knowledge on the effect of mitochondrial metabolic adaptations in redox balance and injury response.

Methods: $Pax8^{Cre}$ was bred into the $Mpc1^{f/f}$ mouse line to generate $Pax8^{Cre+/-}Mpc1^{f/f}$ (Tu-MPC1-KO) and $Pax8^{Cre-/-}Mpc1^{f/f}$ (Tu-MPC1-WT) littermates to disrupt MPC1 in tubular epithelial cells. Mice 8-13 weeks of age were assessed for renal function and biomarkers of kidney injury. C^{13}-lactate/C^{13}-pyruvate tracing was employed to determine the metabolic consequences of TMPC1-KO. Finally, upon sacrifice markers of oxidative stress were studied and kidney tissue was examined histologically. A second cohort of Tu-MPC1-KO and –WT mice underwent cisplatin-induced kidney injury to evaluate survival.

Results: Tu-MPC1-KO resulted in accumulation of C^{13} labeled lactate/pyruvate and the concomitant decrease of C^{13} labeled TCA cycle intermediate metabolites. Significant reduction of C^{13} incorporation into glutamine suggests that mitochondrial oxidative metabolism may be sustained via glutaminolysis. Tu-MPC1-KO mice show no difference in renal histology or renal function compared to TMPC1-WT. Tu-MPC1-KO kidney tissue had a significant increase in oxidative stress markers including 3-nitrotyrosine, % total glutathione as glutathione disulfide, and MnSOD activity. Finally, while Tu-MPC1-KO mice exhibited increased markers of oxidative stress prior to cisplatin treatment compared to WT, no significant difference in survival was observed.

Conclusions: *In vivo* inhibition of tubular mitochondrial pyruvate transport leads to disruption of renal redox metabolism and increased oxidative stress markers in renal tubule cells, which does not affect survival after cisplatin-induced CKD.

TH-PO024

Treatment with Isolated Mitochondria 5 Days After Kidney Ischemia-Reperfusion Injury Reduces Progression to Interstitial Fibrosis and Tubular Atrophy

Thomas V. Rousselle,[1,2] Valeria Mas,[2,1] Amandeep Bajwa.[1,2] *[1]Surgery, UTHSC, Memphis, TN; [2]Surgery, Transplant Research Institute, Memphis, TN.*

Background: Ischemia induces altered bioenergetics with increased mitochondrial swelling, reactive oxygen species and ultimately degradation of cellular function. Therapeutic interventions that target to improve mitochondrial health to repair, reprogram or replace mitochondria to restore respiratory functions are beneficial for treatment of disease.

Methods: Renal injury was assessed by plasma creatinine (PCr; mg/dl). 8-wk old C57BL/6 mice were i.v. injected with healthy isolated mitochondria (2.5 mcg/g) 1, 3 or 5 days after unilateral IRI. Nephrectomy of contralateral control kidney was done 1 day prior to euthanizing mice. Change in fibrosis genes were measured and histological changes with Masson trichrome. For *in vitro* studies, TKPTS were treated with mitochondria (10-50 mcg/ml) 1 day prior to analysis that included measurement of ATP levels, mitochondrial functions (Seahorse), cytokines (RTPCR), and IF microscopy.

Results: *In vivo* studies demonstrated treatment of mice with 2.5 mcg/g of mitochondria at 1, 3 or 5 days after IRI significantly protected the IRI kidney compared to vehicle treated mice [PCr (0.60±0.04 (+1d) vs 0.54±0.18 (+3d) vs 0.46±0.18 (+5d) vs 1.24±0.2), $p<0.05$]. The mice treated with mitochondria 1d, 3d or 5d after IRI had significantly less MT labeling compared to vehicle treated mice. The injected mitochondria is found in kidney in proximal tubule cells (anti-CD13 labeled) and co-localizes with endogenous mitochondria. The mitochondria treated mice had significantly lower levels of fibrosis genes (Acta and Col3a1) and significantly higher PGC1α compared to vehicle treated mice. The mitochondria treated mice had significantly higher populations of Ki67 positive cells in both IRI and contralateral control kidneys compared to vehicle. Treatment of TKPTS cells with mitochondria have significantly higher levels of ATP, higher basal oxygen consumption rate and spare respiratory capacity. Similar to IRI studies, addition of mitochondria on TKPTS significant increases PGC1α gene expression, mtDNA/nDNA ratio, and induces proliferation.

Conclusions: Transfer of healthy mitochondria help maintain bioenergetics through upregulation of PGC1α and induced regeneration of PT cells to lessen progression to fibrosis after IRI. Treatment with healthy mitochondria could be used as a therapeutic modality to lessen progression to IFTA.

Mitochondrial Transplantation by Intra-Arterial Injection Prevents Renal Ischemia-Reperfusion Injury

Alvise Guariento,[3] Ilias P. Doulamis,[3] Samir M. Parikh,[1] Pedro J. Del nido,[3] Amandeep Bajwa,[2] James D. McCully.[3] *[1]BIDMC/Harvard Medical School, Boston, MA; [2]University of Tennessee, Memphis, TN; [3]Harvard Medical School, Boston Children's Hospital, Marblehead, MA.*

Background: Mitochondrial transplantation (MT) is a novel clinically validated strategy for the amelioration of organs subjected to ischemia-reperfusion injury (IRI). In this study we investigated the safety of autologous MT and the therapeutic use for renal protection in a swine model of bilateral IRI.

Methods: Yorkshire pigs (n=24; female, 40-50 kg) underwent selective catheterization of the renal arteries under fluoroscopy (Fig. 1 A). Mitochondria (1 x 10^9 in 10 ml buffer) were delivered as a single bolus (n=6) or serially (3 injections over 60 minutes, n=6) in each of the renal arteries of healthy animals. Another group of animals underwent bilateral temporary occlusion with balloon-catheters (60 minutes of ischemia) followed by 24 hours of reperfusion. Mitochondria (n=6) or Vehicle (n=6) were delivered as a single bolus in each of the renal arteries at the time of reperfusion. Uptake was confirmed by PET-CT images after intra-arterial injection of ^{18}F-Rhodamine-labeled mitochondria (Fig. 1 B).

Results: MT temporarily increased renal function in the healthy kidney. Intra-arterial injection of mitochondria had no side effects on hemodynamics, systemic inflammatory response and organ function. After 24 hours of reperfusion, MT significantly improved renal function in terms of renal output ($p=0.02$), serum creatinine ($p<0.01$), estimated glomerular filtration rate ($p=0.03$) and blood urea nitrogen ($p<0.01$) compared to vehicle treated animals (Fig. 1 C-D).

Conclusions: Mitochondrial transplantation by intra-arterial injection is safe and prevents renal IRI.

Funding: Other NIH Support - This work was funded by the National Institutes of Health (NIH) (Grants: 1R01DK117183-01A1; 5R01HL108107), Private Foundation Support

Mitochondrial Damage Causes Inflammation via cGAS-STING Signaling in AKI

Hiroshi Maekawa,[1] Tsuyoshi Inoue,[1] Tzu-Ming Jao,[2] Hiroshi Nishi,[1] Reiko Inoue,[1] Ouchi Haruki,[1] Rie Fujii,[1] Rie Uni,[1] Tetsuhiro Tanaka,[1] Masaomi Nangaku,[1] Reiko Inagi.[1] *[1]The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan; [2]National Taiwan University Hospital, Taipei, Taiwan.*

Background: Acute kidney injury (AKI) is characterized by mitochondrial dysfunction and activation of the immune response. The cyclic GMP-AMP synthase (cGAS)-stimulator of interferon genes (STING) pathway detects cytosolic DNA and induces innate immunity. We investigated the role of mitochondrial damage and subsequent activation of the cGAS-STING pathway in cisplatin (cis)-induced AKI.

Methods: The human proximal tubular cell line, HK-2, treated with 20 μM of cis and the renal cortex of WT (C57BL/6) or STING KO mice injected with 25 mg/kg of cis for 48 or 72 hr were analyzed. The changes in cGAS-STING activation, mitochondrial damage, mitochondrial DNA (mtDNA) leakage or neutrophil infiltration were evaluated by flux analyzer, mitochondrial membrane potential analysis, real-time PCR, western blotting, or immunostaining. The culture supernatants of cis and/or STING siRNA-treated HK-2 were used for cytokine arrays and migration assays. Ethidium bromide (EtBr) and extracted mtDNA from HK-2 were used for mtDNA depletion and mtDNA transfection (to increase cytosolic mtDNA), respectively.

Results: In cis-treated HK-2 or kidney cortex of cis-induced AKI mice, cGAS and STING were upregulated and STING translocated from the ER to the Golgi apparatus,

indicating STING activation. Subsequently, the cGAS-STING axis was activated via cis-mediated phosphorylation of TBK-1 and P65, leading to induction of inflammatory cytokines (IL-6, IL-8, ICAM-1, CXCL10, and GM-CSF) and neutrophil chemotaxis. The inflammatory response by cis was ameliorated in STING-knockdowned HK-2 or STING KO mice. Cis impaired tubular mitochondrial function: reduction of mitochondrial respiration and mitochondrial fatty acid β-oxidation with subsequent decrease in ATP production. Moreover, cis permeabilized mitochondrial membrane. Following the mitochondrial dysfunction, cis-mediated mtDNA leakage to the cytosol was induced in tubular cells both in vivo and in vitro. mtDNA depletion inhibited the inflammation by cis in HK-2, whereas mtDNA transfection activated cGAS-STING axis, indicating that leaked cytosolic mtDNA acts as a ligand for the cGAS-STING pathway in cis-induced tubular inflammation.

Conclusions: Mitochondrial damage leads to mtDNA leakage, activating cGAS-STING signaling and subsequent inflammation in cis-induced AKI.

TH-PO027

Mitochondrial Dysfunction in an In Vitro and an In Vivo Model of Aristolochic Acid Nephropathy

Pauline Mosseray,[1] Inès Jadot,[1] Louise Pierre,[1] Florian Juszczak,[2] Olivia Botton,[1] Joelle L. Nortier,[3] Thierry Arnould,[1] Anne-Emilie Decleves,[2] Nathalie Caron.[1] *[1]University of Namur, NAMUR, Belgium; [2]UMONS, Mons, Belgium; [3]Hospital Erasme, Brussels, Belgium.*

Background: Mitochondrial (mt) dynamics is a key player during AKI and CKD. Indeed, mt provide energy to cells thereby supporting many cellular processes. They are of high importance in kidneys, more specifically regarding proximal tubular epithelial cells (PTEC). Aristolochic Acid Nephropathy (AAN) is a rapidly progressive tubulointerstitial nephritis characterized by necrosis of PTEC. In these cells, mt play a major role since PTEC ensure reabsorption and secretion functions. Our study aimed to investigate the mt dysfunction during AAN using both C57Bl/6 male mice and HK-2 cells.

Methods: C57Bl/6 male mice were divided into CTL or AA groups. AA groups received four ip injections of AAI (3.5 mg/kgBW) from D1 to D4 and were sacrificed at D4, D5 and D10. The mt ultrastructure's were analyzed by TEM while kidney function and structure were assessed by BUN, plasma and urinary creatinine, GFR and histological analysis. For the *in vitro* part, confluent HK-2 cells (human PTEC) were exposed to AAI at 0, 1, 10 or 25 μM during 24h, 48h or 72h. FACS and confocal analysis were performed to analyze the mt abundance and network as well as the cellular granularity. Moreover, cellular ATP contents were quantified.

Results: During progression of AAN in mice, structural damages in mt, consisting in the loss of mt cristae and/or contents, were observed, attesting the loss of their integrity and morphology. These observations were concomitant with AAN progression and development of AKI, as shown by a significant increase in BUN and plasma creatinine as well as a significant decrease of GFR. Moreover, at day 10, mt were either absent or only observable as mt debris in necrotic cells where the population of mt exhibiting alterations was increased in remaining cells. During AA-intoxication in HK-2 cells, the fragmentation of mt network and an increase of cellular granularity were observed throughout the protocol while an increase of mt abundance was reported at three days of AA-intoxication, concomitant with a decrease of ATP contents.

Conclusions: We demonstrated the impairment of mt morphology and network during AA-intoxication in both models. Regarding the data, proteins involved in fusion and fission process must be investigated in order to identify molecular actors that may lead to mt dysfunction.

TH-PO028

TREM1/3 Deficiency Impairs Tissue Repair After AKI and Mitochondrial Metabolic Flexibility in Tubular Epithelial Cells

Alessandra Tammaro. *Amsterdam UMC, Amsterdam, Netherlands.*

Background: Long-term sequelae of acute kidney injury (AKI) are associated with incomplete recovery of renal function and the development of chronic kidney disease (CKD), which can be due to a maladaptive repair characterized by aberrant innate immune activation, mitochondrial pathology and accumulation of senescent tubular epithelial cells (TECs). TREM-1 is an innate immune receptor expressed by inflammatory and epithelial cells, both players in renal repair after ischemia/reperfusion (IR)-induced AKI. Despite this, the role of TREM-1 in renal repair has never been investigated.

Methods: WT and TREM1/3 KO mice were subjected to different models of renal IR (severe and mild). Animals were sacrificed 1, 5 and 10 day after surgery. Blood was collected to determine renal function parameters. Kidneys were harvested for hystological examination, RNA isolation and protein determination. For ex-vivo studies, primary TECs were isolated from WT and TREM1/3 KO animals and exposed to hypoxia/re-oxygenation experiments. Seahorse analysis, metabolomics, senescence and wound healing assays were used as readout for in vitro studies.

Results: TREM1/3 KO mice displayed no major differences during the acute phase of injury, but increased mortality was observed in the recovery phase. This detrimental effect was associated with maladaptive repair, characterized by persistent tubular damage, inflammation, fibrosis, TEC senescence and metabolic reprogramming. In vitro, we observed an altered mitochondrial homeostasis and cellular metabolism in TREM1/3 KO TECs. This was associated with G2/M arrest and increased ROS accumulation. Further exposure of cells to ROS-generating triggers drove the cells into a stress-induced senescent state, which was partly reverted by treatment with a mitochondria anti-oxidant.

Conclusions: In summary, we have unraveled a novel (metabolic) mechanism by which TREM1/3 deficiency drives senescence in TECs. This involves redox imbalance, mitochondrial dysfunction and a decline in cellular metabolic activities. These finding suggest a novel role for TREM-1 in maintaining tubular homeostasis through regulation of mitochondrial metabolic flexibility. Finally, this study demonstrates a novel link between immunometabolism and tubular epithelial senescence.

Sulfotransferase 1C2 or Its Mitochondria Membrane Product, Cholesterol Sulfate, Increases Maximum Rates of Mitochondria Redox Reactions and Utilization of Tricarboxylic Acid Intermediates

Robert L. Bacallao,[1,2] Glenn T. Nagami,[3] David P. Basile.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Medicine, Richard Roudebush VAMC, Indianapolis, IN; [3]VA Greater Los Angeles Healthcare System, Los Angeles, CA.*

Background: In prior communications we have demonstrated that the SULT1C2 gene can induce a state of ischemia preconditioning in the kidney by increasing state II/III mitochondria respiration and membrane potential. In other studies, we have found sulfotransferase 1C2 increases state II/III mitochondria respiration when added to purified mitochondria. Thin layer chromatography studies demonstrated that sulfotransferase 1C2 converts mitochondria membrane cholesterol to cholesterol sulfate. Furthermore, adding cholesterol sulfate to purified mitochondria recapitulates the effect sulfotransferase 1C2 has on mitochondria function.

Methods: To assess the substrate specificity of carbon source utilization in S3 proximal tubule cells, we measure reduction rates of tetrazolian red in response to a supply of a single source of substrates. These studies were performed in permeabilized S3 cells with baseline measurements or following treatment with sulfotransferase 1C2 or cholesterol sulfate. OD_{560} was measured every 5 minutes for 12 hours at 37° C. The maximum rate of change in OD per minute was calculated from the colormetric assay.

Results: Both cholesterol sulfate or sulfotransferase 1C2 triple maximum reduction rates of tetrazolian red in response to the following substrates; cis-aconitic acid, α-keto-glutarate, succinate, fumarate, α-keto-butyrate, glutamate, glutamine, and pyruvate with 100 μM malic acid ($p \leq 0.001$ for all reactions) (See accompanying graph).

Conclusions: This data demonstrates that sulfotransferase 1C2 and its mitochondria product, cholesterol-SO4 increase substrate utilization rates of tricarboxylic acid intermediates in immortalized S3 proximal tubule cells. The results show that sulfotransferase 1C2 has a novel role in cellular control of mitochondria physiology.

Cyclophilin D Interacts with PPARα to Regulate Fatty Acid Oxidation in Cisplatin AKI

Hee-Seong Jang,[1] Mira Noh,[1] Babu J. Padanilam.[1,2] *[1]Cellular and Integrative Physiology, University of Nebraska Medical Center, Omaha, NE; [2]Internal Medicine, Section of Nephrology, University of Nebraska Medical Center, Omaha, NE.*

Background: Regardless of the etiology, acute kidney injury (AKI) involves aspects of mitochondrial dysfunction and ATP depletion. Fatty acid oxidation (FAO) is the preferred energy source of the kidney and is inhibited during AKI. A pivotal role for the mitochondrial matrix protein, cyclophilin D (CypD) in regulating overall cell metabolism is being unraveled. We hypothesize that mitochondrial interaction of proximal tubule CypD and PPARα modulate FAO in cisplatin-induced AKI (cisplatin AKI).

Methods: Using genetic and pharmacological intervention and protein-protein interaction studies, we investigated whether proximal tubule CypD modulates FAO in cisplatin AKI through mitochondrial CypD-PPARα binding and its sequestration.

Results: Cisplatin injury resulted in histological and functional damage in the kidney with downregulation of FAO genes and increase of intrarenal lipid accumulation. However, proximal tubule (PT)-specific deletion of CypD protected cisplatin-induced renal damage by inhibiting impairment of FAO and intrarenal lipid accumulation. Immunoprecipitation and BioID methods demonstrated mitochondrial translocation of PPARα and its binding to CypD and sequestration. This led to inhibition of nuclear translocation of PPARα and transcription of PPARα-regulated FAO genes during cisplatin AKI. Genetic or pharmacological inhibition of CypD suppressed mitochondrial CypD-PPARα binding in cisplatin AKI, preventing the impairment of FAO and intracellular lipid accumulation.

Conclusions: These results uncover a novel mechanism by which mitochondrial interaction between CypD and PPARα impairs FAO in cisplatin AKI. Targeting their interaction may be a potential therapeutic strategy to prevent energy depletion and cell death in AKI.

TH-PO031

The Role of Cyclophilin D in Acute vs. Chronic Aristolochic Acid Nephropathy

David J. Nikolic-Paterson,[1,2] Khai Gene Leong,[1,2] Elyce Ozols,[1,2] John Kanellis,[1,2] Frank Y. Ma.[1,2] *[1]Department of Nephrology, Monash Health, Clayton, VIC, Australia; [2]Centre for inflammatory diseases, Monash University, Clayton, VIC, Australia.*

Background: Cyclophilin D (CypD) facilitates mitochondrial-dependant cell death during pathological conditions. CypD-/- mice are protected from acute kidney injury (AKI) following ischaemia/reperfusion injury and show reduced renal fibrosis in the unilateral ureteric obstruction model. However, the contribution of CypD in aristolochic acid (AA) induced AKI or AA-induced chronic kidney disease (CKD) is unknown. We aim to determine the role of CypD in: 1) acute AA-induced nephropathy (AAN); and 2) chronic AAN.

Methods: Groups (n=10) of CypD-/- and wild type (WT) C57BL/6J mice were used. Study 1: Mice were given an intraperitoneal (IP) injection of 5mg/kg AA and killed 3 days later. Study 2: Mice were given IP injections of 2mg/kg AA every 2nd day and killed on day 28. Controls were untreated.

Results: Study 1: Acute high dose AA caused renal failure in WT mice (39.7±7.1mmol/L vs 13.5±2.3mmol/L serum creatinine (SCr) in controls; P<0.0001) with evidence of tubular damage and cell death on PAS sections and increased cleaved caspase-3+ cells. Acute AAN also caused inflammation with infiltrating neutrophils and T cells and up-regulation of IL-36a mRNA levels. CypD-/- mice were protected from AA-induced acute renal dysfunction (18.9±9.5 mmol/L SCr; P<0.0001 vs WT AAN). CypD-/- mice showed reduced tubular damage and cell death on PAS and reduced cleaved caspase-3+ cells (both P<0.001 vs WT AAN), as well as reduced neutrophil infiltration and IL-36α mRNA levels (both P<0.001 vs WT AAN). Study 2: Chronic AA administration caused renal impairment in WT mice (34.3±9.9mmol/L SCr), with evidence of chronic tubular damage (KIM-1 & a-Klotho mRNA levels), increase in tubular cell death (cleaved caspase-3+ cells), and significant renal fibrosis (increased collagen IV deposition). However, CypD-/- mice were not protected from chronic AA-induced renal dysfunction (37.0±14.3 mmol/L SCr; P=NS) and showed no reduction in tubular damage, cell death or renal fibrosis.

Conclusions: CypD contributes to tubular cell death and renal inflammation in acute AAN. However, CypD does not contribute to the transition of AKI to CKD in chronic AAN.

TH-PO032

Succinate Dehydrogenase Plays a Critical Role in Hypoxia/Reoxygenation-Induced Apoptosis in Renal Proximal Tubular Cells

Xujiao Chen, Ying Hu. *Department of Nephrology, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China.*

Background: Acute kidney injury (AKI) has become a worldwide public health problem because high risk of death and progression to chronic kidney disease. Renal ischemia-reperfusion (IR) injury is one of major causes of AKI. Many pathological factors and mechanisms are involved in I/R injury. Among them, overproduced reactive oxygen species (ROS) plays an important role in mitochondrial dysfunction and endoplasmic reticulum stress(ERS) which finally lead to the cell apoptosis. Succinate dehydrogenase (SDH) is an intermediate both of the mitochondrial citric acid cycle and electron cycle transport. Recent studies demonstrate that ischemia-related succinate accumulation followed by increased SDH activity after reperfusion as key drivers of ROS formation in heart and brain IR injury. But it is still unclear and controversial in kidney IR injury. We hypothesized that accumulated succinate during hypoxia and increase SDH activity during reoxygenation contribute to a large burst of ROS. Increased ROS levels induced mitochondrial damage and ERS which finally lead to cell apoptosis.

Methods: For hypoxia/reoxygenation, renal proximal tubular cells (RPTC) were cultured in hypoxic conditions for 4 hours followed by normoxic conditions for 2 hours. Succinate abundance, SDH activity were assessed by kits and mitochondrial ROS was assessed by confocal. Mitochondrial function and dynamics were assessed by measuring mitochondrial membrane potential(DY_m), ATP content, Mfn2/Drp1 expression and mitochondrial morphometry. ERS were assessed through IRE1a-XBP1, PERK-eIF2α and ATF6 pathways. Cell apoptosis were determined by TUNEL assay and Caspase-3 activity.

Results: Succinate accumulated during hypoxia and SDH activity increased after reoxygenation. ROS production significantly increased in response to H/R and induced downstream of mitochondrial dysfunction(DY_m and ATP content decreased) and mitochondrial fission(Mfn2 and mitochondrial morphometry decreased while Drp1 increased). ERS were also activated by ROS. Apoptosis ratio increased in response to H/R. Malonate can attenuates H/R-induced renal tubular epithelial cells injury through inhibiting SDH activity.

Conclusions: Inhibition of SDH activity can attenuate hypoxia/reoxygenation induced ROS overproduction, mitochondrial dysfunction, ERS and apoptosis in RPTC. Our findings provide a new perspective in treating renal ischemia-reperfusion injury.

GSK3β Regulates Toxic Nucleophosmin (NPM)-T^{95} Phosphorylation During Ischemic AKI

Zhiyong Wang,[1] Erdjan Salih,[2] Ramon G. Bonegio,[1] Andrea Havasi,[2] Chinaemere Igwebuike,[3] John H. Schwartz,[4] Steven C. Borkan.[1] *[1]Boston Medical Center, Boston, MA; [2]Boston University Medical Center, Boston, MA; [3]Boston Univerisity School of Medicine, Boston, MA; [4]Boston Medical Center-Evans Biomedical Center, Boston, MA.*

Background: GSK3β promotes regulated renal cell death partly by phosphorylating and activating Bax. Here, we document that GSK3β also phosphorylates and activates NPM, a key Bax chaperone, during ischemic renal injury *in vitro* and AKI *in vivo*. We hypothesize that: (1) antagonizing NPM phosphorylation is effective for ameliorating acute renal cell injury that contributes to organ failure during AKI and (2) phosphorylated NPM detects acute renal cell injury.

Methods: To determine the extent to which GSK3β mediates ischemia-induced NPM phosphorylation, constitutively active or inactive GSK3β mutant proteins were expressed in primary murine and human proximal tubule cells (PTEC). GSK3β was also subjected to pharmacologic inhibition by TDZD-8 or CRISPRi-mediated knockdown. GSK3β activity was estimated from steady state p-NPM-T^{95} content and correlated with intracellular NPM localization and cell survival.

Results: Transfection of primary PTEC with constitutively active, inactive or wild type GSK3β resulted in an expected increase in total GSK3β content compared with empty vector. In contrast, CRISPRi caused an 80% reduction in GSK3β expression. TDZD-8 decreased GSK3β kinase activity without affecting its content. Only active GSK3β promoted NPM T^{95} phosphorylation, NPM translocation from the nucleus to the cytosol and positively correlated with cell death during ischemia. Both TDZD-8 and CRISPRi–mediated GSK3β knockdown significantly reduced NPM T^{95} phosphorylation and cell death induced by constitutively active GSK3β. Furthermore, T^{95} NPM is detectable in both urine and cortical kidney homogenates harvested from humans and mice within hours after acute renal ischemia.

Conclusions: GSK3β promotes ischemia-induced renal cell death by phosphorylating an activating NPM, an essential partner for Bax during regulated cell death. Thus, manipulation of NPM phosphorylation is likely to be an effective therapeutic maneuver for ameliorating AKI and phosphorylated NPM is a novel marker of acute renal cell injury.

SIRT5 Alleviates Ischemia-Induced Mitochondrial Dysfunction in Human Proximal Tubular Epithelial Cells

Timo N. Haschler,[1] Harry Horsley,[1] Monika Balys,[4] Glenn W. Anderson,[4] Jan-Willem Taanman,[5] Robert J. Unwin,[2,3] Jill T. Norman.[1] *[1]Department of Renal Medicine, University College London, London, United Kingdom; [2]University College London Medical School, London, United Kingdom; [3]Early Clinical Development, Cardiovascular, Renal and Metabolism (CVRM), AstraZeneca Biopharmaceuticals, Gothenburg, Sweden; [4]Great Ormond Street Hospital for Children, London, United Kingdom; [5]UCL Queen Square Institute of Neurology, London, United Kingdom.*

Background: Acute kidney injury (AKI) is a major global health concern with a high mortality and poorly effective therapies. The most common cause of AKI is renal hypoperfusion, leading to ischemia/reperfusion injury (IRI). Mitochondria are highly dynamic organelles required for energy production that undergo constant fission and fusion to meet metabolic requirements. Accumulating evidence has identified excessive mitochondrial fragmentation causing mitochondrial dysfunction as a central pathologic feature of IRI. Recently, the mitochondrial NAD^+-dependent lysine-desuccinylase/demalonylase sirtuin 5 (SIRT5) has emerged as a key regulator of mitochondrial form and function, but its role in renal IRI is unknown.

Methods: Male C57Bl/6J mice underwent renal IRI or sham-surgery. Kidneys were screened for SIRT5 by immunohistochemistry. Human proximal tubular (PT) cells (HKC-8) were exposed to oxygen/nutrient-deprivation (OND; 1%O_2+HBSS), an *in vitro* model developed to mimic renal ischemia *in vivo*, and analysed by qPCR and Western blot (WB). A SIRT5 RNA interference (RNAi) strategy combined with OND was applied, followed by assessment of mitochondrial form and function using confocal/ transmission electron microscopy, ATP assay, Seahorse, FACS and WB.

Results: SIRT5 expression was increased in murine PTs after renal IRI and in HKC-8 cells exposed to OND. Knockdown of SIRT5 impaired glycolytic and mitochondrial ATP generation, reduced mitochondrial membrane potential and induced mitochondrial fragmentation. WB analysis of proteins involved in mitochondrial dynamics revealed that SIRT5 depletion disrupted the fission/fusion equilibrium by increasing pro-fission proteins (DRP1, DRP1-S616) and decreasing pro-fusion proteins (MFN1/2, OPA1), and that this effect was exacerbated by OND. Finally, combining the OND model with SIRT5 RNAi showed that SIRT5 reduced mitochondrial swelling and increased respiration (OXPHOS) to improve mitochondrial function in PT cells exposed to ischemia.

Conclusions: Our findings suggest SIRT5 is a central component of the endogenous stress response that alleviates ischemia-induced mitochondrial dysfunction in PTs and, therefore, may be a promising therapeutic target in AKI.

Effect of Calorie Restriction on Cisplatin-Induced Nephrotoxicity

Min Jung Kong,[2] Jisu Kim,[2] Jee in Kim,[1] Kwon Moo Park.[2] [1]*Keimyung University, Daegu, Republic of Korea;* [2]*Kyungpook National University, Daegu, Republic of Korea.*

Background: Calorie restriction is associated with the resistance of mitochondria against stresses. Although cisplatin is a widely used and very effective anticancer drug, its nephrotoxicity limits its use. Cisplatin nephrotoxicity is associated with its mitochondrial accumulation following oxidative stress induction, so here, we investigated whether the control of food supply affects cisplatin nephrotoxicity.

Methods: C57BL6 male mice were subjected to a high-fat diet (HFD) supply, fasting, and refeeding after fasting. Afterwards, mice were administered with either cisplatin or 0.9% saline. Mitochondrial morphology and dynamics were evaluated by transmission electron microscope and mitochondrial fission and fusion regulating protein expression. ROS production and mitochondrial antioxidant enzymes were biochemically analyzed.

Results: Cisplatin increased blood urea nitrogen (BUN) concentration in mice. These increases were significantly greater in the HFD-feeding mice when compared with mice given a normal diet. In contrast, fasting and refeeding significantly reduced cisplatin-induced increase of BUN. Cisplatin increased mitochondrial reactive oxygen species (ROS) level, oxidative stress, and mitochondrial fragmentation in the kidney tubular cells. These increases were greatest in HFD feeding mice and least in fasting mice. After cisplatin injection, expression of Opa1, a mitochondria fusion protein, was most greatly decreased in HFD feeding mice and least in fasting mice. In contrast, expression of fis1, a mitochondria fission protein was highest in HFD feeding mice and lowest in fasting mice. In addition, the expression of peroxisome proliferator-activated receptor γ coactivator 1α (PGC-1α), a transcription coactivator for mitochondrial biogenesis, were most greatly decreased in the HFD feeding mouse kidneys.

Conclusions: These results indicate that fasting reduced cisplatin nephrotoxicity, whereas HFD feeding aggravated cisplatin nephrotoxicity, suggesting that the regulation of calorie restriction may be useful for the reduction of cisplatin nephrotoxicity.

Sirt3 Modulates Fatty Acid Oxidation and Attenuates Cisplatin-Induced AKI in Mice

Ming Li,[2] Canming Li,[1] Zengchun Ye,[1] Hui Peng,[1] Tan-qi Lou.[1] [1]*The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China;* [2]*Nephrology Department, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Acute kidney injury (AKI) induced by cisplatin is very common in the clinic. Fatty acid oxidative damage is an important mechanism of renal fibrosis. Sirt3 has been shown to alleviate AKI by improving mitochondrial function and was found to be involved in the regulation of fatty acid oxidation (FAO) in other disease models. However, it is not clear whether Sirt3 is involved in regulating FAO to improve the prognosis of AKI.

Methods: Male SV129 and Sirt3 knockout (KO) mice were administered a single intraperitoneal (i.p.) injection of cisplatin (20 mg/kg) with or without treatment with honokiol (5mg/kg/day). Additionally, cultured mouse renal tubule epithelial cells (mRTECs) were treated with cisplatin (5μmol/L). Then, FAO and renal injury were evaluated.

Results: Oil red O staining and free fatty acids(FFA) analysis of kidney tissues from WT cisplatin-treated mice showed fatty acid oxidative damage and extensive lipid deposition in the mice. Metabolomics analysis revealed decreased ATP production and the presence of disordered energy metabolism. Additionally, fatty acid accumulation induced the apoptosis of mRTECs. The expression of Sirt3 was decreased in mice with cisplatin-induced AKI compared to that in control mice. Sirt3 deletion aggravated FAO dysfunction, resulting in the increased apoptosis of kidney tissues and aggravated renal injury. The activation of Sirt3 by honokiol improved FAO and renal function and reduced fatty acid deposition. In vivo and in vitro experiments confirmed that Sirt3 regulates fatty acid oxidation by deacetylating LKB1 and activating AMPK. In addition, Sirt3 increased ATP production and reduced ROS and lipid peroxidation by improving mitochondrial function.

Conclusions: These findings indicated that activated Sirt3 could protect against cisplatin-induced acute kidney injury, possibly by improving FAO and mitochondrial function, and that improving FAO in AKI may be a potential therapeutic strategy in the future.

TH-PO037

Sirtuin 3 Suppresses Ferroptosis in Cisplatin-Induced AKI

Canming Li, Zengchun Ye, Ming Li, Hui Peng, Tan-qi Lou. *The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Sirtuin 3 (SIRT3) is a mitochondrial deacetylase that protects against acute kidney injury (AKI) by mitigating renal oxidative stress. Ferroptosis, a recently characterized form of regulated cell death triggered by massive lipid peroxidation, is known to play a critical role in the pathogenesis of AKI. However, the role of SIRT3 in regulating ferroptosis in cisplatin-induced AKI (Cis-AKI) is unclear. Therefore, we aim to determine whether SIRT3 protects kidney function by restraining ferroptosis in Cis-AKI.

Methods: Male 129 wild type (WT) and SIRT3 knockout (KO) mice received cisplatin by a single intraperitoneal injection with or without Fer-1 (a ferroptosis inhibitor) and honokiol (a SIRT3 activator). AKI was determined by serum creatinine (Scr), blood urea nitrogen (BUN), and tubular damage on PAS staining 72h after cisplatin injection. Ferroptosis was assessed by multiple indicators, including the extent of lipid peroxidation (4-hydroxynonenal (4-HNE), malondialdehyde (MDA), and glutathione/oxidized glutathione (GSH/GSSG) ratio), and the level of glutathione peroxidase 4 (GPX4) and xCT. The expression of SIRT3 was detected by qPCR, western blot and immunohistochemistry. In addition, the status of p53 acetylation was evaluated by immunoprecipitation.

Results: Both WT and SIRT3 KO mice developed AKI after cisplatin injection. In response to cisplatin treatment, sirt3 expression levels were markedly decreased. In AKI groups, kidney function (Scr and BUN) and tubular damage extent on PAS staining were more severe when SIRT3 was missing. Ferroptosis indicators, including the increased levels of 4-HNE and MDA, the reduced ratio of GSH/GSSG, and the decreased expression of GPX4 and xCT, were also had more significant changes in SIRT3 KO mice than in the WT mice after cisplatin treatment. In contrast, honokiol protects against Cis-AKI as demonstrated by improved renal dysfunction, attenuated renal pathological changes, and decreased ferroptosis. In addition, Fer-1 exhibited protection against AKI in WT mice, but not in SIRT3 KO mice. Mechanistic studies demonstrated that cisplatin treatment induced p53 acetylation, and the acetylation of p53 in SIRT3 KO mice was more pronounced than in WT mice.

Conclusions: These data indicate that ferroptosis might be modulated by SIRT3 through p53 acetylation and suggest that ferroptosis is an important death mechanism in Cis-AKI.

TH-PO038

Impact of Mechanical Ventilation Time on Ferroptosis in Renal Ischemia-Reperfusion Injury in Rats

Fangfang Zhou,[1] Yi Yang,[2] Lianxin Luo,[1] Qun Luo.[1] [1]*Dept. of Nephrology, HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo City, China;* [2]*Zhejiang University, Hangzhou, China.*

Background: Prolonged mechanical ventilation was considered as a risk factor for acute kidney injury(AKI) in previous studies, while the underlying mechanisms remain unclear. Ferroptosis is a recently discovered form of programmed cell death that is characterized by iron-dependent accumulation of reactive oxygen species. The present study aimed to investigate the impact of mechanical ventilation (MV) time on ferroptosis in renal ischemia/reperfusion injury (IRI) in rats.

Methods: 32 Male-adult SD rats were divided into 4 groups: Group 1 (Sham operation); Group 2 (IRI: subjected to 45-min bilateral renal ischemia); Group 3 (IRI and underwent MV 4hours); Group 4 (IRI and underwent prolonged MV (12hours)). At 12hours after IRI, animals were euthanized. Kidney function was evaluated by Scr. Morphological changes associated with kidney injury and ferroptosis were assessed by HE staining and electron microscopy. Central regulator of ferroptosis GPX4, GSH, the lipid peroxidation markers 4HNE and SOD2 were measured in kidney tissue by Western blot analysis. The level of inflammatory cytokine (TNF-α) was assessed in plasma by ELISA.

Results: Scr was significantly higher in Group 4 than in Groups 1, 2 ($P<0.01$). Scr also increased in Group 3 than Groups 1,2, but with no statistical significance ($P>0.05$). By HE staining, Group 4 showed the most severe morphological kidney damage, characterized by increased interstitial edema and tubular dilatation than Group 1,2,3. Plasma TNF-α increased with the prolonged MV time, and Group 4 showed the highest level, achieving statistical significance when compared to Group 1 ($P<0.05$). In kidney tissue, protein expressions of GPX4, GSH and SOD2 progressively decreased from Groups 1 to 4, and Group 4 showed the lowest level, achieving statistical significance(GPX4 and GSH, $P<0.05$; SOD2, $P<0.01$). Protein expressions of 4HNE progressively increased from groups 1 to 4, and Group 4 showed the highest level, achieving statistical significance($P<0.05$). Electron microscopy also revealed abnormal mitochondrial morphology of ferroptosis in Group 4, which is characterized by the presence of smaller mitochondria and reuced/absent cristae.

Conclusions: Our present data showing that prolonged MV time may worsen kidney injury by ferroptosis, which is linked to the GPX4-GSH system, following lipid peroxidation. It may be mediated by stimulated inflammation.

TH-PO039

Myeloid Ferritin Heavy Chain Protects Against Ferroptosis in Ischemic AKI

Laurence M. Black, Kayla R. Mccullough, Amie Traylor, Evan Boitet, Jeremie M. Lever, Stephanie Esman, Daryll R. Spangler, Abolfazl Zarjou, Alecia K. Gross, Subhashini Bolisetty. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Ferritin is classically involved in iron storage and metabolism and is made up of 24 subunits of two distinct types: light chain (FtL) and heavy chain (FtH). The latter confers ferroxidase activity, allowing for storage of iron in a safe, bioavailable form in the ferritin shell. Iron metabolism is in part regulated by myeloid cells. Furthermore, acute kidney injury (AKI) causes perturbations in iron metabolism, both highlighting the importance of studying the importance of FtH in preventing oxidative damage during AKI.

Methods: Previously characterized mice deficient in myeloid-FtH ($FtH^{LysM-/-}$) and their floxed controls ($FtH^{fl/fl}$) were subjected to bilateral renal ischemia-reperfusion injury (IR; 20 minutes). We measured renal function, inflammatory response, cell death, and cell proliferation on days 1 and 2 post-IR.

Results: Though $FtH^{LysM-/-}$ and $FtH^{fl/fl}$ mice both experienced a similar rise in serum creatinine levels ($FtH^{fl/fl}$1.6 ± 0.11 mg/dL; $FtH^{LysM-/-}$ 1.3 ± 0.12 mg/dL) and structural damage on day 1 following IR, renal function and damage in myeloid-FtH deficient

mice continued to worsen (2.4 ± 0.38 mg/dL), which subsequently results in mortality. Interestingly, $FtH^{LysM-/-}$ mice also had lesser polymorphonuclear (PMN), natural killer, B, and T cell density post-IR compared to floxed controls, as well as significantly exacerbated cell death ($p<0.0001$) as early as 1-day post-IR. Myeloid-FtH deficiency also was associated with reduced cell proliferation after IR. Due do perturbations observed in iron metabolism in $FtH^{LysM-/-}$ mice, we hypothesized that treatment with ferrostatin-1 (Fer-1), a potent ferroptosis inhibitor, would ameliorate injury in the absence of myeloid FtH. Here, we report significant protection from AKI by serum creatinine in $FtH^{LysM-/-}$ mice treated with Fer-1 (0.97± 0.29 mg/dL), compared to vehicle controls (2.05 ± 0.36 mg/dL).

Conclusions: Our findings demonstrate for the first time a crucial role for myeloid FtH in protecting against ferroptosis in renal IR. This study highlights the significance of controlling iron metabolism during injury for AKI resolution and prevention of disease.

Identification of Anti-Ferroptosis Drugs Functioning as Lipid Peroxyl Radical Scavengers and Its Protective Effect Against AKI

Eikan Mishima,[1] Takehiro Suzuki,[1] Sadayoshi Ito,[2] Takaaki Abe.[1] *[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Katta Hospital, Shiroishi, Japan.*

Background: Ferroptosis, a lipid oxidation-dependent cell death mediated by free radical reactions, is a therapeutic target because of its role in organ damages including acute kidney injury (AKI). Ferroptosis-causing radicals that are targeted by ferroptosis suppressors have not been unequivocally identified. Because certain cytochrome P450 (CYP) substrate drugs can prevent lipid peroxidation via obscure mechanisms, we evaluated their anti-ferroptotic potential and used them to identify ferroptosis-causing radicals.

Methods: We screened of CYP substrate compounds by a cell-based assay to identify drugs with anti-ferroptotic activity, and investigated the mechanism. Radical scavenging activity was evaluated using ESR-spin trapping methods and NBD-Pen, a lipid radical probe that we established. We evaluated the therapeutic potency of the drugs in mouse cisplatin-induced AKI models.

Results: We identified clinically-available various drugs and hormones with anti-ferroptotic properties including rifampicin, promethazine, omeprazole, indole-3-carbinol, carvedilol, propranolol, estradiol, and thyroid hormones. The anti-ferroptotic effects of the drugs were closely associated with the scavenging activity of lipid peroxyl radicals and not much related to interactions with other radicals. The elevated lipid peroxyl radical levels were associated with ferroptosis onset, and known ferroptosis suppressors such as ferrostatin-1 were also lipid peroxyl radical scavengers. The drugs showed anti-ferroptotic effect in various types of cells including tubular cell, podocyte, and renal fibroblast. Moreover, the drugs suppressed tissue lipid peroxidation and ameliorated cisplatin-induced renal injury.

Conclusions: The elevated lipid peroxyl radical would be a trigger for onset of ferroptosis, whereas lipid peroxyl radical scavenging drugs can control ferroptosis-related disorders including AKI.

TH-PO041

Asparaginyl Endopeptidase Deficiency Protects Against AKI via Inhibition of Tubular Ferroptosis

Chuanai Chen, Xiaoyue Tan, Dekun Wang, Yong Zhao, Yangyang Yu. *The School of Medicine, Nankai University, Tianjin, China.*

Background: Lysosomal endopeptidase AEP (Asparaginyl Endopeptidase) is required for the maintenance of normal kidney physiology and homeostasis; AEP knockout aggravates interstitial fibrosis in the mouse model of obstructive nephropathy. However, role and underlying mechanism of AEP in the acute kidney injury (AKI) is unclear.

Methods: AKI was induced by bilateral ischemia–reperfusion of renal arteries or folic acid treatment in $AEP^{+/+}$ and $AEP^{-/-}$ mice. We assessed the indexes of renal tubular injury, inflammatory infiltration and programmed cell death. Tubular injury markers Kim-1 and NAGL was measured as well. *In vivo*, ferroptosis was evaluated via assessment of MDA, 4-HNE and degradation of GPX4. *In vitro*, we compared hypoxia- or erastin- induced ferroptosis in the primary tubular cells isolated from $AEP^{+/+}$ and $AEP^{-/-}$ mice. Supplement of FAC and downregulation of GPX4 were used to evaluate the role of AEP in hypoxia- or erastin- induced ferroptosis. Further, we analyzed the lysosomal degradation of GPX4. Coimmunoprecipitation was used to determine the interaction between AEP and GPX4. For tentative treatment, a synthetic AEP inhibitor RR-11a delivered by AEP-targeted nanoparticles was used in the IRI model.

Results: AEP deficiency attenuated IRI-induced tubular injury, inflammation and programmed cell death compared with control. Ferroptosis, a regulated necrosis characterized with lethal lipid peroxidation was also inhibited in $AEP^{-/-}$ mice, manifested as decreased 4-HNE, MDA and degradation of GPX4. *In vitro*, ferroptosis induced either by hypoxia or by erastin was dampened in the primary $AEP^{-/-}$ tubular cells compared with $AEP^{+/+}$control. Supplement of FAC or downregulation of GPX4 rescued ferroptosis in $AEP^{-/-}$ *cells*. IP assay and immunofluorescence staining showed interaction between AEP and GPX4. Moreover, knockout of AEP prevented lysosomal degradation of GPX4. Administration of RR-11a-containing nanoparticles ameliorated renal injury induced by IRI.

Conclusions: Our data suggest that interaction of AEP and GPX4 contributes to the lysosomal degradation of GPX4, facilitating the process of ferroptosis. Therefore, Deficiency of AEP inhibits ferroptosis and attenuates IRI-induced AKI. Inhibition of AEP could be a potential strategy benefit for the treatment of AKI.

TH-PO042

Pretreatment with Roxadustat (FG-4592) Attenuates Folic Acid-Induced Kidney Injury by Decreasing Ferroptosis

Xue Li. *Department of Histology and Embryology, Shen yang, China.*

Background: Folic acid (FA)-induced kidney injury model is characterized by progressive tubular damage at early stage and interstitial fibrosis at later stage. Ferroptosis, has been thought to be one of the main causes for the acute kidney injury (AKI) by the iron-dependent accumulation of lipid peroxidation, therefore disrupting antioxidant defense system. FG-4592 is hypoxia inducible factor (HIF) prolyl hydroxylase inhibitor (HIF-PHI) often used for improving anemia in patients with chronic kidney disease (CKD) through activating HIF-1a. What is more, precondition HIF-1a can enhance antioxidant capacity and iron mobilization through Nuclear erythroid 2 related factor 2 (Nrf2) signaling. Nrf2 is a key transcriptional factor which regulates almost all genes that are associated with ferroptosis. Given its anti-oxidant roles, FG-4592 was introduced in this study as a preconditionor to see if it had effects on FA-induced AKI and the mechanism.

Methods: Mice were divided into 4 groups, control group(n=12);FG-4592 group(n=12) pretreatment with FG-4592 for 2 days, mice were sacrificed 2 days (n=6 per group) or14 days later(n=6 per group); FA(folic acid-induced kidney injury) group(n=12); FA + FG-4592 group(n=12). In FA and FA+FG-4592 groups, mice were sacrificed 2 days (n=6 per group) or14 days(n=6 per group) after folic acid injection. Renal function, renal morphology, MDA, 4-HNE, GSH, Fe, HIF-1a, Nrf2, GPX4, HO-1, SLC7A11, ferroportion, IL-1β,TNF-α,F4/80, Fn, colIV,vimentin were assessed.

Results: pretreatment with FG-4592 improved kidney injury and inflammation in FA-induced kidney at early stage by upregulating antioxidant enzyme (GPX4 and HO-1) and GSH, meanwhile downregulating lipid peroxidation (MDA and 4-HNE) and iron. Furthermore, FG-4592 activated Nrf2 and upregulated antioxidant enzyme (GPX4 and HO-1), SLC7A11 (responsible for GSH synthesisthe) and ferroportin (an iron export protein), resulting in a reduction of ferroptosis. Further studies showed that Nrf2 was up-regulated by increased AKT and GSK-3βphosphorylation. Finally, pretreatment with FG-4592 ameliorated kidney fibrosis at later stage after FA-induced kidney injury.

Conclusions: pretreatment with FG-4592 plays an important role in the prevention of the transition from AKI to CKD through Nrf2-mediated anti-ferroptosis, and pretreatment with FG-4592 prevents FA-induced kidney injury partially via the AKT/GSK-3β-mediated Nrf2 activation.

TH-PO043

Effects of Paricalcitol on Ferroptosis in Cisplatin-Induced AKI

Zhaoxin Hu,[1] Wei Zhang,[2] Hao Zhang.[2] *[1]Central South University, Changsha, China; [2]The Third Xiangya Hospital, Central South University, Changsha, China, Changsha, China.*

Background: Ferroptosis is a newly defined form of non-apoptotic cell death characterized by the accumulation of iron-dependent membrane lipid peroxides. At present, ferroptosis is widely studied in rhabdomyolysis and ischemia/reperfusion-induced acute kidney injury (AKI), but the research on nephrotoxic AKI such as cisplatin is not deep enough. In this study, we explore whether ferroptosis occurs in cisplatin-induced AKI and the effect of paricalcitol on ferroptosis.

Methods: Twenty-five C57BL / 6 mice were randomly divided into control group, cisplatin + vehicle of Ferrostatin-1 (DMSO) group, cisplatin + Ferrostatin-1 (Fer-1) group, cisplatin + vehicle of paricalcitol (propylene glycol) group, cisplatin + paricalcitol group, 5 mice in each group. All drugs were injected intraperitoneally, and all mice were sacrificed 48 hours after cisplatin injection to collect serum and kidney tissue. The levels of serum creatinine and blood urea nitrogen were detected. The morphological changes of renal tubules were observed by HE staining. Cell death was observed and assessed by TUNEL fluorescence staining. The mitochondrial morphology was observed under electron microscope. Western blot was used to detect the expression level of glutathione peroxidase 4 (GPX4) in tissues, and the expression of 4-hydroxynonenal (4HNE) in renal cortex was observed by immunohistochemistry.

Results: Compared with the normal control group, the levels of serum creatinine and blood urea nitrogen were significantly increased in the cisplatin + DMSO group and cisplatin + propylene glycol group. At the same time, tubular damage and cell death were observed in the mouse tissues, the mitochondria volume was smaller and mitochondrial mites decrease or disappear, GPX4 expression decreases, and 4HNE expression increases in these two groups. Compared with the respective vehicle groups, the levels of serum creatinine and blood urea nitrogen were significantly lower in the cisplatin + Fer-1 group and the cisplatin + paricalcitol group, while renal tubular injury, cell death and mitochondrial morphological changes were significant relief, GPX4 expression was increased, and 4HNE expression was decreased.

Conclusions: Ferroptosis is involved in cisplatin-induced AKI. Paricalcitol inhibits ferroptosis by GPX4 to attenuate cisplatin-induced AKI.

Insights into the Pathophysiological Role of Gasdermin D: Assessment of Murine AKI and Human Biopsies

Wulf Tonnus,[2,1] Andreas Linkermann.[3] AG Linkermann *[1]Clinic for Internal Medicine III, Universtitätsklinikum Carl Gustav Carus Dresden, Dresden, Germany; [2]Faculty of Medicine, Technische Universität Dresden, Dresden, Germany; [3]University Hospital Carl Gustav Carus Dresden, Dresden, Germany*.

Background: Regulated cell death (RCD) has been used synonymously to apoptosis for years; however, within the last decade it was discovered that necrotic cell death can be regulated as well. Some forms of RCD, namely necroptosis and ferroptosis, have been found to be critically involved in the pathogenesis of acute kidney injury (AKI) in vivo. Pyroptosis is another form of regulated necrosis, which depends on cleavage of Gasdermin D by inflammatory caspases, such as CASP-1 and CASP11. After cleavage, Gasdermin D N-terminal domains assemble and form pores in the cell membrane. As pyroptosis is highly immunogenic, we aimed to evaluate whether pyroptosis is involved in the pathogenesis of AKI.

Methods: We evaluated GSDMD-deficient mice in two commonly-used models of AKI: Ischemia-Reperfusion-injury (IRI) and Cisplatin-induced AKI. Additionally, we generated mice deficient for both necroptosis and pyroptosis (GSDMD-MLKL-dko mice) to test them in the same models. Furthermore, we stained human kidney biopsy samples immunohistochemically for cleaved GSDMD.

Results: We found GSDMD-deficient mice to be sensitive when AKI was induced by the chemotherapeutic agent cisplatin as assessed by serum markers of AKI (creatinin and urea) and histological damage 24h and 48h after cisplatin injection. In renal ischemia-reperfusion injury (IRI), and in contrast to the protective effects of necroptosis-deficiency or pharmacological ferroptosis inhibition, GSDMD-deficient mice were not protected in this model, but rather demonstrated slightly deteriorated functional values. Also, we evaluated our freshly-generated GSDMD-MLKL-dko mice in the above-mentioned models. The results have not been entirely read out by the time of abstract submission. Finally, we detected cleaved GSDMD in human biopsy samples; thus, demonstrating involvement of pyroptosis in human AKI for the first time.

Conclusions: In conclusion, the role played by Gasdermin D in AKI is unexpected: whereas inhibition of other forms of regualted necrosis is known to be beneficial, inhibition of pyroptosis increased kidney damage. This raises questions regarding the complex interplay between different forms of regulated necrosis in AKI.

Sodium Channel Alpha Subunit Deletion in the Endothelium Reduces Renal Ischemia-Reperfusion Injury

Jonatan Barrera-Chimal,[1] Antoine Tarjus,[3] Cecilia González,[1] Isabel Amador-Martinez,[1] Rebeca Lopez-Marure,[2] Frederic Jaisser.[3] *[1]Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México and Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico; [2]Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico; [3]INSERM, UMRS 1138, Team 1, Centre de Recherche des Cordeliers, Sorbonne University, Paris Descartes University, Paris, France*.

Background: The epithelial sodium channel (ENaC) has a well described role in epithelia, however its role in endothelial cells remains to be further characterized. It has been suggested that endothelial ENaC modulates endothelial cell stiffness and this in turns regulates nitric oxide (NO) synthesis through the endothelial nitric oxide synthase (eNOS). The physiological relevance of endothelial ENaC in pathological conditions where reduced NO bioavailability plays an essential role remains largely unexplored. Renal ischemia/reperfusion (IR) injury is characterized by vasoconstriction, sustained decrease in renal perfusion and reduced oxygen supply causing tubular and endothelial cell injury. The decline of kidney blood flow is partly explained by a reduction in NO bioavailability. ENaC regulation of eNOS activity might have an influence in ischemic AKI. We aimed to explore if endothelial ENaC deficiency has an impact on the severity of renal injury induced by IR.

Methods: Male mice with specific alpha ENaC subunit gene inactivation in the endothelium (endo-αENaC^{KO}, n=26) and control littermates (n=26) were subjected to bilateral renal ischemia of 22 min or sham surgery. Kidney tissue hypoxia was evaluated at 3 hours by pimonidazole staining in 5 mice of each group. After 24 hours of reperfusion, kidney function and tubular injury was evaluated. Human endothelial cells (HMEC-1) in culture were used to study eNOS activation state under ENaC inhibition with amiloride 1mM for 24 hours, as compared to control cells.

Results: In control littermates, renal ischemia induced an increase in plasma creatinine (2-fold) and urea (1.7-fold), augmented Kim-1(100-fold) and NGAL (40-fold) mRNA levels and produced severe tubular injury as quantified by the tubular injury score. The absence of endothelial alpha ENaC subunit ameliorated renal tubular injury ($p<0.05$) and renal dysfunction ($p<0.001$). Moreover, endo-αENaC^{KO} mice recovered faster from renal hypoxia after the ischemia episode as compared to littermates as shown by reduced pimonidazole staining. In HMEC-1 cells, pharmacological ENaC inhibition promoted eNOS coupling and activation.

Conclusions: Our data suggest an important role for endothelial αENaC in renal IR, through improving eNOS activation and kidney perfusion.

Inhibition of the VE-PTP Phosphatase Protects the Kidney from Ischemia-Reperfusion Injury

Yanyang Li,[1,2] Tuncer Onay,[1,2] Mohammed Javeed Ansari,[1,2] Susan E. Quaggin.[1,2] *[1]Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, CHICAGO, IL; [2]Division of Nephrology/Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL*.

Background: The endothelial angiopoietin (ANG)–Tie2 signaling pathway is required for vascular development and homeostasis. Dysregulation of ang-Tie2 pathway has been implicated in diseases including venous malformation, glaucoma, diabetic nephropathy, and acute kidney injury (AKI). The endothelial-specific phosphatase VE-PTP/PTPRB is a crucial negative regulator of Tie2 phosphorylation status. We have previously shown that inhibition of VE-PTP is a promising therapeutic target for diabetic kidney injury in mice, but its role in acute kidney injury has not been studied. Here we hypothesize that inhibition of VE-PTP will protect the kidney from AKI due to ischemia-reperfusion injury (IR-AKI).

Methods: A bitransgenic doxycycline-inducible system (Veptp$^{flox/flox}$, Rosa26-rtTA$^{+/+}$, tetO-Cre$^{Tg/+}$) was used to knockout the VE-PTP gene from the vasculature of mice at postnatal day 0 (VE-PTPiKO). 3 month-old male VE-PTPiKO and littermate control mice underwent bilateral renal ischemia reperfusion injury (IRI) or sham surgery. Serum creatinine was measured on day1, day3 and day7 after surgery by HPLC method. Data were analyzed using two-way ANOVA. Kidney and lung tissues were harvested on day 7 for histology (H&E, PAS), immunohistochemistry and RNA/protein analysis.

Results: Genetic deletion of VE-PTP robustly enhanced Tie2 phosphorylation in vasculature of lung tissue and kidney tissue *in vivo*. Western blot analysis showed VE-PTP protein levels were increased in kidneys post-IRI and following hypoxia-inducible factor stabilization. While serum Creatinine was elevated 1day post-IRI in control mice, this increase did not occur in VE-PTP iKO mice ($p=0.0055$). A corresponding increase in fibrogenic factor and FOXO1 target gene CTGF was observed in control mice compared to VE-PTPiKO mice.

Conclusions: In sum, our data identify VE-PTP as a promising therapeutic target for renal protection following IR-AKI.

Hypoxic Renal Tubular Epithelial Cell-Derived Exosomes Promoted Peritubular Endothelial Cell Proliferation via Transfer of Vascular Endothelial Growth Factor A in Ischemic Kidney Injury

Xin Zhong, Ye Feng, Zuolin Li, Tao-Tao Tang, Bi-Cheng Liu, Linli Lv. *Zhongda Hospital, Southeast university, Nanjing, China*.

Background: Acute kidney injury (AKI) is characterized by substantial injury of renal tubular epithelial cells (TECs) and peritubular capillaries(PTCs) rarefaction. Our previous studies revealed that increasing number of exosomes were secreted by hypoxic TECs during AKI. However, the effect of TECs exosomes on the injury and repair of the closely located PTCs remains unknown.

Methods: Ischemia-reperfusion (I/R) injury mice was established and sacrificed at Day 1, 3, 7. Tie2-GFP mice were treated with exosomes purified from hypoxia TECs labled with DII fluorescent via the renal parenchymainjection to track exosomes internalized by PTCs. *In vitro*, exosomes released by HK-2 were applied to HUVEC or a transwell co-culture system was conducted. Exosome secretion was inhibited by knockdown of Rab27a *in vivo* through lentiviral shRNA administration in I/R mice.

Results: Histologically, tubulointerstitial inflamation and microvascular rarefaction were observed in I/R treated kidneys at Day 3, 7. Tubular injury marker KIM-1, and kidney VCAM-1, ICAM-1 mRNA was induced significantly compared to sham mice. Increasing proliferation of TECs and PTCs were observed by PCNA staining. TEM and NTA showed typical morphology and size of exosome structures purified from TECs. WB showed the expression of exosome markers, Alix and CD63. I*n vivo*, DII labeled TECs exosomes were readily detected in glomerular and PTCs in Tie2-GFR mice. Besides, Knockdown of Rab27a reduced PTCs proliferation and aggravated PTC rarefaction after ischemic injury. *In vitro*, uptake of exosomes from hypoxia-treated TECs markedly enhance endothelial cell proliferation. Interestingly, VEGFA was significantly up-regulated in both cellular and exosomes fractions of TECs under hypoxic conditions. Exosomes from HK-2 cells with VEGFA siRNA attenuated cell proliferation induced by exosomes in HUVECs. Transwell co-culture study showed that exosomes travel through membrane and were internalized by HUVEC. Importantly, flow cytometry showed that internalization of exosomes significantly decreased when VEGFR was knock down in Endothelial cells.

Conclusions: Increasing release of exosomes from hypoxia TECs promoted PTCs proliferation via transfer of VEGFA, which may represent a novel protective response through which to ameliorate PTC rarefaction in AKI.

TH-PO048

A Powerful Anti-Angiogenic Activity in Extracellular Vesicles Isolated from Kidney Endothelial Cells

Sarvesh Chelvanambi, Mervin C. Yoder, Matthias Clauss, David P. Basile. *Indiana University School of Medicine, Indianapolis, IN*.

Background: Acute kidney injury and chronic kidney disease are associated with capillary rarefaction, which promotes hypoxia and hastens renal fibrosis. The lack of renal vascular repair following injury is not clearly understood. We hypothesized that kidney

endothelial cells have intrinsic signaling properties that impair growth and angiogenesis, thereby contributing to poor vascular repair.

Methods: Rat or mouse primary kidney endothelial cells (rKEC or mKEC) were isolated using Dynabeads conjugated to CD45 (negative selection) and CD31 (positive selection) antibodies. Cells were grown in EGM2 (Lonza) on collagen-coated plastic to evaluate growth rates (MTT) or placed on Matrigel to quantify branching capacity.

Results: Previous studies demonstrated that rKEC grew slower than rat pulmonary EC (rPEC). rKEC consistently grew slower (<5% increase in cell number between day 1-4) than EC from brain, spleen or aorta (~60-100%, $p<0.01$ vs KEC). rKEC could not form branching structures on matrigel, but integrated into networks formed by rPEC when plated at a 1:100 ratio (KEC to PEC). Increasing ratios of rKEC:rPEC lead to a decline in branch formation with no rPEC branches at a ratio of 50:50. Co-culture of rKEC also inhibited branching of rat brain and aortic EC and human cord blood derived endothelial colony forming cells (ECFC), while EC from other tissues did not convey similar inhibitory activity. Increasing rKEC proliferation with hTERT overexpression did not attenuate rKEC's ability to disrupt branch formation of ECFC. We hypothesized that KEC secrete an anti-angiogenic factor which may impair cell growth. Conditioned media (CM) isolated from rKEC reduced growth of the highly proliferative human ECFC by ~ 40% ($p<0.001$). Similarly, CM isolated from primary mouse KEC decreased ECFC growth by ~50% ($p<0.001$). CM isolated from mouse heart or lung EC did not contain inhibitory activity. Specifically, only the extracellular vesicle (EV) fraction isolated from mKEC inhibited growth (40% decrease, $p<0.001$), while the EV depleted supernatant had no effect on ECFC proliferation.

Conclusions: Kidney endothelial cells possess an anti-angiogenic activity that is not observed in EC from other tissues. EV secreted from KEC may contain anti-angiogenic cargo that slow EC growth in vitro. Such activity may underlie impaired renal vascular repair following injury.

TH-PO049

PAC-Mediated AKI Protection Is Critically Mediated but Does Not Exclusively Depend on Cell-Derived Microvesicles

Daniel Patschan. *Innere Medizin 1 - Kardiologie, Angiologie, Nephrologie, Medizinische Hochschule Brandenburg, Brandenburg, Germany.*

Background: Acute Kidney Injury (AKI) significantly worsens the prognosis of hospitalized patients. In recent years, cell-based strategies have been established as reliable option for improving AKI outcomes in experimental AKI. Own studies focused on so-called Proangiogenic Cells (PACs). Mechanisms that contribute to PAC-mediated AKI protection include production / secretion of extracellular vesicles (EV). In addition, the cells most likely act by paracrinic processes (secretome). The current study evaluated whether AKI may be preventable by the administration of either PAC-derived EV and / or the secretome alone.

Methods: AKI was induced in male C57/Bl6N mice (8-12 weeks) by bilateral renal ischemia (IRI - 40 minutes). Syngeneic murine PACs were stimulated with either melatonine, Angiopoietin-1 or -2, or with Bone Morphogenetic Protein-5 (BMP-5) for one hour, respectively. The four mediators were chosen since previous own studies showed improved PAC-mediated AKI protection after cell preconditioning with these substances. PAC-derived EV and the vesicle-depleted supernatant were subsequently collected and i.v. injected post-ischemia. Mice were analyzed 48 hours later.

Results: IRI induced significant kidney excretory dysfunction as reflected by higher serum cystatin C levels. The only measure that improved AKI was the injection of EV, collected from native PACs. The following conditions worsened post-ischemic renal function even further: EV+Ang-1, EV+BMP-5, EV+melatonin, and EV+secretome+Ang-1.

Conclusions: Together, our data show that PAC-mediated AKI protection substantially depends on the availability of cell-derived EV. The secretome, either collected from native or preconditioned cells does not prevent mice from ischemia-induced dysfunction. However, since previous data showed improved AKI-protection by PACs after cell preconditioning with certain mediators (Ang-1 and -2, melatonine, BMP-5), other than exclusively vesicle-dependent mechanisms must be involved in PAC-mediated AKI protection. We suggest, that the mere presence of intact cells in the post-ischemic tissue is necessary for improving functional and structural outcome parameters under certain conditions.

TH-PO050

Microparticles Released in Response to Oxidative Stress from the Renal Epithelium Carry Active Neprilysin

Begoña Campos,[1] Sabrina I. Bernardo,[1] Nicholas A. Heuker,[1] Samuel P. Bockhorst,[2] Charuhas V. Thakar.[1,3] *[1]University of Cincinnati, Cincinnati, OH; [2]University of Louisville School of Medicine, Loveland, OH; [3]Renal Section, Cincinnati VAMC, Cincinnati, OH.*

Background: Acute kidney injury (AKI) is associated with significant morbidity, including remote organ dysfunction. In response to stress, cells release phenotypically and quantitatively distinct microparticles (MP). MP are microvesicles (1000 nm) derived from several cell types and released in response to stress or injury. Neprilysin (CD10), is a membrane-bound zinc activated endopeptidase, richly expressed in the renal proximal tubular epithelial cell (RPTEC) brush border. Neprilysin catalyzes the degradation of endogenous vasodilator/natriuretic peptides suggesting that its physiological action modulates the hemodynamic balance. Whether MP containing neprilysin released by renal epithelium can be mediators of biological activity is not known.

Methods: Human RPTEC immortalized cell line was used. Cells were exposed to 0.03 molar H_2O_2 for 1 hour and compared to controls in 3 or more different sets of experiments. We evaluated the levels of neprilysin using an ELISA assay and enzymatic activity with a fluorometric assay. Human samples (citrated plasma) were tested for the presence of biologically activity (Neprilysin levels and peptidase assay) derived from prospectively collected samples in AKI cases and controls.

Results: We have shown that neprilysin is present in RPTEC using immunofluorescence. We also reported that under conditions of oxidative stress the level of released MP is significantly different when compared to controls. To evaluate if the released MP are biologically active, we assessed the protease activity characteristic of neprilysin. The results showed that the maximal activity of neprilysin was in healthy cells and was 5-fold lower after treatment with oxidative stress. We then evaluated the protease activity in MP released from RPTEC under the same conditions. Our results showed that the peptidase activity was present and the activity correlated directly with the protein concentration. In a pilot of 30 cases and controls of AKI, we were able to measure the levels of plasma neprilysin using the ELISA assay as well as the confirm the peptidase activity in the MP derived from human samples.

Conclusions: The release of Neprilysin in microparticles derived from renal tubular epithelial cells are functionally active, and could serve as a biological link between epithelium and micro-vasculature

Long-Term Outcome of Biopsy-Proven Cholesterol Crystal Embolism

Naoya Toriu,[2,1] Keiichi Sumida,[3] Hiroki Mizuno,[2] Masayuki Yamanouchi,[4] Junichi Hoshino,[2] Yoshifumi Ubara.[2] *[1]Kyoto university, Kyoto, Japan; [2]Toranomon Hospital, Tokyo, Japan; [3]University of Tennessee Health Science Center, Memphis, TN; [4]Okinaka Memorial Institute for Medical Research, Tokyo, Japan.*

Background: Cholesterol crystal embolism (CCE) causes renal damage, and there is an extremely high risk of end-stage renal disease. However, the time course of CCE-related renal deterioration varies and little is known about the subsequent risk of dialysis among patients with biopsy-proven CCE.

Methods: We performed a retrospective cohort study of 38 Japanese patients in whom a histological diagnosis of CCE was made from September 1992 to July 2005. Competing risk regression analysis was used to investigate the association between declining renal function (≥ 1.5-fold elevation of serum creatinine within 26 weeks after CCE) or its subtypes (acute [<1 week after CCE], subacute [1 to <6 weeks], and chronic [6 to <26 weeks]) and the risk of dialysis, with adjustment for age, baseline serum creatinine, and the precipitating event.

Results: During a median follow-up period of 25.9 weeks, 14 patients (35.9%) started dialysis. Multivariable analysis showed that patients with declining renal function had a higher risk of commencing dialysis than those without declining function (subdistribution hazard ratio [SHR]: 9.47; 95% confidence interval [CI]: 1.34-66.8). Patients with different renal presentations had a similarly increased risk of commencing dialysis, with the risk being significantly higher for the subacute and chronic patterns of declining renal function (adjusted SHR [95% CI] for acute, subacute, and chronic declining renal function[vs. no decline]: 7.36 [0.85-63.6], 11.9 [1.36-101], and 10.7 [1.49-77.0], respectively).

Conclusions: Declining renal function after CCE, even later than 6 weeks, was significantly associated with the subsequent risk of dialysis.

TH-PO052

Urinary Neutrophil Gelatinase Associated Lipocalin Is Elevated in Neonates Who Develop AKI After General Surgical Procedures

Cara L. Slagle, Kelli A. Krallman, Brenda Poindexter, Alexandra Schmerge, Bradley S. Gerhardt, Melinda Tepe, Meera Kotagal, Alexander Bondoc, Stuart Goldstein. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Acute Kidney Injury (AKI) occurs commonly in critically ill neonates after surgery. AKI diagnosis by serum creatinine and urine output has significant limitations in this population. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) has been shown to predict AKI in many pediatric cohorts, but no study has assessed uNGAL performance to predict AKI in neonates after general surgical intervention.

Methods: Infants undergoing a surgical procedure were prospectively enrolled in this observational study. Urine was obtained pre-operatively and at 12, 24, 36, 48, 72 and 96 hours post-operatively. uNGAL was measured by The uNGAL Test™ (BioPorto, Denmark). AKI was defined by 2014 modified Kidney Disease Improving Outcomes (KDIGO) criteria. Mann-Whitney U tests were performed compare uNGAL levels of AKI and non-AKI groups.

Results: A total of 61 neonates had 70 surgical procedures at an average corrected gestational age of 41 weeks (*SD* ±8 weeks). AKI occurred in 18 (25%) patients. uNGAL levels above the published normative values occurred after 41 (58%) procedures - in 13 (72%) patients with AKI and in 28 (54%) patients without AKI. Post-op uNGAL values were elevated in infants with AKI with peak uNGAL values most commonly occurred approximately 48 hours after surgical intervention. (Table 1). The AUC-ROC for uNGAL to predict AKI at 48 hours was 0.74 (0.61-0.88).

Conclusions: Elevation of uNGAL occurs at 36-72 hours post-operatively in neonates who develop AKI after general surgical procedures. A substantial proportion of non-AKI patients had elevated uNGAL levels suggesting potential sub-clinical renal insult and this relationship should further be explored. Few patients were premature, however given that normative uNGAL values vary with gestational age, we intend to examine this relationship in the future.

Funding: Private Foundation Support

Table 1 – Median [IQR] uNGAL levels in patients with vs. without AKI after surgery

	12 hour uNGAL	24 hour uNGAL	36 hour uNGAL	48 hour uNGAL	72 hour uNGAL	96 hour uNGAL	Mean uNGAL for all timepoints	Peak uNGAL

Fibroblast Growth Factor 23, a Novel Biomarker for AKI in Patients with Acute Decompensated Heart Failure

Nattha Pramong,[1] Pongsathorn Gojaseni,[1] Sarunyoo Suttipongkeat,[1] Kraiwiporn Kiattisunthorn,[2] Anutra Chittinandana.[1] *[1]Bhumibol Adulyadej hospital, Bangkok, Thailand; [2]Siriraj Medical School, Mahidol University, Bangkok-noi, Thailand.*

Background: Acute kidney injury (AKI) in acute decompensated heart failure (ADHF) is associated with poor prognosis. Recent evidences have proved that early rising of plasma Fibroblast Growth Factor 23 (FGF23) can predict AKI and adverse events in patients undergoing cardiac surgery and critically ill patients, but it remains unknown in ADHF patients. This study aimed to investigate the prognostic value of plasma FGF23 for predicting the occurrence of AKI.

Methods: A single center cohort study is performed in patients admitted for ADHF in Bhumibol Adulyadej hospital. Plasma c-terminal FGF23 (c-FGF23) was measured 2 times at baseline and 24 hours later after diagnosing ADHF. Serum creatinine was measured every other day or more frequently as appropriate according to general treating standards and AKI was assessed and defined using KDIGO criteria.

Results: The study enrolled 62 patients diagnosed with ADHF. The incidence of AKI is 45% and significantly increased risk of death. Patients who developed AKI had significantly higher levels of plasma c-FGF23 at baseline in comparison with AKI-free patients (median value 1,258.5 Ru/mL vs. 230.2 Ru/ml, p = 0.005). During the first 24 hours, plasma c-FGF23 levels in AKI-free group decreased more than AKI group, but the difference is not statistically significant. ROC analysis of both first time and second time of plasma c-FGF23 collecting yielded an AUC of 0.71 for prediction of AKI incident. With the cut-off point at 450 RU/ml, the sensitivity and specificity of plasma c-FGF23 at baseline for predicting AKI were 71.4% and 61.8% respectively.

Conclusions: Plasma c-FGF23 may serve as a novel biomarker for incident of AKI in patients with acute decompensated heart failure which should be measured immediately or within 24 hours after diagnosing ADHF.

Funding: Government Support - Non-U.S.

Serum Cystatin C on Admission: A Potential Predictor for Hospital-Acquired AKI in Patients with an Acute Exacerbation of Chronic Obstructive Pulmonary Disease

Dawei Chen. *Nanjing First Hospital, Nanging, China.*

Background: Hospital-acquired acute kidney injury (HA-AKI) was associated with poor prognosis. In this study, we performed to determine whether serum Cystatin C on admission could predict AKI in patients with acute exacerbations of chronic obstructive pulmonary disease (AECOPD).

Methods: This study was conducted from January 2014 to January 2017, and data from adult inpatients with AECOPD were analyzed retrospectively. A total of 1035 patients were included, 79 patients were identified with HA-AKI. Univariate and multivariate logistic regression analyses were used for investigating the predictors for HA-AKI in patients with AECOPD.

Results: Prevalence of HA-AKI was 7.6%. HA-AKI was also associated with poor prognosis, and was an independent risk factor for inpatient mortality for patients with AECOPD. Compared with patients without AKI, age, and the level of urea, Cystatin C, and platelet count on admission were four independent factors for HA-AKI in patients with AECOPD. Cystatin C (OR, 5.22; 95% CI, 2.49-10.95; $P < 0.001$) was the independent and significant predictor for AKI in patients with AECOPD. HA-AKI in patients with AECOPD could be identified with a sensitivity of 73.5% at specificity of 75.9% (AUC = 0.803, 95% CI 0.747 - 0.859) by Cystatin C (cut-off value = 1.3 mg/L). In addition, HA-AKI in patients with AECOPD could be identified with a sensitivity of 75.9% at specificity of 82.0% (AUC = 0.853, 95% CI 0.810 - 0.896) by the model.

Conclusions: Serum Cystatin C on admission may be adopted to predict the potential risk of HA-AKI in patients with AECOPD.

TH-PO055

Urinary Activin A: A Novel Biomarker for Monitoring the Severity of AKI

Izumi Nagayama, Akito Maeshima, Daisuke Nagata. *Jichi Medical University, Shimotsuke, Japan.*

Background: Acute kidney injury (AKI) is a common but complex condition that is associated with increased morbidity and mortality. There is a need for biomarkers to predict AKI development and severity in critically ill patients. We previously reported that activin A, a member of the TGF-beta superfamily, which was absent in normal kidney, was increased in the ischemic rat kidney and negatively regulates the repair process of the kidney after injury (Maeshima et al. J Am Soc Nephrol 2001). However, the dynamics and significance of urinary activin A have not been clarified in humans. To address this issue, we examined whether urinary activin A can be detectable in human AKI and may serve as a biomarker to predict AKI development and severity.

Methods: Thirty three patients with AKI (renal AKI 22, pre-renal AKI 11) were enrolled in this study approved by the institutional review board of the Jichi Medical University Hospital (Approved number A18-081, A18-089). Written informed consent was obtained from all participants. The Kidney Disease Improving Global Outcomes (KDIGO) classification was used to diagnose and classify patients developing AKI. Serum and urinary activin A was measured by ELISA. Correlations of urinary activin A with other clinical parameters were analyzed.

Results: Urinary activin A, which was almost undetectable in pre-renal AKI, was significantly increased in renal AKI (6.0 ± 3.17 vs. 204.8 ± 96.6 pg/mL, $p<0.05$). Urinary activin A level in patients with AKI stage III was significantly higher than that in patients with AKI stage I + II (199.4 ± 102.8 vs. 32.8 ± 16.3 pg/mL, $p<0.05$). There was a significant correlation of urinary activin A level with urinary NGAL, NAG, and alpha-1 microglobulin, but not with L-FABP, urinary protein, serum creatinine, and serum activin A. In one patient with drug-induced AKI who recovered renal function to normal, urinary activin A rapidly decreased before the normalization of serum creatinine, NGAL and L-FABP. In other patient with AKI due to contrast nephropathy, who did not recover renal function, urinary activin A remained at high level at 1 month after the initiation of hemodialysis therapy.

Conclusions: Urinary activin A can be detected in human with AKI and might be a useful and non-invasive biomarker for monitoring the severity of AKI.

Description of [TIMP-2] [IGFBP7] Significative Values at 72 Hours After Cardiac Surgery for Predicting AKI

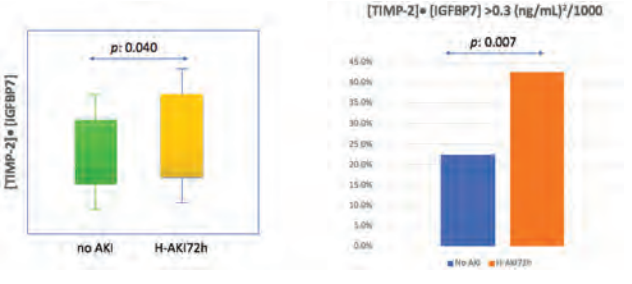
Lilia M. Rizo Topete,[1] Claudio Ronco,[2] Anna Lorenzin,[3] Fiorenza Ferrari,[4] Gregorio A. Romero.[5] *[1]Hospital Universitario, UANL, Monterrey, Mexico; [2]University of Padova, IRRIV, San Bortolo Hospital, Vicenza, Italy; [3]IRRIV, Vicenza, Italy; [4]I.R.C.C.S. policlinico San matteo, Pavia, Italy; [5]Hospital Universitario Basurto, Bilbao, Spain.*

Background: AKI is common in critically ill patients and has been identified as an independent mortality predictor. Multiple biomarkers has been discovered in order to improve tools for AKI diagnosis. The aim of this study was AKI within the first 72 hours after cardiac surgery. Secondary endpoints were severity of AKI within 72 h, need for RRT, length of stay in the UCI and death during the ICU stay in relation with [TIMP-2] [IGFBP7]

Methods: Observational, prospective study. Patients 18Y, with or without AKI who underwent cardiac surgery, June to December 2016. A statistical analysis was performed. Urine samples for measurement of [TIMP-2] [IGFBP7] were collected 4 h after ICU admission. High risk for AKI was defined as urinary [TIMP-2] [IGFBP7] 0.3 (ng/mL)2/1000.

Results: 383 patients, 77 (20.1%) developed AKI within 72 h. At baseline (pre-ICU) age was AKI group [67 (58 – 74) vs74 (70 – 78); p=<0.0001]. The diuretic use [122 (41.5%) vs 42 (56.8%); p= 0.026]. Vancomycin during the surgery was significantly higher in the AKI group [122 (41.4%) vs 42 (56.8%); p=0.026]. The prevalence at 72 h of ICU admission was 77 (20.1%) patients and the severity AKI 1 60 (15.7%) patients, AKI 2 11 (2.9%) patients and AKI 3 6 (1.6%) patients. In those patients with AKI within 72 hours and [TIMP-2][IGFBP7] >0.3 (ng/mL)2/1000 had higher significantly FB in the first 6h [2.05 ± 933.84 vs 252.97 ± 761.26; p=0.016]. Cardiac arrest [1 (0.3%) vs (6 (8.2%); p=<0.0001], reintervention during the ICU stay [6 (2%) versus 6 (8.2%); p=0.017], LOS in ICU [7 (6 – 10) vs 9 (7 – 15.5); p=<0.0001] and death [52 (17%) vs 23 (29.9%); p=0.015] were significantly higher in the AKI group.

Conclusions: In high risk patients, [TIMP-2][IGFBP7] should be considered together with other clinical parameters to predict AKI and adverse outcomes (Cardiac arrest, Length of stay and death).



Variable		NC Negative <=0.3	NC positive >0.3	p Value
FB within 6 hours of ICU admission (mL, mean ± SD)		2.05 ± 933.84	252.97 ± 761.26	0.016
Norepinephrine max dose ICU (µg/kg/min, mean ± SD)		0.007 ± 0.06	0.009 ± 0.04	0.015
MAP (mmHg, mean ± SD)		78.48 ± 13.78	75.27 ± 12.97	0.043
Maximum AKI stage in the first 72h (n, %)				0.037
	AKI 1	36 (13.1%)	24 (22%)	
	AKI 2	6 (2.2%)	5 (4.6%)	
	AKI 3	3 (1.1%)	3 (2.8%)	

Outcomes between NC positive (>0.3) and negative (<=0.3) first 72h

TH-PO057

Urinary TIMP2 and IGFBP7 as Early Biomarkers of Nephrotoxicity

Akalya K,[1] Horng-Ruey Chua,[2,3] Tanusya M. Murali,[3] Boon Wee Teo,[3,2] Sanmay Low.[4] *[1]National University Hospital, Singapore, Singapore, Singapore; [2]National University Health System, Singapore, Singapore; [3]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [4]National University Hospital System, Singapore, Singapore.*

Background: Elevated levels of urinary tissue inhibitor of metalloproteinases-2 (TIMP2) and insulin-like growth factor-binding protein 7 (IGFBP7) predate severe AKI by >12 hours in critical illness; these biomarkers may help predate and predict drug-induced acute kidney injury (DI-AKI).

Methods: Prospective study involving serial urine collection in hospitalized patients, during course of therapy with nephrotoxic drugs. Absolute and normalized (against urine creatinine) levels of TIMP2 and IGFBP7 were examined in days leading up to study endpoint: onset of AKI by KDIGO criteria, or final day of nephrotoxic drug therapy in non-AKI patients.

Results: Twenty-two of 135 patients developed DI-AKI (16%), including 8 patients with KDIGO stage 2/3 AKI. Urinary biomarker analyses were performed for 21 AKI patients with available pre-AKI samples, and 28 non-AKI matched-controls. They were aged 57(±14) and 52(±15) years with baseline eGFR of 102(92-116) and 103(89-118) mL/min/1.73m^2, respectively, with corresponding drug therapy duration of 15(14-25) versus 14(10-21) days (all p=NS). Comparing biomarker trends at 4–6 days, 2–3 days, and 1–2 days before study endpoint; significantly higher TIMP2 and IGFBP7 levels ($p<0.05$) were observed in the absolute(ng/mL), normalized (µg/mmol) and composite ((ng/mL)^2/1000) of these markers as early as 2-3 days prior to AKI onset. The respective absolute and normalized TIMP2 levels (2-3 days prior) in AKI versus non-AKI patients were 4.9 versus 2.2 (p=0.02) and 1.2 versus 0.6 (p=0.005); corresponding levels for absolute and normalized IGFBP7 were 12.9 versus 1.2 (p=0.005) and 1.9 versus 0.3 (p=0.01); absolute [TIMP2]*[IGFBP7] level was 0.07 versus 0.005(p=0.007). Highest absolute and normalized TIMP2 levels at 2–3 days pre-AKI predicts AKI with an average AUROC of 0.75 and 0.81 respectively; correspondingly the average AUROC for both IGFBP7 values was 0.73. [TIMP2] *[IGFBP7] was able to predict AKI with 74% accuracy and the optimal biomarker cut-off level was determined to be 0.01(ng/mL) ^{2}/1000.

Conclusions: Elevated urinary TIMP2 or IGFBP7 predate and predict DI-AKI by 2–3 days during course of nephrotoxic drug therapy in hospitalized patients.

Time of Surgery Is Associated with Greater Increase in Urinary KIM-1 in Patients with Major Elective Abdominal Nonvascular Surgery-Associated AKI

Graziela R. de Souza. *Clinical, São Paulo University, São Paulo, Brazil.*

Background: Acute kidney injury (AKI) is a complex syndrome that occurs in a wide variety of surgical situations, and has been associated with the surgery time (ST). The aim of this study is to assess if the ST in patients (pts) developing AKI after major elective abdominal non-vascular surgeries (MEANVS) is associated with the intensity of urinary biomarkers (uBM) changes after surgery.

Methods: We studied a prospective cohort of MEANVS pts, which did the post-operatory (post-op) period in intensive care units (ICU) in a university hospital. AKI diagnosis was made by serum creatinine (SCr) or urinary output (UO) KDIGO criteria. SCr was analyzed in pre-operatory time, ICU admission and daily up to 7 days or ICU discharge. UO was evaluated hourly (mL/kg/h) trough 24 h every day. The uBMs (NGAL, KIM-1 and Nephrochek - NC) were analyzed in the immediate post-op (time 0, ICU admission) and 12 h after ICU admission. Diagnosis of chronic kidney disease stages IV/ V, nephrotoxic drugs use before surgery and ICU stay < 48 h were exclusion criteria. Statistical significance was $p < 0.05$.

Results: The sample was composed by 297 pts ≥ 18 y old. The most frequent surgeries were hepatectomy and gastrectomy. Among the 297 pts, 197 (66.3%) developed AKI, mostly KDIGO stage 1 (60% of 197). Using SCr criteria 71 pts were diagnosed, while the UO criteria diagnosed 126 pts (62 pts has simultaneous SCr and UO changes). Eight pts (2.6%) needed hemodialysis. Mortality in AKI pts was 9.1% and without AKI 1.9%, p = 0.0149. Among pts developing AKI 53.3% had ST ≥ 300 min. The values of all uBMs were similar at time 0, independently of the ST. At 12 h KIM-1 values were significantly higher em pts with ST ≥ 300 min as compared to < 300 min: 2.42 vs 1.62 ng/mL, p = 0.011. The values of NGAL and NC were higher at 12h in the ST ≥ 300 group, but did not reached statistical significance: 214 vs 147 ng/mL for NGAL, p = 0.387 and 18.9 vs 14.6 ng/mL, p = 0.223, for NC.

Conclusions: In conclusion, longer ST was associated with increased KIM-1 in MEANVS-associated AKI pts, suggesting an occurrence of more severe tubular injury.

Hemoglobin Is a Strong and Independent Predictor of Major Adverse Kidney Events

Samuel Short,[1] Subhash Chander,[1] Sushrut S. Waikar,[1] Andrew S. Allegretti,[2] David E. Leaf.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Anemia is an established risk factor for acute kidney injury (AKI). However, most prior studies assessed anemia as a dichotomous variable, and were further limited by modest sample sizes, incomplete adjustment for confounders, and failure to account for dialysis and death as competing risks.

Methods: We performed a retrospective cohort study of patients who underwent cardiac surgery (CS) or were admitted to an ICU at two medical centers in Boston, MA, between 2005-2018. We excluded patients with ESRD and those who already had AKI. Our final cohort included 18,784 CS and 30,633 ICU patients. The primary exposure was the most proximal Hgb before surgery or ICU admission. The primary endpoint was any Major Adverse Kidney Event within 7 days (MAKE7) after CS or ICU admission. MAKE7 was defined as an increase of serum creatinine (SCr) ≥100%, dialysis, or death. We used multivariable logistic regression to adjust for potential confounders.

Results: The incidence of MAKE7 was 6% in the CS cohort and 14% in the ICU cohort. In both cohorts, we observed a monotonic increase in risk of MAKE7 with lower

Hgb values. Patients who underwent CS with a Hgb<9 vs. 12-15 g/dL had a 7.3-fold (95% CI, 5.7-9.4) higher risk of MAKE7 in a model adjusted for preoperative SCr, urgent/emergent surgery, and 11 additional key variables. Additionally, each 1 g/dL decrease in Hgb associated with a 1.6-fold higher risk of MAKE7 in adjusted models (95% CI, 1.5-1.7). ICU patients with a Hgb<6 vs. 12-15 g/dL had a 2.3-fold (95% CI, 1.9-2.9) higher risk of MAKE7 in a model adjusted for baseline SCr, sepsis, shock, mechanical ventilation, and 13 additional key variables.

Conclusions: Lower Hgb associates monotonically, independently, and strongly with higher risk of MAKE7 in patients undergoing CS and in those admitted to the ICU.

Red Blood Cell Distribution Width and Risk for Contrast-Induced AKI After Percutaneous Coronary Intervention

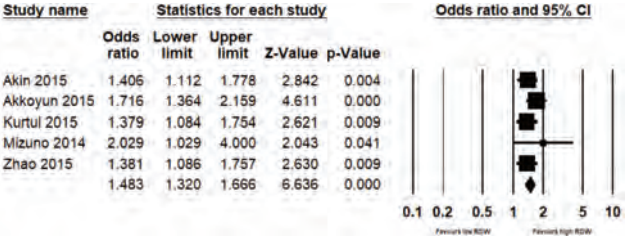
Takayuki Yamada,[1,3] Hiromichi Wakui,[3] Kouichi Tamura,[3] Alfred Burger,[1] Steven G. Coca.[2] *[1]Mount Sinai Beth Israel, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Yokohama City University, Yokohama, Japan.*

Background: Contrast-induced acute kidney injury (CI-AKI) is a major complication following percutaneous coronary intervention (PCI) and is associated with greater morbidity and mortality. Accumulating evidence suggests that inflammation and oxidative stress play an important role in the development of CI-AKI. Red blood cell distribution width (RDW) is a possible marker of oxidative stress and inflammation. In this study, we performed a systematic review and meta-analysis to investigate the association between RDW levels and CI-AKI after PCI.

Methods: We assessed clinical studies through Pubmed, Embase, and the Cochrane Library that investigated the association between RDW and a risk of CI-AKI in patients after PCI up to April 2019. The primary outcome was CI-AKI.

Results: A total of five observational studies met the inclusion criteria. The pooled population consisted of 2,432 patients. Using multivariable logistic regression analysis, increased RDW (cutoff between 13.25 to 15.2) was independently associated with greater risk for CI-AKI after PCI (pooled adjusted odds ratio (OR), 1.48; 95% confidence interval (CI), 1.32 to 1.67; I2 = 0%) (Figure). Subgroup analysis in patients with ST elevation myocardial infarction demonstrated a similar tendency (OR, 1.58; 95% CI, 1.35 to 1.85; I2 = 0%).

Conclusions: Increased RDW is associated with increased risk of CI-AKI after PCI. Further studies are needed to assess the utility of RDW as a risk-stratifier for CIN.



TH-PO061

Clinical Significance of Hypoalbuminemia for AKI in Patients with Scrub Typhus

Ju hwan Oh, In O Sun. *Presbyterian Medical Center, Jeonju, Korea, Jeonju, Republic of Korea.*

Background: The aim of this study is to investigate the clinical significance of hypoalbuminemia (HA) for acute kidney injury (AKI) in patients with scrub typhus.

Methods: From 2010 to 2017, 449 patients were diagnosed with scrub typhus. We divided the patients into two groups [normoalbuminemia (NA) vs. hypoalbuminemia (HA)] based on the serum albumin level of 3.5 g/dL, and compared the incidence, clinical characteristics, and severity of AKI based on RIFLE classification between two groups.

Results: Of the total 449 patients, 52 (11.6%) were categrized as HA group. Compared with patients in NA group, patients in HA group were older (74 ± 8 vs. 63 ± 13, P<0.01) and had higher total leukocyte counts (10.4 × 10^3/ mL vs. 6.9 × 10^3/mL, P<0.01). HA group showed significantly longer hospital stay (10.1 ± 4.7 vs 8.8 ± 4.5, p<0.01) and higher incidence of acute kidney injury (56% vs. 19%, p<0.01). The overall incidence of AKI was 22.9%; of which, 12.2%, 10.0% and 0.7% were classified as Risk, Injury and Failure, respectively. In a multivariate logistic regression analysis for predciting AKI, age, presence of chronic kidney disease, leukocytosis and hypoalbuminemia were significant predictors of AKI. Most patients recovered baseline renal function without renal replacement therapy following antibiotics therapy and supportive care.

Conclusions: Hypoabluminemia was closely associated with AKI in patients with scrub typhus.

TH-PO062

Prediction of AKI in ICU Using Routinely Collected Data by Machine-Learning Algorithms and Its Visualization

Noriaki Sato,[2,1] Eiichiro Uchino,[2,1] Ryosuke Kojima,[1] Shusuke Hiragi,[3] Motoko Yanagita,[2] Yasushi Okuno.[1] *[1]Department of Biomedical Data Intelligence, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]Division of Medical IT and Administration Planning, Kyoto University Hospital, Sakyo-ku, Japan.*

Background: Acute kidney injury (AKI) is associated with high mortality, and occur frequently particularly in the intensive care unit (ICU), due to various conditions such as septic shock. It is clinically important to identify high-risk patients with AKI in advance and perform appropriate interventions. There have been many studies that predicted the onset of AKI using data like medication or laboratory data so far, but few studies have utilized time series vital data to predict AKI, and have assessed which time point is important for the prediction in each patient. In this study, we attempt to predict the onset of AKI by applying machine learning algorithms to vital data acquired routinely in most ICU patients from the publicly available dataset, followed by the visualization of the rationale behind the prediction.

Methods: We used publicly disclosed dataset named Medical Information Mart for Intensive Care three. AKI was defined based on KDIGO serum creatinine criteria. We included patients with stage 2 or higher AKI within 48 hours after admission to ICU. The onset of AKI was defined as when the high creatinine level was first detected. We included data of systolic, diastolic, and mean blood pressure, heart rate, respiratory rate, body temperature, and SpO2. In addition, age and the baseline serum creatinine level were collected. We utilized machine learning algorithm of XGBoost and 1-dimensional convolutional neural networks (1D-CNN). We predicted the onset of AKI in 24 to 48 hours using data collected in 0 to 24 hours after admission to ICU. We evaluated the performance of the model using area under receiver operating characteristic curve (AUROC), with five-fold cross-validation. We applied Grad-CAM to visualize the rationale behind the prediction in 1D-CNN.

Results: The highest performance was obtained by XGBoost when minimum, maximum and mean value of vital data and age, serum creatinine data was combined (AUROC: 0.793±0.34). Using only vital data, the performance was 0.666±0.046, 0.675±0.053 for XGBoost, 1D-CNN respectively. Using Grad-CAM to the 1D-CNN model, some visualization results suggested that the time period of lower blood pressure might contribute to the prediction.

Conclusions: It was suggested that XGBoost and 1D-CNN could predict the onset of AKI and visualize its rationale behind the prediction.

TH-PO063

Predicting AKI After Cardiac Surgery by Using Machine Learning Methods

Po-Yu Tseng,[1] David Chih-Yu Yang.[2] *[1]Far Eastern Memorial Hospital, New Taipei, Taiwan; [2]Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Acute kidney injury (AKI) is an important complication of the cardiac surgeries. Small increases in serum creatinine (SCr) after cardiac surgery have been associated with a significant increase in 30-day mortality. A model that accurately estimates a patient's risk for AKI after cardiac surgery is important in clinical practice. Several risk models have been developed to predict postoperative AKI after cardiac surgery. However, there is less study analyzing clinical big data with the application of machine learning to predict AKI after cardiac surgery.

Methods: We retrospectively enrolled the patients undergoing cardiac surgery (coronary artery bypass graft or valve surgery) in Far East Memorial Hospital from August 2016 to August 2018. The primary outcome was the development AKI.The following machine learning techniques were used: decision tree, random forest, gradient boosting, and support vector machine. The performance of these techniques was compared with that of logistic regression analysis regarding the area under the receiver-operating characteristic curve (AUC). We also used importance matrix plot and shap value to determine the importance of each variables.

Results: A total of 671cases received cardiac surgery. AKI developed in 163(24.3%) patients during the first postoperative week. The highest AUC is 0.829 by the random forest with oversampling. The important matrix plot of random forest revealed that intraoperative urine output, pRBC transfusion during the surgery and and preoperative preoperative serum creatinine were the top three variables contribute to the model.

Conclusions: We successfully use the perioperative parameters to develop the predictive model for AKI after cardiac surgery by using machine learning method.

TH-PO064

Central Venous Pressure and the Risk of Diuretic-Associated AKI in Patients After Cardiac Surgery

Ian Mccoy, Maria E. Montez-Rath, Glenn M. Chertow, Tara I. Chang. *Stanford University School of Medicine, Stanford, CA.*

Background: Clinicians strive to weigh the benefits of diuretic therapy for treating and preventing fluid overload against the risks, including acute kidney injury (AKI) due to excessive or overly rapid diuresis. We hypothesized a lower risk of AKI after diuretic administration in patients with higher central venous pressure (CVP) following cardiac surgery.

Methods: We used the MIMIC-III database to study adults admitted to the post-cardiac surgical intensive care unit between 2001 and 2012, excluding those on maintenance dialysis, at an urban academic medical center. Multivariable logistic regression models included adjustments for demographics, comorbidities, admission diagnosis, procedures (cardiopulmonary bypass, coronary artery bypass grafting, left heart catheterization), medications, and severity of illness (mean arterial pressure, admission creatinine, vasopressor use, mechanical ventilation, and platelet count). Inverse probability treatment weighting estimated the risk of diuretic-induced AKI across tertiles of CVP.

Results: Among 4,164 patients receiving intravenous loop diuretics, in contrast to our a priori hypothesis, the adjusted odds of subsequent AKI were 1.11 (95% confidence interval [CI] 1.08-1.13) times higher per mmHg increase in mean CVP on ICU day 1. This association was log-linear across the entire range of CVP observed. The odds ratios were higher for more severe AKI (KDIGO Stage 1: 1.09 (95% CI 1.06-1.11), KDIGO Stage 3: 1.23 (95% CI 1.15-1.31). Among the 5,396 patients including those not on intravenous loop diuretics, the risk ratio for AKI with diuretic use was 1.59 (95% CI 1.39-1.82); results did not materially differ when examined by CVP tertile.

Conclusions: Higher rather than lower CVP is an independent marker of AKI risk. Further research should aim to identify better tools to assess volume status and to determine ICU patient groups for whom diuretics can be most safely administered.

Relation Between Biomarkers of Decongestion and Kidney Function with Outcomes in Acute Decompensated Heart Failure

Wendy I. McCallum, Hocine Tighiouart, Marvin Konstam, James Udelson, Mark J. Sarnak. *Tufts Medical Center, Boston, MA.*

Background: In-hospital acute declines in kidney function occur in approximately 20-30% of patients admitted with acute decompensated heart failure (ADHF), but it remains unknown whether these declines are associated with improved or worse outcomes, and whether incorporation of markers of congestion modifies these associations.

Methods: Using data from the Efficacy of Vasopressin Antagonism in Heart Failure Outcome Study With Tolvaptan (EVEREST) trial, multivariable Cox regression models were used to evaluate the association between in-hospital changes in eGFR and changes in brain natriuretic peptide (BNP) with death and a composite outcome of death or rehospitalization. The association of eGFR decline with outcomes within subgroups of changes in other surrogate markers of congestion including N-terminal prohormone of brain natriuretic peptide, hematocrit, and weight was also examined.

Results: Among 3,988 patients over a median 8-month follow-up, in-hospital decline in eGFR was not significantly associated with outcomes (HR=1.09 [95% CI 0.96, 1.24] for death per every 30% decline in eGFR; 1.03 [95% CI 0.95, 1.12] for composite per every 30% decline in eGFR), whereas there was a 24% reduction in risk of death for every halving of BNP (HR=0.76 [95% CI 0.71, 0.83]). There was no significant interaction between decline in eGFR and change in BNP for either death (p-interaction =0.09) or the composite of death or rehospitalization (p-interaction =0.35) (Figure). Decline in eGFR was not found to be significantly associated with either improved or worse outcomes in any subgroups of either increasing or decreasing markers of congestion (p-interaction $\rangle$0.12 for all subgroups).

Conclusions: Achieving decongestion is an important goal for patients with ADHF and declines in BNP are associated with better prognosis. The prognostic significance of declines in eGFR, however, remains less clear, even if occurring in the setting of achieving decongestion.

Funding: Other NIH Support - NIH Training Grant T32 DK007777

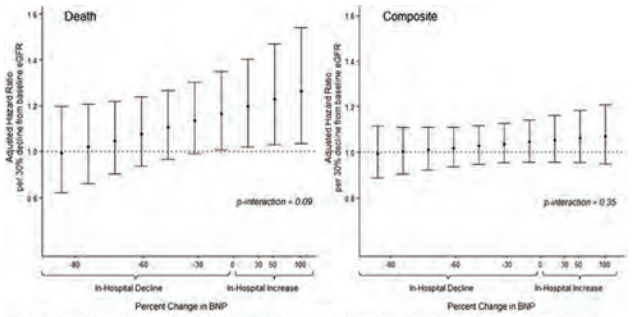

Figure. Adjusted hazard ratios for death (left) and for composite of death or rehospitalization (right) based on fixed estimated glomerular filtration (eGFR) decline of 30% and varying changes in brain natriuretic peptide (BNP).

TH-PO066

A Modified Renal Angina Index by Using the Kinetic Glomerular Filtration Rate for Predicting AKI

Rolando Claure-Del Granado,[1] Adriana V. Silva-Rojas,[2] Brandon Valencia-Coronel.[2] *[1]Hospital Obrero #2 - C.N.S.; Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [2]Hospital Obrero #2 - C.N.S., Cochabamba, Bolivia, Plurinational State of.*

Background: Reliable prediction of AKI has the potential to optimize its treatment. Recently Goldstein SL et al. proposed an empiric clinical model of renal angina to identify critically ill children who would be at higher risk of AKI. In children the combination of the renal angina index (RAI) and AKI biomarkers has an excellent diagnostic performance. The purpose of this study was to evaluate the performance of a modified RAI using kinetic glomerular filtration rate (*Ke*GFR) for the prediction of AKI in a cohort of critically ill adults.

Methods: We included 208 consecutive patients admitted to our medical ICU. Serum creatinine (sCr) was measure every 24 hours for 7 consecutive days following ICU admission. RAI was calculated 24 hours after ICU admission (day 1) using the following formula: **Risk level** (presence of sepsis, use of vasopressors and/or use of invasive mechanical ventilation, and presence of diabetes mellitus) ***x*** **Injury level** (changes in kidney function based on *Ke*GFR). *Ke*GFR was calculated from the change in consecutive values of sCr using the formula developed by Chen S. We used KDIGO AKI sCr criteria to diagnose AKI. In patients with no baseline sCr available we back calculated baseline sCr using MDRD equation (for an eGFR = 75 ml/m/1.73m^2). We analyzed if a modified RAI score ≥6 points could predict subsequent AKI (after 48 hours).

Results: From 208 patients enrolled in the study 101 patients developed AKI (48.6 %). Age, baseline sCr, and eGFR (CKD-EPI) we not different between patients with AKI and patients without AKI. At 24 hours post ICU admission patients with AKI had lower *Ke*GFR (47.7 ml/m vs. 81.1 ml/m; p < 0.0001). A renal angina index ≥6 points was able to identify individuals who developed AKI after 48 hours of ICU admission, with a ROC-AUC of 0.697 (95% CI 0.626-0.769), p < 0.0001. A Renal Angina Index of ≥6 points had an OR of 9.9 (95% CI 2.65 – 37.11; p < 0.0001) for subsequent development of AKI after 48 hours of ICU admission.

Conclusions: A modified renal angina index by using the *Ke*GFR provides a clinically feasible methodology to identify critically ill adults at high risk of developing AKI before a rise in serum creatinine occurs. This tool would permit the early identification of AKI to initiate preventive and treatment strategies minimizing extension of kidney injury.

TH-PO067

Using Kinetic eGFR to Predict AKI in Pediatric Intensive Care Unit

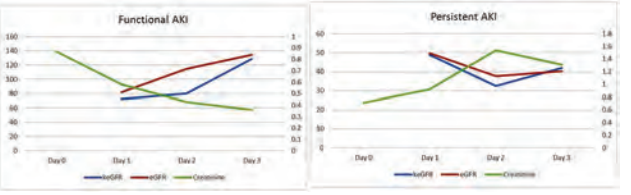
Shina Menon,[1] Stuart Goldstein,[2] Rajit K. Basu.[3] *[1]Seattle Children's Hospital, Seattle, WA; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Children's Healthcare of Atlanta, Atlanta, GA.*

Background: Acute kidney injury (AKI) is common in intensive care unit (ICU). The ability to distinguish between functional and persistent AKI is important. Creatinine (Cr), commonly used for diagnosis is imperfect; combining it with urinary biomarkers may help differentiate the two. Kinetic estimated GFR (keGFR) has been used to predict AKI and likelihood of renal recovery. It uses creatinine values at two time points for a dynamic assessment of renal function. It can improve understanding of AKI trajectory and has been used to predict AKI. There are limited data on its use in pediatrics. We hypothesized keGFR would improve clinical and prognostic information beyond Cr or eGFR (modified Schwartz GFR)

Methods: We performed secondary analysis of data from Acute Kidney Injury in Children Expected by Renal angina and Urinary Biomarkers (AKI-CHERUB), a prospective, observational study of children 3months- 25 years age admitted to ICU. For this analyses, only those with complete data upto day 3 were analyzed. keGFR was calculated on Days 1-3. Functional AKI (fAKI) was defined as return to baseline Cr by Day 3 and persistent AKI (pAKI) was absence of recovery by Day 3. Primary outcome was pAKI and secondary outcomes were AKI stage 2/3 during the first 7 days and fAKI

Results: 169 patients were analyzed (50% female). AKI at admission was seen in 40 (23.6%). Of those, 23 had fAKI and 13 had pAKI. keGFR pattern was similar to that of eGFR (Fig 1) for both groups. Of those who did not have AKI at admission, 17 developed stage 2/3 AKI during the first 7 days in PICU. Median keGFR for these patients was 85.5 mL/min/1.73 m2 compared to eGFR of 79.5 mL/min/1.73m2

Conclusions: AKI diagnosis is mostly dependent on a rise in Cr which is an imperfect and late marker. The key to improving outcomes in AKI is early prediction of Cr trajectory and appropriate intervention. Although keGFR has been used in adults for this purpose, our analysis shows that it may not be ready for use in pediatrics. It can be used in conjunction with eGFR to identify AKI patterns but it is not superior to eGFR



TH-PO068

AKI and Long-Term Renal Dysfunction After Nonrenal Solid Organ Transplant

Shina Menon,[1] Ari Pollack,[1] Erin M. Sullivan,[1] Jodi M. Smith.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]Children's Hospital & Regional Medical Center, Seattle, WA.*

Background: Solid-organ transplantation (SOT) is the treatment of choice for end-stage organ disease. Improved long term survival after SOT has uncovered chronic morbidity including chronic kidney disease (CKD). AKI is common after SOT and associated with increased morbidity, mortality, long term CKD

Methods: Retrospective cohort study using PEDSnet database. We studied rates of AKI and CKD after non renal SOT and relationship between the two. First-time heart (n=109), liver (n=112) transplant recipients ≤21 years age included. Perioperative AKI (pAKI) was AKI ≤ 7days post transplant (txp); CKD was eGFR< 60 mL/min/1.73m2 for ≥ 3 months. Incidence of CKD calculated using Product-limit Kaplan-Meier estimates & compared with log rank test. Effect of txp, time since txp, age, pAKI &successive AKI in first year post txp on the slope of eGFR assessed using multivariate linear regression

Results: pAKI seen in 50.3% (112/221). pAKI after liver txp was more common in older children and those with acute liver failure. Among heart txp, it was more common in younger patients. It was associated with longer ICU and hospital length of stays, lower eGFR at follow-up, and higher incidence of CKD (Figures 1 and 2).

Conclusions: pAKI is common after NRSOT- particularly after heart txp. Cumulative incidence of CKD is higher after heart txp than liver. Post liver txp, incidence of CKD is higher in those with pAKI than those without. pAKI and subsequent AKI episodes are both associated with significant decreases in eGFR during follow up. Patients who develop AKI need close monitoring for CKD and may benefit from kidney sparing immunosuppression.

Demographics and Outcomes- Liver

	No Perioperative AKI (N=69)	Perioperative AKI (N=43)
Female (%)	36 (52.2%)	17 (39.5%)

Novel Algorithm for AKI Detection in Outpatient Settings

Chin-Chi Kuo. *Big Data Center, China Medical University Hospital, Taichung, Taiwan.*

Background: Existing acute kidney injury (AKI) diagnostic criteria is restricted to inpatients. We proposed an AKI algorithm for outpatients(AKI_{OPT}) and evaluated how AKI_{OPT} modifies the course of chronic kidney disease (CKD).

Methods: The occurrence of AKI_{OPT} were analyzed retrospectively among CKD patients who were enrolled into the pre-dialysis care program in a tertiary hospital in Taiwan. AKI_{OPT} was detected by the definition of a 50% increase in serum creatinine (S-Cre) or a fall in eGFR by 35% in the 180-day period prior to pre-dialysis care program enrollment. Outcomes were progression to end-stage renal disease (ESRD) and all-cause mortality. The association analyses were performed using multiple Cox regression and coarsened exact matching (CEM) analysis.

Results: Among the total of 6046 patients, 31.5 % (1905 patients) had ever developed AKI_{OPT} within the 180-day period before the enrollment. The fully adjusted hazard ratios (aHRs) of the 1-year and overall risk of ESRD among patients with preceding AKI_{OPT} were 1.78 (95% CI, 1.50, 2.12) and 1.50 (1.32, 1.71), respectively, compared with those without history of AKI_{OPT}. For 1-year and overall risk of all-cause mortality, patients with AKI_{OPT} had respectively a 120% (95% CI 73-182%) and 74% (95% CI, 48-106%) higher risk than those without AKI_{OPT}. This statistical inference remained robust in CEM analysis. We discovered a complete reversal in the eGFR slope before and after the AKI_{OPT} from −10.61 ± 0.32 to 0.25 ± 0.30 mL/min/1.73 m^2 per year; however, the loss of kidney function is not recovered (Figure).

Conclusions: The new AKI_{OPT} diagnostic algorithm fits the outpatient setting and provides a prognostic significance in patients with CKD.

Funding: Government Support - Non-U.S.

Development and Validation of a Risk Score for AKI After Cardiac Surgery

Subhash Chander, Shreyak Sharma, Samuel Short, James Rawn, David E. Leaf. *Renal Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: AKI is a frequent and important complication of cardiac surgery. However, existing prediction models for cardiac surgery-associated AKI are limited by reliance on diagnostic and billing codes, lack of external validation, and inclusion of variables that can only be determined postoperatively (e.g., cardiopulmonary bypass time). Most importantly, existing models are mainly limited to prediction of severe AKI, whereas accurate risk stratification of more mild forms of AKI is crucial for enrichment of patients in early phase clinical trials.

Methods: We collected data from adults who underwent cardiac surgery between 2008 and 2018 at two major academic medical centers in Boston, MA. Data were obtained by querying the Society for Thoracic Surgeons National Database, along with electronic medical records. The primary exposures included clinically plausible demographics, comorbidities, laboratory values, and surgical characteristics, each of which was available preoperatively. The primary endpoint was AKI, defined according to KDIGO criteria as follows: an increase in serum creatinine ≥ 0.3 mg/dl within 48 hours, ≥50% in 7 days, or dialysis. We used forward selection, with a p value cutoff of 0.05, to develop the model, using a development (n=10,387) and external validation (n=8132) approach. The final model included 12 variables.

Results: The AKI event rate in the development and validation cohorts was 11% and 19%, respectively. A higher score monotonically predicted a higher risk of AKI in both cohorts (AUC 0.75 in the development cohort; AUC 0.71 in the validation cohort). The positive predictive value of a score >8 was 37% and 48% in the development and validation cohorts, respectively. The model was similarly predictive of more severe stages of AKI.

Conclusions: We present a 12-variable risk prediction score for AKI following cardiac surgery. We propose that this model could be used for both clinical prognostication and for research purposes.

Risk Factor	Points
Male gender	1
eGFR (ml/min/1.73m²)

TH-PO071

The Scoring Model for Prediction of Acute Renal Replacement Therapy in Intensive Care Unit Patients with AKI in a Limited-Resource Country

Wanjak Pongsittisak,[1] Kashane Phonsawang.[2] [1]*Medicine, Navamindradhiraj University, Bangkok, Thailand;* [2]*Faculty of medicine, Vajira hospital, Bangkok, Thailand.*

Background: Acute kidney injury (AKI) is a common problem with high mortality in clinical practice, especially in the intensive care unit (ICU) patients. Making-a-decision of Acute Renal replacement therapy (ARRT) initiation has still been state-of-the-arts. This study aimed to generate and validate a scoring model for prediction of ARRT in ICU patients with AKI (ARRT score).

Methods: We performed a retrospective cohort study of ICU patients with AKI in a university hospital, Thailand. Risk factors of 7-day AKI requiring ARRT (7d-ARRT) were derived from the medical records between January 2013 and June 2015 (derivation cohort; der-cohort). We generate an ARRT score by the significant risk factors from the multivariate logistic analysis. To find the best model, we applied the area under the receiver operating characteristic curve (AUROC) analysis and Akaike information criterion (AIC). The ARRT score was validated by the data between June 2015 and December 2015 (validation cohort; val-cohort).

Results: The study included 292 patients in a der-cohort and 57 patients in a val-cohort. We found the best model to predict 7d-ARRT was oliguria (<0.5 ml/kg/hr after resuscitation), advanced CKD (eGFR < 45 ml/min/1.73m²) and severity of AKI at ICU admission [der-cohort: AUROC = 0.768, AIC = 201.02, val-cohort: AUROC = 0.845, AIC = 57.04]. These risk factors were used for generation of ARRT score by weighting their score from coefficients value of each risk factors (figure 1). At 4 points of the ARRT score, specificity was 84.2%, 81.6% and sensitivity was 55.8%, 73.7% for der-cohort and val-cohort respectively.

Conclusions: We strongly recommend that ARRT score ≥ 4 points could predict 7d-ARRT. We suggest further large prospective cohort study to validate our ARRT scoring.

Funding: Government Support - Non-U.S.

Figure 1 Demonstrate the ARRT score and the points of each risk factors (A). Sensitivity, specificity, PPV, NPV, and Youden index analysis of each cut-off value (B). AUROC and AIC analysis of the derivation cohort and validation cohort (C).

A	ARRT score			B	Derivation cohort				
Risk factors	Coefficients	Points		Cut-off	Youden index	Sensitivity	Specificity	PPV	NPV
eGFR < 45 ml/min/1.73m²	0.7833	1.6		1	0.360	0.84	0.52	0.39	0.90
UO < 0.5 ml/kg/hr	1.3350	2.7		2	0.384	0.78	0.61	0.41	0.88
AKI staging				3	0.370	0.58	0.79	0.50	0.84
-Stage 2	0.4888	1		4	0.400	0.56	0.84	0.56	0.84
-Stage 3	1.5020	3		5	0.359	0.43	0.93	0.69	0.82
C	AUROC	AIC		6	0.129	0.14	0.99	0.79	0.76
Derivation cohort	0.768	277.2		Validation cohort					
Validation cohort	0.845	57.0		4	0.553	0.74	0.82	0.67	0.87

A: The ARRT score was used for evaluation in patients with AKI at ICU admission by summary the points of 3 risk factors. Parameter defined as following: eGFR, the lowest baseline eGFR that calculate by CKD-EPI equation in past 12 months; UO, the amount of urine output after adequate fluid resuscitation in 1 hour; AKI staging, define by creatinine criteria as AKIN classification.
B: Analysis of sensitivity, specificity, PPV, NPV, and Youden index of each cut-off value showed ARRT score ≥ 4 points could predict ARRT within 7 days.
C: Comparison of AUROC, AIC for derivation cohort and validation cohort represented good accuracy of ARRT score.
Abbreviation: AIC, Akaike information criterion; AKI, acute kidney injury; ARRT, acute renal replacement therapy; AUROC, area under the receiver operating characteristic curve; eGFR, estimated glomerular filtration rate; ICU, intensive care unit; NPV, negative predictive value; PPV, positive predictive value; UO, urine output.

TH-PO072

The Role of Concurrent Major Complications in the Association Between AKI and Survival After Coronary Artery Bypass Grafting Surgery

Dadi Helgason,[1,2] Sólveig Helgadóttir,[3] Runolfur Palsson,[1,2] Martin I. Sigurdsson,[1,2] Tomas Gudbjartsson,[1,2] Olafur S. Indridason.[1] *[1]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [2]University of Iceland, Reykjavik, Iceland; [3]Uppsala University Hospital, Uppsala, Sweden.*

Background: Acute kidney injury (AKI) is associated with decreased survival following coronary artery bypass grafting (CABG). In this study, we evaluated the impact of AKI and concurrent major complications on short- and long-term survival after CABG.

Methods: A retrospective study of all isolated primary CABG cases in Iceland in 2001-2013. AKI was defined by the KDIGO criteria and major postoperative complications comprised myocardial infarction, reoperation, stroke, mediastinitis, sternum dehiscence, acute respiratory distress syndrome and multiple organ failure. Patients were divided into four groups: AKI with or without major complications and non-AKI with or without major complications. Survival was plotted by Kaplan-Meier method and 30-day mortality evaluated by logistic regression. Predictors of long-term survival were only evaluated for patients without concurrent major complications using Cox regression.

Results: Of 1710 patients, 184 (11%) developed AKI. Major complications occurred in 21% of the AKI patients compared with 10% non-AKI patients (p<0.001). Overall survival was lower in patients with AKI compared with non-AKI patients (p<0.001, **Figure 1**). In adjusted analysis, AKI patients with major complications (OR=30.3 [95%-CI, 9.1-105.8]) and non-AKI patients with major complications (OR=11.6 [4.2-34.9]) had higher risk of 30-day mortality than non-AKI patients without major complications, while the risk of death for AKI patients without major complications was not significantly increased (OR=3.4 [0.8-13.3]). AKI was not significantly associated with 5-year mortality (HR=1.4 [0.8-2.4]). However, when the entire follow-up time (median 6 years, range, 0-13.5) was included, AKI predicted higher mortality (HR=1.6 [1.1-2.2]).

Conclusions: AKI associated with decreased survival following CABG. However, this relationship can to a great extent be explained by concurrent major complications, particularly in case of early mortality.

Funding: Government Support - Non-U.S.

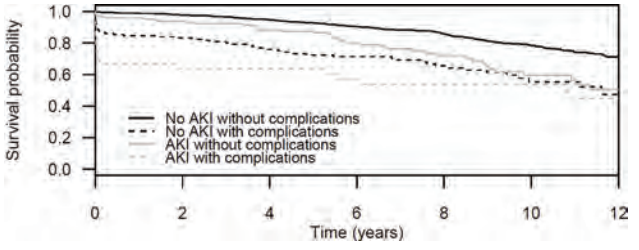

Figure 1. Overall unadjusted survival of AKI vs. non-AKI patients categorized based on whether they developed concurrent major complications or not.

TH-PO073

Incidence and Risk Factors of AKI After Total Knee Arthroplasty (TKA) or Revision (TKA-R) in Kidney Transplant Recipients (KTx)

Sorkko Thirunavukkarasu, Ziad Zoghby. *Mayo Clinic, Rochester, MN.*

Background: Kidney transplant recipients have an increased risk of complications following knee arthroplasties and revisions compared to non-transplant patients. The incidence of AKI is reported to be as high as 15.6 % and has been associated with increased mortality, morbidity, and length of hospital stays (LOS). Our AIM was to determine the incidence of AKI in KTx patients undergoing primary knee arthroplasty (TKA) or secondary revision (TKA-R), identify risk factors associated with AKI and evaluate its effect on allograft function at one year.

Methods: Using the orthopedic and transplant databases we designed a case-control study of 82 patients undergoing a total of 101 TKA and knee revisions between 2000 and 2018 at the Mayo Clinic. Information not available through the databases was obtained through chart review. AKI was defined per current KIDGO guidelines.

Results: The average age at surgery was 65 years (range 35-83); with 58% male and 98% white. The most common surgical indication was degenerative joint disease (80%). The incidence of AKI was 7 % in TKA and no patients developed AKI in the TKA-R group. All were stage 1 as per AKIN criteria. The LOS for those with AKI was 4.9 days compared to 3.5 days for those without AKI (p = 0.04). Mean anesthesia time was similar in patients with AKI (170 vs 189 min, p = 0.3). There was no significant difference between pressor requirements, estimated blood loss, need for transfusion, or amount of fluid administered between the AKI and Non-AKI groups. At one year, the mean eGFR change in the AKI group was (- 11.8 ml/min) compared to (-0.9 ml/min) in the Non-AKI group, p=0.065.

Conclusions: The incidence of AKI after total knee arthroplasty in KTx was 7 % and associated with longer hospitalization. All cases of AKI were mild, with renal function improving by hospital discharge. At one year, patients with AKI did have a lower eGFR compared to the non-AKI group but the difference did not reach statistical significance. Further larger studies are needed to assess the effect of TKA on allograft function.

TH-PO074

AKI Following Cardiac Bypass Surgery in Jamaica: Observations from a Low-Resource Country

Lori- Ann M. Fisher,[1] Sunil Stephenson,[2] Marshall K. Tulloch-Reid,[3] Simon G. Anderson.[2] *[1]University Hospital of the West Indies, Kingston, Jamaica; [2]University of the West Indies, Bridgetown, Barbados; [3]The University of the West Indies, Kingston, Jamaica.*

Background: AKI following cardiac surgery requiring cardiopulmonary bypass (CPB) is a common but serious complication with an incidence of 25-40%. It is associated with a 3 to 8 times increase in mortality, increased hospital length of stay and Chronic Kidney Disease. Little is known about the incidence and impact of AKI following CPB in the Caribbean. We describe the incidence and outcomes of AKI following CPB at a referral cardiac surgery centre in the Caribbean.

Methods: Medical records of adult patients with no prior ESRD or dialysis requirement who underwent cardiac surgery requiring CPB at the University Hospital from January 1, 2016 to December 31, 2017 were reviewed. All cause mortality was the defined end-point. Demographics, pre-operative status, intraoperative and post operative data were abstracted by two independent reviewers. AKI was based on KDIGO criteria using serum creatinine measurements obtained within 72 hours post-operatively. Multivariate logistic regression was used to examine the risk factors for and impact of AKI on all-cause mortality

Results: 125 patients (57% male) with mean age 57.4±12.9 years and mean pre-operative creatinine levels of 84.6 ± 33.7 μmol/L underwent cardiac surgery. The incidence of AKI was 31.2% (39/125), Of these 41% (16/39) were KDIGO I, 23% (9/39) KDIGO II and (14/39) 36% KDIGO III. Renal replacement therapy was required in 4% (5) of patients. In logistic regression analyses male sex (OR 0.46,95%CI: 0.2-0.9), and higher preoperative haemoglobin (OR 0.69,95% CI: 0.5-0.9) reduced the likelihood of AKI, whereas preoperative CKD (eGFR<60) (OR 8.6, [95% CI:1.7-43.6]) and prolonged bypass time (OR per 1 hour=2.9[95% CI 1.18-7.2]) increased risk. There was no association of age, cross clamp time or type of surgery (valve replacement or CABG) with AKI. Approximately 21%[26/125] of patients died in hospital. AKI was associated with four fold increased risk for death after adjusting for age and sex (OR[95% CI]=4.2[1.6-10.5])

Conclusions: The incidence of AKI following CPB is similar in our cohort to that reported in high income countries and significantly increases the risk of in hospital mortality. Larger multicentre prospective studies to predict risk, identify interventions to reduce mortality and assess long term complications of AKI following CPB in low resource countries are needed.

TH-PO075

Risks and Outcomes of Postoperative Dialysis-Requiring AKI in Patients Who Underwent Coronary Artery Bypass Grafting Surgery: A Large Retrospective Study

Ijen Chiu,[2,1] Li-Li Hsiao,[1] Yung-Ho Hsu.[2] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical University, Boston, MA; [2]Renal Division, Shuang-Ho Hospital, Taipei Medical University, New Taipei City, Taiwan.*

Background: In-hospital acute kidney injury (AKI) has been linked to higher mortality and kidney disease progression. We aim to evaluate the associated factors and long-term outcome from patients underwent coronary artery bypass grafting (CABG) surgery, who developed dialysis-requiring AKI.

Methods: Data were collected by the National Health Insurance Research Database of Taiwan from 2002 to 2012. Individuals 18 and older, who underwent scheduled isolated CABG were identified (n=33790). Patients who were ESRD or received renal replacement therapy (RRT) within one year before surgery were excluded. AKI requiring dialysis was identified by the dialysis procedure code. The long-term mortality and ESRD were examined using multivariate Cox regression.

Results: The incidence of dialysis-requiring AKI after CABG is 7.6% (2,575). Patients with age 65 and older, history of Type 2 diabetes (T2DM), hypertension (HTN) and use of Angiotensin receptor blocker (ARB), erythropoietin (EPO) as well as on-pump CABG were the risk factors. And older age (>=65 y.o), T2DM and in-hospital RRT were associated with increased long-term mortality (HR 2.62, 1.49 & 4.47, p<0.0001). RRT also had a significantly increased risk of progression to ESRD (HR 17.16, p<0.0001). Neither on-pump nor off-pump CABG affects long-term mortality (HR 0.95, p=0.051), but on-pump CABG patients had a higher risk of developing ESRD (HR 1.19, p=0.001). While preoperative statin use linked to lower long-term mortality (HR 0.82), it caused a higher risk of ESRD progression (HR 1.23m)(p<0.0001). A similar observation was also seen in ARB use (HR 1.23, p< 0.0001). Furthermore, EPO use significantly increased the risk of progression to ESRD (HR 7.10, p<0.0001) despite no worsening effect on long-term mortality (HR 0.77, p=0.13)

Conclusions: We have identified the risk factors that increase the incidence of dialysis-requiring AKI after CABG; we further identified factors that affect the risk of mortality and ESRD progression. Statin appears to have protective effects in mortality and on-pump CABG showed higher risks in developing post-operative AKI and ESRD progression. Our finding may serve as a guideline for risk assessment and managing those who undergo CABG.

TH-PO076

Incidence and Prevention of Contrast-Induced Nephropathy in Percutaneous Coronary Intervention

Rana R. Garris,[1] Prem Patel,[1] Radhika Tailor,[1] Trina Pal,[1] Ian Laxina,[1] Yudi Camacho,[1] Stephen Biggiani,[1] Mina Sourial,[1,2] Chandra B. Chandran,[1] Ahmad H. Abuarqoub,[1] Hiten Patel,[1] Fayez Shamoon.[1] *[1]St. Joseph's Health/NYMC, Nutley, NJ; [2]Montefiore Medical Center, Bronx, NY.*

Background: Contrast induced nephropathy (CIN) has been reported in 20% of patients who undergo percutaneous coronary intervention (PCI). Contrast induces nephrotoxicity through direct tubule toxicity, capillary obstruction, vasoconstriction and hypoxia. Patients who have poor renal reserve with comorbidities are more susceptible, while the pleiotropic effects of statins may be nephroprotective. Prior studies have debated the role of contrast in the development of renal insufficiency. We hypothesize that while post-PCI acute kidney injury is multifactorial, the occurrence of CIN is likely understated. This is of clinical importance, because CIN is related to worse outcomes and longer hospital stays. Patient risk stratification can mitigate this risk.

Methods: Our study evaluates the incidence of CIN among 1521 patients at our hospital over 1 year. We used SAS 9.4 to perform logistic regression to assess the occurrence of CIN among patients with pre-PCI normal versus abnormal renal function (determined by GFR and Cr) in regards to underlying comorbidities. We also incorporated a CIN risk-calculator into our hospital EMR system and PCI practices.

Results: Our results showed that 15.3% of patients who underwent PCI developed CIN. Advanced age (OR 1.014, p = 0.02); race (blacks had OR 1.8, p = 0.01); underlying heart failure (OR 1.6 p = 0.004), especially among those with BNP > 400 (OR 4.5, p < 0.001) or EF < 40% (OR 1.47, p = 0.04); and diabetes (OR 2.0, p = 0.002) increased the probability of CIN. Patients with Cr > 1.2 were 3X more likely to get CIN (p < 0.001). GFR 30 – 60 and GFR < 30 increased the odds of CIN by 2.5 and 5 times, respectively (p < 0.01). By each unit decrease in hemoglobin, the odds of CIN increased by 5.5% (p = 0.002). Statin use reduced CIN by 42.9% (p = 0.001). Most notably, CIN also occurred in 9.1% of patients with normal baseline kidney function; among these patients, diabetes and age were the only contributory covariants.

Conclusions: Patients who undergo PCI are at significant risk of CIN. While baseline renal dysfunction and comorbidities are contributory, patients without these risk factors also developed CIN. Statins were renal-protective.

Impact of Contrast Media Volume on the Onset of Contrast-Induced Nephropathy During Coronary Angiography: A Retrospective Study

Agnieszka Pozdzik.[1,2] Nephrology and Dialysis Clinic, Centre Hospitalier Universitaire, Brugmann, Hospital, Brussels, Belgium and Cardiology Department, Centre Hospitalier Universitaire, Brugmann, Hospital, Brussels, Belgium *[1]Nephrology, Dialysis, Centre Hospitalier Universitaire, Brugmann Hospital, Brussels, Belgium; [2]Faculty of Medicine, Université Libre de Bruxelles (ULB), Brussels, Belgium.*

Background: Contrast media administration after coronary angiography can be complicated by a contrast-induced nephropathy (CIN). The toxicity threshold volume of contrast media remains undefined. The objective is to study (1) the relationship between the volume of injected contrast media and the occurrence of CIN and (2) the existence of a possible formula to calculate the threshold volume of toxicity of the contrast media for each patient after acute percutaneous coronary intervention.

Methods: We performed a retrospective study in 4773 patients who received percutaneous coronary intervention for acute coronary syndrome between 2012 and 2018. Contrast-induced nephropathy was defined as an increase of ≥ 0.5 mg/dL or ≥ 25% of serum creatinine compared to its baseline value between the 1st and 10th day following contrast media injection. Predictive factors independent of CIN adjusted to their observed mean was introduced into the formula calculate the threshold volume for renal toxicity.

Results: Of the 3073 patients analysed, 724 (23.6%) developed CIN. In our population, age, diabetes, PC volume, basal CrS and basal DFG are independent predictors of CIN, the risk of CIN is lower in men. Diabetes almost doubles the risk of NIC. A positive correlation was found between the volume of contrast media and the variation of basal serum creatinine. Patients receiving a higher amount of contrast media are significantly more likely to develop nephropathy (p<0.001). The volume of contrast media is an independent predictive factor of the occurrence of contrast nephropathy. We have developed a threshold volume prediction formula with a negative predictive value of 82%.

Conclusions: The volume of contrast media influences the occurrence of CIN. Therefore, there is an interest in reducing the amount of injected contrast during the intervention despite a weak relationship. A toxic PC volume threshold is difficult to establish given the different factors involved in the development of CIN. Nevertheless, the proposed formula could provide an additional tool for optimizing the prevention of renal toxicity.

TH-PO078

The Impact of Iodinated Contrast Media on Renal Outcomes in Diabetes and CKD

Sheila M. Fernandes,[1] Beatriz D. Brandi,[1] Karina B. Peres,[1] Cassiane D. da Fonseca,[3] Luciana soares C. Santos,[1] Miriam M. Watanabe,[2] Maria De Fatima Vattimo.[1] Group of Studies on Acute Kidney Injury (GERA) *[1]School of Nursing, Universidade de São Paulo, São Paulo, Brazil; [2]Faculdades Metrpolitana Unidas, São Paulo, Brazil; [3]School of Nursing, Federal University of Sao Paulo, Sao Paulo, Brazil.*

Background: Iodinated radiocontrast media induced nephropaty (CI-AKI) is a major clinical problem accounting for 12% of all hospital-acquired cases of acute kidney injury (AKI), especially in patients with Chronic Kidney Disease (CKD) and Diabetes Mellitus (DM). Aim of this study was to estimate the influence of DM and CKD regarding the incidence of CI-AKI in rats. Renal function, global and renal hemodynamics were measured and the discriminating value of NGAL for assessing early renal injury was evaluated.

Methods: Wistar, adult, male rats were randomized into four groups: Sham (control); Citrate (citrate buffer, streptozotocin vehicle); CKD (5/6 nefrectomy); DM (streptozotocin, 65 mg/kg, iv); CKD+IC (CKD that received iodinated contrast-IC, 6ml/kg); DM+IC (DM animals that received IC, 4 weeks after DM, 6 ml/kg, ip). Renal function (inulin clearance), urinary neutrophil gelatinase (uNGAL), global and renal hemodynamics (systemic blood pressure, renal blood flow, renal vascular resistance) were evaluated.

Results: Renal hemodynamics showed an increase in renal vascular resistance in CKD and DM, while IC enhanced this damage. Also, CKD and DM rats presented lower inulin clearance and higher uNGAL levels. These paramethers were worsened when IC was associated.

Conclusions: Our results indicated that CKD and DM improves renal vulnerability to the toxicity of IC, once association between CKD or DM with CI predisposes to severe kidney injury by modulating renal hemodynamics in rats. NGAL showed to be a sensitive marker for CI-AKI when comorbidities are involved.

Funding: Government Support - Non-U.S.

TH-PO079

Renal Events Following Iodinated Contrast Aggravate Diabetic Nephropathy

Sheila M. Fernandes,[1] Beatriz D. Brandi,[2] Karina B. Peres,[3] Luciana soares C. Santos,[2] Cassiane D. da Fonseca,[5] Miriam M. Watanabe,[4] Maria De Fatima Vattimo.[2] Group of Studies on Acute Kidney Injury (GERA) *[1]University of São Paulo, Carapicuíba, Brazil; [2]Universidade de São Paulo, São Paulo, Brazil; [3]EEUSP, São Paulo, Brazil; [4]Faculdades Metrpolitana Unidas, São Paulo, Brazil; [5]School of Nursing, Federal University of Sao Paulo, Sao Paulo, Brazil.*

Background: Iodinated contrast (IC) is a leading cause of AKI (CI-AKI) and occurs more frequently in individuals with increasingly common risk factors, including diabetes. IC-AKI has been growing in recent years faced with the more frequent diagnostic needs in old patients and with comorbid conditions such as diabetes. This complication is due to a number of factors, including the osmolality of the IC. The aim of this study is to evaluate the injury in kidneys of diabetic rats submitted to treatment with high- osmolar and low-osmolar iodinated contrast, evaluating the impact on hemodynamic and renal function in addition to oxidative profile.

Methods: Wistar rats, male and adult, weighing 250-290g were randomized into four groups: Citrate, Diabetes Mellitus (DM), Diabetes+low-osmolar iodinated contrast (DM+LIC) and DM+high-osmolar iodinated contrast (DM+HIC). Physiological parameters (body weight, water and food intake, glycemia and kidney/body weight ratio); renal function (Inulin Clearance; urinary neutrophil gelatinase/uNGAL); hemodynamics (arterial blood pressure; renal blood flow/RBF; renal vascular resistance/RVR) and oxidative profile (urinary peroxides/UP, urinary TBARS, renal tissue thiols and urinary nitric oxide/NO) were evaluated.

Results: Diabetic groups showed polyphagia, polydipsia, polyuria, high levels of blood glucose and reduction in body weight. DM group showed a reduced inulin clearance, elevated uNGAL, elevated RVR, reduced RBF, elevated UP, TBARS and NO and a consumption of antioxidant reserve. When IC was introduced, the parameters of renal function, renal hemodynamic and oxidative profile became worse, specially in the group DM+HIC.

Conclusions: The use of high and low osmolarity IC promoted additional deleterious action to renal function and hemodynamics with oxidative injury in diabetic rats, with a more expressive effect in the group submitted to high osmolality contrast treatment.

Beneficial Effect of Statin on Preventing Contrast-Induced AKI in Patients with Renal Insufficiency: A Meta-Analysis

Ajin Cho,[1] Jung-woo Noh,[2] Juhee Kim.[3] *[1]Hallym university Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [2]Chun & Cho's Medical Clinic & Dialysis Center, Seoul, Republic of Korea; [3]Department of Internal Medicine-Nephrology, Gangnam Sacred Heart Hospital, Korea, Republic of, Seoul, Republic of Korea.*

Background: Renal insufficiency is an important predictor of contrast-induced acute kidney injury (CI-AKI). We performed a meta-analysis to examine the effects of short-term statin therapy on the incidence of CI-AKI, particularly in patients with renal insufficiency.

Methods: A systematic search was conducted to retrieve randomized controlled trials (RCTs) that investigated the impact of statin pretreatment before administration of contrast media on the development of CI-AKI in patients with mild to moderate renal insufficiency. The primary outcome was development of CI-AKI. The secondary outcome was the incidence of AKI requiring hemodialysis.

Results: Data analysis from eight RCTs, which included a total of 2313 subjects in the statin-treated group and 2322 in the control group, showed that statin pretreatment was associated with significant reduction of the risk of CI-AKI (Relative Risk (RR) = 0.59; 95% Confidential Interval (CI) 0.44 to 0.79; $p = 0.0003$, $I^2 = 0\%$). A beneficial effect of statin on preventing CI-AKI was consistent, regardless of the dose of statin and use of N-acetylcysteine. The incidence of hemodialysis was low after contrast administration in the statin-treated group, but the reduction was not significant (RR = 0.28; 95% CI 0.05 to 1.70; $p = 0.17$, $I^2 = 0\%$). In subgroup analysis based on baseline estimated glomerular filtration rate (eGFR), patients with baseline eGFR < 60 ml/min/1.73 m^2 (RR = 0.63; 95% CI 0.41 to 0.98; $p = 0.04$, $I^2 = 0\%$) and 30 < eGFR < 90 ml/min/1.73 m^2 (RR = 0.56; 95% CI 0.39 to 0.82; $p = 0.003$, $I^2 = 0\%$) showed significant reduction of risk of CI-AKI.

Conclusions: Statin pretreatment is effective at preventing CI-AKI and should be considered in patients with pre-existing renal insufficiency.

TH-PO081

AKI Is a Rare Complication of Therapeutic Paracentesis Among Inpatients with Cirrhosis

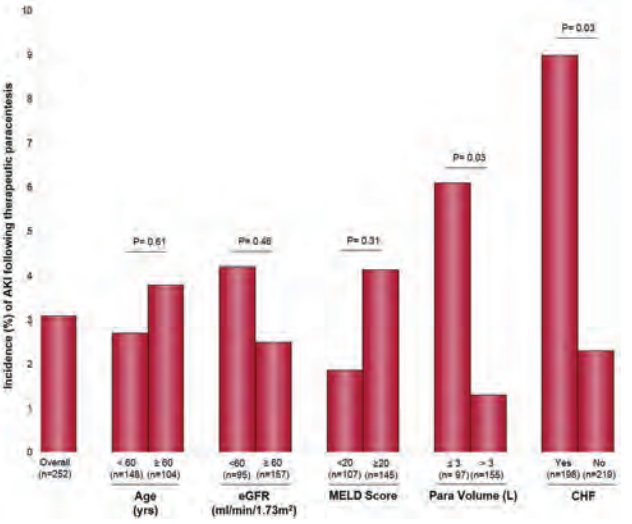
Shreyak Sharma,[1] Harish Shanthanu Seethapathy,[2] Sophia Zhao,[2] Andrew S. Allegretti,[2] David E. Leaf.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Brookline, MA.*

Background: AKI is a feared complication of therapeutic paracentesis. However, prior studies that assessed AKI incidence following paracentesis were limited by small sample sizes (most had <40 patients) and restricted generalizability (e.g., exclusion of inpatients).

Methods: We conducted a large, retrospective, "real-world" cohort study of all adult inpatients with cirrhosis who underwent a therapeutic paracentesis (>1L) while admitted to Massachusetts General Hospital between 2016 and 2018. We assessed the incidence and severity of paracentesis-associated AKI based on changes in SCr. AKI and its severity were defined based on KDIGO guidelines. We also performed stratified analyses to assess whether the incidence of AKI differed across subgroups.

Results: A total of 252 paracenteses were performed in 101 cirrhotic patients. IV albumin was administered in 77% of paracenteses. The overall incidence of AKI was 3%. AKI severity was as follows: 50% stage 1, 12.5% stage 2, and 37.5% stage 3. The incidence of AKI was similar when stratified by age (<60 vs. ≥60 years), baseline eGFR (<60 vs. ≥60 ml/min/1.73m²), and MELD score (<20 vs. ≥20). Patients who received lower compared to higher volume paracenteses (≤3L vs. >3L) had a higher incidence of AKI (6% vs. 1.3%; P=0.03), however, these patients were also less likely to have received IV albumin (65% vs. 84%; P<0.001). Patients with CHF had higher rates of AKI compared to patients without CHF (9% vs. 2.3%; P=0.03).

Conclusions: In a large cohort of inpatients with cirrhosis undergoing therapeutic paracentesis, we found that post-procedure AKI rates were low. This finding was consistent across multiple subgroups, with the notable exception of CHF. Therapeutic paracentesis with IV albumin replacement is a procedure that can generally be performed without significant concern for AKI.



TH-PO082

An Evaluation of the Prevalence of Kidney Diseases in Patients with Inflammatory Bowel Diseases in a Nationwide Analysis

Manish K. Saha,[1] Edward L. Barnes,[2] Ronald J. Falk,[1] Patrick H. Nachman,[3] Kim L. Isaacs,[2] Carolyn T. Thorpe,[2] Susan L. Hogan,[2] Abhijit V. Kshirsagar.[2] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC; [3]University of Minnesota, Minneapolis, MN.*

Background: Up to 40% of patients with Inflammatory bowel diseases(IBD) may have extra-intestinal manifestations, mainly involving liver, skin, and joints. Anecdotal reports suggest renal involvement, but there are no estimates of prevalence. Our aim was to examine the prevalence of kidney diseases among hospitalized patients with IBD, along with the prevalence of kidney disease among patient with collagen vascular diseases (CVD) and among patients without IBD and CVD

Methods: We analyzed 2000-2014 data from the Healthcare Cost and Utilization Project-Nationwide Inpatient Sample database which captures annual hospital discharge data for 20% stratified sample of U.S.community hospitals. We used International Classification of Diseases, Ninth Revision, diagnosis codes to identify three subsamples. Kidney diseases include acute kidney injury, glomerular diseases and others. CVD included systemic lupus erythematosus, rheumatoid arthritis and others.

Results: Among 713,902 hospitalized IBD patients, we identified 69,049 individuals with kidney diseases(9.6%), representing a weighted national estimate of 341,946 individuals with kidney diseases. The prevalence of kidney disease among patients with IBD was 9.6%,11.9% in patients with CVD, and 8.5% in the general population (all p<0.001). Baseline characteristics of patients in three groups are given in Table1. Patients with IBD had a younger age distribution, higher distribution of white race, and a lower prevalence of hypertension, diabetes, and CHF when compared to patients with CVD or the general population without IBD or CVD

Conclusions: The burden of renal disease among patients with IBD is greater than that of the general population, which is notable given their lower traditional risk factors for kidney disease;and similar to CVD which is an immune-mediated systemic disorder. Coexisting renal disease should be considered among patients with a known diagnosis of IBD

Table	All IBD N=713,902	All CVD N=1,809,221	All pts - IBD- CVD N=94,215,528	p-value*
Age				<0.001
18-39	30.5%	10.7%	25.0%	
40-59	33.2%	28.1%	25.5%	
>60	36.2%	61.0%	48.6%	
Female	56.9%	78.8%	60.0%	<0.001
Race(White)	67.1%	59.2%	56.2%	<0.001
HTN	27.2%	44.9%	35.4%	<0.001
DM	13.3%	21.5%	21.3%	<0.001
CHF	6.3%	15.8%	13.0	<0.001
% with Kidney Diseases	9.6%	11.9%	8.5%	<0.001

* Chi-square testing, including pairwise comparisons with Bonferroni correction, was used for all evaluations. In pairwise comparisons of disease states, patients with IBD were compared to patients with CVD and those patients without IBD or CVD; patients with CVD were compared to patients with IBD and patients without IBD or CVD(all p<0.001).

Table1

TH-PO083

EPILAT-IRA Study: A Contribution to the Understanding of the Epidemiology of AKI in Latin America

Raul Lombardi,[1] Alejandro Ferreiro,[2] Rolando Claure-Del Granado,[3] Guillermo J. Rosa diez,[4] Emmanuel A. Burdmann,[5] Luis Yu,[6] Mauricio Younes-Ibrahim.[7] on behalf of EPILAT-IRA Study Group. AKI Committe Latin American Society of Nephrology and Hypertension *[1]Nephrology, Universidad de la República, Montevideo, Uruguay; [2]School of Medicine, Montevideo, Uruguay; [3]Hospital Obrero #2 - C.N.S.; Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [4]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [5]University of Sao Paulo Medical School, Sao Paulo, Brazil; [6]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [7]Internal Medicine, University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Acute kidney injury (AKI) is a public health problem, due to its high and rising frequency, its association with increased morbidity and mortality, and the economical burden related to its care. Considering the limited data on AKI epidemiology in Latin America and the Caribbean, we performed a prospective observational study to determine risk factors, clinical profile, process of care and outcomes of AKI in the region

Methods: Participants were recruited by open invitation through the Latin American Society of Nephrology and Hypertension. Patients meeting the KDIGO AKI definition, during hospitalization, were included over a a 9-month period and designated as community or hospital acquired. De-identified clinical and lab data was entered in a specifically designed on-line platform. Co-variables potentially linked to AKI were recorded and correlated with mortality at hospital discharge and 90 days using a multiple logistic regression model

Results: A total of 57 participants from 15 countries provided data on 905 patients, the majority of them with acceptable coverage of basic needs. Median age was 64 (50-74) yrs. and 61% were male. Comorbidities were present in 77% of the patients. AKI was community-acquired in 62%. Dehydration, shock and nephrotoxic drugs were the most usual AKI causes. Seventy-seven percent of the patients were assessed by nephrologists. Renal replacement therapy was performed in 29% of cases. All-cause in-hospital mortality was 26.5% and was independently associated to older age, chronic liver disease, hypotension, shock and cardiac disturbance as etiologic factors, infection and sepsis as in-hospital complications, need of renal replacement therapy and mechanical ventilation. Mortality at 90-days follow up was 25%.

Conclusions: This study provides new information on the characteristics and outcomes of AKI patients in Latin America and Caribbean region. Notwithstanding, this study represents partially the AKI situation in the participant countries rather than the actual epidemiology of AKI in Latin America, a pending and needed task.

TH-PO084

Increased Mortality Among AKI Patients Attending the Emergency Department: A Retrospective Hospital-Based Cohort Study

Asmaa Y. Al- Chidadi,[1] Soha Choi,[4] Dimitra Stathi,[2] Steady Chasimpha,[3] Bahareh Arsalanizadeh,[1] Sourjya Kar,[4] Floyd Pierres.[4] *[1]Department of Nephrology, North West Anglia NHS Foundation Trust, Peterborough, United Kingdom; [2]North Anglia Trust, Peterborough, United Kingdom; [3]London School of Hygiene and Tropical Medicine, London, United Kingdom; [4]North West Anglia NHS Trust, Peterborough, United Kingdom.*

Background: It is well documented that acute kidney injury (AKI) is associated with increased inpatient mortality, but this association is poorly described in the emergency department (ED) setting.

Methods: Between April 2016 and March 2017, we randomly selected electronic records of 365 patients from 1695 presented to ED with AKI using an electronic AKI reporting system, and compared them to 379 randomly selected patients without AKI. The cohort was followed up till the end of April, 2019. Mortality as well as other demographic characteristics were compared.

Results: Incidence of AKI was 5.3%. AKI was associated with significantly higher risk of death 50.27% compared with 22.96% amongst those with no AKI (p< 0.001). Those whose AKI worsened while inpatients had a higher mortality risk of 63.6% compared to 49.09% in these whoms AKI did not progress to a higher stage, although it did not reach statistical significance (p=0.11). Risk of inpatient mortality was significantly higher amongst the AKI group (34.4% vs 0.0% P=<0.0001). Risk of readmission within 30 days did not significantly differ between the 2 groups (16.5% vs 21.4%, P=0.14). At 12 months, 71.9% of the AKI group developed CKD progression or de novo CKD compared to 54.6% in controls (P=<0.0001). Average follow-up time was 3.14 years. After adjusting for age, gender, ethnicity, 13 comorbidities, serum sodium and albumin, AKI was still independently associated with increased mortality (adjusted HR 1.93, CI 1.4-2.7). Hypoalbuminemia (HR 2.1 CI 1.5-2.9 P=<0.0001), being 75-84 years old (HR 1.7 CI 1.1-2.7 P=0.02), or over 85 years (HR 2.3 CI 1.5-3.5, P=<0.0001), as well as having at least one comorbidies (HR 1.5 CI 1.1-2.1, P=0.02) were all independently associated with mortality.

Conclusions: Presentation to ED with AKI is independently associated with inpatient deaths as well as overall mortality and morbidity.

TH-PO085

Renal Failure After Knee Arthroplasty and Antibiotic Cement: Role of Dialysis

Pradeep Vaitla,[1] Swetha Rani Kanduri,[1] Prakrati C. Acharya,[2] Karthik Kovvuru,[2] Rachana Marathi.[3] *[1]Nephrology, University of Mississippi, Jackson, MS; [2]University of Mississippi Medical Center, Ridgeland, MS; [3]University of mississippi, Madison, MS.*

Introduction: Two-step arthroplasty procedures have become the standard of care in the treatment of prosthetic joint infections. Antibiotic spacer placement is associated with renal failure requiring dialysis depending on the type and amount of antibiotics. We present a case of renal failure post-antibiotic cement placement. To our knowledge, our case reports one of the highest serum tobramycin levels post spacer impregnation

Case Description: A 65-year-old female with a history of left knee replacement presented with worsening pain and an inability to extend the knee. Bedside arthrocentesis was consistent with an infected prosthetic left knee. She underwent elective arthroplasty. She had no h/o CKD, DM, HTN. She underwent the first step of revision arthroplasty with successful fusion nail and placement of antibiotic cement. Intraoperatively she sustained hypotensive episodes requiring levophed for a brief period. Post-op she had hypoxic respiratory failure associated secondary to laryngeal swelling and stridor, which resolved with steroids On postoperative (POD) day 2 nephrology was consulted for oliguric renal failure with a serum creatinine of 3.06 mg/dl (Pre-op creatinine 0.7 mg/dl). Renal failure was speculated to be from nephrotoxic medications and Ischemic acute tubular necrosis. Surgery consisted of placing an antibiotic cement spacer, which contained a total of 12 grams of vancomycin and 15 grams of Tobramycin Drug levels obtained on POD 3 were 38mcg/ml of Vancomycin and 20 mcg/ml of Tobramycin. Her renal failure continued to worsen with a peak serum creatinine of 4.9 mg/dl, developed anuria. She was started on hemodialysis and received 5 sessions over the next 7 days. Dialysis sessions were extended to 4 hours to achieve drug clearance. POD day15, levels decreased to 6.6 mcg/ml of tobramycin and 18.3 mcg/ml of Vancomycin. She demonstrated renal function recovery with a reduction in Tobramycin levels. With an improvement in the renal function explantation of the antibiotic spacer was not required

Discussion: Arthroplasty procedures with antibiotic cement impregnation are associated with significant AKI with incidence varying from 4.8% - 26%. Early recognition of toxicity and timely hemodialysis sessions may help the recovery of renal function and avoid re-exploration and explanation of prosthetic joints and antibiotic spacers

TH-PO086

Incidence and Risk Factors of AKI After Total Hip Arthroplasty or Revision in Kidney Transplant Recipients (KTx)

Sorkko Thirunavukkarasu, Ziad Zoghby. *Mayo Clinic, Rochester, MN.*

Background: Immunosuppressive regimens increase the risk of bone complications such avascular necrosis and osteoporosis in KTx. Treatment of choice is Arthroplasty but limited data show that adverse events, specifically AKI is higher in KTx (16-26.6%) compared to the general population (1.1%). AKI has been linked to increased morbidity and mortality. Our aim was to determine the incidence of AKI in KTx undergoing primary hip arthroplasty (THA)or revision (THA-R), identify risk factors associated with AKI and evaluate its effect on allograft function at 1 year.

Methods: Using the orthopedic and transplant databases, we designed a case-control study of 102 patients undergoing a total of 141 THA and THA-R between 2000 and 2018 at the Mayo Clinic. Variables of interest not available in the databases were obtained through chart review. AKI was defined per the current KIDGO guideline.

Results: The average age at surgery was 59 years (range 27-82); with 58% male and 96% white. The most common surgical indications for THA were degenerative joint disease (57%), avascular necrosis (27%), and fractures (12%); and for THA-R, loosening (28%), dislocation (22.7%) and Infection (9%). The incidence of AKI was 10.4% and 17% in THA and THA-R, respectively (p=0.36). All AKI were stage 1 per AKIN criteria. Anesthesia time was longer in patients with AKI (232 vs 196 min, p = 0.055) and in those undergoing THA-R compared to THA (256 vs 182 min <0.001). The length

of hospitalization for those with AKI was 5.1 vs. 4.3 days for those without AKI (p = 0.2). There was no significant difference between vasopressors use, blood loss, need for transfusion, crystalloid or colloid administration between the AKI and Non-AKI groups. At one year, mean change in eGFR was not different between the two groups (AKI: -1.7 ml/min; Non-AKI: -2.6 ml/min; p = 0.7).

Conclusions: The incidence of AKI after total hip arthroplasty in KTx was 10.4% (17% after revision arthroplasty) and associated with longer hospitalization. However, all cases of AKI were mild, resolved by hospital discharge and did not affect allograft function at 1 year.

TH-PO087

Risk Factors of AKI in Upper Urinary Tract Obstruction

Bong gyun Sun, Jihyun Yang, Hyeonjin Min, Young-Bin Son, Eunho Choi, Kijoon Lim, Kyungmi Lee, Sewon Oh, Myung-Gyu Kim, Sang-Kyung Jo. *Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea.*

Background: Obstruction to urine flow occurs at any site in the urinary tract and development of post-renal acute kidney injury (AKI) depends on whether it is acute or chronic, unilateral or bilateral and presence of combined sepsis. However, incidence, etiologies, risk factors or prognosis of post-renal AKI in urinary tract obstruction are largely unknown due to paucity of extensive epidemiologic data.

Methods: We conducted a retrospective analysis of 1,784 patients who received percutaneous nephrostomy (PCN) due to upper urinary tract obstruction in 3 university hospitals in Korea from January 1, 2002 to August 16, 2018. AKI was diagnosed according to KDIGO AKI criteria and analyzed risk factors of AKI using multivariate logistic regression analysis.

Results: AKI developed in 79.9% of patients who underwent PCN. Patients with post-renal AKI were more likely to be male (50.4 vs 51.1%, p<0.01)), older (64 vs 57yrs, p<0.01) and associated with decreased baseline renal function (eGFR 72.88 vs 90.79 ml/min/1.73m2, p<0.01). Prevalence of hypertension (47.5 vs 35.5%, p<0.01)), ischemic heart disease (5.4 vs 2.3%, p=0.013), peripheral arterial occlusive disease (7.1 vs 3.9%, p=0.03), heart failure (4.5 vs 1.1%, p<0.01) or cancer (68.5 vs 53%, p<0.01) was significantly higher in patients with AKI compared with those without AKI. Mean hemoglobin level, protein, albumin and tCO2 level were significantly lower while uric acid, CRP and procalcitoning level were significantly elevated in patients with AKI. In multivariate logistic regression analysis, lower tCO2 (OR 0.835, 95% CI 0.716-0.975, p=0.022) and albumin level (OR 0.190, 95% CI 0.049-0.739, p=0.017), and high uric acid level (OR 2.004, 95% CI 1.252-3.208, p=0.004) were significantly associated with the development of AKI in these patients.

Conclusions: The incidence of AKI was very high (79.7%) in patients who underwent PCN due to upper urinary tract obstruction. Anemia, leukocytosis, hyperuricemia, and underlying hypertension are found to be independent risk factors for AKI with male predominancy.

TH-PO088

Risk Factors of AKI in Patients with Decompensated Cirrhosis

Lianxin Luo, Fangfang Zhou, Lina Han, Qun Luo. *Hwamei Hospital, University of Chinese Academy of Sciences, Ningbo, China.*

Background: Acute kidney injury(AKI)is a common complication with high mortality and morbidity in decompensated cirrhotic patients. However, few studies concerning the risk factors of cirrhosis-associated AKI have been published. In our study, we aim to investigate the risk factors of AKI in patients with decompensated cirrhosis in our hospital from 2012 to 2016.

Methods: We performed a single-center retroperspective stuty. Clinical data of patients with decompensated cirrhosis were collected from Dept. of Liver diseases, Hwamei Hospital, University Of Chinese Academy of Sciences from 2012 to 2016. According to the KDIGO criteria, patients were divided into AKI group and non-AKI group. Risk factors for AKI were analyzed by univariate and multivariate analysis methods.

Results: 945 inpatients with decompensated cirrhosis (mean age was 55.42 and 65.3% were male.) were enrolled, with the incidence of AKI being 17.7%. The mean course of cirrhosis was (5.59±4.94) years and the average **length of stay** was (20.01±14.00) days. Multivariate Logistic regression analysis showed that increased age (OR=1.031, p=0.001), infection (OR=7.125, p<0.001), decreasing eGFR (OR=0.845, p<0.001), ascites (OR=5.012, p<0.001), and ACEI/ARB use (OR=7.882, p=0.003) were independently correlated with patients with decompression cirrhosis complicated with AKI.

Conclusions: There was high incidence of AKI in patients with decompensated cirrhosis, whose independent risk factors were associated with increasing age, infection, decreasing eGFR, ascites and using of ACEI/ARB.

TH-PO089

AKI in Hospitalized Patients Who Underwent Percutaneous Kidney Biopsy

Henrique P. Konigsfeld,[1] Thais O. Santos,[1] Marcelino S. Durao.[2,1] *[1]UNIFESP, São Paulo, Brazil; [2]Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: Performing a kidney biopsy is necessary to accurately diagnose diseases such as glomerulonephritis and tubulointerstitial nephritis, among other such conditions. These conditions predispose patients to chronic kidney disease, as well as acute kidney injury (AKI). Notably, most epidemiological studies describing AKI have not investigated this patient population.

Methods: Included patients admitted to the nephrology ward of a tertiary hospital who underwent percutaneous kidney biopsy. AKI was diagnosed based on the Kidney Disease: Improving Global Outcomes criteria.

Results: Of the 223 patients investigated, 140 (62.8%) showed AKI. Of these, 91 (65%), 19 (13.6%), and 30 (21.4%) presented with AKI classified as stages 1, 2, and 3, respectively. The primary indication for performing biopsy was nephrotic syndrome or nephrotic proteinuria (73 [52.1%] in the AKI vs. 51 [61.4%] in the non-AKI group, p=0.048). Focal segmental glomerulosclerosis was the most prevalent primary disease (24 [17.1%] in the AKI vs. 15 [18.0%] in the non-AKI group, p=0.150). Multivariate analysis of risk factors associated with AKI showed hemoglobin levels (odds ratio [OR] 0.805, 95% confidence interval [CI] 0.681–0.951, p=0.011), serum high-density lipoprotein cholesterol levels (HDL-c, OR 0.970, 95% CI 0.949–0.992, p=0.008), and baseline serum creatinine levels (OR 2.703, 95% CI 1.471–4.968, p=0.001) were significantly associated with AKI.

Conclusions: We observed a high incidence of AKI in hospitalized patients who underwent kidney biopsy to investigate their renal disease, particularly glomerulonephritis. Higher levels of hemoglobin and serum HDL-c were associated with a lower risk of AKI.

TH-PO090

Incidence and Risk Factors of AKI and Tumor Lysis Syndrome in Patients with Multiple Myeloma Treated with Bortezomib

Seungmin Song, Kyungho Park, Kyungho Lee, Hye Ryoun Jang, Wooseong Huh, Yoon-Goo Kim, Dae joong Kim, Jung eun Lee. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Nephrotoxicity of bortezomib, a proteasome inhibitor, has not yet been described frequently, while tumor lysis syndrome (TLS) associated with multiple myeloma (MM) has been increased after introduction of the drug. This study compared the incidence and risk factors of acute kidney injury (AKI) and TLS in patients with MM after bortezomib-based chemotherapy to investigate the drug-related nephrotoxicity.

Methods: From 2006 to 2017, 276 patients who underwent first cycle of bortezomib-based chemotherapy for MM were identified in single tertiary hospital. Laboratory TLS was defined according to the Cairo-Bishop definition. Development of AKI was assessed by AKI Network criteria within 7 days after first chemotherapy.

Results: The age was 65 [56-72] years old, and 47% (n=131) of participants were female and baseline estimated glomerular filtration rate (eGFR) was 61.3 [34.1-89.1] mL/min/1.73m^2. The incidences of AKI and laboratory TLS were 17% (n=47) and 13% (n=36), respectively. Ten (3.6%) subjects corresponded to the both AKI and TLS criteria. Multivariate analyses showed that lower eGFR category (30~59, odds ratio [OR]=3.063 [1.278-7.339]; 15~29, OR=3.417 [1.088-10.726]; <15, OR=10.080 [2.677-37.951] vs ≥ 60), lower serum albumin level (OR=0.491 [0.278-0.868], *P*=0.0144) and renal amyloidosis (OR=11.174 [3.974-31.420], *P*<0.0001) were predictors of development of AKI. MM stages and β2-microglobulin were not associated with AKI occurrence. Regarding laboratory TLS, MM stage and β2-microglobulin were higher in those with TLS. In multivariate analyses, β2-microglobulin levels (OR=1.194 [1.066-1.337], *P*=0.0021) and any chromosomes abnormalities at high risk (OR=0.115 [0.026-0.503], P=0.0041) were associated with higher risk of TLS.

Conclusions: Development of AKI was often observed without being accompanied by TLS in patients with MM after treatment of bortezomib. In addition, risk factors of AKI and TLS were widely different. These findings implicated the potential nephrotoxicity of bortezomib besides TLS in patients with decreased kidney function. The efforts to prevent the developments of AKI are needed in patients with risk factors, when initiating bortezomib treatment.

TH-PO091

Clinical Significance of AKI in Lung Cancer Patients

Semin Cho,[1] Eunjeong Kang,[1] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[2] Hajeong Lee.[2] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: Acute kidney injury (AKI) in cancer patients is related to increased morbidity and mortality. Previous our exploration of AKI in cancer patients showed unexpectedly a higher incidence of AKI in lung cancer patients than those with other malignancy. This study aimed to evaluate the clinical significance of AKI in lung cancer patients.

Methods: The patients diagnosed as lung cancer from 2004 to 2013 in Seoul National University Hospital were enrolled. They were categorized into two groups by an occurrence of AKI, and the patients with AKI were categorized into three groups by AKI stage. AKI was defined according to KDIGO-AKI guideline. Demographic factors, co-morbidities, laboratory findings, count of contrast-enhanced computed tomography (CE-CT), pathologic types, and treatment options such as surgery and chemotherapy were included as covariates. We performed Cox proportional hazard modeling for mortality among patients who survived more than 1 year after cancer diagnosis.

Results: A total of 3,202 patients were included in the final analysis. Mean age was 63.8±10.34 years and 68.6% were male. AKI occurred in 1,783 (55.7%) patients during the follow-up period. Most AKI was mild AKI with stage 1 (75.8%). We found that the development of AKI were independently associated with older age, higher systolic blood pressure, diabetes mellitus, high initial serum creatinine, anemia, hyperkalemia,

hypophosphatemia, hyperuricemia, hypoalbuminemia, acidosis, frequent CE-CT, and chemotherapy. During follow-up duration (2.64±2.18 years), 21 (0.7%) patients reached end-stage kidney failure and all of them were experienced AKI. In the survival analysis, we found that not only AKI development but also AKI severity was an independent risk factors for mortality even after adjustment with cancer-specific variables including stage or pathologic type.

Conclusions: In this study, more than half of lung cancer patients experienced AKI during their diagnosis and treatment period. Moreover, AKI occurrence and more advanced AKI were associated with higher mortality risk. Further studies about risk factor analysis for AKI occurrence should be needed to prevent AKI in lung cancer patients.

TH-PO092

Characteristics and Outcomes of Hospitalized Homeless AKI Patients

Nattawat Klomjit,[1,2] Janina Paula T. Sy-Go,[2] Roland C. Ng.[2] *[1]Mayo Clinic, Rochester, MN; [2]University of Hawaii Internal Medicine Residency Program, Honolulu, HI.*

Background: Hawaii has the highest rate of homeless population per capita. Homeless people are a vulnerable group and prone to multiple health problems, including kidney diseases. Little is known about the characteristics and outcomes of acute kidney injury (AKI) in this population.

Methods: This is a retrospective study of homeless and domiciled patients who were admitted to a tertiary medical center in Honolulu, Hawaii between 2015-2016, with AKI diagnosis present on admission by ICD10 code and meeting 2012 KDIGO criteria for AKI.

Results: Between 2015 and 2016, we identified 324 patients who were admitted with AKI of which 6.48 % were homeless. Mean age of homeless patients was 56.9±8.75 compared to domiciled patients 65.85±17.59 with p<0.01. Homeless patients tended to be female (80.85%) compared to domiciled patients (52.81%), p<0.01. Caucasian race was a majority of the homeless patients, 47.62%, compared to 21.45% in domiciled patients. 71.43% of the homeless patients had a pre-renal cause of AKI compared to 38.61% in domiciled patients, p=0.06. There was no difference in percentage of underlying chronic kidney disease between homeless and domiciled patients, p=0.89. 38.10% of homeless patients visited the emergency room within 1 month prior to an index admission compared to 17.49% in domiciled patients, p=0.02. Homeless patients were more likely to be a substance user, current smoker, and alcohol abuser compared to domiciled patients, all p<0.01. Homeless patients were more likely to be discharged with a lower serum creatinine, p<0.01, and significantly shorter hospital stay, p=0.04.

Conclusions: Homeless AKI patients tended to be younger, more likely a substance user, current smoker, alcohol abuser, and with liver disease than domiciled patients. Caucasian race was the majority of homeless patients, whereas Asian race was the majority of domiciled patients. Although pre-renal cause was the most common cause of AKI in both groups, the rate of pre-renal cause in homeless patients was almost twice that of domiciled patients. There was no difference in admission serum creatinine, but the homeless were discharged with lower serum creatinine likely due to a higher rate of reversible kidney injury. There was no difference in mortality or dialysis rate.

TH-PO093

Incidence, Associated Factors, and the Survival After 1-Year Follow-Up in Patients with Community-Acquired AKI Admitted to the Emergency Room

Diego F. Argudo sanchez, L. M. Perez-Navarro, Maribel Merino, Rafael Valdez-Ortiz. *Hospital General de Mexico, Mexico City, Mexico.*

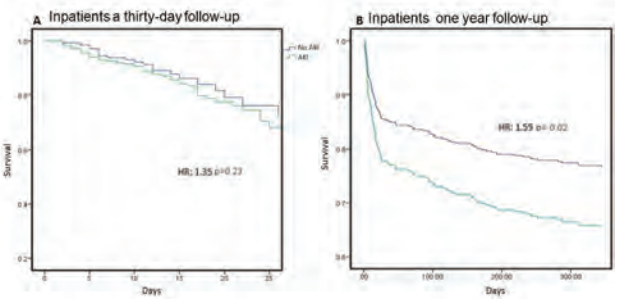
Background: Community acquired acute kidney injury (AKI-CA)is defined in patients who, at the time of admission to the hospital, present criteria for acute kidney injury diagnosis. The acute kidney injury (AKI) is frequent complication among inpatients in the emergency room (ER). Our aims were to know the incidence, associated factors and the one-year survival of patients with AKI-CA.

Methods: Prospective cohort of admitted patients in the ER. The AKI was defined according to KDIGO 2012 criteria. The groups were compared using the Student's t-distribution or the X2 distribution, logistic regression was performed for OR and a Cox regression for HR and survival with IC 95% and p≤0.05.

Results: Eight hundred thirteen patients with an average age of 52.4±18 years were included. The 55% (443) were men. The incidence of AKI-CA was 55%, where 32.5% was due to AKI-1, 15% AKI-2, and 7.5% AKI-3. The associated factors with the develop of AKI-CA were hypertension (OR: 1.5, IC95% 1.1-2), liver failure (OR: 3.5, IC95% 1.8-6.3), chronic kidney disease (OR:3.82, IC95% 1.7-8.3), sepsis OR:3.48, IC95% 2.3-5.1), and surgical pathology (OR:2.55, IC95% 1.7-3.8). According to the state of AKI the inpatients days increased (AKI-1:10.7, AKI-2:12.8, AKI-3:14.2 days, p< 0.001). The risk of death during the inpatients days did not exhibit significant differences among the patients with and without AKI (p=0.23, Figure 1). However, the analysis after a one-year follow up showed a mortality of 64% in patients with AKI-CA versus 36% in patients that did not suffer it (p<0.001), with increased mortality risk (Figure 1b).

Conclusions: A high incidence of AKI at the time of admission and with an impact on survival over one year of follow-up.

Figure 1. Survival of patients with Acute Kidney injury



TH-PO094

Community-Acquired AKI in Older Adults Admitted to the Emergency Medical Service: At 1-Year Follow-Up

Diego F. Argudo sanchez, L. M. Perez-Navarro, Ivan Rosero, Maria F. Garcia-Guevara, Rafael Valdez-Ortiz. *Hospital General de México Dr. Eduardo Liceaga, México, Mexico.*

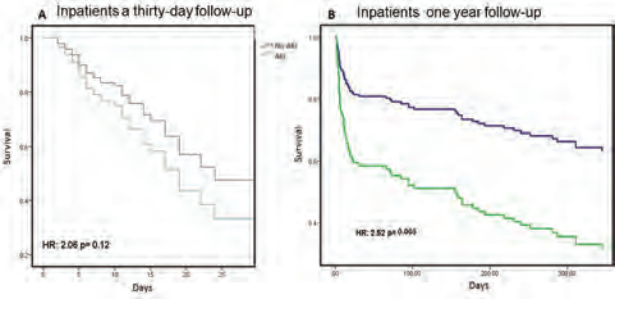
Background: Community acquired acute kidney injury (AKI-CA)is defined in patients who, at the time of admission to the hospital, present criteria for acute kidney injury diagnosis. Older adults are recognized as a vulnerable population for the development of AKI. The objective of this study was to determine the risk factors and the prognosis at one year follow-up of older adult's patients suffering from AKI-CA.

Methods: Cohort study in patients with ≥65 years old admitted in the emergency room, from March to May of 2018. The AKI-CA was according to the criteria of KDIGO 2012. The groups were compared using the Student's t-distribution or the X2 distribution depending on the type of variable, logistic regression was performed for OR, and a Cox regression for HR and survival with IC 95% and p ≤0.05.

Results: A total of 221 patients that satisfied the inclusion criteria, the average age was 75.1±7.6, the 44% (97) were men. The incidence of the AKI-CA was 58.8% being more common in patients with sepsis (p< 0.001), this was the principal associated factor with the development AKI-CA (OR: 3.52, IC95% 1.6-7.1). It was noticed that the highest stage of the AKI occurs in patients with previous chronic kidney disease (AKI1: 6.4% AKI2: 5.7% AKI 3: 41.2 % p< 0.001), or presence of sepsis (AKI1: 50.7% AKI2: 55.9% AKI 3: 57.1 % p= 0.009). It was not identified increase in risk of inpatient's mortality in patients with AKI-CA. In contrast, a relation between them was noticed after one year follow-up (Figure 1).

Conclusions: Older adults patients that suffer AKI-CA exhibit worst outcomes after one year follow up.

Figure 1. Survival of older adults patients suffering acute Kidney injury



TH-PO095

Differences on Outcomes Between AKI and AKI on CKD in Community-Acquired AKI

Rolando Claure-Del Granado,[1] Susana G. Ramirez-Yapura,[3] Emmanuel A. Burdmann,[4] Luis Yu,[5] Mauricio Younes-Ibrahim,[8] Alejandro Ferreiro,[6] Guillermo J. Rosa diez,[7] Raul Lombardi.[2] On behalf of EPILAT-IRA study group. AKI Committee of the Latin American Society of Nephrology and Hypertension (SLANH) *[1]Hospital Obrero #2 - C.N.S.; Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [2]Servicio Medico Integral, Montevideo, Uruguay; [3]Hospital Obrero #2 - C.N.S., Cochabamba, Bolivia, Plurinational State of; [4]University of Sao Paulo Medical School, Sao Paulo, Brazil; [5]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [6]School of Medicine, Montevideo, Uruguay; [7]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [8]University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: AKI is a frequent disorder in community-based populations. Most studies have focused on hospital-acquired AKI and very few have explored characteristics and outcomes of patients with community-acquired AKI (CA-AKI). CKD may adversely affect kidney repair and recovery from AKI. We therefore aimed to explore characteristics and outcomes of CA-AKI in patients with and without CKD.

Methods: We conducted a prospective observational study (EPILAT-IRA) within the ER of a University Hospital, screening for any patient ≥16 years. We included patients meeting sCr KDIGO AKI definition over a 9-month period and designated as community acquired. De-identified clinical and lab data was entered in a specifically designed on-line platform. Co-variables potentially linked to AKI were recorded and we analized if there were differences in short and long-term outcomes between patients with and without CKD.

Results: During study period we screened 1,210 patients, CA-AKI incidence was 11.65% (n = 141) most patients were male (55.32%) and the mean age was 67,9±2 years. There were no differences in risk factors between patients with AKI and AKI on CKD. Nephrotoxic drugs were the most common cause of CA-AKI in both groups (AKI 92.2% vs. AKI on CKD 87.2%; p= 0.72) followed by dehydration (AKI 81.3% vs AKI on CKD 76.9%; p 0.65) and systemic disease (AKI 81.3% vs. AKI on CKD 82.0%; p = 0.64). Different outcomes are reported in table.

Conclusions: CA-AKI in developing countries is common and potentially preventable since the two main etiology factors were dehydration and nephrotoxins. Hospital, 90-day and one year mortality were not different between AKI and AKI on CKD; however, RRT requirement was higher and partial recovery of renal function was lower in patients with AKI on CKD which indicates that CKD may adversely affect kidney repair and recovery. Our study provides important information that contributes to a better knowledge of CA-AKI.

Table 1. Comparison of the different outcomes between CA-AKI with and without CKD.

Variable	AKI (N=102)	AKI on CKD (N=39)	*P* value
90-day renal recovery			
Complete renal recovery	11.7%	23%	0.30
Partial renal recovery	50.9%	20.5%	0.01
Non-recovery	17.5%	23%	0.34
Required RRT	7.8%	15.4%	0.041
Nephrology consultation	51.5%	64.1%	0.16
Hospital length of stay (days)	14.4±12.2	11.2±8.7	0.016
In-hospital mortality	14.7%	15.4%	0.34
90-day mortality	24.7%	30.7%	0.428
One-year mortality	36.1%	47.4%	0.181

TH-PO096

Comparison of Urinary Biomarkers in Critically Ill Children: Early Detection of AKI, Prediction of Mortality, and Confounding Factors

Yanhong Li. *Department of nephrology, children hospital of Soochow University, Suzhou, China.*

Background: Most AKI biomarkers are susceptible to confounding factors in the prediction. We aimed to compare the performance of urinary biomarkers for early detection of AKI and the prediction of PICU mortality, and investigate the impact of confounding factors on these biomarkers in critically ill children.

Methods: Urine samples were serially collected in 123 children during the first 7 d of PICU stay for measurement of NGAL, KIM-1, TIMP2, IGFBP7, L-FABP, TIMP1, Renin, trefoil factor 3 (TFF-3), interferon-inducible protein-10 (IP-10). AKI diagnosis was based on KDIGO classification.

Results: Of the children, 35 developed AKI, including 12 with stage 1, 14 with stage 2 and 9 with stage 3, and 15 died during PICU stay. (1). The initial urinary biomarkers, associated with AKI stage 3 in univariate analysis, were TIMP1, KIM-1, NGAL, TIMP2, Renin and L-FABP; and achieved AUC of 0.75, 074, 0.74, 0.71, 0.70, and 0.68 for early detection of AKI stage 3. The initial TIMP1, TIMP2, NGAL, IP-10, KIM-1, L-FABP, TFF-3, Renin and IGFBP-7 achieved AUC of 0.84, 079, 0.78, 0.77, 0.76, 0.74, 0.73, 0.67 and 0.65 for predicting mortality. However, only initial TIMP1 remained associated with AKI stage 3 (P=0.016) and mortality (P=0.038) after adjustment for age, body weight and illness severity. (2). Peak urinary KIM-1 and TIMP2 remained associated with AKI stage 3; and peak KIM-1, NGAL, L-FABP, and IP-10 remained associated with mortality after adjustment. (3). Illness severity assessed by PRISM III was identified as an independent factor associated with all the initial and peak urinary biomarkers. Sepsis had an impact on initial and peak levels of NGAL, KIM-1 and IP-10 and peak Renin levels. Furosemide was independently associated with initial and peak levels of NGAL, L-FABP, TIMP1 and Renin and peak KIM-1, TIMP2 and TFF3 levels.

Conclusions: Although a higher initial urinary level of TIMP1, NGAL, KIM-1, TIMP2, Renin or L-FABP is predictive of severe AKI and mortality in critically ill children, these urinary biomarkers are significantly associated with illness severity and influenced by confounding factors. Sepsis has an impact on levels of NGAL, KIM-1, Renin and IP-10. Furosemide affects NGAL, FABP-1, TIMP1 and Renin. Sepsis appeared not to have impact on urinary TIMP1 and TIMP2, in contrast to NGAL and KIM-1, in critically ill children.

TH-PO097

Biomarkers in the Prediction of Contrast Media Induced Nephropathy: The BITCOIN Study

Felix S. Seibert, Nikolaos Pagonas, Timm H. Westhoff. *University Hospital Marien Hospital Herne, Herne, Germany.*

Background: Subjects with chronic kidney disease (CKD) are at increased risk for the development of contrast-induced acute kidney injury (CI-AKI). It remains elusive, whether urinary biomarkers are able to identify subjects at increased risk as well. The present prospective trial examines the predictive value of urinary neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), calprotectin, and Dickkopf-3 (DKK3) for the development of CI-AKI.

Methods: We enrolled 489 patients undergoing coronary angiography, 137 subjects had a CKD. An increase of serum creatinine concentration ≥ 0.3 mg/dl from baseline to day 2-3 was defined as CI-AKI and primary endpoint. Urinary calprotectin, NGAL, KIM-1 and DKK3 concentrations were assessed < 24h before coronary angiography.

Results: 30 (6.1%) patients suffered from CI-AKI (27 AKIN stage I, 3 AKIN stage II, none AKIN stage III). Those subjects with CI-AKI showed significantly higher concentrations of NGAL (p=0.001) and DKK3 (p=0.001) at baseline. No difference was obtained for KIM-1 (p=0.057) and calprotectin (p=0.36). Predictive accuracy was assessed by receiver operating characteristics (ROC) calculations yielding an area under the curve (AUC) of 0.69 each. CI-AKI was twice as prevalent in 137 patients with CKD (n=15, 11%; no AKIN III, 2 CIN AKIN II). The AUC of eGFR to predict CI-AKI in the overall study population was 0.59.

Conclusions: The present study is the largest prospective study so far, investigating the use of urinary biomarkers for the risk assessment before application of contrast-media. Urinary NGAL and DDK3 are able to identify patients at risk for CI-AKI, whereas KIM-I and calprotectin do not.

TH-PO098

Admission Plasma Uromodulin and the Risk of AKI in Hospitalized Patients with Cirrhosis

Kavish R. Patidar,[3] Pranav S. Garimella,[2] Etienne Macedo,[2] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]University of California San Diego, San Diego, CA; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: Acute kidney injury (AKI) is a common complication in patients hospitalized with decompensated cirrhosis. Current methods for identifying patients at risk for AKI are suboptimal. Uromodulin, a protein uniquely produced by the kidney and released both in the urine and circulation, has been shown to regulate AKI and is linked to tubular reserve. Although low levels of urine uromodulin are associated with an increased risk of AKI after cardiac surgery, it is unclear whether circulating uromodulin can stratify the risk of AKI, particularly in a susceptible population such as patients with cirrhosis.

Methods: Patients admitted with cirrhosis were monitored for subsequent hospital-acquired AKI (defined by a rise in serum creatinine more than 0.3mg/dL within 48 hours or 1.5 fold increase compared to baseline). Plasma levels of uromodulin were measured at the time of hospital admission. Multivariable logistic regression adjusted for significant clinical variables was used to evaluate the associations between admission uromodulin and odds of developing AKI.

Results: 98 patients [mean age 54 years, Model for Endstage Liver Disease Sodium score (MELD-Na) 19, and baseline creatinine of 0.95 mg/dl] were included, of which 13% (n=13) developed AKI. Median uromodulin levels were significantly lower in patients who developed AKI compared to patients who did not (9.30 vs. 13.35 ng/mL, p=0.02). After adjusting for age, sex, diabetes, hypertension, albumin, and MELD-Na score (which includes kidney function) as co-variates, uromodulin was independently associated with AKI [OR of 1.19 (95% CI 1.02, 1.37; p=0.02)].

Conclusions: Lower uromodulin levels on admission are associated with increased odds of subsequent AKI in hospitalized patients with cirrhosis. To our knowledge, this is the first study linking plasma uromodulin with AKI development, albeit in a unique population of patients with cirrhosis. If validated in larger studies, the measurement of circulating uromodulin on admission could enhance our clinical decision making for risk assessment of AKI in patients with liver disease.

TH-PO099

Effect of 3% Saline and Furosemide on Biomarkers of Kidney Injury and Renal Tubular Function and GFR in Healthy Subjects: A Randomized Controlled Trial

Frank H. Mose,[1,2] Marie H. Vrist,[1,2] Jesper N. Bech.[1,2] *[1]University Clinic in Nephrology and Hypertension, Hospital Unit West Jutland, Holstebro, Denmark; [2]Aarhus University, Holstebro, Denmark.*

Background: Chloride is speculated to have nephrotoxic properties. In healthy subjects we tested the hypothesis that acute chloride loading with 3 % saline would induce kidney injury, which could be prevented with furosemide.

Methods: The study was designed as a randomized, placebo-controlled, crossover study. Subjects were given 3 % saline accompanied by either placebo or furosemide. Before, during and after infusion of 3 % saline we measured GFR, fractional excretion of sodium (FE_{Na}), urinary chloride excretion (u-Cl), urinary excretions of aquaporin-2 (u-AQP2), neutrophil gelatinase-associated lipocalin (u-NGAL) and kidney injury molecule-1 (u-KIM-1) as marker of kidney injury and vasoactive hormones: renin (PRC), angiotensin II (p-AngII), aldosterone (p-Aldo) and arginine vasopressin (p-AVP). Four days prior to each of the two examinations subjects were given a standardized diet and fluid intake.

Results: After 3% saline infusion u-NGAL and KIM-1 excretion increased slightly (u-NGAL: 17+/- 24 during placebo vs. -7 +/- 23 ng/min during furosemide, p=0.039, u-KIM-1: 0.21 +/- 0.23 vs -0.06 +/- 0.14 ng/ml, p<0.001). The increase in NGAL was absent when furosemide was given simultaneously, and the responses in NGAL were not significantly different from placebo control. Furosemide changed responses in KIM-1 where a delayed increase was observed. GFR was increased by 3 % saline but decreased when furosemide accompanied the infusion. U-Na, FE_{Na}, u-Cl, and u-osmolality increased in response to saline, and the increase was markedly pronounced when furosemide was added. FE_K decreased slightly during 3 % saline infusion, but simultaneously furosemide increased FE_K.U-AQP2 increased after 3 % saline and placebo, and the response was further increased by furosemide. 3 % saline significantly reduced PRC, p-AngII and p-Aldo, and responses were attenuated by furosemide. p-AVP was increased by 3 % saline, with a larger increase during furosemide.

Conclusions: This study shows minor increases in markers of kidney injury after 3% saline infusion Furosemide abolished the increase in NGAL and postponed the increase in u-KIM-1. The clinical importance of these findings needs further investigation.

Sarcopenia May Be a Protective Factor for Mortality in Severe AKI Patients Requiring Continuous Renal Replacement Therapy

Jung Nam An,[1] Hyung Jung Oh,[3] Jung Pyo Lee,[1] Dong Ki Kim,[4] Dong-Ryeol Ryu,[5] Sejoong Kim.[2] *[1]Seoul National University Boramae Medical Center, Seoul, seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, GyeonGgi-Do, Republic of Korea; [3]Ewah Womans' University, Mokdong Hospital, Seoul, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea; [5]Ewha Womans University, Seoul, Republic of Korea.*

Background: Sarcopenia can be defined as degenerative loss of skeletal muscle, which has been associated with poor prognosis in patients with chronic kidney disease or end-stage renal disease. However, the clinical impact of sarcopenia in acute kidney injury (AKI) has not been studied extensively.

Methods: Among the patients diagnosed with severe AKI requiring continuous renal replacement therapy (CRRT) at multi-center from May 2017 to March 2018, Inbody, impedance body fat analyzer, was measured at the start of CRRT. We measured muscle mass, body fat mass, and water content using an inbody, and analyzed the long-term outcome including mortality.

Results: A total of 417 patients were enrolled. We calculated the dry weight of the patients using the Tahara edema index to rule out the possibility that the fluid overload would have caused the body weight to be higher than actually measured. The calculated dry body weight was used for the study. Sarcopenia was defined as an appendicular skeletal muscle mass (ASM)/body weight (ASM%) beyond two standard deviations below the gender-specific mean for healthy young adults according to nationwide health examinations of the Korean population (ASM% <29.0 in men or <22.9 in women was considered to indicate sarcopenia). Of these, 71 (17%) had sarcopenia. Patients diagnosed with sarcopenia were more males, older, with more diabetes and congestive heart failure. However, age-modified CCI, baseline renal function, APACHE II score, and SOFA score were not different between two groups. When mortality was defined as the primary outcome, mortality was significantly lower in the patients with sarcopenia (HR 0.47; 95% CI 0.24-0.91; P = 0.026).

Conclusions: In this study, muscle mass was directly measured in patients with AKI, and the relationship between sarcopenia and long-term outcome was investigated. Further studies on specific mechanisms and causes will be needed.

Cell Cycle Biomarkers and Soluble Urokinase-Type Plasminogen Activator Receptor for the Prediction of Septic AKI Courses Requiring Renal Replacement Therapy: An Explorative Study

Christian Nusshag,[2] Christoph Rupp,[2] Claudius Speer,[2] Florian Kälble,[2] Ellen Krautkrämer,[2] Martin G. Zeier,[2] Jochen Reiser,[3] Markus A. Weigand,[2] Florian Uhle,[2] Uta Merle,[1] Christian Morath,[4] Thorsten Brenner.[2] *[1]University Hospital Heidelberg, Heidelberg, Germany; [2]Heidelberg University Hospital, Heidelberg, Germany; [3]Rush University Medical Center, Chicago, IL; [4]University of Heidelberg, Heidelberg, Germany.*

Background: Sepsis-induced acute kidney injury (AKI) is the dominant AKI etiology in critically ill patients and is often associated with the need for renal replacement therapy (RRT). The timinig of RRT is an ongoing controversy. A major issue that persists is the early differentiation of patients with progressive AKI and need for RRT from those with autonomous renal recovery. We hypothesized, that the product of the two cell cycle arrest and tubular injury biomarkers tissue inhibitor of metalloproteinase-2 and insulin-like growth factor-binding protein 7 ([TIMP-2]*[IGFBP7]), and the soluble urokinase-type plasminogen activator receptor (suPAR) are of diagnostic value for the prediction of septic AKI courses requiring RRT.

Methods: 100 critically ill patients were enrolled prospectively after the fulfillment of Sepsis-3 criteria. Urinary [TIMP-2]*[IGFBP7] levels over time and serum suPAR levels once at inclusion were measured. The primary clinical endpoint was the occurrence of need for RRT within 7 days. Area under the receiver-operating characteristic curves (AUC-ROC), deLong's tests and logistic regression models were calculated.

Results: Nineteen patients developed need for RRT. Diagnostic performance of urinary [TIMP-2]*[IGFBP7] improved significantly over time with the highest AUC of 0.89 (95%CI 0.80-0.98) at 24h after study inclusion. SuPAR levels at inclusion showed an AUC of 0.83 (0.75-0.92). The best discrimination ability for the primary outcome measure was achieved for [TIMP-2]*[IGFBP7]24h by applying a cut-off value of ≥0.6 (ng/ml^2)/1000 (sensitivity 90.9, specificity 67.1). SuPAR at inclusion performed best by using a cut-off value of ≥8.53 ng/mL (sensitivity 84.2, specificity 82.7). The combination of newly tested biomarkers with cystatin C (CysC) resulted in a significantly improved diagnostic accuracy. CysC in combination with [TIMP-2]*[IGFBP7]24h outperformed all present standard renal parameters (AUC 0.93 [0.86-1.00]).

Conclusions: [TIMP-2]*[IGFBP7] levels after the initiation of therapeutic measures and suPAR levels at baseline are promising biomarker candidates for the risk stratification of septic AKI patients with the need for RRT.

Assessment of Urinary Biomarkers for AKI in Major Elective Nonvascular Abdominal Surgeries

Lia J. Marçal,[1] Graziela R. de Souza,[1] Dirce M. Zanetta,[2] Luis Yu,[1] Leila Antonangelo,[1] Emmanuel A. Burdmann.[1] *[1]University of Sao Paulo Medical School, Sao Paulo, Brazil; [2]University of São Paulo, S Paulo, Brazil.*

Background: Data on the role of renal injury urinary biomarkers (uBMs) to predict AKI in patients (pts) submitted to major elective non-vascular abdominal surgeries (MENVAS) are scarce.

Methods: A total of 298 pts submitted to MENVAS were prospectively assessed and evaluated, pre, peri-operatively and from the ICU admission up to 7 days. Serum creatinine (SCr) was assessed before surgery and once a day up to 7d or until ICU discharge. Hourly urinary output (UO) (ml/kg/h) was measured. AKI was diagnosed by either SCr or/and UO (KDIGO definitions). Urine was collected 1d before surgery (baseline), 30 min, 12 and 24h after ICU admission. Monocyte chemotactic protein 1 (MCP-1), interleukin 18 (IL-18), kidney injury molecule-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), tissue inhibitor of metalloproteinase 2 (TIMP-2) and insulin-like growth factor-binding protein 7 (IGFBP-7) were assessed by Luminex x-MAP. Data are median (1st and 3rd quartiles) or frequency. AUC of ROC curves was assessed using non-AKI/AKI KDIGO I as controls and AKI KDIGO II/III as positive results. We assessed different combinations of uBMs to find the better performance. Statistical significance was p<0.05.

Results: Overall, age was 56±15y, 59.1% were female, hospital LoS was 17.7±16.2d, ICU LoS was 3.1±2.9d and 90d mortality was 6.4%. A total of 197 pts (60.1%) developed AKI, mostly KDIGO I (118 pts, 59.9%). The uBMs combination with the higher AUC was KIM-1 vs NGAL vs IGFBP-7 (baseline: 0.65; 30min: 0.72; 12h: 0.79; 24h: 0.72), which was better than any of the uBMs alone, or other combinations, including the product TIMP-2 vs. IGFBP-7(baseline: 0.62; 30min: 0.65; 12h: 0.75; 24h: 0.72).

Conclusions: We found a strikingly high incidence of MENVAS-associated AKI diagnosed by KDIGO criteria in patients admitted at the ICU. The uBM with the better performance to diagnose moderate and severe AKI was the combinations of KIM-1 vs. NGAL vs. IGFBP-7 12h after ICU admission.

TH-PO103

Low Fractional Excretion of Urinary Sodium Is a Common Finding During Acute Tubular Injury Presenting with Abundant Muddy Brown Granular Casts

Maria Soledad Rivera,[1,2] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Clinical School, The University of Queensland, New Orleans, LA; [2]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Fractional excretion of urinary sodium (FENa) remains the most widely utilized diagnostic test in clinical practice for the evaluation of acute kidney injury (AKI). A low FENa (<1%) is considered consistent with prerenal azotemia and not due to overt acute tubular injury (ATI). However, presence of muddy brown granular casts (MBGCs) during microscopic examination of the urinary sediment (MicrExUrSed) are deemed pathognomonic of ATI. We hypothesized a lack of concordance between the two tests.

Methods: We conducted a prospective observational study in patients seen in the inpatient nephrology consultation team with AKI stage ≥ 1 (AKIN) over a 1.5-yr period. On the day of the consult and 48 hrs later, MicrExUrSed was performed to determine the percentage of low power fields (lpf) containing MBGCs. FENa was calculated on the same day to compare it with MBGCs abundance. Outcome measure was ≥ 50% increase from baseline serum creatinine (sCr) at discharge.

Results: Both FENa and presence of MBGCs by MicrExUrSed was completed in 135 patients, 57 (42%) were female, median age was 59 (25 - 88). The median sCr at the time of AKI was 3.2 (2.5 - 4.6) mg/dL. The etiology of AKI (pure *de novo* AKI 57%, AKI on CKD 43%) was ischemic ATI (40%), toxic ATI (15%), ischemic/toxic ATI (19%) and others (27%). MBGCs were found in 71 patients (53%) in our cohort. Among those, 56 (42%) and 32 (24%) had >10% and ≥50% lpf with MBGCs, respectively. FENa was <1% in 24/56 (44%) and 13/32 (41%) of those with >10% and ≥50% lpf with MBGCs, respectively. Thus, the concordance between FENa and MicrExUrSed for ATI diagnosis was deemed poor (estimated kappa coefficient 0.3018). In addition, ≥50% lpf with MBGCs was associated with greater risk for ≥ 50% increase from baseline sCr at discharge [relative risk (RR) 1.5, CI 1.1 – 2.0, p = 0.012], whereas FENa >1% did not predict that outcome [RR 1.1, CI 0.8 – 1.5, p = 0.39].

Conclusions: Close to half of the patients in our cohort who exhibited abundant MBGCs during MicrExUrSed presented with FENa <1%. "Sheets" of MBGCs were associated with greater risk for more sustained elevation in sCr after AKI, whereas FENa >1% was not predictive. These data strongly suggest that sole reliance in low FENa to exclude ATI should be abandoned and MicrExUrSed should be pursued for AKI diagnosis.

TH-PO104

Urinary Tubular Epithelial Cells as a Tool for Diagnosis and Prognosis Estimation in AKI

Jacob Kujat, Christopher Skopnik, Paul Freund, Diana Metzke, Philipp Enghard. *Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Acute kidney injury (AKI) is a common clinical condition with serious short- and long-term consequences. Present classifications focus on serum creatinine (SCr) and urine output, though these are functional damage markers and only allow indirect conclusions about the actual structural damage taking place. In this project we quantified the amount of tubular epithelial cells (TECs) in urine as a marker for kidney damage at the cellular level.

Methods: Urinary samples were taken from inpatients with AKI according to the KDIGO classification (n=50) and from inpatients with cardiological disease but without AKI according to the KDIGO classification (n=8; control group). Samples were analyzed within 72 hours after the initial SCr increase using flow cytometry. A marker combination of cytokeratin, CD13 and CD10 was used to detect proximal TECs (pTECs) and a combination of cytokeratin, CD326 and CD227 was used to detect distal TECs (dTECs). The cell counts were calculated as cells per 100 ml urine. Patients with renal replacement therapy or with inflammatory cause of the AKI were excluded from this study.

Results: Both the amounts of pTECs and dTECs correlated with the relative increase of SCr from the baseline value to the maximum value within the AKI (pTECs: p=0,0006; dTECs: p=0,0004; Spearman). Samples of the control group contained significantly lower amounts of TECs compared to the AKI cohort (pTECs: p=0,0001; dTECs: p<0,0001; Mann-Whitney-Wilcoxon). Some donors (n=5) with a low relative increase of SCr showed very high amounts of urinary TECs. These donors either did not recover from the AKI or showed acute cardiovascular decompensation on the day of sample uptake. Furthermore, both the amounts of pTECs and dTECs correlated with the change of the eGFR stage according to KDIGO from baseline value to the value at hospital discharge (pTECs: p=0,0176; dTECs: p=0,0282; Spearman).

Conclusions: Urinary TECs are an innovative, non-invasive possibility to quantify structural kidney damage during an AKI. As a potential new biomarker for prognosis of AKI, TECs additionally allow predictions about the renal filter function during the course of the hospital stay. High amounts of urinary TECs in donors who only had a modest SCr increase may have detected severe structural kidney damage.

TH-PO105

Urinary Waxy Casts Are Associated with Greater Severity of Acute Tubular Injury

Maria Soledad Rivera,[1,2] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Clinical School, The University of Queensland, New Orleans, LA; [2]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: Waxy casts (WxCs) constitute a recognized finding during microscopic examination of the urinary sediment (MicrExUrSed) and they are classically linked to chronic kidney disease (CKD). It is less clear whether WxCs are a relevant finding in acute kidney injury (AKI). We hypothesized that identification of WxCs in AKI due to acute tubular injury (ATI) provides prognostic information.

Methods: We conducted a prospective observational study in patients seen in the inpatient nephrology consultation team with AKI stage ≥ 1 (AKIN) over a 1.5-yr period. On the day of the consult, MicrExUrSed was performed to determine the percentage of low power fields (lpf) with WxCs and to assess a validated score for ATI based on granular casts and tubular epithelial cells per lpf [Perazella score (PS): score ≥ 2 consistent with ATI]. The primary outcome measure was need for dialysis at 30 days (RRT).

Results: Urine specimens from 167 patients [median age 58 (25 – 88), 43% women] were assessed. The etiology of AKI (pure *de novo* AKI 56%, AKI on CKD 44%) was ischemic ATI (41%), toxic ATI (14%), ischemic/toxic ATI (17%) and others (28%). WxCs were found in 47 patients (28%), 33 (70%) of which had pure *de novo* AKI. Median serum creatinine for those with WxCs was 3.7 (2.8 – 4.9) mg/dL compared to 3.1 (2.4 – 4.6) mg/dL for those without WxCs (p = 0.087). Having >10% lpf w/ ≥1 WxCs was associated with greater risk for RRT [relative risk (RR): 2.3, CI 1.4 – 3.5, p = 0.0003). As reported by others, PS ≥ 2 was associated with increased risk for RRT (RR: 2.6, CI 1.1 - 6.6, p = 0.04). When presence of WxCs was added to a PS ≥ 2, the RR for need for RRT became stronger (RR: 6.0, CI 2.9 - 12.5, p< 0.0001). In addition, the greater the abundance of WxCs, the greater the need for RRT: need for RRT was 26% (31/120), 43% (20/47), 59% (13/22), and 60% (6/10) for those with none, >0%, >10% and ≥50% lpf w/ ≥1 WxCs, respectively (p = 0.0003 for chi-square for trend).

Conclusions: WxCs can be found in a significant proportion of patients with AKI, even among those without preexisting CKD. Among patients with ATI, the presence and abundance of WxCs are associated with a greater risk for need for RRT, suggesting that WxCs carry similar and potentially additive prognostic value to that of granular casts.

TH-PO106

Urinary Biomarkers Normalization by Urinary Creatinine in Patients Submitted to Major Elective Nonvascular Abdominal Surgeries: Is It Necessary?

Lia J. Marçal,[1] Graziela R. de Souza,[1] Dirce M. Zanetta,[2] Luis Yu,[1] Leila Antonangelo,[1] Emmanuel A. Burdmann.[1] *[1]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]University of São Paulo, S Paulo, Brazil.*

Background: There is no consensus regarding urinary biomarkers (uBM) performance using absolute and normalized by urinary creatinine concentration.

Methods: A total of 298 patients (pts) submitted to major elective non-vascular abdominal surgeries (MENVAS) were prospectively assessed. Serum creatinine (SCr) was assessed before surgery and once a day up to 7d post-op or ICU discharge. Hourly urinary output (ml/kg/h) was measured daily. AKI was diagnosed using either SCr or/and urinary output (UO) according to KDIGO definitions. Urinary samples were collected 1 day before surgery (baseline), and 30 min, 12 and 24h after ICU admission. Urinary Cr (uCr) and 7 uBMs were assessed: monocyte chemotactic protein 1 (MCP-1), interleukin 18 (IL-18), kidney injury molecule-1 (KIM-1), osteopontin (OPN), neutrophil gelatinase-associated lipocalin (NGAL), tissue inhibitor of metalloproteinase 2 (TIMP-2) and insulin-like growth factor-binding protein 7 (IGFBP-7) by Luminex x-MAP method. Data are presented as AUC from ROC curves. Statistical significance was p<0.05.

Results: A total of 197 pts (60.1%) developed AKI, mostly KDIGO I. Those developing AKI KDIGO II and III had significantly higher uBMs compared to AKI KDIGO I or non-AKI in all times. We used non-AKI and AKI KDIGO I as controls and AKI KDIGO II and III as positive results to develop of ROC curve. The uBMs' AUC results (w/ or w/o uCr) are presented in table 1. AUC w/o uCr normalization results were consistently higher for all uBMs. AUC normalized for uCr loses the AUC significance for NGAL at baseline and IL-18 at 24h.

Conclusions: uBMs had better performance w/o normalization for uCr in all periods after surgery and a similar performance in baseline. These results suggest that uBMs results should not be normalized for uCr after MENVAS.

Funding: Government Support - Non-U.S.

Prognostic Biomarkers of Kidney Function and Steroid Responsiveness After Acute Interstitial Nephritis

Dennis G. Moledina,[1] Francis P. Wilson,[1] Mark A. Perazella,[1] Gilbert W. Moeckel,[3] Lloyd G. Cantley,[3] Chirag R. Parikh.[2] *[1]Yale School of Medicine, New Haven, CT; [2]Johns Hopkins University, Baltimore, MD; [3]Yale University School of Medicine, New Haven, CT.*

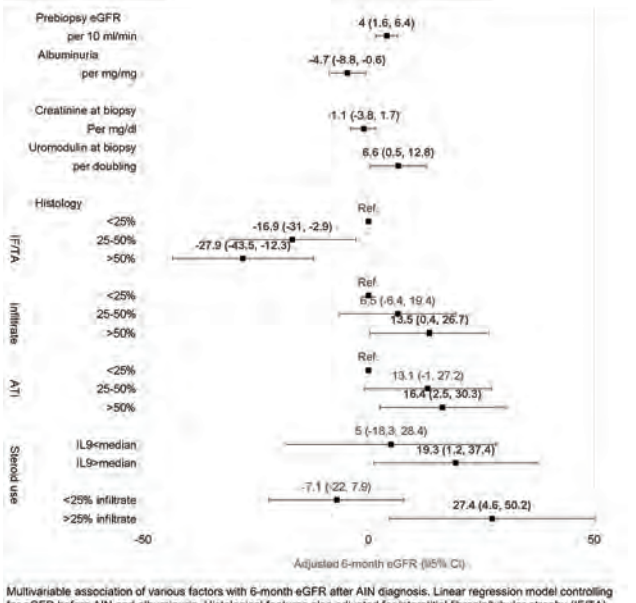
Background: Predictors of kidney injury, inflammation and function after AIN can guide therapeutic strategies.

Methods: In participants with adjudicated AIN, we examined the relationship of conventional and novel biomarkers of kidney structure and function (glomerular filtration rate [eGFR] before biopsy, histology), injury (urine uromodulin, NGAL, KIM-1, IL-18, microscopy) and inflammation (TNFa, IFNg, IL4, IL5, IL6, IL9, IL13) with eGFR measured 6 months (6m) after biopsy controlling for eGFR before biopsy and albuminuria. We also evaluated the impact of steroids on 6m eGFR.

Results: We ascertained 6m eGFR in 51 (93%) out of 55 participants. Mean (SD) eGFR before, during, and 6m after AIN was 41.6 (26.3), 15.6 (10.5), and 33.4 (24.3) ml/min, respectively. Urine uromodulin at time of AIN diagnosis was independently associated with 6m eGFR (Figure), whereas other novel biomarkers were not associated with 6m eGFR. Among the histological features, higher interstitial fibrosis/tubular atrophy (IF/TA) was associated with lower 6m eGFR, whereas interstitial infiltrate and tubular injury were associated with higher 6m eGFR. We noted that steroid use was associated with higher 6m eGFR in those with ≥25% inflammatory infiltrate on biopsy but not in those with <25% involvement, and in those with urine IL-9 level above the median (0.75 ng/mg) but not in those with IL-9 levels below the median.

Conclusions: Higher urine uromodulin level at the time of AIN diagnosis was associated with higher 6m eGFR independent of prebiopsy eGFR and albuminuria. Steroid use was associated with higher 6m eGFR in those with active inflammation at the time of biopsy. These findings could help prognosticate kidney function after AIN and guide initiation of steroid therapy.

Funding: NIDDK Support



Multivariable association of various factors with 6-month eGFR after AIN diagnosis. Linear regression model controlling for eGFR before AIN and albuminuria. Histological features also adjusted for interstitial fibrosis/tubular atrophy (IF/TA) score. Association of steroid use reported separately by degree of interstitial infiltrate (<25% vs. >25%; interaction P=0.048) and urine IL-9 level above or below median (interaction P=0.097).

TH-PO108

Risk Factors and Outcomes of AKI Subphenotypes Based on Serum Creatinine Trajectory After Vancomycin Exposure

Juan Carlos Ramirez-Sandoval,[2] Jose A. Paz-Cortes,[1] Lourdes G. García-Sánchez,[2] Josue J. Vergara-Juarez,[2] Ricardo Correa-Rotter.[3] *[1]Universidad Nacional Autónoma de México, Mexico City, Mexico; [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Mexico City, Mexico; [3]Institutor Nacional de la Nutricion, Mexico City, Mexico.*

Background: Vancomycin-associated (VA) acute kidney injury (AKI) is poorly characterized. We hypothesized that the phenotyping of VA-AKI according to the time course of changes in serum creatinine (sCr 'trajectory') could identify different risk factors and prognosis.

Methods: Cohort study. We included all subjects (2017 to 2019) admitted to a tertiary referral hospital exposed to vancomycin IV ≥4 days without CKD G5 or dialysis treatment. We collected daily sCr and vancomycin serum concentrations, calculated the area under the concentration-time curve (AUC24h), and eGFR 30-days after hospital discharge.

Results: We included 361 subjects. In survivors (332/361,94%), we identified 4 phenotypes based on sCr trajectory: **1** ***No AKI-VA*** (n=229, 68%): subjects without AKI who did not have sCr changes during exposure; **2** ***Severe AKI-VA*** (n=19,6%): subjects with an accelerated rise in sCr not related to other clinical factors, with a median time of vancomycin exposure 10 days (IQR: 7-18) with tubular injury (biopsy in 2 cases); **3** ***non-severe AKI-VA*** (n=55, 17%): subjects who at the beginning of vancomycin prescription had AKI, which was improving but had slight and slow sCr increases during treatment, usually in context of other AKI risk factors (sepsis relapsed, nephrotoxic drugs, bleeding); **4** ***recovery of AKI*** (n=29, 9%): subjects with sepsis induced AKI who had improvement without relapses during treatment. In a multivariate analysis, risk factors for group 2 were the slope of the initial day 2-4 vancomycin drug levels (OR:2.0 95%IC 1.22-2.7) and baseline sCr (OR:1.7 95%IC 1.1-2.8). Risk factors for group 3 non-severe AKI-VA were vancomycin drug levels >15 ng/mL (OR 1.6 per each 10 ng/mL, 95%IC 1.1-3.5) and AUC24h target of ≥ 600 mg*h/L (OR 2.9 95%IC 1.6-5.9). After 30-d of discharge, severe AKI-VA was usually reversible (12% had CKD G3A1). Group 3 had a higher frequency of CKD (78% CKD G3) compared to other groups. Total daily vancomycin dose, accumulated dose, and duration of therapy were not risk factor for any group.

Conclusions: VA-AKI occurs in different clinical presentations. Abrupt and severe AKI-VA can be predicted according to slope change in first doses of vancomycin levels. Non-severe AKI-VA was multifactorial, had a higher risk of CKD, and had pre-AKI high vancomycin trough levels.

TH-PO109

Plasma Neutrophil Gelatinase Associated Lipocalin (NGAL) and the Prediction of Sustained AKI and Worsening Renal Function in Hospitalized Kidney Transplant Recipients

Jutta S. Swolinsky,[1] Ricarda M. Hinz,[1] Carolin E. Markus,[1] Eugenia Singer,[1] Klemens Budde,[1] Kai-Uwe Eckardt,[1] Timm H. Westhoff,[3] Kai M. Schmidt-Ott.[1,2] *[1]Charité-Universitätsmedizin, Berlin, Germany; [2]Berlin Institute of Health, Berlin, Germany; [3]Ruhr Universität Bochum, Bochum, Germany.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL) and Calprotectin (CPT) have been validated as biomarkers of acute kidney injury (AKI) in multiple clinical settings. The utility of these biomarkers in post-transplant care of kidney transplant recipients (KTR) remains largely unclear. We hypothesized that NGAL and CPT levels, measured at the time of any unscheduled hospital admission after kidney transplantation, would be associated with episodes of sustained AKI (sAKI) and worsening renal function (WRF).

Methods: As part of a monocentric cohort study of 709 KTR, plasma and urinary NGAL and CPT levels were measured in 164 KTR at the time of hospital admission for any non-elective cause. sAKI was defined as an increase in creatinine by ≥0.3 mg/dl or by ≥1.5-fold compared to outpatient baseline that did not normalize within 72 hours (h). WRF was defined as an increase in creatinine by ≥0.5 mg/dl within 72 h after admission. ROC analyses, univariable and multivariable logistic regression analyses and net reclassification improvement (NRI) were assessed for the biomarkers in predicting sAKI and WRF.

Results: 33 KTR developed sAKI, 12 developed WRF. Plasma NGAL (pNGAL) had the highest diagnostic accuracy compared to urinary NGAL, urinary and plasma CPT. Median pNGAL levels at admission were significantly higher in patients with sAKI (332 [IQR 247.5-633] ng/ml versus no sAKI 275 [IQR 193-363] ng/ml, p<0.05) and WRF (395 [IQR 305-639] ng/ml versus no WRF 278.5 [IQR 193.5-378.8] ng/ml, p<0.05). ROC analyses for pNGAL showed an AUC ROC of 0.66 for sAKI and of 0.75 for WRF. A pNGAL level >410 ng/ml had positive likelihood ratios of 2.3 (95% CI 1.38-3.81) for sAKI and of 2.0 (95% CI 1.15-4.1) for WRF. In multivariable logistic regression, pNGAL was an independent predictor of sAKI when combined with other predictors (serum creatinine, coronary artery disease, congestive heart failure, p<0.05). Adding pNGAL to conventional predictors of sAKI resulted in an NRI of 20.5% (p<0.01).

Conclusions: Elevated pNGAL at the time of hospital admission may be useful in identifying KTR at risk of sustained or progressive acute kidney injury. Although test characteristics speak against its use as a single biomarker, it may contribute to prognostication.

TH-PO110

Urinary Exosomal MicroRNA-21 as a Marker of Scrub Typhus-Associated AKI

In O Sun, Ju hwan Oh. *Presbyterian Medical Center, Jeonju, Korea, Jeonju, Republic of Korea.*

Background: Extracellular vesicles contain various molecules including DNA, mRNA, and microRNA (miRNA), and are involved in cell-to-cell communication. MiRNA-21 is reported to be a biomarker for detection of acute kidney injury (AKI). The aim of this study is to investigate the clinical significance of urinary exosomal miRNA-21 for AKI in patients with scrub typhus.

Methods: In a cross-sectional study, we collected 138 urine samples at the time of admission from 145 patients with scrub typhus. For 25 patients with scrub typhus-associated AKI and 25 age, sex-matched patient without AKI, we measured miRNA-21 in urinary exosomal fraction. Then, we investigated correlation between urinary exosomal miRNA-21 and clinical parameters.

Results: Compared with patients in the non-AKI group, patients in the AKI group had worse renal function (30 ± 13 vs. 56 ± 20 mL/min/1.73m^2, P<0.01) at admission and higher total leukocyte counts(10.4 × 10^3/ mL vs. 5.2× 10^3/mL, P<0.01). Serum NGAL (404 ± 269 vs. 104± 51 ng/mL, P<0.01) and urine NGAL/creatinine values (371± 672 vs. 37± 57 ng/mg, P<0.01) were higher in the AKI group than in the non-AKI group. The levels of urinary exosomal miRNA-21 (17.8 ± 1.8vs. 20.1± 1.2 ΔCt value of miRNA-21, P<0.01) were higher in the AKI group than in the non-AKI group, while those levels in urinary supernatant were not different between two groups. Urinary exosomal miRNA-21 levels correlated directly with total leukocyte counts and serum NGAL values and inversely with estimated glomerular filtration rate. The reciver operator characteristics curve analysis for urinary exosomal miRNA-21 showed good discriminative power for detectng scrub typhus-associated AKI, with area under the curved value of 0.887.

Conclusions: Urinary exosomal miRNA-21 could be a surrogate markers for the diagnosis of scrub typhus–associated AKI.

TH-PO111

Impact of Elevated Echocardiographic Index of Left Ventricular Filling Pressure on AKI After Aortic Valve Replacement

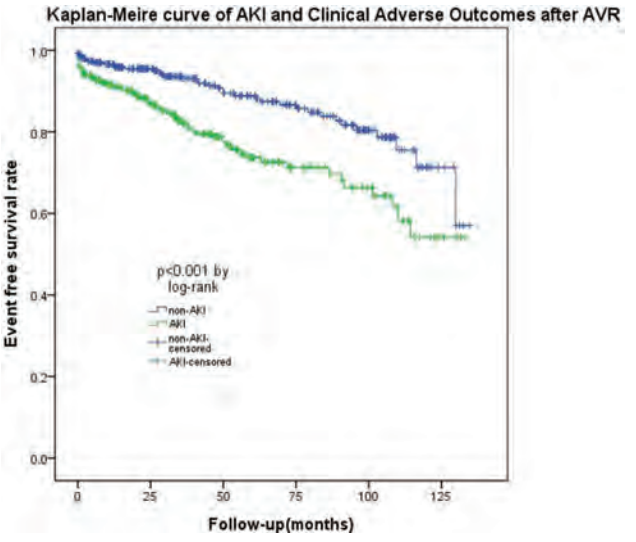
Soo youn Lee, Jae young Kang. *Sejong General Hospital, Bucheon, Republic of Korea.*

Background: Increased LV filling pressure was found to be associated with deterioration of renal function in patients with congestive heart failure. However, it remains unclear how to contribute to cardio-renal interaction in patients who underwent aortic valve replacement (AVR). We sought to evaluate the association between preoperative echocardiographic index of left ventricular (LV) filling pressure and postoperative acute kidney injury (AKI), and impact of AKI on clinical adverse outcomes after surgical AVR.

Methods: We conducted a retrospective study of 576 patients (292 males, mean age 68±10 years) who underwent surgical AVR. Patients were stratified according to E/e' ratio above and less than 15, and assessed for AKI using the KDIGO criteria, defined as either a serum creatinine rise >0.3 mg/dl, or an increase in serum creatinine ≥1.5 times baseline within 7 days after AVR. The clinical adverse outcomes were early and long-term mortality, and hospitalization due to heart failure.

Results: Patients with E/e'ratio ≥15 had more AKI complication after surgical AVR (52.1% vs. 38.2%, p=0.001), In multivariable analysis, E/e'ratio ≥15 was independently associated with AKI after surgical AVR (odd ratio [OR], 1.66; 95% confidence interval [CI], 1.17–2.34 p=0.005). The Cox hazard model reveals that AKI (hazard ratio [HR], 1.57; 95% CI, 1.03-2.39, p=0.037) and advanced age (HR, 1.07; 95% CI, 1.04-1.11, p<0.001), coronary artery disease (HR 1.54, 95% CI, 1.02-2.32, p=0.04) were poor prognostic factors for clinical adverse outcomes after surgical AVR.

Conclusions: Among patients who undergoing surgical AVR, preoperative elevated LV filling pressure is associated with increased risk for AKI, and AKI is related to postopearative adverse clinical outcomes.



TH-PO112

Endothelial Glycocalyx Shedding and Microcirculatory Impairment in Traumatic Haemorrhagic Shock Are Early Markers of AKI

Jennifer R. Joslin,[1] David N. Naumann,[2] Kate Bramham,[1] Sam Hutchings.[3] *[1]Renal Sciences, King's College London, London, United Kingdom; [2]University of Birmingham, Birmingham, United Kingdom; [3]King's College Hospital, London, United Kingdom.*

Background: Microcirculatory disruption is evident in the pathogenesis of many acute kidney injury (AKI) causes, and regulation of microvascular perfusion is dependent on the integrity of the endothelial glycocalyx (Glx). We hypothesised that systemic Glx shedding and microcirculatory impairment are associated with AKI. The MICROSHOCK study reported on multiple organ dysfunction syndrome; we report the association with Glx and microcirculatory changes and AKI outcomes for the first time.

Methods: Patients with traumatic haemorrhagic shock from two UK Major Trauma Centres underwent plasma sampling for Syndecan-1 (Syn-1, Glx constituent) and sublingual Incident Dark Field (IDF) microscopy on admission. IDF videos were analysed to quantify perfused vessel index (PVD) and microvascular flow index (MFI). Presence and stage of AKI within 7 days were recorded.

Results: 45 patients were included; 10 (22%) female and 35 (78%) male. Mean age was 45 (SD 26) years. 34 of 45 (76%) developed AKI within 7 days; 15 (44%) stage 1; 12 (35%) stage 2; and 7 (21%) stage 3. Syn-1 results were available for 17 patients. Admission Syn-1 concentration was significantly higher (representing increased Glx shedding) in patients who did (n=11) than did not (n=6) develop AKI within 7 days, p = 0.0183 (Figure 1). PVD and MFI results were available in all 45 patients. Both PVD and MFI were significantly lower (representing impaired microcirculatory perfusion) in patients who went on to develop stage 2 or 3 AKI (Table 1).

Conclusions: This novel study provides preliminary evidence that Glx shedding and impaired microcirculatory perfusion parameters can predict AKI. Further research in other and larger cohorts is needed and planned. We propose that Syn-1 may be a mechanistic biomarker for AKI.

Table 1: PVD and MFI in patients who did and did not develop AKI

	AKI	No AKI		Severe (stage 2 or 3) AKI	No severe AKI	
Median [IQR] PVD (mm/mm2)	10.2 [7.9,12.0]	10.5 [9.6,11.0]	NS	8.7 [7.6,10.9]	11.1 [10.3,12.5]	p=0.0102
Median [IQR] MFI	2.70 [2.57,2.85]	2.81 [2.64,2.88]	NS	2.62 [2.25,2.71]	2.82 [2.71,2.90]	p=0.0026

Serum α1-Antitrypsin Predicts Severe AKI After Cardiac Surgery

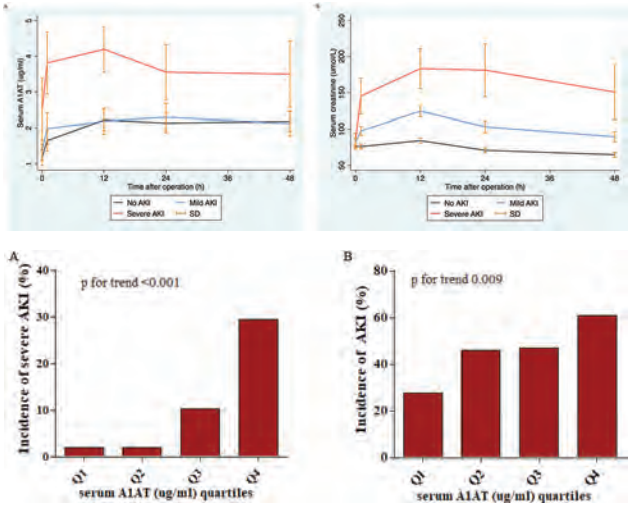
Jun Ai, Zhiwen Xiao, Jianwei Tian. *State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Human α1-antitrypsin (A1AT), a binding protein with affinity to hemin, is an acute phase glycoprotein with broad anti-inflammatory properties. It is involved in the pathophysiologic processes underlying ischemic AKI and could exert dramatic renoprotective effects. Our objective is to assess the ability of serum A1AT (sA1AT) to predict AKI in adults undergoing heart surgery.

Methods: We conducted a prospective, single-center, cohort study in 201 patients undergoing cardiac surgery in our center since 1st July to 31st December 2017. We analyzed levels of sA1AT and other injury biomarkers during the perioperative period. Severe AKI was defined as Kidney Disease Improving Global Outcomes (KDIGO) stage 2 or 3. Overall AKI was defined as KDIGO stage 1.

Results: Of the 201 patients entered the final analysis, 69 (34.3%) developed mild AKI, and 22 (10.9%) developed severe AKI. sA1AT level increased immediately 1h after operation, maintained at the peak for 12 hours, and subsequently decreased in patients who developed severe AKI. After multivariate adjustment, sA1AT 1h after CPB independently associated with the development of severe AKI (OR, 1.46; 95% CI, 1.10-1.95; P=0.009) compared with mild AKI and no AKI, and the highest quartile of sMMP-7 level associated with 23-fold higher odds of severe AKI compared with the lowest quartile. For predicting severe AKI, sA1AT had an area under the receiver operating characteristic curve of 0.814, outperforming uTIM-1 and the clinical model. Elevated sA1AT level associated with longer stay in the intensive care unit and hospital.

Conclusions: sA1AT is a valuable potential predictor for severe AKI and poor in-hospital outcomes in patients after cardiac surgery.



TH-PO114

Incidence and Predictors of Nephrology Follow-Up After AKI in Critically Ill Patients

Emily J. See, David Ransley. *Austin Health, Melbourne, VIC, Australia.*

Background: Acute kidney injury (AKI) is a common complication of critical illness, and survivors are at increased risk of chronic kidney disease, end-stage kidney disease, and death. International guidelines have recommended that patients with AKI are evaluated after hospital discharge to assess for complications; however, follow-up rates have been reported to be low, and they have never been studied in critical care or Australian settings.

Methods: We conducted a retrospective study of all critically ill adults admitted with AKI between 1 January 2012 and 31 December 2016 to a single centre in Melbourne, Australia. Eligible patients were required to have a baseline eGFR >30 mL/min/1.73m^2 and to be alive and independent of renal replacement therapy at 30 days after hospital discharge. Logistic regression models were used to examine the primary outcome, which was nephrology review within the first year. Candidate predictors were screened for inclusion using univariable models and a backward stepwise elimination approach was used to remove covariates whose multivariable p value was >0.2.

Results: A total of 702 critically ill patients with AKI were included in the study (mean age 66 years, 64% male, baseline eGFR 78 mL/min/1.73m^2). Only 43 patients (6%) received nephrology follow-up in the first 3 months, while 63 patients (9%) were reviewed within a year. The median time to review was 41 days (interquartile range 23-136). Nephrology follow-up occurred more frequently in patients with a higher baseline creatinine (OR 1.02, 95% CI 1.01-1.03), a higher discharge creatinine (OR 1.01, 95% CI 1.01-1.02), and a greater severity of AKI (stage 3 OR 3.26, 95% CI 1.50-7.10). Traditional risk factors for chronic kidney disease, including older age and a history of hypertension, diabetes, or cardiovascular disease, did not prompt referral.

Conclusions: Despite international recommendations, few critically ill patients with AKI currently receive nephrology follow-up after discharge. The presence of other risk factors for chronic kidney disease was not associated with outpatient review. This represents a missed opportunity for the early detection of chronic kidney disease after AKI and prevents the timely implementation of preventative strategies to improve patient outcomes.

TH-PO115

A Modified Renal Angina Index Predicts Poor Outcomes After Pediatric Cardiac Surgery

Katja M. Gist,[1] Megan Soohoo,[1] Catherine Krawczeski,[3] David S. Cooper,[4] Emily Mack,[5] David M. Kwiatkowski,[6] Jeffrey Alten,[4] Stuart Goldstein,[4] Rajit K. Basu.[2] *[1]University of Colorado, Children's Hospital Colorado, Aurora, CO; [2]Children's Healthcare of Atlanta, Atlanta, GA; [3]Nationwide Children's Hospital, Columbus, OH; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Childrens Hospital Colorado, Arvada, CO; [6]Stanford University School of Mediicine, Palo Alto, CA.*

Background: Children undergoing congenital cardiac surgery are at high risk for poor outcomes including those related to acute kidney injury (AKI), prolonged mechanical ventilation and death. Early adjudication of risk for poor outcome may identify opportunities for early mitigative or preventative actions We hypothesized modification of the renal angina index (RAI), a composite score of patient risk and early signs of renal dysfunction, for use in patients following cardiac surgery would predict AKI related poor patient outcomes.

Methods: The cRAI, combining risk factors and clinical signs of kidney dysfunction [Figure] was studied in a multicenter derivation analysis to compare predictive performance for poor outcome to prediction by the individual cRAI terms. Poor outcome was defined as Day 3 AKI or ≥5 days of mechanical ventilation or death.

Results: 308 patients (64% male, med age 37 days (IQR:5-152 days) were analyzed. Half had single ventricle heart disease. The cRAI ≥10 outperformed individual and combination risk and injury factors for prediction of the composite outcome and demonstrated the optimal balance of sensitivity and specificity (AUC=0.77)[Table].

Conclusions: Derivation data indicates the cRAI, assessed soon after surgery, may optimize prediction for poor outcomes in children undergoing cardiac surgery. Future prospective studies are needed to validate the cRAI encompassing factors that may enhance its performance.

Table. Sensitivity analysis for individual and combination risk and injury factors

	Sensitivity (95% CI)	Specificity (95% CI)	Positive Predictive Value (95% CI)	Negative Predictive Value (95% CI)	Youden

Creatinine-Cystatin C Ratio Is Associated with Mortality in ICU Patients Undergoing Continuous Renal Replacement Therapy

Chan-Young Jung, Byounghwi Ko, Wonji Jo, Tae-Hyun Yoo, Jung Tak Park. *Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Development of acute kidney injury (AKI) in intensive care patients considerably increases the risk of mortality. Although several factors that are related to outcome have been recognized in this patient group, stratifying mortality risk still remains

a challenge. While serum creatinine levels are confounded by muscle wasting in critical illness, cystatin C is expected to be less modulated by muscle mass. Speculating that the ratio between serum creatinine and cystatin C may reflect muscle mass in critically ill AKI patients, we evaluated the association between creatinine-cystatin C ratio and mortality in patients requiring continuous renal replacement therapy (CRRT) in the intensive care unit (ICU).

Methods: Retrospective analyses were conducted on 443 ICU patients who underwent CRRT between August 2009 and October 2016 at Severance Hospital of Yonsei University Health System, Seoul, South Korea. The patients were divided into four groups based on creatinine-cystatin C ratio at the time of CRRT commencement. The primary outcome was 90-day mortality after CRRT initiation.

Results: The mean age was 64 ± 15 years, and 57.3% of patients were male. The most common cause of AKI was sepsis. The median and range of the creatinine-cystatin C ratio was 0.83 (0.13-6.20). The 90-day mortality rate for each creatinine-cystatin C ratio quartiles 1, 2, 3, and 4 were 76.6%, 73.9%, 61.3%, and 51.8%, respectively. Multiple Cox proportional hazard models revealed that the creatinine-cystatin C ratio was an independent predictor of 90-day mortality even after adjusting for confounding factors (Hazard ratio, 0.97; 95% confidence interval, 0.95-0.99, P<0.01). The prediction of mortality was significantly improved when creatinine-cystatin C ratio was considered compared to APACHE-II or SOFA scores alone.

Conclusions: Creatinine-cystatin C ratio is associated with mortality in ICU patients undergoing CRRT, and may be a practical marker in predicting survival among ICU patients with AKI.

TH-PO117

In the Aftermath of Hurricane Maria, a New Threat Arises

Krystahl Z. Andujar,[1] Ileana E. Ocasio Melendez,[1] Fatima B. Cintron-Rosa,[1] Pedro Vargas Otero,[2] Carlos G. Rivera-Bermudez,[1] Melanie Quintana-Serrano.[2] *[1]Nephrology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico; [2]Internal Medicine, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico.*

Introduction: The 2017 Atlantic Hurricane Season was among the most active in history and on September 20th, Hurricane Maria struck the island of Puerto Rico. Human leptospirosis is endemic in Puerto Rico and reaches epidemic levels after natural disasters.

Case Description: A 51-year-old farmer presented after a 5-day history of cough with bloody sputum, yellow skin, fever, nausea, vomiting and myalgias. Symptoms began after consuming a banana found on the ground weeks after Hurricane Maria. Vital signs were unremarkable. Physical examination revealed lung rales, conjunctival suffusion and jaundice. Laboratories showed leukocytosis, anemia and thrombocytopenia; creatinine 6.27, BUN 123 and bilirubin 27.4 mg/dL; ALT 44 and AST 114 U/L. ABGs revealed hypoxemia. Chest CT scan without IV contrast was positive for diffuse bilateral ground glass opacities and interlobular septal thickening, worrisome for alveolar hemorrhage. Ultrasound revealed normal liver and bile ducts, and normal kidneys without obstruction. Leptospirosis was considered as a cause of illness and he was started on Ceftriaxone. Within the first 8 hours of admission, his respiratory function deteriorated requiring mechanical ventilation. Daily high-dose hemodialysis was prescribed. Serology was positive for Leptospirosis. Due to respiratory deterioration and rise in bilirubin levels, the decision was made to begin plasma exchange. Over the next 48 hours of admission, he underwent two 4-liter exchanges using fresh frozen plasma. After two plasma exchange sessions, there was a reduction of serum bilirubin to 7.6. Respiratory function improved and patient was extubated. He had recovery of renal function and hemodialysis was discontinued.

Discussion: Puerto Rico has reported at least 76 cases of suspected and confirmed leptospirosis in the aftermath of Hurricane Maria. Our patient presented the most severe form of leptospirosis, Weil's disease, that comprises jaundice, renal and respiratory failure and a high mortality rate. There are few case reports documenting the benefits of plasma exchange with severe leptospirosis. Given the dramatic recovery of our patient after plasma exchange, we conclude that more research is needed to define its role in patients with severe leptospirosis without clinical improvement after standard therapy.

TH-PO118

Intravenous Contrast on Continuous Renal Replacement Therapy: Does It Matter?

Ali Mehdi, Mark A. Marinescu, Susana Arrigain, Jesse D. Schold, Christopher Coppa, Gordon Mclennan, Sevag Demirjian. *Cleveland Clinic Foundation, Cleveland, OH.*

Background: Acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) is commonly encountered in the intensive care unit (ICU). Clinicians caring for ICU patients are often forced to weight the risks of aggravating the AKI before using intravenous (IV) contrast agents when obtaining diagnostic imaging studies for patients on CRRT. We hereby describe the risk of dialysis dependency (DD) or persistent severe kidney dysfunction (SKD), defined as creatinine >4 mg/dL at discharge, among ICU patients receiving IV contrast while on CRRT for AKI.

Methods: All ICU patients at our institution who underwent a CT scan while on CRRT between 2013-2017 were identified. ESRD patients, those with baseline eGFR <15 mL/min per 1.73 m^2, and those without overnight ICU stay were excluded. Cases were grouped according to IV contrast exposure as contrast-enhanced (CECT) or unenhanced (UCT) groups. We compared baseline characteristics, mortality, and DD/SKD at discharge between the groups using Wilcoxon Rank-sum and Chi-square tests. We fitted a competing risk regression model for DD/SKD at discharge with death as a competing risk adjusted for demographics and known comorbidities.

Results: A total of 189 CECT and 644 UCT patients were included in the final analysis. Baseline characteristics were similar between groups including baseline creatinine and CKD stage as defined by the Kidney Disease Outcomes Quality Initiative cutoffs. The CECT group had significantly higher ICU length of stay (median 24 vs 17 days; p<0.001) and required more days on CRRT (median 10 vs 6; p<0.001). 58.7% of CECT and 51.6% of UCT died during hospitalization (p=0.08), while 27.5% and 27% had DD/SKD at discharge respectively (p = 0.89). Similarly, no significant difference was found in competing risk model for DD/SKD (SHR for CECT vs UCT: 0.81; 95% CI: 0.60-1.10; p=0.18)

Conclusions: Despite the apparently sicker CECT group, IV contrast administration while on CRRT for AKI was not associated with an increased risk of DD/SKD at discharge. This study suggests that contrast enhanced imaging need not be withheld from AKI patients on CRRT, particularly when valuable information can be gained from the contrast study with potential therapeutic implications.

TH-PO119

Incidence of Amoxicillin-Induced Crystal Nephropathy

Jean francois Augusto,[1] Benoit Brilland,[2] Samuel Wacrenier,[3] Jean-Francois Subra,[1] Anne-Sophie Garnier.[4] *[1]CHU Angers, Angers, France; [2]CHU d'Angers, Angers, France; [3]Nephrology, CHU Angers - CH Le Mans, Angers, France; [4]Angers University Hospital, Angers, France.*

Background: Amoxicillin (AMX)-induced crystal nephropathy (AICN) has been considered as a rare complication of high dose intravenous AMX. However, in the recent years, its incidence seems to be increasing. Occurrence of AICN has been observed exclusively with intravenous (IV) administration and mostly under daily doses over 8 g/day. AMX cristalluria is a major diagnostic criterion but is rarely performed by practitioners. Thus, the real incidence of AICN may be underestimated. The objective the present study was to determine the incidence of AICN in the current practice.

Methods: We conducted a retrospective study between the 01/01/2015 and 01/01/2018 in Angers University Hospital. Inclusion criteria were admission in Angers University Hospital, age over 18 years-old, and administration of more than 8g/day of AMX using IV route for more than 24h. Patients admitted directly into the intensive care units were excluded. Medical records of patients that developed KDOKI stage 2-3 AKI were reviewed by a nephrologist and a specialist in pharmacovigilange in a blinded fashion. AICN was retained if temporality analysis was conclusive, after exclusion of other causes of AKI, in absence of other nephrotoxic drug administration and if evaluations were concordant.

Results: During the 3 -years period of the study, 1303 patients received IV AMX for at least 24h, 358 (27.5%) were exposed to AMX doses over 8g/day and were included in the study. Patients were predominantly males (68.2%) with a mean age of 69.1 years-old. AMX was administered in surgical context in 21.5% of cases and in a medical context in 78.5% of cases. Patients received a mean dose of AMX of 11.2 g/day, representing a mean dose of 153.9 mg/Kg/day. Seventy-four patients (20.7%) developed AKI, 42 (56.8%) of KDIGO stage 2 or 3. Among patients with KDIGO 2-3 AKI, AICN diagnosis was retained in 16 (38.1%) patients, representing an incidence of 4.47%. As compared to other AKI patients, female proportion was significantly higher in AICN group as compared to other AKI (p=0.013). As compared to non AKI patients, no prédictive factor of AICN could be identified.

Conclusions: This study suggests that AICN incidence is underestimated and may represent as much as one third of AKI developping under AMX treatment.

TH-PO120

AKI Is Not an Independent Risk Factor for Low Probability of Target Attainment (PTA) of Piperacillin

William H. Fissell,[2] Edward D. Siew,[2] Rachel C. Evans,[2] Sylvia M. Verhoven,[2] C. B. Creech,[2] Andrew J. Vincz,[2] Pratish C. Patel,[2] Matthew S. Shotwell.[1] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Infection is the leading cause of death in patients with acute kidney injury (AKI). Most antibiotics are renally cleared. Dose adjustments are based on imperfect estimates of renal function. We have shown that patients with severe AKI (e.g., continuous dialysis) are often underdosed. We hypothesize that piperacillin is underdosed in less severe AKI as well.

Methods: In a prospective study, patients admitted to the intensive care unit (ICU) had piperacillin concentrations measured in residual blood samples (RBS). Concentration-time curves for each patient were estimated from RBS values using nonlinear mixed-effects methods and a two-compartment model in NONMEM and R. AKI was assessed on each day of ICU admission based on modified KDIGO criteria. Patients were grouped according to the most severe AKI observed during their admission. Piperacillin PTA for patients with KDIGO classes 0,1,2, or 3 were estimated from concentration-time curves during the dosing period in which the first RBS was collected. PTA frequencies were compared using Pearson chi-square test. For this analysis, an MIC of 16μg/ml piperacillin was used, as it is the CLSI susceptibility breakpoint for clinical isolates of *Enterobacteriaceae*. PTZ was infused over 4 hours, per institutional protocol, to optimize pharmacodynamics.

Results: We measured piperacillin levels of 386 patients, of whom 86 were excluded due to incomplete data (74) or RRT for non-renal indications (12). Of the remaining patients, 113 met KDIGO 1-3 AKI criteria and 187 had no AKI. There were no significant differences in age, weight, or gender between groups. Most patients received 3.375 gm PTZ q8h; 28% of the AKI group received 3.375 gm q12h. 93% of the AKI group and 77% of the non-AKI group achieved a of fT>MIC > 50% (P < 0.001). These percentages decreased to 48% and 41% respectively for fT > MIC = 100% (P = 0.226).

Conclusions: ICU patients with AKI are not at increased risk of failing to achieve a commonly accepted PK target for piperacillin compared to patients without AKI. The biosample collection may not be synchronized to the AKI occurrence. However, given that fewer than 50% of critically ill patients attain a conservative target of ft > MIC = 100%, strategies to improve dosing and measure variation in exposure are urgently needed.

Use of Caplacizumab in Germany to Treat Acquired Thrombotic Thrombocytopenic Purpura in a Real-World Setting

Linus A. Volker,[3,1] Jessica K. Kaufeld,[2] Paul T. Brinkkoetter,[3,1] Jan Menne.[4] *[1]CECAD, University of Cologne, Cologne, Germany; [2]Medical School of Hannover, Hannover, Germany; [3]University Hospital Cologne, Cologne, Germany; [4]Medical School Hannover, Hannover, Germany*.

Background: Acquired thrombotic thrombocytopenic purpura (aTTP), a form of thrombotic microangiopathy, is a rare but life-threatening disease, which is characterized by microangiopathic hemolysis and thrombocytopenia with and without end-organ damage. It results from an autoantibody mediated inhibition of the metalloproteinase ADAMTS13 that is required for the degradation of ultra-large von-Willebrand-factor multimeres. Two recent seminal trials (HERCULES and TITAN) demonstrate the efficacy of the new nanobody caplacizumab for the treatment of this condition. To assess the utility and role of caplacizumab in the treatment of aTTP patients, we analyzed the first 22 German patients that had been treated with the new drug since Mai 2018.

Methods: Retrospective analysis of epidemiologic and treatment related data of the first 23 German aTTP patients undergoing caplacizumab treatment in 12 German medical institutions between Mai 2018 and April 2019.

Results: Between Mai 2018 and April 2019, 22 patients (age range 26-83 years) were treated with caplacizumab in addition to pulsed steroids, plasma exchange and rituximab. On average, patients received 32 daily doses of caplacizumab, and treatment was initiated on day 7 after disease onset. Patients received an average of 12 plasma exchanges. 36 percent of all patients relapsed, however, most patients received caplacizumab only as treatment of refractory disease or relapse and not as front-line therapy. This resulted in only 20% of patients being treated strictly according to the HERCULES trial protocol. One patient died from microangiopathic complications despite early caplacizumab treatment. One patient suffered major bleeding complications, one patient an allergic reaction to the drug; in general, minor bleeding complications were reported but scarce.

Conclusions: Caplacizumab appears to be efficacious and reduced the time to platelet normalization in a real-world setting. Caplacizumab augments therapy options for patients with aTTP. The data presented here and future experience will help address pending questions about patient selection for caplacizumab treatment, therapy monitoring, timing of treatment cessation, and drug safety.

TH-PO122

Acute Interstitial Nephritis After Treatment with the Human Anti-CD20 Antibody Ocrelizumab: First Case Report

Hassan Alhalabi. *Dallas Nephrology Associates, Irving, TX*.

Introduction: Acute interstitial nephritis (AIN) is an important cause of acute kidney injury and is commonly caused by drugs. Ocrelizumab, a humanized anti-CD20 antibody, was recently approved as a treatment for primary progressive and relapsing multiple sclerosis. Here we report a patient who developed severe AIN requiring hemodialysis after receiving Ocrelizumab.

Case Description: A 64-year-old female with a history of diabetes and hypertension received the first infusion of Ocrelizumab 300 mg for multiple sclerosis. One week later she presented to the emergency room complaining of fatigue and generalized weakness. Laboratory findings were significant for a creatinine of 5.5 mg/dL (was 0.9 mg/dL a few days prior). Her creatinine continued to increase to 10 mg/dL on hospital day 4 requiring initiation of hemodialysis. Urinalysis showed moderate blood, +3 protein, 21 RBC's, 11 WBC's. Serologic work-up included a normal C3, C4, ANA, ANCA, anti-GBM, and SPEP/UPEP. Renal ultrasound was normal. A kidney biopsy was performed which demonstrated a moderate mixed interstitial infiltrate with many eosinophils, in a background of interstitial edema. The tubules were dilated and showed significant degenerative changes in tubular epithelial cells, with intratubular calcium oxalate crystals and intratubular degenerative debris. No viral inclusions were seen and there was minimal to mild interstitial fibrosis. The patient was started on oral prednisone 60 mg daily with a subsequent slow taper. Renal function significantly improved with the creatinine trending down to 2.4 mg/dL two weeks later on clinic follow-up.

Discussion: Ocrelizumab, a humanized anti-CD20 monoclonal antibody, was recently approved for the treatment of primary progressive and relapsing multiple sclerosis. To our knowledge, this is the first report of severe AIN associated with an anti-CD20 antibody. In this case, the patient responded well to treatment with high dose steroids. Our report highlights the need to monitor patients closely for potential renal toxicities that may be associated with such medications.

TH-PO123

Incidence and Risk Factors of AKI in Cancer Patients with Multi-drug-Resistant Infections Treated with Colistin

Ayesha Iftikhar, Dr Junaid Iqbal, Umm-e-Rubab Syeda, Aun Raza, Muhammad Abu bakar, Faisal Sultan. *Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan*.

Background: Developing countries have seen a resurgence in the use of Colistin in recent years, for treatment of multidrug resistant (MDR) gram-negative bacterial infections. Colistin is associated with increased risk of nephrotoxicity and consequently poor outcomes in high-risk patients. We studied cancer patients at our centre to determine incidence, risk factors and outcomes of acute kidney injury (AKI) associated with use of Colistin.

Methods: We reviewed patient medical records using electronic information system (eHIS), from January 2015 to December 2018, in this single centre cross-sectional study using secondary data analysis. Adults with solid organ or hematological malignancies with confirmed or suspected multi drug resistant gram-negative infections, who received colistin for at least 48 hours, were included. Outcomes of AKI including need for renal replacement therapy (intermittent or continuous), length of hospital stay and mortality were studied. Patients were followed for 3-6 months following an episode of AKI to review development of chronic kidney disease (CKD). AKI was defined according to Kidney Disease Improving Global Outcomes (KDIGO).

Results: A total of 115 patients were studied. Mean age was 42.6 ± 15.4 years and Mean weight was 60.3 ± 14 kilograms. Majority (68.7%) were male. In multivariable analysis, three independent variables including weight (adjusted odds ratio [AOR] 1.04; 95% confidence interval [CI] 1.01-1.10), underlying malignancy (solid versus hematological (AOR 3.39; 95% CI (1.15-9.98), 0.02) and need for admission to intensive care unit (ICU) (AOR 2.75; 95% CI (1.00-7.82), 0.05) were identified as significant independent risk factors for nephrotoxicity. In patients who had AKI (n=75, 65.2%), mean length of hospital stay was 21.7 ± 13.7 days, 20% required renal replacement therapy (RRT), 10.4% developed residual CKD and 60% died.

Conclusions: Increased weight, solid organ malignancy and ICU admission were significantly associated with increased risk of AKI in this cohort. Patients who required RRT had worse outcomes.

TH-PO124

A Case of Steroid-Dependent Interstitial Nephritis Related to Pembrolizumab Use

Naveen Punchayil narayanankutty,[1] Jiny Olickal,[1] Gayathri Devi,[2] Jair Munoz Mendoza,[3] Marie A. Sosa.[3] *[1]Jackson Memorial Hospital, Miami Beach, FL; [2]Providence hospital, Miami, FL; [3]University of Miami, Miami, FL*.

Introduction: Pembrolizumab is a humanized monoclonal antibody belong to class of Immune check point inhibitor (ICI)used in cancer immunotherapy which targets the programmed cell death protein 1 receptor of lymphocytes. Ever since the FDA approval of ipilimumab in 2011 for Metastatic melanoma, there has been a rapid advancement in the use of ICI in various forms of cancer. Every year the use of ICI is rising so do adverse events related to the use of Immune check point inhibitors

Case Description: 77 y/o female with h/o metastatic lung cancer, on chemotherapy, transferred to ER from clinic after labs showed Creatinine of 8.95 and potassium: 7.4 compared to a baseline creatinine of 1.1 six weeks prior. Her Urinalysis showed 62 wbcs with rest of the labs unremarkable except for metabolic acidosis with a bicarbonate level of 16. She was managed supportively and subsequently a renal biopsy was done which showed diffuse severe acute tubulointerstitial nephritis with eosinophils consistent with a hypersensitivity reaction, marked interstitial fibrosis, marked arteriosclerosis and mild arteriolosclerosis. Her history is significant for biopsy proven adenocarcinoma of the lung diagnosed in June 2017 Started on chemotherapy with Carboplatin, pemetrexed initially. She had Left upper lobectomy and wedge resection in Oct 2017, followed by maintenance immunotherapy with Pembrolizumab only since Decmeber 2017. Considering the pathology finding patient was started on high dose prednisone for AIN. Eventhough creatinine improved to 1.71 on follow up visit she remained steroid dependent and her AKI progressed to CKD IV with recent EGFR of 27

Discussion: The presence of Acute interstitial nephritis (AIN) secondary to Immune check point inhibitors has been described before but usually with the cessation of drug and with high dose prednisone therapy for few weeks renal function improves. We present a case of Acute interstitial nephritis related to pembrolizumab use which presented a year after initiation of therapy and despite early initiation of steroids, she remained steroid dependent with progression of Acute Kidney injury (AKI) to Chronic Kidney disease (CKD). Our case emphasis on keeping AIN on top of differential diagnosis in patients treated with ICI even if ICI use is not recent and patient can develop steroid dependency with progression of AKI to CKD

TH-PO125

Spontaneous Late Acute Cholesterol Emboli with Acute Hydrophilic-Polymer Kidney Injury in a Renal Allograft

Asad Riaz,[1] Oluwafisayo O. Adebiyi,[1] Muhammad S. Yaqub,[2] Tim E. Taber,[1] Asif A. Sharfuddin.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University, Indianapolis, IN.*

Introduction: Hydrophilic coatings are used on intravascular devices to avoid thrombosis, and vasospasm during endovascular procedures. We report a very rare case of Acute Kidney Injury caused by this coating.

Case Description: 58 year old male underwent his second left sided renal transplant in March 2017. Prior to transplant he has mild- to moderate aortic stenosis. However subsequent to his transplant in October 2017 he was found to have critical aortic stenosis. For which he underwent a transcatheter -aortic valve replacement via right transfemoral percutaneous approach with the insertion of a bioprosthetic aortic valve. His renal function function remained stable at 1.4mg/dl range at the time of the aortic valve replacement. Three months in January 2018 later he presented with oliguric acute kidney injury with a creatinine of 5mg/dl. Urinalysis revealed microscopic hematuria and 1+ proteinuria. Doppler evaluation revealed elevated velocities within the proximal, midportion, the renal artery. with features suggestive of renal artery stenosis. The biopsy showed Acute tubular necrosis; Arteriole with isolated cholesterol embolus; Glomerular capillaries with intraluminal embolic material which was nonpolarizable which appeared weakly eosinophilic, periodic acid–Schiff (PAS)-negative, largely silver-negative with speckled granular positivity, and light blue-gray on trichrome stain. This was consistent with hydrophilic-polymer emboli per prior case reports. The biopsy was complicated by acute hemorrhage and the patient had to have angiogram showing a severe 90% stenosis at the origin of the renal transplant artery. The lower pole segmental artery had to be embolized along with a 5 mm self-expanding bare-metal stent with resultant brisk flow through the stent into the transplant kidney. After 6 weeks of needing dialysis he recovered from his acute kidney injury with a creatinine back down to 1.6mg/dl.

Discussion: To date, only 4 cases of hydrophilic polymer emboli have been reported to involve the kidneys, of which 2 were in a renal allograft.(Chen et al NEJM 2015). This case provides evidence that renal lesions may be induced by hydrophilic-polymer emboli due to the transcatheter aortic valve procedures in conjunction with spontaneous acute atherosclerotic cholesterol emboli.

TH-PO126

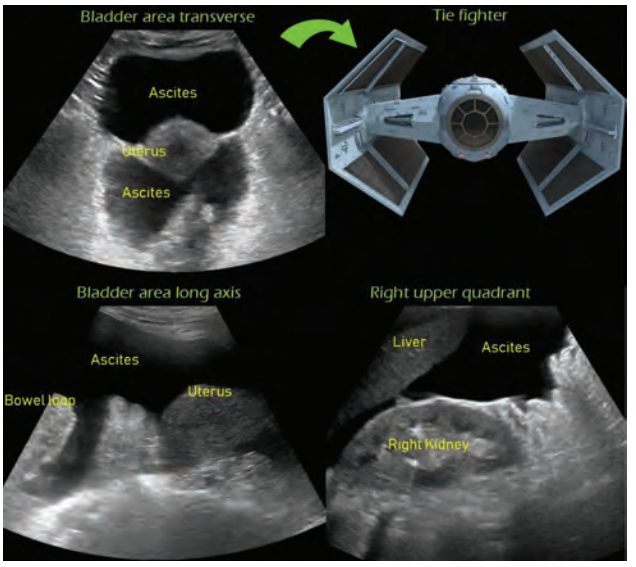
Focus on POCUS: Do Not Blindly Trust the Bladder Scanner in Patients with Ascites

Harini Bejjanki,[1] Abhilash Koratala.[2,1] *[1]University of Florida, Gainesville, FL; [2]University of Texas Health Science Center, San Antonio, TX.*

Introduction: Urethral catheterization, an invasive procedure with infection risk, was regarded as gold standard for measuring residual urine volume(UVol). It has now been superseded by portable automated bladder scanners(BS) performed by nurses at the patient's bedside. The benefits include fewer invasive catheterizations and increased patient comfort. However, caution has to be exercised when using BS to identify UVol in complex cases such as patients with ascites or other pelvic pathology. We report a case of pelvic ascites, where nephrologist-performed point-of-care ultrasonography (POCUS) has facilitated the correct diagnosis.

Case Description: A 45-year-old woman with history of liver cirrhosis was admitted for failure to thrive. Hospital course was complicated by decompensated cirrhosis, septic shock, and Acute Kidney Injury requiring renal replacement therapy. A routine BS to monitor renal recovery revealed UVol of ~800ml. However, there was no urine return on insertion of a urethral catheter. Urology consult was requested to assist with the catheter placement. Meanwhile, nephrology team performed POCUS, which demonstrated a large amount of anechoic fluid in the pelvis, which was 'continuous' with the peritoneal cavity in the longitudinal plane indicating that it is pelvic ascites and not the urinary bladder. In the transverse plane, uterus was seen floating in the pelvic ascites and together with ovarian ligaments, gave the appearance of a "TIE fighter" ('Star Wars' fictional Starfighter) [Figure]. A CT scan obtained later confirmed decompressed bladder deep in the pelvis.

Discussion: The blind nature of BS measurement does not allow differentiation of bladder from other fluid collections. Hence, nephrologists should perform POCUS and need to be aware of the pelvic anatomy in patients prone to ascites, which likely avoids unnecessary consultations and catheterizations.



TH-PO127

Acute Interstitial Nephritis Presenting with Isolated Glycosuria

Benjamin Schwartz,[1] Jason M. Kidd.[2] *[1]Virginia Commonwealth University, Richmond, VA; [2]VCU Medical Center, Richmond, VA.*

Introduction: Acute Interstitial Nephritis (AIN) is often induced by drugs and is a common cause of acute kidney injury. The classical triad of AIN consists of eosinophilia, rash, and fever. However, clinically diagnosing AIN can often be challenging as these signs and symptoms rarely present in concert. The inflammatory pathology of AIN leads to renal tubule dysregulation which can be clinically observed as glycosuria, eosinophilia, leukocytes or white blood cell casts and proteinuria. We present a case of AIN presenting with acute kidney injury and isolated glycosuria without pyuria.

Case Description: A 34-year-old female presented to our institution with nausea, vomiting and abdominal pain. She had been treated for tonsillitis with amoxicillin a month prior to presentation. She had a blood pressure of 169/104 mmHg without antecedent history of hypertension. She was afebrile. Her physical exam was significant for trace lower extremity edema. She had no rashes. On admission, her serum creatinine was 7.7 mg/dL with a potassium of 3.1 mmol/L, and hemoglobin of 11.7 g/dL. Her white blood cell count was 10.2 without eosinophilia. Urinalysis was significant only for glycosuria of over 500 mg/dL with a serum glucose of 119 mg/dL. Urine sediment examination was unremarkable. Hepatitis and HIV serologies were negative, complement levels were normal, and urine immunofixation was negative. Ultrasound of kidneys was normal. Throughout admission she sustained glycosuria with normoglycemia. She underwent renal biopsy which demonstrated acute interstitial nephritis. She was started on high dose prednisone that was tapered over the course of three months. Two months following presentation her glycosuria resolved, and four months following presentation her serum creatinine was 1.2 mg/dL.

Discussion: This patient had an atypical presentation of AIN that lacked classical diagnostic lab features and has been rarely reported. She had profound glycosuria in setting of normoglycemia, which resolved following a course of corticosteroids. Glycosuria was most likely due to proximal tubule damage from AIN. This case supports previous hypotheses that drug-induced AIN can cause SGLT dysfunction resulting in glycosuria in the absence of other identifiable proximal tubule dysregulations. We propose that resolution of AIN involves the repair and restoration of SGLT function.

TH-PO128

Sizzurp Joins the List: AKI from Recreational Drug Use

Cecille Marie C. Sales,[1] Farida Migally,[2] Roger A. Rodby.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Nephrology Associates of Northern Illinois and Indiana, Chicago, IL.*

Introduction: Synthetic cannabinoids and bath salts, both popular for their psychoactive effects have been associated with acute kidney injury (AKI). Another recreational drug "sizzurp" (also known as "purple drank", and "lean") was first used in the 1960s and made popular in the 1990s by the hip hop community. It consists of the antihistamine promethazine +/- codeine, typically mixed with a sweet soft drink, and ingested in higher than prescribed doses. Promethazine causes CNS depression, cholestatic jaundice and hypotension. Codeine can cause behavioral changes, respiratory depression, and cardiac arrest. Promethazine induces codeine metabolism to morphine via CYP2D6, potentiating a "high" and intensifying the sedative effects. Sizzurp is desired for creating euphoria accompanied by a "dissociative feeling". Often ingested with alcohol, its risk profile is magnified.

Case Description: We have a 39-y/o man with no PMH, who presented with abdominal pain after taking sizzurp for several days. He had scleral icterus and a BP of 150/96. Labs: WBC 25.4, Hgb 13.2 g/dl, Plt 367k, BUN 80 mg/dl, Cr 8.3 mg/dl. Total

bilirubin was 12 mg/dl with a mild transaminitis and a CK of 1500 units/L. The UA showed mild hematuria and proteinuria with urine P/C ratio of 1.2 g/g. The urine drug screen was positive for cannabinoids. Serologies, SPEP and UPEP were negative. The kidneys were normal in size and echogenicity and without hydronephrosis. Liver US showed fatty infiltration and liver biopsy revealed drug induced injury. A renal biopsy had 11 nl glomeruli with diffuse ATN, focal interstitial nephritis and a negative bile stain. IF was negative. He was oliguric and required dialysis for one month but had eventual renal recovery with a Cr of 1.3 mg/dl.

Discussion: Little is known about the mechanism of AKI in many recreational street drugs including sizzurp. It may be directly toxic (nephrotoxic ATN) or it may be associated with hypoperfusion leading to ischemic ATN. Sizzurp should be added to the list of recreational drugs associated with AKI.

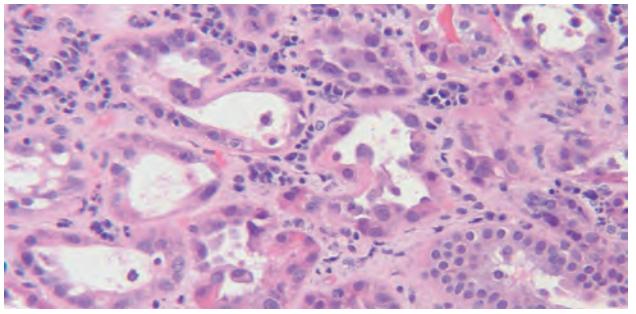


Figure 1. ATN with focal interstitial nephritis.

TH-PO129

An Unusual Case of Atypical Hemolytic Uremic Syndrome Triggered by Acute Infectious Mononucleosis Infection Presenting Without Thrombocytopenia

Rishabh K. Jain, Virginia E. Duncan, Vinay Narasimha Krishna, Emmy K. Bell. *University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is characterized by abnormal clotting with features of intravascular hemolysis, thrombocytopenia, and acute kidney injury. Athrombocytopenia has rarely been associated with aHUS. Approximately one half of patients with aHUS have pathogenic gene variants of the complement pathway and gene variants in the coagulation pathway of unclear pathogenicity have also been identified. We describe a patient with acute Epstein Barr virus (EBV) infection who developed aHUS without thrombocytopenia in the setting of gene mutations of both the complement and coagulation pathways.

Case Description: A 26-year-old female with acute infectious mononucleosis diagnosed a week before, presented with malaise, hypertension (148/98 mm) and oliguria. Laboratory data revealed hemoglobin 7.9 gm/dl, BUN 123 mg/dl, creatinine 11.3 mg/dl, UPCR of 5.6 mg/mg with a nephritic sediment. Moderate schistocytes were seen in the peripheral smear but platelets were normal. ADAMS13 was normal. Renal biopsy showed acute and subacute thrombotic microangiopathy. Other than a recent positive IgM Monospot, autoimmune and other infectious studies were unremarkable. She had elevated Ba fragment, Bb fragment and soluble level sMAC/C5b-9. Genetic panel found a likely pathogenic variant in the CFH gene and a novel variant of unknown significance in the PLG (plasminogen) gene. Treatment with eculizumab resulted in discontinuation of dialysis after 4 weeks. Follow up at 6 months showed improved UPCR to 1.5 mg/mg.

Discussion: aHUS is characterized by uncontrolled activation of the alternate pathway of complement at the cell surface. Mutations of the complement pathway are implicated in disease pathogenesis and coagulation pathway genetic variants have been associated. Our patient's finding of EBV-triggered aHUS has been rarely reported and even less commonly in association with athrombocytopenia. The patient has a rarely described combination of a likely pathogenic variant in the complement pathway CFH gene and a variant in the coagulation pathway PLG gene. Due to absence of causal relationships, these findings may be coincidental in this patient with EBV-triggered aHUS. Further research is needed to elucidate the pathophysiology of aHUS

TH-PO130

Diagnosing Atypical HUS in the Setting of Complement Amplifying Conditions (CAC): A Case Series

Karthik Kovvuru, Maria Lourdes Gonzalez Suarez, Swetha Rani Kanduri. *University of Mississippi Medical Center, Jackson, MS.*

Introduction: Diagnosing aHUS in the setting of complement amplification conditions (CAC'S) is challenging. We report 2 cases of aHUS which presented as treatment resistant Lupus, and unresolving sepsis from influenza in post partum period.

Case Description: **Case 1:** 20 Yr old African American woman with Lupus (diagnosed at age 16, chronically low complements, partially controlled with Azathioprine, Rituximab, Mycophenolate and recently started on Cyclophosphamide (CYC) for class IV lupus nephritis, received 3 doses) presented to hospital for confusion and seizures. Started on pulse dose steroids for possible Lupus cerebritis. Labs were significant for microangiopathic hemolytic anemia, thrombocytopenia and low complements. Considering her resistant lupus despite outpatient CYC and inpatient pulse dose steroids, she was started on plasmapharesis (TPE) after sending ADAMTS13 and genetic panel for aHUS. No clinical or lab improvement was noted after 5 sessions of TPE. Genetic panel for aHUS resulted equivocal with heterozygous missense mutations in *CFH, CFHR1-CFHR3* gene. Started on Eculizumab (ECU) for aHUS (900 mg/week for 4 weeks). Serum creatinine and hemolysis labs improved significantly. She was maintained on ECU (1200mg/ 2 weeks) for 8 months after which she suffered sudden death. **Case 2:** 38 Yr old African American woman with hypertension presented with headaches in her 3rd trimester (first pregnancy); underwent C-section at 27 weeks due to pre-eclampsia. Post-op she was transferred to ICU for hypoxic respiratory failure (ARDS) and sepsis. She was treated with antibiotics initially and changed to Oseltamivir due to positive Influenza PCR. She developed AKI requiring CRRT. Due to lack of clinical response, low complements and slowly declining platelet counts, further workup showed microangiopathic hemolytic anemia. TPE was started after sending ADAMTS13 and genetic panel for aHUS. Hemolysis labs and platelet levels partially improved after 10 sessions of TPE. aHUS genetic panel showed heterozygous missense mutation for *CFHR3*. Started on ECU 900 mg/week for 4 weeks, followed by 1200 mg/ 2 weeks for 3 doses. Her renal function and other lab parameters returned to normal, and remained stable for past 18 months.

Discussion: Clinicians should have low threshold for suspecting aHUS if CAC's do not respond to appropriate therapy.

TH-PO131

Don't Judge a Book by Its Cover: The Challenges of Diagnosing Nondilated Obstructive Uropathy

Muhammad A. Shahzad,[2] Pravir V. Baxi,[1] Roger A. Rodby.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Louis Weiss Memorial Hospital, Chicago, IL.*

Introduction: Nondilated obstructive uropathy (NDOU) is a rare and elusive cause of AKI since the diagnosis of obstructive uropathy (OU) depends on the demonstration of a dilated collecting system while the lack of rules it out. Reported in <5% of OU, NDOU has been associated with retroperitoneal malignancy, lymphadenopathy and fibrosis. The diagnosis requires a high index of suspicion and intervention despite normal radiographic screening studies. We present a case of AKI thought to be ATN where recognition and treatment of NDOU prevented irreversible ESRD.

Case Description: A 60-y/o woman with breast cancer complicated by metastasis to the retroperitoneal lymph nodes with a baseline serum creatinine (sCr) of 0.6 mg/dl was given zoledronic acid and one month later had a sCr of 1.3. She had decreased urine output and abdominal pain. Ultrasound and CT imaging showed no evidence of hydronephrosis. Her UA was benign. She became anuric and HD was initiated. Her AKI was postulated to be ATN from bisphosphonate use. A renal biopsy could not be performed because of DVTs requiring anticoagulation. She was discharged on HD. Despite normal imaging and a potential explanation for her AKI, there remained a clinical concern for NDOU. Bilateral retrograde pyelogram performed two weeks post-discharge showed no hydronephrosis. There were questionable areas of mild ureteral segmental narrowing and because her clinical course suggested obstruction, bilateral stents were placed. There was an immediate diuresis with an average output of about 300 ml/hr. Her sCr improved from 8.6 mg/dL to 0.8 mg/dL over the next 24 hrs (Fig.1).

Discussion: NDOU is a rare diagnosis that requires a high level of clinical suspicion. The lack of dilatation in NDOU has many pathophysiologic explanations, but is felt mainly to be secondary to the encasement of the collecting system. Direct visualization via retrograde or antegrade pyelography with empiric stent or nephrostomy tubes placement may be necessary when the concern for NDOU is high despite imaging lacking evidence of hydronephrosis.

TH-PO132

Benefits of Renal Artery Stenting in Select Cases with Severe Renal Artery Stenosis and AKI

Aniesh Bobba,[2] Andy Chuu,[2] Steven C. Cheng,[1] Anitha Vijayan.[2] *[1]Washington University School of Medicine, St. Louis, MO; [2]Washington University in St. Louis, St. Louis, MO.*

Introduction: Prevalence of RAS in US is estimated to be 7% in those >65 years. Two large RCTs demonstrated that RA stenting do not improve CV and renal outcomes. We present 2 cases of oliguric AKI 2º to RAS who had prompt improvement in renal function after RA stenting.

Case Description: Case 1: A 78-year-old WF with hx of uncontrolled HTN and baseline SCr 1.3-1.5 mg/dL presented with SOB, edema, and AKI. Admission SCr was

2.7 mg/dL and she developed oliguric AKI.Renal US with Doppler was consistent with bilateral RAS (Table1). Right RA stenting was performed, with immediate improvement in UO and SCr (Fig1&2A/B). At 6-mo f/u, her SCr is 3.3 mg/dL with BP of 114/62 mmHg on 3 meds, incl ACEI. **Case 2:** A 72-year-old WF with hx of uncontrolled HTN, CKD (baseline SCr 1.8-2.5 mg/dL) and recurrent hospitalizations for vol overload, presented with SOB and oliguric AKI.Renal US with Doppler revealed L RAS (Table 1). She developed oliguric AKI and left RA stenting was performed (Fig 1), with prompt improvement in renal function. At 5-mo f/u, her BP is 138/64 mmHg on 3 meds, including an ARB, and her SCr was 1.62mg/dL. She has not had any further hospitalizations for vol overload.

Discussion: After publication of 2 large RCTs (ASTRAL & CORAL), RA stenting has fallen out of favor in tx of RAS. However, it is important to note that these studies excluded patients with severe disease, pulm edema and renal failure. Thus, determination for risks and potential benefits of RA stenting needs to be individualized high-risk pts. RA stenting in our 2 pts with high CV risk averted imminent dialysis, improved BP and allowed use of RAAS blockade.

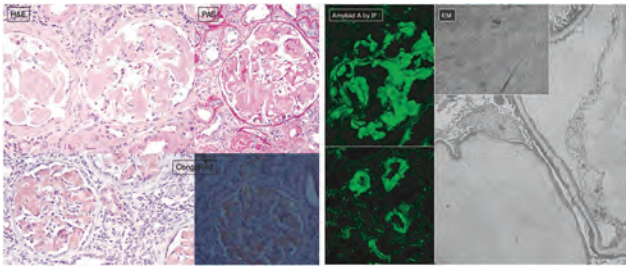
Renal Amyloidosis and Intracranial Mucormycosis in an Intravenous Drug User

Mon-Wei Yu,[1,2] Ashish Verma,[1,2] Veronica E. Klepeis,[1] Eugene P. Rhee,[1] Andrew Z. Fenves.[1] *[1]Massachusetts General Hospital, Newton, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Introduction: Mucormycosis is a rare but fatal fungal infection commonly seen in immunocompromised states such as end-stage kidney disease and post-renal transplantation. Here we report a unique case of invasive mucormycosis associated with severe acidemia in a patient with impaired renal function and AA amyloidosis.

Case Description: A 37-year-old Caucasian man with a history of active intravenous drug use including heroin was admitted for one week of slurred speech, right-sided weakness and right facial droop. CTH showed a 2x3 cm lesion in the left deep frontal white matter with surrounding vasogenic edema. His labs showed a serum creatinine (SCr) of 15.04 mg/dL (estimated GFR: 4 mL/min/1.73m2), BUN of 120 mg/dL, and bicarbonate of 10 mmol/L. The pH and pCO2 of the first venous gas were 7.14 and 28 mmHg respectively. His urinalysis was positive for 3+ glucose with a pH of 8.0. A spot urine protein/creatinine ratio was 6.87. A brain biopsy confirmed the diagnosis of mucormycosis and a renal biopsy was subsequently performed. Outcomes: The patient received maintenance isotonic bicarbonate fluid with daily urine output about 3-4L. His SCr improved but plateaued at 7 mg/dL. A course of IV amphotericin B, IV micafungin, and oral posaconazole were implemented. Renal biopsy (Fig.1) demonstrated AA amyloidosis, with greater than 90% of glomeruli showing mostly global involvement by amyloid. There was also vascular and tubulointerstitial involvement, and approximately 70-80% interstitial fibrosis and tubular atrophy were noted. He was eventually started on peritoneal dialysis and remains on posaconazole.

Discussion: Invasive intracranial mucormycosis can occur in patients with profound acidemia. Therefore, aggressive bicarbonate repletion is essential to control the infection in addition to appropriate antibiotic treatment. Glucosuria and bicarbonate wasting in our patient may suggest proximal tubular injury from AA amyloidosis. A comprehensive history taking is pivotal to diagnose heroin-related AA amyloidosis, which results from chronic subcutaneous injections.



TH-PO134

Silicone Implant-Induced Granulomatosis and IgA Nephropathy in a Male-to-Female Transgender Person

Karina P. Verma,[1] Christina Irene Mejia,[2] Muhammad O. Hanif,[3] Suzanne Boyle.[1] *[1]Drexel University College of Medicine, Pawtucket, RI; [2]Drexel University Section of Nephrology/Hahnemann University Hospital, Philadelphia, PA; [3]Drexel University, Philadelphia, PA.*

Introduction: Silicone implants, used in cosmetic procedures, induce local and systemic inflammatory reactions. We describe a case of silicone implant-induced granulomatosis (SIG) presenting with hypercalcemia and AKI.

Case Description: A 58-year-old male-to-female transgender was referred to nephrology for symptomatic hypercalcemia (11.7 mg/dl) and AKI (Cr 1.46 mg/dl; baseline 0.88 mg/dl). Her history included well-controlled HIV, HTN, gender reassignment surgery, breast augmentation, perineal/gluteal silicone implantation in the 1990s. Evaluation of hypercalcemia revealed a suppressed PTH (12 pg/mL), normal PTHrP and SPEP, and high ACE and 1,25 vitamin D levels, suggestive of granulomatous disease. There was no evidence of TB. Urine protein/Cr was 0.360 mg/g and urinalysis was bland. Other studies showed the following: CT scan, calcified granulomas on breasts and gluteal areas with portacaval and retroperitoneal lymphadenopathy; renal ultrasound, increased cortical echogenicity and non-obstructing left renal calculi; inguinal node biopsy, granulomatous inflammation and non-polarizable injectable material consistent with silicone implant. Renal biopsy showed acute mild tubular injury, mild focal interstitial calcification without significant scarring or granulomas; 2-3+ mesangial IgA deposits with 30% foot process effacement. Resection of the granulomas was impossible. Low-dose prednisone was initiated for chronic management of hypercalcemia with normalization of serum calcium (9.6. mg/dl) and Cr (0.9 mg/dl).

Discussion: Bioimplants, like silicone, trigger local and systemic immune reactions by acting as T-cell-directed antigens or as adjuvants – substances that enhance the antigen-specific immune response. The systemic inflammatory responses that ensue have been labeled autoimmune/inflammatory syndrome induced by adjuvants (ASIA). ASIA can present as granulomatous disease, lupus-like syndromes, or vasculitis weeks to decades following receipt of the bioimplant. Our patient presented with hypercalcemia mediated by SIG an unanticipated finding of IgA nephropathy on biopsy, but no evidence of renal granulomatous disease. It is unknown if IgA nephropathy is a manifestation of ASIA or a coincidental diagnosis in this case. With increasing prevalence of cosmetic procedures, nephrologists should be aware of potential latent complications of bioimplants.

TH-PO135

First Case of Leptotrichia goodfellowii Endocarditis-Associated Glomerulonephritis

Guneet S. Kochar, Ann Herron, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Infective endocarditis is a well described cause of glomerulonephritis (GN), but can be difficult to diagnose. We present the first case of ANCA-associated immune complex GN from Leptotrichia goodfellowii endocarditis with initial diagnosis made by kidney biopsy.

Case Description: A 57 year old male with hypertrophic cardiomyopathy with an ICD was found to have an acute rise of his creatinine to 3.4 mg/dL from a baseline of 1.1 mg/dL prior to his left heart catheterization in preparation for a septal myectomy. He noted two weeks of lower extremity edema, chills, subjective fevers, and poor oral intake. Workup notable for a UPCR 1.9 mg/mg, 415 RBC/HPF with dysmorphic RBCs, low C3 and C4 at 35 and 8 mg/dL respectively, atypical ANCA staining with positive MPO and PR3, and type II cryoglobulinemia. Remainder of serologic workup was negative. Creatinine worsened so methylprednisolone 1 gram daily was started and a renal biopsy

was performed showing IgM dominant, predominantly mesangiopathic immune complex and necrotizing crescentic glomerulonephritis suggestive of endocarditis, as well as diffuse tubular injury. He developed acute severe mitral valve regurgitation due to a torn chordal tissue with vegetations seen on the mitral valve and an ICD lead. He was started on broad spectrum antibiotics and steroids stopped. Blood cultures grew Leptotrichia goodfellowii, likely from recent dental work, and antibiotics narrowed to ceftriaxone and metronidazole with subsequently cleared blood cultures. He required initiation of hemodialysis a week after his biopsy, but after completing antibiotic treatment, he had renal function recovery allowing stoppage of hemodialysis after two months with most recent creatinine 1.9 mg/dL.

Discussion: To our knowledge, this is the first reported case of endocarditis-associated GN from Leptotrichia goodfellowii, a gram negative fusiform bacteria found in oral flora. It highlights the importance of considering indolent infectious etiologies in patients with acute renal failure. Clues suggesting subacute endocarditis-associated GN include presence of cardiac devices, low C3 and C4, and ANCA positivity, though kidney biopsy is key in confirming the diagnosis. While the role of immunosuppression in these patients is unclear, renal recovery can be seen with antimicrobial therapy alone, underscoring the need for isolation of the pathogen.

TH-PO136

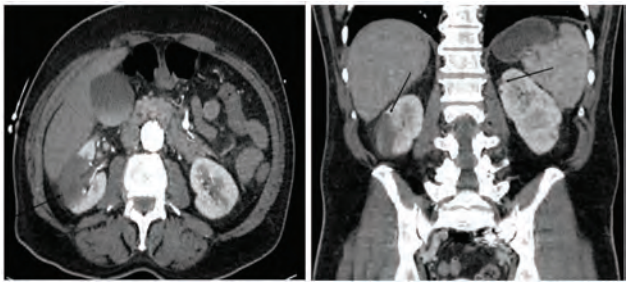
Bilateral Renal Infarction: An Uncommon Presentation of Multiple Myeloma

Jayesh B. Patel, Swe Zin Mar Win Htut Oo, Melissa L. Swee, Mony Fraer. *University of Iowa Hospitals and Clinics, Iowa city, IA.*

Introduction: We report on a case of bilateral renal infarction from disseminated intravascular coagulation, secondary to a previously undiagnosed multiple myeloma. This cause of acute renal infarction is uncommon and may have a misleading presentation, leading to diagnostic delays/misdiagnosis, reason for us highlighting it here.

Case Description: A 70-year-old male with coronary disease, hypertension, repaired abdominal aortic aneurysm, presented with acute onset severe abdominal pain, nausea and a 25 lbs weight loss (in 6 months). Blood pressure was 185/96 mm Hg. He had abdominal tenderness. Labs showed hyponatremia (normal plasma osmolality) and creatinine was 1.43. CBC showed leukocytosis, anemia and thrombocytopenia. Peripheral smear showed Rouleaux formation and plasma cells (plasma cell count was 1239/mm3). Also, there was an elevated LDH, D-Dimer, and low fibrinogen, haptoglobin. He had an elevated bilirubin, alkaline phosphatase and AST with normal ALT. Prothrombin time and INR were elevated. A CT scan showed wedge-shaped opacifications within the right kidney and the left renal cortex without thrombi. Procalcitonin was normal and factor 5 Leiden mutation was absent. A 2D-echo was negative for any valvular disease. EKG showed sinus rhythm. With concerns for multiple myeloma (age, creatinine, rouleaux formation, increased plasma cells), we observed a monoclonal protein in SPEP. SIFE showed monoclonal IgG-Lambda protein. Kappa/Lambda free Light chain ratio was 0.01. Bone marrow biopsy revealed 20% plasma cells. FISH showed an IgH/MAF rearrangement (seen in plasma cell disorders). Carfilzomib, cyclophosphamide and dexamethasone as well as anticoagulation were initiated. Partial remission was achieved within two cycles of chemotherapy. Creatinine came down to 1.0.

Discussion: Multiple myeloma is a hematological malignancy that similar to other malignancies, can lead to disseminated intravascular coagulation and infarction at unusual places. We want to bring to the clinicians' attention this relatively uncommon causes of renal infarction.



CT scan of Abdomen showing bilateral renal infarction

TH-PO137

Acute Tubulointerstitial Nephritis Associated with a Vaccination of Japanese Encephalitis Virus: A Case Study

Keisuke Nakano, Tomomichi Iida, Michihiro Hosojima, Guili Chu, Kiyoko Hosaka, Yumi Ito, Suguru Yamamoto, Shin Goto, Ichiei Narita. *Clinical Nephrology and Rheumatology, Niigata University, Niigata, Japan.*

Introduction: Common causes of acute tubulointerstitial nephritis (ATIN) include infectious diseases, collagen diseases, sarcoidosis, or a reaction to certain drugs (e.g., nonsteroidal anti-inflammatory drugs, antibiotics). In Asia, according to frequency and severity, Japanese encephalitis virus (JEV) is the most important cause of viral encephalitis and vaccinations are recommended at ages 3, 9, and 17 years in Japan.

Case Description: A 17-year-old healthy Japanese male received the JEV vaccine in September, 2018. He was not on any previous medications. A few days after vaccination, he began to feel fatigue. He underwent a check-up at a local clinic and was diagnosed as having acute kidney injury (serum creatinine [Cr] 2.91=mg/dl). He was admitted to our hospital for further examination. Upon admission, laboratory tests revealed the following values: serum Cr=4.41 mg/dl, urinary protein=0.22 g/day, urine sediment erythrocytes=<1/HPF, and urinary β_2-microglobulin=12,034 ng/ml. Gallium scintigraphy showed uptake in the bilateral kidneys. Renal biopsy showed almost normal glomeruli. We observed inflammatory cells and the infiltrate was mainly composed of lymphocytes and a few eosinophils, with a granuloma formation in the interstitium. The proximal tubular epithelial cells also showed a moderate degree of atrophy and tubulitis. However, deposition of immunoglobulin and complements were not observed. Moreover, immunostaining showed a predominance of CD4-positive T cells in the interstitium. Finally, a drug lymphocyte stimulation test (DLST) for the JEV vaccination was positive. The patient received 500 mg methylprednisolone intravenously for 3 days, followed by oral prednisolone (40 mg/day). His serum Cr and urinary β_2-microglobulin levels decreased by 2.51 mg/dl and 1,116 ng/ml, respectively.

Discussion: In this case, our findings suggest that the JEV vaccine is the cause of ATIN associated with a Type IV allergy. To our knowledge, this is the first report of ATIN associated with JEV vaccination. We should be aware of ATIN as a reaction to the JEV vaccination, in addition to other well-known side effect, such as acute disseminated encephalomyelitis.

TH-PO138

A Case of Severe AKI from Cutaneous Contact with Cresol

Jonathan D. Pankow,[1] Dia R. Waguespack,[2] Wut yi Hninn.[3] *[1]University of Texas Medical Center, Houston, TX; [2]McGovern Medical School - UTHealth - Houston, Houston, TX; [3]UTHealth, Houston, TX.*

Introduction: Cresol is a hydroxytoluene of ortho-, meta-, and para-isomers that are precursors to various compounds including household pesticides, disinfectants, and dyes. Although cresol is harmless in low concentrations in the environment, it can be inadvertently absorbed through intact skin, respiratory, and gastrointestinal tracts causing multiple organ dysfunction.

Case Description: A 29-year-old man presented to the emergency department after an accidental spill of cresol to his upper body and thighs at an alcohol-manufacturing chemical plant. He had no history of prior kidney disease. Physical exam revealed sharply demarcated dark brown discolorations with first degree burns to the exposed areas. A small amount of green urine was produced after bladder catheterization. The serum creatinine on arrival was 1.7 mg/dL, and he was oliguric despite fluid resuscitation. Liver enzymes were normal. Over the next two days the creatinine increased to 9.63 mg/dL and hemodialysis was initiated. Abdominal ultrasound and computed tomography were normal. The patient continued to require thrice weekly hemodialysis during his two-week hospitalization. Although he became non-oliguric, he was discharged with scheduled outpatient dialysis because a 24-hour creatinine clearance at time of discharge was 11 mL/minute.

Discussion: Cresol exposure is a rare cause of acute kidney injury. Previous cases of cresol toxicity have focused on ingestions that report multiple organ dysfunction with a high prevalence of liver dysfunction. Only a handful of cases describe cutaneous absorption of cresol, usually associated with severe acute kidney injury without evidence of significant liver injury. This observation is likely because cutaneous cresol absorption bypasses the portal venous system and reduces the liver's exposure to the toxin. The cause of acute kidney injury in cases of cresol intoxication is acute tubular necrosis based on a limited number of biopsy and autopsy case studies. Treatment is supportive with the potential for requiring prolonged hemodialysis depending on extent of exposure.

TH-PO139

A Case of BK Nephropathy in a Newly Diagnosed HIV Patient

Lesley anne G. Tubio, Filoteo Ferrer. *Makati Medical Center, Malate, Philippines.*

Introduction: BK virus-related nephropathy has been reported more among post-transplant patients with immunosuppressive therapy but is less identified among non-transplant and HIV patients.

Case Description: We report at 52-year-old male, admitted due to chronic cough. He was incidentally found to be Human Immunodeficiency Virus (HIV) positive with CD4 254 cells/μL and was empirically treated for possible Pulmonary Tuberculosis (PTB) reactivation and Pneumocystis pneumonia (PCP). During his hospital stay, his serum creatinine (sCr) was noted to be increasing reaching level of 3.82 mg/dL (from baseline of 0.82 mg/dL one year prior). He was then dialyzed and underwent kidney biopsy which showed minor glomerular abnormalities, acute interstitial nephritis with acute tubular injury, mild interstitial fibrosis and tubular atrophy with 6% global glomerulosclerosis. Trial of steroids was given and was started on antiretrovirals (ARVs). His kidney function stabilized without dialysis support over the next two months. Persistence of non oliguric acute kidney injury incompatible with his seemingly stable clinical state prompted further investigation, trial of drug holiday (off ARVs), and a repeat kidney biopsy was done. Results showed acute interstitial nephritis with acute tubular injury, moderate interstitial fibrosis and tubular atrophy with 20% global glomerulosclerosis; additional SV 40 stain was requested and showed positive results – supportive of BK nephropathy (BKN). Previous biopsy tissue was reviewed and re-examined. SV40 stain was requested and patient was already positive for SV40 stain. BK virus load was at 262,577 copies/mL and was placed on trial of fluoroquinolone. Patient's renal function no longer recovered with peak sCr of 18.65 mg/dL, is currently maintained on intermittent hemodialysis, and ARVs were resumed.

Discussion: This is an interesting case of a biopsy-proven BK nephropathy in a native kidney of a newly diagnosed HIV patient with a CD4 count of more than 200 cells/μL. Most published data on BK nephropathy in HIV patients have CD4 of less than 50 cells/μL.

BKN may be considered as a differential diagnosis in HIV or immunocompromised patients with progressive renal failure.

TH-PO140

AKI Secondary to Thrombotic Microangiopathy (TMA) in a Myeloma Patient: Scleroderma Renal Crisis (SRC), A Paraneoplastic Phenomenon

Parth Visrodia, Ana Maheshwari, Ruben A. Peredo, Krishnakumar D. Hongalgi. *Albany Medical Center, Albany, NY.*

Introduction: AKI due to TMA in a myeloma patient is an uncommon presentation. Rheumatic paraneoplastic syndromes have atypical presentations and are typically a result of anti-tumor immune responses. These subsets of diseases occur simultaneously or in close temporal relation to the diagnosis of an underlying malignancy. Our case report describes scleroderma as a likely cause of AKI/TMA and a paraneoplastic manifestation of multiple myeloma.

Case Description: A 47-year-old man with no prior renal disease presented with peripheral neuropathy, hypertensive urgency, seizures, microangiopathic hemolytic anemia (MAHA), and acute renal failure. AKI work up revealed paraproteinemia and subsequent bone marrow biopsy confirmed multiple myeloma (MM). On examination, he was found to have findings suspicious for scleroderma including telangiectasia, limited cutaneous thickening, salt-and-pepper skin changes, and abnormal nailfold capillaroscopy. CT Abdomen revealed distal esophageal and rectal thickening and esophagram showed esophageal dysmotility. Worsening kidney function, new skin findings, and MAHA lead to a kidney biopsy, which demonstrated findings of severe thrombotic microangiopathy (TMA) with no evidence of cast nephropathy. Deep skin biopsy was compatible with papillary and mid dermal sclerosis. Although autoantibodies were negative, patient was diagnosed clinically with scleroderma with scleroderma renal crisis (SRC) which appeared to be a paraneoplastic presentation of MM. Patient was treated with captopril initially for SRC and subsequently Eculizumab. Interestingly, his skin findings have not progressed after treatment for MM but remains dialysis dependent.

Discussion: AKI due to TMA in a patient with MM and SRC is a diagnostic dilemma. Paraproteins are associated with mimics of rheumatic diseases; however, there are rare reports on the coexistence of MM and paraneoplastic scleroderma. TMA is known to be associated with both MM and SRC, and although the clinical presentation was suggestive of scleroderma, the negative serologies challenged the diagnosis. Further studies are required to determine whether MM can induce SRC and if chemotherapy can improve scleroderma outcomes in these patients.

TH-PO141

Rhabdomyolysis Associated with Aspirin-Mediated Hyperthermia

Mhd hussam Al jandali, Laurel Mueller, Bilal shahzad azam Khan, James E. Novak. *Henry Ford Hospital, Detroit, MI.*

Introduction: Salicylate toxicity and rhabdomyolysis are both potentially life-threatening conditions. Only 2 reports have previously described an association between salicylate toxicity and rhabdomyolysis. We present a case of non-traumatic rhabdomyolysis occurring after aspirin overdose.

Case Description: A 36-year-old male with a history of chronic aspirin use (~2,600 mg daily) presented to the emergency department with dyspnea. A few hours earlier, he had taken approximately 20 tablets of aspirin (325 mg each) to treat a headache. He denied trauma. Within an hour, he developed hypoxic respiratory failure requiring intubation and mechanical ventilation. His initial salicylate level was 76.1 mg/dL. Other laboratory values on presentation included serum creatinine 2.7 mg/dL, total CO2 18 mmol/L, arterial pH 7.22, and creatine kinase (CK) 436 U/L. Pressors were initiated for worsening hypotension. The patient became hyperthermic to 41.7°C. The aspirin overdose was initially treated with intravenous sodium bicarbonate, but when the patient became anuric on hospital day 2, continuous renal replacement therapy was initiated. Evaluation of stage 3 acute kidney injury (AKI) revealed that CK increased to 28,880 U/L by hospital day 3, and then slowly returned to normal limits over the next 2 weeks. Kidney function recovered sufficiently to stop hemodialysis on hospital day 27.

Discussion: Two cases, published in 1989 and 1994, describe rhabdomyolysis and AKI in patients presenting with acute aspirin overdose. Both cases describe patients with hyperthermia, attributed to aspirin-mediated mitochondrial toxicity, followed by rhabdomyolysis. A case report from 2016 describes a young patient presenting with temperature 41.1°C, CK 57,050 U/L, and AKI after use of K2, a synthetic cannabinoid. Exertional hyperthermia is a well-known cause of rhabdomyolysis, but drug-induced hyperthermia is less frequently described. High fever may be an important link between aspirin overdose and rhabdomyolysis.

TH-PO142

Atypical Multiorgan Disease Possibly Associated with IgG4RD

Kathleen Leger,[1] John Huston,[2] Namrata Krishnan,[2] Mark A. Perazella,[3] Justin M. Belcher.[4] *[1]Yale University School of Medicine, New Haven, CT; [2]Yale University School of Medicine, Yale New Haven Hospital, New Haven, CT; [3]Yale School of Medicine, Cheshire, CT; [4]Yale University, New Haven, CT.*

Introduction: IgG4 related disease (IgG4RD) is associated with multi-system disease processes. Hallmarks include lymphoplasmacytic infiltration with a predominance of IgG4+ plasma cells with associated storiform fibrosis and elevated serum IgG4 levels. We report a patient with multiple yet atypical manifestations suspicious for IgG4RD.

Case Description: 38yo man with UC, T2DM, proteinuric CKD-2 (Cr-1.2) and hematuria was admitted for AKI and hyperkalemia. Chief complaints were chronic diarrhea and fatigue. Labs showed K-6.3, HCO3-9, Cr-2.6 and alk phos-861. U/A revealed hematuria and low-grade proteinuria. Renal u/s demonstrated right kidney-13cm and left-14cm. Abdominal u/s revealed dilated intrahepatic ducts. MRCP was unremarkable except for hepatomegaly and splenomegaly. CT abdomen/pelvis 3 months prior demonstrated enlarged retroperitoneal lymph nodes but no hepatomegaly/splenomegaly. Kidney biopsy revealed diabetic nephropathy and plasma cell rich interstitial infiltrate with 20% IgG4+ (>50/HPF) without storiform fibrosis. Serum IgG was 2424 (694-1618) with IgG1-1117 (382-929) and IgG4-338 (4-86). Liver biopsy revealed minimal plasma cell infiltrate with negative IgG4 staining and no sclerosing cholangitis. CT revealed increased retroperitoneal and inguinal lymphadenopathy. Prednisone 60 mg was initiated. He was subsequently re-admitted for brawny LE edema and SOB. Repeat CT demonstrated bilateral cavitary lung lesions and increased retroperitoneal/pelvic lymphadenopathy. Blood cultures were positive for MSSA, TEE revealed normal leaflets and no vegetations. Repeat kidney biopsy again revealed plasma rich interstitial infiltrate (>30 IgG4+ cells/HPF) and diabetic kidney disease. Lymph node biopsy was recommended but patient left prior to procedure.

Discussion: IgG4RD is challenging to diagnose due to multiple disease manifestations. In our patient, findings consistent with IgG4RD include those on kidney biopsy along with retroperitoneal lymphadenopathy and possible fibrosis. However, not all diagnostic criteria were met and he did not respond to a course of steroids. Other diseases potentially associated with IgG4+ plasma cells within tissues (drugs, sarcoidosis, syphilis, GPA) were excluded in our patient. Our case may represent an atypical case of IgG4RD or manifestation of a yet to be diagnosed disease.

TH-PO143

Urinary Ascites from Spontaneous Bladder Rupture: Rare Cause for Pseudo AKI

Vivek Sharma,[1] Imtiyaz H. Hakeem,[2] Faris Q. Hashim,[1] Nimrit Goraya.[1] *[1]Nephrology, Texas A&M Univ COM, Baylor Scott & White, Temple, TX; [2]Baylor Scott & White Health/Texas A&M COM-HSC, Temple, TX.*

Introduction: Spontaneous intraperitoneal bladder rupture is a rare entity. Diagnosis can be challenging. Symptoms are non-specific and misleading which delays the diagnosis and treatment of SUBR. In the pediatric population, the leading causes of rupture in reported cases are patients with neurogenic bladders, bladder diverticulum, bladder outlet obstruction, and history of bladder augmentation surgery. Symptoms of urinary leakage into the peritoneum include abdominal pain and distension, oliguria or anuria, and elevated serum creatinine. Elevation of the creatinine from resorption of peritoneal fluid results in elevation of serum creatinine, termed as pseudo-renal failure. Measuring the creatinine of the ascitic fluid can help aid in accurate diagnosis of an intraperitoneal bladder rupture. We present an interesting case of a 13 year old boy who presented with abdominal distension and pain with rapidly rising creatinine.

Case Description: 13 y.o. male with urachal cyst excision 6 years ago, presented with abdominal pain and elevated creatinine. Imaging studies revealed mild ascites. Liver morphology was reported normal. Elevation in creatinine was attributed to pre-renal etiology and was encouraged hydration. He presented back 3 months later with increasing abdominal distension and discomfort, rapid elevation of the creatinine with hematuria. With rapid rise in creatinine and positive urinary sediment, renal biospy was done. Biopsy was suggestive of MPGN with faint IgM and C3 deposits. He was started on urgent dialysis for elevated creatinine and steroids initiated. Peritoneal fluid creatinine was reported high consistent with urine leak in the peritoneum. CT Cystogram confirmed urinary leak. He was emergently taken up by urology for cystorraphy.

Discussion: This case highlights phenomenon of bladder rupture, urinary ascites and pseudo-renal failure. Bladder rupture can occur following trauma, irradiation, iatrogenic or spontaneous. Pseudo renal failure is the elevation of the creatinine from the resorption of the peritoneal fluid from urinary leak. If the ascitic fluid creatinine is significantly higher than serum levels, one should consider spontaneous bladder perforation as the etiology for the urinary ascites. CT cystogram is the gold standard imaging technique for diagnosis.

TH-PO144

Cocaine-Associated Atypical Haemolytic Syndrome in a Genetically Susceptible Individual

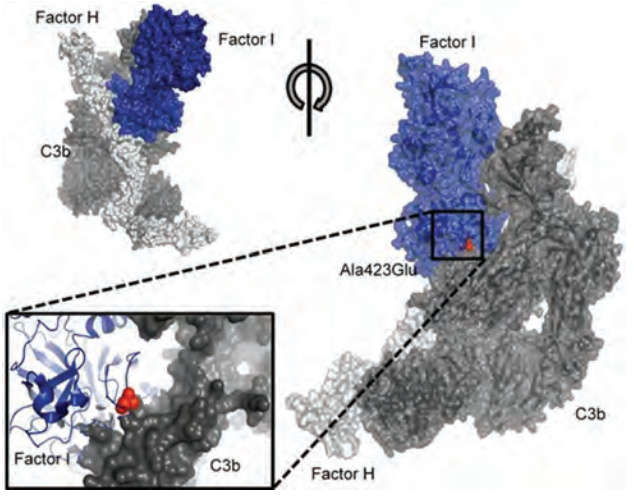
Elisa K. Bongetti,[2] David Kavanagh,[1] Kylie Martin,[2] Adam G. Steinberg,[3] Yogeshwar S. Rajaram,[2] Francesco L. Ierino.[2] *[1]National Renal Complement Therapeutics Centre, Newcastle upon Tyne, United Kingdom; [2]St Vincent's Hospital Melbourne, Airport West, NSW, Australia; [3]Royal Melbourne Hospital, Carlton North, VIC, Australia.*

Introduction: Atypical haemolytic uraemic syndrome (aHUS) is characterised by thrombocytopaenia, renal impairment and non-autoimmune haemolytic anaemia that requires early recognition and urgent treatment. Genetic variants predispose to this condition when a trigger, or, 'complement amplifying condition', is supplied. Identification of new genetic variants and of lesser known complement amplifying conditions are crucial for furthering the understanding of this serious condition.

Case Description: A forty-seven-year-old man presented to the emergency department and was found to have an acute kidney injury, thrombocytopenia, non-immune haemolytic anaemia and hypertension (205/150mmHg). He had smoked cocaine for the first time two weeks prior. The patient was taken to the intensive care unit for urgent plasma exchange with fresh frozen plasma. An urgent ADAMTS13 demonstrated normal level (44.1% [40-130]). Treatment with eculizumab was commenced and the patient responded well. Six months following his initial presentation, the patient was weaned off haemodialysis. The patient was heterozygous for the c.1268C>A p.(Ala423Glu) variant in the *CFI* gene.

Discussion: This case highlighted several important points. Firstly, our patient was found to be heterozygous for a rare gene variant previously detected in only two aHUS

patients. Although genetic analysis can uncover definitively pathogenic mutations which predispose to aHUS, the interpretation of variants of unknown significance remains a challenge. Secondly, there are few reports of an association between cocaine and aHUS. In our case, it is unclear whether aHUS was triggered by cocaine or hypertension. It responded well to rapid treatment with eculizumab supporting the hypothesis of an underlying immunological complement-based pathogenesis. Furthermore, in the absence of gold standard diagnosis of aHUS in the acute setting, prompt treatment with eculizumab can be challenging and delayed.



TH-PO145

Immune-Complex Glomerulonephritis Following PD-1 and PD-L1 Therapy in Renal Cell Carcinoma

Kathleen Leger,[1] Corey J. Cavanaugh,[2] Anushree C. Shirali.[2] *[1]Yale University School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT.*

Introduction: Inhibition of the Programmed cell death-1 (PD-1) pathway is associated with interstitial nephritis. Vascular endothelial growth factor (VEGF) inhibition via receptor tyrosine kinase blockade (RTKi) is associated with hypertension (HTN), proteinuria, thrombotic microangiopathy (TMA), and podocytopathies. Here we describe the development of Immune-complex glomerulonephritis (ICGN) in a patient who was treated with PD-L1 inhibitor, atezolizumab, and PD-1 inhibitor, nivolumab.

Case Description: A 49-year-old male with metastatic RCC and nephrectomy presented with worsening HTN and found with acute kidney injury (AKI). Initial treatment for RCC prior included bevacizumab (VEGF), pegylated interferon, and atezolizumab (anti-PD-L1). Following cycle 4, bevacizumab was held due to HTN and new proteinuria of 1.9 g/g. Despite this, proteinuria worsened to 5.2g/g and treatment changed to sunitinib and nivolumab. Following the initiation of this new regimen, he was admitted for AKI (with serum creatinine (SCr) increasing from 1.6 mg/dl to 2.6mg/dl), proteinuria of 9.2g/g, and a serum albumin that fell to 1.6g/dl from 3g/dl. Renal biopsy showed no interstitial infiltrate but one glomerulus displayed thickened. Electron microscopy showed segmental subepithelial, subendothelial, and numerous mesangial deposits with global foot process effacement. Immunofluorescence could not be obtained. These findings were consistent with an ICGN. Prednisone and a loop diuretic were initiated. Nivolumab was held and sunitinib was continued. At 1 month follow up, his NS improved along with serum albumin that rose to 2.3g/dl. Unfortunately, his RCC continued to progress and he subsequently passed away.

Discussion: PD-1 inhibition has become a cornerstone of many immunotherapeutic regimens for various malignancies. We describe a case of progressive proteinuria, AKI, and subsequent NS with biopsy proven ICGN following PD-L1 and PD-1 inhibition that responded to corticosteroids. This case describes a novel case of ICGN, seen rarely with anti-VEGF therapy, now seen with PD-L1 and PD-1 inhibition.

TH-PO146

Infliximab-Associated Focal Segmental Glomerulosclerosis in a Patient with Crohn Disease: A Case Report

Avantee V. Gokhale, Priya Deshpande. *Icahn SOM at Mount Sinai, NY, NY.*

Introduction: Infliximab is a monclonal antibody against tumour necrosis factor alpha (TNFα) used for immune mediated disorders such as ulcerative Colitis, Crohn's Disease, ankylosing spondylitis. Renal effects of Infliximab are uncommon and are poorly understood. Effects mentioned in literature review include acute tubulo-interstitial nephritis, focal segmental glomerulosclerosis (FSGS) and membranous nephropathy. Herein we present a case of biopsy proven FSGS in the setting of Infliximab use in a patient with Crohn's disease.

Case Description: We present a case of a 36 years old male Caucasian patient with Crohn's disease on treatment with Infliximab for 20 months, who presented with a symptom of urinary frequency. His urinalysis demonstrated microhematuria and urine protein excretion was 2.1g with serum albumin level of 3.2 g/dL. He underwent a renal biopsy that showed FSGS tip lesion with acute tubular necrosis. His Infliximab dose was titrated off. Subsequently, he was started on an angiotensin receptor blocker losartan at 25 mg and the dose was increased as tolerated. His proteinuria and hematuria improved with this therapy and after 2 months a repeat urinalysis showed 0.3g of proteinuria and absence of microhematuria. This is only the third known case of biopsy proven FSGS reported with Infliximab use.

Discussion: Our case highlights an uncommon adverse effect of a commonly used medication. Contrary to the other two cases, which reported renal effects within first 6 months of infliximab therapy, we found renal involvement even after 20 months of infliximab suggesting possibility of delayed effects on kidneys. The possible mechanism responsible for the development of renal complications during anti-TNFα infliximab administration implicates an interaction of anti-TNFα antibodies with TNFα present on glomerular visceral epithelial cells. These effects of the TNFα inhibitors should trigger screening urinalysis in patients on these medications for early diagnosis and management of renal effects. Future research should elucidate the links behind the renal effects of infliximab.

TH-PO147

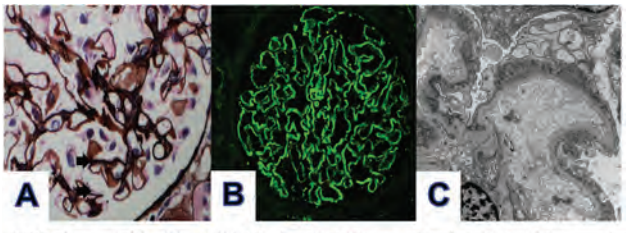
Membranous Glomerulonephritis as an Immune-Related Adverse Effect of Checkpoint Blockade Therapy

Colton Jensen,[1] Agnes Ounda,[1] Danniele G. Holanda,[2] Douglas L. Somers,[1] Melissa L. Swee.[1] *[1]University of Iowa, Waukee, IA; [2]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Immune checkpoint inhibitors are being used more frequently to treat various cancers, leading to immune related adverse effects (irAE). Although data on checkpoint inhibitor-induced nephrotoxicity is limited, a link to tubulointerstitial nephritis has been previously documented. We present a case of a patient who received ipilipumab and nivolumab, who developed membranous glomerulonephritis (MGN).

Case Description: A 20-year old Caucasian male with fibrolamellar-variant hepatocellular carcinoma (HCC) treated with nivolumab for the prior 2 years and additional ipilimumab for the prior 2 months presented with shortness of breath and pedal edema. Vital signs were notable for a heart rate of 100. Exam revealed tachycardia with no murmurs, lungs had inspiratory crackles bilaterally at the bases, and abdomen was soft, non-tender, and non-distended. On initial labs, albumin was 1.2 g/dL. Urinalysis demonstrated 4+ protein, and urine protein/creatine (UPC) ratio was 14. He was found to have bilateral pleural effusions. Kidney biopsy demonstrated membranous glomerulonephritis negative for staining with PLA2R and THSD7A. Immune checkpoint inhibitors were discontinued and tacrolimus 2mg twice daily and prednisone 60mg daily were initiated. The patient was discharged home on lisinopril, rosuvastatin, and bumetanide. UPC ratio was 6.5 at discharge and 0.7 a month after discharge.

Discussion: This is a case of a patient with HCC on immune checkpoint blockade therapy developing membranous nephropathy. Although HCC may also cause MGN, the rapid improvement of MGN with cessation of therapy more strongly suggests that this was an irAE. Given the increased use of checkpoint inhibitors, nephrologists should be mindful of this complication.



A) Light microscopy (LM), ~600x: A) JMS stain: glomerulus with sparse capillary loop spikes and holes, suggestive of MGN (arrows). B) Immunofluorescence (IF), ~400x: IgG stain: positive, global granular pattern of glomerular capillary loop staining. C) Electron microscopy (EM), ~6,000x: Glomerular capillary loops with regularly distributed, subepithelial immune-complex mediated type electron dense deposits.

TH-PO148

Tocilizumab-Induced Immune Complex Glomerulonephritis in a Patient with Rheumatoid Arthritis

Shinya Hibino,[1] Satoshi Hara,[1] Takahiro Yamano,[1] Hiroyuki Kawahara,[1] Takeshi Zoshima,[1] Ryo Nishioka,[1] Kiyoaki Ito,[1] Ichiro Mizushima,[1] Hiroshi Fujii,[1] Masayoshi Hirata,[2] Mitsuhiro Kawano.[1] *[1]Division of Rheumatology, Department of Internal Medicine, Kanazawa University Graduate School of Medicine, Kanazawa, Kanazawa, Japan; [2]Takaoka City Hospital, Takaoka, Japan.*

Introduction: Anti-TNF-α inhibitors used in the treatment of rheumatoid arthritis (RA) often cause immune complex glomerulonephritis (IC-GN) as part of biologics-induced autoimmune renal disorder. However, similar effects due to anti-IL-6 receptor inhibitors are very rare. Here, we report a case of tocilizumab (TCZ)-induced IC-GN in a patient with RA.

Case Description: A 70-year-old Japanese man was admitted to our hospital due to acute nephritic syndrome. He was diagnosed with RA 14 years previously and had received methotrexate (MTX) and biologics. Three years ago, the biologic was switched from adalimumab to TCZ. RA had been in remission, and his serum creatinine (Cr) was 0.8 mg/dL. One month ago, after showing flu-like symptoms, he developed bilateral lower leg edema, renal dysfunction (Cr 1.3 mg/dL), hematuria, and proteinuria, indicating acute nephritic syndrome. On admission, renal dysfunction (Cr 1.77 mg/dL, eGFR 30.7 ml/min/1.73 m^2), urinary protein 0.75 g/gCr, urinary red blood cells 50–99/high power field,

and hypocomplementemia (C3, 24 mg/dL; C4, 1 mg/dL; CH50, 0 IU/L) were found. Anti-nuclear antibody, anti-dsDNA antibody, parvoviral B19DNA, and anti-streptolysin O were negative, whereas cryoglobulin was weakly positive. Renal biopsy revealed mesangial cell proliferation and endocapillary hypercellularity with partial crescent formation. Immunofluorescence analysis indicated IgG, IgA, IgM, C3, and C1q deposition in the mesangium, so a diagnosis of IC-GN was made. After discontinuing TCZ and MTX, intravenous methylprednisolone was administered at a dose of 500 mg/day for three days and then prednisolone (PSL) was initiated at 60 mg/day. His renal function and urinary abnormalities improved, and serum complement levels increased. After 5 months of treatment, his renal function has been maintained using PSL 10 mg/day.

Discussion: The anti-IL-6 receptor antibody, TCZ, may lead to the development of IC-GN, similar to anti-TNFα inhibitor. The mechanism remains unknown because only one case of TCZ-induced IC-GN has been reported to date. Rheumatologists and nephrologists should be aware of this lesion and similar cases should be collected in future.

TH-PO149

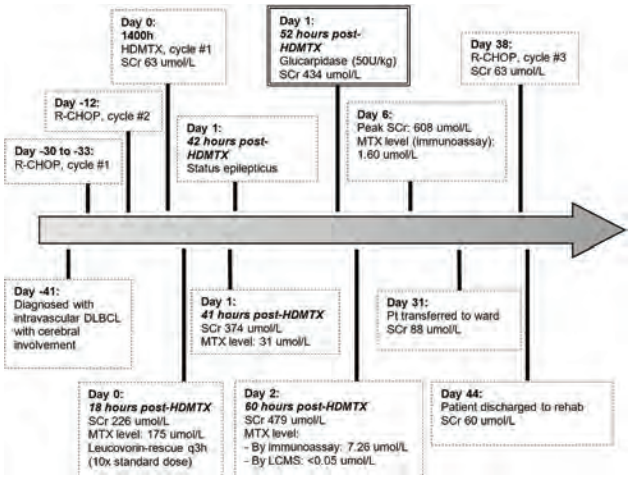
DAMPAned Methotrexate Levels: A Case Report of Acute Methotrexate Toxicity

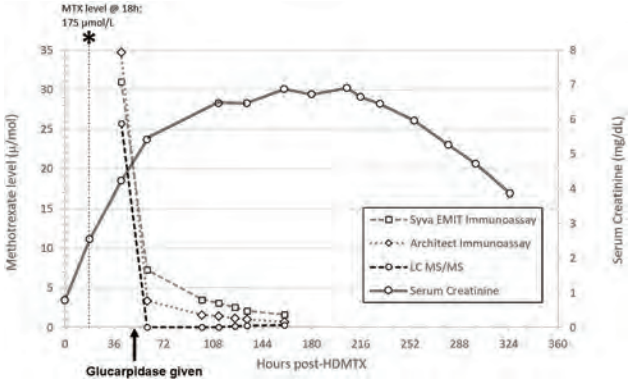
Ann Young,[1,2] Jeffrey Perl.[3] *[1]University of Toronto, Toronto, ON, Canada; [2]Nephrology, St. Michael's Hospital, Toronto, ON, Canada; [3]Nephrology, St. Michael's Hospital, Toronto, ON, Canada.*

Introduction: New guidelines exist on the management of methotrexate-induced nephrotoxicity, focusing on the use of glucarpidase (Voraxaze®). We describe an application of these guidelines and highlight nuances around drug procurement and post-intervention laboratory monitoring.

Case Description: A 61-year old male with diffuse large B-cell lymphoma (DLBCL) with cerebral involvement was admitted for his first cycle of high-dose methotrexate (HDMTX). He previously received two cycles of R-CHOP chemotherapy. Baseline serum creatinine (SCr) was 63 μmol/L. Following HDMTX, his methotrexate level was 175 μmol/L. Despite extracellular volume expansion, urinary alkalinization, and leucovorin rescue, he developed severe acute kidney injury (SCr 374 μmol/L) and subsequently went into status epilepticus. He was given glucarpidase at 52-hours post-HDMTX. Methotrexate level 8 hours after glucarpidase was 7.26 μmol/L by immunoassay, but <0.05 μmol/L by mass spectrometry. Interference due to the DAMPA metabolite resulted in falsely elevated levels by immunoassay for > 5 days after glucarpidase administration. He remained non-oliguric. Serum creatinine peaked at 608 μmol/L then trended down. He ultimately avoided the need for dialysis and had full renal and neurologic recovery.

Discussion: Glucarpidase is an effective option for non-renal elimination of toxic methotrexate concentrations in patients with nephrotoxicity. Awareness of how to access the drug, protocolization of monitoring including specific laboratory requirements, and knowledge of alternative treatments is necessary for centres where HDMTX therapy is used.





TH-PO150

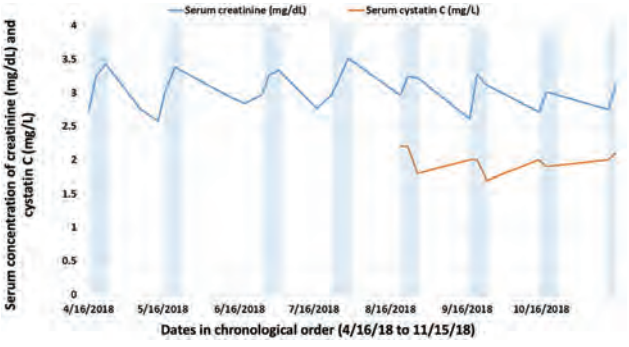
Azacitidine Inhibition of Creatinine Tubular Secretion: A Case Report

Christos Kallis,[1] Selina Luger,[2] Jonathan J. Hogan,[1] Abdallah Sassine Geara.[1] *[1]Division of Renal, Electrolytes and Hypertension, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Division of Hematology/Oncology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.*

Introduction: It is well documented that a number of medications lead to mild to moderate and reversible elevations of serum creatinine (SCr) without affecting glomerular filtration rate. In many instances, the discovery of this effect is a result of clinical observation with high index of suspicion. Such as an observation is also illustrated in our case report on a patient who has been receiving azacitidine.

Case Description: A 63-y/o male with PMH of FLT3+ AML in remission and stage 4 CKD was referred for episodic worsening of SCr. The initial presentation of AML was with a blastic crisis and AKI due to tumor lysis syndrome requiring urgent hemodialysis (HD). He was continued on intermittent HD for an additional 2 months and was able to come off HD with a new baseline SCr of 2.5 mg/dL. Around the same time, he was initiated on chemotherapy with azacitidine 75 mg/m^2 of body surface area subcutaneously daily for 7 days every 4 weeks. Upon evaluation of the patient in our Clinic 9 months after his AML diagnosis, transient elevations in SCr were noted, as illustrated in figure 1. The sharp rise in SCr was noted at the dates during which azacitidine was administered. Following careful review of history, which was unrevealing as to the cause of fluctuating SCr, decision was made to monitor SCr concurrently with serum cystatin C during and after administration of azacitidine. Serum cystatin C did not follow the same trend, raising suspicion for inhibition of creatinine tubular secretion by azacitidine without affecting renal function per se.

Discussion: The current drug label for azacitidine recommends that if unexplained elevations of SCr occur, the next cycle of therapy to be delayed until values return to normal or baseline and the dose to be reduced by 50%. To our knowledge, inhibition of creatinine tubular secretion by azacitidine was not previously reported. This case calls for the effects of azacitidine on renal proximal tubular transporters to be defined with physiologic studies, as this would have important implications on the underlying diseases being treated.



TH-PO151

Membranous Nephropathy Associated with Immune Checkpoint Inhibitors: A Report of Two Cases

Alejandro Y. Meraz-Munoz,[1] Christopher T. Chan,[1] Carmen Avila-Casado,[2] Abhijat Kitchlu.[1] *[1]Nephrology, University Health Network, Toronto, ON, Canada; [2]University Health Network, University of Toronto, Toronto, ON, Canada.*

Introduction: Immune checkpoint inhibitors (ICI) are novel cancer immunotherapies with recognized nephrotoxicities. The most common toxicity is acute tubulointerstitial nephritis, but cases of glomerular injury have been reported. We describe 2 patients with membranous nephropathy (MN) associated with pembrolizumab.

Case Description: Case 1: 52-year-old woman with stage III ovarian cancer, treated with pembrolizumab. She presented with frothy urine and edema. Urine sediment was bland. Investigations demonstrated albumin 3 g/dL, proteinuria 12 g/d and serum creatinine (sCr) 0.7 mg/dL. A biopsy showed thickened glomerular capillary walls. Immunofluorescence showed staining for IgG3(+), Anti-Phospholipase-A2-Receptor antibody [PLA2R](-) and Thrombospondin Type-1 Domain Containing 7A antibody [THSD7A](+). Electron microscopy (EM) showed subepithelial immune-type electron-dense deposits with diffuse effacement of the podocyte foot processes consistent with MN. Pembrolizumab was held and she received prednisone 1 mg/kg with remission of proteinuria. She was re-challenged with pembrolizumab with recurrence of proteinuria. Pembrolizumab was stopped and she received prednisone with resolution of proteinuria. **Case 2:** 39-year-old man with stage IV colon cancer, treated with pembrolizumab. He presented with proteinuria 2.2 g/d, sCr 1.1 mg/dL, albumin 3.3 g/dL and bland urine sediment. Biopsy revealed staining for IgG3(+2), Anti-PLA2R(-) and anti-THSD7A(+). EM showed subepithelial immune-type electron-dense deposits with diffuse podocyte effacement. The findings were consistent with MN. He received prednisone and pembrolizumab was held with resolution of proteinuria (0.3 g/d).

Discussion: These are the first reported cases describing the association of MN and pembrolizumab. Although MN is well-described in solid tumors, the timing of onset and remission of proteinuria in these cases is suggestive of immunotherapy-related glomerular

injury. Clinicians should be aware of the risk of this nephrotoxicity. Additional studies may elucidate patient and malignancy-related risk factors

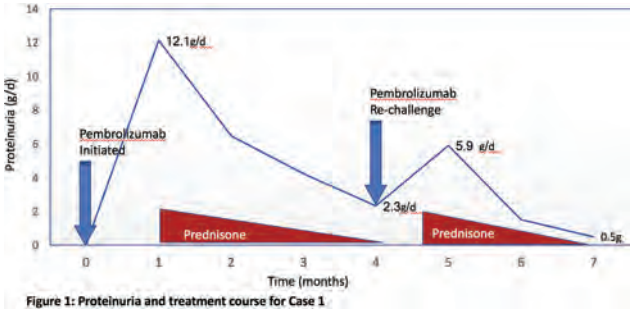


Figure 1: Proteinuria and treatment course for Case 1

Case 1

TH-PO152

Bevacizumab-Associated Thrombotic Microangiopathy Treated with Eculizumab

Rachel Hilburg, Matthew Palmer, Robert Burger, Elaine Chiang, Ashley Graul, Sonali Patankar, Abdallah Sassine Geara, Jonathan J. Hogan. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Bevacizumab is a recombinant monoclonal antibody neutralizing VEGF-A that has demonstrated efficacy as an anti-neoplastic agent. Thrombotic microangiopathy (TMA) is a well-described complication of VEGF inhibitors. A previous case series described treatment of VEGF inhibitor-associated TMA with eculizumab. Here, we present two cases of bevacizumab-associated TMA with biopsy-proven kidney involvement who were treated with eculizumab.

Case Description: Case 1: A 68 yo woman with recurrent, metastatic ovarian high-grade serous carcinoma received pegylated liposomal doxorubicin (PLD) and bevacizumab. She developed new onset HTN, proteinuria (UPCR 0.6 from 0.1 g/g), and AKI (SCr 1.5 from 0.9 mg/dL). Her HTN and AKI improved with holding bevacizumab. Bevacizumab was restarted and she again developed HTN, proteinuria (UPCR 3.1 g/g) and AKI (SCr 1.5 mg/dL). Despite drug discontinuation for over two months, she developed hypertensive emergency, PRES, nephrotic syndrome, and microangiopathic hemolytic anemia (haptoglobin <30 mg/dL, LDH 282 U/L, schistocytosis) consistent with systemic TMA. A kidney biopsy showed severe chronic TMA. Eculizumab was initiated (900mg IV x 4 doses). Hemolysis and HTN resolved, and SCr improved to 2.7 mg/dL. Case 2: A 52 yo woman with HTN and stage IIIC poorly differentiated serous carcinoma was treated for progression of disease with PLD, atezolizumab, and bevacizumab. She had near complete response but developed palmar-plantar erythrodysesthesia attributed to PLD followed by worsening HTN, proteinuria (UPCR 1.6 from 0.1 g/g), and AKI (SCr 1.7 from 0.7 mg/dL). Bevacizumab was held, but SCr increased to 2.2 mg/dL. Further evaluation revealed evidence of systemic TMA (haptoglobin <30 mg/dL, LDH 425 U/L, schistocytosis). Kidney biopsy showed chronic TMA. Despite several months off bevacizumab, her TMA failed to improve. She received eculizumab, which was stopped after 2 doses for rash of unclear etiology. However, her hemolysis resolved, thrombocytopenia improved, and SCr stabilized at 1.6 mg/dL.

Discussion: We present two cases of severe bevacizumab-associated TMA with renal involvement who had evidence of disease improvement or stabilization with eculizumab treatment. The role of complement in VEGF inhibitor-associated TMA and treatment with complement blockade deserves further study.

TH-PO153

Nivolumab-Related ANCA-Negative Focal Necrotizing Glomerulonephritis

Wut yi Hninn,[2] Kim Phung L. Nguyen,[1] Sara Faiz,[3] William F. Glass,[4] Ala Abudayyeh.[5] *[1]University of Texas Health Science Center at Houston, McGovern Medical School, Houston, TX; [2]UTHealth, Houston, TX; [3]University of Texas Houston, Houston, TX; [4]University of Texas – Houston Medical School, Houston, TX; [5]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Introduction: Immune checkpoint (ICP) inhibitors have revolutionized treatment options for many types of cancers. Adverse events associated with ICP inhibitors are mainly due to uninhibited immune system causing autoimmune diseases. Acute tubulointerstitial nephritis (ATIN) is the most commonly described kidney injury secondary to ICP inhibitors. Few case reports also identified glomerulonephritis (GN) induced by ICP inhibitors. Here we present a case of ICP associated focal necrotizing pauci-immune GN.

Case Description: Patient, 65-year-old man with aortic valve replacement, prior embolic stroke, was diagnosed with left lower quadrant de-differentiated liposarcoma on 7/21/2018, and treated with nivolumab on 9/6/2018. A month later he underwent excision of tumors, resection and anastomosis of small intestine and revascularization of femoral/popliteal/iliac arteries. His baseline Cr of 0.8-1.12 mg/dL. His course was complicated with infections and was treated with ciprofloxacin and developed an allergic reaction with a rash. Thereafter, he started having increase in creatinine with a peak of 7.53 mg/dL on 12/16/2018. His urine analysis was significant for hematuria and proteinuria of 2 grams. Renal ultrasound did not show hydronephrosis. ANA, dsDNA Ab, c/p-ANCA, anti-GBM Ab, C3 and C4, hepatitis A/B/C and HIV1/2 were all negative. Patient underwent a renal biopsy that revealed pauci- immune vasculitis with minor mesangial IgA and C3 positive staining. Patient was started on prednisone, Rituximab, and plasmapheresis with improvement in renal function and finally came off dialysis and creatinine stabilized at 2.0 mg/dL two months later.

Discussion: Use of ICP have resulted in improvement in patient survival compared to standard chemotherapy; however, there has been increasing appreciation for the adverse events associated. Therefore, obtaining a kidney biopsy and early recognition of ICP associated renal toxicity is essential to further optimize cancer patient's morbidity and mortality.

TH-PO154

Abiraterone Acetate: Enough of the S.A.M.E. Old Steroids

Anita Shah,[1] Maulin Shah.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E. Debakey Veterans Affairs Medical Center, Houston, TX.*

Introduction: Abiraterone acetate is an androgen synthesis inhibitor, which suppresses testosterone production, utilized in the treatment of castrate-resistant prostate cancer. We report a case of syndrome of apparent mineralocorticoid excess (SAME) caused by abiraterone.

Case Description: A 82-year-old male, with a past medical history of metastatic prostate cancer on treatment with leuprolide, abiraterone, and prednisone, presented with progressive weakness and falls. Prednisone was discontinued two months prior due to concerns for steroid myopathy. On examination he was hypertensive, delirious, and had diffuse weakness. Labs illustrated hypokalemia (K 1.7 mg/dl) and metabolic alkalosis (HCO3 34 mmol/L, pH 7.62). Additionally, he had suppressed aldosterone and renin levels with an elevated aldosterone/renin ratio of 60, high ACTH level, and low serum morning cortisol. These findings are consistent with the SAME secondary to abiraterone. The patient was treated with resumption of prednisone and initiated on eplerenone.

Discussion: Abiraterone suppresses testosterone production by inhibiting the 17-alpha-hydroxylase and $C_{17,20}$-lyase enzymes. Consequently, cortisol production decreases, adrenocorticotropic hormone (ACTH) increases, and corticosterone increases, presenting as the SAME with hypokalemia, hypertension, and edema. Glucocorticoid administration with abiraterone inhibits ACTH and reduces corticosterone, thereby reducing the SAME risk. Eplerenone, a mineralocorticoid receptor antagonist, is the first-line treatment. Eplerenone avoids possible androgen receptor agonism, which can occur with spironolactone, and can be detrimental in treating metastatic prostate cancer. Conclusion: Abiraterone is an effective steroidal inhibitor for castrate-resistant prostate cancer, but can lead to the SAME, which clinicians should be able to recognize and treat.

TH-PO155

Renal Limited Anti-GBM Glomerulonephritis with Negative Serology in a Patient Following Immunotherapy with Checkpoint Inhibitors

Periklis P. Kyriazis, Abhinav K. Tiwary, Daniel L. Landry, Gregory L. Braden. UMMS-Baystate *Baystate Medical Center, Springfield, MA.*

Introduction: A growing body of evidence implicates checkpoint inhibitor (CPI) immunotherapy as a cause of AKI. Two individual cases of CPI-induced anti-GBM glomerulonephritis (GN) have been reported. We now report the first case of diffuse linear IgG 3+, IgA 2+, Kappa 2+, lambda 1+ anti-GBM GN with negative serology in a patient following CPI exposure.

Case Description: A 58-year-old male undergoing immunotherapy for metastatic melanoma presented with AKI and proteinuria. He had been started on ipilimumab & nivolumab almost a year prior to presentation which was complicated by dermatitis, colitis & hepatitis leading to discontinuation of therapy 3 months later. Due to persistent bilateral lung metastases he was initiated on dabrafenib & trametinib for the next 6 months until he developed AKI with proteinuria. Serologic testing was negative for ANCA, PR-3, MPO, and anti-GBM antibody. Complement levels were normal. Renal biopsy showed focal crescentic (2 of 15 glomeruli with cellular crescents), proliferative and sclerosing GN with diffuse linear staining of glomerular capillary loops dominant for IgG (3+), IgA (2+), Kappa (2+) and lambda (1+). Repeat anti-GBM testing remained negative & the patient's creatinine eventually rose to a peak of 3.8 mg/dL. He had no signs of lung hemorrhage. Dabrafenib & trametinib were discontinued and he was initiated on oral cyclophosphamide (2 mg/kg/day) and pulse intravenous methylprednisolone (1000 mg daily for 3 consecutive days) followed by 1 mg/kg/day of prednisone. Immunosuppression with cyclophosphamide was discontinued after four months of therapy & he was weaned off of prednisone by 6 months. His renal function remained stable for the ensuing 12 months but it started to slowly decline & eventualy he was started on HD.

Discussion: This is a case of anti- GBM GN with negative serology & linear IgG 3+, IgA 2+, Kappa 2+, lambda 1+ anti-GBM likely secondary to treatment with CPI immunotherapy which has been linked to different GN including anti-GBM up to 10 months after therapy. BRAF inhibition only causes AIN or ATN within 2 months of therapy and is not consistant with the time course of renal injury in our case. Discontinuation of all immunotherapeutic agents and treatment with prednisone and cyclophosphamide stabilized our patient's GFR.

TH-PO156

Dasatinib Induced Thrombotic Microangiopathy

Bessy Suyin Flores Chang,[2] Rushang Parikh,[2] Rimda Wanchoo,[2] Vanesa Bijol,[1] Kenar D. Jhaveri.[2] *[1]Pathology, Zucker School of Medicine at Hofstra/Northwell, NY, Manhasset, NY; [2]Nephrology, Zucker School of Medicine at Hofstra Northwell, Great Neck, NY.*

Introduction: Treatment of chronic myeloid leukemia (CML) is complex. With the development of tyrosine kinase inhibitors (TKI), disease control is now possible. Dasatinib, a second-generation TKI, has proven to be effective for the long-term treatment of CML. Nephrotic range proteinuria has been reported with this agent, however a kidney biopsy is rarely performed. We present a case of a patient with CML who developed nephrotic-range proteinuria after initiation of dasatinib therapy that resolved after changing treatment to Imatinib.

Case Description: A 48-year-old female with CML was started on dasatinib. Three months into treatment, her dose was increased. Two months later, she developed worsening hypertension, nephrotic range proteinuria (6gm/24 hours) and hypoalbuminemia (2.4g/dl). Her urinalysis was otherwise unremarkable. She had no laboratory signs of microangiopathic hemolytic anemia. She had not been on any other chemotherapy or targeted therapy. A kidney biopsy was performed. Pathological findings of kidney biopsy specimen by light microscopy and electron microscopy were consistent with acute and chronic thrombotic microangiopathy. There were no signs of podocyte injury. These pathological findings were compatible with renal-limited thrombotic microangiopathy induced by dasatinib. After change of treatment to imatinib(gleevac), levels of proteinuria dropped to less than 1gm/24 hours and she was taken off her blood pressure medications. Her CML is responding to imatinib.

Discussion: We present a case of acute kidney injury, hypertension and proteinuria that developed during treatment with dasatinib for CML. Pathological findings revealed endothelial injury consistent with a renal-limited thrombotic microangiopathy. Patient's proteinuria and hypertension resolved after changing therapy from dasatinib to imatinib. These findings are suggestive of dasatinib as the culprit drug. We should be aware of this off-target adverse effects of dasatinib on the kidney.

TH-PO157

Bevacizumab-Associated IgA-Dominant Membranoproliferative Glomerulonephritis

Liann Abu Salman,[1] Christos Kallis,[2] Matthew Palmer,[2] Jehan Z. Bahrainwala,[2] Abdallah Sassine Geara.[2] *[1]Lankenau Medical Center, Wynnewood, PA; [2]University of Pennsylvania, Philadelphia, PA.*

Introduction: Bevacizumab, a recombinant monoclonal antibody that blocks the vascular endothelial growth factor A (VEGF-A), is known to induce a renal-limited thrombotic microangiopathy (TMA), hypertension and proteinuria. A chronic bevacizumab-associated TMA can eventually lead to a glomerulopathy with membranoproliferative glomerulonephritis (MPGN) histology. We describe the unique case of IgA-dominant MPGN induced by bevacizumab in the absence of TMA.

Case Description: A 29-year-old male patient, with a history of neurofibromatosis type II and bilateral vestibular schwannomas treated with bevacizumab, is evaluated for nephrotic range proteinuria with preserved renal function eighteen months after initiation of therapy. Bevacizumab was initially held and the serologic evaluation for proteinuria was negative. The proteinuria was persistent and worsening (24h-urine protein: 6460 mg/24h) despite cessation of bevacizumab for 9 months and treatment with ACE Inhibitor eventually leading to a kidney biopsy. The kidney biopsy showed segmental endocapillary hypercellularity with thickening of the glomerular capillary walls and segmental double contours. The immunofluorescence was positive for IgG, IgM, IgA, Kappa and Lambda with IgA dominant pattern. The electron microscopy showed subendothelial and mesangial deposits. No TMA was seen. The final diagnosis was MPGN with IgA-dominant immune complex deposition. The patient was treated with Mycophenolate Mofetil with poor response after 4 months of therapy.

Discussion: VEGF-A secretion by the podocytes is essential in maintaining a healthy glomerular capillary endothelium. Disruption of this interaction by bevacizumab leads to a renal-limited TMA that is reversible after stopping the medication. Few previous case reports described IgA deposits in patients with bevacizumab-induced TMA. Previous reports of bevacizumab-associated TMA are well described, and a link between these two differing lesions may be possible but presently remain speculative. As the use of these agents is becoming more prevalent, further studies are needed to identify the mechanism and potential risk factors for renal disease to help guide treatment.

TH-PO158

Immune Checkpoint Inhibitor Use in a Patient with a History of Familial Anti-GBM Disease: A Clinical Dilemma

Ranine Ghamrawi, Sandhya Manohar, Fernando C. Fervenza, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Introduction: Immune checkpoint inhibitors (ICIs) have gained increasing use for the treatment of lung adenocarcinoma. Its utilization in patients with underlying autoimmune diseases is a challenge due to the fear of disease relapse or flare. Here, we present the case of a familial anti-GBM disease that received pembrolizumab for lung cancer.

Case Description: 71 -year-old lady was evaluated 6 years ago for worsening kidney function. A kidney biopsy led to a diagnosis of anti GBM-disease. Circulating anti-GBM antibodies were positive. She was treated with steroids, cyclophosphamide and plasmapheresis. Interestingly, her family history was significant for familial anti-GBM disease affecting 2 of her siblings. Her creatinine peaked at 12.7 mg/dl and with treatment nadired at 1-1.2 mg/dl, with anti-GBM undetectable after therapy. Three years later, she was diagnosed with left lung adenocarcinoma and underwent surgical resection, followed by external beam radiation and chemotherapy (carboplatin and paclitaxel). Unfortunately, her disease progressed and since she had positive Programmed Death-Ligand (PD L1) staining of her tumor cells; she was considered for starting on immunotherapy with pembrolizumab as a second line. She was evaluated by nephrology prior to initiation. Her baseline anti-GBM antibodies, ANCA antibodies and Anti-nuclear antibodies (ANA) were negative. Mutual decision with the patient was made to proceed with pembrolizumab with close monitoring of these tests and her serum creatinine. Seven months after treatment, her creatinine remains stable at 1.2-1.3 mg/dl with undetectable Anti-GBM, ANCA and ANA antibody titers.

Discussion: Checkpoint inhibitors are agents that unleash the immune system against cancer cells. Its use in patients with pre-existing autoimmune diseases pose a major clinical challenge. With cautious monitoring patients can use checkpoint inhibitors as a therapeutic option.

TH-PO159

Checkpoint Inhibitors: The Double-Edged Sword in Kidney Transplant Patients

Omar Mamlouk,[1,2] Biruh Workeneh,[2] Sreedhar A. Mandayam.[3] *[1]University of Texas Health Science Center at Houston, Houston, TX; [2]MD Anderson Cancer Center, Houston, TX; [3]UT MD Anderson Cancer Center, Bellaire, TX.*

Introduction: Immunotherapy in the form of Checkpoint inhibitors (CPI) has significantly improved outcome and survival in patients with melanoma and its use has extended to multiple malignancies with good outcome. However around 50% allograft rejection is reported in patients with renal transplant who were treated with CPI with median time of 21 days from initiation of therapy

Case Description: 40-year-old man with deceased donor kidney transplantation 7 years ago was diagnosed with metastatic melanoma of the right scalp and underwent wide excision followed by Dabrafenib and Trametinib and then switched to Nivolumab and Ipilimumab. His baseline creatinine was1.8 mg /dl. After 2 cycles of immunotherapy, he was noted to have severe acute kidney injury with Creatinine of 8.5 mg/dl. Renal biopsy showed acute T cell mediated rejection Banff grade IIA and suspicioun for acute antibody mediated rejection with positive peritubular capillaries for C4d. patient was treated for acute rejection with IV Methylprednisolone, rituximab, plasmapheresis (3 sessions) and intravenous immunoglobulin. Patient didn't have renal recovery and a decision was taken to sacrifice the allograft and continue immunotherapy for Melanoma

Discussion: The complex mechanism for acute rejection in renal transplant patient with use of CPI is still under investigation. One suggested mechanism is related to the inhibition of programmed death ligand 1 (PDL1) that involved in increasing graft tolerance by increasing T regulatory (Treg) cells and limiting the function of effectors T cells. The current recommendation for treatment of malignancy in patients with renal transplant is to reduce the immunosuppression by stopping the anti-metabolites and possibly switching to mTOR inhibitors. However, these guidelines predated the era of immunotherapy for metastatic malignancy and need to be reevaluated. Currently there are no established guidelines to help guide the prevention and treatment of acute rejection in this population and no clear studies about the safety of anti-rejection therapy on tumor progression. With the reported high probability of graft loss, the nephrologist and oncologist should have an extensive discussion with the patient prior to starting CPI to guide with treatment decision that will impact patient lifestyle and cancer response

TH-PO160

Intravitreal Injection of Avastin over Time Can Be Associated with Thrombotic Microangiopathy in the Native Kidney

Wenqing Yin,[2,1] Ping L. Zhang.[3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Boston Medical Center, Boston, MA; [3]William Beaumont Hospital, Royal Oak, Royal Oak, MI.*

Introduction: Avastin, an inhibitor of vascular endothelial growth factor, has been used for treating various metastatic cancers. Its side effects leading to renal thrombotic microangiopathy (TMA) has been well known. Intravitreal injection of Avastin (IIA) has been used to treat macular proliferation or degeneration in patients. A recent study of 69 patients with IIA showed no side effects, while there were two case reports suggested a link with IIA and native renal failure in 5 patients without proven biopsies. Whether IIA over time can lead to renal TMA in diabetic patients remain controversial. This case reports the presence of renal TMA after months of IIA in a diabetic patient.

Case Description: A 56 years old diabetic man received IIA for macular edema and proliferative retinopathy over the past few months was found to have deteriorated renal function (serum creatinine up to 2.47 mg/dl) with a nephrotic range of proteinuria (protein/creatinine ratio 4.7). All his serology tests were negative. A renal biopsy was performed to evaluate pathologic changes in the kidney (Light microscopy revealed mesangial nodular expansion, characteristic for diabetic nephropathy but with additional sub-endothelial expansion and lamination around the diabetic nodules. The acute tubular injury was present on PAS-stained sections. No thrombi formation was noted in glomeruli or vessels.

Immunofluorescent studies reveal moderate nearly linear IgM staining around diabetic nodules with positive fibrinogen staining. Electron microscopy showed double contoured glomerular basement membranes with subendothelial edema causing detachment of glomerular endothelial cells. Overall findings supported a diagnosis of chronic active TMA on top of diabetic nephropathy background and secondary acute tubular injury.

Discussion: Patient's ophthalmologist was informed of the result. A follow-up will be conducted (IIA may be discontinued). The finding of this case suggestive the link between repeat IIA and renal TMA, where a small leakage of Avastin from repeat IIA could be a thread to interact with glomerular podocytes and endothelial cells leading to chronic active TMA in the kidney, resulting in renal failure and proteinuria.

TH-PO161

Wiedemann-Steiner Syndrome Presenting as Bladder Outlet Obstruction

Edward M. Zitnik, Mary-Alice Abbott. *Pediatrics, Baystate Medical Center, Springfield, MA*.

Introduction: Wiedemann-Steiner syndrome is a rare autosomal dominant disorder associated with pathogenic variants in the *KMT2A* (Lysine Methyltransferase 2A) gene, which encodes a histone methyltransferase thought to regulate transcription via methylation of histone H3KA. This gene has targets in many human tissues, including multiple HOX and WNT genes. The disorder classically presents as prenatal and postnatal growth restriction with atypical facial features. While renal involvement has been seen in some cases, this has never been described as a presenting feature, as in this case.

Case Description: This late-preterm SGA newborn boy presented with anuria for the first 2 days of life and a distended bladder. There was a prenatal diagnosis of hydronephrosis later described as bilateral grade IV hydronephrosis with hydroureter on US and isolated left grade V reflux on VCUG, not due to PUV or ureterocele. SCr on DOL 2 was 1.9 with improvement to 1.2 after a suprapubic tube was placed for urine output. He was evaluated by genetics in the early newborn stage who appreciated hypertrichosis, upslanted palpebral fissures, and clinodactyly. After recurrent UTIs, a voiding cystourethrogram was performed and showed a severely distorted left upper tract collecting system. A skeletal survey showed no signs of skeletal dysplasia and a chromosome microarray was normal. Endocrine evaluation for his short stature (height and weight below the 3rd percentile) revealed no obvious hormone-mediated disease process. Whole Exome Sequencing (WES) identified a de novo autosomal dominant pathogenic variant in the *KMT2A* gene (p.R1151*, c. 3451 C>T), consistent with the diagnosis of Wiedemann-Steiner syndrome. He went on to develop stage III chronic kidney disease within his first year of life, and is expected to require kidney transplant by the age of 5 after vesicostomy closure and self-catheterization for renal protection.

Discussion: This case illustrates an atypical presentation of a rare genetic disorder and adds to the phenotype of Wiedemann-Steiner syndrome.

TH-PO162

Unraveling the Genotype to Phenotype Correlation: A Child with PH1 and a Novel Mutation Responsive to Pyridoxine Therapy

Ana L. Prashad cortez,[2] Rasheda Amin.[1,3] *[1]Pediatric Nephrology, Pediatric Specialists of Virginia, Fairfax, VA; [2]Pediatrics, Inova Fairfax Hospital, Falls Church, VA; [3]Pediatrics, Inova Fairfax Hospital, Falls Church, VA.*

Introduction: Primary hyperoxaluria type 1 (MIM 259900) is a rare genetic disease with an estimated prevalence of 1-3 cases per 1 million population worldwide. Primary hyperoxaluria type 1 (PH1) is an autosomal recessive disorder, caused by a mutation in the *AGXT* gene, and characterized by an accumulation of calcium oxalate in various body tissues, particularly the kidney. Disease expression is variable, ranging from nephrocalcinosis during infancy to recurrent or infrequent nephrolithiasis in childhood or adulthood and renal failure in 20-50% of patients. Over 175 mutations have been identified to date. About 10 to 30% of patients with PH1, particularly those with p.Gly170Arg or p.Phe152Ile mutations, respond to pyridoxine therapy with a significant reduction of urinary oxalate excretion. We present a patient with PH1, found to have a previously undescribed mutation in the *AGXT* gene, who showed excellent response to pyridoxine therapy.

Case Description: AS, now a nine year old male, born in Afghanistan to consanguineous parents, initially presented with a history of flank pain, failure to thrive and bilateral nephrolithiasis at the age of five years. He underwent several rounds of extracorporeal shock wave lithotripsy (ESWL) for significant stone burden. Upon establishing care with nephrology in the U.S., his workup revealed hypocitraturia, elevated 24 hour oxalate level at 127mg/day (normal range 20-40) and a urine glycolate level of 249 mg/gram of creatinine (normal range <75), raising concern for PH. He was empirically started on vitamin B6, potassium citrate and advised to increase hydration. Genetic testing confirmed PH1 with a homozygous mutation in *AGXT* (c.352C>T; p.Arg118Cys), reported as a variant of uncertain significance. Follow up urine testing at 3 and 7 months showed a reduction in oxalate levels by 35% and 58%, respectively. He remains asymptomatic, has normal GFR, with no evidence of systemic oxalosis and stable right sided nephrolithiasis since last ESWL in 2017.

Discussion: We conclude that in this patient with classic PH1 phenotype, the finding of a homozygous variant in *AGXT* is not only pathogenic, but also responsive to pyridoxine therapy. We hope this case will add to the knowledge base of PH1 and help guide management in patients with a similar genotype. Pyridoxine therapy has been life changing for AS and his family.

TH-PO163

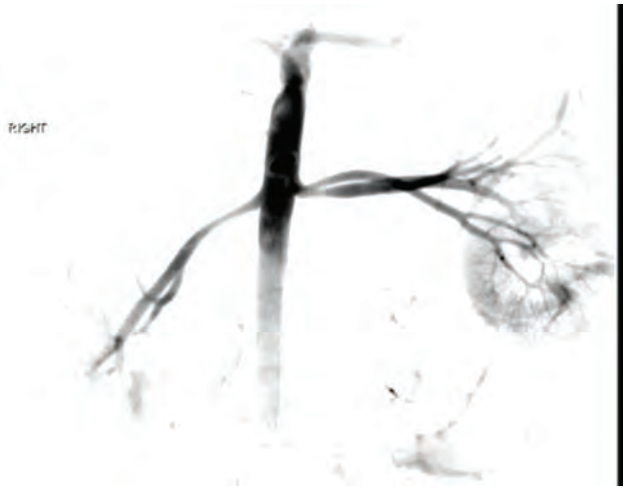
A Case of Childhood Bilateral Renal Artery Stenosis Not Seen on Angiography

Ashley E. Rawson,[1] Elizabeth Spiwak,[2] Andrew L. Schwaderer,[3] David S. Hains.[1] *[1]Pediatric Nephrology, Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University- Riley Hospital for Children, Indianapolis, IN; [3]Indiana University, Zionsville, IN.*

Introduction: Renovascular hypertension (HTN) is an important cause of secondary HTN in children. Multiple imaging modalities are considered for detection of renal artery stenosis (RAS) such as: duplex ultrasound, CTA, and MRA. However, the gold standard for detection is conventional angiography. We present a case of bilateral RAS that was undetected by angiography.

Case Description: A 12 year old previously healthy female presented to a well-child exam with a BP 180/111 mmHg. Her BMP was remarkable for a serum K+ of 3.2 mmol/L and normal eGFR. Renal US was unremarkable and UA demonstrated microscopic hematuria (5-10 RBCs/hpf). She also had left ventricular hypertrophy on echocardiogram. Hypertension work up included: plasma aldosterone, serum free metanephrines, ACTH, monogenic HTN panel, and serum cortisol levels. Work up was negative other than an elevated aldosterone. A CTA demonstrated "string of beads appearance of the bilateral renal arteries and lobar segments suggestive of bilateral fibromuscular dysplasia and focal moderate-severe stenosis of the proximal left renal artery." Angiography did not demonstrate RAS. She was started on captopril and elevation in creatinine was noted. She was then sent to a vascular surgeon for a second opinion. At that time, angiography was repeated and bilateral renal vein renin measurements were elevated. Via imaging, she had ostial left RAS and mid-right RAS. She is currently managed on clonidine, HCTZ, and lisinopril. She is scheduled for bilateral renal revascularization.

Discussion: This case illustrates the importance of multiple imaging modalities in the work up of renovascular HTN. Our patient underwent angiography by a skilled radiologist and bilateral RAS was not detected, thus we highlight the value of specialized vascular surgery centers for cases with a high index of suspicion.



Angiography showing pt's bilateral RAS.

TH-PO164

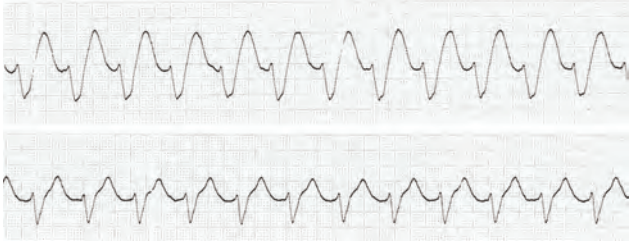
A Case of Pilsicainide Hydrochloride Toxicity That Relapsed After Discontinuation of Hemodialysis

Takayuki Yamada,[1,4] Hiromichi Wakui,[4] Kouichi Tamura,[4] Toshiya Takahashi,[2] Takahiko Miura,[3] Toshikazu Takizawa,[2] Alfred Burger,[1] Elliot M. Charen.[1] *[1]Mount Sinai Beth Israel, New York, NY; [2]Hadano Red Cross Hospital, Hadano, Japan; [3]Yokohama Sakae Kyosai Hospital, Kanagawa-ken, Japan; [4]Yokohama City University, Yokohama, Japan.*

Introduction: Pilsicainide is a class I C sodium channel blocker known to be effective in treating atrial fibrillation (Afib). However, the high plasma concentration of pilsicainide can trigger ventricular tachycardia (VT) and ventricular fibrillation. We present a case of pilsicainide induced VT, which relapsed after discontinuation of hemodialysis (HD).

Case Description: An 84-year-old male with a history of hypertension, paroxysmal Afib on pilsicainide, and Parkinson's disease developed a cough and fever three days before admission. One day prior, he became lethargic and was brought to a local hospital. A 12-lead electrocardiography (ECG) showed VT. He was transferred to our hospital due to pilsicainide toxicity. His creatinine increased to 6.2mg/dL secondary to sepsis (baseline 0.9 mg/dL). We initiated emergent HD, which narrowed the QRS instantly (Figure). We performed 3 hours of HD. Two hours after ending HD his QRS prolonged again; we resumed HD followed by direct hemoperfusion. The QRS remained narrow after the 2nd HD session. He remained hemodynamically stable and was transferred to the initial hospital. Serum pilsicainide levels were: at previous hospital 3.47 μg/mL, on admission 2.61 μg/mL, after 1st HD 2.31 μg/mL, after 2nd HD 1.1 μg/mL, and after hemoperfusion 0.76 μg/mL.

Discussion: Pilsicainide is excreted by the kidney; therefore, elimination is prolonged in patients with chronic kidney disease (CKD). The mean clearance of this drug by HD is 32 %. Interestingly, the QRS was narrow during HD even though the serum pilsicainide level was high. The volume of distribution of this medication is 1.7 L/kg in CKD patients; most of the drug is distributed in the tissue. We infer that the drug in the tissue was re-distributed after HD. In conclusion, pilsicainide should be administered cautiously to elderly patients even if the serum creatinine is normal. Serum pilsicainide level may not correlate with EKG findings.



TH-PO165

Vedolizumab, a Monoclonal Antibody for Treating Crohn Disease, Can Cause T-Cell-Mediated Interstitial Nephritis and CKD

Wenqing Yin,[2,1] Ping L. Zhang.[3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Boston Medical Center, Boston, MA; [3]William Beaumont Hospital, Royal Oak, Royal Oak, MI.*

Introduction: Vedolizumab (Vedo), a gut-selective humanized monoclonal antibody, binds specifically to the α4 β7 integrin as a lymphocyte homing antagonist. Previously, Bailly et al have reported the first case of Veldo induced acute interstitial nephritis (AIN) (*Am J Kid Dis* 2017), with good renal recovery after the standard steroid treatment. Here, we report another case of Vedo associated AIN which resulted in CKD despite the standard steroid treatment. She was subsequently received steroid treatment without significant improvement of renal function (serum creatinine 1.8 mg/dl at the 3nd month follow-up following the biopsy). The case indicates that Vedo associated T cell medicated AIN can lead to a substantial CKD.

Case Description: A 33 years old woman with Crohn's disease involving her small bowel and colon developed acute kidney injury with rising serum creatinine (from 0.7 to more than 2.0 mg/dl) after her receiving 3 standard doses of Vedo infusions over 2 months. Without signs of recovery after stopping the Vedo treatment, a renal biopsy was performed to evaluate her renal pathology. Light microscopy revealed AIN with only 10 % of B lymphocytes, 10% of CD8 positive macrophages, but 80% of T lymphocytes in the interstitium and mild tubulitis. Further stains showed 60% CD4 regulatory T lymphocytes and 40% of CD8 positive cytotoxic T lymphocytes. No eosinophils, neutrophils or granulomas were present. Kidney injury molecule-1 staining was positive in proximal tubules, consistent with an acute tubular injury secondary to AIN. Trichrome stained sections showed moderate interstitial fibrosis and tubular atrophy. Immunofluorescent studies and electron microscopy did not reveal additional specific findings.

Discussion: She has subsequently received steroid treatment without significant improvement of renal function (serum creatinine 1.8 mg/dl at the 3nd-month follow-up following the biopsy). The case indicates that Vedo associated T cell medicated AIN can lead to a substantial CKD.

TH-PO166

Cefepime-Induced Neurotoxicity in a Patient with ESRD

Parikshit Duriseti,[1] Dalya Alqaysi,[1] James Tasch,[2] James A. Strom.[1] *[1]St. Elizabeth's Medical Center, Allston, MA; [2]St. Elizabeth's Medical Center, Watertown, MA.*

Introduction: Cefepime causes neurotoxicity with an increased risk in patients with renal dysfunction.

Case Description: A 59-year-old male with ESRD on hemodialysis (HD) on Tuesday/Thursday/Saturday, hypertension and peripheral arterial disease was admitted with altered mental status of 2 days duration. Patient was admitted 1 month prior to presentation for elective amputation of right third/fourth toes due to dry gangrene of the right foot. His wound cultures grew Citrobacter and Serratia sensitive to ceftriaxone. He was discharged on oral cefpodoxime. He was transitioned to cefepime (2 gm IV on Tuesday/Thursday and 3 gm IV on Saturday following dialysis) after a wound culture grew Pseudomonas. He developed altered mental status presenting as disorientation with decreased consciousness and paranoid hallucinations one day after a single dose of 3 gm IV cefepime. On admission, BP was 213/123. Exam revealed bilateral myoclonic jerks involving all extremities. Head CT and brain MRI without contrast showed no acute process without any evidence of hypertensive encephalopathy. Cefepime was discontinued. His symptoms of hallucinations and delirium lasted for about a week. After 3 daily sessions of HD, his mental status eventually returned to his prior baseline with resolution of his myoclonus. Patient was discharged with close follow-up with nephrology.

Discussion: Cefepime causes neurotoxicity with an increased risk in patients with renal dysfunction, critical illness, advanced age and inappropriate dosage for renal function. It is postulated that neurotoxicity results from inhibition of GABA receptors in the CNS. Manifestations include decreased level of consciousness, myoclonus, agitation, seizures and non-convulsive status epilepticus. Median onset of neurotoxicity was observed 4 days after initiation (range 1 to 10 days) often with median resolution of symptoms within 2 days of appropriate therapy (range 1 to 4 days). Hemodialysis is an effective treatment option with a reported 60 to 70% decrease in cefepime level after a single session. Unique characteristics of our case include rapid onset of symptoms after a single high dose, longer duration of symptoms and prolonged dialysis needs to clear the antibiotic. Physicians should be aware of drug-induced neurotoxicity in patients taking cefepime and should be cautious with excessive dosing in patients with renal dysfunction.

TH-PO167

An Unexpected Complication After a Motor Vehicle Accident: Propofol Infusion Syndrome

Yamiris Rodriguez, Mariela Marquez Pantoja, Keysha Lopez vega, Ileana E. Ocasio Melendez, Fatima B. Cintron-Rosa. *Nephrology, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico*.

Introduction: Propofol is the most commonly used parenteral anesthetic in the United States due to its rapid onset and reversal of action. Propofol infusion syndrome (PRIS) is a serious complication associated with multiorgan failure. An incidence of less than 1% have been reported for this life-threatening complication, making its early recognition critical for a favorable outcome.

Case Description: A 59-year-old woman was admitted due to multiple body trauma after a motor vehicle accident. She was intubated for airway protection and propofol was used for sedation. Hospitalization complicated with acute kidney injury (AKI) and Nephrology service was consulted. Examination revealed a critically ill patient sedated with an intravenous infusion of propofol at a 0.83 mg/kg/hr rate and norepinephrine for hemodynamic support. Propofol drip was infused for more than 48 hours. Physical exam revealed adequate urine output, clear lungs and no edema. Laboratory tests with increased lactate levels from 37.4 to 54.8 mg/dl, bicarbonate 13.6 mEq/L and pH of 7.24. Anion gap (AG) was 17.9. Creatinine worsened from 0.55 to 1.12 mg/dl. Creatinine phosphokinase level of 3,421 U/L was observed. Triglyceride levels increased from 171 to 372 mg/dl. Laboratory findings were consistent with high AG metabolic acidosis, AKI, rhabdomyolysis and hypertriglyceridemia. Based on clinical course and risk factors for PRIS including critical illness, prolonged sedation and catecholamine infusion; propofol was discontinued and altered laboratories showed marked improvement.

Discussion: Our patient received a prolonged infusion of propofol and exhibited risk factors previously stated for developing this rare complication. He had a worsening metabolic acidosis with additional findings not explained by other causes of acidosis. Moreover, improvement of parameters after discontinuation of propofol infusion supports our diagnosis of PRIS. This syndrome should be suspected in any patient with prolonged infusion of propofol and the cardinal features of this syndrome, including cardiovascular collapse, lactic acidosis, AKI, rhabdomyolysis and hypertriglyceridemia. PRIS suspicion should prompt immediate propofol weaning, since this complication carries a high mortality risk. In our case, early recognition and proper management lead to a satisfactory outcome.

TH-PO168

Chondrodysplasia Punctata in a Baby Born to a Woman with Lupus Nephritis Who Received Belimumab

Mirmohd M. Hossain,[1] Osama A. Osman,[2] Sharon E. Maynard.[1] *[1]Lehigh Valley Health Network, Emmaus, PA; [2]Lehigh Valley Hospital, Allentown, PA.*

Introduction: Belimumab is a human monoclonal antibody that inhibits B-cell activating factor, used to treat extrarenal systemic lupus erythematosus. Experience with belimumab in pregnancy is limited.

Case Description: A 28 year old presented for evaluation of lupus nephritis (LN) in pregnancy. She had been diagnosed with class 4 LN in 2008. She achieved remission after induction with mycophenolate mofetil (MMF). A 2013 relapse was treated with MMF (no response), cyclophosphamide (stopped due to neutropenia), and rituximab, with partial remission. In 2018 she had worsening renal function, and biopsy revealed class 4 LN with crescents, moderate activity, and severe chronicity. She was treated with cyclophosphamide but again developed severe leukopenia. She received no further induction therapy for LN, but was started on belimumab for extrarenal lupus symptoms. Shortly after her 3rd infusion of belimumab, pregnancy was diagnosed. She was maintained on azathioprine, hydroxychloroquine, nifedipine, and low-dose aspirin. Renal function and proteinuria remained stable (serum creatinine 2.0-2.2 mg/dl, proteinuria 3-5 g/day). Complement levels were slightly low, and anti-double stranded DNA antibody titer was negative. Fetal ultrasound at 17 weeks gestation showed absent nose and palate, hemivertebrae, brachycephaly, and shortened long bones. Amniocentesis showed no genetic or chromosomal abnormalities. At 30 weeks, she was delivered due to superimposed preeclampsia. Her infant was diagnosed with chondrodysplasia punctate based on morphologic features.

Discussion: Chondrodysplasia punctata (CDP) is a skeletal abnormality characterized by premature foci of calcification within the cartilage. Features include proximal shortening of the limbs and stippled epiphyses. CDP can be caused by inborn error of metabolism, disruption of vitamin K metabolism, chromosomal abnormalities, and maternal factors. There are 21 published cases of neonates with CDP born to women with autoimmune diseases, including SLE and Sjögren syndrome. Our patient was exposed to belimumab in early pregnancy. CDP has not previously been reported with belimumab exposure, and limited data do not suggest teratogenicity. It is unknown if our case of CDP was caused by belimumab or maternal lupus. Belimumab should be avoided in pregnancy until more safety data are available.

TH-PO169

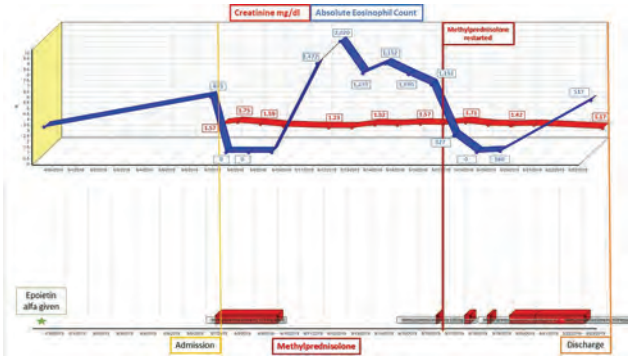
DRESS to Impress: Unusual Case of Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) due to Epoetin Alfa

Yelixa Santos Roman,[1] Carlos Cortes.[1,2] *[1]Veterans Affairs Caribbean Healthcare system, Coto Laurel, PR; [2]Puerto Rico Kidney Care, San Juan, PR.*

Introduction: DRESS syndrome is a severe life-threatening hypersensitivity reaction to medication or its active metabolites. It manifests with fever, rash & organ involvement, kidneys & liver most commonly. It has a 10% mortality rate. More frequently associated with DRESS are sulfonamides, anti-inflammatory medications & anticonvulsants. There is only one case report of epoetin alfa related DRESS syndrome in the literature, and herein we present the second.

Case Description: 92 y/o man with hypertension, A. fib. & CKD IIIa arrived at ED due to generalized pruritic skin eruption since 7 days ago. Physical exam: generalized non-blanching erythematous patches on lower extremities, torso & upper extremities. Few violaceous purpuric patches on extremities, petechias on palms & feet. Labs: WBC: 17.9 x10^3/UL, Plt: 270 10^3/UL, Eosinophils: 895. BUN: 50.7 mg/dL & Cr.: 1.8 mg/dl (base:1.2), ALT: 39, AST: 23 & CRP: 127.3. He was started on epoetin alfa 8 days prior, which was discontinued upon admission. Dermatology biopsied a lesion & recommended methylprednisolone (MP) IV for 2 days. Rash, eosinophils & creatinine improved. MP was discontinued as per derm. recc. but rash, eosinophils & creatinine again worsened. Biopsy: spongiotic dermatitis w/parakeratosis, pustules in stratum corneum, dermal perivascular lymphocytic infiltrate & scanty eosinophils. Allergist recc. restart MP for epoetin alfa related DRESS. See Fig 1 for data on MP, creatinine & eosinophils. He improved & was discharged on a steroid tapering

Discussion: The European Registry of severe cutaneous adverse reactions is a scoring system to help yield the diagnosis of DRESS, a score of 6 makes it definitive, as presented in this case. Only ~11% of patients with DRESS manifest with renal disease. After literature review, this is only the second case of epoetin alfa associated DRESS. **Epoetin alfa is a commonly used drug in patients with CKD & physicians should be aware of this potentially fatal adverse effect.**



Changes in eosinophilia and creatinine with methylprednisolone dose

TH-PO170

Fanconi Syndrome in an Elderly Patient with Membranous Nephropathy During Treatment with Immunosuppressant Mizoribine

Sho Nishikawa, Naoki Takahashi, Yudai Nishikawa, Sayu Morita, Kazuhisa Nishimori, Mamiko Kobayashi, Sachiko Fukushima, Seiji Yokoi, Daisuke Mikami, Hideki Kimura, Kenji Kasuno, Masayuki Iwano. *Nephrology, University of Fukui, Fukui, Japan.*

Introduction: Acquired Fanconi syndrome (FS) is often caused by drugs (antibacterial drugs, antiviral agents and anticancer agents), is sometimes caused by autoimmune diseases, monoclonal light chain associated diseases and heavy metal poisoning. Mizoribine (MZR) is an oral immunosuppressant inhibiting inosine monophosphate dehydrogenase, widely used in Japan for treatment of autoimmune diseases, nephrotic syndrome and renal transplantation. Recently several studies have shown that a combination of steroids and MZR is effective in patients with membranous nephropathy (MN). Furthermore, there is an interesting report that the addition of steroid after MZR monotherapy for two or three months may be beneficial for patients with MN.

Case Description: An 80-year-old man was referred to our hospital with FS, acute kidney injury (AKI) and severe proteinuria (15 g/gCr). Two months before this admission, he was diagnosed with primary MN by his renal biopsy. He and his wife chose outpatient treatment because of his mild dementia due to ageing. Oral administration of MZR was started prior to prednisolone administration. One month later, serum creatine was rapidly increased from 1.9 to 2.7 mg/dL with nephrotic-range proteinuria. In addition, serum albumin was decreased to 1.1 g/dL, and various abnormalities of laboratory data including glucosuria, hypokalemia, hypophosphatemia and hypouricemia were newly recognized. He had no history of exposure to heavy metals or administration of any other additional drug, including Chinese medicines. Hypokalemia, hypophosphatemia, glucosuria, hypouricemia and severe proteinuria were gradually improved by discontinued administration of MZR, additional oral administration of prednisolone followed by single intravenous injection of rituximab. He was finally diagnosed with MZR-induced FS from this clinical course and his typical laboratory data except proximal tubular acidosis.

Discussion: To the best of our knowledge, this is the first report demonstrating FS induced by MZR. Although the mechanisms induced proximal tubular dysfunction with MZR are unknown, nephrologists should pay attention to the onset of FS during treatment with MZR.

TH-PO171

Atazanavir Crystal-Induced Chronic Granulomatous Interstitial Nephritis

Vipin Varghese,[2] Juan Carlos Q. Velez.[1,2] *[1]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]University of Queensland - Ochsner Clinical School, New Orleans, LA.*

Introduction: Atazanavir (ATZV) is a protease inhibitor used in the treatment of human immunodeficiency virus (HIV) infection. Highly active antiretroviral therapy (HARRT)-related nephrotoxicity is primarily linked to tenofovir (TFV) or to the no-longer-used drug, indinavir. We describe a case of biopsy-proven atazanavir crystal-induced chronic granulomatous interstitial nephritis (CGIN) and review previously reported cases.

Case Description: A 51-year-old black man with HIV infection presented to renal clinic for evaluation of worsening kidney function. He was asymptomatic. He denied NSAID use and was on ritonavir (RTV), ATZV, abacavir and lamivudine. Physical examination was unremarkable. Laboratory data showed a serum creatinine (sCr) 2.7 mg/dL (3 months prior 1.7 mg/dL; 9 months prior 1.2 mg/dL). CD4 count was 327 and HIV-1 RNA viral load was undetectable. Hepatitis B and C were negative. Complements, lupus serology and serum protein electrophoresis were within normal limits. Urinalysis showed 20-30 white blood cells/hpf. Urine protein-creatinine ratio (UPCR) was 450 mg/g. Urine culture was negative. Renal ultrasound was normal. One month later, sCr rose to 3.3 mg/dL. A kidney biopsy was performed and the specimen showed: interstitial mononuclear infiltrate with numerous eosinophils, a granulomatous process with central necrosis, crystal-like material and neutrophils, moderate interstitial fibrosis, and 9/15 obsolescent glomeruli. ATZV was stopped and prednisone was begun. After 8 months, sCr gradually improved to a new baseline of 2.0 mg/dL. Our case is only the 10th reported (see Table

Discussion: ATZV must be considered as a potential cause of chronic progressive nephropathy in patients on HAART and can present as CGIN and acute interstitial nephritis (AIN).

Comparison of ATZV nephropathy case reports

Successful Treatment of Chronic Osteomyelitis with Avoidance of Amputation During PCSK9-inhibitor Treatment for Cardiovascular Diseases in Patients with Diabetes Mellitus and CKD

Htet Htet Kyaw,[1] Alexander M. Swan, Jr.,[1] Htun M. Aung,[1] May T. Tun,[1] Myat E. Mon,[1] Tracy T. Swan,[1] Yadana Oo,[1] Thar Sann Oo,[1] Aye M. Thida,[1] May T. Zin,[1] Alexander M. Swan.[2,1] *[1]Department of Medicine, Nephrology Hypertension Renal Transplant & Renal Therapy, LLC., Avenel, NJ; [2]Department of Medicine, Rutgers New Jersey Medical School, Newark, NJ.*

Introduction: Management of DM patients with chronic osteomyelitis (OM) of the foot can be challenging. Even with targeted antimicrobial therapy tailored to culture and sensitivity results, due to micro-and-macrovascular ischemia, patients' conditions usually deteriorate leading to subsequent amputation. We present a case series of 5 patients whose chronic OM recovered during treatment with PCSK9(Proprotein Convertase Subtilisin Kexin type 9) inhibitor to reduce the risk of myocardial infarction, stroke, and coronary revascularization.

Case Description: The patients (age 65-91 years) have a common history of chronic DM-2 (20-35 years) and multiple comorbidities such as coronary artery disease, CKD, CHF, chronic diabetic complications, and peripheral artery disease(PAD). History of DM foot ulcer began as a minor injury, precipitated by DM peripheral neuropathy and atherosclerosis, worsened to cellulitis and subsequent OM. Appropriate antibiotics were used guided by wound culture and sensitivity results without improvement, instead deterioration of infection. Imaging studies of the foot revealed OM. Patients underwent surgical debridement and prolonged antibiotic courses without success, requiring amputation to avoid septicemia and death. However, one month after initiation of PCSK9-inhibitor treatment for cardiovascular co-morbidities, complete wound healings were achieved in those patients, avoiding all planned amputations.

Discussion: Patients with DM have a 10-fold increased risk for lower extremity amputation and almost twice as likely to require re-amputation compared to patients without DM. PCSK9-inhibitor is a human monoclonal IgG preventing PCSK9-mediated LDL-receptor degradation, and allowing LDL-receptor to recycle back to the liver cell surface, thus lowering serum LDL cholesterol. It is speculated that PCSK9-inhibitor may improve circulation, promoting antibiotic penetration into the wound, thus wound healing. We suggest that PCSK9-inhibitor should be used in all patients with PAD and chronic

nonhealing wounds as prevention of future amputation. It may also be advantageous to initiate PCSK9-inhibitor in all DM foot ulcer patients during treatment of chronic OM or even before the development of cellulitis or OM.

Far Infrared Therapy May Improve Arterial Insufficiency and Joint Inflammation in CKD Stage 5 Patients

Siddique Akbar,[1] Christina Irene Mejia,[1] Rudava Ullah,[2] Sayeda Humaira,[2] Ziauddin Ahmed,[1] Ridwan Faruq,[2] Hasan Arif.[3] *[1]Nephrology and Hypertension, Drexel University College of Medicine, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA; [3]Drexel University, Philadelphia, PA.*

Introduction: Far infrared (FIR) induces expression of endothelial heme oxygenase-1, reduces monocyte adhesion to endothelial cells, and provides a strong anti-inflammatory benefit to the vascular endothelium. It has been shown that FIR therapy improves dialysis fistula flow, maturation, and patency and leads to decreased pain and hematoma formation with needling in CKD stage 5 and 5d patients. It is also effective in relieving pain in patients with chronic pain syndromes like fibromyalgia and phantom limb after amputation through thermal and non-thermal effects. In the past we reported an improvement in graft stenosis and resolution of internal jugular vein thrombus associated with tunneled catheter insertion in two dialysis patients with FIR therapy. Now we report 3 CKD stage 5 patients with improvement of arterial insufficiency, frozen shoulder and partial rotator cuff injury using FIR therapy.

Case Description: Case 1. A 68 year old man with CKD 5 due to FSGS and HTN developed significant claudication on his right leg and discoloration of his second toe. An arteriogram showed substantial small arterial disease not amenable to bypass and below knee amputation was recommended by his surgeon. A trial of FIR therapy on his leg was done, and after three weeks, claudication and toe discoloration resolved. FIR therapy was stopped and he remained pain free after 2 years of follow-up. Case 2. A 67 year old man with CKD 5d due to HTN developed left shoulder pain with restricted range of motion. Analgesics and 3 weeks of physical therapy (PT) did not provide relief. A trial of 40 minutes of FIR therapy 3 times a week during dialysis was done. After 3 weeks, his frozen shoulder improved completely. Case 3. A 75 year old woman with CKD 5 developed right partial rotator cuff tear after a fall. Diagnosis was confirmed by MRI and surgery was recommended. She refused surgery and tried 2 months of PT, which did not provide relief. Trial of FIR therapy was done with complete resolution of pain and stiffness after 3 weeks.

Discussion: FIR therapy may have beneficial effect on arterial insufficiency and joint injury and inflammation and should be considered in CKD 5 patients suffering from these conditions. It is non-invasive and can be easily done as 40-minute sessions in the clinic or during dialysis treatments.

TH-PO174

Denosumab-Induced Severe Hypocalcemia and Hyperparathyroidism in a Peritoneal Dialysis Patient

Akintunde M. Akinjero, Chelsea C. Estrada, Heesuck Suh. *Stony Brook University Medical Center, Stony Brook, NY.*

Introduction: Denosumab is increasingly used in the treatment of osteoporosis in patients with End Stage Renal Disease (ESRD). The safety of Denosumab in ESRD is unproven. We report a case of severe hypocalcemia and hyperparathyroidism after Denosumab use in ESRD.

Case Description: A 56-year-old woman with history of osteoporosis, secondary hyperparathyroidism and ESRD on peritoneal dialysis for the past eight years, presented to clinic with complaint of paresthesias of hands and feet for two weeks. Vital signs and physical exam were unremarkable. Laboratory work-up showed profound hypocalcemia (corrected calcium of 6.8 mg/dL) and markedly high intact PTH (iPTH) of 3448 pg/mL (Table 1), with normal phosphate (5.1 mg/dl) and alkaline phosphatase (193 U/L). Upon medication review, she notably received denosumab 60 mg subcutaneously for the first time, two weeks prior to her visit. Before the use of denosumab; calcium, phosphorus, and 25-vitamin D were normal, with mildly high iPTH (Table 1). We gave total daily doses of 3,000 mg oral calcium and 4,000 mg Renvela. With these drugs, her symptoms resolved with normalization of serum calcium six weeks later, and iPTH ten weeks later (Table 1). She was later closely monitored in clinic.

Discussion: Denosumab is a monoclonal antibody used to treat osteoporosis; it binds to receptor activator of nuclear factor-kappa B ligand, an osteoclast differentiating factor, to inhibit bone resorption and increase bone mineral density. Bisphosphonates are first line treatment for osteoporosis. However, bisphosphonates are contraindicated in ESRD due to impaired clearance. Denosumab is not renally cleared, hence seen as an alternative for treating osteoporosis in ESRD. Decreased phosphate clearance, reduced production of 1α hydroxylase, and elevated fibroblast growth factor-23 all predispose ESRD patients to hypocalcemia. Denosumab further increases this risk by downregulating osteoclast activity. Denosumab continues to be used in ESRD, with increasing reports of hypocalcemia. Our case outlines the life-threatening hypocalcemia that may occur, and highlight the need for closer monitoring in ESRD patients receiving denosumab.

Table 1. Changes in Calcium and iPTH levels after Denosumab.

	Before Denosumab	2 weeks after Denosumab	6 weeks after Denosumab	10 weeks after Denosumab
Corrected Calcium	9.7	6.8	8.7	10.6
iPTH	584	3448	3526	399

TH-PO175

Topical Vitamin A Ointment-Induced Hypercalcemia and Renal Stones in CKD

Thomas A. Brevik, Savneek S. Chugh, Marta Christov, Sanjeev Gupta. *Nephrology, Westchester Medical Center, Valhalla, NY.*

Introduction: Hypervitaminosis A is a rare cause of hypercalcemia, possibly secondary to the effect of vitamin A on bone to stimulate osteoclastic resorption and/or inhibit osteoblastic formation. Since Vitamin A metabolites are renally excreted, patients with chronic kidney disease (CKD) are at high risk of developing hypercalcemia even with lower dose of vitamin A. We present an unusual case of hypercalcemia from topical vitamin A ointment in a patient with CKD.

Case Description: A 55 year old male with past medical history of intellectual disability and CKD 3A with baseline serum creatinine (S.Cr.) of 1.4mg/dL was admitted to the hospital for hypercalcemia and acute kidney injury on CKD. On presentation, his S.Cr. was 1.9mg/dL, calcium was 11.4 mg/dL, albumin was 4.4 g/dL and parathyroid hormone (PTH) was 5 pg/mL. Renal ultrasound demonstrated a 7 mm nonobstructive stone with mild to moderate hydronephrosis of the left kidney. Serum phosphorous, PTH related protein, 25-hydroxyvitamin D, 1,25-hydroxyvitamin D, serum protein electrophoresis and serum free light chains were within normal limits. Vitamin A level was elevated at 156 mcg/dL (reference range 38-98 mcg/dL). Medication review found that the patient was using a vitamin A and D topical ointment for perianal dryness as a preventative measure. The topical ointment was stopped and within a month his S.Cr. stabilized to 1.5mg/dL, calcium came down to 10.6 mg/dl and vitamin A level returned close to normal at 106 mcg/dL.

Discussion: Hypercalcemia is a rare but reported side effect of oral all-trans-retinoic acid, a vitamin A metabolite, used for acne treatment. It is also known to occur from over the counter vitamin A supplements. We present the first case of topical vitamin A induced hypercalcemia in CKD. Vitamin A toxicity should be considered in the differential diagnosis of hypercalcemia and clinicians should be aware of the potential of vitamin A containing preparations causing hypercalcemia, especially in CKD populations. Our case highlights the importance of a thorough review of medications, including over the counter and topical medications in workup of hypercalcemia.

TH-PO176

A Unique Case of Metformin-Associated Lactic Acidosis

Ashish C. Ahuja. *UPMC Mercy, Pittsburgh, PA.*

Introduction: Metformin intoxication with lactic acidosis may develop in diabetic patients when the drug dose is inappropriate or its clearance is reduced. Comorbid medical conditions can make the diagnosis difficult, especially in the critical care unit. In this case, we present a patient who presented with AMS, found to have severe acidemia, with co-existing myxedema coma and urosepsis.

Case Description: A 62 year-old female presented for altered mental status. She takes Metformin 1 gm BID and recently started Liraglutide 1.2 mg daily. EMS found her at home, notably hypoxic, hypotensive and hypothermic. On arrival, she was found to have dysarthria but was able to convey a 2-week history of non-bloody diarrhea. Vitals revealed T 93.3C, BP 89/49, HR 79, RR 20, SpO2 100%. VBG showed severe acidemia with pH 6.97, pCO2 22, HCO2 6. Labs revealed lactic acid 13.5, AKI (72/13.6 from baseline 16/0.9), K 6.3, Mg 0.7, Ca 5.8, PO4 13.1, glucose 13. UA positive for infection. TSH found to be >500.00 with free T4 <0.2. She was given stress dose steroids followed by IV levothyroxine, ceftriaxone and bicarbonate infusion. One hour after arrival, her lactate rose to 15.6 with levophed at 0.4 mcg/kg/min. At this point, metformin intoxication was suspected and intermittent hemodialysis with dialysate flow rate of 300mL/min was initiated. Both blood pH and lactate level showed dramatic improvement after 6 hours of IHD. After a 14-hour IHD session, CHD was conducted through day 2. Urine culture grew Enterococcus faecalis and Aerococcus urinae and the patient received 3 days IV ceftriaxone. Levothyroxine 200mcg daily was started and steroids were stopped with pre-treatment AM cortisol level 62.1. Temporary dialysis catheter was removed on day 5 and the patient was discharged home on day 6. She was started on Repaglinide 0.5mg TID and asked to avoid metformin for the rest of her life.

Discussion: MALA is generally treated with supportive therapy, including initiation of RRT. In our case, we initiated a prolonged course of sustained low-efficiency dialysis (SLED) followed by CHD for one additional day to prevent rebound acidosis. This case is meant to highlight the importance of the early initiation of RRT and prevention of mortality. Additionally, it is important to manage comorbid conditions, such as myxedema coma and urosepsis, which may predispose patients to acute kidney injury and development of MALA.

TH-PO177

Resolution of Intramuscular Calcifications on CT Scan Correlating with Severe Hypercalcemia in the Recovery of Rhabdomyolysis

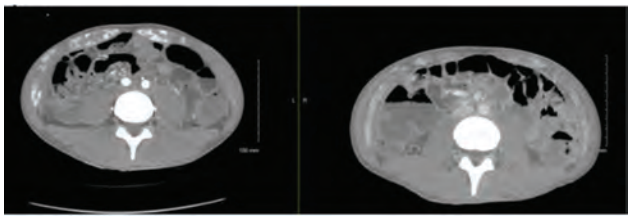
Andrew S. Maike, Judith Maddatu, Matthew R. Vickery, Daniel A. Sturgill. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Calcium homeostasis in rhabdomyolysis often follows a biphasic pattern of hypocalcemia during the oliguric phase followed by potentially life-threatening hypercalcemia during the non-oliguric phase. We present a case of sudden onset severe hypercalcemia corresponding with improved urine output and dissolution of intramuscular calcium deposits as identified on commuted tomography (CT).

Case Description: A 23-year-old male was admitted after drowning and subsequent cardiac arrest resulting in anuric AKI due to rhabdomyolysis. Initial lab work demonstrated

a creatinine kinase > 50,000 μ/L, hyperkalemia, hypocalcemia, and hyperphosphatemia. On the day the patient became non-oliguric his calcium began gradually rising to a peak ionized calcium of 1.91 mmol/L requiring multiple sessions of hemodialysis. Workup demonstrated depressed intact parathyroid hormone, Vitamin D 25-OH and 1-25$(OH)_2$ Vitamin D as well as ongoing hyperphosphatemia and a marginally elevated 24-hour urine calcium. Comparison of two CT scans obtained during the oligoanuric/hypocalcemic and non-oliguric/hypercalcemic phases of AKI demonstrated a clear reduction in intramuscular calcification. Calcium levels improved spontaneously after 11 days along with complete renal recovery.

Discussion: Sudden onset of severe hypercalcemia during the non-oliguric phase of AKI in the setting of rhabdomyolysis is due to mobilization of intramuscular calcium as evidenced by decreased intramuscular calcification observed on CT scan, a novel finding. Previous cases have described secondary hyperparathyroidism as the driving cause of hypercalcemia, although PTH was appropriately suppressed in this case, which is a unique finding. The temporal relationship between renal recovery and hypercalcemia could be explained by contemporaneous recovery of renal and skeletal tissue. Nephrologists must remain vigilant during the recovery phase of rhabdomyolysis and monitor for potentially life-threatening hypercalcemia.



CT abdomen on days 14 (L) and 29 (R) during the oliguric and non-oliguric phases of rhabdomyolysis induced AKI with improving intramucular calcification

TH-PO178

Survival After Severe Metformin-Associated Lactic Acidosis (MALA) with Aggressive Dialysis and Massive Bicarbonate Administration

Neil K. Agarwal, Natalia Plotskaya, Jesse M. Goldman. *Drexel University College of Medicine, Philadelphia, PA.*

Introduction: MALA is a severe condition affecting fewer than 1 in 10,000 people. Mortality is often above 20%. We present a case of intentional metformin overdose surviving after combined dialysis modality use and massive parenteral sodium bicarbonate ($NaHCO_3$) administration.

Case Description: 52-year-old male with PMH: HIV on HAART, DM, HTN, Hep C and cocaine use who intentionally ingested 60g Metformin in the ED without staff knowledge. 12 hours later, patient was found lethargic with a blood glucose of <10 mg/dl. Arterial blood gas: pH 7.02, $PaCO_2$ 23.3mmHg, PaO_2 128mmHg. Serum chemistry: Na 144mmol/L, K 3.8mmol/L, Cl 98mmol/L, Cr 1.57mg/dL, HCO3 12mmol/L, ALT 64unit/L, AST 74unit/L, AG 32, lactic acid >25.0 mmol/L. Patient was intubated, hyperventilated and begun on 3 vasopressors for hypotension. No GI lavage performed. Next, simultaneously started 150meq $NaHCO_3$ infusion at 150mL/hr and intermittent HD (IHD) for 3 hours with O200, Qb 400mL/min and Qd 800mL/min, Bicarb bath: 40meq/L. He was transitioned directly onto CVVHD using Prismasate 4/2.5 with Qb 300mL/min and Qd 3L/hr, later increased to 5L/hr. The $NaHCO_3$ infusion was increased to 600mL/hr due to persistent pH <7.2. An additional 50meq of $NaHCO_3$ was added to each dialysate bag. The patient's pH remained <7.2 throughout renal replacement therapy (RRT). A Metformin level prior to any RRT was 67mcg/dL. 11.5 hours after IHD and CVVHD initiation, the Metformin level fell to 23mcg/dL. CVVHD was continued due to anuria and high fluid requirements. 24 hours after initiating RRT, pH and HCO_3 improved to 7.35 and 23mmol/L, respectively. Serum lactic acid fell from >25mmol/L to 13.7mmol/L. The patient was extubated, weaned off vasopressors and discharged after delayed renal recovery on hospital day 25 with Cr 3.41mg/dl.

Discussion: Metformin (molecular weight 129, minimal protein binding) is rapidly distributed into tissue compartments. The large volume of distribution (300-1000L) prevents complete clearance by conventional IHD resulting in prolonged toxicity. In our case, 11,780meq of $NaHCO_3$ was given IV over 24-hours. He also received additional $NaHCO_3$ from 3 hrs of IHD in a 40meq/L dialysate bath followed by CVVHD using 32meq/L bags, later increased to 42meq/L. High UF rate with RRT allowed massive delivery of IV $NaHCO_3$ in combo with dialysis for aggressive treatment of MALA.

TH-PO179

Mannitol Therapy for Choroidal Hemorrhage: A Nephrological Challenge

Elixabeth L. Sullivan,[1] Rickinder Grewal,[1] Tramanh Phan.[2] *[1]University of Rochester Medical Center, Rochester, NY; [2]Nephrology Division, Rochester, NY.*

Introduction: Mannitol is an osmotic diuretic that reduces intraocular pressure (IOP). Hyponatremia and acute renal failure are complications that can occur in high risk patients. We report a case of hyperosmolar hyponatremia and oliguria necessitating hemodialysis (HD) after mannitol infusion for choroidal hemorrhage.

Case Description: A 91 year old female with chronic kidney disease (CKD) stage 3 on angiotensin II receptor blocker, coronary artery disease, hypertension, and chronic hyponatremia presented to the hospital with left eye pain and redness concerning for choroidal hemorrhage after her ophthalmologist discovered elevated IOP. Laboratory testing revealed a serum sodium concentration [Na] of 128 mg/dL and a serum creatinine concentration [Cr] of 1.21 mg/dL, at her baseline. She was given 2 g/kg of 20% mannitol. Seven hours later, testing revealed serum [Na] 123 mg/dL, serum [Cr] 1.49 mg/dL, and serum osmolality gap (OG) of 19 mOsm/kg with improvement in IOP. The following morning, serum [Na] remained 123 mg/dL, serum [Cr] increased to 2.03 mg/dL with a serum OG of 19 mOsm/kg. Due to recurrent eye pain, a second dose of 2 g/kg mannitol was given. Three hours later, serum [Na] decreased to 111 mg/dL, serum [Cr] increased to 2.54 mg/dL, with a serum OG of 83 mOsm/kg and serum osmolality of 322 mg/dL. Nephrology was consulted and recommended normal saline 500 ml bolus followed by continuous infusion at 125 mL/hr. However, over the next 12 hours, urine output continued to decline with serum [Na] decreased to as low as 107 mg/dL with serum [Cr] 4.90 mg/dL. Though serum osmolality decreased to 296 mg/dL, serum OG remained 60 mOsm/kg. Given progressive oliguria, azotemia, and hyperkalemia, emergent HD was performed with repeat serum [Na] 117 mg/dL, serum OG 31 mOsm/kg, and improved urine output. After repeat HD, serum [Na] increased to 129 mg/dL with a normal OG. Oliguria resolved and mental status improved.

Discussion: Mannitol can be used to manage elevated IOP but high and frequent dosing can lead to oliguric renal failure with profound hyperosmolar hyponatremia, particularly in elderly patients with CKD. Our case highlights the importance of recognizing hyperosmolar hyponatremia as a distinct clinical entity and emphasizes reversibility of renal failure with early HD. It also raises thoughts regarding alternative therapies for elderly patients with CKD and increased IOP.

TH-PO180

A Case of Hyperosmolar Hyponatremia from Polyethylene Glycol (PEG)

Max Nutt,[1] Thomas D. DuBose,[1] James L. Pirkle,[2] Bryan Tucker.[2] Wake Forest Baptist Health - Nephrology *[1]Internal Medicine, Wake Forest Baptist Health Internal Medicine, Winston Salem, NC; [2]Internal Medicine - Nephrology, Wake Forest Baptist Health, Winston Salem, NC.*

Introduction: N/A

Case Description: 69 year old man with pulmonary sarcoidosis presented to the ER with shortness of breath, diagnosed with acute pneumonia and treated with antibiotics, with gradual improvement in dyspnea. Hospital course was complicated by an ileus, for which increasing amounts of polyethylene glycol (PEG) was prescribed. On hospital day 10 the laboratory data revealed acute worsening of hyponatremia (123mmol/l), hyperkalemia (5.5mmol/l), and a mild non-oliguric AKI, prompting nephrology consultation.

Discussion: The measured serum osmolality of our patient was normal (277 mOsm/kg), and a low whole blood sodium (127mmol/L) ruled out pseudohyponatremia. The serum osmolar gap was elevated at nearly 20 mOsm/kg, indicating the presence of an unmeasured osmolyte. A negative correlation between the patient's serum sodium and potassium was observed, such that when $[Na^+]$ decreased, $[K^+]$ increased (Image 1). Searching the chart for known etiological agents that may act as an effective osmole and produce these series of events was unsuccessful. Our attention was focused on PEG, which was being administered in high doses (170 grams cumulatively) in the absence of a bowel movement. A dose-dependent temporal relationship between PEG administration and hyponatremia was observed, supporting the diagnosis of PEG-induced hyponatremia. A proposed mechanism is outlined and illustrated in Image 2. When PEG was discontinued by Nephrology, the electrolyte abnormalities corrected rapidly.

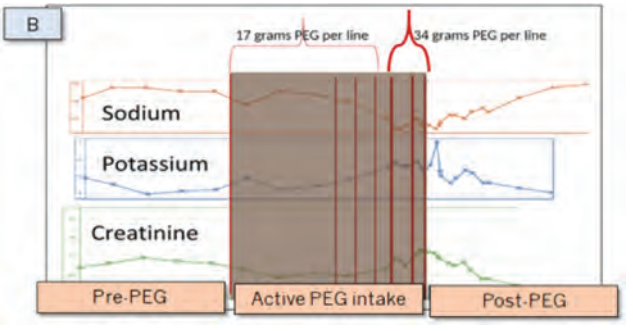


Figure 1. Lab Data relevant to PEG dosing

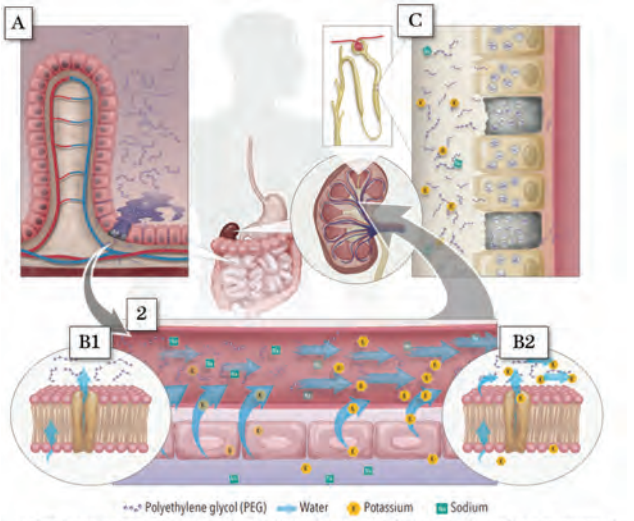

(A)Small intestine permeability: Ileus is a risk factor for increased PEG absorption, and due to increased contact with small intestinal mucosa and reduced function of cell-cell barriers more PEG can be absorbed..
(B1) Hyperosmolar hyponatremia: PEG exerts an osmotic force and pulls water into the intravascular compartment, causing dilutional hyponatremia
(B2) Solvent drag: Intracellular K^+ is dragged with intracellular water
(C) Osmotic nephropathy: Proximal tubular epithelial cells are unable to degrade PEG, and it builds up in intracellular lysozymes, leading to cellular death

TH-PO181

Severe Hypermagnesemia-Induced Ischemic Colitis in a Patient with AKI

Rebecca Levy,[2,1] Kalyan Prudhvi,[1] Jyotsana Thakkar.[1] [1]*Nephrology, Montefiore Medical Center, Bronx, NY;* [2]*Pediatric Nephrology, Montefiore Medical Center, New York, NY.*

Introduction: Severe hypermagnesemia is a rare complication seen with laxative/antacid overdose, usually in patients with acute kidney injury(AKI). We present a case of marked hypermagnesemia leading to ischemic colitis with perforation, pancreatitis and multi system organ failure in a patient with AKI.

Case Description: A 54 year old female with hypertension, asthma, and chronic neurogenic bladder presented with abdominal pain and vomiting for one day. She was taking magnesium hydroxide 1200mg four times a day for constipation. She was hypotensive on arrival with blood pressure of 70/50mmHg. Labs were remarkable for AKI with serum creatinine of 6.8mg/dL (baseline 0.9mg/dL) and severe hypermagnesemia (>10mg/dL, baseline of 2.2mg/dL about one month ago). Other significant lab findings were microangiopathic hemolytic anemia (MAHA) and lactic acidosis. She was intubated, started on vasopressors and admitted to the intensive care unit. CT abdomen revealed free air suggestive of perforation, reactive pancreatitis and ischemic colitis. Emergent exploratory laparotomy was performed which showed cecal ischemia. She also received plasma exchange for for MAHA which was stopped after three treatments given normal ADAMTS13 activity. Continuous renal replacement therapy (CRRT) was started for hypermagnesemia and oliguria. Her renal function and hypermagnesemia improved and she was weaned off CRRT. The etiology of AKI was presumed to be multifactorial in the setting of obstructive uropathy from neurogenic bladder, acute tubular necrosis from hypotension and thrombotic microangiopathy. Severe hypermagnesemia was attributed to high dose oral magnesium supplementation in the setting of AKI. She showed significant improvement in her follow up labs in renal clinic two months later with magnesium level of 2.2mg/dL and serum creatinine of 0.9mg/dL.

Discussion: Hypermagnesemia is known to induce hypomotility of gut leading to ileus, colitis, intestinal perforation and toxic megacolon, especially in the setting of AKI. Our patient developed severe refractory hypermagnesemia requiring CRRT complicated by ischemic colitis, bowel perforation and reactive pancreatitis. High index of suspicion for these bowel complications is warranted if patients present with hypermagnesemia and abdominal symptoms.

TH-PO182

Noninvasive Left Ventricular End-Diastolic Pressure (LVEDP): A Novel Volume Assessment Tool

Eric Jia Yi Xu,[1] Harry A. Silber,[1] Surekha U. Mullangi,[1] Seungyoung Hwang,[1] Luis F. Gimenez,[1] Bernard G. Jaar,[1] Tariq Shafi.[2,1] [1]*Johns Hopkins University, Baltimore, MD;* [2]*University of Mississippi Medical Center, Jackson, MS.*

Background: Objective assessment of volume is a major barrier to improving volume management in dialysis patients. The Valsalva maneuver is a well-recognized bedside marker of central volume overload. We tested a novel non-invasive handheld device that combines Valsalva maneuver with finger photoplethysmography to reliably estimate LVEDP. The goal of our pilot study was to determine the associations of non-invasive LVEDP measurements with common volume-related hemodialysis parameters.

Methods: We assessed predialysis LVEDP in 67 patients undergoing maintenance hemodialysis at two dialysis units in Baltimore. Patients also underwent extracellular water measurement by bioimpedance (BIA), in addition to routine dialysis parameters. We assessed the association of these parameters with changes in systolic blood pressure during dialysis.

Results: Mean age of the participants was 57 years, 63% were male, and 76% black. Predialysis LVEDP was 16 ± 6 mm Hg (normal: <12 mm Hg) with a range of 5 mm Hg to 33 mm Hg. Among the parameters assessed, only LVEDP was associated with a significant fall in systolic blood pressure (SBP) during dialysis (Table). However, LVEDP was not associated with any of the commonly used definitions of intradialytic hypotension. R^2 was 47% for a model of change in SBP that included predialysis SBP, LVEDP, interdialytic weight gain (IDWG), extracellular water, ultrafiltration (UF) volume, UF rate, and treatment time, suggesting that >50% of the variability in the change in SBP during dialysis remains unaccounted for by these variables.

Conclusions: Non-invasive LVEDP is a novel parameter that can provide additional information to guide volume assessment in hemodialysis patients. However, 50% of the variability in the change in SBP remained unexplained, pointing to the need to fully understand the pathophysiology of fall in SBP during hemodialysis.

Funding: NIDDK Support

Predictors of change in SBP (adjusted for age, sex, and race)

Predictor	Mean ± SD	Change in SBP (Post – Pre) per 1 SD decrease in predictor [SE]	p

TH-PO183

Fluid Volume Overload and Vascular Stiffness in Hemodialysis Patients

Aya Lafta,[1] Judy A. Ukrainetz,[2] Aminu K. Bello,[1] Branko Braam.[1] [1]*University of Alberta, Edmonton, AB, Canada;* [2]*Alberta Health Services, Edmonton, AB, Canada.*

Background: Fluid overload (FO) and vascular stiffness are prominent features of end-stage renal disease patients. Although both are risk factors for cardiovascular events, the relationship between these two factors has not yet been fully elucidated. We hypothesized that FO is associated with high vascular stiffness which can only be partly corrected by ultrafiltration (UF) of fluid during the hemodialysis (HD). We aimed to determine whether vascular stiffness is higher in fluid overloaded (FO) vs. non-fluid overloaded (non-FO) HD patients. Also, we investigated the effect of fluid removal on vascular stiffness of a single HD run.

Methods: Fluid status and arterial stiffness were tested in 20 FO and 19 non-FO HD patients. 26 healthy subjects were evaluated as controls. Fluid status was assessed by bioimpedance spectroscopy device. Pulse wave velocity (PWV) and augmentation index (AIx), as markers of vascular stiffness, were measured using Arteriograph24™. The PWV and AIx were performed for 5 hours, starting 30 minutes before and ending 30 minutes after the HD run. All measurements were done during the mid-week HD session. In healthy controls, 5-hour measurement of PWV and AIx was performed as time control. HD subjects were divided into three tertiles according to the baseline PWV measurement.

Results: The median age of HD patients was 60 (29-56) and 49 (29-56) years in healthy subjects. Fluid status in healthy controls, FO and non-FO HD patients was 0.05 (-0.6-0.5), 2.9 (1.7-5.2), and 0.3 (-0.3-0.6), respectively. As anticipated, PWV and AIx were higher in HD patients vs. healthy controls. FO was not associated with a higher PWV (m/s) in FO 10.0 (9.2-11.1) vs non-FO 10.0 (8.8-11.4) HD groups. A significant positive linear relationship was observed between dialysis UF (L) and intradialytic PWV changes in the upper-tertile group (r^2= 0.223; P<0.05). The latter group showed significant changes in AIx (%) -20.0±55.5 compared to the lower-tertile 15.7±27.1 (P<0.05).

Conclusions: The PWV and AIx were higher in HD patients compared to healthy subjects. Surprisingly, there was no difference in PWV/AIx between the two HD groups. Dialysis treatment appears to be a detrimental factor in improving the vascular status of patients with higher PWV and/ or AIx. However, an additional interventional study would be needed to further delineate the relationship between fluid status and arterial stiffness.

TH-PO184

Calculation of Extracellular Fluid Volume from Regular Blood Test Results of Patients Undergoing Hemodialysis

Shigeru Nakai,[1] Kazuhiko Shibata,[4] Ikuto Masakane,[3] Takahito Ito,[2] Teppei Matsuoka,[5] Takeshi Aoki,[6] Takahiro Shinzato,[9] Hiroki Hayashi,[7] Naotake Tsuboi,[7] Midori Hasegawa,[7] Daijo Inaguma,[7] Yukio Yuzawa,[7] Susumu Ookawara.[8] [1]*Fujita Health University School of Health Scieneces, Toyoake, Aichi, Japan;* [2]*Kataguilli Medical Center, Shibata, Japan;* [3]*Honcho-Yabuki Clinic, Yamagata, Japan;* [4]*Yokohama Minami Clinic, Yokohama, Japan;* [5]*taiseikai medical corporation, ogaki-city Gifu pref., Japan;* [6]*Nagoya Municipal Industrial Research Institute, Iwakura-shi, Aichi-ken, Japan;* [7]*Fujita Health University School of Medicine, Aichi, Japan;* [8]*Saitama Medical Center, Jichi Medical University, Saitama-city, Japan;* [9]*Daiko Medical Engineering Research Institute, Nagoya-shi, Japan.*

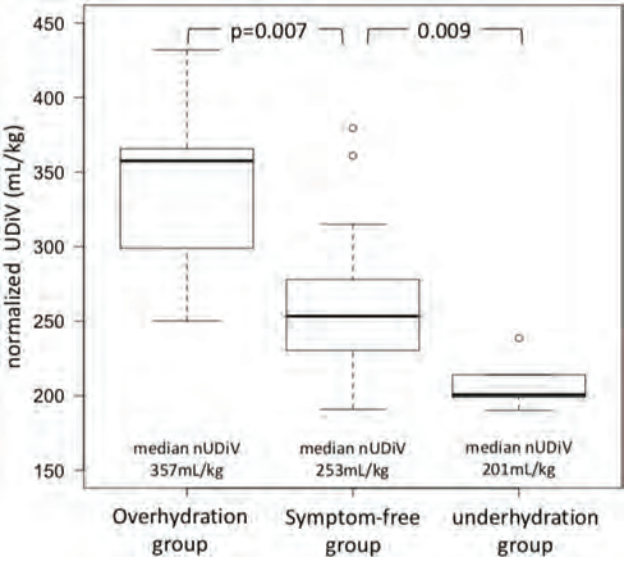
Background: Uric acid (UA) is a solute that cannot cross cell membranes in the general tissues via simple diffusion, facilitated diffusion, or active transport, indicating that the UA distribution volume (UDiV) is equal to the extracellular fluid volume (ECFV). At ASN 2018, we reported that UDiV is closely correlated with ECFV predicted using

the bioimpedance method (BIA-ECFV); however, whether UDiV is a useful tool for distinguishing different hydration statuses remains unclear.

Methods: We compared UDiV calculated from regular blood test results with BIA-ECFV of 53 patients undergoing hemodialysis (HD) predicted using BCM (Fresenius Medical Care). Further, we compared UDiV normalized with the post-HD body weight (nUDiV) in nine patients with pedal edema (overhydrated patients), five with intradialytic hypotension (underhydrated patients), and 24 without any clinical symptoms relating to hydration status (symptom-free patients).

Results: We observed a significant correlation between UDiV (x) and BIA-ECFV (y) ($y = 0.69\mathbf{x} + 3.25$; *r-square* = 0.61; $p < 0.0001$). The regression line substantially coincided with the line of identity. Bland-Altman analysis showed a systematic error for UDiV versus BIA-ECFV. In addition, we found a significant difference between UDiV and BIA-ECFV (mean difference = 0.94 L; 95% CI = 0.37-1.52 L). As shown in the figure, the nUDiV could help distinguish different hydration statuses.

Conclusions: UDiV is a plausible alternative marker of BIA-ECFV for the assessment of the hydration statuses of HD patients.



nUDiV and hydration statuses

TH-PO185

Overhydration Is an Independent Risk Factor for Postdialysis Hypertension and Predicts Mortality in Hemodialysis Patients

Hae Yeul Park,[1] Kwon soo Jung,[1] Moon hyoung Lee,[1] Hoon Young Choi,[1] Hyunwook Kim,[1] Jung eun Lee,[3] Hyung Jong Kim,[2] Hyeong cheon Park.[1] *[1]Gangnam Severance Hospital, Seoul, Republic of Korea; [2]Bundang CHA Medical Center, CHA University, Seongnam, Gyeonggi-do, Republic of Korea; [3]Yongin Severance Hospital, Gyeonggi-do, Republic of Korea.*

Background: Accurate volume assessment is important for hemodialysis (HD) patients because chronic fluid overload leads to increased cardiovascular morbidity and mortality. Postdialysis hypertension (PDHYPER) has been reported to occur commonly in HD sessions but the cause of PDHYPER remains to be determined. Our aim was to ascertain the association between volume status and PDHYPER and the influence of PDHYPER on mortality in HD patients.

Methods: A cross-sectional multi-center study enrolled clinically stable HD patients. All patients underwent a bioimpedance analysis (BIA) after a midweek HD session to assess volume status. PDHYPER was defined as an increase in systolic blood pressure (SBP) of 10mmHg or more after dialysis. Delta SBP was calculated by SBP difference between before and after HD.

Results: A total of 254 prevalent HD patients (158 men and 96 women) with a mean age of 59.0±12.8 years were included in this study. Patients were divided into 2 groups according to the SBP change after dialysis: the hypertensive group (29.1%), and the non-hypertensive group (70.9%), those with less than 10mmHg or no increase in SBP. The hypertensive group showed older age (64.3±11.9 vs 56.8±12.6, p<0.001), more use of diuretics (45.9% vs 29.4%, p=0.016), higher ECW(Extracellular water)/TBW(Total body water) (0.400±0.014 vs 0.389±0.015, p<0.001), lower phase angle (4.4±1.6 vs 5.3±1.4, p<0.001), higher BNP (1034.1±1122.4 vs 519.0±758.7, p=0.029), and lower albumin (3.77±0.42 vs 3.97±0.34, p=0.01) than non-hypertensive group. In Pearson correlation, delta SBP showed a significantly positive correlation with ECW/TBW (r=+0.334, p<0.001). In multiple logistic regression analysis, ECW/TBW was the only independent risk factor affecting PDHYPER. Ultrafiltration volume, however, was not significantly associated with PDHYPER. PDHYPER was also associated with 4-year all cause mortality (30.2% vs 15.9%, p=0.017).

Conclusions: Our data demonstrated that increased ECW/TBW is a potential risk factor of PDHYPER and such PDHYPER independently predicts 4-year all cause mortality in HD patients. HD patients who experience frequent increase in postdialysis SBP should be reassessed for their volume status and target dry weights, with emphasis on increased the ECW/TBW ratio.

TH-PO186

Thoracic Electrical Bioimpedance Measurement in Monitoring Cardiac Index and Thoracic Fluid Content During Hemodialysis

Jining Wu, Zhuo Xu, Hong Ye, Junwei Yang. *Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Hemodynamic stress during hemodialysis (HD) results in recurrent segmental ischemic injury that drives cumulative cardiac damage. Thoracic electrical bioimpedance (TEB) has been shown to provide accurate, noninvasive, continuous, measurements of cardiac index (CI) and thoracic fluid content (TFC). We performed this study to evaluate the changes in TFC in comparison with fluid removal (FR) and to understand the trends in CI changes in HD patients.

Methods: In this observational study, we enrolled 114 patients from a single hemodialysis unit. Minute-by-minute changes in TFC and CI were collected using the TEB (BioZ) in HD patients. Change in body weight (DW) and amount of FR were measured.

Results: The TFC decreased in all patients by an average of 4.6±2.4 1/kΩ, weight decreased by 2.05±1.12kg, and FR averaged 2.5±0.98 L in HD session. There were good correlations between change in TFC and DW (R=0.74, P<0.001) and FR (R=0.82, P<0.001). A 1/kΩ change of TFC correlates with an 150mL change in total body water. The change in CI (-0.42 ±0.51L/min/m^2) during HD did not correlate with FR (R=0.14, P=NS). Changes in TFC represented the monitored variable most closely related to FR. Interestingly, during the first 5 mins of HD, CI and stroke volume index reduced obviously compared to the base lever before dialysis.

Conclusions: It suggested that thoracic electrical bioimpedance could monitor the acute cardiac effects of dialysis during hemodialysis treatment.

Funding: Government Support - Non-U.S.

TH-PO187

Change in Extracellular Fluid Volume (ECV) Calculated with a Plasma Uric-Acid Kinetic Model May Reflect True ECV Better Than That with Body Weight in Hemodialysis Patients

Takahito Ito,[1] Takahiro Shinzato,[2] Kazuhiko Shibata,[5] Shigeru Nakai,[3] Takeshi Aoki.[4] *[1]Kataguilli Medical Center, Shibata, Japan; [2]Daiko Medical Engineering Research Institute, Nagoya-shi, Japan; [3]Fujita Health University School of Health Scieneces, Toyoake, Aichi, Japan; [4]Nagoya Municipal Industrial Research Institute, Iwakura-shi, Aichi-ken, Japan; [5]Yokohama Minami Clinic, Yokohama, Japan.*

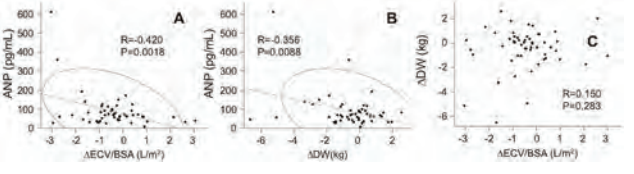
Background: In Kidney Week 2018 (SA-PO-867 and 868), we reported a novel method to calculate extra-cellular fluid volume (ECV) of hemodialysis (HD) patients, which is based on a kinetic model of plasma uric acid (UA) concentration. In this study, we compared annual change of clinically adjusted dry weight (DW) with that of ECV calculated by our method.

Methods: Among 79 Japanese HD outpatients who were enrolled in the previous study, 53 patients maintaining stable blood flow and ultrafiltration rates on the days of blood sampling both at April 2018 and at April 2019 were included in this analysis (64.8 ± 10.5 y, male 69.8%). They had no cardiac event at least for two years. DW of each patient had been adjusted throughout the period by a nephrologist-in-charge using cardio-thorax ratio and blood pressure. ECV values at post-HD were calculated by our method and were standardized by the body surface area (BSA). Demographic and biochemical data used below were obtained at April 2018. An annual increment is designated as Δ.

Results: DW and ECV/BSA values decreased during the period (-0.51 ± 1.71 kg and -0.42 ± 1.22 L/m^2, paired Wilcoxon P=0.0377 and 0.0078, respectively). Both were not associated with age, sex, total protein, albumin, creatinine, corrected-calcium, phosphate, urea nitrogen, hemoglobin, nPCR, and diabetic history. ΔECV/BSA was not associated with ΔDW at all (R=0.141, P=0.3133) (**Fig**). ΔECV/BSA correlated positively with dialysis vintage (R=0.307, P=0.0251) and negatively with Δalbumin (R=-0.402, P=0.0029), but ΔDW did not. ΔECV/BSA showed better correlation with plasma atrial natriuretic peptide concentration measured in 2018 (R= -0.420, P= 0.0018) than ΔDW (R=-0.356, P=0.0088) (**Fig**).

Conclusions: ΔECV, which is calculated with our plasma UA kinetic model, was consistent with clinical data better than ΔDW. Our results suggest that ΔECV/BSA rather than ΔDW reflects true change of ECV in HD patients.

Funding: Clinical Revenue Support



Although ΔECV/BSA (***A***) and ΔDW (***B***) from April 2018 to April 2019 negatively correlated with plasma ANP concentration measured at April 2018, both did not correlate with each other (***C***).

TH-PO188

Oxidative Stress Is Associated with Overhydration and Sarcopenia in Hemodialysis Patients

Cheolsu Kim,[1] Sung gyun Kim,[2] Hyungseok Lee,[1] Narae Joo,[1] Hyung jik Kim.[1] *[1]Hallym University Sacred Heart Hospital, Anyang, Republic of Korea; [2]Hallym University, Anyang, Republic of Korea.*

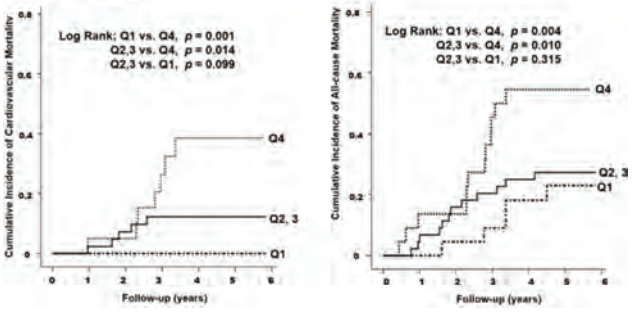
Background: Increased oxidative stress is regarded as an important nontraditional risk factor in patients undergoing hemodialysis (HD). However, studies examining the long-term effect of oxidative stress by direct measurement of these markers and its association with volume status and sarcopenia are limited.

Methods: In this longitudinal observational study, serum protein carbonyl levels were measured in 88 stable HD patients. Additionally, multifrequency body composition analysis and handgrip strength (HGS) and nutritional assessments were performed and followed prospectively for up to 6 years.

Results: The mean patient age was 60.6 ± 13.5 years, and the mean HD duration was 50.8 ± 41.3 months. In total, 16 patients (18.2%) were overhydrated, 49 (55.7%) had low HGS and 36 (40.9%) had low muscle mass. Serum protein carbonyl levels were associated with serum levels of albumin, prealbumin and transferrin, hydration status and low HGS. Overhydration, prealbumin, subjective global assessment score and sarcopenia were significant predictors for serum protein carbonyl levels in the highest quartile. Multivariate analysis showed that the serum levels of protein carbonyl, albumin, prealbumin, overhydration and sarcopenia were independent determinants of all-cause and cardiovascular mortality. (Figure 1.)

Conclusions: Serum protein carbonyl was significantly associated with overhydration, nutritional status and sarcopenia and could be an important predictor of long-term outcomes in patients undergoing HD

Figure 1. Cumulative incidence of Cardiovascular mortality and All-cause mortality according to quartile of serum protein carbonyl



TH-PO189

The Role of sCD146 in Assessing Hydration State of Hemodialysis Patients

Yanna Dou, Jing Xiao, Zhanzheng Zhao. *Nephrology Hospital, the First Affiliated Hospital of Zhengzhou University, Henan, China, Zhengzhou, China.*

Background: sCD146 is a marker of endothelial cell injury and also a biomarker of systemic circulation congestion. There is no study on the relationship between sCD146 and water load hydration state in dialysis patients in Chinese dialysis patients. We will study the role of sCD146 and NT-proBNP in assessing hydration state in hemodialysis patients.

Methods: The maintenance hemodialysis patients of the First Affiliated Hospital of Zhengzhou University from September 2018 to January 2019 were screened. And 10 healthy people were enrolled to measure the level of sCD146 as control. Clinical data were collecting, including sex, age, height, type of dialysis pathway, systolic blood pressure (sBP), hemoglobin (Hb), serum albumin (Alb), blood urea nitrogen (blood Urea Nitrogen, BUN), uric acid (UA), creatinine (Serum Creatinine), total cholesterol (TC) were collected. Triglycerid (TG), potassium, phosphorus, dialysis effectiveness index Kt/V, parathyroid Hormone (PTH). The blood was taken in the morning to measure the concentration of sCD146. Body weight was measured before and after dialysis on dialysis day, and bioelectrical impedance was measured by Xitro4200 bioelectrical impedance meter. Total body water (TBW), Extracellular Fluid Volume (ECV) and excess water (M_{EXF}) were calculated. Ultrafiltration volume was recorded.

Results: Compared with 10 healthy controls, plasma sCD146 levels in hemodialysis patients increased before and after dialysis (275.58 [209.00, 370.80] VS. 187.03 [152.01, 214.09] ng/ml, P < 0.05), (233.00 [172.50, 442.59] VS. 187.03 [152.01, 214.09] ng/ml, P < 0.05). Pearson or Spearman correlation analysis showed that sCD146 before dialysis was positively correlated with M_{EXF} (r = 0.400, P < 0.05) before dialysis, negatively correlated with age (r = 0.394, P < 0.05), but not with pre-dialysis body weight (r = 0.030, P = 0.872), blood pressure (r =-0.085, P = 0.646), ECV/TBW (r = 0.269, P = 0.136).

Conclusions: sCD146 may be a new biomarker for the overhydration state in hemodialysis patients.

Relationship Between Interdialytic Weight Gain and Change in Whole Body Extracellular Resistance

Fansan Zhu,[1] Peter Kotanko,[1,2] Nathan W. Levin.[2,3] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]DialyzeDirect, New York, NY.*

Background: Estimation of interdialytic fluid gain is essential to determine ultrafiltration volume (UFV) in routine hemodialysis (HD). The aim of this study was to evaluate the relation between interdialytic changes in whole body extracellular resistance (Re) and interdialytic weight gain (WG) to facilitate prescription of ultrafiltration volumes (UFV) and rate (UFR).

Methods: Ambulant patients were studied at ≥4 successive HD sessions. Whole body and calf bioimpedance were measured pre- and post-HD to obtain whole body extracellular resistance (Re) and calf normalized resistivity (CNR). Interdialytic weight change (ΔWt), change in Re (ΔRe), and CNR (ΔCNR) between pre- and post-HD (calculated as pre-HD minus post-HD of the preceding HD session), UFV, and UFR were recorded per HD session. Simple and multiple regression analysis were used to determine the relationship between ΔWt and ΔRe.

Results: Thirty-eight patients (age 54.3±14 years, 17 females, BMI 26.4±7.4 kg/m^2) were studied. We collected 387 measurements (10.2±6 per patient; table 1). UFV and UFR were 2.98±0.9 L and 0.78±0.24 L/h, respectively. ΔWt correlated inversely with ΔRe (average R^2=0.71; range 0.44 to 0.91) with a slope of -53.3 (range -182 to -18) kg/Ω and an intercept of -12.9 (range -110 to 99) kg. As an example, Fig 1 and 2 show the relationship between ΔRe to ΔWt and to ΔECV in the same patient. Multiple regression analysis indicated that the slope was determined by UFR (p<0.01) and pre-HD CNR (p<0.05).

Conclusions: This study demonstrates that interdialytic weight gain can be predicted in individuals by whole body extracellular resistance. This method may be useful in patients who cannot be weighed. Using ΔRe to predict fluid gain is based on the high correlation between extracellular resistance and extracellular volume. Once corroborated in an elderly, non-ambulant population, this method may provide guidance for UFV prescription, a problem encountered occasionally in patients undergoing dialysis at home or – more frequently - in nursing homes.

Table 1

	ΔWt kg	ΔECV L	ΔRe Ω	ΔCNR 10^{-2}Ωm^3/kg
Mean±SD	2.54±1.0	2.27±1.0	-131±72	-3.4±1.7
95% CI	2.2; 2.9	1.9; 2.6	-154; -107	-4.0; -2.8

TH-PO191

Lung Ultrasound for Fluid Status Assessment in Dialysis Patients: An Option to Consider

Marta Arias, Jose J. Broseta Monzo, Elena Guillen, Gastón J. Piñeiro, Lida M. Rodas Marin, Miquel G. Umbert, Francisco Maduell. *Hospital Clínic de Barcelona, Barcelona, Spain.*

Background: Lung ultrasound (LUS) has been postulated as a possible tool to evaluate fluid status in dialysis. Objective:To verify if lung comets determination (LC), in comparison with Spectroscopic Bioimpedance-BCM and Blood volume monitoring-BVM could be a practical instrument for daily fluid status evaluation and its relationship with cardiovascular events and mortality

Methods: Two-year prospective follow-up study in 120 patients (84% hemodialysis, 16% peritoneal dialysis) 61.7±5.6 years. Two measurements were taken at the start of intermediate dialysis session: BCM to evaluate extracellular water excess(ECW%) and lung ultrasound (Philips CX50®, convex probe) to detect LC. BVM data and blood samples were also collected and an echocardiogram performed. Follow-up until death was also censored if patients moved dialysis center or received kidney transplant

Results: LC average was 3±1.3. Two groups were established according to LC number. Patients with ≥5 LC were mainly men (61.1%), younger (57.8±9.3 years), diabetic (89%), with higher CRP (1.75±1.3 mg/dL) and higher pulmonary arterial pressure (PSAP) estimated by echocardiography (37.9±2.4 mmHg) and more overhydrated by BCM(p <0.009). No differences observed in BVM. During the follow-up, 8 patients presented non-fatal cardiovascular events and 21 died. Mild pulmonary congestion (LC≥5)(p <0.028) and ECW≥20%(p <0.001) were associated with higher mortality risk (Figure 1), but not with a cardiovascular event.

Conclusions: Strengthen nephrologists' lung ultrasound skills could be appropriate for optimizing fluid status in patients with high PSAP in those departments with US device and the right probe available, since its predictive mortality value has been demonstrated even in patients with a low LC number.

Figure1. Kaplan-Meier analysis for all causes of mortality according to LC number (a) and ECW% (b)

Lung Ultrasound: A New Technique for Fluid Status Assessment in an Asian Haemodialysis Cohort

Yan Ting Chua, Weng K. Wong, Clara L. Ngoh. *National University Hospital, Singapore, Singapore, Singapore.*

Background: Studies in non-Asian haemodialysis (HD) cohorts have shown that lung congestion is an insidious problem with negative impact on cardiovascular outcomes. However, assessment of extravascular lung water (EVLW) clinically is difficult. Markers such as plasma N-terminal pro-B-type natriuretic peptide (NT-pro BNP) and bioimpedance analysis (BIA) have uncertain correlations with EVLW. In recent years, point-of-care lung ultrasound (POCLUS) has emerged as a new technique to assess EVLW. However, there is a dearth of Asian studies. We compared the performance of a 28-point POCLUS protocol against clinical examination, NT-pro BNP and BIA in an Asian HD cohort.

Methods: We performed a prospective observational study of 20 HD patients undergoing dialysis at our institution. Patients were assessed pre- and post-HD using a 28-point POCLUS protocol, with physical examination for lung crepitations and pedal oedema, and with plasma NT-pro BNP and BIA. BIA was performed using the Bodystat Quadscan 4000 (BQ4000). Patients with active cardiac disease (angina and recent myocardial infarction in last 6 months), lung pathology (infection, interstitial lung disease or malignancy), cardiac devices and limb amputations were excluded.

Results: Pre-HD, 18 (90%) of the patients had moderate fluid overload, defined as ≥15 B-lines. However, 4 (22%) of this cohort had neither lung crepitations nor pedal oedema detected clinically. Pre-HD B-line score was positively correlated with pre-HD NT-pro BNP (rho=0.654, p=0.006), but not with pre-HD positive hydration status by BIA (p=0.051). B-line score significantly decreased post-HD (pre-HD 51.7 ± 32.5 to post-HD 24.9 ± 26.4, p<0.001). Reduction in B-lines from pre- to post-HD was associated with a corresponding reduction in NT-pro BNP (rho = 0.994, p<0.001). Post-HD, 2 out of 7 of patients who achieved weights within 0.5kg of dry weight still had ≥15 B-lines on POCLUS. Both patients did not manifest lung crepitations or pedal oedema post-HD.

Conclusions: In this cohort of patients, POCLUS showed good correlation with NT-pro BNP, but not with BIA. It also demonstrated significant promise in recognising asymptomatic pulmonary congestion. Further longitudinal studies are required to investigate for potential benefits of POCLUS in volume management of HD patients.

TH-PO193

Lung Ultrasonography in the Assessment of Volume Overload: An Extra Tool to Improve Patient Care and Clinical Skills in Nephrology Fellows

Karla G. Carias martinez,[5] Gerardo Zablah,[1] Saul N. Gonzalez Montalvo,[2] Naveen Punchayil narayanankutty,[2] Vasuki N. Venkat,[3] Daniel J. Soberon,[3] Marco A. LadinoAvellaneda.[4] *[1]University of Miami, Miami, FL; [2]Jackson Memorial Hospital, Miami, FL; [3]Bruce W. Carter VA Medical Center, Hialeah, FL; [4]Miami VA Medical Center/University of Miami/ Jackson Memorial Hospital, Plantation, FL; [5]Jackson Health System, Miami, FL.*

Background: Estimating euvolemia in patients with end stage renal disease (ESRD) is critical in their management. Nephrologists use their clinical judgment and skills to estimate the volume status. Lung ultrasonography (LU) is a tool that allows clinicians to have an objective evaluation of volume status. B-lines on lung ultrasound have been validated as a sign of pulmonary congestion and volume overload. This study evaluates the use of LU in the clinical assessment of volume status in the patient that is admitted to the hospital with ESRD.

Methods: Twenty patients with ESRD, admitted with volume overload were evaluated on admission with LU. Physical exam on all the patients didn't show physical signs of volume overload, on 9 patients the chest X-ray was clear, on 8 patients the CXR showed signs of congestion and on 3 patients the CXR showed mild-moderate pulmonary edema. A LU using a GE VScan portable ultrasound was done on all the patients.

Results: B-lines were found in the 20 patients, LU was suggestive of volume overload (B-lines present). Hemodialysis/Ultrafiltration was provided for all the patients, 10 patients needed extra ultrafiltration sessions in the following days for a complete resolution of the B-lines which was evidenced with subsequent use of LU.

Conclusions: LU guided fluid management protocol improves the clinical evaluation in ESRD patients. Clinical judgment and integrated lung ultrasonography for management of volume in hemodialysis patients improves outcomes and facilities the clinical management of hypervolemia. LU is an objective tool to assess volume overload in this patient population.

Seeing the Volume for the Bs: Longitudinal Variation in Ultrasound-Guided Volume Assessment in Hemodialysis Patients

Anubhav Kumar, Courtney R. Cassella, Alexander Bonnel, Isaac Matthias, Christy Moore, Nova Panebianco. *University of Pennsylvania, Philadelphia, PA.*

Background: Ultrasound (US) studies in hemodialysis (HD) patients have demonstrated improvements in lung water from the beginning to the completion of HD. These studies, however, have focused primarily on the pre-, intra-, and immediate post-dialytic periods. There are no published studies examining how fluid shifts between the intravascular and interstitial compartments in the post-dialysis period. This study aimed to characterize this phenomenon.

Methods: In this single-center, prospective observational study, patients with acute kidney injury and end-stage renal disease receiving HD in an inpatient HD unit at an urban academic medical center were recruited to receive three US volume assessments: first within two hours before HD, second within an hour following HD conclusion, and third four hours

after HD conclusion. US volume assessment consisted of assessment of inferior vena cava (IVC) variability and 28-point lung ultrasound (LUS) with B-line scoring per zone (BLZ).

Results: In a preliminary analysis, IVC variability increased a mean of 21.1% in three of the four subjects (range 29.9 to 23.2%) between the pre-HD and post-HD period. At the extended post-HD period, the same three subjects demonstrated a mean decrease in IVC variability of 19.1% (range 10.9 to 23.2%), whereas a fourth subject experienced an increase in IVC variability of 19.9%. The BLZ results were mixed, without clear signal across the four patients.

Conclusions: In preliminary analysis, IVC variability appeared to decrease in the extended post-HD period compared to the immediate post-HD period. BLZ did not show a signal for increase or decrease in the same period. The study is continuing to recruit patients for further analysis.

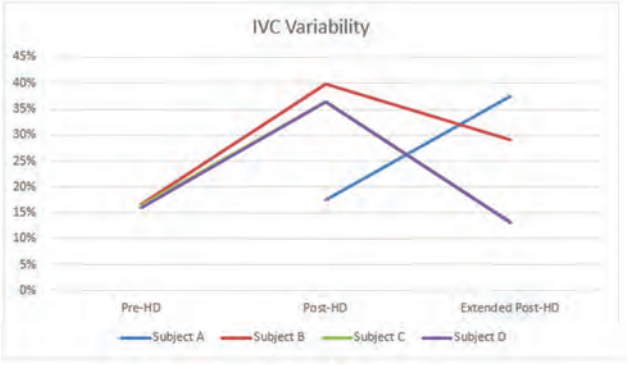

Fig. 1: IVC variability among study subjects against time.

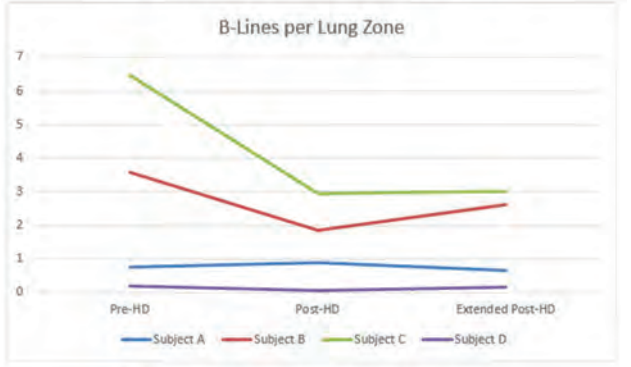

Fig. 2: B-lines per lung zone among subjects against time.

Unilateral Pulmonary Edema in Dialysis Patients

Prem P. Varma,[1] Geet Bajpai,[2] Elly Varma.[3] *[1]Nephrology, Venkateshwar Hospital, Delhi, India; [2]Nephrology, Venkateshwar Hospital, Delhi, India; [3]Banner University Medical Center, University of Arizona, Tucson, Tucson, AZ.*

Introduction: Unilateral pulmonary edema (UPE) usually affects right upper lobe & is seen in less than 2% cases of cardiac failure. Severe mitral regurgitation (MR) is the commonest underlying cause. We report 4 cases of UPE in Hemo dialysis (HD) patients which resolved following dialysis.

Case Description: Four cases of Diabetic Nephropathy on MHD, presented with breathlessness. There was no preceding H/O chest pain/fever/hemoptysis. ECHO showed moderate MR in 2, mild & severe MR in one each. All had hypoalbuminemia (2.8-3.6 gm/dl). In view of Unilateral opacities on chest X-ray (Fig 1-4), patients were started on broad spectrum antibiotics. Following dialysis surprisingly there was clearance of opactites in all of them.(Fig 5-8)

Discussion: UPE is a rare manifestation of cardiogenic pulmonary edema. Severe MR associated regurgitant blood in right pulmonary vein, poor lymphatic drainage of the right lung & hypoalbuminemia are the main contributing factors. Our cases show that UPE can affect any zone of right lung. We feel that, in fluid overloaded dialysis patients even mild/moderate MR is enough to cause UPE of any zone. High index of suspicion for UPE and impressive clinical response following dialysis warrants repeat chest skiagram. Clearance on X-ray gives diagnosis avoids antibiotic therapy.

Lung Ventilation Abnormalities in Chronic Hemodialysis Patients with Hyperpolarized ^{129}Xe Gas Magnetic Resonance Imaging

Fabio R. Salerno,[1,2] Rachel Eddy,[1,3] Alexander M. Matheson,[1,3] Grace Parraga,[3,1] Christopher W. McIntyre.[2,1] *[1]Medical Biophysics, Western University, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Robarts Research Institute, Western University, London, ON, Canada.*

Background: Shortness of breath is common among chronic HD patients, usually attributed to congestive heart failure and volume overload. However, it may be the hallmark of an underlying lung airway disease, such as asthma or COPD, which are often undiagnosed and there may be unique pathomechanisms in dialysis patients (e.g. salt loading). In this study, we used inhaled hyperpolarized xenon-129 (^{129}Xe) gas magnetic resonance imaging (MRI) to directly measure lung ventilation abnormalities in prevalent HD patients.

Methods: Ten chronic HD patients underwent ^{1}H and ^{129}Xe lung MRI on a non-HD day. ^{129}Xe MRI was acquired during breath-hold at end-inspiration, after inhalation of a fixed volume of hyperpolarized ^{129}Xe, and co-registered with proton images with matching lung volumes. Patients were scanned before and after administration of salbutamol to evaluate reversibility. Static ventilation ^{129}Xe images were analyzed with a semiautomated software pipeline implemented in Matlab (2018b; Mathworks, Natwick MA) to calculate the ventilation defect percent (VDP).

Results: In the study sample, three main ventilation patterns were identified: Normal, Single Defect, Multiple Defects (Figure 1A). Partial ventilation improvement after salbutamol administration was also observed (Figure 1B).

Conclusions: Underlying lung airway diseases as detected by ^{129}Xe lung MRI are common and may help explain the pathophysiology of shortness of breath in prevalent HD patients.

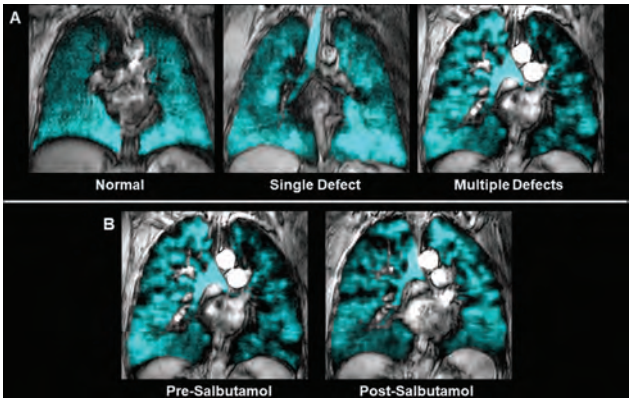

Figure 1. (A) ^{129}Xe MRI ventilation images showing three ventilation patterns: Normal, Single Defect and Multiple Defects. (B) ^{129}Xe MRI ventilation images showing partial improvement after salbutamol administration.

Changes in Ultrafiltration Rate (UFR) with Relative Blood Volume Monitoring (RBV-M)

Paul Balter,[1] Yisha Li,[2] Patrice B. Taylor,[2] Claudy Mullon,[2] Robert J. Kossmann,[3] Linda Ficociello.[2] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: High UFRs during hemodialysis (HD) have been linked to increased risk of mortality, and avoidance of UFR ≥13 ml/hr/kg has been advised. However, limiting UFR may lead to volume overload. We examined the changes in UFR and related parameters among patients who were part of a one-year fluid management QI project with RBV-M at 20 Renal Research Institute clinics.

Methods: Patients included in the analysis were receiving HD at Baseline (BL; month before QI project) and at Month 12 of the QI project (M12). Crit-Line monitor (CLM-III, CLM-IV, or CLiC) was used to monitor relative blood volume during the QI project. All available data on ultrafiltration volume (UFV), HD treatment duration (TD), UFR, interdialytic wt gain (IDWG), and post-HD body weight (wt) were averaged monthly for each patient. Paired t-tests and McNemar's tests were used to test for differences between BL and QI month 12 (M12).

Results: Treatment parameters at BL and M12 stratified by BL UFR are shown in Table. Pts with UFR<10 ml/kg/h experienced an increase in UFR by M12 (0.43 ml/kg/h) along with decreases in Post-HD wt of -1.1 kg and -1.0 kg in pre-HD wt. Pts with UFR>13 ml/kg/h experienced an average decrease in UFR of -2.34 ml/kg/h accompanied by a decrease in IDWG with no change in post-HD wt or TD. A similar, but less pronounced, pattern was observed for pts with UFR 10-13 ml/kg/h.

Conclusions: During a one-year fluid management QI project utilizing RBV-M, pts with UFR<10 ml/kg/h at baseline experienced an increase in UFR with a decrease in post-HD wt. Patients with UFR>10 ml/kg/h at baseline experienced a decrease in UFR accompanied by improvements in IDWG with stable post-HD wts. Treatment duration remained unchanged for all groups.

TH-PO198

Decline in Hemodialysis Ultrafiltration Rate (UFR), 2012-2018

Eric W. Young,[2] Dongyu Wang,[1] Jeffrey Pearson,[1] Alissa Kapke,[1] Delia Houseal,[3] Amanda Szymanski,[1] Marc Turenne,[1] Alan B. Leichtman.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Arbor Research, Ann Arbor, MI; [3]Centers for Medicare and Medicaid Services, Woodlawn, MD.*

Background: UFR has received heightened attention due in part to several observational studies that reported higher mortality at UFRs above 10 to 13 ml/kg/hour. Several organizations have proposed quality measures to discourage high UFR. We examined national UFR trends for US patients.

Methods: We evaluated trends in UFR and its components (pre- and post-dialysis weight, dialysis session time) from 2012-18 as reported by dialysis facilities through the CROWNWeb system. Medicare-certified dialysis facilities began reporting UFR data for the last hemodialysis session of each month in 2012, and for a full week of sessions in 2018 in accordance with the ESRD Quality Incentive Program.

Results: Data for monthly UFR were submitted for 88-98% of patients. Average UFR declined steadily from 9.3 to 7.8 ml/hour/kg between 2012 and 2018. The percent of dialysis sessions with a UFR>13 ml/kg/hour declined from 19% to 10%. The percent of dialysis sessions with a UFR>10 ml/kg/hour fell from 39% to 26%. The decline in UFR was largely driven by interdialytic weight gain, which fell from approximately 3.3% to 2.8% of body weight (~2.6 to 2.2 kg). Dialysis treatment time and patient weight trended upward, but these made a relatively small contribution to the decline in average UFR.

Conclusions: The average UFR has declined from 2012 to 2018, largely driven by lower interdialytic weight gain. One possible explanation is that dialysis facilities provide patients with better education about fluid and dietary intake and patients follow such advice more carefully. However, we believe a more likely explanation comes from other studies reporting a secular decline in the average dialysate sodium concentration, which suppresses thirst and fluid intake. Although the strength of current evidence has not supported specific UFR guidelines, the changes responsible for the declining UFR were potentially motivated by published studies and expectations of forthcoming guidelines and incentives related to UFR management.

Electronic Health Record-Based E-Alerts for Ultrafiltration Rate in Prevalent Dialysis Patients: A Quality Improvement Project

Rajesh B. Kumar,[1] Rachana H. Jasani,[1] Viswanath Billa,[3] Shrirang Bichu,[3] J. Kothari,[2] Alam Mohd shah,[1] Virendra Gupta,[1] Paras Dedhia.[1] *[1]Apex Kidney Care, Mumbai, India; [2]Hinduja Hospital, Healthcare & Apex Kidney Foundation, Mumbai, India; [3]Bombay Hospital, Mumbai, India.*

Background: Studies have shown an association between higher ultrafiltration rate and mortality in prevalent dialysis patients. Ultrafiltration rate exceeding 10mL per kg per hour has been associated with greater mortality even when calculations are normalized to various anthropometric measurements.

Methods: We recorded interdialytic weight gain (IDWG) for one week of thrice a week prevalent dialysis patients. Also baseline characteristics of study population were noted. Our dialysis data is recorded in AXIS renal data solution (electronic health record designed and conceptualized by Nephrologist). IDWG was calculated as predialysis weight minus the post dialysis weight of the previous hemodialysis session. The ultrafiltration rate was calculated by dividing the ultrafiltration volume (ml) by the target dry weight (kg) and length of time of the dialysis session (hours). Average ultrafiltration rate for all 3 sessions of hemodialysis and percentages of dialysis session where UF rate exceeded 10mL per kg per hour were calculated. After preliminary data collection, we are planning to introduce electronic alert (e alert) within AXIS system whenever ultrafiltration rate exceeds 10mL per kg per hour. This e alert will be sent to patient's caregiver as well as will serve as a teaching tool for dialysis nurse.

Results: Of the 387 subjects, 62% were males. The average age was 53.1± 13.6 years. The average dialysis vintage was 4.0 ± 3.4 years. 33.6 % had diabetes, 85.5 % had hypertension and 10.0 % had history of ischemic heart disease. Average UF rate of first session of week (after weekend) was 13.8 ± 5.7mL per kg per hour. Average UF rates of mid week and last session of week were 10.5 ± 10.5 and 10.0 ± 4.5mL per kg per hour respectively. About 75.7% of HD sessions after weekend had UF rate more than 10mL per kg per hour whereas 48.3 % and 47.8 % sessions of remaining week exceeded safe UF rate limits.

Conclusions: About 75% of dialysis sessions after weekend gap exceeded safe limits for ultra-filtration rates in prevalent dialysis patients. This calls for quality improvement initiative to improve knowledge and to monitor in change in behavior among dialysis patients, caregivers and providers regarding safe limits of UF rate.

TH-PO200

Ultrafiltration Does Not Correlate with the Difference Between Pre-Dialysis and Post-Dialysis Blood Pressure

Christina Irene Mejia,[1] Neil K. Agarwal,[1] Sandeep Aggarwal,[1] Ziauddin Ahmed,[1] Rudava Ullah.[2] *[1]Drexel University College of Medicine, Division of Nephrology and Hypertension, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA.*

Background: Hypervolemia contributes to blood pressure (BP) elevations in hemodialysis (HD) patients and is addressed with ultrafiltration (UF). However, high UF rates (UFR) are generally avoided as it is associated with intradialytic hypotension. It is unknown whether the amount of UF or volume removed actually correlates with the change between pre and post dialysis BPs. We hypothesize that there is an inverse correlation, with higher UF resulting in larger decreases in post HD BP.

Methods: We reviewed the records of 24 ESRD patients receiving HD in a single outpatient center in Philadelphia over a 2 month period. Patients on midodrine were excluded, and treatments with missing pre and post HD BPs and without UF were not analyzed. Using Pearson r, we correlated intradialytic weight change (pre minus post HD weight) and achieved UF rate (UFR, ml/kg/hr) with changes in systolic BP, diastolic BP and mean arterial pressure during HD (post minus pre HD SBP, DBP and MAP). Patients were further stratified into those who received UFR < vs ≥ 10 ml/kg/hr and with intradialytic weight (IDW) changes < vs ≥ 3kg.

Results: Individual intermittent HD treatments were analyzed (n=363). We found no significant correlation between IDW change and change in SBP (r= -0.024), DBP (r= -0.012) and MAP (r= -0.019). IDW change ≥ 3kg correlated better with a decrease in SBP post HD, although it did not reach statistical significance (r= -0.24, p=0.08). There was also no correlation between achieved UFR and change in SBP (r= -0.061), DBP (r= -0.021) and MAP (r= -0.04). There was still no significant correlation even in patients who received high UFRs (≥ 10 ml/kg/hr).

Conclusions: Our study showed that UFR and IDW change did not correlate with the difference in pre and post dialysis BPs. This suggests that other factors, in addition to volume, play important roles in intradialytic BP regulation and should be explored. To our knowledge, only one other smaller study looked at similar parameters and reported a significant but weak correlation between UF and change in MAP (r=0.17, p=0.045, 136 treatments) (Kovacic, et al, 2003). Larger studies are necessary.

TH-PO201

Prevalence of Body Weight Variations in the Pre-Dialysis Period and the Effect of Hemodialysis Initiation: A Single-Centre Retrospective Observational Study

Azharuddin Mohammed, Monther N. Alazwari. *Nephrology and Kidney Transplantation, Armed Forces Hospital-Taif Region, Taif, Saudi Arabia.*

Background: Body weight(BW) changes rapidly during pre-dialysis(pre-D) period and is regularly monitored during pre-D clinics but less utilised as an indication for RRT initiation in isolation. Hemodialysis(HD) provides a target weight (TW). **Aims:**To 1) Assess prevalence and magnitude of BW changes during pre-D 2) Measure the effect of RRT initiation on BW 3 months(m) post HD

Methods: We retrospectively examined BW changes of a large cohort of incident HD patients who attended ***Pre-D clinics*** between 2012-2016 (n=103). ***Excluded:***Those with missing BW between 2-5 m in pre-D and 2-5 m after RRT initiation, previous PD, HD or fluid overload as indication for RRT initiation (n= 38). W0, W1and W2 are the corresponding BW at -3 m(Pre-D clinic), pre-weight at 1stHD initiation and post-HD TW after +3 m. Delta BW is calculated as absolute and % change for Pre-D(W0-W1) and HD period(W1-W2). Weight loss and Weight gain data analysed using Past.V3 software.

Results: n= 65**,** mean age 68±12 yr, M:F 44:21. HD was RRT in all. Pre-D and HD intervals were similar 99 ± 29 Vs. 92 ± 13.6 days. Post-weight and TW were within 0.5±0.4 Kg. Weight loss seen in both pre-D and HD; it slowed modestly after HD initiation (66.4% to 56.9%) mainly in 0-5% (40% Vs. 26%) ***(Fig 1)***. **Weight gain** was mostly 0 - 9.9% on HD as compared to pre-D (38.4 Vs 27.7). High weight gainers of >10% BW reduced from 7.7% in the pre-D period to 4.6% on HD, probably reflecting closer monitoring of TW. However, **group comparison** of pre-D and HD for % BW changes did not reach statistical significance for weight loss (difference between means 1.47, 95% CI -1.45 to 4.48, p=0.35) or weight gain (difference between means 0.12, 95% CI -2.86 to 3.11, p=0.93).

Conclusions: Uremic state is predominantly catabolic in both pre-D and HD period; RRT initiation can provide anabolic milieu. Increased recognition/incorporation of BW changes is needed as an added indication for RRT initiation. Body composition monitor use could well extend into pre-D clinics to guide bedside decisions.

Impact of Extracellular Volume Overload on Ambulatory Blood Pressure in Hemodialysis Patients with and Without Intradialytic Hypertension

Meredith McAdams,[3] L Parker Gregg,[4,2] Michael L. Concepcion,[5] Swati Lederer,[7] Jeffrey G. Penfield,[6] Peter N. Van Buren.[1,2] *[1]UT Southwestern, Dallas, TX; [2]Dallas VA Medical Center, Dallas, TX; [3]UTSW, Dallas, TX; [4]University of Texas Southwestern, Dallas, TX; [5]Dallas Veterans Hospital, Dallas, TX; [6]VA North Texas Health Care System, Terrell, TX; [7]VA North Texas, Dallas, TX.*

Background: Hemodialysis (HD) patients with recurrent intradialytic hypertension (IH) have higher ambulatory blood pressure (BP) and atypical ambulatory BP patterns compared to HD controls. Recurrent IH is also associated with increased extracellular volume (ECV) and intradialytic vasoconstriction surges. We examined how these variables influence ambulatory BP in HD patients with and without IH.

Methods: In a case-control study of recurrent IH patients (systolic pre to post-HD BP increase >10 mmHg in 4/6 treatments) and hypertensive HD controls we obtained pre and post-HD ECV/weight with bioimpedance spectroscopy and total peripheral resistance index (TPRI) with a cardiac output monitor. Linear regression measured associations of peridialytic variables on 44-hr ambulatory BP measurements.

Results: There were 18 IH subjects and 57 controls. Those with IH had higher ECV than controls (0.27±0.04 L/kg vs. 0.23±0.04, p=0.002) and different intradialytic TPRI changes than controls (385±840 dyn/sec/cm^2/m^2 vs.-478±700, p=0.001). Mean ambulatory BP was nonsignificantly higher in IH subjects (147±13 mmHg vs. 142±14, p=0.1), and BP slopes were different in hours 1-24 (-0.14±0.9 mmHg/hr vs. 0.42±0.9, p=0.04) but not hours 1-44. ECV/weight was associated with mean ambulatory BP in IH subjects and ambulatory BP slope in controls (Table). Post-HD BP associated with ambulatory BP in both groups.

Conclusions: Chronic ECV overload is a primary factor associated with ambulatory BP in IH patients, but interdialytic weight gain and intradialytic vasoconstriction surges are not. In controls, ECV overload is associated with a blunted ambulatory BP rise. Intra- and interdialytic BP patterns may help guide diagnosis and management strategies of ECV in HD patients.

Funding: NIDDK Support, Veterans Affairs Support

Regression Coefficients and P-values for Variables Using Mean Ambulatory Blood Pressure and Ambulatory Blood Pressure Slope as Dependent Variables in Subjects With and Without Intradialytic Hypertension

	Dependent Variable: Mean Ambulatory Systolic BP				Dependent Variable: Ambulatory Systolic BP Slope (Hours 1-44)

Aquapheresis: An Institutional Experience at Lenox Hill Hospital

San K. Khine,[1] Eric H. Lam,[3] Kush R. Dholakia,[4] Samuel J. Scheinerman,[5] Maria V. DeVita.[2] *[1]Nephrology, Lenox Hill Hospital, New York, NY; [2]Lenox Hill Hospital- Northwell Health System, New York, NY; [3]NYITCOM, Flushing, NY; [4]Northwell Health - Lenox Hill Hospital, New York, NY; [5]Lenox Hill Hospital - Northwell Health, New York, NY.*

Background: Aquapheresis (AQ) is the extracorporeal extraction of plasma water from the vascular space across a semipermeable membrane in response to a transmembrane pressure gradient, which efficiently removes extravascular fluid from the patient without compromising electrolytes. It is primarily used in the management of patients (pts) with diuretic resistant heart failure (CHF). AQ is comparable to isolated ultrafiltration (UF) performed on those pts requiring dialysis, but utilizes a machine that is smaller, and easier to operate compared to traditional dialysis equipment. Three major

studies on the use of AQ compared to diuretics have shown mixed results: UNLOAD (2007), found that UF produced greater fluid loss and also a 53% reduction in the 90-day rehospitalization; in contrast, in CARRESS-HF (2012), the use of AQ did not relieve CHF and caused worsening of renal function; AVOID (2016), supported the use of AQ to lower re-hospitalization rates in CHF pts. There are no reports of the use of AQ in clinical studies outside of decompensated CHF.

Methods: A retrospective study of AQ utilization at Lenox Hill Hospital, a tertiary care hospital in NYC. Records of pts who received AQ therapy were reviewed. The patient list was generated by searching for keyword "Aquaph" in our EMR. Pts were categorized by indication for AQ and hospital location. Additional information includes duration of treatment (days), changes in creatinine, and total volume removed.

Results: The search generated 28 pts, 5 were excluded as they never actually received AQ. Indications for AQ went into 5 categories: cardiogenic shock including post cardiothoracic procedure (10); anasarca (5); ATN with volume overload (4); ESRD with bridge ultrafiltration between hemodialysis treatments (2); post-op volume overload (2). There were 16 pts from Cardiothoracic ICU, 5 pts from CCU, 1 pt from the Medical ICU and 1 pt from the Surgical ICU. The average duration per patient was 4.26 days. The mean aquapheretic volume per day was 1954 mls, and per encounter was 8323 mls with no significant change in creatinine.

Conclusions: We found that aquapheresis can be safely utilized in situations other than diuretic resistant heart failure. Also to consider, is the ease in which this less complicated aquapheresis machine can be operated compared to the more complex hemodialysis equipment.

TH-PO204

Over-Ultrafiltration May Increase the Risk of Ischemic Cerebral Small Vessel Disease in Hemodialysis Patients

Ke Zheng,[1] Yujun Qian,[2] Haiyun Wang,[1] Xuemei Li.[1] *[1]Peking Union Medical College Hospital, Beijing, China; [2]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Dongcheng District, Beijing, China.*

Background: Cerebral small vessel disease (CSVD) is an important cause and risk factor of stroke and dementia. Recently, CSVD in patients with end-stage renal disease and undergoing dialysis had attracted great attentions. A higher prevalence of CSVD in hemodialysis patients had been shown in others' and our previous studies. Hemodialysis is a complicated procedure with multiple factors that could affect cerebrovascular disease. Ultrafiltration could bring hemodynamic instability during the hemodialysis. The aim of this study is to discovery the relationship between ultrafiltration and ischemic CSVD

Methods: In this retrospective study, we collected a whole year's ultrafiltration information before the brain MRI scan of the HD participants in our dialysis cohort of 2013~2014 CSVD/CI study in which the CSVD were assessed by magnetic resonance imaging. We analyzed average ultrafiltration volume (UV mean), fluctuation of ultrafiltration volume (UV CV) and ultrafiltration volume over 6% dry weight (UV mean - 6%W), and their influence to ischemic CSVD findings (lacune and white matter hyperintensity) in MRI. Multivariable analysis was used to explore the relevance between ultrafiltration parameters and CSVD.

Results: In our 2013~2014 dialysis CSVD/CI cohort, 119 participants were on HD, and among them, 50.9% were male. The average age was 56.6yr, average dialysis vintage was 58 months. Median UV mean was 2.3 (0.2~ 4.6) L, UV CV was 21.4 (0.0 ~ 78.1) mL and "UV mean - 6%W" was -1.3 (-4.6 ~ 1.4) kg. The prevalence of lacune in MRI was 28.6% and WMH was 38.7%. By multivariable analysis, we found that UV and UV CV were not relative to both features of CSVD, but the "UV mean - 6%W" was relative to increased risks for lacune and WMH with OR1.74 (1.06, 2.87) and 1.89 (1.16, 3.08), respectively. In further analyzed, it showed that ultrafiltration mainly affected subcortical white matter lacune (OR 1.98 (1.09, 3.59)) and periventricular white matter hyperintensities (OR1.81 (1.08, 3.03)), rather than deep CSVD lesions.

Conclusions: Over ultrafiltration during hemodialysis procedure could increase the risk of ischemic CSVD, especially the risk of subcortical white matter lacune and periventricular white matter hyperintensities. "6% dry weight" could be considered as ultrafiltration cut-off values in hemodialysis therapy in order to avoid ischemic CSVD.

TH-PO205

Ultrafiltration Rate Correlates Better with Intradialytic Weight Change Indexed to Body Weight Than Absolute Weight Change

Christina Irene Mejia,[1] Neil K. Agarwal,[1] Sayeda Humaira,[2] Sandeep Aggarwal,[1] Ziauddin Ahmed.[2] *[1]Drexel University College of Medicine, Division of Nephrology and Hypertension, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA.*

Background: Intradialytic weight change (IDW change), ultrafiltration rate (UFR), and total ultrafiltration (UF) are used to quantify volume removal during hemodialysis (HD) treatments. These parameters are frequently used in clinical research to find associations between volume removal and outcomes like mortality and intradialytic complications. IDW change expressed as a proportion of body weight (indexed weight change) is rarely used both in the clinics and research. The objective of this study is to explore how indexed weight change correlates with the commonly used volume parameters during HD.

Methods: We reviewed records of 28 ESRD patients receiving HD in a single outpatient center in Philadelphia over a 2 month period. Treatments without UF were excluded from analysis. Correlations between absolute IDW change (pre minus post HD weight), achieved UFR (ml/kg/hour), and indexed weight change (IDW change divided by pre HD weight) were calculated using Pearson r. Range and mean of indexed weight change was also calculated and expressed as a percent of body weight lost (indexed weight change multiplied by 100).

Results: Individual intermittent HD treatments were analyzed (n=422). Absolute IDW change had a significant and strong correlation with achieved UFR (r=0.745, p<0.00001) and indexed weight change (r=0.824, p<0.00001). Interestingly, UFR correlated strongly and better with indexed weight change (r=0.963, p<0.00001) than with absolute IDW change. During treatments, patients lost an average of 2.13% ± 1.22% of their body weight with a range of 0.08 to 5.65%.

Conclusions: Our results show that UFR, absolute IDW change, and indexed weight change all correlate strongly. However, UFR correlates better with indexed weight change than absolute IDW change. Indexed weight change takes into account differences in body habitus of individual patients, and by transitivity, differences in their body surface area and total body water. Indexed weight change may be an important clinical parameter that could be used to guide UF prescriptions and more studies are needed to look into its association with hemodynamic changes during hemodialysis.

TH-PO206

Rise of Plasma Sodium Levels Is Followed by an Increase of Plasma Syndecan 1 in Hemodialysis Patients

Josephine Koch,[1] Nienke Idzerda,[2] Esmee Ettema,[2] Wendy Dam,[2] Casper F. Franssen,[1] Jacob van den Born.[2] *[1]Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands.*

Background: In hemodialysis (HD) patients, endothelial dysfunction (ED) contributes to atherosclerosis. A major hallmark of ED is loss of glycocalyx evidenced by shedding of syndecan-1 into the blood stream. Release of syndecan-1 is seen in pro-inflammatory and pro-oxidative conditions such as in HD patients. HD by the Hemocontrol biofeedback system (HHD) is characterized by initially higher dialysate and plasma sodium levels. Using HHD as a model for an acute increase in plasma sodium, we investigated associations between courses of plasma sodium and syndecan-1 during HHD and standard HD (SHD).

Methods: Plasma syndecan-1 was measured by ELISA in blood samples obtained from a cohort of 29 prevalent HD patients before, during and after HHD and SHD (randomized sequence). Wilcoxon signed-rank test or paired student's t-test was used to compare syndecan-1 levels between SHD and HHD. Intradialytic shedding of syndecan-1 was determined by area under the curve analyses. Associations with the intradialytic course of syndecan-1 were analyzed with a mixed effects repeated-measures model.

Results: During HHD, plasma sodium increased early after the start of HD (predialysis 139,1 mmol/L; at 30 minutes of HD 142.3 mmol/L; P<0.0001) whereas sodium did not increase significantly during SHD. During HHD, plasma syndecan-1 increased after 120 minutes of HD (P=0.007). Plasma syndecan-1 also increased significantly during SHD (within 120 minutes; P=0.003) but at 120 minutes, the rise in syndecan-1 levels was significantly higher in HHD as compared to SHD (+42.9% vs. +17.2%; P=0.021). The total amount of shed syndecan-1 was higher during HHD than during SHD, albeit at borderline significance (P=0.05). Lower plasma sodium and osmolality before dialysis were independent predictors of syndecan-1 increase during dialysis (P=0.001 for both groups). In HHD, a higher cumulative UF volume was independently associated with more intradialytic syndecan-1 shedding (P=0.001).

Conclusions: Plasma syndecan-1 levels increased significantly during both HHD and SHD. In HHD, this rise was significantly greater and occurred earlier as compared to SHD. This may reflect ED resulting from increased sodium load. Further research to assess long term effects and clinical implications of high salt exposure is needed.

TH-PO207

Home vs. In-Center BP in Hypertensive Hemodialysis Patients

Ambreen Gul,[1] Dana Miskulin,[2] Huan Jiang,[1] S. Paine,[1] V. Shane Pankratz,[3] Antonia Harford,[1] Saeed K. Shaffi,[4] Philip Zager.[1] *[1]Dialysis Clinic, Inc., Albuquerque, NM; [2]Tufts Medical Center, Boston, MA; [3]UNM Health Sciences Center, Albuquerque, NM; [4]University of New Mexico, Albuquerque, NM.*

Background: In hemodialysis (HD) patients, home blood pressures (HBP) are stronger than dialysis unit BP as predictors of adverse outcomes. In the BID pilot study, we assessed safety and feasibility of treating hypertensive HD patients to a standardized predialysis systolic BP (SDUBP) of 110-140 mm Hg vs. 155-165 mm Hg. Participants measured HBP according to American Heart Association guidelines twice on the day after the midweek HD. We assessed left ventricular mass index (LVMI) using MRI at baseline and at the end of the 1-year intervention. The present study assessed the differences between HBP and SDUBP within individuals.

Methods: To be included patients had to have ≥ 6 pairs of standardized predialysis BPs from a midweek HD and a time-matched HBP the following day. Patients were assigned to one of 3 clusters, based on the average SDUBP to HBP differences and the variability of the difference within an individual, using cluster analysis in R.

Results: There were 97 patients with an average of 26 pairs of SDUBP and HBP who were included in the cluster analysis. This resulted in three clusters; (1) SDUBP > HBP (n=31); (2) no significant difference (n=36); and (3) HBP > SDUBP (n=30). LVMI in Cluster 3 (84.5, 95% CI 75.5, 93.6) were significantly higher than Cluster 1 (72.7, 95% CI 65.8, 79.6; p= 0.06) and 2 (71.5, 95% CI 65.3, 77.7; p=0.03). Within Cluster 3 there was no difference in LVMI by treatment arm. At baseline, the participants in Cluster 3 had higher LVMI than those in Clusters 1 and 2. Contrary to Cluster 1 and 2, systolic BP post-dialysis (151.7 mm Hg) was significantly higher than pre-dialysis (149.1 mm Hg) in Cluster 3 (p= 0.001). Variability was similar across clusters.

Conclusions: Patients in Cluster 3 (HBP higher than SDUBP) had higher LVMI at baseline and after the 12-month intervention than those in Clusters 1 and 2. Patients

in Cluster 3 frequently had an increase in SBP during HD. Monitoring home BP measurements may improve care of HD patients.

Patient Engagement with a Digital Health Intervention (patientMpower) to Optimise Interdialytic Fluid Management in Ambulatory Hemodialysis Patients

Amy Hudson,[1] Binu Vasu,[2] Colin Edwards,[3] Martin Holmes,[3] Kevin Doyle,[3] Donal J. Sexton,[4] Conall M. O'Seaghdha.[2] *[1]Nephrology, Beaumont Hospital, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland; [3]patientMpower, Dublin, Ireland; [4]Trinity Health Kidney Center, Trinity College Dublin, Dublin, Ireland.*

Background: Many aspects of a chronic illness rely heavily on patient self-care and engagement. While promising, studies on the use of digital medicine platforms to empower patients to self-manage have suffered from low patient engagement. This pilot-scale study (NCT03403491) evaluated a mobile digital health intervention+weighing scales+blood pressure (BP) meter [patientMpower intervention (pMp)] in ambulatory hemodialysis patients treated in a clinical setting. Patient-reported weight and BP were captured by wireless connection to pMp (cellular or Bluetooth).

Methods: 43 patients (28M/15F; age 51±14y) entered an open-label, randomised, random-order, 2 x 28-day crossover comparison of pMp vs. a sham intervention. Patients were asked to record weight, BP, symptoms, fluid intake & medicines adherence every day during the pMp period. pMp calculated and displayed weight gain relative to individualised target (dry) weight to each patient. An algorithm within pMp delivered tailored feedback messages (dependent on actual weight gain) to optimise fluid intake between dialysis sessions. Primary endpoint was patient engagement with pMp.

Results: Engagement was high. 35 patients (81%) recorded weight on ≥21 days of the pMp period. Engagement metrics in the 28-day pMp period are shown below. However, only 2 patients recorded medicines adherence on pMp. Patients were asked to complete an online survey to feed back opinion of pMp. 23 gave feedback. 19(83%) reported pMp gave them a greater sense of control & had positive impact on their well-being, 18(78%) wished to continue using pMp after study, 21(91%) rated pMp as easy to use and 15(65%) liked using pMp (score ≥8/10 on rating scale).

Conclusions: This study demonstrated that ambulatory hemodialysis patients are willing and engaged in using a mobile digital health intervention with connected devices to regularly monitor body weight and BP to help them optimise fluid intake. The high engagement by these patients suggests that this methodological approach could be useful in future studies of optimisation of dry weight estimation and/or fluid intake.

TH-PO209

Assessment of Hemodialysis Patients' Knowledge of Fluid and Blood Pressure Management

Gwendolyn Derk,[1] Priyanka Bahel,[3] Kenneth R. Wilund,[1] Amy B. Pai.[2] University of Illinois Renal and Cardiovascular Disease Research Lab *[1]University of Illinois, Urbana, IL; [2]University of Michigan, Ann Arbor, MI; [3]University of Illinois- Urbana Champaign, Naperville, IL.*

Background: Hemodialysis (HD) patients are expected to minimize interdialytic fluid gains and manage their blood pressure (BP) with antihypertensive (AHT) medications. Due to a paucity of data reporting patients' knowledge and understanding of fluid and BP management, we conducted a prospective cross-sectional survey with retrospective medical record review at three HD clinics in Illinois.

Methods: HD patients were consented and interviewed using a standardized cross-sectional survey consisting of 50 questions on fluid and BP management. Patients were paid $10 for their participation. Six months of retrospective data was collected from medical records.

Results: Ninety-two patients completed the survey, and 38/92 were not aware of the last time their dry weight (DW) was changed. Patients reported their last DW change was made 5.93 +/- 15.3 months ago on average. Of the 54 patients who reported knowing the last time their DW was changed, 31/54 reported it was raised, 17 lowered, and 6 were not sure what changes were made. Medical records indicated that patients were not aware of the majority of DW changes. Over 3 months, DWs were changed an average of 2.54 +/- 2.18 times. Twenty four patients (26%) could not list their current or any previous DWs, while those who listed a DW were on average 3.73 +/- 10.16 kg away from the DW listed within their medical record. Forty-six patients were currently on 1 or more AHT medications. Of these, the average time since AHT medications were last changed was 15.22 +/- 16.4 months. The majority of patients (78/ 92) patients were interested in (or already) measuring their BP at home. Figure 1 shows how patients rated the likeliness of a direct relationship of their interdialytic fluid gains and BP.

Conclusions: Despite a desire to learn, most HD patients lack an understanding of the basic principles of fluid & BP management. There is a need for a structured education program for those initiating dialysis that encompasses fluid and BP management.

TH-PO210

Factors Influencing Hourly Hemodynamic Changes During Hemodialysis

Sadia anjum Ashrafi, Luis M. Perez, Kenneth R. Wilund. *University of Illinois at Urbana Champaign, Urbana, IL.*

Background: The cardiovascular system adapts to maintain blood pressure during hemodialysis primarily by altering cardiac output and systemic vascular resistance. However, many dialysis patients develop intradialytic hypotension (IDH) or hypertension, both having serious consequences. While blood pressure is consistently monitored during dialysis, other hemodynamic variables are not. The purpose of our study is to examine changes in total peripheral resistance index (TPRI) and cardiac power index (CPI) during each hour of dialysis to determine the primary factors causing IDH and intradialytic hypertension throughout a dialysis session.

Methods: Intradialytic systolic blood pressure (SBP), mean arterial blood pressure (MAP), CPI and TPRI were evaluated hourly using peripheral bioimpedance (NiCaS, Inc) in 27 HD patients. Measurements were taken at baseline and after each hour of dialysis for a total of 198 hourly measurements. IDH was defined as a drop of hourly SBP ≥ 20 mmHg or drop of hourly MAP ≥ 10mmHg. Intradialytic hypertension was defined as a rise in hourly BP ≥ 15 mmHg. Measurements of blood pressure not meeting the definitions were defined as non-IDH or non-intradialytic hypertension time periods. Hourly changes in CPI and TPRI were compared.

Results: During the 1st hour of dialysis, neither SBP, CPI nor TPRI changed significantly. During the 2nd hour of dialysis, the average hourly TPRI changes in IDH and non-IDH groups were -211.5 ± 480.6 and 145.6 ± 572.1 (p=0.03). During the 3rd hour, the hourly CPI change was 0.12 ± 0.1 in the intradialytic hypertensive and -0.04 ± 0.1 in non-hypertensive groups (p= 0.02) whereas the average TPRI change was -476.6 ± 701.7 in IDH and 168.4 ± 812.5 in non-IDH groups (p=0.008). During the 4th hour, the hourly CPI change was -0.06 ± 0.07 in the intradialytic hypertensive group and 0.04 ± 0.1 in intradialytic non-hypertensive group (p=0.03).

Conclusions: The predominant change responsible for IDH in the 2nd and 3rd hour of dialysis appears to be reduction in TPRI. By contrast, intradialytic hypertension in the 3rd hour appears to be primarily mediated by increases in CPI. In the 4th hour, there was a paradoxical reduction in CPI in the intradialytic hypertensive group. More closely monitoring hemodynamic changes during dialysis may provide information that could be used to intervene medically to prevent these dialysis-associated complications.

TH-PO211

Crit-Line Monitoring Decreases Intradialytic Hypotension

Antonia Harford, Donna D. Whittle, Michael A. Young, S. Paine, Huan Jiang, Ambreen Gul, Philip Zager. *Dialysis Clinic Inc, Albuquerque, NM.*

Background: Published clinical studies on the use of blood volume monitoring to guide ultrafiltration in hemodialysis (HD) have had mixed results. We conducted a continuous quality improvement (CQI) project to assess the impact of Crit-Line monitoring during routine care in a chronic HD facility operated by a large, non-profit dialysis provider. We postulated that Crit-Line monitoring would decrease intradialytic hypotension & hospitalization due to fluid overload.

Methods: After a 6-month baseline period, we conducted 1 month staff training on Crit-Line use, followed by a 2nd 6-month period with Crit-Line monitoring with each HD. 29 HD patients contributed a mean of 62 & 61 treatments to the baseline & Crit-Line periods, respectively. Mean & 95% confidence intervals (95% CI) for age & vintage were 62.6 (57.6, 67.6) & 4.7 (2.2, 7.2) years, respectively. Males & diabetics comprised 72% & 38% of the patients, respectively. Hypotension was defined as systolic blood pressure (BP) < 100 mmHg or symptoms associated with a drop in BP. Dialysate temperature & composition did not change significantly between the 2 time periods. We used Poisson regression models, adjusted for sex, diabetes, vintage & BMI, to compare treatment related events including cramping, symptomatic hypotension, & leaving treatment > 1 kg from estimated dry weight (EDW) & hospitalization during the baseline period & the 6-months in which Crit-Line monitoring was used.

Results: Intradialytic hypotension was significantly lower during Crit-Line monitoring (OR 0.37, 95% CI 0.2, 0.7). Other adverse events including all-cause & cardiovascular hospitalization rates did not differ across the 2 time periods (see table).

Conclusions: Crit-Line use was associated with a statistically significant decrease in the frequency of intra-dialytic hypotension; however there was no association with hospitalization. Well trained staff are essential to the optimal use of Crit-Line monitoring.

Funding: Commercial Support - Dialysis Clinic, Inc.

Frequency of Dialysis Related Symptoms

Complication	Baseline n (%)	Crit-Line n (%)	Odds Ratio (95% CI)	*P*-value

Characterisation of Haemodynamic Responses to Haemodialysis Using Frequency Analysis

Venkata R. Gullapudi,[1,2] Jill Stewart,[4] Kelly White,[2] Paul Stewart,[3] Mohamed T. Eldehni,[2] Maarten W. Taal,[1,2] Nicholas M. Selby.[5,2] Centre for Kidney research and Innovation *[1]Centre for Kidney research and Innovation, University of Nottingham, Derby, United Kingdom; [2]University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; [3]University of Derby UK, Derby, United Kingdom; [4]University of Derby, Derby, United Kingdom; [5]University of Nottingham, Derby, United Kingdom.*

Background: Intradialytic haemodynamic instability remains a significant problem, leading to ischaemic end-organ damage. Extrema points frequency analysis of blood pressure (BP) is a method of assessing beat to beat variation in BP, which may have relevance to end-organ perfusion. Our aim was to utilise this method to describe the patterns of individual cardiovascular response to haemodialysis (HD), study its variability and identify factors associated with higher BP frequencies.

Methods: 50 participants aged >18 years were recruited from our prevalent HD population. Participants' demographics, HD background, HD prescription and laboratory parameters at each session were recorded. All participants had continuous non-invasive haemodynamic monitoring using pulse wave analysis (Finapres NOVA) during the entirety of three consecutive dialysis treatments. The data generated were then analysed by identifying the frequency and amplitude of local extrema points for mean arterial pressure (MAP).

Results: In total, 44 participants completed all three dialysis sessions with continuous haemodynamic monitoring. 61% were males, mean age was 62.3±16yrs and 43% had diabetes. Analysis of intradialytic trends of haemodynamic measures demonstrated a gradual near-linear decline in BP, cardiac output, stroke volume; and a rise in total peripheral resistance. In frequency analysis, overall MAP frequency across the study population for the first monitored session was 0.54 Hz (IQR: 0.18). The frequency extracts varied through the dialysis sessions, generally rising and reaching peak in 3rd hour of dialysis. There was intra-individual variation between dialysis sessions, with Coefficient of Variation of average frequency values of 0.01-0.53. MAP frequencies correlated with dialysis vintage (r=0.307, p=0.043), pro-BNP levels (r=0.318, p=0.038), Baroreflex sensitivity (r=0.319, p=0.035) and average real variability of SBP (r=0.393, P=<0.0001), MAP (r=0.631, P=<0.0001) and DBP (r=0.512, p=<0.0001).

Conclusions: Frequency analysis of BP provides additional information regarding the variability in BP during HD, and this may be of importance when considering effects of HD on organ perfusion. Prospective follow up of participants in this study will allow us to establish the relationship of BP frequency analysis and patient outcomes.

TH-PO213

Blood Pressure Variability and Prognosis in Hemodialysis Patients: A Systemic Review and Meta-Analysis

Yuliang Zhao,[1] Letian Yang,[1] Ping Fu.[2] *[1]Division of Nephrology, West China Hospital of Sichuan University, Chengdu, China; [2]West China Hospital of Sichuan University, Chengdu, China.*

Background: As the prognostic value of blood pressure variability (BPV) in hemodialysis patients had previously been inconclusive, this work performed a systematic review and meta-analysis to assess the association between BPV and clinical outcomes in the hemodialysis population.

Methods: Pubmed/Medline, EMBASE, Ovid, the Cochrane Library, and the Web of Science databases were searched through March 5, 2019 for full text articles in English. Cohort studies on the association between BPV and prognosis in hemodialysis patients were selected. Study selection and data extraction were performed by two reviewers independently, with adjudication by a third reviewer. Hazard ratios and 95% confidence interval were pooled in a random-effects model for the primary outcomes of all-cause and cardiovascular mortality. Statistical analysis was performed using STATA 14.0 (STATA Corp., Texas, USA).

Results: A total of 13 studies (37,827 patients) were eligible. Systolic BPV was associated with higher all-cause mortality (HR: 1.12, 95% CI: 1.06-1.19, P < 0.001) and cardiovascular mortality (HR: 1.16, 95% CI: 1.10-1.22, P<0.001), while diastolic BPV was not associated with them (P = 0.14, 0.56). Long-term systolic BPV (inter-dialytic or inter-visit BPV) was shown to be a risk factor for all-cause (HR: 1.11, 95% CI: 1.05-1.17, P = 0.001) and cardiovascular (HR: 1.14, 95% CI: 1.06-1.22, P<0.001) mortality, but short-term systolic BPV (intra-dialytic or ambulatory) was only associated with cardiovascular mortality (HR: 1.19, 95% CI: 1.09-1.29, P < 0.001). The associations between systolic BPV and mortality events were not affected by region (North America-Europe vs. Asia), follow-up time (≤2.5 years vs. >2.5 years) or variable type (BPV as a categorical vs. continuous variable). Among the different BPV metrics, the coefficient of variation (CV) of systolic blood pressure was identified as predictor of both all-cause (P=0.012) and cardiovascular (P=0.002) death.

Conclusions: In the hemodialysis population, systolic BPV was associated with both increased all-cause and cardiovascular mortality, while diastolic BPV was not associated with the clinical outcomes. CV of systolic blood pressure was identified as a predictor for both all-cause and cardiovascular mortality, while the utility of other BPV metrics requires further investigation.

Comparison of Pressure-Independent Pulse Wave Velocity Between Haemodialysis Patients and Patients with Preserved Kidney Function

Alexander Reshetnik,[2] Daniel Wrobel,[1] Georg Wirtz,[3] Kai-Uwe Eckardt,[2] Markus van der Giet.[2] *[1]DIAVITAL, Kamen, Germany; [2]Charité – Universitätsmedizin Berlin, Berlin, Germany; [3]Dialysezentrum Kamen, Kamen, Germany.*

Background: Chronic kidney disease (CKD) is associated with progressive arteriosclerosis and increased arterial stiffness (AS) – expressed as higher measured aortic pulse wave velocity (aPWV) – has been frequently described in dialysis patients. However, the intrinsic physiologic relationship between aPWV and prevailing arterial pressure complicates the direct comparison of aPWV values between different collectives. An individual pressure-independent expression of aPWV could be a possible solution.

Methods: Hemodialysis patients were age- and sex-matched with patients with preserved kidney function. Long-term measurements (24 hours for patients with preserved kidney function and 44 hours for haemodialysis patients) of blood pressure (BP) and aPWV were obtained. aPWV was then adjusted to 120 mmHg central systolic BP (PWV120) based on individually determined relationship and mean PWV120 was compared between the two collectives.

Results: 45 patients were included in each group. Haemodialysis group had significantly higher prevalence of diabetes mellitus and significantly more patients with hyperlipoproteinemia, history of coronary heart disease, stroke and peripheral artery disease, while patients with preserved renal function had significantly higher systolic and diastolic BP. PWV120 did not differ between the groups.

Conclusions: In our study, we used BP-adjustment for pressure-independent expression of aPWV. Our results show that pressure-independent aPWV did not differ between patients on haemodialysis and with preserved kidney function. This finding is in contrast to previous reports and prompts questions about association between AS and CKD. However, more data are needed to reproduce the results for further assessment.

Haemodynamic parameters

systolic blood pressure, mmHg	119.4±13.6	134.9±16.2
diastolic blood pressure, mmHg	67.8±10.5	78.3±8.6
heart rate, beats/min	68.3±9.3	69.7±10.0
central systolic blood pressure, mmHg	106.6±13.1	122.3±14.0
aortic Pulse wave velocity, m/s	11.0 [9.2-12.8]	10.9 [9.1-12.8]
PWV120, m/s	10.9±2.5	10.8±2.5

TH-PO215

Body Composition Analyzer Monitoring Improves Dialysis in Maintenance Hemodialysis Patients Role in Hypotension

Jun Yin. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*.

Background: Exploring the role of body composition analyzer (BCM) monitoring in improving dialysis hypotension in patients undergoing maintenance hemodialysis (MHD)

Methods: 51 patients with dialysis hypotension in our center, 27 females and 24 males, with an average age of (55±8.7) years old, were monitored and adjusted by BCM. The patients were re-evaluated and adjusted for 1 month before and after BCM monitoring. The incidence of hypotension and changes in mean arterial pressure.

Results: The average dry weight before BCM monitoring was (53.2±7.9) kg, and the average dry weight after BCM monitoring was (55.8±8.1) kg. The incidence of dialysis hypotension before BCM monitoring was 38%, and the incidence after monitoring was significantly reduced to 14%. The incidence of dialysis hypotension was significantly reduced after BCM was monitored and up-regulated ($P<0.001$). There was no significant change in the mean arterial pressure after BCM monitoring and up-regulation of dry weight ($P>0.05$).

Conclusions: BCM monitoring can improve the dialysis hypotension of patients with MHD without increasing the patient's water and sodium retention, and does not increase the blood pressure before transfusion. It can quickly and accurately regulate the patient's dry weight.

TH-PO216

Standing Blood Pressure Differentiates True and Pseudo Intradialytic Hypertension

Han-Cheng Chen,[2] L Parker Gregg,[2] Jeffrey G. Penfield,[3] Swati Lederer,[5] Michael L. Concepcion,[4] Peter N. Van Buren.[1,3] *[1]UT Southwestern, Dallas, TX; [2]University of Texas Southwestern, Dallas, TX; [3]VA North Texas Health Care System, Terrell, TX; [4]Dallas Veterans Hospital, Dallas, TX; [5]VA North Texas, Dallas, TX*.

Background: Intradialytic hypertension (IH) is a blood pressure (BP) increase from pre to post-hemodialysis (HD). While IH occurs sporadically in nearly all HD patients, recurrent IH is clinically significant and associated with extracellular volume (ECV) excess, intradialytic vasoconstriction and mortality. We investigated if standing BP measurements from a single HD treatment with seated IH could distinguish patients with recurrent vs sporadic IH.

Methods: Among HD patients with increases in seated systolic BP from pre to post-HD in a single treatment, we compared ECV/weight (biompedance spectroscopy) and cardiac hemodynamics from that treatment and intradialytic BP trends in the prior 6 months between those with increases (true IH) or decreases (pseudo IH) in standing BP from pre to post-HD.

Results: There were 18 subjects with true IH and 7 with pseudo-IH with no differences in age or demographics. True IH subjects had higher post-HD ECV/weight, intradialytic TPRI increases, and more IH episodes in the past 6 months compared to pseudo IH(Table). The intradialytic BP patterns (excluding pre and post-HD seated measurements) are shown (Figure).

Conclusions: Patients with seated, but not standing, IH in a single treatment have a different physiologic phenotype than those with true-IH. The clinical significance of IH in an individual treatment can be assessed by determining the changes in standing SBP from pre to post-HD.

Funding: NIDDK Support, Veterans Affairs Support

Comparison of Subjects with Pseudo IH and True IH

	Pseudo IH (n=7)	True IH (n=18)	p-value
Seated pre-HD systolic blood pressure (mmHg)	146 (14)	137 (14)	0.6
Seated post-HD systolic blood pressure (mmHg)	167 (12)	155 (18)	0.07
Standing pre-HD systolic blood pressure (mmHg)	160 (17)	134 (14)	0.002
Standing post-HD systolic blood pressure (mmHg)	130 (19)	150 (14)	0.02
Post-HD ECV/body weight (L/kg)	0.23 (0.04)	0.27 (0.04)	0.02
Intradialytic Change in Total Peripheral Resistance Index	-491 (470)	577 (840)	0.005
Mean change in systolic blood pressure from pre to post-HD over prior 6 months (mmHg)	-10.4 (12)	4.6 (8)	0.005
Percentage of treatments with seated IH in prior 6 months	20 (14)	43 (15)	0.001

Effect of Sodium and Ultrafiltration Modeling vs. Low-Temperature Dialysate on Prevention of Intradialytic Hypotension: Single-Center Study from India

Anil Bhalla,[1] Yogeshman Anand,[2] Devinder S. Rana,[2] Ashwani Gupta,[1] Manish Malik,[3] Anurag Gupta,[4] Vinant Bhargava,[1] Vaibhav Tiwari.[2] *[1]Sir Ganga Ram Hospital, New Delhi, India; [2]Sir Ganga Ram Hospital, New Delhi, India; [3]Sir Ganga Ram Hospital and GRIPMER, New Delhi, India; [4]Synegy Hospital, Uttarakhand, India*.

Background: Symptomatic intradialytic hypotension is the most frequent complication in patients receiving hemodialysis. It complicates 5 to 30 percent of all dialysis treatments. In our study, we aimed to compare the effect of sodium and ultrafiltration modeling versus low-temperature dialysate on the occurrence of intradialytic hypotensive episodes.

Methods: A total of 320 patients with chronic kidney disease (CKD) stage V on conventional hemodialysis (HD) for at least twice weekly for a minimum of 3 months were observed for the occurrence of ≥1 intradialytic hypotensive episodes per month. After full filling the inclusion and exclusion criteria, 60 patients were randomized into two groups based on computer-generated randomization numbers allotted to them by the dialysis coordinator. Group 1: Underwent dialysis with sodium and Ultrafiltration modeling (Linearly decreasing dialysate sodium from 141 mmol/L to 128 mmol/L and linearly decreasing ultrafiltration rate). Group 2: Underwent dialysis with low-temperature dialysate (36 degrees Celsius). Both groups underwent 240 sessions of hemodialysis.

Results: Intradialytic hypotension was found in 18.75 % of patients. Diabetic nephropathy (61.66%) was the leading cause of end-stage renal disease in these patients. There was no significant difference between the two groups in mean arterial blood pressure, hemoglobin, cardiac status, and serum albumin before dialysis. Both groups had a similar incidence of intradialytic hypotensive episodes ($P>0.05$). Interdialytic weight gain and ultrafiltration volume removed per session were also similar in both groups.

Conclusions: Sodium and ultrafiltration modeling and low-temperature dialysate were both equally effective in the prevention of intradialytic hypotensive episodes.

TH-PO218

True Arterial Stiffness Does Not Change Between Dialysis Sessions During 1 Week in Outpatients on Intermitted Hemodialysis

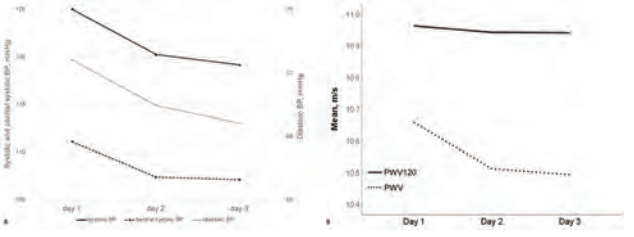
Alexander Reshetnik,[1] Daniel Wrobel,[2] Georg Wirtz,[3] Kai-Uwe Eckardt,[1] Markus van der Giet.[1] *[1]Department of Nephrology and Intensive care medicine, Charité – Universitätsmedizin Berlin, a corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany; [2]DIAVITAL, Kamen, Germany; [3]Dialysezentrum Kamen, Kamen, Germany*.

Background: End-stage renal disease (ESRD) is associated with exponentially elevated cardiovascular mortality. Higher pulse wave velocity (PWV) values are frequently observed in patients with ESRD. However, the intrinsic physiologic relationship between PWV and prevailing arterial pressure can deteriorate its cardiovascular predictive value making an individual pressure-independent expression of PWV essential.

Methods: Dialysis patients from a single outpatient unit obtained repeated measurements of blood pressure (BP) and pulse wave analysis during each dialysis session of one week. Aortic PWV was then adjusted to 120 mmHg central systolic BP based on individually determined relationship.

Results: 54 subjects were included. The median age was 75.5 years. Mean systolic/diastolic BP was 121.4/70.5 mmHg and the median heart rate was 64.6 beats/min. Mean PWV was 10.9 m/s and mean PWV120 was 11.3 m/s. PWV120 did not change across single dialysis session during one week, while systolic, diastolic BP, PWV and ultrafiltration volume differed significantly.

Conclusions: Our data suggest that true AS does not change in the short-term course in dialysis patients and observed changes in PWV are rather associated with BP change due to intrinsic pressure-dependence. Our analytical approach represents a novel method for this purpose, which is easy in performance and also applicable for large interventional trials and clinical practice.



Change in A- systolic, diastolic, central systolic blood pressure (BP) and B- pulse wave velocity (PWV) and PWV adjusted to 120 mmHg central systolic blood pressure (PWV120) between the dialysis days of one week

TH-PO219

Serum Fibroblast Growth Factor 21 Level Is a Risk Factor for Central Arterial Stiffness in Maintenance Hemodialysis Patients

Liang-Te Chiu,[1] Lin Lin,[1] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Fibroblast growth factor 21 (FGF21) is a hepatic hormone in the regulation of glucose and lipid metabolism. Serum FGF21 levels were higher in patients with carotid atherosclerosis and in patients with coronary artery disease. The aim of this study was to evaluate the relationship between serum FGF21 levels and carotid-femoral pulse wave velocity (cfPWV) values in patients on hemodialysis (HD).

Methods: Blood samples and baseline characteristics were obtained from 130 HD patients. Serum FGF21 concentrations were determined by enzyme-linked immunosorbent assay kit. Central arterial stiffness was defined as carotid-femoral pulse wave velocity (cfPWV) values >10 m/s according to the ESH-ESC 2013 guidelines.

Results: Among 130 HD patients, 54 patients (41.5%) were in the central arterial stiffness group. When compared to those in control group, the central arterial stiffness group had high prevalence of diabetes mellitus ($P < 0.001$), hypertension ($P = 0.026$), and older age ($P = 0.036$), higher body weight ($P = 0.027$), body mass index ($P = 0.048$), systolic blood pressure ($P = 0.044$), C-reactive protein ($P = 0.040$), and higher serum FGF21 level ($P < 0.001$). Multivariable logistic regression analysis of the factors significantly associated with central arterial stiffness revealed that FGF21 levels (odds ratio (OR): 1.001, 95% confidence interval (CI): 1.000–1.001, $P = 0.001$), age (OR: 1.043, 95% CI: 1.002–1.085, $P = 0.042$), and diabetes mellitus (OR: 4.495, 95% CI: 1.703–11.867, $P = 0.002$) were the independent predictors of central arterial stiffness in HD patients. Multivariable forward stepwise linear regression analysis also showed that logarithmically transformed FGF21 level (log-FGF21, $\beta = 0.301$, adjusted R^2 change = 0.105, $P < 0.001$) was an independent predictor of cfPWV values in HD patients. The area under the receiver-operating characteristic (ROC) curve predicting central arterial stiffness by serum FGF21 level in HD patients was 0.693 (95% CI: 0.606-0.771, $P < 0.001$).

Conclusions: Serum FGF21 level positively correlated with cfPWV values and is also the independent predictor of central arterial stiffness among HD patients.

TH-PO220

Correlation Between Arterial Stiffness and Body Fat in Hemodialysis Patients

Lulu Wang,[1] Bing Zhuang,[2] Xueqin Bian,[2] Yuan Luo,[2] Hong Ye,[2] Junwei Yang.[2] *[1]Nanjing Medical University, Nanjing, China; [2]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Arterial stiffness is common in chronic kidney disease. It has been known that the traditional risk factors such as ageing, hypertension and diabetes are linked to aortic elasticity. Few studies have focused on peripheral arterial elasticity. Some clinical trials have found a nonlinear relationship between body fat percentage and atherosclerosis in general population. Here, we explore the correlation between body fat and arterial elasticity in hemodialysis patients by measuring a variety of body fat indexes.

Methods: A total of 166 patients on maintenance were included in the study. All subjects underwent arterial elasticity examination and body fat assessment. Basic information of body fat was collected including height,weight,waist circumference, hip circumference, triceps skin fold thickness, and subscapular skin fold thickness. We used human body composition analyzer (Inbody S10) to assess body fat mass, body fat percentage and visceral fat area.

Results: The mean age were 49.9±11.2 years old. Median cfPWV and crPWV was 9.3±2.8 m/s and 9.6±1.7 m/s,respectively. After adjusted to age, sex and other confounding factors, only skin fold thickness(β=-0.041,p=0.022) was associated with cfPWV. Body fat indexes including triceps and subscapular skinfold thickness, BMI, body fat percentage, body fat mass, visceral fat area were significantly negative correlated with crPWV (all p<0.001). We performed a gender- stratified subgroup analysis and found that significant associations between triceps(β=-0.065,p=0.009), subscapular skinfold thickness(β=-0.063,p<0.001)and crPWV were observed in male patients.

Conclusions: The effect of body fat indexes on arterial elasticity was mainly concentrated in peripheral artery. The association between subcutaneous fat and peripheral arterial stiffness significant mainly in males rather than in females.

Post-Dialysis Orthostatic Blood Pressure Is Not Associated with Extracellular Volume in Hemodialysis Patients

Prince M. Aryeetey,[1] L Parker Gregg,[1] Swati Lederer,[3] Michael L. Concepcion,[4] Jeffrey G. Penfield,[5] Peter N. Van Buren.[1,2] *[1]UT Southwestern, Dallas, TX; [2]Dallas VA Medical Center, Dallas, TX; [3]VA North Texas, Dallas, TX; [4]Dallas Veterans Hospital, Dallas, TX; [5]VA North Texas Health Care System, Terrell, TX.*

Background: Blood pressure (BP) measurements are obtained before, during, and after hemodialysis (HD) for safety monitoring. The pattern of intradialytic seated BP changes is becoming recognized as an extracellular volume (ECV) assessment tool. It is unknown if orthostatic BP changes after HD provide information on ECV.

Methods: In a cohort of 55 hypertensive HD patients, we identified those with and without orthostatic BP decreases, defined as a >10 mmHg decrease in systolic BP from seated to standing position (both post-HD). We compared post-HD ECV/body weight using bioimpedance spectroscopy between the groups. We also compared orthostatic BP changes among tertiles of post-HD ECV/weight.

Results: Compared to those with orthostatic decreases (n=26), those without orthostatic BP decreases (n=29) were more likely to be African American. There were no differences in presence of diabetes or distribution of antihypertensive drug class. There were no differences in ECV/weight or cardiac hemodynamics between the groups (Table). There were no differences in orthostatic BP changes among tertiles of ECV/weight (Figure).

Conclusions: We found no associations between ECV/weight and post-HD orthostatic BP changes. Seated to standing BP changes should not be used to diagnose post-HD ECV overload or depletion in HD patients.

Funding: NIDDK Support, Veterans Affairs Support

Differences in Volume and BP Related Variables

Oxygen Extraction Ratio (OER) and Intradialytic Hypotension

Silverio Rotondi, Lida Tartaglione, Sandro Mazzaferro. *Sapienza University of Rome, Roma, Italy.*

Background: Intradialytic hypotension (IDH) worsens treatment tolerance, and outcome of hemodialysis (HD) patients. Attention has been given to the role of HD-induced hypoxia, evaluated by measuring arterial oxygen saturation (SaO2) and central venous saturation (ScvO2), in IDH prone patients. Oxygen Extraction Ratio (OER), the ratio between SaO2 and ScvO2, better than the two parameters alone theoretically describes intra-HD hypoxia. OER basal values and its changes occurring during HD (deltaOER) have been associated with mortality in Hd patients. A delta OER>40% seems to identify patients experiencing sub-clinical hypoxia and parenchymal stress. Aim of our study was to evaluate if delta OER could help identify patients at higher risk of IDH.

Methods: We enrolled clinically stable patients on HD since 3 months, with Central Venous Catheter. we sampled arterial SO2 (oxymeter) and ScvO2 (blood gas analysis) to calculate OER basally and at the end of HD, for three consecutive HD sessions. Average individual measurements were obtained to divide patients into two groups with delta OER > or <40 %. we recorded IDH in each subject, during a 24-months follow-up period.

Results: We divided patients into two group according to delta OER (threshold 40%). The group were not different for age, HD vintage, systolic (SBP) and diastolic blood pressure (DBP) and pulse rate. The group with delta OER >40% had a number of

IDH significantly higher than delta OER<40% group (30±20vs.10±20;p= .011), which was associated with lower pre-HD OER (30±4vs.36±8;p<.025) and similar post HD OER values.

Conclusions: Our study indicates that in HD patients, delta OER associate with IDH, with a threshold value set at >40% the basal value. We suggest that we could use OER to identify patients at higher risk of IDH, deserving more intensive intradialytic monitoring. Regrettably, it is applicable only in patients with CVC.

TH-PO223

High Serum Calcium and Parathyroid Hormone Are Risk Factors of Intradialytic Hypotension in Hemodialysis Patients

Ning Su, Mengjun Liang, Zongpei Jiang. *The Six Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Hypercalcemia and high serum intact parathyroid hormone(iPTH) are involved in the pathogenesis of vascular calcification. But the relationship between hypercalcemia and iPTH with intradialytic hypotension (IDH) is unclear.

Methods: This is a retrospectively cohort study, 922 HD patients were enrolled from 10 HD facilities in China. The patients were categorized into hypercalcemia group and hypocalcemia group according whether the serum corrected calcium levels ≥ 8.67mg/dl (the median of serum corrected calcium in all patients), which were further categorized into high PTH(serum intact PTH>300pg/ml) and low PTH(serum intact PTH≤300pg/ml) groups. Not only the clinic characters, especially the pre and post dialysis blood pressure were analyzed between the four groups, but also the risk factors of IDH were studied by multiple logistic regression in all HD patients.

Results: The prevalence of IDH was much higher in patients of hypercalcemia and high PTH than those of hypocalcemia and low PTH (21.1% vs. 9.6%, p<0.001). Adjusted with age, dialysis vintage, gender, diabetes mellitus, BMI, Kt/V, serum albumin, and hemoglobulin, logistic multiple regression analysis determined that hypercalcemia (OR:2.477, 95%CI: 1.632-3.758, P<0.001) (Model1), and hypercalcemia accompany with high PTH (OR:2.634, 95%CI: 1.378-5.031, P=0.003) (Model2) were risk factors of IDH. Furthermore, increasing ultrafiltration was also risk factor of IDH (Model1OR:1.409, 95%CI: 1.072-1.851, P=0.014; Model2 OR:1.397, 95%CI: 1.061-1.839, P=0.017). However, hemodiafiltration (HDF) was a protective factor of IDH in the patients (Model1 OR:0.441, 95%CI: 0.281-0.693, P<0.001; Model2 OR:0.442, 95%CI: 0.281-0.694, P<0.001).

Conclusions: Not only increasing ultrafiltration, but also high serum calcium and PTH are the risk factors of IDH. Furthermore, the hemodiafiltration will lower the risk of IDH compared with hemodialysis.

Intradialytic Hypertension Increases Non-Access-Related Hospitalization and Mortality in Maintenance Hemodialysis Patients

Tarun K. Jeloka, Gajanan K. Kale, Manishkumar S. Mali, Amit Bhangale, Jaymin P. Somani. *Aditya Birla Memorial Hospital, Pune, India.*

Background: Intradialytic hypertension, in patients on maintenance hemodialysis, is associated with increased morbidity and mortality. This study was aimed to determine the prevalence and outcome of intradialytic hypertension (IDH) in a tertiary care dialysis centre in India.

Methods: This was a prospective analytical study of 120 patients on hemodialysis. At screening phase, all patients were subjected to fluid optimization and adjustment in the antihypertensive medicines for appropriate control of blood pressure (BP). BP measurements during hemodialysis were recorded. The prevalence of IDH was noted. IDH was defined as increase in systolic BP of > 10 mmHg from pre to post hemodialysis or after 2nd hour of dialysis when significant ultrafiltration had occurred, on 3 consecutive sessions. Factors associated with IDH were evaluated and compared with cohort without IDH. The outcome of these patients in terms of morbidity and mortality over a follow up period of 12 months were recorded.

Results: The prevalence of IDH was 21.9%. The baseline demographic parameters of patients in both the groups (with and without IDH) including age, sex, dialysis access, duration of dialysis and comorbidities were similar. Laboratory parameters were similar except serum potassium and serum phosphorus, which were lower in patients with IDH. Out of all the variables studied, only low serum phosphorus was associated independently with IDH. During follow up, at 6 month, 19/71 (26%) non IDH and 12/20 (60%) IDH patients (p = 0.006) and at 12 month, 30/71 (42%) non IDH patients and 12/20 (60%) IDH patients required admission (p = 0.05). Mortality at 6 months was similar, 5/71 (7%) in non IDH and 4/20 (20%) in IDH (p = 0.10) patients, but was higher at 12 months, 11/71 (15.5%) in non-IDH and 8/20 (40%) in IDH (p = 0.028).

Conclusions: Incidence of intradialytic hypertension is high in India (21.9%) with increased morbidity in terms of hospitalization and increased mortality over a period of one year.

TH-PO225

Effect of Impaired Orthostatic Blood Pressure Homeostasis on Brain Network in Patients on Maintenance Hemodialysis

Wenjin Liu,[1] Ruihong Shang,[2] Lulu Wang,[3] Yifan Zhu,[2] Chun Yuan,[1] Xuesong Li,[2] Junwei Yang.[3] *[1]University of Washington, Seattle, WA; [2]Beijing Institute of Technology, Beijing, China; [3]Center for Kidney Disease, Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Patients with renal failure are at excessive risk of developing impaired orthostatic BP homeostasis. We have recently demonstrated that it is associated with memory deficit in dialysis patients. However, the neurobiological basis of this link remains poorly understood. The aim of this study was to evaluate the effect of impaired orthostatic BP homeostasis on brain network in ESKD patients leveraging the advances of graph-theory based network analysis and machine learning.

Methods: This is a data-driven analysis of the baseline neuroimaging data from an ongoing prospective cohort study which has enrolled 166 dialysis patients. Patients were excluded if they had a previous history of stroke or any other neurologic disease.

Results: Orthostatic BP reduction was defined as seated systolic / diastolic BP minus the minimum of three standing systolic / diastolic BPs. Functional, structural, and diffusion MRI data sets were obtained with a 3T scanner. After preprocessing, we constructed the whole-brain structural and functional networks using GRETNA software. We combine powerful MRI and machine learning to decode the relationship. Whole-brain structural connectivity (SC) and SC strength (SCs) were extracted as prediction features. After selecting significant features by Pearson coefficient from 141 participants, we use Extremely Randomized Tree model and the predict error is measured by Mean absolute error, Mean Square Error or corrections between actual and predicted values. By using the most accurate predicting model, we further investigate the biologic essence provided by

the predicting model. The data showed that the connections of BG-MTG and Amyg-FuG is stronger than other regions in predicting systolic orthostatic blood pressure reduction, while the connections strength in Amyg-pSTS holds the major contribution in predicting diastolic reduction.

Conclusions: Our analysis suggests that impaired orthostatic BP homeostasis has a significant effect on brain network in dialysis patients. These results provide further insight into the association between orthostatic hypotension and cognitive impairment and indicate that maintaining orthostatic homeostasis might be an effective strategy for the prevention of cognitive decline in the patients.

TH-PO226

Pilot Study to Measure Indicators of Blood Flow in the External Auditory Meatus During Haemodialysis

Suree Yoowannakul,[1] Terence Leung,[2] Andrew Davenport.[3] *[1]Bhumibol Adulyadej Hospital, Bangkok, Thailand; [2]University College London, London, United Kingdom; [3]Royal Free Hospital, London, United Kingdom.*

Background: Intradialytic hypotension remains the most common complication of outpatient haemodialysis (HD) sessions. As such, there is a need to develop non-invasive monitoring devices, which would then allow for therapeutic interventions to prevent hypotension. We report on a pilot study monitoring indicators of blood flow in the outer auditory meatus.

Methods: We measured the maximum pulse wave amplitude and indicators of blood flow by red and green pixel values in the outer auditory meatus from video recordings made using an otoscope fitted with a digital camera in adult patients undergoing haemodialysis treatments.

Results: We studied 61 patients, 43 (71.5%) male, mean age 64.9 ± 12.7 years during their dialysis session. Weight fell from 72.8±22.5 pre-dialysis to 71.5±22.1 kg post-dialysis ($p<0.001$). Blood pressure did not significantly change (pre-dialysis 142±29/67±18 to 143±25/68±17 mmHg post-dialysis). The maximum pulse wave amplitude in the external auditory meatus fell from 0.21 (0.1-0.55) to 0.14 (0.04-0.4) after 90 minutes, $p<0.001$, and remained low thereafter, and the change at the end of the dialysis session was associated with percentage weight loss ($r= -0.37$, $p=0.003$). Green and red pixel values did not change (pre-dialysis 0.339 (0.333-0.345) to 0.302 (0.291-0.33) post, and 0.301 (0.293-0.328) pre-dialysis to 0.339 (0.334-0.347), respectively).

Conclusions: This pilot study showed that the maximum pulse wave amplitude measured in the external auditory meatus fell during the dialysis session, and that the fall was associated with fluid removal. This could potentially lead to the development of a monitoring device which could fit in the ear and record during the dialysis session.

Uric Acid Distribution Adjusted by Urea Distribution Volume Is a Promising Marker of Hydration Status in Hemodialysis Patients

Norio Hanafusa,[1] Shunji Suzuki,[2] Kenichi Akiyama,[1] Daigo Kamei,[1] Nobue Tanaka,[1] Misao Tsukada,[3] Kosaku Nitta,[1] Ken Tsuchiya.[1] *[1]Tokyo Women's Medical University, Shinjuku-ku, Japan; [2]Tokyo Woman Medical University, Tokyo, Japan; [3]Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Hemodialysis (HD) patients are prone to developing volume disturbance. Bioelectrical impedance analysis (BIA) provides indices for evaluating volume status, although this requires a dedicated machine, which precludes it from other general clinical use. Uric acid (UA) barely crosses the cell membrane, while urea does so readily. The volume of distribution (Vd) of UA and urea can be considered markers of extracellular water (ECW) and total body water (TBW), respectively. We investigated whether the ratio of the Vd of UA and urea (V_{UA}/V_{UN}) can be a surrogate marker of ECW/TBW measured by BIA.

Methods: In total, 108 patients who were receiving HD at our facility and who underwent BIA in 2018 were included in this study. V_{UA}/V_{UN} was calculated using the single-pool model. We compared ECW/TBW values after dialysis measured by BIA (InBody S10; InBody, Tokyo, Japan). We investigated factors associated with residuals from regression. We also evaluated the predictive ability of overhydration (ECW/TBW ≥ 0.4) or dehydration (ECW/TBW < 0.38) in two randomly selected groups, the training group and the validation group.

Results: V_{UA}/V_{UN} and ECW/TBW were 0.646 ± 0.062 and 0.393 ± 0.014, respectively. ECW/TBW was highly correlated with V_{UA}/V_{UN} (ECW/TBW = 0.274 + 0.184* V_{UA}/V_{UN}). Multivariate analysis demonstrated that only creatinine and ECW/TBW were significantly associated with the regression residuals. The cut-off values of V_{UA}/V_{UN} for overhydration and dehydration were 0.666 and 0.579, respectively, in the training group. The corresponding area under the receiver operating characteristic curves were 0.872 and 0.898, respectively. The sensitivity and specificity values in the validation group were 0.571 and 0.868 for overhydration and 0.444 and 0.953 for dehydration, respectively.

Conclusions: V_{UA}/V_{UN} was not only associated with ECW/TBW but was also highly predictive of hydration status evaluated by BIA. We need only blood tests before and after the dialysis session for estimating V_{UA}/V_{UN}, so this measure is widely applicable, even in epidemiological studies, without the need for dedicated devices.

TH-PO228

Ambulatory Blood Pressure Monitoring and Other Blood Pressure Measures in the BID (Blood Pressure in Dialysis) Pilot Study

Ambreen Gul,[1] Antonia Harford,[1] Dana Miskulin,[2] Huan Jiang,[1] S. Paine,[1] V. Shane Pankratz,[3] Saeed K. Shaffi,[4] Philip Zager.[1] *[1]Dialysis Clinic Inc, Albuquerque, NM; [2]Tufts Medical Center, Boston, MA; [3]UNM Health Sciences Center, Albuquerque, NM; [4]University of New Mexico, Albuquerque, NM.*

Background: Ambulatory blood pressure monitoring (ABPM) is the gold standard for diagnosis and management of hypertension. However, poor adherence limits its use in clinical practice. In the BID pilot, we used predialysis standardized dialysis unit systolic blood pressure (SDUSBP) to drive BP management. We also compared this measure to ABPM, standardized home SBP (SHSBP), intradialysis SBP (IDSBP), and postdialysis SBP (PDSBP).

Methods: The BID protocol called for a 44-hour ABPM after the mid-week dialysis at baseline and quarterly in 5 geographic hubs, SDUSBP before each dialysis, SHSBP weekly the day after the mid-week HD treatment and also IDSBP and PDSBP with each treatment. Outcomes included the quantitative differences between these measures and their ability to predict left ventricular hypertrophy (LVH) on cardiac MRI at baseline and quarter four by analyzing the area under receiver operator characteristic (ROC) curves (AUC).

Results: Ninety-four out of 95 patients and 53 out of 84 patients eligible for ABPM, had both an ABPM and cardiac MRI at baseline and in quarter 4 respectively. The differences between average daytime SBP on ABPM vs. other measures in quarter 4 were as follows 1) SDUSBP – 3.36 (95% CI -8.72, 2.00) mm Hg; 2) IDSBP 1.63 (95% CI -2.73, 5.99) mm Hg and 3) PDSBP 1.40 (95% CI -2.90, 5.71) mm Hg. Forty-four patients in quarter 4 had ABPMs in addition to SHBP measurement. Mean difference between average day SBP on ABPM vs. SHSBP was 0.35 (95% CI -5.45, 6.16) mm Hg. The AUCs used to compare the ability of the different BP measures to predict LVH are shown.

Conclusions: Although difference between daytime SBP on ABPM and SDUSBP were higher than the other measures, the differences were modest. HSBP, IDSBP and PDSBP demonstrated similar values when compared to ABPM. ABPM was the strongest and SDUSBP the weakest predictor of LVH. Dialysis units should encourage adherence with ABPM and HBP measurements.

Funding: NIDDK Support, Commercial Support - Dialysis Clinic, Inc

AUC for relationship of different BP measurements with LVH

BP Measure	Systolic BP AUC (95% CI)	Diastolic BP AUC (95% CI)
ABPM at baseline	0.77 (0.65, 0.88)	0.70 (0.58, 0.82)
ABPM in quarter 4	0.71 (0.55, 0.87)	0.74 (0.57, 0.90)
HSBP	0.61 (0.44, 0.79)	0.69 (0.51, 0.86)
SDUBP	0.51 (0.32, 0.69)	0.64 (0.47, 0.82)
Intradialytic BP	0.62 (0.45, 0.79)	0.61 (0.44, 0.79)
Post Dialysis BP	0.67 (0.51, 0.84)	0.67 (0.50, 0.83)

Higher Dialysis Dose and Less Intradialytic Hypotension Are Associated with Improvements in Longitudinal Changes in Dialysis Recovery Time

Murilo H. Guedes,[5] Roberto Pecoits-Filho,[5] Juliana E. Leme,[5] Yue Jiao,[2] Jochen G. Raimann,[3] Yuedong Wang,[4] Peter Kotanko,[3,7] Thyago P. Moraes,[5] Ravi I. Thadhani,[6] Franklin W. Maddux,[1] Len A. Usvyat,[2] John W. Larkin.[2,5]
[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]University of California - Santa Barbara, Santa Barbara, CA; [5]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [6]Cedars-Sinai, Los Angeles, CA; [7]Icahn School of Medicine at Mount Sinai, New York, NY.

Background: We studied if higher hemodialysis (HD) dose and less intradialytic hypotension (IDH) would associate with longitudinal improvements in dialysis recovery time (DRT).

Methods: We used data from adult HD patients at a large dialysis organization who responded to DRT survey ≤180 days from first date of dialysis (FDD) during 2014 to 2017. DRT survey asks: "How long does it take you to be able to return to your normal activities after your dialysis treatment?". Answers are: <0.5, 0.5-1, 1-2, 2-4, or >4 hours. A logistic regression model computed odds ratio for increased/maintained longer DRT (increase above DRT >2 hours) in reference to decreased/maintained shorter DRT (decrease below DRT <2 hours, or from DRT >4 hours). Changes in DRT were calculated from incident (≤180 days FDD) to prevalent (>365-to-≤545 days FDD) year. Model included/adjusted for incident DRT, age, comorbidities, HD with IDH episodes/month, Kt/V, and HD start before/after 1200 hours.

Results: Among 98616 incident HD patients (age 62.6±14.4 years), higher incident spKt/V associated with 13.5% (OR=0.865; 95%CI 0.801-to-0.935) lower odds of increased/maintained longer DRT in the prevalent year (Figure 1). A higher incident number of HD sessions with IDH episodes/month and change to a higher number associated with 0.8% (OR=1.008; 95%CI 1.001-to-1.015) and 2.2% (OR=1.022; 95%CI 1.015-to-1.028) higher odds of increased/maintained longer DRT in the prevalent year, respectively.

Conclusions: Incident patients who had higher spKt/V with a low number of HD sessions with IDH episodes had a lower likelihood of increased/maintained longer DRT in first year of HD. Dose optimization strategies with cardiac stability in fluid removal should be tested.

Funding: Commercial Support - Fresenius Medical Care North America

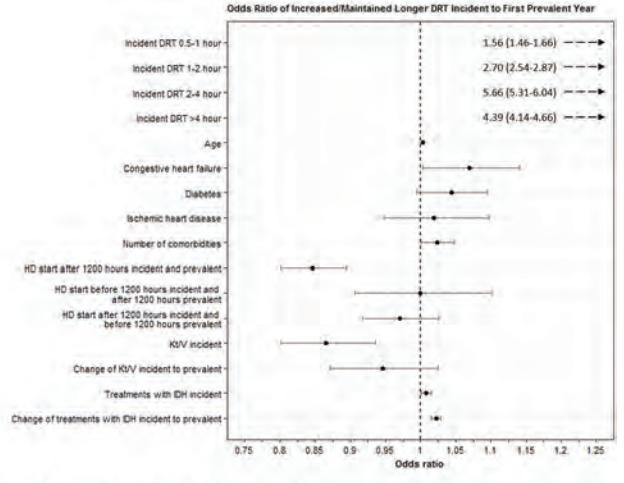

Figure 1: Forest plot of odds ratio and confidence intervals for variables associated to increased/maintained longer DRT from the incident to first prevalent year in reference to a decreased/maintained shorter DRT.

Fluid Overload and Obstructive Sleep Apnea in Hemodiafiltration

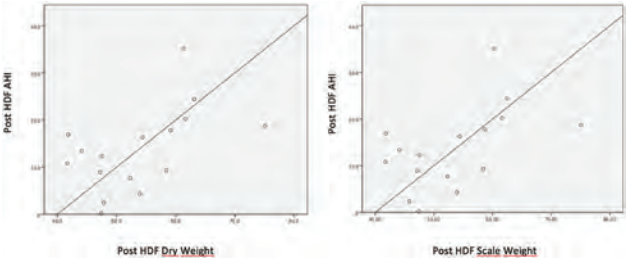
Marcos G. Nava, Jennifer D. Escobar alvarado, Gabriela Leal, Hector P. Grovas, Francisco eugenio R. Castellanos, Julio Sandoval zarate, Magdalena Madero.
Instituto Nacional de Cardiologia, Ciudad de Mexico, Mexico.

Background: Obstructive sleep apnea (OSA) seems to be more common in patients with end-stage renal disease (ESRD) than in the general population with a prevalence as high as 50 to 70%.Fluid overload leading to greater accumulation in the neck when supine may contribute to increased upper airway collapsibility. The aim of the study was to evaluate the impact of ultrafiltration on the apnea-hypopnoea index (AHI) in prevalent hemodiafiltration (HDF) patients.

Methods: We included patients from the HDF unit at the Instituto Nacional de Cardiologia from July 2018 to April 2019. Bioimpedance and overnight polysomnography were done the day before and the day after HDF. The primary outcome was AHI index. T test was used for within group comparisons (pre and post HDF) and Rho Spearman was used for correlations.

Results: 16 patients were included, 10 had mild AHI, 3 moderate AHI and 3 had severe AHI. After HDF, 11 patients improved the number of apnea/hyponea events. Patients with severe AHI significantly improved after HDF (38±6.4 to 25.2±9.4, p=0.03). Total body water/ extracellular relationship (TBW/ECW), thoracic TBW/ECW, scale and dry weight were all significantly associated with AHI improvement. There was a significant correlation between AHI and post HDF weight scale and dry weight (r = 0.56, p = 0.022 and r= 0-59, p = 0.016 respectively)(Figure).

Conclusions: AHI is improved with HDF, in particular in those with moderate and severe OSA. Volume overload appears to contribute to OSA in this population.



TH-PO231

Patient-Reported Quality of Life in Dialysis Compared with Non-Dialysis CKD Patients with Hyperkalemia in the United States and European Union 5: Results from the KDQOL

Eskinder Tafesse,[2] James Jackson,[1] Rebecca Moon,[1] Gary R. Milligan,[1] Jennifer Kim.[2] *[1]Adelphi Real World, Macclesfield, United Kingdom; [2]AstraZeneca, Gaithersburg, MD.*

Background: Patients with chronic kidney disease (CKD) have an increased risk of hyperkalemia (HK), which increases with CKD progression. Patients on hemodialysis report negative impact to quality of life (QoL), though evidence is limited. The increased risk of HK and associated morbidity and mortality may further add to patient burden.

Methods: Data from the 2015 and 2018 Adelphi CKD Disease Specific Programmes were pooled to create a cross-sectional dataset of patients, including data from physicians and their CKD patients across France, Germany, Italy, Spain, the UK and USA. Patients completed the KDQOL, a measure targeted at specific concerns of individuals with CKD. A multiple linear regression was performed, for each of the 5 KDQOL domains, to study the association between non-dialysis dependent (NDD) patients with HK (K^+ >5.0 mmol/L), DD patients without HK (K^+ 3.5-5.0 mmol/L) and DD patients with HK to a reference group of NDD patients without HK (and their interaction), adjusting for age, sex, eGFR level, and presence of heart failure and diabetes.

Results: Results from 1,242 patients showed an incremental decrease in QoL across each patient group for 2 of the 5 KDQOL domains. When compared to the reference group, NDD patients with HK experienced significantly poorer QoL across all 5 of the KDQOL domains. However, DD patients with HK experienced an additional significant deterioration in QoL across 4 of the 5 domains, compared with NDD patients without HK (Table 1).

Conclusions: This study highlights the negative impact that HK contributes to CKD patients, leading to further decrements in QoL, particularly among DD CKD patients. Innovative HK treatment approaches should be an important consideration by physicians to contribute to improved QoL in this patient population.

Funding: Commercial Support - AstraZeneca

Table 1: KDQOL values vs. CKD and Hyperkalemia Status

KDQOL domains, mean (n)	NDD without HK	NDD with HK	DD without HK	DD with HK
Burden of kidney disease	62.44 (774)	57.61 (178); p=0.030	44.78 (190); p=<0.001	46.96 (100); p=<0.001
Symptoms/problems	83.67 (760)	80.03 (177); p=0.012	78.60 (188); p=0.005	76.77 (101); p=0.002
Effect of kidney disease	78.42 (759)	69.68 (174); p=<0.001	68.29 (186); p=<0.001	61.26 (100); p=<0.001
SF-12 physical summary score	41.81 (741)	39.37 (171); p=0.002	38.30 (178); p=<0.001	38.39 (98); p=0.005
SF-12 mental summary score	47.42 (741)	45.53 (171); p=0.025	45.33 (178); p=0.050	45.85 (98); p=0.020

lower scores represent poorer quality of life; p-values show the comparison to the reference group

TH-PO232

Quality of Life in Caregivers of Patients Receiving Standard vs. Extended Hours Hemodialysis: The Co-ACTIVE Substudy of the ACTIVE Dialysis Trial

Melissa S. Nataatmadja,[1,2] Rathika Krishnasamy,[1,2] Li Zuo,[3] Daqing Hong,[4,5] Brendan Smyth,[5,8] Min Jun,[5] Janak de Zoysa,[6,7] Kirsten Howard,[8] Lu Chunlai,[9] Vlado Perkovic,[5] Meg J. Jardine,[5,10] Nicholas A. Gray.[1,2] *[1]Department of Nephrology, Sunshine Coast University Hospital, Birtinya, QLD, Australia; [2]School of Medicine, The University of Queensland, Herston, QLD, Australia; [3]Peking University People's Hospital, Beijing, China; [4]Sichuan Provincial People's Hospital, Chengdu, China; [5]The George Institute for Global Health, Sydney, NSW, Australia; [6]Renal Service, Waitemata District Health Board, Auckland, New Zealand; [7]Department of Medicine, University of Auckland, Auckland, New Zealand; [8]University of Sydney, School of Public Health, Sydney, NSW, Australia; [9]Department of Nephrology, Shanghai 85th Hospital, Shanghai, China; [10]Department of Renal Medicine, Concord Repatriation General Hospital, Sydney, NSW, Australia.*

Background: Caregivers of dialysis patients experience significant burden and lower quality of life (QOL) compared to the general population. Extended hours dialysis has benefits for the patient, however little is known about its effects on caregivers.

Methods: We evaluated QOL amongst caregivers of the ACTIVE Dialysis trial participants who were randomised for 12 months to receive extended (median 24 hours/week) or standard (12 hours/week) hemodialysis. Caregivers completed the EuroQOL-5 Dimension-3 Level (EQ5D-3L), Short Form-36 (SF-36) physical component summary (PCS), mental component summary (MCS) and SF-6D, and Personal Wellbeing Index (PWI). Primary outcome was change in QOL scores from study entry to follow-up.

Results: A total of 40 participated in this longitudinal study. Most caregivers were female (64%) and Asian (94%). At baseline, QOL scores in caregivers of patients randomised to standard and extended hours hemodialysis were similar (Table 1). At follow-up, there was a significant difference in the mean change in EQ5D-3L between those allocated to standard versus extended hours dialysis (-0.022±0.16 vs -0.197±0.30, p=0.04). There were no differences between standard and extended hours groups in mean change in PCS (-5.6±9.8 vs -1.2±9.8, p=0.2), MCS (-0.5±7.1 vs -4.1±11.2, p=0.4), SF-6D (-0.04±0.1 vs 0.03±0.12, p=0.8) or PWI (0.00±20.4 vs -2.3±17.6, p=0.9).

Conclusions: Our study found significantly poorer health utility amongst caregivers of patients randomised to extended hours dialysis, but no difference in QOL measures. This suggests extended hours dialysis may have a negative impact on caregivers, although our study has a number of limitations including small sample size and short follow-up, and the results should be regarded as exploratory. Further studies are needed to better understand the impact of dialysis on caregivers to inform the provision of support services.

Table 1. Baseline characteristics of caregivers in the Co-ACTIVE study

	Standard (n=16)	Extended (n=24)	p-value
Mean age, years (SD)	54.6 (10.3)	53.4 (13.0)	0.9

TH-PO233

Travel Arrangements in In-Center Hemodialysis: A Qualitative Study

Janewit Wongboonsin, Joseph R. Merighi, Paul E. Drawz. *University of Minnesota, Minneapolis, MN.*

Background: For people with end-stage renal disease, "travel" and "independence" are rated as 2 of the top 5 factors that inform their treatment modality choice. The limits imposed by in-center hemodialysis (IHD) treatment can present a variety of challenges for patients who wish to travel. This exploratory study investigated how IHD patients managed their travel and the role of dialysis social workers in executing travel arrangements for patients.

Methods: An interview-based, qualitative study was conducted with IHD patients being treated at a University-affiliated hospital and community-based dialysis social workers. Patients were screened from an inpatient nephrology consult panel and, after enrolling in the study, provided contact information for their dialysis social workers. Two coders used a grounded theory (constant comparative) approach to analyze the data from verbatim transcriptions.

Results: Sixteen patients and eight social workers were enrolled in the study. The patient sample included 8 women (50%), 13 whites (81.3%), and a mean dialysis vintage of 5 years. The social worker were all women and had a mean of 6 years of practice experience. Three overarching themes emerged from the interviews: the process, barriers, and facilitators of travel. The travel process subthemes included communication, dialysis schedule, and travel itinerary. The barrier and facilitator subthemes were categorized into patient, dialysis unit, and supporting factors. These subthemes addressed caregiver roles, being flexible, staff professionalism, and managing unanticipated situations. Overall, there was lack of uniform infrastructure and understanding regarding the travel process at the patient level, provider level, and system level.

Conclusions: This study identified multiple perspectives surrounding travel arrangements in chronic IHD patients. There is limited research on travel issues for chronic IHD patients and this investigation is among the first to articulate barriers and facilitators associated with travel from the perspective of patients and social workers. Promoting and supporting travel for IHD patients can serve to increase their sense of autonomy and provide opportunities to improve their quality of life.

TH-PO234

Hemodialysis Transportation, Compliance, and Quality of Life

Yevgeniy Borshchenko, Antonia Tharian, James Drakakis, Naveed N. Masani, Minesh Khatri, Candace D. Grant. *Nephrology, NYU Winthrop Hospital, Mineola, NY.*

Background: A common reason for nonadherence to hemodialysis (HD) treatments is difficulty with transportation. This difficulty can also be the catalyst for mental stress surrounding getting to the dialysis unit on time. Health disparities reflect social, economic, and/or environmental disadvantages. As modality used for transportation is dependent on a patient's socioeconomic status, it can be related to health disparities. Identifying how transportation modality affects adherence to HD regiments and a patients perceieved quality of life can hopefully lead to improved strategies in HD transportation and improve clinical outcomes for all HD patients. We examined transportation modality, HD treatment compliance and its relationship with quality of life.

Methods: We reviewed the electronic charts of patients enrolled at our large hospital based non-profit dialysis network. We identified eligible patients that had documented transportation modality and Kidney Disease and Quality of Life (KDQOL-36) scores as well as health insurance information. HD compliance was calculated for the group between April 2014 to April 2018. The modes of transportation were designated as self/family (SF), ambulance/ambulette (AMB) and Taxi/AbleRide (TX). Health insurance was divided into three groups: Medicare (MCR), Medicaid (MCD) and private insurance/self-pay (PVT).

Results: The study population (n=249) was 46% white, 60% male, and had a median age of 62 years. The average compliance for the group was 91.6% with 76% of the patients at or above 90% compliance. 60%, 15% and 25% of the patients had MCR, MCD, or PVT insurance respectively. HD compliance by primary insurance varied at 93.3%, 92.14%, and 86.46%, for PVT, MCR and MCD, respectively (P<0.01). The average compliance was 92.7%, 90.8%, and 87.8% for travel by SF, AMB, and TX, respectively. There was a significant difference in the MCS component of the KDQOL-36 among the different modes of transportation with 48.4±10.4, 49.8±9.5, and 52.5±9.6, for travel by AMB, TX, and SF, respectively (p<0.02).

Conclusions: Our findings suggest that health insurance and transportation modality plays a significant role in hemodialysis treatment compliance. Transportation modatlity also plays a significant role in the mental health component of the KDQOL survey. Further prospective studies are required to confirm these relationships.

TH-PO235

Assessing the Impact of Hyperkalemia on the Quality of Life of Dialysis Patients Compared with Non-Dialysis Patients: Results from a Real-World Study in the United States and European Union 5

Eskinder Tafesse,[2] James Jackson,[1] Rebecca Moon,[1] Gary R. Milligan,[1] Jennifer Kim.[2] *[1]Adelphi Real World, Macclesfield, United Kingdom; [2]AstraZeneca, Gaithersburg, MD.*

Background: Patients with chronic kidney disease (CKD) are at increased risk for hyperkalemia (HK), which increases with CKD disease severity. Quality of life (QoL) may be impacted by the presence of HK, which is associated with greater risk of sudden cardiac death and hospitalization among hemodialysis patients. Only limited data exists on the impact of HK on the QoL of CKD patients who are dialysis dependent (DD) compared with non-dialysis dependent (NDD) patients, with and without HK.

Methods: Data from the 2015 and 2018 Adelphi CKD Disease Specific Programmes were pooled and analyzed. These real-world surveys collected data from physicians and patients with CKD in France, Germany, Italy, Spain, the UK and the USA. Patients completed the EuroQol-5D-3L (EQ-5D) questionnaire and the EuroQol visual analog scale (EQ-VAS). Physicians provided data on patient demographics, disease characteristics and comorbidities. A multiple linear regression was performed for EQ-5D utility and EQ-VAS to assess the association between NDD patients with HK (K^+ >5.0 mmol/L), DD patients without HK (K^+ 3.5-5.0 mmol/L), and DD patients; with HK to a reference group of NDD patients without HK (and their interaction), adjusting for age, sex, eGFR level, HF and diabetes.

Results: NDD patients with HK (n=176) had a significantly lower mean EQ-5D utility score than NDD patients without HK (n=766) (0.788 vs. 0.825; p=0.039). DD patients with HK (n=100) reported an additional deterioration in mean EQ-5D utility scores compared with NDD patients without HK (0.755; p=0.009) indicating poorer health status among this cohort. EQ-VAS mean scores also showed a significantly poorer QoL for NDD patients with HK (n=175) compared to NDD patients without HK (n=766; 64.7 vs. 67.5; p=0.048). Further reduction in QoL was observed for DD patients with HK (n=100) (62.3 vs. 67.5; p=0.015), compared with NDD patients without HK.

Conclusions: HK is associated with reduced EQ-5D health state utility scores in CKD patients. DD patients with HK experienced significantly greater negative impact on their QoL compared with NDD patients without HK. New therapeutic options and effective management of HK in DD CKD patients may positively improve QoL in this population.

How Does Starting Dialysis Impact Quality of Life in Patients and Their Partners? A Longitudinal Study

Currie R. Moore,[1] Lesley-Anne Carter,[1] Alison J. Wearden,[1] Suzanne M. Skevington,[3] Sandip Mitra.[2] *[1]University of Manchester, Manchester, United Kingdom; [2]Manchester University Hospitals, UK, Sale, United Kingdom; [3]Univ. of Manchester, UK, Bath, United Kingdom.*

Background: For patients and their families, quality of life (QOL) while on dialysis is of central importance. Despite this, limited research exists on how (QOL) changes as patients transition onto dialysis. The present study aimed to investigate changes in QOL in renal patients and their partners (spouses or significant others) during the critical period of preparing for dialysis and over the first 12 weeks on dialysis. We also aimed to determine whether psychosocial factors measured during pre-dialysis can predict QOL outcomes 12 weeks after starting dialysis.

Methods: 10 renal units in England took part in this observational, longitudinal study. 88 couples completed baseline questionnaires during pre-dialysis; 50 couples completed follow-up questionnaires at 6 weeks after starting dialysis; and 40 couples completed further follow-up questionnaires at 12 weeks after starting dialysis. At each time point patients and their partners completed a QOL questionnaire (WHOQOL-BREF), study specific questionnaires on psychosocial factors (Expectations, Accepting Dialysis, and Patient-Partner Relationship Characteristics), affect (HADS), and symptoms (POS-S Renal or Generic).

Results: Preliminary analyses show significant positive changes in QOL in patients from pre-dialysis to 6 weeks (b=0.3, p <0.001, 95% CI (0.17, 0.45). No significant differences were found in changes in partners' scores over this time period (b=0.2, p=0.134, 96% CI (-0.1, 0.6)). QOL remained steady over the subsequent 6 weeks (patients b=0.2, p=0.357, 95% CI (-0.2, 0.5); partners b=-0.1, p=0.793, 95 %CI (-0.5, 0.4)). Further analyses will be conducted once data collection concludes in June 2019. Multi-level modelling will be used to estimate the changes in QOL between patients and partners. Baseline scores on the psychosocial factor scales will then be tested as predictors of QOL outcomes at 12 weeks.

Conclusions: This research is one of the first to investigate QOL in patients and their partners as they transition onto dialysis and to explore the impact of psychosocial variables on QOL. These findings could assist renal clinicians in targeting couples who may need support and may suggest the key psychological and relationship factors which will facilitate better QOL during this stressful period.

TH-PO237

Effectiveness of Decision Aids in Promoting Knowledge and Shared Decision Around Treatment for ESRD: A Systematic Review and Meta-Analysis

Bjoerg Thorsteinsdottir,[1] Aditya S. Pawar,[1] LaTonya J. Hickson,[1] Cristina Wirtz,[1] Navdeep Tangri,[2] Nilay D. Shah.[1] *[1]Mayo Clinic, Rochester, MN; [2]Department of Medicine, Seven Oaks General Hospital, University of Manitoba, Winnipeg, MB, Canada.*

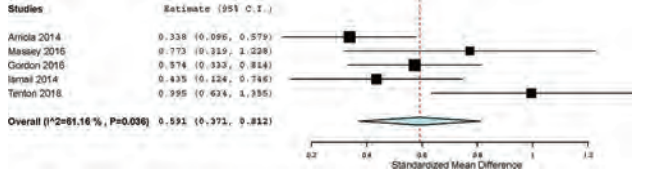
Background: Renal replacement therapy (RRT) for end stage renal disease (ESRD) is a preference-sensitive decision yet patients do not perceive they have a choice. Guidelines have called for increased shared decision making in this space especially for higher risk patients for whom there is equipoise regarding the balance of benefits and harms. Decision aids have been proposed to ensure goal concordant care. We systematically reviewed the performance of decision aids for ESRD treatment choice.

Methods: Multiple databases were searched for comparative studies of using decision aids to help advanced kidney failure patients choose between different types of RRT from inception to January 30, 2018. PRISMA guidelines were followed with two reviewers independently screening abstracts, performing full text assessment of inclusion criteria and extracting study design, outcomes and risk of bias.

Results: Of 1083 articles screened and 90 reviewed in full text, 10 were included, tested in a total of 1114 patients (range 35-569). There was great heterogeneity of measured and reported outcomes and few used validated tools. Pre-planned meta-analyses of knowledge showed significant increase in standardized mean difference of 0.598 but with high heterogeneity I^2 61%.

Conclusions: Decision aids appear to increase patient knowledge in ESRD but their outcome reporting is heterogeneous which limits the strength of inferences. To move the field forward, international consensus is needed on the most meaningful outcome measures and best practices in future decision aid research.

Funding: NIDDK Support, Other NIH Support - National Institute on Ageing K23AG051679 (B.T.); and National Institutes of Health National Institute of Diabetes and Digestive and Kidney Diseases grant K23 DK109134 (L.J.H.).



TH-PO238

Week-to-Week Variability of Dialysis Recovery Time

Wael F. Hussein,[1,2] Vishal Duggal,[2,1] Sumi J. Sun,[1] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Department of Medicine, Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA.*

Background: Fatigue is identified by patients as a priority for research. Post-dialysis fatigue is common and associated with poor outcomes. Unpredictability of symptoms worsens the impact of these symptoms on patients. In a previous study, we prospectively recorded weekly dialysis recovery time (DRT) for four weeks in patients with prolonged DRT at baseline [Duggal et al. HDI. 2019]. Here, we report on the weekly variability of DRT in these patients.

Methods: Patients with DRT data from all four weeks were included in this study. We hypothesized that a change in DRT of four hours or more from the previous week was a significant fluctuation to impact symptom predictability and patient's ability to plan activities after dialysis. We report on the proportion of patients who had at least two such fluctuations during the follow-up period. In addition, we report on within-patient week-to-week variability using within-patient ranges, standard deviations (SD), coefficients of variation and mean absolute differences (MAD).

Results: Seventy-four patients were included in this analysis; median age 64 years (IQR: 59 - 75), 32% female. During the follow-up period, 26% of patients had at least two recorded DRTs that were four hours or more different from the prior week. Median within-patient week-to-week DRT range, SD and MAD were 525 (180-960), 230 (77 – 464) and 209 (80 – 440) minutes respectively, and the coefficient of variation was 0.48 (0.22 – 0.87).

Conclusions: Among patients with long recovery time at baseline, we report substantial variability in week-to-week DRT. These fluctuations in symptoms increase the burden on hemodialysis patients. More attention is needed to study the variability of symptoms and its burden in terms of extent and effect.

TH-PO239

The Impact of Extended Hours Haemodialysis on Quality of Life, Vascular Access, Mortality, and Residual Renal Function: Systematic Review and Meta-Analysis

Katherine L. Hull,[1,2] Daniel S. March,[2] Darren R. Churchward,[2] Matthew P. Graham-Brown,[1,2] James Burton.[1,2] *[1]John Walls Renal Unit, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [2]Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom.*

Background: Patients with end-stage renal failure on conventional haemodialysis (CHD) experience significant morbidity and mortality. There is increasing evidence that extending weekly haemodialysis (HD) time is associated with improvements in quality of life (QoL), biochemical and cardiovascular parameters, and mortality. However, there is concern that increasing HD duration or frequency accelerates the loss of residual renal function (RRF) and increases vascular access adverse events. This systematic review aims to determine the impact of extended HD in comparison to CHD on QoL, vascular access events, mortality and RRF.

Methods: Randomised and non-randomised controlled trials of adult prevalent HD patients comparing extended hours HD (> 12 hours of HD in 1 week) to CHD were eligible. Outcomes of interest were quantitative measures of QoL, vascular access adverse events, all-cause mortality and RRF. Data from randomised and non-randomised trials were pooled separately using a random-effects model.

Results: 476 patients from 6 trials were eligible. The number of trials available for meta-analysis varied for each outcome. There was no significant change in QoL when comparing extended HD to CHD (SF-36 PCS standardised mean difference 0.61, 95% CI -0.10 to 1.31, *P*=0.09, SF-36 MCS standardised mean difference -0.04, 95% CI -0.61 to 0.54, *P*=0.90). There was no significant change in vascular access adverse events (relative risk ratio 1.25, 95% CI 0.88 to 1.77, *P*=0.21) or mortality (relative risk ratio 2.29, 95% CI 0.60 to 8.71, *P*=0.22). RRF was only assessed in one report which demonstrated a potential reduction over 12 months with extended HD, however, RRF was not a pre-specified secondary outcome. All trials had a high risk of bias.

Conclusions: In this systematic review, we demonstrated no significant difference between extended HD and CHD on QoL, adverse vascular access events and mortality. There was only a single trial with data regarding the changes in RRF. The majority of the included trials were either low or very low in quality. This supports the need for further adequately powered randomised controlled trials.

Comparison of Approaches to the Identification of Symptom Burden in Hemodialysis Patients Utilizing Electronic Health Records

Lili Chan, Kelly H. Beers, Kinsuk Chauhan, Neha Debnath, Pattharawin Pattharanitima, Steven G. Coca, Tielman T. Van Vleck, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Symptoms are common in patients on maintenance hemodialysis (HD), however identification within the electronic medical record (EMR) is challenging. Natural language processing (NLP) can be utilized to identify symptoms from narrative clinical documentation by physicians and other providers.

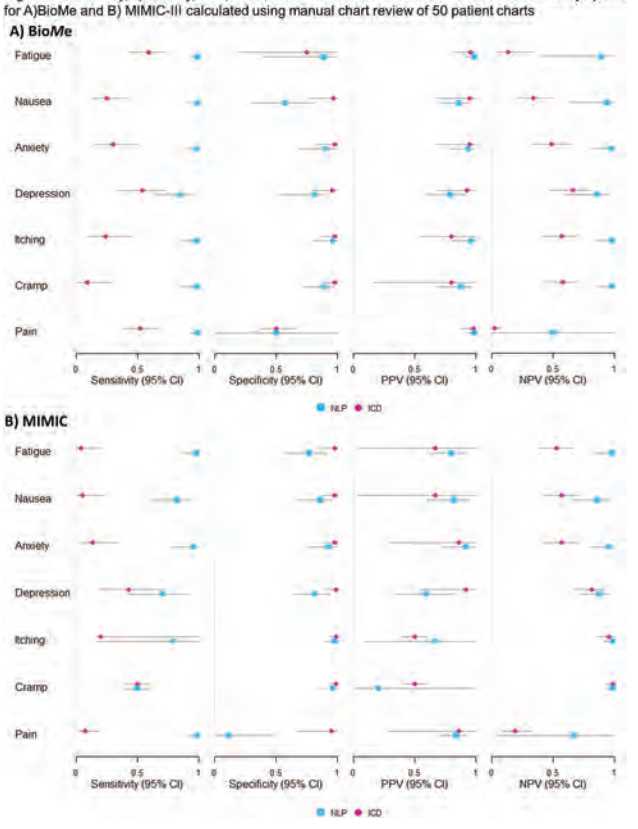
Methods: We utilized NLP to identify 7 patient symptoms from clinical notes of HD patients from the Bio*Me* Biobank and validated our findings using the MIMIC-III database. We compared NLP performance with ICD codes and validated the performance of NLP and ICD codes vs. manual chart review.

Results: We identified 1034 and 519 HD patients from Bio*Me* and MIMIC-III, respectively. In Bio*Me*, the most frequent symptoms identified were pain (NLP 93% vs. ICD 46%, P<0.001), fatigue (NLP 84% vs. ICD 41%, P<0.001), and nausea and/or vomiting (NLP 74% vs. ICD 19%, P<0.001). Sensitivity for NLP ranged from 0.85 (95% CI 0.65-96) for depression to 0.99 (95% CI 0.93-1) for fatigue while sensitivity for ICD ranged from 0.09 (95% CI 0.01-0.29) for cramps to 0.59 (95% CI 0.43-0.73) for fatigue. Results were similar in MIMIC-III. ICD codes were significantly more specific for nausea and/or vomiting in Bio*Me* and for fatigue, depression, and pain in MIMIC-III. A majority of patients in both cohorts had ≥4 symptoms. Patients with more symptoms identified by NLP, ICD, and chart review had more clinical encounters. Results were similar in a subgroup of 608 patients who had ≥2 years of follow up with only 1 year of notes reviewed.

Conclusions: NLP had higher sensitivity compared to ICD codes for identification, with comparable specificity for most symptoms and may be useful for the high-throughput identification of patient-centered outcomes.

Funding: NIDDK Support

Figure 1: Sensitivity, specificity, PPV, NPV, and F1 score of NLP vs. ICD for identification of symptoms for A)BioMe and B) MIMIC-III calculated using manual chart review of 50 patient charts



TH-PO241

Symptom Burden in Renal Patients Under the Care of Single United Kingdom Center

Venkata R. Gullapudi, Komal Chauhan, Hari Dukka. *University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom.*

Background: Renal patients suffer from a high and variable symptom burden, irrespective of the standard of care provided. We assessed the symptom burden of a cohort of renal patients under our care to understand the extent of the problem in our center.

Methods: NHS England health survey questionnaire was used to evaluate symptoms suffered by patients with chronic kidney disease (CKD) stage 4/5 and those receiving renal replacement therapy (RRT). Age, Urea clearances, Charlson comorbidity index (CCI), eGFR and RRT vintage were noted.

Results: 290 patients completed the questionnaire. Median age was 64.5 (IQR: 21), 60.3% were males with median CCI of 3.5 (IQR: 6). The whole cohort experienced a median of 3.5/17 symptoms (IQR: 6). Weakness (53.45%), poor mobility (40.69%) and difficulty sleeping (33.96%) were the top 3 symptoms complained. Table 1 summaries the distribution and top 3 symptoms suffered by patients with CKD and those on RRT. Symptom burden was significantly less in the transplant cohort. Age, renal clearances (eGFR in CKD and tranplant cohorts; Kt/V in dialysis cohorts) did not correlate with symptom burden, however CCI score statistically (r=0.193, p=0.001) correlated to the symptom burden.

Conclusions: Renal patients experience multitude of symptoms and symptom burden is similar in CKD and those on RRT. The standards of care provided to renal patients should include symptom assessment and management where possible.

Table 1

	CKD N=63	Haemodialysis N=111	Home therapies N=49	Transplant N=67
Median number of symptoms experienced*	4 (IQR: 7)	5 (IQR: 6)	4 (IQR: 5)	1 (IQR: 4)
1st most common Symptom and % experiencing	Weakness 50.8%	Weakness 63.96%	Weakness 55.10%	Weakness 37.31%
2nd most common Symptom and % experiencing	Poor Mobility 38.1%	Poor Mobility 57.66%	Poor Mobility 40.81%	Difficulty Sleeping 31.34%
3rd most common Symptom and % experiencing	Difficulty Sleeping 38.1%	Difficulty Sleeping 43.24%	Difficulty Sleeping 40.81%	Feeling anxious & Shortness of Breath 20.9%

*Questionnaire explored 17 symptoms in total

TH-PO242

Symptom Burden with Calcium Carbonate Compared to Sevelamer in Haemodialysis Patients

Fei Fei M. Pan,[1,2] Nigel D. Toussaint,[1,2] Jo-anne M. Moodie,[1] Tessy Isac,[3] Edward R. Smith,[1,2] Paul J. Champion de Crespigny,[1] Timothy D. Hewitson,[1,2] Stephen G. Holt.[1,2] *[1]The Royal Melbourne Hospital, Parkville, VIC, Australia; [2]The University of Melbourne, Parkville, VIC, Australia; [3]Melbourne health, Melbourne, NSW, Australia.*

Background: Patients with CKD frequently experience a considerable symptom burden which interferes with quality of life. Gastrointestinal tract (GIT) symptoms, including nausea, vomiting, constipation and diarrhoea, affect 10-40% of CKD patients. Medications, including phosphate binders (PB), often contribute to this symptom burden. We compared symptoms on the calcium-based phosphate binder, calcium carbonate (CC) therapy with those on sevelamer in a clinical trial.

Methods: Prevalent haemodialysis (HD) patients were recruited into a randomised study (*n*=37). Total study duration was 37 weeks, including 1 week of PB 'washout'. Participants were randomised to either i) 36 weeks of CC therapy or ii) 12 weeks of CC, followed by 24 weeks of sevelamer therapy. Patient symptoms were assessed with the Palliative Care Outcome Scale-Renal Version (POS) and analysed according to total scores and individual scores for specific GIT symptoms.

Results: 26 participants completed the study, and were analysed according to intention-to-treat analysis. 10 participants were randomised to the CC only arm, whilst 16 to the CC/sevelamer arm. There were no statistically significant differences in baseline demographics or co-morbidities between the groups. At baseline, median total POS scores were 10 (interquartile range: [IQR] 7-14) in the CC only arm vs. 13 (IQR 3-19) in the CC/sevelamer arm. At study completion, median POS scores were 12 (IQR 7-13) in the CC only arm, vs 8 (IQR 2-13) in the CC/sevelamer arm, with no statistically significant differences between groups at any timepoint. With regards to GIT symptoms, the proportion of patients experiencing improvement in nausea from baseline to study end were 30% and 44% in the CC only and CC/sevelamer arms respectively, and for vomiting, 10% vs 25% experienced improvement in the respective groups. 20% of CC only patients had more severe constipation at study end vs 31% in the CC/sevelamer group; and for diarrhoea, 30% of CC only vs 35% of CBPB/sevelamer patients reported increased symptoms. None of the changes in specific GIT symptoms were statistically significant.

Conclusions: Symptom burden of patients on HD did not change significantly with different PB therapy in our study, with similar changes in GIT symptoms over time comparing CC and sevelamer therapy.

Pruritus and Mortality in Hemodialysis Patients: Results from the International DOPPS

Nidhi Sukul,[2] Angelo Karaboyas,[1] Hugh C. Rayner,[3] Pablo A. Urena Torres,[5] Philipp Csomor,[7] Thilo Schaufler,[8] Warren Wen,[10] Frederique Menzaghi,[9] Takeshi Hasegawa,[4] Yuqing Chen,[11] Issa Al Salmi,[6] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Heart of England NHS Foundation Trust, Birmingham, United Kingdom; [4]Showa University, Yokohama, Japan; [5]Department of Dialysis, AURA Nord Saint Ouen and Department of Renal Physiology, Necker Hospital, University of Paris Descartes, Paris, France; [6]The Royal Hospital, Muscat, Oman; [7]Vifor Fresenius Medical Care Renal Pharma Ltd., Glattbrugg, Switzerland; [8]Vifor Pharma Management Ltd., Glattbrugg, Switzerland; [9]Cara Therapeutics, Inc., Stamford, CT; [10]Cara Therapeutics, Stamford, CT; [11]Institute of Nephrology, Peking University First Hospital, Beijing, China.*

Background: Chronic kidney disease-associated pruritus (CKD-aP) has been previously associated with poorer quality-of-life and increased risk of depression and death in hemodialysis (HD) patients. We sought to assess the association between pruritus and mortality in a large, contemporary, international cohort of HD patients.

Methods: We analyzed 25,916 HD patients from 21 countries in the Dialysis Outcomes and Practice Patterns Study (DOPPS) phases 4-6 (2009-2018) who self-reported the degree to which they were bothered by itchy skin (5-category ordinal scale from "Not at all" to "Extremely"). We used Cox regression to investigate the association between pruritus and all-cause mortality, adjusted for confounders.

Results: The proportion of patients who were at least moderately bothered by pruritus was 37% overall, and ranged from 27% in Germany to 47% in the UK. The groups with more severe pruritus had lower mean hemoglobin and albumin, a higher proportion of catheter use, and a higher prevalence of cardiovascular comorbidities, diabetes, and psychiatric disorders. The death rate was 0.106/year over a median (IQR) follow-up of 17 (9, 27) months (4,063 deaths). Compared to the reference group of patients not at all bothered by itching, the adjusted mortality HR (95% CI) was 1.02 (0.93, 1.11) for somewhat bothered, 1.13 (1.03, 1.24) for moderately bothered, 1.08 (0.98, 1.21) for very much bothered, and 1.30 (1.15, 1.48) for extremely bothered (Figure).

Conclusions: Analyzing these recent data, survival was shorter for HD patients who were moderately-to-extremely affected by pruritus. These results underscore the importance of diagnosing, evaluating possible causes of, and treating CKD-aP, with the goal of reducing symptom severity, in hopes of improving patient outcomes.

Cox models stratified by DOPPS phase and country; adjustments: age, sex, black race, ESRD vintage, 13 comorbidities, BMI, albumin, hemoglobin, phosphorus, and catheter use.

TH-PO244

Pruritus and Patient-Reported Outcomes (PROs): Associations Between the Skindex-10 and PROs in Hemodialysis Patients

Angelo Karaboyas,[1] Ronald L. Pisoni,[1] Hugh C. Rayner,[3] Fitsum Guebre Egziabher,[4] Philipp Csomor,[6] Thilo Schaufler,[7] Warren Wen,[9] Frederique Menzaghi,[8] Takeshi Hasegawa,[5] Yuqing Chen,[10] Saeed Al-Ghamdi,[11] Nidhi Sukul.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Heart of England NHS Foundation Trust, Birmingham, United Kingdom; [4]Hospital Albert Michallon, La Tronche, France; [5]Showa University, Yokohama, Japan; [6]Vifor Fresenius Medical Care Renal Pharma Ltd., Glattbrugg, Switzerland; [7]Vifor Pharma Management Ltd., Glattbrugg, Switzerland; [8]Cara Therapeutics, Inc., Stamford, CT; [9]Cara Therapeutics, Stamford, CT; [10]Institute of Nephrology, Peking University First Hospital, Beijing, China; [11]King Faisal Speciialist Hospital & Research Center-Jeddah, Jeddah, Saudi Arabia.*

Background: Chronic kidney disease-associated Pruritus (CKD-aP) is a prevalent and distressing symptom in hemodialysis (HD) patients that affects Health Related Quality of Life (HR-QoL), but remains poorly characterized.

Methods: We analyzed 5418 HD patients from 17 countries in phase 5 (2013) of the Dialysis Outcomes and Practice Patterns Study (DOPPS) who self-reported being bothered by itchy skin (yes/no). "No" responses were assigned a Skindex-10 (SK-10) score of 0. Patients responding "Yes" then answered 10 questions about the frequency (0-6 scale) they were distressed by various aspects of CKD-aP. We investigated the association between SK-10 score (0-60 range; higher = more bothered) and 4 outcomes: (1) Physical and (2) Mental Component Summary (PCS; MCS) scores from the SF-12 (higher score = better HR-QoL) using linear mixed models; (3) Center for Epidemiologic Studies-Depression (CES-D) score ≥10 (indicative of depressive symptoms) and (4) Poor sleep quality (≥3 nights/week of restless sleep), both using modified Poisson regression.

Results: Mean SK-10 score was 12.2 overall and 27.4 among those affected by CKD-aP (Yes responders); 45% of patients had SK-10 score >0, including 17% with 1-20, 19% with 21-40, and 9% with 41-60. In adjusted models, lower PCS and MCS scores, poorer sleep quality, and greater likelihood of CES-D ≥10 were observed with increasingly higher SK-10 scores (Figure). SK-10 was highly correlated (r=0.71) with a separate summary question about the extent patients were bothered by itchy skin in the past 4 weeks.

Conclusions: Pruritus severity, reflected by the SK-10, was clearly and monotonically associated with other PROs including physical and mental HR-QoL, depression, and sleep quality, further emphasizing the importance of identifying and treating CKD-aP. Given its strong correlation with the SK-10 score, the single summary question could make routine assessment of pruritus in HD patients more concise and efficient.

Skindex-10 score calculated as in Mathur et al. (*CJASN 2010*); Linear mixed models (QOL) and modified Poisson regression (≥3 nights/week of restless sleep; CES-D ≥10) models adjusted for age, sex, black race, ESRD vintage, 13 comorbidities, BMI, albumin, hemoglobin, phosphorus, catheter use.

TH-PO245

Difelikefalin Improved Quality of Life (5-D Itch Scale-Domains) in Hemodialysis Patients with Pruritus in an 8-Week Phase 2 Randomized, Placebo-Controlled Study

Steven Fishbane,[1] Robert H. Spencer,[2] Catherine Munera,[2] Frederique Menzaghi.[2] *[1]Northwell Health, Commack, NY; [2]Cara Therapeutics, Inc., Stamford, CT.*

Background: Among patients with chronic kidney disease (CKD) undergoing hemodialysis (HD), >40% have moderate-to-severe pruritus, which is associated with poor quality of life (QoL). Difelikefalin (DFK; CR845) is a selective kappa opioid receptor agonist that acts peripherally with a dual anti-inflammatory/antipruritic effect and to date has negligible abuse potential. In a Phase 2 study of HD patients with CKD associated pruritus, it was previously reported that DFK significantly reduced itch intensity. Itch reduction, assessed by the Worst Itching Intensity Numerical Rating Scale (WI-NRS) score correlated with significant improvements in itch-related QoL measures, as measured by the Skindex-10 and 5-D Itch scales. To further characterize the impact of itch reduction on patient QoL, we present results using the 5-D Itch scale domains.

Methods: Patients were randomized 1:1:1:1 to receive an IV bolus of DFK 1.5, 1.0, 0.5 mcg/kg or placebo (PBO), at the end of each dialysis over an 8-week (Wk) treatment period. The 5-D Itch scale domains were used to measure Degree, Duration, Direction [change over time of itch], Disability [sleep, leisure/social, housework/errands, work/school], and Distribution [body location of itch] – each ranked on a 5-point increasing severity scale. This analysis focused on the 0.5 mcg/kg dose that was advanced into Phase 3 studies.

Results: Patients treated with DFK 0.5 mcg/kg (n=44) exhibited a clinically meaningful improvement in 5-D Itch total scores vs PBO (n=45) at Wk 8 (-5.7 vs -2.8 LS mean [p<0.001 vs PBO]), with a significant correlation between WI-NRS and 5-D total scores (r= 0.71, p<0.0001). Except for Distribution (-0.6 vs -0.4 [p=0.368]), significant improvements from baseline were reported across all subdomains in DFK vs PBO groups at the end of Wk 8; Degree: -1.1 vs -0.5 [p<0.001 vs PBO]; Duration: -1.2 vs -0.6 [p=0.003]; Direction: -1.6 vs -0.7 [p<0.001]; Disability: -1.2 vs -0.5 [p=0.004].

Conclusions: This analysis further characterized the impact of itch severity reduction with DFK indicating significant improvement in QoL as measured by the 5-D Itch multidimensional questionnaire. Results demonstrate itch intensity reduction with DFK is associated with improved QoL.

Moisturizer Improves Pruritus in Dialysis Patients by Increasing Water Content in the Stratum Corneum: A Multicenter, Randomized, Confirmatory Study

Yukie Yoshida,[1] Akio Hirama,[1] Kazumasa Hashimoto,[1] Takeshi Sato,[2] Noritsugu Yokota,[3] Hidehisa Saeki,[4] Momoyo Kishida,[5] Akira Kanakubo,[5] Shuichi Tsuruoka.[6] *[1]Kidney Clinic, Nippon Medical School, Tokyo, Japan; [2]Department of Nephrology, Koyama Memorial Hospital, Ibaraki, Japan; [3]Moka Hospital, Tochigi, Japan; [4]Department of Dermatology, Nippon Medical School, Tokyo, Japan; [5]Maruho Co., Ltd., Osaka, Japan; [6]Department of Nephrology, Nippon Medical School, Tokyo, Japan.*

Background: Dialysis patients often have skin dryness and pruritus that are treated with moisturizers without sufficient evidence. We had reported an exploratory study on the efficacy of a heparinoid moisturizer for asteatosis in dialysis patients at Kidney Week 2017. In this confirmatory study, the efficacy and safety of additional 4-week treatment was evaluated in a larger population.

Methods: This study was an open-label, randomized, before-after, parallel group comparison, multi-center study conducted after approval by the Institutional Review Board. The study was funded by Maruho Co., Ltd., and registered at the University Hospital Medical Information Network (ID: UMIN000029360). In total, 71 Japanese chronic renal failure patients on dialysis with asteatosis applied a topical heparinoid (Maruho) twice a day on dryness/pruritus areas, including the lower ribs where water content in stratum corneum (WCSC) was measured using a Corneometer (Courage+Khazaka, Cologne, Germany), at proper dose by finger-tip unit for 2 weeks in Group A and 8 weeks in Group B. The primary endpoint was WCSC at Week 4 and secondary were trends in WCSC, pruritus visual analogue scale (VAS), dryness symptoms and dermatology life quality index (DLQI). Safety endpoint was adverse events (AEs).

Results: WCSC at Week 4 of group B (n=35) was significantly higher than Group A (n=36). WCSC, pruritus VAS and dryness symptoms improved until Week 2 in both groups. After Week 2, improvement sustained in Group B, but exacerbated in Group A. DLQI showed the same trend, especially in "symptoms and feelings" subscale. AEs occurred in 51 patients (107 events); 1 patient had treatment-related rash/eruption.

Conclusions: Heparinoid moisturizer increased WCSC, which subsequently improved pruritus and QOL. Continuous treatment at proper dose is necessary to maintain efficacy for asteatosis and pruritus in dialysis patients.

TH-PO247

Difelikefalin Significantly Reduced Sleep Disturbance in Hemodialysis Patients with Moderate-to-Severe Pruritus in an 8-Week Phase 2, Randomized, Placebo-Controlled Study

Sarbani Bhaduri,[1] Robert H. Spencer,[2] Catherine Munera,[2] Frederique Menzaghi.[2] *[1]CARA, El Paso, TX; [2]Cara Therapeutics, Inc., Stamford, CT.*

Background: Patients with chronic kidney disease (CKD) undergoing hemodialysis (HD) often have CKD-associated pruritus (CKD-aP), a debilitating chronic systemic itch. More than 40% of CKD patients suffer from moderate-to-severe itch with associated poor quality of life (QoL) and sleep disturbance.[4] Sleep disturbance in CKD is associated with an increased mortality risk.[5] Difelikefalin (DFK, CR845) is a selective kappa opioid receptor agonist that acts peripherally with dual anti-inflammatory and antipruritic effects. In an 8-week Phase 2 study in HD patients with moderate-to-severe pruritus, DFK demonstrated significant efficacy in reducing itch intensity and improved itch-related QoL measures. To further characterize the impact of itch reduction with DFK, we report results regarding changes in sleep disturbance.

Methods: Patients were randomized 1:1:1:1 to receive an intravenous bolus injection of DFK 1.5, 1.0, or 0.5 mcg/kg, or PBO at the end of each dialysis over an 8-week treatment period. The sleep disturbance subscale is part of the MOS sleep scale (MOS-S) and focuses on trouble falling asleep, sleep restlessness, awakening during sleep, and time to fall asleep during the past week. The MOS-S was administered on Day 1 (predose) and at Week (Wk) 4, Wk 8, and at the end of treatment (EOT, Day 57). This analysis focused on the DFK 0.5 mcg/kg dose, which was advanced into Phase 3 studies.

Results: Patients treated with DFK exhibited a significant reduction in sleep disturbance compared with PBO, with a mean change from baseline in DFK 0.5 mcg/kg (n=44) and PBO (n=45) groups, respectively, of -8.6 vs 2.2 [p=0.013] at Wk 4; -9.8 vs -2.2 [p=0.077] at Wk 8; -13.8 vs -1.3 [p=0.006] at EOT.

Conclusions: Significantly improved MOS-S sleep disturbance scores were obtained after DFK treatment, indicating a clinically sustained improvement in sleep through Wk 8 that was associated with a robust and sustained reduction in itch intensity. The effects of DFK on sleep, as well as long-term efficacy and safety of DFK, are currently under investigation in patients with CKD-aP in ongoing Phase 3 studies. **Reference:** [4]Shirazian S et al. *Int J Nephrol Renovasc Dis* 2017;10:11; [5]Benz R et al. *Am J Kidney Dis* 2000;35:1052

TH-PO248

Arterial Pulse Enhancement Technology (A-PET) Therapy Using VascuPump for Relief of Symptoms in Restless Legs Syndrome (RLS) in Patients on Dialysis

Anil Bhalla,[1] Ravi K. Singh,[1] Devinder S. Rana,[1] Ashwani Gupta,[1] Anurag Gupta,[2,1] Vinant Bhargava.[1] *[1]Sir Ganga Ram Hospital, New Delhi, India; [2]Synegy Hospital, Uttarakhand, India.*

Background: Restless legs syndrome (RLS) occurs in 25% to 40% patients on hemodialysis. In patients on dialysis poly-pharmacy and pill burden is a significant risk factor and there is a need for treatment which is noninvasive, non-pharmacologic, time efficient and has long lasting response. Arterial Pulse Enhancement Technology (A-PET) therapy delivered using VascuPump is noninvasive, non-pharmacologic treatment given during dialysis for 15 minute on both legs (no extra visit). VascuPump device uses inflatable cuffs, placed around calf, to rhythmically compress the limb with each heartbeat to enhance blood flow down the limb.

Methods: Open labelled treatment for patients on maintenance hemodialysis thrice per week. Six treatments were given during consecutive dialysis sessions. Patients with DVT, aortic insufficiency, leg wound or ulcer, acute thrombophlebitis and medically unstable patients were excluded. Baseline Doppler study was done to exclude DVT. To assess RLS, International RLS Study Group Rating Scale (IRLSSG) was used, range 1-40. Wong Baker Pain Scale (WBPS) was used before and after treatment, range 0-10.

Results: 52 patients with mean age 58.4 yr (range 26-77), male 32 (62%), diabetes 40 (77%). RLS score at start of the treatment was 27.1 (17-39) which dropped to 20 (14-34) at the end of the last treatment. WBPS before and after treatment was 7.6 (2-10) and 3.3 (2-8) respectively. The acute response after cumulative 270 treatments was a 41% decrease in pain. There was a trend towards consistent decrease in the baseline WBPS of individual patients with multiple treatments. Average Relief lasted for an average of 55 hours (range 0-172 hrs) after individual treatment. A total of 14 patients did not complete the six treatments due to unstable clinical condition or no response. One patient had worsening cramps in the legs. There were no other complications observed after 270 cumulative treatments in these patients on dialysis. A total of 73% (38/52) patients benefitted from the treatment.

Conclusions: A-PET therapy during dialysis is an effective non pharmacologic therapy for RLS patients on maintenance hemodialysis. Further randomized controlled studies are needed in larger population.

TH-PO249

Effective Analysis of Electroacupuncture Treatment for Restless Legs Syndrome in Maintenance Hemodialysis Patients

Shensen Li. *Sir Run Run Hospital, Nanjing Medical University, Nanjing, China*.

Background: Restless legs syndrome (RLS) is a common complication in patients with end stage renal disease. Current study was conducted to analysis the effect of electroacupuncture in the treatment of RLS.

Methods: A total of 7 regular hemodialysis (HD) patients (5 Male and 2 Female) in our center were enrolled to conduct before and after self-control study. Demographic, clinical, and pretreatment laboratory data were collected. After one month of pharmacological washout period, patients received 12 sessions of electroacupuncture on three acupoints (Zusanli (ST36), Sanyinjiao (SP6) and Taichong (LR-3)) during HD. Changes of RLS were rated by International Restless Legs Syndrome Study Group rating scale (IRLS) pre-, post- and one month after the therapy.

Results: The average age of enrolled patients was 53.0±9.6 years, with median dialysis duration of 3.0 years. The hemoglobin level were 125.9±22.9 g/l. The IRLS score was significantly lower after electroacupuncture treatment (9.4±3.9) than that before treatment (17.3±4.3) (P=0.0004). One month after the end of treatment, the quantitative IRLS score was 9.7±1.2, which was still significantly lower than that before treatment (P=0.0068). Both the frequency (2.9±0.6 days/week pre-treatment vs. 1.9±1.0 days/week post-treatment, P=0.02) and severity (1.7±0.7 points vs. 1.0±0 points, P<0.05) of RLS were significantly improved after electroacupuncture. These improvement trends were able to maintain after the treatment was discontinued for one month.

Conclusions: Electroacupuncture on the acupoints in the legs during HD was as an effective treatment for attenuating the symptoms of RLS in hemodialysis patients, and the therapeutic effect maintain for at least one month.

TH-PO250

Frailty, Age, and Post-Dialysis Recovery Time in an Incident Hemodialysis Population

Jessica Fitzpatrick,[1] Stephen M. Sozio,[3] Bernard G. Jaar,[3] Michelle M. Estrella,[2] Dorry L. Segev,[3] Jose M. Monroy-Trujillo,[3] Rulan S. Parekh,[1] Mara McAdams-DeMarco.[3] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [3]Johns Hopkins University, Baltimore, MD.*

Background: Frailty, a phenotype characterized by an inability to recover from a stressor, may help identify incident hemodialysis patients at risk for longer recovery time. Recovery time has been associated with downstream outcomes including quality of life and mortality. We characterize post-dialysis recovery times in incident in-center hemodialysis patients and quantify the association of frailty and recovery time.

Methods: In 285 incident hemodialysis patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in End Stage Renal Disease (PACE) study, frailty was classified by the Fried phenotype as non-frail, intermediately frail, or frail. Post-dialysis recovery time was assessed by asking, "How long does it take you to recover from a dialysis session?" We estimated the association of frailty and post-dialysis self-reported recovery time using negative binomial regression after adjusting for clinical confounders.

Results: Mean age was 55 years, 24% were >65 years, and 73% were African American. Median recovery time was 20 min (IQR: 10, 120). Age <65 was independently associated with longer recovery time (IRR 2.36; 95%CI: 1.44-3.85). Intermediate frailty and frailty were associated with 2.56-fold (95%CI: 1.45-4.52) and 1.72-fold (95%CI: 1.03-2.89) longer recovery times. In particular, frail participants <65 were more likely to report longer recovery times (IRR 2.55; 95%CI: 1.46-4.43).[Figure] In non-frail participants, however, age was not associated with recovery time.

Conclusions: In adults initiating hemodialysis, frailty was independently associated with prolonged post-dialysis recovery. Future studies should assess the impact of frailty-targeted interventions on recovery time to improve clinical outcomes.

Funding: NIDDK Support

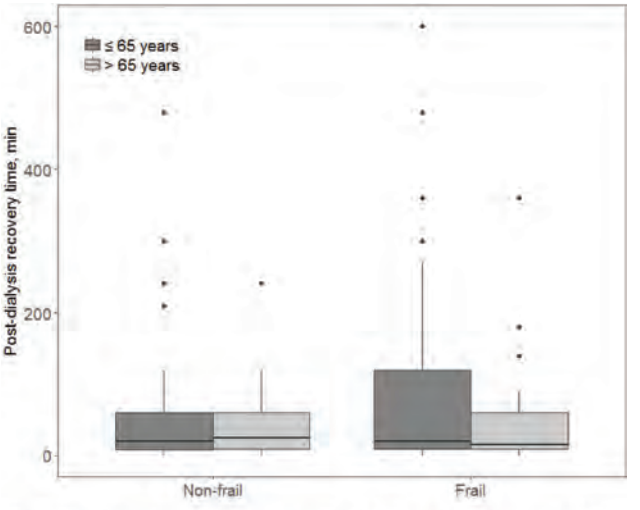

Figure. Distribution of post-dialysis recovery time by frailty status and age among adults initiating hemodialysis.

TH-PO251

Frailty in Prevalent Hemodialysis Patients: Regina Frailty Study

Maryam Jafari,[2] Kavaljeet K. Tondon,[2] Bhanu Prasad.[1] *[1]Nephrology, Regina General Hospital, Saskatchewan Health Authority, Regina, SK, Canada; [2]RQHR- Research and Performance Support, Regina, SK, Canada*.

Background: Frailty is characterized by accumulating physiological deficits in patients across many domains and puts individuals at a higher risk of poor health outcomes. The prevalence of frailty is disproportionately increased in patients on Hemodialysis (HD) when measured either at entry to the dialysis unit or once stabilized on HD. However, trajectory of frailty on serial measurements and its relationship to level of independence, cognition, quality of life (QoL) and mood has not yet been explored.

Methods: We conducted a prospective longitudinal study amongst 100 prevalent HD patients at the Regina General Hospital, Canada from Jan 2015 to Jan 2016. Patients were reevaluated one year after the initial assessment. Four levels of dependence were defined: independent, independent with family support, requiring home care assistance, and long-term care home resident. Frailty was measured using the Fried Criteria (score of ≥3/5), cognitive function was assessed with Montreal Cognitive Assessment, mood was assessed using the Geriatric Depression Scale and QoL was measured with EuroQol-5D at each assessment. To determine associations, chi square and McNemar's tests were used.

Results: At baseline, the mean age was 62.86 ± 15.44 years, 58% were men, and majority (73%) were Caucasian. 68% were frail, 53% screened positive for depressive symptoms and 69% had impaired cognitive function. After one year, the % of independent patients decreased (81.5% vs. 63.1%), and more patients required additional support at home

(17% vs. 31%). Higher proportion of patients experienced challenges with mobility (67.7% vs. 83.1%, p= 0.02), as well as with self– care (6.2% vs. 18.5%, p=0.02). Non–frail patients had more favorable cognition scores in comparison to the frail cohort [24 (21–26) vs. 21 (15–24), p=0.006]. Of the 21 patients who died at one year follow up, 62% were frail.

Conclusions: Two thirds of established dialysis patients met the criteria for frailty. Frail patients are more likely to be dependent on their family members and need greater number of support systems in place. The collective impact of multiple comorbidities, depression, cognitive impairment, reduced QoL and frailty on HD patients, and its consequent impact on health care delivery will have to be proactively addressed in a multidisciplinary manner. We suggest sequential frailty measurements in HD units to improve care delivery of patients.

TH-PO252

Fall Risks in Chronic Hemodialysis and Peritoneal Dialysis Patients in the United States (2006-2016)

Xinju Zhao,[1] Yun Han,[2] Jennifer L. Bragg-Gresham,[2] Kevin He,[3] Li Zuo,[1] Rajiv Saran.[2] *[1]Peking University People's Hospital, Beijing, China; [2]University of Michigan, Ann Arbor, MI; [3]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI.*

Background: Patients with end stage kidney disease (ESKD) have a substantially higher risk of falls, but the burden of fall events has not been sufficiently characterized in this population. We compared trends in minor and major fall rates in both hemodialysis (HD) and peritoneal dialysis (PD) patients in the US between 2006 and 2016.

Methods: Analysis included 4,766,341 dialysis patients (HD: 4,343,752; PD: 422,589) in the US Renal Data System database (2006-2016). ICD-CM diagnosis codes were used to identify major and minor falls. Major falls included those in combination with fractures, brain injuries, or joint and ligament dislocation. Minor falls included falls without these complications. Fall rates expressed per 1000 patient-years (py) were calculated and patient characteristics compared for both types of falls by dialysis modality.

Results: Overall, HD patients were older and more likely to be male compared with PD patients (mean age: 63.6 vs 57.5 years, male: 56.3% vs 54.7%). Over the past decade, patients on HD experienced higher rates of both major and minor falls than those on PD (Figure 1). The rate of major falls gradually decreased from 2006-2014, and grew substantially after 2014 among both populations (HD vs PD: 227 vs 157 per 1000 py in 2016). There was a notable increase in the rate of minor falls among both populations during the period from 2006-2016 (HD: 125 to 190 per 1000 py; PD: 66 to 119 per 1000 py). Patients who were female, white, age >45 years and prevalent dialysis patients had a higher risk of falls than their counterparts who were male, other ethnicity origins, age ≤45 and incident dialysis patients.

Conclusions: Fall risk is high for the ESKD population, especially among those undergoing HD, aged >45years, white, female and prevalent dialysis. Falls are a safety issue can cause serious injuries with resultant complications along with increased resource utilization. Further research and implementation projects designed to lower fall risk among ESKD patients are urgently warranted.

TH-PO253

Physical Activity in Patients on Hemodialysis and Its Relation to Fatigue and Depression

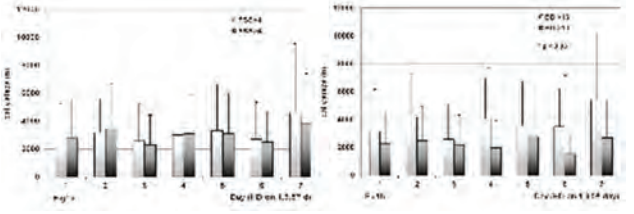
Astrid Brys,[1,2] Maurizio Bossola,[1] Bert Lenaert,[2] Filippo Biamonte,[3] Giovanni Gambaro,[1] Enrico Di stasio.[3] *[1]Department of Nephrology; Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Rome, Italy; [2]Department of Neuropsychology and Psychopharmacology, Faculty of Psychology and Neuroscience, Maastricht University, Maastricht, Netherlands; [3]UOC Chimica, Biochimica e Biologia Molecolare Clinica, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Rome, Rome, Italy.*

Background: Hemodialysis (HD) patients are less active than healthy sedentary adults. Fatigue and depression are considered main reasons for physical inactivity in HD patients and are associated with impaired quality of life (QOL). A better understanding of the relation between fatigue, depression and physical activity (PA) is crucial in order to develop effective therapies and improve QOL. Measurement of PA is however challenging, as it is usually assessed by subjective self-report questionnaires. Recently, objective assessment of PA with motion sensors has gained interest. Therefore, we aimed to objectively measure HD patients' daily PA and to explore its relation with fatigue and depression.

Methods: PA was assessed in 37 HD patients (mean age 61 years) based on the daily step count measured with the SenseWear™ Armband for 7 days. The Fatigue Severity Scale (FSS) and Beck Depression Inventory-II (BDI) were administered to evaluate fatigue and depressive mood.

Results: Median physical activity was 2247 steps a day, [IQR:614-4363], and no significant differences in PA were observed between treatment and non-treatment days. PA per measurement day did not correlate with fatigue experience (r_s=0.04, p=0.499), and did not significantly differ between patients that were categorized as fatigued (n=23, FSS≥4) or not (n=14, FSS<4) (Fig.1a: p's 0.745-0.988; Cohen's d's <0.20). In contrast, PA per measurement day significantly though inversely correlated with depressive mood (r_s=-0.22, p<0.001) and significantly differed between high-depressed (n=18, BDI>13) and low-depressed subjects (n=19, BDI≤13) (p=0.004), who made on average 1.7 times more steps a day than their high-depressed counterparts. The main differences in PA were observed on non-treatment days (Fig.1b: p's 0.017-0.105; Cohen's d's 0.57-0.90).

Conclusions: Objective assessment of PA with motion sensors is feasible in HD patients. Depressive mood, in contrast to fatigue experience, seems to be associated with PA. These findings may help to increase awareness about the need for intervention trials to assess the effect on PA in HD patients by improving their mood, or vice versa.



TH-PO254

Psychosocial Interventions for Preventing and Treating Depression in Dialysis Patients: A Cochrane Review and Meta-Analysis

Patrizia Natale,[1,2] Suetonia Palmer,[3] Marinella Ruospo,[1] Jorgen B. Hegbrant,[1] Giovanni F. Strippoli.[1,2] *[1]Diaverum, Lund, Sweden; [2]University of Bari, Bari, Italy; [3]University of Otago, Christchurch, New Zealand.*

Background: People with end-stage kidney disease treated with dialysis are frequently affected by major depression. Psychological and social support are potential treatments for depression, although a Cochrane review in 2005 identified zero eligible studies. This is an update of the Cochrane review published in 2005 to evaluate the available evidence for using psychosocial interventions to prevent and treat depression in patients treated with dialysis for end-stage kidney disease (ESKD).

Methods: The specialized register of Cochrane Kidney and Transplant was searched for randomized trials (RCTs) reporting psychosocial interventions for prevention and treatment of depression among adults treated with long-term dialysis. Two authors independently screened citations for eligibility, extracted data, and assessed risk of bias using the Cochrane tool. Evidence certainty was evaluated using GRADE.

Results: Thirty-one studies (1820 participants) were eligible. Twenty-four new studies were added to this 2018 update. Seven studies originally excluded from the 2005 review were included as they met updated review eligibility criteria. Trial duration ranged between three weeks and one year. Median study age was 50.8 years. Methodological reporting was incomplete for most studies. Cognitive-behavioural therapy probably improves depression symptoms (mean difference [MD] -6.10, 95% confidence interval [CI] -8.63 to -3.57; moderate certainty) and health-related quality of life (standardized MD [SMD] 0.51, 95% CI 0.19 to 0.83; moderate certainty). Exercise probably improves depression symptoms (MD -7.61, 95% CI -9.59 to -5.63; moderate certainty) and health-related quality of life (MD 3.06, 95% CI 2.29 to 3.83; moderate certainty). Counselling and relaxation techniques probably reduce depressive symptoms (MD - 3.84, 95% CI -6.14 to -1.54; moderate certainty and MD -5.77, 95% CI -8.76 to -2.78; moderate certainty, respectively). In very low certainty evidence, the effects of acupressure, telephone support, and meditation were uncertain. Data on adverse events were sparse.

Conclusions: Cognitive-behavioural therapy, exercise, counselling, or relaxation techniques probably reduce depressive symptoms for adults with ESKD treated with dialysis. Evidence for other psychosocial interventions is uncertain.

TH-PO255

Effects of Intravenous L-Carnitine (LC) Administration in Improving Muscle Strength in Hemodialysis (HD) Patients

Takashi Miyamoto,[1] Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[1] Kenji Sawase,[1] Tayo Kawazu,[1] Takuya Kubara,[1] Sayaka Miyazaki,[1] Masatoshi Hayashida,[2] Mashumi Ide,[1] Tomoya Nishino,[3] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Renal Center, Nagasaki, Japan; [3]Nagasaki University School of Medicine, Nagasaki, Japan.*

Background: Several clinical studies have suggested that LC, a naturally occurring compound involved in bioenergetic processes, may improve muscle function of HD patients. In this study, our aim was to evaluate the effect of intravenous administration of LC on muscle strength measured by isometric handgrip strength (HGS) in HD patients.

Methods: After appropriate IC 172 HD patients on HD were enrolled in this study. Intravenous L-carnitine (1000 mg) was administered after each HD session. HGS was measured using a dynamometer before and 12 weeks after LC administration in female

(n=56) and male (n=116) patients of different ages (median age: 68.2±33.3 years) as well as various clinical parameters were determined. Using the Asian Working Group for Sarcopenia criteria the subjects were divided into 2 groups by initial HGS: cut-off score of 18 kilograms (kg) for female and 26 kg for male.

Results: As shown in Figure, significant increase was obtained both in female and male among weaker HGS groups, but not normal HGS groups. There was no significant difference in nutrition parameters such as serum albumin or cholinesterase between weaker and normal HGS groups in females or males.

Conclusions: In our study the administration of intravenous LC has potentially contributes to muscle strength in patients on maintenance HD. LC can be one of the candidates for improving sarcopenia in patients on HD.

TH-PO256

A 6-Month Program of Intradialytic Cycling Results in a Reduction in Associated Healthcare Costs in Patients Receiving Prevalent Hemodialysis

Daniel S. March,[1] Adam W. Hurt,[1] Alice C. Smith,[1] James Burton.[1,2] *[1]University of Leicester, Leicester, United Kingdom; [2]Loughborough University, Loughborough, United Kingdom.*

Background: Individuals receiving hemodialysis have complex medical needs. Interventions that reduce health care utilization can improve patient outcomes, and therefore decrease the financial burden. The aim of this health economic analysis is to investigate the effect of a 6-month program of intra-dialytic cycling exercise (IDE) on health care costs.

Methods: This is a retrospective complete case analysis of a 100 participants enrolled in CYCLE-HD, an open-label, blinded end-point, cluster randomised control trial investigating the benefit of IDE. Participants were randomised to either a 6-month progressive program of IDE (30 minutes of thrice weekly, moderate intensity cycling at RPE 12-14) or standard care (control). Data on hospital admissions, length of stay, clinic appointments, A&E attendances, primary care appointments and prescribed medications were extracted from medical records for the 6-months before, during and after the IDE intervention. Costs of healthcare utilization were calculated using the National Health Insurance National Tariff Payment System, and prescribed medications were calculated using the British National Formulary. Data are presented as mean difference (95% confidence interval) or mean (95% confidence interval).

Results: Data from a 100 participants (control *n*=49 and IDE *n*=51) were included in our complete case analysis. Time-series with incomplete data sets were excluded. There was no difference between groups for the before (£284.30 (-£4550.24 to £5118.83), *P*=0.9075) or during (-£2124.67 (-£6466.69 to £2217.35), *P*=0.3342) periods. However following the IDE program there was a significant reduction in cost of -£8199.438 (-£15137.43 to -£715.4473, *P*=0.0227) per participant between IDE and control groups. Similarly, post IDE number of admissions (IDE; 0.8 (0.4-1.2), control; 1.2 (0.8-1.6)) and length of stay (IDE; 3.1 (0.2-6.0) days, control; 4.4 (2.4-6.3) days) were also reduced.

Conclusions: These data show a 6-month of program IDE can reduce associated health economic costs. The overall reduction appears to be driven by a reduction in hospital admissions and length of stay. These results strengthen the argument that IDE programs should be routinely offered and are of crucial importance to commissioners of dialysis care.

TH-PO257

Intradialytic Isometric Handgrip Training Seems to Be Safe: A Pilot Study on Hemodialysis Patients

Heitor S. Ribeiro,[1] Vinícius A. Cunha,[2] Victor M. Baião,[2] Marvery P. Duarte,[2] Helton L. Carvalho,[1] Gustavo D. França,[2] Renato N. Ferreira,[1] Lucas D. Almeida,[2] Antonio Jose Inda-Filho,[1] Aparecido P. Ferreira.[1] Grupo of Studies in Exercise Physiology and Health (GEFES) *[1]University Center ICESP, Brasilia, Brazil; [2]Catholic University of Brasília, Brasília, Brazil.*

Background: Cardiovascular capacity of chronic kidney disease (CKD) patients tends to decline with the natural progression of the disease. In this sense, resistance training is an important non-pharmacological tool in the control of cardiovascular (CDV) parameters. However, there is no evidence of isometric handgrip training (IHT) protocols in this population. Thus, the aim of this study was to verify the safety of two isometric RT protocols on CDV variables in hemodialysis (HD) patients.

Methods: This was an experimental study, with acute intervention, cross-over design and sample of 8 patients, mean age 56.63 ± 12.66 years, who undergoes HD at a private clinic in the city of Brasília – DF. The participants were randomly assigned to three different moments to analyze the response of the variables heart rate variability (HRV) and blood pressure (BP), being: 1) control; 2) low-intensity; 3) moderate-intensity. Variables were collected at the beginning of session 5, 15, 30, 40, 60 minutes and immediately after the end.

Results: IHT protocols, regardless of intensity, did not show a significant change for both HRV and BP variables during their performances, nor when compared to the control moment. When the moments immediately before and after exercise were analyzed, a significant increase was observed for SBP (120,3±4,6 vs 126,7±4,6, p<0.05) and DP (8634,5±398,5 vs 9419,1±545,3, p<0.05) in the protocol of moderate-intensity, but returning to normal values 10 minutes later.

Conclusions: Therefore, we conclude that the intradialytic IHT seems to be a safe therapeutic tool for the intradialytic control of cardiovascular parameters in this population.

L-Carnitine Supplementation Enhances Physical Activity and Improves Muscle Quality in Hemodialysis Patients

Junko Yano,[1] Sakuya Ito,[1] Yusuke Kaida,[2] Yosuke Nakayama,[1] Goh Kodama,[1] Kei Fukami.[1] *[1]Kurume University School of Medicine, Division of Nephrology, Kurume, Japan; [2]Kurume university, Kurume, Japan.*

Background: Carnitine plays a central role in the activation of fatty acid b-oxidation and energy production by transporting long-chain fatty acids from the cytoplasm to mitochondria. We previously reported that serum carnitine levels are significantly decreased in hemodialysis (HD) patients and thereby involved in muscle atrophy and decreased quality of life. Moreover, recent evidence has suggested that ergometer exercise can be effective against sarcopenia and frailty in HD patients. However, whether L-carnitine supplementation or ergometer exercise can improve HD-related impairment of physiological activity and muscle quality is yet to be elucidated. Here we prospectively examined this issue.

Methods: Twenty patients undergoing HD were divided into two groups: L-carnitine group (n = 10) and exercise group (n = 10). Patients were treated with L-carnitine supplementation (1000 mg intravenously) for 3 months. Muscle and fat mass were measured using impedance methods. Physical activity was evaluated using indices, including grip strength, lower limb extension strength, chair stand up time, 10 m walking times (10 mWT), functional reach test, time up & go test, and the Borg Scale. We further evaluated muscle mass quality using magnetic resonance imaging.

Results: Total and free carnitine levels in the serum significantly decreased in HD patients than in healthy subjects (both p < 0.001). At baseline, muscle mass and the Borg scale were positively associated with free carnitine levels; however, the other variables were not. L-carnitine supplementation significantly increased muscle mass (p = 0.023) and thigh circumstance (p = 0.019), decreased fat mass (p = 0.007), and improved chair stand up time (p = 0.003) and 10 mWT (p = 0.004). Ergometer exercise did not improve any physical activity. Notably, the intramuscular fat fraction significantly decreased with L-carnitine supplementation (p = 0.023), suggesting the improvement of muscle quality.

Conclusions: Compared with ergometer exercise, L-carnitine supplementation had superior effects on physical activity and muscle quality in HD patients. These observations suggest that L-carnitine supplementation may be a novel therapeutic strategy for HD-related sarcopenia and frailty.

TH-PO259

Use of a Wrist-Based Monitoring Device Among Hemodialysis (HD) Patients: A Feasibility Study

Maggie Han,[1] Priscila Preciado,[1] Ohnmar Thwin,[1] Xia Tao,[1] Mirell Tapia,[1] Lemuel Rivera Fuentes,[1] Susmita Mullick,[1] Nadja Grobe,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine, New York, NY.*

Background: Pervasive sensing technologies allow healthcare providers to gain insights into patients' status outside the clinical setting. To adopt widespread use of remote monitoring devices we must first study their feasibility. We aim to quantify how long patients will use a wearable device before requiring an intervention to maintain use of the device.

Methods: HD patients were enrolled from 3 clinics in New York City starting in May 2019. Patients ≥18 years, on HD ≥3 months, able to walk, owning a smartphone, tablet or PC were enrolled and provided with a wrist-based monitoring device (Fitbit Charge 2). Participants were instructed on how to use the device. If a patient failed to sync data for 7 consecutive days, a text message or email reminder was sent. We evaluated time to first notification using Kaplan Meier analysis. Patients were censored at 5/15/2019.

Results: 89 patients were enrolled into our study with 6 patients screen-failed. At enrollment patients were 55±12 years old with a dialysis vintage of 5.8±6.3 years. 36% lived alone, 54% were single, 57% unemployed, 68% were African-American, and 49% had an education level of some college or higher. 61% of the patients required a notification to continue using the device. Mean and median time to first notification were 95 days (95%CI 66 to 125) and 44 days (95%CI 32 to 70 days), respectively. The probability of being on the study without intervention is shown in Figure 1.

Conclusions: We found that most patients will require some counseling to maintain the use of a wrist-based wearable device for remote monitoring. While most patients require an intervention before 90 days into wear, the patients who can maintain use independently after that point are likely to do so for longer.

TH-PO260

The Relationship Between the Patient Activation Measure and Changes in Patient Self-Efficacy on In-Center Hemodialysis

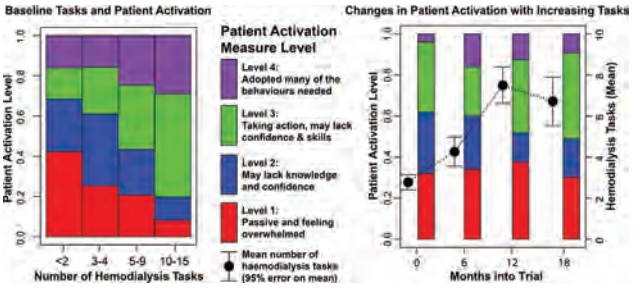
James Fotheringham,[1,3] Pannn Ei Hnynn Si,[1] Paul Laboi,[2] Andy Henwood,[2] Sonia K. Lee,[1] Steven M. Ariss,[3] Martin E. Wilkie.[1] SHAREHD *[1]Sheffield Kidney Institute, Sheffield, South Yorkshire, United Kingdom; [2]York Hospital, York, United Kingdom; [3]University of Sheffield, Sheffield, United Kingdom.*

Background: The patient activation measure (PAM) assesses the knowledge, skills and confidence to manage their health condition. Low PAM is associated with worse outcomes and increased healthcare cost, and is increasingly seen as an endpoint for complex interventions in chronic diseases. PAM includes many domains applicable to in-center (ICHD) and home (HHD) hemodialysis but its sensitivity to change in more objective measures of self-efficacy in ICHD and HHD patients is unknown.

Methods: A stepped wedge randomised trial involving 12 centers supported patients to learn and undertake ICHD-related tasks over 18 months. PAM and how many of 15 ICHD tasks patients were undertaking was measured on 4 occasions. The relationship between within-patient changes in PAM (scored 0-100%) and the endpoints of numbers of ICHD tasks and moving to HHD were assessed using mixed-effects linear regression models, adjusting for patient characteristics.

Results: 534 patients completed 1611 PAM questionnaires during the study. The proportion of patients doing 5+ tasks increased from 44.3% to 52.3% (P=0.01), with 10.3% performing HHD or ICHD independently by the end of the study. At baseline (left figure) performing 5+ tasks was associated with a 10.7% difference in PAM score (95% CI 6.8 – 14.6). During the study (right figure) moving from <5 to 5+ tasks was associated with a 4.3% change in PAM (95% CI 2.3 – 6.4%) and 4.8% (95% CI 0.4 – 9.2%) moving to independent ICHD or HHD.

Conclusions: This supported learning intervention was effective at increasing patient participation in ICHD-related tasks. Despite a strong baseline relationship between PAM and ICHD tasks, the longitudinal change in PAM with increased ICHD tasks, independent ICHD and HHD only just exceed the minimum clinically meaningful difference (4%). The relationship between PAM and self-efficacy is complex and greater understanding of their measurement is needed to avoid potential underestimation of benefits of complex interventions.



TH-PO261

Natural Killer Cell Activity Contributes to Development of Sarcopenia in Hemodialysis Patients

Hyeong cheon Park,[1] Jung eun Lee,[2] Hae Yeul Park,[3] Kwon soo Jung,[3] Moon hyoung Lee,[3] Hoon Young Choi.[1] *[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Yongin Severance Hospital, Yongin-si, Republic of Korea; [3]Gangnam Severance Hospital, Seoul, Republic of Korea.*

Background: Sarcopenia, a syndrome of reduced skeletal muscle mass and function, is associated with decrease immune system responsiveness. Decreased natural killer (NK) cell activities have been suggested in hemodialysis (HD) patients. The aim of this study is to determine the relationship between NK cell activity and sarcopenia in HD patients.

Methods: We enrolled 116 clinically stable HD patients (62 male) and clinical data such as age, sex, height, weight, dialysis duration, and comorbidities were collected. Biochemical parameters, including white blood count, hemoglobin, albumin, C-reactive protein, and iron profiles were determined before the dialysis session. Muscle mass was evaluated by bioimpedance analysis (Inbody S10, Biospace Co., Korea) and hand grip strength was assessed using digital hand grip dynamometer. The diagnosis of sarcopenia was made according to the guidelines of Asian Working Group for Sarcopenia. Cytotoxic activity of NK cells was determined using commercial blood test assay (NK Vue, ATGen, Seongnam, Korea) that uses serum of ex vivo stimulated whole blood to detect interferon (IFN)-γ secreted from NK cells as an indicator of NK cell activity. IFN-γ levels were further quantitated by ELISA. Univariate and multivariate binominal logistic regression analyses were used to determine the association between clinical variables including NK cell activity and sarcopenia in HD patients.

Results: A total of 29 patients (25%) were diagnosed as sarcopenia among 116 HD patients. The sarcopenic HD patients were significantly older (70.1 ± 8.1 vs. 61.1 ± 11.3 years, P<0.001) and had longer HD vintage (63.1 ± 54.0 vs. 38.5 ± 38.9 months, P=0.029), whereas showed lower body mass index (BMI) (20.7 ± 3.8 vs. 23.4 ± 6.2 kg/m2, P<0.01), lower appendicular lean muscle mass (ALM, 8.26 ± 2.8 vs. 9.83 ± 4.5 kg/m^2, P<0.01), and lower activity of NK cell (392 ± 517 vs. 876 ± 667 pg/mL, P=0.001). Low NK cell activity had a very significant correlation with sarcopenia, and the statistical significance was maintained even after adjustment for age, sex, BMI, ALM in multivariate regression analysis [Exp(B) 0.104(0.033, 0.324), P<0.001].

Conclusions: Our results show that the NK cell activity of sarcopenic HD patients is significantly decreased and such low NK cell activity may contribute to development of sarcopenia in HD patients.

TH-PO262

Skeletal Muscle Chaperone and Co-Chaperone Proteins Are Elevated in Maintenance Hemodialysis Patients

Hsin-Yu Fang,[1] Stephan Van vliet,[2] Amadeo F. Salvador,[1] Colleen F. McKenna,[1] Nicholas A. Burd,[1] Kenneth R. Wilund.[1] *[1]University of Illinois Urbana-Champaign, Urbana, IL; [2]Duke University, Durham, NC.*

Background: Various chaperone and co-chaperone proteins are required for the assembly and maintenance of the sarcomere to allow for maintenance of muscle tissue. We have previously established that both myofibrillar protein synthesis rates and markers of proteolysis are elevated in patients on maintenance hemodialysis (HD) when compared to BMI-matched controls. This result potentially underpins poor structural integrity that ultimately leads to poor physical performance in HD patients. Therefore, we aimed to determine whether HD patients have a higher abundance of chaperone and co-chaperone proteins involved in sarcomere integrity as compared to age- and BMI-matched controls.

Methods: Six HD patients (sex: 83.3% male; age: 58±13 y; BMI: 32±7 kg/m^2) and six controls (sex: 66.7% male; age: 51±7 y; BMI: 31±4 kg/m^2) received biopsies from the

vastus lateralis after an overnight fast on a non-dialysis day to assess the relative protein content of Unc45b, Smyd1, Stub1, MuRF1, Hsp40, Hsp70, Hsp90α, and αβ-crystallin by Western blotting. We also determined plasma C-reactive protein (CRP) concentrations by ELISA. Pearson's correlation coefficient or the Spearman correlation coefficient were used to test the associations between systemic inflammation and sarcomere integrity.

Results: The skeletal muscle protein contents of Stub1 (P=0.032), MuRF1 (P=0.025), Hsp40 (P=0.039), and αβ-crystallin (P=0.019) were all elevated in HD patients when compared to controls, but the protein expressions of Unc45b (P=0.073), Smyd1 (P=0.922), Hsp70 (P=0.636), and Hsp90α (P=0.434) were not different. Among the four chaperones and co-chaperones whose protein expressions increased in HD patients, Stub1 (r_s=0.833, P=0.010) and Hsp40 (r=0.896, P=0.003) were positively correlated with plasma CRP concentrations. However, neither MuRF1(r_s=0.450, P=0.224) nor αβ-crystallin (r_s=0.417, P=0.265) were associated with plasma CRP concentrations.

Conclusions: We demonstrated that the protein expression of several chaperones and co-chaperones in skeletal muscle were upregulated and positively correlated with the level of systemic inflammation in HD patients. Future studies are required to identify if dampening the inflammatory and uremic milieu can restore the regulation of muscle mass to a more 'normal-state' in HD patients.

TH-PO263

Reliability of Appendicular Muscle Mass Assessment by Bioelectrical Impedance Analysis vs. Dual-Energy X-Ray Absorptiometry in Hemodialysis Patients

Kwon soo Jung,[1] Moon hyoung Lee,[1] Hae Yeul Park,[1] Hoon Young Choi,[1,2] Hyunwook Kim,[2,1] Hyeong cheon Park.[1,2] *[1]Gangnam Severance Hospital, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Loss of skeletal muscle mass(MM) increases the risk for morbidity and mortality in hemodialysis (HD) patients. Dual energy X-ray absorptiometry (DXA) is a valid tool for assessing skeletal MM but limited by cost and radiation exposure. In contrast, bioelectrical impedance analysis (BIA) is cheap and has no radiation exposure risk. Aim of this study was to assess the concordance between MM measured by BIA and DXA in HD patients.

Methods: We enrolled 55 clinically stable HD patients. Body composition, including appendicular lean muscle mass (ALM), was evaluated by BIA (Inbody S10) and whole body DXA (HOLOGIC®). Hand grip strength (HGS) was performed to evaluate muscle performance. Agreement between tools was assessed by means of the Bland Altman method. Multiple linear regression was used to develop an ALM value by BIA closed to that by DXA.

Results: The mean age was 63.4±11.29 years (range 39 to 88 years) and 65.5% were men. The prevalence of diabetes and hypertension was 54.5% and 94.5%, respectively. There was a significant association between muscle mass index which determined via DXA and BIA. The mean value of ALM divided by the height^2 (AMMI) was found to be 5.98±0.90 kg/m^2 and 7.90 ±1.39 kg/m^2 by DXA and by BIA, respectively, indicating overestimation of ALM in BIA method. BIA overestimated total body lean mass in 98% of participants. Bland-Altman plots for differences in AMMI between BIA and DXA showed large bias (Mean= 1.92kg/m^2), with significant mean differences ([0.29, 3.55], P<0.001). After adjusting for sex, age and BMI, AMMI by BIA was significantly correlated with those measure by DXA (R2=0.643, P<0.001). Using the formula, we can estimate the AMMI by DXA with AMMI by BIA (DXA=0.859+0.452BIA+0.068BMI, R2=0.709, P<0.001). Mean HGS was 24.6±7.90 kg and AMMI showed no correlation with the HGS.

Conclusions: Our results showed that AMMI measured by BIA is reliable but overestimated in HD patients. Further reinfinement of adaptation formula for use BIA is needed to obtain accurate measurement of AMMI close to that measured by DXA.

TH-PO264

Wrist-Based Accelerometry and Physical Function in Dialysis Patients

Sonia Kotwani,[4] Lovepreet S. Randhawa,[4] Samhitha Munugoti,[4,3] Solomon Dalezman,[1] Kate Nam,[2] Antonio C. Elters,[4] Sandheep Venkataraman,[3] William Paredes,[4] Nitin Ohri,[4,3] Matthew K. Abramowitz,[4] Jose S. Ibarra.[4] *[1]Island Nephrology Services, Flushing, NY; [2]Albert Einstein Medical School, Scarsdale, NY; [3]Montefiore Medical Center, Bronx, NY; [4]Albert Einstein College of Medicine, Bronx, NY.*

Background: Poor physical function is a powerful predictor of adverse outcomes in dialysis patients. Whether daily activity monitoring can detect patients with lower levels of physical function is unknown.

Methods: We conducted a prospective study of wrist-based accelerometry in a single outpatient dialysis unit. Fifty patients receiving thrice-weekly hemodialysis were enrolled and wore a commercial fitness tracker for 6 months. Physical function was assessed by usual gait speed, grip strength, and the Short Physical Performance Battery (SPPB, range 0-12, higher is better). Information on the composite outcome of emergency department (ED) visits or hospitalizations was obtained from monthly patient questionnaires, dialysis unit records, and our hospital electronic medical record. Mixed effects models were created to examine the association of daily step counts with each functional outcome. Poisson regression using generalized estimating equations was used to examine associations with the composite outcome. Models were adjusted for age, sex, race, BMI, and diabetes status.

Results: Data were excluded for 3 patients who did not perform physical function testing. Daily step counts at baseline averaged 4538 +/- 3001. The mean age of the cohort was 60+/-13, 49% were women, 40% were black, 47% had diabetes, and the mean BMI was 28+/-7 kg/m^2. For each 1000 steps more per day, gait speed was 1.2 cm/sec faster (95%CI 0.1-2.3); dominant hand grip strength was 0.6 kg higher (95%CI: 0.1-1.1) and SPPB was 0.13 (95% CI: 0.02- 0.23) points higher. Neither SPPB, gait speed, nor grip strength was associated with the composite outcome. However, step counts were associated with the composite outcome even among patients with high SPPB scores: among patients with SPPB>8, every 1000 steps more per day was associated with 50% decreased risk (IRR 0.5, 95% CI 0.39- 0.63); among those with SPPB≤8, there was a 14% decreased risk (IRR 0.86, 95%CI 0.73- 1.00).

Conclusions: Lower step counts are associated with poorer performance on several measures of physical function in dialysis patients and are associated with the risk of hospitalization and ED visits even among patients with preserved physical function.

TH-PO265

Dialysis Recovery Time and Physical Activity Levels

Lovepreet S. Randhawa,[4] Sonia Kotwani,[4] Samhitha Munugoti,[4,3] Solomon Dalezman,[1] Kate Nam,[2] Sandheep Venkataraman,[3] William Paredes,[4] Nitin Ohri,[4,3] Matthew K. Abramowitz,[4] Antonio C. Elters,[4] Jose S. Ibarra.[4] *[1]Island Nephrology Services, Flushing, NY; [2]Albert Einstein Medical School, Scarsdale, NY; [3]Montefiore Medical Center, Bronx, NY; [4]Albert Einstein College of Medicine, Bronx, NY.*

Background: Longer post-dialysis recovery times are associated with an increased risk of mortality. Factors accounting for this finding have yet to be elucidated. We examined whether lower physical activity levels could be one explanation.

Methods: We conducted a prospective study of wrist-based accelerometry in a single dialysis unit. Fifty patients receiving thrice-weekly hemodialysis were enrolled and wore a commercial fitness tracker for 6 months which provided daily step count data. Average monthly post-dialysis recovery times were assessed by asking **"**How long does it take you to recover from a dialysis session?" Mixed effects models adjusted for age, sex, race, BMI, diabetes status, and ultrafiltration volume, with random coefficients for follow-up time, were created to examine the association of recovery time with daily step counts.

Results: Only the 48 patients who had at least a month of step-count data available were included in the analysis. The cohort consisted of 51% women, 40% African-Americans and 47% were diabetic. Patients who reported recovery time of <15 minutes walked 5576(+/-427) steps per day in comparison to patients who reported recovery time of > 12 hours and walked 3260(+/- 573) steps. After adjustment, compared with patients in the <15 min recovery time group, those in the 15min-2 hr group took 271 fewer steps(95% CI, -1038 to 496), 2-6 hours recovery took 1635 fewer steps(95% CI,-2456 to-812), 6-12 hours recovery time group took 2129 fewer steps(95% CI,-4417 to 170) and >12 hours recovery time took 2367 fewer steps (95% CI, -3397 to -1336). In comparison, 10 years older age was associated with 1060 fewer steps per day (95% CI,-1350 to -770). Diabetes, gender, race and ultrafiltration amount were not associated with step counts.

Conclusions: Longer recovery time after dialysis is strongly associated with lower physical activity level. This is not explained by the amount of ultrafiltration. Studies should examine the effectiveness of increasing physical activity to improve outcomes in these patients.

TH-PO266

Wrist-Based Accelerometry and Risk of Emergency Department Visit or Hospitalization

Samhitha Munugoti,[3,4] Sonia Kotwani,[3] Lovepreet S. Randhawa,[3] Solomon Dalezman,[1] Antonio C. Elters,[3] Kate Nam,[2] Jose S. Ibarra,[3] Sandheep Venkataraman,[4] William Paredes,[3] Nitin Ohri,[3,4] Matthew K. Abramowitz.[3] *[1]Island Nephrology Services, Flushing, NY; [2]Albert Einstein Medical School, Scarsdale, NY; [3]Albert Einstein College of Medicine, Long Island City, NY; [4]Montefiore Medical Center, Bronx, NY.*

Background: Sedentary behavior has been associated with poor outcomes in dialysis patients. Whether changes in physical activity yield additional prognostic information is unknown.

Methods: We conducted a prospective study of wrist-based accelerometry in a single outpatient dialysis unit. 50 patients receiving thrice-weekly hemodialysis were enrolled and wore a commercial fitness tracker for 6 months which provided daily step count data. Information on emergency department (ED) visits and hospitalizations were obtained from monthly patient questionnaires, dialysis unit records, and our hospital electronic medical record. Each patient's baseline activity level was defined as the mean step count during the 2 weeks following study entry. Poisson regression using generalized estimating equations and adjusted for age, sex, race, BMI, diabetes status, and follow-up time was conducted to examine the association of step counts with the composite outcome of ED visit or hospitalization, and with hospitalization alone.

Results: Data were excluded for 2 patients who wore the device <1 month. Daily step counts at baseline averaged 4538 +/- 3001. The mean age of the cohort was 60+/-13, 49% were women, 40% were black, 47% had diabetes, and the mean BMI was 28+/-7 kg/m^2. Compared with participants in the highest step count tertile, those in the lowest step count tertile were older but did not differ by other baseline characteristics. There were 38 occurrences of the composite outcome in 17 patients. After adjustment, each 1000-step reduction in daily step count was associated with 28% increased risk of both the composite outcome (incidence rate ratio (IRR) 1.28, 95% CI 1.07-1.53) and hospitalization alone (IRR 1.28, 95% CI 1.21-1.61). Each 10% reduction from an individual's baseline activity level was associated with a 17% increased risk of the composite outcome (IRR: 1.17, 95%CI: 1.02-1.34).

Conclusions: Step count monitoring using a wearable device identifies changes in activity that are associated with increased risk of hospitalization or ED visit. Future studies should examine whether this approach could provide a real-time prediction of adverse events.

TH-PO267

Dialysis Recovery Time as a Predictor of Hospitalization Among Incident Hemodialysis Patients

Vladimir Rigodon,[2] Murilo H. Guedes,[5] Roberto Pecoits-Filho,[5] Juliana E. Leme,[5] Yue Jiao,[3] Jochen G. Raimann,[4] Peter Kotanko,[4,7] Thyago P. Moraes,[5] Ravi I. Thadhani,[6] Franklin W. Maddux,[1] Len A. Usvyat,[3] John W. Larkin.[3,5] *[1]Fresenius Medical Care, Waltham, MA; [2]Frenova Renal Research, Waltham, MA; [3]Fresenius Medical Care North America, Waltham, MA; [4]Renal Research Institute, New York, NY; [5]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [6]Cedars-Sinai, Los Angeles, CA; [7]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Dialysis recovery time (DRT) is the perceived time it takes patients to recover their ability to undertake daily activities after hemodialysis (HD). DRT is a meaningful variable to assess health related quality of life (HRQOL) in HD patients. As such, DRT as a predictor of hospitalization could be looked at as an early indicator of treatment success or impending morbidity. We characterized the hospital admission rates based on DRT categories among incident HD patients treated at a large dialysis organization (LDO).

Methods: We used data at an LDO during 2014 through 2017 for patients who completed a DRT survey ≤180 from first date of HD. DRT survey was administered as part of KDQOL questionnaire. DRT survey asks: "How long does it take you to be able to return to your normal activities after your dialysis treatment?". Categorical answers were: <0.5, 0.5-1, 1-2, 2-4, >4 hours. Hospital admission rates were compared by DRT category (DRT <0.5 hour reference) via unadjusted Poisson models.

Results: We included data from 98616 incident HD patients (age 62.6±14.4 years; 57.8% male). There were 25.2%, 19.1%, 17.3%, 15.5%, and 22.9% of HD patients reporting a DRT of <0.5, 0.5-1, 1-2, 2-4, and >4 hours, respectively. We observed 6-, 12-, and 24-month crude admission rates of patients rose with each longer DRT category (all p<0.001), as compared to patients with a DRT <0.5 hour (Figure 1).

Conclusions: Findings suggest longer DRTs in incident HD may associate with progressive increases in crude short- and long-term admission rates. DRT is an important marker of how well the patient feels and tolerates HD therapy. Optimizing the HD treatment around DRT in the incident period may have the ability to improve HRQOL and outcomes.

TH-PO268

Perspectives of Pakistani Patients Receiving Maintenance Dialysis on End-of-Life and Dialysis Decision-Making

Fahad Saeed,[1] Muhammad Sardar,[2] Khalid Rasheed,[3] Raza Naseer.[4] *[1]University of Rochester Medical Center, Pittsford, NY; [2]Monmouth Medical Center, Long Branch, NJ; [3]Army Medical College, Pakistan, Islamabad, Pakistan; [4]Liaquat University of Medical and Health Sciences, Elgin, IL.*

Background: There is a paucity of literature on end-of-life care (EoLC) and treatment preferences of Pakistani patients receiving maintenance dialysis. Most of the literature on these issues report beliefs of Western dialysis patients; however, both patient populations may differ in their cultural and religious beliefs about EoLC issues.

Methods: Using a convenient sampling method, we surveyed 522 dialysis adult patients from 7 different dialysis units across 4 cities of Pakistan from March through June 2015. The survey was adapted from the previous literature and translated in the Urdu language.

Results: The majority of the patients wanted detailed information about their disease (67.6%), and prognosis (54.4%). However, 81% reported not having prognostic discussions with their nephrologists. Only a small percentage of patients' self-reported knowledge about services such as hospice (5%) and palliative care (8%). Nearly forty-seven percent of the respondents said that they would choose a course of treatment focused on relieving pain rather than extending life (19%). The decision to initiate dialysis over conservative management was made by doctors in 54% of the respondents. Almost 35% of the patients were not satisfied with their decision to start dialysis.

Conclusions: Pakistani patients receiving maintenance dialysis wish to receive better education on their prognosis and end-of-life care issues. Interventions to improve dialysis decision-making processes and uptake of hospice and palliative care services are needed in this population.

TH-PO269

The EDITH Kidney Patient Survey on Modality Choice Among More Than 8000 European Dialysis and Transplant Patients

Rianne W. de Jong,[2] Vianda S. Stel,[2] Raymond C. Vanholder,[3] Ziad Massy,[1] Kitty J. Jager.[2] *[1]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [2]ERA-EDTA Registry, Department of Medical Informatics, Amsterdam Public Health Research Institute, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands, Amsterdam, Netherlands; [3]University Hospital Gent, Gent, Belgium.*

Background: Renal replacement therapy (RRT) modality selection may be challenging for both patients and nephrologists. Within the EDITH project we surveyed adult European dialysis and kidney transplant patients on factors influencing modality choice and their satisfaction with the modality choice made.

Methods: The EDITH kidney patient survey (online and on paper) was translated into 30 languages. European adults with end-stage kidney disease treated by dialysis or kidney transplantation were eligible to participate between November 2017 and November 2018.

Results: 8133 patients from 40 European countries participated. Age, gender and modality characteristics (56% male, mean age 59 years (SD 14), 66% on haemodialysis (HD), 6% on peritoneal dialysis (PD), 29% on transplantation (Tx)) reflected the European RRT population in the ERA-EDTA Registry. A quarter of the patients did not receive any information on any modality before the start of RRT. 44% received no information on home haemodialysis (HHD), 24% nothing on PD and resp. 23% and 20% nothing on living and deceased kidney donor Tx. The majority of those who received information, were (very) satisfied with the information (range 57% for HHD to 86% for deceased kidney donor Tx). Two-thirds of the patients reported that decision making was shared with their doctor and most patients (83%) were satisfied with way the decision was made. The main reasons for patients not having a particular treatment are listed in Table 1. Most important factors influencing modality choice were quality of life, survival and safety (resp. 97.3%, 96.6% and. 92.2% rated as (very) important). Results were similar by age group, sex, educational level and start of RRT time period.

Conclusions: Though most patients seem to be satisfied with the information provision and modality choice, there remains room for improvement as a quarter of all patients did not receive any information on treatment modalities before start of RRT. Better education may also influence patients to choose a home-based form of dialysis or empower them to find a living donor.

Funding: Government Support - Non-U.S.

Table 1 Main reasons not to have a certain treatment

HHD
Don't want treatment at home (34%)
Treatment is not available in my hospital (26%)
Discomfort with no supervision (24%)
PD
Don't want treatment at home (34%)
Dislike of abdominal catheter (23%)
Fear of peritonitis (22%)
Living Tx
No living kidney donor available (37%)
Don't want to ask potential donors (31%)
Concerns about the health of the donor (18%)
Deceased donor Tx
Not healthy enough (25%)
Currently on waiting list (22%)
Too old (18%)

TH-PO270

Functional Status Index Directed Care in the Patient-Centered Supportive Care Pilot

Hao Han, Sheetal Chaudhuri, Jessica Demaline, Cheryl E. Casamento, Karen G. Butler, Marta Reviriego-Mendoza, John W. Larkin, Dugan Maddux, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: A large dialysis organization (LDO) developed a functional status index (FSI) that can identify hemodialysis (HD) patients who are experiencing a lower level of functional status. The LDO performed Patient Centered Supportive Care (PCSC) pilot that identified HD patients with a decreasing/diminished FSI and provided targeted interventions based on identified barriers. We assessed if the FSI-directed intervention was associated with improvements in the FSI score.

Methods: We used data from 8 PCSC pilot clinics between 04/13/2018 to 10/30/2018. The FSI uses an array of clinical data and is computed via Z scores and weighted assignments of parameters. In the PCSC pilot, FSI-directed intervention was provided over 28 weeks to patients with a low and decreasing trend in their FSI score. This intervention included targeted clinical recommendations related to treatment adherence, weight management, nutrition, financial assistance, medications and comorbidities, as well as, external referrals to specialists. We calculated the percent of patients who had an increase in their FSI score from baseline in the FSI-directed intervention (FSI positive) versus standard of care (SOC) group who did not have an intervention (FSI negative).

Results: We analyzed data from 497 HD patients at the 8 PCSC pilot clinics. FSI-directed intervention was provided to 42 patients. Patients with a low/decreasing FSI score had a higher mortality rate (14% FSI positive and 6% FSI negative SOC). Over the course of the pilot, 58% of the survivors with FSI-directed intervention had an increase in their FSI score compared to baseline. In the SOC group, 47% of survivors without the intervention had an increase in their FSI score.

Conclusions: The FSI-directed intervention was associated with >10% higher proportion of patients having an improvement in their FSI score. As anticipated, the FSI score identifies patients with higher mortality rates. Additional testing of the FSI-directed intervention is needed to confirm these observations.

"I Didn't Know Better": Family Members' Unexpected Negative Experiences with ESKD Treatments

Nicole DePasquale,[1] Ashley N. Cabacungan,[2] Patti Ephraim,[3] Lapricia L. Boyer,[3] Neil R. Powe,[4] L. Ebony Boulware.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Division of General Internal Medicine, Durham, NC; [3]Johns Hopkins University, Baltimore, MD; [4]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA.*

Background: Understanding the extent to which family members feel prepared for what to expect from patients' end-stage kidney disease (ESKD) treatment could guide the development of family-centered interventions that enhance their treatment preparedness. We examined unexpected negative experiences with ESKD treatments among family members of dialysis and post-transplant patients to inform family-centered research and clinical care.

Methods: Forty-nine family members of patients receiving medical care in the Baltimore, Maryland metropolitan area participated in eight focus groups stratified by their self-reported race (African American or non-African American) and patients' treatment experience in the past year (in-center hemodialysis, home hemodialysis, peritoneal dialysis, or live donor kidney transplantation). Focus group discussions were analyzed thematically. Themes present in discussions from multiple treatment groups were highlighted to provide insight into common experiences. Exemplar quotes are provided for each theme.

Results: Four themes were identified. *Becoming a caregiver* reflected family members' unpreparedness for caregiving responsibilities ("I didn't expect to have to be involved") and related consequences ("I couldn't even sleep"). *Psychological responses* captured family members' negative reactions to treatment ("The anxiety") as well as their perceptions of patients' reactions ("I think he's depressed"). *Treatment delivery and logistics* depicted treatment situations family members considered problematic ("Why can't they just use layman's terms?"), challenging ("We had so many medications, it's constantly juggling that"), or inconvenient ("The space it takes to store 3,000 cases of stuff is unbelievable") for themselves and patients alike. *Morbidity* encompassed family members' perceptions of patients' experiences with dialysis-related health problems ("More illnesses since dialysis") and fatigue ("My son was so tired").

Conclusions: Findings suggest patients' family members are unprepared for non-clinical, logistical, and clinical aspects of ESKD treatments. Efforts to prepare families for ESKD treatments through more family-centered care, early and tailored education, and interventions targeting caregiver preparedness are needed.

Funding: NIDDK Support

TH-PO272

Patients' Unexpected Adverse Experiences with Dialysis and Transplantation

Nicole DePasquale,[1] Ashley N. Cabacungan,[2] Patti Ephraim,[3] Lapricia L. Boyer,[3] Clarissa J. Diamantidis,[1] Neil R. Powe,[4] L. Ebony Boulware.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Division of General Internal Medicine, Durham, NC; [3]Johns Hopkins University, Baltimore, MD; [4]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA.*

Background: Patients with end-stage kidney disease (ESKD) desire better education about what to expect from treatment, and preparatory information is associated with positive outcomes for chronic disease patients. Yet, knowledge about the expectedness of ESKD patients' treatment experiences is limited. We studied unexpected adverse treatment experiences among dialysis patients and transplant recipients to understand how providers and pre-treatment interventions can better prepare ESKD patients for treatment experiences.

Methods: Fifty-five patients receiving medical care in Baltimore, Maryland participated in focus groups stratified by their treatment in the past year (in-center hemodialysis, home hemodialysis, peritoneal dialysis, or live donor kidney transplantation) and race (African American or non-African American). Discussions were analyzed thematically. Themes present in discussions from multiple groups were highlighted; exemplar quotes are provided.

Results: We identified five themes. *Psychological responses* reflected patients' negative psychological reactions to treatment, which ranged from feeling different from healthy peers ("I want to be like everybody else who's not on dialysis") to feeling suicidal ("I'm going to kill myself"). *Constrained freedom of choice* captured losses or limitations in recreational ("The only thing I can get on now is the treadmill") and work ("I can't work anymore") activities. *Treatment delivery and logistics* characterized patients' perceptions of painful ("I dislike sticking needles in my arm"), problematic ("I felt like a number in the center"), challenging ("It was hard for me to stay focused on the diet plan"), and inconvenient ("It's not always convenient to dialyze five days a week") treatment situations. *Morbidity* described patients' experiences with treatment complications ("I've had a lot of operations") and comorbidities ("I've had two asthma attacks"). *Finances* pertained to treatment-related expenses, financial strain from unemployment, and hiring caregivers to assist with treatment delivery.

Conclusions: Patients felt unprepared for non-clinical, logistical, and clinical aspects of ESKD treatments. Findings underscore the need for pre-treatment interventions to help patients know what to expect from and feel psychologically prepared for ESKD treatment.

Funding: NIDDK Support

TH-PO273

Patient and Caregiver Experiences and Perspectives on Access to Kidney Replacement Therapy in Rural and Remote Communities: Thematic Synthesis of Qualitative Studies

Nicole J. Scholes-Robertson,[1] Martin Howell,[2] Talia M. Gutman,[2] Jonathan C. Craig,[3] Allison Tong.[1] *[1]The University of Sydney, Armidale, NSW, Australia; [2]University of Sydney, School of Public Health, Sydney, NSW, Australia; [3]Flinders University, Adelaide, SA, Australia.*

Background: Patients with chronic kidney disease requiring kidney replacement therapy in rural and remote communities are at higher risk of mortality when compared with those in urban areas, and encounter many barriers in accessing care. We aimed to describe patient/caregiver perspectives on access to dialysis and kidney transplantation in rural/remote communities. Access is defined as the opportunity to reach and obtain appropriate health care services and includes the right to seek information concerning health issues.

Methods: Medline, Embase, PsycINFO and CINAHL were searched to February 2019. Studies that where qualitative in nature, provided perspectives of patient and/or caregivers who resided in rural/remote communities, patients over 18 years of age and required Kidney replacement therapy were included. Thematic synthesis was used to analyze the findings.

Results: From 18 studies (n= 540 participants) conducted across 8 countries (Australia, Canada, United Kingdom, New Zealand, Ghana, United States, Tanzania, and India), we identified six themes: uncertainty in navigating healthcare services (inadequacy of absorbing information, without familiarity and exposure to options, lacking trust in clinicians and yearning for cultural safety at a local level); fearing separation from family and country (devastating homesickness, unable to fulfil family roles, preserving sense of belonging in community and grieving former roles); intense burden of travel and cost (poverty of time, exposure to risks and hazards, taking a financial toll and tedious pre-transplant testing processes and workup expenses); suffering hardship and loss (making life changing sacrifices, relocation with no return and inadequacy of transitional accommodation); grief, guilt and worry in receiving care (shame in resource usage and harboring concerns for living donor) and; coping and managing in isolation (hesitation about capacity to do home dialysis).

Conclusions: Patients with CKD in rural/remote areas face profound challenges of displacement, financial burden, separation from family in accessing kidney replacement therapy; which can have severe consequences on wellbeing and outcomes. Strategies are needed to improve access for those patients in rural/remote communities.

TH-PO274

Patient Driven Video-Educational Tool in ESRD

R Geoffrey Motz,[3] Janet Boyle,[1] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VAMC, Cincinnati, OH; [3]Univ of Cincinnati, Cincinnati, OH.*

Background: Eeach year, of the ~ 110,000 incident incident end stage renal disease (ESRD) patients in the U.S., ~ 46% have not received pre-ESRD nephrology care. Pre-ESRD patient education improves outcomes and quality of life. There are limited options to incorporate patient experience into pre-ESRD education.

Methods: In a large academic program we designed a educational tool comprised of a patient interview video, in a patients-teaching-patients model. A planning committee (trainees, physicians, nurse educator and patient surveys) determined the components of this tool. The open-ended patient interviews focused on domains pertaining to experience with dialysis modality, preparation towards dialysis/transplant, lifestyle changes, and journey of accepting life after ESRD. After obtaining informed consent patients were interviewed for ~ 4 hours, edited by three reviewers into a 50 min video, and viewed by faculty and trainees to obtain provider feedback.

Results: There were 6 patients with ESRD (3 Women; 1 White and 5 Black); [3 hemodialysis (HD), 2 home dialysis (HD and peritoneal dialysis), and 1 transplant recipient]. Patients had varying degrees of pre-ESRD education, and had different journeys prior dialysis; and were eager to share their experiences with their peers. The patient reported themes included: their pre-determined fear of dialysis was misplaced; they appreciated the value of adherence to life-sustaining therapies; adjustment to diet and lifestyle modifications was a big component in accepting ESRD care; and they did not realize the available flexibility of dialysis care which may allow them to travel, continue employment, and maintain quality of life. As for provider feedback, 100% found this video to be a critically important educational tool. A shorter shorter duration and including more discussion on transplantation was recommneded. Interestingly, patients felt that although they preferred a peer-driven educational component, it cannot replace the healthcare professionals education.

Conclusions: We successfully demonstrated that patient experience can be incorporated into a succinct video-based educational tool. Key peer-driven components may allay fears of dialysis, improve adherence to dietary and lifestyle changes, and

compliment provider education. Future steps include incorporating this tool prospectively, and assess its effectiveness in pre-ESRD educational programs.

TH-PO275

Shared Care in Haemodialysis: A Path to Independence

Nasreen Samad,[2] Sara Z. Khan,[1] Franel Ave,[2] Adrian Capitan.[2] *[1]American University of Antigua, Levittown, NY; [2]Barts Health NHS Trust, Royal London Hospital, London, United Kingdom.*

Background: Most dialysis patients spend many hours every week in hospital, which can leave patients feeling exhausted. Shared care haemodialysis programmes can improve patient satisfaction and may reduce costs. The Queens hospital dialysis unit is a satellite is one of the satellite units of Royal London Hospital, United Kingdom. In order to promote more control of dialysis care to be delegated to patients we aimed to offer shared care programme to all suitable patients coming to the unit which enabled the patients to manage their care with nursing support. Shared haemodialysis care is when patients at dialysis units are supported to undertake tasks involved in their own treatment to the extent that they wish, which would range from performing selected tasks to complete independence in performing haemodialysis in the unit also named as self-care haemodialysis which is suitable for patients with housing issues.

Methods: All patients transferred to the unit were assessed for suitability for shared care. A dedicated link nurse for shared care offered these patients the list of performing 15 different dialysis related tasks. The performance data was collected from January 2018 to April 2019 and 3 monthly progress was noted in patients' capability to perform specific tasks related to haemodialysis care. All these patients were also offered to sign up to "Patient View" a web based system which enabled patients to review there blood results and physician's letters.

Results: In January 2018, at the start of the programme 72 out of 100 (72%) patients were offered to perform the tasks. Only 19% were able to perform 5 or more tasks including 1 patient who could needle fistula independently. By April 2019, 97 out of 105 (92.4%) patients were offered to perform dialysis related tasks and 49.5% were performing 5 or more tasks with 2 patients needling their fistulas independently.

Conclusions: Shared care in haemodialysis is a good way of involving patients in the dialysis care which provides feeling of achievement and independence to patients. It provides dialysis space for patients who cannot perform home haemodialysis due to housing related issues. Achieving complete self care is a daunting task for both the patients as well as responsible health care providers as it was a slow progress to do more complicated tasks. Identifying barriers to achieve these tasks will help in implementation of shared care programme.

TH-PO276

Reasons for Referral to Kidney Supportive Care Clinic and Outcomes in Haemodialysis Population

Sadia Jahan,[1] Louise Purtell,[2,3] Ann Bonner,[2,3] Helen G. Healy,[1,3] Cassandra Rawlings.[1] *[1]Metro North Hospital and Health Service, South Brisbane, QLD, Australia; [2]Queensland University of Technology, Brisbane, NSW, Australia; [3]NHMRC Chronic Kidney Disease Centre of Research Excellence, Brisbane, QLD, Australia.*

Background: In Australia, 32-40% of deaths in the dialysis population are due to treatment withdrawal. Withdrawal from dialysis is usually triggered by failure to thrive on dialysis, high symptom burden, and its associated accelerated chronic comorbid illness. The role of a dedicated multidisciplinary kidney supportive care (KSC) clinic for those on dialysis is not only in managing these symptoms but also providing support surrounding dialysis cessation where appropriate. We aim to analyse the reasons for referral of chronic haemodialysis patients to a KSC clinic and assess decision-related outcomes following the clinic.

Methods: Retrospective analysis of all persons on haemodialysis referred to KSC clinic in the 3 years from inception (February 2016). Reason(s) for referral to clinic, documented advanced care planning, number of visits, potential change of pathway and timing of death were extracted from medical records and analysed descriptively.

Results: Of the total of 364 people referred to KSC clinic, 118/364 (32%) were receiving haemodialysis. Of these, 58% were male with a median age of 69 years (range 27-89 years). Reason for referral were: control of symptom burden (65%), resolve decision-making conflict (25%), advance care planning (50%), education surrounding cessation of dialysis (30%) although some had more than one reason. Post KSC review, 72% had documented advance care plan. Number of visits ranged from 1-12 with a median of 2 clinic reviews. 59/118 (50%) have died at the time of analysis. 38/59 (64%) opted to change pathway from receiving haemodialysis to conservative management pathway before death due to deteriorating health.

Conclusions: Access to KSC is vital in the journey of a patient with chronic kidney disease. A key role of KSC is the discussions on future planning which is usually started by the treating nephrologists and then further elaborated in KSC leading to advanced care planning. This offers tailored, patient-centred care that aligns their beliefs and preferences with their goals, aiming to not only improve quality of life, but quality of death.

TH-PO277

Numeracy Relates to Communication and Clinical Outcomes in ESKD

Devika Nair,[1,2] Marcus G. Wild,[1] Ebele M. Umeukeje,[1,2] Rachel B. Fissell,[1,2] Ken Wallston,[1] Kerri L. Cavanaugh.[1,2] Behavioral Medicine in Chronic Conditions Research Group *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt Center for Kidney Disease, Nashville, TN.*

Background: Numeracy is assessed subjectively via confidence in numerical tasks or objectively via computation. Low numeracy is associated with poor communication with providers and disease control in chronic illness. Understanding kidney function requires interpretation of numerical values, yet numeracy is unexplored in end-stage kidney disease (ESKD). We tested whether numeracy associates with increased confidence in communicating with nephrologists and phosphorus control.

Methods: In a cross-sectional study we recorded demographics, clinical data, and validated surveys. Subjective and objective numeracy were measured via the Subjective Numeracy Scale (SNS) and Wide Range Achievement Test (WRAT), and communication via Patient Perceived Efficacy in Patient Physician Interactions. Pearson's correlations tested associations, and regression models tested associations adjusting for age, sex, race, income, education, cognition, dialysis vintage.

Results: In 150 patients on hemodialysis, subjective and objective numeracy associated with higher income, education, and white race ($p<.01$) (Table). Subjective numeracy associated with confidence in communication ($r=.25, p<.01$) even after covariate adjustment ($\beta=.25, p<.05$), but not with phosphorus ($p=.58$). Objective numeracy did not associate with confidence in communication ($p=.27$) and associated with phosphorus ($r=-.18, p<.05$) but not in adjusted models.

Conclusions: Poor numeracy is common in vulnerable ESKD patients. Supporting efficacy in numeracy may improve communication with nephrologists, but medication and diet control may be more influenced by computation. Numeracy in ESKD education and counseling may enhance patient engagement.

Concerns About and Impacts of Treatment for Kidney Failure from the Perspectives of African American Family Members

Nicole DePasquale,[1] Ashley N. Cabacungan,[2] Patti Ephraim,[3] Lapricia L. Boyer,[3] Neil R. Powe,[4] L. Ebony Boulware.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Division of General Internal Medicine, Durham, NC; [3]Johns Hopkins University, Baltimore, MD; [4]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA.*

Background: Understanding African American families' experiences with treatment for kidney failure is necessary for informing the delivery of family-centered care and the design of appropriate interventions. This qualitative study explored treatment-related questions, concerns, and positive and negative family impacts from the perspectives of African American family members of pre-kidney failure and kidney failure patients.

Methods: Thirty-five African American family members of kidney disease patients receiving medical care in Baltimore, Maryland participated in five focus groups stratified by patients' treatment status in the past year (progressive kidney disease, hemodialysis, peritoneal dialysis, evaluated for living-donor kidney transplantation, or underwent living-donor kidney transplantation). Discussions were analyzed thematically. Themes present in discussions from multiple groups were highlighted to provide insight into common experiences. Exemplar quotes are provided.

Results: Family members raised *questions* and *concerns* about patients' "high risk of" infections, "mental breakdowns," constrained freedom of choice ("Dialysis would just bust her goals"), "the financial aspect" of treatment, and treatment delivery and logistics, specifically inconveniences ("The tube bothers her"), patients' treatment adherence ("Sneaking around and getting the chocolate"), and care quality ("They should have better training"). *Positive family impacts* included improvements in patients' well-being ("He's a lot more compassionate"), "good" patient and family quality of life, strengthened family relationships ("rallying" around the patient), greater freedom of choice ("Going to work again"), and family members' "chance to give life" to patients via transplantation. They identified decrements in patients' well-being ("Her being down on herself"), family members' adverse psychological treatment reactions ("I'm scared"), strained family relationships ("My son and I are not speaking"), and caregiving difficulties ("You as family member need support too") as *negative family impacts*.

Conclusions: Findings underscore the importance of addressing African American family members' perspectives on kidney failure treatment through additional research, early and tailored education, and supportive interventions.

Challenges to Hemodialysis Care and Solutions: Qualitative Analysis of the Can-SOLVE CKD Triple I Study

Clara Bohm,[1,5] Krista F. Rossum,[1] Juli Finlay,[2] Arlene D. Desjarlais,[8] Michael D. Mccormick,[3] Neesh I. Pannu,[7] Matthew T. James,[2] Karthik K. Tennankore,[4] Manish M. Sood,[6] Stephanie E. Thompson,[7] Marcello Tonelli.[2] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]CanSolve CKD, Toronto, ON, Canada; [4]Dalhousie University/NS Health Authority, Halifax, NS, Canada; [5]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [6]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [7]University of Alberta, Edmonton, AB, Canada; [8]Can-solv CKD, Winnipeg, MB, Canada*.

Background: Part of the Can-SOLVE CKD program, 'Triple-I' is a pan-Canadian study that aims to identify top priorities and test solutions for improving patients' hemodialysis (HD) experience in three areas: a) **Information** patients receive b) **Interactions** between provider and patient c) **Individualization** of care. Triple-I follows Can-SOLVE's guiding principles to involve patients in all phases of research as co-creators of knowledge and solutions. In Phase 1, using focus groups and interviews, we identified challenges in HD care and potential solutions in the areas of *information, interaction* and *individualization*.

Methods: From July 1, 2017 to July 31, 2018, we performed focus groups and interviews with HD patients, their caregivers and healthcare providers in 5 academic centres (Edmonton, Calgary, Winnipeg, Ottawa and Halifax). Subsequently, 3 members of the research team conducted a pragmatic categorical analysis to code the data from de-identified transcripts of these sessions. Data were classified by respondent type (patients/caregiver or health care providers).

Results: A total 113 people (64 HD patients, 18 caregivers, 31 health care providers) participated in 8 focus groups or individual interviews, of which 41% were women. Mean age of patients and caregivers was 61 years and mean time on HD was 4.6 years. After accounting for redundancy, a total of 45 recurring challenges in HD care were identified (information n=18; interaction n=16; and individualization n=11). Highly prevalent challenges included *information* on modality/access, transplant and first day of HD; *interactions* with nephrologists, nurses and inconsistency of care with different healthcare providers; and, insufficient *individualization* of session set-up, transportation arrangements and ways to address socio-economic and emotional well-being. Although there were some differences in responses between patients/caregivers and health care providers, many of the challenges coded were identified by both groups.

Conclusions: Although a deeper qualitative analysis of this data is ongoing, the codes/challenges identified in this phase of the study will be used to prioritize challenges and identify and test potential solutions to these challenges in further phases of the study.

TH-PO280

A Cross-Sectional Study of Insomnia in Chronic Hemodialysis Patients

Gregory L. Braden, Daniel L. Landry, Ann Hinckley, Jeffrey Mulhern. *Kidney Care & Transplant Services of New England, Springfield, MA*.

Background: The most frequent complaint in chronic hemodialysis(CHD) patients(pts) is insomnia yet little research has identified all of the causes of this disorder in CHD pts.(Flythe, CJASN,14:150, 2018)

Methods: We conducted a review of sleep patterns in 103 CHD pts on the first & second shifts in our 2 largest dialysis units using these tools: the National Sleep Foundation Survey, the Sleep Diary, Insomnia Severity Index(>8 abnl), Stop-Bang-8 for sleep apnea(SA, 5-8 high risk), Epsworth Sleepineess Scale, Restless Leg(RL) Survey & the International RL Severity Score(>8 abnl).

Results: 25 CHD pts (24%) including 4 with SA had normal sleep patterns averaging 8.1 hours of sleep/nite & <1 awakening from the Sleep Diary & scores of < 7 on the Insomnia Severity Index, 0-3 on Epsworth & 3 or < on Stop Bang-8. Insomnia occurred in 78 CHD pts(76%). Mean duration of sleep ws 3.9 hrs with 2.5 awakenings from the Sleep Diary, p<.001 vs normal CHD pts. The National Sleep Foundation Survey & Epsworth Scale were inconsisitent in identifying these pts. There were no differences in age, duration of dialysis, sex, or causes for ESRD between groups. 24 CHD pts had known SA & in all 24 the STOP Bang-8 was 4 or >, mean 6.2 which is a high risk score for SA. 13 other CHD pts had a Stop Bang-8 of 4 or > & have been sent to sleep medicine. RL occurred in 19 CHD pts with a mean severity score of 25. 14/19 RL pts had iron deficiency vs 22/78(28%) of all other CHD pts with insomnia(p<.01) The levels of serum iron & saturation did not correlate with the RL Severity Score. They are receiving iv iron therapy & will be re-scored. 5 CHD pts had both SA and RL. 13 CHD pts had newly reported causes for insomina : painful neuropathy 9, cramps 2, pruritus, 1 & arthrits 1. Only 13 CHD pts had primary insomnia. Cognitive behavioral therapy(CBT) has started for these pts.

Conclusions: Insomnia occurs in up to up to 75% of CHD pts from diverse causes. The most useful tools to identify insomnia are the Sleep Diary, Insomnia Severity Index & the Stop Bang-8 which correctly identifed all 24 SA CHD pts. RL in CHD pts was associated with iron deficiency. We found 4 new insomnia causes in CHD pts including painful neuropathy, cramps, pruritis & arthritis. Algorithms to treat each cause of insomnia have been developed especailly for safe sedatives for primary insomnia if CBT fails.

Association of Illness and Disability with Elective Withdrawal in Hemodialysis

James B. Wetmore,[1] Heng Yan,[2] David T. Gilbertson,[2] Jiannong Liu.[3] *[1]Hennepin County Medical Center, Minneapolis, MN; [2]Chronic Disease Research Group, Minneapolis, MN; [3]Minneapolis Medical Research Foundation, Minneapolis, MN*.

Background: Few studies have contrasted elective withdrawal with non-withdrawal death by examining factors immediately prior to death.

Methods: Using USRDS data, we performed a retrospective analysis of hemodialysis patients who died 2010-2015. Deaths were divided into withdrawal versus non-withdrawal. A claims-based disability proxy score was used to characterize disability. Logistic regression was used to identify characteristics associated with type of death and death setting. Trajectory models were used to characterize trajectories of medical illness and disability prior to death. Factors associated with in-hospital death were examined.

Results: We identified 14,571 (9.2%) patients who withdrew and 144,305 (90.8%) who died of a non-withdrawal cause. Women were more likely to withdraw (odds ratio [OR] 1.19, 95% confidence interval 1.15-1.24). The most rural patients were more likely to withdraw than the most urban ones (OR 1.37, 1.25-1.50). Medicaid coverage (a marker for impoverishment) was associated with less withdrawal (OR 0.90, 0.86-0.94). Disability proxy score was strongly related to withdrawal: the OR for patients in the highest disability score category was 31.16 (28.40-34.20), vs. a score of 0. While trajectories of traditional medical events did not appear to differ between those who withdrew and those who otherwise died, the trajectory of the disbility score was markedly worse for those who withdrew (Figure). Women and whites (as opposed to blacks) were relatively over-represented in the worse, as opposed to better, trajectory of proxy disability score. In-hospital death was more common in women and minorities than in men and whites, but less common in rural patients.

Conclusions: Worsening disability may be a particularly important marker for elective dialysis withdrawal.

The Effect of Extracorporeal Shock Wave Therapy in Hemodialysis Patients: A Randomized Controlled Trial

Do Hyoung Kim, Younkyung Kee. *Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: Muscle wasting is a common feature in the hemodialysis (HD) patients and associated with comorbid complications, poor quality of life, frailty and premature death. Extracorporeal Shock-Wave Therapy (ESWT) is able to relief pain, as well to positively regulate inflammation (probably as immunomodulator), to induce neoangiogenesis and stem cells activities, thus improving tissue regeneration and healing, and has the advantages of easy application, and minimal risks for these patients. This study aimed to evaluate the effects of intradialytic ESWT.

Methods: This was a single center, prospective, randomized controlled trial. Seventeen HD patients were randomly assigned to either the ESWT group or the control group. The ESWT group received intradialytic ESWT over a 12-week period. Measurement of body composition using a dural energy X-ray absorptiometry, the handgrip strength test, gait speed test, five time sit to stand test, and the timed up and go test for physical function assessment, and blood tests were performed before and after the intervention period.

Results: The ESWT group demonstrated significant improvement compared with the control group in main functional parameters: decreased time in gait speed test (5.5 ± 13.3 vs. -0.5 ± 1.3 sec), five time sit to stand test (3.9 ± 10.7 vs. -1.4 ± 2.8 sec), and the timed up and go test (6.9 ± 17.8 vs. -3.1 ± 4.2 sec). After treatment, lipopolysaccharide concentrations were reduced, and glutathione peroxidase concentrations were increased significantly in ESWT group. However, there was no significant difference in muscle mass and other blood tests.

Conclusions: The ESWT group showed improvement after intervention in physical function test, and oxidative stress parameters. ESWT could be an effective treatment tool for HD patients with either muscle wasting, weakness, or sarcopenia.

TH-PO283

Physical Activity Levels In Hemodialysis Patients: The Fitbit Prospective Study

Ujjala Kumar,[1] Peter Kotanko,[2] Pranav S. Garimella,[1] Danuta Trzebinska,[1] Lisa Cadmus-Bertram,[3] Joachim H. Ix,[1] Rakesh Malhotra.[1] *[1]UCSD, San Diego, CA; [2]RRI, Icahn School of Medicine at Mount Sinai, New York, NY; [3]UW, Madison, WI.*

Background: Physical decline in end stage kidney disease is associated with morbidity and mortality. The aim of this study was to quantify physical activity (PA) in hemodialysis (HD) patients using the Fitbit. We hypothesize that PA measured as by the number of daily steps will be lower in older patients, and those from a rural HD unit.

Methods: In this prospective study, 52 chronic HD patients were recruited from outpatient HD units in urban San Diego and rural Imperial County, CA between March 2018 and April 2019. Key inclusion criteria included: 1) Receiving HD for ≥3 months 2) age ≥18 years and 3) able to walk without assistance or assistive devices. All HD patients wore Fitbit Charge 2 (Fitbit, San Francisco, CA) for 4 weeks. The display of the Fitbit was covered to minimize participation bias. The primary outcome was number of steps per day.

Results: Of 52 enrolled patients, 7 HD patients dropped out before completing 4 weeks study duration. The remaining 45 HD participants (urban=25; rural= 20) were included in the analysis. The mean age was 61 years, 42% were women and 64% were hispanic. The mean dialysis vintage was 4.4 years. On average, HD subjects walked 3687 steps per day. Elderly walked fewer steps compared to younger (age < 65 yrs) HD patients (1359 vs. 4387 steps, p=0.02). Although, not statistically significant average daily steps for participants from rural HD clinic (3141 vs. 4123 steps, respectively) and on dialysis days (3272 vs. 4070 steps, respectively) were less compared to participants from urban HD clinic and non-dialysis days. We found no difference in physical activity levels by gender and dialysis shift (Figure 1). Only about 10 percent of HD participants found activity tracker not comfortable to wear.

Conclusions: Participants on HD were found to be less PA on dailysis days and from rural dialysis clinic. Difference was more pronounced between younger and elderly individuals. Future studies should focus on patient-centered adaptive interventions to sustain and improve PA among HD patients.

Framingham's Cardiovascular Disease (CVD) Risk Score (FRS) and Its Components as Predictors of Mortality in Peritoneal Dialysis (PD) Patients

Chen Zhimin,[1,2] Abdul Rashid T. Qureshi,[3] Xiaohui Zhang,[8] Fei Han,[5] Xishao Xie,[4] Peter Stenvinkel,[6] Bengt Lindholm,[3] Jianghua Chen.[7] *[1]Kidney Disease Center, 1st Affiliated Hospital College of Medicine, Zhejiang University, Hang Zhou, China; [2]Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [3]Karolinska Institutet, Huddinge, Sweden; [4]Kidney Disease Center, The First Affiliated Hospital, Medical School of Zhejiang University, Hangzhou, China; [5]First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [6]Karolinska University Hospital Huddinge, Stockholm, Sweden; [7]Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [8]Zhejiang University, Hangzhou, China.*

Background: Non-traditional risk factors (e g inflammation and oxidative stress) contribute to the high mortality risk due to CVD in patients (pts) with chronic kidney disease (CKD). However, the impact of traditional risk factors represented by FRS, and its components age, sex, hypertension, diabetes mellitus (DM), smoking and hyperlipidemia, is less well documented. We analyzed the associationof FRS with mortality in PD pts.

Methods: In 1276 incident PD pts (median age 50 years, 56 % males), FRS andmetabolicbiomarkers linked to CVD were analysedat baseline. Associations of FRS and its components with all-cause and CVD-related mortality during follow up of up to 60 months (median 44 months) was analysed using regression models with transplantation as competing risk.

Results: Pts in the high tertile of FRS were predominately older men with DM, CVD and high BMI, and low serum creatinine, albumin and parathyroid hormone (iPTH). In linear regression model, FRS associated with CVD, BMI, Hb, iPTH, alkaline phosphatase (ALP), calcium and albumin after adjustments for confounders. *All-cause mortality risk* (expressed as crude sHR) associated with 1-SD higher FRS (sHR 1.50), and its components, higher age (sHR 2.63), female gender (sHR 0.67), and DM (sHR 2.40), and crude *CVD-mortality risk* with 1-SD higher FSR (sHR 1.64), and age (sHR 2.89), DM (sHR 3.41) andcholesterol(sHR 1.08). In competing-risks regression analysis, high vs low tertile of FRS, independently associated with all-cause, sHR 3.65(95% CI 2.07 - 6.44) and CVD, sHR 3.28 (95% CI 1.45 - 7.11) mortality risk after adjusting for CVD, year of recruitment, and 1-SD higher: BMI, creatinine, uric acid, calcium, phosphate, ALP, iPTH, triglycerides, glucose, Hb, ASAT and ALAT.

Conclusions: FRS is independently associated with mortality risk in PD pts, underlining the importance of traditional risk factors in CKD. FRS is a useful risk assessment tool for predicting clinical outcomes in PD pts.

TH-PO285

Relationship of Short-Term and Long-Term Blood Pressure Variability with Death and Cardiovascular Events in Peritoneal Dialysis Patients

Yun Jung Oh,[1] Su mi Lee,[2] Jiwon Ryu,[1] Chungsik Lee.[1] *[1]Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Dong-A University, Busan, Republic of Korea.*

Background: Blood pressure (BP) variability is associated with increased cardiovascular risk, not only in hypertensive patients but also in patients with chronic kidney disease. However, little is known about this association in peritoneal dialysis (PD) patients. This study aims to investigate the relationship of short-term (within 24-hour) and long-term (visit to visit) BP variability with death and cardiovascular events in patients on PD.

Methods: A total of fifty two prevalent PD patients were enrolled and underwent 24-hour ambulatory BP monitoring. Short-term BP variability was assessed with the weighted standard deviation (w-SD) of 24-hour ambulatory systolic BP monitoring and long-term BP variability was assessed with the SD of systolic BP across clinic visits. We assessed the associations of short-term systolic BP variability and long-term systolic BP variability with a composite outcome of death and cardiovascular events.

Results: The average short-term systolic BP variability was 13.3±2.9 mmHg, and average long-term systolic BP variability was 20.6±5.9 mmHg. In unadjusted Cox regression analyses, higher short-term systolic BP variability was significantly associated with increased risk of death and cardiovascular events (HR, 1.437; 95% CI, 1.146-1.801; *P*=0.002). The significant association of short-term systolic BP variability with the composite outcome was also maintained, in adjusted multiple Cox regression model (HR, 1.342; 95% CI, 1.025-1.756; *P*=0.033). However, long-term systolic BP variability was not related to the composite outcome in both the unadjusted (HR, 1.067; 95% CI, 0.958-1.188; *P*=0.239) and adjusted (HR, 1.083; 95% CI, 0.955-1.229; *P*=0.214) models.

Conclusions: In patients on PD, increased short-term systolic BP variability is related to higher risk of death and cardiovascular events, whereas long-term systolic BP variability is not.

TH-PO286

The Beneficial Role of Peritoneal Dialysis on Cardiac Functional Parameters in Patients with Congestive Heart Failure: A 3.5-Year Follow-Up

Panagiotis Pangidis,[1] Andreas Bozikas,[1] Fotini Lazaridou,[2] Styliani Vakiani,[1] Eleni Kitoukidi,[1] Kalliopi Pozoukidou,[1] Evlambia Stamatopoulou,[2,1] Ioannis Tsounos,[2] Sofia Spaia.[1] *[1]Nephrology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [2]Cardiology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece.*

Background: Peritoneal Dialysis (PD) applied in patients (pts) with congestive heart failure (CHF), resistant to diuretic therapy, results in significant improvement of their condition. We examined the effect of PD on extended time period, as a continuous ultrafiltration treatment to pts with CHF (NYHA class IV) and renal disease stage > IIIb on cardiac functional parameters. We performed a detailed Cardiac Ultrasound (CU) in an effort to identify markers to distinguish population that might benefit of early PD application.

Methods: We enrolled 28 pts (mean age 78.3 years) in PD over 42 months (mo). Inclusion criteria were CHF (NYHA class IV) symptoms, resistant to diuretics, and deterioration of renal function. Assessment of cardiac function by CU on the initiation of PD, 6 and 12 mo later. We recorded and evaluated the Ejection Fraction (LVEF), Relative Wall Thickness (RWT), Left Ventricular Mass Index (LV), E/E', Left Atrium Volume Index (LA), Pulmonary Artery Systolic Pressure (PASP), Tricuspid Annular Plane Systolic Excursion (TAPSE).

Results: Mean time on the method was 21 ± 10.16 (7 - 42) mo. Remarkably, significant reduction of all CU parameters, was noted, during period 0 – 6 mo and 6 – 12 mo for every patient. In contrast, no important changes were observed in period 6 – 12 mo. Also, there was substantial decrease of diuretics, as well as elimination of hospitalizations due to CHF decompensation and noteworthy improvement of NYHA class. As it was expected we observed significant body weight decrease in period 0 – 6 mo as well as in 0 – 12 months. But, no important changes in period 6 – 12 mo.

Conclusions: The gradual and continuous removal of excess fluid resulted in clinical improvement of the living status of all our pts. Furthermore, there was a long term improvement of the left and right cardiac functional parameters in CU. Thus, dramatically diminishing hospitalizations, due to decompensation of CHF, and restoring pts autonomy. The application of PD can be an important choice in the management of CHF NYHA class IV. The outcome of this prospective study supports the use of PD in selected pts of this cohort.

TH-PO287

Cardiovascular Effects of Peritoneal Dialysis in a Uremic Rat Model

Victoria L. Nasci, Kathryn A. Goodreau, Alison J. Kriegel. *Medical College of Wisconsin, Milwaukee, WI.*

Background: In the US more than 700,000 people suffer from end stage renal disease (ESRD) of which 97.5% are reliant on dialysis. Among dialysis patients, cardiovascular (CV) related events are the leading cause of death. Despite therapeutic advancements the continued CVD following the onset of dialysis poses an interesting clinical challenge that necessitates further studies into the effects and effectiveness of dialysis. Based on clinical outcomes, we hypothesized that peritoneal dialysis (PD) would have no effect on CV outcomes in the 5/6 nephrectomy (5/6Nx) rat model.

Methods: We performed 5/6Nx (n=13), or sham surgery (n=10), on 10 week old male Sprague-Dawley rats. Peritoneal catheters were implanted 6 weeks post-surgery. PD was initiated 2 days later in some of the 5/6Nx (n=6) and sham (n=5) animals (15ml [Baxter PD-2 2.5%] 1-hour dwell 3x/day x7days). Echocardiography was performed at baseline, 6, and 7 weeks post-surgery. At week 7 pressure volume analysis was performed prior to serum and tissue collection. Statistical significance was determined by two-way ANOVA.

Results: Blood urea nitrogen (BUN) was increased by 5/6Nx (5/6Nx 41.57±2.78 vs. sham 20.25±0.48; p<0.05). PD had no effect on BUN in sham animals, but decreased BUN in 5/6Nx (5/6Nx 41.57±2.78 vs. 5/6Nx+PD 31.5±1.48; p<0.05). PD had no effect on serum sodium, potassium, or bicarbonate levels, nor did it effect serum cholesterol. PD had no effect on albumin excretion in both sham and 5/6Nx animals. PD did not alter kidney weight in sham animals, but reduced remnant kidney weight in 5/6Nx (5/6Nx 0.49±0.03 vs. 5/6Nx+PD 0.39±0.01; p<0.05). 5/6Nx increased heart weight (5/6Nx 0.42±0.02 vs. 0.35±0.01; p<0.05). PD had no effect on heart weight in sham animals, but attenuated the increase in 5/6Nx (5/6Nx 0.42±0.02 vs. 0.39±0.02; p=0.08). PD had no effect on CV functional parameters in sham animals and in 5/6Nx neither improved nor worsened CV outcomes.

Conclusions: These data combined suggests that PD may reduce renal pathology by reducing stress on remaining functional nephrons. Importantly, we did not observe an improvement in CV parameters with PD, which is consistent with persistent CV risk in the PD population. These findings indicate this is an appropriate model for future studies focused on improving dialysis efficacy and CV outcomes for ESRD patients.

TH-PO288

Prognostic Value of Soluble ST2 and Soluble LR11 on Mortality and Cardiovascular Events in Peritoneal Dialysis Patients

Yoon soo Shin,[1] Hyung Jong Kim,[2] Mi Jung Lee,[3] Jung eun Lee.[4] *[1]CHA Hospital Bundang, Gyeonggi-do, Republic of Korea; [2]Bundang CHA Medical Center, CHA University, Seongnam, GyeonGgi-Do, Republic of Korea; [3]CHA Bundang Medical Center, CHA University College of Medicine, Seongnam, Seoul, Republic of Korea; [4]Yongin Severance Hospital, Yongin-si, Republic of Korea.*

Background: Because end-stage renal disease (ESRD) patients are at high risk of cardiovascular (CV) disease, developing a biomarker for CV risk stratification has clinical importance. Soluble form of suppression of tumorigenicity 2 (sST2) and soluble low-density lipoprotein receptor relative with 11 ligand-binding repeats (sLR11) are emerging CV biomarkers, however, to date, the prognostic value of those has not been investigated in patients undergoing peritoneal dialysis (PD).

Methods: We determined serum sST2 and sLR11 concentrations using enzyme-linked immunosorbent assay, and evaluated the association of those biomarkers with all cause mortality and major adverse cardiac and cerebrovascular event (MACCE) in 74 prevalent PD patients.

Results: The median (interquartile range) concentrations of sST2 and sLR11 were 70.9 (57.8-89.8) ng/mL and 15.2 (12.3-19.6) ng/mL, respectively. During a median follow-up of 38.5 months, 13 (17.6%) patients died and MACCE was observed in 23 (31.3%) patients. When patients were dichotomized by the median value of sST2 and sLR11, Kaplan-Meier analyses showed that higher sST2 group was significantly associated with lower event-free survival rates (log-rank test; P=0.002 for all-cause death; P=0.01 for MACCE). In multivariable Cox analyses, higher sST2 was independent risk factor for all-cause mortality (per 1 standard deviation [SD] increase; hazard ratio [HR]=1.947; 95% confidence interval [CI]=1.124-3.371) and MACCE (per 1 SD increase; HR=1.647; 95% CI=1.079- 2.516). In contrast, sLR11 did not have a significant association with all-cause mortality or MACCE. Furthermore, only sST2 provided a significant predictive value for all-cause mortality (AUC=0.699; P=0.03).

Conclusions: sST2, not sLR11, was independently associated with greater risk of all-cause mortality and CV outcome in prevalent PD patients. Additional studies are needed to confirm these findings and examine underlying mechanism between new biomarkers and CV disease in ESRD populations.

TH-PO289

Incremental Peritoneal Dialysis and Clinical Outcomes: A Propensity Score Matching Study

Su mi Lee,[1] Yun Jung Oh,[2] Young ki Son,[2] Seong Eun Kim,[1] Won Suk An.[1] *[1]Dong-A University, Busan, Busan, Republic of Korea; [2]Cheju Halla General Hospital, Jeju, Republic of Korea.*

Background: Incremental peritoneal dialysis (iPD) can be useful in selected patients with higher residual renal function, needing lower financial cost, or wanting less time burden of PD treatment. In addition, patients on iPD would have a reduced risk of peritonitis or peritoneal glucose exposure. However, the long-term effects of iPD on patient survival and PD survival are not clear compared to conventional PD (cPD). The aim of this study to evaluate the patient survival and PD survival in iPD compared to cPD.

Methods: Clinical data was retrospectively collected from a single center between January 2007 and December 2018. We included 303 patients percutaneously inserted PD catheter by surgical methods. An analysis was performed using propensity score matching for age, gender, and the presence of DM. Finally, 96 cPD patients and 48 iPD patients were included. IPD was defined as starting PD with 3 or fewer peritoneal exchanges per day.

Results: Median duration of iPD was 31.2±22.5 months and mean PD duration of iPD was longer than cPD. Initial blood urea nitrogen and serum creatinine levels (7.3±2.7 vs. 9.7±3.7 mg/dL, p <0.001) were significantly lower in iPD patients than cPD patients. Mortality as well as rates of peritonitis and hospitalization was significantly lower in patients with iPD than those with cPD (log-rank, p=0.034, p=0.001 and p=0.023). Mortality and hospitalization rate were prominent in cPD patients with diabetes. However, there was no significant difference in PD survival between iPD and cPD.

Conclusions: Incremental PD may be not only safe PD modality but also has better clinical outcome in less uremic patients to initiate and maintain PD. Further prospective studies are necessary to confirm these benefits in diabetic patients treated with PD.

Excessive Salt Intake Increases Peritoneal Local Production of Interleukin-6 and Baseline Peritoneal Solute Transport Rate in Subtotal Nephrectomized Mice

Yasuhiko Ito,[1] Ting Sun,[2] Yasuhiro Suzuki,[2] Mitsuhiro Tawada,[2] Hironobu Nobata,[1] Hiroshi Kinashi,[1] Makoto Yamaguchi,[1] Takayuki Katsuno,[1] Shoichi Maruyama,[2] Masashi Mizuno.[2] *[1]Aichi Medical University, Nagakute, Aichi, Japan; [2]Nagoya University, Nagoya, Japan.*

Background: Baseline peritoneal permeability varies between patients before exposure to peritoneal dialysis fluid. Dialysate interleukin (IL)-6 was an indicator of peritoneal transport function. Besides, we previously reported upregulation of peritoneal IL-6 level in uremic mice with salt loading. The present study aims to investigate the peritoneal transport and the role of IL-6 in uremic mice with salt loading.

Methods: Sham-operated (Sham) and subtotal nephrectomized (Nx) mice were randomly given tap water or 1% salt (NaCl)-containing water. After 8 weeks, 4.25% glucose-based peritoneal equilibration test was performed to evaluate peritoneal function. Locally overexpressed IL-6 was functionally blocked by rat anti mouse IL-6 receptor antibody (MR16-1) in another study to examine the role of IL-6 in this process.

Results: A significant elevation of D/P Cr and a decrease of D/D0 glucose were observed in Nx+salt group. There was also enhanced angiogenesis and macrophage infiltration in the peritoneum of Nx+salt mice, along with elevated VEGF-A and MCP-1 concentration in the dialysate. Compared to Nx+water group, the increased concentration of effluent but not serum IL-6 and soluble IL-6 receptor α suggested a strong local production in Nx+salt group. IL-6 was expressed in mesothelial cell layer and CD68-positive macrophages in peritoneum of Nx+salt mice. Elevation of peritoneal phosphorylated stat3 indicated an increment of IL-6 signaling. Blockade of IL-6 signaling by MR16-1 alleviated macrophage infiltration and angiogenesis as well as rescued peritoneal transport function in Nx+salt mice. In mesothelial cells, incubation with additional 40mM NaCl in the medium upregulated the expression of IL-6, along with the translocation into the nucleus of transcription factor tonicity-responsive enhancer binding protein (TonEBP), the only known transcription factor responding to high tonicity. Upregulation of IL-6 under hypertonicity induced by NaCl was also observed in mouse peritoneal-derived macrophages and bone marrow-derived M1 macrophages.

Conclusions: These findings suggest that high salt intake under uremic condition could increase peritoneal local IL-6 production leading to higher peritoneal solute transport rate.

TH-PO291

Safety and Efficacy of a Zero Sodium Peritoneal Solution

Jeffrey M. Turner,[1] Fredric O. Finkelstein,[1] Veena Rao,[1] Matthew Griffin,[2] Devin Mahoney,[1] Jeffrey M. Testani.[1] *[1]Yale University, Hamden, CT; [2]Yale School of Medicine, Hamden, CT.*

Background: Sodium (Na) removal with conventional peritoneal dialysis solutions, which have a Na concentration similar to serum, primarily occurs by means of convective clearance. Zero Na peritoneal solution with a high osmolarity may offer more effective Na removal given the large Na concentration gradient to serum. This solution could have clinical application as an intermittent therapy for venous congestion.

Methods: This was a randomized open label crossover study in 10 established peritoneal dialysis patients comparing zero Na dialysis solution (10% dextrose, ~505mOsm/L) to standard 4.25% dextrose solution (485mOsm/L). Patients underwent a 1liter dwell for 120 minutes with both solutions at two separate study visits. Serum and dialysate sodium were monitored every 15 minutes, and intraperitoneal volume was determined using indicator dilution technique with I-131 albumin. (NCT03801226; IND141103)

Results: Total Na removal and ultrafiltration were significantly greater with the zero Na solution, and Na removal rate was highest in the first 30 minutes (figure 1). There was a small decrease in serum Na of 1meq/L after 120 minutes with the zero Na solution. There were no significant differences between the two solutions in non-Na plasma electrolytes at 120 minutes. While serum glucose increased with both solutions, this increase was not significantly different between the two solutions at 120 minutes. There were no significant differences in blood pressure trends.

Conclusions: Despite similar osmolarities, zero Na peritoneal solution results in more effective Na clearance and higher UF volume. The solution was well tolerated without significant adverse changes in blood pressure or off target electrolytes.

Peritoneal Sodium Removal Technique with Salt-Free Solution in Pigs

Jeffrey M. Turner,[1] Fredric O. Finkelstein,[1] Devin Mahoney,[1] Matthew Griffin,[2] Veena Rao,[1] Jeffrey M. Testani.[1] *[1]Yale University, Hamden, CT; [2]Yale School of Medicine, New Haven, CT.*

Background: Over time, interest in the concept of sodium and fluid removal via non-renal routes in heart failure (HF) has grown significantly. One approach to removing sodium and fluid without diuretics is peritoneal dialysis (PD). Traditional PD, however, is ineffecient in that it requires large intraperitoneal volumes with long dwell times while only offering limited sodium and fluid removal. Utilization of salt free peritoneal solution will result in removal of a clinically significant amount of sodium and fluid.

Methods: Eighty kg anesthetized pigs (N=15) underwent surgical implantation of PD catheters. In 5 pigs, we allowed a 6 hour dwell and the intraperitoneal volume was determined serially using indicator dilution technique with I-131 radiolabeled albumin. 10 pigs underwent a 2 hour dwell with fluid volume measured by manual removal. To understand the effects of higher peritoneal solution volumes, 4 of these pigs then underwent 4 cycles of 2.5 L of 10% dextrose with 90 minute dwell times, for a total of 11 L cycled. These 4 animals had plasma volume measured with I-131 radiolabeled albumin prior to and after cycling was complete. Serial plasma and peritoneal fluid samples were obtained and glucose and electrolyte concentrations were determined.

Results: In the 5 animals with a 6 hour dwell, ultrafiltration approached 1.5 L and 5.1 +/- 0.4 grams of sodium was removed. In the 10 pigs that underwent a 2 hour dwell, an average of 0.9 +/- 0.2 L of ultrafiltration occurred with a corresponding 3.9 +/- 0.5 g of sodium removed. Despite a large sodium removal, the average decrease in serum sodium concentration following the 2-hour dwell was only 2.2 +/- 0.3 mmol/L ($P < 0.0001$). In the pigs that underwent fluid cycling, an average of 22.5 +/- 3.5 g of sodium was removed and plasma volume decreased dramatically in these animals.

Conclusions: Peritoneal sodium removal with salt free solution is capable of removing large quantities of fluid and sodium with relatively small intraperitoneal volumes. Additional research is required to understand the safety/tolerability of this

approach in humans, development of optimal solutions and protocols for fluid instillation and removal from the peritoneum.

Is There a Place for Peritoneal Dialysis in Treatment of Refractory Heart Failure?

Ana F. Gomes da silva,[1] Rita Calça,[2] Ana Rita M. Martins,[2] Maria augusta C. Gaspar,[2] Patricia Q. Branco.[3] *[1]Hospital Dr. Nélio Mendonça, Funchal, Portugal; [2]Hospital Santa Cruz, Lisbon, Portugal; [3]Santa Cruz Hospital, Carnaxide, Portugal.*

Background: Ultrafiltration techniques have shown promise in the treatment of diuretic-resistant heart failure (HF). The aim of this study was to describe a single-center experience in the treatment of refractory HF patients with PD.

Methods: Retrospective study of 14 patients presenting symptoms and signs of severe refractory congestive HF despite optimal pharmacological therapy. Baseline characteristics and laboratory data were recorded. Charlson score and Doppler-echocardiogram results were collected at the beginning and end of follow-up period. PD adequacy was evaluated through peritoneal equilibrium test (PET) results.

Results: We followed a cohort of 14 patients with HF, all excluded as candidates for heart transplantation. 12 were males (85.7%) and 2 females (14.3%), with a median age of 72.13 (IQR 42.5 - 75.38) years. The mean following time was 52.5 ± 25.3 (range 18 – 95) months. Seven patients (50%) had hypertension, 7 (50%) were diabetic and 2 (14.3%) had hepatitis C infection. The etiology of HF was arterial hypertension in 7 patients (50%), ischemic cardiopathy in 3 (21.4%), valvular cardiopathy in 3 (21.4%) and in 1 patient (7.1%) congenital cardiopathy. Three patients (21.4%) had been previously treated with intermitent hemodiafiltration, which was suspended due to hemodynamic instability; the other 11 patients started PD *ab initium*. Symptoms of HF improved in 35.7% (N=5) of patients, with an upgrade of New York Heart Association (NYHA) Functional Classification and improvement in ejection fraction (EF). At the beginning of PD treatment the mean Charlson score value was 5.7 ± 2.3, wich reduced to 5.3 ± 2.6 by the end of observation time. There was a positive correlation between the first and the last Charlson score acessed (r=0.984; n=12; p<0.001). Six patients presented 1 episode of decompensated heart failure needing hospitalization, with a median length of stay of 2 (IQR 0 - 6.75) days. During the observation period seven patients were transferred to HD. In 3 cases this was lead by peritonitis episodes and in 4 by ultrafiltration failure. Two patients died, one from an acute hemorrhagic stroke and the other with a septic shock.

Conclusions: PD treatment in refractory HF, in addition to optimal pharmacological therapy, seems to be effective, since it improves quality of life and functional class.

TH-PO294

Follow -Up and Survival in Refractory Congestive Heart Failure Patients Treated with Peritoneal Dialysis

Andreas Bozikas, Styliani Vakiani, Eleni Kitoukidi, Theotokis Kaltzidis, Kalliopi Pozoukidou, Antigoni Martika, Nikolaos Georgilas, Panagiotis Pangidis, Sofia Spaia. *Nephrology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece.*

Background: Data on survival rates of patients (pts) suffering from Refractory Congestive Heart Failure (RCHF) treated with Peritoneal Dialysis (PD) are limited. We have previously reported the beneficial effect of PD application for RCHF for a period of 12 months. According to our results body weight, use of diuretics and hospitalisations were decreased, while clinical status and their New York Heart Association (NYHA) class were improved along with cardiac function parameters on Cardiac Echo. We followed this cohort and evaluated the mortality over a 48 months observational period.

Methods: We had enrolled 18 pts (mean age 82.6 years). Inclusion criteria were NYHA IV symptoms for a 6 months interval with deterioration of renal function. Mean time on PD was 26.7 (6 - 48) months.

Results: Overall, while on PD, 10 pts died (55.5 %) during the 4 year period. Cardiac arrest was the main cause of death (6/10), infections being the second (4/10). Two pts died of complicated urinary tract infection and one of respiratory infection. One patient developed fungal peritonitis, had the PD catheter removed, was transferred to hemodialysis and later died. One patient suffered from Encapsulating Peritoneal Sclerosis and had the PD catheter removed, transferred to hemodialysis and doing well. 7 pts still remain in PD, on good clinical condition and stable body weight. During this period, no hospitalisation was recorded due to RCHF decompensation, in any of the pts. Mean survival time in PD was 32 months ± SE 4 months.

Conclusions: Cardiac arrest is still the major cause of death in this cohort, however, 40 % of pts died of non cardiovascular causes. According to literature < 50 % pts with NYHA class IV RCHF, survive 6 months. Impressively in this cohort mean survival time was 5 times longer indicating that PD not only contributes to life elongation, but also offers better quality.

TH-PO295

Peritoneal Dialysis for Refractory Heart Failure; Decongestion, Cardiac Function, and Functional Status: A Reappraisal

Gajapathiraju Chamarthi, Harini Bejjanki, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: Congestion is an integral component of heart failure (HF) syndrome. Growing evidence points to peritoneal dialysis (PD) as an efficient therapeutic modality for management of fluid overload in refractory HF. Improvement in left ventricular ejection fraction (LVEF) is a frequently reported benefit of PD in this setting. We sought to explore whether the observed salutary impact of PD on cardiac function and functional status is due to efficient decongestion (i.e. Frank-Starling law).

Methods: Available data from contemporary clinical trials of PD in HF (performed between January 2010 and May 2019) that included more than 20 patients were selected and reviewed. Those studies evaluating the impact of PD on LVEF and volume status (assessed through changes in weight) in patients without end-stage kidney disease were included. Pertinent data were extracted and using Pearson product-moment correlation, the degree of linear dependence and correlation between these two variables was determined.

Results: Out of 11 clinical studies meeting the criteria, 1 was a duplicate and 3 did not have the needed data; 7 studies (4 retrospective and 3 prospective) with a total of 399 participants were included. The mean age was 71 years, and the mean baseline LVEF and weight were 35.1% and 76 Kg respectively. The median follow up was 14 months. There was substantial variation in the reporting of time point for cardiac function, functional status, and weight. LVEF changes ranged from -1.4 to +6.0 % (mean 1.51 ± 2.71) and weight changes ranged from -8.3 to +3.3 Kg (mean 2.09 ± 3.95). No correlation was observed between changes in LVEF and weight (r= 0.39, p= 0.37). All studies that evaluated functional status reported on its improvement after PD therapy.

Conclusions: While PD therapy for management of refractory HF is associated with improvement in cardiac function and functional status, data from contemporary trials suggests that changes in LVEF and weight do not have a strong correlation. Therefore, it is unlikely that efficient decongestion could fully explain the beneficial impact of PD on cardiac function. Since these studies did not included nutritional indices, an alternative explanation is that the relationship between weight and volume status in HF may be confounded by changes in in muscle mass after initiation of PD therapy.

TH-PO296

The Effect of Dialysis Modality Choice on Cognitive Functions in Patients with ESRD: A Meta-Analysis

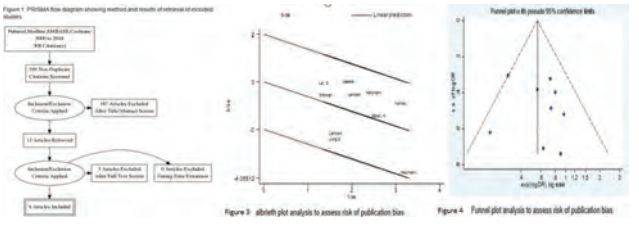
Karim M. Soliman,[1,2] Hatem Ali,[3] Ahmed Daoud,[2] Mahmoud M. Mohamed,[5] Tibor Fulop,[1] Ingi Elsayed.[4] *[1]Medical University of South Carolina, Charleston, SC; [2]Medicine/Nephrology, Cairo University, Cairo, Egypt; [3]Heartlands hospital, Birmingham, United Kingdom; [4]university hospitals of north midlands, Stoke-on-trent, United Kingdom; [5]Aghrass Medical center, Jeddah, Saudi Arabia.*

Background: Cognitive dysfunction is a major debilitating co-morbidity of end-stage renal disease, affecting up to 80% of the dialysis population. However, differential effect of hemodialysis (HD) versus peritoneal dialysis (PD) on cognitive dysfunction remains debated.

Methods: We performed a systematic review in different databases including Pubmed, Medline, Embase and Cochrane to identify studies that assessed effect of different dialysis modalities on cognitive functions. Inclusion criteria for our meta-analysis were all studies that compared effect of PD to intermittent HD on cognitive function. Studies were included with reviewing the journal title, year of publication, name of the first author, country of study and the number of enrolees in the PD and HD arms and the methods of assessment of cognitive functions were reported. A fixed effects model was used for the meta-analysis. Publication bias was assessed using a Funnel plot and Galbreith plot analysis.

Results: Out of 200 abstracts reviewed, 11 papers as well as registry studies were identified for this meta-analysis with a total of 219,320 subjects included (Figure 1). Forest plot analysis for the rate of cognitive impairment in different dialysis modalities showed less cognitive impairment in PD population compared to HD patients (Relative Risk = 0.49, 95% Confidence Intervals: 0.46 - 0.52). There was no evidence of heterogeneity in the forest plot analysis (I^2 = 0.00%, P = 0.58, Figure 2). Moreover, there was no evidence of publication bias among the studies included (Figure 3 and 4).

Conclusions: Patients on PD show less cognitive dysfunction compared to those on HD.



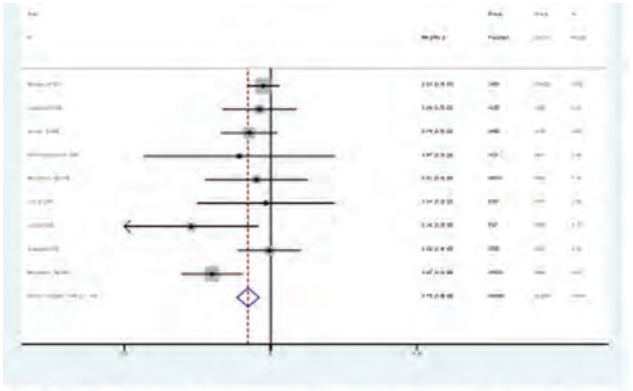


Figure 2: Forest plot analysis for assessment of cognitive impairment in hemodialysis versus peritoneal dialysis

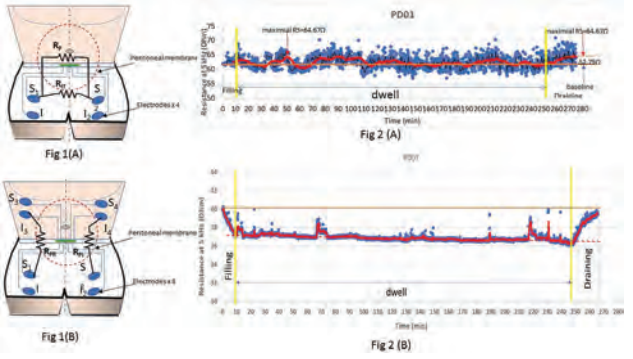

TH-PO297

The Predictive Value of Neutrophil-to-Lymphocyte Ratio in Peritoneal Dialysis

Roberto C. Marques, Eduarda C. Carias, Ana T. Domingos, Anabela M. Guedes, Idalécio Bernardo, Pedro L. Neves. *Centro Hospitalar Universitário do Algarve, Faro, Portugal*.

Background: Neutrophil-to-lymphocyte ratio (NLR) may reflect a shift on immune response towards a pro-inflammatory pattern (i.e. high value of neutrophils) balanced with a depression of cell-mediated immunity (i.e. low values of lymphocytes). It has been used as prognostic factor in cardiovascular and oncologic diseases. In dialysis studies are scarce. The aim of this study was to evaluate NLR as a predictor of mortality in peritoneal dialysis (PD) patients.

Methods: In this longitudinal study, incident PD patients with a peritoneal equilibration test (PET) between 2004 and 2018 were included. Demographic, clinical and laboratory data were collected. Univariate and multivariate Cox regression analysis were performed to determine the association of NLR with survival.

Results: We included 122 PD patients (55.0 ± 17.5 years, 31,1% diabetic, Charlson Comorbidity Index (CCI): 5.0±2.5) with a mean follow-up of 30.2±24.0 months. Our population was dialysed with a mean Kt/V 2.75±0.94, and the mean evaluated parameters were: nGFR 6.7±4.7 ml/min/1.73m2, prealbumin 39.3±11.3 mg/dL, neutrophils 5.6±2.5x10^9/L, lymphocytes 1.8±2.3x10^9/L, NLR 3.99±2.6. Using the Cox model we found that higher CCI (HR=1.650, 95%CI 1.174-2.320), higher NLR (HR=1.662, 95%CI 1.117-2.472) and lower nGFR (HR: 0.706, 95%CI 0.554-0.900) were associated with higher mortality, when adjusted for nutritional status (n.s.).

Conclusions: In dialysis inflammation is associated with global cause mortality. The neutrophil-to-lymphocyte ratio is a simple calculation and it predicted survival in our PD patients.

TH-PO298

Continuous Measurement of Intraperitoneal Volume Using Bioimpedance: Importance of Electrode Placement Sites

Fansan Zhu,[1] Laura Rosales,[1] Maricar Villarama,[1] Peter Kotanko.[1,2] [1]*Renal Research Institute, New York, NY;* [2]*Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Continuous monitoring of intraperitoneal volume (IPV) may benefit peritoneal dialysis (PD) patients, e.g. by determining the peak ultrafiltration volume (UFV). The aim of this study was to optimize the placement sites of bioimpedance electrodes.

Methods: Six PD patients (age 61.3±7.6 years, 5 males, weight 87.3±25 kg) were studied with two different electrode placement sites. In group A, we used 4 and in group B 8 standard ECG electrodes (3M Red Dot Electrode; locations shown in Fig. 1 A and B). Measurements were done with the patients in a sitting position and their legs placed horizontally. We used the Hydra 4200 bioimpedance device (Xitron Technologies) for continuous measurement during the PD session. The PD sessions comprised three phases: filling (dialysate volume 2 L), dialysate dwell time (4 hours), and draining. The drain volume was weighted; we assumed that 1 kg equals 1 L.

Results: The average drain volume was 2.3±0.3 L. 5 kHz resistance data were extracted to assess intraperitoneal fluid changes. While in group A the 3 treatment phases are not obvious (Fig. 2 A), they can be clearly discerned in group B (Fig. 2 B).

Conclusions: These results show that electrode placement is key to successful continuous IPV measurements. In setup A (Fig. 1 A), 2 resistors are in parallel and the interstitial resistance (R_{IT}) is smaller than the peritoneal resistance (R_p); hence the measurement provides information only about the interstitial space. In setup B (Fig. 1B), the current travels through the peritoneal cavity so that IPV changes translate into resistance changes. If corroborated in larger studies, setup B has the potential to evolve into a future standard.

TH-PO299

Dietary Potassium Intake and Hypokalemia in Peritoneal Dialysis Patients in Thailand

Mathurot Virojanawat,[1] Pongpratch Puapatanakul,[1] Chanchana Boonyakrai,[2] Piyatida Chuengsaman,[3] Somchai Eiam-Ong,[1] Kriang Tungsanga,[1] Kearkiat Praditpornsilpa,[1] Talerngsak Kanjanabuch.[1] [1]*Chulalongkorn University, Bangkok, Thailand;* [2]*Taksin hospital, Bangkok, Thailand;* [3]*Banphaeo Hospital, Bangkok, Thailand*.

Background: Poor dietary intake might account for the high prevalence of hypokalemia in peritoneal dialysis (PD) patients in Thailand but the clinical evidence is still lacking.

Methods: A cross-sectional study was performed in stable prevalent PD patients at 4 PD centers in Thailand. Hypokalemia was defined if the average serum potassium level during the last 3 consecutive visits was <3.5 mEq/L, while the patients were considered normokalemic if the average serum potassium was 3.5 to 5.5 mEq/L. Patients were asked to perform 3-day dietary food record and take pre- and post-meal pictures of all foods they had taken following the provided instruction. Daily dietary nutrients including dietary potassium of all eligible patients were then estimated by a dietician using INMUCAL-N software. Total potassium excretion was determined by 24-hour PD effluents and urine collection. Intra- and extra-cellular water status were also assessed by electrical bioimpedance assay to explore the role of intracellular potassium shift and serum potassium status.

Results: Among 60 consecutive eligible PD patients, 19 (31.0%) had hypokalemia. Mean dietary potassium and total calories intake were 28.6±10.3 mEq/day and 1,088.0±335.4 Kcal/day, respectively. Dietary potassium intake was significantly lower in hypokalemic patients compared to normokalemic patients (24.4±11.1 vs. 30.5±9.4 mEq/day, p=0.031). Surprisingly, total potassium excretion was significantly lower in patients with hypokalemia (28.5±8.4 vs. 36.7±11.2 mEq/day, p=0.006). There was no significant correlation between serum potassium and daily PD exchange volume, total Kt/Vurea, urine volume, residual glomerular filtration rate, concurrent medications (insulin, ACEI/ARB, beta blocker, and spironolactone) or intracellular water (ICW). Low dietary potassium was an independent risk factor for hypokalemia after adjustment for insulin therapy, diuretic use, and peritoneal membrane transport. The risk of hypokalemia decreased by 15% for every 10 mEq increase in daily potassium intake.

Conclusions: Low dietary potassium intake, rather than increased potassium excretion or intracellular shift, is the major contributing factor to hypokalemia in Thai PD patients. Dietary intervention or potassium supplement protocol should be implemented.

Dental Care Decreased the Risk of Not Only Cardiovascular Events but Peritonitis for the Patients on Peritoneal Dialysis

Takeyuki Hiramatsu, Yuko Asano, Katsuhiko Suzuki, Daiki Iguchi, Shinji Furuta. *Konan Kosei Hospital, Konan Aichi, Japan*.

Background: Oral disease may be increased in people with end stage renal disease (ESRD) and associated with inflammation, cardiovascular disease and mortality. We had the patient who had severe gingivitis and suffered from sepsis due to oral Streptococcus Salivarius, and followed splenic abscess and peritonitis on January 2010. Hence we noticed the importance of dental care, and after Jan. 2010, we have been recommended to patients on peritoneal dialysis to have dental care, including 3 and more times tooth brushing, oral hygiene, more frequent dental visit and prophylactic antibiotics treatment before scaling or caries treatment.

Methods: We evaluated the difference of the incidence between two groups; peritoneal dialysis (PD) treatment from January 2000 to December 2009 (Group A), and January 2010 to May 2019 (Group B). We compared the admission rate of peritonitis, especially Streptococcus peritonitis, congestive heart failure (HF), acute coronary syndrome (ACS), cerebrovascular disease (CVD), and pneumonia. And the causes of death were also evaluated.

Results: The cumulative annual peritoneal dialysis patients in group A and B were 342 and 65 (mean age; 61.8 vs 65.9 years : $p < 0.01$) respectively, and PD treatment were 3404 vs 6219month·person($p < 0.01$). According to the cause of disease, diabetes was same, but glomerulonephritis was decreased, and nephrosclerosis was increased after 2010.

The incidence of peritonitis (0.275 vs 0.179/person·year:$p < 0.001$), Streptococcal peritonitis (0.081 vs 0.046/person·year : $p < 0.05$), HF (0.159 vs 0.089/person·year: $p < 0.005$), ACS (0.109 vs 0.025/person·year: $p < 0.001$), CVD (0.060 vs 0.029/person·year: $p < 0.05$), Pneumonia (0.078 vs 0.041/person·year:$p < 0.05$) were lower in group B than in group A. Moreover, according to the cause of death, the data were the same fashion as above.

Conclusions: Dental care was beneficial for not only CVD, but also peritonitis, especially Staphylococcal peritonitis. Considering, peritonitis and CVD may provide poor QOL and mortality, dental care (3 and more times tooth brushing, oral hygiene, more frequent dental visit and prophylactic antibiotics treatment before scaling or caries treatment) is important for better QOL and treatment survival and mortality.

The Value of Geriatric Nutritional Risk Index in the Prognosis of Patients with Maintenance Peritoneal Dialysis

Afang Li, Yanna Dou, Jing Xiao, Zhanzheng Zhao. *Nephrology Hospital, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

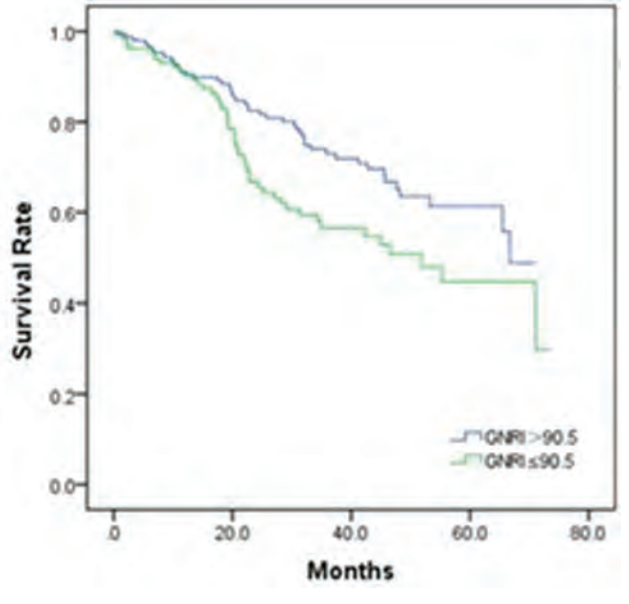
Background: Geriatric Nutritional Risk Index (GNRI) has been reported related to the prognosis and medical expenses of dialysis patients, but there are few related studies about Chinese patients, especially in terms of peritoneal dialysis (PD). The aim of this study was to explore the value of the GNRI in patients with end-stage renal disease at beginning of PD treatment.

Methods: Retrospectively analyze the medical records of patients undergoing peritoneal dialysis catheterization and starting peritoneal dialysis in the First Affiliated Hospital of Zhengzhou University from January 1, 2013 to December 30, 2018. Collect basic data and biochemical indicators of these patients in the first hospitalization for peritoneal dialysis catheterization. Follow-up these patients until March 1, 2019, and using death or turning to hemodialysis as endpoints, divide the patients into two groups according to the GNRI cutoff based on the ROC curve. Compare the clinical data and laboratory test results between the two groups, Kaplan-Meier analysis was used to observe the difference during follow-up,and the relevant factors affecting effect of peritoneal dialysis were estimated by binary logistic regression.

Results: The GNRI cut-off value was determined to be 90.5 according to the ROC curve, and the drop-out rate of GNRI≤90.5 group was significantly higher than the GNRI>90.5 group(35.9% VS 21.6%,*P*=0.003), and Kaplan-Meier survival curves showed a higher rate of peritoneal dialysis in the higher GNRI group during follow-up (*P*=0.021). Logistic univariate regression showed that male, GNRI and Alb were protective factors for PD patients, and after multi-factor correction, male and GNRI were also shown to be protective factors for PD patients.

Conclusions: The baseline GNRI can be used as a prognostic indicator for peritoneal dialysis patients.

Funding: Government Support - Non-U.S.



TH-PO302

Elderly Patients in Peritoneal Dialysis: Concerns Regarding Albumin Loss

Jeison Gois, Rebeca Costa, Géssica S. Barbosa, Lilian Cordeiro, Benedito J. Pereira, Hugo Abensur, Rosa M. Moyses, Rosilene M. Elias. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Albumin loss in peritoneal dialysis is associated with morbidity and mortality among patients on peritoneal dialysis (PD). Since elderly patients had a higher risk of protein-energy wasting, there has been a concern of further impairment of nutritional status in this population.

Methods: This is an observational prospective study that included patients >65 years (elderly group, N=18) compared to patients <65 years (younger group, N=73). Patients were followed for a median period of 21.8 months after PD initiation in a single center.

Results: Patients >65years (50% diabetic, 78% men) started PD with a residual diuresis of 1.4± 0.5L, which did not differ from the young group (1.5± 0.7L); p=0.778. Elderly patients had lower serum creatinine (p=0.0001), serum phosphate (p=0.010), total protein (p=0.010), and higher bicarbonate (p=0.003), denoting impaired nutritional status. Serum 25(OH)-vitamin D at PD initiation was similar between groups (p=0.705). During follow-up, there was a slightly reduction of serum albumin in young patients (from 3.76±0.5 to 3.62±0.6mg/dl, p=0.0001), which did not reach statistical significance in the elderly population (from 3.67±0.4 to 3.57±0.4mg/dl, p=0.335), with a median change overtime of 0.14 and 0.10mg/dl in young and elderly patients, respectively (p=0.834). As expected, there was a weight increase over time, although not different comparing young and elderly patients (p=0.579). In addition, loss of residual renal function, and changes in hemoglobin, serum ferritin, iron saturation, β-2 microglobulin, and parathormone were similar between groups (all p>0.05).

Conclusions: Our findings suggest that there is no medical concern to avoid PD therapy in elderly patients with end-stage renal disease, at least in those who start therapy with no critical nutritional condition.

TH-PO303

Effects of Initial Hypoalbuminemia on the Longitudinal Changes of Residual Renal Function and Peritoneal Membrane in Incident Peritoneal Dialysis Patients: A Single-Center, Long-Term Follow-Up Study

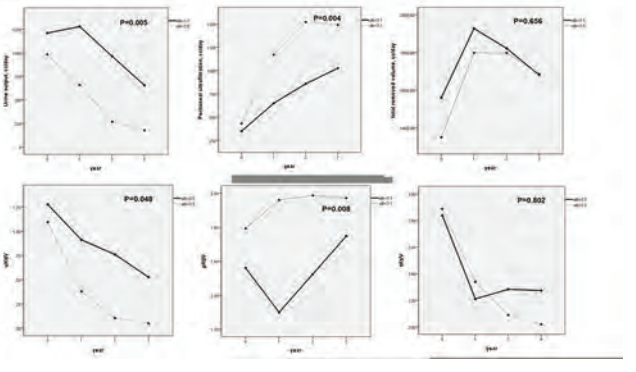
Harin Rhee,[1] Hyeyun Jeong,[1] Miyeun Han,[1] Il Young Kim,[2] Sang Heon Song,[1] Eun Young Seong,[1] Dong Won Lee,[3] Soo Bong Lee.[2] *[1]Pusan National University Hospital, Busan, Republic of Korea; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [3]Pusan National University School of Medicine, Yangsan, Republic of Korea.*

Background: Hypoalbuminemia was reported closely associated with increased patients' mortality and technical failure rate in PD patients. However, there were little studies that compared longitudinal changes of residual renal function or peritoneal membrane function according to the serum albumin level.

Methods: We retrospectively included patients who started PD between January 2010 and December 2015. We divided patients into two groups according to the initial serum albumin level. Hypoalbuminemia was defined as the serum albumin level lower than 3.5 g/dL. To compare longitudinal changes of residual renal function and peritoneal membrane status between two groups, we repeatedly collected data for urine output, uKt/V, peritoneal ultrafiltration, pKt/V, 4hr DPcr ratio per 1 year. We also checked technical failure rate and all-cause mortality rate of them.

Results: A total of 153 patients were included and 36.6% of them had hypoalbuminemia. During the median follow up period of 42.5 months, 9.8% of the patients were dead, 30.3% of the patients received kidney transplantation and the other 30.3% of the patients changed modality to hemodialysis. All-cause mortality rate was significantly higher in the hypoalbuminemia group (log rank 0.001). In both groups, residual renal function showed decreasing trend, peritoneal UF and pKt/V showed increasing trend and their changing rates were more rapid in hypoalbuminemia group (Figure 1).

Conclusions: Initial hypoalbuminemia was associated with rapid decline of residual renal function and increased all-cause mortality rate in incident PD patients. Thus, patients with hypoalbuminemia needed to be closely monitored.



TH-PO304

The Associations of Serum Uric Acid and All-Cause Mortality in Peritoneal Dialysis Patients

Shanfang Qiu. *The first affiliated hospital of xiamen university, Xiamen, China.*

Background: The relationship between serum uric acid and prognosis in diabetic peritoneal dialysis (PD) patients is unclear. This study was investigate whether baseline uric acid (UA) is an independent predictor of all-cause mortality in chronic renal failure patients (CRF) with peritoneal dialysis (PD)

Methods: A retrospective cohort study was designed. A total of 140 patients onstable continuous ambulatory peritoneal dialysis (CAPD) treatment for more than 3 months

were collected and follow up at First affiliated hospital of Xiamen University Peritoneal Dialysis Center during the January 1st,2001 to the December 31st,2017. All demographic and laboratory data were recorded at baseline. The subjects were divided into three groups based on the tertile of UA valu(M1:UA<387umol/L,M2:UA387~519umol/L,M3:UA >519umol/L). Multivariate Cox regression and Kaplan-Meier method was used to calculate the hazard ratio (HR) of all-cause mortality.

Results: A total of 140 CAPD patients were enrolled in this study, including 63 cases of male (45%),77 cases of female (55%). The average age was 57 (range: 44-65) years. The median follow-up time was 31.9 (IQR:19.6,66.0)months. The average UA of all participants was 450.1±146.1 umol/L. No significant differences of baseline characteristics between patients with Age, sex ratio, body mass index, duration of dialysis, proportion of patients with hypertension, diabetes mellitus and cardiovascular diseases. Compared to M1 group, the levels of serum creatinine, urea nitrogen, blood phosphorus and blood potassium were higher in M3 group ($P < 0.05$). Univariate COX regression analysis suggested a positive correlation between all-cause mortality and baseline uric acid (UA HR=1.04,95%CI: 1.00-1.08, P=0.048). Multivariate COX regression analysis showed that increased baseline UA was an independent risk factor for all-cause mortality in PD patients(HR=1.04, 95%CI: 1.00-1.09, p=0.032).

Conclusions: UA was positively correlated with all-cause mortality in patients undergoing maintenance peritoneal dialysis. The increase of baseline UA elevation was an independent risk factor for all-cause mortality in those patients. Thecontrol of UA level may be helpful to prolong the survival time of patients with Peritoneal Dialysis.

TH-PO305

Prognostic Role of Platelet-to-Lymphocyte Ratio in Peritoneal Dialysis

Roberto C. Marques, Ana T. Domingos, Eduarda C. Carias, Anabela M. Guedes, Idalécio Bernardo, Pedro L. Neves. *Centro Hospitalar Universitário do Algarve, Faro, Portugal*.

Background: Platelet-to-lymphocyte ratio (PLR) has been introduced as useful inflammatory marker to predict the outcome for a wide spectrum of diseases such malignancies and cardiovascular pathologies. Since platelets are active players in inflammatory response, both thrombocytosis and high PLR are probably part of the same pathophysiological process. In dialysis studies are scarce. The aim of this study was to evaluate PLR as a predictor of mortality in peritoneal dialysis (PD) patients.

Methods: In this longitudinal study, incident PD patients with a peritoneal equilibration test (PET) between 2004 and 2018 were included. Demographic, clinical and laboratory data were collected. Univariate and multivariate Cox regression analysis were performed to determine the association of PLR with survival.

Results: We included 122 PD patients (55.0 ± 17.5 years, 31,1% diabetic, Charlson Comorbidity Index (CCI): 5.0±2.5) with a mean follow-up of 30.2±24.0 months. Our population was dialysed with a mean Kt/V 2.75±0.94, and the mean evaluated parameters were: nGFR 6.7±4.7 ml/min/1.73m2, prealbumin 39.3±11.3 mg/dL, platelet 269.6±86.5x10^9/L, lymphocytes 1.8±2.3x10^9/L, PLR 195.5±101.7. Using the Cox model we found that higher CCI (HR=1.827, 95%CI 1.284-2.600), higher PLR (HR=1.010, 95%CI 1.004-1.015) and lower nGFR (HR: 0.673, 95%CI 0.513-0.883) were associated with higher mortality, when adjusted for nutritional status (n.s.).

Conclusions: Inflammation is a known risk factor for global cause mortality in dialysis. In this study platelet-to-lymphocyte ratio, which is quite simple and cheap method, was validated as an inflammatory marker in PD patients.

TH-PO306

Impact of Residual Renal Function (RRF) on Phosphate Clearance (PhCl) in Peritoneal Dialysis (PD)

Smitha R. Anam,[1,2] Enrica Fung,[1] Seyed-ali Sadjadi.[1] *[1]Nephrology, Jerry L Pettis VA Medical Center, Loma Linda, CA; [2]Nephrology, Loma Linda University Medical Center, Loma Linda, CA.*

Background: Hyperphosphatemia is common in ESRD & is independently associated with increased risk of death among dialysis patients. In PD, the relationship between PhCl & D/P Cr or D/P PO4 is not well established. There is a suggestion that Low(L)&Low Average(LA) transporters have better PhCl with CAPD than APD. Our aim is to study the effects of RRF on PhCl in patients on APD and if its loss is compensated by adjusting dialysis dose.

Methods: 55 patients on APD were retrospectively reviewed. 30 patients qualified for the study.15 had loss of RRF(Group 1), defined as UOP ≦ 200 cc/24 hr &15 who did not lose RRF(Group 2). PhCl was calculated from the combined 24hr collection of peritoneal effluent and urine.

Results: Patients in both groups were all male & on APD. Most common etiology for ESRD in both groups was diabetes (60%). Group 1 cohort had an average age of 65.2±12.2, body weight 80 kg±18.7 & BMI 26.5 ±5.2. Prevalence of hyperphosphatemia (> 5.5mg/dl) was 53% at the initiation of PD & 60% at loss of RRF with an average follow up of 36 months. PhCl dropped from 61.4L/wk to 41.9L/wk with loss of RRF(Table 1). Group 2 cohort had an average age of 61.7±10.62, body weight 91.33±14.3 & BMI 28.45 ±4.0. Hyperphosphatemia prevalence was 40% at the beginning of PD and 60% at the end of the study period of 36 months while PhCl decreased from 96.5L/wk to 68.5L/wk. In both groups D/P PO4 and D/P Cr remained low throughout the study. Weekly Kt/V decreased significantly but remained adequate for PD treatment (Table 1). There was stronger correlation between PhCl & D/P PO4 than with D/P Cr(R=0.53 vs 0.36), although in multivariate analysis the relationship between D/P PO4 and PhCl was not statistically significant (P=0.6)

Conclusions: Overall prevalence of hyperphosphatemia was no different in the two groups. PhCl correlated better with D/P PO4 than with D/P Cr as in prior studies. Since the numbers in our study are small, effect of transporter status on PhCl was not analyzed. These results need validation in a larger prospective study.

Table 1

	Group 1			Group 2			InterGroup
	Baseline	End of Study	P-Value	Baseline	End of Study	P-Value	P-value
Hyperphosphatemia(%)	53	60	0.11	40	60	0.99	0.50
Total PhCl(L/wk)	61.4	41.9	0.04	96.5	68.5	0.02	0.003
D/P Cr	0.46	0.41	0.39	0.46	0.45	0.78	0.63
D/P PO4	0.29	0.37	0.30	0.26	0.33	0.06	0.54
Renal Kt/V	1.03	0.14	0.0009	1.56	0.78	0.0013	< 0.001
Total Kt/V	3.47	1.94	0.05	4.46	2.94	0.006	0.016

TH-PO307

Use of a Remote Monitoring System to Evaluate Adherence to Peritoneal Dialysis Prescription

Ramón Paniagua. Chronic Kidney Disease Reasearch Network of Instituto Mexicano del Seguro Social *Instituto Mexicano del Seguro Social, Mexico City, Mexico*.

Background: Remote Monitoring (RM) has been incorporated in the new machines for home Peritoneal Dialysis (PD); RM facilitates a more close and personalized surveillance and take proactive behavior about preventable complication. One important advantage of RM is the objective evaluation of the adherence to treatment and medical and non-medical risk factors for non-adherence.

Methods: A cohort of 222 patients starting PD with RM system was analyzed about adherence to the treatment, these mean days per week without connection and incomplete daily schedule. Information from RM was obtained blind for patients and compared with patient self-reported adherence.

Results: With the use of RM, it was detected than 105 (52.7%) of patients loss at least one day/month of treatment, 25.7% loss 4 or more days/month, this means a loss of 15% of the treatment or more. In 20.7% of patients the difference between RM and self-reported adherence was of ≥2 days/month, higher with RM. Among risk factors for lower adherence, low serum albumin level, higher economic income, and lack of couple were significant.

Conclusions: Rate of non-adherence to PD prescription was found higher than other reports. Lack of couple, low albumin level, and high income were risk factors for non-adherence.

TH-PO308

Use of a Remote Monitoring System to Know the Peritoneal Dialysis Prescription Patterns

Ramón Paniagua. *Instituto Mexicano del Seguro Social, Mexico City, Mexico*.

Background: Remote Monitoring (RM) is a new tool recently incorporated in the follow-up of Peritoneal Dialysis (PD) patients; it facilitates a more close and personalized surveillance of patients and take proactive behavior about preventable complication of the treatment. RM also can be used to know how Nephrologist prescribes PD and if prescription is appropriate for the clinical characteristics of patients.

Methods: A cohort of 227 patients starting PD with RM system were analyzed for prescription, this includes dray or wet day, time of nocturnal dialysis, number of exchanges, volume per dwell, and effective time of dialysis.

Results: Total dialysis volume was <10L in 34.4%, 10L in 34.8%, and >10L in 30.8%. Time of dialysis was ≤8hr in 2.6%, 9hr in 79.7%, and ≥9hr in 27.6%. Volume of nocturnal exchanges was ≤3 in 1%, 4 in 61.7%, and ≥5 in 37.4%. Volume/exchange was <2.0L in 11.9%, 2.0L in 57.7%, and >2.0L in 30.4%. Effective time of dialysis increased with the hours of dialysis, however, for the same number of hours it did not increase with more than 5 cycles.

Conclusions: Prescription patterns tend to a uniform schedule; however, the use of more than 5 cycles/night does not offer advantages since it does not increase the effective time of dialysis.

Using a Logic Model to Systematically Evaluate an Initiative to Improve Patient Transition to Home Dialysis Therapies (HDTs)

Alice Wang,[2] Linda Turnbull,[4] Janet L. Williams,[1] Sarah A. Thomas,[1] Sushila Saunders,[1] Adeera Levin,[3] Rajinder S. Singh,[5] Michael A. Copland,[5] Juliya Hemmett.[1] *[1]BC Renal, Vancouver, BC, Canada; [2]UBC, Richmond, BC, Canada; [3]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [4]BC Renal Network, Calgary, AB, Canada; [5]University of British Columbia, Vancouver, BC, Canada*.

Background: The transition from choosing to initiating HDTs is not clearly defined or standardized for patients and staff. This may cause increased anxiety and unaddressed self-management for CKD patients, and lack of confidence in staff who support them. These factors may also lead to delays in transition. To address some of these concerns at BC Renal, a "Transition to HDTs" guidebook (the Guide) was designed, outlining a step-wise approach to transitioning to HDTs for patients. Assessment of this intervention required a structured and practical evaluation strategy. We used the Logic Model evaluation

framework to assess whether having the Guide can improve patient and staff experience with transitioning to HDTs.

Methods: The study ran over a 6-month period at 2 pilot and 3 control sites. The intervention strategies included: 1)Training of front-line staff to use the Guide and 2) Dissemination of the Guide to patients. Evaluation tools measuring data at baseline and at the 6-month point include: 1)Qualitative patient interviews, 2)Quantitative patient surveys, 3)Qualitative staff surveys, 4)Structured feedback session with renal care staff, and 5)Documented transition time between choosing and starting PD.

Results: 43 patients were enrolled in the pilot sites; 9 completed the study (6 PD and 3 HHD). Transition time was improved in pilot vs. control (54.4 vs. 73 days). Patients' anxiety, illness knowledge, and activation of resources improved after PD/HHD training at both pilot and control sites. During interviews, patients confirmed that the Guide was effective and helped retain knowledge. The staff felt that the intervention did not increase their workload and that the Guide was a good communication tool, but used inconsistently.

Conclusions: We present a systematic framework to evaluate a multi-intervention strategy to improve patients' transition to HDTs, which may be applicable to other complex healthcare initiatives. The Guide may help reduce transition time while improving patient anxiety and illness knowledge through enhanced communication between patients and health care providers. Future work is required to standardize the Guide's utilization.

TH-PO310

Use of Peritoneal Dialysis in Urban Boroughs of New York City

Ernie Yap,[1] Shuchita Sharma,[2] Osama El Shamy,[2] Alan D. Weinberg,[2] Jaime Uribarri,[2] Subodh J. Saggi.[1] *[1]SUNY Downstate Medical Center, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Peritoneal Dialysis (PD) is currently underutilized in the United States. Barriers to initiating PD such as geographical limitations, access to catheter care or trained personnel are less relevant in urban metropolitan cities, which may harbor heretofore unknown barriers to PD. We sought to describe the epidemiology of PD utilization within New York City in comparison to Boston, New York State (NYS) and the United States (US).

Methods: From the 2010-2016 US Renal Data Service, we estimated the odds of starting PD compared to hemodialysis (HD) in Brooklyn, Bronx, Queens, and Manhattan in comparison to Boston, NYS and the US. Next, we analyzed whether factors known to influence PD utilization such as diabetes mellitus (DM) as the primary diagnosis, age >65 years, gender and race played a role here. Statistical analysis was performed using SPSS 24.

Results: Between 2010 and 2016, the odds of starting PD vs HD in NYS compared to the rest of the US was 0.49 (95% CI:0.47-0.52; p<0.0001). The odds of starting PD vs HD in Brooklyn, Bronx, Queens and Manhattan in comparison to NYS were 0.30 (0.25-0.36; <0.0001), 0.56 (0.47-0.67; <0.0001), 0.66 (0.54-0.80; <0.0001) and 0.61 (0.52-0.71; <0.0001), respectively. In 2016, the odds of starting PD in Brooklyn, Bronx, Queens, Manhattan and Boston in comparison to the US were 0.14 (0.08-0.22; <0.0001), 0.39 (0.27-0.56; <0.0001), 0.32 (0.23-0.45; <0.0001), 0.54 (0.36-0.79; 0.002) and 0.89 (0.58-1.4; 0.624), respectively. Analysis of factors that influence PD initiation showed the following for Brooklyn: male sex (p=0.18) black race (0.06), age> 65 years (<0.0001) and DM (0.07) and Boston: male sex (0.45), black race (0.36), age> 65 years (<0.001) and DM (0.17). The percentage of residents in Brooklyn and Boston age >65 years in 2018 were 13.5% and 11%, respectively.

Conclusions: Our study demonstrated low odds of PD utilization for ESRD patients in NYC. There were segmental disparities suggesting borough-specific factors, perhaps socioeconomic and cultural. Brooklyn has the highest ESRD rates but lowest PD use. Similar findings were not seen in Boston. Commonly cited factors that influence PD usage such as DM as the primary diagnosis, gender and race were not statistically significant, while age seems to be an important factor. A concerted effort to identify and overcome barriers to PD amongst the elderly is needed

TH-PO311

Impact of a Renal Quality Program in the Peritonitis Rate in a Dominican Republic Continuous Ambulatory Peritoneal Dialysis Program

Erwin I. Campos,[1] Jhanna H. Collado,[1] Elianny S. Polanco,[1] Mercedes Aquey,[1] Alfonso Ramos,[2] Janny Guzman Chavez.[3] *[1]Macrotech, Santo Domingo, Dominican Republic; [2]Baxter Mexico, San Andres Ocotlan, Mexico; [3]Baxter Healthcare, Bogota, Colombia.*

Background: Peritonitis is a frequent complication in the management of peritoneal dialysis (PD), is one of the main cause of hemodialysis transfer with direct impact on a patient's quality of life and healthcare related costs. Also associated with loss of Residual Renal Function, peritoneal sclerosis and adequacy problems (1). Recently, the ISPD Guidelines recommends that regular monitoring of infections associated with peritoneal access should be part of the Continuous Quality Improvement program (CQI). The applications of these programs have shown an impact not only on the reduction of peritonitis events but also an improvement in patients and technique survival.

Methods: In 2015, a CQI program was implemented in 7 PD centers in the Dominican Republic. Lack of structured training and retraining program, home-visit and peritonitis treatment protocols, absence of local scientific committees, lack of standardized registries and key performance indicators were identified as the main problems. After this analysis, nurse activities were defined; structured training and retraining program, home-visit and peritonitis treatment protocols were implemented, a standardized registry was developed, and quality indicators were defined. A multicenter retrospective longitudinal analysis was performed on peritonitis events and outcomes between January 1st, 2015 to December 31st, 2018 were recorded. All patients were in CAPD and used Ultrabag system during all study period. Peritonitis was diagnosed according to the ISPD criteria. A two-time period was considered for technique and patient survival: 1st, 2015-2016 and 2nd, 2017-2018.

Results: During the study period, a total of 1801 patients were analyzed. The mean age was 57± 17 years, 65% were male, diabetes (48%) was the main cause of kidney disease. The median peritonitis rate for 2015: 0.8, 2016: 0.20, 2017: 0.14, 2018 0.12 year at risk, the percentage of patients free of peritonitis were: 75% in 2015, 95% in 2016, 90% in 2017 and 96% in 2018. Cure response rate was: 2015: 63%, 2016 83%, 2017: 90%, 2018: 92%. The mean technique survival was 331 days in period 1 vs 399 d in period 2 p <0.0001.

Conclusions: The use of CQI has proven to be an effective tool to reduce peritonitis in Dominican Republic PD program and improve technical and patient survival.

TH-PO312

Regionalization of Peritoneal Dialysis Services in an Era of Health Reform, 2006-2013

Abby Hoffman,[1] Caroline E. Sloan,[5,2] Matthew L. Maciejewski,[2] Cynthia Coffman,[4,2] Linda L. Sanders,[4] Richard A. Hirth,[3] Shoou-Yih D. Lee,[3] Virginia Wang.[1,2] *[1]Department of Population Health Sci, Duke University, Durham, NC; [2]HSR&D, Durham VAHCS, Durham, NC; [3]University of Michigan, Ann Arbor, MI; [4]Duke University Medical Center, Durham, NC; [5]Div of General Internal Med, Duke University, Durham, NC.*

Background: Over the last 15 years, Medicare has adjusted payment policy to promote peritoneal dialysis (PD) provision and use. Facility PD provision has grown modestly despite notable growth in patient PD use. A potential explanation underlying this trend is possible regionalization of PD services among dialysis chains. Regionalization may improve facility finances while maintaining patient access because: (1) consolidation into fewer chains allows for economies of scale and (2) as a home-based modality, PD requires minimal travel and impacts from regionalization of services. This study is the first to empirically assess the extent of PD program regionalization among dialysis chains.

Methods: We conducted a retrospective cohort study of non-federal US outpatient dialysis chains 2005-2013 with data from the US Renal Data System and Medicare Provider of Service files. Two outcomes were observed at the chain-hospital referral region level in 3-year time periods 2005-2013: - PD regionalization – decrease in PD facilities without decreasing PD patients - PD expansion – increase in PD patients without increasing PD facilities Generalized estimating equations with a logit link identified correlates of PD regionalization and expansion adjusting for chain and market characteristics.

Results: During the study, there were 2,799 market-chains; 49% large dialysis organizations ([LDOs] DaVita or Fresenius). We observed PD regionalization 103 market-chains and PD expansion in 728. Regionalization increased from 29 market-chains in 2005-2007 to 44 in 2011-2013. Expansion also increased from 175 market-chains to 293. In adjusted expansion increased over time (odds ratio [OR] 1.33; 95% confidence interval [CI] 1.18-1.49). Overall, LDOs had higher odds of regionalization (OR 3.92, CI 2.39-6.42) and expansion (OR 1.79; CI 1.48-2.17).

Conclusions: We provide early evidence that chains are expanding PD services and that LDOs are more likely to regionalize PD services. Dialysis chains have not regionalized PD services in response to reforms 2005-2013; but continued monitoring of PD care patterns will inform long-term effects of dialysis payment reform on dialysis industry service strategies and identify important implications for patient care.

TH-PO313

The Feasibility of Using Computerized Adaptive Testing (CAT) to Assess PD Patients' Quality of Life and Symptom Burden

Fredric O. Finkelstein. *Yale University, New Haven, CT.*

Background: Dialysis pts complain of myriad symptoms that negatively impact on their HRQOL and are often not appreciated by health care providers (HCP). How best to document these symptoms and their impact on pts and then incorporate the information into rx plans is challenging. Recent work has suggested that using CAT could provide a useful way for HCP to better understand difficulties experienced by pts.

Methods: This study was undertaken as a feasibility study. 20 questions, incorporating common symptoms reported by ESRD pts, were incorporated into a CAT program developed by the authors and Owl Insights. Questions dealing with pain, depression, anxiety, and sleep would expand from 1-2 items into more robust assessments if responses indicated domains were problematic. For example, depression screening was done with the PHQ2 which expanded to the PHQ9 if PHQ2 scores were ≥3. If pts reported problems with anxiety, then the Generalized Anxiety Disorder (GAD)7 questionnaire was administered. Pts were also given the option to free text any domains they wanted to discuss with their HCP. Questionnaires were given on an iPAD just prior to a clinic visit; results were printed and given to the HCP at the visit. The study was performed over 6 months with pts being asked to complete the questionnaires q 2 mths

Results: All 48 English speaking pts in our inner-city PD program were assked to participate. The mean +/-SD age was 60 +/-14. 55% were male, 43% AA, 33% white, 20% Hisp, 5% Asian. 92% completed the initial questionnaire; 86% completing this questionnaire completed the 2nd. The mean time to complete the questionnaire was 11 +/-2 min. 75% asked for assistance with the questionnaire. 75% complained of restless legs. 47% had PHQ2 scores of ≥3 and completed the PHQ9. 50% reported significant sleep problems and completed the sleep questionnaire. 30% were troubled by anxiety and completed the GAD7. Other problems frequently reported included fatigue, loss of energy, pain, and pruritis. HCPs (4 nurses, 2 dieticians, 7 MDs, 1 sw, and 2 PAs) uniformly

found the questionnaires helpful with their clinic visits, enabling them to focus on reported problem areas.

Conclusions: The present study demonstrates that using CAT questionnaires is feasible and is a useful way to capture PD pt perceptions of their symptoms and HRQOL and can enable HCP to perhaps better address pt domains of difficulty.

Implementing the PD Easy Application in Mobile Phones, Enhancing Self-Management and Communications: Pilot Study

Piyatida Chuengsaman. *Medicine, Banphaeo-Charoenkrung PD Center, Bangkok, Thailand.*

Background: Since implementing Thai PD First Policy, we now take care 880 patients, biggest center in Thailand. Our center developed many retraining styles to capture our patient's diversity. Now, we develop our own mobile phone application, called PDeasy. The objective is to monitor, communicate, self-educate and promote self-management. We try with first 52 volunteer patients, exploring the barriers to implement the application.

Methods: The education level and the past experiences using any other IT device, were collected. The duration before using this fluently, problems and usefulness of this application were asked. We also compared baseline and 6-month self-management score by Wilcoxon signed rank test.

Results: There were 41 patients who completed the questionaire. The average age is 54 (min 23, max 74). The percentage of patients who use the application by themselves is 61% and 39% by their caregivers. Education level, less than 6 years, is 47%. Past experiences of using IT device is 88%. The duration to learn to use this application fluently, less than 3 days, is 83% and most can use it immediately. The self-management score comparing baseline and 6- month, is not different, as shown. 92% of the users give good satisfaction and the most useful part are the self-education and the warning system.

Conclusions: Our mobile phone PDeasy application, is user-friendly and helpful in terms of promoting self-care.

Self-Management score

Self-Management score	Points	Baseline	6-month	P-value
Exchange Procedure	40	36.04 ±4.13	36.31 ±03.73	0.217
Salt and water balance Nutrition management	16	12.38 ± 2.39	12.33 ±2.01	0.115
Drug adherence	12	10.10 ± 2.40	10.12 ±2.15	0.468
Self-assessment	16	13.04 ± 2.10	12.71 ±2.38	0.099
Management of complication	12	9.35 ±2.24	9.56 ±2.15	0.153

TH-PO315

Impact of the Implementation of Management Protocols Using Priority Signals in Automated PD Patients Using Remote Patient Monitoring

Mario Rojas-Diaz,[1,3] Victor A. Mercado,[3] Abril E. Cisneros,[3] Alfonso Ramos,[2] Sergio O. Hernandez-Ordonez.[2] *[1]SEDESA, Mexico, City, Mexico; [2]Baxter Mexico, San Andres Ocotlan, Mexico; [3]Hospital Dr Belisario Dominguez SEDESA, Mexico, Mexico.*

Background: The recent introduction of a two-way Remote Patient Monitoring (RPM) for the management of Automated Peritoneal Dialysis (APD) patient has made it possible to assess patient's adherence to the therapy, as well as dialysis treatment-related complications. This system was introduced in this hospital 2 years ago. The purpose of the study is to assess the impact on the adherence and lost treatment times after the implementation of protocols using the signals provided by the RPM system.

Methods: This is a retrospective study in a cohort of patients receiving APD. 183 patients in the APD program of the Hospital Belisario Dominguez under remote monitoring were included. On the basis of the messages provided by the system, a program was developed in order to prioritize patient care and interventions according to the type and number of flags shown; then, signals were categorized into treatment-related signals and system-related signals. Based on this, protocols of care and management strategies were established, and change in the number medium priority signals (MPS) and High priority signal (HPS), impact on lost treatment times and adherence to treatment were assessed.

Results: Signals from 203 patients provided by the system throughout one week were assessed and dedicated protocols were implemented afterwards. Patients were reassessed 6 months after the implementation of the protocols. Patients without MPS improve 20% ($p<0.001$) and patients with more than 6 MPS reduce 67% (0.0001). Patient without HPS signals improve 36% ($p<0.0001$) and patients with more than 6 HPS decrease 73% ($p<0.0001$). Patients with not loss of treatment time increase 6% and patients with more than 300 minutes lost reduce 20% ($p<0.004$), adherence improve 29% (0.001)

Conclusions: Remote monitoring makes it possible to differentiate treatment-related complications and to establish specific processes of care, allowing for more effective treatment times and enhanced patient's adherence to his/her treatment.

TH-PO316

Factors Associated with Discordance in Initial ESKD Treatment Decision and Eventual Dialysis Modality

Adrian Liew. *Tan Tock Seng Hospital, Singapore, Singapore.*

Background: Pre-Dialysis counselling (DC) prepares patients with ESKD for renal replacement therapy (RRT). However, the eventual RRT modality may differ from the initial decision made at DC, making a prepared start on dialysis challenging. We study the distribution of treatment decisions made after DC and factors associated with a change in the eventual RRT modality at initiation.

Methods: This prospective cohort study included patients who underwent DC from APR 2010 to DEC 2015, and followed till 30 APR 2019 for their eventual RRT modality. All data were collected prospectively, with the study population grouped according to the initial treatment decision and stratified by eventual RRT modality (Table 1). Multivariate logistic regression was performed, examining factors that influence discordance in treatment decision and eventual modality. Variables were included in the model if univariate analysis has p-value<0.20.

Results: 1644 patients (63.3±13.1 years, 57% males, 77% DM) were included in the study, after excluding 47 without any decision and 42 who had not initiated RRT. HD (65.6%) was the most common choice of RRT after DC, while patients who chose PD were less likely to be actualized on their chosen therapy (PD 50.4%, HD 96.9%; $p<0.001$). Patients who chose PD were also more likely to die before needing RRT (PD 12.3%, HD 3.0%; $p<0.001$). Multivariate analysis showed that failure to actualize the decision for PD was associated with factors that suggested greater frailty or potential challenges to PD (Table 2).

Conclusions: Patients who chose PD were less likely to receive this RRT modality. These patients were older and frail, with a high proportion who died before requiring RRT. Difficulties with PD such as obesity, poor diabetic control and lack of home storage space for PD solutions may also influence a subsequent switch to HD.

Table 1: Distribution of Initial Treatment Decision and Eventual RRT Modality

Initial RRT Decision	Eventual RRT Modality					Total
	Death W/O RRT	HD	PD	Palliative	Transplant	
HD	32 (3.0%)	1,045 (96.9%)	0 (0%)	2 (0.2%)	0 (0%)	1,079 (100%)
PD	41 (12.4%)	110 (33.1%)	167 (50.3%)	12 (3.6%)	2 (0.6%)	332 (100%)
Palliative	0 (0%)	1 (0.4%)	0 (0%)	232 (99.6%)	0 (0%)	233 (100%)
Total	73	1,156	167	246	2	1,644

Table 2: Adjusted Factors Associated with Non-Actualization of PD when made as Initial Treatment Decision

Factors	Odds Ratio	95% CI	p-value
Associated with Frailty			
Age	1.020	1.004, 1.037	0.017
Mobility	0.530	0.338, 0.833	0.006

TH-PO317

Incremental Peritoneal Dialysis in Incident ESKD Patients

Hao Yan,[1,2] Joanne M. Bargman.[3] *[1]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China, Shanghai, China; [2]Division of Nephrology, University Health Network, Toronto, Ontario, Canada, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: Incremental peritoneal dialysis (Incre-PD) has been an underused strategy in treating end stage kidney disease (ESKD). This retrospective study analyzed the characteristics and outcomes of ESKD patients undergoing Incre-PD in a large academic center.

Methods: ESKD patients initiating PD with a contact PD volume ≤6 L/day between 2013 and 2017 inclusive were followed up until death, PD cessation, or the end of 2018.

Results: 175 Incre-PD patients were identified, accounting for 85% of the incident patients of that period,and were followed up for 352.6 patient-years. Compared to those with initial PD dose >6 L/day, there were more Asians (24.0% vs. 6.7%, p=0.033) but fewer of African descent (13.7% vs. 36.7%, p=0.002) among the Incre-PD patients. The two cohorts were comparable in comorbidity status except for peripheral vascular disease, which was more common in Incre-PD patients (14.3% vs. 0.0%, p=0.030). The baseline urine volume (1.5±0.7 L/day vs. 1.0±0.9 L/day, p=0.001) and residual kidney function (RKF, 8.3±3.4 mL/min/1.73m^2 vs. 5.5±3.2 ml/min/1.73m^2, $p<0.001$) were greater in Incre-PD patients, and they were less likely to have undergone hemodialysis (HD) prior to PD (19.4% vs. 50.0%, $p<0.001$). The baseline daily contact PD volume was 4.5 (IQR 4.3-6) L, and it was 5.4 (4.5-6.0) L, 6.0 (4.5-7.0) L, 6.0 (4.8-8.0) L, 7.0 (5.7-9.8) L, and 8.0 (6.0-9.8) L at 1 to 5 years on PD, respectively. Fifty-seven (32.6%) patients increased PD dose to

>6 L/day at a median time of 10.3 (6.2, 15.7) months. The unadjusted 1 to 5-year patient survival rate was 90%, 80%, 65%, 63%, and 49%, respectively, and the corresponding PD technique survival rate was 95%, 89%, 89%, 82%, and 77%. The average peritonitis rate and hospitalization rate was 0.12 and 0.65 episodes per patient-year, respectively. The length of hospitalization was 5.9 days per patient-year. Greater initial daily contact PD volume (HR=1.608, 95% CI 1.089-2.375) was associated with death after adjusting for age, Charlson comorbidity index, HD prior to PD, assisted PD and baseline RKF, likely as a result of residual confounding. It was not a factor related to technique failure. Male sex, greater body mass index and lower serum albumin at PD initiation were risk factors for increasing PD dose to >6 L/day within 1 year.

Conclusions: In the largest reported series to date, Incre-PD is a successful and patient-oriented strategy to treat ESKD patients.

TH-PO318

Standardized Outcomes in Nephrology-Peritoneal Dialysis (SONG-PD) Consensus Workshop with Patients, Caregivers, and Health Professionals to Establish a Core Outcome Set for Trials in PD

Karine E. Manera,[1,2] Allison Tong,[1,2] Jonathan C. Craig,[3] Jenny I. Shen,[4] Yeoung Jee Cho,[5,6] David W. Johnson.[5,6] *[1]The University of Sydney, Westmead, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [3]Flinders University, Adelaide, SA, Australia; [4]LaBiomed at Harbor-UCLA, Torrance, CA; [5]Princess Alexandra Hospital, Brisbane, QLD, Australia; [6]The University of Queensland, Brisbane, QLD, Australia*.

Background: Outcomes reported in peritoneal dialysis (PD) trials are very diverse, measured inconsistently and may not be important to patients, families and clinicians. We aimed to establish a core outcome set based on the shared priorities of all stakeholders to improve the consistency and relevance of outcomes to patients and healthcare providers to inform decision-making.

Methods: We convened an international Standardized Outcomes in Nephrology-Peritoneal Dialysis stakeholder consensus workshop in May 2018 in Vancouver, Canada. In facilitated breakout groups, participants discussed the development and implementation of core outcomes for trials in PD.

Results: Nineteen patients/caregivers and 51 health professionals attended the workshop. Participants confirmed that *"life participation" was a main goal of PD,* which reflected the need for flexibility and freedom. Participants regarded life participation to be as important as key clinical outcomes (such as cardiovascular disease, infection or mortality) for indicating treatment success. *Severity and immediacy of symptoms* encompassed the debilitating impact of symptoms such as fatigue, which was identified as a key contributing factor to reduced life participation. *Empowered for preparation and planning* was about ensuring that patients were informed about the status of their membrane function, enabling them to be mentally and physically equipped to deal with potential PD failure. *Demarcating distinct outcomes for clarity* was suggested as participants recognized the conceptual overlap among outcomes, such as membrane function and PD failure. Participants also discussed the importance of the core outcome set to be *measurable and feasible for implementation*, including the need for simple, standardized and validated measures, particularly for life participation.

Conclusions: Patients, caregivers and health professionals supported the inclusion of PD failure, mortality, cardiovascular disease, PD-infection and the patient-reported outcome of life participation as core outcome domains for PD. Recommendations from this workshop will be integrated into the establishment of a core outcome set for use in trials and other research to ensure that research evidence can better inform decision-making.

TH-PO319

Can Cardiovascular Risk Score Calculators Be Used for Nondiabetic Peritoneal Dialysis Patients?

Andreea G. Andronesi,[3,1] Bogdan Obrisca,[3,1] Bogdan M. Sorohan,[3,1] Gabriela Lupusoru,[1] Danut Andronesi,[2] Mircea Lupusoru,[1] Gener Ismail.[3,1] *[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]General Surgery and Liver Transplantation Department, Fundeni Clinical Institute, Bucharest, Romania; [3]Nephrology Department, Fundeni Clinical Institute, Bucharest, Romania*.

Background: Cardiovascular diseases caries a significant burden upon peritoneal dialysis (PD) patients. Despite overwhelming data regarding the usefulness of cardiovascular risk score calculators in the general population, only very few studies addressed this issue in PD.

Methods: We performed a prospective study. Three risk score calculators were evaluated at inclusion in the study: SCORE chart, Framingham and simplified Framingham risk score calculators. We excluded diabetic patients since they are already at increased cardiovascular risk. Predictive power for cardiovascular diseases was assessed using *Receiver Operating Characteristic curve* analysis by *IBM SPSS ver. 20.0.*

Results: We included 246 non-diabetic patients (118F), mean age 56.3 ± 15.7 years in stable PD for at least 6 months. Mean follow up time was 6.2 years. All the three risk scores where significantly higher in patients with renal hypertensive disease, compared to patients with glomerulonephritis, tubular interstitial diseases and other end stage renal disease etiologies (Table 1). The two Framingham risk scores were also significantly higher in patients with subclinical atherosclerosis as appreciated by an intima-media thickness (IMT) ≥0.9 mm at carotid ultrasound and the best predictive value for an IMT ≥0.9 mm was obtained by Framingham risk score (Tables 2 and 3). The best predictive value for developing acute coronary syndrome (ACS), heart failure (HF) and cardiovascular death (CvD) during the follow up period was obtained by Framingham risk score (AUC 0.887 for ACS, 0.731 for HF, and 0.809 for CvD), and by simplified Framingham risk score for ischemic stroke (AUC 0.883).

Conclusions: Risk score calculators, especially the Framingham one, may be useful in non-diabetic PD patients to both predict subclinical atherosclerosis and established cardiovascular disease and thus improve patients' management. Our results need to be validated in larger multi-center studies.

Table 1. Risk score calculators and renal disease etiologies

	Renal hypertensive disease	Glomerulonephritis	Tubular interstitial diseases	Other	p
Framingham mean ± SD	38.3 ± 2.3	11.2 ± 2.6	19.7 ± 6.6	16.1 ± 4.8	<0.001
Simplified Framingham mean ± SD	39.7 ± 4.5	11.4 ± 1.8	23.9 ± 3.5	14.1 ± 3.7	<0.001
SCORE mean ± SD	6.3 ± 4.8	2.2 ± 2.4	3.9 ± 3.2	2.1 ± 1.1	0.02

Table 2. Risk score calculators and IMT

	IMT<0,9	IMT≥0,9	p
Framingham mean ± SD	15.0±4.8	32.5±9.5	0.001
Simplified Framingham mean ± SD	16.1±5.6	34.2±7.6	0.001
SCORE mean ± SD	3.3±1.5	4.9±2.6	NS

Table 3. Predictive value for IMT ≥ 0.9 mm

Risk score	AUC
Framingham	0.773
Simplified Framingham	0.759
SCORE	0.622

TH-PO320

Mouse Model of Venous Stenosis

Salvatore DiBartolo, Mehmet M. Altintas, Beata Samelko, Monnie Wasse. *Rush University Medical Center, Chicago, IL*.

Background: A response of the vein wall to balloon angioplasty results in post-angioplasty restenosis (PARS). PARS impedes normal blood flow leading to a spectrum of complication and morbidities that exacerbates the outcome of vascular diseases, and remains a limiting factor for successful vascular intervention. Previous studies have indicated that mice of different inbred backgrounds have differences in arterial remodeling response, however, have not assessed the venous remodeling response.

Methods: To objectively evaluate the influence of uremia on venous remodeling, we utilized a CKD mouse model and developed a surgical technique that mimics the vascular damage of angioplasty. We recapitulated renal failure by inducing chronic renal function insufficiency via partial nephrectomy (2/3-nephrectomy) model with a high protein diet, and model venous restenosis via wire injury to the external jugular vein (EJV). To provide the basis for a genetic analysis of venous remodeling, we subjected 3 different inbred strains of mice; chosen based on their remodeling response to arterial injury (C57BL6, FVB, and SJL/J), to EJV wire injury to evaluate the cellular response involved in venous remodeling influenced by uremia.

Results: We developed a model that mimics venous stenosis in mice. Our model was validated via assessing vascular composition by immunological and histological staining and geometrical analysis (i.e., the evaluation of the lumen, intimal and medial area) by microscopy of the injured vein.

Conclusions: Our model helps us elucidate and further understand the pathophysiology of venous remodeling that occurs in hemodialysis vascular access dysfunction.

TH-PO321

Uremia Induces Functional and Histological Changes in a Mouse Model of Arteriovenous Fistula (AVF) Stenosis

Taylor G. Lewis,[1] Aous Jarrouj,[2] Li H. Wang,[6] Begoña Campos,[3] Keith L. Saum,[3] Jaroslav Janda,[1] Albert P. Owens,[3] Prabir Roy-Chaudhury,[4] Diego Celdran-Bonafonte.[5] *[1]University of Arizona, Tucson, AZ; [2]Banner-University of Arizona, Tucson, AZ; [3]University of Cincinnati, Cincinnati, OH; [4]University of North Carolina, Chapel Hill, NC; [5]University of Arizona / BIO 5 Institute, Tucson, AZ; [6]The Second Hospital of Tianjin Medical University, Tianjin, China*.

Background: Arteriovenous Fistula (AVF) stenosis is responsible for a very significant morbidity, mortality and economic cost. Despite the magnitude of the clinical problem there are currently no effective therapies for AVF stenosis. The focus of this project was therefore to identify uremia specific functional and histological differences in AVF stenosis in a mouse model.

Methods: Mice were made uremic through the removal of the upper and lower poles of one kidney followed by a nephrectomy of the contralateral kidney. AVFs were created through an end (vein) to side (artery) anastomosis using standard techniques. Functional parameters included flow mediated dilation (FMD) and the area enclosed within the elastic lamina at 100 micron intervals x 12 from the AV anastomosis. The histological end point was the ratio of thrombus area/perimeter at 100 micron intervals x 12 from the AV anastomosis (with the first 600 microns being considered proximal and the second 600 microns as distal).

Results: A total of 22 mice were used in these experiments. The mean +/- SE for BUN in the uremic animals was 109+/-4.8 mg/dL as compared to 17.4 +/- 1.0 mg/dL in the control animals ($p<0.05$). FMD at 60 seconds was decreased significantly in uremic animals (13.4 +/- 1.5%) as compared to the control animals (19.5 +/- 1.1%), although there was no difference at the 90 second peak. There was a trend towards a smaller area enclosed by the elastic lamina (an indicator of inward remodeling) in the uremic animals,

although this achieved statistical significance only in the distal segments (at 1000-1200 microns beyond the AV anastomosis). Finally, uremic animals had significantly more attached thrombus (thrombus area/perimeter) in the distal portions of the AVF (9414.7 +/- 7187.5) as compared to the proximal portions (1055.0 +/- 529.5).

Conclusions: These data document impairment of endothelial linked, functional (FMD and inward remodeling) and histological (thrombus formation) pathways in a mouse model of AVF stenosis. Further elucidation of the uremia specific mechanistic pathways responsible for these differences, could result in the development of novel drugs and devices for the treatment of AVF stenosis in patients with CKD and ESRD.

TH-PO322

Hemodynamic and Geometrical Characteristics of Rat Arteriovenous Fistula: Effect of Nitric Oxide Treatment

Hannah M. Northrup,[1] Yan-Ting Shiu,[1] Daniel Pike,[1] Isabelle D. Falzon,[1] Maheshika S. Somarathna,[2] Lingling Guo,[2] Timmy C. Lee.[3] *[1]University of Utah, Salt Lake City, UT; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Nitric oxide regulates endothelial function and promotes vascular health. Overexpression of endothelial nitric oxide synthase has been shown to improve arteriovenous fistula (AVF) maturation in mice. AVF maturation is dependent on hemodynamics and remodeling of the vessel wall. Here we investigate the impact of localized delivery of nitric oxide on AVF lumen hemodynamics and geometry in rats.

Methods: Femoral AVFs were created in 12-16 week old male Sprague-Dawley rats. At the time of creation AVFs were treated with NO releasing nanomatrix gel therapy (treatment gels) (n=4). Gels without nitric oxide (placebo gels) were used as a control (n=3). 7 days post creation, animals were subject to non-contrast MRI scans, and the MR images were used for reconstruction of the AVF lumen and computational fluid dynamic simulations of the AVF blood flow. Hemodynamic parameters (velocity, fluid wall shear stress (FWSS), and vorticity) and geometrical analysis (anastomosis angle (AA), tortuosity, and nonplanarity angle (NA)) were calculated.

Results: As shown in Fig. 1, AVF vein velocity, FWSS, and vorticity of placebo gels were significantly higher than treatment gels ($p<0.05$). AA were not significantly different between placebo and treatment gels. Tortuosity of the AVF showed a higher trend in treatment gels than control gels, with NA showing a slight decrease in treatment gels.

Conclusions: The NO treatment leads to significantly lower hemodynamics than the placebo, suggesting the return of velocity, FWSS, and vorticity to the pre-surgery baseline levels in the native vein by NO. However, localized treatment of NO releasing nanomatrix gels does not result in significant differences in AVF lumen geometry.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

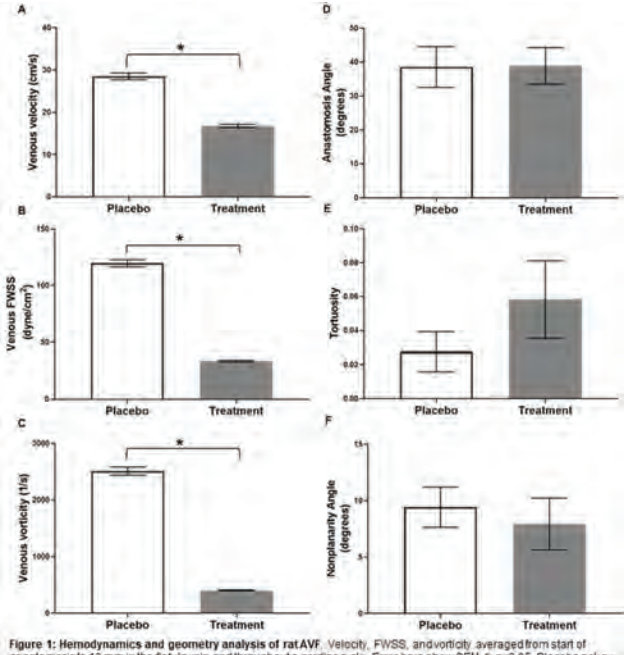

Figure 1: Hemodynamics and geometry analysis of rat AVF. Velocity, FWSS, and vorticity averaged from start of anastomosis to 10 mm in the flatula vein and throughout a cardiac cycle. Error bars show SEM. *: $p<0.05$. Placebo gel n= 3. Treatment gel n=4.

TH-PO323

Effect of Endothelial Nitric Oxide Synthase on Geometrical Parameters of Murine Arteriovenous Fistulas

Isabelle D. Falzon,[1] Yan-Ting Shiu,[1,2] Daniel Pike,[1] Hannah M. Northrup,[1] Maheshika S. Somarathna,[3] Lingling Guo,[3] Timmy C. Lee.[3,4] *[1]University of Utah, Salt Lake City, UT; [2]VASLCHCS, Salt Lake City, UT; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Veterans Affairs Medical Center, Birmingham, AL.*

Background: Arteriovenous fistula (AVF) maturation failure is a significant clinical issue. Endothelial nitric oxide synthase (NOS3) leads to the production of nitric oxide, a vasodilator, which contributes to successful AVF maturation in mice. Previous small clinical studies have reported the association between the AVF geometrical parameters and AVF maturation. Here we investigated the effect of NOS3 on AVF geometry in mice.

Methods: Carotid-jugular AVFs were created in NOS3 over expression (OE) and NOS3 knock out (KO) mice on C57BL/6 background, with C57BL/6 mice as wild type (WT) control (n=1 per strain). Black-blood MR images were taken at Day 7 and Day 21 post AVF creation and used to reconstruct AVF lumen geometries. Geometrical analysis (Fig. 1A) quantified the anastomosis angle (AA), nonplanarity angle magnitude (NA), and tortuosity of the AVF vein.

Results: The AVF lumen area was bigger in the NOS3 OE mice than in NOS3 KO and WT mice. Lumen reconstructions are shown in Fig. 1B. Overexpression of NOS3 led to a reduced AA and NA by 16° and 10°, respectively, from Day 7 to Day 21, indicating that the AVF vein remodeled to align more parallel with and on the same plain of the feeding artery. In contrast, NOS3 KO increased NA by 14° and decreased AA by 0.3° from Day 7 to Day 21. WT increased AA and NA by 17° and 5°, respectively, from Day 7 to Day 21. While OE and KO decreased in tortuosity by 0.15 and 0.14, respectively, WT increased tortuosity by 0.08 from Day 7 to Day 21.

Conclusions: Geometrical parameters differ with varying NOS3 expression and over time. More research is needed to understand how these geometrical parameters affect AVF maturation and the mechanisms leading to geometrical changes.

Funding: NIDDK Support, Other NIH Support - NHLBI, Veterans Affairs Support

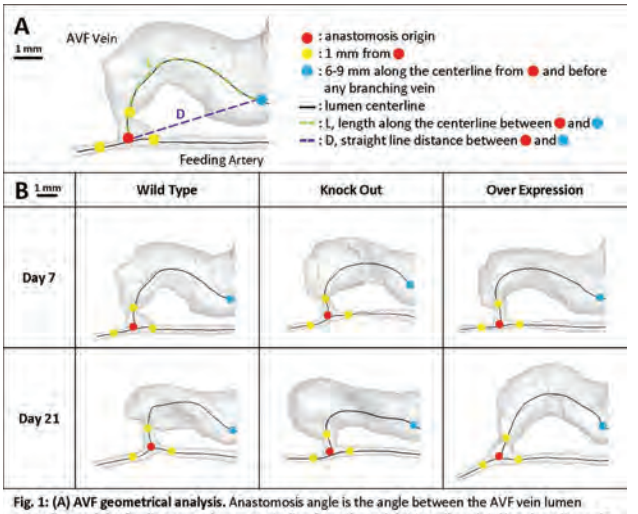

Fig. 1: (A) AVF geometrical analysis. Anastomosis angle is the angle between the AVF vein lumen centerline and the feeding artery lumen centerline from the red dot to yellow dot. Nonplanarity angle is the angle between D and a plane created with the 3 yellow dots. Tortuosity of the AVF vein is L/D−1. **(B) AVF Geometry Over Time.** Scale bar in (B) applies to all geometries in (B).

TH-PO324

Activation of Formyl Peptide Receptor 1 Causes Arteriovenous Fistula Failure in Rats

Laisel Martinez,[1] Roberto I. Vazquez-Padron,[1] Diana R. Hernandez,[1] Marwan Tabbara,[2] Juan C. Duque,[1] Loay H. Salman.[3] *[1]University of Miami, Miami, FL; [2]University of Miami, Miller School of Medicine, Miami, FL; [3]Albany Medical College, Albany, NY.*

Background: Formyl peptide receptor 1 (FPR1) is a recognition receptor for damage-associated molecular patterns. It is best known for mediating myeloid cell chemotaxis and activation to bacterial formylated peptides. However, it can also recognize mitochondria-derived proteins from apoptotic/necrotic cells due to the evolutionary origins of mitochondria. In a recent transcriptomics analysis of human arteriovenous fistulas (AVFs) that matured or failed after creation, higher expression of FPR1 in the native vein was associated with non-maturation. Immunohistochemistry analyses demonstrated that FPR1 was expressed in smooth muscle cells (SMCs) in the media, where it possibly sensed apoptotic/necrotic cells as a result of vascular trauma after AVF creation. In this study, we tested the effects of FPR1 activation in the maturation of experimental fistulas. **We hypothesized that activation of FPR1 at the time of AVF creation would increase the frequency of fistula failure.**

Methods: AVFs were created in Sprague Dawley rats (n=16) by anastomosing the superficial epigastric vein to the nearby common femoral artery. Twenty nanograms

(20 ng) of the FPR1 agonist fMLF were applied perivascularly to eight AVFs in 200 uL of Matrigel at the time of fistula creation. The remaining eight fistulas received Matrigel plus vehicle (control group). AVFs were harvested at 21 days after creation.

Results: Five out of eight AVFs (62.5%) failed to mature in the fMLF-treated subgroup, compared to one out of eight (12.5%) in control animals. Blood flow decreased from 19.2 [8.5-32.4] mL/min in control AVFs to 0.0 [0.0-6.6] mL/min in fMLF-treated fistulas (P=0.018). Venous distensibility was also significantly lower in the latter than in control AVFs, both in the juxta-anastomotic area and in the distal fistula (P<0.05).

Conclusions: Together with the human transcriptomics data, these results suggest that FPR1 activation is implicated in AVF maturation failure.

TH-PO325

Decreased Jagged1 Expression in Vascular Smooth Muscle Cells Delays Maturation of Arteriovenous Graft

Qunying Guo, Shaozhen Feng, Ming Liang, William E. Mitch, Jizhong Cheng. Internal Medicine/Nephrology *Baylor College of Medicine, Houston, TX*.

Background: It is well-known that endothelial dysfunction promotes activation of vascular smooth muscle cell (VSMC). Whether decreased accumulation of VSMCs affects endothelial regeneration and functions in arteriovenous graft (AVG) remodeling has not been studied. We plan to identify mechanisms by which the Notch ligand, Jagged1, in VSMCs regulates EC functions in AVGs.

Methods: AVGs were created in transgenic mice bearing VSMC-specific knockout (KO) or overexpression of Jagged1. VSMC migration, EC regeneration and its barrier functions as well as AVG remodeling were evaluated.

Results: Jagged1 expression was induced in VSMCs of neointima in the AVGs. Jagged1 KO in VSMCs inhibited the accumulation of extracellular matrix as well as VSMC migration. Fewer α-SMA-positive VSMCs were found in AVGs created in Jagged1 KO mice vs. results in WT mice. Decreased VSMCs in AVGs were associated with deteriorated the EC functions. In AVGs created in transgenic mice bearing Jagged1 KO in VSMCs exhibited delayed EC regeneration and impaired EC barrier function. Barrier dysfunction of ECs increased the inflammatory cell infiltration and dysregulation of AVG arterialization. In contrast, AVGs created in mice with overexpression of Jagged1 in VSMCs exhibited improved EC regeneration plus decreased macrophage infiltration. This led to AVG remodeling and arterialization. In co-cultures of ECs and VSMCs, Jagged1 deficiency in VSMCs suppressed N-cadherin and integrin β3 expression in ECs. Inhibition of integrin β3 activation delayed EC spreading and migration. Notably, Jagged1 overexpression in VSMCs stimulated the expression of N-cadherin and integrin β3 in ECs. Jagged1-induced responses were blocked by inhibition of Notch signaling.

Conclusions: our results demonstrate that Jagged1 expression in VSMCs maintains EC barrier functions and blocks infiltration of macrophages. These responses promote remodeling and arterialization of AVGs.

TH-PO326

p-Cresyl Sulfate Induced Oxidative Stress and Inflammation on Endothelial and Vascular Smooth Muscle Cells

Shina Lee, Seung-Jung Kim. *Ewha Womans University Mokdong Hospital, Seoul, Republic of Korea*.

Background: Vascular access dysfunction affects negatively patient morbidity and mortality. The most common problem in AVF and AVG is venous stenosis, resulting from a neointimal hyperplasia development. Recent study reported that p-Cresyl sulfate was related to the outcome of vascular access in hemodialysis patients. p-cresyl sulfate (p-CS), poorly removed by conventional dialysis, has been known to exhibit pro-oxidant properties in renal tubular cells by enhancing NAD(P)H oxidase activity and induce reactive oxygen species(ROS) production in endothelial cells. However, the mechanism of vascular toxicity induced by p-CS was poorly understood. The aim of the study was to determine whether p-CS enhances the production of ROS in vascular endothelial cell and proliferation of smooth muscle cell resulting in neointimal hyperplasia. Additionally, we aimed to determine whether p-CS induces the expression of ICAM-1 and MCP-1 by ROS induced activation of NK-KB in endothelial cell.

Methods: Aortic smooth muscle cells (SMCs) were treated with p-CS (10-1000 μmol/L), and aortic SMC proliferation was measured Bromodeoxyuridine cell proliferation assay. Western blot analysis was done for ERK1/2 and p38 MAPK. Human umbilical vein endothelial cells (HUVEC) were also treated with p-CS (1000 μmol/L). The productions of NF-κB, ICAM-1, MCP-1 and eNOS in HUVEC were assessed using RT-PCR and ELISA.

Results: p-CS stimulated the proliferation of aortic SMCs in a dose dependent manner, and promoted the phosphorylation of ERK1/2 and p38 MAPK. In HUVEC, p-Cresyl sulfate induces ROS production by enhancing NAD(P)H oxidase and upregulates the expression of ICAM-1 and MCP-1 by ROS-induced activation of NF-kB. However, NO synthase seemed not to be involved in p-cresyl sulfate induced oxidative stress in HUVEC.

Conclusions: Our data confirmed that p-CS was attributed to vascular SMC proliferation and inflammation and oxidative stress in HUVECs in vitro. Further evaluation will be needed to clarify the role of p-CS in vascular access stenosis and neointimal hyperplasia.

TH-PO327

Human Arteriovenous Fistula Wall Thickness in the First 6 Months After Creation

Yingnan Li,[1] Spencer B. Tingey,[2] Alfred K. Cheung,[2] Yan-Ting Shiu.[2] *[1]Division of Nephrology, Baodi Clinical College of Tianjin Medical University, Tianjin, China; [2]Division of Nephrology, University of Utah, Salt Lake City, UT*.

Background: Previous studies of the arteriovenous fistula (AVF) maturation process have focused almost exclusively on enlargement of the AVF lumen to allow increases in AVF blood flow. There is a lack of information regarding AVF wall thickness. Here we assess the change in AVF wall thickness, in conjunction with AVF lumen area, during the first 6 months after creation. We hypothesize that during AVF development, the wall thickens in response to lumen enlargement to maintain the structural strength and integrity of the wall.

Methods: Non-contrast black-blood magnetic resonance imaging (MRI) scans were performed on newly-created AVFs at 3 post-operative time points (1-3 days, 6 weeks and 6 months) in 10 ESRD patients at the University of Utah Hospital. MRI images were used to reconstruct 3D geometries of the AVF veins, from which the lumen area and wall thickness were calculated for the cross sections perpendicular to the lumen centerline at 1 mm intervals for 20 mm along the AVF length starting from the anastomosis.

Results: Fig. 1A-B shows the lumen area and wall thickness of each AVF at 3 sequential MRI scans. The lumen area increased from 14.26±5.40 mm^2 at 1-3 days to 21.91±8.79 mm^2 at 6 weeks to 30.62±12.78 mm^2 at 6 months (p=0.0005 by ANOVA for 3 time points), while the wall thickness increased from 0.76±0.09 mm at 1-3 days to 1.05±0.23 mm at 6 weeks to 1.21±0.18 mm at 6 months (p<0.0001 by ANOVA for 3 time points). During this 6-month period, the lumen area change was positively associated with the wall thickness change (p=0.0369) (Fig. 1C).

Conclusions: In ESRD patients, AVF wall thickened as their AVF lumen area enlarged. More rigorous validation of this observation using a larger cohort is necessary.

Secondary Hyperparathyroidism Stimulates Neointimal Hyperplasia of Arteriovenous Fistula in Mice

Chung-te Liu. *Division of Internal Medicine, Wanfang Hospital, Taipei Medical University, Taipei, Taiwan*.

Background: Arteriovenous fistula (AVF) is the preferred vascular access due to superior patency and lower infection rates. Nonetheless, its suboptimal maturation rate remains to be resolved. Previous clinical studies had shown that elevated parathyroid hormone (PTH) associated with AVF maturation failure. In thisstudy, we try to repeat this finding in a mice model of secondary hyperparathyroidism and AVF.

Methods: Chronic kidney disease (CKD) and secondary hyperparathyroidism were induced by feeding diet containing 0.2% adenine (adenine group) or 0.2% adenine and additional 2% phosphorus (high P group) in C57BL/6 mice. After 8 weeks of induction, AVF was created by aortocaval puncture. AVF was resected 6 weeks later. AVF was stained for α-smooth muscle actin (αSMA) to show neointimal hyperplasia. The severity of neointimal hyperplasia was expressed by ratio of area of αSMA/entire AVF.

Results: At the 8th week, renal function CKD was induced in adenine group and high P group (Figure 1A-B). Serum phosphorus level was insignificantly higher in high P group (Figure 1C). Compared with control group, serum PTH level was insignificantly higher in adenine group, while it was significantly higher in high P group (Figure 1D), indicating successful induction of secondary hyperparathyroidism in high P group. The severity of AVF neointimal hyperplasia was similar between control group and adenine group, while it was significantly more severe in high P group (Figure 1E-H). The above findings showed that secondary hyperparathyroidism may stimulate neointimal hyperplasia in AVF and play a role in AVF maturation failure.

Conclusions: The deleterious effect of PTH on AVF maturation shown will be confirmed by pharmaceutical suppression of PTH to reverse neointimal hyperplasia.

Far Infrared Ray Irradiation Inhibits Platelet Aggregation Pathway Through Increasing ADAMTS13 Production to Cleave Length of von Willebrand Factor on Cell Surface and Decreasing Platelet Adhesion to Human Umbilical Vein Endothelial Cells

Shang-Jyh Hwang,[1,2] Wen-Yi Chen,[3] Daw-yang Hwang.[1,4] *[1]Divsion of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Faculty of Medicine, and Faculty of Renal Care, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Divsion of Nephrology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kashsiung, Taiwan; [4]National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan.*

Background: Far-infrared Ray (FIR), wavelength between 3-1000 μm, bears multiple effects on cardiovascular system and thrombogenesis. The von Willebrand factor (vWF), a large multimeric plasma glycoprotein as crucial player in arterial thrombus formation, can be cleaved by metalloprotease ADAMTS13 at its A2 domain cryptic in normal circulating vWF. We hypothesized FIR may induce ADAMTS13 release and decrease platelet adhesion to endothelial cells.

Methods: Cultured HUVECs treated with FIR irradiation for 30 minutes. Extracted mRNA and protein were measured by real time PCR, western blot, or ELISA. Supernatants were subjected to nonreducing gel electrophoresis to assess vWF multimer patterns by western blot. Platelet-HUVEC interactions were done by labeling platelet with calcein AM and co-cultured calcein AM-labeled platelet with FIR-treated or controlled HUVECs, followed by fluorescence microscopy analysis. Peripheral blood samples from 14 healthy volunteers before and after FIR irradiation were measured for ADAMTS13 by immunoassay and multimeric vWF pattern by SDS-agarose gel western blot.

Results: The mRNA level of ADAMTS13 after FIR irradiation showed a time-duration dependent effect. FIR also stimulated ADAMTS13 but not vWF protein expressions in HUVECs. The levels of ADAMTS13 and vWF D4-CK domain in culture media measured showed increased after FIR irradiation. These findings reflected the possibility of vWF been cleaved from cell surface into medium, and it was demonstrated by the significantly reduced vWF D4-CK terminal expression on the surface of endothelial cells after FIR irradiation. The vWF multimer patterns in supernatants showed less presence of higher molecular weight forms, and binding of platelets to HUVEC cells was significantly reduced in FIR-treated cells. In healthy subjects, FIR irradiation increased blood levels of ADAMTS13 and reduced higher molecular weight forms of multimers of vWF.

Conclusions: We concluded FIR irradiation may inhibit platelet adhesion to endothelial cells via induction of ADAMTS13 which cleaves vWF on cell surface and results in decrease of platelet adhesion to endothelial cells. Our results provide information for further exploring the mechanisms of FIR in prevention of thrombus formation.

Perivascular Administration of Sirolimus During Arteriovenous Access Surgery: Delivering Therapeutic Outcomes Minimizing Risk of Systemic Side Effects

Maria V. DeVita,[1] Sriram Iyer.[2] *[1]Lenox Hill Hospital- Northwell Health System, New York, NY; [2]Lenox Hill hospital, New York, NY.*

Background: Unmitigated cell proliferation at and around the vascular anastomosis resulting in flow limiting stenosis is an important cause of access dysfunction. *m*TOR (mammalian target of rapamycin), controls cell growth, proliferation and survival. *Oral* sirolimus is an immunosuppressant. Sirolimus (cytostatic) delivered *locally* to site(s) of vascular injury downregulates *m*TOR and inhibits cell proliferation by causing cell cycle arrest between G1 & S phases. *Perivascular delivery* of sirolimus is a novel method of harnessing its anti-proliferative effect with the intent of improving access outcomes. A prior Paclitaxel (cytotoxic; anti-mitotic) perivascular AVG study was prematurely terminated because of excessive infections.

Methods: Data from 56 AVF pts (includes open label subset of a US Phase 3 randomized, *data safety monitored* study; 55 ESRD) and 12 AVG pts (Paulson NDT 2012) treated with perivascular sirolimus at & around the anastomosis (AVF) & venous anastomosis (AVG) delivered from a collagen matrix (Sirogen™ Vascular Therapies, Cresskill NJ) were analyzed. Access functional outcomes were evaluated using 2 needle cannulation for dialysis. Blood drawn at protocol specified time points yielded pharmacokinetic (PK) data.

Results: One AVF wound dehiscence required secondary suturing & local treatment with subsequent healing & preserved 12 mo. fistula primary functional patency; no cases of local infection. PK: Sirolimus levels peak ~6 hrs. after start of drug delivery (4-5ng/ml), declines to <1ng/ml by 96 hrs. PK profile for AVF and AVG are similar. Key efficacy metrics are tabulated.

Conclusions: 1. Perivascular sirolimus delivery with targeted high local concentrations of sirolimus achieves therapeutic effectiveness without increasing risk of problems with wound healing and infection. 2. Systemic release of sirolimus is negligible and levels are sub-therapeutic for systemic immunosuppression. 3. The US Phase 3 study is nearing enrollment completion.

A Pilot Study to Measure Distensibility Using Open-Source Software

Lenar T. Yessayan,[1] William Weitzel.[2] *[1]University of Michigan, Ann Arbor, MI; [2]VA Ann Arbor Health System, Ann Arbor, MI.*

Background: Arteriovenous fistulas (AVF) are the preferred access for hemodialysis. Yet, they often fail to mature. Doppler ultrasound has been employed for enhancing the preoperative examination of the patient prior to AVF construction. Blood vessel distensibility may be useful in predicting fistula maturation. This pilot study reports on the feasibility of measuring distensibility using conventional ultrasound data and an open-source ultrasound software program that our group developed based on ultrasound speckle tracking.

Methods: Ten patients were enrolled for this study after obtaining informed consent. Demographics and clinical data were collected. Ultrasound scanning of the brachial and radial artery were performed. Conventional digital imaging and communications in medicine (DICOM) format data were collected from the ultrasound exam. The distensibility of arteries were computed from the DICOM data using our open-source software to track the frame to frame displacement of user selected pixels located at the near

and far field edge of the vessel wall. Exploratory relationships between baseline brachial and radial artery distensibility and clinical covariates are also reported.

Results: Of the total 10 patients, there were 10 males, 8 had history of diabetes, 9 had hypertension. The mean age was 70.2 ± 5.4 years, BMI 28.0 ± 5.0 kg/m2, systolic pressure 128 ±26 mmHg, diastolic pressure 65 ±8 mmHg. The baseline distensibility of the branchial artery and radial artery were 2.8% ± 1.1% and 1.8% ± 0.8% respectively. Distensibility of both arteries increased with increases in systolic and diastolic blood pressures. Plots of distensibility versus peak systolic velocity and baseline vessel diameter are shown.

Conclusions: This study demonstrates that distensibility measurement using an open-source automated ultrasound software program is feasible.

Effectiveness of Flow Volume Measurement Training Using Custom-Made Doppler Flow Simulator

Cheolsu Kim,[2] Sung gyun Kim,[2] Hyungseok Lee,[1] Narae Joo.[2] Department of Nephrology, Hallym University Sacred Heart Hospital *[1]Hallym University Sacred Heart Hospital, Anyang, Republic of Korea; [2]Department of Nephrology, Hallym University, Anyang, Republic of Korea*.

Background: The purpose of this paper was to present the effectiveness of custom-made Doppler ultrasound (DU) flow simulator, vascular phantom, and Doppler test fluid in training dialysis staffs on the flow volume (FV) measurement for arteriovenous (AV) access of hemodialysis (HD) patients.

Methods: A DU flow simulator was constructed using a continuous renal replacement therapy machine. Vascular phantoms were made with a rubber enema tube and keyboard cleaning gel. Doppler test fluid consisted of freeze-dried instant coffee granules and 0.9% saline. This easy and affordable simulator was applied to the training DU flow volume measurement on 12 dialysis staffs who had never experienced DU examination. After 3 days of theoretical education, dialysis staffs performed DU on AV access of HD patients. Thereafter, they underwent a 3-day training course using the simulator and then measured FV of AV access again. Each dialysis staff assessed FV 3 times, and the mean values of measurements between pre and post-training were analyzed by paired t-test.

Results: The difference in mean value of FV measurements from the reference value decreased from 131.6 ml/min to 62.5 ml/min (95% CI 30.0-108.0, P = 0.002), and the standard deviation of FV measurements were decreased from 96.9 ml/min to 47.0 ml/min (95% CI 7.9-91.8, P = 0.023) after DU training with the simulator.

Conclusions: The accuracy and reproducibility of FV measurement by dialysis staffs were markedly improved after training using the current simulator, and it may be helpful to medical practitioners participated in the management of AV access and HD treatment.

TH-PO333

Performance Characteristics of Criteria for Hemodialysis Arteriovenous Fistula Clinical Maturation

Jia Hwei Ng, Wei Yang, Sidney M. Kobrin, Laura M. Dember. *University of Pennsylvania, Philadelphia, PA*.

Background: A barrier to conducting and interpreting clinical studies of interventions for improving fistula outcomes is the lack of standardized and readily ascertainable criteria for defining fistula maturation. Using data from the multicenter, prospective NIDDK Hemodialysis Fistula Maturation (HFM) study, we determined performance characteristics of more readily ascertainable alternatives to the HFM clinical maturation criteria.

Methods: We included the 544 participants for whom clinical maturation was ascertained during the HFM study. The HFM criteria for maturation required fistula use for ≥75% of dialysis sessions within any 4-week period with either a) dialysis machine blood pump speed ≥300 ml/min or b) spKt/V ≥1.4. The criteria had to be met within 9 months of fistula creation or 8 weeks of dialysis initiation, whichever was later. For the current analysis, we developed alternative maturation criteria that incorporated one or more of the following domains: 1) # of sessions of fistula use, 2) dialysis machine blood pump speed, 3) small solute clearance, 4) no use of an alternative access, and 5) time from fistula creation.

Results: Mean age was 56 years, 69% were men, 45% were Black, and 64% had diabetes. 396 (72%) had successful fistula maturation (either assisted or unassisted) by HFM criteria. Performance characteristics of our alternative criteria are shown in the Table. All criteria had high specificity (93-100%), but criteria that require only 3 months for ascertainment had low sensitivity (36-67%).

Conclusions: Several alternatives to the HFM maturation outcome that are easier to ascertain have high predictive utility and, thus, could potentially simplify the conduct of research studies. However, an ascertainment period that extends beyond 3 months after fistula creation is required for adequate sensitivity.

Funding: NIDDK Support

Table. Performance characteristics of alternative criteria for fistula maturation using the HFM criteria for maturation (either assisted or unassisted) as the reference

	Met within 3 months of fistula creation			Met within 6 months of fistula creation		
	Sensitivity	Specificity	AUC	Sensitivity	Specificity	AUC
HFM criteria within earlier time points	43% (39-49)	99% (96-100)	0.71 (0.69-0.74)	86% (82-90)	98% (94-100)	0.92 (0.90-0.94)
Fistula use for ≥75% of dialysis sessions within a 4-week period	67% (62-72)	96% (91-99)	0.81 (0.79-0.84)	94% (91-96%)	93% (87-96)	0.93 (0.91-0.96)
4 consecutive uses of fistula with dialysis machine pump speed ≥300ml/min	40% (35-45)	100% (98-100)	0.72 (0.68-72)	84% (80-88)	99% (95-100)	0.90 (0.89-0.93)
4 consecutive uses of fistula	55% (49-59)	96% (91-99)	0.75 (0.72-0.78)	91% (88-94)	93% (88-96)	0.92 (0.90-0.95)
No use of alternative access for ≥4 weeks	36% (32-41)	95% (91-98)	0.66 (0.63-0.69)	83% (80-87)	93% (87-96)	0.88 (0.85-0.91)

Proving the Value of the Bluedop™ Device in the Renal Unit

David H. King,[1] Abdelgalil A. Ali.[2] *[1]Mid Essex Hospitals, Chelmsford, United Kingdom; [2]Broomfield Hospital, Chelmsford, United Kingdom*.

Background: Static Pressure Ratio *SPR*, showed early promise as a monitoring device in prediction of Arteriovenous Fistula Failure. 'Arterial' needle pressure is monitored with dialysis pump switched off. Blood pressure on the venous outflow will rise towards central arterial level in the presence of a 'blood flow limiting' venous stenosis. The method is not widely used, possibly due to difficulties in compensating for hydrostatic height difference between needle and mean blood pressure *MAP* measured on the contralateral arm. We suggest a simpler alternative using identical principles solves many of the practical problems associated with the earlier technique.

Methods: The Bluedop™ device is intended to measure mean blood pressure non-invasively, without the use of needles, is unaffected by pump speed and can be applied at any suitable part of the AVF without any requirement for hydrostatic height correction. We have named our parameter 'Non Invasive Static Pressure Ratio' *SPRn*. A Doppler Ultrasound probe is used to sample blood flow waveforms from the distal brachial artery. A patented function based on blood velocity waveform shape calculates non-invasive intra AVF mean perfusion pressure *MPP* [2]. This is comparable to the needle pressure measured directly in the *AVF*. *SPRn* is calculated as *SPRn = MPP/MAP*. The complete measurement takes approximately 5 minutes. and can be carried out by regular Renal Unit Staff without significantly interfering with their normal duties.

Results: The range of SPRn values in normally functioning AVF was established in 479 dialysis patients. Following this 340 prospective measurements were made on 73 patients over a 10 week period. SPRn in 27 AVF rose above the +2SD normal limit. Of these 23 had 60% or greater focal stenosis shown on Duplex scanning, 2 were maturing AVF and 2 had no significant stenosis. A review of clinically identified 'failing' AVF in the same unit showed that 48% were found to be 'false alarms' in Duplex studies. Bluedop™ reduced the number of false alarms to 18%.

Conclusions: Bluedop™ offers a practical solution to the perennial problem of unheralded AVF failure. It also has the desirable property of indicating AVF status during the maturing phase References: 1 A Besarab et al, Vol.47, no.5, pp 1364-1373, 1995 2 D H King et al, J Vasc Access, 2015, 16 (3):211-217, DOI: 10.5301/jva.5000324

Algorithmic Estimation of Vascular Access Dysfunction from Serial Bruit Recordings

Niraj Desai,[1,2] Steve Majerus.[2] *[1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Louis Stokes Cleveland VA Medical Center, Cleveland, OH*.

Background: Hemodialysis vascular access dysfunction accounts for a large fraction of hospital visits for dialysis patients and has significant implications on cost of care, morbidity and mortality. This study examined if mathematical analysis of serially-recorded bruits could detect changes in bruit pitch indicative of imminent vascular access dysfunction.

Methods: An algorithm was developed to detect bruit pitch shifts between recording locations along the vascular access. The algorithm produced a single value for each location which monotonically increased with bruit pitch caused by turbulent blood flow. Algorithm performance was validated on a phantom vascular access at flows of 80-1,200 mL/min and stenoses ranging from 10-85%. Prognostic value in predicting vascular access dysfunction was tested longitudinally in 24 patients at an outpatient Veteran's Affairs HD unit. Bruit recordings were made using a digital stethoscope (Littman 3200) 1-4 times per month just prior to HD. In each evaluation, 10-s bruit recordings were obtained at 5-9 serial locations, 3 cm apart along an upper extremity arteriovenous fistula (AVF) or graft (AVG). Recordings were made from the arterial anastomosis to beyond the cannulation zone (for AVF) or to the venous anastomosis (for AVG). True positive detection of access dysfunction was counted when the algorithm value exceeded a fixed threshold at one or more recording sites and when clinical evidence of access dysfunction occurred within 30 days after the recording date. Evidence of access dysfunction included prolonged post-HD bleeding or access rupture, access pain, radiologic intervention, non-functional access, or unexplained KT/V below 1.3.

Results: 3,441 bruits were recorded for 24 Veterans (age 67 years, HD vintage 51 months, 96% male, 83% Black) over an average of 13 months per patient. 71 instances of access dysfunction were observed in 18 patients (median 3 per patient). Use of the algorithm showed 89% sensitivity, 83% specificity, and 92% accuracy at predicting access dysfunction up to 30 days in advance.

Conclusions: Prospective use of serial bruit recordings and algorithmic analysis positively identified at-risk patients up to 30 days before clinical evidence of access dysfunction. This technique may help prevent emergency interventions or hospital admissions for access dysfunction.

TH-PO336

The Use of Doppler Ultrasound in Hemodialysis Patients for Vascular Access Surveillance: Arguing the Revised Hemodialysis Vascular Access Guidelines

Georgios Spanos,[1] Stylianos Fragkidis,[1] Ioannis E. Giannikouris,[2] Christos Bantis,[1] Styliani Paschou,[1] Gerasimos I. Bamichas.[1] *[1]Nephrology Department, General Hospital of Thessaloniki "G. Papanikolaou", Thessaloniki, Greece; [2]Medifil SA Private Hemodialysis Center, Athens, Greece.*

Background: The Kidney Disease Outcomes Quality Initiative (K/DOQI) guidelines for the management of vascular access (VA) in hemodialysis (HD) is currently in external review process. Only clinical monitoring is being clearly suggested for VA surveillance. Our experience implies a promising role for the use of diagnostic methods like Doppler ultrasound (US) in daily practice. The aim of this study is to explore the use of Doppler US audit in HD patients with arteriovenous fistulas (AVF) and grafts (AVG), performed by nephrologists.

Methods: This is a single centre study with prospective evaluation of AVF or AVG in stable HD patients. Patients' VA was assessed by the same nephrologist with the use of a color Doppler US in a twelve-month monitoring period. Basic VA anatomical and functional parameters like mean volume flow (MVF) and percentage of change in mean volume flow (ΔMVF), stenosis and other abnormalities were recorded. Demographic and clinical characteristics were assessed, while cumulative secondary survival (CSS) and secondary patency rate (SPR) along with abnormality rates were calculated and further analysed.

Results: A total of 43 patients (30 male), 21% diabetic, age 61.5±13 years, enrolled in the study. 76.7% of patients had an AVF while 23.3% had an AVG. At baseline, 18.6% of patients had a MVF<600 ml/min, while 18.3% appeared to have significant stenosis in the access circuit. ΔMVF was categorized as stable or reduced in the event of a change in mean VF>30%. At the end of the study, SPR for all VA was 76.74%, (81.82% for AVF and 40% for AVG). Cumulative secondary survival was 65±26 months for the above study population, and when comparing AVF and AVG, CSS was 78.61±24 months and 21.80±13 months respectively (p=0.001). In univariate analysis, age, the presence of diabetes, ΔMVF, and the presence of stenosis were correlated with CSS. In a multivariate model only age and the presence of stenosis in the access circuit retained correlation with CSS.

Conclusions: In a hemodialysis unit where VA assessment with an US by nephrologist is available, frequent audit seems to offer an additional benefit for patients' VA survival to clinical surveillance.

TH-PO337

Vascular Access Surveillance: Impact of an Intensive Ultrasound Surveillance Protocol in Arteriovenous Fistulae and Arteriovenous Grafts Patency Rates

Ioannis E. Giannikouris,[1] Stavros Spiliopoulos,[2] Periklis P. Kyriazis,[3] Giuseppe Bacchini.[4] *[1]Medifil SA Private Hemodialysis Center, Athens, Greece; [2]ATTIKO University Hospital, Athens, Greece; [3]Beth israel Deaconess Medical Center, Chicopee, MA; [4]Nephrology, Hemodialysis and Peritoneal Dialysis Unit, Vascular Access Unit and Renal Transplanation, A. Manzoni Hospital, Lecco, Italy.*

Background: Impact of an intensified monthly ultrasound surveillance protocol for vascular access (VA) in the patency rates of native arteriovenous fistulae (AVF) and arteriovenous grafts (AVG) for hemodialysis.

Methods: Prospective observational study that involved hemodialysis patients receiving treatment from either an AVF or an AVG in an in Center Hemodialysis facility in Greece, from January 2016 to December 2018. Patients were assigned to an intensified VA surveillance protocol, according to which were followed monthly by Color Doppler ultrasound. When was needed, patients were referred to for pre-emptive corrective procedures. The number of procedures, frequency of primary repair, percentage of primary assisted patency (APP), secondary patency (SP) and failure rates of VA were all reviewed.

Results: Two hundred twenty-three patients completed the study (243 VA, 192 AVF and 51 AVG). In total, 56 pre-emptive corrective interventions were performed (0.13 procedures per 12 months) from which 34 involved AVF patients (0.09 procedures/12 months) and 22 patients with AVG (0.40 procedures/12months). Totally observed were 33 VA failures (0.06 failures/12 months), 17 in patients with AVF (0.04 failures/12 months) and 16 in AVG (0.20 failures/12 months). Percentages of APP and SP for all VA were 83% and 93% in 12 months of follow-up, respectively, whereas for 24 months was 75% and 88% and for 36 months 72% and 83%. The percentage of APP and SP among patients with AVF was 89% and 96% in 12 months follow-up period, 81% and 93% in 24 months and 80% and 89% in 36 months, respectively. On the contrary, the percentage of APP and SP among patients with AVG was 56% and 80% in 12 months follow-up, 44% and 65% in 24 months and 39% and 54% in 36 months, respectively.
